Received 28 September 2011; accepted 4 October 2011

Key indicators: single-crystal X-ray study;  $T = 293$  K; mean  $\sigma(C-C) = 0.008$  Å; H-atom completeness 93%; disorder in solvent or counterion;  $R$  factor = 0.032;  $wR$  factor = 0.080; data-to-parameter ratio = 16.2.

The title  $Pd^{II}$  coordination compound,  $(C_9H_6ClINO)[PdCl_2(C_9H_4ClINO)] \cdot 2H_2O$ , was prepared as a potential anticancer agent. Its structure is ionic and consists of a square-planar  $[PdCl_2(CQ)]^-$  complex anion ( $CQ$  is 5-chloro-7-iodoquinolin-8-olate), with the  $Pd^{II}$  atom surrounded by two chloride ligands in a *cis* configuration and one  $N,O$ -bidentate  $CQ$  molecule, a protonated anion of  $CQ$  as counter-cation and two non-coordinated water molecules. The water molecules are involved in O—H···O and N—H···O hydrogen bonds, which interconnect the  $HCQ^+$  cations into a chain parallel to [010]. Apart from these interactions, the structure is also stabilized by face-to-face  $\pi-\pi$  interactions [centroid–centroid = 3.546 (3) Å], which occur between the phenolic parts of the complex anions and cations.

## A potential anticancer agent: 5-chloro-7-iodo-8-hydroxyquinolinium dichlorido(5-chloro-7-iodoquinolin-8-olato- $\kappa^2N,O$ )palladium(II) dihydrate

P. Vranec and I. Potocnák

### Comment

Square-planar complexes of platinum and palladium, as potential chemotherapeutics, are studied worldwide (Bruijnincx & Sadler, 2008 and Bielawska *et al.*, 2010). Unfortunately, many of these anticancer drugs exhibit significant side effects and their activity is relatively low (Screni & McKeage, 1999). One of the approaches to overcome limitations connected with platinum- or palladium-based chemotherapy, new square-planar coordination compounds of these metals with biologically active ligands should be prepared. One of the examples of such ligand is 5-chloro-7-iodo-8-hydroxyquinoline (clioquinol, CQ), as it exhibits wide range of biological activity, including anticancer activity. CQ's favourable effect to human cancer cells is ascribed to its ability to chelate metal ions (Ding *et al.*, 2005). In our efforts to prepare novel square-planar complexes of Pt and Pd with clioquinol of  $\text{Cat}[\text{MCl}_2(\text{CQ})]$  ( $\text{M} = \text{Pt}$  or  $\text{Pd}$ ;  $\text{Cat} = \text{cation of } +1 \text{ charge, such as } \text{Na}^+, \text{K}^+ \text{ or } \text{Cs}^+$ ) composition, we prepared crystals of  $\text{HCQ}[\text{PdCl}_2(\text{CQ})] \cdot 2\text{H}_2\text{O}$  (I) ( $\text{HCQ} = \text{protonated molecule of CQ}$ ), which we believe has an increased anticancer activity. Here we present the structure of the title compound.

The molecular structure of the ionic  $\text{HCQ}[\text{PdCl}_2(\text{CQ})] \cdot 2\text{H}_2\text{O}$  (I) compound consists of discrete  $[\text{PdCl}_2(\text{CQ})]^-$  anion in which the central  $\text{Pd}^{II}$  atom has a distorted square-planar configuration, protonated molecule of CQ ( $\text{HCQ}^+$ ) as cation, and two non-coordinated water molecules (Fig. 1). Complex anion is formed by  $\text{Pd}^{II}$  atom which is surrounded by two chlorido ligands in *cis*- configuration at 2.271 (1) ( $\text{Pd1—Cl1}$ ) and 2.311 (1) Å ( $\text{Pd1—Cl2}$ ) distances, which are close to  $\text{Pd—Cl}$  distances observed in other square planar  $\text{Pd}^{II}$  complexes (Cui *et al.*, 2009), and one bidentately coordinated CQ molecule. This is bound to  $\text{Pd}^{II}$  atom by nitrogen atom of pyridine part and oxygen atom, which is ready to coordinate after deprotonation of the CQ's hydroxyl group in phenolic part; the  $\text{Pd1—N1}$  (2.009 (4) Å) and  $\text{Pd1—O1}$  (2.035 (3) Å) distances are normal (Yue *et al.*, 2008). Both the coordinated and free protonated CQ molecules are nearly planar, with the largest deviation of atoms from the mean planes through the aromatic rings being 0.05 (1) Å. The geometric parameters within the individual rings resemble those found in similar compounds containing pyridine and phenolic rings (Guney *et al.*, 2011 and Kapteijn *et al.*, 1996). The  $\text{C—X}$  bonds ( $X = \text{Cl}$  and  $\text{I}$ ; 1.742 (10) and 2.098 (2) Å in average, respectively) are usual for single  $\text{C}_{\text{sp}2}—\text{X}$  bonds (Fazeli *et al.*, 2009 and Gniewek *et al.*, 2006).

Besides the ionic forces, the structure is also stabilized by  $\pi$ - $\pi$  interactions and hydrogen bonds.  $\pi$ - $\pi$  interactions occur between the phenolic parts of the complex anion and the cation. The distance between centroids of these parts ( $\text{CgAn—CgCat} = 3.546$  (3) Å) and angle between normal to the plane and vector connecting the two centroids ( $16.46^\circ$ ) are consistent with the values typical for the face-to-face  $\pi$ - $\pi$  interactions (Janiak, 2000). Moreover, the distance between  $\text{Pd1}$  atom and  $\text{CgCat}^i$  of another adjacent cation ( $i = x, 1 + y, z$ ) of 3.497 Å and the angle between normal to the plane of  $\text{HCQ}^+$  cation and vector connecting  $\text{CgCat}^i$  and  $\text{Pd1}$  of  $171.96^\circ$  indicate possible  $\eta^6$  semi coordination of the phenyl ring of the cation. Thus the coordination number of Pd atom can be considered as 4 + 1 with a tetragonal pyramidal coordination polyhedron. Due to these intermolecular contacts the cations and anions are linked to form a chain parallel with [010] (Fig. 2).

## supplementary materials

Two uncoordinated water molecules interconnect the  $\text{HCQ}^+$  cations *via* hydrogen bonds into a chain running along [010] (Fig. 3). Distances and angles characterizing these bonds are summarized in Table 2.

### Experimental

Ethanolic solution of  $\text{PdCl}_2$  prepared from  $0.2 \text{ cm}^3$  40% water solution of  $\text{PdCl}_2$  in  $8 \text{ cm}^3$  of ethanol (0.048 g  $\text{PdCl}_2$ ; 0.27 mmol) was cooled down to -15 °C and mixed with a cold (-5 °C) THF solution of CQ (0.17 g CQ dissolved in  $15 \text{ cm}^3$  of THF; 0.54 mmol). Resulting solution was stirred at -15 °C for a while and then a cold (3 °C) aqueous solution of  $\text{CsCl}$  (0.046 g of  $\text{CsCl}$  dissolved in  $2 \text{ cm}^3$  of water; 0.27 mmol) was added. Yellow precipitation of I, which formed immediately after mixing, was filtered off, dried on air and analyzed by IR and elemental analysis. Mother liquor was left for crystallization in refrigerator at -5 °C and after few days we obtained a small amount of orange-red crystals of I. Crystals were filtered off, dried on air and analyzed by IR spectroscopy to prove their identity with the precipitation.

### Refinement

H atoms of the CQ moieties were inserted in calculated positions appropriate for the data collection temperature with isotropic displacement parameters riding on that of the parent C and O atoms,  $U_{\text{iso}}(\text{H}) = 1.2\text{U}_{\text{eq}}(\text{C})$  and  $U_{\text{iso}}(\text{H}) = 1.5\text{U}_{\text{eq}}(\text{O})$ . The hydrogen atom coordinated on the N2 atom in  $\text{HCQ}^+$  was found in the difference electron map and refined freely, water H atoms were found with the program CALC-OH (Nardelli, 1999) and were refined with fixed bond distances and angles. Hydrogen atoms could be found only for one disordered position (O4A).

### Figures

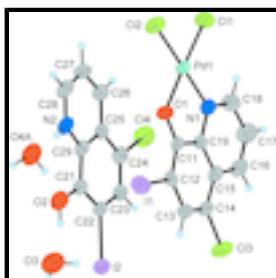

Fig. 1. The structure of I. Displacement ellipsoids are drawn at the 50% probability for non-H atoms. H atoms are represented as small spheres of arbitrary radii. Only one position of the disordered O4 water molecule is shown.

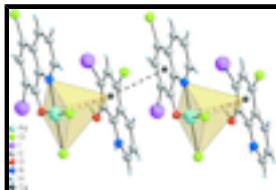

Fig. 2. Parallel stacking of the cation and the complex anion enabling  $\pi$ - $\pi$  interactions in I (shown by dashed lines);  $i = x, 1 + y, z$ . Possible penta-coordination of  $\text{Pd}^{\text{II}}$  is suggested.

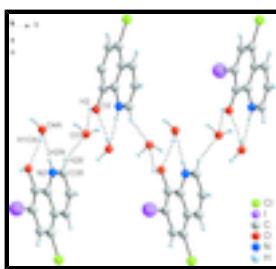

Fig. 3. The system of hydrogen bonds (dashed lines) in I formed in the direction of  $b$  axis. Complex anions are not shown because of clarity.

## Special details

**Experimental.** CrysAlis RED, Oxford Diffraction (2007), Analytical numeric absorption correction using a multifaceted crystal model.

**Geometry.** All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

**Refinement.** Refinement of  $F^2$  against ALL reflections. The weighted  $R$ -factor  $wR$  and goodness of fit  $S$  are based on  $F^2$ , conventional  $R$ -factors  $R$  are based on  $F$ , with  $F$  set to zero for negative  $F^2$ . The threshold expression of  $F^2 > \sigma(F^2)$  is used only for calculating  $R$ -factors(gt) etc. and is not relevant to the choice of reflections for refinement.  $R$ -factors based on  $F^2$  are statistically about twice as large as those based on  $F$ , and  $R$ -factors based on ALL data will be even larger.
