mon phenomenon and probably an important mechanism for regulating their function during immune responses. For instance, the splice variants of both CD28/CTLA-4 and their ligands B7-1/B7-2 have been identified, and these isoforms have been shown to play a role in regulating T-cell responses^[7-10]. Recently, an alternative variant of *PD-L2* that lacks an Igv-like domain has been identified in mice^[6], and a human *PD-L2* variant lacking an Igc-like domain has also been described^[11]. However, no such splice variant of human *PD-L1* has been reported to our knowledge. In the present study, we identified an alternatively spliced variant of *PD-L1* mRNA encoding an isoform lacking the Igv-like domain. The novel variant was generated through splicing out exon 2, encoding an Igv-like domain but retaining all other exons without a frame-shift. The PD-L1II isoform was located at an intracellular compartment, which was likely to be the endoplasmic reticulum. In contrast, the conventional product of PD-L1 was located on the plasma membrane. Moreover, *PD-L1II* mRNA was expressed in resting PBMC but diminished or was absent in activated cells dependent on stimulating mitogens. Our results suggest that alternative splicing may be one of the mechanisms for modulating *PD-L1* expression and function in peripheral blood cells.

As the Igv-like domain of PD-L1/PD-L2 is critical for binding to PD-1^[2], any isoform of PD-1 ligands lacking the Igv-like domain does not bind to PD-1. For instance, Latchman *et al* found that an alternatively spliced variant of murine PD-L2, with the Igv-like exon being deleted, did not bind to PD-1-Ig, indicating that the Igv-like domain is necessary for ligand binding^[6]. Moreover, molecular modeling and site-directed mutagenesis indicates that the binding sites of PD-L1/PD-L2 for PD-1 are largely located within the Igv-like domain^[16]. Therefore, the novel PD-L1II isoform identified in this study would not bind to the receptor PD-1 because of the absence of the Igv-like domain, although direct measure-

Figure 6. Reverse transcription polymerase chain reaction (RT-PCR) analysis of *PD-L1* splice variant expression in freshly isolated and mitogen-activated human peripheral blood mononuclear cells. The cDNA of the house-keeping gene, glyceraldehyde-3-phosphate dehydrogenase (GAPDH), was amplified as a control. Ion, ionomycin; PDB, phorbol dibutyrate; PHA, phytohemagglutinin.

ment needs to be carried out. In addition, this isoform was located in the intracellular compartment and was unable to be transported onto the cell surface, suggesting that it would not function properly because only those expressed on the cell surface can interact with receptors. We have found similar results for the PD-L2 isoform lacking the Igc-like domain, which is also located mainly in intracellular compartments^[11]. Why these isoforms could not be transported to the cell surface was unclear when the study was carried out, but this was probably a result of incorrect folding and/or defects in glycosylation of the *PD-L1*III isoform in the endoplasmic reticulum. The present study shows that the glycosylation extent of PD-L1III is lower than that of PD-L1I, suggesting that potential glycosylation sites on the Igv-like domain may be important for PD-L1 transportation to the cell surface.

PD-L1 and PD-L2 are two ligands for PD-1, a costimulatory molecule that plays an inhibitory role in regulating T-cell activation in the periphery^[4,6,17,18]. Their expression is thus modulated precisely during immune responses^[21]. PD-L1 and PD-L2 share 40% amino acid identity and are more homologous to each other than to other ligands of the B7 family^[2]. However, the expression pattern of these molecules is significantly broader than that of other B7 family ligands. The transcripts of both *PD-L1* and *PD-L2* were detected at high levels in the placenta and at low levels in the spleen, lymph nodes, and thymus, and were absent in the brain^[4-6]. Expression of *PD-L1* and *PD-L2* in both lymphoid and nonlymphoid tissues suggests that the PD-1/PD-1 ligand pathway may modulate immune responses in secondary lym-

phoid organs as well as in peripheral sites. We^[19] and other investigators^[5] have found that the resting T cells do not express PD-L1, but mitogen activation of human T cells results in cell surface expression of PD-L1 in addition to PD-1. Similarly activated B cells express PD-L1 and PD-L2 in addition to PD-1^[4,6,20]. This suggests that at the interface of T and B contact, antigen signals can be modulated bidirectionally through PD-1, thereby limiting T-cell-receptor and B-cell-receptor signaling after activation. However, the results presented here show that the PD-L1III splice variant can be detected by RT-PCR in the resting PBMC, suggesting that the mRNA transcripts of *PD-L1* were actually produced in the resting cells, but may be alternatively spliced to generate a variant encoding the PD-L1III isoform. Because of its intracellular localization as revealed by an EGFP tag, the PD-L1III isoform could not be detected using surface staining. Thus, alternative splicing prevented PD-L1 from expression on the surface of the resting cells, thereby blocking its function. Although the expression of PD-L1II at the protein level in PBMC awaits confirmation, our results suggest that PD-L1 expression may be modulated at the posttranscriptional level through alternative splicing of its transcript.

To conclude, we identified an mRNA variant encoding a novel isoform of PD-L1, which was localized in the intracellular compartment, probably the endoplasmic reticulum. Our data also demonstrate the importance of the Igv-like domain of PD-L1 for targeting it to the cell surface.

Abstract

Aim: To design the effective directed differentiation medium to differentiate bone marrow cells into hepatocyte-like cells. **Methods:** Bone marrow cells were cultured in the directed differentiation media including fibroblast growth factor-4 (FGF-4) and oncostatin M (OSM). Hepatocyte-like cells from directed differentiation of bone marrow cells were identified through cell morphology, RNA expressions by reverse transcriptase-polymerase chain reaction (RT-PCR), protein expressions by Western blot, and hepatocellular synthesis and metabolism functions by albumin ELISA, Periodic acid-Schiff staining and urea assay. **Results:** Some epithelial-like cells or polygonal cells appeared and increased in the course of the cell directed differentiation. Hepatocyte nuclear factor-3 β (HNF-3 β), albumin (ALB), cyokeratin 18 (CK18), transthyretin (TTR), glucose-6-phosphate (G-6-Pase), and tyrosine aminotransferase (TAT) mRNA were expressed in the course of the directed differentiation. The directed differentiated cells on d 21 expressed HNF-3 β , ALB, and CK18 proteins. The directed differentiated cells produced albumin and synthesized urea in a time-dependent manner. They could also synthesize glycogen. **Conclusion:** Our differentiation media, including FGF-4 and OSM, are effective to differentiate bone marrow cells into hepatocyte-like cells, which could be used for hepatocyte resources for bioartificial liver or hepatocyte transplantation.

Introduction

Liver transplantation is one of the most effective treatments for patients with acute and chronic liver failure^[1]. However, since donor livers are scarce, only a small number of patients can receive a replacement liver in time. Thus, it is necessary to seek alternative therapies to replace liver transplantation.

Bioartificial liver or hepatocyte transplantation, serving as temporary liver support, can provide necessary liver functions^[2-3]. The functional hepatocyte is the core of the temporary liver support. Since donor hepatocytes are limited, it is imperative to explore ways to gain functional hepatocytes. Stem cells are defined as cells that have clonogenic and self-renewing capabilities, and can differentiate into multiple different cell types that make up the organ under the right con-

dition or given the right signals^[4]. Thus, stem cell can be an ideal resource of functional hepatocytes.

Hepatocytes originating from bone marrow stem cells were first observed in rats after combined bone marrow transplantation and liver damage. In rats, a combination of hepatotoxin, which induces widespread liver damage, and 2-acetylaminofluorene, which prevents endogenous liver repair, were used. Then, a combination of Y chromosome fluorescence *in situ* hybridization (FISH) and transgene expression were used to confirm that bone marrow stem cells were the source of resultant hepatocytes^[5]. The same results were demonstrated in mice^[6] and humans^[7,8]. In a later study, Lagasse *et al* demonstrated that transplantation of xc-kit^{high}Thy1^{low}Lin⁻Sca-1⁺(KTLS) bone marrow cells to irradiated hosts could treat an inborn error of hepatic metabolism^[9]. Multipotent adult progenitor cells (MAPCs), a sub-

population of mesenchymal stem cells in the bone marrow, were found to differentiate into many kinds of cells including hepatocytes^[10]. Recently, it has been reported that bone marrow stromal cells can develop into hepatocyte-like cells^[11]. Thus, we can confirm from these findings that stem cells in bone marrow exist and can differentiate into hepatocytes *in vivo* and *in vitro*.

The differentiation processes of stem cells are likely to be complex, but must exist in the microenvironment of the cells, the signals which originate from the extracellular matrix through adhesion-related events^[12], and the cocktail of soluble ligands now known to control cell growth, differentiation, and morphogenesis^[13]. In the course of hepatic differentiation, some cytokines, including fibroblast growth factor-4 (FGF-4)^[14], oncostatin M (OSM)^[15], hepatocyte growth factor (HGF)^[16] and epidermal growth factor (EGF)^[17], control the hepatic differentiation and maturation. In the present study, we used the cell directed differentiation medium including FGF-4 and OSM, to investigate hepatocyte-like cells from the directed differentiation of mouse bone marrow cells *in vitro*.

Materials and methods

Materials C57BL/6 mice (3–4 weeks old) were purchased from the Model Animal Research Center of Nanjing University (Grade: SPF, No 041117035). The mice were kept individually in pathogen-free conditions with a 12-h light/dark cycle and were fed sterile food and water. All animals were treated in accordance with the guidelines of the European Community Standards on the Care and Use of Laboratory Animals (No 28871-22A9).

Dulbecco's modified essential media-low glucose (DMEM-LG), Iscove's modified Dulbecco's medium (IMDM), *L*-glutamine, and fetal calf serum (FCS) were obtained from Hyclone Laboratories (South Logan, UT84321, USA). MCDB-201, insulin-transferrin-selenium (ITS), dexamethasone, ascorbic acid 2-phosphate, benzylpenicillin, streptomycin, and fibronectin were obtained from Sigma-Aldrich (Saint Louis, Missouri 63103, USA). FGF-4 and OSM were obtained from R&D Systems (Minneapolis, MN 55413, USA).

The antibody against mouse albumin was obtained from Dako Systems (DK-2600, Glostrup, Denmark). The antibody against mouse cytokeratin 18 was obtained from Chemicon (Temecula, Ca 92590, USA). Fluorescein (FITC)-conjugated secondary antibody, phycoerythrin (PE)-conjugated secondary antibody, and rhodamine (TRITC)-conjugated secondary antibody were obtained from Sigma-Aldrich (Saint Louis, Missouri 63103, USA). Trizol reagent was also purchased

from Sigma-Aldrich. A TITANIUM™ one-step RT-PCR kit was purchased from Clontech (Palo Alto, CA 94303-4230, USA). Periodic acid-Schiff (PAS) staining solution was purchased from Shanghai Bioengineer Company (590 Zhaojiabang Road, Shanghai, China). A Colorimetric assay kit was purchased from Randox Laboratories (Randox Laboratories, Antrim, UK).

Preparation of bone marrow cells Bone marrow cells were prepared as previously described^[18]. Fresh bone marrow aspirate extracted from the tibias and the femora of the C57BL/6 mice was suspended in DMEM-LG media and was centrifuged to pellet the cells, and the fat was removed. The cell pellet was resuspended in DMEM-LG media and fractionated on a density gradient generated by centrifugation of 1.077 g/L percoll solution at 1150×g for 30 min at the room temperature. The cells in the percoll interface were then collected and rinsed twice. Cell viability was determined by the trypan blue exclusion test. Only suspensions with cell viability of 95% were used.

Directed differentiation of bone marrow cells Bone marrow cells were inoculated in bone marrow cells' directed differentiation media at 5×10⁵ cells/cm² in 10 mg/L fibronectin-coated culture flasks. Bone marrow cells' directed differentiation media consisted of the following: 54% DMEM-LG, 36% MCDB-201, 10% FCS with 1×ITS, 1×10⁻⁸ mol/L dexamethasone, 1×10⁻⁴ mol/L ascorbic acid 2-phosphate, 100 U/L benzylpenicillin, 100 mg/L streptomycin, 30 μg/L FGF-4, 30 μg/L OSM. As a negative control, bone marrow cells' culture medium was similar to the directed differentiation medium but without FGF-4 and OSM. Cells were cultured in a humidified atmosphere of 5% CO₂ and 95% air at 37 °C. After 72 h, non-adherent cells and debris were removed, and the adherent cells were cultured continuously. Cultures were maintained by media exchange every 3 d.

Cell morphology was observed under Olympus phase contrast microscope (CX40RF200, Olympus optical Co LTD, Japan). On d 0, 3, 6, 9, 12, 15, 18, 21, some cells were detached with 0.25% trypsin-EDTA solution and collected for RNA extraction. Cells on d 21 were detached with the same method and used for experiments. Cell supernatant on d 0, 3, 6, 9, 12, 15, 18, 21 were collected for albumin ELISA.

Hepatocyte isolation and culture Hepatocytes were isolated from 3–4 weeks old C57BL/6 mice by a conventional two-step collagenase liver perfusion^[19] and cultured on fibronectin-coated flasks 10 mg/L in IMDM containing 10% FCS, *L*-glutamine 2 mmol/L, dexamethasone 1 μmol/L, insulin 1 μmol/L, benzyl penicillin 100 U/L, and streptomycin 100 mg/L. Cultures were maintained by media exchange every 3 d.

RNA extraction and RT-PCR analysis Total RNA was

extracted by using Trizol reagent from C57BL/6 mouse hepatocytes, fresh bone marrow cells, cultural bone marrow cells, and directed differentiated bone marrow cells. In total, 1 µg RNA was used for cDNA synthesis and amplification by one-step RT-PCR kit. For hepatocyte nuclear factor-3β (HNF-3β), albumin (ALB), cytokeratin18 (CK18) and transthyretin (TTR), the following reaction conditions were used: reverse transcription at 50 °C for 1 h, denaturation of RNA/DNA hybrid and inactivation of reverse transcriptase at 94 °C for 5 min. Polymerase chain reaction (PCR) was used for 40 cycles, denaturation at 94 °C for 30 s, annealing at 60 °C for 1 min, extension at 72 °C for 1 min, final extension at 72 °C for 5 min. For glucose-6-phosphatase (G-6-Pase) and tyrosine aminotransferase (TAT), the following reaction conditions were used: reverse transcription at 50 °C for 1 h, denaturation of RNA/DNA hybrid and inactivation of reverse transcriptase at 94 °C for 5 min. PCR was used for 30 cycles, denaturation at 94 °C for 1 min, annealing at 55 °C for 1 min, extension at 72 °C for 1 min, final extension at 72 °C for 5 min.

Primers used for amplification are listed in Table 1. All primers were synthesized by Shanghai Sangon Biological Engineering Technology & Service Co Ltd, (Shanghai, China). mRNA levels were normalized using β-actin as a housekeeping gene. The amplified products were subjected to electrophoresis in 1% agarose gels and stained with ethidium bromide.

Western blot analysis Cells, including C57BL/6 mouse hepatocytes, fresh bone marrow cells, cultural bone marrow cells, and directed differentiated bone marrow cells, were washed with 0.01 mol/L PBS and lysed with lysis buffer. About 50 µg of proteins in each supernatant were boiled for

5 min in a sodium dodecyl sulfate (SDS) sample buffer and subjected to electrophoresis on 10% SDS-PAGE gels. The proteins were transferred to Polyvinylidene Fluoride (PVDF) membrane through semidry transfer at 210 mA for 0.5 h. The membrane was blocked for 30 min at room temperature in 3% nonfat milk in Tris-buffered saline (TBS) with 0.05% Tween20, and incubated with primary antibodies against mouse ALB (1:1000), mouse HNF-3β (1:500), and mouse CK18 (1:500) at room temperature for 1 h. The membrane was rinsed and washed 3 times in TBS-Tween20 for 10 min each, and then incubated at room temperature for 1 h with a Horseradish peroxidase (HRP)-conjugated second antibody (1:1000). After adequate washes with TBS, the membrane was stained with diaminobenzidine (DAB) stain at room temperature for 2–3 min, and then washed with PBS.

Albumin ELISA Cell culture media at various time points were collected as samples for ALB ELISA. One microlitre of a monoclonal antibody against mouse ALB was diluted with 100 µL coating buffer for each well and incubated for 60 min. After incubation, the capture antibody solution was aspirated and washed with wash solution. Total 200 µL of blocking solutions were added to each well and incubated for 30 min. After incubation, the blocking solution was removed and each well was washed. One hundred microlitre standards or samples were transferred to assigned wells and incubated for 60 min. After incubation, standards or samples were removed, and each well was washed. 100 µL HRP conjugate (1:10000) were transferred to each well and incubated for 60 min. After incubation, the HRP conjugate were removed and each well was washed. Tetramethylbenzidine (TMB) 100 µL were transferred to each well and incubated for 30 min. To stop the TMB reaction, 100 µL of H₂SO₄ 2 mmol/L were applied to each well. The plate was read at the wavelength 450 nm for TMB through the microtitration plate reader (TECAN A-S002, Austria).

Periodic acid-Shiff (PAS) staining Cells were fixed with 20% formaldehyde and intercellular glycogen was stained with PAS staining solution according to the standard protocol.

Urea assay Urea concentrations were measured through a colorimetric assay kit. The mouse bone marrow cells were plated at 5×10⁵ cells/cm² on 1 mg/L fibronectin (FN)-coated 6-well plates in bone marrow cells' directed differentiated medium or cultural medium. The cells (on d 3, 6, 9, 12, 15, 18, and 21) were incubated in 2 mL medium containing 5 mmol/L NH₄Cl for 24 h in 5% CO₂ at 37 °C. After incubation, the urea concentrations in the supernatant were measured. Mouse hepatocytes grown in the monolayer with the same density was used as positive control and culture medium used as

Results

Changes of cell amount and morphology The changes in cell amount and morphology could be seen in the course of the cell-directed differentiation. Bone marrow cells were inoculated at the density of 5×10^5 cells/cm². However, when the nonadherent cells were removed 3 d later, we found that the adherent cells' density was suitable for the adherent cells to grow well. On d 12, we could see some epithelial-like cells or polygonal cells in the directed differentiation medium, and the number and sizes of colonies of epithelial-like cells or polygonal cells increased in the course of the cell directed differentiation. On d 21, cells were detached and counted. The yield of the cells was approximately 8×10^3 /cm². In the negative group, we could see many fibroblast-like cells or fusiform cells, and only slight polygonal cells (Figure 1).

Gene expressions of liver specific markers To assess the directed differentiation of bone marrow cells into hepatic lineages, we first examined mRNA expressions of endoder-

mal and liver specific genes including HNF-3 β , ALB, CK18, TTR, G-6-Pase, and TAT, which could not be detected in fresh bone marrow cells and cultural bone marrow cells (Figure 2). In the bone marrow cells' directed differentiation culture group, HNF-3 β , ALB, and CK18 mRNA expressions first appeared within 6 d, and lasted throughout the later directed differentiation. TTR mRNA was expressed within 9 d, and its expression lasted throughout the later directed differentiation. From our research, we found that G-6-Pase and TAT mRNA expressions could be detected within 12 d, and their expressions lasted in the course of the later directed differentiation (Figure 2).

Protein expressions of liver specific markers We found that fresh bone marrow cells and cultural bone marrow cells on d 21 did not express any HNF-3 β , ALB or CK18, but directed differentiated bone marrow cells on d 21 expressed HNF-3 β , ALB, and CK18 (Figure 3).

Hepatocyte functional activity ALB secretion was measured at various times throughout the cell differentiation. Undifferentiated bone marrow cells and cultural bone marrow cells did not secrete any ALB. Following treatment with FGF-4 and OSM, directed differentiated bone marrow cells

Figure 1. Cell morphology was observed with an Olympus phase contrast microscope. (A) Directed differentiated bone marrow cells on d 12; (B) directed differentiated bone marrow cells on d 21; (C) cultural bone marrow cells in the culture media; and (D) mouse hepatocytes. ($\times 200$).

Figure 2. Some genes were selected and reverse transcriptase-polymerase chain reaction was performed. Lane 1-Lane 8 presented respectively: directed differentiated bone marrow cells on d 0, 3, 6, 9, 12, 15, 18, 21; Lane 9: mouse hepatocytes; Lane 10: cultural bone marrow cells in the culture media.

produced ALB in a time-dependent manner. On d 15, the amount of secreted albumin reached the maximum amount (Figure 4).

Intracellular glycogen accumulation, one feature of adult liver, was analyzed by staining the cells with the PAS reagent. A slight accumulation of glycogen was detected in the course of directed differentiation, while no accumulation of glycogen was found in the culture media without FGF-4 and OSM (Figure 5).

We then assessed urea production at various time point throughout the differentiation. Undifferentiated bone marrow cells and cultural bone marrow cells did not produce

urea. In the directed differentiated group, directed differentiated bone marrow cells produced urea 3 d later, and in a time-dependent manner. On d 15, the amount of urea produced by directed differentiated bone marrow cells reached the maximum amount (Figure 6).

Discussion

In the present study, we selected bone marrow cells for further differentiation study because no matter hematopoietic stem cells, multipotent progenitor cells, and bone marrow stromal cells, they share common aspects. As bone marrow cells, they exist in the same bone marrow cell-cell microenvironment. They share the same character-stem cell plasticity, which means they have the ability to differentiate into cells of different tissue under certain microenvironments^[20]. It has recently been founded by reseachers that there are ways of seperating hematopoietic stem cells and multipotent progenitor cells from bone marrow, but there is no good way to propagate hematopoietic stem cells *in vitro*. The multipotent progenitor cells could be propagated *in vitro*, but its cultural condition or requirement is very harsh^[10]. In the present study, bone marrow stromal cells were shown to differentiate into hepatocyte-like phenotypes given the HGF induction, but these hepatocyte-like cells only expressed ALB and α -fetoprotein^[11]. Furthermore, in the course of the organ development including the developing liver, cell-cell interactions are very important for modulating cell growth, migration, and/or differentiation, and are imperative for coordinated organ function^[21]. A directed differentiated culture system, in which all bone marrow stem cells could differentiate into hepatocytes would be beneficial. From our study, we found that bone marrow cells grow easily and differentiate well in the induction of differentiation into

Figure 5. Intracellular glycogen accumulation was analyzed by PAS staining. (A) No glycogen particles could be seen in the cytoplasm of cultural bone marrow cells. (B) Some glycogen particles could be seen in the cytoplasm of directed differentiated bone marrow cells on d 21. ($\times 1000$).

hepatocytes.

Liver development is known to proceed through several distinct steps and many growth factors and cytokines are involved in each step. In mice, the initial event in liver development occurs at E9. The foregut endoderm becomes the liver through interaction with the cardiogenic mesoderm^[22,23]. FGF-4 is involved in endoderm specification and hepatic differentiation in this step^[14]. OSM, an interleukin (IL)-6 family cytokine, is a paracrine factor produced by hematopoietic cells and plays an important role in hepatic maturation during the mid to late fetal stages^[15]. HGF has been shown to be important components of liver development and the differentiation process. However, HGF is different from OSM in inducing hepatic maturation, as it seems to be a paracrine factor that is involved in postnatal hepatic maturation^[16]. Some other cytokines, including (EGF), insulin, TGF, appear

to play important roles in liver development and regeneration^[17]. The question is asked: *in vitro*, which cytokines will affect hepatocyte from the directed differentiation of stem cells? Some answers include: HGF^[11,24,25], HGF and EGF^[26], HGF and FGF^[27]. We established a differentiation culture system including FGF-4, HGF, OSM, and EGF, where hepatocytes were in the presence of FGF-4, HGF, OSM and EGF in the cell culture system. (SHI *et al*, unpublished data). We then adopted a uniform design method to research the most effective density of each cytokine and get the most effective match of these cytokines. We have sifted through the most effective directed differentiation culture system including FGF-4 and OSM (SHI *et al*, in press). From our research, we used the most effective directed differentiation culture system and researched the differentiation of bone marrow cells into hepatocytes.

In the present study, we found that these hepatocyte-like cells expressed HNF-3 β , ALB, CK18, TTR, G-6-Pase, and TAT at the gene level and/or protein level. HNF-3 β is a hepatocyte nuclear factor, which occurs in the cell nucleus of the premature or mature hepatocyte. Expression of ALB, the abundant protein synthesized by mature hepatocytes, starts in early fetal hepatocytes and reaches the maximal level in adult hepatocytes^[28]. CK18 is a cytoskeletal protein and is expressed in mature hepatocytes. TTR represents endodermal differentiation and is expressed throughout liver maturation^[29]. G-6-Pase is predominantly expressed in the liver^[28]. TAT represents an excellent enzymatic marker for peri- or postnatal hepatocyte-specific differentiation. Since hormone-regulated TAT activity is strictly limited to the parenchymal cells of the adult liver, it has been used extensively for monitoring cellular differentiation in experimental models

for liver development/maturation *in vitro*^[30]. Furthermore, these hepatocyte-like cells had some hepatocellular synthesis and metabolism functions, which would be used for hepatocyte transplantation or bioartificial liver.

Bone marrow stem cell can differentiate into hepatocytes, which is referred to as stem cell plasticity. There are many published studies explaining stem cell plasticity. First, multiple stem cells can coexist in multiple tissues, even after birth, and they proliferate and differentiate in response to local stimulation^[31]. Second, multipotent stem cells, which are akin to ES cells, persist past initial lineage specification^[10]. Third, cells can undergo de- and re-differentiation^[32]. Cell fusion has recently been suggested as another explanation of stem cell plasticity^[33]. Irrespective of the explanations of stem cell plasticity, the fact that bone marrow stem cell can differentiate into hepatocyte *in vitro* holds great promise for the treatment of inherited and degenerative liver diseases.

From our research, we can conclude that our differentiation media, including FGF-4 and OSM, are effective for differentiating bone marrow cells into hepatocyte-like cells, which were identified at the gene level and protein level and had some hepatocellular synthesis and metabolism functions. Thus, we will serve these functional hepatocyte-like cells as hepatocyte resources for bioartificial liver or hepatocyte transplantation.

Abstract

Aim: To investigate the possible inducible effects of icariin, icaritin, and desmethylicaritin on the directional differentiation of embryonic stem (ES) cells into cardiomyocytes *in vitro*. **Methods:** ES cells were cultivated as embryoid bodies (EBs) in hanging drops with icariin, icaritin, or desmethylicaritin. ES cells treated with retinoic acid and with solvent were used as positive and negative controls, respectively. The cardiomyocytes derived from the ES cells were verified using immunocytochemistry. The expression of cardiac developmental-dependent genes was detected using the reverse transcription-polymerase chain reaction (RT-PCR) method. Cell cycle distribution and apoptosis were analyzed using flow cytometry to determine the partly inducible effect mechanisms involved. **Results:** The total percentage of beating EBs treated with 1×10^{-7} mol/L icariin, icaritin, or desmethylicaritin was 87% ($P < 0.01$), 59% ($P < 0.01$), and 49%, respectively. All the beating cardiomyocytes derived from the ES cells expressed cardiac-specific proteins for α -actinin and troponin T. Among them, 1×10^{-7} mol/L icariin treatment resulted in a significantly advanced and increased mRNA level of α -cardiac major histocompatibility complex (MHC) and myosin light chain 2v (MLC-2v) in EBs in the early cardiac developmental stage. Before shifting to the cardiomyocyte phenotype, icariin could evoke the accumulation of ES cells in G₀/G₁ and accelerate apoptosis of the cell population ($P < 0.05$). **Conclusion:** Icariin facilitated the directional differentiation of ES cells into cardiomyocytes at a concentration of 1×10^{-7} mol/L. The promoting effect of icariin on cardiac differentiation was related to increasing and accelerating gene expression of α -cardiac MHC and MLC-2v, as well as regulating the cell cycles and inducing apoptosis.

Introduction

Embryonic stem (ES) cells are pluripotent cells derived from the inner cell mass of the pre-implantation blastocyst^[1]. These cells can proliferate in an undifferentiated state and remain totipotent when grown on a suitable fibroblast feeder layer. Under certain conditions ES cells are capable of differentiating into a variety of cell types *in vitro*, including spontaneously beating cardiac myocytes^[2,3]. The entire differentiating process is rich in developmental-dependent biological information, for example, the sequence of expression of cardiac-specific genes and proteins during differentiation of ES cells *in vitro* accords with that *in vivo*^[4]. Control of the

ES cell mitotic cycle displays an unusual feature, and regulation of the cell cycle is critical in maintaining the transition towards differentiation^[5,6]. The apoptotic signaling potential of ES cells is necessary to trigger ES cell differentiation^[7,8]. Therefore, the system of ES cells can provide a platform for studying the effects of drugs on differentiation and detecting the specific or unique targets of drug action.

Up to now, the interfering effects of the traditional Chinese medicine on ES cells and their directional differentiation *in vitro* have not been investigated. Icariin (ICA), icaritin (ICT), and desmethylicaritin (DICT) (Figure 1) are constituents of *Epimedium*, a traditional Chinese herbal medicine that has

Figure 1. Molecular structure of related compounds.

many biological functions, particularly in cardiovascular function improvement, hormone regulation, immunological function modulation, and antitumor activity^[9]. Our former work has shown that icariin can be metabolized to icaritin and demethylcaritin by human intestinal bacteria *in vitro*^[10]. Furthermore, icaritin and desmethylcaritin, but not icariin, exert estrogen-like activity using the estrogen receptor-positive human breast adenocarcinoma MCF-7 cell proliferation assay^[11]. In addition, icariin is the major active part in “Xin-shen-ning” tablets, which are used for the treatment of heart disease^[12]. However, the pharmacological effects and mechanism of the icariin series on the cardiovascular system are not yet known.

In the present study, the inducible effects of icariin, icaritin, and desmethylcaritin on the directional differentiation of ES cells into cardiomyocytes were examined *in vitro*. The cardiomyocytes derived from ES cells were verified using immunocytochemistry. The possible mechanisms of inducible action in transcription level, cell cycle distribution and apoptosis were investigated using reverse transcription-polymerase chain reaction (RT-PCR) and cell cycle analysis, with a view to detecting the targets of drug action on promoting ES cells to differentiate in this culture system.

Materials and methods

Animals and cells NIH mice (male, weighing 24±2 g; female, weighing 22±2 g) were obtained from the Experimental Animal Center, Zhejiang University, Hangzhou, China (Grade II, Certificate No. 22-9601018). Mice were housed under 12-h light/12-h dark and 21±1 °C conditions. To obtain fetuses, mice (3 female and 1 male) were housed together at 17:00. The following morning, when a copulation plug was detected, was defined as d 0 of gestation. The permanent ES cell line D3 (ES-D3) was obtained from the American Type

Culture Collection (CRL-1934)^[2].

Drugs and reagents Icariin was obtained from the Drug Biology Product Examination Bureau, Beijing, China (Batch No. 0737-200011, purity 99%); icaritin was prepared using the cellulose hydrolysis method from icariin, and icaritin was demethylated using boron tribromide to obtain desmethyl-icaritin^[6]. Purification was carried out by preparative high-performance liquid chromatography (HPLC) and identification was conducted using liquid chromatography/electrospray ionization mass spectrometry (LC/ESI-MS). The purities of these compounds were above 98%. Retinoic acid (RA), β-mercaptoethanol, and the antibodies were from Sigma Corporation, St Louis, Missouri, USA; Dulbecco's modified Eagle's minimal essential medium (DMEM) and fetal calf serum (FCS) were from Gibco Invitrogen Corporation, Grand Island, NY USA; the non-essential amino acids (NEAA) were from Hyclone Logan UT, USA; mitomycin C was from Kyowa Hakko Kogyo (Tokyo, Japan); and recombinant mouse leukemia inhibitory factor (LIF) was from Chemicon International Inc, Temecula, CA, USA. The reagents for the RT-PCR were purchased from the Shanghai Sangon Biological Engineering and Technological & Service Company (Shanghai, China).

Cultures of undifferentiated ES cells Fetuses were obtained from the mice on d 13 of gestation for the preparation of embryonic fibroblast (MEF) cells^[13]. The MEF cells of generation three to generation five were used as feeder cells, which were treated with 1 mg/L mitomycin C for 1 h and plated at an appropriate density. ES-D3 cells were maintained in an undifferentiated state by culturing on a monolayer of MEF feeders in DMEM, supplemented with 10% FCS, 0.1 mmol/L β-mercaptoethanol, NEAA, and 1×10⁶ U/L LIF.

Differentiation determination of cardiomyocytes and icariin, icaritin or desmethylcaritin treatment For differentiation of ES cells, EBs were generated using the hanging drop method^[14,15]. Thirty microlitre of drops containing approximately 600 ES-D3 cells were placed on the lids of Petri dishes filled with D-Hanks solution, and cultivated in hanging drops for 3 d followed by another 2 d in the Petri dishes. On d 5, EBs were plated separately onto gelatin-coated 24-well culture plates in differentiation medium that consisted of DMEM, 20% FCS, 0.1 mmol/L β-mercaptoethanol, and NEAA. Icariin, icaritin, or desmethylcaritin were added to the differentiation medium at a concentration of 1×10⁻⁷ mol/L according to the preliminary test. Our previous study examining the concentration-effect relationship of icariin revealed that treatment with icariin 1×10⁻⁷ mol/L significantly enhanced cardiac differentiation (unpublished data). Thus, a concen-

tration of 1×10^{-7} mol/L was used in the present experiment. ES-D3 cells treated with RA 1×10^{-8} mol/L and with 0.1% Me₂SO were used as positive and negative controls, respectively.

In the experiment, d 1 referred to the day of dissociation of ES cells from MEF and the initiation of differentiation by the formation of EBs. EBs were observed with light microscopy every day to record the morphology and the number of the spontaneously beating EBs from d 7 to d 7+23. According to the percentage of the beating EBs, the inducing effects of icariin, icaritin, or desmethylcaritin on the directional differentiation of ES-D3 cells into cardiomyocytes were evaluated using the time-effect relationship curve. Rhythmically beating EBs were considered to be spontaneously beating cardiomyocytes in EB outgrowths, and were defined as the marker of successful differentiation^[14,15].

Expression of cardiac-specific proteins analyzed using immunocytochemistry Cardiomyocytes were isolated from the beating areas of EBs using a modified procedure described by Maltsev *et al*^[16,17]. For immunostaining, cells were rinsed twice with PBS, and fixed with cold acetone for 10 min. After being treated with goat serum for 30 min, specimens were incubated at 4 °C overnight with the primary antibody, monoclonal anti-sarcomeric-actinin (clone number EA-53, 1:200 dilution, Sigma) or monoclonal anti-tropomyosin T (clone number JLT-12, 1:100 dilution, Sigma). The following day, the specimens were washed with PBS three times and incubated with the fluorescent antibody: FITC-conjugated F(ab)₂ fragment of affinity-purified goat anti-mouse IgG (1:1000 dilution, Rockland Inc Gilbertsville, PA, USA) for 1.5 h at 37 °C. Specimens were then rinsed in PBS, mounted onto a coverslip with 90% glycerol in PBS and examined using a fluorescence microscope (Leica DMIL, California Nevada, Germany).

Expression of cardiac-specific genes using semi-quantitative RT-PCR The expression of the cardiac-specific α -myosin heavy chain (α -MHC) gene and myosin light chain-2v (MLC-2v) in EBs was confirmed using semi-quantitative RT-PCR. Total RNA was isolated from EBs ($n=20$) induced by 1×10^{-7} mol/L icariin, icaritin, or desmethylcaritin, and 1×10^{-8} mol/L RA or solvent, respectively, at d 7+0, d 7+5, d 7+9 using the Trizol reagent according to the manufacturer's instructions. After extraction, mRNA was precipitated using the recommended procedures and dissolved in 0.1% diethylpyrocarbonate solution. To synthesize first strand cDNA, 7 μ L total RNA was incubated in 0.5 μ g of oligo (dT) 6 primer and 5 μ L deionized water at 65 °C for 15 min. Reverse transcription reactions were carried out with 200 U of M-MuLV reverse transcriptase in 5 \times reaction buffer and 1 mmol/

L dNTP mixture for 1 h at 42 °C. Multiplex polymerase chain reactions of 50 μ L contained 1 μ L of the RT reaction product, 10 \times PCR buffer, 25 U *Taq* polymerase, 1 μ L of 10 mmol/L dNTP mixtures, and 30 pmol of each primer. The specific primer pairs were designed as follows: the cardiac-specific α -MHC gene (5'-CTGCTGGAGAGGTTATTCCTCG-3', 5'-GGAAGAGTGAGCGGCGCATCAAGG-3'; 301 bp)^[18] and MLC-2v (5'-TGTGGGTCACCTGAGGCTGTGGTTCAG-3', 5'-GAAGGCTGACTATGTCCGGGAGATGC-3'; 189 bp)^[18], and the housekeeping gene β -actin was used as an internal standard (5'-TGACGGGGTACCCACACTGTCCCATCTA-3', 5'-CTAGAAGCATTGCGGTGGACGATGGAGGG-3'; 660 bp).

For the semi-quantitative determination of α -MHC and MLC-2v mRNA levels, the products of the reverse transcription reactions were denatured for 3 min at 94 °C, followed by 40 cycles (α -MHC), 45 cycles (MLC-2v), and 30 cycles (β -actin) of amplification in the reaction with Ampli *Taq* DNA polymerase: 45 s denaturation at 94 °C, 40 s annealing at 66.4 °C (α -MHC) or 61.1 °C (MLC-2v) or 55 °C (β -actin) and 45 s elongation at 72 °C. The PCR products were analyzed using 1.5% agarose gel electrophoresis, visualized with ethidium bromide staining, and quantified using a bio-imaging analyzer (Bio-Rad, Hercules, CA, USA), and the density of the products was quantified using Quantity One version 4.2.2 software (Bio-Rad).

Analysis of cell cycle and apoptosis by flow cytometry To analyze the cell cycle distribution of ES cells and apoptosis as parameters in the early differentiation phase, ES-D3 cells were cultivated without MEF feeders and LIF, and treated with 1×10^{-7} mol/L icariin, icaritin, or desmethyl-icaritin, or 1×10^{-8} mol/L RA. After 48 h, the cells were harvested and 1×10^6 cells were placed into a polypropylene tube and centrifuged at 90 $\times g$. The supernatant was removed and 70% EtOH 1 mL in 4 °C was dropped into the cell pellet while vortexing. The cells were kept at 4 °C until the DNA was stained. Fixed cells were treated with RNase A in PBS for 1 h, followed by staining with 50 mg/L propidium iodide in PBS. Flow cytometric analysis of the cell cycle distribution and apoptosis was carried out using a BD FACSCalibur with a 488 nm (blue) argon (Becton Dickinson, San Jose, CA, USA). Data acquisition was carried out with CellQuest 3.1 software and the data were analyzed with ModFit LT 3.0 software (Variety Software House, Topsham, ME, USA).

Statistical analysis Each data point represents the mean \pm SD. At least three independent experiments were carried out. Statistical significance was evaluated using one-way ANOVAS with SPSS 10.0 for WINDOWS software. $P < 0.05$ was considered statistically significant.

Results

Apparent cell morphological changes during the course of differentiation ES-D3 cells grew aggregates with clear boundaries and appeared ovoid or nodule shaped on MEF feeder cells (Figure 2A). Representative EBs at 5 d after the initiation of differentiation, and just prior to plating onto gelatin-coated 24-well culture plates, were formed by hang-

Figure 2. Cell apparent morphological changes during the course of differentiation. (A) Colonies of ES-D3 cells on a feeder layer of murine embryonic fibroblasts (arrows refer to colonies of ES-D3 cells). (B) Embryoid body before plating onto gelatin-coated 24-well culture plates. (C) Synchronously contracting, functional syncytium of cardiac clusters derived from EBs treated with icariin 1×10^{-7} mol/L at d 7+5 (rectangular frames refer to the contracting areas; arrows point to contraction foci).

ing drop cultures. EBs kept globular shaped structure. (Figure 2B). After plating for 2 d, cells started outgrowing from the EBs, and cardiomyocytes appeared as spontaneously contracting cell clusters^[14] (Figure 2C). One EB contained one or more beating areas in which the enlarged size, increased contracting strength, and beating frequency were observed during the subsequent differentiation phase.

Inducible effect of icariin, icaritin, and desmethylcaritin on the directional differentiation of ES-D3 cells into cardiomyocytes Icariin, icaritin, and desmethylcaritin influenced the degree of cardiac differentiation of ES-D3 cells. During the course of differentiation (from d 7+2 to d 7+23), the total percentage of beating EBs treated with 1×10^{-7} mol/L icariin, icaritin, and desmethylcaritin was 87% ($P < 0.01$), 59% ($P < 0.01$), and 49%, respectively. In particular, in the case of icariin at a concentration of 1×10^{-7} mol/L the inducing effect on the directional differentiation of ES-D3 cells into cardiomyocytes was remarkable compared with the control ($P < 0.05$). Although only 46% of the EBs in control samples contained beating clusters, 68% of the EBs treated with 1×10^{-8} mol/L RA differentiated into beating cardiac clusters (Figure 3A).

The results of the time-effect relationship revealed that the percentage of differentiation cultures containing contracting EBs with icariin 1×10^{-7} mol/L reached a peak level of 85% at d 7+10 and 10% at terminal stages. The potential of EBs treated with icariin 1×10^{-7} mol/L undergoing cardiac differentiation was enhanced compared with control cells over the period from d 7+5 to d 7+23 ($P < 0.05$). Treatment of EBs with icaritin 1×10^{-7} mol/L also resulted in a remarkable increase in the number of EBs with spontaneously beating cardiomyocytes between d 7+9 and d 7+17 ($P < 0.05$), whereas the differentiation effect of EBs induced by desmethylcaritin 1×10^{-7} mol/L was only prominent from d 7+9 to d 7+11 ($P < 0.05$) (Figure 3B).

If culture of differentiation was continued, the numbers of spontaneously beating foci increased and the spontaneously contractile activity of cardiac myocytes strengthened^[19].

Detection of cardiac-specific proteins during the differentiation phases of ES-D3 cells into cardiomyocytes To identify whether the observed cell types derived from ES-D3 cells expressed cardiac-specific proteins, indirect immunofluorescence was carried out. The results verified that differentiated beating cardiac cells stained positively with anti- α -actinin mAb and anti-troponin T mAb, and these results support previous studies^[20] (Figure 4).

Effect of icariin, icaritin, and desmethylcaritin on the level of α -cardiac MHC and MLC-2v mRNA during the early cardiac developmental stage To explore whether icariin,

icaritin, and desmethylicaritin influence the expression level of a-cardiac MHC and MLC-2v mRNA during cardiomyocyte

differentiation, the beating EBs outgrowths differentiated from ES-D3 cells were studied using semi-quantitative RT-

Figure 5. The mRNA level of α -MHC and MLC-2v in icariin (ICA), icaritin (ICT), and desmethylcaritin (DICT)-treated EBs compared with control cells analyzed using semi-quantitative RT-PCR. The ethidium-bromide-stained gels of PCR products (A) were analyzed using computer-assisted densitometry and the data are plotted for α -MHC (B) and MLC-2v (C) genes in relation to β -actin gene expression. Similar data were obtained in three independent RT-PCR experiments. MW, molecular weight; ES, embryonic stem cells; H, 16-d-old embryonic heart of mouse.

PCR analysis. mRNA expression levels of α -MHC by 1×10^{-7} mol/L icariin, icaritin, and of MLC-2v by 1×10^{-7} mol/L icariin increased during an early cardiac developmental stage for the period between d 7+0 and d 7+9. In particular, 1×10^{-7} mol/L icariin-induced MLC-2v expression was detected as early as d 7+0, whereas increased expression in control cells was not observed until d 7+5. The experiments also revealed that there was almost no difference between 1×10^{-7} mol/L desmethylcaritin treated cells and control cells from d 7+0 to d 7+9 (Figure 5).

Analysis of cell cycles and apoptosis using flow cytometry The cell cycle distribution of ES-D3 cells was considered to be a parameter of their differentiation state^[5,6], which enabled us to determine the effect of icariin, icaritin, and desmethylcaritin on early differentiation events before a shift to the cardiomyocyte phenotype. The results of the cell cycle analysis on propidium-iodide-stained cells showed a smaller percentage of ES-D3 cells in the G_0/G_1 phase compared with differentiation cells in control samples (approximately 30% and 40%, respectively). Icariin, icaritin, and

desmethylcaritin 1×10^{-7} mol/L induced the accumulation of cells in G_0/G_1 (approximately 44%, 40%, and 35%, respectively). In particular, the effect of icariin on the G_0/G_1 was remarkable compared with control cells ($P < 0.05$). Treatment of 1×10^{-8} mol/L RA let ES cells present a similar effect on the accumulation of cells in G_1 (48%). Proportions of S phase cells in either 1×10^{-7} mol/L icariin-treated cells or 1×10^{-8} mol/L RA-treated cells were remarkably reduced (29% and 27%, respectively, versus 47% of S phase in ES-D3 cells; $P < 0.05$) (Figure 6).

Apoptosis plays a vital role in development by removing unwanted cells^[21], which is a possible checkpoint for the transition towards differentiation of ES cells. In the present study, ES-D3 cells induced by icariin 1×10^{-7} mol/L for 48 h showed greater levels of apoptosis (10%) than control cells (4%) ($P < 0.05$). In contrast, treatment with icaritin 1×10^{-7} mol/L or desmethylcaritin resulted in apoptosis levels of approximately 9% and 8%, respectively. RA 1×10^{-8} mol/L treatment for 48 h also led to 8% apoptosis ($P < 0.05$; Figure 6).

Cell cycle phase	G ₀ /G ₁ (%)	S (%)	G ₂ /M (%)	Apoptosis (%)
ES-D3 cells	30.8±2.2	46.6±6.4	21.8±6.3	1.6±0.3
Control	39.7±1.3 ^c	33.5±4.9 ^b	23.6±6.3	3.6±1.2 ^b
RA 10 ⁻⁸ mmol/L	48.3±0.6 ^{ef}	26.7±0.4 ^c	16.8±1.0	8.5±1.5 ^{ce}
ICA 10 ⁻⁷ mol/L	43.9±1.2 ^{ce}	28.7±0.2 ^c	17.4±1.4	10.1±2.5 ^{ce}

Discussion

ES cell differentiation into cardiomyocytes *in vitro* is a unique system that not only provides opportunities to study cardiomyocyte differentiation, but also offers a platform for evaluating the effects of drugs and detecting the specific targets of drug action during cardiogenesis. In the present study, the possible inducible effects of icariin, icaritin, and desmethylicaritin on the directional differentiation of ES cells into cardiomyocytes *in vitro* were explored. To investigate the partly inducible effect mechanisms of the three compounds involved in ES cell differentiation, the expression of cardiac developmental-dependent genes was detected using RT-PCR. Cell cycle distribution and apoptosis were analyzed using flow cytometry.

Our results revealed that treatment of EBs with icariin resulted in increased and accelerated differentiation into beating cardiomyocytes. The degree of the inducible effect of icaritin was less than that of icariin, and desmethylicaritin had the least inducing effect on the directional differentiation of ES cells into cardiomyocytes *in vitro*. Moreover, cardiac-specific sarcomeric proteins in the cardiomyocytes derived from ES-D3 cells were identified, since one of the major questions in muscle development is how a large number of protein subunits assembles into the remarkably regular structure known as the sarcomere^[20]. Our results confirmed that the cardiomyocytes were derived from ES-D3 cells.

ES-cell-derived cardiomyocytes express the cardiac genes in a developmentally controlled manner, that is, atrial natriuretic factor (ANF), α-MHC, β-MHC, and MLC-2v^[4]. In our

experiment, α -MHC and MLC-2v were chosen as the evaluation targets for the directional differentiation. Our experiments demonstrated that icariin significantly advanced and increased the mRNA levels of α -MHC and MLC-2v at an early stage of differentiation, which suggested a partial mechanism for icariin involving in differentiation could be related to the expression of the cardiac developmental-dependent genes^[4,22,23]. However, icaritin and desmethylcaritin had less effect on improving the mRNA level of α -MHC and MLC-2v during cardiac differentiation. Other studies have shown that α -MHC is expressed relatively early during the course of cardiogenesis^[24]; however, MLC-2v mRNA is highly expressed relatively late in the process and is spatially restricted to the ventricular portion^[25,26]. Our results support these studies. One of the mechanisms of icariin in differentiation is to increase and accelerate the mRNA level of α -MHC and MLC-2v at an early stage of differentiation.

Icariin is a new type of biological response modifier and differentiation agent^[27] and can induce some cells to differentiate by regulating the cell cycle^[27,28]. The cell cycle distribution of ES cells was considered to be a parameter of their differentiation state^[5,6]. This system of ES cell differentiation could recapitulate the *in vivo* differentiation process, including the occurrence of apoptosis accompanying differentiation. Furthermore, the potential in ES cell apoptotic signals is necessary to trigger ES cell differentiation. Alternatively, it is possible that some cells enter apoptosis and the remainder differentiate, and this may depend on their stage in the cell cycle^[7,8]. To elucidate the mechanism of icariin action on differentiation before a shift to the cardiomyocyte phenotype, we examined the distribution of the ES cell cycle and apoptosis using flow cytometry. Our experiment showed that the induction of icariin was associated with remarkable enrichment of ES-D3 cells in the G₀/G₁ phase and a significant reduction in cells in the S phase. In addition, icariin-mediated differentiation leads to higher apoptosis. These results suggest that the effect of icariin is associated with cell cycle arrest and apoptosis. The balance between positive and negative regulators of the ES cell cycle is important in maintaining the transition towards differentiation. The apoptotic signal in ES cells also triggers the differentiation of ES cells^[7].

In conclusion, ES-D3 cells could be remarkably induced to directionally differentiate into cardiomyocytes by icariin at a concentration of 1×10^{-7} mol/L. The promoting effect of icariin on cardiac differentiation depended on the advancing and increasing gene expression of α -cardiac MHC and MLC-2v. At an early differentiation stage, the inducible effect of icariin was related to the regulation of the cell cycle and the

induction of apoptosis.

Abstract

Aim: We have recently shown that engagement of membrane immunoglobulin (mIg) induced upregulation of inhibitor of differentiation 3 (Id3) mRNA, resulting in growth arrest at G1 phase in WEHI-231 cells. In the present study, we examined whether engagement of mIg will affect promoter activity of the Id3 gene in WEHI-231 cells. **Methods:** DNA fragments corresponding to the 5'-flanking region of mId3 gene were amplified by polymerase chain reaction (PCR) using genomic DNA as the template. Three DNA fragments upstream of the transcription start site (+1) of the mId3 gene were subcloned into the luciferase reporter vector PGV-B2. The recombinant constructs were transiently transfected into WEHI-231 cells by an electroporation method. After incubation for 24 h, WEHI-231 cells were stimulated with 10 mg/L anti-IgM or irradiated CD40L-expressing NIH3T3 cells or control NIH3T3 cells for further 24 h, followed by assay for luciferase activity. **Results:** The luciferase analysis demonstrated that basal promoter activity of the Id3 gene was found in the region between -200 and +54. The Id3 promoter activity was increased 2-fold following stimulation with anti-IgM, but not CD40L, compared with medium alone. **Conclusion:** The mIg-mediated upregulation of Id3 expression is controlled, at least in part, through transcriptional regulation, as assessed by luciferase assay.

Introduction

Signalling transduction molecule(s) through B cell antigen receptor (BCR) are considered to play a crucial role in the regulation of B cell fate. The engagement of BCR leads to activation or inactivation of B cells, depending on B cell developmental stage as well as interaction with other cells including T cells expressing CD40 ligand (CD40L)^[1–3]. The molecular mechanisms underlying BCR-mediated activation and/or inactivation remain largely unresolved. WEHI-231 B lymphoma cells, representing immature stage of B cells, have been widely used as an *in vitro* model system to analyze B cell-unresponsiveness^[4–6], since costimulation with CD40L rescues anti-IgM-induced growth arrest and/or apoptosis^[7,8].

The basic helix-loop-helix (bHLH) family of transcrip-

tion factors including E2A play a key role in proliferation and/or differentiation in a variety of cell types^[9,10]. The E protein contains a highly conserved HLH dimerization domain and a DNA-binding basic region that binds a conserved E-box. Another category of HLH protein, the inhibitor of differentiation (Id) family possess homologous HLH domain, but not DNA-binding domain^[11,12]. Thus, Id proteins function as a dominant-negative (dn) regulator of transcription upon binding with other HLH proteins. The Id proteins are thought to promote cell cycle progression from G1 to S phase, while E2A proteins are thought to prevent it^[9,13]. These findings indicate that E2A/Id proteins function to promote or inhibit proliferation in a context of cell types in divergent stimuli. For example, mature B cells from Id3-deficient mice failed to proliferate in response to anti-IgM^[14]. Contrary to this current notion, we have recently demonstrated that anti-

IgM-induced G1 arrest appears to result from the anti-IgM-induced upregulation of Id3 expression at both mRNA and protein levels in WEHI-231 cells^[15], as reported in other cell types^[16]. In the present study, we examined whether anti-IgM-induced upregulation of Id3 mRNA resulted from transcriptional regulation of the Id3 gene.

Materials and methods

Cell culture WEHI-231 B lymphoma cells were maintained in RPMI-1640 medium supplemented with 10% fetal bovine serum (FBS), 2-mercaptoethanol 50 μ mol/L, and kanamycin 100 mg/L at 37 °C in 5% CO₂.

Isolation of 5'-flanking region of mouse Id3 Genomic DNA was extracted from WEHI-231 cells using QIAGEN Genomic DNA Kit according to the manufacturer's instruction. DNA fragments corresponding to the 5'-flanking region of the mouse Id3 gene were isolated from the genomic DNA by polymerase chain reaction (PCR) using Id3-specific primers and high fidelity KOD DNA polymerase (Toyobo Co, Ltd, Japan) (Figure 1), based on the reported nucleotide sequences (GenBank accession number, AL935264). The nucleotide sequences of the primers were the following: forward with a *Kpn* I restriction enzymatic site underlined, Id3 -1981/+54, (5'-CGGGGTACCCATACAGAAGTCTTCA-CGAGAG-3'); Id3 -1012/+54 (5'-CGGGGTACCTGGCTGCC-CTCCACAACAG-3'); Id3 -200/+54 (5'-CGG GGTACC TCCTCGCATCCGAGGCTCC-3'). Reverse for the three fragments with a *Hind* III restriction enzymatic site underlined, (5'-CGGAAGCTTGAGAGTAGAGATAGAGAGGGAG-3'). The DNA fragments Id3 -1981/+54 (Id3/2k), Id3 -1012/+54 (Id3/1k), and Id3 -200/+54 (Id3/254) were cloned into pCR-Blunt II-TOPO vector by Zero Blunt PCR Cloning Kit (Invitrogen, USA). The nucleotide sequences of the fragments were confirmed to be identical to the reported sequences (GenBank) using ABI PRISM BigDye™ Terminator Cycle Sequencing Ready Reaction Kits (Applied Biosystems, USA).

Figure 1. Isolation of DNA fragments containing 5'-flanking region of the Id3 gene by PCR. The DNA fragments containing Id3 promoter were amplified by PCR using the Id3-specific primers. To obtain three different fragments, sets of primers (forward, → and reverse, ←) were employed.

Plasmid construction for transient transfection assay

The fragments of the Id3 promoter spanning nucleotides -1981/+54, -1012/+54, and -200/+54 were subcloned into the firefly luciferase reporter PGV-B2 vector lacking the promoter and enhancer (Tokyo-Inki, Tokyo, Japan) (Id3/PBV-B2), as previously described^[17], resulting in Id3/2k-Luc, Id3/1k-Luc, and Id3/254-Luc, respectively.

Transient transfection of WEHI-231 cells was carried out by an electroporation method^[17]. WEHI-231 cells (1.2×10^7 per 0.7 mL) containing 20 μ g of the reporter constructs and 400 ng of internal control pRL-CMV Renilla luciferase vector were pulsed (400 V, 500 μ F) using Gene Pulser (Bio-rad, USA). Following a 24-h incubation, the cells were further stimulated with 10 mg/L anti-IgM mAb or medium alone for 24 h, or cocultured with irradiated CD40L-expressing NIH3T3 cells or control NIH3T3 cells. The cells were harvested and lysed in lysis buffer (Promega, USA), followed by an assay for luciferase activity using a Dual-Luciferase Reporter Assay System (Promega), according to the manufacturer's instructions. Both firefly and Renilla luciferase activities were monitored with a Lumat LB9507 luminometer (Bert-hold). The ratio of firefly/renilla values was calculated to normalize report activity. Normalized data are expressed as relative luciferase activity compared with that seen for PGV-B2 vector alone.

Statistical analysis Data were expressed as mean \pm SD. For single comparison, statistical significance between groups was determined by Student's *t*-test. Significance for multiple comparisons was determined by one-way ANOVA. $P < 0.05$ was considered to indicate statistically significant differences.

Results

Structure of the functional Id3 locus We have recently found that anti-IgM upregulated Id3 mRNA expression, while CD40L downregulated it in WEHI-231 cells^[15]. To analyze whether engagement of mIg influences transcriptional regulation of the Id3 gene, the three fragments containing the 5'-flanking region of the murine Id3 gene were isolated by PCR using Id3-specific primers. These fragments were subcloned into PGV-B2 vector to measure the promoter activity of the Id3 gene (Figure 2). Nucleotide sequence analysis confirmed the fidelity of the all constructs generated.

Basal promoter activity in the 5'-flanking region of the Id3 gene WEHI-231 cells were transfected with the constructs Id3/2k-Luc, Id3/1k-Luc, or Id3/254-Luc in combination with internal control vector and incubated with medium alone for 24 h, followed by assay for luciferase activity (Figure

Figure 2. Procedures to create luciferase reporter vectors. The three distinct DNA fragments (Id3/2k, Id3/1k, and Id3/254) generated by PCR were cloned into pCR-Blunt II-TOPO, followed by digestion at sites (*Kpn I*/*Hind III*) to subclone into the luciferase reporter vector PGV-B2, resulting in Id3/2k-Luc, Id3/1k-Luc, and Id3/254-Luc, respectively.

3A, 3B). The basal promoter activity in these fragments Id3/2k, Id3/1k, or Id3/254 was increased 24-fold, 36-fold, and 54-fold, respectively, compared with the control vector (Figure 3B). These results suggest that the 254-bp fragment contains some positive regulatory element(s) of the Id3 gene, as reported by Yeh and Lim^[18]. It is also possible that there are putative negative regulatory elements in the region from -1981 to -201.

Anti-IgM, but not CD40L, upregulates the promoter activity of the Id3 gene To examine whether transcriptional regulation is involved in the anti-IgM-induced upregulation of the Id3 gene, the WEHI-231 cells co-transfected with the Id3/2k-Luc, Id3/1k-Luc, Id3/254-Luc constructs and internal control vector were stimulated with 10 mg/L anti-IgM for 24 h, followed by assay for luciferase activity. The stimulation with anti-IgM enhanced the promoter activity of the Id3

Figure 3. Basal promoter activity in the 5'-upstream region of the Id3 gene. (A) Structure of the reporter plasmids. The transcription start site is indicated by +1. (B) WEHI-231 cells were transfected with 20 mg/L Id3/2k-Luc, Id3/1k-Luc, Id3/254-Luc, or control vector alone, in combination with internal control vector. Following 24-h incubation, extracts were taken, and dual luciferase assay was carried out. The results were presented as the means±SD from three independent experiments. ^c*P*<0.01 vs PGV-B2 control. ^{cc}*P*<0.05, ^{efi}*P*<0.01 vs Id3/2k-Luc. ⁱ*P*<0.05 vs Id3/1k-Luc.

gene which increased up to two-fold as compared with the activities in unstimulated cells, as assessed by luciferase activity (Figure 4A). The CD40L stimulation slightly decreased it, but the difference was not statistically significant (Figure 4B).

In our previous study, with Northern blot assay we observed an upregulation of Id3 mRNA expression in WEHI-231 cells after anti-IgM stimulation to reach levels 5-fold greater than that seen in unstimulated cells. There are many reasons to explain the inconsistent results between luciferase activity assay and northern blot. Besides the stability of the luciferase and mRNA, additional mechanisms may exist that contribute to the upregulation of Id3 expression at transcription level following anti-IgM stimulation. These results suggest that the mIg-mediated upregulation of Id3 expression is controlled, at least in part, through transcriptional regulation, as assessed by luciferase assay.

Discussion

Id proteins, a member of the HLH family proteins, play a

Figure 4. Upregulation of the Id3 promoter activity following stimulation with anti-IgM, but not CD40L. Twenty four hours after transfection of the Id3-Luc constructs, the cells were stimulated with 10 mg/L anti-IgM (A), or cocultured with CD40L-expressing NIH3T3 or control NIH3T3 cells (B). Following further 24-h incubation, the lysates were assayed for luciferase activity. The results were presented as the mean±SD from three independent experiments. ^c*P*<0.01 vs PGV-B2 control. ^d*P*>0.05, ^e*P*<0.05, ^f*P*<0.01 vs unstimulated cells.

crucial role in proliferation, differentiation, and apoptosis in a variety of cells including lymphocytes^[9-11]. The mature B cells from Id3-deficient mice failed to proliferate in response to anti-IgM, whereas they showed proliferation comparable to those from control mice in response to LPS or CD40L^[14], suggesting that Id3 promotes mIg-mediated B cell growth, as demonstrated in some cell types^[11]. However, WEHI-231 cells, representing immature B cells, displayed growth arrest at the G1 phase of the cell cycle, accompanied by upregulation of Id3 mRNA following stimulation with anti-IgM^[15]. In this study we examined whether the mIg-mediated upregulation of Id3 mRNA expression resulted from transcriptional activation and found that anti-IgM upregulated Id3 expression at least through transcriptional activation.

The nucleotide sequences of the 5'-upstream fragments isolated from WEHI-231 genomic DNA were confirmed to be identical with the published sequences^[18] (GenBank accession number, AL935264). Consistent with the observation

of Yeh and Lim^[18] using C2C12 muscle cells, the 254-bp fragment had substantial basal promoter activity of the Id3 gene (Figure 3). Indeed, several putative binding sites (*ATF*, *Sp1*, *Egr1*, *Cre*) for transcription factors were found using TRANSFAC databases^[18]. Interestingly, when the longer fragments Id3/2k-Luc or Id3/1k-Luc was used, the basal promoter activity decreased compared with Id3/254-Luc (Figure 3B). These results might suggest that the promoter activity of the Id3 gene be regulated by both positive and negative regulatory elements, as reported in the transcriptional regulation of a variety of genes in eukaryotes^[19]. A sufficient promoter activity was also found in other several B lymphoid lineage cell lines BAL17 and J558L (Li and Hata unpublished observation, 2003), although it is not dependent on B cell development.

The promoter activity of the Id3 gene was increased following engagement of mIg, but not CD40 (Figures 4A and 4B), resulting in the upregulation of the Id3 mRNA in WEHI-231 B lymphoma cells^[15]. Although the Id3 upregulation through engagement of T cell receptor for antigen was abrogated by MEK1 inhibitor PD98059^[20], the mIg-mediated upregulation of the Id3 message was not affected (Li and Hata, unpublished observation), suggesting that antigen receptor-mediated upregulation of Id3 expression is differently regulated between T and B cells.

In contrast to anti-IgM, CD40L decreased Id3 mRNA levels in WEHI-231 cells^[15]. The promoter activity of the Id3 gene in response to CD40L was somewhat low, but not significant, compared with medium alone, suggesting that CD40-mediated down-regulation of Id3 mRNA expression is controlled post-transcriptionally. In our preliminary experiments, pretreatment with proteasomal inhibitor lactacystin restored CD40L-mediated down-regulation of Id3 protein expression (Li and Hata, unpublished observation), as suggested by Bounpheng *et al*^[21]. These findings suggest that CD40-mediated down-regulation is controlled post-translationally.

Following an encounter with antigen, immature B cells undergo growth arrest/apoptosis unless T cell-derived signals such as CD40L are provided^[7,22]. Since transduction of Id3 gene into WEHI-231 cells results in growth arrest at the G1 phase of the cell cycle^[15], Id3 appears to contribute to G1 arrest in immature B cells. The cell cycle progression from G1 to S phase in mammalian cells is tightly regulated by a cyclin-dependent kinase (CDK) and cyclin^[23]. CDK activity is controlled by CDK inhibitors (CKIs) including p21^{Cip1} and p27^{Kip1}^[24]. Anti-IgM induced growth arrest through an upregulation of p27^{Kip1} and down-regulation of cyclins^[25]. It remains unclear how Id3 relates to p27^{Kip1}-me-

diated signalling pathway in B cells.

In contrast to our findings, Pan *et al* reported that anti-IgM-induced proliferative responses were severely reduced in mature B cells from Id3-deficient mice, compared with those from control mice^[14]. Id3 appears to promote cell cycle progression in mature B cells upon encounter with antigen, whereas it prevents cell cycle progression in immature B cells, which could be accounted for by differential target(s) of Id3 molecule between mature and immature B cells. Experiments to examine this possibility are in progress.

In the present study, we clarified that engagement of mIg increased the promoter activity of the Id3 gene, probably resulting in an enhanced Id3 expression. The mIg-mediated Id3 upregulation appears to contribute to growth arrest, which could be reversed by the addition of CD40L, at least in part, through down-regulation of Id3 expression. Our results would be valuable for analysis of mIg-mediated unresponsiveness in B cells.

Abstract

Aim: To investigate the effect of 7-hydroxystaurosporine (UCN-01), a selective protein kinase C (PKC) inhibitor, on cell growth, migration, and invasion in invasive human glioblastoma U-87MG cells. **Methods:** PKC activity was determined based on the PKC-catalyzed transfer of the ³²P-phosphate group from [g-³²P]ATP into a PKC-specific peptide substrate. Cell viability was measured by MTT assay. Cell invasion and migration were evaluated by a Boyden chamber assay and scratch wound assay, respectively. Protein expression was analyzed using Western blot assay. The formation of 3-dimensional cellular aggregates was examined by a cell-cell aggregation assay. **Results:** UCN-01 treatment resulted in concentration- and time-dependent inhibition of U-87MG cell growth at higher doses (> 100 nmol/L), and reduced cell invasion and migration capability at less cytotoxic doses (<100 nmol/L). UCN-01 significantly repressed PKC activity. Consistent with this result, UCN-01 blocked cell invasion stimulated by phorbol 12-myristate-13-acetate (PMA) and ethanol (EtOH), 2 PKC activators. Enforced expression of the tumor suppressor genes BRCA1 and PTEN increased the anti-invasion potential of UCN-01. Exposure to UCN-01 caused a dose-dependent increase in cell adhesion molecule E-cadherin. The effect of UCN-01 on the formation of cell-cell aggregation was significantly reduced by the addition of an anti-E-cadherin antibody. **Conclusion:** UCN-01 inhibits the invasion and migration of human glioma cells. Accordingly, UCN-01 can have potential clinical applications for the treatment of human glioma metastasis.

Introduction

Protein kinase C (PKC) is a family of serine/threonine protein kinases that transduce signals for tumorigenesis, tumor cell invasion, and metastasis, and has thus been newly targeted for use in cancer treatment^[1]. Activation of PKC augments tumor cell metastatic potential, whereas suppression of PKC activity through PKC inhibitors reduces tumor cell invasion and migration^[1,2]. 7-Hydroxystaurosporine (UCN 01) is a selective PKC inhibitor derived from the non-selective protein kinase inhibitor staurosporine^[3]. A number of studies, including some conducted in our own laboratories, have revealed that UCN-01 holds promise for use as a

single agent or in combination with other chemotherapeutic agents, such as camptothecin, 5-fluorouracil, tamoxifen, and ionizing radiation, in inhibiting tumor cell growth *in vitro* and *in vivo*^[3–9].

Our previous studies corroborate other studies, which indicate that the anti-tumor activities of UCN-01 are associated with arrest of cell cycle progression, including G1/S and/or G2/M^[4,5], apoptosis induction^[5–7,10], and the inhibition of DNA repair^[11,12]. Most notably, UCN-01 abrogates the S or G2 arrest caused by chemotherapeutic agents^[4]. It has also been found that UCN-01 inhibits microvessel formation (angiogenesis), which is required for tumor formation and growth^[13,14]. Taken together, these studies indicate

that UCN-01 is a profound anti-tumor agent in several different tumors, including glioma. Moreover, UCN-01 has entered Phase I trials as a single agent in the USA and Japan^[3,15].

In the present study, the effects of UCN-01 on cell growth, invasion, and migration were investigated in U-87MG, an invasive human glioblastoma cell line. The purpose of this study is to explore whether UCN-01 can be used as a new therapeutic agent in the treatment of glioblastoma growth and invasion.

Materials and methods

Cell culture and chemicals The human glioblastoma cell line U-87MG was purchased from the American Type Culture Collection (ATCC, Manassas, VA, USA) and maintained as monolayer cultures in D-MEM supplemented with 10% fetal calf serum (FCS), glutamine 2 mmol/L, streptomycin 100 mg/L, and 100 kU/L benzylpenicillin G (BioWhittaker, Walkersville, MD, USA). Cell number and viability were determined by staining a small volume of cell suspension with 0.4% trypan blue saline solution and examining the cells using a haemocytometer. The doubling time of U-87MG cell was approximately 30 h under our culture conditions. UCN-01 was obtained from the Laboratory of Molecular Pharmacology, Division of Basic Science, NCI, NIH (Bethesda, MD, USA) and stored at -20 °C as a 10 mmol/L stock solution in 20% Me₂SO. Phorbol 12-myristate-13-acetate (PMA) and ethanol (EtOH) were purchased from Sigma Chemical Company (St Louis, MO, USA). PMA was dissolved in 20% Me₂SO and frozen at -20 °C for storage purposes. UCN-01, PMA, and EtOH were further diluted in 2% medium prior to use.

Expression vectors and transfection A full-length BRCA1 or PTEN cDNA was expressed in a pCMV-Tag2B vector (Stratagene, La Jolla, CA, USA), which allows for the expression of proteins with an N-terminal FLAG sequence, as described previously^[16]. Transfection of BRCA1 or PTEN was performed using a transfection reagent, Lipofect-Amin 2000, according to the manufacturer's instructions (Invitrogen, Gaithersburg, MD, USA) as described previously^[16]. The efficiency of gene transfer was determined by a β -galactosidase assay using co-transfection with plasmid pRSV- β -gal.

Measurement of PKC activity Aliquots of 4×10^6 untreated and treated cells were washed with ice-cold Dulbecco's phosphate-buffered saline (PBS), suspended in a homogenization buffer (0.05 mol/L Tris-HCl, pH 7.5, containing EDTA 5 mmol/L, EGTA 10 mmol/L, β -mercaptoethanol 0.6 g/L, leupeptin 10 mmol/L, PMSF 1 mmol/L), and broken

by probe sonication. The nuclei and unbroken cells were removed using low-speed spin, and the resulting supernatant was spun at $100\,000 \times g$ for 30 min. The nuclear pellet was resuspended in HB and was referred to as a whole cell lysate. The $100\,000 \times g$ supernatant was termed the soluble or cytosolic fraction. The $100\,000 \times g$ pellet was washed with homogenization buffer, suspended by probe sonication in homogenization buffer containing 0.1% Triton X-100, incubated on ice for 1 h, and spun again at $100\,000 \times g$. The resulting supernatant was termed the particulate or membrane fraction.

Total PKC activity in the three fractions was estimated using a commercially available assay system (Amersham Life Science, Arlington Heights, IL, USA) according to the manufacturer's instructions. This assay is based on the PKC-catalyzed transfer of the ³²P-phosphate group from [γ -³²P] ATP into a PKC-specific peptide substrate (amino acids 65-658 of the EGF receptor with the phosphorylation site on Thr-654) in the presence of Ca²⁺ phosphatidylserine, and phorbol 12-myristate 13-acetate. All 3 fractions were diluted with 0.05 mol/L Tris-HCl (pH 7.5), and 25 μ g of each were added to equal volumes of reaction solution (consisting of Tris-HCl 0.05 mol/L, CaCl₂ 1.5 mmol/L, dithiothreitol 7.5 mmol/L, PKC peptide substrate 45 mmol/L, and dioleoyl-glycerol 82 mmol/L) as provided by the manufacturer. Reactions were carried out at 37 °C for 15 min. After 15 min, the reactions were stopped using a stop reagent (provided by the manufacturer); one hundred microlitre of each were blotted on glass fiber filters and extensively washed with 0.1% orthophosphoric acid. The bound radioactivity was counted using liquid scintillation spectroscopy. The protein content in each of the 3 fractions was measured. Radioactivity values resulting from the phosphorylation of endogenous substrates were subtracted from all determinations. Reactions were performed in triplicate and the values were averaged. Each assay was performed at least 3 times.

Measurement of cell viability Cell viability, an indicator of cytotoxicity, was evaluated using an MTT assay as described previously^[17]. Four sets of experiments were performed in 10 wells for each treatment.

In vitro invasion assay *In vitro* invasion assay was performed with a modified Boyden chamber^[17]. The surfaces of filter (0.8 μ m pore size) were coated with 25 μ g Matrigel of uniform thickness for 1 h at room temperature. The uniformity of the coating was checked by Coomassie blue staining and low-power microscope observation. The lower chamber was filled with 10% FCS medium containing fibronectin (16 μ g per chamber) as the chemoattractant. Cells (1×10^8 cells/L) re-suspended in the medium containing 2% FCS and 50 or

100 nmol/L UCN-01 were carefully transferred onto the upper surface of the filters in the chamber. After a 48-h incubation, the filter was gently removed from the chamber. The cells on the upper surface were removed with a cotton swab, cells that had passed through the Matrigel and attached themselves to the lower surface of the filter were fixed, stained with hematoxylin and eosin, and counted in 15 randomly selected microscopic fields ($\times 400$) per filter. Experiments were performed at least 3 times, independently. In the trials for determining the effect of UCN-01 on the PMA- and EtOH-promoted cell invasion, fibronectin was not added to the lower chamber.

Scratch wound assay The spreading and migration capabilities of U-87MG cells were assessed using a scratch wound assay^[17] which measures the expansion of a cell population on surfaces. The cells were seeded into 6-well tissue culture dishes at a concentration of 2.5×10^5 cells and cultured in medium containing 10% FCS to nearly confluent cell monolayers, which were then carefully wound using 1-mL sterile pipette tips. Any cellular debris was removed by washing with PBS. The wounded monolayers were then incubated in 10% FCS medium containing UCN-01 (50 or 100 nmol/L) for 24 h or 48 h, then photographed under a light microscope ($\times 200$). The experiments were repeated in quadruplicate wells at least 3 times.

Immunoblot assay Protein expression was assessed using an immunoblot assay as described previously^[16]. A monoclonal E-cadherin antibody was purchased from Transduction Laboratories (Lexington, KY, USA). A mouse monoclonal anti-FLAG antibody M2 (Stratagene, La Jolla, CA, USA) was used to detect expression of the FLAG-tagged BRCA1 and PTEN proteins. Equal protein loading and the protein transfer were confirmed by immunoblotting for the determination of α -actin protein using a polyclonal α -actin antibody (I-19, Santa Cruz, Hercules, CA, USA) on the same Western blots stripped. A colored marker (Bio-Rad Laboratories, Hercules, CA, USA) was used as a molecular size standard.

Reverse transcription-polymerase chain reaction (RT-PCR) mRNA was assayed by RT-PCR as described in previous studies^[16]. cDNA was synthesized from 2 μ g of total RNA in a 30- μ L reaction mixture containing 5 \times reverse transcriptase reaction buffer (Life Technologies, Inc, Gaithersburg, MD, USA), dNTP 200 μ mol/L, 100 μ mol/L solution of primers, 50 units of RNasin (Promega, Madison, WI, USA), dithiothreitol 10 mmol/L, and 100 units of reverse transcriptase (Life Technologies, Inc). The mixture was incubated at 37 °C for 60 min, heated to 95 °C for 10 min, and then chilled on ice. PCR was carried out in a 50- μ L volume con-

taining 10–20 ng cDNA, chelating buffer (Perkin-Elmer/Cetus, Norwalk, CT, USA), 20 μ mol/L dNTP mixture, 1.5 units of *Taq* DNA polymerase (Perkin-Elmer/Cetus), and 0.5 μ mol/L of the following E-cadherin-specific primer pairs: 5'-CAATCTCAAGCTCATGG-3' (forward) and 5'-CCATTCGTTCAAGTAGTC-3' (backward). The PCR was processed at 94 °C for 1 min, 54 °C for 1 min, and 72 °C for 1 min. To ensure that the RNA was of sufficient purity to undergo RT-PCR, a PCR assay using primers specific for the β -actin gene cDNA was performed for each sample through the same PCR process. β -Actin specific primer pairs were as follows: 5'-GTC AAC GGA TTT GGT CTG TAT T-3' (forward); 5'-AGT CTT CTG GGT GGC AGT GAT-3' (backward). Semi-quantitative PCR conditions for E-cadherin and β -actin are 28 cycles and 22 cycles, respectively. The PCR products were electrophoresed on a 5% nondenaturing polyacrylamide gel. The gel was then dried and exposed to an imaging plate, and the radioactivity was determined using a Bioimage Analyzer (Bas1000; Fuji, Kanagawa, Japan).

Cell-cell aggregation assay Cells were harvested using HBSS buffer containing 0.01% trypsin and centrifuged at 100 000 $\times g$ for 5 min. Cell pellets were re-suspended in a HCMF buffer (NaCl 160 mmol/L, Na_2HP_4 0.6 mmol/L, 0.1% w/v glucose, and 0.01% HEPES, pH 7.4) containing CaCl_2 4 mmol/L at a cell density of 1×10^5 cell/ml. Total 1 mL aliquots of a single cell suspension were transferred to microcentrifuge tubes. UCN-01 (50 or 100 nmol/L), anti-E-cadherin antibody (0.5 mg/L, Transduction Laboratories, Lexington, KY, USA), or a combination of both was added. The cell cultures were then put on a shaker maintained at 37 °C for 60 min and 0.02 mL aliquots from all cell cultures were removed and fixed in 0.060 mL of glutaraldehyde. The total number of particles (that is, cells or aggregates) were counted by two investigators, using a haemocytometer. The degree of aggregation is represented by the aggregation index calculated by $N_{t=60}/N_{t=0}$, where $N_{t=0}$ is the number of single cells before the incubation and $N_{t=60}$ is the number of single cells after the incubation for 60 min. $N_{t=60}/N_{t=0} > 1$ = no cell-cell adhesion; $N_{t=60}/N_{t=0} < 1$ = specific cell-cell adhesion.

Statistical analysis Each assay was performed at least 3 times. Statistical significance for the results was assessed using Student's *t*-test. $P < 0.05$ suggests a statistically significant difference.

Results

Effect of UCN-01 on proliferation of U-87MG cells Using an MTT assay, we determined the cell viability of U-87MG glioblastoma cells after treatment with various doses of UCN-01 for 24 or 48 h. As shown in Figure 1A, exposure

to UCN-01 resulted in a loss of cell viability in a concentration- and time-dependent manner. ID₅₀, a dose at which 50% of the cells lost their viability, was approximately 400 nmol/L and 260 nmol/L after the 24-h and 48-h treatments, respectively ($P < 0.01$). At UCN-01 < 100 nmol/L doses, no significant effect on cell viability was observed at any exposure time points ($P > 0.01$). UCN-01 doses of < 100 nmol/L were thus selected for use in further studies. We also determine the cytotoxicity of UCN-01.

Effect of UCN-01 on PKC activity of U-87MG cells

Subconfluent cells were left untreated or treated with 100 nmol/L UCN-01 for 4 h and then harvested for assay of PKC activity. The membranous fractions (404 ± 23 pmol ³²P/min,

$P < 0.01$) and cytosolic fractions (114 ± 46 pmol ³²P/min, $P < 0.01$) were significantly inhibited in the cells treated with UCN-01 compared to the untreated control cells (885 ± 42 pmol ³²P/min for the membranous fractions, 289 ± 65 pmol ³²P/min for the cytosolic fractions). Similarly, reduced PKC activity was also observed after treatment with 50 nmol/L UCN-01 (data not shown).

Effect of UCN-01 on invasion and motility of U-87MG cells

Cell invasion and migration are crucial processes in tumor metastasis. A modified Boyden chamber assay was performed in order to determine the ability of U-87MG cells to invade through biological matrices *in vitro*, based on the percentage of cells able to penetrate the reconstituted base-

Figure 1. Effect of UCN-01 on U-87MG cell viability, invasion, and migration. (A) MTT assays of cell viability. Mean±SEM. n=3. (B) *In vitro* invasion assay. Data (mean±SEM) are expressed as the percentage of the control response from 3 independent experiment assays that yielded similar results. (C) Scratch wound assay

ment membrane-coated filters and attach to the lower surface of filter. As shown in Figure 1B, the invasion capacity of U-87MG cells was markedly inhibited when UCN-01 was present in the upper chamber; a reduction of approximately 12% and 25% ($P < 0.01$) was observed for 50 and 100 nmol/L UCN-01 after 48-h treatment, respectively. A similar inhibition of cell invasion activity by UCN-01 was also observed in U-373, another glioblastoma cell line (data not shown).

To examine whether UCN-01 anti-invasion potential is associated with its ability to suppress cell spreading and migration, the effect of UCN-01 on U-87MG cell motility was also analyzed using a scratch wound assay. As demonstrated by the representative fields shown in Figure 1C, 50 nmol/L UCN-01 markedly inhibited the flattening and spread of both cell lines along the edges of the wound compared to the untreated control cells. When this experiment was repeated using a UCN-01 dosage of 100 nmol/L instead of 50 nmol/L, the anti-migration observed was more significant.

Effect of UCN-01 on PMA- and EtOH-stimulated cell invasion We determined the effect of UCN-01 on the stimulation of cell invasion caused by PMA and EtOH, two PKC activators. U-87MG cells spontaneously penetrated through an artificial basement membrane, and the number of invading cells significantly increased when PMA or EtOH was included in the cell suspension [invasion index 58 ± 4 (PMA), 62 ± 6 (EtOH) versus the untreated control, 46 ± 3 ; $P < 0.01$]. However, both spontaneous invasion and PMA- or EtOH-promoted cell invasion were markedly inhibited by UCN-01 (Figure 2A). The ability of UCN-01 to suppress PMA- and EtOH-promoted cell invasion could not be attributed to increased cytotoxicity, since UCN-01 did not significantly affect the cytotoxicity of PMA or EtOH (Figure 2B).

Effect of BRCA1 and PTEN on anti-invasion activity of UCN-01 To determine the effect of the tumor suppressor genes BRCA1 and PTEN on the anti-invasion potential of UCN-01, we compared the invasion behavior of U-87MG cells that had been transiently transfected with the BRCA1 or PTEN gene in the presence and absence of UCN-01 (100 nmol/L). The full-length BRCA1 or PTEN cDNA was expressed in a pCMV-Tag2B vector, which allows for the expression of proteins with an N-terminal FLAG sequence. Exponentially growing cells (3×10^5 cell/well) in 6-well tissue culture dishes were transfected with either the BRCA1 or PTEN vector (5 μg /well) overnight, washed, and then incubated for 48 h. Overexpression of the BRCA1 or PTEN transgene was confirmed by the determination of BRCA1 or PTEN protein using an anti-FLAG antibody (M2). Significant expression levels of the BRCA1 (220 kDa) and PTEN (67 kDa) proteins were observed in U-87MG cells 48 h after trans-

Figure 2. Effect of UCN-01 on PMA- and EtOH-induced promotion of cell invasion. (A) Subconfluent U-87MG cells were trypsinized and counted. Cell viability was also assessed using the MTT assay 48 h after treatment with UCN-01 (100 nmol/L) and/or PMA (1 $\mu\text{mol/L}$) or EtOH (40 mmol/L) in 96-well tissue culture plates (B) Mean \pm SEM. $n = 3$ independent experiments.

fections (Figure 3A). The transfected cells were collected and subjected to the *in vitro* invasion assay. As shown in Figure 3B, the transfection with the “empty” pCMV-Tag2B control vector had no effect on UCN-01 modulation of cell invasion, whereas overexpression of the BRCA1 or PTEN transgene significantly enhanced the anti-invasion potential of UCN-01. BRCA1 or PTEN transfection alone caused a 20% reduction in cell invasion; 100 nmol/L UCN-01 inhibited 30% of cell invasion. However, UCN-01 caused an 87% and a 90% inhibition in invasion in cells transfected with BRCA1 and PTEN, respectively. These results suggest that a combination of UCN-01 and BRCA1 or PTEN transgene synergistically inhibits the invasive behavior of glioblastoma cells.

UCN-01 increases E-cadherin expression To explore the mechanism(s) underlying the effect of UCN-01 on U-87MG cell invasiveness and migration, we analyzed the expression of E-cadherin protein, an adhesion molecule, by an immunoblot assay, following treatment with UCN-01. As illustrated in Figure 4A, U-87MG cells contained a low basal

Figure 3. Effect of BRCA1 or PTEN on anti-invasion potential of UCN-01. Cells harvested and subjected to the immunoblot assay (A) and the *in vitro* invasion assay (B) 48 h after transfections. A representative set of experiments from 3 individual transfections is shown.

level of the endogenous E-cadherin protein. Forty-eight hours exposure to UCN-01 resulted in a significant dose-dependent increase. UCN-01(50 and 100 nmol/L resulted in approximate 2.2- and 6.3-fold increases in the E-cadherin protein. Similar results were obtained for E-cadherin mRNA expression in response to UCN-01 treatment (Figure 4C).

Effect of UCN-01 and anti-E-cadherin antibody on formation of cell-cell aggregates To ascertain whether E-cadherin plays an important role in the protection of UCN-01 against the migration and invasion activity of U-87MG cells, we examined the effect of UCN-01 on the formation of cell-cell aggregates. UCN-01 100 nmol/L significantly inhibited the formation of 3-dimensional cellular aggregates (aggregation index=1.3, $P<0.01$) compared to the untreated control U-87MG cells, which showed a significant degree of cell-cell aggregation (aggregation index=0.65). However, in the presence of the E-cadherin antibody, the protective ability of UCN-01 against the formation of cell-cell aggregates was

Figure 4. Effect of UCN-01 on E-cadherin expression. Cells were treated with indicated concentration of UCN-01 for 24 h and subjected to Western blotting for protein expression (A) and RT-PCR (C) for mRNA expression. Protein expression (B) and mRNA (D) expression bands were quantitated by densitometry and expressed relative to the α-actin bands and the untreated control band from 2 experiments, respectively. Standard errors were less than 5%.

markedly reduced (aggregation index=0.8). Similar results were observed in another human glioblastoma cell line, U-373 (data not shown). These results suggest that E-cadherin can play a critical role in the anti-invasion potential of UCN-01.

Discussion

PKC is viewed as a new target for suppressing tumor cell

invasion and migration, and therefore metastasis^[1,2]. In the present study we found that in human gliocarcinoma U-87MG cells, UCN-01 inhibits cell proliferation in a concentration- and time-dependent fashion at higher doses (>100 nmol/L). Furthermore, at less cytotoxic doses (<100 nmol/L), UCN-01 reduces the PKC activity and suppresses the cell invasion and migration capabilities. The anti-invasion and anti-migration potential of UCN-01 was confirmed by further experiments in which the PMA- or EtOH-promoted activities of cell invasion were blocked by UCN-01. Both PMA and EtOH are potent activators of PKC^[1,18]. These findings corroborate previous observations that PKC plays a central role in the invasion of glioblastoma-derived cell lines^[19]. Therefore, the profound inhibition of tumor cell invasion and migration are novel features that contribute to the anti-tumor properties of UCN-01.

Although the mechanisms by which suppression of cell invasion and migration by UCN-01 have yet to be discovered, our study has revealed an important finding: despite the inhibition of PKC activity, up-regulated expression of the cell adhesion E-cadherin protein accompanies UCN-01-modulated cell invasion and migration activity. Moreover, a significant reduction of UCN-01 resulted in increased formation of cell-cell aggregates by the E-cadherin antibody. E-cadherin, a transmembrane glycoprotein, is a key mediator of cell-cell adhesion, which acts via the formation of a complex with 3 major cytoplasmic catenins (α , β , and γ), and reportedly plays a key role in controlling the invasive and metastatic progression of a variety of human carcinoma cells, including glioblastoma^[20]. Disruption of the E-cadherin/catenin complex, due primarily to decreased or lost expression of E-cadherin, is shown to be correlated with increased cell proliferation, motility, and invasiveness associated with the progression of tumors^[21]. Moreover, it is also found that tamoxifen, a PKC inhibitor, blocks the invasion and migration of tumor cells by increasing the expression and functions of E-cadherin/catenin complexes^[1]. Therefore, E-cadherin is believed to be a critical mediator of the anti-tumor invasion and migration potential of UCN-01, although further experiments are needed for clarification of the relationship between E-cadherin expression and PKC activity.

In addition, we also found that the enforced expression of two tumor suppressor genes, BRCA1 or PTEN, by a transient transfection assay significantly affects the inhibition potential of UCN-01 on U-87MG glioblastoma cell invasion in a synergistic manner. BRCA1 (Breast Cancer susceptibility gene 1) is located at human chromosome 17q21, and mutations of BRCA1 are known to confer an added risk for breast and ovarian cancers in women, and for prostate

cancer in men^[22]. Increasingly, evidence indicates that invasive breast tumors show decreased BRCA1 mRNA expression and a loss of BRCA1 immunochemical staining relative to non-invasive tumors and benign tissues^[23]. A clinical observation suggests that E-cadherin expression is potentially correlated with BRCA1-associated breast cancer^[24]. Our recent studies also found that indole-3-carbinol, a promising phytochemical produced by cruciferous vegetables, results in up-regulation of BRCA1 and E-cadherin/catenin complex expression, which results in the suppression of tumor invasion and migration^[17]. In addition, we also found that alcohol promotes tumor cell invasion and migration and is associated with down-regulation of BRCA1^[24].

Phosphatase and tensin homologue deleted from chromosome 10 (PTEN) was identified in the 10q23 chromosome region and is often found in mutated forms in a wide range of human malignancies, including glioblastoma^[25]. The restoration of the PTEN gene into U-87MG cells has been found to markedly suppress cell migration and invasion by negative regulation of the signals generated at the focal adhesions, and by the direct dephosphorylation and inhibition of FAK, which is involved in the cell's interactions with extracellular matrix proteins responsible for the migration and enhancement of cell spreading through phosphorylation of its tyrosine^[26]. Loss of PTEN expression and inactivation of wild-type PTEN function can often be observed in advanced or invasive tumors. Accordingly, these findings suggest that both BRCA1 and PTEN can function as inhibitors of tumor invasion and metastasis. Thus, our present findings provide *in vitro* evidence to suggest that a combination of UCN-01 function along with BRCA1 or PTEN gene therapy could be potentially useful in the clinical prevention and treatment of glioblastoma, although it is evident that for this to occur, further studies are required.

In conclusion, we discovered that UCN-01, as a selective PKC inhibitor, suppressed the cell migration and invasion and inhibits the PMA- and EtOH-promoted cell invasion in human glioblastoma U-87MG cells. Moreover, this inhibition of glioblastoma cell invasion and migration by UCN-01 is characterized by an enhanced expression of cell adhesion molecule E-cadherin. Therefore, UCN-01 can be a potent anti-tumor agent in the therapy of glioblastoma, not only via the suppression of proliferation of glioblastoma cells, but also via the inhibition of cell invasion and metastasis. Our results, which support previous studies^[19], also indicate that the PKC signal transduction pathway can play an important role in glioblastoma cell invasion and metastasis, and that the suppression of this pathway may significantly impair the malignant progression of human glioblastoma.

Abstract

Aim: To build up a theoretical model of organic compounds for the prediction of the activity of small molecules through the blood-brain barrier (BBB) in drug design. **Methods:** A training set of 37 structurally diverse compounds was used to construct quantitative structure-activity relationship (QSAR) models. Intermolecular and intramolecular solute descriptors were calculated using molecular mechanics, molecular dynamics simulations, quantum chemistry and so on. The QSAR models were optimized using multidimensional linear regression fitting and stepwise method. A test set of 8 compounds was evaluated using the models as part of a validation process. **Results:** Significant QSAR models ($R=0.955$, $s=0.232$) of the BBB penetration of organic compounds were constructed. BBB penetration was found to depend upon the polar surface area, the octanol/water partition coefficient, Balaban Index, the strength of a small molecule to combine with the membrane-water complex, and the changeability of the structure of a solute-membrane-water complex. **Conclusion:** The QSAR models indicate that the distribution of organic molecules through BBB is not only influenced by organic solutes themselves, but also relates to the properties of the solute-membrane-water complex, that is, interactions of the molecule with the phospholipid-rich regions of cellular membranes.

Introduction

The two barriers separating the central nervous system (CNS) from the periphery are the blood-brain barrier (BBB), located at the endothelial cells of the brain tissue capillaries, and the blood-cerebrospinal fluid barrier (B-CSF-B), at the choroids plexus and the circumventricular organs^[1]. Formed by complex tight junctions of the brain capillary endothelial cells, the BBB segregates the circulating blood from interstitial fluid in the brain^[2]. The capillary endothelial cells regulate the permeability property of the BBB. However, there are at least four kinds of cells that comprise the brain microvasculature, and all contribute to the regulation of the cerebral microvasculature and, indirectly, to the regulation of BBB permeability. The endothelial cell and the pericyte share a common capillary basement membrane. There is approximately one pericyte for every two to four endothe-

lial cells^[3]. Also, immunohistochemistry is a widely used research technique in BBB research for the cellular localization of proteins of interest in normal vessels and the documentation of altered expression following disease states, for the identification of cultured cells and for the spatial localization of novel gene products^[4].

Although the BBB was thought to act as a static wall protecting the brain, application of recent advanced methodologies to study the BBB has led to the new concept that the BBB acts as a dynamic regulatory interface. Using primary cultured bovine brain capillary endothelial cells, Tsuji *et al*^[5,6] have found that P-glycoprotein (ABCB1) acts as an efflux pump for the anti-cancer drugs, vincristine, at the BBB. Schinkel *et al*^[7-9] have developed the *mdr 1a* gene knockout mouse and proved that P-glycoprotein (ie, *mdr 1a* gene products) plays a key role in restricting the apparent cerebral distributed vinblastine (a substrate of P-glycoprotein)

across the BBB. However, several hydrophilic substrates such as metabolites of cerebral neurotransmitters are present in the brain, which reduce the cerebral concentration, and as a result, could play an important role in CNS detoxification.

To be effective, CNS therapeutic agents must have the ability to cross over the BBB whereas peripherally acting drugs should hardly be able to pass the BBB. The uptake of a compound into the brain is a complex process. The moderately lipophilic drugs can pass the BBB by passive diffusion and the hydrogen bonding properties of drugs significantly influence their particular CNS uptake profiles. Polar molecules are generally poor CNS agents unless they undergo active transport to pass the CNS. Size, ionization properties, and molecular flexibility are other factors observed to influence transport of an organic compound across the BBB^[10-13]. Recently, there has been a surge in computational efforts to evaluate absorption, distribution, metabolism, excretion, and toxicity (ADME/T) properties of drugs. These new computational approaches remain to focus on modeling structurally diverse data sets by dealing with the properties of the solutes. These properties are limited to relative lipophilicity indices, solvation and hydrogen bond parameters, topological indices, and limited three-dimensional solute properties^[14-19]. Iyer *et al*^[20] have developed a methodology called membrane-interaction (MI)-QSAR analysis, where structure-based design methodology is combined with classic intramolecular QSAR analysis to model different compounds interacting with cellular membranes. They have also built a predictive model of BBB penetration of organic compounds by simulating the interaction of an organic compound with the phospholipide-rich region of cellular membranes. As a result, they indicated that BBB penetration of an organic compound depended upon PSA, ClogP, and the conformational flexibility of the compounds as well as the strength of their "binding" to the model biologic membrane. The BBB penetration process can be reliably described for structurally diverse molecules whose interactions with the phospholipide-rich regions of cellular membranes are explicitly considered. There are other important applications of MI-QSAR analysis. For example, it can be used as a computational approach to estimate ADME properties such as the transport of organic solutes through biological membranes; and by this way, we can forecast intestinal absorption^[21] of drugs and construct MI-QSAR model for skin irritation^[22], and eye irritation^[23]. However, as a prediction measure, the MI-QSAR computational model is itself somewhat inconvenient. It is quite easily susceptible to manipulation during the prediction process, and so models with more reliability can still have a reasonable-looking

MI-QSAR model. Moreover, there are several non-MI-QSAR computational models including other descriptors besides PSA and ClogP reported to describe and predict BBB penetration. Lombardo and colleagues^[17] reported about computing BBB penetration of organic solutes via free energy calculations. Keseru *et al*^[24] clarified a high-throughput prediction of BBB penetration of organic molecules using a thermodynamic approach. Crivori *et al*^[25] elucidated a method to predict BBB penetration from a three-dimensional molecular structure. Their research results showed that the BBB penetration only relies on one or two descriptors, which leads to the simplification of the prediction model of BBB.

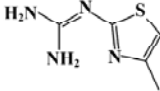

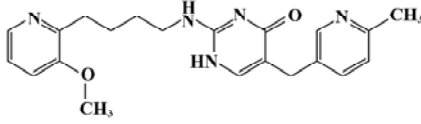

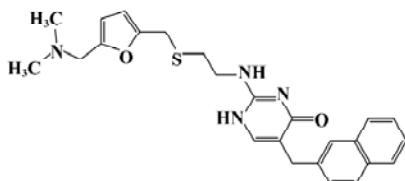

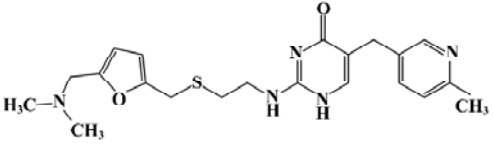

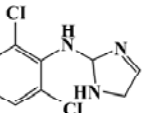

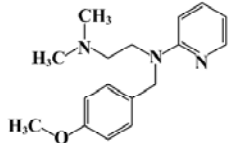

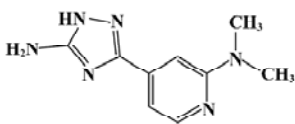

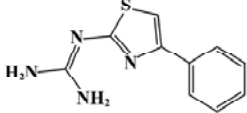

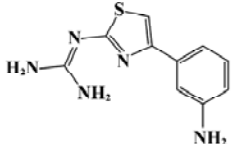

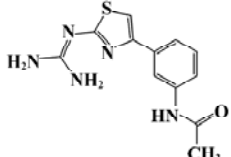

In this article, we focus on constructing the predictive models of BBB penetration of organic compounds on the basis of QSAR analysis and MI-QSAR analysis.

Materials and methods

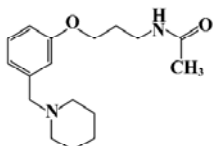

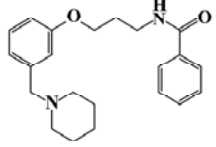

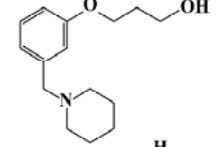

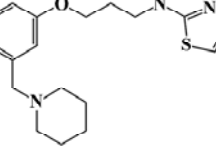

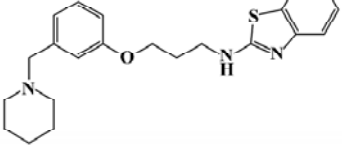

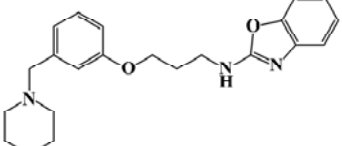

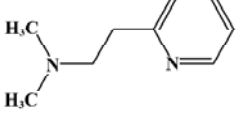

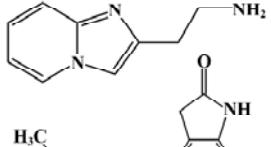

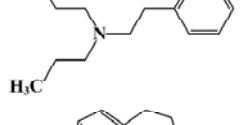

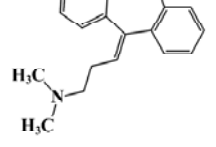

Building solute molecules A training set of 37 organic compounds^[26,27] (Table 1) and a test set of 8 organic compounds (Table 2) were selected. These compounds had ranges in molecular weights from 16.03 to 448.58, whose concentrations in blood and brain (C_{blood} and C_{brain}) were measured in units of mmol/L, and there were variations in net charge at pH 7.4^[26]. The dependent variable used in this theoretical model was the logarithm of the BBB partition coefficient, $\log \text{BB} = \log (C_{\text{brain}}/C_{\text{blood}})$ ^[27]. Experimental values of $\log \text{BB}$ published to date covered the range of about -2.00 to +1.04. Within this range, compounds with $\log \text{BB} > 0.30$ cross the BBB readily while compounds with $\log \text{BB} < -1.00$ are poorly distributed to the brain^[20,27]. All these compounds were built on a PC computer using the Build module of the commercial software packages Hyperchem 6^[28]. First, the geometry of these compounds were optimized using the Amber 94 force field in gas state. Second, they were placed in a periodic solvent box whose volume was $X=16\text{\AA}$, $Y=10\text{\AA}$, $Z=18\text{\AA}$, which included 96 water molecules. Here, temperature was 300 K and pressure was 101.325 kPa. Then the compounds in water were minimized by the above method. Third, the compounds in water were simulated by the Monte Carlo method and minimized by the above method.

Molecular modeling of a DMPC membrane monolayer complex with a layer of water (DMPC-water model) A model of dimyristoylphosphatidylcholine (DMPC) membrane monolayer was constructed using the software Material Studio^[29], and minimized for 200 steps with the smart minimizer. According to the work done by van der Ploeg and Berendsen^[30], the DMPC monolayer was composed of 25 DMPC molecules ($5 \times 5 \times 1$).

Here, the unit cell parameters used for building the DMPC monolayer were $a=8\text{\AA}$, $b=8\text{\AA}$, and $\gamma=96.0^\circ$, which yield an average surface area per phospholipid of 64\AA^2 that was similar to Stouch's research results^[31]. Moreover, we added a layer of water ($40\times 40\times 10$) including 529 water molecules to the polar side of the DMPC monolayer.

Molecular dynamic simulation (MDS) of a solute-membrane-water complex In order to prevent unfavorable van der Waals interactions between a solute molecule and the membrane DMPC molecules, one of the “center” DMPC molecules was removed from the DMPC-water model and an organic compound (solute) was inserted in the space cre-

Structure of a single DMPC molecule

ated by the missing DMPC molecule to form a solute-membrane-water complex. The solute was inserted at three different positions in the DMPC-water model and three corresponding MDS models were generated for each compound. MDS of the complex was performed for 1000 steps using Material Studios^[29] with a Compass force field. Here, the three-dimensional volume was restricted to a boundary of $X=40\text{\AA}$, $Y=40\text{\AA}$, $Z=91.76\text{\AA}$, and $\gamma=96.0^\circ$.

Calculation of descriptors Most of the intramolecular solute descriptors were calculated by the commercial software packages CS Chem3D Ultra7.0^[32], which included molecular mechanism (MM) parameters, quantum chemistry parameters, hydrophobic parameters (such as ClogP), stereo parameters (such as Es and Balaban Index) and so on. The MM parameters comprised bending energy, stretch-bend energy, torsion energy, total energy, van der Waals energy and others. The quantum chemistry parameters consisted of electronic energy, HOMO energy, LUMO energy, total energy, and so on. The data of molecular PSA (polar surface area) came from Iyer and colleagues^[20].

The intermolecular solute-membrane interaction descriptors were extracted directly from the MDS trajectories in which the solute-membrane-water complex had the lowest energy geometry. These descriptors were mainly energy parameters. The total energy of a system could be expressed as follows^[20]:

$$E_{\text{total}} = E_{\text{valence}} + E_{\text{crossterm}} + E_{\text{nonbond}}$$

Here, the valence interactions include bond stretching (bond), valence angle bending (angle), dihedral angle torsion (torsion), and inversion, also called out-of-plane interactions (oop) terms, which are part of nearly all forcefields for covalent systems. In addition, a Urey-Bradley term (UB) may be used to account for interactions between atom pairs involved in 1, 3 configurations (ie, atoms bound to a common atom). $E_{\text{valence}} = E_{\text{bond}} + E_{\text{angle}} + E_{\text{torsion}} + E_{\text{oop}} + E_{\text{up}}$. Modern (second-generation) forcefields generally achieve higher accuracy by including crossterms to account for such factors as bond or angle distortions caused by nearby atoms. Crossterms can include the following terms: stretch-stretch,

stretch-bend-stretch, bend-bend, torsion-stretch, torsion-bend-bend, bend-torsion-bend and stretch-torsion-stretch. The interaction energy between non-bonded atoms is accounted by van der Waals, electrostatic (Coulomb), and hydrogen bond terms in some older forcefields. $E_{\text{non-bond}} = E_{\text{van-der-Waals}} + E_{\text{Coulomb}} + E_{\text{hydrogen-bond}}$. Restraints that can be added to an energy expression include distance, angle, torsion, and inversion restraints. Restraints are useful if you, for example, are interested in only part of a structure for information on restraints and their implementation, use, and also the documentation for the particular simulation engine.

Construction and testing of MI-QSAR models MI-QSAR models of some organic compounds through BBB were constructed by partial sum of squares for regression using software SPSS. A training set of 37 structurally diverse compounds whose BBB partition coefficients had been measured was used to construct MI-QSAR models. MDSs were used to determine the explicit interaction of each test compound with the DMPC-water model. An additional set of intramolecular solute descriptors were computed and considered in the trial pool of descriptors for building MI-QSAR models. The QSAR models were optimized using multidimensional linear regression fitting and stepwise method. A test set of 8 compounds was evaluated using the MI-QSAR models as part of a validation process.

Results

Building solute molecules A training set of 37 organic compounds and a test set of 8 organic compounds were built and minimized, dissolved in liquid, and optimized by Monte Carlo method and MM. Finally, the dominant conformations of these compounds were obtained (Figure 1).

MDS of a solute-membrane-water complex The result revealed that the energy of a solute inserted at the middle position of the DMPC-water model was lower than that of the other two positions. Figure 2 shows the dominant conformation of a solute-membrane-water complex in the MDS.

Construction and testing of MI-QSAR models MI-QSAR analysis was used to develop predictive models of some organic compounds through BBB and to simulate the interaction of a solute with the phospholipide-rich regions of cellular membranes surrounded by a layer of water. Molecular descriptors of 37 compounds in the training set were listed in Table 3. Six MI-QSAR equations were constructed based on Table 3 and were listed as follows:

$$\begin{aligned} \log \text{BB} &= 0.552 - 1.73 \times 10^{-2} \text{PSA} \\ n &= 37 \quad R = 0.835 \quad S = 0.398 \\ \log \text{BB} &= 0.229 - 1.70 \times 10^{-2} \text{PSA} + 0.131 \text{Clog P} \end{aligned} \quad (1)$$

Figure 1. The dominant conformation of Number 1 compound labeled by balls and cylinders in water. The box denotes the water solvent box defined in Monte Carlo simulation.

Figure 2. The dominant conformation of a solute-membrane-water complex in the MDS. The DMPC molecules appear as black stick. The upper molecules show water molecules. The center ball molecule expresses organic compound. The black box displays the border of volume.

$$n=37 \quad R=0.878 \quad S=0.352 \quad (2)$$

$$\log BB=4.965 \times 10^{-2} - 1.28 \times 10^{-2} \text{ PSA} + 0.211 \text{ Clog P} - 6.40 \times 10^{-7} \text{ BIndx}$$

$$n=37 \quad R=0.924 \quad S=0.285 \quad (3)$$

$$\log BB=6.262 \times 10^{-2} - 1.36 \times 10^{-2} \text{ PSA} + 0.205 \text{ Clog P} - 7.11 \times 10^{-7} \text{ BIndx} - 0.185 E_{sb}$$

$$n=37 \quad R=0.938 \quad S=0.264 \quad (4)$$

$$\log BB=6.580 \times 10^{-2} - 1.21 \times 10^{-2} \text{ PSA} + 0.206 \text{ Clog P} - 7.77 \times 10^{-7} \text{ BIndx} - 0.197 E_{sb} + 1.330 \times 10^{-3} \Delta E_{total}$$

$$n=37 \quad R=0.947 \quad S=0.248 \quad (5)$$

$$\log BB=8.730 \times 10^{-2} - 1.04 \times 10^{-2} \text{ PSA} + 0.222 \text{ Clog P} - 9.60 \times 10^{-7} \text{ BIndx} - 0.183 E_{sb} + 1.364 \times 10^{-3} \Delta E_{total} - 2.68 \times 10^{-3} \Delta E_{torsion}$$

$$n=37 \quad R=0.955 \quad S=0.232 \quad (6)$$

where PSA is the polar surface area, ClogP is the calculated logP (the logarithm of the partition coefficient for octanol/water), BIndx is the Balaban Index, namely connective index of molecular average total distance (relative covalent radius), and E_{sb} is the stretch-bend energy of a molecule. These intramolecular solute descriptors came from CS calculation. In addition, calculated from the MDS, intermolecular descriptors ΔE_{total} and $\Delta E_{torsion}$ are related to interactions between a solute and the DMPC-water model. They display the change in the total potential energy and the dihedral torsion energy of the solute-membrane-water complex comparing with that of the DMPC-water model, respectively. Here, n is the number of organic compounds, R is the correlation coefficient, and S is the standard deviation.

With the increase of the variable from one to six, the relativity of MI-QSAR equations was also improved, and the predictive ability of the models was enhanced. Figure 3 display a diagnostic plot of the MI-QSAR models. Here, equation 6 was the most significant, which means that the capability of an organic compound through BBB depends upon PSA, ClogP, BIndx, E_{sb} , ΔE_{total} , and $\Delta E_{torsion}$. Moreover, the potential of an organic compound through BBB is directly proportional to ClogP and ΔE_{total} , but inversely proportional to PSA, BIndx, E_{sb} , and $\Delta E_{torsion}$. The observed and predicted log BB values of the training set are listed in Table

Figure 3. A diagnostic plot of the MI-QSAR models. R is the correlative coefficient and s is the standard deviation of the best x -term model, where x is plotted on the X-axis for the 37 compounds of the training set.

Table 3. The values of molecular descriptors of 37 organic compounds in the training set.

5 and plotted in Figure 4. The predicted log BB value of compound 18 in the training set was much higher than observed, and this molecule has also been identified as an outlier in other studies^[20]. Protonation of the molecule could account for its low log BB value.

A test set of 8 organic compounds was constructed as a way to attempt to validate the MI-QSAR models given by the six equations mentioned. The compounds of the test set were selected so as to span almost the entire range in BBB penetration. The observed and predicted log BB values for

this test set are given in Table 6 and plotted in Figure 5. It seems that the 5–6 terms MI-QSAR models could predict log BB for other compounds in drug design.

Discussion

We have built up a theoretical model of BBB penetration of organic compounds by simulating the interaction of an organic compound with the phospholipid-rich regions of cellular membranes. The family of these MI-QSAR models

**Figure 4.** Comparison of the experimental log BB values (—x—) with the corresponding predicted log BB as predicted by the 5-term MI-QSAR model (—□—) and by the 6-term MI-QSAR model (—△—) for all the molecules of the training set.**Figure 5.** Comparison of the experimental log BB values (—x—) with the corresponding predicted log BB as predicted by the 5-term MI-QSAR model (—□—) and by the 6-term MI-QSAR model (—△—) for all the molecules of the test set.

reveal that the capability of an organic compound through BBB focus on six significant features, which are PSA, ClogP, Blndx, E_{sb} , ΔE_{total} , and $\Delta E_{torsion}$. The descriptor PSA is found as a dominant descriptor in these MI-QSAR models, which is related to the aqueous solubility of the solute and can be used as a direct lipophilicity descriptor^[19]. When the value of PSA lessens within the range from 0 to 108.80 Å², the value of log BB will increase. This is consistent with the experimental result that the higher polarity it possesses, the more difficultly a molecule enters the hydrophobic environment of BBB^[31]. Along with PSA, many descriptors can display various other kinds of the hydrophobic parameters of compounds, such as ClogP. In some cases it may be appropriate to display the parameter in the form of meshes, such as PSA. The higher the hydrophobic property, the greater the value of ClogP is. And the value of log BB of a molecule increases with the increase of ClogP. It means that the hydrophobic molecule can pass through BBB more easily than the hydrophilic molecule does, which is supported by the experimental results^[33]. As stated, Blndx is the connective index of molecular average total distance, which pertains to the volume parameter. Our research result reveals that with the accretion of its bulk, a molecule becomes more and more difficult to cross over BBB by diffusion. The presence of the descriptor E_{sb} suggests that with the decrease of the stretch-bend energy the value of log BB increases.

Interestingly, the other two descriptors, ΔE_{total} , and $\Delta E_{torsion}$, reflect the interaction of the solute with the membrane and the behavior of the entire membrane-solute complex. Here, the more the value of ΔE_{total} changes, the more the value of log BB increases. This is because that small molecule acrossing the BBB membrane leads to the change in the structure of the complex, which therefore, results in a greater change of total potential energy, and the accretion of the energy change is the most important cause

for the increase of BBB penetration of small molecules. In contrast, the less the difference in the torsion energy is, the larger the value of log BB is. It displays that a small molecule tightly combined with the membrane-water complex has a higher value of log BB. The relationship suggests that as the solute becomes more flexible within the membrane-water complex, its log BB value would increase, which is in agreement with the research results by Iyer *et al*^[20].

As an extra bonus of our work, we have developed an extension of traditional computational approaches that combines QSAR with solute-membrane-water complex. There is an obvious difference between our method and Iyer's method, which is the addition of a layer of water on the hydrophilic side of the DMPC membrane monolayer. So it is more analogous to the true BBB environment. Our results revealed that the distribution of organic molecules through BBB was not only influenced by the properties of organic solutes, but also related to the property of the solute-membrane-water complex. The former involves the polarity, hydrophobicity, size, and conformational freedom degree of organic molecules. The latter deals with the strength of an organic molecule to combine with the BBB membrane and the structural changeability of a solute-membrane-water complex. Moreover, the capability of a small molecule across BBB is mainly related to four physicochemical factors, which are the relative polarity of a small molecule, the molecular volume, the strength of a small molecule to combine with DMPC-water model, and the changeability of the structure of a solute-membrane-water complex. The MI-QSAR model shows that, relatively, less polar and more hydrophobic small molecules, which tightly combine with the membrane-water complex and are more flexible within the complex, can easily pass through BBB and enter the brain to be effective. In drawing conclusions from our model, it seldom matters if one or two parameters are slightly off (eg, *BIndx*), but it is often critical if some parameters are actually in the wrong value (eg, *ClogP*, *PSA*, or *E_{sb}*): that will change which molecules are in a position to penetrate through BBB.

Incidentally, since the molecular structures in the training set are not very comparable, our MI-QSAR equations possess universal significance. Nevertheless, the precision of the MI-QSAR equation is so low that there is still some time before it can be applied. If a series of organic compounds with similar structures were chosen to construct a training set, the precision of MI-QSAR simulation may be largely increased, while the prediction of the analogues through BBB will be greatly improved.

In conclusion, we have developed an extension of traditional computational approaches that combines QSAR with

solute-membrane-water complex to simulate the BBB environment, which resembles Iyer's method, but differs from it by adding a layer of water on the hydrophilic side of the DMPC membrane monolayer. Our modified MI-QSAR method is more approximate to the body condition than Iyer's MI-QSAR analysis and possesses higher ability to predict organic compounds across BBB. Moreover, while still applying the structural information in a two-dimensional, "structure-function relationship" fashion, this method also takes into account the powerful three-dimensional information displayed by membrane structures, and thus improves existing MI-QSAR method. The MI-QSAR models indicate that the distribution of organic molecules through BBB was not only influenced by organic solutes themselves, but also related to the properties of the solute-membrane-water complex, that is, interactions of the molecule with the phospholipid-rich regions of cellular membranes.

Abstract

Telomerase is a ribonucleoprotein that directs the synthesis of telomeric sequence. It is detected in majority of malignant tumors, but not in most normal somatic cells. Because telomerase plays a critical role in cell immortality and tumor formation, it has been one of the targets for anti-cancer and regeneration drug development. In this review, we will discuss therapeutic approaches based mainly on small molecules that have been developed to inhibit telomerase activity, modulate telomerase expression, and telomerase directed gene therapy.

Introduction

Telomeres are specialized protein-DNA structures at the end of eukaryotic chromosomes. They protect chromosomes from end-to-end fusion and nuclease degradation. In humans, telomeres consists of approximately 4–14 kb of TTAGGG duplex repeats and 150–200 bases of single-stranded DNA overhang running 5' to 3' toward the end of chromosome^[1]. Because of the end replication problem^[2,3], telomeres in human cells erode by approximately 100 bp with each cell division^[4]. Telomerase is the key enzyme for the stabilization of telomere by adding TTAGGG repeats to telomere ends^[5]. It is a ribonucleoprotein that utilizes its RNA component as the template to synthesis telomere repeats. In humans, telomerase activity is not detected in most somatic cells^[6,7]. Progressive telomere shortening after each cell division leads to cellular senescence after 60–80 population doublings^[4]. Escaping senescence leads to further shortening of telomeres and can eventually cause cells to enter crisis and cell death^[8]. Cells at this stage appear aneuploidy because telomere loss induces chromosome instability through the breakage/fusion/bridge cycles^[9]. Few cells stabilize telomere length through activating telomerase activity^[10]. Indeed, telomerase activity is detected in approximately 90% to 95% of human immortal cell lines and up to 85% of cancers^[6,7]. In the remaining 5% to 10% immortal cells, telomerase-

independent telomere maintenance mechanism, also known as the alternative lengthening of telomeres (ALT), were used to maintain telomere length^[11]. These cells could then divide with great capacity.

Because telomerase is an essential component for the proliferation of cancer cells, targeting telomere and telomerase has drawn the interests of scientists in anti-cancer and regeneration drug development. In the present study, we discuss various approaches used including the small molecules that have been developed using telomere and telomerase as targets for chemotherapeutic developments.

Inhibition of telomerase activity

Although tumors are caused by mutations that activate oncogenes and repress tumor suppressor genes, they still need to overcome telomere-dependent senescence for their indefinite divisions. Because telomerase activity is crucial for supporting indefinite proliferation of most tumor cells, selective inhibition of telomerase activity only limits the proliferation capacity of tumor cells^[12]. In principle, a telomerase-specific inhibitor is expected to affect telomere maintenance. It has been proposed that a telomerase inhibitor can be utilized as complementary therapy in cancer chemotherapeutics^[12,13]. However, more and more studies indicate that telomerase also plays an important role in the telomere-cap-

ping function^[14]. Inhibition of telomerase can affect the survival of cancer cells. Indeed, several published reports have found that the inhibition of telomerase can cause apoptosis without long-term treatment of the cells^[15–17]. Thus, it is expected that the inhibition of telomerase activity in cells produces different effects depending on the means of inhibition. Because telomerase activities are also presented in human germline cells, stem cells, peripheral blood mononuclear cells, and normal fibroblasts^[6,18,19], it is likely that telomerase inhibition also affects these cells. The potential risks of telomerase inhibition have to be carefully evaluated in these cells.

Targeting telomerase Telomerase is a unique reverse transcriptase consisting of two major components, the RNA template (*hTR*) and the catalytic subunit (hTERT). Both components have been used as targets for telomerase inhibition. The first successful case was reported in 1995 where antisense RNA against the first 185 nucleotides of the *hTR* molecule was introduced into HeLa cells and caused progressive telomere shortening and eventually cell crisis^[20]. Similarly, short peptide nucleic acid (PNA) or 2'-*O*-methyl-RNA (2'-*O*-meRNA) oligomers with enhanced binding properties to *hTR* efficiently inhibit telomerase activity, and lead to progressive telomere shortening in immortal breast epithelial cells^[21]. Synthetic oligonucleotides applying 2–5A (5'-phosphorylated 2'-5'-linked oligoadenylate)-linked antisense approaches were used to degrade *hTR* and caused apoptosis in several cancer models including glioma^[15]. Utilizing ribozymes to cleave *hTR* has also been reported in several published studies^[13,22]. These small catalytically-active RNA molecules cleave their RNA substrate in a sequence-dependent manner. Interestingly, the inhibition of telomerase activity using hammerhead ribozyme against *hTR* appears to sensitize the breast epithelial cells to topoisomerase inhibitors^[13]. Another approach is to target the catalytic subunit of telomerase hTERT. A dominant negative mutant of hTERT was identified that caused complete inhibition of telomerase activity, telomere shortening, and increased cell apoptosis when introduced into cancer cells^[16,17]. This dominant negative-hTERT also reduced tumorigenicity in nude mice^[16].

Even though antisense, ribozyme, and dominant negative approaches showed promising results in inhibiting telomerase activity, these approaches were less applicable because the techniques for effective and convenient delivery of RNA or proteins were not available for clinical settings. Thus, small molecule compounds that inhibit telomerase activity appear to be more suited. There were several types of compounds identified, including nucleotide analogs that inhibit the catalytic activity of the enzyme and non-nucleotide

analogues that have inhibitory effects less characterized. As these molecules have been extensively reviewed recently^[23,24], they will not be discussed further here. However, it is worthy of noting that compound BIBR1532 was shown to inhibit telomerase non-competitively^[25] and cause telomere shortening and senescence in cancer cells^[26]. Moreover, cancer cells pretreated with BIBR1532 showed a reduced tumorigenic potential in the mouse xenograft model^[26]. With the IC₅₀ value at nanomolar concentration, BIBR1532 and several other compounds should have the potential for further developments^[26–28].

Targeting telomeres In humans, the G-rich telomeric DNA tails are capable of forming a planar structure, termed G-quadruplexes, through non-Watson-Crick Hoogsteen hydrogen bonding *in vitro*^[29]. A recent study has detected the G-quadruplex-induced fluorescence in telomeres of metaphase chromosomes using a G-quadruplex-selective fluorescent compound BMVC [3,6-*bis*(1-methyl-4-vinylpyridinium) carbazole diiodide], providing the first evidence for the presence of G-quadruplexes inside human cells^[30]. In addition to telomeres, the G-quadruplex structure was also reported in the transcriptional regulatory region of several important oncogenes that their expression could be regulated by them^[31]. Thus, even though telomeres in human cells were shown to form T-looped structures^[32], it appears that human telomeres could also form G-quadruplex structures inside cells. The function of G-quadruplex structure in telomeres is not clear. However, because G-quadruplexes formed by telomeric DNA sequences were not the substrates for telomerase^[33], the G-quadruplex structure might have a role in telomere maintenance and transcriptional regulation of oncogene expression. Agents that stimulate the formation or stabilize G-quadruplexes become important targets for drug design.

Several researchers have adopted a structure-based design and synthesis approach to identify lead compounds that interact with G-quadruplexes^[24]. Successful lead compounds that were identified include derivatives of proflavins^[28], porphyrins^[34], acridines^[35], anthraquinones^[36], triazines^[37], and carbazoles^[27]. All of these identified compounds have planar aromatic rings. Molecular modeling studies have indicated that these planar structures bind to the G-quadruplexes through a series of interactions to the planar and loop structures of G-quadruplexes^[28,38,39]. These interactions stabilize the structure of G-quadruplexes and increase the melting temperature upon binding. For example, a carbazole derivative BMVC increases the melting temperature (T_m) of G-quadruplexes formed by human telomeric DNA by as much as 13 °C^[40]. It is interesting to note that these planar compounds appear to be very effective in affecting telomerase

as several of these compounds have the IC_{50} at the range of nanomolar concentration^[27,28,37].

Modulation of telomerase expression

Direct inhibition of telomerase at the activity level provides a simpler mean to target telomerase for cancer therapy. In recent years, several reports have also attempted to target the expression of telomerase at the gene level. Repression of telomerase expression in cancer cells would have applications in anti-cancer chemotherapies whereas activation of telomerase expression in normal cells would have applications in regeneration therapies.

Repressing hTERT expression in cancer cells In human cells, the expressing of telomerase catalytic enzyme hTERT correlates well with the telomerase activity^[41]. It also appears that regulation at the transcriptional level was the most important step for hTERT expression^[42] even though regulation at the splicing^[43,44], post-translational modification^[45-48], or subcellular localization^[49] were also reported. Thus, targeting hTERT transcription is the focus for developing agents that repress hTERT expression. However, there were only a limited number of reports targeting hTERT expression. Retinoic acid represents the most characterized small molecule in this category. Retinoic acid at the micromolar concentration down-regulates telomerase activity in human leukemia cells^[50,51]. Long-term treatment of leukemia cells with retinoic acid leads to telomere shortening and eventually cell death^[50]. The specificity of retinoic acid is a concern in future drug development. An ideal compound should only affect the expression of the hTERT gene. Nevertheless, repressing hTERT expression is an effective way to limit the proliferation capacity of cancer cells. Recently, a cell-based system was developed that enables the screening of small molecule compounds for repressing hTERT expression^[52]. The hTERT promoter was ligated downstream to a reporter gene, GFP or SEAP (secreted alkaline phosphatase), and introduced into human cancer cells. The expression of hTERT could then be monitored by the reporter genes. A series of anthraquinone derivatives were tested for their ability to repress hTERT expression using this cell-based system^[52]. Even though anthraquinone derivatives did not repress hTERT expression, it is anticipated that small molecule compounds that repress hTERT expression could be screened and identified using this approach.

Activating hTERT expression in normal cells While telomerase inhibition or hTERT repression could have applications in anticancer therapeutics, telomerase activation could serve as a mean to extend the lifespan of normal cells and to treat degenerative diseases. For example, liver cir-

rhotic pathology is caused by continual hepatocyte destruction over many years. The end-stage of cirrhosis is characterized by extensive fibrotic replacement and cessation of hepatocyte proliferation. In a mouse experimental liver cirrhosis model, the pathology is alleviated through activation of telomerase activity^[53]. Also in Werner syndrome cells, the accelerated aging phenotype is reversed by telomerase activation^[54]. Moreover, the life span of human bone marrow stromal stem cells are achieved by telomerase expression^[55,56]. These *ex vivo* expanded stem cells could have profound applications in, for instance, tissue engineering.

Ectopically expressed hTERT by introducing a virus promoter-driven hTERT gene into normal human cells has been found to be very effective in increasing hTERT mRNA expression and telomerase activity, and extending the life span of normal cells^[10,57]. For example, the replication capacity of skin fibroblasts^[10] and adult mesenchymal stem cells^[58] could be expanded with the introduction of a viral promoter driven hTERT gene. However, given the role of telomerase in cancer and the introduced DNA which integrates randomly into chromosomes, this type of approach might cause some risks. Although some reports indicated that ectopic expression of telomerase did not cause transformation phenotypes or cancer-associated changes^[59,60], more and more studies raise concerns about the future application of cells immortalized by ectopic hTERT expression in normal cells. Telomerase overexpression in mice has been found to increase epidermal tumors and promote mammary carcinomas^[58,61,62] and that expressing hTERT in human mesenchymal stem cells renders these cells tumorigenic^[58]. Thus, the ideal situation would be controlled expression of hTERT in target cells to avoid unnecessary side-effects. One approach is using small molecules that activate telomerase upon addition and return to the repressed state upon removal which might provide the solution for controlled expression of hTERT. This approach also avoids the uncertainty concerning the integration of DNA into chromosomes.

There are several molecules which have been identified that affect hTERT expression through inhibiting DNA methylation or histone deacetylation. Normal human fibroblast treated with 5-azacytidine (5-AZC) can cause demethylation of the CpG islands within hTERT promoter. It then turns on hTERT mRNA expression and activates telomerase activity^[63,64]. Similarly, histone deacetylase inhibitor trichostatin A (TSA) causes activation of hTERT mRNA expression and telomerase activity in human normal cells^[65,66]. However, because both DNA methylation and histone deacetylation are general mechanisms in controlling gene expression in human cells, the treatment of 5-AZC or TSA would have

broad effects on cellular gene expressions. To achieve selective activation of hTERT expression, a more specific promoter-targeted agent is desired. Sequence analysis of hTERT promoter reveals an estrogen response element (ERE) located upstream to the transcription start site. The function of ERE is established in normal human ovary epithelium cells where the addition of 17 β -estradiol activates the expression of hTERT and telomerase activity^[67]. Thus, telomerase activity could be activated by estrogen in cells with estrogen receptors. However, since estrogens also activate the telomerase activities in cancer cells with estrogen receptor^[67-69], the applicability of estrogen or its analogs in clinics remains to be evaluated. Similar to the approach used in identifying small molecule compounds, a cell-based reporter system was developed in normal human cells that enabled the identification of several *bis*-substituted derivatives of anthraquinones that activate hTERT^[52]. Unlike inhibitors of DNA methylation or histone deacetylation, the repression of hTERT expression by these anthraquinones appears to be specific as they do not activate the expression of reporter gene driven by a virus promoter. Using a similar cell-based chemical screening strategy, compound CGK1026 was also identified to activate hTERT expression in normal human fibroblasts^[70]. CGK1026 activates hTERT expression by affecting the interaction between E2F-pocket protein and histone deacetylase. The effect of CGK1026 on other promoters is still unclear.

Telomerase-directed tumor gene therapy

One of the major goals in anticancer therapies is to target toxic agents to tumor cells specifically to minimize the effects toward normal cells. The specific expression of telomerase hTERT in most types of tumors provides a good discrimination between cancer and normal cells^[6,7]. Deletion analysis of the hTERT promoter reveals a core promoter region located approximately 200 bp upstream of the transcription start site, and is sufficient to confer its specific expression in cancer cells^[71]. The property of hTERT promoter has been applied to restrict the expression of therapeutic genes in tumors. The therapeutic genes utilized include apoptosis-inducing^[72-74], toxin-encoding^[75], chemotherapeutic sensitizer^[71], xenoantigen^[76] genes, or genes used in gene-directed enzyme prodrug therapy (GDEPT)^[77,78]. These hTERT promoter-driven therapeutic genes were introduced into tumor cells through liposome- or virus-mediated pathways. As expected from the expression pattern of telomerase, this type of approach selectively kills virtually all types of telomerase-positive cancer cells without affecting the viability of telomerase-negative cells in both cellular and animal xenograft models. Thus, hTERT directed tumor

gene therapy appears to be a promising approach in treating telomerase-positive tumors. Because hTERT expression varies in different telomerase-positive cells^[72-74], it is anticipated that telomerase-directed tumor gene therapy would work better in cancer cells with high levels of hTERT expression.

Summary

Because of the unique property of telomere and telomerase in cancer and the aging process, they have been the targets for new drug developments toward anticancer or regenerative disease therapeutics. In addition to various approaches that have been described here, other approaches based on the property of telomerase have also been reported. For example, hTERT has been reported as a tumor-associated antigen in a wide range of tumors. These hTERT-derived tumor antigens could be recognized by cytotoxic T lymphocytes that could then be applied in designing anticancer immunotherapeutic strategies^[79,80]. It is anticipated that other novel approaches based on telomere functions will be developed.

Abstract

Aim: To explore the underlying mechanism of tau hyperphosphorylation in an Alzheimer's-affected brain and the possible arresting strategies. **Methods:** MTT (3-[4,5-dimethylthiazol-2-yl]-2,5-diphenyl-tetrazolium bromide), crystal violet assay, phase-contrast, dead end colorimetric apoptosis detection system (TUNEL) and electron microscopy were used to detect cell viability, morphology and apoptosis. Western blot, ³²P-labeling and the detection of malondialdehyde level and superoxide dismutase activity were used respectively for the phosphorylation level of tau, the activity of glycogen synthase kinase (GSK-3), and oxidative stress measurement. **Results:** Exposure of the cells to wortmannin resulted in an obvious lipid peroxidation, reduction of cell viability, cell process retraction, and plasma vacuolation, but with no obvious cell apoptosis. We also found that preincubation of the cells with melatonin or vitamin E attenuated differentially wortmannin-induced oxidative stress as well as GSK-3 overactivation and tau hyperphosphorylation. **Conclusion:** Wortmannin is an effective tool for reproducing Alzheimer-like tau hyperphosphorylation cell model and melatonin/vitamin E can effectively protect the cells from wortmannin-induced impairments.

Introduction

Alzheimer disease (AD) is neuropathologically characterized by cell loss and formation of amyloid plaques and neurofibrillary tangles (NFTs), which are composed of paired helical filaments formed by abnormally hyperphosphorylated microtubule associated protein tau^[1]. Studies have shown that tau regulates microtubule dynamics, axonal transport, and neuronal morphology by binding and stabilizing the microtubule structure^[2,3]. In AD, abnormally phosphorylated tau associated with paired helical filaments decreases affinity in binding to the microtubules and balks its normal microtubule-related function^[4]. Therefore, understanding the regulatory mechanism for tau hyperphosphorylation and aggregation is critical in designing the strategies to arrest it.

A defect in the regulation of protein kinases/protein phosphatases is responsible for tau hyperphosphorylation. Among them, glycogen synthase kinase-3 (GSK-3) is a recognized tau kinase that plays a crucial role in AD pathology^[5]. GSK-3 phosphorylates tau both *in vivo* and in intact cells,

and enhanced expression of GSK-3 leads to tau hyperphosphorylation^[6,7]. In an Alzheimer's-affected brain, GSK-3 is activated in pretangle neurons and accumulates in paired helical filaments^[8]. We also found that the activation of GSK-3 by brain injection of wortmannin led to hyperphosphorylation of tau and spatial memory impairment in a rat brain^[9]. These data together indicate that GSK-3 can serve as a crucial target for reproducing an AD-like experimental model and for screening potential therapeutic reagents. However, it is not known whether wortmannin also induces tau hyperphosphorylation in neuroblastoma N2a cells, and whether wortmannin treatment affects cell viability, what kind of cell death wortmannin might induce, and if melatonin, as an effective antioxidant secreted from pineal gland^[10], which has been used in our previous studies^[11–13], influences wortmannin-induced alterations in N2a cell and by which mechanism melatonin works.

Therefore, in the present study, we examined the effect of wortmannin, an indirect GSK-3 activator, on cell viability and tau phosphorylation, and the effect and mechanism of

melatonin on wortmannin-induced cytotoxicities in N2a cells. We found that the treatment of cells with 1 $\mu\text{mol/L}$ wortmannin induced GSK-3 activation and tau hyperphosphorylation. Although reduced cell viability and increased cell retraction were observed, no obvious cell apoptosis was detected. Melatonin not only attenuated wortmannin-induced lipid peroxidation but also counteracted wortmannin-induced GSK-3 overactivation and tau hyperphosphorylation.

Materials and methods

Measurement of cell viability and metabolism N2a cell, a gift from Dr HX XU (The Burnham Institute, San Diego, USA), was propagated in Dulbecco's modified Eagle's medium with 5% fetal bovine serum (5% CO_2 and 95% air) (GIBCO, NY, USA). The cells were then grown and differentiated in 96-well culture plates at density of 1.5×10^5 cells in 100 μL . Cells were exposed to various concentrations of wortmannin for 2 h at 37 $^\circ\text{C}$ in the presence or absence of a 12-h-preincubation with melatonin 25, 50, and 100 $\mu\text{mol/L}$ or Vitamin E (VE). Dimethylsulfoxide (Me_2SO , 0.01%), in which wortmannin, melatonin and VE were dissolved, served as a vehicle control. Then, 0.2% crystal violet or 1% MTT (3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl-tetrazolium bromide) in phosphate-buffered saline (PBS) were added and incubated for 3 min or 4 h at dark and read at 570 nm (TECAN Austria, Salzburg, Austria). All assays were performed with five repeats. Wortmannin, Me_2SO and melatonin were purchased from Sigma (St Louis, MO, USA).

Morphology features of N2a cells with phase-contrast and electron microscopy Morphology changes of N2a cells treated by wortmannin with or without preincubation of melatonin or VE were examined under phase-contrast microscope. For electron microscopy, cultures were fixed in 2.5% glutaraldehyde/0.2% tannic acid in 0.1 mol/L cacodylate buffer (pH 7.4) overnight at 4 $^\circ\text{C}$ and then post-fixed in 1% osmium tetroxide/1.5% ferrocyanide solution for 30 min at room temperature. Cells were dehydrated in ethanol, embedded in Epon resin, and heat polymerized. Epon blocks were cut, double stained with uranyl acetate and lead citrate, and observed under an Opton EN/10C electron microscope (Opton, Oberkochen, Germany).

TUNEL assay and cleavage of caspases-3 To determine the form of cell death in wortmannin-treated cells and relationship of tau phosphorylation and apoptosis, we used the Dead End TM Colorimetric Apoptosis detection system (TUNEL) (Promega Corp, Madison, USA) and immunofluorescence of cleaved caspase-3 to measure DNA fragmentation and caspase-3 activation. Positive control of apoptosis

was treated with 1 $\mu\text{mol/L}$ staurosporine, an apoptosis inducer for 3 h. For TUNEL, cells were fixed in 4% paraformaldehyde solution for 25 min at room temperature, rinsed in phosphate buffered saline (PBS), and permeabilized by immersing the slides in 0.2% Triton X-100 solution. Cells were incubated with terminal deoxynucleotidyl transferase (TdT) reaction mixture containing biotinylated nucleotides and TdT at 37 $^\circ\text{C}$ for 60 min, rinsed with SSC (Sodium Chloride-Sodium Citrate Buffer) and PBS. Streptavidin HRP (Horseradish Peroxidase) was added to cells. Slides were then stained with diaminobenzidine system (DAB).

For caspases-3 immunofluorescence assay, cells were fixed for 15 min with 4% paraformaldehyde in 0.1 mol/L phosphate buffer and immunostained by sequential reaction with a rabbit polyclonal antibody caspase-3 (1:200) (Cell Signaling Technology Inc, Beverly, MA, USA), followed by FITC (Fluorescein isothiocyanate)-conjugated goat anti-rabbit IgG (Dianova GmbH, Hamburg, Germany). Sections were analyzed with a 525-nm filter (FITC staining) with a fluorescence microscope (Olympus, Hamburg, Germany).

Western blot Total cell lysates of N2a from each treatment were separated on 10% SDS-PAGE (PolyAcrylamide Gel Electrophoresis) and the protein were transferred onto the nitrocellulose membranes. Membranes were blocked in Tris-buffered saline containing 5% non-fat milk followed by incubation with primary antibody at 4 $^\circ\text{C}$ for 24 h. Primary mouse monoclonal antibodies including Tau-1 and PHF-1 and rabbit polyclonal antibodies 92e which recognized phosphorylated tau and non-phosphorylated tau were gifts from Dr BINDLE (North Western University, Chicago, Illinois), Dr DAVIES (Albert Einstein College of Medicine, Bronx, NY), and Drs Iqbal and Grundke-Iqbal (NYS Institute for Basic Research, Staten Island, NY, USA). GSK3 β and phospho-GSK3 β (serine9) were obtained from Cell Signaling Technology Inc (Beverly, MA, USA). The blots were developed by enhanced chemiluminescence (Santa Cruz Biotechnology Inc, Santa Cruz, CA, USA) and computer image analysis software (Image-Pro Plus, Media Cybernetics, Silver Spring, MD) was used for quantitative analysis of the blots.

Kinase assay Activity of GSK-3 was measured using phospho-GS (Upstate Biotechnology, Lake Placid, NY, USA) as substrate. Cells were treated with factors as described earlier and lysed at 4 $^\circ\text{C}$ in a solution containing (in mmol/L) Tris-HCl 10 (pH 7.4), edetic acid 10, NaCl 0.15, NaF 50, Na_3VO_4 0.2, 1% NP40, phenylmethylsulfonyl fluoride 1, and 2 $\mu\text{g}/\mu\text{L}$ aprotinin. Cell lysates were clarified by centrifugation at 15 000 $\times g$ at 4 $^\circ\text{C}$ for 10 min. The samples were incubated with the substrates in buffer containing 30 mmol/L Tris-HCl (pH 7.4), 10 mmol/L MgCl_2 , 10 mmol/L NaF,

1 mmol/L Na₃VO₄, 2 mmol/L Na₄EGTA, 10 mmol/L β-mercaptoethanol, 0.2 mmol/L (1500 cpm/pmol) [γ -³²P] ATP (Beijing Yahui Biologic and Medicinal Engineering Co, Beijing, China) at 30 °C for 30 min. Reaction was stopped by adding 12.5 μL *o*-phosphoric acid (300 mmol/L). A total of 20 μL of incubation mixture was applied in duplicates to phosphor cellulose units. The filters were washed 3 times with 75 mmol/L *o*-phosphoric acid and then dried. The radioactivity incorporated into the substrates was analyzed by liquid scintillation counting at 30 °C. The protein concentration of the cell lysates was estimated by bicinchoninic acid (BCA) method (Micro BCA Protein Assay Reagent Kit, Pierce Biotechnology, Rockford, IL, USA). GSK-3 activity was expressed as nmol·min⁻¹·g⁻¹ protein at 30 °C.

Assay of malondialdehyde (MDA) and superoxide dismutase (SOD) The amount of MDA was measured by the thiobarbituric acid (TBA) assay, which is based on the reaction of MDA with TBA to produce a red species with excitation at 515 nm and emission at 553 nm measured in Shimadzu-RF-5000 (Kyoto, Japan)^[14]. The activity of SOD was measured according to the method established previously^[15].

Data analysis Data were expressed as mean±SD and analyzed using SPSS 10.0 statistical software (SPSS Inc, Chicago, Illinois, USA). The one-way ANOVA procedure followed by Student's *t*-test was used to determine the differences among groups.

Results

Effect of wortmannin, melatonin, and VE on cell viability and morphology Wortmannin induced decreased cell viability in a concentration-dependent manner from 0.1 μmol/L to 10 μmol/L in 2 h (Figure 1A). Therefore, 1 μmol/L wortmannin, represented 20%–30% inhibition of MTT and crystal violet, was used for all subsequent experiments. Exposure of the cells to 50 μmol/L melatonin (Figure 1B) or 50 μmol/L VE (Figure 1C) before administration of wortmannin resulted in protective effects. However, the premixing of melatonin or VE with wortmannin did not show protection in cell viability (data not shown).

By phase-contrast microscopy, we observed that in the control group the border of the cells was clear with plenty of processes, and treatment of the cells with 1 μmol/L wortmannin induced retraction of cell processes, with some cells detaching from the plate. Preincubation of the cells with 50 μmol/L melatonin or 50 μmol/L VE protected against the morphology changes induced by wortmannin, although the cell body was still larger than normal cells (Figure 2). With electron

Figure 1. Effect of wortmannin, melatonin and VE on cell viability and metabolism measured by MTT and crystal violet staining. A dose-dependent decrease of cell viability and metabolism was observed when the cells were exposed to 0.1 μmol/L or 10 μmol/L wortmannin for 2 h (A). These cytotoxicities were inhibited by pretreatment of the cells with melatonin (B) or VE (C) for 12 h. *n*=5. Mean±SD. ^b*P*<0.05, ^c*P*<0.01 vs control.

microscopy, we found that treatment of cells with wortmannin induced organelle vacuolation and mitochondrial swelling (markers of degeneration), but no cellular shrinkage and chromatin condensation (markers of apoptosis) was observed. Pretreatment with melatonin or VE partly protected cells from the degeneration induced by wortmannin (Figure 3).

Effect of wortmannin on cell apoptosis Very few positive cells were detected in the 1 μmol/L wortmannin-treated samples. However, numerous apoptotic cells were seen in positive control of 1 μmol/L staurosporine-treated cells (Figure 4).

Effect of wortmannin, melatonin, and VE on tau phosphorylation, and the activity of GSK-3β Tau was hyperphosphorylated at both tau-1 (recognized non-phosphorylated tau at Ser-199/202) and PHF-1 (recognized phos-

Figure 2. Effect of wortmannin, melatonin and VE on cell morphology measured by phase-contrast microscopy. Most of the normal cells showed bipolar and long-cylindrical processes (A). Cells exposed to 1 $\mu\text{mol/L}$ wortmannin for 2 h revealed loss of neurites with nuclear pyknosis, some of them detached from the plate (B). Cells were partially rescued from wortmannin exposure by pretreatment with 50 $\mu\text{mol/L}$ melatonin (C) or 50 $\mu\text{mol/L}$ VE (D) for 12 h. (Scale Bar 15 μm).

Figure 3. Effect of wortmannin, melatonin and VE on the ultrastructure of the cells. Compared with control (A), treatment of the cells with 1 $\mu\text{mol/L}$ wortmannin for 2 h (B) induced organelle vacuolation (arrow) and mitochondrial swelling (arrow head), but pretreatment of the cells with 50 $\mu\text{mol/L}$ melatonin (C) or 50 $\mu\text{mol/L}$ VE (D) for 12 h partly protected cells from wortmannin-induced alterations (Scale Bar 1 μm).

phorylated tau at Ser-396/404) epitopes by treatment with wortmannin for 2 h. The hyperphosphorylation of tau was blocked by preincubation of the cells with melatonin and VE. Melatonin showed a more efficient protective effect than VE (Figure 5). We also found that wortmannin increased activity of GSK-3, pretreatment with melatonin almost completely reversed wortmannin-induced activation of GSK-3, and preincubation of VE partially restored the activity of GSK-3 (Figure 6).

As GSK-3 β activity is regulated by the phosphorylation and dephosphorylation on its serine-9 (Ser-9)^[16], we further detected the expression of total and phosphorylated GSK-3 β . We found that wortmannin treatment did not change the expression of the total GSK-3 β , but markedly decreased the expression of phosphorylated-GSK-3 at Ser-9. We also demonstrated that preincubation of melatonin or VE obviously arrested wortmannin-induced decrease of phosphorylated GSK-3 β at Ser-9 (Figure 7A, 7B).

Effect of wortmannin, melatonin, and VE on lipid peroxidation The level of MDA was significantly higher, but the activity of SOD was significantly lower in wortmannin-treated cells than the vehicle control samples. After preincubation of 50 $\mu\text{mol/L}$ melatonin or VE, the MDA level and SOD activity was partially restored, and the protective effect of melatonin was stronger than that of VE at the same concentration (Table 1).

Figure 4. Effect of wortmannin on cell apoptosis. Apoptosis was not detected by TUNEL (A) nor by activated caspases-3 staining (C) in wortmannin-treated cells, but it did show in the positive control cells treated with 1 μmol/L of staurosporine (B and D) (Scale Bars 15 μm).

Figure 5. Effect of wortmannin, melatonin, and VE on tau phosphorylation. Representative Western blots (A) and quantitative analysis (B) of tau phosphorylation at Tau-1 and PHF-1 sites, which was normalized by the total tau (probed by 92e). *n*=5. Mean±SD. ^b*P*<0.05, ^c*P*<0.01 vs control. ^e*P*<0.05, ^f*P*<0.01 vs wortmannin-treated cells.

Discussion

Abnormal hyperphosphorylation of tau is a recognized pathological process, which might be responsible for the disruption of microtubules and thus neurodegeneration seen in the brain of patients with Alzheimer’s disease (AD). Many

Figure 7. Effect of wortmannin, melatonin and VE on the expression of GSK-3 β protein. Western Blots (A) and quantitative analysis (B) of Ser-9-phosphorylated GSK-3 β and the total level of GSK-3 β , or ratio of Ser-9-phosphorylated GSK-3 β to total GSK-3 β in cells treated as indicated. $n=5$. Mean \pm SD. ^c $P<0.01$ vs control. ^e $P<0.05$, ^f $P<0.01$ vs wortmannin-treatment.

protein kinases are reported to phosphorylate tau at some of the AD sites and can lead to the dysfunction of tau in maintaining stability of cytoskeleton. Among them, GSK-3, a major tau kinase, is a leading candidate for initiating pathologic tau hyperphosphorylation^[5,7]. GSK-3 forms a complex with tau in the microtubule fraction from the bovine brain and it is co-localized with phosphorylated tau during development^[17]. Hyperphosphorylation of tau by GSK-3 accelerates neurodegeneration and induces fibrillary tau inclusions both *in vivo* and *in vitro*^[18]. As direct GSK-3 activator is not commercially available at the moment, wortmannin, an inhibitor of phosphatidylinositol 3-kinase (PI3K), has been widely used in activating GSK-3 indirectly through protein kinase B (PKB)-mediated signal transduction pathway; that is, wortmannin turns down PKB through inhibiting PI3K and thus activates GSK-3 by decreasing the phosphorylation level of GSK-3 at its serine residues^[6,18,19]. We previously reported that wortmannin could induce Alzheimer's-like hyperphosphorylation of cytoskeleton proteins in a rat brain^[9,20]. To further explore the mechanism of how wortmannin influences tau phosphorylation, and thus to establish an AD-like cell model, we used wortmannin to treat N2a, a neuroblastoma cell line widely used in the AD field^[21-23], in the present study. We have found that wortmannin activates GSK-3 and leads to tau hyperphosphorylation in N2a cell line, demonstrating that wortmannin can be used for reproducing a cell model with AD-like tau hyperphosphorylation. We have also observed that wortmannin treatment induces

oxidative stress as displayed by the increase of MDA level and the decrease of SOD activity. This suggests the crucial role of oxidative stress in wortmannin-induced tau hyperphosphorylation.

Although the treatment of the cells with wortmannin led to significantly decreased cell viability, we did not see a typical cell apoptosis in the present study. The cells show evident hyperphosphorylation of tau, which is considered to be one of the earliest signs of neuronal degeneration and appears to precede tau aggregation or amyloid formation^[24]. Tau abnormality provides the basis for the unequivocal diagnosis. However, its role in AD pathogenesis, especially in cell loss, is still not understood. The results observed in this study are consistent with the observations of SY5Y cells that tau phosphorylation can be an anti-apoptosis^[25]. In another project, we also found that treatment of cells with calyculin A (a protein phosphatase inhibitor) led to neurofilament hyperphosphorylation and aggregation with minimal apoptosis^[12]. Neurons in AD were not co-labeled with AT8 (an antibody that probes phosphorylated tau) and an antibody to activate caspase-3^[26]. Similarly, activated JNK, p38, and ERK1/2 (phosphorylated forms of these proteins) co-localized with hyperphosphorylated tau in an AD brain, but not with markers of apoptosis^[27,28], indicates that increased tau phosphorylation seems to resist apoptotic stimuli. Therefore, although many *in vivo* and *in vitro* data support the involvement of apoptosis in neurodegenerative processes, there is considerable evidence suggesting that very complex events can contribute to neuronal death with possible repair mechanisms^[29], elucidation of which could prove useful for future investigation of the mechanisms of cell death in these disorders and their relations to cytoskeletal abnormalities, as well as prevention and therapy of neurodegenerative disorders.

AD is the most common cause of dementia and there is no specific and effective cure for this disorder to date. Recently, increasing data suggests that melatonin might play an important role in the development of AD and serve as a candidate for arresting AD-like pathological processes^[30,31]. Patients with AD have a more profound reduction of melatonin in the brain and in cerebrospinal fluid^[31,32]. The efficacy of melatonin in inhibiting oxidative damage has been tested in a variety of neurodegenerative disease models, including Huntington's disease, Parkinson's disease and AD, induced with quinolinic acid, MPTP, β -amyloid, and OA (okadaic acid) respectively in rat brain or in cultured cells^[33-36]. In the present study, we have found that melatonin rescues cell viability and reverses tau hyperphosphorylation induced by wortmannin in N2a neuroblastoma cells. At the same time,

melatonin decreases the level of lipid peroxide and increases the activity of antioxidant enzymes. This is consistent with previous findings that melatonin prevents oxidative damage to the cell membrane, organelles, nuclear and mitochondrial DNA by donating electrons^[37]. From this data, we speculate that melatonin might prevent wortmannin-induced tau hyperphosphorylation through its antioxidant effects. We have also found that melatonin obviously inhibits wortmannin-induced activation of GSK-3, suggesting that melatonin might act not only against free radicals, but also indirectly as an enzyme modulator^[31] in rescuing wortmannin-induced tau hyperphosphorylation; further study is needed to explore the mechanism. We also observed that melatonin acted more efficiently than vitamin E not only as an antioxidant but also in restoring GSK-3 activity and tau hyperphosphorylation. Melatonin is a small amino acid hormone secreted mainly in the pineal gland. Specific characters of melatonin, such as its solubility in both lipids and water that allow it to be easily penetrated into the cells and pass through the blood brain barrier, can make it totally different from other antioxidant. In addition to its role in rescuing AD-like tau abnormalities, melatonin is also reported to protect β -amyloid peptide-induced cell injuries^[38,39]. Therefore, melatonin might become a promising candidate thwarting the two hallmark abnormalities in AD patients.

Melatonin could function through its membranous and nuclear receptors in peripheral tissues; melatonin receptors are widely expressed in different organs, such as the brain hippocampus, retina, lung, liver, and kidney^[40]. Melatonin could also function through non-receptor mediated pathways^[41]. In N2a cells, whether melatonin functions through the receptor-dependent pathway or receptor-independent pathway, needs further study.

Taken together, we have found in the present study that wortmannin induces overactivation of GSK-3 and tau hyperphosphorylation with a concurrent lipid peroxidation and reduction of cell viability in the N2a cell line. Melatonin rescues not only wortmannin-induced oxidative stress, but also GSK-3 overactivation and tau hyperphosphorylation.

Abstract

Aim: To comparatively study the pharmacological profiles of 3-methyl-3-azabicyclo(3,3,1)nonanyl-9- α -yl- α -cyclopentyl- α -phenyl- α -glycolate (phencynonate hydrochloride, CPG), an anticholinergic agent, and its enantiomers [*R*(–)- and *S*(+)-CPG]. **Methods:** The affinity and relative efficacy were tested using radioligand-binding assay with muscarinic acetylcholine receptors from rat cerebral cortex. The pharmacological activities were assessed in three individual experiments: (1) potentiating the effect of subthreshold hypnotic dose of sodium pentobarbital; (2) inhibiting oxotremorine-induced salivation; and (3) inhibiting the contractile response to carbachol. **Results:** The order of potency of phencynonate hydrochloride and its optical isomers to inhibit the binding of [³H]quinuclidinyl benzilate ([³H]QNB) was *R*(–)-CPG ($K_i=46.49\pm 1.27$ nmol/L) > CPG ($K_i=271.37\pm 72.30$ nmol/L) > *S*(+)-CPG ($K_i=1263.12\pm 131.64$ nmol/L). The results showed that *R*(–)-CPG had the highest affinity to central muscarinic receptors among the three compounds, but did not show any central depressant effects at dose from 10.00 to 29.15 mg/kg. CPG increased the effects of subthreshold hypnotic dose of sodium pentobarbital induced-sleeping [the $ED_{50}\pm 95\%$ LC value was 21.06 ± 3.04 mg/kg]. CPG and *R*(–)-CPG displayed nearly equipotent effect in depressing oxotremorine-induced salivation [the $ED_{50}\pm 95\%$ LC for *R*(–) and CPG were 1.10 ± 0.28 and 1.07 ± 0.15 mg/kg, respectively], and the contractile response to carbachol (pA_2 values for *R*(–) and CPG were 6.84 and 6.80, respectively). *S*(+)-CPG presented the lowest anticholinergic profiles, but could potentiate effects of its enantiomers in some manner. **Conclusions:** These data suggested that *R*(–)-CPG acted as an eutomer in racemate and a competitive antagonist to acetylcholine muscarinic receptors, but *S*(+)-CPG was less active in comparison to *R*(–)-CPG and its racemate. The central depressant effects of *R*(–)-CPG and *S*(+)-CPG were lower in comparison to its racemate.

Introduction

Molecular handedness is a crucial structural feature of biologically active compounds, since opposite configurations at pharmacophoric groups frequently influence the biological response, mainly in terms of affinity, toxicity, and receptor subtype selectivity^[1]. Therefore, the stereoisomeric composition of drugs is currently receiving considerable attention owing to its pharmacological as well as industrial and regulatory implications^[2,3].

3-Methyl-3-azabicyclo(3,3,1)nonanyl-9- α -yl- α -cyclopentyl- α -phenyl- α -glycolate (phencynonate hydrochloride, CPG) is a central anticholinergic agent synthesized at the Beijing Institute of Pharmacology and Toxicology. It has been developed as a new medicine for motion sickness. Our previous studies revealed that CPG prevented motion sickness with higher efficacy and lower central inhibitory side effects compared to other motion sickness drugs, such as dimenhydrinate and scopolamine HBr^[4]. There is one chiral carbonic atom in the molecular structure of CPG (Figure 1).

Figure 1. Chemical structure of CPG and its optical isomers.

Thus, there were two optical isomers of CPG with *R*(-) and *S*(+)-different configurations. The pharmacological effects of these isomers remained unknown. In order to study the pharmacological differences between the stereoisomers and develop more safe drugs, we investigated the pharmacological characteristics of these two chiral muscarinic antagonists by comparing their effects on muscarinic receptors *in vivo* and *in vitro*.

Materials and methods

Chemicals [^3H]QNB [^3H -quinuclidiny benzilate] (43.3 Ci/mmol) was purchased from Amersham Co (Uppsala, Sweden) (TRK604). CPG and its isomers were synthesized at our institute. CPG comprised nearly the same proportion for *R*(-) and *S*(+)-CPG. Atropine, pentobarbital sodium, oxotremorine, and carbachol were from Sigma Co (St Louis, USA).

Animals The experiments were carried out in accordance with the Guide for the Care and Use of Laboratory Animals,

National Research Council, 1996. Animals used in the study were: male or female Wistar rats weighing 180–220 g, [Grade II, Certificate No scxk (Jing) 2002-0003] and male guinea pigs (200–300 g, Grade II, Certificate No (Jing) 2003-0005), which were purchased from Lianhelihua Co (Beijing, China); Kunming species mice [18–22 g, Grade II, Certificate No SCXK-(Army) 2002-001] were provided from the animal center at our institute.

Binding assays on rat cerebral cortex homogenate Male or female Wistar rats were killed by decapitation. The cerebral cortex was immediately removed and processed as described by Yamamura and Snyder^[5]. Protein concentration was determined by the method of Lowry *et al*^[6]. Homogenate (50 mg of protein) was incubated for at 37 °C for 30 min in 0.5 mL of assay buffer containing 6 nmol/L [^3H]QNB and various concentrations of drugs. In saturation binding assays, the homogenate was incubated in the presence of [^3H]QNB (0.25–20 nmol/L). Non-specific binding was defined as binding in presence of atropine (1 $\mu\text{mol/L}$). Each sample was filtered through GF/C glass fibers with a vacuum. The filters were rinsed three times with 3 mL cold buffer, and placed in scintillation vials containing 3 mL of scintillation fluid. Radioactivity trapped on the filters was determined by liquid scintillation spectrometry at approximately 40%–50% efficiency.

Carbachol-induced contraction Male guinea pigs were killed by cervical dislocation. The organs required were set up rapidly under 1 g of tension in 20 mL organ baths containing physiological salt solution (PSS), which was kept at 37 °C and aerated with 5% CO_2 and 95% O_2 . Two-centimeter-long portions of terminal ileum were taken at about 5 cm from the ileum-cecum junction and mounted in PSS at 37 °C. The composition of PSS was as the following (mmol/L): NaCl (118), NaHCO_3 (23.8), KCl (4.7), $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$ (1.18), KH_2PO_4 (1.18), CaCl_2 (2.52), and glucose (11.7). Tension changes were recorded isototically. Tissues were equilibrated for 90 min before the experiments began.

The concentration was increased in a stepwise manner after the response to the previous concentration had reached a plateau to make concentration-response curve for carbachol. After cumulative concentration-response curves were generated in the absence of any antagonist, the ileum strips were washed several times with PSS and allowed to relax to baseline. After 60 min, the strips were incubated with *R*(-), *S*(+), or CPG for 10–15 min. The concentration-response curves for carbachol were then obtained in the presence of increasing concentrations of different antagonists.

To assess the potency of the antimuscarinic action, the ratio of the ED_{50} values for the carbachol-induced contrac-

tions in the presence and in the absence of antagonist were obtained. Schild plots were obtained by plotting logarithmic (dose ratio-1) against the logarithmic molar concentration of the antagonist, and pA_2 values were derived from the Schild plots according to the method described by Arunlakshana and Schild^[7].

Effect on sub-threshold hypnotic dose of sodium pentobarbital induced-sleeping Four dosage groups were used for each drug and each group consists of 10 mice of each sex. CPG and its optical isomers were injected intra-peritoneally (ip). Fifteen minutes later, subthreshold hypnotic dose of sodium pentobarbital (30 mg/kg) was applied ip and lossing in the righting reflex was observed as the score to present the central inhibitory effect of the drugs. The ED_{50} values of these three drugs were estimated to compare the central inhibitory effect of the indicated agents.

Inhibiting oxotremorine-induced salivation Four dosage groups were used for each compound and each group consisted of 10 mice of each sex. CPG and its optical isomers were applied ip 15 min prior to the use of oxotremorine (3 mg/kg) subcutaneously (sc). ED_{50} values were utilized to evaluate the anti-secretive potencies of above described compounds.

Statistics

Binding assay The IC_{50} values were obtained from at least three separate experiments performed in triplicate with between 6 and 8 different concentrations of drugs. Hill coefficients and IC_{50} values were determined using the ORIGIN6.0 software program and inhibition constants (K_i values) were calculated utilizing the Cheng-Prusoff equation^[8].

Functional assay In carbachol induced-contraction, the E_{max} value (the maximum contractile response) was obtained from the maximum stress developed, and the ED_{50} value was calculated from a semi-logarithmic plot of the percentage of the maximum response versus drug concentration. Statistical analyses for comparison between groups and between concentration-response curves were performed using analysis of variance (ANOVA). $P < 0.05$ was considered statistically significant. In the experiments for observing the effects of CPG and its optical isomers on salivation and sedation induced by oxotremorine and sodium pentobarbital, ED_{50} values were calculated utilizing the Bliss method. Data were shown as mean \pm SD.

Results

Competitive binding of CPG and its optical isomers to rat central muscarinic acetylcholine receptors The K_d

values for [³H]QNB binding to receptors were 6.66 ± 0.95 nmol/L. The B_{max} values were 0.758 ± 0.086 fmol/mg. The competition binding potency of *R*(-)-CPG for [³H]QNB corresponded to a K_i value of 46.49 ± 1.27 nmol/L ($n=4$). An average Hill coefficient (n_H) was 1.54 ± 0.06 . The affinity of *R*(-)-CPG at central muscarinic acetylcholine receptors was greater than that of CPG ($K_i=271.37 \pm 72.3$ nmol/L, $n_H=1.48$). *S*(+)-CPG displayed the lowest affinity to muscarinic receptor ($K_i=1263.12 \pm 131.64$ nmol/L, $n_H=1.12$). The results showed that the isomer with *R*(-)-configuration was more potent than the isomer with *S*(+)-configuration and CPG (Figure 2).

Figure 2. Effects of CPG and its optical isomers on the binding of [³H]QNB to rat central muscarinic acetylcholine receptors. Rat cerebral cortex homogenate was incubated with 6 nmol/L [³H]QNB at 37 °C for 30 min in the absence and presence of increasing concentrations of different drugs. Data were the means from four independent experiments performed in duplicate.

Effect of CPG and its optical isomers on carbachol-induced contraction Carbachol (1×10^{-8} – 1×10^{-2} mol/L) caused concentration-dependent contraction of guinea pig ileum. The E_{max} values for the carbachol-induced contractions were 2.9 ± 0.2 g ($n=30$). CPG and *R*(-)-configuration (1×10^{-8} – 1×10^{-7} mol/L) caused typical rightward shifts in the concentration-response curves for carbachol, except for a higher concentration (1×10^{-6} mol/L) of *R*(-)- and CPG, which caused decreases of about 80% of the maximum contractile responses to carbachol. However, *S*(+)-CPG only caused decreases of about 10%–20% of the maximum contractile effects induced by carbachol at the dose of 1×10^{-6} mol/L, the difference was not significant ($P > 0.05$). All slopes of the regression lines of Schild plots were close to unity in Figure 3. The IC_{50} value of *R*(-)- and CPG are shown in Figure 4. The rank order of pA_2 values was: CPG (6.80)≈*R*(-)-CPG (6.84) (Table 1).

Potentiating the effect of sub-threshold hypnotic dose of sodium pentobarbital Pentobarbital (ip 30 mg/kg) alone did not cause loss in righting reflex in mice ($n=50$). Pretreatment

Figure 3. Effects of CPG and *R*(-)-CPG (1×10^{-8} , 1×10^{-7} , and 1×10^{-6} mol/L) on the concentration-response curves for carbachol in guinea ileum. For each experiment, contractile responses were expressed as percentages of the maximum contractile response in the absence of any antagonist. Each point represented the mean \pm SD of the results from six separate experiments.

Figure 4. Concentration-response curves for *R*(-)-CPG and CPG (1×10^{-9} – 1×10^{-5} mol/L) on the maximum contractile response induced by carbachol (1×10^{-4} mol/L) in guinea pig ileum. For each experiment, contractile responses were expressed as percentages of the maximum contractile response in the absence of any antagonist. Each point represented the mean \pm SD of the results from six separate experiments; if not shown, SD bars fall within the size of the symbol.

with CPG (14.28–41.64 mg/kg) at 15 min intervals potentiated

the effect of sub-threshold hypnotic dose of sodium pentobarbital in a dose-dependent manner (Table 2). The ED_{50} value and its 95% confident limits of CPG was 21.06 (18.02–24.10) mg/kg. The isomer with *R*(-)- and *S*(+)-configuration did not show any effects on pentobarbital induced-sleeping at the dose from 10.00–29.15 mg/kg. The result suggested that the central depressant effect of CPG was more potent than the other two isomers used separately.

Table 2. The effect of CPG and its optical isomers on sub-threshold hypnotic dose of sodium pentobarbital induced-sleeping. For each experiment, the rate of loss in righting reflex was expressed in the ratio of mice lost in righting reflex to 10 mice.

Oxotremorine (sc 3mg/kg) induced an obvious salivation in mice ($n=50$). Whereas, CPG and its optical isomers showed antagonistic effects on oxotremorine-induced salivation in dose-dependent manner when pre-administered. The $ED_{50} \pm 95\% LC$ for CPG, *R*(-)-, and *S*(+)-configuration were 1.07 ± 0.15 , 1.10 ± 0.28 , and 16.69 ± 4.82 mg/kg, respectively, which indicated that CPG was equivalent to *R*(-)-CPG and more potent than *S*(+)-CPG in inhibiting glandular secretion (Table 3).

Table 3. Effect of CPG and its optical isomers on oxotremorine-induced salivation. (For each experiment, the rate of anti-salivation was expressed as the ratio of mice lost in righting reflex to 10 mice).

Discussion

Motion sickness is a common disease in modern society. The pathogenic mechanism inducing the sickness is not fully understood. However, the etiologic theory that cholinergic hyperfunction of the vestibular system excites the vomiting center and the central cholinergic neuron system plays an important role in the neural mechanism of motion sickness is generally accepted^[9,10]. The anticholinergic agents, such as scopolamine, when used for preventing motion sickness, present some disadvantages at the effective dose, especially the troublesome central inhibitory effect^[11].

The new central anticholinergic drug CPG has been widely used in clinic. Animal experiments and clinic research have demonstrated that CPG was more potent and had lesser central inhibitory side effects in the prevention of motion sickness (airsickness and seasickness) than those of central cholinergic drugs, such as scopolamine HCl and dimenhydrinate^[12]. There was the same proportion of two enantiomers in the race mixture of CPG. In order to illuminate the pharmacological profiles of its optical isomers, we compared the affinity of CPG and its optical isomers to muscarinic acetylcholine receptors. In the competitive binding assay, it was found that R(-)-CPG inhibited the binding of [³H]QNB with the highest potency ($K_i=46.49\pm 1.27$ nmol/L) compared with CPG ($K_i=271.37\pm 72.3$ nmol/L) and S(+)-CPG ($K_i=1263.12\pm 131.64$ nmol/L). In the functional study, CPG and R(-)-CPG (1×10^{-8} – 1×10^{-6} mol/L) caused parallel rightward shifts of the concentration-response curves for carbachol-induced ileum contraction. All the slopes of the regression

lines of Schild plots were close to unity, which implied a competitive antagonism. S(+)-configuration slightly decreased the maximum contractile response at the dose of 1×10^{-6} mol/L. The order of potencies of these agents to inhibit the contractile responses was R(-)-CPG≈CPG>S(+)-CPG. The same result was obtained in inhibiting glandular secretion. These results revealed that R(-)-CPG acted as an active composition of racemate with competitive antagonistic mechanism to muscarinic acetylcholine receptors, but S(+)-CPG less bioactivity. It also had been to be noted that there was 50% of S(+)-CPG with lower binding affinity in racemate CPG; according to binding assay, CPG should less potent in suppressing smooth muscle contraction and glandular secretion. These results suggest that S(+)-configuration may increase the potencies of its enantiomer in some manner. Furthermore, at the same dose, S(+)- and R(-)-configuration did not display any synergistic effect on sub-threshold hypnotic dose of sodium pentobarbital, but their racemate, CPG, revealed remarkable central sedation effects. One possible explanation for these results was that S(+)-configuration might play a role in modulating the binding of R(-)-configuration by allosteric mechanism. In contrast, muscarinic acetylcholine receptors (mAChRs) modulate the activity of an extraordinarily large number of physiological functions. Individual members of the mAChR family (M₁–M₅) are expressed in a complex, overlapping fashion in most tissues and cell types. The M₁ and M₃ subtypes are the major muscarinic acetylcholine receptors in the salivary gland and M₃ is reported to be more abundant^[13,14]. Guinea pig ileum smooth muscle is enriched with muscarinic receptors, the majority of which are of the M₂ subtype whereas the remaining minority belongs to the M₃ subtype^[15,16]. The M₁, M₂, and M₄ subtypes of mAChRs are the predominant receptors in the CNS^[17]. Our experiments were performed in different species and tissue *in vivo* and *in vitro*, preferential binding of one isomer to muscarinic subtype receptor may cause differences in pharmacological action. Drug enantiomers have identical properties in an achiral environment, but should be considered as different chemical compounds. This is because they often differ considerably in potency, pharmacological activity, and pharmacokinetic profile, since the modules with which they interact in biological systems are also optically active. Interactions of both isomers may differ at the active sites through which pharmacological action is mediated. For this, there were possible subtype and stereochemical selective mechanisms that account for the different actions and levels of activity of the CPG and its enantiomers. Hence, further studies were necessary to resolve the underlying mechanisms of muscarinic receptor with these compounds.

Taken together, the present work demonstrated that *R*(-)-CPG acted as an active component in racemate and a competitive antagonist to acetylcholine muscarinic receptors, but *S*(+)-CPG displayed less activities in comparison to *R*(-)-CPG and its racemate. In contrast to its racemate, both of the enantiomers showed lower central depressant effects.

Abstract

Aim: Recent studies have shown that *l*-tetrahydropalmatine (*l*-THP), an active component of *Corydalis yanhusuo*, can inhibit the development of the conditional place preference induced by opioid receptor agonists, but the effects of *l*-THP on locomotor sensitivity induced by opioid receptor agonists have not been documented. In the present study, the effects of *l*-THP on locomotor sensitization to oxycodone, which is an opioid receptor agonist, were studied. **Methods:** Mice treated daily for 7 d with 5 mg/kg oxycodone and challenged with the same dose after 5 days of washout showed locomotor sensitization. In order to study the effects of *l*-THP on locomotor sensitization induced by oxycodone, *l*-THP was administered at doses of 6.25, 12.5, and 18.75 mg/kg, 40 min prior to treatment of oxycodone. **Results:** *l*-THP *per se* did not affect the locomotor activity at the doses of 6.25, 12.5, and 18.75 mg/kg, but could antagonize the hyperactivity induced by oxycodone (5 mg/kg). Co-administration of *l*-THP (18.75 mg/kg), 40 min prior to oxycodone, could inhibit the development of sensitization to oxycodone. In addition, *l*-THP (6.25, 12.5, and 18.75 mg/kg, ig) dose-dependently prevented the expression of oxycodone sensitization. **Conclusion:** These results suggested that *l*-THP could attenuate the locomotor-stimulating effects of oxycodone and inhibit the development and expression of oxycodone behavioral sensitization.

Introduction

The term 'behavioral sensitization' is used to describe the augmented behavior activity produced by a given dose of an opioid-drug after repeated intermittent injections^[1]. Recently, the importance of behavioral sensitization in drug abuse research has been realized. Studies have shown that behavioral sensitization has a close relationship with relapse, compulsive drug-seeking and drug-taking behaviors^[2-5]. Investigation of sensitization may be helpful for better understanding of the relapse mechanisms and for providing new strategies for the treatment of drug addiction.

Oxycodone (4,5-epoxy-14-hydroxy-3-methoxy-17-methyl-morphinan-6-one) is a semi-synthetic derivative of the naturally occurring opium alkaloid, thebaine. Oxycodone is an opioid receptor agonist similar to morphine^[6-8]. It is reported

that the abuse potential of oxycodone is equivalent to that of morphine^[9]. It has been found that withdrawal syndrome may occur in patients when high doses or the chronic treatment of oxycodone is broken or weakened, but the effects of oxycodone on locomotor behavior sensitivity in animals has not been documented. Therefore, the present study was designed to investigate whether acute injection of oxycodone would induce hyperlocomotor activity and chronic administration of oxycodone would induce locomotor sensitization in mice.

l-Tetrahydropalmatine (*l*-THP) is an active principle of *Corydalis yanhusuo*, a Chinese traditional herb used as an analgesic^[10]. It is reported that *l*-THP possesses a blocking effect on dopamine D₁ and D₂ receptors and voltage-sensitive Ca²⁺ channels^[11]. It has been suggested in recent studies that *l*-THP can inhibit physical dependence in morphine-

dependent mice and significantly reduce the development of the conditional place preference induced by morphine in mice^[12,13]. However, no research has been carried out on the effects of *l*-THP on locomotor sensitization. Therefore, it is interesting to determine whether pretreatment with *l*-THP prior to administration of oxycodone would inhibit the hyperactivity induced by oxycodone and prevent the development and expression of locomotor activity to oxycodone.

Materials and methods

Animals Kunming mice, initially weighing 18–22 g, were purchased from the Experimental Animal Center of Beijing Institute of Pharmacology and Toxicology. The animals were fed *ad libitum* and were housed in a room with a controlled ambient temperature (22±2 °C), humidity (50%±10%), and a 12-h light/dark cycle. Animals were acclimated to the housing conditions and handled for 3–4 d before experiments. All experiments were performed between 08.00 h and 16.00 h. All experiments were conducted according to the NIH Guide for the Care and Use of Laboratory Animals (NIH Publications No. 80-23, revised 1996). The experimental procedures were approved by the local Committee on Animal Care and Use.

Drugs Oxycodone, obtained from Beijing Four-Ring Pharmaceutical Factory (Beijing), was dissolved in 0.9% saline injected subcutaneously. *l*-THP, kindly provided by Professor Guo-zhang JIN (Shanghai Institute of Materia Medica, Chinese Academy of Sciences), was dissolved in distilled water and administered intragastrically.

Apparatus Locomotor activity was counted automatically with Small Animal Locomotion Recording Apparatus (Institute of Materia Medica, Chinese Academy of Medical Science), which consisted of four boxes (20 cm in diameter and 15 cm in height) with six photoelectric infrared sensors 2 cm above the floor of each box. The sensors detect the movements of the mice through infrared radiation.

Experimental procedures

Acute effects of oxycodone on locomotor activity in mice

Mice were put into the test boxes immediately after treatment with saline or oxycodone (1.25, 2.5, and 5.0 mg/kg, sc). Locomotor counts were measured every 10 min for 90 min.

Development of locomotor sensitivity to oxycodone in mice Two groups of 10 mice each were given oxycodone or saline for 7 consecutive days, and their activity was measured for 60 min immediately after each administration. The experimental period for the 7 d remained at approximately the same time every day during the daytime.

Effects of acute and chronic *l*-THP on locomotor activity in mice

Four groups of mice were given *l*-THP (6.25, 12.5, and 18.75 mg/kg) or saline, respectively, once per day for 7 consecutive days, followed by a 5-d withdrawal period. On d 13, all animals were challenged with saline. On d 1, 7, and 13, after 40-min treatment with *l*-THP or saline, the mice were put into the test boxes and locomotor activity was monitored for 60 min.

Effects of *l*-THP on the acute oxycodone-induced hyperactivity in mice

Five groups of mice were administered with one of the following drug pairs: saline+saline, saline+oxycodone, and *l*-THP (6.25, 12.5, and 18.75 mg/kg)+oxycodone with a 40-min interval between the two treatments. After the second treatment, the mice were put into the test boxes to record their locomotor activity for 60 min.

Effects of *l*-THP on the development of oxycodone sensitization

To assess the effects of *l*-THP on the development of oxycodone sensitization, five groups of mice were administered for 7 consecutive days with one of the following drug pairs: saline+saline, saline+oxycodone, and *l*-THP (6.25, 12.5, and 18.75 mg/kg)+oxycodone. The interval between *l*-THP and oxycodone injections was 40 min, with *l*-THP given prior to the oxycodone. After 5 washout periods, all animals were injected with oxycodone (5 mg/kg) and then put into the test chambers to record their locomotor activity for 60 min.

Effects of *l*-THP on the expression of oxycodone sensitization

Mice were injected with 5 mg/kg oxycodone for 7 consecutive days to induce locomotor sensitization. After 5 days of washout, the mice were challenged with 5 mg/kg oxycodone, and with either saline or *l*-THP (6.25, 12.5, and 18.75 mg/kg), given 40 min prior to the oxycodone challenge. The locomotor activity of the mice was then measured for 60 min.

Statistics

The results were expressed as the mean±SEM. In experiment acute effects of oxycodone on locomotor activity in mice and development of locomotor sensitivity to oxycodone in mice locomotor activity was analyzed using a two-way ANOVA. *Post hoc* comparisons were performed using Tukey's test. For the other experiments, statistical analyses were performed using one-way ANOVA and a *post hoc* Tukey's test. $P<0.05$ was considered statistically significant. Calculations were performed using the SPSS statistical package.

Results

Acute effects of oxycodone on locomotor activity in mice

Mice were given saline, oxycodone (1.25, 2.5, or 5 mg/kg), then locomotor activity was monitored for 90 min. Locomotor accounts showed a great difference between saline-treated

mice and oxycodone-treated mice. Oxycodone dose-dependently induced locomotor response in mice during the 90-min test session [F (treatment) (3, 33)=16.598, $P<0.01$; F (treatment×time) (24, 424)=6.080, $P<0.01$]. During the first and the last 10 min, there was a significant difference between the saline-treated and oxycodone-treated group (5 mg/kg, sc). The climax of oxycodone-induced hyperactivity appeared approximately 30–40 min after the treatment of oxycodone. The psychomotor effect of 5 mg/kg oxycodone lasted about 90 min, and 1.25, 2.5 mg/kg oxycodone increased locomotor activity only at some time points (Figure 1).

Figure 1. Acute effects of oxycodone on locomotion in mice. Mice were put into the test boxes immediately after treatment with saline or oxycodone (1.25, 2.5, and 5.0 mg/kg, sc). Locomotor counts were measured for 90 min. Mean±SEM. $n=10-12$. ^b $P<0.05$, ^c $P<0.01$ vs saline group.

Development of locomotor sensitivity to oxycodone in mice Figure 2 showed the total 60-min activity counts after 7 repeated administrations of oxycodone or saline to the mice in the test boxes. The activity counts were dependent on the drug [F (1,126)=20.764, $P<0.01$] and number of administrations [F (6,126)=73.246, $P<0.01$]. There was a significant interaction between the drug given and the number of administrations [F (6,126)=45.00, $P<0.01$]. The locomotor activity showed significant enhancement in the fourth injection compared to the initial injection. There was no significant difference among saline groups.

Effects of acute and chronic *l*-THP on locomotor activity in mice Mice were given *l*-THP (6.25, 12.5, and 18.75 mg/kg, ig) for 7 consecutive days, then subjected to withdrawal from *l*-THP for 5 d. On d 13, all animals were challenged with saline. On d 1, 7, and 13, 40 min after injection of *l*-THP or saline, the mice were put into the test boxes and locomotor counts were measured for 60 min. On d 1 and 7, there was no difference

Figure 2. The development of locomotion sensitivity to oxycodone in mice. Two groups of 10 mice each were given oxycodone or saline for 7 consecutive days and their locomotor activity was measured immediately for 60 min after each administration. The experimental time remained approximately at the same time everyday during the daytime. Mean±SEM. $n=10$. ^c $P<0.01$ vs saline group. ^e $P<0.05$, ^f $P<0.01$ vs the first administration within group.

between the *l*-THP groups (6.25, 12.5, and 18.75 mg/kg) and saline group [F (3, 37)=1.360, $P>0.05$, F (3, 37)=0.348, $P>0.05$, respectively]. On d 13, there was also no significant difference between *l*-THP groups and saline groups after administration of saline [F (3, 37)=1.532, $P>0.05$]. These results indicated that acute or chronic pretreatment with *l*-THP at the dose of 6.25, 12.5, and 18.75 mg/kg might not affect locomotor activity in mice (Figure 3).

Effects of *l*-THP on acute oxycodone-induced hyperactivity in mice Locomotor counts were greatly increased in the oxycodone group compared with the saline group. *l*-THP at doses of 6.25, 12.5, and 18.75 mg/kg antagonized hyperactivity induced by oxycodone [F (4, 60)=15.76, $P<0.01$] (Figure 4).

Effects of *l*-THP on the development of oxycodone sensitization Figure 5 showed that the psychomotor effect of oxycodone was significantly enhanced in mice pretreated with oxycodone (5 mg/kg×7, sc), 5 d cessation of treatment. *l*-THP (6.25, 12.5 mg/kg) did not affect the magnitude of sensitization, but there was a marked difference between oxycodone+oxycodone group and *l*-THP (18.75 mg/kg)+oxycodone+oxycodone group, indicating that *l*-THP (18.75 mg/kg) greatly inhibited the development of oxycodone sensitization [F (4, 62)=8.766, $P<0.01$].

Effects of *l*-THP on expression of oxycodone sensitization Our protocol induced great locomotor sensitization to oxycodone in oxycodone+oxycodone group compared to the saline+oxycodone group. There were great differences between oxycodone+oxycodone group and *l*-THP (6.25, 12.5, 18.75 mg/kg)+oxycodone+oxycodone groups [F (4, 65)=

Figure 3. Effects of acute and chronic *l*-THP on locomotor activity in mice. Mice were given *l*-THP (6.25, 12.5, and 18.75 mg/kg) or saline once per day for 7 consecutive days, followed by a 5-d withdrawal period. On d 13, all mice were challenged with saline. On d 1, 7, and 13, 40 min after treatment with *l*-THP or saline, the mice were put into test boxes and locomotor activity was monitored for 60 min. $n=10$ in each group. Mean \pm SEM.

Figure 4. Effects of *l*-THP on the acute oxycodone-induced hyperactivity in mice. Five groups of mice were administered with one of the following drug pairs: saline+saline, saline+oxycodone, and *l*-THP (6.25, 12.5, and 18.75 mg/kg)+oxycodone with a 40-min interval between the two treatments. After the second treatment, the mice were put into the test boxes for recording of their locomotor activity for 60 min. $n=10-12$. Mean \pm SEM. ^c $P<0.01$ vs saline+saline group. ^e $P<0.05$, ^f $P<0.01$ vs saline+oxycodone group.

24.128, $P<0.01$]. In all, *l*-THP (6.25, 12.5, and 18.75 mg/kg), administered 40 min before the challenge doses of oxycodone, inhibited the expression of oxycodone sensitization (Figure 6).

Discussion

In our research, acute administration of oxycodone increased locomotor activities in mice and those effects were progressively enhanced by the repeated injection of oxycodone, indicated by the development of behavioral locomotor activity (Figure 1). In addition, locomotor activities were increased when the mice were treated with oxycodone after a 7-d period of washout, which attributed to the expression phase (Figure 2). Oxycodone has been used clinically for

Figure 5. Effects of *l*-THP on the development of oxycodone locomotor sensitization. Mice were administered for 7 consecutive days with one of the following drug pairs: saline+saline, saline+oxycodone, and *l*-THP (6.25, 12.5, and 18.75 mg/kg)+oxycodone. The interval between *l*-THP and oxycodone injections was 40 min, with *l*-THP given prior to the oxycodone. After 5 washout period, all animals were injected with oxycodone (5 mg/kg) and then put into the test chambers to record their locomotor activity for 60 min. $n=12-14$. Mean \pm SEM. ^b $P<0.05$, ^c $P<0.01$ vs saline+oxycodone group. ^e $P<0.05$ vs oxycodone+oxycodone group.

Figure 6. Effects of *l*-THP on the expression of oxycodone sensitization. Mice were injected with 5 mg/kg oxycodone for 7 consecutive days to induce behavioral sensitization. After 5 d of washout, all mice were challenged with 5 mg/kg oxycodone, and with either saline or *l*-THP (6.25, 12.5, 18.75 mg/kg), given 40 min prior to the oxycodone challenge. The locomotor activity of the mice was then measured for 60 min. $n=12-14$. Mean \pm SEM. ^b $P<0.05$ vs saline+oxycodone group. ^f $P<0.01$ vs oxycodone+oxycodone group.

over 80 years, but its pharmacological properties are still poorly characterized. The present results showed that the repeated administration of oxycodone in mice induced behavioral locomotor sensitization similar to morphine.

l-THP, an active principle of *Corydalis yanhusuo*, at doses of 6.25, 12.5, and 18.75 mg/kg *per se* did not affect locomotor activity in mice treated with acute or chronic administration, but inhibited hyperactivity, and the development and expression of locomotor sensitivity induced by oxycodone (5 mg/kg, sc).

Behavioral sensitization consists of two phases: development/induction and expression. There is evidence suggesting that the induction and the expression of sensitization to opioids involve different anatomical and physiological mechanisms. The development of sensitization consists of the immediate molecular and/or cellular effects that induce behavioral sensitization and are altered by drug actions in the somatodendritic regions of the A10/A9 dopamine neurons^[14]. Changes in dopamine transmission within the nucleus accumbens seems to be responsible for the expression of sensitization, which refers to the long-term consequences of molecular and/or cellular effects that induce behavioral sensitization^[14]. The present results demonstrated that pretreatment with *l*-THP not only inhibited the development, but also inhibited the expression of oxycodone.

It has been hypothesized that dopamine (DA) is one of the important neurotransmitters involved in locomotion. Measurement of spontaneous locomotor activity has been used to obtain preliminary information on the behavioral properties of drugs acting on dopaminergic system^[15,16]. Morphine is known to activate ventral tegmental area dopamine neurons indirectly as a consequence of inhibiting non-dopamine, presumably γ -GABA, neurons of the ventral tegmental area, leading to increased dopamine release in the nucleus accumbens^[17]. Direct infusions of morphine or μ -receptor-selective peptides into the ventral tegmental area elicit locomotion, which can be blocked by DA receptor antagonist administration into the nucleus accumbens. Following repeated administration of morphine, there is a marked increase in the induction of locomotor-stimulating effects of morphine, there is general agreement that the mesoaccumbens DA system is the anatomical locus for sensitized locomotion^[18]. Kalivas and Stewart (1991) presented preliminary results showing that either systemic or intra-ventral tegmental area administration of sch23390 prevented sensitization to systemic morphine, when the combinations were given every other day for 8 d. They also suggested DA D₁ receptor involvement in the development of morphine sensitization^[14]. In other studies, the blockade of the dopamine D₂ receptor by haloperidol significantly antagonized the effects of opioid on locomotor activity^[19]. Thus, dopamine D₁ and D₂ receptors play important roles in the acceleration of opioid sensitization^[20]. Although the mechanisms of action through which *l*-THP attenuates the psychomotor effect of oxycodone are not clear, one reason maybe relevant to dopamine D₁ and D₂ receptors, which are involved in oxycodone-induced hyperactivity and locomotor sensitivity. *l*-THP, which has affinity for D₁ as well as D₂ receptors, is a dopamine receptor

antagonist^[11]. *l*-THP may inhibit mesolimbic dopamine D₁ and D₂ receptors and attenuate psychomotor effects of oxycodone. Our recent studies also showed that oxycodone (2.5 mg/kg, sc) increased dopamine-concentrations of dialysates with microdialysis in the striatum of rat. *l*-THP (25 mg/kg, ig) *per se*, did not affect dopamine release, but pretreatment of rats with *l*-THP (25 mg/kg, ig) significantly inhibited oxycodone-induced increases in extracellular dopamine concentrations [$F_{(3,18)}=5.068, P<0.05$] (Liu *et al*, unpublished data, 2004). These results indicate that the inhibiting locomotor sensitivity effect of *l*-THP might be connected with the DA system. *l*-THP could inhibit dopamine release in the mesolimbic system, induced by oxycodone, and then inhibit the development and expression of locomotor sensitization.

Another reason might be connected with L-type Ca²⁺ channels. Recent reports show that L-type Ca²⁺ channels may play an important role in the development of morphine behavioral sensitization. Co-administration with L-type Ca²⁺ channel blockers attenuates the development of morphine tolerance, dependence, and sensitization, suggesting that the L-type Ca²⁺ channel might play a role in morphine-induced neural and behavioral plasticity^[21,22]. In contrast, L-type Ca²⁺ channel blockers have antidopaminergic properties^[23]. L-type Ca²⁺ channel blockers such as nimodipine, nifedipine, and verapamil, dose-dependently antagonize apomorphine-induced yawning and penile erections in rats^[24,25]. Nimodipine and verapamil inhibits locomotor activity induced by morphine^[26]. Therefore, L-type Ca²⁺ channel blockers could attenuate morphine-induced hyperactivity through an antidopaminergic action. The inhibitory effect of *l*-THP on the development and expression of sensitivity of oxycodone might also be a result of the inhibitory effect of *l*-THP on L-type Ca²⁺ channel. Previous studies show that *l*-THP is also an L-type calcium antagonist. Using the patch-clamp technique, *l*-THP causes both tonic and use-dependent reduction of Ca²⁺ current in single ventricular myocytes of guinea pigs, has a moderate inhibitory effect on L-type Ca²⁺ current, and has inhibitory effects on [Ca²⁺]_i in myocytes by blocking voltage-dependent calcium channels similar to verapamil^[27-29]. Therefore, the inhibitory effect of *l*-THP on L-type Ca²⁺ channel might be included in mechanisms of action through which *l*-THP attenuated locomotor sensitization to oxycodone.

In conclusion, the present data indicates that *l*-THP attenuated psychomotor effects of oxycodone, and the development and expression of locomotor sensitivity of oxycodone. The exact mechanisms of the inhibitory effect of *l*-THP on oxycodone sensitivity need further investigation.

Abstract

Aim: To investigate the effect of aluminum (Al) on high voltage-dependent calcium current (I_{HVA}) and its modulation by ginkgolide B (Gin B). **Methods:** The whole-cell, patch-clamp technique was used to record I_{HVA} from acutely isolated hippocampal CA1 pyramidal neurons in rats. **Results:** Al 0.1 mmol/L (low concentration) reduced I_{HVA} ; Al 0.75 and 1.0 mmol/L (high concentrations) increased I_{HVA} , and Al decreased and increased I_{HVA} at intermediate concentrations of 0.25 and 0.5 mmol/L. The increase of I_{HVA} by Al 1.0 mmol/L was enhanced by the adenylyl cyclase (AC) agonist forskolin and was partly abolished by the cyclic adenosine monophosphate (cAMP)-dependent protein kinase A (PKA) antagonist H-89, whereas the decrease observed with Al 0.1 mmol/L was neither reversed by forskolin nor affected by H-89. Gin B had no effect on I_{HVA} in normal neurons, but canceled the increase in I_{HVA} by 1.0 mmol/L Al. **Conclusion:** The results indicate that the mechanism of Al affecting I_{HVA} differs at different concentrations, and this may be attributed to its complex actions. Gin B could prevent neurons from injury by inhibiting calcium influx.

Introduction

The accumulation of aluminum (Al) within the body can result in many mental diseases. For example, Al is concentrated in the neurofibrillary tangles and senile plaques of patients with Alzheimer disease (AD)^[1]. Al can be attributed to several neurological disorders, such as dialysis syndrome and Guamanian amyotrophic lateral sclerosis-Parkinson's dementia^[2]. A number of studies have implicated that Al has no effect on long-term potentiation (LTP)^[3]. However, more and more studies have shown that Al can impair LTP^[4] and evoke potential in the hippocampus^[5]. Studies have also shown that Al affects amino acid neurotransmitters in the hippocampus and enhances glutamate-mediated excitotoxicity, which may be one of the causes of its toxicity^[6]. Reports about its mechanism involving ion channels are few and controversial^[7–9].

Extracts from leaves of *Ginkgo biloba* (EGb) and one of its constituents ginkgolide B have been demonstrated to protect cardiomyocytes and cultured neurons from the in-

jury induced by hypoxia, ischemia, and the neurotoxicity induced by $A\beta^{[10–12]}$. However, it is not known whether the mechanism of this protection of neurons involves ion channels, such as voltage-dependent calcium channels (VDCC).

The present study investigated the actions of Al on I_{HVA} and its modulation by Gin B to examine the neurotoxic mechanisms of Al and the neuroprotective mechanisms of Gin B.

Materials and methods

Reagents Pronase E, forskolin, TEA-Cl, H-89, and HEPES were purchased from Sigma Chemical Company (St Louis, MO, USA). H-89 was dissolved in pipette solution and stored at -20°C . After the whole-cell configuration was constructed, H-89 was dialyzed into the cell through the pipette. Ginkgolide B (BN52021, purity 98.2%) was from the Wuhan Institute of Botany, Chinese Academy of Sciences (Wuhan, China). AlCl_3 was from Jinghua Chemical Company (Beijing, China). The remaining chemicals, unless otherwise

stated, were all purchased from the Shanghai Chemical Reagent Plant (Shanghai, China).

Cell isolation Animals were provided by the experimental animal center of Tongji Medical College (Grade II, Certificate No. 19-050). Hippocampal CA1 neurons were acutely isolated by enzymatic digestion and mechanical dispersion from 7 to 10-d-old Wistar rats as described in a previous study^[13], with a few modifications. After the animals were killed, the hippocampi were removed and coronary slices were cut at a thickness of approximately 500 μm in ice-cold oxygenated incubation solution within 30 s. The slices were incubated in an external solution saturated with pure O_2 at 32 °C for 1 h, treated with Pronase E 6.0–7.0 kU/L for 25 min in the oxygenated external solution at 32 °C. After digestion the slices were washed six times with external solution and incubated in the same solution saturated with pure O_2 at room temperature. CA1 regions were dissected out and transferred into centrifuge tubes. Hippocampal neurons were dispersed by gentle pipetting using fine glass tubes. After 5 min, the cell suspension was transferred into the recording chamber with a glass coverslip filled with external solution. The cells were left for approximately 30 min before beginning the experiments.

Electrophysiology The cells were placed in a recording chamber mounted on the stage of an inverted microscope (Carl Zeiss, Germany) and superfused with extra cellular solution at room temperature (21–22 °C). Extracellular solution for recording I_{HVA} was composed of (mmol/L): NaCl 150, KCl 5, MgCl_2 1.1, CaCl_2 2.5, HEPES 10, glucose 10, TTX 0.001, and the pH was adjusted to 7.4 with NaOH. Extracellular application of drugs was carried out by perfusing cells with extracellular solution containing the drugs.

Whole-cell patch experiments were carried out using an Axopatch 200A amplifier (Axon Instruments, Foster City, CA, USA) driven by ISO2 software (MFK, Frankfurt, Germany). In the voltage-clamp experiments, the cells were stepped from -80 mV (50 ms) to -40 mV (200 ms), and then depolarized to 0 mV (200 ms) after briefly hyperpolarizing the membrane potential for 10 ms to -45 mV. The I_{HVA} was activated by the second depolarization. The protocol was applied every 5 s. For analysis of the current-voltage (I - V) relationship, voltage steps (200 ms) were used to depolarize from -40 mV to +40 mV in 10 mV increments. Glass pipettes were used with a resistance of about 3–5 M Ω when filled with a pipette solution composed of (mmol/L): CsCl 140, MgCl_2 2, Mg-ATP 4, TEA-Cl 2, HEPES 10, egtazic acid 11, and the pH was adjusted to 7.2 with CsOH.

Data were acquired at a sampling rate of 10 kHz, filtered at 2 kHz, stored on hard disk and analyzed off-line using the

ISO2 analysis software package (MFK, Frankfurt, Germany).

Data analysis The amplitude of I_{HVA} was calculated as the difference between the instantaneous current at the beginning of the experiment and the maximum activating current. Currents were normalized to membrane capacitance to calculate current densities ($\text{pA}\cdot\text{pF}^{-1}$). Cell membrane capacitance (C_m) was determined online using the ISO2 software program. The activation rate constant and inactivation rate constant were obtained using the ISO2 analysis software. Graphical and statistical data analyses were carried out using Sigmaplot 2001 (SPSS, Chicago, IL, USA) and Origin 6.0 (Microcal Software, Inc, Northampton, MA01060, USA). Data were presented as mean \pm SEM where appropriate. Statistical analysis were carried out using Student's paired and unpaired t -tests and values of $P < 0.05$ were considered statistically significant.

Results

Action of Al on I_{HVA} Bath application of AlCl_3 0.01 mmol/L had no effect on I_{HVA} . The current densities before and after AlCl_3 application were $18.5 \pm 2.4 \text{ pA}\cdot\text{pF}^{-1}$ and $18.5 \pm 2.2 \text{ pA}\cdot\text{pF}^{-1}$, respectively ($n=11$, $P > 0.05$) (Figure 1A).

Bath application of AlCl_3 0.1 mmol/L caused a reduction in I_{HVA} from $17.7 \pm 1.6 \text{ pA}\cdot\text{pF}^{-1}$ to $12.7 \pm 1.4 \text{ pA}\cdot\text{pF}^{-1}$ ($n=27$, $P < 0.01$), that is, a reduction of $30.5\% \pm 4.1\%$. The reduction of I_{HVA} by AlCl_3 did not recover after the AlCl_3 was washed out (Figure 1B).

AlCl_3 0.25 mmol/L caused a reduction in I_{HVA} in 80% (8/15) of the neurons, and an increase in 20% (4/15) of the neurons. AlCl_3 0.50 mmol/L caused a reduction in I_{HVA} in 50% (7/14) of the neurons, and an increase in I_{HVA} in 50% (7/14) of the neurons. In contrast, AlCl_3 0.75 mmol/L increased I_{HVA} by $30.8\% \pm 5.2\%$ ($n=15$, $P < 0.01$) in all neurons tested (from $17.8 \pm 1.8 \text{ pA}\cdot\text{pF}^{-1}$ to $23.0 \pm 2.5 \text{ pA}\cdot\text{pF}^{-1}$). AlCl_3 1.0 mmol/L increased I_{HVA} by $37.3\% \pm 7.8\%$ (from $19.6 \pm 3.1 \text{ pA}\cdot\text{pF}^{-1}$ to $26.2 \pm 4.3 \text{ pA}\cdot\text{pF}^{-1}$) ($n=21$, $P < 0.01$). I_{HVA} increased by AlCl_3 was irreversible after AlCl_3 was washed out (Figure 1C).

At both low and high concentrations, AlCl_3 inhibited or increased the maximum amplitude of I_{HVA} , but had no effect on the activation threshold potential of I_{HVA} in the I - V relationship (Figure 2A, B). The G - V curve was unaffected by AlCl_3 0.1 mmol/L ($n=5$, $P > 0.05$) or AlCl_3 1.0 mmol/L ($n=5$, $P > 0.05$) (control: $V_{0.5} = -12.8 \text{ mV} \pm 4.4 \text{ mV}$, $k = 5.5 \pm 3.8$; AlCl_3 0.1 mmol/L: $V_{0.5} = -12.0 \text{ mV} \pm 4.5 \text{ mV}$, $k = 5.0 \pm 4.0$; AlCl_3 1.0 mmol/L: $V_{0.5} = -13.6 \text{ mV} \pm 5.3 \text{ mV}$, $k = 5.2 \pm 4.4$) (Figure 2C). In addition, AlCl_3 had no effect on the activation rate constants at concentrations of 0.1 mmol/L ($n=8$, $P > 0.05$) or 1.0 mmol/L ($n=9$, $P > 0.05$).

Figure 1. Effect of AlCl₃ on *I*_{HVA} at concentrations of 0.01, 0.1 and 1.0 mmol/L (A, B, C, respectively). *I*_{HVA} current was recorded at different concentrations of AlCl₃ (left). (a) Before the application of AlCl₃; (b) Application of AlCl₃; (c) washout. The time course of the experiment corresponding to left-hand panels (right).

To gain a better understanding of the action of Al on *I*_{HVA}, we explored its action on the steady-state inactivation curve of *I*_{HVA}. AlCl₃ shifted the curve to a depolarizing voltage at 1.0 mmol/L ($n=5, P<0.05$), whereas it shifted the inactivation curve to a hyperpolarizing voltage at 0.1 mmol/L ($n=5, P<0.05$). (Control: $V_{0.5}=-35.4\pm3.3$ mV, $k=-14.3\pm2.5$; 0.1 mmol/L AlCl₃: $V_{0.5}=-41.1\pm2.7$ mV, $k=-9.2\pm2.0$; 1.0 mmol/L AlCl₃: $V_{0.5}=-29.8\pm6.9$ mV, $k=-10.8\pm2.4$). AlCl₃ 0.1 mmol/L decreased the inactivation rate constant by $27.3\%\pm6.3\%$ ($n=5, P<0.01$), whereas 1.0 mmol/L AlCl₃ increased the inactivation rate constant by $44.7\%\pm3.4\%$ ($n=7, P<0.01$) (Figure 3).

Effect of Gin B on *I*_{HVA} in hippocampal neurons Gin B at doses of 0.01–20 μmol/L had no effect on *I*_{HVA} in normal hippocampal neurons ($P>0.05$) (Table 1). Gin B inhibited the

increase of *I*_{HVA} by AlCl₃ 1.0 mmol/L. After a steady increase in the action of AlCl₃, Gin B at concentrations of 0.01 μmol/L,

Table 1. Effect of Gin B at different concentrations (0.01, 0.1, 1.0, 10, and 20 μmol/L) on the amplitude of *I*_{HVA}. $n=6$. Mean±SD.

Gin B/μmol·L ⁻¹	<i>I</i> _{HVA} /pA·pF ⁻¹	
	Control	Gin B
0.01	19.6±2.9	19.1±3.9
0.1	19.1±3.2	19.6±2.2
1.0	19.4±1.9	18.8±1.6
10	20.0±1.2	18.7±0.8
20	17.2±0.9	17.2±1.3

Figure 2. (A) Effect of Al at different concentrations on the amplitude of I_{HVA} . $^cP < 0.01$ vs control. (B) Effect of Al at different concentrations on the current-voltage (I - V) relationship of HVA. (C) Effect of Al at different concentrations on the steady-state conductance (G) and voltage (V) curve. Data were transformed from the I - V data shown in B. G - V parameters were fitted to the Boltzman equation: $G/G_{max} = 1/[1 + \exp(V_m - V_{1/2})/k]$, where G_{max} is the maximum conductance, $V_{1/2}$ is the membrane potential at which 50% of activation was observed, and k is the slope of the function.

0.1 μ mol/L, 1.0 μ mol/L, and 10 μ mol/L reduced I_{HVA} by 21.0% \pm 4.6% ($n=7$, $P < 0.05$), 57.9% \pm 7.8% ($n=6$, $P < 0.01$), 79.3% \pm 2.7% ($n=6$, $P < 0.01$), and 82.4% \pm 7.3% ($n=6$, $P < 0.05$), respectively. The concentration producing 50% inhibition by Gin B of Al 1.0 mmol/L is 0.0359 μ mol/L \pm 0.0038 μ mol/L (Figure 4).

Co-superfusion AlCl₃ 0.1 mmol/L plus Gin B 10 μ mol/L was applied in the same way as AlCl₃ 1.0 mmol/L. For all

Figure 3. Effects of Al at different concentrations on the steady-state inactivation curve. I_{HVA} was measured using a 200 ms test pulse to 10 mV by 3 s conditioning prepulse ranging from -80 mV to +20 mV, with 10 mV increments. Data were fitted to the Boltzman equation: $I/I_{max} = 1/[1 + \exp(V_{1/2} - V_m)/k]$, where $V_{1/2}$ is the membrane potential at which 50% of activation was observed, and k is the slope of the function.

Figure 4. Concentration-response relationship for the inhibition of Gin B on the action of AlCl₃ (1.0 mmol/L) in hippocampal neurons. In the concentration-response curve for Gin B each point represents the mean \pm SEM of the percentage inhibition of Gin B from six to seven cells. The curve shown is the fit of the data to the logistic equation $Y = Y_{max}/[1 + (IC_{50}/C)^n]$, where C is the concentration of Gin B, Y is the fraction of the maximal inhibition response value, n is the Hill coefficient, and IC_{50} is the concentration of Gin B producing 50% inhibition on the increase in I_{HVA} by 1.0 mmol/L Al.

tested neurons ($n=15$), there was no change in I_{HVA} in 53.3% of the neurons and a slight increase in I_{HVA} in the remaining neurons ($P > 0.05$). This result indicated that Gin B had no effect on the action of Al 0.1 mmol/L.

Mechanism of action of high concentrations of Al on I_{HVA} Application of forskolin 10 μ mol/L (an agonist of adenylyl cyclase) increased I_{HVA} by 30.8% \pm 7.5% ($n=14$, $P < 0.05$). Bath application of forskolin 10 μ mol/L in combination with Al 1.0 mmol/L increased I_{HVA} by 68.3% \pm 8.7% ($n=31$, $P < 0.05$) (Figure 5A).

Figure 5. (A) Percentage of increased action by AlCl₃ 1.0 mmol/L and AlCl₃ co-superfusion with forskolin. (B) Percentage of increased action by AlCl₃ 1.0 mmol/L in the presence and the absence of H-89. ^b*P*<0.05 vs AlCl₃ 1.0 mmol/L.

Figure 6. (A) Percentage of inhibitory action by AlCl₃ 0.1 mmol/L (27.5%±5.6%) and AlCl₃ co-superfusion with forskolin (28.2%±7.3%). (B) Percentage of inhibitory action by AlCl₃ 0.1 mmol/L in the presence (39.9%±5.7%) and absence of H-89 (27.5%±5.6%).

H-89 is a selective antagonist of PKA. In this study, adding H-89 in the pipette solution reduced the amplitude of I_{HVA} by 42.0%±4.1% (from 20.2±3.3 pA·pF⁻¹ to 13.9±3.1 pA·pF⁻¹, *n*=6, *P*<0.01) within approximately 80–100 s. AlCl₃ 1.0 mmol/L was bath applied in the presence of H-89 (10 μmol/L) in the pipette solution. Aluminum increased I_{HVA} by 17.2%±5.8% (*n*=10, *P*<0.05). Compared with the effect of Al 1.0 mmol/L on I_{HVA} without H-89 (*n*=29, *P*<0.05), the reduction in I_{HVA} in the presence of H-89 was significant, indicating that H-89 could, in part, abolish the increase in I_{HVA} by Al at high concentrations (Figure 5B).

Mechanism of action of low concentrations of Al on I_{HVA} To investigate the mechanism by which Al inhibited I_{HVA} at low concentrations, AlCl₃ 0.1 mmol/L was applied first and I_{HVA} was reduced to 12.9±1.1 pA·pF⁻¹ from 18.5±1.7 pA·pF⁻¹ (*n*=12, *P*<0.01). After the current was stable, forskolin 10 μmol/L and AlCl₃ 0.1 mmol/L were co-applied. Forskolin did not cancel the inhibition of I_{HVA} by 0.1 mmol/L AlCl₃. The I_{HVA} after forskolin application was 12.5±0.9 pA·pF⁻¹

(*n*=12, *P*>0.05) (Figure 6A).

In the presence of H-89 (10 μmol/L), I_{HVA} was reduced to 13.1±2.5 pA·pF⁻¹ from 20.1±4.2 pA·pF⁻¹ (*n*=8, *P*<0.01). After the current was stable, AlCl₃ 0.1 mmol/L was bath applied, and I_{HVA} was reduced to 12.5±2.5 pA·pF⁻¹. There was no difference in the percentage inhibition with and without H-89 application (*n*=33, *P*>0.05) (Figure 6B).

Discussion

VDCC in hippocampal neurons are divided into high voltage-dependent channels (HVA) and low voltage-dependent channels (LVA) according to the difference in activation threshold. In the present study we demonstrated that the effect of Al on I_{HVA} differed at different concentrations. Al reduced the amplitude of I_{HVA} irreversibly at low concentrations (0.1 mmol/L). This result supports a previous report on dorsal root ganglion (DRG) neurons^[7]. However, Al inhibited and enhanced I_{HVA} as Al concentrations increased

(between 0.25 mmol/L and 0.50 mmol/L), and the percentage of enhanced I_{HVA} by Al in the neurons examined increased with increased Al concentrations. When 0.75 mmol/L and 1.0 mmol/L Al were bath applied, the amplitude of I_{HVA} in all neurons tested increased.

The toxic effect of Al in humans is chronic and accumulative and leads to degradation and apoptosis of cells^[14]. Acute application of Al inhibits LTP on hippocampal slices of rats as well as *in vivo* by intracerebroventricular injection. Studies have shown that a series of molecular mechanisms involved in synaptic plasticity, including protein phosphorylation, gene expression, and neurotransmitter release, were regulated by VDCC^[15]. LTP induced in different areas of the hippocampus has an intimate relationship with VDCC^[16]. The inhibition of I_{HVA} by Al at low concentrations could lead to a reduction in calcium influx, resulting in the reduced release of some neurotransmitters, which might explain impaired LTP in this concentration range. Aluminum increased the amplitude of I_{HVA} at high concentrations and, thus, led to increased calcium influx, resulting in a series of pathological changes, which could cause impairment of LTP and neuronal damage.

In our study, the actions of Al on I_{HVA} differed at different concentrations; thus, it is possible that the mechanism of action is different at different Al concentrations. Protein phosphorylation modulates the function of VDCC and the AC-cAMP-PKA system plays a key role^[17]. Thus, forskolin and H-89 were used to investigate whether the action of Al on I_{HVA} is involved in this mechanism. H-89 markedly abolished the increase of I_{HVA} by Al 1.0 mmol/L. Co-superfusion with forskolin plus Al at high concentrations caused more Ca^{2+} influx. Together these results indicate that an Al-induced increase in I_{HVA} possibly results from activating cAMP-PKA. However, H-89 did not reverse the action of $AlCl_3$ totally, suggesting that other mechanisms must contribute to its action on I_{HVA} at high concentrations.

Platt^[7] reported that the interactions of aluminum with two different binding sites (within and outside) of calcium channels might contribute to the reduction of VDCCs on DRG neurons. Al has been reported to inhibit Mg-dependent enzymes and to interact with phosphorylation sites^[18]. In the present study, the co-application of forskolin and Al did not cancel the reduction and the action of 0.1 mmol/L Al was not affected by H-89, indicating that the mechanism by which Al reduces I_{HVA} at low concentrations might not be involved in the cAMP-PKA system. In addition, Gin B effectively canceled the increase of I_{HVA} by Al at high concentrations, but had almost no effect on the reduction of I_{HVA} by Al at low concentrations, further suggesting that the

action of Al at low concentrations on I_{HVA} occurs via a different mechanism. The mechanism by which Al reduced I_{HVA} requires further examination. At intermediate concentration ranges, Al both reduced and enhanced I_{HVA} . The mechanism is not known, but may result from a difference in neurons or from the concentration of Al itself, which indicated that this concentration might be the point at which I_{HVA} moves from being inhibited to enhanced and this might be the reason for its complexity and diversity.

EGb is a complex mixture containing 24% flavonoid glycosides, 6% terpene lactones, such as ginkgolide A, B, C, J and bilobalide, a number of organic acids, and various other constituents. Studies have shown that Gin B has many pharmacological effects (ie preventing atherosclerosis, diminishing coagulation of platelets, ameliorating the circulation system) and has a distinctively protective effect on the central nerve and cardiovascular systems. Clinical studies have shown that oral administration of *EGb* in human patients with dementia is effective^[19]. Gin B can protect cardiomyocytes and cultured neurons from injury by hypoxia and ischemia through many pathways, for example, by acting as an anti-oxidant^[20], acting as the antagonist of platelet-activating factor^[21] and by inhibiting NO-stimulated PKC activity^[22]. Furthermore, Gin B has been shown to prevent neurons from glutamate excitotoxicity through a reduction in $[Ca^{2+}]_i$ ^[23] and to have an effect on the glycine-gated chloride channel^[24]. The present study provides the first evidence that Gin B can cancel the increase of I_{HVA} by Al, and that Gin B can protect neurons by inhibiting I_{HVA} , providing a possible mechanism for clinical treatment in a number of nervous system diseases. The detailed mechanism by which Gin B inhibits I_{HVA} remains to be investigated.

Abstract

Aim: To examine whether the protective effect of remifentanil preconditioning (RPC) on postischemic hearts is mediated by protein kinase (PKC) activation in comparison with ischemic preconditioning (IPC). **Methods:** Male Sprague-Dawley rats were anesthetized and their chests were opened. The experiment was performed with chelerythrine (CHE, 2 mg/kg), GF109203X (0.05 mg/kg) protein kinase C (PKC) inhibitors administered before RPC (remifentanil 6 $\mu\text{g}\cdot\text{kg}^{-1}\cdot\text{min}^{-1}\times 3$ cycle) or IPC, respectively. Infarct size (IS), as a percentage of the area at risk (AAR), was determined by triphenyltetrazolium staining. **Results:** In groups subjected to IPC and RPC the IS/AAR were significantly reduced (IS/AAR from 52.7% \pm 5.5% to 12.9% \pm 3.4%, $P < 0.01$ vs CON and 16.2% \pm 6.4%, $P < 0.01$ vs CON), respectively. CHE and GF, both PKC inhibitors, administered 5 min before RPC or IPC completely abolished the cardioprotective effect of RPC (IS/AAR: CHE+RPC 51.2% \pm 5.0%, GF+RPC 53.6% \pm 6.1%, $P > 0.05$ vs CON) or IPC (CHE+IPC 53.7% \pm 4.3%, GF+IPC 54.1% \pm 6.2%, $P > 0.05$ vs CON). The difference was not significant in any of the hemodynamic parameters between control and treatment groups during ischemia and reperfusion. **Conclusion:** Remifentanil confers myocardial protection against ischemic injury through a mechanism that is similar to IPC and involves PKC activation.

Introduction

Several studies found opioids preconditioning had a protective effect on the postischemic heart^[1–5]. Remifentanil has been demonstrated to mimic the cardioprotective effect of ischemic preconditioning (IPC) in anesthetized open-chest rats, which reduced infarct size (IS) dose-dependently^[5].

Remifentanil is an ultra-short-acting phenylpiperidine opioid analgesic agent, which is rapidly metabolized by non-specific blood and tissue esterases^[6]. It has an analgesic potency similar to fentanyl and 100 times greater than morphine^[7]; the opioids that have been most extensively studied in cardioprotection. The effect of remifentanil preconditioning (RPC) was abolished by blockade of any one of the μ -, δ -, and κ -opioid receptors (OR). This means all three OR are involved in cardioprotection by RPC^[5].

Opioid-induced cardioprotection and IPC seem to share

a common pathway^[8,9]. Several studies have demonstrated that fentanyl and morphine significantly reduced IS, and that this effect was blocked by the protein kinase C (PKC) inhibitor chelerythrine (CHE)^[4,10]. However, no study has examined the role of PKC in the protection conferred by remifentanil-induced preconditioning.

Therefore, we decided to examine whether the protection effect of RPC on postischemic hearts was mediated by PKC in comparison with IPC.

Materials and methods

Surgical preparation Our preparation and measurements have been described previously in detail^[5]. Briefly, male Sprague-Dawley rats weighing 300 to 350 g were used. The rats were anesthetized by intraperitoneal administration of pentobarbitone (50 mg/kg bodyweight) and maintained by

repeat doses of 25 mg/kg every 60–90 min. All of the animals underwent tracheotomy and endotracheal intubation. Mechanical ventilation was provided with a Harvard Apparatus Rodent Respirator (Boston, MA, USA) and the rats were ventilated with room air at 60 to 70 breaths per min. Body temperature was monitored and maintained at 37 ± 1 °C (mean \pm SD) using a heating pad. The carotid artery was cannulated to measure mean blood pressure (MBP) via a pressure transducer, and a Lead-II electrocardiogram, via subcutaneous stainless steel electrodes, monitored heart rate (HR). These were connected to a PowerLab monitoring system (ML750 PowerLab/4sp with MLT0380 Reusable BP Transducer, AD Instruments, USA). The right jugular vein was cannulated to infuse saline or drugs. A left thoracotomy was performed to expose the heart at the fifth intercostal space. After removing the pericardium, a 6-0 Prolene loop, along with a snare occluder, was placed at the origin of the left coronary artery (LCA). Regional ischemia was achieved by pulling the snare and securing the threads with a mosquito hemostat. Ischemia was confirmed by a substantial fall in left ventricular pressure, ECG changes, and cardiac cyanosis. After surgical preparation, the rat was allowed to stabilize for 15 min.

Study groups and experimental protocol Rats were randomly assigned to one of nine groups. All animals received 30 min of occlusion of the left coronary artery followed by 2-h reperfusion: Group 1, Control (CON, saline vehicle); Group 2, chelerythrine^[11,12], (CHE, a PKC inhibitor, Sigma Chemical Co, Saint Louis, USA) 2 mg/kg iv 5 min before ischemia; Group 3, GF109203X^[12], (GF, another potent and selective PKC inhibitor, Tocris Cookson Ltd, Bristol, UK) 0.05 mg/kg iv 5 min before ischemia; Group 4, RPC, RPC hearts were subject to three 5-min cycles of infusion of remifentanyl (Glaxo Wellcome Operations, Greenford, Middlesex, UK) at $6\ \mu\text{g}\cdot\text{kg}^{-1}\cdot\text{min}^{-1}$ interspersed with 5-min drug-free periods before 30 min of occlusion of the left coronary artery and 2 h of reperfusion; Group 5, IPC, before the 30-min occlusion, rats were subjected to preconditioning by ischemia (IPC, 5-min occlusion, 5-min reperfusion \times 3); Group 6, CHE+RPC; Group 7, CHE+IPC (2 mg/kg, iv, 5 min before RPC or IPC); Group 8, GF +RPC; and Group 9, GF+IPC (0.05 mg/kg, iv, 5 min before RPC or IPC).

Determination of infarct size On completion of the reperfusion period, the heart was excised, transferred to a Langendorff apparatus, and perfused with normal saline for 1 min at a pressure of 100 cmH₂O to flush out blood. The snare was securely re-tightened and 0.25% Evans blue dye was injected to stain the normally perfused region of the heart. This procedure allowed visualization of the normal,

non-ischemic region and the area at risk (AAR). The heart was then weighed, frozen, and cut into 2-mm slices. Thereafter, the slices were stained by incubation at 37 °C for 20 min in 1% 2,3,5-triphenyltetrazolium (TTC, Sigma Chemical Co, Saint Louis, USA)^[1,13,14] in phosphate buffer (pH 7.4), and then were immersed in 10% formalin, to enhance the contrast of the stain. The areas of infarct (TTC negative) and risk zone (TTC stained) for each slice were traced and digitized using a computerized planimetry technique (SigmaScan 4.0, Systat Software Inc, CA, USA). The volumes of the left ventricles, IS and AAR were calculated by multiplying each area with slice thickness and summing the product. The IS was expressed as a percentage of the AAR (IS/AAR).

Statistical analysis Data analysis was performed with a personal computer statistical software package (Prism v4.0, GraphPad Software, San Diego, USA). Data were expressed as mean \pm SD. Hemodynamics were analyzed using 2-way analysis of variance (ANOVA) with *Bonferroni post-hoc* test for multiple comparisons if significant *F* ratios were obtained. IS (expressed as percentage of the area at risk) were analyzed between groups using ANOVA with a Student-Newman-Keuls *post-hoc* test for multiple comparisons. Statistical differences were considered significant if $P<0.05$.

Results

Effects of RPC and IPC on cardiac morphology LV+RV volume average was $0.99\pm 0.22\ \text{cm}^3$ and the AAR ranged from 0.378 ± 0.061 to $0.440\pm 0.056\ \text{cm}^3$. There was no difference in LV+RV and AAR between the control and treatment groups (Table 1). The IS, expressed as a percentage of the AAR, of the control group was $52.7\%\pm 5.5\%$. In groups subjected to IPC and RPC the infarct sizes were significantly reduced. IPC and RPC markedly reduced IS/AAR from $52.7\%\pm 5.5\%$ to $12.9\%\pm 3.4\%$ ($P<0.01$ vs CON) and $16.2\%\pm 6.4\%$ ($P<0.01$ vs CON), respectively. CHE 2 mg/kg, a PKC inhibitor, or GF 0.05 mg/kg, another selective PKC inhibitor, administered 5 min before RPC or IPC completely abolished the cardioprotective effect of RPC (IS/AAR: CHE+RPC $51.2\%\pm 5.0\%$, GF+RPC $53.6\%\pm 6.1\%$, $P>0.05$ vs CON) or IPC (CHE+IPC $53.7\%\pm 4.3\%$, GF+IPC $54.1\%\pm 6.2\%$, $P>0.05$ vs CON). Neither CHE nor GF by itself modified IS in non-PC hearts (Figure 1).

Effects of RPC and IPC on hemodynamics As shown in Table 2, administration of remifentanyl at $6\ \mu\text{g}\cdot\text{kg}^{-1}\cdot\text{min}^{-1}$ significantly reduced the HR, MBP, and RPP ($P<0.01$ vs baseline). HR in CHE+RPC or GF+RPC group was not reduced significantly after pretreated with remifentanyl, and the difference was significant compared with RPC group ($P<0.05$, respec-

tively). The bradycardia produced by remifentanyl was abolished with pretreatment of CHE or RPC. There was no difference in any of the hemodynamic parameters between control and treatment groups during ischemia and reperfusion.

Discussion

The present results demonstrated that remifentanyl conferred cardioprotection against injury induced by ischemic reperfusion, which was completely abolished by CHE and GF, both PKC inhibitors, and suggests that RPC, like IPC, protects myocardium by a mechanism that involves PKC activation.

Miki *et al*^[10] found that the cardioprotective effect of morphine could be blocked by the PKC inhibitor CHE and

OR participate in the triggering effect of IPC through activation of PKC. Also, Kato *et al*^[4] suggested that fentanyl limited infarction size through mediation by PKC activation. Our data showed that CHE or GF abolished the protective effect of RPC, suggesting that like morphine and fentanyl, the protective effect of RPC on postischemia myocardial injury is mediated by a PKC activated pathway. In agreement with previous studies, we also found blockade of PKC abolished the effect of IPC.

The cellular mechanisms by which RPC exerts its postischemic protective action are unknown. Ligand-binding data show that remifentanyl has a high degree of μ -opioid receptor selectivity (EC_{50} =2.6 nmol/L) with a lower affinity for δ (EC_{50} =66 nmol/L) and κ (EC_{50} = 6.1 μ mol/L) opioid receptors. Previously, we found remifentanyl reduced IS dose-dependently in open chest anesthetized rats^[5]. The protective effect of RPC was abolished by all three OR antagonists CTOP, naltrindole, and nor-binaltorphimine, indicating that the effect of remifentanyl is mediated via μ -, δ -, and κ -OR^[5]. The OR are known to couple to pertussis toxin sensitive G proteins such as G_i or G_o ^[15,16]. If opioid receptors act by activation of PKC, then they must couple to a phospholipase. In the heart, δ - and κ -OR stimulation could increase the level of inositol 1,4,5-triphosphate, suggesting phospholipase C or D-mediated turnover of phosphatidylinositol^[17]. Opioids are linked to PKC and are therefore putative mediators in RPC or IPC.

Furthermore, intracellular signaling pathways, which mediate subtype of the OR-induced cardioprotection have been studied previously. Fryer *et al*^[12] found that TAN-67, a selective δ_1 -OR agonist, had an IS reduction effect that was abolished by CHE and GF, two PKC inhibitors that act on different binding sites on PKC to produce an inhibitory effect. In contrast, our lab showed that the cardioprotection of

activation of κ-OR and IPC was significantly attenuated by blockade of PKC with PKC inhibitor CHE in the isolated rat heart^[14,18,19] and myocytes^[19]. These results provided evidence that the effect of RPC on postischemic hearts was partially mediated via a PKC activated pathway.

The role of PKC in IPC and opioid-induced PC is not fully understood^[20,21]. Generally, opioids activate δ- and κ-OR, which lead to PKC activation. Activated PKC acts as an amplifier of the preconditioning stimulus and stabilizes, by phosphorylation, the open state of the mitochondrial K_{ATP} channel and the sarcolemmal K_{ATP} channel. PKC-δ translocation seems to be responsible for activating mitochondrial K_{ATP} channels and PKC-ε translocation for the establishment of late preconditioning by phosphorylating nuclear targets. The opening of K_{ATP} channels ultimately elicits cytoprotection by decreasing cytosolic and mitochondrial Ca²⁺ overload^[22].

Although our data also show that pretreatment with PKC inhibitor CHE or GF could prevent HR from decreasing led by RPC, the difference was significant among all treatment groups and control. It suggests that PKC is also involved in the bradycardia response of remifentanyl.

We conclude that RPC limits infarction in open chest rat hearts via PKC activation mechanism, which mimics the effect of IPC.

Abstract

Aim: To examine the effects of ginseng saponins on the heterologously expressed human ether-a-go-go related gene (HERG) that encodes the rapid component of the delayed rectifier K⁺ channel. **Methods:** A two-electrode voltage clamp technique was used. HERG currents were recorded in *Xenopus oocytes* injected with HERG cRNA. **Results:** Crude saponins of Korean red ginseng (GS) induced a minimal increase of the maximal HERG conductance without changes in the voltage-dependent HERG current activation and inactivation curves. GS, however, decelerated HERG current deactivation in a concentration-dependent manner, which was more noticeable with panaxitriol (PT) than panaxidiol (PD). Consistently, ginseng saponins increased the HERG deactivation time constants with the order of potency of Rg₁ (a major component of PT) > Rf₁ > Rb₁ (a major component of PD). Re had little effect on HERG deactivation. During a cardiac action potential, GS increased the outward HERG current. **Conclusion:** Ginseng saponins enhance HERG currents, which could be in part a possible mechanism of the shortening cardiac action potential of ginseng saponins.

Introduction

Ginseng, the root of *Panax ginseng* CA Meyer, has been used for more than 2 000 years as a general tonic and restorative agent. Ginseng saponins, also called ginsenosides, are one of the main molecular ingredients responsible for the actions of ginseng. Ginseng saponins have beneficial effects on cardiovascular functions^[1,2], including the antihypertensive effect^[3], the protective effect against ischemia/reperfusion injury^[4], the negative chronotropic and inotropic effects^[5], and the antiarrhythmic effect^[6,7].

The delayed rectifier K⁺ current is critical for repolarization of cardiac action potential^[8], which represents the sum of two components; the rapidly (I_{Kr}) and slowly activating components (I_{Ks})^[9]. The human ether-a-go-go-related gene (HERG) is expressed in the heart of mammalian species including humans^[10]. It encodes the pore-forming subunit of I_{Kr} ^[11,12], which initiates repolarization and terminates the plateau phase of the cardiac action potential. Heterologously

expressed HERG currents share pharmacological and biophysical properties with I_{Kr} . It has been shown that channels formed by coexpression of MinK-related protein, MiRP1 and HERG resemble native cardiac I_{Kr} channels^[13]. Mutations in the HERG channel gene cause inherited long QT syndrome (LQT), a disorder of cardiac repolarization that predisposes affected individuals to lethal arrhythmias^[11,14]. Acquired LQT is far more common and is most often caused by commonly used medications blocking cardiac HERG channels^[15–18]. Thus I_{Kr} /HERG is especially relevant to both acquired and inherited forms of LQT^[19,20].

Ginseng saponins decreased the action potential duration of cardiac myocytes^[21,22] and showed antiarrhythmic effects^[6,7]. HERG/ I_{Kr} has been regarded as a common target of pro- and anti-arrhythmic drugs^[19]. Therefore, it can be assumed that ginseng saponins may shorten action potential duration and exert antiarrhythmic effects by altering HERG channel activities. To investigate the possibility, we examined the effect of ginseng saponins on the HERG current

expressed in *Xenopus* oocytes. We found that ginseng saponins enhanced the HERG current in a concentration- and structure-dependent manner during cardiac action potential.

Materials and methods

Oocyte preparation Ovarian lobes were excised from anesthetized *Xenopus laevis* (Xenopus I, Dexter, MI, USA) through a small abdominal incision and were treated with Ca^{2+} -free Barth's solution containing 0.2% collagenase (type II, Sigma-Aldrich, St Louis, MO, USA) for 1–2 h and then the remaining inner ovarian epithelium, theca, and follicular cell layers were removed with fine forceps. The composition of Ca^{2+} -free Barth's solution was as follows (mmol/L): NaCl 88.7, KCl 1.0, NaHCO_3 2.4, $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$ 0.8, HEPES 5 (pH=7.5). Only healthy, stage V or VI oocytes were selected for cRNA injection. cRNA of HERG was synthesized from the linearized cDNA using an *in vitro* transcription kit (Ambion, Austin, TX, USA) and stored at -80°C until used. Denuded oocytes were then injected manually with 50 nL cRNA (0.3–1.0 g/L) using a glass capillary connected with a microdispenser (VWR Scientific, West Chester, PA, USA). For controls, oocytes were either injected with 50 nL distilled water or left uninjected. After injection, oocytes were cultured at 18°C in Barth's solution containing (mmol/L): NaCl 88.0, KCl 1.0, NaHCO_3 2.4, $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$ 0.8, $\text{Ca}(\text{NO}_3)_2 \cdot 4\text{H}_2\text{O}$ 0.3, CaCl_2 0.4, HEPES 5 (pH=7.5), supplemented with pyruvate 2 mmol/L and gentamicin sulfate 50 mg/L. The culture medium was changed daily. Currents were recorded 2–7 d after injection.

Whole cell current recording in *Xenopus* oocytes HERG currents were recorded using a two-electrode voltage-clamp amplifier (OC-725C; Warner Instruments, Hamden, CT, USA) from the oocytes placed in the recording chamber (2.0 mL) superfused with Oocyte-Ringer solution containing (mmol/L): NaCl 96.0, KCl 2.0, MgCl_2 1.0, $\text{CaCl}_2 \cdot 2\text{H}_2\text{O}$ 1.8, HEPES 5.0 (pH=7.5). Stimulation and data acquisition were controlled with Digidata 1200 (Axon Instruments, Union City, CA, USA) and pClamp 6.04 (Axon Instruments). Electrodes were fabricated from glass capillaries containing an inner filament (OD 1.5 mm, ID 1.12 mm; WPI, Sarasota, FL, USA). Electrodes filled with 3 mol/L KCl had a resistance of 1–2 $\text{M}\Omega$ for current-passing electrodes and 2–4 $\text{M}\Omega$ for voltage-recording electrodes.

Data analysis The voltage dependence of HERG current activation was determined for each oocyte by fitting peak values of tail current (I_{tail}) versus test potential (V_t) to Boltzmann's function:

$$I_{\text{tail}} = \frac{I_{\text{tail}}^{\text{max}}}{1 + \exp\left(\frac{V_{1/2} - V_t}{k}\right)}$$

where $I_{\text{tail}}^{\text{max}}$ is maximum tail current, $V_{1/2}$ is the voltage at which 50% of the channels are activated, and k is the slope factor. To examine steady-state inactivation, conditioning pulses between -130 and $+20$ mV in 10-mV increments for 60 ms were applied after a depolarizing pulse to $+20$ mV for 900 ms, followed by a common test pulse to $+20$ mV. The peak current amplitudes during test pulses were plotted as a function of the previous conditioning pulses. Normalized steady-state inactivation as a function of prepulse of test potential was also fitted to Boltzmann's function. The data were expressed as mean \pm SEM. Statistical analysis were carried out using one-way ANOVA or Student *t*-test when appropriate.

Drugs All drugs except ginsenosides were purchased from Sigma. Lyophilized ginsenosides were kindly donated by Dr PARK of Korean Tobacco and Ginseng Institute.

Results

The HERG potassium current was recorded by a two-electrode voltage-clamp from the *Xenopus* oocyte expression system. Steady-state current was recorded by depolarization to potentials between -60 and 40 mV and the holding potential was maintained at -80 mV for 4 s. Tail currents were recorded upon repolarization to -60 mV. This voltage protocol was repeated and the amplitude of the current was monitored until no changes in current amplitude could be recorded for 3 min. Figure 1 shows current records obtained in the absence or the presence of 30 mg/L crude saponin of Korean red ginseng (GS). HERG current amplitudes and deactivation kinetics were changed by bath application of GS, but not by intraoocyte injection of the same concentration of GS (30 mg/L).

Figure 2A shows the effect of extracellular GS (30 mg/L) on the amplitude of steady-state current that was measured at the end of depolarizing pulse and peak tail current. The steady-state current first appears at -50 mV test potential, and the peak tail current is maximal at $+10$ mV test potential. GS (30 mg/L) induced a minimal increase in steady-state current and peak tail currents (Figure 2A, 2B). The increase of steady-state currents were observed only at more negative membrane voltages than 0 mV, where HERG channel inactivation was observed, while the increase of peak tail currents were observed at all tested voltages. Drugs that changed ion channel activities often alter the voltage dependence of channel kinetics. Therefore, we analyzed the

Figure 1. Selective effect of ginseng saponins (GS) on HERG current expressed in *Xenopus* oocyte. Traces of HERG current were recorded before and after exposure to 30 mg/L GS for 10 min with intra-oocyte injection (A) and bath application (B). Voltage protocol consisted of depolarizing steps from a holding potential of -80 mV in 10 mV increments from -60 to +40 mV for 4 s and repolarizing step to -60 mV for 6 s (inset). Steps were repeated at 30 s intervals.

Figure 2. Effect of ginseng saponins (GS) on voltage-dependent kinetics and maximal conductance of HERG current. (A) Current-voltage relation curves were plotted from the current measured at the end of depolarizing test pulse ranging from -60 to +40 mV (4 s in 10 mV increments) from a holding potential of -80 mV ($n=6$). (B) Voltage-dependent activation curves plotted from peak tail currents during a repolarizing step to -60 mV after depolarizing to various voltages ($n=6$). (C) Steady-state inactivation curves of HERG channels before and after GS exposure. Solid lines indicate the product of the fitted steady-state inactivation curves with Boltzmann's equation on experimental data. (D) Current-voltage plot was obtained from peak tail currents ranging from -130 to +20 mV following a 750-ms prepulse to +40 mV from a holding potential of -80 mV. To clarify the change of slope conductance, current amplitudes were plotted between -130 and -50 mV. $n=6$. Mean \pm SEM. ^b $P<0.05$ vs control.

voltage dependence of activation of the HERG current in the absence or presence of GS. Peak amplitudes of tail currents were plotted as a function of test potential as shown in Figure 2B, and were fitted with Boltzmann's function. In the control experiment, the activation curve had a mid-point of -18.1 ± 2.2 mV and a slope factor of 6.5 ± 0.2 mV ($n=6$), which is similar to previous reports^[12,23]. In the presence of GS (30 μ mol/L), a mid-point of -19.6 ± 1.9 mV and a slope factor of 7.1 ± 0.2 mV ($n=6$), the difference compared with control was not significant.

We also analyzed the steady-state HERG inactivation in the absence and presence of GS. Steady-state inactivation currents were measured with the following protocol: channels were inactivated at a holding potential of +20 mV before short test pulses. Potentials ranging from -120 mV to +20 mV (15 ms, 10 mV-increments) were applied to recover the channels from inactivation. Membrane potential returned to a holding potential of +20 mV after these test pulses evoked large outward inactivating currents. After having obtained a measurement under control conditions, the oocyte was clamped at a holding potential of -80 mV during a 10-min wash (30 mg/L GS), which was necessary to avoid destruction of the cell. Peak outward current amplitudes after the return to the holding potential were normalized and fitted to Boltzmann's function, which elicited significant left shift in the steady-state inactivation curve ($n=6$, Figure 2C). In the absence of GS, the inactivation curve had a mid-point of -69.7 ± 2.8 mV and a slope factor of -11.6 ± 0.8 mV ($n=6$). These values were -78.7 ± 4.5 mV and -15.3 ± 0.7 mV ($n=6$), respectively, in the presence of GS (30 mg/L, 10 min).

To examine whether the increase in HERG current represents the change in HERG conductance, we measured maximal HERG conductance in the absence or presence of GS. For this purpose, we studied the fully activated *I-V* relationships by applying various test potentials after a depolarizing conditioning pulse (Figure 2D). A conditioning pulse to +40 mV, which induced a full activation, for 750 ms was applied from a holding potential of -80 mV, followed by test pulses to various potentials between -130 and +20 mV in 10-mV increments. The amplitude of the current was measured at its peak before the time-dependent change proceeded, and plotted as a function of test potential. GS increased maximal HERG conductance obtained from the slope of the curve (Figure 2D). The slope conductance was obtained from the slope of the *I-V* curves between -130 and -110 mV. The value of the slope was 0.11 ± 0.01 and 0.14 ± 0.01 for control and 30 mg/L GS (Figure 2D).

To evaluate the most prominent effect of GS on HERG current, decelerating current deactivation, we analyzed the

time constant for the deactivation of HERG tail current. For this purpose, we used long hyperpolarizing test pulses following a depolarizing conditioning pulse (Figure 3A). Deactivating currents during test pulses were well fitted to a double-exponential function. GS (3–30 mg/L) increased both fast and slow deactivation time constants of HERG tail current in a concentration-dependent change at all repolarizing tested voltage. The fast deactivation time constants at repolarizing test voltage of -60 mV were increased from 1.5 ± 0.3 s of control to 2.2 ± 1.1 , 3.2 ± 1.0 , 4.1 ± 1.0 , and 5.1 ± 1.2 s by GS 3, 10, 30, and 100 mg/L, respectively (Figure 3B). The slow deactivation time constants at -60 mV of control were increased from 6.0 ± 1.4 s to 7.0 ± 0.3 , 9.2 ± 1.0 , 11.1 ± 1.2 , and 17.0 ± 2.7 s by GS 3, 10, 30, and 100 mg/L, respectively (Figure 3B).

GS may include many different ginsenosides classified into panaxadiol (PD) and panaxatriol (PT) saponins according to their chemical structures. To know the possible structure-dependent effect of ginsenosides on HERG current, we examined the effect of PD and PT on the deactivation of the HERG tail current. PT evoked more potent deceleration of the HERG deactivation than PD did (Figure 4A). Consistently, deceleration of HERG current was more pronounced by ginsenoside Rg₁ and Rf₁ the major components of Korean red ginseng (KRG) PT than by ginsenoside Rb₁, the major component of PD (Figure 4B). Interestingly, another PT ginsenoside, Re had little effect on HERG current.

To evaluate the physiological significance of enhancement of HERG by ginsenoside, we examined the effects of GS on repolarizing currents with ramp pulses. In the ramp protocol that involved an initial step depolarization from -80 to +10 mV, followed by a slow ramp (1.7 s) to -80 mV, GS (10 mg/L), induced a significant enhancement of the outward current upon slow repolarization (Figure 5).

Finally, we investigated the possible subcellular mechanism of GS effects on HERG currents. We used PTX to test the possible involvement of PTX-sensitive G-protein in GS effects on HERG currents. Pretreatment with PTX (2 mg/L, 16 h), however, did not affect HERG current modulation by GS (Figure 6A). To examine whether the intracellular Ca²⁺ was involved in the modulation of HERG current, we used intracellular Ca²⁺ buffer, BAPTA. Intraoocyte injection of BAPTA had no effect on GS modulation of the HERG current (Figure 6B).

Discussion

We have shown that ginsenosides enhance the HERG current expressed in *Xenopus* oocytes. Ginsenosides are

Figure 3. Effects of ginseng saponin on HERG current deactivation. (A) Representative HERG deactivation before and after exposure to GS. Currents were stimulated by a 2 s prepulse to +20 mV followed by test pulses ranging from -80 to -50 mV for 23 s. (B) Effects of different concentrations (3–100 mg/L) of ginseng saponin on HERG deactivation time constants. The deactivation time constants were determined from tail currents recorded during the long-lasting test potentials. Current decay was fitted with a double exponential function. $n=7$ experiments. Mean \pm SEM. ^b $P < 0.05$ vs control.

Figure 4. Effects of various ginsenosides on HERG current deactivation. Effects of panaxadiol (PD) and panaxatriol (PT) saponins (A), and ginsenoside Rg₁, Rf₁, Re, and Rb on HERG current deactivation (B). The pulse protocol is the same as in Figure 3. The fast and slow deactivation time constants of HERG were shown before and after the application of ginsenosides (30 mg/L). $n=4-6$ experiments. Mean \pm SEM. ^b $P < 0.05$, ^c $P < 0.01$ vs control.

Figure 5. Effects of ginseng saponin (GS) on the HERG current during cardiac action potential. Representative current traces recorded during voltage protocol mimicked cardiac action potential in the absence and presence of GS (30 mg/L). HERG currents were stimulated by depolarization pulse to +10 mV following repolarization pulse to -80 mV for 500 ms (inset).

known to be effective against cardiac arrhythmias and elicit APD shortening and I_{K_r} inhibition^[21]. It is well known that heterologously expressed HERG currents share pharmacological and biophysical properties with I_{K_r} ^[11,12,24,25]. The characteristics of the current recorded in the present study correspond to HERG current; slow current activation at negative potentials, large long-lasting tail currents on repolarization, strong inward rectification and sensitivity to class III methanesulfonanilides (data not shown). The present study is the first to characterize the interaction between ginseno-

sides and the HERG channels. The major finding of the present study was that ginsenosides enhanced HERG channel activities in a structure- and concentration-dependent manner. Considering all of this, ginsenosides may induce APD shortening partly through enhancement of HERG/ I_{K_r} as well as I_{K_s} ^[21]. This finding provides a clearer ionic mechanism of the antiarrhythmic effect of ginsenosides. That is, HERG is another target of ginsenosides.

Mutations in HERG that cause LQT can reduce the amplitude of I_{K_r} by several different mechanisms. The most common mechanism is a loss of channel function and a dominant negative effect^[26]. Therefore mutation in HERG also accelerated the rate of channel deactivation and would cause a net reduction in outward current during slow repolarization typical of a cardiac action potential. In the present study, we have shown that GS increased the maximal conductance of HERG potassium channel and it also increased the deactivation time constants of HERG potassium current. Our results, therefore, indicate that the effects of GS on HERG potassium channel may improve the LQT through speed repolarization and shorten the action potential.

To clarify the biophysical mechanism of HERG potentiation by ginsenosides, we analyzed the effect of ginsenosides on HERG current using various pulse protocols. The results suggest that ginsenosides affect preferentially the deactivation of HERG channels with a maximal conductance increase. The rate of recovery from inactivation and the rate

Figure 6. Effect of ginseng saponin (GS) on HERG current in different conditions. Deceleration of HERG current deactivation by GS was not altered by extracellular PTX pretreatment (2 mg/L, 16 h) (A) or by intra-oocyte injection of BAPTA (1 mmol/L) (B). Representative currents stimulated by a series of step pulses. The pulse protocol is the same as in Figure 4.

of deactivation are major HERG channel kinetic factors determining the duration of the action potential^[27]. HERG modulation is expected to speed repolarization and shorten the action potential, which could decrease the inter-spike interval and accelerate the heart rate.

How might a GS contribute to the enhancement of HERG potassium current? The heart is presented with continually varying cardiovascular demands that require dynamic responses, both inotropic and chronotropic. Most cardiac adaptation that occurs is the result of changes in autonomic/hormonal stimulation involving G-protein-coupled receptors^[28]. In a previous study, ginsenosides were shown to increase the Ca²⁺-activated Cl⁻ current in *Xenopus* oocytes through a signaling pathway linked to the muscarinic ACh receptor, which involves G protein-coupled PLC activation and Ca²⁺ mobilization from IP₃-sensitive intracellular store^[29]. In our experiments, the effects of GS on HERG potassium currents were not blocked by intracellular Ca²⁺ chelation and intraoocyte injection of BAPTA nor pretreatment with PTX (2 mg/L, 16 h) (Figure 6A, 6B). Therefore, it should be noted that ginsenoside Rf could regulate GIRK channels with unidentified proteins derived from the rat brain through PTX-insensitive G proteins^[30]. However, we still cannot exclude the possibility of direct interaction between ginsenosides and HERG channel proteins.

Approximately 30 different ginsenosides have now been isolated and identified from *Panax ginseng*. Studies have shown that certain ginsenosides are more potent than others^[31]. It should be noted that ginsenoside Re had no effect on HERG currents, showing the structure-dependence of HERG modulations by ginsenosides. HERG currents were enhanced by PT and PD as well as by ginsenoside Rb₁, Rg₁, and Rf with different potency. Crude saponin of KRG used in this experiment contained 56.3% of ginsenosides. Therefore, the effect of KRG-CS on the HERG potassium current was mainly a result of the saponin fraction of KRG.

Synthetic molecules such as fenamates and other openers of the K⁺ channel offer a novel therapeutic approach to stabilizing and controlling cellular function^[32]. Our results, demonstrate for the first time a link between ginseng saponin and the electrophysiological properties of the HERG channel. The positive regulation by ginseng saponin on HERG and the previously described effects on I_{Ks}^[21,22], suggest a potential role for ginseng saponin in the prevention or treatment of long QT syndrome.

Abstract

Aim: To compare the effects of AMP579 and adenosine on L-type Ca^{2+} current ($I_{\text{Ca-L}}$) in rat ventricular myocytes and explore the mechanism by which AMP579 acts on $I_{\text{Ca-L}}$. **Methods:** $I_{\text{Ca-L}}$ was recorded by patch-clamp technique in whole-cell configuration. **Results:** Adenosine (10 nmol/L to 50 $\mu\text{mol/L}$) showed no effect on basal $I_{\text{Ca-L}}$, but it inhibited the $I_{\text{Ca-L}}$ induced by isoproterenol 10 nmol/L in a concentration-dependent manner with the IC_{50} of 13.06 $\mu\text{mol/L}$. Similar to adenosine, AMP579 also showed an inhibitory effect on the $I_{\text{Ca-L}}$ induced by isoproterenol. AMP579 and adenosine (both in 10 $\mu\text{mol/L}$) suppressed isoproterenol-induced $I_{\text{Ca-L}}$ by 11.1% and 5.2%, respectively. In addition, AMP579 had a direct inhibitory effect on basal $I_{\text{Ca-L}}$ in a concentration-dependent manner with IC_{50} (1.17 $\mu\text{mol/L}$). PD116948 (30 $\mu\text{mol/L}$), an adenosine A_1 receptor blocker, showed no action on the inhibitory effect of AMP579 on basal $I_{\text{Ca-L}}$. However, GF109203X (0.4 $\mu\text{mol/L}$), a special protein kinase C (PKC) blocker, could abolish the inhibitory effect of AMP579 on basal $I_{\text{Ca-L}}$. So the inhibitory effect of AMP579 on basal $I_{\text{Ca-L}}$ was induced through activating PKC, but not linked to adenosine A_1 receptor. **Conclusion:** AMP579 shows a stronger inhibitory effect than adenosine on the $I_{\text{Ca-L}}$ induced by isoproterenol. AMP579 also has a strong inhibitory effect on basal $I_{\text{Ca-L}}$ in rat ventricular myocytes. Activation of PKC is involved in the inhibitory effect of AMP579 on basal $I_{\text{Ca-L}}$ at downstream-mechanism.

Introduction

Recent studies showed that AMP579 was a novel adenosine agonist with high affinity for adenosine A_1 and A_2 receptors^[1,2]. Experiments in animal models have demonstrated that AMP579 reduced infarct size by 50% to 98% when administered before a final ischemic event (mediation of ischemic preconditioning) or just before reperfusion (attenuation of reperfusion injury)^[3,4]. Further experiments on pigs, dogs, and rabbits suggested that AMP579 was more powerful than adenosine in attenuating polymorphonuclear neutrophil-mediated inflammatory responses, dilating the coronary artery, reducing myocardial contracture and limiting infarct size^[5,6]. Although the protective effect of AMP579 required adenosine receptor activation, adenosine could not duplicate the effects.

The difference between pharmacologic effect of AMP579

and adenosine might reflect the differences in ionic mechanisms. It has been established that adenosine could cause an attenuation of basal $I_{\text{Ca-L}}$ only in unstimulated atrial myocytes, but under conditions of isoproterenol stimulation, adenosine could markedly attenuate isoproterenol induced- $I_{\text{Ca-L}}$ in both atrial and ventricular myocytes. However, little is known about the electrophysiological effects of AMP579 so far. This study will examine the effects of AMP579 and adenosine on L-type calcium channel and elucidate the mechanisms underlying the cardioprotective effect of AMP579 and its utility in treatment of myocardial ischemia-reperfusion injury.

Materials and methods

Rat myocardial cell isolation Ventricular myocytes were obtained from Wistar male rats (250–300 g) by enzymatic

isolation procedure. In brief, rats were killed by cervical dislocation and the heart was then immediately removed, cannulated through the aorta and perfused through the coronary artery with Ca^{2+} -free Tyrode's solution for 10 min. The composition of Ca^{2+} -free Tyrode's solution was: NaCl 140.0 mmol/L, KCl 5.4 mmol/L, MgCl_2 1.0 mmol/L, NaH_2PO_4 0.3 mmol/L, glucose 10.0 mmol/L, HEPES 5.0 mmol/L; pH adjusted to 7.4 with NaOH at room temperature. The heart was then perfused with enzymatic solution, which was low Ca^{2+} (CaCl_2 150 $\mu\text{mol/L}$) Tyrode's solution with collagenase P (0.3g/L) for about 8–10min. The left ventricle was then removed. The cells were isolated by gentle agitation and kept in Krebs buffer (KB) solution, which contained: KOH 85.0 mmol/L, *L*-glutamic acid 50.0 mmol/L, KCl 30.0 mmol/L, taurine 20.0 mmol/L, KH_2PO_4 30.0 mmol/L, MgCl_2 1.0 mmol/L, HEPES 10.0 mmol/L, glucose 10.0 mmol/L and egtazic acid 0.5 mmol/L; pH adjusted to 7.4 by KOH.

Electrophysiological measurement Whole-cell patch-clamp was used to record $I_{\text{Ca-L}}$ (L-type Ca^{2+} currents) and membrane capacitance was measured with a P-clamp 5.51 software package (Axon Instruments, USA). Patch electrodes were made from thin-walled glass capillaries (1.5 mm outside diameter) using a two-stage vertical microelectrode puller (model PP-83, Narishige Scientific Instruments, Japan). The electrode resistance ranges 3 $\text{M}\Omega$, when filled with pipette solution.

For the measurement of $I_{\text{Ca-L}}$, the extracellular solution contained: NaCl 140.0 mmol/L, CaCl_2 1.8 mmol/L, MgCl_2 1.0 mmol/L, KCl 5.4 mmol/L, glucose 10.0 mmol/L, NaH_2PO_4 0.3 mmol/L, and HEPES 10.0 mmol/L; pH adjusted to 7.4 with NaOH. The pipette solution contained: egtazic acid 10.0 mmol/L, KCl 140.0 mmol/L, Na_2ATP 2.0 mmol/L, HEPES 5.0 mmol/L, 4-AP 5.0 mmol/L, MgCl_2 1.0 mmol/L; pH adjusted to 7.4 with KOH. The calcium current was expressed as membrane current density (pA/pF). The cell capacitance was measured by the method previously described by Coetzee *et al*^[9]. $I_{\text{Ca-L}}$ was measured according to the method described by Hartzell *et al*^[10]. The AMP579 was a gift from Department of Cardiothoracic Surgery Research Laboratory, Emory University School of Medicine, USA. AMP579 was dissolved in small volumes of Me_2SO , then diluted to the desired final concentration before each experiment.

Statistic analysis Data were expressed as mean \pm SD. Statistical significance was determined by Student's *t*-test and $P < 0.05$ was considered significant.

Results

Detection of L-type calcium channel current The cal-

cium current was activated by depolarizing pulse from a holding potential of -40 mV to +10 mV at 50 mV step-voltage. This inward current could be completely inhibited by 1 $\mu\text{mol/L}$ verapamil, the basic characteristics indicated that the current present in rat ventricular myocytes was L-type Ca^{2+} current.

Effect of AMP579 and adenosine on L-type calcium current In the presence of adenosine at 10 nmol/L, 1, 10, and 50 $\mu\text{mol/L}$, $I_{\text{Ca-L}}$ varied from 4.9 ± 0.9 to 4.8 ± 0.9 , 4.9 ± 0.9 , 4.9 ± 0.9 , 4.7 ± 0.9 pA/pF, respectively ($n=5$, $P > 0.05$). Adenosine had no effect on basal $I_{\text{Ca-L}}$. However, when $I_{\text{Ca-L}}$ was augmented to 2.7 ± 0.6 pA/pF by 10 nmol/L isoproterenol, adenosine at 10 nmol/L, 1, 10, and 50 $\mu\text{mol/L}$ significantly reduced it to 2.4 ± 0.6 , 2.1 ± 0.6 , 2.0 ± 0.5 , and 1.9 ± 0.5 pA/pF, respectively ($n=4$, $P < 0.05$). Adenosine showed an inhibitory effect on isoproterenol-induced $I_{\text{Ca-L}}$ in a concentration-dependent manner with the IC_{50} of 13.06 $\mu\text{mol/L}$ (Figure 1, 2).

Figure 1. Effect of adenosine on $I_{\text{Ca-L}}$ in isolated rat ventricular myocytes. (a) Control; (b) 50 $\mu\text{mol/L}$ adenosine.

Effect of AMP579 on $I_{\text{Ca-L}}$ Isoproterenol 10 nmol/L augmented $I_{\text{Ca-L}}$ to 3.8 ± 0.7 pA/pF. AMP579 10 $\mu\text{mol/L}$ reduced $I_{\text{Ca-L}}$ to 2.4 ± 0.1 pA/pF ($P < 0.05$, $n=3$, Figure 3), AMP579 also showed an inhibitory effect on isoproterenol-induced $I_{\text{Ca-L}}$. AMP579 and adenosine (both 10 $\mu\text{mol/L}$) suppressed isoproterenol-induced $I_{\text{Ca-L}}$ by 11.1% and 5.2%, respectively. AMP579 had a stronger inhibitory effect. In contrast to adenosine, AMP579 possessed a direct inhibitory effect on basal $I_{\text{Ca-L}}$ in a concentration-dependent manner with the IC_{50} of 1.17 $\mu\text{mol/L}$ (Table 1, Figure 4).

AMP579 10 $\mu\text{mol/L}$ markedly reduced basal $I_{\text{Ca-L}}$ from 2.5 ± 1.2 to 2.0 ± 1.0 pA/pF ($n=5$, $P < 0.05$). Infusion of PD116948 30 $\mu\text{mol/L}$, an adenosine A_1 receptor blocker, did not abolish the inhibitory effects of AMP579 on $I_{\text{Ca-L}}$ (1.9 ± 0.6 vs 2.0 ± 1.0 pA/pF, $P > 0.05$). But under the same conditions AMP579 10

Figure 2. The inhibitory effect of adenosine on I_{Ca-L} induced by isoproterenol in isolated rat ventricular myocytes. (a) Control; (b) isoproterenol 10 nmol/L; (c) adenosine 50 μ mol/L.

Figure 3. The inhibitory effect of AMP579 on I_{Ca-L} induced by isoproterenol in isolated ventricular myocytes. (a) Control; (b) isoproterenol 10 nmol/L; (c) AMP579 10 μ mol/L.

μ mol/L markedly reduced the I_{Ca-L} from 2.4 ± 0.4 to 1.8 ± 0.4 pA/pF ($n=4$, $P<0.01$). Infusion of 0.4μ mol/L GF109203X, a PKC blocker, significantly reversed it to 2.2 ± 0.4 pA/pF ($P<0.05$, Figure 5). So GF109203X could abolish the inhibitory effect of AMP579, indicating that the inhibitory effect on basal I_{Ca-L} by AMP579 was induced through activating PKC but not linked to the adenosine A_1 receptor.

Table 1. Effect of AMP579 on basal I_{Ca-L} in rat ventricular myocytes. $n=5$. Mean \pm SD. ^b $P<0.05$, ^c $P<0.01$ vs corresponding control group.

AMP579 concentration	I_{Ca-L} value/ pA·pF ⁻¹	Change rate/ %
0 (Control)	2.80 ± 0.75	
10 nmol/L	2.66 ± 0.75^b	-5.0
1 μ mol/L	2.36 ± 0.71^b	-15.7
10 μ mol/L	2.03 ± 0.72^c	-27.5
50 μ mol/L	1.78 ± 0.70^c	-36.4

Change rate=(the current value after administration of drug-control value)/control value \times 100%

Figure 5. Abolition of inhibitory effects of AMP579 on I_{Ca-L} by a PKC blocker in isolated rat ventricular myocytes. (a) Control; (b) AMP579 10 μ mol/L; (c) GF109203X 0.4 μ mol/L.

Discussion

In cardiac tissue, a direct inhibition of basal I_{Ca-L} by adenosine has only been demonstrated in guinea-pig atrial and ferret ventricular myocytes^[11,12]. But in the presence of isoproterenol stimulation, adenosine has prominent inhibitory effects on I_{Ca-L} in ventricular myocytes^[13]. These may reflect differences in receptor-effector coupling mechanisms, the level of basal adenylate cyclase activity, the basal phosphorylated state of Ca^{2+} channels and/or the effect of phosphorylation on the gating of L-type Ca^{2+} channel. Consistent with previous reports, our experiment shows that adenosine has no direct inhibitory effect on basal I_{Ca-L} in the rat ventricle, but in the condition that isoproterenol was previously administered, adenosine shows an inhibitory effect on the I_{Ca-L} induced by isoproterenol with an IC_{50} of 13.06 $\mu\text{mol/L}$, suggesting that adenosine exerts an indirect inhibitory effect on I_{Ca-L} in the rat ventricle by inhibition of isoproterenol stimulation.

In contrast to adenosine, AMP579 shows a direct inhibitory effects on basal I_{Ca-L} in the rat ventricle with IC_{50} of 1.17 $\mu\text{mol/L}$. The blocking of Ca^{2+} influx by L-type Ca^{2+} channel could serve as an efficient method for protecting the ischemic myocyte by minimizing ischemia-induced Ca^{2+} overload and irreversible cell contracture and autodigestion by Ca^{2+} -dependent proteases^[14]. Therefore, by reducing both basal I_{Ca-L} and isoproterenol-induced I_{Ca-L} , AMP579 will play a more important role in negative chronotropic and negative dromotropic effects. These action mechanism differences between AMP579 and adenosine may account for the contribution of AMP579 in reducing neutrophil-mediated inflammatory reaction, inhibiting cardiac contraction, dilating coronary vessels, attenuating ischemia and reperfusion injury.

Our study does not show that adenosine A_1 receptor is linked to inhibition of AMP579 on basal I_{Ca-L} . At present, available data indicate that three pathways are involved in receptor-linked downstream mechanisms for inhibition of I_{Ca-L} by adenosine. The first is cAMP-PKA, as PKA increase I_{Ca-L} by phosphorylation on the gating of the L-type calcium channel, inhibitions of adenylate cyclase and reductions of cAMP and PKA levels by adenosine result in attenuation on I_{Ca-L} ^[12]. Second is that activation of guanylate cyclase results in increments of intracellular cGMP and PKG concentration, which in turn inhibits phosphorylation on the gating of the L-type calcium channel^[15]. The third is modulated by PKC, because there are different PKC subunits which result in different effects^[16]. Our experiment finds that special PKC antagonist GF109203X can totally eliminate inhibitory effects of AMP579 on I_{Ca-L} , suggesting that AMP579 exerts a direct inhibitory effects on the L-type

calcium channel through the PKC pathway.

Abstract

Aim: To investigate the effect of 5-hydroxytryptamine transporter (5-HTT) inhibitor fluoxetine and antisense oligodeoxynucleotide (ODN) to extracellular signal-regulated kinases (ERKs) on pulmonary arterial smooth muscle cells (PASMCs) proliferation induced by 5-HT. **Methods:** Liposomal transfection was used to introduce ODNs to ERK1/2 into cultured rat PASMCs and the transfection efficiency was measured by observing the uptake of the fluorescein isothiocyanate (FITC)-labeled antisense ODN in PASMCs. The effects of 5-HTT selective inhibitor fluoxetine and ODNs on the proliferation of PASMCs were evaluated by cell number counting and cell cycle analysis, and measured by microculture tetrazolium (MTT) assay and flow cytometry (FCM), respectively. **Results:** Liposomes mediated the transfection of ODNs into PASMCs with high efficiency. MTT assay showed fluoxetine (10 $\mu\text{mol/L}$, 1 $\mu\text{mol/L}$, and 100 nmol/L) concentration dependently inhibited the proliferation of PASMCs induced by 5-HT (1 $\mu\text{mol/L}$) *in vitro*. The proliferation rate of PASMCs by 5-HT was significantly inhibited by pretreatment with ERK1/2 antisense ODN (0.2 $\mu\text{mol/L}$) from 251% \pm 18% to 86% \pm 5% ($P<0.01$). Flow cytometric analysis of cell cycle distribution showed that the increase of 5-HT induced S phase fraction (SPF) and proliferation index (PI) were significantly inhibited by fluoxetine (1 $\mu\text{mol/L}$) or antisense ODN with SPF from 36% \pm 4% to 26% \pm 3% and 24% \pm 4%, and PI from 34% \pm 2% to 29% \pm 2% and 24% \pm 2%, respectively. **Conclusion:** 5-HTT mediates the mitogenic effect of 5-HT on PASMCs and the proliferation of PASMCs induced by 5-HT is dependent on ERKs signal pathway.

Introduction

Exposure to acute or chronic hypoxia leads to the development of pulmonary arterial hypertension (PAH). The cardinal features of PAH are persistent vasoconstriction and structural remodeling of the pulmonary vessels^[1]. Hypertrophy of pulmonary artery smooth muscle cells (PASMCs) is the main component of pulmonary vascular remodeling which is associated with progressive elevation in pulmonary arterial pressure^[2]. However, the exact mechanism of the proliferation of PASMCs was unclear.

Several studies have shown that 5-hydroxytryptamine (5-HT), endothelin-1 (ET), platelet derived growth factors

(PDGF), angiotensin II (Ang II), and epidermal growth factor (EGF) participate in the regulation of proliferation in PASMCs^[3]. Among these mediators, 5-HT plays an important role in the pathogenesis of PAH. 5-HT exerts potent mitogenic and comitogenic effects on PASMCs, and these effects are associated with cellular internalization of 5-HT mediated by the 5-hydroxytryptamine transporter (5-HTT)^[4,5]. Yet, it is not clear if inhibition of 5-HTT may abolish the proliferation of PASMCs to 5-HT.

Furthermore, mitogen activated protein kinases (MAPKs) are a superfamily of serine/threonine protein kinases distributed extensively in cytoplasm. Many stimuli resulting in cell

growth, differentiation, and vascular contraction may activate MAP kinase-dependent signaling pathways.

Among this family, extracellular signal-regulated kinases (ERKs) are activated in response to growth and differentiation factors^[6-8]. Previous studies have shown that 5-HT induced ERK1/2 activation in rat aortic smooth muscle cells and rabbit isolated renal artery smooth muscle cells^[9,10]. However, whether the intracellular signal pathway of 5-HT in PSMCs is dependent on the ERKs activation is largely unconcerned. Therefore, the present study was designed to observe the effect of fluoxetine, a selective inhibitor of 5-HTT, on the proliferation of PSMCs in response to 5-HT, and then to study the effect of downregulation of ERK1/2, using antisense oligodeoxynucleotides (ODNs), on the proliferation of 5-HT-stimulated PSMCs *in vitro*.

Materials and methods

Drugs and reagents Dulbecco's modified Eagle's medium (DMEM), fetal bovine serum (FBS), and trypsin were purchased from Gibco Co (Grand Island, New York, USA). 5-HT and propidium iodide (PI) were purchased from Sigma Co (St Louis, USA). Lipofectin reagent was from Life Technologies Inc, Ltd (Rockville, USA). Fluoxetine hydrochloride was from Eli Lilly Co (Indianapolis, USA). ODNs were synthesized by Sangon (Shanghai, China).

Pulmonary artery smooth muscle cell culture Lungs were removed from male Wistar rats weighing 250–300 g (supplied by the Animal Center of China Medical University, Grade II, Certificate No. LN 03-0009). Under aseptic conditions, proximal pulmonary arteries were isolated. After removing the tissue around the arteries, the pulmonary arteries were cut into small pieces about 1 mm² and then seeded into 30-mm Petri dishes and cultured in DMEM (containing 20% FBS, 100 kU/L of penicillin and 100 mg/L of streptomycin, pH 7.2). Then these explants were incubated at the atmosphere of 37 °C and 95% O₂/5% CO₂^[11]. When the cells had grown out from the explants and reached the confluence of more than 70%, cells were passaged to T25 flasks. Cells used in experiments were from passages 3 to 9.

Oligodeoxynucleotides On account of GCG package locating in the translation initiation region of rat ERK1/2 mRNA, the sequences of antisense ODN were designed as follows: 5'-GCC GCC GCC GCC GCC AT. This ODN has been used successfully to downregulate ERK1/2 in VSMCs, rat cardiac myocytes and rat cardiac fibroblasts^[12]. Sense ODN (5'-AT GGC GGC GGC GGC GGC), random ODN (5'-CGC GCG CTC GCG CAC CC) were used as controls. All bases were protected by phosphorothioation. One batch of antisense ODN

was labeled with fluorescein isothiocyanate (FITC) used in fluorescence microscopy experiments.

Microculture tetrazolium (MTT) assay Cells were seeded into 96-well plates at a density of 1×10⁴ cells/well. The cells were then incubated in medium containing vehicle (5% FCS DMEM) and 5-HT (1 μmol/L) for 24 h with or without fluoxetine (10 μmol/L, 1 μmol/L, and 100 nmol/L) added 30 min before 5-HT. The effect of different ODNs (0.2 μmol/L) on the proliferation induced by 5-HT was also observed after transfection. The group with the cells incubated in serum-free medium was used as the control. At the end of this period, MTT (5 g/L) was added to each well, and incubation proceeded at 37 °C for 4 h. Thereafter, the medium was removed and the cells were solubilized in 150 μL Me₂SO. Optical density (OD) of each well was determined by enzyme-linked ELISA at 490 nm of wavelength. Then the proliferation rates (PR) of each group were calculated.

$$PR = (OD_{\text{experiment}} - OD_{\text{control}}) / OD_{\text{control}}$$

Flow cytometry (FCM) PSMCs grown in T25 plates were treated with fluoxetine or antisense ODN (0.2 μmol/L) before 5-HT was added. The cells were harvested by trypsinization, washed twice with PBS, and the pellets were resuspended in 0.5 mL of PBS containing 100 mg/L RNase for incubation at 37 °C for 30 min. Then, 0.5 mL of PI solution (100 mg/L in PBS) was added, and the mixture was incubated in the dark at 4 °C for 30 min. The cells were analyzed with a FACScan flow cytometer. Then S-phase cell fractions (SPF) and proliferation index (PI) of each group were calculated. $SPF = S / (G_0G_1 + S + G_2M)$; $PI = (G_2M + S) / (G_0G_1 + S + G_2M)$.

Liposomal transfection Prior to transfection, PSMCs were cultured in serum-free medium for 24 h. ODNs were mixed with antibiotic- and serum-free medium to a concentration of 0.8 μmol/L, then mixed with equal volume of medium containing 80 mg/L of lipofectin and incubated at room temperature for 15 min. ODN/lipofectin mix 20 μL was added to each well of a 96-well plate, 200 μL to each well of a 12-well plate, and 1000 μL to the T25 plates, with equal volume of antibiotic- and serum-free medium. The cells were incubated for a further 6 h with gentle agitation every 2 h. The medium was then replaced with the same volume of liposome-free medium containing the same concentration of ODN and 5% FBS. Cells were incubated for another 24 h before MTT assay and FCM.

Fluorescence microscopy PSMCs were seeded into 12-well plate and transfected using FITC-labeled antisense ODN. After 24 h and 48 h of incubation, the cells were viewed by fluorescence microscopy.

Statistical analysis All the data are presented as mean±SD, and assessed by ANOVA and *t*-test. *P*<0.05 was

considered significant.

Results

Uptake of ODNs by PASCs Twenty four hours after liposomal transfection, FITC-labeled antisense ODN were observed in both cytoplasm and the nuclei of PASCs (Figure 1). More than 90% of the cells exhibited fluorescence.

Figure 1. Fluorescence photomicrograph of PASCs taken 24 h after transfection with the FITC-labeled antisense ODN (× 400). Fluorescence were observed in both cytoplasm and the nuclei of PASCs.

Effect of fluoxetine and ODNs on the proliferation of PASCs induced by 5-HT MTT assay showed that 5-HT (1 μmol/L) induced increased proliferation of PASCs and the PR in response to 5-HT increased from 172%±5% to 217%±4% compared with the vehicle. Pretreatment of the cells with fluoxetine (10 μmol/L, 1 μmol/L, and 100 nmol/L) could produce a concentration-dependent reduction in PR (Figure 2). According to these results, 1 μmol/L was chosen as the concentration of fluoxetine used in following experiments.

Pretreatment of PASCs with ERK1/2 antisense ODN resulted in a significant inhibition of 5-HT-induced PASCs proliferation (Figure 3) and this inhibitory effect is rather more potent than fluoxetine. In contrast, sense ODN and random ODN did not have such effect.

Effect of fluoxetine and antisense ODN on cell cycle Flow cytometric analysis of cell cycle distribution showed that the cells treated with 5-HT had larger values of S-phase cell fraction (SPF) and PI than the vehicle. But pretreatment with fluoxetine or antisense ODN decreased these values (Figures 4, 5). These results indicated that 5-HT promoted the PASCs from the G₀/G₁ phase of the cell cycle into S phase

Figure 2. Effect of different concentrations of fluoxetine on the proliferation of PASCs induced by 5-HT. Experimental groups: 1) vehicle (5% FBS DMEM); 2) 5-HT (1 μmol/L); 3) 5-HT (1 μmol/L)+fluoxetine (100 nmol/L); 4) 5-HT (1 μmol/L)+fluoxetine (1 μmol/L); 5) 5-HT (1 μmol/L)+fluoxetine (10 μmol/L). n=3. ^cP<0.01 vs control. ^fP<0.01 vs 5-HT (1 μmol/L).

Figure 3. Effect of different ODNs on the proliferation of PASCs induced by 5-HT. Experiment groups: 1) vehicle (5% FBS DMEM); 2) 5-HT (1 μmol/L); 3) 5-HT (1 μmol/L)+random ODN (0.2 μmol/L); 4) 5-HT (1 μmol/L)+sense ODN (0.2 μmol/L); 5) 5-HT (1 μmol/L)+antisense ODN (0.2 μmol/L). n=3. ^cP<0.01 vs control. ^fP<0.01 vs 5-HT (1 μmol/L).

Experiment groups: 1) control; 2) vehicle (5% FBS DMEM); 3) 5-HT (1 μmol/L); 4) 5-HT (1 μmol/L)+fluoxetine (1 μmol/L); 5) 5-HT (1 μmol/L)+antisense ODN (0.2 μmol/L). n=3. ^cP<0.01 vs control. ^fP<0.01 vs 5-HT (1 μmol/L).

and this effect was inhibited by fluoxetine and antisense ODN.

Figure 5. Effect of fluoxetine and antisense ODN on proliferation index of PSMCs. Experiment groups: 1) control; 2) vehicle (5% FBS DMEM); 3) 5-HT (1 $\mu\text{mol/L}$); 4) 5-HT (1 $\mu\text{mol/L}$)+fluoxetine (1 $\mu\text{mol/L}$); 5) 5-HT (1 $\mu\text{mol/L}$)+antisense ODN (0.2 $\mu\text{mol/L}$). $n=3$. ^b $P<0.05$, ^c $P<0.01$ vs control. ^e $P<0.05$, ^f $P<0.01$ vs 5-HT (1 $\mu\text{mol/L}$).

Discussion

Results from the present study demonstrated that 5-HTT played a key role in the mitogenic effect of 5-HT on PSMCs. Fluoxetine, a highly selective inhibitor of 5-HTT inhibited the proliferation of PSMCs induced by 5-HT *in vitro*. Meanwhile, antisense ODN to ERK1/2 inhibited 5-HT-induced proliferation of PSMCs. These findings suggest that 5-HT-induced proliferation of PSMCs is 5-HTT and ERK pathway dependent.

In response to hypoxia, 5-HT is released from pulmonary neuroendocrine cells and neuroepithelial bodies distributed throughout the airways. An increase in 5-HT may contribute to secondary pulmonary artery hypertension^[13]. The proliferation of PSMCs induced by 5-HT is an important component of pulmonary arterial remodeling. RT-PCR analyses of PSMCs indicated the presence of 5-HT_{1B/1D}, 5-HT₂ receptors and 5-HTT mRNA^[14,15]. The present results show that the proliferation of PSMCs induced by 5-HT is inhibited by fluoxetine in a manner that is concentration-dependent. In contrast, the 5-HT_{1B/1D} receptor antagonist GR127935, the 5-HT_{2A} receptor antagonist ketanserin, or the 5-HT_{2B/2C} receptor antagonist SB206553 had no this effect^[16]. It has been recently reported that exposure of PSMCs to hypoxia increased 5-HTT expression and activity, and this effect was associated with potentiation of the mitogenic action of 5-HT^[5,17]. Some scholars found that mice deficient in 5-HTT or treated with selective inhibitors of 5-HTT developed less PAH than controls when exposed to hypoxia^[18,19]. These evidences suggest that 5-HTT in PSMCs may be a key determinant of pulmonary arterial remodeling and the development of PAH. Therefore, our result means that 5-HTT is one of the important mechanisms of PAH and this may provide a novel therapeutic target for PAH.

The uptake of FITC-labeled antisense ODN by PSMCs with liposomes proved the high efficiency of transfection. In the present study, the antisense ODN to ERK1/2 delivered by lipofectin resulted in an effective suppression of the proliferative response to 5-HT in PSMCs. Meanwhile, the effect of antisense ODN stronger than fluoxetine suggests that antisense ODN to ERK1/2 could inhibit the proliferation of PSMCs not only induced by 5-HT, but also by the serum^[20]. The present study proves that 5-HT induced the proliferation of PSMCs and is dependent on the activation of ERK1/2. Therefore, it is reasonable to consider that 5-HT induced activation of ERKs through 5-HTT in PSMCs. Previous studies showed that 5-HT induced the Tyr phosphorylation of GTPase-activating protein (GAP) and the effect was mediated by 5-HTT, which was the upstream of the ERK pathway, not by 5-HT receptors^[21]. The mechanism of 5-HT signaling for PSMCs through 5-HTT has also been shown to involve the production of reactive oxygen species (ROS) such as superoxide and H₂O₂ via the activation of NAD(P)H oxidase, and the activation of the ERK pathway occurs secondary to ROS formation^[22,23]. Therefore, the activation of ERKs induced by 5-HT is mediated by 5-HTT.

The present study showed that fluoxetine concentration-dependently inhibited 5-HT-induced proliferation of PSMCs *in vitro*, and demonstrated that antisense ODN to ERK1/2 significantly inhibited mitogenesis of PSMCs. Therefore, we concluded that 5-HT-induced mitogenesis of PSMCs was mediated by 5-HTT, in which the signal transduction for 5-HT was dependent on ERKs signal pathway.

Abstract

Aim: To investigate the effects of the agonists of proteinase activated receptor (PAR)-2, and histamine on degranulation of human mast cells. **Methods:** Human mast cells were enzymatically dispersed from tonsil and skin tissues. The dispersed cells were then cultured with various stimuli, and tryptase and histamine levels in cell supernatants collected from challenge tubes were measured. **Results:** PAR-2 agonist peptide SLIGKV provoked a dose-dependent release of histamine from skin mast cells. It also induced tryptase release from tonsil mast cells. tc-LIGRLO appeared less potent than SLIGKV in induction of release of histamine and tryptase. Trypsin was able to induce a “bell” shape increase in tryptase release from tonsil mast cells. It was also able to induce a dose-dependent release of histamine from both tonsil and skin mast cells. The actions of trypsin on mast cells were inhibited by soy bean trypsin inhibitor (SBTI) or α_1 -antitrypsin (α_1 -AT). Time course study revealed that both stimulated tryptase or histamine release initiated within 10 s and reached their peak release between 4 and 6 min. Pretreatment of cells with metabolic inhibitors or pertussis toxin reduced the ability of mast cells to release tryptase or histamine. **Conclusion:** It was demonstrated that the *in vitro* tryptase release properties of human tonsil and skin mast cells suggested a novel type of mast cell heterogeneity. The activation of mast cells by PAR-2 agonists indicated a self-amplification mechanism of mast cell degranulation.

Introduction

Recently, it was summarized that apart from allergic disease, mast cells were associated with at least 35 different non-allergic clinical disorders^[1]. The increased numbers of mast cells or mast cell degranulation being observed in these diseases implied that this cell type was most likely involved in the pathogenesis of these diseases. Since mast cells carry out their functions mainly through their released mediators including histamine, tryptase, chymase, heparin, cytokines, and other products^[2,3], the understanding of mediator release properties of mast cells is crucial for our study on the roles of mast cells in diseases.

Tryptase is a tetrameric serine proteinase that constitutes some 20% of the total protein within human mast cells and is stored almost exclusively in the secretory granules of mast cells^[4] in a catalytically active form^[5]. Upon degranulation,

tryptase is released from mast cells along with histamine and other mast cell products.

For more than four decades, histamine has been widely used as a marker of mast cell degranulation *in vitro*, and numerous anti-allergic drugs such as sodium cromoglycate, lodoxamide, salbutamol, ketotifen, terfenadine, and cetirizine^[6,7], and salmeterol^[8] were reported to inhibit anti-IgE induced histamine release from human tonsil, skin, or lung mast cells. Therefore, both tryptase and histamine were used as markers of mast cell degranulation in the current study.

In recent years, it was found that PAR-2, a receptor of trypsin and tryptase^[9] was expressed on human mast cells^[10] and PAR-2 agonists were reported to be capable of activating rat peritoneal mast cells^[11] and human gut mast cells^[12]. However, the potential effects of PAR-2 agonists including trypsin, SLIGKV, and tc-LIGRLO^[13] on human tonsil and skin mast cells have not been examined. Therefore, the actions of

these PAR-2 agonists on tonsil and skin mast cells were investigated in the current study. We reported that histamine was able to activate gut mast cells, which presents a self-amplification mechanism of mast cell degranulation^[14]. Since human mast cells from different anatomical sources may respond to a stimulus to different extents, which has long been known as mast cell heterogeneity^[15], the effect of histamine on tryptase release from human tonsil and skin mast cells was also examined in this study.

Materials and methods

Dispersion of mast cells Human tonsil and skin tissue were obtained at tonsillectomy and circumcision, from the Pathology Department of Shantou University Medical College (Shantou, China). Informed consent from the patients and agreement of the Ethical Committee of the college were obtained. Only macroscopically normal tissues were used for the study. The mast cell dispersion procedures employed were similar to that described previously^[16]. Briefly, finely chopped tissue was incubated with 1.5 g/L collagenase (Sigma, USA) and 0.75 g/L hyaluronidase (Sigma) in minimum essential medium (MEM, Gibco, Invitrogen Corporation, USA) containing 25 mmol/L *N*-2-hydroxyethyl-piperazine-*N'*-2-ethane sulphonic acid (HEPES) and 2% foetal calf serum (FCS, 1 g tonsil/10 mL buffer and 1 g skin/15 mL buffer) at 37 °C for 60–70 min. Dispersed cells were separated from undigested tissue by filtration through nylon gauze (pore size 100 µm diameter), washed and maintained in MEM (containing 10% FCS, 200 kU/L benzylpenicillin, and 200 mg/L streptomycin) on a roller overnight at room temperature. Mast cell purity, as determined by light microscopy after staining by alcine blue, ranged from 0.5% to 1.1% for tonsil cells and 3.5% to 5.8% for skin cells.

Mast cell challenge Dispersed cells were resuspended in HEPES buffered salt solution (HBSS, pH 7.4) with CaCl₂ and MgCl₂ (complete HBSS). Aliquots of 100 µL containing 4×10³–6×10³ mast cells were added a 50-µL of tc-LIGRLO (Meilian, GuZhen Town, China), tc-OLRGIL (Meilian), SLIGKV (Meilian), VKGILS (Meilian), trypsin (Sigma), tryptase (self-prepared^[17]), histamine (Sigma), anti-IgE antibody (Serotec, Oxford, UK), calcium ionophore (CI) (Sigma), SBTI (Sigma), or α₁-AT (Sigma), and incubated at 37 °C for 15 min. The reaction was terminated by addition of 150 µL ice cold incomplete HBSS and tubes were centrifuged immediately (500×g, 10 min, 4 °C). All experiments were performed in duplicate. For measuring of total histamine or tryptase concentrations, four tubes were either boiled for 6 min or the freeze-thaw cycle was repeated five times. Supernatants were stored at -20 °C until tryptase and histamine concentrations

were determined (in duplicate for each tube).

Inhibition of release of tryptase or histamine When added, SBTI or α₁-AT were incubated with trypsin for 20 min on ice before adding to cells. Data were expressed as the percentage inhibition of tryptase or histamine release, taking into account histamine or tryptase release in presence and absence of the inhibitor. When the experiments with pertussis toxin were performed, cells were incubated with 1.0 mg/L pertussis toxin at 37 °C for 4 h, and then washed with HBSS before stimulus being added. When the experiments with metabolic inhibitors were performed, cells were incubated with 2-deoxy-*D*-glucose (10 mmol/L, Sigma) and antimycin A (1 µmol/L, Sigma) at 37 °C for 40 min before being challenged with stimulus.

Tryptase and histamine measurement Tryptase concentrations were measured with a sandwich ELISA procedure with a specific polyclonal antibody against human tryptase as the capture antibody and AA5 a monoclonal antibody specific for human tryptase (both donated by Dr Andrew FW, University of Southampton, UK) as the detecting antibody^[18]. Histamine concentrations were determined using a glass fibre-based fluorometric assay^[16].

Statistical analysis Statistical analysis were performed by using SPSS software. Data were expressed as mean±SD. Where analysis of variance indicated significant differences between groups with ANOVA, for the preplanned comparisons of interest, Student's *t*-test was applied. *P*<0.05 was taken as a statistically significant difference.

Results

Effect of PAR-2 agonists and their reverse peptides on tryptase and histamine release from tonsil and skin mast cells PAR-2 agonist peptide SLIGKV at the concentrations of 1, 10, and 100 µmol·L⁻¹ was able to induce a dose-dependent release of histamine (ranging from 8.9% to 13.8% net histamine release), but not tryptase (data not shown) from skin mast cells. However, SLIGKV at 300 µmol·L⁻¹ failed to induce histamine release from skin mast cells. In the same experiments, a reverse peptide of SLIGKV, VKGILS had little effect on histamine release. In contrast to skin mast cells, tonsil mast cells released more tryptase, but not histamine (data not shown) in response to SLIGKV. In the same experiments, VKGILS induced significantly less tryptase release from tonsil cells than SLIGKV did. Another PAR-2 agonist peptide tc-LIGRLO was able to induce significant release of histamine from skin mast cells and release of tryptase from tonsil mast cells, but the extent of histamine and tryptase release induced by tc-LIGRLO appeared less than that induced by its reverse peptide tc-OLRGIL (Table 1).

Table 1. Effects of PAR-2 agonists and their reverse peptides on tryptase release from human tonsil mast cells and histamine release from human skin mast cells. *n*=4. Mean±SD. ^b*P*<0.05 vs baseline release. ^e*P*<0.05 vs the corresponding concentration of the reverse peptide.

Cells were incubated with peptides at 37 °C for 15 min.

Effects of trypsin, anti-IgE, CI, and histamine on tryptase release from tonsil and skin mast cells Trypsin was able to induce a “bell” shape increase in tryptase release from tonsil mast cells. The maximum of net tryptase release was 19.4% induced by 1 mg/L trypsin (Figure 1). With the same experimental procedure, trypsin failed to induce significant tryptase release from skin mast cells (Figure 2). Anti-IgE was able to stimulate tryptase release from both tonsil and skin mast cells (Figure 1, 2). The maximum release of tryptase from tonsil cells was 17.7% induced by 10 mg/L anti-IgE. CI at the concentrations of 0.1, 0.3, and 1 mg/L was able to provoke a dose-dependent release of tryptase from tonsil mast cells (Figure 1). The maximum release of tryptase from tonsil cells was 22.8% induced by 1 mg/L CI (Figure 1). CI at the concentration of 1 mg/L was also able to induce significant tryptase release from skin mast cells (Figure 2).

Effects of trypsin, anti-IgE, CI, and tryptase on histamine release from tonsil and skin mast cells Trypsin at the concentrations of 0.1, 1.0, 10, and 100 mg/L was able to induce a dose-dependent release of histamine from skin mast

Figure 1. Induction of tryptase release from tonsil mast cells by trypsin, anti-IgE antibody (aIgE), calcium ionophore (CI), and histamine. *n*=4. Mean±SD. ^b*P*<0.05 vs baseline. Stimulus or HBSS alone was incubated with cells for 15 min before termination of the reactions.

Figure 2. Induction of tryptase or histamine release from skin mast cells by trypsin, anti-IgE, and calcium ionophore (CI). *n*=4. Mean±SD. ^b*P*<0.05 vs control. ^e*P*<0.05 vs the corresponding tryptase release. Stimulus or HBSS alone was incubated with cells for 15 min before termination of the reactions.

cells (Figure 2). The maximum of histamine release was 13.9% induced by 100 mg/L trypsin. Trypsin at the concentrations of 10 and 100 mg/L was also able to induce significant histamine release from tonsil mast cells (Figure 3).

Figure 3. Induction of histamine release from tonsil mast cells by trypsin, anti-IgE, CI, and trypsin. *n*=4. Mean±SD. ^b*P*<0.05 vs control. Stimulus or HBSS alone was incubated with cells for 15 min before termination of the reactions.

Similarly, anti-IgE and CI were able to induce a dose-dependent release of histamine from tonsil mast cells. Up to 12.8% release of histamine from tonsil mast cells was observed when cells were incubated with trypsin 10 mg/L (Figure 3).

Time course for trypsin and histamine release from tonsil mast cells Time course study revealed that both trypsin and histamine release induced by anti-IgE, histamine, and CI from tonsil mast cells initiated within 10 s when cells were incubated with stimulus. Up to 45% and 31% of the maximum trypsin and histamine release were observed 10 s after cells were incubated with stimulus. The peak trypsin release from tonsil cells occurred at 4 min for CI and histamine, and 6 min for anti-IgE following incubation (Figure 4). In comparison, the peak of histamine release induced by anti-IgE or CI occurred at 5 min and 6 min, respectively (Figure 4). Similarly, tc-LIGRLO, trypsin, and CI-induced histamine release from skin mast cells all started within 10 s of stimulation. But the peak histamine release occurred at 4 min for CI and 6 min for tc-LIGRLO and trypsin (Figure 5).

Inhibition of trypsin-induced trypsin and histamine release by trypsin inhibitors The trypsin-induced trypsin release from tonsil mast cells was inhibited by approximately 65.1% and 62.2% by SBTI or α₁-AT, respectively (Table 2). Similarly, the trypsin-induced histamine release from tonsil mast cells was inhibited by approximately 82.4% and 80.4% by SBTI or α₁-AT, respectively (Table 2). SBTI or α₁-AT

μmol/L of antimycin A) reduced trypsin-induced tryptase release from tonsil cells and histamine release from skin cells by 79.4% and 61.9%, respectively. Metabolic inhibitors were also able to inhibit histamine-induced tryptase release from tonsil mast cells, and tc-LIGRLO and SLIGKV-induced histamine release from skin mast cells. Pretreatment of cells with 1 mg/L pertussis toxin diminished both trypsin and histamine-induced tryptase release from tonsil mast cells, and trypsin, tc-LIGRLO, and SLIGKV-provoked histamine release from skin mast cells. Similarly, metabolic inhibitors and pertussis toxins were able to inhibit both anti-IgE and CI-induced tryptase and histamine release from both tonsil and skin mast cells (Table 3).

Discussion

We have reported the *in vitro* tryptase release properties of human tonsil and skin mast cells. This was particularly important when tryptase and histamine, the two major mast cell mediators were investigated in parallel in the same experiments, which not only proved that the quantities of

the two mediators released from mast cells were in an inconstant ratio, but also revealed that the pace of release was different between histamine and tryptase upon mast cell degranulation. These phenomena were similar to our previous findings with human colon mast cells^[12].

Trypsin at 1 mg/L was able to stimulate the maximum tryptase release (19.4%), but not significant histamine release from tonsil mast cells. In contrast, trypsin at 100 mg/L was able to stimulate 16.4% histamine release, but not significant tryptase release from tonsil mast cells. These are surprising observations, which suggests strongly that tryptase and histamine release from tonsil mast cells induced by trypsin may be involved in different mechanisms. Since anti-IgE and CI also showed “bell” shape tryptase release and dose-dependent histamine release patterns in the same experimental system, these observations may reflect a common phenomenon of tonsil mast cell degranulation. It is most likely that tryptase release pathway of tonsil mast cells has the ability to prevent itself from strong stimulation. However, more experiments are needed to prove this. In contrast to mast cells from tonsil, mast cells from skin released only histamine, but not tryptase in response to trypsin, which indicated further that tryptase and histamine release from human mast cells induced by trypsin was through different mechanisms. The difference in the ability of trypsin inhibitors to inhibit trypsin induced histamine release (up to 82.4%) and tryptase release (up to 65%) may also suggest the different mechanisms involved in tryptase and histamine release from tonsil mast cells.

Moreover, PAR-2 agonist peptides SLIGKV and tc-LIGRLO showed different effects on tryptase and histamine release from mast cells. As for trypsin, SLIGKV was also able to stimulate histamine release, but not tryptase release

nd=not done; na=not applicable; ns=no stimulation before pertussis toxin and metabolic inhibitor treatment.

from skin mast cells. The extent of histamine release induced by SLIGKV was similar to that induced by trypsin, indicating that the actions of trypsin on skin mast cells may be through PAR-2. Because VKGILS (a reversed peptide of SLIGKV) had little effect on tryptase and histamine release from skin mast cells, the action of SLIGKV on skin mast cells was a specific one. Different from skin mast cells, tonsil mast cells released tryptase but not histamine in response to SLIGKV. This suggested that trypsin induced histamine release from tonsil mast cells might not be through a PAR-2 related mechanism. It suggested also that release of tryptase and histamine from tonsil mast cells upon stimulation might not occur simultaneously. Another PAR-2 agonist peptide tc-LIGRLO had a similar effect to SLIGKV on skin mast cells, confirming further the functional expression of PAR-2 on these cells. Interestingly, tc-OLRGIL a reversed peptide of tc-LIGRLO appeared a potent stimulus of histamine release from skin mast cells, and a secretagogue of tryptase release from tonsil mast cells. The physiological or pathophysiological meaning of the action of tc-OLRGIL on mast cells requires further investigation to be understood.

Consistent with our previous findings^[14,15], histamine exhibited its ability to stimulate tryptase release from tonsil mast cells, and tryptase showed its ability to provoke histamine release from mast cells. These implicated that there were at least two self-amplification mechanisms of mast cell degranulation in the human tonsil; the histamine associated mechanism and the tryptase associated mechanism.

Approximately 30% tryptase and histamine release occurred within 10 s of IgE-dependent stimulation, suggesting that tonsil mast cells were able to quickly respond to allergen challenge, but to reach their full capacity (maximum histamine or tryptase release) a minimum of 5 min was required. The time courses for CI were similar to those for anti-IgE, except for a minimum 4 min being required to reach the full tryptase and histamine release capacity. The reasons for the relatively slow release of mediators from human mast cells remain unclear. Approximately 45% tryptase release induced by histamine was completed within the first 10 s of stimulation, indicating that the process may be different from the one induced by anti-IgE or CI. The time courses for histamine release from skin mast cells induced by CI and tc-LIGRLO were quite similar, indicating tc-LIGRLO may act like CI on induction of mast cell degranulation.

Pretreatment of cells with metabolic inhibitors abolished the actions of anti-IgE and CI on mast cells, indicating that tryptase and histamine release induced by them was a non-cytotoxic process, and was dependent on cell energy supply. The inhibition of tryptase and histamine release by pertus-

sis toxin suggested that the release process was associated with activation of G-protein coupled receptors.

In conclusion, it was found that tryptase release properties of human tonsil and skin mast cells were similar to the histamine release properties of these cells in response to anti-IgE and CI. In contrast, tryptase release properties were quite different from histamine release properties in response to PAR-2 agonists including trypsin, tc-LIGRLO, and SLIGKV, which uncovered a novel type of mast cell heterogeneity in response to different stimulation. The activation of mast cells by PAR-2 agonists may indicate a self-amplification mechanism of mast cell degranulation in humans.

Congratulations to Dr Hua-liang JIANG, an Editorial Board member of *Acta Pharmacologica Sinica*, for his extraordinary career accomplishment!

It is time to celebrate!

We are very proud to announce that, since 2003, Dr Hua-liang JIANG have had 27 citations to his article, **A 3D MODEL OF SARS_COV 3CL PROTEINASE AND ITS INHIBITORS DESIGN BY VIRTUAL SCREENING** [by Bin XIONG, Chun-shan GUI, Xiao-ying XU, Cheng LUO, Jing CHEN, Hai-bin LUO, Li-li CHEN, Guo-wei LI, Tao SUN, Chang-ying YU, Li-duo YUE, Wen-hu DUAN, Jin-kang SHEN, Lei QIN, Tei-liu SHI, Yi-xue LI, Kai-xian CHEN, Xiao-min LUO, Xu SHEN, Jian-hua SHEN, Hua-liang JIANG. *Acta Pharmacol Sin* 2003, 24 (6): 497–504. Received 2003-05-16 Accepted 2003-05-18].

What's more, the number of citations of this article received has placed it in the top 1% within its field according to *Essential Science Indication*SM. His work is highly influential and is making a significant impact among his colleagues in his field of study.

It is worth pointing out that it were Dr Jiang HL *et al* who firstly constructed a three-dimensional model for the 3C like proteinase of SARS coronavirus and designed anti-SARS drugs by virtual screening. Based on the finding published in *Acta Pharmacologica Sinica*, Dr Jiang managed to find a new strategy to discover anti-SARS compounds from the existing drugs by combining computationally virtual screening with bioassay. His latest work has been accepted by *Journal of Virology* recently and will be published as a Spotlight Paper soon.

Abstract

Aim: To investigate the effect of the peroxisome proliferator-activator receptor (PPAR)- γ agonist, pioglitazone, on insulin resistance in low-dose streptozotocin and high sucrose-fat diet induced obese rats. **Methods:** Normal female Wistar rats were injected intraperitoneally with low-dose streptozotocin (STZ, 30 mg/kg) and fed with a high sucrose-fat diet for 8 weeks. Pioglitazone (20 mg/kg) was administered orally to the obese and insulin-resistant rats for 28 d. Intraperitoneal glucose tolerance tests, insulin tolerance tests and gluconeogenesis tests were carried out over the last 14 d. At the end of d 28 of the treatment, serums were collected for biochemical analysis. Glucose transporter 4 (GLUT4) and insulin receptor substrate-1 (IRS-1) protein expression in the liver and skeletal muscle were detected using Western blotting. **Results:** Significant insulin resistance and obesity were observed in low-dose STZ and high sucrose-fat diet induced obese rats. Pioglitazone (20 mg/kg) treatment significantly decreased serum insulin, triglyceride and free fatty acid levels, and elevated high density lipoprotein-cholesterol (HDL-C) levels. Pioglitazone also lowered the lipid contents in the liver and muscles of rats undergoing treatment. Gluconeogenesis was inhibited and insulin sensitivity was improved markedly. The IRS-1 protein contents in the liver and skeletal muscles and the GLUT4 contents in skeletal muscle were elevated significantly. **Conclusion:** The data suggest that treatment with pioglitazone improves insulin sensitivity in low-dose STZ and high sucrose-fat diet induced obese rats. The insulin sensitizing effect may be associated with ameliorating lipid metabolism, reducing hyperinsulinemia, inhibiting gluconeogenesis, and increasing IRS-1 and GLUT4 protein expression in insulin-sensitive tissues.

Introduction

Insulin resistance is a major characteristic of various metabolic disorders, including type 2 diabetes and obesity^[1]. There is strong evidence that an important factor leading to obesity and insulin resistance is an increase in energy intake^[2]. Our previous study demonstrated that high-fat, high-sucrose feeding led to insulin resistance and impaired glucose tolerance in female Wistar rats^[3]. In our study, female rats were given a relatively low-dose of streptozotocin (STZ), followed by a high sucrose-fat diet containing 52% sucrose, 24% fat, and 18% protein (4.8 cal/g chow). Compared to the control

group, which did not receive either STZ or a high sucrose-fat diet, the treatment group showed obvious obesity and impaired glucose tolerance after 8 weeks. Fasting blood glucose levels increased slightly or moderately, and were accompanied by hyperinsulinemia, dyslipidemia, enhanced gluconeogenesis, and reduced insulin tolerance. These characteristics indicated insulin resistance and obesity with mild β -cell dysfunction, which was further induced by the high sucrose-fat diet. A similar result is observed in humans. Our results suggested that this model was a successful insulin-resistant rat model and is useful in the study of insulin resistance and insulin sensitivity.

Thiazolidinediones (TZDs), a new class of insulin sensitizing drugs including troglitazone, pioglitazone, and rosiglitazone, provide an effective approach for treating type 2 diabetes. TZDs improve insulin sensitivity, impair glucose tolerance and dyslipidemia in type 2 diabetics^[4], as well as in obese non-diabetic subjects^[5]. Similar findings have been demonstrated in a number of genetic and non-genetic animal models of diabetes/insulin resistance^[6,7]. TZDs elicit their effects through activating the peroxisome proliferator-activator receptor (PPAR)- γ , a nuclear hormone receptor. When ligands stimulate the PPAR- γ nuclear receptor, a variety of response genes are stimulated or repressed. The TZD PPAR- γ agonists improve insulin sensitivity via multiple mechanisms. Although the exact target genes for insulin sensitization remain unknown, it has been demonstrated *in vitro* and *in vivo* that treatment with TZDs affects a variety of factors involved in lipid metabolism, insulin signal pathways, glucose phosphorylation, and glucose transport.

In the present study, we evaluated the effect of pioglitazone, a PPAR- γ agonist, on insulin resistance and related abnormalities in low-dose STZ and high sucrose-fat diet induced obese rats. Our findings demonstrated that PPAR- γ agonist treatment reduced circulating and stored lipids and improved the insulin-resistant status in model rats.

Materials and methods

Animals Thirty female Wistar rats, weighing 225–250 g, were obtained from the Experimental Animal Center, Chinese Academy of Medical Sciences, Beijing, China [Certificate No. SCXK(Jing)2000-0006], and maintained in individual cages with a 12-h/12 h light-dark cycle. All animals were allowed free access to water. At the beginning of the study, rats were randomly assigned to control ($n=8$) and experimental groups ($n=22$). Experimental groups were injected intraperitoneally with low-dose STZ, 30 mg/kg (Sigma, St Louis, MO, USA). After 2 weeks, a glucose tolerance test was carried out and 15 rats that had developed impaired glucose tolerance in the STZ-treated group were selected and received a high sucrose-fat diet (containing 52% sucrose, 24% fat, 18% protein, and 4.8 cal/g chow). Rats in the control group were fed *ad libitum* on a standard chow.

After 8 weeks on a high sucrose-fat diet, weight-matched, fasting-blood-glucose-matched STZ rats were randomly divided into two groups, a STZ group and a pioglitazone group. STZ rats ($n=8$) were given vehicle solution and pioglitazone rats ($n=7$) were orally administered pioglitazone (20 mg·kg⁻¹·d⁻¹; the pioglitazone was a gift from Prof Yu-ling LIU) as a suspension in 1% Tween 80 solution (the high sucrose-fat diet

was given to the rats during this period). Rats in each group were treated for 28 d. Glucose tolerance tests, insulin tolerance tests and gluconeogenesis tests were carried out over the last 14 d of the experiment. At the end of the treatment period, all animals were decapitated after a 4-h fast. Blood samples were collected and serum was prepared and kept at -20 °C for the determination of serum lipids and immunoreactive insulin. Celiac fats were excised for weighing. Skeletal muscles and livers were separated and frozen immediately in liquid nitrogen, and stored at -70 °C for further analysis of GLUT4 and IRS-1.

Biochemical analysis Serum glucose levels were assayed using the glucose oxidase method. Serum insulin was determined using a radioimmunoassay kit (China Institute of Atomic Energy, Beijing, China). Free fatty acid (FFA) concentrations were measured using the Cu²⁺ reagent method. Triglyceride (TG), total cholesterol (TC), and HDL-cholesterol (HDL-C) levels were determined using the colorimetric method with commercial kits (Zhong sheng bei kong Bio-Technology and Science, Beijing, China).

Intraperitoneal glucose tolerance test (IPGTT) Baseline glucose levels were determined after a 4-h fast, after which glucose (2 g/kg body wt) was administered intraperitoneally to non-sedated animals. Tail vein blood was sampled for glucose determination 30 and 120 min after glucose administration.

Insulin tolerance test (ITT) Baseline glucose levels were determined after a 4-h fast. Insulin (0.4 U/kg body wt) was injected subcutaneously. Blood was sampled from the tail tip 40 and 90 min after insulin administration, and the glucose concentration was determined. Insulin injections and blood glucose sampling took approximately the same amount of time per animal (ie 25 animals were injected in 12 min and blood glucose sampling of those same 25 animals also took approximately 12 min), so that the sample times are accurate for each animal.

Gluconeogenesis test Baseline glucose levels were determined after an overnight fast. DL-alpha alanine was injected intraperitoneally. Blood was sampled from the tail and glucose levels were determined at 0 and 60 min. The percent increase in glucose level at 60 min was calculated. Higher values indicated higher levels of gluconeogenesis.

GLUT4 and IRS-1 protein expression Protein extractions and immunoblots for the determination of GLUT4 were carried out on frozen skeletal muscle from 12 rats using a modified Klip's method^[8]. Skeletal muscle (1 g) was powdered under liquid nitrogen and homogenized for 20 s in buffer (pH 7.4) containing sucrose 250 mmol/L, Tris 50 mmol/L and edetic acid 0.2 mmol/L. The homogenates were centrifuged

at 9000×g for 10 min (4 °C) and the supernatants were reserved. The pellet was cleaned with buffer and centrifuged three times. All three supernatants were mixed and centrifuged at 190 000×g for 60 min (4 °C). The resulting pellet was resuspended in a small amount of buffer (about 0.5 mL) as a total membrane fraction. Protein concentrations of the suspensions were determined using the Coomassine brilliant blue method^[8] prior to Western blot analysis.

Frozen tissues (100 mg liver, 100 mg skeletal muscle) were ground into a fine powder with a mortar and pestle and homogenized in the buffer (1% Triton X-100, sodium pyrophosphate 100 mmol/L, HEPES 50 mmol/L, pH 7.4, NaF 100 mmol/L, PMSF 2 mmol/L, 0.1% aprotinin, sodium edetic acid 10 mmol/L, Na₃VO₄ 10 mmol/L) with a polytron homogenizer at 4 °C for 6 (for muscle) or 10 (for liver) times^[9,10]. The homogenates were centrifuged at 10 000×g at 4 °C for 60 min and the supernatants were collected for IRS-1 analysis.

Protein extracts were resuspended in Laemmli buffer and separated using sodium dodecylsulfate-polyacrylamide gel electrophoresis (SDS-PAGE) on 10% (for GLUT4) or 7.5% (for IRS-1) polyacrylamide gels. Proteins were electrophoretically transferred to nitrocellulose membranes. The nitrocellulose membranes were incubated in phosphate buffer saline contained 0.1% Tween-20 overnight at 4 °C to reduce non-specific binding and blotted with GLUT4 (anti-rabbit carboxy-terminal GLUT4, Santa Cruz Biotechnology, California, USA 1:1000) and IRS-1 (anti-rabbit carboxy-terminal IRS-1, Santa Cruz Biotechnology) antibodies according to the manufacturer's instructions. After incubation with peroxidase-conjugated secondary antibodies (1:2500, Santa Cruz Biotechnology), proteins were visualized using enhanced chemiluminescence. Band intensities were quantified by densitometry.

Statistical analysis The values presented are expressed as mean±SD. Statistical analyses were carried out using ANOVA. *P*<0.05 was considered to be statistically significant.

Results

Effect of pioglitazone on body weight, adipose weight, fasting blood glucose (FBG), fasting blood insulin (FBI), and insulin sensitivity index (ISI) STZ rats had significantly elevated levels of glucose and insulin compared with control rats (*P*<0.01) (Table 1). Reduced ISI (1/FBG×FBI) values revealed that insulin resistance developed in STZ rats. Treatment with pioglitazone for 28 d significantly lowered fasting glucose and insulin levels, and improved insulin sensitivity. STZ rats had significantly increased body weight and mass of celiac fat (*P*<0.01). There was no significant difference in

Table 1. Effects of pioglitazone (20 mg/kg, *po*) on body weight (BW), adipose tissue weight (AW) in the abdominal cavity, FBG, FBI and ISI in low-dose STZ rats. *n*=7–8. Mean±SD. ^c*P*<0.01 vs control group. ^e*P*<0.05, ^f*P*<0.01 vs STZ group.

body weight and adipose tissue weight between STZ animals and pioglitazone-treated animals (Table 1).

Effect of pioglitazone on glucose tolerance in STZ rats The IPGTT results revealed that rats in the STZ group had significantly impaired glucose tolerance compared with those in the control group. Surprisingly, the area under the curve (AUC) indicated that no effect attributable to pioglitazone administration on glucose tolerance was observed in the pioglitazone-treated group, although fasting glucose was slightly but significantly decreased (Table 2).

Table 2. Effect of pioglitazone (20 mg/kg, *po*) on glucose tolerance in low-dose STZ rats. *n*=7–8. Mean±SD. ^b*P*<0.05, ^c*P*<0.01 vs control group. ^f*P*<0.01 vs STZ group.

Effect of pioglitazone on insulin tolerance in STZ rats The results of the ITT showed that insulin resistance had developed significantly in STZ rats. Treatment with pioglitazone for 19 d markedly decreased glucose levels at every point, including AUC, indicating that insulin sensitivity was improved. In particular, the data suggested a prolongation in insulin action (Table 3).

Effect of pioglitazone on gluconeogenesis in STZ rats Under conditions of insulin resistance, gluconeogenesis from non-glucose substrates was always elevated in STZ rats. Our results showed that pioglitazone significantly reduced glucose production from alanine, which was assessed by a percentage increase in blood glucose levels at 60 min (Table 4).

Effect of pioglitazone on lipid profiles in serum, liver, and muscle The changes in lipid contents in these three

groups (Table 5) indicated that the serum TG, TC, and FFA levels were all elevated significantly in the untreated STZ group, whereas HDL-C decreased. Pioglitazone treatment decreased TG, TC, and FFA and increased HDL-C levels significantly. Elevated liver TG, TC, FFA levels and muscle TG were observed in STZ rats and were normalized by pioglitazone treatment. These findings may indicate that tissue lipid levels are closely associated with insulin sensitivity. The TC/HDL-C ratio is considered to be a predictor of cardiovascular disease (CVD). TC/HDL-C values suggested that pioglitazone diminished the potential risk of CVD by correcting dyslipidemia.

Effect of pioglitazone on GLUT4 content in skeletal muscle membrane Membrane GLUT4 protein content was decreased by 68.7% in skeletal muscles from untreated STZ rats compared with control rats (Figure 1). Pioglitazone treatment increased GLUT4 protein levels significantly.

Figure 1. GLUT4 protein content in skeletal muscle membrane using Western blot analysis. GLUT4 protein was detected using rabbit polyclonal antibody. Control, lanes 1–4; STZ, lanes 5–8; pioglitazone, lanes 9–12. Blots were quantified using densitometry and expressed as mean±SD (*n*=4). ^c*P*<0.01 vs control group. ^e*P*<0.05 vs STZ group.

Effect of pioglitazone on IRS-1 expression in liver and skeletal muscle Statistically significant (A, 26.7%; B, 28.6%) decreases in IRS-1 proteins were observed in untreated STZ rats compared with control rats (Figure 2). Pioglitazone treatment for 28 d increased IRS-1 protein expression in liver and skeletal muscle significantly.

Discussion

Insulin resistance is a characteristic feature of type 2 diabetes and other pathophysiological states in humans. Therefore, amelioration of insulin sensitivity is an important therapeutic goal. Diet plays an important role in the development of insulin resistance and type 2 diabetes. An excessive intake of fat and sugar can lead to obesity and diabetes^[11]. Previous studies have shown that high fat (59%) feeding for 24 d leads to significant insulin resistance. Euglycemic clamp revealed that glucose disposal rate (GDR) decreased by 50%; however, hyperglycemia was not observed^[12]. Pascoe and Storlien reported that low-dose STZ (45 mg/kg body wt) administration to neonatal rats caused no change in glucose and insulin levels after 8 weeks; however, hyperglycemia

Figure 2. IRS-1 protein expressions in liver and skeletal muscle using Western blot analysis. IRS-1 protein was detected using rabbit polyclonal antibody. Blots were quantified using densitometry and expressed as mean±SD (n=3-4). ^bP<0.05, ^cP<0.01 vs control group. ^eP<0.05, ^fP<0.01 vs STZ group. (A) IRS-1 protein in liver. and insulin resistance developed after high-fat feeding for 1 week^[13]. In the present study, we injected STZ at low doses to Wistar rats to induce light damage of islet cells, leading to glucose intolerance. On this basis, a high sucrose-fat diet was followed to induce obesity. Our previous study reported that glucose infusion rate (GIR) decreased significantly in model rats compared with control rats (15.1±4.8 vs

27.3±2.9 mg/kg per min, P<0.01)^[14]. This model is similar to the genetically insulin-resistant obese Zucker rats, which are characterized by a range of metabolic abnormalities including severe hyperinsulinemia, dyslipidemia and adipocyte hypertrophy; however, they possess normal blood glucose levels^[15]. The precise mechanisms responsible for this defect remain unknown.

Major progress has been made in understanding the mechanisms that causally underlie the metabolic actions of TZDs. Although the exact mechanisms remain uncertain, it has been widely reported that TZDs activate PPAR-γ and stimulate adipocyte differentiation, which might modulate the glucose metabolism of other tissues.

In the present study, we investigated the effects of a particular TZD, pioglitazone, on insulin resistance induced by low-dose STZ and a high sucrose-fat diet in Wistar rats. The model rats showed significant elevation in fasting blood glucose and insulin levels, as well as in circulating TG, TC, and FFA levels. Pioglitazone treatment markedly normalized serum lipid contents and decreased lipid storage in insulin-sensitive tissues. In our previous study, a strong correlation was found between circulating triglycerides and *in vivo* insulin resistance as assessed by the hyperinsulinemic-euglycemic clamp. Evidence from other studies also suggests an important role for tissue lipid levels in insulin action^[16]. It was, therefore, suggested that regulating lipid metabolism might play an important role in the insulin sensitizing effect of pioglitazone.

Studies *in vitro* have shown that a major effect of TZDs is the inhibition of gluconeogenesis in isolated hepatocytes^[17]. Our gluconeogenesis test revealed that pioglitazone significantly inhibited the impaired gluconeogenesis in STZ rats.

Our study also shed some light on the potential molecular mechanisms underlying amelioration of insulin resistance. We focused on the insulin sensitive tissues, that is, liver and skeletal muscle. It has been reported that glucose transport decreases in the skeletal muscle of high-fat or high-sucrose induced insulin-resistant rats, and that GLUT4 mRNA and protein expression also decrease^[18]. In insulin-deficient type 1 diabetic rats, GLUT4 expression also decreased^[19]. Our results are consistent with these reports and show a 68.7% decrement in skeletal GLUT4 protein content in STZ rats compared with control rats, although we did not measure plasmid membrane GLUT4 content during insulin stimulation, which reflects GLUT4 translocation. Although it is unlikely that changes in GLUT4 content entirely explain the insulin sensitizing effects of pioglitazone treatment because of various defects in the intracellular insulin-signaling pathway, GLUT4 is contributing to a certain extent.

IRS-1 is a well-described insulin receptor substrate that, after tyrosine phosphorylation, is associated with and activates PI3-kinase, and plays an important role in insulin signaling^[20]. Our results showed a marked deficiency in IRS-1 protein content in untreated STZ rats, with a significant improvement towards normal levels after pioglitazone treatment. Pioglitazone induced increases in GLUT4 and IRS-1 protein expression, which were associated with improvements in glucose transport and insulin signaling pathways, and this may explain the effects of pioglitazone in improving insulin resistance in the model animals.

In the present study, pioglitazone treatment improved insulin sensitivity as assessed by both ISI and ITT; however, pioglitazone had no effect on glucose intolerance in STZ rats. Glucose intolerance pre-existed prior to high sucrose-fat diet feeding, which means that the impaired glucose tolerance was originally caused by STZ administration, and developed gradually with feeding. The reasons for this remain uncertain and require further investigation, particularly the effects on β -cell function.

In conclusion, our studies showed a marked state of insulin resistance and obesity in STZ rats that is associated with various defects in glucose and lipid metabolism, including the insulin signaling–glucose transport pathway. Despite the persistence of obesity in these animals, pioglitazone treatment led to an apparent improvement in overall insulin sensitivity by ameliorating dyslipidemia, hyperinsulinemia, and gluconeogenesis, as well as affecting glucose transport and insulin signaling.

Abstract

Aim: To investigate the effects of a tissue-specific selective estrogen receptor modulator, idoxifene, on hepatic fibrosis in rats. **Methods:** Hepatic fibrosis was induced by dimethylnitrosamine (DMN) in male rats. The DMN model of hepatic fibrosis and the hepatocytes undergoing oxidative stress were treated with idoxifene respectively. The effect of idoxifene on hepatic fibrosis in the DMN model was examined by immunohistochemistry. Effects of idoxifene on antioxidant enzyme levels of copper, zinc-dependent superoxide dismutase (CuZn-SOD), and cellular glutathione peroxidase (GSHPx) were measured by ELISA. Effects of idoxifene on activation, proliferation, and apoptosis of culture-activated hepatic stellate cells (HSC) were analysed by immunohistochemistry, bromodeoxyuridine (BrdU) uptake, and flow cytometry, respectively. **Results:** Idoxifene could markedly suppress DMN-induced hepatic fibrosis in male rats. A treatment of 0.4 mg·kg⁻¹·d⁻¹ of idoxifene reduced the protein levels of collagen in the DMN model by 41.19% (*P*<0.05). Protein level of CuZn-SOD and activity of GSHPx in liver treated with DMN plus 0.4 mg·kg⁻¹·d⁻¹ of idoxifene were 2.65 times (*P*<0.05) and 2.08 times greater (*P*<0.05) than that of liver treated with DMN alone respectively. The protein level of CuZn-SOD and activity of GSHPx in cultured rat hepatocytes treated with ferric nitrilotriacetate (FeNTA) plus 1×10⁻⁷ mol/L of idoxifene were 3.43 times (*P*<0.05) and 2.52 times (*P*<0.05) greater than that treated with FeNTA alone. Idoxifene could inhibit HSC activation. Compared with the control, the uptake of BrdU in HSC cultured with 1×10⁻⁷ mol/L of idoxifene was reduced by 51.87% (*P*<0.05), and the number of apoptotic HSCs cultured with 1×10⁻⁷ mol/L of idoxifene increased by 94.52% (*P*<0.05). **Conclusion:** Idoxifene showed inhibitory action on hepatic fibrosis in male rats.

Introduction

Chronic injury leading to liver fibrosis occurs in response to a variety of insults, including viral hepatitis, alcohol abuse, drugs, metabolic diseases due to overload of iron, *etc.* Hepatic fibrosis is reversible, whereas cirrhosis, the end-stage consequence of fibrosis, is generally irreversible. Suppression of hepatic fibrogenesis and prevention of cirrhosis has attracted the attention of researchers from a therapeutic perspective. Hepatic fibrosis induced by dimethylnitrosamine (DMN) in rats is generally used as a model of hepatic fibrosis^[1,2]. Female hormone 17β-estradiol possesses inhibitory effect on DMN-induced hepatic fibrosis in rats^[1]. However,

administration of estrogen leads to some potential risks including breast cancer.

Idoxifene (*E*-1-[2-[4-[1-(4-iodophenyl)-2-phenyl-1-butenyl]-phenoxy] ethyl] pyrrolidine) is a novel tissue-specific selective estrogen receptor modulator (SERM). Idoxifene was originally developed for the treatment of advanced breast cancer^[3] and had no side effects of estrogen^[4]. Idoxifene possessed the protective roles in vascular smooth muscle cells by its blunting the angiotensin II-induced production of reactive oxygen species (ROS)^[5]. Chronic liver injury causes overproduction of ROS which result in oxidative stress and oxidative stress is a link between chronic liver injury and hepatic fibrosis. Moreover, idoxifene could also protect hepa-

toocytes from inflammatory cell injury^[6].

Based on the information, the aim of present study is to ascertain the effect of idoxifene on DMN-induced hepatic fibrosis in rats.

ROS are by-products of the inflammatory response, and contribute to both onset and progression of hepatic fibrosis^[7]. Copper, zinc-dependent superoxide dismutase (CuZn-SOD) and cellular glutathione peroxidase (GSHPx) are important enzymatic antioxidants in cells. Hepatic stellate cells (HSCs) play a central role in the development and resolution of hepatic fibrosis^[8-10]. In response to liver damage, HSCs "activate" to a myofibroblast-like (α -SMA-expressing) phenotype. Activation of HSCs is a critical step in hepatic fibrogenesis. Culturing quiescent HSC on plastic plates causes spontaneous activation leading to a myofibroblast-like phenotype, mimicking the process seen *in vivo*. This provides a simple and useful model for studying HSC activation. Therefore, in this report the impacts of idoxifene on enzymatic antioxidant and on cultured HSCs were explored.

Materials and methods

DMN model Thirty male Wistar rats (200±6 g, provided by the Animal Center of Nan Tong Medical College) were used for the DMN model of hepatic fibrosis (five groups of six each). The animals, were administered a single intraperitoneal injection of DMN (Sigma, St Louis, MO) (diluted with saline) at a dose of 40 mg/kg body weight^[11]. After the DMN treatments, the rats received daily oral gavage of idoxifene (synthesized at SmithKline Beecham Pharmaceuticals, King of Prussia, PA) in a dosing vehicle (methylcellulose) at a dose of 0.02 mg·kg⁻¹·d⁻¹, 0.1 mg·kg⁻¹·d⁻¹, or 0.4 mg·kg⁻¹·d⁻¹ respectively for two weeks^[11]. The controls received vehicle. After two weeks, the livers were removed and the protein levels of collagen were measured; hepatic fibrosis was shown by immunohistochemistry using an antibody against type I collagen. The protein levels of CuZn-SOD and the activities of cellular GSHPx in the liver were also detected.

Cell culture Hepatocytes were isolated from the livers of male Wistar rats (500–550 g) as described previously^[11]. Approximately 5×10⁵ cells were introduced into 20-mm diameter plastic dishes. Cells were cultured in 1 mL Williams medium E supplemented with 5% fetal bovine serum (FBS), penicillin 100 kU/L, streptomycin 0.1 g/L, and *L*-glutamine 2 mmol/L at 37 °C in 5% CO₂ atmosphere and 100% humidity. Overnight, the cell medium was removed, and the serum-free medium with 1×10⁻⁹, 1×10⁻⁸, or 1×10⁻⁷ mol/L of idoxifene was added to the cells respectively. After incubation for 1 h, FeNTA was added into the wells at a final concentration of 100

μmol/L which is generally used to cause oxidative stress in cultured hepatocytes^[6,12,13]. After 24 h^[12], the cells were collected and the protein levels of CuZn-SOD and the activities of cellular GSHPx were measured.

Isolation of HSCs from the liver of male Wistar rats (500–550 g) and the assay of purity and viability of isolated HSCs were performed as described previously^[14]. Both cell purity and viability was in excess of 90%. After HSCs were cultured in Dulbecco's modified Eagle's medium (DMEM) supplemented with 10% FBS on uncoated plastic culture dishes for 5 d, the activation of HSCs occurred^[2]. In present experiment, HSCs were initially cultured in DMEM supplemented with 10% FBS on uncoated plastic culture dishes for several days, then the culture medium was removed and the same medium with or without idoxifene was added to the cells which were cultured for an additional time. After the time, examination of activation, proliferation, and apoptosis of HSCs were performed.

Collagen determination Protein levels of collagen were determined as described previously^[2]. A portion of each liver was homogenized in 35 volumes (mL/g) of 0.5 mol/L acetic acid at 4 °C; homogenates were disrupted by freeze-thawing and sonicated for 2 min for collagen determination. The fraction of insoluble collagen after the acid extraction was then heated at 80 °C for 60 min and then converted into soluble gelatin. The collagen and gelatin contents of the acid extract were assayed using the Sircol collagen assay kit (Biocolor, Belfast, Northern Ireland) according to the manufacturer's directions.

Immunohistochemistry Immunohistochemical examination of the liver fibrosis was performed using polyclonal antibody against type I collagen (Chemicon International, Temecula, CA, diluted 1:100) as described previously^[2]. Briefly, after incubation with the antibody against type I collagen, liver samples were washed and were incubated with the biotin-conjugated IgG F(ab')₂ (DAKO, diluted 1:200), and finally with the avidin-biotin complex (Vectastain ABC reagent, Vector Laboratories, Burlingame, CA). Reaction products were visualized with diaminobenzidine and photographed.

For immunohistochemical examination of α -SMA, HSCs were initially cultured for 2 d in DMEM supplemented with 10% FBS. The culture medium was then removed and the same medium with or without 1×10⁻⁷ mol/L of idoxifene was added to the cells and the cells were cultured for an additional 4 d. During this period, the medium was replaced every other day. An immunohistochemical examination of α -SMA was performed as described previously^[14]. Briefly, after incubation with the a monoclonal antibody against α -

SMA (DAKO, diluted 1:50), cells were washed and were incubated with the biotin-conjugated IgG F(ab')₂ (DAKO, diluted 1:200), and finally with the avidin-biotin complex (Vectastain ABC reagent, Vector Laboratories, Burlingame, CA). Reaction products were visualized with diaminobenzidine and were photographed.

Antioxidant enzyme assays Liver tissues were washed with a 0.5% heparin sodium solution in PBS, and were then homogenized on ice in 6 volumes (mL/g) of Tris buffer (50 mmol/L Tris-HCl, pH 7.5, 5 mmol/L ethylenediaminetetraacetic acid and 1 mmol/L diethiothreitol). Cultured hepatocytes were washed twice with ice-cold PBS, and lysed directly in 150 μL of Tris buffer. The resulting homogenate and cells were disrupted by sonication for 1 min. The suspension was then centrifuged at 14 000×g at 4 °C for 30 min. Aliquot samples of the supernatants were analyzed for antioxidant enzymes. Protein level of CuZn-SOD was detected using an enzyme-linked immunosorbent assay (ELISA) system kit (Amersham, Little Chalfont, UK). GSHPx activities were determined using a cellular glutathione peroxidase assay kit (Calbiochem, San Diego, CA). Enzyme assays were performed according to each manufacturer's recommendation protocol.

Cell proliferation assays DNA synthesis in cultured HSCs was measured using a Cell Proliferation Biotrack ELISA system (Amersham, Little Chalfont, UK). HSCs were cultured in DMEM supplemented with 10% FBS in 96-well plate for 4 d. In the period, the medium was replaced every other day. After 4 d, the culture medium was removed and the same medium with or without 1×10⁻⁹, 1×10⁻⁸, or 1×10⁻⁷ mol/L of idoxifene was added to the cells respectively. After the cells were cultured for an additional 24 h, bromodeoxyuridine (BrdU) was added into each well at a final concentration of 10 μmol/L and the cells were incubated with BrdU for 24 h. The incorporated BrdU was detected according to the manufacturer's recommended protocol.

Early apoptosis detection A combination of FITC-conjugated annexin V and propidium iodide (PI) is a powerful and selective tool for measuring early apoptosis by flow cytometry. HSCs cultured in DMEM supplemented with 10% FBS in 6-well plates for 5 d. In the period, the medium was replaced every other day. After 5 d, the cultured medium was removed and the same medium with or without 1×10⁻⁷ mol/L of idoxifene was added to the cells. The apoptotic cells were detected using an ANNEXIN V FITC kit (Immunotech, Marseille, France) according to the manufacturer's recommended protocol. Flow cytometric analysis was performed on an ELICS XL flow cytometer (Coulter, Hialeah, FL).

Statistical analysis Data were expressed as mean±SD. Comparisons among groups were performed by an analysis of variance and Scheffe's test. *P*<0.05 was considered statistically significant.

Results

Effects of idoxifene on hepatic fibrosis The protein level of collagen increased in rat liver treated with DMN; 0.1 mg·kg⁻¹·d⁻¹ or 0.4 mg·kg⁻¹·d⁻¹ of idoxifene could inhibit the production of collagen induced by DMN in liver and 0.4 mg·kg⁻¹·d⁻¹ of idoxifene reduced the protein level of collagen induced by DMN in liver by 41.19% (*P*<0.05, Table 1). Immunohistochemistry study indicated that in DMN model, 0.4 mg·kg⁻¹·d⁻¹ of idoxifene markedly suppressed the expression of type I collagen (Figure 1) which is the most excessive extracellular matrix protein in hepatic fibrosis.

Table 1. Effects of idoxifene on protein levels of collagen in DMN model of rat hepatic fibrosis. *n*=6. Mean±SD. ^b*P*<0.05 vs Normal; ^c*P*<0.05 vs DMN ; ^d*P*<0.05 vs DMN+idoxifene.

Effects of idoxifene on antioxidant enzymes Compared with the normal (control), the protein levels of CuZn-SOD and the activities of GSHPx both in liver treated with DMN alone and in hepatocytes cultured with FeNTA alone evidently declined, whereas all the decline were inhibited by idoxifene (Table 2, 3). The protein level of CuZn-SOD and the activity of GSHPx in the liver treated with DMN plus 0.4 mg·kg⁻¹·d⁻¹ of idoxifene were 2.65 (*P*<0.05) and 2.08 (*P*<0.05) times greater than that in liver treated with DMN alone (Table 2). The protein level of CuZn-SOD and the activity of GSHPx in hepatocytes cultured with FeNTA plus 1×10⁻⁷ mol/L of idoxifene were 3.43 (*P*<0.05) and 2.52 (*P*<0.05) times greater than that in hepatocytes cultured with FeNTA alone (Table 3).

Effects of idoxifene on culture-activated HSCs Idoxifene evidently suppressed HSC activation (Figure 2), inhibited culture-activated HSC proliferation in a dose-dependent manner (Figure 3), and induced culture-activated HSC apoptosis in a time-dependent manner (Figure 4). Compared with the control, the uptake of BrdU in HSCs cultured with

The incorporated BrdU was detected. *n*=4. Mean±SD. ^b*P*<0.05 vs the 0 mol/L (control).

1×10⁻⁷ mol/L of idoxifene increased by 94.52% (*P*<0.05) (Figure 4D).

Discussion

Hepatic fibrogenesis is a process where production of extracellular matrix surpasses degradation. Collagen is the main component of extracellular matrix. Abnormal accumulation of collagen in chronic liver injury is a direct index that indicates the hepatic fibrogenesis. Data in this report showed that idoxifene could reduce the protein level of

Figure 4. Effects of idoxifene on apoptosis of cultured rat HSCs. After cultured for 5 d, HSCs were incubated without (A, control) or with (B, C, D) idoxifene (1×10^{-7} mol/L) for additional 0 (A), 1 (B), 2 (C), 3 (D) d, respectively. Flow cytometric analysis of the apoptotic cells was performed. Total numbers of cells examined in each sample was 25 000. In each panel (A, B, C, D), the lower right quadrant demonstrated the apoptotic cells. The ratios of apoptotic cell numbers to total cell numbers: A (26.84%), B (33.5%), C (42.44%), D (52.21%).

collagen in DMN model of hepatic fibrosis in a dose-dependent manner. Immunohistochemical studies directly showed that idoxifene markedly suppressed hepatic fibrosis induced by DMN. Together, these data demonstrated the inhibitory effect of idoxifene on hepatic fibrosis in rats.

ROS mainly include superoxide anion and its metabolin such as hydrogen peroxide and lipid peroxide. Since overproduction of ROS results in oxidative stress which is a link between chronic liver injury and hepatic fibrosis, reduction of oxidative stress by antioxidants can prevent hepatic fibrogenesis. Idoxifene evidently inhibited the decline in enzymatic antioxidant levels of CuZn-SOD and GSHPx, which can neutralize the effects of ROS, both in DMN model of hepatic fibrosis and in hepatocytes undergoing oxidative stress. CuZn-SOD can eliminate superoxide anion and GSHPx can eliminate hydrogen peroxide and lipid peroxide. The data partly suggested the inhibitory mechanisms of idoxifene on rat hepatic fibrosis.

Activated HSCs are proliferative and are responsible for the majority of extracellular matrix protein deposition that forms scar tissue during liver fibrogenesis. Idoxifene clearly suppressed HSC activation and culture-activated HSC proliferation. The data were consistent with the inhibitory effect of idoxifene on rat hepatic fibrosis.

Accumulating evidence has indicated that oxidative

stress plays critical roles in activation of HSC^[8,15,16]. Hepatocytes and Kupffer cells after chronic liver injury are a potent source of reactive oxygen intermediates^[17]. These compounds exert paracrine stimulation of stellate cells. In cultured stellate cells, conditioned medium from hepatocytes undergoing oxidative stress increases proliferation and collagen synthesis^[18]. Thereby the effects of idoxifene on the antioxidant enzymes (CuZn-SOD, GSHPx) *in vivo* and *in vitro* as shown in results suggested that idoxifene could inhibit HSCs activation at least through indirectly blunting the roles of ROS.

Recovery from established experimental fibrosis can occur through apoptosis of activated HSCs and is associated with reductions in liver collagen^[10,19]. The result that idoxifene effectively induced culture-activated HSC apoptosis further supported the inhibitory effect of idoxifene on hepatic fibrosis in rats.

Oxidative stress in liver causes hepatocyte apoptosis^[20] which promotes the activation of HSCs and hepatic fibrogenesis^[21-23]. Our recent results showed that idoxifene at 1×10^{-7} mol/L could markedly inhibit oxidative stress-induced hepatocyte apoptosis^[24]. Those results demonstrated the protective effect of idoxifene on hepatocytes and implied another inhibitory mechanism of idoxifene on hepatic fibrosis in rats.

Collectively, our data provides evidence that idoxifene possesses the inhibitory effect on hepatic fibrosis in rats. The inhibitory effect of idoxifene on hepatic fibrosis in rats was, at least in part, through maintaining antioxidant enzyme levels (CuZn-SOD and GSHPx).

SERMs are a diverse group of compounds that bind with specific, high-affinity binding to the estrogen receptor (ER) and can act as either ER agonists or antagonists. Tamoxifen, one of SERMs, increases fibrogenesis in CCl₄-induced liver fibrosis, showing estrogen antagonist activity^[25]. The data presented in the present study demonstrates the inhibitory effect of idoxifene on DMN-induced liver fibrosis in rats, showing the potential of idoxifene as an estrogen agonist in rat liver. The different biologic actions can be related to the ER subtype involved, different conformational changes of the ER according to the ligand, and steroid receptor coactivators and corepressors that modulate the cellular response to the ER-ligand complex^[26]. It is known that the alterations in the conformation of receptors influence their abilities to interact with coactivators and corepressors^[27].

Estrogen can suppress the hepatic fibrosis^[1], but it leads to serious side effects which restricts its application. The side effects of idoxifene is presently unknown. Idoxifene has been used for the treatment of advanced breast cancer

and also has no side effects of estrogen^[4], the findings in this report suggest that idoxifene might be useful in developing new therapeutic strategies for the treatment and prevention of hepatic fibrogenesis.

Abstract

Aim: To study the antiviral effect of *Oenanthe javanica* flavones (*OjF*) on human hepatoma HepG2.2.15 culture system and duck hepatitis B virus (DHBV) infection. **Methods:** (1) After incubation for 24 h, the 2.2.15 cells were treated with different concentrations of *OjF* for 12 d. The cell alteration was observed by microscope. The presence of HBsAg and HBeAg were measured using the enzyme immunoassay kit after 2.2.15 cells were treated with *OjF* for 9 d. (2) Ducklings infected with DHBV intravenously were divided into 5 groups and treated with *OjF*, acyclovir (ACV), and normal saline respectively for 10 d. All the ducklings were bled before, during, and after treatments at different times, and serum levels of DHBV-DNA were detected by a dot-blot hybridization assay. **Results:** (1) The 50% toxic concentration (TC₅₀) of *OjF* was 2.28 g/L. The maximum nontoxic concentration (TC₀) was 1.00 g/L. In nontoxic concentrations, *OjF* significantly inhibited HBsAg and HBeAg in 2.2.15 cells after 9 d of treatment ($P < 0.05$, $P < 0.01$). (2) The DHBV-DNA levels decreased significantly after the treatment with 0.50 and 1.00 g/kg of *OjF* ($P < 0.01$). The inhibition of the peak of viremia was maximum at a dose of 1.00 g/kg and reached 54.3% on d 5 and 64.5% on d 10, respectively. **Conclusion:** The results demonstrate that *OjF* is a strong inhibitor of HBsAg and HBeAg secretion in 2.2.15 cells and DHBV-DNA levels in the HBV-infected duck model.

Introduction

Oenanthe javanica (*Oj*), umbelliferate, has been widely used in traditional Chinese medicine for treatment of jaundice, hypertension, and polydipsia diseases for many years^[1]. Previous studies have shown that it has liver-protective^[2], hypotensive^[3], anti-arrhythmic^[4], anti-anaphylactic^[5], and antidiabetic^[6] effects. Recent studies also show that *Oj* was helpful in treatment of hepatitis B virus (HBV) infection in clinical trials^[7], and had an inhibitory effect on duck hepatitis B virus (DHBV)-induced hepatitis in Nestling ducks *in vivo*^[8] and *in vitro*^[9]. However, which is the active part and what are the active components of *Oj* in inhibiting HBV remain unclear. Using modern techniques, it has been revealed that *OjF* is one of the main active parts against HBV and it comprises approximately 2.2% of the whole plant content.

The present study aimed to investigate the anti-hepatitis activity of *OjF* in 2.2.15 cells *in vitro* and duck HBV infection in a duck model *in vivo*.

Materials and methods

Preparation of *OjF* *Oj* was collected from the Yanbian Autonomous Region in autumn and identification was performed by Prof Hui-zhong XIAO, Department of Phytochemistry, Yanbian Medical University. Dried whole plant was pulverized and extracted with 80% ethanol, and subsequently partitioned in ethyl acetate. The ethyl acetate soluble materials were fractionated by ethanol and distilled water gradient of column chromatography in polyamide. *OjF* was eluted and the content was determined according to aluminium nitrate reagent method. The content of hyperoside,

the major ingredient of *OjF*, was determined by reverse phase-high performance liquid chromatography (RP-HPLC)^[10,11]. The contents of *OjF* and hyperoside were 51.67% and 7% in whole extracts, respectively. The concentration used in the experiment was based on the dry weight of the extract.

Experimental animals Beijing ducklings within 1 d of hatching were obtained from an animal breeding farm, Chinese Academy of Medical Sciences [SCXK- (Beijing) 2002-001].

Reagents Minimum essential medium (MEM) was obtained from Gibco BRL (Gaithersburg, MD, USA). Fetal bovine serum (FBS) and G-418 were purchased from HyClone (Logan, Utah, USA). *L*-glutamine was obtained from Sigma (St Louis, MO, USA). HBsAg and HBeAg enzyme immunoassay (EIA) kits were purchased from China Isotope Co (Beijing, China).

Cell culture and treatment HepG2.2.15 cells (clonal cells derived from human hepatoma cell line G₂) were from the Institute of Medicinal Biotechnology, Chinese Academy of Medical Sciences. The 2.2.15 cells were cultured in complete MEM (containing 10% FBS, 100 kU/L benzylpenicillin, streptomycin, G-418, *L*-glutamine 0.03%, pH 7.0) in 75-cm² tissue culture flasks at 37 °C in a humidified 5% CO₂.

Cytotoxic studies The 2.2.15 cells were first seeded into 96-well plates (Corning Inc, Corning, NY, USA) at a density of 1.0×10⁵ cells per mL and cultured in 200 μL complete MEM containing 10% FBS. After 24 h of incubation, cells were washed three times with phosphate-buffered saline (pH 7.0) and treated with different concentrations (0.125, 0.25, 0.50, 1.00, 2.00, and 4.00 g/L) of *OjF* in serum-free medium for 12 d. The medium was replaced every 4 d in MEM supplemented with various concentrations of *OjF*. Untreated cells were used as control. The cell pathological changes (CPE) were observed by microscope. The degree of CPE was graded as: all positive cells (–), the number of negative cells <25% (+), 25%–49% (++), 50%–75% (+++), and >75% (++++).

Determination of HBsAg and HBeAg The 2.2.15 cells were incubated in 24-well plates at a density of 1.0×10⁵ cells per mL in 1 L MEM medium containing 10% FBS. After 24 h, the 2.2.15 cells were treated with different concentrations of *OjF* (0.125, 0.25, 0.50, and 1.00 g/L) in serum-free medium. Cells grew in the presence of drugs for 9 d with changes of medium every 3 d. After 6 and 9 d, supernatant was collected and performed at -20 °C. The HBsAg and HBeAg in culture medium were simultaneously measured by EIA kits on d 6 and d 9.

Experimented animals infection and drug treatment Beijing ducklings within 1 d of hatching were inoculated

intravenously with DHBV-DNA-positive serum from Shanghai ducks (0.2 mL/animal). Seven days after infection, ducklings were divided into five groups: the control group (normal saline); the positive drug group (ACV, 0.1 g·kg⁻¹·d⁻¹); and the *OjF* 0.25, 0.50, and 1.00 g·kg⁻¹·d⁻¹ groups. Drugs were administered orally, bid for 10 d. Serum samples were obtained before treatment (d 0), d 5, and d 10 during treatment, and d 3 (d 13) after the cessation of treatment. The serums were stored at -70 °C for future analysis.

Viremia analysis Viremia was assessed throughout the treatment and follow-up period by a semi-quantitative detection of DHBV-DNA in duck serum using a dot-blot hybridization. Fifty microliters of serum was spotted directly onto nitrocellulose filters. After denaturation and neutralization, the filters were hybridized with a full-length DHBV genomic DNA probe labeled with ³²P. The filters were autoradiographed and the spots were counted in a scintillation counter.

Histopathological examination of hepatocytes On d 13, each duckling was laparotomized to obtain the liver immediately after collecting blood from the leg vein. Fragments of the ducklings liver were fixed in 10% formalin solution, dehydrated with ethanol solution from 50% to 100%, embedded in paraffin and cut into 5 μm sections, and stained using haematoxylin-eosin dye for photomicroscopic observations.

Statistics The data were expressed as mean±SD, and analyzed by one-way repeated-measure ANOVA and *t*-test for comparisons between groups. *P*<0.05 was considered statistically significant.

Results

The cytotoxicity of *OjF* in 2.2.15 cells *OjF*-induced cytotoxicity was observed by microscope. After 12 d of incubation with 1.00 g/L *OjF*, no significant difference was found from that of the control. However, when *OjF* concentration increased, cell injury caused by *OjF* was observed (Table 1). The 50% toxic concentrations (TC₅₀) was 2.28±0.13 g/L and the maximum nontoxic concentrations (TC₀) was 1.00 g/L.

Inhibition of HBsAg and HBeAg production in 2.2.15 cells After 9 d of incubation, HBsAg and HBeAg production in the culture medium were determined (Table 2). The results showed that *OjF* suppressed HBsAg and HBeAg production in the 2.2.15 cells with median effective concentration (IC₅₀) of about 0.56 and 0.41 g/L respectively on d 6, 0.64 and 0.30 g/L respectively on d 9 (Table 3). *OjF*-induced suppression of HBsAg and HBeAg production in 2.2.15 cells was also reflected by the inhibition rate percentage (Figure 1, 2). The inhibitory effects appeared when cells were treated with 0.25 g/L *OjF*. A substantial increase of

inhibitory effects was observed from 0.50 g/L *OjF*. When treated with 1.00 g/L *OjF*, the inhibition rate percentage on HBsAg and HBeAg in 2.2.15 cells were both more than 50%. The inhibition rate percentage on HBsAg was dose-dependent, and the inhibition rate percentage on HBeAg was both time- and dose-dependent.

Inhibitory effect of *OjF* on DHBV-DNA During the course of this study, no obvious side effects were observed in animals receiving antiviral therapy or in control animals.

The effects of *OjF* and ACV, which were used for comparison, on DHBV replication *in vivo* were determined

by quantification of DHBV-DNA by dot-blot hybridization. The levels of serum viral DNA were recorded in the 5 groups before the experiment. During treatment, serum levels of DHBV-DNA decreased in all 16 ducks treated with *OjF* 0.50 and 1.00 g·kg⁻¹·d⁻¹ (Table 4). The mean percentage inhibition of viral DNA levels with *OjF* 0.50 and 1.00 g·kg⁻¹·d⁻¹ was 54.3% and 64.5% respectively on the last day of treatment

(Table 5). But 3 days after the cessation of treatment with ACV, the viral replication level returned to the pretreatment baseline. In ducks treated with *OjF*, the effect of DHBV-DNA inhibition lasted. No significant decrease of serum DHBV-DNA was observed during treatment with *OjF* 0.25 g·kg⁻¹·d⁻¹. In the control group, serum DHBV-DNA remained unaffected during the course of the study.

Histopathological features Histopathological profiles of the liver from model group ducklings revealed necrosis, steatosis, and often swelling of the hepatic cytoplasm. The protective effect of *OjF* was confirmed by histopathological examinations. Administration of *OjF* to the experimental animals (1.00 g·kg⁻¹·d⁻¹) showed a significant improvement of the hepatocellular architecture over the model group, as evident from a considerable reduction in necrosis and vacuolation (Figure 3).

Discussion

Hepatitis B virus causes acute and chronic hepatitis, which affects nearly 360 million people worldwide^[12]. Chronic infection with HBV has been associated with a high risk for the development of primary hepatocellular carcinoma^[13,14]. Effective antiviral therapy against HBV infection has not been fully developed. Studies have been hampered by the extremely narrow host range and limited access to experimental culture systems. Fortunately, techniques have been

developed to propagate hepadnaviridae in tissue culture^[15,16] and animal systems^[17]. The 2.2.15 cells contain all HBV particles, and the Peking ducks allow multiplication of the HBV-like virus, which make it possible to study the various aspects of the viral life cycle and to examine the effectiveness of potential antiviral drugs.

In a previous study, we have shown that the acid-base extracts of *Oj* could protect hepatic cells, decrease the content of ALT, AST, and BiliT on a liver damage model caused by carbon tetrachloride (CCl₄) in rats^[18], and inhibit DHBV^[7,8]. Similar results of the inhibitory effect of *Oj* extracts on HBsAg and HBeAg production in cultured 2.2.15 cells was also observed^[19]. However, what the active part of *Oj* against HBV is is still unknown. *OjF* was obtained through extraction and separation, which made up more than 50% in the whole extracts. It might be an active part against HBV.

Through subsequent purification of *OjF*, hyperoside, persicarin, isorhamnetin, and quercetin were obtained. Among them, the assay of hyperoside was the highest (purity>96%), which was used as the criterion to control the quality of *OjF*.

This study demonstrated the inhibitory effect of *OjF* on HBsAg and HBeAg secretion by human hepatoma 2.2.15 cells and on serum DHBV-DNA levels of ducklings infected with hepatitis B virus. TC₅₀ of *OjF* was 2.28 g/L and TC₀ was 1.00 g/L in 2.2.15 cells, which suggested that the inhibitory action of *OjF* had no cytotoxicity. In nontoxic concentrations, *OjF* significantly inhibited the secretion of HBsAg and HBeAg. With *OjF* concentration increasing, a dose-dependent response was observed. At a TC₀ of 1.00 g/L, the inhibition rate percentage of *OjF* on HBsAg and HBeAg in 2.2.15 cells were both more than 50%, and the inhibition rate per-

centage on HBsAg exceeded that of *OjF* on HBeAg.

These results clearly illustrate an inhibitory effect of *OjF* on HBsAg and HBeAg production in 2.2.15 cells, which provide strong evidence to evaluate the effect of drugs against HBV in a cellular model, but it is still necessary to verify this in an animal model. Therefore, the inhibitory effect of *OjF* in the duck HBV model was investigated. Our experiments with *OjF* (0.50 and 1.00 g·kg⁻¹·d⁻¹) in ducklings pointed to a suppressive action on DHBV replication *in vivo*. With *OjF* 1.00 g·kg⁻¹·d⁻¹, the therapy caused a more pronounced decrease (64.5%) in viremia. It was well known that most antiviral medicines had the inevitable rebound effect after drug cessation. This shortcoming had limited the therapy to those diseases infected by viruses such as HB or AIDS. The similar phenomena appeared in the positive control drug ACV in the present study. *OjF* showed therapeutic effects as well as ACV, and no difference was observed after cessation of *OjF* therapy compared to *OjF*-treated animals. It suggested that *OjF* could maintain for a long time in treating viremia of HBV and the effect of DHBV-DNA inhibition showed a concentration-dependent response. Histopathological examination also confirmed the function of *OjF* protecting the liver in DHBV-infected ducklings. Xiong Q *et al*^[19] reported that *Apocynum ventum* extracts containing hyperoside and quercetin had hepatoprotective activity, and *OjF* contained these two compounds. These results demonstrated the antihepatitis B virus effect of *OjF*, which were consistent with antiviral activity of *OjF*^[7,8], making *OjF* a candidate for future evaluation in patients with HBV infection.

In order to elucidate the possible mechanism of *OjF* towards DHBV-DNA on DHBV-infected ducklings, the effect of *OjF* on DHBV-DNA was investigated (data not shown). Our results indicate that *OjF* might inhibit the DNA-dependent DNA polymerase reaction, which results in the termination of replication of DHBV-DNA. This hypothesis is currently under investigation in our laboratory.

In conclusion, *OjF* possessed the significant antiviral activity *in vitro* and *in vivo*, and it was one of the main active parts of *Oj* against HBV. Elucidation of the mechanism of its antiviral activity and identification of the active components in *OjF* will greatly enhance the understanding of viral gene expressions and provide new clues to assist in the development antiviral agents in the future.

Abstract

Aim: To study the anti-endotoxic effect of *o*-aminobenzoic acid (OABA) isolated from Banlangen (BLG). **Methods:** OABA was extracted and isolated from BLG and diluted into 0.5% solution. The concentration of endotoxin (ET) pretreated with OABA was quantitatively detected using Limulus test. The inhibition of ET-induced fever by OABA was measured in rabbits. The rates of lipopolysaccharides (LPS)-induced death in mice pretreated with or without OABA were then compared. The influence of OABA on the release of TNF- α and NO from macrophages induced by LPS was examined in mice. **Results:** After pretreatment with OABA, 84.4% of ET was destroyed. The ET-induced fever in rabbits decreased significantly and the rate of LPS-induced death in mice dropped from 70% to 20%. The release of TNF- α and NO induced by LPS in mice was inhibited dose-dependently when the concentration of OABA was between 0.125% and 0.5%. **Conclusion:** OABA isolated from BLG has an anti-endotoxic effect.

Introduction

The pharmacological action of antipyretic and detoxicant materials is mainly related to their antibiotic and anti-endotoxic effects. It has been reported that Radix Isatidis (Banlangen, BLG) has antagonistic effects on endotoxin (ET) produced by *E Coli* O₁₁₁B₄^[1–6]. In all chemical constituents, the *o*-aminobenzoic acid (OABA) represented 70% of the total five organic acids^[7]. The Tachypleus Amebocyte Lysate (TAL) test *in vitro* showed that OABA had the strongest anti-endotoxin action^[8]. In the present study, the anti-endotoxic effect of the OABA was studied.

Materials and methods

Extraction and isolation of OABA BLG, which was grown in Xingtai, Hebei, China and identified as the root of *Isatis indigotica* Fort belonging to *Cruciferae*, was infused in ethanol for 72 h and percolated by ethanol after being powdered. Being concentrated in depression, the extract formed was extracted repeatedly by petroleum ether. When the petroleum ether was removed, the remaining was extracted by chloromethane so the F₀₂ part was obtained (0.8%). To

get a purer active ingredient, the F₀₂ part was isolated on silica gel column chromatography and the mobile phase was a mixture of CHCl₃-CH₃OH with different proportions. Four different polar fractions were obtained. By doing tests *in vitro* and *in vivo*, the F₀₂₂ part was found to have the strongest anti-endotoxic activity with a productivity of 0.31%^[9,10]. By further isolation with other proportions of CHCl₃-CH₃OH, we got another 14 components. Using the same method, we found that the part of F₀₂₂₀₉ whose productivity was 0.093% had the strongest activity among the 14 parts. The component was identified as OABA by Shanghai Institute of Materia Medica, Chinese Academy of Sciences (purity 99.7%).

Preparation of OABA solution With some flux being added, 0.5 g OABA was heated in a water bath until melted, then diluted in distilled water to 100 mL and adjusted to pH 6–7 with NaOH solution kept for later use after disinfection.

Reagents and instruments Lipopolysaccharides (LPS, *E Coli* O₂₆B₆, 5 mg each unit) were purchased from Sigma (St Louis, MO, USA). Working standard materials of Bacterial Endotoxin (Endotoxin, ET, *E Coli* O₁₁₁B₄, 120 EU each unit, batch No 2000-4) were supplied by the National Institute for the Control of Pharmaceutical and Biological Products

(Beijing, China). Tachypleus Amebocyte Lysate (TAL, with a sensitivity of 0.05 EU/mL, batch No 0008152) and water for bacterial endotoxin test (BET water, with the content of endotoxins below 0.015 EU/mL, batch No 000308) were the products of Zhanjiang A&C Biological Ltd (Guangdong Zhanjiang). Bacillus Calmette-Guerin (BCG, 50 mg per unit) was provided by Shanghai Institute of Biologicals (Shanghai, China). TNF- α reagent box (Biotinge Biomedicine Limited Company (Peking, China); N-1 Naphthalene ethylenediamine (the pure analysis, Chemical Reagent Research Institute, Tianjing, China); NaNO₂ (Germany, loaded separately, in chemical factory of Hubei University); sulfanilic amine (pure of analysis, FangCao Chemical Research Company in Beijing).

EDS98-Bacterial ET Detector was provided by Beijing Jinshan Science Development Co Ltd (Beijing, China). DG3022A type of enzyme-linked immunodetection instrument (Huangdong Radio Tube Company, Nanjing); 1815 TC type of the CO₂ cultivated box (Shel-Lab Company, USA); and XW-Vortex mixer from Instrumental Factory of Shanghai Medical University (Shanghai, China).

Animals Japanese big-ear rabbits of both sexes (weighing 2.0–2.5 kg) and Kunming strain mice of both sexes (weighing 16–18 g) were provided by the Experimental Animal Center of Tongji Medical College, Huazhong University of Science and Technology.

Quantitative determination of ET after being destroyed by *o*-aminobenzoic acid (OABA)

Preparation of ET solution One unit of ET (120 EU each unit) was dissolved in BET water to 1 mL, and spun homogeneously on XW-Vortex mixer for 30 s with concentration of 120 EU/mL.

Calibration curve A series of ET solution of 5.0, 2.5, 1.0, 0.5, 0.25, and 0.1 EU/mL were prepared. For every concentration, two tubes of TAL were used (two-tube method) and 0.2 mL solution was moved into either of them. When air bubbles disappeared by vibrating, the two tubes were rapidly inserted into the access holes of quantitative detector for bacterial endotoxins and the formation time of gel (Tg) was recorded. Correlation between Tg and lgC was analyzed with linear regression. The regression equation was: Tg=2.80049–0.23326 lgC, and the regression coefficient (r) was 0.9905. If the concentration of ET was in the range of 5.0–0.1 EU/mL, the linearity was fine and the lowest detecting limit was 0.05 EU/mL.

Recovery rate Tg of 4 EU/mL ET was determined in the same way as described above. When the data were put into the regression equation, the result was 4.218±0.243 EU/mL and the recovery ratio was (105.45±10.52)%.

Measurement of samples OABA solution 0.5 mL (0.5%) was homogenized with 0.1 mL ET (4 EU/mL), spun for 30 s, incubated in water bath at 37±1 °C for 60±2 min. Then 0.1 mL of the mixture was diluted in 0.4 mL fresh BET water. The final concentrations of OABA and ET were adjusted to 0.833 g/L and 4 EU/mL, respectively, serving as sample groups. We used 0.833 g/L OABA as a negative control and 4 EU/mL ET as a positive control. Tg of each group was determined and put into the regression equation, so concentrations of ET in each group and the destroy rate of OABA against ET could be obtained. The basal destroying rate was calculated according to the formula: $r=[1-(\text{Sample group}-\text{Negative group})/(\text{Positive group}-\text{Negative group})]\times 100\%$ ^[11].

Effects of OABA on ET-induced fever in rabbits

Preparation of reagent One unit of ET (120 EU) was diluted to 6 mL with sodium chloride injection and the concentration was 20 EU/mL.

Operation Before the experiment, rabbits were placed in the experimental environment and fed for a week. Three days before the experiment, anal temperatures of the rabbits were measured twice a day. The rabbits were fed only water as of the afternoon before the experiment day. Before administration, anal temperature was measured every 30 min. Fifteen rabbits whose anal-temperature fluctuations were below 0.2 °C were divided into three groups at random. Each group had five rabbits of both sex. Rabbits in the sample group and the negative group were given OABA (0.5%) 5 mL/kg via the marginal ear-vein. At the same time, the rabbits in the positive group were given a sodium chloride injection 5 mL/kg. Ten minutes later, the rabbits in the sample group and the positive group were injected with ET (20 EU/mL) at a dose of 2 mL/kg. Half an hour after the injection, the anal temperature of each rabbit was measured every 0.5 h for 4 h^[12].

Protective effect of OABA on LPS-induced toxicity in mice

BCG-induced enhancement of endotoxin sensitivity BCG (50 mg) was dissolved with sodium chloride injection and diluted to 5 mL (10 g/L). According to the method previously reported^[13], each mouse was intraperitoneally injected with BCG at a dose of 0.4 mL, then reared in the conventional way. Nine days after the injection the mice were given water, but no food. The experiment began on the tenth day.

Operation After fasting for 16 h, the mice were randomly divided into three groups ($n=20$; in each group, either sex). The mice in the OABA group and the negative control group were given OABA (0.5%) at a dose of 0.4 mL/20 g. The mice in the LPS model group were all intraperitoneally injected with the same dose of sodium chloride injection at the start of the

experiment. An hour and a half later, they were injected with the same dosage of injection again. Half an hour after this injection, the OABA and the LPS groups were injected with LPS at a dose of 0.2 mL/20 g. Time of death for all mice was observed over the next 72 h .

Effect of OABA on the LPS-induced release of TNF- α and NO in the serum of mice

Preparation of sample solution OABA solution was diluted with BET water from 0.5% to 0.25% and 0.125%.

Preparation of LPS solution One unit of LPS (5 mg) was dissolved in BET water to 10 mL (500 mg/L), spun for 30 s; then 0.8 mL was diluted in fresh BET water to 100 mL (4 mg/L).

Preparation of serum samples Thirty mice, each ip BCG 3 mg, were fasted without water for 12 h before the experiment. They were randomly divided into five groups, six mice per group in each experiment. The three experiment groups were ig 0.5%, 0.25%, 0.125% of sample solution at dose of 0.4 mL respectively. The control group and model group were administered NS. After 0.5 h the experiment group and the model group were iv LPS 0.2 mL/20 g from tail vein, 9 h later, they were anaesthetized with ether and blood was taken from the eye sockets. The serum were kept in -20 °C.

TNF- α examination Using the ELISA method, we proceeded examination according to the instruction in reagent box. On the enzyme-marked single quilted plank with anti-human cell factor, we added standard solution with which we acquired a series of concentration and 100 μ L serum sample. In the meantime, we established the blank group (double tube method), and added TMB substrate to display the color for 15 min after function for 60 min at 37 °C. The absorbance at 450 nm was checked, and the standard curve was drawn. As a result, the curve was in linearity at 10–1000 ng/L. We also tested the serum sample by using the same method, and calculated the concentration of TNF- α according to the standard curve.

NO examination Using the Griess reagent method, we took NaNO₂ 1 g precisely in a 100 mL volumetric flask and dissolved it with water. Then we took precisely 1 mL of this, and added water to 100 mL (100 mg/L) and diluted it to obtain a series of solutions. Each solution was 50 μ L and the Griess liquid was added (containing 1% Sulfanilic amine, 0.1% N-1 Naphthalene ethylenediamine, 2.5% phosphoric acid) 50 μ L, respectively, placed at room temperature (20 °C) for 10 min, and the absorbance value was tested at 550 nm. On the enzyme-linked immunodetection instrument, a standard curve was drawn. As a result, the curve had a line behavior at 1–100 mg/L. We added Griess liquid at the same volume to 50 μ L serum of mice, tested in the same way, and calculated

the concentration of NO according to the standard curve.

Results

Destroying rate of OABA against ET The concentrations of ET were 0.668 EU/mL in the sample group, 4.036 EU/mL in the positive group, and 0.045 EU/mL in the negative group. We concluded that 0.833 g/L OABA could destroy ET directly and the destroy rate was $[1-(0.668-0.045)/(4.036-0.045)] \times 100\% = 84.4\%$.

The ability to induce fever by ET after pretreatment with OABA If the average body temperature before injection was taken as basal body-temperature and the difference between the maximum body-temperature and basal body-temperature was taken as maximum rising temperature, the average DT_{max} of each group could be obtained. The temperature reaction index in 4 h (TRI₄) and DT_{max} are listed in Table 1.

Table 1. Restraining action of OABA to ET-induced fever in rabbits. *n*=5. Mean \pm SD. ^b*P*<0.05 vs positive group.

Groups	Basal body-temperature/°C	TRI ₄ /cm ²	DT _{max} /°C
Sample group	39.16 \pm 0.28 ^b	1.26 \pm 0.18 ^b	0.32 \pm 0.14 ^b
Positive control	39.04 \pm 0.18	3.28 \pm 0.42	1.21 \pm 0.32
Negative control	39.32 \pm 0.36	0.63 \pm 0.15	0.26 \pm 0.12

Table 1 shows that typical fever reaction occurred in rabbits given ET (40 EU/kg), while the TRI₄ and DT_{max} dropped when the rabbits were given the OABA solution (5 mL/kg) before the same dosage of ET was administered. The difference between the two groups was significant and OABA did not have the activity to induce fever.

The mortality rate of mice treated with OABA Four of the 20 mice died within 10 h in the OABA group with a mortality rate of 20%. Fourteen of 20 mice died within 5 h in the ET model group with a mortality rate of 70%. In the negative control group, all of the 20 mice survived after 72 h. There was a significant difference in mortality between the OABA group and the LPS group.

The inhibitory function of OABA on the excessive release of TNF- α and NO in the serum of mice induced by LPS Administering different concentrations of F022 part to mice, then also giving LPS at equal dosage, the TNF- α and NO in the serum and the percentage of inhibition were shown in Table 2. The formula of inhibitory percentage follows^[11]: IP%=[1-(specimen group-blank control group)/(model group-

Table 2. Inhibitory influence of OABA from Radix Isatidis on the level of TNF- α and NO in mice serum induced by LPS. $n=6$. Mean \pm SD. ^b $P<0.05$ vs LPS model group.

Groups	Concentration (%)	LPS (mL/20 g)	TNF- α (ng·L ⁻¹)	Percentage of inhibition (%)	NO (mg·L ⁻¹)	Percentage of inhibition (%)
Experimental group	0.5	0.2	126.6 \pm 12.3 ^b	85.44	13.5 \pm 4.2 ^b	90.73
	0.25	0.2	213.5 \pm 58.6 ^b	70.88	36.3 \pm 9.5 ^b	62.16
	0.125	0.2	587.1 \pm 123.3	8.25	73.8 \pm 20.5	15.16
Model group	–	0.2	636.3 \pm 215.3	–	85.9 \pm 21.4	–
Control group	–	–	39.8 \pm 5.4	–	6.1 \pm 3.3	–

blank control group)] \times 100%

Table 2 shows OABA from Radix Isatidis had inhibitory function on the release of TNF- α and NO induced by LPS in mice, the percentage of inhibition was dependent on the dosage when the concentration was between 0.125% and 0.5%.

Discussion

The chemical components of traditional Chinese medicine (TCM) were the substance basis of its pharmacology. Studying the Radix Isatidis's traditional function of reducing heat and detoxification was to study TCM with modernization research. Further study showed that organic acids of Radix Isatidis (quinazolinone acid, OABA, syringic acid, salicylic acid, and benzoic acid) had anti-endotoxic effects *in vitro*^[14–19]. The study showed that OABA had anti-endotoxic effect *in vivo* and *in vitro*. The OABA content in the Radix Isatidis was higher than other organic acids and had strong anti-endotoxic activity. It could be taken as a single active anti-endotoxic ingredient. The OABA could be used in the quality control production of Radix Isatidis medicinal materials, technology of preparation, and manufacture.

The dynamic color matrix method has many merits such as simple procedures, economy, high sensitivity, and wide detectable area. Normally, ET content between 0.05–300 EU/mL can be quantitatively measured. The content of ET was decreased to 0.668 g/L with the destroying rate being up to 84.4% when 4 EU/mL ET reacted with 0.833 g/L OABA.

One of the features of ET is its ability to induce fever. Rabbits are often used to screen antipyretic drugs because they are sensitive to ET. The dosages reported to induce fever in rabbits were not consistent, and we found that the results between the positive control group given *E Coli* O₁₁₁B₄ endotoxin at 40 EU/kg and the negative control group given 0.5% OABA solution was comparable well.

The sensitivity of different kinds of experimental animals

to LPS varies greatly. The lethal dose of 50% (LD₅₀) in mice was 25 mg/kg^[13]. After being sensitized by BCG, 2.42 mg/kg LPS could induce fatalities in 70% of mice. As BCG could stimulate T-cells to activate macrophages, the mitosis and metabolism in macrophages were strengthened substantially and the recognition ability of macrophages increased, so the quantity of LPS decreased. We also found that if OABA was given before LPS, OABA could exert a protective action on mice, while if OABA given after LPS, the protective action of OABA disappeared. The results showed that the action of OABA on LPS happened before the immune system was activated.

There is more and more evidence about the function of excessive release of TNF- α and NO in the disease process of shock induced by LPS. Some measures of anti-TNF- α will become important pathways of prevention and cure for LPS-induced shock. The release of a large quantity of NO is the main factor of endotoxin shock, low blood pressure, and exhausted function of many organs. It could cause tissues and organs to be scathed when NO was combined with anion of oxidated subnitryl. In the shock and exhaustion of many viscera, inhibiting the release of a large quantity of NO could prevent low blood pressure and alleviate the oxidized harm of tissues. Radix Isatidis was able to inhibit the function of the excessive release of TNF α and NO induced by endotoxin in mice macrophages.

Abstract

Aim: To determine whether mycophenolate mofetil (MMF) has beneficial effects on refractory idiopathic thrombocytopenic purpura (ITP) and the corresponding cellular mechanism. **Methods:** Twenty refractory ITP patients resistant to corticosteroid and/or splenectomy and chemical therapy were given MMF 1.5–2.0 g/d orally for a 2 to 4-month period. Serum immunoglobulin was detected by rate nephelometry. Platelet-associated antibodies (PAIgG) were assayed by enzyme-linked immunosorbant assay. The immunophenotypic analysis was performed on a flow cytometer and cell apoptosis was detected with transferase mediated dUTP biotin nick end labeling (TUNEL) method. **Results:** Sixteen of the 20 (80%) patients had responses to MMF treatment; 9 (45%) achieved a complete response, 4 (20%) achieved a partial response, and 3 (15%) achieved a minor response. The therapeutic effects were found to be better in male patients than female patients. The number of CD3⁺ peripheral blood cells (PBCs) and CD4⁺ PBCs increased and the number of CD8⁺ PBCs decreased. The plasma level of IgG, IgM, IgA and platelet associated IgG (PAIgG) decreased in 86% of the patients. TUNEL assay showed that mycophenolate acid (MPA) 0.1 mmol/L induced apoptosis of peripheral blood mononuclear cells isolated from refractory ITP patients. The apoptosis rate was increased in male patients after treatment with MPA, but was unchanged in female patients. **Conclusion:** Therapy for a period of 8 to 16 weeks with median-dose of MMF was valuable for the treatment of refractory ITP.

Introduction

Idiopathic thrombocytopenic purpura (ITP) is a common autoimmune hemorrhagic disorder, and the treatments are based on individual experience^[1]. In the clinic, the first line treatment is steroid therapy, and splenectomy is recommended as an alternative. However, 20% to 30% of ITP patients failed to respond to these two treatments, especially patients with refractory ITP^[2]. As the new immunosuppressive agent, mycophenolate mofetil (MMF) is widely used in renal transplantations and its relative safety has already been confirmed^[3,4]. In recent times, MMF has been used in the treatment of autoimmune disorders such as nephrotic syndrome^[5], Crohn's disease^[6], and autoimmune myasthenia gravis. The immunosuppressive ability of MMF is mainly derived from the inhibition of inosine monophosphate de-

hydrogenase^[7]. It has been reported that MMF can selectively inhibit the proliferation of T and B-lymphocytes, the generation of the antibodies, and the production of the cytotoxic T cells induced by immune stimuli. This also provided a strong basis for MMF as a novel therapeutic agent to treat refractory ITP. Here we reported the long-term therapy with MMF of 20 patients with refractory chronic ITP.

Materials and methods

Patients Twenty patients (12 males and 8 females), aged between 11 and 80 years (median 44.3 years) participated in the study; each patient gave their informed consent. The Ethics Committee of the 2nd Hospital of Xi'an Jiaotong University approved the study. Each patient was diagnosed as

refractory ITP in accordance with the following criteria: (1) thrombocytopenia (a platelet count $<50 \times 10^9/L$) over 6 months, unrelated to any underlying viral infection, collagen vascular diseases, malignancy, or medications; (2) without or with slight splenomegaly, with a normal or increased number of megakaryocytes in bone marrow, and no failure of maturing; (3) the failure of drug treatment and surgery treatment (prednisone, vincristine, danazol, long-term use of traditional Chinese medicine or intravenous injection of high doses of immunoglobulin G and splenectomy) (Table 1).

Therapeutic regimen MMF (250 mg/capsule, Shanghai Roche Pharmaceuticals Ltd, Shanghai, China) was taken orally at a dosage of 1.5–2.0 g/d for 4 weeks as 1 period of treatment. Patients who had responses to MMF continued taking MMF for another 2–4 periods. The therapy was discontinued in patients who achieved complete response during therapeutic period and in all patients after 16 weeks. Patients were given prednisone ($1 \text{ mg} \cdot \text{kg}^{-1} \cdot \text{d}^{-1}$) orally and hemostasia therapy concurrently with MMF. Follow-up was performed on each patient for 2–6 months (median, 3 months). Full blood platelet count was evaluated before and after MMF treatment in every period. Serum immunoglobulin IgG, IgM, and IgA were detected by rate nephelometry with the Array 360 system and associated reagents (Beckman Coulter Inc,

Fullerton, CA, USA). Platelet-associated antibodies (PAIgG) were assayed by enzyme-linked immunosorbant assay (ELISA, PeproTech Inc, Rocky Hill, NJ, USA). The normal value of PAIgG is $<60 \mu\text{g/L}$. Peripheral blood mononuclear cells (PBMNCs) were isolated by a Ficoll gradient (Ficoll-Hypaque, Density=1.077 g/L, Amersham-Pharmacia, Piscataway, NJ, USA). Fluorescein-conjugated monoclonal antibodies against CD3 (SK7 clone) and CD4 (SK3 clone) and phycoerythrin (PE)-conjugated monoclonal antibodies against CD8 (SK1 clone) were obtained from Becton Dickinson (Mountain View, CA, USA). Appropriate isotype-matched controls were included. PBMNCs were incubated with the monoclonal antibodies on ice for half an hour, then washed in phosphate buffered solution (PBS) three times, and suspended in PBS supplemented with 0.5% bovine serum albumin (BSA). A phenotypic analysis of cell populations was performed on a FACScan flow cytometer by using LYSIS software (Becton Dickinson, Franklin Lakes, NJ, USA). The criteria for response were defined as follows: (1) complete response: thrombocyte count rose above $300 \times 10^9/L$, and blood platelet count rose above $100 \times 10^9/L$. There was no bleeding for at least 3 months and no relapse for 2 years; (2) partial response: blood platelet count was above $50 \times 10^9/L$ or $30 \times 10^9/L$ higher than that before MMF treatment. There

Table 1. Characteristics and previous treatments of the 20 patients with refractory idiopathic thrombocytopenic purpura.

Case	Age	Sex	Course of ITP	Symptoms	Previous therapies	Response
1	37	F	14 months	Menorrhagia, petechia	Pred, VCR, CsA, splenectomy	No

Pred: prednisone; CsA: cyclosporine; VCR: vincristine; CTX: cyclophosphamide; IVIgG: intravenous immunoglobulin G; TCM: traditional Chinese medicine; F: female; M: male.

was no bleeding for 2 months; (3) minor response: increase in blood platelet count not exceeding $30 \times 10^9/L$ after MMF treatment. Bleeding symptoms were improved for 2 weeks; (4) no response: blood platelet was unchanged and bleeding symptoms were neither improved or worsened.

TUNEL assay Peripheral blood lymphocytes isolated from 20 refractory ITP patients were grown with or without mycophenolic acid $0.1 \mu\text{mol/L}$ (MPA, Sigma, St Louis, USA) for 3 d. The apoptosis was analyzed by transferase-mediated dUTP-biotin nick-end labeling (TUNEL) using a TUNEL kit (Boster Co, Wuhan, China). TUNEL assay were performed at room temperature unless indicated. Cells were fixed in 4% paraformaldehyde/1×PBS at for 10 min. After pouring off paraformaldehyde cells were incubated with PBS containing glycine 50 mmol/L for 10 min. Cells were permeabilized by 0.5% Triton X-100 in PBS for 10 min. After washing thrice in PBS, cells were equilibrated in equilibration buffer [200 mL of 1×terminal deoxynucleotidyl transferase (TdT) buffer+1 mmol/L cobalt chloride) under a $60 \text{ mm} \times 24 \text{ mm}$ coverslip for 5 min. Cells were incubated in 1×TdT buffer containing cobalt chloride 1 mmol/L , 25 units TdT $100 \mu\text{L}$, and 0.25 nmol/L biotin labeled dATP $100 \mu\text{L}$ at 37°C for 1 h in humidified chamber (petri dish, lined with filter paper, soaked PBS). The tailing reaction was terminated by 4×standard saline citrate (SSC). After applying $200 \mu\text{L}$ of 4×SSC with 2 g/L BSA and 1:100 dilution of fluorochrome-avidin under a coverslip, cells were incubated at 37°C for 1 h in humidified chamber. Then cells were washed in dark in 4×SSC for 5 min, 4×SSC/0.1% Tween 20 with 0.01 g/L DAPI for 5 min, and 4×SSC for 5 min, respectively. The TUNEL-positive cells were analyzed by fluorescence microscopy.

Statistical analysis Statistic analysis was performed by the χ^2 test and the paired *t*-test. All data are expressed as the mean±SD. $P < 0.05$ was considered to be significant.

Results

Therapeutic effects of MMF Sixteen of the 20 (80%) patients had responses to MMF treatment; 9 (45%) achieved a complete response, 4 (20%) achieved a partial response, and 3 (15%) achieved a minor response. The platelet count increased in 4 patients after 2 weeks of MMF treatment; it was above $50 \times 10^9/L$ in 7 patients after 4 weeks of MMF treatment and was above $100 \times 10^9/L$ in 10 patients after 6 weeks of MMF treatment. The responses of the 16 patients were sustained overtime after the withdrawal of MMF for 1 month, but less patients had a relapse after treatment discontinuation.

Twelve men had responses to MMF treatment; 8 (66.7%) achieved a complete response, 2 (16.7%) achieved a partial response, and 2 (16.7%) achieved a minor response. From the 8 women, only 1 (12.5%) achieved a complete response,

2 (25%) achieved a partial response, 1 (12.5%) achieved a minor response, and 4 (50%) had no response. These results indicate that the therapeutic effects of MMF are relatively better in male patients than female patients.

Side effects of MMF During the early stages of treatment, 7 patients experienced transient adverse reactions such as abdominal distension, anorexia, and nausea; these symptoms were later treated. No blood infection, bone marrow suppression, hypertension, severe headache, or muscle pain was observed in the 20 patients after MMF treatment. All of the patients completed the scheduled treatment suggesting that these patients had no tolerance of MMF.

Effect of MMF on immunophenotypics The percentage of $\text{CD}3^+$ and $\text{CD}4^+$ lymphocytes increased, but the percentage of $\text{CD}8^+$ lymphocytes decreased. Thus, the $\text{CD}4^+/\text{CD}8^+$ ratio elevated after MMF treatment (Table 2). The plasma levels of IgG, IgM, IgA, and PAIgG were markedly reduced in 17 patients after more than 2 weeks of MMF treatment (Table 3).

Table 2. Effect of mycophenolate mofetil on immunophenotypes of peripheral blood mononuclear cells in patients with refractory idiopathic thrombocytopenic purpura. $n=20$. Mean±SD. ^b $P < 0.05$ vs before treatment.

	Before	After
$\text{CD}3^+$ (%)	65 ± 5	69 ± 4^b
$\text{CD}4^+$ (%)	32 ± 4	39 ± 4^b
$\text{CD}8^+$ (%)	34 ± 3	30 ± 5^b
$\text{CD}4^+/\text{CD}8^+$ (%)	0.95 ± 0.15	1.31 ± 0.22^b

Table 3. Effect of mycophenolate mofetil on serum immunoglobulin and platelet associated antibodies (PAIgG) in patients with refractory idiopathic thrombocytopenic purpura. $n=20$. Mean±SD. ^b $P < 0.05$ vs before treatment.

	Before	After
$\text{IgG/g} \cdot \text{L}^{-1}$	14 ± 5	11.8 ± 2.9^b
$\text{IgA/g} \cdot \text{L}^{-1}$	3.3 ± 1.8	2.4 ± 1.0^b
$\text{IgM/g} \cdot \text{L}^{-1}$	2.0 ± 1.0	1.6 ± 0.6^b
$\text{PAIgG}/\mu\text{g} \cdot \text{L}^{-1}$	202 ± 147	102 ± 109^b

Effect of MPA on cell apoptosis After the peripheral blood mononuclear cells isolated from the patients were incubated with MPA $0.1 \mu\text{mol/L}$ for 3 d, a number of TUNEL-positive mononuclear cells were observed in male patients, ($P < 0.05$), indicating that the peripheral blood mononuclear

cells underwent apoptosis. The difference in apoptosis rate in female patients before and after MPA treatment was not significant ($P>0.05$).

Discussion

ITP is a common immune disorder caused by platelet-reactive autologous antibodies. In some patients, platelet production is decreased as well. ITP in adults does not generally remit spontaneously, and most patients need

hemostasia therapy. Corticosteroids, danazol, immunoglobulin, anti-D antibody, and several other agents inhibit clearance of the antibody-coated platelets, but the effect is not sufficient. Most patients will sustain a hemostatic response after splenectomy, although relapses can occur at any time^[8]. Refractory idiopathic thrombocytopenic purpura represents a life-threatening condition that fails to respond to a variety of therapeutic measures^[9]. In recent years, immunosuppressive agents such as cyclosporine A and MMF were used to treat refractory ITP as second line drugs. However, cyclosporine A has apparent side effects including hypertension, headache, and muscle pain. Thus, splenectomy could not be avoided, but could only be postponed in refractory ITP patients after they received cyclosporine A treatment. Howard *et al* reported that 4 patients with autoimmune haemolytic anemia and 5 of the 6 patients with autoimmune thrombocytopenia purpura showed a complete or good partial response to MMF^[10], confirming the beneficial effects of MMF on refractory ITP. However, only 6 patients participated in the study. In the present study, MMF treatment was sustained for at least 1 month. Sixteen of the 20 (80%) patients had responses to MMF treatment; 9 (45%) achieved a complete response, 4 (20%) achieved a partial response, and 3 (15%) achieved minor response. The curative rate was 80%. The results indicated that MMF could be used as a second line agent for the treatment of refractory ITP. We also found that men achieved better response to MMF than women which was not been reported in other published studies^[12]. The cell apoptosis rate was consistent with this conclusion. In long-term clinical observations, we also found that female ITP patients did not achieve better responses than male patients. We speculated that the difference might be related to different hormone levels and different MMF metabolism. However, the mechanism requires further study. MMF selectively inhibited the proliferation and survival of lymphocytes by inducing apoptosis and suppressing glycosylation and expression of adhesion molecules such as P-selectin, etc, which were over-expressed in ITP^[13]. Our result that MPA induced apoptosis of PB lymphocytes from ITP patients *in vitro* was consistent with a previous report^[14].

In contrast to MMF, we found that prednisone caused a significant increase in the number of myocarditis lesions. This is consistent with earlier studies that corticosteroids increased the severity of the disease during the acute phase of viral myocarditis in murine models^[15]. In conclusion, long-term therapy with a median-dose of MMF is valuable for the treatment of refractory ITP. Randomized clinical trials need to be performed in the future.

Abstract

Aim: To investigate curcumin (diferuloylmethane) induced apoptosis and its molecular mechanism of action in B-NHL cell line Raji cells. **Methods:** Raji cells were cultured in RPMI-1640 medium and treated with curcumin in different concentrations. 3-(4,5-Dimethyl-2-thiazolyl)-2,5-diphenyl-2*H*-tetrazolium (MTT) assay was used to detect growth inhibition and Hoechst 33258 staining was used to detect apoptosis. Immunocytochemistry and Western blot were used to detect the expressions of histone deacetylase 1, 3, and 8 (HDAC1, HDAC3, and HDAC8) and acetylated histone H4 (Ac-histone H4) protein. **Results:** Curcumin inhibited the proliferation of B-NHL cell line Raji cells with a 36-h IC₅₀ value of 24.1±2.0 μmol/L. Hoechst 33258 staining showed that curcumin could induce Raji cell apoptosis. The expression levels of HDAC1, HDAC3, and HDAC8 proteins were downregulated following curcumin treatment in Raji cells, whereas Ac-histone H4 protein expression was upregulated after treatment with curcumin. **Conclusion:** Curcumin, as a new member of the histone deacetylase inhibitors, can inhibit the expression of class I HDACs (HDAC1, HDAC3, and HDAC8), and can increase the expression of Ac-histone H4 in Raji cells. Curcumin plays an important role in regulating B-NHL cell line Raji cell proliferation and apoptosis.

Introduction

Histone acetylation/deacetylation is a key mechanism for regulating transcription. Acetylation of the ε-amino group of specific lysine residues within the N-terminal tail of core histones results in location chromatin relaxation. In general, histone acetylase activity is correlated with transcription activation, whereas histone deacetylase activity is correlated with transcription repression^[1,2]. Significant progress has been made in the use of histone deacetylase inhibitors as antineoplastic drugs. Several reagents have been shown to be histone deacetylase inhibitors (HDACIs), including TSA (Trichostatin A), butyrate, FR90228, and sulindac^[3,4]. The mechanism of HDACIs relates to inducing cell cycle arrest and apoptotic responses, and is regulated by changes in histone acetylation and deacetylation. Emerging evidence suggests that a family of histone deacetylases may exist to

regulate diverse cellular functions, including chromatin structure, gene expression, cell cycle progression, and oncogenesis^[5].

Curcumin, the major component of the spice turmeric and the yellow pigment in curry powder, has been widely used in India and other parts of South-East Asia as a spice and a coloring agent in cooking. Many studies have shown that curcumin (diferuloylmethane) has significantly antiproliferative and apoptotic effects for cancer treatment, including pancreatic carcinoma, liver carcinoma, and leukemia^[6,7]. Experimental studies have also revealed that curcumin regulates molecules in the cell signal transduction pathways, including NF-kappaB, Akt, MAPK, p53, AR, Ras, and ER pathways^[8,9]. Research has shown that curcumin is structurally related to sulindac, and the latter is a member of HDACs. Sulindac exerts significant chemopreventive activity, which is related to cell cycle arrest and the histone acetylation/

deacetylation state^[10]. In a previous study we revealed that curcumin inhibited K562 cell proliferation by Janus kinase-signal transducer and by activating transcription and activator protein-5 signaling pathways^[11]. In the present study, we chose the B-NHL cell line as the target. We assumed that curcumin could inhibit carcinoma cell proliferation by regulating Raji cells and we explored the underlying mechanism of curcumin regulating the histone acetylation/deacetylation pathway.

Materials and methods

Drugs and reagents Curcumin was purchased from Sigma Chemical Company (St Louis, MO, USA) and initially dissolved in dimethylsulfoxide (Me₂SO), stored at -20 °C, and thawed before use. 3-(4,5-Dimethyl-2-thiazolyl)-2,5-diphenyl-2*H*-tetrazolium (MTT) was purchased from Janssen Chimica Company (New Brunswick, NJ), and RPMI-1640 medium, Hoechst 33258, and Me₂SO were purchased from Sigma. Anti-HDAC1, anti-HDAC3, anti-HDAC8, and anti-Ac-histone H4 were purchased from Santa Cruz (California, USA). Streptavidin peroxidase (SP) reagent kits were purchased from Zhongshan Company (Beijing, China). Chemiluminescence (ECL) reagent kits were purchased from Pierce Biotechnology, Inc (Rockford, IL). The Raji cell line was obtained from China Center for Typical Culture Collection (Wuhan, China). The following treatments were applied: untreated Raji cells and Raji cells treated with 6.25 μmol/L, 12.5 μmol/L, and 25 μmol/L of curcumin for 24 h. All cell groups were grown in RPMI-1640 culture medium containing 10% fetal calf serum (FCS) and 2 mmol/L *L*-glutamine at 37 °C in a 5% CO₂ incubator.

MTT assay The antiproliferative effects of curcumin against different cell groups were determined using the MTT dye uptake method. In brief, the cells (40 000 per well) were incubated in triplicate in a 96-well plate. Different concentrations of curcumin were added, and the final concentrations were 6.25, 12.5, 25, 50, and 100 μmol/L. The plates were in the presence or absence of the indicated test samples for 0, 24, 36, 48, 60, and 72 h. The largest Me₂SO dissolved concentration group acted as the control group. Thereafter, 20 μL MTT solution (5 g/L in phosphate-buffered saline [PBS]) was added to each well. After 4 h at 37 °C, the supernatant was removed and 150 μL Me₂SO was added. When the blue crystal was dissolved, the optical density (*OD*) was detected in the microplate reader at 570 nm wavelength using a 96-well multiscanner autoreader (Biotech Instruments, New York, USA). The following formula was used: Cell proliferation inhibited (%) = [1 - (*OD* of the experimental samples / *OD* of the

control)] × 100%.

Apoptosis assay Curcumin-induced apoptosis was monitored by the extent of nuclear fragmentation. Nuclear fragmentation was visualized by Hoechst 33258 staining of apoptotic nuclei. Apoptotic cells were collected by centrifugation, washed with PBS, and fixed in 4% paraformaldehyde for 20 min at room temperature. Subsequently the cells were washed and resuspended in 20 μL PBS before being deposited on poly lysine-coated coverslips and left to adhere to the cover slips for 30 min at room temperature, after which the cover slips were washed twice with PBS. The adhered cells were then incubated with 0.1% Triton X-100 for 5 min at room temperature and rinsed with PBS three times. The coverslips were treated with Hoechst 33258 at 37 °C for 30 min, rinsed with PBS, and mounted on slides with glycerol-PBS. The cells were viewed with an Olympus BH-2 fluorescence microscope (Japan).

Immunocytochemistry analysis Curcumin-treated cells were plated onto a glass slide, air dried for 1 h at room temperature, and fixed with cold acetone. After brief washing in PBS, the slides were blocked with 5% normal goat serum for 1 h and incubated with HDAC1, HDAC3, HDAC8, and Ac-histone H4 (dilution 1:100, respectively). After being left overnight at 4 °C the cells were treated with biotinylated link secondary antibody and peroxidase-labeled streptavidin followed by diaminobenzidine (DAB). The cells were viewed with an Olympus microscope and their individual *OD* values were recorded using an HPIAS 1000 Image Analysis System (High Resolution Pathological Image & Word Analysis System, Beijing, China).

Western blot analysis Lysates were prepared from 1 × 10⁷ cells by dissolving cell pellets in 100 μL of lysis buffer (Na₂PO₄ (pH 7.4) 20 mmol/L, NaCl 150 mmol/L, Triton X-100 1%, aprotinin 1%, phenylmethylsulfonyl fluoride 1 mmol/L, leupeptin 10 g/L, NaF 100 mmol/L, and Na₃VO₄ 2 mmol/L). Lysates were centrifuged at 18 000 × *g* for 15 min and the supernatant was collected. Protein content was determined using a Bio-Rad protein assay (Bio-Rad Laboratories, Hercules, CA, USA). Sodium dodecylsulfate-polyacrylamide gel electrophoresis (SDS-PAGE) sample buffer (10 mmol/L Tris-HCl, pH 6.8, 2% SDS, 10% glycerol, 0.2 mol/L DTT) was added to the lysates. Lysates were heated to 100 °C for 5 min, and 80 μg of protein was loaded into each well of a 10% SDS-PAGE gel. Resolved proteins were electrophoretically transferred to nitrocellulose and blocked with 5% non-fat milk, and the primary antibodies HDAC1, HDAC3, HDAC8, and Ac-histone H4 were added. After overnight incubation at 4 °C the blots were washed, exposed to HRP-conjugated corresponding secondary antibodies for 1 h, and finally detected by ECL.

Quantification of the bands was carried out using densitometric analysis software, Quantity One (Bio-Rad), and processed as described previously^[12].

Statistical analysis All data were expressed as mean±SD using SPSS 10.0 for windows 98. Using linear *t*-tests for statistics analysis, *P* values of less than 0.01 or 0.05 were considered to be statistically significant.

Results

Effects of curcumin on the proliferation of Raji cells by MTT Raji cells treated with different concentrations of curcumin for 0, 24, 36, 48, 60, and 72 h resulted in the inhibition of cell proliferation in a dose- and time-dependent manner. The *OD* value of curcumin-treated groups decreased significantly compared with the untreated group. Results reveal great differences between curcumin-treated groups and the untreated group (Figure 1). The *IC*₅₀ of 36 h is 24.1±2.0µmol/L.

Figure 1. Antiproliferation effect of curcumin in Raji cells. Raji cells were treated with various concentrations of curcumin as indicated for 0, 24, 36, 48, 60, and 72 h. Growth inhibition was determined using a MTT assay and shown as inhibitory rate.

Nuclear damage observed using Hoechst 33258 staining Apoptotic nuclear morphology was assessed using Hoechst 33258 staining. Hoechst 33258 staining of untreated Raji cells and cells treated with 25 µmol/L curcumin for 24 h was conducted. Curcumin permeates the cell and is known to play a role in cancer chemoprevention and tumor growth suppression. Exposure of tumor cells to curcumin *in vitro* results in the inhibition of cell proliferation and the induction of apoptosis. Consistent with previous reports on other cell lines^[9,11], treatment of Raji cells with curcumin (24 h exposure to 25 µmol/L curcumin) induces apoptosis (Figure 2).

Figure 2. (A) Untreated Raji cells. (B) Cells treated with 25 µmol/L curcumin for 24 h. Photographs were taken under an Olympus BH-2 fluorescence microscope (×40). Arrows indicate apoptotic nuclear fragmentation.

Expression of HDACs and Ac-histone H4 on Raji cells and curcumin-treated cells using immunocytochemistry Our results reveal that the expression of HDAC1, HDAC3, and HDAC8 was significantly higher in Raji cells compared with curcumin-treated cells (25 µmol/L for 24 h) (*P*<0.05). The expression of Ac-histone H4 was significantly higher in curcumin-treated cells (25 µmol/L for 24 h) than in Raji cells (*P*<0.05)(Figure 3). Photos were analyzed using a HPIAS 1000 Image Analysis System and *OD* values were recorded (Figure 4).

Expression of HDAC1, HDAC3, and HDAC8 on Raji cells and curcumin-treated cells using Western blot Our results reveal that curcumin can induce antiproliferation and apoptosis in Raji cells. However, it is unclear how curcumin induces this antiproliferation and apoptosis. Cells treated with 6.25, 12.5, and 25 µmol/L of curcumin for 24 h were lysed and resolved in 10% SDS-PAGE, and Western blot analysis was carried out using anti-HDAC1, anti-HDAC3, and anti-HDAC8. Figure 5 shows considerable changes in HDAC1, HDAC3, and HDAC8 following curcumin treatment.

Figure 3. (A, B) Expression of HDAC1 in control and curcumin-treated cells; (C, D) Expression of HDAC3 in control and curcumin-treated cells; (E, F) Expression of HDAC8 in control and curcumin-treated cells; (G, H) expression of Ac-histone H4 in control and curcumin-treated cells.

These results indicate that HDAC1, HDAC3, and HDAC8 are related to curcumin-mediated apoptosis. The levels of HDAC1, HDAC3 and HDAC8 protein decreased in a dose-dependent manner (Figure 5).

Expression of Ac-histone H4 in Raji cells and curcumin-treated cells The expression of Ac-histone H4 was significantly greater in curcumin-treated Raji cells (6.25, 12.5, and 25 $\mu\text{mol/L}$, for 24 h) than that in Raji cells ($P < 0.05$, Figure 6).

Figure 4. OD value of HDAC1, HDAC3, HDAC8, and Ac-histone H4 in Raji cells and curcumin-treated Raji cells (25 μmol/L, 24 h). ^b*P*<0.05 vs control.

Figure 6. Effect of curcumin on the expression of Ac-histone H4 in Raji cells. Cells were treated with different concentrations of curcumin for 24 h and Ac-histone H4 expression was tested using Western blot analysis. 1, 2, 3, and 4 are the control, and curcumin 6.25, 12.5, and 25 μmol/L, respectively. *n*=3. Mean±SD. ^b*P*<0.05 compared with the control.

Figure 5. Effects of curcumin on the expression of HDACs in Raji cells. Cells were treated with different concentrations of curcumin for 24 h and HDACs expression was tested using Western blot analysis. 1, 2, 3, and 4 are the control, and curcumin 6.25, 12.5, and 25 μmol/L, respectively. *n*=3. Mean±SD. ^b*P*<0.05, ^c*P*<0.01 compared with the control.

Discussion

Reversible histone acetylation occurs in the ε-amino group of the specific internal lysine residues located at the highly basic N-terminal domains of core histones. Histone acetyltransferase (HAT) and HDAC control the addition and removal of acetyl groups on proteins and maintain a dynamic balance of steady-state acetylation^[13]. A balance between the acetylation and deacetylation states of these pro-

teins forms the basis for the regulation of transcription. Research has shown that HDACs have wide ranges of effects on cell function. These effects include specific gene activation, inhibition of cell proliferation and cell cycle arrest, as well as induction of cell differentiation^[14]. Multiple forms of HDACs have been identified in mammalian cells. In humans, at least 11 HDACs have been uncovered. They are classified into three general classes: class I (HDAC1, 2, 3, 8, and 11), class II (HDAC4, 5, 6, 7, 9, and 10) and class III^[15]. Class I enzymes are smaller polypeptides of approximately 500 amino acids, whereas class II HDACs are much larger proteins with approximately 100 amino acids. Most class II HDACs shuttle between the cytoplasm and nucleus and regulate myogenesis. HDACs can react with co-repressor (Mad/Max, N-CoR, SMRT) to regulate cell proliferation and change the dynamics of chromatin structure^[16]. In general, HDAC1, HDAC3, and HDAC8 are located in the cell nucleus. Many signal transfer pathways (RAS/MAPK, JAK-STAT) and transcriptional factors related to hematopoietic stem cells are regulated by HDACs and HATs.

B-NHL plays an important role in blood system tumors. We chose the Burkitt lymphoma cell line Raji as the research target. Previous studies have revealed that lymphoma is related to the rearrangement of BCL6. Several studies have shown that BCL6 is rearranged in 30%–40% of diffuse large cell lymphoma (DLCL) and 6%–14% of follicular lymphomas (FL). In addition, the chromosomal band 3q27 affects IG gene loci that lead to lymphoma. Abnormal BCL6 can regulate cell-cycle factors (pRB, PLZF) by recruiting HDACs,

and can affect the cell cycle. As the result of an abnormal recruiting function, many transcriptional factors can suppress specific genes, which can lead to carcinogenesis. HDACs can cure cancer by inhibiting HDACs and blocking abnormal recruitment.

Chemoprevention is a rapidly growing field in cancer research that focuses on inhibiting and delaying the onset of carcinogenesis. A large number of natural products have been evaluated as potential chemopreventive agents. Numerous studies have shown that curcumin could suppress the proliferation of many cancer cells. In the present study, we found that curcumin could inhibit the proliferation of Raji cells, and that the effects were time- and dose-dependent. The 36 h IC_{50} of curcumin was $24.1 \pm 2.0 \mu\text{mol/L}$. Curcumin can lead to the apoptosis of Raji cells, and can affect cell cycles. The cell cycle was arrested in G_0/G_1 and G_2/M phases, and the S phase also decreased (data not shown). However, the mechanisms of apoptosis and cell cycle arrest are not clear. In our study, the expression of HDAC1, HDAC3, HDAC8 and Ac-histone H4 on B-NHL cell line Raji and curcumin-treated Raji cells (different concentrations for 24 h) was examined using immunocytochemistry and Western blot analysis. The expression of HDAC1, HDAC3, and HDAC8 proteins on Raji cells decreased compared with the control Raji group, whereas Ac-histone H4 expression increased compared with the control Raji group in a dose-dependent way.

Trichostatin (TSA) was the first discovered HDAC inhibitor (HDACI), followed by sodium butyrate, sulindac, MS-27-275, and FR90228^[10]. *In vitro* and *in vivo* studies examining HDACs reveal that HDACs affect many cell functions, such as cell proliferation, chromosome remodeling, and gene transcription. The mechanism of action relates to inhibiting HDACs, increasing the function of HATs, and increasing histone deacetylation. Hu *et al*^[15] found that TSA decreased the expression of HDAC1, HDAC3, and HDAC8 in SW620 in a dose-dependent way. The IC_{50} was approximately 0.1–0.3 nmol/L. In addition, TSA can increase the expression of Ac-histone H4 and lead to apoptosis, which is related to the SV40 promoter. Balasubramanyam *et al*^[13] reported that curcumin was a specific inhibitor of p300/CBP HAT activity, but not of PCAF, *in vitro* and *in vivo*. Furthermore, curcumin can also inhibit the p300-mediated acetylation of p53 *in vivo*. Curcumin specifically represses the p300/CBP HAT activity-dependent transcriptional activation from chromatin, but not from a DNA template.

Thus, we believe that curcumin, as a new member of the HDACs, can inhibit the expression of HDAC1, HDAC3, and HDAC8 in curcumin-treated Raji cells and can increase the

expression of Ac-histone H4. In addition, curcumin can inhibit cell proliferation and induce apoptosis. Dysfunction of histone acetyltransferases and histone deacetylases is often associated with the manifestation of several different types of cancer. These enzymes, therefore, are potential new targets for therapy. However, the mechanism by which the abnormal function of HDAC1, HDAC3, and HDAC8 regulates gene transcription remains to be determined. The increase in Ac-histone H4 highlights whose gene will be opened and provides a new field to examine the action mechanism of curcumin.

Abstract

Aim: To construct a recombinant retrovirus vector carrying human promyelocytic leukemia (PML) cDNA and identify its expression and biology role in bladder cancer UM-UC-2 cells for future gene therapy. **Methods:** PML full-length cDNA was inserted into the *EcoR* I and *BamH* I site of pLXSN vector containing the long terminal repeat (LTR) promoter. The vector was identified by restriction enzyme digestion and then transfected into PA317 packaging cell line by calcium phosphate coprecipitation. PML cDNA was detected by polymerase chain reaction (PCR) and the protein was identified by laser confocal microscopy and Western blot in bladder cancer cells, respectively. The morphology was observed by inverted phase contrast microscope, and MTT assay determined growth curve of the bladder cancer cells. **Results:** Restriction enzyme digestion proved that a 2.1 kb PML cDNA was inserted into the pLXSN vector. PCR assay demonstrated that 304 bp fragments were found in UM-UC-2/pLPMLSN transfects. Laser confocal microscopy showed speck dots fluorescence in the UM-UC-2/pLPMLSN nucleus. A 90 kD specific band was found by Western blot. MTT assay demonstrated the UM-UC-2/pLPMLSN bladder cancer growth inhibition. **Conclusion:** The retrovirus pLPMLSN vector was successfully constructed and could generate high effective expression of human PML in bladder cancer cell UM-UC-2, suggesting that PML recombinant retrovirus have potential utility in the gene therapy for bladder cancer.

Introduction

Promyelocytic leukemia (PML), which encodes a growth transformation suppressor^[1] and pro-apoptosis factor, mediating cell death by apoptosis^[2], is disrupted by 15:17 chromosomal translocation in acute promyelocytic leukemia. The physical function of the PML gene was complicated and the PML gene has an altered expression during human oncogenesis. Its expression was reduced dramatically when cancer turned invasive^[3]. Cells deficient in PML are resistant to apoptosis by multiple apoptotic stimuli, suggesting that PML is a pro-apoptosis factor^[2]. Overexpression of PML protein could inhibit various human tumor growth *in vitro* and *in vivo*, such as in Hela cell^[4], prostate cancer cells (PC-3, DU145, LNCaP)^[5], breast cancer^[6], and bladder cancer cells (5637; UM-UC-2 unpublished data)^[7]. This evidence suggests that

PML could be a candidate gene for human tumor gene therapy.

In this study, we further detected whether the PML as a growth suppressor could be a potential candidate gene for bladder cancer gene therapy. We constructed a recombinant retrovirus carrying the PML gene, which was controlled by long terminal repeat (LTR) promoter, and we want to study whether recombinant PML retrovirus has a high level PML protein expression in bladder cancer UM-UC-2 cells and whether overexpression of PML could inhibit bladder cancer cell growth.

Materials and methods

Cell culture and reagents UM-UC-2 cells^[8] were cultured in Dulbecco's modified Eagle's medium (DMEM) at

37 °C supplemented with 10% fetal calf serum (FCS). PA317 packaging cells and NIH3T3 cell were maintained in RPMI-1640 medium supplemented with 10% fetal bovine serum (FBS). Each medium was supplemented with penicillin (50 kU/L) and streptomycin (50 kU/L). The GST-PML antibody and PGS5-PML vector were obtained from Dr K S CHANG (MD Anderson Cancer Center, The University of Texas, USA). The PLXSN vector was purchased from Clontech Company.

Construction and amplification of pLPMLSN The PML retroviral vector pLPMLSN was constructed by inserting the full-length PML cDNA^[1] into the *EcoR* I and *BamH* I restriction site of the pLXSN retroviral vector. The reconstructed plasmid DNA used for transfection was purified by the plasmid purification kit (Huashun Inc, Shanghai, China) according to the manufacturers' instruction. DNA concentration was determined by UV spectrophotometer^[4].

Generation of viral particles and infection to target cells pLXSN and pLPMLSN were transfected into the PA317 packaging cell lines by calcium phosphate coprecipitation^[9]. PA317 packaging cells were split and grew in the selective medium with 800 mg/L of G418. After 2 weeks, G418 resistant colonies were picked and expanded in medium with 200 mg/L G418 and the supernatant viral particles were collected. The titer of viral stocks was calculated by infection of mouse fibroblast NIH 3T3 cell^[11]. The titer of pPMLSN and pLXSN retrovirus was 1.3×10^9 CFU/L and 2.1×10^9 CFU/L, respectively.

The UM-UC-2 cells, as target cells, were infected with recombinant PML retrovirus and the control virus respectively by the supernatant gene transfer technique, as previously described^[10]. In brief, UM-UC-2 cells in exponential growth were plated in 60-mm culture dishes 1 day before recombinant virus infection. Each culture dish was then fed with 10 mL of recombinant viral supernatant containing polybrene at a final concentration of 8 mg/L. The UM-UC-2 cells were then infected with viral particles for 48 h. The viral supernatant was prepared by incubating fresh medium for 1 day with the growth-accelerated viral producer and then used directly for further experiments.

Identification of PML cDNA in transfected cells Genomic DNA was prepared from UM-UC-2, UM-UC-2/pPMLSN, UM-UC-2/pLXSN cells and used for polymerase chain reaction (PCR) with primers specific for PML (forward 5'-CTT GAA CCT CCT CGT TCG ACC-3' reverse 5'-GTACAA CAG GTA GCG GAT CCC-3'). The forward primer was specifically designed for pLXSN vector, and the reverse primer was for PML cDNA. The reaction mixture for PCR amplification was subjected to 30 cycles of denaturation (95 °C, 60 s),

annealing (56 °C, 60 s), and extension (72 °C, 60 s). The amplification products were identified by 2% agarose-gel electrophoresis.

Identification of PML protein expression in transfected cells by immunofluorescence staining and Western blot Western blot and immunofluorescence staining of bladder cancer UM-UC-2 cells infected with recombinant PML retrovirus and control virus were carried out as described in our previous report^[5]. Briefly, UM-UC-2 cells were seeded on coverslides for at least 4 h, and then recombinant PML retrovirus was added and incubated at 37 °C for 24 h. Cells were washed in phosphate-buffered saline (PBS) twice and fixed in 4% paraformaldehyde for 20 min and 0.1% Triton X-100 for 10 min, followed with three washes in PBS containing 0.1% BSA. Cells were then incubated in the washing buffer for 20 min at room temperature. Immunofluorescence staining was performed using the affinity-purified antipeptide polyclonal antibody GST-PML at dilution of 1:2000 for 1 h at 37 °C, and then goat anti-rabbit IgG-fluorescein isothiocyanate secondary antibody (Sabc Inc, Beijing, China) was added for another 1 h. Confocal microscopy analysis was performed by using a Zeiss (New York, NY, USA) laser scanning confocal microscope at 494-nm stimulated wavelength.

Western blot of PML protein was performed using RIPA lysis buffer and 8% SDS-PAGE gel electrophoresis. Proteins were transferred to NC filter (Bio-Rad) and blocked with 5% non-fat milk for 1.5 h. The filters were then incubated for 2 h with a dilution of 1:2000 GST-PML antibody and then for 1 h with the secondary antibody at dilution of 1:500. Immunodetection was performed using the ECL Western blot detection system.

Cell viability UM-UC-2 Cell viability was evaluated by 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) assay. In brief, we selected 1 d, 2 d, 3 d, and 4 d as different times for observation points. Bladder cancer cells (1×10^4) were plated in 96-well tissue culture plates in DMEM containing 10% FBS in a final volume of 0.2 mL. When the cells reached 50% confluence, they were treated with recombinant PML retrovirus and control virus. After 24 h of culture, cell proliferation was assessed by directly adding 50 μ L of 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide 7 dye (0.005 mg/L) to the medium for another 4 h, and then bladder cancer cells were solubilized in Me₂SO (150 μ L/well) on a shaker at room temperature for 10 min before reading the absorbance at 570 nm using a Biorad Technologies Microplate Reader.

Statistical analysis The experimental results shown were repeated three times, unless otherwise indicated. Results are expressed as mean \pm SD. Statistical analysis was carried

out using Student's *t*-test and one-way ANOVA. Significance was set at $P < 0.05$. Statistical analyses were performed using SPSS10.0 (SPSS Inc, Chicago, IL, USA).

Results

Identification of the recombinant retrovirus vector

pLPMLSN The full-length PML cDNA was excised by *EcoR* I and *Bgl* II from the plasmid pSG5PML^[1], and then ligated into the *EcoR* I and *Bam*H I digested restriction site, for *Bgl* II and *Bam*H I are isocaudamers, which have the same cohesive terminus. The constructed plasmid was digested with *Kpn* I, and three fragments of 2.0 kb, 2.9 kb, and 3.1 kb are acquired on agarose-gel electrophoresis. Two 2.3 kb and 5.7 kb fragments were obtained by *EcoR* I and *Hind* III (Figure 1). It suggests that PML cDNA had been inserted into retrovirus vector pLXSN successfully.

Figure 1. Identification of the recombinant retro-virus vector pLPMLSN. Lane 1: λ DNA/*Hind* III marker. Lane 2: pLPMLSN digested with *Kpn* I, three fragments of 2.0 kb, 2.9 kb, and 3.1 kb acquired. Lane 3: 2.3 kb and 5.7 kb fragments digested by *EcoR* I and *Hind* III as shown by the arrow. Lane 4: linear by single *EcoR* I site. Lane 5: control plasmid.

Identification of PML cDNA in transfected cells PCR was performed using total DNA samples prepared from UM-UC-2 cell culture after the recombinant retrovirus particles were transduced into the cultured cells. The PCR products of 304 bp fragments for PML were amplified from UM-UC-2/pLPMLSN cells but not from control cells infected with UM-UC-2/pLXSN and UM-UC-2 parental cells (Figure 2).

Determination of PML expression after recombinant PML retrovirus infection by immunofluorescence Immunofluorescence staining was performed to confirm whether

the reconstructed retrovirus could infect and express PML protein in bladder cancer cells UM-UC-2. As shown in Figure 3, both the number and intensity of PML specific nuclear speckle significantly increased in UM-UC-2/pLPMLSN cells, while in parental cells only a little poor and nonspecific signal was detected.

Figure 2. IPML cDNA in transfected cells determined by PCR. Lane 1: λ DNA/*Hind* III marker. Lane 2: UM-UC-2/pLPMLSN cell, 304 bp PCR product as indicated by arrow. Lane 3: 200 bp ladder marker. Lanes 4 and 5: the UM-UC-2 cells infected with the pLXSN control retrovirus and parental UM-UC-2 cells, respectively.

Demonstration of PML expression after recombinant PML retrovirus infection by Western blot

Western blot analysis showed that the bladder cancer UM-UC-2 cells infected with recombinant PML retrovirus expressed a high level of 90 kDa PML protein. The protein was undetectable in the parental bladder cancer UM-UC-2 cells by Western blot (Figure 4).

Effect of PML overexpression on cell growth We had previously shown that PML could repress the growth of prostate cancer LNCap, DU145, and PC-3 cells^[5]. Now, to further test the effect of increased expression of PML on bladder cancer UM-UC-2 cell growth, MTT assay was used. As shown in Figure 5, UM-UC-2/pLPMLSN grew significantly more slowly than the parental UM-UC-2 and control UM-UC-2/pLXSN cells ($P < 0.05$).

Morphological changes were also observed under phase contrast and light microscopes. As shown in Figure 6A and 6B, UM-UC-2 and UM-UC-2/pLXSN control cells showed

Figure 3. Expression of PML protein in UM-UC-2 cells infected with retro-PML detected by immunofluorescence staining. (A) FITC labelling immunofluorescence staining of PML protein in UM-UC-2 cells infected with retro-PML as indicated by arrows. (B) parental UM-UC-2 cells.

(C) UM-UC-2/pLPMLSN easily detaching from the plate surface ($\times 40$ magnification). Remaining cells are shrunk.

Discussion

In recent years, studies have been provided that activated oncogene or loss of tumor suppressor leads to the development of human cancer. Based on this concept, new effective therapeutic regimens have been developed as alternatives to conventional cancer therapy. One field that most scientists focused on is gene therapy, which is to suppress the overexpressed oncogene or rebuild the function of tumor suppressor^[12]. To deliver a gene into tumor cells, two major vector systems, such as viral system and non-viral system, have been thrown into research studies and clinical trials. The latter has relative low transduction efficacy and required some special equipment, therefore was not widely used. Compared to the adenovirus system, the retrovirus systems have some advantages in tumor gene therapy because of the following reasons. First, infection by retrovirus depends on host cell division. Most tumor cells are active in cell mitosis, which made wide range infection to carrier cells^[13]. Second, retrovirus can integrate into host genome, which can stably and continuously express targeting protein as host cell growth^[13]. Third, a recent study demonstrated that the entrance of adenovirus to the host cell must be mediated by the specific receptor. For example coxsackie and adenovirus receptor (CAR), whose protein expression level is reduced and even lost when breast cancer^[14], urothelial cancer^[15,16], head, and neck cancers^[17] are in high-grade or become invasive as adenovirus mediated gene therapy is not adapt to high-grade, late-stage invasive tumor^[14-17]. While the retrovirus does not have these limitations. This is one good reason why we constructed the recombinant PML retrovirus. Finally, when adenovirus infects the host cells for gene therapy, frequent administration of recombinant adenovirus were required to achieve therapeutic efficacy. Because of a strong immunological response, it could not operate repeatedly^[5]. In contrast, the retrovirus did not have the adverse immunological response.

We constructed recombinant retrovirus vector carrying PML gene, which was involved in the 15:17 translocation in acute promyelocytic leukemia (APL), and is a growth and transformation suppressor and plays an essential role in multiple pathways of apoptosis^[1,2]. PML is lost or reduced in solid tumor of several histological origins^[4-7] and is found to be more frequently lost in late-stage or metastatic cancer^[3]. Our previous study demonstrated that endogenous PML expression was related to the stage, grade, and invasiveness of bladder cancer. Stably overexpressed PML protein leads to decreased cell growth and tumorigenicity of bladder cancer *in vivo*^[7] and prostate cells *in vitro* and *in vivo*^[5]. Overexpression of PML induced G1 cell cycle arrest and subsequently trig-

gered cell death by apoptosis in breast cancer cells^[6].

In addition, PML is a much more stable protein with long half-life of about 6 h compared to other tumor suppressor genes such as p53 which has a half-life of 1.5 h. This suggest that long-time and high concentration of protein could accumulate in tumor cells and a better therapeutic effect could be obtained^[5].

These results strongly indicate that PML has therapeutic potential in the gene therapy of human tumors.

In conclusion, we constructed recombinant retrovirus stable expressed PML. PCR confirmed that the recombinant retrovirus could infect bladder cancer cells. Laser scanning confocal microscope and Western blot showed high level PML protein could be expressed. Overexpression of PML could inhibit the growth of bladder cancer. It may be an attempt for human tumor gene therapy in future.

Abstract

Aim: To assess the inhibitory effect of agmatine on tumor growth *in vivo* and tumor cell proliferation *in vitro*. **Methods:** The transplanted animal model, [³H]thymidine incorporation assay, 3-[4,5-dimethylthiazol-2-yl]-2,5-diphenyltetrazolium assay, and lactate dehydrogenase (LDH) release assay were performed. **Results:** Agmatine, at doses of 5–40 mg/kg, suppressed the S₁₈₀ sarcoma tumor growth dose-dependently in mice *in vivo* and the highest inhibitory ratio reached 31.3% in Kunming mice and 50.0% in Balb/c mice, respectively. Similar results were obtained in the transplanted B₁₆ melanoma tumor model. Agmatine (1–1000 μmol/L) was able to attenuate the proliferation of cultured MCF-7 human breast cancer cells *in vitro* in a concentration-dependent manner and the highest inhibitory ratio reached 50.3% in the [³H]thymidine incorporation assay. Additionally, in the LDH release assay, spermine (20 μmol/L) and spermidine (20 μmol/L) increased the LDH release significantly, but agmatine (1–1000 μmol/L) did not, indicating that the inhibitory effect of agmatine on the proliferation of MCF was not related to cellular toxicity. In the [³H]thymidine incorporation assay, putrescine (12.5–100.0 μmol/L) could reverse the inhibitory effect of agmatine on the proliferation of MCF concentration-dependently, suggesting that the inhibitory effect of agmatine on the proliferation of MCF might be associated with a decreased level of the intracellular polyamines pool. **Conclusion:** Agmatine had significant inhibitory effect on transplanted tumor growth *in vivo* and proliferation of tumor cells *in vitro*, and the mechanism might be a result of inducing decrease of intracellular polyamine contents.

Introduction

Polyamines, including putrescine, spermidine, and spermine, are required for cell proliferation and homeostasis. The intracellular pool of polyamines is precisely regulated through their biosynthesis, degradation, uptake, and excretion^[1]. The disorder of intracellular polyamines plays an important role in carcinogenesis. Polyamines can promote the neoplastic transformation of normal cells, stimulate the proliferation of tumor cells, and facilitate angiogenesis in tumor tissues. Therefore, their metabolism pathway is an interesting anticancer drug target^[2].

Agmatine, one of the analogs of polyamines, is the product of *L*-arginine decarboxylation and was initially believed

to be present only in bacteria, plants, and invertebrates. Now it has been shown to be present in mammals^[3]. The accumulated results show that agmatine has some important biological activities^[4]. Among them, the inhibitory effect of agmatine on cell proliferation is of great interest.

The current results show that agmatine is able to modulate the cellular concentration of polyamines^[5]. Agmatine can be hydrolyzed to putrescine and urea. Putrescine is then converted into spermidine and spermine by spermidine/spermine synthases^[6]. So agmatine might have the capacity to increase the level of intracellular polyamines. In addition, agmatine has been postulated to decrease the cellular level of polyamines. There is much evidence to support this hypothesis. First, because agmatine and polyamines are

structurally analogous and derived from same precursor, *L*-arginine^[7], administration of exogenous agmatine would be able to reduce the synthesis of polyamines by a back-feed way. Second, as a competitor, agmatine can retard putrescine intake by the same carrier^[8]. Most importantly, besides polyamines, agmatine is the only known molecule that has the capacity to induce antizyme^[9]. Antizyme is the only known endogenous protein that binds to ornithine decarboxylase, inhibiting its activity and accelerating its degradation. Indeed, when tested *in vitro*, agmatine inhibited DNA synthesis and proliferation in some cell lines^[10]. Moreover, Regunathan *et al*^[11] reported that agmatine inhibited proliferation of human coronary artery vascular smooth muscle cells by stimulation of imidazoline receptors. Satriano *et al*^[12] claimed that agmatine dramatically decreased the ratio of DNA synthesis on mouse kidney proximal tubule cells by attenuation of the cellular polyamine level. In 2003, Gardini *et al*^[13] found that agmatine inhibited the proliferation of rat hepatoma cells. These results indicate that agmatine might be an endogenous anti-proliferation factor, and whether the pharmacological effect of exogenous agmatine on cells *in vivo* is the same as *in vitro* is an interesting question.

In the present study, we investigated the inhibitory effects of agmatine on several classical tumor cells *in vivo* and *in vitro* and explored its possible mechanisms *in vitro*.

Materials and methods

Reagents and drugs Agmatine sulfate was obtained from the Beijing Institute of Pharmacology and Toxicology; cyclophosphamide was manufactured by Hengrui Pharmaceutical Co (Lianyungang, Jiangsu, China); spermine, spermidine, putrescine, 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT), and sodium dodecylsulfonate (SDS) were obtained from Sigma Chemical (St Louis, MO, USA); Roosevelt Park Memorial Institute medium (RPMI-1640) was purchased from Gibco (Carlsbad, CA, USA); and [³H]thymidine was obtained from DuPont/NEN Company (Boston, MA, USA).

Animals Male Kunming, Balb/c, and C₅₇ mice [20±2 g, Grade II, Certificate No SCXK (Jun) 2002-001, Experimental Animal Center of Academy of Military Medical Sciences] were used. After transplanted with tumor cells, animals were randomly distributed into different groups. The control group was administered with saline alone and the others were treated with different drugs. All drugs were dissolved in normal saline and freshly prepared on the experimental day. Both normal saline and agmatine were administered subcutane-

ously (sc) and cyclophosphamide was injected intraperitoneally (ip) in a volume of 10 mL/kg. All of the animals were housed and maintained in a temperature-controlled room (22 °C–24 °C) with free access to qualified food and water at all times.

Cell culture MCF-7 human breast cancer cells were maintained in RPMI-1640 medium with 10% fetal bovine serum (FBS), 100 kU/L penicillin and 100 kU/L streptomycin. Cells were incubated at 37 °C in a humidified 5% CO₂ atmosphere and subcultured every 3 d.

Evaluation of agmatine's inhibitory effects on the growth of tumor cells *in vivo* S₁₈₀ sarcoma and B₁₆ melanoma cells were subcultured in the abdominal cavity of mice for 8 d. The resulting ascites were diluted with saline to form a suspension containing 2×10¹⁰ cells/L. Aliquots of cell suspensions (0.2 mL) were injected (sc) into the right armpit of the mice. From the 1st day after implantation, saline, agmatine (5–40 mg/kg, tid, sc), or cyclophosphamide (20 mg/kg, qd, ip) were administered for 10 d. At d 10, the animals were killed and the tumors were chipped from their armpits. The tumor weights (g) were measured and the mean tumor weight of every group was calculated. The anti-tumor activities of the drugs were determined by a comparison between the inhibitory ratios obtained from the treated groups and the control group. The inhibitory ratio of drugs was expressed as [(average tumor weights in saline group–average tumor weights in drug treated group)/(average tumor weights in saline group)×100].

Measurement of proliferation *in vitro* in [³H]thymidine incorporation assay Proliferation of the MCF cells was assessed by [³H]thymidine incorporation assay. Briefly, cells suspended in RPMI-1640 medium with 10% FBS were seeded into a 96-well cell culture plate (80 μL/well) at a density of 6000 cells/well. Then they were treated with saline (control), or different concentrations of agmatine (1, 10, 100, 200, 500, or 1000 μmol/L), respectively, at a volume of 20 μL. Drugs were added for a total period of 48 h and [³H]thymidine (3.7×10⁴ Bq/well) was added at 36 h of incubation. The medium was removed and the cells were washed three times with phosphate-buffered saline and then twice with ice-cold 10% trichloroacetic acid. Fixed cells were then solubilized in 0.2 mol/L NaOH (100 μL/well) and sonicated for 15 min. After mixing with scintillant liquid (1 mL) for 24 h, an aliquot (90 μL/well) was used for scintillation counting. Then the radioactivity was determined with a Multi-purpose Scintillation Counter (Columbus Instruments, Columbus, OH, USA). The mean cpm value of every group was calculated. The anti-proliferation potency of the drugs was determined by a comparison between the inhibitory ratios obtained from the

treated groups and the control. The inhibitory ratio of the drugs was expressed as [(average cpm value in control group–average cpm value in drug treated group)/(average cpm value in control group)×100%].

Measurement of proliferation *in vitro* Cell proliferation was also confirmed again by measuring with MTT assay based on the colorimetric measurement of formazan dye formed from MTT by mitochondrial dehydrogenases. Exponentially growing cells were plated at a seeding density of 7.5×10^4 cells/mL in 96-well plates (80 μ L/well). Then they were treated with saline (control), or different concentrations of agmatine (100, 200, 500, or 1000 μ mol/L), respectively, at a volume of 20 μ L. After they were incubated with or without drugs for 44 h, 20 μ L of MTT reagent (0.5 g/L) was added to each well. The plates were incubated at 37 °C for another 4 h. At the end of the incubation, the formazan crystals formed by MTT metabolism were solubilized by the addition of 100 μ L of 10% SDS to each well. After 16 h, the absorbance of the solubilized product was measured at 570 nm in a Micro-plate Reader (Molecular Devices Corporation, Sunnyvale, CA, USA). The anti-proliferation potency of the drug was determined by a comparison between the inhibitory ratios. The percentage of growth inhibition was calculated by comparison of the absorbance of the treated group versus the control [(average absorbance value in control group–average absorbance value in drug treated group)/(average absorbance value in control group)×100].

Lactate dehydrogenase release assay To assess whether the reduction of cell numbers was attributable to the cellular toxicity of polyamines or agmatine, we measured the release of lactate dehydrogenase (LDH) in cell medium after drug treatment. Cells were cultured at a seeding density of 7.5×10^4 cells/mL in 24-well plates (800 μ L/well). They were treated with saline, a range of concentrations of agmatine, spermidine, or spermine, respectively, at a volume of 200 μ L and incubated at 37 °C and 5% CO₂ for 48 h. Then 0.8 mL of the supernatant of each well was used for analysis by an Automatic Biochemical Analyzer (Hitachi7020, Tokyo, Japan). The release of LDH from the treated cells was compared to the control.

Statistical analysis Data were expressed as mean±SD. SAS software (SAS Inc, Raleigh, NC) was used to conduct a one-way ANOVA. $P < 0.05$ was considered statistically significant.

Results

Inhibitory effects of agmatine on the growth of S₁₈₀ sarcoma tumor cell lines in Kunming and Balb/c mice In Kunming mice transplanted with S₁₈₀ sarcoma tumor cell lines,

the S₁₈₀ cells grew well and the average tumor weight reached 1.6 g in the normal, saline-treated group. Meanwhile, cyclophosphamide, a clinically approved anticancer agent, exhibited significant anti-tumor activity. In the cyclophosphamide-treated group (20 mg/kg, qd, ip), the average tumor weight was only 0.7 g and the inhibitory ratio was 56.3%. Agmatine also exerted a remarkable inhibitory effect on tumor growth. In the agmatine-treated groups (5–40 mg/kg, tid, sc), the tumor weights were significantly reduced ($n=27$, $P < 0.05$) in a dose-dependent manner. The inhibitory ratio of tumor growth reached 31.3% at a dose of 40 mg/kg (Table 1).

Table 1. Anti-tumor activity of agmatine on S₁₈₀ in Kunming mice. The S₁₈₀ sarcoma tumor cells were inoculated (sc) into Kunming mice on d 0. The bearing mice were randomly distributed into 6 groups. Each group contained 27 mice. From d 1, they were injected with saline, cyclophosphamide, or different doses of agmatine, respectively, at a volume of 0.1 mL/10 g. After 10 d, tumor weight was measured. $n=27$. Mean±SD. ^c $P < 0.01$, compared with the saline-treated group. “–” represents 0.1 mL/10 g saline.

	Dose /mg·kg ⁻¹	Tumor weight /g	Ratio of inhibition/%
Saline	–	1.6±0.9	
Cyclophosphamide	20	0.7±0.2 ^c	56.3
Agmatine	5	1.7±0.4	-6.3
	10	1.3±0.7	18.8
	20	1.1±0.6 ^c	31.3
	40	1.1±0.8 ^c	31.3

In Balb/c mice transplanted with S₁₈₀ sarcoma tumor cell lines, we obtained similar results. The average tumor weight was 1.0 g in the normal, saline-treated group. Cyclophosphamide (20 mg/kg, qd, ip) inhibited tumor growth significantly, and the inhibitory ratio reached 50.0%. Agmatine also inhibited the growth of tumors in a dose-dependent manner ($n=10$, $P < 0.05$). The inhibitory ratio of agmatine on tumor growth was 50.0% at a dose of 40 mg/kg (Table 2).

Inhibitory effects of agmatine on the growth of B₁₆ melanoma tumor cell lines in C₅₇ mice In C₅₇ mice transplanted with B₁₆ melanoma tumor cells, the tumor weight was 1.8 g in the normal, saline-treated group. In the cyclophosphamide-treated group (20 mg/kg, qd, ip), the tumor weight decreased to 1.0 g and the inhibitory ratio reached 44.4%. Agmatine (2.5–20.0 mg/kg, tid, sc) significantly suppressed the growth of the tumor ($n=10$, $P < 0.05$), but the effect did not exhibit an obvious dose-dependent relationship (Table 3).

Inhibitory effect of agmatine on the proliferation of MCF cells *in vitro* In the [³H]thymidine incorporation assay, the

Table 2. Anti-tumor activity of agmatine on S₁₈₀ cell growth in Balb/c mice. In Balb/c mice transplanted with S₁₈₀ sarcoma tumor cell lines as well, we acquired similar results. On d 0, the S₁₈₀ sarcoma cells were inoculated (sc). The 60 bearing mice were randomly distributed into 6 groups. Each group contained 10 mice. From d 1, they were injected with saline, cyclophosphamide, or different doses of agmatine, respectively, at a volume of 0.1 mL/10 g. After 10 d, tumor weight was measured. *n*=10. MCF cells grew well and the average cpm value was 3143.8 in the normal, saline-treated group after a 48-h incubation. Agmatine showed anti-proliferation activity compared with the saline-treated group in a concentration-dependent manner. The cpm value was significantly reduced (*n*=8, *P*<0.05) after pretreatment with agmatine (1–1000 μmol/L). The inhibitory ratio of cell proliferation was 50.3% at a concentration of 1000 μmol/L (Table 4).

This effect of agmatine on cellular proliferation was further proved with the MTT assay. The MCF cells grew well and the absorbance value was 0.99 in the normal, saline-treated group after a 48-h incubation. Agmatine showed

Table 4. Effect of agmatine on MCF-7 human breast cancer cells proliferation in a [³H]thymidine incorporation assay. In the assay, the cells were seeded into a 96-well cell culture plate at a density of approximately 6000 cells/well. Then they were treated with saline (control), or different concentrations of agmatine (1, 10, 100, 200, 500, or 1000 μmol/L), respectively, at a volume of 20 μL. Each group contained 8 wells. Drugs were added for a total period of 48 h, and [³H]thymidine (3.7×10⁴ Bq/well) was added at 36 h of incubation. To evaluate the anti-proliferation effect, the cpm value was counted and the inhibitory ratio was calculated. *n*=8. Mean±SD. ^b*P*<0.05, compared with control.

	Concentration /μmol·L ⁻¹	[³ H]thymidine incorporation/cpm	Inhibitory ratio/%

We then investigated the time-dependent effect of agmatine on MCF cell proliferation. MCF cells were cultured for different lengths of time in the presence of 1 mmol/L agmatine, and cell viability was evaluated by a [³H]thymidine incorporation assay. Over 48 h, the inhibitory potency of agmatine strengthened gradually with prolonged time ($n=8$, $P<0.01$). The inhibitory ratio was 10%, 17%, 38%, and 62% at 12 h, 24 h, 36 h and 48 h, respectively (Figure 1).

Figure 1. Time-dependent effect of agmatine on MCF-7 human breast cancer cells proliferation. MCF cells were cultured for different lengths of time in the presence of 1 mmol/L agmatine, and cell viability was evaluated by [³H]thymidine incorporation assay. Over 48 h, the inhibitory potency of agmatine strengthened gradually with prolonged time. Mean±SD for 4 experiments. $n=8$. ^c $P<0.01$, compared with the saline-treated group.

Effect of agmatine on LDH release in the medium To assess whether the reduction of cell numbers was attributable to toxicity of polyamines or agmatine, we measured the release of LDH in cell medium after drug treatment. Administration on MCF cells for 48 h, spermine (20 μmol/L) or spermidine (20 μmol/L) significantly increased the activity of LDH in the medium, but agmatine (1–1000 μmol/L) did not. At a concentration of 1000 μmol/L, agmatine decreased the LDH activity significantly ($n=8$, $P<0.05$; Table 6).

Putrescine reverses agmatine's inhibitory effect on MCF cell proliferation As polyamines are essential growth factors, their dramatic intracellular decrease may be the main mechanism of the anti-proliferation action of agmatine. To check whether this is the mechanism involved, MCF cells were treated simultaneously with agmatine (1 mmol/L) and putrescine (12.5–100.0 μmol/L). Putrescine counteracted the inhibitory effect of agmatine on MCF cell proliferation in a concentration-dependent manner ($n=8$, $P<0.05$; Table 7).

Table 6. Effect of agmatine, spermidine, or spermine on lactate dehydrogenase (LDH) release in MCF-7 human breast cancer cells. To assess whether the reduction of cell numbers was attributable to toxicity of polyamines or agmatine, we measured the release of LDH in cell medium after drug treatment. The cells were plated at a seeding density of 7.5×10^4 cells/mL in 24-well plates. Then they were treated with saline (control), spermine (20 μmol/L), spermidine (20 μmol/L), or different concentrations of agmatine (1, 10, 100, or 1000 μmol/L), respectively, at a volume of 200 μL. Each group contained 8 wells. Drugs were added for a total period of 48 h and then 0.8 mL of the supernatant of each well was used for analysis by the Automatic Biochemical Analyzer (Hitachi7020, Tokyo, Japan). The percentage release of LDH from the treated cells was calculated by comparing it to the control cells. $n=8$. Mean±SD. ^b $P<0.05$, ^c $P<0.01$, compared with control.

Discussion

The present study demonstrated the inhibitory properties of agmatine toward S₁₈₀ sarcoma and B₁₆ melanoma cells *in vivo*. We found that, at doses of 5–40 mg/kg, agmatine suppressed S₁₈₀ and B₁₆ cell growth in three kinds of mice *in vivo*. The highest inhibitory ratio was more than 50.0%. We applied for a Chinese patent with these results in 2002 (02125495.8). Although Gardini *et al* reported that agmatine inhibited the proliferation of rat hepatoma cells *in vitro* by modulation of polyamine metabolism in 2003^[13], they did not report anything related to the inhibitory effects of agmatine on the growth of transplanted tumors *in vivo*; in addition, the paper by Gardini *et al*^[13] was published much later than when we applied for the Chinese patent. It is reasonable to state, therefore, that our current results demonstrate for the first time that agmatine has an inhibitory effect on S₁₈₀ and B₁₆ cell lines *in vivo*.

Polyamines play an essential role in proliferation, differentiation, and neoplastic transformation in mammalian cells^[1]. Indeed, cellular polyamine levels are higher in tumor cell lines. Conversely, the depletion of polyamines results in growth arrest of neoplastic cells *in vitro*. The polyamine-biosynthetic pathway is an inviting target for the development of agents inhibiting carcinogenesis and tumor growth. The present therapeutic agents acting on this pathway are α -difluoromethylornithine (DFMO) and polyamine analogs^[2]. They influence both polyamine synthesis and degradation and are now being used in clinical trials.

Agmatine is an analog of polyamines and can modulate the cellular concentration of polyamines^[14]. As an intermediate of putrescine, agmatine may be a factor for increasing the cellular concentration of polyamines. Although tumor cells and tissues have been reported to have increased polyamines levels compared with normal cells, this increase is often in the range of 2- to 3-fold. When putrescine levels are approximately 10-fold higher than those present in cancer cells, the cells undergo apoptosis^[15]. It has also been reported that overloaded polyamines have toxic effects on some normal cells. The toxicity of polyamines was studied in a well-characterized neuronal system of cerebellar granule cells *in vitro*. Twenty-four-hour exposure to spermine (1–500 μ mol/L) resulted in a concentration-dependent death of granule cells, with the half of lethal dose (LD₅₀) being reached at a concentration below 50 μ mol/L. Putrescine was moderately toxic, with the LD₅₀ at a concentration of only 500 μ mol/L. The LD₅₀ of spermidine was tested between concentrations of 50 and 100 μ mol/L and its toxicity has been evaluated to be approximately 50% of that of spermine^[16]. This was con-

sistent with our results (data not shown). In contrast, agmatine has been postulated to decrease the cellular level of polyamines by inducing antizyme, competing with putrescine on transporter and other mechanisms.

So, in theory, agmatine might have double-edged effects on cell growth. But, to date, there has been no report that agmatine can enhance the proliferation of cells. Conversely, there is much evidence that agmatine can suppress cell proliferation, including different cells and malarial parasites^[17,18]. Consistent with these studies, the present study proves agmatine has a significant inhibitory effect on cell proliferation in several classical solid tumors in a transplanted model *in vivo* and in an MCF model *in vitro*. Putrescine prevented the effect of agmatine on [³H]thymidine incorporation in MCF cells. This effect of agmatine is similar to that of DFMO, which can block the synthesis of polyamines significantly. These results suggest that the effect of agmatine might be related to its influence on the synthesis of polyamine.

In addition, polyamines can interact with DNA directly^[19], so, in our experiments, the decreased [³H]thymidine incorporation may be caused by the inhibitory synthesis of DNA. As putrescine plays a partial role in energy supply^[20], the results of the MTT assay indicate that agmatine might inhibit MCF cell proliferation by influence on energy metabolism. In addition, the effect on LDH activity in the medium showed that agmatine (1–1000 μ mol/L) exhibited no cellular toxicity, whereas spermidine (20 μ mol/L) and spermine (20 μ mol/L) did. To sum up, these results partly demonstrate that agmatine does not increase the level of cellular polyamines and supports the conclusion that the anti-proliferation effect of agmatine is a result of polyamine limitation.

Currently, we know that agmatine's toxicity is low and its effects on tumor cells are not similar to those of classical chemotherapeutic drugs. Regarding its low toxicity, its enhancement of opioid analgesia, and its antidepressant effect^[21,22], we hope that agmatine could efficiently improve life quality of cancer patients. There are still many issues to be explored, and further experiments should be carried out to confirm our results.

In conclusion, agmatine has significant inhibitory effects on transplanted tumor growth *in vivo* and proliferation of tumor cells *in vitro*. The possible mechanisms might be related to inducing decrease of intracellular polyamine contents.

Abstract

Aim: To investigate the apoptosis-inducing effect of cheliensisin A (GC-51), a novel styryl-lactone isolated from *Goniothalamus cheliensis*, on human promyelocytic leukemia HL-60 cells and the mechanism of action involved. **Methods:** Apoptotic cell death was determined by morphological examination and DNA agarose gel electrophoresis. The activity of caspase-3 was assessed using Western blotting and the expression of *Bcl-2* and *Bax* genes was analyzed using the reverse transcription-polymerase chain reaction (RT-PCR) method. **Results:** GC-51 significantly inhibited the proliferation of HL-60 cells with an IC₅₀ of 2.4±0.2 μmol/L and effectively induced apoptosis in HL-60 cells. Exposure of HL-60 cells to 10 μmol/L GC-51 for 8 h resulted in approximately 53% of the cells undergoing apoptosis. Caspase-3 was activated in GC-51-treated cells, which was manifested by the appearance of the 17 kDa active form of caspase-3 and the cleavage of poly(ADP-ribose) polymerase (PARP). Meanwhile, GC-51 markedly reduced the expression of the anti-apoptotic gene *Bcl-2* and increased the expression of the pro-apoptotic gene *Bax*. The apoptosis-inducing effect of GC-51 was cAMP-dependent protein kinase (PKA) dependent because PKA, but not the protein kinase C, specific inhibitor H-89, blocked the induction of apoptosis by GC-51 in HL-60 cells. **Conclusion:** The results demonstrate that GC-51 effectively induces apoptosis in HL-60 cells and that this effect is PKA-dependent and involves the downregulation of *Bcl-2* expression and the activation of caspase-3.

Introduction

Apoptosis is defined by distinct morphological and biochemical changes, mediated by a family of cysteine aspartases (caspases) that are expressed as inactive zymogens and are proteolytically processed to an active state following an apoptotic stimulus^[1]. Two pathways leading to caspase cascade activation, including an intrinsic pathway and an extrinsic pathway, have been characterized^[2,3]. Both pathways may involve the release of mitochondrial proteins, such as cytochrome c, Smac/DIABLO, and HtrA2, into the cytosol to trigger the activation of caspases, including initiator caspase-9 and effector caspase-3. The release of mitochondrial proteins into the cytosol usually depends on mitochondrial membrane permeabilization, which is regulated by pro-

and anti-apoptotic *Bcl-2* family members^[1]. In theory, factors capable of regulating the activities of caspases and/or the functions of *Bcl-2* family members are able to induce or prevent apoptotic cell death.

Styryl-lactones are a new class of compounds with potential anti-tumor activities^[4,5]. Most styryl-lactones are isolated from the genus *Goniothalamus* (Annonaceae)^[4]. The mechanisms of action by which styryl-lactones exert their anti-tumor activity are currently unknown. The suggested mechanisms include non-steroid, receptor-mediated anti-proliferative effects^[6], disruption of mitochondrial transmembrane potential^[7], and the induction of apoptosis^[8]. GC-51, a novel styryl-lactone isolated from *Goniothalamus cheliensis*, has previously been shown in our laboratory to

possess potent cytotoxicity against human promyelocytic leukemia HL-60 cells^[9]. In the present study, we investigated the potential apoptosis-inducing effect of GC-51 and the possible mechanism of action involved.

Figure 1. Chemical structure of GC-51.

Materials and methods

Chemicals GC-51 [6(7,8-epoxy-styryl)-5-acetoxy-5,6-dihydro-2-pyrone] was purified from *Goniothalamus cheliensis* at the Kunming Institute of Botany, Chinese Academy of Sciences, Kunming, China, as previously described^[9] (Figure 1). GC-51 is a white crystal powder and its purity is greater than 99.0%. H-89 and chelerythrine chloride were purchased from Calbiochem (San Diego, USA). Propidium iodide and 4',6'-diamino-2-phenylindole (DAPI) were purchased from Sigma (St Louis, USA). RNase, polyclonal antibodies against caspase-3 and PARP were purchased from Becton Dickinson (Franklin Lakes, USA). Trizol and RPMI-1640 medium were purchased from Gibco (Grand Island, New York, USA).

Cell culture and treatment Human promyelocytic leukemia HL-60 cells were from the American Type Culture Collection (Manassas, VA 20108 USA). HL-60 cells were maintained in RPMI-1640 medium containing 10% heat-inactivated fetal bovine serum, 100 kU/L penicillin, and 100 mg/L streptomycin. Cells were cultured in a humidified incubator at 37 °C in 5% CO₂/air. GC-51 was dissolved in dimethylsulfoxide and diluted in culture medium just prior to use. The final concentration of dimethylsulfoxide was less than 0.1% which had no effect on cell proliferation and the assay system.

Morphology staining Morphological changes in HL-60 cells were determined by staining the cells with DNA-specific dye, DAPI, after the GC-51-treated cells were fixed with methanol for 10 min at room temperature. Stained cells were observed under a fluorescence microscope (Olympus, Tokyo, Japan).

Cell cycle analysis The DNA content of the cells was

analyzed as previously described^[10,11]. In brief, untreated and treated cells were harvested by centrifugation, washed in phosphate-buffered saline (PBS containing 137 mmol/L NaCl, 2.7 mmol/L KCl, 10 mmol/L Na₂HPO₄, 1.8 mmol/L KH₂PO₄, pH 7.4), and fixed in ice-cold 70% ethanol overnight. Following fixation, the cells was stained with PBS containing 50 mg/L propidium iodide, 0.1% Triton X-100, and 20 mg/L RNase. The fluorescence of individual cells was measured using FACStar plus flow cytometer (Becton Dickinson, Franklin Lakes, USA).

DNA agarose gel electrophoresis Analysis of DNA fragmentation was carried out using DNA agarose gel electrophoresis as described previously^[11]. In brief, DNA extracted from untreated and treated cells was loaded onto a 1.8% agarose gel in TBE (Tris 45 mmol/L borate buffer, edetic acid 1 mmol/L, pH 8.0), and electrophoresed at 40 V for 5 h. DNA in the gels was visualized under UV light after staining with ethidium bromide 5 mg/L.

Western blotting Western blot analysis was carried out as described previously^[12,13]. After treatment with GC-51, cells were washed twice with ice-cold PBS and total cell lysates were collected in sodium dodecylsulfate (SDS) sample buffer (50 mmol/L Tris-HCl, pH 6.8, 100 mmol/L DTT, 2% SDS, 0.1% bromophenol blue, 10% glycerol). Cell lysates containing equal amounts of protein were separated by sodium dodecylsulfate-polyacrylamide gel electrophoresis (SDS-PAGE) and transferred to polyvinylidene difluoride membranes. After blocking in 5% non-fat milk in TBST (Tris-buffered saline with 0.1% Tween 20, pH 8.0), the membranes were incubated with the appropriate primary antibodies at 4 °C overnight. Membranes were washed three times in TBST and exposed to secondary antibodies for 2 h at room temperature, and then washed four times in TBST. Immunoreactive proteins were visualized using the enhanced chemiluminescence system from Pierce (Rockford, IL, USA).

RNA isolation and RT-PCR Total mRNA was prepared from HL-60 cells using Trizol (Sangon, Shanghai, China). The cDNA was synthesized using random hexamers from 1 µg of mRNA. To amplify the cDNAs, a 2 µL aliquot of the reverse-transcribed cDNA was subject to 29 cycles of PCR in 50 µL of 1×buffer (10 mmol/L Tris-HCl, pH 8.3, 1.5 mmol/L MgCl₂, 50 mmol/L KCl, 50 µmol/L dNTP, three units of *Taq* DNA polymerase and 0.2 µmol/L specific primers). Each cycle consisted of denaturation at 94 °C for 30 s, annealing at 60 °C for 40 s, and extension at 72 °C for 40 s. The amplified products were separated by electrophoresis on 1.0% agarose gel. Each RT-PCR was repeated three times using different preparations of RNA. The RT-PCR of GAPDH was used as an internal control with all samples. The PCR primers used are

listed in Table 1.

Table 1. The primer sequences used for amplifying the desired genes

Genes	PCR primers	Product size/bp
<i>Bcl-2</i>	5'TGC ACC TGA CGC CCT TCA C 3' (sense) 5'AGACAAGGAGAAATCAAACAG 3' (antisense)	293
<i>Bax</i>	5'ACCAAGAAGCTGAGCGAGTGTC 3' (sense) 5'ACAAAGATGGTCACGGTCTGCC 3' (antisense)	265

Statistical analysis Data were analyzed using Student's *t*-tests. *P* values less than 0.05 were considered significant.

Results

Inhibition of cell proliferation and induction of cell apoptosis by GC-51 The effect of GC-51 on cell proliferation was determined by counting the cell number using the Trypan blue exclusion method. After a 48-h treatment, GC-51 markedly inhibited the proliferation of HL-60 cells in a concentration-dependent manner with an IC₅₀ of 2.4±0.2 μmol/L (95% confidence: 1.5–3.3 μmol/L, Figure 2A). The inhibition of cell proliferation was also time-dependent (data not shown).

To further identify the inhibitory effect of GC-51 on cell proliferation, we examined the apoptosis-inducing effect of GC-51 on HL-60 cells. Incubation of HL-60 cells with GC-51 (2.5–10 μmol/L) for various times (2–8 h) resulted in dramatic morphological changes in the treated cells typical of apoptosis, such as cell shrinkage, chromatin condensation, and nuclear fragmentation (Figure 2B). Treatment of cells with 10 μmol/L GC-51 for 4 h was enough to induce cell apoptosis.

Figure 2. GC-51 inhibited HL-60 cell proliferation (A) and induced HL-60 cell apoptosis (B, C, D). (A) Cells were treated with different concentrations of GC-51 for 48 h, and the cell number was counted using the Trypan blue exclusion method. *n*=3. Mean±SD. **P*<0.01 vs control. (B) Cells untreated (left) or treated with 10 μmol/L GC-51 for 8 h (right) were stained with DAPI and observed under fluorescence microscope (×200). (C) Agarose gel electrophoresis of DNA extracted from cells treated with 10 μmol/L GC-51 for 8 h. (D) DNA content analysis using flow cytometry of the cells untreated (left) or treated with 10 μmol/L GC-51 for 8 h (right). B, C, D represent at least three independent experiments with identical results. Ap, apoptotic cells.

The apoptosis-inducing effect of GC-51 was confirmed by the appearance of a DNA “ladder”, another major hallmark of apoptosis (Figure 2C).

It is widely accepted that apoptotic cells have reduced DNA stainability following staining with a variety of fluorochromes, including propidium iodide. Thus, the appearance of cells with low stainability (ie sub- G_1 peak) in cultures has been considered to be another marker of apoptosis and has been used to quantify the extent of apoptosis. GC-51 treatment led to the formation of a “sub- G_1 ” peak in the DNA content frequency distribution (Figure 2D) and caused apoptosis in a concentration- and time-dependent manner. Exposure of HL-60 cells to 10 $\mu\text{mol/L}$ GC-51 for 2 h, 6 h, and 8 h resulted in $3.5\% \pm 3.0\%$, $26.2\% \pm 4.3\%$, and $53.0\% \pm 7.2\%$ cells undergoing apoptosis, respectively, whereas GC-51 treatment for 8 h at concentrations of 5, 10, and 25 $\mu\text{mol/L}$ led to apoptotic cell death in $7.3\% \pm 3.5\%$, $54.2\% \pm 9.2\%$, and $78.7\% \pm 10.2\%$ cells, respectively.

Activation of caspase-3 in GC-51-treated apoptotic cells

Cell death is executed by effector caspases such as caspases-3, thus, the activation of caspase-3 is the critical cellular event during apoptosis. Intact caspase-3 was a 32 kDa protein as detected in control cells and was processed into its catalytically active p17 subunits in GC-51-treated HL-60 cells (Figure 3A). To confirm the activation of caspase-3, we evaluated the cleavage of PARP, a major substrate of caspase-3. GC-51 treatment caused the cleavage of 116 kDa PARP into a 85 kDa form (Figure 3B), indicating that caspase-3 was indeed activated during GC-51-induced HL-60 cell apoptosis.

Figure 3. GC-51 activated caspase-3 (A) and stimulated the cleavage of PARP (B). Cells treated with 10 $\mu\text{mol/L}$ GC-51 for different time periods were lysed, and the proteins were separated by SDS-PAGE and detected by Western blotting using specific antibodies against caspase-3 and PARP, respectively.

Downregulation of *Bcl-2* mRNA expression by GC-51

Caspase-3 activation requires the release of a number of proteins, including cytochrome c, from mitochondria and this release is, in general, determined by the permeability of the

mitochondrial membrane. Members of the *Bcl-2* family regulate the release of cytochrome c from mitochondria, primarily by affecting the permeability of the mitochondrial membrane. Thus, we tested the effect of GC-51 on the expression of the anti-apoptotic gene *Bcl-2* and the pro-apoptotic gene *Bax*. Exposure of HL-60 cells to 10 $\mu\text{mol/L}$ GC-51 for 8 h led to a significant reduction in *Bcl-2* gene expression. In contrast, the expression of the *Bax* gene markedly increased after GC-51 treatment. As a control, GC-51 had no effect on the expression of the GAPDH gene (Figure 4). Regulation by GC-51 of the expression of the *Bcl-2* and *Bax* genes resulted in a decrease in the ratio of *Bcl-2/Bax*, which will make the cells more susceptible to apoptosis inducers.

Figure 4. GC-51 reduced the expression of the *Bcl-2* gene and increased the expression of the *Bax* gene. Cells were treated with 10 $\mu\text{mol/L}$ GC-51 for 8 h and the total mRNA from treated cells was extracted and the expression of *Bcl-2*, *Bax*, and *GAPDH* genes was detected using RT-PCR with specific primers.

Induction of apoptosis by GC-51 in HL-60 cells was PKA dependent

Bullatacin, a bioactive component isolated from *Annonaceous*, induces cell apoptosis by reducing the intracellular cAMP level^[14]. Thus, we tested the role of cAMP in GC-51-induced HL-60 cell apoptosis. If induction of HL-60 cell apoptosis by GC-51 occurs via a similar mechanism to that of bullatacin, forskolin, an adenylate cyclase activator that effectively increases intracellular cAMP level, should block the apoptosis-inducing effect of GC-51. We did not record a significant effect of forskolin on induction of apoptosis by GC-51 in HL-60 cells (Figure 5A). To our surprise, H89, a PKA-specific inhibitor, blocked induction of HL-60 apoptosis by GC-51, whereas chelerythrine, a protein kinase C inhibitor, had no effect on the action of GC-51 (Figure 5B), suggesting that GC-51 induction of HL-60 apoptosis is specifically dependent on PKA activity.

Discussion

Defects in apoptosis underpin both tumorigenesis and drug resistance, and most anticancer drugs exert their che-

Figure 5. GC-51 induced apoptosis in HL-60 cells in a PKA-dependent manner. Cells were treated with 10 μmol/L GC-51 for 8 h in the presence of 10 imol/L forskolin (Fors), 1 imol/L H-89, or 10 imol/L chelerythrine chloride (Che), respectively, and DNA was extracted from treated cells and subject to DNA agarose gel electrophoresis.

motherapeutic effect by inducing tumor cell apoptosis^[1]. Therefore, the discovery and development of drugs targeting the apoptotic pathway represent a novel and rational strategy for the treatment of cancers.

GC-51 a novel styryl-lactone isolated from *Goniothalamus cheliensis*, which is a widely occurring plant in Southwest China, exhibits a potent cytotoxicity in HL-60 cells^[9]. In the present study, GC-51 significantly inhibited HL-60 cell proliferation, which is consistent with a previous report^[9]. GC-51 inhibits cell proliferation or induces cell apoptosis based on the concentrations applied (low vs high concentrations). Induction of apoptosis by GC-51 was confirmed by the appearance of characteristic morphological changes, including a DNA “ladder” and a “sub-G₁ peak” in DNA content frequency distribution. Our results demonstrate that GC-51, like other styryl-lactones, is a potent inducer of cell apoptosis.

Caspase-3 is an effector caspase whose activation is critical for the execution of apoptotic death of tumor cells. We clearly showed in the present study that caspase-3 was activated during GC-51-induced HL-60 cell apoptosis and the activation was further verified by the cleavage of PARP, a preferred substrate of caspase-3 in apoptotic cells. Our results combined with findings from other laboratories^[7,8] suggest that the activation of caspase-3 is a common mechanism responsible for styryl-lactone-induced apoptosis.

It is generally accepted that the ratio of *Bcl-2/Bax* determines the permeability of mitochondrial transmembranes, and

this permeability controls the release of a number of proteins, such as cytochrome c, from the mitochondria into the cytosol^[1]. GC-51 treatment significantly inhibited the expression of anti-apoptotic gene *Bcl-2* and increased the expression of the pro-apoptotic gene *Bax*. This effect of GC-51 on the expression of members of the *Bcl-2* family is, at least in part, contributing to the activation of caspase-3 and the subsequent apoptosis of HL-60 cells. To our knowledge, this is the first study to show that GC-51, a styryl-lactone compound, induces HL-60 cell apoptosis via reduction of the expression of the *Bcl-2* gene.

cAMP is a critical mediator of apoptosis^[15-18]. cAMP triggers apoptosis by stimulating its major effector protein PKA, which phosphorylates the cAMP response element-binding protein (CREB), activates caspase-3, and induces apoptosis^[18]. Kim *et al*^[19] showed that 8-Cl-cAMP, an analogue of cAMP, induced cell-cycle-specific apoptosis in HL-60 cells. In contrast, PKA phosphorylates Bad, a member of the *Bcl-2* family, to prevent apoptosis^[1]. Bullatacin induces hepatoma cell apoptosis by decreasing the intracellular cAMP level^[14]. In the present study, we examined whether GC-51 induced HL-60 cell apoptosis via a similar mechanism. The data showed that forskolin had no significant effect on induction of cell apoptosis by GC-51, whereas in contrast H-89, the PKA-specific inhibitor, blocked the apoptosis-inducing effect of GC-51. Our results suggest that GC-51 induction of apoptosis is dependent on PKA. The opposite effects of GC-51 and bullatacin on intracellular cAMP levels is not surprising considering that these two compounds are totally different in structure: GC-51 is a styryl-lactone compound, whereas bullatacin is an annonaceous acetogenin compound. In addition, the cells used in these two experiments were also different, leukemia HL-60 cells compared with hepatoma 2.2.15 cells, and it is well known that effect of cAMP on cell apoptosis is cell-type specific^[18]. We postulate that GC-51 induces HL-60 cell apoptosis via a similar mechanism to that demonstrated by Zhang and Insel^[18]. However, further investigations are needed to confirm this hypothesis.

In conclusion, GC-51 effectively induces HL-60 apoptosis. The apoptosis-inducing effect of GC-51 is PKA-dependent and involves the downregulation of anti-apoptotic *Bcl-2* gene expression and the activation of caspase-3.

Abstract

Aim: To construct a *Bifidobacterium infantis*/CD targeting gene therapy system and observe the antitumor effect of cytosine deaminase/5-fluorocytosine (CD/5-FC) suicide gene therapy system mediated by *Bifidobacterium infantis* on melanoma *in vitro* and *in vivo*. **Methods:** A recombinant CD/pGEX-1LamdaT plasmid was transfected into *Bifidobacterium infantis* by electroporation. *Bifidobacterium infantis* transfected by recombinant CD/pGEX-1LamdaT plasmid was incubated with 5-FC anaerobically. Then the supernatant fluid was collected and added to melanoma B16-F10 cells to observe the killing effect for B16-F10 cells. Mice were inoculated with melanoma B16-F10 cells to establish animal models. The mice were then injected with 5-FC and *Bifidobacterium infantis* transfected by recombinant CD/pGEX-1LamdaT plasmid. **Results:** Two segments of approximate 4.9 kb and 1.3 kb were extracted from the 6.2 kb recombinant plasmid, which were equal to the size of the pGEX-1LamdaT plasmid and CD gene, respectively. Sequencing results showed that the full length and sequence of nucleotide acid of the inserted gene in extracted recombinant plasmid was completely identical to the CD gene. *In vitro*, B16-F10 cells treated by supernatant fluid were remarkably damaged morphologically, and the cell growth was significantly inhibited. Experiments on the mice melanoma model showed that after treatment with a combination of transfected *Bifidobacterium infantis* and 5-FC, the tumor volume was significantly inhibited compared with controls. **Conclusion:** The foreign gene, CD gene, was correctly inserted into pGEX-1LambdaT plasmid and transferred into *Bifidobacterium infantis*. CD/5-FC suicide gene therapy system mediated by *Bifidobacterium infantis* demonstrated a good antitumor effect on melanoma *in vitro* and *in vivo*.

Introduction

Suicide gene therapy is a highlight in tumor gene therapy at present. Therapy using cytosine deaminase/5-fluorocytosine (CD/5-FC) is one of the most widely studied systems, in which CD can convert relatively nontoxic 5-fluorocytosine (5-FC) into a toxic metabolite 5-fluorouracil(5-FU) and kill tumor cells^[1-4].

Transfer vectors are a key factor in the tumor gene therapy system, which directly influences tumor targeting. It is evi-

dent that most of the interest and effort in cancer gene therapy in the coming years should be focused on transfer vectors. So far viruses are the most widely used suicide gene vectors. However, viruses are relatively poor in tumor targeting and safety, which has badly impeded tumor gene therapy^[5,6]. It is crucial to search for a novel gene vector that has good tumor targeting and is relatively safe.

It is evident that the center of a solid tumor is generally found at a low level of oxygen, and anaerobic bacteria tend to colonize in a low oxygen environment. Therefore, anaero-

bic bacteria is a potential vector for tumor gene therapy^[7-9]. In a previous study, our laboratory selected a strain of *Bifidobacterium infantis* proven to be good for targeting solid tumors and non-pathogenic^[10]. The aim of the present study was to transfer the CD gene into *Bifidobacterium infantis* to construct a *Bifidobacterium infantis*/CD targeting gene therapy system and observe the antitumor efficacy of a CD/5-FC suicide gene therapy system mediated by *Bifidobacterium infantis* on melanoma *in vitro* and *in vivo*.

Materials and methods

Materials pGEX-1LamdaT plasmid was kindly provided by Research Unit of Infection & Immunity, West China School of Preclinical and Forensic Medicine, Sichuan University, China. Strains of *E Coli* K12 λ were purchased from Chengdu Institute of Biological Products, China. Strains of *Bifidobacterium infantis* 2001 were obtained from West China School of Stomatology, Sichuan University, China.

LA *Taq* DNA polymerase, T4 DNA ligase and λ -*Eco*T14 I digest DNA Marker were purchased from TaKaRa, Japan. 200 bp DNA Ladder Marker was purchased from Sino-American Biotechnology, China. Purification kit of plasmid, Wizard PCR Preps DNA Purification Resin, *Eco*R I and *Bam*H I were purchased from Promega (Madison, WI, USA).

Mouse melanomocytes B16-F10 were provided by China Center for Typical Culture Collection. Female C57BL/6 mice (class 1, aged 6–8 weeks) were provided by the Experimental Animal Center of Sichuan University.

Methods

Amplification of CD gene Strains of *E Coli* K12 λ were inoculated into 5 mL LB liquid medium with shaking, overnight at 37 °C. The next day, genomic DNA was prepared by phenol/chloroform method and used as template DNA to perform PCR for the amplification of CD gene. Specific primers of CD gene were designed based on published sequences (Genebank, NC-0009131). The upstream primer is 5'-ATG GAT CCG GAG GCT AAC AAT G-3' and the downstream primer is 5'-GGG GAA TTC TGT AAC CCA GTC GT-3'. The amplification cycle was repeated 35 times with the condition of denaturation at 94 °C for 30 s, annealing at 55 °C for 30 s and extension at 72 °C for 2 min. Amplified products were purified with Wizard PCR Preps DNA Purification Resin and separated with electrophoresis of 0.8% agarose gel to confirm whether amplified products had the desired size of 1.3 kb.

Digestion of CD gene and pGEX-1LamdaT plasmid CD gene 1 μ g and pGEX-1 LamdaT plasmid 1 μ g were added

into 10 μ L 10 \times Buffer E reactions, separately. The plasmid and CD gene were digested with dual restriction endonucleases (1 μ L *Eco*R I+1 μ L *Bam*H I) for 3 h. Once the digestion was complete, the DNA fragments were separated by electrophoresis with 0.8% agarose gel. The desired bands of 4.9 kb and 1.3 kb were cut out from the gel. The DNA fragments in the gel were extracted and recovered with gel extraction kit. Recovered pGEX-1LamdaT plasmid vector fragment was dephosphorylated with calf intestinal phosphatase.

Ligation of plasmid vector fragment and CD gene fragment Recovered CD gene fragment 10 μ L, recovered pGEX-1LamdaT plasmid vector fragment 10 μ L, and 1U T4 DNA ligase were added into the microfuge tube. The reactions were incubated at 16 °C overnight. Then the ligation products, recombinant CD/pGEX-1LamdaT plasmid were separated by electrophoresis to confirm whether the ligation products had the desired size.

Transfection of *Bifidobacterium infantis* Suspensions of *Bifidobacterium infantis* 10 mL were washed with ice-cold pure water and resuspended in 40 μ L ice-cold 10% glycerol. Recombinant CD/pGEX-1LamdaT plasmid 5 μ L was added to the bacterial suspensions, then mixed and transferred to electroporation cuvette. Electroporation was carried out to transfect recombinant CD/pGEX-1LamdaT into *Bifidobacterium infantis* at 2.0 kV for 10 ms.

Culture of transfected *Bifidobacterium infantis* and detection of positively transfected bacterial colony When electroporation was completed, 1 mL MRS liquid medium was added into the electroporation cuvette to resuspend bacteria. Then the bacteria suspensions were transferred into a 1.5 mL EP tube and incubated in an anaerobic jar at 37 °C. Two hours later, bacteria suspensions were plated on MRS solid medium with ampicillin and incubated in an anaerobic jar at 37 °C. After 72 h, a single positively transfected bacterial colony of *Bifidobacterium infantis* was picked up and inoculated into 5 mL MRS liquid medium. Two to three drops of liquid paraffin was added to the medium and then the cultures were incubated overnight at 37 °C. The next day, recombinant plasmid was extracted from the incubated bacteria using Purification kit of plasmid. Extracted recombinant plasmid was separated with electrophoresis to confirm whether the recombinant plasmid is the recombinant CD/pGEX-1LamdaT plasmid. In addition, the extracted recombinant plasmid from positively transfected bacterial colony was digested with dual restriction endonucleases of *Eco*R I and *Bam*H I as described previously. The size of digested segments were analyzed by electrophoresis with 0.8% agarose gel.

Sequencing of inserted gene segment in recombinant

plasmid Sequencing of inserted gene segment in recombinant plasmid extracted from positively transfected bacteria was performed according to the method of Sanger dideoxynucleotide triphosphate chain termination. Shanghai Genebase Gen-tech (Shanghai, China) carried out the sequencing.

Processing of positively transfected *Bifidobacterium infantis* Suspension of positively transfected *Bifidobacterium infantis* 20 mL was incubated at 37 °C anaerobically overnight. The next day, 5-FC with final concentration 1 mmol/L was added and then the incubation continued. After 24 h, 10 mL bacteria suspension was taken and centrifuged for 5 min. The supernatant fluid was collected and 2 mL ethyl acetate was added and mixed to make the supernatant fluid suspension in ethyl acetate properly. The mixture was centrifuged (150×g) at 4 °C for 10 min. The organic fluid was transferred to EP pipette and dried in a vacuum. The dried product was resolved in 1 mL 0.9% saline to be used as the positive treatment fluid. Suspension of untransfected *Bifidobacterium infantis* was processed with the same method and used as the negative treatment fluid.

Killing effects of treatment fluid on melanomacyste B16-F10 Melanomacysts B16-F10 were first digested with 0.125% trypsin and counted. They were then diluted to a final concentration of 1.5×10^5 cells/mL and inoculated into six wells at 1.8 mL/well in 6-well cell culture cluster. The six wells were randomized into two groups with three wells in each group. When 50%–60% of the wells were covered by cells, 200 µL positive treatment fluid and 200 µL negative treatment fluid were separately added to the two groups with one well from each group added with saline as the control. The cell culture cluster was placed in a 5% CO₂ incubator at 37 °C. After 24 h, the morphology of cells was observed and the number of cells was counted using trypan blue dye exclusion method to calculate the suppression rate of each test group, namely; $\text{Suppression rate} = (N_n - N) / (N_n - N_0) \times 100\%$ (N_0 : number of inoculated cells; N : number of cells in test well after 24 h; N_n : number of cells in control well after 24 h).

Antitumor effect in vivo Mouse melanomacysts B16-F10 were inoculated in the muscle of the right thigh of the female C57BL/6 mice at 5×10^6 cells/mouse to establish a melanoma model. The experiment was initiated when the tumor grew to 0.8–1.0 cm in diameter (d 10 after inoculation). Twenty tumor-bearing mice were divided into test group ($n=10$) and control group ($n=10$) randomly. Diluted suspension 0.2 mL of positively transfected *Bifidobacterium infantis* containing 5×10^6 – 6×10^6 bacteria was injected into the mice in the test group through the tail vein. The control group were injected with the same volume and number of untrans-

ferred *Bifidobacterium infantis*. After 7 d, 5-FC was injected intraperitoneally for each mouse in both groups at a dose of 500 mg each day, consecutively for 7 d. From the first day of 5-FC injection, the length and width of the tumor were measured every two days. The volume was calculated using the formula $V=1/2 \times A \times B^2$ (A: length; B: width) and the measurement continued for 21 d.

Statistic methods Comparison of tumor growth suppression rates was examined by chi-square test of four-fold table. Tumor volume was compared by *t*-test. The results were analyzed using statistic software STATA5.0.

Results

Detection of positively transfected *Bifidobacterium infantis* colony Electroporation method was used to transfect recombinant CD/pGEX-1LamdaT plasmid into *Bifidobacterium infantis*. After 72 h, sparse bacterial colonies were observed on MRS solid medium containing ampicillin. A single positively transfected bacterial colony was picked up and cultured, then the recombinant plasmid in the positively transfected *Bifidobacterium infantis* was extracted. The size of extracted recombinant plasmid was approximately 6.2 kb (Figure 1, lane A), which was equal to the size of recombinant CD/pGEX-1LamdaT plasmid.

Detection of recombinant plasmid digested with dual restriction endonucleases After the recombinant plasmid extracted from the positively transfected bacteria was digested with dual restriction endonucleases of *Bam*H I and *Eco*R I, two fragments with sizes of approximately 1.3 kb and 4.9 kb were obtained, which were consistent with the sizes of CD gene and pGEX-1LamdaT plasmid, respectively (Figure 1, lane B).

Sequencing of inserted gene segment in recombinant plasmid extracted from positively transfected *Bifidobacterium infantis* Sequencing results showed that the size and sequence of nucleotide acid of inserted gene segment were completely consistent with the size and sequence of nucleotide acid of CD gene (Genebank: NC-000913). The full length of inserted gene fragment was 1309 bp. The sequence of two ends of the inserted gene was also consistent with *Bam*H I site and *Eco*R I site. The sequencing identified that the foreign gene, CD gene, was correctly inserted into pGEX-1LambdaT plasmid and transferred into *Bifidobacterium Infantis*. Targeting gene therapy system of *Bifidobacterium Infantis*/CD was successfully constructed.

Morphologic changes of B16-F10 cells after treatment After being treated with the positive treatment fluid for 24 h, most B16-F10 cells were killed and only a few grew along the wall.

Figure 1. The electrophoregram of recombinant plasmid (0.8% agarose gel). Lane A: recombinant plasmid extracted from positively transfected *Bifidobacterium infantis* (approximately 6.2 kb). Lane B: digested fragments with dual restriction endonucleases of recombinant plasmid extracted from positively transfected bacteria (approximately 4.9 kb and 1.3 kb, respectively). Lane M: λ -EcoT14 I digest DNA Marker

Most cells floated and quantities of cell debris were observed in the medium. The cells left on the wall underwent significant changes in morphology; the original shape was gone, cytoplasm became rougher, the nucleus showed pycnosis and the refraction decreased (Figure 2), demonstrating obvious cellular damages. In contrast, B16-F10 cells treated with negative treatment fluid did not appear to have obvious morphologic changes compared with the control (Figures 3, 4).

Figure 2. B16-F10 cells treated with positive treatment fluid ($\times 100$).

Examination of tumor cell growth suppression rate The negative treatment fluid had no significant effects on tumor cell growth. The cells growth suppression rate was 4.8%. The B16-F17 cells treated with positive treatment fluid grew at a critically lower rate. The cells growth suppression rate

Figure 3. Control B16-F10 cells without any treatment ($\times 100$).

Figure 4. B16-F10 cells treated by negative treatment fluid ($\times 100$).

was 80%, which was significantly higher than that of group treated with negative treatment fluid (chi-square test: $\chi^2=7.02$, $\nu=1$, $P<0.01$) (Table 1).

Antitumor effects *in vivo* There was no significant difference between the tumor volumes in the test group and control group before treatment. On the d 7 after 5-FC injection, tumor volumes in the test group were considerably smaller than those in the control group ($P<0.05$), and the difference became greater over time until the end of observation (Figure 5).

Discussion

It has been proved that a hypoxic region exists in many human and mouse tumors, especially in solid tumors, which kill over 90 % of cancer patients. Vaupel^[11] made his study on cancer patients using oxygen electrode measurement. In his study, Vaupel found the average oxygen partial pressure in normal tissues read 24–66 mmHg, whereas the readings dropping to 10–30 mmHg in a tumor tissue with a marked central region where the readings went below 2.5 mmHg.

Figure 5. Tumor volume changes of test group and control group.

Based on the presence of a hypoxic metabolic region in a solid tumor and tendency of anaerobic bacteria to hypoxic environment, anaerobic bacteria can be used as transfer vectors for tumor targeting gene therapy.

Compared with viral or other non-viral vectors, the anaerobic bacteria is advantageous for tumor targeting^[13-17]. Yazawa *et al*^[9] injected non-pathological strains of *Bifidobacterium* 105-A and 108-A into mice bearing lung cancer. After 168 h, both strains of bacteria were observed to have targeted and colonized in the tumors, whereas no bacteria were found in the liver, spleen, kidney, normal lung tissues or other normal tissues. When the anaerobic bacteria were used as the gene transfer vector, it could specifically proliferate and directly express foreign gene products in tumor tissues. There is no need to transform cancer cells, which highly improves the gene expression^[9,13,14]. Most of the transfer vectors used in current studies are strains of *Bifidobacterium*. *Bifidobacterium* is a non-pathogenic anaerobic bacteria. It resides in the lower section of the small intestine and in the large intestine of humans or rodent animals, and is good for the health of its host and widely used in food manufacturing and medicine^[9,12-15]. It has been proved in animal experiments that *Bifidobacterium* has no obvious influence on body weight, peripheral leukocytes, temperature, or survival time of mice, hamsters, guinea pigs or rabbits^[13]. Moreover, anaerobic

bacteria are highly vulnerable to antibiotics and very low doses of antibiotics are enough to kill them. Even in the case of overgrowth, the bacteria can be easily controlled by antibiotics, which further the safety.

In the present study, we used *Bifidobacterium infantis* as a CD gene transfer vector, then transferred the CD gene into *Bifidobacterium infantis* and successfully constructed a *Bifidobacterium infantis*/CD targeting gene therapy system.

In the *in vitro* experiment, positively transfected *Bifidobacterium infantis* was incubated anaerobically with 5-FC overnight. The supernatant fluid of the bacteria culture was extracted and resolved in saline. The final solution was added to the melanomocyte B16-F10 and it was observed that the growth of melanomocyte B16-F10 was obviously suppressed at a rate of 80% and the morphology of the cells was also damaged. It was also observed in our study that the growth of tumors were greatly inhibited on mice that were injected with 5-FC and positively transfected *Bifidobacterium infantis*. These results indicate that positively transfected with *Bifidobacterium infantis* can express CD *in vitro* and *in vivo*, which can convert 5-FC into 5-FU to inhibit tumor growth.

CD/5-FC suicide gene therapy system mediated by *Bifidobacterium infantis* has primarily demonstrated its antitumor effects *in vivo* and *in vitro* in this experiment. This system shows promise as a novel tumor targeting gene therapy system and is worthy of further study.

Abstract

Aim: To study the effects of {2-[(3-carboxy-1-oxopropyl)amino]-2-deoxy-*D*-glucose (COPADG) on cultured human hepatocellular carcinoma cells (HepG₂). **Methods:** HepG₂ cells were cultured in RPMI-1640 medium. Cell proliferation was determined by MTT assay. Apoptosis was determined by fluorescence microscopy, transmission electron microscopy, agarose gel electrophoresis of DNA fragmentation, and flow cytometry. **Results:** At the concentration ranging between 1–30 μmol/L, COPADG potently inhibited the growth and induced apoptosis of HepG₂ cells. **Conclusion:** COPADG could effectively induce apoptosis in human hepatocellular carcinoma cells. More investigations are warranted for the potential use of this compound as a new agent for the non-surgical management of human hepatocellular carcinoma.

Introduction

Apoptosis is a cellular suicidal process that plays an important role in the elimination of unwanted or damaged cells. Under the physiological condition, apoptosis counteracts with cellular proliferation to maintain homeostasis. Dysregulated apoptotic response has been associated with certain diseases such as neural degenerative disorders and cancers. Many chemotherapeutic agents, radiation therapy, and therapeutic cytokines are known to induce apoptosis. Thus, apoptosis has been recognized as one of the major modes of cell death in cancer therapy. Resistance to undergo apoptosis is one of the important mechanisms that leads to treatment failure in cancer^[1–2].

In recent years, agents or treatment modalities that result in apoptosis have become a new focus in cancer therapy^[3–5]. {2-[(3-carboxy-1-oxopropyl)amino]-2-deoxy-*D*-glucose} (COPADG)^[6] is a derivative of *D*-glucose (molecular structure shown in Figure 1). *D*-amino-glucose is a monose that comes from the chitosan's degradation. Previous studies by others have discovered that some *D*-amine-glucose de-

rivatives were able to induce leukemia cells K562 to differentiate into macrophages^[7]. However, it is still unknown whether derivatives of *D*-amine-glucose can induce apoptosis in tumor cells. In this study, we aimed to determine whether COPADG could induce apoptosis on human hepatocellular carcinoma cells (HepG₂).

Materials and methods

Materials Human hepatocellular carcinoma cells (HepG₂) were provided by the Department of Pathology, Fourth Military Medical University, China. COPADG was newly synthesized by the Lanzhou Institute of Chemical Physics, Academy of Sciences, China, and was dissolved in distilled water, filter-sterilized with 0.22 μm filter disc, and stored at 4 °C until use. The structure of COPADG is shown in Figure 1. RPMI-1640 medium was purchased from Invitrogen (Invitrogen Corporation, CA, USA). MTT, agarose, and all routine chemicals were purchased from Sigma-Aldrich (Sigma-Aldrich Chemicals, Louis Mo, USA). Trypsin, acridine orange, and fetal calf serum were purchased from Shanghai Biological

Figure 1. Chemical structure of 2-[(3-carboxy-1-oxopropyl)amino]-2-deoxy-*D*-glucose.

Engineering Limited (Shanghai, China).

Cell culture HepG2 cells were cultured in RPMI-1640 medium supplemented with heat inactivated 10% fetal calf serum (FCS), streptomycin 100 mg/mL and benzylpenicillin 100 mg/mL. Cells were maintained in a humidified atmosphere of 5% CO₂ with 95% air at 37 °C. Medium is changed every 48 h.

MTT colorimetric assay The MTT test is based on the enzymatic reduction of the tetrazolium salt MTT in viable/metabolically active cells. Cells at approximately 85%–90% confluency were harvested with 0.25% Trypsin/0.02% edetic acid solution and seeded into a 96-well plate at a density of 4×10³ cells/well. Cells were incubated with various concentrations (1–30 μmol/L) of COPADG for indicated time (24–96 h). Control cells were treated in the same way except that COPADG was replaced by sterile PBS. After treatment, medium was changed to fresh medium, and cells were incubated with 5 g/L of MTT for 4 h. MTT was then dissolved with 150 μL of 10% Me₂SO for 1 h. The optical densities (*OD*) in the 96-well plates were determined using a microplate reader at 490 nm. Cell growth inhibition was estimated by using the following formula:

$$\% \text{ Growth inhibition} = 1 - \frac{OD(\text{treated cells})}{OD(\text{control cells})} \times 100\%$$

Morphological study of apoptosis by acridine orange Acridine orange (AO) is a membrane-permeable fluorescent dye. It is specific for apoptotic cell death and does not significantly stain necrotic cells^[8]. Apoptotic nuclei exhibiting typical changes such as nuclear condensation and segmentation will be stained yellow by AO. Cells (2×10⁵/well) were seeded into 6-well plate, grown to approximately 85% confluency, treated with various concentrations of COPADG for various durations, fixed in methanol: glacial acetic acid (3:1) for 30 min at room temperature, washed in PBS, and stained with 0.01% AO. Stained cells were washed with distilled water, viewed under a fluorescence microscope. Apoptotic cells were counted and expressed as a percentage of the total number of cells counted.

Transmission electron microscopies (TEM) Cells were processed for TEM to further evaluate apoptosis. Cells of logarithmic growth were treated as described above, harvested by trypsinization, fixed in 3% glutaraldehyde for 1 h. After removal of the primary fixative, cells were washed three times in MOPS buffer, post fixed in 1% osmium tetroxide (OsO₄), dehydrated in graded alcohol, and embedded in epoxy resin. Ultra thin sections were double-stained with lead citrate/uranyl acetate before being examined using JEF-100CX transmission electron microscope (Japan).

Agarose gel electrophoresis for detection of DNA fragmentation Upon completion of treatment, cells were processed for DNA fragmentation analysis by agarose gel electrophoresis as described previously^[9]. Briefly, cells (detached and attached) were incubated in 400 μL of lysis buffer (Trinton X-100, 10 mmol/L Tris, 1 mmol/L edetic acid, pH 8.0) for 30 min. The whole cell lysates were centrifugated at 12 000 rpm at 4 °C for 15 min. The supernatants were then incubated with 1 g/L proteinase K at 56 °C for 3 h followed by incubation with 2 g/L RNase A for 2 h. The solution was then sequentially extracted with an equal volume of phenol (pH 8.0), phenol/chloroform (1:1), and chloroform/isoamyl alcohol (24:1). Total genomic DNA was precipitated by adding 1/10 volume of 3 mol/L sodium acetate (pH 5.2) and 2 volumes of ice-cold ethanol for overnight at -20 °C. DNA was collected by centrifugation at 13 000 rpm at 4 °C for 10 min. The pellets were washed once with 70% alcohol and air-dried before being dissolved in TE buffer (10 mmol/L Tris-HCl, pH 8.0, 1 mmol/L edetic acid). DNA concentration was measured at *OD* 260 nm, and 5 μg was loaded onto a 1.5% agarose gel in TAE buffer. Electrophoresis was performed at 35 V for 4 h, the gel was stained with ethidium bromide, viewed under UV illumination, and photographed.

Flow cytometry analysis Following treatment, cells were rinsed with PBS, trypsinized by 0.25% trypsin/0.02% EDTA solution, and collected by centrifugation at 1000 rpm at 4 °C for 5 min. The cell pellets were fixed in 70% ethanol at 4 °C for at least 1 h. The fixed cells were washed twice with PBS, resuspended in PBS containing 50 g/L RNase A and 50 mg/L of propidium iodide (PI). The suspension was incubated at 37 °C for 30 min, filtered through 200 μm nylon mesh, and were analyzed by flow cytometer (Coulter EPICS XL). The apoptotic population was identified as cells appeared in sub-G₀/G₁ peak. Multicycle software was used for data analysis.

Statistical analysis The results are presented as mean±SD. Each experiment was repeated at least three times. Statistical differences between each group were determined by single factor analysis of variance and correlation analysis.

Results

Proliferation inhibition of HepG₂ cells by COPADG As indicated by MTT assay results, proliferation of HepG₂ cells was significantly inhibited by COPADG in a dose-dependent manner (Figure 2A). The inhibitory effect started at 24 h, and reached maximum at 48 h (Figure 2B).

Figure 2. Inhibition of HepG₂ cell growth by COPADG. (A) HepG₂ cells were treated with various concentrations of COPADG for 48 h. (B) HepG₂ cells were treated with 10, 20, and 30 $\mu\text{mol/L}$ of COPADG for 24, 48, 72, and 96 h. The results shown were the averages of three separate experiments. Mean \pm SD.

Apoptosis inhibition in HepG₂ cells by COPADG

Apoptosis morphology by acridine orange fluorescence staining Apoptosis was first detected by typical morphology after staining with acridine orange (AO), one of the early techniques used for apoptosis detection. When HepG₂ cells were treated with 20 $\mu\text{mol/L}$ of COPADG for 48 h, cells with condensed or fragmented chromatin indicative of apoptosis were frequently observed, as compared to control cells which showed evenly distributed yellowish-green

Figure 3. Fluorescence microscopy of HepG₂ cells treated with (B) or without (A) COPADG and stained with acridine orange. In panel B, HepG₂ cells were treated with 20 $\mu\text{mol/L}$ of COPADG for 48 h. Note the presence of chromatin condensation and nuclear fragmentation indicative of apoptosis, as compared to untreated HepG₂ cells in panel A. The results shown were representatives of three separate experiments. (Magnification: $\times 200$).

fluorescent chromatin (Figure 3).

Induction of apoptosis by COPADG was in a dose- as well as a time-dependent manner, with 30 mmol/L of COPADG induced approximately 60% of apoptosis at 48 h. Figure 4 showed the quantitative results of COPADG-induced apoptosis in HepG₂ cells.

Ultrastructure of apoptosis by transmission electron microscopy (TEM) At the ultrastructural level, features of apoptosis were also observed by TEM. In HepG₂ cells treated with 20 $\mu\text{mol/L}$ of COPADG for 48 h, some nuclei displayed characteristic changes of apoptosis: chromatin condensation and margination, as well as nuclear fragmentation, cell shrinkage and cell blebbing (Figure 5). The intracellular organelles such as endoplasmic reticulum become loose and fuse with cell membrane resulting in vacuolation. These

Figure 4. Quantitative analysis of apoptosis of HepG2 cells treated with COPADG. Cells were either treated with various concentrations of COPADG for 48 h (A), or treated with 20 $\mu\text{mol/L}$ of COPADG for various durations (B). The results were mean values of three separate experiments.

changes were in sharp contrast to untreated HepG2 cells, which showed normal cell membrane and nuclei with evenly distributed chromatin, as well as intact intracellular organelles.

DNA fragmentation by agarose gel electrophoresis
In order to investigate whether COPADG kills HepG2 cells by apoptosis, agarose gel electrophoresis of genomic DNA from COPADG-treated HepG2 cells were performed. As shown in Figure 6, typical DNA laddering patterns suggestive of apoptosis were observed when HepG2 cells were treated with 20–30 $\mu\text{mol/L}$ of COPADG for 48 h (lanes 4 and 5, respectively).

FACS analysis of apoptosis These biochemical features were verified by FACScan analysis, in which apoptosis was indicated by the presence of cells in the sub- G_0/G_1 peak. As shown in Figure 7 and Table 1, HepG₂ cells treated with 10 $\mu\text{mol/L}$, 20 $\mu\text{mol/L}$, and 30 $\mu\text{mol/L}$ of COPADG for 48 h displayed a dose-dependent accumulation of cells in the apoptosis peak (panel B, 17.4%; panel C, 26.8%; and panel D, 34.3%, respectively), as compared to untreated control (panel A).

Figure 5. Transmission electron microscopy of HepG2 cells treated with 20 $\mu\text{mol/L}$ of COPADG for 48 h (B). Cells displayed chromatin condensation and fragmentation. The fragmented and condensed chromatin marginate around the nuclear envelope, forming crescent-like structures. In certain fields, pyknotic apoptotic bodies were observed. The micrograph was representative of three separate experiments. (A) untreated control cells.

Figure 6. DNA fragmentation analysis by agarose gel electrophoresis. HepG2 cells were either treated with 0 $\mu\text{mol/L}$ (lane 2, control), 10 $\mu\text{mol/L}$ (lane 3), 20 $\mu\text{mol/L}$ (lane 4), and 30 $\mu\text{mol/L}$ (lane 5) of COPADG for 48 h. Lane 1 was molecular marker. The result was representative of three separate experiments.

Figure 7. FACS analysis of HepG2 cells by PI staining. HepG2 cells were exposed to 0 μmol/L (A, control), 10 μmol/L (B), 20 μmol/L (C), and 30 μmol/L (D) of COPADG for 48 h. Apoptotic cells with a subdiploid amount of DNA appeared on the left side of the G_{0/1} peak (sub-G_{0/1}) as a result of loss of internucleosomal DNA cleavage fragments. The values represent the percentage of cells in the sub-G_{0/1} phase of the cell cycle. The result was representative of three separate experiments.

Table 1. FACScan analysis of HepG2 cells by PI staining. HepG2 cells were exposed to 0, 10, 20, and 30 μmol/L of COPADG for 48 h. Apoptosis is indicated by the presence of G_{0/1} peak (sub-G_{0/1}) as a result of loss of internucleosomal DNA cleavage fragments. The result is the average of three separate experiments.

COPADG /μmol·L ⁻¹	G1	S	G2	Sub-G _{0/1} peak /%
0 (control)	74.9±0.81	24.0±0.38	1.10±0.12	1.70±0.32
10	64.4±2.30	33.1±2.10	2.50±0.80	17.4±1.21
20	84.2±3.82	12.0±1.83	3.80±0.85	26.8±2.18
30	87.5±2.95	8.10±1.01	4.40±0.75	34.3±1.80

Discussion

D-glucose is a low molecular weight compound with multiple biological activities. Studies also have shown that *D*-glucose could inhibit tumor cell growth; some of the partial derivatives of *D*-glucose could potently induce the differentiation of tumor cells^[10]. Our study was aimed to test whether the newest derivative of *D*-glucose (COPADG) had any effect on the proliferation and apoptosis in human hepatoma cells. We utilized several different methods to measure the effect of COPADG on cell proliferation and apoptosis. By MTT assay, it was shown that COPADG could effectively inhibit HepG2 cell proliferation in a dose-depen-

dent manner. The inhibition of cell proliferation was associated with profound induction of cell apoptosis, as demonstrated by a series of complementary techniques for apoptosis detection, including morphologic study by acridine orange fluorescence staining and TEM, both showed typical morphology of apoptosis: cell pyknosis, chromatin condensation, and nuclear fragmentation. The nature of apoptotic cell death was also demonstrated by the presence of its biochemical feature (ie, typical "DNA ladder" on agarose gel electrophoresis indicating internucleosomal DNA fragmentation). These characteristics were further verified by FACScan analysis, which showed the presence of apoptotic peak in subG₀/G₁ peak. These results suggest that COPADG exerts its anti-tumor effects via two fundamental processes: suppression of cell proliferation and induction of apoptosis.

Under the physiological conditions, apoptosis is programmed cell dying process controlled by numerous genes^[11-13]. The balance between well-controlled apoptosis and cell proliferation is an important determinant of cell fate. Thus, impaired apoptotic response or overactive proliferation is among the mechanisms of cancer initiation and progression. Human hepatocellular carcinoma (HCC) is one of the most common and chemoresistant cancers. At the present, there is no effective therapy against this deadly cancer, especially when it reaches advanced stage. Thus, novel and effective treatments are desperately needed. Agents or treatments that inhibit proliferation and /or promote apoptosis are under intensive investigation for their potential use in liver cancer therapy.

Our preliminary *in vitro* study suggested that COPADG could potentially suppress proliferation and induce apoptosis in HepG2 cells. However, further studies are necessary to test the effect of this agent on other HCC cell lines or other types of cancer cells to make sure the effects we observed were not cell line specific. Studies are also warranted to elucidate the underlying mechanisms by which COPADG inhibits proliferation and induces apoptosis in HCC cells. *In vivo* studies in HCC-bearing nude mice may be also necessary to test the toxicity of this agent.

In conclusion, our current study has demonstrated that COPADG is a potent antiproliferative and proapoptotic agent

against HepG2 cells. More studies are currently underway to expand these results to other cell lines.

Abstract

Antibody-based therapeutics are beginning to realize the promise enclosed in their early denomination as “magic bullets”. Initial disappointment has turned into clinical and commercial success, and engineered antibodies currently represent over 30% of biopharmaceuticals in clinical trials. Recent structural and functional data have allowed the design of a new generation of therapeutic antibodies, with strategies ranging from complement-mediated and antibody-dependant cellular cytotoxicity enhancement to improved cytotoxic payloads using toxins, drugs, radionucleids and viral delivery. This review considers the structure of different types of recombinant antibodies, their mechanism of action and how their efficacy has been increased using a broad array of approaches. We will also focus on the additional benefits offered by the use of gene therapy methods for the *in vivo* production of therapeutic antibodies.

Introduction

Monoclonal antibodies (mAb) are unique and versatile molecules that have been found applications in research, diagnosis, and in the treatment of multiple diseases, including cancer. The advent of hybridoma technology for mAb production in 1975^[1] was a breakthrough in the field of biomedicine; 30 years later, a plethora of biotech companies produces thousands of mAb, and at least 17 of them have FDA (US Food and Drug Administration) approval for therapeutic use in patients, with hundreds of them still in the pipeline.

However promising their future is, the development of therapeutic mAb suffered a number of serious drawbacks, which considerably reduced faith in their clinical applicability. These disappointments were caused by their inability to trigger human effector functions, and because repeated administration provoked an immune response against murine antibody (Ab) domains (HAMA, human anti-murine Abs)^[2]. Recently developed technologies (phage display and

transgenic mice) allow the selection and identification of fully human Ab, as well as the improvement of Ab affinity^[3]. The ability to generate human mAb achieved 2 important goals: it overcame most host anti-Ab responses, and it extended the half-life of the reagent to something closer to that of normal IgG. As a result of these advances, mAb are starting to fulfill their potential as therapeutics.

Not surprisingly, Ab engineering has constituted its own field. Mutations can be introduced in the variable regions to increase the affinity of the Ab for its antigen or in the constant region to enhance its natural effector functions. Pharmacokinetics and avidity are improved by multimerization of Ab fragments. Ab molecules have been dissected to their basic elements, and then rearranged to produce a variety of formats not found in nature that display new properties. Moreover, these “building blocks” have been incorporated into multiple types of fusion proteins, soluble (immunocytokines, immunotoxins), as well as part of artificial cell surface receptors and viral envelopes for the retargeting of both effector cells and virus particles (Figure 1).

Figure 1. (A) Schematic representation of an intact IgG molecule. All Ig monomers are composed of 2 identical light chains (L) and 2 identical heavy chains (H). The 4 chains are covalently bonded together by disulfide bonds. Light chains are composed of 1 constant domain (CL) and one variable domain (VL), whereas heavy chains consist of 3 constant domains (CH1, CH2 and CH3) and 1 variable domain (VH). Ab functions can be separated into 2 proteolytic fragments by cleavage with the enzyme papain in the hinge region. The Fab fragment (fragment antigen binding) retains the antigen-binding activity, whereas the Fc fragment (fragment crystalizable) mediates effector functions. The minimal fragment that still contains the whole antigen-binding site is composed of both V_H and V_L domains. This heterodimer, called Fv fragment (for fragment variable) is still capable of binding the antigen. Bottom: strategies for enhancing the potency of therapeutic Ab by Fc domain manipulation. Key Fc regions can be engineered to enhance effector functions or to increase the Ab half-life. (B) Dissection of the binding region of an Ab in progressively smaller fragments. $F(ab')_2$ and Fab fragments are obtained by proteolysis with pepsin and papain, respectively. (C) Using scFv (single-chain Fv, obtained by linking V_H y V_L with a flexible polypeptide) as building blocks, different multivalent Ab fragments can be engineered. Shortening the intradomain linker connecting the V_H and V_L chains results in the formation dimers, (diabodies), trimers (triabodies) and tetramers (tetrabodies). To create a miniantibody, a scFv is genetically linked to the IgG1 CH3 domain via connecting peptides. A bispecific and tetravalent recombinant Ab can be constructed by linking four Ab variable domains (V_H and V_L) of 2 different specificities into a single chain construct. They can either form bivalent bispecific Abs by diabody-like folding (sc-diabodies) or dimerize with the formation of tetravalent bispecific Abs (tandem diabodies). The efficacy of tandem diabody (tandab) formation is dependent on the length of the linker between 2 halves of the molecule. (D) Ab can be “armed” by incorporation (by chemical conjugation or at genetic level) of a variety of moieties, including radionuclides, chemotherapeutics, toxins and cytokines. (E) Surface-bound, scFv-based molecules comprise chimeric immune receptors (CIR) and engineered viral surfaces. CIR comprise a recognition unit (the Ab fragment) attached to the transmembrane and intracytoplasmic sequences of a signaling molecule. Viral envelopes or capsids can be designed to incorporate scFvs for virus retargeting.

Making better mAb: how to improve their “natural” effector functions

Ab contains two functionally and molecularly separable modules (Figure 1A): one module for antigen binding (Fab) and another for triggering effector functions (Fc). The antigen-binding region can be manipulated to increase both binding affinity and specificity. Methods of Ab affinity maturation are based on the principle of changing parts of the variable domains while keeping the specificity. Different approaches are: chain-shuffling (substitution of the native light chain with a new light-chain repertoire, but retaining the variable heavy chain), randomization of complementarity determining regions (CDR), and generation of Ab libraries with mutations within the variable regions by error-prone PCR, and *E coli* mutator strains or site-specific mutagenesis^[4].

Fragment crystallizable (FC) domains contain motifs for the activation of both effector immune cells and the classical pathway of the complement (C1q) responsible, respectively, for Ab-dependent cellular cytotoxicity (ADCC) and complement-dependent cytotoxicity (CDC). A variety of immune cells express on their surface receptors for the Fc domain of IgG1 and IgG3: FcγRI, FcγRIIa, FcγRIII are stimulatory and FcγRIIb is inhibitory. The Fc domain sequence can be manipulated (Figure 1A) to increase its affinity for the stimulatory receptors or to decrease its binding to the inhibitory one, modulating the activity of the whole Ab^[5]. Similarly, point mutations in the Fc domain can increase the binding to C1q, improving complement activation^[6]. Modification of Fc glycosylation can also enhance its ability to support ADCC^[7].

The Fc region of human Ab also contains a binding motif for the receptor FcRn that protects immunoglobulins (Ig) from intracellular degradation (Figure 1A). By contrast, rodent mAb fail to bind to FcRn and are rapidly removed from the circulation. Using combinatorial phage display libraries, mutations in the Fc region have been identified with higher binding affinity to FcRn, implying longer half-life of the mAb^[8].

New formats, new functions

The domain architecture of Ig has facilitated the creation of both smaller and larger forms with variable valency for one or more target antigens and pharmacokinetic properties that are tunable to specific settings^[9]. Non-natural Ab formats (Figure 1C), such as the single-chain fragment variable (scFv) and the diabody, are rapidly emerging as key players in the engineered Ab field. A scFv (~30 kDa) comprises the V domains of the heavy and light chains (VH and VL) of a

mAb joined by a linker sequence^[3]. A diabody (~60 kDa) is produced when scFv contain short interdomain linkers (5 aminoacids or less)^[10]. This prevents intramolecular pairing of the VH and VL domains on the same chain, but allows interchain pairing to form dimers. Reducing further the linker length promotes the assembly of scFv into trimers (triabodies, ~90 kDa) or tetramers (tetrabodies, ~120 kDa). The increased binding valency of these multimers results in high avidity and low off-rates.

Given that Ab fragments lack the Fc region, their biological effects can not be attributed to CDC or ADCC. In this context, the nature of the target is crucial, as Ab fragments function by blocking the action of specific molecules or by acting as signaling molecules. The blocking activity is achieved by preventing growth factors, cytokines or other soluble mediators reaching their target receptors, accomplished either by the Ab binding to the factor itself or to its receptor. The signaling effect is based on the crosslinking of receptors that are, in turn, connected to mediators of cell division or programmed cell death^[4].

Diabodies constitute the most effective way to generate bispecific Ab fragments through their ability to bind to 2 different antigens and used to crosslink various cells and molecules. Bispecific Ab offer a variety of new effector mechanisms: retargeting of effector cells (cytotoxic T cells, NK cells, and macrophages), recruitment of effector molecules (toxins, drugs, prodrugs, cytokines, radioisotopes, and complement system) and retargeting of carrier systems (viral vectors for gene therapy)^[11].

Ab fragments as Fab and scFv offer several advantages because of their small size when compared to parental Ig (150 kDa): (i) they are easy to produce in bacterial systems; (ii) extravasate more efficiently; and (iii) their tissue penetration ability is higher. However, recombinant proteins that are smaller than 60 kDa are taken up by the kidney and excreted into the urine. Therefore, these molecules tend to have a short circulating half-life. As Fab and scFv fragments lack the Fc region altogether, they can not be saved from degradation by FcRn. Multimerization is an obvious strategy to increase the size, and therefore, the half-life of Ab fragments (triabodies, tetrabodies). The use of bispecific Ab fragments for retargeting serum Ig provides with the Fc-associated effector functions and prolongs the residence time in serum. A new approach is the pegylation of Ab fragments, achieved by chemical coupling of polyethylene glycol (PEG) to amino groups in the protein structure, increasing the size of the molecule above the glomerular filtration limit^[12].

Naked versus armed mAb: acquisition of new effector functions

In cancer therapy, Ab fragments are fused (chemically or at genetic level) with a range of molecules to introduce different functionalities, including cytotoxic drugs, toxins, or radionuclides for cancer cell killing, enzymes for prodrug therapy and cytokines to stimulate the antitumor immune response (Figure 1D). These “armed” Ab exhibit considerably better therapeutic performance than their “naked” counterparts (for a review on the topic, see Ref [2]).

Incorporation of agents with direct toxic effect The most widely explored strategy for enhancing the efficacy of anti-tumor Ab is direct arming by linkage to cytotoxic agents or radionuclides. In fact, 3 of the approved mAb for use in patients belong to this group: gemtuzumab ozogamicin was the first (2000), followed by ibritumomab tiuxetan and tositumomab (2002 and 2003, respectively). Gemtuzumab ozogamicin is an anti-CD33 (antigen expressed in 90% of acute myeloid leukemias) mAb conjugated to calicheamicin. Calicheamicins and maytansinoids are (100–1000)-fold more potent than conventional chemotherapeutics and constitute the most extensively evaluated small-molecule toxins used for Ab arming^[2]. Biological toxins, such as ricin or diphtheria toxin, can be attached to an Ab (native Ig or recombinant fragments), although their clinical application has been hampered by their high toxicity. It has recently been published that a single point mutation in ricin toxin can eliminate vascular damage without compromising its action^[13].

Ibritumomab tiuxetan and tositumomab are anti-CD20 mAb conjugated, respectively, to ⁹⁰Y and ¹³¹I, and approved for non-Hodgkin lymphoma treatment. Radioimmunotherapy (RAIT/RIT) has the advantage to kill bystander cells, especially interesting when not all the tumor cells express the antigen recognized by the Ab^[14].

ADEPT: Ab-directed enzyme prodrug therapy ADEPT involves the pre-targeting of prodrugs to tumors. An Ab-enzyme fusion protein is first administered and allowed to localize to the tumor, followed by the administration of the prodrug which is activated by the enzyme at the tumor site^[15,16]. This strategy has proven highly effective in pre-clinical tumor models, allowing 4–12 fold higher intratumor drug concentrations and up to 5-fold lower extratumor drug concentration^[2]. An interesting approach is the use of Abs with inherent catalytic activity, so the conjugation to an enzyme is not required^[17].

Immunocytokines Several cytokines have demonstrated their potent antitumoral effect, but unfortunately their side effects limit their administration. In order to accumulate preferentially the cytokine in the tumor, fusion proteins

(immunocytokines) consisting of a targeting mAb specific for a tumor antigen and the selected cytokine (IL-2, IL-12, TNF- α and GM-CSF) have been designed^[18]. These immunocytokines allow the local activation of the antitumoral immune response, avoiding the toxicity associated with systemic cytokine administration^[19,20]. A different approach is based on the targeting of tumor vasculature using cytokines with recognized antiangiogenic effect, as IL-12^[21].

Gene therapy: new scenarios

The practical utility of Ab fragments has been limited by problems related to large-scale production and biodistribution. Monovalent Ab fragments exhibit rapid blood clearance and poor retention time on the target, which results in the necessity of frequent delivery of such Ab fragments. To circumvent these limitations, Ab-based gene therapy approaches have been developed. *In vivo* production makes the Abs less immunogenic and better tolerated and results in effective and persistent levels of Ab fragments, compensating for the rapid blood clearance of scFvs. Moreover, genetic approaches provide Ab molecules with new functions in unexpected scenarios^[22].

Secretion of soluble Abs by genetically modified cells *In vivo* production of therapeutic mAb by genetically engineered cells could advantageously replace the injection of purified Ab in cancer treatment. The feasibility of the *in vivo* production and systemic delivery of mAb by different cells/tissues has now been demonstrated using different techniques, as *ex vivo* genetically modified autologous or encapsulated heterologous cells and *in vivo* gene transfer using viral vectors^[23].

In the first work reporting a therapeutic effect associated to *in vivo* mAb production, an anti-erbB-2 scFv was expressed using an adenoviral vector. In this model, a human ovarian cancer cell line erbB-2⁺ was established in the context of athymic nude mice. Whereas exponential growth in tumor volumes was noted in the control groups, a clear inhibition of tumor growth was observable for the animals treated with the adenoviral vector encoding anti-erbB-2 scFv^[24].

We have demonstrated that both monospecific and bispecific Ab can be efficiently produced by mammalian cells with a clear therapeutic effect. Using an anti-laminin scFv with antiangiogenic activity^[25,26], we assessed that gene-modified human fibrosarcoma cells failed to grow to detectable tumors when inoculated in athymic mice^[27]. In another set of experiments, functionally active diabody (anti-CEA x anti-CD3) was secreted from stably transfected human cells and promoted unstimulated human primary T cells to proliferate and kill CEA-expressing cancer cells. Importantly,

locally produced diabodies showed significant cytotoxic activity *in vivo* against established tumors and only required the infusion of small numbers of functional T cells^[28].

Surface-bound Abs: chimeric immune receptors Adoptive cellular immunotherapy of cancer has been limited mostly because of the poor immunogenicity of tumor cells and the difficulties in obtaining tumor-specific MHC-restricted cytotoxic T lymphocytes (CTL) in large numbers^[29]. To circumvent these limitations, new strategies have been designed in order to target CTL to relevant tumor cell surface antigens, including genetic manipulation of T cells to graft them with new recognition specificities^[30].

Chimeric immune receptors (CIR) genes are composed of a recognition unit attached to the transmembrane and intracytoplasmic sequences of a signaling molecule. Most Ab-derived CIR use scFvs as recognition domains. Signaling molecules belong to a family of structurally and functionally related proteins that include TCR-associated polypeptides and some Fc receptors. As the requirements of MHC restriction are bypassed, the tumor cell recognition of CTL grafted with CIR is not hampered by the down-regulation of HLA class I molecules usually found in tumors^[30].

The utility and effectiveness of the CIR approach has been demonstrated in a variety of animal models where tumor-specific CIR drove the adoptive transferred autologous T-lymphocytes to accumulate at the tumor site *in vivo* and prevented the growth of syngenic tumors that grow rapidly in the native host. Target antigens include CEA (colorectal cancer), PSMA (prostate cancer), erbB-2 (breast and others), CD19 and CD20 (B-cell malignancies), CD30 (lymphomas), GD2 (neuroblastoma) and the tumor neovasculature receptor VEGFR-2^[22]. Recently, human peripheral blood leukocytes genetically modified to target CD19 were shown to eliminate systemic B-cell tumors in immunodeficient mice^[31]. Primarily investigated in T cells, CIR have also proven useful in the retargeting of NK cells^[32].

Recent studies have established that the provision of additional or co-stimulatory signals is essential for the expansion and activity of adoptively transferred T cells. We have reported that CD28-based CIRs were stably expressed as functional cell surface receptors and that Ag-specific co-stimulatory signals could synergize with signals mediated through the native TCR/CD3 complex or TCRz-based CIR to produce optimal levels of IL-2^[33]. Moreover, CIR providing both primary and costimulatory signaling in T cells from a single gene product have been described^[34].

Viral surface engineering Most of the viral vectors developed for gene therapy have a broad tissue tropism. The development of viral vectors targeted into a selected

type of cell or tissue, without losing virus infection efficiency or causing toxicity, is critical for their clinic application. Cancer cells represent major targets in this strategy, as they often express lower levels of viral receptors compared to normal cells^[35].

Using Ab directed against tumor-associated antigens expressed on the cell surface for virus pseudotyping has been successfully associated with different viral vectors in directing them to cancer cells. Adenovirus (AdV) has been extensively studied in this approach, especially in the context of capsid engineering. The most recent developments in this approach have overcome several limitations in this strategy, including the need for correct ligand folding, the structural and biosynthetic compatibility of ligands with the AdV, along with the fact that in this strategy, viruses have to be specifically engineered for each particular targeting situation. Thus, several groups have used similar strategies by incorporating an IgG-binding domain of staphylococcal protein A into the AdV fiber protein, allowing the vectors to form a stable complex with either full size mAb or fusion proteins consisting of a targeting scFv fused to an Ig Fc domain^[36,37].

Another group of preferred vectors in preclinical and clinical settings for cancer gene therapy are the murine leukemia virus (MLV)-based retroviral vectors. Several groups have inserted a scFv moiety in the virus envelop to obtain cell-specificity^[38-41]. Using a different strategy, the IgG-binding domain of protein A was inserted into the envelope, allowing the redirecting lentiviral vectors to target cells through adaptors as described for AdV^[42].

The attenuated measles virus (MV) is another vector with great therapeutic potential in gene therapy. The feasibility to expand MV tropism by virtue of a scFv displayed on its H protein was demonstrated using an anti-CEA scFv^[43]. Replicating MV have been obtained which are capable of entering CD20⁺ or CD38⁺ target cells through interaction between either an anti-CD20 or anti-CD38 scFv and the cognate antigen molecules on the cell surface. Both studies have shown significant antitumor effects *in vivo*^[44,45].

Intrabodies Intracellular Ab (intrabodies) constitute neutralizing molecules with a great potential in gene therapy and represent an alternative to other methods of gene inactivation as antisense RNA and RNA interference (RNAi). When provided with the corresponding protein trafficking signals, intrabodies can be directed to endoplasmic reticulum via addition of a SEKDEL retention signal, nucleus via the SV40-derived nuclear localization signal, inner face of the plasma membrane by the addition of farnesylation signals or cytoplasm simply by the deletion of the leader peptide. Although

classically designed to divert proteins from their usual cellular compartment or to block protein-protein or protein-nucleic acid interactions, this concept is currently in expansion, with intrabodies capable of directly inhibiting the function of an enzyme, activating intracellular proteins, as caspase-3, or leading proteins to degradation in the ubiquitin-proteasome pathway using F-box-intrabody fusions^[46].

ScFvs are the preferred format for intrabodies, but their stability is affected by the reducing conditions inside the cell, which prevent the formation of intradomain disulphide bonds and blocks their proper folding. Efforts to generate functional intrabodies include the isolation of naturally occurring intrabodies from large libraries and the creation of an artificial intrabody framework that relies on the pre-determined ability of certain scFv to fold adequately and remain stable in the cellular milieu^[46,47]. While scFv intrabodies are the most common, alternative formats have been shown to be equally effective, including single Ab domains (“came-lized” or not) and bispecific Ab, known as “intra-diabodies” which are able to downregulate simultaneously 2 cell surface receptors^[48].

Regarding their application in cancer therapy, intrabodies are suitable to downregulate proteins overexpressed in tumors, such as EGFR, erbB-2, cathepsin L^[49], and cyclin E or to target mutant oncogenic forms of Ras and p53 and fusion proteins as BCR-ABL. Apoptosis of tumor cells can be promoted by downregulation of Bcl-2 or activation of caspase-3, and the uptake of cytotoxic drugs can be increased blocking the multidrug resistance (MDR) gene product^[22]. Inhibition of tumor neovascularization is a promising approach for cancer therapy. Recently, an adenoviral vector was used to deliver a scFv capable of blocking surface expression of an endothelial cell-specific receptor and significantly inhibited growth of human xenografts in a murine model^[50].

Conclusions

Antibody engineering represents an emerging technology that holds great promise for medical science. With the plethora of new molecular techniques at hand, many innovative approaches to diagnostics and therapeutics applications are under consideration. The development of protein engineering techniques to reduce immunogenicity, alter half-life, improve efficacy, and increase tumor targeting has provided the new types of antibodies that are moving rapidly from the bench to the clinic. In fact, engineered antibodies now represent over 30% of biopharmaceuticals in clinical trials. Furthermore, genetic approaches provide antibody molecules with new functions in unexpected scenarios: expression of

antibody domains in precise intracellular locations and grafting of new binding activities to engineered cells. Further improvement will require the design of *in vivo* selection systems to generate antibodies fully active in specific cellular compartments, and the use of antibodies as tools for functional gene identification and drug target validation (genomics- and proteomics-based high-throughput systems) and for better understanding of disease pathways.

Abstract

One of the major obstacles in the development of bispecific antibodies (BsAb) has been the difficulty of producing the materials in sufficient quality and quantity by traditional technologies, such as the hybrid hybridoma and chemical conjugation methods. In contrast to the rapid and significant progress in the development of recombinant BsAb fragments (such as diabody and tandem single chain Fv), the successful design and production of full length IgG-like BsAb has been limited. Compared to smaller fragments, IgG-like BsAb have long serum half-life and are capable of supporting secondary immune functions, such as antibody-dependent cellular cytotoxicity and complement-mediated cytotoxicity. The development of IgG-like BsAb as therapeutic agents will depend heavily on our research progress in the design of recombinant BsAb constructs (or formats) and production efficiency. This review will focus on recent advances in various recombinant approaches to the engineering and production of IgG-like BsAb.

Introduction

Antibodies quickly evolve by recombination, somatic mutation, and clonal selection *in vivo* to acquire the exquisite specificity and high affinity needed for an effective immune response. The modular structure of antibodies that permits *in vivo* reorganization also makes them exceptionally amenable to molecular manipulation, and facilitates the development of desirable properties. As a result, the field of antibody engineering has developed rapidly in recent years, as researchers exploit the ease with which antibodies can be genetically modified to develop ever more powerful therapeutics. So far, 18 antibody-based products have been approved by the FDA for therapeutic applications, including 8 for oncology indications. While the inoculation of animals with antigen and high-throughput screening of hybridoma clones is still common practice, *in vitro* selection is rapidly becoming the norm. Through the use of synthetic or semi-synthetic libraries in microscopic selection techniques (such as phage display^[1], yeast surface display^[2], and ribosomal display^[3]), identifying an antibody to a given target has become a routine, although by no means trivial, matter.

Once an antibody specific to a particular antigen is identified, numerous mechanisms of action can be exploited

for therapy. These mechanisms include: (1) as an antigen (growth factor or cytokine) sequestrant, the antibody binds a soluble antigen and prevents it from interacting with other molecules, such as its receptors. Avastin (Genentech, South San Francisco, CA), an anti-angiogenic therapy for colon cancer, binds vascular endothelial growth factor (VEGF) and blocks its interaction with the receptors^[4]. Remicade (Centocor, Malvern, PA), a treatment for auto-immune disorders such as Crohn's disease and rheumatoid arthritis, works by sequestering tumor necrosis factor- α ^[5]. A number of antibodies to sequester anthrax toxin^[6] and botulinum toxin^[7] are also being developed; (2) as a receptor antagonist, the antibody binds a cell surface receptor and inactivates it by blocking the binding site of an activating ligand. Erbitux (ImClone, New York, NY), an antibody for the treatment of colon cancer, binds epidermal growth factor receptor (EGFR) at the EGF-binding site and blocks activation by both EGF and transforming growth factor- α ^[8]. Alternatively, the antibody may not directly block ligand/receptor interaction but rather exerts its effects by preventing receptor dimerization/multimerization, which is required for activation. For example, Omnitarg, also known as 2C4 (Genentech), an anti-HER2 antibody currently under clinical development, is believed

to inhibit tumor cell growth by blocking HER2 from dimerizing with EGFR and HER3 (there is no ligand identified so far for HER2)^[9]; (3) as an agonist, the antibody binds to and cross-links multiple membrane bound receptors, mimicking the function of a natural ligand, and activating the receptor. There are a number of antibodies that mimic the function of Apo2L (ligand) and trigger apoptosis by activation of death receptor 5^[10,11]; (4) as an effector function activator, the antibody binds a cell surface target and acts as an immune system identifier for antibody dependent cellular cytotoxicity (ADCC) or complement-mediated cytotoxicity (CMC). Rituxan (Genentech), an antibody for the treatment of CD20-positive, B-cell non-Hodgkin's lymphoma^[12], and Herceptin (Genentech), an antibody for the treatment of HER2 positive metastatic breast cancer^[13,14], are postulated to exert their effect in part by this mechanism^[15]; (5) as a chemotherapy or radiotherapy adjunct, the antibody acts as a carrier molecule to deliver an attached chemotherapeutic agent or toxin, or radioisotope to cells displaying a specific antigen. A number of antibody conjugates have been approved by the FDA for oncology indications, including Mylotarg (Wyeth, Madison, NJ), an anti-CD33 antibody-calicheamicin conjugate for the treatment of CD33 positive acute myeloid leukemia; Zevalin (Biogen Idec, Cambridge, MA), a ⁹⁰Y-labeled anti-CD20 antibody, and Bexxar (GlaxoSmithKline, Brentford, UK), an ¹³¹I-labeled anti-CD20 antibody for non-Hodgkin's lymphoma^[16]; (6) as a means to redirect cytotoxic agents or immune effector cells to target sites, such as tumors, in the form of a bispecific antibody (BsAb), which is discussed in detail in the present paper.

Bispecific antibodies

BsAb are antibody-based molecules that can simultaneously bind two separate and distinct antigens (or different epitopes of the same antigen). The primary use of BsAb has been to redirect cytotoxic immune effector cells for enhanced killing of tumor cells by ADCC. In this context, one arm of the BsAb binds an antigen on the tumor cell, and the other binds a determinant expressed on effector cells, such as CD3, CD16, or CD64, which are expressed on T lymphocytes, natural killer (NK) cells, or other mononuclear cells^[17-20]. By cross-linking tumor and effector cells, the BsAb not only brings the effector cells within the proximity of the tumor cells but also simultaneously triggers their activation, leading to effective tumor cell-killing. Preliminary but promising clinical benefits have been observed in a number of early stage trials^[21]. In addition, BsAb has also been used to enrich the tumor/normal tissue localization ratio of chemo-

or radiotherapeutic agents. In this setting, one arm of the BsAb binds an antigen expressed on the cell targeted for destruction, and the other arm binds a chemotherapeutic drug, radioisotope, or toxin. The naked BsAb is administered first, and after sufficient time has passed for the BsAb to bind tumor cells and to clear from normal tissue, the cytotoxic molecule is delivered, with rapid accumulation in the tumor, because of its affinity for the tumor bound BsAb^[21-25]. Recently, a novel concept has emerged - the development of BsAb that target two tumor-associated antigens (eg, growth factor receptors) for down-regulation of multiple distinct cell proliferation/survival pathways, which provides enhanced antitumor activity^[26-28].

A major obstacle in the general development of BsAb has been the difficulty of producing materials of sufficient quality and quantity for both preclinical and clinical studies. Initially, the main route to the production of BsAb was by co-expression of both the light chains (LC) and both the heavy chains (HC) of two parent antibodies of different specificities (antibody A and antibody B) in a single cell through either the hybrid hybridoma technique^[29] or DNA co-transfection. Unfortunately, assuming that all the four polypeptide chains are equally expressed and there is no pairing preference between any particular LC and HC, in addition to the desired heterodimeric BsAb product (LC_A-HC_A plus LC_B-HC_B), there is also a large number of undesired products formed from the ten molecules that result from the 16 permutations LC and HC pairings (Figure 1). Consequently, the desired binding-competent BsAb are a minor product (in theory, an eighth of the total), and purification from the other products is very difficult. Another traditional method for BsAb production is chemical conjugation of two antibodies (or their fragments) of different specificities^[30], although this method is by no means simple. Furthermore, the chemical modification process may inactivate the antibody or promote aggregation. As purification from undesired products remains difficult, the resulting low yield and poor quality BsAb makes this process, like the hybrid hybridoma and DNA co-transfection, unsuitable for the large scale production required for clinical development.

Thus the major requirements of efficient BsAb production are: (1) a novel structural format that promotes or obligates the formation of homogenous, bispecific proteins; and (2) an efficient expression system in prokaryotic or eukaryotic cells that leads to high-level production. Significant progress has been made in the past decade towards the development of BsAb fragments^[31,32], which have various advantages and disadvantages. Firstly, they are smaller than full length IgG, so they have better solid tumor penetration

rates, but their small size and lack of an intact Fc also results in rapid clearing from circulation, leading to a short *in vivo* half-life. Secondly, the BsAb fragments do not require glycosylation, so they can be produced in high yield in bacteria. Compared to the full length IgG-like BsAb, these fragments are, however, incapable of promoting effector function such as ADCC and CMC (unless one arm of the BsAb fragments is specifically targeted to bind an effector cell determinant or certain components of the complement proteins, eg, C1q). The engineering and application of various BsAb fragments have been discussed in a recent review by Kontermann^[33]. Our review will thus focus on the latest advancements and ongoing developments in recombinant production of full-length, IgG-like BsAb.

Recombinant approaches to IgG or IgG-like BsAb

Increasing heterodimer : homodimer ratio

“Knobs-into-holes” BsAb IgG Because one of the major barriers to the production of BsAb in a single cell system, such as hybrid hybridoma, is the undesired formation of HC homodimers (Figure 1), a first and obvious solution is to re-engineer the CH3 domain of the Fc so as to favor HC heterodimerization over homodimerization. This concept, first developed by Carter *et al* at Genentech^[34], is based on

the idea that simple mutations can be introduced into one half of the CH3 dimer, such that the steric complementarity required for CH3/CH3 association obligates the mutated CH3 domain to pair with a CH3 domain that has different, accommodating mutations (Figure 2). Specifically, a “knob” mutation (T366W in the CH3 domain, chosen by inspection of the crystal structure of the Fc^[35]) is made into one HC to introduce a larger residue at the CH3 dimer interface and create a steric barrier to homodimerization. To promote heterodimerization, an accommodating “hole” (Y407A) mutation is engineered into the CH3 domain of the other HC. Co-expression of these two HC results in the formation of a mostly (92%) heterodimeric product, but with a stability that is significantly lower than that of the wild-type (knob: T366W+hole: Y407A mutant, $T_m=65.4^\circ\text{C}$; wild-type, $T_m=80.4^\circ\text{C}$). To optimize and stabilize the heterodimerized molecules, variants with enhanced stability were selected from a phage display library in which residues near the “hole” (T366, L368, Y407) were randomized^[36]. The resulting variant (knob: T366W; hole: T366S, L368A, Y407V) has an increased T_m (69.4°C) and formed predominantly heterodimers, when co-transfected in 293 cells. This example clearly demonstrates the utility of the knob-into-holes approach. It is possible there are other sets of residues within the CH3 domains that could be mutated/optimized to further increase BsAb stability and the heterodimer: homodimer ratio.

Figure 1. Chain mispairing is a major obstacle to BsAb production using both the hybrid hybridoma and DNA co-transfection methods. Random pairings of the two heavy and the two light chains from two different antibodies results in 10 possible combinations, only one of which is the desired bivalent, bispecific product. The use of knob-into-holes technology disfavors the formation of the six possible HC homodimeric products (dashed box). Use of a common LC eliminates all the LC/HC mispairings (solid box), and when combined with knob-into-holes engineered HC, renders all LC/HC pairings binding competent, and results in the preferential formation of the bivalent, bi-specific molecule (top row).

Figure 2. Schematic of recombinant BsAb formats. Details of each construct are described in text. HC constant domains, grey (and dark grey for knobs-into-holes); LC constant domain, white (and diagonal hashed for knobs-into-holes IgG); VH binding to antigen A, red; VL binding to antigen A, light red; common LC for knobs-into-holes, patched light red and light purple; VH binding to antigen B, purple; VL binding to antigen B, light purple; covalent polypeptide linkers, black; interchain disulfide bonds, orange; antigens A and B are indicated by colored crosses, red and purple, respectively. N- and C-terminal are indicated for each polypeptide chain.

While this approach solves the HC homodimerization problem, and reduces the total number of potential LC/HC pairings in a co-transfected single host from ten to four

(Figure 1) thus, in theory, increasing the production of the functional BsAb from 12.5% to 25%, it does not address the equally problematic mispairing of LC and HC from two differ-

ent antibodies (eg, LC_A-HC_B and LC_B-HC_A mispairing, instead of the correct LC_A-HC_A and LC_B-HC_B pairing). This can be resolved by similarly redesigning the LC-HC interaction to incorporate knobs and holes at the VL-VH interface^[37]. Based on inspection of the VL-VH interface of the anti-HER2 Fab fragment, 4D5 Fab^[38], knob mutations and the complementary hole mutations were designed for a diabody fragment containing the Fvs of 4D5 and an anti-CD3 antibody. For one of the variants (termed “v5”; knob: VH-V37F, L45W; hole: VL-Y87A, F98M) 92% of the products were heterodimers, and near wild-type affinity for antigens was retained. Although these mutations were used to promote heterodimerization in a bispecific diabody, the principle should translate easily to a full length IgG format.

Common light chain BsAb IgG An alternative approach to solve the LC-HC mispairing problem is to construct BsAb using two antibodies of different specificities that share an identical LC^[39] (Figures 1, 2). In a “proof-of-concept” study, a large scFv phage display library was used to screen for antibodies to a variety of antigens. The VL fragments of selected scFv were compared and those with identical amino acid sequences, but paired with different VH fragments for different antigen binding specificity, were selected to create BsAb. Functional IgG-like BsAb were formed with high yield (>95% of total IgG products) when a single LC was co-transfected in a host with two different HC that were engineered to incorporate the original knobs and holes mutations (knob: T366W, hole: T366S, L368A, Y407V) and a heterodimer promoting/stabilizing disulfide bond (S354C, Y349’C).

This highly engineered system demonstrates that the knobs-into-holes principle, when combined with a common light chain, can be used to effectively produce a near homogenous population of BsAb IgG. It also suggests that there are multiple ways in which the knob-into-holes approach can be applied, and that BsAb with even higher ratios of heterodimer formation may be achieved with further engineering. However, an obvious drawback of this method is that the inclusion of multiple mutations in the CH3 domains might pose an immunogenic risk in a therapeutic setting. Furthermore, it requires the identification of antibodies with common LC, which is rare, particularly for high-affinity antibodies.

Single chain Fv-Fc “knobs-into-holes” BsAb The LC-HC mispairing problem may also be circumvented by fusing the VL and VH in a single-chain Fv (scFv) format^[40]. In this construct, an anti-HER2 scFv is fused to an Fc with the “knob” mutation T366Y, and an anti-CD16 scFv is fused to an Fc with the “hole” mutation Y407T (Figure 2). Efficient pairing of the two chains, through the knobs-into-holes

mechanism, was demonstrated (but not quantitated), and specificity for both antigens was confirmed by cell surface binding analysis. The scFv-Fc knobs-into-holes molecule is also able to crosslink the two target antigens, as shown by its ability to induce higher NK cell-mediated cytotoxicity than a monospecific anti-HER2 antibody alone. One could hypothesize that this format, which is slightly smaller (120 kDa) than a normal IgG (150 kDa), might provide slight gains in tumor penetration, while maintaining the longer half-life and effector functions provided by the intact Fc region.

IgG-scFv fusions To circumvent the LC-HC mispairing and HC homodimerization issues completely, a number of formats have been developed to construct and produce BsAb that achieve their bi-specificity and product homogeneity not by molecular alteration of the component domains, but by direct addition of a new antigen binding specificity to a fully functional antibody or an antibody-like molecule, such as an IgG antibody or a scFv-Fc fusion protein (Figure 2).

C-terminal scFv fusion One approach is to fuse a scFv specific for one antigen to the carboxy terminus of a full-length IgG antibody specific for another antigen, creating a tetravalent bispecific IgG-like antibody^[41] (Figure 2). The specificity at the N-terminal end (in this case, for dextran) is defined by a normal Fab. The specificity at the C-terminal end (in this case, for dansyl) is conferred by an anti-dansyl scFv. The fusion construct has an affinity approximately 10-fold lower for dansyl than expected (as compared to its parent IgG), primarily because of a slower on-rate. This may be a result of steric hindrance from the rest of the IgG, an inability of both scFv fragments to bind antigen simultaneously (whether all four binding sites were occupied was not tested), or an artifact resulting from conversion of the original anti-dansyl IgG to scFv format. Regardless, the constructs in both a full-length IgG-like format (VL_A-CL plus VH_A-CH1-CH2-CH3-scFv_B)₂ and a F(ab’)₂-like format (VL_A-CL plus VH_A-CH1-scFv_B)₂ were capable of binding both target antigens. Furthermore, the IgG-like version is capable of binding C1q, presumably through the intact Fc fragment, although it is unable to trigger a complete complement cascade. This format has the potential to allow the creation of tetravalent molecules with some effector function, but the full potential of the latter remains to be investigated.

N-terminal scFv fusion In an alternative approach, the two scFv of different specificities are fused, respectively, to the N-termini of the constant light (CL) and the first-constant heavy (CH1) domains of an IgG: (scFv_A)-CL and (scFv_B)-CH1-CH2-CH3. Co-expression of the two polypeptide chains in a single host results in the formation of a tetravalent bispecific molecule, Bs(scFv)₄-IgG (Figure 2)^[42]. Only ho-

homogenous BsAb are generated as a result of the natural heterodimerization between the CL and the CH1 domains. Similar to the C-terminal fusion, this molecule is also amenable to truncation: a bivalent bispecific Fab-like molecule can be created without the Fc fragment. The ability of this construct to crosslink antigen (in this case, two distinct epitopes on vascular endothelial growth factor receptor 2 (VEGFR2)) was demonstrated, but it is not clear whether all four binding sites are or can be occupied simultaneously.

Two other Bs(scFv)₄-IgG molecules were recently constructed, using the same two scFv fragments directed against EGFR and insulin-like growth factor receptor (IGFR), but in different fusion orientations^[28]. Both constructs, scFv_{anti-EGFR}-CL plus scFv_{anti-IGFR}-CH1-CH2-CH3, or scFv_{anti-IGFR}-CL plus scFv_{anti-EGFR}-CH1-CH2-CH3, blocked EGF and IGF from binding their respective receptors and inhibited signal transduction pathways activated by both EGF and IGF, whereas a monospecific antibody only inhibited the pathway stimulated by a single ligand. In addition, the BsAbs inhibited tumor cell proliferation *in vitro* at a level that is on par with the combination of the two parental IgG antibodies. Furthermore, both Bs(scFv)₄-IgG demonstrated very good stability when incubated *in vitro* in mouse serum at 37 °C for 7 d. We believe that this Bs(scFv)₄-IgG format should be applicable to BsAb construction from two antibodies directed against any pair of antigens. A drawback of the format is its low expression level in mammalian cells, probably because of both its large size (~200kDa) and structural complexity.

Diabody-Fc fusions Another method by which homogenous populations of IgG-like BsAb can be constructed is by replacement of the Fab fragment with a bispecific diabody. Diabodies are a derivative of the scFv construct^[43]. An scFv is composed of a VH and a VL domain connected by a flexible linker of approximately 15 amino acids, such as (Gly₄Ser)₃, that permits self assembly into an antigen binding competent form. If the linker is shortened to 5 amino acids, such as Gly₄Ser, self assembly is impossible, and two scFv interact with each other to form a bivalent molecule of two interlinked polypeptides, the VL of one chain associating with the VH of the other. If VL and VH with specificities for different antigens comprise the diabody; namely, VH_A-VL_B and VH_B-VL_A (the two so-called “cross-over” scFv), bispecific bivalent diabodies are formed, with one binding site for each antigen. In addition to assembling as functional heterodimers, the cross-over scFv can also assemble as non-functional homodimers. Fortunately, purification of properly heterodimerized molecules can easily be achieved by one round of affinity chromatography. And as noted earlier, the

knobs-into-holes technique can be used to re-engineer the Fv interface to promote the correct heterodimeric VH-VL pairing^[37]. Diabodies have shown to be useful for antigen cross linking^[43,44], and their small size is valuable for tumor penetration^[45]. However, like many other smaller bispecific fragments, diabodies lack functional Fc domains and the corresponding effector function^[46]. Recently, they have been fused to the Fc domain of an IgG to create tetravalent IgG-like BsAb.

Single chain diabody-Fc fusion Kipriyanov *et al* have developed a “single chain” diabody (scDb) by fusing both “cross-over” scFv of a bispecific diabody with a flexible linker^[47]. This construct is fused to an Fc fragment (or just a CH3 domain) to create a tetravalent bispecific IgG-like molecule (Figure 2). In this format, one polypeptide with six domains is produced: VH_A-VL_B-VH_B-VL_A-CH2-CH3, which then assembles into IgG-like dimers through the Fc domains^[48]. The scDb-Fc is bispecific and bivalent for both antigens, and has a full Fc (although effector function activity was not tested). The stability of the scDb-Fc fusion was not reported, but the multiple exposed non-human polypeptide linkers within the molecule may not only subject the BsAb to proteolytic cleavage, but may also introduce a potential immunogenic risk, thus lowering the utility of the molecule *in vivo*. Finally, this format lacks sufficient levels of expression (~5 mg/L) to make a practical transition to a therapeutic molecule.

Di-diabody An alternative diabody-Fc fusion format is the so-called “di-diabody”. In this construct, one half of a diabody; namely, one “cross-over” scFv, is fused to the Fc domain, creating a “heavier chain” (VL_A-VH_B-CH2-CH3) and the other “cross-over” scFv associates with it as a “lighter chain” (VL_B-VH_A)^[27]. The heavier and lighter chains assemble with each other through the VH-VL interfaces, and two heavier chains homodimerize through the Fc regions to form an IgG-like tetravalent BsAb (Figure 2). Although lighter chains can homodimerize to form non-functional diabodies, they are easily removed when the full length functional di-diabody is purified by protein A chromatography. A similar but smaller di-diabody construct can also be created by just using the CH3 domain for dimerization, namely, VL_B-VH_A plus VL_A-VH_B-CH3^[49]. As a precautionary measure to avoid potential immunogenicity in human therapy, a human sequence, the first 5 amino acids of the human IgG CL(Kappa) domain, is used as the linker between the variable domains^[44], instead of a “standard” Gly₄Ser linker. A di-diabody that binds both EGFR and IGFR was constructed using the variable domains of an anti-EGFR and an anti-IGFR antibody. The di-diabody has affinity for its antigens, EGFR and IGFR, similar

to that of the parental antibodies from which the VL and VH were derived. The di-diabody blocks both EGF and IGF from binding their respective receptors and down-regulates the signal transduction pathways activated by each ligand. In addition, the di-diabody induces efficient ADCC activity against tumor cells that express EGFR and/or IGFR, indicating that the di-diabody possesses an intact and unhindered Fc domain. It also has an *in vivo* half-life that is equivalent to that of an intact human IgG. Finally, the di-diabody effectively inhibits the growth of two different human tumor xenografts in nude mice. Unlike the Bs(scFv)₄-IgG format discussed previously, the di-diabody construct is expressed in mammalian cells at much higher levels (>400 mg/L in unoptimized conditions), which could greatly facilitate the transition from “proof-of-concept” to therapeutic application. Unfortunately, the di-diabody construct has a tendency to form inactive molecules *in vivo* that lack the lighter chain, a result of dissociation between the heavier and the lighter chains (caused by the inherent instability of diabodies) followed by the rapid clearance of the lighter chain from the circulation. Hopefully, this shortcoming will be surmounted by either the introduction of disulfide bonds^[37,50,51] or improved packing^[52] to stabilize the VL-VH interfaces in the diabody.

Future perspective

Other novel IgG-like BsAb constructs

BsAb IgG using single domain antibodies as building blocks The aforementioned methods use some form of Fv, comprised of a VL and a VH, to bind antigen. An emerging and promising novel approach in which BsAb can be constructed is to use the VL and VH as independent binding units. It has been observed that some camel antibodies are composed of only heavy chains^[53]. This observation has led to the development of human “single domain” antibody fragments, in which a VL or a VH alone comprises the binding unit^[54,55]. These fragments can then be used to construct tetravalent IgG-like BsAb by fusing a single domain of one specificity to CL and a single domain of a different specificity to the CH1 of an IgG. Preferably, one single domain would be derived from a VL, and the other from a VH, to provide increased stability using a VL-VH interface, in addition to that of the CL-CH1 interface (ie, VL_A-CL plus VH_B-CH1-CH2-CH3) (Figure 2), but an IgG-like molecule with bispecific binding capacity derived from any single domain combination could be imagined (ie, VL_A-CL plus VL_B-CH1-CH2-CH3, or VH_A-CL plus VH_B-CH1-CH2-CH3).

Tandemabs An interesting application of antibody

engineering that could readily be applied to the construction of BsAb is an expansion of the multivalent Fab constructs developed by Presta *et al* at Genentech^[56]. Based on the observation that cross-linking increases the biological efficacy of some antibodies, a series of multivalent antibody constructs were developed from the interaction of an identical LC with tandem repeats of the VH-CH1 unit fused to the Fc. If one were to construct a pseudo-tandem repeat of the form VH_A-CH1-VH_B-CH1-CH2-CH3, and pair that with a common LC unit VL-CL, one could achieve tetravalent (or possibly higher order) bispecific (or tri-specific) antibodies (Figure 2). Again, the challenge here is to identify antibodies of different specificities that share identical LC.

Novel applications of BsAb As noted earlier, most of the efforts in BsAb development have been focused on the use of BsAb as means to redirect either effector cells or cytotoxic agents, including chemotherapeutic drugs, radioisotopes, and toxins, to the sites of destruction, such as tumors. There are a number of novel benefits of BsAb that can be exploited for more efficacious human therapy.

Binding avidity enhancement One very valuable benefit of BsAb is the enhanced avidity they pose for their antigen^[57]. In addition to having intrinsic high affinity on a binding unit (ie, a Fab) to antigen basis, normal IgG antibodies also exploit the avidity effect to increase their association with antigens as a result of their bivalent binding towards the targets. Except for the knob-into-holes BsAb format, which is monovalent for each antigen, all the IgG-like BsAb discussed here are bivalent for each antigen. Consequently, these IgG-like BsAb, once bound to cell-surface antigens, are expected to dissociate at a very slow rate: two dissociation events must occur simultaneously for the BsAb to be free from the cell. High binding affinity (or avidity) is usually beneficial and, in some cases, may even be required for the biological activity of a therapeutic antibody. In addition, bivalent binding to a target, particularly a cell-surface receptor, is under many circumstances a prerequisite for antibody function, such as cross-linking the receptors in order to stimulate activation, to induce apoptosis, or to promote receptor internalization.

Epitope cross-linking for acquired antagonistic activity A BsAb directed against two separate epitopes on the same antigen molecule may not only provide the benefit of enhanced binding avidity (because of bivalent binding), but may also acquire novel properties that are not associated with either of the parent antibodies. For example, we have demonstrated that a bispecific diabody that binds two distinct epitopes on VEGFR2 cross-links the epitopes and effectively blocks the binding of VEGF to the receptor, whereas

the parent scFv from which the bispecific diabody is derived do not, on their own or in combination, block VEGF binding^[57]. Cross-linking two separate epitopes within the same receptor molecule may introduce new steric hindrance for ligand binding, and/or induce conformation changes in the receptor, preventing it from binding ligand. It will be interesting to see if this principle is applicable to antibodies to other receptors for which ligand-blocking antibodies are difficult to identify.

Fine-tuning antibody specificity towards tumor cells
An emerging and intriguing concept is the use of BsAb to further fine-tune the specificity of antitumor antibodies to target cells. In this context, a BsAb is constructed from two antibodies directed against different tumor antigens, each of low to moderate binding affinity. Only simultaneous binding (or cross-linking) to the two target antigens on the same tumor cell surface by BsAb leads to strong association (ie, high avidity resulting from bivalency), which is required to trigger biological processes, such as ADCC, CMC, and down-regulation of signaling pathways. In contrast, weak association, which may not be sufficient to induce any meaningful cellular activity, would result from monovalent binding of the BsAb to cells that only express one of the target antigens. This is significant as most of the targets currently being used as tumor cell identifiers are, in fact, not truly “tumor-specific” but rather “tumor-associated”, that is, they are also expressed in certain normal tissues/cells, albeit at lower density than in tumor cells. By identifying and constructing BsAb to pairs of targets simultaneously expressed on a given type of tumor, one could expect enhanced antibody specificity towards the targeted cells while sparing normal cells of unwanted side effects.

Simultaneous blockade of two signaling pathways
Perhaps the most promising application of BsAb is the ability to simultaneously block the signaling pathways of two targets with one molecule^[26–28,58]. As demonstrated with the anti-EGFR×anti-IGFR BsAb, either in the form of di-diabody or Bs(scFv)₄-IgG^[27,28], it is possible to achieve the effects of administering two antibodies with one IgG-like BsAb. This provides a promising alternative to the development of antibody combination therapies, as in the latter each antibody has to be approved separately by regulatory agencies before being approved as a combination. Furthermore, if BsAb can be produced in similar quantities as normal IgG, then significant cost savings can be achieved.

Conclusion

Recently, developments in the design of IgG-like BsAb have provided some success in overcoming the major

obstacles to BsAb production. It is now possible to use a novel structural format that promotes or obligates the formation of homogenous, bispecific proteins, and some of these constructs can be efficiently produced in eukaryotic cells in quantities sufficient for clinical development. Furthermore, IgG-like BsAb offer the benefits of normal IgG, including long half-life and native effector function, along with the additional capability of being able to act as two drugs in one by simultaneously addressing two disease-relevant targets in a highly specific manner, thus making them in many ways superior to BsAb fragments. We believe that IgG-like BsAb will undoubtedly challenge monospecific antibodies as the champion of therapeutic proteins in coming years.

Abbreviations

ADCC, antibody-dependent cellular cytotoxicity; BsAb, bispecific antibody; CL, constant domain of light chain; CH, constant domain of heavy chain; CMC, complement-mediated cytotoxicity; Fab, antigen binding fragment; Fc, crystallized fragment; Fv, variable fragment (VL+VH); EGFR, epidermal growth factor receptor; HC, heavy chain; IGFR, insulin-like growth factor receptor; LC, light chain; scFv, single-chain variable fragment (VL and VH tethered by a 15 amino acid linker); VEGF, vascular endothelial growth factor; VEGFR2, vascular endothelial growth factor receptor 2; VH, variable heavy domain; VL, variable light domain.

Abstract

Specific chromosome aberrations are frequently detected during the development of hepatocellular carcinoma. Molecular cytogenetic approaches such as comparative genomic hybridization and loss of heterozygosity analyses have provided fruitful information on changes in HCC cases at the genomic level. Mapping of chromosome gains and losses have frequently resulted in the identification of oncogenes and tumor suppressors, respectively. In this review, we summarize some frequently detected chromosomal aberrations reported for hepatocellular carcinoma cases using comparative genomic hybridization and loss of heterozygosity studies. Focus will be on gains of 1q, 8q, and 20q, and losses of 4q, 8p, 13q, 16q, and 17p. We then examine the candidate oncogenes and tumor suppressors located within these regions, and explore their possible functions in hepatocarcinogenesis. Finally, the impact of microarray-based screening platforms will be discussed.

Introduction

Hepatocellular carcinoma (HCC) is one of the most common human malignant neoplasms, with a particularly high incidence in Chinese and African populations^[1]. In 2000, HCC ranked as the fifth most frequent cancer, but the third leading cause of cancer death worldwide^[2]. Unlike other cancers, the main causative agents for HCC, hepatitis B virus (HBV), hepatitis C virus (HCV) and aflatoxin (AFB), are well studied. Yet little is known about the molecular pathogenesis of HCC^[3]. In fact, the majority of HCC are associated with a background of chronic liver disease. Therefore, hepatocarcinogenesis is believed to be a long-term process that involves multiple genetic alterations.

Recurrent chromosome alterations

Chromosome aberrations are a hallmark of solid tumors and it has been known for decades that chromosome rearrangements exist in most if not all human tumors^[4]. Additionally, cytogenetic study followed by molecular analysis of recurring chromosome changes has greatly facilitated the identification of crucial oncogenes and tumor suppressors^[5]. For example, the tumor suppressor gene Rb was identified

based on the observation of chromosome deletion del(13)(q14) in retinoblastoma^[6] and the proto-oncogene myc was shown to be involved in the chromosome translocation t(8;14) in human Burkett's lymphoma^[7]. The conventional comparative genomic hybridization (CGH) method provides a powerful means of global analysis of segmental chromosome gains or losses^[8]. Since it was developed, CGH has been widely applied to the detection of recurrent chromosomal alterations in various cancers, including HCC^[9–13]. Frequent non-random chromosomal gains and losses detected by CGH are summarized in Table 1, including gains of 1q, 6p, 8q, 17q, and 20q, and losses of 1p, 4q, 5q, 6q, 8p, 9p, 10q, 13q, 16q, 17p, 19p, and 22q^[9–13]. In addition, the loss of heterozygosity (LOH) assay is used to define chromosomal regions with allelic deletions, and results revealed that LOH was frequently detected in 1p, 4q, 6q, 8p, 13q, 16q, and 17p^[14–16]. These studies suggest the presence of multiple oncogenes or tumor suppressor genes in regions of recurrent gain or loss, respectively.

To avoid overlap with comprehensive reviews that have been published recently^[3,17], this review will mainly focus on chromosomal gains on 1q, 8q, and 20q, and losses on 4q, 8p, 13q, 16q, and 17p in HCC. For simplicity, gene symbols will

be used for all genes described throughout the review (details for all genes are summarized in Table 2).

Chromosome gains

Gain of 1q Gain of 1q is one of the most frequently detected alterations in HCC and has been suggested as an

early genomic lesion in the process of HCC development^[18], although the target oncogene within the amplified region has not been identified. CGH studies showed that the gain of 1q was detected in 58%–86% of HCC cases^[9–13], with about 10% high-copy number amplification^[12]. Several minimal amplifying regions (MAR) were mapped including 1q12-q22^[12,19], 1q23.3-q25.3^[20] and 1q24.2-1q43^[21]. In an attempt

Table 2. Summary of candidate cancer-related genes within abnormal chromosomal regions

Gene name	Symbol	Locus	Reference
Oncogenes			
Jumping translocation breakpoint	JTB	1q21-q22	22
SHC (Src homology 2 domain containing) transforming protein 1	SHC1	1q21-q22	22
Chaperonin containing TCP1, subunit 3 (gamma)	CCT3	1q21-q22	22

Chromosome 17 open reading frame 25	C17orf25	17p13.3	58

to identify candidate oncogene(s) at 1q12-q22, Wong *et al* examined the expression level of several candidate oncogenes in this region using reverse transcription-polymerase chain reaction (RT-PCR). Significant overexpression of 4 genes known as *JTB*, *SHC1*, *CCT3*, and *COPA* were observed in tumors as compared with paired adjacent liver tissues^[22].

Gain of 8q Gain of 8q is frequently observed in HCC (48%–77%)^[9–13]. The gain of 8q is also frequently detected in many other solid tumors including those of the prostate^[23], lung^[24], esophagus^[25], nasopharynx^[26], ovary^[27] and breast^[28]. Amplification and overexpression of the *c-myc* oncogene has been reported in various solid tumors, including HCC. In our recent study, amplification of *c-myc* was correlated with HCC tumor size, tumor metastasis and recurrence. Amplification of *c-myc* was found in 11/13 (85%), 9/25 (36%) and 4/12 (33%) cases of large HCC (>9 cm), medium HCC (4–9 cm) and small HCC (<4 cm), respectively. In addition, a higher frequency of *c-myc* amplification was detected in metastatic tumors (45%) than in their primary HCC (29%), and in recurrent tumors (60%) than in their primary HCC (38%)^[18]. Because the gain of 8q involved the entire long arm in this study, it is highly likely that one or more novel oncogenes are involved in HCC development apart from *c-myc*. In a recent report, Okamoto *et al* suggested 2 candidate oncogenes as amplification targets at 8q23-q24 known as *PTK2* and *EIF3S3*. *PTK2* encodes focal adhesion kinase, while *EIF3S3* encodes the p40 subunit of eukaryotic translation initiation factor 3. Overexpression of these genes may be involved in HCC progression^[29].

Gain of 20q Gain of 20q was detected in 3/5 CGH studies with a frequency of 20%–37%^[9,10,12]. Gain of 20q was also frequently detected in breast cancer, and a steroid receptor coactivator, *AIB1*, has been identified within the commonly amplified region at 20q12^[30,31]. Interestingly, gain of 20q is significantly associated with clinical stages and tumor size of HCC. Guan *et al* reported that gain of 20q occurred in 10/40 (25%) of stage II and III HCC but in 0/10 stage I HCC^[12]. In addition, Wong *et al* reported that significantly more 20q gain was found in non-cirrhotic HCC. Strikingly, gain of 20q was observed in 9/12 (75%) non-cirrhotic, while only in 16/55 (29%) cirrhotic HCC ($P=0.003$)^[10]. In our recent study, amplification of the *AIB1* gene was correlated with HCC metastasis and recurrence. The amplification frequency of *AIB1* was significantly higher in metastatic HCC (41%) than in matched primary HCC (23%), as well as being higher in recurrent HCC (60%) than in matched primary HCC (29%) ($P < 0.05$)^[18].

Chromosome losses

Loss of 4q Loss of chromosome 4q was detected by

CGH in 32%–70% of HCC cases^[9–13]. Deletion of 4q has been well described because of its specificity for HCC. Several minimal deletion regions (MDR) on 4q have been detected by LOH including 4q12-q23, 4q13.1-q21.23, 4q13-q34, 4q21-q25, 4q24-q28, 4q28.2-q34.3, and 4q35^[32–34]. In addition, Yeh *et al* reported recently the mapping of a 17.5 cM MDR between D4S1534 and D5S1572 by screening 149 HCC: a few candidate genes were found to be downregulated^[35]. Biological evidence for tumor suppressor genes on 4q comes from a study that reversed the tumorigenic phenotype of a teratoma cell line by introducing a normal chromosome 4 into malignant teratoma cells using microcell-mediated chromosome transfer^[36]. To date, candidate tumor suppressor genes correlated with 4q loss have remained unidentified. A recent report by Deng *et al* described the role of *PRDM5* at 4q26 as a suppressor in various tumors including HCC. *PRDM5* encodes a protein belonging to the PR-domain protein family. Epigenetic silencing was evident for this gene and its overexpression resulted in proapoptotic and growth suppressive functions^[37].

Loss of 8p Loss of 8p is well documented in HCC with a frequency of 29%–77%^[9–13]. By analyzing 50 HCC cases, we observed a correlation of 8p loss with advanced stage of disease and tumor size; most strikingly, 8p loss was present in 8/13 (62%) of large, 7/25 (28%) of medium, but only 1/12 (8%) of small HCC cases ($P=0.014$)^[12]. Furthermore, 8p deletion was associated with HCC metastasis, suggesting the presence of one or more candidate gene(s) are involved in HCC progression^[19]. Using the high-resolution LOH strategy, Jou *et al* reported that 50% of HCC showed LOH in chromosome 8p and the percentages of 3 MDR at 8p23.3-p23.1 (D8S504–D8S277), 8p22-p21.3 (D8S1106–D8S258) and 8p21.3-p12 (D8S258–D8S283) were 71%, 69%, and 63%, respectively^[34]. Several candidate tumor suppressors have been isolated within these regions, including *PINX1* at 8p23^[38], *FGL1* at 8p22^[39] and *DLC1*^[40] at 8p22-p21.3 regions. In the 8p23 region, Liao *et al* observed the under-expression of *PINX1* (*LPTS*) in HCC cells and tissues, while ectopic expression of this gene in liver cancer cells SMMC-7721 resulted in growth suppression^[38]. At 8p22, Yan *et al* reported reduced or undetectable expression of *FGL1* in HCC specimens, and found a significant correlation with tumor differentiation^[39]. Interestingly, Wong *et al* reported the significant under-expression of *DLC1* mRNA and promoter hypermethylation was found in 24% of primary HCC cases, suggesting a role of epigenetic silencing in *DLC1* downregulation^[41]. *DLC-1* belongs to the rho family GTPase-activating proteins (RhoGAP) specific to RhoA and cdc42, which are implicated in cell migration control. Re-expression of *DLC1*

in HCC cells resulted in caspase-3-dependent apoptosis, inhibition of cell growth and invasiveness *in vitro*, and reduction of tumor formation in nude mice^[42]. Furthermore, candidate tumor suppressors known as *PDGFRL*^[43] and *TUSC3*^[44] were identified in the 8p22-p21.3 region.

Loss of 13q Loss of 13q was detected in 16%–37% of HCC cases^[9–13]. LOH analyses also showed a high percentage of allelic deletion on 13q (40%–55%)^[14–16]. Jou *et al* identified 5 MDR with high frequencies of LOH including 13q12.11-q12.3 (71%), 13q13.1-q22.1 (79%), 13q31.3-q32.2 (67%), 13q32.2-q33.3 (73%) and 13q33.3-q34 (75%)^[34]. MDR in 13q13.1-q22.1 (D13S171–D13S156) showed the highest frequency of LOH, and well-documented tumor suppressors including *BRCA2* and *RB* are located in this region. In 13q33.3-q34 MDR, one candidate tumor suppressor known as *P33ING1* has been isolated^[45]. Overexpression of *p33ING1* inhibited cell cycle progression and the repression function of *p33ING1* was enhanced by the Ras/Raf pathway^[46]. Recently, another candidate tumor suppressor known as deleted in liver cancer 2 (*DLC2*) was identified on 13q12.3. It shows homology to tumor suppressor gene *DLC1* located at 8p22-p21.3. *DLC2* encodes a protein with RhoGAP, SAM and START domains and is significantly underexpressed in only 8 of 45 (18%) HCC, as compared with its ubiquitous expression in normal tissues^[47].

Loss of 16q One of the most frequent losses in HCC cases is located in the long arm of chromosome 16. Loss of 16q was detected in 30%–70% of HCC cases by CGH studies^[9–13]. LOH also revealed allelic deletions in 55%–59% of HCC^[14–16]. Two MDR at 16q in HCC have been reported to include 16q12.1-q23.1 (71%) and 16q23.1-q24.1 (71%)^[33]. Several candidate tumor suppressors have been reported in recent publications. The loss of 16q has also been reported as a frequent genomic alteration in ovarian^[27] and prostate cancer^[48]. The loss of 16q24.1-q24.2 in prostate cancer has been associated with aggressive behavior of the disease, recurrent growth, poor differentiation of the tumor, and a poor prognosis for the patient^[48]. The best-studied tumor suppressor gene is E-cadherin (*CDH1*) at 16q22.1. Interestingly, expression of the E-cadherin gene is reduced by a hypermethylation mechanism although no somatic mutations of the E-cadherin gene in HCC have yet been described^[49,50]. Bando *et al* identified a distinct commonly deleted region at 16q24.1-24.2 (D16S534 and D16S3091) near novel sequence *HSRG1*^[51]. Another candidate tumor suppressor known as WWOX was identified at 16q23.3-q24.1: absence or reduced expression of WWOX was observed in 60% of HCC cell lines compared with normal liver^[52].

Loss of 17p Loss of 17p is one of the most frequent

chromosomal alterations in HCC as determined by both CGH^[2,11–13] and LOH^[14–16]. Deletion of 17p is common in various cancers including breast^[53] and colon cancer^[54]. The frequent deletion of 17p may affect the tumor suppressor gene *TP53* on 17p13.1. *TP53* is frequently inactivated in various types of malignant tumors, including HCC^[55]. However, Yumoto *et al* showed that loss of 17p occurred in 18/31 HCC cases (58%) by LOH, whereas *TP53* mutation was only observed in 8/31 HCC cases (26%)^[56]. Our recent study revealed that loss of one allele at 17p13.3 distal to the *TP53* gene was observed in 48/94 HCC (51%), whereas LOH at 17p13.1, near the *TP53* gene, was detected in 30/94 HCC (32%) and p53 mutation was only detected in 22/94 HCC (23%)^[57]. These results suggest that another tumor suppressor gene at 17p13.3 may be involved in the pathogenesis of HCC. One candidate suppressor, *C17orf25*, has been isolated from this region^[58]. Downregulated expression of *C17orf25* was found in HCC samples matched to adjacent non-tumor liver tissues. Furthermore, transfection of *C17orf25* into the hepatocellular carcinoma cell SMMC-7721 inhibited cell growth^[58].

Conclusion

Molecular cytogenetic approaches such as CGH and LOH provide important clues to the identification of novel genes involved in the multistage development of HCC. In this review, we discussed some of the most common chromosome aberrations, including gains of 1q, 8q, and 20q, and loss of 4q, 8p, 13q, 16q, and 17p, followed by candidate oncogenes and tumor suppressors that may be involved within these regions. Due to the heterogeneity of HCC, it has been suggested that gains or losses of specific chromosomal loci rarely affect more than half of them, and specific HCC-related genes have not been identified in most of the above-mentioned chromosomal regions^[3]. Results obtained with traditional approaches such as cytogenetic CGH and LOH studies are relatively low in resolution and are labor intensive. Advances in microarray-based approaches are beginning to reverse this situation by providing an integrated view of genetic alterations during tumorigenesis and progression^[59].

Different microarray-based CGH (aCGH) platforms are emerging that allow high-resolution genomic profiling^[60–62]. For instance, Hashimoto *et al* reported the use of cytogenetic CGH and aCGH in the identification of genes involved in HCV-related HCC^[63]. In a recent article, Ishkanian *et al* reported the construction of submegabase resolution tiling genomic arrays (SMRT arrays) containing 32 433 overlapping BAC clones. This allows the detection of cryptic chro-

mosomal changes down to microgain and microloss resolution^[64]. In addition, some groups have used oligonucleotide arrays for high-resolution CGH and LOH studies. Single nucleotide polymorphism (SNP) arrays have been employed for high-resolution LOH studies in small cell lung cancer samples^[65] and have permitted the simultaneous detection of copy number changes and LOH in a single experiment^[66].

In another approach, chromosomal bias of gene expression signature was studied in HCC cases^[67,68]. Using a recently developed technique known as expression balance map analysis, Midorikawa *et al* identified regions with frequent chromosomal aberrations in HCC based solely on expression data. Common alterations, including gain of 1q21-q23 and loss of 4q13, were found in 74% and 48% of HCC cases, respectively^[67]. These matched well with previous CGH analyses. In conclusion, a combination of these powerful technologies provides a more comprehensive view of the development of HCC, and identification of novel gene candidates may provide better diagnosis and prognostication of HCC.

Abstract

Aim: To investigate the gene expression profile changes in the cerebral cortex of mice injected icv with amyloid beta-protein (A β) fragment 25-35 using cDNA microarray. **Methods:** Balb/c mice were randomly divided into a control group and A β -treated group. The Morris water maze test was performed to detect the effect of A β -injection on the learning and memory of mice. Atlas Mouse 1.2 Expression Arrays containing 1176 genes were used to investigate the gene expression pattern of each group. **Results:** The gene expression profiles showed that 19 genes including *TBX1*, *NF- κ B*, *AP-1/c-Jun*, *cadherin*, *integrin*, *erb-B2*, and *FGFR1* were up-regulated after 2 weeks of icv administration of A β ; while 12 genes were down-regulated, including *NGF*, *glucose phosphate isomerase 1*, *AT motif binding factor 1*, *Na⁺/K⁺-ATPase*, and *Akt*. **Conclusions:** The results provide important leads for pursuing a more complete understanding of the molecular events of A β -injection into mice with Alzheimer disease.

Introduction

Alzheimer disease (AD) is the most common cause of dementia in the elderly, affecting 7%–10% of individuals over 65 years of age and approximately 40% of persons over 80 years old^[1]. The disease is characterized behaviorally by global cognitive decline, and defined histologically by two distinguishing pathologies: amyloid plaques, which are extracellular deposits consisting mainly of aggregated amyloid beta-protein (A β), and neurofibrillary tangles (NFT), which are intracellular deposits consisting predominantly of hyperphosphorylated tau protein^[2]. Epidemiological and molecular studies suggest that AD has multiple etiologies, including genetic mutations, susceptibility genes and environmental factors that promote formation and accumulation of insoluble A β and hyperphosphorylated tau. An animal model that mimics the progression of AD was developed using icv injection of A β into mice^[3–5]. This was accompanied by impairment in learning and memory in addition to biochemical changes and neuronal degeneration.

Recently, a high-throughput technique was developed using cDNA microarrays, in which labeled RNA hybridizes

to DNA molecules attached at specific locations on the surface of microarray membrane^[6]. One of the most attractive applications of microarrays is in the study of differential gene expression in disease and animal models. Microarrays are extensively employed to study global changes in gene expression in post-mortem tissues, cultured cells, animal models, and in response to drug treatment. The expression pattern of a gene provides indirect information about function, drug target and cause of a disease. In this study we used cDNA microarrays (Clontech Laboratories, Palo Alto, CA, USA) to investigate gene expression patterns in an icv A β mouse model for AD in the cerebral cortex. This approach provided an additional insight into gene processes, which occur not only in AD animal model but also in other neurodegenerative disorders. The knowledge of specific cascades of events leading and causing neurodegeneration will be the key factor in developing and using neuroprotective drugs.

Materials and methods

Reagents A β ₂₅₋₃₅ (Sigma Chemical, St Louis, MO, USA)

was dissolved in sterile normal saline at a concentration of 1 g/L and aggregated by incubation at 37 °C for 72 h. Sodium Dodecyl Sulfate (SDS) was also the product of Sigma. Trizol Reagent was purchased from Gibco-BRL (New York, NY, USA). [α - 32 P]-dATP was from Amersham Pharmacia Biotech (Piscataway, NJ, USA). MMLV reverse transcriptase was from Promega (Madison, WI, USA). Polyclonal integrin α M, c-Jun, and phosphor-c-Jun antibody were purchased from Santa Cruz Biotechnology (Santa Cruz, CA, USA). Atlas Mouse 1.2 Expression Arrays and Atlas cDNA Expression Array Kit were provided by Clontech Laboratories. On each array membrane there are 1176 gene cDNA fragments with lengths of 200–600 bp. The name, coordinate, Gene-Bank Number, and other related information for these genes are available on Clontech's homepage (www.clontech.com).

Animals Male Balb/c mice weighing 22–24 g (Institute of Experimental Animal of Chinese Academy of Medical Sciences, Certificate No SCXK11-00-0006) were maintained in a climate-controlled room at 22±1 °C on a 12 h light/dark cycle with free access to food and water. They were acclimatized to laboratory conditions for 5 d before experiments.

Aggregated A β ₂₅₋₃₅ was icv injected into mice according to the method described by Maurice *et al*^[3]. In brief, a 28-gauge stainless-steel needle was inserted unilaterally 1 mm to the right of the midline point, equidistant from each eye, at an equal distance between the eyes and the ears and perpendicular to the plane of the skull. A β ₂₅₋₃₅ or sterile normal saline at a volume of 5 μ L was delivered gradually within 15 s.

Water maze task The Morris water maze test began on d 11 after A β -injection as described^[7]. The experimental apparatus consisted of a circular water tank (diameter=80 cm) filled to a depth of 15 cm with water maintained at 23±1 °C. The water was made opaque by adding black ink. A platform (diameter=8 cm) was submerged 0.5 cm below the water surface and placed at the midpoint of one quadrant. Two training trials each day were conducted for 4 consecutive days. On each trial, the mice were placed in the pool at one starting position. They were allowed to swim freely or until they found the platform. The time required to escape onto the hidden platform was recorded. Mice that found the platform were allowed to remain on the platform for 10 s and were then returned to the home cage. If a mouse did not reach the platform within 120 s, it was gently guided to platform by the experimenter, where it remained for 10 s. Statistic comparison of the water maze test between the A β -treated and control group was analyzed by two-way analysis of variance (ANOVA).

RNA preparation Mice were killed after the water maze test. Total RNA was extracted from the cerebral cortex with

Trizol according to the manufacturer's instructions. RNA extracts from 10 mice of each group were pooled to provide sufficient material for both cDNA microarray and reverse transcription-PCR analysis. Total RNA was treated with RNase-free DNase at 37 °C for 20 min to avoid contamination of genomic DNA. The RNA quality and concentration were assessed using agarose gel electrophoresis and spectrophotometric reading.

Probe preparation and hybridization Total RNA (5 μ g) was reverse transcribed using reagents provided in the Atlas cDNA Expression Array Kit and radiolabeled with [α - 32 P]-dATP. The array membranes were prehybridized for 1 h at 68 °C in ExpressHyb solution containing 100 mg/L of heat-denatured salmon testis DNA. The denatured 32 P-labeled cDNA was added to Express Hyb hybridization solution at a final concentration of 4.0 MBq/L and array membranes were hybridized with the labeled cDNA overnight at 68 °C. The next day, the membranes were washed three times for 30 min with pre-warmed (68 °C) washing solution 1 [2×SSC (1×SSC is 15 mmol/L sodium chloride, 15 mmol/L sodium citrate), 1% SDS] and once for 30 min with pre-warmed (68 °C) washing solution 2 (0.1×SSC, 0.5% SDS) with continuous agitation at 68 °C. After a final wash with 2×SSC at room temperature for 10 min, the membrane was immediately wrapped in plastic film and exposed to X-ray film at -70 °C.

Detection and analysis Gene expression levels were assessed according to autoradiographic intensity of hybridization signals by software. Only those autoradiograms with similar background and identical signal intensity of housekeeping genes were comparable. Genes that showed an increase or decrease of 2.0-fold or greater were considered as differentially expressed genes. Each group sample was carried out three times, those genes that were all differentially expressed in the three hybridizations were reported as mean±SEM.

Semi-quantitative RT-PCR Expressions of 6 genes were randomly selected to be further confirmed by RT-PCR. Primers were designed using DNA Star software (Perkin Elmer, Norwalk, Conn, USA) and synthesized by Sbs Bio Inc (Beijing, China). Reverse transcription reaction was catalysed by MMLV. PCR was performed for 30 s at 94 °C, 30 s at 55 °C, and 1 min at 70 °C for a cycle, 32 cycles were completed (25 cycles for *GAPDH* gene), and finally 10 min at 72 °C. The RT-PCR products were subjected to electrophoresis in 1% agarose gels and quantitative analysis was carried out using the YLN 2000 Gel Analysis System (Yalien, Beijing, China). The gene expression levels were assessed according to the gray ratio value of the target genes and housekeeping gene, *GAPDH*. The PCR primers used were as follows: *GAPDH*,

forward primer, 5'-CAG CAA CTC CCA CTC TTGCC CCT CCT GTT ATT AT-3'; *AP-1*, forward primer, 5'-AGGCAGAGAGGAAGCGCAT-3', reverse primer, 5'-TGGCACCCACTGTTAACGTG-3'; *NF- κ B*: forward primer, 5'-GCAGCCTATCACCAACTCT-3', reverse primer, 5'-TACTCCTTCTTCTCCACCA-3'; *integrin α M*, forward primer, 5'-TTAATGACTCTGCGTTTGCCC-3', reverse primer, 5'-TCATGTCTTGTACTGCCGCT-3'; *ATPase*, forward primer, 5'-CCATCTTCTGCACCATCGTTC-3', reverse primer, 5'-AGACGCCCTGCCTCTTTCAG-3'; *nerve growth factor α (NGF α)*, forward primer, 5'-ACTGGTGTCTCACAGCTGCC-3', reverse primer, 5'-CGCAGCAGCATCAGGTCAT-3'; *Akt*, forward primer, 5'-CCTGTCTCGAGAGCGTGTGTT-3', reverse primer, 5'-CATAGTGGCACCGTCCTTGA-3'.

Western blot analysis After decapitation, the cerebral cortex from 5 mice were immediately homogenized in 5 volumes of homogenization buffer [Tris-HCl 50 mmol/L (pH 7.5), NaCl 150 mmol/L, 1 % Triton-X 100, 1 % sodium deoxycholate, 0.1 % SDS]. After sonication and centrifugation at 4 °C (10 min, 10 000 \times g), the supernatant was used for determination of protein concentrations, and the equal amounts of total solubilized proteins were eluted by heating with SDS-PAGE sample buffer and separated by SDS-polyacrylamide gel electrophoresis. Proteins were then transferred to the nitrocellulose membrane. The membrane was blocked at room temperature with 5 % non-fat dry milk in Tris-buffered saline with 0.1 % (v/v) Tween-20 (TBST) and incubated with polyclonal integrin α M, c-Jun and phosphor-c-Jun antibody (1:1000) overnight at 4 °C. After washing, the membrane was incubated with horseradish-labeled secondary antibody for 1 h. After five additional washes in TBST, the membrane was incubated with an enhanced chemiluminescence detecting reagent according to the manufacturer's protocols and exposed to X-ray film.

Results

Effects of icv injection of $A\beta_{25-35}$ on performance of the Morris water maze task Effect of $A\beta$ -injection on learning and memory revealed a significant difference between the two groups. $A\beta$ -injected mice exhibited an obvious learning deficit compared to the saline-injected mice. ANOVA analysis showed a significant decrease in the latency time for the control group during the 8 training trials, but not for the experimental group (Figure 1).

Gene expression analysis of mice cerebral cortex after icv injection of $A\beta_{25-35}$ The human cerebral cortex serves to control functions such as speech, memory, logical and emotional response, as well as consciousness, interpretation of

Figure 1. $A\beta_{25-35}$ induced impairment on learning and memory in mice in the Morris water maze task. Ten days after icv administration of the sterile normal saline (Ctr) or the aggregated $A\beta_{25-35}$, mice were subjected to the Morris water maze test. The training trials were carried out on d 11–14. $n=10$. Mean \pm SEM. ^b $P<0.05$, ^c $P<0.01$ vs Ctr group.

sensation, coordination of voluntary movement, and these are all greatly involved and damaged in AD. In our study, we used cDNA microarray to investigate the molecular events of neuronal toxicity induced by $A\beta_{25-35}$ in the cerebral cortex of mice. We compared the gene expression levels in the cerebral cortex of $A\beta$ -injected mice and saline-injected mice. Of 1176 known mouse genes represented on the array, we detected 31 genes differentially expressed in the mice cerebral cortex. Among them 19 genes showed up-regulation in expression after injection of $A\beta$, including *TBX1*, *NF- κ B*, *AP-1/c-Jun*, *cadherin*, *integrin*, *erb-B2*, and *FGFR1*; while expression of 12 genes were down-regulated, including *NGF*, *glucose phosphate isomerase 1*, *AT motif binding factor 1*, *Na⁺/K⁺-ATPase*, and *Akt*. All differentially expressed genes were functionally characterized as a diverse spectrum of the biologic process, including transcription factor, cell cycle protein, cytokines, signal transduction, energy metabolism, neurotrophic factor, and so on (Table 1).

Semi-quantitative RT-PCR To confirm the results of cDNA array, RT-PCR analysis was performed to examine the expression level of 6 genes that were up-regulated or down-regulated in the cerebral cortex of mice. The RT-PCR results indicated that 6 genes showed identical results to that of the microarray (Figure 2).

Western blot analysis The expression of integrin α M and activated AP-1/c-Jun of the cerebral cortex were investigated by Western blot analysis. Although total c-Jun was unchanged in intensity between the two groups, the increased expression of integrin α M and phosphorylated c-Jun were found in the cerebral cortex of $A\beta$ -treated mice (Figure 3).

Discussion

Ample experimentation indicates that icv injection of A β to rodents can induce learning and memory impairments as well as neurodegeneration in brain areas related to cognitive function^[3-5]. This model of A β exposure is a useful model *in vivo* for AD. In the present study, we used the Morris water maze test to detect the effect of aggregated A β_{25-35} injection on the learning and memory of mice. Our results corresponded to previous reports that A β_{25-35} could significantly impair the spacial learning ability and memory of mice.

Microarray provides a promising approach to explore novel molecular and cellular mechanisms that may contribute to some diseases. Gene expression changes in the mice cerebral cortex between icv injection of A β_{25-35} and sterile normal saline were analyzed by using cDNA microarray. In total, 31 genes were differentially expressed, of which 19 genes were increased and 12 were decreased. This implies that only a small fraction of the surveyed genes were affected by A β_{25-35} , while most stayed at a stable expression level. The up-regulation or down-regulation of these genes may be responsible for A β -induced memory impairment in mice.

In the present study, we found that several genes encoding transcription and chromatin-modifying factors were differentially expressed after icv administration of A β_{25-35} . For example, *TBX1*, *transcription factor 21*, *transcription factor AP-1/c-Jun*, and *NF- κ B* showed an increased expression level, while *engrailed homeobox protein 1* and *Oct-1* were decreased in expression. *AP-1* complex is composed of a heterodimer *Fos* and *Jun*, the latter is involved in p38/c-Jun N-terminal MAPK pathway (JNK) and considered as a major regulator of both neuronal death and regeneration^[8,9]. A number of reports indicate that *NF- κ B* regulates the expression of various genes that play critical roles in apoptosis, viral replication, tumorigenesis, various autoimmune

diseases, and inflammation^[10,11]. Studies of postmortem brain tissue from patients with AD have revealed increased NF- κ B activity in cells involved in the neurodegenerative process. This is consistent with increased p65 immunoreactivity in neurons and astrocytes in the immediate vicinity of amyloid plaques in brain sections from AD patients^[12]. It is reported that A β can activate *NF- κ B* in the cultured neurons^[13], suggesting a molecular mechanism by which A β may act during AD pathogenesis. We also noticed that the most dramatic change in gene expression was for the transcript encoding for *TBX1*, a member of the T-box binding gene family^[14]. There are at least 21 members of this gene family. The T-box region, which mediates DNA binding, is highly conserved from *Drosophila* to humans. Human and mice *TBX1* proteins share 98% amino acid identity overall and are identical except for 2 residues within the T-box domain. Expression of human *TBX1* in adult and fetal tissues, as determined by Northern blot analysis, were similar to that found in the mice^[15]. These transcription factors are involved in the regulation of developmental processes, where they seem to be required for tissue-specific development. In particular, the *TBX1* gene is a major genetic determinant in Del22q11.2 syndrome in human beings, which is characterized by a 3-Mb deletion on chromosome 22q11.2, cardiac abnormalities, T-cell deficits, cleft palate facial anomalies, and hypocalcemia^[16]. However, there is little known about specific target genes for *TBX1* proteins and the relationship between this gene and AD. The function of the most up-regulated gene, *TBX1*, in the A β -injection mice should be further studied.

Integrin α M and *integrin α L*, two cell adhesion receptors with an A β binding site and involved in the uptake of A β in neurons and glial cells^[17], were observed to be up-regulated in the A β -treated mice. Adhesion proteins usually transduce the extracellular signal into cells and change the cell cytoskeleton. It is very possible that A β binds to integrin proteins and activates the focal adhesion (FA) proteins, paxillin and focal adhesion kinase (FAK). In this regard, fibrillar A β could promote dystrophy by aberrantly activating FA signal transduction cascades that would be involved in A β -induced neuronal dystrophy or cell death^[18,19]. Moreover, the binding of A β to integrin proteins would induce sustained activation of MAPK pathways followed by neurite degeneration and hyperphosphorylation of tau proteins^[20]. N-cadherin, another cell-adhesion protein, also showed an increase in expression after A β -injection. It is a cell surface glycoprotein that mediates calcium-dependent adhesion between neural cells and affects a wide range of cellular processes, including cell adhesion, cell morphogenesis and cell migration.

Two protein tyrosine kinases, *erb-B2*, and *FGF receptor 1*, were increased in expression after A β -injection. Erb-B2 is the receptor of neuregulin, and overexpression has been demonstrated to activate mitogenic signal transduction and enhance proliferative, prosurvival, and metastatic signals in cell lines. The activity of the MAPK pathway is up-regulated in cells overexpressing *erb-B2*^[21,22]. However, the understanding of the function of *erb-B2* in neural cells is very limited. This basic growth factor has pleiotropic effects and plays a regulatory role in angiogenesis, smooth muscle cell growth and wound healing through fibroblast growth factor receptors (FGFR)^[23]. FGFR1 activation is followed by intracellular signaling cascades involving Ca²⁺ channels, phospholipase C, src family kinases, mitogen-activated kinases and the Grb2/Sos signaling complex^[24,25]. An increase of FGFR2 in brain neurons and retinal pigment epithelial cells can lead to the activation of L-type channels of neuroendocrine and induce gene expression through the phosphorylation of CREB (cyclic AMP-responsive element binding protein)^[26]. Whether the up-regulation of neuroendocrine protein 1 resulted from the increase of FGFR 1 in our study still needs to be studied further.

It is well known that A β can impair mitochondria energy metabolism and selectively inhibit Na⁺/K⁺-ATPase activity both *in vivo* and *in vitro*. From our present results, we found that two Na⁺/K⁺-ATPase related genes, *AT motif-binding factor 1 (ATBF1)*, and *Na⁺/K⁺-ATPase 2 β 2*, were down-regulated. This is consistent with previous studies. ATBF1 is a large transcription factor protein containing four homeodomains and 23 zinc finger motifs. It also includes several motifs that were found in ATPases^[27]. The ATPase activity has been reported to be associated with ATBF1 activity in a unique DNA/RNA-dependent manner that requires both homeodomain and zinc finger motifs^[28].

Interleukin 3 receptor has been reported to have a neurotrophic effect on central cholinergic neurons^[29]. Down-regulation of this gene may be responsible for cholinergic dysfunction induced by A β . Another two growth factors, *NGF* and *glucose phosphate isomerase 1*, were also down-regulated. A large number of reports have shown that these neurotrophic factors have beneficial effects on neural cell survival both *in vivo* and *in vitro*.

The expression of an apoptosis associated protein, *Akt*, decreased in the A β -injected mice. This protein can protect cells from a variety of death-promoting insults in several different cell types, including A β toxicity^[30]. Activated Akt would lead to phosphorylation of the proapoptotic protein Bad, stimulate Bcl-2 and Bax expression, decrease the interaction of Bad with Bcl-xL, increase the Bcl-xL/Bad ratio, even-

tually promoting cell survival^[31].

In summary, we observed extensive activation of transcription factors and the signal transduction system, which may result in neuron apoptosis, energy metabolism and calcium ion homeostasis dysfunction, cell adhesion and neuronal dystrophy. A number of the candidate genes we describe have not been linked to AD in previous publications, and define novel injury pathways warranting further studies. The genes found from the cDNA microarray provide some clues for pursuing a more complete understanding of the molecular mechanism of A β -induced neural degeneration and memory impairment.

Abstract

Aim: To study the effects of huperzine A (HupA) on neurotogenic activity and the expression of nerve growth factor (NGF). **Methods:** After being treated with 10 $\mu\text{mol/L}$ HupA, neurite outgrowth of PC12 cells was observed and counted under phase-contrast microscopy. Mitogenic activity was assayed by [³H]thymidine incorporation. Cell cytotoxicity was evaluated by lactate dehydrogenase (LDH) release. AChE activity, mRNA and protein expression were measured by the Ellman's method, RT-PCR, and Western blot, respectively. NGF mRNA and protein levels were determined by RT-PCR and ELISA assays. **Results:** Treatment of PC12 cells with 10 $\mu\text{mol/L}$ HupA for 48 h markedly increased the number of neurite-bearing cells, but caused no significant alteration in cell viability or other signs of cytotoxicity. In addition to inhibiting AChE activity, 10 $\mu\text{mol/L}$ HupA also increased the mRNA and protein levels of this enzyme. In addition, following 2 h exposure of the astrocytes to 10 $\mu\text{mol/L}$ HupA, there was a significant up-regulation of mRNA for NGF and P75 low-affinity NGF receptor. The protein level of NGF was also increased after 24 h treatment with HupA. **Conclusion:** Our findings demonstrate for the first time that HupA has a direct or indirect neurotrophic activity, which might be beneficial in treatment of neurodegenerative disorders such as Alzheimer disease.

Introduction

Nerve growth factor (NGF) is a member of the neurotrophin family that promotes the survival and outgrowth of central cholinergic neurons^[1]. The decrease in trophic support for the neurons in the aging brain is associated with neuronal death and appearance of neurodegenerative disorders such as Alzheimer disease (AD)^[2]. A case study showed that topical application of NGF into the brain of one AD patient relieved symptoms of dementia^[3]. However, the clinical utility of NGF is limited by an inability to cross the blood-brain barrier, necessitating invasive neurosurgical procedures for administration. In contrast, pharmacological stimulation of endogenous NGF synthesis or mimicking of NGF activity by compounds that penetrate membrane barriers may provide an alternative means to provide equivalent trophic actions in the central nervous system.

Accumulated data suggest that cholinergic mechanisms are involved in the regulation of NGF synthesis and release. It has been suggested that cholinergic activity in basal forebrain neurons may stimulate NGF synthesis in appropriate target areas during early postnatal development^[4]. Additionally, substances that augment cholinergic function, such as nicotine, muscarinic receptor agonists, and acetylcholine-releasing agents, can increase NGF expression and synthesis^[5,6]. Although there have been no reports that acetylcholinesterase (AChE) inhibitors elevate NGF production, some AChE inhibitors are known to exert NGF-like activity by potentiating the neurotogenic effect of NGF^[7] or increasing choline acetyltransferase (ChAT) activity^[8]. These actions appear to be independent of AChE inhibition. Such findings led us to suspect that the neurotrophic effects of huperzine A (HupA), a novel acetylcholinesterase inhibitor isolated from the Chinese herb *Huperzia serrata*, involve

NGF-like activity, directly or indirectly.

HupA has been proved to be one of the most promising new agents for AD therapy^[9]. Our previous studies showed that, in addition to its potent inhibition of AChE, HupA exhibited neuroprotective effects both *in vivo* and *in vitro*^[10,11]. For example, just as NGF can ameliorate neuronal degeneration in rat cerebral cortex and hippocampus after ischemic insult^[12], HupA will attenuate ischemic damage from transient global ischemia in gerbils and hypoxic-ischemia (HI) in neonatal rats^[13,14]. A multicenter, randomized, double-blind, placebo-controlled clinical trial in China proved that HupA markedly improved the cognitive function of vascular dementia (VD)^[15-17]. In view of these findings it is natural to ask if HupA might influence intrinsic neurotrophic factors. The aim of this study was to examine the effects of HupA on neurogenesis in rat pheochromocytoma cells and on the expression and secretion of NGF in primary cultures of rat cortical astrocytes.

Materials and methods

Materials HupA, provided by the Department of Phytochemistry at Shanghai Institute of Materia Medica is a colorless powder with mp 230 °C, and purity >99%. It was dissolved and diluted in phosphate-buffered saline (PBS). RPMI-1640 medium, DMEM/F12 medium, fetal bovine serum, horse serum, and N-2 supplement were purchased from Gibco (CA, USA). Cell cytotoxicity Kit, NGF E_{max}[®] Immunoassay System, Reverse Transcription System were purchased from Promega (Madison, WI, USA). Mouse monoclonal anti-AChE antibody was purchased from BD Biosciences (CA, USA). TRIzol reagent was purchased from Invitrogen (CA, USA). ECL kit was purchased from Pierce (Rockford, USA).

PC12 cell culture and neurite outgrowth assay Undifferentiated PC12 rat pheochromocytoma cells were obtained from ATCC. The cells were maintained in RPMI-1640 media containing 10% FCS, 5% HS, 100 kU/L penicillin, and 100 kU/L streptomycin in a humidified atmosphere of 95% air and 5% CO₂ at 37 °C. For each experiment, cells (3.5×10⁴ cells/well) were seeded into a 12-well collagen-coated plate and cultured overnight. Subsequently the cells were washed once with PBS and transferred to fresh serum-free DMEM containing an N-2 supplement. After a 2-h incubation with serum-free DMEM, NGF or HupA was added to the cultures, which were incubated for a further 48 h. Neurite formation was examined under a phase-contrast microscope, and processed longer than one cell diameter were scored as neurites. The percentage of neurite-bearing cells in relation to the total number of cells was examined in four fields from

each of the eight culture wells per treatment condition.

Mitogenic activity and cytotoxicity assay To analyze the effects of HupA on mitogenic activity, PC12 cells were seeded into 96-well plate at a density of 1×10⁴ cell/well. After incubation of the cells with 10 μmol/L HupA for 48 h at 37 °C, [³H]thymidine (37 000 Bq) was added to the cultures and incubation was continued for another 8 h. The cells were harvested onto filters using a cell harvester and the retained radioactivity was determined in a scintillation counter. HupA cytotoxicity was evaluated by an assay kit, following the manufacture's protocol to detect lactate dehydrogenase (LDH) release.

AChE activity assay AChE activity was measured by a standard spectrophotometric method^[18].

Western blot analysis Changes in AChE levels were assessed by Western blot. For this purpose, cultured cells harvested 48 h after treatment with HupA were lysed in 1×SDS PAGE gel loading buffer [Tris-HCl 50 mmol/L pH 6.8, DTT 100 mmol/L, 2% (w/v) SDS, 10% (w/v) glycerol, 0.1% Bromophenol Blue] and boiled in a water bath for 10 min. Equal amounts of protein (40 μg) were loaded in each gel lane and, after electrophoresis, proteins were transferred to a nitrocellulose membrane. The membranes were blocked with TBST containing 5% non-fat milk and then were incubated at 4 °C overnight with primary antibody (a mouse monoclonal antibody raised against human AChE and crossreactive with rat AChE). Finally the blots were incubated with HRP-conjugated anti-mouse IgG at 37 °C for 2 h and target protein bands were detected by the ECL method according to the manufacture's instruction.

Astrocytes cultures and experimental treatment For studies of NGF expression, primary cultures of astrocytes were prepared from 1-day-old neonatal Sprague-Dawley rats. Cerebral cortices were stripped of meninges and dissected in Ca²⁺-, Mg²⁺-free D-Hanks' solution. Next the samples were trypsinized and passed through a monofilament mesh (pore size 80 μm). Cells were collected by centrifugation and resuspended in DMEM/F12 containing 10% FCS, 100 kU/L penicillin and 100 kU/L streptomycin for culture in a humidified atmosphere (95% air and 5% CO₂) at 37 °C. Astrocytes were grown to confluence and oligodendrocyte and microglial cells were removed by shaking and washing with cold D-Hanks' solution. The astrocytes were then trypsinized and plated onto 24-well plates at a density of 1×10⁴ cell/cm², washed with D-Hanks' solution, and exposed for 24 h to serum-free medium. After this incubation, culture medium was collected and centrifuged to remove cell debris.

NGF content assay Released NGF was measured in the supernatant by a two-site enzyme-linked immunosorbent

assay (ELISA) using the NGF E_{max}[®] Immunoassay system.

RT-PCR analysis RT-PCR was performed to determine the expression of mRNA for AChE in PC12 cells and for NGF and P75^{NTR} in astrocytes. Total cellular RNA was isolated using TRIzol reagent following the manufacturer's protocols and quantified by absorbance at 260 nm. RNA purity was determined using the A₂₆₀/A₂₈₀ ratio (average ratio > 1.85). Total RNA of each sample was reverse-transcribed into cDNA using Reverse Transcription System. The cDNAs were amplified with the following specific primers. AChE: 5'-TCTTTGCTCAGCGACTTA-3' (upstream), 5'-GTCACAGG-TCTGAGCATCT-3' (downstream); NGF: 5'-CTTCAGCATT-CCCTTGACAC-3' (upstream), 5'-AGCCTTCCTGCTGAGCA-CACA-3' (downstream); P75^{NTR}: 5'-AGCCAACCAGACCG-TGTGTG-3' (upstream), 5'-TTGCA GCTGTTCCACCTCTT-3' (downstream); β-actin: 5'-CCTGCGTCTGGACCTGGCTG-3' (upstream), 5'-CTCAGGAGGAGCAATGATCT-3' (downstream). Amplifications were performed as follows: AChE: 30 cycles, 94 °C for 45 s, 56 °C for 45 s, 72 °C for 45 s; NGF: 24 cycles, 94 °C for 30 s, 60 °C for 30 s, and 72 °C for 60 s; P75^{NTR}: 25 cycles, 94 °C for 45 s, 55 °C for 30 s, and 72 °C for 90 s; β-actin: 30 cycles, 94 °C for 45 s, 57 °C for 45 s, and 72 °C for 60 s. The PCR products were normalized in relation to standards of β-actin mRNA.

Statistical analysis Data were expressed as mean±SEM. Statistical analysis was performed by one-way analysis of variance (ANOVA) followed by Duncan's multiple-range test, with P<0.05 as the significant level.

Results

Mitogenic activity and cytotoxicity of HupA on PC12 cells

There was no effect on cell proliferation during a 48-h exposure of PC12 cells to HupA 10 μmol/L. Likewise, measures of LDH release showed that HupA 10 μmol/L did not induce any cytotoxic effects (Figure 1).

Effects of HupA on neurite outgrowth

Most PC12 cells displayed a flat, polygonal, undifferentiated morphology after incubation under control conditions for 48 h, and only 5.5% of them exhibited neurites. However, after incubation with HupA 10 μmol/L for 48 h more cells differentiated and nearly twice as many (10.4%) were found to bear neuritis. Moreover, 14.2% of PC12 cells exhibited neuritis after incubation with 2 μg/L NGF (Figure 2).

Effects of HupA on activity, expression, and protein levels of AChE

In PC12 cells the activity of AChE was inhibited substantially by HupA treatment. The expression of AChE was also affected. AChE mRNA was increased at 6 h and 10 h. Consistent with the late rise in mRNA, AChE protein levels rose after a 48-h incubation with HupA (Figure 3).

Figure 1. Effects of huperzine A on PC12 cell proliferation and viability. (A) Proliferation was measured by [³H]thymidine incorporation. The [³H]thymidine incorporation of control cells was 62690±1242 cpm per 1×10⁴ cells. n=33. (B) Cytotoxicity was assessed by the release of LDH. The average absorbance of control cell supernatant was 0.214±0.009; of total control cell lysate was 2.68±0.11. n=18. Mean±SEM.

Effects of HupA on the expression and secretion of NGF

Effects of HupA on NGF and P75^{NTR} mRNA were determined by RT-PCR in primary rat cortical astrocytes, a cell type known to express the corresponding proteins. Figure 4A represents an example of RT-PCR products visualized after electrophoresis in 1.5% agarose gel containing ethidium bromide. The results suggested that NGF mRNA transcripts were slightly upregulated at 2, 4, and 6 h, while the levels of mRNA for P75^{NTR} appeared greatly increased. Moreover, an ELISA for NGF protein showed a large and statistically significant increase in cultures incubated with HupA 10 μmol/L for 24 h when compared to controls incubated for the same length of time in normal medium (Figure 4B).

Discussion

PC12 cells cannot secrete NGF, but they have NGF receptors and can respond to NGF. In the presence of NGF, PC12 cells cease cell division, differentiate into sympathetic neuron-like cells, and extend neuritis. So it is a putative model to

Figure 2. Effects of huperzine A on neurite outgrowth in PC12 cells. Top panels, representative phase contrast micrographs ($\times 200$). PC12 cells were incubated for 48 h under control conditions (A), with 1 $\mu\text{mol/L}$ HupA (B), with 10 $\mu\text{mol/L}$ HupA (C), and with 2 $\mu\text{g/L}$ NGF (D). Bottom panels, quantitative effects of HupA on neurite outgrowth. Three independent experiments were carried out. $n=8$ for each independent experiment. Mean \pm SEM. $^{\circ}P<0.01$ vs control.

determine the neurotogenic activity^[19]. Different from PC12 cells, astrocytes can secrete NGF. In the injured brain, for example, astrocytes play an important role in neurotrophic support^[20]. So the two different cells were used to determine the direct or indirect neurotrophic activity of HupA. In the present study, HupA was demonstrated to increase neurite outgrowth from undifferentiated PC12 cells and to enhance the expression and secretion of NGF in primary astrocytes. These findings indicate that HupA is not only an effective AChE inhibitor, but it also possesses NGF-inducing activity and an ability to induce certain NGF-like effects. The question arises whether these effects are closely linked, and what

Figure 3. Effects of huperzine A on AChE mRNA expression and immunoreactive protein levels and inhibition of AChE activity. (A) Representative RT-PCR pattern. Lane 1, control; lanes 2–5: 10 $\mu\text{mol/L}$ HupA incubated for 2, 4, 6 and 10 h, respectively. (B) Representative Western blot pattern. Lane 1: control; lane 2: treated with 10 $\mu\text{mol/L}$ HupA for 48 h. (C) Inhibition of AChE activity in PC12 cells after treatment with 10 $\mu\text{mol/L}$ huperzine A for 48 h. AChE activity of control was (1.80 ± 0.15) OD_{440} values per mg protein. $n=6$. Mean \pm SEM. Note that the true level of inhibition during incubation is probably underestimated, owing to the reversible nature of HupA interaction with AChE. $^{\circ}P<0.01$ vs control.

kind of relation they have to AChE. It has been reported that AChE plays an important role in neuronal proliferation and differentiation during early development of the central and peripheral nervous system. Neural AChE typically appears while axons are growing and before synaptic connections form^[21]. Accumulating evidence indicates that AChE may influence neurite outgrowth through a non-catalytic mechanism such as cell-cell or cell-substratum adhesion^[22]. It has been observed that the trophic activity of AChE is blocked by inhibitors that interact with the peripheral anionic site (PAS) but not by inhibitors that interact only with the active site, deep within the catalytic gorge^[23,24]. Such findings sug-

Figure 4. Effects of huperzine A on NGF and P75^{NTR} mRNA expression and NGF secretion in rat cortical astrocytes. (A) Representative RT-PCR pattern. Lane 1: control; Lanes 2–4: 10 μmol/L HupA incubated for 2, 4, and 6 h, respectively. The PCR products were normalized with reference to β-actin mRNA. (B) Huperzine A enhances NGF protein level in rat cortical astrocytes. Astrocytes serum deprived for 24 h were incubated with vehicle or 10 μmol/L HupA for another 24 h. NGF protein level was determined directly in the culture medium by NGF-ELISA. n=9. Mean±SEM. ^bP<0.05 vs control.

gest strongly that surface features of AChE rather than catalytic activity are responsible for its trophic effect. Hence, it is not contradictory to find that HupA affected neurite outgrowth in a positive rather than negative manner despite causing marked AChE inhibition. In fact, the differentiation-promoting effect of HupA may well reflect increased amounts of AChE protein. In other cell lines and to some extent *in vivo*, increased neurite outgrowth has been seen to parallel the level of AChE expression^[25–27]. Conversely, decreasing expression of AChE expression, using antisense techniques, reduced outgrowth^[28]. Our present results showed that AChE mRNA expression and protein levels were significantly up-regulated after treatment with HupA. This finding is consistent with other reports of increased AChE gene expression after exposure to AChE inhibitors^[29,30]. It remains to be determined whether feedback regulation of AChE synthesis is involved in these changes.

Previous observations suggest that NGF regulates the phenotype and survival of basal forebrain cholinergic neurons^[31] and protects hippocampal and cortical neurons against excitotoxic and ischemic damage^[32]. Neurons surviving from transient ischemia highly expressed P75^{NTR}, suggesting that this low affinity neurotrophin receptor could contribute to the cytoprotective effect of NGF^[33]. Our results showed that HupA enhanced the expression and secretion of NGF as well as increasing P75^{NTR} mRNA level in astrocytes. We conclude that these two responses may be key to the neuroprotective effects that have been observed *in vitro* and *in vivo* after treatment with HupA.

The exact mechanism by which HupA increases NGF secretion remains to be determined. There is evidence that cholinergic and adrenergic mechanisms as well as PKC activation all affect NGF gene expression in astrocytes. Our previous studies have demonstrated that HupA has enhancing effects on PKC^[34], and on cholinergic and adrenergic systems^[35]. Such effects may participate in the modulation of NGF synthesis. This provides another possible mechanism for HupA to promote survival of damaged neurons, which may interact synergistically with other pathways to exert the neuroprotective effect of this drug.

In the present study, HupA induced the NGF synthesis of cultured astrocytes and enhanced the neurite outgrowth of undifferentiated PC12 cells *in vitro*. These effects provide the possibility that HupA increase NGF-induced enhancement of neurons survival and their function improvement that was helpful in the rescue of injured neurons.

In summary, our study has demonstrated for the first time that HupA induces neurite outgrowth in PC12 cells and stimulates expression of NGF, P75 mRNA, and secretion of NGF in cultured rat cortical astrocytes. These effects might be helpful to restore and maintain neural cells in neurodegenerative disease.

Abstract

Aim: To investigate the effect of dishevelled-1 (DVL-1) on wortmannin-induced Alzheimer-like hyperphosphorylation of cytoskeletal proteins in mouse neuroblastoma 2a (N2a) cells. **Methods:** Cultured N2a cells were transiently transfected with DVL-1 expression plasmid using Lipofectamine™ 2000. Western blot and immunofluorescence microscopy were used to measure the phosphorylation of neurofilament and tau. **Results:** Level of phosphorylated neurofilament at SMI31 epitope and phosphorylated tau determined by PHF-1 was increased at 1 h and 3 h and back to normal at 6 h after wortmannin 1 μmol/L treatment. The highest level of phosphorylated neurofilament and phosphorylated tau was seen at 1 h and 3 h after wortmannin treatment, respectively. When DVL-1 protein was overexpressed, the hyperphosphorylation of neurofilament at SMI31 and SMI32 epitopes and tau at PHF-1 (Ser-396/404), M4 (Thr-231/Ser-235), and Tau-1 (Ser-198/199/202) epitopes was attenuated. **Conclusion:** Overexpression of mouse DVL-1 protein inhibits wortmannin-induced hyperphosphorylation of neurofilament and tau in N2a cells.

Introduction

Abnormally phosphorylated microtubule-associated protein tau is the major protein subunit of paired helical filaments (PHF) in the brain of Alzheimer disease (AD) patients, and accumulation of PHF in affected neurons leads to formation of neurofibrillary tangles (NFT)^[1]. In addition, neurofilament, another neurospecific intermediate filament, is also hyperphosphorylated and accumulated in AD brain^[2,3]. Although the precise mechanism for cytoskeleton hyperphosphorylation is not currently understood, it is widely recognized that an imbalanced regulation in phosphorylation (catalyzed by protein kinases) and dephosphorylation (catalyzed by protein phosphatases) system may play an important role in this pathological process.

Studies have shown that various protein kinases, such as mitogen-activated protein kinases (MAPK), protein kinase A (PKA), cyclin-dependent kinase (CDK), and glycogen synthase kinase-3 (GSK-3), phosphorylate tau at several sites found in AD brain. Among them, GSK-3 is one of the most implicated^[4]. Recent studies have shown that tau

becomes a more favorable substrate for GSK-3 when it is prephosphorylated in rat brain^[5]. GSK-3 is co-localized with hyperphosphorylated tau in degenerating neurons in AD brain^[6]. It also phosphorylates neurofilament proteins^[7,8]. GSK-3 is a downstream element of phosphatidylinositol-3 kinase (PI-3K), and it is inhibited by protein kinase B (PKB)-catalyzed phosphorylation at Ser-9 of GSK-3β and Ser-21 of GSK-3α. PKB in activity is stimulated by PI-3K-mediated phosphorylation^[9]. As there is no direct GSK-3 activator available now, wortmannin is generally used to activate GSK-3 indirectly through inhibiting PI-3K^[10] and overactivated GSK-3 phosphorylates tau in rat brain^[11,12]. Based on the above information, we used wortmannin to produce a cell model with hyperphosphorylation of cytoskeletal proteins in the present study.

To search for the strategies in arresting Alzheimer-like hyperphosphorylation of cytoskeletal proteins, we used overexpression of dishevelled (DVL) protein. DVL is a cytoplasmic protein involved in the wingless signaling (Wnt) pathways^[13]. Studies have shown that Wnt signaling pathways play important roles in AD. Overexpression of DVL-1

protein inhibits GSK-3 β -mediated phosphorylation of tau in transfected CHO cells^[14] and increases secreted amyloid precursor protein α (sAPP α) production in transfected HEK293 cells^[15]. There is no report about the role of DVL-1 on neurofilament phosphorylation, and the role of DVL-1 on tau phosphorylation in neuronal cells is also not known.

In the present study, we used wortmannin to produce hyperphosphorylation of neurofilament and tau in N2a cells and then determined the effect of mouse DVL-1 protein overexpression on neurofilament and tau hyperphosphorylation.

Materials and methods

Chemicals Polyclonal antibody 111e against total tau, monoclonal antibody PHF-1 against PHF-tau phosphorylated at Ser396/404, monoclonal antibody M4 against PHF-tau phosphorylated at Thr231/Ser235, and monoclonal antibody Tau-1 against PHF-tau unphosphorylated at Ser198/199/202 were gifts from Dr Grundke-Iqbal (New York State Institute for Basic Research, Staten Island, NY, USA), Dr Davies (Albert Einstein College of Medicine, Bronx, NY, USA), and Dr Binder (Northwestern University, Chicago, IL, USA). Monoclonal antibodies SMI31 against phosphorylated neurofilament and SMI32 against unphosphorylated neurofilament were purchased from Sternberger Monoclonals, Inc (Baltimore, MD, USA). Oregon Green 488-conjugated goat anti-mouse IgG (H+L) was from Molecular Probes (Eugene, OR, USA). Mouse monoclonal antibody c-Myc Ab-2 and wortmannin were purchased from Sigma Chemical Co (St Louis, MO, USA). Bicinchoninic acid (BCA) protein detection kit was obtained from Pierce Chemical Company (Rockford, IL, USA).

Cell culture, plasmid and transfection Mouse neuroblastoma 2a (N2a) cells were obtained from Dr Hua-xi XU (Rockefeller University, NY, USA). The cells were cultured in a medium containing 50% Dulbecco's modified Eagle's medium (DMEM) and 50% Opti-MEM, supplemented with 5% fetal bovine serum (Gibico BRL, Gaithersburg, USA) in 5% CO₂ at 37 °C.

Mouse DVL-1 subcloned into the ClaI site of pCS2+ in frame with 6-Myc epitope at the C termini was a gift from Dr Lin MEI (University of Alabama at Birmingham, USA). The plasmid and the vector as a control were prepared using a maxi-prep endotoxin-free kit (Qiagen, Crawley, West Sussex, UK) and transfected into N2a cells using LipofectamineTM 2000 (Invitrogen, Carlsbad, California, USA) in a 6-well format. The amounts and volumes were given on a per well basis. One day before transfection, about (2–8)×10⁵ cells were plated in 2 mL of growth medium without antibiotics and the

confluence of the cells was about 90%–95% at the time of transfection. For each transfection, 4.0 μ g DNA in 250 μ L of Opti-MEM medium and 10 μ L LipofectamineTM 2000 in 250 μ L of Opti-MEM medium were prepared and incubated for 5 min at room temperature. Then, the diluted DNA and the diluted LipofectamineTM 2000 were mixed gently and incubated for another 20 min at room temperature. The mixture was then added to each well and incubated with the cells at 37 °C in a CO₂ incubator for 48 h prior to determination of the expression of transfected genes. Then the cells were treated with wortmannin 1 μ mol/L^[16] and harvested at 0, 1, 3, or 6 h after the treatment.

Western blot Cultures were homogenized in the buffer containing 50 mmol/L Tris-HCl (pH 8.0), 150 mmol/L sodium chloride, 1% NP-40, 0.5% sodium deoxycholate, 0.1% sodium dodecyl sulfate, 0.02% sodium azide, 0.1 g/L phenyl-methylsulfonyl fluoride, and 1 mg/L aprotinin. Protein concentration was determined with BCA Protein Assay Reagent. A middle-molecule weight protein marker was used (Pierce, USA). Equal amounts of protein were separated on either 7.5% or 10% SDS-polyacrylamide gel and transferred onto nitrocellulose membranes (Amersham Pharmacia Biotech, USA). The membranes were blocked with 3% BSA in TBS at room temperature for 1 h, then incubated with primary antibodies and secondary antibodies, and finally developed using the Enhanced Chemiluminescence (ECL) detection system (Amersham Pharmacia Biotech, USA).

Immunofluorescence microscopy Culture medium was carefully removed. After two rinses in PBS, the cells were fixed in a freshly prepared solution of 4% paraformaldehyde for 1.5 h. After two more rinses in PBS, the cells were permeabilized in 1% Triton X-100 in PBS for 15 min. Then the cells were incubated in 3% BSA in PBS for 1 h and incubated with primary antibody at 4 °C overnight. After three rinses with PBS, cells were incubated in Oregon Green 488-conjugated secondary antibody (1:1000; Molecular Probes) for 1 h at room temperature. After three more rinses in PBS, fluorescence was observed using a fluorescence microscope (BX60; Olympus, Tokyo, Japan) with appropriate filter sets.

Statistical analysis All data were presented as mean \pm SD and analyzed by ANOVA followed by Student-Newman-Keuls test to determine the differences among groups.

Results

Wortmannin induces transient hyperphosphorylation of neurofilament and tau in N2a cells Phosphorylation of neurofilament and tau in N2a cells were measured by Western blot. The level of phosphorylated neurofilament determined by SMI31 antibody was increased at 1 h and at 3 h,

Figure 1. Wortmannin induced transient hyperphosphorylation of neurofilament (A) and tau (B) in N2a cells. N2a cells were cultured in the presence of 1 $\mu\text{mol/L}$ wortmannin, harvested at different time points as indicated, and the supernatant was analyzed by Western blotting for neurofilament and tau phosphorylation. The intensity of immunoreactivity was quantitated by densitometry and presented under each blot. The highest phosphorylation of neurofilament and tau was detected at 1 h and 3 h, respectively. The data (mean \pm SD) were from three to five independent experiments. ^b $P < 0.05$; ^c $P < 0.01$ vs 0 h control group.

and it was restored to normal level at 6 h (Figure 1A); phosphorylation of tau recognized by PHF-1 antibody was elevated at 1 h, peaked at 3 h, and then back to the normal level at 6 h (Figure 1B) after treatment of the cells with wortmannin (1 $\mu\text{mol/L}$). The highest level of neurofilament and tau phosphorylation was seen at 1 h and 3 h, respectively (Figure 1). These data demonstrate that wortmannin can induce hyperphosphorylation of neurofilament and tau in N2a cells.

Overexpression of mouse DVL-1 protein inhibits wortmannin-induced neurofilament and tau hyperphosphorylation in N2a cells As wortmannin induces neurofilament and tau hyperphosphorylation most efficiently at 1 h and 3 h, respectively, in N2a cells, we investigated the effect of mouse DVL-1 protein overexpression on neurofilament and tau hyperphosphorylation at these two time points. The

enhanced SMI31 (recognizes phosphorylated epitope) and the dimmed SMI32 (recognizes unphosphorylated epitope) immunoreactivity induced by wortmannin were efficiently attenuated when DVL-1 protein was overexpressed (Figure 2A, 2B), suggesting the role of DVL-1 in arresting wortmannin-induced neurofilament hyperphosphorylation. DVL-1 overexpression also efficiently arrested wortmannin-induced tau hyperphosphorylation at PHF-1 (recognizes phosphorylated epitope, Figure 2C), M4 (recognizes phosphorylated epitope, Figure 2D), and Tau-1 (recognizes unphosphorylated epitope, Figure 2E) sites. Neither wortmannin alone nor wortmannin in combination with DVL-1 or with vector changed the level of total tau determined by 111e antibody (Figure 2F). The overexpression of DVL-1 protein was confirmed with anti-c-Myc tag antibody (Figure 2G). Inhibition of wortmannin-induced tau hyperphosphorylation at both PHF-1 and Tau-1 sites was also observed by immunofluorescence staining of the cells (Figure 3). We also noticed that the immunostaining pattern of Tau-1 antibody was different from that of PHF-1 and 111e and the distribution of Tau-1 staining was more concentrated into the cell membrane, especially in the cells transfected with DVL-1 and treated with wortmannin (Figure 3).

Discussion

Abnormal hyperphosphorylation and accumulation of tau protein in the affected neurons are recognized early pathological processes in AD brain. Several protein kinases are reported to hyperphosphorylate tau at some of the AD epitopes and GSK-3 is one of them^[4]. In addition, GSK-3 also phosphorylates neurofilament *in vitro*^[7] and in transfected cells^[8]. As there is no direct activator for GSK-3, wortmannin, a specific inhibitor of PI3K^[10], has been used to stimulate GSK-3 indirectly to phosphorylate tau *in vivo*^[11,12]. In the present study, we used wortmannin to treat N2a cells and observed that wortmannin induced neurofilament and tau hyperphosphorylation, thus a cell model with Alzheimer-like hyperphosphorylation was established. We also noticed that the number of positive staining bands for tau and neurofilament was different when different antibodies were used. It is known that tau has at least six isoforms by alternative splicing^[17]. The number of isoforms of tau and neurofilament shown on the blots depends on the species of the samples, the exposure of epitopes, and the degree of posttranslational modifications, such as phosphorylation.

Though hyperphosphorylation of cytoskeletal proteins plays a critical role in AD pathogenesis, there is no effective tool to arrest the pathological processes. In the present

Figure 2. Overexpression of mouse DVL-1 protein inhibited neurofilament and tau hyperphosphorylation induced by wortmannin in N2a cells. DVL-1 protein overexpression inhibited neurofilament hyperphosphorylation examined at 1 h by SMI31 (A) and SMI32 (B). Similarly, DVL-1 protein overexpression efficiently arrested wortmannin-induced tau hyperphosphorylation examined at 3 h at PHF-1 (C), M4 (D) and tau-1 (E) sites. The phosphorylation level of tau was normalized by total tau (F). The expression of DVL-1 protein was determined with anti-c-Myc tag antibody (G). The intensity of immunoreactivity was quantitated by densitometry and presented under each blot. The data (mean \pm SD) were from three to five independent experiments. ^b*P*<0.05, ^c*P*<0.01 vs untreated group. ^e*P*<0.05, ^f*P*<0.01 vs wortmannin treated group.

study, we observed that mouse DVL-1 protein overexpression efficiently inhibited wortmannin-induced hyperphosphorylation of neurofilament at SMI31 and SMI32 epitopes

and tau at PHF-1 (Ser-396/404), M4 (Thr-231/Ser-235) and Tau-1 (Ser-198/199/202) epitopes in N2a cells. As wortmannin is an indirect activator of GSK-3, we speculate that DVL-1

Figure 3. DVL-1 protein overexpression inhibited tau hyperphosphorylation induced by wortmannin in N2a cells by immunofluorescence. DVL-1 protein overexpression attenuated wortmannin-induced tau hyperphosphorylation examined at 3 h at PHF-1 and tau-1 sites as indicated. Neither wortmannin alone nor wortmannin in combination with DVL-1 or with vector changed the level of total tau determined by 11e antibody. The data represents three to five independent experiments. Bar: 20 μ m.

may function through arresting the activity of GSK-3. DVL-1 is a component of the wingless pathway (Wnt signaling) and activation of wingless results in inhibition of GSK-3^[18] and tau dephosphorylation in hippocampal neurons^[19]. In *Drosophila* imaginal disc cells, overexpression of DVL-1 mimics the wingless signal^[20]. These data suggest that loss of function of Wnt signaling may be involved in the pathological process of AD and that inhibition of GSK-3 activity by overexpression of DVL-1 may be useful in antagonizing Alzheimer-like hyperphosphorylation of cytoskeletal proteins. It was also reported that inactivation of GSK-3 induced by wingless may involve activation of PKC^[18]. The precise mechanism through which DVL-1 functions is complex and further study is needed to illustrate the underlying mechanisms. Additionally, we also noticed that Tau-1 staining was more concentrated into the cell membrane after DVL-1 transfection and wortmannin treatment in immunocytochemistry study. We currently do not understand the meaning and the mechanism for this translocation of tau.

Taken together, we have found that overexpression of DVL-1 protein effectively attenuates wortmannin-induced neurofilament and tau hyperphosphorylation in N2a cells.

Abstract

Aim: To determine the distribution of cysteinyl leukotriene receptor 2 (CysLT₂), one of the cysteinyl leukotriene receptors, in human brains with traumatic injury and tumors. **Methods:** Brain specimens were obtained from patients who underwent brain surgery. CysLT₂ in brain tissues was examined using immunohistochemical analysis. **Results:** CysLT₂ was expressed in the smooth muscle cells (not in the endothelial cells) of arteries and veins. CysLT₂ was also expressed in the granulocytes in both vessels and in the brain parenchyma. In addition, CysLT₂ was detected in neuron- and glial-appearing cells in either the late stages of traumatic injury or in the area surrounding the tumors. Microvessels regenerated 8 d after trauma and CysLT₂ expression was recorded in their endothelial cells. **Conclusion:** CysLT₂ is distributed in vascular smooth muscle cells and granulocytes, and brain trauma and tumor can induce its expression in vascular endothelial cells and in a number of other cells.

Introduction

Cysteinyl leukotrienes (CysLTs), including LTC₄, LTD₄ and LTE₄, are potent inflammatory mediators. In peripheral inflammatory diseases such as asthma and rhinitis, CysLTs can induce smooth muscle constriction, microvascular leakage, eosinophilic recruitment and other responses^[1–3]. In the central nervous system (CNS), the level of CysLTs increases after brain injuries such as cerebral ischemia, brain trauma and tumors^[4–6]. The increase in CysLTs after traumatic brain injury peaks at 4 h and again at 7 d, and is related to edema and cellular inflammatory responses in the rat brain^[5]. In addition, the increase in CysLTs in metastatic tumors and gliomas is considered to be a factor promoting peritumoral edema^[4,7].

The cloned CysLT receptors include CysLT₁ and CysLT₂, both of which are classic G protein-coupled receptors with seven transmembrane domains^[8,9]. Human CysLT₂ is highly expressed in the spleen, placenta, heart, and peripheral blood

leukocytes, and weakly expressed in the brain, prostate, skeletal muscle, kidney and ovary^[8–10]. Using a ribonuclease protection assay, the highest expression of murine CysLT₂ was detected in the spleen, adrenal gland and thymus, and weaker expression was recorded in the kidney, brain and peripheral blood leukocytes^[11]. In human and murine brains CysLT₂ is expressed much more than CysLT₁ using Northern blot and RT-PCR^[11,12]. However, the distribution of CysLT₂ in the brains of animals including humans is still unknown.

Recently, we examined CysLT₁ expression in human brain specimens from patients with traumatic brain injury and brain tumors^[13]. We found that CysLT₁ is mainly distributed in the vascular endothelium, which is consistent with the inhibiting effects of CysLT₁ antagonists on plasma extravasation and brain edema in the brains of focal cerebral ischemic rats^[14]. In the present study, we examined the distribution of CysLT₂ in human brains after traumatic injury and in brains with tumors.

Materials and methods

Human brain specimens This study was approved by the ethics committee of the Second Affiliated Hospital, School of Medicine, Zhejiang University, Hangzhou, China. Brain specimens were obtained from 24 patients who underwent brain surgery because of traumatic brain injury, brain tumors, or benign meningioma (Table 1). The diagnosis of each patient with brain tumor was based on criteria pertaining to the clinical MRI picture, appropriate laboratory data and biopsy findings. Astrocytomas and gangliogliomas were classified as low (grades I–II) or high (grades III–IV) grade according to the Daumas-Duport criteria.

Immunohistochemistry Brain tissues were fixed in 4% formaldehyde for 24–48 h, and then embedded in paraffin. A 6 μm thick paraffin section was stained with hematoxylin and eosin (HE). Another section was incubated with a primary polyclonal antibody against CysLT₂ for 1 d at 4 °C (5 mg/L, rabbit IgG, Cayman, USA). This section was sequentially treated with anti-rabbit IgG biotinylated secondary antibody and avidin biotin complex (Zymed, USA). Finally, the section was visualized with 0.01% diaminobenzidine tetrahydrochloride (DAB) and 0.005% H₂O₂ in 50 mmol/L Tris-HCl, pH 7.6. Control sections were treated with normal goat serum instead of the primary antibody to test the specificity of the immunohistochemical reaction. Nuclei of cells were counter stained using hematoxylin.

Results

The control sections treated with normal goat serum showed no positive immunostaining (data not shown). CysLT₂ was highly expressed in the smooth muscle cells of

both arteries and veins, but not in the endothelial cells (Figure 1A,1B). Brain tissues surrounding benign meningioma appeared relatively normal using MRI and HE staining (data not shown). In such relatively normal brain tissues, CysLT₂ was not detected in microvascular endothelial cells or in other cells (Figure 1C, Table 1).

CysLT₂ expression in human brains after traumatic injury Within 3 d after traumatic brain injury, mild expression of CysLT₂ was frequently detected in the neuron- and glial-appearing cells in a number of human brain specimens (Figure 2A, Table 1), but rarely in the microvascular endothelial cells (Figure 2B, Table 1). However, 8 d after trauma, microvascular regeneration was observed and CysLT₂ was highly expressed in the regenerated microvascular endothelial cells and glial-appearing cells (Figure 2C, Table 1), but no CysLT₂ positive cell was found in the necrotic regions (Figure 2D). In addition, in one patient, MPO-positive granulocytes were found within vessels and in the brain parenchyma (data not shown), and CysLT₂ was highly expressed in the granulocytes both within vessels (Figure 2E) and in the brain parenchyma (Figure 2F).

CysLT₂ expression in human brain tumors In brain tumors, no CysLT₂ was detected in the center of glioma, ganglioglioma and metastatic carcinomas (Figure 3A,3B, Table 1), but strong CysLT₂ immunostaining was found in neuron- and glial-appearing cells surrounding tumors (Figure 3C, Table 1).

Discussion

In this study, the first finding is the specific distribution pattern of CysLT₂ in brain vessels. CysLT₂ was highly ex-

Figure 1. CysLT₂ expression in the vessels of the human brain. Brain samples were obtained from two patients with astrocytoma (Patient numbers 21 and 22 from Table 1 in A and B, respectively) and one patient with benign meningioma (Patient number 1 from Table 1 in C). CysLT₂ expression was detected using immunohistochemistry. CysLT₂ immunoreactivity (brown) was found in the smooth muscle cells of veins (A) and arteries (B), but not in endothelial cells (red arrows), microvascular endothelial cells (C, red arrows) or other cells within the brain tissues. The inserts are amplifications from the black boxes in A and B. Scale bar is 50 μm .

Table 1. Patient profiles and the immunohistochemical results for CysLT₂. NA, not applicable; -, absent; ±, weak or few; +, mild; ++, marked; ?, not detected; L, left; R, right; T, temporal lobe; F, frontal lobe; P, parietal lobe. Samples were from the tissues surrounding (*) and within (**) the injured regions or the tumors; NAC, neuron-appearing cells; GAC, glial-appearing cells; VEC, microvascular endothelial cells.

pressed in the smooth muscle cells of arteries and veins, but rarely in vascular and microvascular endothelial cells in relatively normal brain tissues or in tissues within 3 d of brain trauma. This pattern is different from that of CysLT₁, which is primarily expressed in endothelial cells as found in our previous study^[13]. However, strong expression of CysLT₂ was found in the regenerated microvascular endothelial cells 8 d after trauma, suggesting an inducible CysLT₂ expression. This result is similar to that of the human heart, in which CysLT₂ mRNA has been detected in myocytes, fibroblasts and vascular smooth muscle cells, but not in endothelial cells^[15]. Moreover, CysLT₂ has been reported to be expressed primarily in human umbilical vein endothelial cells (HUVECs)^[16],

and may play a role in inflammation during atherogenesis or leukocyte infiltration into tissues^[17]. A recent study using CysLT₂-deficient mice confirmed that CysLT₂ mediates an increase in vascular permeability in IgE-dependent passive cutaneous anaphylaxis^[18]. Our present results showed that unlike peripheral tissues (HUVECs), CysLT₂ was only expressed in the endothelial cells of injured brain tissues after a longer duration. This result implies that CysLT₂ might be involved in inflammatory responses in the CNS.

The second finding of this study is the inducible CysLT₂ expression in neuron- and glial-appearing cells after brain trauma and in brain tumors. We have recently reported inducible CysLT₁ expression in neuron- and glial-appearing

Figure 2. CysLT₂ expression in human brains after traumatic brain injury. Brain samples were from patients 14 h (A; patient number 5), 15 h (B, E, F; patient number 6), or 8 d (C, D; patient number 15) after traumatic brain injury. At 14 or 15 h after injury, mild expression of CysLT₂ were found in neuron- and glial-appearing cells (A), and in microvascular endothelial cells (B). At 8 d after injury, microvessels had regenerated, and CysLT₂ was highly expressed in the microvascular endothelial cells, glial-appearing cells and granulocytes (C), but not in the necrotic region (D). CysLT₂ was also highly expressed in granulocytes both within vessels (E) and within brain tissues (F). The inserts are amplifications from the black boxes in E and F. Scale bar is 50 μ m.

Figure 3. CysLT₂ expression in human brains with tumors. Samples were obtained from patients with astrocytoma (A, C; patient number 19) or metastatic carcinoma (B; patient number 24). CysLT₂ was not found within astrocytomas (A) or metastatic carcinomas (B), but was highly expressed in neuron- and glial-appearing cells surrounding the astrocytoma (C). Scale bar is 50 μ m.

cells after traumatic brain injury and brain tumors^[13]. Unlike CysLT₁, the inducible CysLT₂ expression in these cells was much reduced within 3 d after trauma, but was strong 8 d after trauma and surrounding the tumors. The pathophysiological implications of CysLT₂ in the brain are unknown,

but CysLT₂ may be involved in intracerebral cell proliferation because CysLTs can promote astrocyte and intestinal epithelial cell proliferation^[19,20]. Recently it has been reported that bleomycin-induced pulmonary fibrosis is increased in CysLT₁-deficient mice, but decreased in CysLT₂-deficient-

mice^[18,21]. Therefore, the inducible CysLT₂ expression 8 d after trauma might be responsible for cell regeneration and/or proliferation.

In addition, CysLT₂ was highly expressed in the granulocytes in both vessels and brain tissues. This result is consistent with previous reports that show that CysLT₂ is expressed in peripheral blood leukocytes^[10] and is responsible for chemotaxis^[22]. However, according to the results of guinea pig brain perfusion with human neutrophils, Di Gennaro *et al*^[23] hypothesized that CysLT₁ in leukocytes and CysLT₂ in endothelial cells might be involved in the adherence and intrusion of leukocytes in brain inflammatory reactions. However, our results examining the distributions of CysLT₁ and CysLT₂ in human brains do not support their hypothesis.

In summary, we found that CysLT₂ was expressed in smooth muscle cells and granulocytes, suggesting that CysLT₂ might play a role in cerebral circulation and the inflammatory response that occurs in human brains after injury. The induced CysLT₂ expression in microvascular endothelial cells, and neuron- or glial-appearing cells after traumatic injury and in brain tumors requires further investigation.

Acknowledgment

We thank Prof Pei-hui CHEN from the Department of Pathology, the Second Affiliated Hospital, School of Medicine, Zhejiang University, for his help with the analysis of brain sections.

Abstract

Aim: To investigate the fibrin(ogen)olytic character of FII_a isolated from *Agkistrodon acutus* venom *in vitro* and *in vivo*. **Methods:** ¹²⁵I-labeled human plasma clot lysis was measured *in vitro* and rabbit carotid artery thrombosis was as an *in vivo* model. **Results:** *In vitro*, urokinase (UK) at 25, 35, 40, 45, 60 kU/L and FII_a at 0.08, 0.23, 0.4, 0.5, and 0.7 g/L resulted an equivalent clot lysis (20%, 40%, 50%, 60%, and 80%). UK at 25–60 kU/L induced 27.3%±3.6%, 35.2%±2.3%, 39.3%±2.4%, 44.2%±4.6%, and 51.1%±1.2% fibrinogen degradation. But FII_a at 0.08–0.7 g/L induced 95.4%±0.3%, >95.6%, >95.6%, >95.6%, >95.6% fibrinogen degradation respectively. *In vivo*, UK 40 kU/kg and FII_a 1.0 mg/kg reduced the weight of residual thrombus to 9.0±2.5 mg and 7.8±3.5 mg compared with negative control group (30.0±5.4 mg). But the fibrinogen degradation rate after UK 40 kU/kg and FII_a 1.0 mg/kg treatment was 24.4%±6.2% and 4.1%±7.8%, respectively ($P < 0.05$, $n=6$). The order of the lysis speed after UK 125 kU/L treatment was platelet poor plasma (PPP) clots>the whole blood clots>platelet rich plasma (PRP) clots. The sequence for FII_a 0.4 g/L was PRP>PPP>whole blood clots. **Conclusion:** At the same percentage of clot lysis, FII_a degraded more fibrinogen than UK did *in vitro* but less fibrinogen than UK did *in vivo*. The order of the lysis speed was PPP>whole blood clots>PRP clots for UK and PRP>PPP>whole blood clots for FII_a.

Introduction

Fibrin-specific clot lysis was initially the major goal to offer the opportunity for effective lysis of pathological thrombus without the risks of a systemic haemorrhagic diathesis^[1]. But clinical studies show that even tissue plasminogen activator (t-PA), which exhibits strict selectivity toward fibrin-bound plasminogen, is associated with a significant although variable degree of fibrinogenolysis^[2–4].

In our previous studies, fibrinolytic enzyme FII_a from *Agkistrodon acutus* venom was shown to dissolve both fibrin and fibrinogen *in vitro*. *In vivo*, FII_a was able to dissolve thrombus without hemorrhage at an effective dose for thrombolysis^[5–7]. A few experiments were performed to investigate the fibrin(ogen)olytic character of FII_a such as the specificity to fibrin and fibrinogen and the specificity to different types of clots.

In this study, we compared fibrin(ogen)olytic character

of FII_a with urokinase (UK) *in vitro* and *in vivo*.

Materials and methods

Snake venoms *Agkistrodon acutus* venom was collected in Yuanling, Hu-nan Province and lyophilized and stored in desiccator.

Reagents DEAE-Sephadex A-50 and Sephadex G-75 were from Pharmacia (Uppsala, Sweden); human fibrinogen (95% clottable) and bovine fibrinogen (70% clottable) was from Sigma (Saint Louis, USA); aprotinin was from Dadel Biochemistry and Pharmaceutical Co Ltd (Lanzhou, China); thrombin was from Zhuhai Biochemical Pharmaceutical Factory (Zhuhai, China); UK was from Tianpu Biochemistry and Pharmaceutical Co Ltd (Guangzhou, China); ¹²⁵I-labeled fibrinogen was from the Department of Experimental Nuclear Medicine of our college by the method of chloramines-T; fibrinogen concentration determination reagent pack (Claus

method) was from Sun Biotechnology Company (Shanghai, China); human plasma was from Guangzhou Blood Center was centrifugated at $3800\times g$ for 8 min; whole blood was collected from healthy volunteers ($n=5$ male, age 24.0 ± 4.2 a, weighing 61 ± 2.4 kg). All materials were of analytical grade from commercial sources.

Animals Male New Zealand white rabbits (3–4 months old, weighing 2.2 ± 0.1 kg, Grade II, certificate No 2001A033) were provided by the Experimental Animal Center of Zhongshan Medical College.

Purification of the enzyme FII_a, the fibrinolytic enzyme from *Agkistrodon acutus* venom was prepared according to the method described by Chen *et al*^[7].

Lysis of ¹²⁵I-labeled human plasma clots *In vitro*, ¹²⁵I-labeled clots were prepared by the modified method of Gurewich *et al*^[8]. Human plasma 5.5 mL were mixed with ¹²⁵I-labeled fibrinogen (6.105×10^4 Bq) plus 55 μ L CaCl₂ (1 mol/L). This solution (0.5 mL) was added to 5-mm (ID) glass tube in the presence of 5 μ L thrombin (100 kU/L). The clots were incubated at 37 °C for 30 min and kept overnight at room temperature. All the clots were washed three times with 0.9% saline and the total radioactivity was measured before being transferred to 10-mm (ID) test tubes.

Plasma (4 mL) were incubated (37 °C, 6 h) with radiolabeled clots in the presence of UK 20, 30, 40, 60, and 80 kU/L or FII_a 0.05, 0.1, 0.2, 0.4, and 0.8 g/L, respectively. The reaction was terminated by adding aprotinin (1×10^6 kU/L final concentration) into test tubes containing different concentrations of UK or edetic acid (5 μ mol/L final concentration) into test tubes containing different concentrations of FII_a. Aliquots (1 mL) were removed for the measurement of radioactivity.

Clot lysis was calculated according to the formula: Clot lysis = Radioactivity in aliquot (modified volume)/total radioactivity $\times 100\%$. The concentrations of UK or FII_a which could induce 20%, 40%, 50%, 60%, and 80% clot lysis were determined based on the concentration-response curve.

The same experiments were repeated with UK and FII_a at the concentrations that could induce 20%, 40%, 50%, 60%, and 80% clot lysis. Aliquots were removed for the measurement of fibrinogen concentration to get the fibrinogen degradation at the same percent of clot lysis.

Each experiment was performed three times.

Fibrinogen degradation Fibrinogen degradation was performed according to the reagent pack instruction by the Clauss method.

Carotid artery thrombosis The rabbit carotid artery thrombosis model was established according to the method of Wang *et al*^[9]. Forty-eight rabbits were randomly divided

into 8 groups ($n=6$): 0.9% saline 1 mL/kg, as the negative control group; UK 5, 10, 20, and 40 kU/kg group; FII_a 0.5, 1.0, and 2.0 mg/kg group.

Two hours after the initiation of the carotid thrombosis, UK and FII_a were administered via ear-edge vein of rabbit. One hour later, the residual thrombus within the carotid artery was excised and blotted. The wet weight was measured. Blood was drawn from the right femoral artery cannula before and 1 h after administration for the measurement of plasma fibrinogen concentration. The blood sample was drawn into a plastic syringe containing 3.8% sodium citrate as the anticoagulant (1: 9 v/v, citrate/blood) and was centrifuged at $1500\times g$ 4 °C for 15 min. The platelet-free plasma was stored at -70 °C until assayed.

Lysis of platelet-rich plasma (PRP) clots, platelet-poor plasma (PPP) clots, and whole-blood clots Whole blood from healthy volunteers was mixed with 3.8% sodium citrate (1:9 v/v, citrate/blood) and immediately centrifuged at room temperature at $250\times g$ for 10 min to obtain PRP. PPP was obtained by centrifuging the original blood sample at $1500\times g$ for 10 min^[10]. ¹²⁵I-labeled clots made from PRP, PPP, and whole blood were prepared as described above.

Plasma (4 mL) were incubated with these three types of radiolabeled clots in the presence of FII_a 0.4 g/L or UK 125 kU/L (final concentration) at 37 °C. Aliquots were removed for the measurement of radioactivity in plasma at subsequent times during a course of 12 h. The time-response relationship of FII_a and UK for these three types of clots were compared. Each experiment was performed three times^[11].

Data analysis Values were expressed as mean \pm SD. Analysis of variance and *t*-test was used for comparisons of the mean values. $P < 0.05$ was considered significant.

Results

Fibrin(ogen)olytic character of FII_a *in vitro* *In vitro* both UK and FII_a dose-dependently dissolved clots. Based on the dose-effect relationship of UK and FII_a, UK at 25, 35, 40, 45, 60 kU/L and FII_a at 0.08, 0.23, 0.4, 0.5, and 0.7 g/L caused an equivalent clot lysis (20%, 40%, 50%, 60%, and 80%, Figure 1, 2).

At the calculated concentration, which could induce the same clot lysis, the fibrinogen degradation induced by FII_a was much higher than that induced by UK. In the negative control group, the fibrinogen degradation was $0.01\% \pm 0.02\%$ (0.02 ± 0.05 g/L).

Fibrin(ogen)olytic character of FII_a in rabbit carotid artery thrombosis UK or FII_a reduced the weight of residual thrombus and the level of fibrinogen in plasma in a

Figure 1. UK dose-dependently dissolved ¹²⁵I-labeled human plasma clots. In the negative control group, the clot lysis was 11.0%±1.0%.

Figure 2. FII_a dose-dependently dissolved ¹²⁵I-labeled human plasma clots. In the negative control group, the clot lysis was 11.0%±1.0%.

dose-dependent manner. In the group treated with UK 40 kU/kg, the weight of residual thrombus was 9.0±2.5 mg. In the group treated with FII_a 1.0 mg/kg, the weight of residual thrombus was 7.8±3.5 mg. The fibrinolytic effects of these two groups were approximately the same, but the fibrinogen degradation of these two groups were 24.4%±6.2% and 4.1%±7.8%, respectively ($P<0.05$, $n=6$). In the negative control group, the weight of residual thrombus was 30.0±5.4 mg, and the fibrinogen degradation was 2.7%±2.7%. The difference between UK and control or FII_a and control was statistically significant ($P<0.01$, $n=6$, Table 3, 4).

Fibrin(ogen)olytic character of FII_a in lysis of platelet-rich clots, platelet-poor clots and whole-blood clots The kinetics of FII_a-induced lysis were characterized by an initial lag phase followed by an accelerated lysis, whereas lysis by UK lacked the lag phase. The order of the lysis speed after UK 125 kU/L treatment PPP clots>the whole blood clots>PRP clots. The sequence for FII_a 0.4 g/L was PRP clots>PPP clots>whole blood clots. The clot lysis of these three types

Discussion

In this paper, the fibrin(ogen)olytic character of FII_a was studied and compared with UK. The *in vitro* results showed that both FII_a and UK degraded clots and fibrinogen in a dose-dependent manner. FII_a degraded 95.4%±0.3% fibrinogen when the clot lysis was 20% and UK degraded 51.1%±1.2% fibrinogen when the clot lysis was 80%. *In vitro*, FII_a degraded more fibrinogen than UK did at the same percentage of clot lysis.

The *in vivo* results showed that both FII_a and UK could dose-dependently dissolve clots and fibrinogen. The fibrinolytic effects of UK 40 kU/kg or FII_a 1.0 mg/kg were approximately the same, but the fibrinogen degradation effects were 24.4%±6.2% and 4.1%±7.8%, respectively (*P*<0.05, *n*=6). *In vivo*, FII_a degraded less fibrinogen than UK did at the same percentage of clot lysis. The *in vivo* and *in vitro* results of the experiments are in accordance with the data of our previous studies^[5,6,12].

UK and FII_a have different sensitivity and kinetics to different types of clots. UK dissolved most effectively the PPP clots, then the whole blood clots and PRP clots. The sequence for FII_a was PRP>PPP>whole blood clots.

Attention should be paid as to why the conclusion *in vitro* did not accord with the conclusion *in vivo*. It could be explained that the dosage of FII_a was much higher *in vitro* than that used *in vivo*, while the dosage of UK was opposite. The dosage was at least one of the causes of the inconsistency.

The main component of thrombus in rabbit carotid artery thrombosis model was platelet^[9] and the main component in *in vitro* clots was fibrin. FII_a dissolves most effectively the platelet rich clots compared with UK that dissolves most effectively fibrin rich clots (Figure 3 and 4), which could explain why FII_a dissolved clot at less dosage *in vivo* than *in vitro* but the clot lysis effect of UK was just the opposite.

Our previous study showed that FII_a influenced blood coagulation by inhibiting platelet aggregation induced by ADP in rat PRP and degrading factor X and prothrombin^[12]. It is also one of the reasons in the dosage inconsistency.

There are two opinions about the mechanism of the fibrinolytic enzyme from snake venom inhibiting platelet aggregation. (1) Fibrinolytic enzymes inhibit platelet aggregation by hydrolyzing α-fibrinogen to prevent fibrinogen from combining with fibrinogen receptor (GPIIb-IIIa), such as α-fibrinolytic enzyme from *Agkistrodon contortrix contortrix*^[13], *A rhodostoma*^[14], and *T mucrosquamatus*^[15]. (2) The disintegrin-like domain may target the fibrinolytic enzyme to a particular site such as platelets where the metalloproteinase domain may cleave relevant substrates including integrins, coagulant proteins, matrix, or other latent proteins^[16]; such as collagen receptor antagonist *Jararhagin* from *Bothrops jararaca*^[17], *Mutalysin I* from *Lachesis muta muta*^[16], *Crovidisin* from *C viridis*^[18]; such as GPIIb-IIIa antagonist *Barbourin*^[19] with KGD sequence. Our previous study showed FII_a degraded α and β chains of fibrinogen^[5]. Is there any relationship between the inhibitory activity of FII_a on platelet aggregation and the proteolytic activity of FII_a on fibrinogen or membrane protein? This topic will be further explored in the near future.

Abstract

Aim: To investigate the effect of simvastatin on the cardiac contractile function and the alteration of gene and protein expression of the sarcoplasmic calcium regulatory proteins, including sarcoplasmic reticulum Ca²⁺-ATPase (SERCA), phospholamban (PLB), and ryanodine receptor 2 (RyR2) in rat hearts. **Methods:** Langendorff-perfused rat hearts were subjected to 60-min perfusion with different concentrations of simvastatin (1, 3, 10, 30, or 100 µmol/L), and the parameters of cardiac function such as left ventricular developed pressure (LVDP), +dp/dt_{max}, and -dp/dt_{max} were determined. The cultured neonatal rat ventricular cardiomyocytes were incubated with simvastatin (1, 3, 10, 30, and 100 µmol/L) for 1 h or 24 h. The levels of SERCA, PLB, and RyR2 expression were measured by reverse transcription-polymerase chain reaction and Western blot. Cytotoxic effect of simvastatin on ventricular cardiomyocytes was assessed by the MTT colorimetric assay. **Results:** LVDP, +dp/dt_{max}, and -dp/dt_{max} of hearts were increased significantly after treatment with simvastatin 3, 10, and 30 µmol/L. In simvastatin-treated isolated hearts, the levels of mRNA expression of SERCA and RyR2 were elevated compared with the control (*P*<0.05), while the mRNA expression of PLB did not change. After the cultured neonatal rat ventricular cardiomyocytes were incubated with 3, 10, 30, and 100 µmol/L simvastatin for 1 h, SERCA and RyR2 mRNA expressions of cardiomyocytes rose, but there was no alteration in protein expressions. However, with the elongation of simvastatin treatment to 24 h, the protein expression of SERCA and RyR2 were also elevated. Additionally, simvastatin (1–30 µmol/L) had no influence on cell viability of cultured cardiac myocytes, but simvastatin 100 µmol/L inhibited the cell viability. **Conclusion:** Simvastatin improved cardiac performance accompanied by the elevation of SERCA and RyR2 gene and protein expression.

Introduction

There is evidence that early initiation of statins, HMG-CoA reductase inhibitors, in patients is associated with markedly reduced fatal or non-fatal myocardial infarction and the mortality of cardiovascular event. Scandinavian Simvastatin Survival Study (4S) and Heart Protect Study (HPS) test have demonstrated that simvastatin could decrease the incidence of ischemic stroke, myocardial infarction, and the mortality of severe cardiovascular events in atherosclerotic and hypercholesterolemic patients^[1,2]. However, it is unclear

whether treatment with simvastatin would influence cardiac function.

It is well known that Ca²⁺ plays a central role in excitation-contraction coupling of myocardium. Intracellular Ca²⁺ ([Ca²⁺]_i) is from both of release of Ca²⁺ from intracellular Ca²⁺ stores and influx of extracellular Ca²⁺ across the plasma membrane. Several main proteins in sarcoplasmic reticulum (SR), such as SERCA and RyR2, are involved in the release, uptake, and storage of cardiac muscle Ca²⁺. Contraction is mediated through the release of Ca²⁺ from the SR by IP₃R (Ca²⁺ pool sensitive to IP₃) and RyR (Ca²⁺ pool insensitive to

IP₃), while relaxation involves the active re-uptake of Ca²⁺ into the SR lumen by sarcoplasmic reticulum Ca²⁺-ATPase (SERCA). In cardiac muscle, the SERCA activity is under reversible regulation by phospholamban (PLB).

As previous studies revealed, simvastatin induced an increase in [Ca²⁺]_i through two different pathways (*ie* the Ca²⁺ release from intracellular stores sensitive to thapsigargin and ryanodine and the Ca²⁺ influx from extracellular solution in endothelial cells^[3,4], L6 rat myoblasts^[5], or cultured cardiomyocytes^[6]). In some pathophysiological conditions, statins can prevent Ca²⁺ overload. For example, liposoluble HMG-CoA reductase inhibitors could markedly inhibit [Ca²⁺]_i induced by angiotensin II, LPC, and noradrenaline^[7-9]. Atrovastatin prevented the enhanced uptake of Ca²⁺ by sarcoplasmic reticulum (SR) and non-SR Ca²⁺ stores in diabetic dyslipidemic pigs^[10]. However, it is still unclear whether simvastatin can induce the alteration of expression of SERCA, PLB, and RyR2. Thus, the present study was designed to evaluate the effect of simvastatin on cardiac contractile function and gene and protein expression of SR calcium regulatory proteins, such as SERCA, PLB, and RyR2, which are related with the alteration of [Ca²⁺]_i.

Materials and methods

Drugs Simvastatin (gifted by Merck Sharp & Dohme, Hertfordshire, UK), a lactone prodrug, was diluted in 0.5 mL of 100% ethanol, mixed with 0.75 mL of 0.1 mol/L NaOH, heated at 50 °C for 2 h, neutralized with 0.1 mol/L HCl to pH 7.2, adjusted with deionized water to a final concentration of 5 mmol/L, sterilized by filtration, and stored in aliquots at -20 °C^[11]. Other main reagents in this experiment include: Trizol (Invitrogen, CA, USA); MMLV and pUC19 DNA/*Msp*I (HpaII) Marker (MBI Fermentas, Vilnius, Lithuania); *Taq* plus DNA polymerase and primers (Sangon, Shanghai, China); DMEM (Gibco, Invitrogen); trypsin 1:250 (Amresco, Solon OH, USA); collagenase I (Sigma, St Louis, MO, USA); 5-bromo-2-deoxyuridine (Sigma); fetal bovine serum (Hangzhou-Sijiqing Biological Engineering Materials Co Ltd, China); rabbit anti-rat myosin heavy chain antibody (Novocastia Lab Ltd, USA); FITC-conjugated goat anti-rabbit IgG (Amersham, Buckinghamshire, UK); monoclonal mouse antibody to SERCA, PLB and RyR2 (ABR corporation); secondary anti-goat antibody (Beijing Zhongshan Biotechnology, Beijing, China); MTT (Sigma); EZ-ECL Chemiluminescence Detection Kit for HRP (Biological Industries, Haemek, Israel).

Animals Male Sprague-Dawley (SD) rats (240–270 g) and 1–3 d old SD rats were purchased from the Experimental

Animal Center, Chinese Academy of Sciences (Shanghai, China) and all procedures in our experiments were approved by the Animal Care and Use Committee of Zhejiang University.

Isolated heart perfusion Rats were anesthetized with sodium pentobarbital (60 mg/kg), then the hearts were excised and perfused in a non-recirculating Langendorff apparatus with modified Krebs-Henseleit (KH) solution (in mmol/L: NaCl 118, KCl 4.7, CaCl₂ 1.5, KH₂PO₄ 1.2, MgSO₄ 1.2, NaHCO₃ 25.2, and glucose 11.1, pH 7.4). The coronary perfusion pressure was 100 mmHg and KH solution was bubbled with 95% O₂:5% CO₂ at 37 °C. A water-filled latex balloon-tipped catheter was inserted into the left ventricle via the left atrium and connected to a computer coupled with MedLab software (Nanjing MedEase Science & Technology Co Ltd, China) through a pressure transducer. The volume of the balloon was adjusted to a left ventricular end-diastolic pressure of 6–8 mmHg during the initial equilibration, then remained constant throughout the experiment. Left ventricular developed pressure (LVDP) and the maximum rate of intraventricular pressure development and relaxation ($\pm dp/dt_{\max}$) were measured during perfusion.

All hearts were equilibrated for 15 min for baseline measurements, and were then subjected to 60 min of reperfusion with or without simvastatin at 1, 3, 10, 30, or 100 μmol/L. After perfusion, the hearts were removed with the right ventricle and connective tissues, freeze-clamped into liquid nitrogen, then stored at -80 °C.

Cell culture Primary cultures of neonatal rat ventricular cardiomyocytes from 1–3 d old SD rats were performed as described previously^[12]. Briefly, the ventricle was dissociated with the admixture of 0.25% trypsin and 0.1% collagenase I, then cell suspensions were washed with DMEM supplemented with 20% fetal bovine serum (FBS) and centrifuged at 1000 rpm for 6 min. The centrifuged cells were then resuspended in 10% FBS containing DMEM. These cells were preplated for 1 h in order that nonmyocyte readily attached to the bottom of the culture dishes. Unattached cells, which were enriched with cardiac myocytes, were plated onto 6-well dishes at a density of 0.5×10⁶ cells/well. BrdU (0.01 mmol/L) was added during the first 72 h to prevent proliferation of nonmyocytes^[12] (Figure 1).

Myocardial cells were incubated in DMEM containing non-bovine serum albumin for 24 h prior to respective simvastatin (1, 3, 10, 30, or 100 μmol/L) treatment for 1 h or 24 h.

RT-PCR Total RNA was extracted using TRIZOL reagent from rat heart tissues and cultured neonatal rat ventricular cardiomyocytes according to the manufacturer's instruction. First-strand cDNA was generated by adding 2 μg total RNA,

Figure 1. The identification of cultured neonatal rat ventricular cardiomyocytes. Confocal micrographs of the cultured cardiomyocytes. Immunofluorescence with FITC labeled anti-rat Myosin Heavy Chain (slow) antibody (red). (A) cultured neonatal rat ventricular cardiomyocytes; (B) non-cardiac cell from neonatal rat heart ($\times 100$).

5 μL of 5 \times reverse transcriptase buffer, 3 μL (0.5 $\mu\text{g}/\mu\text{L}$) randomhexamer primers, 2 μL (10 mmol/L) dNTP, 1 μL (200 U/ μL) M-MLV reverse transcriptase and autoclaved water in a final volume of 20 μL . Reverse transcription was carried out at 42 $^{\circ}\text{C}$ for 90 min, followed by heat inactivation at 70 $^{\circ}\text{C}$ for 5 min, terminated at 70 $^{\circ}\text{C}$ for 10 min. Then, PCR was run in a DNA thermal cycler (PTC150 Thermo-Cycler, MJ Research, Inc, Waltham, MA, USA). The primers were up primer 5'-AAG-CAG-TTC-ATC-CGC-TAC-CT-3' and down primer 5'-AGA-CCA-TCC-GTC-ACC-AGA-TT-3' for SERCA; up primer 5'-TAC-CTT-ACT-CGC-TCG-GCT-ATC -3' and down primer 5'-CAG-AAG-CAT-CAC-AAT-GAT-GCA-G-3' for PLB; and up primer 5'-ACT-GCT -AAA-GTG-ACC-AAC-AG-3' and down primer 5'-TTG-CAT-CGC-TGA-AAT-CTA-GT-3' for RyR2. The β -actin gene (up primer 5'-GAG-ACC-TTC-AAC-ACC-CCA-GCC-3', down primer 5'-GGC-CAT-CTC-TTG-CTC-GAA-GTC-3') was used as control. *Taq* poly-

merase 1.5 units, 2 μL cDNA, 1 μL (10 $\mu\text{mol}/\text{L}$) each primer, 1 μL (10 $\mu\text{mol}/\text{L}$) β -actin, 1 μL of 10 mmol/L dNTP solution, 2.5 μL PCR buffer solution and ultrapure autoclaved water were used to reach a total reaction volume of 25 μL . The cycling parameters were as follows: 5 min of 1 cycle at 94 $^{\circ}\text{C}$, 45 s at 94 $^{\circ}\text{C}$, 1 min at 57 $^{\circ}\text{C}$, and 1 min of 23 cycles at 72 $^{\circ}\text{C}$ (SERCA); 30 sec at 94 $^{\circ}\text{C}$, 1 min at 55 $^{\circ}\text{C}$, and 1 min of 24 cycles at 72 $^{\circ}\text{C}$ (PLB); 45 s at 94 $^{\circ}\text{C}$, 1 min at 57 $^{\circ}\text{C}$, and 1 min of 27 cycles at 72 $^{\circ}\text{C}$ (RyR2); and 10 min of 1 cycle at 72 $^{\circ}\text{C}$. The gray scales of absorbance in goal gene and β -actin gene were determined and assayed with Kodak digital science Electrophoresis Documentation and Analysis System 120.

Western blot Heart tissue 50 mg was homogenized in 1 mL modified tonic sucrose^[13] (0.3 mol/L sucrose, 10 mmol/L imidazole, 10 mmol/L sodium metabisulfite, 1 mmol/L DTT, 0.3 mmol/L PMSF) and centrifuged at 13000 $\times g$ at 4 $^{\circ}\text{C}$ for 15 min. Cultured cells were scraped in ice-cold RIPA solubilization buffer consisting of 50 mmol/L Tris-HCl (pH 7.4), 150 mmol/L NaF, 1% sodium deoxycholate, 1% Nodinet-P40, 0.1% sodium dodecylsulfate, 2.5 mmol/L pretreated sodium orthovanadate, 125 $\mu\text{mol}/\text{L}$ phenylarsine oxide, and 2 mmol/L phenylmethyl sulphonyl fluoride^[14] and centrifuged at 14 000 $\times g$ for 30 min. The protein concentration was determined by the Brandford method.

Aliquots containing 24 μg of protein for SERCA or 10 μg of protein for PLB were loaded on the SDS-polyacrylamide gel and separated by electrophoresis (6% or 10% acrylamide separating gel, respectively, for 30 min). The separated proteins were electrophoretically transferred onto nitrocellulose membranes (Amersham) at 200 mA at 4 $^{\circ}\text{C}$ for 90 min in a buffer containing 25 mmol/L Tris base, 192 mmol/L glycine, and 20% methanol by using the Bio-Rad Trans-Blot electrophoretic transfer system (Bio-Rad). Aliquots of 6 μg RyR2 SDS-digested homogenate protein were loaded on the SDS-polyacrylamide gel, separated by electrophoresis (4% acrylamide stacking gel and 6% acrylamide separating gel), and were electrophoretically transferred onto polyvinylidene difluoride membranes (Bio-Rad) at 250 mA at 4 $^{\circ}\text{C}$ for 3 h and then at 50 V for about 12 h. These membranes were incubated at 4 $^{\circ}\text{C}$ overnight with mouse-anti-SERCA, mouse-anti-PLB, or mouse-anti-ryanodine receptor at 1:1000 dilution in 5% Carnation instant milk/TBS. After incubation with a secondary anti-goat antibody at a 1:500 dilution in 5% Carnation instant milk-TBS-Tween 20, the blot was developed using enhanced chemiluminescence according to the manual (Beit Haemek LTD) and exposed to X-ray film^[11].

MTT assay Cells were incubated in the absence or presence of simvastatin for 24 h, and then the cytotoxic effect was assessed using MTT assay method. Each well of plates

was added with 10 μL MTT (5 g/L) per 100 μL of medium, and were incubated at 37 $^{\circ}\text{C}$ for 4 h. Then, the medium in each well was replaced with 100 μL dimethylsulfoxide and the plates were incubated for 5–10 min at room temperature for color development. Finally, 96-well of plates was read by enzyme-linked immunosorbent assay (ELISA) reader (570 nm) to get the absorbance density values^[15].

Statistics Data were presented as mean \pm SD. To correct for variability in basal values, changes in left ventricular development pression, $+dp/dt_{\text{max}}$ and $-dp/dt_{\text{max}}$ were calculated as a percent of the initial basal values for each heart. Various kinds of indexes between the control group and simvastatin-treated groups were analyzed by one way ANOVA with SPSS 10.0 software. $P < 0.05$ was considered the threshold for statistical significance between the control group and the experimental groups.

Results

Effect of simvastatin on cardiac performance To determine whether simvastatin exerted any direct cardiodynamic effect, the isolated rat hearts were initially perfused without or with simvastatin for 60 min in this experiment. The results showed that simvastatin 1 $\mu\text{mol/L}$ had no impact on cardiac performance in the isolated rat hearts compared with control (LVDP: $68.9\% \pm 17.0\%$ vs $71.7\% \pm 10.6\%$, $P > 0.05$; $+dp/dt_{\text{max}}$: $69.3\% \pm 5.3\%$ vs $72.1\% \pm 7.5\%$, $P > 0.05$; $-dp/dt_{\text{max}}$: $67.3\% \pm 5.5\%$ vs $68.5\% \pm 6.1\%$, $P > 0.05$). However, simvastatin 3, 10, and 30 $\mu\text{mol/L}$ significantly increased the levels of LVDP and $\pm dp/dt_{\text{max}}$ of rat hearts compared with those of control (LVDP: $95.8\% \pm 17.4\%$, $85.9\% \pm 8.6\%$, $96.9\% \pm 7.0\%$ vs $71.7\% \pm 10.6\%$, $P < 0.01, 0.05, 0.01$; $+dp/dt_{\text{max}}$: $89.5\% \pm 4.4\%$, $97.2\% \pm 10.8\%$, $89.8\% \pm 6.7\%$ vs $72.1\% \pm 7.5\%$, $P < 0.01$ all; $-dp/dt_{\text{max}}$: $82.9\% \pm 4.7\%$, $88.6\% \pm 11.0\%$, $79.6\% \pm 6.6\%$ vs $68.5\% \pm 6.1\%$, $P < 0.01$ all, respectively).

When 100 $\mu\text{mol/L}$ simvastatin was applied in isolated rat hearts, sudden arrest of the isolated heart, following transient increased contractile performance, occurred. The scope of sudden death time interval was from 14 to 20 min. Thus, the measurement of LVDP% and $\pm dp/dt_{\text{max}}$ % were recorded every 2 min until 14 min (Figure 2).

Gene expression of SR protein in isolated rat hearts and cultured cardiomyocytes After being treated with simvastatin at different concentrations (3, 10, and 30 $\mu\text{mol/L}$), SERCA and RyR2 mRNA levels of isolated heart tissue were increased. However, no alteration was found in heart tissue after simvastatin 1 or 100 $\mu\text{mol/L}$ treatment. There was no difference in PLB mRNA levels of rat hearts between the control group and simvastatin-treatment groups (Figure 3).

Simvastatin 3–100 $\mu\text{mol/L}$ had no influence on PLB gene

Figure 2. Alterations of LVDP (A), $+dp/dt_{\text{max}}$ (B), and $-dp/dt_{\text{max}}$ (C) of the isolated hearts after simvastatin 100 $\mu\text{mol/L}$ treatment. The rat hearts received 14-min exposure to Krebs-Henseleit solution with simvastatin after 15-min stabilization. $n=8$ in control group. $n=5$ in simvastatin group. Mean \pm SD. ^b $P < 0.05$, ^c $P < 0.01$ vs the baseline.

expression of neonatal rat ventricular cardiomyocytes, but markedly increased SERCA and RyR2 gene expression (Figure 4).

Additionally, sequencing analysis showed 100% coincidence rates of SERCA, PLB, and RyR2 cDNA sequences, which came from the final products of RT-PCR compared with those in GeneBank, indicating that the amplified fractions had high specificity.

Expression of SR protein in isolated rat hearts and cultured cardiomyocytes No alteration in the protein levels of SERCA, PLB, and RyR2 was found after simvastatin 1, 3, 10, 30, or 100 $\mu\text{mol/L}$ treatment (Figure 5).

In order to test whether the changes in protein levels occurred with the elongation of simvastatin treatment, we supplied cultured cardiomyocytes with different concentration simvastatin for 1 h and 24 h. The results showed that incubation with simvastatin for 1 h in the cultured cardiomyocytes had no effect on the protein expression of

Figure 3. Alterations of SERCA (A), PLB (B), RyR2 mRNA (C) expression treated with simvastatin for 1 h in heart tissue. The expression of SERCA and RyR2 increased after simvastatin 3, 10, and 30 μ mol/L treatment. Lane 1: DNA size marker; Lane 2: control group; Lane 3: simvastatin 1 μ mol/L; Lane 4: simvastatin 3 μ mol/L; Lane 5: simvastatin 10 μ mol/L; Lane 6: simvastatin 30 μ mol/L; Lane 7: simvastatin 100 μ mol/L. β -Actin was used as an internal standard. $n=8$ separate hearts for control group and 1–30 μ mol/L simvastatin group. $n=5$ separate hearts in 100 μ mol/L simvastatin-treatment group. Mean \pm SD. ^b $P<0.05$ vs the corresponding control (Lane 2).

SR calcium regulatory protein, whereas longer period (24 h) of simvastatin 3–100 μ mol/L treatment increased SERCA and RyR2 protein level, except PLB protein levels of cardiomyocytes (Figure 6).

Effect of simvastatin on the cytotoxicity in cultured neonatal rat ventricular cardiomyocytes Simvastatin 1–30 μ mol/L did not induce alteration of mitochondrial activity, whereas simvastatin 100 μ mol/L produced a rapid drop of mitochondrial activity (Table 1).

Discussion

It is well known that simvastatin can produce some

Table 1. Effects of simvastatin (1–100 μ mol/L) on neonatal cultured cardiomyocytes after a 24-h incubation. $n=8$ in each group. Mean \pm SD. ^c $P<0.01$ vs control.

Group	Concentration/ μ mol·L ⁻¹	OD _{570 nm}
Control		1.19 \pm 0.13
Simvastatin	1	1.27 \pm 0.07
	3	1.16 \pm 0.14
	10	1.18 \pm 0.07
	30	1.12 \pm 0.06
	100	0.78 \pm 0.04 ^c

Figure 4. Effect of simvastatin on SERCA (A), PLB (B), and RyR2 (C) gene expression in cultured primary ventricular myocytes for 1 h. Enhanced expression of SERCA and RyR2 mRNA was observed after simvastatin 3, 10, 30, and 100 $\mu\text{mol/L}$ treatment. beneficial effects independent of the lowering cholesterol level^[16-19], so the direct pharmacological effect of simvastatin on the initial management and prevention of the disease are paid more attention. Our study was performed to identify whether simvastatin induced intrinsic alteration of cardiomyocyte contraction and related calcium regulatory protein, which might explain the effect of simvastatin on cardiac performance.

The present study demonstrated that simvastatin treatment (3, 10, and 30 $\mu\text{mol/L}$) resulted in the increase of LVDP, $+dp/dt_{\text{max}}$, and $-dp/dt_{\text{max}}$ in isolated perfused hearts, while simvastatin 100 $\mu\text{mol/L}$ induced sudden heart related death. It has been shown that an increase of nitrogen monoxide (NO) and a decrease of ubiquinone and oxygen-derived free

radicals were involved in the possible protective mechanism in isolated rat hearts^[20-22], while impairment of mitochondria was associated with injury mechanism in ischemic rat hearts^[23]. Previous studies also reported^[6] that under normoxic conditions simvastatin caused an increase in $[\text{Ca}^{2+}]_i$, which is the key event in excitation-contraction coupling in cardiac myocytes. Therefore, the improvement of cardiac performance in isolated rat hearts during 1 h of perfusion can be explained by NO elevation, decrease of oxygen-derived free radicals, and an increase of $[\text{Ca}^{2+}]_i$ and so on.

Using RT-PCR assay, we found the elevation of RyR2 and SERCA mRNA in isolated hearts treated with simvastatin for 1 h and not in those treated with vehicle. Similar to these results, in neonatal cultured cardiac myocytes, the gene

Figure 5. Western blot of PLB (A), SERCA (B), and RyR2 (C) protein levels in isolated heart after 1 h of simvastatin treatment. No alteration of the protein levels was shown after simvastatin treatment at different concentrations. Bars represent cumulative data of Mean \pm SD from eight hearts (1–30 μ mol/L simvastatin groups) and five hearts (100 μ mol/L simvastatin group). ^b $P < 0.05$ vs control.

levels of RyR2 and SERCA were both elevated after a 1-h incubation. As intracellular second messenger of the organism information transmission, Ca^{2+} is involved in some gene expression. Even transient calcium transport elevation can induce mRNA transcription for a long time. Therefore, the results in our experiment suggested that simvastatin-induced SERCA and RyR2 expression were involved in the mechanisms mentioned above. However, a 1-h treatment with

simvastatin (1, 3, 10, 30, or 100 μ mol/L) in the isolated hearts and cultured cardiomyocytes did not influence the protein levels of SERCA, PLB, or RyR2, while a 24-h incubation of simvastatin in cultured cardiomyocytes increased SERCA and RyR2 protein level, except PLB protein. It has been shown that several main proteins in SR, such as SERCA and RyR2, are implicated in the release, uptake, and storage of calcium in cardiac muscle. Contraction is mediated through the release of Ca^{2+} from the SR by ryanodine receptor, while relaxation involves the active re-uptake of Ca^{2+} into the SR lumen by SERCA. The SERCA activity is under reversible regulation by PLB^[24]. Thereby, it is possible that although the expression of RyR2, SERCA, and PLB were not directly correlated with the cardiodynamic increase of isolated perfused hearts, simvastatin-induced SERCA and RyR2 expression may influence cardiac performance during extended periods of perfusion. Thus, there is reason to believe that alteration of gene and protein expression of SERCA and RyR2 might be a prophetic index of cardioprotective effect of simvastatin. Furthermore, the effect of simvastatin on SR calcium regulation protein gave a clue that the molecular biological mechanism could be a new approach to explain the alteration of cardiac performance affected by simvastatin in future.

In the meantime, the present study discovered that elevation of SERCA and RyR2 mRNA were shown in cultured cardiomyocytes, but not found in isolated rat hearts in the presence of simvastatin 100 μ mol/L. We suspect that the result was due to insufficient expression time due to the cardiac sudden death in isolated rat hearts. The MTT assay, as an index of cell viability and cell growth^[25,26], revealed that the survival rate of cardiac cells was markedly reduced with simvastatin 100 μ mol/L treatment, while cell viability was not influenced by simvastatin 1, 3, 10, 30 μ mol/L. Perhaps the toxic effect of overdose simvastatin promoted decrease of cardiac cells, which may indirectly explain the sudden arrest of isolated hearts with simvastatin 100 μ mol/L.

Based on our research, it is concluded that simvastatin, at reasonable pharmacological concentration, would enhance cardiac performance concomitant with gene expression increase of calcium regulatory protein. Meanwhile, it should be noted that overdose of simvastatin (100 μ mol/L) can produce a deterioration effect on hearts.

Abstract

Aim: To examine if cadherins are expressed constitutively in human bone marrow stromal cells (hBMSC) and investigate the regulation of cadherin expression by various osteotropic hormones and local factors. **Methods:** Cadherin expression was examined in first passaged (secondary) hBMSC as well as in the conditionally-immortalized human osteoprogenitor cell line (hOP-7). Using a monoclonal antibody (MoAb C-1821) to a cytoplasmic domain common to all known cadherins (pan-cadherin MoAb), cadherins were immunolocalized in first passaged hBMSC as well as in hOP-7 cells. In addition, intense immunostaining for cadherin expression was associated with alkaline phosphatase (ALP) in nodules formed in the high density cultures of hOP-7 cells. Human E-cadherin (HECD) was specifically detected by Western blotting in extracts of untreated hBMSC using an anti-HECD MoAb 004FD. **Results:** Differential regulation of cadherin expression by various osteotropic hormones and local factors (parathyroid hormone, dexamethasone, estradiol, prostaglandin E₂, basic fibroblast growth factor, and tumor necrosis factor- β) was also observed. In addition, blocking cadherins with the MoAb C-1821 increased basal ALP activity and had an additive effect on 1, 25(OH)₂D₃-induced ALP activity. **Conclusion:** Cadherins are expressed in human osteoprogenitor cells and are involved in the osteogenic differentiation. The differential modulation of cadherin expression by osteotropic agents indicates that these agents may regulate osteoprogenitor cells through different cadherins and these cadherins may play different roles.

Introduction

Cell adhesion molecules (CAM) are believed to play a key role in morphogenesis by modulating cellular proliferation and differentiation through cell-cell interaction and/or cell-matrix interactions^[1]. In bones, the differentiation of human bone marrow stromal cells (hBMSC) into mature osteoblasts is essential for bone formation^[2]. However, the mechanisms by which CAM modulate this process are still poorly understood. Cadherins, a family of transmembrane glycoproteins, are calcium-dependent homophilic cell-cell adhesion molecules, which have been shown to play an important role in the differentiation of a wide variety of cells and tissues^[3].

Cadherins are divided into subclasses, all of which share a common basic structure. Four subclasses have been well characterized at the molecular level and they have about 50% amino acid sequence identity. These include E-cadherin, P-cadherin, and N-cadherin^[3]. The extent of conservation varies depending on the region of the molecule with the cytoplasmic domain being the most conserved. A monoclonal antibody to this cytoplasmic domain designated pan-cadherin MoAb was produced, which can be used to recognize novel cadherins in a variety of cells and tissues and displays a broad interspecies cross-reactivity^[4]. The evidence that cadherin-mediated interactions can actually modulate cell differentiation has been accumulated^[5].

For example, N-cadherin has been demonstrated to be present in the limb mesenchyme in a development-specific manner *in vivo* and *in vitro*. In addition, functional N-cadherin is necessary for limb mesenchymal cells to undergo condensation and progress through chondrogenesis *in vitro* and *in vivo*^[6].

Cadherin has recently been found in the cells of osteoblastic lineage^[7]. E-cadherin is expressed by the UMR 106-H5 rat osteoblastic osteosarcoma cells as well as by the mouse calvarial MC3T3-E1 cells, and its expression is regulated by PTH in the UMR 106-H5 cells^[8]. E-cadherin also plays a role in the generation of multinucleated osteoclasts by mediating fusion of mononuclear cells in murine marrow^[9]. In addition, specific osteoblast-like cadherin (OB-cadherin) has been found to be expressed in osteoblasts^[10]. However, it remains unclear whether these or other ubiquitous cell adhesion molecules are involved in the differentiation of human osteoblast precursors, which are derived mainly from hBMSC^[2]. For better understanding of osteoblast lineage differentiation, this study was to examine the cadherins expression pattern and their regulation by osteotropic agents including systemic hormones and local growth factors in hBMSC.

Materials and methods

Antibodies and chemicals Mouse monoclonal antibody to pan-cadherins (MoAb C-1821) (mouse IgG₁ isotype) was purchased from Sigma Chemical Co (St Louis, USA); Mouse monoclonal antibody to human E-cadherin (MoAb 004FD) (mouse IgG₁ isotype) was purchased from R & D Systems Europe Ltd (Oxon, UK). Recombinant human (rh)-tumor necrosis factor (TGF)- β was a gift from Genentech Inc (CA, USA). Recombinant human basic fibroblast growth factor (bFGF) was a gift from Schering Research Laboratories (Berlin, Germany). Stock concentration: 1 mg/L and it was diluted into 1 μ g/L in PBS containing 0.1% BSA and aliquots of this was stored at -70 °C. 1,25(OH)₂D₃ was a gift from Hoffmann-La Roche, Inc (Nutley, NJ, USA). Dexamethasone (Dex), parathyroid hormone (PTH) and estradiol (E₂) were purchased from Sigma Chemical Co. Other chemicals were purchased from Sigma Chemical Co.

Cultures of human bone marrow stromal cells Primary cultures of hBMSC were described previously^[11]. Briefly, when the cells became confluent (3-4 weeks after seeding) in the primary cultures, they were subcultured onto glass coverslips, Petri dishes, or into flasks as necessary. At confluence, first passage cells were treated with 1,25(OH)₂D₃ (50 nmol/L), PTH (100 nmol/L), E₂ (10 nmol/L), Dex (10 nmol/L),

prostaglandin E₂ (PGE₂ 10 nmol/L), bFGF (1 and 10 μ g/L), and TGF- β (1 and 10 μ g/L) for 7 d. The doses for the tested agents were selected based on our previous works and others were used for examining osteogenic differentiation of hBMSC^[2,7,12-18]. The cell lysates were extracted with RIPA buffer containing 1% NP-40, 1% Triton X-100, 2 mmol/L CaCl₂, 0.5% NaCl, 0.1% SDS in PBS with fresh protease inhibitors, including phenyl methyl sulfonyl fluoride (PMSF), pepstatin, 1,10-phenanthroline and E-64.

Cultures of conditionally immortalized hBMSC hBMSC were transfected with a viral vector coding a temperature-sensitive mutant of the SV40 large T antigen. The growth characteristic of this immortalized hBMSC is controlled by this temperature-sensitive large T antigen. The large antigen expression was activated at 33 °C and this allowed the cells to proliferate, producing a large population of homogeneous hBMSC. While, the large T antigen was disabled at 39 °C allowing these immortalized hBMSC to undergo osteogenic differentiation. One of nine clones obtained, hOP-7, was well characterized for osteogenic differentiation. These cells were induced to differentiate into osteoblasts by Dex and 1,25(OH)₂D₃ at 39 °C. Therefore, this cell line is thought to be a good model for the study of osteogenic differentiation^[19].

hOP-7 cells were seeded onto LabTek chamber slides and maintained for 1-2 d at 33 °C before being switched to 39 °C to allow osteogenic differentiation. In some cases, cultures were plated out initially at a higher density to allow formation of nodules. These were also maintained at 33 °C and thereafter switched to 39 °C for a further 5 d.

Immunolocalization of cadherin expression Cells on coverslips or on chamber slides fixed with 4% paraformaldehyde were incubated with 5% goat serum for 30 min to block non-specific binding, followed by incubation with a murine monoclonal anti-pan-cadherin antibody (MoAb C-1821) (diluted 1:200 or 1:500) or a mouse monoclonal antibody to human E-cadherin (MoAb 004FD) (diluted 1:200) for 1 h at room temperature. The mouse calvarial cell line MC3T3-E1 was used as a positive control for pan-cadherin immunostaining^[8], and MDCK cells for E-cadherin^[20]. Mouse ascites fluid and PBS were used to substitute primary antibodies as negative controls. Then, these cells were washed with high salt buffer for 10 min, and twice with TBS for 15 min each. Thereafter, these cells were incubated with biotinylated secondary antibody for 45 min at room temperature and then washed as before. Immunoreactivity was detected using the Vectastain ABC-AP kit. Incubation was for 45 min at room temperature, followed by staining for alkaline phosphatase in the presence of 1 mmol/L levamisole, to block endogenous

alkaline phosphatase. The cells were washed again with TBS and the nuclei was stained with DAPI. After the coverslips and chamber slides were mounted with Kaiser's glycerol jelly, immunostaining was visualized under fluorescence-microscopy using a filter appropriate for rhodamine and another for ultraviolet, and then photographed. Cadherin antigenicity appears as a red coloration, while the nuclei are blue.

Histological staining for alkaline phosphatase (ALP) and biochemical determination of its activity in cultured hBMSC

Histochemical staining of ALP At the end of the culture period, cells on chamber slides were washed twice with PBS and fixed with 4% paraformaldehyde at 4 °C for 30 min, washed three times with distilled water and then air-dried for 10 min. The cells were then stained for ALP for 30 min with fresh naphthol AS-MX phosphatase solution (0.2 g/L) containing fast red violet B salt (0.42 g/L) in 100 mmol/L Tris-HCl (pH 0.9) at room temperature and then photographed. Under these conditions, ALP-positive cells were stained pink or red.

Biochemical determination of ALP activity At the end of the incubation period, the culture medium was removed from wells, and the cell layers were washed three times with ice cold PBS (pH 7.4). The cells were scraped off the plates into 300–500 μ L ice-cold 0.1% Triton-X100 using a 'rubber policeman'. The cell lysates were transferred into plastic tubes (LP4) on ice and subjected to mild sonication (3 \times 5 s bursts, peak amplitude 10 μ m at a frequency of 20 kHz) to completely solubilize these cells. The cell lysates were stored at -20 °C until they were assayed. ALP activity was measured using 2 mmol/L para-nitrophenyl phosphate (*p*-NPP) in assay buffer (0.1 mol/L diethanolamine+1 mmol/L MgCl₂+2 mmol *p*-NPP, pH 10.5) at 37 °C for 10–60 min. Protein content was determined using the Bio-Rad protein assay kit using BSA as a standard according to the manufacturer's manual. ALP activity was expressed as μ mol \cdot h⁻¹ \cdot g⁻¹ protein.

Western blot analysis At the end of incubation with the various hormones and/or growth factors, media were removed from Petri dishes and cells were washed with PBS at room temperature, after which the cells were scraped into RIPA buffer (PBS, 1% NP40, 0.5% sodium deoxycholate, 0.1% SDS, 2 mmol/L CaCl₂) containing fresh protease inhibitors on ice. Cell lysates were then passed repeatedly through a 21-gauge needle, incubated for 30 min on ice, and then centrifuged for 20 min at 4 °C. Thereafter, the supernatants were harvested and the protein content was determined using the Bio-Rad protein assay.

Protein 10 μ g was loaded into each lane, separated on a

7.5% SDS polyacrylamide gel and transferred onto nitrocellulose membrane in transblotting buffer containing 20 mmol/L Tris, 150 mmol/L glycine, and 20% methanol (pH 8.0). The membranes were blocked with blocking buffer consisting of 1% non-fat dry milk, 1% BSA, 0.05% Tween-20 in TBS buffer for 30 min and immunoblotted with the MoAb C-1821 diluted 1:3000 in blocking solution (Blotto B) for 45 min at room temperature. Thereafter, the membranes were washed three times, incubated with biotin-conjugated rabbit anti-mouse Ig G for 45 min, followed by incubation with streptavidin-conjugated horseradish peroxidase (HRP) for 30 min.

At the end of this incubation, the membranes were washed again three times and incubated with Amersham enhanced chemiluminescence (ECL) reagents for exactly 1 min. Excess ECL reagents were removed and the membranes were sealed in plastic wrap and exposed to ECL hyperfilms in a darkroom for 30 s. Then, the films were developed as for autoradiograph. Finally, the intensity of the two major cadherin bands on the hyperfilms was analyzed by scanning laser densitometry (discovery pDi densitometer, Pharmacia, Uppsala, Sweden). The intensity of control bands is expressed as 100%, and the others are expressed as percentage of respective control bands.

Membranes were also stripped of bound antibodies and re-probed by submerging them in stripping buffer (100 mmol/L 2-mercaptoethanol, 2% SDS, 62.5 mmol/L Tris-HCl, pH 6.7) and incubating at 50 °C for 30 min with occasional agitation. Then, the membranes were washed twice with TBS-Tween-20 at room temperature for 10 min. Following this, the membranes were blocked in blocking solution for 1 h after which immunodetection of HECD was performed using MoAb 004FD as described previously.

Statistical analysis Results of representative experiments are presented except where otherwise indicated. Biochemical determinations of ALP were performed in triplicate or quadruplicate and specific enzyme activity were presented as mean \pm SEM.

Statistical significance of difference within experiments was assessed using one factor analysis of variance (one way ANOVA). Values of *P* refer to a comparison of measured activity with that of control.

Results

Detection of cadherins expression in human bone marrow stromal cells Immunolocalization was performed to determine whether human bone-derived cells expressed cadherins using MoAb C-1821 in first passaged hBMSC and in hOP-7. Under fluorescence microscopy, there was no

staining for cadherins in the negative controls (such as mouse ascites fluid and PBS), while MC3T3-E1 cells were found to be stained for cadherin expression as a positive control (Figure 1B). Interestingly, strong cadherin expression was observed in first passaged hBMSC (Figure 1D) and hOP-7 (Figure 1F).

In the high-density cultures of hOP-7 cells, discrete nodules were formed and there were focal areas of intense

immunostaining for cadherins in these nodules. However, staining at the periphery of the nodules was much weaker than at the center of the nodules. In addition, there was positive staining for ALP in the center of these nodules, while sparse ALP staining at the periphery of the nodules. This suggests an association between the expression of cadherins and ALP (Figure 1G and H), in which a close interaction of cells at the center of the nodules stimulates osteo-

Figure 1. Expression of cadherins in MC3T3-E1 cells, hBMSCs, and hOP-7 cells. Cells cultured in coverslips or LabTek chamber slides were fixed with 4% paraformaldehyde, and immunolocalization was performed as described in 'Materials and methods'. In MC3T3 cells (A and B), hBMSC cells (C and D), and hOP-7 cells (E and F), an irrelevant isotype-matched antibody CB11 was used as control (A, C, and E) and cadherin expression was detected by MoAb C-1821 (B, D, and F). Associated expressions of ALP and cadherins were found in the nodules formed in the high density cultures of hOP-7 cell line. Histochemical staining for ALP (G) and immunolocalization of cadherin expression (H) using the MoAb C-1821 were carried out in these nodules. The green arrow points to the staining for cadherin expression and the red arrow indicates the ALP staining in a nodule. $\times 100$

blast differentiation. Human E-cadherin (HECD) expression was confirmed in the positive control cells, MDCK cells. However, HECD was not detectable by immunolocalization in hBMSC (Figure 2D). To clarify the expression of cadherins in these cells identified by immunolocalization as described above, Western blotting was performed using MoAb C-1821 in untreated hBMSC extracts and this revealed the presence of two bands (139.7 kDa and 118.6 kDa), associated with several small bands (Figure 3B).

After being stripped, the membranes previously used for detection of cadherins were immunoblotted again with mouse anti-human E-cadherin (MoAb 004FD). Although human E-cadherin was not detectable in hBMSC by immunocytochemistry using MoAb 004FD, it was demonstrated by Western blot using the same antibody (MoAb 004FD) and there was only one band with a M_r of approximately 118.6 kDa, which was corresponding to the major band detected using anti-pan-cadherin antibody and was different from that of cadherins (Figure 3D). This indicates that MoAb 004FD specifically recognizes human E-cadherin.

Figure 2. Expression of human E-cadherin in the kidney epithelium cell line MDCK (A and B) and lack of expression in hBMSCs (C and D). MDCK cells and hBMSCs cultured in coverslips were fixed with 4% paraformaldehyde, and immunolocalization was performed using anti-human E-cadherin MoAb 004FD. An irrelevant isotype-matched antibody CB11 was used as control (A and C) and anti-human E-cadherin MoAb 004FD was applied to detect human E-cadherin expression (B and D).

Figure 3. Detection of cadherin expression in hBMSCs by Western blot analysis. The cell layer was extracted with RIPA buffer and 10 μ g proteins/lane were separated by 7.5% SDS-PAGE, and immunoblotted with either MoAb C-1821 or control antibody. After detection of cadherins using the anti-pan-cadherins MoAb, the membranes (A and B) were stripped of bound antibodies with a stripping buffer, and then immunoblotted for human E-cadherin expression. An irrelevant isotype-matched antibody CB11, which recognizes a fragment of denatured type II collagen, was used as a negative control (A and C). The anti-pan-cadherin MoAb C-1821 was applied to blot for cadherin expression (B) and the anti-human E-cadherin MoAb 004FD for human E-cadherin expression (D). Lane 1: molecular weight marker and Lane 2: cell lysates from untreated first passaged hBMSC.

Regulation of cadherins expression by osteotropic hormones and local growth factors hBMSC were treated with different agents for 7 d and the cell lysates were examined by Western blot. Using the ECL system, two major bands of cadherins with M_r 139.7 kDa and 118.6 kDa were examined using MoAb C-1821. These two bands were diminished in the 50 nmol/L $1,25(\text{OH})_2\text{D}_3$ -treated cellular extracts, in comparison to the control (Figure 4A). Similarly, in Dex-treated-cellular extracts, the two major bands were also abolished (Figure 4B). This suggests that $1,25(\text{OH})_2\text{D}_3$ and Dex inhibit cadherin expression. With regards to 10 nmol/L PGE_2 , band a (M_r about 139.7 kDa) was inhibited, but band b (M_r about

118.6 kDa) was increased nearly 1.5-fold. The expression of cadherins was also found an increase by PTH, E_2 , bFGF, and TGF- β . All these agents increased band a more than band b in comparison to respective controls. PTH increased band a by more than 5-fold relative to the control and increased band b by only 1-fold. TGF- β enhanced band a by up to 3-fold and slightly stimulated band b. bFGF increased band a by up to 2-fold and also slightly enhanced band b (Figures 4C and D).

Effect of pan-cadherin MoAb on ALP activity To investigate a possible role of cadherins in the osteogenic differentiation of hBMSC, cadherins were blocked with MoAb C-

Figure 4. Regulation of cadherin expression by $1,25(\text{OH})_2\text{D}_3$, dexamethasone (Dex), prostaglandin E₂ (PGE_2), tumor necrosis factor (TGF)- β , basic fibroblast growth factor (bFGF), estradiol (E_2), and parathyroid hormone (PTH) in human bone marrow stromal cells. First passaged human bone marrow stromal cells were treated with $1,25(\text{OH})_2\text{D}_3$ (50 nmol/L) (A), dexamethasone (10 nmol/L), PGE_2 (10 nmol/L) (B), TGF- β (0.1 and 1 $\mu\text{g/L}$) (C), bFGF (1 and 10 $\mu\text{g/L}$), estradiol (10 nmol/L), PTH (100 nmol/L) (D) for 7 d. Two major bands of cadherins (a and b) were examined using MoAb C-1821.

1821 and ALP activity was examined. In these experiments, treatment of hBMSC with MoAb C-1821 for 48 h increased the level of ALP activity to about 125.9% of control ($P < 0.05$ vs control), and it also enhanced the effect of $1,25(\text{OH})_2\text{D}_3$ on ALP activity ($P < 0.05$ in experiment 1 and $P < 0.01$ in experiment 2, compared to $1,25(\text{OH})_2\text{D}_3$ -treated cells) (Figure 5).

Discussion

There is a repertoire of cadherins expressed in osteoblasts. There are several subclasses of cadherins previously reported in cells of the osteoblast lineage, including E-cadherin^[8], cadherin-4, cadherin-8, cadherin-11, protocadherin-43^[14], and specific osteoblast-cadherin (OB-cadherins)^[10]. In the present study, we demonstrated that cadherins were expressed in human osteoprogenitors. Cadherin expression was found to be associated with that of ALP in higher density cultures of hOP-7 cells. Furthermore, their expressions are regulated by osteotropic agents. These suggest that cadherins are involved in the process of osteogenic differentiation and some of the effects of these agents on bone are mediated, in part, via regulation of cadherins and possibly other cell adhesion molecules.

In the immunoblotting experiments, there were two major bands identified in hBMSC with molecular weights approximately 139.7 kDa and 118.6 kDa, along with several small bands using the anti-pan cadherin MoAb C-1821 (Figure 1), and this observation was consistent with a previous report using the same MoAb^[4]. There was only one band with a M_r of 118.6 kDa using anti-human E-cadherin MoAb 004FD, which was in close agreement with human E-cadherin size

(120 kDa)^[21]. In this case, one of two major bands demonstrated by MoAb C-1821 may be human E-cadherin, another may be other cadherins, for example, osteoblast-like cadherin or N-cadherin, which was demonstrated to be specific for osteoblasts and its expression in the osteoblastic cells was up-regulated during differentiation, indicating an important role in osteogenic differentiation^[10]. The results presented here are supported by a previous report in osteoblastic UMR106-H5 rat osteosarcoma cells^[8]. It is necessary to determine whether all the polypeptides identified by the anti-pan cadherin MoAb C-1821 represent cadherin products encoded by distinct genes. Although roles of N-cadherin and osteoblast-like cadherins remains unknown, our data and others strongly suggest they are important regulators of osteoblast differentiation and osteogenesis and play a role in normal and pathological bone formation^[8,10,13-18, 22].

On the basis of detecting cadherin expression in hBMSC, we investigated the regulation of cadherin expression by osteotropic hormones and local growth factors. All of these factors are thought to play important roles in bone remodeling^[23]. Up until now, little was known of the role of cadherins in bone remodeling, particularly in osteogenic differentiation and whether osteotropic hormones and local growth factors regulate the expression of cadherin. With treatments of hBMSC with various hormones and growth factors for 7 d, it was observed that both $1,25(\text{OH})_2\text{D}_3$ and dexamethasone inhibited the expression of cadherins. In contrast, PTH, PGE_2 , estradiol, bFGF, and $\text{TGF-}\beta$ increased the expression. However, these agents are found to differentially modulate these two bands. In these experiments, band a was enhanced more by certain agents than band b, and PGE_2 inhibited band

Figure 5. Effect of pan-cadherin antibody (MoAb C-1821) on alkaline phosphatase (ALP) activity in human bone marrow stromal cells (hBMSC). First passaged hBMSC were treated with the anti-pan-cadherin MoAb (1:200 dilution), in the presence or absence of $1,25(\text{OH})_2\text{D}_3$ (50 nmol/L) for 48 h, in MEM containing 2% FCS. ^b $P < 0.05$ vs control. ^e $P < 0.05$, ^f $P < 0.01$ vs $1,25(\text{OH})_2\text{D}_3$ treatment.

a, but increased band b. These results suggest that there may be more than one subclass of cadherins expressed in hBMSC and osteotropic hormones and growth factors may differentially regulate these individual cadherins. Certain factors, such as TGF- β , PTH, and E_2 , had more specific effects on Band a, and these two bands may represent different cadherin expressions. PTH was shown to increase the expression of E-cadherin in mouse MC3T3-E1 osteoblastic cells^[8] and increase mRNA level of the neural-cadherin-like adhesion molecule (N-CAD) *in vitro* and *in vivo*^[15]. Dexamethasone was shown to decrease N-CAD and to completely inhibit cadherin mRNA in rats^[15]. In addition, dexamethasone was also found to increase steady state mRNA for cadherin-4, but decrease mRNA expression for N-cadherin^[14]. However, steady-state mRNA expression for protocadherin and cadherin-11 was not affected by dexamethasone^[14]. Estradiol was shown to cause a rapid and significant increase in the ovarian E- and N-cadherin mRNA levels in mice *in vivo*^[24]. It was reported that TGF- β up-regulated N-cadherin expression at mRNA level in mesenchymal cells obtained from early chick limb bud, which can differentiate into chondrocytes when plated at a high density^[25].

It was known that osteogenic differentiation of hBMSC was stimulated by $1,25(\text{OH})_2\text{D}_3$ ^[12] and dexamethasone^[11], and the proliferation of these cells is inhibited by the two agents^[11,12]. PTH was shown to be mitogenic for human osteoblast-like cells^[26]. Estradiol stimulates the proliferation of osteoblast-like cells derived from explants of rat trabecular bone and the immortalized rat calvarial RCT-3 cell line^[27], mouse MC3T3-E1 osteoblastic cells^[28] and human osteoblastic osteosarcoma SAOS-2 cell line^[29]. The local factor PGE₂ was demonstrated to stimulate the proliferation of bone cells^[30]. In addition, TGF- β and bFGF inhibit osteogenic differentiation of hBMSC and stimulate cell proliferation^[12,31]. Taken together, it seems likely that the agents that promote osteogenic differentiation and inhibit cell proliferation may decrease certain cadherin expression, while other agents that inhibit osteogenic differentiation and stimulate cell proliferation may increase certain cadherin expressions, indicating that an increase in cadherin expression is associated with cell proliferation and a decrease in cadherin expression with osteogenic differentiation at a 'specific stage' of differentiation.

Because the C-terminal regions of cadherins are essential domains for function, and the anti-pan cadherin MoAb C-1821 recognizes this site, this MoAb was used as a function-perturbing antibody for examining a possible role for cadherins in osteogenic differentiation of hBMSC. A perturbing function of the cadherins with the MoAb caused the fibroblast-like hBMSC to become more or less polygonal

observed under microscope (data not shown here). It was also observed that this block with the MoAb significantly increased alkaline phosphatase activity, and enhanced $1,25(\text{OH})_2\text{D}_3$ -induced increase in ALP activity in which first passaged hBMSC were induced for osteogenic differentiation. This indicates that cadherins may play a role in differentiation of hBMSC. Based on 1:500 dilution used in immunolocalization described previously, a 1:200 dilution was used in these experiments. It remains possible that ALP activity may be increased more if higher concentrations of the MoAb are used. However, the MoAb C-1821 is expensive, so reasonable dilution 1:200 was applied to the experiments. As mentioned above, $1,25(\text{OH})_2\text{D}_3$ inhibited the cadherin expression in hBMSC and $1,25(\text{OH})_2\text{D}_3$ promoted osteogenic differentiation^[12], including enhancement of ALP activity and osteocalcin expression. These suggest that the role of $1,25(\text{OH})_2\text{D}_3$ on osteoblast differentiation may be partially through mediating the cadherin expression. There may be other cell adhesion molecules involved in the mediation of $1,25(\text{OH})_2\text{D}_3$ -induced effect on ALP activity. A role for E-cadherin in osteogenic differentiation had also been indicated in the fetal rat calvarial (FRC) osteoblast system. In these FRC cultures, treatment of FRC osteoblasts with polyclonal antibodies to murine E-cadherin significantly increased mineralized bone nodule formation^[32]. Taken together, these data indicate that some specific cadherins may negatively regulate osteogenic differentiation at a 'specific stage' during osteogenic differentiation.

In conclusion, the effects of osteotropic hormones and local growth factors on osteogenic differentiation of hBMSC may be, at least, partially via regulation of cell adhesion molecules, such as cadherins. Cadherins may function as mediators of transition between proliferation and differentiation and then negatively regulate osteogenic differentiation.

Abstract

Aim: To determine the frequencies of polymorphism and haplotype in the transforming growth factor-beta 1 (TGF- β 1) gene promoter in the Chinese population and to investigate the susceptibility of this population to chronic obstructive pulmonary disease (COPD). **Methods:** The target fragments of the TGF- β 1 gene promoter were amplified and analyzed by polymerase chain reaction-restriction fragment length polymorphism technique in 84 COPD patients and 97 age- and sex-matched healthy controls. The test for Hardy-Weinberg equilibrium was performed using HWE program of the LINKUTIL package and statistical analysis was carried out with the SPSS statistical package. An expectation maximization algorithm was used for the pairwise linkage disequilibrium test and haplotype analysis. **Results:** More carriers of the -800A allele, or fewer carriers of the -509T allele, were detected in the COPD patients compared with the non-symptomatic control subjects [for the -800A allele, 29.8% vs 14.4%, respectively, $\chi^2=6.257$, degrees of freedom (df)=1, $P=0.012$; for the -509T allele, 27.3% vs 44.3%, respectively, $\chi^2=5.582$, df=1, $P=0.018$]. The prevalence of the -800A allele was significantly higher in the COPD patients than in control subjects ($P=0.009$), whereas the frequency of the -509T allele was significantly higher in control subjects than in the COPD patients ($P=0.008$). In addition, this distribution tendency for the -800A or -509T allele was similar in heavy smokers (smoking history ≥ 20 pack years); (number of packs of cigarettes per day multiplied by the number of years of smoking) $\chi^2=7.235$, $P=0.007$, and $\chi^2=5.636$, $P=0.018$, respectively). The linkage disequilibrium was found between -800 G \rightarrow A and -509 C \rightarrow T ($D>0.60$, $P<0.0001$), and the frequency of the AC haplotype, consisting of the least common base at -800 and the most common base at -509, was significantly higher in patients with COPD than in controls (0.056 vs 0.021, $P<0.05$). **Conclusions:** The single nucleotide polymorphism (SNP) in the TGF- β 1 gene promoter might be associated with COPD, and the -800A/-509C haplotype is possibly one of the susceptibility factors for COPD.

Introduction

Chronic obstructive pulmonary disease (COPD) is currently the leading cause of disability-adjusted life years. Globally, it is projected to be the 3rd most important cause of death by the year 2020, and it is estimated that the national prevalence is up to 3.1% in the Chinese adult population.

Cigarette smoking is the major risk factor for COPD; however, only approximately 15% of smokers develop clinically relevant airflow obstruction^[1]. This variation in the susceptibility to cigarette smoke in combination with the familiar aggregation of COPD suggests that there may be a genetic component to the development of COPD. Multiple studies in diverse populations have shown evidence for a large

genetic contribution to the variability in pulmonary function and for the familial aggregation of COPD patients^[2,3]. As expected, segregation analysis suggests that multiple genes may be involved. At present, however, only a single gene, α 1-antitrypsin, a potent inhibitor of inflammatory cell protease in the lung, has been unequivocally implicated in the development of COPD. The association between the ZZ type polymorphism of this gene and COPD has been established^[4]. Furthermore, the associations between COPD and polymorphisms in several other genes of potential importance to COPD pathogenesis also have been studied. These include α 1-antichymotrypsin^[5], microsomal epoxide hydrolase^[6], vitamin D-binding protein^[7], and tumor necrosis factor- α ^[8].

Transforming growth factor- β (TGF- β) is a multifunctional cytokine that regulates the proliferation and differentiation of a wide variety of cell types *in vitro*. In humans, the TGF- β family includes 3 isoforms (TGF- β 1, TGF- β 2, and TGF- β 3) with great structural and functional similarities^[9]. TGF- β 1 is the most abundant isoform and is highly conserved in primary sequence through evolution. It is synthesized as precursor latent forms (390 amino acids long), which have no known biological activity^[10]. The active form of TGF- β 1 is released proteolytically from the precursor form^[11] and consists of a disulphide-linked 25 kDa homodimer of two 112 amino acid peptides. The coding region of the TGF- β 1 gene consists of 7 exons and 6 introns^[12].

The expression of TGF- β 1 is influenced by polymorphisms in the TGF- β 1 gene, and some of these polymorphisms may be associated with COPD and other diseases^[13-15]. Wu *et al* investigated the association between the single nucleotide polymorphism T+869C (Leu10Pro) at exon 1 of the TGF- β 1 gene with COPD in a Caucasian Americans white population^[16]. There are several registered polymorphisms within the TGF- β 1 gene that might be functional and might be associated with COPD. In particular, a promoter polymorphism at -509 C/T is associated with the diagnosis of asthma and may enhance TGF- β 1 gene transcription^[17], but whether there is an association between the -509 C/T polymorphism and COPD has not yet been investigated. The aim of present study was to screen for DNA sequence variants in the TGF- β 1 promoter, to establish the prevalence of each genotype in individuals with COPD and controls in a Chinese population, and to identify any haplotypes associated with a predisposition to COPD.

Materials and methods

Subjects Eighty-four patients with COPD were recruited

from the West China Hospital, Sichuan University, Chengdu, China. The definition of COPD was consistent with that in the American Thoracic Society (ATS) consensus statement. The patients had a history of chronic or recurrent productive cough for >2 years and decreased maximum expiratory flow, which had been slowly progressive and irreversible. The presence of other lung or cardiac diseases as the cause of patient symptoms was excluded by clinical and radiographic examinations. The criteria for enrolment were as follows: (i) individuals with a forced expiratory volume in 1 s (FEV₁) <70% of predicted, an FEV₁/forced vital capacity (FVC) ratio of <70%, and an increase in FEV₁ of <12% 15 min after the inhalation of 400 μ g Fenoterol HBr MDI (Berotec; Boehringer Ingelheim, Ridgefield, CT, USA); and (ii) patient consent to participate in the study. Most of the patients were receiving oral methylxanthine, inhaled anticholinergic agents, and inhaled β 2-agonists as needed. The patient's name, age, sex, family history, smoking habits, the number of cigarettes smoked, the duration of diseases, and chest radiographic findings were recorded. Pulmonary function testing (CHESTAC-33-8800, Chest Ltd, Tokyo, Japan) was performed according to the ATS performance requirements. Ninety-seven unrelated, age-matched healthy subjects, who had no known medical illness or family disorders and were not taking any medications, acted as control subjects. This study was approved by the Internal Review Board of the West China Hospital, Sichuan University, and signed informed consent forms were obtained from all subjects.

DNA preparation and polymerase chain reaction amplification Genomic DNA was prepared from peripheral blood leukocytes using the "salting-out"^[18] procedure and stored at 4 °C. Fragments containing the single nucleotide polymorphism (SNP) G-800A or T-509C were amplified by polymerase chain reaction (PCR). The primer sequence was based on the DNA sequence from GenBank accession numbers NM_000660 and X05839. For the detection of polymorphism at nucleotide acid -800, the primer pairs were 5'-CTGGCAGT-TGGCGAGAACA-3' (sense) and 5'-TAGAAAGGACAGAA-GCGGTG-3' (antisense); and the generated PCR product size was 326 base pairs (bp). The primer pairs for delineating the polymorphism at nucleotide acid -509 were 5'-CCAGCTAAGGCATGGC ACCG-3' (sense) and 5'-GCGGTGTGGTCA-CCAGAGA-3' (antisense); the PCR product size from these primers was 300 bp. Each PCR amplification mixture contained 0.1 μ g genomic DNA, 0.2 μ mol/L primers, 50 μ mol/L deoxyribonucleotide triphosphate (dNTP), and standard PCR buffer in a total volume of 50 μ L. The reaction mixture was preheated at 94 °C for 4 min. Subsequently, 0.4 units of *Taq* polymerase was added. The 30 cycles of PCR amplification

were performed with a temperature profile consisting of denaturation at 94 °C for 45 s, annealing at 58 °C and 61 °C for 30 s, extension at 72 °C for 30 s, and final extension at 72 °C for 10 min. The reactions were carried out in a PTC-200 Programmable Thermal Controller (MJ Research, Watertown, MA, USA).

Genotyping Genotyping for the -800G/A and -509C/T polymorphisms was performed by digestion of PCR product with the restriction enzymes MaeIII and SauI (Amersham Biosciences, Piscataway, NJ, USA), respectively. After PCR, 10 µL of the reaction mixture was digested with 1 U MaeIII or SauI in 1×buffer M (Amersham Biosciences) for 3 h at 37 °C. The digest mixture was resolved on a 2.0% agarose gel stained with ethidium bromide. For the -800G/A polymorphism, DNA from individuals with the homozygous G genotype (GG) produced 1 band at 326 bp; the homozygous A genotype (AA) produced 2 bands, 1 at 206 bp and 1 at 120 bp; and the heterozygous genotype (GA) produced all 3 bands. A gel of the restriction fragment length polymorphism digestion products is shown in Figure 1A. For the -509C/T polymorphism, individuals with the homozygous C genotype (CC) produced 1 band at 300 bp; the homozygous T genotype (TT) produced 2 bands, 1 at 202 bp and 1 at 98 bp; and the heterozygous genotype (CT) produced all 3 bands, as shown in Figure 1B. Control DNA samples representative of each of the different genotypes were included in each digestion. Repeat genotyping was performed on 5 of every 100 samples chosen by random selection. Genotyping errors are estimated to have occurred at a frequency of <1%.

Statistical analysis Data analyses were performed with the Statistical Package for the Social Science (SPSS, version 10.0, Inc in Chicago, Illinois, USA). Data were expressed as mean±SEM. The significance level for statistical tests was taken to be 0.05. Deviation of the genotype counts from the

Hardy-Weinberg equilibrium was tested using a χ^2 test with 1 degree of freedom (df). Differences between the patients with COPD and the controls with respect to the allele frequencies and genotype distributions were analyzed by χ^2 test or Fisher's exact test when necessary. Haplotype frequencies for pairs of alleles, as well as χ^2 values for allele associations, were estimated by the Estimating Haplotype-frequencies software program^[19-20]. Linkage disequilibrium coefficients $D'=D/D_{\max}$ (D is the difference between the observed and the expected gamete frequency, D_{\max} is the maximum disequilibrium, which occurs when all double heterozygotes are either in linkage phase (AB/ab) or in repulsions phase (Ab/aB). were calculated by the 2LD program^[21].

Results

General characteristics The study population consisted of 84 patients with COPD and 97 control subjects (Table 1).

Table 1. General characteristics of the study population (mean±SEM). FEV₁, forced expiratory volume in 1 s; FVC, forced vital capacity.

Variable	Controls (n=97)	COPD (n=84)	P
Age/years	65±8	63±9	>0.1
No. men/%	83 (85.6)	74 (88.1)	>0.1
Smoking history			
0–20 pack years ¹	26	17	>0.05
≥20 pack years	71	67	>0.05
FEV ₁	1.87±0.60	0.97±0.32	<0.01
FEV ₁ /Predicted/%	93.7±3.4	49.0±0.4	<0.01
FEV ₁ /FVC	78.0±4.6	59.2±8.3	<0.01

¹ Pack years: number of packs of cigarettes per day multiplied by the number of years of smoking.

Figure 1. Agarose gel showing restriction fragment length polymorphism for polymorphisms in the transforming growth factor- β 1 gene at nucleotide -800 (A) and nucleotide -509 (B). (A) M: marker, 250 bp DNA ladder; lanes 1 and 6 show the GG genotype; lanes 2 and 4 show the GA genotype, and lanes 3 and 5 show the AA genotype. (B) M, 100 bp DNA ladder; lane 2 shows the TT genotype; lane 3 shows the CC genotype; and lanes 1 and 4 show the TC genotype.

The COPD cases and control subjects did not differ significantly in sex, age, and smoking history characteristics. The parameters used for FEV_1 , FEV_1 /predicted, and FEV_1 /FVC were significantly decreased in the COPD case subjects compared with the controls (Table 1, $P < 0.01$).

Distribution of the G-800A and C-509T in COPD patients and controls To determine the prevalence of the SNP G-800A and C-509T, we screened them in all the 84 COPD patients and in the 97 controls. The genotype distribution and allele frequencies are listed in Table 2. No deviation from Hardy-Weinberg equilibrium (for SNP G-800A, $\chi^2 = 1.379$, $df = 1$, $P = 0.240$ in the COPD group, $\chi^2 = 1.737$, $df = 1$, $P = 0.188$ in controls; for SNP C-509T, $\chi^2 = 1.488$, $df = 1$, $P = 0.222$ in the COPD group, $\chi^2 = 2.400$, $df = 1$, $P = 0.121$ in controls) was noted in the COPD or control groups. As a result, more carriers of the -800A allele, or fewer carriers of -509T allele, were detected in the COPD patients compared with in the control subjects (for the -800A allele, 29.8% vs 14.4%, $\chi^2 = 6.257$, $df = 1$, $P = 0.012$; for the -509T allele, 27.3% vs 44.3%, $\chi^2 = 5.582$, $df = 1$, $P = 0.018$). The prevalence of the -800A allele was significantly higher in COPD patients than in control subjects ($P = 0.009$), whereas the frequency of -509T allele was significantly decreased in COPD patients compared with

that in control subjects ($P = 0.008$).

Relationship between cigarette smoking and the distribution of TGF-β1 gene polymorphisms The allele and genotype distributions were compared in heavy smokers (smoking history ≥ 20 pack years (number of packs of cigarettes per day multiplied by the number of years of smoking) to determine whether the prevalence of different alleles or genotypes was associated with smoking. Results showed that the frequency of the -800A allele was still significantly higher and the frequency of the -509T allele was significantly decreased in patients with COPD (group A) than in control subjects (group B) ($\chi^2 = 7.235$, $P = 0.007$, and $\chi^2 = 5.636$, $P = 0.018$, respectively; Table 3).

Linkage disequilibrium between -800G/A and -509C-T polymorphisms in the TGF-β1 gene We analyzed the relationship between -800G/A and -509C-T polymorphisms and their effects on COPD. The extent of D in pairwise combinations of alleles in loci at the TGF-β1 promoter was estimated by means of maximum likelihood from the frequency of diploid genotypes in the patients with asthma and controls. Haplotype frequencies and the coefficient of linkage disequilibrium (D') are given in Table 4. It was clear that the D' values for polymorphisms at nucleotides -800 bp and -509 bp

B	71	60 (84.5)	11 (15.5)	0 (0.0)	131 (92.3)	11 (7.7)	37 (52.1)	29 (40.8)	5 (7.1)	113 (84.3)	39 (27.5)

Table 4. Estimate of pairwise haplotype frequencies and disequilibrium statistics.

Polymorphic sites and subjects	Estimated haplotype frequency				D (difference between observed and expected gamete frequency)	D_{\max} (maximum disequilibrium)	D' (linkage disequilibrium coefficients)	P
	GC	AC	GT	AT				
G-800A/C-509T								
COPD patients	0.795	0.056	0.088	0.061	0.086	0.124	0.691	<0.0001
Controls	0.716	0.021	0.207	0.056	0.036	0.057	0.632	<0.0001

differ significantly from zero, and the frequency of the AC haplotype, consisting of the least common base at -800 and the most common base at -509, was significantly higher in patients with COPD than in controls (0.056 vs 0.021, respectively, $P < 0.05$).

Discussion

We have shown that the A allele at position -800 in the promoter region of the TGF- β 1 gene is more common and the T allele at position -509 is less common in subjects with COPD than in control subjects. Some evidence has shown a correlation between the 2 polymorphisms (G-800A, C-509T) and the concentration of TGF- β 1 in human plasma^[22]. The G-800A substitution is thought to disrupt a consensus half-site for the binding of the nuclear transcription factor CRE (cyclic AMP-responsive element)-binding protein, and it was found that the presence of the A allele is significantly associated ($P < 0.05$) with lower levels of total TGF- β 1 in the circulation^[22]. Conversely, the -509T allele has been shown to be associated with higher levels of TGF- β 1 in serum and increased TGF- β 1 mRNA in peripheral blood mononuclear cells^[22]. These findings indicate that the G-800A and C-509T polymorphisms may be involved in the modulation of expression of the TGF- β 1 gene and therefore a predisposition for COPD could be linked to particular alleles of this gene. The high producer genotype for TGF- β 1 may protect against the development of COPD. A recent study by Wu *et al* has shown that the +869Pro allele, associated with higher serum concentrations of TGF- β 1, was less common in subjects with COPD than in control subjects^[16].

A recent study using an animal model of emphysema adds plausibility to the suggestion that increased production of TGF- β 1 can protect against the development of COPD. The integrin $\alpha_v\beta_6$ activates latent TGF- β ^[23]. Mice that lack this integrin (Itgb6 null mice) develop age-related emphysema. When transgenes for TGF- β 1 were inserted into these mice

so that they constitutively expressed active TGF- β 1, the changes in the lung associated with the deletion of the integrin gene no longer occurred. In these mice, the productive effects of TGF- β 1 appear to be related to inhibition of macrophage metalloelastase (MMP12), which degrades elastin.

More than 100 SNP and other genetic variants have been identified in genes of the TGF- β 1 signaling pathway, and a few of these have been associated with disease^[13]. C-509T was chosen as the sole candidate SNP because previous studies suggest that it is associated with altered serum levels of TGF- β 1, asthma diagnosis, asthma severity, and serum IgE levels^[22,24,25]. For example, in a study involving 84 monozygous and 86 dizygous twins, Grainger *et al* showed that TGF- β 1 levels in plasma were under genetic control (heritability estimate 0.54) with the C-509T SNP being responsible for 8.2% of the additive genetic variance^[22]. The T allele was associated with higher levels of TGF- β 1 than the C allele was, and there was an allele dose effect, with the highest levels in TT individuals (7.62 ng/mL), intermediate levels in CT individuals (5.06 ng/mL), and the lowest levels in CC individuals (3.83 ng/mL)^[25].

A wide variety of functions have been attributed to TGF- β 1 (such as reduction of inflammation and promotion of wound healing^[26], immunosuppression^[27], regulation of cell proliferation, differentiation and migration^[9]), and regulation of extracellular matrix production^[28,29]. Some of these functions could protect against the development of COPD. TGF- β 1 can inhibit matrix metalloproteinases that may contribute to the development of emphysema through the digestion of elastic fibers^[30,31]. It also promotes the formation of elastin^[32,33] and this could help repair damage to the lungs of individuals who are smokers and who are risk of developing COPD. Recently, TGF- β 1 was located on chromosome 19q, a genomic region linked to the diagnosis of COPD in some genome-wide scans^[34]. Our study strengthens this association between TGF- β 1 and COPD.

In summary, our results suggest that genetic variation at

the promoter of the TGF- β 1 gene might be associated with TGF- β 1 levels and predisposition to the complex COPD. The distributions of TGF- β 1 polymorphisms are different between different ethnic groups. Further replication is essential for the validation of this association in Caucasian, African, or other ethnic populations, and, to elucidate the role of TGF- β 1 in COPD, future work is needed to establish the exact effect of TGF- β 1 polymorphisms on the activation process of the protein and its function.

Abstract

Aim: To investigate the preventive and protective effects of bendazac lysine (BDL) on experimental early diabetic nephropathy (DN) rats. **Methods:** After an early DN model was induced by streptozotocin, rats were administered BDL at doses of 100, 200, and 400 mg/kg for 8 weeks. Blood glucose, microalbuminuria, kidney index, total antioxidative capacity, laminin, advanced glycation end products (AGE), aldose reductase (AR) activity, and the relative quantity of transforming growth factor β 1 (TGF- β 1) mRNA were measured by different methods. The ultrastructural morphology was observed by transmission electron microscope. **Results:** The physical behaviors of early DN rats were hypopraxia, cachexia, and polyuria, while those treated with high doses of BDL were vibrant and vigorous. For BDL-treated DN rats, when compared with vehicle-treated DN rats, the blood glucose level and the intensity of oxidative stress were ameliorated. Also, the microalbuminuria level, AGE either in serum or in renal, and AR activity were significantly reduced. Furthermore, the expression of TGF- β 1 mRNA in the kidney cortex was declined and the thickness of glomerular base membrane was decreased significantly. The ultrastructure of glomerulus and mesangial matrix of BDL-treated DN rats were ameliorated. **Conclusion:** BDL has protective effects on several pharmacological targets in the progress of DN and is a potential drug for the prevention of early DN.

Introduction

Diabetic nephropathy (DN) is now a leading cause of end-stage renal failure in many countries. More than 30% of diabetes mellitus patients develop clinically evident DN 10 to 20 years after the onset of diabetes mellitus. DN seems to occur as a result of interaction of metabolic and hemodynamic factors. Several biochemical pathways, such as increased oxidative stress and advanced glycation end-products (AGE)^[1,2], hyperactivity of aldose reductase (AR) in the polyol pathway^[3], and hyperactivity of pro-sclerotic cytokine, such as transforming growth factor- β 1 (TGF- β 1)^[4] and connective tissue growth factor (CTGF)^[5], have been proposed as candidates for explaining the mechanism of the progressive cause of DN. For the complexity of mechanism,

there is still no definitive therapy halting the development of DN that afflicts diabetic patients. Therefore, it is necessary to develop a novel therapy strategy for DN that can deal with more than one pharmacological target in this intricate mechanism.

Bendazac lysine (BDL) is one of agents that have been introduced for the management of cataracts, protecting the level of vision in patients, thus delaying the need for surgical intervention. Its principal effects are to inhibit the denaturation of proteins and AR activity, responsible for the accumulation of sorbitol and water retention in the lens fibers^[6]. Several studies show that BDL has an inhibitive effect on AR^[7], a main enzyme in the polyol pathway, an antioxidative effect^[8], and an inhibitive effect on glycosylation^[9], all of which are included in the progression of DN. Since there are

still very few published reports focused on the effects of BDL on DN. Therefore, it is worthwhile for us to explore its potential effects on preventing the progression of DN.

To evaluate the effects of BDL on DN, we studied the possible influence of BDL on the parameters that indicate protective effects against the progress of DN, such as blood glucose level, AR activity, AGE level, laminin level in the kidney cortex, thickness of the glomerular base membrane (GBM) and expression of TGF- β 1 mRNA in the kidney cortex on early experimental DN rats, and observe their morphological changes.

Materials and methods

Drugs BDL was synthesized by Supereyes (Lot No 020818, Zhejiang, China), and was dissolved in 1% carboxymethyl cellulose (CMC) solution. Streptozotocin (STZ) (Lot No P5639) was purchased from Biomol Research Lab (Plymouth Meeting, PA, USA). Epalrestat (Lot No 990921), an aldose reductase inhibitor, serving as a positive control drug, was kindly presented by Shanghai Institute of Materia Medica and suspended in 1% CMC solution.

Animals Male Sprague-Dawley rats (Grade I, Certificate No SYXK 2001-0010), weighing 162.5 ± 6.7 g (150–175 g) were obtained from Laboratory Animal Center of Nanjing Medical University. Animal experiments followed the Guideline Principles for Care and Use of Laboratory Animals of Nanjing Medical University.

Induction of DN model and study protocol Diabetic rats were induced with an ip injection of 60 mg/kg of STZ (dissolved in pH 4.5 citrate buffer immediately before injection), while controlled normal standard rats (NS group, $n=10$) received 2.5 mL/kg of citrate buffer. Induction of the diabetic state was confirmed by measuring the blood glucose level at the 72 h after the injection of STZ. The rats whose blood glucose concentrations were ≥ 13.88 mmol/L were randomly allotted into 5 groups: DN rats treated with 1% CMC solution (DN group, $n=10$); DN rats treated with 100, 200, and 400 mg/kg of BDL for BL group (low dose, $n=10$), BM group (moderate dose, $n=11$), and BH group (high dose, $n=10$), respectively; and DN rats treated with 100 mg/kg of epalrestat (EPS group, $n=10$). The same volume of CMC solution was administered to the NS group ($n=10$). The animals were housed in a controlled environment (24 ± 1 °C, 12-h light: 12-h dark cycle, onset of light at 07:00 AM) and were allowed food and water *ad libitum*. After 8 weeks, urine and blood samples were collected. After animals were sacrificed, fresh kidney cortices were stored in formaldehyde solution for light microscopic observation, and 1 mm \times 1 mm \times 1

mm cubes of kidney cortices were fixed in 2.5% glutaraldehyde for electron microscopic measurement. The rest of the kidneys were stored at -75 °C for the later analysis.

Measurement of renal function and biochemical parameters Kidney index was the ratio of kidney weight versus body weight. Blood glucose was measured by the glucose oxidase method with kits purchased from Dong-Ou Bioengineering (No 2002110002, Wenzhou, China). The value of microalbuminuria was represented by the ratio of urinary albumin versus creatinine measured in urine, where urinary albumin was determined by the radioimmunoassay method, whose reagent kit was purchased from the Department of Isotope, China Institute of Atomic Energy (No 20021203, Beijing, China), and creatinine was assayed by the picric acid method.

To analyze the total antioxidative capability, 2.0 mL of ABTS [2,2'-azinobis-(3-ethylbenzothiazoline-6-sulphonic acid)/myoglobin reagent was mixed with 20 μ L of sample and a further 180 μ L of diluent, which flushed the sample probe. The initiator of the reaction, hydrogen peroxide (0.675 mmol/L, 250 μ L), was added last to get a final concentration in the cuvette of 75 μ mol/L. After a 6-min incubation, the optical density (OD) of ABTS⁺ was read at 734 nm by spectrophotometer (UV-1600, Beijing, China), and the value of total antioxidative capability was calculated^[10].

The AR activity was measured by fluorospectrophotometer (Shimadzu, RF-5300, Kyoto, Japan) with reagents of β -NADPH (Lot No 81k7059, Sigma, St Louis, MO, USA) and DL-glyceraldehyde (Lot No 120k2618, Sigma) and its activity is defined as the amount of micromole of β -NADPH oxidized per minute at 37 °C^[11].

Laminin, a main component of the extracellular matrix, was determined by the radioimmunoassay method, using kits from Shanghai High Biotech Center (No 20021201, Shanghai, China). AGE either in renal cortex or in serum was measured by fluorescence spectrophotometry (fluorospectrophotometer, Shimadzu) and the concentration of AGE was represented by the fluorescence optical density (OD). The final value of AGE in tissue was modulated by the total protein in tissue which was measured by biuret colorimetry.

RT-PCR for the relative quantity of TGF- β 1 mRNA in kidney cortex RT-PCR was performed to determine the relative quantity of TGF- β 1 mRNA in the kidney cortex, whereas β -actin mRNA, a housekeeping gene, was used as an internal control^[12]. Briefly, total RNA was extracted from the kidney cortex with TRIzol (Lot No 1134369, Invitrogen, Carlsbad, CA, USA). First-strand cDNA synthesis was reversely transcribed from 2 μ g of mRNA in transcription buffer and 200U MMLV reverse transcriptase (System Lot No

160419, Promega, Madison, WI, USA) at 42 °C for 1 h, followed by immediate cooling on ice. PCR amplification was performed using *Taq* polymerase (Lot No 101405, Promega, Shanghai, China) in a total volume of 50 µL. The upstream and downstream primers for rat TGF-β1 mRNA were 5'-CCCGCATCCCAGGACCTCTCT-3' and 5'-CGGGGGACTGGCGAGCCTTAG-3', yielding a 519 bp product, whereas those for β-actin were 5'-GCTGCGTGTGGCCCCTGAG-3' and 5'-ACGCAGGATGGCATGAGGGA-3', yielding a 252 bp product. PCR conditions were as follows: 35 cycles, denaturing at 94 °C for 30 s, annealing at 54 °C for 60 s and extending at 72 °C for 60 s with initial heating at 94 °C for 5 min and final extending at 72 °C for 7 min. The PCR products were separated by 1% agarose (Lot No 051363, Biowest, Miami, FL, USA) electrophoresis and the band densities were analyzed using laser densitometry (Gel Doc 1000, Bio-Rad, Richmond, CA, USA). The relative quantity of TGF-β1 mRNA in the kidney cortex was represented by the ratio of band density of TGF-β1 versus that of β-actin.

Morphological observation and measurement of thickness of GBM Kidney cortex samples stored in formaldehyde solution were embedded with paraffin and stained with HE. Each HE-stained sample in each group was observed under light microscope. Three kidney samples from each experimental group were randomly chosen for electron microscopic observation. Specimens were embedded in epoxy resin and cut into ultrathin sections and then stained with plumbum citrate for ultrastructural observation under transmission electron microscope (JEM 1200EX, Jeol, Tokyo, Japan). Five photos were taken at different views for each kidney sample. The images were amplified 10K and the photos were scanned into a computer to measure the thickness of GBM using an image analysis system (Leica Qwin Standard V2.6, Leica Microsystems, Welzlar, Germany).

Statistical analyses Statistical analysis was performed to compare the effects of BDL on early DN rats using one-way analysis of variance (ANOVA) and Dunnett's *t*-test (2-side) for the different groups using SPSS 10.0. Data were expressed as mean±SD. *P*<0.05 was considered statistically significant.

Results

Effects of BDL on physical behaviors, blood glucose, microalbuminuria, and kidney index In our experiment, rats in the DN group displayed the following physical characteristics: hypopraxia, cachexia, yellowish and damp fur, kyphosis, body shake, ptosis, polyuria polydipsia and tardy weight gain; while rats in NS and BH groups were

vibrant, vigorous, with white and tidy fur, and weight gain.

The blood glucose level, microalbuminuria, and kidney index of the DN group were significantly higher than those of NS group (*P*<0.01), indicating that our early DN model was successful. Low doses of BDL slightly reduced blood glucose in DN rats, but greatly reduced microalbuminuria (*P*<0.01). High doses of BDL significantly reduced blood glucose and microalbuminuria level in DN rats (*P*<0.01). BDL (low, moderate and high doses) and epalrestat slightly reduced the kidney index, but differences were not significant (Table 1).

Table 1. Effects of bendazac lysine(BDL) on blood glucose, microalbuminuria, and kidney index of rats. Mean±SD. ^c*P*<0.01 vs NS group. ^f*P*<0.01 vs DN group.

Group	<i>n</i>	Blood glucose /mmol·L ⁻¹	Microalbuminuria /µg·(molCr) ⁻¹	Kidney index (×1000)

Effects of BDL on laminin level in kidney cortex and thickness of GBM The level of laminin in the kidney cortex of early DN rats significantly increased, when compared with that of normal rats (*P*<0.01). Three doses of BDL caused a decrease in the level of laminin, but a greatly significant decrease can be found only in high doses (*P*<0.01) (Figure 1A).

There was a significant difference in the thickness of GBM between the NS group and DN group (*P*<0.01). The thickness of GBM decreased with increasing doses of BDL. Compared with the DN group, there were significant differences in the thickness of GBM of BL, BM, BH and EPS groups (*P*<0.05, or *P*<0.01) (Figure 1B).

Effect of BDL on AR activity in erythrocyte AR activities in the erythrocyte of NS and DN groups were 6.90 and 27.29 U, respectively (*P*<0.01). Significant differences of AR activities at low, moderate, and high dose BDL-treated rats existed when compared with CMC-treated DN rats (*P*<0.01). Furthermore, AR activity and BDL doses showed good dose-dependence. Epalrestat, an AR inhibitor, also significantly reduced AR activity from 27.29 to 11.07 U, showing a very significant difference (*P*<0.01) (Figure 2).

Effects of BDL on AGE and oxidative stress AGE levels

Figure 1. Effects of BDL on (A): laminin level in kidney cortex and (B): glomerular base membrane (GBM) of rats. NS, DN, BL, BM, BH, EPS represent normal standard rats, CMC treated DN rats, 100 mg/kg of BDL treated DN rats, 200 mg/kg of BDL treated DN rats, 400 mg/kg of BDL treated DN rats, 100 mg/kg of epalrestat treated DN rats, respectively. Mean±SD. ^c*P*<0.01 vs NS group. ^e*P*<0.05, ^f*P*<0.01 vs DN group.

Figure 2. Effect of BDL on aldose reductase (AR) activity in erythrocyte of rats. Mean±SD. ^c*P*<0.01 vs NS group. ^f*P*<0.01 vs DN group.

in the kidney cortex and in the serum of DN rats were greatly higher than those of normal rats (*P*<0.01). Both in the kidney

cortex and in serum, there were significant decreases in AGE levels for BL, BM, and BH groups when compared with the DN group (*P*<0.05, or *P*<0.01), whereas epalrestat had the same significant difference (*P*<0.01). In contrast, the total antioxidative capability in serum, which expresses the antioxidative status of animals, was reduced significantly in DN rats. Three doses of BDL and epalrestat significantly enhanced the total antioxidative capability of DN rats (*P*<0.01) (Table 2).

Table 2. Effects of BDL on advanced glycation end products (AGE) and total antioxidative capability (T-AOC) in serum of rats. Mean±SD. ^c*P*<0.01 vs NS group. ^e*P*<0.05, ^f*P*<0.01 vs DN group.

Effect of BDL on the relative quantity of TGF-β1 mRNA in kidney cortex After the RT-PCR procedure, the amplified products of TGF-β1 mRNA were completely separated by electrophoresis (Figure 3A). The relative quantity of TGF-β1 mRNA in the kidney cortex of the DN group significantly increased when compared with that of NS group (*P*<0.01). Low, moderate, and high dose BDL caused the level of TGF-β1 mRNA to decrease, and statistical differences existed when compared with CMC-treated DN rats (*P*<0.01). Epalrestat had the same effect as a moderate dose of BDL (*P*<0.01) (Figure 3B).

Effects of BDL on morphological change in kidney The light microphotograph showed that glomerular mesangial hyperplasia existed (Figure 4). In the transmission electron micrographs, the ultrastructure of glomerulus of the CMC-treated DN rat was changed. The GBM was wrinkled and partly thickened, with effacement of some visceral epithelial cell foot processes and microvillus transformation. After 8 weeks of treatment with 400 mg/kg of BDL, the glomerular capillary loops, GBM, pedicelsa and mesangial matrix of rats appeared to be almost normal (Figure 5).

Discussion

Oxidative stress plays an important role in the etiology

Figure 3. Effect of BDL on the relative quantity of TGF-β1 mRNA in kidney cortex of rats. NS, DN, BL, BM, BH, EPS represent normal standard rats, CMC treated DN rats, 100 mg/kg of BDL treated DN rats, 200 mg/kg of BDL treated DN rats, 400 mg/kg of BDL treated DN rats, 100 mg/kg of epalrestat treated DN rats, respectively. (A): cDNA samples obtained from kidney cortex of each rats were amplified for the detection of TGF-β1 mRNA. β-Actin was used as the internal standard in each sample. (B): RT-PCR data for relative quantity of TGF-β1 mRNA performed by densitometric analysis. Mean±SD. ^c*P*<0.01 vs NS group. ^f*P*<0.01 vs DN group.

of diabetic complications^[13], and the formation of reactive oxygen species is a direct consequence of hyperglycemia. In our study, we found that the total antioxidative capability (a common indicator for changes in the antioxidation system), which includes ascorbate, protein thiols, bilirubin, urate and α-tocopherol, was significantly increased by BDL, strongly suggesting that BDL has an effect on antioxidative capability *in vivo*. This result is consistent with a former report, in which BDL inhibited *in vitro* depolymerisation of hyaluronic acid by free hydroxyl and superoxide radicals from a sodium ascorbate system^[14]. Furthermore, we also found that BDL, even in low doses, significantly decreased AGE levels either in the kidney cortex or in serum. Thus, the antioxidative effect of BDL is very important and can be of great clinical significance for DN.

The status of oxidative stress in intensity and durability facilitates the formation of AGE, which is the result of a reaction between carbohydrates and free amino group of proteins. AGE accumulates in extracellular matrix proteins as a physiological process during ageing. However, this accumulation happens earlier, and with an accelerated rate, in diabe-

lial cells^[17]. In reverse, the interaction between AGE and their specific receptor (RAGE) induces the activation of oxidative stress, and stimulates the production and release of cytokines, amplifying the tissue damage^[2]. It can be concluded that oxidative stress and AGE interact with and upregulate each other. As already stated, the major metabolite of bendazac inhibited glycosylation by sugar in a dose-dependent manner^[18], and also bendazac and its metabolite (5-hydroxybendazac) inhibit the carbamylation of soluble lens proteins *in vitro*^[19]. Furthermore, in our study, BDL significantly decreased AGE levels both in the kidney cortex and in serum. These data strongly suggest the anti-AGE

character of BDL and this could be of benefit for the prevention of DN.

Our data shows that BDL has an inhibitory effect on the relative quantity of TGF- β 1 mRNA in the kidney cortex of DN rats, which is commonly considered as a pivotal cytokine in mediating the progression of DN. *In vitro*, studies have shown that a range of stimuli increase TGF- β 1 expression, such as hyperglycemia, AGE, and various products of oxidative stress^[20,21]. Indeed, TGF- β 1 seems to be an important site of interaction between hemodynamic and metabolic pathways, playing a key role in the synergy between hypertension and hyperglycemia in mediating DN^[22]. Therefore,

having an inhibitory effect on TGF- β 1, BDL affects the regulation of several cytokine in the progression of DN, and is a prime candidate for developing appropriate agents in the prevention and treatment of DN.

Laminin, kidney index and the thickness of GBM are usually enlarged during the progression of DN and serve as persuasive parameters for describing glomerular hypertrophy. Although a decrease in the kidney index for 3 doses of BDL were not defined significantly in our experiment, the thickness of GBM, another significantly decreased morphological parameter in our study, together with laminin, which describes the level of extracellular matrix, still suggest that BDL can aid in preventing renal hypertrophy.

The accumulation of polyols in the kidney has been suggested to be involved in the development of DN. In diabetic patients, AR activity is greatly enhanced by high glucose and accumulated sorbitol, which is associated with the depletion of myoinositol and changes in the cellular redox potential^[23], resulting in deteriorative function in nephropathy, retinopathy, and neuropathy. The importance of AR relevant to DN has also been emphasized with the demonstration that the increase of AR activity is associated with enhanced protein kinase C activation and TGF- β 1 production in human mesangial cells in response to glucose^[24]. In experimental diabetes, several studies have examined the effects of AR inhibition on various functional and structural markers of DN. In an *in vitro* experiment, the AR inhibitor, epalrestat, effectively corrected glucose-induced imbalances of the polyol pathway and myo-inositol uptake in neutrophils and was capable of ameliorating the neutrophil dysfunction^[25]. Also, epalrestat lowers the level of Nepsilon-(carboxymethyl)lysine (CML) and associated variables, and polyol metabolites are correlated with CML in the erythrocytes of diabetic patients^[26]. In a clinical study, the effects of epalrestat on autonomic and somatic neuropathy were assessed, suggesting that epalrestat has therapeutic value at early stages of DN^[27]. In our current experiment, we found that BDL significantly lowered AR activities in rats from 27.29 U to 18.38 U (low dose), 16.92 U (moderate dose), and 6.39 U (high dose), while epalrestat lowered AR activities to 11.07 U (100 mg/kg). The effect of high doses of BDL on AR activity was stronger than that of a common dose of typical AR inhibitor, epalrestat, and therefore, testifying that BDL is a strong inhibitor for AR. Hence, besides its recognized cataract delaying effect on the communal pathway in the pathology of cataracts, BDL can be justified in its clinical application for DN treatment.

BDL is an oxyacetic acid with protein antidenaturant, anti-inflammatory, antinecrotic, choleric and antilipidemic

properties. *In vitro*, BDL inhibited the carbamylation of soluble lens proteins, and the depolymerisation of hyaluronic acid by free hydroxyl and superoxide radicals from a sodium ascorbate system^[14]. Bendazac also has scavenger-like activity as a result of its interaction with protein molecules^[6]. In our experiment, BDL and epalrestat (a commonly used DN-treatment agent) ameliorated the physical morbidity, reduced microalbuminuria, laminin level, thickness of GBM, AGE level, total antioxidative capability, AR activity, and TGF- β 1 mRNA levels in DN rats. What must be pointed out is that BDL significantly decreased blood glucose and ameliorated the persuasive pathological changes by light and electron micrograph, while epalrestat has no effect on them. In the complicated mechanisms of DN development, the pathway of hyperglycemia-oxidative stress-AGE/TGF- β 1 is assuredly very important. Many renal changes are the consequences of changes in blood glucose levels, and many ameliorative effects of BDL on DN may be closely dependant on its effect on the blood glucose level. Therefore, compared with epalrestat, BDL might have more widely therapeutic points for DN.

To sum up, in our STZ induced early DN rat model, BDL decreased the blood glucose level, reduced the level of AGE, the intensity of oxidative stress, AR activity, and the relative level of TGF- β 1 mRNA and, furthermore, lowered the laminin level in the kidney cortex and decreased the thickness of GBM, and therefore ameliorated the morbidity in physical behavior, morphology, and microalbuminuria. In conclusion, BDL has protective effects on several pharmacological targets in the complicated pathology mechanism of DN. It is therefore worthwhile to study further its potential protective effects on early DN.

Abstract

Aim: To investigate the influence of picroside II on hepatocyte apoptosis and its mechanism. **Methods:** Morphological changes and quantification of apoptotic cells were determined under transmission electron microscopy and flow cytometry respectively. DNA fragmentation was visualized by agarose gel electrophoresis. Semi-quantitative reverse transcription-PCR (RT-PCR) was used to analyze the expression of *bcl-2* and *bax* genes. The content of manganese-superoxide dismutase (SOD) in liver mitochondria was detected by the Marland method. The content of malonic aldehyde (MDA) and the protein level in liver tissue were determined by thiobarbituric acid colorimetry and Lowry method. **Results:** Picroside II decreased the levels of alanine aminotransferase and aspartate aminotransferase in the serum resulting from acute-liver injured mice induced with *D*-GalN and LPS; it also reduced the content of MDA, and thus, enhanced the activity of SOD. Picroside II 10 mg/kg was found to protect hepatocytes against apoptosis in a dose-dependent manner; it up-regulated the expression of *bcl-2* genes, thus increased the *bcl-2/bax* ratio. **Conclusion:** Picroside II can protect hepatocytes against injury and prevent hepatocytes from apoptosis. It might be upregulating the *bcl-2* gene expression and antioxidation.

Introduction

Picrorhiza scrophulariiflora belongs to the plant family, scrophularia. Dried rhizome from *Picrorhiza scrophulariiflora* is used for medicine benefits. Many published studies have found that it can protect hepatocytes from many kinds of injury, but the mechanism has not been clearly elucidated. Picroside II is one of the most effective components extracted from *Picrorhiza scrophulariiflora*. To investigate the mechanism of picroside II's protective effects on hepatocytes, we have established hepatocyte apoptosis models *in vivo* and *in vitro*. Transmission electron microscopy, agarose gel electrophoresis of DNA and flow cytometry were used to evaluate apoptosis of hepatocytes. Semi-quantitative RT-PCR together with image manipulation were used to analyze *bcl-2* and *bax* mRNA which are highly related to apoptosis; immunohistochemistry was used to observe the protein expression of Bcl-2 and Bax. Together with several other oxidation indexes, we tried to demonstrate the mechanisms of picroside II's effect on liver protection in apoptosis.

Materials and methods

Animals Seventy-two mice of Kunming strain (20±2 g) and 2 SD rats (70±10 g) were supplied by the Animal Center of Academy of Military Medical Sciences (Beijing China), with the number of males and females being equivalent.

Materials Picroside II was supplied by the Bescholor Research Center of Peking University (Beijing China). Dicarboxylate pilules (DDB) were obtained from Beijing Union Pharmaceutical Factory (Beijing China). *D*-galactosamine (*D*-GalN), lipopolysaccharide (LPS), actinomycin-D (Act-D), and tumor necrosis factor- α (TNF- α) were purchased from Sigma (St Louis, Mo, USA). RNase A, diethylpyrocarbonate (DEPC), fetal bovine serum (FBS), and Trizol reagent were purchased from Gibco/BRL (California, USA). The *Bcl-2* monoclonal and *Bax* polyclonal antibodies were purchased from Santa Cruz Biotechnology (California, USA). Reverse Transcriptional kit was obtained from Promega Chemical Co (Wisconsin,

medison,USA). Alanine aminotransferase (ALT) and aspartate aminotransferase (AST) detection kits, malondialdehyde (MDA, Mn-Superoxide dismutase (Mn-SOD), and streptavidin-peroxidase (SP) were all domestic products.

Models establishing and treatment

In vivo Before experiments were started, 72 mice were divided into 6 groups randomly. Five groups were treated with *D*-GalN (700 mg/kg, ip) and LPS (1 µg/kg, ip) to establish hepatocyte apoptosis model *in vivo*, among which the 4 groups were infused (ig) with picoside II 5 mg/kg, 10 mg/kg, 20 mg/kg, or vehicle (0.9 % NaCl) 10 min before and 4 h after the *D*-GalN and LPS administration, respectively. One group received biphenyl dimethyl dicarboxylate pilules (DDB) (200 mg/kg) with the same manipulation acts as a positive control. The remained group was the negative control. Five hours after the model was established, the blood of 6 mice from each group was sampled through eye socket veins. ALT and AST in serum were then monitored (by continuously using the monitoring method, recommended by National Clinical Chemistry League). Cut sections of liver tissue (left part) of the remaining 6 mice of each group were prepared for pathology evaluation and immunohistochemistry detection of Bcl-2/Bax proteins. The liver suspending liquid (20%) was made from the rest of the liver and stored at under -20 °C, in order to detect SOD in liver mitochondria (by the Marland method), protein level (by the Lowry method) and the content of MDA of liver tissue (by TBA colorimetry). Another 1 mL of liver suspending liquid was centrifuged at 12 000×*g* for 20 min. 400 µL upper liquid, 1 mL ethanol and 50 µL (5 mol/L) was mixed together and stored at under -20 °C for DNA fragmentation analysis.

In vitro Primary culture of hepatocytes from rats were isolated as previously described^[1]. Rats were decapitated under anesthesia. *In situ* perfusion was then performed with calcium and magnesium-free Hanks' salt solution followed by a medium containing collagenase through the hepatic portal vein of rats, the suspending liquid containing rat liver cells were collected. The suspending liquid was then centrifuged at 120×*g* at 4 °C for 5 min. The cell pellets were washed twice with cold Hanks' solution and the cell concentration was modulated to 1×10⁹/L. The cells were seeded in 24-well culture plates in the growth medium consisting of DMEM with 20% FBS, at 37 °C in a water-saturated atmosphere of 5% CO₂. After 24 h, the culture medium was abandoned, and cells were exposed to a series of concentrations of picoside II (0.005, 0.01, and 0.02 mmol/L). After 1 h, Act-D 50 µg/L was added, and 30 min later TNF-α 3000 kU/L was added consecutively to the well for another 24 h. A negative control group was set which was exposed to the normal culture

medium. An assessment of hepatocyte apoptosis and apoptosis-related genes *bcl-2* and *bax* mRNA extraction was then performed.

The Marland method was used to detect the content of SOD in liver mitochondria. MDA content of liver tissue was detected by TBA colorimetry and the protein level of liver was analyzed using Lowry method. ALT and AST in serum were detected by the continuous monitoring method (recommended by International Clinical Chemistry League).

Immunohistochemistry analysis Liver tissues were fixed in 4% formaldehyde for 24 h and embedded in paraffin routinely, followed by 5 µm slicing up. The streptavidin-peroxidase (SP) method was assumed. The *bcl-2* monoclonal antibody (1:50) or Bax polyclonal antibody (1:50) as primary antibodies was applied and incubated overnight at 4 °C or for 60 min at room temperature. The slices were observed and photographed through light microscope and the percentage of the positive staining area of *bcl-2* or *bax* were semiquantitatively analyzed by using CMIAS-008 Image Analyser (Beijing, China).

Reverse transcriptase polymerase chain reaction assay

Total cytoplasmic RNA of each group was isolated from 1.5×10⁷ cultured cells by the TRIZOL method (according to GIBCO specification). The concentration of RNA was determined by absorbance at 260 nm, and its integrity was confirmed by means of electrophoresis on 1% agarose gels, and then stained with 0.1 mg/L ethidium bromide (EB). A total of 1 µg of RNA was converted to complementary DNA (cDNA) using 15 U reverse transcriptase in 20 µL buffer, which contained 1 mmol/L deoxy-NTP, 1 U RNase inhibitor and 0.5 µg oligo (deoxythymidine)₁₅ primer. An aliquot (5%) of cDNA was amplified using the reverse (5'-AGA GGG GCT ACG AGT GGG AT-3') and forward primer (5'-CTC AGT CAT CCA CAG GGC GA-3') to yield 450 bp polymerase chain reaction (PCR) product for *bcl-2*, the reverse (5'-GGT TTC ATC CAG GAT CGA GAC GG-3') and forward primer (5'-ACA AAG ATG GTC ACG GTC TGC C-3') to yield a 429 bp PCR product for *bax*. In order to verify the equal amounts of cDNA were presented in the PCR reaction, β-actin was separately co-amplified with the *bcl-2* and *bax* cDNA, with the reverse (5'-TAA AGA CCT CTA TGCCAA CAC AGT-3') and forward primer (5'-CAC GAT GGAGGG GCCGGA CTC ATC-3') to yield a 240 bp PCR product. The PCR conditions were as follows: pre-denaturation at 94 °C for 5 min, denaturation at 94 °C for 30 s, annealing at 60 °C (*bcl-2* and β-actin) or 64 °C (*bax*) for 40 s, and polymerisation at 72 °C for 40 s with *Taq* DNA polymerase. After 28 cycles, 20 µL *bcl-2* or *bax* PCR product together with the β-actin PCR product of the same template were separated by electrophoresis and

revealed by EB staining. Then each band of the electrophoresis gel was semiquantitatively analyzed using Imagemaster and Software Image Analyser (Beijing,China). The *bcl-2* and *bax* mRNA levels were expressed as the ratio of signal intensity for the target genes in relation to that for the coamplified β -actin.

Flow cytometry analysis Cultured hepatocytes $1 \times 10^9/L$ of each group were harvested, washed with PBS at 4 °C, and exposed to pre-chilled ethanol at 4 °C for 30 min. They were then washed again with PBS, exposed to PI 50 mg/L, 0.1% TritonX-100, 0.01 mmol/L EDTA (Na)₂ and RNase 50 mg/L at normal temperature in darkness for 12–24 h. Specimen were then presented to the FACS-420 Flow Cytometry Analyser (New York, Becton Dickinson and Company, American) to evaluate apoptosis levels.

DNA fragmentation analysis The cultured hepatocytes of each group were lysed in Tris-HCl 20 mmol/L (pH 8.0), EDTA 10 mmol/L, and 0.5% lauryl sarcosyl containing 200 mg/L of proteinase K. DNA was extracted by supercentrifugation, precipitation with ethanol and was treated with RNase. The DNA was then loaded onto 1%–2% agarose gel containing ethidium bromide (EB), which was observed and photographed under UV transillumination.

Morphological evaluation light microscope assay Serial slices of liver tissues were prepared from mice in each group and stained with hematoxyline-eosin (HE) and then observed under light microscope at 200× or 400× magnification.

Transmission electron microscopy assay Liver tissue specimen were fixed and postfixed with glutaraldehyde and osmium tetroxide respectively, dehydrated by acetone, imbedded in epoxy resin. Ultrathin sections were collected and counterstained with lead citrate and viewed with a JEM100CX transmission electron microscope (Tokyo, Japan).

Statistical analysis All results were expressed as mean±SD. Data were assessed by using *t*-test, and $P < 0.05$ was considered statistically significant.

Results

Effects of picoside II on ALT and AST in serum of mice suffered from acute liver injury induced by D-GalN and LPS ALT and AST values were markedly higher in the model group than those in negative control ($P < 0.01$). Picoside II decreased ALT and AST values in a dose-dependent manner ($P < 0.05$ or $P < 0.01$ vs model control). ALT and AST values of the positive control group treated with DDB 200 mg/kg also decreased, especially ALT. The results revealed that picoside II can protect liver tissue from D-GalN and LPS-induced acute injury, and it was more powerful than

DDB (Table 1).

Table 1. Effects of picoside II on ALT and AST in serum of mice suffering from acute liver injury induced by D-GalN and LPS. $n=12$. Mean±SD. ^b $P < 0.05$, ^c $P < 0.01$ vs model control. ^d $P < 0.01$ vs negative control.

Group	Dose/mg·kg ⁻¹	ALT/U·L ⁻¹	AST/U·L ⁻¹
Negative control		48±15	130±74
Model control		512±256 ^f	563±19 ^f
Positive control	200	270±138 ^c	378±190 ^b
Picoside II	5	404±21	416±230
Picoside II	10	294±177 ^b	402±181 ^b
Picoside II	20	242±164 ^c	277±85 ^c

Effects of picoside II on MDA and SOD content of mice suffered from acute liver injury induced by D-GalN and LPS The SOD value of model group decreased, but the MDA value increased compared with negative group ($P < 0.01$). The content of MDA of all groups exposed to picoside II markedly decreased, whereas SOD increased compared with the model group. This effect suggested a dose-dependent manner ($P < 0.05$ or $P < 0.01$) (Table 2).

Table 2. Effects of picoside II on MDA and SOD in liver of mice suffered from acute liver injury induced by D-GalN and LPS. $n=12$. Mean±SD. ^b $P < 0.05$, ^c $P < 0.01$ vs model control. ^d $P < 0.01$ vs negative control.

Group	Dose/mg·kg ⁻¹	SOD/kNU·L ⁻¹	MDA/nmol·L ⁻¹
Negative control		256.8±14.9	4.51±0.66
Model control		222.7±18.3 ^f	8.64±1.69 ^f
Positive control	200	241.5±14.1 ^b	5.80±1.00 ^c
Picoside II	5	237.2±11.6 ^b	6.77±1.26 ^c
Picoside II	10	247.2±13.1 ^c	5.47±0.67 ^c
Picoside II	20	249.2±11.7 ^c	4.51±0.89 ^c

Immunohistochemistry analysis of Bcl-2 and Bax A few pale yellow granula (Bcl-2 protein) were detected in hepatocytes cytoplasm of the negative group. There were more granula in the model group and the most were found in the groups treated with picoside II (Figure 1A). Little buff granula (Bax protein) was detected in normal hepatocytes. The amount of the granula was more in the model group, and existed dispersedly or in focus with the color more heavily than others. Bax protein expression in groups treated with picoside II decreased (Figure 1B). The difference between

Figure 1. The Bcl-2 and Bax expression of each group ($\times 400$). Bcl-2 expression of negative group (A), Bcl-2 expression of model group (B), Bcl-2 expression of groups treated with picriside II (C); Bax expression of negative group (D), Bax expression of model group (E), Bax expression of groups treated with picriside II (F).

groups treated with picriside II and the group of negative control was evidently significant ($P < 0.05$ or $P < 0.01$). The difference between picriside II groups and model control group was also significant ($P < 0.05$ or $P < 0.01$, Table 3).

Table 3. Bcl-2 and Bax protein expression levels of each group. $n=10$. Mean \pm SD. ^b $P < 0.05$, ^c $P < 0.01$ vs negative control. ^f $P < 0.01$ vs model control.

Group	Bcl-2 protein/%	Bax protein/%
Negative control	4.82 \pm 0.26	4.76 \pm 0.16
Model control	5.26 \pm 0.34 ^b	7.24 \pm 0.38 ^c
Picriside II group	9.42 \pm 0.36 ^{ce}	6.22 \pm 0.24 ^b

These results suggested that picriside II could effectively up-regulate the expression of apoptosis-related gene *bcl-2* and inhibit *bax* expression. The increased *bcl-2/bax* ratio, thereby counteracted the hepatocyte apoptosis.

Semiquantitative RT-PCR analysis of apoptosis-related genes *bax* and *bcl-2* mRNA The total RNA extracted from each group were loaded onto 1% agarose gel; 28 s, 18 s, and 5 s bands could be clearly observed, which confirmed the integrity of the total RNA (Figure 2). In the present study, 20 μ L *bcl-2* or *bax* PCR product together with β -actin PCR product of the same template were separated by electrophoresis and revealed by EB staining. PCR products of *bcl-2*, *bax*, and β -actin were 450 bp, 429 bp, 240 bp,

Figure 2. Total RNA of groups with different doses of Picriside II. 1: negative group; 2: model group; 3: treated with picriside II 20 mg·mL⁻¹; 4: treated with picriside II 10 mg·mL⁻¹; 5: treated with picriside II 5 mg·mL⁻¹.

respectively (Figure 3). The *bcl-2* mRNA was the most in the group treated with picriside II 20 g/L, and the least in the negative group; *bax* mRNA was the most in model group, followed by the negative group, and the least in the groups treated with picriside II.

Morphological evaluation by light microscope assay Hepatocytes exhibited acidophilic trait induced by *D*-GalN and LPS, and there were acidophilic bodies in cytoplasm. There was no obvious pathological change observed in groups treated with picriside II 10 and 20 g/L (Figure 4).

Transmission electron microscopy assay Normal hepatocyte was capsule intact, cytoplasm well-diffused, and karyotheca distinct and bears large nuclei. Apoptotic cells

in the initial stages had shrunken and compacted with condensed or marginal chromatin. Chromatin spalls to pieces or semilunar body gradually and cytoplasm becomes condensation. In addition, blebbing of the plasmalemma, forming apoptosis body, a hall marker of apoptosis was then be observed (Figure 5).

DNA fragmentation analysis Figure 6 shows that the model groups (lanes 2 and 7) exhibited the characteristic DNA ladder. In the groups treated with picroside II 5, 10, 20 g/L (lane 6, 5 and 4, respectively), the DNA ladder became less characteristic. Groups treated with picroside II 20 g/L (lane 4) were similar to negative group (lane 3).

Flow cytometry analysis of apoptosis Apoptosis rate of primary hepatocytes of the negative group was 4.1%, the model group was 22.3%, groups treated with picroside II 20, 10, 5 g/L were 6.9 %, 10.7 % and 15.1 %, respectively, which suggested that picroside II could protect hepatocyte against

apoptosis, and it acted in a dose-dependent manner (Figure 7).

Discussion

The pathogenesis mechanisms of viral hepatitis is closely related to hepatocyte necrosis as well as apoptosis closely. Invasion of hepatitis virus to liver or hepatocytes canceration will result in hepatocyte apoptosis^[9-11]. In inflammatory hepatitis, acidophilic body (shrunken necrosis, apoptosis corpuscula) and piece-meal necrosis were the characteristic morphological manifestation of apoptotic hepatocytes. Apoptosis of hepatocytes infected by virus can be a protective mechanism of the host to protect against virus replication and distribution from the infected cells^[12]. Apoptotic cell death contributes to the removal of infected or cancerized cells, but over-apoptosis results in fulminate hepatitis^[13,14]. Commonly, drugs are used to block hepatocyte apoptosis in

Figure 5. Transmission electron microscopy assay. (A): negative primary hepatocytes ($\times 26500$); (B): apoptotic primary hepatocytes ($\times 7350$).

order to cure hepatitis gravis, and to induce hepatocyte apoptosis for removing infected and cancerized cells^[15-20].

One important molecular mechanism for cell apoptosis might be the modulation of the expression of *bcl-2* gene family, which plays a critical role for the common pathway of apoptosis. Previous studies showed that proteins of Bcl-2 family could inhibit apoptosis of chronic infective hepatocytes, marrow stem cells, and nerve cells. The biological function of Bcl-2 is to increase the power to resist many apoptotic factors, counteract the effect of apoptosis, and extend lifespan. Bax, another important apoptosis-modulating gene product, is highly related to Bcl-2. Bax inactivates Bcl-2 by binding it to form a heterogeneous dimer. The mRNA and protein ratio of Bcl-2 to Bax is a pivotal factor in determine whether or not apoptosis can happen to cells exposed to many injuries^[21]. Studies have revealed that

Figure 7. Flow cytometry analysis of apoptosis. (A) negative group; (B) model group; (C) group treated with picoside II $20 \text{ g}\cdot\text{L}^{-1}$; (D) group treated with picoside II $10 \text{ g}\cdot\text{L}^{-1}$; (E) group treated with picoside II $5 \text{ g}\cdot\text{L}^{-1}$.

TNF- α could induce hepatocyte apoptosis, thus to participate in the onset of liver diseases. However, TNF- α itself does not act *in vivo* and *in vitro* unless it is used together with Act-D and D-GalN^[22]. Act-D is an inhibitor of RNA transcription, and could sensitize cells to the toxicity of TNF- α ^[23]. Therefore, the combination of Act-D and TNF- α is frequently used to establish models of hepatocyte apoptosis *in vivo* as well as *in vitro*^[24]. The present study assumed that Act-D together with TNF- α to establish experimental apoptosis model, agarose gel electrophoresis of DNA, and flow cytometry were used to evaluate hepatocyte apoptosis; light and transmission electron microscopy were used to observe morphological changes of cells and tissues; and quantitatively analysed the hepatocytes apoptosis. These results indicated that Picoside II evidently inhibited the morphological changes of hepatocytes, DNA fragmentation, and the increase of sub-G1 spike (represents proportion of apoptosis). Immunohistochemistry and semi-quantitative RT-PCR analysis of the Bcl-2 and Bax expression and mRNA of *bcl-2* and *bax* genes suggested that both *bcl-2* and *bax* increased after hepatocyte injury, especially *bax*. The *bcl-2* level and the ratio of *bcl-2/bax* increased markedly in groups treated with picoside II and apoptosis changes were also inhibited.

MDA is a lipid peroxide, whose content usually reflects the level of lipid peroxidation and indirectly reflects the extent of injury *in vivo*. SOD is a pivotal factor influencing the balance of oxidation and antioxidation, and its activity could indirectly reflect the capability of removing oxygen free radical. Biomembrane is the main place to undertake lipid peroxidation injury. Active oxygen from inflammatory cells could induce apoptosis in cells when lipid peroxidation injury occurs to the membranes of mitochondria and microsome. Changes of cell phenotype through gene transcription might be one of the mechanisms of apoptosis induced by oxidation injury. The present study also suggested that picoside II could simultaneously decrease the level of MDA, ALT, AST, and increase the activity of SOD in liver mitochondria.

In conclusion, we have shown for the first time that picoside II is able to protect hepatocytes against injury and counteract apoptosis through its anti-oxidation effect, and it can act by decreasing MDA level, increasing the activity of SOD in liver mitochondria and upregulating *bcl-2* gene expression.

Abstract

Aim: Correlation of cytochrome P450 (CYPs) with preneoplastic changes in the early stage of hepatocarcinogenesis is still unclear. To detect the expression of carcinogen-metabolizing related microsomal P450 enzymes, namely the CYP1A1, CYP1A2, CYP2B1/2, CYP2E1, and CYP3A, we performed the medium-term bioassay of Ito's model in Sprague-Dawley rats. **Methods:** The amount and activity of CYP were assessed by biochemical and immunohistochemical methods in week 8. The correlation between CYP expression and microsomal oxidative stress was investigated by comparing the generation of microsomal lipid peroxidation in the presence or absence of specific CYP inhibitor. **Results:** In the DEN-2-AAF and 2-AAF alone groups, the expression of CYP1A1 and CYP2E1 were up-regulated and the expression of CYP2B1/2 and CYP1A2 were quite the contrary. Strong staining of CYP2E1 and CYP2B1/2 was found around the centrolobular vein and weak staining in the altered hepatic foci revealed by immunohistochemical procedure. There was no significant change in the activity of CYP3A among the 4 groups. Altered hepatic tissue bore more microsomal NADPH (nicotinamide adenine dinucleotide phosphate, reduced form)-dependent lipid peroxidation than normal tissue. And the difference among the 4 groups disappeared when CYP2E1 was inhibited. More microsomal lipid peroxidation was generated when incubated with CYP1A inhibitor α -naphthoflavone. **Conclusion:** CYP altered their expression levels and these alterations can play important roles in the alteration of cell redox status of preneoplastic tissue in the early stage of hepatocarcinogenesis.

Introduction

Cytochrome P450 (CYP) plays a pivotal role in oxidative metabolism of lipophilic drugs and xenobiotics (some of them are carcinogens), which will then be transformed into more polar water soluble molecule^[1]. During these processes, activation or detoxication takes place. A prominent phenomenon during hepatocarcinogenesis is an alternation of the expression of drug metabolism enzymes^[2]. CYP can be influenced by a number of exogenous and endogenous factors and its induction is of the utmost interest in carcinogenesis^[3,4].

The underlying mechanisms by which CYP enzymes involved in the process of hepatocarcinogenesis have not been elucidated clearly or in detail. Some probable mechanisms have been suggested including the metabolism of exogenous

chemicals involved in the generation of reactive oxygen species and oxidative DNA damage, which are associated with apoptosis and cell cycle arrest^[5]. Moreover, alteration of the activities of CYP in rats could be an important factor in determining resistance or susceptibility to xenobiotics in the early stage of hepatocarcinogenesis^[6].

Preneoplastic and neoplastic lesions induced by various different treatment regimens have a decrease in expression of phase I enzymes and an increase in expression of phase II enzymes in common^[7]. The decrease in expression of CYP in preneoplastic lesions could alter the synthesis and/or inactivate endogenous and/or exogenous substance, which act as tumor promoters or comitogens, thus resulting in the selective growth of a subset of hepatic hyperplastic lesions^[7,8].

CYP1A family might be marker enzymes that indicate the carcinogenic potential of xenobiotics. Most polyhalogenated aromatic hydrocarbons that have proven to be carcinogens have a common induction of CYP1A1. A previously published study demonstrated that the level of N-nitrosodimethylamine demethylase activities (mainly catalysed by CYP2E1) and CYP2E1 protein content were lower in hepatomas than in the corresponding host liver^[9]. However, the change of CYP2E1 expression in the early stage of hepatocarcinogenesis and the probable role in the process of hepatocarcinogenesis was unclear.

Oxidative stress interacts with all 3 stages of the cancer process. Higher levels of reactive oxygen species (ROS) have been found in neoplastic nodules of rat liver than in the surrounding normal tissue. ROS can be generated from several intracellular locations including microsomal pathway and the mitochondrial electron transport chain. Microsomal generated ROS is one of the most significant causes of liver injury^[10]. The existence of NADPH-dependent production of ROS by animal liver microsomes has been linked to CYP. The uncoupling of electron transfer and oxygen reduction from monooxygenation by CYP2B1 and CYP2E1 could result in the release of O_2^- and H_2O_2 . A recent study has demonstrated that this step is also involved in CYP1A1, CYP3A, and CYP4A isoforms^[11]. Within these isozymes, CYP2E1 is a major inducible hepatic microsomal CYP involved in the hydroxylation of fatty acids, and can initiate the autopropagative process of lipid peroxidation if they are not countered efficiently by antioxidants. In the present paper, a reconstituted microsomal lipid peroxidation system consisting of rat liver microsomal NADPH-cytochrome P450 reductase and cytochrome P450 incorporated into phospholipid vesicles was developed to investigate the possible role of the specific CYP to generate microsomal lipid peroxidation that resulted in the different cell redox status among the 4 groups.

The medium-term bioassay, which was developed by Ito *et al* in 1989 to detect the carcinogenic potential and their postinitiation modifying effects^[12], is of relatively short duration, but results in sufficient lesions to allow statistical comparisons^[13]. To investigate the induction and inhibition of CYP in the early stage of hepatocarcinogenesis induced by DEN and 2-AAF, we performed the medium-term bioassay. In the present study, we investigated the major carcinogenesis related to CYP isozymes, namely CYP1A1, CYP1A2, CYP2B1/2, CYP3A, CYP2E1, and indicated their respective role in the formation of hyperplastic foci.

Materials and methods

Chemicals Diethylnitrosamine (DEN), 2-acetylaminofluorene (2-AAF), α -naphthoflavone, 8-methoxypsoralen were purchased from Sigma Chemical Co. Ethoxyresorufin and resorufin were obtained from Molecular Probes. Erythromycin was purchased from Shanghai Sangon Co Ltd. All the antibodies, except those mentioned (later), were purchased from Chemicon International Institute. Enhancing chemiluminescence (ECL) was obtained from Amersham Life Sciences (Amersham, United Kingdom).

Animal experiment Sixty male pathogen-free Sprague-Dawley rats (70–80 g) were obtained at 6 weeks of age from the Shanghai Laboratory Animal Center, Chinese Academy of Sciences (Shanghai, China), and housed in plastic cages with wood chips for bedding in a temperature and humidity-controlled animal facility center with a daily photoperiod of 12 h of light and 12 h of darkness. Forty rats which had no abnormal findings after a 1-week acclimatization period, were randomly divided into 4 groups referred to as group A, B, C, and D, each consisting of 10 animals. Group D (control) was maintained on a basal diet without carcinogen treatment; group A received a single ip injection of DEN (200 mg/kg) in 0.9% NaCl, and 2 weeks later were placed on a diet containing 2-AAF (100 ppm) for 6 weeks. Group B received a single ip injection of DEN (200 mg/kg) dissolved in 0.9% NaCl and was then maintained on the basal diet for 8 weeks; group C were placed on a diet containing 2-AAF (100 ppm) from week 2 to week 8 without DEN initiation. All groups received partial hepatectomy (two-thirds of the total liver) in the third week. At week 8 all the rats were anesthetized with diethyl ether; liver perfusion was performed with ice-cold perfusion buffer [1.15% KCl, 1 mmol/L⁻¹ EDTA, 0.25 mmol/L phenylmethylsulfonyl fluoride (PMSF)] at room temperature. Separate portions were fixed in 10% phosphate-buffered formalin, partially frozen in liquid nitrogen and stored at liquid nitrogen for molecular assessment. Microsomes were prepared by differential centrifugations as described previously and stored at -80 °C until use.

Biochemical assay

Ethoxy O-dealkylase activity assay The metabolism of ethoxyresorufin is associated with CYP1A1 and CYP1A2, with CYP1A1 metabolizing ethoxyresorufin to a much greater extent than CYP1A2 when both CYP are present. The dealkylation of ethoxyresorufin by microsomes was quantified by measurements of increased resorufin fluorescence over time using a Polar star* fluorescence microplate reader (BMG Labtechnologies Pty Ltd, Melbourne, Australia). Microsome protein (50–150 μ g) was added to 0.1 mol/L potas-

sium phosphate buffer pH 7.6, along with 2 $\mu\text{mol/L}$ ethoxyresorufin in the total reaction volume of 2.0 mL. This microsome substrate solution was incubated at 37 °C for 3 min prior to initiation of the reaction with 0.5 mmol/L NADPH. The reaction continued for the next 5 min, the formation of resorufin was measured at the excitation wavelength of 535 nm and emission wavelength of 590 nm. The standard curve was performed with the known amounts of resorufin.

***p*-Nitrophenol hydroxylase (PNPH) assay** PNPH was assayed as described previously. The reaction mixtures contained a 0.1 mol/L potassium phosphate buffer, pH 6.8, 1.0 mmol/L ascorbic acid, 0.1 mmol/L *p*-nitrophenol, 100 μL 25% microsome protein and 1 mmol/L NADPH in a total volume of 1.0 mL. The reaction was initiated by adding NADPH after incubation at 37 °C for 3 min. After a 10-min incubation at 37 °C, the reaction was stopped by adding 0.5 mL 0.6 mol/L HClO_4 . The 4-nitrocatechol formed was determined spectrally at 510 nm in 1.0 mL of the supernatant at 546 nm after the addition of 0.1 mL 10 mol/L NaOH.

Erythromycin N-demethylase activity assay The microsomal erythromycin N-demethylase activity was performed as previously described. The reaction mixture included 0.6 mL 50 mmol/L potassium phosphate buffer (pH 7.25), 0.1 mL 150 mmol/L magnesium chloride, 0.1 mL 10 mmol/L erythromycin and 0.1 mL microsome suspension. After adding NADPH to initiate the reaction, the reaction mixture was incubated at 37 °C for 10 min. The reaction was then terminated by 0.5 mL ice-cold 12.5% (w/v) trichloroacetic acid. After centrifuge, the same volume of NASH reagent (NASH reagent containing 150 g ammonium acetate, 3.0 mL glacial acetic acid and 2.0 mL acetylacetone per liter of aqueous solution) was added to supernatant. The formaldehyde formed was determined spectrally at 412 nm after heating at 50 °C for 30 min.

Western Blot Microsomal fractions of the liver samples were separated by SDS-PAGE and electrophoretically transferred to polyvinylidene fluoride (PVDF) membranes, incubation with rabbit anti-rat CYP1A1, CYP1A2, CYP2B1/2, CYP2E1 (1:1000) at 4 °C overnight, followed by peroxidase-conjugated goat anti-rabbit IgG (1:4000) at room temperature for 1 h. Binding was visualized with an enhanced chemiluminescence.

Immunohistochemistry

glutathione S-transferase placental (GST-P) immunohistochemistry Immunohistochemical staining using rabbit anti-GST-P IgG (ready to use; Medical Biological Laboratories Co, Nagoya, Japan), was performed by avidin-biotin complex method. Quantitation of GST-P-positive foci was performed using 2-dimension evaluation only. The areas of

GST-P-positive foci greater than 0.2 mm in diameter and the total areas of the liver sections were measured using Leica QFAB Image Processing (Leica Imaging Systems Ltd, Cambridge, England) and analysis system to give values per cm^2 of liver section.

Immunohistochemistry of proliferating cell nuclear antigen (PCNA) PCNA was detected from formalin-fixed paraffin-embedded tissue sections. Immunohistochemical staining using monoclonal mouse anti-PCNA IgG (1:100 diluted in 0.01 mmol/L PBS, pH 7.2) and biotinylated rabbit anti-mouse immunoglobulins (1:300 diluted in 0.01 mmol/L PBS, pH 7.2) was performed by avidin-biotin complex method. Antigen retrieval was performed by boiling for 10 min in a microwave oven (600W). The number of nuclei and PCNA-positive nuclei were counted under a light microscope. Ten random fields (approximately 2000 nuclei) per section were assessed under 40 \times objective lens.

Liver microsomal NADPH-dependent lipid oxidation: thiobarbitric acid reactive substances (TBARS) assay Fe^{3+} /ADP-induced: liver microsomes (300 μg of protein per mL) were preincubated in 150 mmol/L Tris/HCl buffer, pH 7.4. After 10 min incubation at 37 °C, lipid peroxidation was initiated by the addition of 2 $\mu\text{mol/L}$ FeCl_3 /200 $\mu\text{mol/L}$ ADP (previously complexed), and 200 $\mu\text{mol/L}$ NADPH. The total volume was 0.5 mL, and all additions expressed earlier were final concentration in the incubation system. Incubations were carried out at 37 °C. Lipid peroxidation was monitored by the formation of TBARS reactions.

Not Fe^{3+} /ADP-induced: the microsomal protein (200 μg in 50 mmol/L phosphate buffer saline, pH 7.4) was incubated in the presence of 0.23 mmol/L NADPH at 37 °C for 10 min before analysis of thiobarbitric acid (TBA) reactive substances. For pharmacological inhibition studies, microsomal protein was pre-incubated for 10–30 min at room temperature in the presence of either diethyldithiocarbamate (CYP2E1 inhibitor, 50 $\mu\text{mol/L}$) or α -naphthoflavone (CYP1A inhibitor, 10 $\mu\text{mol/L}$), 8-methoxypsoralen (CYP1A and CYP2A6 inhibitor, 1 $\mu\text{mol/L}$). α -Naphthoflavone is 10 times more potent as an inhibitor of CYP1A2 than CYP1A1. 8-Methoxypsoralen has a similar inhibition of CYP1A1 and CYP1A2. The microsomal NADPH-dependent lipid peroxidation was performed as described earlier.

Glutathione assay Glutathione level in the homogenates was assayed with a microplate reader using the GSH test kit. The GSH test kit was obtained from the Nanjing Jiancheng Bioengineering Institute (Nanjing, China).

Statistical methods Data were expressed as mean \pm SEM. After homogenetic analysis, homogeneous data were analyzed with one-way analysis of variance and a post hoc test

of least significant difference. Heterogeneous data were analyzed using the *t*-test. $P < 0.05$ was considered significant.

Results

Body and liver weights The toxicity and abnormal proliferation induced by DEN and 2-AAF was evident in data for body or relative liver weights. The body weights of both groups A and B decreased significantly compared with that of group D. There were no significant alteration in absolute liver weight in all 4 groups. But the relative liver weights (relative to body weights) significantly ($P < 0.05$, $n=5$) increased in DEN+2-AAF, DEN, and 2-AAF group (Table 1).

Table 1. Body and liver weights. $n=5$. Mean \pm SEM. ^b $P < 0.05$ vs control group.

Group	Body weight/g	Liver weight	
		Absolute/g	Relative/%
DEN+2-AAF	360 \pm 25 ^b	13.5 \pm 1.3	3.78 \pm 0.49 ^b
DEN	379 \pm 35 ^b	13.0 \pm 1.6	3.44 \pm 0.43 ^b
2-AAF	412 \pm 44	13.3 \pm 1.3	3.22 \pm 0.20
Control	452 \pm 52	13.0 \pm 0.7	2.87 \pm 0.25

Carcinogenic potential assay: GST-P and PCNA immunohistochemistry Carcinogenic potential assay was performed by comparing the numbers and areas of GST-P-positive foci. The numbers and areas of GST-P-positive foci significantly increased in group A as compared with that of groups B and D (Figure 1A, Table 2). With the present carcinogenic protocol, treatment of rats with single injection of DEN alone did not induce altered hepatic foci but treatment with DEN plus 2-AAF induced many altered hepatic foci in the liver.

PCNA was used as an indicator of cell proliferation. Immunohistochemistry detection of PCNA is a common method used to grade proliferative activity in a given tissue. The number of PCNA-positive cells in groups A and C were remarkably ($P < 0.05$, $n=5$) more than that of control group (Table 2, Figure 1B).

Western blot analysis of Cytochrome P450 isozymes In the present experiments, we used liver samples without isolation of hyperplastic nodules for the analyses of CYP enzymes, because each hyperplastic nodule was too small to isolate. Western blot analysis revealed a slight increase of CYP2E1, significant decrease of CYP1A2 and CYP2B1/2 in both groups A and C. There was no detectable difference of CYP2E1, CYP1A2, and CYP2B1/2 between the DEN-PH

Figure 1. Immunohistochemical staining of GST-P and PCNA in the tissue of group A. (A) GST-P ($\times 15$); (B) PCNA ($\times 30$).

Table 2. Carcinogenic potential assay. Total areas of GST-P-positive foci and the number of PCNA positive nuclei per 1000 cells. ^c $P < 0.01$ vs control group. ^e $P < 0.05$, ^f $P < 0.01$ vs group DEN group.

Group	GST-P foci area/ mm ² ·cm ²	PCNA (+) nuclei (1000 cells)
DEN+2-AAF	17.13 ^c	135 \pm 30 ^{c,f}
DEN	1.16	68 \pm 45
2-AAF	1.08	115 \pm 28 ^{c,e}
Control	Not detectable	32 \pm 13

group and the control group. CYP1A1 was almost undetectable in the control group, but the induction of CYP1A1 in group C was greater than DEN+2-AAF group and DEN group (Figure 2).

Measurement of ethoxy-O-dealkylase activity, p-nitrophenol hydroxylase (PNPH) activity, and erythromycin N-demethylase activity assay The results of these experiments showed that treatment of DEN-PH-2-AAF statistically ($P < 0.01$, $n=5$) increased the liver microsomal PNPH activity approximately 40% more than that of control group; treatment of 2-AAF-PH-2-AAF increased PNPH activity by

Figure 2. Western blot analysis of CYP1A1, CYP1A2, CYP2E1, CYP2B1/2. Lane A: group DEN+2-AAF; lane B, group DEN; lane C, group 2-AAF; lane D, group control. Microsomal protein 80 μg consisting of 3 samples of different rats was loaded into each band.

approximately 30%, but the treatment of a single injection of

DEN had no influence on the PNP activity. These results were in accordance with our Western blot analysis and immunohistochemistry results (Table 3).

Treatment with 2-AAF dramatically increased the ethoxy-O-dealkylase activity approximately 7 times than that of control group. However, treatment with DEN-PH-2-AAF only increased the ethoxy-O-dealkylase activity 1.6 times more (Table 3).

There were no differences of the liver microsomal erythromycin N-demethylase activity among the 4 experiment groups (Table 3).

Immunohistochemistry of CYP2E1 and CYP2B1/2 In the normal liver tissue, immunohistochemical staining of CYP2E1 showed moderate or weak staining around the centrolobular vein (Figure 3C, 3D). In the DEN-2-AAF group

Table 3. Biochemical assay of hepatic microsomal CYP enzymes. Metabolism of *p*-nitrophenol is associated with CYP2E1. Metabolism of ethoxyresorufin is associated with CYP1A1 and CYP1A2, with CYP1A1 metabolizing ethoxyresorufin to a much greater extent than CYP1A2 when both CYP are present. *n*=5. and 2-AAF alone group, the positive staining area was extended and the staining was stronger than that of the control group (Figure 3A). The staining of CYP2E1 was also not seen in the hepatocytes within the altered hepatic foci (Figure 3B).

In the normal liver tissue, immunohistochemical staining of CYP2B1/2 showed a strong centrolobular staining pattern; no staining of CYP2B1/2 was found in the periportal area (Figure 3G, 3H). In the liver treated with DEN-2-AAF, centrolobular staining of CYP2B1/2 was relatively weak and the number of positive hepatocytes was less than that in the normal tissue (Figure 3E). There was no staining of CYP2B1/2 in the altered hepatic foci hepatocytes, except some positive staining hepatocytes scattered among the negative hepatocytes (Figure 3F).

Liver microsomal lipid peroxidation and glutathione level

Treatment with DEN/PH/2-AAF significantly ($P < 0.01$, $n=5$) increased the ability of liver microsome to generate the lipid peroxidation whether in the presence or absence of $\text{Fe}^{3+}/\text{ADP}$. Treatment with 2-AAF or a single injection of DEN could also increase the generation of lipid peroxidation without the presence of $\text{Fe}^{3+}/\text{ADP}$. However, in the presence of $\text{Fe}^{3+}/\text{ADP}$, no remarkable alteration existed between the groups DEN, 2-AAF, and control group, probably because $\text{Fe}^{3+}/\text{ADP}$ presence could increase the normal liver microsomal lipid peroxidation and obliterate the difference. In the presence of CYP2E1 inhibitor diethyl-dithiocarbamate, the generation of lipid peroxidation decreased remarkably ($P < 0.01$, $n=5$) in all 4 groups. The difference between the groups was obliterated. All 4 groups bore the higher lipid peroxidation in the presence of CYP1A inhibitor α -naphthoflavone and $\text{Fe}^{3+}/\text{ADP}$, than in the absence of α -naphthoflavone (Figure 4). This can indicate the specific role of CYP2E1 and CYP1A2 in the generation of microsomal lipid peroxidation.

Glutathione depletion in the DEN-2-AAF group was evident in the data of the glutathione level in the liver homogenization (Table 4).

Discussion

With the present carcinogenic protocol, treatment of rats with single injection DEN or 2-AAF alone for 6 weeks only induced sporadic, little-altered hepatic foci or GST-P positive cells, but treatment of DEN as initiator and 2-AAF as promoter induced many altered hepatic foci in the liver. It has been demonstrated that neoplastic or preneoplastic changes of the liver results in a decrease in the amount of total P450 and the altered expression of CYP isozymes in the liver^[14]. Some isozymes can be overexpressed, at the same

Figure 4. Effect of P450 enzyme inhibitor on microsomal NADPH-dependent lipid peroxidation in 4 groups with Fe^{2+} induction (A) or no Fe^{2+} induction (B). Before the reaction, microsome was incubated with or without specific P450 inhibitor for 10–30 min. Diethyldithiocarbamate is a CYP2E1 inhibitor; naphthoflavone is a CYP1A inhibitor (mainly CYP1A2); 8-methoxypsoralen is a CYP1A (with a similar effect on CYP1A1 and CYP1A2) and CYP2A6 inhibitor. The lipid peroxidation was measured by the formation of thiobarbituric acid reactive substances (TBARS). TBARS are reported in terms of malondialdehyde (MDA). ^b $P < 0.05$, ^c $P < 0.01$ vs DEN; ^e $P < 0.05$, ^f $P < 0.01$ vs 2-AAF; ^h $P < 0.05$, ⁱ $P < 0.01$ vs control.

Table 4. Glutathione level in the homogenate. $n=5$. Mean \pm SEM. ^b $P < 0.05$, ^c $P < 0.01$ vs control group.

Group	GSH/mg·g ⁻¹ protein
DEN+2-AAF	46.03 \pm 2.90 ^c
DEN	53.25 \pm 2.33 ^b
2-AAF	55.12 \pm 2.21 ^b
Control	65.82 \pm 5.02

time, other isozymes are downregulated expressed. The present work confirmed the alteration expression of CYP1A1, CYP1A2, CYP2B1/2 and CYP2E1. As we expected, CYP1A2 was down-regulated in groups A and C. As the previous report demonstrated^[15], the expression of CYP1A2 was reduced preferentially in the liver bearing hyperplastic nodules. CYP1A1 which was undetectable in control rat liver, appeared in the groups A, B, and C. It was not expected that treatment with DEN alone significantly increased ethoxy-O-dealkylase activity, as DEN has no capacity for inducing CYP1A1 *in vitro*. This unexpected change was similar to those observed previously in the treatment of rats with DEN alone^[15]. The mechanism of the unexpected appearance of CYP1A1 in the liver treated with DEN alone remains unclear and requires further study. It has been proposed that a link exists between the capacity of agents and their ability to promote hepatocarcinogenesis^[16]. The altered hepatic foci that shows reduction of expression of CYP2B1/2 might have more potential to grow into hyperplastic nodules^[17]. In the present study, CYP2B1/2 was down-regulated in groups A and C. However, CYP2B1/2 was down-regulated expression in the cells within the altered hepatic foci the same as the previous report.

CYP2E1 is a major microsomal source of hydrogen peroxide and NADPH-dependent lipid peroxidation^[18]. In the present study, CYP2E1 inhibitor inhibited most microsomal lipid peroxidation production in all 4 groups and obliterated the difference among the groups. Thus, the increasing lipid microsomal peroxidation might be induced by overexpression of CYP2E1. This result was in accordance with the major role of CYP2E1 in the generation of microsomal hydrogen peroxide. Immunohistochemical assay indicated that CYP2E1 mainly expressed around the centrolobular vein and most of hepatocytes in the altered hepatic foci were negative. Thus, the hepatocytes within the altered hepatic foci might bear less peroxidation injury than that in the surrounding area. This could contribute to the formation of a resistant phenotype. Studies *in vitro* have indicated that CYP2E1 overexpression has left cells vulnerable to death from GSH depletion^[19]; the different susceptibilities to ROS between hepatocytes within the altered hepatic foci and surrounding tissue can be partially explained by the depletion of glutathione, which was confirmed by the present assay of glutathione in the liver.

The previous study demonstrated that xenobiotic AHR (Aryl Hydrocarbon Receptor) ligands were mechanistically involved in toxicological processes of oxidative stress, generally resulting in increasing ROS production in microsomes^[20]. The specific role of CYP1A1 and CYP1A2 that contributed

to the generation of microsomal lipid peroxidation seemed to be contrary. CYP1A1 appeared to be an important contributor to a microsomal oxidative stress response. However, CYP1A2 decreased the microsomal hydrogen peroxidation generated by CYP2E1 and CYP1A1 by acting as an electron acceptor to prevent the uncoupled electron transferring from NADPH to O₂^[21]. The present results indicate that CYP1A inhibitor α -naphthoflavone promotes the generation of lipid peroxidation in the presence of Fe³⁺/ADP and did not effect the generation of lipid peroxidation in the absence of Fe³⁺/ADP. Because α -naphthoflavone is a more potent inhibitor of CYP1A2 than CYP1A1, and CYP1A2 was an antioxidant enzyme, we proposed that more lipid peroxidation production in groups A and C could result not only from overexpression of CYP2E1 and CYP1A1, but also from decreased expression of CYP1A2.

Changes in CYP isozymes expression can directly produce interindividual differences in susceptibility to carcinogenic compounds; toxicities are modulated by these enzymes. N-nitrosodiethylaminie (DEN) is a widely occurring carcinogenic nitrosamine that requires oxygenation of the α -carbon catalyzed by CYP (mainly by CYP2E1) for its DNA-damaging activity^[22]. The first necessary step for 2-AAF activation is N-hydroxylation mediated by CYP1A to form the proximate carcinogen N-OH-AAF^[23]. In normal rat livers, the relevant isozyme mediated N-hydroxylation of 2-AAF is CYP1A2, but in the liver in which CYP1A1 was induced, we speculated that this step was mediated primarily by CYP1A1, because CYP1A1 N-hydroxylated 2-AAF 6 times more rapidly than CYP1A2. Therefore, in the present study, DEN+2-AAF, DEN, and 2-AAF group, in which CYP1A1 was induced, might have more susceptibility to 2-AAF. Although we are unable to explain the high induction of CYP1A1 in the rat liver of the DEN-PH group, the induction of CYP1A1 after a single injection of DEN might result in more 2-AAF being transformed to N-OH-AAF. Based on this proposal, it can be concluded that alteration of expression of CYP1A1/2 contributed to the hepatocytes within the preneoplastic foci acquisition of resistance to 2-AAF.

In conclusion, the expression of CYP was altered in the early stage of hepatocarcinogenesis and these alterations have an affect on the alteration of cell redox status and the metabolism of carcinogen.

Abstract

Aim: Melatonin-selenium nanoparticle (MT-Se), a novel complex, was synthesized by preparing selenium nanoparticles in a melatonin medium. The present investigation was designed to determine the protective effects of MT-Se against immunological liver injury in mice induced by bacillus Calmette-Guérin (BCG)/lipopolysaccharide (LPS). **Methods:** The model of immunological liver injury in mice was prepared. The levels of alanine aminotransferase, aspartate aminotransferase, nitric oxide (NO) in serum, malondialdehyde content, superoxide dismutase (SOD), and glutathione peroxidase (GSH-px) activities in a liver homogenate were assayed by spectrophotometry. The content of tumor necrosis factor- α (TNF- α) and interleukin-1 (IL-1) were determined by ELISA. The splenocyte proliferation was assayed by 3-[4,5-dimethylthiazol-2-yl]-2,5-diphenyltetrazolium bromide (MTT) dye reduction. Meanwhile, a hepatic pathological examination was observed. **Results:** In the BCG/LPS-induced hepatic injury model, MT-Se administered at doses of 5, 10, or 20 mg/kg to the BCG/LPS-treated mice for 10 d significantly reduced the increase in serum aminotransferase, reduced the severe extent of hepatic cell damage and the immigration of inflammatory cells. It also attenuated the increase in the content of thiobarbituric acid-reactive substances and enhanced the decrease in activities of SOD and GSH-px. In contrast, the treatment with MT-Se suppressed the increase in NO level in both the serum and liver tissue. Furthermore, MT-Se significantly lowered an increase in TNF- α and IL-1 β levels in the liver and inhibited the production of TNF- α and IL-1 β by peritoneal macrophages. A downregulation effect of MT-Se on splenocyte proliferation was also observed. **Conclusion:** MT-Se showed a hepatic protective action on immunological liver injury in mice.

Introduction

Hepatic damage, both acute and chronic, is a common pathology worldwide quite often characterized in its chronic evolution by a progressive process from steatosis to hepatocellular carcinoma through chronic hepatitis, fibrosis, and cirrhosis. The main etiology is represented by viral infections (HBV, HDV, and HCV) and alcohol abuse^[1]. The injection of bacillus Calmette-Guérin (BCG) followed by lipopolysaccharide (LPS) is useful for the creation of experimental models of immunological hepatic damage^[2]. It is

known that *Propionibacterium acnes* or BCG priming and LPS challenge in mice causes massive liver injury, which consists of priming and eliciting phases. *P. acnes* or BCG priming induces mononuclear cell infiltration into the liver lobules and granuloma formation. The subsequent LPS injection elicits acute and massive hepatic injury, with a host release of reactive oxygen species, nitric oxide (NO) and pro-inflammatory cytokines such as tumor necrosis factor α (TNF- α), interleukin-1 β (IL-1 β)^[3-5].

Melatonin participates in many important physiological

processes, including anti-inflammatory^[6] and immunoregulatory^[7] processes, as well as acting as an antioxidant^[8,9]. It not only functions as a direct antioxidant; that is, as a scavenger of various oxygen free radicals including hydroxyl radical, singlet oxygen, hydrogen peroxide (H₂O₂) and peroxy radical, but it also functions as an indirect antioxidant through the enhancement of antioxidant enzyme activities in tissues such as the liver and the brain. Furthermore, melatonin also neutralizes ONOO⁻ and inhibits the production of NO. In addition, our and other published reports have shown that melatonin protects against liver injury through its antioxidant action^[10,11].

Selenium (Se) is an essential element for humans and can improve the activity of the seleno-enzyme and glutathione peroxidase (GSH-px), and can also prevent free radicals from damaging cells and tissues *in vivo*. One of its best-understood functions is that it is present in the active center of GSH-px, an antioxidant enzyme that scavenges various peroxides and protects membrane lipids and macromolecules from oxidative damage^[12]. The supplementation of food with selenium is usually limited to selenium-containing compounds, such as sodium selenite (Na₂SeO₃), ebselen, and other organoselenium compounds. However, several studies have been focused on the elemental selenium (Se⁰). It is currently known that gray and black elemental particulate selenium, observed in several bacteria, which could provide environmental protection from pollution caused by excessive selenium^[13]. These elemental selenium particles are formed in the bacteria to detoxify the excess selenium. In the work of Zhang *et al*^[14], it was found that selenium nanoparticles had a higher bioavailability, much less acute toxicity and better scavenging effect compared with organic and other inorganic selenium-containing compounds.

In the present paper, based on the antioxidant and immunoregulatory actions of melatonin and elemental selenium nanoparticles, we combined selenium nanoparticles with melatonin in order to obtain useful materials for medication. Melatonin-selenium nanoparticle (MT-Se), a novel complex, was synthesized by preparing selenium nanoparticles in melatonin medium. In this study, the mechanisms of the protective effects of MT-Se on immunological liver injury induced by BCG plus LPS were investigated.

Materials and methods

Preparation of melatonin-selenium nanoparticle MT-Se was prepared by reducing selenious acid with ascorbic acid in the presence of melatonin. In a synthetic process, the appropriate amount of selenious acid (the water solution of SeO₂) was thoroughly mixed with melatonin. Then excessive ascorbic acid was added into the selenious acid/melatonin mixture to initiate redox reaction^[15].

After the reaction mixture was mixed for approximately 30 min, the product showing light red was obtained. In the reaction process, melatonin molecules could be strongly absorbed on the surface of nascent selenium seeds. Melatonin not only served as a seed growth controller, but also prevented selenium nanoparticles from congregating. Transmission electron microscopy (TEM) images of the product, as shown in Figure 1, were captured on a JEOL-JEM 200CX instrument (JEOL Company, Japan) at an accelerating voltage of 100 kV. From the image, it can be seen that uniform spherical selenium nanoparticles were produced. The final product prepared for medicine application was the complex made up of 95% melatonin, 1% elemental selenium, and 4% ascorbic acid/dehydroascorbic acid. It was dissolved with absolute ethanol and then stabilized and suspended briefly in 0.5% carboxymethylcellulose (CMC) before use.

Materials MT-Se, provided by the Department of Chemistry, Anhui University, was dissolved with absolute

Figure 1. Transmission electron microscopy images of melatonin-selenium nanoparticles.

ethanol and then stabilized and suspended briefly in 0.5% CMC. Melatonin, purchased from Sigma Chemical (St Louis, MO, USA), was suspended in 0.5% CMC with absolute ethanol ($\leq 0.01\%$, v/v) and stored at $-20\text{ }^{\circ}\text{C}$. LPS from *Escherichia coli* were obtained from Sigma Chemical. Commercial kits used for determining lipid peroxidation (TBRAS), GSH-px and superoxide dismutase (SOD) activity were obtained from the Jiancheng Institute of Biotechnology (Nanjing, China). Other chemicals used in these experiments were analytical grade from commercial sources.

Animals Male Kunming mice ($20\pm 2\text{ g}$), obtained from the Animal Department of Anhui Medical University, were maintained on a 12 h light/12 h dark cycle from 6:00 AM to 18:00 PM under a regulated environment ($20\pm 1\text{ }^{\circ}\text{C}$). Animals were housed in plastic cages with free access to food and water. All procedures followed the guidelines for human treatment of animals set by the Association of Laboratory Animal Sciences and the Center for Laboratory Animal Sciences at Anhui Medical University.

Establishment of acute liver injury model BCG (viable bacilli), 2.5 mg suspended in 0.2 mL saline, was injected through the tail vein in mice, and 10 d later they were injected with 7.5 μg LPS dissolved in 0.2 mL saline. The mice were anesthetized with ether then killed 16 h after LPS injection by cervical dislocation. The trunk blood was collected into heparinized tubes (50 kU/L) and centrifuged ($1500\times g$, 10 min, $4\text{ }^{\circ}\text{C}$). Serum was aspirated and stored at $-70\text{ }^{\circ}\text{C}$ until assayed as described below. The liver was also removed and stored at $-70\text{ }^{\circ}\text{C}$ until required^[2, 10].

Drug treatment Seven groups of mice, 10 in each, were arranged as follows: (1) normal untreated mice; (2) model mice; (3) model mice treated with different drugs: (a) three MT-Se groups (5, 10, and 20 mg/kg respectively); (b) bifendate group (100 mg/kg). In the treatment groups, different drugs were administered orally by gastric intubation 10 d prior to LPS injection. The mice in normal and model control groups were fed the same volume of vehicle only.

Measurement of serum alanine aminotransferase and aspartate aminotransferase Serum alanine aminotransferase (ALT) and aspartate aminotransferase (AST) were determined using commercial kits produced by Jiancheng Institute of Biotechnology (Nanjing, China). Their activities were expressed as an international unit (U/L).

Histological analysis Formalin-fixed specimens were embedded in paraffin and stained with hematoxylin and eosin for conventional morphological evaluation. After decapitation of rats, small hepatic specimens were placed in 10% (v/v) formalin solution and processed routinely by embedding in paraffin. Tissue sections (4–5 μm) were stained with hema-

toxylin and eosin and examined under light microscope (Olympus IX70, Japan). An experienced histologist, who was unaware of the treatment conditions, made histological assessments.

Measurement of malondialdehyde, SOD, and GSH-px in liver homogenate Lipid peroxidation production in the liver tissue was determined by measuring thiobarbituric acid-reactive substances (TBARS)^[16]. TBARS were measured using the thiobarbituric acid method, with 1,1,3,3-tetramethoxypropane as a standard. Hepatic protein was assayed by the method of Lowry *et al* using bovine serum albumin as a standard^[17]. The amount of TBARS was expressed as nmol malondialdehyde (MDA)/mg protein. The assay for total SOD was based on its ability to inhibit the oxidation of oxymine by the xanthine-xanthine oxidase system^[18]. Results were expressed as U per microgram protein. The activity of GSH-px was determined by quantifying the rate of H_2O_2 -induced oxidation of GSH to oxidized glutathione (GSSH). A yellow product with absorbance at 412 nm was formed as GSH reacted with dithionitrobenzoic acid^[19]. One unit of GSH-px was defined as the amount that reduced the level of GSH by 1 $\mu\text{mol/L}$ in 1 min/mg protein.

Measurement of NO in serum and liver NO in the serum and the liver was measured by a microplate assay using Griess reagent, which produces a chromophore with the nitrite^[20]. Briefly, 100 μL of supernatants were removed and incubated with 100 μL of Griess reagent (1% sulfanilamide and 0.1% *N*-1-naphthylethylenediamine dihydrochloride in 2.5% phosphoric acid) in a 96-well plate. The plate was incubated for 10 min at room temperature. Nitrite production was quantified spectrophotometrically using an automated colorimetric procedure. Absorbance at 540 nm was measured using a microplate reader (318MC, Shanghai Sanco). The nitrite concentration was calculated by comparing samples with standard solutions of sodium nitrite produced in the culture medium. All samples were assayed in triplicate. Results were expressed as $\mu\text{mol/L}$.

Splenocytes proliferation assay Mice were killed by cervical dislocation. Spleens were removed in sterile conditions and splenocytes were collected. Then the cells were suspended in RPMI-1640 medium at a concentration of 1×10^7 cell/L. The cell suspension (100 μL) and concanavalin A (ConA) (100 μL with final concentration of 3 mg/L) or LPS (100 μL with final concentration of 4 mg/L) were seeded to a 96-well culture plate simultaneously. Triplicates were designed. The cultures were incubated at $37\text{ }^{\circ}\text{C}$ in an atmosphere of 5% CO_2 for 48 h. Two hours before completion, 10 μL of MTT (5 g/L) was added to each well. The absorbance was measured on an EJ301 ELISA Microwell Reader (Wuxi

Keda, China) at 570 nm. The results were described as the average of triplicate A.

Preparation of peritoneal macrophages and induction of TNF- α and IL-1 β Mice PM Φ were collected in D-Hanks' medium by routine method. Then PM Φ was resuspended in RPMI-1640 medium at 1×10^9 cell/L and the cell suspension was seeded into a 24-well culture plate, 1 mL per well. After incubation at 37 °C for 2 h in 5% CO₂ atmosphere, supernatants were removed and the adherent cells were washed 3 times with Hanks' medium, which contained 5% neonatal bovine serum. Thus, the monolayer of PM Φ was obtained. LPS, with a final concentration of 4 mg/L, was added to each well and RPMI-1640 was also added to make a final volume per well of up to 1 mL. The plate was then incubated at 37 °C in air with 5% CO₂ for 48 h. After being centrifuged (500 \times g, 10 min), all the supernatants containing extracellular TNF- α and IL-1 β were collected and stored at -20 °C until assay.

Measurement of TNF- α and IL-1 β in liver and culture supernatants The TNF- α and IL-1 β levels in the liver homogenate and culture supernatants were determined using rat ELISA kits. Their levels were expressed as ng/L.

Statistical analysis All values are presented as mean \pm SD. A two-tailed, non-paired, Student's *t*-test was used to evaluate differences between means. Statistical significance was set at $P < 0.05$.

Results

Effect of MT-Se on serum ALT and AST concentration

The model group (treated with BCG plus LPS) manifested severe liver damage with an elevation of serum aminotransferase, compared with the normal group. In the group of mice treated with MT-Se (5, 10, and 20 mg/kg), serum levels of liver enzymes were significantly decreased as compared with BCG plus LPS-treated mice. Similarly, bifendate (100 mg/kg) reduced the levels of liver enzymes as opposed to BCG plus LPS-treated mice (Table 1).

Effect of MT-Se on liver histology No histological abnormalities were observed in normal mice. There was severe necrosis of hepatocytes with marked mononuclear infiltration, seen after LPS injection in the BCG-primed mice. In the MT-Se (5, 10, and 20 mg/kg) treated groups, the area and extent of necrosis was attenuated and the immigration of inflammatory cells was reduced (Figure 2).

Effect of MT-Se on liver homogenate MDA content and SOD, GSH-px activities Injection of LPS after BCG priming in mice caused a significant elevation in MDA levels in the liver tissue. MT-Se (5, 10 and 20 mg/kg) reduced the elevation of MDA levels in the liver. The activities of antioxidant enzymes including GSH-px and SOD were significantly in-

hibited in the liver tissues of mice injected with LPS after BCG priming. Treatment with MT-Se (10 and 20 mg/kg) increased the activity of GSH-px and MT-Se at doses of 10 and 20 mg/kg elevated the activity of SOD (Table 2).

Effect of MT-Se on serum and liver levels of NO The levels of NO in serum and liver tissue were significantly increased in BCG-primed mice challenged with LPS. MT-Se (5, 10, and 20 mg/kg) reduced the elevation of NO levels in serum and liver tissue (Figure 3).

Effect of MT-Se on TNF- α and IL-1 β concentration in the liver As shown in Table 3, when mice were first injected with BCG and then challenged with LPS, the proinflammatory cytokines, such as TNF- α and IL-1 β , were significantly elevated. MT-Se (5, 10, and 20 mg/kg) decreased the levels of TNF- α and IL-1 β in a liver homogenate. Bifendate had no effect on TNF- α and IL-1 β (Table 3).

Effect of MT-Se on splenocyte proliferation in mice with immunological liver injury Treatment with MT-Se suppressed the accentuation of splenocyte proliferation induced by LPS or ConA (Figure 4).

Effect of MT-Se on production of TNF- α and IL-1 β by PM Φ The levels of TNF- α and IL-1 β in culture supernatants of PM Φ were significantly increased in immunological liver injury mice. MT-Se (5, 10, and 20 mg/kg) inhibited the production of TNF- α and IL-1 β (Table 4).

Discussion

The findings of the present study showed that MT-Se, a new chemical compound that is composed of melatonin and red elemental selenium particles, prevented the development of immunological liver injury induced by BCG plus LPS. It markedly reduced the severe liver injury in mice as demon-

Figure 2. Histologic examination of liver sections (hematoxylin and eosin stains, ×200) from: (A) a normal mouse showing no histological abnormality; (B) a BCG-primed and LPS-treated mouse showing severe degeneration of hepatocytes with marked mononuclear infiltration; (C, D) a mouse treated with melatonin-selenium nanoparticle (MT-Se) and bifendate, respectively. Images show the area and extent of necrosis was attenuated and the immigration of inflammatory cells was reduced compared to BCG-primed and LPS-treated mouse.

strated by a significant reduction in the serum transaminase levels and amelioration of severe hepatic pathological abnormalities. Meanwhile, MT-Se decreased MDA content and NO levels, and increased the antioxidant capacity, including SOD and GSH-px activity. In addition, MT-Se played an immunoregulatory role in decreasing proinflammatory cytokines and inhibiting splenocyte proliferation. We propose that oxidative stress and proinflammatory cytokine overproduction imposed on the liver play an important role in the pathogenesis of hepatic damage, and these results are attenuated by the antioxidant and immunoregulatory activity of MT-Se.

The current results confirmed that MT-Se’s protection against hepatic injury was associated with the antioxidant property of melatonin and selenium. Melatonin combined with selenium could induce synergistic effects, indicated by improved free radical scavenging activity of MT-Se. Selenium, an integral part and located at the catalytic site of GSH-px, is now known to be of fundamental importance to human health^[21]. Recent evidence has shown that treatment with selenium and other antioxidants results in positive clinical responses in various liver diseases associated with increased oxidative damage^[22]. GSH-px and some seleno-compounds such as ebselen have also been shown to protect

against hepatic injury^[23,24]. Selenium also appears to be protective for individuals infected with the hepatitis virus (B or C) against the progression of the condition to liver cancer^[25]. These effects may prove selenium to be beneficial as an

adjuvant therapy for liver disease. However, it must be remembered that selenium is a toxic mineral with a fairly small therapeutic window. Seleno-compounds, especially inorganic selenium, could be hepatotoxic and teratogenic in animals and humans. In some sensitive individuals, the maximum safe dietary intake may be as low as 600 μg per day. It would therefore seem prudent to restrict adult intake from all sources to an upper limit of 400–450 μg/day as recommended by several expert panels^[26]. Although the toxic effect of elemental selenium nanoparticles is less, the selenium contents percentage in MT-Se is only 1% and the dose of selenium less than 200 μg in our experimental design. The current study confirmed that selenium at doses of 50 to 200 μg reinforced the endogenous anti-oxidative systems in comparison with melatonin or selenium alone; suggested by MT-Se blunting of lipid peroxidation and increased GSH-px activity.

Melatonin is also well known to be a multi-faceted free radical scavenger and antioxidant^[8,9]. Previous studies have shown that melatonin could protect against several models of liver injury by inhibiting oxidative and nitrosative damage. Calvo *et al* found that melatonin protected against alpha-naphthylisothiocyanate (ANIT)-induced liver injury with cholestasis in rats, and suggested that this protective effect was a result of its antioxidative properties and above all to its capacity to inhibit liver neutrophil infiltration, a critical factor in the pathogenesis of ANIT-induced liver injury^[27]. Melatonin at high doses (10–100 mg/kg) could also dose-dependently reduce liver lipid peroxide content in CCl₄-treated rats. This indicates that melatonin exerts a therapeutic effect on CCl₄-induced acute liver injury in rats, possibly through its antioxidant action^[28]. Melatonin plays a cytoprotective role in the liver affected by ischemia and reperfusion through its ability to prevent hepatic malfunction and inhibit the gen-

eration of free radicals and accumulation of neutrophils in the damaged hepatic tissue^[29]. Moreover, melatonin appeared to be significantly more potent than N-acetylcysteine in reversing the oxidative damage induced by ischemia and reperfusion^[30]. In bile duct ligated rats, melatonin was much more effective than vitamin E in reducing liver injury and oxidative stress^[31]. Acetaminophen at high doses can cause fulminant hepatic necrosis and nephrotoxic effects, and melatonin can reverse these effects with its higher efficacy in scavenging various free radicals and also because of its ability in stimulating the antioxidant enzymes^[32]. In our previous study, we also observed that pretreatment with melatonin had a protective effect on immunological hepatic damage induced by BCG and LPS. In this study, it is confirmed that MT-Se also had a hepatic protective effect through the synergistic antioxidant effect of melatonin and selenium.

As is well known, TNF- α is considered to be a common early effector molecule for liver injury, in addition to its direct cytotoxic effects, this cytokine is able to induce chemokines, macrophage chemotactic protein-1, and adhesive molecules (vascular-cell adhesion molecule-1), which are key to inflammation and consequent liver damage. The prevention of liver injury has been observed upon neutralization of TNF- α with anti-TNF- α antibody, prevention of translation of primary RNA transcript of TNF- α by antisense oligonucleotide and interaction of TNF- α with soluble TNF- α receptors. Although IL-1 itself does not damage the liver, its elevation could stimulate inflammatory cells to excrete many other cytokines including TNF- α , IL-6, and IL-8. Our results suggest that the elevation of inflammatory cytokines, including TNF- α and IL-1 β , in the liver tissue and PM Φ cell culture supernatants are contributing to the mechanisms of immunological liver injury. MT-Se decreased TNF- α and IL-1 β levels in the liver inhibiting their production by PM Φ . These results are consistent with the literature suggesting melatonin's immunosuppressive effect on the production of inflammatory cytokines. Shin *et al*^[33] found that low levels of Bacillus anthracis were known to induce the release of cytokines such as TNF- α , and thereby exposure of melatonin (1×10^{-7} – 1×10^{-6} mol) to anthrax lethal toxin-treated macrophages also decreased the release of TNF- α to the extracellular medium as compared with the control. Sacco *et al*^[34] found that the administration of melatonin to mice (5 mg/kg, sc, 30 min before or simultaneously with LPS) inhibited serum TNF- α levels by 50%–80% and improved the survival of mice treated with a lethal dose of LPS. It was also previously reported that melatonin had a protective role in LPS-induced septic shock by suppressing proinflammatory cytokines, prostaglandins and NO production^[35]. Thus, the present

study revealed that MT-Se had an immunoregulatory effect on immunological liver injury in mice by inhibiting proinflammatory cytokine production. Moreover, in our *in vivo* experiment, MT-Se suppressed the proliferation of spleen cells induced by ConA or LPS. These findings suggest that MT-Se may alleviate immunological liver injury not only through inhibiting the activation of PM Φ , but also by inducing the dysfunction of activated lymphocytes.

In summary, the results obtained in the present study indicate that the mode of MT-Se's hepatic protective action is, at least in part, related to its antioxidant properties, such as inhibiting lipid peroxidation and NO production, as well as increasing the antioxidant enzyme capacity. Furthermore, we found that it appeared that MT-Se had an immunoregulatory effect on inhibiting proinflammatory cytokines and activated lymphocytes. MT-Se, a novel complex, may be beneficial as a valuable drug for protection against liver injury. However, further investigation is required to clarify the detailed mechanism of the therapeutic effect of MT-Se on liver injury.

Abstract

Aim: To study the effect of peroxisome proliferator-activated receptor γ (PPAR γ) ligands on cell proliferation and apoptosis in human renal carcinoma cell lines. **Methods:** The expression of PPAR γ was investigated by reverse transcriptase polymerase chain reaction (RT-PCR), Western blot and immunohistochemistry. The effect of thiazolidinedione (TZD) PPAR γ ligands on growth of renal cell carcinoma (RCC) cells was measured by MTT assay and flow cytometric analysis. Cell death ELISA, Hoechst 33342 fluorescent staining and DNA ladder assay were used to observe the effects of PPAR γ ligands on apoptosis. Regulatory proteins of cell cycle and apoptosis were detected by Western blot analysis. **Results:** PPAR γ was expressed at much higher levels in renal tumors than in the normal kidney (2.16 ± 0.85 vs 0.90 ± 0.73 ; $P < 0.01$). TZD PPAR γ ligands inhibited RCC cell growth in a dose-dependent manner with IC₅₀ values of 7.08 μ mol/L and 11.32 μ mol/L for pioglitazone, and 5.71 μ mol/L and 8.38 μ mol/L for troglitazone in 786-O and A498 cells, respectively. Cell cycle analysis showed a G₀/G₁ arrest in human RCC cells following 24-h exposure to TZD. Analysis of cell cycle regulatory proteins revealed that TZD decreased the protein levels of proliferating cell nuclear antigen, pRb, cyclin D₁, and Cdk4 but increased the levels of p21 and p27 in a time-dependent manner. Furthermore, high doses of TZD induced massive apoptosis in renal cancer cells, with increased Bax expression and decreased Bcl-2 expression. **Conclusion:** TZD PPAR γ ligands showed potent inhibitory effect on proliferation, and could induce apoptosis in RCC cells. These results suggest that ligands for PPAR γ have potential antitumor effects on renal carcinoma cells.

Introduction

Peroxisome proliferator-activated receptor γ (PPAR γ) belongs to the superfamily of nuclear hormone receptor transcription factors^[1–3]. PPAR γ forms a heterodimer with another nuclear receptor, retinoid X receptor α (RXR α)^[4]. In the presence of their ligands, PPAR γ /RXR α heterodimer binds to a specific DNA sequence designated peroxisome proliferating response element (PPRE) located in the promoter region of PPAR γ target genes and modulates their transcription^[5]. Thus far, hundreds of PPAR γ target genes have been identified and most of them are involved in adipogenesis^[6], glucose metabolism^[7] and angiogenesis^[8]. Since the dis-

covery of specific ligands for PPAR γ , including synthetic antidiabetic thiazolidinediones (TZD) and endogenous 15-deoxy-*D*^{12,14}-PGJ₂ (15dPGJ₂) and some polyunsaturated fatty acids, accumulating evidence using many experimental systems suggests that PPAR γ plays an important role in carcinogenesis in both adipose and nonadipose cells. It has been known that PPAR γ expression is up-regulated in many tumor tissues and its ligands, including pioglitazone, troglitazone and roglitazone, can induce apoptosis and exert antiproliferative effects in human colon cancer^[9], breast cancer^[10], pituitary adenomas^[11], gastric cancer^[12] and bladder cancer^[13]. Moreover, PPAR γ may play an important role in inducing cell differentiation or growth inhibition in patients

with liposarcoma^[14] and prostate cancer^[15]. Therefore activation of PPAR γ seems to be a potential approach for treatment of some malignant tumors.

Renal cell carcinoma (RCC) is the most common renal tumor and the third malignancy within urological oncology. It makes up approximately 2%–3% of all adult malignancies. At present, more than 50% of all RCC are found incidentally, which results in a high proportion of patients with progressive metastasis at the time of diagnosis^[16,17]. Surgery remains the only effective therapeutic option. Although combination of chemotherapy and/or radiotherapy might help in survival rate, it is considered to be of limited value for the treatment of RCC. Therefore, improvement of life span in patients with renal cell carcinoma greatly depends on the identification of novel treatment strategies. An alternative treatment may include activation of PPAR γ , as PPAR γ has been shown to be expressed in the kidney^[18], and its ligands can induce cell growth inhibition and terminal differentiation in many other malignancies^[9–14].

In the present study, we examined the expression of PPAR γ in human primary RCC and RCC cell lines, and determined the biological events of PPAR γ activation in inducing RCC cell cycle arrest and apoptosis. We have also explored the molecular mechanism through which PPAR γ agonists inhibit cell growth and induce cell death in RCC cell lines.

Materials and methods

Chemicals Pioglitazone and troglitazone were kindly gifted by Park-Davis Pharmaceutical Research (Ann Arbor, MI, USA) and Takeda Chemical Industries (Osaka, Japan). All other chemicals were purchased from Sigma (St Louis, MO, USA). Stock solutions of pioglitazone or troglitazone were made at 100 mmol/L concentration in dimethyl sulfoxide and added to the culture medium at the final concentration of less than 0.1%.

Cell lines and culture conditions Human RCC-derived cell lines 786-O and A498, human proximal tubular cell line (HK-2), and human mesangium cell line (HMCL) were cultured in Hepes-buffered RPMI-1640 medium (Gibco BRL, Grand Island, NY, USA) supplemented with 10% FBS, 100 kU/mL penicillin G, 100 g/L streptomycin, and 2 mmol/L *l*-glutamine in a humidified 5% CO₂ atmosphere at 37 °C. The media were changed every 3 d, and the cells were separated by trypsinization using trypsin/edetic acid when they reached 90% confluence.

Tumor specimens and immunohistochemistry Specimens were obtained from 120 patients with RCC and 20 patients with normal kidney (NK) who underwent total

nephroureterectomy as a result of ureteral cancer or trauma. All patients were treated at the Institute of Urology in Peking University between June 1999 and June 2001. No patients had received irradiation or chemotherapy prior to surgery. Tumor samples with the highest nuclear grade were selected. All tissues were preserved in 10% formalin serially sectioned onto microscope slides with a thickness of 4 μ m/L. Sections were immunostained with polyclonal antibody to human PPAR γ (1:100, Santa Cruz Biotechnology, Santa Cruz, CA, USA) using avidin-biotin-complex-peroxidase and counterstained with hematoxylin. Negative control slides were prepared by omitting the primary antibody. The intensity of immunostaining and the ratio of the positive cells were roughly graded into four scores (0, 1, 2, 3, and 4) by two observers who did not know the origin of the samples on two occasions. The score 4 was defined as maximum intensity of immunostaining throughout the section, while the score 0 implied that staining was absent throughout the specimen.

Measurement of PPAR γ mRNA by reverse transcription-polymerase chain reaction Total RNA from 15 RCC tissues, 10 NK tissues, RCC cell lines 786-O and A498, HK-2 cells and HMCC (normal kidney derived mesangium cell line). Cells was isolated using TRIzol reagent (Invitrogen, Carlsbad, CA, USA). Contaminated genomic DNA in total RNA was removed by RNase-free DNase I digestion. Reverse transcription was performed in a total volume of 25 μ L using 3 μ g of total RNA, oligo-dT primer and MMLV reverse transcriptase (Amersham, Buckinghamshire, UK). Primers used for the amplification of PPAR γ cDNA were synthesized at the SBS Gene Company (Beijing, China). The sense primer was 5'-AGAGATGCCATTCTGGCC-3' and antisense primer was 5'-GTGGAGTAGAAATGCTGGAGA-3'. Polymerase chain reaction (PCR) amplification yielded a PCR product of 130 bp. Primers used for amplifying a 500-bp of β -actin cDNA as an internal control were as follows: 5'-ACTGACTACCTCATGAAGATC-3' (sense) and 5'-CGTCATACTCCTGCTTGC-3' (anti-sense). The PCR condition was 40 s (denaturation) at 94 °C, 35 s (annealing) at 60 °C and 35 s (extension) at 72 °C for 33 cycles. PCR products were separated in 1.5% agarose gel and visualized after ethidium bromide staining.

Growth inhibition of RCC cell lines by PPAR γ agonists The effect of PPAR γ ligands on cell proliferation of RCC cells was determined using MTT assay^[13]. Briefly, cells of 0.5×10^4 cells/well were inoculated into a 96-well plate (Costar, Cambridge, MA, USA), treated with pioglitazone or troglitazone at various concentrations. After an incubation for 24 h, 20 μ L/well 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl tetrazolium bromide (MTT, 5 g/L) was added to each well, the me-

dium was then removed, and 200 μL of 0.04 mol/L HCl in isopropanol was added to dissolve the reduced formazan product. The plate was read in a microplate reader (model 3550, BIO-RAD, Richmond, CA, USA) at 590 nm.

Flow cytometry assay RCC cell lines 786-O and A498 treated with pioglitazone (20 $\mu\text{mol/L}$) and troglitazone (30 $\mu\text{mol/L}$) for 24 h were harvested and washed with PBS. Cells of 1×10^6 were fixed in 75% ethanol at 4 °C for 24 h, washed in PBS, resuspended in 0.5–1.0 mL PBS containing 100 mg/L RNase A at 37 °C for 30 min, incubated in 10 mg/L propidium iodide in dark at 4 °C for 30 min, and sorted in a Coulter EPICS-XL Cytometer (Becton Dickinson and Beckman-Coulter, San Jose, CA, USA).

Apoptosis assay Cytosolic histon-bound DNA fragments caused by apoptosis were detected using a cell death ELISA kit (Roche Applied Science, Mannheim, Germany) according to manufacturer's protocol. Briefly, 1×10^4 cells were seeded in a 96-well microplate and incubated for 4 h at 37 °C. Pioglitazone 0–100 $\mu\text{mol/L}$ or troglitazone was added and incubated for 48 h. Cells were then lysed with lysis buffer for 30 minutes at 25 °C. Supernatant 20 μL was transferred into the streptavidin coated multiplate, 4 μL anti-histon-biotin and 4 μL anti-DNA-POD were added to each well, and the plate was shaken for 2 h. After being washed with incubation buffer, 100 μL ABTS (2,2'-Azino-di[3-ethylbenzthiazoline-sulfonate]) solution was pipetted into each well. The absorbance was read immediately in a microplate reader (BIO-RAD, model 3550) at 405 nm. Furthermore, apoptosis of RCC cell lines induced by 70 $\mu\text{mol/L}$ troglitazone or 80 $\mu\text{mol/L}$ pioglitazone was also assayed using two other methods. Morphological changes resulting from apoptosis were determined by Hoechst 33342 staining. Cells suspended in PBS were stained with 2 mg/L Hoechst33342 and observed under fluorescence microscope using a blue filter. Cells showing cytoplasmic and nuclear shrinkage and chromatin condensation or fragmentation were defined as apoptotic cells. DNA fragmentation manifested as laddering in agarose gel was also examined. After drug treatment, the cells pellet was lysed in 10 mmol/L Tris-HCl pH 8.0, 150 mol/L NaCl, 10 mmol/L edetic acid and 0.5% SDS on ice for 10 min, and treated with RNase A and proteinase K for 1 h. Following DNA precipitation with ethanol and ammonium acetate at -20 °C for 10 h, DNA was dissolved in TE buffer, electrophoresed in 1.8% agarose gel, and visualized under UV light.

Western blot analysis Cells before and after drug treatment were extracted with lysis buffer containing 50 mmol/L Tris-HCL, pH 8.0, 150 mmol/L sodium chloride, 1% TritonX-100, 0.02% sodium azide, 100 mg/L phenylmethylsulfonyl fluoride and 1 mg/L aprotinin. The protein content in cell lysate

was determined by bicichoninic acid assay using bovine serum albumin as the standard. Cell lysate containing 50–60 μg protein was resolved by SDS-polyacrylamide gel electrophoresis and electrophoretically transferred onto a polyvinylidene difluoride membrane (Millipore, Bedford, MA, USA). The membrane was blotted by antibodies against human PPAR γ (1:500), proliferating cell nuclear antigen (PCNA; 1:1500), pRb (1:1000), p21 (1:1000), p27 (1:1000), cyclinD₁ (1:1000), Cdk₄ (1:1000), Bcl-2 (1:1000) and Bax (1:800) (Santa Cruz Biotechnology). Blotted antibody was developed by horseradish peroxidase-conjugated secondary antibody and enhanced chemiluminescence detection system (Amersham Pharmacia Biotech, Uppsala, Sweden).

Statistical analysis The experimental results shown were repeated twice or three times, unless otherwise indicated. Results are expressed as mean \pm SD. Statistical analysis was carried out using Student's *t*-test and one-way ANOVA. Significance was set at $P < 0.05$. Statistical analyses were performed using SPSS10.0 (SPSS Inc, Chicago, IL, USA)

Results

PPAR γ expression in human RCC tissue and RCC cell lines Using RT-PCR and Western blot analysis PPAR γ mRNA expression was detected in 15 human RCC tissues, 10 normal kidney tissues, 2 RCC cell lines (786-O and A498) and 2 normal kidney cell lines (HK-2 and HMCL). PPAR γ expression at both mRNA (Figure 1A) and protein level (Figure 1B) was detected in all tissues and cell lines examined. Much higher PPAR γ expression levels were observed in human RCC tissues and cell lines (786-O and A498) compared to normal renal tissues and cell lines (Figure 1A, 1B). Immunostaining analysis further demonstrated that PPAR γ immunoreactivity was much higher over cancer cells in human RCC tissues compared to adjacent normal tissues and normal renal tissues (Figure 1C).

Strong staining of PPAR γ was observed in 118 out of 120 human RCC tissues. PPAR γ protein was predominantly localized to nucleus and cytoplasm areas of the cells. In contrast, although 16 out of the 20 normal renal samples showed PPAR γ protein expression, only weak PPAR γ expression was observed in cytoplasm of the medullary collecting duct cells. Statistically, the intensity of PPAR γ immunoreactivity was much higher in human RCC tissues than in normal renal tissues (2.16 ± 0.85 vs 0.90 ± 0.73 ; $P < 0.01$).

PPAR γ agonists inhibited proliferation of RCC cell lines To determine the effect of PPAR γ ligands on growth of human RCC cell lines, the exponentially growing 786-O and A498 cells were treated with 0–50 $\mu\text{mol/L}$ pioglitazone and

Figure 1. (A) RT-PCR analysis showing expression of PPAR γ mRNA in human RCC tissues, normal kidney (NK) tissues, RCC cell lines 786-O and A498, and normal renal cell lines HK-2 and HMCL. β -actin was used as an internal control for RNA loading. (B) Immunoblotting analysis showing that PPAR γ protein (55 kDa) was detected in all tissues and cell lines. β -Actin (47 kDa) was used as a protein loading control. Note: higher levels of PPAR γ mRNA and protein in human RCC tissues and cell lines. (C) Immunohistochemistry analysis of PPAR γ in human RCC tissues (a and c) and normal kidneys (b and d). The slides were counterstained with hematoxylin; a and b ($\times 100$) and c and d ($\times 400$). Note much higher staining of PPAR γ in human RCC tissues than normal kidneys and intense immunoreactivity was observed over malignant cells with little staining in surrounding non-tumor cells (a&c).

troglitazone for 24 h. Cell growth was determined by an MTT assay. Figure 2 showed that two TZD PPAR γ agonists pioglitazone and troglitazone significantly inhibited the cell growth of RCC in a dose-dependent manner, with the calculated IC₅₀ values of 7.08 and 11.32 $\mu\text{mol/L}$ for pioglitazone and 5.71 and 8.38 $\mu\text{mol/L}$ for troglitazone in 786-O and A498 cells, respectively.

Effect of PPAR γ agonists on cell cycle of RCC cell lines

Cell cycle analysis was performed in two RCC cell lines after exposure to 20–30 $\mu\text{mol/L}$ pioglitazone and troglitazone for 24 h. In both cell lines, pioglitazone and troglitazone caused

Figure 2. MTT assay showing effect of two TZD PPAR γ agonists, pioglitazone and troglitazone, on the growth of human RCC cell lines. RCC 786-O cells (A) and A498 cells (B) were cultured and treated with pioglitazone and troglitazone at various concentrations. Cell growth of both 786-O and A498 cells was determined by MTT assay. Both TZD compounds inhibited cell proliferation of RCC cells in a dose-dependent manner. $n=8$. Mean \pm SD. $^{\circ}P<0.01$ versus corresponding control group.

a dose-dependent increase in the G₀/G₁ phase and decrease in the S phase (Figure 3).

Effect of PPAR γ ligands on cell cycle protein expression in human RCC cell lines

The cell cycle is tightly regulated through a complex network of positive and negative regulatory molecules including cyclin dependent kinases (Cdks), cyclins, and Cdk inhibitors (Cdkis). To elucidate the role of these molecules in the inhibition of cell cycle induced by pioglitazone and troglitazone in RCC cell lines, protein extract was prepared from the cells treated with 30 $\mu\text{mol/L}$ pioglitazone or troglitazone for 0, 12, and 24 h. Immunoblotting was performed using antibodies against human PCNA, pRb, cyclin D₁, p21, p27, and Cdk4. As shown in Figure 4, pioglitazone and troglitazone treatment time-dependently caused a marked decrease in PCNA, pRb, Cyclin

Figure 3. Flow cytometry analysis demonstrating the effect of pioglitazone and troglitazone on cell cycle of two RCC cell lines, 786-O cells (A–E) and A498 cells (F–J). (A) and (F), control cells; (B) and (G), cells treated with 20 $\mu\text{mol/L}$ troglitazone; (C) and (H), cells treated with 30 $\mu\text{mol/L}$ troglitazone; (D) and (I), cell treated with 20 $\mu\text{mol/L}$ pioglitazone; (E) and (J), cells treated with 30 $\mu\text{mol/L}$ pioglitazone. The two TZD PPAR γ ligands induced the G₀/G₁ phase proportion and decreased the S phase proportion in both RCC cell lines. $n=3$. Mean \pm SD. $^{\circ}P<0.01$ vs control cells.

Figure 4. Western blot analysis showing the effect of PPAR γ activation on the levels of proteins involved in cell cycle regulation in RCC cells. 786-O and A498 cells were treated with 30 $\mu\text{mol/L}$ pioglitazone and troglitazone for 0, 12, and 24 h. Equal amount of cell lysate containing 50 μg protein was separated and blotted by specific antibodies as described in “Materials and Methods”. Actin was used as a sample loading control.

D₁ and Cdk4 expression and a significant increase in p21 and p27 expression.

PPAR γ agonist induced apoptosis in human RCC cell lines The ability of pioglitazone and troglitazone to induce apoptosis in two RCC cell lines was initially determined by the cytosolic histon-bound DNA fragments and cell death

ELISA assay. We found that pioglitazone and troglitazone treatment for 48 h significantly increased apoptotic cell numbers in a dose-dependent manner, with IC₅₀ values of 67.73 $\mu\text{mol/L}$ and 78.12 $\mu\text{mol/L}$ for pioglitazone and 65.11 $\mu\text{mol/L}$ and 63.91 $\mu\text{mol/L}$ for troglitazone in 786-O and A498 cells, respectively (Figure 5). When 786-O and A498 cells were exposed to either 80 $\mu\text{mol/L}$ pioglitazone or 70 $\mu\text{mol/L}$ troglitazone for 48 h, they exhibited typical morphological changes of apoptosis including cytoplasmic and nuclear shrinkage, chromatin condensation and fragmentation after staining with Hoechst 33342 (Figure 6). The genomic DNA of treated cells exhibited a characteristic ladder pattern after electrophoresis in agarose gel (Figure 7). To further explore the mechanisms involved in PPAR γ agonist-induced apoptosis, the expression of proteins involved in the Bcl-2 apoptotic pathway was examined in RCC cell lines. Treatment of RCC cells with pioglitazone or troglitazone for 48 h decreased the levels of Bcl-2 expression in a time-dependent manner in both 786-O and A498 cells. In contrast, the expression of Bax was increased following TZD treatment (Figure 8).

Discussion

PPAR γ is a nuclear receptor transcription factor and plays an important role in many biological processes including adipogenesis, cell growth regulation, and cell differentiation. The synthetic TZD class of compounds, including pioglitazone and troglitazone, are originally developed as therapeutic

Figure 5. Cell death ELISA assay showing apoptosis of RCC cells induced by pioglitazone and troglitazone. (A) 786-O cells treated with two PPAR γ ligands at various concentrations; (B) A498 cells treated with pioglitazone and troglitazone. Note low concentrations of the ligands had no apoptotic effect on both 786-O and A498 cells, but at concentrations exceeding 50 $\mu\text{mol/L}$, pioglitazone and troglitazone markedly induced apoptosis in the cells in a dose dependent manner. Experiments were carried out in triplicate. $n=3$. Mean \pm SD. $^{\circ}P<0.01$ versus corresponding baseline (0 $\mu\text{mol/L}$).

tic agents for diabetes mellitus and have been recently found to be specific ligands for PPAR γ with high affinity. In the past decade, evidence began to emerge suggesting TZD PPAR γ agonists not only exert antidiabetic effect in type II diabetes mellitus but also induce cell growth arrest, apoptosis and terminal differentiation in many human malignant tumors including colon cancer, breast cancer, pituitary adenomas, pancreatic carcinoma and esophageal cancer^[9-11,19,20], suggesting PPAR γ may be a potential therapeutic target for treatment of certain human cancers. The present study provides evidence that high expression of PPAR γ was observed in human RCC tissues and cell lines, and activation of PPAR γ resulted in G₀/G₁ cell cycle arrest and apoptosis involved Bcl-2 pathway.

In the present study, we observed that PPAR γ was abun-

Figure 6. Fluorescence micrographs of 786-O and A498 cells stained with Hoechst 33342 ($\times 400$). Cells were treated with 80 $\mu\text{mol/L}$ pioglitazone or 70 $\mu\text{mol/L}$ troglitazone for 48 h. (A) and (D), control cells; (B) and (E), treated with 70 $\mu\text{mol/L}$ troglitazone; (C) and (F) treated with 80 $\mu\text{mol/L}$ pioglitazone. The PPAR γ ligand-induced apoptosis was characterized by nuclear condensation and fragmentation.

Figure 7. Agarose gel pictures showing DNA fragmentation in 786-O (A) and A498 cells (B) after treatment with 70–80 $\mu\text{mol/L}$ pioglitazone or troglitazone for 48 h. Lanes M1 and M2, DNA molecular standards; lanes 1, 2, 1', and 2', untreated cells; lanes 3 and 3', after treatment with 70 $\mu\text{mol/L}$ troglitazone, respectively; lanes 4 and 4', after treatment with 80 $\mu\text{mol/L}$ pioglitazone, respectively. Note DNA ladder was observed in lanes 3, 4, 3', and 4'.

dantly expressed in almost all high-grade human RCC specimens (98.3%), and two RCC cell lines were examined. Its intracellular distribution was mainly localized in nuclear area. In contrast, although PPAR γ immunostaining was also positive in most normal renal tissues, its expression was much lower than that in RCC tissues and limited in medullary collecting duct cells in the kidney. Furthermore, its subcellular localization was predominantly in the cytoplasm. The differ-

Figure 8. Western blot analysis showing Bcl-2 and Bax expression in 786-O and A498 RCC cells. Cells were exposed to 70 $\mu\text{mol/L}$ troglitazone or 80 $\mu\text{mol/L}$ pioglitazone for 0, 12, 24, and 48 h. Cell lysate containing 50 μg protein was separated and blotted with the antibodies. Actin was used as a sample loading control.

ences of PPAR γ in quantity and intracellular distribution between human RCC and normal kidney tissues may implicate an important role of PPAR γ in tumorigenesis of renal cell carcinoma.

Consistent with a previous study^[21], activation of PPAR γ in two human RCC cell lines resulted in inhibition of RCC cell growth as assessed using MTT assay and Flow Cytometry. As seen in other tumor cells, treatment of RCC cells lines with pioglitazone and troglitazone for 24 h caused G₀/G₁ phase arrest and blocked cells from entering the S phase^[13,19,22-24]. To explore the mechanism involved in PPAR γ -induced cell growth arrest, RCC cells were treated with pioglitazone and troglitazone and expression of cell cycle proteins was examined. We observed a marked reduction in PCNA, pRb, Cdk4 and Cyclin D1 expression and a dramatic increase in p21 and p27 expression in TZD-treated RCC cells. Down-regulation of PCNA, a nuclear protein essential for DNA replication and repair by DNA polymerase δ ^[25], is in agreement to the low proliferation rate observed in these treated RCC cells. Proliferation of eukaryotic cells is tightly regulated by expression and sequential activation of cell cycle-dependent cyclins, Cdks and CdkIs^[26]. pRb, a key regulator of G₁ cell cycle progression, is phosphorylated by a set of Cyclin-Cdk complexes, such as the complexes of Cyclin D and Cdk4/6 or cyclin E and Cdk2^[27,28]. In its dephosphorylated state, pRb binds to E2F and inhibits G₁-S phase transition. In contrast, phosphorylation of pRb causes breakdown of E2F/pRb complex, and initiates DNA synthesis. In the present study, Decreased expression of phosphorylated pRb was found in these treated cells. CdkIs are cell cycle regulatory molecules having negative effects on cell cycle machinery by binding to various cyclin-Cdk complexes and inhibiting their activities. In mammals, there are two structurally defined classes of

CdkIs, the INK4 family and the KIP/CIP family^[29]. The KIP/CIP family, including p21^{CIP}, p27^{KIP1}, and p57^{KIP2}, interacts with cyclin E-Cdk2, cyclin D-Cdk4, cyclin D-Cdk6, and cyclin A-Cdk2 complexes, and inhibits their activities^[28]. The decrease of cyclin D1 and Cdk4 and increased expression of CdkI proteins including p21 and p27 strongly suggest TZD PPAR γ agonists induced the overexpression of the members of KIP/CIP family which sequentially inhibited the activities of cyclin D1-Cdk4 complex, the phosphorylation of pRb, and the G₁-S phase transition. These findings are consistent with the observation that two TZD PPAR γ agonists decreased cell proliferation in MTT assay and arrested cells in G₀/G₁ phase by flow cytometry.

Cell cycle status and cell programmed death are usually closely associated^[13]. Besides the cell cycle arrest, the inhibition of cell growth observed in RCC cells treated with pioglitazone and troglitazone may also be a result of the increase in apoptosis^[30]. Cells failing to progress to mitosis phase are destined for apoptosis. TZD have been reported to be potent agents in inducing apoptosis in many human tumors including breast cancer, pituitary tumors and gastric cancer^[10-12]. In the present study, we clearly demonstrated that at high concentrations PPAR γ agonists pioglitazone and troglitazone caused marked apoptosis in human RCC cells as assessed by morphological change, DNA fragmentation and the cell death ELISA assay. These studies suggest that TZD may exert pro-apoptotic effect on human RCC cells.

Multiple pathways are involved in apoptosis including Bcl-2 system, fas/fasL pathway, and caspase cascade^[31-33]. To explore the molecular mechanism through which TZD PPAR γ agonist induces apoptosis in human RCC cells, we examined Bcl-2 and Bax expression following pioglitazone and troglitazone treatment in 786-O cells and A498 cells. We observed for the first time that activation of PPAR γ by both TZD markedly decreased Bcl-2 protein expression but increased Bax protein expression. Because Bcl-2 protects cells from apoptosis, while the increase of Bax induces apoptosis^[34,35], our findings suggest that decreased Bcl-2 expression and increased Bax expression may participate in TZD PPAR γ agonist-induced apoptosis in human RCC cells.

PPAR γ agonists, such as 15-dPGJ₂, troglitazone, have been shown to possess effects not involving PPAR γ ^[36,37]. For instance, the potencies for inhibition of cholesterol synthesis by troglitazone is mechanistically distinct from the transcriptional regulation by PPAR γ ^[38]. In the present study, low doses of TZD fail to induce RCC cell death. It has been reported that TZD promote T cell survival at doses that induce optimal PPAR γ transcriptional activity^[39], and cell deaths induced by TZD always use concentrations of TZD several

orders of magnitude higher than K_D for PPAR γ ^[39,40]. Moreover, troglitazone could induce apoptosis of rat hepatoma cells, but rosiglitazone, a potent PPAR γ agonist, did not have the same effect^[41], indicating that PPAR γ independent pathways, such as TZD-induced loss of mitochondrial membrane potential^[42], may be involved in the mechanisms of TZD induced cell apoptosis. Furthermore, it has also been reported that PPAR γ agonists could induce apoptosis in non-malignant cells, including isolated rat mesangial cells^[43]. Thus the mechanisms of anticancer effect of TZD need to be further explored.

In summary, the present study provides evidence that PPAR γ is highly expressed in human renal cell carcinoma cells. Activation of PPAR γ by TZD PPAR γ agonists results in inhibition of cell proliferation, likely by arresting the cells in G₀/G₁ cell cycle phase. In addition, PPAR γ agonists also induce marked apoptosis partly through decreased Bcl-2 and enhanced Bax protein expression in human RCC cells. Additional research will need to be performed to explore the mechanism of TZD which induced cell apoptosis, and the potential therapeutic value of PPAR γ agonists in renal cell carcinoma.

Abstract

Aim: To evaluate the *in vivo* antitumor effects of Cantide and the combined effect with 5-fluorouracil. **Methods:** An *in situ* human hepatocellular carcinoma model was established in mice livers orthotopically. Drugs were administered intravenously and tumor sizes were monitored with calipers. Plasma alpha-fetoprotein (AFP) were detected by radiation immunoassay. Morphology of tumors was evaluated by hematoxylin-eosin (H&E) staining of histological sections. Human telomerase reverse transcriptase (hTERT) protein levels were detected by Western blotting. **Results:** Cantide significantly inhibit *in situ* human hepatocellular carcinoma growth in mice with a 75 and 50 mg·kg⁻¹·d⁻¹ administration of Cantide compared to the saline group in a dose-dependent manner, which included injecting Cantide 25 mg·kg⁻¹·d⁻¹–75 mg·kg⁻¹·d⁻¹ by iv for 20 d after surgically removing the tumor in liver. Cantide was also found to prevent tumor recurrence in the liver and metastasis in the lung, showing a dose-dependent response. When Cantide was administered by iv combined with 5-fluorouracil, it resulted in a significant reduction in tumor growth compared to either agent alone treatment group. After the treatment with Cantide alone or combined with 5-fluorouracil, plasma AFP concentration decreased in a dose-dependent manner. **Conclusion:** These results demonstrated that Cantide was an effective antitumor antisense oligonucleotide *in vivo* and has the potential to be developed into a clinical anti-cancer drug.

Introduction

Telomerase is a unique ribonucleoprotein enzyme responsible for adding telomeric repeats onto the 3' ends of chromosomes^[1,2]. Telomerase plays an important role in the development of cellular immortality and oncogenesis. Previous published studies have shown that telomerase activity is found in 85%–90% of all human tumors, but not in their adjacent normal cells. This makes telomerase a good target not only for cancer diagnosis, but also for the development of novel therapeutic agents^[3,4].

A series of experimental strategies have been employed to block either telomerase function or expression, both *in vitro* and *in vivo* in several tumor cell lines derived from a number of species^[5,6]. Antisense oligonucleotide (ASODN) is a new class of antineoplastic agents that can prevent the

initiation and progression of specific human cancers when targeted to appropriate molecular targets^[7,8]. Since the first antisense drug Vitravene was approved by the American Food and Drug Administration (FDA) in 1998, it has been our hope that this class of compound will represent a whole new class drug with potential therapeutic application against a variety of disease, including cancer. Human telomerase reverse transcriptase (hTERT) is a catalytic subunit of telomerase. There are many published studies which have found that more than 90% of examined tumors show telomerase activity in connection with the expression of the activity-limiting component hTERT^[9,10]. The inhibition of telomerase activity in tumor cells can lead to telomere destabilization and consequently to growth inhibition and cell death. Therefore, targeting the catalytic subunit of hTERT represents a promis-

ing approach for diminishing telomerase function. Phosphoro-thioate antisense oligonucleotides targeted to hTERT had been studied and has been found to have growth inhibitory efficacy to cancer cells *in vitro*^[11,12], but only few detected ASODN activity in animal models^[13,14]. Our previous study had shown that an ASODN complementary to hTERT, Cantide, had a specific inhibitory effect on tumor cell growth after *in vitro* treatment, down-regulated hTERT mRNA expression and telomerase activity, and triggered apoptosis through the activation of the caspase family^[15].

In the present study, we used an *in situ* human hepatocellular carcinoma (HCC) model to further assess the effect of Cantide in *in vivo* growth of HCC in mice and the combined effect of Cantide with 5-fluorouracil (5-FU). Our findings demonstrated that systemic administration of phosphorothioate antisense ODN to hTERT mRNA resulted in a significant growth inhibition of *in situ* HCC tumors and prevented tumor recurrence in the liver and metastasis in the lung.

Materials and methods

Oligonucleotides and drug Antisense phosphorothioate oligonucleotide Cantide (5'-ACTCACTCAGGCCTCAGACT-3') and sense phosphorothioate oligonucleotide (5'-AGTCT-GAGGCCTGAGTGAGT-3') were synthesized by an Applied Biosystems Model 391 DNA synthesizer on solid supports using Oligo Pilot II DNA (Amersham-Pharmacia, Piscataway, NJ, USA) and purified by high-performance liquid chromatography (HPLC) (Waters Delta Prep 4000, Milford, MA, USA) with SOURCE 15Q (Amersham Pharmacia, Piscataway, NJ, USA), the purity of oligonucleotides was over 95%. The sense sequence was used as a control. 5-Fluorouracil was purchased from the Shanghai Donghaipu Pharmaceuticals Company (Shanghai, China) as a positive control. A radiation immunoassay (RIA) kit was purchased from the China Institute of Atomic Energy (Beijing, China).

Animals and *in situ* human hepatocellular carcinoma model Experiments were carried out in virgin female Balb/c mice raised at the PLA 202 hospital. All animal studies were conducted in accordance with the highest standards of animal care as outlined in the NIH guide for the Care and Use of Laboratory Animals. Human hepatocellular carcinoma (HCC) high metastasis tumor line HCM-Y89, established in 1989 by PLA 202 Hospital, was derived from a HCC surgical specimen, and has been maintained by serial transplantation in animals. Briefly, the HCM-Y89 tumor was cut into 1 mm×1 mm×1 mm tissues, BALB/c mice (4–6 weeks old, weighing 18–22 g) were anesthetized with propofol (2 mg/kg, intra-venously).

A small incision was made in the left liver and a fragment of tumor was implanted. The incision was closed using a Ethicon black braided silk suture. Twenty days later, the mice were killed by cervical dislocation and the tumors were removed. A histological evaluation of tumor tissues was performed, organs were fixed in neutral buffered 10% formalin, processed by standard methods, embedded in paraffin, sectioned and stained with H&E. This model showed various features in clinical liver cancer patients including local growth, regional invasion, spontaneous intrahepatic, lymph nodes and pulmonary metastasis, peritoneal seeding with bloody ascites, and secretion of alpha-fetoprotein in recipient animals.

Treatment of *in situ* HCC xenograft with cantide and anticancer drug Two days after the *in situ* HCC models were established, mice were injected by iv with saline (vehicle control), Cantide with 12.5, 25, 50, 75 mg·kg⁻¹·d⁻¹ or 5-FU 10 mg·kg⁻¹·d⁻¹ for 20 d, either alone or in combination. The body weight and general physical status of the animal were recorded daily. At the endpoint of the study, mice were killed by cervical dislocation and the tumors were removed and weighed. Tumor sizes were monitored with calipers, the tumor volume (V, mm³) was calculated as $(L \times W^2)/2$, where L=length (mm) and W=width (mm). The percentage of tumor growth inhibition was calculated as:

Inhibitory rate (%) = $(W_{\text{control}} - W_{\text{treat}}) / W_{\text{control}} \times 100$. Tissues for histopathological analysis were fixed in 10% buffered formalin.

Determination of tumor recurrence and metastasis The *in situ* HCC model was established according to above method, when the xenograft tumor had grown to 5 mm×5 mm×5 mm. An operation was then performed to remove the tumor. Three days later, saline and Cantide at 12.5, 25, 50, 75 mg·kg⁻¹·d⁻¹, or 5-FU 10 mg·kg⁻¹·d⁻¹ were administered by iv for 20 d. Tumor sizes were recorded as mentioned earlier. A histological evaluation of microscopic recurrence and metastasis was performed for the liver and lung, and tissues were fixed in 10% buffered formalin.

Histopathological analysis Tissues were excised and fixed in 10% buffered formalin. Representative fragments were embedded in paraffin, 5-μm sections were obtained and stained with H&E for microscopic observations.

Detection of plasma AFP concentration Animal serum was collected after the mice were killed. The plasma AFP concentrations were detected by RIA according to the manufacturer's instructions.

Statistical analysis Results of the quantitative studies were expressed as mean±SD. Student's *t*-test was used to determine the significance of differences between the 2 treat-

ment groups. Multiple comparisons were made using one-way analysis of variance (ANOVA), and post-tests comparing different treatment means were conducted using Fisher's test. Differences were considered significant for $P < 0.01$

Results

***In vivo* effects of Cantide treatment on *in situ* hepatocellular carcinoma xenograft growth** The proposed role of the telomerase hTERT subunit has led us to investigate the pharmacological activity of phosphorothioate oligonucleotides targets to hTERT in animal models on tumor growth. In the present study, we used an *in situ* human hepatocellular carcinoma model in mice to evaluate the activity of Cantide. In order to exclude the nonspecific effect of oligonucleotides, we used sense sequence as a control. After establishing the model 2 d later, Cantide with different doses, sense oligonucleotide with $50 \text{ mg}\cdot\text{kg}^{-1}\cdot\text{d}^{-1}$, 5-Fu with $10 \text{ mg}\cdot\text{kg}^{-1}\cdot\text{d}^{-1}$ and saline were administered by intravenous (iv) for 20 d. Tumors were removed after the mice were killed. The tumors were then measured and weighed. The results showed that 75 and $50 \text{ mg}\cdot\text{kg}^{-1}\cdot\text{d}^{-1}$ Cantide treatment resulted in a significant inhibition of tumor growth compared to sense or saline-treated mice. The highest inhibitory efficacy was a 69.55% contrast to the saline group, but for the sense oligonucleotide, the inhibitory rate was only a 19.26% contrast to the saline group. The inhibitory rate of $50 \text{ mg}\cdot\text{kg}^{-1}\cdot\text{d}^{-1}$ was 57.77% compared to the sense treatment group ($P < 0.01$). The effect of Cantide was dose-dependent (Table 1). The mean body weight of the mice were not significantly different from the beginning of the study and between the groups (data not shown). Figure 1 shows the final tumor volumes after a 20-d treatment, which showed a significant decrease in the Cantide treatment group compared to the saline control group ($P < 0.01$). However for the sense oligonucleotide treatment group, there was no significant decrease in tumor volume

Table 1. Effect of Cantide on tumor weight and inhibitory rate in mice with *in situ* HCC. $n=8$. Mean \pm SD. ^b $P < 0.05$, ^c $P < 0.01$ vs the control group.

compared to the saline group ($P > 0.05$). No inflammatory infiltrate was noted surrounding the solid tumor (data not shown).

To determine the effect of Cantide on preventing tumor recurrence and metastasize after surgical removal of the tumors, a highly metastatic HCC model was established in the mice liver according to the above method. When the xenograft tumor had grown to $5 \text{ mm}\times 5 \text{ mm}\times 5 \text{ mm}$, the mice underwent an operation to remove the tumors; 3 d later, animals were injected with different doses of Cantide or saline by iv for 20 d and then checked for a relapse in the liver. Table 2 shows how the Cantide 75 and $50 \text{ mg}\cdot\text{kg}^{-1}\cdot\text{d}^{-1}$ treatment group could significantly inhibit tumor recurrence in livers after operation. However, there was no statistically significant difference in tumor recurrence in livers treated with $25 \text{ mg}\cdot\text{kg}^{-1}\cdot\text{d}^{-1}$ and $12.5 \text{ mg}\cdot\text{kg}^{-1}\cdot\text{d}^{-1}$ in the Cantide treatment group compared to the saline treatment group. 5-FU could not prevent tumor relapse after operation. The relapse tumor volumes also decreased significantly in the Cantide treatment group compared to the Saline control group (Figure 2). No signs of treatment-related toxicity such as inflammation,

bleeding, hepatomegaly and splenomegaly or weight loss was observed in the animals over the course of the study.

Inhibitory effects of Cantide on tumor metastasis in lung

Tumor metastasis in the lung was also monitored after surgical removal of the tumors from the mice livers and treatment with Cantide or saline for 20 d. Cantide can also prevent tumor metastasis in the lung after operating on the liver. The results found that only 10 and 14 of the 24 mice tested showed evidence of tumor metastasis in the lung with 75 and 50 mg·kg⁻¹·d⁻¹ in the Cantide treatment groups, respectively (Table 3). A histological analysis of the lungs showed that the metastatic areas markedly decreased in mice treated with 75 and 50 mg·kg⁻¹·d⁻¹ Cantide compared to the other group, where 5-FU had no effect on tumor metastasis (data not shown).

Effects of Cantide combined with 5-FU on xenograft tumor growth Several studies have shown that antisense oligonucleotides combined with chemotherapeutics can increase drug sensitivity^[16,17]. In order to evaluate whether a

combination effect would occur when Cantide was combined with a chemotherapy drug, Cantide was co-administered with 5-FU by iv for 20 d to mice bearing with *in situ* HCC tumors. The mice were killed and tumor volumes and weight were measured after the 20-d treatment. Table 4 shows that after the 20-d treatment, the tumor weight decreased in the combination treatment group compared to either agent alone treatment group. The tumor growth inhibitory rate also showed significant difference compared to either agent alone treated group (Table 4). Figure 3 shows that at the endpoint of treatment in the combination treatment group, a significant decrease in tumor volumes with respect to tumors growth in either Cantide or the 5-FU alone treatment group was induced.

Histopathological analysis Morphology of tumors from antisense ODN, sense ODN or saline-treated mice was evaluated by H&E staining of histological sections. Tumors were excised at the endpoint of treatment of each protocol. Figure

4 shows representative sections of tumors from each experimental protocol. Tumors from mice treated with Cantide or combined with 5-FU, showed a marked increase in the necrotic area and tumor cells fibrosis compared to saline-treated or normal animals. A large percentage of tumor mass from combination-treated mice was necrotic and fibrotic compared to either agent alone treated mice.

Inhibition of plasma AFP secretion with Cantide treatment Alpha-fetoprotein (AFP) is usually expressed at high concentrations in fetal liver, gastrointestinal tract and the yolk sack. It is transcriptionally down-regulated after birth, frequently re-expressed in HCC, and is a good tumor marker of HCC^[13]. We used RIA to detect serum AFP concentration at the endpoint of treatment. Figure 5 shows how Cantide can significantly decrease AFP secretion at 75, 50, and 25 mg·kg⁻¹·d⁻¹ compared to the saline group. AFP concentration was also correlated with tumor size (data not shown). The plasma AFP was also detected after treatment with Cantide combined with 5-FU. Figure 6 shows how Cantide combined with 5-FU could increase AFP secretion in plasma. In the two combination treatment groups, plasma AFP concentration decreased compared to either the Cantide or 5-FU alone treatment groups, possibly because there were fewer liver tumor cells in the combined treated mice and reduced circulating AFP.

Discussion

In the present study we have demonstrated that systemic administration of phosphorothioate antisense ODNs to hTERT mRNA results in a significant growth inhibition of

Increased regions of necrosis and fibrosis were observed in the combined treatment group compared with the agent alone treatment group.

the *in situ* HCC model in mice. It is worth noting that our experimental model of HCC has some advantages compared to the tumor cell inoculation model. First, the tumor line originated from human HCC; it completely kept the human HCC tissue structure and retained its AFP secretion ability. It also retained the original sensitivity to the antitumor drug, simulated the clinical features of patients with HCC such as the liver, lung and lymph nodes metastasis, and bloody ascites. Second, the pathological evidence suggests that this model exhibits various features seen in clinical HCC patients, so the reaction to antitumor drug can reflect the true clinic results by this model and more accurately to reflect the clinical results of patients. Therefore, our model system has provided a unique tool for exploring *in vivo* antitumor activity of ODN.

We have demonstrated that the antitumor effect of Cantide was because of a specific antisense effect. The inhibition of tumor growth by Cantide was dose-dependent and no abrogation of tumor proliferation was observed in any of the control groups. Another important finding of our present study is that Cantide can effectively prevent tumor recurrence and metastasis. Tumor recurrence and metastasis is a problem encountered during tumor treatment. At present, very few chemotherapeutics can prevent tumor relapse and metastasis after an operation. Pastorino's^[18] study indicates that an antisense targeting to *c-myc* can inhibit tumor growth and metastasis. In the present study we demonstrated that Cantide effectively suppressed tumor metastasis in lungs with 75 mg·kg⁻¹·d⁻¹ treatment. Lung metastasis was found in only 10 mice of the 24 mice (41.7%). Cantide can also prevent local recurrence after an operation. An important factor contributing to these results is that Cantide might inhibit telomerase activity^[15], thus the residue of tumor cells after an operation has less ability to proliferate.

AFP is a secretory protein that is heterogeneously glycosylated. AFP is usually expressed at high concentrations in fetal liver, gastrointestinal tract, and the yolk sack. It is transcriptionally down-regulated after birth and frequently re-expressed in HCC, therefore used as a diagnostic marker for the tumor. Serum AFP is useful not only for diagnosis, but also as a prognostic indicator for HCC patients. AFP mRNA has been proposed as a predictive marker of HCC cells disseminated into the serum circulation and for metastatic recurrence^[19,20]. We detected serum AFP concentration after the surgical removal of tumors and their treatment with Cantide. The results showed that serum AFP secretion was significantly inhibited in a dose-dependent manner in the Cantide treatment groups compared to the saline group. The AFP concentration was also lower than 5-FU group.

The serum AFP concentration and the relapse of tumor volume had a good dependent relationship, which was correlated with AFP as a marker for HCC recurrence and metastasis.

In the past decade, several ASODN have been developed and tested in preclinical and clinical studies. Many have found convincing *in vitro* reduction in target gene expression and promise activity against a wide variety of tumors^[21,22]. However, because of the multigenic alterations of tumors, the use of ASODN as a single agent does not seem to be effective in the treatment of malignancies. Antisense therapy that interferes with signaling pathways involved in cell proliferation and apoptosis are particularly promising in combination with conventional anticancer treatment; several preclinical studies have also been performed using antisense oligonucleotides in combination therapy on human tumors^[23,24]. Our previous study showed that Cantide inhibited tumor cells growth through triggered tumor cells apoptosis^[15], and increasing 5-FU sensitivity in HepG2 cells *in vitro* (data not shown). Zhang and He also show an increased sensitivity to cisplatin caused by hTERT ASODN treatment in leukemia cells^[25]. However, to our knowledge, no published studies have been performed to detect the *in vivo* activity of hTERT ASODN in combination with chemotherapy drugs. We investigated the combinational activity of Cantide with 5-FU in the *in situ* HCC model. The results indicate that 75 or 50 mg·kg⁻¹·d⁻¹ Cantide combined with 10 mg·kg⁻¹·d⁻¹ 5-FU significantly suppresses *in situ* HCC growth in mice. At the endpoint of the treatment, the tumor weight was much lighter than either agent alone treatment (Table 4). These results suggest that the combination of Cantide with 5-FU might sensitize patients with late-stage HCC to chemotherapy.

In summary, we have for the first time directly addressed the potential therapeutic role of Cantide in an *in situ* human HCC model. Significant inhibition of HCC growth was achieved by combining Cantide with 5-FU, indicating that combined targeted therapy with conventional cytotoxic agents are required for the prevention of tumor growth.

Abstract

Many actin-binding proteins are expressed in eukaryotic cells. These polypeptides assist in stabilizing and rearranging the organization of the actin cytoskeleton in response to external stimuli, or during cell migration and adhesion. Here we review a particular set of actin-binding proteins called plastins. Plastins (also called fimbrins) belong to a subclass of actin-binding proteins known as actin bundling proteins. Three isoforms have been characterized in mammals: T-plastin is expressed in cells from solid tissue, whereas L-plastin occurs predominantly in hematopoietic cells. The third isoform, I-plastin, is specifically expressed in the small intestine, colon and kidney. These proteins share the unique property of cross-linking actin filaments into tight bundles. Although plastins are primarily involved in regulation of the actin cytoskeleton, they possess some unique features. For instance, they are implicated in invasion by pathogenic bacteria such as *Shigella flexneri* and *Salmonella typhimurium*. Also, L-plastin plays an important role in leukocyte function. T-plastin, on the other hand, is possibly involved in DNA repair. Finally, both T- and L-plastin are implicated in several diseases, and L-plastin is considered to be a valuable marker for cancer.

Introduction

The actin cytoskeleton of eukaryotic cells is a dynamic meshwork that is involved in many biological phenomena, such as cell motility, cell substrate adhesion, intracellular transport, endo-, and exocytosis, cytokinesis, and cell morphology. The overall organization of the actin cytoskeleton is controlled by a plethora of actin-binding proteins^[1]. Plastins belong to a class of actin-bundling proteins, and they are conserved from lower eukaryotes to humans. In vertebrates, three different plastin isoforms are expressed in a cell-type-specific manner, and these isoforms display distinct properties. Here we review the discovery, biological properties and regulation of plastin isoforms, and, where appropriate, discuss their interest from a medical perspective.

Discovery

The first plastin isoform was discovered in 1979^[2] in microvilli isolated from chicken intestinal brush border as a 68

kDa polypeptide involved in microfilament organization of the microvilli core bundle. This protein was named fimbrin because it was associated with surface structures such as membrane ruffles, microvilli, microspikes and focal adhesions in chicken embryo fibroblasts and cultured rat mammary cells^[3]. Chicken fimbrin was characterized as a monomeric cytoskeletal protein able to bind and cross-link F-actin filaments^[4,5], promoting the formation of rigid straight bundles in which all actin filaments have the same polarity.

Meanwhile, a 68 kDa protein was identified in transformed human fibroblasts (neoplastic cells, hence the name)^[6,7]. This isoform, L-plastin, is also abundantly expressed in untransformed lymphocytes^[8]. Molecular cloning of their corresponding cDNAs and amino acid sequence comparison revealed two highly related proteins with a predicted molecular weight of 64 kDa. These two human cell type-specific isoforms, L- and T-plastin (80% amino acid identity), are expressed in hematopoietic cells and in cells derived from solid tissue, respectively^[9]. In 1990, it was observed that an

amino-terminal sequence containing a potential calcium binding domain was missing in the sequences reported earlier^[10,11]. A third human plastin isoform, called I-plastin, was discovered as a polypeptide that is specifically expressed in the small intestine, colon and kidney, and is 86% identical to the chicken fimbrin (plastin) isoform^[12,13].

Plastin structure

Plastins have a modular structure consisting of 2 amino-terminal EF-hands, variably implicated in Ca²⁺-binding, and two tandem actin-binding domains, each divided into two calponin homology (CH) domains^[14-16] (Figure 1). These CH domains are shared by both signaling and cytoskeletal proteins such as dystrophin, α -actinin, and spectrin, and a tandem CH domain is generally involved in actin-binding.

Each CH domain is composed of four α -helical segments, in which three form a loose bundle of helices, with the fourth α -helix perpendicular to the major bundle. These segments are connected by extended and variable loops and sometimes 2 additional short helices. The complete crystal structure of plastin has not yet been resolved, but the structure of the N-terminal actin-binding domain 1 (ABD1) of T-plastin and the complete cross-linking core of *Arabidopsis thaliana* plastin and of *Schizosaccharomyces pombe* plastin have

been solved^[17,18]. Additional methods, such as electron microscopy, image analysis and homology modeling, have led to a general model of the plastin structure and to a view of how this protein cross-links actin filaments.

The actin cross-linking core of plastin has a compact architecture^[17], and the ABDs pack in such a way that the CH1 domain and the CH4 domain make contact, involving conserved residues on the molecular surface of the CH1-CH4 interface. Electron density in regions connecting the CH domains is poorly defined, indicating that these segments are highly dynamic. The potential structural plasticity of ABD1 by reorganization of the CH domains is also confirmed by other crystal structures of utrophin, dystrophin, plectin and α -actinin^[19-22].

The binding sites of plastin ABD1 on actin are located in two different subdomains (2 and 1) of the actin molecule^[23]. The crystal structure also suggests that the two ABDs have non-identical interactions with F-actin because they each expose different surfaces to the solvent. This suggestion is consistent with the two different actin affinities found in L-plastin^[24], in AtFim1^[25] and in *S pombe* Fim1^[26], and with the finding that the same mutations in both ABDs have different phenotypes in budding yeast^[27]. Very recently, evidence has been put forward indicating that ABD1 of T-plastin is not only involved in actin-bundling, but may also control

Figure 1. Domain organization in plastin isoforms from different species. A scale (in amino acids) is drawn on top of the figure. Domains in blue have no or less functionality. ABD=actin-binding domain. Note that each actin-binding domain consists of two CH domains. Human T- and L-plastin contain an NES, but it is unknown if plastins from other species are also endowed with a similar targeting signal.

actin turnover, stabilization and assembly, independently of its bundling capacity^[28].

Plastins in other organisms

Using an actin affinity matrix to identify actin-binding proteins in the budding yeast *Saccharomyces cerevisiae*, the Sac6 protein was identified, which localizes with cytoplasmic actin cables and cortical actin patches^[29]. Its actin regulatory role was confirmed when the gene encoding this protein was found to suppress an actin mutation^[30]. Sac6p shows 43% and 36% identity with chicken plastin and human plastin, respectively. Mutant budding yeast cells lacking this gene display temperature sensitivity defects in growth, morphology, endocytosis and sporulation^[31,32]. Surprisingly, overexpression of Sac6p is lethal^[33]. This could be explained by competition with an essential actin-binding protein, or by titrating out some other essential factor for growth. Next to stabilizing actin filaments, yeast plastin also has a role in the polymerization of G-actin^[34,35]. Adams and colleagues demonstrated a high degree of functional conservation between evolutionarily divergent plastins^[36]. They demonstrated that human T- and L-plastin could both substitute for yeast plastin in a *Sac6* null mutant, and restore functional defects. However, the third isoform, I-plastin, could not complement this temperature sensitive growth defect, illustrating the functional differences between human isoforms. The fission yeast *Schizosaccharomyces pombe* also contains a plastin homologue, called Fim1. It is not essential for viability but has a role in cell morphogenesis. In mitotic cells, Fim1 plays a role in formation of the actin ring during cytokinesis^[26]. *Dictyostelium discoideum* plastin shows 48%–50% identity with human plastins, and localizes to cortical structures associated with cell surface extensions^[37].

In the ciliate *Tetrahymena*, plastin is localized in the cleavage furrow bundle during cytokinesis of dividing cells^[38]. This protein cross-links actin filaments in a calcium-insensitive manner^[39,40]. *Tetrahymena plastin* has a higher affinity for actin than the other plastin forms^[39].

At least 3 plastin-like proteins may exist in the plant model system *Arabidopsis thaliana*^[25,41]. The AtFim1 isoform contains an additional 65 amino acids at its carboxy-terminal end, and is Ca²⁺ insensitive because of less conserved Ca²⁺-binding domains. AtFim1 inhibits *Zea mays* profilin-induced actin depolymerization *in vitro* and *in vivo*^[25].

L-plastin is often used as a myeloid lineage protein marker in zebrafish (*Danio rerio*)^[42]. Spatio-temporal expression of the L-plastin zebrafish homologue reveals a high level of conservation between zebrafish and mammals. Thus

zebrafish constitutes an informative model system for the study of normal and anomalous human myelopoiesis^[43].

Expression and localization

The three plastin isoforms share approximately 70% homology in their amino acid sequences but are encoded by three distinct genes located on chromosomes 3 (I-plastin), 13 (L-plastin) and X (T-plastin). Analysis of the exon–intron junction sequences of all three human plastin genes indicates that they evolved from a common ancestor^[12] (our unpublished observations). Their tissue-specific expression is strictly regulated: L-plastin expression is controlled by its strong promoter, regulated by its upstream repressor and by steroid hormone receptors^[44,45]; the T-plastin promoter has a weak basal activity, and expression may be controlled by upstream enhancer elements and by methylation of a CpG island^[46].

Generally, plastins are located in focal adhesions, ruffling membranes, lamellipodia, filopodia, or in specialized surface structures with highly ordered microfilament bundles such as microvilli and stereocilia. Sometimes they co-localize with stress fibers.

In adherent macrophages, L-plastin co-localizes with actin in podosomes and filopodia, and also exhibits a punctate distribution in the cytoplasm that overlaps with actin. L-plastin is constitutively phosphorylated, and phosphorylated plastin is concentrated in the insoluble cytoskeletal fraction^[47]. Overexpression of T- or L-plastin in a fibroblast-like cell line induces cell rounding and simultaneous actin stress fiber rearrangements. Both proteins promoted a reduction in the number and size of focal contacts in comparison to untransfected cells. In polarized epithelial cells, overexpression of T-plastin increases the length and density of microvilli. Because both isoforms can associate with different actin structures, they may play different roles in actin filament organization in a cell type-specific fashion^[48].

Plastin is often found in stereocilia. Thus actin bundles formed by plastin may also have a mechano-sensory function by transforming mechanical alterations in signals during chemosensory signal transduction. T-plastin and I-plastin, but not L-plastin, are expressed in rat cochlea auditory hair cell stereocilia^[49]. During postnatal development of the rat organ of Corti, T-plastin is detected in the core of stereocilia from the early stages of hair cell differentiation, and its expression gradually increases in stereocilia as hair cells mature. However, T-plastin is absent from mature hair cell stereocilia. In contrast, I-plastin is expressed in stereocilia and the cuticular plate from the early stages of hair cell differentiation^[50] up to the adult stage^[51–53]. The expression

pattern of T-plastin in hair cell stereociliary bundles seems to be related to the location-specific length of hair cell stereocilia along the cochlear duct. Such temporally restricted expression strengthens the idea of functional differences between plastin isoforms, and suggests that T-plastin could have a specific role in stereocilia formation. Furthermore, plastin is also found in the microvilli of chicken photoreceptors^[54], in microvillar projections in taste receptor cells of the mammalian taste bud^[55], in microvilli from vomeronasal sensory epithelium^[56], and in brush cells of the alimentary and respiratory system^[57,58].

In general, it can be concluded that members of the plastin family have been identified in cellular regions containing polarized actin filaments, and in regions with a high actin filament turnover.

During differentiation of mouse intestine epithelium, three plastin isoforms are expressed in a cell-specific manner^[59]. T- and L-plastin are present during the early stages of intestinal epithelial cell differentiation and localize to the apical and basal surface, respectively, until day 14.5, but disappear after day 16.5. I-plastin is first detected from day 14.5 at the apical surface. These findings suggest that plastin isoforms play different roles during epithelial cell differentiation. T- and I-plastin expression could be decisive for the formation and extension of the microvilli, whereas expression of L-plastin might play a role in controlling cell adhesion.

Because all plastin isoforms regulate the actin cytoskeleton, they have always been considered as cytoplasmic proteins. Very recently, however, we reported that endogenous as well as overexpressed T- and L-plastin were able to shuttle between nucleus and cytoplasm in HeLa and Jurkat cells. In most cells investigated, T-plastin is found exclusively in the cytoplasm, whereas L-plastin is located in the nucleus and cytoplasm^[60]. We identified a strong leucine-rich nuclear export signal (NES) in T-plastin that was less conserved in L-plastin. This is due, in part, to lack of a phenylalanine residue in the weak NES of L-plastin. This particular residue forms part of the core amino acids that constitute the strong NES of T-plastin. When phenylalanine is inserted into the NES of L-plastin, we observed enhanced export activity of L-plastin from the nucleus. It is likely that shuttling occurs in other cell types as well, but this has not yet been demonstrated. The functional relevance of this nucleo-cytoplasmic shuttling of T- and L-plastin remains unclear at present. L-plastin could be implicated in the regulation of nuclear actin. Indeed, actin is an essential component of the pre-initiation complex and cooperates with polymerase I, II, and III in gene expression^[61-63].

Regulation of plastin function

Calcium The two calmodulin-like calcium-binding domains in plastins, the so-called EF-hands, suggest that calcium could regulate actin-binding or other functions of plastins. The rather weak homology in the calcium binding domains of plastin isoforms may suggest that their actin-binding activities are differentially regulated by calcium. Human L-plastin is the only isoform that possesses all the conserved amino acids essential for calcium binding and, indeed, human L-plastin bundles actin filaments in a strictly calcium-regulated manner. Bundles are formed at pCa 7, but not at pCa 6 (free calcium concentration)^[64]. I-plastin bundling activity is also inhibited by calcium^[13]. The calcium sensitivity of T-plastin has not been studied thoroughly in the past, although some reports mention this^[65,23,66]. Recently, this aspect was investigated by Giganti and colleagues, who showed that co-sedimentation of actin with T-plastin was not affected by free calcium concentrations of up to 2.2 $\mu\text{mol/L}$, in contrast to L-plastin activity, which was inhibited by calcium^[28]. Similarly, in an F-actin depolymerization assay, no effect of T-plastin was observed in a free calcium concentration range of 4.6 nmol/L–1.6 $\mu\text{mol/L}$. Strangely, yeast plastin, Sac6p, is regulated by Ca^{2+} , although it does not contain the conserved residues required for calcium binding^[35]. The *Tetrahymena* plastin, Arabidopsis Atfim1 and fission yeast Fim1 bundle actin filaments in a calcium-insensitive manner^[65,26,39]. In contrast, *Dictyostelium discoideum* plastin bundles actin in a calcium-sensitive manner^[37].

Phospholipids Using solid-phase immunoassays it was found that increasing amounts of phospholipids affected the binding between monomeric actin and L-plastin. In the presence of PIP_2 , and to a smaller extent phosphatidylinositol, the level of actin-L-plastin interaction decreases steadily. The observed inhibitory effect reaches 50% at 50 $\mu\text{g/mL}$ PIP_2 . However, diacylglycerol did not produce such an effect^[24]. It remains to be demonstrated if this also applies to other plastin isoforms, and if the plastin-F-actin interaction would also be affected. Nevertheless, these findings may suggest that plastin activity is also susceptible to regulation by phospholipids, and this would tie in with many reports detailing modulation of the cytoskeleton through phospholipid interaction with actin-binding proteins.

Phosphorylation Only L-plastin has been reported to be phosphorylated *in vitro* and *in vivo*. Phosphorylation occurs particularly in hematopoietic cells, although this modification may also take place in malignant cells that express L-plastin. Two amino-terminally located serine residues, Ser5 and Ser7, are involved^[67]. Protein kinase A (PKA) can

phosphorylate plastin *in vitro*^[68,69]. In T-plastin, the Ser-7 residue is conserved, but has never been observed to be phosphorylated.

Ser5 is phosphorylated in HeLa cells. It is possible that Ser 7 is also phosphorylated but only after phosphorylation of Ser 5^[70]. Another intensive study on L-plastin phosphorylation was done by Lin and colleagues^[71]. They used fibroblasts stably transfected with wild type plastin and mutant plastins, in which each of the serines were mutated. Only the wild type was phosphorylated, but not the mutants, pointing to a possible phosphorylation zipper mechanism. All the data available so far point out that phosphorylation of L-plastin involves a complex mechanism that is not yet completely understood. L-plastin phosphorylation is also dependent on cell type and stimulus. Phosphorylation may regulate actin-binding/bundling, or interactions between plastin and other proteins.

Binding partners

Apart from actin, there have not been many plastin-binding partners characterized yet. However, L-plastin has been reported to be in complex with several proteins in hematopoietic cells. Grancalcin is a Ca²⁺-binding protein, which is abundant in human neutrophils. Both proteins interact in hematopoietic cells and their interaction is negatively regulated by Ca²⁺^[72]. In adherent macrophages, L-plastin binds vimentin and Hsp70^[73]. Only the L-plastin-vimentin interaction was further characterized. Plastin forms an adhesion-dependent complex with a vimentin subunit tetramer, but not with vimentin intermediate filaments. Both proteins interact with an affinity of 0.25 μmol/L (K_d) and co-localize in podosomes, filopodia and retraction fibers. Co-localization in or around the nucleus was also occasionally observed. The amino-terminal domain of vimentin was identified as the plastin-binding site, and the vimentin-binding site localizes to the first CH domain of plastin. Phosphorylation of plastin is probably not involved in complex formation. The interaction may play a role in directing the assembly of the vimentin cytoskeleton at cell adhesion sites.

L-plastin also interacts with Iba1, a microglia/macrophage-specific calcium-binding and actin-bundling protein^[74]. In response to stimuli, L-plastin co-localizes with Iba1 and F-actin in membrane ruffles and phagocytic cups. The interaction is direct and independent of Ca²⁺. Furthermore, Iba1 increases the actin-bundling activity of L-plastin.

Cellular functions of plastin isoforms

Phosphorylation and leukocyte function Leukocyte ac-

tivation is an important aspect of inflammation and immunity. Quite a number of studies have addressed the phosphorylation of L-plastin during the activation of hematopoietic cells in response to a variety of signals.

In polymorphonuclear (PMN) leukocytes, L-plastin phosphorylation is induced by IL-1 after glucocorticoid treatment and this is blocked by inhibitors of adenylyl cyclase and protein kinase A, but not by a PKC inhibitor^[75]. In stimulated cells, phosphorylation of L-plastin increases from 5% to 30%^[68]. TNF treatment of peripheral blood mononuclear cells also induces the phosphorylation of L-plastin, but activators of protein kinase A fail to increase phosphorylation, suggesting that other kinases could be involved^[76]. IL-8 and the chemotactic peptide fMLP (both chemoattractants for PMN) also promote phosphorylation of L-plastin. In this study, phosphorylation was inhibited by PKA inhibitors, whereas phorbol 12-myristate 13-acetate (PMA, a direct activator of PKC) stimulated phosphorylation significantly^[77]. However, there is little evidence to support L-plastin phosphorylation by PKC *in vivo*. Nevertheless, these few examples illustrate that several stimulatory signals induce phosphorylation of L-plastin through distinct pathways in which PKA can sometimes act as a direct kinase, with PKC acting as an indirect effector. Bacterial lipopolysaccharide (LPS) also induces phosphorylation of L-plastin in murine peritoneal macrophages^[78]. Phosphorylation closely correlated with cellular responses such as the production of inflammatory substances such as TNF, IL-1 and arachidonic acid, a precursor for prostaglandin synthesis in T-lymphocytes. Phosphorylation of L-plastin was discovered as an accessory receptor-mediated co-stimulatory event^[79].

Apart from the phosphorylation of L-plastin induced by chemoattractants, interleukins, PMA or fMLP in various hematopoietic cells, L-plastin function and phosphorylation in leukocyte activation was also studied by ligation of IgGFc receptors. Ligation of FcγR in PMN by immune complexes leads to several effector events, including the secretion of inflammatory cytokines and vasoactive lipids, phagocytosis, antibody-dependent cell cytotoxicity and a respiratory burst^[80]. Early events following ligation also include the polymerization of actin. More specifically, FcγRII adhesion and phagocytosis of IgG-opsonized particles induces L-plastin phosphorylation and L-plastin localization to the podosomes. L-plastin phosphorylation is not blocked by cytochalasin D^[81], suggesting that phosphorylation does not require an intact actin cytoskeleton.

Integrin αMb2 (CD18) activation in PMN is necessary for sustained adhesion and involves L-plastin phosphorylation. To find out if the N-terminal region of L-plastin is

sufficient for regulating adhesion, L-plastin-derived (mutant) peptides (amino acids 2–19) were used in PMN following fusion with the Tat peptide^[70]. These studies showed that wild type and the Ser5-phosphorylated peptide induced adhesion to serum-coated surfaces, but not activation of the respiratory burst or an increase in $[Ca^{2+}]_{ic}$. A corresponding T-plastin peptide or the L-plastin Ser5/Ala mutant peptide were inactive. Strangely, the activating peptides also induce phosphorylation of endogenous L-plastin. Phosphorylation could be blocked by PKC and PI3K inhibitors, but again L-plastin could not be phosphorylated *in vitro* by PKC.

Interestingly, PMN leukocytes lacking L-plastin are defective for killing pathogens *in vivo* and *in vitro*, even though they show normal migration to the site of infection, adhesion and spreading, and normal phagocytosis. Although L-plastin phosphorylation is known to be implicated in integrin activation^[70,82], it seems not to be required here. L-plastin is involved in activation of the adhesion-dependent respiratory burst by signaling to NADPH oxidase^[83]. L-plastin-deficient PMN cells had no altered morphology, which could be due to redundancy in actin-binding proteins.

Anti-leukoproteinase is a physiological inhibitor of granulocytic serine proteases. Anti-protease treatment reduces the incidence and severity of arthritis, and has a protective effect against cartilage and bone erosion. Anti-leukoproteinase binds to L-plastin and downregulates filamentous actin assembly in response to stimulation with IgG-coated latex beads in granulocytes. Anti-leukoproteinase also exerts additional inhibitory effects on neutrophil functions, such as phagocytosis and oxidative bursts^[84]. Thus anti-leukoproteinase has anti-arthritis potential because of the modulation of L-plastin in neutrophils.

A role for T-plastin during invasion of bacteria T-plastin is involved in invasion by at least two enteropathic bacteria: *Shigella flexneri* and *Salmonella typhimurium*. These two bacteria have different mechanisms for entering non-phagocytic cells by using specific effector proteins. In both cases, T-plastin is involved in cytoskeletal rearrangements during bacterial invasion. These rearrangements consist of distinct nucleation zones involving strong actin polymerization in close proximity to the contact site between bacterium and cell. These structures then push cellular protrusions outward that engulf the entering bacterium. T-plastin is concentrated in the protrusions during invasion of *Shigella flexneri*^[85,86]. Through transfection experiments it can be shown that T- and L-plastin are differentially recruited into *Shigella* entry zones, reflecting their distinct binding specificities. Transient expression of a dominant negative truncated T-plastin mutant decreased *Shigella* entry by 64%,

indicating that T-plastin has a functional role in *Shigella* entry into HeLa cells^[85].

During *Salmonella typhimurium* invasion, T-plastin is first recruited to membrane ruffles induced by the bacterium via a Cdc42-dependent signaling process that is activated by the bacterial secreted protein SopE. Then another secreted bacterial effector protein, SipA, forms a complex with T-plastin and F-actin, which results in a marked increase in the actin-bundling activity of T-plastin. SipA also inhibits actin depolymerization. This leads to stabilization of actin filaments at the point of bacterium-host cell contact, which leads to more efficient *Salmonella* internalization^[66].

Plastins and DNA repair Several independent reports indicate that plastin is involved in the cellular response to DNA-damaging agents and toxins. First of all, T-plastin expression is enhanced in cisplatin-resistant human bladder, prostatic, head and neck cancer cell lines, in comparison to their cisplatin-sensitive counterparts. Cisplatin is an anti-cancer agent that acts by binding to DNA and interfering with DNA repair. T-plastin mRNA is 12-fold more abundant in cisplatin-resistant cells in comparison to parental cells^[87]. Furthermore, T-plastin is also upregulated in UV radiation-resistant cells^[88]. In addition, downregulation of T-plastin expression is associated with increased sensitivity to cisplatin^[87]. Increased expression of T-plastin has been observed in Chinese hamster ovary (CHO) cells in which G2 arrest has been induced by X-radiation and by a topoisomerase II inhibitor, etoposide^[89]. In contrast, when T-plastin expression was downregulated, radiation-induced G2 arrest decreased in CHO cells, indicating a correlation between T-plastin expression and G2/M cell-cycle control.

Vinca alkaloids such as vincristin and vinblastin are chemotherapeutic agents used in the treatment of both childhood and adult cancers. Their main cellular target is the β -tubulin subunit of α/β -tubulin heterodimers, and they inhibit cell division by disrupting microtubule dynamics. Interestingly, L-plastin is downregulated in response to the vincristin treatment of drug-sensitive human leukemia cells and in vinblastin-resistant cells^[90]. These alterations in expression could be involved in several protector functions specific for each drug. For example, T-plastin could play a role in alteration of the intracellular distribution of the drug^[87]. Alternatively, the drug might be trapped in the cytoplasm by plastin-associated actin. T-plastin could also have a direct or indirect role in DNA repair. In UV radiation-resistant cells, this last possibility is a good candidate because these cells have a greater capacity to repair DNA^[91]. Furthermore, T-plastin expression is suppressed in a human colorectal cancer cell line, SW948, because of promoter-specific DNA

methylation^[89], which might be explained by T-plastin's possible role in checkpoint function. Taking everything into consideration, it seems likely that the protecting role of plastin is due to its involvement in DNA repair. Our finding that plastins can shuttle between nucleus and cytoplasm may strengthen this hypothesis^[60].

Cancer A very interesting and uncommon finding is that L-plastin is specifically expressed in many transformed cells but absent in their normal cell counterparts^[6,7]. Indeed, L-plastin has been described as a marker for many human cancer cells of non-hematopoietic origin^[92]. Lin *et al* found that 68% of epithelial carcinomas investigated and 53% of non-epithelial mesenchymal tumors examined expressed L-plastin (remember that L-plastin is normally expressed only in cells of the hematopoietic lineage)^[12]. In addition, examination of human neoplastic cell lines revealed that more than 90% of the cell lines surveyed exhibited widely varying degrees of L-plastin expression^[93]. In particular, cells derived from the reproductive tract expressed L-plastin. In normal cells of reproductive tissues (which are responsive to ovarian steroids), L-plastin synthesis is induced by female hormones. During malignancy, expression becomes hormone-independent^[94]. The L-plastin promoter harbors several hormone receptor-responsive elements; that is, one estrogen-responsive element and three imperfect androgen-responsive elements^[44,45]. Estrogen receptor binding^[95] and cooperative androgen receptor binding have been demonstrated^[45].

In 1997, Zheng and colleagues^[96] found that expression of L-plastin in prostatic epithelial cells was linked to the malignant state. Using antisense L-plastin constructs in prostate carcinoma cell lines (PC-3 and PC-3M cells, the metastatic variant), it was demonstrated that cell proliferation and invasion were drastically reduced^[97].

Because L-plastin expression is generally considered to be a marker for many cancers^[92], new therapeutic tools have been developed aimed at slowing down cancer progression *in vivo* based on the L-plastin gene. Gene therapy experiments in an animal model of colon cancer^[98,99] involving a pro-drug approach have shown promising results: the cytosine deaminase gene, driven by an L-plastin tumor-specific promoter, modifies 5-fluorocytosine into a toxic derivative, fluorouracil. These vectors induced significant toxicity in carcinomas of the breast, ovary and colon *in vitro* and *in vivo*: tumor size as well as tumor cell growth decreased significantly. Mice injected with the expression vector and 5-fluorocytosine lived much longer than their untreated litter mates^[98,99].

Although these approaches are promising, we still lack

fundamental molecular data showing how increased (or ectopic) plastin expression contributes to tumor formation. In the same line, a clear causal relationship between plastin expression and invasion/metastasis, the hallmarks of malignant tumors, needs to be established and worked out at the molecular level. This will allow models to be put forward and thoroughly tested *in vitro* and in animal models. These approaches could help resolve the question of whether plastins could be valuable targets for drug development in the treatment of cancer.

Other diseases In an animal model of the auto-immune disease systemic lupus erythematosus (SLE, a chronic rheumatic disease) and in human patients, antibodies against T- and L-plastin were found in serum^[100,101,102]. The presence of T- and L-plastin antibodies is correlated with the presence of the anti-Sm antibody, a typical SLE auto-antibody that recognizes a nuclear antigen. The stimulus for production of L- and T-plastin auto-antibodies may derive from the destruction of plastin-containing cells, such as replicating white blood cells (L-plastin), or epithelial and mesenchymal surfaces (T-plastin). It remains to be determined if L- and T-plastin antibodies contribute to the loss of cell function or other aspects of lupus. L-plastin has also been identified as a self-antigen associated with Vogt-Koyanagi's syndrome, an autoimmune disease^[103].

Expression of a chimeric mRNA transcript between the LAZ3 gene and the L-plastin gene, resulting from chromosomal translocation, was observed in two B-cell non-Hodgkin-lymphomas. The 13q14 chromosome region, where the L-plastin gene is located, is frequently disrupted in various proliferative disorders, and defines a breakpoint site^[104].

Finally, minimal change nephrotic syndrome (MCNS) is the most frequent glomerular disease in children, and is characterized by heavy proteinuria^[105]. MCNS results from a systemic disorder of T cell function^[106]. Expression levels of L-plastin and grancalcin are increased during the period of disease relapse^[107]. A truncated protein, Tc-mip, was detected in peripheral blood mononuclear cells from MCNS patients. Overexpression of this truncated protein in T cell Jurkat cells induced redistribution of L-plastin, in addition to Src phosphorylation and T cell clustering^[108]. Increased expression and redistribution of L-plastin may result in T-cell dysfunction, causing MCNS. These fragmentary data suggest that plastins contribute to the onset or progression of certain diseases, but it is clear that much more work needs to be done to ascertain their true role in these syndromes.

Concluding remarks and future directions

Although plastins have a clear role in actin-binding, there

is sometimes apparently incongruent information as to their exact actin-binding properties. Actin-bundling activity by mammalian plastins has been clearly established, but there is additional evidence for actin filament stabilization^[26] and for filament anti-depolymerization activities^[109,24,28,27]. In some organisms (yeast and plants), there is even indication that plastin has actin polymerization ability^[35,25].

The depletion of plastin does not promote severe deficiencies at first glance, because the knockout of L-plastin has no influence on embryonic and neonatal development^[83]. However, a lack of L-plastin could lead to immunological problems in a broad sense or complications involving inflammation.

Some culture cells overexpressing T- or L-plastin lose their adhesion properties and round up^[48,110]. It is hard to generate stable cell lines overexpressing plastin^[71,93], and this could be related to the observed invasive behavior of tumor cells (over)expressing plastin.

Future studies are expected to provide more clarity with respect to the functional significance of cell-type-specific expression of the three human plastin isoforms, each with its individual properties and functional regulation. In addition, nucleocytoplasmic shuttling of plastin isoforms elicits the question of what their true function in the nucleus is.

Abstract

NF- κ B, a family of related transcription factors, has been a focus of intense scientific research during the past decade. Multiple stimuli, both extracellular and intracellular, lead to its activation. The NF- κ B pathway regulates expression of a diverse array of genes involved in different biological processes. Various pathological states are characterized by the dysregulated NF- κ B pathway. Recently, NF- κ B activation has been connected with multiple aspects of oncogenesis and serves as an important mechanism to regulate cell survival in response to chemotherapy by activating different genes that inhibit apoptosis. Several methods of inhibiting NF- κ B activation, such as antisense oligonucleotides, proteasome inhibitors and RNA interference (RNAi) are currently under investigation. RNAi represents a powerful tool to better define the role of specific genes in different signal transduction pathways and has recently been used to define the function of genes that regulate the NF- κ B pathway. This review discusses the emerging role of RNAi to dissect the function of regulatory factors in the NF- κ B pathway and its potential use as a targeted therapy.

Introduction

The NF- κ B family is comprised of a variety of homo- and hetero-dimers formed by p50, p52, RelA (p65), RelB, and c-Rel subunits^[1–4]. The best-described form of NF- κ B is constituted by the p50 and p65 heterodimer. This heterodimer is sequestered in the cytoplasm bound to a family of inhibitory proteins known as I κ B^[5,6]. Following cell stimulation, the I κ B proteins become phosphorylated by I κ B kinase (IKK), a large kinase complex consisting of 2 catalytic subunits, IKK α and IKK β , and the regulatory subunit, IKK γ /NEMO^[7–9]. Phosphorylation of I κ B targets this inhibitor for ubiquitination and degradation, which results in the release and subsequent translocation of NF- κ B to the nucleus to activate transcription of a variety of genes^[10] (Figure 1). In this review, we first discuss the current understanding of why RNA-mediated gene silencing by small interfering RNA (siRNA) is important in NF- κ B pathway and then focus on the use of siRNA to analyze the role of cellular factors in regulating the NF- κ B pathway and its potential use as a targeted therapy to inhibit the NF- κ B pathway.

The NF- κ B pathway: mechanisms leading to activation

NF- κ B can be activated by a variety of stimuli, including inflammatory cytokines, such as TNF- α and IL-1, and growth factors as a result of stress response. Intra-cellular events such as DNA damage by radiation or chemotherapy serve as potent stimulus to activate NF- κ B as well. TNF- α and IL-1 are important to the generation of a systemic and local response to infection, injury, and immunological challenges^[2]. The signals from the TNF receptor (TNFR) and IL-1 receptor (IL-1R) are transduced through the TNF receptor-associated factor2 (TRAF2) and 6 (TRAF6), respectively^[11]. These TRAF are believed to function ‘upstream’ of the cascades of IKK and NF- κ B^[12,13]. Many members of the mitogen-activated protein kinase kinase kinase (MAP3K) family including MEKK1^[14], MEKK2, MEKK3^[15], TGF- β -activating kinase1 (TAK1)^[16] and NF- κ B-inducing kinase (NIK)^[17] also activate IKK when overexpressed. However, MEKK3 is an essential signal transducer in both TNFR- and IL-1R-induced NF- κ B activation^[11,18–22].

Figure 1. TRAF2 and TRAF6 mediated NF-κB activation. Both of the TRAF2 and TRAF6 are ubiquitinated in the presence of ubiquitin-activating enzyme (E1) and ubiquitin-conjugating enzyme (E2). Ubiquitinated TRAF2 and TRAF6 bind to TAB2 and activate TAK1. Activated TAK1 leads to IKK activation. In turn, activated IKK results in IκB phosphorylation. Phosphorylated IκB will be rapidly degraded after ubiquitination, and NF-κB (shown as the p50/p65 heterodimer) is translocated into the nucleus. TRAF2 and TRAF6 may also associate with NIK and MEKK3 to activate IKK complex. CYLD binds to NEMO and facilitates the disassembly of K63-linked polyubiquitin chains on TRAF2, TRAF6.

Initial studies on the structure of TRAF showed that the C-terminal domain for TRAF was responsible for protein-protein interactions and the N-terminal region of TRAF, including a RING finger and a variable number of Zn finger domains, was necessary for TRAF mediated activation of downstream signaling pathways^[23,24]. A RING finger with ubiquitin ligase activity^[25] is critical for NF-κB activation by TRAF^[26-28]. TRAF2 and TRAF6 were shown to be able to function as ubiquitin ligases that autoubiquitinate resulting in a lysine-63 (K63)-linked polyubiquitination^[29-31]. Ubiquitinated TRAF can bind to the TAK1, and its adapter proteins TAB1 and TAB2^[18,32,33]. TAB1 binds to TAK1 and is involved in regulating its activity, while TAB2 binds preferentially to K63-linked polyubiquitin chains^[12], resulting in the activation of TAK1^[34]. Activated TAK1 can phosphorylate IKK directly or act on the NF-κB-inducing kinase (NIK), which in turn activates IKK^[16,35]. Thus, the TAK1 complex is an important link between TRAF and the NF-κB pathway (Figure 1). TRAF7 also plays an important role in regulating activation of NF-κB and it can act like TRAF6 in relaying signals and activating the NF-κB pathway^[18].

IKK activation by the TNF-α and IL-1 is a rapid, but transient process, implying a negative feedback regulation of IKK following its activation. This negative regulation of IKK is controlled, at least in part, by deubiquitination, as shown in recent studies on the tumor suppressor cylindromatosis protein CYLD^[36,37]. Loss of CYLD has been linked to a predisposition to cylindromas, a syndrome characterized by benign tumors of the skin appendages. Interestingly, CYLD contains cysteine and histidine boxes found in the ubiquitin-specific protease (UBP) family of deubiquitination enzymes^[38]. Moreover, a portion of the histidine box of CYLD is deleted in some cylindromatosis patients, suggesting a link between the deubiquitination activity of CYLD and its tumor suppressor function. Three independent studies have shown that CYLD binds to NEMO and facilitates the disassembly of K63-linked polyubiquitin chains on TRAF2 and TRAF6^[36,37]. Thus, a critical function of CYLD is to down-regulate NF-κB activation through its deubiquitinating activity^[31].

RNAi-mediated gene silencing

RNAi is associated with a number of practical and theoretic advantages over pre-existing methods of suppressing gene expression (Table 1)^[39-44] and thus provides a useful mean to dissect the role of various factors that regulate the NF-κB pathway. RNAi also has the potential to be developed as a therapeutic modality to knock-down gene products that are important in activating the NF-κB pathway^[45].

Table 1. Advantages and disadvantages of different gene suppression strategies.

Gene suppression	Advantages	Disadvantages
RNAi	Potent, specific and simple Post-transcriptional gene silencing	Transfection-dependent Knock-down not knock-out
Antisense technology	Simple	Efficacy and specificity variable
Knockout mouse	Complete gene silencing.	Time-consuming and laborious to produce
Transfection of dominant negative mutant gene	Ability to determine functions of discrete regions of a protein	Transfection-dependent Variable specificity
Small molecule inhibitors	Simple	Often nonspecific

Several lines of evidence support a role for RNAi in a cell-based defense mechanism that protects the genome against mobile genetic elements such as viruses and transposons^[46,47]. There are 2 classes of small RNA that can silence gene expression. One class is processed from double-stranded (dsRNA) precursor molecules into small interfering RNA (siRNA) by the RNAase III-like nuclease called Dicer; these siRNA act as guides for the siRNA-induced silencing complex (siRISC) to target and cleave complementary mRNA^[48]. Dicer processes another class of small RNA from pre-microRNA into microRNA. These micro RNA act as guides for a multiprotein complex (miRISC) which identifies mRNA and silences gene expression either via destruction of the mRNA or by blocking its translation^[47,49,50]. Dicer was first isolated from extracts of *Drosophila*, but was later shown to exist in a large variety of species ranging from fungi to man^[51]. Two Dicers, Dcr-1 and Dcr-2 were found in *Drosophila*. Dcr-1 processes pre-miRNA^[52,53], while Dcr-2 processes dsRNA. In contrast to their processing specificities, both Dcr-1, Dcr-2 and its associated factor R2D2 are required for assembly of siRNA into siRISC (Figure 2)^[47,54]. Synthetic 21-23 nucleotide double stranded siRNA were synthesized to resemble Dicer cleavage products and could be directly incorporated in the mammalian RISC to target mRNA for degradation^[55]. Another approach relies on stable expression of short hairpin RNA from a plasmid vector down stream from a pol III or U6 promoter to result in a reproducible reduction of target gene expression in mammalian cells^[45]. Various strategies including retroviral, adenoviral and lentiviral vectors have been developed that allow the introduction of siRNA encoding vectors at high efficiency in primary cells. With these technologies, it is now possible to obtain effective gene silencing in transgenic embryos and adult mice^[48]. There have been several reports of successful use of *in vivo* siRNA in different animal models of human diseases; for example, microinjection of siRNA directed against zebrafish dystrophin gene into zebrafish embryos demonstrates the efficacy of

siRNA-based gene silencing in this model and illustrates the potential of this approach to determine the roles of multiple protein products expressed by a single gene during the early stages of development^[56]. Delivery of siRNA directed against either caspase 8 or hepatitis B virus (HBV) by mouse tail vein have been effective in suppressing specific gene expression^[57,58]. In addition, Verma *et al* demonstrated that siRNA directed against β -catenin reduced tumor growth in nude mice when administered by either intravenous or intraperitoneal injections, which suggests that siRNA could have therapeutic potential for inhibiting the expression of genes that enhance the growth of tumors^[59]. RNAi also holds great promise for the treatment of CNS diseases in which neurodegeneration is linked to overproduction of endogenous protein or to synthesis of aberrant proteins coded by dominant mutant alleles^[60].

More recently, many researchers have used plasmid and viral vectors for transcription of short-hairpin RNA (shRNA) that efficiently deliver siRNA into both dividing and non-dividing cells, stem cells, zygotes, and their differentiated progeny. Gene expression was more stably inhibited with these expression systems than with the transient knockdown recorded with chemically synthesised siRNA. A number of groups have used shRNA instead of siRNA to obtain relatively long-lived gene silencing *in vivo*^[61]. The libraries of retroviruses expressing shRNA designed to silence large fractions of all expressed human genes have been produced. These shRNA libraries have the potential to provide mammalian biologists for the first time with a genetic screening tool similar to that which has been used in more primitive organisms.

RNAi is an important tool for analyzing the NF- κ B pathway

Signal transduction pathways, such as the NF- κ B pathway, are modular composites of functionally interde-

Figure 2. siRNA pathways. Long dsRNA is processed by the RNAase III-like nuclease called Dicer2/R2D2 into siRNAs, while pre-miRNA is processed by the RNAase III-like nuclease called Dicer1 into miRNA. The 2 strands of the siRNAs or miRNA are unwound by the siRISC or miRISC, 1 strand is selected to identify a complementary target mRNA which in turn is cleaved by an endonuclease in siRISC or blocking translation in miRISC.

pendent sets of proteins that act in a coordinated fashion to transform environmental information into a phenotypic response. Several mechanisms that cause constitutive NF- κ B activity can be found in different epithelial tumors, tumor cell lines and lymphoid malignancies^[62]. Many different inhibitors affecting the NF- κ B activation pathway that have beneficial effects on tumor development or that increase the response to radiation and chemotherapy have been described. However, most of these inhibitors are not specific and inhibit many other pathways as well^[63]. Using RNAi to stably knock out specific gene expression and function is a highly effective and novel method that is rapidly gaining ground because of an explosion of new and improved techniques. The exquisite sequence specificity of RNAi provides a promising approach to address the complex interactions of viral and cellular regulatory proteins involved in NF- κ B pathway^[64]. As potent small-molecule inhibitors to any gene expression, siRNA can be used to specifically analyze the role of single gene products in NF- κ B pathway to emphasize the selectivity of RNAi-based therapy. Direct evidence, using both *in vitro* and *in vivo* models, indicates that RNAi is a critical tool to inhibit the NF- κ B pathway at multiple levels and study the transmission of signals in both physiologic and pathologic states^[36,37,65-68].

TAK1 is an important upstream mediator of the NF- κ B pathway^[16,34,46]. siRNA directed against TAK1 decreased the amount of both IL-1 and TNF α -induced phospho-I κ B α expression and prevented I κ B α degradation. The loss of endogenous TAK1 by siRNA resulted in impaired DNA-binding of NF- κ B. These results provide the first genetic evidence that supports a role of TAK1 as a critical upstream kinase for IKK α or IKK β in IL-1 and TNF α -induced activation of the NF- κ B pathway^[69]. Takaesu *et al* also reported that endogenous IKK α and IKK β co-immunoprecipitated with TAK1 upon TNF α stimulation. siRNA directed against IKK α and IKK β reduced IL-1 and TNF α -induced activation of the NF- κ B pathway. Simultaneous transfection of both IKK α and IKK β siRNA resulted in further decreases in NF- κ B activation as compared to transfection of each of these individual siRNA. These findings suggest that in addition to IKK α and IKK β , TAK1 is important for NF- κ B activation challenging previous result that only IKK β was involved in NF- κ B activation^[28,70-72].

Bcl-10, a cellular homolog of the equine herpesvirus-2 E10 gene^[73], was found over-expressed in some lymphomas of the mucosa-associated lymphoid tissue (MALT). Bcl-10 has been shown to physically associate with MALT1, which is a member of the paracaspase family and also involved in MALT lymphoma. Bcl-10 and MALT1 are essential for the

activation of IKK and NF- κ B in response to T cell receptor stimulation^[74]. Sun *et al* presented evidence that TRAF2 and TRAF6 mediated IKK activation by Bcl-10 and T cell receptor stimulation. TRAF6 siRNA reduced the activation of IKK by 50% and the same percentage of reduction in IKK activation was observed by TRAF2 siRNA. However, the combination of TRAF2 and TRAF6 siRNA reduced IKK activation by approximately 80%. Thus in T cells, both TRAF2 and TRAF6 are involved in upstream regulation of the NF- κ B pathway in response to T cell receptor stimulation^[64]. In addition, TAK1 siRNA transfection also dramatically reduced IKK activation by T cell receptor stimulation in T cells. Moreover, MALT1 and Bcl-10 have been shown to mediate IKK activation by facilitating the K63 polyubiquitination of NEMO. siRNA that reduced the expression of paracaspase and Ubc13 abrogated the effects of Bcl-10, which indicates that Bcl-10 promotes activation of IKK and NF- κ B through paracaspase- and Ubc13-dependent ubiquitination of NEMO^[75].

The tumor suppressor cylindromatosis protein CYLD belongs to a subfamily of enzymes with deubiquitinase activity^[76,77]. A collection of shRNA that suppress 50 human de-ubiquitinating enzymes were used to identify deubiquitination enzymes and study the mechanism for human cylindromatosis^[36] in the NF- κ B pathway^[45]. The studies from this and other groups show that CYLD binds to NEMO, and appears to regulate its activity through deubiquitination of TRAF2^[38,78]. They also demonstrated that inhibition of CYLD by siRNA enhanced NF- κ B activation and prevented apoptosis, suggesting a mechanism through which loss of CYLD contributes to oncogenesis^[36]. In independent studies, Trompouki *et al*^[37] also used the siRNA method and demonstrated that CYLD interacted with NEMO and negatively regulated NF- κ B signaling by deubiquitination of TRAF2. They have now started to investigate the use of CYLD inhibitors in clinical trials.

Potential therapeutic uses of NF- κ B inhibition by siRNA

The NF- κ B signaling pathway is important in the generation of the monocyte-derived dendritic cells and regulates their functional maturation and activation^[79–81]. Dendritic cells play a prominent role in infectious diseases, immune disorders, and in cancer immunology^[82]. In mammalian cells, NF- κ B/Rel proteins are involved in regulating survival, differentiation, and activation of the dendritic cells^[80,81,83]. Targeted mutations in mice demonstrate that deficits in RelB, cRel, p50, or p52 lead to various immune impairments that

directly implicate dendritic cells. Transfection of dendritic cells with p50 siRNA was tested by Diego^[88] and his colleagues as a way of performing loss-of-function analysis *in vitro* and the results showed strong and specific down-regulation of both p50 mRNA and protein levels. Such interference impaired p50 nuclear localization and DNA-binding in response to CD40 Ligand (CD40L) and IL-1 activation. The cytosolic fraction also showed reduced p50 activity after p50 siRNA transfection^[88].

IL-12 is a cytokine pivotal for the development of cellular immunity and production of high levels of IFN- γ by T cells. A biologically active form of IL-12 (IL-12 α and IL-12 β heterodimer) is produced from the transcription of separate genes which are regulated independently^[89]. Prior results have shown that CD40L alone or in combination with IL-1 induces high levels of IL-12 β transcription^[90]. However, a significantly reduced IL-12 β mRNA level and reduction of the secretion of IL-12 $\alpha\beta$ heterodimer was observed after p50 siRNA, which suggests that p50 siRNA down-regulated the production of IL-12 in response to CD40L and IL-1. These results are consistent with studies of the promoter of the IL-12 β gene, which is NF- κ B inducible and contains sites for the binding of p50 in B cells^[91].

It has been reported that p65 can stimulate HIV-1 transcriptional elongation by binding to the HIV-1 long terminal repeat (LTR)^[92,93]. The use of siRNA directed against p65 resulted in reduced HIV-1 replication, which correlated with the decrease in HIV-1 virions in supernatants from MAGI cells^[66]. CD4-positive human T-lymphocyte cell lines including MAGI have been used to study different aspects of the HIV-1 life cycle. These cells, which stably express CD4 receptors on the cell surface, can be infected by HIV-1. Since they contain a HIV-1 LTR fused to the β -galactosidase gene, infectious virus can transactivate the LTR- β -galactosidase reporter and increase β -galactosidase activity. Thus, staining of MAGI cells to determine β -galactosidase activity makes these cells an excellent indicator to determine the number of HIV-1 infectious particles^[94]. It has been observed that more than 90% of the infected cells transfected with control siRNA demonstrated marked β -galactosidase positivity. In contrast, only a few cells had β -galactosidase activity when the MAGI cells were transfected with p65 siRNA, which indicate that inhibition of HIV-1 replication by p65 siRNA resulted in very low levels of HIV-1 infectious particles^[66]. This finding highlights the importance that NF- κ B plays in the life cycle of HIV-1.

Tumors that have constitutive NF- κ B activity show increased resistance to chemotherapy. Inhibition of NF- κ B does not only lead to enhanced apoptosis but also to in-

creased sensitivity to radiation or chemotherapy in several tumor cells such as fibrosarcoma and colorectal cancer cell lines, as well as xenograft models or pancreatic carcinoma cells^[63]. CPT-11 is a topoisomerase I inhibitor which has efficacy in the treatment of certain neoplasms including colorectal cancer. In spite of the initial response to therapy^[81], most tumors from patients treated with CPT-11 become resistant and exhibit tumor progression^[95]. However, inducible chemotherapy resistance to CPT-11 has been shown to be reversed by inhibiting NF- κ B^[83,96]. More recent studies from Guo *et al*^[65] demonstrate that NF- κ B activation induced by CPT-11 in the relatively resistant HCT116 cell line is effectively inhibited by p65 siRNA both *in vitro* and *in vivo*. Transfection of p65 siRNA into HCT116 cells dramatically reduced the expression of p65. In addition, they found that loss of p65 did not impact cell viability on its own, but p65 siRNA in conjunction with CPT-11 increased tumor cell sensitivity to the cytotoxic effects of CPT-11. P65 siRNA increased apoptosis and reduced NF- κ B-binding activity. The effect on apoptosis could be partly explained by down-regulation of the NF- κ B target genes c-IAP1 and c-IAP2^[65]. These results are consistent with the role that NF- κ B plays in the inhibition of CPT-11 mediated cell killing^[2,97]. Importantly, transient exposure of HCT116 cells to p65 siRNA in cell culture altered the ability of these cells to proliferate following injection into nude mice in the presence of CPT-11 treatment. Systemic therapy with intravenous injection of p65 siRNA did not limit tumor growth. However, when combined with CPT-11, intravenous injection of p65 siRNA significantly delayed tumor growth with dramatic reductions in tumor volume^[65]. These studies demonstrate that delivery of siRNA to tumor cells *in vivo* is feasible and that inhibition of NF- κ B-mediated transcription by p65 siRNA holds therapeutic promise in cancer^[98].

Questions to the safety and efficacy of using RNAi as a therapeutic strategy

Interest in RNAi initially was restricted to basic researchers to study gene function. The subsequent finding that *in vivo* delivery of siRNA to induce RNAi in mammalian cells has generated excitement regarding its potential therapeutic applications. Various approaches have been shown to improve cell and tissue delivery of siRNA and shRNA^[61,99].

A major obstacle to the development of siRNAi as a therapeutic tool is its delivery to the desired cell type in the correct tissue or organ. Hydrodynamic delivery of siRNA that involves the intravascular injection of large fluid volumes in order to locally increase intravascular pressure^[100,101] might

be adapted for local administration of siRNA by arterial or venous catheters in organs such as liver, kidney, heart or lungs, but cannot be utilized for systemic treatment. Intravenous injection of siRNA in large volumes of saline solution, works by creating a back-flow in the venous system that forces the siRNA solution into several organs with lesser efficiency^[102,103]. Using RNAi to silence genes is also limited by the stability of siRNA molecules *in vivo* and the efficiency with which they are taken up by target cells and tissues^[104]. An additional obstacle in exploring siRNA as a therapeutic tool is toxicity. siRNA have the potential to induce a concentration- and cell-type-dependent cell death^[105]. In mammalian cells, the utility of RNAi has been limited by the innate immune response triggered by dsRNA. Long dsRNA induce an interferon response usually resulting in a generalized inhibition of gene expression. However, this response can usually be avoided in mammalian cell cultures by using synthetic siRNA with a length of 21 nt^[105].

Inhibition of viral replication by RNAi has been demonstrated *in vitro* for a variety of viruses, including RNA viruses such as HIV, respiratory syncytial virus, influenza virus, poliovirus, West Nile virus, dengue virus, and foot and mouth disease virus. However, some viruses are resistant to RNAi; for example, although siRNA can inhibit the production of progeny virus, the genomic RNA of respiratory syncytial virus, hepatitis delta virus, and rotavirus are resistant to RNAi, either because of tight shielding by proteins or to sequestration in compartments inaccessible to siRNA^[106–108]. Moreover, some viruses such as influenza and vaccinia produce proteins that actively suppress silencing by RNAi^[109]. Adenovirus was recently shown to block the processing of shRNA in mammalian cells by expressing a viral noncoding RNA at such high levels that it binds most of the available RNAi processing machinery^[110].

Summary

The discovery of RNAi has already provided a powerful tool for basic science researchers to study gene function. More recently the use of RNAi for genetic-based therapies has been widely studied, especially in viral infections, cancers, and inherited genetic disorders. Combined with genomics data, RNAi-directed gene-silencing could allow functional determination of any gene expressed in a cell or pathway. Thus, the therapeutic potential for RNAi is enormous, but the ability to efficiently and stably produce and deliver sufficient amounts of siRNA to the target tissues require refinement before this new technology can be tried clinically^[111].

Abstract

Aim: To investigate whether activation and translocation of extracellular signal-regulated kinase (ERK) is involved in the induction and maintenance of neuropathic pain, and effects of activation and translocation of ERK on expression of pCREB and Fos in the chronic neuropathic pain. **Methods:** Lumbar intrathecal catheters were chronically implanted in male Sprague-Dawley rats. The left sciatic nerve was loosely ligated proximal to the sciatica's trifurcation at approximately 1.0 mm intervals with 4-0 silk sutures. The mitogen-activated protein kinase kinase (MEK) inhibitor U0126 or phosphorothioate-modified antisense oligonucleotides (ODN) were intrathecally administered every 12 h, 1 d pre-chronic constriction injury (CCI) and 3 d post-CCI. Thermal and mechanical nociceptive thresholds were assessed with the paw withdrawal latency (PWL) to radiant heat and von Frey filaments. The expression of pERK, pCREB, and Fos were assessed by both Western blotting and immunohistochemical analysis. **Results:** Intrathecal injection of U0126 or ERK antisense ODN significantly attenuated CCI-induced mechanical allodynia and thermal hyperalgesia. CCI significantly increased the expression of p-ERK-IR neurons in the ipsilateral spinal dorsal horn to injury, not in the contralateral spinal dorsal horn. The time courses of pERK expression showed that the levels of both cytosol and nuclear pERK, but not total ERK, were increased at all points after CCI and reached a peak level on postoperative d 5. CCI also significantly increased the expression of pCREB and Fos. Phospho-CREB-positive neurons were distributed in all laminae of the bilateral spinal cord and Fos was expressed in laminae I and II of the ipsilateral spinal dorsal horn. Intrathecal injection of U0126 or ERK antisense ODN markedly suppressed the increase of CCI-induced pERK, pCREB and c-Fos expression in the spinal cord. **Conclusion:** The activation of ERK pathways contributes to neuropathic pain in CCI rats, and the function of pERK may partly be accomplished via the cAMP response element binding protein (CREB)-dependent gene expression.

Introduction

Peripheral nerve injury induced in various ways may produce chronic pain states characterized by hyperalgesia, allodynia and spontaneous pain. To date, there is no effective treatment for releasing neuropathic pain. Recently, the synaptic plasticity of spinal cord neurons induced by long-

lasting nociceptive stimulation (also called central sensitization) has been under intensive investigation^[1-3]. Several studies have suggested that central sensitization related to pain, and hippocampal long term potentiation (LTP) associated with learning and memory, may share certain mechanisms^[4,5]. For example, activation of *N*-methyl-*D*-aspartate

(NMDA) receptor and the subsequent associated intracellular signal transduction cascades are involved in the induction, development and maintenance of synaptic plasticity in the spinal cord and hippocampus. Like the consolidation of early-phase LTP into late-LTP in the hippocampus, activity-dependent gene expression or transcription, which can increase the expression of pain-related receptors and signal proteins, plays an important role in conversion from acute nociceptive injury to chronic pain states^[6,7]. The transcription factor cAMP response element binding protein (CREB), which can be phosphorylated by multiple intracellular kinases in response to a vast range of physiological and pathological stimuli, is critical for activity-dependent gene expression. Genetic studies have shown that CREB contributes to hippocampal late-LTP and memory consolidation, and CREB activation may serve as a molecular switch to transform short-lasting into long-lasting synaptic plasticity in the hippocampus^[8,9]. Similarly, CREB has been suggested to contribute to the central sensitization associated with persistent pain states^[10-12]. It has been proposed that NMDA activation-induced Ca^{2+} influx can trigger an early phase of CREB phosphorylation and a persistent phase of CREB phosphorylation is mediated by a delayed extracellular signal-regulated kinase (ERK) signal cascade, which is important to the development and maintenance of chronic pain.

ERK, one member of the mitogen-activated protein kinase (MAPK) family, transduces a broad range of extracellular stimuli into diverse intracellular responses by producing changes in the level of gene expression or transcription. Activated ERK translocates from the cytosol into the nucleus and in turn phosphorylates CREB at serine residue 133. Phosphorylation of CREB binding to the cAMP response element (CRE) of the target gene regulates gene expression and mediates the roles of ERK. Many studies found that ERK-mediated CREB phosphorylation is required for the induction of stable, late-phase LTP and long-term memory^[13-15]. It has been reported that ERK may be involved in the modulation of nociceptive information and central sensitization produced by intense noxious stimuli and/or peripheral tissue inflammation^[16-21]. However, few studies have focused on the roles of ERK and the relationship between ERK and CREB in neuropathic pain produced by nerve injury, such as chronic constriction injury (CCI) of the sciatic nerve.

In the present study, we used a CCI model to investigate whether activation and translocation of ERK were involved in the induction and maintenance of chronic neuropathic pain, and to observe the effect of ERK on the expression of pCREB in chronic neuropathic pain.

Materials and methods

Animals One hundred and seventy-four male Sprague-Dawley rats (200–250 g) provided by the Experimental Animal Center of Xuzhou Medical College were kept under a 12 h/12 h light-dark cycle regimen, with free access to food and water. All experiments were approved by the Animal Care and Use Committee at the Xuzhou Medical College and were in accordance with the college's guidelines for the care and use of laboratory animals.

Implantation of intrathecal catheter For intrathecal drug administration, rats were implanted with catheters as described by Yaksh and Rudy^[22]. In brief, under anesthesia with pentobarbital sodium (40 mg/kg, ip), rats were fixed, the occipital muscles were bluntly separated, then the cisternal membrane was exposed. Polyethylene catheters (PE-10) were inserted via an incision in the cisterna magna, and advanced 7.0–7.5 cm caudally to the level of the lumbar enlargement. Correct intrathecal placement was confirmed by injection of 10 μL 2% lidocaine through the catheter. The catheter was judged to be intrathecal if paralysis and dragging of bilateral hind limbs occurred within 30 s of this injection. Animals with signs of motor dysfunction were excluded from the experiment. The rats were housed individually after surgery and allowed to recover 5–7 d before the CCI test.

Chronic constrictive injury CCI of the sciatic nerve was performed as previously described by Bennett and Xie^[23]. Briefly, under anesthesia with isoflurane, the left sciatic nerves of rats were exposed at the level of the middle of the thigh, and then four ligatures (4–0, silk thread) were tied loosely around proximal to the sciatica's trifurcation at 1.0-mm intervals. Sham surgery was done by exposing the left sciatic nerve without ligation.

Drug administration Intrathecal drug administration was accomplished using a microinjection syringe connected to the intrathecal catheter in awake, briefly restrained rats. The injection was performed manually over a 30 s period in a single injection volume of 10 μL followed by a flush with 10 μL physiological saline.

U0126 (Biomol Research Laboratories, Pennsylvania, USA), an MEK inhibitor [dissolved in 5% dimethylsulfoxide (Me_2SO), 0.5 g/L] or ODN (1 g/L) were administered every 12 h, 1 d pre-CCI and 3 d post-CCI. Me_2SO and mis-sense ODN were injected as control.

The sequence of ERK antisense ODN was designed as reported previously^[24]; antisense: 5'-GCCGCCGCCGCC-CGCAT-3', directed against the initiation of the translation start site of rat ERK1 and ERK2 mRNA; mis-sense: 5'-CGCGCGCTCGCGCACCC-3'. ODN was synthesized by Shanghai Sangon (Shanghai, China) and modified with

phosphorothioate. The efficacy of the antisense oligonucleotide in inhibiting ERK expression was confirmed at the protein level by Western blotting. Twelve hours after the last administration of the antisense oligonucleotide, the expression of the ERK protein was reduced by approximately 70% in the rat spinal cord (Figure 1).

Figure 1. Expression of ERK in rat spinal cords after the intrathecal injection of the ERK antisense oligonucleotide. Phosphorothioate-modified antisense oligonucleotides (AS group) (1 g/L) were administered every 12 h for 4 d. Mis-sense oligonucleotides (MIS group) were injected as a control.

Behavioral studies Mechanical allodynia was assessed by using von Frey filaments. Animals were placed on a wire mesh platform and covered with a transparent plastic dome (20 cm×25 cm×15 cm), and the animals were allowed to acclimate to their surrounds for 30 min before testing. Each filament was applied perpendicularly to the plantar surface of the hindpaw (ipsilateral to the side of surgery in nerve-injured animals). The paw withdrawal threshold (PWT) was determined by sequentially increasing and decreasing the stimulus strength (the “up- and-down” method), and the data were analyzed using the nonparametric method of Dixon, as described by Chaplan *et al*^[25].

Thermal hyperalgesia was assessed with the paw withdrawal latency (PWL) to radiant heat according to the protocol of Hargreaves *et al*^[26]. Rats were placed in clear plastic cages on an elevated glass plate and allowed to acclimate to their surrounds for 30 min before testing. A high intensity light beam was focused onto the plantar surface of the hindpaw through the glass plate. The nociceptive endpoints in the radiant heat test were the characteristic lifting or licking of the hindpaw; the time to the endpoint was considered the PWL. To avoid tissue damage, a cut-off time of 30 s was used. There were 3 trials per rat and 5 min intervals between trials.

The tests were performed on each of 3 successive days prior to surgery and alternate days up to 15 d after surgery. Eight animals per group were used for behavior tests.

To study the effect of U0126 and antisense-ODN on the rat’s motor function, motor functions were evaluated by the observation of placing/stepping reflexes and righting reflexes and were conducted 5 min before the assessment of nociceptive responses.

Immunohistochemistry Immunohistochemical studies

were performed as previously described^[27,28]. Briefly, the spinal cord was cut into 40 μm-thick segments. After washing in phosphate buffer saline, the tissue sections were incubated in phosphate-buffered saline containing 5% normal goat serum and 0.3% TritonX-100 at room temperature for 30 min, followed by primary polyclonal mouse-anti-pERK antibody (1:200), primary polyclonal rabbit-anti-ser133-pCREB (1:400) antibody or primary polyclonal rabbit-anti-Fos antibody (1:1000) at 4 °C for 48 h (all antibodies were from Santa Cruz Biotechnology, California, USA). The sections were then incubated in biotinylated goat anti-rabbit or -mouse IgG (1:200) at 37 °C for 1 h and in avidin-biotin-peroxidase complex (1:100) (Vector Labs, California, USA) at 37 °C for 2 h. Finally, the sections were reacted with diaminobenzidine (DAB) for 5–10 min. Sections were rinsed in phosphate-buffered saline to stop the reaction, mounted on gelatin-coated slides, air-dried, dehydrated with 70%–100 % alcohol, cleared with xylene, and cover-slipped for microscopic examination.

We selected 5 spinal cord sections per animal, selecting sections that had the greatest number of positive neurons. For each animal, two measurements were made: (1) total number of positive neurons in the spinal cord dorsal horn ipsilateral to injury; (2) total number of positive neurons in the spinal cord dorsal horn contralateral to injury. All positive neurons were counted without considering the intensity of the staining.

Western blotting The lumbosacral spinal cords of the rats were extracted and stored in liquid nitrogen. Tissue samples were homogenized in lysis buffer A (in mmol/L): HEPES 10.0, Na₃VO₄ 1.0, MgCl₂ 1.5, KCl 10.0, NaF 50.0, edetic acid (EDTA) 0.1, egtazic acid (EGTA) 0.1, phenylmethylsulfonyl fluoride (PMSF) 0.5, dithiothreitol (DDT) 1.0 and 0.02% protease inhibitor cocktail (pH 7.9). After the addition of 90 μL NP-40 (10%), the homogenates were vortexed for 30 s and then centrifuged at 800×g for 15 min at 4 °C. The supernatants were used for Western blot analysis as cytosolic proteins. The nuclear pellets were resuspended in buffer B (in mmol/L): HEPES 20.0, NaCl 420.0, MgCl₂ 1.5, EDTA 1.0, EGTA 1.0, PMSF 0.5, DDT 1.0, 20 % glycerol, and 0.02% protease inhibitor cocktail (pH 7.9). The homogenates were incubated for 30 min in ice-cold water with constant agitation and then centrifuged at 13 000×g for 15 min at 4 °C to separate the nuclear proteins. Protein concentrations were determined using the Bradford method and the protein samples were stored at -80 °C.

Protein samples were dissolved in 4×sample buffer [in mmol/L: Tris-HCl 250.0, sucrose 200.0, DDT 300.0, 0.01% Coomassie brilliant blue-G, and 8% sodium dodecyl sulfate

(SDS), pH 6.8], and denatured at 95 °C for 5 min, then the equivalent amounts of proteins were separated by using 10% SDS-polyacrylamide gel electrophoresis (PAGE) and transferred onto a nitrocellulose membrane. The membranes were incubated overnight at 4 °C with the following primary antibodies: mouse polyclonal anti-pERK antibody and rabbit polyclonal anti-ser133-pCREB. The membranes were extensively washed with Tris-Buffered Saline Tween-20 (TBST) and incubated for 1 h with the secondary antibody conjugated with alkaline phosphatase (AP) at room temperature. The immune complexes were detected by using a NBT/BCIP assay kit (Promega, Shanghai, China). The scanned images were imported into Adobe Photoshop software (Adobe, California, USA). Scanning densitometry was used for semiquantitative analysis of the data.

Experimental groups Rats were divided into six groups in the behavior test: the sham group, CCI group, U0126 group, Me₂SO group, antisense ODN group and mis-sense ODN group. Four groups were included in the immunohistochemistry studies and the Western blot testing: the sham group, CCI group, U0126 group, and antisense ODN group. Because few pERK, pCREB and Fos-positive neurons were expressed in the spinal dorsal horn of sham group rats, these data are not shown in results.

Statistical analysis All data are expressed as mean±SD. Statistical analysis was carried out using one-way ANOVA or Student's *t*-test. *P*<0.05 was considered statistically significant.

Results

Effects of U0126 or ERK antisense ODN on CCI-induced mechanical allodynia and thermal hyperalgesia Intrathecal administration of U0126 or ERK antisense-ODN did not affect the mechanical PWT, the thermal PWL, or motor function in the rats that received implanted intrathecal catheters. CCI, and not sham surgery, produced significant mechanical allodynia and thermal hyperalgesia. The time course of PWT and PWL is presented in Figure 2. Intrathecal injection of U0126 or ERK antisense ODN, and not Me₂SO or mis-sense ODN, attenuated CCI-induced mechanical allodynia and thermal hyperalgesia.

Effects of U0126 or ERK antisense ODN on CCI-induced pERK expression in the spinal cord CCI significantly increased the expression of pERK-IR neurons in the spinal cord dorsal horn ipsilateral to injury. The pERK positive neurons were distributed mainly in laminae I and II of the spinal dorsal horn. Few positive neurons were distributed in other laminae or the contralateral spinal cord. Intrathecal

Figure 2. Intrathecal administration of U0126 or ERK antisense oligonucleotides prevented chronic constriction injury-induced mechanical allodynia (A) and thermal (B) hyperalgesia. Mean±SD. *n*=8. ^b*P*<0.05 vs CCI group.

injection of U0126 or ERK antisense ODN inhibited the increase in pERK expression in the spinal dorsal horn on postoperative d 3 and d 5 (Figure 3).

CCI-induced ERK activation was also confirmed by Western blot analysis. Compared with sham group rats, the levels of both phospho-ERK1 (44 kDa) and phospho-ERK2 (42 kDa), not unphospho-ERK (data not shown), were increased at all measured time points after CCI (Figures 4, 5). The expression of pERK reached a peak level on postoperative d 5. The increase in the nuclear fraction of pERK expression indicated that pERK was translocated into the nucleus from the cytoplasm. Intrathecal injection of U0126 or ERK antisense ODN markedly inhibited the increase in both cytosolic and nuclear pERK expression.

Effects of U0126 or ERK antisense ODN on CCI-induced pCREB expression in the spinal cord The immunohistochemical results revealed that CCI significantly increased the expression of pCREB, and pCREB-positive neurons were distributed in all laminae of the bilateral spinal cord. Expressions in the ipsilateral and contralateral spinal

(Middle) A representative Western blot band for pERK. (Top and bottom) Quantitative data indicating the expression of pERK. ERK expression in the sham group is set at 100%. $n=4$. Mean \pm SD. ^b $P<0.05$ vs CCI group.

Figure 5. Western blot analysis on the effect of intrathecal administration of U0126 or ERK antisense ODN on CCI-induced nuclear pERK expression in the rat spinal cord. (Middle) A representative Western blot band for pERK. (Top and bottom) Quantitative data indicating the expression of pERK. The expression of pERK in the sham group is set at 100%. $n=4$. Mean \pm SD. ^b $P<0.05$ vs CCI group.

cord were not significantly different. Intrathecal injection of U0126 or ERK antisense ODN markedly inhibited pCREB expression in both sides of the spinal cord (Figure 6). Few pCREB positive neurons were found in the sham group rats (data not shown).

Similar to the results of the immunohistochemical studies, the Western blot results showed that nuclear pCREB was highly expressed on postoperative d 3 and d 5. Intrathecal administration of U0126 or ERK antisense ODN significantly inhibited the increase of pCREB expression, especially on postoperative d 5 (Figure 7). These data suggest that activation of ERK contributes to increased pCREB expression in the spinal cords of CCI rats.

Effects of U0126 or ERK antisense ODN on CCI-induced Fos expression in the spinal cord CCI significantly increased the expression of Fos in laminae I and II of the ipsilateral spinal dorsal horn. Dissimilar to the findings for pCREB, few c-Fos positive neurons were found in the contralateral spinal cord. Intrathecal administration of U0126 or ERK antisense ODN also significantly reduced the expression of Fos-positive neurons (Figure 8A, 8B, 8C, and 8D).

Discussion

Central sensitization, an activity-dependent functional plasticity, is one of the main causes of behavior hyperalgesia under pathological conditions. Activation of postsynaptic membrane receptors or ion channels, intracellular kinase cascades and intranuclear gene expression contributes

to the induction, development and maintenance of central sensitization. Intracellular kinase cascades, as the linkage bridge, transduce noxious stimuli into diverse intracellular responses, including changes in the levels of gene expression or transcription. A large number of studies have implicated several protein kinases, for example, protein kinases A (PKA), protein kinases C (PKC) and calcium/calmodulin-dependent protein kinase II (CaMKII), in central sensitization^[29-31]. Recently, several studies have reported that ERK, a mitogen-activated protein kinase, contributes to pain hypersensitivity and central sensitization. Acute noxious stimuli, such as formalin or capsaicin, induce ERK phosphorylation in spinal dorsal horn neurons, and MEK inhibitor PD 98059 or U0126 reduces acute pain behavior after subcutaneous injection of formalin or capsaicin^[16-21]. In agreement with previous reports using other pain models, the present studies indicate that activation of ERK in rat spinal cord contributes to CCI-induced allodynia and hyperalgesia. We demonstrated here, the time course of pERK and the relationship between pERK and pCREB expression in a CCI model. CCI induces long-lasting ERK phosphorylation and nuclear translocation in the spinal cord. The time course of changes in pERK expression, at least in part, correlated significantly with behavior hyperalgesia. Intrathecal injection of U0126 or ERK antisense ODN markedly attenuated CCI-induced mechanical allodynia and thermal hyperalgesia.

Nerve fibers display abnormal ectopic excitability at or near the site of nerve ligation after CCI. The local persistent abnormal excitation of sensory nerves can spread to the pe-

such as glutamate, substance P, and calcitonin gene-related peptide (CGRP) in the central terminals of primary sensory afferents and then activate NMDA and neurokinin (NK) receptors in spinal dorsal horn neurons. Calcium influx through NMDA receptors triggers an increase in the levels of Ras-GTP and in turn leads to the activation of raf/MEK/ERK cascades.

ERK mediates central sensitization by phosphorylating the effector protein. Two potential effectors of ERK related to central sensitization are the potassium channel Kv4.2 and the transcription factor CREB. Recent evidence has shown that ERK integrates PKA and PKC to modulate the K⁺ channel Kv4.2 and A-type K⁺ currents (I_A) in superficial dorsal horn neurons. Kv4.2 and I_A are critical determinants of neuronal excitability in central sensitization^[32–34]. It is possible that modulation of potassium channels may be involved in the short-term or acute effect of pERK. Our unpublished data show that CCI-induced hyperalgesia is reversed 30 min after intrathecal administration of U0126 on postoperative d 5.

Importantly, pERK is able to translocate from the cytoplasm into the nucleus and in turn phosphorylate the transcriptional factor CREB on serine 133. In the current study, CCI significantly increased the expression of pCREB in the rat spinal cord. The time course of pCREB expression correlates with the activation of ERK and behavioral hyperalgesia. Intrathecal injection of U0126 or ERK antisense ODN markedly inhibited the increase in pCREB expression. This suggests that activation of ERK may contribute to increased pCREB expression in the spinal cord of CCI rats, and that the function of pERK is partly accomplished via CREB-dependent gene expression. Phosphorylation of CREB on serine 133 recruits the CREB binding protein, CBP, to the complex and promotes the transcription of downstream genes. Many “pain genes”, which may contribute to central sensitization, are activated by CREB, including the immediate early gene *c-fos*, BDNF, CGRP, the alpha subunit of CaMKII, and the neurokinin 1 receptor. A considerable amount of evidence has indicated that CREB-dependent gene expression is re-

quired for long-term changes in the synaptic plasticity induced by various nociceptive stimuli^[10–12, 35–37].

We found that increases in pCREB expression occurred bilaterally in all laminae of the spinal cord in CCI rats. Expression levels in the ipsilateral and the contralateral sides were not significantly different. Fos protein was expressed only in the ipsilateral spinal dorsal horn. Similar results have been reported in other pain models, for example, formalin injection and carrageenan injection^[11,12,38,39]. However, few interpreted this result consistently. Ji and Rupp speculated that signal strength might affect gene expression differentially with respect to protein phosphorylation^[38]. We, however, favor the explanation that different intracellular signal transduction pathways contribute to pCREB expression in the ipsilateral and the contralateral spinal cords. In the present study, pCREB was expressed in both sides of the spinal cord, but pERK only in the ipsilateral side. These results suggest that pERK contributed to pCREB expression in the ipsilateral spinal cord, but not in the contralateral spinal cord. Intrathecal injection of U0126 or ERK antisense ODN inhibited pCREB expression not only in the ipsilateral spinal cord, but also in the contralateral spinal cord. This suggests that activation of ERK in the ipsilateral spinal cord is also involved in pCREB expression in the contralateral spinal cord. CCI induces ipsilateral primary afferent terminals to release nociceptive neurotransmitters, which induces the NMDA receptor-dependent activation of intracellular kinase cascades, including the ERK pathway, in the spinal cord. Furthermore, cross-talk between intracellular kinase cascades can produce strong activation of signal pathways. Then some kinases phosphorylate CREB and regulate noxious-induced target gene expression, such as c-fos, in a pCREB-dependent manner. But how should we interpret pCREB expression in the contralateral spinal cord, which did not receive noxious inputs? Numerous lines of evidence have shown that unilateral noxious stimuli can indirectly induce the activation of several intracellular signal pathways in the bilateral spinal cord. For example, Solodkin *et al* reported that unilateral hindpaw inflammation produced a bilateral increase in NADPH-diaphorase in rat lumbar spinal cord^[40]. Noxious stimuli also induce glial activation, and excitation of glia at one site can activate distant and even the contralateral dorsal horn glia via gap junctions and propagated calcium waves^[41]. The ipsilateral noxious stimuli-induced activation of several intracellular signal pathways in the contralateral spinal cord may indeed be a critical factor in pCREB expression in the contralateral spinal cord. Because CREB phosphorylation in the contralateral spinal cord does not result from direct extracellular noxious inputs, it cannot

upregulate the expression of the noxious marker gene, c-fos.

In summary, the present study found that activation of the ERK/CREB pathway in the spinal cord contributed to chronic constrictive injury-induced neuropathic pain.

Abstract

Aim: To define the role of enzymes involved in glutathione metabolism in 6-hydroxydopamine (6-OHDA)-induced glutathione alteration in primary cultured astrocytes. **Methods:** Total glutathione (GSx) levels were determined using the modified enzymatic microtiter plate assay. The mRNA levels of γ -glutamylcysteine synthetase (γ GCS), γ -glutamyltransferase (γ GT), glutathione peroxidase (GPx), GR (glutathione reductase), and glutathione transferases (GST) were determined using RT-PCR. γ GT activity was determined using γ GT assay kits. **Results:** In primary cultured astrocytes, 6-OHDA induced a significant elevation of cellular GSx levels after treatment for 24 h. However, the GSx levels decreased after 24 h and the values were even lower than the value in the control group without 6-OHDA at 48 h. RT-PCR data showed that the mRNA levels of γ GCS, the rate-limiting enzyme of γ -L-glutamyl-L-cysteinylglycine (GSH) synthesis, were increased by 6-OHDA after treatment for 24 h and 48 h; the mRNA levels of GPx, GR, and GST did not alter in 6-OHDA-treated astrocytes after treatment for 24 h and 48 h; and 6-OHDA increased the mRNA levels and the activity of γ GT after treatment for 48 h, which induced a decrease in GSx levels, despite the up-regulation of γ GCS after exposure to 6-OHDA for 48 h. **Conclusion:** The change in γ GCS correlated with the increase in GSH levels induced by 6-OHDA after treatment for 24 h. GSx levels decreased because of increased γ GT mRNA levels and γ GT activity induced by 6-OHDA after treatment for 48 h.

Introduction

Parkinson's disease is characterized by the selective demise of dopaminergic neurons. Recent findings in molecular genetics and neurochemistry have suggested that oxidative stress is possibly involved in the aging process and is one of the pathogenic mechanisms of Parkinson's disease^[1].

6-Hydroxydopamine (6-OHDA) is one of the most common neurotoxins used to model nigral degeneration experimentally *in vitro* as well as *in vivo*. 6-OHDA, like dopamine (DA), is a substrate for monoamine oxidase (MAO). This enzymatic reaction gives rise to hydrogen peroxide^[2]. Astrocytes are essential for the cellular defense against reactive oxygen species (ROS)^[3], within which there is a high concentration of the tripeptide glutathione (GSH; γ -L-glutamyl-L-cysteinylglycine)^[4].

Glutathione in astrocytes is very important for cellular defense against ROS. Alterations of the GSH metabolism in the brain have been implicated in oxidative stress and neurodegenerative diseases such as Parkinson's disease^[5]. Sian *et al* found that GSH levels were reduced in substantia nigra in patients with Parkinson's disease (reduced by 40% compared with control subjects)^[6]. This depletion in GSH may increase the susceptibility of brain cells to other harmful events, such as the reduction of mitochondrial energy production.

In addition to the GSH levels, alterations in the specific activities of enzymes involved in GSH metabolism and defense against ROS have been reported. They are^[7]: (1) γ -glutamylcysteine synthetase (γ GCS), the rate-limiting enzyme and the first enzyme used in GSH synthesis, which converts glutamate and cysteine to γ -glutamylcysteine. (2) The

ectoenzyme γ GT (γ -glutamyltransferase), which converts GSH to cysteinylglycine (CysGly) and γ -glutamyl^[8]. CysGly is a precursor for *de novo* GSH synthesis in both astrocytes and neurons^[9]. Inhibition of γ GT prevents the astroglia-induced effect on GSH levels in neurons^[9]. (3) Glutathione peroxidase (GPx) and glutathione reductase (GR), which catalyze the SH/S-S exchange reactions and contribute to protein thiol protection. (4) Glutathione transferases (GST), which use GSH to detoxify peroxides and carbonyl-containing products of lipid peroxidation.

In the present study, we investigated the role of 6-OHDA in astroglial GSH metabolism, and the expression of glutathione-related enzymes, especially γ GCS and γ GT in primary cultured astrocytes induced by 6-OHDA.

Materials and methods

Materials Glutathione reductase, β -NADPH- Na_4 , and 6-OHDA were obtained from Sigma (St Louis, MO, USA). Dulbecco's modified Eagle's medium (DMEM) was obtained from Gibco (Grand Island, NY, USA). γ GT assay kits were purchased from Nanjing Jiancheng Biological Co (Nanjing, China). All PCR primers were purchased from Sangon (Shanghai, China). All reagents for RT-PCR were purchased from Promag (Madison, WI, USA). All other chemicals were obtained from standard commercial sources.

Cell culture Astrocyte-rich primary cultures obtained from the whole brains of neonatal Sprague-Dawley rats were prepared and maintained as described previously^[10]. Briefly, the cortex was incubated in 0.125% trypsin at 37 °C for 8 min and mechanically disrupted by passing the tissue through nylon mesh. After centrifugation (1500 \times g, 5 min), the cell pellet was gently resuspended in a small volume of tissue growth medium (DMEM containing 10% fetal bovine serum, 100 kU/L penicillin and 100 mg/L streptomycin) and plated in the same medium at a density of 1×10^7 cells/L in 12-well plates precoated with poly-lysine for the GSH assay.

GSx assay GSH was assayed as total glutathione (GSx), which was the sum of the reduced and oxidized forms [GSH+2 \times glutathione disulfide (GSSG)] by a modified enzymatic recycling method of Tietze^[11]. Cells were washed in PBS, dissolved in 200 μ L PBS buffer (0.05 mmol/L edetic acid; 0.05% Triton-X 100, pH 8.0), and centrifuged to remove protein. According to the Bradford method^[12], we used a volume of 50 μ L of supernatant for assessing protein by using bovine serum albumin as a standard. A volume of 100 μ L of supernatant was neutralized with 50 μ L of a 5% (w/v) salicylsalicylic acid (SSA) solution. The solution was centrifuged, then the GSH content was determined after the

addition of 4 μ L 10 mmol/L β -NADPH, 3 μ L 10 mmol/L 5, 5'-dithio-*bis*-2-nitrobenzoic acid (DTNB), 2 kU/L GSH reductase. The GSH content was determined by kinetic measurement of the absorbance changes at 412 nm for 5 min and calculated by comparison with standards.

RNA preparation and semiquantitative RT-PCR

Semiquantitative RT-PCR with β -actin as an internal control was performed to examine the expression of messenger RNA for the γ GCS, γ GT, and other GSH enzymes in glial-rich primary cultures. Total RNA (2 μ g) from primary cultured astrocytes was reverse transcribed into single-stranded cDNA in a 20- μ L reaction mixture containing: 10 mmol/L dNTP, 1 μ g oligo (dT) primer, 20 IU RNasin and 200 IU M-MLV reverse transcriptase. The mixture was incubated at 42 °C for 1 h and then the reverse transcriptase was inactivated by heating the reaction mixture to 95 °C for 10 min. PCR amplification was carried out with 1.5 μ L cDNA product in a 30 μ L reaction volume containing 3 pmol of each specific oligonucleotide primer, 10 mmol/L dNTP, and 1.5 IU *Taq* DNA polymerase. For all of the reactions, preliminary experiments were performed to determine the number of PCR cycles at which saturation occurred, and the experiments mentioned were carried out with a number of cycles that precedes saturation. The sequences of the primers, product size, and optimized number of PCR cycles for GSH-related enzymes and β -actin expression analyses were: (1) γ GCS, forward primer: 5'-AGACA-CGGCATCCTCCAGTT-3'; reverse primer: 5'-CTGACACGTAGCCTCGGTAA-3' (GenBank accession no: NM_012815; product size: 801 bp). The thermal cycler unit was programmed for 30 cycles at 95 °C for 1 min, 60 °C for 1 min, then 72 °C for 1 min. (2) γ GT: we used nested RT-PCR for γ GT, in which the reverse transcriptase reaction and two sequential PCR procedures were carried out. The first-round primer pairs were designed from the target mRNA, and the second-round primers were designed from the first-round amplified PCR products. Forward and reverse primers were selected from the coding domain to identify any γ GT mRNA nonselectively; the first-round primers were 5'-GCTTTGTGC-GAGGTGTTCTG-3' and 5'-CCATCGTCTGGAAGGTAGA-3'; the second-round primers were 5'-CTCAGCGGGCCCGTGTG-3' and 5'-GGCGGTTGGGTGAGTGGT-3', in the primary and the secondary PCR reactions, respectively (GenBank accession no: BC078768; product size: 261 bp). The thermal cycler unit was programmed for 30 cycles at 95 °C for 1 min, 55 °C for 1 min, and 72 °C for 1.5 min. (3) GPx, forward primer: 5'-GTATGTCTGCTGCTCGGCTCTC-3'; reverse primer: 5'-AAATGATGTACTIONTGGGGTTCGGTC-3' (GenBank accession no: NM_030826; product size: 450 bp). The thermal cycler unit was programmed for 26 cycles at 94 °C for 45 s, 61 °C for

45 s, and 72 °C for 45 s. (4) GR, forward primer: 5'-ACGA-GGAAGACGAAATGCGTGATG-3'; reverse primer: 5'-AGGATGAATGGCGACCCTATTGTC-3' (GenBank accession no: U73174; product size: 171 bp). The thermal cycler unit was programmed for 24 cycles at 94 °C for 1 min, 56 °C for 1 min, and 72 °C for 1 min. (5) GST, forward primer: 5'- CCAAA-TTGAGAATTCCACAGCGC-3'; reverse primer: 5'-TGCCTGCAGGATCCAATGTGGA-3' (GenBank accession no: NM_017014; product size: 205 bp). The thermal cycler unit was programmed for 22 cycles at 95 °C for 30 s, 63 °C for 45 s, and 72 °C for 30 s. (6) β -actin, forward primer: 5'-CACGATG-GAGGGCCGACTCATC-3'; reverse primer: 5'-TAAAGACCTCTATGCCAACACAGT-3' (GenBank accession no: NM_031144; product size: 240 bp). The thermal cycler unit was programmed for 24 cycles at 94 °C for 30 s, 61 °C for 30 s, and 72 °C for 30 s. PCR products were separated by electrophoresis on a 2% agarose gel and visualized after ethidium bromide staining over UV light.

Determination of γ GT activity After removal of the medium, cells were washed twice with 4 mL ice-cold PBS [10 mmol/L potassium phosphate buffer containing 150 mmol/L NaCl (pH 7.4)] and were lysed by incubation with 500 μ L 20 mmol/L potassium phosphate buffer (pH 7.0) containing 0.2 mmol/L edetic acid for 10 min on ice. The cell lysates were scraped off the flask and transferred to Eppendorf tubes. After centrifugation (15 000 \times g, 5 min, 4 °C), the supernatant was discarded and the pellets were resuspended in 100 μ L of 20 mmol/L potassium phosphate buffer (pH 7.0) containing 200 μ mol/L edetic acid and 1% (w/v) Triton X-100. During 20-min incubation on ice the lysates were resuspended several times. After centrifugation (15 000 \times g, 5 min, 4 °C) the activity of γ GT was measured in 50 μ L aliquots of the supernatants according to the method described by Meister *et al*^[8]. The samples were determined by γ GT assay kits from the Nanjing Jiancheng Biological Co. The protein content of the cultured cells was determined using the Bradford method^[12].

Data analysis All values were presented as mean \pm SD. The *t*-test was used for comparisons and differences were considered significant if *P*<0.05.

Results

Effect of 6-OHDA on endogenous GSx contents in astrocytes To elucidate the relationship between endogenous GSx and 6-OHDA-induced cell damage, we measured the GSx content of astrocytes. The GSx concentration increased from 14.62 μ mol \cdot g⁻¹·protein to 24.02 μ mol \cdot g⁻¹ protein after incubation of the astrocytes with 6-OHDA for 24 h (Figure 1) and decreased to 10.35 μ mol \cdot g⁻¹ protein after exposure to 6-OHDA

for 48 h (Figure 1). The GSx content further reduced to 20% of control levels when cells were incubated with 0.13 mmol/L 6-OHDA for 48 h (Figure 1).

Figure 1. Effect of 6-OHDA on GSx production over time in primary astrocytes. *n*=6. Mean \pm SD. ^b*P*<0.05, ^c*P*<0.01 vs the corresponding value at 0 h.

Effect of 6-OHDA on glutathione enzyme expression in astrocytes To further address whether the 6-OHDA had an effect on glutathione enzymes, we detected the mRNA expression of glutathione enzymes. In this study, all RT-PCR data were normalized relative to levels of β -actin mRNA. Astrocytes were exposed to 6-OHDA for 24 h or 48 h. We found that the levels of cellular GSx and γ GCS mRNA were increased after the cells were incubated with 6-OHDA for 24 h; however, the levels of cellular GSx decreased markedly, whereas γ GCS mRNA expression increased again after exposure for 48 h (Figure 2). However, 6-OHDA failed to alter the levels of GPx, GR, and GST mRNA, after exposure for both 24 h and 48 h (Figure 3). The levels of γ GT mRNA expression in astrocytes were up-regulated after exposure to 6-OHDA for 48 h, but not for 24 h (Figure 4).

Measurement of γ GT activity in astrocytes Specific γ GT activity was measured in astrocytes in the presence and absence of 6-OHDA. We treated astrocytes with 100 μ mol/L 6-OHDA for 24 h or 48 h. γ GT activity did not alter after treatment with 6-OHDA for 24 h, but it increased significantly from an initial value of 0.08 kU \cdot g⁻¹ protein to a plateau value of 0.17 kU \cdot g⁻¹ protein after exposure to 6-OHDA for 48 h. The increase in γ GT activity in astrocytes correlated well with the levels of γ GT mRNA expression in cells (Figure 5).

Discussion

A high intracellular concentration of glutathione protects against a variety of different ROS. GSH reacts directly with

Figure 2. Effects of 6-OHDA (0.1 mmol/L) on γ GCS mRNA expression in astrocytes. The top panel shows the results of RT-PCR, which demonstrates the effect of 6-OHDA on γ GCS mRNA levels (805 bp). The bottom panel shows the mRNA levels of β -actin (240 bp). DNA markers: 2000, 1000, 750, 500, 250, 100 bp. $n=3$. Mean \pm SD. ^c $P < 0.01$ vs the value at 0 h.

radicals in nonenzymatic reactions. It should be noted that GSx, including GSH and GSSG, is very important for cellular defense against ROS. Glutathione levels in the substantia nigra pars compacta of patients with Parkinson's disease is significantly reduced, but the levels do not change in patients with multiple system atrophy or progressive supranuclear palsy^[13]. It has been found that oxidative stress might originate in astrocytes rather than in neurons. Astrocytes surrounding dopaminergic neurons in the brain may be involved in the selective vulnerability of these neurons by scavenging ROS and releasing CysGly by using γ GT, and CysGly is the precursor for GSH synthesis in neurons. Hence, astrocyte function is an important contributor to the pathogenesis of Parkinson's disease.

6-OHDA is known to cause oxidative stress to DA neurons, and it is usually thought to cross cell membrane through dopamine transporters, to inhibit mitochondrial respiration and to generate intracellular ROS^[14]. A previous study has shown that in 6-OHDA-treated rats, the decreased levels of GSH could be due to an increased level of free radical-generated lipid peroxidation^[15].

To investigate the relationship between glutathione and 6-OHDA-induced cell damage, we measured the GSx content of cells by using the enzymatic recycling method with some modifications^[11]. We found that in primary cultured astrocytes, the cytosolic GSx content increased in response

Figure 3. Effects of 6-OHDA 0.1 mmol/L on GPx, GR, and GST mRNA expression in astrocytes. (B) The bottom panel shows the results of RT-PCR, demonstrating the effect of 6-OHDA on GR (171 bp); the top panel shows the mRNA levels of β -actin (240 bp). (C) The upper panel shows the results of RT-PCR, demonstrating the effects of 6-OHDA on GST (205 bp); the bottom panel shows the mRNA levels of β -actin (240 bp). DNA markers: 2000, 1000, 750, 500, 250, 100 bp.

Figure 4. Effects of 6-OHDA 0.1 mmol/L on γ GT mRNA expression in astrocytes. The top panel shows the results of RT-PCR, demonstrating the effects of 6-OHDA on γ GT mRNA levels (260 bp). The bottom panel shows the mRNA levels of β -actin (240 bp). DNA markers: 2000, 1000, 750, 500, 250, 100 bp. $n=4$. Mean \pm SD. ^b $P<0.05$ vs the value at 0 h.

to treatment with different concentrations of 6-OHDA (0.07, 0.1, and 0.13 mmol/L) after incubation for 24 h, but decreased significantly after incubation for 48 h (Figure 1). The data presented here are consistent with the previous findings that treatment with 6-OHDA for 24 h induced up-regulation of GSx levels in astrocytes^[15]. Shimizu *et al* also found a delayed increase in GSH levels after the addition of 6-OHDA in human neuroblastoma SK-N-SH cells^[16]. However, the mechanism by which GSx fluctuates in primary culture astrocytes in response to 6-OHDA is not clear. Some investigators have suggested that in the primary astrocytes, 6-OHDA toxicity may not result from the inhibition of mitochondrial respiration, but may be secondary to auto-oxidation and ROS generation^[17].

More importantly, our results showed that the mRNA expression of γ GCS was up-regulated significantly after incubation of the astrocytes with 6-OHDA for 24 h, which correlated well with the alteration of GSx in the presence of

Figure 5. Activity of γ GT following 48-h exposure to 6-OHDA 0.1 mmol/L in primary cultured astrocytes. $n=4$. Mean \pm SD. ^b $P<0.05$ vs the value at 0 h.

6-OHDA in astrocytes (Figure 2). A previous study has shown that 6-OHDA induced an elevation of GSx contents in astrocyte cells because of an increase of the expression of γ GCS mRNA^[16]. It is well known that γ GCS is the first and the rate-limiting enzyme in the synthesis of GSH. Induction of γ GCS by oxidative stress could play a key role in determining cellular glutathione content^[16]. Recent studies have demonstrated that the antioxidant response element (ARE), a cis-acting enhancer sequence, mediates the transcriptional activation of genes in cells exposed to oxidative stress. The 5'-flanking region of the γ GCS gene also contains several transcription binding sites, including the ARE^[18,19]. These findings support the idea that transcriptional regulation of the γ GCS gene is involved in the antioxidant system of astrocyte cells. Hence, the increased γ GCS levels in 6-OHDA-treated astrocytes may occur by activating ARE, and regulating the γ GCS gene, thereby activating the antioxidative system including GSx. Therefore, the elevation of GSx in astrocytes appears to reflect the resistance and defense mechanisms of astrocytes in the brain against oxidative stress in the early stages. If the toxicity of 6-OHDA continues, massive production of ROS may contribute to the decline in GSx levels in cells.

However, our results showed that γ GCS mRNA expression did not decrease after 48-h incubation with 6-OHDA (Figure 2). This finding was not consistent with the change in GSx in 6-OHDA-treated astrocytes. GSH redox-system genes play a key role in the control of the oxidation and reduction of the SH groups of proteins. For this reason, we detected the mRNA expression levels of other glutathione enzymes, including GPx, GR, GST, and γ GT in astrocytes treated with 6-OHDA for 24 h and 48 h. Our finding that 6-OHDA failed to alter the mRNA levels of GPx, GR, and GST (Figure 3) confirmed the previous finding that the expression levels of GPx mRNA were not changed in astrocytes after paraquat exposure^[20]. However, other studies have shown that GPx and GR expression increased after the expo-

sure of cultured astrocytes to H₂O₂. With regard to this experimental result, we believe that the different results may be related to differences in preparation techniques, to differences in experimental methods, or to differences in culture conditions.

For further investigation, we measured the activity of γ GT in astrocytes treated with 6-OHDA for 24 h and 48 h. The increase in γ GT activity after 6-OHDA treatment for 48 h (Figure 5) was consistent with the change in γ GT mRNA levels. A previous study reported that the activities of enzymes involved in the glutathione cycle were normal with the exception of γ GT, the activity of which was increased in Parkinson's disease^[21]; this was a similar finding to our results. So we conclude that the increase in mRNA levels and the activity of γ GT induced GSx loss after exposure to 6-OHDA for 48 h. The dipeptide CysGly, which is generated from extracellular GSH by a γ GT reaction, may be the most important among the exogenous precursors of GSH, because it is efficiently utilized by neurons in micromolar concentrations. However, dipeptides could be hydrolyzed by neuronal ectopeptidase-generating amino acids such as cysteine, glutamate, and glycine^[22]. Many such amino acids possibly also have toxic effects on neurons^[28].

It has been found that γ GT activity increases in astroglial cultures treated with an nitric oxide donor for 24 h^[23]. Ruedig *et al* suggested that TNF α synthesis in the brain also induced γ GT expression in astrocytes^[24]. Such a scenario can be considered for Parkinson's disease, where an elevated level of TNF α in the substantia nigra and increased immunoreactivity for TNF α in astrocytes^[25] is accompanied by an elevated specific γ GT activity^[6]. Previous findings have shown that 6-OHDA can increase the generation of NO and TNF α in mesencephalic cells^[26,27]. Thus, 6-OHDA may up-regulate γ GT via the activation of the NO or TNF α signaling pathway followed by GSH loss. Increased intracellular GSH content and γ GT activity in astrocytes exposed to 6-OHDA may help to protect neurons *in vitro* by supplying more GSH precursors, and thus elevating neuronal GSH levels.

In the present study, we found that glutathione played an important role in mediating 6-OHDA-induced cell damage in a Parkinson's disease model. We also found that an increase in γ GCS, the rate-limiting enzyme in GSH synthesis, correlated with an increase in GSx after exposure of the cells to 6-OHDA for 24 h. Interestingly, GSx levels decreased because of increased γ GT mRNA levels and γ GT activity, despite up-regulated γ GCS mRNA levels after 48-h incubation with 6-OHDA. The findings in this study may provide useful information for identifying new therapeutic targets for neurodegenerative diseases such as Parkinson's disease.

Abstract

Aim: To examine the tolerance of type 1 diabetic hearts to ischemia and reperfusion injury. Myocardial contents of 27-kDa and 70-kDa heat shock proteins (hsp) as well as phosphorylated hsp27 were also determined. **Methods:** Hearts from hyperglycemic rats 3 weeks after streptozocin injection and age-matched normal rats were subjected to ischemia and reperfusion *in vitro*. Cardiac function and electrocardiogram were recorded throughout experiments. Myocardial heat shock proteins were detected with Western blot. **Results:** Despite depressed systolic function at the baseline, diabetic hearts exhibited considerable enhancement in post-ischemic heart function, manifested by an increase in the maximal rate of left ventricular pressure rise and fall (post-ischemic dp/dt_{max} and dp/dt_{min} were 560 ± 117 and -313 ± 68 mmHg/s in control, $n=7$, 1249 ± 57 and -1204 ± 36 mmHg/s in diabetes, $n=10$, $P < 0.01$). Reperfusion ventricular fibrillation in the diabetic group were attenuated compared with controls (1.5 ± 0.3 vs 7.2 ± 2.1 min in control, $P < 0.01$). The increased heart resistance to ischemia in diabetes was associated with hyperglycemia and accompanied by enhanced expression of myocardial phosphorylated hsp27 with normal aortic vessel relaxation. Cardioprotection was abrogated by metabolic correction with insulin and accompanied by phospho-hsp27 reduction. **Conclusion:** Heart resistance to ischemia is increased in type 1 diabetes, and hyperglycemia may present a mild yet stressful stimulus leading to upregulation of endogenous stress protein, which may play a potential role in cardioprotection and compensate for detrimental effects of hyperglycemia in diabetes.

Introduction

It is well known that cardiovascular disease is the major cause of morbidity and mortality in diabetic patients. However, there exists considerable debate over the causal relationship between diabetes *per se* and cardiovascular disease^[1]. Unlike classical microvascular complications, large vessel atherosclerosis is not correlated with duration and severity of hyperglycemia^[2,3]. Some studies demonstrate that cardiovascular disease prevalence remains constant despite different levels of glycohemoglobin. Furthermore, intensive control of hyperglycemia is not consistently effective

in reducing cardiovascular complications^[4], leaving unanswered the question of whether hyperglycemia contributes to cardiovascular disease in diabetes.

In addition to clinical debates, experimental studies also show inconsistent results regarding the role of hyperglycemia in myocardial ischemia. Studies of animals with type 1 diabetes demonstrate either increased or decreased sensitivity of diabetic hearts to ischemia^[5-7]. Suggested mechanisms for decreased sensitivity include attenuated Na^+H^+ exchanger activity, inhibited glycolysis, and reduced Ca^{2+} overload during reperfusion^[7-9]. Studies demonstrating the detrimental effects of hyperglycemia on ischemia suggest

roles of pseudohypoxia and reactive oxygen species^[6]. Regardless of whether hyperglycemia is the cause of increased cardiovascular disease, it is generally agreed that experimental type 2 diabetes has a detrimental effect on myocardial ischemia^[10] and coexisting cardiovascular risk factors like hypertension and elevated cholesterol contribute significantly to the poor outcome in type 2 diabetes as seen in clinical settings^[11,12]. Type 1 diabetes, however, has severe hyperglycemia and relatively less coexisting cardiovascular disease. Thus, type 1 diabetic animals provide good models for investigating hyperglycemia influence on ischemic outcomes.

The present study was designed to observe heart sensitivity to ischemia in type 1 diabetic rats using functional recovery and creatine phosphokinase as measures of ischemic injury, in addition to arrhythmias. Aortic vessel function was also examined to test whether there was functional impairment of large vessels. As circulating antibody titers to some of heat shock proteins family are increased in type 1 diabetic patients^[13], we observed whether these powerful protective proteins were upregulated in diabetic hearts. Our data indicate that type 1 diabetic hearts are resistant to ischemia/reperfusion with no obvious impairment of large vessel relaxation. The study also reveals increased expression of myocardial phosphorylated heat shock protein 27 (phospho-hsp27) in diabetes. To further examine the association of hyperglycemia and heat shock proteins with heart sensitivity to ischemia, we observed the effects of insulin treatment on ischemic outcomes and phospho-hsp27 by the correction of hyperglycemia.

Materials and methods

Animals Male Sprague-Dawley rats (originally weighing 200–220 g) were injected intraperitoneally with 60 mg/kg of streptozocin (Sigma, St Louis, USA) in citrate buffer (pH 4.5). Age-matched control rats received an injection of citrate buffer. The onset of diabetes was confirmed by measuring blood glucose within 72 h after injection. Rats had free access to tap water and standard laboratory chow and were maintained until the *in vitro* experiment began after 3 weeks of hyperglycemia induction. Another experiment was carried out with one group of rats treated with subcutaneous injection of protamine zinc insulin (9 units/kg) 3 weeks after diabetes induction and a heart ischemia experiment was carried out after 2 d of complete correction of hyperglycemia (duration of insulin administration was 5.1 ± 0.7 d). All experiments conformed to the Guide for the Care and Use of Laboratory Animals (NIH Publication No 85–23, revised 1996).

Isolated heart preparation and ischemia/reperfusion The

hearts were excised under anesthesia with sodium pentobarbital 60 mg/kg, ip, and perfused retrogradely (Langendorff apparatus, IPH-W2, Labo Support, Osaka, Japan) through the aorta with Krebs-Henseleit buffer (KHB) containing: NaCl 118.0 mmol/L, KCl 4.7 mmol/L, CaCl₂ 2.5 mmol/L, MgSO₄ 1.2 mmol/L, KH₂PO₄ 1.2 mmol/L, NaHCO₃ 25.0 mmol/L, glucose 11.0 mmol/L, Na₂-EDTA 0.5 mmol/L. After cannulation of the left atrium the hearts were switched to antegrade perfusion (working heart). Perfusate was kept at 37 °C and bubbled with 95% O₂ and 5% CO₂. Aortic perfusion pressure was set at 60 mmHg and the left atrium at 10 mmHg at the beginning of each experiment. All hearts were allowed to beat spontaneously.

With a catheter inserted into the left ventricular cavity, left ventricular pressure (LVP), left ventricular end-diastolic pressure (LVEDP) and maximal rate of LVP rise (dp/dt_{max}) and fall (dp/dt_{min}) were recorded with a data acquisition system (MPA 2000, Alcott Biotech, Shanghai, China). The hearts were subjected to 30-min global ischemia by clamping both atrial inflow and aortic outflow and followed by 40 min of reperfusion.

Two silver electrodes were inserted into the myocardium and electrocardiogram was recorded continuously. Premature ventricular beats, ventricular tachycardia and fibrillation during reperfusion were recorded. The severity of arrhythmias was scored on a 0 to 9 scale^[14]. The time from the cessation of perfusion to the cessation of heart contraction was recorded as time to arrest.

Creatine phosphokinase and norepinephrine assay Creatine phosphokinase (CPK) was measured in coronary effluent with assay kits (Jian-Cheng Biomedical Engineering, Nanjing, China) according to the manufacturer's protocols. Coronary norepinephrine was determined with high performance liquid chromatography coupled with electrochemical detection (Neurochem Model 5500, ESA, Bedford, MA, USA).

Vessel tension recording Aortic rings were suspended in an organ bath (PowerLab ML0140, ADInstruments, Castle Hill, NSW, Australia) containing KHB. The buffer was bubbled with 95% O₂ and 5% CO₂ and kept at 37 °C. Aortic rings were allowed to equilibrate for 90 min before tension recording. After precontraction with 1×10^{-7} mol/L of norepinephrine, acetylcholine (ACh) was added in a cumulative manner and aorta relaxation was recorded. Vasodilation in the presence of nitric oxide synthase inhibitor, *N*^o-nitro-*L*-arginine methyl ester (*L*-NAME, 1×10^{-4} mol/L) was also measured.

Western blot analysis Left ventricles before and after ischemia were freeze-clamped and homogenized in lysis buffer (pH 7.4) containing: Tris/HCl 50 mmol/L, sucrose 150 mmol/L,

edetic acid-Na₂ 5 mmol/L, egtazic acid 2 mmol/L, Na₃VO₄ 1 mmol/L, NaF 50 mmol/L, phenylmethanesulfonyl fluoride 0.1 mmol/L, leupeptin 1 mg/L. Protein samples were loaded onto 12% SDS-PAGE acrylamide gels and transferred to polyvinylidene difluoride membrane. Blots were incubated with antibodies to either hsp27 or phosphorylated hsp27 at serine 15 and inducible hsp70 (Santa Cruz, Santa Cruz, CA, USA). The immunoreactive bands were visualized using enhanced chemiluminescence detection, and relative levels of heat shock proteins were semiquantified with densitometry (QuantityOne software, Bio-Rad, Hercules, CA, USA) normalizing to actin band.

Statistical analysis Data were expressed as mean±SEM. Parameters were compared with analysis of variance (ANOVA) for repeated measures followed by Student-Newman-Keuls test. The relationship between blood glucose level and ischemic outcomes (arrhythmia score and time to arrest) was evaluated with multiple regression analysis. $P<0.05$ was considered statistically significant.

Results

Effects of diabetes on baseline and post-ischemic heart function A significant elevation in blood glucose was accompanied by a reduction in contractility of the diabetic heart, represented by lower dp/dt_{max} and lower heart work (lower left ventricular developed pressure, LVDP; the difference between LVP and LVEDP). Diabetic hearts also exhibited reduced heart rate and normal LVEDP at baseline perfusion (Table 1).

Although depressed at the baseline, post-ischemic re-

covery of dp/dt_{max} , dp/dt_{min} and LVDP in diabetic hearts was enhanced significantly as compared with controls (Table 1). Coronary perfusion and cardiac output also recovered to better levels after ischemia in diabetes (Table 1). Reperfusion arrhythmias, cardiac CPK release, as well as cardiac norepinephrine release, were reduced in diabetic hearts (Table 2).

Table 2. Duration of arrhythmias, cardiac CPK and norepinephrine released from streptozocin-induced diabetic rat hearts underwent ischemia and reperfusion. Mean±SEM. ^b $P<0.05$, ^c $P<0.01$ vs control.

	Control (<i>n</i> =7)	Diabetes (<i>n</i> =10)
Duration of VT and VF/min	7.2±2.1	1.5±0.3 ^c
Coronary CPK/IU·g ⁻¹ wet weight	642±73	349±90 ^c
Coronary norepinephrine/ pmol·g ⁻¹ wet weight	258±44	121±37 ^b

VT and VF, ventricular tachycardia and fibrillation; CPK, creatine phosphokinase.

Ischemic outcome and correlation with blood glucose level Subgroups of mild or severe hyperglycemia (blood glucose <19 or >20 mmol/L) exhibited different post-ischemic outcomes (Figure 1A). Higher glucose within each group was accompanied by longer time to arrest and less arrhythmias (Figure 1B, 1C).

Aortic relaxation Normal vessel relaxation was found in the diabetic aorta (Figure 2), indicating no obvious impairment of large vessel function in this type of diabetic rat. The ACh-induced relaxation was abrogated by 1×10^{-4} mol/L

Figure 1. Stratification of hyperglycemia and its relationship with ischemic outcomes. Higher blood glucose was associated with longer time to arrest, and higher post-ischemic dp/dt_{max} for diabetic rats (A, $n=5-7$. Mean \pm SEM). Time to arrest was positively related to blood glucose levels *in vivo* (B) and arrhythmia score negatively related to glucose levels (C). Mild DM or severe DM, diabetic rats with blood glucose <19 or >20 mmol/L. ^b $P<0.05$, ^c $P<0.01$ vs age-matched controls; ^e $P<0.05$, ^f $P<0.01$ vs age-matched mild DM.

L-NAME to similar extents in 2 groups.

Myocardial expression of heat shock proteins There were no differences in basal amounts of total hsp27 or inducible hsp70 between diabetic and control groups (Figure 3A, 3B). Because the protective ability of hsp27 depends on its phosphorylation state, we also analyzed phosphorylated hsp27 in the myocardium. Phospho-hsp27 content was found to be significantly higher in diabetic hearts before (Figure 3C) and after ischemia (Figure 3D). To eliminate the possible role of streptozocin in inducing expression of phospho-

Figure 2. Aortic vasodilation in 3-week streptozocin-induced diabetic (DM) and age-matched control rats. There was no significant difference in aortic relaxation in response to acetylcholine (ACh) between diabetic and control rats (A). The vasodilation to ACh was partly abrogated by nitric oxide synthase inhibitor, *N*^o-nitro-*L*-arginine methyl ester (*L*-NAME, 1×10^{-4} mol/L) to a similar extent in both groups (B). $n=5$. Mean \pm SEM.

hsp27, we also examined the content of phospho-hsp27 in rats that failed to develop diabetes after streptozocin injection (15 % of animals receiving streptozocin did not show significant elevation of blood glucose in this study and served as non-diabetic controls). There was no significant change of phospho-hsp27 in those animals (relative density values for myocardial phospho-hsp27 before ischemia were 5.4 ± 0.9 in normal controls vs 6.2 ± 1.0 in non-diabetic controls receiving streptozocin, $n=4$, $P>0.05$).

Ischemic outcomes after metabolic correction Further intervention experiments were carried out with complete correction of hyperglycemia for 2 d prior to the ischemia experiment (Figure 4A). Cardioprotection was abrogated in blood glucose-controlled diabetes, demonstrated by increased reperfusion arrhythmias (Figure 4B) and reduced post-ischemic dp/dt_{max} (Figure 4C). Abrogation of cardioprotection through metabolic control was accompanied by reduction of myocardial phospho-hsp27 (Figure 4D).

Discussion

The present study demonstrated significantly enhanced resistance to ischemia/reperfusion in type 1 diabetic hearts,

Figure 3. Western blot analysis of heat shock proteins in left ventricles of 3-week diabetic rats. There was no significant difference in total hsp27 (A) and inducible hsp70 (B) between diabetic and control hearts before ischemia. Diabetic hearts showed higher levels of phospho-hsp27 before (C) and after (D) ischemia. Densitometric data are mean \pm SEM of 4 to 5 hearts. ^b P <0.05, ^c P <0.01 vs controls.

manifested by improved post-ischemic mechanical function, prolonged time to arrest, attenuated reperfusion arrhythmias and reduced CPK release. Furthermore, there was a significantly increased amount of phospho-hsp27 in diabetic hearts compared with non-diabetic hearts. The reduction of phospho-hsp27 in correlation to hyperglycemia was effective in abrogating heart tolerance to ischemia in diabetes.

Although there is controversy over the effects of hyperglycemia on cardiovascular outcomes, it is important to note that increased tolerance to ischemia is almost exclusively found in type 1 diabetic hearts^[8,9,15,16]. In contrast to decreased sensitivity to ischemia of type 1 diabetic hearts, increased sensitivity to myocardial ischemia was found in type 2 diabetic Otsuka Long-Evans Tokushima Fatty rats^[17]. It is of interest that higher blood glucose induced by sucrose feeding in type 2 diabetes paradoxically attenuated post-ischemic cardiac dysfunction^[17]. There is also a study showing that the correction of metabolic state alone in type 2 diabetes did not improve heart function recovery from ischemia^[10]. These data from type 1 and type 2 diabetes indicate that factors other than hyperglycemia increase heart sensitivity to ischemia in type 2 diabetes, and marked high

glucose or other factors secondary to elevated glucose can participate in preconditioning hearts to resist ischemia insult in type 1 diabetes.

A striking finding of the present study is that increased myocardial resistance to ischemia was accompanied by increased amounts of phospho-hsp27 in diabetic hearts. Because there is no significant change in myocardial phospho-hsp27 of rats that failed to develop diabetes after injection of streptozocin, the increase of phospho-hsp27 in streptozocin-induced diabetes is not likely to be induced by this toxic agent used for destroying pancreas beta-cells and induction of type 1 diabetes. Here we suggest for the first time that hyperglycemia can present a chronic and mild, yet stressful, stimulus to myocardium inducing upregulation of some stress proteins in diabetic hearts, which may in turn enhance heart tolerance to ischemia.

Elevated levels of hsp27 are reported to participate in cardioprotection by maintaining the integrity of microtubules and actin cytoskeleton, and can protect endothelium from ischemia^[18]. The phosphorylation and translocation of hsp27 from cytosol to myofibril or nucleus is found to be especially important for protecting actin fragmentation and microtu-

Figure 4. Ischemic outcomes after insulin treatment. Complete correction of hyperglycemia with insulin (A) for 2 d abrogated protection in 3-week diabetic hearts subjected to ischemia as shown by increased arrhythmias (B) and reduced post-ischemic dp/dt_{max} (C) in insulin-treated diabetic rats (DM+Insulin). There was concomitant reduction of phospho-hsp27 as compared with diabetes control without insulin injection (DM) (D). $n=5-6$. Mean \pm SEM. ^b $P<0.05$, ^c $P<0.01$ vs controls; ^e $P<0.05$, ^f $P<0.01$ vs DM without insulin.

bule degradation^[19]. In the present study, hyperglycemia did not affect total hsp27 but significantly increased the amount of phospho-hsp27, indicating the potential cardioprotective role of phospho-hsp27 during ischemia and reperfusion of diabetic hearts. The elevated lipid peroxidation product found in our previous work and other works^[6,20] indicates higher oxidative stress in type 1 diabetes, while upregulation of protective proteins may compensate for such detrimental effects of hyperglycemia.

Inhibited glycolysis could result in myocardial salvage as a result of less accumulation of lactate during ischemia^[21]. In accordance with previous published reports, we also found decreased lactate production from diabetic hearts^[20], which possibly contributed to the observed cardioprotection. In addition to the above mechanisms, decreased cardiac norepinephrine may also account for improved mechanical function, in accordance with our previous finding that norepinephrine reduction conferred significant cardioprotection during ischemia^[22]. Because Na^+-H^+ exchanger enhances norepinephrine release, diminished activation of Na^+-H^+ exchanger in diabetic hearts^[8] may be one explanation for

reduced norepinephrine release. This needs further investigation.

There is a report that early type 1 diabetes was found to have increased aortic relaxation^[23]. In this study, no significant large vessel dysfunction was found in this early stage of type 1 diabetes. The relatively higher post-ischemic coronary flow in the diabetic group also indicated no impairment of coronary vessel function. The elevated coronary perfusion may be a result of myogenic dilation, a main determinant for myocardial perfusion, as during reperfusion the diabetic hearts relaxed significantly more than the controls. The improved coronary perfusion in turn enhanced myocardial salvage during reperfusion.

In summary, the present study reveals that the hearts of early-stage type 1 diabetes are resistant to ischemic injury. The concomitant upregulation of phospho-hsp27, in addition to inhibited glycolysis and reduced norepinephrine release, may participate in protecting diabetic hearts from ischemia. Hyperglycemia may contribute to the induction of the stress protein. However, caution should be taken when extrapolating the present results to clinical settings as most

diabetic patients have type 2 diabetes commonly associated with other risk factors. Further investigation on the combination of hyperglycemia and other conventional risk factors will lead to a better understanding of the complex pathogenesis of diabetes mellitus.

Abstract**Aim:** To examine if isoflurane preconditioning can attenuate ischemia/reperfusion injury by reducing cytochrome c release from inner mitochondrial membrane.**Methods:** Isolated hearts of Sprague-Dawley rats were perfused on Langendorff apparatus. Hearts were randomly assigned to a non-treated group (CON group, $n=12$) or three isoflurane preconditioning groups (0.5% ISC group, 1.0% ISC group, and 2.0% ISC group; $n=12$). In the latter three groups, isoflurane was given at concentrations of 0.5%, 1.0%, and 2.0% for 15 min with 15-min washout before 30-min ischemia. Subsarcolemmal mitochondria of the myocardium were isolated after 60-min reperfusion. Hemodynamics of the each heart was recorded, infarct size of the hearts and contents of cytosolic cytochrome or mitochondrial cytochrome c were measured at the end of reperfusion. Morphology of isolated mitochondria in the four groups was evaluated, respectively. **Results:** Compared with the CON group, cytosolic cytochrome c in 0.5% ISC group, 1.0% ISC group, and 2.0% ISC group were significantly decreased along with a significant increase of mitochondrial cytochrome c. Infarct size of the hearts in the four groups were $56\% \pm 12\%$, $41\% \pm 12\%$, $32\% \pm 7\%$ and $33\% \pm 11\%$, respectively. The values of the three isoflurane preconditioning groups were significantly lower than that of the CON group ($P < 0.05$). Isoflurane exposure before ischemia can attenuate the change of morphology of mitochondria after reperfusion. The effects of 2.0% isoflurane on reducing cytochrome c release were more remarkable than 0.5% and 1.0% concentrations of isoflurane. **Conclusion:** Myocardioprotective effects of isoflurane preconditioning were associated with attenuation of cytochrome c loss from the inner membrane of subsarcolemmal mitochondria.**Introduction**

Volatile anesthetics can protect against reperfusion injury after myocardial ischemia *in vitro* and *in vivo*^[1–4]. And isoflurane is one of the drugs most commonly used to maintain the state of general anesthesia. Isoflurane preconditioning, a temporary exposure to isoflurane followed by its complete washout, can protect against cardiac ischemia-reperfusion injury. It has been reported that isoflurane preconditioning can mimic ischemia preconditioning to protect against reperfusion injury after myocardial ischemia *in vitro*

and *in vivo*^[3,4]. However, to date, the mechanism of isoflurane preconditioning remains unclear. It has been reported that ischemic preconditioning can induce mitochondrial tolerance by using the loss of cytochrome c as an indication of mitochondrial dysfunction^[5]. It is not known whether the cardioprotective effect of isoflurane preconditioning can also be achieved by inducing mitochondrial tolerance.

Mitochondria sustains progressive damage during ischemia. Cardiac mitochondria exist in two functionally distinct populations. Subsarcolemmal mitochondria (SSM) are located beneath the plasma membrane, whereas interfibrillar

mitochondria (IFM) are located between the myofibrils. These two mitochondria are affected differently in myocardial pathology and ischemia. The progression of ischemic damage is more rapid in SSM^[6,7]

In the present study, we examined if isoflurane preconditioning protected against a detrimental ischemic insult by attenuating cytochrome c release from the inner membrane of subsarcolemmal mitochondria

Materials and methods

Isolated heart preparation and measurements Experiments were performed on adult male Sprague-Dawley rats weighing 230–300 g. The rats were housed in plastic cages with soft bedding and free access to food and water under a 12-h day/12-h night cycle. Rats were supplied by the Experimental Animal Center of Xuzhou Medical College. All experiments were approved by the Animal Care and Use Committee at the college and were in accordance with the Guidelines for Care and Use of Laboratory Animals. Pentobarbital 40 mg/kg and heparin 500 U/kg were injected intraperitoneally into 44 Sprague-Dawley rats weighing 250–300 g. After thoracotomy, the hearts were isolated and immediately placed in 4 °C Krebs-Henseleit (K-H) solution, then rapidly prepared using the Langendorff method and perfused at 55 mmHg with K-H solution at 37 °C. The perfusate was equilibrated with mixed gas of 95% O₂ and 5% CO₂ to meet standards (pH, 7.4±0.02; carbon dioxide partial pressure, 25±4 mmHg; oxygen partial pressure, 570±20 mmHg). The composition of K-H perfusate was as follows: NaCl 118 mmol/L, KCl 4.7 mmol/L, KH₂PO₄ 1.2 mmol/L, CaCl₂ 2.5 mmol/L, MgSO₄ 1.2 mmol/L, NaHCO₃ 25 mmol/L, glucose 11.1 mmol/L, Na₂-EDTA 0.125 mmol/L.

Left ventricular pressure (LVP) and *dp/dt* were measured isovolumetrically with a saline-filled latex balloon inserted into the left ventricle through a cut in the left atrium. At the beginning of the experiment, the balloon volume was adjusted to achieve a diastolic LVP of 0 mmHg, so that any subsequent increase in diastolic LVP indicated an increase in left ventricular wall stiffness or diastolic contracture. Baseline hemodynamics were recorded 20 min after stabilization. Hearts were randomly assigned to a non-treated group (CON group, *n*=12) or three isoflurane preconditioning groups (0.5% ISC group, 1.0% ISC group and 2.0% ISC group; *n*=12) and were perfused with K-H solution saturated with 0.0%, 0.5%, 1.0%, and 2.0% isoflurane, respectively, for 15 min and followed by a 15-min washout with normal K-H solution before 30 min ischemia and 60 min reperfusion. Isoflurane was bubbled into the perfusate with an isoflurane

vaporizer (Ohmeda, West Yorkshire, England) placed in the oxygen-carbon dioxide gas mixture line. Vapour concentrations were measured continuously by an anesthetic gas detector (Capnomac; Ultima, Datex-Engstrom, Helsinki, Finland). LVP, *dp/dt*, and HR were monitored continuously during the whole experiment using Maclab 4.0 software (AD Instruments, Australia).

Measurement of infarct size The 2,3,5-triphenyltetrazolium chloride (TTC) staining technique was used to determine infarct size after 60-min reperfusion. Fresh TTC was prepared in 0.1 mol/L phosphate buffer adjusted to pH 7.4. TTC stained the non-infarcted myocardium a bright red color, caused by reduction of TTC by dehydrogenases present in viable tissues. Hearts stored at -70 °C after each experiment were taken up and sliced into 4–6 transverse sections (3-mm thickness). The sections were immersed in 1% TTC solution and incubated for 30 min at 37 °C. All slices were digitally imaged by a photoscanner^[8], and the infarcted areas of each slice were measured in a blinded fashion by planimetry using Imagemaster VDS (Pharmacia Biotec, USA).

Isolation of subsarcolemmal rat heart mitochondria and cytosolic fractions Subsarcolemmal mitochondria were isolated from the ventricles as follows: the ventricles were rapidly dissected and rinsed in ice-cold homogenization buffer (CP1: KCl 100 mmol/L, MOPS 50 mmol/L, MgSO₄ 5.0 mmol/L, edetic acid 1.0 mmol/L, ATP 1.0 mmol/L, at pH 7.4). The ventricles were blotted dry, weighed, minced, and washed with CP1. The mince was homogenized at 20 mL/g tissue in cold CP2 (CP1+BSA 2.0 g/L). The homogenate was then centrifuged at 584×*g* for 10 min. The supernatant was filtered through double layer gauze and centrifuged at 3015×*g* for 10 min. The mitochondrial pellet was resuspended in 5 mL CP2 per gram of heart and centrifuged at 3015×*g* for 10 min, and finally subsarcolemmal mitochondria were resuspended in 2.5 mL KME (100 mmol/L KCl, 50 mmol/L MOPS, 5 mmol/L egtazic acid) per gram of heart and centrifuged at 3015×*g* for 10 min. Subsarcolemmal mitochondria was resuspended into KME at a final protein concentration of approximately 1.5 g/L. The first 3015×*g* supernatant represented the cytosolic fraction (protein concentration of approximately 2.0 g/L). All manipulations were carried out at 4 °C. Protein concentration was determined using Bradford assay, with BSA as standard.

Detection of cytochrome c by Western blotting Mitochondria prepared from isolated rat hearts were added 0.25% volume of 2×sample buffer (250 mmol/L Tris-HCl, 8.0% SDS, 700 mmol/L sucrose, 300 mmol/L DTT, 0.01% bromophenol blue, at pH 6.8). Samples were loaded onto 15% Tris-buffered polyacrylamide gels and component proteins resolved

by SDS-PAGE. Proteins were electroblotted onto a nitrocellulose membrane and cytochrome c was detected using monoclonal anti-cytochrome c (Santa Cruz Biotechnology, Inc, USA) as primary antibody and anti-mouse IgG conjugated to alkaline phosphatase as secondary antibody. Primary antibody binding was visualized with an alkaline phosphatase based chemiluminescence system.

Electron microscopy Mitochondria isolated from the myocardium in several kinds of buffer by density centrifugation was resuspended and fixed with 2% glutaraldehyde in 0.1 mol/L PBS buffer. Mitochondria were post-fixed using 1% OsO₄. En bloc staining with uranyl acetate was followed by dehydration and embedding. Embedded samples were sectioned and affixed to grids according to standard protocols. Mitochondrial ultrastructure was then evaluated by transmission electron microscopy.

Statistical analysis All data were expressed as mean±SD. Statistical analysis of data within and between groups was performed with analysis of variance (ANOVA) for repeated measures followed by Turkey multiple-comparison *post-hoc* test. *P*<0.05 was considered statistically significant.

Results

Changes in hemodynamics Figures 1–3 show changes in LVP, *dp/dt*_{min}, *dp/dt*_{max}, and HR of hearts in each of the four

groups during the time course of the experiment. There was no difference in baseline hemodynamics among experimental groups. A concentration-dependent depression of left ventricular systolic pressure (LVSP), *dp/dt*_{max}, and heart rate was observed after 15 min of isoflurane treatment. After 60 min of reperfusion, hemodynamic function decreased in each group compared with baseline values. Left ventricular end diastolic pressure (LVEDP) was lower in the three isoflurane-preconditioning groups than in the CON group at 30 and 60 min reperfusion, but there was no significant difference in LVSP, *dp/dt*_{min}, *dp/dt*_{max}, and HR among the four groups.

Infarct size Figure 4 shows that the infarct size of the CON group was 56%±12%, isoflurane-preconditioning (0.5%, 1.0%, and 2.0 %) significantly reduced infarct size to 41%±12%, 32%±7%, and 33%±11%, respectively (*P*<0.05). But there was no significant difference among the three isoflurane-preconditioning groups.

Morphology of isolated mitochondria Electron microscopy analysis (×10 000) reveals basically formed membranes and clearly discernable cristae in the mitochondria isolated from hearts. The outer membranes of mitochondria isolated from CON groups were partly disrupted, and mitochondria were severely swollen, with fragmentation of the cristae. Isoflurane preconditioning attenuated morphological changes of mitochondria after ischemia and reperfusion. Mitochondria in the 2% isoflurane-preconditioned group appeared to

Figure 1. Time course of left ventricular pressure (LVP) and left ventricular end diastolic pressure (LVDEP) in CON group and isoflurane preconditioning groups. Isoflurane caused a significant decrease in systolic LVP in a concentration-dependent manner, but after reperfusion no difference between groups was observed. Isoflurane preconditioning group showed a lower elevation of LVDEP vs untreated control hearts after 15 min of reperfusion, whereas there was no difference among the isoflurane preconditioning groups. *n*=10. Mean±SD. ^b*P*<0.05 vs CON.

Figure 2. Time course of dp/dt_{max} (contractility) and dp/dt_{min} (relaxation) in CON group and isoflurane preconditioning groups. dp/dt_{max} and dp/dt_{min} were depressed during isoflurane exposure. During the early reperfusion, the contraction and relaxation indices were improved in isoflurane preconditioning group compared with non-treated ischemia hearts, but no significant difference between the isoflurane preconditioning groups was observed at the end of the experiments. $n=10$. Mean \pm SD. ^b $P<0.05$ vs CON.

Figure 3. Time course of heart rate (HR) in CON group and isoflurane preconditioning groups. Isoflurane exposure caused a decrease of HR in a concentration-dependent manner. After the onset of reperfusion among the four groups there was no significant difference. $n=10$. Mean \pm SD. ^b $P<0.05$ vs CON.

be morphologically better than those of the other preconditioning groups.

Western blot analysis of the release of mitochondrial cytochrome c Isoflurane-preconditioning reduces ischemia reperfusion-induced cytochrome c release from the mitochondria in a concentration-related manner. The results showed the amounts of cytosolic cytochrome c significantly decreased ($P<0.05$ vs CON group) in an isoflurane concentration-related manner, while the amounts of mitochondrial cytochrome c markedly increased ($P<0.05$ vs CON group). The results indicate that mitochondrial dysfunction occurred after reperfusion and was attenuated by isoflurane-precon-

Discussion

In the present study, by Western blot examining of cytochrome c in mitochondria and cytosol, we observed that isoflurane increased the content of cytochrome c in mitochondria while reduced it in cytosol in a concentration-dependent manner. Isoflurane at concentration of 2% showed the most significant effect on cytochrome c loss in the mitochondria. Furthermore, mitochondria isolated from three isoflurane preconditioning groups were morphologically better than that isolated from CON. Similarly, isoflurane preconditioning significantly reduced the infarct size of hearts at the end of reperfusion. Therefore, we concluded that cytochrome c release from the mitochondria played a key role in the pathogenesis of ischemia/reperfusion injury and cardioprotective effects of isoflurane preconditioning

were associated with the attenuation of cytochrome c loss from the inner membrane of subsarcolemmal mitochondria.

Cytochrome c is a 12-kDa protein which functions in the mitochondrial electron transport chain. At physiological ionic strength, cytochrome c diffuses in the aqueous phase between the inner and outer membranes (outer compartment) and between complex III (cytochrome bc_1) and complex IV (cytochrome aa_3). But as a small and water-soluble molecule, cytochrome c is easier to be released from mitochondria than other mitochondrial proteins. Studies have shown that the loss of cytochrome c from mitochondria could occur during ischemia and after reperfusion^[9,10]. Ischemia tolerance induced by sublethal ischemia is associated with mitochondrial protection (attenuating cytochrome c release from mitochondria) *in vitro* and *in vivo*^[5].

Increasing evidence suggests that lethal reperfusion injury possibly consists of two forms of cell death, necrosis and apoptosis. The apoptotic process is initiated shortly

Figure 6. Western blot analysis of cytosolic and mitochondrial cytochrome c in CON group and isoflurane preconditioning groups. Left, cytochrome c from the cytosolic fraction in the control and three isoflurane preconditioning (0.5%, 1.0%, and 2.0%) groups. Right, cytochrome c from the mitochondrial fraction. The results show the amount of cytosolic cytochrome c significantly decreased by isoflurane in a concentration-dependent manner, while the amounts of mitochondrial cytochrome c markedly increased. $n=4$. after the onset of ischemia, and becomes markedly enhanced during reperfusion. Inhibition of the apoptotic process can then attenuate irreversible injury in connection with reperfusion^[11]. One of the main mechanisms of cellular death induced by ischemia/reperfusion appears to be mitochondrial dysfunction. The cytochrome c release from mitochondria is a rapid and apoptosis-specific process within 1 h after the induction of apoptosis^[12]. In the process of apoptosis, cytochrome c is released from the mitochondria to cytosol and caspase-3 is activated^[13]. At the same time, the loss of cytochrome c could also lead to the formation of free radicals, and disturbances of oxidative phosphorylation. Whether the release of cytochrome c leads to necrotic or apoptotic cellular death depends largely on intracellular ATP levels. Most of this protein release from mitochondria to cytosol results in ATP depletion associated with necrotic cell death. Therefore, loss of cytochrome c is considered to be an indication of mitochondrial dysfunction^[14,15]. Our results show a possible involvement of mitochondria in the cellular death pathway that is initiated during ischemia/reperfusion. Compared with the other groups, more cytochrome c of CON group was released from mitochondria to cytosol. Also the infarct size in the CON group was higher than those of the isoflurane preconditioning groups. Isoflurane preconditioning attenuated cytochrome c release along with reduced in-

farct size. Our study demonstrates for the first time in isolated hearts that isoflurane preconditioning is able to attenuate cytochrome c release from mitochondria in a concentration-dependent manner. Meanwhile, isoflurane preconditioning significantly decreased infarct size and morphologically ameliorated mitochondria injury suffered from ischemia and reperfusion. This result also indicated that the redistribution of cytochrome c was highly correlated with cellular death.

The mechanism by which isoflurane preconditioning induces mitochondrial tolerance via attenuating cytochrome c loss is not clear. The effect of preconditioning may first be on cytosolic factors, which lead to mitochondrial tolerance that persists until mitochondria were isolated for testing. Mitochondrial ATP-sensitive potassium (K_{ATP}) channels appear to be involved in the process of anesthetics-preconditioning^[15-21]. Recent studies have shown that activation of K_{ATP} channels reduces the loss of mitochondrial cytochrome c through the protein kinase C signaling^[22]. Anesthetic-induced preconditioning reduced cytosolic Ca^{2+} loading, one factor of cytochrome c release, in part through mitochondrial K_{ATP} channels^[15,23]. Furthermore, Bcl-2 family proteins are important endogenous factors in regulating cytochrome c release from mitochondria, in which antiapoptotic proteins (eg, Bcl-2, Bcl-X_L, etc) inhibit, but proapoptotic proteins (eg,

Bax, Bad, *etc*) enhance, cytochrome c release^[24,25]. Therefore, the expression and redistribution of Bcl-2 family proteins is possibly another important factor of isoflurane preconditioning inducing mitochondria tolerance by attenuating cytochrome c release. There is evidence that ischemia and some pharmacological preconditioning are able to induce transcription and expression of Bcl-2 and Bcl-X_L without changing transcription and the expression of Bax^[26–28].

In the present study, isoflurane preconditioning reduced cytochrome c loss from mitochondria in a concentration-dependent manner. There was a remarkable reduction in cytochrome c release associated with higher concentrations of isoflurane preconditioning. However, infarct size was no further reduced by 2.0% isoflurane, which indicated that isoflurane preconditioning reduced infarct size with a peak effect at a concentration of approximately 1%. Although the release of cytochrome c from mitochondria is the main pathway of cellular death, it is not the only one. For example, members of the death receptor family, such as the Fas receptor and the tumor necrosis factor receptor also play a role in cellular death. Isoflurane preconditioning significantly attenuated cytochrome c release, but the effects of isoflurane preconditioning on other cell death signaling pathways is unclear. It is possible that other pathways of inducing cellular death contributed to the myocardial infarct in 2.0% ISC group. In the present study, however, it can be inferred that isoflurane preconditioning can protect against myocardial ischemic/reperfusion injury in part through attenuating cytochrome c loss. At the same time, it is not appropriate to tell directly whether the cytochrome c release from mitochondrial is likely to be a final step or trigger factor of myocardial injury from the present study. Further studies should be taken to examine if blocking of isoflurane preconditioning could abolish the attenuated release of cytochrome c.

In conclusion, the present study demonstrated that isoflurane preconditioning was capable of protecting against myocardium ischemia/reperfusion injury in part by attenuating the release of cytochrome c from the mitochondria.

Abstract

Aim: To investigate effects of taurine on ischemia/reperfusion (I/R)-induced compartment syndrome in rabbit hind limbs. **Methods:** Rabbits underwent femoral artery occlusion after ligation of branches from terminal aorta to femoral artery. After a 7-h ischemia, reperfusion was established with the use of heparinized polyethylene shunts. Rabbits received taurine (1 g/kg) or normal saline (control) by iv infusion 10 min before shunt placement. During reperfusion, anterior compartment pressure (ACP) was monitored continuously in the left lower extremity. Gastrocnemius muscle triphenyltetrazolium chloride (TTC) level, taurine content and myeloperoxidase activity were assayed. Oxidative stress was induced in the *in vitro* gastrocnemius muscle slices by free radical generating systems (FRGS), and the malondialdehyde content was measured in presence or absence of taurine. **Results:** After 7 h of ischemia, none of the parameters that we measured were different from those before ischemia, except that TTC reduction decreased by 80%. In the control group, after 2 h of reperfusion, ACP increased 4.5-fold, and gastrocnemius muscle taurine content was reduced by 33%. In taurine-treated animals, at 2 h reperfusion, the mean arterial blood pressure and heart rate were increased, by 6% and 10%. ACP decreased by 39%, muscle edema decreased by 16%, TTC reduction increased by 150%, and lactate dehydrogenase decreased by 36% compared to control group. Plasma and muscle taurine content increased by 70% and 88%, respectively. In the taurine-treated group, at 2 h reperfusion, plasma malondialdehyde and conjugated diene content were decreased by 38% and 23%, respectively, and muscle malondialdehyde and conjugated diene content decreased by 22% and 30%, respectively compared to the control group. At 2 h reperfusion, myeloperoxidase activity was increased 3.5-fold in control animals. In the *in vitro* study, taurine decreased malondialdehyde content in muscle slices incubated with hypochlorous acid in a dose-dependent manner, but there was no change when incubated with hydrogen peroxide and xanthine oxidase. **Conclusion:** Treatment with taurine inhibited I/R-induced compartment syndrome by at least in part attenuating oxidative stress injury induced by I/R, suggesting clinical application of taurine might be a new strategy for the prevention and treatment of compartment syndrome.

Introduction

Compartment syndrome is characterized by increased tis-

sue hydrostatic pressure within a closed fascial space and by secondary compromise of skeletal-muscle capillary perfusion, with resultant ischemia, tissue necrosis and po-

tential systemic toxicity^[1]. The exact mechanisms of compartment syndrome are poorly understood; thus, effective treatments are deficient. The surgical management of compartment syndrome has changed little in the 70 years since fasciotomy was first described. Although effective, fasciotomy increases morbidity, length of hospitalization and patient suffering, and may require subsequent skin grafting. Prevention of compartment syndrome by pharmacological methods, therefore, is an attractive prospect.

Ischemia/reperfusion (I/R) injury is one of the main factors contributing to increased anterior compartment pressure (ACP) and tissue necrosis after trauma. I/R disturbs oxygen-derived free radical metabolism and induces lipid peroxidation injury, which is considered to be the most important mechanism of I/R injury pathogenesis^[2]. Recently, more attention has been paid to the application of free radical scavengers and cytoprotective agents^[3,4].

Taurine (2-aminoethane sulfonic acid), a sulfur-containing amino acid derived from the metabolism of methionine, is the most abundant intracellular amino acid in humans and is implicated in numerous biological and physiological functions. Taurine is not used in protein synthesis but rather is found free or in simple peptides. The diet of healthy individuals is the major source of taurine, although in the presence of vitamin B₆, taurine is also synthesized from methionine and cysteine. Taurine has been considered to be a strong endogenous cytoprotective agent. Its bioactions include inhibition of lipid peroxidation, detoxification, membrane stabilization, osmoregulation, modulation of cellular calcium levels, and it possibly acts physiologically as a trap for hypochlorous acid (HOCl). Exogenous administration of taurine has a preventive and therapeutic effect on tissue I/R injuries to the heart^[5], liver^[6], kidney^[7] and hind limb muscles^[8]. To explore the possibility of taurine therapy for compartment syndrome, we observed the alterations in muscular taurine content in the hind limbs of rabbits with I/R-induced compartment syndrome and the therapeutic effects of supplemental taurine on anterior compartment pressure and tissue damage.

Materials and methods

Reagents Taurine, triphenyltetrazolium chloride (TTC), sulphosalicylic acid, 3,3',5,5'-tetramethylbenzidine (TMB), thiobarbituric acid and 1,1,3,3-tetraethoxypropane were purchased from Sigma Company (St Louis, MO, USA). Other chemicals and reagents were of analytical purity.

Animals White rabbits weighing 1.5 kg to 2.0 kg were purchased from the Animal Center, Health Science Center,

Peking University (Beijing, China). All animal experiments in this study were carried out with the approval of the Animal Care Committee of the First Hospital, Peking University, in accordance with the Chinese Council on Animal Care Guidelines. The rabbits were divided randomly into a taurine-treated group and a control group.

Preparation of ischemia-induced compartment syndrome model^[9]. Briefly, white rabbits were anesthetized with intramuscular ketamine HCl (40 mg/kg) and acepromazine maleate (1 mg/kg) supplemented with 0.5% lidocaine HCl. A PE-50 tube filled with 0.9% NaCl and 10 kIU/L heparin was inserted into the right common carotid artery through a neck midline incision. The mean arterial blood pressure (MABP) and heart rate (HR) were recorded on a microcomputer-controlled physiological polygraph (PowerLab, 4s, Castle Hill location, Australia). A venous catheter was inserted into the right external jugular vein for collecting blood. A lower midline incision was made and extended across the groin. The dissection was carried caudally to the popliteal arteries. All arterial branches of the aorta, including the internal iliac arteries, were isolated, ligated with 4-0 silk sutures, and divided. The right hind limb was used for tibialis anterior muscle sampling for determination of TTC levels. The left hind limb was preserved for monitoring ACP. Ten minutes before ligation of both femoral arteries, animals given systemic infusions of heparin (100 IU/kg) to prevent aortic thrombosis. Just before femoral artery ligation, a full-thickness tibialis anterior muscle sample of the right hind limb was obtained to determine content of TTC, malondialdehyde and conjugated diene (CD), and venous blood was collected for assay of plasma malondialdehyde and CD content. After arterial ligation, the wounds were closed in a single layer with 3-0 silk sutures. The animals were allowed to recover and placed individually in a padded heated pen.

At the completion of the 7 h ischemic period, the animals were re-anesthetized and the lower midline incision and leg wounds were opened. Circulation between the proximal and the distal femoral arteries was restored by interposing a heparin-flushed polyethylene (PE 200) shunt. Five minutes before shunt placement, the animals received intravenous injections of heparin (100 IU/kg). Just before re-establishment of arterial flow, samples of tibialis anterior muscle were again obtained from the right hind limb. The pressure within the anterior muscle compartment of the left hind limb was measured with the use of the slit catheter technique, the catheter being connected to a saline-filled central venous pressure manometer^[10]. Compartment pressure was monitored continuously and recorded at 1 h and 2 h of reperfusion. Beginning 10 min before shunt placement, experimental ani-

mals received 20 min intravenous infusions of taurine (1 g/kg in 8 mL normal saline) and the control group received 8 mL/kg normal saline only. Lactated Ringer's solution (10 mL·kg⁻¹·h⁻¹) was infused via an ear vein throughout each experiment. At the completion of each experiment, animals were humanely killed via lethal urethane injection.

Measurement of taurine content in plasma and gastrocnemius muscle Gastrocnemius muscle samples (0.2 g) were homogenized in 5 volumes of normal saline. The homogenate was mixed with 5 volumes of 10% sulphosalicylic acid and centrifuged at 1000×g for 10 min at 4 °C. Plasma was obtained from collected blood by centrifugation at 2500×g for 10 min at 4 °C. Taurine content in the tissue supernatant and plasma was determined by use of a high-performance amino acid analyzer (Hitachi Model 835, Hitachi, Japan).

Assay for TTC content and dry:wet ratios of tibialis anterior muscle The details of reduced TTC content as an estimate of oxidative metabolism have been reported by Belkin *et al*^[11]. A spectrophotometric standard curve was constructed before each experiment. The TTC assay was repeated in duplicate at each of the experimental phases. In addition, at these intervals, minced samples of tibialis anterior muscle were weighed and allowed to dry at 90 °C for 24 h. Samples were then re-weighed, and the dry weight : wet weight ratio value was calculated. These determinations were also carried out in duplicate.

Measurement of gastrocnemius muscle myeloperoxidase activity^[12] Tissue myeloperoxidase activity was assessed by measuring the H₂O₂-dependent oxidation of TMB. The reactive mixture contained 2.1 mL of buffer-based (0.1 mol/L potassium phosphate buffer, pH 5.4) solution of H₂O₂ (0.1 mmol/L), 0.6 mL of the same buffer and 0.1 mL of TMB (1.6 mmol/L). The reaction was started by adding 200 μL of extract of tissue (at a protein concentration of 0.20 g/L), and the absorbance was measured every minute for 4 min. One unit of enzyme activity was defined as the amount of myeloperoxidase present that caused a change in absorbance of 1.0/min at 655 nm.

Assay of plasma lactate dehydrogenase (LDH) activity and content of malondialdehyde and CD in muscle and plasma Plasma LDH activity was measured by use of an automatic biochemistry analyzer. Malondialdehyde content was measured by use of the thiobarbituric acid reaction. Standard malondialdehyde was prepared by acid hydrolysis of 1,1,3,3-tetraethoxypropane^[13]. CD content was determined according to the method reported by Waller *et al*^[14].

Incubation of muscle slices with oxidative stress *in vitro* The gastrocnemius were taken from another 6 normal anesthetized rabbits, and tissue slices (3 μm) were prepared. The

50 mg of prepared muscle slices was incubated in 1 mL of Krebs-Henseleit buffer at 37 °C, equilibrated with 95% O₂ and 5% CO₂. The muscular oxidative stress was induced *in vitro* by adding three exogenous free radical-generating systems (FRGS): 400 μmol/L HOCL, 1.0 mmol/L hydrogen peroxide (H₂O₂), or an enzymatic system, composed of 20 IU/L of xanthine oxidase (XO) and its substrate xanthine (Xn, 0.5 mol/L). In each group, taurine (0, 5, 10, and 20 mmol/L)^[15] was added. At the end of the incubation (10 min and 20 min, respectively), tissue slices were washed 3 times with ice-cold Krebs-Henseleit buffer, and homogenized for malondialdehyde determination.

Statistical analysis The data are expressed as mean±SD. Statistical analyses comparing multiple variables were carried out using ANOVA with the Student-Newman-Keuls test. For comparisons between 2 variables, the unpaired Student's *t*-test was used. *P*<0.05 was considered statistically significant.

Results

Ischemia/reperfusion-induced compartment syndrome in rabbits After 7 h of ischemia, the MABP, HR, ACP, muscular dry:wet ratio, taurine content and plasma LDH activity remained unchanged, but the TTC level was reduced by 80% (*P*<0.01). Compared with 7 h ischemia, 2 h reperfusion resulted in decreased MABP and HR (*P*<0.01); however, ACP increased 4.5-fold (*P*<0.01) (Figure 1) and plasma LDH activity increased 2.5-fold (*P*<0.01). Muscles showed edema, the dry:wet ratio decreased by 14%, and taurine content was reduced by 33% in gastrocnemius muscle, but increased by 37% in plasma. The muscular TTC level was not further altered from that after ischemia (Table 1).

Figure 1. Changes in anterior compartment pressure (ACP). ^c*P*<0.01 vs control at 7 h ischemia; ^f*P*<0.01 vs control at 2 h reperfusion. *n*=8. Mean±SD. cb, control basal; ci, control ischemia; cr, control reperfusion; tb, taurine basal; ti, taurine ischemia; tr, taurine reperfusion.

Treatment with taurine inhibited skeletal muscle I/R injury After ischemia, the values of various parameters were not statistically different between the control and taurine groups. At 2 h reperfusion, the administration of taurine before reperfusion resulted in a stable MABP and HR, the values being higher than those in the control group ($P < 0.01$). The ACP was lowered by 39% ($P < 0.01$). The muscular dry:wet weight ratio increased by 16%. Tissue taurine content was elevated by 88%, but plasma LDH activity was decreased by 36% ($P < 0.01$). Muscular TTC content was 1.5-fold higher than controls (Table 1).

Treatment with taurine inhibited muscular myeloperoxidase activity induced by I/R After 7 h of ischemia, the gastrocnemius muscle myeloperoxidase activity remained unchanged. However, 2 h reperfusion resulted in a significant 3.5-fold increase in gastrocnemius muscle myeloperoxidase activity ($P < 0.01$). Administration of taurine before reperfusion inhibited the myeloperoxidase activity by 48% compared with the control group ($P < 0.01$, Figure 2).

Supplementation of taurine attenuated lipid-peroxidation injury induced by I/R Ischemia (7 h) alone did not significantly change the levels of plasma and muscular lipid peroxidation products from those before ischemia (all $P > 0.05$). After 2 h of reperfusion, the control group rabbits showed a significant increase in malondialdehyde and CD content in plasma and tibialis anterior muscle compared with before reperfusion (all $P < 0.01$). The taurine group showed an inhibited formation of lipid peroxidation products: decreased plasma and muscle malondialdehyde content, by 38% and 22% ($P < 0.01$), and decreased CD content, by 23% and 30% ($P < 0.01$), respectively, compared with the control group (Table 2).

Figure 2. Changes of gastrocnemius muscle myeloperoxidase (MPO) activity. $n=5$. Mean \pm SD. ^c $P < 0.01$ vs control at 7 h ischemia. ^f $P < 0.01$ vs control at 2 h reperfusion. cb, control basal; ci, control ischemia; cr, control reperfusion; tb, taurine basal; ti, taurine ischemia; tr, taurine reperfusion.

Protective effects of taurine against *in vitro* FRGS-induced oxidative stress In our experiment the concentrations of three FRGS all induced lipid peroxidation, and malondialdehyde content increased to a resemble level ($P < 0.01$). Taurine decreased malondialdehyde content in a concentration-dependent manner in tissue slices incubated with H_2O_2 for 20 min ($P < 0.01$) and 20 mmol/L taurine slightly decreased malondialdehyde content in tissue slices incubated with H_2O_2 for 10 min ($P < 0.05$). Taurine did not change malondialdehyde content when incubated with XO and Xn (produced O_2^-) ($P > 0.05$). In muscle slices incubated with HOCl, taurine decreased malondialdehyde content in a concentration- and time-dependent manner ($P < 0.01$). The effect was stronger than that against H_2O_2 and O_2^- (Figure 3, 4).

Table 1. Mean arterial blood pressure (MABP) (mmHg), heart rate (HR) (beat/min), anterior compartment pressure (ACP)(mmHg), dry weight : wet weight ratios, content of triphenyltetrazolium (TTC) (μ g/mg protein) and taurine (μ mol/L, μ mol/g ww) and activity of lactate dehydrogenase (LDH)(IU/L) in plasma of rabbits with compartment syndrome. $n=8$. Mean \pm SD. ^c $P < 0.01$ vs control basal. ^f $P < 0.01$ vs control ischemia 7 h; ^g $P < 0.05$; ⁱ $P < 0.01$ vs control reperfusion 2 h.

Discussion

A realistic, working definition of compartment syndrome is skeletal muscle injury that leads to partial or total destruction of the integrity of cell walls, with partial or total release of intracellular contents into the interstitial fluid space. Once in the interstitial fluid, these contents change the osmotic gradient of the tissues, with a subsequent shift of fluid from the circulation to the injured tissues, increasing the pressure within muscles encased in fascial sheaths. In compartment syndrome, swelling caused by the osmotic gradient increases the local pressure above the systolic pressure and hence suppresses blood flow within the muscular anatomic unit. This process leads to prolonged ischemia and further cell death with the additional release of intracellular contents.

The exact mechanism of compartment syndrome is not fully understood. Perler *et al*^[16] reported that free radical-mediated reperfusion injury was the most important factor in compartment syndrome. Ablating free radicals by scavenging superoxide radicals at reperfusion with superoxide dismutase or by blocking secondary hydroxyl radical formation with deferoxamine significantly ameliorated the increased compartment pressure and improved muscle I/R injury. Oxidative stress can lead to compartment syndrome, as ischemia and hypoxia, reperfusion-induced alteration of intracellular osmolarity, induced cellular swelling, Ca²⁺ overload, decreased stability of cell membranes and leaking cytosolic enzymes.

Taurine is a strong endogenous cytoprotective agent and has multiple functions such as in membrane stabilization, detoxification, antioxidation, osmoregulation and calcium modulation^[17]. Because taurine has protective effects in I/R injury in various organs^[5-7], we investigated its possible effect in protecting skeletal muscle against I/R-induced com-

partment syndrome.

We chose the rabbit hind-limb model of compartment syndrome because the fascial compartments of rabbits are anatomically similar to those of humans. The elevation in ACP after 2 h of reperfusion was dramatic. The tissue showed edema, and the intracellular contents leaked into the extracellular space. TTC-level reduction, an indirect measure of oxidative metabolism, was decreased during ischemia and reperfusion and indicated that muscle viability was reduced. These observations have been reported in the literature^[9]. During reperfusion, the taurine content of the gastrocnemius muscle was significantly reduced but that in plasma increased, which suggests increased release of taurine content out of the tissue. Administration of taurine before reestablishment of arterial flow increased tissue taurine content and resolved features of the compartment syndrome: MABP and HR were restored, ACP declined, and muscular edema and necrosis were relieved. Zhang *et al*^[8] reported that taurine improved rat hind-limb I/R injury induced by a tourniquet through inhibiting lipid peroxidation. In this study, we found that malondialdehyde and CD levels, the final products of lipid peroxidation, were elevated during reperfusion, but pretreatment with taurine effectively inhibited the formation of lipid-peroxidation products, which suggests that taurine could be effective in ameliorating compartment syndrome. To illustrate the pathway by which taurine inhibited lipid peroxidation, we observed myelo-peroxidase activity in gastrocnemius muscle from rabbits with I/R injury. Muscular myeloperoxidase activity increased significantly showed that neutrophil infiltrated and HOCl induced oxidative stress injury during I/R. The results from these *in vitro* studies further confirmed that taurine could reduce the level of oxidative injury caused by HOCl specifically.

Taurine is a sulfur-containing amino acid, the most abundant free amino acid in excitable tissues and cells, including those in nerves and muscles. Experimental data reveals that many functions of taurine, such as membrane stabilization, osmoregulation and calcium modulation, could be considered to be beneficial for compartment syndrome. Transport of taurine across cell membranes is one of the major steps in its physiological roles. For example, the biophysical and biochemical properties of taurine make it an excellent candidate for osmoregulation. During hyper-osmolar conditions, the increase in cell taurine content appears to be achieved primarily by active transport of taurine into the cell, while under hypo-osmolar conditions, a decrease in intracellular taurine content is a consequence of a marked stimulation in taurine efflux, which protects cells from dehydration with edema^[18]. Taurine regulates the metabolism of phospholipid,

the main content of the cellular membrane, and directly affects the stability of the membrane. In addition, taurine maintains the homeostasis of calcium by regulating the interaction between Ca^{2+} and the membrane^[19].

In addition, taurine is an antioxidative agent and prevents injury from lipid peroxidation. However, the mechanism by which it does this is unclear. In the present study, muscular myeloperoxidase activity was increased significantly in I/R-induced compartment syndrome, which suggested that HOCl-induced oxidative stress might play an important role in I/R-induced compartment syndrome. Aneja *et al*^[20] reported that extensive I/R-induced tissue injury was associated with neutrophil infiltration and myeloperoxidase activity enhancement. Myeloperoxidase is a major neutrophil protein and is also present in monocytes. In neutrophils, it is stored in azurophilic granules and released during phagocytosis. It is a heme enzyme that uses the superoxide and hydrogen peroxide generated by the neutrophil oxidative burst to produce hypochlorous acid and other reactive oxidants. The role of HOCl is well established in tissue damage associated with reperfusion injury. HOCl is a major oxidant produced by neutrophils and monocytes, via the myeloperoxidase-catalyzed oxidation of chloride by hydrogen peroxide. HOCl is a potent oxidant capable of damaging host tissue during inflammation^[21]. The strong oxidizing species HOCl plays a highly significant role in the bactericidal function of the neutrophil. However, inappropriate and/or excessive activation of neutrophils leads to oxidative stress and collateral damage to surrounding tissues.

As an antioxidant, taurine could effectively antagonize the toxic effect of HOCl. More recent information has revealed that taurine could interact with peroxide anions to form stable products such as taurine chloramine (TauCl). TauCl is formed through the sequestration of taurine with HOCl and has been found to be an exceptionally stable and long-lived compound with cytoprotective properties due to its ability to preserve cellular function in response to physiological stress^[19]. In *in vitro* studies, taurine greatly inhibited lipid peroxidation induced by OCl^- , indicating the important protective role of taurine against OCl^- attack^[22]. It is reasonable that taurine ameliorates ACP in compartment syndrome induced by I/R at least in part through scavenging HOCl and attenuating lipid peroxidation.

At present, the only approach to relieving compartment syndrome is surgical fasciotomy to allow decompression of the elevated intracompartmental pressure, thereby facilitating microvascular perfusion. Although highly effective, fasciotomy is an imperfect treatment, so effective pharmacological approaches to treat compartment syndrome are

required. Taurine is an endogenous substance in the body; it is therefore not associated with toxicity or drug dependence, and is well tolerated when used clinically^[23]. It is reasonable to suggest that the clinical application of taurine could be a new strategy for the prevention and treatment of compartment syndrome.

Abstract

Aim: To study the effect of hydrogen peroxide (H₂O₂) on persistent sodium current ($I_{Na,P}$) in guinea pig ventricular myocytes. **Methods:** The whole-cell, cell-attached, and inside-out patch-clamp techniques were applied on isolated ventricular myocytes from guinea pig. **Results:** H₂O₂ (0.1 mmol/L, 0.5 mmol/L and 1.0 mmol/L) increased the amplitude of whole-cell $I_{Na,P}$ in a concentration-dependent manner, and glutathione (GSH 1 mmol/L) reversed the increased $I_{Na,P}$. H₂O₂ (1 mmol/L) increased persistent sodium channel activity in cell-attached and inside-out patches. The mean open probability was increased from control values of 0.015±0.004 and 0.012±0.003 to 0.106±0.011 and 0.136±0.010, respectively ($P < 0.01$ vs control). They were then decreased to 0.039±0.024 and 0.027±0.006, respectively, after the addition of 1 mmol/L GSH ($P < 0.01$ vs H₂O₂). The time when open probability began to increase and reached a maximum was shorter in inside-out patches than that in cell-attached patches (4.8±1.0 min vs 11.5±3.9 min, $P < 0.01$; 9.6±1.6 min vs 18.7±4.7 min, $P < 0.01$). **Conclusion:** H₂O₂ increased the $I_{Na,P}$ of guinea pig ventricular myocytes in a concentration-dependent manner, possibly by directly oxidating the cell membrane.

Introduction

The persistent sodium current ($I_{Na,P}$) in ventricular myocytes results from inactivate-resistant sodium channels continuing to open for long periods during prolonged depolarization. It plays an important role in maintaining the plateau of the action potential (AP), determining AP duration and transmural dispersion of repolarization, and development of cardiac arrhythmias^[1]. Some studies suggest that hypoxia can increase cardiomyocyte $I_{Na,P}$ and the potentiated $I_{Na,P}$ can induce intracellular calcium overload and ischemic arrhythmias^[2,3]. Recently, we studied the mechanisms of $I_{Na,P}$ generation and augmentation in normoxic and hypoxic conditions. The results suggest that excess nitric oxide (NO) produced during hypoxia can increase ventricular myocyte $I_{Na,P}$ by oxidizing cell membrane sodium channel protein, and the reducing agent dithiothreitol (DTT) can block the potentiated $I_{Na,P}$ completely. This implies that oxidants can increase cardiac $I_{Na,P}$, and that reducing and the antioxidation agents can reduce $I_{Na,P}$ ^[4]. A burst of hydrogen

peroxide (H₂O₂) is generated in the myocardium during ischemia. Its effects on cell damage and membrane lipid peroxidation have been reported widely. However, reports on the effect of H₂O₂ on $I_{Na,P}$ in ventricular myocytes are scarce and contradictory^[5,6]. In the present study, we examined the effects of H₂O₂ on $I_{Na,P}$ in guinea pig ventricular myocytes and explored the possible mechanisms underlying them.

Materials and methods

Isolation of guinea pig ventricular myocytes Adult guinea pigs (250 g–300 g, of either sex, Grade II, Certificate No 19-023, the Experiment Animal Center of Wuhan University of Science and Technology, Wuhan, China) were anesthetized with pentobarbital sodium (30 mg/kg, ip) 20 min after an intraperitoneal injection of 2000 units of heparin. Hearts were excised rapidly and perfused retrogradely on a langendorff apparatus (with a Ca²⁺-free Tyrode's solution for 5 min), before the perfusate was switched to an enzyme-

containing solution [0.1 g/L collagenase type I, 0.01 g/L protease E, 0.5 g/L bovine serum albumin (BSA) in the same solution] for 8 min–10 min. The perfusate was finally changed to KB solution containing: 70 mmol/L KOH, 20 mmol/L taurine, 50 mmol/L glutamic acid, 40 mmol/L KCl, 20 mmol/L KH_2PO_4 , 3 mmol/L MgCl_2 , 0.5 mmol/L egtazic acid, 10 mmol/L HEPES, and 10 mmol/L glucose, pH 7.4, for a 5 min period. These perfusates were bubbled with 100% O_2 and maintained at 37 °C. The ventricles were cut into small chunks and gently agitated in KB solution. The cells were filtered through nylon mesh and stored in KB solution at 4 °C.

Electrical recordings Myocytes were transferred to a chamber mounted on the mechanical stage of an inverted microscope (XDS-1, Chongqing, China), and perfused with normal Tyrode's solution containing: 135 mmol/L NaCl, 5.4 mmol/L KCl, 1.8 mmol/L CaCl_2 , 1 mmol/L MgCl_2 , 0.33 mmol/L NaH_2PO_4 , 10 mmol/L HEPES, 10 mmol/L glucose, pH 7.4. Patch electrodes were pulled with a 2-stage puller (PP-830, Narishige Group, Tokyo, Japan). For whole-cell recordings, their resistances were in the range of 1.5 M Ω –3 M Ω when filled with a pipetted solution containing: 120 mmol/L CsCl, 1.0 mmol/L CaCl_2 , 5 mmol/L MgCl_2 , 5 mmol/L Na_2ATP , 10 mmol/L TEACl, 11 mmol/L egtazic acid, and 10 mmol/L HEPES, pH 7.3. The external solution was Tyrode's solution with CdCl_2 (200 $\mu\text{mol/L}$). For single-channel recordings, the shanks of pipettes with resistance of 6 M Ω –10 M Ω were coated with Sylgard and the tips were heat polished. The pipettes were filled with a solution composed of 180 mmol/L NaCl, 1.3 mmol/L KCl, 1.5 mmol/L CaCl_2 , 0.5 mmol/L MgCl_2 , 5 mmol/L Na_2ATP , 3.0 mmol/L CoCl_2 , 10 mmol/L TEACl, 10 mmol/L 4-AP, 10 mmol/L CsCl, 5 mmol/L HEPES, and 5 mmol/L glucose, pH 7.4. For single-channel cell-attached recordings, the myocytes were perfused with normal Tyrode's solution. For single-channel inside-out recordings, the perfusate was composed of 120 mmol/L KCl, 0.1 mmol/L CaCl_2 , 2.0 mmol/L MgCl_2 , 0.1 mmol/L egtazic acid, and 10 mmol/L HEPES, pH 7.4. These perfusates were bubbled with 100% O_2 . All experiments were carried out at room temperature (21±2 °C). Currents were obtained with a patch-clamp amplifier (EPC-9, Heka Electronic, Lambrecht, Pfalz, Germany), filtered at 2 kHz, digitized at 10 kHz, and stored on a computer hard disk for further analysis.

Drugs and reagents Collagenase type I and CsCl were obtained from Gibco (GIBCO TM, Invitrogen Co., Paisley, UK). Protease E, 4-AP, TEACl, Na_2ATP , and egtazic acid were purchased from Sigma Chemical Co (Saint Louis, Missouri, USA). Bovine serum albumin, HEPES, and taurine were obtained from Roche (Basel, Switzerland). Tetrodotoxin (TTX) was purchased from Hebei Fisheries Research Institute (Qinhuangdao, China). H_2O_2 was a production of

Wuhan Zhongnan Chemical Reagent Co (Wuhan, China). Reduced GSH was a product of Shanghai Bio Life Science and Technology (Shanghai, China).

Data analysis Whole-cell recordings were analyzed using PulseFit (V8.65, HEKA). Current density was calculated by dividing the current amplitude by the cell capacitance. Single-channel recordings were analyzed using TAC+TACFit (X4.0.9, Bruyton, Seattle, Washington, USA). Capacitance transients and leakage currents were nullified by off-line subtracting fits of average blunt traces. The channel activity after a 50 ms depolarization pulse was calculated as persistent sodium channel. Open probability was calculated from the total open times of 50 sweeps divided by the total sweep duration. Histograms of channel open time distribution were fitted to single exponentials using TACFit. All data were expressed as mean±SD. Student's *t*-test was used for simple comparisons and ANOVA was used when appropriate. $P < 0.05$ was considered to be statistically significant.

Results

H_2O_2 increases the amplitude of $I_{\text{Na,P}}$ in a concentration-dependent manner The experiments were carried out in the whole-cell configuration of the patch-clamp techniques. Currents were evoked by a 500 ms pulse to -30 mV from a holding potential of -120 mV. TTX (1.5 $\mu\text{mol/L}$) blocked completely the smaller persistent inward current, but had less effect on the transient sodium current ($I_{\text{Na,T}}$), ($n=7$ cells from 4 guinea pigs; Figure 1). The recorded current was proved to be $I_{\text{Na,P}}$.

Figure 1. Effect of tetrodotoxin (TTX) on persistent sodium current ($I_{\text{Na,P}}$) in guinea pig ventricular myocytes. The figure shows the current curves before and after exposure to TTX (1.5 $\mu\text{mol/L}$).

Using the pulse protocol described above, 4 cells were perfused with H_2O_2 (0.5 mmol/L) after the $I_{\text{Na,P}}$ had stabilized. $I_{\text{Na,P}}$ began to increase at approximately 5 min and reached a

maximum at 10–12 min after perfusion with H_2O_2 . The current is able to last for another 30 min at this level. In another 8 cells, H_2O_2 was added into solution in a cumulative manner after the control $I_{\text{Na,P}}$ values were recorded. Cells were perfused with H_2O_2 (0.1 mmol/L, 0.5 mmol/L and 1.0 mmol/L) and GSH (1.0 mmol/L) at 10 min intervals, and the currents were recorded in the same cell. H_2O_2 increased the amplitude of $I_{\text{Na,P}}$ in a concentration-dependent manner, while GSH reversed the increased $I_{\text{Na,P}}$ (Figure 2). The amplitude of $I_{\text{Na,P}}$ was recorded at 200 ms of the pulse to eliminate the effect of $I_{\text{Na,T}}$. H_2O_2 (0.1 mmol/L, 0.5 mmol/L, and 1.0 mmol/L) increased the mean current density of $I_{\text{Na,P}}$ from the control value 0.385 ± 0.032 pA/pF to 0.578 ± 0.080 pA/pF, 0.763 ± 0.094 pA/pF, and 1.007 ± 0.179 pA/pF, respectively ($n=8$, $P < 0.01$ vs control). The mean current density was decreased to 0.329 ± 0.063 pA/pF after the application of 1.0 mmol/L GSH ($n=8$, $P < 0.05$ vs control).

Figure 2. Effect of H_2O_2 on persistent sodium current ($I_{\text{Na,P}}$) in guinea pig ventricular myocytes. (A) H_2O_2 (0.1 mmol/L, 0.5 mmol/L and 1.0 mmol/L) increases $I_{\text{Na,P}}$ in a concentration-dependent manner, and glutathione (GSH; 1.0 mmol/L) reverses the increased $I_{\text{Na,P}}$ induced by H_2O_2 . (B) The mean current densities of $I_{\text{Na,P}}$ under different conditions. $n=8$ cells. Mean \pm SD. $^bP < 0.05$; $^cP < 0.01$ vs control.

Effect of glutathione on persistent sodium channel activity induced by H_2O_2

The experiments were carried out in

cell-attached and inside-out patches. Currents were activated by a 700 ms voltage pulse to -50 mV from a holding potential of -120 mV.

In cell-attached recording (the resting membrane potential was -74.6 ± 7.7 mV, $n=12$, which was measured in current-clamp mode under identical conditions), bath solution with 1 mmol/L H_2O_2 was used to perfuse the cell. In 17 cell-attached patches, persistent sodium channel activity increased remarkably at 11.5 ± 3.9 min. The current type was changed from background currents to burst currents (flaring up rapidly but subsiding over a very long period). At 18.7 ± 4.7 min the channel activity reached a maximum. In 6 of the 17 patches, the channel activity could maintain for another 30 min at this level (Figure 3).

Figure 3. H_2O_2 increases persistent sodium channel activity in a time-dependent manner. The figure shows the mean open probability changing course with time in cell-attached ($n=6$) and inside-out ($n=5$) patches after the application of 1 mmol/L H_2O_2 . The abscissa shows the action time of H_2O_2 . The ordinate shows the mean open probability. $n=5-6$ patches. Mean \pm SD. $^bP < 0.05$; $^cP < 0.01$ vs cell-attached patches group.

In 5 of the 17 patches, lidocaine (100 $\mu\text{mol/L}$) was added to the bath solution and the increased $I_{\text{Na,P}}$ was blocked completely at approximately 5 min (Figure 4).

We applied 1 mmol/L GSH in 6 other patches. The presentation traces are shown in Figure 5. Before exposure to H_2O_2 , channel activity was very low or often absent (Figure 5A). After 10-min treatment with H_2O_2 , persistent sodium channel activity increased markedly (Figure 5B) and reached a maximum at 20 min (Figure 5C). GSH (1 mmol/L) reversed the increase in sodium channel activity caused by H_2O_2 (Figure 5D). H_2O_2 (1 mmol/L) increased the mean open probability and mean open time from control values of 0.015 ± 0.004 and 0.744 ± 0.190 ms to 0.106 ± 0.011 and 1.966 ± 0.539 ms, respectively ($n=6$, both $P < 0.01$ vs control). They were then decreased to 0.039 ± 0.024 and 1.137 ± 0.153 ms, respectively,

Figure 4. Lidocaine blocks persistent sodium channel activity induced by H₂O₂. The individual current traces were evoked by a voltage step to -50 mV from a holding potential of -120 mV in a cell-attached patch. (A) Control, (B) H₂O₂ (1 mmol/L) and (C) lidocaine (100 μmol/L).

after the application of 1 mmol/L GSH ($n=6$, both $P<0.01$ vs H₂O₂). Figure 6 gives an example of corresponding all-time histograms and mean open-time histograms from another cell-attached patch.

The results for inside-out recordings were similar to those for cell-attached recordings. In the 10 inside-out patches, persistent sodium channel activity increased markedly at 4.8 ± 1.0 min and reached maximum at 9.6 ± 1.6 min after the application of 1 mmol/L H₂O₂. Compared with the cell-attached recordings, the times when the sodium channel activity in inside-out recordings began to increase (4.8 ± 1.0 min vs 11.5 ± 3.9 min, $P<0.01$) and reached a maximum (9.6 ± 1.6 min vs 18.7 ± 4.7 min, $P<0.01$) were shorter. In 5 of the 10 patches, the channel activity could be maintained for another 30 min at this level (Figure 3). In the other 5 patches, 1 mmol/L GSH was applied. H₂O₂ (1 mmol/L) increased the mean open probability and mean open time from the control value 0.012 ± 0.003 and 0.537 ± 0.015 ms, respectively, to 0.136 ± 0.010 and 0.966 ± 0.130 ms, respectively ($n=5$, both $P<0.01$ vs control). They were decreased to 0.027 ± 0.006 and 0.672 ± 0.042 ms, respectively, after the application of 1 mmol/L GSH ($n=5$, both $P<0.01$ vs H₂O₂).

Discussion

A large number of studies have reported that H₂O₂ in

cardiomyocytes is increased during ischemia. The excessive amount of H₂O₂ leads to intracellular Ca²⁺ overload and cell damage. Recent reports show that hypoxia can increase $I_{Na,P}$ in ventricular myocytes, induces intracellular sodium overload, which promotes Ca²⁺ overload via reverse Na⁺-Ca²⁺ exchange, and prolongs the duration of action potential (AP) after-depolarization^[2,3]. Thus, the present study on the effect of H₂O₂ on $I_{Na,P}$ is very important to further understand the mechanisms of cardiomyocytes injury induced by H₂O₂, and the nature of $I_{Na,P}$.

In whole-cell patch-clamp recordings, 1.5 μmol/L TTX blocked completely the smaller inactivation-resistant inward current (Figure 1). Similarly, in cell-attached recordings, 100 μmol/L lidocaine blocked the potentiated inward currents induced by H₂O₂ (Figure 4). These results affirm that the recorded currents are $I_{Na,P}$. Barrington *et al* reported that there were no effects from a 30-min exposure to 1 mmol/L H₂O₂ on the slowly inactivating sodium currents of feline ventricular myocytes, so hydroperoxide could not induce an intracellular sodium overload^[5]. However, our study shows that H₂O₂ increases the amplitude of whole-cell $I_{Na,P}$ of guinea pig ventricular myocytes in a concentration-dependent manner (Figure 2) and the activity of persistent sodium channel in both single-channel recordings (Figures 3–6). These results confirm that H₂O₂ can increase $I_{Na,P}$ of guinea pig

Figure 5. Effect of glutathione (GSH) on persistent sodium channel activity induced by H_2O_2 . The individual current traces were evoked by a voltage step to -50 mV from a holding potential of -120 mV in a cell-attached patch. The upper four traces in each of parts (A–D) are original current records whereas the fifth trace in each panel shows the average of 50 sweeps. (A) Control, (B) 10 min after perfusion with 1 mmol/L H_2O_2 , (C) 20 min after perfusion with 1 mmol/L H_2O_2 and (D) GSH (1 mmol/L).

ventricular myocytes, which is different from the report of Barrington *et al*. The disparity may be attributable to species differences. The result that H_2O_2 increases $I_{\text{Na,P}}$ in a concentration-dependent manner is similar to our previous report that hypoxia increases the $I_{\text{Na,P}}$ of guinea pig ventricular myocytes in a time-dependent manner^[4], further suggesting that the increase in $I_{\text{Na,P}}$ is closely associated with reac-

tive oxygen species. Ward and Giles observed that H_2O_2 produced a marked prolongation of the AP by slowing inactivation of the TTX-sensitive sodium current, which was verified by the single-channel cell-attached recording results that late opening events were enhanced when 200 $\mu\text{mol/L}$ H_2O_2 was included in the recording pipette^[6]. Bisindolylmaleimide, the protein kinase C (PKC) blocker, significantly

Figure 6. Effect of glutathione (GSH) on mean open probability and mean open time of persistent sodium channels enhanced by H₂O₂. Each figure comes from 50 individual current traces in a cell-attached patch. Parts (A–C) show the all-point histograms, and (D–F) show the mean open time histograms. (A,D) Control, (B,E) H₂O₂ (1 mmol/L) and (C,F) GSH (1 mmol/L). The fitted mean open times were 0.750 ms, 2.076 ms and 1.338 ms in (D–F), respectively.

delayed and attenuated the development of AP prolongation, which indicated involvement of an intracellular second messenger-PKC pathway^[6]. In our study, H₂O₂ increased the persistent sodium channel activity in both the inside-out and cell-attached patches, which suggests that H₂O₂ may take effect by directly oxidizing the cell membrane in addition to its involvement as an intracellular second messenger. These results are consistent with the findings of Hammarström and Gage who reported that hypoxia, NO, and sodium cyanide could increase persistent sodium channel activity in rat hippocampal neurons in inside-out recordings, which could then be reversed by DTT^[7,8].

H₂O₂ increased the persistent sodium channel activity in

both cell-attached and inside-out patches (Figure 3). However, the time when the persistent sodium channel activity began to increase and reached a maximum was significantly shorter in inside-out patches compared with cell-attached patches. One possible explanation is that the inside-out patches, which were directly exposed to H₂O₂, lost the protection of intracellular antioxidant enzymes and antioxidants such as superoxide dismutase, catalase, glutathione peroxidase, ascorbic acid, α-tocopherol and glutathione.

Glutathione inhibited the H₂O₂-elicited persistent sodium channel activity (Figures 2,5,6), which suggested that H₂O₂ could take effect by oxidation. It is similar to our previous

report, which shows that excessive NO produced during hypoxia can increase the I_{NaP} of ventricular myocytes by oxidizing cell membrane sodium channel proteins and generating I_{NaP} under normoxic conditions, probably in association with the oxidation state of channel proteins^[4]. H_2O_2 is a cysteine-specific oxidant^[9] and GSH is an important antioxidant that can protect the protein's thiol group from oxidation^[10]. The present study shows that GSH can reverse the persistent sodium channel activity caused by H_2O_2 . Therefore, we think that persistent sodium channel activity may be associated with oxidation state, and oxidants can increase activity by oxidizing the channel protein. H_2O_2 as an oxidant may increase persistent sodium channel activity by oxidizing the thiol group of proteins in cell membranes.

Abstract

Aim: To study the protein and mRNA expressions of pro-inflammatory and anti-inflammatory cytokines in the brain of rats with atherosclerosis (AS) and the effects of *Ginkgo biloba* extract (*GbE*) on expressions of cytokines. **Methods:** The experimental model of AS in rats were established by intraperitoneal injection of vitamin D₃ with high fat/cholesterol diet. *GbE* 100 mg/kg was administered to rats by ig. After 8 weeks, the expressions of IL-1 β , TNF- α , IL-10, and IL-10R in the brain tissues of AS rats were detected by enzyme-linked immunosorbant assay, immunohistochemistry, Western blotting, and reverse transcriptase polymerase chain reaction. **Results:** The protein and mRNA expressions of IL-1 β , TNF- α , and IL-10 in the brains were markedly higher in AS groups than that in control groups (6.11 \pm 0.15, 1.55 \pm 0.14, 0.54 \pm 0.04 ng/g wet weight vs 0.80 \pm 0.14, 0.33 \pm 0.09, and 0.33 \pm 0.02 ng/g wet weight, respectively). The protein and mRNA expressions of IL-1 β and TNF- α in the brains were markedly lower in *GbE* groups (3.82 \pm 0.54, 0.95 \pm 0.08 ng/g wet weight) than that in AS groups, the protein and mRNA expressions of IL-10 and IL-10R in the brains were markedly higher in *GbE* groups (0.85 \pm 0.06 ng/g wet weight) than that in AS groups. **Conclusion:** *GbE* inhibited production of pro-inflammatory cytokines IL-1 β and TNF- α , but up-regulated the production of anti-inflammatory cytokines, IL-10 and IL-10R in brain, which might be related with its anti-AS actions.

Introduction

Atherosclerosis (AS) is not merely a disease in its own right, but a process that is the principal contributor to the pathogenesis of cardiovascular and cerebrovascular diseases. Despite the universal occurrence of atherosclerosis in the world, the pathogenesis of disease remains incompletely understood. In the injury theory of Ross, atherosclerosis can be considered to be a modified form of chronic inflammation. Uptake of oxidized low density lipoprotein (ox-LDL) by the macrophages through scavenger receptor (SR) will lead to foam cells formation and numerous cytokines; cell adhesion molecules, chemotactic factor and growth factors were excreted. All these factors induce the migration and proliferation of smooth muscle cells (SMC), this process repeats until the formation of atherosclerotic plaque. In re-

cent years research results have indicated that an anti-inflammatory cytokine such as IL-10 is also concerned in the generation and development of AS, and can play an important protective role^[1].

The rat was considered suitable for establishing cardiovascular disease model including cardiac hypertrophy, hypertension, and heart failure; but it is not such a good model in atherosclerosis due to its hyperlipidemia-resistant property. Recently, our task-group established the experimental model of AS in rats by combining the high fat/cholesterol diets containing sodium cholate and propyl-thyralil with injection of vitamin D₃^[2].

Ginkgo biloba extract (*GbE*) has beneficial effects on cardiovascular disease. Our previous study showed that the inhibitory effects of *GbE* on vascular endothelial growth factor-induced permeability of bovine coronary endothelial cells

indicated that *GbE* had the potential to protect against atherosclerosis^[3].

Up to now, whether the expression of anti-inflammatory cytokines will have a change in the brain of rat with atherosclerosis remains unknown. The present study aims to investigate whether the anti-AS effect of *GbE* was related with the expression of pro-inflammatory cytokines such as IL-1 β and TNF- α , and anti-inflammatory cytokines such as IL-10 and IL-10R in the brain.

Materials and methods

Reagents *GbE* (containing 24% flavone glycosides and 6% ginkgo lactone) was presented by Prof Wei-zhou CHEN (Shanghai Institute of Material Medica, Shanghai, China). Rat IL-1 β , TNF- α , and IL-10 ELISA kit were purchased from Biosource (Camarillo, California, USA); Tissue/Cell Total RNA Isolation Kit was purchased from Watson Co (Shanghai, China); TaKaRa RNA PCR kit (AMV) Ver 2.1 was purchased from TaKaRa Biotechnology Co (Dalian, China). The antibodies for IL-1 β , TNF- α , and IL-10 were purchased from Santa Cruz Biotechnology, Inc (Santa Cruze, CA, USA). Streptavidin/oxidase (SP) kit and diaminobenzidine (DAB) kit were purchased from Zhongshan Biotechnology Co (Beijing, China).

Experimental protocol Thirty male Wistar rats were supplied by the Shanghai Experimental Animal Center of the Chinese Academy of Sciences. Qualification number is SCXK (hu) 2002-0010. The AS rat model was established by intraperitoneal injection with a single dose of vitamin D₃ 600 kU/kg in addition to loading with high fat/cholesterol diet containing sodium cholate and propyl-thyracil as described previously^[2]. The rats were divided into three groups: control, AS, and *GbE*. The control group was fed with ordinary forage, while the AS and *GbE* groups were fed with high fat/cholesterol diet after injection of vitamin D₃. At the same time, *GbE* group rats were administered *GbE* 100 mg/kg through intra-gastric method every day for 8 weeks.

Enzyme-linked immunosorbant assay (ELISA) The rat brains were homogenated with normal saline at 2:1 ratio. The supernatant was used for the measurement of cytokine protein by ELISA as described in kit specification.

Immunohistochemistry The brain tissue was fixed in 4% paraformaldehyde and embedded in paraffin. Immunohistochemistry analysis was performed as specified by the kit protocol. Rabbit normal immune serum was used to replace primary antibody in the negative control group. PBS was used to replace immediate antibody in the control group.

Western blotting was performed to detect the cytokine protein expressions. Rat brain tissues were cut into small

pieces. Protein extracts were prepared by homogenizing the 1 g brain tissues in cold 3 mL radioimmunoprecipitation (RIPA) buffer with a glass tissue homogenizer. The tissue homogenates were centrifuged at 10 000 \times g 4 °C for 10 min. The supernatants were collected and centrifuged at 10 000 \times g 4 °C for 10 min again. Protein concentration in the supernatant was determined by BCA method. Two times of loading buffer was then added to each supernatant with equal volume containing equal amounts of protein, which was subsequently boiled for 5 min and then electrophoresed on a 10% SDS-polyacrylamide gel. Proteins were transferred to nitrocellulose membrane and incubated sequentially with antibodies, and then with peroxidase-conjugated secondary antibodies in the second reaction. Detection was performed with enhanced chemiluminescence reagent.

RT-PCR for detection of the cytokine mRNA expressions Total RNA was isolated by Tissue/Cell Total RNA Isolation Kit. Total RNA was quantified with the ratio of absorption values of RNA samples at 260 nm and 280 nm. RT-PCR was performed by RNA PCR kit. Beta-actin was used as an internal positive control. Specific primer sequences of beta-actin, IL-1 β ^[4], TNF- α , IL-10^[5], and IL-10R^[6] were as follows and the sizes of production were 587, 578, 315, 174, and 319 bp, respectively:

β -actin: sense 5'-AAGGCCAACCGTG AAAAGATGAC-3'; antisense 5'-GGGTACATGGTGGTGCCACCAGAC-3';

IL-1 β : sense 5'-GACCTGTTCTTTGAGGCTGAC-3'; antisense 5'-TCCATCTTCTTCTTTGGGTATTGTT-3';

TNF- α : sense 5'-CATGATCCGAGATGTGGAAGTGGC-3'; antisense 5'-CTGGCTCAGCCACTCCAGC-3';

IL-10: sense 5'-TAAGGTTACTTGGGTTGCCAAGCC-3'; antisense 5'-AGGGGAGAAATCGATGACAGCG-3';

IL-10R: sense 5'-CCAAGTGGACCATCACTGAAACTC-3'; antisense 5'-GCCTTGTTAATTCGGGATTCCAC-3'.

The temperature profile of the amplification consisted of 45-s denaturation at 94 °C, 45-s annealing at 50 °C, and 2-min extension at 72 °C at 35 cycles. PCR products were sequenced to verify that desired product was amplified.

Statistical analysis Data were presented as mean \pm SD. Statistical significance was assessed by ANOVA test. $P < 0.05$ was considered statistically significant.

Results

The experimental model of AS in rat was established (Figure 1).

IL-1 β , TNF- α , and IL-10 protein levels in brain of AS rat by ELISA The protein levels of IL-1 β , TNF- α , and IL-10 in the brains of the AS group were significantly increased compared with the control group. *GbE* 100 mg/kg inhibited the

protein levels of IL-1 β and TNF- α , but up-regulated the protein levels of IL-10 (Table 1).

IL-1 β , TNF- α , and IL-10 protein expressions in brain of AS rat Immunohistochemistry analysis showed that the expressions of IL-1 β , TNF- α , and IL-10 were significantly in-

Table 1. Effects of *GbE* 100 mg/kg on the level of IL-1 β , TNF- α , and IL-10 in brain of atherosclerotic rat. $n=6$. Mean \pm SD. ^c $P<0.01$ vs control group. ^f $P<0.01$ vs AS group.

Group	IL-1 β / ng·g ⁻¹ wet weight	TNF- α / ng·g ⁻¹ wet weight	IL-10/ ng·g ⁻¹ wet weight
Control	0.80 \pm 0.14	0.33 \pm 0.09	0.33 \pm 0.02
AS	6.11 \pm 0.15 ^c	1.55 \pm 0.14 ^c	0.54 \pm 0.04 ^c
AS+ <i>GbE</i>	3.82 \pm 0.54 ^f	0.95 \pm 0.08 ^f	0.85 \pm 0.06 ^f

creased in the cerebral cortex, hippocampus, and hypothalamus of AS rats compared with the control group. After the AS rats were given *GbE* 100 mg/kg ig, the expressions of IL-1 β and TNF- α in brain were decreased in the cerebral cortex, hippocampus, and hypothalamus but the expression of IL-10 was higher than pretreatment (Figure 2).

IL-1 β , TNF- α , and IL-10 protein expressions in brains of AS rats Western blotting analysis indicated that in the brains of the control group IL-1 β and TNF- α were both expressed, and IL-10 had nearly no expression. The expressions of IL-1 β , TNF- α , and IL-10 protein were all significantly increased in brain of AS rats compared with the control group.

Figure 2. Effects of *GbE* on expressions of IL-1 β , TNF- α , and IL-10 in hippocampus of AS rat. (A) Control; (B) AS; (C) AS+*GbE*. (1) IL-1 β ; (2) TNF- α ; (3) IL-10. ($\times 200$).

The expressions of IL-1 β and TNF- α in brains were markedly lower in the *GbE* group than that in AS group; but the expression of IL-10 in brains were markedly higher in the *GbE* group than that in the AS group (Figure 3).

IL-1 β , TNF- α , IL-10, and IL-10R mRNA expressions in the brains of AS rats RT-PCR analysis showed that IL-1 β , TNF- α , IL-10, and IL-10R mRNA were all seldom expressed in the brains of the control group. The expressions of IL-1 β , TNF- α , IL-10, and IL-10R mRNA were all markedly increased in the brains of AS rats compared with the control group. The expressions of IL-1 β and TNF- α were lower, but the expressions of IL-10 and IL-10R mRNA were higher in the *GbE* group than that in the AS group (Figure 4).

Discussion

We observed that the expressions of IL-1 β , TNF- α , IL-10, and IL-10R in the brain were markedly higher in the AS rats than that in the control. The mRNA and protein expressions of IL-1 β and TNF- α in the brains were markedly lower, but the mRNA and protein expressions of IL-10 and IL-10R in the brains were markedly higher in the *GbE* 100 mg/kg group than that in the AS group. Our results were consistent with the recent findings that the serum levels of TNF- α and IL-1 β in all patients with coronary heart diseases were higher than those in controls^[7-9].

IL-10 was an anti-inflammatory cytokine with powerful immunoregulation potential^[10]. It was excreted from mono-

cyte/macrophages and smooth muscle cells under certain conditions. Mallat *et al* found that IL-10-deficient mice fed with an atherogenic diet and raised under specific pathogen-free conditions exhibited a significant three-fold increase in lipid accumulation compared with wild-type mice^[11]. Interestingly, the susceptibility of IL-10-deficient mice to atherosclerosis was more higher (30-fold increase) when the mice were housed under conventional conditions. Atherosclerotic lesions of IL-10-deficient mice showed increased T-cell infiltration, abundant interferon- γ expression, and decreased collagen content. *In vivo*, transfer of murine IL-10 achieved a 60% reduction in lesion size. These results indicated the critical roles of IL-10 in both atherosclerotic lesion formation and its stability. Serum levels of the anti-inflammatory cytokine, interleukin-10, are decreased in patients with unstable angina^[12], this important finding also suggests that IL-10 has a protective role in atherosclerosis.

In other countries *GbE* was used to treat cardiovascular and cerebrovascular diseases such as coronary heart diseases and stroke^[13-18]. Our findings showed that *GbE* inhibited the mRNA and protein expression of pro-inflammatory cytokines IL-1 β and TNF- α , and up-regulated the mRNA and protein expression of anti-inflammatory cytokines, IL-10 and IL-10R in the brain of AS rats, which might be related with its anti-AS effects.

Abstract

Aim: To study the effect of genistein (GST) on carotid baroreceptor activity (CBA). **Methods:** The functional curve of carotid baroreceptor (FCCB) was constructed and the functional parameters of carotid baroreceptor were measured by recording sinus nerve afferent discharge in anesthetized male rats with perfused isolated carotid sinus. **Results:** GST at 50, 100, and 200 $\mu\text{mol/L}$ inhibited the CBA, which shifted FCCB to the right and downward, with a marked decrease in peak slope and peak integral value of carotid sinus nerve discharge in a concentration-dependent manner. Pretreatment with 100 $\mu\text{mol/L}$ *N*^G-nitro-L-arginine methyl ester, an inhibitor of nitric oxide synthase, did not affect the effect of GST on CBA. Pretreatment with 500 nmol/L Bay K8644, an agonist of calcium channels, could completely abolish the effect of GST on CBA. A potent inhibitor of tyrosine phosphatase, sodium orthovanadate (1 mmol/L), could attenuate the inhibitory effect of GST. **Conclusion:** GST inhibits CBA, and the effect may be mediated by protein tyrosine kinase inhibition and a decrease in Ca^{2+} influx through the stretch-activated channels.

Introduction

Phytoestrogens are plant-derived diphenolic compounds that are structurally and functionally similar to estradiol. Accumulating evidence indicates that phytoestrogens may confer cardiovascular protection^[1–3]. Genistein (GST), one of the most well-known phytoestrogens, is an isoflavone that is also a specific inhibitor of protein tyrosine kinase (PTK)^[4]. It has been demonstrated that GST has a hypocholesterolemic effect in animals and humans, and is able to inhibit low density lipoprotein (LDL) oxidation, endothelial cell proliferation and angiogenesis^[5], and to enhance the dilator response to acetylcholine of atherosclerotic arteries^[6]. All of these effects may predict a favorable impact on the cardiovascular system. Li *et al* reported that GST decreased the contractile response of the aortic artery *in vitro*^[7]. Furthermore, our previous studies showed that GST decreased the vascular tone in the femoral, renal and mesenteric vascular beds via protein tyrosine kinase (PTK) inhibition^[8], reduced infarct size and apoptosis of myocytes in ischemia/reperfusion rabbit heart^[9], and inhibited the volt-

age-dependent Ca^{2+} channel in isolated guinea pig ventricular myocytes^[10]. Whether GST affects carotid baroreceptor activity (CBA) remains to be clarified. The aim of the present study was to observe the effects of GST on CBA in anesthetized male rats with perfusing isolated carotid sinus, and to elucidate the mechanism involved.

Materials and methods

Animals Sprague-Dawley rats (δ , 350 ± 20 g, Grade II, Certificate No 04036), obtained from the Experimental Animal Center of Hebei Province, were anesthetized with urethane 1.0 g/kg, ip. The trachea was cannulated for ventilation.

Perfusion of left carotid sinus The method of isolating the carotid sinus was described in our previous study^[11,12]. The left carotid sinus areas were fully exposed by turning the trachea and the esophagus rostrally. Sternohyoideus muscles and superior laryngeal nerves were sectioned. The bilateral aortic nerves, right carotid sinus nerves, cervical sympathetic nerves and recurrent laryngeal nerves were all sectioned. The common, external and internal carotid

arteries and smaller arteries originating from these vessels were exposed and ligated, while carefully leaving the left carotid sinus nerve undisturbed. Ligation of the occipital artery at its origin from the external carotid artery excluded chemoreceptors from the isolated carotid sinus, thereby preventing chemoreceptor activation secondary to decreased carotid sinus pressure. A plastic catheter introduced into the left common carotid artery in the antegrade way (serving as an inlet tube) was attached to a peristaltic pump that controlled the intrasinus pressure (ISP). ISP was monitored by a polygraph (RM-6240, Chengdu Instrument Factory, Chengdu, China) connected to the inlet tube. A plastic catheter inserted into the external carotid artery served as an outlet tube. The carotid sinus was then perfused with warm (37 °C) modified Krebs-Henseleit (K-H) solution (NaCl 118.0 mmol/L, NaHCO₃ 25.0 mmol/L, KCl 4.7 mmol/L, KH₂PO₄ 1.2 mmol/L, MgSO₄ 1.2 mmol/L, CaCl₂ 2.5 mmol/L, glucose 5.6 mmol/L, pH 7.35–7.45) bubbled with 95% O₂ and 5% CO₂.

Recording of sinus nerve afferent discharge The left carotid sinus nerve was cut near the glossopharyngeal nerve and desheathed carefully. The isolated sinus nerve and surrounding structures were immersed in warm (37 °C) liquid paraffin to avoid drying of the tissues. The sinus nerve was placed on a bipolar platinum electrode and the bioelectrical signal was recorded on a polygraph (RM-6240, Chengdu Instrument Factory), with an integral time of 5 s. ISP and discharge of sinus nerve were recorded synchronously and at the end of the experiment, the integral of sinus nerve activity (ISNA) was obtained and measured.

Protocols With a computer-controlled program^[13], ISP was altered in a stepwise manner by perfusing the left carotid sinus with K-H solution. After ISP was lowered from 100 mmHg to 0 mmHg, it began to increase slowly to 240 mmHg in a staircase manner, and then decreased to 0 mmHg in the same manner, and again stabilized at 100 mmHg. Each step of the staircase changed the ISP by 30 mmHg and lasted for 15 s. The functional curve for the ISP-ISNA relationship was constructed, and the functional parameters of carotid baroreceptor activity, such as peak slope (PS), peak integral value (PIV), threshold pressure (TP), saturation pressure (SP) and operation range (OR) were determined. TP was the ISP at which ISNA began to increase by 15% in response to an increase in ISP. SP was the ISP at which ISNA just showed no further increase with an increase in ISP. OR was calculated as the difference between SP and TP.

On perfusing the carotid sinus with K-H solution, the functional curve of carotid baroreceptor (FCCB) was drawn, obtaining the control parameters of TP, SP, OR, PS, and PIV.

ISP was then fixed at 100 mmHg for 20 min, and K-H solution containing GST at 50, 100, and 200 µmol/L was then perfused to examine the changes in ISNA, followed by measurement of the parameters again. Finally, the carotid sinus was perfused with K-H solution as a postcontrol.

The effect of *N*^G-nitro-*L*-arginine methyl ester (*L*-NAME) on the response to GST was examined. After the control parameters of CBA were obtained, the isolated carotid sinus was perfused with K-H solution containing 100 µmol/L *L*-NAME for 20 min, and the above parameters were measured. Then GST 100 µmol/L was added to perfuse the sinus area. The parameters were measured within 15 min, and the drugs were then washed out with K-H solution. To determine whether Ca²⁺ was involved in the effect of GST, one experimental group was treated with 500 nmol/L Bay K8644 for 20 min before GST was added. To further determine the involvement of PTK, pretreatment with a potent inhibitor of tyrosine phosphatase, sodium orthovanadate (1 mmol/L), was carried out.

Drugs Genistein (purity 99%, Sigma, St Louis, MO, USA) was prepared with dimethyl sulphoxide. The final concentration of dimethyl sulphoxide in the perfusing solution was lower than 0.05%. *L*-NAME (Sigma) and sodium orthovanadate (Sigma) were dissolved in saline. Bay K8644 (Sigma) was dissolved in 99% ethyl alcohol. No changes in ISNA were observed during perfusion with ethyl alcohol (1:2000).

Statistical analysis All data are presented as mean±SD. The significance of group differences was determined by ANOVA and *t*-test. Differences were considered significant when *P*<0.05.

Results

Effect of GST on carotid baroreceptor activity By perfusing carotid sinus with K-H solution and elevating ISP from 0 mmHg to 240 mmHg in a stepwise manner, ISNA was increased. There was no difference in CBA parameters among the controls. As compared with control groups, treatment with GST decreased PIV and PS, and increased TP and SP, shifting FCCB to the right and downward (Table 1, Figure 1). The above effects occurred within 5 min of perfusing the carotid sinus with GST, and reached a peak during 8–12 min. Figure 2 is an original tracing showing the effects of GST on ISNA.

Effect of *L*-NAME on GST responses *L*-NAME (100 µmol/L) did not induce any change in the functional parameters of the carotid baroreceptor, and also did not influence the effect of 100 µmol/L GST (Table 2).

Figure 1. Effect of different concentrations of genistein (GST) on the functional curves of carotid baroreceptor in rats. $n=6$. Mean \pm SD. $^{\circ}P<0.01$ vs control. $^fP<0.01$ vs GST (50 μ mol/L). $^iP<0.01$ vs GST (100 μ mol/L). ISP, intrasinus pressure; ISNA, integral of sinus nerve activity.

Effect of Bay K8644 on GST responses Bay K8644 (500 nmol/L) did not produce any change in the functional

parameters of the carotid baroreceptor, but completely blocked the action of GST (Table 2).

Effect of sodium orthovanadate on GST responses Sodium orthovanadate (1 mmol/L) did not change CBA, but completely blocked the effect of GST (Table 2).

Discussion

The present study demonstrated that GST inhibited CBA in a concentration-dependent manner. By perfusing the left carotid sinus baroreceptor with GST, the FCCB were shifted to the right and downward, with a reduction in PS and PIV, indicating the inhibitory action of GST on CBA. It is well established that the arterial baroreceptors play an important role in the short-term control of cardiovascular activity. Inhibition of CBA is inclined to cause increased arterial blood pressure that can antagonize hypotensive effects caused by other ingredients.

As nitric oxide synthase (NOS) is present in afferent baroreceptor fibers innervating the carotid sinus^[14], and increasing evidence has shown that nitric oxide (NO) may suppress the action potential of baroreceptors^[15,16]. Furthermore, our previous study demonstrated that 17 β -estradiol inhibited CBA via endothelial NO release. NO suppressed Na⁺ current in baroreceptor neurons and activated the cal-

cium-dependent K⁺ channels localized in vascular smooth muscle, then hyperpolarized baroreceptor neurons^[17]. Both of these mechanisms may account for the inhibitory effect of 17β-estradiol on CBA. In the present study, pretreatment with *L*-NAME, a non-selective inhibitor of NOS, did not affect the action of GST, thus suggesting that locally released NO was not involved in the effect of GST on CBA. This result indicated that GST and 17β-estradiol inhibited CBA via different pathways.

It has been reported that a mechanosensitive ion channel is localized on the baroreceptor neurons, and that vascular distention is effectively translated to the deformation of the afferent nerve endings as arterial pressure rises. Deformation then depolarizes the nerve endings by opening non-selective cation channels to create a generator potential that triggers action potential discharge^[18,19]. Moreover, it has been demonstrated that stretching of the walls of the carotid sinus may induce an increase in Ca²⁺ influx on baroreceptor neurons, which is mediated by stretch-activated channels^[16]. Suppressing Ca²⁺ influx through the stretch-activated channels may be an important pathway in regulating CBA. Studies have shown that agmatine^[20], cholecystokinin octapeptide^[21] and aminoglycoside antibiotics (such as streptomycin)^[22] can inhibit CBA in this way. We have observed that pretreatment with L-type calcium channel agonist Bay K8644 completely blocks the inhibitory effect of GST on CBA. Based on the above observations, it may be concluded that GST inhibits CBA through a decrease in Ca²⁺ influx by blocking the stretch-activated channels.

Genistein has also proved to be a specific inhibitor of PTK. Evidence has been presented to suggest that enhanced tyrosine phosphorylation participates in the mechanisms that regulate the contraction of smooth muscle^[5]. Vanadate, an inhibitor of tyrosine phosphatase, can enhance protein tyrosine phosphorylation^[6]. PTK has been described as an important modulator regulating the tone of vascular smooth muscle^[23]. Our present study showed that the effect of GST on CBA was inhibited by pretreatment with sodium orthovanadate, suggesting that the PTK pathway is involved. From this data together with our previous findings, it may be inferred that GST inhibits PTK, relaxes the vascular smooth muscle, and then attenuates the stretch-activated Ca²⁺ channels on the baroreceptor neurons.

In summary, the present study has revealed that GST inhibits CBA, and the effect may be mediated by PTK inhibition and a decrease in Ca²⁺ influx through the stretch-activated channels.

Abstract

Aim: To construct pEGFP-N3 recombinant vectors carrying adrenomedullin (*AM*) or fragments of the *AM* gene, and to express *AM* or fragments of *AM* from the pEGFP-N3 recombinant vectors (pEGFP-N3-AM1-2 and pEGFP-N3-AM1-3) and study their biological properties on cultured rat renal mesangial cells (RMC).

Methods: Total RNA of rat kidney was obtained using TriZol reagent. The cDNA was synthesized by reverse transcriptase using oligo-deoxythymidine as primer. The fragments of *AM* gene were then amplified by polymerase chain reaction (PCR) with specific upstream and downstream oligonucleotides. The PCR products were digested with *Eco*RI and *Bam*HI and subcloned into the plasmid pEGFP-N3. Facilitated by cationic liposomes, RMC were transfected with pEGFP-N3-AM1-2 or pEGFP-N3-AM1-3. After 24 h, green fluorescent protein (GFP) fluorescent images were examined with a fluorescence microscope. After 48 h, the proliferation of RMC was detected using the MTT assay, and the mRNA expression of *transforming growth factor- β 1* (*TGF- β 1*) was measured by semiquantitative PCR.

Results: DNA sequence reports verified that pEGFP-N3-AM1-2, which carried the full length *AM* gene translation fragment (preproadrenomedullin preproAM₁₋₁₈₅), and pEGFP-N3-AM1-3, which carried the translation fragment of preproAM [without adrenotensin (ADT, preproAM₁₅₀₋₁₈₅)], were constructed successfully. After 24 h, green fluorescence was observed in RMC into which either pEGFP-N3-AM1-2 or pEGFP-N3-AM1-3 was transfected, while in the control cells no fluorescence was observed. Either pEGFP-N3-AM1-2 or pEGFP-N3-AM1-3 delivery inhibited the proliferation of RMC ($P < 0.01$) and decreased the mRNA transcription level of *TGF- β 1* in RMC ($P < 0.05$). However, no significant difference was observed between the effects of pEGFP-N3-AM1-2 and pEGFP-N3-AM1-3.

Conclusion: pEGFP-N3-AM1-2 and pEGFP-N3-AM1-3 were constructed successfully and were functionally expressed in RMC. Expressing the fragment of *AM* without ADT has similar inhibitory biological effects on RMS proliferation and *TGF- β 1* transcription with full length preproAM.

Introduction

Adrenomedullin (*AM*) was discovered in tissue extracts of human pheochromocytoma by Kitamura *et al* in 1993^[1]. Subsequently identified as a potent vasodilator, *AM* was detected to be expressed in a wide range of tissues, such as the adrenal gland, kidney, heart, lung, spleen, and brain^[2]. *AM* has since been suggested to play important roles in a

great number of disease areas, “ranging widely from heart failure through to oncology”, especially in cardiovascular and renal diseases^[3,4]. Previous studies revealed that plasma *AM* levels were increased in hypertension and renal failure^[5,6]. Researches have also shown that *AM* can improve cardiac function, renal function, and survival rate in hypertensive rat models^[7,8].

The gene encoding preproadrenomedullin (preproAM),

a precursor molecule of *AM*, is termed as the *AM* gene. Sequence analysis of cloned rat *AM* showed that this precursor consisted of 185 amino acids, including a signal peptide^[9]. After synthesis, the signal peptide is cleaved between Thr21 and Ala22. The remaining fragment of preproAM, which is termed as proadrenomedullin (proAM), is cleaved specifically by endopeptidase at Lys43–Arg44, Lys92–Arg93 and Arg145–Arg149, resulting in the production of four proAM-derived peptides: PAMP (proadrenomedullin N-terminal 20 peptide, preproAM₂₂₋₄₁), preproAM₄₅₋₉₁, AM (preproAM₉₄₋₁₄₃) and ADT (adrenotensin or preproAM₁₅₀₋₁₈₅)^[9,10] (Figure 1).

Finding out the appropriate expression pattern is one of the major topics in gene delivery. It is well known that peptides derived from a common polypeptide precursor may have different, even opposite biological properties. Previous studies suggest that ADT may play a role that is opposite in effect to AM^[11,12]. The present study was carried out in order to explore the different effects of expressing full length preproAM and a fragment of preproAM without ADT on renal mesangial cells (RMC).

Materials and methods

Materials pEGFP-N3 vector was obtained from BD Biosciences Clontech (Bedford, MA, USA). Top10 *Escherichia coli* was obtained from Invitrogen (Carlsbad, CA, USA) and primary rat RMC was a gift from the Department of Pathology, Shanghai Medical College (Shanghai, China).

Reagents Trizol, AMV reverse transcriptase, *Taq* DNA polymerase, Silver Beads DNA Gel Extraction Kit, kits for total RNA extraction, endonucleases *Eco*RI and *Bam*HI, and T4 DNA ligase were purchased from Sangon (Shanghai, China). Lipofectamine™ 2000 was from Gibco (Grand Island, NY, USA), and MTT, dimethyl sulfoxide (Me₂SO) and

Dulbecco's Modified Eagle's Medium (DMEM)/F-12 were from Sigma (St Louis, MO, USA).

Construction and confirmation of expression of vectors pEGFP-N3-AM1-2 and pEGFP-N3-AM1-3 Total RNA was isolated from rat kidney tissue samples using Trizol reagent. The full coding region of the *AM* gene was generated by reverse transcription-polymerase chain reaction (RT-PCR) using the following oligonucleotide primers: AM-1, 5'-TAC TGA ATT CGC CAC CAT GAA GC-3'; and AM-2, 5'-TTG CGG ATC CTA ACC TAG AGA C-3'. After an initial denaturation step at 94 °C for 3 min, PCR were carried out for 30 cycles at 94 °C for 30 s, 58 °C for 30 s, and 72 °C for 1 min, and then 72 °C for 10 min. The PCR products and pEGFP-N3 were digested with restriction endonucleases *Eco*RI and *Bam*HI (recognition sites in bold) and the purified digestion products were subcloned into the *Eco*RI and *Bam*HI sites of pEGFP-N3 with T4 DNA ligase. The recombinant plasmids were then transformed into competent Top10 *E. coli* and amplified in the hosts. DNA sequencing was carried out to identify purified recombinant vectors. The recombinant vector carrying the full coding region of the rat *AM* gene was named pEGFP-N3-AM1-2. Using the same method (with oligonucleotide primers: AM-1, 5'-TAC TGA ATT CGC CAC CAT GAA GC-3'; and AM-3, 5'-TTG CGG ATC CAT AGC CTT GAG-3'), we developed another recombinant pEGFP-N3 vector (pEGFP-N3-AM1-3) with a fragment encoding a region of the rat *AM* gene in which the sequence encoding ADT was absent.

Cell culture and transfection Primary rat mesangial cells were cultured in DMEM/F-12 containing 10% heat-inactivated fetal calf serum (FCS) and incubated in a humidified 5% CO₂ incubator at 37 °C. Cells were growth-arrested in DMEM containing 1.0% FCS for 24 h prior to transfection. pEGFP-N3-AM1-2 or pEGFP-N3-AM1-3 was transfected into

Figure 1. Schematic presentation of the biosynthesis of AM and ADT.

cultured RMC facilitated by cationic liposomes Lipofectamine™ 2000. At 24 h after transfection, phase contrast and fluorescence microscopy were carried out using a BX61 Olympus microscope (Melville, NY, USA)

Detection of cell proliferation by MTT assay Cellular proliferation was determined in triplicate with a colorimetric non-radioactive MTT proliferation assay. RMC were plated at 3×10^3 cells/well into 96-well plates and cultured in DMEM/F-12 medium supplemented with 10% FCS at 37 °C in a humidified atmosphere of 5% CO₂ for 24 h. The cultures were replaced with medium containing 1.0% FCS for another 24 h, and the cells were then transfected with pEGFP-N3-AM1-2 or pEGFP-N3-AM1-3 for 48 h. The effects of pEGFP-N3-AM1-2 and pEGFP-N3-AM1-3 on the proliferation of RMC were measured by MTT assay. Briefly, a 20 µL aliquot of 5 mg/mL MTT solution was added to each well. After 4 h of incubation, the absorbance of each well was measured at 490 nm.

Reverse transcription-polymerase chain reaction analysis of transforming growth factor-β1 gene expression Expression of the *transforming growth factor-β1* (*TGF-β1*) gene was analyzed by semiquantitative PCR using glyceraldehyde-3-phosphate dehydrogenase (*GAPDH*) as an internal standard. Total RNA was isolated from cultured RMC following the protocol of RNA extraction kits. The amount of RNA isolated was determined by measuring the specific absorption at 260 nm. The integrity of the RNA isolated was confirmed by agarose gel electrophoresis, run under denaturing conditions. cDNA was synthesised in 40 µL reaction mixtures using 1 µg of total RNA; 2 µL of the cDNA solution was used for PCR amplification. The primers for the *TGF-β1* and *GAPDH* genes were as follows: *TGF-β1* sense, 5'-AAG TGG ATC CAC GAG CCC AA-3'; *TGF-β1* antisense, 5'-GTC GCA CTT GCA GGA GCG CA-3'; *GAPDH* sense, 5'-ACC ACA GTC CAT GCC ATC AC-3'; *GAPDH* antisense, 5'-CCA CCA CCC TGT CAT GCC ATC AC-3'. After an initial denaturation step at 94 °C for 3 min, PCR was carried out for 30 cycles and 94 °C for 30 s, 55 °C for 30 s, and 72 °C for 1 min, and then at 72 °C for 10 min.

Statistical analysis Statistical analysis was carried out using the statistical program SPSS 11.0 (Chicago, Illinois, USA). The data were expressed as mean±SD and the one-way analysis of variance (ANOVA) *t*-test was used for statistical analysis. *P*<0.05 was accepted as statistically significant.

Results

Construction and identification of pEGFP-N3-AM1-2 and pEGFP-N3-AM1-3 The full coding region of the rat *AM*

gene and the fragment of coding region without ADT were subcloned separately into pEGFP-N3, producing pEGFP-N3-AM1-2 and pEGFP-N3-AM1-3, respectively. The construction of pEGFP-N3-AM1-2 and pEGFP-N3-AM1-3 was confirmed by DNA sequencing.

Expression of pEGFP-N3-AM1-2 and pEGFP-N3-AM1-3 in renal mesangial cells Cultured RMC were transfected with pEGFP-N3-AM1-2 or pEGFP-N3-AM1-3. After 24 h, green fluorescence was detected using a fluorescence microscope. Both pEGFP-N3-AM1-2 and pEGFP-N3-AM1-3 were expressed in RMC as bright green fluorescence was observed, indicating that the in-frame GFP-tagged *AM* sequences were expressed and translated successfully. The expression of GFP was observed in above 95% transfected RMC. No green fluorescence was detected in untransfected RMC (Figures 2–4).

biological activities of the recombinant vectors, proliferation of RMC was analyzed using the MTT assay 48 h after pEGFP-N3-AM1-2 or pEGFP-N3-AM1-3 delivery. Significant changes in optical density values at 24 h after transfection were observed with recombinant plasmids compared with the controls, indicating that pEGFP-N3-AM1-2 and pEGFP-N3-AM1-3 elicited a decrease in RMC proliferation ($P < 0.01$) (Figure 5).

Analysis of the effects of pEGFP-N3-AM1-2 and pEGFP-N3-AM1-3 on *TGF- β 1* gene expression Along with the control experiments, which indicated that product accumulation did not reach a plateau at 30 cycles under the assay condi-

tions used, our results for semiquantitative PCR indicate that, compared with the control group, transfection of pEGFP-N3-AM1-2 and pEGFP-N3-AM1-3 suppressed *TGF- β 1* mRNA expression in RMC (Figure 6).

Discussion

As an endogenous vasodilator and natriuretic peptide, AM is thought to have great potential in the treatment of cardiovascular and renal diseases^[13,14]. However, there are still some impediments to understand AM's biological functions and the promising clinical uses of AM. One of the obstacles is the short half-life of AM. The plasma half-life of AM is estimated to be about only 22 min^[15]. Gene transfer is a novel means of providing sustained and localized delivery of the required therapeutic protein. In order to achieve long-term expression of AM, AM gene delivery has been used in recent years. The studies show that AM gene delivery has multiple functions in protection against hypertension, renal damage, cardiac fibrosis and cardiac hypertrophy^[16–20].

Currently, both non-viral and viral vectors are used to express the heterogeneous genes, each of them with their

own advantages and disadvantages. The advantages of non-viral vectors are: (i) non-viral vectors do not integrate the heterogeneous genes into recipient-cell genome, therefore it is considered safe for researchers and will have higher clinical acceptability; (ii) there are minimal or no immune effects, and none of the safety concerns regarding infection is found with viral vectors^[21]; (iii) manipulate and delivery of plasmids into cells is much easier; and (iv) although plasmid-delivered DNA does not integrate into the recipient-cell genome, delivery of plasmids *in vivo* can maintain very prolonged effects^[22]. In the present study, we chose plasmid pEGFP-N3 as the vector.

In our experiment, for the first time, the recombinant vector pEGFP-N3-AM1-3, which carries the DNA fragment encoding the AM protein without the ADT sequence, was designed and constructed successfully. It is well known that peptides derived from a common polypeptide precursor may have different, even opposite biological properties. As prior studies have demonstrated, ADT has some quite opposite vascular effects to those of AM^[11,12]. We therefore hypothesized that the absence of ADT might have more effective effects in protecting heart and kidney.

The pEGFP-N3-AM1-2 and pEGFP-N3-AM1-3 plasmids were constructed successfully. As the fluorescent images showed, both of these vectors were expressed efficiently in RMC. Our data analysis showed that either pEGFP-N3-AM1-2 or pEGFP-N3-AM1-3 delivery inhibited the proliferation of RMC ($P < 0.01$) and decreased the mRNA transcription of *TGF-β1* in RMC ($P < 0.05$). However, no significant difference was observed between the effects of pEGFP-N3-AM1-2 and pEGFP-N3-AM1-3.

In kidney, mesangial cells have a central function in maintaining structural and functional integrity of the glomerulus, including “structural support of the capillary tuft, modulation of glomerular hemodynamics, and a phagocytic function allowing removal of macromolecules and immune complexes”, and the proliferation of mesangial cells is a pivotal feature of glomerular disease^[23]. Our results are in agreement with prior studies showing that AM can suppress RMC proliferation^[24–26], and this may be one of the mechanisms by which AM gene delivery protects renal function. So far, no data about the effects of ADT on the proliferation of mesangial cells have been reported.

Transforming growth factor-β1 is a multifunctional peptide that regulates manifold cellular functions including cell proliferation, differentiation and apoptosis^[27]. As a potent inducer of extracellular matrix synthesis leading to progressive glomerular fibrosis, TGF-β1 is also thought to be the major pathogenic factor in the development of renal fibrotic

disorders^[28]. A previous study showed that chronic AM infusion significantly reduced the *TGF-β/GAPDH* mRNA levels in the renal cortex^[7]. In the present study, we demonstrated that either pEGFP-N3-AM1-2 or pEGFP-N3-AM1-3 delivery could decrease the mRNA transcription level of *TGF-β1* in RMC ($P < 0.05$). This may contribute to the renal protective effects of AM gene delivery; the function of ADT in the regulation of *TGF-β1* mRNA expression requires further study.

In the present experiment, a very interesting phenomenon was observed in that there was no difference between pEGFP-N3-AM1-2 and pEGFP-N3-AM1-3 in their effects on the proliferation of RMC and the mRNA transcription level of *TGF-β1* in cultured RMC. Although ADT plays some opposite vascular effects to AM, previous studies indicate that there are complicated mutual regulation interactions between ADT and AM. In incubated blood vessels, AM could inhibit the synthesis and release of ADT, whereas ADT could enhance the synthesis and release of AM^[29]. Therefore, in order to understand the mechanism of why pEGFP-N3-AM1-2 and pEGFP-N3-AM1-3 had similar effects on cultured RMC, further investigations are indispensable.

In conclusion, recombinant vectors pEGFP-N3-AM1-2, expressing preproAM, and pEGFP-N3-AM1-3, expressing a fragment of preproAM without ADT, were constructed successfully. The biological activity studies of pEGFP-N3-AM1-2 and pEGFP-N3-AM1-3 on cultured RMC showed that expressing the fragment of preproAM without ADT and the full-length preproAM had similar inhibitory effects on cell proliferation and *TGF-β1* gene transcription. As for the mechanism of why pEGFP-N3-AM1-2 and pEGFP-N3-AM1-3 had similar effects on cultured RMC, and what may be the effects of the 2 vectors on the kidney *in vivo*, further investigations are required.

Abstract

Aim: To investigate the effects of renal ischemic preconditioning (IPC) on both renal hemodynamics and the renal interstitial concentrations of adenosine and adenine nucleotides induced by ischemia-reperfusion injury. **Methods:** Renal hemodynamics responses to ischemia-reperfusion injury in mongrel dog models were determined with or without multiple brief renal ischemic preconditioning treatments, as well as the adenosine A₁ receptor antagonist (KW-3902), respectively. The renal interstitial concentrations of adenosine and adenine nucleotides in response to ischemia-reperfusion injury, either following 1–3 cycles of IPC or not, were measured simultaneously using microdialysis sampling technology. **Results:** One 10-min IPC, adenosine A₁ receptor antagonist (KW-3902) also shortened the recovery time of renal blood flow (RBF) and urine flow (UF), as well as mean blood pressure (BP). Advanced renal IPC attenuated the increment of adenosine and adenine nucleotides, as well as recovery time during the 60-min reperfusion which followed the 60-min renal ischemia. All of these recovery times were dependent on the cycles of 10-min IPC. The renal interstitial concentrations of adenosine and adenine nucleotides increased and decreased during renal ischemia and reperfusion, respectively. **Conclusion:** A significant relativity in dog models exists between the cycles of 10-min renal IPC and the recovery time of BP, UF, and RBF during the 60-min renal reperfusion following 60-min renal ischemia, respectively. Renal IPC can protect against ischemia-reperfusion injury and the predominant effect of endogenous adenosine induced by prolonged renal ischemia; renal adenosine A₁ receptor activation during the renal ischemia-reperfusion injury is detrimental to renal function.

Introduction

Renal dysfunction is a serious and common complication of ischemia-reperfusion injury^[1], and the onset of acute renal failure secondary to ischemia-reperfusion injury implies a poor prognosis and is frequently associated with a high mortality rate^[2]. In animal and human models, it has been demonstrated that prolonged ischemia results in an immediate decrease in renal blood flow (RBF) and glomerular filtration rate (GRF)^[3].

Recent developments in renal physiology have deter-

mined that rat kidneys can be ischemic preconditioned against ischemia-reperfusion injury^[4]. A possible candidate mediator of ischemia-reperfusion injury is adenosine, which has been shown to be involved in ischemic-induced renal vasoconstriction via its effects on adenosine A₁ receptors. Its antagonist has a partial protective effect against renal vasoconstriction during ischemia^[5]. Extensive evidence exists demonstrating the beneficial effects of ischemic preconditioning (IPC) in cardiac muscle^[6,7]. However, evidence supporting a role for IPC in protecting against ischemia-reperfusion injury in kidney is minimal and controversial^[4,8,9].

Recently, Lee and Emala^[4] demonstrated that IPC (4 cycles of 8-min renal ischemia followed by 5-min reperfusion) protected renal function after ischemia and reperfusion (45 min of renal ischemia followed by 24-h reperfusion). However, Islam *et al*^[8] failed to demonstrate protective effects of renal IPC in rats (4 cycles of 4-min renal ischemia followed by 11-min reperfusion periods).

Lee and Emala^[4] reported that in the rat kidney, adenosine or A₁ receptor agonist infusions before ischemic insult protected renal function via A₁ adenosine receptor activation. However, Sugino *et al*^[10] reported that the adenosine A₁ receptor antagonist failed to abolish the post-ischemic renal protective effects of IPC or exogenous adenosine in the rat kidney. The results of these experiments indicate that IPC appears to increase extracellular adenosine concentration, which in turn mimics post-ischemic renal function. Our previous study showed that renal interstitial adenosine^[11] concentration significantly increased during ischemia. Adenosine has been demonstrated to elicit renal vasoconstriction^[12-14], it is suggested that extracellular adenosine could be involved in the mediation of post-occlusion renal ischemia^[15-17]. However, findings in the above literature are indirect and do not provide any data supporting the renal interstitial concentrations of adenosine and adenine nucleotides during IPC followed by ischemia and reperfusion. In addition, it is not clear if IPC protects against post-ischemic renal functions in the dog kidney. The beneficial effects of using multiple cycles over single cycle IPC, that is, cycles of multiple brief IPC, is correlative to its protective effect and is poorly understood. As well as this, the influence of IPC on the intrarenal hemodynamics is unclear.

The aim of the present study is to confirm the protective role of IPC on ischemia-reperfusion injury in dogs, and to determine that a correlation exists between the cycles of IPC and its protective effects. This study was also undertaken to determine the relationship between multiple brief ischemic preconditioning and the intrarenal hemodynamics of adenosine and adenine nucleotide, including the role of the adenosine A₁ receptor. In the present study, microdialysis sampling technology was introduced to measure the intrarenal hemodynamics as well as the dynamics of renal interstitial concentration of adenosine, adenine nucleotide during IPC and ischemia-reperfusion.

Materials and methods

General procedure All surgical and experimental procedures were performed according to the guidelines for the care and use of animals as established by the Kagawa Medical University. Adult mongrel dogs weighting 10–15 kg were

used. They had been maintained on standard laboratory food for 1 week. The surgical preparation of the animals and basic experimental techniques are identical to those previously described^[11,8]. The animals were anesthetized with sodium pentobarbital (0.03 g/kg, iv) and given additional doses as required. After tracheotomy, the animals were mechanically ventilated with Harvard apparatus ventilator (Harvard Apparatus, Millis, MA, USA). A polyethylene catheter was inserted into the right brachial vein for infusion of isotonic saline or drug solution. Isotonic saline or drug solution was infused at a rate of 0.2 mL·min⁻¹·kg⁻¹ throughout the experiment. Another catheter was placed in the abdominal aorta via the right femoral artery, and mean arterial pressure (MBP) was continuously measured and recorded with a pressure transducer (NEC-San-ei Model No 361, Tokyo, Japan) and a polygraph (NEC-San-ei Model No 361, Tokyo, Japan). An adjustable clamp was placed on the renal artery to be used later as an occlusion device.

The left kidney was exposed through a retroperitoneal flank incision. The kidney was carefully denervated by dissecting all visible nerve fibers, as well as the tissue connecting the renal hilum cephalic, to the renal artery. An electromagnetic flowmeter (MFV-1200, Nihon Kohden, Tokyo, Japan) was positioned around the renal artery, and renal blood flow (RBF) was continuously monitored. A polyethylene catheter was inserted into the left ureter, and urine samples were continuously collected in tubes. The total of urine collected in every consecutive 10-min period was used to calculate urine flow (UF) rate (L/min). The renal capsule was carefully opened along the convexity, and the microdialysis probes were gently implanted into the renal cortex as shown by Nishiyama *et al*^[11,19]. The probes were connected to a CMA/100 microinfusion pump (Carnegie Medicine, Stockholm, Sweden) and were perfused with isotonic saline solution with heparin (0.03 units/L) containing iodotubercidine (10 μmol), an inhibitor of adenosine kinase, and *erythro*-9-(2-hydroxy-3-nonyl)adenine (EHNA) (100 μmol), an inhibitor of adenosine deaminase, at a rate of 5 μL/min. The dialysate was collected in a chilled tube over a 5-min sample period and analyzed for adenosine concentration as well as inosine, hypoxanthine, xanthine, and uric acid concentrations. Samples were stored at -70 °C prior to analysis. After surgery, the dogs were left alone for 90 min for the tissue to recover from the trauma produced by insertion of the probes and to allow for the stabilization of mean arterial pressure, renal blood flow, and renal interstitial adenosine concentration. At the end of each experiment, the exact position of the probe was verified by inspection. If the probe was situated in the outer medulla at least in part, we omitted

the data of these dialysates.

Characteristics of microdialysis probe For the determination of renal interstitial concentrations of adenosine, inosine, hypoxanthine, xanthine, and uric acid, we used a microdialysis probe. The dialysis membrane is made from cuprophane fiber, measuring 15-mm in length with a 5500-Da transmembrane diffusion cut off (Toyobo, Otsu, Japan). Thin stainless steel tubes (outer diameter: 190 μm , inner diameter: 100 μm) were inserted into both sides of the cuprophane fiber. The inflow and outflow ends were inserted into the polyethylene tubes (PE-10) and sealed in place with glue. Preliminary results from *in vitro* experiments demonstrated that a negligible amount of adenosine, inosine, hypoxanthine, xanthine, and uric acid would stick to the polyethylene tubes.

The efficiency of the microdialysis probe was determined as follows. Briefly, the probes were soaked in beakers containing saline solution with different concentrations (0.1–5 $\mu\text{mol/L}$) of adenosine, inosine, hypoxanthine, xanthine, and uric acid ($n=26$). The probes were perfused with saline solution with heparin (0.03 units/L) containing iodotubercidine (10 μmol) and EHNA (100 μmol) at a rate of 5 $\mu\text{L}/\text{min}$. The dialysates were collected, and the equilibrium rates for adenosine, inosine, hypoxanthine, xanthine, and uric acid were calculated by dividing the concentrations in the dialysates at the concentrations in the medium. At a perfusion rate of 10 $\mu\text{L}/\text{min}$, the relative equilibrium rates of adenosine, inosine, hypoxanthine, xanthine, and uric acid were $36.9\% \pm 1.9\%$, $39.7\% \pm 3.2\%$, $50.3\% \pm 4.1\%$, $46.9\% \pm 2.5\%$, and $34.7\% \pm 4.2\%$, respectively.

Experimental protocols

Effects of ischemic-preconditioning on renal hemodynamics and renal interstitial concentration of adenosine and adenine nucleotides Dogs were randomized to 60-min renal ischemia and 60-min reperfusion (No IPC) group, which were treated with the adenosine A_1 receptor antagonist in advance, three ischemic preconditioning groups were treated with 1–3 cycles of 10-min renal ischemia and 10-min reperfusion, using an adjustable renal arterial clamp, respectively, followed by 60-min renal ischemia. During each ischemia-reperfusion interval, 5 min was allowed for stabilization before samples from all 5 probes used for measurements of adenosine, inosine, hypoxanthine, xanthine and uric acid were collected. After the initial stabilization period, the experimental protocols were started with renal interstitial adenosine and adenine nucleotides collections, and MBP, UF as well as RBF measurements for 2 consecutive 10-min periods. After collection or measurements of the second control sample, 60-min renal ischemia followed by 60-min reperfusion or IPC treatment were performed. At the same

time, UF and RBF were also measured continuously.

Effects of ischemia-reperfusion on renal hemodynamics during treatment with KW3902 KW3902 (Kyowa Hakkō Kogyo Co Ltd, Tokyo, Japan), a highly selective adenosine A_1 receptor antagonist, was dissolved in the lactated Ringer's solution containing 1% dimethylsulfoxide and 0.01 mol/L NaOH. After twice 10-min sampling periods, KW3902 (priming dose, 0.1 $\text{mg}\cdot\text{kg}^{-1}\cdot\text{min}^{-1}$; sustaining dose, 0.01 $\text{mg}\cdot\text{kg}^{-1}\cdot\text{min}^{-1}$) was administered in anesthetized dogs ($n=11$) during the following 60-min ischemia period simultaneously. At 60 min following KW3902 administration, the kidneys of the dogs were perfused again and urine flow and renal blood flow were measured continuously.

Analytical procedures

Adenosine Adenosine in the dialysate was measured according to the method developed by Miura *et al*^[20]. The procedure is briefly described as follows: 100 μL of 1 mol/L acetate buffer (pH 4.5) and 4.5 μL of 40% chloroacetaldehyde were added. The preparation was incubated at 60 °C for 4 h to allow for the conversion of adenosine to a fluorescent 1, N^6 -ethenoadenosine. After the incubation, the sample was mixed with a double volume of alaminefreon reagent and was centrifuged at 1000 $\times g$ for 3 min, and the upper aqueous phase was collected. For high performance liquid chromatography, a reverse-phase column (Nucleosil 7C18, 4.6 $\text{m}\times 25$ cm, Nagel) was maintained at 30 °C with a column oven (655A-52, Hitachi Ltd, Tokyo, Japan). An isocratic elution with 7.5 % acetonitrile in 20 mmol/L potassium phosphate buffer (pH 5.7) at a flow rate of 1.32 mL/min was performed with a pump (L-600, Hitachi Ltd, Tokyo, Japan). Fifty microliters of the sample were injected with an autosampler (655A-40, Hitachi Ltd, Tokyo, Japan) and the elution was monitored using a fluorescence spectrometer (F-1000, Hitachi Ltd, Tokyo, Japan) at an excitation wavelength of 280 nm and an emission wavelength of 410 nm. A chromatographic integrator (D-2000, Hitachi Ltd, Tokyo, Japan) was used for recording.

Inosine, hypoxanthine, xanthine, and uric acid One hundred microliters of dialysate were directly applied onto the reverse-phase HPLC column (Nucleosil 7C18, 4.6 $\text{mm}\times 25$ cm, Nagel). The column was developed isocratically with 3.5% methanol in 10 mmol/L KH_2PO_4 at a flow rate of 1 mL/min. The effluent was monitored at a wavelength of 254 nm by an ultraviolet monitor. In every 10 samples, a standard sample was also injected.

Statistical analysis The values were presented as mean \pm SD. Statistical comparisons of mean values across multiple treatment groups were performed by a one-way ANOVA as appropriate, followed by Scheffe's *post hoc* test. A *P*-value below 0.05 was taken to indicate significant

difference.

Results

Effects of IPC on renal hemodynamics During 60-min renal ischemia, RBF and UF decreased from 78 ± 18 mL/min to 0, and 260 ± 80 μ L/min to 0 respectively, whereas MBP increased slightly (Figure 1). After the release of the renal arterial clamp, RBF and UF increased to 59 ± 27 mL/min, 170 ± 150 μ L/min, respectively (Table 1). In 1, 2, and 3 cycles of the preconditioning groups, RBF and UF descended to 0 during 60-min renal ischemia. During the reperfusion period, RBF increased to 76 ± 11 , 74 ± 15 , and 119 ± 18 mL/min in 1, 2 and 3 cycles of the preconditioning of kidneys respectively (Table 1). UF gradually increased to 180 ± 100 , 110 ± 70 , and 260 ± 170 μ L/min in 1, 2, and 3 cycles of the preconditioning of ischemic kidneys, respectively. However, the recovery time of UF and RBF in the 3 cycles of the preconditioning of ischemic kidneys was markedly shorter compared to those of the 1 cycle or 2 cycles preconditioning of ischemic kidneys which were evaluated by percentage of changes in RBF and UF respectively (Figure 2, 3).

Table 1. Mean values of changes of renal hemodynamics in dogs during control, 60-min periods for ischemia reperfusion. Mean \pm SD. $n=26$. ^b $P < 0.05$ vs control.

Figure 3. Percentage of change in urine flow (UF) during reperfusion from no ischemic preconditioning (IPC) ($n=6$), IPC 1 ($n=6$), IPC 2 ($n=7$), and IPC 3 ($n=7$) groups, respectively. ^b $P < 0.05$ vs IPC 1. ^c $P < 0.05$ vs IPC 2. Mean \pm SD.

0.16 to 0.85 $\mu\text{mol/L}$, 3.61 to 10.09 $\mu\text{mol/L}$, 0.72 to 7.50 $\mu\text{mol/L}$, and 1.89 to 3.20 $\mu\text{mol/L}$, respectively. After release of the clamp, adenosine, and other nucleotides concentrations, returned to their respective pre-ischemic levels in all cases. IPC1, IPC2, and IPC3 in Figure 4 show the renal interstitial concentrations of adenosine, inosine, hypoxanthine, xanthine and uric acid during 60-min ischemia and reperfusion in response to the 1, 2, and 3 cycles of IPC, respectively. In the single cycle of the preconditioning of kidneys during ischemia, adenosine, inosine, hypoxanthine, xanthine, and uric acid levels increased to 8.04, 0.42, 7.90, 7.50, and 1.84 $\mu\text{mol/L}$, respectively. The concentration of adenosine, inosine, hypoxanthine, xanthine, and uric acid was lower than that of the non-preconditioning ischemic kidneys (adenosine, inosine, and hypoxanthine, $P < 0.05$). Similar patterns were also observed in the 2 and 3 cycles of the preconditioning ischemic kidney. However, the levels of adenosine, inosine, hypoxanthine, xanthine, and uric acid were markedly lower in 3 cycles of the preconditioning of ischemic kidneys than those in 1 and 2 cycles of preconditioning or non-preconditioning of ischemic kidneys (hypoxanthine and xanthine, $P < 0.01$; adenosine, $P < 0.05$; inosine and uric acid: $P > 0.05$. Figure 4).

Effects of ischemia-reperfusion on renal hemodynamics during treatment with KW3902 An adenosine A_1 receptor antagonist, KW3902, shortened the recovery time of renal blood flow and urine flow, respectively, compared with the control groups during the reperfusion state following 60-min renal ischemia (Figure 5).

Discussion

The detrimental effects of renal ischemia-reperfusion injury, which are evident by increases in blood urea nitrogen (BUN) and creatinine (Cr)^[4], reduction in the glomerular filtration rate (GFR) and renal blood flow (RBF), as well as morphological renal injury, have been well-studied *in vivo* or *in vitro* experiments. In the present study, we recognized mongrel dog renal hemodynamics parameters, urine flow (UF), RBF, mean blood pressure (BP), as well as renal interstitial adenosine and adenine nucleotide as experimental measurements using microdialysis sampling technology. Since the protective effects of ischemic preconditioning against ischemia-reperfusion injury are, at least in part, mediated by sympathetic nerves, as the protective effects were abolished by denervation^[21], we denervated the dog kidneys before the experiments. Generally, during the renal 60-min ischemia followed by the 60-min reperfusion, the hemodynamic results were consistent with the data from previously pub-

lished literature, returning to the respective control level quite slowly.

In 1986, it was first discovered by Murry *et al*^[22] that multiple brief ischemia, which was defined as ischemic preconditioning (IPC) from then on, followed by the prolonged ischemia-reperfusion periods, could strengthen ischemia endurance of dog cardiac muscle and protect against post-ischemic myocardial injury and dysfunction. To date, a variety of studies have confirmed that IPC has species and organ generalization. However, evidence supporting a role for IPC in protecting against ischemia-reperfusion injury in kidneys is minimal and controversial^[8,10,22-25]. In the present study, we proved that IPC with 1, 2, or 3 cycles of 10-min ischemia followed by 10-min reperfusion markedly increased 60-min post-ischemic UF and RBF, indicating the protective effects of IPC on dog renal ischemia-reperfusion injury. It is evident from our experimental results that IPC of 1 to 3 cycles with a 10-min interval shortened the recovery time of UF, RBF, and BP more significantly than that of without IPC in advance, which parallels the data reported in cardiac^[6]. Previous studies^[8,23] have suggested that IPC with brief cycles of ischemia and reperfusion is not effective in kidneys. However, recent studies^[4,10,24,25], including the present one, have confirmed that there is an IPC effect in rat kidneys as well as dog kidneys. The discrepancies between the results of the earlier and recent studies might have arisen from the different preconditioning schedules.

A single cycle of brief ischemia is thought to be all that is needed to induce preconditioning, but most laboratories often use repetitive cycles of brief ischemia to the phenomenon. However, the beneficial effects of using multiple cycles over single cycle IPC is poorly understood. To clarify, we examined the effects of 1, 2, or 3 cycles of IPC on the renal function in ischemia-reperfusion kidney. As shown in our study, along with the increase of cycles of 10-min IPC, less recovery time during the 60-min reperfusion following 60-min ischemia is needed. To our knowledge, this is the first study that determines the cycles of 10-min renal IPC and the recovery time of BP, UF as well as RBF during 60-min renal reperfusion following 60-min renal ischemia, respectively, in dogs. The post-ischemic recovery of BP, UF as well as RBF occurred faster than that without IPC, and recovery time of BP, UF as well as RBF inversely related to the number of cycles, that is, more cycles of 10-min IPC (within 3 cycles), the shorter recovery time of BP, UF as well as RBF during the 60-min renal reperfusion following 60-min renal ischemia, respectively. Collectively, we can speculate that more cycles of renal IPC can protect against the renal ischemia-reperfusion injury better. In our present study, 10-min is-

Figure 4. Changes in the renal interstitial concentration of adenosine, inosine, hypoxanthine, xanthine, and uric acid during ischemia-reperfusion, measured from no IPC ($n=6$), IPC 1 ($n=6$), IPC 2 ($n=7$), and IPC 3 ($n=7$) groups, respectively. C, control. Mean \pm SD.

chemia time intervals were chosen, which performed well during the experiment, even though it had been reported that 10-min renal ischemia produced some degree of cellular injury^[8]. In our future experiments, we will increase the cycles of IPC and change the ischemia intervals. We will also prolong monitoring time after 60-min renal ischemia following

different cycles of IPC in order to investigate the optimum duration of IPC and whether the “memory function” exists in the effect of IPC, that is, the protective effect of renal ischemic preconditioning under “optimum duration of IPC” can last very long time.

The precise mechanism of ischemic preconditioning, even

Figure 5. Comparison of changes in the mean renal blood flow (MRBF) during ischemia-reperfusion, with or without the treatment of KW3902, a highly selective adenosine A₁ receptor antagonist. C, control. ^b*P*<0.05. *n*=11. Mean±SD. A similar pattern was observed for the comparison of urine flow.

in cardiac muscle, is not fully elucidated. However, numerous studies have been carried out to elucidate the mechanism of IPC, and special attention has been given to the finding that adenosine pretreatment mimics ischemic preconditioning in cardiac and renal tissue, and adenosine appears to be mediator of ischemic preconditioning^[6,26,27]. Adenosine is released in large quantities within seconds after the onset of ischemia, including in the kidneys. The general concept is that a build-up of endogenous adenosine during the brief ischemia period (IPC period) can trigger protection via activation of adenosine receptors.

Previous studies suggest that renal ischemia increases the renal interstitial concentrations of adenosine and adenosine nucleotide^[11], and increased extracellular adenosine has been suggested as a regulator of renal hemodynamics in postischemia^[15–17]. However, these findings are indirect and do not provide any data about the renal interstitial concentrations of adenosine and adenosine nucleotides during IPC followed by ischemia and reperfusion. Therefore, the present study was performed to determine the levels of adenosine and adenosine nucleotide in renal interstitial fluid during preconditioning followed by ischemia and reperfusion. Our results show that levels of adenosine and adenosine nucleotides increase during IPC and the ischemic period. However, during ischemia, levels of adenosine and adenosine nucleotides in renal interstitial fluid were lower than those of non-IPC kidney, and among the IPC groups, renal interstitial concentrations of adenosine and adenosine nucleotides were markedly lower in ischemic kidney of 3 cycles IPC groups. The mechanism of IPC that decreased the levels of adenosine and adenosine nucleotide during the ischemic period is not clear. Further research is necessary to evaluate how IPC lower renal interstitial concentrations of adenosine and adenosine nucleotide during ischemic period.

Previous studies have shown that IPC improves the post-ischemic recovery of UF in rats^[10]. In that study, the rats were subjected to 2 cycles of 3-min ischemia and 5-min

reperfusion. The UF was examined at 90–120 min after ischemia. In the present experiment, dogs were subjected to 1, 2, or 3 cycles of 10-min ischemia and 10-min reperfusion. Our results also show that IPC improves the post-ischemic recovery of UF within 60 min. However, one important finding of our study is that IPC with 3 cycles is more protective compared to single or 2 cycles of IPC. The mechanism of more protective effects of IPC with multiple cycles is not clear. However, our results show that renal interstitial concentrations of adenosine and nucleotides are inversely related to the number of cycles. Therefore one possibility is that renal protective effect of IPC with 3 cycles is more effective because of lower renal interstitial concentrations of adenosine and adenosine nucleotides during ischemic insult.

At present, only 2 studies using the long duration of multiple cycles IPC have suggested the role of adenosine in IPC in the rat kidney^[4,10]. In those studies, they have demonstrated that adenosine pretreatment or adenosine A₁ receptor activation by adenosine A₁ receptor agonist before ischemic insult protects post-ischemic renal function. However, Sugino *et al*^[10] reported that adenosine A₁ receptor antagonist failed to abolish the post-ischemic renal protective effects of IPC or adenosine infusion in the rat kidney. In our study, the results using adenosine A₁ receptor antagonist consequently seem to indicate that the adenosine A₁ receptor activation deteriorates the renal function, supporting previously published studies^[28], but is contradictory to the finding of Lee HT^[4]. Agmon Y *et al*^[29] found that interrenal adenosine reduced cortical blood flow and predominantly increased medullary flow via the A₁ and A₂ receptors, respectively. Also, it has been suggested^[30] that vasoconstriction following brief renal artery occlusion is mediated by an increased accumulation of adenosine during the period of ischemia. Nishiyama *et al*^[31], however, suggested that ischemia-induced accumulation of renal interstitial adenosine elicited renal vasoconstriction, at least in part, but might not have been the primary mediator of renal vasoconstriction in the maintenance phase of postischemia. At present, it is also suggested that renal IPC initiates the protective endocellular system and kidneys can release several kinds of interstitial mediators mediating the conduct of cell signals, including adenosine, which is recognized as an important factor in the protective effect of IPC. Collectively, we speculate that the conclusive effect of endogenous adenosine during ischemia-reperfusion is detrimental to the renal hemodynamics. This is because of the marked regional heterogeneity of the 3 adenosine receptor subtype distribution in dog kidneys which attenuate and prolong the recovery time of RBF and UF, respectively.

In summary, these results indicate that IPC protects post-ischemic renal function, and decreases the renal interstitial concentrations of adenosine and adenine nucleotides in ischemic kidneys. The present study showed that the shortened recovery time of BP, UF as well as RBF during the 60-min renal reperfusion following 60-min renal ischemia was progressively greater with multiple cycles of brief IPC. We have also confirmed that renal IPC can protect against ischemia-reperfusion injury. The predominant effect of endogenous adenosine induced by renal ischemia is detrimental to renal function because of the marked regional heterogeneity of the 3 adenosine receptor subtype distribution in dog kidneys.

Important Announcement: the Online Manuscript Submission and Review System was Launched!

Acta Pharmacologica Sinica is happy to announce that the online manuscript submission and review system, ScholarOne Manuscript Central (<http://mc.manuscriptcentral.com/aphs>), was launched on May 25, 2005.

As the leading web-based peer-review system, Manuscript Central is a complete, database-driven software for the online submission and review of full-text manuscripts and graphics. The system provides fully electronic workflow and will speed up the time from submission to decision.

We strongly recommend authors to submit manuscript via this system, which enables us to handle your manuscript quickly and efficiently. Please read the User Guide before submitting your manuscript online. For more detailed submission instruction, please consult the Manuscript Central Online User Guide (<http://mcv3help.manuscriptcentral.com/tutorials/>). You may also contact the Editorial Office who will be pleased to help you.

Abstract

Aim: To evaluate whether estrogen receptor α (ER- α) and vitamin D receptor (VDR) genes are associated with the age at menarche in Chinese women. **Methods:** A total of 390 pre-menopausal Chinese women were genotyped at the ER- α *PvuII*, *XbaI*, and VDR *ApaI* loci using polymerase chain reaction (PCR)-restriction fragment length polymorphism (RFLP). **Results:** Neither the ER- α gene nor the VDR gene individually had significant effects on the age at menarche in our subjects ($P>0.10$). However, evidence of interaction effects between the two genes were observed: with the aa genotype at the VDR *ApaI* locus, subjects with haplotype PX at the ER- α gene had, on average, 6 months later onset of menarche than the non-carriers ($P=0.01$). **Conclusion:** We found that neither the ER- α gene or the VDR gene had a significant association with the age at menarche individually. However, potential interaction effects between the two genes were observed in Chinese women.

Introduction

Menarche, the first occurrence of menstruation, is a marked characteristic of a woman's sexual maturation and a biological signal for the onset of reproduction. Age at menarche is an important anthropological variable, which influences the total duration of women's estrogen exposure and thus has major implications for a woman's health later in life. Early menarche is associated with an increased risk of breast and endometrial cancer^[1]. Delayed menarche increases the risk of Alzheimer's disease^[1] and osteoporosis^[2], but decreases the incidence of coronary heart disease^[1]. Therefore, from a clinical point of view, it is of interest to identify factors that influence the variation of menarcheal age.

Age at menarche is known to be a complex trait that is determined by multiple genetic and environmental factors, including nutrition, exercise, socioeconomic conditions, childhood experience, and general health^[1,3-5]. The importance of genetic factors in determining menarcheal age has recently been recognized. Twin studies have shown that genetic factors can explain more than 50% of the variation of

menarcheal age^[4]. There are highly significant correlations between age at menarche in mothers and daughters^[3], and family history is a strong predictor for early menarche^[5]. Recently, some candidate genes, such as the androgen receptor (AR) gene^[6], the cytochrome P450 c17 α (CYP17) gene^[7,8] and the CYP3A4 gene^[8], have been tested for association with age at menarche. The results so far have been inconsistent, and the specific gene responsible for age at menarche is still not clear.

The onset of menstruation is determined by the hypothalamic-pituitary-gonadal axis and is initiated by an increased amplitude of estrogen exposure of tissues^[9]. Estrogen signal receptors including estrogen receptor α (ER- α) play an important role in mediating the specific effects of the estrogen on development, proliferation and differentiation of reproductive tissues^[10]. In addition, mice deficient in ER- α are infertile and exhibit atrophy of the oviduct and uterus^[11]. Thus, the ER- α gene may be a candidate gene for the onset of menstruation. An association has been observed between the ER- α gene and age at menarche in Greek adolescent females^[12] but not in other populations^[7,13,14].

The vitamin D receptor (VDR) gene may be another potential candidate gene for age at menarche. The expression of VDR is detected in reproductive organs^[15]. In vitamin D-deficient mice, uterine hypoplasia with impaired folliculogenesis was found in the female reproductive organs^[16]. The VDR gene has been associated with several diseases that may be related to total tissue estrogen exposure, including breast cancer^[17], cardiovascular disease^[18], and osteoporosis^[19]. Recently, the VDR gene has been associated with the age of menarche in Japanese girls^[20].

In the present study, we intended to investigate whether the ER- α and VDR genes, as well as interactions between the two, had effects on the age at menarche in the Chinese female population.

Materials and methods

Subjects The study subjects were selected from 401 nuclear families used in our previous epidemiological study^[21], which was approved by the Research Administration Departments of the Shanghai Sixth People's Hospital and Hunan Normal University. All the subjects were recruited from the Shanghai urban area. They were all of the Han ethnic group, which accounts for more than 93% of the total Chinese population. Informed consent was obtained from each subject. For the study subjects, a detailed medical history, including menstrual history, was recorded by nurse-administered questionnaires. The sampling scheme and exclusion criteria have been detailed elsewhere^[21].

For the present study, we randomly chose one pre-menopausal daughter from each nuclear family. Four hundred and one unrelated pre-menopausal women, who were all in good general health as defined by our exclusion criteria, were sampled. Among these women, 11 had no information of menarcheal age. Thus the 390 remaining pre-menopausal women were available for analysis. The women were unrelated and had regular menstrual cycles.

Genotyping Genomic DNA was isolated using the phenol-chloroform extraction method from whole blood. All subjects were genotyped by polymerase chain reaction followed by restriction fragment length polymorphism procedures (PCR-RFLP). For the ER- α gene, the forward primer (5'-CTG CCA CCC TAT CTG TAT CTT TTC CTA TTC TCC-3') and reverse primer (5'-TCT TTC TCT GCC ACC CTG GCG TCG ATT ATC TGA-3') were used to amplify a 1.3 kb DNA fragment in intron 1. For the *Apal* inside the VDR gene, a 745 bp DNA fragment was produced using the forward primer in intron 8 (5'-CAG AGC ATG GAC AGG GAG CAA G-3') and the reverse primer in exon 9 (5'-GCA ACT CCT CAT GGC TGA GGT CTC A-3'). The PCR mix contained 50 ng genomic

DNA, each of the four deoxyribonucleotides (dNTPs; 0.2 mmol/L), 0.6 U *Taq* polymerase (Sangon, Shanghai, China), MgCl₂ (1.5 mmol/L), each primer (0.4 μ mol/L), and 1 \times PCR buffer in a total volume of 25 μ L. PCR was performed in 38 cycles as follows: denaturation at 95 °C for 30 s, annealing at 50 °C for 30 s, and extension at 72 °C for 60 s on a PE9700 Thermal Cycler (Perkin-Elmer Cetus, Norwalk, CT, USA). After amplification, 8 μ L of the PCR products was digested with the respectively restriction endonucleases *PvuII*, *XbaI*, and *Apal* (Promega, Madison, WI, USA) at 65 °C for 4 h and electrophoresed on 2% agarose gel, stained with ethidium bromide, and visualized under UV light. The genotypes were designated as PP, Pp, and pp for *PvuII*, XX, Xx, and xx for *XbaI*, and AA, Aa, and aa for *Apal*. Uppercase and lowercase letters represent the absence and presence of restriction sites, respectively.

Statistical analysis The χ^2 test was performed to test for the Hardy-Weinberg equilibrium (HWE) at the studied marker loci. The phenotypic values were verified for normal distribution by using the Shapiro-Wilks test. The Program SimWalk2 (available at <http://www.genetics.ucla.edu/home/software.htm>) was used to reconstruct the ER- α haplotypes according to the genotypes of all the subjects in the nuclear families, because the ER- α *PvuII* and *XbaI* were in strong linkage disequilibrium (LD)^[22]. Analysis of variance (ANOVA) was used to evaluate the effects of the ER- α and VDR gene polymorphisms on age at menarche. The frequency of genotype AA for the VDR gene (6.2%) was low in our subjects. If the subjects were divided into three groups, AA, Aa, and aa, the sample sizes for some groups were small, and it was not appropriate to analyze the interaction effect. Then the subjects were divided into two groups, those with and without the minor allele A. To analyze the effect of a special ER- α haplotype, the subjects with this haplotype were denoted as "1"; those without it were denoted as "0". The effect of a given ER- α gene haplotype was tested according to the special VDR genotypes. When a significant result appeared, it was regarded as indicative of an interaction between the ER- α and VDR genes. These statistical analyses were conducted using SAS version 6.12 (SAS Institute, Cary, NC, USA).

Results

Descriptive characteristics of the study subjects The basic characteristics of the 390 unrelated pre-menopausal women are summarized in Table 1. Allele frequencies at the three polymorphic sites in our subjects are summarized in Table 2. All three loci were in HWE ($P > 0.10$). When the genotypes of the ER- α gene were defined according to the

Table 1. Descriptive characteristics of all the subjects. Values are expressed as mean±SD.

Subjects	
Sample size	390
Age/a	31.0±5.5
Height/cm	159.8±5.3
Weight/kg	55.0±8.1
Age at menarche/a	13.6±1.4

Table 2. Allele frequencies at the three polymorphic sites.

Allele frequencies/%	
ER-α <i>PvuII</i>	P=37.1 p=62.9
ER-α <i>XbaI</i>	X=22.4 x=77.6
ER-α haplotype	PX=16.0 px=56.6 Px=21.0 pX=6.4
VDR <i>ApaI</i>	A=27.4 a=72.6

The *PvuII* and *XbaI* polymorphisms of the ER-α and the *ApaI* polymorphism of the VDR were in Hardy-Weinberg equilibrium ($P>0.10$).

haplotypes, ten genotypes were found, with pxpx as the most common (frequency=0.331) and pXpX as the least common (frequency=0.002).

Association of the ER-α and VDR genes with the age at menarche We did not find a significant association between age at menarche and either the ER-α individual polymorphisms or the ER-α haplotypes, or the VDR *ApaI* locus ($P>0.10$) (Table 3). Evidence of an interaction between the ER-α and VDR genes was observed. With the aa genotype at the VDR gene, subjects with haplotype PX at the ER-α gene had, on average, 6 months later onset of menarche than the non-carriers ($P=0.01$) (Table 4).

Discussion

Age at menarche is an important complex trait, which is controlled by both genetic and environmental factors. Some genetic studies have been performed in white and black women, and significant differences between different ethnic populations have been observed, that is, the average onset of menstruation in African-American girls is 9 months earlier than that in Caucasians^[23]. However, few genetic studies

Table 3. Association analyses for the ER-α and VDR genes with age at menarche.

Polymorphisms		<i>n</i>	Age at menarche/ years
ER-α <i>PvuII</i>	PP	50	13.4±1.5
	Pp	189	13.7±1.4
	pp	151	13.5±1.4
	<i>P</i> value		0.36
ER-α <i>XbaI</i>	XX	14	13.4±1.3
	Xx	147	13.7±1.4
	xx	229	13.5±1.4
	<i>P</i> value		0.57
ER-α haplotype	PX/px	73	13.7±1.2
	PX/Px	29	13.8±1.7
	px/px	129	13.5±1.4
	px/Px	89	13.7±1.5
	px/pX	21	13.6±1.2
	Px/pX	24	13.6±1.4
<i>P</i> value		0.74	
VDR <i>ApaI</i>	AA	24	13.4±1.3
	Aa	166	13.5±1.3
	aa	200	13.7±1.4
	<i>P</i> value		0.52

All data are presented as mean±SD of the age of menarche. Only 6 combinations of *PvuII* and *XbaI* genotypes were included in the analysis, because the number of other possible genotypes is small. *P* values are the results of ANOVA.

Table 4. Interaction effects between the ER-α and VDR genes on the age at menarche.

		VDR gene	
		A	B
ER-α PX	0	13.6±1.4 (127)	13.5±1.4 (148)
	1	13.3±1.2 (63)	14.0±1.4 (52)
	<i>P</i> value	0.19	0.01
ER-α px	0	13.1±1.3 (33)	13.8±1.6 (45)
	1	13.6±1.4 (157)	13.6±1.4 (155)
	<i>P</i> value	0.10	0.45
ER-α Px	0	13.5±1.3 (118)	13.6±1.4 (119)
	1	13.5±1.4 (72)	13.8±1.6 (81)
	<i>P</i> value	1.00	0.23
ER-α pX	0	13.5±1.4 (167)	13.6±1.5 (174)
	1	13.7±1.3 (23)	13.6±1.4 (26)
	<i>P</i> value	0.56	1.00

All data are presented as mean±SD of the age of menarche. The sample size is listed in parentheses. “1” denotes carriers and “0” denotes non-carriers of the corresponding ER-α haplotype. “A” denotes the subjects with allele A (the AA and Aa genotypes) at the VDR *ApaI* locus and “B” denotes the subjects without allele A (the aa genotype) at the VDR *ApaI* locus.

have been conducted in Chinese. In this study, the potential interaction effects between the ER- α and VDR genes were observed, although neither of them was significantly associated with the age at menarche individually.

A preliminary study in Greek adolescent females has shown an association between ER- α *Xba*I and *Pvu*II and age at menarche^[12]. Subjects with the genotype XX had later onset of menarche than those with genotypes Xx or xx. The study also found that haplotype PX homozygotes were correlated with later onset of age at menarche. However, such an association was not observed in Japanese women^[7] or Dutch women^[13,14]. Similar to these findings, we did not find any significant association between the ER- α *Xba*I or *Pvu*II polymorphisms and age at menarche in Chinese women.

For the VDR *Apa*I locus, no association was obtained in the present study. However, in a Japanese population, a significant association was found between the VDR gene and age at menarche^[20].

Discrepancies between our study and the other studies may be due to differences in ethnic background, sample size, ascertainment schemes, and statistical methods. For example, if the sample sizes are limited, the power to detect the association will be very low. However, for a single candidate gene that can explain approximately 10% of the variation of menarcheal age, our study sample has about 70% power to detect its association with age at menarche. In addition, gene-by-gene or gene-by-environment interactions may also influence the results of association. For example, interaction between the ER- α and VDR genes was observed in our study. To our best knowledge, this is the first study to find an interaction effect between these two genes on age at menarche. This finding suggests that the magnitude and the direction of the effects of genotypes at one locus may be affected by the specific genotype at the other loci. It also implies that the combination of genotypes at several loci may be more important than a single one. The gene-by-gene interactions may be different in different populations, so the interaction effects observed here have yet to be confirmed by separate analyses in various populations or ethnic groups.

The mechanism by which these two genes interact with each other to affect the onset of menstruation is not clear; however, from a physiological point of view, interaction is possible. An estrogen-responsive promoter region has been characterized in the VDR gene. Transcription of the VDR promoter is dependent on the estrogen receptor^[24]. On the other hand, vitamin D may influence the balance between androgens and estrogens, which in turn modulates the availability of steroid hormones for their receptors^[25]. In addition,

vitamin D may act at several points along the estrogen response pathway, affecting the levels of estrogen receptor as well as their ability to function as enhancers of transactivation^[26].

Noticeably, there was a multiple-testing problem, because we tested multiple alleles in our analyses. If we use the *Bonferroni* correction to adjust for the multiple testing ($P \leq 0.006$ as the significant level), the interaction between the ER- α and VDR genes ($P=0.01$) will be close to, but not reach, statistical significance. In this situation, the *Bonferroni* correction is likely to be too conservative because it assumes that all variants are independent^[27]. However, the statistical tests in the present study are expected to be highly correlated. For example, the *Xba*I and *Pvu*II polymorphisms are only 45 bp apart and in strong LD. Thus multiple testing corrections may lead to power loss and an increased rate of false-negative associations. To report some potentially important associations that are likely to be worthwhile pursuing further, we report the original statistical results.

For genetic investigations of complex traits, phenotype definition is a critical issue. In the present study, age at menarche was determined retrospectively based on self-report, and recall error may be inevitable. However, menarche is one of the most important milestones in a woman's life and retrospective recall is known to be reasonably accurate: recent studies have shown a high correlation between the recalled and actual ages at menarche^[28]. Furthermore, it seems unlikely that this recall bias differs in different genotypes. Thus, our results based on the recalled age at menarche may be valid. Menarcheal age is affected by nutritional level and other living environmental factors. Such information was not recorded and was not used as covariates to adjust the raw data in the present study. In this study, we tried to limit the unrelated subjects to a similar age, so they would have a similar living environment. Such a method of subject ascertainment will have improved the accuracy of our association results.

In summary, the ER- α and VDR genes individually were not associated with the age of menarche in Chinese women. However, potential interaction effects between them were observed. Further studies in other populations with larger sample sizes and denser markers are required to confirm the findings reported here.

Abstract

Aim: To design and synthesize a series of novel amino acid-binding 1,5-diarylpyrazole derivatives, which are intended to act as prodrugs with better aqueous solubility than celecoxib, and which will exert potent anti-inflammatory activities after being converted to their parent compounds *in vivo*. **Methods:** To introduce an amino acid, celecoxib analogs containing amino or methylamino group were synthesized first through multi-step chemical reactions. All the synthesized compounds were screened in an intact cell-based assay *in vitro* and in carrageenan-induced mouse paw edema *in vivo*. Some active compounds were selected for further evaluation in a carrageenan-induced rat paw edema model. The preliminary pharmacokinetics experiments were conducted using high performance liquid chromatography/mass spectrometry (HPLC/MS). **Results:** Celecoxib, 6 of the 1,5-diarylpyrazole class of celecoxib analogs, and their amino acid derivatives (hydrochloride salts) were synthesized. *In vitro* screening, the hydrochloride salts showed decreased inhibitory effects on cyclooxygenase (COX)-1 and COX-2 compared with their parent compounds, but some exhibited potent anti-inflammatory activity *in vivo*. Compound 4a was selected for further evaluation, and its anti-inflammatory effect was equivalent to that of celecoxib after oral administration in the carrageenan-induced rat paw edema model. At three doses (25 mg/kg, 50 mg/kg, and 100 mg/kg) the percentage inhibition on edema was 20.7%, 52.6%, and 62.6% (for compound 4a) and 27.8%, 38.4%, and 40.1% (for celecoxib), respectively. Preliminary pharmacokinetic evaluations support the hypothesis that compound 4a was actually converted to its parent compound, compound 4. **Conclusion:** The compound bound with amino acid acts like prodrug, which can exert anti-inflammatory effect similar to celecoxib after being converted to its parent compound. This finding will be of great benefit in carrying out structural modifications of prodrug-like selective COX-2 inhibitors.

Introduction

Nonsteroidal anti-inflammatory drugs (NSAIDs) are widely used in the treatment of pain and inflammation. NSAIDs act by inhibiting the catalytic activity of cyclooxygenase (COX), which results in a blockage of the formation of prostaglandins (PGs). COX exists as two distant isoforms (COX-1 and COX-2)^[1,2]. Inhibition of COX-2 accounts for

the anti-inflammatory effects of NSAIDs, whereas interruption of COX-1 leads to gastrointestinal toxicity^[2,3]. Therefore, it is proposed that a selective COX-2 inhibitor would have a superior safety profile^[4] to traditional NSAID.

Since the discovery of COX-2, a large number of selective COX-2 inhibitors have been described^[5-8], of which vicinal diaryl heterocycles represent the most important group^[9-12]. These selective COX-2 inhibitors have pronounced anti-

inflammatory effects with reduced or no gastrointestinal side effects. Celecoxib, in the 1,5-diarylpyrazole class of compound^[13], was the first launched selective COX-2 inhibitor, and has excellent selectivity and potent anti-inflammatory activity; however, its aqueous solubility is relatively low, which decreases its oral bioavailability^[14]. One approach to address this problem is to convert the compound into a prodrug that is readily soluble in water. Researchers attempted to create a water-soluble form by *N*-acetylation of the sulfonamide group of celecoxib followed by preparation of its sodium salt^[15], but the result was unsatisfactory. The acetylation product had a lower level of inhibitory effect on rat paw edema than that produced by celecoxib.

Recently, the cardiovascular safety of coxibs has raised serious concerns; Merck & Co even voluntarily withdrew a rofecoxib product from the market because of an increased risk of cardiovascular events. Although there has been concern about adverse cardiovascular events associated with the use of selective COX-2 inhibitors^[16], there is still no evidence indicating that cardiac toxicity is linked with all COX-2 inhibitors^[17,18]. Selective COX-2 inhibitors are still under development^[5,19,20]. It has been proposed that drugs with higher selectivity for COX-2 tend to induce cardiovascular disease^[18,21]. Therefore, we chose the moderately selective COX-2 inhibitor, celecoxib, as a target for modification (the COX-1/COX-2 IC₅₀ ratios of etoricoxib, rofecoxib, valdecoxib and celecoxib are 106, 35, 30, and 7.6, respectively).

To improve the oral absorption of celecoxib, a prodrug strategy was used in this study. In our experiments, we were mindful of the following: (1) conserving the main structure of celecoxib, including the trifluoromethyl and benzenesulfonamide groups, which contribute to its inhibitive qualities and selectivity of COX-2^[13]; (2) partially containing the methyl group in cycle C, because it can be metabolized to the corresponding hydroxymethyl and carboxylic acid analogs (glucuronide conjugation of the carboxylic acid metabolite is a major pathway of elimination in humans^[22]); (3) introducing some polar groups, such as amino or methylamino groups, into cycle C; (4) binding with a natural amino acid followed by preparation of its hydrochloride acid salt. The amide bonds are inclined to be hydrolyzed *in vivo*, and the

cleaved natural amino acid part is safe for humans.

Based on these considerations, in the present study, we designed and synthesized some 1,5-diarylpyrazole derivatives. These hydrochloride salts were expected to have good aqueous solubility and act like prodrugs, which can exhibit potent anti-inflammatory activity *in vivo* after being converted to their parent compounds.

Materials and methods

Animals Female Kun-ming mice (grade SPF II, certificate No SCXK 2003-0003) weighing 18–22 g and male Sprague-Dawley (SD) rats (grade SPF II, certificate No SCXK 2003-0003) weighing 180–200 g were provided by the Shanghai Experimental Animal Center, Chinese Academy of Sciences. These animals were fasted with free access to water for at least 12 h prior to the experiments. All the animal treatments were strictly in accordance with the Chinese National Institute of Health's Guide for the Care and Use of Laboratory Animals (National Research Council, 1996).

Chemicals and reagents Substituted acetophenone and ethyl trifluoroacetate were purchased from Aldrich (St Louis, MO, USA) and Acros (Geel, Belgium). The tert-butoxycarbonyl (BOC)-protected amino acid was from GL Biochem (Shanghai, China). The other reagents were from the Shanghai Chemical Reagent Co (Shanghai, China). All the chemicals were analytical grade or above.

Chemistry To obtain the expected prodrugs, celecoxib (positive drug), and celecoxib analogs (parent compounds) containing amino or methylamino groups were synthesized first as follows.

4-[5-(4-Methylphenyl)-3-(trifluoromethyl)-1*H*-pyrazol-1-yl]benzenesulfonamide (celecoxib) Celecoxib (compound 2) was synthesized as described previously^[13] with some modifications. In first step, sodium methanol was replaced with sodium ethanol, and the reaction time was reduced from 24 h to 4 h. In second step, dione 1 reacted with (4-sulfamoylphenyl)hydrazine hydrochloride (self-preparation) to produce celecoxib in the form of white crystals (Scheme 1, a-b). Purity as assessed by high performance liquid chromatography (HPLC) was 99.8%. The structure was identified by EI-MS, Mp, and ¹H-NMR.

Celecoxib analogs containing amino or methylamino groups (parent compounds) Three classes of 6 compounds were synthesized as followed.

1. 4-[5-(3-Amino-4-methylphenyl)-3-(trifluoromethyl)-1*H*-pyrazol-1-yl]benzenesulfonamide (compound 4) Celecoxib was treated with diluted HNO₃ 2 mol/L and concentrated H₂SO₄ to give the nitration product 3. Then the nitro group was reduced to an amino group by 10% Pd/C

and H₂ to obtain compound 4. To introduce one methyl group on the N atom of the amino group, the N-formyl amine was obtained by the N-formylation of compound 4 with formic acid, then it was reduced by lithium aluminum hydride (LiAlH₄)^[23] to give the desired N-monomethyl aromatic amine compound 5 (Scheme 1, c-e).

2. 4-[5-(3-Methyl-4-aminophenyl)-3-(trifluoromethyl)-1H-pyrazol-1-yl]benzenesulfonamide (compound 9) 3-Methyl-4-nitro acetophenone (compound 6) as a starting material was prepared as described previously^[24] (Scheme 2, a-c). We tried the same method as used in the preparation of celecoxib, but did not obtain the desired compound 7. After different bases and solvents were experienced in step d, we found that the presence of benzene and tert-butanol potassium were suitable for dione (compound 6) synthesis, and

that the temperature should be kept at less than 0 °C. Then compounds 9 and 10 were produced (Scheme 2, d-f) by similar method as Scheme 1.

3. 4-[5-(4-Aminophenyl)-3-(trifluoromethyl)-1H-pyrazol-1-yl]benzenesulfonamide (compound 11) 4-Nitro acetophenone was used as the starting material. Compounds 11 and 12 were synthesized in the same way as compounds 9 and 10.

All the 6 compounds were identified by EI-MS, Mp, and H¹NMR, and their purities as determined by HPLC were all above 99.3%.

Synthesis of prodrug derivatives The 3 classes of celecoxib analogs containing amino or methylamino groups reacted with several kinds of tert-BOC-protected amino acids in the presence of 1-(3-dimethylaminopropyl)-3-ethyl-

Scheme 1. HCOOH, toluene, refluxed for 3 h, yield 98%; ii. LiAlH₄/THF, -5-0 °C, 2 h, yield 57%.

Scheme 2. (a) PCl₅, benzene, refluxed for 2 h; (b) C₂H₅OMg CH (COOC₂H₅)₂/Et₂O/EtOH/benzene, refluxed for 0.5 h; (c) HOAc/H₂SO₄/H₂O, refluxed for 5 h. (a-c: overall yield 55%–65%); (d) CF₃COOC₂H₅, *t*-BuOK, benzene, ice-water bath, 3 h, yield 78%; (e) (4-sulfamoylphenyl)hydrazine hydrochloride, EtOH, refluxed for 5 h, yield 89%; (f) 10%Pd/C, H₂, EtOH, rt, 3 h, yield: 90%.

Scheme 3. (a) EDCI, BOC-AA-OH, THF, rt, overnight, yield 67%–92%; (b) saturated HCl-CH₃COOC₂H₅ solution, rt, overnight, yield 82%–93%. R₁= H or CH₃; R₂= H or CH₃; AA = amino acid.

carbodiimide hydrochloride (EDCI). Then the intermediates bound with the BOC group were deprotected with saturated hydrochloride-ethyl acetate solution to obtain the final amino acid hydrochloride salt (Scheme 3). All products were checked by EI-MS, Mp, ¹H NMR, IR, and HRMS.

Biological assays

In vitro biochemical assays Cell-based assays were performed as described previously^[25]. In brief, the drugs were pre-incubated with infected *Spodoptera frugiperda* (Sf9) cells for 15 min prior to a 10 min challenge with 10 μmol/L arachidonic acid. The concentration of prostaglandin E₂ (PGE₂) was determined by interpolation from a standard curve and inhibition was calculated by comparison of PGE₂ production by drug-treated cells with that of Me₂SO-treated cells.

In vivo screening methods. Carrageenan-induced rat paw edema^[26] Test compounds were suspended in 0.5% carboxymethylcellulose solution and intragastrically administered to rats at three doses (25 mg/kg, 50 mg/kg and 100 mg/kg) before carrageenan was injected. The control group rats received the same volume of vehicle (0.5% carboxymethylcellulose solution) according to their weight. Paw edema was then induced by subplantar injection of 50 μL 1% (w/v) sterile carrageenan in saline into the right hindpaw. Paw volume was measured before and 3 h after carrageenan injection with a plethysmometer (Shandong Academy of Medical Sciences, China). The extent of paw edema in the treatment group was compared to that of the vehicle control group and percentage inhibition was calculated in comparison to the vehicle group.

In the preliminary screening of mice *in vivo*, the inflammatory index was paw weight instead of volume, which was used for the rats.

Preliminary pharmacokinetic study of prodrugs As described previously^[27], HPLC/MS was used to confirm the conversion of prodrug-like derivatives *in vivo* in rats. A single dose (100 mg/kg) of the selected compound (that

showed potent inhibitory effects on rat paw edema), was orally administered to rats (*n*=6). Blood samples (50 μL) were taken before and 0.5 h, 2 h, 6 h, 12 h, 18 h, 24 h, 30 h, 36 h, 48 h, 60 h, and 72 h after intragastric administration, and immediately centrifuged at 10 000×g at 4 °C for 15 min. The plasma samples were stored at -20 °C.

Plasma concentration-time curves were evaluated by InnaPhase Kinetica (InnaPhase Corporation, Philadelphia, PA, USA)

Statistical analysis Data were expressed as mean±SEM (unless noted otherwise), and subjected to one-way analysis of variance (ANOVA) and Dunnett's test. *P*<0.05 was considered to be statistically significant.

Results

Chemistry Celecoxib, 6 of the 1,5-diarylpyrazole class of celecoxib analogs, and their amino acid derivatives (hydrochloride salts) were synthesized. Three kinds of BOC-protected natural amino acids were selected for introduction. They were glycine, *L*-alanine, and *L*-phenylalanine. The main analytical data, from ¹H NMR and HRMS, are summarized in Table 1.

The aqueous solubility of the hydrochloride salts was greatly improved compared with that of their parent compounds and celecoxib. Their aqueous solubilities were, respectively, 10–33 g/L, 0.1–1 g/L, and <0.05 g/L at 18 °C.

In vitro biochemical screening All the compounds were evaluated using the intact cell assay. Parent compounds 4, 5, 9, and 10 exhibited potent and selective inhibition of COX-2 activity *in vitro* (Table 2), whereas the inhibitory activities of the hydrochloride salts were greatly decreased compared with their parent compounds.

In vivo biological evaluation Although none of the hydrochloride salts had any anti-inflammatory activity *in vitro*, they could be expected to exert anti-inflammatory effects once they were converted into their parent compounds.

Compound 4	0.33	14.34
Compound 5	0.12	1.51
Compound 9	3.12	6.32
Compound 10	0.46	1.76

Average of at least three determinations, and the deviation from the mean is <10%.

Based on our preliminary biological evaluation in mice (data not shown), compound 4a was selected for further evaluation in carrageenan-induced rat paw edema because of its potent inhibitory effect on edema. Three doses (25 mg/kg, 50 mg/kg and 100 mg/kg) of each of celecoxib, compound 4, and compound 4a, respectively, were orally administered to rats. Compound 4a had a high level of efficiency, which was identical to that of the possible parent compound 4 and similar to that of celecoxib (Table 3). Furthermore, compound 4a

Table 3. *In vivo* data for compounds celecoxib (positive drug), compound 4 (parent compound), and compound 4a (prodrug compound) on carrageenan-induced rat paw edema. *n*=8. Mean±SEM. ^b*P*<0.05, ^c*P*<0.01 vs control vehicle groups.

Dose /mg·kg ⁻¹	Inhibition/%		
	Celecoxib	Compound 4	Compound 4a
25	27.76±4.35 ^b	26.63±6.47 ^b	20.68±5.44 ^b
50	38.4±3.87 ^b	57.41±2.83 ^b	52.55±3.26 ^b
100	40.12±4.45 ^b	67.29±3.69 ^b	62.55±3.48 ^c

dose-dependently inhibited the inflammatory response to carrageenan-induced edema.

Preliminary pharmacokinetic study A preliminary pharmacokinetic study of compound 4a in rats (*n*=6) was undertaken to prove that it was converted *in vivo* to compound 4. Figure 1 shows the representative chromatograms of blank plasma, plasma containing compound 4, compound 4a, and internal standard (IS), and plasma sample added with IS 6 h after intragastric administration. The retention times of compound 4a, compound 4, and IS were 5.71 min, 7.91 min, and 6.56 min in blank plasma, respectively. In a plasma sample 6

Figure 1. Representative chromatograms of (A) blank plasma; (B) plasma containing compound 4, compound 4a, and internal standard (IS); (C) plasma sample added with IS 6 h after intragastric administration.

h after intragastric administration, the retention times of compound 4a, compound 4 created from the conversion of compound 4a, and IS were 5.68 min, 7.88 min, and 6.53 min, respectively. The corresponding chromatography peak was identified by MS. We thus proved that compound 4a was actually converted to compound 4 after oral administration.

The pharmacokinetic parameters of compound 4 released from compound 4a were calculated by non-compartmental model analysis based on the drug concentration-time curve of 0–72 h sample dotting. Peak plasma concentration (C_{max}), the corresponding time (T_{max}), the area under the plasma concentration-time curve ($AUC_{0-\infty}$), and $T_{1/2}$ were 7.7 ± 1.1 mg/L, 13.2 ± 2.7 h, 165.3 ± 21.8 mg·L⁻¹·h, and 6.4 ± 1.3 h, respectively.

Discussion

In the present study, a series of amino acid-binding 1,5-diarylpyrazole derivatives were designed and synthesized as prodrugs. As expected, the aqueous solubility of these compounds was greatly improved compared with celecoxib. For example, the solubility of compound 4a in water at 18°C was 15–18 g/L, whereas that of celecoxib was <0.05 g/L. Good aqueous solubility should enhance the dissolution rate of a drug and thus improve its oral bioavailability^[14].

In *in vitro* biological evaluations, it was found that the parent compounds 4, 5, 9, and 10 exhibited potent selectivity and inhibition of COX-2, although they all did not exceed celecoxib (Table 2). From the results, it was also found that the compounds containing the methylamino group had more potent inhibitory effects than those containing the amino group. In addition, all the hydrochloride salts showed extremely weak inhibition on COX activity.

Based on a previous hypothesis, the hydrochloride salt should bring about beneficial anti-inflammatory effects after

delivering its parent compound *in vivo*. Therefore, anti-inflammatory evaluation *in vivo* was performed in carrageenan-induced mouse and rat paw edema models. Compound 4a brought about the expected potent inhibition of edema after intragastric administration. Furthermore, at doses of 50 mg/kg and 100 mg/kg, the anti-inflammatory effect of compound 4a was a little stronger than that of celecoxib, and identical to that of compound 4 (Table 3). Preliminary pharmacokinetic studies in rats also proved that compound 4a actually acted as a prodrug, which has an anti-inflammatory effect once it is converted into its active form, compound 4.

In the preliminary pharmacokinetic studies, the T_{max} of compound 4 (as derived from compound 4a) was found at 12 h after oral administration; however, the T_{max} of celecoxib was at 3 h after administration^[28]. In our experiments, we only observed the inhibitory effects on edema at 3 h after oral administration. Therefore we predicted that when the concentration of compound 4 (as derived from compound 4a) reached a maximum, it should have stronger anti-inflammatory activity.

Although compound 4a did not exhibit more potency *in vivo* than its parent, compound 4, its potency was comparable with that of celecoxib (Table 3). We suppose that compound 4a was not completely converted to its parent compound, compound 4, or it produced other metabolisms *in vivo*. Similar prodrug conversion pharmacokinetics have been investigated by Mamidi *et al*^[28]. Prodrugs derived from the same parent compound will have different activity *in vivo* when they are connected to different groups. Connecting more amino acids to the parent compound might offer an exciting prospect for developing prodrug-like NSAIDs.

In summary, by introducing an amino or methylamino group, 6 celecoxib analogs were synthesized as parent compounds. The 6 compounds were combined with three

kinds of natural amino acids to obtain a series of novel hydrochloride salts. By biological evaluation *in vitro* and *in vivo*, and by further preliminary pharmacokinetic studies, compound 4a was discovered, which was confirmed to act as a prodrug, and exhibited marked anti-inflammatory activity *in vivo*. This finding will be of great benefit to the structural modifications of prodrug-like selective COX-2 inhibitors.

Abstract

Aim: To investigate anticancer effects and molecular mechanism of deguelin on human Burkitt's lymphoma Daudi cells *in vitro* and compare the cytotoxicities of deguelin on Daudi cells and human peripheral blood mononuclear cells (PBMC).

Methods: The effects of deguelin on the growth of Daudi cells were studied by 3-(4, 5-dimethyl-2-thiazolyl)-2,5-diphenyl-2H-tetrazolium (MTT) assay. Apoptosis were detected through Hoechst 33258 staining and Annexin V/PI double-labeled cytometry. The effect of deguelin on the cell cycle of Daudi cells were studied by a propidium iodide method. The expressions of cyclin D1 and pRb were checked by Western blot. **Results:** The proliferation of Daudi cells were decreased in deguelin-treated group with a 24-h IC₅₀ value of 51.55 nmol/L. Deguelin induced Daudi cells apoptosis was in a time- and dose-dependent manner. G₀/G₁ phase increased and S phase decreased in Daudi cells treated with deguelin. With deguelin 0, 5, 10, 20, and 40 nmol/L treatment for 24 h, G₀/G₁ phase increased from 37.34% to 56.56%, whereas S phase decreased from 37.72% to 21.36%. PBMC was less sensitive to the cytotoxic effect of deguelin than Daudi cells. The expression of cyclin D1 and pRb protein were decreased sharply in Daudi cells treated with deguelin. **Conclusion:** Deguelin is able to inhibit the proliferation of Daudi cells by regulating the cell cycle that arrested cells at G₀/G₁ phase and inducing the cell apoptosis. Moreover, deguelin selectively induced apoptosis of Daudi cells with low toxicity in PBMC. The antitumor effects of deguelin were related to down-regulating the expression of cyclin D1 and pRb protein.

Introduction

A large number of natural products have been evaluated as potential chemopreventive agents. Deguelin (Figure 1), a natural plant-derived rotenoid, most commonly used as an insecticide in Africa and South America, has been isolated from several plant species, including *Mundulea sericea* (*Leguminosae*). Its main active composition is rotenone, and it has very strong photodissociation^[1]. The recent research has indicated that deguelin usually has a very strong antitumor function, and can suppress many kinds of tumors cell at nmol levels^[1]. Notably, deguelin can suppress colon-cancer cell HT-29 growth^[2], inhibit the growth of precancerous and cancerous lung cells, and induce premalignant and malignant human bronchial epithelial (HBE) cells apoptosis

Figure 1. Structure of deguelin.

with no toxic effects on normal cells^[3]. These recent experiments verified that deguelin could lead the cell cycle to block and induce apoptosis, however, its mechanism is not yet completely clear.

Burkitt's lymphoma (also called small noncleaved cell lymphoma) is a type of on-Hodgkin's lymphoma, a cancer in the lymphatic system. Despite recent advances in radiotherapy, chemotherapy, and stem cell transplant, the severe morbidity from lymphoma has not been improved^[4]. Much effort has been focused on the discovery and development of new chemopreventive agents, especially agents targeted at mechanisms known to be involved in the process of carcinogenesis. Therefore, we have sought to identify novel agents that can prevent lymphoma carcinogenesis effectively but with minimal toxicity.

This study was designed to explore the mechanism of deguelin-induced apoptosis in Daudi cells. We studied deguelin on human Burkitt's lymphoma Daudi cells *in vitro* and compared the cytotoxicities of deguelin on Daudi cells with human peripheral blood mononuclear cell (PBMC), and focused on the changes in the expression of cyclin D1 and phosphor-Rb, and analyzed its underlying mechanism.

Materials and methods

Drugs and reagents Deguelin was purchased from the Sigma Chemical Company (St Louis, MO, USA) and initially dissolved in dimethylsulfoxide (Me₂SO), and stored at -20 °C, and thawed before use. MTT was purchased from Janssen Chimica Company (New Brunswick, NJ, USA). RPMI-1640 medium, Hoechst 33258, and Me₂SO were purchased from Sigma Co. Anti-cyclin D1 and anti-phosphor Rb antibodies were purchased from Santa Cruz (California, USA). Chemiluminescence (ECL) reagent kits were purchased from Pierce Biotechnology, Inc (Rockford, IL, USA). Daudi cells line was obtained from China Center for Typical Culture Collection (Wuhan, China). PBMC were obtained by Ficoll-Hypaque density gradient centrifugation. All kinds of cells were grown in RPMI-1640 culture medium containing 10% fetal calf serum (FCS) and 2 mmol/L L-glutamine at 37 °C in a 5% CO₂ incubator.

MTT assay The antiproliferative effects of deguelin against different group cells were determined by the MTT dye uptake method. Briefly, the Daudi cells and PBMC (40 000 per well) were incubated in triplicate in a 96-well plate. Different concentrations of deguelin were added, and the final concentrations were 0, 5, 10, 20, 40, 80, and 160 nmol/L. The plates were in the presence or absence of the indicated test samples for 0, 24, 36, 48, 60, and 72 h. The group in maximal Me₂SO dissolution concentration acted as the control group. Thereafter, 20 μL MTT solution (5 mg/mL in phosphate-buffered saline [PBS]) was added to each well. After 4 h at 37 °C, the supernatant was removed and 150 μL

Me₂SO was added. When the blue crystal was dissolved, the optical density (OD) was detected at 570 nm wavelength using a 96-well multiscanner autoreader (Biotech Instruments μQuant, New York, USA). The following formula was used: Cell proliferation(%)=[1-(OD of the experimental samples/OD of the control)]×100%.

Hoechst 33258 staining Deguelin-induced apoptosis was monitored by the extent of nuclear fragmentation. Nuclear fragmentation was visualized by Hoechst 33258 staining of apoptotic nuclei. The apoptotic cells were collected by centrifugation, washed with PBS and fixed in 4% paraformaldehyde for 20 min at room temperature. Subsequently, the cells were washed and resuspended in 20 μL PBS before deposition on poly lysine-coated coverslips and were left to adhere on cover slips for 30 min at room temperature and then the coverslips were washed twice with PBS. The adhered cells were then incubated with 0.1% Triton X-100 for 5 min at room temperature and rinsed with PBS three times. The coverslips were treated with Hoechst 33258 for 30 min at 37 °C, rinsed with PBS and mounted on slides with glycerol-PBS. The cells were viewed with an Olympus BH-2 fluorescence microscope (Tokyo, Japan).

Annexin V-PI assay The cells were collected and washed with PBS, followed by being resuspended in binding buffer (HEPES-NaOH 10 mmol/L, pH 7.4, NaCl 140 mmol/L, CaCl₂ 2.5 mmol/L). The samples were incubated with 5 μL Annexin-V in dark for 15 min, washed with binding buffer and resuspended in 1% formaldehyde in the binding buffer at 4 °C for 30 min. After being washed with binding buffer again, the cells were stained with 500 μL PI (1 μg/ml, Sigma) for 15 min then measured on flow cytometry (Stanford, Becton Dickinson, USA).

DNA content and cell cycle analysis Untreated and treated cells were collected, after cultured in the presence or absence of deguelin for the indicated time, rinsed with PBS, and suspended in 75 % ethanol at -20 °C overnight. Fixed cells were centrifuged at 1200×g and washed with PBS twice. To detect DNA content, cells were contained in the dark with PI 50 mg/L and 0.1 % RNase A in 400 μL PBS at 25 °C for 30 min. Stained cells were analyzed on FACSsort (Becton Dickinson). The percentage of apoptotic cells was determined using the CellQuest software program.

Western blot analysis Lysates were prepared from 1×10⁷ cells by dissolving cell pellets in 100 μL of lysis buffer Na₂HPO₄ pH 7.4 20 mmol/L, 150 mmol/L NaCl, 1% Triton X-100, 1% aprotinin, 1 mmol/L phenylmethylsulfonyl fluoride, 10 g/L leupeptin, 100 mmol/L NaF, and 2 mmol/L Na₃VO₄. Lysates were centrifuged at 18 000×g for 15 min and the supernatant was collected. Protein content was determined

using a Bio-Rad protein assay (Bio-Rad Laboratories, Hercules, CA, USA). Sodium dodecylsulfate-polyacrylamide gel electrophoresis (SDS-PAGE) sample buffer (10 mmol/L Tris-HCl, pH 6.8, 2% SDS, 10% glycerol, 0.2 mol/L DTT) was added to the lysates. Lysates were heated to 100 °C for 5 min, and 80 µg of protein was loaded into each well of a 10% SDS-PAGE gel. Resolved proteins were electrophoretically transferred to nitrocellulose and blocked with 5% non-fat milk, and the primary antibodies cyclin D1 and phosphor Rb (dilution 1:200), respectively. After overnight incubation at 4 °C the blots were washed, exposed to HRP-conjugated corresponding secondary antibodies for 1 h, and finally detected by ECL. Quantification of the bands was carried out using densitometric analysis software, Quantity One (Bio-Rad), and processed as described previously.

Statistical analysis All data were expressed as mean±SD using SPSS 10.0 for windows 98. Using linear *t*-tests for statistics analyses, *P* values of less than 0.01 or 0.05 were considered to be statistically significant.

Results

Effects of deguelin on proliferation of Daudi cells and PBMC Daudi cells and PBMC treated with deguelin for 0 h, 24 h, 36 h, 48 h, 60 h, and 72 h, respectively, resulted in the inhibition of cell proliferation in a dose- and time-dependent manner. The *OD* value of the deguelin-treated group decreased significantly compared with the untreated group and PBMC group. There are significant differences between the deguelin-treated and untreated group (Figure 2). It has also shown great difference between deguelin-treated and PBMC group (Figure 3). The *IC*₅₀ value of 24 h on Daudi cell was 51.55 nmol/L, whereas the *IC*₅₀ value of 24 h on PBMC was 1.63 µmol/L. The *IC*₅₀ value of 24 h on PBMC was higher than Daudi cell group with great significance (*P*<0.01).

Hoechst 33258 staining We used Hoechst 33258 staining to investigate the changes in the nucleus of cells, and many apoptotic bodies containing nuclear fragments were found in deguelin-treated (40 nmol/L for 24 h) cells, but none in untreated cells. Arrows indicate apoptotic nuclear fragmentation (Figure 4). At the same time, cytoplasmic shrinkage was observed in cells cultured with deguelin.

Annexin V-PI assay All untreated cells were Annexin-V negative, which meant no apoptosis occurred. In contrast, when Daudi was treated with deguelin, apoptotic cells became Annexin-V positive and PI negative almost all the apoptosis occurred in cells undergoing the G1-phase. With the increasing dose of deguelin, early apoptotic cells increased from (15.46%±0.62%) to (18.48%±2.98%) with 20

Figure 2. Antiproliferation effect of deguelin on Daudi cells. Daudi cells were treated with various concentrations of deguelin as indicated for 0, 24, 36, 48, 60, and 72 h. Growth inhibition was determined using a MTT assay and shown as an inhibitory rate. *n*=3.

Figure 3. Comparison of the cytotoxicities of deguelin on Daudi cells and human peripheral blood mononuclear cell (PBMC). *n*=3.

nmol/L and 40 nmol/L deguelin, respectively (Figure 5). It meant that deguelin could induce G1-phase specific apoptosis.

Cell cycle analysis Figure 6 illustrates changes in DNA content distribution treated with deguelin 0, 5, 10, 20, 40, and 80 nmol/L for 24 h. As the treatment dose increased, the percentage of cells in G₁/G₀ phase increased and S phase decreased accordingly. Treated with 0, 5, 10, 20, 40, and 80 nmol/L deguelin for 24 h, the rate of G₁/G₀ phase cells were increased by 37.34%, 40.91%, 44.69%, 52.45%, and 56.56% in a dose-dependent manner. Meanwhile, the rate of S phase cells were decreased by 37.72%, 35.97%, 34.91, 24.11, and 21.36% in a dose-dependent manner. It showed few changes in G₂/M phase. These results illustrated that deguelin arrested the Daudi cells at G₁/G₀ phase *in vitro*.

Cyclin D and pRb analysis by Western blot After treated with 0, 50, 100, 200, and 400 nmol/L deguelin for 24 h, both the expression of cyclin D1 and pRb were down-regulated dramatically in a dose-dependent manner. The *OD* values of

Figure 4. (A) Untreated Daudi cells; (B) Cells treated with 50 nmol/L deguelin for 24 h. Photographs were taken under an Olympus BH-2 fluorescence microscope ($\times 40$). Arrows indicate apoptotic nuclear fragmentation.

cyclin D1 and pRb on Daudi cells were greatly significant compared with the control cells, and *P* values were less than 0.05 or 0.01, respectively (Figure 7).

Discussion

Several natural compounds, especially plant products and dietary constituents, have been found to exhibit chemopreventive activities both *in vitro* and *in vivo* in model systems. Their mechanisms of action vary widely, with many suppressing cell growth or modulating cell differentiation and a few also inducing apoptosis. Rotenoids, which constitute a class of compounds from the flavonoid family, have chemopreventive activity, act by inhibiting NADH: ubiquinone oxidoreductase activity, and by suppressing steady-state mRNA levels and enzymatic activity of 12-*O*-tetradecanoylphorbol-13-acetate (TPA)-induced ornithine decarboxylase (ODC) activity^[5]. One rotenoid, deguelin, has been

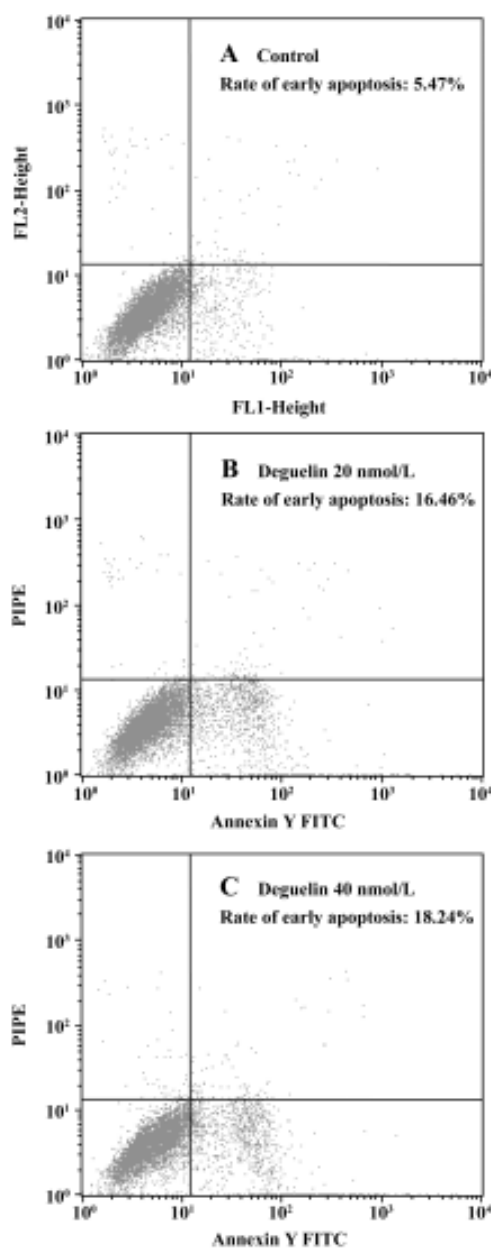

Figure 5. The rate of early apoptosis induced by deguelin with Annexin V-PI assay. A, B, and C show treatment with 0, 20, and 40 nmol/L deguelin for 24 h, respectively.

isolated from several plant species, including *Mundulea sericea* (Leguminosae)^[6]. Deguelin has been shown to have cancer-chemopreventive effects in models of skin, mammary, and lung tumorigenesis. Deguelin has been widely used as an insecticide in Africa, South Africa, and China^[7].

This experiment also founded that deguelin could suppress Daudi cell selectively, and it had low toxicity on human peripheral blood monocular cells (PBMC). Deguelin-

	Control	5 nmol/L	10 nmol/L	20 nmol/L	40 nmol/L	80 nmol/L
G ₀ /G ₁	37.34	40.91	44.69	52.45	56.51	45.77
S	37.72	35.97	34.90	24.10	21.36	32.78
G ₂ /M	22.69	20.82	18.21	21.09	19.72	18.25

Figure 6. The distribution of cell cycle by deguelin with FACSsort (Becton Dickinson, USA). A, B, C, D, E, and F are the control, and deguelin 5, 10, 20, 40, and 80 nmol/L for 24 h, respectively.

Figure 7. Effects of deguelin on the expression of cyclin D1 and pRb in Daudi cells. 1, 2, 3, 4, and 5 are control, and deguelin 50, 100, 200, and 400 nmol/L, respectively. $n=3$. Mean \pm SD. ^b $P<0.05$, ^c $P<0.01$, compared with control. ppRb* was inactive form. pRb was active form.

induced antiproliferative effects on Daudi cells, indicating that deguelin may have potential as they accumulated in the G_0/G_1 phase of the cell cycle and underwent apoptosis in a dose- and time-dependent manner. We found that deguelin decreased the expression of cyclin D1 and pRb in Daudi cells, suggesting that changes in the ratio of cyclin D1 and pRb might contribute to the apoptosis-promoting activity of deguelin in these cells. Cyclin D1 and pRb are important proteins for regulating cell cycle. Chun *et al*^[4] found that deguelin could inhibit both premalignant and malignant HBE cells and these were more sensitive to deguelin than normal HBE cells. They also found deguelin increased the expression of Bax and decreased the expression of Bcl-2 in premalignant and malignant HBE cells, suggesting that changes in the ratio of Bax to Bcl-2 might contribute to the apoptosis-promoting activity of deguelin in these cells. This suggests that mechanisms of regulating cell cycle may contribute to the sensitivity of tumor cells to deguelin.

The results of Hoechst 33258 staining and Annexin V-PI assay showed that deguelin could induce Daudi cells apoptosis in a dose-dependent way. Arrows indicate apoptotic nuclear fragmentation. Apoptotic cells presented typi-

cal characteristics including the cell nuclear concentration, nucleus gathered by the core. With the increasing dose of deguelin, early apoptotic cells increased from 15.46% \pm 0.62% to 18.48% \pm 2.98% with 20 nmol/L and 40 nmol/L deguelin, respectively. The latest research materials indicate that deguelin can inhibit other tumor cell proliferation such as breast cancer, lung cancer, colon-cancer, and so on. Its underlying mechanism relates to inducing inhibition of cyclooxygenase-2 and extracellular signal-regulated kinase expression, participating in the phosphatidylinositol 3-kinase/Akt pathway^[7-9].

The cell cycle is an ordered set of events, culminating in cell growth and division into two daughter cells. Non-dividing cells are not considered to be in the cell cycle. Severe defects in chromosomes block progression through the cell cycle, and can lead to cell suicide or apoptosis. In addition, cells have a finite lifespan, and at some point are no longer able to divide. Deguelin usually acts on different stages of the cell cycle of tumor cells and plays an antitumor role, and this may be one of its pharmacological mechanisms. In this report, Daudi cells were arrested in the G_0/G_1 phase mainly by deguelin, meanwhile the proportion of S phase was gradually reduced. After a different dose of deguelin for 24 h, cells in G_0/G_1 phase were most early influenced and increased gradually in a dose-dependent way with 40 nmol/L, and reached peak value. At the same time, cells in S phase were decreased gradually with 40 nmol/L resulting in the lowest value. The above data shows that deguelin usually regulates the G_1/S checkpoint. Deguelin regulating G_1/S checkpoint was verified in other tumor cells. Chun *et al*^[4] found that after treatment with 1×10^{-9} mol/L deguelin on premalignant and malignant HBE cell, the rate of G_0/G_1 cells increased from 76.1% to 91.2%. At the same time, deguelin arrested premalignant and malignant HBE cells in G_2/M phase that increased from 9.6% to 40.2%.

Rapidly developing technology in the field of molecular biology enables estimation of control mechanisms of cancer cells at the molecular level. Much interest has focused on the proteins participating in cell cycle control. The sequential transcriptional activation of cyclins, the regulatory subunits of cell-cycle-specific kinases, are thought to regulate progress through the cell cycle^[10]. The orderly progression of dividing mammalian cells through the G_1 , S, G_2 , and M phases of the cell cycle is governed by a series of proteins called cyclins, which exert their effects by binding to and activating a series of specific cyclin-dependent kinases (CDK). Cyclins are therefore potential oncogenes. Cyclin D1 overexpression and/or amplification at its genomic locus, 11q13, are common features of several human cancers. The

cyclin D1 gene, which acts at the mid-portion of the G₁-S transition, is often overexpressed in human breast, colon, and squamous carcinomas, and several other types of cancer, and the cyclin E gene, which acts in late G₁ is also overexpressed and dysregulated in a variety of human cancers^[11]. In mechanistic studies we demonstrated that overexpression of cyclin D1 played a critical role in Burkitt lymphoma carcinogenesis. Therefore, cyclin D1 may be a useful biomarker in molecular epidemiology studies, and inhibitors of its function may be useful in both cancer chemo-prevention and therapy.

Retinoblastoma (Rb) is a rare tumor of the retina, associated with mutations of chromosome 13q14. The protein encoded by the Rb gene, pRb, normally plays a key role as a negative regulator of the G₁/S transition in the cell cycle by binding the transcription factor E₂F and preventing it from activating the transcription of genes required for the S phase^[12]. pRB gene product nuclear phosphoprotein undergoes differential phosphorylation during the cell cycle^[13]. A number of cellular proteins interact with hypophosphorylated pRb including: E₂F transcription factor, several cyclins, RBP-1, RBP-2, c-myc, N-myc, and p46. During G₁-phase, pRb is predominantly in a hypophosphorylated state and it becomes increasingly phosphorylated through the cell cycle until the end of mitosis when substantial dephosphorylation^[14-16]. To further investigate the role of cyclin genes in mammary tumorigenesis, we analyzed the expression of cyclins D1 and pRb in Daudi cells by Western blot. In this study, deguelin was shown to down-regulate the expression of cyclin D1 and pRb on Daudi cells in a dose-dependent way. This incident was closely related to arrest in G₀/G₁. This shows that deguelin can regulate the function of molecule cyclin D1 and control cell cycle, reduce the expression of pRb, and realize its regulation and control function of G₁/S checkpoints.

B-NHL plays an important role in blood system tumor. Though traditional chemotherapy and radiotherapy can achieve progress, the long-term result of treatment is not obvious^[17]. We chose Burkitt's lymphoma cell line Daudi cells as a research target. We found that deguelin could arrest Daudi cells in G₀/G₁ phase and induce apoptosis, and did not have any obvious poisonous function on the normal cell. As the source of deguelin is abundant and cheap, hopefully it will become a new-type of powerful antineoplastic medicine in treatment with B cells lymphoma.

Notice of duplicate publication

Publication of the same research data in two or more journals (duplicate or redundant publication) is a practice that does not serve the interest of the medical community. Virtually most medical journals have policies against duplicate publication, and according to the recommendations of the International Committee of Medical Journal Editors (<http://www.icmje.org>), significant infractions should be reported to readers.

Now we regret to inform our readers of an article by Zhu *et al* published in *Acta Pharmacol Sin* 2004; 25 (8): 1045–1051 belongs to duplicate publication which shares the same data with another paper published in *Zhongguo Zhong Yao Za Zhi* (China J Mat Med 2004; 29(8): 777–781. in Chinese), just with different submission date and author sequence.

As our Information for Authors points out, prior and duplicate publication are not permitted. When submitting a paper, the authors must make a full statement to the editor about all submissions and previous reports that might be regarded as redundant or duplicate publications of their work. Abstract

Aim: To investigate the inhibitory effect of a new compound of GLB on tumor metastasis *in vivo* and analyze its actions on tumor cell adhesion to clarify its mechanism. **Methods:** The effect of GLB on tumor metastasis was analyzed by Lewis lung carcinoma model. The pathological morphology of lung alveolar was evaluated by hematoxylin-eosin staining. The effect of GLB on the proliferation of human prostate cancer cell (PC-3M, with a high metastatic characteristic) was studied using the MTT method, and its actions on PC-3M cell adhesion to human umbilical vein endothelial cells (HUVEC) and laminin were analyzed *in vitro*. **Results:** GLB (100 mg·kg⁻¹·d⁻¹ for 28 d, ig) reduced the number of lung colonies of Lewis lung carcinoma metastasis significantly ($P < 0.05$). Simultaneously, GLB could mitigate the damage of lung alveolar caused by metastatic tumor deposits. *In vitro*, GLB inhibited dramatically the adhesion of PC-3M cells to HUVEC ($P < 0.01$) and laminin ($P < 0.05$), without cytotoxic or anti-proliferative action on PC-3M cells. **Conclusion:** GLB has anti-tumor metastatic activity, which partly depends on its inhibition of tumor adhesion.

Introduction

The ability to metastasis is the most fearsome aspect of cancer and most cancer deaths are the sequel of metastatic diseases rather than primary tumor growth. In order to form overt metastases, a cell must complete the metastatic cascade, a series of well-defined steps including local invasiveness, intravasation, circulation, adhesion and extravasation, survival, proliferation and angiogenesis^[1]. Within this multistep process, adhesive ability of metastatic tumor cells is a critical factor in extravasation and formation of new tumor foci^[2-6].

Cancer continues to represent the largest cause of mortality in the world and claims over 6 million lives every year^[7]. An extremely promising strategy for the management of cancer today is chemoprevention, which is defined as the use of synthetic or natural agents (alone or in combination) to block the development of cancer in humans^[8,9]. Studies on the pharmacological mechanisms and the search for new anticancer and anti-metastasis drugs are necessary and hold

great interest for scientists. The compound GLB, (2''S,3aR, 6S,7aR)-3''-acetyl-3a,7a-dihydro-2,2,2',2'-tetramethyl-5''-(4-bromophenyl)-spiro{spiro[1,3-dioxolo(4,5-D)-pyrane-6(7H), 5'(4'H)-1',3'-dioxolo]-7(6H),2''(3'H)-(1,3,4)-oxadiazole} (Figure 1), was synthesized by Prof Zhong-jun LI (School of Pharmacy, Peking University) in 2000 and was patented by National Patent of China (No 03119612.8). It is structurally based on fructose. Previous studies showed that the com-

Figure 1. Chemical structure of GLB.

pound could inhibit the growth of S180 carcinoma in ICR and LACA mice. However, its precise function and mechanism of action on tumor and tumor metastasis have not been determined in full. In the present study, we investigated the effect of GLB on tumor metastasis in mice treated orally and examined its effect on the adhesion of tumor cells *in vitro* to clarify its possible mechanism of anti-metastasis.

Materials and methods

Cell culture Human umbilical vein endothelial cells (HUVEC) were isolated by collagenase I (1 g/L, Invitrogen, USA) digestion of umbilical veins from undamaged sections of fresh cords. HUVEC were grown in Medium 199 (Gibco, USA) supplemented with 20% heat-inactivated fetal bovine serum (FBS), 20 mg/L endothelial cell growth supplement (ECGS, Sigma, USA), 1×10^5 IU/L penicillin, 100 mg/L streptomycin and 2 mmol/L *L*-glutamine. Replicate cultures were obtained by trypsinization and cells of passages 3–6 were used in the experiments. The identification of HUVEC was confirmed by their polygonal morphology and by detecting their immunoreactivity for factor VIII-related antigens^[10]. Human prostate carcinoma cells (PC-3M) were cultivated in RPMI-1640 containing 10% heat-inactivated FBS, 1×10^5 IU/L penicillin and 100 mg/L streptomycin in a humidified incubator with 5% CO₂ in air at 37 °C.

Assay of PC-3M cell adhesion to HUVEC PC-3M cells were labeled with CFDA (carboxyfluorescein diacetate, Sigma, 100 mg/L) for 30 min at 37 °C^[11]. Cells were washed twice with phosphate-buffered saline (PBS) to remove residual fluorescent dye. The viability of the cells was not compromised by this labeling protocol, as indicated by Trypan blue exclusion.

HUVEC were cultured to confluence in 96-well dishes coated with 2% gelatin. Confluence was confirmed using microscopy and CFDA-labeled PC-3M cells were washed and resuspended in culture medium. One hundred microliters of the tumor-cell suspension (about 1×10^4 cells) was added to HUVEC monolayers in 96-well dishes and co-cultured for 30 min at 37 °C. At the end of the experiment, the wells were washed twice with PBS to remove non-adhering PC-3M cells. The adherent cells were counted under a fluorescence microscope using an excitation wavelength of 492 nm, using five fields in each well^[10].

Assay of PC-3M cell adhesion to laminin The 96-well plates were coated with laminin (extracted by the Department of Cytobiology, Peking University) and incubated in RPMI-1640 containing 0.02% bovine serum albumin (BSA) for 15 min at 37 °C. In a total volume of 100 μ L RPMI-1640,

8×10^4 PC-3M cells were added to each well and incubated for 4 h at 37 °C in the presence of GLB. After removing unattached cells with two washes with PBS, the attached cells were incubated with 20 μ L sterile MTT dye (Sigma) for a further 2 h at 37 °C. The medium was then removed, and 100 μ L dimethyl sulfoxide (Me₂SO) was added and mixed thoroughly. Spectrometric absorbance at 540 nm (for formazan dye) and 690 nm (as background level) was measured using a microplate reader (Bio-Rad, USA)^[12].

Proliferation assay PC-3M cells (1×10^4 cells/well) were cultured in 24-well plates and incubated for 1, 2, 3, 4, 5, and 6 d in the presence of GLB at various concentrations. The medium with GLB was changed every 48 h. After incubation the cells were harvested and washed with PBS. The number of viable cells in each well was then determined and counted using the Trypan blue exclusion assay^[13].

Lewis lung carcinoma *in vivo* model Female C57BL/6 mice weighing 18 g–20 g were used and purchased from the Experimental Animal Center of Peking University (Grade II, Certificate No 11-00-0004). Lewis lung carcinoma (provided by the Chinese Medical Science Institute) was maintained in C57BL/6 mice by subcutaneous injection in the axillary's region of 0.2 mL of homogenized tumor tissue [tumor tissue (g): 0.9% sodium chloride (mL), 1:3] prepared from donors similarly inoculated for experimental tumor transplantation^[14].

Metastasis *in vivo* GLB was suspended in 0.5% (w/v) sodium carboxyl methylcellulose (CMC-Na) in distilled water and administered orally for 27 d (25, 50, and 100 mg·kg⁻¹·d⁻¹) from the next day of tumor cell injection. After the d 6, the tumor volumes of mice were measured every 3 d. At the d 28, the mice were killed and the lungs and primary tumors were removed and weighed. The number of metastasized pulmonary colonies was counted and lung tissues were fixed in formalin for further analysis. The inhibitory rate of lung metastasis (%) was calculated using the equation $(W_{\text{model}} - W_{\text{treatment}}) / (W_{\text{model}} - W_{\text{control}}) \times 100\%$, where *W* is lung wet weight^[14–16].

Pathological evaluation of lung The fixed lung tissue samples were embedded in paraffin, sectioned at 5 μ m and stained with hematoxylin and eosin to evaluate alveolar integrity by counting area percentage of alveolus in lung. A total of 5 fields from each lung sample were screened randomly; the mean value was accepted as representative of the sample^[17].

Statistical analysis The experimental results were expressed as mean \pm standard deviation (SD). Statistical analysis was carried out using one-way analysis of variance (ANOVA) followed by Dunnett's test with SPSS version

10.0. $P < 0.05$ was considered to be statistically significant.

Results

Inhibitory effects of GLB on spontaneous metastasis of Lewis lung carcinoma in mice We investigated the effect of oral administration of GLB on the spontaneous metastasis of Lewis lung carcinoma. GLB at the dose of 100 mg/kg significantly reduced the number of pulmonary metastatic colonies of Lewis lung carcinoma cells ($P < 0.05$). The inhibitory rate of colony formation was approximately 31%. During the drug treatment, we found neither body weight loss nor toxic death in the GLB-treated mice. In addition to a reduction in the number of lung colonies by GLB, the survival rate of mice treated with GLB was significantly higher than that of untreated mice bearing Lewis lung carcinoma (Table 1). Although the mean weight and volume of the primary tumor in GLB-treated mice were less than those of vehicle-treated mice, there was no statistical difference ($P > 0.05$, Table 1, Figure 2).

Figure 2. Effect of GLB on Lewis lung carcinoma primary tumor of C57BL/6 mice. C57BL/6 mice were implanted with Lewis lung carcinoma cells and systemic treated with vehicle (model) and doses of 25 mg/kg GLB (GLBL), 50 mg/kg GLB (GLBM) or 100 mg/kg GLB (GLBH) intragastrically once a day. After the 6 d, the mice tumor volume was measured every 3 d. $n > 7$ mice. Mean \pm SD.

Effect of GLB on alveolar integrity in mice with Lewis lung carcinoma cells Alveolar integrity of lungs with metastatic tumor deposits in mice bearing Lewis lung carcinoma cells was significantly worse than that of normal lung tissue (area percentage of alveolus in lungs: $37.8\% \pm 7.44\%$ vs $44.9\% \pm 7.6\%$, $P < 0.05$). The lung tissue of mice treated with 100 mg/kg GLB was clearly better than that of tumor transplanted mice (area percentage of alveolus in lungs: $45.1\% \pm 6.13\%$ vs $37.8\% \pm 7.4\%$, $P < 0.05$) (Figure 3).

Inhibitory effects of GLB on metastatic adhesion function of tumor cells We evaluated the effects of GLB on the metastatic adhesion functions of tumor cells by examining its effect on PC-3M cell adhesion to endothelial monolayers and laminin. GLB, at the concentrations of 1×10^{-5} mol/L and 10^{-6} mol/L, inhibited significantly the adhesion of PC-3M cells to HUVEC ($P < 0.01$, Figure 4). GLB at these concentrations also inhibited the attachment of PC-3M cells to the laminin ($P < 0.05$, Figure 5). To clarify whether the inhibitory action on adhesion function could be due to a cytotoxic effect, GLB was tested for its effect on PC-3M cell proliferation (Figure 6). GLB had no substantial effect on the growth of tumor cells after up to 5 d incubation. Until the latter period of cell growth (d 6 and 7), the proliferation of PC-3M cells treated with 1×10^{-5} mol/L and 1×10^{-6} mol/L GLB showed signs of a slight decrease.

Discussion

As has been demonstrated, the sequential process of micrometastasis formation by Lewis lung carcinoma includes single cells in the blood circulation escaping from the immune system, adhering to epithelial cells, migrating into the tissue, proliferating and making colonies in the lung^[18]. Investigate the earliest events during micrometastasis formation is useful and could be simply applied for the estimation of anti-metastatic and anti-adhesive effects of various anti-cancer agents^[12].

activity against the cells of 4 human tumor cell lines^[20] and 2, 5-disubstituted-1,3,4-oxadiazole compounds, which are potential anticancer agents^[21]. The present study demonstrated that oral administration of GLB inhibited the spontaneous pulmonary metastasis of tumor cells in C57BL/6 mice and increased the survival rate. GLB significantly inhibited the adhesion by PC-3M cells without affecting cell proliferation *in vitro*. The present data suggest that GLB prevents tumor metastasis partly by inhibiting the metastatic adhesion of tumor cells.

Tumor cell adhesion to endothelial monolayers is a critical step in tumor metastasis^[22], as is laminin expression in

Figure 5. Inhibitory effect of GLB on adhesion of PC-3M to laminin. PC-3M cells were added to wells coated with laminin and incubated at 37 °C for 4 h in the presence of GLB. The number of adhesive cells per well was determined using the MTT assay and are shown as absorbance. n=6 wells. Mean±SD. ^bP<0.05 vs control.

Figure 6. Effect of GLB on proliferation of PC-3M cells. PC-3M cells were cultured for 7 d in the absence (■) or presence of either 1×10⁻⁶ mol/L (□) or 1×10⁻⁵ mol/L (▲) GLB. n=4 wells. Mean±SD. ^bP<0.05 vs control.

endothelial cells, being one of the earliest extracellular matrix (ECM) proteins. Laminin interaction with the β-1 integrin has been shown to have an important role in the regulation of tumor-to-endothelial cell adhesion^[10]. We demonstrated that GLB significantly inhibited the adhesion of tumor cells to laminin, using the same doses of GLB as had been found to inhibit adhesion of tumor cells to endothelial cells. This suggests that the anti-adhesion activity of GLB might be due to its effect on laminin, one of many other factors involved in adhesion.

β-1 Integrin is known to recognize many ECM proteins as ligands, such as laminin, collagen and fibronectin. Laminin has been identified as the most important of these ligands for β-1 integrin in the cell adhesion process^[23,24]. Whether GLB exerts its function through β-1 integrin or not is yet to be determined.

In the present study, GLB showed no effect on the weight of the primary tumor site in C57BL/6 mice subcutaneously injected with a Lewis lung carcinoma tumor cell suspension (Table 1). In a preliminary experiment where S180 carcinomas were implanted subcutaneously into ICR and LACA mice, GLB-treated mice (50 mg·kg⁻¹·d⁻¹ for 12 d, ip) showed a significant decrease in tumor weight, with inhibitory rates of 43% and 32% (tumor weight at d 12, mean±SD: 1.16±0.67 g vs 2.05 ± 0.64 g, *P*<0.01 for ICR mice; 1.81±0.68 g vs 2.65±0.81 g, *P*<0.05 for LACA mice; *n*=10 mice). The different effects of GLB on these *in vivo* assay models may be dependent on the kind of tumor, the period of the experiment and route of administration. We speculate that there might be other mechanisms of action for GLB that require further study, including the relationship between its effects on tumor growth or metastasis and its inhibition of angiogenesis.

In conclusion, the compound GLB prevents tumor metastasis by inhibiting tumor adhesion. This suggests it has potential for future anti-metastatic development.

Abstract

Aim: To evaluate the effect of tetramethylpyrazine (TMP) injection on retinal damage induced by *N*-methyl-*N*-nitrosourea (MNU) in rats and on nuclear factor-kappa B (NF- κ B) family members. **Methods:** Female Sprague-Dawley (SD) rats were randomly divided into groups: (i), control group; (ii), model group; and (iii), TMP-injection groups, in which the rats were subdivided into 40 mg/kg, 80 mg/kg and 160 mg/kg groups. Drugs were injected ip into 47-day-old SD rats once a day. At 50 days of age, all rats in the model group and drug groups also received a single ip injection of 60 mg/kg MNU. Rats in group 1 received ip injection of physiological saline. All rats were killed at different times after MNU or physiological saline treatment. The apoptotic index of photoreceptor cells was calculated by TUNEL labeling; retinal damage was evaluated based on retinal thickness and the expression of NF- κ B family members was detected by Western blot. **Results:** TMP injections, in a dose-dependent manner, suppressed photoreceptor cell apoptosis and decreased its loss in the peripheral retina. As compared with the MNU-treated group, TMP injection at a dose of 160 mg/kg also time-dependently upregulated the NF- κ B/p65 protein level in the nucleus and downregulated the I κ B α protein level in the cytoplasm. However, no protective effect of TMP injection on MNU-induced central retinal damage was found. **Conclusion:** TMP injection partially protects against MNU-induced retinal damage by upregulating the nuclear translocation of p65 to inhibit photoreceptor cells apoptosis.

Introduction

Apoptosis has been described as the final common pathway to photoreceptor cell death in many eye diseases, such as age-related macular degeneration (AMD), retinal detachment and retinal light damage^[1]. It has also been found to occur in the hereditary retinal degeneration, retinitis pigmentosa (RP)^[2]. However, it is not obvious how the initial insult to the retina, which could be genetic, environmental, or both, drives the photoreceptor cell toward cell death. Therefore, an understanding of mechanisms that control apoptosis is integral to the treatment and prevention of retinal diseases. Recent studies have shown that light-induced retinal damage is regulated by the transcriptional factor of

nuclear factor- κ B (NF- κ B)^[3,4].

NF- κ B was identified in 1986 as a nuclear factor that bound to an enhancer element of the immunoglobulin (Ig) κ light-chain gene and was believed to be specifically expressed in B cells^[5]. It has recently been implicated in cellular apoptosis. Subunits of NF- κ B, p50, and p65 (RelA) form a heterodimer that exhibits DNA binding potential. NF- κ B typically resides in the cytoplasm bound to an inhibitory subunit, I κ B α or I κ B β , which prevents its translocation to the nucleus^[6]. NF- κ B is constitutively active in several cell lines including THP-1 cells^[7], thymocytes^[8], neurons^[9], and photoreceptor cells^[3] and thus may be universally important to cell survival.

RP is not only a progressively recessive disease, but

also a progressive dystrophia. Thus, we observed *in vivo* the retinoprotective effects of tetramethylpyrazine (TMP), which has the role of promoting blood circulation, on *N*-methyl-*N*-nitrosourea (MNU)-induced retinal damage and elucidated the involvement of NF- κ B in the protection mechanism.

Materials and methods

Animals Six-week-old female Sprague-Dawley (SD) rats were purchased from Zhongshan Medical College, Sun Yat-sen University. Animals were maintained on a basal diet with free access to food and water and were housed in plastic cages in an air-conditioned room at 22 ± 2 °C with a 12-h light/dark cycle.

Drugs and reagents MNU was purchased from Sigma (St Louis, MO, USA) and kept at -20 °C in the dark. The MNU solution was freshly prepared, dissolved in physiological saline, just before use. The *in situ* Cell Death Detection Kit was purchased from Roche Applied Science (Indianapolis, IN, USA). Mouse monoclonal Abs to rat NF- κ B p65(sc-8008), I κ B α (sc-1643), mouse β -actin (sc-8432) and HRP-conjugated antimouse IgG secondary Ab were purchased from Santa Cruz Biotechnology (Santa Cruz, CA, USA). The gel shift assay systems were purchased from Bio-Rad (Bio-Rad, CA, USA). The TMP injection was provided by Changzhou Pharmaceutical Factory (Changzhou, Jiangsu, China).

Morphometric analysis of retinal layers Animals were classified randomly into five groups as follows: (i), Control group ($n=6$); 47-day-old rats received a daily ip injection of physiological saline for 4 days. (ii), Model group ($n=6$); 47-day-old rats received a daily ip injection of physiological saline for 4 days. At 50 days of age, rats also received a single ip injection of 60 mg/kg body weight of MNU. (iii), TMP injection groups ($n=18$); rats were subdivided into 40 mg/kg, 80 mg/kg and 160 mg/kg groups. Drugs were injected ip into 47-day-old SD rats for 4 days, respectively. At 50 days of age, all rats received a single ip injection of 60 mg/kg MNU after TMP treatment for 12 h. All rats were killed 7 d after MNU or physiological saline treatment. Eyes were quickly removed and fixed overnight in 10% neutral buffered formalin. Tissues were processed routinely for paraffin embedding and stained with hematoxylin and eosin (HE). Each eye section was cut at the central part of the retina which was aligned parallel to the optic axis and nerve. Total retinal thickness (thickness from the internal limiting membrane to the pigment epithelium) as well as outer retinal thickness (thickness of the outer nuclear layer and photoreceptor layer) in the peripheral retina (average of approximately 400 mm

from both sides of the ciliary body) and central retina (average of approximately 400 mm from both sides of the optic nerve) were measured. The HE specimens of the retina were prepared in a magnification of 40×10 and examined on an OLYMPUS BX 40 electron microscope (Carl Zeiss, Germany)^[10].

***In situ* detection of apoptosis** The treatment schedule was the same as detailed in the above method. All rats were killed 24 h after MNU or physiological saline treatment and both eyes were quickly removed. The TUNEL method was performed in the formalin-fixed tissue samples by using an apoptosis detection kit according to the manufacturer's instructions^[11]. The apoptotic index of the outer nuclear layer (number of fragmentation nuclei/number of whole photoreceptor cell nuclei $\times 100$) of retina was determined at twenty different fields in each section under $\times 400$ magnification.

Preparation of cytoplasmic and nuclear extracts TMP injection at a dose of 160 mg/kg was injected ip into 47-day-old SD rats, once a day. At 50 days of age, rats were given a single ip injection of 60 mg/kg MNU. Control and model groups were the same as above. Each group had 4 rats. Rats were killed 12 and 24 h, and 3 and 7 d after MNU treatment, respectively. Nuclear and cytoplasmic extracts were prepared according to nuclear extract kits^[7]. Whole retinas were isolated from the eyes of rats in each group, minced and homogenized. The pelleted cells were resuspended in 600 mL 1 Hypotonic buffer (10 mmol/L Hepes, pH 7.9, 1.5 mmol/L MgCl₂, 10 mmol/L KCl, 10% glycerol, 1 mmol/L DTT, 0.5 mmol/L PMSF) and incubated for 15 min on ice. Then 30 mL detergent was added and centrifuged for 30 s at $14\ 000\times g$ at 4 °C. The supernatants (cytoplasmic fraction) were collected and stored at -80 °C. The nuclear pellets were resuspended in 200 mL complete lysis buffer (20 mmol/L Hepes, pH 7.9, 400 mmol/L NaCl, 1.5 mmol/L MgCl₂, 0.2 mmol/L EDTA, 20% glycerol, 1 mmol/L DTT, 0.5 mmol/L PMSF). Following a 30-min incubation on ice, the samples were centrifuged ($14\ 000\times g$, 10 min, 4 °C), and the resulting supernatants (nuclear extracts) were transferred to a fresh microfuge tube and stored at -80 °C.

Western blot analysis Each protein sample (20 g) was denatured in boiling water for 10 min, loaded onto 10% SDS-PAGE and transferred to nitrocellulose membrane. Membranes were blocked overnight with a 5% (w/v) non-fat dry milk solution containing 10 mmol/L Tris-HCl, pH 8.0, 150 mmol/L NaCl and 0.1% Tween 20 (TBST) before incubation with primary antibodies (1 h for NF- κ B p65, I κ B α and β -actin antibodies). Primary antibodies were diluted in TBST (1:200 for NF- κ B p65, I κ B α and β -actin). After washing, the membranes were incubated for 1 h with horseradish peroxidase-labeled

secondary antibody diluted 1:1000 in TBST, and the labeled proteins were detected using enhanced chemiluminescence reagents as described by the manufacturer (Amersham Pharmacia Biotech, Piscataway, NJ, USA). The results were expressed as AU ($D_{\text{area}} \cdot D_{\text{density}}$). The ratio of arbitrary unit (AU, $D_{\text{area}} \cdot D_{\text{density}}$) of target protein over β -actin was used for expressing the relative level of target protein.

Statistical analysis Data were expressed as mean \pm standard deviation and analyzed by SPSS 10.0 software. One to one comparisons among multiple-samples were made using one-way analysis of variance (ANOVA). $P < 0.05$ was considered significant.

Results

Effect of TMP injection on retinal thickness of MNU-treated retina in SD rats Compared with retinas from the age-matched control SD rats (Figures 1A, 2A), peripheral or central retinas from MNU-treated animals showed thinning with selective loss of the photoreceptor cells 7 days after MNU injection (Figures 1B, 2B). While in rats pretreated with TMP injections, the total as well as outer retinal thickness of the peripheral retina was significantly greater than that of model rats in a dose-dependent manner (Figure 1C, 1D, 1E). However, no protective effects of TMP injections on MNU-induced central retinal damage were found (Figure 2C, 2D, 2E). The results are shown in Table 1.

Table 1. Effect of TMP injections on total retinal thickness and outer thickness of MNU-treated rats. Mean \pm SD. ^c $P < 0.01$ vs group 1. ^d $P > 0.05$, ^e $P < 0.05$, ^f $P < 0.01$ vs group 2. Each group consists of 12 eyes.

Group	MNU/ mg·kg ⁻¹	TMP/ mg·kg ⁻¹	Peripheral retina		Central retina	
			Total retina/mm	Outer retina/mm	Total retina/mm	Outer retina/mm
1	0	0	87 \pm 2	45 \pm 1	135 \pm 3	62 \pm 2
2	60	0	37 \pm 2 ^c	3 \pm 1 ^c	69 \pm 2 ^c	5 \pm 1 ^c

Effect of TMP injection on apoptotic index of photoreceptor cells induced by MNU in SD rats As TMP injection had no protective effect on damage to the central retina induced by MNU, we just detected the apoptotic index of photoreceptor cells in the peripheral retina. In MNU-treated rats, the 24 h post-MNU was (38.0 \pm 3.6)% in the peripheral retina.

Figure 1. The protective effect of TMP injections on peripheral retina at the 7th day after MNU treatment. A: control group, the morphology of photoreceptor cells was uniform and the orientation of the photoreceptor segments was normal. B: model group, the photoreceptor cells disappeared. C, D, E: pretreatment with TMP injection 40, 80, and 160 mg/kg. HE \times 400.

When TMP at doses of 40, 80 and 160 mg/kg were injected ip into 47-day-old SD rats for 4 d, the apoptotic indexes were significantly decreased to (30.0 \pm 3.0)% ($P < 0.05$), (15.6 \pm 1.7)% ($P < 0.01$), and (8.4 \pm 2.6)% ($P < 0.01$), respectively.

Effect of TMP injection on NF- κ B p65 and I κ B α protein levels in MNU-induced retinal damage of SD rats As compared with the untreated control, low levels of p65 protein were detected in the nuclear fraction only after MNU treatment for 12 h and 24 h (Figure 3A). While for pretreatment with TMP injection of 160 mg/kg, the nuclear levels of p65 protein were significantly increased after MNU treatment for 24 h and at the 3rd and 7th days ($P < 0.01$) (Figure 3A). The relative level of p65 protein was at its peak at 24 h and was 2.3-fold than that of the MNU-treated group (Figure 3B).

After MNU treatment for 12 h, the I κ B α protein levels in

Figure 2. The protective effect of TMP injection on central retina after MNU treatment for 7 d. A: normal control. B: at the 7th day after MNU treatment, the photoreceptor cells were lost. C, D, E: pretreatment with TMP injection 40, 80 and 160 mg/kg. HE×400.

the cytoplasm were markedly increased ($P<0.05$), and at a peak at 7 d (Figure 4A). In contrast to the MNU-treated group, TMP injection at 160 mg/kg time-dependently induced the down-regulation of cytoplasmic IκBα protein levels (Figure 4A). The relative level of IκBα protein in cytoplasm was 0.8-fold than that of the MNU-treated group at the 7th d of MNU treatment ($P<0.05$) (Figure 4B).

Discussion

The incidence of RP is approximately 1 in 4000, making it one of the major causes of blindness in humans. Although

several genetic mutations have been implicated in RP, the final common pathway of the disease is apoptotic cell death of photoreceptor cells. Up to now, available treatments are of limited use in retarding this disease’s progression. RP is not only a progressively recessive disease, but also pro-

gressive dystrophia. The change of retinal vessels associated with RP is also a prominent and common phenomenon. It has been reported that the blood volume of choroidal vessels became decreased and the choroidal capillaries became atrophic in RP^[12].

According to above viewpoints, inhibition of apoptosis and promoting blood circulation will have common applicability and feasibility. The manipulation of factors that influence the apoptotic pathway and the blood supply of choroidal vessels may be of potential value for RP therapy. Thus, we observed *in vivo* the retinoprotective effect of Chinese medicines, which have the role of promoting blood circulation by removing blood stasis and activating the collaterals, on MNU-induced photoreceptor cell apoptosis in SD rats. TMP, one of the alkaloids in *Ligusticum wallichii* Franch (*L. wallichii*), an active ingredient in Chuanxiong, dilates arterioles, decreases blood and plasma viscosity and improves microcirculation of blood supply of important organs such as the eyes, brain, heart and so on^[13,14]. It has been widely used, especially in the treatment of patients with cerebrovascular diseases in China where its therapeutic actions have been manifested. The present study indicates that MNU-induced retinal damage in rats was partially suppressed by the ip administration of TMP injection through the inhibition of photoreceptor cell apoptosis. However, TMP injection had no protective effect on central retina damage induced by MNU. As in MNU-induced retinal injury, photoreceptor cell apoptosis was evident at 12 h and peaked at 24 h, followed by extensive photoreceptor cell loss 7 days later. Moreover, the apoptotic index was higher in central than peripheral retina after MNU treatment^[10,11]. It indicated that the damage preceded from the central to peripheral retina, the posterior portion of the retina around the optic nerve was more severely damaged than the peripheral retina. Therefore, the scheme of administration was different from clinical administration. We observed the preventive effect of TMP on MNU-induced retinal damage and found that the rapid and extensive cell loss in the central retina was beyond the rescue capacity of TMP. In contrast to the MNU-induced retinal damage, human disease starts in the equatorial area. The mean duration of visual loss in RP patients was 17 years. While, our study showed that TMP injection had a markedly protective effect on slow cell loss. So, it was possible that TMP could prevent the progress of disease and protect the central vision in RP patients. In order to best provide the clinical basis of TMP injection, we would investigate whether TMP injection could rescue photoreceptor cells in retinal degeneration slow (rds) mice in a similar way to human RP.

In 1999, Krishnamoorthy *et al* reported that the presence of NF- κ B RelA subunit in the nucleus was essential for protection of photoreceptor cells against apoptosis^[3]. Crawford *et al* also reported that bcl-2 overexpression protected photooxidative stress-induced apoptosis of photoreceptor cells through NF- κ B preservation^[4]. So, we investigated NF- κ B family members in the present study to elucidate the molecular mechanisms of the protective effect of TMP injection on MNU-induced photoreceptor cell apoptosis in SD rats. In the classical model of NF- κ B activation, NF- κ B p65 exists in the cytoplasm of unstimulated cells in an inactive form associated with the inhibitory protein, I κ B α . Following cell stimulation by extracellular stimuli, I κ B α is phosphorylated through a cascade of inducible protein kinase, and selectively degraded in cytoplasm by the proteasome. Rapid degradation of I κ B α allows for nuclear translocation of NF- κ B where it binds specific DNA motifs in the promoter/enhancer regions of target genes and activates transcription^[15,16].

Under our experimental conditions, the results showed that the amounts of I κ B α in the cytoplasm were significantly accumulated in a time-dependent manner in the MNU-treated retina. It indicated that increases of I κ B α would block the nuclear translocation of NF- κ B. Very low levels of p65 protein in the nuclear extracts were only detectable post-MNU for 12 and 24 h, and no p65 protein was found on the 3rd and 7th days after MNU treatment. But using pretreatment with TMP injection, the cytoplasmic I κ B α protein levels were time-dependently down-regulated. So, more cytoplasmic p65 protein was in a free condition and then moved to the nucleus to regulate the anti- and pro-apoptotic gene expression. It was in accordance with our results that the nuclear levels of p65 protein were significantly increased in the TMP-treated group, and TMP injection markedly increased photoreceptor cells compared with the MNU-treated group. It was further demonstrated that the p65 subunit of NF- κ B may be important for photoreceptor cell survival. Meanwhile, the severe damage of central retina induced by MNU was beyond the protective effect of TMP injection, we also found that the cytoplasmic I κ B α protein was increased and nuclear p65 protein was decreased at the 7th day after MNU treatment.

TMP exerts a variety of effects through antilipid peroxidation, inhibiting calcium overload, decreasing the activity of nitric oxide synthase and the expression of Fas protein, raising the ratio of Bcl-2/Fas protein and so on^[17,18]. Therefore, TMP may also provide retinoprotection by multiple mechanisms. This needs to be further demonstrated. Although the factors that trigger or impede programmed cell death in photoreceptor cells have yet to be clarified, and the

apoptotic cascade may differ between rats and humans, the present findings indicate that TMP can prevent MNU-induced photoreceptor cell apoptosis and may provide a basis for the clinical use of TMP to protect or rescue human RP patients.

Abstract

Aim: To study phase II metabolites of etofesalamide in filamentous fungi. **Methods:** Seven fungi were screened to transform etofesalamide. The metabolites of etofesalamide were assayed using liquid chromatography coupled to mass spectrometry. The major metabolite was subject to enzymatic hydrolysis to confirm its structure. **Results:** Etofesalamide was converted into two phase II metabolites: glucoside and riboside conjugates. Glucoside conjugate was the major product with a yield greater than 90%; no phase I metabolites were detected. **Conclusion:** Glucoside and riboside conjugations of etofesalamide in filamentous fungi differ from the phase II metabolism of glucuronidation in mammals.

Introduction

Etofesalamide [*N*-(4-ethoxyphenyl)-2-hydroxybenzamide] is a new drug that has been developed by Shenyang Pharmaceutical University^[1]. Etofesalamide is applied to acne, psoriasis, sensitization dermatitis, chronic eczema, and neurodermatitis in clinical use. The metabolism of etofesalamide in rabbits has been well studied^[2,3], and etofesalamide-2-glucuronide is the major metabolite.

Biotransformation of drugs by microbes has been examined extensively^[4]. In recent years, a number of studies have shown that some fungi, particularly *Cunninghamella* spp, possess cytochrome P-450 monooxygenase systems analogous to those in mammals and phase II drug metabolism enzymes^[5–7]. The present study uses etofesalamide as a substrate to explore the ability of fungi to convert etofesalamide into phase II metabolites, and compares these results with the results of etofesalamide metabolism in mammals to further investigate special characteristics of filamentous fungi in drug metabolism.

Materials and methods

Chemicals Etofesalamide was provided by the School of Pharmaceutical Engineering, Shenyang Pharmaceutical

University (Shenyang, China) (purity >99%). β -D-glucosidase (EC 3.2.1.21) was purchased from Sigma (St Louis, MO, USA). All solvents used for assay were high performance liquid chromatography (HPLC) grade; the remaining chemicals were analytical grade or biochemical reagents.

Microorganisms *Aspergillus niger* and *Penicillium* were supplied by the Department of Microbiology, Shenyang Pharmaceutical University (Shenyang, China). *Mucor circinelloides* (AS 3.3421) was purchased from the Institute of Applied Ecology, Chinese Academy of Sciences (Shenyang, China). Other filamentous fungi, *Cunninghamella elegans* AS 3.156, *Cunninghamella elegans* AS 3.2028, *Cunninghamella echinulata* AS 3.2004, and *Cunninghamella blacksleana* AS 3.153, were purchased from the Institute of Microbiology, Chinese Academy of Sciences (Beijing, China).

Cultures Microbial cultures were maintained on potato dextrose agar slants at 4 °C and transferred every 6 months to maintain viability.

The broth consisted of glucose 20 g, peptone 5 g, yeast extract 5 g, K₂HPO₄ 5 g, and NaCl 5 g. These ingredients were mixed in 1 000 mL of distilled water, and the pH was adjusted to 6.0 with HCl (6.0 mol/L). The broth was autoclaved in individual Erlenmeyer flasks at 115 °C for 30 min and cooled before incubation.

Microbial transformation Special strains kept at 4 °C were transferred to respective solid cultures and incubated at 28 °C for 7 d to obtain well-grown mycelium with spores. In first-stage fermentation, a loop of fresh spores was inoculated with a 250 mL Erlenmeyer flask containing 50 mL broth. The cultures were incubated at 28 °C for 24 h on a rotary shaker operating at 220 rpm to receive seed culture. A 1.0 mL portion from the first-stage flask was inoculated with a second-stage 100 mL flask containing 20 mL broth. After 24 h incubation, etofesalamide dissolved in acetone was added to yield a final concentration of 0.25 g/L and incubated for an additional 48 h. After microbial transformation, the flask contents were centrifuged at 1 500×g for 20 min, and the supernatant was transferred to tubes and kept at -20 °C until analysis.

Two types of controls were run synchronously with the fermentation and worked-up using the same method. One was a blank fungi control that was used to define and exclude the indigenous secondary metabolites generated by the fungi. The other was a blank substrate control (ie the culture with the etofesalamide but without the fungi) that was used to test whether etofesalamide would be chemically decomposed or spontaneously transformed under broth and microbial transformation conditions.

Enzymatic hydrolysis A 1.0 mL portion of each sample transformed by fungi was screened and incubated with β -D-glucosidase (100 kU/L) at 37 °C for 24 h after adjusting the pH to 5.0 using 50 mmol/L $\text{NH}_4\text{H}_2\text{PO}_4$ buffer (pH 3.0). Control experiments were carried out concurrently in the absence of α -D-glucosidase. Incubations were stopped by using solid-phase extraction (SPE) and analyzed using the liquid chromatography coupled to multistage mass spectrometry (LC/MSⁿ) method.

Extraction of metabolites and LC/MSⁿ assay After thawing, a 1.0 mL portion of each sample was applied to a Bond Elute C₁₈ SPE column (Fuji Company, Tianjin, China) preconditioned with 2 mL methanol and 2 mL water. After loading the sample, the column was washed with 1 mL water and eluted with 2 mL methanol. The sample was evaporated to dryness at 35 °C under a gentle stream of nitrogen, and the residue was reconstituted with the addition of 100 μ L of the mobile phase. A 20 μ L aliquot of the solution was injected into the LC/MSⁿ system.

LC/MSⁿ analysis was carried out using a Finnigan LCQ ion trap mass spectrometer (San Jose, CA, USA) equipped with an electrospray ionization (ESI) source system, a Shimadzu LC-10AD pump (Kyoto, Japan) and a data system (Version 1.2, Finnigan). The interface was adjusted to the following conditions: ion mode, positive; spray voltage, 4.5

kV; capillary temperature, 200 °C; sheath gas (nitrogen), 0.75 L/min; auxiliary gas (nitrogen), 0.15 L/min. MS/MS spectra were obtained by collision-induced dissociation (CID) using helium (He) as the collision gas. The HPLC conditions were as follows: the column was a Diamonsil C₁₈ column (particle size 5 μ m, 4.6 mm × 200 mm ID, Dikma Company, Beijing, China). The mobile phase consisted of methanol-water (80:20, v/v) at a flow rate of 0.5 mL/min.

Results

Fungal metabolite profile of etofesalamide *C. blacksleana* AS 3.153 supported significant metabolism and was chosen to illustrate the identification of metabolites. The microbial transformation and control samples were extracted and analyzed as described above. The chromatograms of the blank fungi controls showed no metabolites or etofesalamide and the blank substrate controls revealed only the presence of etofesalamide and no metabolites of etofesalamide. Authentic etofesalamide could generate a pseudomolecular ion $[\text{M}+\text{H}]^+$ at m/z 258. Compared with the standards, two $[\text{M}+\text{H}]^+$ ions correlated with the metabolism of etofesalamide were observed in the total ion current (TIC) of the sample transformed by *C. blacksleana* AS 3.153, including ions at m/z 420 (M1) and m/z 390 (M2) (Figure 1). The LC/MSⁿ data of etofesalamide and its two metabolites are shown in Table 1.

Table 1. Multistage mass spectrometry characteristics of metabolites and etofesalamide.

Metabolite and substrate	$[\text{M}+\text{H}]^+$ (m/z)	MS ² fragment (m/z)	MS ³ fragment (m/z)	t_R (min)
M1	420	258	121, 138	9.59
M2	390	258	121, 138	11.20
Etofesalamide	258	121, 138	–	20.25

t_R , retention time.

The pseudomolecular ion of M1 was at m/z 420, 162 higher than that of etofesalamide, which suggests that the corresponding metabolite might be a glucoside conjugate. The MS/MS spectrum of the ion at m/z 420 yielded a single ion at m/z 258 similar to the $[\text{M} + \text{H}]^+$ ion of etofesalamide. In addition, the MS³ spectrum of the M1 ion at m/z 258 yielded the same fragment ions as the MS/MS spectrum of etofesalamide, indicating that M1 could be the glucoside conjugate of etofesalamide.

Figure 1. Chromatograms of total ion current (TIC, I) and selected ion monitoring (SIM, II, III, IV) scan modes in the LC/MS assay of authentic etofesalamide (A) and transformed etofesalamide (B).

According to the process described above, M2 could be a riboside conjugate of etofesalamide. Proposed metabolic pathways of etofesalamide in filamentous fungi are shown in Figure 2.

Enzymatic hydrolysis To further investigate the structure of M1, the sample of etofesalamide transformed by *C. blacksleana* AS 3.153 was subjected to enzymatic hydrolysis. The results are expressed as the percentage of metabolite that was hydrolyzed with β -D-glucosidase compared to the control, which was hydrolyzed spontaneously. Treatment with β -D-glucosidase led to a greater than 50% reduction in M1. This result provides further evidence that M1 is

the metabolite conjugated with glucoside because β -D-glucosidase is substrate selective.

Microbial transformation of etofesalamide by the screened fungi Table 2 shows the percentages of etofesalamide metabolized by different strains of fungi. In the seven fungi screened, *Aspergillus niger* and *Penicillium* had no ability to transform etofesalamide; four strains of *Cunninghamella spp* resulted in almost complete metabolism, particularly the *C. blacksleana* AS 3.153 strain. *Mucor circinelloides* AS 3.3421 had a similar ability to *Cunninghamella spp* to transform etofesalamide. Etofesalamide was converted into two phase II metabolites by these fungi, glucoside and riboside conjugates, in which glucoside conjugate was the major product with the highest yield (94.5%). In addition, no phase I metabolites were detected, and *C. blacksleana* AS 3.153 supported significant metabolism, which may be useful in the study of phase II metabolism of etofesalamide *in vitro*.

Figure 2. Proposed metabolic pathways of etofesalamide in filamentous fungi.

Discussion

In this study, seven filamentous fungi were screened for their abilities to metabolize etofesalamide. Four strains of *Cunninghamella* species showed a strong ability to convert etofesalamide into the phase II metabolites, glucoside and riboside

Table 2. Yields of transformation products and remaining etofesalamide by different fungal strains.

Strain	Total phase I metabolites* (%)	Glucoside* (%)	Riboside* (%)	Remaining etofesalamide (%)
<i>C. blacksleana</i> AS 3.153	0	94.5	1.5	4.0
<i>C. echinulata</i> AS 3.2004	0	90.8	2.1	7.1
<i>C. elegans</i> AS 3.2028	0	74.6	7.9	17.5
<i>C. elegans</i> AS 3.156	0	93.2	0	6.8
<i>Mucor circinelloides</i> AS 3.3421	0	38.8	9.2	52.0
<i>Aspergillus niger</i>	0	0	0	100
<i>Penicillium</i>	0	0	0	100

*The percentage of one metabolite compared to the total percentage of metabolites and remaining substrates. $n=3$.

conjugates. No phase I metabolites were observed. The high potential of certain fungal strains to produce phase II metabolites was illustrated by these results.

Our results show that a number of filamentous fungi transform etofesalamide by phase II reactions to excretable sugar conjugates. Glucoside and riboside conjugations differ from the phase II metabolism observed in mammals. In mammalian species, such as rabbits, glucuronide conjugation rather than glucoside conjugation is the major metabolic pathway for etofesalamide^[2,3]. Conjugations with glucuronic acid are considered to be a dominant metabolic pathway in humans for detoxifying and eliminating lipophilic chemicals from the body^[8]. In comparison with glucuronide conjugation, there is only limited information in the literature regarding the glucoside conjugation process in humans. At present, apart from N-linked glucoside drug metabolites, only two O-linked glucosides of mycophenolic acid and morphine have been identified in humans^[9,10]. In addition, glucuronide conjugation, which is a characteristic conjugation in humans, is rarely found in microorganisms, and only two examples of glucuronide conjugation have been reported^[11]. Compared with the phase II reactions in humans, glucoside conjugation is the major metabolic pathway in microorganisms, and it is used extensively to study the detoxification of cytotoxins and carcinogens^[12-14]. Riboside conjugation is obviously another potential phase II reaction in biotransformation in filamentous fungi, but only one such conjugate has been reported recently^[15].

Abstract

Ataxia telangiectasia (AT) is a rare human disease characterized by extreme cellular sensitivity to radiation and a predisposition to cancer, with a hallmark of onset in early childhood. Several human diseases also share similar symptoms with AT albeit with different degrees of severity and different associated disorders. While all AT patients contain mutations in the AT-mutated gene (ATM), most other AT-like disorders are defective in genes encoding an MRN protein complex consisting of Mre11, Rad50 and Nbs1. Both ATM and MRN function as cellular sensors to DNA double-strand breaks, which lead to the recruitment and phosphorylation of an array of substrate proteins involved in DNA repair, apoptosis and cell-cycle checkpoints, as well as gene regulation, translation initiation and telomere maintenance. ATM is a member of the family of phosphatidylinositol 3-kinase-like protein kinases (PIKK), and the discovery of many ATM substrates provides the underlying mechanisms of heterologous symptoms among AT patients. This review article focuses on recent findings related to the initial recognition of double-strand breaks by ATM and MRN, as well as a DNA-dependent protein kinase complex consisting of the heterodimer Ku70/Ku80 and its catalytic subunit DNA-PKcs, another member of PIKK. This possible interaction suggests that a much greater complex is involved in sensing, transducing and co-ordinating cellular events in response to genome instability.

Ataxia telangiectasia clinical presentation

Ataxia telangiectasia (AT) is a rare human disease characterized by extreme sensitivity to radiation^[1–5]. AT is a progressive neurodegenerative disorder causing a predisposition to cancer, with a hallmark of onset in early childhood^[6–9]. AT is seen in approximately 1 in every 40 000 live births in the USA, although the frequency varies from country to country^[10]. At birth, infants appear normal and begin walking at a normal age (approximately age 1 year); however, by age 2–3 ataxia (loss of muscle co-ordination) becomes visible and generally by age 10 patients are confined to a wheelchair^[10]. Ataxia generally precedes telangiectasia, which is described as the chronic dilation of a group of capillaries causing elevated, dark red blotches on the skin or eyes^[11]. This disease is additionally characterized by cerebellar degeneration, and immune system defects^[12–14]. In younger children, diagnosis of AT is somewhat obscure as the cerebellum appears

to be of normal size for several years although onset of ataxia is prevalent. However, by age 10 magnetic resonance imaging (MRI) generally shows an abnormal cerebellum that has decreased in volume^[15]. Studies have shown a gradual decrease in granular and Purkinje cells, which are large branching cells of the nervous system and are located in the middle layer of the lower part of the brain, or the cerebellum^[14–16]. Unfortunately, there is currently no treatment for AT except for supportive therapy of secondary symptoms^[17].

In addition to an up to several hundredfold increase in developing certain types of cancers (eg lymphoma) in AT patients, epidemiological studies suggest that heterozygote AT mutation carriers are also at increased risk for cancer, particularly breast carcinoma^[18,19]. This is of great significance as it is estimated that approximately 1% of the population are AT carriers. However, it is noted that a recent study showed that heterozygous AT mutations did not confer genetic predisposition to early onset of breast cancer^[20].

Serum alphafetoprotein (AFP) levels are elevated in more than 95% of AT patients, which is therefore used to diagnose AT and to distinguish from AT variants^[4,5,10,21]. When dealing with AFP it is important to note that AFP levels are normally higher at birth than those at age 2, thus diagnostics for AT using AFP cannot be conducted until after the age of 2. There are known malignancies associated with AFP^[10,22]. For example, AFP is known to be elevated in case of spina bifida and anencephaly, and this elevation is the hallmark test for early detection of both conditions. Spina bifida is part of a group of birth defects called neural tube defects, which affect embryonic structures that eventually develop into the brain, spinal cord and tissues that enclose them. Anencephaly is a congenital condition in which portions of the brain fail to develop. Because AFP is such a diagnostic hallmark for AT, it is surprising that the mechanism of AFP upregulation in normal and AT cells has not been reported. Nevertheless, given the commonality of AFP elevation in all of the above 3 diseases, it is conceivable that the increased AFP level is responsible for the Purkinje cell degeneration in AT patients.

Ataxia telangiectasia-related diseases

There are several human deficiencies and diseases that are closely related to AT. For example, molecular cloning has now allowed for the distinction between AT and other autosomal recessive cerebellar ataxias (ARCA) such as Friedreich ataxia or A-T_{Fresno}, an old-fashioned term for an AT variant^[23–25], oculomotor apraxias 1 (aprataxin deficiency), oculomotor apraxias 2 (senataxin deficiency), aicardi syndrome and AT-like disorder (ATLD)^[26–29].

AT-like disorder is a very rare disorder with clinical features similar to those of AT, with the most prominent similarity being progressive cerebellar ataxia. However, ATLD patients that do not present with telangiectasia^[30,31], have a later onset of neurological features, slower progression, and thus milder symptoms compared to AT patients^[27].

Closely related to AT and ATLD is the Nijmegen breakage syndrome (NBS)^[23–25]. NBS and ATLD have some overlapping features such as hypersensitivity to ionizing radiation and genome instability, and both are characterized by neurological deficits^[32,33]. Thus, NBS was long considered as a clinical variant of AT. Clinical distinction has been made as NBS patients also present with a characteristic facial appearance and microcephaly as well as growth retardation^[34]. Clearly the above AT-related human conditions suggest deficiency at common cellular function(s) and genetic pathway(s) with AT.

Laboratory findings in ataxia telangiectasia and ataxia telangiectasia-related patients

Laboratory findings in patients with AT show: immunodeficiencies emerging as decreased IgA, IgE and IgG2 levels^[5,21,35–38], characteristic chromosomal aberrations and an increased rate of telomeric shortening^[39], radiosensitivity^[1–5], as well as sensitivity to other DNA damaging agents and non-DNA damaging agents^[40]. Chromosome instability, cell-cycle checkpoint defects^[3] and elevated serum levels of AFP^[21,22] are prevalent in most AT patient cells. In addition, approximately one-third of AT patients develop cancer, which is usually lymphoid^[10].

Both NBS and ATLD cells share a number of cellular phenotypes with AT cells, with the most prominent being the increased sensitivity to ionizing radiation, abnormal cell-cycle checkpoints, chromosome instability, immunodeficiency and accelerated shortening of telomeres^[41,42]. In particular, all 3 disorders show an increased level of chromosome translocation in the peripheral blood between the loci of the immunoglobulin and T-cell receptor genes on chromosomes 7 and 14^[43,44]. Hence, laboratory findings are most consistent with all 3 diseases belonging to a group of disorders referred to chromosome instability syndromes.

Molecular basis of ataxia telangiectasia and related diseases

AT is the result of mutations in the AT-mutated (*ATM*) gene, which was discovered in 1995^[45,46]. AT patients suffer as a result of over 400 distinct *ATM* mutations, of which 85% are accounted for by null mutations in the *ATM* gene^[21,47,48]. Thus, approximately 85% of AT sufferers have no detectable *ATM* protein^[21,48]. There are a few reported genuine AT cases with normal *ATM* protein levels; however, in these cases the protein is defective in *ATM* enzyme activity^[49,50]. The establishment of AT as a monogenetic disease assisted in efficient diagnosis and reevaluation of “AT variants”. The fact that some AT patients carry hypomorphic *ATM* mutations (ie mutations with partial functions) provides an underlying explanation for atypical AT patients with minimal signs of symptoms, such as very mild or late-onset of syndromes or a subset of disorders^[51].

The *ATM* protein is a member of the phosphatidylinositol 3-kinase-like family of serine/threonine protein kinases (PIKK)^[13,52]. It is thus grouped because all PIKK contain a conserved kinase domain initially reported in phosphatidylinositol 3-kinase. This family represents an atypical subclass of protein kinases responsible for phosphorylation of its substrates on serine or threonine followed by glutamine

(SQ or TQ)^[53-55]. The mammalian PIKK known to be involved in the DNA damage response are: DNA-PKcs (the catalytic subunit of DNA-dependent protein kinase), ATM (ataxia telangiectasia gene product), ATR (ATM and Rad3-related), mTOR/FRAP (mammalian target of rapamycin/FKBP-rapamycin-associated protein) and ATX/SMG1^[13].

The ATM protein is a fairly large (approximately 350 kDa) protein that can be divided into several structural and functional domains (Figure 1A). The first is an FAT domain, which is conserved among the PIKK family of proteins FRAP, ATR and TRRAP; the second is a phosphoinositide 3,4-kinase (PI3K) domain, which ATM has in common with DNA-PKcs; and the third is an FAT carboxy-terminal domain (FATC)^[56]. In addition, the amino terminus of the ATM protein contains multiple HEAT (huntingtin, elongation factor 3, A subunit of protein phosphatase 2A and TOR1) repeats^[57]. A recent resolution structure analysis of the FATC domain^[58] revealed an α -helix and a disulfide-bonded loop that undergoes conformational changes. Hence, the FATC domain may regulate protein activity and stability. The precise function of HEAT repeats is currently unknown, although it is speculated to be involved in the interaction with other proteins, as these repeats are anti-parallel α -helices linked by a flexible loop^[40,57].

The overall shape of ATM is very similar to DNA-PKcs and is comprised of a head and a long arm that is thought to wrap around double-stranded DNA after a conformational change^[59-63]. One of the hallmarks of the ATM protein is its rapid increase in kinase activity immediately following exposure to ionizing radiation (IR), or in the presence of double-strand breaks (DSB)^[64,65].

The gene mutated in NBS was identified as *NBS1*^[25,66,67] whereas ATLD is caused by mutations in the *MRE11* gene^[29]. Unlike AT, which can result from complete inactivation of the coding gene, all NBS and ATLD patients carry hypomorphic mutations that express some level of corresponding protein, either truncated or full length with amino acid substitutions^[27,68]. Indeed, attempts to create null *Mre11* mutations in mouse embryonic stem cells has failed and conditional knockout experiments demonstrated that this gene is required for normal cell proliferation^[69], suggesting that *MRE11* is an essential gene in mammals. Similarly, complete *Nbs1* knockout mice are embryonic lethal^[70,71]. This assertion is further confirmed by a report that disruption of mouse *Rad50*, encoding the third component of the MRN (MRX in yeast) complex consisting of Mre11, Rad50, and Nbs1 (aka nibrin and p95; Xrs2 in yeast), also causes embryonic stem

Figure 1. Schematic representation of the ATM, Mre11 and Nbs1 proteins. (A) ATM and its functional domains. Most domains have been discussed in the text. The letter “P” indicates the phosphorylation site required for its activation. (B) Mre11 and its functional domains. The asterisks represent the known mutations that cause ataxia telangiectasia-like disorder (ATLD). Note that only two families of ATLD with *MRE11* mutations were reported. One is homozygous for the mutation C1897T, resulting in R633 Δ (stop codon), whereas the second family is heterozygous for A350G (N117S) and C1714T (R572 Δ). (C) Nbs1 and its functional domains. The asterisks indicate the known *NBS1* mutations that cause Nijmegen breakage syndrome (NBS), among which the homozygous 657 Δ 5 mutation accounts for over 90% of NBS patients. 657 Δ 5 contains a 5-bp deletion, resulting in a truncated 26 kDa protein with only forkhead-associated (FHA) and BRCA1 C-terminus (BRCT) domains. Other *NBS1* mutations cause various degrees of symptoms.

cell lethality^[72].

The human *MRE11* gene was initially isolated by its possible protein interaction with DNA ligase I^[73] and was predicted to encode a 708-amino acid protein. However, subsequent reports appear to favor an Mre11B sequence (Figure 1B), which is different from Mre11 primarily at the C-terminal region and significantly strengthens its similarity with Mre11 from other species^[74]. Mre11 contains a phosphoesterase motif at the N-terminal region that is highly conserved among all eukaryotic Mre11 and a similar motif is also found in *Escherichia coli* SbcD^[75]. It also contains DNA-binding domains at the C-terminal region and region(s) for homodimerization^[76,77]. Structural analyses^[78–80] indicate that the MRN complex consists of two molecules of Mre11 and Rad50 (an *E. coli* SbcC homolog) forming a rope-and-hook structure capable of bridging two DSB ends. *In vitro* characterization of the Rad50–Mre11 complex^[76,81–84] demonstrates that it possesses 3′ to 5′ exonuclease and single-strand endonuclease activities, as well as ATP-dependent DNA binding and limited unwinding activity.

The phenotypic similarity between NBS and ATLD patients is attributed to the fact that both corresponding proteins are components of the MRN complex. Mre11 interacts with both Rad50 and Nbs1/Xrs2, and its homodimerization or self-interaction appears to be important for the Mre11–Rad50 and Mre11–Nbs1/Xrs2 interactions^[76,77]. Interestingly, deficiency of the Mre11 protein results in decreased cellular levels of Nbs1 and Rad50, suggesting that the MRN complex is required for protein stability. The primary cellular function of MRN is a sensor for DNA strand breaks and to activate signaling pathways leading to cell-cycle checkpoint and recombination repair^[32,85,86]. While Mre11 and Rad50 are highly conserved in eukaryotes, from unicellular yeasts to human cells^[87,88], the third component, Nbs1, is less conserved structurally among eukaryotes, although the mammalian Nbs1 and yeast Xrs2 play similar roles within their respective MRN/MRX complex. Nbs1 has been suggested to be a regulatory subunit of MRN that is essential for Mre11 phosphorylation upon DNA damage^[89] and its biochemical activities, such as ATP-dependent DNA unwinding and nuclease activity^[90]. Although Nbs1 or Xrs2 is not required for the Mre11–Rad50 enzymatic activity *in vitro*, its activity appears to be absolutely required for MRX activity *in vivo*, as inactivation of any 1 of the 3 genes in yeast cells leads to complete loss of the MRX activity and indistinguishable cellular phenotypes^[91–93]. This essential function of Nbs1/Xrs2 is probably due to its role in recruiting ATM/Te11^[94]. The Nbs1 protein has 4 known functional regions: the N-terminal forkhead-associated (FHA) domain followed by a

BRCA1 C-terminus (BRCT) domain, a C-terminal Mre11-binding domain and an ATM-binding domain at the extreme C-terminus (Figure 1C). Interestingly, over 90% of all NBS patients analyzed to date contain a homozygous 5 bp truncating mutation, 657Δ5^[25], resulting in the production of a 26-kDa protein with FHA and BRCT domains but lacking the Mre11-binding domain (Figure 1C). Knockout mice producing similar truncated Nbs1 proteins are viable and develop symptoms characteristic of the human disease^[95,96], thus providing an animal model suitable for NBS research.

Phenotypic manifestation of genetic defects in ataxia telangiectasia and related diseases

One of the hallmarks of the ATM protein is its rapid increase in kinase activity immediately following DSB formation^[64,65], and its kinase activity remains its only known function to date. The phenotypic manifestation of AT is due to the broad range of substrates for the ATM kinase, as compiled recently^[40], involving DNA repair, apoptosis, G₁/S, intra-S checkpoint and G₂/M checkpoints, gene regulation, translation initiation, and telomere maintenance. Protein phosphorylation and de-phosphorylation is an important cellular regulatory mechanism that governs protein activity, stability, subcellular location and complex formation. We propose that although the primary ATM kinase substrates appear to be related to cellular response to DNA damage, novel ATM substrates and subsequent effects may explain all observed syndromes of AT patients, including elevated AFP level. We also propose that the multiple HEAT repeats in ATM may serve as a platform to interact with various regulatory and substrate proteins and to control its kinase activity in the aftermath of DNA damage. For example, the increased risk for breast cancer in AT patients has been implicated by the involvement of ATM in the interaction and phosphorylation of BRCA1 and its associated proteins following DNA damage^[97,98].

The ATM protein also has the ability to interact with the ends of double-stranded DNA^[99]. A recent model suggests that ATM is in an inactive dimeric or polymeric configuration, in which the kinase domain of each molecule is blocked by the FAT domain of the other^[100]. Following DNA damage, each ATM molecule phosphorylates the other on a serine residue at position 1981 within the FAT domain and thus converts into fully active monomers. It was shown that protein serine-threonine phosphatase 5 (PP5) is required for the activation of ATM and its subsequent kinase activity^[101].

The symptom similarity among AT, ATLD and NBS is apparently due to physical and genetic interactions between

ATM and MRN. Experimental results suggest that the ATM-MRN interaction in response to IR is complicated. First, the histone H2A isoform H2AX is rapidly phosphorylated (within 5 min) after irradiation in an ATM-dependent manner^[102,103], and the phosphorylated gH2AX interacts with MRN via the FHA/BRCT region of Nbs1^[103]. This interaction has been deemed indispensable for the recruitment of MRN^[41]. Second, in response to IR, ATM phosphorylates Nbs1 *in vivo*^[104], which is required for the subsequent phosphorylation of Mre11. Finally, phosphorylation and activation of the S-phase checkpoint effector Smc1 by ATM requires phosphorylated Nbs1^[105,106]. The above observations suggest that ATM acts upstream of MRN and is required to recruit MRN to the damage sites observed as distinct nuclear foci. On the other hand, MRN/MRX is known to bind DSB ends and a careful choreographic analysis in yeast^[107] indicates that MRX localization to nuclear DSB foci precedes and is required for that of Tel1, a yeast ATM ortholog^[108,109]. In mammalian cells, Mre11 appears to be required for ATM activation as well^[110], and this interaction was further reinforced very recently by an *in vitro* experiment showing that the MRN complex acts as a DSB sensor for ATM and recruits ATM to broken DNA molecules^[111]. Interestingly, the unwinding of DNA ends by MRN appears to be essential for ATM stimulation^[111], indicating that the MRN enzymatic activity plays a role in this process. In addition, a recent study^[112] shows that NFB1/MDC1, which interacts with MRN, is required for ATM activation under certain conditions. Alternatively, NFB1/MDC1 may help to recruit substrates, including Nbs1^[113,114], to ATM^[113–123]; suppression of NFB1/MDC1 leads to decreased ATM activation and decreased phosphorylation of ATM substrates^[112]. These observations support an assertion that MRN plays a crucial role in ATM phosphorylation of other substrates in response to DSB. The argument that MRN functions upstream of ATM is further strengthened by a very recent report that the extreme C-terminal 21 amino acid peptide of Nbs1 is required and sufficient for the interaction with ATM *in vivo* and *in vitro*, and that this interaction mediates ATM deposition to the sites of DNA damage and its checkpoint functions^[94]. The above genetic and physical interactions between MRN and ATM underlie the molecular basis for the shared cellular functions in cell-cycle checkpoints and recombination repair of DSB, as well as common syndromes among AT, ATLD and NBS.

DNA-PK: a missing link?

Despite the great advances made in the past decade re-

garding AT research, many questions remain to be answered. One question that remains unsolved is the involvement of Ku70/Ku80 in ATM-mediated cellular events in response to DSB. Ku70 and Ku80 form a heterodimer as DNA end-binding subunits of DNA-PK^[59–62]. It would be plausible to suggest that Ku70/Ku80 may also assist ATM's translocation to DSB, as Ku70/Ku80 is known to play such a role for DNA-PKcs, another member of PIKK with overall structural similarity to ATM^[124]. Like ATM, DNA-PKcs recognizes the same consensus phosphorylation sequence SQ/TQ, and also undergoes DSB-induced autophosphorylation, which is required for DSB repair^[125]. In addition, inactivation of either DNA-PK or ATM results in immunodeficiency; the former results in defective V(D)J recombination that leads to *scid* (severe combined immune deficiency) mutations^[126,127], whereas the latter results in the disruption of immune gene rearrangement^[128]. We propose that in the presence of Ku70/Ku80, DNA-PKcs and ATM may undergo conformational changes to be suitable for the suggested role of further wrapping around DNA^[59–63]. Indeed, recent electron microscopy-based structural analyses of both DNA-PKcs^[129–131] and ATM^[63] suggest a similar architecture consisting of a "head" and a "palm" domain connected by an "arm". The palm domain binds DNA, which induces conformational changes and triggers an interaction between initially distant palm and head regions^[130]. These DNA-induced conformational changes alter the catalytic core and regulate the kinase activity^[131]. The difference between DNA-PKcs and ATM is that DNA-PKcs is activated in G₁ and is required for non-homologous end joining (NHEJ) and apoptosis if DNA damage is excessive^[132], while ATM is activated in S and G₂ phases and is required for S-phase checkpoint and homologous recombination (HR)^[40].

Another connection between ATM and Ku70/Ku80 is that yeast MRX is not only required for DSB signaling and HR, but also works with Ku70/Ku80 for NHEJ^[133–136] and telomere maintenance^[77,93,137,138]. The budding yeast *Saccharomyces cerevisiae* predominantly employs HR to repair DSB over NHEJ. On some occasions when DSB repair can be processed by either process, NHEJ was shown to precede HR^[139]. A compiled model can be proposed in which the telomere acts as a repository for Ku proteins, which relocate to DSB after DNA damage^[140] and recruit MRX^[141]. MRX can assist to recruit and activate Lif1 and Dnl4^[142], resulting in ligation of the broken ends. However, in budding yeast, the MRX complex most likely initiates 5' to 3' end resection^[76], hence committing to repair by HR. This commitment is probably due to the broken DSB ends that are unsuitable for direct ligation, or to the recruitment of Tel1 by MRX that

activates cell-cycle checkpoints and subsequent recruitment of other HR proteins^[107]. A similar regulatory cascade may also exist in higher eukaryotes; however, because mammalian cells have an extended G₁ phase, the initial DSB binding by Ku70/Ku80 may stimulate NHEJ more frequently than in yeast. In addition, mammalian cells contain 3 major PIKK family proteins, namely ATM, ATR and DNA-PKcs, involved in different modes of DNA repair and overlapping signal transduction in response to DNA damage. The mechanism of their recruitment to sites of DNA damage is conserved via a newly discovered motif^[94]. For example, ATR is recruited to a single-stranded DNA by ATRIP (ATR-interacting protein)^[143,144], whereas DNA-PKcs and ATM are recruited to DSB by Ku70/K80 and MRN, respectively. Based on the above observations, we have proposed a working model of cellular response to DSB in mammals, as presented in Figure 2.

Finally, the physical and functional interactions among Ku, MRN/MRX and ATM/Tel1 can also be found in telomeres. Both yeast^[145] and human^[146] Ku is bound to

telomeric DNA and protects its 3' overhang. The MRX complex in budding yeast is also associated with telomeres, and mutants deficient in Ku or MRX activity exhibit telomere shortening^[137,147]. Similar phenotypes are also observed in their homologous mutants in fission yeast and plants^[148-150]. Tel1 works together with MRX by either regulating the access of telomerase to the DNA end^[151], and/or preventing telomere end-to-end fusion^[152]. Tel1 is activated by the MRX complex and in turn phosphorylates MRX^[153], suggesting functional conservation between yeast and mammals. However, unlike Tel1, ATM has not been implicated in telomerase access to the telomere. Nevertheless, AT patient cells were shown to have shortened telomeres^[39,154], as well as other telomere abnormalities^[155,156]. Furthermore, transgenic mice defective in both ATM and telomerase dramatically increase telomere dysfunction compared to single mutants^[157], suggesting roles of ATM in telomere maintenance. The telomeric functions of ATM may be related to some symptoms of AT patients.

Figure 2. A proposed model for cellular response to DNA double-stranded breaks (DSB) in mammalian cells. The Ku70/Ku80 heterodimer binds to the broken DNA ends first, followed by the recruitment or the independent binding of the MRN complex (consisting of Mre11, Rad50 and Nbs1). If DNA-PKcs is recruited by interacting with the C-terminus of Ku80, cells are committed to non-homologous end joining. On the other hand, if ATM is recruited by interacting with the C-terminus of Nbs1, Ku70/Ku80 may be released and cells are probably committed to homologous recombination repair. Recruitment of ATM also leads to substrate phosphorylation and cell-cycle checkpoints. It should be noted that MRN may also bind to DNA ends without the assistance of Ku70/Ku80. Recent literature suggests that unwinding of DNA ends by MRN activates ATM and cell-cycle checkpoints, whereas DNA end resection by MRN initiates homologous recombination. The 2 processes may be co-regulated.

Conclusions

Since the initial discovery of the AT mutated gene 10 years ago, knowledge regarding the molecular mechanisms of AT and its related diseases has accumulated rapidly. It is now clear that the primary function of ATM and MRN, which is related to NBS and ATLD, is to respond to DNA damage, especially DSB. Two primary activities are cell-cycle checkpoint and DNA repair through HR, and these are achieved mainly via protein phosphorylation of various substrates, including ATM and MRN themselves. ATM and MRN are also involved in telomere maintenance and protection from chromosomal translocation, as well as efficient immune gene recombination. Although these cellular phenotypes are able to explain most phenotypes observed in AT and AT-related disease, some other associated symptoms may be due to diverse ATM substrates, unique MRN functions not shared by ATM, as well as the hypomorphic nature of the disease. Despite great advances in research, many questions remain to be answered especially with regard to treatment. Future efforts shall be directed to translational research for the cure and prevention of AT its and related diseases.

Acknowledgements

The authors wish to thank Michelle HANNA for proof-reading the manuscript and other laboratory members for their helpful discussion. This work is supported by a Canadian Institutes of Health Research operating grant (MOP-53240) to WX.

Abstract

Cardiovascular disease is the most common cause of death in the diabetic population and is currently one of the leading causes of death in the United States and other industrialized countries. The health care expenses associated with cardiovascular disease are staggering, reaching more than US\$350 billion in 2003. The risk factors for cardiovascular disease include high fat/cholesterol levels, alcoholism, smoking, genetics, environmental factors and hypertension, which are commonly used to gauge an individual's risk of cardiovascular disease and to track their progress during therapy. Most recently, these factors have become important in the early prevention of cardiovascular diseases. Oxidative stress, the imbalance between reactive oxygen species production and breakdown by endogenous antioxidants, has been implicated in the onset and progression of cardiovascular diseases such as congestive heart failure and diabetes-associated heart dysfunction (diabetic cardiomyopathy). Antioxidant therapy has shown promise in preventing the development of diabetic heart complications. This review focuses on recent advances in oxidative stress theory and antioxidant therapy in diabetic cardiomyopathy, with an emphasis on the stress signaling pathways hypothesized to be involved. Many of these stress signaling pathways lead to activation of reactive oxygen species, major players in the development and progression of diabetic cardiomyopathy.

Introduction

Cardiovascular disease is the leading cause of death in Western societies, causing approximately one million deaths annually^[1]. It is both a primary and a secondary disease, resulting from several other disorders, such as hypertension, diabetes, alcoholism, obesity and the metabolic syndrome. Cardiovascular disease is defined as any disorder that decreases normal heart and/or vascular function. One of the leading causes of cardiovascular disease is diabetes, of both type 1 and type 2 origins. The incidence of diabetes is predicted to double by the year 2030 because of people's sedentary lifestyles and an ever-growing cluster of pre-diabetic syndromes including metabolic syndrome, obesity, and insulin resistance^[2]. Almost all of these metabolic disturbances

are considered major risk factors in the development of heart dysfunction and congestive heart failure^[3–7]. Nevertheless, the cellular mechanisms that relate to the development of cardiovascular complications in patients with diabetes have not been fully elucidated.

Diabetes mellitus is a group of metabolic disorders that are characterized by hyperglycemia resulting from defects in insulin secretion, action or both. Chronic hyperglycemia causes end-stage organ damage, dysfunction and failure of various organs, including the kidneys, nerves, eyes, blood vessels and hearts. Several pathological processes are involved in the development of diabetes, ranging from autoimmune destruction of the β -cells of the pancreas with resultant insulin deficiency (type 1 diabetes) to abnormalities that result in resistance to insulin (type 2 diabetes).

Impairment of insulin action and resistance to the action of insulin often coexist in the same patient, so it is unclear which abnormality is responsible for the hyperglycemia. Symptoms of chronic hyperglycemia include polyuria, polydipsia, weight loss and blurred vision. Long-term complications of diabetes include retinopathy^[8] with potential loss of vision; peripheral neuropathy^[9] with risk of amputation; autonomic neuropathy causing gastrointestinal, genitourinary and cardiovascular symptoms; and nephropathy^[10] leading to kidney failure.

Functional alterations in diabetic cardiomyopathy

Sustained diabetes mellitus leads to a deterioration of heart function that is known as diabetic cardiomyopathy, which occurs independently of the macro- and micro-vascular diseases that are frequently seen in diabetic patients^[11]. Diastolic dysfunction is the most prominent mechanical defect in diabetic cardiomyopathy and is characterized by decreased compliance and slower rates of myocardial relaxation^[11–13]. Both systolic and diastolic dysfunctions have been characterized to include prolonged contraction and relaxation, reduced velocity of contraction and relaxation, and depressed myocardial contractility in whole heart, tissue, and isolated ventricular myocytes from both diabetic patients and experimental animals^[11–13]. Functional changes have been observed by electrocardiogram and echocardiography, which are manifested by shorter left ventricular ejection time, increased pre-ejection period, increased wall stiffness, decreased fractional shortening, decreased rate of left ventricular filling and increased action potential duration in diabetes^[14,15]. All of these findings suggest that diabetic cardiomyopathy is represented by left ventricular dysfunction.

The chronic alterations at the end stages of diabetes are believed to be due to increased glucose levels^[16,17]. Although the pathogenesis of diabetic cardiomyopathy has not been precisely described, several mechanisms have been speculated, including reduced energy production because of decreases in mitochondrial respiration and pyruvate dehydrogenase activity, accumulation of free radical species, glucose toxicity-induced oxidative stress and malfunction of cardiac contractile and intracellular Ca²⁺ regulatory proteins such as myosin, sarco(endo)plasmic reticulum Ca²⁺-ATPase (SERCA), and Na⁺-Ca²⁺ exchanger^[18–21]. The increased risk of diabetic cardiomyopathy and other heart complications warrants stringent and aggressive treatment against hyperglycemia, hyperinsulinemia, dyslipidemia and oxidative stress.

The most commonly used therapeutic regimes in diabetic patients with heart dysfunction include angiotensin-convert-

ing enzyme inhibitors, digoxin, diuretics, β -blockers, Ca²⁺ antagonists and spironolactone. Insulin-sensitizing agents such as thiazolidinediones are often prescribed in the treatment of diabetes more often than insulin-secretion-enhancing agents to avoid hyperinsulinemia and insulin resistance. In addition to pharmacological interventions, primary care for diabetic patients also includes lifestyle modifications such as smoking cessation, weight control, exercise and dietary restriction^[7].

Diabetic cardiomyopathy type 1 diabetes

Type 1 diabetes mellitus leads to a cardiomyopathy in both human and animal models. The existence of a diabetic cardiomyopathy in humans is based on the presentation of ventricular dysfunction in patients without evidence of any other known cardiovascular disease (reviewed in Sowers *et al*^[22] and Spector^[23]). The clinical presentation of diabetic cardiomyopathy in type 1 diabetic patients was first presented by Rubler *et al*^[24] based on four diabetic patients who suffered from congestive heart failure (CHF) in the absence of discernable coronary artery disease, valvular or congenital heart disease, hypertension or alcoholism. Numerous studies carried out since 1972 have supported the view that diabetic cardiomyopathy is a pervasive problem in type 1 diabetes and is first manifested by diastolic dysfunction^[11,23]. Diabetic cardiomyopathy in experimental animal models of type 1 diabetes is characterized by phenotypic changes in the ventricular myocytes that occur in the presence or absence of coronary artery disease. This cardiomyopathy is well described in animal models with long-term type 1 diabetes and results in abnormal cardiomyocyte excitation-contraction (E-C) coupling [eg, prolonged action potentials, slowed cytosolic Ca²⁺ effluxes and slowed myocyte shortening and relengthening (reviewed by Pierce and Russell^[25] and Chatham *et al*^[26])]. The cellular mechanisms that contribute to myocyte dysfunction involve depressed expression and function of SERCA and Na⁺/Ca²⁺ exchanger (NCX)^[27]. Regulation of E-C coupling is also impaired in diabetic hearts, such that β -adrenergic receptor signaling is depressed, which may result from changes in β -adrenergic receptor density or redistribution of β -adrenergic receptor subtypes^[28], or perhaps signaling downstream of the receptors^[29]. Elevated protein kinase C (PKC) activity and changes in the expression of specific PKC isoforms are also found in type I diabetic hearts^[30,31].

Diabetic cardiomyopathy in type 2 diabetes

The more prevalent type 2 diabetes is a combination of

resistance to insulin action and an inadequate compensatory insulin secretory response. Type 2 diabetic patients are able to survive with little or no insulin supplementation; however dietary modification and exercise are imperative for living with the disorder. Diabetic cardiomyopathy has also been determined clinically in the type 2 diabetic patients. Investigators in the Strong Heart Study (SHS) performed detailed echocardiographic analysis of a population of American Indians with a high rate of type 2 diabetes and reported that diabetes was associated with increased left ventricular (LV) mass, LV wall thickness, reduced systolic and particularly diastolic function, independent of hypertension^[32,33]. Similar to diabetes, investigators from the Framingham Heart Study reported increased LV mass and wall thickness in individuals with glucose intolerance and insulin resistance^[34]. There was also an association between left atrial (LA) size and insulin resistance. Since no relationship was found between systolic function and insulin resistance, one explanation for the relationship between LA size and insulin resistance offered was that the rising LA size might reflect the presence of diastolic dysfunction in insulin resistance (type 2 diabetes)^[34]. Other studies in patients with diagnosed type 2 diabetes support the notion that the earliest cardiac abnormality is diastolic dysfunction^[35]. Several investigators have experimentally shown that diabetes mellitus is associated with a specific cardiomyopathy^[12,13] and depressed cardiac function independent of macro-/micro-vascular disease, suggesting the existence of a primary myocardial defect in both type 1 and type 2 diabetes mellitus^[13,36].

Impaired insulin action (ie, insulin resistance) is characterized by a compensatory hyperinsulinemia and hyperlipidemia, which are major metabolic dysfunctions associated with the early stages of type 2 diabetes. Elevated plasma insulin and lipid levels can lead to numerous metabolic and pathophysiological derangements in various tissues, including the heart. Abnormal ventricular systolic and diastolic functions are reported in type 2 patients presenting without macrovascular disease or hypertension, providing indirect evidence that there is a diabetic cardiomyopathy in humans^[37]. Furthermore, there is a considerable evidence that diastolic dysfunction occurs early in the disease process, which may contribute to high cardiac mortality among diabetic patients^[38,39]. In clinical studies, detectable cardiac dysfunction has been reported to occur as early as the glucose intolerance phase (ie, hyperinsulinemia and hyperglycemia) that follows insulin resistance^[40].

The risk of congestive heart failure and other cardiovascular diseases is greatly increased in diabetic patients^[41]. The Framingham Heart Study revealed that diabetic men had

more than twice the frequency of congestive heart failure than did non-diabetic males, whereas diabetic women had a risk that was five times greater than non-diabetic women^[34]. The development of diabetic cardiomyopathy is dependent on many factors; however, it is likely that all patients with diabetes will eventually develop some degree of diabetic cardiomyopathy.

Mechanisms of diabetic cardiomyopathy

Diabetic cardiomyopathy is a major reason for the high morbidity and mortality in diabetic populations^[41], particularly among elderly people and postmenopausal women. In adult patients with diabetes, the risk of cardiovascular disease is three to five times greater than that in the general population. Several mechanisms for the development of cardiomyopathy have been postulated, including alterations in intracellular ion homeostasis, reduction in intracellular energy metabolism, alteration in glucose metabolism, disrupted polyol pathway and enhanced oxidative stress. Several mechanisms have been proposed to explain how all of the pathologies involved in the progression of diabetic cardiomyopathy can result from hyperglycemia. Four main hypotheses have been presented to describe how hyperglycemia can cause all of these diabetic complications^[42]: increased polyol pathway flux, increased advanced glycation end-product (AGE) formation, increased protein kinase C isoform expression, and increased hexosamine pathway flux (Figure 1). We hope to show that all of these pathways, as well as several others, lead to hyperglycemia and increased reactive oxygen species (ROS) formation, causing diabetic cardiomyopathy.

Alterations in intracellular ions

Changes in intracellular cations are directly related to the altered electromechanical activities of diabetic hearts. Alterations in intracellular Na^+ are often accompanied by a decrease in K^+ and Ca^{2+} in diabetic heart, which may be related in part to a diabetes-induced conformational change in the Na^+ - K^+ -ATPase pump^[43]. Decreases in Ca^{2+} uptake, Ca^{2+} binding to the sarcolemma and Ca^{2+} intake by the myofibrillar Ca^{2+} -ATPase activity have all been shown in diabetic rat hearts^[43], which are partially reversible by insulin supplementation. Although the importance of these alterations in myocardial dysfunction seen in diabetes is not yet clear, the presence of abnormalities in Ca^{2+} handling and β -adrenergic stimulation is of paramount importance in understanding these myocardial dysfunctional changes^[26]. Alterations in α_1 -adrenergic signaling in streptozotocin (STZ)-induced dia-

Figure 1. Schematic diagram showing the possible contributing factors to oxidative stress en route to the onset of diabetic cardiomyopathy in both type 1 and type 2 diabetes.

betic rat hearts have also been shown.

Increased polyol pathway flux

Increased glucose utilization by aldose reductase has been implicated in the development of diabetes complications. Aldose reductase is the first enzyme in the polyol pathway, which catalyses the NADPH-dependent reduction of carbonyl compounds, including glucose. In the polyol pathway, glucose is reduced to sorbitol by aldose reductase in the presence of NADPH, and sorbitol is then oxidized by sorbitol dehydrogenase (SDH) to fructose at the cost of NAD^+ . Normally, aldose reductase has a low affinity for glucose in the non-diabetic, low-glucose state. However the affinity for glucose is dramatically increased in the diabetic, high-glucose state, which converts glucose to sorbitol, with resultant decreases in NADPH. It has been demonstrated that increased aldose reductase activity in diabetic animals is correlated with increased $NADH/NAD^+$ ^[44]. There is further support from the facts that sorbitol and fructose levels in diabetic hearts are approximately nine-fold higher, and $NADH/NAD^+$ levels in diabetic hearts are approximately four-fold higher than in normal hearts^[44]. Experiments have demonstrated that cytosolic $NADH/NAD^+$ was reduced by both SDH^[45] and aldose reductase inhibition^[44,46]. These data indicate that the polyol pathway is a target for cardioprotective interventions. This notion is supported by the observation

that nitric oxide (NO) maintains aldose reductase in an inactive state and that this repression is relieved in diabetic tissues^[47]. Thus, increasing NO availability may be a useful strategy for inhibiting the polyol pathway and preventing the development of diabetes complications. It is worth mentioning that contributions of the polyol pathway in diabetes are often tissue- and species-specific and may not fully explain the pathogenesis of all forms of diabetic complications^[42].

One mechanism whereby increased polyol pathway flux leads to the complications of diabetes discussed earlier is that oxidation of sorbitol by NAD^+ increases the cytosolic $NADH:NAD^+$ ratio, leading to inhibition of the enzyme glyceraldehydes-3-phosphate dehydrogenase (GADPH) and increased concentrations of triose phosphate^[42]. Increased triose phosphate could potentially increase the formation of AGEs and diacylglycerol (DAG), thus activating PKC isoforms^[42].

Another mechanism whereby increased polyol pathway flux causes deleterious effects is that reduction of glucose to sorbitol by NADPH consumes NADPH, a cofactor in the generation of reduced glutathione (GSH), which could lead to increased oxidative stress. It has been shown that decreased levels of GSH are present in the lenses of transgenic mice overexpressing aldose reductase^[48]. These observations have led many people to believe that this is the main mechanism whereby increased polyol pathway flux leads to

many of the complications seen in diabetes.

Increased advanced glycation end products formation

Advanced glycation endproducts are enhanced in the presence of hyperglycemia and oxidative stress^[49,50]. They bind to their cell-surface receptors (RAGE) resulting in the activation of postreceptor signaling, generation of intracellular ROS and the activation of gene expression^[51–58]. AGEs have also been shown to be mediators of late diabetic complications and chronic vascular disease^[59].

The importance of AGEs in the development of diabetic complications is seen in the observation that two structurally similar AGE inhibitors partially prevented diabetic complications in the retina, kidney and nervous system^[60–62]. One of the mechanisms how AGE precursors target cells is through the binding of AGE receptors to endothelial cells, mesangial cells and macrophages, inducing receptor-mediated production of ROS. This receptor ligation increases the production of the transcription factor NF- κ B, also causing increased oxidative stress.

Some of the most striking data on the role of AGE and the development of diabetic complications has been obtained when looking at the receptor for AGE, RAGE. RAGE suppressed the formation of macrovascular disease in a type I diabetic mouse model in a glucose- and lipid-independent fashion^[63]. It has also been shown that blockage of RAGE inhibited the formation of diabetic nephropathy and enhanced wound repair (known to be a problem in diabetics) in murine models. The mechanism involved in RAGE-associated development of diabetic complications appears to be related to increased production of ROS^[42].

Activation of protein kinase C isoforms

Protein kinase C is also increased in the tissues of diabetic patients^[64]. Activation of the PKC pathway by hyperglycemia can occur directly or indirectly (via ligation of AGE receptors^[65] or increased activity of the polyol pathway^[66]) and can synergize with other kinase pathways, that is, the MAPK pathway. Interactions between these pathways are likely to play a role in determining the long-term effects of hyperglycemia. As discussed earlier, sorbitol, whose formation from glucose is catalyzed by aldose reductase, is increased when intracellular glucose concentrations rise^[67], and can accumulate intracellularly, which can cause cell damage. The p38 mitogen-activated protein kinase (MAPK) and c-Jun N-terminal kinase (JNK) pathways are also activated by sorbitol. The significance of the sorbitol pathway

as a cause of diabetic complications was demonstrated in transgenic mice that overexpressed the aldose reductase gene^[48,68–70] and by data showing that inhibitors of this enzyme prevent the development of long-term diabetic complications in these animals^[71].

Increased hexosamine flux and glucose auto-oxidation

Hyperglycemia increases flux through the hexosamine pathway by providing more fructose-6-phosphate for glutamine: fructose-6-phosphate amidotransferase (GFAT), the rate-limiting enzyme of the pathway. The effect of hyperglycemia on flux of the hexoasamine pathway probably reflects increased fructose-6-phosphate levels, which result from inhibition of GAPDH by ROS^[72].

Recently, ROS formation due to glucose autooxidation has been hypothesized to play a role in the pathogenesis of diabetic cardiomyopathy in diabetic populations; however, no unifying hypothesis exists as to how glucose autooxidation causes any of the complications seen in diabetes.

Alterations in stress signaling pathways

Hyperglycemia in diabetes causes changes in membrane function and metabolic and biochemical alterations within days, changes in contractile function within weeks, and morphological changes and heart dysfunction within months^[26]. A significant increase in oxidative damage via lipid peroxidation was observed in the hearts of diabetic rats^[73]. Production of hydroxyl radicals was also detected in diabetic rats induced by streptozotocin^[74]. In the heart, hydroxyl radical production and elevated blood glucose concentration were directly correlated with the amount of STZ injected into rats, up to 60 mg/kg body weight^[74]. With the use of fluorescent probes, myocytes isolated from STZ-induced diabetic mice were used to detect hydrogen peroxide and hydroxyl radicals, and increased ROS was observed compared with control mice^[21]. Oxidative damage caused by ROS has been shown to lead to multiple complications of diabetes^[75–78]. Blocking ROS and superoxide formation, however, has been shown to prevent hyperglycemia-induced organ damage in diabetes^[79].

One major intracellular target of hyperglycemia and oxidative stress is NF- κ B^[80–84], which can be activated by a variety of exogenous and endogenous stimuli, including hyperglycemia, elevated free fatty acids, ROS, tumor necrosis factor- α (TNF- α) and other proinflammatory cytokines, p38 MAP kinase and ultraviolet irradiation^[82]. NF- κ B plays a crucial role in mediating immune and inflammatory responses and apoptosis. Alterations in NF- κ B signaling are

associated with a number of chronic diseases, such as diabetes and atherosclerosis. The c-jun NH(2)-terminal kinases (JNK) and p38 MAPKs are members of the complex superfamily of MAP serine/threonine protein kinases and are known as stress-activated kinases. This is due to the fact that the activities of these enzymes are stimulated by a variety of exogenous and endogenous stress-inducing stimuli, including oxidative stress, ROS, hyperglycemia and proinflammatory cytokines^[85]. JNK is activated by hyperglycemia-induced oxidative stress and is probably involved in apoptosis, which can be suppressed by the antioxidant vitamin C^[86] and enhanced by angiotensin II^[87]. p38 MAPK is also activated in response to hyperglycemia and in diabetes. In the glomeruli of STZ-induced diabetic rats, p38 MAPK activity was increased compared with control rats, followed by increased phosphorylation of heat shock protein (HSP) 25, a downstream substrate of p38 MAPK. These effects appeared to be the result of increased ROS production^[88]. Taken together, these data suggest that NF- κ B, JNK and p38 MAPK pathways are potential stress-signaling systems that can lead to late complications of diabetes.

Nitric oxide is an important regulator of cardiac function. However, NO may react with the surrounding O₂⁻ to form peroxynitrite (ONOO⁻). Peroxynitrite, a very active radical similar to the hydroxyl radical, interacts with cytoplasmic proteins to form nitrotyrosine, which has been indicated as a marker for reactive nitrogen species-induced oxidative damage under *in vivo* conditions^[21,89]. It has been suggested that excessive NO is pathophysiological because of its ability to form pro-oxidants. Cardiac NO production and NOS protein levels have been found to be elevated in the hearts of diabetic animals^[90]. This is consistent with the observation of a significant increase in nitrotyrosine concentration in myocytes in the hearts of diabetic mice^[21].

Role of antioxidants in diabetic cardiomyopathy

Mitochondrial damage is related to ROS formation and plays an important role in the development of diabetic cardiomyopathy^[91,92]. Coenzyme Q (CoQ) is an important component in mitochondrial energy metabolism and is also a potent endogenous antioxidant *in vivo*. In heart mitochondrial preparations of diabetic rats, the concentration of α -tocopherol was increased; however, the concentration of both CoQ-9 and CoQ-10 was decreased^[92]. Data from our group have shown that the reduction in coenzyme levels from diabetic animals is attenuated with the supplementation of insulin-like growth factor I (IGF-1)^[19].

It is important to note that contractile function of the heart requires a high metabolic demand, and the mitochon-

drial respiratory chain is the primary energy-releasing system in the myocyte. Through the respiratory chain, a series of oxidation-reduction reactions continually take place in the myocyte. Therefore, an efficient antioxidant system, including superoxide dismutase (SOD), catalase, glutathione peroxidase (GPX), glutathione (GSH) and α -tocopherol are critical to effective functioning of the myocardium. However, in experimental animal models, the heart levels of these antioxidants are much lower than in other organ systems, even in non-diabetic normals^[93,94]. In addition, hyperglycemia can impair and decrease the amount of antioxidants within the heart of a diabetic animal^[95-97] making it more vulnerable to ROS-induced damage.

The increase in ROS serves to decrease the antioxidant capacity of the diabetic myocardium, contributing significantly to oxidative stress and resultant myocardial damage. This damage causes cardiac morphological and functional abnormalities. Epstein and colleagues^[98,99] showed that type 1 diabetic cardiomyopathy could be prevented when the antioxidants metallothionein (MT) and catalase were overexpressed specifically in the heart. They also showed that ROS production was enhanced in genetically diabetic mice (OVE26), which could be prevented by genetically crossing the diabetic mice with those overexpressing the MT or catalase genes^[98,99].

Cell death is an important determinant of cardiac remodeling because it causes a loss of contractile units, compensatory hypertrophy of myocardial cells and reparative fibrosis^[17]. Apoptotic cell death associated with increased oxidative stress in multiple organ systems of diabetes mellitus has been well documented^[100-102]. Recent *in vivo* experiments have demonstrated the induction of myocardial cell apoptosis in experimental diabetic rats^[103], mice^[21] and diabetic patients^[89]. Heart specimens from diabetic patients (both hypertensive and non-hypertensive) showed an increase in myocyte, endothelial and fibroblast apoptosis^[89]. The increased cell death was associated with an increase in ROS formation^[21,89,103]. However, the precise mechanism(s) by which ROS accumulation leads to compromised heart function and the effect of antioxidant therapy in diabetic subjects is largely unknown. Therefore, it is important to study the signaling pathways and molecular mechanisms by which hyperglycemia-induced (or, presumably, STZ-induced) oxidative stress leads to cell death and myocardial pathogenesis.

Role of the renin-angiotensin system in the development of diabetic cardiomyopathy

The renin-angiotensin system (RAS) is known to play a major role in the regulation of blood pressure and other func-

tions of the cardiovascular system^[104]. Enhanced RAS is implicated in the development of diabetic cardiomyopathy and other heart dysfunctions including coronary insufficiency, congestive heart failure and hypertensive cardiomyopathy^[105]. The growth-promoting effects of angiotensin II are mediated primarily through its type 1 receptor (AT₁) and the action of RAS is speculated to contribute to diabetic cardiomyopathy^[105]. It has been shown that stimulation of the AT₁ receptor generates oxygen-derived free radicals, having detrimental effects on the cardiovascular system^[106,107]. The AT₁ receptor has been shown to be coupled to several postreceptor signaling pathways, including Janus kinase (JAK)/signal transducer and activator of transcription (STAT) and NADPH oxidase^[104,108,109]. However, the precise role of RAS, in particular the AT₁ receptor, in the development of diabetic cardiomyopathy is still speculative and further study is warranted.

Future directions

Diabetic cardiomyopathy is a clinical problem that is present in both type 1 and type 2 diabetes, which potentially involves myocyte death and interstitial fibrosis. These myocyte and non-myocyte alterations may contribute to compromised ventricular function in diabetes, which is one of the leading causes of death in the world today. It is critical to investigate the underlying (myocyte) causes of diabetic cardiomyopathy and the synergistic impact of oxidative stress in combination with antioxidant therapy on the development of heart dysfunction associated with diabetes.

Abstract

The occurrence of cardiac arrhythmias is related to the abnormality of ion channels not only in sarcolemma but also in the sarcoplasmic reticulum, which regulates the process of calcium release and up-take intracellularly. Patterns of ion channelopathy in the sarcolemma can be divided into single channel disorder from gene mutations and multiple channels disorder in a diseased hypertrophied heart. Abnormal RyR2, FKBP12.6, SERCA2a, and PLB are also involved in the initiation of cardiac arrhythmias. Maladjustment by hyperphosphorylation on the ion channels in the sarcolemma and RyR2-FKBP12.6 and SERCA2a-PLB is discussed. Hyperphosphorylation, which is the main abnormality upstream to ion channels, can be targeted for suppressing the deterioration of ion channelopathy in terms of new drug discovery in the treatment and prevention of malignant cardiac arrhythmias.

Introduction

Cardiac arrhythmias mostly occur in diseased hearts as a result of an abnormality in ion channels^[1]. Diseased hearts with overt cardiac remodeling are at risk of developing severe and life-threatening arrhythmias. Patients suffering from sudden coronary death (SCD) were monitored with ECG to manifest ventricular tachyarrhythmias. Between 50% and 80% of deaths in patients suffering from congestive heart failure are caused by cardiac arrhythmias^[2]. There have been significant advances in the molecular biological considerations of cardiac arrhythmias^[3], however, there has been no success in suppressing ventricular tachyarrhythmias using antiarrhythmic agents^[4,5]. Electronic devices and electrical defibrillators remain the first choice in controlling ventricular tachyarrhythmias.

Continuous effort has been made to search for new and effective antiarrhythmic agents for controlling life-threatening cardiac arrhythmias. The efficacy of antiarrhythmic agents to prevent cardiac sudden death was evaluated in patients with post-infarcted heart in clinical trials. Cardiac Arrhythmias Suppressing Trial (CAST, 1989) reported an

increase in the mortality of the treated groups (flecainide and encainide) against the placebo^[6]. A dramatic shift from Class I agents to Class III agents was made^[4], and pure Class III drugs were considered as ideal agents (*d*-sotalol) in survival test with oral *d*-sotalol (SWORD, 1994). The *d*-sotalol, which is free from β -adrenergic blocking activity but can block the rapid component of delayed rectifier outward K^+ currents (I_{Kr}), only failed again with a higher mortality (3.9%) than that in the placebo (2.0%)^[4,5]. The lack of success in the development of antiarrhythmic agents is likely because of the lack of awareness of the mechanisms of ion channelopathy in the diseased myocardium.

Effort to gain more insight into molecular aspects of ion channelopathy in cardiac arrhythmias in both the inherited long QT syndrome (LQTS) and cardiac remodeling of diseased hearts has been ongoing^[7]. Cardiac remodeling resulting from infarction or cardiomyopathy has been targeted to investigate the mechanisms underlying cardiac arrhythmias. Aberrant molecular biology and ion channelopathy are focused on the affected myocardium. The responses to varying drug treatments are compared in amelioration and exacerbation of cardiac arrhythmias.

Different patterns of sarcolemmal ion channelopathy

Single channelopathy in LQTS Gene mutations which alters the peptide sequence of the K^+ and Na^+ ion channels in cardiomyocytes caused LQTS. There are three kinds of LQTS^[1,7,8]: (i) downregulation of the slow component of delayed rectifier outward K^+ currents (I_{Ks}) by mutations in the *KvLQT1* (*KCNQ1*), and *HMINK* (*KCNE1*) gene; (ii) downregulation of the I_{Kr} channels by mutations in the *HERG* (*KCNHI*) gene; (iii) upregulation of the sodium currents (I_{Na}) by mutations in the *SCN5A* gene. Ion channelopathy induced by mutations only involves an individual channel^[9,10]. Two mutations in the *HERG* gene were found. An early appearance of STOP codon located at the nucleotide binding domain left one dysfunctional channel responsible for LQTS, but another in the minor region of the peptide chain as a result of polymorphism did not cause the change of QT interval^[10].

Multi-channelopathy in cardiac remodeling In the hypertrophied ventricle following myocardial infarction or cardiomyopathy, the multiple ion channels involving the Na^+ , K^+ and Ca^{2+} currents in the lipid membrane were downregulated in function or mRNA abundance^[11-13], rather than being limited to a single one^[14]. In the pulmonary hypertension the downregulation of the genes encoding the I_{to} channels (*Kv 4.2* and *Kv 4.3*) was found in the hypertrophied right ventricle, but not the left ventricle^[15]. The ion channelopathy in cardiac remodeling can be referred to as multiple and non-selective channelopathy, and is likely to be secondary to the pathological lesions upstream to the ion channels, including lesions in the affected lipid membrane and the altered transmembrane signaling system^[9,10]. Ion channelopathy can be regressed when lesions upstream to the ion channels are relieved.

Upregulation of ion channels in cardiomyopathy by L-thyroxin A model of cardiomyopathy in rats was induced by repeated administration of *L*-thyroxin for 10 d which manifested exaggerated cardiac arrhythmias after ischemia/reperfusion^[16]. The arrhythmogenesis in the model was associated with remarkable cardiac remodeling and an imbalance of transmembrane distribution of cation, shown by an augmented activity of Na^+/K^+ ATPase and Ca^{2+} ATPase in the sarcolemma and mitochondria^[17,18].

The channels of slow component of delayed rectifier outward K^+ currents (I_{Ks}) and the rapid component of delayed rectifier outward K^+ currents (I_{Kr}) were upregulated accompanied with myocardium remodeling induced by *L*-thyroxin^[19] which would cause a shortened action potential duration (APD). However, the $I_{Ca,L}$ was exacerbated in

isolated myocytes in this model which had the potential to prolong APD^[20]. The length of APD, in general, is not dependent on ions movement in a single channel, but is modulated by the balance of total currents in the repolarization of the membrane^[9]. A simple mathematic equation denotes the balance between the influx and efflux of ions across the membrane: $APD = (I_{Ca,L} \cdot I_{Na}) / (I_{Kr} \cdot I_{Ks})$. The final impact on the APD is dependent on the net influence summarized by the individual ion current. Varied repolarization, which contributes to cardiac arrhythmias in a diseased heart, shows retardation and dispersion of APD. The abnormality of repolarization can be measured by the length of either APD or the QT interval in ECG traces. Dispersion of APD between the right and left ventricle in association with arrhythmogenesis was developed in a hypertrophied canine heart by chronic destruction of the atrioventricular node^[21]. More dispersed ion currents in repolarization create a higher risk of developing life-threatening arrhythmias. Arrhythmic models of the canine diseased heart and rat cardiomyopathy by *L*-thyroxin share important properties of dispersed repolarization and disturbed multiple ion channels^[21,22].

The normal function of some ion channels is modulated by phosphorylation at the nucleotide binding domains of the channel peptide, mediated by cAMP and PKA^[3,22]. Hyperphosphorylation under the pathological condition serves as an important etiological factor to develop severe cardiac arrhythmias in diseased status. The upregulation of I_{Ks} , I_{Kr} , and $I_{Ca,L}$ in cardiac remodeling by chronic administration of *L*-thyroxin was likely to cause overphosphorylation, so arrhythmias in this model were effectively suppressed by propranolol^[16].

Ion channelopathy in sarcoplasmic reticulum

RyR2 and SERCA2a in the sarcoplasmic reticulum (SR)

A rise of free calcium in the cytosol is initiated by an influx of Ca^{2+} through $I_{Ca,L}$ and is amplified up to 10-fold by calcium release from the RyR2/calcium release channels, which is mediated by the calcium-induced calcium release (CICR) that promotes a boost of free calcium in the systole. A rapid conversion into the diastolic phase is performed by SERCA2a/calcium-uptaking channels. The calcium-release channels (RyR2) and the uptake channels (SERCA2a) of the SR are modulated separately by two proteins, calstabin 2 protein (FKBP12.6, the stabilizing FK 506 binding protein) and phospholamban (PLB), which are under the control of the phosphorylation of PKA^[23]. The association of FKBP 12.6 to the macromolecule RyR2 is essential in stabilizing the Ca^{2+} releasing function by tightly closing the channel against the low level of Ca^{2+} in the diastolic period. The movement

of the free calcium from cytosol into the SR by SERCA2a is slow as a result of suppression by PLB at the resting state. The efficacy of SERCA2a increases significantly when the PLB is phosphorylated. This is caused by the removal of the suppression through PLB phosphorylation. An abnormal boost of the free calcium in the diastolic phase is provided by the derangement of either RyR2-FKBP12.6 or PLB-SERCA2a systems that play active roles in exhibiting cardiac arrhythmias during stress-related conditions^[3,24,25].

Inherited arrhythmogenic disorders from mutations of RyR2 gene There are two inherited diseases that manifest cardiac arrhythmias stemming from RyR2 gene mutations. Arrhythmogenic right ventricular dysplasia/cardiomyopathy (ARVD/C) shows distinguished morphological changes in the right ventricle where myocytes are replaced by fibrosis and adipose tissue^[26,27]. Catecholaminergic polymorphic ventricular tachyarrhythmias (CPVT)^[28] is another inherited disease that puts patients at risk of developing arrhythmias during physical exercise, but not in a resting state^[29]. More catecholamines are released in the process of physical exercise to initiate early after depolarization (EAD) and delayed after depolarization (DAD) in these patients through a mechanism of the triggering activity, as a consequence malignant ventricular arrhythmias are more likely to occur. Mutations in the RyR2 gene attenuated the affinity of RyR2 to FKBP12.6 which resulted in tachyarrhythmias.

Hyperphosphorylation of ion channels Both sarcolemmal ion channels and calcium-release and uptake channels in the sarcoplasmic reticulum can be hyperphosphorylated.

Hyperphosphorylation of ion channels in lipid membrane There is a nucleotide binding domain in the sequence of the channel peptide of I_{Kr} , I_{Ks} , and $I_{Ca,L}$. Hyperphosphorylation of the channel peptide promotes an upregulation that is likely to provide a molecular basis for the varying function of the ion channels in a diseased heart. The up-regulated I_{Kr} and I_{Ks} in *L*-thyroxin-induced cardiomyopathy^[30] contributed to the retardation of APD. In contrast, an unregulated $I_{Ca,L}$ ^[31], another consequence of hyperphosphorylation, offered the potential to shorten the APD by facilitating repolarization. The co-existence of two factors to prolong or shorten APD is responsible for the dispersion of repolarization in cardiac remodeling under the control of PKA phosphorylation. The existence of hyperphosphorylation has been evidenced by a significant increase in the PKA mRNA in the injured myocardium induced by *L*-thyroxin.

The post-infarcted rat heart with a hypertrophied ventricle presents a mild enhancement in cardiac arrhythmias that occur in the ischemia/reperfusion procedure using Langendorff apparatus. After a treatment with isoproterenol

for 5 d, the severity of cardiac arrhythmias and cardiac remodeling are greatly exacerbated, which can be attributed to PKA-hyperphosphorylation. The impact of cardiac hypertrophy on the $I_{Ca,L}$ is uncertain, however, the intensity of the $I_{Ca,L}$ in the infarcted and isoproterenol treated rat model is augmented significantly in the left ventricle, but not in the right ventricle. A significant dispersion of the $I_{Ca,L}$ current by hyperphosphorylation has been found to be responsible for the exaggerated arrhythmias.

Hyperphosphorylation of RyR2-FKBP12.6 macromolecule complex Hyperphosphorylation of the RyR2 macromolecule complex that dissociates the FKBP12.6 from its binding site on the RyR2 can be developed by an overactivation of the β -adrenergic receptors^[23]. This is presented in a failing heart with relevant cardiac arrhythmias^[24,25]. Hyperphosphorylation converts the normal function of RyR2 into an oversensitive state towards the low diastolic low calcium levels. A substantial leakage of Ca^{2+} at the diastole, which is the main result of dissociation of FKBP12.6, contributes to a partial depolarization process by a boost in Ca^{2+} ion in repolarization. The delayed process of repolarization causes a prolonged APD that promotes EAD and DAD, and eventually induces cardiac tachyarrhythmias.

Hyperphosphorylation of PLB-SERCA2a system A maladaptive response to PLB by hyperphosphorylation^[3,32] causes a depressed SERCA2a capacity, after which elevated Ca^{2+} levels at the diastole are initiated. Hyperphosphorylation of PLB could negatively modulate the maximal capacity of SERCA2a by means of transgenic procedure, possibly involving other phosphorylated proteins^[3]. The mechanism of hyperphosphorylation might participate in arrhythmogenesis induced by *L*-thyroxin where the mRNA of SERCA is altered significantly.

The post-infarcted rat heart shows a mild-depressed SERCA2a mRNA and less severe cardiac arrhythmias, possibly reflecting hyperphosphorylation to a lesser extent^[33]. After a 5-d treatment with isoproterenol, the infarcted heart was converted into a significantly augmented arrhythmia accompanied with more depressed mRNA of SERCA2a which was mediated by PKA-hyperphosphorylation.

Dispersion of the calcium-handling system by over-phosphorylation We demonstrated that the significant dispersion of depressed mRNA abundance of RyR2 and SERCA and upregulated mRNA abundance of sodium calcium exchanger (NCX) in infarcted heart was associated with an increase in arrhythmic score after an isoproterenol treatment. The mRNA abundance of RyR2 and SERCA2 were decreased by 83.6% and 77.6% in left ventricle and by 36.7% and 38.1% in right ventricle, respectively. The mRNA abundance of

NCX1 was increased by 63.8% in left ventricle and 40.4% in right ventricle. The difference between left and right ventricle was significant. This implies that the free calcium levels in the left ventricle could be relatively higher than in the right ventricle under hyperphosphorylation. An elevated diastolic calcium level is likely to be the result of an alternative route, which could be sourced by an increase in NCX under hyperphosphorylation. An up-regulated NCX mRNA in the left ventricle possibly indicates more calcium than that in the right ventricle^[33]. A dispersion of the calcium-handling system under the control of PKA-overphosphorylation in an infarcted heart can be the basis for initiating cardiac arrhythmias under stress. The onset of severe cardiac arrhythmias based on not only the dispersion of the ion channels in the lipid membrane, but also the release, uptake, and exchange of the calcium-handling system.

The maladjustment in RyR2-FKBP12.6 and SERCA2a-PLB by hyperphosphorylation happened in various conditions (eg, in failing hearts and over-stimulation of the β -adrenergic receptors by activated sympathetic impulses). Sudden cardiac death results from the over-activation of PKA^[34]. The aberrant RyR2-FKBP12.6 and SERCA2a-PLB are important to develop malignant arrhythmias in an affected heart and serve as new targets for drug intervention to suppress cardiac tachyarrhythmias. The severely exaggerated cardiac arrhythmias provoked by an ischemia/reperfusion episode in the hypertrophied ventricle are produced either by repeated administration of *L*-thyroxine or isoproterenol in chronic infarcted rat heart. These could be related to the dispersion of deranged activity of the intracellular calcium-handling system as a consequence of hyperphosphorylation of the SR.

Direct and indirect effects of drugs on ion channels

Direct effect on the ion channels The effects of antiarrhythmic agents on ion channels could be recognized as either, a direct action on ion channels or an indirect effect, with which an improvement can be achieved on the altered ion channels by relieving the upstream lesions. Using the regular micro-electrode and patch-clamp techniques we observed that CPU 86017 blocked sodium, potassium, and calcium channels. A biphasic effect on the APD is suggested to be the result of a multi-channel blockade^[35]. So CPU 86017 could modulate APD in two directions, either prolonging the already shortened APD or shortening the already lengthened APD caused by lesions in a diseased myocardium. Therefore, reducing the dispersion of APD in a diseased heart to prevent cardiac arrhythmias is hopeful^[36]. Prolonging APD by

anti-arrhythmic agents is not beneficial for inhibiting ventricular tachyarrhythmias. In contrast, it always implies a potential of an adverse reaction by producing an increased incidence of *Torsades de pointes* (TdP)^[37], a dangerous ventricular tachycardia with a greater tendency to ventricular fibrillation.

Most electrophysiological data of anti-arrhythmic agents on individual ion channels are collected from freshly isolated myocytes. However, cardiac arrhythmias appear frequently in diseased and remodeled rather than normal hearts, and the molecular biological properties of the myocardium are markedly different in many aspects between the normal and diseased hearts. Dispersed repolarization stems from disturbed channels in the diseased myocardium only. It is worthy of investigating drug effects on altered ion currents in isolated myocytes of diseased hearts.

Indirect effects on ion channelopathy Cardiac arrhythmias could be suppressed by chronic drug therapy for restoring the altered channels. The restoration of up-regulation of the I_{Kr} , I_{Ks} and I_{CaL} current of isolated myocytes is confirmed by chronic medication of the propranolol, bepridil, and CPU 86017 in *L*-thyroxine-induced cardiomyopathy^[30,31].

The ion channels in a chronically infarcted heart is mostly down-regulated. Therefore, it is confusing to face the fact that an anti-arrhythmic agent could stop tachyarrhythmias by overlapping its suppressive effect on a depressed channel in a remodeled myocardium. There should be some up-regulated ion channels in diseased hearts. The up-regulated channels, which are denoted clearly in the cardiomyopathy induced by *L*-thyroxine, are linked with the occurrence of cardiac arrhythmias and serve as the target for anti-arrhythmic therapy. The action of drugs on the ion channels can be described as direct and chronic rather than a direct effect alone (Figure 1). The ability of drugs to restore the diseased channels either mediated by an indirect action on the upstream lesion to the ion channels via chronic medication or an acute suppression on an individual current contributes to the correction of disordered channels and prevention from the sudden episode of cardiac death resultant from deterioration of ventricular fibrillation on stress-related events.

Phases of ion channelopathy

Two phases of ion channelopathy The pathological progression of ion channels in the myocardium either in the sarcolemmal membrane or in the SR could be subdivided into two different stages: the basal phase, in which no presentation of arrhythmias can be found; and the activated phase, in which arrhythmias appear when ion channelopathy

Figure 1. A diagram shows direct and indirect effect of drugs on ion channels and cardiac arrhythmias. The mechanisms underlying the arrhythmogenesis and ion channelopathies in relation to hyperphosphorylation are denoted in a diseased heart. Hyperphosphorylation, possibly including oxidative stress, is considered as crucial lesions at the upstream to ion channels and causes upregulation of ion channels and dispersion of repolarization.

is deteriorated.

Basal channelopathy with disturbed ion channels, which indicate an abnormal repolarization in the myocardium, manifests no arrhythmia. This is because of a reservoir of repolarization. The normal period of repolarization is less than 460 ms and an APD/QTc is referred as prolonged when beyond 460 ms. Malignant arrhythmias are most likely to occur when an APD/QTc is longer than 520 ms. A prolongation of APD/QTc in the range of 460 ms to 520 ms is considered as a repolarization reservoir at risk of developing TDP, however, there is no arrhythmia at the resting state. It is common that patients who either inherit mutation in genes of the *LQTS*, the *ARVD/C*, and *CPVT*, or possess predominant cardiac remodeling, exhibit no arrhythmia at the resting state, suggesting that prolonged APD/QTc is still within the repolarization reservoir. However, if an APD/QTc is prolonged over 520 ms, the incidence of malignant arrhythmias is very high and arrhythmias are more likely to occur sooner.

Ion channelopathy can be deteriorated. The occurrence of ventricular tachyarrhythmias needs an activation of the channelopathy accompanied with an over-activation of the β -adrenergic receptors induced by heavy physical or mental stress. The process involves a burst of oxidative stress and

an imbalance of the oxygen supply and demand in the diseased myocardium. Hyperphosphorylation of RyR2 and PLB is involved in the exaggeration of the channelopathy by dissociating the FKBP12.6 and depressing the activity of SERCA2a, respectively. The process is not merely induced by the activation of β -adrenergic receptors, and the oxidative stress and activation of the ET-1 system and rennin-angiotension system are likely to mediate the activation pathological process.

Many kinds of drugs, such as ACEI, AT1 receptor blockers, endothelin receptor antagonists, the β -blockers, and anti-oxidative agents have antiarrhythmic effects by diminishing upstream lesions to relieve related channelopathy (ie, the cardiac remodeling and the abnormality of the transmembrane signaling system). Endothelins are biosynthesized and released in a substantial amount from the diseased myocardium and exert harmful effects on myocardium by stimulating cell proliferation, inducing apoptosis, and activating the production of free radicals. An excess of ET-1 promotes oxidative stress which is mediated by an increase in iNOS activity to form peroxynitrite ONOO^- . Peroxynitrite is cytotoxic to myocardium and is likely to take an active part in the progression of ion channelopathy and cardiac arrhythmias. The endothelin ET_A/ET_B receptor antagonists reduced cardiac remodeling and cardiac failure by blocking the overactivation of the ET system^[37-39]. It is interesting to find that an endothelin receptor antagonist, Dajisentan (CPU 0213), is effective in suppressing cardiac arrhythmias after ischemia/reperfusion in *L*-thyroxin-induced cardiomyopathy, but has no effect on ischemia/reperfusion-induced arrhythmias in a normal rat heart.

Class III anti-arrhythmic agents

In controlling ventricular tachyarrhythmias the Class I agents (I_{Na} blocking agents) are not recommended to patients with a diseased ventricle because of their strong potency to induce arrhythmias by suppressing the propagation of impulse^[40]. It is still questionable whether pure Class III antiarrhythmic agents would suppress ventricular tachyarrhythmias effectively and safely in a diseased heart. To date, the common opinion is that it is favorable to use the complex Class III agents, such as a low dose of amiodarone, rather than the pure Class III agents in treating ventricular tachyarrhythmias (Figure 2).

Pure Class III agents Dofetilide and ibutilide belong to pure Class III agents that prolong APD remarkably by inhibiting the I_{Kr} currents only^[41,42]. The two agents are favorable in the treatment of atrial fibrillation and flutter, but not in the

Figure 2. The Class III antiarrhythmic agents: CPU 86017, Azimilide, Amiodarone, Dronedarone, Dofetilide, and CPU 228.

control of ventricular tachyarrhythmias. Physicians should take care of monitoring the QTc in treatment of atrial flutter/fibrillation because of the high incidence of *Torsades de Pointes* when using the two agents. The outcome of clinical trials of dofetilide on mortality in the treatment of ventricular arrhythmias is neutral^[40,42].

Complex Class III agents Complex Class III anti-arrhythmic agents block not only I_{Kr} currents but also other channels and receptors.

Complex Class III anti-arrhythmic agents block I_{Ks} . These include amiodarone, dronedarone, azimilide, CPU 86017, and so on. Blocking I_{Ks} is important to shorten the APD and control cardiac arrhythmias by reducing the interference of β -receptor stimulation that causes an exacerbated I_{Ks} .

Complex Class III anti-arrhythmic agents block I_{CaL} . These include amiodarone^[43], dronedarone^[44], azimilide^[45], and CPU 86017^[46]. An upregulation of the I_{CaL} channels is associated with an enhancement of arrhythmogenesis in *L*-thyroxin-induced cardiac remodeling^[20] and in an infarcted heart after isoproterenol treatment^[31]. Blocking I_{CaL} is beneficial to control arrhythmia by relieving calcium overload and restoring a disordered calcium-handling system in the diseased myocytes. In addition, an inhibition of the calcium current helps to prevent cardiac arrhythmias by restoring the imbalance of the altered ion currents during repolarization in diseased hearts.

Dofetilide has the potential to develop TdP by its tremendous effect in prolonging APD. A combination with an I_{Na} blocking agent was successful in attenuating the incidence of TdP induced by a pure Class III agent^[47]. According to the mathematic equation to calculate the length of APD mentioned previously, we hypothesize that shortening in APD by blocking I_{CaL} could reduce the incidence of TdP. Therefore, CPU 228 was created by modification on the moiety of dofetilide. Treatment with CPU 228 significantly decrease the incidence of TdP in the rabbit model^[41]. CPU 228 can block both I_{CaL} and I_{Kr} , so it is being converted from a pure Class III antiarrhythmic agent, dofetilide, into a complex Class III agent that has more potency to control arrhythmias in an animal model.

Conclusion

The concepts and targets for the development of antiarrhythmic drugs are evolving^[48]. It is hopeful that more safe and effective agents will be obtained from continuous efforts based on regressing and relieving the basal ion channelopathy and preventing the deterioration of channelopathy in the view of biomolecular mechanisms. Propranolol and verapamil inhibit mRNA expression of RyR2 and SERCA in *L*-thyroxin-induced rat ventricular hypertrophy^[49]. β -Adrenergic stimulation increases current amplitude and activation of I_{CaL} ^[31] and I_{Ks} ^[50], causing dispersion of repolarization. More research at the molecular level will be needed on ion channelopathy. The safe and effective agents in controlling life-threatening arrhythmias can be obtained by relieving upstream lesions to ion channels, mainly through anti-hyperphosphorylation.

Abstract

Aim: COX-2(cyclooxygenase-2) has sparked a surge in pharmaceutical interest since its discovery at the beginning of the 1990s. Several COX-2 selective inhibitors that avoid gastrointestinal side effects have been successfully launched into the market in recent years. The first selective COX-2 inhibitor, celecoxib, entered the market in December 1999. However, there are a few organs that physiologically and functionally express COX-2, particularly the glomeruli of the kidney and the cortex of the brain. Inhibition of COX-2 expression in these organs possibly causes heart attack and stroke in long-term COX-2 inhibitor users. Recently, a USA Food and Drug Agency (FDA) advisory panel re-evaluated COX-2 inhibitors and unanimously concluded that the entire class of COX-2 inhibitors increase the risk of cardiovascular problems. Thus the use of COX-2 inhibitors is still controversial, and there is a challenge for not only pharmacologists, but also the pharmaceutical industry, to develop improved painkilling and anti-inflammatory drugs. This may involve exploring a new generation of COX-2 inhibitors with different inhibitory mechanisms through computer-aided design, screening different sources of inhibitors with lower selectivity, or seeking completely new targets. Synthetic COX-2 inhibitors have high selectivity and the advantage of irreversible inhibition, whereas naturally derived COX-2 inhibitors have lower selectivity and fewer side effects, with the medical effects in general not being as striking as those achieved using synthetic inhibitors. This review discusses the mechanism of COX-2 inhibitor therapy and a possible new way of exploration in the development of anti-inflammatory, analgetic, and antipyretic drugs.

Introduction

Cyclooxygenase (COX) is a key enzyme in the conversion of polyunsaturated fatty acids and arachidonic acid to prostaglandin (PG) H₂, which is further converted into various prostanoids (PGs, prostacyclins and thromboxanes). Our knowledge about COX constantly changes, but basically COX-1 is constitutively expressed in most tissues, where it synthesizes physiological amounts of prostaglandins. COX-2, on the other hand, is normally expressed in activated macrophages and becomes strongly upregulated after exposure to growth factors or inflammatory stimuli, and is elevated in malignant cells to promote angiogenesis in tumors^[1–4]. It

has been long believed that many of the side effects of non-steroidal anti-inflammatory drugs (NSAIDs), for examples, gastrointestinal ulceration and bleeding, and platelet dysfunction, are due to the suppression of COX-1-derived prostanoids, whereas the inhibition of COX-2-dependent prostaglandin synthesis accounts for the anti-inflammatory, analgesic and antipyretic effects. Consequently, it has been hypothesized that specific inhibition of COX-2 might have therapeutic actions similar to those of NSAIDs, but without the unwanted side effects. This was the fundamental rationale for the development of selective inhibitors of the COX-2 enzyme as a new class of anti-inflammatory and analgesic agent with improved gastrointestinal tolerability. However,

the potential of this new class of drugs has not been realized, even though the rationale underpinning their use is likely to be correct.

COX-2 was discovered in the early 1990s, and a large amount of effort has been expended since then by the pharmaceutical industry in the search for COX-2 inhibitors. In 2000, COX-2 inhibitors were involved in clinical trials for the treatment of colon and rectal cancers because COX-2 overexpression had been found in malignant tumor samples. However, at this point, the risk of heart attack and stroke emerged, and this is possibly because COX-2 is physiologically expressed in the glomeruli and cortex, and COX-2 may also have an anti-inflammatory role^[5]. Recently, a number of events regarding COX-2 inhibitors have attracted the attention of the media. Rofecoxib (Vioxx, Figure 1) was withdrawn by Merck & Co in September 2004 following the finding from the Vioxx Gastrointestinal Outcomes Research (VIGOR) trial for colon and rectal cancers that there were severe risks for the heart. Similar claims were made when a COX-2 inhibitor was used in the adenoma prevention with celecoxib (APC) trial, which was eventually suspended in December 2004 because analysis by an independent Data Safety and Monitoring Board showed that there was a risk of fatal and non-fatal major cardiovascular disease (CVD)^[6]. On February 20, 2005, a US Food and Drug Agency (FDA) advisory panel unanimously concluded that all classes of COX-2 inhibitors increase a person's risk of heart attack and stroke, and recommended that, despite the risks, drugs including Vioxx should remain on the market but be accompanied by strong warnings. Following the FDA's decision, the European Union and countries in which COX-2 inhibitors were used imposed similar restrictions. Because the drugs are now "tainted",

physicians are reluctant to prescribe them, and patients do not want to risk the health of their heart to ease pain, the sales of Celebrex, valdecoxib (Figure 1) and rofecoxib have dropped dramatically. As COX-2 inhibitors have become controversial, many pharmaceutical companies are having to renew their research efforts in the search for new effective anti-inflammatory drugs to treat arthritis and other inflammatory diseases^[7].

Regulation of COX-2 expression during inflammation

One of the main reasons for COX-2 attracting pharmaceutical interest is its strikingly different method of gene regulation from COX-1. The genes of COX-1 and COX-2 are located in human chromosomes 9 and 1, respectively, with COX-1 lacking a TATA box^[8]. The promoter of the immediate-early gene COX-2 contains a TATA box and binding sites for several transcription factors that are different from those of COX-1 (Table 1). The expression of COX-2 is regulated by a broad spectrum of mediators involved in inflammation. In general, lipopolysaccharides and proinflammatory cytokines, for example, interleukin- (IL)-1 β , tumor necrosis factor (TNF), and growth factors, induce COX-2; whereas IL-4, IL-13 and the anti-inflammatory cytokine IL-10 inhibit the expression of the enzyme^[9,10]. A recent study has shown that there is a positive feedback loop in COX-2-dependent prostaglandin production at the sites of inflammation. In particular, a COX-2 product, PGE₂ upregulates COX-2 expression by virtue of its cAMP-elevating capacity in human blood monocytes^[11]. COX-2 is also regulated at the post-transcriptional level. Recently, a 3'-untranslated region of the COX-2 mRNA has been shown to contain multiple copies of adenylate- and

Figure 1. COX-2 inhibitors originating from nature and designed chemically using computer-aided design.

Table 1. Differences in the expression, regulation, and enzyme kinetics of COX-1 and COX-2.

Structural functional class	Isoforms of COX	
	COX-1	COX-2
Location on chromosome	9q32–q33.3	1q25
Amino acid homology	60% identity to COX-2 75% similarity to COX-2	60% identity to COX-1 75% similarity to COX-1
Enzyme location	Endoplasmic reticulum	Nuclear envelope
Size of gene	22 kb, 11 exons	9.4 kb, 10 exons
Size of mRNA	2.8 kb	4.5 kb
Length of 3' UTR	800 bp	2200 bp
3' UTR Shaw/Kamen sequence	Not present	17
Size of polypeptide	70 kDa, 604 amino acids	70 kDa, 604 amino acids
Regulation	Usually constitutive	Inducible
Range of induced gene expression	2–4 folds	10–80 folds
Rate of gene activation	24 h	0.5 h
Effect of glucorticoids	Little or no effect	Inhibit expression
RNA instability elements, AUUUA in 3' UTR	Not present	Yes
TATA box	Not present	Yes

UTR=untranslated region.

uridylate-rich elements (AREs) that may confer post-transcriptional control of COX-2 expression by acting as mRNA instability determinants or as translation inhibitory elements. Loss of this post-transcriptional regulation of COX-2 through the mutation of proteins that specifically interact with the COX-2 ARE may lead to COX-2 overexpression, and this process has been proposed as a crucial factor in colon carcinogenesis^[12,13]. The sustained increase of COX-2 expression is apparently due (at least in part) to IL-1A increasing the stability of COX-2 mRNA. This type of regulatory mechanism may play an important role in chronic inflammatory conditions.

Development of COX-2 inhibitors

Both COX-1 and COX-2 produce prostaglandin H₂, which is further converted to different prostanoids, including PGD₂, PGE₂, PGF₂α, PGI₂ and thromboxane A₂. COX-2-dependent prostaglandins have been implicated in various physiological events, including male fertility, menstruation, ovulation, pregnancy, implantation, and in the pathological action of different inflammatory and neoplastic diseases, notably arthritis and cancer. In the US, one-third of the adult population, or approximately 70 million people, are affected by arthritis or chronic joint symptoms, making arthritis one of the most prevalent diseases in that country. Onset of the disease starts at around the age of 30 years, and women have a higher incidence than men. Arthritis is the leading

cause of disability in the US, accounting for 17.5% of all those on disability pensions. Thus there is an urgent need for the development of COX-2 inhibitors, and the development of suitable drugs would also be associated with large profits for pharmaceutical companies.

Inhibition of cyclooxygenases with aspirin can be traced back to ancient times. Chinese and Greek healers used willow bark that contained salicylic acid before AC aspirin, a modified form of acetylsalicylic acid developed by a German pharmacological chemist in 1898, was accepted as a safe and effective remedy for backache in 1903, for headache in 1923, and for arthritis in 1933 worldwide. The mechanism by which aspirin exerts analgesic and antipyretic effects was found to be the inhibition of cyclooxygenase-dependent prostaglandins in 1971^[14]. In the 1980s, aspirin was suggested to reduce the risk of heart attack by suppressing the production of prostacyclin in platelets^[15]. Aspirin also slows the development of cataracts and reduces migraine attacks. However, gastrointestinal (GI) toxicity induced by aspirin and other NSAIDs is among the most common serious adverse drug events in the industrialized world^[16]. Gastrointestinal ulcers can be found by endoscopy in 10% to 20% of patients who take NSAIDs on a regular basis. For decades, it has been a dream of pharmacologists to overcome this issue.

In the early 1990s, cyclooxygenase was found to exist in two distinct isoforms^[1,2]. It was then very rapidly found that the COX-1 isoform is located in all tissues except red blood

cells, and is constitutively expressed in the stomach, kidneys, platelets, and endothelial cells under normal physiological conditions. In contrast, COX-2 is induced by proinflammatory substances, such as lipopolysaccharides, TNF- α , IL-1, platelet-derived growth factor (PDGF), and other growth factors. COX-2 is involved in inflammation, for example in macrophages, monocytes and synoviocytes that emerge in acute and chronic inflammatory states. COX-2 therefore became a very attractive pharmaceutical target, even though it was later found that COX-2 is constitutively expressed in pancreatic beta-cells^[17], at the distal end of the vas deferens^[18], and also functionally and physiologically expressed in the kidney glomeruli and cortex^[19]. COX-2 was quickly crystallized and the structure was resolved by X-ray diffraction crystallography, which is a crucial step in drug design. The techniques of investigating the docking between small molecules and determining the structure of COX-2 were able to be carried out using different platforms. These approaches help to understand the mechanisms involved in protein-ligand binding in general, as well as helping to understand the details of the interactions in a specific protein or protein-ligand complex of interest^[20]. Celecoxib was the first drug that was chemically designed by computer, and was exceptionally quickly approved for release by the FDA in December 1998. Rofecoxib and valdecoxib subsequently entered the market later. The makers of a new product containing lumiracoxib (Novartis) are now in the process of applying for a license. Lumiracoxib is claimed to reduce the risk of cancer. Prescriptions for COX-2-selective inhibitors represented up to 61% of total prescriptions for NSAIDs in 2001 and 2002. In 2003, celecoxib was the ninth best-selling drug in the US, with sales of US\$2.6 billion according to Forbes. Another impetus for COX-2 inhibitor development is for cancer chemotherapy. In one study, COX-2 knockout mice showed a reduced incidence of tumors^[21], and COX-2 is overexpressed in many kinds of cancers, including colon, prostate and lung cancer. The function of COX-2 inhibitors that is relevant for cancer treatment is that they also induce apoptosis.

Mechanism of action of COX-2-dependent PGE₂ in pain perception

Inflammation causes an increased synthesis of COX-2-dependent PGs, which sensitize peripheral nociceptor terminals and produce localized pain hypersensitivity. A significant portion of these nociceptors are not activated by physiological stimuli such as gentle pressure or temperature. PGs regulate the sensitivity of so-called polymodal nociceptors

that are present in nearly all tissues. PGE₂ and other inflammatory mediators facilitate the activation of tetrodotoxin (TTX)-resistant Na⁺ channels in dorsal root ganglion neurons. These small dorsal root ganglion neurons are unmyelinated nerve fibers, conducting nociceptive stimuli. During inflammatory states, PGE₂ receptor E1 may significantly increase the excitability of nociceptive nerve fibers, thereby contributing to the activation of "sleeping" nociceptors, and also act in the central nervous system to produce hyperalgesia. COX-2 inhibitors act primarily in the dorsal horn to cause analgesia. The sensation of pain is assembled in the cortex. COX-2 is expressed constitutively in the dorsal horn of the spinal cord, and becomes upregulated briefly after a trauma, such as damage to a limb, in the corresponding sensory segments of the spinal cord. The induction of spinal cord COX-2-dependent PGs facilitates transmission of the nociceptive input^[22]. Similar to *in vitro* IL-1-induced COX-2 expression, IL-1 β was demonstrated to be the major inducer of COX-2 upregulation in the central nervous system. Accordingly, intraspinal administration of an interleukin-converting enzyme or COX-2 inhibitor is accompanied by decreases in both inflammation-induced central PGE₂ levels and mechanical hyperalgesia^[23, 24]. For analgesia alone, opioid drugs are more effective in moderate-to-severe pain than NSAIDs, and possess other significant advantages including titratability, reversibility and lack of prostaglandin-associated side effects. Cocktails of weak opioids and other analgesic agents, such as tramadol plus acetaminophen, have been shown to have some merits^[25].

After a debate lasting 30 years, the mechanism by which acetaminophen (commercial name Tylenol) exerts its analgesic and antipyretic action has also been elucidated by cyclooxygenase isoform studies. In contrast to the acidic antipyretic selective COX-2 inhibitors, due to the non-acidic chemistry of acetaminophen, the drug reaches higher concentrations within the central nervous system as compared with the acidic antipyretic analgesics (eg, aspirin and indomethacin) that accumulate in peripheral compartments with acidic extracellular pH (eg, inflamed tissue). Acetaminophen may inhibit nociception-induced spinal prostaglandin synthesis, and hydroperoxide may confer cellular selectivity on acetaminophen's inhibition of COX-2 activity^[26]. In addition, acetaminophen has been suggested to inhibit a newly discovered COX isoform, derived from the same gene as COX-1 and referred to as COX-1b or COX-3. Acetaminophen's role in analgesia and hypothermia is due to the inhibition of COX-3, which is more dominantly involved in fever in children^[27].

Synthetic COX-2 selective inhibitor with nephrotoxicity and cardiovascular disease

COX-2 immediately became a drug target after it was characterized as an inducible isoform in the early 1990s. Several crystal structures of COX-2 were quickly solved through the crystallization of the protein in different laboratories within a few years. In 1996, Searle improved the model and built up a structure with a high resolution of 2.15 Å. It was found that one of the enzymatic channels in COX-2 is wider than that of COX-1, and COX-2 has an open side pocket where the sulfonamide group of the selective inhibitors can bind. Human COX-2 has four amino acids that are different from COX-1 in the region corresponding to the side pocket. The most important difference is at position 523, where COX-1 has a bulky isoleucine and COX-2 has a valine that takes up less space^[28]. The formation of five different hydrogen bonds between the selective inhibitors and the pocket of COX-2 is a strong and time dependent binding reaction, and site-directed mutations in the pocket region resulted in weaker binding and fewer hydrogen bonds^[20,29]. The selectivity of COX-2 $IC_{50}/COX-1 IC_{50}$ is 0.003 (or selective fold is 375:1) for celecoxib, 0.0026 for rofecoxib, and 166 for aspirin. The high selectivity of celecoxib is due to the phenylsulfonamide moiety, which binds in a pocket that is more restricted in COX-1 and is unoccupied in complexes of COX-2 with non-selective inhibitors. This pocket branches off from the main channel that leads to the cyclooxygenase active site, and is more accessible in COX-2, primarily because of the previously mentioned substitution of isoleucine at position 523 in COX-2 to valine in COX-1. Aspirin mainly inhibits COX-1 irreversibly because it blocks the channel for accessing the substrate by permanently acetylating the serine of the cyclooxygenase enzymes. Celecoxib's reversibility and selectivity provided a new insight into drug design approaches for the pharmaceutical industry.

Nevertheless, the COX-2 inhibitors are associated with a number of potential pitfalls, which can be even more lethal than the side effects of other non-selective NSAIDs. These pitfalls arise from the fact that COX-2 induction is not exclusively associated with the onset of an inflammatory reaction. In fact, COX-2 can also be expressed chronically, and is seen during the resolution of inflammation and in areas of wound-healing^[5]. Through studies of COX-2 knockout mice, COX-2 inhibition has been directly linked to several adverse outcomes, including reproductive failure, and reduced renin expression in the kidney. Renin is an active enzyme that converts angiotensinogen into angiotensin, which maintains or modulates the salt metabolism. It has been shown that

renin expression is decisively regulated by COX-2 in kidney, especially in the abnormal intake of NaCl^[30]. COX-2-deficient mice also develop lung fibrogenesis^[31], which is a common attribute of lung cancer in humans. The application of COX-2-selective inhibitors during these periods has been shown to be deleterious, so that resolution of inflammation and gastric ulcer healing are actually delayed and, in some patients, ulcers have even been found to progress further to perforation. The suggestion has now been made that, in these situations, COX-2 may actually help resolve the pathology, perhaps by generating an alternative series of PGs, such as the cyclopentenone PGs. The finding that these PGs can affect proteins by direct chemical modifications as well as by having their own receptor families has rekindled debate on the deleterious and beneficial effects of COX-2-dependent prostanoids, and on the implications of inhibiting the production of these mediators in the body^[32].

COX-2-synthesized PGs have important roles in the modulation of renal physiology. A number of pooled analyses have suggested the possibility of an increased risk of CVD, particularly acute myocardial infarction, because of a blunted PG response due to COX-2 inhibition in the kidney and blood vessels, which may depend on the individual to a certain extent. Many reports have stated that COX-2 inhibitors have the same nephrotoxicity as non-selective NSAIDs. PGs have a counterbalancing effect because they modulate the local actions of systemic and locally produced vasoconstrictor hormones. For this role, a variety of PGs with diverse biological effects are produced and metabolized by the kidney^[33]. The major ones, synthesized at distinct anatomical locations within the renal parenchyma, include PGI₂, PGE₂, thromboxane A₂, and PGF₂. Of these, PGI₂ (produced most abundantly in the renal cortex by cortical glomeruli and arterioles) and PGE₂ (synthesized in the juxtamedullary glomeruli, medullary interstitial cells, and the medullary portion of the collecting duct) are physiologically predominant^[34,35]. It used to be believed that the only side effects of COX-2 inhibitors were toxicity in the kidney. But now COX-2 has been found to be constitutively expressed in the endothelial cells of the arteries, arterioles, lung and brain, in addition to its highly constitutive expression in the vas deferens and beta-cells of the pancreas. COX-2 expression in the cortical thick ascending limb of the loop of Henle (medullary rays and macula densa) affects chloride ion pumps. In the medulla, COX-2 expression was detected in the endothelial lining of the vasa recta in 52 cases and in the collecting ducts in 5 cases. These data demonstrate significant constitutive expression of COX-2 in normal kidney and underscore the need for caution in the use of COX-2 selective inhibitors, especially on a long-

term basis. All in all, there is not much remaining of the original dogma that COX-1 is the housekeeping good guy and COX-2 is the perpetrator that mediates inflammation and damage. These findings are consistent with recent clinical data showing that COX-2 inhibitors are associated with CVD risk^[36,37].

Naturally derived COX-2 inhibitors for anti-inflammation, and alternative targets for painkilling

Given that salicylic acid (later developed to aspirin) was originally extracted from the bark of the willow tree, there is a definite possibility of also finding COX-2 inhibitors in nature. In fact, there are some already known COX-2 favorable inhibitors of natural origin, and some of them have been used as natural modulators of inflammation in adjuvant chemotherapy. A recent review details a number of natural COX-2 inhibitors with different chemical structures and different modes of action^[38]. It has been reported that ginger, curcumin, thunder god vine, plantago, and others contain COX-2 inhibitors. Some of these compounds not only inhibit COX-2, but are also antioxidants, for example resveratrol, which is found in the skin of grapes and inhibits the transcription or post-translation of the COX-2 gene^[39]. Small synthetic COX-2 inhibitors can be inserted into loops that are different from COX-1. But there are many different methods of inhibition, and in general, there is no correlation between inhibition and the similarity of the chemical structures. Some characterized fatty acid COX-2 inhibitors, such as linoleic acid (LA), alpha-linolenic acid (alpha-LNA), myristic acid and palmitic acid have been isolated from different plant roots or leaves, and have IC₅₀ values for cyclooxygenase ranging from 3.9 to 180 μmol/L. The compound alpha-LNA is one of the most selective towards COX-2, with COX-2/COX-1 ratios of 0.1^[40, 41].

In addition to fatty acids, steroid-like molecules are also attractive candidates for COX-2 inhibitors. A hexane structure of ursolic acid (Figure 1) has been investigated by bioactivity-directed fractionation. This triterpenoid had a COX-2 inhibitory effect, directly affecting the enzyme activity, with an IC₅₀ value of 130 μmol/L and a COX-2/COX-1 selectivity ratio of 0.6. The structural isomer oleanolic acid is less active than ursolic acid, with an IC₅₀ value of 295 μmol/L, but has a similar selectivity ratio (0.8). The direct inhibitory effect of ursolic acid and oleanolic acid on COX-2-catalyzed prostaglandin biosynthesis increased with preincubation, indicating a time-dependent inhibition. Interestingly, the effect on COX-1 was independent of preincubation time^[42]. The problem with natural COX-2 inhibitors is the slower *on-*

set of relief *in vivo*. Effort needs to be directed towards screening natural anti-inflammatory/analgesic products that offer more effective inhibition, or stronger instantaneous relief of pain with no (or less) GI and cardiovascular risk. If this were to occur, then a natural COX-2 inhibitor, whether a single compound or a combination of multiple compounds, could be developed to provide gentle, effective and long-term relief.

Summary

Cyclooxygenases, particularly COX-2 inhibitors associated with CVD problems, have shown us that there are probably no absolute perpetrators and protectors in nature. However, selective COX-2 inhibitor studies and chemotherapy have extended our understanding of this system. All COX-2 inhibitors remain available for use in certain patients, such as those at risk of ulcers. COX-2 inhibitors can be explored further for cancer therapy, where because of their anti-angiogenic apoptosis-promoting properties, they might benefit those patients who are overexpressing COX-2. Rather than inhibitors, it is also possible to identify more COX-2 modulators, which could be found by screening small molecules from herbs or other natural sources. For simple painkilling, it is better to target end effectors. Screening for E1 receptor inhibitors is a new possibility because the analgesic actions of NSAIDs in inflammatory pain, especially visceral stimuli, are mediated to a significant degree by the inhibition of signaling through the E1 receptor. The absence of EP1 receptors results in structurally normal kidney, and does not result in a lowering of resting blood pressure^[43].

SCI Impact Factor of Acta Pharmacologica Sinica increased to 1.125

According to the latest Journal Citation Report 2004 (JCR 2004) published by Institute for Scientific Information (ISI, USA), we are greatly pleased to announce that the Science Citation Index (SCI) Impact Factor of Acta Pharmacologica Sinica (APS) has risen from 0.884 to **1.125**, ranking the 132nd out of 187 journals in the category of PHARMACOLOGY & PHARMACY, and the 49th out of 125 journals in the category of CHEMISTRY, MULTIDISCIPLINARY. APS is continued to be the only journal listed in the SCI in Chinese Pharmacology and Pharmacy and ranked the 8th out of 71 Chinese journals listed in SCI.

Here we would like to share the good news with all our authors, reviewers and readers. Without your long-term contribution, APS cannot achieve such a progress! Hope to have your support continuously!

Abstract

Aim: Interleukin-1 beta (IL-1 β) has been implicated as an extracellular signal in the initiation of apoptosis in neurons and oligodendrocytes after spinal cord injury (SCI). To further characterize the apoptotic cascade initiated by IL-1 β after SCI, we examined the expression of IL-1 β , p38 mitogen-activated protein kinase (p38 MAPK) and caspase-3 after SCI, and further investigated whether p38 MAPK was involved in neuron apoptosis induced by IL-1 β . **Methods:** Adult rats were given contusion SCI at the T-10 vertebrae level with a weight-drop impactor (10 g weight dropped 25.0 mm). The expression levels of IL-1 β , p38 MAPK and caspase-3 after SCI were assessed with Western blots, immunohistochemistry staining, and real time reverse transcription polymerase chain reactions (RT-PCR). Neuron apoptosis was assessed with the terminal deoxynucleotidyl transferase-mediated deoxyuridine triphosphate-biotin nick end labeling (TUNEL) method. **Results:** Increased levels of IL-1 β and p38 MAPK were observed soon after injury, with a peak in expression levels within 6 h of injury. By 24 h after injury, caspase-3 expression was markedly increased in the injured spinal cord. TUNEL-positive cells were first observed in the lesioned area 6 h after SCI. The largest number of TUNEL-positive cells was observed at 24 h post-SCI. Intrathecal injection of the IL-1 receptor antagonist IL-1Ra significantly reduced expression of p38 MAPK and caspase-3, and reduced the number of TUNEL-positive cells. Moreover, intrathecal injection of an inhibitor of p38 MAPK, SB203580, also significantly reduced the expression of caspase-3, and reduced the number of TUNEL-positive cells in the injured spinal cord. **Conclusion:** The p38MAPK signaling pathway plays an important role in IL-1 β mediated induction of neuron apoptosis following SCI in rats.

Introduction

Traumatic spinal cord injury (SCI) often results in complete loss of voluntary motor and sensory function below the site of injury. Extensive evidence indicate that secondary injury of the cord involving widespread apoptosis of neurons and oligodendroglia after the trauma contributes significantly to long-term neurological deficits^[1,2]. Interleukin-1 beta (IL-1 β) induces apoptosis in neurons *in vitro*^[3] and in cultured human astrocytes^[4] and oligodendrocytes *in vivo*^[5]. IL-1 β expression is upregulated rapidly at the lesion site after SCI^[6-8]. Furthermore, injection of an

IL-1 receptor antagonist (IL-1Ra), a potent anti-inflammatory cytokine, reduces IL-1 β production in the spinal cord and thereby may promote functional recovery following SCI^[9]. Thus a rapid accumulation of IL-1 β following SCI may initiate apoptosis in neurons and glial cells. The intracellular signaling events initiated by IL-1 β that lead to apoptotic cell death *in vivo* however are not well understood.

Caspase-3 is a potential mediator of apoptosis after central nervous system (CNS) injury^[10,11] and its activation may be as a marker of apoptotic cell death. Several studies have provided evidence that cell death from moderate traumatic spinal cord injury is regulated, in part, by apoptosis that

involves the caspase family of cysteine proteases^[9,11]. In the hippocampus of aged rats, the concentration of IL-1 β is increased and this increase is accompanied by enhanced caspase-3 activity indicative of cell death^[12]. These findings suggest that neuron apoptosis in the CNS is induced by increased IL-1 β through activity of the caspase-3 apoptotic pathway.

p38 Mitogen-activated protein kinase (p38 MAPK) is a pivotal molecule in the signal pathway initiated by IL-1R1^[13]. A subset of cyclin-dependent kinase/mitogen-activated protein kinase superfamily kinases has been implicated in neuron apoptosis^[14,15]. In neurons of the hippocampus, inhibition of p38 MAPK activation induced by SB203580 blocks suppression of long term potentiation evoked by IL-1 β ^[16] and cellular stress responses to IL-1 β ^[17]. In addition, the cardiovascular and behavioral responses induced by intracerebral ventricular (icv) injection of IL-1 β were abrogated by pretreatment with the p38 inhibitor SB203580 (icv) in awake rats^[18]. These findings suggest that the effects of IL-1 β are partially dependent upon p38 MAPK activation. In addition, IL-1 β concentration was found to be increased and accompanied by enhanced caspase-3 activity in the hippocampus of aged rats^[12]. Analysis of colocalization of activated caspase-3 with activated p38 MAPK (p-p38) in the hippocampus of aged rats, suggested that p-p38 was necessary for activation of caspase-3; while *in vitro* analysis indicated that the IL-1 β -induced increase in caspase-3 activity was abrogated by the p38 MAPK inhibitor, SB203580^[12]. Thus apoptosis activated by increased IL-1 β after SCI may be dependent, at least in part, upon the activation of p38 MAPK.

In the present report, expression of IL-1 β as well as expression of its potential downstream target molecules p38 MAPK and caspase-3 was examined in rats following SCI. If p38 MAPK signaling mediates IL-1 β genetic induction of apoptosis, then p38 MAPK expression should be elevated after SCI together with IL-1 β expression. Likewise, if the apoptotic program initiated by IL-1 β involves caspase-3 as an effector of apoptosis, then a subsequent increase in caspase-3 levels should also be observed following SCI.

We further tested pharmacologically whether the apoptotic cascade initiated by IL-1 β after SCI involved p38 MAPK signaling and caspase-3. If post-injury caspase-3 increases were induced by IL-1 β signaling, then blocking IL-1 receptors should attenuate caspase-3 upregulation after injury. Moreover, if IL-1 β induction of apoptosis after SCI was mediated by MAPK signaling, which then resulted in caspase-3 upregulation, then blocking MAPK activity should also attenuate caspase-3 upregulation as well as reduce the amount of apoptotic cells observed after SCI.

Materials and methods

Materials Rabbit antibodies directed against IL-1 β , caspase-3 and normal rabbit serum were purchased from Sigma Biotechnologies (Sigma-Aldrich, Inc, Saint Louis, Missouri, USA). p38 MAP Kinase Assay Kits were purchased from Cell Signaling TechnologyTM (Cell Signaling, Beverly, USA). The p38 inhibitor 4-(4-fluorophenyl)-2-(4-methylsulfonylphenyl)-5-(4-pyridyl)-1H-imidazole (SB203580) was purchased from Calbiochem (Calbiochem, La Jolla, CA). Recombinant rat IL-1ra was purchased from R & D Systems (Minneapolis, MN, USA). Terminal Deoxynucleotidyl Transferase-Mediated Deoxyuridine Triphosphate-Biotin Nick End Labeling (TUNEL) detection kits were purchased from Sino-American Biotechnology Co (Sino-American Biotechnology Co, Luo Yang, China).

Spinal cord injury and pharmacological treatment Adult male Wistar rats, weighing about 250 g each (range from 220 g to 270 g), were used in this study (provided by the Experimental Animal Center of Shantou University Medical College). Rats were assigned randomly to either the SCI group, the sham-operated control group ($n=54$ for each group) or the drug-treated group (including SB203580; IL-1Ra; vehicle, $n=18$ for each group). Rats' spinal cords were contused extradurally with a 10-g weight-drop impactor dropped 25.0 mm onto the T9-T10 region of the cord exposed by laminectomy as described previously^[19]. Drug treatments were given intrathecally immediately after the injury. Recombinant rat IL-1Ra (10 μ g) was given to antagonize IL-1 receptors and SB203580 (4 μ g in 10 μ L) was given to inhibit p38 MAPK^[9,20,21]. The animals in the sham-operated control group underwent a T9 laminectomy without injury and received intrathecal injections of only vehicle (10 μ L saline). All animal care and surgical procedures were approved by the institutional animal care and use committee of Shantou University.

RNA purification and RT-PCR At several time points following impact, 4-mm thick tissue sections were collected by deep anesthesia and stored frozen at -80 °C. Total tissue RNA was purified by homogenization of 20 mg spinal cord using the RNeasy Mini kit (Qiagen, Valencia, CA) according to the manufacturer's instructions. RNA was washed, dried, resuspended in sterile nuclease-free water, and stored at -80 °C. After spectrophotometric quantification, the purified RNA was separated on a formaldehyde-agarose gel to assess the extent of degradation.

One microgram total RNA was reverse-transcribed into cDNA in each 50 μ L reaction mixture, using one-step RT-PCR (QIAGEN One Step RT-PCR Kit, Qiagen, Valencia, CA)

according to the manufacturer's instructions. The sequences of forward and reverse primers for amplifying IL-1 β cDNA were 5'-AGCTATGGCAACTGTCCCT-3' and 5'-AGCTATGGCAACTGTCCCT-3', respectively. After amplification, RT-PCR products were quantified with real time PCR.

Real time quantitative RT-PCR To compare the mRNA content of IL-1 β in spinal cord after SCI with pharmacological treatment, reverse-transcribed cDNA standards and samples were amplified in parallel by PCR on a LightCycler using additional sequence-specific hybridization probes in combination with the LightCycler. PCR with *Taq* polymerase (Taqman; Applied Biosystems, Foster City, CA) on the cDNA samples was performed on a sequence detector (Prism 7700; Applied Biosystems, Foster City, CA). Equal amounts of cDNA were used in duplicate and amplified with the PCR mix (Taqman Master Mix; Applied Biosystems). Real time PCR protocols were performed as described previously^[22]. Briefly, the PCR reaction mixture contained 2 mmol/L MgCl₂, 20 pmol of both PCR primers, 1 pmol of each hybridization probe, 2 μ L of LightCycler. DNA master hybridization mix (Roche, Germany) and 2 μ L of reverse-transcribed samples in a final volume of 25 μ L. The PCR conditions were set at 50 °C for 2 min, 95 °C for 10 min followed by 40 cycles of 95 °C for 30 s and 60 °C for 1 min. Additional reactions were performed on known dilutions of rat IL-1 β cDNA as a PCR template to construct a standard curve relating threshold cycle to template copy number.

The sample copy numbers were calculated using the LightCycler analysis software (Roche, Mannheim, Germany). The LightCycler software system analyzed the spectral data collected at the end of the annealing phase of each cycle and plotted fluorescence intensity versus cycle number. The cDNA standard curve was generated by the LightCycler. The Cts value against the logarithm of the calculated initial copy numbers was plotted by the Software system. The unknown initial sample copy numbers were then calculated automatically from their Cts, as compared to the cDNA standard curve.

Taq polymerase primer and probe sets for IL-1 β were designed from sequences in the GenBank database of NCBI on DNAMAN. GenBank is provided in the public domain by the National Center for Biotechnology Information, Bethesda, MD (<http://www.ncbi.nlm.nih.gov/Genbank>). The primer and probe sequences used were as follows: IL-1 β forward primer: 5'-CTGCACTGCAGGCTTCGA-3'; reverse primer: 5'-TGGA-GAGCTTTCAGCTCACATG-3'; Taqman probe: 5'-FAM-ATGAACAACAAAATGCCTCGTGCTGTCTGTAMRA-3'.

Western blot analysis At 30 min, 6 h, 24 h, 72 h after injury ($n=3$ per time point), an 8-mm spinal cord segment was

dissected 4 mm rostral and 4 mm caudal from the lesion epicenter from each group. The cord tissues were resuspended in a lysis buffer (Cell Signaling, Beverly, USA) and homogenized in a dounce homogenizer on ice. Tissue homogenate samples were centrifuged at 14 000 rpm for 10 min at 4 °C, and the supernatant samples were stored at -30 °C. Protein concentrations in the cell lysates were determined by Bio-Rad (Richmond, CA) protein assay, as recommended by the manufacturer. For analyses by Western blot, 20 μ L of each suspension sample was separated in 12% SDS-PAGE, and the proteins were transferred to polyvinylidene difluoride membranes. Blots were blocked with 5% nonfat dry milk in tris-buffered saline (TBS) for 1 h at room temperature and then the membranes were incubated with 1:200 diluted monoclonal rabbit anti-rat antibodies against IL-1 β (Sigma) or caspase-3 (Sigma) overnight at 4 °C. The membranes were then processed with HRP-conjugated goat anti-rabbit secondary antibody (1:500; Sigma). Immunoreactive bands were quantified using image analysis software.

p38 MAPK enzymatic activity was measured using a p38 MAP Kinase Assay Kit (Cell Signaling), and the protocol was performed according to the manufacturer's instructions. Briefly, 200 μ L of protein content in clear supernatant was immunoprecipitated using immobilized phospho-p38 MAP kinase (Thr180/Tyr182) monoclonal antibodies with gentle shaking overnight at 4 °C. The immunoprecipitate was washed twice with 500 μ L ice-cold cell lysis buffer and twice with 500 μ L ice-cold kinase buffer (25 mmol/L Tris (pH 7.5), 5 mmol/L β -glycerolphosphate, 2 mmol/L DTT, 0.1 mmol/L Na₃VO₄, and 10 mmol/L MgCl₂) at 4 °C. The kinase reactions were conducted in the presence of 200 μ mol/L ATP and 2 μ g activating transcription factor-2 (ATF-2) fusion protein at 30 °C for 30 min. After the reaction had been terminated by the addition of 3 \times SDS sample buffer, the mixture was boiled for 5 min, followed by brief centrifugation. Phospho-p38MAPK was selectively measured by Western immunoblotting as described previously^[23], and then immunoreactive bands were quantified using image analysis software.

Immunohistochemistry At several time intervals after SCI (30 min, 6 h, 24 h, 72 h, 1 wk, 6 wk), animals were deeply anesthetized and perfused via cardiac puncture with 0.1 mol/L phosphate-buffered saline (PBS) 150 mL (pH 7.4) and subsequently with 4% paraformaldehyde in 0.1 mol/L PBS 250 mL. The spinal cord was carefully dissected, and an 8-mm segment containing the injured epicenter was dissected out and post-fixed by immersion in 4% paraformaldehyde for 3 h and then cryoprotected by immersion in 20% sucrose of PBS overnight. Tissue segments were embedded in OCT and frozen as described previously^[24]. Free-floating transverse

sections (10 μm) were cut with a cryostat.

Immunohistochemical staining was performed by the avidin-biotin complex method as described previously^[25]. The concentration for rabbit anti-IL-1β and rabbit anti-caspase-3 primary antibodies was 1:200. The concentration for biotinylated anti-rabbit antibodies was 1:200. Positive immunoreactive labeling was observed qualitatively.

Terminal deoxynucleotidyl transferase-mediated deoxyuridine triphosphate-biotin nick end labeling (TUNEL) Spinal cord specimens used for TUNEL staining were collected as described above for immunohistochemistry methods. The segment was embedded in paraffin as previously described^[24] and 5 μm-thick serial transverse sections were collected. The sections were processed for TUNEL staining with an in site cell apoptosis detection kit, and the staining protocol was performed according to the manufacturer's instructions. The sections were counterstained with hematoxylin. The ratios of TUNEL positive cells to total cells were counted and analyzed by computer. All TUNEL analyses were carried out by investigators who were blind as to the experimental conditions.

Statistical analysis Data are expressed as mean±SD. Statistical significance was assessed with one-way ANOVA. The significant difference between pairs of groups was tested by *post hoc* analysis. *P*<0.05 was considered significant in all cases.

Results

Rapid expression of IL-1β in spinal cord after SCI The temporal expression of IL-1β mRNA and protein at pre-defined time intervals (30 min, 6 h, 24 h, 72 h after SCI; *n*=3 for each time point) was examined. Absolute quantification real-time reverse PCR (Q-RT-PCR) analysis revealed that by 30 min after the contusion injury, IL-1β mRNA levels (6.75±0.42, log of the copy number of IL-1β cDNA) were significantly increased in the cords of injured rats relative to sham surgery control rats (4.98±0.49). IL-1β mRNA levels continued to rise, reaching peak levels at 6 h post-injury (6.97±0.75) (*P*<0.01 vs control group), then falling by 24 h.

Western blot analysis also showed an increase in IL-1β levels following SCI (Figure 1). IL-1β protein was increased significantly by 30 min after the injury, reached peak levels by 6 h after the injury and declined thereafter. Both Western blot analysis (Figure 1) and immunohistochemistry examination (Figure 2A) revealed low levels of IL-1β protein in the sham controls. As early as 30 min after injury IL-1β immunoreactivity was observed in neurons within the gray matter in the lesion area, as well as in neurons located several

Figure 1. Western blot analysis of IL-1β protein level in the spinal cord after traumatic spinal cord injury (SCI). Each value was measured by densitometric analysis of the Western blots bands. Data were converted to percentages as compared to the sham-operated control as 100%. Mean±SD. ^a*P*>0.05, ^b*P*<0.05, ^c*P*<0.01 vs control group.

microns, rostral and caudal of the lesion. The peak of immunoreactivity was observed 6 h after SCI (Figure 2B).

p38 MAPK activation in the spinal cord after injury Immunoprecipitation and Western blot examinations revealed that 6 h after SCI total p38 MAPK levels in the spinal cord had not changed after contusion (Figure 3A). P-p38 MAPK levels however were significantly increased following the injury. This increase was detectable at 30 min after contusion and reached a peak at 6 h. P-p38 MAPK returned to basal levels by 72 h post-injury (Figure 3B). These data indicate that increases in p-p38 after SCI are caused by increased phosphorylation rather than by elevated substrate.

Induction of caspase-3 after injury The post-injury temporal profile of caspase-3 expression was examined by immunohistochemistry and Western blot analysis. Both injured and sham-operated spinal cords were evaluated for caspase-3 expression at four pre-defined time points (30 min, 6 h, 24 h, and 72 h after SCI; *n*=3 for each time point). As expected, little caspase-3 immunoreactivity was observed in sham-operated spinal cords (Figure 2C). Weak caspase-3 immunoreactivity was first detected in a few neurons within the gray matter of the lesioned area 6 h after injury. Intense caspase-3 immunoreactivity was seen in gray matter neurons 24 h after injury and decreased thereafter (Figure 2D). Western blot analyses also showed that caspase-3 expression was up-regulated after SCI. Caspase-3 protein was detectable by 6 h, peaked 24 h post-injury and decreased thereafter (Figure 4).

Figure 2. Immunocytochemical detection of IL-1, caspase-3 and TUNEL labeling after spinal cord injury. $\times 400$. (A) IL-1 β immunoreactivity in the sham-operated spinal cord, little IL-1 β immunoreactivity (arrow) was detected. (B) IL-1 β immunoreactivity (arrow) was intense in a section of the injured cord 6 h after SCI. (C) Little caspase-3 immunoreactivity (arrow) was observed in sham-operated spinal cords. (D) Intense caspase-3 immunoreactivity (arrow) in the gray matter neurons 24 h after injury. (E) Few caspase-3 positive immunoreactivity neurons (arrow) 24 h after SCI treated with IL-1Ra. (F) TUNEL positive cells (arrow) in vehicle group. (G) IL-1Ra treatment significantly reduced the number of TUNEL-positive cells (arrow) in the cord relative to vehicle controls. (H) SB203580 treatment significantly reduced the number of TUNEL-positive cells (arrow) in the cord relative to vehicle controls.

SCI-induced p38 MAPK activation is mediated by IL-1 β

To test whether IL-1 β plays a role in p38 MAPK activation after SCI, the IL-1 receptor antagonist, recombinant rat IL-1ra, was given after SCI. Western blot data showed an increase in p-p38 in spinal cord 6 h after SCI. Treatment with IL-1Ra markedly inhibited the injury-induced activation of p38 MAPK. These data suggest that p38 MAPK activation in spinal cord after SCI is mediated by IL-1 β (Figure 5).

Inhibition of caspase-3 expression and reduction of apoptosis by IL-1Ra after injury To demonstrate whether the IL-1 β induced expression of caspase-3 and the subsequent increased apoptosis of neurons after contusion injury, we compared both expression of caspase-3 and the number

of apoptotic cells in the presence or absence of IL-1Ra after SCI. As shown in Figure 6, the induction of caspase-3 protein was inhibited significantly by IL-1Ra treatment. Few TUNEL-positive cells were initially present in the lesion area within 6 h of injury. The greatest numbers of TUNEL-positive cells were observed 24 h after injury. Treatment with IL-1Ra markedly reduced the number of TUNEL-positive cells in the cord relative to vehicle controls at 24 h after injury (Figure 2F, 2G).

p38 MAPK inhibition reduces neuron apoptosis and caspase-3 expression after SCI Treatment of the injured spinal cord with SB203580 resulted in a marked reduction in the number of TUNEL-positive cells as compared to that

Figure 3. p38 MAPK activation in the spinal cord after injury. (A) Total nonphosphorylated p38 MAPK levels in the spinal cord did not change after contusion. (B) Phospho-p38 levels were significantly increased in the injured spinal cord, and peaked 6 h after SCI. ^a $P > 0.05$, ^b $P < 0.05$, ^c $P < 0.01$ vs control group.

Figure 4. Western blot analysis showed time-dependent changes in caspase-3 protein levels in the spinal cord after injury. Sample from sham control and injured spinal cords were prepared for Western blotting at 30 min, 6 h, 24 h, 72 h after SCI. Caspase-3 protein levels peaked 24 h after injury and declined thereafter. ^a $P > 0.05$, ^c $P < 0.01$ vs sham-operated control group.

found in vehicle controls (Figure 2H). Notably, at 24 h post-injury the number of TUNEL-positive cells was reduced by 50% with the SB203580 treatment. The induction of caspase-3 protein was also inhibited significantly by treatment with SB203580 (Figure 7).

Figure 5. Treatment with IL-1Ra attenuated the injury-induced activation of p38 in the spinal cord. The phospho-p38 protein level in the IL-1Ra-treated group was significantly less than that in the vehicle group at 6 h post-injury. Sham operated group was 100%. ^b $P < 0.05$ vs vehicle group.

Figure 6. Treatment with IL-1Ra markedly inhibited the injury-induced activation of Caspase-3 in spinal cord. The caspase-3 protein level in the IL-1Ra treated group was significantly less than that in the vehicle group at 24 h. Sham operated group was 100%. ^c $P < 0.01$ vs vehicle group.

Figure 7. Caspase-3 protein level was significantly reduced in rats treated with SB203580 relative to the vehicle group at 24 h post-injury. Sham operated group was 100%. ^c $P < 0.01$ vs vehicle group.

Discussion

Injury to the spinal cord induces a complex cascade of cellular reactions at the local lesion area that results in inflammation and secondary cell death^[26]. IL-1 β is a major mediator of inflammation and may play an important role in the consequences of traumatic spinal cord injury. Numerous studies have confirmed an increase in IL-1 β expression after SCI^[6-8]. In the present study, the expression of IL-1 β and its mRNA was assessed in the rat spinal cord following a standardized contusion injury. IL-1 β mRNA levels, as measured by quantitative RT-PCR, were significantly increased in the lesion area by 30 min after SCI, peaked at 6 h and returned to normal at 72 h post-injury. IL-1 β protein levels, as measured by Western blot and immunohistochemical staining, were increased significantly in the lesion area by 30 min post-injury, peaked at 6 h and then remained significantly higher than normal through at least 3 d post-injury. These findings, along with the findings by others^[6-8], suggest that the increased IL-1 β mRNA and protein levels are an early and local response at the lesion site that could trigger other, later, responses to traumatic SCI.

The function of IL-1 β remains unclear. Some evidence indicates that IL-1 β may exert beneficial effects on the CNS after injury such that IL-1 β and its type 1 receptor may be involved in the maintenance of cell survival rather than induction of neuronal death. Direct application of inflammatory cytokines with SCI has been shown to reduce tissue loss^[27]. On the contrary, however, findings of several studies are consistent with the view that an increased level of IL-1 β after injury is adverse. Namely, increased IL-1 β in spinal cord has been associated with neuronal apoptosis^[4,9]. Direct injection of IL-1 β into the spinal cord enhances vascular permeability and produces lymphocyte recruitment^[28]. As such, an early and rapid production of IL-1 β after injury appears to be deleterious to the CNS by triggering apoptosis. It may be that whether one sees enhanced cell survival or augmented apoptosis depends of the dose of IL-1 β present in the cord.

The IL-1 β expression peak (6 h post-injury) occurred when few TUNEL-positive apoptotic cells were present in the lesion area. The number of observed apoptotic cells peaked much later, 24 h after the contusion injury. IL-1 β receptor antagonism with IL-1Ra significantly reduced the number of apoptotic cells present after injury. These data suggest that IL-1 β plays a causal role in neuronal apoptosis in the early phase of SCI. However, the intracellular signaling events initiated by IL-1 β that lead to apoptotic cell death remain largely unknown.

A number of studies have provided evidence that cell death from moderate traumatic spinal cord injury is regulated, in part, by apoptosis that involves the caspase family of cysteine proteases. A recent study demonstrated that spinal cord injury rapidly increased activation of the effector caspase, caspase-3. The caspase-3 message was present and upregulated several fold after traumatic spinal cord injury^[29]. Moreover, upstream and downstream components of the caspase-3 apoptotic pathway are activated after traumatic spinal cord injury in rats. These effects occur early in neurons in the injury site and hours to days later in oligodendrocytes adjacent to and distant from the injury site^[11]. Nestic O *et al*^[9] showed that downstream components of the caspase-3 apoptotic pathway were activated after SCI in the rat. Furthermore caspase inhibition reduced post-traumatic lesion size and improved motor performance^[10], indicating that caspase-3 is a potential mediator of apoptosis following CNS injury^[10,11]. However it has not been shown definitively whether IL-1 β induces apoptosis after SCI by activating caspase-3. The present Western blot and immunohistochemistry analyses results showed that caspase-3 expression was up-regulated in a relatively small number of neurons within the gray matter of the lesioned area at 6 h after SCI. Intense caspase-3 immunoreactivity was seen in gray matter neurons by 24 h after injury. Furthermore, IL-1 receptor antagonist treatment after SCI attenuated injury-induced upregulation of caspase-3 gene expression and resulted in fewer TUNEL-positive cells. Thus, these results are consistent with the hypothesis that IL-1 β -induced apoptosis is mediated via induction of caspase-3 expression following SCI.

The MAPKs are a family of signaling molecules that transduce extracellular stimuli into intracellular responses in a wide variety of circumstances^[15,30]. p38 MAPK is a key component in stress-induced signal transduction pathways. To test whether p38 MAPK signaling is involved in IL-1 β induction of apoptosis, we examined the expression of p38 MAPK after SCI with immunoprecipitation and Western blot techniques. Increased levels of phospho-p38 MAPK were observed following SCI. Intrathecal injection of IL-1Ra attenuated the expression of caspase-3, and reduced the number of TUNEL-positive cells. In addition, treating the injured spinal cord with the MAPK inhibitor SB203580 resulted in a marked reduction in the expression of caspase-3 and the number of TUNEL-positive cells in the cord as compared to that observed in vehicle controls. These results are consistent with the hypothesis that IL-1 β -induced apoptosis is mediated in part by p38 MAPK activation following SCI, and further that the apoptotic signal may then subsequently be

mediated by caspase-3.

In conclusion, our study provides evidence that IL-1 β serves as an external apoptosis triggering signal in the spinal cord after injury. Our results further suggest that the apoptotic cell death induced by IL-1 β is mediated, in part, by phosphorylation of p38 MAPK and subsequent activation of the apoptotic gene caspase-3. These findings suggest that inhibition of p38 MAPK after SCI (ie by SB203580) may prevent neuronal cell death after SCI.

Important Announcement: the Online Manuscript Submission and Review System was Launched!

Acta Pharmacologica Sinica announced that its online manuscript submission and review system based on ScholarOne Manuscript Central (<http://mc.manuscriptcentral.com/aphs>) was launched on May 25, 2005.

As the leading web-based peer-review system applied by many journals, Manuscript Central is a complete, database-driven software for the online submission and review of full-text manuscripts and graphics. The system provides fully electronic workflow and will speed up the time from submission to decision.

Acta Pharmacologia Sinica strongly recommend its authors to submit manuscript via this system, which enables this journal to handle the manuscript quickly and efficiently. Please read the User Guide before submitting manuscript online. For more detailed submission instruction, please consult the Manuscript Central Online User Guide (<http://mcv3help.manuscriptcentral.com/tutorials/>). You may also contact the Editorial Office who will be pleased to help you.

Abstract

Aim: To observe whether an amyloid β ($A\beta$)-induced increase in interleukin (IL)-1 β was accompanied by an increase in the p38 mitogen-activated protein kinase (MAPK) pathway and a decrease in the cell survival pathway, and whether sodium ferulate (SF) treatment was effective in preventing these $A\beta$ -induced changes.**Methods:** Rats were injected intracerebroventricularly with $A\beta_{25-35}$. Seven days after injection, immunohistochemical techniques for glial fibrillary acidic protein (GFAP) were used to determine the astrocyte infiltration and activation in hippocampal CA1 areas. The expression of IL-1 β , extracellular signal-regulated kinase (ERK), p38 MAPK, Akt/protein kinase B (PKB), Fas ligand and caspase-3 were determined by Western blotting. The caspase-3 activity was measured by cleavage of the caspase-3 substrate (Ac-DEVD-pNA). Reverse transcription-polymerase chain reaction was used to analyze the changes in IL-1 β mRNA levels.**Results:** Intracerebroventricular injection of $A\beta_{25-35}$ elicited astrocyte activation and infiltration and caused a strong inflammatory reaction characterized by increased IL-1 β production and elevated levels of IL-1 β mRNA. Increased IL-1 β synthesis was accompanied by increased activation of p38 MAPK and downregulation of phospho-ERK and phospho-Akt/PKB in hippocampal CA regions prepared from $A\beta$ -treated rats, leading to cell death as assessed by activation of caspase-3. SF significantly prevented $A\beta$ -induced increases in IL-1 β and p38 MAPK activation and also $A\beta$ -induced changes in phospho-ERK and phospho-Akt/PKB expression levels. **Conclusion:** SF prevents $A\beta$ -induced neurotoxicity through suppression of p38 MAPK activation and upregulation of phospho-ERK and phospho-Akt/PKB expression.

Introduction

Alzheimer disease (AD) is a neurodegenerative disorder characterized by progressive deposition of amyloid- β ($A\beta$) peptide in the brain to form senile plaques^[1]. Neuronal cell loss is one feature of AD. Despite the ambiguity of the effectors of neuron loss in the AD brain, recent reports demonstrate that it is an apoptotic process. Cultured cortical neurons exposed to $A\beta_{1-40}$ exhibited increased expression of the proapoptotic protein Bax, increased activation of

caspase-3 (a marker of apoptotic cell death), and increased terminal deoxynucleotidyl transferase-mediated dUTP nick-end labeling reactivity^[2]. Neuronal apoptosis is also seen in human AD brain^[3]. Activation of the apoptotic cascade induced by $A\beta$ could also explain many of the features of the disease and its progression. Furthermore, the proinflammatory cytokine, interleukin (IL)-1 β , plays a significant role in mediating the effects of $A\beta$ ^[2]. However, the underlying mechanisms of toxicity and activation of the neuronal cellular signaling cascades induced by $A\beta$ are not fully understood.

It has become increasingly evident that there is a complex balance between survival and apoptotic signaling pathways in neurons that determines whether they will survive or die. For example, the serine/threonine kinase Akt/protein kinase B (PKB) is activated via a phosphoinositide 3-kinase (PI3K)-dependent signaling pathway when cells or tissues are exposed to growth factors, insulin, and certain cytokines^[4]. Akt/PKB has received widespread attention as an important anti-apoptotic protein^[5]. The extracellular signal-regulated kinase (ERK) pathway plays a major role in regulating cell growth and differentiation^[6]. In contrast, the stress-activated protein kinases, including Jun N-terminal kinase (JNK) and p38 mitogen-activated protein kinase (MAPK), have been proposed to be important signaling components linking extracellular stimuli to cellular responses. JNK and p38 are highly activated in response to a variety of stress signals^[7,8]. Their activation is most frequently associated with induction of apoptosis. However, the role of the MAPK and PI3K/Akt pathways in A β toxicity is unclear.

Sodium ferulate (SF), extracted from a traditional Chinese herbal medicine, has potent antioxidant^[9] and anti-inflammatory activities^[10]. It has recently been reported that long-term administration of ferulic acid protects mice against learning and memory deficits induced by centrally administered β -amyloid^[11]. The primary site of action of ferulic acid could be microglia^[12]. These previous reports prompted us to examine whether SF can suppress the A β -induced inflammatory response and neuronal apoptotic death in rat hippocampus. In addition, we considered that increased IL-1 β concentration and upregulation of the IL-1 β -induced cell signaling cascades might be accompanied by downregulation of survival signals. Therefore, in the present study, we investigated the MAPK and Akt/PKB signaling events in the inflammatory response and apoptosis evoked by preaggregated A β ₂₅₋₃₅, and the protective effect caused by the oral administration of SF *in vivo*. A β ₂₅₋₃₅, a short synthetic peptide possessing properties similar to A β ₁₋₄₀ and A β ₁₋₄₂^[13,14], is suitable to be used in the study of A β toxicity.

Materials and methods

Materials Amyloid- β ₂₅₋₃₅ (Sigma Chemical Co, St Louis, MO, USA) was resuspended at a concentration of 1 mmol/L. To obtain the aggregated form of A β ₂₅₋₃₅, the peptide solution was placed in an incubator at 37 °C for 48 h. SF, a colorless powder with purity >99%, was obtained from Suzhou Changtong Chemical Co (Suzhou, China). Anti-phospho-ERK1/2 (Thr202/Tyr 204), anti-ERK1/2, anti-phospho-p38 MAPK (Thr180/Tyr182), anti-phospho-Akt/PKB (Thr-308),
