Received 22 November 2011; accepted 24 November 2011

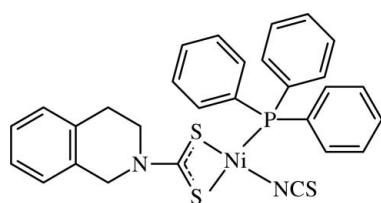

Key indicators: single-crystal X-ray study; $T = 292\text{ K}$; mean $\sigma(\text{C}-\text{C}) = 0.005\text{ \AA}$;

R factor = 0.042; wR factor = 0.123; data-to-parameter ratio = 22.4.

The Ni^{II} atom in the mononuclear title compound, $[\text{Ni}(\text{C}_{10}\text{H}_{10}\text{NS}_2)(\text{NCS})(\text{C}_{18}\text{H}_{15}\text{P})]$, exists within a S_2PN donor set that defines a distorted square-planar geometry. A significant asymmetry in the $\text{Ni}-\text{S}$ bond lengths support the less effective *trans* effect of SCN^- over PPh_3 .

Comment

Dithiocarbamates are versatile ligands which have been shown to bind to all transition elements supporting a wide range of oxidation state (Hogarth, 2005). They have been shown to possess a broad spectrum of biological activities such as fungicidal (Ozkirimli *et al.*, 2005) and bactericidal (Gunay *et al.*, 1999). Nickel complexes of phosphine ligands have been studied for their anticancer activity (Jarret *et al.*, 1993). Nickel(II) dithiocarbamates are borderline acceptors and they can react with Lewis bases such as phosphines as well as hard bases such as nitrogenous ligands (Srinivasan *et al.*, 2009; Travnicek *et al.*, 2008). In view of these importance we have undertaken the crystal structure determination of the title compound, and the results are presented here.

The X-ray study confirmed the molecular structure and atomic connectivity for (I), as illustrated in Fig. 1.

The structure consists of distorted square planar metal coordination with NiS_2PN chromophore. Deviation of the plane from a perfect square is caused by the small bite angle subtended by the sulfur atoms of the chelating dithiocarbamate at the nickel atom. The Ni—S bond distances [2.218 (1) and 2.162 (1) Å, respectively] are significantly different, due to the different trans influences exerted by phosphine and NCS^- . PPh_3 being a good π -acceptor has a greater trans influence and hence the Ni—S bond trans to P is longer than the one trans to NCS anion.

The shortening of Ni—P distance is due the strong back bonding in nickel atom. The C—P—C angles deviate appreciably from the normal tetrahedral angle due to the crowding of the phenyl rings. The short Ni—N distance, 1.867 (2) Å, shows the effective bonding between the nickel atom and NCS^- . The Ni—N—C angle 170.9 (2)° indicates deviation from the linearity and is due to steric compulsions of the bulky PPh_3 group.

The C—S bond lengths are 1.707 (3) and 1.717 (3) Å which are shorter than the typical single bond value of 1.81 Å and longer than C=S distance of 1.69 Å, indicating partial double bond character. The short thioureide C—N distance, 1.315 (3) Å indicates that the π -electron density is delocalised over the S_2CN moiety and that this bond has partial double bond character.

In addition to the van der Waals interactions, the molecular structure is influenced only by intramolecular C—H···S hydrogen bonds involving sulphur atoms S1 and S2. (Fig. 2 and Table 1).

Experimental

Compound (I) was prepared according to the literature procedure (Valarmathi *et al.*, 2011). Single crystals of (I) were obtained by slow evaporation of dichloromethane and ethanol (2:1) solution of (I) at room temperature.

supplementary materials

Refinement

H atoms were placed in idealized positions and allowed to ride on their parent atoms, with C—H distances of 0.93–0.97 Å, and $U_{\text{iso}}(\text{H}) = 1.2U_{\text{eq}}(\text{C})$ for H atoms.

Figures

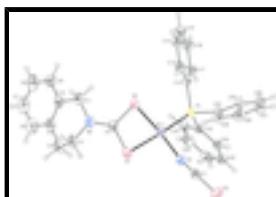

Fig. 1. The molecular structure of the title compound, showing the atom-numbering scheme. Displacement ellipsoids are drawn at the 30% probability level

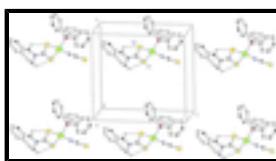

Fig. 2. Molecular packing of the title compound, viewed along the b axis; H-bonds are shown as dashed lines. For the sake of clarity, H atoms, not involved in hydrogen bonds, have been omitted

0 restraints	$\Delta\rho_{\min} = -0.30 \text{ e } \text{\AA}^{-3}$

Special details

Geometry. All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.

Refinement. Refinement of F^2 against ALL reflections. The weighted R-factor wR and goodness of fit S are based on F^2 , conventional R-factors R are based on F, with F set to zero for negative F^2 . The threshold expression of $F^2 > 2\text{sigma}(F^2)$ is used only for calculating R-factors(gt) etc. and is not relevant to the choice of reflections for refinement. R-factors based on F^2 are statistically about twice as large as those based on F, and R- factors based on ALL data will be even larger.
