Received 9 January 2011; accepted 22 January 2011

Key indicators: single-crystal X-ray study; $T = 295$ K; mean $\sigma(\text{C}-\text{C}) = 0.004$ Å; disorder in main residue; R factor = 0.033; wR factor = 0.088; data-to-parameter ratio = 13.3.

The title structure, $\{[\text{Ba}_{0.71}\text{Sr}_{1.29}(\text{C}_4\text{HO}_4)_4(\text{H}_2\text{O})_{10}]\cdot\text{H}_2\text{O}\}_n$, is built from dimers of edge-sharing monocapped square antiprisms $[(\text{Ba}/\text{Sr})\text{O}_3(\text{H}_2\text{O})_6]$, in which barium and strontium are statistically disordered [ratio 0.353 (8):0.647 (8)] on the same crystallographic site. Such dimers are connected *via* bidentate hydrogen squarate groups $[\text{HC}_4\text{O}_4]^-$, leading to chains that propagate along the b axis. Inter- and intramolecular O—H...O hydrogen bonds maintain the crystal packing through a three-dimensional network.

Comment

Squaric acid, (3,4-dihydroxycyclobut-3-ene-1,2-dione, $H_2C_4O_4$, H_2sq), synthesized for the first time by Cohen *et al.* (1959), has been of interest because of its cyclic structure and its possible aromaticity. (West *et al.*, 1963) have described the preparation from aqueous solutions of 'isostructural' divalent metal squarates of general formula $MC_4O_4 \cdot 2H_2O$, and predicted a chelated linear polymer structure, the structure of $Ni(C_4O_4) \cdot 2H_2O$ being reported later by (Haben-schuss *et al.*, 1974). In the structurally well understood metal squarates $M(C_4O_4)(H_2O)_4$ ($M = Mn, Fe, Co, Ni, Zn$) (Lee *et al.*, 1996), the $C_4O_4^{2-}$ entity serves as a bridging ligand between two metal ions (μ -2) in *trans* positions while it acts as a fourfold monodentate (μ -4) ligand between metals in the three-dimensional polymeric structures of $M(C_4O_4)(H_2O)_2$ ($M = Mn, Fe, Co, Ni, Cu, Zn$). However, the cyclic group only chelate the largest cations such as alkaline earth (Robl & Weis, 1986, 1987; Robl *et al.*, 1987; Bouayad *et al.*, 1995) or rare earth elements (Trombe *et al.*, 1988; Trombe *et al.*, 1990; Trombe *et al.*, 1991; Bernard-Rocherullé & Akkari, 2005).

Surprisingly, the crystal structures of barium squarate hydrate and strontium squarate hydrate are rather different. It is of interest to explore the possibilities of mixing cations, to obtain new compounds or solid solutions. Here, we synthesized hemi hydrate barium strontium squarate, $[Ba_{0.35} Sr_{0.65} (HC_4O_4)_2 (H_2O)_5] \cdot 0.5 H_2O$, for which the Ba / Sr ratio has been determined from EDX and single-crystal diffraction data.

The asymmetric unit contains two metal atoms, two hydrogen squarate anions, five aqua ligands and half water molecule. The Barium and Strontium ions are disordered on the same site as well as a solvent water molecule situated on the twofold axis at (4 e; 0, y, 1/4).

The structure is formed from chains, bridged by the hydrogeno squarate group acting as a bidentate ligand in a *trans* position (Fig. 2). The three-dimensionality is ensured by a strong O—H \cdots O hydrogen bond (Table 1). The free water molecule is sandwiched between these chains.

Experimental

All chemical were commercially available and used as received. For convenience, 3,4-dihydroxycyclobut-3-ene-1,2-dione ($H_2C_4O_4$) is named squaric acid hereafter. Typically, Poly [pentaqua di squarato barium strontium] hemi hydrate was synthesized by hydrothermal reaction starting from a mixture of barium chloride $BaCl_2 \cdot 2H_2O$ (2 mmol), strontium chloride $SrCl_2 \cdot 6H_2O$ (2 mmol) squaric acid $H_2C_4O_4$, oxalic acid $H_2C_2O_4 \cdot 2H_2O$ (1 mmol) and water (4 ml). The whole was stirred for 30 minutes until homogeneous. The final mixture was sealed in a 23 ml Teflon-lined acid digestion bomb (Parr) and heated at 423 K for 48 h under autogeneous pressure and then cooled down to room temperature. The yellow crystalline product obtained were collected by filtration, thoroughly washed with distilled water and ethanol, and finally dried at room

supplementary materials

temperature. The chemical formula was derived from the Ba/Sr ratio (1/2) obtained by energy dispersive X-ray spectrometry (EDX), and from the crystal structure determination reported below.

Refinement

All H atoms were localized on Fourier maps and refined isotropically, except for H atoms for hydroxy groups of hydrogenosquarate (H4 and H8) which were introduced in calculated positions and treated as riding on their parent O atom (with O—H = 0.82 Å and $U_{\text{iso}}(\text{H}) = 1.5U_{\text{eq}}(\text{O})$). Some distances (O—H) of coordinate water molecule are refined with soft constraints, the O—H distances is restrained to 0.85 Å. (O11W—H11A, O9W—H9A and O1W—H1W).
