Received 10 March 2011; accepted 16 April 2011

Key indicators: single-crystal X-ray study; $T = 296\text{ K}$; mean $\sigma(\text{C}-\text{C}) = 0.011\text{ \AA}$; R factor = 0.064; wR factor = 0.225; data-to-parameter ratio = 13.3.

In the title compound, $\{[\text{Zn}_3(\text{C}_9\text{H}_3\text{O}_6)_2(\text{H}_2\text{O})_8]\cdot 4\text{H}_2\text{O}\}_n$, there are two crystallographically independent Zn^{II} ions. One presents a trigonal-bipyramidal coordination geometry defined by five O atoms [three from two carboxylate groups of two benzene-1,3,5-tricarboxylate (BTC) ligands and the other two deriving from three water molecules], while the other lies on an inversion centre and exists in a slightly distorted octahedral coordination geometry defined by six O atoms (two from two carboxylate groups of two BTC ligands and the others from four water molecules). A three-dimensional framework is further strengthened via $\text{O}-\text{H}\cdots\text{O}$ hydrogen-bonding interactions.

Comment

The exploring of metal-organic frameworks (MOFs) has attracted considerable attention not only owing to their intriguing structural architectures and topologies, but also because of their many potential applications in catalysis, ion exchange, and magnetic, optical, and porous materials (Batten & Murray, 2003; Zhong *et al.*, 2008; Qiu *et al.*, 2010). 1,3,5-benzenetricarboxylate with six O atoms from its three carboxylate groups is a good choice of O-donor ligand. And such ligand has been widely used to synthesize metal compounds (Yaghi *et al.*, 1997; Xu *et al.*, 2008; Xu *et al.*, 2007; Liang *et al.*, 2009; Wang *et al.*, 2009). Thus, we synthesize a new three-dimensional Zn-BTC metal-organic compound, $\{[\text{Zn}_3(\text{BTC})_2(\text{H}_2\text{O})_8](\text{H}_2\text{O})_4\}$, with achiral channels along *b* direction, which was generated by the reaction of zinc sulfate heptahydrate, 1,3,5-benzenetricarboxylic acid and water at 150°C for 3 days.

There are two kinds of zinc atoms in the title compound (I) (Fig. 1). One is surrounded by five O atoms (three from two carboxylate groups of two BTC ligands and the other two deriving from three water molecules), exhibiting a trigonal bipyramidal geometry, the other is coordinated with six O atoms (two from two carboxylate groups of two BTC ligands; the others from four water molecules) and displays a slightly distorted octahedral geometry. All the BTC ligands have the same coordinated modes and each ligand coordinated to three zinc atoms. The bond distances of Zn—Ochelated carboxylate range from 1.999 (5) Å to 2.412 (6) Å. While the bond lengths of Zn—Omonodentate carboxylate fall between 1.946 (6) Å and 2.049 (5) Å. And the Zn—O_w distances are in the normal range of 1.965 (6)–2.150 (6) Å (Table 1). All the distances of Zn—O in compound (I) are comparable to those found in the literatures (Hua *et al.*, 2010; Chen *et al.*, 2010; Yang *et al.*, 2008; Xu *et al.*, 2007). And there are weak interactions between Zn1 and C1 with the distances of 2.554 Å and Zn1 and H2WB with the distances of 2.0711 Å. A three-dimensional architecture is strengthened by the extended O—H···O hydrogen-bonding interactions (Table 2, Fig. 2)

Experimental

A mixture of zinc sulfate heptahydrate (0.287 g; 1 mmol), benzenetricarboxylic acid (0.210 g; 1 mmol) and water (10 ml) was sealed in a 23 ml Teflon-lined stainless steel reactor and heated at 120°C under autogenous pressure for 72 h. Then the mixture was cooled down to room temperature at a rate of 5°C per hour, and colorless block crystals were obtained in a yield of 49% based on Zn

Refinement

water H atoms were located in a difference Fourier map and were refined isotropically. Other H-atoms on aromatic ring were placed in calculated positions with C—H = 0.93 Å; refined using a riding model with $U_{\text{iso}}(\text{H}) = 1.2 U_{\text{eq}}(\text{C})$.

$Z = 2$	

Data collection

Bruker SMART APEX CCD diffractometer	2729 independent reflections
Radiation source: fine-focus sealed tube graphite	1990 reflections with $I > 2\sigma(I)$
ω scans	$R_{\text{int}} = 0.047$
Absorption correction: multi-scan (<i>SADABS</i> ; Sheldrick, 1996)	$\theta_{\text{max}} = 25.2^\circ, \theta_{\text{min}} = 2.0^\circ$
$T_{\text{min}} = 0.521, T_{\text{max}} = 0.569$	$h = -17\text{--}17$
7485 measured reflections	$k = -8\text{--}8$
	$l = -18\text{--}11$

Refinement

Refinement on F^2	Primary atom site location: structure-invariant direct methods
Least-squares matrix: full	Secondary atom site location: difference Fourier map
$R[F^2 > 2\sigma(F^2)] = 0.064$	Hydrogen site location: inferred from neighbouring sites
$wR(F^2) = 0.225$	H-atom parameters constrained
$S = 1.13$	$w = 1/[\sigma^2(F_o^2) + (0.124P)^2 + 4.534P]$ where $P = (F_o^2 + 2F_c^2)/3$
2729 reflections	$(\Delta/\sigma)_{\max} = 0.002$
205 parameters	$\Delta\rho_{\max} = 1.89 \text{ e \AA}^{-3}$
1 restraint	$\Delta\rho_{\min} = -0.90 \text{ e \AA}^{-3}$

Special details

Geometry. All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

Refinement. Refinement of F^2 against ALL reflections. The weighted R -factor wR and goodness of fit S are based on F^2 , conventional R -factors R are based on F , with F set to zero for negative F^2 . The threshold expression of $F^2 > \sigma(F^2)$ is used only for calculating R -factors(gt) etc. and is not relevant to the choice of reflections for refinement. R -factors based on F^2 are statistically about twice as large as those based on F , and R -factors based on ALL data will be even larger.
