Received 19 October 2011; accepted 14 November 2011

Key indicators: single-crystal X-ray study; $T = 293$ K; mean $\sigma(\text{Pr}-\text{Br}) = 0.001$ Å; R factor = 0.026; wR factor = 0.059; data-to-parameter ratio = 11.3.

The crystal structure of the praseodymium(III) oxide bromide, PrOBr, can be best described with layers of agglomerated square antiprisms $[\text{PrO}_4\text{Br}_4]^{9-}$. These slabs are stacked along the c axis and linked *via* two different secondary contacts between Pr^{3+} and Br^- . The Pr^{3+} cations occupy the Wyckoff site $2c$ with $4mm$ symmetry and carry four O^{2-} anions as well as four primary Br^- anions, yielding a coordination number of 8. While the Br^- anions exhibit the same site symmetry as the Pr^{3+} cations, the oxide anions are located at the Wyckoff position $2a$ with site symmetry $\bar{4}m2$ and have four Pr^{3+} cations as neighbours, defining a tetrahedron.

The *matlockite*-type praseodymium(III) oxide bromide PrOBr

P. Talmon-Gros, C. M. Schurz and T. Schleid

Comment

With the exception of PrOF (Baenziger *et al.* 1950) all praseodymium(III) oxide halides of the general composition PrOX ($X = \text{Cl} - \text{I}$; Zachariassen 1949, Potapova *et al.* 1977) crystallize with the *matlockite*-type structure (Nieuwenkamp & Bijvoet, 1932). The tetragonal crystal structure of the here presented praseodymium(III) oxide bromide PrOBr can be best described with layers of agglomerated square antiprisms $[\text{PrO}_4\text{Br}_4]^{9-}$ ($d(\text{Pr}^{3+}-\text{O}^{2-}) = 234.96$ (4) pm, $d(\text{Pr}^{3+}-\text{Br}^-) = 324.57$ (8) pm, $d(\text{Pr}^{3+}\cdots\text{Br}^-) = 360.8$ (1) and 385.9 (1) pm; Figure 1). These slabs are stacked along the c -axis and linked via two different secondary contacts between Pr^{3+} and Br^- (Figure 2). According to the ionic radii ($r_{\text{Cl}} = 180$ pm, $r_{\text{Br}} = 195$ pm, $r_{\text{I}} = 220$ pm; Shannon, 1976) of the halide anions involved the expansion of the unit-cell dimensions occurs in quite an usual range, but the c -axes become significantly longer than the a -axes (a -axes: from 405.3 pm to 408.6 pm; c -axes: from 679.9 pm to 916.2 pm) along the $\text{Cl}^- - \text{Br}^- - \text{I}^-$ track. The lattice parameters of single crystalline PrOBr ($a = 406.71$ pm, $c = 746.69$ pm) fit almost perfectly with that from a previous powder diffraction study ($a = 407.1$ pm, $c = 748.7$ pm; Mayer *et al.* 1965). Differences in the molar volumes of the PbFCl-type praseodymium(III) oxide halides ($V_m(\text{PrOCl}) = 33.6$ cm³/mol, $V_m(\text{PrOBr}) = 37.2$ cm³/mol, $V_m(\text{PrOI}) = 46.1$ cm³/mol) correspond well with the differences of the molar volumes of the respective halide anions ($V_m(\text{Cl}^-) = 16.3$ cm³/mol, $V_m(\text{Br}^-) = 19.2$ cm³/mol, $V_m(\text{I}^-) = 24.5$ cm³/mol; Biltz 1934). However, the Pr^{3+} cations occupy the *Wyckoff* site $2c$ (symmetry: $4mm$) and bond four O^{2-} anions as well as four *one+one* Br^- anions ending up with a total coordination number of $8+1+1$ (Figure 1). While the Br^- anions exhibit the same site symmetry as the Pr^{3+} cations, the oxide anions are located at *Wyckoff* position $2a$ with the site symmetry $\bar{4}m2$. *Bond-Valence* and *MAPLE* calculations support the interpretation of one important ($d(\text{Pr}^{3+}\cdots\text{Br}^-) = 360.8$ (1) pm) and one less important secondary contact ($d(\text{Pr}^{3+}\cdots\text{Br}^-) = 385.9$ (1) pm): The valency and ECoN for the first bond amounts to values of about 0.08 (with $R_0 = 267$ pm, $b = 37$ pm; Brown, 2002) and 0.12 (Hoppe, 1975), but almost *nil* for the second one, since this next nearest contact to bromide has only very low influence on the effective coordination sphere of the Pr^{3+} cations (ECoN = 0.03).

Experimental

Pale green, transparent, plate-shaped single crystals of PrOBr were obtained as by-product from a mixture of 0.06 g Pr, 0.38 g PrBr_3 and 0.01 g NaN_3 , along with 0.30 g NaBr added as a flux. The mixture was kept at 800 °C for 7 days in an evacuated, sealed fused-silica vessel designed to produce the praseodymium(III) nitride bromide Pr_3NBr_6 in analogy with La_3NBr_6 (Lulei, 1998) and Ce_3NBr_6 (Mattausch & Simon, 1996).

Refinement

The highest peak and the deepest hole in the final difference Fourier map are 95 pm and 84 pm apart from Pr.

0 restraints

Extinction coefficient: 0.032 (5)

Special details

Geometry. All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.

Refinement. Refinement of F^2 against ALL reflections. The weighted R-factor wR and goodness of fit S are based on F^2 , conventional R-factors R are based on F , with F set to zero for negative F^2 . The threshold expression of $F^2 > 2\sigma(F^2)$ is used only for calculating R-factors(gt) etc. and is not relevant to the choice of reflections for refinement. R-factors based on F^2 are statistically about twice as large as those based on F , and R-factors based on ALL data will be even larger.
