# Molecular Complexes Exhibiting Polarization Bonding. IV. The Crystal Structure of the Anthracene-s-trinitrobenzene Complex

BY D. S. BROWN, S. C. WALLWORK AND (IN PART) A. WILSON

Department of Chemistry, University of Nottingham, England

(Received 19 December 1962 and in revised form 10 April 1963)

The crystal structure of the 1:1 complex formed between anthracene and s-trinitrobenzene has been determined at room temperature and at low temperature (ca. -100 °C). The structure is basically the same at the two temperatures though there are small differences in atomic positions. The crystals are monoclinic with four molecules of complex in a cell of dimensions a = 11.70, b = 16.20, c = 13.22, all  $\pm 0.02$  Å,  $\beta = 132.8^{\circ} \pm 0.5^{\circ}$  at room temperature, and a = 11.35, b = 16.27, c = 13.02, all  $\pm 0.02$  Å,  $\beta = 133.2^{\circ} \pm 0.5^{\circ}$  at low temperature, giving the maximum contraction approximately along the [103] crystal direction. The space group is C2/c. The structure has been determined at each temperature by three-dimensional Fourier and least-squares methods. The component molecules are stacked alternately, each in two different orientations, in infinite columns along the c axis and the most important intermolecular contacts are approximately along this direction.

#### Introduction

The complex between anthracene,  $C_{14}H_{10}$ , and s-trinitrobenzene,  $C_6H_3(NO_2)_3$ , is one of the series of trinitrobenzene complexes discussed briefly in part III (Wallwork, 1961). The conclusion drawn for the series as a whole was that if there are charge transfer forces operating in the crystal lattices, they must be weak. On the other hand the orange colour of the crystals of the anthracene complex and the evidence from spectroscopic studies of the complex in solution (Briegleb & Czekalla, 1955; McGlynn & Boggus, 1958) suggest that there is a certain amount of charge transfer. Since this complex is one of the more highly coloured and one of the more stable of the aromatic hydrocarbon-trinitrobenzene series, it was felt that a detailed crystallographic examination would be of interest.

### Experimental

Crystals were deposited slowly as orange needles after warm solutions of the components in ethanol had been mixed and allowed to cool. In polarized light at room temperature, the crystals exhibited pleochroism (with colours ranging from orange to yellow) with the maximum absorption of light when the electric vector was parallel to the needle axis. At the low temperature (ca. -100 °C) attained by blowing the vapour from boiling liquid nitrogen over the crystal, its general colour changed to pale yellow, and in polarized light the pleochroic colours ranged from pale yellow to pale green, but with the direction of maximum absorption still parallel to the needle axis.

X-ray photographs were taken by the multiple-film Weissenberg technique, those at low temperature  $(ca. -100 \,^{\circ}\text{C})$  being obtained by the method described elsewhere (Brown & Wallwork, 1962). At room temperature complete three-dimensional data (327 reflexions) were obtained up to the point of fade-out of the reflexions, but for the low-temperature data the apparatus restricted the observable layer lines to those with  $\mu < 20^{\circ}$  so that 919 independent reflexions were observed corresponding to about a half of those within the copper sphere. The intensities were estimated by a microphotometer method (Wallwork & Standley, 1954) and were converted to  $|F_o|^2$  and  $|F_o|$ by applying the usual corrections. No corrections were made for either absorption or extinction since each of the crystals used for the more accurate low-temperature measurements had a maximum dimension of only about 0.2 mm. In obtaining the room-temperature data the intensities of ten reflexions were only roughly estimated, since the spots were too large for the aperture of the microphotometer. These ten reflexions were subsequently omitted from the final least-squares analysis.

### Crystal data

C<sub>14</sub>H<sub>10</sub>. C<sub>6</sub>H<sub>3</sub>(NO<sub>2</sub>)<sub>3</sub>,  $M = 391 \cdot 5$ . Monoclinic,  $a = 11 \cdot 70$ ,  $b = 16 \cdot 20$ ,  $c = 13 \cdot 22$ , all  $\pm 0 \cdot 02$  Å,  $\beta = 132 \cdot 8^{\circ} \pm 0 \cdot 5^{\circ}$ ,  $U = 1838 \cdot 4$  Å<sup>3</sup> (at room temperature).  $a = 11 \cdot 35$ ,  $b = 16 \cdot 27$ ,  $c = 13 \cdot 02$ , all  $\pm 0 \cdot 02$  Å,  $\beta = 133 \cdot 0 \pm 0 \cdot 5^{\circ}$ ,  $U = 1758 \cdot 5$  Å<sup>3</sup> (at approx.  $-100 \,^{\circ}$ C). F(000) = 808, Cu K $\alpha$ ,  $\lambda = 1 \cdot 542$  Å,  $\mu = 10 \cdot 6 \, \text{cm}^{-1}$ . Absent spectra, *hkl* when h + k odd, *hol* when *l* odd. Space group C2/c (no. 15) or Cc (no. 9). Negative pyroelectric test indicates C2/c and this is confirmed by refinement of the structure.

#### Structure analysis

The dichroic effect was interpreted in the light of results obtained by Nakamoto (1952) to indicate stacking of the molecules in a plane-to-plane manner down the needle (c) axis. If the space group is C2/c, which has an eightfold general position, the four molecules of each type in the cell must occupy special positions. Of those available, the s-trinitrobenzene can only occupy (e)  $0, y, \frac{1}{4}; 0, \overline{y}, \frac{3}{4}; \frac{1}{2}, \frac{1}{2}+y, \frac{1}{4};$  $\frac{1}{2}, \frac{1}{2}-y, \frac{3}{4}$ ; implying a twofold symmetry axis in the molecule, because the other fourfold positions require a centre of symmetry. The anthracene molecules were placed in the special positions (a)  $0, 0, 0; 0, 0, \frac{1}{2};$  $\frac{1}{2}, \frac{1}{2}, 0; \frac{1}{2}, \frac{1}{2}, \frac{1}{2}$ . A trial structure was obtained with the molecules occurring alternately along the c axis and with the planes of the molecules perpendicular to this direction. The orientation of the aromatic rings in the anthracene molecule was found to be the same as that of the aromatic ring in the trinitrobenzene molecule, by the observation of only six intense areas near the 'benzene circle' in the hk0 weighted reciprocal lattice.

The structure at room temperature was refined initially by electron-density projections and threedimensional sections and lines. Thereafter, refinement was carried out by nine cycles of least-squares analysis with the SFLS (ISO) program written by J. S. Rollett (Mills & Rollett, 1961). This program refines atomic coordinates, individual temperature factors and the scale factor, using the block diagonal approximation of the normal equations matrix. Hydrogen atoms were not included in the calculations. A weighting scheme,

$$\sqrt{w} = 1$$
 if  $|F_o| < F_A$ 

 $\sqrt{w} = F_A / |F_o|$ 

was employed, and scattering factors of Berghuis (Berghuis, Haanappel, Potters, Loopstra, MacGillavry & Veenendaal, 1955) for carbon and of Freeman (1959)

otherwise

for oxygen and nitrogen were used. The reflexions too weak to be observed as well as the ten roughly estimated intensities referred to above were omitted from

Fig. 1. Composite Fourier diagram of sections parallel to (100) (room temperature). Contours at 2, 3, 4, ... e.Å<sup>-3</sup>.

the analysis. Convergence was reached with a reliability index of 0.180.

The final composite electron-density diagram is shown in Fig. 1 and final coordinates, standard deviations (derived from the least-squares variances) and molecular dimensions are summarized in Tables 1–3. The molecular dimensions and intermolecular approaches less than 3.6 Å were calculated with the use of the distance-angle routine of R. A. Sparks (Mills & Rollett, 1961).

The X-ray photographs at low temperature showed that the structure must undergo very little change on cooling. The low temperature structure was therefore assumed initially to have the same atomic positions as at room temperature and was then refined by

#### Description and discussion of the structure

The structure of the complex at the two temperatures is basically the same. The molecules are arranged alternately in infinite columns parallel to the c axis and are stacked plane-to-plane. Fig. 4 shows part of one column; there is another identical column related to it by the C face centring. When seen edge-on in the h0l projection, the planes of the aromatic rings of the trinitrobenzene and the anthracene molecules make an angle of 83° with the c axis. However, they are not quite parallel since the plane of the aromatic ring of the trinitrobenzene molecule is parallel to the b axis, whereas that of the anthracene molecule makes an angle of 8° with this direction.

Fig. 4. Part of the cell contents, showing the stacking of molecules along the c axis. There is a similar column of molecules related to the one shown by the C face centring.

There are no abnormal intermolecular contacts at either temperature between adjacent columns of molecules. The closest low-temperature approaches of this type are  $C \cdots O$  of 3.22 Å and  $O \cdots O$  of 3.08 Å  $(\overline{3\cdot32}$  and  $\overline{3\cdot23}$  respectively at room temperature), both between adjacent trinitrobenzene molecules. The  $C \cdots C$  contacts of this type are all larger than 3.6 Å at either temperature. These are of the same order as generally accepted van der Waals distances and are similar to the intermolecular  $C \cdots O, O \cdots O$ and C · · · C contacts found in *m*-dinitrobenzene (Trotter, 1961). Within any one column of molecules, however, there are some intermolecular contacts which are shorter than the expected van der Waals distances. All the approaches of this type less than 3.4 Å are shown in Fig. 5. At low temperature the closest C-C distance is 3.30 Å between C(7') and MC(1) (see Fig. 3 for numbering) and there are several contacts of approximately 3.35 Å. The corresponding room temperature values are in general slightly higher.

The molecular dimensions were reliably established only in the low-temperature structure determination. They are shown in Figs. 3(a) and 3(b), and Tables 5 and 6; the approximate dimensions obtained from the room temperature study are given in Tables 2 and 3. The large standard deviations of the room temperature dimensions mean that the differences between these and the low temperature dimensions are unlikely to be significant. The low temperature di-

mensions of the anthracene molecules in the complex are very similar to those obtained for anthracene alone (Cruickshank, 1956) and those for s-trinitrobenzene are consistent with dimensions in other aromatic nitrocompounds, particularly nitrobenzene (Trotter, 1959), *m*-dinitrobenzene (Trotter, 1961) and *p*-dinitrobenzene (Abrahams, 1950). As in these compounds, the nitro groups in s-trinitrobenzene deviate from coplanarity with the aromatic ring by varying amounts. The two related nitro groups attached to C(9) and C(9') are twisted through  $18^{\circ}$  whereas that attached to MC(2) is coplanar with the ring. As a further distortion, the  $\overline{C}(9)$ -N(1) bond is moved out of the plane of the aromatic ring through  $2\frac{1}{2}^{\circ}$ . The temperature factors for the atoms of the anthracene molecule show, at each temperature, a general increase with increasing distance of the atoms from the centre line C(7)-C(7'). This may be interpreted in terms of oscillation of the whole molecule about this line. In the trinitrobenzene molecule the B values for the carbon atoms are of the same order as those for the atoms in the central ring of the anthracene molecule, but the atoms of the nitro groups show abnormally high values, particularly at room temperature. This is presumably related to the apparent looseness of packing in the region of these groups. Further evidence of the thermal effects in the structure may be obtained from the thermal contraction ellipsoid, calculated from the change in cell dimensions with temperature. The ellipsoid as seen in the h0l projection is shown in Fig. 6. The direction of maximum contraction is

Fig. 6. Projection along the b axis of the ellipsoid showing the total percentage contraction from room temperature to ca. -100 °C.

approximately at right angles to the stacking direction and represents a total contraction of 3.5% from room temperature to low temperature. The corresponding total contraction along the stacking direction is 1.9%, whilst in a direction parallel to the b axis there is a corresponding expansion of 0.4%. The shape and orientation of the ellipsoid indicate that, as the molecular planes within each column move closer together, there is an even greater sideways movement of adjacent columns. This increases the efficiency of packing in the regions of the nitro groups and is accompanied by a large reduction in thermal motion of these groups in particular, as evidenced by the changes in the Bvalues. The slight expansion in the direction of the baxis presumably allows modification of the packing to take place in the most efficient way consistent with the retention of normal intermolecular distances. It is likely, however, that the change in colour of the complex on cooling is due more to the reduction in the plane-to-plane separations within each column of molecules than to these changes in the environment of each molecule in sideways directions.

The conclusions from this work are that there are no unusual molecular or intermolecular dimensions apart from the rather close contacts between the molecules in directions approximately perpendicular to their planes. The latter would suggest the possibility of a small amount of charge transfer by  $\pi-\pi$  orbital overlap, as indicated also by spectroscopic studies, even though the relative orientations of the molecules to each other do not seem specially favourable for this (Wallwork, 1961). It seems that the formation of the complex is due primarily to the existence of charge transfer forces, although the crystal structure is a compromise between molecular orientations most favourable to  $\pi-\pi$  interaction and those which give the most efficient molecular packing.

We are indebted to the Director of the Oxford University Computing Laboratory for allowing computing facilities on the Mercury computer, and to the authors of the programs used, particularly Dr J. S. Rollett, Mr O. S. Mills and Dr R. A. Sparks. We are grateful to the Royal Society for a grant towards the cost of apparatus and one of us (D.S.B) thanks the Department of Scientific and Industrial Research for a maintenance grant. We wish also to thank Mrs D. H. Thomas for assistance with the diagrams.
