Molecular Complexes Exhibiting Polarization Bonding. VIII. The Crystal Structures of the 1:1 Complexes formed by *p*-Chlorophenol and *p*-Bromophenol with *p*-Benzoquinone.

By G. G. Shipley* and S. C. Wallwork

Department of Chemistry, University of Nottingham, England

(Received 11 June 1966)

The isomorphous structures of the 1:1 complexes formed by *p*-chlorophenol and *p*-bromophenol with *p*-benzoquinone were determined by Patterson and electron-density projections of the bromo-complex. The structure of the chloro-complex was then refined by anisotropic structure-factor least-squares methods. The crystals are triclinic, space group PI, with two molecules of the complex in each unit cell. The phenol and quinone molecules are stacked alternately, plane-to-plane, in infinite columns and the columns are linked in pairs by hydrogen bonds between the phenol and quinone molecules. The structural relationships between the 1:1 and 2:1 complexes are discussed.

Introduction

Although phenol forms only a 2:1 complex with *p*benzoquinone (Harding & Wallwork, 1953), *p*-halogenophenols form both 2:1 and 1:1 complexes. The isomorphous structures of the 2:1 complexes of *p*chlorophenol (PCP) and *p*-bromophenol (PBP) with *p*-benzoquinone (Q) have already been described in part VII (Shipley & Wallwork, 1967) and the present paper describes the isomorphous structures of the corresponding 1:1 complexes (QmonoPCP and Qmono-PBP). The reason for the existence of both 2:1 and 1:1 complexes is discussed in terms of the roles of charge-transfer interaction and hydrogen bonding.

Experimental

Orange needle-shaped crystals of the OmonoPCP and QmonoPBP complexes were deposited when warm concentrated solutions of the appropriate components in light petroleum were mixed in a 1:1 molecular ratio and allowed to cool. In plane-polarized light the crystals exhibited pleochroism, the colour being deeper when the electric vector was parallel to the needle (b)axis, suggesting that the molecules are probably stacked in columns parallel to this axis. Crystals were sealed into thin-walled glass capillary tubes for X-ray photography and Weissenberg photographs with the crystals oscillating about each of the three crystallographic axes showed that the crystals belong to the triclinic system and permitted the determination of the unit-cell dimensions for each of the complexes. Exposures for intensity estimation were made with Cu $K\alpha$ radiation by the multiple-film, equi-inclination Weissenberg technique. The 0kl and h0l reflexions were recorded in the case of the OmonoPBP complex, and 0kl to 3kl and

hol to h4l reflexions in the case of the QmonoPCP complex. The intensities for the QmonoPBP structure were measured by a photometer method (Wallwork & Standley, 1954) and those for QmonoPCP were estimated visually by comparison with a series of timed exposures of a selected reflexion. The intensities were converted into F_o^2 values in the usual way and no corrections were made for absorption or extinction effects. For the QmonoPCP complex the number of independent F_o^2 values was 1127.

Crystal data

(a) QmonoPBP, C₆H₄O₂.*p*-BrC₆H₄OH, $M=281\cdot1$ $a=6\cdot84$, $b=7\cdot86$, $c=12\cdot49$, all $\pm 0\cdot03$ Å $\alpha=105\cdot8^{\circ}$, $\beta=104\cdot4^{\circ}$, $\gamma=58\cdot7^{\circ}$, all $\pm 0\cdot5^{\circ}$ U=548 Å³; F(000)=280 $D_m=1\cdot71$ g.cm⁻³, Z=2, $D_c=1\cdot70$ g.cm⁻³. Space group $P\bar{1}$ (indicated by pyroelectric and statistical tests); Cu $K\alpha$ ($\lambda=1\cdot542$ Å).

(b) QmonoPCP, C₆H₄O₂. *p*-ClC₆H₄OH, $M=236\cdot6$ $a=6\cdot80$, $b=7\cdot90$, $c=12\cdot25$, all $\pm 0\cdot03$ Å $\alpha=106\cdot9^{\circ}$, $\beta=106\cdot5^{\circ}$, $\gamma=58\cdot0^{\circ}$, all $\pm 0\cdot5^{\circ}$ U=527 Å³; F(000)=244 $D_m=1\cdot48$ g.cm⁻³, Z=2, $D_c=1\cdot49$ g.cm⁻³. Space group $P\bar{1}$ (indicated by statistical tests); Cu K α ($\lambda=1\cdot542$ Å).

Structure determination and refinement

The hol Patterson projection for the QmonoPBP structure revealed the positions of the bromine atoms, and a Fourier electron density projection based on signs calculated for the contributions of the bromine atoms only to the structure factors showed the general arrangement of the whole structure, with phenol and quinone molecules almost exactly overlapping in this projection. Successive structure-factor calculations, with a constant overall temperature factor $B=3\cdot5$ Å²,

and Fourier syntheses reduced the agreement index, $R = \Sigma ||F_o| - |F_c|/|\Sigma |F_o|$, to 0.21 and gave the electron density map shown in Fig.1. The hol projection of the isomorphous QmonoPCP structure was solved and refined similarly to the point where R was 0.25.

Attempts were made to derive the 0kl projection for QmonoPBP in the same way, but the Patterson map could not be interpreted unambiguously even when compared with the corresponding projection of the QmonoPCP structure. A solution was obtained eventually after calculation of a three-dimensional Patterson function for the QmonoPCP structure, and the

0kl projection for the QmonoPBP complex was refined to an R value of 0.24 with the use of temperature factors B=1.5 Å² for bromine and 3.5 Å² for all other atoms. Table 1 gives the final, approximate, atomic coordinates for QmonoPBP ($\sigma \simeq 0.005$), and the final calculated structure factors are compared with the observed structure amplitudes in Table 2.

The approximate coordinates for the QmonoPCP structure, derived from the h0l projection and the threedimensional Patterson function, were refined by the block-diagonal structure-factor least-squares method with the program written by Dr J.S. Rollett (Pepinsky, Robertson & Speakman, 1961) for the Oxford MER-CURY computer and a modification of the same program written by Dr R.D.Diamand for the ATLAS computer. Atomic positions and anisotropic temperature factors for all atoms other than hydrogen were refined, together with an overall scale factor (a total of 145 parameters), 1127 independent observations being used. In the early stages of the refinement the F_o values were all given unit weights, but later the terms larger than a selected value F^* were downweighted according to the scheme $\sqrt{w} = F^*/F_o$ with F^* equal to 600 (on the scale of Table 4). The refinement converged with R=0.18, probably owing to the use of rather restricted visual data of only moderate quality. In view of this, it is felt that little significance can be attached to the anisotropy of the atomic vibrations and only spherically averaged values are quoted in Table 3. The final atomic positions and their standard deviations obtained by inversion of the normal equations matrix are also given in Table 3. The observed structure factors are compared with the final calculated values in Table 4.

Results and discussion

In both complexes the phenol and quinone molecules are stacked alternately along the b axis but with their plane normals tilted approximately 30° away from this axis. This tilt brings the C-O or the C=O groups of

successive molecules approximately over the centres of the rings of the adjacent molecules as shown in Fig. 3, indicating a specific interaction involving these groups (Prout & Wallwork, 1966). Such a staggered arrangement of molecules in an infinite stack inevitably brings the C-halogen bond in each phenol molecule into a position adjacent to a quinone ring on one side, and this causes the average molecular separation to be larger in this direction (3.35 Å in QmonoPCP, compared with 3.27 Å in the opposite direction) as well as

Table 4. Comparison of observed and final calculated structure factors on 50 times the absolute scale for QmonoPCPThe asterisked line gives h, k. Other lines gives values in the order l, F_o, F_c ,

causing a dihedral angle of about 3° between the two molecular planes. In this way the closest C · · · Cl distance is 3.61 Å, to C(7), whereas the C \cdots O interaction distances are of the order of 3.3 Å, as shown in Fig.2. There are no close approaches between molecules in adjacent stacks apart from the $OH \cdots O = C$ hydrogen bond of length 2.70 Å between the phenol molecule in one stack and a quinone molecule approximately coplanar with it in an adjacent stack. Because of the 1:1 stoichiometry of the complex only one of the two C = Ogroups in each quinone molecule is hydrogen-bonded in this way and the centrosymmetric repetition of this hydrogen bond causes the stacks of molecules to be linked in pairs in the z direction. The pairs of stacks are then held together in the x and z directions by van der Waals forces.

The dimensions of the two component molecules in OmonoPCP are shown in Fig.4. The standard deviations of the bond distances are all approximately 0.02 Å, apart from that of the C-Cl bond, which is 0.013 Å. The bond angles have standard deviations of about 1.5° . The dimensions appear normal within the rather wide limits of accuracy, and, as in the case of the 2:1 complex of *p*-chlorophenol, the irregularity of bond angles at the point of attachment of the OH group to the ring of the phenol molecule can be explained in terms of repulsion between the OH group and the C(5)-H group adjacent to it in the ring. In both the 2:1 and 1:1 complexes there is a tendency for the pair of ring C-C bonds parallel to the C-Cl and C-OH bonds to be larger than the other four bonds. The difference is not statistically significant in either structure, but its appearance in both structures suggests that it is probably real. The lengths of these two types of bonds, averaged between the two structures, are 1.41 and 1.38 Å. The corresponding bonds in the quinone molecules (which are formally C = C and C - C respectively) have lengths 1.34 and 1.46 Å when averaged between the two structures. The other bond lengths, similarly averaged, are C-Cl 1.76, C-OH 1.38, C=O 1.21 Å, and these all compare reasonably well with expected dimensions (cf. 1.322, 1.477, 1.222 Å found for the lengths of C=C, C-C and C=O in *p*-benzoquinone; Trotter, 1960).

It is interesting to compare the crystal structures of the 1:1 phenol-quinone complexes with those of the 2:1 complexes already reported (Shipley & Wallwork, 1967). The 2:1 stoichiometry permits each carbonyl oxygen atom to be hydrogen bonded to a phenolic OH group, but this is achieved at the expense of restricting the intermolecular charge-transfer interaction to isolated groups of three molecules (one quinone sandwiched between two phenol molecules). The combined effect of both types of interaction is to form bands of molecules one unit cell wide (the limit of the chargetransfer interaction), which extend indefinitely in the hydrogen-bonded direction. The 1:1 complexes, on the other hand, have infinite stacks of charge-transferlinked molecules with the stacks hydrogen-bonded into pairs so that, again, infinite bands of molecules are formed, which are one unit cell wide (the limit of the hydrogen-bond interaction). The fact that the 2:1 and 1:1 complexes are formed under similar conditions, the product depending on the composition of the solution, and appear to be about equally stable, indicates that the charge-transfer forces and the hydrogen bonding are roughly similar in energy. No 1:1 complex has been reported between unsubstituted phenol and pbenzoquinone, so presumably the increased van der Waals forces due to the halogen atoms are necessary to stabilize the structure of the 1:1 complex. In quin-

Fig. 3. Projections of (a) p-chlorophenol on to the p-benzoquinone molecule below (smaller y coordinate) and (b) p-benzoquinone on to the p-chlorophenol below, showing the mode of overlap in relation to the close approaches designated as in Fig. 2.

hydrone, both charge-transfer interaction and hydrogen bonding are optimized in the 1:1 structure, so it is not surprising that there is no 2:1 complex in this case.

The authors wish to thank Professor J.S. Anderson for drawing their attention to the existence of these complexes, the Directors of the Manchester University and the Science Research Council Computer Laboratories for computing facilities, J.S. Rollett, R.D. Diamand, O.S. Mills, R.A. Sparks, M. M. Harding and J.H. Rayner for the use of their computer programs, the Council of the Royal Society for contributing to the cost of the apparatus, Mrs D.H. Thomas for assistance with the preparation of the diagrams and The Shell Petroleum Company Limited for a maintenance grant (to G.G.S.).

A comparison of analytical and numerical methods for the evaluation of the absorption correction in crystal structure analysis.* By P. COPPENS, Chemistry Department, Brookhaven National Laboratory, Upton, L. I., New York, U.S.A. and J.DE MEULENAER[†] and H.TOMPA, Union Carbide European Research Associates, Brussels 18, Belgium.

(Received 30 June 1966)

A comparison is made between analytical evaluation of the absorption correction using Howells polyhedra and numerical calculation with the Gaussian method. It is shown that convergence can be reached with the numerical method, provided a sufficiently fine grid is chosen. When absorption is large (*i.e.* > 70-80 %) the analytical method is to be preferred as it produces the required accuracy in a much smaller amount of computer time.

An analytical method of evaluating the absorption correction in crystal structure analysis has been described recently (de Meulenaer & Tompa, 1965). The only completely general method available previously was introduced by Busing & Levy (1957) and is based on a numerical evaluation of $\int \exp(-\mu L) dV$ (see also Coppens, Leiserowitz & Rabinovich, 1965). The accuracy of this method depends evidently on the formula and the number of points used. Busing & Levy claim specifically a precision of 0.2%for transmissions between 50 and 62% using Gauss's formula and an $8 \times 8 \times 8$ grid and it is intuitively clear and easy to verify that for a constant grid the accuracy decreases with increasing absorption coefficient μ . Clearly, any desired accuracy can be obtained by using finer grids, but it is the purpose of this note to point out that great care must be taken to verify that the number of points used is sufficient for the desired accuracy, and that the computation effort required may become prohibitive.

* Research performed in part under the auspices of the U.S. Atomic Energy Commission.

We have recomputed, using the analytical method, the transmission for some of the reflexions of a needle-shaped crystal of YFeO₃ (μ =878·8 cm⁻¹ for Cu K α radiation) investigated recently (Coppens & Eibschütz, 1965) and find values differing from those obtained by the Busing & Levy method using a 12×12×32 grid. We have, therefore, repeated the computation on a finer grid and have obtained values which converge towards those of the analytical method, as shown in Table 1.

Table 1. Transmission of some reflexions of a crystal of YFeO₃ (Coppens & Eibschütz, 1965) computed by Gaussian integration on the grids indicated and by the analytical method of de Meulenaer & Tompa (1965)
