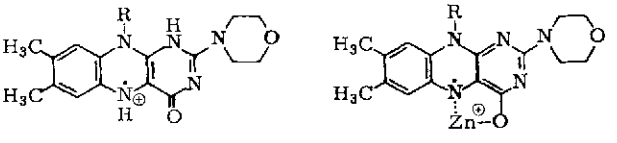
The position of the main band is practically the same, and that of the secondary band is more bathochromic for $[Zn\dot{F}lH]^{\oplus}$, since this compound exists entirely in the 4-iminol form. The visible spectrum of the chelates $[M\dot{F}lH]^{\oplus}$ is practically independent of the nature of the metal ion; the stability constants K^{M}_{FlHM} follow the normal sequence [78] $Mn^{2+} < Fe^{2+} < Co^{2+} < Ni^{2+}$



(57a) R = Tetraacetylribityl *(57b)*

$> Zn^{2+} > Cd^{2+}$ [49]. These radical chelates *(55)* and *(57b)* exhibit an additional weak characteristic absorption band in the near infrared [79]. In the region from 600 to above 1100 mμ the charge transfer band of the flavohydroquinone $(FlH_2)_2$ is diffuse ($\lambda_{max} \approx 1000$ mμ), but the radical chelate band is very sharp. The maximum occurs at 825 ⊥ 5 mμ for all the above-named divalent

[76] K^{B}_{AB} is the stability constant relating to the dissociation $AB \rightleftharpoons A+B$, cf. *J. Bjerrum, G. Schwarzenbach*, and *G. Sillén*: Stability Constants. Chem. Soc. Publ. No. 6, London 1957.

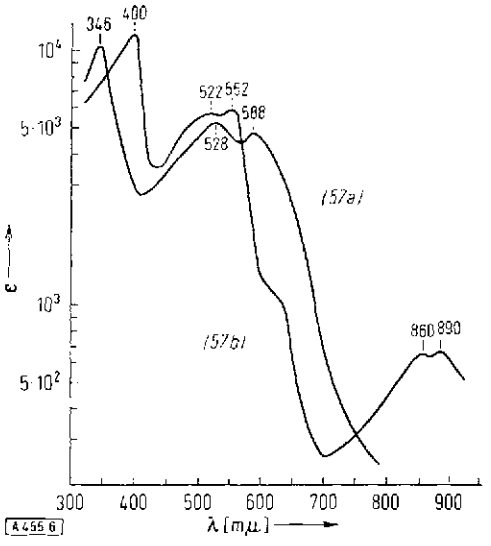

Fig. 6. Spectrum of a pure flavin radical chelate $\dot{F}lRZ_n^{\oplus}$ *(57b)* and of the isoelectronic $\dot{F}lRH_2^{\ominus}$ *(57a)* in $CHCl_3$; taken from [80]. To produce *(57a)*, $Fl_{ox}R$ in $CHCl_3$ is reduced to $Fl_{red}RH_2$ by shaking with aqueous $S_2O_4^{2-}$. Mixing with an identical volume of untreated solution in a Thunberg cell gives 50 % reduction. One drop of anhydrous formic acid or 1 equivalent of zinc acetate in CH_3CN plus 1 drop of triethylamine are then added. On exposure to air, $Fl_{ox}R$ is immediately and quantitatively reformed in both cases.

metal ions. This band is independent of the polarity of the medium and obeys Beer's law [80]. In contrast, the end absorption of the charge-transfer chelates in this region is more intense, but diffuse.

The hyperfine structure of the ESR spectrum of $ZnFlH^{\oplus}$ is entirely different from that observed for free $\dot{F}lH_2$. "Radical chelates" of paramagnetic ions exhibit no ESR signal (because of spin-spin coupling?). Further evidence for the reversal of the disproportionation of $\dot{F}lH_2$ by metal ions, first demonstrated potentiometrically (Fig. 5), is provided by the twentyfold increase of the ESR intensity on addition of diamagnetic Zn^{2+} or Cd^{2+} to a suitably buffered solution of the half-reduced flavin system [81].

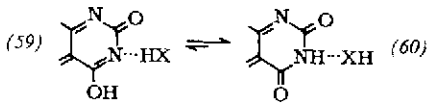
To sum up, flavosemiquinone is the redox state with the relatively highest metal affinity, while flavoquinone possesses absolute specificity for d-electron donating metal ions. Metal coordination provides a reasonable thermodynamic explanation for the stabilization of the radical state.

As expected, flavohydroquinone has no metal affinity [53], since the NH group in position 5 in $Fl_{red}H_3$ has no basic or acidic properties.

VI. Biochemical Aspects

1. Coenzyme Fixation in Flavoproteins

The flavoproteins contain coenzyme-apoenzyme bonds of widely different strength. The "old yellow enzyme" is the prototype of a flavoprotein which dissociates reversibly into coenzyme and apoprotein. On the basis of biochemical data, *Theorell et al.* [82] postulated a hydrogen bond at N–3 as the most likely mode of protein fixation. In view of the chemical evidence discussed above, position 3 is indeed the most plausible site of a directed, reversibly dissociable link between the apoprotein and the flavin nucleus, since it is the only position, the properties of which are almost independent of the redox state. The absorption maximum of the "old yellow enzyme" (λ_{max} = 464 mμ) is at a longer wavelength than that of the free coenzyme (FMN) (λ_{max} = 446 mμ). This shift is not due to H-bonding of the protein



(cf. Section VI,3). It seems impossible that a hydrogen bond at N–3 should favor the tautomeric iminol form of the flavoquinone; rather, the equilibrium *(59)* ⇌ *(60)* must be assumed to be completely displaced to the right, even in enzymatically bound flavin (cf. Section IV,4).

In succinic dehydrogenase [83] the flavocoenzyme is so tightly bound that it could so far not be dissociated from the apoprotein. *Wang et al.* [84], in substantial confirmation of the data found by *Kearney* [85], obtained an FAD-hexapeptide by enzymatic proteolysis of succinic dehydrogenase. From this the adenyl residue was removed by hydrolysis and the ribityl chain by photolysis without splitting off the peptide fragment. Further (alkaline) hydrolysis leads to opening of the pyrimidine ring of the flavin system with liberation of urea. Accordingly, the peptide fragment cannot be linked to the flavin nucleus in positions 1, 2, 3, or 10. The authors postulate a link in position 4. However, as shown in Section IV, substituents such as OR, NHR, SR, aryl, or alkyl can be eliminated from 4-substituted flavins by hydrolysis or mild oxidation. Thus position 4 can be excluded as the site linking the coenzyme with the apoprotein. Substitution in position 5 (*N*-quaternization) would bring about drastic changes in the spectrum. The homoaromatic part of the flavin nucleus is therefore left as the only possible bonding site. In this connection, the functional character of the 8-methyl group of flavoquinone seems relevant (cf. Section IV, 2).

2. FMN-FAD Interconversion in Flavoproteins

Firm evidence is available that both FMN and FAD are native. Nevertheless, *Massey* and *Swoboda* [86] have concluded that mitochondrial flavoproteins do not contain FMN, but that the latter is formed from FAD during preparation of the enzyme (as a result of pyrophosphatase present in the preparations?). *Cremona et al.*

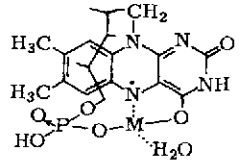
[86] *V. Massey* and *B. E. P. Swoboda*, Biochem. Z. *338*, 474 (1963).

[87] have doubted this conclusion and postulated a non-mitochondrial origin for the labile FAD found side by side with the FMN. However, since no labile FAD is found in the "electron transfer particles" (ETP) of *Crane et al.* [88], this postulate seems also doubtful. It is certain that labile FAD is found in mitochondrial NADH dehydrogenase [89]. Thus labile FAD can only be formed during fractionation of the electron transfer particles, so that a relationship between FMN–FAD interconversion and enzyme activity cannot be ruled out.



(61)

Since the phosphate groups may participate in metal coordination, *e.g. (61)*, autocatalysis of the FAD splitting by enzymatic iron seems at least possible [2], either in the native enzyme complex or "artificially" in the fractionated enzyme.

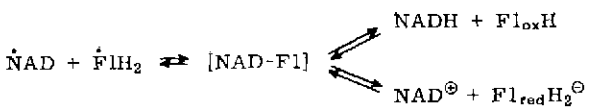
3. Red Intermediates in Flavoprotein Oxidoreduction

A shift of the main flavin absorption band towards the red has been observed with numerous flavoproteins, first of all by *Haas* [90] on reduction of the "old yellow enzyme" with dihydropyridine nucleotide. This shift must, however, not be taken to indicate the formation of "radical" intermediates unless a quantitative correlation of the visible and ESR spectra has been obtained.

As has been shown in Section IV, the only red radical species of metal-free flavin so far known is the cation $\dot{F}lH_3^{\oplus}$. In the free state, this cation is so strongly acidic that its stabilization at pH 7–8 by enzyme protein is highly improbable. Stabilization is effected in flavin metal chelates which are consequently red (cf. Section VI). However, they can be designated as "radicals" only when they contain diamagnetic metal ions (Zn^{2+}, Cd^{2+}) [81], as for example the Zn flavoproteins described by *Gregolin* and *Singer* [91].

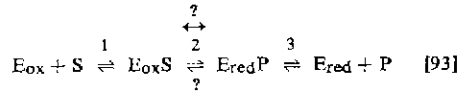
In many other cases the radical content of red intermediates is evidently due merely to a – possibly artificial – admixture of a small quantity of flavin radicals which do not contribute much to the visible spectrum. This is true mainly of crystalline preparations in which a thermodynamically unstable proportion of radicals may be "frozen in" [62].

As discussed in Section IV,8, a shift towards the red can occur quite generally in sandwich complexes, for example in the (NAD–Fl) of the "old yellow enzyme" [90,92]. These complexes are diamagnetic but can readily dissociate into radicals. A determination of the valence state of their components, if at all possible, has to rely upon physical means. Three dissociation paths are possible:



Neither the positions of these equilibria nor the kinetics of the dissociation permit an unambiguous interpretation of the structures of these complexes.

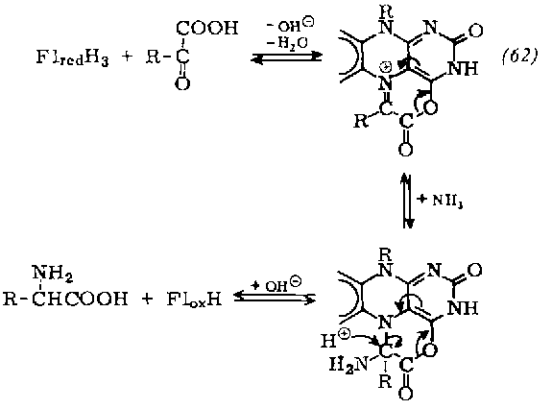
In the redox-catalysis exhibited by the flavoproteins it is debatable whether the second step of the sequence



[93]

represents a chemical reaction or merely a change in charge distribution (mesomerism). The latter seems to be the case with S = Fe^{2+} and P = Fe^{3+} (cf. Section V).

In addition to the sandwich complexes and metal chelates, red flavin intermediates with a purely covalent E_{ox}-substrate or E_{red}-product bonds appear possible. Thus a cyclic flavohydroquinone-azomethinium salt structure *(62)* might be tentatively assigned to the red (E_{red}-P)-complex arising from D-amino acid oxidase



(62)

(P = α-keto acid) [94]. According to the arguments advanced in Section IV,5, this compound represents a resonance-stabilized coplanar derivative of flavohydroquinone, for which a relatively intense absorption at about 500 mμ is to be expected; on decomposition it should give either E_{ox} + substrate or E_{red} + product, while radical dissociation is unlikely unless artificially (*e.g.* photochemically) induced [94]. – This purely hypothetical scheme is advanced merely in order to show that it is not absolutely necessary to look for "non-classical" types of bonds to explain such reactions.

The third possible explanation of the red intermediates is an indirect one. Reaction of a flavoenzyme with its substrate or an inhibitor can alter the tertiary structure of the active center to such an extent that the neighborhood of the flavin assumes a more lipophilic character. Such a change in polarity of the environment can bring about red shifts, *e.g.* in benzene-soluble derivatives of the free coenzyme with an unchanged flavoquinone chromophore [51,65].

Red intermediates are also encountered in flavoproteins which contain redox-active thiol groups (Section VI, 4) and in

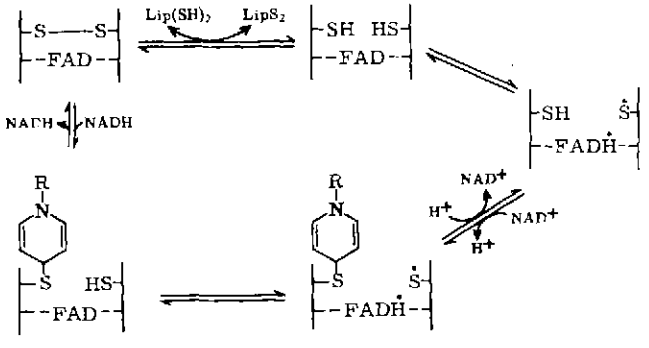
metal flavoproteins which exhibit red color in the aerobic resting state (cf. Section VI, 5).

It should be remembered that flavosemiquinone $\dot{F}lH_2$ is blue even in the protein-bound form (Section IV, 4), while the optical absorption of the radical anion $\dot{F}lH^{\ominus}$ remains to be established. Since the dissociation $\dot{F}lH_2 \rightleftharpoons \dot{F}lH^{\ominus} + H^{\ominus}$ occurs in position 1 or 4, a bathochromic effect is to be expected and accordingly $\dot{F}lH^{\ominus}$ should not be red.

4. Contact between Flavin and Sulfur in Flavoproteins

Massey and *Veeger* [95] were the first to show in the case of lipoamide dehydrogenase (≡ *Straub*'s diaphorase) that the system 2 RSH $\rightleftharpoons$ $(RS)_2 + 2\,H^+$ can participate as the corresponding redox system in the oxidoreduction of flavin, *i.e.* one cysteine group per flavin molecule participates in the active site of lipoamide dehydrogenase (and of other flavoproteins) [95–97].

On reduction with dihydrolipoamide or NADH, red, diamagnetic, stable intermediate forms of the enzyme are formed. Further reduction to flavohydroquinone is possible with NADH only if the product NAD^+ is removed from the equilibrium mixture. The enzyme is then no longer active. Dihydrolipoamide cannot, however, reduce



Scheme 8. Dihydrolipoamide dehydrogenase reaction, simplified scheme, taken from [95]. NAD = Nicotinamide adenine dinucleotide.

Prosthetic groups with a dot denote radicals or flavosemiquinone oxidation levels but not paramagnetic species; the overall spin is zero in each case.

the enzyme to the $Fl_{red}H_3$ stage. *Massey* and *Veeger* [95] interpret the reactions as shown in Scheme 8. The nature of the (Fl–S)-interaction remains unknown; certainly no well-defined oxidation states, in particular no radical character, can be assigned to the constituents of an (FlS) complex.

Evidently it is common to both metal-containing and metal-free flavoproteins that, under native conditions, complete reduction to the flavohydroquinone state need not take place at all. The two types of flavoprotein differ in that one-electron steps are possible in the metal flavoproteins. Here, transition to the oxidized state, which implies dissociation of the complex, appears to be difficult. This type of stability was found in the model chelate peracetylriboflavin-Cu(I) [55], which under anhydrous conditions is oxidized very slowly by oxygen.

5. Flavin-Metal Contact in Flavoprotein

Metal flavoproteins contain iron and sometimes also molybdenum. The ratio flavin : Mo is generally 1 : 1, while that of flavin : Fe varies between 1 : 1 and 1 : 4 and more [98]. In all iron flavoproteins except succinic dehydrogenase, the flavocoenzyme can be irreversibly detached. The residual iron protein then can no longer be reduced by the flavoprotein substrate but requires an artificial reducing agent ($S_2O_4^{2-}$). As *Handler et al.* [98] have shown, the residual iron proteins retain the optical and ESR properties of the flavoproteins. Hence the red color of the iron flavoproteins in the aerobic resting state is due mainly to the iron protein. In the half-reduced state this is not necessarily so [99], since properties of the protein-free model (cf. Section V) indicate that interaction between Fl_{ox} and Fe_{ox} takes place only after addition of an electron (charge-transfer chelate) or of two electrons (radical chelate).

Only recently direct proof of contact between the flavin and the metal in metal flavoproteins has been obtained from studies of the ESR relaxation of flavosemiquinone in metal-free and metal-containing flavoproteins (Fig. 7) [100].

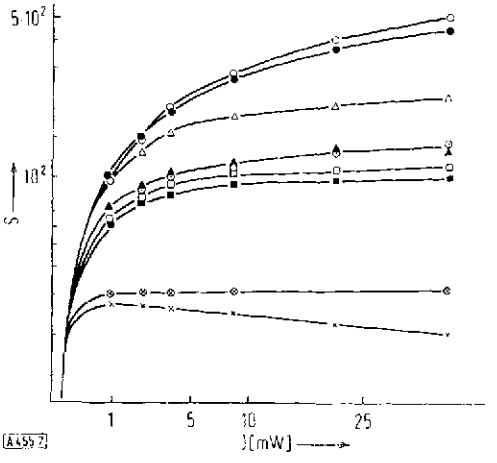

Fig. 7. Spin relaxation of the flavosemiquinone (g = 2.00) in flavoproteins and free flavocoenzymes; taken from [100].
o : Xanthine oxidase
● : dihydroorotic dehydrogenase
△ : NADH dehydrogenase
○ : succinic dehydrogenase
▲ : succinic acid-ubiquinone oxidoreductase
□ : aldehyde oxidase
■ : free flavin + 10 equivalents of Ni^{2+}
⊗ : lipoic dehydrogenase
x : all other metal-free flavoproteins and free flavocoenzymes.
Ordinate: Normalized signal amplitude (S).
Abscissa: Microwave intensity (J).

In all metal enzymes the excited spin of the free radical electron (g = 2.00) falls back to the ground state at a rate at least one order of magnitude greater than in any of the metal-free proteins. d-Metal ions affect the spin relaxation in model flavosemiquinones only when N–5 is unsubstituted, *e.g.* in *(63)*, R = H, but not in *(63)*, R = alkyl. The formation of a σ-bond between Fe and Fl, albeit

[98] *P. Handler, K. V. Rajagopalan*, and *V. Aleman*, Federat. Proc. *23*, 30 (1964).

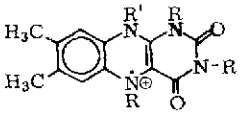
short-lived, is therefore essential; a pure π-type contact is not sufficient.



(63)

Accordingly, the flavin within a metal flavoprotein is only temporarily coordinated, *viz.* during the intermediate stage of the reduction. The equilibrium concentration of the metal-bound flavin fraction may vary widely from enzyme to enzyme.

It is thus the apoprotein which primarily determines the coordination sphere of the flavoprotein iron. For this reason, the influence of the substrate, artificial reducing agents, or inhibitors on the optical properties of metal flavoproteins is exceedingly complicated. An interpretation on a molecular basis is almost impossible in the absence of information about the environment of the iron [101].

6. The Bonding of Non-Heme Iron in Flavoproteins

The only reliable indication for an intact metal coordination sphere in non-heme iron proteins is the characteristic ESR signal appearing on reduction (Fig. 8) [102]. The asymmetry of the signal ($g_z \approx 2.00$, $g_x \approx g_y \approx 1.94$) indicates a coordination polyhedron of no more than rhombic symmetry. In the absence, up to very recently,

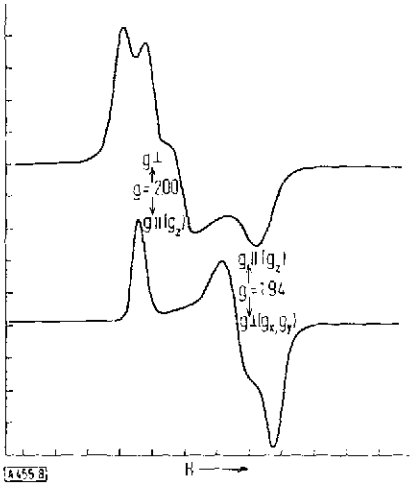


Fig. 8. Comparison of the ESR signals of a reduced non-heme iron protein (Fe-protein from *Azotobacter*, bottom curve), taken from [103], and of the first iron complex of well-defined structure, $Fe(CN)_5NO^{3-}$, with the same g-values; taken from [104].

In the upper curve, $g_\parallel$ shows the ^{14}N-hyperfine structure, due to interaction of the unpaired electron with the nuclear spin $I = 1$ of ^{14}N in the NO ligand of the model.

In contrast, the shoulder in $g_\parallel$ of the iron-protein spectrum must be ascribed to splitting into g_x, g_y which results from the lower symmetry of the natural Fe-coordination polyhedron as compared with the $Fe(CN)_4$ tetragon. Thanks are due to Prof. *Beinert*, Madison, for taking these spectra.

of well defined Fe(II) complexes with g values below 2.00, there was a good deal of doubt about the assignment of the "g = 1.94 signal" to such a complex, particularly since no such spectrum could be expected for Fe(II) in ligand fields of any strength. However, *Beinert et al.* [103] have meanwhile confirmed this assignment by comparison of the ESR spectra of ^{56}Fe- and ^{57}Fe-protein: The preparation containing the ^{57}Fe-isotope exhibited the hyperfine broadening to be expected from the non-zero nuclear spin of the metal.

Accordingly it was to be expected that low-spin Fe(II) with one additional, strongly delocalized electron must be involved in the "g = 1.94"-iron. This calls for the presence of at least one redox-active ligand. Together with *Beinert* and *van Voorst* we found a model of similar field symmetry and electron distribution, namely $[Fe(CN)_5NO]^{3-}$. This compound has a strong field with tetragonal symmetry and an unpaired electron which is so strongly delocalized that a well-resolved ^{14}N-hyperfine structure in addition to the g splitting is observed ($g \approx 1.93$, $g_x = g_y \approx 2.00$) (Fig. 8). The absolute g values are practically the same as in the ESR-active Fe proteins, although here sulfur seems to be the stabilizing acceptor ligand rather than nitrogen (*e.g.* the flavin N–5 atom) [105]. ESR-active Fe-proteins contain stoichiometric amounts of metal and sulfur; the latter can be liberated as H_2S with acid [106], so that normal cyst(e)ine cannot be the source. The chemical nature of this biochemically important "labile" sulfur remains to be explored. Presently it seems that in the non-heme iron four coordination sites are fixed in a strong ligand field, not tetragonally as in heme–Fe but in a (distorted) tetrahedron, so that bidentate redox-active ligands such as disulfides and/or flavin can enter into the reactive cis-positions 5 and 6. The stability of such a configuration must be governed by kinetic or steric factors, so that a good low molecular-weight model will not be easily found. This explains why in aqueous solution Cu(I) serves as a better model for the natural flavin-metal interaction than Fe(II).

Note added in proof: This survey was intentionally completed before the International Symposium on Flavins and Flavoproteins took place at Amsterdam, June 10th–15th, 1965. For the most recent developments as presented at this meeting the reader is referred to the Proceedings of this symposium (*E. C. Slater* and *C. Veeger* ed., Elsevier, Amsterdam, in the press).

The Free-Radical Nature of Nitroso Compounds

By Prof. Dr. W. Theilacker, Dipl.-Chem. A. Knop, and Dr. H. Uffmann

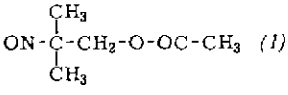
Institut für Organische Chemie
der Technischen Hochschule Hannover (Germany)

Dedicated to Professor F. Micheel on the occasion of his 65th birthday

2-Methyl-2-nitrosopropyl acetate *(1)*, obtained from propene [1], is colorless in the solid state but deep blue in solution; it exhibits paramagnetic resonance absorptions and has therefore free-radical character [2].

We have investigated this phenomenon using 0.1 M solutions in benzene or toluene at room temperature and have found that *N*-nitroso compounds do not give ESR signals; neither do nitrobenzene, azobenzene, azoxybenzene, nor 9,10-diazaphenanthrene-9,10-dioxide. *C*-Nitroso compounds such as *p*-nitrosodimethylaniline, 2-chloro-2-nitrosopropane, and 1-chloro-1-nitrosocyclohexane, which exist only as monomers, also give no ESR signal.

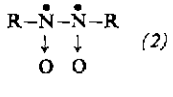
The ESR spectrum of *(1)* exhibits hyperfine structure with three sharp bands of equal intensity and of width 1 gauss with a splitting constant of 14.5 gauss. The splittings in the hyperfine structure in the ESR spectra of aromatic nitroso compounds such as nitrosobenzene, *p*-nitrosotoluene, and *p*-nitrosochlorobenzene are much more complex owing to interaction with the aromatic ring, but here too, resolution into three groups of bands (splitting constant for nitrosobenzene ca. 11 gauss) is apparent. These spectra show free radicals with a high probability for residence of the unpaired electron on the nitrogen to be present.



(1)

A broad band has been observed [3] for nitrosobenzene in ethanol and has been ascribed to a triplet state. We found no such broad band indicative of a triplet state with *(1)* in toluene but only three sharp bands with a g-value of about 2.00; there are no other resonance absorptions on either side of these bands within 2500 gauss, so it is certain that a triplet state is not present.

We assume that *(1)* occurs in the form of a biradical *(2)* in which no interaction occurs between the unpaired electron on one nitrogen atom and the nuclear moment of the other nitrogen and in which the field of each unpaired electron shields the other nitrogen atom. If this is true, 0.1 M solutions in toluene of *(1)* and of nitrosobenzene contain respectively 6 and 0.04% of the biradical form *(2)*. The free radical content increases strongly on passing from the solid (dimeric) nitroso compound to the solution. However, the free radical is not merely an intermediate in the dissociation of the dimer into the monomer, because the formation of the radicals proceeds much more slowly and the equilibrium dimer $\rightleftharpoons$ 2 monomer is attained before the sample is ready for ESR measurement [4].



(2)

The free radicals detected very probably are derived from the dimer, because nitroso compounds which exist as monomers do not give an ESR spectrum, and because the spectrum of 9-nitrosotrypticene, apart from the coupling with the ^{14}N nucleus, shows a further coupling with a *single* proton (hyperfine splitting 3 gauss), which can only be due to steric interaction with a definite proton in one of the aromatic rings. Only in the dimer is the nitroso oxygen sterically fixed in the neighborhood of a single proton.

The ESR spectra of *(1)* and nitrosobenzene in the solid (dimeric) state are more complicated. Although we observed three sharp bands with a splitting constant of 14.5 gauss with *(1)*, the spectrum is overlapped by a broad flat band extending over 50 gauss. Nitrosobenzene exhibits merely a broad unresolved doublet extending over 130 gauss.

Received: May 14th, 1965 [Z 4/829 IE]
German version: Angew. Chem. 77, 717 (1965)

[1] Another synthesis has been described by *J. R. Schwarz*, J. Amer. chem. Soc. 79, 4354 (1957).

[2] The ESR spectrum observed cannot be due to NO, for the latter gives nine lines with a triplet splitting of 100 gauss and a hyperfine structure constant for ^{14}N of 27 gauss. Moreover, decomposition to free NO does not occur since the ESR spectrum of *(1)* remains constant for a month.

[3] *O. Ristau, H. Rein*, and *F. Jung*, Naturwissenschaften *51*, 262 (1964).

[4] An activation energy of 22.5 kcal/mole for the dissociation of the dimeric form of *(1)* into the monomeric form in toluene can be derived from the rate of dissociation (measured from the rate of disappearance of the dimer using ultraviolet spectroscopy or the rate of appearance of the monomer using visible or ultraviolet spectroscopy). *Schwartz* [1] found a value of 23.5 kcal/mole in benzene. The temperature dependence of the rate of free-radical formation from *(1)* gives a value for the activation energy of this reaction of 1–2 kcal/mole; this value is however doubtful owing to experimental uncertainties.

Synthesis of Diazomethyl Ketones without Using Diazomethane

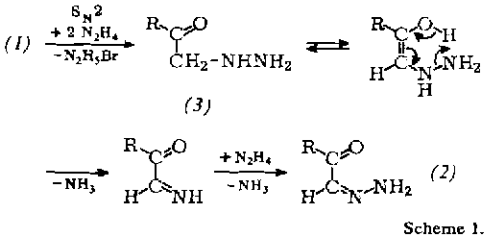
By Prof. Dr. S. Hauptmann, Chem.-Ing. M. Kluge, cand. chem. K.-D. Seidig, and cand. chem. H. Wilde

Institut für Organische Chemie der Universität Leipzig (Germany)

Diazo ketones such as diazomethyl phenyl ketone were previously always made from acid chlorides and diazomethane [1]. We have found that phenacyl bromide *(1)*, R = C_6H_5, reacts with hydrazine in ethanol at 60 °C according to Equation (a) to give a 60% yield of 2-phenylglyoxal monohydrazone *(2)*,

(1) *(2)* (a)

R = C_6H_5. Phenacylhydrazine *(3)*, R = C_6H_5 [2], can be isolated from the reaction mixture below 5 °C. This suggests that the reaction proceeds by the mechanism illustrated in Scheme 1. As in the formation of osazones, the oxidative action of hydrazine is only apparent.



(3) *(2)*

Scheme 1.

The 2-phenylglyoxal monohydrazone can be dehydrogenated by manganese dioxide hydrate [3] in chloroform at 20 °C

to form diazomethyl phenyl ketone *(4)*, R = C_6H_5, in 80% yield. Twenty other known diazo ketones and the

$$\underset{(2)}{R-CO-CH=N-NH_2} \xrightarrow{MnO_2} \underset{(4)}{R-CO-\overset{\ominus}{C}H-\overset{\oplus}{N}\equiv N}$$

unknown diazomethyl ketones listed in Table 1 were prepared in an analogous manner. The yields of the hydrazones

Table 1. New diazomethyl ketones *(4)*

(4), R =	M.p. [°C]	*(4)*, R =	M.p. [°C]
p-C_2H_5-C_6H_4	46–46.5	*p*-CH_3S-C_6H_4	101
p-$(CH_3)_2CH$-C_6H_4	67–68	*p*-$(CH_3)_2N$-C_6H_4	118–119
p-$(CH_3)_3C$-C_6H_4	82.5–83.5	*p*-NC-C_6H_4	142–144
p-Cyclohexyl-C_6H_4	107–108	3-Br-4-CH_3O-C_6H_3	133.5
p-F-C_6H_4	72.5		

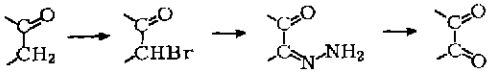
(2) lie between 50 and 70%, and the yields from the dehydrogenations between 80 and 85%.

Diazoketones R–CO–CN_2–C_6H_5 of the azibenzil type can be produced analogously from desyl halides R–C_6H_4–CO–$CH(C_6H_5)X$, but the yields of monohydrazone are only 30–40%. The new α-diazobenzyl phenyl ketones listed in Table 2 have been prepared in this way.

Table 2. New α-diazobenzyl phenyl ketones R–CO–$\overset{\ominus}{C}(C_6H_5)$–$\overset{\oplus}{N}\equiv N$

R	M.p. [°C]	R	M.p. [°C]
p-Cl–C_6H_4	80	*p*-Br–C_6H_4	95
p-CH_3–C_6H_4	87–88	*p*-CH_3O–C_6H_4	93–94

Since the hydrazones *(2)* are readily converted by HNO_2 into the free 1,2-diketones, a new method is available for the oxidation of carbonyl-activated methyl and methylene groups (see Scheme 2).



Scheme 2.

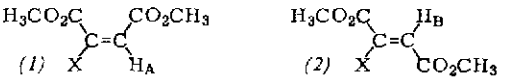
The Stereochemistry of Additions to Acetylenic Triple Bonds

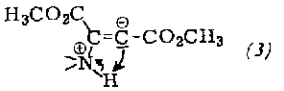
By Priv.-Doz. Dr. E. Winterfeldt and H. Preuss

Organisch-Chemisches Institut der Technischen Universität Berlin (Germany)

It has been observed that the addition of secondary amines to dimethyl acetylenedicarboxylate proceeds *via cis*-addition leading to products of type *(1)* independent of the solvent and basic catalysts used. On the other hand, the addition of alcohols catalysed by tertiary amines such as *N*-methylmorpholine proceeds almost stereospecifically to the *trans*-adducts of type *(2)*. The stereochemistry of the products can be recognized from the chemical shift of the olefinic proton (see Table).



The *trans*-addition can be readily understood in terms of the mechanism formulated by *Truce* [2]. The *cis*-addition can be interpreted as occurring *via* a cyclic electron shift as represented in *(3)*.



(3)

In order to test this hypothesis, the addition of aziridine onto dimethyl acetylene dicarboxylate was studied, because here, owing to the high ring strain in the complex *(3)*, deprotonation might occur readily – perhaps already during the formation of *(3)*. This should then give rise to a *trans*-addition, because a free proton is then added from the reaction medium and not intramolecularly *via* the cyclic mechanism. We found – in agreement with *Dolfini* [1] – that the *trans*-adduct *(2)* is in fact produced in 10% yield alongside 90% *cis*-adduct in ether as solvent. Thermal, non-catalysed addition of alcohols yields *cis*-adduct *(1)* in accordance with the mechanism expressed in *(3)*. Hence the configurational stability of the *trans*-adduct under the conditions of the reaction is assured.

These findings are in agreement with observations of *Jones* and *Whiting* on hydroxyacetylenecarboxylic esters [3] and refute the statement by *Hendrickson* [4] that compounds with mobile hydrogen always afford the *trans*-adducts.

Reversibility of Betaine Formation during the Wittig Reaction

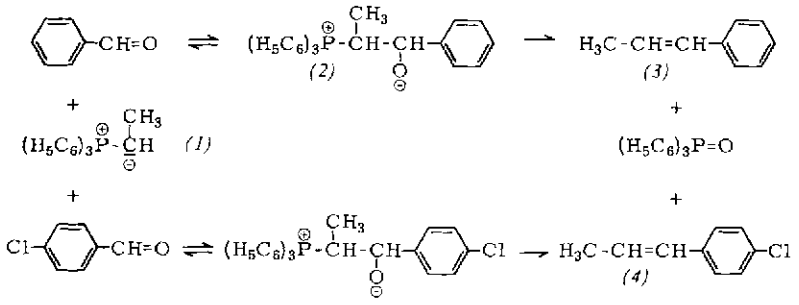
By Dr. M. Schlosser and cand. chem. K. F. Christmann

Organisch-Chemisches Institut der Universität Heidelberg (Germany)

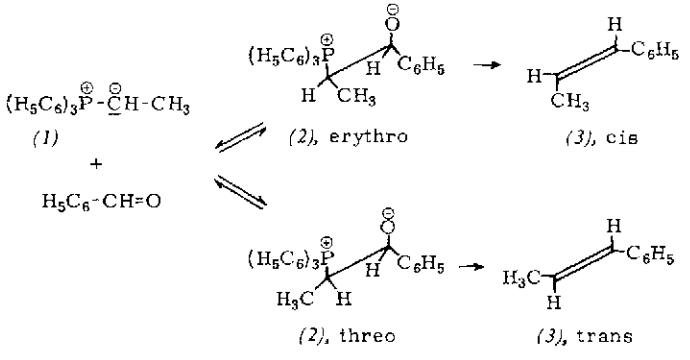
In connection with the stereochemistry of the Wittig carbonyl olefination reaction, the possibility has been discussed [1,2] that even betaines which are derived from non-stabilized phosphorus ylides can redissociate into their components. We have now shown by two different methods that this dissociation takes place.

p-Chlorobenzaldehyde was added to a suspension in benzene or a solution in ether/t-butanol of a mixture of the *threo*- and *erythro*-forms of the betaine *(2)* [3]. The chlorobenzaldehyde trapped some of the ylide *(1)* [3] which together with benzaldehyde is present in equilibrium with *(2)*. When the components were shaken for 16 h at 20 °C, a mixture of *cis*- and

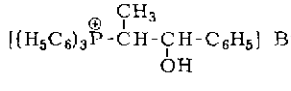
trans-p-chloro-β-methylstyrene *(4)* was obtained in 38% yield in the benzene and in 52% yield in the ether/t-butanol mixture; in addition, 25% and 18% respectively of a mixture of *cis-* and *trans*-β-methylstyrene *(3)* was also formed [4].



Moreover, it proved possible to convert mixtures in which either the *threo-* or *erythro*-forms of *(2)* were enriched, into the normal equilibrium mixture of the diastereoisomers of *(2)*. When *(2)* having a ratio of *threo*-form to *erythro*-form of 90:10 or 99:1 was shaken for 30 h in suspension in benzene at 20 °C, about 50% of *(2)* with the new *threo*:*erythro* composition of 95:5 was recovered in both cases. A 10:90 mixture of the *threo-* and *erythro*-forms of *(2)* had acquired the composition 75% *threo*: 25% *erythro* after the same time.



The ratios of the diastereoisomers were determined by treating *(2)* with HBr in ether, isolating the mixture of the *threo-* and *erythro*-forms of the α-methyl-β-hydroxyphenethyltriphenylphosphonium bromide *(5)* formed, and converting it with potassium t-butoxide into *cis-* and *trans*-β-methylstyrene *(3)*. The salt *(5)* was crystallized from dichloro-



methane in fractions enriched in either the *threo-* or *erythro*-component, *e.g.* with 94% *erythro*-form, m.p. 185–187 °C, or with 90% *threo*-form (solidified oil). Such well-defined mixtures of the diastereoisomeric forms of *(5)* are transformed by phenyl-lithium into the corresponding mixtures of the diastereoisomers of the betaine *(2)*.

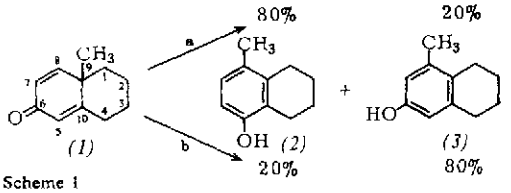
A New Rearrangement of ar-Tetralols with Perchloric Acid [1]

By Dr. med. W. H. Hopff and Prof. Dr. A. S. Dreiding

Organisch-Chemisches Institut der Universität Zürich (Switzerland)

Dedicated to Professor Eugen Müller on the occasion of his 60th birthday

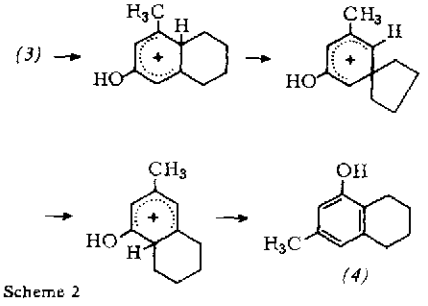
When 1,2,3,4,6,9-hexahydro-6-oxo-9-methylnaphthalene *(1)* was subjected to the dienone-phenol rearrangement by treating it with a little concentrated sulfuric acid in acetic anhydride (conditions a), the only product isolated was 8-methyl-5-tetralol *(2)* [2], whereas with 30–50% aqueous mineral acid (conditions b) the main product was 5-methyl-7-tetralol [3]. Gas-chromatographic analysis of the reaction products has now given the results shown in Scheme 1 [4].



Scheme 1

The carbon skeletons in the phenols *(2)* and *(3)* remain unchanged under both conditions a and b and hence we conclude that both reactions are kinetically controlled [5].

During the course of these investigations we discovered a new thermodynamically controlled rearrangement. On treatment of the dienone *(1)* with 70% perchloric acid, only one rearrangement product is formed, *viz.* 7-methyl-5-tetralol *(4)*, which was shown to be identical with an authentic sample [6]. If the 70% perchloric acid were to convert the dienone *(1)* first into the phenol *(3)* – as does dilute aqueous mineral acid – then the thermodynamic control would have to be ascribed to the rearrangement *(3)* → *(4)*. When *(3)* was treated with 70% perchloric acid at 80 °C for 2 h, the phenol *(4)* was in fact formed in 80% yield. We therefore consider the mechanism shown in Scheme 2 to be applicable to this new "phenol-phenol rearrangement".



Scheme 2

This rearrangement also occurs with *ar*-β- and *ar*-α-tetralol, an approximately 1:1 equilibrium mixture being produced from both substances. In contrast, the equilibrium in the system *(3)* ⇌ *(4)* lies almost entirely on the side of *(4)*.

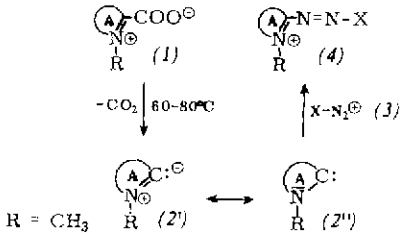
Formation of Nucleophilic Carbenes from Heterocyclic N-Methyl Betaines

By Dr. H. Quast and E. Frankenfeld

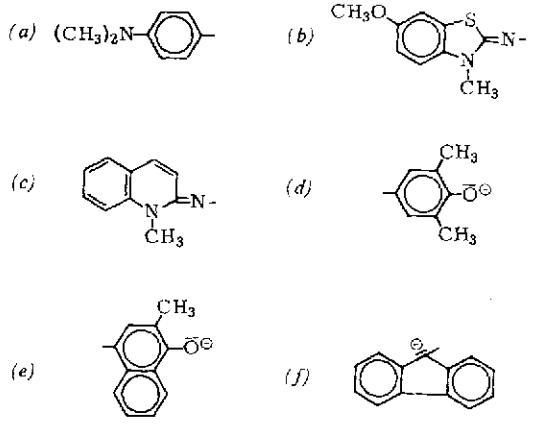
Chemisches Institut der Universität Würzburg (Germany)

We have found that the betaines *(1u)*, *(1v)*, and *(1w)* with the heterocycles A = 2-pyridine [1], 2-quinoline [2], or 1-isoquinoline [3] are decarboxylated by merely warming to 40–80 °C in an aprotic solvent. The ylides *(2)* formed [4] can be trapped by *N*-electrophiles *(3)* to form the colored compounds *(4)*.



X–$N_2^{\oplus}$	Proportion *(3)* : *(1)*	Yield [%] in *N*-methylpyrrolidone of *(4)* from *(1a)* at 80 °C	*(1b)* at 60 °C	*(1c)* at 60 °C
(3a)	1.3:1	11	55–60 [5]	45
(3b)	2:1	26	55	79
(3c)	2:1	—	56	—
(3d)	2:1	—	12–18	—
(3e)	2:1	—	11–17	—
(3f)	3:1	—	1	—

Substituents X in compounds *(3)* and *(4)*:



The rate-determining step in the reaction is apparently the decarboxylation, for the rate of liberation of CO_2 is not affected by the nature of the electrophile *(3)* although the yields of *(4)* depend in a characteristic fashion on the reactivity of the trapping reagent.

The betaines *(1x)*, *(1y)*, and *(1z)* with the heterocycles A = 4-pyridine [1], 4-quinoline [6], and 3-isoquinoline [3] decompose some 50–100 °C higher than *(1u)*, *(1v)*, or *(1w)*. They do not form dyes *(4)* with *(3a)* and *(3b)* under the conditions mentioned above. The greater stability of *(1x)* is in accordance with the results of kinetic experiments [7] where it was found that the rates of decarboxylation of 2-, 3-, and 4-pyridine betaines at 196 °C in ethylene glycol containing 5% quinoline were in ratios of 1600:2.8:1. In order to explain these findings it is assumed that the stabilization of *(2)* is due to an inductive effect of the nitrogen and the mutual steric hindrance of the carboxyl and methyl groups in the ground state of *(1)* [7]. However, comparison of *(1v)* and *(1w)* with *(1z)* reveals that the stability of the ylide *(2)* and hence the activation energy for the decarboxylation are intimately connected with the formation of a low-energy limiting structure *(2'')*.

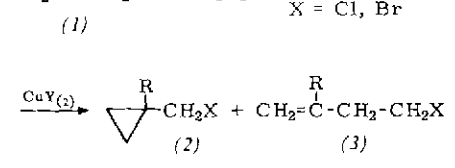
Reaction of Allyl Halides with Diazomethane Catalysed by Copper Salts

By Prof. Dr. W. Kirmse and Dipl.-Chem. M. Kapps

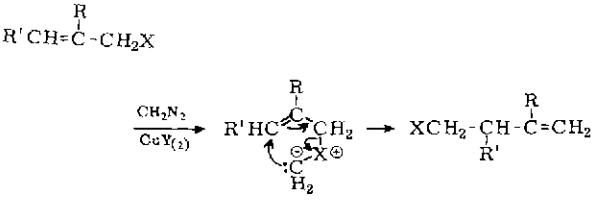
Chemisches Institut der Universität Marburg/Lahn (Germany)

Catalytic decomposition of diazomethane by copper salts in the presence of olefins [1] or aromatic compounds [2] causes insertion of methylene to give cyclopropane or cycloheptatriene derivatives. When this reaction was applied to allyl halides *(1)*, two products were obtained, *viz.* cyclopropylmethyl halides *(2)* and 4-halogenobutenes *(3)*; the total yield based on diazomethane was between 20 and 60%.



When X = Cl, the main product is *(2)*, but when X = Br, preferentially *(3)* is produced. The formation of *(3)* in preference to *(2)* is also promoted when R = Cl. Numerous anhydrous salts of copper(I) and copper(II) can be used as catalysts in this reaction. The use of Cu(I) halides precludes exchange with the halogen of the allyl halide.

The formation of *(2)* is in accordance with known examples [1] and occurs stereospecifically [3]. The 4-halogenobutenes *(3)* are not formed by rearrangement of *(2)*, nor by insertion of H_2C into the C–X bond as in the photolysis of diazomethane in the presence of alkyl halides [4]. It was shown with deuterated and methyl-substituted compounds that the formation of *(3)* is accompanied by a complete allyl rearrange-



ment. We consider this unusual reaction to be due to an electrophilic attack of the H_2C on the halogen with a subsequent S_Ni' reaction.

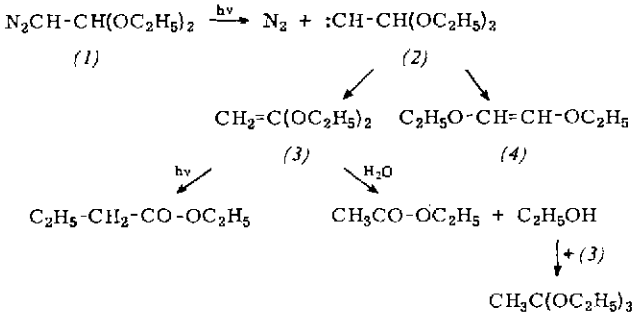
Rearrangement of β-Alkoxyalkylcarbenes

By Prof. Dr. W. Kirmse and Dipl.-Chem. M. Buschhoff

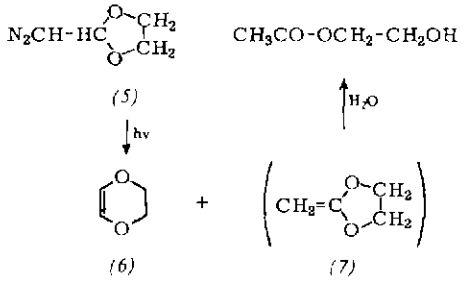
Chemisches Institut der Universität Marburg/Lahn (Germany)

Diazoacetaldehyde diethylacetal *(1)* was obtained in solution by alkaline cleavage of the corresponding nitrosourea. Photolysis or catalytic decomposition of *(1)* with Cu or CuCl leads to ketene diethylacetal *(3)* and 1,2-diethoxyethylene *(4)*, the latter in a *cis*:*trans* ratio of about 1:2. Compound *(3)* was detected only when the solution of *(1)* had been dried over sodium; otherwise ethyl acetate and ethyl orthoacetate are obtained as hydrolysis products of *(3)*. On prolonged irradiation, *(3)* is transformed into ethyl butyrate.

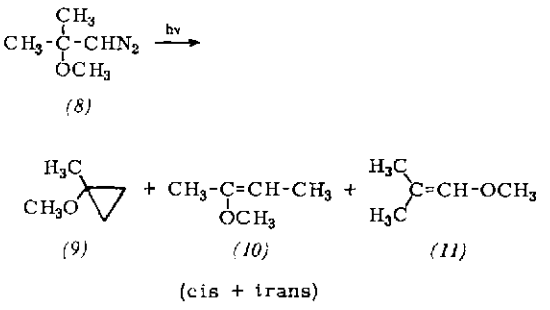


We consider *(3)* and *(4)* to be stabilization products of the carbene *(2)*. No *(4)* is formed by proton-catalysed decomposition of *(1)*. Although carbenes are known to cause hydrogen shifts [1], migration of an alkoxyl group has not been observed previously.

Diazoacetaldehyde ethyleneacetal *(5)* was also prepared and reacted in the same way. Here alkoxyl migration leads to 1,4-dioxene *(6)*. Ketene ethyleneacetal *(7)* is highly reactive and could be procured only in the form of its hydrolysis product, glycol monoacetate.



Irradiation of 1-diazo-2-methoxy-2-methylpropane *(8)* results apart from the usual intramolecular insertion reaction leading to *(9)*, mainly in methyl migration to give 2-methoxy-2-butene *(10)*; only traces of 1-methoxy-2-methylpropene *(11)*, which is formed by a methoxyl shift, were found.



This example demonstrates that the alkoxyl group is not particularly prone to migrate but rather that a β-alkoxyl group tends to promote migration of other β-substituents such as alkyl or alkoxyl [2]. This effect is probably due to the stabilization of a partial positive charge in the transition state [3].

[1] Cf. *W. Kirmse*: Carbene Chemistry. Academic Press Inc., New York 1964, pp. 47–64.

[2] Little or no alkyl migration is observed with alkyl carbenes such as $(CH_3)_3C-CH$: [1].

[3] An analogous effect involving *intermolecular* insertion is discussed by *W. v. E. Doering*, *L. H. Knox*, and *M. Jones*, J. org. Chemistry *24*, 136 (1959).

Bond Angles in Metal Carbonyl and Metal Nitrosyl Compounds [1]

By Priv.-Doz. Dr. W. Beck, Dr. A. Melnikoff [2], and cand. chem. R. Stahl

Anorganisch-Chemisches Laboratorium der Technischen Hochschule München (Germany)

The angle between equivalent metal-carbonyl and metal-nitrosyl bonds can be determined from the ratio of the absolute infrared intensities I of the symmetric (I_s) and asymmetric

$$I = \lim_{c \cdot d \to 0} \frac{1}{c \cdot d} \int \log (I_0/I)_\nu \, d\nu$$

(I_{as}) carbonyl and nitrosyl valence vibrations. The premise is made that the intensity of a band is proportional to the square of the change in dipole moment occurring during the vibration. This transition moment is derived from the representation of the stretching modes by vector addition of the equivalent changes in dipole moment of the carbonyl or nitrosyl bonds [3]. The angle α between the carbonyl groups and the n-fold axis can be calculated for a series of metal carbonyl complexes using the relationships given in the third column of the Table; β is the calculated angle between two neighboring carbonyl groups and β_{exp} is the value found by X-ray or electron diffraction. Plausible values are also obtained for pentacarbonyl manganese compounds and for $Co(CO)_2(NO)P(C_6H_{11})_3$. This method appears to be applicable to metal carbonyl and metal nitrosyl compounds, in which the carbonyl or nitrosyl stretching vibrations are strictly localized. Since the calculated values for the angles are not sensitive to small changes in I_{as}/I_s, experimental errors in I are relatively unimportant. To a rough approximation the bond angle can be arrived at simply from the ratio of the maximum absorptivities: for

Compound	Symmetry of the $M(CO)_x$ group	$(I_{as}/I_s)_{calc}$	$I_s \times 10^4$	$I_{as} \times 10^4$	α	β	β_{exp}

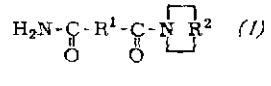
Production of Mixed Dicarboxamides from Cyclic Secondary Amines and Cyclic Dicarboximides. Products of the Reaction of Aziridine with Maleimide

By Dr. J. Sambeth and Dr. F. Grundschober

Chemistry Department, Battelle Institute, Geneva (Switzerland)

Mixed amides of type *(1)* derived from dicarboxylic acids, ammonia, and a cyclic secondary amine can generally be



(1)

made by aminolysis of the corresponding dicarboxylic ester chlorides ROOC–R^1–COCl *(2)* with a secondary amine and subsequent ammonolysis of the ester group with concentrated aqueous ammonia (Method A).

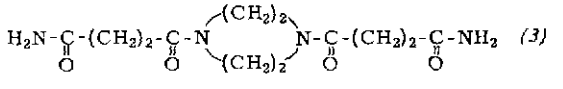
Practical Procedure [1]: A solution of 1 mole of β-methoxycarbonylpropionyl chloride [2] in ether is cooled in ice and 2.2 moles of a cyclic secondary amine is added slowly. The hydrochloride formed is filtered off, and the filtrate is concentrated and vacuum distilled. The resultant β-methoxycarbonylpropionamide is left standing for 4 days with excess 25% aqueous ammonia; the solution is then concentrated and the diamide produced recrystallized from acetone. – In order to procure the aziridine derivative *(1a)*, the ammonolysis must be carried out with anhydrous ammonia in methanol.

It is preferable to treat higher homologues of the cyclic secondary amine (more than 3 carbon atoms) simply with dicarboximides in order to make the mixed dicarboxamides *(1)* [Method B]. In practice, the dicarboximides are heated to boiling with a slight excess (about 10%) of the cyclic secondary amine; the product precipitated on cooling is filtered off and recrystallized from acetone. All the compounds listed in Table 1 are soluble in organic solvents and in water [hot water in the case of *(1e)*].

Table 1. Mixed dicarboxamides *(1)*.

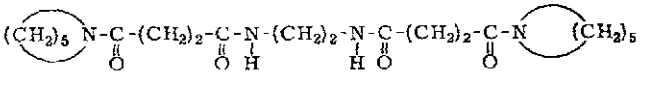
	R^1	R^2	Method A M.p. [°C]	Method A Yield [%]	Method B M.p. [°C]	Method B Yield [%]
(1a)	$(CH_2)_2$	$(CH_2)_2$	85–87	39	–	0
(1b)	$(CH_2)_2$	$(CH_2)_4$	105–108	23	105–107	96
(1c)	$(CH_2)_2$	$(CH_2)_5$	104–105[1]	44	103–105	94
(1d)	$(CH_2)_2$	$(CH_2)_6$	74–76	49	74–78	92
(1e)	$(CH_2)_2$	$(CH_2)_{12}$	–		136–139	85
(1f)	$(CH_2)_2$	$(CH_2)_2$–O–$(CH_2)_2$	–		115–116	95
(1g)	$(CH_2)_3$	$(CH_2)_5$	–		85	90
(1h)	*o*-Phenylene	$(CH_2)_5$	–		120	82

The mixed amide *(3)*, m.p. 200–203 °C, is formed in 50% yield by the reaction of 2 moles of succinimide with 1 mole of



(3)

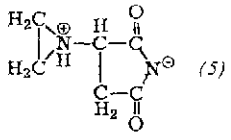
piperazine in triethylene glycol dimethyl ether at 150 °C. *N*-Substituted dicarboximides also react according to Method B. When *N,N′*-ethylenebissuccinimide is heated in a sealed tube at 160 °C with a threefold excess of piperidine, an 85% yield of the mixed amide *(4)* is formed; m. p. 143 to 144 °C.



(4)

Cyclic dicarboximides react at about 80 °C without solvent with aziridine (ethylenimine) by ring opening of both components to give polymers [3]; the reaction of aziridine with maleimide, on the other hand, is strongly exothermic and leads to ill-defined dark products. However, when a solution of aziridine in ether is added dropwise with vigorous stirring to an equimolar amount of maleimide in ether at 25 °C, a white crystalline powder crystallizes out which after recrystallization from acetone melts at 123–125 °C. Its elemental composition and molecular weight indicate it to be 3-(1-aziridinyl)succinimide [4]. Its infrared spectrum contains the bands at 1775 and 1680 cm^{-1} characteristic of the

–CO–NH–CO– group in cyclic imides. Hydrolysis of the compound with dilute acid or alkali releases 1 mole of ammonia. The aziridine ring in the molecule can be determined by acidimetric titration after addition of sodium thiosulfate [5]. The compound is readily soluble in water and on potentiometric titration with 0.1 N NaOH requires 1 mole of sodium hydroxide to neutralize its acidic imide hydrogen. Its aqueous solution has a neutral reaction hence the compound is here probably in the form of an intramolecular salt *(5)*. On melting, the compound undergoes an exothermic reaction to form a strongly cross-linked infusible polymer, which



(5)

is insoluble in organic solvents but swells readily in water; this polymer is hydrolysed by prolonged heating with acids and alkalies and decomposes at 300 °C.

N,N'-Polymethylenebismaleimides with the bridging elements $-(CH_2)_6-$, $-(CH_2)_{12}-$, and $-C_6H_4-CH_2-C_6H_4-$ add on two molecules of aziridine in the same way to give two sirupy products and a crystalline compound that melts at 123–126 °C. On prolonged heating polymerization occurs.

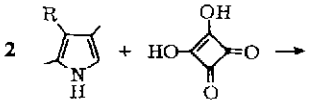
Cyclotrimethine Dyes Derived from Squaric Acid

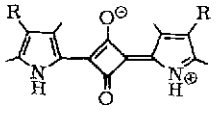
By Prof. Dr. A. Treibs and Dipl.-Chem K. Jacob

Organisch-Chemisches Institut der Technischen Hochschule München (Germany)

1,2-Dihydroxycyclobutenedione or squaric acid *(1)* [1,2] can be condensed with highly reactive pyrroles [3] to give red-violet dyes which are similar to the cyclotrimethine dyes [4]. Owing to the acidity of squaric acid *(1)*, which is still maintained in the dye bridge, the dyes are intramolecular salts, whereas the dipyrrylmethine and dipyrrylpolymethine dyes known to date are salts of dye bases.



(1)

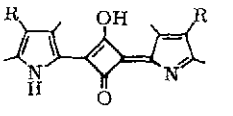


(2)

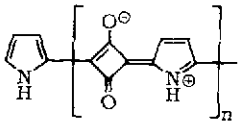
(2a), R = H
(2b), R = $CO_2C_2H_5$
(2c), R = $CO\text{-}CH_3$
(2d), R = C_2H_5

Judging from their mode of formation, elemental composition, and infrared and ultraviolet absorption spectra, the new dyes should have the betaine structure *(2)*, which is stabilized by resonance. The positions and intensities of the absorption bands of the new dyes in particular correspond to the salt form of the trimethine and cyclotrimethine dyes with five- to eight-membered carbo- and heterocyclic rings [4, 5]. The carbonyl absorption in the infrared is at an extremely long wavelength (1620 cm^{-1}) owing to the peculiar bonding arrangement. The possibility of the existence of a tautomeric form *(3)* of *(2)* cannot be excluded; the yellow to red solutions given by the dyes in alkali are probably derived from the form *(3)*. NMR measurements to decide this question could not yet be carried out because of the poor solubility of the new dyes. The dyes *(2a)* and *(2b)* are decolorized rather rapidly by solutions of amines in ethanol. With *(2a)* this reaction is not merely salt formation, for the regeneration of the dye with acid occurs very slowly.

Pyrrole, *N*-methylpyrrole, and pyrrole derivatives with both α-positions free give only blue to blue-green insoluble polymers by polycondensation; these probably have the formula



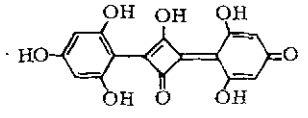
(3)



(4)

(4). Dyestuffs are also formed with 2-substituted indoles, but indole itself undergoes secondary reactions.

Phenols and pyrroles have many reaction features in common. Thus phloroglucinol also condenses smoothly with squaric acid. The resultatet deep red-violet crystalline dyestuff proba-



(5)

bly has the structure *(5)* or a tautomeric polar form of it. The presence of a polar form is not excluded by the position of the absorption due to the carbonyl group on the four-membered ring at 1635 cm^{-1}. Methylation or acetylation dispels the dye character of *(5)* completely. Resorcinol also gives rise to a dye with squaric acid, but phenol does not and can therefore be used as solvent for the reactions described.

Synthesis of (2a): 2,4-Dimethylpyrrole is condensed with squaric acid in a molar ratio of 2:1 in ethanol by heating at 70 °C or by prolonged standing at 20 °C with catalytic amounts of perchloric acid. The violet crystals of *(2a)* are obtained in 65 % yield after washing with ethanol, water, ethanol, and ether, and are recrystallized from chloroform. These crystals release 1 mole of water of crystallization at 90 °C in vacuum and then melt at 240–250 °C (decomp.); the ultraviolet spectrum of *(2a)* in chloroform has $\lambda_{max} = 550 m\mu$ ($\varepsilon = 1.2 \times 10^5$); its infrared spectrum in KBr has ν_{NH} at 3230 cm^{-1} (w) and ν_{CO} at 1635 (vs) and 1610 cm^{-1} (vs).

Synthesis of (5): Quadratic acid is refluxed for 4 h with a twofold molar amount of phloroglucinol in a twentyfold amount of acetic acid. The dye starts to crystallize from the hot solution and is obtained in 67 % yield; it is recrystallized from boiling glacial acetic acid; m.p. 340–345 °C (decomp.) [6]; infrared spectrum in KBr: $\nu_{OH} = 3300–2950$ cm^{-1} (s); $\nu_{CO} = 1635$ cm^{-1} (s); $\nu_{CO(?)} = 1585$ cm^{-1} (s). On drying at 95 °C in vacuum the dye loses 0.5 mole of acetic acid of crystallization.

1,2:3,4:5,6-Tris-(2,2'-biphenylylene)borazole — a Trimer of 9,10-Azaboraphenanthrene

By Dr. R. Köster, Dr. S. Hattori, and Y. Morita

Max-Planck-Institut für Kohlenforschung, Mülheim/Ruhr (Germany)

N,N',N''-Tris-(2-biphenylyl)borazole *(1)* is produced in about 90 % yield by heating 2-aminobiphenyl and triethylamine-borane above 60 °C, hydrogen and triethylamine being liberated.

$$o\text{-}C_6H_5\text{–}C_6H_4\text{–}NH_2 + 3\ H_3B\leftarrow NR_3 \rightarrow [C_6H_5\text{-}C_6H_4\text{–}NBH]_3 + 6\ H_2 + 3\ NR_3$$

(1)

When the colorless crystals of *(1)*, m.p. 179–180 °C, ν_{BH} = 2490, 2510 (shoulder), and 2250 cm^{-1}, ν_{BN} = 1400 and 1425 cm^{-1} [1], are heated to 400–410 °C, hydrogen is evolved; the amount is about 80 % of that to be expected from Equation (a).

$$(1) \rightarrow 3\ H_2 + (C_{12}H_8)_3B_3N_3 \qquad (a)$$

(2)

On cooling, the yellow-brown resin formed deposits an 18 % yield of yellow needles, 1–2 cm long; these are stable in air and are analytically pure after mere washing with benzene; they turn brown above 360 °C and melt at 400–403 °C, ν_{BN} = 1362 cm^{-1} [2]. This compound does not exhibit the infrared bands characteristic of monosubstituted aromatic compounds at 700 cm^{-1} and of the BH bonds between 2480 and 2600 cm^{-1} which appear in the spectrum of *(1)*. Instead, bands for *o*-disubstituted aromatics are observed between 725 and 765 cm^{-1}.

The new product *(2)* is insoluble in benzene, dichloromethane, tetrahydrofuran, sulfolane, and methanol, and slightly soluble in pyridine; its molecular weight was found by mass spectrometry to be 531. The molecular formula for the compound was determined by high-resolution mass spectrometry [3] from the ions $[(2)]^{2\ominus}$ and [9,10-azaboraphenanthrene]$^{\oplus}$ (found 265.618 and 177.073; calc. 265.613 and 177.075). These values indicate a molecular weight of 531.236 or 531.216. Within the range of error, they coincide with the value of 531.226 calculated for $^{12}C_{36}{}^{1}H_{24}{}^{11}B_3{}^{14}N_3$ (^{12}C = 12.0000). The substance sublimes at about 300 °C/0.4 mm and has been assigned the structure of 1,2:3,4:5,6-tris-(2,2'-biphenylylene)borazole *(2)*.

N-Diazonium Salts of Iminophosphoranes

By Dr. K. Bott [1]

Institut für Organische Chemie der Universität München (Germany)

If a solution of triphenylchlorophosphonium or tri-n-butylchlorophosphonium hexachloroantimonate *(1)* in nitrobenzene is stirred with an equimolar amount of anhydrous sodium azide at room temperature and the sodium chloride which precipitates is filtered off, the iminophosphorane-*N*-diazonium hexachloroantimonates *(2a)*, m.p. 166–169 °C, and *(2b)*, m.p. 155–159 °C, can be obtained in respective yields of 83 and 78 % in pure form by addition of ether or carbon tetrachloride.

$$R_3\overset{\oplus}{P}\text{-Cl}\ \ SbCl_6^{\ominus} \xrightarrow[-NaCl]{+NaN_3} R_3P{=}N\text{-}\overset{\oplus}{N}_2\ \ SbCl_6^{\ominus}$$

(1) *(2)*

$$\xrightarrow[-NaCl]{+NaN_3} R_3P{=}N\text{-}\overset{\oplus}{N}_2\ \ SbCl_5N_3^{\ominus}$$

(3)

(a), R = Phenyl
(b), R = n-Butyl

Both compounds crystallize as almost colorless needles that are stable towards atmospheric moisture; their infrared spectra contain a sharp absorption maximum at 2170 cm^{-1} as is to be expected for the N–N vibration of the diazonium grouping.

Reaction of *(1a)* with 2 moles of sodium azide leads to iminotriphenylphosphorane-*N*-diazonium azidopentachloroantimonate *(3a)*, m.p. 90–94 °C in 85 % yield. The color of *(3a)* and the occurrence of an additional, broad infrared band at 2080 cm^{-1} are in good agreement with the structure proposed.

The reactivity of the central phosphorus atom in chlorotripiperidinophosphonium hexachloroantimonate, m.p. 183 to 186 °C, is reduced to such an extent that replacement of the halogen by an azido group under the above conditions occurs only in the hexachloroantimonate anion.

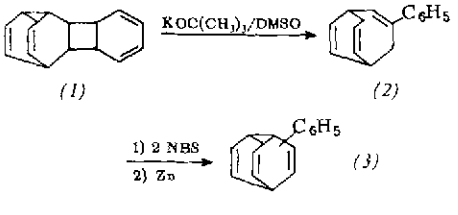
Synthesis and Properties of Phenyltricyclo[3.3.2.0^{4,6}]deca-2,7,9-triene (Phenylbullvalene) [1]

By Priv.-Doz. Dr. G. Schröder

Institut für Organische Chemie der Technischen Hochschule Karlsruhe (Germany)

The dimer *(1)* of cyclooctatetraene, m.p. 76 °C [2], is converted by potassium t-butoxide in dimethyl sulfoxide at about 50 °C within about 50 h into 3-phenylbicyclo[3.3.2]deca-2,6,9-triene *(2)*, m.p. 69 °C, in 70–80 % yield. On catalytic hydrogenation over Pd, *(2)* takes up 3 moles of hydrogen to give $C_{16}H_{22}$, m.p. 74 °C. The ultraviolet spectrum of *(2)* in hexane has a maximum at 242 mμ (ε = 4000); its NMR spectrum has a singlet at 2.87 τ (phenyl protons), a multiplet centered around 4.15 τ (olefinic protons), a multiplet at 7.15 τ (bridgehead protons), and two multiplets centered at 7.45 τ



(1) *(2)* *(3)*

and 7.75 τ (protons of the two methylene groups); the peak areas are in ratios of 5:5:2:2:2.

The hydrocarbon *(2)* reacts smoothly with 2 moles of *N*-bromosuccinimide to give a viscous oil which probably contains a dibromide. Dehalogenation of the oil with zinc powder in refluxing t-butanol in the presence of a trace of solid sodium hydroxide produces phenylbullvalene *(3)* [3] in 5-10% yield [based on *(2)*]. It is advantageous to purify the crude dibromide before dehalogenation by chromatography on silica gel (0.05–0.20 mm grain size) with ether/pentane. The crude phenylbullvalene is purified by distillation in a suitable apparatus, *e.g.* a cold finger, and recrystallization from ethanol/ether, and then melts at 74–76 °C.

On catalytic hydrogenation over Pd, *(3)* absorbs four moles of hydrogen to yield a liquid, $C_{16}H_{22}$. The ultraviolet spectrum of *(3)* in hexane has λ_{max} at 262 mμ (ε = 8500). When heated briefly to 300 °C, *(3)* rearranges to β-phenylnaphthalene.

The NMR spectrum of *(3)* [4] varies with temperature. At −40 °C, 5 phenyl protons can be detected as a singlet at 2.83 τ, 5 olefinic protons as a multiplet at 4.17 τ, and 4 aliphatic protons as multiplets around 7.27 τ and 7.80 τ. It follows from the ratio of 5 olefinic to 4 aliphatic protons that an equilibrium mixture of isomers is present in which the phenyl group is situated on a doubly bonded carbon atom. At 90 °C the NMR spectrum comprises a singlet at 2.85 τ and a singlet (line width 4 cps) at 5.72 τ in area ratios of 5:9. At higher temperatures the nine bullvalyl protons have thus equivalent chemical shifts.

Preliminary experiments have shown that it is possible to synthesize bromophenylbullvalene and t-butoxyphenylbullvalene by a method analogous to that used to prepare bromobullvalene and t-butoxybullvalene [5].

Synthesis of Aryl Iminomethyl Disulfides

By Prof. Dr. W. Walter and Dipl.-Chem. P. M. Heil

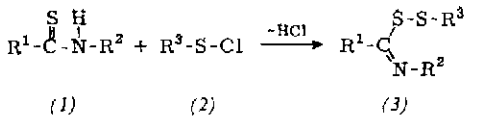
Chemisches Staatsinstitut, Institut für Organische Chemie, Universität Hamburg (Germany)

During the oxidation of thiobenzanilide or thioacetanilide *(1)* with hydrogen peroxide, oxygen adds onto the sulfur atom to form thioanilide *S*-oxides [1].

We have found that the thioanilides *(1)* also react with arenesulfenyl chlorides *(2)* at the sulfur atom to produce aryl phenyliminomethyl disulfides.

In order to establish the constitution of *(3)*, it had to be shown that the R^3S group did not become attached to the nitrogen atom, for it is known that carboxamides react with sulfenyl chlorides at their nitrogen atom to yield *N*-sulfenylcarboxamides [2]. The presence of the disulfide bond was proved by splitting *(3)* with cyanide, when the thioanilides *(1)* were re-formed.

The C=N bond in *(3)* results in a doublet in their infrared spectra in KBr between 1580 and 1640 cm^{-1}; this can be

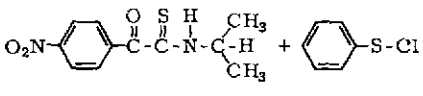


(1) *(2)* *(3)*

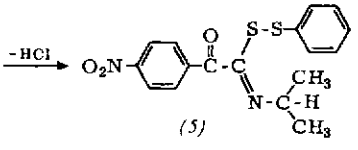
(3a): $R^1 = R^2 = R^3 = C_6H_5$, m.p. 82–83 °C
(3b): $R^1 = CH_3$; $R^2 = R^3 = C_6H_5$, m.p. 28–29 °C
(3c): $R^1 = R^2 = C_6H_5$; $R^3 = o\text{-}O_2N\text{–}C_6H_4$, m.p. 78 °C

assigned to a C=N valence vibration coupled with the remaining groups in the molecule. The peaks for *(3a)* lie at 1608 and 1586 ± 1 cm^{-1}; when *(3a)* is labelled with 97% ^{15}N, the doublet merges to a single intense band at 1574 ± 1 cm^{-1} [3].

Even thioamides which do not form *S*-oxides react with aromatic sulfenyl chlorides. For example, although no *S*-oxide can be detected after oxidation of *N*-isopropyl-*C*-(*p*-nitrobenzoyl)thioformamide *(4)* with H_2O_2 [4], *(4)* does react with benzenesulfenyl chloride to give *N*-isopropylimino-*p*-nitrobenzoylmethyl phenyl disulfide *(5)*, m.p. 97–98 °C. The structure of *(5)* was also proved by cleavage to *(4)* with cyanide and by its infrared spectrum.



(4)



(5)

Phenyl α-Phenyliminobenzyl Disulfide (3a): A solution of 5.33 g of thiobenzanilide in 180 ml of anhydrous ether is cooled to −15 °C, and 2.00 ml of pyridine is added. A solution of 3.61 g of benzenesulfenyl chloride in 50 ml of dry ether is then added to the cold stirred solution over 30 min. The reaction mixture is allowed to warm up to room temperature, and the pyridine hydrochloride which has separated is filtered off and washed with dry ether. Evaporation of the ether from the filtrate leaves an oily residue which crystallizes within a few minutes. Recrystallization from ethanol affords 5.3 g (66%) of pure *(3a)*.

Isolation of Higher Cyclooligoamides from Polyamides [1,2]

By Dr. P. Kusch and Prof. Dr. H. Zahn

Deutsches Wollforschungsinstitut an der Technischen Hochschule Aachen (Germany)

The cycloamides c[Cap]$_{2-5}$, c[Und]$_2$, c[B–A]$_{1-3}$, and c[B–Seh] have been isolated from nylon-6, nylon-11, nylon-6,6, and nylon-6,10, respectively [3]. We have now isolated the higher cyclic oligoamides c[Cap]$_{6-8}$, c[Und]$_3$, c[B–A]$_4$, c[B–Seb]$_2$, and the c[Dod]$_2$ contained in nylon-12, all on a preparative scale by gel filtration of the polyamide extracts on Sephadex G 25 [Pharmacia, Uppsala (Sweden)] and Bio-Gel P10 [Bio-Rad Laboratories, Richmont, Calif. (U.S.A.)]; some of these compounds had previously been merely detected in the polymers by chromatography [4–6].

	M.p. [°C]	Crystal form
c[Cap]$_6$	260	Needles
c[Cap]$_7$	243	Triangular platelets
c[Cap]$_8$	254	Needles
c[Und]$_3$	184	Needles
c[Dod]$_2$	212	Needles
c[B–A]$_4$	273	Needles
c[B–Seb]$_2$	225	Needles

Shreds of polyamide (nylon-11, nylon-12, nylon-6,6, or nylon-6,10) were extracted with acetic acid/formic acid at about 100 °C; nylon-6 was extracted by precipitation from formic acid/ethanol. The extracts were evaporated, the residues were dissolved in 30–50 % acetic acid and loaded onto a column of gel (4 cm diam., 500 cm long); the fractions were eluted with the same solvent. The cycloamides obtained in this way were recrystallized from 30–40 % acetic acid and identified by comparison on thin-layer chromatograms with authentic synthetic samples and by their elemental analyses. All the cycloamide mixtures could be separated with equal ease on Sephadex G 25 and Bio-Gel P10.

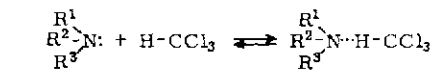
Investigation of Steric Features by Proton Magnetic Resonance

By Dr. H. J. Friedrich

Chemisches Institut der Universität Würzburg (Germany)

Chloroform exhibits only a single proton magnetic resonance signal in basic solvents owing to the formation of hydrogen bonds with rapid proton exchange; the chemical shift observed depends on the position of the association equilibrium. The shift is especially strong in amines and is hardly affected



by alkyl groups R provided the latter do not cause steric hindrance to the association; for example, δ = 520 cps in methylamine. If the alkyl groups exert a steric effect, characteristic changes in the chemical shift occur.

The proton magnetic resonance of chloroform was measured in various sterically hindered amines. The PMR signal varies according to R within a range of 90 cps at 60 Mc. The resonance frequencies bear a characteristic relationship to the E_S parameters of *Taft* [1], which give a measure of the steric requirements of alkyl groups (see Table). A linear correlation is obtained which is simple to apply in order to determine steric parameters by proton magnetic resonance.

Table 1. Relationship between the chemical shift δ of the PMR signal of $CHCl_3$ in amines and the E_S parameters of *Taft* [1]. The measurements were made with approx. 0.5 % solutions of $CHCl_3$ at 20 °C with tetramethylsilane as internal standard in a Varian A 60 instrument.

$R^1R^2R^3N$			ΣE_S R (cf. [1])	δ [cps at 60 Mc/s [a]
R^1	R^2	R^3

CONFERENCE REPORTS

Meeting of South-West German Chemistry Lecturers

The meeting took place in Mainz (Germany) from April 28th to 30th. Altogether 110 papers were presented, in part in three parallel sessions. In order to avoid repetition of publication, only those lectures will be summarized the contents of which have not yet been published or submitted for publication. The abstracts are arranged alphabetically according to authors. For a subject index, see page 727 of this issue.

1

The Polymerization of Isoprene Initiated by Organolithium Compounds

F. Bandermann and *H. Sinn,* München (Germany)

At initiator concentrations above 10^{-5} mole/l in n-heptane, ether, or mixtures of both, the concentrations of the undissociated monomeric organolithium compound and of the isoprene are rate-determining. Solvation by ether reduces the reactivity of the initiator. The overall reaction rate in ether is therefore higher or lower than in heptane, depending on the concentration [1] (double-dilatometer technique in the range of low concentrations).

On the basis of the kinetic data and a postulated reaction mechanism, a system of differential equations and equilibrium relations was set up and solved numerically with an analogue computer. The calculated conversion-time curves agreed up to 90 % conversion with the experimental curves within the computing error of 1–3 %.

Solutions of butyl-lithium in n-heptane were found to have the resistances tabulated below (cell constant = 0.01 cm^{-1}):

[1] Cf. *H. Sinn* and *F. Patat,* Angew. Chem. 75, 805 (1963); Angew. Chem. internat. Edit. 3, 93 (1964); Fig. 1.

Conc. [mmoles/l]	Resistance [Ohm]	Conc. [mmoles/l]	Resistance [Ohm]
0.0016	5×10^{11}	3.40	9.2×10^{7}
0.003	3.6×10^{11}	5.70	7.4×10^{7}
0.006	1.7×10^{10}	7.90	6.5×10^{7}
0.009	1.4×10^{10}	12.0	5.8×10^{7}
0.012	1.3×10^{10}	28.8	4.7×10^{7}
0.027	8.4×10^{9}	45.4	4.3×10^{7}
0.043	8.3×10^{9}	69.6	4.1×10^{7}
0.027	8.4×10^{9}	45.4	4.3×10^{7}
0.043	8.3×10^{9}	69.6	4.1×10^{7}
0.065	7.2×10^{9}	93.0	3.9×10^{7}
0.088	6.4×10^{9}	132.0	3.9×10^{7}
0.108	6.0×10^{9}	167	3.7×10^{7}
0.572	2.4×10^{8}	236	3.7×10^{7}
0.595	2.6×10^{8}	358	3.8×10^{7}
1.17	1.4×10^{8}		

The step-like course of the conductance-concentration curve can be explained by ionic interactions. The values show that butyl-lithium is practically undissociated even at the lowest concentrations studied.

2

Infrared Spectra and Frequency Assignment of some Aminoboranes Containing ^{10}B

H.-J. Becher and *H.T. Baechle*, Stuttgart (Germany)

From boric acid having 92 % of the boron present as ^{10}B, boron trichloride was made with aluminium tricbloride *via* boron triphenolate. With the aid of well-known amination reactions, the BCl_3 was converted to $Cl_2BN(CH_3)_2$, $ClB[N(CH_3)_2]_2$, and $B[N(CH_3)_2]_3$, and the corresponding derivatives with diethylamino groups. The infrared spectra of these aminoboranes and of the corresponding compounds with the natural ^{11}B: ^{10}B abundance ratio were measured. Owing to frequency coupling, the introduction of ^{10}B displaces the NC vibration bands and one CH_3 deformation band (per compound) as well as the BCl and BN bands. The band displacements are almost always less than 10 cm^{-1}, and were therefore generally not observed previously in the spectra of aminoboranes without ^{10}B-enrichment. With the present measurements, previous assignements can be completed, and more precise information on the nature of the BN, NC, and CH vibrations in the region 900–1550 cm^{-1} can be given.

3

Fulminato-Metal Complexes

W. Beck, *E. Schuierer*, and *K. Feldl*, München (Germany)

Visible and ultraviolet absorption spectra show that a strong ligand field is produced by the ion CNO^-. This can also be derived from the diamagnetism of Fe(II)[*o*-phenanthroline]$_2$-$(CNO)_2$. The smaller d–d splitting Δ compared to cyano compounds is probably due to a smaller amount of metal → ligand π-back-donation in the fulminato complexes. The fulminate ion should be placed approximately after the cyanide ion in the spectrochemical series [1]. Thus the electronic spectra also indicate the presence of M–CNO bonds in the fulminato complexes; a substantially lower d-d splitting would be expected for structures with M–ONC bonds [1].

Reaction of the tetrafulminato complexes of Ni(II), Pd(II), and Pt(II) with phosphines gives the thermally stable compounds $(R_3P)_2M(CNO)_2$ [2]. The yellow diamagnetic Pd-complexes $[(C_6H_5)_3P]_2PdX_2$ ($X = NCO^-$, NCS^-, $C(CN)_3^-$, N_3^-) are prepared similarly from aqueous solutions of $Pd(NO_3)_2$, the corresponding alkali metal salt, and triphenylphosphine.

The *trans*-compounds $(R_3P)_2M(CNO)_2$ (M = Pd, Pt; R = C_2H_5, C_6H_{11}) react with bromine or iodine to give the yellow, diamagnetic complexes $M(PR_3)_2(CNO)_2X_2$ (X = Br, I). Dipole moment measurements show like ligands to be in *trans*-positions in these six-coordinate compounds, as expected.

In the infrared spectra of various metal fulminates, the ν_1 (νNO) and ν_3 (νCN) frequencies increase in the sequence alkali metal fulminates < complex metal fulminates < non-ionogenic heavy metal fulminates [*e.g.* $Hg(CNO)_2$] < aryl metal fulminates [*e.g.* C_6H_5HgCNO] < organic nitrile oxides. From infrared absorption measurements on ^{15}N-containing metal fulminates the force constants can be determined (CNO^-: $k_1 = 6.8$; $k_2 = 15.5$, $k_{12} = 1.3$ mdyne/Å). Gaseous fulminic acid, which is generally written as CNOH, has the structure of a hydrocyanic acid oxide HCNO according to the infrared spectrum, which contains the following bands: $\nu_1 = 3340$ cm^{-1} (ν C–H), $\nu_2 = 2191$ cm^{-1} (ν CN), $\nu_3 = 1250$ cm^{-1} (ν NO, type B band), $\nu_5 = 538$ cm^{-1} (δ CNO, type A band). On the other hand, bands at 3600 cm^{-1} (ν OH), 1300 cm^{-1} (δ OH, type A band), and 900 cm^{-1} would be expected for CNOH.

4

Surface Compounds on Diamonds

H. P. Boehm and *R. Sappok*, Heidelberg (Germany)

On the surface of a diamond crystal, the space lattice of the tetrahedrally linked carbon atoms is interrupted. The "broken" valences are very reactive, since their mutual saturation is possible only at the expense of strong distortion of the tetrahedral arrangement. Surface oxides are formed with oxygen. The surface of a diamond which has been oxidized with oxygen at 400 °C or with aqueous oxidizing agents is weakly acidic and hydrophilic. The higher the oxidation temperature, the more oxygen is bound. Oxygen is slowly absorbed even at room temperature. Continuous combustion to carbon oxides occurs only above about 380 °C.

Attempts to elucidate the constitution of the surface oxides showed the acidity to be due to relatively few carboxyl groups, which are probably attached at the crystal edges. Determinations of the active hydrogen showed that the major part of the oxygen is not bound in the form of carboxyl or hydroxy groups. An infrared absorption band at 1760 cm^{-1} indicates the presence of carbonyl groups; weak bands in the range 1000–1300 cm^{-1} may be ascribed to ether-like groups. Diffraction studies with low-energy electrons [1] showed that the diamond lattice in the oxidized surface is distorted. Only low concentrations of free radicals were detected at the surface.

A hydride surface is formed with hydrogen at 800 °C; C–H absorption is observed at 2850 cm^{-1} in the infrared spectrum. Fluorine and chlorine are also bound at the surface. Bound chlorine is very resistant to hydrolysis. The absorption band at 1410 cm^{-1} indicates a very much stronger bond than in normal organic chloro compounds.

When diamond is heated to 800 °C under low pressure of oxygen (about 0.1 mm), black carbon is formed on the surface [2], whereas in a high vacuum, no transformation occurs even at 1300 °C.

5

Fractionation of Polystyrene by Gel Chromatography

D. Braun and *G. Heufer*, Darmstadt (Germany)

For the fractionation of polystyrene, a gel prepared by free-radical polymerization of ethylidene dimethacrylate in isoamyl acetate at 60 °C is particularly suitable; it makes

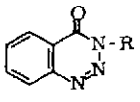
possible separations at room temperature and avoids the difficulties caused by adsorption on cross-linked polystyrene gels. The efficiency of fractionation depends on the network structure of the gel and *inter alia* on the concentration and volume of the sample solution, nature of the swelling and eluting agents, and on column dimensions. Combination of gels of different pore size is necessary for fractionation of polymers having a relatively broad distribution of molecular weights. The distribution curves obtained by gel chromatography agree with those obtained by other methods, *e.g.* fractional precipitation.

6

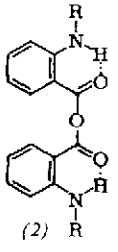
Photolysis of 3,4-Dihydro-4-oxobenzo-1,2,3-triazines Substituted in the 3-Position

G. Ege, Heidelberg (Germany)

3,4-Dihydro-4-oxobenzo-1,2,3-triazines *(1a)–(1c)* having a saturated substituent at N-3 remain unchanged even on prolonged irradiation with a high-pressure mercury vapor lamp (450 W, λ_{max} = 366 mμ). If R is unsaturated, nitrogen is liberated, and various products are obtained depending on the solvent used [1].



(1)



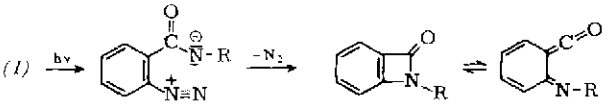
(2)

(a): R = H
(b): CH_3
(c): CH_2–CO–C_6H_5
(d): C_6H_6
(e): 2,4,6-trimethylphenyl (mesityl)
(f): *p*-toluenesulfonyl (tosyl)
(g): benzoyl

Irradiation of *(1d)* in methanol, ethanol, or isopropanol leads to the esters of *N*-phenylanthranilic acid in 90 % yield. In ethyl acetate and in the presence of morpholine, *N*-phenylanthranilic morpholide is formed. In acetone, acridone is obtained, which is also formed in the pyrolysis of *(1d)* [1].

In ethyl acetate, *(1d)* gives rise to the anhydride *(2d)*, m.p. 154 °C; infrared absorptions at 3330 cm^{-1} (NH), 1740 cm^{-1}, and 1680 cm^{-1} (CO). The yield of *(2d)* is 70 % when *(1d)* and 1 equivalent of *N*-phenanthranilic acid in ethyl acetate are irradiated.

In all these reactions *(1)* presumably first dissociates to give *(3)*, from which nitrogen is split off with formation of *(4)* which is valence - tautomeric with *(5)*. Addition of alcohol, morpholine, or *N*-phenylanthranilic acid (formed from *(5)* by addition of water) onto *(5)* then results in the products named above.



(1) *(3)* *(4)* *(5)*

On irradiation of *(1e)*, the anhydride *(2e)* is formed; m.p. 205 °C. In the solvents investigated (dichloromethane, acetone, methanol), *(1f)* gives *N*-tosylbenzamide, together with formaldehyde formed from methanol. In ethyl acetate, *(1g)* yields benzoylanthranil.

To enable the possible empirical formulae of a compound to be determined from C and H analyses, 63000 sum formulae CHNO (S) up to $C_{40}N_6O_{12}$ were tabulated, together with the corresponding molecular weights and percentages of the elements. The table is to be published shortly by Verlag Chemie, Weinheim/Bergstr. (Germany).

7

Isotopic Exchange Reactions of Alkyl Halides

H. Elias, Darmstadt (Germany)

We have investigated the kinetics of homogeneous isotopic exchange reactions between alkyl halides and halide ions

$$R\text{–}X + {}^*X^- = R\text{–}{}^*X + X^-$$

in order to determine the influences of the residue R, the halogen X, and the solvent.

Comparative experiments with ^{36}Cl- or ^{82}Br-labelled 1-chlorohexane *(1)*, 2-chlorohexane *(2)*, 3-chlorohexane *(3)*, 1-bromohexane *(4)*, 2-bromohexane *(5)*, 3-bromohexane *(6)*, chlorocyclopentane *(7)*, chlorocyclohexane *(8)*, chlorocycloheptane *(9)*, chlorocyclooctane *(10)*, and isopropyl chloride *(11)* in anhydrous dimethylsulfoxide (DMSO), dimethylformamide (DMFA), and diethyleneglycol (DEG) gave the following results:

1. In the systems *(1)*, *(2)*, or *(3)*/Cl^-/DMSO and *(4)*, *(5)*, or *(6)*/Br^-/DMSO, the isotopic exchange reaction is bimolecular (S_N2). The rate constants at 25 ° are in the ratios $k_{(1)}$: $k_{(2)}$: $k_{(3)}$ = 28.4:1:0.87 and $k_{(4)}$: $k_{(5)}$: $k_{(6)}$ = 22.7:1:1.30. The bromides *(4)*, *(5)*, and *(6)* react about 100 times faster than the corresponding chlorides.

2. The exchange in the systems *(7)*, *(8)*, *(9)*, *(10)*/Cl^-/DMSO is bimolecular (S_N2). At 25 °C, the rate constants are in the ratio $k_{(7)}$: $k_{(8)}$: $k_{(9)}$: $k_{(10)}$ = 156:1:77.4:8.10.

3. The exchange at 25 °C in the system *(1)*/Cl^-/DMSO is 245 times faster than in the system (1)/Cl^-/DEG, which also reacts bimolecularly.

4. In the system *(11)*/Cl^-/DMFA the exchange is bimolecular (S_N2); a first-order reaction (S_N1) does not occur.

5. At 70 °C, tetrabutylammonium bromide (< 0.03 mole/l) is completely dissociated in DMSO. The dissociation constants in the systems LiCl/DMSO, tetrabutylammonium chloride/DMFA, and LiCl/DEG at 30 °C are 2.4×10^{-2}, 4.1×10^{-2}, and 17.9×10^{-2} mole/l, respectively.

8

NMR-Spectroscopic Conformational Analysis of Menthylamines and Carvomenthylamines

H. Feltkamp, Tübingen

Measurements of conformational equilibria have to date been made almost exclusively on monosubstituted cyclohexanes. In order to test the applicability of the methods to more highly substituted cyclohexanes, we have studied 16 stereoisomeric alcohols of the menthol type and 8 stereoisomeric menthylamines and carvomenthylamines together with the 8 corresponding nitromenthanes.

The menthylamines were prepared by oxidizing menthol with chromosulfuric acid in ether to menthone, which was rearranged to a mixture of menthone and isomenthone with sulfuric acid. The mixture of the oximes was separated by column chromatography on silica gel using a mixture of 25 % ammonia, acetone, benzene, and petroleum ether (1:49:200:750) at 50–70 °C, the pure oximes were reduced with sodium in ethanol, and the mixture of amines was separated by countercurrent distribution. The carvomenthylamines were prepared from carvacrol. The mixture of oximes was separated by chromatography on silica gel with benzene/ethyl acetate/petroleum ether (2:3:20) at 50–70 °C, and the pure oximes reduced as above. The resulting mixture of amines was separated by crystallization of the hydrochlorides, column chromatography, and preparative thin-layer chromatography. The pure amines were oxidized to the nitro compounds with peroxyacetic acid.

The NMR-spectroscopic analysis of the configuration and conformation of the compounds showed that the menthyl and neomenthyl forms are fixed, as are the neoiso forms of the nitro compound and neoisocarvomenthylamine. The functional groups in the menthyl and fixed neoiso forms are equatorial, those in the neo forms axial. Neoisomenthylamine and the iso compounds are conformationally non-uniform.

9

Isomerism of Complexes of the Type $[\pi\text{-}C_5H_5M(CO_2)_2]$

R. D. Fischer and *A. Vogler*, München (Germany)

Dimeric cyclopentadienyl - metal carbonyl complexes $[CpM(CO)_n]_2$ (n = 1–3) can exhibit a considerable dipole moment in solution even when they have a center of symmetry in the crystalline state.

The dependence of the ν(C–O) frequencies of the terminal and bridging CO ligands of the complexes with n = 2 on the solvent, the central metal, and the temperature indicates the presence of four (sometimes coexisting) isomers. Chief characteristics are the presence or absence of a center of inversion and of two CO bridges. A center of symmetry is found only in the solid state. The tendency to bridge formation decreases with increasing atomic number of M. For example, $[CpFe(CO)_2]_2$ exists in the solid state only as the CO-bridged *trans*-form, whereas dissolved $[CpOs(CO)_2]_2$ exists as the pure *cis*-form with a direct Os–Os bond. The Ru complex in solution is an equilibrium mixture of the *cis*-bridged and *cis*-nonbridged isomers.

The preferred existence of the *cis*-isomers in nonpolar solvents is ascribed to weak interactions of, in first approximation, nonbonding electrons of the metal.

10

Proton Magnetic Resonance Measurements on Hydrogen-Bond Associates of Chloroform

H. J. Friedrich, Würzburg (Germany)

The dependence of the proton magnetic resonance frequency of chloroform on the diamagnetic susceptibility of the solvent ($\chi_v = -0.460\times10^{-6}$ to -0.856×10^{-6} EMU/ml) has been studied systematically by measurements in 60 solvents (cylindrical sample tubes, externally standardized). The proton magnetic resonance signals of tetramethylsilane (TMS) in the same solvents were also measured. The TMS-signals were found to occur within a frequency range of 50 c.p.s. (at 60 Mc/sec) and to accurately obey the linear equation for the susceptibility shift $(\Delta H/H)_s$:

$$(\Delta H/H)_s = (2\pi/3)\Delta\chi_v$$

All other effects of the medium can therefore be neglected in comparison to the effect of the susceptibility.

On the other hand, the $CHCl_3$-signal (at 20 °C) varies over the range of 100 c.p.s., since the medium causes association shifts $(\Delta H/H)_A$ by hydrogen-bond formation, in addition to the susceptibility shifts; thus:

$$\Delta H/H = (\Delta H/H)_s + (\Delta H/H)_A$$

For solvents of similar structure and with the same functional groups, the $(\Delta H/H)$ *vs.* χ_v diagrams are still linear with slope $2\pi/3$, since the association shift is specific to structure and functional grouping. Exceptions are the media in which the hydrogen bonding to chloroform is sterically hindered; the degree of hindrance can be obtained from the $(\Delta H/H)$ *vs.* $\Delta\chi_v$ diagram.

The straight lines of $(\Delta H/H)$ *vs.* $\Delta\chi_v$ for the sterically unhindered chloroparaffins, nitriles, ethers, alcohols, ketones, and amines are displaced with respect to those for the paraffins, with which chloroform cannot form H-bond associates, to decreasing fields by the characteristic amounts $(\Delta H/H)_A$ (see Table below). These displacements are a measure of the strengths of the hydrogen bonds, and can according to *W. G. Schneider* be related to the dipole moments of the hybrid atomic orbitals of the proton acceptor atom involved in the bond. These orbital dipole moments were calculated for pure sp, sp^2, and sp^3 atomic orbitals (see Table) according to the AO theory of *C. A. Coulson*. A good

Solvent	$(\Delta H/H)_A$ for $CHCl_3$ [ppm] at 20 °C	Atomic orbital dipole moments μ [Debye]
Paraffins	0	–
Chloroparaffins	0.22	Cl(sp^3): 2.44
Nitriles	0.53	N(sp): 3.74
Ethers	0.70	O(sp^3): 2.78
Alcohols	0.87	O(sp^3): 2.78
Ketones	0.90	O(sp^2): 3.03
Amines	1.53	N(sp^3): 3.25

correlation is obtained, except for the nitriles, when a pure N(sp) atomic orbital is assumed. The deviation can be explained by assuming a higher s-character and by taking into account the magnetic anisotropy of the nitrile triple bond.

11

^{1}H-NMR-Investigations of Organic Platinum and Rhodium Compounds

H. P. Fritz and *K.-E. Schwarzhans*, München (Germany)

In earlier work [1], a π-cyclopentadienyl ligand was postulated to occur in $(CH_3)_2PtC_5H_5$. By comparison with the NMR-spectra of six other platinum cyclopentadienyl complexes and with ultraviolet spectra of σ-cyclopentadienyl compounds it could now be shown that the assumed regular pentagonal ring structure is not correct, but that the conjugated diene system remains intact.

In the synthesis of similar compounds of ^{103}Rh, which is also magnetically active, an intermediate was found, the structure of which was established as

$$Rh_2I_2(CH_3)_4[S(CH_3)_2]_3$$

on the basis of spin-spin coupling in the NMR-spectrum. From this substance, the crystalline, red-brown compound

$$\pi\text{-}C_5H_5Rh(III)(CH_3)_2S(CH_3)_2$$

was isolated. The compound dissolves in organic solvents and is stable in air. Above 100 °C it decomposes with liberation of iodine. Addition of NaC_5H_5 leads to a splitting of the iodo and dimethylsulfide bridges and formation of rhodium cyclopentadienyl compounds.

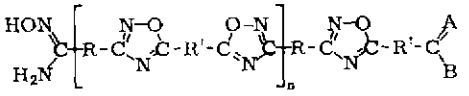
12

Polymers with 1,2,4-Oxadiazole and 1,2,4-Oxadiazoline Rings

W. Funke, Stuttgart (Germany)

Polycondensates from diamide oximes and dicarboxylic dichlorides or dialdehydes were cyclocondensed intramolecularly to yield poly-[1,2,4-oxadiazoles] *(1)* or poly-[1,2,4-oxadiazolines] by heating in dimethylformamide/benzene and distilling off the benzene and the resulting water, or by fusion with $ZnCl_2$.

For the preparation of *(1)*, products obtained by interfacial polycondensation were also cyclocondensed by heating in diphenyl/diphenyl oxide or in *N*-methylpyrrolidone.



(1)

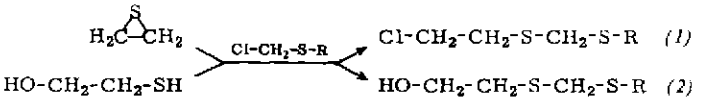
The melting points of the usually powdery products were between 100 and 360 °C. Their molecular weights were found by end-group analysis and cryoscopic measurements to be in the range 1500–2000. The degrees of polycondensation are relatively low because the solubilities of the intermediate polycondensates decrease rapidly with increasing molecular weights.

13

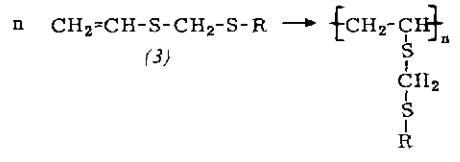
Synthesis and Polymerization of S-Vinylmercaptals of Formaldehyde

K. Gollmer and *H. Ringsdorf*, Marburg (Germany)

From α-chloromethyl thioethers [1] and ethylene sulfide or β-mercaptoethanol, β-chloroethylmercaptals *(1)* and β-hydroxyethylmercaptals *(2)* of formaldehyde were prepared.



By splitting off HCl from *(1)* and H_2O from *(2)* with KOH/NaOH (3:1) at 180–300 °C/3–100 mm Hg, the corresponding formaldehyde-*S*-vinylmercaptals *(3)* were obtained in yields of 50–70 %. The monomers could be polymerized radically with azobisisobutyronitrile and cationically with boron trifluoride.



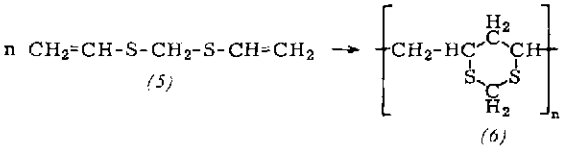
(3)

R = CH_3, C_2H_5, n-C_3H_7, iso-C_3H_7, t-C_4H_9, C_6H_5.

Benzoyl peroxide does not function as initiator, since the –S–CH_2–S– group induces acyl peroxide decomposition with the formation of carboxylic acids and acyloxymercaptals.

The concentration of the free-radical initiator does not influence the degree of polymerization (about 100) to any great extent. This may be explained by the reactivity of the mercaptal group, which acts as a chain-transfer agent. The transfer constants of 15×10^{-4} to 30×10^{-4} found for styrene and saturated mercaptals agree with this explanation.

The polymerization was followed dilatometrically. The influence of the substituent R on the rate of radical polymerization corresponds to a superposition of inductive and steric effects.



(5) *(6)*

Polymerization of formaldehyde-*S*,*S*'-divinylmercaptal *(5)* [2] in toluene leads *via* an intramolecular reaction to soluble polymers *(6)*.

[1] *H. Böhme, H. Fischer*, and *R. Frank*, Liebigs Ann. Chem. *563*, 59 (1949).

14

Five-Membered Heterocycles from Hydrazomethane, Aromatic Aldehydes, and Dipolarophiles

R. Grashey, München (Germany)

The reaction of aromatic aldehydes with *N*,*N*'-dimethylhydrazine gives rise to 1,2,4,5-tetramethyl-3,6-diarylhexahydro-1,2,4,5-tetrazines in high yield. The reaction of these compounds with unsaturated systems gives access to many five-membered heterocycles. It is plausible that the hexahydrotetrazines are first split into two molecules of *C*-aryl-*N*,*N*'-dimethylazomethinimine, which then combines with the dipolarophile; other mechanisms are, however, also possible. When the dipolarophiles used are α,β-unsaturated carbonyl compounds or nitriles, pyrazolidine derivatives are obtained in good yields. Among the phenyl-conjugated alkenes, acenaphthylene was found to be a suitable coreactant.

The reaction of the hexahydrotetrazines with isocyanates and isothiocyanates gives especially high yields. Degradation experiments and spectral data show that this reaction usually leads to 1,3,4-triazolidin-5-ones and triazolidin-5-thiones. Δ^3-1,2,4-Triazolines are accessible through reactions of hexahydrotetrazines with thiocyanates, *e.g.* benzyl thiocyanate. The reactions with CS_2 as dipolarophile run particularly smoothly: 3,4-dimethyl-2-aryl-1,3,4-thiadiazolidin-5-thiones can be isolated in high yields.

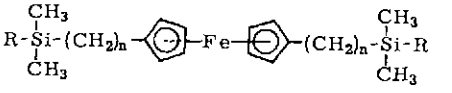
The isolation of the hexahydrotetrazines is not essential. The adducts described can also be obtained directly by heating the three components (aromatic aldehyde, *N*,*N*'-dimethylhydrazine, and dipolarophile). Since, however, side reactions become more important in this procedure, the yields obtained are often poor.

15

Silicon-Organic Polymers Containing Ferrocene

G. Greber and *M. L. Hallensleben*, Freiburg (Germany)

In the H_2PtCl_6-catalysed addition of 1,1'-bis(dimethylhydrosilyl)ferrocene or 1,1'-bis(dimethylhydrosilylmethyl)ferrocene onto acetylene, vinylacetylene, and isopropenylacetylene, 1,1'-disubstituted ferrocene derivatives *(1)*–*(6)* with two functional groups are formed.



(1), R = CH=CH_2, n = 0
(2), R = CH=CH_2, n = 1
(3), R = CH=CH–CH=CH_2, n = 0
(4), R = CH=CH–CH=CH_2, n = 1
(5), R = CH=CH–C(=CH_2)–CH_3, n = 0
(6), R = CH=CH–C(=CH_2)–CH_3, n = 1

Treatment of the divinyl derivative *(1)* with sodium in anhydrous tetrahydrofuran gives a double radical anion capable of initiating the polymerization of vinyl monomers (*e.g.* styrene, methyl methacrylate, acrylonitrile). By transfer of this reaction to products of higher molecular weight with two CH_2=CH–$Si(CH_3)_3$-ferrocene end groups, block copolymers were synthesized.

In contrast to *(1)*, the divinyl derivative *(2)*, in which a methylene bridge separates the ferrocene from the organosilicon group, does not form radical ions.

The bisdiene derivatives *(3)–(6)* can be polymerized by organolithium compounds such as phenyl-lithium or n-butyllithium. The polymers obtained up to 15 % conversion are soluble, and have a "ladder" or double-chain structure, as suggested by their infrared spectra.

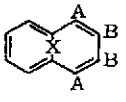
The compounds *(3)–(6)* also undergo Diels-Alder reactions. With difunctional organosilicon philodienes, products with molecular weights around 4000 are obtained in a poly-Diels-Alder reaction. These products contain cyclohexene rings in the main chain in addition to the organosilicon and the ferrocenyl residues. With monofunctional philodienes such as maleic anhydride, difunctional ferrocene derivatives are formed.

16

The Aromatic Character of Systems with Ten π-Electrons: ^{1}H-NMR Spectra of 1,6-Methano- and 1,6-Oxidocyclodecapentaene

H. Günther, Köln (Germany)

1,6-Methanocyclodecapentaene *(1)* [1] and 1,6-oxidocyclodecapentaene *(2)* [2] can be treated NMR-spectroscopically as A_2B_2 systems. For *(1)* the chemical shifts (on the τ-scale) ν_A = 2.73 p.p.m. and ν_B = 3.05 p.p.m. are found. This assignment is supported by a long-range coupling of the A-protons with those of the methylene bridge. For *(2)*, ν_A = 2.54 p.p.m. and ν_B = 2.74 p.p.m. Here the assignment of resonance frequencies is not unambiguous, but in analogy to *(1)* it may be assumed that $\nu_A < \nu_B$. The methylene protons in *(1)* absorb at 10.51 p.p.m.



(1), X = CH_2
(2), X = O

The signals of the peripheral ring protons occur about 1 p.p.m. below those of olefinic protons in comparable structures because of the ring current of the π-electrons. The Pople approximation [3] gives for *(1)* ν_A = 1.80 p.p.m. and ν_B = 2.20 p.p.m., relative to ν = 4.23 p.p.m. for 1,3-cyclohexadiene. The relative chemical shift $\delta\nu$ between the signals of the A- and B-protons is reproduced well by these values, but the absolute values are too low. The presence of a cyclopropane ring in *(1)* can also be excluded on the basis of the ^{13}CH-coupling of the methylene bridge (142 ± 1 c.p.s.) and of the geminal coupling constant (6.9 ± 0.3 c.p.s.) found for the monodeuterated compound.

All HH-coupling constants of *(1)* are very close to those of *(2)*, which indicates that the compounds are stereochemically similar and that the influence of the bridge is not important. The vicinal coupling constants for *(1)* are J_{AB} = 8.97 c.p.s. and J_{BB} = 9.19 c.p.s., for *(2)* J_{AB} = 8.77 c.p.s. and J_{BB} = 9.28 c.p.s. In contrast to cyclic olefins (*e.g.* 1,3-cyclohexadiene, cycloheptatriene) and in agreement with aromatic molecules, the vicinal coupling constants are almost equal. The constants of coupling across more than three bonds are $J_{AB'} \approx 0$ and J_{AA} = 1.46 c.p.s. for *(1)* and $J_{AB'}$ = 0.28 c.p.s. and J_{AA} = 1.13 c.p.s. for *(2)*, departing from the values 1–3 c.p.s. for J_{meta} and 0–1 c.p.s. for J_{para} of classical aromatic compounds, possibly because the relevant CH bonds are not completely coplanar.

The NMR signal of chloroform in a mixture with *(1)* or *(2)* shows an association shift towards higher field, similarly to mixtures of $CHCl_3$ with benzene or its derivatives. Relative to unassociated chloroform the value at infinite dilution is + 1.30 p.p.m. with *(1)* and + 0.97 p.p.m. with *(2)*. The results can be explained by assuming delocalization of the 10 π-electron systems of *(1)* and *(2)*.

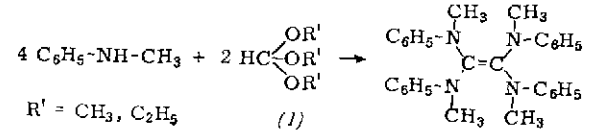
17

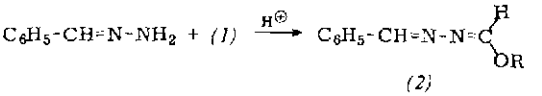
Reactions of Triethyl Orthoformate with some Nitrogen Compounds

Ilse Hagedorn, *K. E. Lichtel*, and *H. D. Winkelmann*, Freiburg (Germany)

1. Triethyl orthoformate *(1)* reacts with *N*-methylaniline to give tetra-(*N*-methyl-*N*-phenylamino)ethylene. *N*-Ethylaniline reacts analogously. The compounds formed are related structurally to bis-(1,3-diphenylimidazolidin-2-ylidene) described by *Wanzlick* [1].

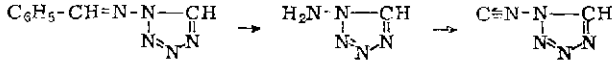


2. Alkoxymethylenazines *(2)* [2] are obtained in excellent yields from *e.g.* benzaldehyde hydrazone and *(1)*.



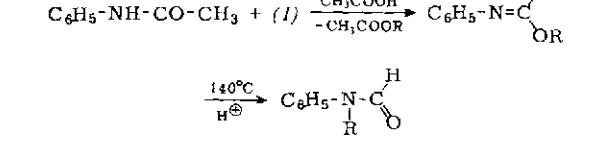
a) Mixed (arylalkyl)azines are obtained from *(2)* by treatment with Grignard reagents, *e.g.*

b) Treatment of *(2)* with HN_3 gives 1-benzylidenaminotetrazole, which on hydrolysis leads to 1-aminotetrazole. The latter can be converted to the *N*-isonitrile with $CHCl_3$ and KOH.



c) Triphenylmethylsodium causes the α-elimination of alcohol from *(2)* with formation of the conjugated *N*-isonitrile [2].

3. Acetanilide reacts with *(1)* in the presence of an equimolar amount of glacial acetic acid to give *N*-phenylformimidic ester and acetic ester. On catalysis with H_2SO_4, an *N*-alkylformanilide, the rearrangement product of the imidic ester, is obtained.



4. *N,N*-(Bisarylsulfonyl)formamidines [3] are alkylated by *(1)*.

18

Acetic Acid Solvates of Nickel and Copper Salts

H. D. Hardt, H. Pohlmann, and *M. Eckle*,
Saarbrücken (Germany)

From the tetrahydrate $Ni(O_2CCH_3)_2 \cdot 4H_2O$, the following products were isolated with glacial acetic acid in the pure, crystalline state:

$Ni(O_2CCH_3)_2$	*(1)*
$Ni(O_2CCH_3)_2 \cdot H_2O$	*(2)*
$Ni(O_2CCH_3)_2 \cdot {}^1/_2\ H_2O \cdot {}^1/_2\ CH_3CO_2H$	*(3)*
$Ni(O_2CCH_3)_2 \cdot {}^1/_2\ CH_3CO_2H$	*(4)*
$NiCl_2 \cdot {}^1/_2\ CH_3CO_2H$	*(5)*
$Ni(O_2CCH_3)_2 \cdot CH_3CO_2K$ (in acetic anhydride); μ_{eff} = 3.22–3.97 B.M.	*(6)*

The compound *(4)* cannot be decomposed to *(1)*, and *(1)* cannot be solvated to *(4)*, suggesting the existence of polynuclear complexes in solvate-free nickel acetate.

In contrast to *(5)*, the solvate of $NiBr_2$ is very unstable and decomposes at room temperature. With iodide ions, NiI_2 is obtained directly.

The presence of acetatonickelate ions in *(6)* is concluded from a shift in the absorption bands in the remission spectrum from 400 mμ for *(1)* to 416 mμ for $K[Ni(O_2CCH_3)_3]$ [*(6)*, yellow-green]. A similar shift occurs when solutions of *(1)* or *(4)* in acetic are heated.

From solutions of $Cu(O_2CCH_3)_2$ in glacial acetic acid/CH_3COCl (1:1), $CuCl_2 \cdot 3/2\ CH_3CO_2H$ *(7)* is precipitated. The solvate-free $CuCl_2$ can then be obtained with pure acetyl chloride either directly or *via* the hemisolvate $CuCl_2 \cdot {}^1/_2\ CH_3CO_2H$ *(8)*.

When *(8)* is washed with anhydrous benzene or ether, solvate-free $CuCl_2$ is easily obtained. With anhydrous acetone it yields a trichlorocuprate(II) and a black precipitate which is identical with a modification of the mixed-valence copper(I,II)chloride hemisolvate $Cu_x(CuCl_{2+x}) \cdot {}^1/_2 CH_3CO_2H$ [1].

An analogous mixed-valence compound is obtained by precipitating copper(II) bromide with 10 equivalents of acetyl bromide in glacial acetic acid. The compound decomposes above 75 °C to a heterogeneous mixture of $CuBr_2$ and CuBr and is also decomposed by water.

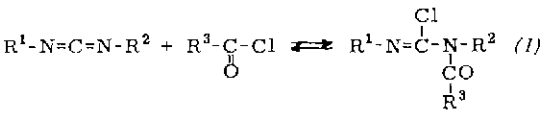
19

The Reactions of Carbodiimides with Acid Chlorides

K. Hartke, Marburg (Germany) and
E. Palou, Concepción (Chile)

Carbodiimides react with acid chlorides to give acylchloroformamidines *(1)*, which usually cannot be isolated owing to their thermal instability. The rates of the reactions can be determined by infrared spectrophotometry by following the disappearance of the valence vibration bands of the carbodiimide at 4.7 μ and of the acid chloride at 5.5–5.7 μ, and the formation of two new bands around 6 μ (C=O and −C=N− valence vibrations of the acylchloroformamidines).



Reaction rates and equilibrium constants for aliphatic carbodiimides depend on the size of the substituents R^1 and R^2 and on the reactivity of the acid chloride. If R^1 and R^2 are primary aliphatic residues (such as n-propyl), the reaction with aliphatic carbonyl chlorides is practically instantaneous. The acylchloroformamidines can be isolated by distillation and can be stored for weeks at room temperature.

Inorganic acid chlorides (*e.g.* sulfuryl chloride, thionyl chloride, nitrosyl chloride) react in the course of a few hours. With increasing size of R^1 and R^2, the reaction rate decreases, as does the number of acid chlorides with which the reaction goes to completion. Isopropyl-t-butylcarbodiimide and di-t-butylcarbodiimide do not react with carbonyl halides. Aromatic carbodiimides do not react completely with carbonyl halides, but form equilibium mixtures. Only with phosgene does the reaction go to completion.

20

Structure and Properties of some Salts of Phosphoric Monoesters

K. Hartl, Heidelberg (Germany)

Crystalline salts of divalent cations with phosphoric monoesters exhibit one-dimensional swelling with water and water-like liquids, as well as with long-chain polar n-alkyl compounds [1].

Further insight into this swelling behavior was provided by X-ray analysis of calcium mono-n-alkylphosphate hydrates with the overall formula $CaPO_4R \cdot 2H_2O$. The orthorhombic crystals are composed of electrically neutral, two-dimensionally infinite $Ca(H_2O)PO_4$ layers, between which the ester residues and the molecules of the swelling liquid are arranged.

In the layers of both the methylphosphate and ethylphosphate, the calcium ions are surrounded by four water molecules in square planar coordination, and *vice versa*. The PO_4 tetrahedra are arranged symmetrically on both sides of this plane with one face parallel to it. The calcium ions then have a total of eight coordination sites occupied by oxygen, with mean Ca–O distances of 2.70 and 2.82 Å, respectively. The ester residue is attached to the PO_4-oxygen atom pointing away from the layer, to which the second water molecule of the formula unit is loosely attached.

In the allylphosphate and n-propylphosphate salts, the PO_4 groups alternate on both sides of a $Ca-H_2O$ layer. The calcium ions have six-fold coordination to oxygen; the mean Ca–O distance is 2.55 Å. Ester groups and loosely bound water are accomodated as in the ethyl and methyl derivatives.

The swelling of the allylphosphate and ethylphosphate is particularly uniform in the homologous n-alkylamines and n-alkanols, which are held to the $Ca(H_2O)PO_4$ layers by their polar groups. From the mean increase of the layer distance by 1.26 and 1.20 Å, respectively, per carbon atom of the swelling molecule, their arrangement between the layers can be deduced. The alkyl chains are stretched and have their long axis oblique to the layer planes at an angle of 90° and 73°, respectively. This arrangement agrees with the observed ratio of salt:swelling compound = 2:1.

In the methylphosphate, the unswollen state is favored by van der Waals forces between the closely spaced layers.

Channels are present in the structure of the n-propylphosphate, into which polar compounds can be included, as in zeolite compounds.

Proton magnetic resonance measurements showed that the protons of the ester groups and the water molecules have a restricted mobility similar to that in ice.

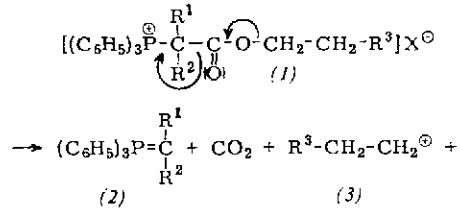
21

Thermal Decomposition of Alkoxycarbonylmethyltriphenylphosphonium Halides

H. Hartung, Erlangen (Germany)

Alkoxycarbonylmethyltriphosphonium halides *(1)* decompose on being heated into an alkylidenetriphenylphosphorane *(2)*, carbon dioxide, a carbonium ion *(3)*, and a halide ion.



(1)

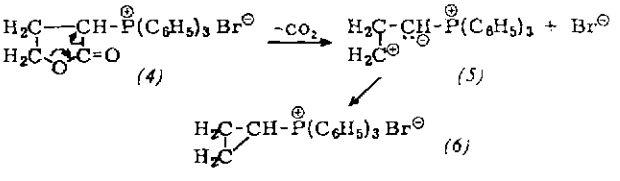
(2) *(3)*

Depending on the nature of the substituents R^1 and R^2, there are three possibilities for the stabilization of the products.

(a) For $R^1 = R^2 = H$, X = Br, a proton is transferred to the alkylidenephosphorane to give a phosphonium salt and an olefin.

(b) When R^1 is an acyl residue and $R^2 = H$, X = Cl, the alkylidenetriphenylphosphorane *(2)* and the alkyl halide corresponding to *(3)* are isolated.

(c) When 2-oxotetrahydrofuran-3-yltriphenylphosphonium bromide *(4)* is decomposed, *(5)* is proposed as intermediate, which is alkylated intramolecularly to cyclopropyltriphenylphosphonium bromide *(6)*.



(4) *(5)*

(6)

22

Protecting Effects in Styrene-Acrylonitrile Copolymers During the Action of Ionizing Radiation

H. Heusinger and *E. J. Weber*, München (Germany)

In order to determine the extent to which the components of a copolymer influence each other during irradiation, the amount of hydrogen evolved on radiolysis of styrene-acrylonitrile copolymere was measured as a function of copolymer composition. A protecting effect was observed which is particulary efficient at low styrene contents. Possible causes are:

Addition of hydrogen onto styrene with formation of hexadienyl radicals; unequal distribution of the energy absorbed between π- and σ-electrons; energy transfer.

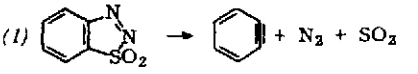
The experimental results show that energy transfer must be primarily responsible for the protecting effect. The occurrence of a maximum in the degree of protection at a styrene content of about 0.05 mole-% shows further that the protecting effect depends not only on the concentration and radiation resistance of the components, but evidently also on the monomer sequence in the polymer chain.

23

Decomposition of 1,2,3-Benzothiadiazole 1,1-Dioxide

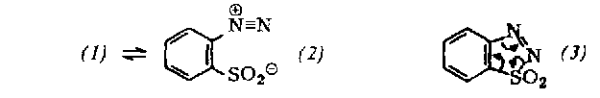
R. W. Hoffmann, *W. Sieber*, and *G. Guhn*, Heidelberg (Germany)

1,2,3-Benzothiadiazole 1,1-dioxide *(1)* is smoothly decomposed in solution at 0–20 °C to dehydrobenzene, sulfur dioxide, and nitrogen [1]. The decomposition in benzene was followed by measurement of nitrogen evolution, and was



(1)

found to have the activation parameters $\Delta H^{\neq} = 27.8 \pm 0.9$ kcal/mole, $\Delta S^{\neq} = 16.6 \pm 1.8$ cal deg^{-1} mole^{-1}. Changing the solvent (*e.g.* from tetrahydrofuran to dimethylsulfoxide) altered the rate of decomposition by at most a factor of 4. Addition of $LiClO_4$ also had only a small effect, which indicates only a small change in polarity in going from reactants to the transition state. Since *(1)* and *(2)* are in a



(1) *(2)* *(3)*

rapidly established equilibrium with each other, it cannot be decided whether the decomposition proceeds from *(1)* or *(2)*. The former is more likely because of the low polarity of the transition state. The substituent effect (10^4 k [sec^{-1}] in benzene at 20 °C for 5-CH_3: 2.75; 5-Cl: 3.82; 5-Br: 5.08; 5-OCH_3: 1.23) can be explained by a concerted decomposition of *(1)* as depicted in *(3)*.

[1] *G. Wittig* and *R. W. Hoffmann*, Chem. Ber. *95*, 2718 (1962).

24

Reactions of Silylamines with Hydrocyanic Acid and Cyanogen Halides

J. Hundeck, München (Germany)

The reaction rate of hydrocyanic acid with organic silylamines [1] is increased by the corresponding organic chlorosilane [2]. Organic cyanosilanes are obtained, *e.g. (1)*.

$$(H_3C)_3Si{-}N(C_2H_5)_2 + (H_3C)_3SiCl + 2\ HCN \rightarrow 2\,(H_3C)_3Si{-}CN + N(C_2H_5)_2H{\cdot}HCl$$

(1)

Organic cyanosilanes are also formed in the reaction of cyanogen iodide with alkyldialkylaminosilanes in yields of up to 60 %.

$$R_3Si{-}NR'_2 + ICN \rightarrow R_3Si{-}CN + NR'_2I$$

The course of the reaction is strongly influenced by the substituents on the silicon and nitrogen as well as by conditions such as temperature, solvent, *etc.*

Triethylsilylamine and bis(trimethylsilyl)amine react with cyanogen iodide at 100 °C in a sealed tube to give bis(trialkylsilyl)carbodiimides:

$$2\,(H_5C_2)_3Si{-}NH_2 + ICN \rightarrow (H_5C_2)_3SiN{=}C{=}NSi(C_2H_5)_3 + NH_4I$$

Cyanogen bromide and chloride react similarly with bis(trimethylsilyl)amine (X = Br, Cl):

$$4\ [(H_3C)_3Si]_2NH + 3\ XCN \rightarrow 3\ (H_3C)_3SiN{=}C{=}NSi(CH_3)_3 + 2\ (H_3C)_3SiX + NH_4X$$

Cyanogen bromide – in contrast to cyanogen iodide (cf. above) – also reacts with trimethyldiethylaminosilane, forming trimethylbromosilane (yield 85 %) and diethylcyanamide:

$$(H_3C)_3Si{-}N(C_2H_5)_2 + BrCN \rightarrow (H_3C)_3SiBr + N(C_2H_5)_2CN$$

Tris(trimethylsilyl)amine reacts only incompletely with cyanogen chloride, even at 200 °C:

$$[(H_3C)_3Si]_3N + ClCN \rightarrow (H_3C)_3SiCl + (H_3C)_3SiN{=}C{=}NSi(CH_3)_3$$

25

Intermolecular Interactions in the Heat-Induced Aggregation of Globular Proteins in Solution

R. Jaenicke, Frankfurt/Main (Germany)

The heat-induced aggregation of dissolved globular proteins is generally brought about by coagulation and exchange processes. The types of bonds formed can be determined by the use of specific inhibitors or by degradation of the aggregates.

Coagulation by non-covalent bonds in principle seems to be the precursor reaction of the exchange mechanism; it exceeds the covalent aggregation by disulfide- and lanthionine-bonds under all conditions of experiment.

Ion-pair attractions can be excluded as a cause of coagulation, since guanidinium chloride and urea are equally effective in dissociating the aggregates. The behavior of dinitrophenylated and acetylated proteins also provides an indication against ion-pair binding. Inhibitors can be used to distinguish between hydrogen bonds and hydrophobic interactions: the aggregation is inhibited at all pH values by formaldehyde, dioxane, 2-chloroethanol, and ionic detergents. Together with measurements of optical rotatory dispersion, these results show that when the native conformation is retained (λ_c = const.), only hydrogen bonds take part in the coagulation. A partial denaturation, on the other hand, gives rise in addition to hydrophobic bonding among the particles forming the aggregates.

The results verify the principle of tertiary structure derived from X-ray analysis in the case of the protein in solution.

26

The System Lithium Oxide/Uraninium(V) Oxide

Sibylle Kemmler, Tübingen (Germany)

The compounds $LiUO_3$, 0.5 $Li_2O{\cdot}U_2O_5$, and 0.15 $Li_2O{\cdot}U_2O_5$ exhibit paramagnetism with an anomalous temperature dependence. The strong influence of the ligand field on the magnetic moment indicates less effective shielding of the 5f electrons compared to the 4f electrons. Similar behaviour was found for other ternary uranium(V) oxides ($NaUO_3$; KUO_3; $RbUO_3$; $MgO{\cdot}U_2O_5$; $CdO{\cdot}U_2O_5$; 2 $PbO{\cdot}U_2O_5$; 2.5 $PbO{\cdot}U_2O_5$; $La_2O_3{\cdot}U_2O_5$; $Sc_2O_3{\cdot}U_2O_5$). None of these compounds obey the Curie or the Curie-Weiss laws. The experimental data were found to obey the equation

$$\chi_M = (N\beta^2\mu_{eff}^2/3\ kT) + N\alpha = (C/T) + A$$

When the molar susceptibility χ_M was split up into a temperature-independent part A and a temperature-dependent part C/T, then A was found to be almost constant for the various compounds studied ($A \approx 400\times10^{-6}$), and the Curie constants C were found to be distributed about two means depending on the coordination number N of the uranium, *viz.* C = 0.05–0.07 for N = 6, and C = 0.13–0.16 for N = 8. The Curie constants calculated for the electronic configuration $5f^1$ with the ligand field theory have similar values. This agreement shows the electronic configuration of uranium in the U(V) compounds to be $5f^1$.

Triuranium octoxide U_3O_8 has magnetic properties similar to those of 0.15 $Li_2O{\cdot}U_2O_5$, and should therefore probably be formulated as $U_2O_5{\cdot}UO_3$.

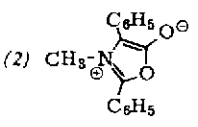
27

Mechanism of the Dakin-West Reaction

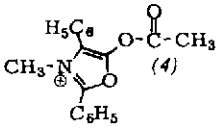
R. Knorr, München (Germany)

The decarboxylating acetylation of α-amino acids with acetic anhydride/pyridine, known as the Dakin-West reaction, occurs *via* cyclic intermediates. The intermediate formation and acylation of azlactones from glycine derivatives has been described [1]; the reaction requires the presence of base and of acetic acid.

The azlactone-analogous intermediate formed from *N*-benzoyl-*N*-methyl-α-phenylglycine *(1)* is anhydro-2,4-diphenyl-5-hydroxy-3-methyloxazolium hydroxide *(2)*, a mesoionic compound [2]. In the presence of acetic acid (> 0.4 mole/l), *(1)* gives, *via (2)*, CO_2 and *N*-benzoyl-*N*-methyl-α-amino-α-phenylacetone *(3)* in 75 % yield. The second intermediate *(4)* can be isolated as the perchlorate; in acetic

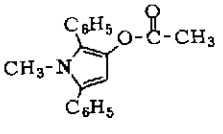


(2)

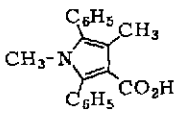


(4)

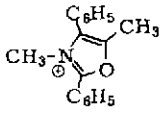
anhydride it is found by ultraviolet absorption measurements to be present to about 1 %. It reacts further by nucleophilic attack in position 2 of the oxazole ring; effective nucleophiles are acetate, the carbanion *(5)* of acetic anhydride occurring in the Perkin cinnamic acid synthesis, or chloride ions. In the absence of acetic acid or in the presence of only small amounts (< 0.2 moles/l), *(5)* is converted by O → C acetyl migration to position 4 of the oxazole ring and subsequent 1,3-dipolar CO_2-elimination into the pyrroles *(6)* and *(7)*, and acetate is converted into the enol acetate of *(3)* and the oxazolium ion *(8)*. The branching of the



(6)



(7)



(8)

reaction starting from *(4)*, manifested in these products, can also be shown from kinetics: thus acetic acid inhibits the reaction by removal of *(5)*. No base catalysis occurs; the salt effect is positive.

The reaction of acetyl chloride with *(2)* is a new variant o, the Dakin-West reaction: by attack of chloride ions on *(4)*f the product *(8)* is obtained in 70 % yield. It is assumed that all Dakin-West reactions in which cyclic intermediates occur take place according to this mechanism.

[1] *G. H. Cleland* and *C. Niemann*, J. Amer. chem. Soc. *71*, 841 (1949).

[2] *R. Huisgen, H. Gotthardt, H. O. Bayer*, and *F. C. Schaefer*, Angew. Chem. *76*, 185 (1964); Angew. Chem. internat. Edit. *3*, 136 (1964).

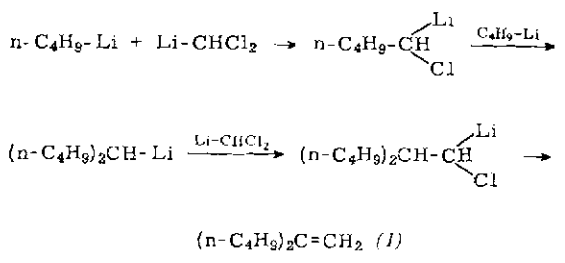
28

Stability and Reactivity of α-Halogen-Carbanions

G. Köbrich, K. Flory, H. R. Merkle, and *H. Trapp,*
Heidelberg (Germany)

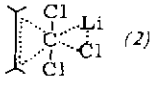
Compounds of the type $>C(Hal)Li$ are more stable at low temperatures in tetrahydrofuran (THF) as solvent than in diethyl ether. Substances in which β-elimination is possible behave exceptionally: trichlorovinyl-lithium decomposes more rapidly in THF than in diethyl ether.

Organic α-halogeno lithium compounds, besides possessing the nucleophilic character expected for organolithium compounds, also have electrophilic properties: dichloromethyl-lithium reacts smoothly at −74 °C with an equimolar amount of n-butyl-lithium to give 1-chloro-1-pentyl-lithium, which yields mainly 1,1-di-n-butylethylene *(1)*.



$$(n\text{-}C_4H_9)_2C{=}CH_2 \quad (1)$$

At −74 °C, dichloromethyl-lithium does not react with cyclohexene, and even on being heated above the decomposition temperature (−60 °C) forms only traces of chloronorcarane. Trichloromethyl-lithium in THF at −100 °C is stable and inert to cyclohexene. On short-term heating to −72 °C, partial decomposition is observed (mean: 36 %). Since the decomposition is increased by addition of cyclohexene (mean: 54 %), and the yield of dichloronorcarane (mean: 16 %) corresponds to this increase within the limits of error, it is concluded that the cyclopropane is formed by the trichloromethyl-lithium in a reaction competing with the thermal decomposition. The substituent effect in the cycloaddition to other olefins (tetramethylethylene, α-methylstyrene, vinyl ethyl ether) suggests that this reaction takes place by an electrophilic attack at the double bond without the occurrence of significant partial charges on the olefin carbon atoms.



(2)

The transition state is therefore best represented by the formula *(2)*, which corresponds to the transition state of the Simmons-Smith reaction.

These examples show that organic α-halogeno lithium compounds are capable of electrophilic reactions with olefins and organolithium compounds, reactions which were previously regarded as typical carbene reactions.

29

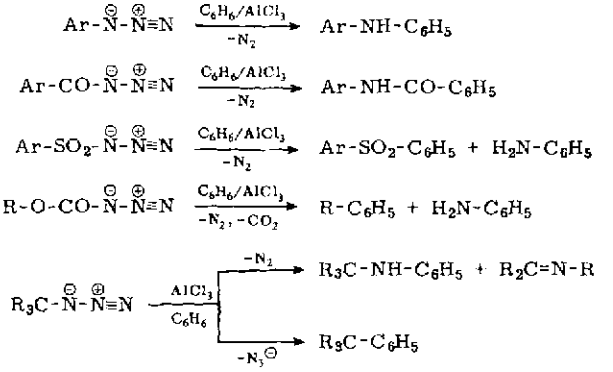
Reactions of Organic Azides under the Conditions of the Friedel-Crafts Reaction

R. Kreher and *G. Jäger,* Darmstadt (Germany)

Organic azides split off N_2 or $N_3^{\ominus}$ under the influence of aluminum trichloride. The ionic intermediates expected are stabilized by reaction with benzene or by rearrangement.

Whereas aryl, acyl, sulfonyl, and alkoxycarbonyl azides react primarily with evolution of N_2, alkyl azides also split off significant amounts of $N_3^{\ominus}$.

The behaviour of azides depends also on the solvent. For example, alkoxycarbonyl azides in cyclohexane react with elimination of N_2 and CO_2, presumably *via* alkyl azides, to give azomethines.



30

Trifluorophosphine Complexes of Nickel, Cobalt, and Iron

Th. Kruck, K. Baur, W. Lang, and *A. Prasch,*
München (Germany)

Tetrakis(trifluorophosphine)nickel, $Ni(PF_3)_4$, can be prepared from metallic nickel, as well as from nickel(II) iodide in the presence of copper powder under pressure of PF_3.

The PF_3 ligands can be substituted by triphenylphosphine, triphenylphosphite, or carbon monoxide, to give $Ni(PF_3)_{4-n}[P(C_6H_5)_3]_n$ (n = 1 and 2), $Ni(PF_3)[P(OC_6H_5)_3]_3$, and $Ni(CO)_4$, corresponding to the different donor-acceptor properties of these substituents. The shift of the P–F valence absorptions to longer wavelenghts for phosphine- and phosphite-substituted nickel trifluorophosphines is ascribed to an increase in the Ni → PF_3 back donation and the related decrease of the π-bonding character of the P–F bond.

The reaction of PF_3 with $ReCl_5$ and copper powder in an autoclave gives the colorless, crystalline chloropentakis(trifluorophosphine)rhenium, $Re(PF_3)_5Cl$ [1]. Deep red $Fe(PF_3)_4I_2$ and orange $Fe(PF_3)_4Br_2$ are obtained from pentakis(trifluorophosphine)iron and iodine in petroleum ether and from $Fe(PF_3)_5$ and bromine vapor, respectively. Iodotetrakis(trifluorophosphine)cobalt, $Co(PF_3)_4I$, is formed from a mixture of CoI_2 and copper powder even at temperatures as low as 20 °C and PF_3 pressures of less than 50 atm, or from $HCo(PF_3)_4$ and iodoform. All halogenotrifluorophosphine-metal compounds are as volatile as the metal trifluorophosphines, and are readily soluble in nonpolar solvents. These properties indicate an essentially nonionic metal-halogen bond, with the resonance structure $\overset{\oplus}{X}{-}\overset{\ominus}{M}{\leftarrow}PF_3$ probably having a considerable weight.

31

Synthesis of 3'-Aminonucleosides

F. W. Lichtenthaler, H. P. Albrecht, G. Olfermann, and *J. Yoshimura,* Darmstadt (Germany)

The dialdehyde-nitromethane cyclization can be extended to "nucleoside dialdehydes" resulting from nucleosides by periodate oxidation [1]. On condensation with nitromethane/sodium methoxide in methanol and subsequent neutralization, mixtures of 3'-deoxy-3'-nitronucleosides

are obtained, which can be separated by fractional crystallization, by preparative layer chromatography in chloroform/methanol, or on silica gel columns with butanol/water. The main product is the *gluco*-isomer. Catalytic hydrogenation leads to the corresponding 3'-amino-3'-deoxynucleosides. The configurational proof was derived from the NMR spectra of the *N*-acetates and tetraacetates, and by characterization of the amino-sugars formed on acid hydrolysis.

Nitromethane cyclization of "inosine dialdehyde" gives a mixture of 9-(3'-deoxy-3'-nitroglucopyranosyl)hypoxanthine (38 %) and 9-(3'-deoxy-3'-nitrogalactopyranosyl)hypoxanthine. "Adenosine dialdehyde" analogously gives two 3'-nitronucleosides with D-*gluco* and D-*manno* configurations respectively [2]. By deamination with sodium nitrite/acetic acid, 9-(3'-deoxy-3'-nitroglucopyranosyl)adenine and 9-(3'-deoxy-3'-nitromannopyranosyl)adenine can be converted to the hydroxylamine derivatives. Cyclization of "xanthosine dialdehyde" with nitromethane also gives two 3'-nitronucleosides which have *gluco* (35 %) and *galacto* (22 %) configuration.

1-(β-D-Glucopyranosyl)thymine can be converted by periodate oxydation into "thymine dialdehyde", which on nitromethane cyclization gives 1-(3'-deoxy-3'-nitroglucopyranosyl)thymine in 45 % yield.

[2] *J. J. Fox* et al. obtained 3-amino-3'-deoxyhexosyladenine by the same reaction as a mixture of the D-*gluco*, D-*manno*, and D-*galacto* isomers (personal communication).

32

Binding of Actionomycin on Apyrimidinic Acid

M. Liersch and *G. Hartmann*, Würzburg (Germany)

The antibiotic actinomycin associates with deoxyribonucleic acid (DNA), thereby blocking its biological function in the synthesis of nucleic acids. According to a hypothesis of *Hamilton* et al. [1], the helix structure of DNA is necessary for the binding of the antibiotic. We have therefore investigated the binding of actinomycin on apyrimidinic acid [2], which cannot have a helix structure because of its base composition.

On addition of apyrimidinic acid to an aqueous solution of actinomycin, similar changes of the ultraviolet spectrum are observed as with thymus DNA. In the presence of excess actinomycin, the apyrimidinic acid becomes saturated with it. Calculation from the extinction coefficients shows that under these conditions one actinomycin molecule is bound per 5.7 base residues of apyrimidinic acid. The value obtained is almost the same as for the associate of thymus DNA and actinomycin.

Optical measurements at concentrations between 10^{-5} and 10^{-6} M of actinomycin and nucleic acid show that the affinity of apyrimidinic acid for the antibiotic is not much lower than that of native DNA.

Addition of urea leads to dissociation of the associates, as of the complex with thymus DNA. Evidently the bonding is similar in the two different associates.

These experiments, and similar ones with single-stranded DNA from the phage fd, show that the helix structure of DNA is not necessary for the association of actinomycin with DNA.

[1] *L. Hamilton, W. Fuller,* and *E. Reich,* Nature (London) *198*, 538 (1963).

[2] Apyrimidinic acid was prepared from thymus DNA by hydrazinolysis of the pyrimidine bases.

33

The Action of Diazooxonorleucine and Albizziin on the Biosynthesis of Aromatic Amino Acids in Saccharomyces Cerevisiae and Escherichia Coli

F. Lingens and *Gerhard Müller,* Tübingen (Germany)

The biosynthesis of aromatic amino acids occurs *via* the ether of 3-enolpyruvic acid with *trans*-3,4-dihydroprotocatechuic acid, also known as chorismic acid. We detected this compound in culture media of tryptophane-deficient mutants (try$^-$) and phenylalanine-tyrosine-deficient mutants (phen$^-$,tyr$^-$) of *Saccharomyces cerevisiae*. Chorismic acid accumulates in particular when 6-diazo-5-oxo-L-norleucine or *p*-fluorophenylalanine is added to the try$^-$-mutant, or when 6-diazo-5-oxonorleucine, albizziin (L-α-amino-β-ureidopropionic acid), or 4-methyltryptophane is added to the phen$^-$, tyr$^-$-mutant. Diazooxonorleucine and albizziin inhibit the amine transfer from glutamine in the biosynthesis of anthranilic acid. *p*-Fluorophenylalanine acts as a feedback inhibitor in the transformation of chorismic acid into prephenic acid. 4-Methyltryptophane presumably inhibits the first step in the conversion of chorismic acid to anthranilic acid. Mutants having a genetic block behind a metabolic branching point accumulate mixtures of substances, the composition of which can be influenced by the inhibitors mentioned above. Diazooxonorleucine causes the accumulation of *p*-hydroxybenzoic acid and of phenylpyruvic acid in wild strains of *S. cerevisiae* and *Escherichia coli*. A (try$^-$) mutant of *E. coli* normally accumulating anthranilic acid also produces, on addition of diazooxonorleucine, *p*-hydroxybenzoic acid and phenylpyruvic acid, which are postulated to be formed enzymatically from chorismic acid.

34

The Behavior of Neptunium and Various Uranium Fission Products in Heterogenous Reactions of Neutron-Irradiated Uranium Compounds with Complexing Agents

F. Lux and *F. Ammentorp-Schmidt,* München (Germany)

Uranium dioxide was irradiated with neutrons. Lattice transformations were produced in the product by alternating treatment with air (or N_2O) and ethanol vapor in a nitrogen stream at 200–450 °C which contained a complexing agent (acetylacetone or phthalodinitrile). In other experiments, a phthalodinitrile melt with or without phthalocyanine was used as complexing agent.

With acetylacetone, Np and Ru are separated as volatile complexes. With phthalocyanine, Np does not form volatile complexes, but Ce, Nd, Zr, and Ru are partially separated. The partial separation of Mo and Tc observed with both acetylacetone and phthalocyanine can also be explained by the formation of the oxides. The yields of the fission products separated were generally below 1 %.

Instead of the system uranium/oxygen (which is unfavorable from the point of view of complex formation) the system uranium/uranium hydride was chosen for further experiments. The neutron-irradiated uranium was converted to uranium hydride, which was heated with phthalocyanine in a terphenyl melt to 300–400 °C. Subsequently the terphenyl was sublimed off, then the phthalocyanine at 450–500 °C in a high vacuum. In the phthalocyanine sublimate, 3–7 % of Np was present, and only 0.1–0.01 % of the fission products Ce, Nd, Zr, and Ru. Since the specific activity of Np in the phthalocyanine is unchanged by re-sublimation, an Np-phthalocyanine complex subliming at 450–500 °C in high vacuum must be formed. Zone melting experiments support this conclusion. To our knowledge, a volatile Np complex has not been described previously. If the Np sublimes in the form of an iodide formed from fission-produced iodine, the

sublimate would contain ^{133}I or ^{131}I, which however is not the case.

From UCl_4 and Li_2pc (pc = phthalocyanine residue), $U(pc)_2$ was prepared, which presumably has a bipyramidal structure in analogy with $Sn(pc)_2$ [1]. $U(pc)_2$ cannot be sublimed.

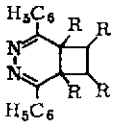
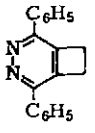
Attempts to Prepare Compounds with the 3,4-Diazabicyclo[4.2.0]octa-2,4-diene and 3,4-Diazabicyclo-[4.2.0]octa-2,4,7-triene Ring Structure

G. Maier, Karlsruhe (Germany)

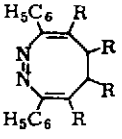
In connection with the investigation of the valence-tautomeric system diazanorcaradiene ⇌ diazacycloheptatriene [1] we are interested in the structural relationships between compounds of the types *(1)* and *(3)* and their monocyclic valence tautomers [*e.g. (2b)*].



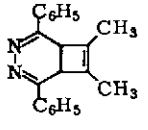
(1a) R = H
(1b) R = CH_3



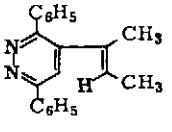
(4)



(2b) R = CH_3



(3)



(5)

Compound *(1a)*, prepared from 5-oxo-2-phenyl-3,4-diazabicyclo[4.2.0]oct-2-ene with phenyl-lithium, cannot be isolated, but is transformed spontaneously with elimination of hydrogen into 3,6-diphenyl-4,5-cyclobutenopyridazine *(4)*.

The reaction of 1,2-dimethyl-*cis*-3,4-dibenzoylcyclobutene with hydrazine also does not lead to the desired bicyclic compound *(3)* but its rearrangement product *(5)*.

If dehydration is made impossible by substitution, derivatives of *(1)*, *e.g.* the compound *(2b)*, can be isolated [2]. At present we have no indication for the existence of *(2b)*. We assume that *(1b)* is in valence-tautomeric equilibrium with *(2b)*, but that the concentration of the monocyclic tautomer is too low for direct detection.

36

The New Europium Isotopes ^{142}Eu and ^{143}Eu

H. Münzel, Karlsruhe (Germany)

The Eu isotopes formed by bombardement of ^{144}Sm with high-energy deuterons were investigated. Analysis of the decay curve of the chemically separated europium fraction showed the presence of 5 components with half-lives of 1.1 min, 2.5 min, 8.8 min (^{143}Sm), 72 min (^{142}Sm) and >10 h. The two short-lived components were identified as the as yet unknown nuclides ^{142}Eu and ^{143}Eu. The following data on the decay of these nuclides were obtained:

	$T_{1/2}$ [min]	E_γ [MeV]	β^+ [MeV]
^{142}Eu	1.1	0.77; 1.03	> 3
^{143}Eu	2.5	1.11; 1.55	> 3

To separate the europium from the radioisotopes of other rare earth elements, the target material was dissolved in 1 N HCl and extracted with sodium amalgam. The separation is complete after about 50 sec.

37

Structural Relationships between Basic Mercuric Chloride, $HgCl_2 \cdot 4\,HgO$, and the Modifications of Mercuric Oxide, HgO

G. Nagorsen and *A. Weiss*, Heidelberg (Germany)

The orthorhombic and the hexagonal modifications of mercuric oxide are composed of infinite —Hg—O—Hg— chains. In the former, the chains are zig-zag and parallel; in the latter, they are spirally coiled. The Hg—O bond length is about 2.03 Å in each case; the O—Hg—O bond angle is almost 180°, and the Hg—O—Hg angle roughly tetrahedral.

Our previous suggestion [1] that $HgCl_2 \cdot 4\,HgO$ has a layer lattice is in disagreement with new results. For the interpretation of the lattice parameters of the isostructural bromide, as well as of the lattice defects observed for the chloride when crystallized at low temperature, other positions must be assumed for the oxygen atoms. The mercury and chloride lattices of the previous model are retained, but a new pattern is assumed for the —Hg—O—Hg— chains in the c-direction. The Hg—O bond length is about 2.03 Å, the angle at the oxygen atom around 114°. From the interatomic distances it must be concluded that the $HgCl_2$ is present in the ionic form in the lattice. The lattice defects are probably false chain links of the type found in the orthorhombic modification of HgO; the defects occur in the same plane in all chains and affect the diffraction pattern like a stacking fault of a layer lattice with a displacement vector a/2. From the line broadening of the (310) reflection of a single crystal it was deduced that the ordered regions in the c-direction are on the average about 8 times the thickness of the unit cell.

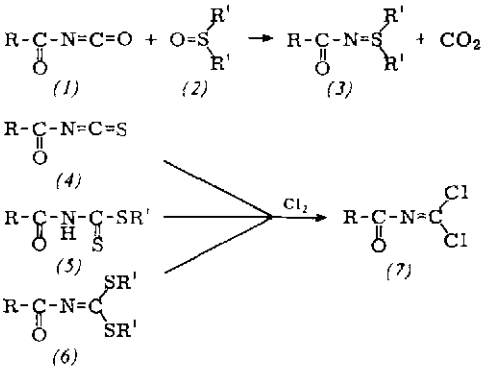
Syntheses and Reactions of N-Acylisonitrile Derivatives

R. Neidlein and *W. Haussmann*, Marburg (Germany)

The reaction of phosphorus pentachloride with aroyl isocyanates leads to α-chloroalkylidenecarbamidic chlorides. In contrast, aliphatic acylisocyanates, such as mono-, di-, or tri-chloroacetyl isocyanate, under the same conditions give mixtures of α,α-dichloroalkyl isocyanates and α-chloroalkylidinecarbamoyl chlorides. The structures of these compounds were ascertained from their infrared spectra.

Acyl isocyanates *(1)* react with dialkyl sulfoxides *(2)* to *N*-acylsulfimines *(3)*, the structures of which were proved by synthesis *via* other routes [1].



N-Acylisonitrile dichlorides *(7)*, of which previously only the benzoylisonitrile dichloride [2] was known, were prepared by chlorination [3] of *N*-acylisothiocyanates *(4)* or of *N*-acyldithiocarbamates *(5)*; in some cases ultraviolet light or heating were necessary.

The cleavage of *N*-acyliminodithiocarbonates *(6)* [4] with chlorine also led to *N*-acylisonitrile dichlorides *(7)*.

N-Acylisonitrile dichlorides react with primary and secondary amines, thiols, dithiols, and ethanolamines to give *N*-acylguanidines, *N*-acyliminothiocarbonate chlorides, *N*-acyliminodithiocarbonates, and β-hydroxyethylformamidinium chlorides, respectively. From phosphorus pentachloride and acylisonitrile dichlorides, α,α-dichloroalkylisonitrile dichlorides are formed.

39

The Induced Decomposition of Acyl and Alkyl Peroxides

W. P. Neumann, *K. Rübsamen*, and *R. Sommer*, Gießen (Germany)

Free-radical decomposition of diacetyl and dibenzoyl peroxide is induced strongly by organic tin hydrides, *e.g.* triethyl- or tributyltin hydride [1]. The attacking species are stannyl radicals. The same is true for dilauryl peroxide and t-butyl perbenzoate, but not for di-t-butyl and cumyl t-butyl peroxide. The presence of at least one carbonyl group besides a peroxy bridge is thus required for induction to occur; the different dissociation energy of the O–O bond in the various compounds does not play a significant part.

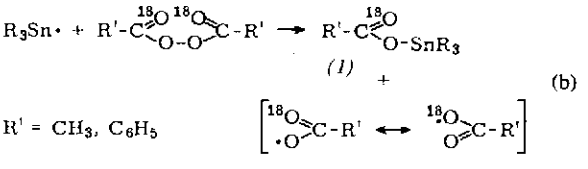
All free radicals formed are captured by excess organotin hydride (usually 3–4 moles per mole of peroxide). Thus t-butanol is formed quantitatively from di-t-butyl peroxide.

$$(CH_3)_3C{-}O{-}O{-}C(CH_3)_3 + 2\ R_3SnH \rightarrow 2(CH_3)_3C{-}OH + R_3Sn{-}SnR_3 \qquad (a)$$

The further decomposition of the t-butoxy radicals into acetone and methyl radicals, which other radical scavengers do not suppress completely, does not take place here.

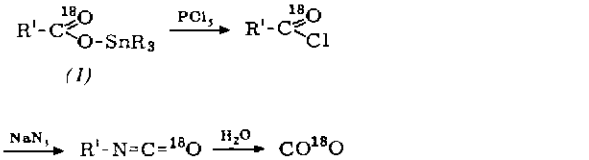
From cumyloxy radicals also, no acetophenone is formed. Only lauryloxy radicals decompose partly to CO_2 and undecane.

It was shown by ^{18}O-labelling of the carbonyl groups that stannyl radicals induce the decomposition of dibenzoyl and diacetyl peroxide by a synchronous mechanism. In the course of the reaction they become attached to one of the peroxy oxygen atoms [Eq. (b)].



(b)

By degradation of the stannyl ester *(1)* to the acid chloride transformation to the isocyanate, and hydrolysis to CO_2 it



was shown that 75 % of the ^{18}O remained in the carbonyl group. This means that only half of the peroxide molecule occurs as a free acyloxy radical.

Further evidence for (b) is given by the $^{18}O{=}C$ band at 1622 cm^{-1} ($R{=}C_2H_5$, $R'{=}CH_3$ in CCl_4).

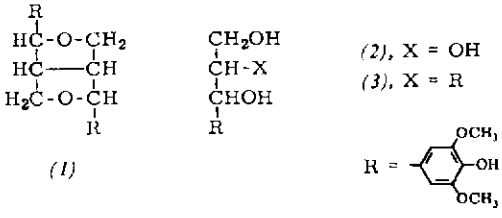
40

The Structure of Beech Lignin

H. Nimz, Heidelberg (Germany)

When pre-extracted beechwood powder is percolated with water at 100 °C for several weeks, 40 % of the wood and of the lignin go into solution; mild hydrolysis with almost complete suppression of condensation reactions, which always occur in the presence of mineral acids, takes place. After fractionation of the concentrated extract by countercurrent distribution, at least 20 low-molecular weight phenols can be detected by chromatography, including D,L-syringaresinol *(1)*, dimethylpyrogallylglycerol *(2)*, and 1,2-bis-(3,5-dimethoxy-4-hydroxyphenyl)propane-1,3-diol *(3)*.

The degradation product *(2)*, which is present in the largest amount, indicates the presence of β-aryl ethers of arylglycerol, which are the most important compound types in spruce lignin as well. The compound *(3)* is of a type not previously encountered in lignin. On being heated with sodium hydroxide solution, it gives rise to hydroxystilbene. Another hydroxystilbene is obtained from spruce under similar conditions [1]. Therefore the presence of 1,2-diarylpropane units can be assumed for spruce lignin, too.



(1) *(2)*, X = OH; *(3)*, X = R

41

Cleavage of the Si-N Bond of Silazanes by Phosphorus Halides

H. Nöth, *L. Meinel*, and *H. Madersteig*, München (Germany)

Silazanes usually react with acid halides EX according to Equation (a). Chlorodiphenylphosphine Ph_2PCl and hexamethyldisilazane in boiling toluene or trimethylchlorosilane give rise to bis(diphenylphosphino)amine, m.p. 146 °C [Eq. (b)]; in *e.g.* petroleum ether at room temperature the adduct $(Ph_2P)_2NH{\cdot}PH_2PCl$ is formed preferentially, [Eq. (c)]. In acetonitrile, NH_4Cl is precipitated [Eq. (d)]. The $(Ph_2P)_4NCl$ simultaneously formed is obtained in high purity according to Eq. (e) in petroleum ether.

$$EX + R_3Si{-}NR'_2 \rightarrow E{-}NR'_2 + R_3SiX \qquad (a)$$

$$2\ Ph_2PCl + (Me_3Si)_2NH \rightarrow (Ph_2P)_2NH + 2\ Me_3SiCl \qquad (b)$$

$$3\ Ph_2PCl + (Me_3Si)_2NH \rightarrow (Ph_2P)_2NH{\cdot}Ph_2PCl + 2\ Me_3SiCl \qquad (c)$$

$$12\ Ph_2PCl + 4\ (Me_3Si)_2NH \rightarrow NH_4Cl + 3\ (Ph_2P)_4NCl + 8\ Me_3SiCl \qquad (d)$$

$$3\ Ph_2PCl + Ph_2PN(SiMe_3)_2 \rightarrow (Ph_2P)_4NCl + 2\ Me_3SiCl \qquad (e)$$

The formation of $[Ph_3P{-}N(PPh_2)_2]Cl$ from Ph_2PCl and $Ph_3P{=}NSiMe_3$ is closely related to Reactions (d) and (e).

A simple synthesis of triphenylphosphine-*N*-trimethylsilylimine was devised according to Eqs. (f) and (g). Reactions (f) and (g) were carried out in acetonitrile, Reaction (h) in toluene or ether.

$$Ph_3PBr_2 + (Me_3Si)_2NH \rightarrow [Ph_3P{-}NHSiMe_3]Br + Me_3SiBr \quad (f)$$

$$[Ph_3P{-}NHSiMe_3]Br + (C_2H_5)_3N \rightarrow Ph_3P{=}NSiMe_3 + (C_2H_5)_3N{\cdot}HBr \quad (g)$$

$$2\ Ph_2PCl + Ph_3P{=}NSiMe_3 \rightarrow [Ph_3P{=}N(PPh_2)_2]Cl + Me_3SiCl \quad (h)$$

NMR-Spectroscopic investigations on $(Ph_2P)_4NCl$ and $[Ph_3P{-}N(PPh_2)_2]Cl$ can be reconciled with the structures

$[Ph_2P{-}PPh_2{=}N{=}PPh_2]Cl$ and $[Ph_3P{=}N{=}PPh_2{-}PPh_2]Cl$

respectively.

42

Dichloroborazide

P. I. Paetzold, München (Germany)

Dichloroborazide *(1)* is a model substance which allows the explosive decomposition of borazides to be compared with the kinetically controlled thermal decomposition.

Borazides tend the more to explosion-like decomposition the stronger the Lewis acid BX_3, *i.e.* the tendency to explode increases in the sequence $NR_2 < Ar < CH_3 < Cl < Br < N_3$ for X. The tendency of the X_2BN_3 molecules to associate *via* the azide α-nitrogen with formation of B–N–B bridges runs parallel to this sequence. The trimeric (at room temperature), crystalline compound *(1)* was shown to have D_{3h} symmetry by vibrational analysis [1], *i.e.* the structure of *(1)* is a regular six-membered B–N ring. At low temperatures, $(CH_3)BN_3$ also is associated.

The controlled thermal decomposition of X_2BN_3 is determined by anchimeric assistance given by the residue X which migrates from the B atom to the α-N atom. Kinetic measurements showed increasing decomposition rates for $X = NR_2 < Cl < Ar$. The controlled decomposition of *(1)*, which leads to hexachloroborazole as main product [2], is therefore – in contrast to the explosive decomposition – less favored than that of Ar_2BN_3. The strengths of the B–X bonds broken and of the N–X bonds formed in the transition state are a basis for satisfactory explanation of this result.

43

Cis-Trans-Isomeric Mixed-Ligand Complexes of Iridium and Osmium

W. Preetz, Saarbrücken (Germany)

On treatment of the hexachloro complexes of the platinum elements with a mixture of HCl and HBr, mixed-ligand complexes $[MCl_xBr_{6-x}]^{2-}$ (M = Ir(IV), Os(IV); x = 0,1,2,..6) [1–3] are formed. The seven complexes possible are present in an equilibrium mixture. They have different mobilities in an electric field. High-voltage electrophoresis gives approximately equidistant, cleanly separated zones of different colors.

Cis-trans-isomers are possible for $[MCl_2Br_4]^{2-}$, $[MCl_3Br_3]^{2-}$, and $[MCl_4Br_2]^{2-}$, but cannot be separated electrophoretically. Their preparation is effected by utilizing the different *trans*-effects [4] of the ligands Cl^- and Br^-. From the hexachloro complexes and HBr, the *trans*-isomers are obtained; from the hexabromo complexes and HCl, the *cis*-forms are obtained by directed (stereospecific) ligand exchange. They are separated from the equilibrium mixture by high-voltage electrophoresis, eluted from the paper strips, and precipitated as the Rb or Cs salts.

The isomers have different colors; the absorption spectra contain many bands and exhibit systematic shifts. The spectra of the Ir complexes agree with those of the Os complexes except for a shift of about 6000 cm^{-1} to longer wavelengths. The previously obtained [3], not characteristic spectra of the mixed-ligand complexes $[MCl_xBr_{6-x}]^{2-}$ (x = 2,3,4) are superpositions of the spectra of the *cis*- and *trans*-isomers.

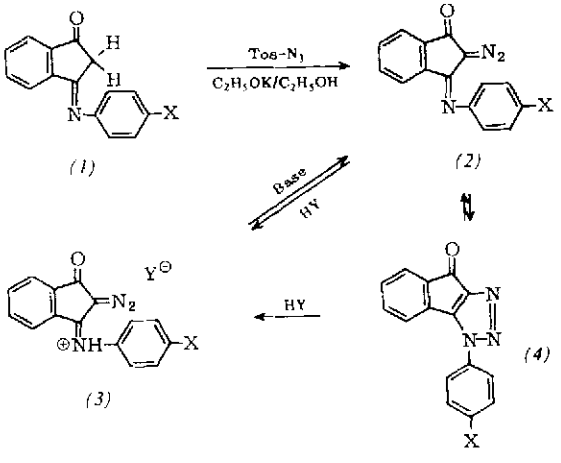
44

Synthesis of 1,2,3-Triazoles and Isomeric α-Diazoimines by Diazo-Group Transfer with Tosyl Azide

M. Regitz, Saarbrücken (Germany)

If a diazo group is introduced into compounds of general formula $-CO-CH_2-\overset{|}{C}=N-$ with tosyl azide, cyclization occurs to 1,2,3-triazoles [1]. On the other hand, stable α-diazoimines *(2)* are formed on diazo-group transfer from the carbanions of *(1)*, X = H or Cl.



Substituents X with (–E)-effect (*e.g.* CH_3, I, OCH_3) here also effect the triazole ring closure to *(4)*. On brief fusion and cooling, *(4)* gives back the isomeric α-diazoanils *(2)*. With strong mineral acids HY (Y = Cl, Br, ClO_4), *(4)* or *(2)* give rise to the stable α-diazoimonium salts *(3)*. The α-diazoimines *(2)* recyclize to 1,2,3-triazoles *(4)* on being recrystallized from high-boiling solvents, if $X = CH_3$, I, or OCH_3.

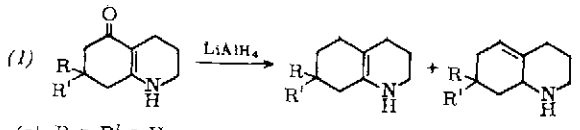
45

Reduction of Vinylogous Amides with Lithium Aluminum Hydride

H. Reinshagen, Darmstadt (Germany)

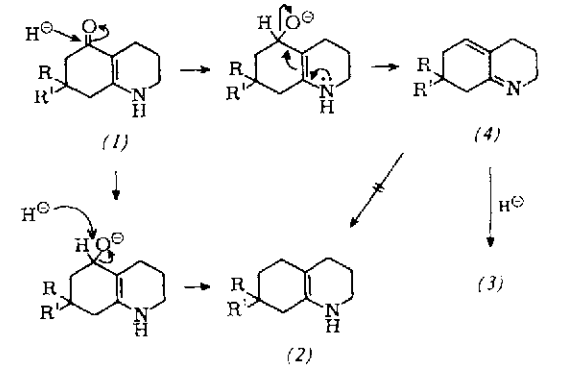
Octahydroquinoline ketones *(1)* are reduced by $LiAlH_4$ in boiling THF. Thus *(1a)* gives the enamine (2), and *(1b)* and *(1c)* give the allylamines *(3)*.



(a), R = R' = H
(b), R = H, R' = CH_3
(c), R = R' = CH_3

The reduction is independent of the solvent, but not of the temperature. The compounds *(1b)* and *(1c)* are redueed in boiling dioxane to mixtures of *(2)* and *(3)*. The ratio enamine:allylamine is similar in both cases.

In the reduction of vinylogous amides with $LiAlH_4$, one equivalent of hydride attacks at the carbonyl group. In the reaction leading to allylamines, there follow oxygen elimination and reduction of the C = N double bond of the intermediate hexahydroquinoline *(4)*. Since *(2a)* is not formed by reduction of *(4a)*, the enamines must be formed by another route. Evidently oxygen is displaced here in a nucleophilic substitution by a second equivalent of hydride. The fact that the reduction to the enamine is favored at higher temperatures shows that a high energy barrier must be surmounted in this reaction.

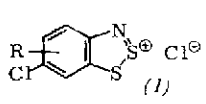


46

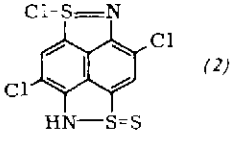
The Herz Reaction with 1,5-Diaminonaphthalene

W. Ried and *J. Valentin*, Frankfurt/Main (Germany)

The action of excess S_2Cl_2 on primary aromatic amines leads to "thiazthionium chlorides" of the general formula *(1)*.



By the action of S_2Cl_2 on 1,5-diaminonaphthalene, *M. Schubert* obtained a beautifully violet compound of the composition $C_{10}H_3N_2Cl_3S_3$, which has properties different from those of thiazthionium chlorides. The structure *(2)* is proposed for this substance.



The structure is based on the following evidence:

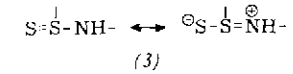
1. Compound *(2)* is also formed from 2,6-dichloro-1,5-diaminonaphthalene.

2. One of the three sulfur atoms can be split off by thermolysis, or by silver nitrate or zinc dust in glacial acetic acid, giving pale yellow products.

3. Reductive degradation gives, depending on the conditions, derivatives of 1,5-diaminonaphthalene or of dimercapto-1,5-diaminonaphthalene, proving the presence of two N–S and two C - S bonds.

4. Introduction of one or two atoms of oxygen imparts the character of sulfochlorides on *(2)*. Together with the infrared spectral data, this result indicates the presence of the group –N=S–Cl.

More vigorous oxidation leads to substitution of one sulfur atom by an oxygen atom. Together with the infrared spectra and the behavior mentioned under 2. above, this suggests a thiosulfinic amide grouping *(3)*.



47

A New Indole Synthesis

P. Rosenmund, *W. Haase*, and *D. Sauer*, Frankfurt/Main (Germany)

From *o*-nitrophenylacetyl chloride and 1-(*N*-morpholino)-cyclohexene *(1)*, -cyclopentene *(2)*, and -1-phenylethene *(3)*, 1,3-diketones are obtained in good yields according to the method of *Hünig* [1]. 2-(*o*-Nitrophenyl)cyclohexanone is formed from *(1)*. With the exception of the diketones from *(2)*, the products crystallize readily. All products give the $FeCl_3$ reaction of enolizable compounds and show in their infrared spectra a characteristic band, strongly shifted to longer wavelengths, of a chelated carbonyl group. On reduction with $SnCl_2$ in ether, mainly indoles are obtained, identified by analysis, by the cinnamaldehyde reaction, and by their ultraviolet spectra. By condensation of the aromatic amino group, which results from reduction of the nitro group, with the δ-carbonyl group, the isomeric benzazepines are formed as by-products. They can be quantitatively and preparatively separated on silica gel columns with chloroform/ethyl acetate. The azepines contain a vinylogous amide structure which is conjugated to the aromatic ring and which explains their ultraviolet spectra (λ_{max} = 335 mμ).

Reduction of 2-(2-oxocyclohexyl)indole with $NaBH_4$ or Raney nickel gives alcohols with different *cis-trans* ratios. By hydrogenation in the presence of ammonia or methylamine, the corresponding primary and secondary amines, respectively, are obtained. Benzaldehyde reacts smoothly with 2-(2-aminocyclohexyl)indole to give 3,4-tetramethylene-1-phenyl-1,2,3,4-tetrahydro-5*H*-pyrido[4,3-*b*]indole. From 2-(2-methylaminocyclohexyl)indole and ethyl bromoacetate, 2-(*N*-ethoxycarbonylmethyl-*N*-methyl-2-aminocyclohexyl)indole is obtained, which can be hydrolysed to the acid. Cyclization at 110 °C with polyphosphoric acid gives rise to a basic compound, the ultraviolet spectrum of which (λ_{max} = 298 mμ) corresponds to that of indole-3-carboxaldehyde and to that of 3-acetylindole. Possibly a new seven-membered ring is formed by elimination of water and condensation with the 3-position of indole, in which case a part of the structure of the iboga alkaloids would have been built up by total synthesis.

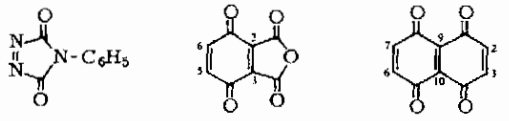
48

Reactivity of Dienophiles and Ability to Form Charge-Transfer Complexes

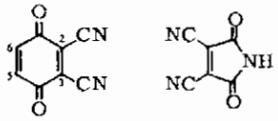
J. Sauer and *B. Schröder*, München (Germany)

The dienophiles *(1)*–*(5)* were studied in preparative and kinetic experiments. The rate constant k for the addition of *(1)* onto *trans,trans*-1,4-diphenylbutadiene, 2-chlorobutadiene, and hexachlorobutadiene exceeds that of tetracyanoethylene by a factor of 10^2–10^4 (at 20 °C in dioxane). Solu-

tions (10^{-3} M) of the Diels-Alder adducts of *(1)* with 9,10-dialkoxyanthracenes partially decompose at 20 °C into the

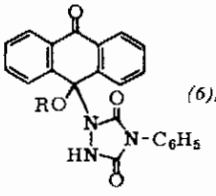


(1) *(2)* *(3)*



(4) *(5)*

original components. In the presence of traces of acid they are converted in good yield into anthrone derivatives *(6)*. Compounds *(2)* and *(4)* take up isoprene, 2,3-dimethylbutadiene, and cyclopentadiene at the more strongly activated 2,3-double bond; *(3)* adds the dienes at the central 9,10-double bond. With butadiene, *(2)* also reacts at the 2,3-bond, but *(3)* gives a 1:1 adduct (addition of the diene at the 9,10 position) besides a 2:1 adduct (addition of the diene at the 2,3- and 6,7-bonds).



(6), R = CH_3, C_2H_5

The rates of Diels-Alder reaction of *(2)* and *(5)* with 2,3-dimethylbutadiene, anthracene, and 2-methylbutadiene exceed, in part considerably, those of tetracyanoethylene, which in turn are higher than those of *(4)*.

No clear relationship is obvious between the reactivity of the dienophiles *(2)*, *(4)*, *(5)*, and tetracyanoethylene and the formation of charge-transfer complexes of these compounds with hexamethylbenzene, durene, pyrene, naphthalene, and anisole.

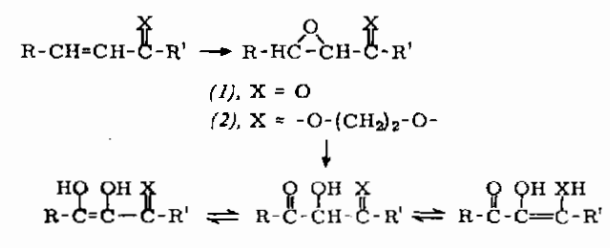
49

A New, General Synthesis of Reductones and Their "Ketals"

K. Schank and *D. Wessling*, Saarbrücken (Germany)

Aci-reductones [1] were previously prepared by *reduction* from 1,2,3-triketones or by *exchange* of halogen, acyloxy, or diazo groups in α-monosubstituted β-dicarbonyl compounds or β-monosubstituted α-dicarbonyl compounds for hydroxy groups.

We have now discovered an *oxidative* reductone synthesis. Acyloxiranes *(1)* or their ketals *(2)*, which are readily accessible from α,β-unsaturated carbonyl compounds and their ketals, respectively, by epoxidation, can be oxidized to the



(1), X = O
(2), X = -O-$(CH_2)_2$-O-

(3), X = O
(4), X = -O-$(CH_2)_2$-O-

R, R' = Alkyl, H

reductone stage *(3)* with dimethylsulfoxide/boron trifluoride [2]. The free reductones *(3)* and their "ketals" *(4)* were obtained in yields of 20 % and 15 %, respectively. The compounds *(4)* are stable in the pure state, and even in aqueous solution in the absence of acid.

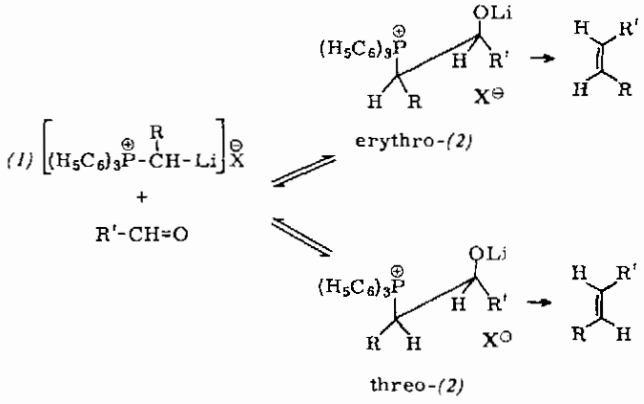
50

Stereoselective Wittig Reactions

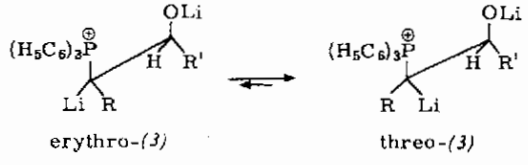
M. Schlosser and *K. F. Christmann*, Heidelberg (Germany)

Cis-selective Wittig reactions are brought about by kinetic control: the phosphorus ylide-LiX adduct *(1)* reacts with the aldehyde primarily to the *erythro*-betaine-LiX adduct *(2)*; this must be rapidly transformed to the *cis*-olefin before it can isomerize to *threo-(2)* [1]. With thermodynamic control, the olefinations are *trans*-selective: if the equilibrium between *erythro-(2)* and *threo-(2)* is rapidly established, but the olefins [2] form only slowly, the more stable *trans*-olefin is obtained preferentially.



(1) erythro-*(2)* threo-*(2)*

These principles can however be applied only occasionally with success. We have found that *trans*-olefins are obtained in high yields if the betaine-LiX adducts are again treated with phenyl-lithium. The resulting derivatives *(3)*, which are both P–O betaines and P–C ylides, are interconverted extremely rapidly, and the equilibrium lies considerably on the side of the *threo*-form.



erythro-*(3)* threo-*(3)*

By Li^+–H^+ exchange, *threo-(3)* gives the betaine *threo-(2)* and thence the *trans*-olefin. The *trans*:*cis* ratio in the product usually is higher than 95:5.

51

Alkylation of Phosphine Chalcogenides and Phosphinylamines

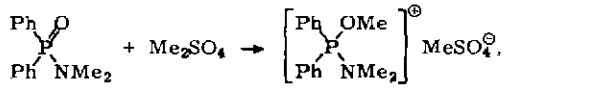
A. Schmidpeter, *Barbara Wolf*, and *Krista Düll*, München (Germany)

Compounds having an alkoxyphosphonium structure *(1)* occur as unstable intermediates in a number of reactions (*e.g.* Michaelis-Arbusow reaction, phosphine oxidation with di-

alkyl peroxides). They decompose with cationic transfer of the alkyl residue and formation of the phosphine oxide.

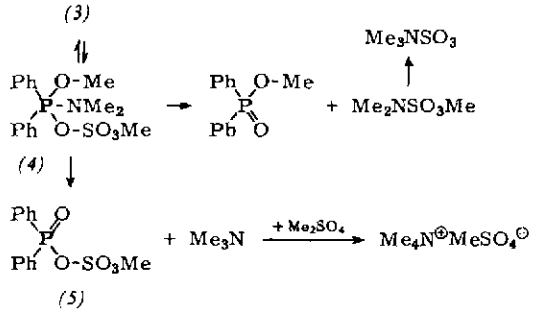
(1)

Stable members of the class of compounds *(1)* were obtained by the reverse reaction, *viz.* by alkylation of phosphine oxides. From triphenylphosphine oxide with dimethyl sulfate and $PF_6^{\ominus}$ or $SbCl_6^{\ominus}$, or directly from trialkyloxonium salts, triphenylalkoxyphosphonium salts are formed. Their stability depends on the alkyl residue as well as on the anion present. Triphenylphosphine sulfide reacts analogously and yields the very stable triphenylalkylthiophosphonium salts $Ph_3\overset{\oplus}{P}S\overset{\ominus}{R}X$. In the reaction of diphenylphosphinyldimethylamine *(2)* with dimethyl sulfate, diphenyl(dimethylamino)methoxyphosphonium methyl sulfate *(3)* is formed at first by methylation of the oxygen atom; it was identified by NMR spectroscopy.



(2) *(3)*

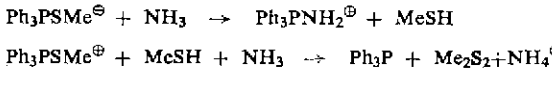
Trimethylamine sulfur trioxide, tetramethylammonium methyl sulfate, methyl diphenylphosphinate, and probably diphenylphosphinyl methyl sulfate *(5)* are subsequently formed from *(3)*. It is assumed that these products arise *via* a pentacovalent form *(4)* which is in equilibrium with *(3)*.



(5)

All products were isolated, with the exception of *(5)*, which was hydrolysed to diphenylphosphinic acid during work-up. Methylation of diphenylthiophosphinyldimethylamine stops after the formation of the diphenyl(dimethylamino)methylthiophosphonium ion.

Ammonolysis of triphenylmethylthiophosphonium salts takes place according to:



52

Mixed-Crystal Formation of Lithium Indium Oxide with Magnesium Oxide, and a Contribution to the "Gadolinium Corner"

H. Schwarz and *D. Bommert*, Karlsruhe (Germany)

Because of the ordered distribution of the Li and In ions, $LiInO_2$ crystallizes with the tetragonal superstructure of the NaCl lattice. All attempts to crystallize $LiInO_2$ in a cubic form with random distribution of the cations have been unsuccessful. Cubic mixed crystals are however formed with MgO. In samples quenched from 1000 °C, mixed crystals are formed in the range from 0 to about 95 mole-% of $Li_{0,5}In_{0,5}O$. In this range the lattice parameters lie on a Vegard straight line. This range borders on a two-phase region from 95 to about 99 mole-% in which the cubic and tetragonal phases coexist. A very narrow region of mixed-crystals with tetragonal structure follows. With decreasing temperature the coexistence curve between the mixed-crystal region and the two-phase region shifts towards the MgO-rich side of the system, and the two-phase region becomes broader (750 °C: 78 mole-%; 675 °C: 72 mole-%; 600 °C: 53 mole-% $Li_{0,5}In_{0,5}O$).

The so-called gadolinium corner, *i.e.* the discontinuity at Gd in the dependence of certain properties of the triply charged rare earth ions Ln^{3+} on the atomic number Z, is now well established. Crystallographic data of isostructural compounds frequently however do not show this discontinuity. For example, no discontinuities are observed for numerous compounds [Ln_2O_3 (C-type), $Ln_2Sn_2O_7$, $LnVO_4$, $LnCrO_4$, LnOCl, LnF_3, LnOF, Ln_2O_2S] in the unit-cell volume of the lattice. For some other compounds, however, [*e.g.* LnN, LnAs, LnSb, LnC_2], in which the Ln^{3+} ions occupy a particularly high proportion of the total lattice volume, a more or less pronounced effect is observed. That the occupation of a large fraction of the lattice volume by Ln ions does not alone determine the occurrence of the gadolinium corner is shown by the discontinuities observed at Gd in the graph of cell volume against Z, for the compounds $SrO \cdot Ln_2O_3$ and $BaO \cdot Ln_2O_3$ [1] (rhombic $CaO \cdot Fe_2O_3$ type). The effect appears to depend strongly also on the structural type.

53

Stability and Coordination of Alkali Chlorometalates(II) of the Light Transition Elements

H. J. Seifert, Giessen (Germany)

The phase diagrams of some systems (alkali metal chloride)/(dichloride of a light transition metal) were determined by differential thermal analysis. The number and compositions of compounds formed, as well as their relative stabilities were investigated. The coordination numbers C.N. of the transition metal ions were determined by X-ray analysis. The occurence of the C.N. 6 was confirmed for all the ions except Zn^{2+} but the C.N. 4 was also found for some of the metals. Tetracoordination in the compounds of Mn^{2+} to Zn^{2+} is due the smaller radii compared to the first half of the group (Ca^{2+} to Cr^{2+}) and the polarizing action of the ions, which increases towards Zn^{2+}. In addition, the site-preference energy of the crystal field theory has the effect that *e.g.* in the system $CsCl/NiCl_2$, the only stable compound formed is $CsNiCl_3$ with 6-coordinate nickel. For the double chlorides $AMCl_3$, which crystallize with a perovskite-like lattice, the decrease in stability, with decreasing radius of the alkali metal ions A, is due to the increasing difference in radius between alkali metal ions and chloride ions. It is evident from the phase diagrams and was confirmed for the chloromanganates(II) by calometric measurements in solution.

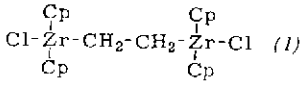
54

The Reaction of Triethylaluminum with Biscyclopentadienyltitanium(IV) and Zirconium(IV) Compounds

H. Sinn and *E. Kolk* [1], München (Germany)

Biscyclopentadienyltitanium(IV) chloride is reduced by excess triethylaluminum within several tenths of a second to Ti(III) compounds. A gas is liberated consisting of 50% ethane, 45% ethylene, and 5% C_4-hydrocarbons. If the gas is collected in fractions, excess ethane is found in the early fractions, and excess ethylene in the later ones. The corresponding zirconium compound also reacts with triethylaluminum; however only ethane is present in the reaction gas. The reaction is slow and results in a yellow, diamagnetic compound, which can be freed from aluminum by extraction with

tetrahydrofuran. The Al-free compound takes up one mole of HCl per mole of Zr and liberates half a mole of ethane. It is therefore thought that the structure *(1)* is present (Cp = cyclopentadienyl).



(1)

With the assumption of an analogous titanium compound, which decomposes to ethylene and Ti(III) compounds, the slower evolution of ethylene compared to ethane can be explained.

The ethane split off on reduction is formed from an ethyl group which obtains the sixth hydrogen atom from the methyl part of another ethyl group, not from the methylene part.

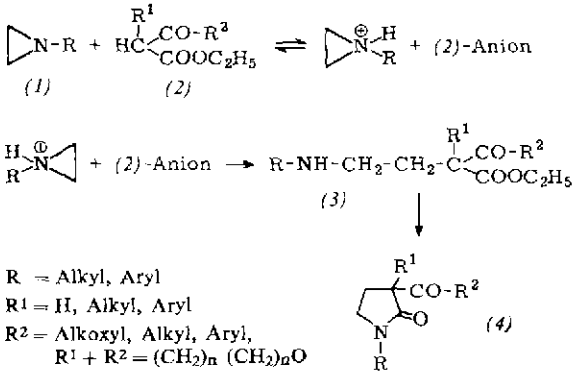
[1] Extract from the Doctorate Dissertation of *E. Kolk*, Technische Hochschule München, 1964.

55

β-Aminoethylation of Malonic Esters and of β-Keto Esters with Aziridines

H. Stamm, Marburg (Germany)

The ring opening with substitution of aziridines *(1)* by the anions of malonic esters or β-keto esters *(2)* takes place above 100 °C in the presence of a large excess of ester, which makes *(1)* reactive by protonation.



(1) *(2)* *(2)*-Anion *(3)*

R = Alkyl, Aryl
R^1 = H, Alkyl, Aryl
R^2 = Alkoxyl, Alkyl, Aryl,
$R^1 + R^2 = (CH_2)_n\ (CH_2)_nO$

(4)

The yields are poor because the preceding equilibrium is unfavorable and because the anion of *(2)* also undergoes other reactions with free ester. If, however, this anion is used in the form of the almost undissociated Li salt (the system being diluted with aromatic hydrocarbons), and at the same time the protonation equilibrium is shifted to the right by the addition of lithium salts as Lewis acids satisfactory yields of *(4)* (up to 70 %) are obtained at 80–145 °C. The excess of ester *(2)* can be recovered almost quantitatively. Open-chain amides are formed as by-products from *(3)* and *(2)*. In 2,2-dimethylaziridines, the anion of *(2)* attacks in the unsubstituted 3-position.

The primary product *(3)* can be isolated when R is bulky (*e.g.* t-butyl or tolyl).

56

Activation of Molecular Vibration Bands by Lattice Disorders

W. Sterzel, Frankfurt/Main (Germany)

Of the possible normal modes of vibration of a highly symmetrical molecule, the modes in which no change in dipole moment occurs are usually inactive in the infrared. The symmetry of such molecules (or complex ions) can be retained on crystallization, or previously inactive vibration bands can be activated by a lowering of the symmetry class by the crystal field. In crystals which do not lower the symmetry of the constituent molecules or ions, local lattice defects should effect activation of vibration bands.

Such an effect was observed in experiments on calcite, cadmium carbonate, and sodium nitrate. The infrared-inactive, symmetrical valence vibration ν_1 of the CO_3^{2-} anion in calcite and cadmium carbonate was activated by intense plastic deformation. The new band caused by lattice disorders occurs at 1085 cm^{-1} for calcite and 1076 cm^{-1} for cadmium carbonate. Formation of defects was confirmed by X-ray diffraction data. The lattice deformations also give rise to a broadening of the normal vibration bands to different extents, the effect being particularly pronounced for the symmetrical valence vibration band of aragonite, which also gains in total intensity; *i.e.* this vibration is activated by lattice defects in addition to the normal activation by the crystal field. Otherwise the intensity of the ν_1 band of aragonite would decrease on deformation, since partial transformation to calcite occurs.

Lattice defects were also produced by doping of crystals and by mixed-crystal formation. $BaSO_4$–$PbSO_4$ mixed crystals show a weak band at 450 cm^{-1} which is present in neither of the pure components. This band probably corresponds to the symmetrical deformation vibration ν_2 of the SO_4^{2-} anion, which is infrared-inactive in crystals of pure $PbSO_4$ and $BaSO_4$.

57

Synthesis and Properties of 4-Pyridyl Phosphate

A. Stock, Frankfurt/Main (Germany)

Nicotinamide adenine dinucleotide (NAD) phosphorylated in the pyridine ring possibly plays a part as an energy-rich intermediate in the respiratory chain phosphorylation. Therefore 4-pyridyl phosphate was synthesized as a model substance from 4-pyridone and phosphorus oxide chloride in chloroform with subsequent hydrolysis with a solution of potassium hydrogen carbonate. On electrophoresis at pH 7 the compound migrates to the anode. It is completely hydrolysed within 10 min in 1 N acid at 90 °C to pyridone and phosphoric acid. The pH-dependence of the ultraviolet spectrum is similar to that of 4-chloropyridine and of 4-methoxypyridine, but different from that of *N*-methyl-4-pyridone. These results show that the phosphorylation has taken place at the O atom, and not the N atom. The values obtained are:

pH > 7: $\lambda_{max} = 253$ mμ, $\varepsilon_{max} = 1000$
pH 5.5–7: $\lambda_{max} = 241$ mμ, $\varepsilon_{max} = 9400$
pH 1: $\lambda_{max} = 230$ mμ, $\varepsilon_{max} = 8000$

The first H^+ion therefore adds onto the N atom (around pH 7).

The crude product (25 % 4-pyridone, 75 % phosphorylated compound) is cleaved to an extent of 50 % in 3 h at 25 °C and pH 0, in 17 h at pH 3.5, in 14 days at pH 7, in 24 h at pH 14; no decomposition is detected at pH 10.5.

On chromatography of 4 mmoles of the crude product on 600 g of Dowex 1X8 (carbonate-bicarbonate form), 1.2 mmole of 4-pyridone was eluted with water, and by a $KHCO_3$/K_2CO_3 solution (pH 10) of concentration increasing up to 1 M $KHCO_3$, various phosphorylation products of 4-pyridone are obtained:

70 μmoles of 4-oxo-1-pyridyl phosphate ($\lambda_{max} = 262$ mμ, $\varepsilon_{max} = 16000$)

150 μmoles of di-(4-pyridyl) phosphate ($\lambda_{max} = 253$ mμ, $\varepsilon_{max} = 2000$)

240 μmoles of 4-pyridyl phosphate

40 μmoles of an *O*-phosphorylated compound (presumably 4-pyridyl pyrophosphate), the hydrolysis of which yields 4-pyridone and phosphoric acid in the ratio 1:2.

7 µmoles of a compound containing 2 pyridine groups, of which one is phosphorylated at the N atom and the other at the O atom.

Altogether 45% of the substance was recovered by elution.

Analogously the potassium salt of 2-pyridyl phosphate was obtained from 2-pyridone and phosphorus oxide chloride/pyridine in benzene with subsequent hydrolysis by $KHCO_3$ solution. This salt decomposes at 25 °C and pH 7 to 2-pyridone and phosphoric acid to the extent of 50% in 15 min.

58

Nucleophilicity and Basicity of Amines

H. Suhr, Tübingen (Germany)

The nucleophilic character of an amine in reactions with various types of aromatic and aliphatic coreactants is almost constant. It is therefore possible to express the nucleophilicity n_a of an amine by the logarithms of the rate constants of nucleophilic reactions with aromatic substances. The reaction with 4-fluoronitrobenzene at 50 °C in dimethyl sulfoxide was chosen as standard. The validity of these n_a values within wide limits raises the question of their relation to basicity. Both parameters are determined by polar and steric effects. Strongly basic amines often are weakly nucleophilic because steric effects are of secondary importance for basicity, but of considerable importance for nucleophilicity. In sterically equivalent compounds, such as the substituted anilines, the basicities and the rate constants of nucleophilic substitution follow the Hammett equation with roughly equal values of ρ. The relation between nucleophilicity and basicity of aliphatic amines also can be described with the aid of polar and steric constants. The basicities can be represented by the equation [1]

$$pK_a = -3.1\ \Sigma\sigma^* + 13$$

The nucleophilicities of all groups of sterically equivalent amines show a similar dependence on the polar constant σ*, whereas the differences between these groups are a function of the steric constant E_s. The n_a values of primary and secondary amines can therefore be represented by the equation

$$n_a = -2.0\ \Sigma\sigma^* + 2.1\ E_s + 5.4$$

In sterically little hindered aliphatic amines, basicity and nucleophilicity are simply related by $n_a - ApK_a + b$, where the constants depend on the halogen compound and the solvent used.

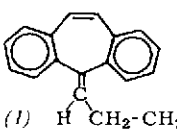
59

Intramolecular Mobility of Di- and Tribenzocycloheptatriene Derivatives

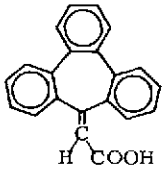
W. Tochtermann, H. Küppers, and *A. Mannschreck*, Heidelberg (Germany)

As shown by the ^{1}H-NMR spectra, the energy barrier for the inversion of the seven-membered ring of tribenzocycloheptatrienone dimethylacetal ($\Delta G^{\neq}$ above 180 °C > 23 kcal/mole) is considerably higher than in the analogous 2,3;6,7-dibenzo compounds ($\Delta G^{\neq}$ at 30 °C = 14.9± 0.2 kcal/mole) [1].

Since the amine *(1)* [2] and the carboxylic acid *(2)* [3] can be resolved into optical antipodes, the influence of the third benzene ring on the ring inversion can also be estimated from a comparison of the rates of racemization of *(1)* and *(2)*.



(1) H CH_2-CH_2-$N(CH_3)_2$



H COOH *(2)*

From the result that *(1)* racemizes even at 20 °C (E_A = 22 kcal/mole) [2], but *(2)* only at 139 °C with comparable rate ($\Delta G^{\neq}$ at 139 °C = 32 kcal/mole), an energy difference similar to that found for the acetals by NMR spectroscopy is obtained.

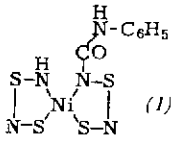
60

Preparation and Structure of a Monophenyl Isocyanate of $Ni(HN_2S_2)_2$

J. Weiss and *U. Thewalt*, Heidelberg (Germany)

When $Ni(HN_2S_2)_2$ is heated at about 65 °C for about 3 h with a 3-fold excess of phenyl isocyanate in THF, a dark olive-green solution is obtained. The residue obtained on evaporation is washed with small amounts of acetone and benzene, and recrystallized from acetone to give black crystals of the compound $Ni(C_7H_7ON_5S_4)$., m.p. 170 °C (decomp.), yield ca. 40%, which dissolve in organic solvents to give olive-green solutions.

The structure was determined by X-ray analysis. The compound crystallizes in the monoclinic system with the space group C^5_{2h}–$P2_1/a$, with four molecules in the unit cell; a = 14.08 Å, b = 5.11 Å, c = 17.77 Å, β = 98.3 °. The positions of the nickel and the four sulfur atoms were determined from the 3d Patterson synthesis. Fourier projections ρ(xz) and 3d Fourier syntheses gave the positions of all atoms. The R-value (B = 3.5) after the last Fourier synthesis was 0.151 for all of the 921 observed F(hkl). Subsequent "back-shift" correction improved the R-value to 0.146. The structure obtained is shown as *(1)*.



(1)

61

The Chemistry of Bis(trimethylsilyl)halogenoamines

N. Wiberg, F. Raschig, and *K. H. Schmidt*, München (Germany)

Reaction of bis(trimethylsilyl)amine with *N*-bromosuccinimide or of lithium bis(trimethylsilyl)amide with chlorine or iodine chloride gives brown $(Me_3Si)_2NBr$, b.p. 176 °C, yield 65%; light yellow $(Me_3Si)_2NCl$, b.p. 145 °C, yield 60%; deep brown $(Me_3Si)_2NI$, b.p. 196 °C, yield 55%.

Bis(trimethylsilyl)halogenoamines react with cleavage of either the *N*-halogen bond or the N-Si bond. Thus bis(trimethylsilyl)sodamide reacts with bis(trimethylsilyl)chloroamine or bromoamine to give the radical *(1)*. This abstracts

$$(Me_3Si)_2N\text{–}Hal + NaN(SiMe_3)_2 \rightarrow NaCl + 2\,(Me_3Si)_2N\cdot \quad (1)$$

hydrogen atoms from diethyl ether or toluene with formation of bis(trimethylsilyl)amine. In benzene solution *(1)* undergoes the following reaction:

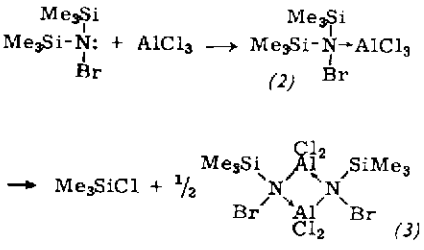
$$4\ (1) \rightarrow$$

$$(Me_3Si)_2NH + (Me_3Si)_2N\text{–}Si(Me_2)\text{–}N(SiMe_3)\text{–}CH_2\text{–}N(SiMe_3)_2$$

Dimerization of *(1)* to the hypothetical tetrakis(trimethylsilyl)hydrazine $(Me_3Si)_2N$–$N(SiMe_3)_2$ was not observed.

The cleavage of the N–Si bond of bis(trimethylsilyl)chloroamine and bromoamine occurs with Lewis acids. From the chloroamine and boron trichloride, hexachloroborazole is formed in over 60% yield. Aluminum trichloride reacts with the bromoamine to give a dark yellow compound *(3)* which decomposes at about 80 °C. The Lewis acid probably first

adds on to the lone electron pair at the nitrogen atom in *(2)*; trimethylchlorosilane is then split off. The intermediate *(2)*



was isolated in the reaction of bis(trimethylsilyl)amine with aluminum or gallium trichloride in the form of $(Me_3Si)_2NH{\rightarrow}MCl_3$ (M = Al, Ga.).

62

NMR-Spectroscopic Determination of the Configurations of Carbohydrates and Cyclanols Using Their Trimethylsilyl Ethers

J. Yoshimura and *F. W. Lichtenthaler*, Darmstadt (Germany)

The trimethylsilyl ethers (trisylates) of cyclanols and sugars were prepared by the reaction of the hydroxy compounds with trimethylchlorosilane in pyridine at 130 °C. Better results were obtained from the reaction with hexamethyldisilazane in dioxane in the presence of boron trifluoride. Under these conditions (3h at 100 °C), di-*N*-acetyl-*neo*-inosa-1,4-diamine gives the tetratrisylate in 72% yield; 1,4-dideoxy-1,4-dinitro-*neo*-inosite *(1)* in 100% yield already at 25 °C. Analogously, cyclohexane-1,3-diol, 2-nitrocyclohexane-1,3-diol, α-methyl-D-xyloside, and α-benzyl-*N*-acetyl-D-glucosamide give the completely trisylated compounds in yields of 50 to 85%. In the reaction of *(1)* with hexamethyldisilazane in dioxane (100 °C without catalyst), selective trisylation occurs with the formation of 2,3,6-tris(trimethylsilyl)-1,4-dideoxy-1,4-dinitro-*neo*-inosite in 20% yield. The NMR spectra obtained in $CDCl_3$ showed sharp signals around 9.7–10 τ due to the methyl protons of the trisyloxy group. The exact value depends on the orientation of this group. In the cyclanol series the signals occur at 9.73–9.86 τ for axial and at 9.83 to 9.96 τ for equatorial trisyloxy groups, in the sugar trisylates at 9.80–9.88 τ for equatorial orientation.

The use of trisylates for the NMR-spectroscopic determination of conformation has the following advantages over the use of acetyl compounds: The $(CH_3)_3SiO$ signals are in a region where no other protons absorb; they are three times as strong as the CH_3CO signals; and they allow an unambiguous assignment of configuration particularly for aminocyclanols and amino sugars by NMR analysis of the *N*-acetyl-*O*-trisyl compounds.

[VB 925/240 IE]

Modern Analytical Methods in the Chemistry of Foodstuffs and in Biological Chemistry

The "Analytical Chemistry" and "Foodstuffs Chemistry and Forensic Chemistry" Groups of the Gesellschaft Deutscher Chemiker, as well as the Gesellschaft für Physiologische Chemie and the Deutsche Gesellschaft für Klinische Chemie organised a symposium in Heidelberg from 17th to 19th March 1965.

From the lectures:

Quantitative Determination of β-Aminoisobutyric Acid by Thin-Layer Chromatography

H. W. Goedde, H. Brunschede, and *R. Hoffbauer*, Freiburg/Br. (Germany)

β-Aminoisobutyric acid can be extracted by ether after quantitative reaction with 1-fluoro-2,4-dinitrobenzene. Routine chromatography involves a single rising development on silica gel G in chloroform/pyridine/glacial acetic acid [1] (50:50:1; v/v), elution of the (dinitrophenyl-β-amino)isobutyric acid (DNP-β-AIB) with 10% (v/v) acetic acid, and measurement of the optical density at 366 mμ. The calibration curve is linear over the region 10–700 mμmoles; the standard deviation of a measurement is less than ± 5%. Rechromatography affords 80% of the DNP-β-AIB extracted with ether. Repeated chromatography after removal of protein (best by ultrafiltration) is required for more sensitive detection of this amino acid in plasma and organ homogenates. After development in pyridine/chloroform/n-heptane/acetic acid (50:25:25:1; v/v) and drying for 3 hours in a desiccator, further separation is effected by the rising method with chloroform/glacial acetic acid (100:1;v/v) in a chamber with a very small volume (BN-Kammer, Messrs. Desaga). To improve the separation and shorten the running time in this process, the silica gel is scraped off from the starting point to about 1 cm below the β-AIB band [2]. If separation is still incomplete, a further run can be made, after short drying, with the same liquid phase. 4–300 mμmoles of β-aminoisobutyric acid (purity > 98·5%) can be detected with a yield of 80–90%. Absorption spectra show that the pH value has no effect on the position or height of the maximum at 360 mμ ($\varepsilon_{366} = 15{\cdot}0\times10^3$ cm² mole^{-1}). Dinitrophenyl derivatives of β-amino acids appear to be insensitive to light, in distinction from the derivatives of α-amino acids.

[1] The chloroform contains 1% absolute alcohol.

Detection and Determination of Amines on the 10^{-10} Molar Scale. Separation of 5-Dimethylamino-1-naphthalenesulfonamides on Thin-Layer Chromatograms

N. Seiler, Frankfurt/Main (Germany)

Quantitative reaction of primary and secondary amines and phenols with 5-dimethylamino-1-naphthalenesulfonyl chloride (DANS-Cl) permits detection and determination of these compounds in the 10^{-10} molar region by means of the intense fluorescence of the amide and phenol esters of the corresponding acid. Two-dimensional thin-layer chromatography is suitable for separation of 25 biologically important amines. Development is effected on silica gel (Kieselgel G) plates in the first direction with ethyl acetate/cyclohexane (75:50; v/v) and, after reactivation of the plates by heat at 100°, in the second direction with either benzene/methanol/cyclohexane (85:5:10; v/v) or benzene/triethylamine (100:20; v/v). The chromatograms are readily reproducible, so that the amides can be identified by their position and, in some cases, by the color of their fluorescence. DANS-amino acids remain on or near the starting point, so that they do not disturb chromatography of the amines. Only very little decomposition or autoxidation occurs during this treatment. For quantitative determination of the DANS-amides on

thin-layer plates, removal of the spots and extraction of the silica gel with methanol containing 5 % of concentrated ammonia solution are recommended. After excitation with the 365 mμ Hg line, the intensity of fluorescence of the extract is determined at 520 mμ for DANS-amides and at 530 mμ for phenol- and pyrocatechol-amine derivatives. Reproducibility is 3–5 % for concentrations of 2×10^{-10} mole/cm³.

Use of Chromatography on Anion-exchangers for Determination of Low Phosphate Contents

J. Wernet, *J. Ebert*, and *R. Adrian*,
Knapsack bei Köln (Germany)

The usual methods of paper-chromatographic separation and determination of condensed phosphates require concentrations of 1 to 5 g/l of each phosphate. In samples of water or foodstuffs, and in biological chemistry, the phosphate contents to be determined are usually considerably less than this. Concentration by evaporation would, *inter alia*, alter the form of the phosphates as a result of hydrolysis. Chromatography on anion-exchangers is suitable for determination of phosphates in these circumstances. It permits dissolved ionogenic phosphates to be separated and indications of the distribution of dissolved, non-ionogenic, inorganic and organic phosphates to be obtained. Dissolved, ionogenic, condensed phosphates can be separated and determined in concentrations down to less than 1 mg of total P_2O_5 per litre. In phosphate-treated drinking water, in river water, and in effluent water seven forms of phosphate could be determined in presence of each other: dissolved, non-ionogenic, highly condensed, inorganic and organic phosphates – dissolved ionogenic compounds, separated into mono-, di-, tri-, total > tri- and meta-phosphates – and highly condensed phosphates. [VB 923/230 IE]

Mode of Action of the Thiamine Antagonists Pyrithiamine and Oxythiamine in Rat Brain

C. J. Gubler, Freiburg/Breisgau (Germany)

Thiamine in the form of its pyrophosphate ester is involved as coenzyme in the decarboxylation of pyruvate and α-oxoglutarate. Prolonged deficiency of thiamine can lead to damage of the nerves.

Injection of the thiamine antagonist pyrithiamine into rats causes polyneuritis and a large decrease in the content of thiamine in the brain. Injections of oxythiamine do not affect the thiamine content. These findings were clarified by experiments *in vitro*. Inactive thiamine can be phosphorylated in brain tissue to give the active pyrophosphate [1]. The activating enzyme, thiamine pyrophosphokinase, was concentrated by a factor of 12. Pyrithiamine inhibits this enzyme 1000 times more strongly than oxythiamine ($K_{i\ (pyrithiamine)} = 1.3\times10^{-7}$; $K_{i\ (oxythiamine)} = 1.5\times10^{-4}$). Hence thiamine is not phosphorylated in the presence of pyrithiamine; instead, it is catabolized and excreted.

In contrast to pyrithiamine but like thiamine, oxythiamine is phosphorylated by thiamine phosphokinase, and the phosphate then inhibits the enzymes transketolase and pyruvate and α-oxoglutarate dehydrogenase.

Experiments with thiamine antagonists labelled with ^{14}C and ^{35}S revealed that the oxythiamine injected penetrates into the brain but in concentrations too low to prevent phosphorylation of the thiamine, and that pyrithiamine suppresses the production of thiamine phosphate in the brain.

The Stereochemistry of Sulfoxides

K. Mislow, Princeton, N.J. (U.S.A.)

Three major problems in sulfoxide stereochemistry are: the absolute and relative configuration of optically active sulfoxides, the relation between structure and optical rotatory power of sulfoxides, and the inversion of the sulfoxide pyramid.

The absolute configuration of menthyl *p*-iodobenzenesulfinate *(1)* was established by X-ray diffraction [1]. The configurations of menthyl *p*-toluenesulfinate *(2)* and of *(1)* were correlated, utilizing an asymmetric synthesis of the esters from (–)-menthol and an excess of the corresponding sulfinyl chloride. Reaction of *(2)* with a variety of alkyl- and arylmagnesium halides by an inversion mechanism led to optically active *p*-tolyl alkyl and aryl sulfoxides of known absolute configuration. Reaction of diastereomerically enriched menthyl 1-butanesulfinate (which had been prepared by asymmetric synthesis from (–)-menthol and 1-butanesulfinyl chloride) with methylmagnesium bromide led to optically active methyl n-butyl sulfoxide of known absolute configuration. This constitutes the first preparation of an optically active dialkyl sulfoxide lacking other functionalities. The optical rotatory dispersions of the abovementioned sulfoxides were measured and could be conveniently discussed from the viewpoint that the C_6H_5SO- moiety represents an inherently dissymmetric chromophore whose chirality determines the signs of the Cotton effects above 200 mμ.

Optically active sulfoxides containing aromatic nuclei may be racemized (a) thermally, by heating at temperatures near 200 °C (depending on the structure), (b) photochemically by irradiation (at room temperature) in the wavelength region above 285 mμ, and (c) chemically, by the catalytic action of hydrogen chloride in non-aqueous solvents.

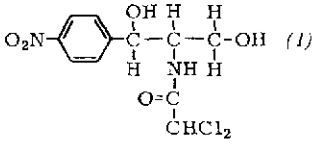
The last sentence of this lecture summary should begin: "Compound *(6)* with R = CH_3....."

SELECTED ABSTRACTS

A table of the masses of molecules and molecular fragments for help in identifying compounds by high-resolution mass spectrometry has been compiled by *D. D. Tunnicliff*, *P. A. Wadsworth*, and *D. O. Schissler*. An electronic computer was used to arrange the sum formulae of all possible combinations of elements (and their commonest isotopes) into two tables in order of increasing masses. The first table (215781 entries) gives combinations of the elements C, H, O, and N up to mass numbers of 600, the second (545017 entries) gives selected combinations of the elements C, H, O, N, F, Cl, Br, I, S, P, Si, B, Ga, Fe, Sn, and Al up to mass numbers of 400./Analytic. Chemistry *37*, 543 (1965)/–Hz. [Rd 311/520 IE]

Cyanamide formation under primaeval conditions was observed by *A. Schimpl, R. M. Lemmon*, and *M. Calvin*: on irradiating ammoniacal solutions of $NH_4{}^{14}CN$ with ultraviolet light, a 3.5 % yield of dicyanamide, the product of dimerization of cyanamide, was obtained. Irradiation of a methane/ammonia/water mixture also led to dicyanamide. Since dicyanamide and cyanamide effect the formation of pyrophosphate from orthophosphate, of glucose 6-phosphate from glucose and orthophosphate, and of adenosine 5'-phosphate from adenosine and H_3PO_4 (1–3 % yield at room temperature after several hours), they possibly are key compounds in chemical evolution. / Science (Washington) *147*, 149 (1965) / –De. [Rd 244/453 IE]

Chloramphenicol can serve as sole source of nitrogen for algae; this follows from experiments by *F. C. Czygan* with *Ankistrodesmus braunii* and *Chlorella ellipsoidea* in normal, low-nitrogen, and nitrogen-free culture solutions. The algae convert the chloramphenicol *(1)* into 1-(*p*-aminophenyl)- and 1-(*p*-nitrophenyl)-2-amino-1,3-propanediol, ethanolamine, *p*-aminobenzoic acid, and *p*-aminobenzaldehyde. The last three compounds can also be used as nitrogen sources by both species of algae. The *p*-amino analogue of chloramphenicol does



(1)

not occur in the culture medium but was produced from *(1)* with a hydrogenase from *A. braunii*. / Naturwissenschaften *51*, 541 (1964) / –De. [Rd 231/439 IE]

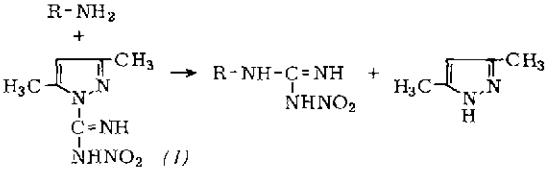
Reversible changes in the conformation of myoglobin from the sperm whale and in that of apomyoglobin were detected by *S. C. Harrison* and *E. R. Blout* using optical rotatory dispersion (ORD). The haem group can be removed from the myoglobin (Mb) by treating it with acetone at a low pH, the helix content being thereby reduced from 60 % (Mb) to 51 % (apo-Mb). It follows from results of ORD measurements that the major portion of the apo-Mb helical regions behave as though they were in an organic solvent and not in water, the medium in which the measurements were carried out. Consideration of the structural model for Mb proposed by *Kendrew* confirms that the helical regions are partly engulfed in a hydrophobic environment owing to inclusion inside the globular protein. Apo-Mb is completely unfolded in 8 M urea and has no helical regions. The ORD values then correspond to those for a peptide chain immersed completely in an aqueous medium. Removal of the urea by dialysis restores a 48 % helix content. The apo-Mb re-formed in this way combines completely with haem to give Mb which is indistinguishable from native Mb. The reversibility of the changes in conformation is particularly interesting because Mb has no disulfide bridges or thiol side chains. These results support the "thermodynamic" hypothesis of the formation of the tertiary structure of the protein. / J. biol. Chemistry *240*, 299 (1965) / –Hö. [Rd 302/511 IE]

The diffusion of boron in graphite has been investigated by *G. Hennig*. Boron is probably the only element that can be accomodated in lattice sites of graphite. The mobility of boron atoms in single crystals of graphite was measured as follows. The single crystals were etched and subsequently shadowed with gold, which condenses preferentially on the etched sites, rendering them visible in the electron microscope. The mobility of the boron atoms is largely independent of the concentration between B:C atom ratios of 10^{-2} and 10^{-8}. The diffusion constants between 1700 and 2400 °C can be represented by the expressions $6320\exp(-157000/RT)$ for motion parallel to the lattice layers and $7.1\exp(-153000/RT)$ for motion normal to the lattice layers. / J. chem. Physics *42*, 1167 (1965) / –Hz. [Rd 310/519 IE]

Dissociation constants of acidic hydrocarbons in the pK range 18–34 have been measured in cyclohexylamine by *A. Streitwieser, J. I. Brauman, J. H. Hammons*, and *A. H. Pudjaatmaka*. The equilibrium concentrations of the hydrocarbons and their carbanions were measured for the transanionization by spectrophotometry (the Beer-Lambert law is fulfilled). The equilibria were adjusted so that measureable concentrations of all four components were present. The technique can be applied whenever the anion and the corresponding acid (*i.e.* the hydrocarbon) can be distinguished by spectroscopy. 9-Phenylfluorene was taken as a standard with a known pK value (18.5 ± 0.1 in aqueous sulfolane). pK values of 22.9, 32.5, and 34.1, reproducible to within ±0.2 pK units, were found for fluorene, triphenylmethane, and diphenylmethane, respectively. / J. Amer. chem. Soc. *87*, 384 (1965) / –Eb. [Rd 273/482 IE]

$$C^{\ominus}M^{\oplus} + C^1H \rightleftharpoons CH + C^{1\ominus}M^{\oplus}\ (M = Li \text{ or } Cs)$$

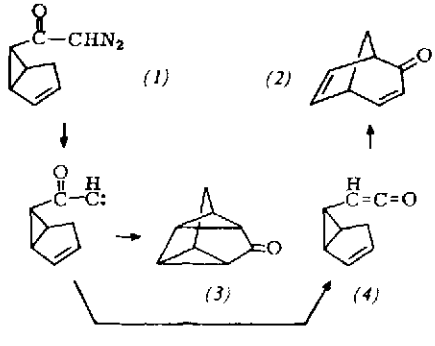
A new reagent for nitroguanylating proteins has been discovered by *A. Habeeb*. It is 1-nitroguanyl-3,5-dimethylpyrazole *(1)*. For example, the free amino groups in a 1 % aqueous solution of bovine serum albumin are almost completely nitroguanylated by a 0.025 M solution of *(1)* at pH 9.5 and room temperature without attack of the functional



(1)

groups in tyrosine, tryptophan, or histidine residues. Nitroguanylation is an important reaction for intentional modification of enzyme molecules. Hitherto *S*-methyl-1-nitroisothiourea was used instead of *(1)*, but the former does not react as completely as *(1)* with the free amino groups. The new reagent is made from nitroaminoguanidine and acetylacetone. / Biochim. biophysica Acta *93*, 533 (1964) / –Hö. [Rd 261/470 IE]

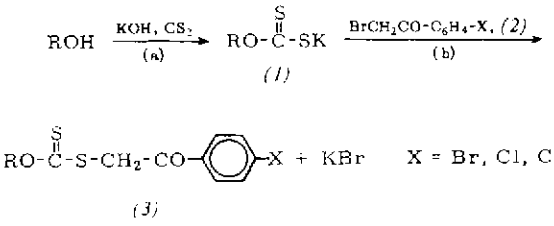
An unusual valence-bond isomerism was observed by *P. K. Freeman* and *D. G. Kuper*. Photolysis of a 1.5 % solution in tetrahydrofuran of *endo*-6-diazomethylcarbonylbicyclo[3.1.0]hex-2-ene *(1)*, which is obtained from bicyclo[3.1.0]hex-2-ene-6-*endo*-carbonyl chloride and diazomethane, affords the bicyclic ketone *(2)* resulting from valence-bond isomerization of the ketene intermediate *(4)*, which arises by Wolff rearrangement of *(1)*. The main product obtained is bicyclo[3.2.1]octa-3,6-dien-2-one *(2)*, but the tetracyclic ketone



(1) *(2)* *(3)* *(4)*

tetracyclo[3.3.0.0^{4,6}0^{2,8}]octan-3-one is formed as a by-product by intramolecular carbenoid addition to the double bond in competition to the Wolff rearrangement; the total yield of ketones is 50 %. The ketone *(3)* was recently synthesized by *Lebel*, and can also be prepared in 30 % yield from *(1)* by heating its solution in benzene with copper powder. / Chem. and Ind. *1965*, 424, 425 / –Ma. [Rd 285/494 IE]

Characterization of primary and secondary alcohols as their *O*-alkyl *S*-phenacyl dithiocarbonates *(3)* is described by *J. Berger* and *J. Uldall*. The potassium xanthates *(1)* are converted into the phenacyl derivatives *(3)*, which – contrary to the xanthates – crystallize well and have sharp melting points



(3)

In acetone, the KBr formed precipitates out and Reaction (b) goes almost to completion. When water is added, the KBr redissolves, and *(3)* precipitates out. In practice, 4 mmoles of *(1)* are dissolved in 10 ml of acetone plus 1–3 ml of water, and 3.6 moles (1.0 g) of *p*-bromophenacyl bromide *(2)*, X = Br, in 10 ml of acetone are added. After 5 min, water is added, and the whole is shaken vigorously. The precipitate consisting of *(3)*, X = Br, is sucked off and recrystallized from ethanol, the melting points and elemental analysis then being satisfactory. ROH = methanol leads to *(3)*, R = CH_3, of m.p. 94–95 °C. Polymorphism is occasionally observed. The technique can be applied on the micro scale down to 5 mg of *(1)*. / Acta chem. scand. *18*, 1353 (1964) / –Eb.

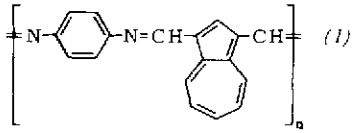
[Rd 235/443 IE]

Biological C-methylation by methionine was studied by *E. Lederer* et al., who found that only 2 hydrogen atoms of the methyl group are transferred to the acceptor. The origin of the 10-methyl group of tuberculostearic acid and of the 28-methyl group of ergosterol from methionine is known. *Lederer*'s group cultivated *Mycobacterium smegmatis* in the presence of 100 mg/l of methionine that was trideuterated at the methyl group. The tuberculostearic acid was separated from the cultures and examined by mass spectrometry for its deuterium content. It was found to contain only two deuterium atoms. This result was in agreement with that of the mass spectrographic analysis of ergosterol isolated from analogous cultures of *Neurospora crasse*. The analyses reflected the content of only two deuterium atoms per molecule so precisely that isotope exchange or dilution is cannot be an explanation for the deuterium loss. In addition, the methionine synthesis by the bacteria is almost completely suppressed by the high methionine content of the culture medium. It is not known which intermediate of the transmethylation reaction undergoes the loss of a deuteron. / Biochemistry *4*, 347 (1965) / –Hö. [Rd 304/513 IE]

Separation of lactic dehydrogenase isoenzyme bands into sub-bands by electrophoresis in polyacrylamide gels has been observed by *P. J. Fritz* and *K. B. Jakobson*. The separation of lactic dehydrogenase (LDH) into 5 bands (isoenzymes) with different rates of migration in electrophoresis has already been closely studied. It now appears that the isoenzymes in turn also consist of up to five components with only small differences in their mobilities, but there is a striking constancy in the distances between the sub-bands. The separation of the sub-bands depends on the pH (the optimum separation for LDH from mouse skeletal muscle occurs at 8.6) and on the concentration of 2-mercaptoethanol in the buffer. Separation is also observed in two-dimensional electrophoresis. Reversal of the current causes reunification of all the components at the starting point. These phenomena were observed with LDH from mouse skeletal muscle, mouse heart muscle, and rabbit skeletal muscle. The results do not depend on the purity of the LDH. The isoenzyme with the lowest mobility ("band 5") was generally found to be split into the largest number of sub-bands. / Biochemistry *4*, 282 (1965) / –Hö.

[Rd 305/514 IE]

Polyazomethines with azulene residues inserted in the main chain were prepared by *S. S. Stivala, G. R. Sacco*, and *L. Reich* from azulene-1,3-dicarboxaldehyde and 1,6-hexamethylene diamine, 1,4-diaminobenzene, 4,4'-diaminobiphenyl, 1,5-diaminonaphthalene, *etc.* The reagents are heated together, first in dimethylformamide at 100 °C for 8 h and then, after removal of the solvent, for a further 4 h at 250 °C. The polymers, *e.g. (1)*, are only slightly soluble in concentrated sul-



(1)

furic acid or formic acid and are stable *in vacuo* to 400 °C. This confirms the expectation that because of its resonance energy, which is of the same order of magnitude as that of benzene, azulenylene residues confer the same thermostability on the polymers as the phenylene residue. / Polymer Letters *2*, 943 (1964) / –Hl. [Rd 270/479 IE]

Pure phenyldifluorophosphine $C_6H_5PF_2$ was prepared by *R. Schmutzler* from $C_6H_5PCl_2$ with a suspension of sodium fluoride in tetramethylene sulfone at 180 °C and separated by vacuum distillation (b.p. 31 °C/11 mm). The compound does not etch glass and has a pleasant odor; it is oxidized slowly in air to $C_6H_5POF_2$ but does not ignite spontaneously. In contrast to CH_3PF_2 [cf. Equation (a)], it does not disproportionate under normal conditions. The compound was identified as $C_6H_5PF_2$ by elemental analysis and by its ^{31}P and ^{19}F nuclear magnetic resonance spectra. Being a strong π-electron donor, $C_6H_5PF_2$ reacts with metal carbonyls according to Equation (b). The redox reaction shown in Equation (c) proceeds completely stoichiometrically.

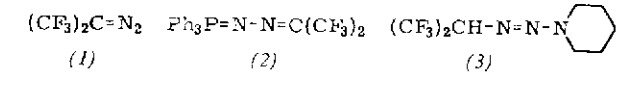
$$10\ CH_3PF_2 \rightarrow 5\ CH_3PF_4 + (CH_3P)_5 \quad (a)$$

$$Ni(CO)_4 + 4\ C_6H_5PF_2 \rightarrow Ni(C_6H_5PF_2)_4 + 4\ CO \quad (b)$$

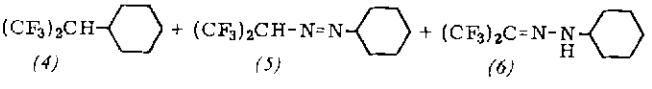
$$3\ C_6H_5PF_2 + 2\ SbF_3 \rightarrow C_6H_5PF_4 + 2\ Sb \quad (c)$$

A compound of b.p. 64–70 °C previously described as $C_6H_5PF_2$ [1] must obviously have a different composition. / Chem. Ber. *98*, 552 (1965) / –Gn. [Rd 271/480 IE]

Bistrifluoromethyldiazomethane *(1)*, the first perfluorinated diazo compound, was synthesized by *D. M. Gale, W. J. Middleton*, and *C. G. Krespan* by oxidation of the hydrazone of benzonitrile with lead tetraacetate. It is a pale yellow compound, b.p. 12–13 °C, and can be stored at –78 °C, but decomposes slowly at room temperature with release of nitrogen. It reacts with triphenylphosphine to give the phosphazine *(2)* and with piperidine to give the triazene *(3)*. When heated with benzene for 8 h at 200 °C, *(1)* yields 7,7-bistrifluoromethyl-1,3,5-cycloheptatriene (88 %) and hexafluoroisopropylbenzene (12 %) at 70 % conversion. On



(1) *(2)* *(3)*

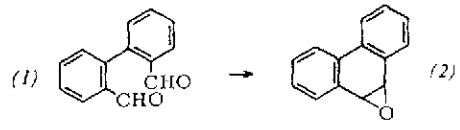


(4) *(5)* *(6)*

pyrolysis at 150–200 °C over quartz in an atmosphere of helium *(1)* gives hexafluoropropene and tetrakis(trifluoromethyl)ethylene. On heating in cyclohexane for 8 h at 150 °C, *(1)* yields 12 % hexafluoroisopropylcyclohexane *(4)* plus 52 % *(5)* and 36 % *(6)*; the latter two compounds have probably been formed by a radical chain reaction. / J. Amer. chem. Soc. *87*, 657 (1965) / –Ma. [Rd 291/500 IE]

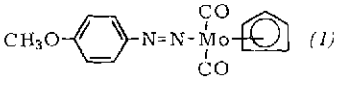
[1] Zhur. obshch. Khim. *29*, 3957 (1959).

A new cyclization reaction leading to epoxides of aromatic hydrocarbons has been discovered by *M. S. Newman* and *S. Blum*. Treatment of *o,o'*-diformylbiphenyl *(1)* with trisdimethylaminophosphine causes exothermic formation of 87 % 9,10-dihydro-9,10-epoxyphenanthrene *(2)*, m.p. 104 to



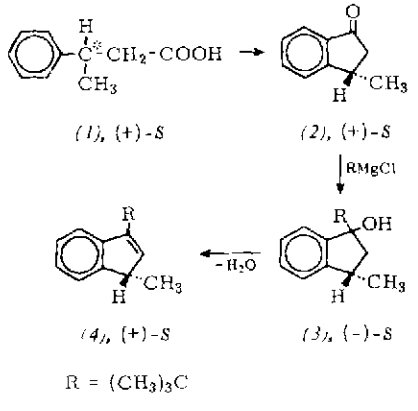
105 °C. 3,4-Dihydro-3,4-epoxybenz[*a*]anthracene, m.p. 119 to 120 °C (decomp.) and 3,4-dihydro-3,4-epoxy-10-methylbenz[*a*]anthracene, m.p. 117–120 °C, were obtained analogously. The three compounds are the first examples of epoxides of aromatic hydrocarbons; on treatment with acids, they isomerize to phenols. / J. Amer. chem. Soc. *86*, 5598 (1964) / –Ma. [Rd 253/462 IE]

An arylazo derivative of molybdenum, the first compound with an arylazo group attached directly to a transition metal, has been synthesized by *R. B. King* and *M. B. Bisnette*. *p*-Anisyldiazonium tetrafluoroborate was treated with excess $NaMo(CO)_3C_5H_5$ in tetrahydrofuran at room temperature; evaporation of the solvent and extraction of the residue with CH_2Cl_2 afforded a 20 % yield of *(1)*, which forms orange-red crystals, m.p. 78–79 °C, from pentane. The complex de-



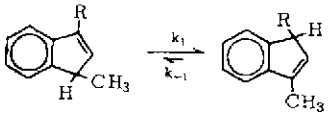
composes within a few hours on exposure to air. The structure *(1)* is reconcilable with the NMR spectrum of the compound. The complex is diamagnetic. / J. Amer. chem. Soc. *86*, 5694 (1964) / –Ma. [Rd 254/463 IE]

Optically active indenes have been obtained from β-phenylbutyric acid *(1)* by *A. M. Weidler* and *G. Bergson* by ring closure in a Friedel-Crafts reaction, conversion of the resultant indanone *(2)* with t-butylmagnesium chloride into *(3)*, R = t-butyl, or with $LiAlH_4$ into *(3)*, R = H, and dehydration of *(3)* with acid. Racemic *(1)* was resolved with optically



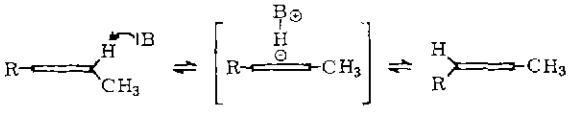
active α-phenylethylamine, the ammonium salts precipitated being recrystallized from aqueous ethanol, m.p. 135–140 °C. Three more recrystallizations raised the m.p. to 144.5–146 °C. The acid released from this product had a specific rotation $[\alpha]_D^{25}$ of +52.2 ° in benzene. The *(S)*-configuration of the (+)-acid *(1)* was already known. Since both antipodes of α-phenylethylamine were available, both enantiomorphic β-phenylbutyric acids could also be prepared. It is assumed that the acids (+)-*(1)* and (–)-*(1)* were optically almost pure and that the subsequent operations involved in the ring closure effected at the most only partial racemization. (+)-*S*-*(4)*, R = H, was also obtained with $[\alpha]_D^{25}$ = +182.1 ° in benzene, and (+)-*S*-*(4)*, R = t-butyl, with $[\alpha]_D^{25}$ = +110.2 °. / Acta chem. scand. *18*, 1483 (1964) / –Eb. [Rd 236/444 IE]

An ion-pair mechanism for the tautomerization of substituted indenes was discovered by *A. M. Weidler* and *G. Bergson*. 1-Methylindene *(1)* is stable in pyridine, but on addition of triethylamine or other aliphatic amines, it isomerizes to 3-methylindene *(2)*. This tautomerism can be followed by measuring the increase in intensity of the NMR signal of the olefinic methyl group. The isomerization is practically irreversible ($k_1 \gg k_{-1}$) and is pseudomonomolecular. k_1 is proportional to the concentration of amine catalyst. With (+)-1-methylindene *(1)*, the addition of catalyst causes the specific rotation to fall off to zero at the same rate as is observed for the isomerization. When R = t-butyl, the specific rotation attains a



(1), R = H *(2)*, R = H

limiting value with a sign opposite to that of the original rotation. The rate constants derived by polarimetry, too, are always the same as those measured by NMR spectroscopy. The stereospecificity of the reaction and the lack of deuterium-hydrogen exchange during the isomerization in the presence of D_2O can be explained by a mechanism involving prototropy *via* an intramolecular ion pair; a synchronous mechanism was shown not to occur. In dimethyl sulfoxide, the race-



mization of (+)-1-methylindene *(1)* was faster than the isomerization. Here the ion pair appears to dissociate partially to the free carbanion and $BH^{\oplus}$, and thus the stereospecificity of the preceding intermediate is lost. / Acta chem. scand. *18*, 1487 (1964) / –Eb. [Rd 237/445 IE]

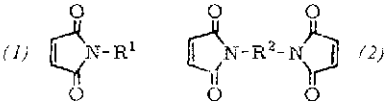
Dipeptide phosphates are intermediates of enzymatic tripeptide syntheses; this was shown by *J. S. Nishimura*, *E. A. Dodd*, and *A. Meister*. γ-L-Glutamyl-L-α-aminobutyryl phosphate is an intermediate in the synthesis of ophthalmic acid (γ-glutamyl-α-aminobutyrylglycine), which is catalysed by the glutathione synthetase from yeast. The reaction takes place in two steps:

$$\text{Dipeptide} + \text{ATP} \rightleftharpoons \text{Dipeptide phosphate} + \text{ADP} \quad (1)$$

$$\text{Dipeptide phosphate} + \text{Glycine} \rightleftharpoons \text{Tripeptide} + \text{Phosphate} \quad (2)$$

Both reactions are catalysed by the enzyme, and the intermediate remains attached to the enzyme protein. Four reactions catalysed by glutathione synthetase reveal the overall process: (a) formation of dipeptide hydroxamic acid from the dipeptide, ATP, and hydroxylamine; (b) formation of dipeptide hydroxamic acid from the tripeptide and hydroxylamine in the presence of phosphate or arsenate; (c) exchange between free glycine and that bound in the tripeptide; and (d) cleavage of the tripeptide into the dipeptide in the presence of arsenate. The Reactions (a)–(d) require catalytic amounts of ADP, which appears to be an essential part of the active enzyme-substrate complex. γ-L-Glutamyl-L-α-aminobutyryl phosphate was synthesized from *N*-carbobenzoxy-α-benzyl-γ-L-glutamyl-L-α-aminobutyric acid and phosphoric acid in the presence of dicyclohexylcarbodiimide. Its role as an intermediate was proved by its introduction during the enzyme reaction: in the course of Reaction (2), it condenses with glycine to form the tripeptide, while the reverse of Reaction (1) leads to the formation of ATP and the dipeptide when ADP is added. / J. biol. Chemistry *239*, 2553 (1964) / –Hö. [Rd 265/474 IE]

Vulcanization of styrene/butadiene copolymers with maleimides of types *(1)* and *(2)* can be carried out according to *P. O. Tawny, W. J. Wenisch, S. van der Burg*, and *D. I. Relyea* with peroxides and sulfur-containing accelerators of the thiazole type. The cross-linking activity of *(1)* and *(2)* depends



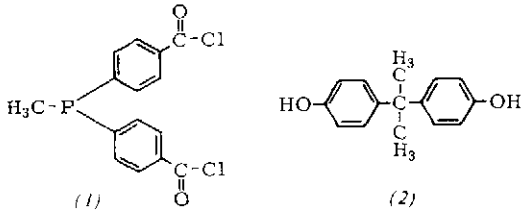
(1) *(2)*

largely on the nature of the substituents R^1 (*e.g. p*-ethoxyphenyl > *m*-chlorophenyl > *o*-nitrophenyl) and R^2 (*e.g. m*-phenylene > 1,2-(*p,p'*-diphenylene)ethylene > *p,p'*-biphenylyl). For example, 100 g of a 24:76 styrene/butadiene copolymer can be vulcanized by treatment with 0.85 g of *N,N'*-phenylenebismaleimide and 0.7 g of dicumyl peroxide (40 % activity) for 22 min at 155 °C. The physical properties of the vulcanized product are independent of the vulcanization temperature. In contrast to vulcanization with sulfur, the maleimide vulcanization systems have no significant effect on the crystallizability of the elastomers on stretching. Maleimides of type *(1)* in which $R^1 = SCCl_3$ or *p*-$HOOC-C_6H_4$, for example, are suitable as self-accelerating vulcanizing agents or as adhesives. / *J. appl. Polymer Sci. 8*, 2281 (1964) / –Hl. [Rd 268/477 IE]

The origin of the nitrogen in quinoline made by the Skraup synthesis was investigated by *M. Wahren*. He studied how the nitrogen from the coreagents aniline and nitrobenzene is distributed in the reaction products. It is generally accepted that the nitro compound used as dehydrogenating agent for the intermediate dihydroquinoline is reduced to the aniline derivative, which then acts as additional "starting material." – Nitrobenzene or aniline was labelled with ^{15}N, and the reaction products were processed in five fractions: unreacted nitrobenzene, aniline, quinoline, resin (residue from the steam distillation of the bases), and residues (mother liquors, *etc.*, of undefined composition). Kjeldahl nitrogen estimations and mass-spectrometric analysis of the ^{15}N content of the nitrogen led to the following results: In contrast to the conventional opinion, only about 2 % of the quinoline contains nitrogen originating from the nitrobenzene; this percentage rises slowly as the overall conversion increases, but the content of ^{15}N from $C_6H_5{}^{15}NO_2$ is always higher in the aniline in the reaction mixture than in the quinoline; hence the low incorporation that does take place very probably proceeds *via* the aniline. Over 90 % of the nitrobenzene nitrogen recurs in the nitrobenzene and resinous fractions; after complete reaction, it is primarily in the resins, mainly in functional groups with N–N or N–O bonds. It follows that unlabelled nitrobenzene can be used to prepare [^{15}N]-quinolines from [^{15}N]-aniline. / Tetrahedron *20*, 2773 (1964) / –Bi. [Rd 267/476 IE]

Connections between the structures and long-wave infrared spectra of aliphatic amides have been demonstrated by *J. E. Katon, W. R. Feairheller*, and *J. V. Pustinger* for 78 compounds of this class in the region between 700 and 250 cm^{-1}. Here all amides have 2–4 absorption bands between the limits 700–550, 520–430, and 390–305 cm^{-1}. The exact positions of the peaks give information on finer structural details, *e.g.* the amount of branching and the approximate length of the aliphatic chain. The regions of characteristic absorption were tabulated for primary, secondary, and tertiary amides with diverse aliphatic substituents. Assignments of the bands to the following modes of vibration of the molecular skeleton were considered: The band near 600 cm^{-1} is due to deformation of the N–C=O group; the band at 500 cm^{-1} is probably due to a C–C=O deformation, for this band is absent in formamides; the origin of the band near 350 cm^{-1} is still unclear, but it is assumed to arise from a non-planar deformation vibration of the amide group. / Analytic. Chem. *36*, 2126 (1964 / –Hz. [Rd 234/442 IE]

The synthesis of polyamides containing phosphorus by interfacial polycondensation is described by *V. V. Korshak, S. V. Vinogradov*, and *U. Ban-Yuan*'. The reaction is carried out in 0.05 N solution in chloroform with vigorous stirring (6000 r.p.m.). Reaction of bis-(*p*-chlorocarbonylphenyl)methylphosphine *(1)* with 2,2-bis(*p*-hydroxyphenyl)propane *(2)* and hexamethylene diamine, for example in proportions of 2:1:1,



(1) *(2)*

yields a polyamide (η_r = 0.43 in tricresol, softening point ca. 160 °C) with a nitrogen content almost the same as that of the monomer mixture. The solubility of the polyamides in dioxane/CCl_4 depends on the ratio of monomers in the starting mixture and decreases with increasing hexamethylenediamine concentration. Since the yield of polymer in interfacial polycondensation depends on the surface area, the yields increase as the stirring becomes faster. At the same time, more hexamethylenediamine is incorporated, for it is apparently more reactive than *(2)*. / Polymer Sci. USSR *5*, 18 (1964) / – Hl. [Rd 269/478 IE]

The mechanism of the iodination of aromatic compounds with iodine/peroxyacetic acid in acetic acid [1] has been elucidated by *Y. Ogata* and *K. Nakajimi* by studying the effect of the acidity, the temperature, the solvent, and the nature of the peroxyacid on the yield of aryl iodide [see Equations (a) to (d)]. The overall rate of iodination is independent of the pH and of the concentration of the aromatic compound; instead, it is determined by the rate of the (pH-independent) reaction of the iodine with the peroxyacetic acid. However, since addition of sulfuric acid increases the yield of iodo compound (*e.g.* for benzene from 60.9 to 77.3 % iodobenzene with a molar ratio $H_2SO_4:I_2$ of 1.23:1.00, reaction for 160 min at 70 °C), it is concluded that a protonation of the iodinating reagent occurs. On the other hand, the yield of iodobenzene falls to 1.3 % if the peroxyacetic acid/acetic acid is replaced by peroxybenzoic acid/chloroform (270 min at 60 °C; here the weak iodinating agent is possibly I_2O, but the main product is HIO_3). When acetic acid is added in a molar ratio $CH_3COOH:I_2$ of 11:1, up to 5 % iodobenzene is formed. The importance of the peroxyacetic acid is due to the formation from it of acetyl hypoiodite; the species which then conducts an electrophilic attack on the aromatic compound is probably protonated acetyl hypoiodite $(CH_3COOHI)^{\oplus}$.

$$I_2 + CH_3CO_3H + H_2O \xrightarrow{\text{slow}} 2\,HOI + CH_3CO_2H \quad (a)$$

$$HOI + CH_3CO_2H + H^{\oplus} \underset{}{\overset{\text{fast}}{\rightleftharpoons}} (CH_3CO_2HI)^{\oplus} + H_2O \quad (b)$$

$$(CH_3CO_2HI)^{\oplus} + ArH \xrightarrow{\text{fast}} ArI + CH_3CO_2H + H^{\oplus} \quad (c)$$

$$HOI + 2\,CH_3CO_3H \longrightarrow HIO_3 + 2\,CH_3CO_2H \quad (d)$$

ArH can be benzene, toluene, *m*-xylene, cumene, anisole, naphthalene, chloro- or bromonaphthalene, or benzoic acid; the yields lie between 35 and 84.6 % ArI within 90–330 min at 50–90 °C. / Tetrahedron *20*, 2751 (1964) / –Bi. [Rd 277/486 IE]

[1] *Y. Ogata* and *K. Nakajima*, Tetrahedron *20*, 43 (1964); cf. Angew. Chem. *76*, 507 (1964).

An improved apparatus for continuous electrophoresis without a support has been developed by *K. Hannig*. In contrast to previous equipment, the electrophoresis cell (48×48 cm^2; 0.5 mm layer thickness) is mounted vertically and has a uniform flow of buffer normal to the electric field, achieved by introducing the buffer through six inlets at the upper edge and removing it from fifty leads at the lower edge. The solution to be separated can be fed in continuously to the buffer stream close to the upper edge at one of several points. Previously, the problem of non-uniform cooling prevented vertical arrangement of the electrophoresis cell, for the slightest temperature gradients caused disturbances of the laminar flow of buffer owing to convection currents. This difficulty has been overcome by covering the rear wall of the cell uniformly with Peltier batteries. About 2500 v at about 160 mA is used. – The apparatus can separate protein mixtures continuously even when the molecules in the mixture differ by only one charge unit. Because of the vertical arrangement, the range of application of the instrument could be extended even to particles which in horizontal cells sediment out on the lower plate and upset the separation. Clean separations of cellular constituents (*e.g.* chloroplasts, mitochondria, cell nuclei, and nuclear fragments from spinach leaves) and even of intact cells (*e.g.* human and rabbit erythrocytes or Walker ascites tumor cells and leucocytes) were achieved with the new instrument. The fractions exhibited excellent homogeneity in the electron miscroscope. Even virus mutants can be separated. / Hoppe-Seylers Z. physiol. Chem. *338*, 211, 278 (1964) / –Hö. [Rd 266/475 IE]

BOOK REVIEWS

Ionenaustausch-Chromatographie (Ion-Exchange Chromatography). By *K. Dorfner*. Akademie-Verlag, Berlin 1963. 1st edit., X + 236 pp., 149 illustrs., 14 tables, linen DM 32.50 (about $ 8.25).

The author, a former coworker of *B. Sansoni* in Marburg (Germany), has recorded his knowledge and experience in the field of ion exchangers in two books; in the present volume he presents a review of ion-exchange chromatography, starting from elementary fundamentals that can be understood by all. It is simultaneously the second volume in the series "Ionenaustauscher in Einzeldarstellungen" (Monographs on Ion Exchangers) edited by *Griessbach*. The book has two main divisions: methods of ion-exchange chromatography (fundamentals of chromatography, ion-exchange chromatography, types of ion exchangers, apparatus), and their applications in inorganic and organic chemistry (including natural products). The ordering principles applied are the groups of the periodic system of the elements and the compound classes in organic chemistry.

The text is augmented by 149 figures and 14 tables, and 946 literature references are given, covering publications up to about 1960. Within the aims of the book, all the essentials are well dealt with. The subject matter is well arranged, and the style of the writing is fluent, so that the book well fulfils its purpose of providing an introduction to the subject and serving as a source of information.

E. Blasius [NB 377/235 IE]

Die Nucleinsäuren (Nucleic Acids). By *E. Harbers* in collaboration with *G. E. Domagk* and *Werner Müller*. Eine einführende Darstellung ihrer Biochemie und Funktionen (An Introductory Description of their Biochemistry and Functions). Georg Thieme Verlag, Stuttgart 1964. 1st edit., XII + 303 pp., 155 figs., 20 tables, linen DM 68.– (about $ 17.25).

This monograph on nucleic acids does not merely bring a discussion of the fundamental facts in this field; the breadth and depth of the data given are sufficient to satisfy even high demands – in their didactic nature as well. The book is intended for all scientists with an interest in biology and to medical researchers occupied with biochemical problems.

The chemistry of nucleic acids and their constituents is given an exemplary historical and theoretical treatment by *W. Müller*, together with many practical tips for laboratory work. The biosynthesis of purines, pyrimidines, pentoses, and nucleotides is described by *G. E. Domagk*. There follow chapters on the metabolism of DNA and RNA, the transfer of genetic information from cell to cell, the induction of mutations, nuclei acids in tumor cells, interference of drugs in nucleic acid metabolism, and the effects of radiation on nucleic acids.

The newcomer to this field will welcome the appendix, which records some classical methods for metabolic studies and for preparative, analytical, and physico-chemical experimentation with nucleic acids. An unusually large list of sources of information and, in contrast, a very meagre subject index close the book, which is highly recommendable in view of its copious content. It is to be hoped that a more reasonable price will make a second edition available to a broader readership.

H. Matthaei [NB 383/241 IE]

Essays on Coordination Chemistry. Dedicated to Gerold Schwarzenbach on his 60th Birthday, 15 March, 1964. Edited by *W. Schneider*, *G. Anderegg*, and *R. Gut*. Experientia Supplementum IX, Birkhäuser Verlag, Basel-Stuttgart 1964. 1st Edit., 305 pp., numerous figures and tables, linen, DM 48.– (about $ 12.00).

Gerold Schwarzenbach is one of the most prominent scientists and responsible for significant advances in the modern development of complex chemistry. It is therefore only fitting that the scientific world should mark the special occasion of his sixtieth birthday, and all with an interest in coordination chemistry will certainly appreciate the fact that this was done in the form of an anthology of essays written by outstanding workers in this field.

Most of the 23 articles dedicated to *Schwarzenbach* are directly related in some way to his own work. This can be said in particular of the first contribution by *W. Schneider*, which is an appraisal of *Schwarzenbach*'s research in the field of organic chemistry, if the compounds investigated are considered. Actually, the problems studied were more of a physical-chemical nature, as for example the protogenic properties of organic acids in dependence upon the nature of the substituents. A list of papers published by *Schwarzenbach* up to 1963 is appended to this article.

The main credit due to *Schwarzenbach* is for his work on the chemistry of complexes in aqueous solutions. One of the most important results of this work is complexometry, which is now known to every chemist as an invaluable analytical tool. It is therefore not unwarranted that seven essays deal with the coordination chemistry of aqueous solutions, *e. g. L. G. Sillen*'s article (Thoughts during a Walk in Lappland), the value of which lies in its intimate personal note. Naturally *J. Bjerrum* is not missing among the authors. His essay deals with the behavior of $Hg^{2\oplus}$ towards ethylene diamine in contrast to that of $Ag^{\oplus}$ and frequently touches closely upon *Schwarzenbach*'s own work. The solid state also comes under discussion: *W. Feitknecht* describes the composition and structure of the hydroxide salts of bivalent metals formed during complex-chemical reactions.

Other articles in the book are important for the theoretical treatment of questions in coordination chemistry (problems

concerning the nature of the bonding, and stability problems, particularly in connection with coordination). These include, for example "Die Bedeutung quantenmechanischer Modelle für die Chemie" (the importance of quantum-mechanical models in chemistry) by *H. Hartmann*, "Inorganic Chromophores" by *C. K. Jörgensen*, "The Stabilisation, Stereochemistry, and Reactivity of Five-coordinated Compounds" by *R. S. Nyholm* and *M. L. Tobe*, and the "Structure and Bonding in Transition Metal Complexes of Some Unsaturated Ligands" by *R. Masen* and *G. Wilkensen*.

O. Schmitz-DuMont [NB 333/191 IE]

Chemotaxonomie der Pflanzen (Chemical Taxonomy of Plants). By *R. Hegnauer*. Vol. 3. Dicotyledoneae. Part 1: Acanthaceae-Cyrillaceae. Chemical Series, Vol. 18. Birkhäuser Verlag, Basel-Stuttgart 1964. 1st edit., 744 pp., 14 figs., 17 tables, clothbound DM 123.– (about $ 31.50).

When conservative standards are applied, dicotyledons are divided into about 270 families; 79 of these are discussed in the present volume [1]. The book therefore deals with some 3500 genera comprising about 45000 species. These include some very large families or genera that are important in other connections, including the Compositae, the Apocynaceae, Cruciferae, *etc.* Chemists interested in plant products will therefore want to inspect this volume with careful attention.

The organization of the material within each family discussed corresponds to that used in earlier volumes: first come a short botanical description and the systematic classification, then a summary of important morphological and chemical characteristics, the latter frequently being subdivided according to substance classes, and finally literature references and concluding remarks which contain the essence of the taxonomic features of the plants. Mostly the main chemical constituents of the plants are critically appraised here whenever they appear very frequently in a certain family and are highly typical for it in contrast to other families. In this way, sometimes clear-cut decisions can be made in favor of one or another known system of plants. The dangers of taxonomic classifications based on single substances are emphasized. There are of course many examples of individual chemical compounds that occur sporadically in plants which are definitely not interrelated, *e.g.* lysergic acid derivatives in certain species of Convulvulaceae or Ascomycetes. The reader again observes that extremely widespread and thoroughly investigated materials such as the carotenoids contribute but little to the solution of taxonomic problems.

In contrast to the volumes that have already appeared, on account of the immense amount of material dealt with, the literature and individual compounds have not been comprehensively reviewed. Nonetheless, a great deal of otherwise difficultly accessible literature has been evaluated. The organic chemist will be surprised to find that the formulae shown have again been drawn with complete disregard of the stereochemistry of the compounds concerned. The author indicates many deficiencies in phytochemical research and may thus provide incentives for new research work.

Misprints and factual errors are few; the quality of the paper, print and binding are as usual excellent.

C. H. Eugster [NB 409/266 IE]

The Monosaccharides. By *J. Staněk*, *M. Černy*, *J. Kocourek*, and *J. Pacák*. Academic Press, New York-London, and Publishing House of the Czechoslovakian Academy of Sciences, Prague, 1963. 1st edit., 1006 pp., 40 figs., 64 tables, linen $ 32.–.

An English translation is now available of the book "Monosacharidy" by *J. Staněk* et al. The appearance of this translation is to be welcomed, for now this monograph on a well defined section of carbohydrate chemistry is available to a much larger public. The English edition is not merely a simple translation of the first Czechoslovakian edition; the contents have been considerably reshuffled and extended, producing a great improvement in the book. Moreover, work published up until about 1962 has now also been included.

In the monograph, the most diverse derivatives of this class of substances are described, and their manifold reactions are discussed in detail, often exhaustively. The specialist in this field will therefore gladly take first recourse to this work for rapid orientation. The book is also aimed at satisfying the demands of other chemists associated in part with carbohydrate chemistry in close connection with their own investigations, *e.g.* biochemists and industrial chemists, for here they find a well arranged wealth of information. Numerous tables interspersed between the text give rapid information on the derivatives of the monosaccharides prepared to date. The list of references given has been compiled with especial care. Each chapter contains references to large review articles to facilitate the search for particular details or for original publications. The literature from relatively obscure journals has also been almost completely scanned, and even the specialist may find many a reference he has previously overlooked.

The book contains a short but fully satisfactory chapter for superficial information on the biochemical syntheses and conversions of sugars in biological systems. Further details on this rapidly advancing subject can be found in scientific journals in any case. However, a more extensive treatment of modern investigations into stereochemical topics and reaction mechanisms would have been preferable. Aspects such as conformational analysis, the mechanisms of substitution reactions and the associated questions of stereochemistry and neighboring-group participation, and applications of NMR spectroscopy are at the focus of attention in the carbohydrate field at present and will be studied more intensely in future. These suggestions might be considered for future editions.

The present volume is thus an important source of information for a large circle of users and deserves a place in every chemical library. A second volume on "The Oligosaccharides" has already been announced which ought to provide a supplement to the present book.

H. Paulsen [NB 370/228 IE]

The Proteins. Composition, Structure, and Function. Vol. I. Edited by *H. Neurath*. Academic Press, NewYork-London 1963. 2nd edit., XIII + 665 pp., numerous illustrs. and tables, linen $ 22.–.

The following topics are dealt with in six chapters: 1. "Amino-Acid Analysis of Peptides and Proteins" (*A. Light* and *E. L. Smith*) with an appendix on "Amino-Acid Analysis of Certain Proteins" by *G. R. Tristram* and *R. H. Smith*; 2. "Synthesis and Function of Peptides of Biological Interest" (*K. Hofmann* and *P. G. Katsoyannis*); 3. "Chemical Aspects of Protein Synthesis" (*J. S. Fruton*); 4. "Concepts and Experimental Approaches in the Determination of the Primary Structure of Proteins" (*R. E. Canfield* and *C. B. Anfinson*); 5. "Intramolecular Bonds in Proteins, I. The Role of Sulfur in Proteins" (*R. Cecil*); 6. "II. Non-covalent Bonds" (*H. A. Scheraga*).

The survey shows that the subjects dealt with are arranged less systematically than in the first edition, being aimed more directly at individual acute problems. The subtitle of the book reveals the reason for this selection, namely the coordination of chemical structure and biological function, as is prominently apparent, particularly in the second chapter. Following a discussion of the modern methods of peptide synthesis, their application to the preparation of hypophyseal hormone, angiotensin, bradykinin, and kallidin peptides is described, and the structure-function relationships are illuminated, particularly for the oxytocin-vasopressin group and for the melanophore-stimulating systems. The first chapter is also highly instructive, but a little more emphasis

[1] For reviews of Vols. 1 and 2 see Angew. Chem. *76*, 312 (1964); Angew. Chem. internat. Edit. *3*, 452 (1964).

on chromatography and its auxiliary methods might have been desirable. In the third chapter, a compromise had to be made, for it was impossible to give a detailed treatment of the biochemistry of nucleic acids alongside the discourse on protein biosynthesis, despite the equal importance of both fields. The solution found in the book can be considered ideal; however, since the manuscript was completed in June 1962, a few of the latest important results are missing, because of the rapid current developments in this field.

It is obvious from the fourth chapter that its authors are well familiar with the experimental side of their work; despite the brevity of their essay (61 pp.), it leaves little room for improvement. The same cannot be said without reservation for Chapter five: the discussion of the function of groups containing sulfur in proteins receives too little attention (7 pp. compared with 73 pp. devoted to analytical methods and chemical reactions). Chapter six furnishes a comprehensive review of the statistical thermodynamic theories of non-covalent interactions, with particular emphasis on hydrophobic bonds, and the part played by such phenomena in denaturation, ionization, proteolysis, and association. The reader can derive enormous value from the subject matter in this chapter, but will have to apply almost as much effort in order to work through it. Simplified, easily understandable summaries to each section would be a great help here.

Although the contributions in this first volume of the second edition of the book are of such great value, and although its authors are certainly excellent authorities in their fields, it does not appear to make the first edition completely redundant. It might have been better to publish supplementary volumes instead of a completely new edition. As far as can be judged, the selection of topics for inclusion in the new edition already marks a step in this direction.

F. Turba [NB 360/218 IE]

Introduction to Infrared and Raman Spectroscopy. By *N. B. Colthup, L. H. Daly,* and *S. E. Wiberley.* Academic Press, New York-London 1964. 1st edit., XII + 511 pp., numerous figs. and tables, linen $ 12.–.

Up to the present, it has always been difficult to recommend a single book for conveying an introduction to vibration spectroscopy, because in all the well-known monographs on this topic, either a theory of vibration spectroscopy is developed, or the stress is placed upon experimental or applied technical aspects, or only infrared group frequencies are listed and discussed. In the present introduction, an attempt is made to present all these aspects in a single book, and it must be said, with good success. An introductory chapter is devoted to an elementary treatment of the theory of rotation and vibration spectra, and despite its highly condensed form, all the important concepts are done justice. In the second chapter, the structural elements or infrared and Raman spectrographs and experimental questions are discussed. In a chapter on the classification of molecules, the symmetry properties of molecules are explained, and the group theory is presented up to the point required for comprehension of the classification of normal vibrations. Besides character tables for the point groups, many examples are given of molecules investigated. In the next nine chapters, group frequencies are summarized and discussed in detail. Following a very lucid explanation of the alteration of group frequencies caused by interactions with other vibrations, the characteristic frequencies are given, arranged according to groups. The literature on this material is evaluated up to 1961, sometimes until 1963. In a further chapter, the group frequencies are again given, this time arranged according to spectral regions and together with correlation charts. In addition, the absorption spectra of 624 molecules are given, mostly with indication of the characteristic group frequencies; this greatly facilitates introductions to the analytical applications of vibration spectroscopy. In the final two chapters, a theoretical vibrational analysis and a calculation of the thermodynamic functions with chloroform as an example are given, An extensive author and subject index greatly simplifies the use of the volume.

The book can be recommended to all chemists occupied with any problems in infrared or Raman spectroscopy and to students with interests in this field. It ought to prove an excellent introduction even for those who wish to conduct specialized spectroscopic investigations.

W. Liptay [NB 350/208 IE]

Les Réactions Chimiques dans les Solvants et les Sels Fondus (Chemical Reactions in Solvents and Molten Salts). By *G. Charlot* and *B. Trémillon.* Gauthier-Villars, Paris 1963. 1st Edit., VII + 602 pp., 114 figures, 157 tables, linen, NF 94.– (about $ 20.00).

The rapid advances of inorganic chemistry over the past decades has led to the initiation of new journals and new monograph series devoted to this subject: Journal of Inorganic Chemistry (U.S.A.), Journal of Inorganic and Nuclear Chemistry (U.S.A.), Journal of the Less-Common Metals (England); *A. Cotton*: Progress in Inorganic Chemistry; *H.J.Emeleus* and *A. G. Sharpe*: Advances in Inorganic Chemistry and Radiochemistry. Following the initiative of *A. Chrétien* of the Sorbonne, a journal "Revue de Chimie Minerale" (Reviews of Inorganic Chemistry) and a monograph series "Monographies de Chimie minerale" (Monographs in Inorganic Chemistry), both published by Gauthier-Villars, have been founded in France. This book on the chemistry in non-aqueous solvents and in molten salts forms the first volume of the new monograph series, which promises further volumes on polyanions and polycations, solubility diagrams, contact catalysis, and non-stoichiometric compounds.

In the introduction to the present volume, *A Chrétien* gives a brief review of the development of inorganic chemistry within recent times and points out the directives followed in planning future volumes of the series: only fields which have recently undergone widespread investigations will be dealt with, and particular stress will be laid upon broad literature coverage; on the other hand a critical and lucid picture of the subject under discussion is to be given, so that not only mere literature compilations will result. The present volume adheres rigorously to these general principles. In the first five chapters (158 pp.) general reviews are given of acid-base reactions in weakly and strongly dissociating solvents, of complexes (here including undissociated species such as $CdCl^{\oplus}$ and $CdCl_2$), of redox reactions, and of solubility phenomena. The next ten chapters (420 pp.) deal with individual solvents and contain abundant literature references. Nine of these chapters are devoted to low-melting – mainly organic – solvents, and only the last chapter, which is particularly long, deals with molten inorganic salts. Here a theoretical introduction is given.

The book gives a good survey of the field and will be particularly useful as a work of reference.

W. Klemm [NB 334/192 IE]

Ion Exchange Separations in Analytical Chemistry. By *C. Samuelson.* Almquist & Wiksell, Stockholm-Göteborg-Uppsala, and John Wiley & Sons, New York-London 1963. 2nd edit., 474 pp., numerous illustrs., linen Sw. Kr. 65.– (about $ 12.50).

It is more than ten years since the first well known review of the analytical applications of ion exchangers appeared in its first edition; its title has been altered a little in this second edition. A new edition had become essential in view of the ever increasing number of publications on this subject and because of the enhanced importance of its methods in practice. Although the author himself can look back on many years of experience in this field, he now applies himself to this task with counseling cooperation from a number of experts on the subject, and with highly successful results.

The literature has been completely cited until about 1960/61; Russian and Japanese publications are notably well covered. The subject matter is divided into three main sections, as in the first edition: fundamentals, practical aspects, and applications. Mainly ion exchange resins are dealt with. In the discussion of their applications, in contrast to the treatment in the first edition, the author has now restricted his discourse to inorganic chemistry. This chapter makes up about half of the book and describes the determination of the total salt concentration, removal of interfering ions of opposing charge, inorganic colloids and highly polymeric electrolytes, isolation of trace components, separations of metals, chromatographic separation of anions, and inorganic qualitative analysis.

Since in many of the separations described, recourse must still be taken to original publications, the reviewer thinks it would be better in future editions to introduce tabulated surveys for individual elements or groups of elements. This would leave more room for standard practical procedures, some of which might still have to be developed.

Nonetheless, the nature of the presentation in the text, figures, and tables reveals that the author has full command of the topic of his book. The work can therefore be recommended to all who are occupied in any way with the analytical applications of ion exchangers.

E. Blasius [NB 378/236 IE]

Kinetics of Precipitation. By *A. E. Nielsen.* International Series of Monographs on Analytical Chemistry. Chief editors: *R. Belcher* and *L. Gordon.* Vol. 18. Pergamon Press, Oxford-London-Edinburgh-NewYork-Paris-Frankfurt 1964. 1st edit., X + 153 pp., numerous illustrs., several tables, linen £2.0.0 (about $ 5.50).

This monograph deals with the kinetics of crystal growth in the situation where numerous crystallization nuclei are formed simultaneously, as in most analytical and technical crystallizations. The author has succeeded in covering the whole of this complex field very comprehensively in 12 well arranged chapters. This he achieves by neglecting to give a detailed discourse on the confusingly large variety of experimental reports on this topic and by placing the theoretical aspects in the forefront instead. Experimental results appear only when compared with the results of theory or when used for making premises. The relationships between the formulae are developed lucidly and the most important quantities are often expressed explicitly in various forms. Aspects considered in detail include work of nucleation, frequency of nucleation, diffusion-controlled growth, nucleation-controlled growth, and growth influenced by dislocations, combination of growth mechanisms, homogeneous and heterogeneous nucleation, Ostwald ripening, growth forms, and adsorption. The reviewer considers the last two chapters to be rather weak. Here the relation between equilibrium form and growth form is not quite clear, and that between surface energy and nucleation energy is unfortunately not described correctly. Nevertheless, this condensed and clear presentation of the subject will be of great value to all associated with the kinetics of crystal growth.

H. Heyer [NB 351/209 IE]

Advances in Organic Chemistry. Methods and Results. Edited by *R. A. Raphael, E. C. Taylor,* and *H. Wynberg.* Vol. 4. Interscience Publishers, a Division of John Wiley & Sons, New York-London 1963. 1st edit., VII + 361 pp., numerous tables, linen £5.10.0 (about $ 15.25).

Here *J. Szmuszkovicz* gives the most comprehensive survey to date (113 pp., 282 references) on aminoalkenes and aminodienes with the exception of their *N*-, α-, and β-acyl derivatives. Aspects dealt with include the preparation, physical properties, alkylation, acylation, halogenation, arylation, and reactions with azides, diazonium salts, and sulfonyl chlorides, of this class of compounds. Six practical procedures are appended. The section on "basicity" is misleading, for it centers on the erroneous idea that 1-aminoalkenes are more strongly basic than aminoalkanes. In their well presented review of "Synthetic Methods in the Carotenoid and Vitamin A Fields" (109 pp., 335 refs.), *O. Isler* and *P. Schudel* first describe chain-extension methods and syntheses of symmetrical C_8 to C_{30} intermediates, then the synthesis of carotinoids according to the scheme $C_x + C_y + C_x \rightarrow C_{40}$, dehydration reactions, rearrangements, and oxidations and reductions on the carotinoid skeleton. A table lists information on total syntheses of C_{40} all-*trans*-carotinoids. In the final article, "Coupling of Acetylenic Compounds", *G. Eglinton* and *W. McCrae* review methods for linking two acetylenic compounds to give 1,3-diynes. In addition to the classical symmetrical coupling of acetylenes in the presence of copper salts, much attention is given to the unsymmetrical coupling of one acetylene unit with a bromoacetylene in the presence of Cu_2Cl_2, a technique discovered in 1957. The terse and well arranged presentation is supplemented by extensive tables, 232 references (unfortunately not in alphabetical order), and descriptions of practical preparations.

The literature has been reviewed up to 1961. Addenda indicate the rapid developments in these fields, but also the length of time that has elapsed between submission of the manuscripts and the appearance of the book. This is another successful volume of highest quality and appearance in this admirable series. *G. Opitz* [NB 375/233 IE]

The Ring Index. A List of Ring Systems Used in Organic Chemistry. A Publication of the Chemical Abstracts Service. American Chemical Society, Washington. Supplement I to the 2nd edit. (1957–1959): 1963, XV + 371 pp., linen $ 8.75. Supplement II (1960–1961): 1964, X + 515 pp., linen $ 10.–.

The Ring Index, which appeared in second edition in 1960, is now extended with two supplementary volumes, in which new ring systems described in the literature between January 1st, 1957 and December 31st, 1961 are recorded. As emphasized in the foreword, the two volumes make a claim to absolute completion, thanks to close cooperation with the indexing staff of the Chemical Abstracts Service, and thus not only give reliable information on the all-too-frequently intricate nomenclature, but also indicate whether a ring system is already known or not. Together with the basic volume, the work has thus now catalogued 11524 ring systems. It is therefore hardly necessary to point out its value. Supplement II contains the first index of rings with heteroelements (with the exception of rings having only N, O, and/or S in addition to carbon). It also contains the complete subject index for all three volumes, in which errata are also indicated.

Chemists have become accustomed to expect exceptionally high standards from the Chemical Abstracts Service, and the Ring Index completely fulfils these expectations.

H. Grünewald [NB 361/219 IE]

Techniques for the Use of Radioisotopes in Analysis. A Laboratory Manual. By *D. A. Lambie.* General and Industrial Chemistry Series. Edited by *H. M. Bunbury.* E. and F. N. Spon Ltd., London 1964. 1st edit. VI + 135 pp., numerous figs., linen £2.0.0 (about $ 5.50).

It is the aim of this book to acquaint its readers with the applications of radioactive materials in analytical chemistry and to give some indication of special practical procedures and measuring techniques. The author begins with descriptions of radiometric procedures. Here the accent lies on isotope dilution analysis, the use of radioactive reagents, and activation analysis, less attention being paid, for example, to Hevesy-Paneth analysis, which is so important in biochemistry, pharmacology, and agronomy.

By far the largest portion of the presentation is devoted to introductions to the methods and to the prerequisites for work with radioactive substances. It is emphasized that application of the methods given to solve problems in analytical chemistry demands no or only insignificant radiation precautions, and that thus radiometric work can be done in any well equipped laboratory without any great additional expenditure. It is commendable that data are given for the permissible concentrations and amounts of radioactive wastes that may be present in effluent in England.

It is to be hoped that the book will be read by many analysts, for they will certainly be thankful to the author for his fine presentation, which goes into all the essential points.

H. Götte [NB 363/221 IE]

Practical Optical Crystallography. By *N. H. Hartshorne* and *A. Stuart*. Edward Arnold Publishers Ltd., London 1964. 1st edit., VI + 326 pp., numerous illustrs., linen £2.0.0 (about $ 5.50).

The present volume offers a very comprehensive introduction to the application of crystal optics to the investigation of crystalline structures. Not only are experimental methods discussed, but the fundamentals of geometrical optics and crystallography are also dealt with. However, the treatment in some parts assumes dimensions that are no longer in keeping with the prime purpose of the book. For example, allocation of 30 pages to crystal morphology tends to overemphasize this topic. The same may be said of the presentation of structural theory, which is also rather subjective in nature. On the other hand, a section is lacking which goes into more detail on the relation between crystal optics and crystalline structure. The book does not place high demands on the background of its reader and should therefore serve students well as an introduction to the subject. All the important methods for examining crystals with the polarization microscope are presented, but U-table methods are omitted.

The book contains some elementary errors. For example, on pp. 37 and 98 it is stated that crystals with mirror planes cannot be optically active, but every textbook of crystal physics quotes m, mm 2, and $\bar{4}2$ m as crystal classes in this category which may possess optical activity. Recent publications on the treatment of the Becke line are overlooked; this phenomenon is now known to be an effect of diffraction optics rather than of geometric optics.

Apart from these flaws, the new book offers a most useful opportunity for becoming acquainted with the fundamentals of geometrical crystal optics. The theoretical fundamentals should be improved in a later edition.

H. Jagodzinski [NB 347/205 IE]

Surface Properties of Silicate Glasses. By *G. Korányi*. Akadémiai Kiadó, publisher for the Hungarian Academy of Sciences, Budapest 1963. 1st edit., 104 pp., 39 figs., linen DM 15.20 (about $ 3.90).

Almost simultaneously with *L. Holland*'s book on "The Properties of Glass Surfaces", this short monograph by the Hungarian author on the same topic has appeared. It can be appreciated just how much literature is available today on the physical and chemical properties of glass surfaces from the fact that apart from the numerous articles reviewed by both authors, there are many publications which are dealt with in only one or the other of the two books. In *Koranyi*'s work, these are mainly numerous contributions from the eastern hemisphere and about 200 patents, which indicate his preferential consideration of technological aspects. The presentation is terse, despite the abundance of the literature reviewed, but often the personal opinions and experiences of the author shine through. The content is divided up as follows. 1. Morphology of glass surfaces (as a result of mechanical or chemical processing); 2. surface hardness; 3. sorption properties compared with liquid, dissolved, and gaseous materials – coating of glass surfaces for technical improvement; 4. wetting properties and adhesion; 5. and 6. surface conductivity and interactions with electrons and ions; 7. dealkalization and leaching.

The book provides a good survey of the complete field for the practical worker and is also a useful vade-mecum for the specialist.

H. Schröder [NB 348/206 IE]

Spectrometric Identification of Organic Compounds. By *R. M. Silverstein* and *G. C. Bassler*. John Wiley & Sons, Inc., New York-London 1963. 1st edit., 177 pp., linen $ 8.60.

Mass spectrometry, proton magnetic resonance spectroscopy, and infrared and ultraviolet spectroscopy are invaluable aids in organic chemistry nowadays. Every chemistry student becomes acquainted with the fundamentals of these methods during his studies, but this is generally not enough. More exercises in the practical applications of these methods to chemical problems should be included in study courses than has hitherto been the case. A relatively easy way in which an important step in this direction can be taken is revealed in this book by *Silverstein* and *Bassler*, which provides an excellent guide to the interpretation of the spectra of organic compounds.

The book contains only the basic essentials of the theory and of the instrumental techniques of mass spectrometry, and infrared, ultraviolet, and proton magnetic resonance spectroscopy. However, adequately detailed data on the relationships between the spectra and molecular structure are given for each method, and the main stress is laid upon empirical facts and the information that is of use for practical application.

In the second part of the book, twenty examples are taken to illustrate with a detailed discussion how the mass, PMR, infrared, and ultraviolet spectra of various types of organic substances (containing the elements C, H, O, N, S, and halogens, with molecular weights of up to 250) can be used without elemental analysis and without any other chemical information to derive the structural formulae of the compounds in question. Naturally one cannot expect to obtain such definitive structural knowledge from the spectra of all compounds, but the examples demonstrate impressively just how much information can be derived from exhaustive interpretation of spectra alone – especially mass spectra. For ten further substances, only the spectra are given; their appraisal is left to the reader, who can however check his conclusions by consulting Beilstein's handbook, for references for the pertinent compounds are given. The last ten examples are given without such references. Anyone who works through these 40 examples with care, even if he does not perhaps find all the correct answers, will have learned something of great importance, namely, routine in dealing with spectra, and this, together with the information given in the first part of the book, will aid him immensely in the solution of other problems.

There are of course more complete, more systematic, and, as far as details are concerned, even more competent books on each of the methods dealt with here, even on their practical application in organic chemistry. However, the present volume is outstanding in that it is a book for learning and for practice which teaches with method and in a minimum of space how to combine all four techniques. This approach seems to be of great importance at a time when the trend towards specialization has brought about the situation where an expert on mass spectrometry, for instance, cannot be an authority on proton magnetic resonance. Only the mutual support of the individual methods increases their efficiency to the extent that affords the greatest value to the organic chemist interested in structural problems.

The Silverstein-Bassler monograph can be highly recommended to any student interested in these topics and above all, to lecturers and demonstrators for use in practical classes and seminars.

The Formula of Benzene

A Short History of the Problem

BY PROF. DR. H. HARTMANN

INSTITUT FÜR PHYSIKALISCHE CHEMIE DER UNIVERSITÄT FRANKFURT/MAIN (GERMANY)

In 1865, while he was Professor at Ghent, *August Kekulé* published two papers dealing with aromatic compounds [1]. In the second of these, the now familiar hexagonal symbol made its first appearance, although the lines indicating double bonds were omitted. These were first incorporated in a third paper [2] on aromatic compounds published in 1872.

In the earlier paper in the Annalen, *Kekulé* referred to the benzene molecule as a "closed chain" or a "symmetrical ring". His proof was based on the observation of isomerism. It is remarkable that the absence of the "extra" isomers, which would be expected if the double bonds were fixed, was not found to be disturbing. Although *Kekulé* emphasized that his benzene theory was based on the "atomicity of the elements", like a true theorist he regarded the concept of "atomicity" simply as a heuristic tool, and when the use of this tool had led him to the theory of the six-membered ring, he set about trying to find experimental proof of this theory. Pedantic objections arising only from the original hypothesis were brushed aside. The question of the extra isomers to be expected if the double bonds were fixed is discussed in detail only in the second paper in the Annalen (1872). The first paper in the Annalen dealt mainly with the problem of the equivalence of the six hydrogen atoms. *Kekulé* also showed himself to be a true theorist in another particular. Unlike his contemporaries, as well as too many of those who followed, he recognized a more comprehensive system into which chemical phenomena can be classified. He wrote: "Although we still lack a truly mechanical concept in chemistry, it nevertheless seems to me that a mechanical approach must and can, in our present state of knowledge, at least be sought." *Kekulé*'s benzene formula has since proved to be one of the most valuable contributions to organic chemistry. In one respect, however, it was and still is unsatisfactory: the relatively saturated, specifically aromatic character of benzene could not be explained in terms of *Kekulé*'s scheme.

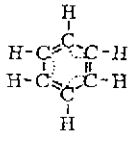
[1] *A. Kekulé*, Bull. Soc. chim. *1*, 98 (1865); Ann. Chem. Pharmac. *137*, 129 (1865).

[2] *A. Kekulé*, Ann. Chem. Pharmac. *162*, 77 (1872).

In order to explain the usual, but by no means universal, 1,4 mode of addition to butadiene, *J. Thiele* [3] developed the idea of residual or partial valences, which, under suitable environmental conditions, can be saturated in the same way as normal valences. Residual valences are pictured as arising when the second bond of a double bond does not exhaust the combining power of the atoms involved. According to *Thiele*, butadiene should be formulated as *(1)*. The application of the idea of

(1)

partial valences to the benzene molecule leads us to the formulation *(2)*. Thus *Thiele*'s benzene formula eliminates, or at least covers up, the most glaring deficiency



(2)

of *Kekulé*'s formulation.

With the advent of quantum mechanics, all the requirements for the application of *Kekulé*'s "mechanical approach" in chemistry were satisfied. *Heitler* and *London* [4] showed in 1927, for the example of the hydrogen molecule, that the puzzling phenomenon of covalence can be explained in mechanical terms. Since then "quantum chemistry" has developed in two forms. The object of absolute quantum chemistry is the physical treatment of real molecules. It is only in the simplest cases, however, which are today of little interest to chemists, that this treatment yields results which are at all reliable, since even the simplest atomic and molecular systems are so complicated that approximations have to be made in the calculations. A fundamentally different procedure is used in the quantum chemistry of models [5]. Models are invented to represent the molecules of a class of substances, and the models are then subjected to the quan-

[3] *J. Thiele*, Liebigs Ann. Chem. *306*, 87 (1899).

[4] *W. Heitler* and *F. London*, Z. Physik *44*, 455 (1927).

[5] *H. Hartmann*, S.-Ber. wiss. Ges. Univers. Frankfurt/Main *2*, 5 (1963).

tum-theoretical treatment. Since the models themselves do not occur in nature, they cannot be discovered, but invented models can be more or less useful.

E. Hückel's great contribution to the problem was that he found an eminently suitable model for benzene and related substances. *Hückel* divided the electron system of the molecule in question into so-called σ electrons and π electrons. In his quantum-theoretical treatment [6], he made use of two approximation methods known at that time. One method that proved particularly useful had been developed by *F. Hund* [7], and represents molecular orbitals (MO) by linear combinations of atomic orbitals (LCAO method). In the "second approximation method" used by *Hückel*, the interaction of the π-electrons with one another is represented by an equivalent field. Thus this theory, which is now known as the HMO theory after *Hückel*, has the particularly simple form of a "one-electron theory"; this means that it assumes the existence of molecular orbitals which are occupied (Aufbau principle) by the π electrons (in accordance with the Pauli principle).

The HMO theory comprises a topological part and an energy part. The word "topological" here means that this part of the theory is concerned only with concepts relating to environmental situations of the C atoms in the molecule. The energies ε_i assigned to the molecular orbitals (MO) denoted by the subscript i can be calculated from the so-called Hückel numbers ρ_i of the orbitals by means of the equation:

$$\varepsilon_i = f(\rho_i) \qquad (a)$$

using a function f which is characteristic of all π-electron systems. The Hückel numbers are the roots of the algebraic equation:

$$| t_{jk} + \rho \cdot \delta_{jk} | = 0 \qquad (b)$$

The left-hand side is a determinant in which the number of rows and columns is equal to the number of C atoms with π-electrons in the molecule. Suppose that these atoms are arbitrarily but permanently denoted by the numbers j and k.

Here $\delta_{jk} = 1$ when $j = k$; otherwise $\delta_{jk} = 0$. Furthermore, $t_{jk} = 0$ when $j = k$; $t_{jk} = 1$ when the j-th atom and the k-th atom are neighbors; when the j-th atom and the k-th atom are further apart, $t_{jk} = 0$.

Equation (b) for benzene becomes:

$$\begin{vmatrix} \rho & 1 & 0 & 0 & 0 & 1 \\ 1 & \rho & 1 & 0 & 0 & 1 \\ 0 & 1 & \rho & 1 & 0 & 0 \\ 0 & 0 & 1 & \rho & 1 & 0 \\ 0 & 0 & 0 & 1 & \rho & 1 \\ 1 & 0 & 0 & 0 & 1 & \rho \end{vmatrix} = 0$$

or after expansion of the determinant:

$$\rho^6 - 6\rho^4 + 9\rho^2 - 4 = 0 \qquad (c)$$

This equation has the roots

$$\rho_1 = 2 \qquad \rho_4 = -1$$
$$\rho_2 = 1 \qquad \rho_5 = -1 \qquad (d)$$
$$\rho_3 = 1 \qquad \rho_6 = -2$$

Thus according to Equation (a), orbitals 2 and 3 have equal energies, as do orbitals 4 and 5.

The characteristic function f was given by *Hückel* as:

$$\varepsilon = \alpha - \rho\beta \qquad (e)$$

where α and β are parameters having the dimensions of energies. Since $\beta > 0$, orbitals for which ρ is positive have low energies and *vice versa*. The graph of the Hückel characteristic function is a straight line with a negative gradient (Fig. 1).

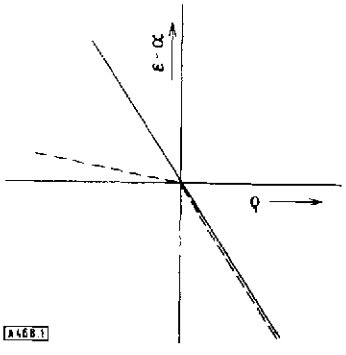


Fig. 1. Graph of the Hückel function $\varepsilon = \alpha - \rho\beta$. Full line: calculated. Broken curve: probable course on the basis of theoretical considerations [8].

The energy diagram of the molecular orbitals as found from Equations (c) and (d) is shown in Figure 2a. The distribution of the six π-electrons over the molecular orbitals in the ground state is also shown. Comparison of the diagram with the analogous diagram for *e.g.* the neon atom (Fig. 2b) reveals that the benzene molecule, like rare-gas atoms, has a "closed electron shell". This is therefore connected with the fact that the "breaking open" of the π-electron system to enable an addition reaction requires a high energy, and so provides an easy explanation of the aromatic character of benzene.

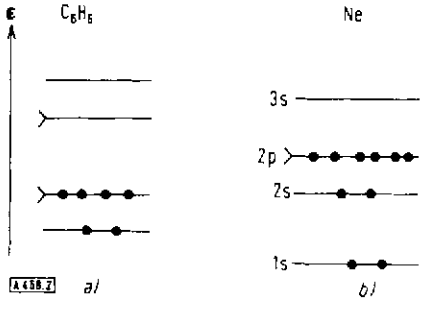

Fig. 2. Energies (ε) of the molecular orbitals (a) in benzene and (b) in the neon atom (diagrammatic).
The dots represent the electron distribution in the ground state.

Since the Hückel theory is made up of a topological part and an energy part, and since the important, *i.e.* qualitative, results of the theory are determined almost exclusively by the topological Hückel numbers ρ_i, the

[6] *E. Hückel*, Z. Physik *60*, 423 (1930); *70*, 204 (1931); *72*, 310 (1931); *76*, 628 (1932).

[7] *F. Hund*, Z. Physik *51*, 759 (1928); *63*, 719 (1929).

[8] *H. Hartmann*, Z. Naturforsch. *15a*, 993 (1960); *E. Ruch*, *ibid.* *16a*, 808 (1961); *H. Hartmann*, Adv. chem. Physics *5*, 1 (1963).

energy part of the theory, *i.e.* the characteristic function f, can be changed without essentially altering the results. Theoretical considerations suggest that f should follow the course shown by the broken curve in Figure 1 [8]. It is possible in this way to describe other observations, such as the Scheibe phenomenon [9], in terms of *Hückel*'s one-electron theory of the π-electron system.

The development of the benzene theory from *Kekulé* to *Hückel* is an inspiring chapter of chemical history. It is characterized by an intimate combination of experimental chemical ingenuity and a mechanical approach.

[9] *i.e.* the observation that the difference of the ionization potential and the first excitation energy is the same for many aromatic hydrocarbons.

1,2-Dehydrobenzene [*]

BY PROF. DR. G. WITTIG

ORGANISCH-CHEMISCHES INSTITUT DER UNIVERSITÄT HEIDELBERG (GERMANY)

The historical development of the methods to generate dehydrobenzene is outlined. Dehydrobenzene readily adds nucleophilic as well as electrophilic partners. Diels-Alder addition to dienes is moreover a valuable synthetic principle. The intermediacy of dehydrobenzene has been proved for polar additions by labeling with ^{14}C or with a substituent. The same conclusion has been reached in Diels-Alder additions by competition experiments. The considerable selectivity displayed by dehydrobenzene in both types of reaction is not caused by solvation, since recently the existence of dehydrobenzene in the gas phase has been established, where it reacts similarly as in solution.

I. Introduction

In the first volume of his textbook "Organische Chemie" [1], published in 1861, *August Kekulé* wrote: "Apart from the laws of constant and multiple proportions..., chemistry as it stands has established no laws with certainty. We have no precise knowledge regarding the cause of the difference among the elements, the nature of the force that gives rise to chemical compounds, the laws that govern chemical metamorphoses, *etc*... Thus we cannot yet speak in chemistry of a real *theory*. All so-called theoretical considerations are simply considerations of *probability* and *convenience*. Deduced from a large number of facts, and found to apply to others, they must be regarded for the present as expressions approaching fact, but not as established fact."

This conveys the impression that chemistry 100 years ago was like a building site on which were piled roughhewn stones, which the as yet absent architect was to fit together. *Kekulé* was the master builder who, with the structural theory which he expounded in the same book, laid down the objective of "seeking a point of view which fits the largest number of facts with a minimum of difficulty, which represents the chemical processes as simply and as completely as possible, and which, while perhaps not explaining these processes, at least gives a reasonably clear picture of them."

The structural theory first molded by *Kekulé* from the principle of economy of thought, and which a few years later encompassed the structure of benzene, contributed decisively to the rapid development of organic chemistry. Of equal importance in inorganic chemistry is *Alfred Werner*'s theory of coordination compounds, which brought together a bewildering profusion of experimental observations and placed them on a common and at that time bold conceptual basis. Both concepts have condensed from the original speculative stage to well-knit theories, which although subsequently refined and extended, could not be refuted, and which, as we see today, have together helped to open up the common field of organic and inorganic chemistry.

It is not my intention to trace the effects of the benzene structure conceived by *Kekulé* in 1865 on the development of the chemistry of aromatic compounds. We shall consider only one branch of this tree of development, relating to a derivative of benzene, formally obtained by removal of two *ortho* hydrogen atoms from the aromatic ring, and which I accordingly call dehydrobenzene. The justification for speaking about this compound here at the Kekulé Celebration is that the six-membered aromatic ring remains intact in the new type of compound; moreover, this intermediate which, unlike benzene, cannot be isolated, has in the past few decades given fresh impetus to aromatic chemistry and to the investigation of short-lived intermediates which can be detected only by indirect evidence.

[*] From a lecture at the Kekulé Celebration in Bonn on September 15th, 1965.

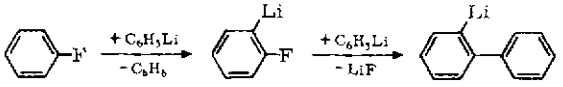
II. History of the Discovery of Dehydrobenzene

A C_6H_4 species as an intermediate in certain aromatic reactions has repeatedly been suggested [2], but the idea was neither substantiated nor pursued further. The first attempt to classify a large body of experimental facts relating to organometallic reactions by the postulated intermediate formation of dehydrobenzene was made at Freiburg [3] in 1940.

The surprisingly fast formation of biphenyl from phenyllithium and fluorobenzene, compared to the reactions with the other three halogenobenzenes, was explained by assuming that, owing to the strong inductive effect of the fluorine substituent, the *ortho* hydrogen is particularly readily displaced by the lithium atom, and the *o*-fluorolithiobenzene *(1)* reacts with the phenyl-lithium still present.



(1) *(2)*

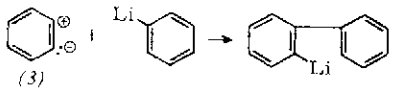
The expected *o*-lithiobiphenyl *(2)* was detected as 9,9-diphenylfluorene by reaction with benzophenone to form the corresponding carbinol, followed by ring closure. Since it was shown that biphenyl does not form a lithium compound under the conditions of the reaction, the rapid formation of biphenyl from fluorobenzene and phenyl-lithium was apparently explained.

It was still puzzling, however, why the fluorine attached to the aromatic nucleus becomes so reactive after the replacement of an *ortho* proton by a lithium cation. The key to the problem was provided by our further discovery [4] that olefinic halides such as ω-chlorostyrene are readily converted into acetylene derivatives by organolithium compounds. This process was interpreted as resulting from the introduction of metal into the β-position, followed by the elimination of lithium halide:

$$C_6H_5\text{-}CH{=}CH\text{-}Cl + 2\ C_6H_5Li \rightarrow C_6H_5\text{-}C{\equiv}C\text{-}Li + 2\ C_6H_6 + LiCl$$

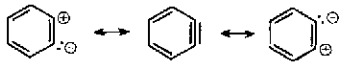
In applying the substitution-elimination mechanism to aromatic halides, it was postulated [5] that the formation of a halogenobenzene anion leads to the elimination of the fluoride ion, and that the intermediate dehydrobenzene *(3)*, in its dipolar form, combines with the nucleophilic phenyl-lithium to form the observed *o*-lithiobiphenyl *(2)*.

This explanation agreed with the fact that it was not possible to detect *o*-lithiohalogenobenzene at that time, *e.g.* as its adduct with benzophenone [*].



(3) *(2)*

The resonance of dehydrobenzene (which favors the elimination of metal halide, owing to the associated decrease in energy) should, according to this interpretation, lead to equivalence of the dehydrogenated ring atoms, so that nucleophilic addition should lead to the formation of isomers. However, we found no experimental support for this conclusion [6]. Although we did find clear indications of the existence of the



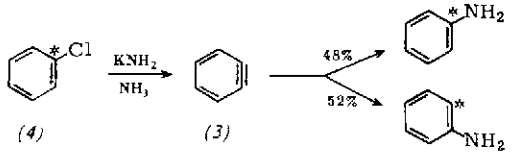
(3)

short-lived, electrophilic dehydrobenzene, which were supplemented by the results of reactions between halogenobenzenes and phenyl-lithium in the presence of tertiary amines (to be discussed later), we had no proof.

III. Evidence of the Occurrence of Short-Lived Dehydroaromatic Compounds

a) Dehydrobenzene in Solution

The first convincing arguments for the occurrence of dehydrobenzene arose from work carried out by *Roberts* and co-workers in Pasadena [7], who independently demonstrated the equalization effect in 1953. In the reaction of [1-^{14}C]-chlorobenzene *(4)* with potassium amide in liquid ammonia, they obtained both of the expected labelled anilines in approximately 50 % yields.



(4) *(3)*

The name "aryne" proposed by *Roberts et al.* for their postulated intermediate seems unfortunate, since this term specifies the presence of a normal C–C triple bond [cyclohexadienyne *(3)*], against which, however, on the basis of *Kekulé*'s benzene structure, one could with equal justification propose a triply cumulated system of double bonds [cyclohexatetraene *(5)*].

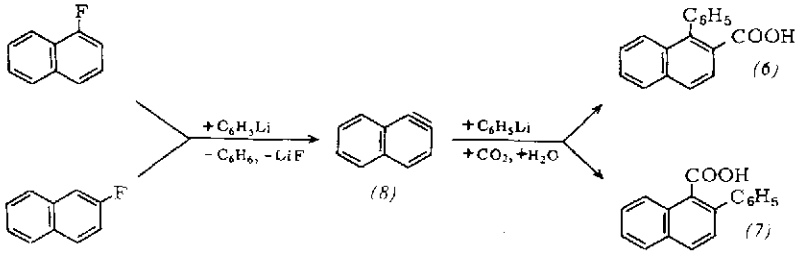
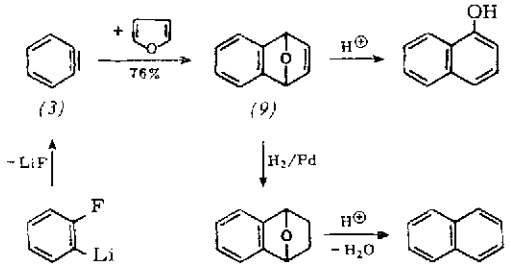
In 1954, *Huisgen* and *Rist* [8] in Tübingen reported an investigation in which they had treated 1- and 2-fluoronaphthalenes with phenyl-lithium; after carboxylating the reaction mixture, they obtained 1-phenyl-2-naphthoic acid *(6)* together with the isomeric 2-phenyl-1-naphthoic acid *(7)*.

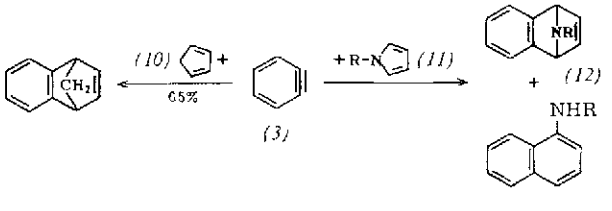


This discovery supplemented *Roberts*' results, since it shows that this reaction also proceeds *via* a short-lived intermediate, namely 1,2-dehydronaphthalene *(8)*.

Wittig and *Pohmer* [9] argued on an entirely different basis, contending that dehydrobenzene should react as a dienophile. They treated *o*-bromofluorobenzene with lithium amalgam in furan, which as an ether should promote organometallic reactions, and as a diene should intercept the dehydrobenzene formed *in situ* by a Diels-Alder reaction. The product isolated was the endoxide *(9)*, the structure of which was confirmed *inter alia* by acid-catalysed isomerization to α-naphthol, hydrogenation and subsequent dehydration to naphthalene.



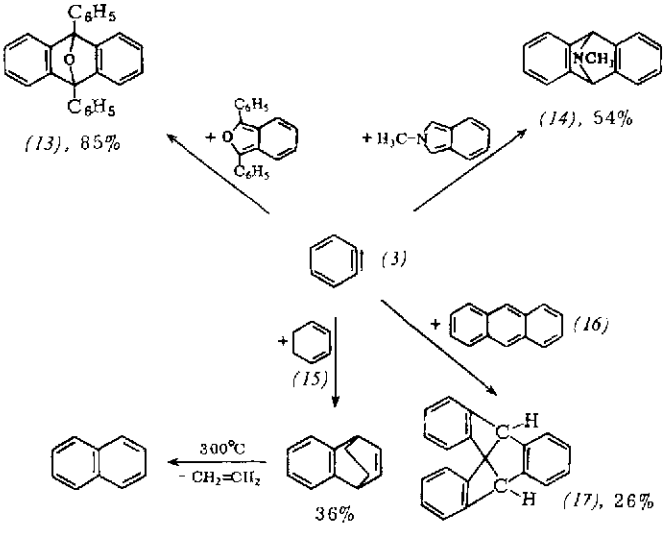
Similar diene additions to dehydrobenzene have also been observed in the presence of pyrrole derivatives *(11)* [10] and cyclopentadiene *(10)* [11].



During the reaction, the unstable endamine derivatives *(12)* are largely converted into the isomeric naphthylamines and to carbazoles.

Dehydrobenzene, generally produced from *o*-bromofluorobenzene and magnesium in boiling tetrahydrofuran, has been used in the synthesis of new heterocyclic systems, such as *(13)* and *(14)* [12]:

In analogy with the Diels-Alder reaction of dehydrobenzene with cyclohexadiene *(15)* [13], anthracene *(16)* has been converted in the same way into triptycene *(17)* [14].



A variant of the formation of dehydrobenzene from fluorobenzene and phenyl-lithium has proved advantageous in this case. The concentration of the phenyl-lithium is buffered to a very low value by the reversible formation of the ate complex with pentaphenylantimony, so that the addition of phenyl-lithium to dehydrobenzene no longer competes with

$$\mathrm{Li\,[Sb(C_6H_5)_6]} \rightleftharpoons (\mathrm{C_6H_5})_5\mathrm{Sb} + \mathrm{C_6H_5Li}$$

the addition of anthracene, and triptycene is formed in 26 % yield [15].

Cycloadditions of this type were later used as a test for the occurrence of short-lived dehydroaromatics in the course of reactions. New routes to dehydrobenzene not involving organometallic compounds were thus found. A significant example is the thermolysis of benzenediazonium *o*-carboxylate *(18)* investigated by

[8] *R. Huisgen* and *H. Rist*, Naturwissenschaften *41*, 358 (1954); Liebigs Ann. Chem. *594*, 137 (1955).

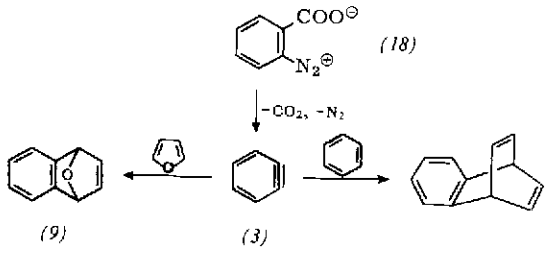
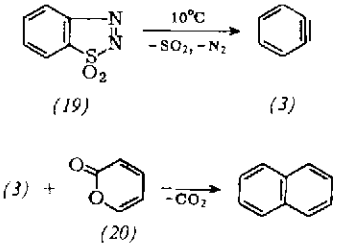
Stiles and *Miller* [16], which in boiling furan leads to the endoxide *(9)*. The high dienophilic activity of dehydrobenzene, which is even capable of adding on benzene [17], is manifested in this reaction.



(18) *(9)* *(3)*

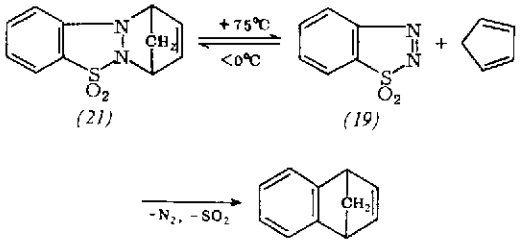
A related procedure is that developed by *Wittig* and *Hoffmann* [18] for the generation of dehydrobenzene from benzothiadiazole dioxide, which exists as the heterocyclic system *(19)*, and not as a betaine. Dehydrobenzene reacts with the lactone *(20)* to form naphthalene with the elimination of CO_2.



(19) *(3)* *(20)*

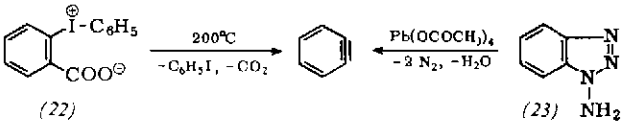
With the aid of the compound *(19)* and its derivatives, which already decompose at room temperature, it is possible to study the behavior of dehydroaromatics under mild conditions, as will be discussed later.

At temperatures below 0 °C, *(19)* reacts with cyclopentadiene to form the adduct *(21)*, which can be isolated, and which dissociates into its components at 75 °C by a retrodiene reaction. The resulting dehydrobenzene is captured by the cyclopentadiene as 1,4-dihydro-1,4-methanonaphthalene.



(21) *(19)*

Temperatures up to 200 °C are required for the formation of dehydrobenzene from the iodonium compound *(22)* [19], whereas room temperature suffices in the oxidation of *N*-aminobenzotriazole *(23)* with lead tetraacetate in benzene [20,21]. The addition of 1,2,3,4-tetraphenyl-1,3-cyclopentadienone to dehydrobenzene leads to the elimination of CO and formation of 1,2,3,4-tetraphenylnaphthalene.

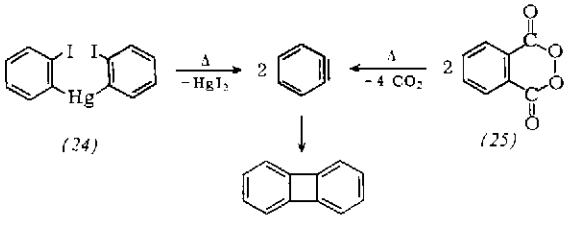


(22) *(23)*

Huisgen and *Knorr* [22] also used cycloadditions to prove the intermediate formation of dehydrobenzene. These authors treated dehydrobenzene, formed from *o*-bromofluorobenzene and magnesium in tetrahydrofuran, simultaneously with furan and cyclohexadiene, and found the competition constant of the simultaneous Diels-Alder additions to be $K \approx 20$. Since this agreed closely with the competition constants obtained for the liberation of dehydrobenzene from benzenediazonium *o*-carboxylate *(18)* and from benzothiadiazole dioxide under comparable conditions, it follows that the same intermediate, *i.e.* dehydrobenzene, reacts in all the above examples.

b) Dehydrobenzene in the Gaseous State

Experiments carried out by *Wittig* and *Ebel* [23], in which biphenylene was formed by the decomposition of bis-*o*-iodophenylmercury *(24)* or of phthaloyl peroxide *(25)* under reduced pressure of argon at 600 °C, show that dehydrobenzene without a solvation sheath, *i.e.* in the gaseous state, also exists for short periods.



(24) *(25)*

When furan was passed in behind the decomposition zone, α-naphthol resulted from the further reaction of the initially formed 1,4-dihydro-1,4-oxidonaphthalene *(9)*. *Ebel* and *Hoffmann* [24] determined a maximum lifetime of 20 msec for dehydrobenzene under these conditions.

By a combination of flash photolysis and mass spectrometry, *Berry et al.* [25] found that the decomposition of benzenediazonium *o*-carboxylate *(18)* yields only dehydrobenzene (m/e = 76), N_2 (28), and CO_2 (44). The peak at m/e = 76 reaches a maximum when the ultraviolet spectrum contains a broad absorption at 2430 Å, which is assigned to dehydrobenzene. This gives way to the spectrum of biphenylene, which is observed in the mass spectrum at m/e = 152.

IV. Structural Problems

Whereas the structure of the C_6H_4 fragments produced from 1,3- and 1,4-benzenediazonium carboxylates is not yet known [26], all the evidence available indicates

(3b) *(3a)* *(3c)*

that the bonding in 1,2-dehydrobenzene is probably described by the resonance *(3b)* ↔ *(3a)* ↔ *(3c)* [27].

With retention of the aromatic 6 π-electron system, the sp^2 orbitals freed by removal of two *ortho* substituents, which are coplanar with the benzene ring, will overlap as indicated in *(3a)*. The energy gained facilitates the elimination of metal halide from *o*-lithiohalogenobenzene to form dehydrobenzene. Owing to the ring strain in dehydrobenzene, however, the overlap can only be slight in comparison with the overlap in acyclic acetylenes, explaining the enhanced dienophile reactivity of the dehydro bond.

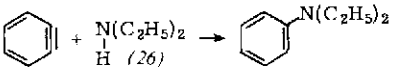
The relative weakness of the dehydro bond, however, also explains its susceptibility to attack by nucleophiles such as phenyl-lithium, which intercepts dehydrobenzene as *o*-lithiobiphenyl, as described earlier. The polarizability of the dehydro bond makes possible a rearrangement to the dipolar limiting form *(3a)* or *(3b)* in the transition state by approaching reactants [28].

V. Dehydroaromatic Compounds as Electrophiles and Nucleophiles

The pronounced electrophilic character of dehydroaromatic compounds has been confirmed in numerous investigations, of which some examples will now be given.

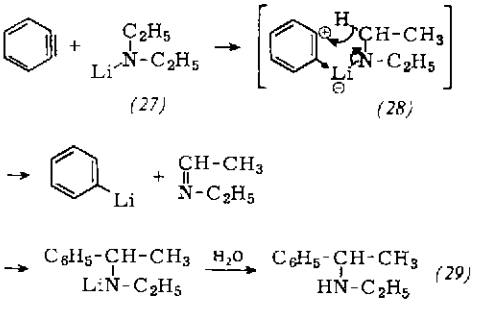
Lithium piperidide or phenyl-lithium add smoothly to dehydrobenzene to form *N*-phenylpiperidine or biphenyl, as was found by *Huisgen et al.* [29]. These authors concluded from the competitive addition of *e.g.* lithium piperidide and phenyl-lithium that the selective intermediate for which these nucleophiles are competing is short-lived "benz-yne."

The complexity of these reactions can be seen *inter alia* from work carried out by *Wittig*, *Schmidt*, and *Renner* [30], who found that the reactions of fluorobenzene with lithium diethylamide and with diethylamine *(26)* give widely varying yields of diethylaniline and α-phenyldiethylamine, depending on the molar ratio of the reactants. It was shown that the free amine probably takes part in the formation of diethylaniline, while



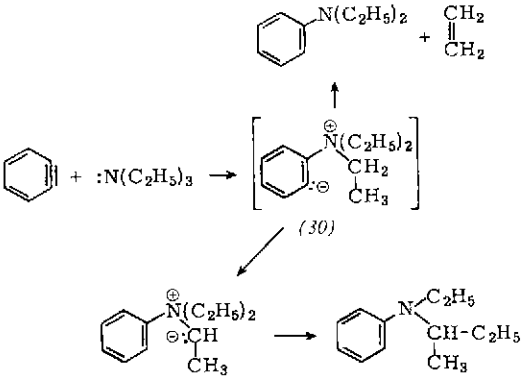
(26)

lithium diethylamide *(27)* probably reacts *via* the ate complex *(28)* by a redox reaction to form ethylidin ethylamine and phenyl-lithium, which then react further to form the isomeric α-phenyldiethylamine *(29)*.



(27) *(28)* *(29)*

Dehydrobenzene liberated from fluorobenzene and phenyl-lithium also suffers nucleophilic attack by tertiary amines, as shown below for triethylamine [31].



(30)

The betaine intermediate *(30)* is discharged to form diethylaniline and ethylene, and undergoes a Stevens rearrangement to *N*-ethyl-*N*-(1-methylprop-1-yl)aniline.

The nucleophilic reactivity of nitrogen bases towards dehydroaromatic compounds makes possible preparations based on intramolecular ring closure. For example, cyclic amines with large rings, such as *(31)* and *(32)*, have been synthesized in this way [29].

[26] *R. S. Berry, J. Clardy*, and *M. E. Schafer*, Tetrahedron Letters *1965*, 1001, 1011.

[27] Cf. *R. Huisgen* and *J. Sauer*, Angew. Chem. *72*, 107 (1960).

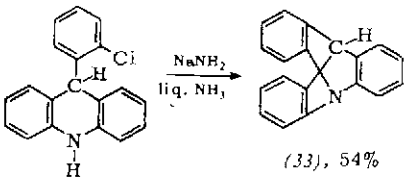
[28] It would be of interest in this connection to study the reactivity of the dehydro bonds in the unstrained bisdehydroannulene; cf. *F. Sondheimer, Y. Gaoni, L. M. Jackman, N. A. Bailey*, and *R. Masoni*, J. Amer. chem. Soc. *84*, 274 (1962); *86*, 521 (1964).

[29] Reviews: *R. Huisgen* and *J. Sauer*, Angew. Chem. *72*, 91 (1960); *R. Huisgen*: Theoretical Organic Chemistry. Butterworths, London 1959, p. 158 *et seq.*; *R. Huisgen* in *H. Zeiss*: Organometallic Chemistry. Reinhold, New York 1960, p. 78.

[30] *G. Wittig, H.J. Schmidt*, and *H. Renner*, Chem. Ber. *95*, 2377 (1962).

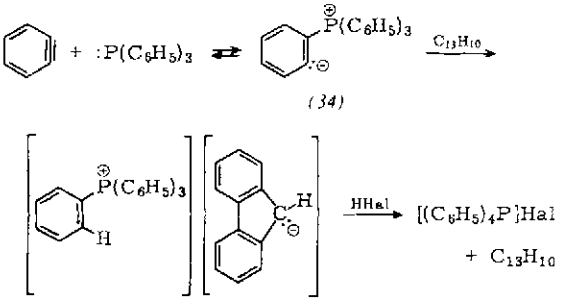
[31] *G. Wittig* and *E. Benz*, Chem. Ber. *92*, 1999 (1959).

The theoretically interesting, strongly basic azatriptycene *(33)* has also been made available by the same method of ring closure [32].



(33), 54%

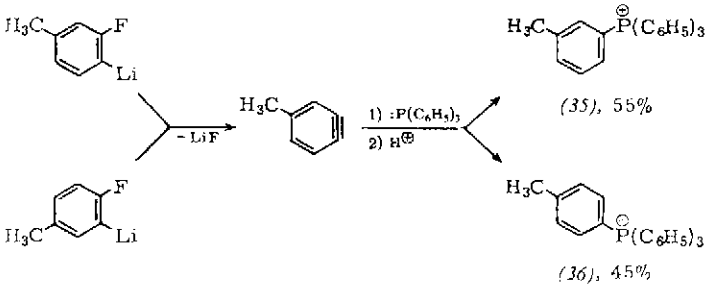
A clear case of a nucleophilic addition to dehydrobenzene is the reaction with triphenylphosphine. The *o*-lithiofluorobenzene prepared by *Gilman* and *Gorsich* [33] reacts with triphenylphosphine in the presence of fluorene ($C_{13}H_{10}$) only above −70 °C, where the elimination of metal halide begins [34].



(34)

The resulting tetraphenylphosphonium halide, which was isolated in good yield, is formed from the betaine adduct *(34)* with the aid of the proton-donating fluorene, the anion of which colors the solution deep red.

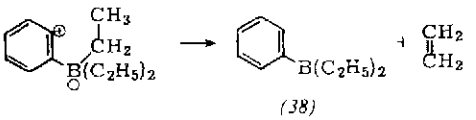
It can be shown that the first step of this quaternization of aromatic phosphines, which is generally applicable under mild conditions, does not involve the direct nucleophilic displacement of the fluoride ion by the tertiary phosphine, since the reaction of fluorotoluene under the same conditions always yields the same mixture of isomeric triphenyltoluylphosphonium salts *(35)* and *(36)*, irrespective of the position of the methyl group in the aromatic ring.



(35), 55%

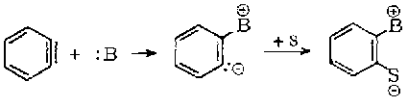
(36), 45%

In the presence of triphenylboron, the phosphonium betaine *(34)* which is initially formed from triphenylphosphine and dehydrobenzene is stabilized by formation of the isolable betaine *(37)*; this is a further indication that the reaction proceeds *via* dehydrobenzene [31]. That the latter can also act as a nucleophile is shown by its behavior towards triethylboron, which is converted into diethylphenylboron *(38)* [31].

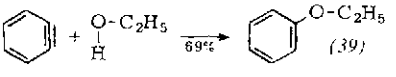


(38)

The fact that reactions of dehydrobenzene with triphenylphosphine yield the phosphonium betaine *(34)* as the initial product confirms the high polarizability of the dehydro bond in the vicinity of nucleophilic reagents. However, the addition of diethylamine to dehydrobenzene shows that the process (shown below) leading by a further step to the end product does not always prevail, but that additions which circumvent charged intermediates are also possible. Synchronous



additions of this type have been observed, *e.g.* in the decomposition of benzothiadiazole dioxide *(19)* in ethanol, which leads to good yields of phenetole *(39)* [18].



(39)

From the postulate that the sp^2 orbitals of the dehydro bond spread out in the plane of the benzene nucleus (*i.e.* perpendicular to the 6 π-electron system), it follows that the direction of addition to unsymmetrically substituted dehydroaromatics is largely determined by the inductive effect of the remaining substituent [35].

This is confirmed by the addition of ethanol to 3,4-dehydrotoluene (which is formed from 5- and 6-methylbenzenethiadiazole dioxides), which again gives the same mixture of *m*- and *p*-methylphenetoles (62 % and 38 % respectively), irrespective of the starting material used.

Conversely, owing to the different electron-density distribution, the addition of ethanol to 3,4-dehydronitrobenzene yields a mixture of nitrophenetoles in which the *p*-isomer predominates (75 %) [36] [*].

Hoffmann investigated this synchronous addition of ethanol on a wider basis [37], and concluded that the relationship between the isomer ratio and the inductive effect of the substituent can be expressed by a Hammett relationship (involving σ').

Only a little phenetole is formed if benzothiadiazole dioxide is decomposed in ethanol containing lithium

[*] *G. Wittig* and *H. F. Bertorello* obtained the same isomer ratio of 75% *p*- and 25% *m*-ethoxydiphenyl sulfone from the addition of ethanol to 3,4-dehydrodiphenyl sulfone.

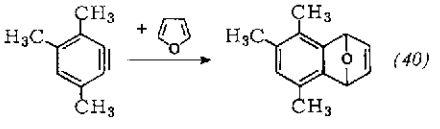
[37] *R. W. Hoffmann*, *G. E. Vargas-Núñez*, *G. Guhn*, and *W. Sieber*, Chem. Ber., in press.

halide. In this case the two-step addition evidently predominates, since the main product is halogenobenzene, the yield of this product increasing with the nucleophilic strength of the halide ion. This is shown particularly impressively by the formation of dehydrobenzene in ethanol containing equimolar quantities of chloride, bromide, and iodide ions, as can be seen from Table 1 [38].

Table 1. Decomposition of 5 mmole of benzothiadiazole dioxide *(19)* in ethanol in the presence of foreign substances.

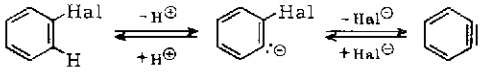
Foreign substance	Product	Yield [%]	Competition constant
50 mmole LiCl	Chlorobenzene	0.7	1
50 mmole LiBr	Bromobenzene	5.4	8
50 mmole LiI	Iodobenzene	46	65
850 mmole C_2H_5OH	Phenetole	0.4	—

The results show the surprisingly high selectivity of dehydrobenzene, from which it can he concluded to have an appreciable life-time. A relatively long life of dehydroaromatic compounds may also be responsible for the reaction of *o*-bromofluoropseudocumene with butyl-lithium in furan to give an 81 % yield of the endoxide *(40)*, whereas only 76 % of the unsubstituted



(40)

endoxide is obtained from *o*-bromofluorobenzene [39]. Furthermore, the fact that halide ions add to dehydrobenzene to form halogenobenzene shows that the elimination of lithium halide from *o*-lithiohalogenobenzene must be described by two [7, 29] reversible steps:



I *(41)* I'

Hoffmann [40] showed that the intermediate *(41)* between the halogenobenzene and dehydrobenzene can be reached directly by the base-catalysed fragmentation of ethyl 2-halogenobenzeneazocarboxylate *(42)*.

[40] *R. W. Hoffmann*, Chem. Ber. *98*, 222 (1965); cf. also the pyrolysis of metal salts of 2-halogenobenzoic acid: *G. Köbrich*, Chem. Ber. *92*, 2985 (1959); *96*, 2544 (1963); Liebigs Ann. Chem. *664*, 88 (1963).

From the constants of the competing protonation (Ia) and dehalogenation (IIa) of the 2-halogenophenyl anion *(41)*, and the relative rates of addition of halides to dehydrobenzene, *Hoffmann* was able to estimate the relative equilibrium constants for the reactions (II). The equilibrium favors dehydrobenzene most in the case of the bromide [40, 41].

VI. The Industrial Importance of Research on Dehydrobenzene and Closing Remarks

The influence of research on dehydrobenzene on chemical technology is of interest here, inasmuch as dehydroaromatic compounds also play a part in industrial processes. Thus in the alkaline hydrolysis of chlorobenzene to phenol, *Lüttringhaus* and *Ambros* [42] found by-products such as *o*- and *p*-hydroxybiphenyl, which are also formed by the action of phenylsodium on diphenyl ether [43]. In studies carried out by *Bottini* and *Roberts* [44] on the alkaline hydrolysis of [1-^{14}C]-chlorobenzene, the distribution of the hydroxyl groups in the products showed that the reaction proceeds *via* the short-lived intermediate dehydrobenzene.

The same conclusion is indicated *inter alia* by the predominance of resorcinol in the products of the alkali fusion of *m*- and *p*-halogenobenzenesulfonates [45]. *Kekulé*, who discovered this method of preparing phenols in 1864 [46], even then expressed doubt regarding the retention of structure during this operation.

The answer to the question of whether through consistent application of *Kekulé*'s structural theory, dehydrobenzene might have been discovered earlier, is probably negative, since although the vocabulary of the new language was there, the grammar had not yet developed to a sufficient degree. On this point, I shall close with *Kekulé*'s words on the 25th anniversary of the benzene theory [47]: "We all stand on the shoulders of our predecessors; is it surprising, therefore, that we have a wider view than they?"

Valence-Bond Isomers of Aromatic Systems

BY PROF. DR. E. E. VAN TAMELEN

DEPARTMENT OF CHEMISTRY, STANFORD UNIVERSITY, STANFORD, CALIFORNIA, U.S.A.

The prefix $\varkappa^n$ is proposed for the classification of valence-bond isomers of aromatic systems, where n is the change in the number of rings or in the number of π-bonds on isomerization. Representatives of the $\varkappa^1$-series are Dewar benzene and 9,10-dihydronaphthalene. Benzvalene and prismane belong to the $\varkappa^2$ and $\varkappa^3$ series, respectively. Various derivatives of such valence-bond isomers have recently become known.

I. Introduction

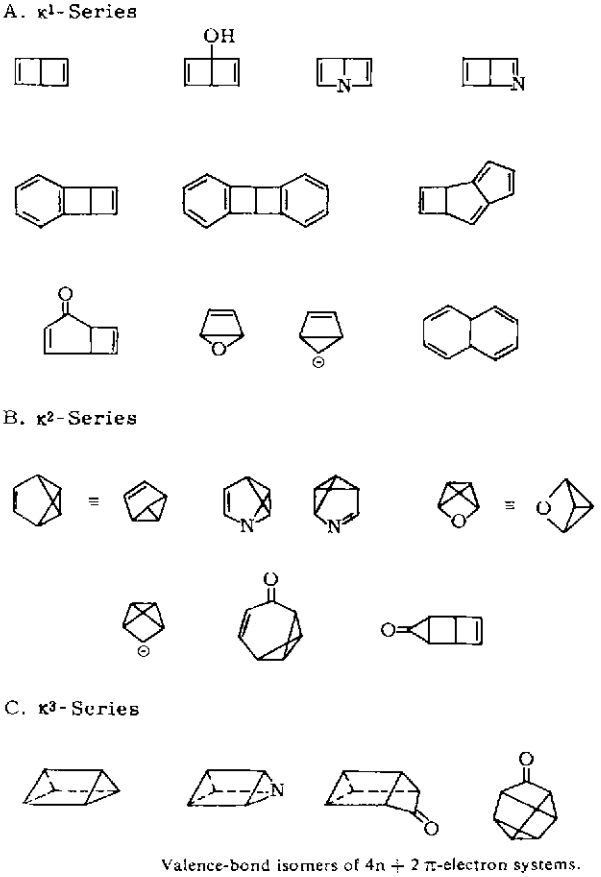
Approximately one hundred years ago, when the structural theory of organic chemistry was in its infancy, the founding fathers were concerned especially with benzene and its derivatives. During the nineteenth century, various non-Kekulé representations *(1)*–*(5)*

(1) *(2)* *(3)* *(4)* *(5)*

originated, most of which have little significance in terms of modern theory of aromatic compounds and remain only as epitaphs in present-day descriptions. However, the so-called "Dewar benzene" structure *(1)* (named after *Sir James Dewar*, who recorded it as a less desirable alternative to the Kekulé proposal [1]) has lived on as a minor contributor to the resonance hybrid emerging from the valence bond description of the benzene ring [2]. In addition, it has long been recognized that structures *(1)* and *(2)* have physical meaning as non-planar forms, and should be capable of independent existence as "valence-bond isomers" of benzene. Despite this obvious but sound theoretical basis, for many years organic chemists did not seriously consider the capture of such isomers, but by and large suspected that they would be too unstable for normal laboratory handling. Only recently have valence-bond isomers of traditional aromatic molecules been synthesized, identified, and shown to be substances of reasonable stability.

II. Classification and Nomenclature

Many types of valence bond isomers of aromatic $(4n + 2)$ π-electron systems can be imagined, and the number of individual possibilities is limitless; thus a system of classification is desirable. Of the several possible means for systematizing structures, some are ambiguous or arbitrary. For example, since π-electrons are implicit in aromatic structures, definition of valence-bond isomers thereof by reference to the number of such electrons in the non-aromatic isomer (*e.g.* "Dewar benzene" would be in the 4n π-electron group) could be considered. However, many aromatic systems incorporate, as an integral part of the aromatic bonding, electron pairs on heteroatoms which in the non-aromatic partner would be non-bonding (*e.g.* "Dewar furan"); thus, in the same "series" the number of π-electrons can vary (*i.e.* "Dewar benzene" has 4 π-electrons; "Dewar furan" has 2 π-electrons). Clearly, the common denominator for the valence-bond isomer types is the difference in the number of rings, π-electrons, or formal single bonds. We suggest the prefix $\varkappa^n$ (n = change in the number of rings, or in the number of π-bonds) [3]



Valence-bond isomers of 4n + 2 π-electron systems.

[3] Gr. κύκλος = ring or circle.

as a means for classifying members of valence-bond isomer systems according to their order. Examples are given below [4].

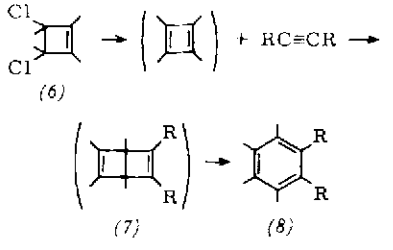
Aromatic members are obviously $\varkappa^{-n}$ valence bond isomers of their non-aromatic counterparts. Here we shall consider mainly the $\varkappa^1$ category, since (with one exception) [5] members of the $\varkappa^2$ and $\varkappa^3$ group have so far not been isolated.

III. $\varkappa^1$-Valence-Bond Isomers of 6 π-Electron Aromatic Systems

A. Bicyclo[2.2.0]hexa-2,5-dienes ("Dewar benzenes")

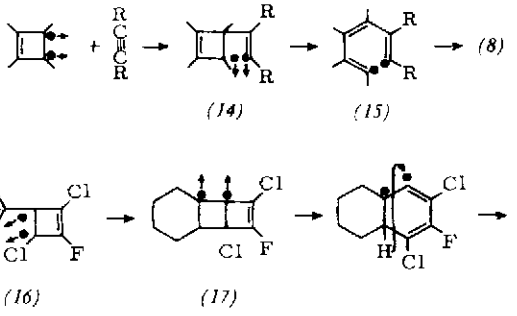
i. Dewar Benzenes as Intermediates

During the early 1960's there were invoked on occasion $\varkappa^1$-valence bond isomers of aromatic systems as unstable intermediates in certain unusual transformations. For example, 3,4-dichloro-1,2,3,4-tetramethylcyclobutene *(6)*, on treatment with metallic zinc in the presence of 2-butyne or diethyl acetylenedicarboxylate, affords the benzene derivative *(8)*, supposedly *via* the unstable non-planar Dewar benzene *(7)* [6].



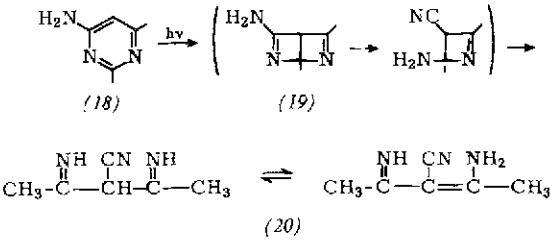
Similarly, triethylamine-induced elimination of hydrogen fluoride from the cyclohexenylcyclobutene *(9)* leads to formation of the tetralin derivative *(13)*, for which reaction the intermediates *(10)–(12)* were proposed [7].

In each of these cases, the "Dewar benzene" is assumed to be generated from a cyclobutadiene. The latter would presumably exist and react as a triplet in the ground state so that the ground state (singlet) "Dewar benzene" could not form directly. After reaction with the cyclobutadiene is initiated, time may be available for other processes to occur, *e.g. (14)* → *(15)*; *(16)* → *(17)*; and thus, for these changes, a Dewar benzene intermediate

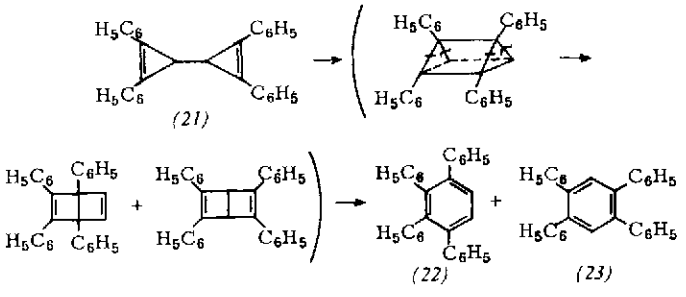


is not obligatory. Alternatively, a triplet state Dewar benzene may be involved, which, being of higher energy, may proceed ultimately to observed aromatic product without traversing the ground state Dewar benzene route.

In the heterocyclic series, the novel formation of 2-amino-3-cyano-pent-2-ene-4-imine *(20)* from 2,6-dimethyl-4-aminopyrimidine *(18)* may be initiated by photo-induced formation of a "Dewar pyrimidine" *(19)* [8].



Finally, *Breslow* [9] has suggested that the isomerization of the tetraphenylbicyclopropenyl *(21)* to the tetraphenylbenzenes *(22)* and *(23)* involves transient Dewar benzene intermediates, in addition to prismane.



In all these cases, the idea of a Dewar structure is interpretative or conjectural – neither was the Dewar-type molecule isolated, nor was additional evidence adduced for its intermediacy.

[4] Inclusion of a given example carries no implication as to lifetime or isolability.

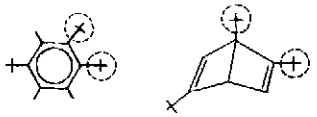
2. Synthesis and Properties of Bicyclo[2.2.0]hexa-2,5-dienes

In 1960, at which time the synthesis of a "Dewar benzene" was being seriously considered in the author's laboratory, it was not possible to predict the stability of a member of this unknown class. Efforts therefore were made to secure one of the more stable representatives imaginable; concurrently, one promising route to the parent bicyclo[2.2.0]hexa-2,5-diene was initiated.

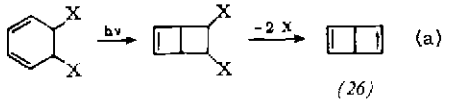
Preparation of a stable Dewar benzene was achieved by irradiation of 1,2,4-tri-t-butylbenzene *(24)*. In selecting this case for study we reasoned that the high degree of steric interference between the bulky 1,2-t-butyl groups would have a stabilizing effect on the non-planar Dewar form *(25)*, in which the two large substituents are farther separated in space relative to the



(24) *(25)*

benzenoid isomer. Ultraviolet radiation proved to be a suitable energy source for the required type of change. The product, 1,2,5-tri-t-butylbicyclo[2.2.0]hexa-2,5-diene *(25)*, structural assignment to which depends on spectral and other considerations, was found to be stable at room temperature and to be converted (incompletely) to starting 1,2,4-tri-t-butyl benzene on being heated to 200 °C for 15 minutes. These results [10], reported in 1962, established for the first time the existence of a non-planar Dewar benzene, and taken together with the synthesis of the parent compound, opened up a new and viable field of research.

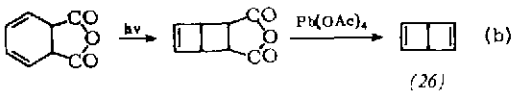
By 1963, several years of persistent effort in our laboratory were rewarded with the preparation and identification of the second known Dewar benzene, the parent compound, C_6H_6 *(26)* [11]. The synthesis route selected for this goal is expressed in general terms as (a) below.



(a)

(26)

Among the factors which were considered to be of prime importance, two should be mentioned here. First, because of over-all geometrical as well as stereoelectronic (see below) considerations, existence of a preformed cyclobutene moiety in the last intermediate was regarded as highly desirable, in that this structural feature would offer some insurance against formation of ordinary benzene in the last step. Second, this final step should be carried out under the mildest possible conditions with respect to temperature, pH, and nature of the reagent. The reaction we used is shown as (b) below.

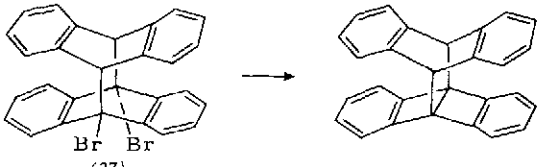


(b)

(26)

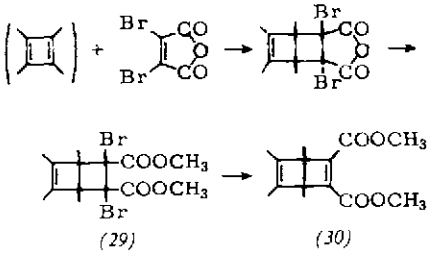
Parent Dewar benzene *(26)* can be chromatographed in the vapor phase and can he stored for several months in pyridine solution below 0 °C. At room temperature in pyridine, its half-life is about two days; at 90 °C, conversion to benzene is very rapid and complete. The bicyclohexadiene exhibits two NMR signals, one at 3.45 τ (triplet) and the other at 6.16 τ (quintuplet) (pyridine solution, 60 Mc/sec), in the ratio of 2:1. Diimine reduction [11a] gives bicyclo[2.2.0]hexane.

In the following year, four additional Dewar benzenes were reported from other laboratories. *Applequist* and *Searle* [12] described the dehalogenation of the anthracene dimer *(27)*, the product of which was assigned structure *(28)*. This anthracene derivative should be regarded



(27) *(28)*

as a "formal" non-planar Dewar benzene, in that the intrinsic properties of the distinguishing moiety are obscured by 1) incorporation of the unsaturated edges in *bona fide* benzene rings, and 2) the geometrical impossibility of its conversion to a normal benzene derivative. *Criegee* and *Zanker* [13], using a modification of reaction (a), reported that zinc-copper dehalogenation of the ester *(29)* derived from the tetramethylcyclobutadiene/dibromomaleic anhydride adduct leads to tetramethyl-"Dewar phthalic acid" dimethyl ester *(30)*,



(29) *(30)*

a stable solid (m.p. 32–33 °C) which quantitatively generates dimethyl tetramethylphthalate at 130 °C. The presumed stability of this Dewar benzene under the conditions used by *Cookson* et al. [6] in their attempted route to the same product implies that the substance was not involved in their system. *Arnett* and *Bollinger* described in the latter part of 1964 [14] an interesting variant (see Section 3 below) of the original 1,2,4-tri-t-butylbenzene irradiation, namely the photo-induced

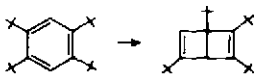
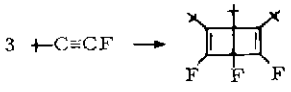
conversion of 1,2,4,5-tetra-t-butylbenzene *(31)* to Dewar-1,2,3,5-tetra-t-butylbenzene *(32)*. Finally, *Viehe*



(31) *(32)*

and co-workers recently reported the startling trimerization of t-butylfluoroacetylene, in which process a Dewar benzene *(33)* and a $\varkappa^2$-isomer ("benzvalene") are formed in addition to the true benzenoid trimer [5].



(33)

The "Dewar pyridine" reported [15a] to be formed by photolysis of 2-amino-5-chloropyridine has been shown [15b] to be a normal dimer.

Because the preparation and isolation of non-planar Dewar benzenes has met with surprise [16] and even skepticism [17], it may be in order to comment briefly on various factors relating to the system's stability. Two thermodynamic factors, namely the strain of Dewar benzene and the resonance stability of normal benzene, reinforce each other and make for a considerable difference in ground state energies between the two structures. Morphologically, the difference between benzene and the bicyclohexadiene is so small that entropy factors should not present any great barrier to isomerization. If no other factor were at play, the energy path to normal benzene would be largely downhill. What property, then, is responsible for the stability of Dewar benzene? The answer must be given in terms of bond rehybridization, including the stereoelectronic factors at work in the thermally induced ring opening of a cyclobutene to a 1,3-diene [20–22]. In the absence of unusual restraints, *cis* and *trans*-3,4-disubstituted cyclobutenes, on being heated, exhibit clean stereochemical behavior [18,19], each giving rise to one diene geometrical isomer: *(34)* → *(35)*; *(36)* → *(37)*.

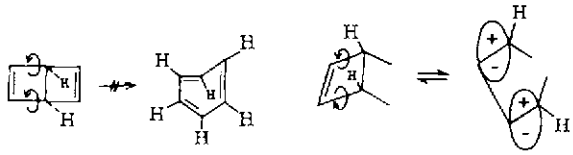
In the case of *cis*-bicyclo[2.2.0]hexa-2,5-diene *(38)*, this preferred (conrotative) mode of stereoisomerization cannot operate, since an extraordinarily strained *cis,cis*,

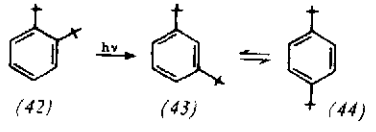


(38) *(39)* *(40)* *(41)*

trans-cyclohexa-1,3,5-diene *(39)* would result. In the stereoelectronically less preferred (disrotative) course of ring opening, molecular orbital symmetry [*(40)* → *(41)*] [20–22] preference defers to stability of the 6 π-electron product, but the transition state energy is raised and Dewar benzene enjoys comparative stabilization.

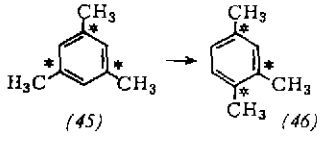
3. Excited Valence-Bond Isomers of Benzenes

After identifying tri-t-butyl Dewar benzene, we examined the ultraviolet irradiation of the simpler *o*-di-t-butyl benzene *(42)* [23]. In that case, no Dewar benzene product could be isolated. Instead, *m*- and *p*-di-t-butylbenzene *(43)* and *(44)* were formed, and it was readily



(42) *(43)* *(44)*

established that there existed a photochemical equilibrium between these two isomers, with a component ratio of 58 *p*: 42 *m* [24]. In 1964, *Wilzbach* and *Kaplan* [25] described photo-induced isomerizations among *o-m-p* isomers in even simpler alkyl systems. In neither laboratory were "cross-alkylations" detected; thus, isomerization by way of migrating free alkyl radicals was considered less likely than some type of annular isomerization [23]. The latter possibility was confirmed recently [26] with the demonstration that during the



(45) *(46)*

isomerization of [1,3,5-$^{14}C_3$]mesitylene *(45)* to 1,2,4-trimethylbenzene *(46)*, methyl substituents remained attached to labelled ring carbons. These results can be taken to indicate isomerization through a prismane *(47)*, a benzvalene *(48)*, or a set of equivalent equilibrating Dewar benzenes *(49a)–(49c)*, any of which

[23] *K. Kirk*, Ph. D. Thesis, University of Wisconsin, 1963.

[24] After learning about our prior results (personal communication), *A. W. Burgstahler* and *P.-L. Chien* published independently their confirmatory observations: J. Amer. chem. Soc. *86*, 2940 (1964).

[25] *K. E. Wilzbach* and *L. Kaplan*, J. Amer. chem. Soc. *86*, 2307 (1964).

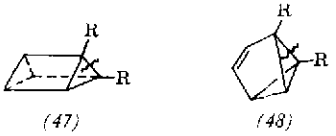
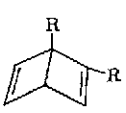
valence-bond isomer types could permit the series of bond-making and -breaking processes required for overall alkyl isomerization. In view of the apparent

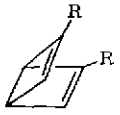


(47)

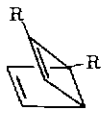
(48)



(49a)

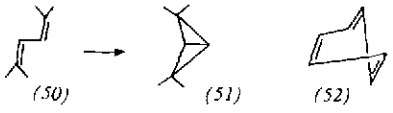


(49b)



(49c)

dependence of photo-induced 1,3-diene → bicyclobutane isomerizations on the ground state conformation of starting material *(50)* [27,28], photochemical formation of a benzvalene *(48)* seems less likely – the



(50) (51) (52)

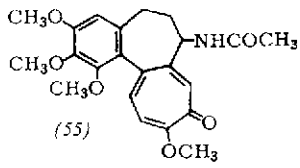
required ground state conformation *(52)*, a severely racked "benzene" ring, would be unavailable. *o*-Di-t-butylbenzenes are probably not planar, *(53)*, but warped, *(54)* [29], and thereby suffer from lessened π-orbital overlap. Conditions are proper, therefore, for easy conversion to an excited state "aromatic" having the same

(53) (54)

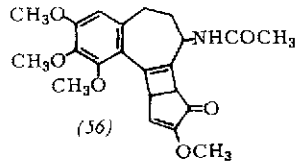
geometry as *(54)*, which intermediate can then readily rehybridize, with attendant minor geometrical changes, to a Dewar benzene system, presumably either in an excited electronic state or merely vibrationally excited. Ultimately, there is released ground state Dewar benzene. The latter cannot – as shown above – undergo the stereoelectronically preferred thermal conrotatory [21] isomerization to parent aromatic, and cannot absorb to any great measure the ultraviolet radiation used for its production; therefore it survives. Clearly, ring closure of an excited Dewar benzene to a prismane remains a possibility deserving consideration.

B. Other π^1-Valence-Bond Isomers of 6 π-Electron System

In 1955, on the basis of extensive chemical studies, *Forbes* [30] proposed the correct structure *(56)* for the monomeric lumicolchicines, obtained years earlier by illumination of the natural product *(55)*. This structural assignment was amply confirmed by subsequent investigators [31,32], who determined the stereochemistry

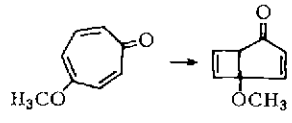


(55)

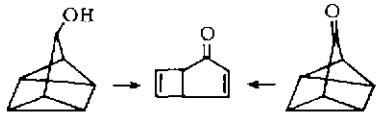


(56)

as well. Photochemistry of simpler tropone derivatives has also been pursued, including, for example, isomerization of γ-tropolone methyl ether *(57)* to the bicyclic ketone *(58)* [33]. In 1965, the parent bicycloheptadienone *(60)* was reported, which arises either from *(59)* under Oppenauer oxidation conditions, or from *(61)* by the action of alumina [34]. All of these substances – valence-bond isomers of the $(4n + 2)$ π-electron

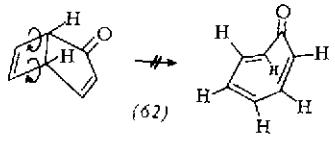


(57) (58)



(59) (60) (61)

aromatic type, tropone – are remarkably stable, temperatures in the vicinity of 350 °C being used for conversion to the monocyclic parent. As in previous cases discussed herein, their stability is explicable by inhibition *(62)* of the normally stereoelectronically preferred conrotatory conversion to *trans-cis*-1,3-diene.



(62)

In a similar situation, *N*-methylpyridone and α-pyrone, when irradiated in solvent by ultraviolet light, form the relatively stable valence isomers *(63)* and *(64)* [35].

IV. χ^1-Valence-Bond Isomers of 10 π-Electron Aromatic Systems

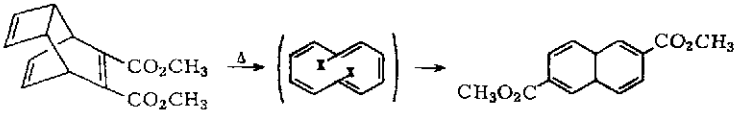
A. 9,10-Dihydronaphthalenes

1. Early Observations

In 1956 *Prelog* referred to the structural relation between two substances unknown at that time, cyclodecapentaene *(65)* and 9,10-dihydronaphthalene *(66)* [36,37]. Some-

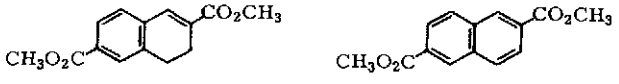
(65) *(66)*

what later, *Nenitzescu* et al. [38] claimed the isolation of the dicarbomethoxy-9,10-dihydronaphthalene *(69)*,



(67) *(68)*, X = CO_2CH_3 *(69)*

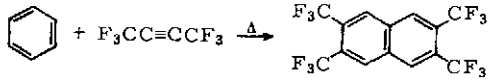
presumed to arise *via* the isomeric cyclodecapentaene *(68)* during the pyrolysis of the cyclooctatetraene-dimethyl acetylenedicarboxylate adduct *(67)*. Later investigations [39,40] revealed, however, that the substance isolated by *Nenitzescu* et al. was actually dimethyl 3,4-dihydronaphthalene-2,6-dicarboxylate *(70)*. Whether this material or a companion product, dimethyl naph-



(70) *(71)*

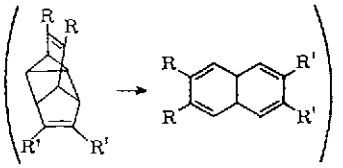
thalene-2,6-dicarboxylate *(71)*, is formed through a route involving a 9,10-dihydronaphthalene or a cyclodecapentaene, remains unanswered.

In order to explain the formation of 2,3,6,7-tetrakis(trifluoromethyl)naphthalene *(72)* by interaction of hexafluorobut-2-yne and benzene, *Krespan*, *McKusick*, and *Cairns* [41] suggested a mechanism featuring ring-opening of a hexafluorobutyne-bis(trifluoromethyl)-



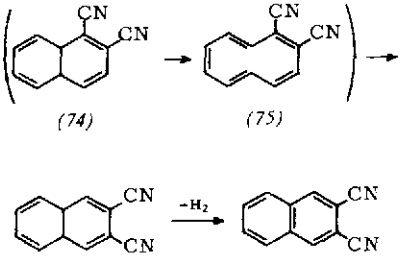
(72)

barrelene adduct *(73)*, R=R'=CF_3) to a 9,10-dihydronaphthalene (both unisolated) followed by dehydrogenation to the observed product. *Zimmermann* and *Grunewald* [42] subsequently reported that barrelene and



(73)

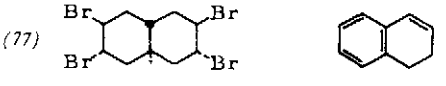
either dimethyl acetylenedicarboxylate or dicyanoacetylene at lower temperatures yield a well-defined adduct *(73)*, R=H; R'= $-COOCH_3$ or $-CN$, which on further pyrolysis gives rise to 1,2-dicyano- or 1,2-dicarbomethoxynaphthalene. These results suggested a "reverse Diels-Alder" reaction of *(73)* to give a 9,10-dihydronaphthalene, an unisolated progenitor of the observed product. The fact that a small amount of 2,3-dicyanonaphthalene results from these rearrangements is in keeping with the conversion of *(74)* to cyclodecapentaene *(75)*, followed by valence-bond isomerization to 2,3-dicyano-9,10-dihydronaphthalene *(76)*.



(74) *(75)*

(76)

Mention may also be made here of early attempts [43] in the author's laboratory to dehydrohalogenate the tetrabromo-*trans* decalin *(77)* to *trans*-9,10-dihydronaphthalene, which elimination, however, led to the



(77)

known 1,2-dihydronaphthalene. In this process, as in those referred to earlier in this section, no 9,10-dihydronaphthalene was isolated; no supporting evidence for its role in this, and in the other overall changes, is available.

2. Synthesis and Properties of 9,10-Dihydronaphthalenes

In addition to the *Nenitzescu* dihydronaphthalene, another substance assigned to the 9,10-dihydronaphthalene category was reinvestigated a few years ago. During the 1930's, *Diels* and *Alder* published several papers [44] on the 1:2 adducts, usually a pair of "labile"

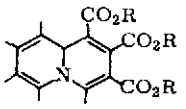
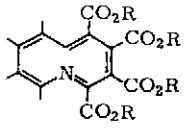
and "stable" isomers, secured when a pyridine is treated with acetylenedicarboxylic ester. Although the zwitterionic structure originally proposed for the former type is unacceptable, the constitution *(78)* preferred by *Diels* and *Alder* for the "stable" system is a reasonable



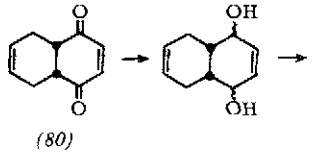
(78)



(79)

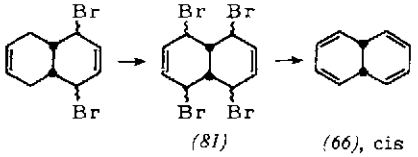
construction. The possibility that either of the adducts is the planar azacyclodecapentaene *(79)*, a valence-bond isomer of *(78)*, was considered early by us and induced further structural investigations. Detailed spectral -- especially NMR -- analysis of various members of the "labile" class revealed that the representation *(78)* in fact expresses the nature of this type whereas the "stable" isomers possess another structure, arising from *(78)* by proton shift [45]. As far as can be determined, the "labile" pyridine-acetylenedicarboxylic ester adducts are the first authenticated 9,10-dihydro(aza)-naphthalene derivatives. The finding that the quinolizine *(78)* molecule apparently is energetically preferred to the 10 π-electron valence-bond isomer *(79)* was significant, all the more so because it foreshadowed the results of experiments with the parent 9,10-dihydronaphthalene system.

In 1963 we synthesized and identified 9,10-dihydronaphthalene [46]. Starting from the available quinone-butadiene adduct *(80)* the route involved the inter-



(80)

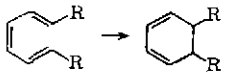
(c)



(81) *(66)*, cis

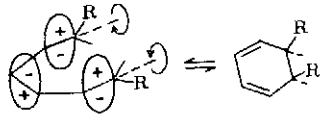
mediates shown in sequence (c). Lithium-amalgam dehalogenation of the tetrabromide *(81)* led to a hydrocarbon, which chemical and spectral studies showed to be the *cis*-9,10-dihydronaphthalene *(66)*. Neither heat nor light converted this bicyclic hydrocarbon to the monocyclic valence-bond isomer *(65)*. In the range 150–200 °C, only naphthalene was formed; ultraviolet irradiation produced unknown material which exhibited only end absorption in that region of the spectrum.

The tendency of 1,6-disubstituted 1,3,5-trienes *(82)* to thermally induced, stereospecific ring closures to 1,2-disubstituted cyclohexa-3,5-dienes *(83)* has been established [47] and rationalized in terms of favorable



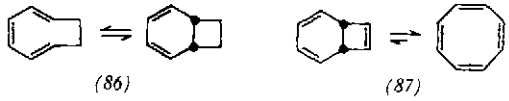
(82) *(83)*

symmetry properties of the highest occupied molecular orbital of the triene system *(84)*; the reverse reaction



(84) *(85)*

is considered to be subject to similar control [21, 22]. These generalizations are in keeping with the readily induced equilibration between the partners in the classical Cope valence isomerization *(86)* [48], and the more recently observed rapid conversion of triene *(87)* to cyclooctatetraene [49].



(86) *(87)*

Of importance in this discussion is 1) the stereoelectronically preferred conversion of triene of geometry *(84)* to *cis*- rather than *trans*-1,2-disubstituted-3,5-cyclohexadiene *(85)*, and 2) the geometrical course of the reverse process. Thus the *cis*-, but not the *trans*-, 9,10-dihydronaphthalene should afford all-*cis* or di-*trans* cyclodecapentaene, if similar considerations apply, and the activation energy for conversion of the less stable to the more stable isomer should be relatively low in the *cis* series. It is reasonable to conclude, then, that maintenance of the *cis*-9,10-dihydronaphthalene structure reflects the lower thermodynamic stability of cyclodecapentaene. It appears thus that the unsubstituted 10 π-electron system is indeed severely destabilized by 1,6-

(88)

hydrogen interactions *(88)*, as suggested by *Mislow* [50] and remains still unknown.

More recently *Vogel* [51] described the diester *(89)* and its behavior when it is heated. At 90 °C a mixture of

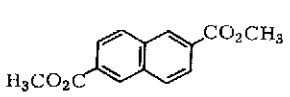
[49] *E. Vogel, H. Kiefer*, and *W. R. Roth*, Angew. Chem. *76*, 432 (1964); Angew. Chem. internat. Edit. *3*, 442 (1964).

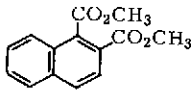
[50] *K. Mislow*, J. chem. Physics *20*, 1489 (1952).

[51] *E. Vogel, W. Meckel*, and *W. Grimme*, Angew. Chem. *76*, 786 (1964); Angew. Chem. internat. Edit. *3*, 643 (1964).

isomeric 9,10-dihydronaphthalenedicarboxylic esters results; at 150 °C, dehydrogenation occurs, and naphthalenedicarboxylic esters *(90)*, *(91)*, and *(92)* are formed. It seems likely that the 1,5- and 2,6-diesters arise



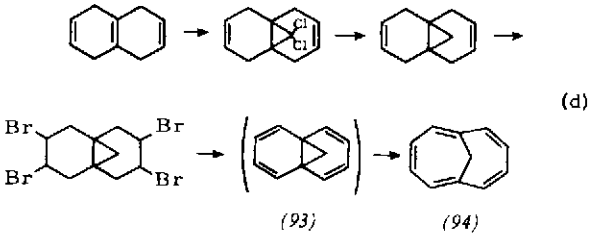
(91)



(92)

by isomerization, *via* the transient cyclodecapentaene, of starting material to 1,5- and 2,6-dihydronaphthalene diesters, followed by aromatization [52]. Thus, insofar as *simple* monocyclic cyclodecapentaenes are concerned, certain facts suggest their momentary appearance as intermediates during various reaction sequences; however, they seem to be unstable relative to the valence isomeric 9,10-dihydronaphthalene.

This situation changes when certain steric constraints are imposed on the 10-membered ring. *Vogel* and *Roth* [53] showed that the cyclodecapentaene nucleus is stabilized if a methylene group is used to bridge the 1,6-carbons in the ring, thereby removing the "overlapping" 1,6-hydrogens. The synthesis of 1,6-methanocyclodecapentaene *(94)* involves the series of reactions (d), and proceeds to final product by way of the 9,10-dihydro-



(d)

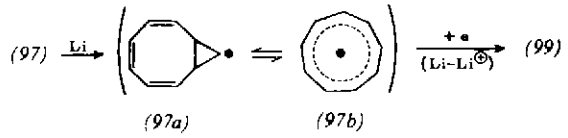
(93) *(94)*

naphthalene intermediate *(93)*. By similar means, the systems bridged with oxygen *(95)* and nitrogen *(96)* were later secured [54, 55]. Chemical and spectral

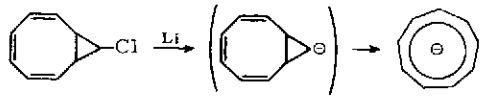
(95)  *(96)* 
properties of the methylene-bridged molecule suggest that it indeed possesses aromatic character [56].

B. The Bicyclo[6.1.0]nonatrienyl and Cyclononatetraenyl Anions

In their preparation of the aromatic cyclononatetraenyl anion *(99)*, both *Katz* and *Garratt* [57] as well as *LaLancette* and *Benson* [58] developed a pathway from the bicyclo[6.1.0]nonatriene system.



(97a) *(97b)*

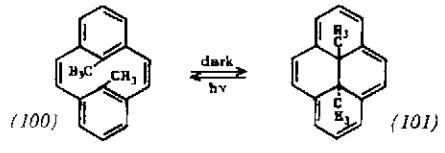


(97) *(98)* *(99)*

Lithium metal was used to abstract halogen from the cyclopropyl chloride *(97)*; assuming a 2-electron exchange without valence isomerization, this process leads to the bicyclo[6.1.0]-nonatrienyl anion *(98)*, a valence-bond isomer of the more stable 10 π-electron configuration [59].

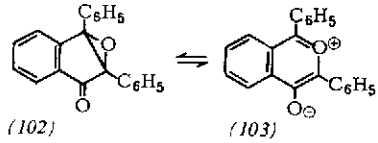
V. Miscellaneous

Several additional, intriguing valence isomerizations involving aromatic rings have appeared in the literature of the 1960's. *Heilbronner*, *Boekelheide*, and co-workers [60] have described the interconversion of metacyclo-



(100) *(101)*

phane *(100)* and dimethyl dihydropyrene *(101)*. In an earlier study, *Ullman* and *Milks* [61] demonstrated the equilibrium between benzopyrylium oxide *(103)* and



(102) *(103)*

indenone oxide *(102)*, the former constituent being responsible for the thermochromic properties of the system.

Valence-Bond Isomers of Substituted Benzenes [*]

BY DR. H. G. VIEHE

UNION CARBIDE EUROPEAN RESEARCH ASSOCIATES, BRUSSELS (BELGIUM)

Dewar benzene, Ladenburg benzene (prismane), and a combination of these bond systems (benzvalene) have variously been discussed as planar limiting structures of benzene, although they have no physical reality. If, however, we regard these systems as non-planar structures (as did their originators), they become chemical individuals, derivatives of which have recently been isolated. In addition to being a valence-bond isomer of benzene, benzvalene is also the first member of a still largely hypothetical series of molecules (the valenes), in which the skeleton atoms can change places with their neighbors to produce the valence-bond isomers. The best-known representative of this class is bullvalene.

Introduction

Kekulé at first wrote the formula of benzene in the now unfamiliar notation that he used for paraffin chains *(1)* [1]. This first formulation *(2)* [2] was intended to be illustrative, but not structural or, as *Kekulé* expressed it, constitutional. Soon afterwards he used the now well-known formula *(3)*. Only a few years later he was confronted with the counterproposals *(4)–(7)* of his contemporaries, which were in part also regarded as structural.

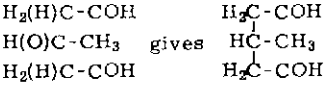
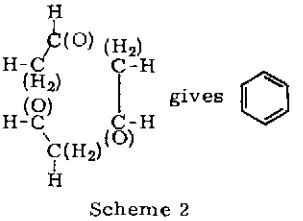
[6] *A. Ladenburg*, Ber. dtsch. chem. Ges. *2*, 140 (1869); *5*, 322 (1872).

In 1872 *Kekulé* examined these proposals [8]. He ruled out formulae *(4)* and *(6)* on the grounds of the equivalence of the six H atoms. The "saturated" structures *(5)* and *(7)* could not, in his opinion, be reconciled with the ability of benzene to add on bromine. The possibility of a combination of systems *(6)* and *(7)* to give a formula *(8)* was mentioned, but was thought to be unlikely for reasons of symmetry.

When *Ladenburg* insisted on his prismatic formula [6], offering as his argument the formation of benzene by non-planar condensation of acetylene, *Kekulé* replied that planar trimerization of acetylene could equally be imagined Nevertheless, he tried to reach a decision by experiment. By analogy with the known condensation of acetone to mesitylene (trimethylbenzene), he tried to prepare benzene by the stepwise condensation of acetaldehyde. He reasoned that if this reaction gave branched-chain intermediates (Scheme 1), then *Ladenburg*'s prismatic structure would be more likely than the planar triene structure, which could only be formed in accordance with Scheme 2 [9a].



Scheme 1



Scheme 2

[7] *E. Hückel* has discussed this system as a planar form: Z. Elektrochem. *45*, 752, 760 (1937). In 1964 we isolated a derivative of tricyclohexane which we named benzvalene [25]. *E. E. van Tamelen* and *S. P. Pappas* [14] discussed a similar structure for a product of photo-isomerization of 1,2,4-t-butylbenzene, which however has a Dewar structure. Cf. also [34] and *E. E. van Tamelen*, Angew. Chem. *77*, 759 (1965); Angew. Chem. internat. Edit. *4*, 738 (1965).

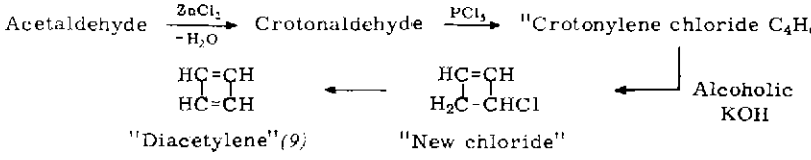
[8] *A. Kekulé*, Liebigs Ann. Chem. *162*, 77 (1872).

[9] a) [8] p. 91; b) [8] p. 98.

The fact that *Kekulé* could not make much progress beyond the unstable crotonaldehyde, formed from two molecules of acetaldehyde, is not surprising. Moreover, since he then attacked the even now unsolved problem of cyclobutadiene [he called it "diacetylene" *(9)*], his experimental failure deserves at least our respectful historical interest [9b].

"Treatment of crotonaldehyde with phosphorus perchloride yields ... crotonylene chloride ... When crotonylene chloride is brought into contact with alcoholic caustic potash, potassium chloride ... precipitates. It seemed likely that hydrochloric acid had been eliminated to form the chloride C_4H_5Cl, and I even hoped to be able to obtain the much-sought diacetylene by the further removal of hydrochloric acid."

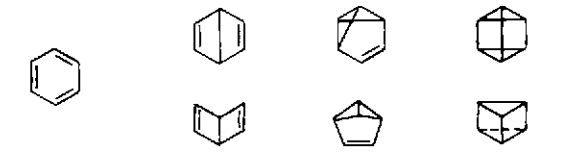
"Unfortunately, I have not yet succeeded in doing this. My experiments indicate very strongly that the reaction of at least part of the crotonaldehyde proceeds in this



direction, but although I used more than a pound of crotonaldehyde for these experiments, I have been unable to obtain either the chloride C_4H_5Cl or diacetylene in the pure form."

We now know from physical measurements that the benzene molecule has a planar symmetrical structure [10]. *Kekulé*'s cyclohexatriene formula is the notation most commonly used, although, as *Kekulé* himself recognized [8], it does not fully satisfy these conditions. According to current concepts, the benzene molecule cannot be completely described by a single Kekulé formula. The ground state can according to the "valence bond" treatment [11] be described to a first approximation by the linear combination of two cyclohextriene structures. A better approximation is obtained if three planar Dewar structures are introduced. In these mathematical discussions, the Ladenburg and benzvalene structures are neglected for the description of the benzene ground state [11]. It is important to remember, however, that the structures proposed by *Kekulé (3)*, *Dewar (6)*, and *Ladenburg (7)*, as well as benzvalene, are only conceived as planar systems without physical reality as isolable entities.

If, on the other hand, the valence-bond isomeric [12] formulae are regarded in the sense of their authors, *i.e.* as being non-planar, they become individual compounds, whose isomerism is due only to the different arrangements of their valences (Scheme 3).



Scheme 3. The valence isomers of benzene

Valence-Bond Isomers of Benzene

Owing to the resonance-stabilization of the planar "Kekulé benzene" and the steric strain in the three non-planar valence isomers of benzene, these should have relatively unfavorable energies and should isomerize more or less readily to the planar benzene. Up to three years ago, despite repeated experiment and discussion, no valence isomers of benzene had been isolated. In 1962, however, *Van Tamelen* used a particularly suitable benzene derivative, namely 1,2,4-tri-t-butylbenzene (which had been prepared by *Hoogzand* and *Hübel* [13]) for photo-isomerization to the Dewar benzene derivative [14]. A year later, the same author carried out an elegant synthesis of Dewar benzene itself, again *via* a bicyclohexene derivative of photochemical origin [15]. Finally, two further syntheses of Dewar structures have recently been achieved, one by *Criegee* et al. [16], apparently by the interception of a "cyclobutadiene" derivative, and the other by *Arnett* et al. [17] by the photoisomerization of 1,2,4,5-tetra-t-butylbenzene.

We entered the field of the valence isomers of benzene from an entirely different point. We had for some years been interested in heterosubstituted acetylenes [18], since owing to the electronic interactions of the triple bond and the heterosubstituents, the linear bond system *(10)* of these compounds is particularly suited to the study of substitution on unsaturated C atoms, without interference (as occurs in alkenes and aromatic com-

pounds) by short-range effects among the substituents *(11)* [19].

(10) *(11)*

The same is true of additions, and particularly cycloadditions. In linear heterosubstituted acetylenes, the electronic influence of a single hetero-atom decides the direction and rate of the addition. A precise knowledge of this theoretically simple class of compounds is therefore desirable, even though their high reactivity causes considerable experimental difficulties.

Of the particularly interesting acetylenes containing elements of Groups V, VI, and VII as substituents, the alkyne ethers and thioethers are well known, mainly as a result of the work of *Arens* and his school [20]. Of the other two groups, *i.e.* the fluoroalkynes and ynamines, on the other hand, not even the parent compounds were known until recently. Since these compounds should be very reactive, their synthesis is of preparative as well as theoretical interest.

Monofluoroacetylene, which is now obtainable by several methods [21, 22], exhibits surprising chemical behavior [21]. The acidity of the hydrogen is low, but the fluorine atom can be readily substituted, whereas the chlorine atom in chloroacetylene is much more difficult to replace [21]. Thus fluoroalkynes appear to be the most suitable starting material for the anionic introduction of other substituents, particularly heteroatoms, into acetylenes [23].

After many unsuccessful attempts, the first alkylfluoroacetylene, namely tertbutylfluoroacetylene, was synthesized [24]. This compound can only be stored as a gas or in solution at low temperatures. Like monofluoroacetylene [21], it gives a characteristic infrared and NMR spectrum, and has also been characterized by its molecular weight (determined from vapor-density and mass-spectrometric measurements) and by analytical data on its oligomers.

Oligomerization of t-Butylfluoroacetylene

The surprising characteristic of t-butylfluoroacetylene is that it undergoes spontaneous exothermic oligomerization in the liquid phase to trimers and tetramers [25].

[23] For example, ynamine syntheses *via* fluoroalkyne intermediates: *H. G. Viehe*, Angew. Chem. *75*, 638 (1963); Angew. Chem. internat. Edit. *2*, 477 (1963); *H. G. Viehe* and *M. Reinstein*, Angew. Chem. *76*, 537 (1964); Angew. Chem. internat. Edit. *3*, 506 (1964).

[24] *H. G. Viehe, R. Merényi, J. F. M. Oth*, and *P. Valange*, Angew. Chem. *76*, 888 (1964); Angew. Chem. internat. Edit. *3*, 747 (1964).

Two of the three non-aromatic the valence-bond isomers of the substituted benzene can be isolated from the trimer fraction, which accounts for two-thirds of the entire reaction product, and which consists of roughly equal parts of the Dewar benzene derivative *(12)* and the compound we have named benzvalene *(13)*, together with 1–3 % of a product first formulated as a prismane on the basis of preliminary molecular-weight determinations [25]. X-ray data however showed eight t-butylfluoroacetylene molecules to be present in the unit cell, and redeterminations of the molecular weight when more material had been isolated showed that the compound is a tetramer of t-butylfluoroacetylene and not a prismane. An X-ray structure analysis of this product is in progress.

If this oligomerization is allowed to take place without cooling and in the absence of solvent, the Dewar benzene *(12)* in the product is replaced by the aromatization product 1,2,3-tri-t-butyltrifluorobenzene *(15)*, the structure of which is proved beyond doubt by its nuclear magnetic resonance spectrum and other data.

Thermal and catalytic trimerizations of acetylene are known since the time of *Berthelot*. All previous experience had indicated that monosubstituted acetylenes give benzene derivatives with substituents in the 1,2, and 4 or 1,3, and 5 positions, apparently *via* planar intermediates similar to the Kekulé structures [26]. Our trimerization product *(15)*, on the other hand, corresponds to a 1,2,3-trimerization which had not previously been observed, being similar to that imagined by *Ladenburg* and sought by *Kekulé* [8]. However, not only the 1,2,3-arrangement of the substituents, but also their volume, points to the participation of non-planar intermediates. The volume occupied by the t-butyl group makes even a planar trimerization to 1,2,4-tri-t-butylbenzene unlikely, and a 1,2,3-trimerization should only be possible in a non-planar structure.

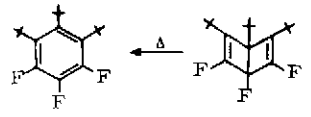
The readily crystallizable 1,2,3-tri-t-butyltrifluorobenzene *(15)* exhibits greater steric strain than any other benzene derivative known at that time. Its formation is all the more surprising in that even *o*-di-t-butylbenzenes had been thought to be sterically incapable of existing until products of this kind were prepared by *Hoogzand* and *Hübel* [13], *Arnett* [13a], and others [13b]. In the meantime, *Arnett* has also obtained a derivative of 1,2,3-tri-t-butylbenzene [17] in which, as in our compound, the steric strain is shown *inter alia* by the ease of thermal or photochemical elimination of a t-butyl group as isobutylene.

The main source of difficulty in the isolation of the non-aromatic valence isomers *(12)* and *(13)* is their limited stability. The thermal stability of these compounds increases from Dewar benzene *(12)* to benzvalene *(13)* [25]. This result was at first surprising. Later the author, together with *J. F. M. Oth* and *R. Merényi*, determined the activation energies of the isomerizations to the aromatic systems [*(12)* → *(15)* and

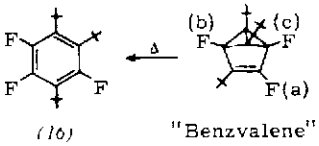
[25] *H. G. Viehe, R. Merényi, J. F. M. Oth, J. R. Senders*, and *P. Valange*, Angew. Chem. *76*, 922 (1964); Angew. Chem. internat. Edit. *3*, 755 (1964).

[26] *W. Hübel* and *C. Hoogzand*, Chem. Ber. *93*, 103 (1960).

(13) → *(16)*] [27]. The results agree approximately with those obtained by subtracting the strain energy and the resonance energy (allyl resonance stabilization) from the C–C single bond energy [28]. The decrease in



1,2,3-Tri-t-butyl-trifluorobenzene *(15)* — „Dewar benzene" *(12)*



(16) — "Benzvalene" *(13)*

instability of these compounds is not surprising, since the phenyl substituents should facilitate the rupture of a C–C bond in the prismane skeleton by resonance-stabilization of the resulting benzyl radical. The synthesis of prismanes containing aliphatic substituents, preferably those that exert a sterically stabilizing action, should be the next aim.

We know from interception reactions during the oligomerization of t-butylfluoroacetylene in styrene or acrylonitrile (without polymerization of these olefins!) that the oligomerization proceeds *via* two dimeric intermediates [27]. Thus in an eightfold excess of styrene or acrylonitrile, the reaction leads to compounds containing two moles of the acetylene and one mole of the olefinic component in yields of up to 80 %. The formation of tetramers in completely suppressed, and the remainder of the product consists of trimers. This part, too, contains the Dewar benzene derivative *(12)* and the benzvalene derivative *(13)* in roughly the same ratio as

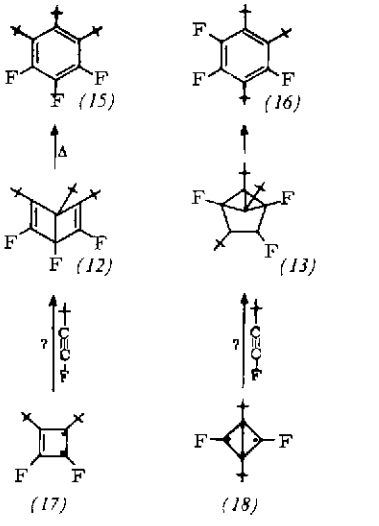
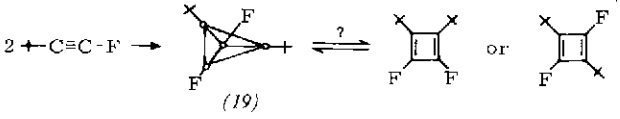
activation energy by resonance stabilization predominates, explaining why the activation energy for isomerization to the more stable aromatic system increases with the number of double bonds in the valence isomer.

For the same reason, bicyclobutane is more stable than cyclobutene, *i.e.* the activation energy of the isomerization to 1,3-butadiene is about 8 kcal/mole higher for bicyclobutane [29]. Cubane is another example of a thermally stable saturated system of condensed microcycles [30].

A different situation obtains for the energies of the valence isomers in the ground state than for the apparent thermal stabilities, which are determined by the activation energies. The resonance-stabilized aromatic system *(3)* has the lowest ground state energy, while prismane probably has the highest. Nothing can be said about the ground-state energies of Dewar benzene and benzvalene until thermochemical data are available.

Tetraphenylprismane and hexaphenylprismane have been postulated as extremely unstable intermediates [31]. The in the undisturbed trimerization of t-butylfluoroacetylene. The structure of the interception products is not known with certainty, but they are probably condensed bicyclobutane derivatives (similar to benzvalene).





Scheme 4. Possible course of the formation of the Dewar benzene and benzvalene derivatives *(12)* and *(13)* from t-butylfluoroacetylene.

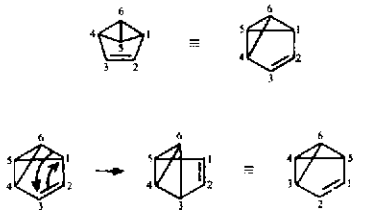
Thus the valence isomers of benzene lead us to those of cyclobutadiene [28a]. Our trimers *(12)* and *(13)* can be formally derived most easily from the biradical forms of cyclobutadiene and bicyclobutane *(17)* and *(18)* corresponding to the cyclobutadiene and tetrahedrane limiting formulae. A tetrahedrane structure with two t-butyl groups and two fluorine atoms seems energetically more favorable than the corresponding planar cyclobutadiene derivative with t-butyl groups in positions 1 and 2. Moreover, an intermediate tetrahedrane structure *(19)* would provide a simple explanation of the simultaneous "head-to-head" and "head-to-tail" trimerization, owing to the possibility of valence isomerization to form either the planar 1,2- or the 3-cyclobutadiene derivative, as shown in Scheme 4. These views are summarized in the hypothetical reaction Scheme 4. The alternatives of tetramer formation by the condensation of dimer and dimer or of trimer and monomer remain undecided.

The Formal Series of Valenes

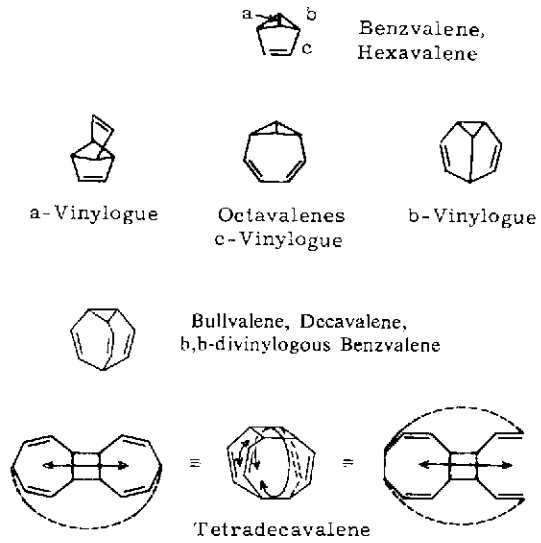
The name "benzvalene" for the compound *(13)* is intended to express two ideas. The first is that the compound is a valence isomer of benzene, and the second is that it is the first member of the hypothetical series of valenes.

If the atoms of benzvalene are numbered as in Scheme 5, the relative positions and linkages of the C atoms in the skeleton can be changed, without the formation of a new molecule, by a valence interchange between the double bond and the cyclopropane rings. If this valence isomerization occurs sufficiently often, the atoms numbered 1–6 in Scheme 5 must ultimately be statistically distributed over the entire molecule. *Doering* has developed similar concepts for bullvalene [28]. The vinylogues of benzvalene should also behave in a similar manner.



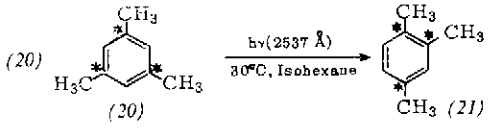
Scheme 5. Isomerization of benzvalene

Benzvalene contains three different types of single bonds, which are indicated by letters in Scheme 6. If these bonds are opened and two C atoms with a new double bond inserted, we obtain three vinylogous octavalenes. The insertion of another vinyl group into the octavalenes yields a series of decavalenes, one of which has recently become well known; this is bullvalene [28, 32], in which the steric and electronic conditions are optimal for valence isomerization. Among the higher vinylogous valenes, a special place is accorded to the hypothetical tetradecavalene. Just as valence isomerization takes place between two double bonds and one cyclopropane ring in bullvalene, so a cyclobutane ring in tetradecavalene would formally migrate in a closed band between the two cycloheptadiene rings, which are linked by three single bonds. Another valence isomerization transverse to this band, with disintegration of the four-membered ring and formation of a three-membered ring, would also be possible, but this would lead to a different molecule.



Scheme 6. Valenes

Evidence of the reality of these ideas has recently been found, at least for benzene. Thus when *o*-xylene is irradiated with ultraviolet light, the *meta* and *para* isomers are formed [33]. Similarly, 1,2,4-trimethylbenzene *(21)* is obtained from 1,2,3-trimethylbenzene *(20)*. For the latter reaction it was shown by labelling with ^{14}C that the methyl groups do not change their positions by separating from the benzene ring [34]. If, however, the bonds between the ring atoms and the methyl groups remain intact during the photoisomerization, then valence isomers of benzene must be involved in this rearrangement. A simple explanation is offered by a benzvalene structure, which is formally equivalent to an excited Dewar benzene structure. However, the question of why the isomers are unequally distributed in the photo-stationary equilibrium still remains unanswered so long as the effect of substituents on the isomerization is unknown. The C atoms in the unsubstituted benzene

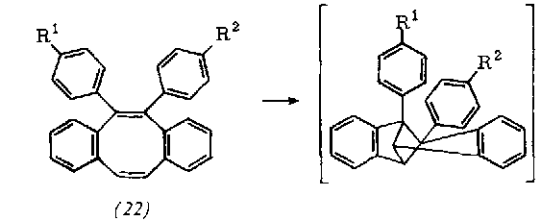


[32] *G. Schröder*, Angew. Chem. *75*, 722 (1963); Angew. Chem. internat. Edit. *2*, 481 (1963).

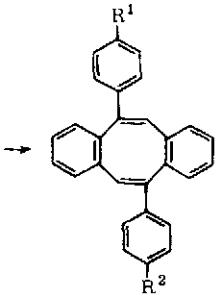
[33] *K. E. Wilzbach* and *L. Kaplan*, J. Amer. chem. Soc. *86*, 2307 (1964).

[34] *L. Kaplan, K. E. Wilzbach, W. G. Brown*, and *Shü Shu Yan*, J. Amer. chem. Soc. *87*, 675 (1965).

should also be statistically distributed under the conditions of the valence isomerization. A similar phenomenon would also explain the recently observed photo-isomerizations of t-butylbenzenes [17, 35]. There is also some evidence of similar valence isomerizations among the octavalenes [36]. Under relatively mild conditions,



(22)



a) $R^1 = R^2 = C_6H_5$
b) $R^1 = R^2 = p\text{-}CH_3\text{-}C_6H_4$
c) $R^1 = R^2 = p\text{-}Br\text{-}C_6H_4$
d) $R^1 = C_6H_5$; $R^2 = p\text{-}Br\text{-}C_6H_4$

for example, the cyclooctatetraene derivative *(22)* undergoes a valence isomerization which is formulated as proceeding *via* an *a*-vinylogous octavalene [36]. It is not yet known whether a similar explanation applies in the case of the Jacobsen rearrangement, which according to recent evidence proceeds by a free-radical mechanism [37]. The photo-isomerization of indazole to benzimidazole [38] also deserves attention in this connection.

Summary

1. Whereas t-butylchloroacetylene is stable for long periods at 150 °C, t-butylfluoroacetylene undergoes an exothermic oligomerization even below 0 °C. Thus there is an analogy to the relationships between tetrafluoroethylene and tetrachloroethylene, and between vinylidene fluoride and vinylidene chloride.

2. The oligomerization of t-butylfluoroacetylene proceeds *via* dimers as shown by interception with styrene or acrylonitrile. The fact that no polymerization of the olefin occurs makes the formation of free-radical intermediates unlikely, even though they are used as limiting formulae to describe the reaction.

3. The dimers react to give products that can be formally explained by the assumption of intermediate biradical limiting structures based on cyclobutadiene and its valence-bond isomer, tetrahedrane.

4. The stability (expressed by the activation energy of the isomerization to the aromatic system) of the non-aromatic valence isomers increases as the number of double bonds decreases.

5. The vinylogous benzvalene may be regarded as the parent member of a hypothetical vinylogous series of valenes, if we define these as compounds whose valence isomerization leads to the mutual displacement of atoms of the skeleton. An example of these compounds is bullvalene, which, as a decavalene, is a member of the series.

Molecules Undergoing Fast, Reversible Valence-Bond Isomerization [1]

(Molecules with Fluctuating Bonds)

BY PRIV.-DOZ. DR. G. SCHRÖDER

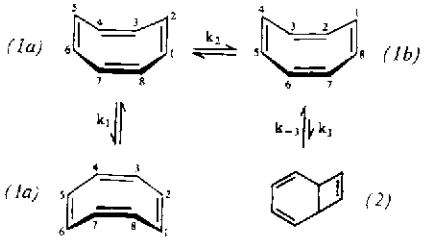
Compounds which undergo fast and reversible valence-bond isomerization (i.e. which have fluctuating cyclopropyl and/or double bonds) are taken to be those in which the average lifetime of the valence-bond isomers at 0 °C is of the order of 100 seconds at most, and for which the maximum activation energy of the bond migration is 20 kcal/mole. The fast, reversible bond shift can scarcely be detected by chemical means, but can be recognized by NMR spectroscopy, since the time for which a proton occupies a position with a given magnetic environment has a pronounced influence on the NMR spectrum. Some examples of molecules with fluctuating bonds are cyclooctatetraene and its derivatives, unsaturated seven-membered ring systems, homotropilidene, bridged homotropilidene systems, bullvalene, and substituted bullvalenes. The last class is particularly interesting, since here the carbon atoms are continually changing their relative positions and neighbors.

I. Introduction

In order to reconcile the equivalence of all six carbon-carbon bonds in benzene with his cyclohexatriene formula, *Kekulé* [2] assumed that "one carbon atom is doubly bonded to one of the adjacent carbon atoms for one unit of time, and to the other adjacent carbon atom for the next . . ." Thus according to the *Kekulé* picture, the bonds in benzene jump backwards and forwards, *i.e.* they oscillate or fluctuate. This attempted explanation is now known to be untenable. The actual structure of benzene is somewhere between two fictitious limiting cyclohexatriene structures; the π-electrons in benzene are delocalized. However, *Kekulé*'s basic postulate of the equivalence of all six carbon-carbon bonds in benzene is correct.

Kekulé's oscillation theory is currently attracting interest again, since it is capable of describing the behavior of molecules with fluctuating bonds. The bonding electrons in these molecules, however, unlike those in benzene, are localized, and depend on valence isomerization for their sudden shift. Valence isomerization is a reorganization of π, or of π and σ, electrons accompanied by changes in interatomic distances and bond angles but without migration of atoms or groups [3]. It is an intramolecular rearrangement which obeys first-order kinetics, is practically uncatalysable, is independent of solvent, and can be influenced only by temperature. It belongs to the class of "no-mechanism" reactions [4].

Of the many molecules that exhibit valence isomerization, we shall be concerned only with those in which the phenomenon is fast and reversible, *i.e.* in which the mean lifetime of the valence-bond isomers at 0 °C is of the order of 100 seconds or less and the activation energy ΔE^* of the isomerization is not greater than 20 kcal/mole. This arbitrary convention is based on the use of NMR spectroscopy as the means of detection. Molecules of this type may be said to have fluctuating bonds. This concept may be illustrated with cyclooctatetraene *(1)* as an example.



This compound can undergo three different isomerizations, the kinetic data for which are given in Table 1:

1. The ring inversion *(1a)* $\rightleftarrows$ *(1a)* (see Section III, 1) is due to rotation about the C–C single bonds. There is no reorganization of the bonding electrons. Consequently this is not a valence - bond isomerization.

2. The reaction *(1a)* $\rightleftarrows$ *(1b)* (see Section III, 1), on the other hand, is characterized by a reversible bond migration involving all four double bonds [5]. The molecular structure remains unchanged, but if we number the carbon atoms, the structures *(1a)* and *(1b)* are different. The two valence isomers have the same energy and the same lifetime $\Delta t_{(1a)}$ of about 1.4×10^{-2} sec at 0 °C. Thus according to our arbitrary condition, this is an example of a fast, reversible valence-bond isomerization.

3. As far as the type of reaction is concerned, there is fundamentally no difference between *(1a)* $\rightleftarrows$ *(1b)* and the dynamic

equilibrium of cyclooctatetraene with bicyclo[4.2.0]octa-2,4,7-triene *(2)* [6,7]. This is again a reversible valence isomerization (equilibrium constant $K = [(1)]/[(2)] \approx 10^4$), but it is not fast, since the lifetimes of *(2)* and *(1)* (carbon atoms not distinguished) at 0 °C are more than 100 sec (see Table 1).

Table 1. Kinetic data for the isomerizations of cyclooctatetraene [5—7]. k = rate constant, $\Delta E^{\neq}$ = activation energy, Δt = lifetime.

II. Detection of Valence-Bond Isomerization

Molecules with fluctuating bonds can scarcely be recognized as such by chemical means. The simplest and best method of detection is NMR spectroscopy. The lifetime Δt of a structure, or in general, the time during which a position with a given magnetic environment is occupied by a proton, has a strong influence on the NMR spectrum.

In infrared and ultraviolet spectroscopy, the energy difference, $\Delta E = h\Delta\nu$, between the individual absorption bands is so large that, even for short-lived structures, the spectrum obtained reflects all the structures present. The chemical shifts in the NMR spectra, on the other hand, correspond to very small energy differences, the measurement of which requires an appreciable time. It follows that the lifetime Δt of a compound plays an important part in NMR spectroscopy. The product $\Delta t\cdot\Delta\nu$ determines the NMR spectra of dynamic systems, where $\Delta\nu$ (in c.p.s.) $= \nu_A - \nu_B$; ν_A and ν_B are the chemical shifts of the same proton in two valence isomers in the absence of exchange [8].

Molecules with fluctuating bonds have temperature-dependent spectra provided that 1. the rate constant for the valence isomerization is such that $10^{-3} < \Delta t\cdot\Delta\nu < 10$, *i.e.* $10^{-3} < k^{-1}\cdot\Delta\nu < 10$; and 2. the valence isomers in equilibrium with one another have identical structures (equilibrium constant $K = 1$), or if the structures are different, they are present in comparable concentrations (equilibrium constant $K < 20$).

The temperature-dependence of the NMR spectra of tricyclo[3,3,2,$0^{4,6}$]deca-2,7-diene (dihydrobullvalene) [9] is shown in Fig. 1. The valence isomers in this case are structurally identical. However, if the carbon (or hydrogen) atoms are distinguished from one another, the two coexisting structures become different.

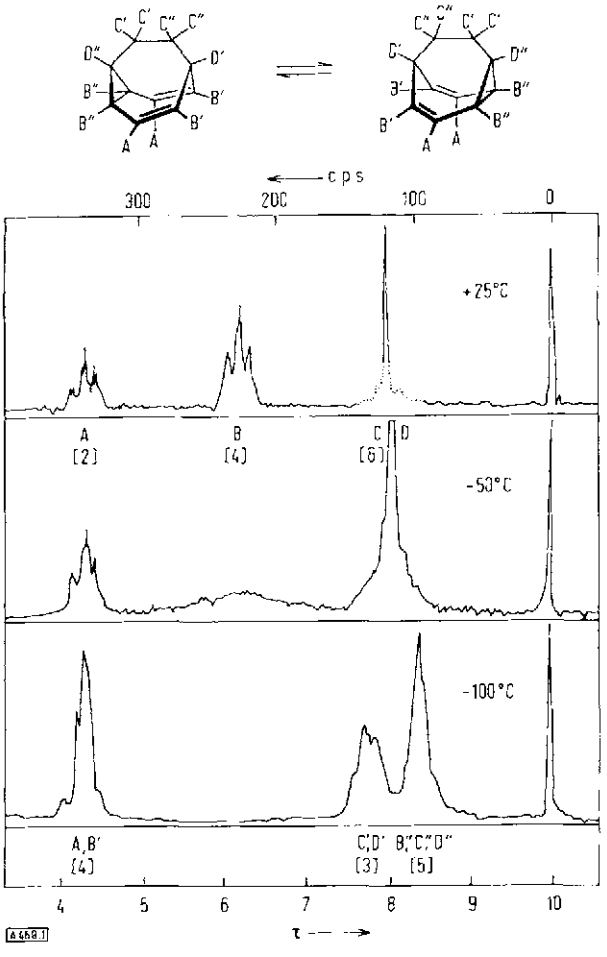

Fig. 1. NMR spectrum of dihydrobullvalene (tricyclo[3.3.2.0.4,6] deca-2,7-diene) [9,10]. Internal standard: tetramethylsilane.

A hydrogen atom B, for example, is attached to a cyclopropane group in one valence isomer, while in the other it is attached to an olefinic group. The average lifetime of the isomers at −100 °C is so long ($\Delta t\cdot\Delta\nu > 10$) that the NMR spectrum contains relatively sharp bands corresponding to the states of the protons. The spectrum can now be said to correspond to the structural formula.

As the average lifetime decreases with rising temperature ($10 > \Delta t\cdot\Delta\nu > 10^{-3}$), the bands for the protons B first become indistinct and then spread until they finally coalesce to form one wide band. Only one maximum is observed at −50 °C.

If the valence isomerization is accelerated by further heating ($\Delta t\cdot\Delta\nu < 10^{-3}$), the NMR spectrum again exhibits sharp bands. As a result of the fast and reversible valence isomerization, pairs of protons become identical and the chemical shifts and coupling constants now have average values. For example, at 25 °C the spectrum contains a band centered at about $\tau = 6.32$, corresponding to the four B protons.

At higher temperatures, therefore, the NMR spectrum reflects the dynamic situation (valence isomerization), while

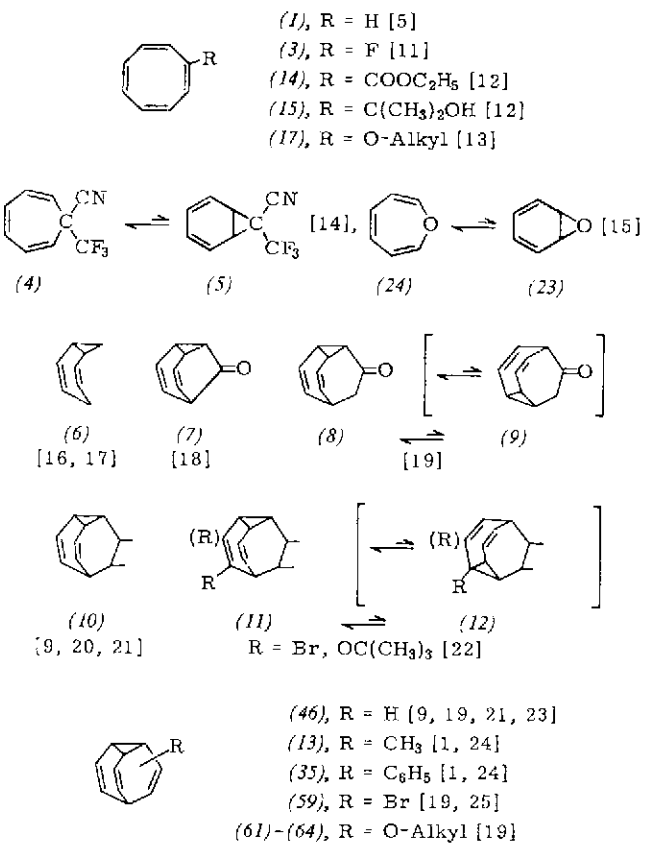
[10] The numbers in square brackets indicate the relative intensities of the signals. The sensitivity of the instrument was occasionally varied during the recording of a spectrum.

at lower temperatures it reflects the static situation, *i.e.* the structure of the compound.

The kinetic data for the valence isomerization can be deduced from the form of the NMR signal at various temperatures [8] (for examples, see Table 3).

III. Known Molecules with Fluctuating Bonds

Several molecules with fluctuating bonds have recently become known. These include cyclooctatetraene *(1)* and some of its derivatives, such as *(3)*, *(14)*, *(15)*, and *(17)*, a number of unsaturated seven-membered ring systems such as *(4)* ⇄ *(5)*, *(23)* ⇄ *(24)*, bicyclo[5.1.0]octa-2,5-diene *(6)* (homotropilidene), bridged homotropilidene systems of the type *(7)*, *(8)* ⇄ *(9)*, *(10)*, *(11)* ⇄ *(12)*, and bullvalene *(46)* and some of its derivatives (see Scheme 1).

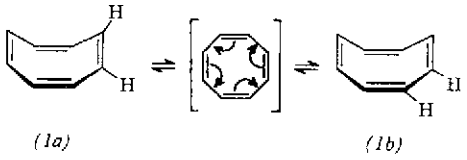


Scheme 1.

1. Cyclooctatetraene and Derivatives

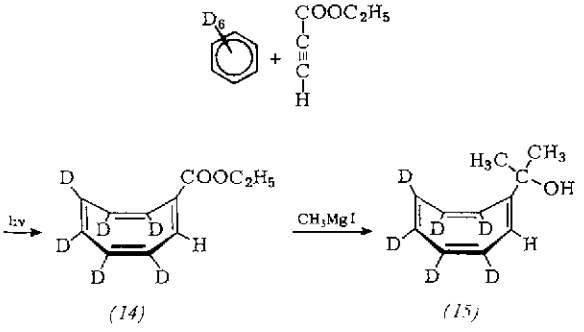
The fluctuation of the bonds in cyclooctatetraene was recently recognized by *Anet* [5] and *Roberts* [11] from the NMR spectra. The ^{13}C satellites in the proton resonance spectrum of this compound (resulting from a spin-spin coupling of the H atoms with the natural ^{13}C in the cyclooctatetraene) change with temperature. The rate constant k for the valence isomerization *(1a)* ⇄ *(1b)* was deduced from the temperature-dependence of the satellites. The free energy of activation is about 13.7 kcal/mole at −10 °C [5].

The valence isomerization very probably passes through a planar cyclooctatetraene in the transition state.

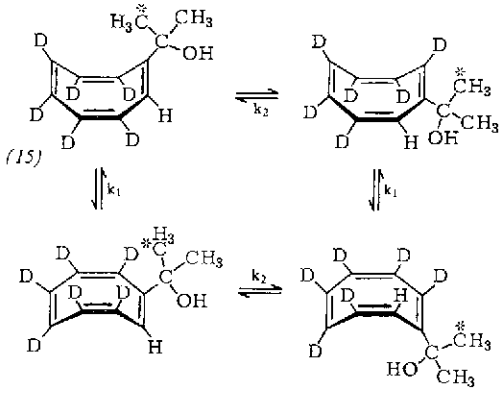


The bonds in the eight-membered ring also fluctuate in substituted cyclooctatetraenes. Thus the fluorine resonance signal of fluorocyclooctatetraene *(3)* undergoes a striking change between room temperature and −65 °C [11]. The free energy of activation for the valence-bond isomerization at −33 °C is about 12 kcal/mole [11].

Anet et al. [12] prepared the derivatives *(14)* and *(15)*.



The kinetic data k_2 for the bond migration in *(14)* and *(15)* and k_1 for the ring inversion in *(15)* were deduced from the temperature-dependence of the ^1H–NMR spectra with additional irradiation at the frequency of deuterium [*]. One of the two (non-equivalent) methyl groups in *(15)* is distinguished by an asterisk.



It can be seen from Table 2 that the bond migration in the ethyl cyclooctatetraene carboxylate *(14)* is faster than in the cyclooctatetraenyldimethylcarbinol *(15)*, and that the free energy of activation for the ring inversion in *(15)* is less than that for the bond migration.

[12] *F. A. L. Anet, A. J. R. Bourn*, and *Y. S. Lin*, J. Amer. chem. Soc. *86*, 3576 (1964).

[*] Simpler spectra are obtained by this additional irradiation because the H/D coupling is eliminated.

The cyclooctatetraenyl alkyl ethers *(17)*, which are prepared by the action of potassium alkoxides on the dibromide *(16)*, also have temperature-dependent NMR spectra [13]. The resonance signal of the proton H_a in *(17a)* is clearly separated in the low-temperature spectrum from the signals of the other

Table 2. Kinetic data for the bond migration k_2 and the ring inversion k_1 in compounds *(14)* and *(15)*. ΔF^*, ΔH^*, ΔS^* = free energy, enthalpy, and entropy of activation, respectively.

Compound	Temp. [°C]	Reaction	k [sec^{-1}]	ΔF^* [kcal/mole]	ΔH^* [kcal/mole]	ΔS^* cal·mole^{-1}·deg^{-1}
(14)	40	k_2	126	15.3	12.8	−8.0
(15)	41	k_2	5.4	17.4	15.4	−6.3

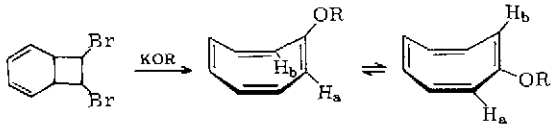
	−2	k_1	7.8	14.7		

protons attached to the eight-membered ring. At higher temperatures, the NMR method cannot distinguish between H_a and H_b. This result shows that the cyclooctatetraenyl alkyl ethers undergo a rapid and reversible valence-bond isomerization *(17a)* ⇄ *(17b)*.



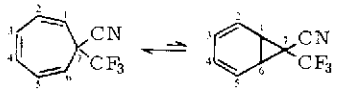
(16) *(17a)* *(17b)*

R = CH_3, C_2H_5, $C(CH_3)_3$

2. Unsaturated Seven-Membered Ring Systems

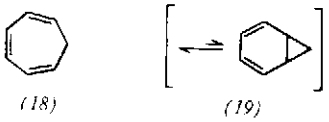
a) A Cycloheptatriene/Norcaradiene Derivative

Cycloheptatriene and norcaradiene were shown by *Ciganek* [14] to be related by a rapid and reversible valence isomerization in the case of a 7-cyano-7-trifluoromethyl derivative *(4)* ⇄ *(5)*.



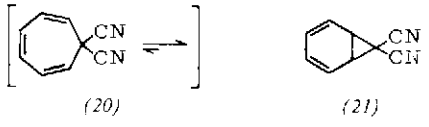
(4) 80% *(5)* 20%

The valence isomers *(4)* and *(5)* have different structures. Since the equilibrium constant is about 4, the valence-bond isomerization can be recognized by the temperature-dependence of the NMR spectrum. At room temperature the ^{1}H-NMR spectrum contains a complex multiplet between τ = 3.2 and 3.8 (protons on C-2, C-3, C-4, and C-5 and a doublet centered at about τ = 5.30 (protons on C-1) and C-6). This doublet widens as the temperature is lowered, and ultimately gives two new signals: a doublet at τ = 4.60 [protons on C-1 and C-6 in *(4)*] and a fairly broad singlet at τ = 7.01 [protons on C-1 and C-6 in *(5)*], the areas being in the ratio 4:1.



(18) *(19)*

NMR measurements on cycloheptatriene *(18)* at various temperatures give no indication of the presence of norcaradiene *(19)* [26]. On the basis of *Ciganek*'s results, it may be assumed that a reversible valence isomerization occurs, but that cycloheptatriene is present to the extent of practically 100%. In the case of a 7,7-dicyano derivative, on the other hand, the equilibrium mixture consists almost entirely of the norcaradiene structure *(21)* [27].



(20) *(21)*

b) Oxepin/Benzene Oxide

Vogel, *Böll*, and *Günther* [15] found that the dehydrohalogenation of 1,2-epoxy-4,5-dibromocyclohexane *(22)* leads to a non-phenolic, orange product in good yield. The temperature-dependence of the NMR spectrum indicates a fast and reversible valence isomerization between oxepin *(24)* and benzene oxide *(23)*. The equilibrium constant appears to be affected by the temperature and (as ultraviolet absorption studies show) by the solvent [*].

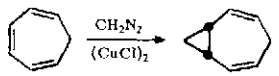
(23) $\underset{k_b}{\overset{k_a}{\rightleftharpoons}}$ *(24)*

k_a = 14.1 · 10^6 sec^{-1}; ΔE_a^* = 9.1 kcal/mole

k_b = 2.29 · 10^6 sec^{-1}; ΔE_b^* = 7.2 kcal/mole.

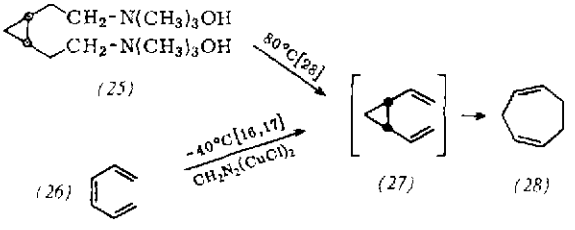
c) Homotropilidene (Bicyclo[5.1.0]octa-2,5-diene)

The reaction of cycloheptatriene *(18)* with diazomethane leads *inter alia* to bicyclo[5.1.0]octa-2,5-diene (homotropilidene *(6)* [16,17].



(18) *(6)*

Homotropilidene contains the *cis*-1,2-divinylcyclopropane grouping. Attempts at the preparation of *(27)* [16,17,28] resulted in the formation of 1,4-cycloheptadiene *(28)*, the valence-bond isomer of *(27)*.

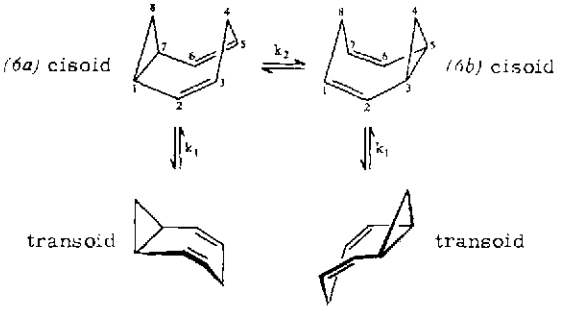


(25) *(26)* *(27)* *(28)*

The formation of *(28)* was explained by postulating the occurrence of *cis*-1,2-divinylcyclopropane *(27)* as an intermediate; this presumably undergoes a very fast Cope rearrangement. The valence-bond isomerization *(27)* → *(28)* is made possible by the reduction of the activation energy owing to the *cis* arrangement of the two vinyl groups on the three-membered ring. The geometry of the transition state is already largely present in the ground state [17,28]. The geometry of the *trans*-isomer, on the other hand, does not favor the rearrangement [3]; this isomer can therefore be isolated, and rearranges into *(28)* only at 190 °C.

The lifetime of the compound *(27)* at −40 °C is evidently still so short that the compound cannot be isolated [17]. If the two vinyl groups in *(27)* are linked by one methylene group, the resulting structure is homotropilidene *(6)*.

The structure of *(6)* is not changed by valence isomerization. If the carbon (or hydrogen) atoms are distinguished from one another, however, the two structures *(6a)* and *(6b)* existing in equilibrium are different.



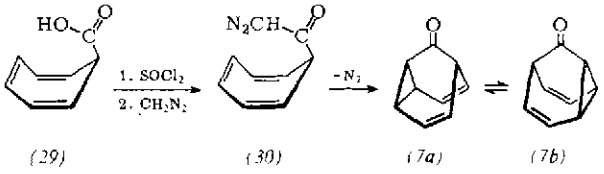
The temperature-dependence of the NMR spectrum of homotropilidene shows it to undergo fast and reversible valence-bond isomerization [29]. The dynamic equilibrium between the two valence-isomeric structures is superposed on an equilibrium between two conformational isomers *(cisoid* and *transoid)*. This makes it difficult to determine the kinetic data for the valence isomerization from the NMR spectra.

[28] *E. Vogel, K.-H. Ott*, and *K. Gajek*, Liebigs Ann. Chem. *644*, 172 (1961).

[29] *Doering* and *Roth* [16,17] coined the term "fluctuating structure" in a study of homotropilidene.

d) Bridged Homotropilidene Systems of the Type *(7)*

The reaction of the acid chloride of cycloheptatrien-7-carboxylic acid *(29)* with diazomethane yields a diazoketone *(30)*, which by elimination of nitrogen forms tricyclo[3.3.1.$0^{4,6}$]nona-2,7-dien-9-one *(7)* [18] [*].

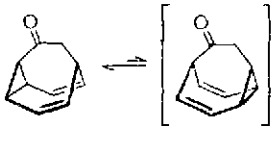


(29) *(30)* *(7a)* *(7b)*

The homotropilidene part of the tricyclic ketone *(7)* is fixed in the *cisoid* configuration by the carbonyl bridge. This compound undergoes a reversible and extremely fast valence-bond isomerization. The NMR spectrum of *(7)* shows little change as a result of cooling to −30 °C. The chemical shifts and coupling constants found for the pairs of identical protons resulting from the valence-bond isomerization *(7a)* ⇄ *(7b)* are average values. The spectrum comprises three groups of bands corresponding to three groups of equivalent protons. Only at about −90 °C does the average lifetime of the isomers becomes sufficiently long to give a spectrum corresponding to the structural formula. The kinetic data for *(7)* were determined by *Lambert* [30] from the NMR spectra. The activation energy ΔE^* of the reaction *(7a)* ⇄ *(7b)* is 8.2 kcal/mole (cf. Table 3).

e) Bridged Homotropilidene Systems of the Type *(8)*

Doering and *Klumpp* [19] synthesized the tricyclic ketone *(8)* by the Al_2O_3-catalysed ring expansion of *(7)* with diazomethane.



(8) *(9)*

Valence-bond isomerization should lead to the formation of the structurally different *(9)* from *(8)*. The NMR spectrum of *(8)* is independent of temperature [19], suggesting that the equilibrium is dominated by a single isomer. Conjugation between the carbonyl group and the three-membered ring evidently makes *(8)* by far the more stable of the two isomers.

f) Bridged Homotropilidene Systems of the Type *(10)*

Homotropilidene systems of the type *(8)* contain an unsymmetrical bridge consisting of two carbon atoms. The two valence-bond isomers therefore have different

[30] *J. B. Lambert*, Tetrahedron Letters *1963*, 1901.

[*] Note added in proof: Reduction of *(7)* with hydrazine hydrate in diethylene glycol/KOH gives *inter alia* tricyclo-[3.3.1.$0^{4,6}$]nona-2,7-diene, which undergoes reversible valence-isomerization with ΔE^* = 8.76 kcal/mole, k (−80 °C) = 8016 sec^{-1}. *(W. v. E. Doering* and *J. H. Hartenstein*, personal communication).

structures. Bridged homotropilidene systems of the type *(10)*, on the other hand, contain a symmetrical bridge of two carbon atoms, and therefore the valence isomers are structurally identical, *i.e.* the equilibrium constant K is unity. The valence-bond isomerization can be studied with the aid of the temperature-dependent NMR spectra, as in the case of tricyclo[3.3.2.0^{4,6}]deca-2,7-diene (Section II). The kinetic data for bridged homotropilidenes of the types *(7)* and *(10)*, as well as for bullvalene, are also given in Table 3.

Table 3. Kinetic data for bridged homotropilidene systems.

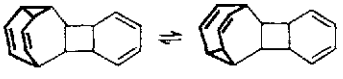
[a] Extrapolated values.

The best synthetic route to bridged homotropilidene systems of the type *(10)* is by way of cyclooctatetraene, which dimerizes on heating or on prolonged standing at room temperature [31]. Four dimers of cyclooctatetraene, $C_{16}H_{16}$, are known with certainty, their melting points being 38.5, 41.5, 53, and 76 °C [32]. The $C_{16}H_{16}$ melting at 76 °C [33] is obtained by heating cyclooctatetraene at 100 °C for 68 h; the yield is 37 % [37] based on the cyclooctatetraene which has reacted. This dimer *(31)* [9, 20, 23] consists of a bicyclo[4.2.0]octa-2,4-diene unit and a homotropilidene unit (shown by thick lines). The homotropilidene system is responsible for the valence-bond isomerization.



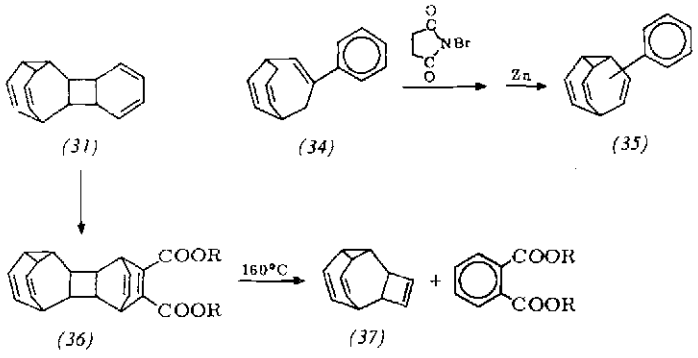
(31a) *(31b)*

The structures *(31a)* and *(31b)* are identical. Two π bonds and one of the σ bonds of the cyclopropane ring fluctuate in the homotropilidene system [as in *(6)*, *(7)*, and probably *(8)*], as can be seen from the temperature-dependence of the NMR spectrum [9]. The areas and the chemical shifts of the proton resonance signal change appreciably with temperature.

The previous interpretation [20] of the mode of formation of *(31)* was based on the incorrect structure *(32)* proposed by *Jones* [33] for a dimeric cyclooctatetraene of m.p. 53 °C. This structure should be replaced [37a] by *(33)*. Surprisingly, cyclooctatetraene dimerizes at 100 °C by 1,2:1,2 cycloaddition to give an all-*cis*-cyclobutane derivative.

(32) *(33)*

When *(31)* is treated with strong bases (*e.g.* potassium t-butoxide in dimethyl sulfoxide), it isomerizes readily to form a hydrocarbon *(34)*, m.p. 69 °C. The reaction of *(34)* with *N*-bromosuccinimide yields a dibromide, which loses both bromine atoms on treatment with zinc to form phenylbullvalene *(35)* [25].

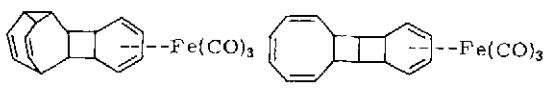


(31) *(34)* *(35)*

(36) *(37)*

Compound *(31)* reacts extremely readily with dienophiles. The adduct *(36)* formed form *(31)* and dimethyl acetylenedicarboxylate decomposes on heating into dimethyl phthalate and a hydrocarbon *(37)* [9, 20], in which the homotropilidene system is bridged by a cyclobutene ring. The NMR spectrum of *(37)* is temperature-dependent [9], showing that this is also a molecule with fluctuating bonds.

The compound *(31)* reacts with iron pentacarbonyl at 160–170 °C to form *inter alia* the complex $C_{16}H_{16}$–$Fe(CO)_3$, m.p. 118 °C. The temperature-dependent NMR spectrum of this complex agrees with the structure *(38)* [38]. X-ray analysis led to the structure *(39)* for a complex having the same overall formula [39]. It was later found, however, that the complex used for the X-ray analysis, obtained by irradiating a mixture of cyclooctatetraene and cyclooctatetraene-$Fe(CO)_3$, has m.p. 172 °C [40].



(38) *(39)*

Other bridged homotropilidene systems of the type *(10)* are derived from bullvalene [cf. compounds *(53)*, *(56)*, and *(57)*]. These are discussed in Section III.3.

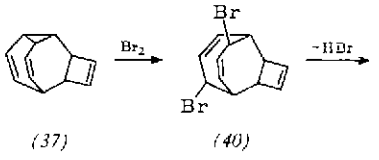
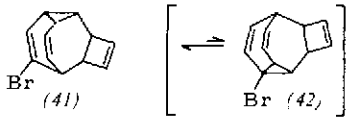
g) Bridged Homotropilidene Systems of the Type *(11)*

The hydrocarbon *(37)* reacts with one mole of bromine to form the dibromide *(40)*, which loses HBr under the influence of bases (potassium alkoxide) with formation of the monobromide $C_{12}H_{11}Br$ *(41)* [22]. This is an unsymmetrically substituted homotropilidene system with a cyclobutene bridge.

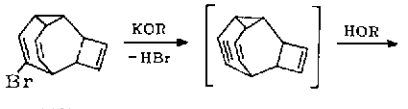


(37) *(40)*

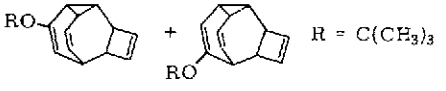


(41) *(42)*

Valence isomerization of *(41)* should lead to the structural isomer *(42)* with the bromine attached to the cyclopropane ring. Compounds *(41)* and *(42)* therefore have different energies. The NMR spectrum of $C_{12}H_{11}Br$ is independent of temperature, showing that the equilibrium mixture consists almost entirely of *(41)*. The latter reacts with potassium t-butoxide to form $C_{12}H_{11}OC_4H_9$. The NMR spectrum of the ether *(45)* corresponding to the bromide *(41)* should be independent of temperature. Since, however, the spectrum of $C_{12}H_{11}OC_4H_9$ is temperature-dependent, this must be a mixture of *(44)* and *(45)* [41], probably formed *via* the intermediate *(43)*. Compounds *(44)* and *(45)* are evidently formed by an elimination-addition mechanism.



(41) *(43)*

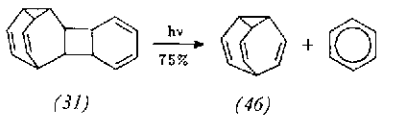


(44) *(45)*

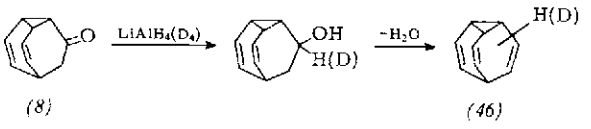
3. Bullvalene and Some of its Derivatives

a) Preparation of Bullvalene

The photolysis of the dimeric cyclooctatetraene *(31)* gives a very good yield of benzene and tricyclo[3.3.2.0^{4,6}]-deca-2,7,9-triene *(46)*, m.p. 96 °C [21,23]. *Doering* and *Roth* [16,17], on the basis of theoretical considerations, postulated the structure *(46)*, predicted its NMR-spectroscopic behavior, and suggested the name "bullvalene". *Doering* and *Klumpp* [19] later synthesized bullvalene (and monodeuterated bullvalene) from the tricyclic ketone *(8)*.



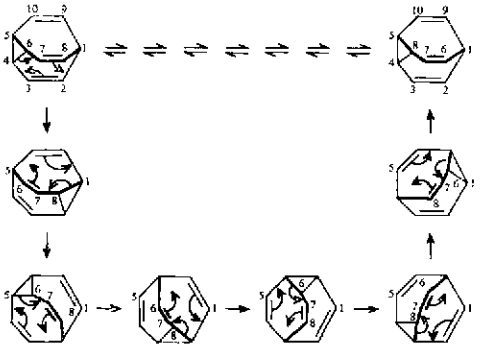
(31) *(46)*



(8) *(46)*

b) The "Bullvalene Principle"

Bullvalene is an unusual member of the class of molecules with fast and reversible valence isomerization. In this molecule, no two carbon atoms remain bonded to each other for any length of time. The ten C atoms are continually changing places and neighbors. No precedent for a molecule with properties of this kind is known in organic chemistry [16,17]. Any carbon atom in bullvalene can be bonded to any other as a result of valence isomerization, as shown in Scheme 2 [42].



Scheme 2.

In homotropilidene *(6)* and the bridged homotropilidene systems of the types *(7)*, *(8)*, *(10)*, and *(11)*, only one cyclopropyl bond can be broken, and only two valence isomers are involved. Bullvalene, on the other hand, possesses a threefold axis of symmetry. The three cyclopropyl bonds are equivalent and have equal statistical weights in a valence isomerization, *i.e.* all three bonds are equally likely to be broken. Thus instead of giving only two structurally identical valence isomers, bullvalene gives 10!/3, *i.e.* about 1.2 million [16,17].

In the course of a few valence isomerizations, each proton in the bullvalene molecule passes through cyclopropyl, olefinic, and bridgehead positions (*e.g.* the C–5 proton in Scheme 2). If the valence isomerization is sufficiently fast, the ten protons of bullvalene become equivalent from the point of view of NMR spectroscopy. At 100 °C the NMR spectrum of bullvalene consists of a single sharp proton resonance signal at $\tau = 5.78$ with a line width of 1.5 c.p.s. (Fig. 2) [9]. This confirms the predictions of *Doering* and *Roth* [16,17].

[41] The valence isomers of *(44)* are structurally identical.

[42] Regarding the bullvalene principle see also [16,17].

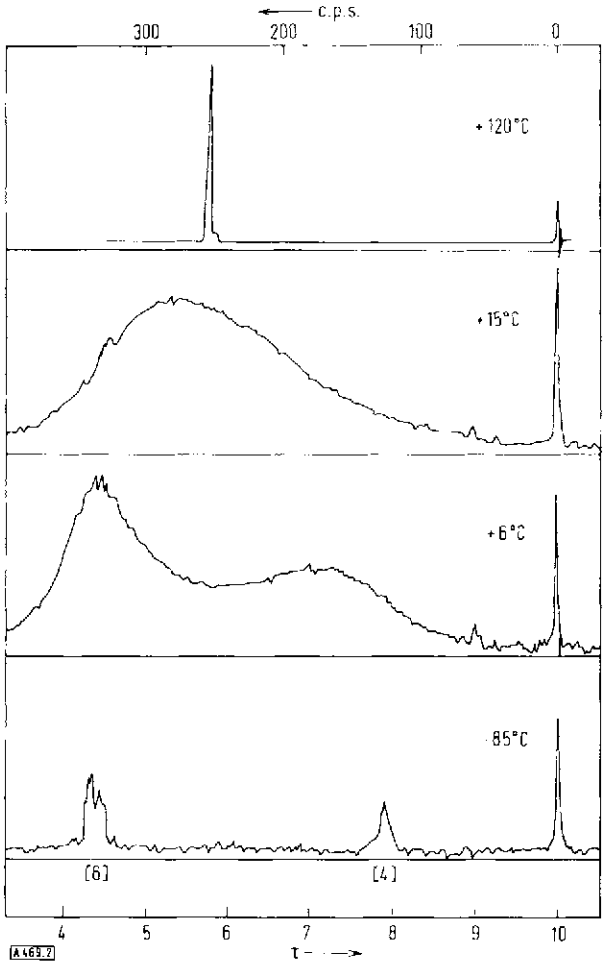


Fig. 2. NMR spectra of $C_{10}H_{10}$, bullvalene *(46)* (0.4 mole/l in CS_2) [9, 10]. Internal standard tetramethylsilane.

The low-temperature spectrum of bullvalene comprises two groups of bands, the areas of which are in the ratio 3:2. A multiplet is found at $\tau - 4.35$, corresponding to the six olefinic protons of bullvalene. The relatively broad band at $\tau = 7.42$ must be assigned to the three cyclopropyl protons and the bridgehead protons. The two groups of bands coalesce at 13 °C, giving the single signal at $\tau = 5.78$ above this temperature (cf. Fig. 2).

The rate constant k and the activation energy ΔE^* of the valence isomerization of bullvalene shown in Table 3 [35, 36] were determined from the NMR spectra at various temperatures with the aid of the line-width theory developed by *Anderson* [43] and *Sack* [44].

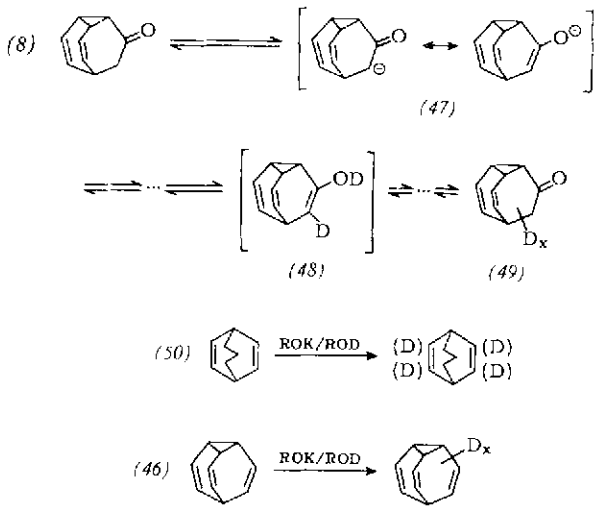
The single proton resonance signal in the high-temperature spectrum of bullvalene is *physical* proof of the constant statistical change of position of the ten C atoms in the molecule. Chemical evidence can be obtained from the base-catalysed hydrogen-deuterium exchange in the tricyclic ketone *(8)* [19] and in bullvalene [21].

Both hydrogen atoms of the methylene group of *(8)* are relatively acidic, and a base-catalysed H/D exchange proceeds *via* the anion *(47)*. Similarly, in the case of bullvalene, deuterated hydroxybullvalene *(48)* is formed as an intermediate. The transposition of the C–D and C–H units should therefore lead to *(49)*, with random distribution of the deuterium in *(8)*. In deuterium oxide at room temperature, all the hydrogen atoms in *(8)* are replaced by deuterium in the presence of 0.1N base [19].

[43] *P. W. Anderson*, J. physic. Soc. Japan *9*, 16 (1954).

[44] *R. A. Sack*, Molecular Physics *1*, 163 (1958).

Bullvalene itself contains three types of hydrogen atom (olefinic, cyclopropyl, and bridgehead protons). There is thus the question as to which type of C–H bond is so strongly activated that a base catalysed H/D exchange

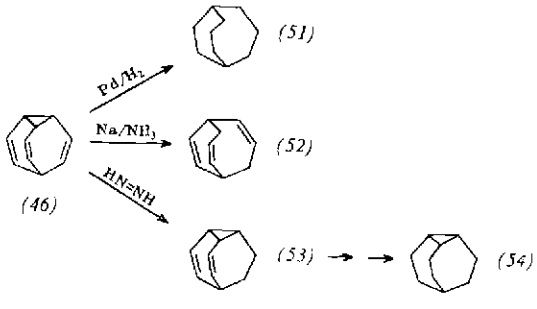


is possible. Bicyclo[3,2,2]nona-2,5-diene *(50)* takes up deuterium in the system ROK/ROD at about 160 °C [45]. In this case only the olefinic protons are replaced. By analogy it is assumed that the most strongly acidic protons in bullvalene are also the olefinic hydrogen atoms. Deuterium entering bullvalene at the double bond should immediately become randomly distributed over the entire molecule. Bullvalene undergoes an H/D exchange in the system ROK/ROD at 160 °C. The infrared spectrum of the product contains distinct C–D stretching vibrations in the olefinic and aliphatic regions [21].

c) The Chemistry of Bullvalene [21]

Bullvalene is exceptionally stable. It decomposes only at about 400 °C; the reaction takes about 10 min and yields naphthalene and hydrogen.

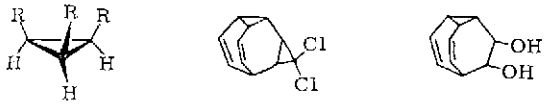
Catalytic hydrogenation over palladium results in the uptake of four moles of hydrogen to form *(51)*, m.p. 180 °C. The action of sodium in liquid ammonia followed by addition of ethanol reduces bullvalene to *(52)*, m.p. 45 °C. Thus the two sodium atoms add in the 1,4-position to the vinylcyclopropyl system in bullvalene. The three double bonds of *(46)* are hydrogenated in succession by diimine. Dihydrobullvalene *(53)*, m.p. 62 °C, can be prepared in this way. This is also a molecule



[45] *G. Schröder*, unpublished work.

with a fluctuating bond, and is the simplest homotropilidene bridged by two carbon atoms. The NMR spectrum of *(53)* is temperature-dependent (Section II). A large excess of diimine leads to *(54)*, m.p. 126 °C.

The three-membered ring in *(46)* can be detected chemically both by the formation of the compound *(54)* and by degradation. The ozonolysis of bullvalene, followed by reduction with sodium borohydride and esterification of the triol (which is not isolated), leads to *cis*-1,2,3-tris-(acetoxymethyl)cyclopropane *(55)*.



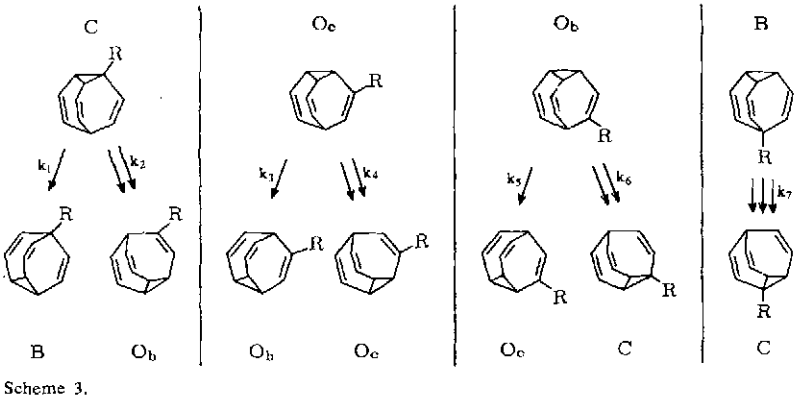
R = CH_2OAc *(55)* *(56)* *(57)*

Bullvalene reacts smoothly with dichlorocarbene and with osmium tetroxide/mannitol to form the products *(56)* and *(57)* respectively. As expected, the NMR spectra of *(56)* and *(57)* are temperature-dependent [9,34]. Kinetic data for *(56)* are given in Table 3.

d) Substituted Bullvalenes

A substituted bullvalene has about 1.2×10^6 valence-bond isomers which unlike those of bullvalene are not all structurally identical [1].

Four positional isomers are possible for monosubstituted bullvalene. Whereas the valence isomerization of bullvalene is characterized by one rate, seven elementary rates of isomerization must be distinguished in monosubstituted bullvalenes. Scheme 3 shows the four positional isomers (C: substituent on the cyclopropane ring; O_c and O_b: on the olefinic double bond near the cyclopropane ring and near the bridgehead respectively; B: on the bridgehead) and the seven rates of isomerization (k_1–k_7) of a monosubstituted bullvalene.

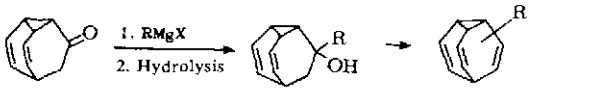


Scheme 3.

The number of positional isomers and the number of possible valence isomerizations increase with the number of substituents. In a bullvalene with nine different substituents, there are 10!/6 = 604800 different chemical environments for the single remaining bullvalyl proton.

e) Preparation of Some Monosubstituted Bullvalenes

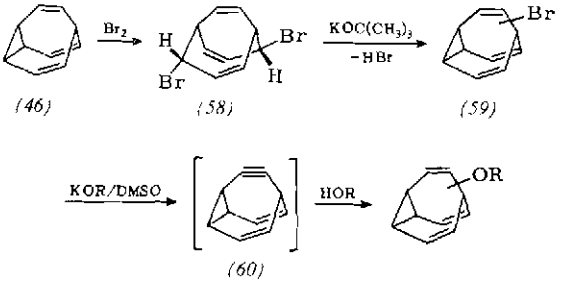
Phenylbullvalene and methylbullvalene were prepared by the reaction of a Grignard compound with *(8)*, followed by the elimination of water from the adduct [19].



(8) R = C_6H_5 *(35)*; R = CH_3 *(13)*

Another synthesis of phenylbullvalene *(35)* has already been mentioned in Section III,2f.

A useful route to monosubstituted bullvalenes is the bromination of bullvalene [1,24]. The dibromide *(58)* loses hydrogen bromide in the presence of potassium alkoxide, giving good yields of bromobullvalene *(59)*, which is used for the preparation of other monosubstituted bullvalenes. Thus *(59)* reacts with alcohol-free potassium alkoxides in dimethyl sulfoxide, presumably *via* dehydrobullvalene *(60)* [*] to form the alkoxybullvalenes *(61)* to *(64)*, with R = $C(CH_3)_3$, $CH(CH_3)_2$, C_2H_5, and CH_3 respectively.



(46) *(58)* *(59)* *(60)*

f) NMR Studies on Monosubstituted Bullvalenes [1]

In bullvalene and substituted bullvalenes there are three courses open to each valence-bond isomerization, *i.e.* any one of the three cyclopropyl bonds can break. Bullvalene itself has a threefold axis of symmetry and each of the three cyclopropyl bonds has an equal probability of being broken. The isomers C, O_c, and O_b (Scheme 3) possess only a plane of symmetry, so that two isomerization processes are possible in each case. The isomer B also has a threefold axis of symmetry and therefore only a single rate of isomerization. The high-temperature spectra of all the monosubstituted bullvalenes studied so far contain only one singlet for the nine bullvalyl protons. On the one hand this proves the bullvalene skele-

[*] Note added in proof: In the presence of furan an adduct $C_{14}H_{12}O$, which exhibits a temperature-dependent NMR spectrum, can be isolated (*H. Röttele*, Doctorate dissertation, Technische Hochschule Karlsruhe).

ton, while on the other it shows that the molecule passes through all the possible valence-isomeric structures.

Table 4. NMR signals of the bullvalyl protons and average rates of isomerization $\bar{k}$ in monosubstituted bullvalene derivatives [46]. τ = chemical shift, τ = 10 for tetramethylsilane as internal standard.

[a] Cf. Scheme 3

The line width of the singlet and the average rate of isomerization $\bar{k}$ at a given temperature depend on the substituent (see Table 4).

If all seven rate constants were equal, 30% of the molecules on the average would be in each of the C, O_c, and O_b structures, while 10% would have the B structure. Certain valence isomerizations, however, are at a disadvantage with respect to others, so that the distribution of the positional isomers depends on the rate constants. Information on rate constants k_1–k_7 can be obtained from the temperature-dependent NMR spectra of monosubstituted bullvalenes (see Table 4); for a discussion cf. [1].

The isomers of monosubstituted bullvalenes in which the substituent occupies an olefinic position (O_b and O_c) are preferentially formed. This is mainly due to the fact that substituents are more firmly bonded to an olefinic than to an aliphatic carbon atom (bond effect).

In the compounds *(35)*, *(62)*, *(63)*, and *(64)*, O_b is strongly preferred owing to the possibility of conjugation between the substituent and the vinylcyclopropyl system of the bullvalene skeleton. In *(61)*, O_b and O_c are present in approximately equal quantities. Owing to steric hindrance, the bulky t-butyl group in this case is twisted into a configuration which does not favor optimum conjugation, so that the conjugation effect is subordinate to the bond effect. It cannot be decided whether O_b and O_c, or O_b alone predominate in the equilibrium mixture in *(59)*.

IV. Conclusion

We speak of molecules with fluctuating bonds when the valence isomers have a mean lifetime of less than about 100 sec at 0 °C. Such molecules can so far be unambiguously recognized and studied only by NMR spectroscopy. The study of the bond shifts in substituted cyclooctatetraenes and bullvalenes is particularly interesting since the rate of shift depends on the substituent. This gives information on the relative importance of bonding, conjugation, steric, and inductive effects.

[46] $\bar{k}$ is that rate constant which, in the case of bullvalene, would give the same line width as the one observed for the derivative studied.

Conformational Analysis in Mobile Cyclohexane Systems

BY PROF. DR. E. L. ELIEL
DEPARTMENT OF CHEMISTRY, UNIVERSITY OF NOTRE DAME, NOTRE DAME, INDIANA (U.S.A.)

By "Conformational Analysis" is meant the analysis of the physical and chemical properties of a compound in terms of its preferred "conformations", i.e. rotational arrangements about single bonds. This particular review deals with cyclohexanoid compounds capable of existing in two or more stable conformations.

I. Historical

That cyclohexane is a puckered, chair- (or boat-)shaped molecule was first suggested by *Sachse* [1] 75 years ago. Because of a lack of appreciation of the restrictions to rotation about single bonds and other misunderstandings, *Sachse*'s theories were rejected for nearly 30 years, to be revived only in 1918 by *Mohr* [2] and soon to be confirmed by the classical work of *W. Hückel* on decalin [3] and of *Boëseken* and coworkers on the acetone and boric acid derivatives of cyclic diols [4]. Still the ideas

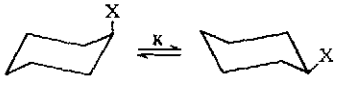
gained only slow acceptance, being used but occasionally by carbohydrate chemists [5]; however, during this period a better understanding of rotational barriers was gained, first in the biphenyls [6] and later in ethane [7], which is now known to exist in the "staggered" rather than the "eclipsed" conformation. This phase of development culminated with some very significant work by *Mizushima* [8] on spectroscopic studies of substituted ethanes, by *Hassel* [9] on X-ray and electron diffraction of simple substituted cyclohexanes, and by *Pitzer* [10] on the shape and thermodynamic properties of cyclohexane derivatives. However, the real breakthrough in the field did not come until 1950 when *D. H. R. Barton*, in a pioneering paper [11], pointed out the consequences of conformational differences on stability and reactivity. This was an area of great interest to organic chemists, first those engaged in natural products research and then also those investigating fundamental molecular behavior, and *Barton*'s ideas were absorbed, utilized and further developed rapidly and intensively. The resulting mushrooming growth of the subject has carried it, within less than 15 years, to the point where a comprehensive review requires the format of a book and two such books have recently appeared [12, 13]. A number of earlier review articles have been listed elsewhere [14, 15].

II. Scope

Clearly only a limited review is within the scope of the present article [16]. Conformational concepts play a part in acyclic, alicyclic and heterocyclic systems; among the cyclic ones, rings from four-membered on are nonplanar and therefore of particular interest in conformational analysis. We shall confine ourselves here to six-membered and, in most instances, carbocyclic rings.

Of the two possible puckered forms of cyclohexane, the chair and the boat, the chair is the more stable because its bonds are all staggered. (In contrast, the boat has four pairs of eclipsed hydrogen plus other unfavorable interactions.) In the chair form, there are two types of bonds, those pointing up and down, called "axial" and those pointing outward, called "equatorial". The two types of bonds are readily distinguished in a model.

In the following discussion, we shall refer, primarily, to "mobile systems" which are defined as systems which can alternate between two or more stable conformations. The monosubstituted cyclohexane *(1)* provides an example; it can exist in two conformations, one with



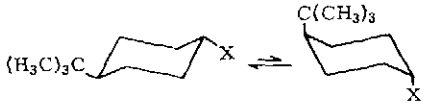
(1a) *(1b)*

the substituent equatorial, the other one with the substituent axial. The two conformations are readily interconvertible (see below) and the equatorial conformation is more stable. Systems of this type are of particular interest because their reactivity depends on the population of the various pertinent conformations.

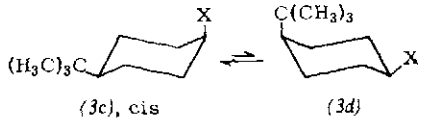
In contrast to mobile systems are rigid systems, such as *trans*-decalin *(2)* or the steroids – in which ring inversion is impossible because the alternate chair form would

(2)

be excessively strained – or biassed systems, such as a 1-halo-4-t-butylcyclohexane *(3)*. X = halogen – in which ring inversion is possible but the molecule exists in one conformation almost to the complete exclusion of the other(s), because of a large difference in stability. In



(3a), trans *(3b)*



(3c), cis *(3d)*

the case of t-butylcyclohexane, it is estimated that the conformation with the equatorial t-butyl group *(3a,c)*, X = H, predominates over that with the axial t-butyl group *(3b,d)*, X = H, by a factor of at least 10000 at room temperature, because the compression of nonbonded atoms in the t-butyl-axial conformation raises the potential energy of this form by over 5 kcal/mole [17, 18]. There are not many other groups which have a similar "reluctance" to occupy the axial position.

It should be pointed out that, although we tend to think of cyclohexanoid molecules as perfectly puckered chairs with tetrahedral angles, such models are oversimplified. In cyclohexane itself the C–C–C bond angle has been found [19] to be 111.5°, somewhat larger than the tetrahedral angle of 109° 28′ and it has been pointed out [20] that the resulting slight flattening of the chair significantly influences the physical and chemical properties of certain cyclohexane derivatives. Moreover, the existence of deformed chairs [21] and even boat forms [22, 23] especially in some substituted cyclohexanones [23a], but also in a few saturated systems [18, 23b] is becoming increasingly recognized. Major deviations from chair geometry probably do not occur in the molecules to be discussed in this review, but the minor flattening of the cyclohexane ring does affect them and will be returned to later.

III. Terminology

The terminology of conformation analysis is now generally known and has been reviewed recently [14]. We wish to introduce only two new terms here [12]. The term "conformational energy" will denote the free energy of a conformation above that of the conformation of minimum energy. For example, the negative of the free energy ΔG° for the process *(1a)* $\rightleftharpoons$ *(1b)* is the conformational energy of the axial form *(1a)*. – The term "*syn*-axial" groups will be used to denote axial groups on the same side of a cyclohexane ring and therefore in close spatial proximity (and frequently steric interaction).

IV. Aims

Monosubstituted cyclohexanes *(1)* can exist in two conformations, one with the substituent equatorial, the other with the substituent axial. The two conformations are readily interconverted through rotations about single bonds attended with slight angle deformations. The potential energy diagram for the interconversion process is shown in Fig. 1. Here, ΔG_X° represents the difference in free energy (*i.e.* the conformational energy) of the two chair forms.

The high energy valley between the more stable chair conformations corresponds to a form in which one side of the chair has been flipped up but the other has not yet been flipped down; this form was originally [1] called the "flexible form" and was later labelled "boat form". In fact, this form (in contrast to the chair) is flexible; model considerations show that various possible boat forms can be interconverted by minor contortions of the molecule. The boat form, however, suffers from unfavorable bond eclipsings [7] on the side of the boat and van der Waals interactions between the hydrogen atoms at the "bowsprit" and "flagpole" positions, and it has been calculated [24] that the most stable conformation of the flexible form is one in between two boat forms, now commonly called the "twist form" or "skew boat". The potential energy of this form has been estimated by computer calculation [24] to be 1.6 kcal/mole less than that of the classical boat but about 5.5 kcal/mole more than that of the chair (cf. Fig. 1); the latter value has been confirmed both through equilibration [18] and heat of combustion [25] measurements involving molecules which, for steric reasons, exist predominantly in the twist form. The energy barrier between the chair and twist forms (Fig. 1) has also been calculated; it is 10–11 kcal/mole above the chair and corresponds to a conformation in which four adjacent atoms of the ring are in a plane ("half-chair"). The value of 10–11 kcal/mole has been confirmed by nuclear magnetic resonance measurements [26, 27] and a similar value was obtained by ultrasonic measurements [28]; it is small enough so that at room temperature substituted cyclohexanes rapidly pass from one chair form into the other by virtue of the thermal excitation of the molecules.

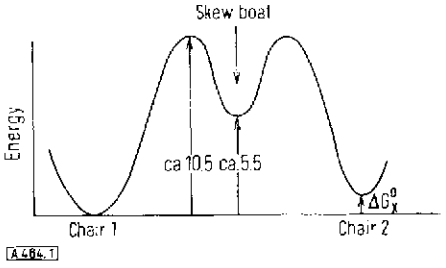

Fig. 1. Potential energy diagram for the chair-chair interconversion of monosubstituted cyclohexanes (schematic). The numbers are energies in kcal/mole.

For the remainder of this review, we shall concentrate on a discussion of the conformational energies $-\Delta G^\circ$ for cyclohexanes with different groups X, their rationale and the ways in which they may be obtained.

V. Results

The $-\Delta G^\circ$ values for all the groups so far studied are given in Table 1. This table represents a summary of data found in about 75 original papers. It is seen that the

conformational free-energy values are not monotonous functions of atom or group size. For example, there is little progression in $-\Delta G^\circ$ value in the halogens from chlorine to iodine; bromocyclohexane has a much smaller conformational energy than methylcyclohexane (although both substituents are ordinarily considered isosteric); the value for cyclohexanecarboxylic acid is smaller than that for methylcyclohexane which is not much smaller than that for isopropylcyclohexane. Tosyloxycyclohexane has about the same conformational energy as cyclohexanol.

In principle, the conformational energy can be calculated from first principles, taking into account the repulsive (or attractive) energy for the atoms in question (or for all the atoms of a group such as methyl) with salient carbon and hydrogen atoms in the ring both in the equatorial and in the axial position and taking the difference. Such calculations [29, 30] have shown that the main interactions are of the equatorial group with adjacent hydrogens (at carbon atoms 2 and 6) and of the axial group with adjacent hydrogens, *syn*-axial hydrogens, and carbon atoms 3 and 5. Other interactions are either negligible or cancel out. Unfortunately, because of insufficient knowledge of the van der Waals potential functions which form the basis of the calculations, the results are not very accurate, which is particularly unfortunate in view of the fact that the differences one looks for are only of the order of 0–2 kcal/mole (Table 1). Therefore at the moment the experimental approach seems to be the only one feasible; and while the calculations are sometimes valuable to indicate trends, it is also worthwhile to acquire some intuitive ideas about conformational energies, based on existing data. It is with this aim in mind that the data will now be discussed.

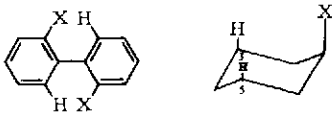
VI. Discussion

As already mentioned, there is not a one-to-one correlation between conformational energies and group sizes as inferred, for example, from the ease of racemization of *ortho*-substituted biphenyls [31]. Thus the halogenocyclohexanes have similar $-\Delta G^\circ$ values although the size of the halogens certainly increases in the order fluorine < chlorine < bromine < iodine. While the value for fluorocyclohexane is somewhat smaller than that for chlorocyclohexane, the value for iodocyclohexane is hardly any larger than that for bromocyclohexane and the latter value is actually slightly but significantly smaller than that for chlorocyclohexane [32]. One reason for this lack of parallel is seen from formulae *(4)* and *(5)*: whereas in the case of *ortho*-substituted biphenyls the interfering groups point toward each other and the interference will become more severe as the bond lengths of the atoms or groups involved increase, the contrary is true in axially substituted



(4) *(5)*

cyclohexanes. Here, the longer the bond to the axial substituent, the further the substituent will be away from the *syn*-axial hydrogens and the carbon atoms 3 and 5 which cause the axial crowding. This, to some extent, compensates for the larger van der Waals radius of the bigger substituents. By the same token, the flattening of the ring [20] leads to a bending outward of the axial substituent, and this motion, by a simple leverage principle, will provide most effective steric relief to the substituents with the longest bonds, *i.e.* the large substituents. These two factors may explain in part why bromocyclohexane (van der Waals radius of Br 1.95 Å) has a much smaller conformational energy (0.4 kcal/mole) than methylcyclohexane (1.7 kcal/mole; van der Waals radius of the methyl group: 2.0 Å).

[31] *R. L. Shriner* and *R. Adams* in *H. Gilman*: Organic Chemistry. Wiley, New York 1943, Vol. 1, p. 362.
[32] a) *E. L. Eliel* and *R. J. L. Martin*, unpublished data; b) *J. Reisse, J. C. Celotti*, and *G. Chiurdoglu*, Tetrahedron Letters *1965*, 397.

There is probably, however, a third reason: the larger atoms such as bromine tend to be more polarizable and therefore the attractive London forces are more important for such atoms. London forces are particularly important just within (and just outside) the van der Waals radial distance. As shown in Figure 2, they would lead to a deeper and shallower well in the van der Waals potential function.

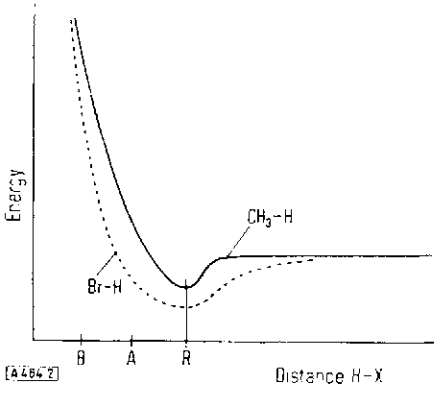


Fig. 2. Potential curves (schematic) for (——) CH_3—H interactions and (. . . .) Br—H interactions. R = van der Waals radius, A = distance between an axial substituent and *syn*-axial hydrogen atoms in monosubstituted cyclohexanes, B = distance between *ortho*-substituents in biphenyl derivatives of type *(4)*.

Since axial atoms and groups usually find themselves just within the van der Waals distance from the offending *syn*-axial hydrogens, *etc.* (point A, Fig. 2), the shape of the curve at this point is quite significant and a group of low polarizability such as methyl (analogous to a hard or wooden sphere) finds much less steric relief due to London attraction than a polarizable group, such as bromine (analogous to a soft or rubbery sphere). In biphenyls *(4)* these considerations are much less important because the interatomic distance of the *ortho*-substituents is much less, and the groups find themselves in a strongly repulsive part of the van der Waals curve (point B, Fig. 2) where attractive London forces ($E \propto 1/r^6$) are no longer important compared to the repulsive force ($E \propto 1/r^{12}$).

Another point of interest in Table 1 is that the atom next to the cyclohexane ring in large measure determines the conformational energy; other atoms attached to the first one are much less important. Thus OH, OAc, OCH_3, OC_2H_5, OTosyl all have very similar conformational energies, as have SH, SCH_3, and SC_6H_5 or CH_3, C_2H_5, and $CH(CH_3)_2$. Model considerations quickly show the reason for this finding; the group may be so rotated that any atom attached to the first points away from the ring. This will, in essence, leave the conformational energy unaffected except for a small decrease in entropy of mixing in the case of the axial substituents because of the elimination of one or two alternate rotational conformations of the axial substituent in which the attached group would point into the ring. In the extreme case, where the equatorial substituent has three equally probable conformations and the axial one has only one, this difference would amount to Rln 3 or 2.2 cal. $mole^{-1}$ $deg.^{-1}$, corresponding to a conformational free energy difference of 0.65 kcal/mole at room temperature. In fact, the difference will always be less than that.

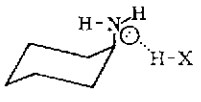
An exception occurs with a substituent with three attached groups, such as t-butyl, $C(CH_3)_3$. In this case one cannot avoid having one group (methyl) point into the ring when the substituent is axial; this results in a very sizeable compression with the *syn*-axial hydrogens and accounts for the great reluctance of the t-butyl group to occupy the axial position (*trans*-1,3-di-t-butylcyclohexane actually prefers the skew-boat conformation to one with axial t-hutyl [18]).

In this context, the relatively small conformational energy of cyclohexyl phenyl sulfone (2.5 kcal/mole) comes as a surprise; in the series of cyclohexanes with SR, S(O)R, $S(O)_2R$ as substituents, the big jump in $-\Delta G^0$ comes between sulfide and sulfoxide, not between sulfoxide and sulfone. This may be a consequence of the difference in hybridization and in bond angle between —SR, —S(O)R, and $-S(O_2)R$.

A comparison of R—COOH with $R-COO^-$, R—SH with $R-S^-$ and $R-NH_2$ with $R-NH_3^+$ (R = cyclohexyl) suggests that the ions are always apparently larger than the parent groups. Presumably this is to be ascribed to solvation which leads to a "swelling" of the ionic substituent.

The effect of hydrogen bonding on group size is evident when one compares the conformational energies of cyclohexylamine in aprotic and protic solvents; the former value is 1.1 kcal/mole, the latter 1.5–1.8 kcal/mole [33]. The size of the hydroxy group is also increased by hydrogen bonding [15, 34]; thus $-\Delta G^\circ$ for cyclohexanol is 0.6 kcal/mole in cyclohexane but 0.9 kcal/mole in isopropyl alcohol [35]. On the other hand, the size of the halogen atoms appears to be largely independent of solvent [32], indicating that hydrogen bonding is too weak to make a difference except possibly in trifluoroacetic acid. While it has not yet been established whether hydrogen bonding affects conformational enthalpy or conformational entropy, the chances are that with a group which has two or three free pairs of unbonded electrons (such as hydroxy) entropy is mainly involved and that the higher conformational energy of an axial substituent capable of hydrogen bonding in a protic solvent is due to the fact that the hydrogen bond forms preferably on the outside of the ring and thus interferes with certain rotational conformations of the axial suhstituent. However, with a group which has only a single pair of unbonded electrons, *e.g.* NH_2 *(6)*, hydrogen bonding may force the axial group into an unfavorable rotational conformation *(7)*.

(6)



(7)

Besides varying with solvent, conformational free energies may also vary with phase. For example, in polymethylcyclohexanes the axial isomers not only have the higher enthalpies

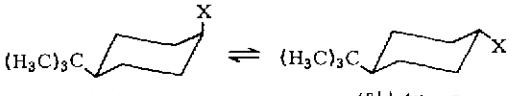
[35] *E. L. Eliel* and *S. H. Schroeter*, J. Amer. chem. Soc., in the press.

but also the higher latent heats of vaporization. This means that the excess energy content of the axial isomer over the equatorial is greater in the vapor phase than in the liquid and, in fact, the best experimental value for the conformational energy of methylcyclohexane is 1.7 kcal/mole in the liquid phase and 1.9 kcal/mole in the vapor.

The figures in Table 1 are free energy differences. As yet, few careful experimental apportionments of these free energies between enthalpy and entropy terms have been made. It might be expected that no conformational entropy differences would be found for spherically or cyclindrically symmetrical groups, such as methyl, halogen, cyano, ethynyl. In fact, however, experimental differences have been claimed for methyl [36], cyano [37], chlorine, and bromine [32b]. The significance of these findings is somewhat uncertain in view of the difficulty of measuring entropy differences to better than 0.5 cal·mole^{-1}·degree^{-1}, but a possible explanation in terms of rotational entropy has been offered [32b]. In the case of non-symmetrical groups, entropy differences would definitely be expected; thus the differences in $-\Delta G^\circ$ for methyl-, ethyl-, and isopropyl-cyclohexanes are adequately accounted for by entropy considerations [38]. Careful measurement has recently been made [39] of the thermodynamic parameters for the equilibrium *(8a)* ⇌ *(8b)* which, presumably, corresponds to the

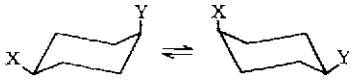


(8a), cis *(8b)*, trans

X = $-CO_2H$

conformational equilibrium of the carboxyl group (see Section VII). Determinations of equilibrium from 212 to 333 °C in dodecane as a solvent indicates $\Delta H^\circ = -1.63 \pm 0.05$ kcal/mole, $\Delta S^\circ = -0.8 \pm 0.2$ cal·mole^{-1}·degree^{-1}, and $\Delta G^\circ = -1.4 \pm 0.1$ kcal/mole (extrapolated to 25 °C). The negative value of ΔS° is surprising at first, as one might have expected an equatorial COOH group to have more conformational freedom than the corresponding axial group. It appears, however, that the equatorial acid is more strongly associated in dodecane solution with a resultant greater loss in translational entropy [*].

As yet, little definite is known about conformational equilibria in di- and polysubstituted cyclohexanes, *e.g.* *(9)*, X + Y. It is generally assumed that the conformational energies are additive, *i.e.* $\Delta G^\circ = \Delta G^\circ_Y - \Delta G^\circ_X$ for the compounds *(9a)* and *(9b)*. Some support for this assumption has been obtained for 1,3- and 1,4-disubstituted cyclohexanes [15, 40, 41] although there are also difficulties [15]. In 1,2-disubstituted cyclohexanes, the principle of additivity cannot be expected to hold for two reasons: one is that, because of the flattening of the ring, *cis*-substituents (equatorial-axial) are closer together and therefore have a greater steric



(9a) *(9b)*

interaction than *trans*-substituents (equatorial-equatorial) [20, 42, 43]; the other is that substituents which are not spherically symmetrical may be forced into different rotational conformations by adjacent substituents [44, 45]. Thus in a *cis*-2-isopropylcyclohexanol, the e-hydroxy,a-isopropyl conformation is unfavorable by much more than the difference in $-\Delta G^\circ$ values of cyclohexanol and isopropylcyclohexane (1.4 kcal/mole [42]). The reason is that the axial isopropyl group cannot readily assume its normal conformation (methyls out of the ring) since this leads to strong steric interaction with the OH group (equivalent to a hydroxymethyl *syn*-axial interaction) [44].

In 1,1-disubstituted cyclohexanes, it has been assumed [46] that the $-\Delta G^\circ$ values are additive. This assumption seems to be justified in 1-chloro-1-methylcyclohexane in which $-\Delta G^\circ$ (1.1 kcal/mole in favor of the a-chlorine, e-methyl conformation) [47] is close to the difference of the conformational energies of methylcyclohexane (1.7 kcal/mole) and chlorocyclohexane (0.4 kcal/mole).

VII. Methodology

Since the equilibrium *(1a)* ⇌ *(1b)* is established in a fraction of a millisecond at room temperature, direct measurement of the position of equilibrium is possible only by physical methods (see below). However, there are various indirect chemical approaches to the problem.

A. Thermochemical Method

In the simplest approach, the conformational equilibrium *(1a)* ⇌ *(1b)* is replaced by a configurational equilibrium – hypothetical or actually achievable – for example *(10a)* ⇌ *(10b)*. Since a *cis*-1,3-disubstituted

cyclohexane exists virtually exclusively in the diequatorial form (the diaxial conformation has a severe 1,3-*syn*-axial steric interaction of the substituents) and each enantiomer of the *trans*-isomer necessarily exists in one of two superimposable equatorial-axial conformations, the enthalpy difference between the two configurational isomers may be equated to the enthalpy difference between equatorial and axial X (assuming that the second substituent does not exert a disturbing influence). The enthalpy difference may be found directly by accurate determination of the heats of combustion of the *cis*- and *trans*- isomers and this approach has been used successfully in the case of the 1,3-dimethylcyclohexanes [48]. The heat of combustion of the *trans*-isomer is 1256.75 kcal/mole and that of the *cis*-isomer 1254.79 kcal/mole (gas phase); the difference of 1.96 kcal/mole thus represents the greater stability of equatorial methyl over axial in the gas phase. The corresponding value in the liquid phase similarly determined is 1.72 kcal/mole.

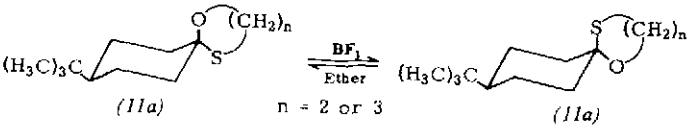
It is clear that in order to achieve an accuracy of approximately $\pm 10\,\%$ in the conformational energy difference required an accuracy of nearly 1 part in 10000 in the heat-of-combustion data themselves. Such accuracy is extraordinarily difficult to achieve, requiring not only very careful measurement but also extremely pure samples. The attendant difficulties have discouraged wide-spread use of the method.

In the case of the 1,3-dimethylcyclohexanes the entropies of the *cis*- and *trans*-(±)-isomers have also been measured [49] and the difference is found to be 1.24 cal·mole^{-1}·degree^{-1} in favor of the *trans*-form, in good agreement with the expected value of 1.38 cal·mole^{-1}·degree^{-1} calculated on the assumption that the only entropic difference between the *cis*- and *trans*-isomers stems from the fact that the *trans*-isomer is a (±)-pair and is therefore favored by an entropy of mixing of R ln 2. From the experimental values of ΔH° and ΔS° for the 1,3-dimethylcyclohexanes one may calculate ΔG° at 25 °C to be −1.59 kcal/mole for the equilibrium *trans* ⇌ *cis* (gas phase). It must be recognized that this value bears no direct relation to the conformational energy of methylcyclohexane. To obtain ΔG° for the conformational equilibrium *(1a)* ⇌ *(1b)*, X = CH_3, it is best to assume that $\Delta S^\circ = 0$ and therefore $\Delta H^\circ = \Delta G^\circ = -1.96$ kcal/mole in the gas phase. The assumption that ΔS° between equatorial and axial methylcyclohexane is zero is best justified by the observation (*vide supra*) that the entropy difference for the dimethylcyclohexane is completely accounted for (within limits of experimental error) by the entropy-of-mixing term (which does not enter into the methylcyclohexane conformational equilibrium).

B. Equilibrium Methods

An alternative and usually experimentally easier approach is to establish the equilibrium *(10a)* ⇌ *(10b)* directly and to measure the equilibrium constant K (*e.g.* by gas chromatographic determination of the equilibrium position); then $\Delta G^\circ = -RT \ln K$. In principle, ΔH° can be measured from the temperature dependence of K, but to effect such measurements with the required degree of accuracy is quite painstaking, and some of the data in the literature in this regard must be viewed with reserve. Short of performing a really careful measurement of ΔH°, it is probably better, for a spherically symmetrical group such as methyl, to assume that ΔS° for the process *(10a)* ⇌ *(10b)* is $-R \ln 2$ and then to calculate ΔH° at the desired temperature. An even safer approach, applicable to all groups, is to assume that $-\Delta G^\circ_X$ for the equilibrium *(1a)* ⇌ *(1b)* may be obtained from $-\Delta G^\circ$ for the process *(10a)* ⇌ *(10b)* by adgdin RT ln 2. This, in essence, entails the assumption that the process *(10a)* ⇌ *(10b)*, but for the equilibrium (optically active *trans*) ⇌ (*meso-cis*) does, in fact, have the same equilibrium constant as *(1a)* ⇌ *(1b)*. These principles were applied to the equilibration of the diethyl hexahydroisophthalates *(10)*, X = $CO_2C_2H_5$, [50] for which equilibrium at 78 °C corresponds to 71 % *cis*- and 29 % *trans*-isomer, $-\Delta G^\circ$ being 0.63 kcal/mole. From this, applying the RT ln 2 correction, $-\Delta G^\circ_{CO_2C_2H_5}$ is 1.11 kcal/mole.

An alternative but related approach is to measure the equilibrium position for *cis*- and *trans*-4-t-butyl isomers *(8)*. Thus, for example, for *(8)*, X = $CO_2C_2H_5$, equilibrium corresponds to 84.7 ± 0.6 % *trans*-isomer [51], whence $-\Delta G^\circ_{CO_2C_2H_5}$ may be directly calculated to be 1.2 kcal/mole. In some cases, where groups cannot readily be equilibrated directly at temperatures in the vicinity of 25 °C, some indirect means of equilibration may be resorted to. For example, the equilibrium constant for the equilibrium *(11a)* ⇌ *(11b)* has been shown to be close to unity [52]. Since it was known from other measurements [53] that $-\Delta G^\circ_{OR} \approx 0.7$ kcal/mole, it may be inferred that $-\Delta G^\circ_{SR}$ is of the same order of magnitude.



(11a) *(11a)*

A somewhat more intricate method of indirect equilibration is shown by formulae *(12a)*–*(12c)*. It is known [54] that equilibration of 4-t-butylcyclohexanol with $LiAlH_4/AlCl_3$/4-t-butylcyclohexanone in ether (probably an oxidation-reduction type of equilibration involving the complex $ROAlCl_2$, cf. [55]) leads to an equilibrium mixture containing over 99.5 % of the *trans*-complex. Therefore, for any R in *(12)* which is appreciably smaller than t-butyl, virtually all the *cis*-isomer exists in the conformation C′ *(12c)*, and what is chemically an

(12a), T *(12b)*, C *(12c)*, C'

equilibration between T *(12a)* and C *(12b)*, thermodynamically may almost be considered as an equilibration of T and C' so that the measured equilibrium constant K_{epi} leads directly to ΔG°_{R}. More exactly, we have an equilibrium between T and (C + C'). Therefore

$$K_{epi} = [T]/([C] + [C'])$$

and

$$1/K_{epi} = [C]/[T] + [C']/[T]$$

$$= 1/K_{OAlCl_2} + 1/K_R$$

$$= 1/K_R + 1/200$$

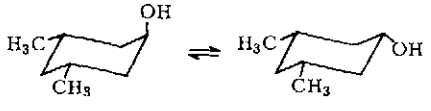
$$1/K_R = 1/K_{epi} - 1/200.$$

Unfortunately, although the method has been successfully applied to alkylcyclohexanes [54, 56], complications of various kinds [42, 57] seem to prevent its application to cyclohexanes containing more polar substituents.

Among other indirect equilibration methods, one which seems to be quite widely applicable involves equilibration (at C-5) of 3β-substituted 6-ketosteroids [58]. Since in a 3β-substituted 5α-ketosteroid the 3-substituent is equatorial but in the corresponding 5β-ketosteroid it is axial, equilibration of the two ketones leads to the $-\Delta G^{\circ}_{X}$ value of the 3β-substituent after a correction is applied for the equilibrium of the unsubstituted 5α- and 5β-ketosteroids.

In yet another interesting indirect equilibration method, $-\Delta G^{\circ}_{CO_2CH_3}$ is correlated with $-\Delta G^{\circ}_{CO_2H}$ through measurement of esterification equilibria [36].

Implicit in the application of the equilibration method, *e.g.* to the process *(8a)* ⇌ *(8b)*, is the assumption that the 4-t-butyl substituent does not affect the position of equilibrium. The only available justification for this assumption lies in the fact that $-\Delta G^{\circ}_{X}$ determined by the equilibrium method using either 4-t-butyl-substituted models *(8)* or 1,3-disubstituted compounds of the type *(10)* agrees with values obtained by other methods. In the case of cyclohexanols, it has been found [59] that $-\Delta G^{\circ}_{OH}$ determined by equilibration of the *cis*-3,5-di-



(13a) *(13b)*

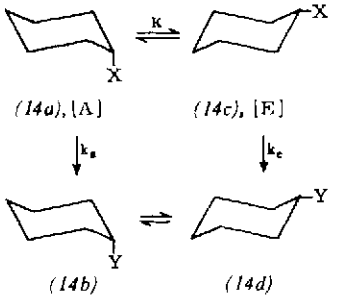
methylcyclohexanols *(13a)* and *(13b)* agrees perfectly with the value (0.93 kcal/mole) derived from similar equilibration of 4-t-butylcyclohexanol; the value of 1.23 kcal/mole derived from equilibration of the 3-t-butylcyclohexanols [42] on the other hand, disagrees completely and is out of line with other values of $-\Delta G^{\circ}_{OH}$. The difficulty here may be due to a strong distortion of the cyclohexane ring, although this point has not been clearly established.

C. The Kinetic Method

One of the earliest methods to assess conformational equilibria, discovered independently in *Winstein*'s laboratory [17] and in the present author's [40] is based on rate measurements. As suggested in formulae *(14a)–(14d)*, the reaction

$$C_6H_{11}X \rightarrow C_6H_{11}Y$$

of a mobile substituted cyclohexane may be looked at as really being two reactions: that of the axial conformational isomer and that of the equatorial conformational isomer.



(14a), [A] *(14c)*, [E]

(14b) *(14d)*

If the concentration of the axial conformer is [A] and its rate constant k_a, and if the concentration and rate constant for the equatorial conformer are [E] and k_e, it follows that

$$\text{rate of reaction} = k_e[E]\,P + k_a[A]\,P,$$

where P is the product of all other concentration terms entering into the rate equation. Experimentally one finds

$$\text{rate of reaction} = k[C]\,P,$$

where [C] is the total concentration of the monosubstituted cyclohexane and k is the observed rate constant. It follows that

$$k_e[E] + k_a[A] = k[C].$$

Remembering that

$$[C] = [E] + [A]$$

and

$$K = [E]/[A],$$

one obtains

$$k_eK + k_a = k\,(K + 1).$$

This equation, in the form

$$k = (k_eK + k_a)/(K + 1)$$

provides a heuristic relationship permitting evaluation of the empirical rate constant k in terms of the rate constants k_a and k_e for the pure conformational isomers and the equilibrium constant K between them. Alternatively, the equation may be regrouped to give

$$K = (k_a - k)/(k - k_e)$$

and, in this form, may serve to assess the conformational equilibrium constant K, if the rate constants k, k_e and k_a are known. It is, of course, simple to determine k; it

[56] *E. L. Eliel* and *T. J. Brett*, Abstracts, 145th Meeting Amer. chem. Soc., New York 1963, p. 19Q. See also [42].

[57] *E. L. Eliel* and *T. J. Brett*, J. org. Chemistry *28*, 1923 (1963).

[58] *D. N. Jones* and *D. E. Kime*, Proc. chem. Soc. (London) *1964*, 334; see also *J. F. Biellman* and *W. S. Johnson*, Proc. nat. Acad. Sci. U.S.A. *53*, 89 (1965).

[59] *E. L. Eliel* and *F. Biros*, unpublished work.

is only necessary to provide a reaction suitable for the substituent under consideration for which a convenient rate measurement is available, *e.g.* saponification for the ester group $CO_2C_2H_5$. The determination of k_e and k_a is much more difficult in principle. *Winstein* has suggested [17] that conformationally biassed systems such as *(3)* will provide suitable models for the determination of k_e [= k_{trans}, *(3a)*] and k_a [= k_{cis}, *(3c)*]; thus the rate constant for the hydrolysis of ethyl *trans*-4-t-butylcyclohexanecarboxylate is $k_e = 8.50 \times 10^{-4}$ l·mole^{-1}·sec^{-1}; k_a for the *cis*-isomer is 0.428×10^{-4} l·mole^{-1}·sec^{-1} and k, the saponification rate of ethyl cyclohexanecarboxylate is 7.25×10^{-4} l·mole^{-1}·sec^{-1}, whence

$$K = (0.428-7.25)/(7.25-8.50) = 6.82/1.25 = 5.45 \text{ at } 25\,^{\circ}C$$

corresponding to $-\Delta G^{\circ}_{CO_2C_2H_5} = 1.00$ kcal/mole.

Although the equation

$$k = (k_eK + k_a)/(K + 1) \text{ [40]}$$

or its equivalent

$$k = N_ek_e + N_aK_a \text{ [17]}$$

(N_a and N_e = mole fractions of the mobile compound in the equatorial and axial conformations)

is rigorously correct, the hypothesis that k_e and k_a can be measured using the appropriate 4-t-butyl analogues is strictly an assumption, which, in turn, involves four postulates:

1) The 4-t-butylcyclohexyl compounds exist virtually exclusively in the conformation with equatorial t-butyl.

2) The t-butyl group exercises no polar effect on the reaction.

3) The t-butyl group exercises no steric effect on the reaction.

4) The t-butyl group does not distort either the ground or transition state of the reaction or, if it does, at least the distortion is compensated in such a way that the activation energy is not affected.

Postulate 1) is well justified by the fact that the conformational energy of the t-butyl group is in excess of 4.4 kcal/mole [42]. Most substituents are small compared to that and it is probably safe to assume, therefore, that the 4-t-butyl-substituted molecules do, in fact, exist in conformations *(3a)* and *(3c)*.

Postulate 2) (absence of polar effects) seems to be justified by the similarity in pK_a of cyclohexanecarboxylic acid (7.82 in aqueous dimethylformamide) and of *trans*-4-t-butylcyclohexanecarboxylic acid (7.79). If there were a major polar effect, it should certainly affect acidity. It must be said, however, that more extensive experimental data [60] suggest that substituents at carbon atom 3 may, in fact, exercise some polar effect, in contrast to those at C-4.

Postulate 3) (absence of **direct** steric effects) is best justified on the basis of molecular models.

[60] *H. van Bekkum, P. E. Verkade,* and *B. M. Wepster,* Proc., Kon. nederl. Akad. Wetensch., Ser. B *64*, 161 (1961).

Postulate 4) (absence of distortive effects) is probably a weak one; since transition states are of relatively high energy, appreciable distortions are likely to occur in them and, especially when the reaction occurs at the ring itself (oxidation of alcohols, S_N1 or S_N2 displacement of cyclohexyl tosylates) the assumption that these distortions affect the ground state and transition state equally in the unsubstituted and 4-t-butyl-substituted homologues may not be warranted. In fact, criticism has been leveled at the kinetic method largely on this ground [61] and it has been pointed out that an analysis of activation parameters in the solvolysis of cyclohexyl tosylates indicates that whereas the free energy of activation of the unsubstituted compound is intermediate between that of the *cis*- and *trans*-4-t-butyl-substituted homologues, the same is not true of the enthalpy and entropy of activation, and the success of the Winstein-Holness (or Eliel-Lukach) relationship therefore is, in this case, a fortuitous circumstance of temperature.

The difficulty in tosylate solvolysis is underscored by recent studies [62] of secondary isotope effects in the solvolysis of [2,2,6,6-D_4]-cyclohexyl tosylates and brosylates [*]. These studies have been interpreted to indicate that the *cis*-4-t-butyl-substituted compound reacts through a chair-shaped transition state whereas the *trans*-isomer reacts through a boat-shaped transition state; most surprisingly, the unsubstituted compound seems to react through a boat-shaped transition state also. Complications have also been found in the reaction of cyclohexyl tosylate and its *cis*- and *trans*-4-t-butyl analogues with thiophenolate [63]; whereas the overall rate constant of the unsubstituted compound (18.8×10^{-5} l·mole^{-1}·sec^{-1}) is appropriately intermediate between that of the 4-t-butyl-substituted prototypes (*cis*: 73.4×10^{-5}; *trans*: 1.72×10^{-5}), the fraction of elimination (as compared to substitution) is greater (0.60) for the unsubstituted compound than either for the *cis*- (0.45) or *trans*- (0.39) 4-t-butyl-substituted one.

Complications of this type are probably exacerbated in the (high-energy) transition states and are therefore more serious in the kinetic method than in other methods; nevertheless, the kinetic method, using 4-t-butyl-substituted models, gives $-\Delta G^{\circ}$ values in accordance with those obtained by other methods so frequently that it appears to be more than a matter of coincidence. As in the case of the equilibrium method, the same is not always true when one uses 3-substituted models which suggests, once again, that any distortion which occurs in the monosubstituted cyclohexane also occurs in the 4-t-butyl- or other 4-alkylcyclohexanes but not necessarily in a 3-alkylcyclohexane. Some pertinent data from recent work [59] are shown in Table 2; clearly the acetylation rates of variously substituted cyclohexanols

[*] Tosyl = *p*-toluenesulfonyl; brosyl = *p*-bromobenzene-sulfonyl.

[63] *E. L. Eliel* and *J. West*, unpublished observations.

of analogous conformation are not constant and it turns out that a value for ΔG°_{OAc} consistent with other values in the literature may be obtained from the 4-t-butyl-substituted models but not, for example, from the *cis*-3,5-dimethyl-substituted models (which would give $\Delta G^{\circ}_{OAc} \approx 0$, an unreasonable value).

Table 2. Rate constants for the acetylation of substituted cyclohexanols at 25 °C [59]. Acetylating agent: acetic anhydride/pyridine. The rate constant for the acetylation of cyclohexanol is k = 8.6×10^{-5} l·mole^{-1}·sec^{-1}.

Equatorial alcohols	$k \times 10^5$ [l·mole^{-1}·sec^{-1}]
trans-4-t-Butylcyclohexanol	10.8

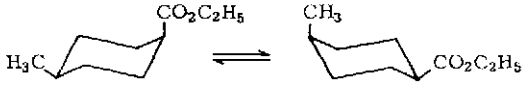
cis-3-Methylcyclohexanol	10.85
cis-3,3,5-Trimethylcyclohexanol	12.2
cis,cis-3,5-Dimethylcyclohexanol	13.1
cis-3-Methyl-*cis*-5-isopropylcyclohexanol	12.4
cis-3-Methyl-*cis*-5-t-butylcyclohexanol	11.5
cis,cis-3,5-di-t-Butylcyclohexanol	11.3
Axial alcohols	
cis-4-t-Butylcyclohexanol	2.92
trans-3-t-Butylcyclohexanol	3.38
trans,trans-3,5-Dimethylcyclohexanol	3.37
trans,trans-3-Methyl-5-isopropylcyclohexanol	3.41
trans,trans-3,5-di-t-Butylcyclohexanol	4.14

Apart from the intrinsic difficulty involved in the kinetic method there is a technical difficulty which is evident from the case of ethyl cyclohexanecarboxylate given earlier. If k is close to either k_e or k_a, either the numerator or the denominator in the equation yielding K will be a small difference of large numbers and the accuracy of K thus determined will be low. In general, this difficulty arises when the monosubstituted cyclohexane exists extensively in the equatorial conformation (*i.e.* if the substituent is relatively large) since in that case k will be close to k_e; the ethoxycarbonyl group is an example. Clearly, better results would be obtained in a system where k is nearly midway between k_e and k_a.



(15a) *(15b)*

Formulae *(15a)* and *(15b)* show such a system; here the ethoxycarbonyl group is counterpoised by the methyl group [*] and equilibrium will lie near 50:50. From the saponification rate constant for this system ($k = 2.65 \times 10^{-4}$ l·mole^{-1}·sec^{-1}) one may readily compute the equilibrium constant

$$K = (k_a - k)/(k - k_e) = 0.38$$

whence ΔG° for this system is +0.57 kcal/mole. Assuming now additivity of conformational free energies (see Section VI for the limitations of this assumption) one has

$$\Delta G^{\circ}_{1} = \Delta G^{\circ}_{CO_2C_2H_5} - \Delta G^{\circ}_{CH_3}$$

[*] A group of this type is called a "conformation-restoring group" by *J. Sicher* (personal communication; see also ref. [81]).

or

$$\Delta G^{\circ}_{CO_2C_2H_5} = \Delta G^{\circ}_{1} + \Delta G^{\circ}_{CH_3}.$$

Taking ΔG°_{Me} as −1.7 kcal/mole, this gives

$$\Delta G^{\circ}_{CO_2C_2H_5} = 1.13 \text{ kcal/mole}$$

in very good agreement with the values given earlier. Some reflection will show that, with $\Delta G^{\circ}_{CH_3} = -1.7$ kcal/mole, *cis*-4-methyl-substituted cyclohexanes will give more accurate conformational energies than monosubstituted cyclohexanes when the conformational energy is in excess of 0.85 kcal/mole. Some conformational energies obtained by the kinetic method, *e.g.* that for the amino group in protic solvents [33], could not have been obtained without resorting to the *cis*-4-methyl-substituted model.

An approach similar to the kinetic method but using equilibrium constants instead of rate constants ($K = N_e K_e + N_a K_a$, where K, K_e, and K_a are equilibrium constants for appropriate chemical equilibria for monosubstituted and *trans*- and *cis*-4-t-butyl-substituted compounds) has also been used occasionally; the derivation of $-\Delta G^{\circ}_{CO_2H}$ from pK data (in essence dissociation equilibrium constants) described in the next Section is of this type.

D. Physical Methods

Since a number of physical properties of substituted cyclohexanes are affected by the equatorial or axial position of the substituent, physical measurements can, in turn, be used to infer conformation. Thus electron diffraction studies have been used to ascertain the position of conformational equilibrium in chloro- [64] and fluorocyclohexane [65]; and the conformational equilibrium of cyclohexanes carrying carboxy and carboxylate groups [36, 60, 66], amino, dimethylamino, ammonium, and dimethylammonium groups [67], and mercaptan and mercaptide groups [68] have been deduced from pK measurements. Measurements of dipole moments served in the assignment of conformation to *trans*-1,2-dibromocyclohexane [69] and the 2-halogenocyclohexanones [70]; optical rotatory dispersion [71] and ultraviolet [72] measurements have also been applied to the latter compounds. stant measurements have been utilized [73] in the determination of conformational equilibrium in bromocyclohexane but seem to be less reliable than other physical methods.

Whereas these methods are limited in applicability to special cases, two fairly general methods of conformational assignment are available in infrared and nuclear magnetic resonance spectroscopy. The infrared spectrum of a substituted cyclohexane $C_6H_{11}X$ in general varies with the equatorial or axial nature of the substituent X. In particular, if bands can be assigned to the C–X stretching frequency, equatorial C–X will be found at higher frequency (by 10–55 cm^{-1}) than axial. In a mobile system, *e.g. (1a)* ⇌ *(1b)*, because of the operation of the Franck-Condon principle (time of vibrational transition ≪ time of conformational interconversion), axial and equatorial C–X stretching frequencies will both be found and the ratio of intensities of the equatorial and axial C–X stretching band will depend on the conformational equilibrium constant K. Two methods are available to obtain K quantitatively from infrared data.

a) In one, the temperature is varied and the ratio of extinctions (integrated band intensities) of the equatorial and axial C–X stretching bands, A_e/A_a, is determined as a function of temperature. Then, assuming that the extinction coefficients for the axial and equatorial stretching bands do not vary with temperature and applying the vant'Hoff relationship, one may deduce [74]:

$$\Delta H = RT_1T_2[\ln(A_e/A_a)T_2 - \ln(A_e/A_a)T_1]/[T_2 - T_1]$$

Unfortunately, since ΔH is generally not very large (less than 1 kcal/mole for most polar substituents), the band intensity ratio changes rather slowly with temperature and application of the above method requires large temperature intervals and accurate measurements of band intensity. As a result, the method is not experimentally very attractive and has been used relatively infrequently.

b) In principle, one could deduce conformational population ratios and, hence, free energies directly from band intensities if one knew the extinction coefficients, since:

$$K = N_e/N_a = \varepsilon_a A_e/\varepsilon_e A_a$$

where ε_e and ε_a are the molar extinction coefficients for the equatorial and axial C–X stretching mode, respectively. It has been suggested [75] that ε_e and ε_a can be measured from the intensity of the C–X stretching bands in the conformationally homogeneous *trans*- and *cis*-4-t-butyl-substituted models. For the moment, this suggestion (which amounts to saying that the 4-t-butyl group does not affect the extinction coefficient for the C–X band, X at C-1) must remain an assumption, since the method has not been applied extensively. In its first application to cyclohexanol [75a] the method failed when the axial C–O stretch was considered, and even application to the supposed equatorial C–O stretching band [75a, 76] gave a range of conformational energies for OH of 0.29–0.41 kcal/mole, well below the now accepted value of 0.6 kcal/mole in solvents which are not hydrogen donors. It has been suggested [77] that the difficulty lies not necessarily in the method but in the problem of discerning a pure equatorial C–O stretching frequency in cyclohexanol; presumably the band at 1069 cm^{-1} which was used has a skeletal vibrational mode mixed in with it.

The temperature-dependent infrared method as applied to cyclohexanols [78] gives a value of 0.31–0.41 kcal/mole for $\Delta H°$. This value may not, however, be too low, since $\Delta S°$ for OH is probably not zero. If one assumes, in the extreme, that an equatorial hydroxy group has three rotational conformations of equal energy, whereas an axial hydroxy group has only two conformations of equal energy (the third conformation, with the hydrogen pointing into the ring, being considered of sufficiently higher energy to be disregarded), then the entropy difference is R ln 3 − R ln 2 or 0.81 cal·mole^{-1}·degree^{-1} in favor of the equatorial isomer and

$$\Delta G^0_{OH} = \Delta H^\circ_{OH} - T\Delta S^0_{OH}$$

would then be calculated to be 0.55–0.65 kcal/mole, in good agreement with values obtained by other methods in aprotic solvents.

Application of the second infrared method to chloro- [32a] and bromocyclohexane [79] gives conformational energy values (0.40 kcal/mole for the chloride, 0.46 kcal/mole for the bromide) which are in good agreement with other values for these atoms; the first infrared method (temperature dependence of intensities) gives reasonable ΔH values for chlorine [78a, 80] but a somewhat low value (0.2 kcal/mole) for bromine [78a]; it seems unlikely that entropy differences between equatorial and axial bromine could account for the discrepancy in this case.

A particularly valuable and apparently reliable application of infrared spectroscopy consists in the measurement of the relative intensities of bonded and unbonded OH-stretching frequencies in appropriately 2-substituted cyclohexanols; this method has been used to assess the position of conformational equilibrium in *trans*-1,2-cyclohexanediols and *trans*-2-aminocyclohexanols *(16)* [81].

Nuclear magnetic resonance is one of the most powerful tools to give direct insight into both the structure and stereochemistry of an organic compound. It is therefore no wonder that the technique has been applied extensively in conformational problems – so extensively, in fact, that its application forms the subject of a separate review in this journal [82]. For this reason we shall discuss here only one application of NMR – that in determining conformational equilibria.

Axial and equatorial protons (similar principles apply to other nuclei susceptible to NMR detection, such as fluorine) generally differ in chemical shift of their NMR signals by 20–40 cps (at 60 Mc) if the chemical environment is otherwise the same. The signal of the axial proton usually appears at higher field. Spin-spin splitting also differs between the two types of signals since axial protons are subject to coupling with both adjacent axial or *anti* ($J_{a,a} \approx 9$ cps) and equatorial or *gauche* ($J_{e,a} \approx 3$ cps) protons whereas equatorial protons couple only with *gauche* protons. As a result, the half-width of an equatorial proton signal (*ca.* 7 cps) is appreciably less than that of an axial proton signal (*ca.* 22 cps). It might be expected, then, in analogy with the situation in infrared spectroscopy, that a mobile cyclohexane system would show two signals for a given proton (*e.g.* the >CHX proton in $C_6H_{11}X$): one for the axial proton of the equatorial isomer and one for the equatorial proton of the axial isomer. However, this is not the case. Because the frequency interval between the two proton signals is only about 30 cps, whereas the rate of interconversion of the two chair forms is well in excess of 1000 sec^{-1} at room temperature, the chair will flip many times in the interval between an equatorial and an axial transition and these transitions will therefore merge into an average signal.

Nevertheless there are two ways in which NMR can be utilized to establish conformational equilibria. It is possible to slow down the equatorial-axial interconversion by lowering the temperature; at about −67 °C, the rate of chair interconversion in cyclohexane is of the same order of magnitude as the chemical shift between the signals of equatorial and axial protons and so the original single peak will begin to split into two separate peaks. (It is from the signal shape at temperatures near this "coalescence point" that the activation parameters for chair-chair interconversion given earlier have been obtained.) At temperatures much below the coalescence point, two clearly divided peaks are found, and from the areas of these peaks, the relative population of equatorial and axial conformations at the temperature in question may be directly computed. This method is theoretically sound but experimentally difficult for two reasons: accurate NMR measurements at definite temperatures much below room temperature are hard to effect (because of difficulty in obtaining and measuring the temperatures required, because of viscosity broadening of the signals, and because of solubility problems) and the conformational equilibrium at the low temperatures needed is biassed very much in favor of the equatorial isomer (*e.g.* an equilibrium constant of 4 at room temperature corresponds to one of 11 at −100 °C, assuming ΔG° to be temperature invariant). Nevertheless the low-temperature NMR method has been used with good results for halogenocyclohexanes [83].

An experimentally simpler method is to base the estimate of the conformational equilibrium on the position of the average proton signal at room temperature. This position will depend directly on the position of equilibrium; in fact, it can be shown [84] that

$$\nu = N_a\nu_a + N_e\nu_e$$

where N_a and N_e are the mole fractions of axial and equatorial conformers, as before, and ν_a and ν_e are the shifts for salient protons (*e.g.* the >CHX proton) in these conformers whereas ν is the shift for the corresponding proton in the mobile system. Clearly, this equation is entirely analogous to the Winstein-Holness equation for rate constants (*vide supra*) and may be transformed [53, 85] into the form

$$K = (\nu_a - \nu)/(\nu - \nu_e).$$

In order to apply this equation to the evaluation of K, it is necessary to establish the values of ν_a and ν_e. This can be done in two ways, either by effecting measurements at very low temperatures [83a, 86] where the signals of the two conformations are separate, or by using model compounds, such as 4-t-butyl-substituted cyclohexanes, to fix the appropriate conformations [32–34, 53, 85, 87, 88]. The use of such model compounds now entails the assumption that the 4-t-butyl substituent does not affect the chemical shift. Contrary to recent assertions [89], this assumption seems to be valid for cyclohexanone dimethyl ketal and 4-t-butylcyclohexanone dimethyl ketal: the (average) signal of the methyl groups in the former (−183.9 cps at 60 Mc) occurs, as exactly as the accuracy of the measurements permits one to say, exactly half-way in between the (resolved) signals of the methyl groups in the latter (−182.9 and −184.9 cps) [90]. Other data, concerned with the shift of the carbinol proton signal in variously substituted cyclohexanols [91], while inconclusive, are not so encouraging as regards the complete absence of an effect of a 4-t-butyl group. The data for the pair chloro-

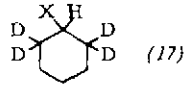
Table 3. Conformational equilibrium of chlorocyclohexane in carbon disulfide.

Compound	NMR signal			$-\Delta G^0$ [kcal/mole]	Ref.
	ν_e [cps]	ν [cps]	ν_a [cps]		
4-t-Butyl-chlorocyclohexane	−218.2 (25 °C)	−231.9 (25 °C)	−259.9 (25 °C)	0.42	[32a]
Chloro-cyclohexane	−224 (−81 °C)	−233.3 (25 °C)	−265.8 (−81 °C)	0.48 [a] 0.74 [b]	[83a]
	−227.4 (−91 °C)	−236.1 (25 °C)	−266.4 (−91 °C)	0.73 [b]	[83b]

[a] Extrapolated value, unspecified process of extrapolation.
[b] Raw value.

cyclohexane/4-t-butyl derivative summarized in Table 3 indicate that though there is a shift, surprisingly, more reasonable ΔG° values are obtained from the data for the 4-t-butyl compound than from the low-temperature data on the unsubstituted compound.

One of the difficulties inherent in the NMR method lies in the fact that the salient peaks are broad (due to extensive coupling) making accurate measurement of signal position problematic. This difficulty has been obviated to a considerable extent by employing [2,2,6,6-D_4]-cyclohexanes *(17)* in which the splitting is reduced by a factor of six [32b, 34, 87].



(17)

An attempt [32a] to achieve the same end more simply by employing double resonance (saturation of the ring protons other than the >CHX one) was unsuccessful since it was found that the chemical shift of the signal of the >CHX proton depended on the amount of RF-power used to saturate the remaining protons; and while it was possible to extrapolate a set of data obtained at varying RF to zero RF, the inaccuracy introduced by this extrapolation is of the same order of magnitude as the inaccuracy in peak measurement in a simple NMR experiment.

It might be mentioned here that the most accurate measurements of the cyclohexane inversion barrier [27] similarly employ[D_{11}]-cyclohexane.

While the spin-spin splitting would thus appear to be a nuisance in measurements of conformational equilibria, it has, on the other hand, also been employed to assess such equilibria [92, 93]. The principle here is that just as the signal position averages in a rapidly flipping substituted cyclohexane, so does the splitting, and if the splitting of both the equatorial and axial conformers is known, the position of conformational equilibrium may, in principle, be deduced from the splitting in the mobile system. This method is discussed in detail in the accompanying review [82].

E. Summary

In reviewing the methods available for determining conformational equilibria, one finds a certain amount of unity in them. In most cases some property of the mobile system (reaction rate, equilibrium constant, appropriate physical property) is compared to a similar property of a rigid or biassed system. If X is the property of the mobile system and the subscripts a and e refer to the axial and equatorial models, respectively, then, in many cases:

$$X = N_e X_e + N_a X_a,$$

which simply means that the property of the mobile system is the weighted average of the properties of its constituent conformational isomers. It follows that the desired equilibrium constant is

$$K = (X_a - X)/(X - X_e).$$

To obtain correct results it is necessary to select appropriate models to obtain the axial and equatorial values X_a and X_e. In many instances 4-t-butyl-substituted systems have been chosen for this purpose with results which, in general, show a remarkable amount of consistency. However, there is no inherent guarantee that the choice of such model systems is sound in all cases. The only theoretically unobjectionable approach is to use the mobile system itself and "freeze" it, either by slowing the interconversion of conformational isomers at low temperatures (low-temperature NMR method) or by using a method which is inherently fast compared to the velocity of ring inversion (such as infrared frequency measurements).

It is of interest that a method has recently been developed [94] in which it is not necessary to determine the properties X_a and X_e of the pure conformers but rather ΔH° is obtained by measurement of the change of the averaged property X (in the case cited, optical rotatory dispersion amplitude) with temperature. The accuracy and generality of this method remain to be established.

VIII. Future Work

It may be well (if risky) to conclude this brief review on conformational analysis in mobile systems by trying to foresee likely future problems (in the absence of any fundamental new breakthroughs).

On the theoretical side, it is likely that the availability of more accurate data on van der Waals radii from molecular beam experiments on one hand and the increasing availability of high-speed computers on the other will lead to more accurate calculations of conformational equilibria in a variety of systems.

In a semi-theoretical area, it is likely that an increasing number of assessments of ΔH° and ΔS° (as distinct from ΔG°) will be made and that, in the process, a better understanding of entropy differences between equatorially and axially substituted cyclohexanes will be gained. A word of caution is in order in this connection: since the thermodynamic differences between conformational isomers are in general quite small, accurate measurements of ΔH° and ΔS° will be difficult. It is deceptively easy to obtain such data from measurements of ΔG° at two temperatures, and, no doubt, a number of data will be turned out in this way and later found to be wanting. Reliable measurements of conformational ΔH°s and ΔS°s will probably require accurate equilibrium measurements at at least four and possibly

[92] *F. A. L. Anet*, J. Amer. chem. Soc. *84*, 1053 (1962).

[93] a) *H. Feltkamp* and *N. C. Franklin*, J. Amer. chem. Soc. *87*, 1616 (1965); b) *H. Feltkamp, N. C. Franklin, K. D. Thomas*, and *W. Brügel*, Liebigs Ann. Chem. *683*, 64 (1965).

as many as six different temperatures over a range of preferably not less than 100 °C. In any case, a careful error treatment is called for in publications of such data. On the more practical side, we may look forward to see measurements on additional groups (such common groups as $-CHO$, $-COR$, $-CH=CH_2$ have not yet had ΔG°-values assigned to them). New methods, such as that based on measurement of the chemical shift of the OH NMR signal [46] may be expected to be devised. A more careful study of the solvent dependence of a number of conformational equilibria, especially those involving polar and hydrogen-bonding groups, may be looked forward to. Conformational equilibria of disubstituted cyclohexanes (1,1- as well as 1,2-, 1,3- and 1,4-disubstituted ones) will be studied to test additivity relationships in ΔG° (*vide supra*).

One very large area which has barely been scratched is that of conformational equilibria in heterocyclic systems. There has recently been much interest in the conformation of the basic piperidine and *N*-methylpiperidine systems [95] with the finding that the unshared electron pair is smaller than hydrogen and much smaller than a methyl group. Nothing is known yet on C-substituted piperidines and only a limited amount of information has been brought to bear on tetrahydropyrans [96] – the parent skeleton of the pyranose sugars – and 1,3-dioxanes [97a]. A number of heterocyclic systems have been considered only from the point of view of the chair-chair interconversion barrier [97b, 98] if at all and there is obviously much scope for further work in this area. Chemists interested in the behavior of natural products, such as sugars, will no doubt continue to consider the conformational implications in these systems; some studies on hexopyranoses and cyclitols [99] are already at hand.

The author wishes to acknowledge with pleasure the stimulation and ideas derived from many conversations with colleagues and coworkers as well as financial support of his research by the Petroleum Research Fund of the American Chemical Society, the National Science Foundation (U.S.A.), the Office of Ordnance Research, U.S. Army, and the U.S. Air Force Office of Scientific Research. Special thanks are due to Dr. J. Sicher whose detailed and constructive criticism has been most helpful in the preparation of this manuscript.

Conformational Analysis of Cyclohexane Derivatives by Nuclear Magnetic Resonance Spectroscopy

BY DR. N. C. FRANKLIN AND PRIV.-DOZ. DR. H. FELTKAMP

PHARMAZEUTISCH-CHEMISCHES INSTITUT DER UNIVERSITÄT TÜBINGEN (GERMANY)

Nuclear Magnetic Resonance is today one of the best methods available for the conformational analysis of cyclohexane derivatives. It is possible with this technique to investigate the spatial orientation of the substituents in fixed molecules, as well as the equilibrium position in mobile systems. For these determinations the areas under the signals, the chemical shifts, the coupling constants, and the band widths of particular signals can be used.

I. Basic Principles

1. Energetic Considerations

In a flexible molecule, the individual groups of atoms can take up different positions with respect to each other. Arrangements which differ from one another by rotations about single bonds are known as the conformations of the molecule. In most cases only a very small amount of energy is required in order to move the molecule from one conformation into the other, and for this reason one is often dealing with mixtures, in which many conformations may be in equilibrium with each other.

The cyclohexane system is particularly suitable for studies of conformational equilibria, as it possesses two favorable conformations, which correspond to the two chair forms of cyclohexane. These two forms can interconvert, but a relatively high energy (about 11 kcal/mole) is required to overcome the torsional rigidity and also to change the bond angles during the intermediate states. During this interconversion, cyclohexane passes through an energy minimum (*ca.* 5.0 kcal/mole), known as the twist (or skew) form [1], which is however considerably above the energy level of the two

[1] *W. S. Johnson, V. J. Bauer, J. L. Margrave, M. A. Frisch, L. H. Dredger*, and *W. N. Hubbard*, J. Amer. chem. Soc. *83*, 605 (1961).

chair forms. Smaller energy maxima (*ca.* 5.5 kcal/mole) correspond to the boat forms of the molecule [2]. At room temperature, the thermal energy is high enough to overcome this energy barrier for the inversion to occur with a high frequency, but at low temperatures the interconversion of the two forms is almost completely prevented.

Two types of protons can be distinguished on the cyclohexane ring: six are perpendicular to the plane of the ring (axial = a), and the remaining six are parallel to the plane of the ring (equatorial = e)[3]. On inversion, these protons (or substituents if present) exchange their positions [4].

(1) (2)

The two chair forms of mono-substituted cyclohexane have different energies because the non-bonding interactions between the substituent and the "syn-axial" hydrogen atoms are larger for an axial substituent than for an equatorial one. The free energy difference ΔG between the two conformations is given by:

$$\Delta G = -RT\ln K \qquad (a)$$

If the molecule contains more than one substituent, *e.g.* X and Y, it has generally been assumed that the ΔG values are additive [5]:

$$\Delta G_{XY} = \Delta G_X + \Delta G_Y \qquad (b)$$

This assumption is however not always correct [6,7]. The equilibrium constant K is given by:

$$K = x/(1-x) \qquad (c)$$

where x is the mole fraction of one of the forms present in the equilibrium mixture. In order to calculate K, the equation

$$K = (P_a - P)/(P - P_e) \qquad (d)$$

has been derived [8], where P_a and P_e are the magnitudes of a property of a molecule with an axial and an equatorial functional group, respectively, and P is the measured value of this property in the mixture. Equation (d) was originally used [8] to calculate K from reaction rates. Figure 1, which was calculated from Equations (a) and (c), shows the relationship between the percentage of the most stable conformer and the ΔG value.

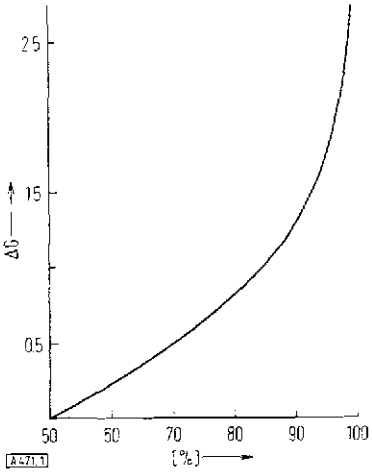

Fig. 1. Dependence of the percentage of the most stable conformer at 25 °C on ΔG.

It is obvious from Figure 1 why a non-chair form usually does not take part in the equilibrium: a ΔG value of approx. 5 kcal/mole corresponds to less than 0·1 % of the energy-rich form. When a substituent is introduced, the difference in energy between the *a*-chair and the non-chair forms is reduced and the percentage of the *a*-chair form is decreased but to the advantage of the *e*-chair, whilst the non-chair form does not occur.

(5)

A fundamental change can, however, occur in disubstituted cyclohexanes (Fig. 2). If the two substituents are so arranged that one of them is in the axial position, the energy content of both chair forms is increased. The ΔG

value, which determines the equilibrium constant, is then the difference between the individual ΔG values (Fig. 2a). If both ΔG values are greater than 5.0 kcal/mole, the twist form becomes the most stable conformer (Fig. 2b).

2. NMR Spectroscopy of Fixed Cyclohexane Derivatives

In the NMR spectrum of a fixed diequatiorially substituted cyclohexane molecule (Fig. 3), it is possible to distinguish between different types of protons which absorb at different fields. The tertiary protons (on C_1

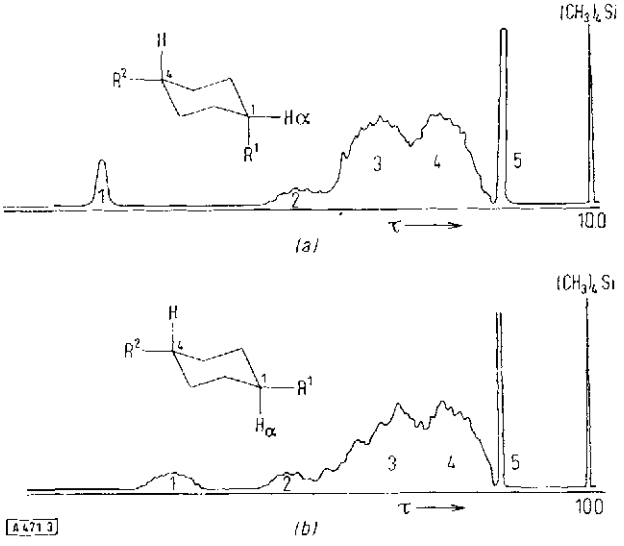

Fig. 3. Schematic NMR spectra of fixed disubstituted cyclohexanes (a) R^1 axial, R^2 equatorial. (b) R^1, R^2 both equatorial. Abscissa: chemical shift (p.p.m.).

and C_4) are those hydrogen atoms which are bonded to the same carbon as the substituents. The secondary protons are those methylene protons which make up the rest of the ring. The tertiary protons have a lower diamagnetic shielding, and thus generally appear at lower field. If the substituent R_1 is much more electronegative than the methylene group, the diamagnetic shielding of the proton on C_1 will be decreased, and its signal (hereafter referred to as the α-proton) will appear at even lower field. For this reason the α-proton signals are of particular value in conformational analysis. In most cases they are so far removed from the remainder of the protons that they become the X part of the spectra in the nomenclature of *Pople, Schneider,* and *Bernstein (PSB)* [9] (signal 1 in Fig. 3). The introduction of an electronegative group affects also the chemical shift of the methylene protons, but this will be neglected for the present.

If the substituent R^2 is an alkyl group (signal 5 in Fig. 3), the signal of the tertiary proton on C_4 will hardly be moved and will appear just below the general methylene absorption (signal 2 in Fig. 3).

Axial and equatorial protons appear at different fields [10] (compare signal 1 in Fig. 3a and 3b). This is equally true for tertiary as for secondary protons, and it is usually [12, 13] observed that the equatorial protons (signal 3) absorb at lower field than the axial protons (signal 4) [11]. The area under a signal is proportional to the number of protons producing it; thus the ratio of the areas of the signals 1–4 (Fig. 3) is 1:1:4:4.

The coupling constant between neighboring axial protons J_{aa} is generally two to three times as large [10] as the coupling constant between an axial and a neighboring equatorial proton, J_{ae}. The coupling constant between two neighboring equatorial protons J_{ee} is even lower [14]; the difference between J_{ae} and J_{ee} is however small. For this reason, amongst others, the axial and equatorial protons adjacent to the α-proton are not identical, and the signal of the α-proton in Figure 3 is the X part of an A_2B_2X system [9]. The difference in coupling constants results in the signal due to the axial α-proton (in Fig. 3b) being broader than that due to the equatorial α-proton (Fig. 3a).

Thus three measurements made from an NMR spectrum can be used in conformational analysis. From the chemical shift or the band width it is possible to decide wether the α-proton is axial or equatorial; from the area under the signal it should be possible to estimate the relative amounts of the conformers. Only fixed molecules, however, have so far been considered. This is a limiting case of conformational analysis, namely configurational analysis.

3. The NMR Spectra of Mobile Cyclohexane Systems

Consideration will now be given to cyclohexane derivatives which are not fixed but are in equilibrium with other conformers. This equilibrium usually involves only the two chair forms. The NMR spectrum would be expected to show two signals in the region of the X-part *i.e.*, a narrow signal at low field due to the equatorial α-proton and a broader signal at higher field due to the axial α-proton. The ratio of the areas of these two signals would be a direct measure of the relative abundance of the two conformers in the mixture (cf. Fig. 4a).

The spectrum actually obtained (Fig. 4b), however, shows in the X region only one signal having a chemical

[9] *J. A. Pople, W. G. Schneider,* and *H. J. Bernstein*: High Resolution Nuclear Magnetic Resonance. McGraw-Hill, New York 1959. If protons of similar chemical shift are coupled, then they are denoted by alphabetically close letters *e.g.* AB; if the chemical shift is, however, large, alphabetically removed letters are used *e.g.* AX. When a number of protons of the same chemical shift are involved, the corresponding letter carries a numerical subscript denoting the number of protons of the same type. Thus an A_2B_2X system consists of 5 protons, two pairs of which are alike.

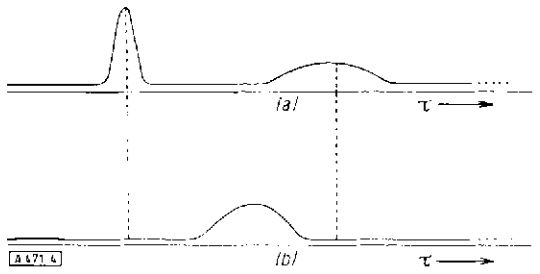

Fig. 4. X part of the spectrum of a mobile cyclohexane derivative. (a): expected, (b): found.

shift and a bandwidth between the two previously expected values [15] (cf. also Fig. 5).

The transition of an excited nuclear spin from the parallel to the antiparallel state, and back again, by which the NMR signal is produced, is relatively slow compared with the rate of inversion of a cyclohexane ring at room temperature. Thus, during one spin transition of the α-proton, the molecule to which the α-proton is attached interconverts very often, and the α-proton itself is many times axial and many times equatorial. Thus the magnetic environment of the α-proton during its transition is an average value of the environments of an *a*- and an *e*-proton (since intermediate forms need not be considered). All properties of the measured signal are therefore average values of the properties due to a completely axial and a completely equatorial proton.

This explanation was verified experimentally. By cooling of the sample the rate of interconversion of the cyclohexane molecule is considerably reduced, while the transition time of a nuclear spin remains unaltered [16]; *i.e.* it is extremely unlikely that the molecule interconverts during the transition of a nuclear spin. A monosubstituted cyclohexane then gives a spectrum (Fig. 5) of the type shown in Figure 4a [17].

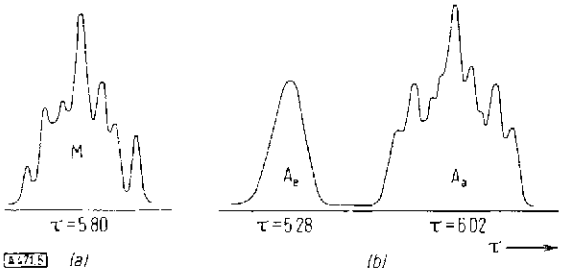

Fig. 5. X part of the NMR spectrum of iodocyclohexane. (a) at 25 °C; (b) at −75 °C. M average value; A_a, A_e areas of the axial and equatorial α-proton signals, respectively.

4. The Selection of Reference Values

The chemical shift, the coupling constants, and thus the band widths of a mobile cyclohexane system are all average values. If the equilibrium constant of an interchanging cyclohexane derivative is to be calculated according to Eq. (d), then the magnitudes of the properties of the individual conformers themselves must be known.

There are two ways of determining these values for the individual conformers. The first has already been mentioned for iodocyclohexane [17]; the mobile system is cooled so that the interconversion rate is reduced almost to zero. The signal due to the α-proton in the two conformers then appears separated in the spectrum, and from these two peaks it is theoretically possible to obtain all the required information. This method however is limited. Many substances for instance do not show a sufficient separation of the α-proton signal when cooled [18], while others crystallize out of the solution too rapidly at low temperatures.

For these reasons another method is more frequently used. The values are measured on reference substances similar to the individual conformers but which cannot interconvert. The t-butycyclohexane derivatives have generally been used for this purpose [19], as the molecule is fixed by the bulky alkyl group; thus in *cis*-4-t-butylbromocyclohexane the bromine group is fixed axially, whilst in the *trans* isomer it is fixed equatorially. This practice involves the assumption that the group preventing the inversion has no influence on the NMR property which is to be measured. Thus the chemical shift of the α-proton in *cis*-4-t-butylbromocyclohexane is the same as that of the α-proton in the conformer of bromocyclohexane with an axial bromine group [20]. This is, however, not true in every case (see Section II,2). Thus selection of suitable reference substances is of critical importance in conformational analysis.

5. Nomenclature

The following suggestions for the unification of terms used in NMR spectroscopy when applied to conformational analysis are limited to those referring to the α-proton; they can however be readily extended if necessary.

1. All subscripts to quantities relating to the α-proton, (such as chemical shift, coupling constant, band width), refer to the orientation of the α-proton. For example, w_a is the band width of the α-proton signal of a substance which has this proton in the *axial* position, *i.e.* the electronegative group is in the *equatorial* position, and τ_a is its chemical shift. This suggestion is opposite to the nomenclature in Equation (d) (see, *e.g.*, [21]). The latter nomenclature has the disadvantage that a measured value pertaining to an axial proton is indicated with the subscript "e".

2. The coupling constant should be characterized by a two-letter subscript, the first letter corresponding to the orientation of the α-proton and the second to the neighboring proton with which it is coupled. J_{ae} therefore denotes the coupling constant of an axial α-proton with an equatorial neighboring proton [22].

[15] *H. S. Gutowsky* and *A. Saika*, J. chem. Physics *21*, 1688 (1953).

[16] *F. R. Jensen, D. S. Noyce, C. H. Sederholm*, and *A. J. Berlin*, J. Amer. chem. Soc. *82*, 1256 (1960).

[22] *D. H. Williams* and *N. S. Bhacca*, J. Amer. chem. Soc. *86*, 2742 (1964), footnote (7).

3. A "time-average" value will be denoted by indices corresponding to the conformations from which this average is derived. Thus J^{ea}_{ae} is the average coupling constant of an axial α-proton with a neighboring equatorial proton, which through inversion changes its position, and w^e_a is the average band width corresponding to this signal. If Eq. (d) is to be used with the chemical shift or the band width, it may be rewritten in the forms:

$$K = (\tau_e - \tau_a)/(\tau_a - \tau_a) \quad (e)$$

$$K = (w_e - w^e_a)/(w^e_a - w_a) \quad (f)$$

6. The Order of the Signals [*]

When the difference in chemical shift between the α-proton and the A and B protons with which it is coupled decreases, the A_2B_2X system becomes an A_2B_2C system. Generally the interest for conformational analysis lies in the X (or C) part of the spectrum. With a sufficiently large difference in chemical shift the splitting of the signal is first order, and completely symmetrical, but if the difference in chemical shift decreases sufficiently, the signal becomes one of higher order [23]. This usually results in the signal becoming asymmetrical and showing a greater number of lines. As a reasonable approximation, a signal shows a first order splitting when the chemical shift between it and the nuclei to which it is coupled is ten times larger than the coupling constants which cause the splitting [24].

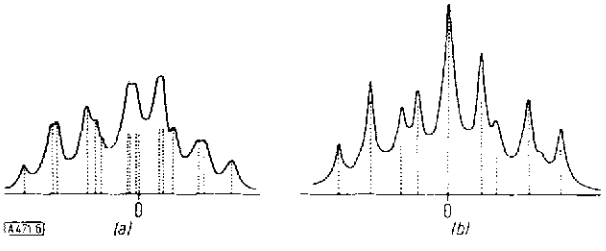

Fig. 6. X Part of the NMR spectrum of nitrocyclohexane (not to scale). (a): At 60 Mc/s, (b): at 100 Mc/s. The broken lines show the positions of the theoretical transitions.

Figure 6 shows the α-proton part of the spectrum of nitrocyclohexane at 60 Mc/s [25]; here the previously mentioned ratio is about 1:5 and the splitting is therefore clearly second order; the signal is unsymmetrical and more lines are present than expected from a simple treatment. Therefore it is not possible here to equate the measured splittings with the coupling constants, or to measure the chemical shift from the geometrical centre. These values must hence be obtained by a complete mathematical analysis of the spectrum, which has seldom been possible for cyclohexane derivatives [26].

[*] A symmetrical signal, in which the splittings can be equated to the coupling constants, is known as a first-order signal. If these conditions are not fulfilled, the signal is of second order.

[24] *R. J. Abraham* and *H. J. Bernstein*, Canad. J. Chem. *39*, 216 (1961).

[25] *H. Feltkamp* and *N. C. Franklin*, unpublished results.

[26] For example, some spectra of deuterated compounds have been analysed using the computer program of *K. B. Wiberg* and *B. J. Nist*: The Interpretation of NMR Spectra. *W. A. Benjamin*, New York 1962.

There is however one property which is common to both first order signals and those of higher order. The width of the signal between the extreme outside lines is independent of order, and corresponds to the sum of the coupling constants involved.

When the spectrum of nitrocyclohexane is recorded at 100 Mc/s [25] instead of 60, the ratio of the coupling constants to the chemical shift increases to about 1:10, owing to the increase in chemical shift, whereas the coupling constants remain constant. The spectrum is now of first order, completely symmetrical, and with splittings corresponding to the coupling constants (cf. Fig. 6b).

The recording of the spectra using higher magnetic fields should yield results which are easier to interpret (given the same resolution). For nitrocyclohexane the change from 60 to 100 Mc/s already resulted in considerable clarification, and this will be much more the case with equipment working at 200 Mc/s or more.

II. NMR Methods of Conformational Analysis

1. The Area of the Signal

The only direct method of investigating conformational equilibria is, up to the present, the measurement of the area under the NMR signal (cf. Fig. 5). All protons which change their position on inversion of the ring may be considered. The most important of these is again the α-proton, but it is possible to use the signal of other proton groups; for example the protons of an axial $-OCOCH_3$ or $-NHCOCH_3$ group absorb at different fields to those of the same group when in the equatorial position [10,27]. Such measurements are only meaningful, however, when the signals are clearly separated, *i.e.* when the measurements are carried out at low temperatures. Thus it was necessary to work at −110 °C in order to prevent the interconversion of 1,1-difluorocyclohexane [28], (although providing the individual peaks are separated it is not necessary to completely prevent the inversion). In the case of iodocyclohexane [17] a temperature of −75 °C was necessary (cf. Fig. 5).

The limitations of this method are almost the same as those discussed in connection with the choice of standard values. When the difference in chemical shift of the conformers is too small, even complete freezing of the equilibrium does not result in separation of the α-proton signal [18]. By deuteration of the positions adjacent to the α-proton the couplings can be removed and the signal becomes narrower, so that on cooling a separation is observed [29].

[27a] *F. W. Lichtenthaler* and *H. O. L. Fischer*, J. Amer. chem. Soc. *83*, 2005 (1961); *F. W. Lichtenthaler*, Chem. Ber. *96*, 2047 (1963).

[27b] *F. A. L. Anet*, *R. A. B. Bannard*, and *L. D. Hall*, Canad. J. Chem. *41*, 2331 (1963).

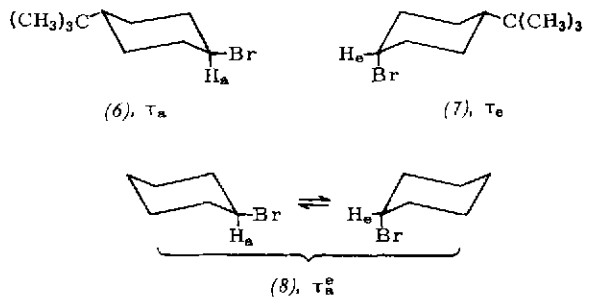
[28] *J. D. Roberts*, Angew. Chem. *75*, 20 (1963); Angew. Chem. internat. Edit. *2*, 53 (1963).

[29] *E. A. Allen*, *E. Premuzic*, and *L. W. Reeves*, Canad. J. Chem. *41*, 204 (1963).

Apart from these difficulties, the measurement of the area under the signal at low temperature is the best method of conformational analysis available.

2. Measurement of the Chemical Shift

The first application of nuclear magnetic resonance to the quantitative conformational analysis of mobile cyclohexane systems was based on the difference in chemical shift between the axial and equatorial protons. *Eliel* studied bromocyclohexane [19] and derived Equation (e). At that time it was reported that the spectrum of bromocyclohexane showed no sign of a splitting of the α-proton signal at the temperatures used; more recently a difference of 0.78 p.p.m. was observed between the axial and equatorial protons at −75 °C [17]). Therefore instead of bromocyclohexane itself, *cis-(7)* and *trans*-4-t-butylbromocyclohexane *(6)* were used to determine the chemical shifts of the α-proton in the individual conformers.



The assumption that the t-butyl group does not affect the chemical shift of the α-proton was later disputed [30], for a study on a series of 4-alkylcyclohexanols showed that the chemical shift of the α-proton varies with the nature of the alkyl substituent. This observation therefore seemed to invalidate the use of fixed substances as standards in conformational analysis. Fortunately, later work on the 4-alkyl-2,2,6,6-tetradeuteriocyclohexanols [5] showed that the chemical shift is indeed independent of the nature of the 4-alkyl group. Thus it is reasonable to assume that a 4-substituted t-butyl group does not cause ring deformation. This was later confirmed for t-butylmenthols [31].

The above disagreement [5,30] is due to the difficulty of measuring the true chemical shift. The signals of the α-protons in the non-deuterated substances [30] are complicated by spin-spin coupling with adjacent protons, and although it was claimed that the signals are symmetrical, and that therefore the geometrical centre can be taken as the chemical shift, this is not necessarily so [32]. By adjacent deuteration these splittings were removed and a sharp signal for the α-proton was obtained which showed the true chemical shift [5].

It therefore appears that if the equilibrium constant is to be measured with any degree of accuracy from the chemical shifts, selective deuteration must be carried out [5,29,33–35]. The fact that small differences of the chemical shifts occur in Equation (e) makes accurate measurements particularly important. Thus the difference in chemical shift between the individual conformers of nitrocyclohexane is only 0.2 p.p.m. [36], and therefore the equilibrium constant is better determined by another method.

The chemical shift of the α-proton in alkyl-substituted cyclohexanes depends on the position of the substituent. Thus the values of τ_a and τ_e obtained from 4-t-butylcyclohexanols or the corresponding 1-amino-4-t-butylcyclohexanes differed from those obtained from the corresponding 3-substituted compounds [37,38]. Again the nature of the alkyl substituent in the 3- and 4-position appears to have no influence on the chemical shift. Thus 1-amino-4-t-butylcyclohexanes can be used as reference substances for cyclohexylamine or 1-amino-4-methylcyclohexane, but for *trans*-1-amino-3-methylcyclohexane, 1-amino-3-t-butylcyclohexanes have to be used [38]. Similar results were found for the corresponding substituted cyclohexanols [37]. These considerations however do not apply to 2-substituted cyclohexanes [39]. Thus fixed menthols cannot be used as standards for flexible menthols [31].

A number of other methods have been described in which the variation of chemical shift is used to determine the equilibrium constant.

The configurations of steroids have been determined by the analysis of the chemical shift of the methyl groups on C–10 or C–13 [40]. Their chemical shift depends on structural elements such as substituents, double bonds, *etc.* the influences of which have been collected in tables. Usually the difference between these expected values and those that are measured is less than 1 cps. The shielding due to axial and equatorial substituents is considerably different and it is therefore possible to distinguish between them. However, deviations from these general rules have been reported [41].

An alternative method of determining the equilibrium constant is based on the difference in chemical shift of the hydroxyl protons in a cyclohexanol [42]. By measurement at different concentrations, the chemical shift at infinite dilution of both the cyclohexanol and the reference substances (fixed cyclohexanols) are found. Here also the choice of reference substances is important. Thus ΔG_{OH} was measured with the aid of the 4-butyl-

cyclohexanols [43], and $\Delta G_{C\equiv CH}$ in 1-ethynylcyclohexanol using the 4-t-butyl-1-ethynylcyclohexanols [42]. However it is questionable whether the $\Delta G_{C\equiv CH}$ value obtained is equally valid for ethynylcyclohexane, because 1-ethynylcyclohexanol, as well as the reference substances, are probably deformed by the 1,1 disubstitution pattern [44].

Recently the chemical shifts of the axial and equatorial protons on C–6 and C–8 have been measured in 1,2-diaza-6-methylspiro[2.5]oct-1-ene [45]. The difference here is so large that Equation (e) can be applied accurately. The difference in chemical shift between the axial and equatorial methylene protons was determined by spin-decoupling at different temperatures. In this way a new determination of the ΔG value of the methyl group was carried out. From this one determination, though, the fact that the measured value is in good agreement with that previously determined cannot be taken as proof that the 1,1-diazirino group has no influence on the conformation of the cyclohexane ring.

3. Measurement of Average Coupling Constants

The coupling constants in mobile cyclohexane systems are averaged by the interchanging of the conformers. It is therefore necessary to take fixed substances as standard compounds.

According to a valence-bond treatment by *Karplus* [46], the coupling constant J_{AB} is related to the angle φ between the planes $H_A-C_A-C_B$ and $C_A-C_B-H_B$ by the expression

$$J_{AB} = k_1 \cos^2 \varphi - k_2 \qquad (g)$$

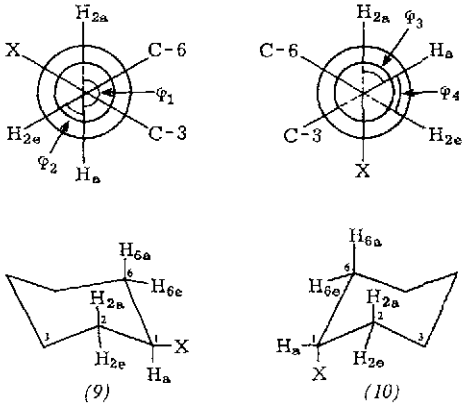
now generally known as the Karplus equation. Originally k_1 and k_2 were regarded as constants, but since then it has been observed that they depend very much on the nature of the system [47–49].

Unfortunately the fact that the coupling constant does not dependent on the angle φ alone is not generally recognized. Thus angles are often calculated from the coupling constants, or *vice versa*, to a degree of accuracy which is not justified [50,51]. Later *Karplus* [52] pointed out, in greater detail, the assumptions made in the theoretical treatment. A more refined calculation [52] leads to the equation

$$J_{HH} = A + B \cos \varphi + C \cos 2\varphi \qquad (h)$$

where the constants depend on the system under consideration. The coupling constants thus also vary with the electronegativity of the substituent [53–56] and with the size of the ring in cyclic olefins [57]. However, even in systems in which these factors are constant, different coupling constants were measured for what was thought to be the same angle.

Consideration of a Newman projection diagram along the C_1-C_2 bond of a non-strained monosubstituted cyclohexane *(9)* shows that the angle φ_1 between the planes $H_\alpha-(C-2)-(C-1)$ and $(C-2)-(C-1)-H_{2a}$ is 180°.



(9) *(10)*

It would therefore be expected that the axial/axial coupling between H_α and H_{2a} would be larger than the axial/equatorial coupling between H_α and H_{2e} as the angle here (φ_2) between the two planes is only 60°.

From the projection diagram of the corresponding conformer *(10)* it might also be expected that the equatorial/equatorial coupling constant should be equal to the equatorial/axial coupling as both correspond to an angle of 60° (*i. e.* $\varphi_3 = \varphi_4$).

From the few values of J_{ee} that have been either measured [14,31] or calculated [58–60], it is apparent that this expectation is not fulfilled. It is also now apparent that, contrary to previous assumptions, it is never possible to equate J_{ea} with J_{ae} [14,22,31].

The best explanation of this phenomenon is the assumption of a ring deformation by the introduction of an axial substituent [31]. Whenever J_{ee} or J_{ea} can be measured, the electronegative group is in the axial position, and owing to the non-bonding interactions with the neighboring protons, the ring is deformed. This deformation is only slight when the electronegative group is in the equatorial position. The angles φ_2, φ_3, and φ_4 (corresponding to J_{ae}, J_{ea}, and J_{ee}) are therefore dif-

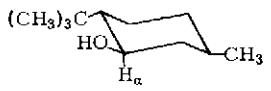
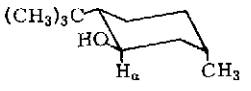
ferent. It is even questionable if the chair form of unsubstituted cyclohexane has angles of 60° between the neighboring coupled protons. Recent evidence suggests that even here there is an inherent deformation [61]. Support for the suggestion that the change in the coupling constants is due to ring deformation was found by examination of the spectra of two isomers of 2-t-butyl-5-methylcyclohexanol, which differ only in the orientation of the methyl group, and both of which are fixed in one conformation [31].



(11)



(12)

A large difference between J_{aa} and J_{ae} was observed in both isomers. This cannot be due to a change in the participating protons themselves, and must therefore be due to the deformation of the ring when the methyl group on C–5 is in the axial orientation.

The suggestion [62] that J_{ea} is smaller than J_{ae} because in this case the electronegative substituent is coplanar with one of the protons which participate in the coupling, cannot explain the difference between J_{ae} and J_{ee} nor the previously mentioned differences in the two t-butylmenthol isomers.

The variation in coupling constants in cyclohexane systems has recently been discussed [63]. Although reservations are expressed therein on the universal application of the Karplus equation to cyclohexane systems it is still true that the theoretical relationship between coupling constant and bond angle has assisted in the understanding of conformational problems.

The previous discussion has been solely concerned with fixed systems. In one of the first measurements of coupling constants in cyclohexane derivatives [64] it was not realised that some of the measurements had been carried out on a mobile system, with the result that the values quoted were *average* coupling constants. The literature also contains values for average coupling constants which have been incorrectly calculated [65 68]. The fact that some of the measured experimental splittings fortuitously agreed with such incorrect average values complicated the situation ever further [65–67]. Later the method of averaging of coupling constants [69] was applied to mobile cyclohexane systems [15, 70], and two expressions (i) and (j) for the average coupling constants

$$J_{aa}^{ee} = x_a J_{aa} + (1-x_a) J_{ee} \quad \text{(i)}$$

$$J^{ea} = x_a J_{ae} + (1-x_a) J_{ea} \quad \text{(j)}$$

were obtained. In several examples "deceptively simple spectra" [24] were obtained in which the splitting cannot be equated with the coupling constants [70].

It is possible to determine the position of the conformational equilibrium from the average coupling constants if the coupling constants in Equations (i) and (j) are known. These can only be determined when certain conditions are fulfilled. First the signal of the α-proton must show a first order splitting so that the average coupling constants may be measured. This is very rarely the case, for very often in monosubstituted cyclohexanes the signal is not even resolved, partly owing to long range couplings. The latter were removed in cyclohexanol by selective deuteration [14].

It is rarely possible to measure the coupling constants of the conformers at low temperatures. Therefore fixed reference substances are used, in which the α-proton signal shows first-order splitting. This also was achieved by partial deuteration, and so it was possible to determine the equilibrium position in cyclohexanol from the average coupling constants [14].

If the signals of the standard substances are not resolved it is possible to estimate the coupling constants from the band widths [70]. It is however simpler to determine the equilibrium from the band widths directly.

4. Measurement of Average Band Widths

One of the first methods to determine the configuration of fixed cyclohexane derivatives was the measurement of the width of the multiplet of the α-proton signal [64], and the variation in the band width was later used as a method of conformational analysis [71–73]. This method has now been extensively applied in the investigation of the conformations of mono-and polysubstituted cyclohexanes [25, 31, 38, 74, 75] and decalins [25, 38, 39] and it has many advantages over the other methods. For example, the conformational equilibrium in nitrocyclohexane has been determined [74], which was not possible from low temperature measurements [17]. Similarly using selected reference substances, the conformations of 2-substituted cyclohexanes were determined [31], which was not entirely accomplished using the chemical shifts.

The band widths are measured between the extreme outer lines of the α-proton multiplet, the assumption being made that the combination lines [*] are so weak that they may be neglected. The band width is then the sum of the coupling constants which cause the splitting. In order to determine the individual coupling constants

[*] Combination lines are due to the simultaneous spin transition of more than one proton.

the system is classified according to the *PSB* system [9]. Fortunately the mobile cyclohexanes systems are mainly of the A_2B_2X, A_2BX, or ABX type and consequently the band widths depend only on the AX and BX coupling constants. For example, the band width between lines 1 and 9 in the nonet often observed in an A_2B_2X system is made up of 2 J_{AX} and 2 J_{BX}, and is independent of J_{AB}.

Analysis of systems has been carried out in which the α-proton multiplet is not completely resolved, but where the position of the extreme outside lines is apparent from inflexions in the curve. If the signal is completely unresolved, it is possible to measure the band width at a predetermined height. For example, in a non-resolved A_2B_2X multiplet, the band width is measured at 1/4 the band height. This procedure is, however, not accurate, as it presupposes first order splitting conditions.

Reference values w_a and w_e have so far not been obtained from low temperature measurements, but only from reference substanecs with the same geometric and magnetic properties. In some cases though it is difficult to find suitable standards [31].

The objection could be raised that the spectra of monosubstituted cyclohexanes are not simple A_2B_2X systems but are complicated by long range coupling and are more of the $A_2B_2C_2D_2E_2X$ type. However, the long range couplings in cyclohexane systems (1–2 cps) are not as strong as in some strained ring systems [76, 77], and have seldom been observed. If such long range coupling is present, it usually occurs between the equatorial protons on C–1 and C–3 [78]. By the selection of suitable reference substances such couplings can be compensated for.

Since the band width is a multiple of the participating coupling constants, it can be measured considerably more accurately than the individual coupling constants.

At this stage it would be advantageous to comment on the relationship between the band width of the absorption due to the methylene protons of the ring and the configuration and conformation of some cyclohexanes. Such a signal is considerably broader in fixed systems than in interchanging flexible systems [79]. A narrow signal is not, however, solely a property of rapidly inverting rings, as the spectra of fixed dialkylcyclohexanes with an axial substituent also show a narrow band [80]. This observation was confirmed by later work on cyclohexylamines [38] for the signal of the ring protons in *cis*-1-amino-4-t-butylcyclohexane at half band height was only 8 cps, and no change was observed at different temperatures. This observation suggests that a fixed axial substituent so influences the chemical shift of the axial and equatorial protons that they appear almost at the same field. This is most likely the reason why *cis*-decalin shows no broadening of the spectra at low temperature [81], for both possible conformations have an axial methylene group at the ring junction.

III. Cyclohexane Derivatives Investigated by NMR Spectroscopy

In Table 1 some examples of NMR-spectroscopic conformational analysis on cyclohexane derivatives are collected. Substances which have been primarily used in configurational analysis are not included [82,83]. Compounds, known not to be in the "perfect" chair form, such as cyclohexenes and cyclohexanones, are also excluded [74,84,85], as are six-membered heterocyclic rings since the ring deformation caused by hetero atoms is not fully understood [86,87].

One of us (N. C. F.) wishes to express his appreciation to the Department of Scientific and Industrial Research (London) for the award of a NATO Post-Doctoral Fellowship.

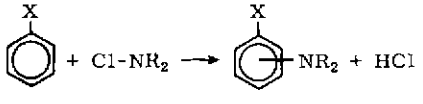
COMMUNICATIONS

Dialkylamination – a New Aromatic Substitution Reaction [1]

By Priv.-Doz. Dr. H. Bock and Dipl.-Chem. K.-L. Kompa [2]

Institut für Anorganische Chemie
der Universität München (Germany)

Aryl dialkylamines are usually prepared from the corresponding nitro compounds by reduction to the amine and alkylation of the resulting arylamine. Dialkylamination of aromatic compounds can now be achieved in a single step using *N*-chlorodialkylamines [3].



This new reaction can be carried out in three ways:

a) By heating the components for 3–6 h in 96 % sulfuric acid at 80–100 °C; addition of metal salts can increase (*e.g.* Na_2SO_4, CuCl, $NiCl_2$, $FeSO_4 \cdot H_2O$, or Hg_2Cl_2) or decrease (*e.g.* $CoCl_2$) the yield.

b) By irradiation of the components in concentrated sulfuric acid for 8–10 h with visible or ultraviolet light.

c) By heating solutions of the components in nitroalkanes at 80–100 °C with Lewis acids, preferably aluminum chloride [4] or ferric chloride.

	Yield [%] of dimethylaminoarene according to method		
	(a) [*]	(b)	(c)
Benzene	81	78	90
Toluene	80	61	50
t-Butylbenzene		58	43
Naphthalene	21	22	35
N,N-Dimethylaniline			21

[*] In a 5 % solution of sodium sulfate in sulfuric acid.

The reaction can be carried out with aromatic compounds, which may contain first-order substituents that are not affected by acids. Occasionally chlorination of the aromatic ring is the predominant reaction, *e.g.* chlorobenzene affords 18 % chlorodimethylaminoanilines by method a) but yields 34 % *o*- and *p*-dichlorobenzene by method c), or anisole yields 57 % chloroanisole by method (b) and 67 % by method (c). The yields of dialkylaminoarenes produced decrease as the length of the alkyl residues on the amine component increases owing to competition with the Hoffmann-Löffler reaction [5]. The new process gives particularly good results with cyclic chloroamines; for example, *N*-chloropiperidine is easy to prepare and reacts with benzene by methods (a)–(c) to give *N*-phenylpiperidine in yields of 60–70 %.

Competition experiments applying method (a) gave relative rate constants for chlorobenzene, benzene, and toluene of 0.1:1.0:9.3. Infrared spectroscopy and gas chromatography were used to determine the proportions of isomers formed in the reaction of toluene with *N*-chlorodimethylamine; the results are as follows (error: *o*- = ± 2 %, *m*-, *p*- = ± 6 %):

(H_2SO_4/Na_2SO_4)	*o*-:*m*-:*p*- = 9:53:38
(H_2SO_4/CuCl	21:46:33
Method (b)	9:53:38
Method (c)	14:27:59

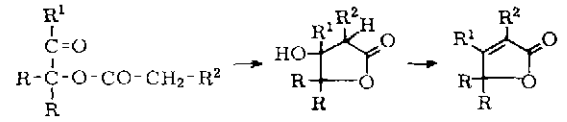
A New Synthesis of Butenolides

By Dr. H.-G. Lehmann

Hauptlaboratorium der Schering AG., Berlin (Germany)

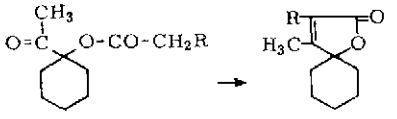
The action of bases (alkali metal hydroxides, alkoxides, amides, or hydrides) on esters of α-hydroxy ketones in aprotic polar solvents such as dimethyl sulfoxide or dimethylformamide leads to a cycloaddition analogous to aldol

condensation and subsequent dehydration to afford butenolides *(1)*.



(1)

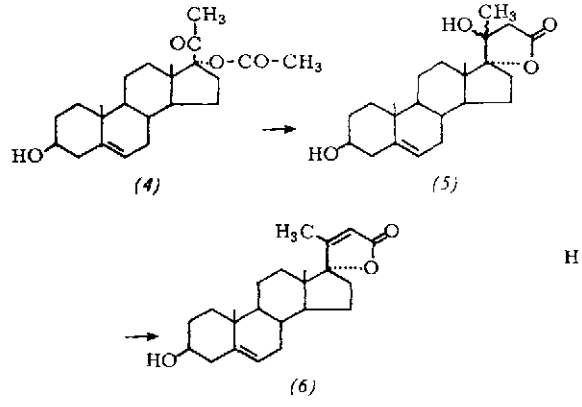
For example, treatment of 1-acetoxy-1-acetylcyclohexane *(2)*, R = H, in dimethyl sulfoxide with 1 mole of sodium hydride for 5 h at room temperature yields 40 % β-[1'-hydroxycyclohexyl]crotonolactone *(3)*, R = H [m.p. 49.5–51 °C, from hexane, ε_{211} = 13300, lactone band at 1752 cm^{-1} in a KBr-pellet].



(2) *(3)*

Similarly, 1-acetyl-1-propionyloxycyclohexane *(2)*, R = CH_3, gives rise to 45 % α-methyl-β-[1'-hydroxycyclohexyl]crotonolactone *(3)*, R = CH_3 [m.p. 65–66 °C, from hexane, ε_{217} = 13370, lactone band at 1750 cm^{-1} in CS_2 or at 1745 in a KBr-pellet].

The analogous reaction with 17α-acetoxy-Δ^5-pregnen-3β-ol-20-one *(4)* affords a 78 % yield of 3β,17α-dihydroxy-$\Delta^{5,20(22)}$-norcholadienic-23 → 17-lactone *(6)*, [m.p. 257–259 °C, from hexane/dichloromethane, ε_{218} = 12000, lactone band at 1743 cm^{-1} in chloroform or 1725 in a KBr-pellet].



(4) *(5)* *(6)*

The β-hydroxybutyrolactone intermediate *(5)* can be isolated if the reaction of *(4)* is conducted with only catalytic amounts of powdered sodium hydroxide in dimethyl sulfoxide at 20 °C and interrupted after 10 min. The 3β,17α,20-trihydroxy-Δ^5-norcholenic-23 → 17-lactone *(5)* melts at 287–288 °C [from ethyl acetate/methanol; lactone band at 1740 cm^{-1} in a KBr-pellet].

Hydroplumbation of Unsaturated Organic Compounds

By Prof. Dr. W. P. Neumann and Dipl.-Chem. K. Kühlein

Institut für Organische Chemie der Universität Gießen (Germany)

Numerous unsaturated organic compounds, *e.g.* those with C=C, C≡C, C=N, or C=O groups, can be hydrostannated [1]. In the organolead hydride series, only attempts to add trimethyl-lead hydride onto ethylene have so far been described; the results are conflicting [2, 3].

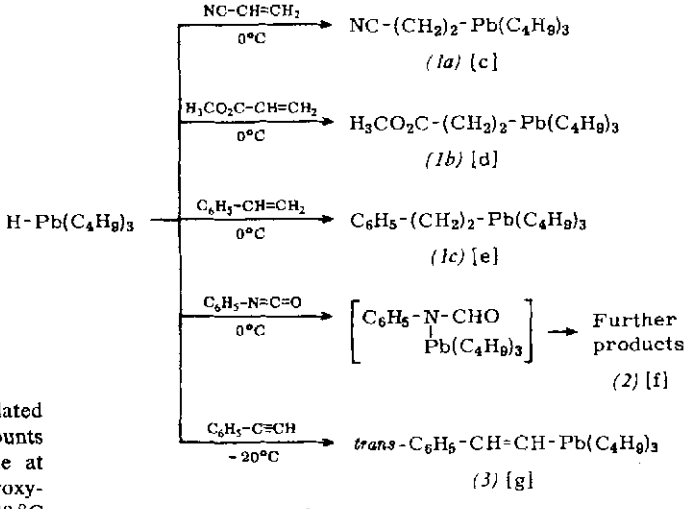
Organolead hydrides of general formulae R_3PbH and R_2PbH_2 were known previously only with R = CH_3 or C_2H_5 [2–5]. They decompose above −20 °C, some even already above −50 °C. In order to obtain compounds which are easier to handle we used larger alkyl residues. We reduced the corresponding chlorides in diethylene glycol dimethyl ether at −60 °C with $LiAlH_4$ and obtained good to excellent yields of the hydrides.

Weaker complexing agents such as ether or tetrahydrofuran allowed the reverse reaction to proceed, and decomposition occurred during isolation. The products are decomposed by light and extremely readily by air but can be kept for a few days at least at 0 °C in the dark.

	R_3PbH				R_2PbH_2
	n-C_3H_7	n-C_4H_9	iso-C_4H_9	cyclo-C_6H_{11}	n-C_4H_9
ν_{Pb-H} [cm^{-1}]	1675 [a]	1680 [a]	1675 [a]	1650 [a]	1640 [b]

[a] In cyclohexane. [b] In diethylene glycol dimethyl ether.

Tributyl-lead hydride adds even at low temperatures and without a catalyst onto α-olefins, isocyanates, and alkynes to *(1a)–(1c)*, *(2)* and *(3)*. The yields obtained with the pure hydride are 90–100 %. The adducts were freed from volatile impurities, distilled if possible, and characterized by their infrared spectra and by C, H, and Ph analyses. Thus a new and very mild method for introducing plumbyl groups into complicated molecules has been established, and numerous organolead compounds containing functional groups – hitherto a very small class of compounds [5] – have become accessible.



(1a) [c] *(1b)* [d] *(1c)* [e] *(2)* [f] *(3)* [g]

[c] B.p. 116–119 °C/0.01 mm.

[d] B.p. 94–97 °C/10^{-4} mm.

[e] B.p. 128–130 °C/10^{-4} mm, with partial decomposition.

[f] The product reacts with both phenyl isocyanate and R_3PbH. Depending on the conditions, a high yield of 1,3,5-triphenyl-isocyanuric acid or of a crystalline compound is formed which decomposes at 170 to 172 °C and probably has the composition $C_{27}H_{22}N_4O_2$. In addition, hexabutyldiplumbane can also be isolated.

[g] This compound decomposes on being distilled.

n-Octene does not react under identical conditions. Pb–H groups can be more reactive than Sn–H groups. Thus acrylonitrile is not attacked by tributyltin hydride at 0 °C without a catalyst within 20 hours, but tributyl-lead hydride adds on completely within 8 hours under the same conditions.

Alkyl halides can be reduced rapidly – often exothermally – to alkanes.

$$R'-I + R_3PbH \rightarrow R'-H + R_3PbI$$

If the alkane is volatile, *e.g.* when $R' = C_2H_5$, this reaction can be used for quantitative estimation of the organolead hydride.

Benzyl chloride, ω-bromoacetophenone, allyl bromide, bromobenzene, and iodobenzene are dehalogenated in this manner at 0 °C; triethyltin chloride gives rise to the hydride, 1,2-dibromoethane to ethylene, and carbon tetrachloride selectively to chloroform or dichloromethane. Benzaldehyde and nitrobenzene are also reduced at 0 °C.

Complexes of Iminophosphoranes with Metal Salts

By Dr. W. Seidel

Institut für Anorganische Chemie der Universität Jena (Germany)

Iminotriphenylphosphorane (triphenylphosphine imine) is a member of the isoelectronic series $(C_6H_5)_3PO - (C_6H_5)_3PNH - (C_6H_5)_3PCH_2$, in which the nucleophilicity increases greatly from left to right. Reactions of the unsubstituted imine and of its *N*-organo derivatives with hydrogen halides, alkyl halides, and Lewis acids have been investigated [1]. However, nothing is known of its ability to form adducts with metal salts. The complexes of triphenylphosphine oxide have been closely examined, and it is known that methylenetriphenylphosphorane condenses with mercuric bromide to give $\{[(C_6H_5)_3PCH_2]_2Hg\}\{HgBr_3\}_2$ [2].

We have found that phosphine imines R_3PNR also form adducts with metal salts. The stability of the adducts depends largely on the nature of the *N*-substituent. *N*-Phenyliminotriphenylphosphorane, $(C_6H_5)_3PNC_6H_5$ *(1)* [3], reacts with mercuric or cadmium iodide in benzene/acetonitrile (1:1 v/v) to give the highly insoluble stable adducts

$(C_6H_5)_3PNC_6H_5 \cdot HgI_2$ *(2)*, yellow, m.p. 178 °C, yield 56 %, and

$(C_6H_5)_3PNC_6H_5 \cdot CdI_2$ *(3)*, colorless, m.p. > 260 °C, yield 78 %.

Compound (2) dissolves in methanol to give a colorless solution and is reprecipitated unchanged on addition of water. It is decomposed by 2 N nitric acid, HgI_2 being liberated. If *(2)* is shaken with ether and a solution of potassium iodide in water containing a little methanol, it is decomposed into K_2HgI_4 and *(1)*, the latter being extracted into the ether phase. An analogous cleavage of *(3)* can be effected with a solution of potassium cyanide.

Complexes of *(1)* with transition metal salts such as $NiCl_2$ or $CoCl_2$ are much less stable. No adduct formation was observed in solvents. However, when the components are fused together, green to blue substances are formed which discolor rapidly in moist air. The colored adducts have the composition $[(C_6H_5)_3PNC_6H_5]_2 \cdot MCl_2$ (M = Co or Ni) and have the magnetic moments expected for weak complexes.

Phosphine Sulfide/Tin Halide Complexes

By Dr. H. Teichmann

Institut für Organische Chemie der Deutschen Akademie der Wissenschaften, Berlin-Adlershof (Germany)

Although numerous adducts of tertiary phosphine oxides are known, the only adduct of phosphine sulfides which has been described is the compound $[(C_6H_5)_3PS]_2PdCl_2$ [1]. We have now found that trialkylphosphine sulfides react in inert solvents such as dichloromethane or hexane with tin(IV) chloride or bromide to give stable 2:1 adducts. High to quantitative yields of the compounds *(1)–(10)* were obtained in this way. The 1:1 adducts *(11)–(14)* were formed analogously from tetraalkylbiphosphine disulfides. The complexes *(1)–(6)* can be sublimed.

$[R_2R'PS]_2SnX_4$ *(1)–(10)* $\quad$ $[R_2P(S)P)(S)R_2]SnX_4$ *(11)–(14)*

	R	R'	X	M.p. [°C]		R	R'	X	M.p. [°C]
(1)	CH_3	CH_3	Cl	196–99	*(8)*	n-C_4H_9	n-C_4H_9	Br	101–02
(2)	CH_3	CH_3	Br	182–84	*(9)*	CH_3	C_6H_5	Cl	174–77
(3)	C_2H_5	C_2H_5	Cl	194–96	*(10)*	CH_3	C_6H_5	Br	155–57
(4)	C_2H_5	C_2H_5	Br	182–84	*(11)*	CH_3	—	Cl	145–47
(5)	n-C_3H_7	n-C_3H_7	Cl	166–66/5	*(12)*	CH_3	—	Br	152–54
(6)	n-C_3H_7	n-C_3H_7	Br	176–77	*(13)*	C_2H_5	—	Cl	146–49
(7)	n-C_4H_9	n-C_4H_9	Cl	93–95	*(14)*	C_2H_5	—	Br	138–39

The electron-donor capacity of the sulfur bonded to phosphorus is less than that of oxygen, as shown by the reaction of the adducts *(1)–(14)* with trimethyl phosphate at room temperature, which releases the phosphine sulfides. However, the adducts are stable towards ether.

The presence of a P=S→Sn coordination in the adducts follows from the bathochromic shifts of the P–S stretching frequencies of up to 45 cm^{-1}.

Triphenylphosphine sulfide does not react with $SnCl_4$ etherate [1], but reacts with $SnCl_4$ in dichloromethane to give an unstable adduct, which decomposes on heating or on treatment with ether.

A One-Step Synthesis of γ-Keto Carboxylic Acids [1]

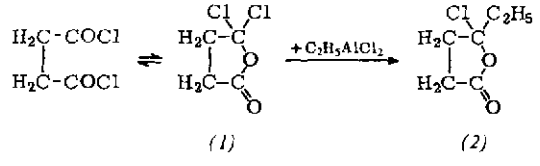
By Dr. H. Reinheckel, Dr. K. Haage, and R. Gensike

Institut für Fettchemie der Deutschen Akademie der Wissenschaften, Berlin-Adlershof (Germany)

Succinyl dichloride *(1)* is readily alkylated at −30 °C by $(C_2H_5)_3Al_2Cl_3$ or $C_2H_5AlCl_2$ in a molar ratio of 1:0.4 or 1:1.2 to yield γ-oxocaproyl chloride, which occurs entirely in

the cyclic form *(2)* [2]. This compound is stable towards even an excess of ethylaluminum halide at this temperature. Hydrolysis of the reaction mixture with dilute sulfuric acid at −25 °C produces γ-oxocaproic acid in 90 % yield.

This reaction can also be applied to higher alkylaluminum halides (see table). The latter are prepared from the corresponding trialkylaluminum compounds [3]. However, the trialkyls can be used directly for the alkylation if a mixture of 1 mole of succinyl dichloride and 2 moles of $AlCl_3$ is used.

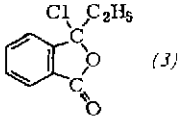


(1) *(2)*

This approach can also be adopted with triethylaluminum but is of little interest because of the ready availability of $(C_2H_5)_3Al_2Cl_3$.

Alkylating agent	Acid obtained	Yield [%]	M.p. [°C]
$(C_2H_5)_3Al_2Cl_3$	γ-Oxocaproic acid	90	34–35
$C_2H_5AlCl_2$		87	33–35
$(C_2H_5)_3Al$		61	33–35
$n\text{-}C_6H_{13}AlCl_2$	γ-Oxocapric acid	80	67
$(n\text{-}C_6H_{13})_3Al$		69	66–67
$(n\text{-}C_8H_{17})_3Al$	γ-Oxolauric acid	81	78
$(n\text{-}C_{12}H_{25})_3Al$	γ-Oxopalmitic acid	40	91

Phthalyl chloride can also be alkylated in the same manner to give γ-keto acids. Both isomers of phthalyl chloride react with $(C_2H_5)_3Al_2Cl_3$ or $C_2H_5AlCl_2$ to give the cyclic form of *o*-propionylbenzoyl chloride *(3)*, which on hydrolysis yields



(3)

propiophenone-*o*-carboxylic acid, m.p. 93 °C. The yields are 74 % from the symmetrical form of phthalyl chloride and 65 % from the unsymmetrical form.

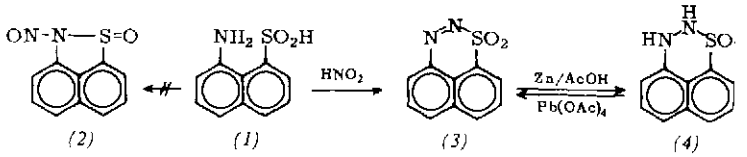
Synthesis of Thieto[2,3,4-ij]naphthalene-1,1-dioxide, a 1,8-Bridged Naphthalene Derivative

By Doz. Dr. R. W. Hoffmann and Dipl.-Chem. W. Sieber

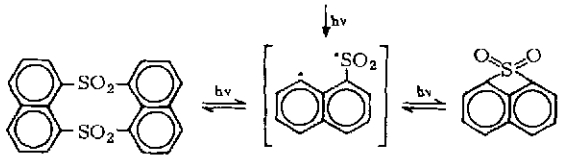
Institut für Organische Chemie der Universität Heidelberg (Germany)

Diazotization of 1-aminonaphthalene-8-sulfinic acid *(1)* leads to 1,2,3-thiadiazino[4,5,6-*ij*]naphthalene-1,1-dioxide *(3)*, m.p. 191 °C, and not, as *Reissert* [1] suspected, to *N*-nitrosothiazolo[3,4,5-*ij*]naphthalene-*S*-oxide *(2)*. This follows from the reduction of *(3)* with zinc plus acetic acid in ethanol to its dihydro derivative *(4)*, m.p. 218 °C (decomp.), in 88 % yield and from the reoxidation of *(4)* to *(3)* by lead tetraacetate in methylene chloride in 50 % yield.

In contrast to 1,2,3-benzothiadiazole-1,1-dioxide [2], which contains a five-membered heterocyclic ring, *(3)* does not release sulfur dioxide or nitrogen until above 200 °C, when it forms the "naphthothiamyl blue" already described by *Reiszert* [1]. This pigment is also formed as the main product on photolysis of *(3)* in benzene for 36 h at 15 °C with ultraviolet light [quartz lamp Q 81 from Messrs. Quarzlampen



(2) *(1)* *(3)* *(4)*



(6) *(7)* *(5)*

GmbH, Hanau (Germany)]. Simultaneously, nitrogen is released to yield 25 % thieto[2,3,4-*ij*]naphthalene-1,1-dioxide *(5)* and 3 % dinaphtho[1,8-*bc*:1′,8′-*fg*]-1,5-dithiocin-1,1,5,5-tetroxide *(6)*. Compound *(5)* melts at 184 °C; its molecular weight was found to be 190 by mass spectrometry and 197 by vapor pressure osmometry in acetone; it has λ_{max} in ethanol at 316 mμ (log ε = 2.6), 284 (3.7), 274 (3.6), and 225 (4.6). Compound *(6)* decomposes above 200 °C, has a mass-spectrometric molecular weight of 380 and an ebullioscopic molecular weight of 375 in the tetrahydrofuran/water azeotrope; λ_{max} in tetrahydrofuran = 295 mμ (log ε = 3.1). Compound *(6)* crystallizes on concentrating the irradiated solution. After complete removal of the solvent, *(5)* can be extracted from the residue with cyclohexane.

The infrared spectra of *(5)* and *(6)* contain characteristic sulfone bands at 1315 and 1130–1165 cm^{-1}.

Photolysis of *(5)* in ethanol gives up to 54 % *(6)*, while analogous irradiation of *(6)* yields 20 % *(5)*. It is possible that the diradical *(7)* appears as an intermediate in these reactions.

The compounds *(3)* and *(5)* are of interest as potential precursors of 1,8-dehydronaphthalene [3]. Pyrolysis of *(5)* at 240 °C under nitrogen gave impure carbonyl compounds [4] plus up to 0.4 % perylene, which was detected by thin-layer chromatography and ultraviolet spectroscopy. It is a moot point whether the perylene is formed *via* 1,8-dehydronaphthalene as an intermediate, for the latter has recently been suggested a likely intermediate in the oxidation of 1-aminonaphtho[1,8-*de*]triazine [3]. We have also studied this oxidation and detected perylene in comparable amounts.

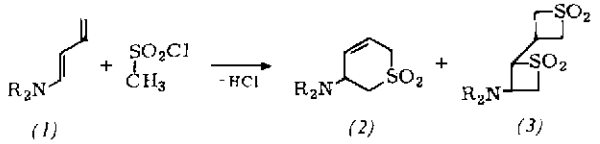
Formation of Cyclic Sulfones from Dialkylaminobutadienes and Methanesulfonyl Chloride

By Priv.-Doz. Dr. G. Opitz and cand. chem. F. Schweinsberg

Chemisches Institut der Universität Tübingen (Germany)

Treatment of 1-dialkylamino-1,3-butadienes *(1)* with methanesulfonyl chloride for 2 h at 15 °C in the presence of 3 moles of triethylamine yields 5-dialkylamino-1-thiacyclohex-3-ene-1,1-dioxide *(2)* plus 3-dialkylamino-2,3′-bithietane-

1,1,1',1'-tetroxide *(3)*. These products can be isolated from the dark brown reaction mixture by fractional crystallization from benzene or by column chromatography on alumina with acetone as eluting agent. The absence of an amino-olefinic grouping in *(2)* and *(3)* follows from their stability towards aqueous acids and excess methanesulfonyl chloride/triethylamine. This also excludes the possibility that the monoadduct is a precursor of the diadduct *(3)*.



(1) *(2)* *(3)*

R_2N	Yield [%]		M.p. [°C]	
	(2)	*(3)*	*(2)*	*(3)*
$(C_2H_5)_2N$	18	60	80–82	139–141
Piperidino	10	48	113–115	149–151
Morpholino	7	20	157–158	181–182

The monosulfones *(2)* have infrared absorptions at 1120, 1270, and 1315 cm^{-1} (SO_2) and at 700 and 1650 cm^{-1} (*cis*-olefin). Their NMR spectra exhibit signals for two olefinic protons at $\tau = 4.1-4.3$, a ring proton on the amino-substituted carbon at $\tau = 5.9-6.2$, and four protons adjacent to the SO_2 group at $\tau = 6.2-6.5$ and 6.8–6.9. The compounds absorb 1 mole of hydrogen over palladium, and afterwards no olefinic double bond can be detected. The chemical and spectroscopic properties of the disulfones *(3)* indicate that they contain no C=C double bond. We consider that the formation of the monosulfones *(2)* is due to a 1,4-cycloaddition of the amino diene *(1)* onto sulfene, $H_2C{=}SO_2$, formed *in situ*, and that the disulfones *(3)* arise by a 3,4-cycloaddition followed by a 1,2-cycloaddition.

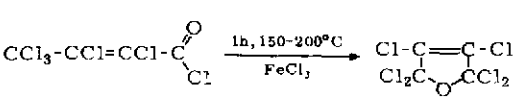
Synthesis of Hexachlorodihydrofuran

By Dr. G. Maass

Chemische Werke Hüls AG, Marl, Kreis Recklinghausen (Germany)

Hexachlorodihydrofuran *(2)* was hitherto only accessible with difficulty from furan by chlorination [1]. It has now been found that perchlorocrotonyl chloride *(1)*, which is readily obtainable by ethoxylation of hexachlorobutadiene and subsequent chlorination [2], rearranges smoothly to *(2)* on heating in the presence of catalytic amounts (0.01–1.0 %) of ferric chloride, ferric acetate, or aluminum trichloride.



(1) *(2)*

The conversion after 1 h at 175 °C lies between 85 and 95 % depending on the catalyst, and *(2)* is almost the only product formed. The course of the reaction can be followed by infrared spectroscopy: *(1)* has a characteristic absorption band at 8.93 μ, *(2)* at 8.30 μ. The product *(2)* is separated from the reaction mixture by distillation (b.p. 209–213 °C) and purified by fractional crystallization at −20 °C and reprecipitation with water from methanol; m.p. 38–39 °C.

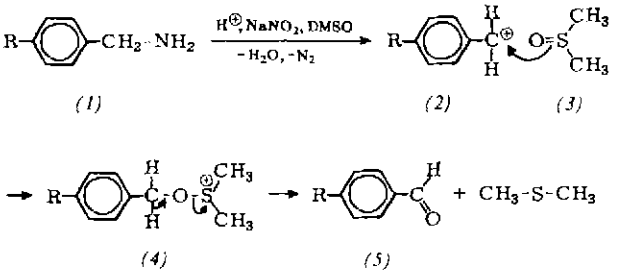
Synthesis of Benzaldehydes by Diazotization of Benzylamines in Dimethyl Sulfoxide

By Dr. K. H. Scheit and Dr. W. Kampe

Chemische Abteilung der Medizinischen Forschungsanstalt der Max-Planck-Gesellschaft, Göttingen (Germany)

If benzylamines *(1)* are diazotized in dimethyl sulfoxide *(3)* in the absence of water, reaction of the carbonium ions *(2)* formed by the elimination of nitrogen with the dimethyl sulfoxide should lead to the intermediates *(4)*, from which the corresponding aldehydes should be obtained. When



(1) *(2)* *(3)* *(4)* *(5)*

benzylamines *(1)* were treated with sodium nitrite and trifluoroacetic acid in a molar ratio of 1:2:3 in dimethyl sulfoxide for 20 h at 100 °C, benzaldehyde derivatives *(5)* were in fact isolated in the form of their 2,4-dinitrophenylhydrazones (R = H, 82 % yield; R = CH_3, 60 %; R = OCH_3, 65 %). The use of isoamyl nitrite instead of sodium nitrite led to lower yields of aldehyde.

Polar Reactions at Covalent Tin-Phosphorus Bonds

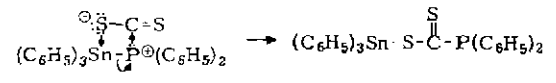
By Dr. H. Schumann, Dr. P. Jutzi, and Prof. Dr. Max Schmidt

Institut für Anorganische Chemie der Universität Marburg (Germany)

Straightforward reactions now enable synthesis of organostannylphosphines [1, 2] and thus the study of the covalent Sn–P bond. Diphenylphosphinotriphenyltin, for example, reacts with CS_2, $CSCl_2$, $CS(NH_2)_2$, $C_6H_5{-}NCO$, $C_6H_5{-}NCS$ (in boiling benzene), and COS (at 100 °C in a sealed tube), but not with CO_2. The products are the new compounds shown in the table below; they were crystallized from benzene/pentane.

$(C_6H_5)_3Sn\ P(C_6H_5)_2$	Product		M.p. [°C]	Yield [%]
CS_2	$R_3Sn{-}S{-}C(S){-}PR_2$	*(1)*	68	64
COS	$R_3Sn{-}O{-}C(S){-}PR_2$	*(2)*	97	63
$CSCl_2$	$R_3Sn{-}S{-}CCl_2{-}PR_2$	*(3)*	93	87
$CS(NH_2)_2$	$R_3Sn{-}S{-}C(NH_2)_2{-}PR_2$	*(4)*	115	22
C_6H_5NCO	$R_3Sn{-}N(C_6H_5){-}C(O){-}PR_2$	*(5)*	58	64
C_6H_5NCS	$R_3Sn{-}N(C_6H_5){-}(CS){-}PR_2$	*(6)*	(decomp.) 87	71

The reactions correspond to the formally analogous insertion reactions at Si–N and Sn–N bonds [3, 4] and probably proceed *via* a polar four-centered concerted mechanism.



Tetrakis(diphenylphosphino)tin [1] reacts with CS_2 or $C_6H_5{-}NCO$ with corresponding cleavage of all four Sn–P bonds in the molecule to give tin tetrakis(diphenylphosphinodithiocarbonate), m.p. 55 °C, or tin tetrakis-(*N*-diphenylphosphinocarbonyl-*N*-phenylamide), m.p. 50 °C. Tris(triphenylstannyl)phosphine [2], on the other hand, does not

undergo such cleavage reactions. This finding also provides support for the assumption of a polar mechanism for the reactions described here. The lone pair of electrons on the phosphorus which initiates the attack is rendered almost inactive in tris(triphenylstannyl)phosphine by interaction with the three tin atoms.

In the infrared spectra of compounds *(1)*–*(4)*, γ(Sn–S) was found at 349 cm^{-1} in *(1)*, at 351 cm^{-1} in *(3)*, and at 352 cm^{-1} in *(4)*, while γ(Sn–O) was found at 541 cm^{-1} in *(2)*. The structures of compounds *(5)* and *(6)* follow from the absence of P–N vibration bands.

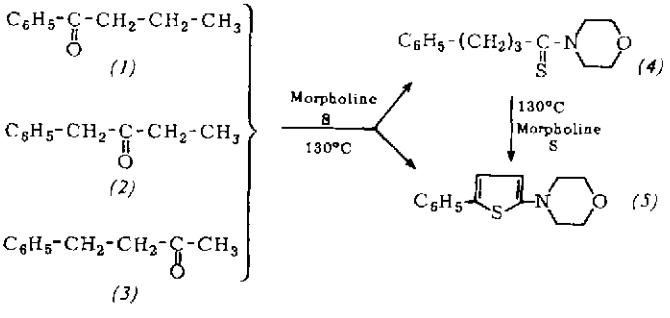
Formation of 2-Morpholino-5-phenylthiophene in the Willgerodt-Kindler Reaction of 1-Phenylbutanones

By Prof. Dr. F. Asinger and Dipl.-Chem. A. Mayer

Institut für Technische Chemie der Technischen Hochschule Aachen (Germany)

If the 1-phenylbutanones *(1)*–*(3)* are treated with 2 moles of morpholine and 2 g-atoms of sulfur per mole of ketone at the boiling point of morpholine (*ca.* 130 °C), 2-morpholino-5-phenylthiophene *(5)* [1], m.p. 134 °C, λ_{max} = 210 mμ, 226 mμ, and 328 mμ in ethanol, is obtained in each case in addition to the expected 4-phenylbutyrothiomorpholide *(4)*, m.p. 57 °C. Compound *(5)* is also formed when *(4)* is subjected to the same treatment.



The structure of *(5)* was established by hydrolysis with 50 % sulfuric acid, which gave 4-oxo-4-phenylbutyric acid, and by its synthesis from 4-oxo-4-phenylbutyromorpholide with P_2S_5.

[1] *T. Bacchetti, A. Alemagna*, and *B. Danieli*, Tetrahedron Letters *1965*, 2001, recently reported the formation of morpholinothiophenes during the Willgerodt-Kindler reaction of alkynyl ketones and β-diketones.

Synthesis of Methyl α-Nitro-β-methoxypropionate, a Protected α-Nitracrylic Ester

By Prof. Dr. K.-D. Gundermann and Dipl.-Chem. H.-U. Alles [1]

Organisch-Chemisches Institut der Bergakademie, Technische Hochschule, Clausthal-Zellerfeld (Germany)

α-Nitracrylic esters should be among the most reactive acrylic acid derivatives owing to the electron-attracting effects of both the nitro and ester groups. Earlier attempts to prepare α-nitro-β-alkoxypropionic esters, *i.e.* compounds of type *(3)*, as precursors of α-nitracrylic esters invariably led to α,α'-dinitro-α-alkoxymethylglutaric esters, the products of a Michael addition of the α-nitracrylic ester onto *(3)* [2].

Methyl α-nitro-β-methoxypropionate *(3)* has now been obtained by dehalogenation of methyl α-bromo-α-nitro-β-methoxypropionate *(2)* with sodium borohydride. A 10 % aqueous solution of $NaBH_4$ is added in 50 % excess to a 5 % solution of *(2)* in methanol at room temperature, the pH being maintained at 4–5 by simultaneous addition of 30 % sulfuric acid. After evaporation of the methanol in vacuum, the solution is extracted with ether. The ether extract is neutralized with sodium hydrogen carbonate and fractionated. The product, b.p. 69 °C/0.3 mm, n_D^{20} = 1.4313, is obtained in 70 % yield. Compound *(2)* can also be dehalogenated with potassium iodide in 10 % aqueous methanolic solution at 0–5 °C. The methanol is removed as above, the solution is shaken with ether, and the ether extract is freed from iodine by shaking it with sodium thiosulfate solution and then fractionated; the yield is again 70 %. The starting material *(2)*, b.p. 73–75 °C/0.3 mm, n_D^{20} = 1.4655 is made from methyl α-bromo-α-nitro-β-hydroxypropionate [3] by treatment for 4 days with trimethyloxonium fluoroborate, or less readily by bromination of methyl α-hydroximino-β-methoxypropionate [2] with *N*-bromosuccinimide and oxidation of the resultant α-bromo-α-nitroso ester with $KMnO_4$.

(1), R = H, R' = Br *(4)*, R = NO_2, R' = CO_2CH_3

(2), R = CH_3, R' = Br

(3), R = CH_3, R' = H

It was shown by trapping reactions that methanol is readily eliminated from *(3)* to give methyl α-nitracrylate. For example, the potassium salt of the aci-form of *(3)* yields the Michael adduct methyl α,α'-dinitro-α-alkoxymethylglutarate on gradual addition of 0.5 equivalent of sulfuric acid to its aqueous solution. When anthracene is heated with *(3)*, 9,10-dihydro-9,10-(1-nitro-1-methoxycarbonylethano)anthracene *(4)* is formed.

Compound *(3)* can be kept unchanged for months at room temperature in contrast to the recently described ethyl α-nitro-β-hydroxypropionate [4], which can also be regarded as a protected α-nitroacrylic ester.

Uncoupling of the Oxidative Phosphorylation in Mitochondria by NH-Acidic Benzimidazoles

By Dr. K. H. Büchel and Prof. Dr. F. Korte

Shell Grundlagenforschung GmbH, Schloß Birlinghoven, Siegburg (Germany) and

Dr. R. B. Beechey

Milstead Laboratory of Chemical Enzymology, Shell Research Ltd., Sittingbourne (England)

Some electronegatively substituted benzimidazoles [1] have a strong herbicidal and in some cases also insecticidal activity. They have pK_a values between 4 and 8 and behave like weak

acids: they dissolve in aqueous sodium carbonate and are reprecipitated by acidification with HCl but do not form hydrochlorides. Their biological activity is related to their pK_a value.

We have studied the action of such compounds on oxidative phosphorylation in isolated mitochondria from rat heart. It was found that the benzimidazoles listed in the table have an uncoupling effect similar to that of 2,4-dinitrophenol. They inhibit the regulation of the mitochondrial respiration by adenosine diphosphate (ADP) and stimulate the respiration beyond the state 3 rate [2]. They also counteract the inhibition of the respiration caused by oligomycin and octylguanidine, and stimulate ATPase as well as or even better than 2,4-dinitrophenol. The reduction of NAD in the electron transport of the mitochondria, which is dependent upon ATP and linked to succinate, is inhibited.

As shown in the table, the uncoupling activity increases exponentially with the N—H acidity of the benzimidazoles. *N*-Methylation leads to a complete loss of their action on the respiratory chain. Tetrachloro-2-trifluoromethylbenzimidazole effects complete uncoupling of oxidative phosphorylation at a concentration as low as 3×10^{-8} M. It is thus the strongest uncoupler known to date.

(1) 	pK_a [a]	Uncoupling concentration [μM/l] [b]
(1) TFB	9.6	500
(2) 5-Chloro-TFB	8.9	14
(3) 5,6-Dichloro-TFB	7.6	0.8
(4) 4,5,6-Trichloro-TFB	6.6	0.2
(5) 4,5,6,7-Tetrachloro-TFB	5.6	0.03
(6) *N*-Methyl-4,5,6-trichloro-TFB	–	inactive

[a] In 50 vol-% aqueous ethanol.

[b] The course of the respiration of rat heart mitochondria was measured at 25 °C [3] using an oxygen electrode [4]. The mitochondria (2—3 mg of protein) were suspended in 0.25 M sucrose/1.0 mM ethylenediaminetetraacetic acid and then added to 3.7 ml of a mixture containing the following components: 9.3 mmole of sucrose, 50 μmole of dipotassium glutamate, and 20 μmole of $MgCl_2$. When state 4 respiration started, 0.4 μmole of ADP was added in order to obtain state 3 respiration. On reattainment of state 4, a solution of the benzimidazole in ethanol was added; an increase in respiratory activity was immediately observed. More ADP was then added. When the second addition of ADP exhibits no further effect on the respiratory activity, the phosphorylation system is uncoupled.

4,5,6,7-Tetrachloro-2-trifluoromethylbenzimidazole

A solution of 93 g (0.5 mole) of 2-trifluoromethylbenzimidazole in dichlorobenzene is heated at 120 °C. The solution is stirred and chlorine is passed through for about 36 h at a rate of 4–5 l/h. The solvent is removed in vacuum and the crude crystalline residue is suspended in boiling water. More chlorine is passed in until the conversion to the tetrachloro derivative is complete (after approx. 24 h). The end point of the chlorination is determined by analysing a sample of the reaction mixture by gas chromatography on Apiezon L at 250 °C with helium in a column 96 cm long. The product is then filtered off and recrystallized from xylene. The yield of colorless crystals, m.p. 269 °C, $\lambda_{max} = 223$, 273, 290, and 301 mμ (log ε = 4.92, 3.94, 3.85, and 3.81), is above 95 %.

Inhibition of Photosynthesis Reactions by NH-Acidic Imidazoles and Benzimidazoles

By Dr. K. H. Büchel and Prof. Dr. F. Korte

Shell Grundlagenforschung GmbH., Schloß Birlinghoven/Siegburg (Germany) and

Prof. Dr. A. Trebst and E. Pistorius

Abteilung Biochemie der Pflanzen, Pflanzenphysiologisches Institut der Universität Göttingen (Germany)

Imidazoles and benzimidazoles containing strongly electronegative substituents, *e.g.* halogens or trifluoromethyl or nitro groups, are strongly acidic at the NH group and sometimes exhibit good herbicidal properties. Since some herbicides, *e.g.* urea derivatives, aminotriazines, and uracils, inhibit the fixation of carbon and release of oxygen by photosynthesis, we have examined the effects of our herbicidal heterocycles on photosynthesis reactions in isolated chloroplasts.

The table shows that these substances inhibit the electron transport in photosynthesis. The compounds with the highest activity have a high NH-acidity [1]. *N*-Alkylation of the acidic secondary amino group, *e.g.* to give *(10)*, causes a reduction in the inhibitory effect. The imidazole anion is probably the species responsible for the effect. Since the release of oxygen is inhibited at concentrations which are insufficient to affect cyclic photophosphorylation, the blockage

Table 1. Relationships between the pK_a (in 50 % aqueous ethanol) of some substituted imidazoles and benzimidazoles and their inhibitory action (pI_{50} = minus the logarithm of the molar concentration which produces a 50 % inhibition) on the release of oxygen and the cyclic photophosphorylation during photosynthesis in isolated chloroplasts [3].

occurs in the region of the second light reaction of photosynthesis (photo-oxidation of water), for this is not required for cyclic phosphorylation. Higher concentrations – generally about ten times greater – cause inhibition of the cyclic photophosphorylation, *i.e.* formation of ATP, as well (see Table). In this respect, the imidazoles and benzimidazoles described here differ from the herbicides of the urea and triazine types, which only affect the cyclic phosphorylation at extremely high concentrations, if at all. The inhibition of the formation of ATP by the benzimidazoles is due to an uncoupling and not to a disturbance of the cyclic electron transport, because photosynthetic reduction of NADP by an artificial electron donor (diaminodurol/ascorbate [2]) is not inhibited even by much higher concentrations of herbicide. Hence the electron transport in the region of the first light reaction is unaffected.

The benzimidazole derivatives listed in the table were prepared by condensation of the correspondingly substituted *o*-phenylenediamines with excess trifluoroacetic acid at 80–100 °C or by substitution of 2-trifluoromethylbenzimidazole *(1)* [6]. Compound *(6)* was made by bromination of *(1)* with a twofold molar excess of bromine in boiling water. Compound *(7)* is obtained in 60 % yield by nitrating *(1)* with HNO_3 (sp. gr. = 1.52) at 60–70 °C and recrystallization from xylene. The *N*-methyl derivative *(10)* is formed by treating the sodium salt of *(4)* with methyl iodide in acetonitrile at 50 °C. The trihaloimidazoles *(8)* and *(9)* were made according to [7].

Received: July 12th, 1965 [Z 39/864 IE]
German version: Angew. Chem. 77, in press.

[1] A similar relationship between the half-neutralization potential of substituted *N*-phenyl amides and the inhibition of the Hill reaction was recently observed: *N. D. Camper* and *D. E. Moreland*, Biochem. biophysica Acta *94*, 383 (1965).

[2] *A. Trebst* and *E. Pistorius*, Z. Naturforsch. *20b*, 143 (1965).

[3] Duplicate experiments were carried out on 3 ml samples containing chloroplast fragments (P_{151} from spinach [4], 0.2 mg of chlorophyll), 80 µmole of tris buffer at pH 8.0, 5 µmole of $MgCl_2$, 10 µmole of potassium phosphate, 10 µmole of ADP, and either 20 µmole of $K_3[Fe(CN)_6]$ or 0.3 µmole of vitamin K_3. The mixtures were exposed to 35000 lux for 15 min under nitrogen. The oxygen produced was determined manometrically and the amount of ATP formed was determined enzymatically with phosphoglycerokinase, triose phosphate dehydrogenase, phosphoglyceric acid, and $NADH_2$. The control value for the oxygen production without addition of inhibitor was 1300 mm^3 per mg of chlorophyll per h.

Photo-initiated Hydrocarboxylation of Mono-olefins

By Dr. B. Fell and Dipl.-Chem. J. M. J. Tetteroo

Institut für Technische Chemie, Technische Hochschule, Aachen (Germany)

During hydrocarboxylation [1] of higher n-alkynes under normal pressure to give α,β-unsaturated carboxylic acids, the length of the inhibition time and the rate of the reaction depend on the intensity of the incident light [2]. We have found that if the reaction is carried out in ultraviolet light, open-chain or cyclic mono-olefins can also be converted into the corresponding carboxylic acids in good conversions and high yields, although these compounds can otherwise seldom be hydrocarboxylated. The results obtained are shown in the table. Each charge comprised 0.25 mole of olefin, 0.15 mole of nickel carbonyl, 5 moles of water, 0.5 mole of HCl (added in the form of concentrated hydrochloric acid), and 200 ml of acetone. The ultraviolet radiation source was a 70 watt Q 81 immersion lamp from Messrs. Quarzlampen GmbH, Hanau (Germany); the reaction temperature was 55–60 °C.

Olefin	Light	Duration of reaction [h]	Product	Conversion [%]	Yield [%]
Cyclohexene	Darkness	6	Cyclohexane-carboxylic acid	9.1	83
	Daylight	6		24	58
	Ultraviolet	6		64	84
	Ultraviolet	9		96	83
n-1-Octene	Darkness	6	No reaction		
	Daylight	6	A mixture of isomeric nonanoic acids [a]	9.1	55
	Ultraviolet	6		86.5	70
	Ultraviolet	9		98	70
cis-n-4-Octene	Daylight	6	No reaction		
	Ultraviolet	6	A mixture of isomeric nonanoic acids [b]	68	17
	Ultraviolet	9		91	17

[a] 37 % 1-nonanoic acid, 61 % 2-nonanoic acid, 1 % 3-nonanoic acid, and 1 % 4-nonanoic acid.

[b] 2 % 2-nonanoic acid, 3.5 % 3-nonanoic acid, and 94.5 % 4-nonanoic acid.

The unconverted olefin is partly isomerized. For example, after hydrocarboxylation of 1-octene in daylight, the unconverted olefin consists of 87.1 % starting material, 2.8 % *cis*-2-octene, and 10.1 % *trans*-2-octene. After irradiation with ultraviolet light, however, the percentages are 28.8, 13.6, and 57.6 %, respectively. After the reaction with *cis*-4-octene, the unchanged olefin comprises 92 % starting material, 5 % *trans*-n-4-octene, and 3 % *trans*-n-3-octene.

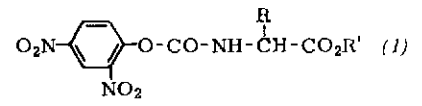
N-(2,4-Dinitrophenyloxycarbonyl)amino Esters – New N-Activated Amino-Acid Derivatives

By Dr. J. Gante

Institut für Organische Chemie der Freien Universität Berlin (Germany)

Reaction of amino esters with bis-(2,4-dinitrophenyl) carbonate [1] in a molar ratio of 1 : 1 in anhydrous ethyl acetate or ethyl acetate/ether (1 : 2 v/v) at room temperature followed by precipitation with petroleum ether gives the *N*-(2,4-dinitrophenyloxycarbonyl)amino esters *(1a)–(1d)*.

Compounds *(1a)–(1d)* are colorless to pale yellow crystalline solids which as *N*-activated amino esters are suitable for peptide syntheses. For example, reaction of *(1a)–(1d)* with an equimolar amount of Cbo-glycine led to the formation



(1)

CONFERENCE REPORTS

The Kinetics of Proton Transfer Processes

A discussion meeting was held by the Faraday Society on "The kinetics of proton transfer processes" in Newcastle-upon-Tyne (England) from April 12 to 14, 1965, at which 20 papers were read.

From the lectures:

In his introductory lecture, *M. Eigen* (Göttingen, Germany) outlined the general aspects of proton transfer processes. The rate of proton transfer is determined essentially by the distance between the proton donor and the proton acceptor at the moment of reaction; therefore, formation of hydrogen bonds between the two participants favors fast proton exchange. The rate constants of the recombinations

$H_3O^+ +$ base

and

$HO^- +$ acid

have been determined for numerous systems in aqueous solution. They approach the value characteristic of a diffusion-controlled reaction ($k = 10^{10}-10^{11}$ mole^{-1}·sec^{-1}). If the basicity of the acceptor is greater than that of the donor, the reaction is diffusion-controlled and is independent of the (positive) pK_a difference. If, on the other hand, $\Delta pK_a \leq 0$, log k will be a linear function of ΔpK_a. When log k is plotted against ΔpK_a, the gradient α decreases from 1 to 0 as ΔpK_a becomes more positive. The width of the ΔpK_a region for $0 \leq \alpha \leq 1$ depends on the nature of the reactants [1].

[1] Cf. *M. Eigen*, Angew. Chem. *75*, 489 (1963).

Brønsted's equation for acid and base catalysis stipulates a linear relationship between log k and the pK_a value of a catalytically active acid or base:

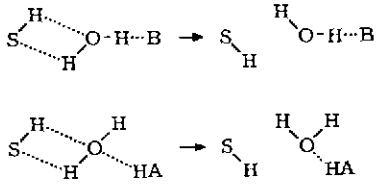
$$\log k = \alpha pK_a + c$$

where α and c are constants.

As long as the branches of the potential curves closely approximate to straight lines, α remains approximately constant. With increasing deviation from a linear shape, α must decrease and eventually become zero. Relaxation measurements carried out on numerous systems (*e.g.* the halogenation of acetylacetone, acetone, and bromoacetylacetone) indeed reveal a continuous change in the value of α between 1 and 0, when pK_a of the catalysing species varies. However, many reactions (*e.g.* mutarotation of glucose, hydration or dehydration of carbonyl compounds, hydrolysis of esters) behave differently. These reactions are governed by general acid-base catalysis:

$$HS + HA \rightleftharpoons HSH^+ + B$$
$$B + HSH^+ \rightleftharpoons HA + SH$$

The plot of log k against ΔpK_a often gives apparently too high rate constants. This finding is explained by simultaneous attack of the acid HA and the base B at the substrate SH, which is aided by the amphoteric nature of water. *Eigen* proposes the following transition complex formed by a concerted mechanism:



This concept of "concerted mechanism" was developed by *Swain* and *Brown* [2] in connection with studies involving amphoteric catalysts in aprotic solvents.

C. Challis and *F. A. Long* (Ithaca, U.S.A.) investigated the kinetics of the protonation of azulene (a weak base) using flow measurements. After making allowance for the solvent effect and a statistical correction, the results were found to be in complete agreement with the data for the acid-catalysed tritium-exchange of [1-T]-azulene and of substituted azulenes. The protonation of azulene can be analogously postulated to proceed in two steps *via* an A–SE2 mechanism [*]. The rate constants for protonation (k_f) and deprotonation (k_r) were determined independently. At perchloric acid concentrations between 1.5 M and 5 M,

$$k_f = 1.52 \times h_0^{1.26}$$

and $$k_r = 110 \times h_0^{-0.68},$$

where h_0 is *Hammett*'s acidity function. It follows from the temperature dependence of the acidity constant $K_{AzH_2^+}$ of the azulenium cation that $\Delta G^\circ = -2.4$ kcal, $\Delta S^\circ = -11$ cal·deg^{-1}, and $\Delta H^\circ = -5.8$ kcal. The small value of ΔG° indicates that azulene and the azulenium cation are of comparable stability.

On the basis of kinetic and equilibrium measurements, *A. J. Kresge et al.* (Chicago, U.S.A.) have refuted the earlier view [3] that proton exchanges in aromatic systems proceed *via* two basically different routes depending on whether they are catalysed by strong or weak acids. The proton exchange of aromatic systems was studied on [4-T]-1,3-dimethoxybenzene in fairly concentrated acid solutions. For the same value of h_0, proton transfer in sulfuric acid proceeds faster by a factor of 2.5 to 3 than in perchloric acid. The equilibrium concentration of protonated azulene in solutions of H_2SO_4 and $HClO_4$ was determined spectroscopically. When the rate of the reactions

$$HAr + H^+ \rightleftharpoons HArH^+$$

is plotted against the concentration ratio c_{HArH^+}/c_{HAr}, the reaction is seen to proceed 5.5 times as fast in sulfuric acid as in perchloric acid. It follows from the variation of the "excess rate" in sulfuric acid with the stoichiometric composition of the solution that HSO_4^- and H_2SO_4 are present as catalytically active species in addition to H_3O^+.

This demonstrates a general acid-base catalysis for the proton exchange in aromatic systems.

E. Grunwald (Waltham, U.S.A.) reported on the kinetics of proton transfer between various amines and solvents of different dielectric constants, *viz.* water, methanol, t-butanol, and glacial acetic acid. Nuclear magnetic resonance measurements allow the determination of reaction rates, and, occasionally, of the number of participating solvent molecules. In solvents of high dielectric constant, the following reactions involve proton exchange:

Acid dissociation of BH^+

$$BH^+ + ROH \underset{k_{-1}}{\overset{k_{+1}}{\rightleftharpoons}} B + ROH_2^+ \qquad (1)$$

Direct proton transfer from BH^+ to B

$$BH^+ + B \xrightarrow{k_2} B + HB^+ \qquad (2)$$

Proton transfer from BH^+ to B *via* a solvent molecule

$$BH^+ + \underset{R}{\overset{|}{O}}H + B \xrightarrow{k_3} B + \underset{R}{\overset{|}{HO}} + HB^+ \qquad (3)$$

Reactions (1) to (3) were investigated with ammonium, methylammonium and sarcosinium ($H_3C-\overset{\oplus}{N}H_2-CH_2-COOH$) ions in water. In these cases, at least two molecules of water are involved in the acid dissociation. The value obtained for k_{-1} indicates that the reaction is governed by diffusion [this does not apply to $(CH_3)_3PH^\oplus$]. Because of increasing steric hindrance and/or increasing energy of desolvation, k_2 rapidly falls with increasing degree of methylation, whereas k_3 is only slightly dependent on the number of substituents present. The involvement of one molecule of water in Reaction (3) has been confirmed.

The behavior of *p*-toluidinium, trimethylammonium, and phenyldimethylphosphonium ions in methanol has been investigated and the results agree with those obtained in water. The value of k_3 for the reaction of the phenyldimethylphosphonium ion is very much smaller than for the ammonium ions ($k_3 < 10^4$ mole^{-1} sec^{-1}). In t-butanol ($\varepsilon = 12.47$), the ammonium salts are present mostly as ion pairs, and proton transfer proceeds predominantly *via* Reaction (4):

$$BH^+X^- + \underset{t\text{-}Bu}{\overset{|}{O}}H \rightarrow B + H^+X^- + \underset{t\text{-}Bu}{\overset{|}{HO}} \qquad (4)$$

The ratio $k_3(H_2O)/k_4(t\text{-}Bu)$ for the trimethylammonium ion is strongly dependent on the nature of the anion, that for the methylammonium ion hardly so. In the latter, two protons are available for hydrogen bond formation with the solvent, without any inhibition of the reaction. The third proton is engaged in forming an ion pair with the anion, as in the case of the single proton of the trimethylammonium ion.

The proton exchange between aliphatic amines B and glacial acetic acid is a first order reaction with respect to BH^+OAc^-, and takes place according to Equations (5) and (6), the latter being the rate-determining step:

$$BH^+OAc^- \rightleftharpoons B{\cdot}HOAc \qquad (5)$$

$$AcOH^* + B{\cdot}HOAc \xrightarrow{k_H} B{\cdot}{}^*HOAc + AcOH \qquad (6)$$

H. Strehlow (Göttingen) reported that the H_3O^+-catalysed hydration of acetylaldehyde in a solution acidified with HCl is accompanied by a broadening of the NMR signals of both the hydrated and the unhydrated aldehyde species. The rate of the reaction was determined from the width of the lines. In solutions containing up to about 10 mole-% of acetaldehyde, hydration results mainly in $CH_3-CH(OH)_2$, whereas in more concentrated solutions the hemihydrate $(CH_3CHOH)_2O$ is formed increasingly. The first step in both reactions is the protonation of the weakly basic acetaldehyde. The variation in the rate constant with *Hammett*'s acidity function indicates that protonation is the rate-determining step or that its rate is at least comparable with that of hydration. Similar experiments in dimethylsulfoxide/water and acetone/water, lead to an estimated pK_a value of the protonated aldehyde of $-8.5 < pK_a < -7.5$. An amphoteric mechanism involving one or more molecules of water cannot be ruled out.

Regarding the intramolecular proton transfer between the positively charged carbon atom and adjacent positions, *D. M. Brouwer* (Amsterdam, Holland) discussed the kinetic inferences that can be drawn from the NMR spectra of the 2,3-dimethylbutyl cation and of several protonated aromatic systems (*i.e.* the cations of hexamethylbenzene, 1,2,3,4-tetramethylbenzene, 5,8-dimethyltetralin, *o*-dimethoxybenzene, and 1,4-benzodioxane). For the aromatic carbonium ions investigated, the rates of the proton transfer differ by more

[2] *C. G. Swain* and *J. F. Brown*, J. Amer. chem. Soc. *74*, 2534, 2538 (1952).

[*] A–SE2 denotes Aromatic substitution, electrophilic, bimolecular.

[3] *V. Gold*, Proc. chem. Soc. (London) *1961*, 453.

than 10^8, and show no correlation with the basicity of the aromatic systems. The rate of transfer is determined to a large extent by the proportion of the positive charge carried by the acceptor carbon atom. In the transition state, the positive charge remains on the carbon atom and a σ-bond is formed between carbon and hydrogen.

According to *A. H. Weller* (Amsterdam, Holland), the fluorescence spectra of β-naphthol and 3-hydroxypyrene vary according to whether the molecules are present in forms *(1)*, *(2)*, or *(3)*:

$$\underset{(1)}{A^*H + B} \rightleftharpoons \underset{(2)}{A^*H \cdots B} \rightleftharpoons \underset{(3)}{A^{*-} \cdots HB^+}$$

(AH and B are an acid and base, respectively, and the asterisk denotes an excited species). If intermolecular hydrogen bonds are formed, then the close dependence on solvent and temperature indicates that proton transfer is favored by highly polar solvents. Solvent orientation may be rate-determining, particularly at low temperatures. In intramolecular proton transfer, on the other hand, the solvent effect is small and operates in the opposite direction. This behavior is due to intramolecular electron displacement, which can partially compensate for the dipole moment of *(3)*. An upper limit of 0.12 kcal/mole is given for the activation energy of the intramolecular proton transfer.

E. U. Franck (Karlsruhe, Germany) has investigated the conductivity of aqueous solutions of KCl, HCl, and H_2SO_4 between 45 and 220 °C and at pressures of up to 8000 bars. According to *Walden*'s rule, the conductivity of such solutions should vary inversely with viscosity as the pressure increases. However, the decrease in conductivity of KCl solutions is less than expected. This is explained by assuming that the effective radius of the hydrated ions is smaller at higher pressures. The conductivity of HCl solutions decreases still less, and at temperatures below 130 °C even shows an initial increase with pressure. This behavior is due to the anomalous mobility of protons. Dilute solutions of H_2SO_4 show a strongly temperature-dependent increase in conductivity with pressure. In this case, the pressure-dependence of the viscosity of water, the anomalous proton mobility, and the dissociation of the HSO_4^- ion all act in the same direction. The values for the dissociation constant K_2 of HSO_4^- for various temperatures and pressures are given in the Table.

Pressure [bars]	K_2 [10^{-3} mole/l] 45 °C	100 °C	160 °C	190 °C
1	6.840	0.821	0.161	0.086
4000	55.93	10.19	1.97	0.72
8000	79.14	47.59	10.36	4.70

G. J. Hills (Southampton, England) reported on the variation in proton transfer in aqueous solutions with temperature and pressure. The structural orientation of the water molecules can be detected even at pressures in excess of 2500 atm, but decreases rapidly with increasing temperature. Ionic transport is related to this orientation and is more highly pressure-dependent than is the fluidity of water. *Hills* illustrated his lecture with numerous diagrams showing the variation in the equivalent conductivity of HCl with temperature and pressure, and gave some data concerning transport numbers and ionic conductivities. He concluded from these data that proton transfer consists essentially of a charge transfer and of a reorientation of the water molecules, the latter process being rate-determining. The Grotthuss mechanism therefore remains valid despite the hydrogen bond structure of water.

German version: Angew. Chem. 77, 814 (1965)

SELECTED ABSTRACTS

Regularities in the field-ion mass spectra of organic molecules are discussed by *H. D. Beckey* and *G. Wagner* with illustrations from amines containing 2–10 carbon atoms in branched or unbranched chains. In conventional mass spectrometers, the ions are created by bombarding the sample with electrons, but in field-ion mass spectrometry they are formed on thin metal wires or needle points in a strong electric field (10^7–10^8 volts/cm). The most striking phenomenon here is that straight chain amines give rise to ions with mass numbers 29 and 30 ($C_2H_5^{\oplus}$ and $CH_2NH_2^{\oplus}$) as the most frequently recurrent fragments; hence two members are split off of the chain at a time. / Z. Naturforsch. *20a*, 169 (1965) / –Hz. [Rd 309/518 IE]

A new method for resolving D,L-amino acids using stereoselective ligand exchange is described by *K. Harada*. For example, if the complex obtained from L-alanine and copper carbonate is left standing for 30 h with D,L-aspartic acid in aqueous solution, the D-aspartic acid/copper carbonate complex is obtained and can be filtered off and decomposed with H_2S in acidic solution. D-Aspartic acid is thus obtained in 95–100 % optical purity (0.54 g from 2.66 g of D,L-aspartic acid) and completely free from alanine. L-Aspartic acid is obtained analogously using D-alanine. Similar reactions occur between the copper carbonate complexes of L-glutamic acid, D-glutamic acid, and L-proline on the one hand, and D,L-aspartic acid on the other. This stereoselective reaction is also of interest in view of the development of optical activity of amino acids in prebiological systems. spontaneously acquired optical activity of one amino acid could have been transferred *via* metal chelates to other amino acids. / Nature (London) *205*, 590 (1965) / –Ma. [Rd 257/466 IE]

The isolation of some aquo and hydroxochloro complexes of Rh(III), Ir(III), and Pt(IV) has been achieved by *E. Blasius* and *W. Preetz*. In contrast to the current opinion that these elements (Rh, Ir, and Pt) occur essentially as hexachloro complexes in HCl solution, stepwise formation of mixed ligand complexes was now observed. The solutions could be separated into their individual metastable components by high-tension ionophoresis. In this way, $[IrCl_2(H_2O)_4]^{\oplus}$, $[IrCl_3(H_2O)_3]$, $[IrCl_4(H_2O)_2]^{\ominus}$, and $[IrCl_5(H_2O)]^{2\ominus}$, for example, were found. A weak zone close to that of $[IrCl_4(H_2O)_2]^{\ominus}$ is probably due to $[Ir(OH)Cl_3(H_2O)_2]^{\ominus}$. / Z. anorg. allg. Chem. *335*, 1 (1965) / –La. [Rd 341/550 IE]

Free dithioperoxodiphosphoric acid $H_4[O_3PSSPO_3]$ was obtained in a concentration of up to 75% in methanol by *F. Fehér* and *F. Vial* by oxidation of a suspension of potassium dihydrogen monothiophosphate KH_2PO_3S in ether with bromine.

$$2\ H_2O_3PS^{\ominus} + Br_2 \rightleftharpoons (HO)_2(O)PS{-}SP(O)(OH)_2 + 2\ Br^{\ominus}$$

The new compound is a strong acid. The differences in the dissociation constants – particularly for the first two steps – are small. The salt KH_2PO_3S was also described for the first

$$PSCl_3 + 6\ KOH \rightarrow K_3PO_3S + 3\ KCl + 3\ H_2O$$
$$K_3PO_3S + 2\ CH_3COOH \rightarrow KH_2PO_3S + 2\ CH_3COOK$$

time and can be readily obtained by hydrolysis of phosphorus thiochloride with KOH and subsequent acidification with acetic acid. / Z. anorg. allg. Chem. *335*, 113 (1965) / –La. [Rd 342/551 IE]

A new synthesis of 1-thiochromones is described by *F. Bossert*. 1-Thiochromones *(1)* could be prepared hitherto only with difficulty and in yields of less than 20 % from *(2)* and *(3)*. However, they can now be obtained easily and in good yields

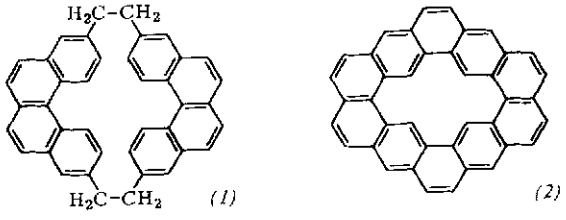
by condensation of thiophenols *(2)* and β-keto esters *(3)* by brief warming with polyphosphoric acid. / Liebigs Ann. Chem. *680*, 40 (1965) / –Ma. [Rd 260/469 IE]

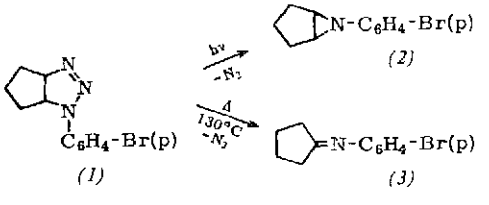
A cyclic hydrocarbon of the benzo[*c*]phenanthrene series *(1)* was synthesized by *R. Peter* and *W. Jenny* during attempts to build up cyclic *kata*-condensed hydrocarbons with a "hollow" in the middle, *e.g. (2)*. Starting from diethyl bis-*p*-tolylmethylmalonate, 3,10-bisbromomethylbenzo[*c*]phenanthrene was prepared *via* a number of steps and then converted with phenyl-lithium into *(1)* in 10 % yield. Bis-(3,10-dimethylene-



(1) *(2)*

henzo[*c*]phenanthrene) *(1)*, $C_{40}H_{28}$, m.p. 400 °C, exhibits a blue fluorescence in the solid state and can probably be aromatized to give *(2)*. / Chimia *19*, 45 (1965) / –Ma. [Rd 252/461 IE]

Aziridines were obtained by photolysis of 1,2,3-triazolines by *P. Scheiner*, nitrogen being eliminated smoothly and quantitatively. Thermal elimination of the nitrogen, on the other hand, leads to the isomeric anilines or to mixtures of both isomers. For example, the triazoline *(1)*, m.p. 122 °C, affords 59 % of the aziridine *(2)*, m.p. 73–74 °C, by the photochemical reaction or 67 % of the anil *(3)*, b.p. 110 to 111 °C/0.4 mm, by thermolysis; *(3)* is not formed by thermal rearrangement from *(2)*, for the latter is completely stable under the conditions of the pyrolysis (130 °C).



(1) *(2)* *(3)*

In practice, 0.08–0.60 M solutions of the triazolines in inert solvents such as acetone, toluene, or dioxane are irradiated with ultraviolet light until the evolution of nitrogen ceases, the temperature being maintained below 35 °C. 1,2,3-Triazolines are easy to prepare, *e.g.* by 1,3-dipolar addition of diazomethane onto anils. / J. org. Chemistry *30*, 7 (1965) / –Bi. [Rd 301/510 IE]

The mode of action of penicillin was investigated by *U. Schwarz* and *W. Weidel* with *Escherichia coli* B. It is known that penicillin inhibits the synthesis of mureine – the polymer that occurs in the cell walls of almost all species of bacteria and which encloses the bacterial cell as a rigid sac. The cell walls of bacteria that are sensitive towards penicillin are burst by it. Materials identified among the degradation products formed from mureine were oligosaccharides containing 2,6-diaminopimelic acid and parts of the muropeptide side chains and their enzymatic degradation products. The penicillin spheroplasts from *E. coli*. contain uridine phosphate-muramyl peptides, which can be regarded as precursors of mureine. It could be shown with [^{14}C]diaminopimelic acid that this amino acid is liberated in the form of oligopeptides under the influence of penicillin both from mureine itself and from its precursors. Penicillin upsets the balance of the enzymes which synthesize and degrade mureine – partial dissolution of the rigid cell sac is necessary for the cell to grow – so that the bacteria are destroyed by their own enzymes. / Z. Naturforschg. *20b*, 147, 153 (1965) / –De. [Rd 294/503 IE]

A "living" polymer was prepared from tetrahydrofuran by *M. P. Dreyfuss* and *P. Dreyfuss* by cationic initiation. Tetrahydrofuran reacts at 25 °C with benzenediazonium hexafluorophosphate $C_6H_5N_2PF_6$ to give a polymer which remains "living". Log [η] varies in a linear manner characteristic for living polymers with log [$C_6H_5N_2PF_6$]. The limited solubility of the initiator in tetrahydrofuran sets a lower limit to the molecular weight of the living polymer. The chain initiation is due either to a phenylcarbonium ion according to Equation (a)

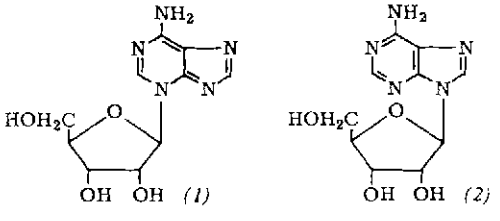
$$C_6H_5N_2^{\oplus}PF_6^{\ominus} \rightarrow C_6H_5^{\oplus} + N_2 + PF_6^{\ominus} \qquad (a)$$

or to phosphorus pentafluoride according to Equation (b).

$$C_6H_5N_2^{\oplus}PF_6^{\ominus} \rightarrow C_6H_5F + N_2 + PF_5 \qquad (b)$$

/ Polymer *6*, 93 (1965) / –Hl. [Rd 295/504 IE]

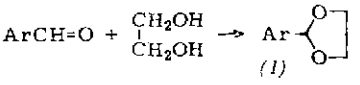
3-Isoadenosine derivatives were synthesized by *N. J. Leonard* and *R. A. Laursen*. Starting from P^1-diphenyl-P^2-[(3-β-D-ribofuranosyladenine)-5']-pyrophosphate, the isoanalogues of adenosine monophosphate (AMP), adenosine diphosphate (ADP), adenosine triphosphate (ATP), and nicotinamide adenine dinucleotide (NAD) were prepared.

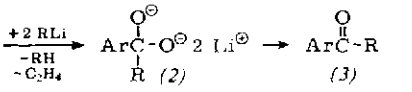


(1) *(2)*

It was investigated whether the derivatives of isoadenosine *(1)* could replace derivatives of natural adenosine *(2)* in biological reactions. Myokinase (adenylic kinase) converts iso-ATP and iso-AMP into iso-ADP. Hexokinase phosphorylates glucose about half as fast with iso-ATP as with ATP to give glucose-6-phosphate. Dehydrogenases reduce iso-NAD at various rates depending on the enzyme concerned. The alcohol dehydrogenase from horse liver reacts with iso-NAD faster (relative rate 140) than with NAD (100), but the alcohol dehydrogenase from yeast reacts much more slowly (6). Assays of iso-ATP with luciferase leads to lower yields than with ATP. Iso-ADP is polymerized by the polynucleotide phosphorylase from *Azotobacter vinelandii* to the corresponding polynucleotide. / Biochemistry *4*, 365 (1965) / –Hö. [Rd 307/516 IE]

The conversion of aromatic aldehydes into alkyl aryl ketones has been achieved by *K. D. Berlin, B. S. Rathore*, and *M. Peterson*. When the 1,3-dioxolanes *(1)* obtained from the aldehydes by condensation with ethylene glycol are treated at 60 °C under nitrogen with an excess of alkyl-lithium (molar ratio about 1:3) in cyclohexane/ether, the ketone derivatives *(2)* are obtained *via* several intermediates;

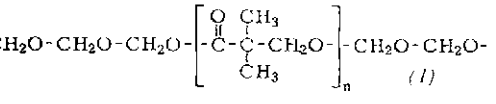




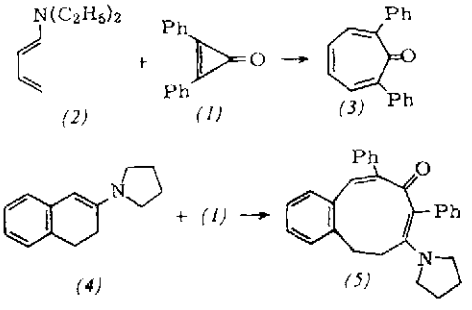
(a) Ar = C_6H_5, R = C_4H_9 (87,5%)
(b) Ar = p-$CH_3C_6H_4$, R = C_6H_{11} (66,5%)
(c) Ar = p-$CH_3OC_6H_4$, R = C_4H_9 (78%)
(d) Ar = p-$CH_3C_6H_4$, R = C_4H_9 (80%)

hydrolysis of *(2)* affords the ketones *(3)* in yields of 66.5 to 80 %, together with equivalent amounts of alkane and ethylene. / J. org. Chemistry *30*, 226 (1965) / –Bi. [Rd 300/509 IE]

A new thermostable copolymer of formaldehyde *(1)* is described by *G. Natta, G. F. Pregaglia, G. Mazzanti, V. Zamboni*, and *M. Binaghi*. It is produced by copolymerization of HCHO with dimethylketene catalysed by tertiary amines. The amount of dimethylketene incorporated depends largely upon the polymerization temperature: 80 % is built in at 0 °C and progressively lesser amounts at higher temperatures, where side reactions also occur. By varying the reaction conditions, copolymers with irregular monomer sequences, block copolymers, or copolymers with alternating structures can be produced. The softening points depend on the composition: 168–174 °C for a polymer with little dimethylketene and 150–155 °C for one containing 10 % dimethylketene. The rate of decomposition at temperatures above 220 °C lies between that of the acetylated homopolymer and that of the trioxane copolymer, which is more stable than *(1)*. / European Polymer J. *1*, 25 (1965) / –Hl. [Rd 323/532 IE]



A cycloaddition of diphenylcyclopropenone onto aminoalkenes has been observed by *J. Ciabattoni* and *G. A. Berchtold*. 1-Diethylamino-1,3-butadiene *(2)* and diphenylcyclopropenone *(1)* react in refluxing benzene to form 2,7-diphenyltropone *(3)* as yellow platelets, m.p. 132–133 °C, in 68 % yield. Similarly, *(1)* and 2-(*N*-pyrrolidino)-3,4-dihydronaphthalene *(4)* afford 2,9-diphenyl-8-(*N*-pyrrolidino)benzo[*d*]cyclonona-2,4,8-trien-1-one *(5)*, m.p. 136–137 °C, in 62 % yield. The reaction involves 1,2- and 1,4-additions, but it is still unknown



whether its mechanism is a one-step cycloaddition or a Michael addition with subsequent cyclization. / J. Amer. chem. Soc. *87*, 1404 (1965) / –Ma. [Rd 331/540 IE]

BOOK REVIEWS

Carbene Chemistry. By *W. Kirmse*, in collaboration with *H. M. Frey, P. P. Gaspar*, and *G. S. Hammond*. Organic Chemistry, a Series of Monographs, edited by *A. T. Blomquist*. Academic Press, New-York-London 1964. 1st edit., VIII + 302 pp., numerous tables, several illustrs., linen $ 9.50.

Prolific developments have taken place in the field of carbene chemistry over the past ten years. Hundreds of publications have appeared, and anyone not working in this field could hardly have read even only the most important of these. The appearance of this monograph – incidentally the first in the series "Organic Chemistry" edited by *A. T. Blomquist* – is therefore highly welcome.

The book deals mainly with the reactions of carbenes and their mechanistic aspects. Following a short introduction, there are nine short but pregnant chapters of the nature of review articles which give a practically flawless survey of the preparation, reactivities, and preparative applications of all the carbenes known to date. There is a carefully compiled bibliography covering literature sometimes until the start of 1964. A welcome feature of the book is that topics on the fringe of carbene chemistry are also dealt with, *e.g.* the synthesis of diazirines or the preparatively important compounds chloromethylzinc and iodomethylzinc, which although not true carbenes, behave as if they were.

Two chapters by competent authors examine theoretical aspects of the subject. In one, *H. M. Frey* relates why it must be assumed that methylene made by photolysis or thermolysis from diazomethane or ketene has excess translational and/or vibrational energy. In the other, *P. P. Gaspar* and *G. S. Hammond* discuss the spin state of carbenes. Here, among other things, the chemist is carefully shown the pitfalls into which he can stumble if he attempts to deduce the electronic state of a carbene from its chemical reactions.

The reviewer found this book a pleasure to read. Since he is convinced that any other scientist interested in the chemistry of short-lived intermediates will enjoy the same experience, he can recommend the book most highly. It is unfortunate that monographs on modern trends become outdated rather rapidly. It would therefore be a commendable undertaking for the author and publisher to produce a translation into German of the work with inclusion of any new material that has appeared.

U. Schöllkopf [NB 394/252 IE]

Handbook of Chemistry and Physics. Edited by *C. D. Hodgman, R. C. Weast*, and *S. M. Selby*. A Ready-Reference Book of Chemical and Physical Data. The Chemical Rubber Company, Cleveland, Ohio, U.S.A., 1964. 45th edit., XXI + 1472 pp., imitation leather, about $ 15.–.

The fact that a reference book has appeared in 45 editions in 45 years is an outstanding proof of its quality, which cannot be diminished or augmented by any review. However, the 45th edition of the "Handbook of Chemistry and Physics" has undergone so many changes in comparison with its predecessors that some appraisal seems justified.

The format of the book has been doubled; this agreeable feature makes the volume handier and easier to peruse.

The sections of the book of greatest interest to chemists have been reorganized. There is a section on "Elements and Inorganic Compounds", another on "Organic Compounds", and a section with data which are of general interest to chemists, including for example, a list of over seven hundred azeotropic mixtures (new), dissociation constants, specific heats and enthalpies of some metals at low temperatures (new), vapor pressures of organic and inorganic compounds, *etc.*

The table of the "Physical Constants of Organic Compounds" (525 pp.) is the most extensive. Here data are listed for over 13500 substances, separate columns being devoted for each to the name, formula, synonyms, molecular weight, crystal form, color and specific rotation, melting point, boiling point, density, index of refraction, solubility in water, alcohol, ether, acetone, benzene, and other solvents, and a literature reference. This table has been extended by about 5000 entries in this edition, and is probably the largest of its kind anywhere.

It would take too long to characterize the variety and abundance of the other tables of chemical, physical, and mathematical content in turn. However, it may be mentioned here that a newly revised table of all known stable and radioactive isotopes is given, that the physical properties of inorganic compounds are given as fully as those of organic substances, and that a short portion of text is devoted to each element – an unusual feature for a handbook – describing its properties, discovery, occurrence, and chemical behavior. The reviewer would find it hard to pose a question within the scope of this book which it would fail to answer.

A few items could be improved in later editions. The table on buffers is too short and does not do justice to the importance of these solutions – especially in biochemistry. The section on the nomenclature of organic compounds contains the IUPAC rules of 1957 and a list of carbocyclic and heterocyclic rings. The reviewer considers this to be insufficient, even though the long table on the physical properties of organic compounds that follows alleviates this situation a little by giving examples. It might be worthwhile to include a short introduction to the nomenclature of functional organic compounds and derivatives. The structural formulae in the large table (particularly on p. C-75) are neither attractive nor clear; in the formula of coniferyl alcohol on p. C-259, the positions of OCH_3 and OH have been interchanged; sometimes, *e.g.* with steroids, one has difficulty in recognizing the compounds portrayed. Here there is definitely room for improvement; the structural formulae should be set by a printer who has the necessary type available. Uniform use of the designations D, L, d, l, (–), and (+) would also be preferred. *H. Grünewald* [NB 395/253 IE]

Organic Experiments. By *L. F. Fieser.* D. S. Heath and Co., Boston 1964. 1st edit., 325 pp., numerous figs., linen about $ 7.00.

The main aim of this new book by *Louis F. Fieser* is the experimental training of students.

Practical experiments, described in every detail, form the mainstay of the book. In addition, particular emphasis is placed upon the identification and characterization of the compounds prepared using chemical and physicochemical methods. Less attention is intentionally paid to reaction mechanisms.

The book starts with descriptions of the equipment required for preparative work in organic chemistry. This is followed by an introduction to elementary practical techniques such as the handling of wash bottles, filter flasks, suction filters, and burners, distillation, crystallization, extraction, *etc.* Even during this introduction to practical techniques exercises are given, *e.g.* the isolation of citral from lemon grass oil during the discussion of steam distillation. In the course of the practical preparations that follow, any new apparatus or methods that are required for the synthesis or separation of the compounds to be made are described separately (*e.g.* chromatography).

There are no old-fashioned, hackneyed procedures, *e.g.* that for the preparation of bromobenzene, included among the selection of examples and instructions given; instead, interesting preparative work applying the most modern methods is described. For example, directions are given for the synthesis of diacetylene, on how to reduce double bonds with $NaBH_4$ or HCl/Pt, for the preparation of hydrazobenzene from azobenzene with diimine, the addition of dichlorocarbene onto *cis,cis*-1,5-cyclooctadiene, the synthesis of tropylium bromide, and the production of trypticene *via* dehydrobenzene. Even an enzymatic reaction has been incorporated, *viz.* the isolation of L-alanine from the racemate of the acetyl derivative, as well as analysis of peptides by chromatography.

In order to introduce the student to the applications of spectroscopic methods, there is a chapter on 1,2-diphenylethane derivatives, which skilfully and instructively combines preparative and spectroscopic methods.

An interesting feature is a chapter on the calculation of costs, for the attention of the student should occasionally be called to such matters too.

The subject matter in each individual chapter is presented with extraordinary clarity; on the margins there are keywords and suggestions and even warnings whenever a reaction could become dangerous. Practical exercises are added at the ends of some chapters. It must be said that every chapter is a success. However, there is no continuous didactic development from chapter to chapter such as is normally encountered in practical textbooks of organic chemistry. It is therefore up to demonstrator or supervisor – who will himself find many instructive exercises in the book – to select a series of preparations to be carried out by the student.

Fieser's "Organic Experiments" should definitely be present in every organic undergraduate laboratory.

H.-J. Bestmann [NB 407/265 IE]

Physikalische Chemie (Physical Chemistry). By *Klaus Schäfer.* Ein Vorlesungskurs (A Lecture Course). Springer-Verlag, Berlin-Göttingen-Heidelberg-New York 1964. 2nd improved and extended edition, XII + 432 pp., 81 figs., linen DM 36.– (about $ 9.00).

The alterations introduced in this new edition of *Schäfer*'s book [*] affect mainly the chapter on the structure of matter, which has been extended and modernized.

The book is divided up as follows: I. States of aggregation and their equations of state (46 pp.); II. Energy content of matter (55 pp.); III. Chemical and thermodynamic equilibria (91 pp.); IV. Electrochemistry (49 pp.); V. Chemical kinetics (21 pp.); and VI. The structure of matter (148 pp.). The book closes with two tables and a subject index. There is no need for an author index since there is only one reference given in the whole book.

In its structure and organization, the book is closely allied to the textbooks by *Eucken*, to which *Schäfer* did of course make many contributions. However, a novel feature of this work is the detailed treatment given to the fundamentals of quantum mechanics and to the theory of the chemical bond. Here the discussion goes into the most recent developments, whereas thermodynamics and electrochemistry, for instance, are dealt with in the conventional way. Kinetics receives only brief treatment on 21 pages, and interfacial phenomena are only briefly touched upon.

The presentation and appearance of the book are attractive.

R. Haase [NB 389/247 IE]

[*] Cf. Chemie-Ing.-Techn. *24*, 471 (1952).

Vanadium. Toxicology and Biological Significance. By *T. G. Faulkner-Hudson*. Elsevier Monographs on Toxic Agents. Edited by *E. Browning*. Elsevier Publishing Co., Amsterdam-London-New York 1964. 1st edit., X + 140 pp., 11 figs., 6 tables, linen DM 19.50 (about $ 3.90).

This small work by a medical advisor in the British vanadium-processing industry will be greeted by all engaged with the functions of vanadium as a trace element or with vanadium poisoning. Topics dealt with include 1. the occurrence in soils, plants, animals, and humans; 2. all the effects of V known so far on metabolism processes (sulfur, cholesterol, lipid, and calcium metabolism, serotonin oxidation, and hemopoesis); 3. questions of vanadium resorption, distribution in the organism, and excretion; 4. experimental production of vanadium poisoning, toxicity phenomena observed in industry, and the pertinent therapy and precautions. Descriptions which go beyond the limits suggested by the title of the book are given of the mineral sources and industrial extraction of the metal and of its compounds and their technical uses. Tables are also given of the world production and export figures for various countries. On the other hand, the chemical properties of vanadium, *e.g.* its great tendency to form complexes, which are undoubtedly important for its biological effects, receive insufficient attention. Although all details cannot be included in view of the broad spectrum of aspects considered, brevity can be no excuse for impreciseness. In addition to incorrect structural formulae (*e.g.* coenzyme A, lipothiamide, p. 25), the work of *Lynen* and *Bloch* is overlooked in the section on the biosynthesis of isoprenoids, a C_5 intermediate of unknown structure in the isoprene series appears as a metabolite of mevalonic acid, *etc.* The latest publications on the specificity of the vanadium uptake by marine invertebrates (tunicates) are not mentioned, although the situation here is probably interesting as a model for that in vertebrates as well. Otherwise the literature is evaluated until 1961. The book can be recommended only to critical readers, but offers these many incentives.

On the Analysis of Photosynthesis by Flashlight Techniques [*]

BY H. T. WITT, B. RUMBERG, P. SCHMIDT-MENDE, U. SIGGEL, B. SKERRA, J. VATER, AND J. WEIKARD

MAX-VOLMER-INSTITUT FÜR PHYSIKALISCHE CHEMIE, TECHNISCHE UNIVERSITÄT BERLIN (GERMANY)

Direct information regarding the primary process in photosynthesis is obtained by measurement of the very short-lived primary and intermediate products with the aid of (1) flash photometry, (2) periodic flash photometry, and (3) flash manometry. The analysis of the primary process using these methods on normal plant cells and chloroplasts and on those which have been chemically or physically modified has led to the formulation of a reaction scheme for the transport of electrons in photosynthesis.

I. Survey [**]

1. Overall Process

Of all the reactions that take place on earth, photosynthesis in green plant cells is the most frequent. When the plants are exposed to light, sugar and other energy-rich substances are synthesized from CO_2 and H_2O. The reaction path from CO_2 to sugar (the Calvin cycle) is well known [5]. However, detailed ideas regarding the primary processes that provide the driving force for this reaction have only recently been obtained, and this is the subject of the present paper.

2. Cleavage of Water

The primary processes take place in highly organized cell components known as the chloroplasts, and consist in the conversion of electromagnetic energy into chemical free energy. Thus water is broken down by the energy of visible light into hydrogen and oxygen [6]. The oxygen escapes into the atmosphere, while the hydrogen is transferred to triphosphopyridine nucleotide (TPN) [***] [7]. *Hill* [8] found that the cleavage of water also occurs in isolated chloroplasts suspended in water, if artificial hydrogen acceptors such as potassium hexacyanoferrate(III) are added instead of the natural acceptor, TPN.

3. Phosphorylation

According to *Arnon et al.* [9], the cleavage of water in the primary process is accompanied by the synthesis of the energy-rich ATP from ADP and phosphate. TPNH and ATP then reduce CO_2 to sugar in dark reactions.

4. The Structure of Chloroplasts

The fact that photosynthesis occurs is due to the special arrangement of the molecules in the chloroplasts. The structure and composition of chloroplasts has therefore been studied in detail [10]. They were found to contain, *inter alia*, cytochrome-f and cytochrome-b [11], plastoquinone [12], ferredoxin [13], flavin [14], manganese [15], and plastocyanine [15a].

5. Active Chlorophyll and Energy Transfer

Rather surprisingly, only about 0.1 % of the total chlorophyll is photochemically active [16]. The remaining 99.9 %, as well as the carotenoids present in the chloroplasts, are so arranged that the light, which they absorb, is led to the active chlorophyll molecules by energy migration [17].

6. Quantum Yield

The values found for the quantum yield are between 3 [18] and 12 quanta per molecule of oxygen formed. The most probable value is 8 to 10 quanta [19].

7. Participation of Two Pigment Systems

Emerson et al. [20–23] studied the oxygen yield as a function of the wavelength of the light, and concluded that probably two pigment systems are involved in the primary processes. The same conclusion was reached later on the basis of fluorescence measurements [24]. Various theories were advanced to explain the Emerson phenomenon [25,26], but no experimental interpretation was at first possible.

In recent years, methods have been developed which permit the direct observation of the primary processes in the chloroplasts (fluorescence [24], phosphorescence [27], electron resonance [28], and absorption measurements). A technique which has proved very succesful is the measurement of absorption changes using static (continous light) [29,30] or dynamic (flashlight) [31,32] methods.

8. Two Coupled Photochemical Reactions

Thus *Kok* [33], *Duysens* [34], and *Witt et al.* [35–37] first showed directly by measurements of absorption changes that two pigment systems with two coupled photochemical reactions take part in the primary processes (Section VII). This conclusion was also reached indirectly on the basis of biochemical studies [38].

9. Primary and Intermediate Products

By means of static measurements of absorption changes, and above all by dynamic measurements using flashlight excitation, nine primary and intermediate products of photosynthesis were identified (Section III).

10. Reaction Scheme

It has been possible, using flashlight methods, to determine some properties of the primary and intermediate products, the order in which they occur, and the kinetics of the reactions. On the basis of these results, a reaction scheme has been formulated, which describes in detail the formation of TPNH, ATP, and O_2 (Section XIII).

II. Flashlight Methods

The direct analysis of the primary processes in photosynthesis requires the use of fast and extremely sensitive techniques, since only 0.1 % of all the chlorophyll molecules are photochemically active, and since the half-lives of the reaction steps are only of the order of $< 10^{-5}$ to 10^{-1} sec.

1. Flash Photometry

This method, which was developed by *Porter* and *Norrish* [39] for inorganic reactions, was first introduced for the study of photosynthesis in 1955 [31]. The highly sensitive apparatus specially developed for this work can record processes lasting from 10^{-5} to 10 sec. Transmission changes of 0.1 % can be recorded in 10^{-5} sec, and the sensitivity is correspondingly greater in the case of slower processes (*e.g.* transmission changes of 0.01 % in 10^{-3} sec). The sensitivity of the measurements increases with the intensity of the measuring light, but the latter must be limited so that the photochemical reaction caused by it is negligible. The intensities used were between about 4 and 200 erg cm^{-2} sec^{-1}, depending on the duration of the processes to be recorded (between 10^{-1} and 10^{-5} sec). The optical bandwidth of the measuring light was 3 mμ (grating, prism) or 10 mμ (interference filter).

2. Periodic Flash Photometry

The technique of periodic relaxation was proposed and developed in 1960 for the study of fast chemical reactions [32]. One such measuring technique is periodic flash photometry [32, 40], which can be used to analyse processes lasting from 10^{-6} to 1 sec. The sensitivity is more than 100 times greater than that of flash photometry: in 10^{-6} sec it is possible to record transmission changes of 10^{-3} %. The time resolution of this method depends only on the duration of the flash.

Whereas in flash photometry the entire sequence of absorption changes following a flash is recorded, only one absorption change at a definite instant (between t and t + Δt) is recorded in the periodic technique, and this measurement can be repeated many times by periodic excitation. Since the accuracy of the measurement increases with the square root of the number of measurements, the absorption change at a given time can be found with very great accuracy. The absorption change at another instant is then measured, and so on until the entire sequence of absorption changes with time has been covered. All operations are carried out electronically and automatically.

3. Flash Manometry

With the aid of flash manometry, which was introduced by *Emerson et al.* [16] in 1932, it is possible to scan reaction steps in photosynthesis indirectly. This technique involves the manometric measurement of the quantity of oxygen formed per flash as a function of the flash frequency. We have used this method under different experimental conditions [41] to obtain information about the kinetics of the cleavage of water (see Section X). The measuring range extends to processes lasting between 10^{-4} and 1 sec.

The efficiencies of the flashlight methods in comparison with other measuring techniques are shown diagrammatically in Fig. 1.

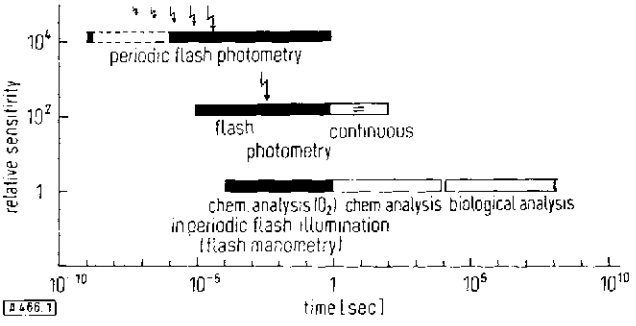

Fig. 1. Sensitivity and time resolution of various methods used in the investigation of photosynthesis.

III. Absorption Changes during Photosynthesis in Green Plant Cells

Using a static method, *Duysens* has demonstrated the participation of a cytochrome in photosynthesis in red algae. He also has observed absorption changes at about 420, 475, and 520 mμ in green cells, but these were not identified [42]. *Kok* [43] discovered absorption changes at about 700 mμ in various plant cells and in chloroplasts, due to the oxidation of a pigment P 700.

With the aid of flashlight methods, we have observed short-lived absorption changes (all lasting less than about 10^{-1} sec at 20 °C) between 240 and 800 mμ in normal green cells *(Chlorella)* and in fully active chloroplasts (spinach). By varying the external parameters and by chemically or physically altering the cell processes, we were able to separate the absorption changes into different types, and to analyse the reactions associated with these types:

1. Formation of the derivate of a particular chlorophyll-a molecule, Chl-a_1-430-520 (Fig. 2b) [44, 45].

2. Oxidation of a particular chlorophyll-a molecule, Chl-a_1-430-703, established by absorption changes at 430 mμ, which are accurately coupled with those of the pigment P 700 at 703 mμ (Fig. 2c) [46–48].

[46] *H. T. Witt, A. Müller*, and *B. Rumberg*, Nature (London) *192*, 967 (1961).

[47] *B. Rumberg* and *H. T. Witt*, Z. Naturforsch. *19b*, 693 (1964).

[48] *B. Rumberg*, Z. Naturforsch. *19b*, 707 (1964).

3. Reaction of a particular chlorophyll-b molecule, Chl-b-478-513-648 (Fig. 2d) [49–52].

4. Oxidation of a cytochrome-f, Cyt-f-407-424-555 (Fig. 2f) [46, 53–55].

5. Reduction of a cytochrome-b^+, Cyt-b-412-435-563 (Fig. 2e) [56].

6. Reduction of plastoquinone Q-254 (Fig. 2g) [57 to 61].

7. Reduction of a substance Z, established indirectly from the kinetics of the absorption changes of Chl-a_I [48, 62].

8. Oxidation of a substance Y, established indirectly from the kinetics of the absorption changes of Chl-b and from the O_2 yield with periodic flashes [41].

9. Reaction of a special chlorophyll-a molecule, Chl-a_{II}, established from the action spectra of the absorption changes [63]. This result confirms measurements reported by *Govindjee et al.* [23], who deduced the existence of a chlorophyll-a_{II} molecule from the Emerson effect.

10. Formation of the π-π^* triplet state in the majority of the chlorophyll-a and chlorophyll-b molecules, Chl-a_0-435-675 and Chl-b_0-475-650, with a change in the chloroplast structure and with deactivated photosynthesis respectively (Fig. 2a) [64].

The following cytochrome reactions occur under abnormal conditions: *Chance et al.* [65] have observed slow ($\geqslant$ 1 sec) changes in the absorption of cytochrome-f in low-chlorophyll and low-carotene mutants under aerobic conditions, and changes in the absorption of cytochrome-b under anaerobic conditions. *Olson et al.* [66] discovered slow ($>$ 10 sec) absorption changes due to cytochrome-b in fragments of *Euglena* chloroplasts which contained no cytochrome-f. *Bonner* and *Hill* [67] have observed changes of this type only in etiolated green cells, but not in normal cells. Changes in the cytochrome absorption measured by *Lundegard* [68] are so slow ($>$10 sec) that they cannot be connected with the primary process [65]. *Kouchkovski et al.* [69] have observed absorption changes at 590 mμ due to a reaction of plastocyanin. It is not yet known to what extent this relatively slow reaction ($>$ 1 sec) is connected with the primary processes.

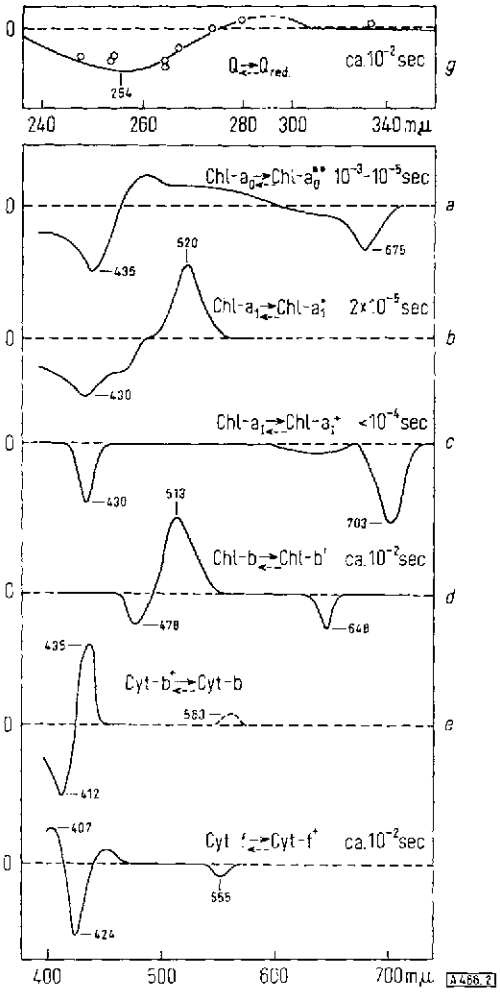

Fig. 2. Difference spectra for green cells (*Chlorella* cells or spinach chloroplasts) irradiated with flash illumination [47]. The spectra were isolated from a complex mixture of absorption changes. The order of magnitude of the absorption changes is about 0.1 %. The figures indicate the absorption-change maxima, and the times are those of the reverse reactions, indicated by the broken arrows. The method of isolation and the meanings of the symbols are described in the text.

Ordinate: Absorption change.
Abscissa: Wavelength.

IV. The Isolated Reaction Cycle I

1. Isolation of the Difference Spectrum of Chlorophyll-a_I-430-703

The triplet state of Chl-a_0 and Chl-b_0 (Fig. 2a) does not occur under „normal" conditions [*] [64]. The derivative formed from chlorophyll-a_1 (Fig. 2b) has a half-life

[*] Normal conditions: *Chlorella* cells or spinach chloroplasts with electron acceptors I. Oxygen production: 1000–3000 mm³ of O_2 per mg of chlorophyll per hour. Irradiation with blue (380 to 480 mμ) or red (620–720 mμ) light.

of only 2×10^{-5} sec [44]. The absorption changes of plastoquinone Q-254 (Fig. 2g) occur only in the ultraviolet region of the spectrum [57]. If we confine ourselves to the visible region (400–800 mμ) and disregard the very fast Chl-a_1 absorption changes, we find under normal conditions a simplified but still complex mixture of absorption changes (Fig. 3a). Four partial reactions can be detected in this spectrum, and these will be discussed *inter alia* in this paper.

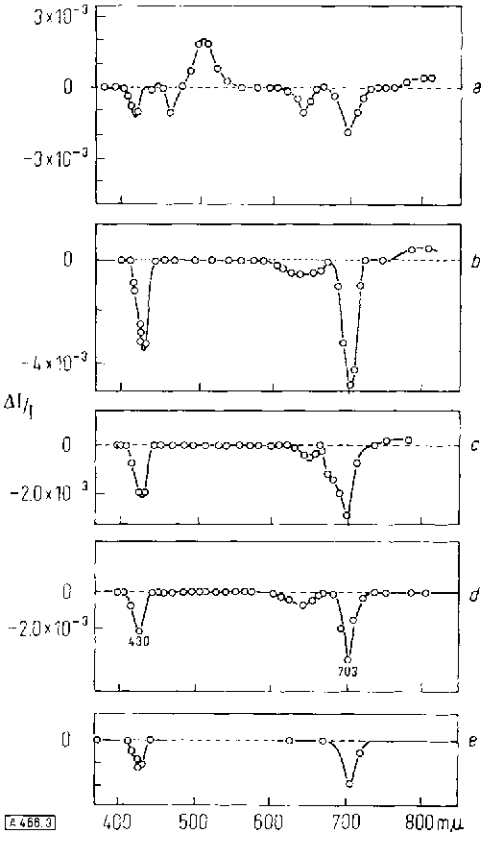

Fig. 3. Difference spectra of illuminated spinach chloroplasts [47].

a) Normal conditions. Addition of benzyl viologen as electron acceptor.

b) After aging and addition of *N*-methylphenazonium methyl sulfate + ascorbate.

c) After treatment with digitonin and addition of *N*-methylphenazonium methyl sulfate + ascorbate.

d) After extraction with petroleum ether.

e) At −150 °C with addition of *N*-methylphenazonium methyl sulfate + ascorbate.

The curves (b)–(e) represent the isolated difference spectrum of the oxidation of chlorophyll-a$_1$–430–703.

Ordinate: Absorption change ΔI/I.
Abscissa: Wavelength [mμ].

The absorption changes at about 700 mμ in Fig. 3a were discovered by *Kok et al.* [70–72], and were attributed to the oxidation of a pigment P 700 (redox potential $E_0 = 0.43$ volt). On the basis of measurements at 430 mμ on acetone-extracted inactive chloroplasts, it was assumed that the pigment P 700 is a chlorophyll-a. However, no direct evidence was offered [47]. In order to identify P 700, we have isolated the reaction characterized by the absorption change at 703 mμ, *inter alia* in active chloroplasts. This was achieved in various ways [47]: (a) Isolated chloroplasts become photosynthetically inactive after a few hours. *Vernon* and *Zaugg* [73] showed that this loss of activity applies only to the cleavage of water. If electron donors are added to aged chloroplasts, they reduce TPN on exposure to light. Using this system (addition of 2,6-dichlorophenolindophenol or *N*-methylphenazonium methyl sulfate with excess ascorbate), we obtained a difference spectrum with changes at about 430 and 703 mμ (Fig. 3b). Similar difference spectra were observed (b) on breaking down the chloroplasts into finely divided particles with the aid of surface active substances (digitonin) (Fig. 3c), (c) in chloroplasts from which plastoquinone had been extracted with petroleum ether (Fig. 3d), (d) in chloroplasts at −150 °C, (e) in chloroplasts after blockage of the cleavage of water by the addition of *N*-*p*-chlorophenyl-*N*-'dimethylurea [47], and (f) in normal chloroplasts on additional continuous exposure to light of wavelength 700–730 mμ [47,48].

The extent to which the simplified difference spectrum is due to the reaction of *one* substance can be ascertained by comparison of the magnitudes and the time variation of the changes at 430 and 703 mμ under various conditions.

2. Time Variation of the Absorption Changes

When a normal chloroplast suspension is illuminated with a flash lasting 3×10^{-6} sec, the absorption at 703 mμ falls off in $< 10^{-5}$ sec (Fig. 4), then returns to the original value in $>10^{-2}$ sec at 20 °C [47,55].

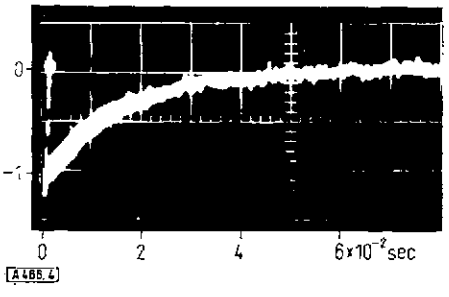

Fig. 4. Time variation of the change in the absorption of chlorophyll-a$_1$ at 703 mμ in spinach chloroplasts. At time t = 0, the sample was illuminated with a flash lasting 3×10^{-6} sec. 20 °C.

Ordinate: Relative absorption change.
Abscissa: Time [sec].

This value for the time taken by the reverse reaction is found only when the sample is also exposed to continuous long-wave illumination (700–730 mμ), such as the measuring light. With very weak additional illumination (intensity of measuring light → 0), the absorption returns to its original value in less than 10^{-4} sec [52] (cf. Section XII).

3. Assignment of the Absorption Changes to a Reaction of Chlorophyll-a_I

The magnitudes and half-lives of the absorption changes at 430 and 703 mμ change in the same manner when the external conditions are altered [47]. For example, Fig. 5

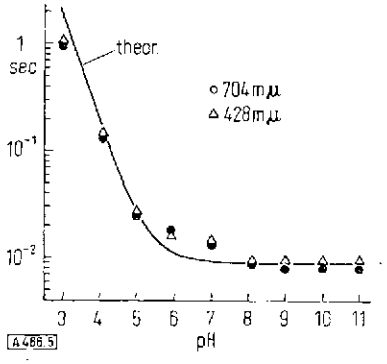

Fig. 5. Half-lives of the absorption changes of chlorophyll-a_I at 428 and 704 mμ for spinach chloroplasts, as a function of the pH. Addition of *N*-methylphenazonium methyl sulfate + ascorbate as electron donor [47].

Ordinate: Half-life [sec].
Abscissa: pH.

shows the half-lives of the two absorption changes as a function of the pH. It can be concluded, therefore, that both absorption changes result from the reaction of *one* substance. Since chlorophyll-a in vivo has absorption maxima at about 430 and 700 mμ, the difference spectra reproduced in Fig. 3b–e must correspond to a photochemically active chlorophyll-a, Chl a_I-430-703 [46,47]. The fall in absorption on flash illumination therefore indicates the formation of a derivative Chl-a'_I, whilst the subsequent increase in absorption is caused by the reverse reaction leading back to the original state Chl-a_I.

4. Oxidation of Chlorophyll-a_I

If *N*-methylphenazonium methyl sulfate and excess ascorbate are added to aged chloroplasts, the reverse reaction is found to be strongly dependent on the concentration of the phenazonium salt (Fig. 6) [47,74].

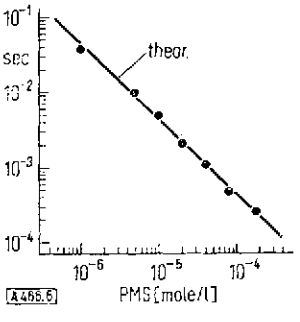

Fig. 6. Half-life of the changes in the absorption of chlorophyll-a_I at 705 mμ in spinach chloroplasts, as a function of the concentration of *N*-methylphenazonium methyl sulfate (PMS) + ascorbate [47,74].

Ordinate: Half-life
Abscissa: Concentration

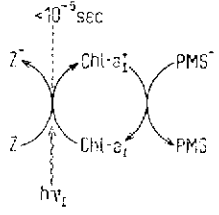
[74] *H.T. Witt, A. Müller*, and *B. Rumberg*, Nature (London) *197*, 987 (1963).

The analysis indicates a first-order reverse reaction, which may be interpreted as a reaction of the derivative Chl-a'_I with reduced phenazonium salt, *i.e.* the derivative Chl-a'_I formed on illumination must be an oxidized product. The pH-dependence of the redox potential (Fig. 8) shows that Chl-a'_I is a cation Chl-a_I^+ (cf. Section V.7). The pH-dependence of the half-live shows that the reduced *N*-methylphenazonium methyl sulfate reacts with Chl-a_I^+ as PMS^-:

$$\text{Chl-a}_I^+ + \text{PMS}^- \rightarrow \text{Chl-a}_I + \text{PMS}$$

The rate constant for this reactions is $k = 1.5 \times 10^7$ l mole^{-1} sec^{-1}. The temperature-dependence gives an activation energy of $E_A = 3.8$ kcal/mole [47].

The electron acceptor involved in the oxidation of Chl-a_I to Chl-a_I^+ is unknown. We shall refer to it as Z. Since the absorption of the Chl-a_I falls off in $< 10^{-5}$ sec on flash illumination ($h\nu_I$), the transfer of the electron from Chl-a_I to Z must take place within this period. These findings are summarized in Scheme 1.



Scheme 1. Oxidation of chlorophyll-a_I on flash illumination ($h\nu_I$) and reduction by reduced *N*-methylphenazonium methyl sulfate.

5. Oxidation of Chlorophyll-a_I as a Primary Process

Chlorophyll-a_I is also oxidized at low temperatures, but the reduction is inhibited under these conditions. This is shown by the irreversibility of the absorption change at −150 °C (Fig. 7).

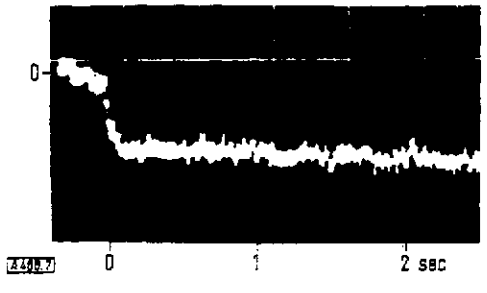


Fig. 7. Time variation of the change in the absorption of chlorophyll-a_I at 426 mμ in spinach chloroplasts at −150 °C [47,75]. Illuminated for 0.2 sec at time t = 0.

Ordinate: Relative absorption change.
Abscissa: Time [sec].

The difference spectrum of the irreversible absorption change at −150 °C (Fig. 3e) is the same as the difference spectra of the reversible absorption changes at 20 °C (Fig. 3b–d). The fact that the oxidation of chlorophyll-a_I is not inhibited at −150 °C shows that it must be a primary act of photosynthesis [46,47].

6. Redox Potential of Chlorophyll-a_I

The oxidation of Chl-a_I *in vivo* can be brought about not only photochemically, but also chemically, with the aid of potassium hexacyanoferrate(III). When $K_3Fe(CN)_6$/$K_4Fe(CN)_6$ is added, the ratio Chl-a_I^+/Chl-a_I changes in favor of Chl-a_I^+ as the concentration of $K_3Fe(CN)_6$ increases. This leads to a decrease in the absorption change brought about by light, since less Chl-a_I is available to the incident light. The redox potential found from the magnitude of the absorption change as a function of the ratio $K_3Fe(CN)_6/K_4Fe(CN)_6$ (Fig. 8) [46,48, 59] is:

$E^0_{Chl\text{-}a_I^+/Chl\text{-}a_I} = 0.46 \pm 0.01$ volt

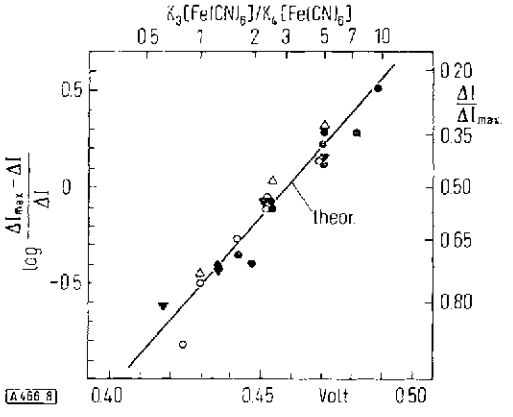

Fig. 8. Changes in the absorption of chlorophyll-a_I at 705 mμ in spinach chloroplasts, as a function of the redox potential of a mixture of $K_3Fe(CN)_6/K_4Fe(CN)_6$ [48, 59].

○ pH 6.0; △ pH 6.7; ● pH 7.2; ▲ pH 7.8.

Ordinate: Relative absorption change.

Abscissa: Top: Concentration ratio.
Bottom: Redox potential [volt].

The independence of the redox potential on the pH points to a pure electron transfer. Using a similar method, *Kok* [71] first found the redox potential of P 700$^+$/P 700 in acetone-extracted chloroplasts to be 0.43 volt.

7. The Natural Electron Donor for the Reduction of Chl-a_I^+

In the isolated reaction of Chl-a_I (Scheme 1), reduced *N*-methylphenazonium methyl sulfate (PMS) acts as the artificial electron donor. Since the absorption changes observed in the isolated system also occur in normal chloroplasts [47,48], the Chl-a^+ in this case must be reduced by a natural electron donor. The time indicated for this reduction at 20 °C by the time variation of the absorption changes is about 10^{-2} sec (Fig. 4).

If the Chl-a_I reaction is isolated from the natural electron donor (by aging of the chloroplasts, extraction with petroleum ether, or addition of digitonin or *N*-*p*-chlorophenyl-*N*-'dimethylurea, Section IV.1), no reduction of the Chl-a_I^+ should occur unless an artificial electron donor is added. This, however, is not the case (Fig. 9b). Instead, absorption changes lasting 10^{-2} sec occur evidently because the electron initially transferred to the natural electron acceptor Z can reduce the Chl-a_I^+ in a reverse reaction lasting about 10^{-2} sec (curved arrow in Scheme 2) [48,62,74].

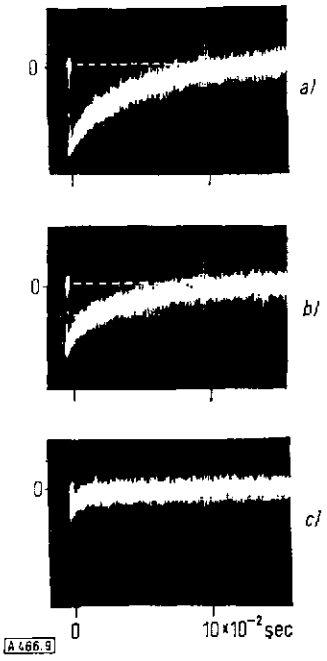

Fig. 9. Time variation of the change in the absorption of chlorophyll-a_I at 705 mμ in spinach chloroplasts (a) without and (b) with added *N*-*p*-chlorophenyl-*N'*-dimethylurea (6×10^{-5} M), and (c) with *N*-*p*-chlorophenyl-*N'*-dimethylurea (6×10^{-5} M) plus benzyl viologen (10^{-4} M). Flash illumination lasting 2×10^{-4} sec at time t = 0 [48].

Ordinate: Relative absorption changes.

Abscissa: Time [sec].

8. Artificial Electron Acceptors for Z$^-$ and the Redox Potential of Z

This reduction of Chl-a_I^+ can be prevented if the electron transferred to Z is intercepted by artificial electron acceptors. Thus the Chl-a_I reaction isolated from the natural electron donor by *N*-*p*-chlorophenyl-*N'*-dimethylurea disappears if *e.g.* benzyl viologen is added to the system as an electron acceptor (Fig. 9c). It is possible in this way, and particularly with the aid of the method described in Section XII.2, to establish which substances attack Z$^-$. These are listed in Table 1, and are referred to as "artificial electron acceptors I" (cf. Scheme 2) [48,62,74].

Table 1. Artificial electron acceptors I which can remove electrons from Z$^-$ [48,74].

	Redox potential (pH 7) [volt]
Potassium hexacyanoferrate(III)	+0.43
p-Benzoquinone	+0.28
m-Cresolindophenol	+0.21
Vitamin K_3	*ca.* 0
Indigosulfonates	−0.05 to −0.16
Riboflavin	−0.21
Flavin mononucleotide	−0.22
Safranine T	−0.29
Neutral red	−0.33
Benzyl viologen	−0.36
Methyl viologen	−0.44

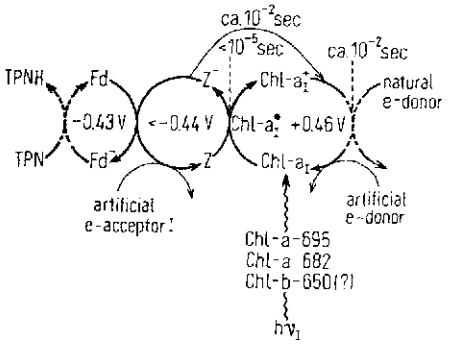
The data in Table 1 indicate that the redox potential of Z is less than −0.44 volt [48,62].

9. TPN and Ferredoxin as Natural Electron Acceptors for Z^-

Using the method described in Section XII.2, it was found that, of the natural electron acceptors present in plant cells, TPN alone cannot act as a natural electron acceptor for Z^-, whereas TPN together with TPN reductase can [74]. Thus TPN reductase contains a redox system which operates between Z and TPN (Scheme 2) [74]. *Tagawa et al.* [13c] had previously shown that TPN reductase [13a, b] is identical with ferredoxin, and that a flavoprotein acts as the carrier between ferredoxin and TPN [14].

10. Scheme of Reaction Cycle I

If we summarize the observations described so far, we obtain the picture shown in Scheme 2 for reaction cycle I.



Scheme 2. Electron flow in reaction cycle I [48, 54, 55, 62, 74]. PMS^- or DPIP + ascorbate can act as artificial electron donors.

Chl-a_I-430-703 is first converted into the excited state Chl-a_I^* by the absorption of light ($h\nu_I$). An electron is transferred from Chl-a_I^* to Z in $< 10^{-5}$ sec. The redox potential of Chl-a_I^* must be lower than −0.44 volt, since the redox potential of $Z/Z^- < -0.44$ volt. The redox potential of Chl-a^+/Chl-a_I is +0.46 volt. The electron is transferred from Z^-, *via* ferredoxin, to TPN. If there is no natural electron acceptor (TPN) available in isolated chloroplasts, the electron can be returned from Z^- to Chl-a_I^+ in about 10^{-2} sec or can be consumed by an artificial electron acceptor I (Table 1). Normally, Chl-a_I^+ is reduced within 10^{-2} sec by an (unknown) natural electron donor. If the cycle I is isolated from the natural electron donor (by aging, extraction with petroleum ether, treatment with digitonin, addition of *N-p*-chlorophenyl-*N'*-dimethylurea, or the use of low temperatures), the function of the latter can be taken over by an artificial electron donor (2,6-dichlorophenolindophenol or *N*-methylphenazonium methyl sulfate + excess ascorbate) [47, 54, 55, 59, 74].

The characteristics of the isolated reaction cycle I are summarized in Table 2 and Fig. 19 (left) [48, 74, 82].

Table 2. Characteristics of the isolated reaction cycles I and II [48, 61, 74, 82].

Property	Reaction cycle I	Reaction cycle II
Change of absorption	Chl-a_I: 430, 703 mμ	(Chl-b): 478, 513, 648 mμ Q: 254 mμ

Sensitive to ageing	no	yes
Sensitive to *N-p*-chlorophenyl-*N'*-dimethylurea (CMU)	no	yes

V. The Isolated Reaction Cycle II

1. Isolation of the Difference Spectrum of Chlorophyll-b-478-513-648

When cycle I is isolated, the absorption changes at 478 and 513 mμ are no longer observed (Fig. 3). It is also possible, by physical or chemical interference with the cell process, to deactivate cycle I and isolate the absorption changes at 478 and 513 mμ, which are associated with cycle II.

a) Physical Isolation

If the cell system is largely screened from continous illumination of wavelength $\lambda > 700$ mμ (this even includes the measuring light) the resulting difference spectrum has maxima at 478, 513, and 648 mμ (Fig. 10b) [52]. The change in the Chl-a_I absorption at 700 mμ (Fig. 10a) has practically disappeared. (For the cause of isolation, see Section XII.1).

b) Chemical Isolation

A similar result is obtained if *e.g.* dichlorophenolindophenol (with $K_3Fe(CN)_6$ as a redox buffer) is added to chloroplasts. The difference spectrum is again characterized by maxima at 478 and 513 mμ (Fig. 10c) [54, 59, 61]. The absorption change at 648 mμ (Fig. 10b) cannot be measured under these conditions, since dichlorophenolindophenol absorbs strongly between 550 and 660 mμ. (For the cause of this chemical isolation, see Section V.10).

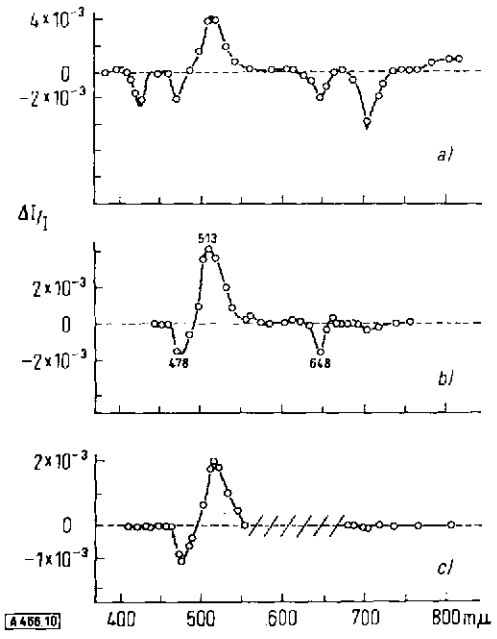

Fig. 10. Difference spectra for illuminated *Chlorella* cells (b) and spinach chloroplasts (a, c) [52, 59]

a) Normal conditions. Addition of benzyl viologen as electron acceptor. Not screened from continuous light of wavelength $\lambda > 700$ mμ.
b) Screened from continuous light of wavelength $\lambda > 703$ mμ [52].
c) With addition of dichlorophenolindophenol + $K_3Fe(CN)_6$ [59, 61].

Curves (b) and (c) represent the isolated difference spectrum of the reaction of chlorophyll-b-478-513-648.

Ordinate: Absorption change ΔI/I.
Abscissa: Wavelength [mμ].

2. Time Variation of the Absorption Changes

On flash illumination, the absorption at 515 mμ increases in $< 10^{-5}$ sec (Fig. 11). The system returns to its original state in about 10^{-2} sec in the dark at 20 °C [76–78].

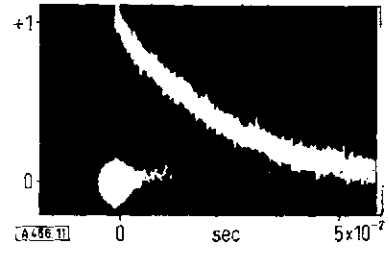

Fig. 11. Time variation of the change in the chlorophyll-b absorption at 515 mμ in *Chlorella* cells. Flash illumination lasting 10^{-5} sec at time t = 0. 20 °C [49].

Ordinate: Relative absorption change.
Abscissa: Time [sec].

3. Assignment of the Absorption Changes to a Reaction of Chlorophyll-b

The magnitudes and half-lives of the absorption changes at 478, 513, and 648 mμ are strongly dependent on the external conditions. Their quantitative relationships, however, are always the same [49–52]. It follows that they must all be due to *one* substance. Two examples are shown in Fig. 12.

The decrease in the absorption at 478 and 648 mμ (Fig. 10) corresponds to the fading of a pigment which absorbs at these wavelengths. Chlorophyll-b *in vivo* has bands at about 478 and 648 mμ. The absorption change is therefore due to the reaction of a chlorophyll-b, Chl-b-478-513-648 [52], leading to the formation of a derivative which absorbs at 513 mμ. The difference spectrum shown in Fig. 10b and 10c can be observed only in plant cells which contain chlorophyll-b (green plant cells). Blue and red algae, which do not contain chlorophyll-b, do not give this spectrum.

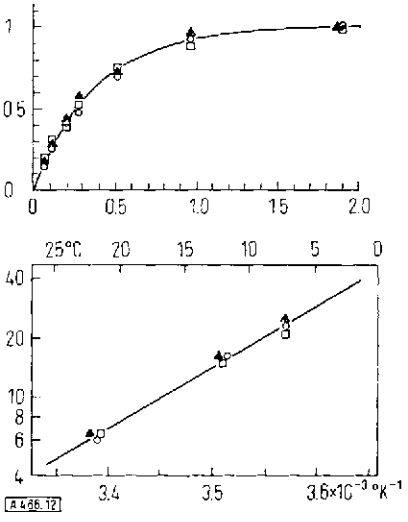

Fig. 12. Changes in the absorption of chlorophyll-b at 473 (o), 515 (□), and 648 (▲) mμ in *Chlorella*, as a function of the light intensity (top) and of the temperature (bottom) [52].

Ordinates: Top: Relative absorption change;
Bottom: Half-life [10^{-3} sec].
Abscissas: Top: Irradiation intensity [10^5 erg cm^{-2} sec^{-1}].
Bottom: Temperature [°C] and reciprocal of the absolute temperature [°K^{-1}].

4. The Chlorophyll-b Reaction as an Indicator Reaction

Chlorophyll-b is not directly involved in the electron flow during photosynthesis. The changes in the absorption of chlorophyll-b can be almost eliminated chemically without appreciably affecting either the change in the absorption of chlorophyll-a_I or the oxygen yield (Fig. 13) [61, 79], *i.e.* the elementary reaction of photosynthesis continues to occur. Chlorophyll-b is therefore simply an indicator for a substance X which is involved in the transfer of electrons. Alcohol dissociates the Chl-b from this substance, without affecting the functioning of the latter. Under normal conditions a reaction of X probably causes a change in the optical properties of the chlorophyll-b in the vicinity. The resulting absorption changes then correspond quantitatively to the reaction

Right: Oxygen yield [mm³ O_2/(mg Chl) h].
Abscissa: Volume ratio ethanol/water.

of X. Since Chl-b acts as an indicator for X. we denote the latter by the symbol (Chl-b).

The absorption increase in $< 10^{-5}$ sec corresponds to the formation of a derivative (Chl-b)′, while the absorption decrease in the dark in about 10^{-2} sec corresponds to the regeneration of (Chl-b).

5. Reduction of (Chl-b)

The difference spectrum of Chl-b can be isolated chemically by the addition of dichlorophenolindophenol + excess $K_3Fe(CN)_6$. The $K_3Fe(CN)_6$ is only of minor importance. It acts as an electron acceptor I to suppress Cycle I (see Section IV.8), and it maintains the dichlorophenolindophenol in the oxidized state. As the concentration of dichlorophenolindophenol is increased, the rate of the regeneration of (Chl-b) from (Chl-b)′ also increases very rapidly [51, 78] (Fig. 14).

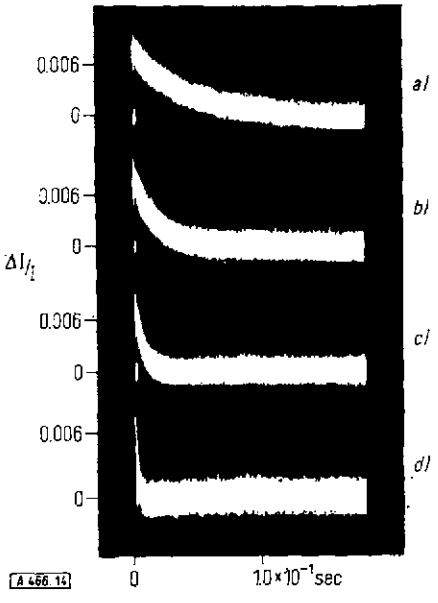

Fig. 14. Time variation of the change in the absorption of chlorophyll-b at 515 mμ in spinach chloroplasts, as a function of the concentration of 2,6-dichlorophenolindophenol [51, 78] [(a) 3.75×10^{-5} M, (b) 5.1×10^{-5}M, (c) 7.8×10^{-5} M, (d) 1.6×10^{-4} M].

The half-lives of the reverse reaction are:

(a) 24 msec, (b) 11 msec, (c) 4 msec, (d) 1 msec [51, 78].

Ordinate: Absorption change ΔI/I.
Abscissa: Time (sec).

It can be shown that dichlorophenolindophenol is reduced in the course of the reverse reaction. (Chl-b)′ must therefore be a reduced form of (Chl-b) formed on exposure to light, which is oxidized by dichlorophenolindophenol (DPIP) in the dark [51].

$$\text{(Chl-b)}^- + \text{DPIP} \rightarrow \text{(Chl-b)} + \text{red. DPIP}$$

The time variation of the dark reaction indicates that it is pseudofirst order, and gives a rate constant of $k = 1.62\times10^6$ lmole^{-1} sec^{-1} [*] and an activation energy of $E_A = 7.4$ kcal/mole [51].

6. Artificial Electron Acceptors II for (Chl-b)⁻

Of various substances with redox potentials between −0.44 and +0.43 volt which were investigated only those listed in Table 3 have been found to act as electron acceptors for (Chl-b)⁻. They are referred to as "artificial electron acceptors II".

Table 3. Artificial electron acceptors which can remove electrons from (Chl-b)⁻ [51].

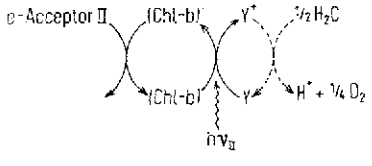
	Redox potential (pH 6.5) [volt]
Methylene blue	+0.03
Thionine	+0.08
Toluylene blue	+0.14
Thymolindophenol	+0.20
2,6,3′-Trichlorophenolindophenol	+0.26
2,6-Dichlorophennlindophenol	+0.26
Phenolindophenol	+0.26

7. The Redox Potential of (Chl-b)

Since only substances with a redox potential $\gtrsim 0$ volt react with (Chl-b)⁻ (Table 3), the redox potential of (Chl-b) must be about 0 volt [51].

8. Water as the Natural Electron Donor for (Chl-b)

From the above it can be seen that exposure to light causes the transfer of an electron from an unknown substance Y to (Chl-b). (Chl-b)⁻ can then give up the electron to one of the electron acceptors II. The ultimate electron donor is water (Scheme 3), as is shown by the following observations:



Scheme 3. Water as the natural electron donor for (Chl-b).

a) *N-p*-Chlorophenyl-*N′*-dimethylurea blocks the cleavage of water, *i.e.* the O_2 production [80]. The addition of increasing quantities of this poison leads also to the

[*] This value was obtained by recent measurements and differs a little from that published in [51].

[80] *N. I. Bishop*, Biochim. Biophysica Acta *27*, 205 (1958).

suppression of the absorption change associated with the isolated (Chl-b) reaction (Fig. 19, right) [46, 53].

b) In the chemically isolated (Chl-b) reaction, under various conditions, there is a quantitative relationship between the reduction of (Chl-b) and the oxygen yield [61].

c) There is also a quantitative relationship between the oxygen and the reduction of dichlorophenolindophenol (electron acceptor II).

9. The Electron Carrier Y

Since the transfer of an electron to (Chl-b) takes place in $< 10^{-5}$ sec (Fig. 11), whereas the liberation of the electron from water takes about 10^{-3} sec [81] (see Section X), there must be at least one carrier Y with a reaction time of 10^{-3} between (Chl-b) and the water. Chlorophyll-a_{II} (see Section V.11) cannot be identical with Y, since no absorption changes lasting 10^{-3} sec have so far been observed for Chl-a_{II}.

10. The Natural Electron Acceptor for $(Chl\text{-}b)^-$

In order to isolate the (Chl-b) reaction chemically from the remainder of the cell processes, we blocked the flow of electrons to the natural electron acceptor by means of the electron acceptors II. The isolated process is referred to as "Reaction Cycle II". The natural electron acceptor is unknown at present. From the time variation of the absorption changes (Fig. 11) it can be concluded that the transfer of electrons to this acceptor takes about 10^{-2} sec at 20 °C.

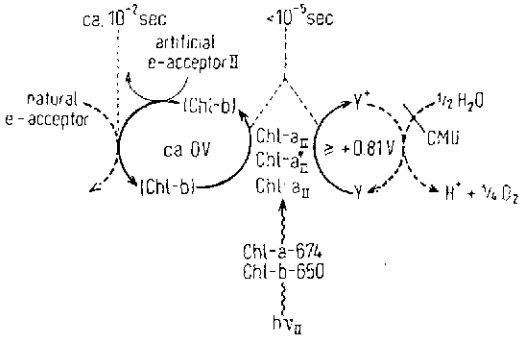
11. Chlorophyll-a_{II} as the Sensitizer for Reaction Cycle II

What photochemically active pigment sensitizes reaction cycle II? Chlorophyll-b is an indicator molecule and can be ruled out for this reason. Some information can be obtained from the action spectrum of reaction cycle II (see Section VI), which shows that the reaction must be sensitized by a chlorophyll-a molecule, which we refer to as Chl-a_{II} [63]. The excited Chl-a_{II} molecule evidently transfers an electron from Y to (Chl-b) so fast that the reaction of Chl-a_{II} has not so far been detected by absorption changes.

12. Scheme of Reaction Cycle II

If we summarize all the observations described so far, we obtain the picture shown in Scheme 4 for reaction cycle II.

On exposure to light ($h\nu_{II}$), the excited Chl-a_{II}^* causes the transfer of an electron from Y to (Chl-b) in $< 10^{-5}$ sec. (Chl-b) has a redox potential of about 0 volt. The electron transfer from $(Chl\text{-}b)^-$ to the natural acceptor takes about 10^{-2} sec at 20 °C. Water is the ultimate electron donor, *i.e.* Y^+ is reduced by water with liberation of $^1/_4$ O_2 and H^+. The



Scheme 4. Flow of electrons in reaction cycle II [54, 55, 61, 62, 74].

redox potential of water is +0.81 volt (pH 7). The redox potential of Y^+/Y must therefore be $\geq$ 0.81 volt [46]. By intercepting the electron from $(Chl\text{-}b)^-$ by one of the artificial electron acceptors II listed in Table 3, cycle II can be isolated from the remainder of the cell processes. The quantitative isolation of cycle II depends on the illumination time, the flash frequency, and the concentration of $K_3Fe(CN)_6$, as well as on the concentration of the electron acceptor II [82]. It has been shown by *Kessler* [15] that manganese ions are involved in the cleavage of water.

The isolated cycle II must be responsible for the system described by *Losada et al.* [38], *i.e.* O_2-producing chloroplasts with added dichlorophenolindophenol and $K_3Fe(CN)_6$ which are incapable of producing ATP.

The characteristics of the isolated reaction cycle II are summarized in Table 2 and Fig. 19 (right) [61, 74, 82].

13. Relationship between (Chl-b) and Plastoquinone

Bishop [83] has shown that on extraction with petroleum ether, chloroplasts lose the ability to cleave water, but they regain their photochemical activity on subsequent recondensation of plastoquinone. It was concluded, therefore, that plastoquinone plays some part in photosynthesis. The redox potential of plastoquinone is about 0 volt, and that of (Chl-b) is also about 0 volt [51].

This agreement, together with the following experiment, led to the conclusion that the two substances must be related. When plastoquinone is extracted, the difference spectrum of Chl-b disappears but reappears in full on condensation of synthetic plastoquinone (Fig. 15) [58, 75, 84]. We have therefore attempted to detect directly the participation of plastoquinone in the electron transport.

14. The Difference Spectrum of Plastoquinone (Q-254)

The reduction of plastoquinone *in vitro* is characterized by absorption changes in the ultraviolet region (maximum at 254 mμ) [90]. A similar difference spectrum is found when spinach chloroplasts [57] or *Chlorella* cells [60] are exposed to light (Fig. 2g). Thus plastoquinone (Q-254), like (Chl-b), is reduced *in vivo* on exposure to light.

[81] *J. Vater, H. Rüppel,* and *H. T. Witt,* unpublished work.

[82] *B. Rumberg, U. Siggel, B. Skerra,* and *H. T. Witt,* Z. Naturforsch., in the press.

[83] *N. I. Bishop,* Proc. nat. Acad. Sci. USA *45,* 1696 (1959).

[84] *H. T. Witt* in *W. Ruhland:* Handbuch der Pflanzenphysiologie. Springer, Berlin 1960, Vol. V/1, p. 634.

15. The Reaction of Plastoquinone in Reaction Cycle II

The changes in the absorption of Q-254 are also observed in the chemically isolated reaction cycle II (Fig. 19, right) [59]. Since, according to Scheme 4, the evolution of oxygen and the reduction of (Chl-b) are connected with each other, the evolution of oxygen and the changes in the absorption of Chl-b and of plastoquinone should be suppressed when plastoquinone is extracted, and should reappear on recondensation of plastoquinone, if plastoquinone is involved in cycle II [53, 85]. The changes in the absorption of Chl-a_I in cycle I must be unaffected by these measures. This is confirmed by the results reproduced in Fig. 15 [59, 61].

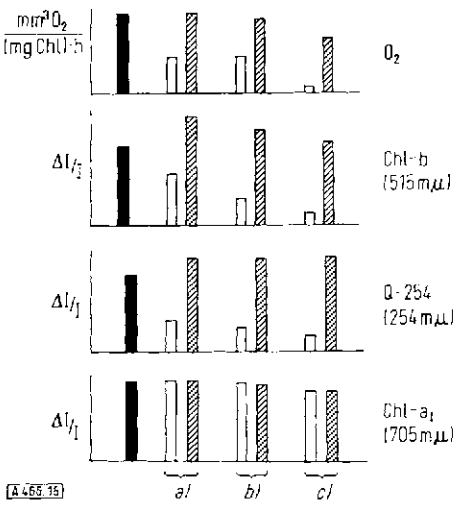


Fig. 15. Relative oxygen production and changes in the absorption of chlorophyll-b, plastoquinone, and chlorophyll-a$_I$ in spinach chloroplasts under normal conditions (black rectangles), after extraction of plastoquinone with petroleum ether (white rectangles), and after subsequent condensation of synthetic plastoquinone (cross-hatched rectangles). The groups marked a), b), and c) differ in the extent of extraction with petroleum ether [59, 61].

16. The Characteristics of the Plastoquinone Reaction

The characteristics of the plastoquinone reaction agree quantitatively with those of the (Chl-b) reaction (Fig. 19, right): pH range 5–8, temperature range $< 40\,^{\circ}C$, sensitive to *N*-*p*-chlorophenyl-*N'*-dimethylurea [61]. The magnitude of the changes in the absorption of plastoquinone depends on the O_2 content of the chloroplast suspension. This indicates that Q^{-}-254 is oxidized by O_2 [59, 60]. This electron transfer is slow (seconds), and is indicated by an arrow in Scheme 8.

17. Chlorophyll-b as an Indicator for the Plastoquinone Reaction

(Chl-b) and Q-254 have roughly the same redox potential, the changes in the absorption of both disappear when plastoquinone is extracted, both are reduced when the isolated cycle II is induced, and their reactions have the same characteristics. It may be assumed, therefore, that (Chl-b) and Q-254 are identical, *i.e.* that the changes in the absorption of chlorophyll-b are indicative of the plastoquinone reaction [58, 61]. Moreover, the time variation of the absorption changes at 515 and 254 mμ under various conditions also agree [59, 61]. This is shown in Fig. 16 for the excitation times. The magnitudes of the changes in the absorption of chlorophyll-b and plastoquinone show the same dependence on flash duration. In the case of prolonged flashes (10^{-1} sec), the quantity of plastoquinone that takes part in the reaction is about four times as great as when the flashes last only $\lesssim 10^{-3}$ sec (Fig. 16) [59–61].

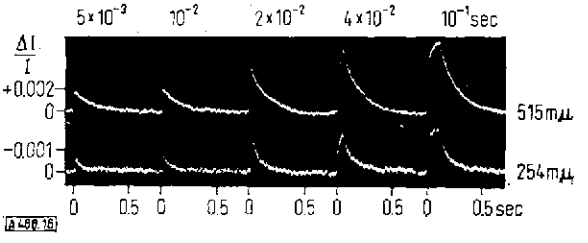

Fig. 16. Time variation of the absorption changes at 515 mμ (chlorophyll-b) and 254 mμ (plastoquinone) in *Chlorella* cells, as a function of the duration of the flash (numbers above the diagram) [61].

Ordinate: Absorption change ΔI/I.
Abscissa: Time [sec].

18. Plastosemiquinone

Under certain conditions, differences are observed in the time variations of the absorption changes at 515 and 254 mμ. These differences indicate the participation of plastosemiquinone and plastohydroquinone. It has not yet been proved which of the two reduced forms is indicated by chlorophyll-b.

VI. The Action Spectra of the Isolated Reaction Cycles I and II

The isolated cycle I can be optically measured by the change in the absorption of Chl-a_I, *e.g.* at 430 mμ and chemically by the rate of reduction of the electron acceptor I, *e.g.* benzyl viologen. The isolated cycle II can be optically measured by the change in the absorption of Chl-b, *e.g.* at 515 mμ, and chemically by the rate of production of oxygen. Fig. 17 shows the action spectra obtained by these methods for the isolated cycles I and II.

The optically measured action spectra are more accurate than those obtained by chemical methods. The shoulders and maxima of the spectra show which of the photochemically inactive chlorophyll types supply the reaction centers Chl-a_I and Chl-a_{II} with energy by energy transfer. Chl-a_I is supplied with energy *via* the chlorophylls Chl-a-682, Chl-a-695, and probably also Chl-b-650 (Scheme 2), and Chl-a_{II} is supplied by Chl-b-650 and Chl-a-674 (Scheme 4). Cycle I can be excited by light of wavelength < 730 mμ, and cycle II only by light of wavelength < 700 mμ (Fig. 17).

According to the laws of energy migration, the absorption maximum of the active chlorophyll in cycle II must be at longer wavelengths than the maximum of the chlorophyll molecules transporting the energy (674 mμ).

[85] *H. T. Witt, A. Müller*, and *B. Rumberg*, Angew. Chem. *73*, 507 (1961).

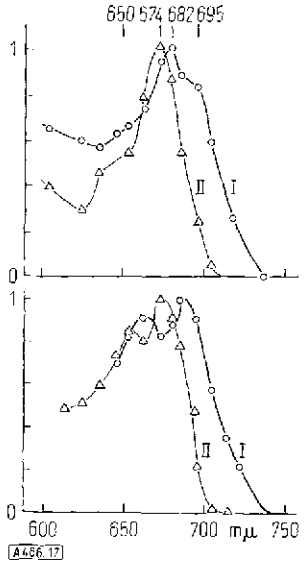

Fig. 17. Action spectra of the isolated reaction cycles I and II in spinach chloroplasts [59, 63].

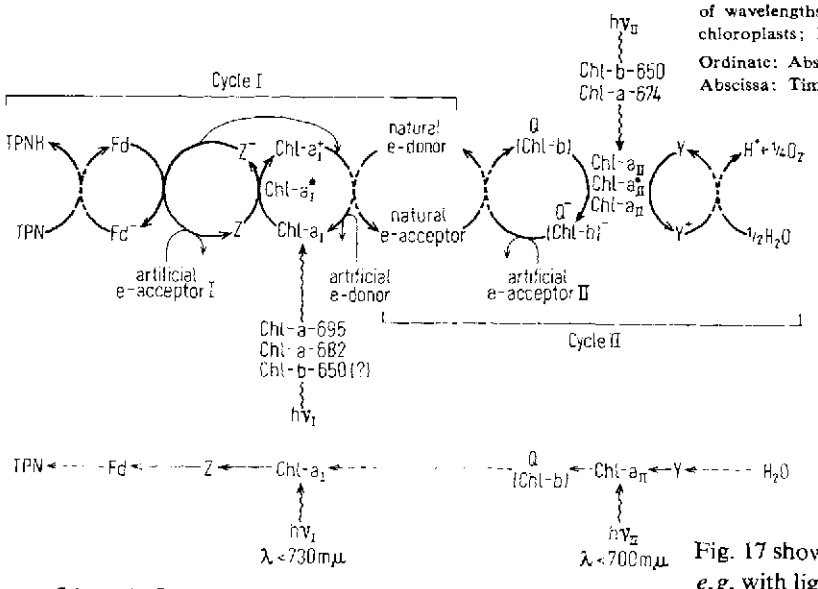
Ordinates: Top: Relative change in the absorption of chlorophyll-a_I at 433 mμ (I) and of chlorophyll-b at 515 mμ (II).
Bottom: Relative reduction of benzyl viologen (I) and production of O_2 (II).
Abscissa: Wavelength of inducing light [mμ] (equal numbers of *incident quanta*).

Maxima above 674 mμ belong to the chlorophyll-a type, so that a chlorophyll-a must be the active molecule in cycle II [63]; this result has already been used in Section V.11, in which the active molecule was denoted by Chl-a_{II}. The same result had previously been deduced from the Emerson effect [23].

VII. Quantitative Coupling of Reaction Cycles I and II in the Complete System

The natural electron donor for cycle I (Scheme 2) and the natural electron acceptor for cycle II (Scheme 4) are unknown. It seems obvious to assume that cycle II acts as the natural electron donor for cycle I, and that cycle I acts as the natural electron acceptor for cycle II (Scheme 5). This coupling of the two cycles in the complete system can be demonstrated in four ways.



Scheme 5. Coupling of reaction cycles I and II in the complete system [46, 54, 55, 62, 74].
Below: simplified line diagram.

1. Demonstration through Chl-a_I

Fig. 17 shows that Chl-a_I can be oxidized *e.g.* with light of wavelength 720 mμ (only $h\nu_I$) (decrease in absorption at 703 mμ) without Chl-a_{II} being excited. On subsequent exposure to light of wavelength *e.g.* 638 mμ ($h\nu_I$ and $h\nu_{II}$), Chl-a_{II} should also be excited and should effect the transfer of an electron from the water to the plastoquinone. If cycles I and II are coupled, Q^- must reduce the Chl-a_I^+, *i.e.* the absorption at 703 mμ must increase. This is verified by Fig. 18, top [59, 60].

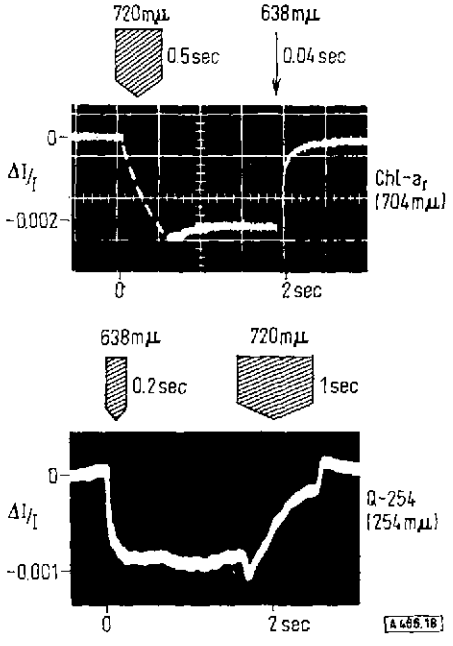


Fig. 18. Time variation of the changes in the absorption of chlorophyll-a_I (704 mμ) on excitation with light of wavelengths 720 mμ and 638 mμ (*top*), and of plastoquinone (254 mμ) on excitation with light of wavelengths 638 mμ and 720 mμ (bottom). Subject: top: spinach chloroplasts; bottom: *Chlorella* cells [59, 60].

Ordinate: Absorption change $\Delta I/I$.
Abscissa: Time [sec].

2. Demonstration through Plastoquinone

Fig. 17 shows that plastoquinone (Chl-b) can be reduced *e.g.* with light of wavelength 638 mμ ($h\nu_I$ and $h\nu_{II}$). This ligth also oxidizes Chl-a_I (Fig. 17). After a long period of darkness, however, it is mainly plastoquinone that is

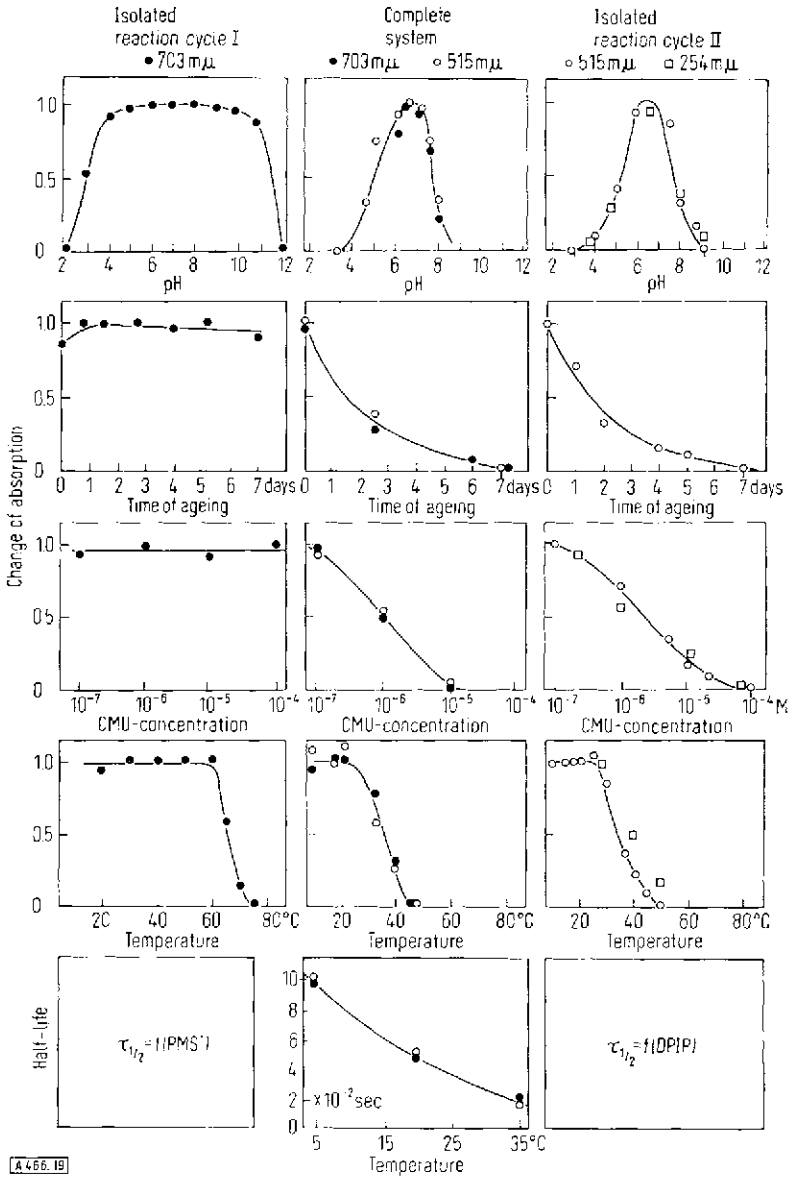

Fig. 19. *Left*: Dependence of the isolated reaction cycle I on various parameters, measured on the basis of the decrease in the absorption of chlorophyll-a_I at 703 mμ.

Right: Dependence of the isolated reaction cycle II on various parameters, measured on the basis of the change in the absorption of chlorophyll-b at 515 mμ and of plastoquinone at 254 mμ.

Center: Dependence of reaction cycles I and II in the complete system on various parameters, measured on the basis of the increase in the absorption of chlorophyll-a_I at 703 mμ and of chlorophyll-b at 515 mμ.

Subject: spinach chloroplasts; for the measurement of the half-lives: *Chlorella* cells [60, 82].

CMU = *N*-*p*-chlorophenyl-*N'*-dimethylurea;- DPIP = dichlorophenol-indophenol.

PMS^- = reduced *N*-methylphenazonium methyl sulfate.

reduced, as is shown by the fact that the absorption at 254 mμ decreases on exposure to light, and that reoxidation no longer takes place as soon as the light is switched off (Fig. 18, bottom). On subsequent exposure to light of wavelength 720 mμ ($h\nu_I$ only), only Chl-a_I is oxidized. If cycles I and II were coupled, Chl-a_I^+ should accept the electron from Q^-, and the absorption at 254 mμ should increase. It can be seen from Fig. 18, bottom, that this is in fact the case [59, 60].

3. Demonstration through Common Characteristics of Cycles I and II

The characteristics of the *isolated* cycles I and II are compared in Table 2 and in Fig. 19. They differ considerably. If the two cycles are coupled, however, they should depend in the same way on various parameters. To show this, Chl-a_I is first oxidized alone by exposure to continuous light of wavelength 720 mμ ($h\nu_I$ only) (decrease in absorption at 703 mμ). On further exposure to light *e.g.* of wavelength 638 mμ ($h\nu_I$ and $h\nu_{II}$), the reduction of Chl-a_I^+, *i.e.* the increase in absorption at 703 mμ, should be dependent on the reduction of plastoquinone [(Chl-b)] in cycle II, *i.e.* the increase in absorption at 703 mμ, and the change at 515 mμ in the *coupled* system should exhibit the same dependence as the change at 515 mμ in the *isolated* cycle II (Fig. 19, right). The good agreement (Fig. 19, center) shows that the coupling between cycles I and II is quantitative [60, 82].

Kinetic Demonstration

In the complete system of *Chlorella* the increase in absorption at 703 (reduction of Chl-a_I) and the decrease at 515 mμ [oxidation of (Chl-b)⁻] have equal half-lives at various temperatures (Fig. 19, bottom center). This provides kinetic evidence of the quantitative coupling between the two cycles [60, 62]. The half-lives are characteristic of the rate-determining step between cycles I and II. Depending on the conditions, half-lives between 1×10^{-2} and 4×10^{-2} sec at 25 °C have been found [60, 82].

5. Feed-Back between Cycles I and II; Reduction of (Chl-b) by Excitation of Chl-a_I and Chl-a_{II}

The difference spectrum of Chl-b is produced by excitation of Chl-a_{II}. It has not yet been pointed out, however, that this applies only for one half of the amplitude, the other half being produced by excitation of Chl-a_I. This is shown by the following observations:

a) If only Chl-a_{II} is excited [deactivation of cycle I with dichlorophenolindophenol + $K_3Fe(CN)_6$], the amplitude of the difference spectrum of Chl-b is only half as great as under normal conditions with excitation of Chl-a_I and Chl-a_{II} (Section V.1 and Fig. 10) [59].

b) If only Chl-a_I is excited (*e.g.* with light of wavelength 720 mμ $h\nu_I$ only), the difference spectrum of Chl-b does not disappear. It is simply reduced [53] to about half of its usual amplitude at the saturation intensity [63, 82, 95].

c) With increasing excitation of Chl-a_I with continuous light (*e.g.* λ = 728 mμ, $h\nu_I$ only), the changes in the absorption of Chl-b that can be stimulated by additional flash illumination (*e.g.* λ – 638 mμ, $h\nu_I$ and $h\nu_{II}$) are reduced to about half (Fig. 20). The continuous illumination evidently saturates the (Chl-b) component that can be stimulated by Chl-a_I [52].

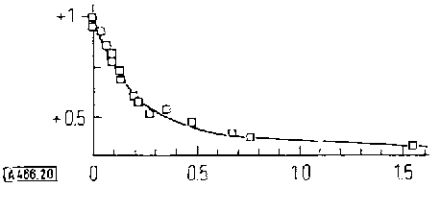

Fig. 20. Changes in the absorption of chlorophyll-b at 515 mμ on flash illumination as a function of the intensity of continuous illumination (λ = 728 mμ).
Subject: *Chlorella* cells [52].
Ordinate: Relative absorption change.
Abscissa: Intensity of illumination [10^5 erg cm^{-2} sec^{-1}].

This result shows that, as mentioned earlier, (Chl-b) is reduced on excitation of cycle II, but that (Chl-b) may also be reduced by the backward flow of electrons from Z^- to (Chl-b), *i.e.* to Q. This is indicated in Scheme 8 by a broken arrow.

If cycle II is deactivated by the addition of *N*-*p*-chlorophenyl-*N*-dimethylurea (Section V.8), the changes in the absorption of Chl b reappear on illumination when dichlorophenolindophenol + excess ascorbate are added to the chloroplast suspension [54]. These changes can be produced by excitation of Chl-a_I alone, *i.e.* with light of wavelength 720 mμ ($h\nu_I$ only) [82]. Thus instead of water, ascorbate can evidently act (*via* dichlorophenolindophenol) as an electron donor for plastoquinone (Scheme 8).

6. Unambiguity of the Representation of Cycle II by Chlorophyll-b [61]

1. The absorption changes at 478, 513, and 648 mμ that characterize cycle II are due to changes in chlorophyll-b (Section V, 3).

2. Chlorophyll-b is simply an indicator, the change in the absorption of which is brought about by the action of another substance, (Chl-b) or plastoquinone (Section V, 4).

3. Alterations of the chloroplasts can cause a breakdown of the coupling between chlorophyll-b and plastoquinone (Section V, 4).

4. (Chl-b) can be reduced by Chl-a_{II} and also by feed-back from cycle I (Section VII, 5).

5. It follows that the changes in the absorption of Chl-b exclusively and unambiguously represent cycle II only if the difference spectrum of Chl-b, which can be induced by cycle I, is suppressed. This is the case:

a) if cycle I is deactivated chemically [addition of an electron acceptor II + $K_3Fe(CN)_6$ (Section V, 1)] or

b) if the feed-back from cycle I is saturated by additional continuous illumination of wavelength 700–730 mμ ($h\nu_I$ only) (Section VII, 5).

These points were borne in mind in determining the characteristics of cycle II.

VIII. The Intermediates

There remains an as yet unexplained difference between the complex difference spectrum under normal conditions and that of Chl-a_I in the blue region of the spectrum between 400 and 460 mμ (cf. Fig. 22a and e). This difference is due to the superposition of the changes in the absorptions of a cytochrome-f and a cytochrome-b [56].

1. The Difference Spectrum of Cytochrome-f-407-424-555 and its Isolation

Fast ($< 10^{-1}$ sec) light-induced reactions of cytochrome-f cannot normally be detected in green cells. However, three methods of altering the cell system [62] can bring about absorption changes which are due to the well-known oxidation of Chl a_I and an oxidation of Cyt-f which cannot otherwise be detected (Fig. 21):

a) illumination at low temperatures (–150 °C) [46],

b) excitation of cycle I alone, *e.g.* with light of wavelength 710 mμ ($h\nu_I$ only) [53],

c) addition of dichlorophenolindophenol to chloroplasts [55].

The changes at about 700 mμ at –150 °C marked by a broken curve in Fig. 21a indicate that Chl-a_I is involved. If *N*-methylphenazonium methyl sulfate is added, only the difference spectrum of Chl-a_I at 150 °C is obtained (Fig. 3e) [46]. If this spectrum is subtracted from the spectrum shown in Fig. 21a or 21b, we obtain the same difference spectrum as is observed on chemical oxidation

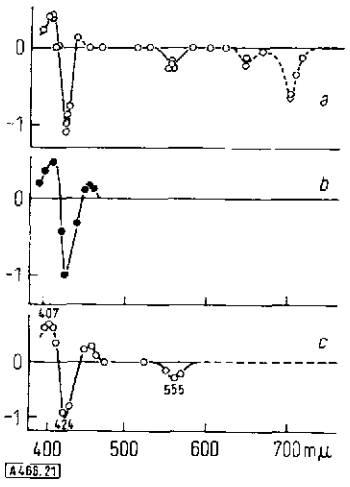

Fig. 21. Difference spectrum of illuminated spinach chloroplasts (a, c) and *Chlorella* cells (b).

a) −150 °C, no additives; broken curve: change in the absorption of Chl-a_I; continuous curve: changes in the absorption of Cyt-f and Chl-a_I [46].

b) 25 °C, excitation with light of wavelength 710 mμ [53].

c) 25 °C, addition of dichlorophenolindophenol [55].
Curve (c) represents the isolated difference spectrum for the oxidation of cytochrome-f-407-424-555.

Ordinate: Relative absorption change.
Abscissa: Wavelength [mμ].

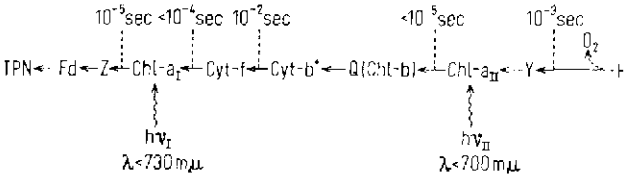
of a cytochrome-f *in vitro* [86]. After the addition of dichlorophenolindophenol the kinetics of the difference spectrum of Chl-a_I are sufficiently different from those of the difference spectrum of Cyt-f that the difference spectrum of the Cyt-f oxidation is obtained directly (Fig. 21c) [55]. The redox potential of Cyt-f *in vivo* was estimated to be about 0.4 volt [53], while the value *in vitro* is 0.37 volt [86].

2. The Chl-a_I-Cyt-f Complex

The difference between the difference spectra at −150 °C shown in Fig. 3e and in Fig. 21a can be explained by complex formation between Chl-a_I and Cyt-f [46,47]. On illumination, Chl-a_I is oxidized first. Cyt-f can then reduce Chl-a_I^+ within the complex, even at −150 °C. Further light quanta oxidize Chl-a_I a second time, so that Chl-a_I^+ and Cyt-f_I^+ are found (Fig. 21a). If at −150 °C an artificial electron donor (*e.g.* > 10^{-4} M reduced *N*-methylphenazonium methyl sulfate) is offered to the Chl-a_I^+, then Cyt-f can no longer act as the electron donor and cannot be oxidized; consequently, only the difference spectrum of Chl-a_I oxidation is observed (Fig. 3e) [47].

3. The Difference Spectrum of Cytochrome-b-412-435-563 and its Isolation

The three sets of conditions described in Section VIII,1 are not the only situations in which cytochrome-f takes part in the transfer of electrons; it is also involved under normal conditions, although in association with cytochrome-b. In the dark, cytochrome-f exists in a reduced form and cytochrome-b in an oxidized form. Cytochrome-b intervenes between Cyt-f and plastoquinone (Scheme 6) [56].



Scheme 6. Positions of cytochrome-b and cytochrome-f in the photosynthetic chain [47, 56].

This is shown by the following observation: if only Chl-a_I is excited, *e.g.* with light of wavelength 720 mμ ($h\nu_I$ only), Chl-a_I and subsequently Cyt-f are oxidized. The difference spectrum obtained must therefore be the sum of the difference spectra of these two substances (Fig. 22b).

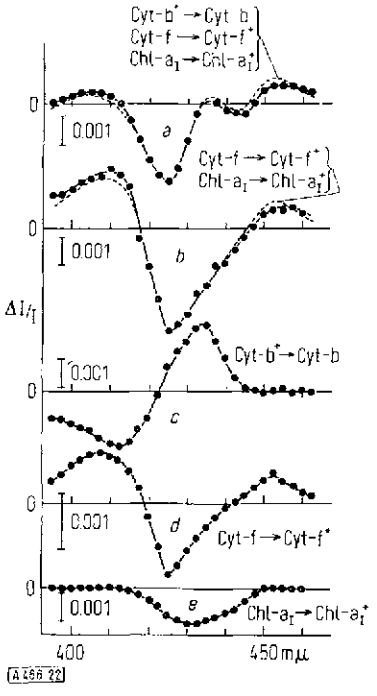


Fig. 22. a) Complex difference spectrum of illuminated spinach chloroplasts under normal conditions (continuous line); sum of the isolated difference spectra c-e (broken line) [56].

b) Difference spectrum on illumination with λ = 720 mμ (continuous curve); sum of the isolated difference spectra d and e (broken curve).

c) Difference spectrum of cytochrome-b on illumination with λ = 650 mμ after pre-illumination with λ = 720 mμ.

d) Difference spectrum of cytochrome-f with the addition of dichlorophenolindophenol (cf. Fig. 21c).

e) Difference spectrum of chlorophyll-a$_I$ on illumination of aged chloroplasts (cf. Fig. 3b).

Curve c represents the isolated difference spectrum for the reduction of cytochrome-b-412-435-563$^+$.

Ordinate: Absorption change $\Delta I/I$.
Abscissa: Wavelength [mμ].

On subsequent excitation of Chl-a_I and Chl-a_{II}, *e.g.* with light of wavelength 650 mμ ($h\nu_I$ and $h\nu_{II}$), the $h\nu_I$ illumination keeps Chl-a_I and Cyt-f in the oxidized state; according to Scheme 6, the $h\nu_{II}$ illumination should reduce Cyt-b$^+$ by an electron transfer from water, *via* Y and plastoquinone. Thus only the difference spectrum due to a reduction of Cyt-b$^+$ should be observed (Fig. 22c). This corresponds indeed to that obtained in the chemical reduction of Cyt-b$^+$ *in vitro*.

[86] *H. E. Davenport* and *R. Hill*, Proc. Roy. Soc. (London), Ser. B, *139*, 327 (1952).

The redox potential of Cyt-b *in vitro* is −0.03 volt [87]. Under normal conditions, the cytochromes cannot be observed directly, since the oxidation of Cyt-f and the reduction of Cyt-b^+ lead to an uncharacteristic interference of the associated absorption changes (Fig. 22c and d). Cytochrome-f, however, appears (Fig. 21) as a result of the alterations mentioned in Section VIII.1, since these suppress the Cyt b reaction and prevent the interference:

a) The electron transfer to Cyt-b^+ is blocked at low temperatures.

b) If only cyle I is stimulated with light of wavelength 710 mμ ($h\nu_I$ only), the reduction of Cyt-b^+ does not occur.

c) When dichlorophenolindophenol is added, the electrons are intercepted from the plastoquinone Q, so that the reduction of Cyt-b^+ is blocked. The electron donor for Cyt f in this case is the dichlorophenolindophenol reduced by Q^-.

IX. Quantitative Analysis of the Short-Lived Absorption Changes during Photosynthesis

The analysis of the absorption changes between 400 and 800 mμ is complete if the sum of the isolated difference spectra of Chl-a_I, Chl-b, Cyt-f, and Cyt-b gives the complex difference spectrum under normal conditions (Fig. 3a or 10a). The absorption changes at 703 mμ are entirely due to Chl-a_I (Fig. 3), those at 648 mμ to Chl-a_I and Chl-b, and those at 478 and 513 mμ entirely to Chl-b (Fig. 10). Between 400 and 450 mμ the absorption changes due to Chl-a_I, Cyt-f, and Cyt-b appear. Their isolated difference spectra are shown in Fig. 22c–e. The sum is indicated by the broken curve in Fig. 22a, which exhibits excellent agreement with the complex difference spectrum under normal conditions (continuous curve, Fig. 22a) [56].

X. Rate of Cleavage of Water

Emerson et al. have measured the oxygen yield of *Chlorella* cells which were illuminated by periodic flashes, as a function of the dark period between the flashes (flash manometry). The time required to obtain half of the maximum yield was taken as the half-live of the rate-determining step of the overall reaction (approximately 10^{-2} sec at 20 °C) [16,84]. We have also used this method, but in a considerably modified form: we determined the oxygen yield in the *isolated* reaction cycle II, and used such a high concentration of dichlorophenolindophenol that the electrons were very rapidly (5×10^{-4} sec) intercepted from $(Chl\text{-}b)^-$, so that this step was no longer rate-determining. Measurements under these conditions should yield direct information regarding the rate-determining step between H_2O and Chl-a_{II}.

[87] *R. Hill*, Nature (London) *174*, 501 (1954).

In order to obtain conclusive results, we used periodic flash illumination and groups of flashes.

The first observations made on excitation with groups of flashes indicated a two-phase formation of O_2, characterized by half-lives of about 10^{-1} and 10^{-3} sec [41]. Periodic flash illumination gave a half-life of 10^{-2} sec, which was explained as the resultant of the partial reactions taking 10^{-1} and 10^{-3} sec. Recent measurements [81] have shown, however, that the reaction with a half-life of 10^{-1} sec was simulated by a fall in the activity of the chloroplasts. Both illumination with groups of flashes and periodic flash illumination give a single-step formation of O_2, characterized only by a half-life of $\tau^A_{1/2} \approx 2\times10^{-3}$ sec (20 °C) (Fig. 23, curve A). This half-life corresponds to the rate of cleavage of water.

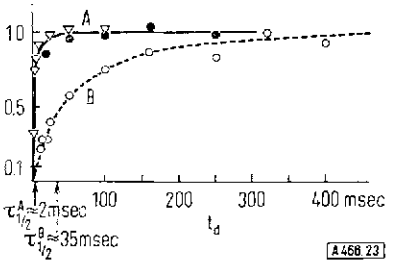

Fig. 23. Relative oxygen yield per flash as a function of the dark time t_d between flashes [81] Subject: spinach chloroplasts. 20 °C.

Curve A: Isolated reaction cycle II on excitation with double flashes (▽) and periodic flashes (●).

Curve B: Complete reaction system on excitation with periodic flashes (○).

Ordinate: (Quantity of O_2 per flash at t_d)/(Quantity of O_2 per flash at t_d = 320 msec).

Abscissa: Dark time t_d between flashes [msec].

XI. Rate of the Overall Reaction and Location of the Rate-Determining Reaction

In agreement with results obtained by *Clendenning et al.* [88], experiments with periodic flash illumination on the complete chloroplast system (cycles I and II) with added electron acceptor I [$K_3Fe(CN)_6$] gave a half-life of $\tau^B_{1/2} \approx 3.5\times10^{-2}$ sec at 20 °C (Fig. 23, curve B) for the rate-determining reaction. This value agrees closely with that deduced in Section VII,4 from absorption changes for the rate-determining step between cycles I and II in *Clorella* cells (1×10^{-2} to 4×10^{-2} sec at 25 °C). From this it follows that the rate-determining step of the overall reaction is located between the cycles I and II.

XII. The Anomalies on Continuous Illumination with Light in the Far Red

Far red light (λ = 700 to 730 mμ, $h\nu_I$ only) excites only Chl-a_I in cycle I (Fig. 17). If the changes in the absorption of Chl-a_I at 703 mμ caused by flashes *e.g.* of wavelength 638 mμ ($h\nu_I$ and $h\nu_{II}$) are measured as a function of the intensity of the additional continuous far red

[88] *K. A. Clendenning* and *H. C. Ehrmanntraut*, Arch. Biochem. *29*, 387 (1950).

illumination, the results obtained are as follows (Fig. 24): With continuous illumination at a *medium* intensity (b in Fig. 24), the absorption changes described earlier (Fig. 4) are observed in *Chlorella* on flash illumination (time t_3). With *weak* continuous illumination I (down to $I \rightarrow 0$), the absorption changes on flash illumination (time t_1) practically disappear completely (a in Fig. 24). With *more intense* continuous illumination (time t_5), the zero-point of the absorption changes moves; this gives rise to positive absorption changes (Fig. 24c) which have already been observed by *Kok* in pigment 700 [43].

1. The Chl-a_I-Cyt-f Complex

The interpretation of curves a and b in Fig. 24 is found in the existence of a Chl-a_I-Cyt-f complex [46] (cf. Section VIII.1). With *weak* additional continuous illumination (curve a), Chl-a_I and Cyt-f are present in the reduced form. On flash illumination (t_1), Chl-a_I is oxidized

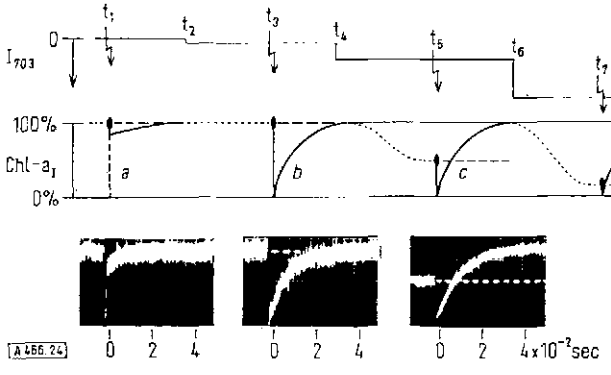

Fig. 24. Time variation of the change in the absorption of chlorophyll-a_I at 703 mμ (bottom) as a function of the intensity of additional continuous light (top) [89]. Wavelength of the continuous light: 703 mμ. Subject: *Chlorella* cells. A course as shown by curve d is not observed experimentally in *Chlorella* cells (see text, Section XII, 1).

Flash illumination lasting 10^{-5} sec at time t = 0.

Ordinate: Top: Intensity of continuous illumination at 703 mμ.

Abscissa: Time [sec].

in $< 10^{-5}$ sec and is so rapidly reduced again in the complex by Cyt-f ($< 10^{-4}$ sec) that the associated absorption changes cannot be observed [52]. (This made possible the physical separation of the difference spetrum of Chl-b from that of Chl-a_I; Section V.1). At *medium* intensities of the continuous illumination (curve b) Cyt-f is permanently oxidized. On flash illumination (t_3), Chl-a_I is also oxidized. The reduction of Chl-a_I^+ cannot be faster than the transfer of an electron from cycle II *via* Cyt-f^+. The time required for this is about 10^{-2} sec (Section VII.4). With *more intense* continuous illumination (curve c), part of the Chl-a_I is permanently oxidized in addition to the Cyt-f. Flash illumination (t_5) can oxidize only the portion of the Chl-a_I that has remained in the reduced form. The negative absorption changes are therefore correspondingly weaker. The electrons supplied by cycle II reduce the Chl-a_I^+ which has been oxidized by the additional continuous illumination and the flash illumination, with consequent positive absorption changes rising above the zero line. All these observations agree with the reaction scheme outlined earlier. However, the fact that Chl-a_I is oxidized only to a maximum extent of 50% by continuous light of *high* intensity still remains unexplained. If oxidation were complete, curve d in Fig. 24 should be obtained. Since this is not the case, about 50% of the Chl-a_I behaves differently from the remainder.

2. The Electron Acceptor I for Z^-

Corresponding measurements on chloroplasts (Fig. 24 refers to *Chlorella* cells) show positive absorption changes only on addition of one of the electron acceptors I listed in Table 1 (Fig. 25a, b). This is understandable, since in the absence of the electron acceptor I, the electrons flow back from Z^- to Chl-a_I^+ (Scheme 2), so that the additional continuous light cannot cause an accumulation of Chl-a_I^+. Electron acceptors I suppress the reverse flow and so permit Chl-a_I^+ to accumulate. Flash illumination (t_2) then causes the oxidation of the remaining Chl-a_I. As in *Chlorella* the electron transfer from cycle II takes 10^{-2} sec; it brings about the reduc-

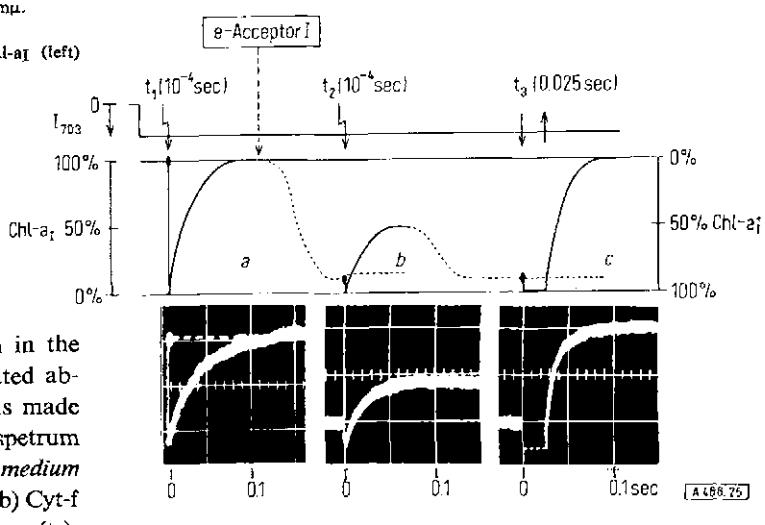

Fig. 25. Time variation of the change in the absorption of chlorophyll-aI at 703 mμ (bottom) as a function of the intensity of the additional continuous illumination (top) [89]. Wavelength of continuous illumination: 703 mμ. Subject: spinach chloroplasts.

Ordinates: Top: Intensity of continuous light at 703 mμ.

Center: Absorption change converted to % Chl-a_I (left) and % Chl-a_I^+ (right).

Abscissa: Time [sec].

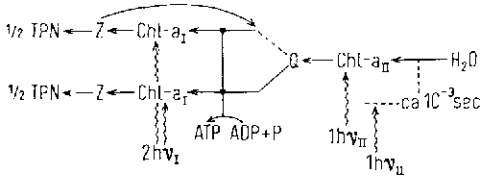
[89] *B. Rumberg*, Doctorate Dissertation, Technische Universität Berlin, 1965.

tion of the Chl-a_I^+ and gives rise to the absorption increase associated with this reduction (Fig. 25b). The transition from negative absorption changes (Fig. 25a) to positive (Fig. 25b) was used to find the electron acceptors I which react with Z^- (Section IV.8) [48,62].

In the presence of electron acceptors I, the total absorption change is halved (Fig. 25a, b); positive absorption changes which correspond in magnitude to the negative changes occur only on flash illumination for a period of $\geqslant 10^{-3}$ sec (t_3) (Fig. 25a,c). Thus approximately 50% of the Chl-a_I molecules in chloroplasts also behave differently from the remainder.

3. Two Reactions of Chl-a_I

50% of the Chl-a_I molecules evidently take part in a reaction which has not yet been detected. A second Chl-a_I cycle may run parallel to cycle I (Scheme 7). It must then be assumed that a cyclic flow of electrons (bent arrow in Scheme 7) takes place in one of the Chl-a_I cycles in *Chlorella*, since only 50% of the Chl-a_I can be accumulated as Chl-a_I^+ (Section XII.1). The fact that the positive absorption changes in chloroplasts are doubled at a flash period of $\geqslant 10^{-3}$ sec (Fig. 25c) is related to the rate of cleavage of water (10^{-3} sec, Section X). In $\geqslant 10^{-3}$ sec, at least two electrons can be transferred from the water to plastoquinone, and thence to Chl-a_I^+.



Scheme 7. Two parallel Chl-a_I cycles. (Concerning the reaction ADP + P → ATP, see Section XIII, 3).

XIII. The Overall Reaction

1. The Flow of Electrons

The facts established so far are summarized in Scheme 8, which shows the transfer of electrons from water, *via* intermediates, to TPN. The heavy continuous arrows indicate the direction of the electron flow, while the heavy broken arrows show the cyclic electron flow from Z^- to Chl-a_I^+ and Q. The thin arrows correspond to the flow of electrons in chloroplasts under artificial conditions: (a) interception of the electrons from Z^- by electron acceptors I (Section IV.8); (b) interception of electrons from $(Chl\text{-}b)^-$, *i.e.* plastoquinone Q^-, by electron acceptors II (Section V.6) and by oxygen (Section V.17). Electron donors such as PMS and DPIP (with ascorbate)

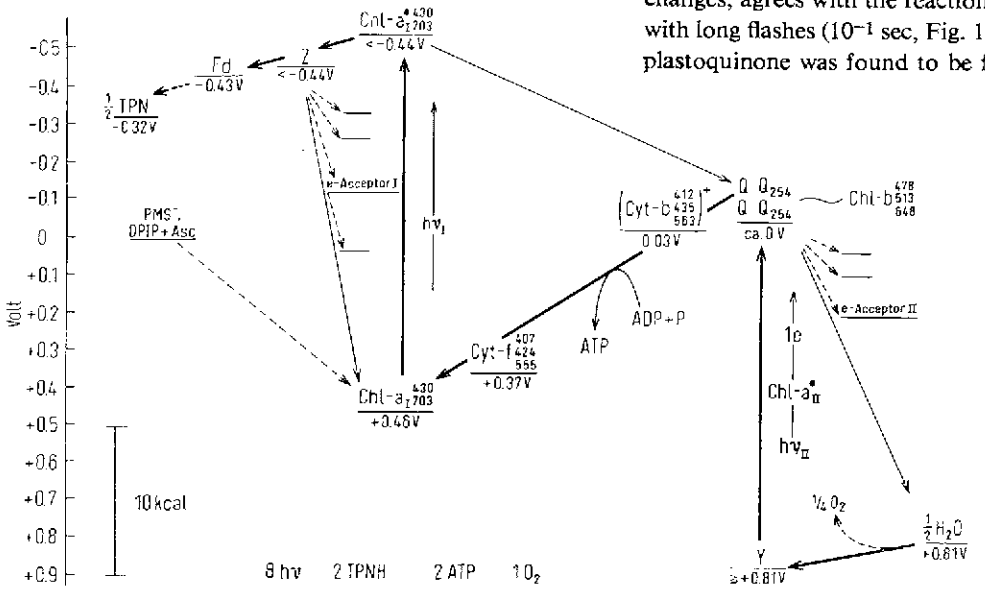
The figures beside the symbols Chl, Cyt, and Q indicate the maxima of the absorption changes. Also indicated are the times required for the various electron transfer processes.

can be coupled to (c) Chl-a_I (Section IV.4), (d) Cyt-f (Section VIII.3), and (e) plastoquinone (Section VII,5). The wavy lines represent the incident light quanta. The times are the durations of the electron transfers. The energy thresholds are overcome by the absorption of energy in Chl-a_I and Chl-a_{II}. The energy of the absorbed light is supplied to these molecules by energy transfer. The chlorophyll types Chl-a-695, Chl-a-682, and probably Chl-b-650 help to supply energy to Chl-a_I, while the types Chl-a-674 and Chl-b-650 help to supply Chl-a_{II}. Chl-a_I can be excited with light of wavelength < 730 mμ, and Chl-a_{II} with wavelengths < 700 mμ. Chl-a_I in the excited state Chl-a_I^* has such a low redox potential (< -0.44 volt) that it is capable of reducing Z (redox potential < -0.44 volt). Chl-a_{II}^* causes an electron transfer from Y to plastoquinone Q. The electron from Z^- is transferred to TPN *via* ferredoxin and flavoprotein. Y^+ is reduced by water, with formation of H^+ and $^1/_4O_2$. Chl-a_I^+ is reduced by Cyt-f, and Cyt-f^+ is reduced in turn by the transfer of an electron from Q^- (*via* Cyt-b^+). We

have placed Cyt-b$^+$ in brackets because its position in the chain is not yet accurately known.

2. The Energy Diagram

It is possible, on the basis of the redox potentials of the intermediates, to construct an energy diagram for the electron transfer (Scheme 9).



Scheme 9. Energy diagram for the electron transfer during photosynthesis, as represented in Scheme 8 [74].
Ordinate: Redox potential.

3. Phosphorylation

The redox potentials show that the transfer of electrons from Q to Cyt-f is accompanied by the liberation of approximately 10 kcal/mole, which may be used to form ATP from ADP and phosphate. For this reason, the phosphorylation step is inserted at this stage in Schemes 8 and 9 [46, 53].

4. Quantum Yields

It can be seen from Schemes 8 and 9 that the absorption of 8 light quanta ($4\ h\nu_I + 4\ h\nu_{II}$) is accompanied by the formation of 2 TPNH, 2 ATP, and 1 O_2. (The formation of 2 ATP is shown by the fact that 1 molecule of ATP is formed during the flow of two electrons [9]). A similar quantum yield is found by direct measurement: 8–10 quanta per molecule of O_2 (Section I.6). According to the Calvin cycle, however, the reduction of CO_2 requires 2 TPNH and 3 ATP [5]. The third molecule of ATP may be formed by the reverse flow of electrons from Z^- to Q (broken arrow in Scheme 8). This requires two further light quanta, so that the formation of 2 TPNH, 3 ATP, and 1 O_2 requires a total of ten light quanta.

5. Stoichiometry of the Primary and Intermediate Products

The extinction coefficients of the pigments *in vitro* and the magnitudes of the absorption changes *in vivo* give concentrations of Chl-a_I [47], Cyt-f, and Cyt-b [56] *in vivo* which are approximately 1000 times smaller than the total chlorophyll concentration. This agrees with the results obtained from oxygen measurements, *i.e.* that only one thousandth of all the chlorophyll molecules present are engaged in photosynthesis (Section I.5). On the other hand, the ratio Chl-a_f:Cyt-f:Cyt-b $\approx$ 1:1:1, as found from the extinction coefficients and absorption changes, agrees with the reaction scheme. On excitation with long flashes (10^{-1} sec, Fig. 16), the concentration of plastoquinone was found to be four times greater than that of Chl-a_I, Cyt-f, and Cyt-b [60] (the total quantity of plastoquinone is actually 40 times greater [90]). This agrees with the fact that extracted plastoquinone returns to its original position when it is recondensed with the system, and is possible only if a large quantity of plastoquinone is located between cycles I and II.

6. Concluding Remarks

The very fast reaction of chlorophyll-a_I [44,45] (see Section III) is not included in Scheme 8. It is perhaps related to the excited states of the Chl-a molecules.

The triplet states of chlorphyll-a_0 and chlorophyll-b_0 [64] (Section III) have so far been detected *in vivo* only after the chloroplast structure had been altered and the photosynthesis deactivated. If these states are involved in photosynthesis, their half-lives must be less than 10^{-5} sec [64].

Ke [91] has confirmed the results discussed in Sections IV, 2 and IV, 4.

Amesz [92] has carried out measurements on *Chlorella* cells and blue algae, and was able to verify the reduction of plastoquinone which we had detected optically in chloroplasts (Section V, 15) [57] and *Chlorella* cells (Section VII, 2) [60].

Chance et al. [93] deduced from kinetic investigation of the cytochrome reaction in bacteria that the primary processes take less than 10^{-5} sec. Thus they cast doubt on the Chl-a_I process in green cells (which according to our results has a half-life of $< 10^{-4}$ sec, but 10^{-2} sec with additional continuous illumination) as a primary process. This conclusion is invalid, however, since the oxidation of cytochrome-f on

[90] *F. I. Crane*, Plant Physiol. *34*, 128, 546 (1959).
[91] *B. Ke*, Biochim. biophysica Acta *90*, 289, 297 (1964).
[92] *I. Amesz*, Biochim. biophysica Acta *79*, 257 (1964).
[93] *B. Chance* and *D. Devault*, Ber. Bunsenges. physikal. Chem. *68*, 722 (1964).

additional continuous illumination (Section XII, 1) was not taken into account.

Duysens [42] obtained a difference spectrum of cytochrome caused by long-wave illumination in red algae. According to our results (Section VII, 1), the oxidation of Cyt-f and that of Chl-a_I occur together under these conditions. The difference spectrum observed by *Duysens* is therefore composed of the absorption changes due to the oxidation of Cyt-f and of Chl-a_I.

Measurements carried out by *Chance* [94], *Rubinstein* [95], *Fork* [96], and *Kok et al.* [70c] led to different views regarding the interpretation of the absorption changes at about 515 mμ. These are partly explained, however, if the results discussed in Section VII, 6 are taken into account.

Scheme 8 represents the present-day knowledge of electron transfer in photosynthesis as analysed by flashlight techniques. It explains the Emerson effect (Section I.8), as well as many phenomena that were not previously understood. It agrees with more recent results obtained by other methods [1–4]. However, it also brings to light a number of new problems (Section XII.3). The Scheme will have to be supplemented and refined by further measurements. It is of particular interest to obtain detailed information on the mechanism of the cleavage of water in reaction cycle II, on the mechanism of phosphorylation and on the structure of the electron transport system described.

Structure Determination of Free Molecules by Electron Diffraction

BY CAND. REAL. A. ALMENNINGEN, PROF. DR. O. BASTIANSEN, DR. A. HAALAND, AND SIV. ING. H. M. SEIP

CHEMISTRY DEPARTMENT, UNIVERSITY OF OSLO (NORWAY)

The intensity of electrons scattered by a gas can be calculated with classical as well as with quantum-mechanical methods. The range of validity of the equations obtained can be found experimentally. Comparison of the calculated and empirical intensity or radial distribution curves allows the determination of the structure and amplitudes of vibration of a molecule. – For example, it has been found that the two bromine atoms in cis-1,3-dibromocyclobutane occupy equatorial positions. The benzene rings in biphenyl derivatives are inclined at about 45° to each other. In biscyclopentadienylberyllium, the metal atom is not located midway between the two rings.

1. Introduction

In a survey article written in 1959 [1] a bright future for the electron diffraction method in the study of gas molecule structures was anticipated. The development during the last five years has shown that this optimism was justified. The established groups are growing, new groups are entering the field, and new and better equipment is being built. On the other hand, experience shows that design and construction of modern electron diffraction apparatuses are more time consuming than usually foreseen, considering the rather simple principles on which the method is based.

The theoretical basis for the method has recently been described in an up-to-date article by *Spiridonov, Rambidi*, and *Alekseev* [2]. We shall therefore confine ourselves to a short review of the theory, including only what is considered necessary for the application of the method. A comprehensive survey of the field will not be attempted; we shall rather outline what we consider to be the main features of the development by a few examples mostly taken from recent work of our own group.

2. Theory

For a rigid molecule the electron diffraction intensity may be approximated by the following classical expression:

$$I_t(s) = \frac{K}{s^4}\left\{\sum_i [(Z_i - F_i)^2 + S_i] + \sum_{i,j}{}' \left[(Z_i - F_i)(Z_j - F_j)\frac{\sin R_{ij}s}{R_{ij}s}\right]\right\} = I_b(s) + I_m(s) \qquad (1)$$

where $s = (4\pi/\lambda)\sin\vartheta$;
λ = wavelength;
ϑ = Bragg angle;
K = a constant at constant electron velocity;
Z_i = atomic number of the ith atom;
F_i = scattering factor of the ith atom;
S_i = incoherent scattering factor of the ith atom;
R_{ij} = distance between the ith and jth atoms.

Only the second term in (1), *i.e.* $I_m(s)$, contains information about the molecular structure, and the discussion will therefore mainly concern this term. Apart from the obviously wrong assumption that the molecule is rigid (this will be discussed later), the expression for $I_m(s)$ given in (1) depends on the validity of the classical treatment of the scattering process. For a better approximation, the problem must be treated quantum mechanically.

In the following, the most important equations will be presented without proof, and the usual approximations will be discussed. Most of the theory can be found in textbooks [3–5] and in the review article [2].

Let the differential scattering cross section be defined by

$$\sigma(\vartheta,\varphi) = (I/I_0)r^2 \tag{2}$$

where I_0 is the electron intensity incident on the scattering center, and $I(\vartheta,\varphi)$ the electron intensity scattered in the directions ϑ, φ at a distance r from the scattering center. The scattering cross section is thus the quantity found by experiment.

The Schrödinger equation for a spherically symmetrical force field V(r) is

$$\left[-\frac{h^2}{8\pi^2 m}\nabla^2 + V(r)\right]\psi(\mathbf{r}) = E\psi(\mathbf{r}) \tag{3}$$

Let the incident wave be along the z-axis. The asymptotic expression ($r\to\infty$) for $\psi(\mathbf{r})$ is

$$\psi(\mathbf{r}) = e^{ikz} + (1/r)e^{ikr}f(\vartheta);\ k^2 = (8\pi^2 m/h^2)E \tag{4}$$

if the potential falls to zero faster than the Coulomb field. From Equation (4) it is seen that the asymptotic wave function is composed of the incident plane wave and a scattered wave; $f(\vartheta)$ is usually referred to as the scattering amplitude. The differential cross section is given by

$$\sigma(\vartheta) = |f(\vartheta)|^2 \tag{5}$$

The solution of (3) may be written

$$\psi(\mathbf{r}) = e^{ikz} - \frac{2\pi m}{h^2}\int \frac{e^{(ik|\mathbf{r}-\mathbf{r}'|)}}{|\mathbf{r}-\mathbf{r}'|}V(r')\psi(\mathbf{r}')d\tau' \tag{6}$$

By letting $r\to\infty$ in Equation (6) and comparing with (4) an expression for $f(\vartheta)$ is obtained.

$$f(\vartheta) = -\frac{2\pi m}{h^2}\int e^{-ik'\cdot r'}V(r')\psi(r')d\tau' \tag{7}$$

k' is a vector of length k in the direction of the scattered wave. An approximate expression for $f(\vartheta)$ may be obtained by neglecting the scattered wave in $\psi(r')$, Eq. (4). This is known as the first Born approximation [6]. Then

$$f(\vartheta)^{Born} = \left(\frac{2\pi m}{h^2}\right)\int e^{-ik'\cdot r'}V(r')\,e^{ikz'}d\tau' \tag{8}$$

and by integration over the angle parameters (ϑ', φ')

$$f(\vartheta)^{Born} = -\frac{8\pi^2 m}{h^2}\int_0^\infty V(r')\frac{\sin(sr')}{sr'}r'^2dr' \tag{9}$$

We now go back to Equation (3) and separate $\psi(\mathbf{r})$ into polar coordinates:

$$\psi(\mathbf{r}) = R_l(r)\cdot Y_l^m(\vartheta,\varphi) = (1/r)u_l(r)Y_l^o(\vartheta) \tag{10}$$

where $Y_l^m(\vartheta,\varphi)$ are the spherical harmonics. For reasons of symmetry ψ is not a function of φ, *i.e.* $m = 0$. The radial equation is then

$$\left[-\frac{d^2}{dr^2} + \frac{8\pi^2 m}{h^2}V(r) + \frac{l(l+1)}{r^2} - k^2\right]u_l(r) = 0 \tag{11}$$

If V(r) may be neglected beyond a certain r value equal to a, the solution of (11) is

$$(1/r)u_l(r) = A_l[\cos\delta_l j_l(kr) - \sin\delta_l n_l(kr)]\ (r > a). \tag{12}$$

$j_l(kr)$ are the spherical Bessel functions, and $n_l(kr)$ are the spherical Neumann functions. By substituting the asymptotic values for $j_l(kr)$ and $n_l(kr)$ in Equation (12) we obtain

$$\frac{u_l(r)}{r} = \frac{A_l}{kr}\sin(kr - l\pi/2 + \delta_l),\ (r\to\infty) \tag{13}$$

The constant introduced above, δ_l, has the physical meaning of a phase shift.

If V(r) falls to zero faster than 1/r, Equation (11) may be written

$$\left[-\frac{d^2}{dr^2} - k^2\right]u_l(r) = 0 \tag{14}$$

when $r\to\infty$.

Expression (13) is obviously the solution of this equation. From (10) it follows that the general solution of (3), having axial symmetry, may be written

$$\psi(\mathbf{r}) = \sum_{l=o}^{\infty} a_l R_l(r)P_l(\cos\vartheta) \tag{15}$$

where P_l are the Legendre polynomials, and a_l is a constant.

By comparing the asymptotic expression $\psi(\mathbf{r})$ according to (15) with (4), A_l and $f(\vartheta)$ may be found. Using an expression of e^{ikz} in terms of Legendre polynomials,

$$e^{ikz} = \sum_{l=o}^{\infty}(2l+1)i^l j_l(kr)P_l(\cos\vartheta), \tag{16}$$

$f(\vartheta)$ is found to be

$$(f\vartheta) = \sum_{l=o}^{\infty}(2l+1)\frac{e^{2i\delta_l}-1}{2ik}P_l(\cos\vartheta) \tag{17}$$

The phase shifts may now be determined by solving (11) for the potential considered and joining the solution smoothly to the expression (12) at r = a. The solution of (11) can always be found by numerical methods. An approximate expression for δ_l valid for $\delta_l \ll 1$ is

$$\delta_l \approx -\frac{8\pi^2 mk}{h^2}\int_0^\infty [j_l(kr')]^2 V(r')r'^2\,dr' \tag{18}$$

[5] *E. Merzbacher*, Quantum Mechanics, Wiley, New York 1961.

[6] *M. Born*, Zeits. f. Physik, *38*, 803 (1926).

It is important to note that $f(\vartheta)$ as given by (17) is complex while $f(\vartheta)^{Born}$ (9) is real.

$f(\vartheta)^{Born}$ may also be obtained by approximating $(e^{2i\delta_l}-1)$ in (17) by $2i\delta_l$. If the potential V(r') calculated from the charge distribution of an atom is introduced into (9), the following expression is obtained.

$$f(\vartheta)^{Born} = (8\pi^2 me^2/h^2)(Z-F(\vartheta))/s^2 \qquad (19)$$

Here $F(\vartheta)$ is the atomic scattering factor introduced in (1). It is interesting to note that (19) is identical with the result of classical treatment.

If the complex function $f(\vartheta)$ is written as

$$f(\vartheta) = |f(\vartheta)|e^{i\eta(\vartheta)}, \qquad (20)$$

the structure-dependent part of the intensity scattered from a rigid molecule is

$$I_m(s) = K \sum_{i,j}' |f_i|\,|f_j| \frac{\sin(sR_{ij})}{sR_{ij}} \cdot \cos[\eta_i(s)-\eta_i(s)] \qquad (21)$$

If $f(\vartheta)^{Born}$ is used, $I^m(s)$ is identical with the second term in (1).

Thus Equation (1) is valid only if the Born approximation is accepted. This approximation is best for fast electrons and light atoms. Usually $f(\vartheta)$ is not too different from $f(\vartheta)^{Born}$; therefore if $|Z_i-Z_j|$ is large, the main difference between the expressions for $I_m(s)$ given by (1) and (21) is caused by the cosine factor.

Obviously, then, a calculation of $f(\vartheta)$ is much more complicated than the calculation of $f(\vartheta)^{Born}$. For many atoms approximate values for $f(\vartheta)$ have been calculated by *Ibers* and *Hoerni* [7] using δ_l from (18) when $\delta_l \ll 1$ and by the use of the W.K.B. method otherwise [4, 5]. In most cases the Thomas-Fermi potential was used.

Recently *Bonham* and *Karle* have calculated f for uranium and fluorine [8], and uranium and argon [9] using different assumptions. The η values obtained were similar to those obtained by *Ibers* and *Hoerni*.

The background term S_i in Equation (1) did not emerge from our quantum mechanical treatment because the atom was treated as a force field. Incoherent scattering has been taken into account in reference [3].

The preceding discussion is based on the assumption that atoms in molecules have spherical symmetry. This might appear to be a poor approximation – particularly in molecules where many of the electrons participate in bond formation. This approximation was first examined by *Massey* [10]. Later *Bonham* and *Iijima* [11–13] calculated the scattering from H_2 using an approximate molecular wave function, and the scattering from H_2^+ from the exact molecular wave function, and compared the results with the intensities calculated from (1). It was found that bonding causes a decrease in the intensity for low scattering angles (for H_2^+ at $s < 5$), but the effect can be largely compensated for by drawing a proper background for low values of s. It is thus probable that the effect of bonding can usually be neglected without serious error.

Let us now return to the question of how the atomic vibrations affect the intensity. If P(r)dr is the probability of an interatomic distance between r and r + dr, it follows from (1) that for a diatomic molecule

$$s^5 I_m(s) = \text{const}(Z_1-F_1)(Z_2-F_2)\int_0^\infty P(r)\frac{\sin(rs)}{r}\,dr \qquad (22)$$

or by a Fourier transformation

$$\frac{P(r)}{r} = \text{const.}\int_0^\infty \frac{s^5 I_m(s)\sin(rs)ds}{(Z_1-F_1)(Z_2-F_2)} = \text{const.}\int_0^\infty I(s)\sin(rs)ds \qquad (23)$$

If the vibrations are assumed to be harmonic, P(r) is a Gauss function. By integration of (22) an approximate expression for the intensity is found. For a polyatomic molecule the result is:

$$I_m(s) = \frac{K}{s^4}\sum_{i,j}' (Z_j-F_i)(Z_i-F_j)\frac{\sin(R_{ij}s)}{R_{ij}s}\exp\left(-\frac{1}{2}u_{ij}^2 s^2\right) \qquad (24)$$

u_{ij} is the root-mean-square deviation from the equilibrium distance. If anharmonic vibrations are considered, one may use the following approximation [14–16]

$$I_m(s) = \frac{K}{s^4}\sum_{i,j}' (Z_i-F_i)(Z_j-F_j)\frac{\sin[s(R_{ij}-s^2\varkappa_{ij})]}{R_{ij}s}\exp\left(-\frac{1}{2}u_{ij}^2 s^2\right) \qquad (25)$$

$\varkappa_{ij}$ is a constant characteristic of the anharmonicity. $\varkappa$ is very small for most bond types and is difficult to determine from electron diffraction data. However, since $\varkappa$ is strongly correlated with R_{ij} it may be worth while to include it in the calculations if it can be estimated from spectroscopic data. Equation (25) shows that anharmonicity causes an increase with s of the wavelength of the intensity function as demonstrated by *Bartell et. al.* in CH_4 [17].

3. Experimental

In accordance with Equation (1) the diffraction pattern of monochromatic electrons scattered from a gas is characterized by diffuse concentric rings superposed on a very steep background which falls off as $1/s^4$. The concentric rings constitute the molecular intensity (Equation (24)) which is the interesting part of the total intensity for determination of a molecular structure. A microphotometer trace of such a diffraction pattern is not suited for deducing the molecular intensity. Most gas

electron-diffraction work done recently is therefore based upon the sector-microphotometer procedure, in which a rotating sector compensates for the rapid decrease of the total intensity with increasing scattering angle. The sector is placed near the photographic plate, with its axis coincidental with the incident beam. In the Oslo apparatus [18] the screening effect of the sector mostly used corresponds to multiplication of the intensity curve with a factor approximately proportional to s^3, except for small diffraction angles where the opening is larger. In spite of the variation of the steep background of an un-sectored pattern from compound to compound because of the factor $(Z_i-F_i)^2$ [Equation (1)], it proves practical and sufficient to use a standard sector of known shape.

The sector correction is based on measurement of the opening of the sector under a microscope. The difference between photometer curves of un-sectored and sectored patterns is most striking. A photometer curve of an un-sectored pattern is almost completely dominated by the rapidly decreasing background intensity, and the diffraction rings are nearly lost. A photometer curve of a sectored diagram, however, exhibits clear maxima and minima.

Special care must be taken in selection of a photographic emulsion, development of the diffraction photographs, and derivation of the blackness correction in order to obtain a quantitative description of the intensity curve. Kodak B 40 plates are used at present. Development is carried out in a thermostat with effective and well controlled mechanical stirring. The blackness correction is redetermined periodically. The photographic plate is oscillated around the center of the pattern during the photometering to reduce noise due to grain size and irregularities in the emulsion.

The concept of a "diffraction point" cannot, of course, be realized experimentally. Any gas jet into vacuum has a density distribution over a certain volume. To obtain the best approximation to the ideal diffraction point and at the same time obtain sufficient gas density, it is necessary to pay particular attention to the gas-nozzle design. The principle is to have the electron beam as close as possible to the nozzle tip without touching the metal. Even the slightest grazing leads to diffraction from the metal that swamps the gas diffraction. In order to maintain a low density of gas in the rest of the camera, an efficient liquid-air trap is placed close to the nozzle.

The distance between the diffraction point and the photographic plate can be varied from a few centimeters up to about 50 cm in the Oslo apparatus. In most cases three standard distances are used. They are approximately 48, 19, and 12 cm covering the s ranges 1.25–21 $Å^{-1}$, 7–45 $Å^{-1}$, and 15–65 $Å^{-1}$, respectively. A series of exposures at each distance is studied, though the 12 cm plates are not always found necessary. It may seem superfluous to work with three different distances and such large overlap ranges. However, experience proves it necessary. Each distance optimizes observation of only a limited s range, and without a large overlap it is difficult to scale the two curves with sufficient accuracy. An error in scaling does not appreciably influence the determination of internuclear distances, but the values of u are sensitive to such errors.

The outer part of the intentity curve is important for resolving almost equal bond distances. On the other hand the contribution of the non-bonded internuclear distances to this part of the curve is damped out by molecular vibrations. The very long internuclear distances which have large amplitudes of vibration contribute only to the inner part of the intensity curve. In order to improve this part, a new camera has just been put into operation which allows exposures at distances up to 2 m between the diffraction point and photographic plate. This camera makes possible intensity studies down to 0.3 $Å^{-1}$ and should lead to a more accurate knowledge of the important s range from 1–5 $Å^{-1}$.

A time-consuming part of an electron-diffraction study is the reading of the photometer curves. Equipment for obtaining the photometer results directly on tape or punched cards is therefore being built in several laboratories.

The most hopeful prospect for the future is the adoption of counting techniques for recording scattered intensities. This would eliminate the cumbersome and inaccurate steps of photographic recording, photometering, and reading of the photometer traces. The rotating sector could be eliminated. The output of the counter would further lend itself to a mechanization of the entire calculation. Also, by counting for a sufficiently long time it may be possible to determine the molecular intensity for all scattering angles. When photographic recording is used, the molecular intensity is most often lost in the background beyond s = 60 $Å^{-1}$.

4. Calculation Methods

A molecular structure can be determined by comparing the observed molecular intensity, I_m, or its Fourier transforms with the curves calculated for various assumed structures.

A radial distribution (RD) curve may be defined by

$$\sigma(r)/r = \int_0^\infty s^5\varphi(s)I_m(s)\sin(rs)ds \qquad (26)$$

The nature of the RD curve obviously depends on the choice of the moderating function [1] $\varphi(s)$. If for a diatomic molecule

$$\varphi(s) = 1/[(1-F_1/Z_1)(1-F_2/Z_2)] \qquad (27)$$

it follows from (23) that

$$\sigma(r)/r \propto P(r)/r \qquad (28)$$

where P(r) is the radial probability function.

In the case of a polyatomic molecule the peak in the RD curve corresponding to a certain internuclear distance, R_{ij}, can be obtained in this form (28) through the choice of a proper $\varphi(s)$.

Usually one selects:

$$\varphi(s) = \frac{\exp(-ks^2)}{(1-F_m/Z_m)(1-F_n/Z_n)} \qquad (29)$$

and introduces the approximate expression (24) for I_m. Then

$$\sigma(r)/r = \int_0^\infty s^5 I_m(s)\varphi(s)\sin(rs)ds = \int_0^\infty I(s)e^{-ks^2}\cdot\sin(rs)ds \qquad (30)$$

where

$$I(s) = \text{const.}\sum \frac{n_{ij}Z_iZ_j}{R_{ij}}\frac{(1-F_i/Z_i)(1-F_j/Z_j)}{(1-F_m/Z_m)(1-F_n/Z_n)}\exp\left(-\frac{1}{2}u_{ij}^2s^2\right)\sin(R_{ij}s) \qquad (31)$$

[18] *O. Bastiansen, O. Hassel,* and *F. Risberg*, Acta Chem. Scand. 9, 232 (1955).

The sum is taken over all different distances in the molecule; n_{ij} is the number of times equivalent distances occur. It is convenient to define a set of normal curves $N_{ij}(\rho)$ by

$$\frac{\sigma(r)}{r} = \sum \frac{n_{ij} Z_i Z_j}{R_{ij}} \cdot N_{ij}(R-r) \tag{32}$$

From (30) and (31)

$$N_{ij}(\rho) = \text{const.} \int_0^\infty \frac{(1-F_i/Z_i)(1-F_j/Z_j)}{(1-F_m/Z_m)(1-F_n/Z_n)} e^{-s^2(k + u_{ij}^2/2)} \cos(\rho s) ds \tag{33}$$

If m and n denote the same kind of atoms as i and j, $N_{ij}(\rho)$ may be integrated analytically, yielding a Gaussian peak. Since the scattering factors usually have approximately the same form, *i. e.*

$$\frac{(1-F_i/Z_i)(1-F_j/Z_j)}{(1-F_m/Z_m)(1-F_n/Z_n)} \approx 1 \tag{34}$$

it follows that the shape of the other peaks will be nearly Gaussian. If not, the curve can be found through numerical integration of (33).

The same technique may be applied if complex scattering factors are used. This will introduce the factor

$$\cos[\eta_i(s) - \eta_j(s)] = \cos[\Delta\eta_{ij}(s)]$$

in the integrand.

Alternatively one can express the factor containing the F values as a series

$$c + \sum_n a_n e^{-b_n s^2} \tag{35}$$

where c, a_n and b_n are constants.

The normal curve will then be a sum of Gauss curves. Similarly, when complex scattering factors are used, an analytical expression for the normal curve may be obtained by introducing

$$\Delta\eta_{ij}(s) \approx a + bs + cs^2 \tag{36}$$

where a, b and c are constants [19]. The effect of complex scattering factors is discussed in Section 6.

It follows from (28) that when $k = 0$, $\sigma(r)$, like $P(r)$, is symmetric in the case of harmonic vibrations. However, a normal curve in $\sigma(r)/r$ is symmetric according to Equation (33). This apparent contradiction is due to the use of the approximate expression for I_m in the derivation of (33). The distance determined from the maximum of the peak in the $\sigma(r)/r$ curve is usually called $r_m(1)$ [14]. The center of gravity of the peak is called $r_g(1)$, while the corresponding parameter in the $\sigma(r)$-curve is r_g or $r_g(0)$.

It may be shown that

$$r_g \approx r_g(1) + u_g^2/r_e \tag{37}$$

where r_e is the real equilibrium distance. The difference between r_g and $r_g(1)$ may be 0.001–0.002 Å for a C–C bond, but more than 0.005 Å for a C–H bond. It is not easy to find an exact relation between r_g and r_e, though for simple molecules good approximations may be obtained [16,20–22].

The experimental RD curve according to (30) requires intensity data from $s = 0$ to $s \to \infty$. Because of experimental limitations, data are known only for a finite s range. The effect of the upper limit in the integration may be suppressed by the artificial damping factor e^{-ks^2}. The lower integration limit will change the zero line in the RD curve. Alternatively one may use theoretical data for the inner part of the intensity curve.

When the first RD curve is obtained, a rough model is deduced. Theoretical intensity curves and RD curves are calculated in order to refine the background and the zero line in the RD curve (*viz.* the inner peak of the experimental intensity curve). One may carry out a complete structure determination by continuing a trial and error procedure with the RD curves. However, one may often achieve the final results easier by a least-squares refinement of the intensity data [23–25].

On a modern computer the calculations are performed very quickly. There are, however, some problems to be discussed. The question of how to weight the data, for example, is of great importance. At present it is common to transfer the photometer curves to tracing paper. At the same time, small irregularities are more or less smoothed out. By this procedure the intensity curve may be slightly too high or too low over a considerable s interval, whereas random errors are small. We may say that the smoothing out procedure increases the correlation between the data.

As a result, the proper weight matrix should perhaps not be assumed diagonal, as is usually done. Even then it is difficult to establish the proper form. By treating many plates independently one may find an experimental weighting function, but the amount of work required is then greatly increased. General experience suggests that the weight function should at least be a function of s, perhaps of the type suggested in Fig. 1. Functions of this type are often

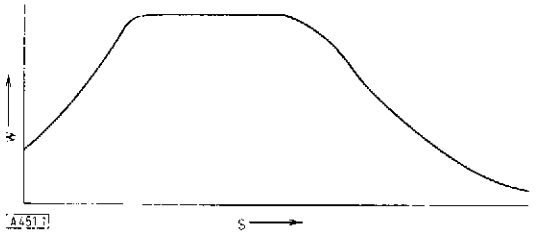

Fig. 1. Example of weight function used in least-squares calculation on intensity data.

used, but the weight should probably be a function of the slope of the photometer curve as well. The smoothing procedure mentioned above will increase the accuracy of the parameter determination by removing coarse errors and random errors to a certain extent, but reduces the estimates of standard deviations unrealistically. This agrees with general experience that standard deviations obtained through

least-squares refinement are smaller than a realistic estimate would suggest. It is possible to treat the data from each plate separately to improve error estimation.

For moderately complicated molecules the least-squares refinement yields the best estimate of the parameters without much work. For more complex molecules one may often refine some of the parameters by this method.

The method works well even when approximation (34) does not hold, and when phase shift cannot be ignored. Of course the results may also be obtained by comparing experimental and theoretical RD curves. However, the u values cannot be found directly from the experimental RD curve for non-Gaussian peaks. If the normal curves are found by numerical integration, the calculation must be carried out for a series of u values, and the correct value is determined by comparing the experimental and theoretical curves.

The examples given in Section 5 show that the interpretation of RD curves is complicated when there are many very similar distances. A peak composed of two slightly separated Gaussian peaks is itself very nearly Gaussian. This fact may be seen from Equation (42) which shows that the intensity contribution from two slightly different distances is a damped sine curve corresponding to the average distance, times a cosine factor. For small values of the argument, the form of the cosine term is very similar to that of an exponential function. Of course, for larger values of the argument the cosine function is very different from an exponential curve. For example, if $r_2 - r_1 = 0.1$ Å, the cosine term vanishes at $s = \pi/(r_2 - r_1) = 31.4$ Å^{-1}. The cosine term will thus in a certain region have nearly the same effect as an additional damping, and this region will be larger the smaller the difference between the distances. A whole series of r and u values may therefore give a good fit between the theoretical and experimental RD peak if the difference in the distances is increased while the two u values are decreased correspondingly. Therefore the outer part of the intensity curve is of great importance for the determination of overlapping distances. It is thus reasonable in such a case to calculate an undamped RD curve or even multiply the intensity data with an antidamping function (*e.g.* $\exp[-\alpha\,(s_{max} - s)]$, where α is a constant). A similar effect is obtained by the auto-correlation and crosscorrelation methods [26].

The convolution of the functions f(t) and g(t) is defined by

$$\varphi(\tau) = \int_{-\infty}^{+\infty} f(t) \cdot g(t-\tau)\,dt\,. \qquad (38)$$

If g is equal to f, $\varphi(\tau)$ is called the auto-correlation coefficient of the function. Otherwise $\varphi(\tau)$ is called the cross-correlation coefficient of the two functions f and g. Since the molecular intensity curve is composed of sine functions, it is clear that the auto-correlation function must have maxima for $\tau = \frac{2\pi n}{R_{ij}}$ (n an integer). By taking the cosine Fourier transform of the auto-correlation function, a power spectrum is obtained with peaks corresponding to the interatomic distances.

To calculate the cross-correlation function it is reasonable to let g be a damped or undamped sine curve. Since experimental intensity data can only be obtained over a finite range, Equation(38) cannot be used without modification for structure determination. However, a short interval function may be defined by

$$\varphi(\tau) = 2\alpha \int_{t_{min}}^{t_{max}} f(t) \cdot g(t-\tau) e^{-2\alpha(t_{max}-t)}\,dt \qquad (39)$$

Here t_{max} and t_{min} are the extremal values of the variable for which experimental data exist. α is a constant chosen such that

$$e^{-2\alpha(t_{max}-t_{min})} \ll 1\,. \qquad (40)$$

The corresponding short interval power spectrum is defined by

$$G(\omega) = 2 \int_{0}^{\infty} e^{-\alpha\tau} \varphi(\tau) \cos(\omega\tau)\,d\tau\,. \qquad (41)$$

The power spectra calculated by these methods give a better resolution of the peaks than the usual RD curve [26] because the intensity data for large s values are given greater weight in a power spectrum calculation than in a sine Fourier transformation of the intensity data. Since the relative errors in I(s) are greater at high than at intermediate s values (see Fig. 1), a compromise must be made between low resolution and high noise level.

5. Application to Structure Problems

The classical electron-diffraction studies of gases and vapors were nearly exclusively concentrated on the determination of the spatial structure of the molecules. During the 35 year history of the method, the accuracy of the determination of internuclear distances has steadily improved. While the method in its early development was rather crude, it has in recent years developed into a precise method, competing faforably with other structure methods. Another characteristic feature of the development of the method is its increased use for studying intramolecular motions. For simple molecules the intramolecular motion is successfully approximated by harmonic oscillations. Using this approximation the root-mean-square amplitudes (u values) are easily obtainable from electron-diffraction studies and in general agree well with those calculated from vibration spectra. In this approximation the peaks of the radial distribution curve, at least for the bond distances, should be very nearly Gaussian in shape if a proper modification function $\varphi(s)$ has been applied. However, close examination of the peaks often reveals a slight deviation from symmetry. For short distances, particularly for the bond distances, the peaks are slightly steeper on the short distance side, while the opposite is often observed for the longer, non-bonded, internuclear distances. This lack of symmetry of the bond distance peaks is associated with vibrational anharmonicity. Though the effect is small and its quantitative interpretation difficult, anharmonicity studies may well be listed among hopeful

[26] *M. Traetteberg* and *R. A. Bonham*, J. chem. Phys. *42*, 587 (1965).

prospects for the future. The asymmetry of the long distance peaks is often associated with more complex intramolecular motion. For example, the so called "shrinkage effect" [27–29], as well as restricted intramolecular torsional oscillations, lead to such asymmetry.

In Figure 2 the upper curve is the experimental RD curve for *cis*-1,3-dibromocyclobutane [30]. There are

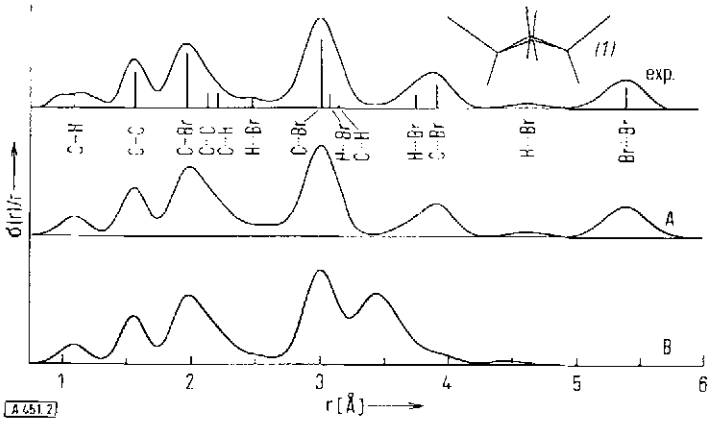

Fig. 2. Experimental and theoretical radial distribution curves for *cis*-1,3-dibromocyclobutane (k = 0.0036). Curve A: e,e conformation, curve B: a,a conformation.

eight individual peaks, each corresponding to easily identified internuclear distances as indicated on the figure. The contribution of each distance to the area under the peak is approximately proportional to the product of the atomic numbers of the two atoms involved and inversely proportional to their separation. In this case the number of internuclear distances that can be obtained directly from the RD curve is large enough for the determination of all the geometric structural parameters of the molecule. Both the bond distances and the longer distances determining the valence angles can be read directly from the curve. The conformation problem connected to the previously discovered deviation from planarity of the carbon skeleton [31,32] is also easily settled. The deviation from planarity makes the two C–X bonds from each carbon atom geometrically different like those in cyclohexanes. In the present molecule *(1)* the bromine atoms prefer the "equatorial" positions rather than the "axial" positions. This is readily seen by comparing the experimental RD curve with the corresponding theoretical ones also given in Figure 2.

The *cis*-1,3-dibromocyclobutane molecule has only one rather rigid conformation and the study of the RD curve leads to a quick and accurate solution for the geometry of the molecule as well as for the u values. Such a molecule is well suited for a least-squares refinement based on the intensity data. In other cases these straightforward procedures fail. An illustrative example is cyclooctane [33]. Bond lengths and valence angles can be readily obtained from the RD curve and can be refined by least-squares calculation. But for the investigation of conformation problems, a tedious study of the RD curve cannot be avoided. Since the inner part of the RD curve only contributes to the determination of bond distances and valence angles, the outer region from r approximately 2,9 Å has to be studied. In Figure 3 the upper curve is the experimental RD curve. Curves A to E are theoretical curves. Since the inner part is identical for all the theoretical curves, it is shown only once. The curves A to D represent examples of "rigid" conformations, *i.e.* conformation models for which the intramolecular motion is restricted to vibrations with small amplitudes. None of these theoretical curves agrees satisfactorily with the experimental curve. A systematic study of a large number of conformations seems to exclude any single "rigid" conformation. Further it can be shown that it is impossible to obtain satisfactory agreement between experimental and theoretical RD curves by combining a small number of different "rigid" conformations. The only solution that seems acceptable is a combination of a whole series of conformations based on a continuous variation of twist parameters. A

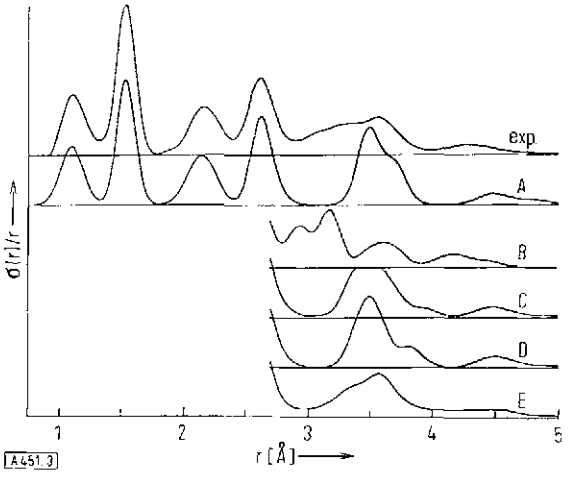

Fig. 3. Experimental and theoretical radial distribution curves for cyclooctane (k = 0.0015). Curves A to D are examples of various "rigid" conformations. Curve E corresponds to a non-rigid conformation.

theoretical RD curve based on such a non-rigid model is presented in curve E. This result does not exclude the existence of a single equilibrium conformation. It only shows that at the temperature of our experiment (40 °C) a large number of conformations occurs with approximately the same probability. These findings may also be described as restricted torsional oscillations of large amplitude.

There are many examples of intramolecular motion of the same degree of complexity as that observed in cyclooctane. In such cases it is necessary to assume that the

intramolecular motion can be separated into a torsional oscillation and the vibration of a hypothetical molecule without torsional oscillation. This latter vibration is often referred to as the framework vibration. An example of considerable interest is the intramolecular motion of biphenyl and its derivatives. Biphenyls are nonplanar in the vapor phase with an angle of approximately 45° between the two ring planes [34–37]. The earlier electron-diffraction studies gave strong indications of a rather large torsional amplitude without giving quantitative information about the amplitude. A recent approach appears encouraging [38]. It is based on the study of the largest Br–Br distance of 3,3′-dibromobiphenyl and 3,5,3′,5′-tetrabromobiphenyl. This distance exhibits a well defined isolated peak on the RD curve near r = 9.2 Å. The peak is asymmetrical, being considerably steeper on the outer side. In order to estimate the framework vibration a similar molecule with a large Br–Br distance unaffected by torsion was studied. The natural choice was 3,5,4′-tribromobiphenyl, a molecule having a long Br–Br distance (3,4′) at r = 9.65 Å. The corresponding peak is less asymmetrical and not as broad as the long Br Br distance peak of the two other biphenyl derivatives. By comparing the u values of the long Br–Br distances, an estimate of the root-mean-square amplitude of the torsion angle is obtained. A preliminary calculation leads to a value of approximately 20°. This result depends on the assumption that the framework vibrational amplitude for the 3–3′ Br–Br distance is the same as the vibrational amplitude of the 3,4′ Br–Br distance in the reference substance. Further the magnitude of the amplitude of the torsional oscillation is very sensitive to errors in the u value determination.

In cases with two or three simultaneously existing conformations, each being rather rigid, the conformation problems are less complex. Classical examples of this are found among derivatives of cyclohexane. Thus *trans*-1,2-dibromo-, *trans*-1,4-dibromo-, and *trans*-1,4-dichlorocyclohexane [39, 40] exhibit two easily recognizable conformations. Other examples are the 1,2-dihaloethanes [41]. These molecules allow *trans* and *gauche* conformations. For 1,2-dichloroethane and 1,2-dibromoethane (Fig. 4) the *trans* form prevails, in agreement with earlier electron-diffraction results [42, 43] and with spectroscopic studies [44, 45]. In the bromo-compound the contribution of the *trans* conformation is 89 % (±5 %) at 20 °C. For the chloro compound the corresponding value is 73 % (±7 %) at 20 °C, a value in agreement with that found by *Ainsworth* and *Karle* [43].

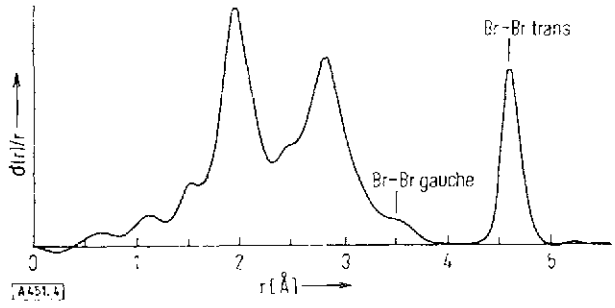

Fig. 4. Experimental radial distribution curve for 1,2-dibromoethane (k = 0.0036).

The difference in energy between the two conformations agrees reasonably with spectroscopic values for both these compounds. (The electron-diffraction values are 1630 cal/mole and 890 cal/mole for the bromo and chloro compounds, respectively; the corresponding spectroscopic values are 1700 cal/mole and 1140 cal/mole).

In 1,2-difluoroethane, however, the *gauche* conformation appears predominant. This is easily demonstrated on the experimental RD curve (Fig. 5) where both the

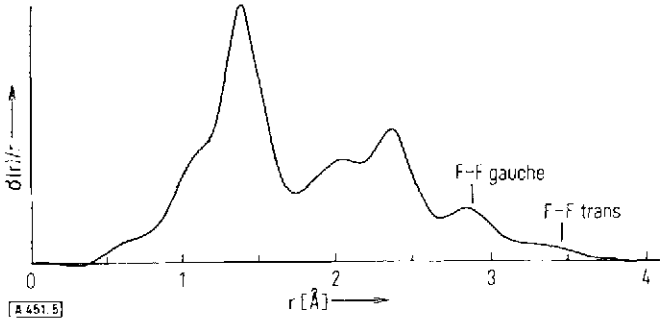

Fig. 5. Experimental radial distribution curve for 1,2-difluoroethane (k = 0.0036).

gauche and *trans* F–F distances are indicated. According to the electron-diffraction results, the fraction of the *gauche* conformation is even greater than the 67 % corresponding to energy equality of the two conformations. Spectroscopic studies by *Klaeboe* and *Rud Nielsen* [46] agree qualitatively with this result. However, they find zero energy difference, while an energy difference in the range 590–1420 cal/mole in favour of the *gauche* conformation is found by this electron diffraction study.

The structures of two sandwich compounds $(C_5H_5)_2Be$ [47] and $(C_6H_6)_2Cr$ [48], have recently been determined by electron diffraction. Careful analysis of the experimental RD curve of $(C_5H_5)_2Be$, shown in Fig. 6 A,

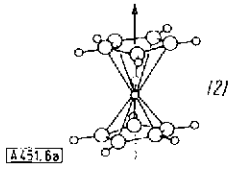
yields the molecular structure *(2)*: The C_5H_5 ligands are planar and symmetrical with a C–C bond distance of 1.424 Å. The rings are parallel and staggered, and



except for the central atom, the molecular symmetry is as in ferrocene, D_{5d}. The beryllium atom may occupy *two* alternative positions on the fivefold axis, 1.48 Å from one ring and 1.98 Å from the other. The molecular symmetry is then C_{5v}. This surprising geometry explains two apparently contradictory observations: the large dipole moment, $\mu = 2.24 \pm 0.09$ D in cyclohexane solution [49], and the fact that the molecule occupies a centrosymmetric site in the crystal [50]. The peak at 1.1 Å in the RD curve corresponds to the C–H bond distance, the peak at 1.4 to the C–C bond distance, and the peak at 2.4 Å to the $C_1 \cdot\cdot H_2$ and $C_1 \cdot\cdot C_3$ nonbonded distances. The complex of unresolved peaks at $r > 3.0$ Å corresponds mainly to distances between atoms in different rings. The partly resolved peak at 1.9 Å must correspond to a Be–C distance; the area under it indicates that there are five such distances. An equally strong peak, corresponding to the five longest Be–C distances, is found at 2.3 Å after subtraction of the stronger $C_1 \cdot\cdot C_3$ and $C_1 \cdot\cdot H_2$ peaks. The difference curve containing only Be–C distances is given in the figure (dashed line). A theoretical RD curve calculated from the parameters of Table 1 is shown in Fig. 6B. An investigation of $(C_5H_5)_2Pb$ has been started. This molecule also has a sizable dipole moment, 1.29 ± 0.04 D in cyclohexane [51]. But the structure is rather different from that of beryllocene, in which the dipole moment arises because the tiny beryllium ion is free to move in the cavity formed between the rings. The large lead ion pushes the ligands apart, and the dipole moment is due to a non-parallel position of the rings. A preliminary RD curve indicates a closest approach of carbon atoms in different rings corresponding to an angle of 140° between the two fivefold axes, but it is not yet clear whether this is an equilibrium position.

Table 1. The molecular structure of $(C_5H_5)_2Be$ (symmetry C_{5v}) and $(C_6H_6)_2Cr$ (symmetry D_{6h}) with estimated errors.

	$(C_5H_5)_2Be$		$(C_6H_6)_2Cr$	
	r_g [Å]	u [Å]	r_g [Å]	u [Å]

(C_1-C_2)	1.425 ± 0.005	0.045	1.424 ± 0.005	0.045
(C–M)	1.918 ± 0.010	0.080	2.152 ± 0.005	0.070
(C'–M)	2.323 ± 0.015	0.080		

Two X-ray studies of the molecular structure of dibenzene chromium, $(C_6H_6)_2Cr$, have been reported. According to one of them the benzene ligands have threefold symmetry with bonds of 1.35 Å alternating with bonds of 1.44 Å, both ±0.014 Å [52]. In the other study no significant deviations from sixfold symmetry were found [53]. The experimental RD curve is very similar to that of $(C_5H_5)_2Be$, the main difference being a strong C–Cr peak at 2.15 Å. A peak at 1.09 corresponds to the C–H bond distance, and a peak at 1.42 Å corresponds to the C–C bond distance or distances, the halfwidth of the peak being determined by the bond-length difference – if any – and the root-mean-square amplitude of vibration.

As pointed out above, the sum of two closely-spaced Gaussian peaks is itself very nearly Gaussian, and a satisfactory fit can be obtained for a rather large range of bond-length differences if the u values are decreased as the difference increases. It is therefore necessary to obtain an independent estimate of u. A comparison of the C–C stretching frequencies of the two compounds shows that the u values of the C–C bond in $(C_6H_6)_2Cr$ must be equal to the corresponding u values in benzene, u = 0.045 Å [54] or slightly larger. The experimental RD curve then offers no evidence for the existence of two different C–C bond lengths: The halfwidth and shape of the peak could be accurately reproduced by assuming 12 identical C–C bonds with u = 0.045 Å. If one regards u = 0.043 Å as the lowest acceptable u value, an upper limit, $\Delta r = 0.02$ Å, on the bond-length difference is obtained.

6. Failure of the First Born Approximation

In Section 2 an expression is given for the molecular intensity when the first Born approximation does not hold [Equation (21)]. It was also shown that, except for small $|Z_i - Z_j|$ values, the main difference between the simple intensity formula (1) and Equation (21) is the factor $\cos(\Delta\eta_{ij}(s))$ [55, 56]. Since η_i is a monotonic increasing function of the atomic number Z_i, the choice of intensity expression is primarily determined by $|Z_i - Z_j|$. The complex scattering factors now available [7–9] suggest that when $|Z_i - Z_j| > 10$ the cosine term is important and should be included. For high atomic

numbers the simple intensity expression may be used for somewhat greater values of $|Z_i - Z_j|$.

A normal curve (Section 4) calculated from an intensity curve containing the factor $\cos(\Delta\eta_{ij}(s))$ will be broader than a Gaussian peak with the same u value, but the form of the peak will be nearly Gaussian for moderate differences $|Z_i - Z_j|$. In such cases the Gaussian peak approximation may be used, but in order to obtain the u value, corrections have to be made. For greater differences in the atomic numbers the normal curve has two separate peaks. This fact may easily be understood by considering the molecular intensity calculated by the simple formula (31) for two nearly equal distances R_1 and R_2. The distances are assumed to have the same u value and the same value of the factor $n_{ij}Z_iZ_j$. Then from Equation (31)

$$I(s) - \text{const} \cdot \left(\frac{1}{R_1}\sin R_1 s + \frac{1}{R_2}\sin R_2 s\right) \exp(-1/2 u^2 s^2)$$
$$\approx \text{const} \cdot \frac{2}{R'} \cdot \sin(R's) \cdot \cos\left(\frac{\Delta}{2} \cdot s\right) \exp(-1/2 u^2 s^2) \quad (42)$$

where

$$R' = (R_1 + R_2)/2, \quad \Delta = R_1 - R_2.$$

In Equation (36), $\Delta\eta_{ij}(s)$ was assumed to be a polynomial of second degree. Curve A in Fig. 9 shows $\Delta\eta(s)$ for Os and O, as calculated by *Ibers* and *Hoerni* [7]. This curve suggests that one may use

$$\Delta\eta_{ij}(s) = b \cdot s \quad (43)$$

as a rough approximation.

It follows from (21) and (42) that the molecular intensity for one distance where the phase shift is included may be approximated by the molecular intensity for two distances calculated by the simple formula if $\Delta = 2b$. The experimental and theoretical molecular intensity curves for OsO_4 are shown in Fig. 7. The theoretica

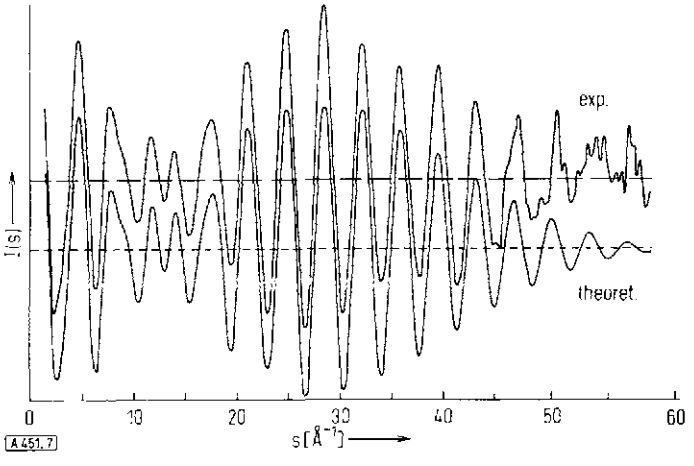

Fig. 7. Experimental and theoretical intensity curve for OsO_4.

curve was calculated using $|f(s)|$ and $\eta(s)$ values for Os and $\eta(s)$ values for O calculated by *Ibers* and *Hoerni* [7], while the assumption $|f(s)| \approx f(s)^{Born}$ was used for O [57]. Near $s = 13$ Å^{-1}, corresponding to $\Delta\eta(s) \approx \pi/2$, the intensities are very low. Fig. 7 shows that the experimental intensity data extend nearly to the point where $\Delta\eta(s) = 3\pi/2$. However, it is not possible to observe the intensity for sufficiently high values of s to see maxima beyond this point.

The theoretical intensity curve in Fig. 7 was calculated using parameters found by a least-squares refinement of the intensity data:

Os–O: $R = 1.7105$ Å ($\pm$ 0.0005); $u = 0.0339$ Å ($\pm$ 0.0007);
O–O: $R = 2.793$ Å; $u = 0.076$ Å ($\pm$ 0.0067).

The standard deviations obtained are given in parentheses; as mentioned in Section 4, they are too small. The weighting scheme used was of the form shown in Fig. 1. The parameters, in particular the distances, were not sensitive to a change in the weighting of the data.

Fig. 8 shows the experimental and theoretical RD curves for OsO_4. The theoretical curve was calculated with the

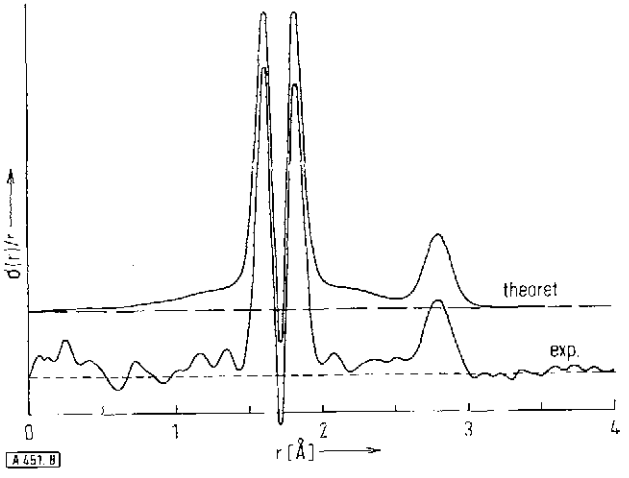

Fig. 8. Experimental and theoretical radial distribution curves for OsO_4 (k = 0.0009).

parameters obtained from the least-squares refinement, and the $|f|$ and η values were the same as used in the calculation of the theoretical intensity curve. In this case, where $Z_{Os} - Z_O = 68$, the RD curve shows two clearly separated peaks corresponding to the Os–O bond. It may be mentioned that the experimental RD curve for MoF_6 also shows a split peak corresponding to the Mo–F bond, though the separation of the maxima is smaller than observed for the Os–O bond, as expected from the smaller difference in atomic numbers ($Z_{Mo} - Z_F = 33$).

The mean amplitudes of vibration in OsO_4 have been calculated from spectroscopic data [58] to be $u_{OsO} = 0.0348$ Å and $u_{OO} = 0.070$ Å. The u values obtained in this way are fairly accurate. The distance parameters are not sensitive to small variations in the values of $|f|$ and η. All the molecular parameters are therefore known to a high degree of accuracy. It is thus possible to obtain experimental $\eta(s)$ values if the $|f(s)|$ functions are considered known. Various $|f|$ functions were assumed, and the constants in the expression (36) for the Os–O bond were obtained by a least-squares refinement of the intensity data. Fig. 9 shows the η function calculated by *Ibers* and *Hoerni* (curve A) and two experimental curves. B is found by using $|f|$ values from *Ibers* and *Hoerni* and C by assuming the same form for the $|f|$ functions for Os and O.

[57] *J. Berghuis, I. M. Haanappel, M. Potters, B. O. Loopstra, C. H. MacGillavry,* and *A. L. Veenendaal,* Acta Cryst. *8*, 478 (1955).

[58] *S. J. Cyvin, J. Brunvoll, B. N. Cyvin,* and *E. Meisingseth,* Bull. Soc. Chim. Belg., *73*, 5 (1964).

The latter approximation corresponds to (34). The result is insensitive to changes in the weighting of the intensity data. It is seen that curve B is very close to the calculated curve (A) except at very low and high s values. The standard deviation is rather high for the parameter c, which greatly influences the outer part of the curve. This investigation indicates that reliable structure determinations may be made

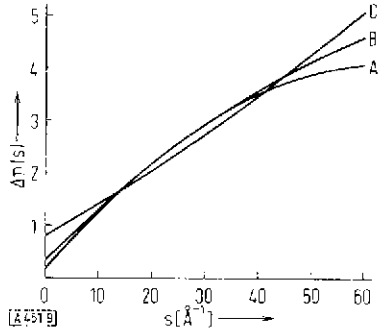

Fig. 9. $\Delta\eta(s)$ Functions for the osmium-oxygen distance.

Curve B: Experimental, based on $|f|$ values from [7].
Curve C: Experimental, assuming $|f_{Os}| \propto |f_O|$.

using $|f|$ and η data from *Ibers* and *Hoerni*. Other molecules (methyl iodide, tetramethyltin, diiodoacetylene, MoF_6, UF_6, WF_6, and TeF_6) are now being studied in a similar way to investigate further the reliability of the calculated scattering amplitudes and how errors in the $|f|$ and η data used influence the determination of structural parameters.

7. Error Estimates

In the following we will first consider experimental errors that lead to a proportionality error in the s scale and in turn to an equally great relative error in the measured distances and amplitude parameters. Errors in 1) the electron wavelength, 2) the adjustment of the accelerating potential, 3) the distance from the diffraction point to the plate, and in 4) the determination of the relative speeds of the photometer chart and plate stage all have this effect.

The wavelength of the electron beam can, of course, be calculated from the accelerating potential by means of the de Broglie relation. But sufficiently accurate measurement of potentials of this order of magnitude is difficult. In this laboratory the wave-length has till now been determined from the scattering pattern of a solid standard. The potential is then reproduced from day to day by means of an accurate potentiometer circuit. Several standards have been tried, but the most reproducible results were obtained from etched gold foil using a beam stop and a rotating sector with opening proportional to s. Eight values of the wavelength are computed and averaged. Each wavelength is calculated from the diameter of one diffraction ring measured on five plates. The difference between these values is insignificant. But the average wavelengths determined in this way over a long period of time have a standard deviation of 0.1 % from their mean. Since they appear to change smoothly with time, the last observed value rather than an average is used for the calculation of s scales. A new wavelength is determined every month. Assuming the variation to be random, we obtain an upper limit, 0.10 %, on the standard deviation of the wavelength from day to day. If it is further assumed that an equally great error is introduced when the diffraction pattern from the gas to be investigated is recorded, the standard deviation for the s scale on the photographic plate is $0.1 \cdot \sqrt{2}$ %. Since the variation of the relative speeds of the photometer chart and plate stage is insignificant, the standard deviation for the final s scale is less than 0.14 %.

The errors mentioned above strongly influence the distance parameters. Other errors influence mainly the u values, but the distance parameters will be affected if the correlation between r and u values is great. This is the case for strongly overlapping distances. Errors in the photographic blackness correction and in the opening of the sector as a function of s introduce errors in each photometer curve, and, more important, make the scaling of curves covering different s intervals uncertain. An error in the determination of the center of a plate will influence the result in a somewhat similar manner.

Large errors in the background are easily detected by comparing the experimental and theoretical intensity and RD curves. Small changes in the background will generally not influence the distance determination very much, but the u values are more sensitive to such changes. Finally, the uncertainties in the form factors should also be mentioned. Particularly for heavier atoms they are not known with the desired accuracy.

How these errors affect the result when different calculation methods are used is still rather uncertain. It was mentioned in Section 4 that the standard deviations obtained through a least-squares procedure are unrealistically small. This is at least partly due to correlation between the observed intensities. Proportionality errors in the s scale are of course not included. It seems likely that for a well separated distance the predominant source of error in r is the s scale. The standard deviation for such a distance is certainly less than 0.14 %. For the determination of u, scale errors are probably negligible compared to the other errors listed above. The magnitude and effect of these errors are hard to estimate but we believe that the u value at least for a non-overlapping C—C bond distance can be determined with an error of a few per cent. For overlapping distances the r and u are correlated, and the error limits must be considerably expanded.

New Methods in Preparative Organic Chemistry IV [*]

New Reactions of Alkylidenephosphoranes and their Preparative Uses III [**]

Alkylidenephosphoranes and Reagents Containing Multiple Bonds

BY PROF. DR. H. J. BESTMANN

INSTITUT FÜR ORGANISCHE CHEMIE DER UNIVERSITÄT ERLANGEN-NÜRNBERG (GERMANY)

A few examples of preparatively useful syntheses using alkylidenephosphoranes and substances containing a C–N or C–C double bond are the preparations of olefins, allenes, pyran derivatives, and cyclopropane derivatives. Olefins, ketones, and monocyclic compounds can be obtained by autoxidation of alkylidenephosphoranes; α,β-dioxo compounds (including cyclicones) can be prepared by oxidation with peroxy-acids. Alkylidenephosphoranes can also be used for the synthesis of azines and Schiff bases. Of the many possibilities offered by the Wittig reaction, only the preparation of tritiated aldehydes and olefins will be considered.

A. Reaction with the Carbonyl Group (The Wittig Reaction)

The renaissance of the chemistry of alkylidenephosphoranes (the first representative was prepared as early as 1919 [1]) began with *Wittig*'s discovery [2a–2c] that the

[*] The contributions in the previous three series have been published collectively in three volumes by Verlag Chemie, Weinheim/Bergstr. (Germany); English edition: Academic Press, New York-London.

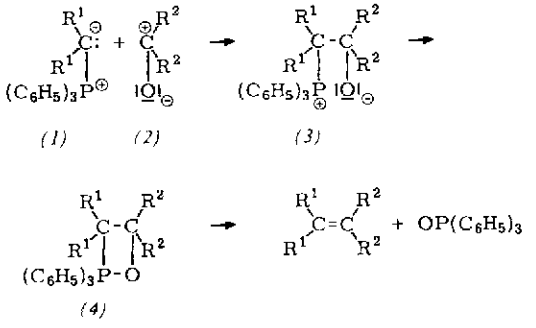
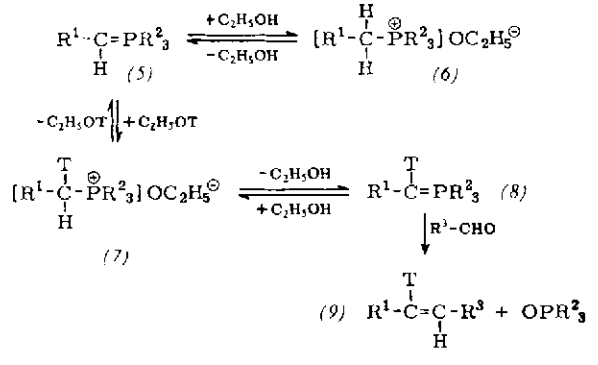
[1] *H. Staudinger* and *J. Meyer*, Helv. chim. Acta *2*, 635 (1919).

polarized C–P double bond of the ylides *(1)* can react with the polarized C–O double bond of carbonyl compounds *(2)*. The product of this reaction is a betaine *(3)*, which decomposes *via* the four-membered ring compound *(4)* into an olefin and triphenylphosphine oxide.



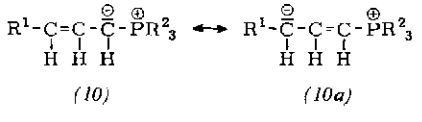
Of the many possibilities offered by the Wittig reaction, we shall discuss only the preparation of olefins labelled with tritium or deuterium [3].

Alkylidenephosphoranes *(5)* and ethanol undergo an equilibrium reaction with formation of the phosphonium ethoxide *(6)* [2c].

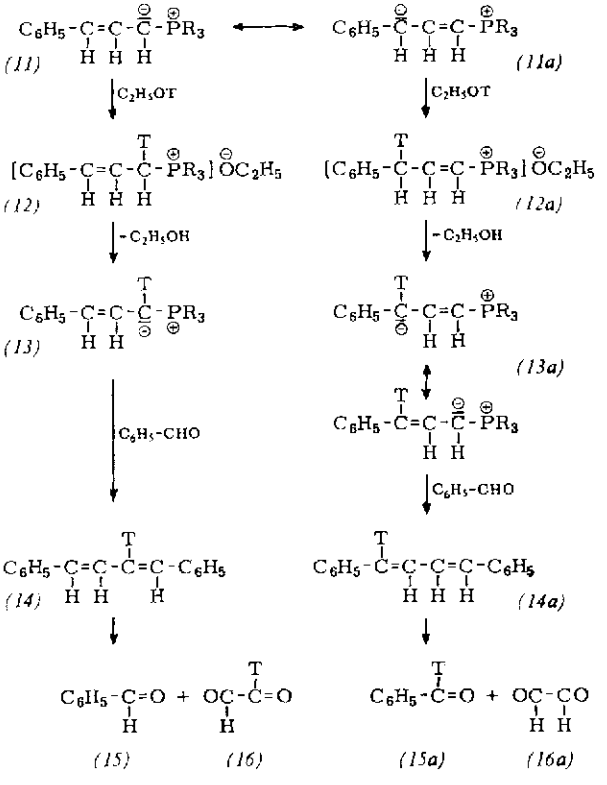


Addition of C_2H_5OT to a solution of an ylide leads to the tritiated phosphonium ethoxide *(7)*, which can lose C_2H_5OH in the equilibrium. The resulting labelled ylide *(8)* can be removed from the equilibrium by Wittig reaction with an aldehyde, giving an olefin with tritium on the C–C double bond.

Since the reaction of alkylidenetricyclohexylphosphoranes with carbonyl compounds leads only to *trans*-olefins [4], this provides a method of stereospecific labelling of olefins. This method was used to demonstrate the resonance of allylidenephosphoranes [3]. Allylidenephosphoranes of the type *(10)* should also be described by the resonance form *(10a)* [5].



Structure *(10)* shows the form which generally takes part in the Wittig reaction. Our own investigations have shown, however, that reactions of *(10a)* must also be expected in some cases, as has been confirmed for the reaction of allylidenetriphenylphosphorane with esters of chloroformic acid [6].



If a cinnamylidenephosphorane is treated with benzaldehyde in the presence of C_2H_5OT, tritium can add to both *(11)* and *(11a)*. The reaction proceeds *via* the phosphonium ethoxides *(12)* and *(12a)* to the labelled ylides *(13)* and *(13a)*, which react with benzaldehyde to 1,4-diphenylbutadienes *(14)* and *(14a)* with the T atoms in different positions. Cleavage of the double bonds with OsO_4/KIO_4 gives both labelled benzaldehyde *(15a)* and labelled glyoxal *(16)*. This shows that tritium was originally added to both *(11)* and *(11a)*.

Procedure:

[1-T]-trans-1,2-Diphenylethylene

An ethoxide solution is prepared under nitrogen from 0.40 g of sodium and 40 ml of absolute ethanol in a Schlenk tube. Most of the alcohol is evaporated off with a filter pump with the exclusion of moisture. 4.0 ml of tritiated absolute ethanol and 6.0 g of tricyclohexylbenzylphosphonium chloride are added, and the mixture is left for 1 h at room temperature to allow the tritium exchange to take place. Freshly distilled benzaldehyde (1.45 g) is then added, and the contents of the reaction vessel are refluxed for $1^1/_2$ h. At this point, it is possible to dispense with the nitrogen atmosphere. The mixture is poured into about 50 ml of 5 N hydrochloric acid, and the *trans*-stilbene which separates is filtered off. After recrystallization from methanol, the product is dried; m.p. 122 °C, yield 2.4 g (90 %).

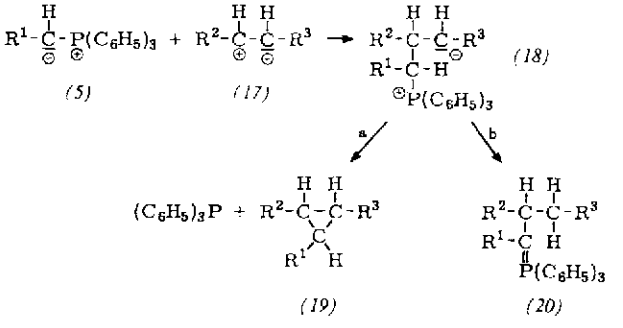
The T-activity of the ethanol before the exchange was 154 counts/min/μmole, and that of the stilbene obtained was found to be 96.2 counts/min/μmole [3].

B. Reaction with the C–C Double Bond

1. General

The Wittig reaction is introduced by a nucleophilic attack of the alkylidenephosphorane *(1)* on the polarized C–O double bond. It was expected that alkylidenephosphoranes would also react with other polarized multiple bonds to form betaines.

A series of systematic investigations was carried out, in which alkylidenephosphoranes *(5)* were treated with compounds *(17)* containing activated C–C double bonds. It was found that the initially formed betaine *(18)* can be stabilized by one of two secondary reactions (path a or path b) [7], and that the path actually followed is determined by group R^1 in the alkylidenephosphorane *(5)*.



(5) *(17)* *(18)* *(19)* *(20)*

2. Formation of Cyclopropane Derivatives

If the residue R^1 in the alkylidenephosphorane *(5)* is electron releasing, the betaine *(18)* (which can be isolated in some cases [8]) is stabilized by loss of triphenylphosphine and formation of the cyclopropane derivative *(19)* [7]. Cyclopropane formation had also been observed earlier in the reaction of a sterically hindered α,β-unsaturated ketone with an ylide [9] and in the reaction of butylidenetriphenylphosphorane with 9-butylidenefluorene [10]. The reaction can also be used for the preparation of cyclopropane derivatives which are difficult to prepare by the carbene method.

Procedure:

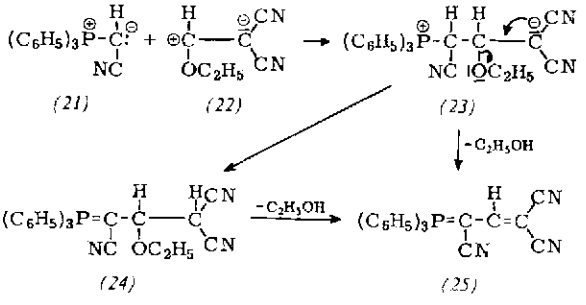
Ethyl 2,3-Dimethylcyclopropanecarboxylate

A salt-free ylide solution in benzene is prepared from 18.5 g (50 mmole) of ethyltriphenylphosphonium bromide, using the sodamide method (see Part I, Section D 2), and 5.7 g of ethyl crotonate is added. The light red solution becomes warm and turns dark red to black. After refluxing for 12 h, the reaction solution is shaken with 10 % sulfuric acid, and the benzene layer is dried over $MgSO_4$ and then boiled for 30 min with 10 g of methyl iodide to remove the triphenylphosphine. Methyltriphenylphosphonium iodide (12.1 g, 60 %) precipitates. The benzene is distilled off, and fractionation of the residue yields 3.6 g of the ethyl 2,3-dimethylcyclopropanecarboxylate, yield 50 %, b.p. 165–170 °C.

3. Michael Addition

If the group R^1 in *(5)* is electron-attracting, it loosens the α-H atom in the betaine *(18)*. The proton then migrates to the negative center of the molecule, with formation of *(20)*. The reaction may be regarded as a Michael addition of the alkylidenephosphorane *(5)* to the olefin *(17)* [7].

A third reaction path is possible if the olefin contains several strongly activating groups [11].



(21) *(22)* *(23)* *(24)* *(25)*

Cyanomethylidenetriphenylphosphorane *(21)* reacts with the strongly activated olefin *(22)* to form the betaine *(23)*. According to *Trippett*, *(23)* is stabilized by direct conversion to *(25)* accompanied by loss of alconol. It is not impossible, however, that the first step is a Michael addition to form *(24)*, followed by elimination of alcohol to give *(25)*. It is therefore not yet certain whether this reaction does in fact involve a third possibility for the stabilization of betaines [11].

Procedure:

1,2-Bis(methoxycarbonyl)-3-benzoylpropylidenetriphenylphosphorane

Equivalent quantities of methyl benzoylacrylate and methoxycarbonylmethylidenetriphenylphosphorane are boiled for 2 h in anhydrous ethyl acetate. The Michael addition product (m.p. 187 °C, yield 74 %) crystallizes on concentration of the solution in vacuum.

4. Synthesis of Pyran Derivatives

Pyran derivatives can be synthesized by Michael addition of acylalkylidenephosphoranes *(27)* to acylallenes *(26)* [12].

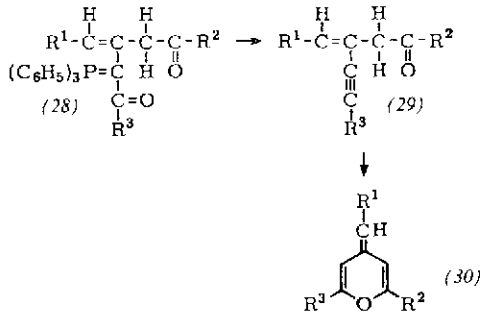
(26) (27)



(28) (29) (30)

The addition product *(28)* loses triphenylphosphine oxide to form the acetylene derivative *(29)*, which undergoes ring closure in its enol form to give the pyran derivative *(30)* [12].

The allene derivative *(26)* is also postulated as an intermediate in the reaction of acid chlorides $R-CH_2-COCl$ with alkylidenetriphenylphosphoranes *(27)*, in which pyran derivatives *(30)* are also formed [12]. The mechanism of this reaction has not been fully elucidated, and no preparative data are available.

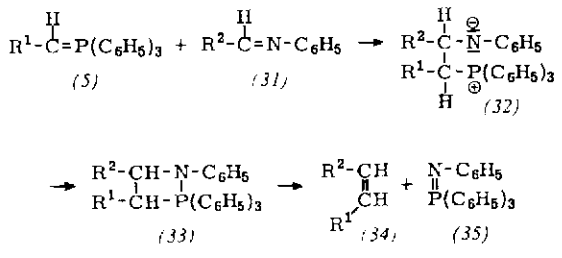
Acylethyleneimines [*(26)*, $R^1-N=$ instead of $R^1-CH=$] react in the same way as acylallenes *(26)* [13]. No preparative data are available as yet for this interesting reaction.

C. Reaction of Alkylidenephosphoranes with the C–N Double Bond

The reactions of alkylidenephosphoranes with the C–O and C–C double bonds suggest that the ylides might also react with the C–N double bond. Two such reactions are known at present [14].

1. Synthesis of Olefins by a Wittig-Type Reaction

Ylides *(5)* with no CH_2 group β to the P atom react with Schiff bases *(31)* at 150 to 180 °C. The reaction resembles the Wittig reaction, and leads to olefins *(34)* and *N*-phenyliminotriphenylphosphorane *(35)*.



(5) (31) (32) (33) (34) (35)

[13] *Idem, ibid. 258*, 6167 (1964).

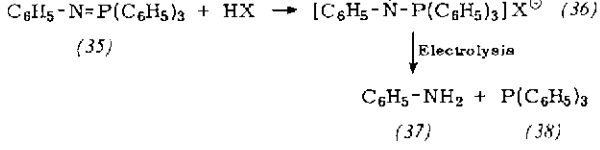
[14] *H. J. Bestmann* and *F. Seng*, Angew. Chem. *75*, 475 (1963); Angew. Chem. internat. Edit. *2*, 393 (1963); Tetrahedron 21, 1373 (1965).

It is assumed that as in the Wittig reaction, the initially formed betaine *(32)* forms a four-membered heterocyclus *(33)*, which then decomposes. Some examples of the resulting olefins *(34)* are given in Table 1.

Table 1. Olefins $R^1CH=CHR^2$ *(34)* obtained from alkylidenephosphoranes *(5)* and Schiff bases *(31)*.

R^1	R^2	Yield [%]
C_6H_5	C_6H_5	72
C_6H_5	$C_6H_5-CH=CH$	68
$C_6H_5-CH=CH$	C_6H_5	68

Triphenylphosphine can be easily recovered from the phenyliminotriphenylphosphoranes *(35)* [8].



(35) (36) (37) (38)

The iminophosphorane *(35)* readily reacts with hydrohalic acids to form a salt *(36)*, which decomposes into aniline and triphenylphosphine *(38)* on electrolysis in aqueous solution.

Procedure:

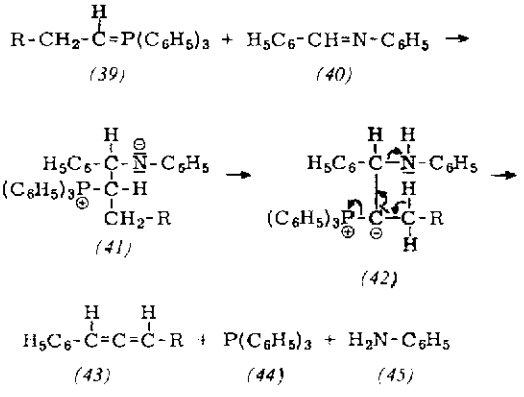
Stilbene

A benzene solution of benzylidenetriphenylphosphorane is prepared by the sodamide method (see Part I, Section D 2) from 7.8 g (20 mmole) of benzyltriphenylphosphonium chloride. 3.6 g (20 mmole) of benzylideneaniline is added to the red solution and the benzene is distilled off. The residue is heated for 5 min at 190–200 °C, cooled, and dissolved in 100 ml of ether. The ether solution is shaken with 100 ml of 2 N sulfuric acid. The ether is evaporated off, and the residue is recrystallized from methanol to give 2.6 g of *trans*-stilbene (72 %; m.p. 121–122 °C).

N-Phenyliminotriphenylphosphorane is precipitated from the acid phase with sodium hydroxide solution. The yield is 4.95 g (70 %), m.p. 131–132 °C.

2. Synthesis of Allenes

Ylides *(39)* with a CH_2 group β to the P atom react with benzylideneaniline *(40)* to form a betaine *(41)*, which decomposes into an allene *(43)*, triphenylphosphine *(44)*, and aniline *(45)* on heating to 120–130 °C [14].



(39) (40) (41) (42) (43) (44) (45)

The betaine *(41)* can be isolated [8]. The decomposition is presumably preceded by a proton shift to form the ylide *(42)*, which then undergoes an intramolecular Hofmann degradation by intramolecular β-elimination (transfer of a proton from the β position with respect to the P atom, to the lone electron pair on the nitrogen). This results in the formation of *(43)*, *(44)*, and *(45)* [cf. also the formation of allenes from alkylidenephosphoranes and 1-dimethylamino-1-chloro compounds, in which the last step of the reaction is similar (Part II, Section B 3b)].

The very high decomposition temperatures (150 to 200 °C) of the betaines *(41)* result in partial rearrangement of the allenes *(43)* formed into the isomeric acetylene derivatives.

Procedure:

Phenylallene

Benzylideneaniline (20 mmole) is added to a salt-free benzene solution of 20 mmole of ethylidenetriphenylphosphorane [*(5)*, R = CH_3] under nitrogen. The mixture is left for 1 h at room temperature, and the benzene is then evaporated off in vacuum at a maximum bath temperature of 60 °C. The betaine which remains solidifies to yellow crystals on addition of petroleum ether/ether (5:2). The crystals are filtered off and decomposed in a rotating bulb tube at about 15 mm Hg, the bath temperature being raised to 190 °C. It is now possible to dispense with the protective nitrogen atmosphere.

The distillate (aniline and phenylallene) is poured into 30 ml of 25 % sulfuric acid. The mixture is extracted with ether, the ether phase is dried, and the solvent is evaporated off. Vacuum distillation of the residue gives phenylallene, b.p. 69–70 °C/11 mm Hg, yield 58 %.

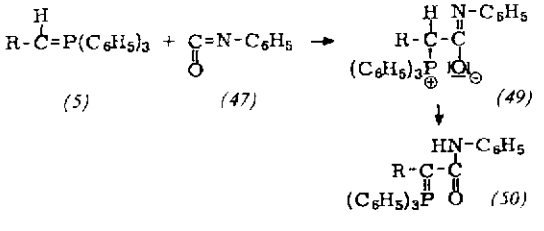
The residue from the decomposition consists of triphenylphosphine which can be recrystallized from methanol. Aniline is obtained from the sulfuric acid solution by treatment with alkali.

3. Reaction of Alkylidenephosphoranes with Phenyl Isocyanate

Diphenylmethylidenetriphenylphosphorane *(46)* reacts with phenyl isocyanate *(47)* to form diphenylketenephenylimine *(48)* [15].

$$(C_6H_5)_2C{=}P(C_6H_5)_3 + O{=}C{=}N{-}C_6H_5 \quad (47)$$
$$(46) \rightarrow (C_6H_5)_2C{=}C{=}N{-}C_6H_5 + OP(C_6H_5)_3$$
$$(48)$$

However, the reaction of phenyl isocyanate with alkylidenephosphoranes *(5)* in which the α carbon carries an H atom follows a different course: the initially formed betaine *(49)* is stabilized in this case by proton migration to form the new ylide *(50)* [16].



It still remains to be seen whether this reaction is generally suitable for the synthesis of anilides of carboxylic acids.

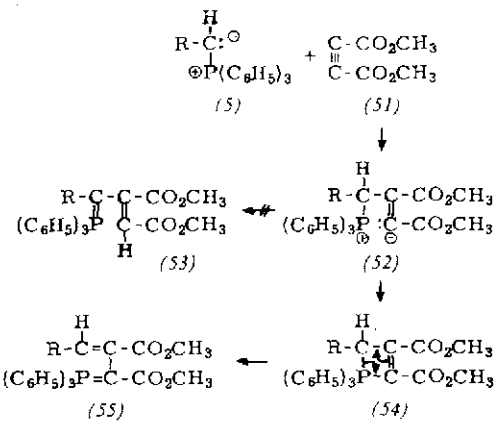
Procedure:

α-Ethoxycarbonyl-α-phenylcarbamoylmethylidenetriphenylphosphorane [(50), R = $CO_2C_2H_5$]

Phenyl isocyanate (2 g) is added to a solution of 3.5 g of ethoxycarbonylmethylidenetriphenylphosphorane in 40 ml of chloroform, and the reaction mixture is allowed to stand for 2 h at room temperature. The solvent is distilled off in vacuum, and the residue is recrystallized from n-butanol; m.p. 189–190 °C, yield 90 %.

D. Reaction of Alkylidenephosphoranes with Esters of Acetylenedicarboxylic Acid

Alkylidenephosphoranes *(5)* react spontaneously with esters of acetylenedicarboxylic acid *(51)* [17].



The initially formed betaine *(52)* is stabilized not by a proton shift to form *(53)* [18], but by formation of the ylide *(54)* *via* the four-membered heterocyclus *(54)*. The structure of *(55)* has been proved by degradation and by its infrared and NMR spectra. Alkylidenephosphoranes with no hydrogen on the α-C atom react similarly [17, 19, 20].

[19] On the basis of analogy, and with no proof of the structure of the products, *G. W. Brown*, *R. C. Cookson*, *I. D. R. Stevens*, *T. C. Mak*, and *J. Trotter*, Proc. chem. Soc. (London) *1964*, 86, postulated an identical mechanism for the reaction of diphenylmethylidenetriphenylphosphorane with esters of acetylenedicarboxylic acid.

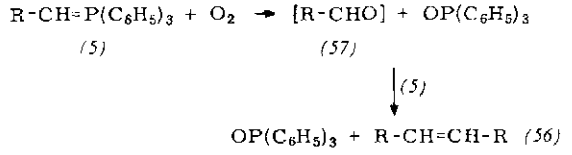
[20] *J. B. Hendrickson*, *R. Rees*, and *J. F. Templeton*, J. Amer. Chem. Soc. *86*, 107 (1964) report, without offering experimental data or evidence, that the reaction of *(51)* with benzoylmethylidenetriphenylphosphorane can yield both a Michael addition product *(53)* and a compound *(54)*. No mention is made in this paper of the article by *J. B. Hendrickson*, J. Amer. Chem. Soc. *83*, 2018 (1961), in which it is reported that this reaction gives rise to a heterocyclic compound containing pentavalent phosphorus.

E. Autoxidation of Alkylidenephosphoranes

1. Olefins from Primary Alkyl Halides or Alcohols

Alkylidenephosphoranes *(5)* with an H atom on the polarized double bond, *i.e.* obtained from primary alkyl halides or primary alcohols, are converted by oxygen into symmetrical olefins *(56)* and triphenylphosphine oxide [21].

It is assumed that one molecule of ylide and one molecule of oxygen first react to form triphenylphosphine oxide and the aldehyde *(57)*. The latter then enters into a Wittig reaction with an unoxidized ylide molecule to give the olefin *(56)* and a second molecule of triphenylphosphine oxide. Thus for ylides of the structure *(5)*, the Wittig reaction is faster than the autoxidation.



Ylides containing an aromatic group R react more slowly than those containing an aliphatic residue. Hexahydrobenzaldehyde [*(57)*, R = cyclohexyl] has been intercepted in 14% yield in the autoxidation of cyclohexylmethylidenetriphenylphosphorane.

Table 2. Olefins R—CH=CH—R *(56)* obtained by autoxidation of alkylidenephosphoranes R—CH=$P(C_6H_5)_3$ [21].

Alkyl halide [a]	R	Yield of olefin [%] [b]
Benzyl chloride	C_6H_5	72
p-Methoxybenzyl bromide	(*p*)$CH_3O-C_6H_4$	60
Ethyl bromide	CH_3	61
n-Propyl bromide	C_2H_5	68
n-Butyl bromide	n-C_3H_7	66
Cyclohexyl bromide	Cyclohexyl	61

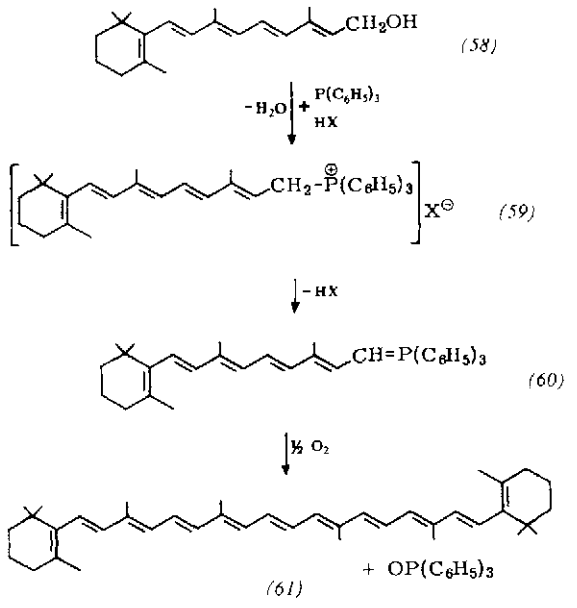
[a] Used for the preparation of the alkylidenephosphorane.

[b] Based on the phosphonium salt used for the preparation of the ylide.

The formation of olefins in the autoxidation of alkylidenephosphoranes makes possible the synthesis of β-carotene from two molecules of Vitamin A *(58)* [22].

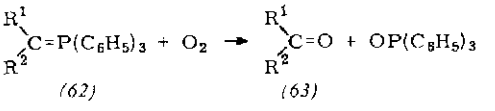
The phosphonium salt *(59)* can be obtained in almost 100% yield from *(58)*, and then converted to the ylide *(60)* [23,24].

If a solution of *(60)* is subjected to autoxidation with oxygen, crystalline β-carotene *(61)* is obtained immediately on working up. The yield of crude product is 35%.

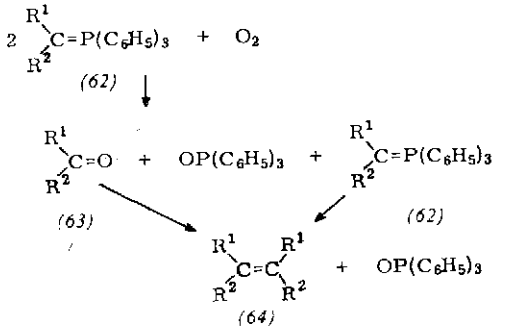


2. Olefins and Ketones from Secondary Alkyl Halides or Alcohols

Alkylidenephosphoranes *(62)* obtained from secondary alkyl halides or alcohols yield ketones *(63)* on autoxidation [21].



Owing to the low reactivity of the initially formed ketones, the autoxidation is faster than the Wittig reaction, so that the tetrasubstituted olefins *(64)* are not formed. These can be obtained, however, by stopping the supply of oxygen after the absorption of $^1/_2O_2$, and allowing the reaction mixture to stand at room temperature or, if necessary, refluxing the reaction mixture. In this case the ketone *(63)* reacts with unoxidized alkylidenephosphorane *(62)* to form the olefin *(64)*. This dimerization does not proceed if R^1 or R^2 is aromatic. The autoxidation of the ylide obtained from cyclohexyl bromide also fails to proceed beyond the cyclohexanone stage.



Alkylidenephosphoranes containing strongly resonance-stabilized groups ($R = CO_2-R^1$ or R^1-CO-) are not attacked by oxygen.

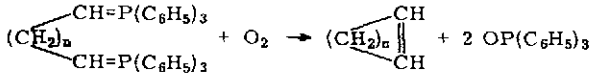
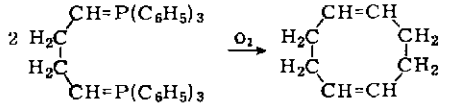
3. Cyclization by Autoxidation of Bis-Ylides. Synthesis of Monocyclic and Polycyclic Compounds

Cycloolefins *(66)* can be obtained by autoxidation of bis(alkylidenephosphoranes) *(65)* [25].



(65) *(66)*

Cyclic dimerization of the bis-ylide *(67)* leads to 1,5-cyclooctadiene *(68)*.



(67) *(68)*

Table 4. Cycloolefins *(66)* obtained by autoxidation of bis(alkylidenephosphoranes) *(65)*.

n	Cycloolefin	Yield [%]
5	Cycloheptene	61
4	Cyclohexene	60
3	Cyclopentene	68
2	1,5-Cyclooctadiene	52

Polycyclic compounds can also be synthesized with the aid of this principle.

The naphthalene derivative *(69)* gives acenaphthalene *(70)* (54% yield), whereas the biphenyl derivative *(71)* yields phenanthrene *(72)* (70%). Autoxidation of *(73a)* leads to dibenzocycloheptatriene *(74a)*, (53%) and that of *(73b)* to dibenzoxepin *(74b)* (52%).

Autoxidation of Alkylidenephosphoranes

The ylide solution is prepared by the sodamide, alkoxide, or dimethylsulfinate method (see Part I, Section D 2), and oxidized in a Schlenk tube having an additional fused-on gas-inlet tube. Fig. 1 illustrates an oxidation apparatus in which a measured volume of oxygen can be recirculated by means of a pump.

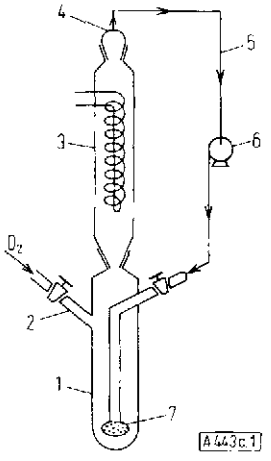

Fig. 1. Apparatus for the autoxidation of alkylidenephosphoranes. 1: Schlenk tube; 2: connector with tap; 3: reflux condenser; 4: olive; 5: tubing; 6: pump [26]; 7: gas-inlet tube with tap.

The apparatus is initially set up under nitrogen, and is then connected to the reservoir buret containing oxygen which has previously been dried over P_2O_5 and sulfuric acid. The pump is then started. The oxygen consumption can be read off from the buret.

In the preparation of olefins from the ylides *(5)* or of ketones from the ylides *(62)*, it is not essential to measure the oxygen consumption accurately. In these cases, dry oxygen can be passed through the solution of the alkylidenephosphorane until the solution is decolorized or undergoes no further color change (it often remains light brown). When R^1 and R^2 in *(5)* and *(62)* are aliphatic, the reaction is exothermic. If R^1 or R^2 is aromatic, the oxidation is best carried out at an elevated temperature. The same applies to the cyclization of bis-ylides by autoxidation.

If it is desired to obtain the olefins from the ylides *(62)*, the oxygen supply must be interrupted after $^1/_2$ molar equivalent of O_2 has been taken up. The oxygen in the apparatus is then displaced by nitrogen, and the reaction solution is allowed to stand at room temperature, or is heated under reflux, until the ylide solution is practically decolorized.

Olefins *(64)* are also obtained by the following variant: The ylide solution is halved. One half is oxidized to the ketone as described, and after the oxygen in the apparatus has been displaced by nitrogen, the unoxidized half is added. The subsequent procedure is as for a normal Wittig reaction.

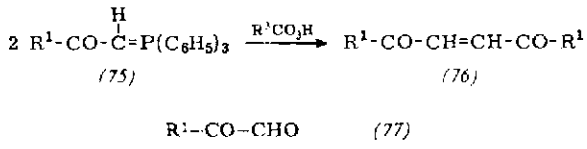
F. Oxidation with Peracids

A valuable complement to autoxidation is oxidation with peracids [27], which oxidize stable ylides not attacked by oxygen. Conversely, peroxy acids do not

[26] The laboratory pump Type LPA manufactured by Messrs. W. A. Bachofen, Basel (Switzerland), has been found to be very suitable.

[27] *G. B. Denney* and *L. C. Smith*, J. Amer. chem. Soc. *82*, 2396 (1960); *D. B. Denney, L. C. Smith, J. Song, C. J. Rossi,* and *C. D. Hall*, J. org. Chemistry *28*, 778 (1963).

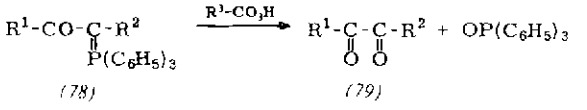
oxidize alkylidenephosphoranes capable of autoxidation. The rules governing both these reactions are the same.



(75) *(76)* *(77)*

Acylalkylidenephosphoranes [*(75)*, R^1 = alkyl, aryl, or OR^2] with an H atom on the C–P double bond are converted by peracids into diacylethylenes *(76)*. The first step is assumed to be the formation of an α-oxoaldehyde *(77)*, which reacts with unchanged ylide *(75)* to form the olefin *(76)*.

Stable alkylidenephosphoranes *(78)* with no H atoms on the C–P double bond are converted by peracids into α,β-dioxo compounds *(79)*. This method has been used



(78) *(79)*

for the preparation of cyclic 1,2-diketones [28].

Procedure:

1,2-Bis-(p-nitrobenzoyl)ethylene [27]

A solution of 2.56 g of peroxycaprylic acid in 20 ml of CH_2Cl_2 is added to a stirred solution of 6.5 g of *p*-nitrobenzoylmethylidenetriphenylphosphorane in 75 ml of CH_2Cl_2 at −30 °C and in an atmosphere of nitrogen. The stirring is continued for 90 min, and the solution is concentrated in vacuum until crystals separate out. These are filtered off, and 1.14 g of 1,2-bis-(*p*-nitrobenzoyl)ethylene are obtained; yield 46 %, m.p. 200 °C.

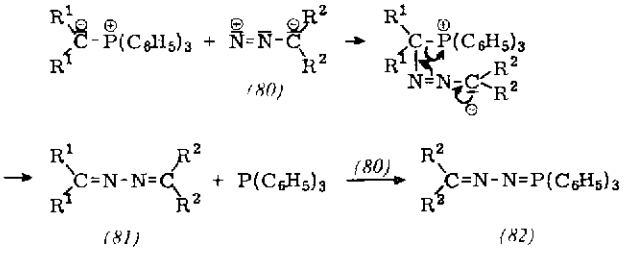
G. Cleavage with Ozone

Acylalkylidenephosphoranes *(78)*, in which R^1 or R^2 may be hydrogen, react with ozone at −70 °C to form α,β-dicarbonyl compounds *(79)* [29].

H. Other Reactions

1. Reaction with Aliphatic Diazo Compounds

Alkylidenephosphoranes react with aliphatic diazo compounds *(80)* to form azines *(81)* and triphenylphosphine [30, 31].



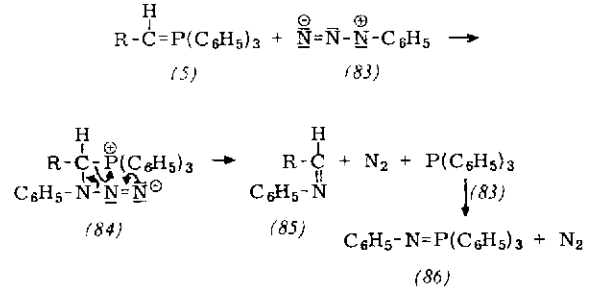
(80) *(81)* *(82)*

The triphenylphosphine formed frequently reacts with another molecule of the diazo compound *(80)* to yield the phosphazine *(82)*, so that the product in these cases contains both *(81)* and *(82)*.

2. Reaction with Phenyl Azide

Alkylidenephosphoranes *(5)* react with phenyl azide *(83)* to form Schiff bases *(85)* and phenyliminotriphenylphosphorane *(86)*, with evolution of nitrogen [32].

The first step is assumed to be the formation of a betaine *(84)*, which decomposes to the Schiff base *(85)*, triphenylphosphine, and nitrogen. The triphenylphosphine



(5) *(83)* *(84)* *(85)* *(86)*

then reacts with a second molecule of azide to form the iminophosphorane *(86)* [1].

It still remains to be seen whether this reaction is generally suitable for the preparation of aldehydes or Schiff bases.

3. Reaction with Carbenes

The electrophilic carbenes react as expected with alkylidene phosphoranes, as was first observed by *Wittig* and *Böll* [33]. Butoxymethylidenetriphenylphosphorane *(87)* breaks down on heating into triphenylphosphine and butoxycarbene *(88)*. This carbene reacts with a second ylide molecule to dibutoxyethylene *(90)* and triphenylphosphine; the betaine *(89)* probably occurs as intermediate.

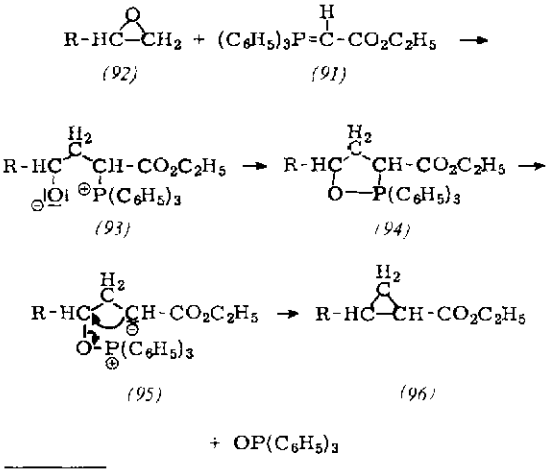
[33] *G. Wittig* and *W. Böll*, Chem. Ber. *95*, 2526 (1962).

The reaction of fluorenylidenetriphenylphosphoranes with halogenocarbenes leads to the formation of dihalogenomethylenefluorenylidenes in yields of 50 to 80 % [34].

4. Reaction of Ethoxycarbonylmethylidenetriphenylphosphorane with Epoxides

Ethoxycarbonylmethylidenetriphenylphosphorane *(91)* reacts with epoxides *(92)* to form ethyl cyclopropanecarboxylates *(96)* [35]. It is assumed that the reaction passes through the intermediates *(93)*, *(94)*, and *(95)* [35, 36a, 36b]. More strongly basic alkylidenephosphoranes do not give uniform reactions with epoxides [36a, 37–39]. An interpretation of the mechanism of this reaction is given by *Trippett* [39].



[34] *R. Oda, Y. Ito,* and *M. Okano,* Tetrahedron Letters *1964*, 7.

[35] *D. B. Denney* and *M. J. Boskin,* J. Amer. chem. Soc. *81*, 6330 (1959); *D. B. Denney, J. J. Vill,* and *M. J. Boskin,* J. Amer. chem. Soc. *84*, 3944 (1962).

Procedure:

Norcaranecarboxylic Acid

A mixture of 5 g of ethoxycarbonylmethylidenetriphenylphosphorane and 10 g of cyclohexene oxide are heated for 9 h at 200 °C. The product is hydrolysed by boiling for 12 h with a mixture of 50 ml of methanol and 15 ml of 6N KOH. The reaction mixture is diluted with 100 ml of water and shaken with chloroform. The aqueous phase is extracted with ether. The norcaranecarboxylic acid enters the ether phase, and can be recrystallized from methanol after the ether has been driven off. Yield 1.5 g (63 %), m.p. 87–89 °C.

It should finally be pointed out that *Wittig*'s investigations, which led to the "rediscovery" of the alkylidenephosphoranes and their reaction with the C–O double bond, are steadily gaining in importance as the basis of many new investigations. They have stimulated a development which has by no means reached its peak.

The work quoted as the author's is the result of investigations carried out in conjunction with B. Arnason, J. Bertold, G. Graf, Dr. H. Häberlein, Dr. H. Hartung, Dr. O. Kratzer, I. Pils, K. Rostock, O. Rothe, Dr. H. Schulz, and Dr. F. Seng. I am sincerely grateful to my co-workers for their perseverance and diligence in the solution of our common problems.

Progress in Optical Circular Dichroism

BY PROF. DR. L. VELLUZ AND DR. M. LEGRAND [*]

CENTRE DE RECHERCHES ROUSSEL-UCLAF, PARIS (FRANCE)

An apparatus first described in 1961 for the measurement of circular dichroism down to 220 mμ has been improved and its range extended down to 185 mμ. Some examples are given in the field of dienes, conjugated ketones, and aromatic chromophores. A more extensive study of protein structures was developed with the following results: a) helical polypeptides show a complex dichroism in the far ultraviolet with three components (192 mμ, 204 mμ, 225 mμ), characteristic of the helical array of peptide groups; b) human serum albumin shows a very similar curve of dichroism and is 60 % helical; c) urea denaturation, as judged by dichroism, is a reversible phenomenon; d) a solvent such as chloroethanol increases the helical content of human serum albumin and clupein and has only a very small action on poly-L-glutamic acid; e) the rupture of S–S bonds in human serum albumin favors the attack of denaturing agents such as urea; f) detergents help to maintain the rigid structure of human serum albumin after the rupture of S–S bonds.

Introduction

The first apparatus for the convenient measurement of optical circular dichroism in the ultraviolet and visible regions, designed and developed in our laboratory [1], has led to a great interest in this subject. Many chemical laboratories working on optically active structures now use this method of analysis, as may be judged by the

[*] In collaboration with *R. Viennet* and *M. Mansart.*

[1] *M. Grosjean* and *M. Legrand,* C. R. hebd. Séances Acad. Sci. *251*, 2150 (1960).

large number of communications published since our first Note in this journal [2].

For the reasons already given [2], the principal chromophore studied has been the carbonyl group present in mono-, bi-, or polycyclic structures such as terpenes and steroids. In these fields, circular dichroism has led to absolute configurational determinations in numerous cases [3], and more recently to the elucidation of conformations, above all by working at low temperatures [4]. A detailed bibliography may be found in our recent monograph [5].

Despite these results, however, most functions other than the carbonyl group remained outside the scope of study because their absorption is either too strong or at too short a wavelength. Indirect methods have been employed for simple molecules, *e.g.* replacing the group by a chromophore of which the induced dichroism is measurable (OH replaced by ONO, NH_2 by $N{=}CH{-}C_6H_4OH$, *etc.* [5]), to increase considerably the usefulness of the method. However, the relationship between conformation and optical activity of complex molecules such as polypeptides and proteins can only be deduced by the direct measurement of circular dichroism.

I. Advances in Instrumentation

Most published results on circular dichroism have been obtained with apparatus similar to that built in 1959 in our laboratory by *Grosjean* and *Legrand* [1]. This design has the advantages of accuracy and rapidity of measurement, but there are some limitations in its use.

First, the limited beam intensity in the useful wavelength range leads to only moderate signal to noise ratios, which precludes accurate measurements when the anisotropy ratio $\Delta\varepsilon/\varepsilon$ of a sample is less than 5×10^{-4} ($\Delta\varepsilon$ is the difference in absorption coefficients for right-hand and left-hand circularly polarized light). The usefulness of the apparatus is therefore questionable for the measurement of the dichroism of allowed transitions of symmetric chromophores when optical activity is due to environment. In this case the absorption coefficient is more than a hundred times higher than that of forbidden transitions such as the $n \rightarrow \pi^*$ transition of the carbonyl group. Very dilute solutions must therefore be used in order to allow sufficient light to reach the photocell. However, for this type of transition, $\Delta\varepsilon$ values remain of the order of a few units. Consequently, the dichroic signal at the output of the photocell is very small and its detection becomes very difficult owing to background noise.

On the other hand, a limitation in wavelength is imposed by the use of natural quartz optics. This material limits to 2100 Å the shortest wavelength at which measurements are still possible. Below this point, the transmission of the optical part of the apparatus decreases abruptly.

In order to increase the range of the dichrograph previously described, it was thus necessary to modify the optics. This study was started by *Grosjean* and *Tari* [6] and has led to the experimental apparatus sketched in Fig. 1. An additive double monochromator is used to disperse and polarize the light at the same time. Light from a source S (deuterium lamp) is focused on the entrance slit f_1 and dispersed for the

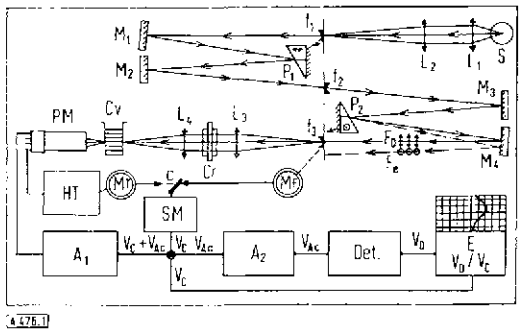

Fig. 1. Schematic design of the new apparatus.

S: light source, L_1–L_4 lenses, f_1–f_3 slits, M_1–M_4 mirrors, P_1, P_2 prisms, Cr polarisation modulator (ammonium dihydrogen phosphate), Cv cell, PM photomultiplier, HT dynode high-tension supply, MT dynode voltage servomotor, MF slits servomotor, SM slits or C dynode voltage servomechanism, A_1, A_2 amplifiers, Det. detector, E recorder, V_C direct voltage, V_{ac} alternating voltage, V_D rectified voltage.

first time by the prism P_1. This is made of crystalline quartz cut with its optic axis perpendicular to the aluminized face of the prism, so that there is no double refraction. Thus, a non-polarized monochromatic light beam coming from slit f_2 falls on the second prism P_2. The latter has its optic axis perpendicular to that of P_1 as shown in Fig. 1. In this way, the beam of light undergoes simultaneously a second dispersion and a polarization, so that two perpendicularly plane-polarized beams making an angle with each other leave the prism. The exit slit f_3 allows only the ordinary beam to pass.

With this design, the spectral purity of the monochromatic light is higher than before. This result is interesting in the short-wavelength range where stray light plays an important role. Further, the functions of the monochromator and polarizer (Rochon prism) of the previous apparatus have now been grouped together and this allows the use of additional optical parts as shown in Fig. 1 without loss of intensity. Finally, the prisms are cut in single crystals of *synthetic* quartz, which is more transparent below 2100 Å. These improvements have led not only to increased light intensity above 2000 Å but also to an extension of the limit of measurement to 1850 Å.

The rest of the apparatus is only slightly different from the first design: two amplifiers only are now necessary, following a small modification in the potentiometric recorder. A new arrangement has been added whereby the apparatus works either with variable slits as before or at fixed slits and variable dynode voltage.

The sensitivity of the apparatus with the modifications outlined above has been increased from 1.5×10^{-4} to 10^{-5} optical density unit per mm of recording chart. In the region below 200 mμ, it is possible to discern an optical activity corresponding to $\Delta\varepsilon/\varepsilon = 2\times10^{-5}$. In the near ultraviolet, where the emission of sources is much more intense, this limiting value becomes about 10^{-5}.

Chromophores with strong absorption such as dienes, trienes, conjugated ketones (transition $\pi \rightarrow \pi^*$), aromatic rings, *etc.* can be studied with this modified apparatus but the principal advantage of the new design is the possibility of determining circular dichroism below 220 mμ, making accessible to this method the important field of polypeptides, proteins, and nucleic acids.

Determinations are made with silica cells of $^1/_{10}$ mm thickness down to 210 mμ and $^1/_{100}$ mm below this wavelength. Such small thicknesses reduce the effect of the absorption of the solvent which is often important at short wavelengths. In

any case, the solutions used should not have optical densities exceeding 1.5.

Six determinations on a solution of poly-L-glutamic acid gave a relative standard deviation of ± 5 % from 185 mμ to 210 mμ and ± 2.5 % at longer wavelengths.

II. Circular Dichroism of Chromophores Strongly Absorbing in the Near Ultraviolet

a) Diene Steroids

Figure 2 shows the dichrogram and the isotropic absorption spectrum of two diene steroids, ergosterol *(1)* and lumisterol *(2)*. The great similarity of the two sets of curves is in good agreement with the theory of *Moffitt* and *Moscowitz* [7] since the transition is electric

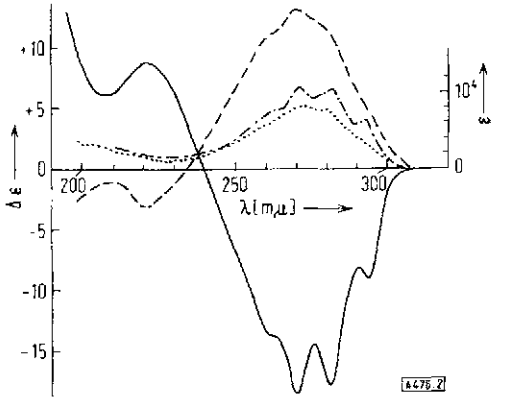

Fig. 2. Circular dichroism and ultraviolet absorption of ergosterol *(1)* and lumisterol *(2)* in ethanol.
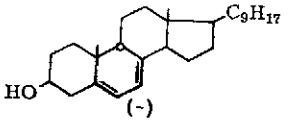
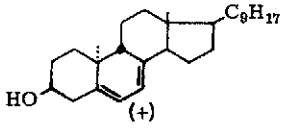
(– · – · –) Absorption and (———) dichroism of ergosterol.
(· · · · · ·) Absorption and (– – –) dichroism of lumisterol.

dipole allowed. The antipodal character of the two dichroism curves seems logical because in this type of ring, the inversion of the two centers 9 and 10 should normally lead to an inversion of conformation.

The high amplitude of the dichroism is related to the bond angles of the carbon atoms 5-6-7-8. According to *Moscowitz et al.* [8], this angle is negative in ergosterol *(1)* and positive [8a] in lumisterol *(2)*.



(1)



(2)

b) Conjugated Ketones

In our preceding researches [5], conjugated ketones have been fairly thoroughly studied in the region of the n→π* absorption, and recently *Snatzke* published a series of papers on this question [9]. The situation is entirely different in the region near 240 mμ because up till now, the high absorption has prevented measurement of the optical activity of the π→π* transition. Figure 3 shows the circular dichroism of the three

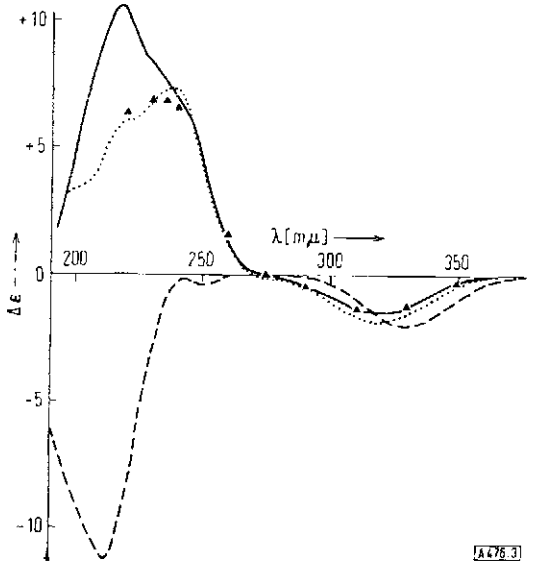


Fig. 3. Circular dichroism of some Δ4-3-keto steroids in ethanol.

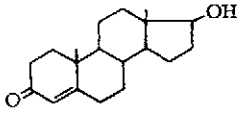
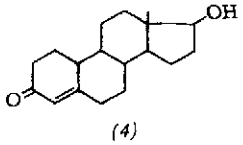
(– · – · –) 10α-Testerone acetate *(5)*.

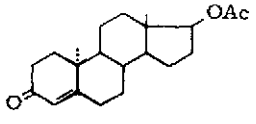
Δ4-3-keto steroids testosterone *(3)*, 19-nortestosterone *(4)*, and 10α-testosterone acetate *(5)* [*] in both wavelength ranges. As was known before, the dichroism of the three compounds is very similar near 330 mμ, but several differences are apparent at shorter wavelengths.



(3)



(4)



(5)

First, two bands are observed with relative amplitudes depending on the structure of the compounds. For instance, the absence of the 10-methyl group in 19-nortestosterone leads to a definite decrease of amplitude of the 220 mμ band but the 235 mμ band remains unchanged. On the other hand, with the 10α epimer of testosterone, the band at 235 mμ has practically disappeared. But the most important observation concerns the inversion of sign of the band at 220 mμ following the epimerization of the 10-methyl group while the optical activity remains the same in the near ultraviolet. This result gives a means of distinguishing this type of iso-

[*] We are indebted to Dr. *R. Wenger* (Zürich) for a sample of 10α-testosterone.

merism. However, it invalidates the hypothesis proposed by one of us according to which the sign of the band at 240 mμ is always the inverse of the sign of the 330 mμ band [5].

c) Aromatic Rings

The circular dichroism of estradiol *(6)* and 9-isoestradiol *(7)* is shown in Fig. 4. It can be seen that the phenolic ring is sensitive to the asymmetry of the neighboring

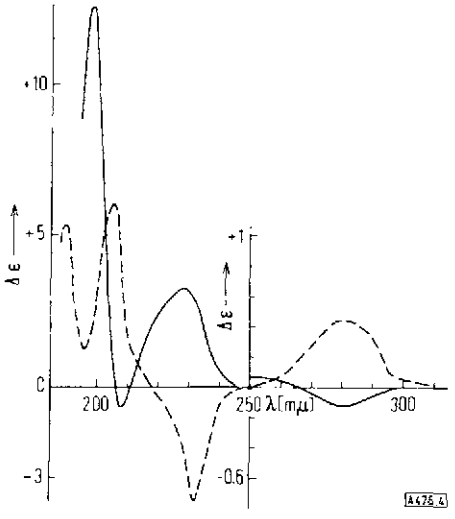

Fig. 4. Circular dichroism of (———) estradiol *(6)* and (– – –) 9-isoestradiol in ethanol.

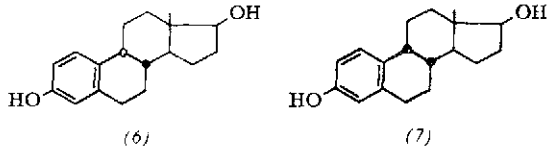
centers. In particular, inversion at center 9 changes the sign of the optical activity of both bands located towards the long wavelength, but is without effect on the 200 mμ band.



(6) *(7)*

For this type of chromophore, dichroism maxima do not correspond to isotropic absorption maxima. This is particularly true for the dichroism band at 230 mμ, a wavelength where the isotropic absorption shows a strong minimum.

d) General Remarks

In these few examples from the field of conjugated chromophores, the anisotropy factor varies from 1.5×10^{-3} (ergosterol) to *ca.* 5×10^{-5} (280 mμ band of the phenol). In the most unfavorable case, it is possible to obtain an accuracy of 15 % by drawing a mean line through the noise background to obtain an average curve, more accurate than the record itself.

The new apparatus recently described by *Grosjean* and *Tari* [6] thus permits precise measurement of optical activity of chromophores with $\Delta\varepsilon/\varepsilon$ *ca.* 2×10^{-5}. Nevertheless, the older dichrograph [*] is still quite satisfactory for work with weakly absorbing chromophores. The new design gives little improvement in this connection. Semi-quantitative determinations of $\Delta\varepsilon/\varepsilon$ around 5×10^{-4} are possible in the old apparatus above 220 mμ if the dilution is chosen such that the isotropic optical density remains below 1.5. If measurements are repeated several times, an accuracy of around 30 % can be reached, thanks to the low background noise of this apparatus; this precision is often sufficient for qualitative discussions. For example, in Figure 3 we give the points obtained for testosterone with the first dichrograph.

On the contrary, for chromophores such as peptides and proteins which we will now discuss, the interesting absorptions are situated below 220 mμ and their optical activity can be measured only with the new design.

III. Circular Dichroism of Some Proteins and Related Substances

The existence of a helical conformation in polypeptides and proteins, as proposed by *Pauling*, *Corey*, and *Branson* [10], and later proved by X-ray analysis of representative compounds, led to a great interest in optical rotatory dispersion in this branch of chemistry. The spatial disposition in the helix of the peptide bonds leads to interactions between the amide groups and consequently gives rise to a splitting of some transitions and a dichroism which is peculiar to this conformation. *Holzwarth* and *Doty* [11] recently found good agreement between experimental results and theoretical predictions by *Moffitt* [12] and by *Woody* [13]. We have studied the circular dichroism of poly-L-glutamic acid, a compound which serves as a model for proteins.

a) Dichroism of Poly-L-glutamic Acid [13a]

Near pH 4, poly-L-glutamic acid is 100 % in helix form. Its dichroism is shown in Figure 5. Three bands, one positive at 191 mμ, two others negative at 209 and 222

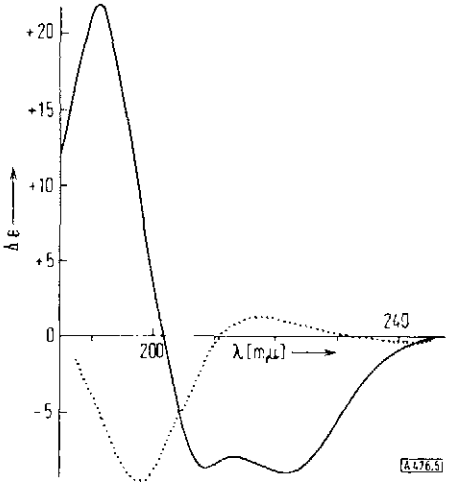

Fig. 5. Circular dichroism of aqueous poly-L-glutamic acid. (———) pH 4.3 (helix), (·····) pH 11 (random coil).

[12] *W. Moffit*, J. chem. Physics *25*, 467 (1956); Proc. nat. Acad. Sci. U.S.A. *42*, 736 (1956).

[13] *R. W. Woody*, Dissertation, University of California, 1962.

[13a] The determinations were made on a sample of high molecular weight (50000) supplied by Mann Research Laboratory.

mμ, are clearly recognizable. Going from short to longer wavelengths, the bands correspond respectively to the $n\rightarrow\pi^*$ transition of the amide group and to the NV_1 transition of the same chromophore which is split by coupling between peptide bonds disposed in helical array.

The overall curve was resolved into three gaussian components by the use of a least squares method. The data obtained are given in Table 1. These results are in satisfactory agreement with *Holzwarth* and *Doty*'s values [11] for the methyl ester of poly-L-glutamic acid.

Table 1. Gaussian components of the dichrogram of poly-L-glutamic acid.

λ_{max} [mμ]	Θ [mμ] [a]	Δε/n [b]	$R\times10^{-40}$ [erg cm³ rad] [c]
192	8.9	27.1	51
204	12.7	9.7	29
224	10	8.1	15

[a] Half the width at 1/e the maximum height.
[b] n = Degree of polymerization.
[c] R = Rotational strength of the transition.

Above pH 6, poly-L-glutamic acid has a random-coil conformation. Its dichroism (Fig. 5) shows two bands. The first, near 218 mμ, is weak and corresponds to the $n\rightarrow\pi^*$ transition of the amide chromophore, the second, at 198 mμ, is much stronger and is probably due to the NV_1 transition although there is a significant wavelength difference between the dichroism maximum (198 mμ) and the isotropic absorption (191 mμ).

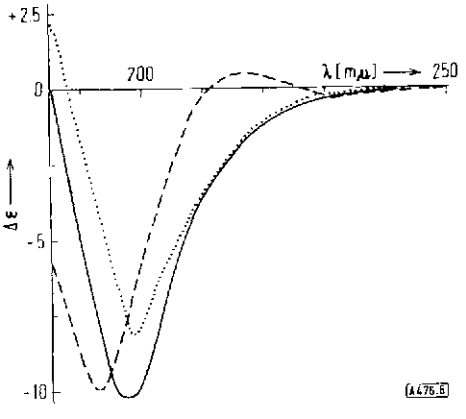

Fig. 6. Circular dichroism of aqueous α-glycyl-L-lysyl-L-glutamic acid at (———) pH 5.9, (— — —) pH 3.1, and (·····) pH 10.75.

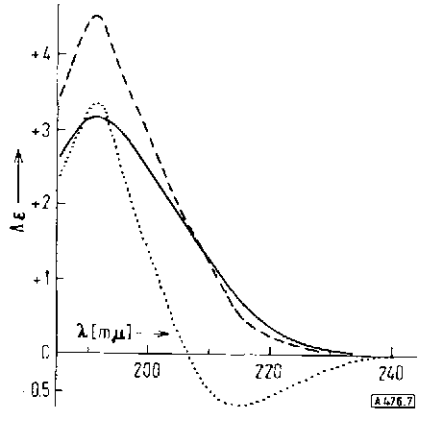

Fig. 7. Circular dichroism of aqueous L-*N'*-methylisoglutamine at (— — —) pH 3.4, (———) pH 6.5, and (·····) pH 10.4.

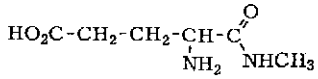
In Figures 6 and 7, it can be seen that a simple tripeptide α-glycyl-L-lysyl-L-glutamic acid and also *N'*-methyl-L-isoglutamine *(8)* [13b] give the same type of dichroism. However, the sign of the dichroism of the last compound is reversed, although it belongs to the same



(8)

optical series. This effect is probably due to the presence of an amine in the α-position to the amide instead of a second amide group. In any case, the dichroism of these two compounds is little affected by change of pH, and the variations observed have no resemblance to that presented by poly-L-glutamic acid. This shows that the peculiar dichroism of the latter in the helix state is due to the helical conformation of the chain and not to a variation of solvation at the level of the monomers as was recently proposed [14].

b) The Helix Content of Native Human Serum Albumin

Figure 8 shows the circular dichroism of human serum albumin (a) in aqueous solution, (b) denatured by urea (9 M), and (c) in 4 M urea, obtained by ultrafiltration of a

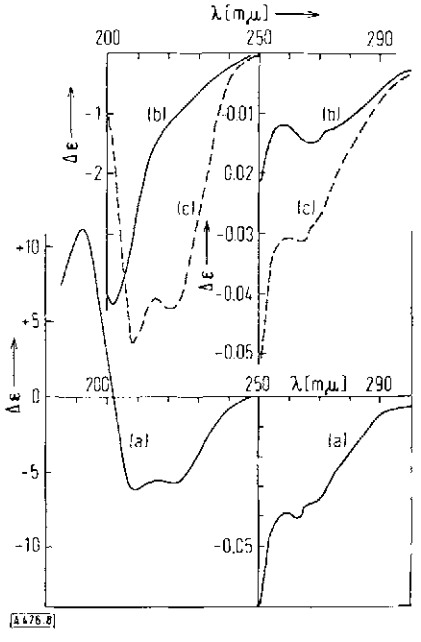


Fig. 8. Circular dichroism of human serum albumin: (a) native, (b) in 9 M urea after being heated at 78 °C for 1 h, and (c) in a solution of 3.9 M urea, obtained by ultrafiltration from a solution corresponding to (b).

9 M urea solution (b). In the case of (b) and (c), the measurements do not extend beyond 200 mμ owing to the absorption of urea at these wavelengths.

[13b] This compound (m. p. 200 °C) was synthesized in our laboratories by *G. Amiard* and *R. Heymes* from bis-(*N*-trityl-methyl-L-glutamic) anhydride by formation of the methyl amide using methylamine, followed by alkaline hydrolysis of the carbomethoxy group and acid hydrolysis of the trityl group.

[14] *L. I. Katzin* and *E. Gulyas*, J. Amer. chem. Soc. *86*, 1655 (1964).

The weak dichroic absorptions observed near 250 mμ arise from tyrosine, tryptophan, histidine and, above all, cystine residues. We have recently shown [15] that these amino-acids have a weak dichroism in this region, due respectively to the chromophoric groups phenol, indole, imidazole, and S–S present in these acids. However, quantitative agreement is not obtained, probably because, in proteins, the optical activity of each of these chromophores is modified by the environment.

Between 185 mμ and 250 mμ, the same type of curve is obtained for native human serum albumin and for helical poly-L-glutamic acid (Figs. 8a and 5). Furthermore, the transition from helix to random coil leads in both cases to a similar transformation of the curve.

From these observations, together with the fact that, after partial elimination of urea, the curve reverts to its original form, it can be inferred that this protein is, at least partially, in helical form.

In order to estimate the relative amounts of helical and random-coil states, we compared the experimental curve (Fig. 8a) with that derived by calculations based on data obtained from fully denatured human serum albumin [φ(λ)] and helical poly-L-glutamic acid [f(λ)] (Figs. 8b and 5). The weighted sum of the normalized curves of the components f(λ) and φ(λ)

$$m\, f(\lambda) + n\, \varphi(\lambda)$$

must be made to reproduce as closely as possible the experimental curve, m and n being determined by a least squares method over several wavelengths. The standard deviation should be of the same magnitude as the experimental error if the coefficients m and n have been correctly chosen [15a]. With native HSA, this method leads to a standard deviation of ± 2%, which is the order of magnitude of the experimental error. The hypothesis of a mixture of helical and random-coil forms in this protein is thus justified. The helical content is about 60%.

We consider that these results on the circular dichroism of human serum albumin, together with the determination of the optical rotatory dispersion curve of bovine serum albumin [16] in the region of 200 mμ, give the most direct proof so far of the existence of helix conformation in certain proteins in solution [17].

c) Denaturation of Serum Albumin

1. Influence of Ionic Strength

The influence of ionic strength was investigated at three pH values (1.5, *ca.* 6, and 12) and for three NaCl concentrations (0.05, 0.2, and 0.4 M). No significant changes were observed and consequently, in the subsequent measurements, no attempt was made to work at constant ionic strength.

2. Influence of pH

The dichroism of human serum albumin remains practically constant between pH 4 and pH 10. Beyond these limits, denaturation is not negligible. The variation of helix content with pH is given in Fig. 9. The curve is

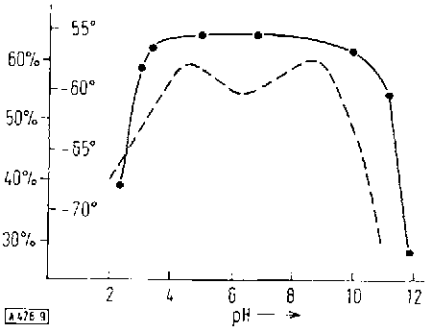

Fig. 9. Helix content [%] of human serum albumin in aqueous solution as determined from circular dichroism (curve ——, left-hand ordinate) and $[\alpha]_D$ according to *Jirgensons* and *Sirotzky* [18] (curve — — —, right-hand ordinate).

very similar to that of $[\alpha]_D$ published by *Jirgensons* and *Sirotsky* [18] which is also given in the figure. There seems to be a more abrupt change of slope at pH 3 in the curve representing helix content; however, the differences are almost within experimental error.

3. Influence of Temperature

The optical activity of human serum albumin is not very sensitive to temperature up to the coagulation limit of the protein [19]. Above this limit, measurement of dichroism is only possible if the aggregates are redissolved by addition of a few drops of concentrated ammonia. Figure 10 shows the dichroism observed under these

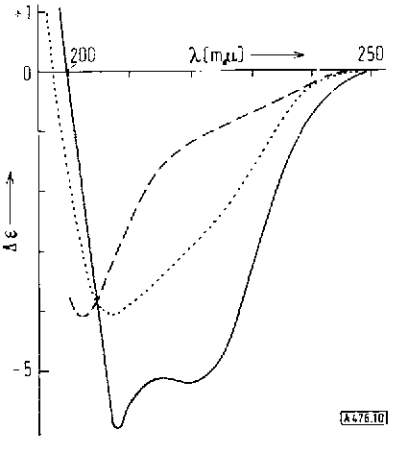

Fig. 10. Heat denaturation of human serum albumin, as evidenced by circular dichroism. (——) in aqueous ammonia; (·····) in aqueous ammonia after being heated for 1 h at 110 °C; (— — —) in 9 M urea after 1 h at 75 °C.

conditions, together with the dichroic curves of the native protein in ammoniacal solution and of the protein denatured by 9 M urea after heating at 75 °C. The results show that the presence of ammonia does not

[15a] We have already applied this method to the study of diketones [2].

[16] *E. R. Blout, I. Schmier*, and *N. S. Simmons*, J. Amer. chem. Soc. *84*, 3193 (1962).

[17] In the solid state, the presence of helical regions has been proved by X-ray analysis; cf. *P. Urnes* and *P. Doty*, Advances in Protein Chemistry *16*, 483 (1961).

[18] *B. Jirgensons* and *S. Sirotzky*, J. Amer. chem. Soc. *76*, 1367 (1954).

[19] *M. A. Golub* and *E. E. Pickett*, J. Polymer Sci. *13*, 427 (1954).

affect the optical activity of native human serum albumin, and that denaturation by heating alone seems to be less important than by urea plus moderate heating.

4. Urea Denaturation

When urea is added to an aqueous solution of human serum albumin at pH 6.9, the circular dichroism is greatly modified (Fig. 11). In particular, the maximum at 222 mμ

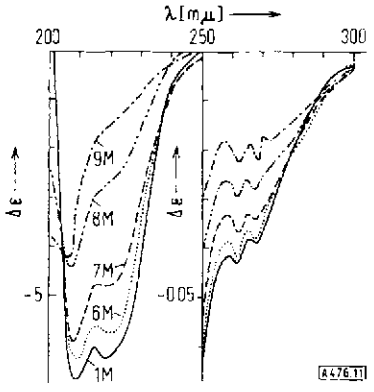

Fig. 11. Circular dichroism of human serum albumin after denaturation at various concentrations of urea.

decreases considerably. Although it is impossible to follow the concomitant modifications of the maximum at 192 mμ because of the absorption of urea, the curves of Figure 11 and the analogy with the "denaturation" of poly-L-glutamic acid (Fig. 5) indicate that urea destroys the helix in the protein, thus confirming the results of *Callaghan* and *Martin* [20]. Calculation of the helix content at 220 and 210 mμ gives the following values:

Urea concentration (moles/l):	2	4	6	7	8	9
% Helix content:	55	55	53	41	22	7

Denaturation occurs only above 6 M; it is not complete at 9 M. The maximum at 222 mμ ($n \rightarrow \pi^*$ transition of the helix form) disappears only after slight heating.

The denaturation seems to be reversible, at least as far as dichroism is concerned, since after partial removal of urea by ultrafiltration (9M → 4 M), the initial dichroism is practically restored. However, if the solution in 9 M urea is heated at 75 °C, no such reversibility is obtained and the dichrogram remains that of a denatured form. This observation indicates that heat plus urea leads to rearrangement of some S–S bonds [21].

5. Solvent Effects

Some solvents favor helix formation in polypeptides and proteins. We chose 2-chloroethanol because of its good transparency in the far ultraviolet. The circular dichroism of clupein sulfate shows that the helical conformation, absent in aqueous solution, appears in 2-chloroethanol (Fig. 12). With a 100% helical polypeptide, no such effect should be found. However, with poly-L-glutamic acid in a 50–50 water-2-chloroethanol solution [*], an apparent increase of about 6% in the helical content is observed, which is probably to be ascribed to the direct effect of the solvent on the dichroism of the helix.

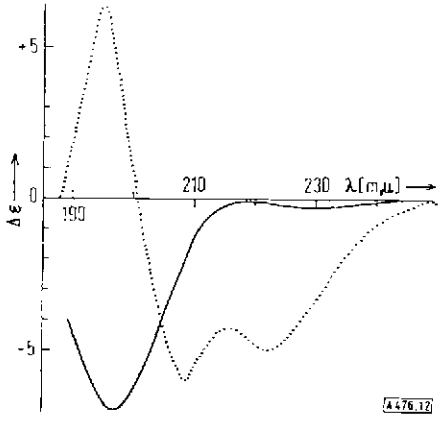

Fig. 12. Circular dichroism of clupein sulfate (———) in aqueous solution at pH 6.15 and (· · · · ·) in 2-chloroethanol.

The helical content of human serum albumin is notably increased in chloroethanol solution. With the method described above, a value of 75% is found, the action of the solvent upon the dichroism of the helix having been taken into account. This value is definitely higher than that in aqueous solution (60%) but still less than 100%. According to *Callaghan* and *Martin* [20], this incapacity to reach 100% helix content is due to structural factors such as S–S bonds.

6. Reduction of Disulfide Bonds

In proteins such as human serum albumin with many S–S bonds linking the protein chain in some points more or less far apart, it can be easily understood that rupture of such bonds leads to conformational changes. However, this phenomenon is difficult to isolate because the protein must first be denatured before the S–S linkage can be severed by chemical means. This denaturation can be effected by adding urea or a detergent such as dodecyl sulfate [22,23].

We denatured human serum albumin with dodecyl sulfate and used the method of reduction of *Würz* and *Haurowitz* [23] using 2-mercaptoethanol. Figure 13 shows the results obtained from which the following conclusions can be drawn:

α) 2-Mercaptoethanol alone does not reduce S–S bonds in human serum albumin.

β) Dodecyl sulfate (0.2 M) decreases the helical content to 40% (least squares method).

γ) Dodecyl sulfate plus 2-mercaptoethanol leads to the almost complete disappearance of the dichroism in the

[20] *P. Callaghan* and *N. H. Martin*, Biochem. J. *83*, 144 (1962).

[*] The compound is insoluble at higher concentrations of chloroethanol.

[22] *G. Markus* and *F. Karush*, J. Amer. chem. Soc. *79*, 134 (1957).

[23] *H. Würz* and *F. Haurowitz*, J. Amer. chem. Soc. *83*, 280 (1961).

250–300 mμ region. This confirms the assignment of the greater part of the optical activity in this region to S–S bonds.

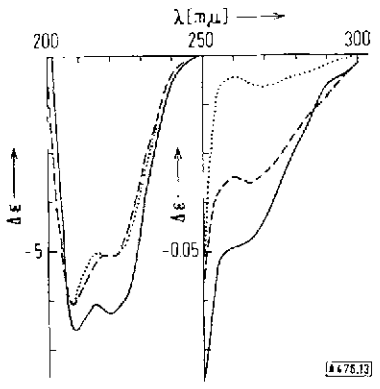

Fig. 13. Reduction of S—S bonds in human serum albumin by mercaptoethanol in the presence of dodecyl sulfate.
(———) in water with mercaptoethanol.
(— — —) in water with dodecyl sulfate.
(·····) in water with dodecy sulfate and mercaptoethanol.

δ) The dichroism in the 250–200 mμ region remains constant, indicating that the helical content is also invariant. This last point confirms that the increase of the molar optical rotation $[M]_D$ during the reduction of S–S bonds is due to the breaking of the S–S bond [23] and not to an increase of the helical content consecutive to the rupture of S–S linkages [22]. Quantitatively, the explanation is not so easy. The increase of $[M]_D$ (by 27 °) cannot be ascribed to the diminution of the negative dichroism at 270 mμ (contribution 2 to 3 ° only). It must be concluded that a strong negative band due to the S–S bond is situated below 200 mμ and cannot be measured in these experiments because of absorption of dodecyl sulfate and 2-mercaptoethanol. Actually, the

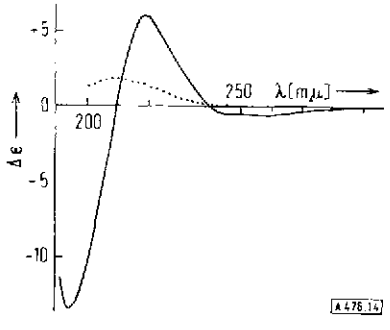

Fig. 14. Circular dichroism in N/10 HCl of (———) L-cystine and (·····) L-cysteine.

dichrogram of cystine shows such a band which is missing in the dichrogram of cysteine (Fig. 14). A crude calculation, based on this hypothesis, gives the right order of magnitude (+ 20 to + 25 °).

If urea is used as denaturing agent instead of dodecyl sulfate, the curves (Fig. 15) are entirely different. The comparison with the dichrogram of Fig. 11 shows that the efficiency of urea is reinforced when 2-mercaptoethanol is present, since the helix content is lowered at a smaller concentration (5 M) than without the reducing agent (7 M). Furthermore, at complete denaturation (9 M urea), the curve differs from that observed for the same concentration in urea but without the reducing agent and seems to be similar to that of random-coil poly-L-glutamic acid.

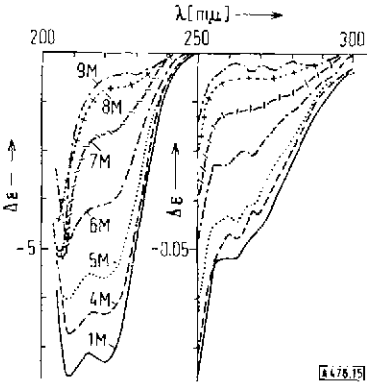

Fig. 15. Circular dichroism of human serum albumin after reduction of S—S bonds with mercaptoethanol in the presence of urea of various concentrations.

This phenomenon may be related to an increased flexibility when S–S bonds are broken. On the other hand, this effect is not observed in the presence of dodecyl sulfate since the curves are practically the same before and after reduction.

From all these observations, we can tentatively deduce that the S–S bonds act as a protector of the rigid structures (helix or random-coil) before denaturation [24], probably by maintaining a conformation which isolates the sensitive groups from the medium [25]. The dodecyl sulfate seems to prevent the collapse of the rigid structures when S–S bonds are broken.

Conclusions

These few examples from the field of polypeptides and proteins show the potentialities of dichroism measurements in the far ultraviolet. The determinations are complicated by the absorption of usual solvents in this region but the difficulties are compensated by the possibility of observing directly the optical activity of transitions which govern the behavior of rotatory power in the near ultraviolet and the visible range.

[24] In native protein, the non-helical portions do not present a periodic geometry but the positions of groups with respect to a coordinate frame attached to the molecule are perfectly determined (see X-ray diagram of proteins). On the contrary, after denaturation, the chain must be flexible.

Chemistry and Biochemistry of α-Lipoic Acid

BY PROF. DR. ULRICH SCHMIDT AND DR. P. GRAFEN

CHEMISCHES LABORATORIUM, UNIVERSITÄT FREIBURG (GERMANY)

AND

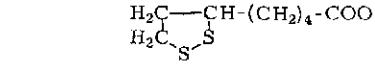
PRIV.-DOZ. DR. H.W. GOEDDE

ABT. BIOCHEMISCHE GENETIK, INSTITUT FÜR HUMANGENETIK UND ANTHROPOLOGIE, UNIVERSITÄT FREIBURG (GERMANY)

The principal physiological function of lipoic acid appears to be its action as coenzyme in the oxidative decarboxylation of α-oxo acids. In order to find out whether lipoic acid is essential to higher organisms, structurally modified lipoic acids were prepared as potential antagonists. Only 4-oxalipoamide promotes the growth of S. faecalis 8043; the other substances tested are inactive or else inhibit growth. In experiments to determine the substrate specificity of lipoamide oxidoreductase and its inhibition by structurally modified lipoic acids, no strong inhibitors were discovered. – Ring strain, spectra, and ring cleavage of compounds containing the 1,2-dithiolane ring are discussed in relation to the biological function and the reactivity of lipoic acid.

A. Introduction

Lipoic acid *(1)* first became known as a growth factor for many bacteria and protozoa under the name of acetate-replacing factor or protogen-A [1–7]. It occurs widely in plants and animals [7a], and acts as a coenzyme



(1)

in many enzyme-catalysed reactions, particularly in oxidative decarboxylations. Several reviews on the chemistry and biochemistry of lipoic acid have been published [8–10]. The present paper gives a detailed survey of the chemical properties and enzymatic function of lipoic acid. The still controversial effect of lipoic acid on photosynthesis and pharmacological reactions is only briefly mentioned.

Table 1 shows the enzymes involved in lipoic acid-dependent reactions. The α-oxo-acid oxidases (or dehydrogenases) mentioned, *e.g.* pyruvate oxidase and α-oxoglutarate dehydrogenase, are multienzyme complexes.

B. The Structures of Enzymes Containing Lipoic Acid

The most thoroughly investigated enzyme containing lipoic acid is the pyruvate oxidase of *E. coli*, a multienzyme complex with a molecular weight of about 4.8×10^6 [25,26]. It consists of pyruvate decarboxylase *(2)*, lipoic acid reductase-transacetylase *(3)*, and lipoamide oxidoreductase *(4)*. The molecular weights of these three enzymes are 1.83×10^5, 1.6×10^6, and 1.12×10^5 respectively; lipoic acid reductase-transacetylase probably consists of sub-units with a molecular weight of 26000 each.

The whole complex appears to contain 16 molecules of decarboxylase, 64 sub-units of lipoic acid reductase-transacetylase, and 8 molecules of lipoamide oxidoreductase. This opinion has been confirmed by *Reed* et al. [25,26] by electron-microscopic studies. According to these authors the complex has the shape of a disk about 350 Å in diameter and about 250 Å in height. The diameters given for the enzyme components *(2)*, *(3)*, and *(4)* are 75, 40, and 64 Å, respectively. Two superimposed rings, each consisting of 8 molecules of pyruvate decarboxylase *(2)* and 4 molecules of lipoamide oxidoreductase *(4)*, surround an aggregate of 64 lipoic acid reductase-transacetylase sub-units *(3)* arranged in four piles. A model is shown in Figure 1.

Fig. 1. Model of the structure of pyruvate dehydrogenase [25,26].

C. Coenzyme Action of Lipoic Acid in Oxidase and Dehydrogenase Systems

The mode of reaction of these oxidases will be explained here using the most thoroughly investigated substrate, *i.e.* pyruvate, as an example. The coenzymes required for the overall oxidative decarboxylation [Equation (a)] of pyruvate are thiamine pyrophosphate (TPP), Mg^{2+}, nicotinamide adenine dinucleotide (NAD), lipoic acid *(1)*, coenzyme A, and flavin adenine dinucleotide (FAD) [84a].

$$CH_3{-}CO{-}CO_2H + NAD^+ + CoA{-}SH \xrightarrow[\text{lipoic acid, FAD}]{\text{TPP, } Mg^{2+}} CH_3{-}CO{-}SCoA + NADH + H^+ + CO_2 \quad (a)$$

The reaction is catalysed by the enzymes *(2)*, *(3)*, and *(4)* described in Section B. It starts with the formation of "active acetaldehyde", *i.e.* 2-(α-hydroxyethyl)thiamine pyrophosphate (HETPP) [88–91], *via* a thiamine pyrophosphate (TPP)-pyruvate compound [91]. Figure 2 shows the component reactions.

In yeast cells there are two routes for the conversion of pyruvate into acetyl-coenzyme A. Equation (b) shows a

$$\text{Pyruvate} \xrightarrow[\text{Pyruvate decarboxylase}]{\text{TPP, } Mg^{2+}} \text{acetaldehyde} \xrightarrow[\text{Acetaldehyde dehydrogenase}]{NAD^+\ (NADP)^+} \text{acetate} \xrightarrow[\text{Thiokinase}]{\text{ATP, } Mg^{2+}\text{, CoA-SH}} \text{acetyl-SCoA} \quad (b)$$

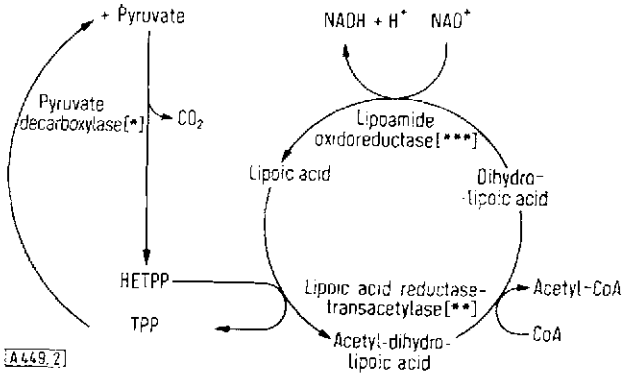

Fig. 2. Reactions participating in the oxidation of pyruvate to acetyl-coenzyme A by the pyruvate oxidase multienzyme complex.

[*] Although the three enzymes have actually been isolated, the revised nomenclature of the Enzyme Commission groups together the decarboxylating and the lipoic acid-reducing and -acetylating activities under the heading pyruvate: lipoate oxidoreductase (acceptor-acetylating), E.C. 1.2.4.1. The corresponding 2-oxoglutarate degrading enzyme is 2-oxoglutarate: lipoate oxidoreductase (acceptor-acylating) E.C. 1.2.4.2.

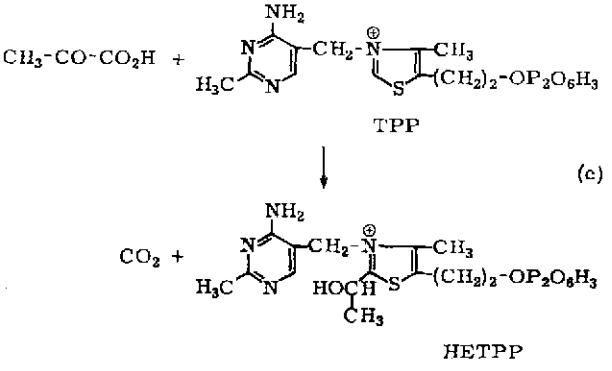
[**] The transacetylating activity with respect to CoA is described by the Enzyme Commission as acetyl-CoA: dihydrolipoate *S*-acetyltransferase, E.C. 2.3.1.12.

[***] E.C. 1.6.4.3.

reaction sequence the intermediates of which were identified by *Holzer* and *Goedde* [23]. *Cutolo* [78] discovered in 1956 that yeast cells contain lipoamide oxidoreductase. In 1957, the present authors [23] showed that in yeast, pyruvate can also be oxidized directly since yeast contains a pyruvate oxidase system which behaves like pyruvate oxidase from animals and bacteria [Equation (a)]. Reaction (b) takes place in the yeast cytoplasm, and Reaction (a) in the mitochondria.

I. Pyruvate Decarboxylase

The synthesis of 2-(α-hydroxyethyl)thiamine pyrophosphate (HETPP) is catalysed by pyruvate dehydrogenase:



The subsequent reactions leading to acetyl-coenzyme A have also been elucidated, except for a few details concerning the action of lipoic acid. [^{14}C]-HETPP obtained by both enzymatic [92] and chemical methods [93,94] has been converted to [^{14}C]-acetyl-CoA [95].

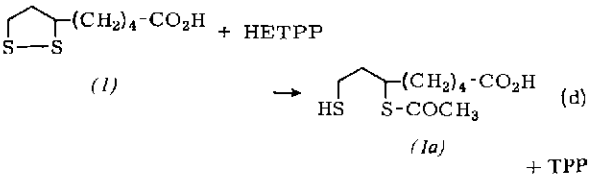
II. Lipoic Acid Reductase-Transacetylase

This enzyme, originally known as thiol transacetylase, was first detected in extracts of *E. coli* by *Gunsalus* [40, 63, 64]. It catalyses the acetylation of lipoic acid *(1)* and the transfer of the acetyl group from acetyldihydrolipoic acid *(1a)* to coenzyme A.



(1) *(1a)* + TPP (d)

(1a) + Coenzyme A → Acetyl–CoA + Dehydrolipoic acid (e)

Acetylthiamine pyrophosphate (acetyl-TPP) was postulated as an intermediate in Reaction (d). This highly unstable compound [96–98] would be the first oxidation product of active acetaldehyde (HETPP). Experiments by *Das* et al. [27] indicated the occurrence of acetyl-TPP in reactions with non-physiological electron acceptors. *Holzer* and *Goedde* [99] have demonstrated the formation of acetate from pyruvate in reaction sequences involving TPP, yeast pyruvate decarboxylase, and 2,6-dichlorophenolindophenol. Further experiments [100] suggested the intermediate formation of acetyl-TPP according to Reaction (f), since acetate was detected and lipoic acid was not involved.

Pyruvate → HETPP → acetyl–TPP → acetate (f)

However, on repeating this experiment with various enzymes [11, 23, 51] and acceptors, and starting with [^{14}C]-HETPP instead of pyruvate, we were unable to detect any intermediate formation of [^{14}C]-acetyl-TPP [101]. Nothing is known yet about the occurrence of acetyl-TPP in the oxidation of pyruvate or of α-oxoglutarate under physiological conditions.

The isolation of acetyl and succinyl thioesters of dihydrolipoic acid by *Gunsalus* [63, 102, 103] proved that lipoic acid acts as an acyl acceptor. *S*-Acetyldihydrolipoic acid [Eq. (d)] is formed by a redox process, in which the oxidation of the aldehyde to the carboxylic acid is accompanied by reductive cleavage of the 1,2-dithiolane ring of lipoic acid. The dihydrolipoic acid is acetylated exclusively at the C-6 sulfur atom [63, 83].

Sanadi et al. [52, 104] and *Goldmann* [44] have prepared lipoic acid reductase-transacetylase from pyruvic oxidase obtained from *M. tuberculosis*. *Hager* et al. [28–30] have purified the enzyme from *E. coli* mutants. According to *Reed* [84], the enzyme reacts with both enantiomers of lipoamide. *Hager* and *Kornberg* [30] developed a test for lipoic acid transsuccinylase obtained from *E. coli* mutants using succinate thiokinase to prepare succinyl-coenzyme A [Eq. (g)] and treating the product with dihydrolipoic acid [Eq. (h)]. This second step is catalysed by lipoic acid transsuccinylase.

ATP + Succinate + CoA–SH ⇌ ADP + P + Succinyl–SCoA (g)

Succinyl–SCoA + Lip(SH)$_2$ ⇌ CoA–SH + Succinyl–S–Lip(SH) (h)

The *S*-succinyldihydrolipoic acid is quantitatively determined as succinylhydroxamic acid obtained by reaction with hydroxylamine (see also [105]).

In the reactions described in Fig. 2, (−)-dihydrolipoic acid appears to be the biologically active form. *Reed* [32, 84] has shown that lipoic acid reductase-transacetylase can react with bound or free *S*-acetyldihydrolipoic acid, as does lipoamide oxidoreductase. In contrast, enzyme-bound lipoic acid is essential to Reaction (d).

a) *Removal of Enzyme-Bound Lipoic Acid Using Lipoamidase, and Reactivation of the Apoenzyme*

Lipoic acid reductase-transacetylase is the only enzyme of the pyruvate oxidase complex containing protein-bound lipoic acid. The latter can he removed using an enzyme from pigeon liver [82, 106]. According to *Reed*, lipoic acid is joined by a peptide linkage to the ε-amino group of one of the lysine residues in the enzyme protein [33]. Correspondingly, lipoamide and dihydrolipoamide are more effective than lipoic acid in model reactions [34, 107, 108]. *Reed* [33, 109] has shown that *N*(ε)-DL-lipoyl-L-lysine is reduced three times as fast as DL-lipoamide by NADH and lipoamide oxidoreductase from *E. coli*.

Two enzymatic reactions are required to link lipoic acid to the apoenzyme: (a) the ATP-dependent activation of lipoic acid to form lipoyladenylate, and (b) the transfer of the lipoyl residue to the apoenzyme. Lipoic acid reductase-transacetylase from which lipoic acid has been removed, can be reactivated by incubating it with ATP plus lipoic acid (or synthetic lipoyladenylate) and a lipoic acid-activating system from *S. faecalis* or *E. coli* [83, 109].

b) *Type of Linkage and Amino-Acid Sequence at the Site of the Lipoic Acid-Protein Link*

Oxo-acid oxidases containing radioactively labelled lipoic acid can be prepared in two ways:

(a) By culturing *E. coli* strains in the presence of [^{35}S]-lipoic acid.

(b) By allowing lipoamidase to act on oxo-acid oxidases. The apoenzyme formed is isolated by centrifugation at 144000 g and is reactivated by incubation with ATP, [^{35}S]-lipoic acid, and the lipoic acid-activating system.

Oxo-acid oxidases containing labelled lipoic acid have been oxidized with performic acid and hydrolysed for 3 h at 100 °C with 12 N HCl. It was possible to isolate

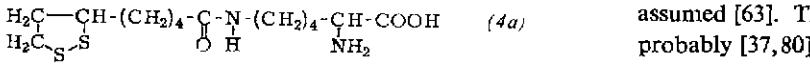
$N(\varepsilon)$-lipoyl-L-lysine *(4a)* [109a], the hydrolysis of which gave L-lysine and lipoic acid in the ratio of 1 : 1 [41,45,83]. This result has been confirmed by *Goldman*.



(4a)

Reed treated highly purified enzyme preparations from *E. coli* containing [^{35}S]-lipoic acid with performic acid and partially hydrolysed the product. The [^{35}S]-peptides of lipoic acid were isolated and identified. From pyruvate dehydrogenase the sequence glycine-asparagine-lipoyllysine-alanine was obtained, while in oxoglutarate dehydrogenase the sequence threonine-asparagine-lipoyllysine-valine-(valine, leucine)-glutamine [112] was present.

III. Lipoamide Oxidoreductase

This flavin-adenine dinucleotide enzyme catalyses the reoxidation of dihydrolipoic acid in the presence of NAD:

$$\text{Dihydrolipoic acid} + \text{NAD}^+ \rightleftharpoons \text{lipoic acid} + \text{NADH} + \text{H}^+ \quad \text{(i)}$$

Lipoamide oxidoreductase has been studied since 1958 [35, 53–58, 65–73, 79, 84, 104, 107, 113–117]. It is identical with the diaphorase [119–121] isolated from heart muscle by *Straub* [118] and *Savage* [74], and can be estimated photometrically by Reactions (i) or (j). In the latter, hexacyanoferrate(III) or 2,6-dichlorophenolindophenol (DCP) can act as hydrogen acceptors.

$$\text{NADH} + \text{H}^+ + \text{Acceptor} \rightleftharpoons \text{NAD}^+ + \text{Acceptor–H}_2 \quad \text{(j)}$$

Unlike lipoic acid reductase-transacetylase, lipoamide oxidoreductase is not specific for either (+)- or (−)-lipoic acid. However, a lipoamide oxidoreductase obtained by *Basu* and *Burma* [122] from *Spinacia oleracea* reacts only with (−)-dihydrolipoic acid.

Flavin-adenine dinucleotide (FAD) can dissociate reversibly from the enzyme. The enzyme is decolorized by NADH or dihydrolipoic acid but the color is restored on addition of lipoic acid. This is taken to indicate that enzyme-bound dihydrolipoic acid is oxidized by FAD, and not directly by NAD, as had previously been assumed [63]. Thus the electron transfer sequence is probably [37, 80]

$$\left[\begin{matrix}\text{oxoglutarate}\\ \text{pyruvate}\end{matrix}\right] \rightarrow \text{lipoic acid} \rightarrow \text{FAD} \rightarrow \text{NAD}.$$

a) *Properties of Lipoamide Oxidoreductase*

Lipoamide oxidoreductase has been detected in the pyruvate oxidase and oxoglutarate dehydrogenase complexes of many organisms (see Table 1) [36, 53, 57, 80, 81, 123]. Highly purified preparations of lipoamide oxidoreductase are intensely yellow, exhibit fluorescence, and have absorption maxima at 273, 359, and 456 mμ with a shoulder at 480 mμ [37].

The highly purified enzyme contains 1.16 % of FAD ≙ 0.56 % of riboflavin [74, 76]. Its fluorescence and the absorption at 456 mμ disappear in the presence of excess NADH. The enzyme is inhibited by *p*-chloromercuribenzoate, and reactivated by glutathione [123].

pH optima of 5.6 to 5.9 and 6.5 to 7.0 are found for lipoic acid and DL-lipoamide, respectively [107]. By reduction of the flavoprotein in various NADH/NAD equilibria *Sanadi* found a reduction potential of about −0.34 volt at pH 7.0 and 22 °C for lipoamide oxidoreductase from pig heart oxoglutarate dehydrogenase [56, 57].

Turnover number: Measurements using Reaction (j) show that 8500 moles of substrate react per minute with 10^5 g of enzyme protein [76] (for data on the reaction of lipoic acid, see [71, 115] and Table 2).

It was originally thought that lipoamide oxidoreductase resulted from the breakdown of cytochrome reductase. *Massey* [71] however disproved this by isolating both enzymes separately from pig heart.

b) The Mode of Action of Lipoamide Oxidoreductase

Lipoic acid transacetylase-reductase containing bound lipoic acid is inhibited by arsenite even in concentrations as low as 10^{-3}–10^{-5} M [40, 52, 59, 66, 125–128]. (For inhibition experiments using other arsenic compounds or heavy metal cations, see [104, 105, 128, 129]). The inhibition can be reversed by the addition of dithiols, *e.g.* 2,3-dimercaptopropanol.

Highly purified lipoamide oxidoreductase, which does not contain bound lipoic acid, is also inhibited by

[109a] Biotin, which plays an important part in carboxylation reactions, (*e.g.* in fatty acid synthesis) likewise occurs bound to lysine. Biocytin [$N(\varepsilon)$-biotinyl-L-lysine] has been isolated from yeast autolysates [110, 111].

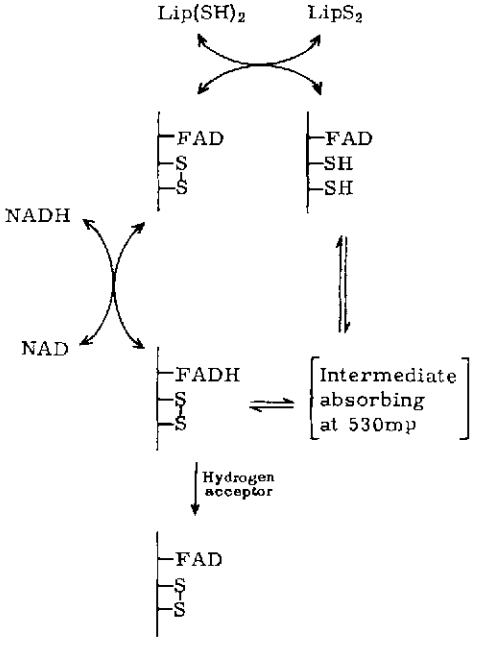
arsenite (or Cd^{2+}) but only if it is reduced by simultaneous incubation with NADH [55, 72, 66, 75]. After reduction, 2 moles of SH groups per mole of enzyme can be detected [55]. Apparently a disulfide bridge between two cysteine residues is cleaved by NADH. By ultracentrifugation experiments in 6.5 M urea, *Massey* [65, 130] was able to show that on reduction of the enzyme its molecular weight decreases to about half. This was taken to indicate that the disulfide bridge cleaved by NADH links two peptide chains in the native enzyme.

When lipoamide oxidoreductase is inhibited by arsenite, only Reaction (i) is affected, *i.e.* the enzyme loses the ability to catalyse the oxidation of dihydrolipoic acid (or the reduction of lipoic acid). However, it still catalyses the transfer of hydrogen from NADH to hexacyanoferrate(III) or 2,6-dichlorophenolindophenol, *i.e.* Reaction (j) is not affected by arsenite [55, 72]. From this it follows that NADH first reduces the FAD component of the enzyme (Scheme 1). The FADH formed then transfers hydrogen to the disulfide bridge of the enzyme, thus forming two SH groups. Under physiological conditions, the disulfide bridge is reduced by dihydrolipoic acid. FAD accepts the hydrogen from the SH groups (with reformation of the disulfide bridge) and transfers it to NAD. Non-physiological hydrogen acceptors (hexacyanoferrate(III) or 2,6-dichlorophenolindophenol) accept hydrogen directly from FADH, *i.e.* without SH groups being involved. Therefore, catalysis of Reaction (j) is independent of arsenite.



Scheme 1. The mode of action of lipoamide oxidoreductase [55, 72].

Savage [74] showed that the addition of NADH to lipoamide oxidoreductase alters the spectrum. The compound formed is stable and it appears to be analogous to flavin semiquinone [131] (see also [57, 113]). The absorption maximum at 530 mμ of the reduced enzyme disappears on addition of arsenite or cadmium ions. ESR-spectrometric investigations showed no free radicals in the reduced enzyme. The intramolecular electron transfer from enzyme dithiol to flavin proceeds *via* an intermediate with an absorption peak at about 530 mμ. An intermediate denoted as a "charge-transfer complex" or as the "red form" was studied by *Sanadi* et al. and also by *Massey* et al. [30, 52, 55, 58, 65, 66, 68, 69, 72, 113]. Its structure remains unidentified.

D. Studies on Modified Lipoic Acids [133]

No avitaminoses or metabolic alterations associated with lipoic acid deficiency have so far been recorded. Whether lipoic acid is an essential factor for higher organisms can be decided only by the use of lipoic acid antagonists. A lipoic acid-free diet can hardly be maintained, since the substance is widely distributed in foodstuffs and presumably is formed by the intestinal flora.

Several laboratories [134–137] have synthesized lipoic acid derivatives in which the carboxy group was altered and the number of ring members was varied. Only one of the diastereomers of 8-methyllipoic acid exhibited a detectable inhibitory effect on the growth of bacteria.

We have synthesized compounds resembling lipoic acid [138, 139a, 139b], to investigate whether the distance of four methyl groups between the carboxy group and the 1,2-dithiolane ring or the length of the (eight-membered) carbon chain is necessary for the action of lipoic acid. Accordingly lipoic acids with the CH_2 groups replaced by heteroatoms (S, O) and, in addition, an acid in which the ring was displaced toward the carboxy group were synthesized. Further, hydroxy groups and carbonyl oxygen were introduced into the ring or side-chain, since these substituents often give rise to antagonistic effects in biologically active substances. Table 2 gives a list of these compounds.

The growth of the following microorganisms depends on lipoic acid: *Tetrahymena pyriformis*, *Corynebacterium bovis*, *E. coli* mutants and lactic acid bacilli. For the growth of the first two organisms lipoic acid is an absolute requirement. In other bacteria (*Lactobacillus casei*, *L. arabinosis*, *S. lactis*, *S. faecalis R.*, *S. faecalis* 8043) lipoic acid reverses the inhibition of growth caused by substances such as propionate. In our studies we used *S. faecalis* 8043 the growth of which is inhibited by 1–3 mg/ml propionate but which starts to grow again after the addition of lipoic acid or some of its analogues (cf. Fig. 3). The rate of growth was determined by measuring the turbidity of a diluted sample of a culture with a Zeiss PMQ II spectrophotometer at 660 mμ [116].

I. Growth and Inhibition Studies on S. faecalis 8043 with Modified Lipoic Acids [116, 138, 139a, 139b]

The results of the growth test are shown in Fig. 3 [116]. Replacement of a CH_2 group in the chain between the carboxy group and the ring by an S-atom [3-thialipoic acid *(13)*] or an O-atom [4-oxalipoic acid *(10)*] leads to compounds which are either inactive or have a very weak activating effect on the growth of *S. faecalis* 8043.

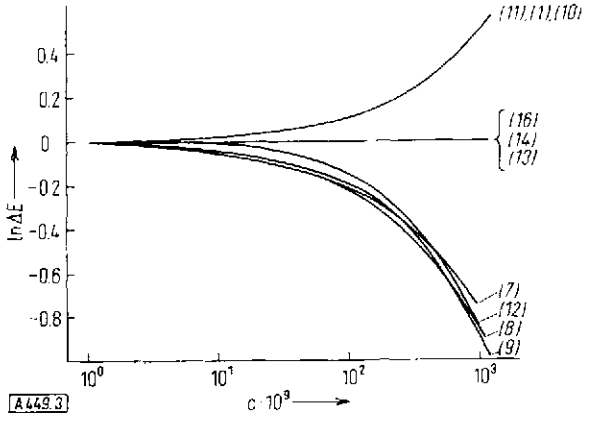

Fig. 3. Rate of growth of *S. faecalis* 8043 in the presence of modified lipoic acids [116].

Abscissa: Concentration of modified lipoic acid in 10^{-9} mole/l.

Ordinate: Natural logarithm of the change in extinction ΔE at 660 mμ in a given time relative to a standard solution containg no bacteria. The smoothed curves were normalized to ln E = 0 at c = 5×10^{-9}/6 mole/l. Compounds *(7)*, *(12)*, *(8)*, and *(9)* inhibit growth, *(16)*, *(14)*, and *(13)* have no effect, while *(11)* like lipoic acid *(1)* and 4-oxalipoic acid *(10)*, stimulates growth.

Introduction of a methyl group [4-methyllipoic acid *(12)*] at the CH_2-chain produces an inhibitory effect whereas introduction of a keto group [5-oxolipoic acid *(14)*] does not. Substitution on the ring carbons leads to compounds with inhibitory action, *e.g.* 7-methyllipoic acid *(7)*, 7-hydroxylipoic acid *(8)*, 7-oxolipoic acid *(9)*, and also the 8-methyllipoic acid synthesized by *Stockstad*. Alterations in ring size or in the position of the disulfide bridge [2,4-lipoic acid *(16)*] lead to loss of activity.

II. Inhibition and Substrate Specificity of Lipoamide Oxidoreductase [115, 138, 139a, 139b]

Since lipoamide oxidoreductase containing modified lipoic acids still reacts with free lipoic acid according to Equation (i), this enzyme is particularly suitable for the investigation of inhibition and substrate specificity. Michaelis constants, turnover numbers, and inhibition constants were determined by the method of *Massey* [53, 66, 71, 107] (see Table 2). 7-Methyllipoic acid *(7)* and 3-thialipoic acid *(13)* are the only acids which give rise to competitive inhibition of the reduction of lipoic acid. The inhibition constant for 7-methyllipoic acid was 2.8×10^{-3}, and that for 3-thialipoic acid 8.0×10^{-4}. The following conclusions may be drawn from the results:

2,4-Lipoic acid *(16)* is inert, *i.e.* it is unable to form an enzyme-substrate complex. Replacement of the carbon atoms 3 or 4 in lipoic acid by a hetero-atom leads to complete loss of activity in 3-thialipoic acid *(13)* and to reduced affinity in 4-oxalipoic acid *(10)*. The amide *(11)* of this latter acid is the only derivative of lipoic acid which has almost the same activity as lipoamide. 4-Methyl- *(12)* and 5-oxolipoic acid *(14)* have properties similar to those of 4-oxalipoic acid, *i.e.* both the reaction rate and enzyme affinity are reduced.

Substitution on C-7 produces varying effects. 7-Methyllipoic acid *(7)* is not transformed by lipoamide oxidoreductase but has an inhibitory effect, while 7-hydroxylipoic acid *(8)* is entirely inactive. 7-Oxolipoic acid *(9)* is transformed more rapidly than the physiological substrate, which indicates an activating effect of the carbonyl group on the S–S bridge. The amides of lipoic acid and 4-oxalipoic acids show high turnover numbers and relatively high Michaelis constants as does lipoylpyridoxamine *(6)* (see also [71, 107]). 2-Fluorolipoic acid *(15)* [117] exhibits no inhibitory action.

E. Further Reactions of Lipoic Acid

The main physiological function of lipoic acid appears to be its role as coenzyme during the oxidative decarboxylation of α-oxo acids. Oxidative splitting of diacetyl by *S. faecalis* requires the presence of lipoic acid in addition to that of TPP and Mg^{2+} [141]. Acetyldihydrolipoic acid is formed intermediately.

Calvin et al. [143–150] have discussed the participation of lipoic acid in photosynthesis. Studies on green algae with [^{35}S]-lipoic acid led to the characterization of several biologically active forms of the acid indicating its participation in the Hill reaction. However, other investigations produced conflicting results [151]. Some evidence for the participation of dihydrolipoic acid in the Hill reaction is provided by the arsenite sensitivity of the latter reaction, which is catalysed by chloroplast preparations from spinach leaves [152].

F. The Pharmacology of Lipoic Acid

The therapeutic use of lipoic acid in liver diseases has not so far given concordant results. The findings of a response of hepatic coma to lipoic acid have not been confirmed, but a beneficial effect on liver afflictions has been reported from numerous sources [153–159]. Many publications have described the protective and curative effect of lipoic acids in heavy-metal poisoning (As, Pb, Hg, Se, $Ni(CO)_4$). The effect produced is frequently superior to that of BAL [159a]. A similar beneficial effect has been reported in liver damage induced experimentally by CCl_4, allyl alcohol, and narcotics. The clinical testing of easily resorbed lipoic acid derivatives, *e.g. (6)* [140], which are readily incorporated into lipoic acid-containing enzymes, appears to be promising [140] (Lipoic acid: DL_{50} (mouse) 160–275 mg/kg intraperitoneally).

G. Reactivity, Ring Cleavage, and Ultraviolet Absorption of 1,2-Dithiolanes

The biological activity of lipoic acid depends on the great reactivity of the disulfide bond of the dithiolane ring. Earlier attempts to interpret this reactivity of (five-membered) 1,2-dithiolanes over the (six-membered) 1,2-dithianes and open-chain disulfides by the higher strain in the five-membered ring [160], and a calculation of the strain from the shift of the ultraviolet absorption towards longer wavelengths [161] were unsuccessful. The strain in the dithiolane ring is only 4–6 kcal/mole [162, 163]. Also, it is not permissible to use thermodynamic data, such as the energy content as expressed by the ring strain, to interpret kinetic factors (reactivity).

Such a relationship is found only in very simple cases, *e.g.* in unsubstituted 1,2-dithiolane and 1,2-dithiane. Here no mesomeric groups are present to influence the S–S bond and no deformation of the ring through steric interactions between substituents is possible, so that bathochromic shift and ring strain are predominantly determined by the interplanar angle. Even so, no quantitative relationship exists among reactivity, ring strain, and ultraviolet absorption.

I. Ring Strain in 1,2-Dithiolanes

The angle φ (Fig. 4) which the two R–S bonds form in strain-free open-chain disulfides is about 90° [164]. Under these conditions the repulsion between the lone p_Z-electron pairs of the sulfur atoms is at a minimum, and an interchange of these electrons with the free d-

levels of the neighboring sulfur atoms is possible to give the S–S bond a partial double bond character (p_π–d_π bonding) [165–167]. The energy required for rotation about the S–S bond, *i.e.* for a reduction of the interplanar angle from 90° to 0°, was found to be 3–14 kcal/mole [168–170]. Measurements by *Fehér* on disulfane seem to confirm the lower value of 3 kcal/mole [168].

It has not been resolved whether the bond between "normal" divalent sulfur atoms is formed by an overlap between pure p- or sp-hybridized orbitals. The bond length gives no indication of the nature of the bond since the "normal" length of the single S–S bond is unknown. In the case of disulfides with potentially mesomeric groups in the conjugated position with respect to the disulfide bridge (*e.g.* in aromatic disulfides), the electrons of the sulfur atoms are included in the mesomeric system. The homolysis of the S–S bond in aromatic disulfides depends on the polarity of the *p*-substituents on the benzene ring [171]. An increase in the electron donating character of the substituents leads to a more ready splitting of the S–S bond in diaryl sulfides by a radical mechanism.

Incorporation of the disulfide group into a carbocyclic ring without deformation of the interplanar angle of about 90° is possible only in large rings. With decreasing number of ring members (7 → 6 → 5) φ becomes smaller and hence the strain increases. For the 1,2-dithiolane ring φ is only about 27°. The double bond character of the S–S bond (p_π–d_π bonding) disappears and almost maximum repulsion of the p_z-electron occurs. In addition, the deformation and alteration of the bond angles at the carbon and sulfur atoms have an effect on the strain of the dithiolane ring.

From a determination of bond lengths and angles by X-ray analysis [173] of 1,2-dithiolane-4-carboxylic acid [172] a value of 16–26 kcal/mole was calculated for the strain energy [171a]. More recent thermochemical measurements have indicated a value of only 4 kcal/mole for unsubstituted dithiolane and a value of 3.5 kcal/mole for lipoic acid [162].

II. Ultraviolet Absorption of 1,2-Dithiolanes

In comparison to the open-chain disulfides, the ultraviolet absorption of 1,2-dithiolanes is strongly displaced toward longer wavelengths [161]. If there are no substituent effects, a simple relationship can be recognized between the ultraviolet absorption of cyclic disulfides and their interplanar angle φ. The interplanar angle diminishes with decreasing size of the ring and the ultraviolet absorption is displaced toward longer wavelengths with a simultaneous fall in the molar extinction (six-membered ring: φ = 60° [172], λ_{max} = 286 mμ: five-membered ring: φ = 27° [172], λ_{max} = 330 mμ). By incorporation into polycyclic systems [172a] the dithiolane ring can be flattened with a further shift of the absorption peak [174] towards longer wavelengths. Tetramethylation at C-3 and C-5 has a bathochromic effect [175, 175a].

Polar and potentially mesomeric substituents have an appreciable effect on the UV absorption of the dithiolane ring. Electron attracting groups are weakly hypsochromic [176]. Carbonyl groups in the neighborhood of the sulfur atoms displace the absorption peaks towards shorter wavelengths. According to *Bergson* [177], however, it is not the absorption of the S–S chromophore which is observed here, but the absorption of the carbonyl group which is disturbed by the S atoms (Table 3).

Table 3. Ultraviolet absorption of organic disulfides.

Disulfide	λ_{max} [mμ]
Dimethyl disulfide	255
Di-t-butyl disulfide	*ca.* 230
1,2-Dithiolane	330
3-Aminomethyl-1,2-dithiolane hydrochloride	322
3,3,5,5-Tetramethyldithiolane	358
1,2-Dithiolane-3-carboxylic acid	280
1,2-Dithiolane-3,5-dicarboxylic acid	250

7-Hydroxylipoic acid *(8)*	340
5-Oxolipoic acid *(14)*	312

In his study of the electronic spectra of aliphatic disulfides, *Bergson* [178] considers the S–S chromophore as an isolated π-electron system and its excitation as a transition from a nonbonding π(3pπ) level to a nonbonding σ(σ3p) level (Fig. 5).

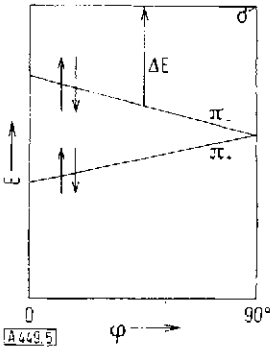

Fig. 5. Dependence of excitation energy ΔE on the interplanar angle φ in the electronic spectra of aliphatic disulfides [178].

[175a] It is not clear whether this effect is produced by the inductive effect of the methyl groups on the S–S bond or whether it is a consequence of the flattening of the ring brought about by steric hindrance between the methyl groups. Disubstitution of adjacent carbon atoms by alkyl or hydroxy groups can likewise produce displacement of the absorption peak when the substituents produce flattening of the ring due to steric hindrance. (7-hydroxylipoic acid: λ_{max} = 340.5 mμ; 7-methyllipoic acid: λ_{max} = 350 mμ).

Because of the different symmetries of the π- and σ-levels with respect to the S–S bond axis, the energy of the ground-state but not that of the excited state must depend on the interplanar angle φ. The result is the angle-dependence of the excitation energy ΔE (Fig. 5).

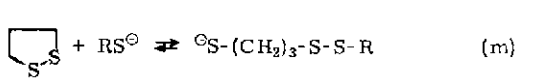
III. The Reactivity of 1,2-Dithiolanes

The fact that 1,2-dithiolanes are more reactive at the S–S bond than open-chain disulfides becomes apparent in radical, electrophilic, and nucleophilic reactions:

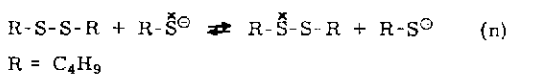
Polymerization to linear disulfides is characteristic of 1,2-dithiolanes. Therefore, solutions of unsubstituted 1,2-dithiolane can be kept only for short periods. The low activation energy (8.6 kcal/mole) [161] and the low collision rate for the thermal polymerization of 1,2-dithiolane in iso-octane point to a free-radical chain mechanism. Opening of the S–S bond by cyanopropyl radicals is much faster in dithiolanes than in dithianes, but the latter still react more rapidly than open-chain disulfides [171].

Electrophilic persulfate oxidation to thiosulfinates does not succeed in the case of open-chain disulfides and (seven-membered) dithiepanes. Dithianes react slowly and dithiolanes most rapidly [161]. Hence the electrophilic attack of the oxidizing agent on a pair of p_z-electrons of one of the S-atoms of the disulfide group proceeds all the more rapidly (the activation energy decreases) the less the electrons participate in the π-electron system of the S–S bond. This participation of the p_z-electrons diminishes as the interplanar angle φ decreases (*i.e.* falls in the order open-chain > seven-membered ring > six-membered ring > five-membered ring disulfides). In addition a bimolecular reaction on a relatively rigid ring has lower entropy of activation than a reaction on a flexible chain. The increase in the rate of electrophilic attack on the disulfide bond on passing from open-chain disulfides to the dithiolane ring *via* dithiepane and dithiane is thus caused by a decrease in activation energy and activation entropy. Hence the interplanar angle (ring strain) and the reactivity of the disulfide group towards electrophilic and radical reagents alter analogously.

Nucleophilic reactions at the sulfur atoms in cyclic disulfides have received little attention in the past. Activation energies for the reaction of 1,2-dithiolane [13 kcal/mole; Equation (m)] and of dibutyl disulfide [14.45 kcal/mole; Equation (n)] with butanethiolate differ only slightly [163] and the difference found may be within the experimental error (the Arrhenius curve of Reaction (m) is not linear).



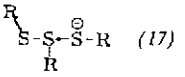
(m)



(n)

R = C_4H_9

The rate of Reaction (m) is almost 10^4 times greater than that of Reaction (n). This must be caused mainly by a much lower activation entropy in the case of Reaction (m). In the transition state *(17)* of the nucleophilic opening of a disulfide ring by a thiolate the three sulfur atoms lie in a straight line, and the two sulfur-sulfur distances are equal; the valence angle at the attacked sulfur atom is decreased to 90° and the bond to be opened is lengthened.



(17)

The ground state of 1,2-dithiolane (valence angle at the S atom: 92°; S–S bond length: 2.1 Å) is therefore much more similar geometrically to the transition state than is the ground state of an open-chain disulfide (valence angle at S: 107°; S–S distance: 2.05 Å). The transition state is therefore reached with greater ease from the 1,2-dithiolane ground state than from that of the open-chain disulfide. The somewhat greater S–S distance in the cyclic disulfide possibly explains the somewhat lower activation energy of Reaction (m) [178a].

Molecular models show that the formation of an analogous transition state in dithianes is much more difficult. It is accompanied by an appreciable deformation of the C–C valence angles and the elimination of the staggered ground-state arrangement of the CH_2 groups. Not surprisingly, sensitive dithianes are therefore less sensitive towards nucleophilic cyanide splitting than are dithiolanes and open-chain disulfides [179].

H. Recent Lipoic Acid Syntheses [180]

Numerous routes lead to octanoic acids carrying halogen, hydroxy, or other groups on the carbon atoms 6 and 8. Treatment of these with HI/thiourea [181], with sodium disulfide [182a, 182b], thiocyanate [182b], thiosulfate [182b], or thioacetate [182b] leads to the formation of lipoic or dihydrolipoic acid. The lengthening of the carbon chain from heptanoic acids by means of the Prins reaction [183] or by acylation of ketones and enamines, *e.g.* by reaction of cyclopentenylpyrrolidine

[178a] *R. E. Davis*, J. Amer. chem. Soc. *85*, 3050 (1963), has pointed out the general relationship between the S–S bond length (which varies between 1.97 and 2.2 Å) and the activation energy of the nucleophilic S–S bond opening. For many compounds the activation energy for the cyanide splitting is given by $E_a = 99.9/r^3$ [kcal/mole] and for the sulfite splitting by $E_a = 110/r^3$ [kcal/mole].

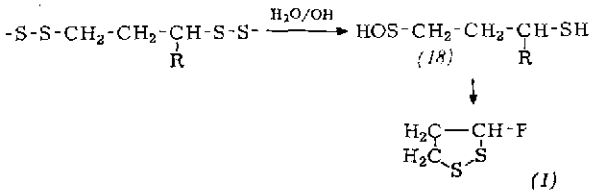
with β-butoxypropionyl chloride [184], cannot compete on a technical scale with the synthesis by addition of ethyl adipate chloride to ethylene to form the 8-chloro-6-oxooctanoate [185]. After elimination of HCl to form 6-oxo-7-octenoic acid, dihydrolipoic acid is obtained directly by treatment with H_2S/H_2 in the presence of MoS_x under vigorous conditions [186]. However, it appears to be difficult to perform this reaction on a large scale. Reduction of the 8-chloro-6-oxo-octanoate with $NaBH_4$ to form the 6-hydroxy compound proceeds particularly readily. The latter is converted into lipoic acid *via* 6,8-dichloro-octanoic acid [187]. Addition of alcohol or carboxylic acids to 6-oxo-7-octenoic acid and catalytic hydrogenation to form ethers or esters of 6,8-dihydroxyoctanoic acid, which can be readily transformed into lipoic acid, have been described [188].

Advantages for the large-scale manufacture are provided by the addition of ethyl adipate chloride to acetylene and treatment of the reaction product with alcohol to form 8,8-dialkoxy-6-oxo-octanoic acid. This compound is then hydrogenated to form 8-alkoxy-6-hydroxy-octanoic acid, whose esters or lactones readily yield dihydrolipoic acid on treatment with HI/thiourea [189].



Almost all these syntheses proceed *via* dihydrolipoic acid. This compound can be oxidized to form lipoic acid with I_2 or $FeCl_3$, or better catalytically with air/$FeCl_3$ [185]. Varying amounts of polymeric disulfides are obtained as by-products, and, provided the molecular weight is not too high, can be thermally depolymerized *in vacuo*. Suprisingly, aqueous solutions of the alkali metal salts of polymeric lipoic acids are depolymerized by small quantities of alkali [190]. Possibly this reaction proceeds *via* a mercaptosulfenic acid *(18)* to lipoic acid.

The Use of Electron Paramagnetic Resonance in Organic Chemistry

BY DR. F. SCHNEIDER, DIPL.-PHYS. K. MÖBIUS, AND DIPL.-PHYS. M. PLATO

AEG-FORSCHUNGSINSTITUT, BERLIN-REINICKENDORF

The more recent applications of electron paramagnetic resonance (EPR) to organic chemistry include the investigation of triplet states, donor-acceptor complexes, short-lived free-radical intermediates, and reaction kinetics. The principles of the theoretical calculations required to obtain the maximum information from EPR spectra are outlined for free radicals containing π-electron systems. EPR intensities, line widths, hyperfine splitting, and g factors permit the determination of free-radical yields, ionic charges, rotation frequencies in rotamers, electron density distributions, electronegativities, intramolecular torsion angles, solvent effects (resulting from hydrogen bonding), and π-orbital energies. -- The production of free radicals with the aid of initiation reactions in flow systems, by irradiation, and by electrolysis seems particularly promising.

I. Introduction

Absorption spectroscopy has always enjoyed an important position among the physical methods used in analytical chemistry. In addition to the classical ultraviolet and infrared absorption spectroscopy, electron paramagnetic resonance (EPR) and nuclear magnetic resonance (NMR) spectroscopy have also become important in recent years. However, electron paramagnetic resonance (EPR) spectroscopy [*] has not yet become so widely used as infrared and nuclear magnetic resonance spectroscopy. There are two reasons for this: infrared and nuclear magnetic resonance spectroscopy are more widely applicable, and the spectra can be identified by

[*] The frequently used abbreviation ESR (electron-spin resonance) is less general than EPR, since the former does not take into account orbital magnetism.

comparison with those of known substances. The individual lines or bands of these spectra are characteristic of certain groups of atoms, so that the spectra of complex molecules can be built up from those of simpler compounds. It has been possible, therefore, to compile collections of infrared and nuclear magnetic resonance spectra, which allow an empirical evaluation by a routine procedure.

EPR spectra, on the other hand, are obtainable only for paramagnetic substances containing unpaired electrons, and the form of the spectrum depends on the structure of the molecule as a whole. Therefore the EPR spectrum of each substance must be analysed individually. It is however now possible to prepare paramagnetic modifications of a large variety of compounds [1] (see Section III), and the theory relating the experimental results to molecular properties has been perfected.

At this stage, we shall give only enough of the theory of electron paramagnetic resonance to enable the reader to understand the first few sections (the theory will be discussed in more detail in Section IV). We start with *Bohr*'s model of the atom, in which the electrons circle the atomic nucleus in definite orbits, while spinning at the same time about their own axes. The orbital motion and the spin give rise to circular electric currents, which produce a magnetic field. The electron is therefore associated with a magnetic moment μ, due partly to the orbital angular momentum and partly to the spin, the two components being combined vectorially.

If an atom is subjected to an external magnetic field H, the total energy of the atom changes by an amount equal to the potential energy of the magnetic dipole in the field H, which depends on the angle between H and μ. Owing to space quantization, only certain discrete angles are possible, so that the original energy level E_0 is split in the magnetic field into discrete levels in accordance with Equation (1) (g is the spectroscopic splitting factor, μ_B is the Bohr magneton, and m_s is the magnetic spin quantum number [*].

$$E_s = E_0 + g\mu_B m_s H \qquad (1)$$

For magnetic fields of about 3000 oersted, which are easily attained, the energy difference $\Delta E = g\mu_B H$ between two adjacent orientations of the magnetic moment is equal to the energy of a microwave quantum with $\nu_0 \simeq 9000$ Mc/s. Transitions between the various energy levels are induced when the atom is irradiated in a magnetic field H_0 with microwaves having a frequency ν_0 given by the resonance condition (2). These transitions are governed by the selection rule $\Delta m_s = \pm 1$, *i.e.* there

$$h\nu_0 = g\mu_B H_0 \qquad (2)$$

can be transitions from a higher to a lower energy level, with emission of energy, as well as from a lower to a higher level, with absorption of energy. Since there are more atoms in the lower energy states, the net result is absorption, referred to as electron paramagnetic resonance. Owing to the interaction of the unpaired electrons in an atom with one another (fine splitting) or with the magnetic moments of neighboring nuclei (hyperfine splitting), EPR spectra can contain a very large number of lines.

EPR spectra are interpreted in three steps. The quantities that characterize the spectrum are first found from the recorded curves; these quantities are the width ΔH, the form f(H), and the number n and relative amplitudes A_i of the individual lines, as well as the field strength H_0 at the center of the spectrum and the distances δH_i between the lines. In the second step these quantities are used to determine the g factor, spin densities, the concentration of free radicals, and relaxation times [1a]. Finally, the quantities derived in the second step are used to obtain information about molecular structure and the course of chemical reactions. The hyperfine structure of the spectrum, for example, permits a very accurate determination of the orbital distribution of the unpaired electron, and hence of the reactivities of the various positions in the molecule. Information about the structure of the molecule can be obtained from the number of lines and their relative intensities. The frequencies of the internal rotations of parts of the molecule can be found from the dependence of the spectra on the temperature. Finally, various details of the spectra offer information regarding the planarity of the molecules, the electronegativities and torsion angles of substituents, the orbital energies of the π-electrons, and the positions of the energy terms of the molecule (cf. Section V).

II. EPR Spectrometers

The EPR spectra of organic radicals always give a g factor of approximately 2; the absorption lines are from 17 milli-oersted to about 3 oersted wide, and are often very weak. The recording instruments used must therefore combine high sensitivity with high resolving power. In all commercially available EPR instruments, the sample is irradiated with microwaves of frequency ν_0, while being exposed to a magnetic field H which varies linearly with time. The microwave energy absorbed when H is equal to the field strength given by the resonance condition (2) is measured. To obtain increased sensitivity, an alternating field $H_1 \cos 2\pi\nu_1 t$, the amplitude of which is small in comparison with the width of the absorption line, is superimposed on the field H. The magnitude of the resulting signal is proportional not to the height of the absorption curve, but to its slope; consequently the recorded curve is not the absorption curve itself, but its derivative.

Spectrometers with $\nu_0 \simeq 9000$ Mc/s (X band), $\nu_1 \simeq 100$ Kc/s, and magnets with pole diameters of 12 to 30 cm have proved useful for the study of organic radicals [*]. With good EPR equipment, it is possible to detect 2×10^{11} unpaired spins at a line-width of 1 oersted [2]. For a mean effective

[1] This is shown, for example, in a collection of spectra started in 1962, which already contains 1200 articles on EPR spectroscopy: NMR, NQR, and EPR Literature Service: Butterworth, London, and Verlag Chemie, Weinheim/Bergstr.

[*] The orbital angular momentum is assumed to be quenched, since this is the case for most free radicals. Small residual contributions of orbital magnetism are taken into account by the factor g.

[1a] *F. Schneider* and *K. Möbius*, Z. Naturforsch. *18b*, 1111 (1963).

[*] The larger magnets do not give increased sensitivity or resolving power. They are used only when more room is required between the pole shoes of the magnet, as for simultaneous optical measurements.

[2] Instruments of this kind are marketed *e.g.* by AEG (Germany), Decca (U.K.), and Varian (U.S.A.).

sample volume of 0.1 ml, therefore, free radicals can be detected at concentrations as low as 10^{-8} to 10^{-9} mole/l, except when polar solvents such as water are used [3]. The resolving power $H_0/\Delta H$ is about 10^5, *i.e.* about 30 milli-oersted. Since the EPR spectra of organic radicals have total widths of about 30 to 50 oersted, the maximum number of resolvable lines is about 1000.

The temperature of the sample in commercial spectrometers can be varied between −170 and +300 °C [4], and auxiliary equipment is available for working at the temperature of liquid helium. For the investigation of short-lived radicals, *Stone* and *Waters* [5] developed a mixing technique that permits the detection of radicals with lifetimes of only 1 msec. Short-lived ion-radicals are produced in an electrolytic cell in the resonator itself [5a]. The instruments can be used to the best advantage only if all factors that lead to broadening of the lines are eliminated, and it is particularly important to ensure that all solutions are free from oxygen [6, 7].

III. The Generation of Free Radicals and the Application of EPR Spectroscopy

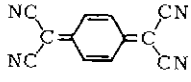
1. Stable Radicals

A general survey of EPR studies on free radicals containing π-electron systems can be obtained from publications by *Ingram* [8], *Blois* [9], *Symons* [10], *Adams* [11], *Kivelson* [12], and *Foster* [13].

Notable advances have recently been made in the EPR investigation of triplet states, particularly in connection with donor-acceptor complexes. In triplet state molecules, two electron spins are coupled to give a resultant spin of S = 1, whereas in biradicals such as those derived from *p*-substituted polyphenyls, the two unpaired electrons are so far apart that interaction between them is very weak, and the spins orient themselves independently of each other in the magnetic field.

Owing to the strong spin-orbital interaction of the two electron spins in triplet states, the energy levels are split even in the absence of a magnetic field, so that the levels $m_s = \pm 1$ are separated from the level $m_s = 0$. As a result of this zero-field splitting the two fine-structure lines due to EPR transitions $\Delta m_s = \pm 1$ are strongly anisotropic, and often can be observed only in oriented triplet molecules built into host single crystals [14]. The fine-structure lines are greatly broadened in solutions or glasses, and have so far only rarely been observed [15]. However, triplet states can also be detected in randomly oriented molecules by transitions in which $\Delta m_s = \pm 2$, which occur at half values of the magnetic field (double g factor) [16]. Although weaker in intensity, these transitions are relatively isotropic, since they do not involve the level $m_s = 0$. This technique, which does not require the use of host single crystals, has already been used for the EPR-spectroscopic investigation of excited triplet states in phosphorescent hydrocarbons [17]. However, the triplet ground state of methylenes and nitrenes has also been confirmed by EPR measurements, *e.g.* on diphenylmethylene and phenylnitrene ($C_6H_5-\dot{N}:$) [15].

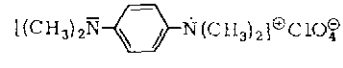
An interesting conversion between singlet, doublet, and triplet states is shown by solid organic charge-transfer complexes which often have the character of ion-radical salts. These complexes are formed from strong electron



(1)

acceptors (A), such as 3,6-bis-(dicyanomethylene)-1,4-cyclohexadiene *(1)* or tetracyanoethylene, and electron donors (D) such as $(C_6H_5)_3PCH_3$, $(C_6H_5)_3AsCH_3$, or Cs [17a].

The magnetic properties of these complexes change from doublet paramagnetism (S = 1/2), through triplet paramagnetism (S = 1), to diamagnetism (S = 0) when the temperature is decreased from about 400 °K, through 200 °K, to only a few °K; at the same time, the electrical conductivity falls from semiconductor values to insulator values. The ion-radical salts of the paramagnetic *N,N,N',N'*-tetramethyl-*p*-phenylenediamine cation, such as Wursters Blue perchlorate *(2)*, are also representatives of these donor-acceptor complexes [18].



(2)

In the case of strong donors and acceptors, electron transfer takes place, so that the structure D^+A^- contributes to the ground state, and paramagnetic properties are to be expected even in the complexes of diamagnetic components A and D. EPR measurements by *Chestnut* and *Phillips* [19] indicate that the radical ions are so close together in the DA crystals that the spins of the unpaired electrons couple in pairs. The temperature-dependence of the EPR signal intensity shows that the ground state of the DA complex is a singlet, and that the triplet state can be excited simply by

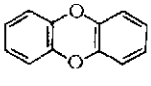
heating. Thus the radical ions dimerize in the ground state. The thermally excitable triplet states are identified by transitions in which $\Delta m_s = \pm 1$ and $\Delta m_s = \pm 2$. In solvents with sufficiently high dielectric constants, the strong DA complexes dissociate into free ion-radicals [20].

2. Unstable Radicals

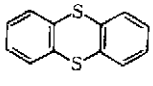
The odd alternant hydrocarbons, such as triphenylmethyl, possess an odd number of π-electrons even in the neutral state, and are therefore paramagnetic. In even alternant hydrocarbons, on the other hand, the spins of the π-electrons are all paired in the neutral state; paramagnetic radical-ions can, however, be produced by the insertion or withdrawal of an electron without appreciably affecting the structure of the molecule [*].

"Free" solvated radical ions are best produced by electrolysis in aprotic solvents of high dielectric constant such as acetonitrile and dimethylformamide [7,21], in which the electron distribution is not affected by solvent effects or by the counter-ion. This method has been used to produce radical ions from unsubstituted hydrocarbons [21], heterocyclic compounds [22–24], quinones, phenols, and carbonyl, nitro, methyl, and amino compounds [25–32] for EPR-spectroscopic investigation. Radical-trianions have even been produced from tetracene and pentacene by electrolysis, and identified by EPR spectroscopy [33].

Radical cations of π-electron systems are usually obtained by dissolving the substances in concentrated sulfuric acid. This often leads to protonation of the aromatic compounds, but radical cations can also be produced by electron withdrawal from many condensed aromatic hydrocarbons such as anthracene, and from condensed heterocyclic compounds such as dibenzo-*p*-dioxin *(3)* [34] or thianthrene *(4)* [24], particularly if oxidizing agents such as H_2O_2 or SO_5^{2-} are added to the sulfuric acid. In nitrogen heterocycles such as pyrazine or phenazine, both nitrogen atoms are protonated in acidic media, with formation of diamagnetic dications. Reduction of these dications with $Na_2S_2O_4$ leads to the introduction of electrons to form radical ions carrying a single positive charge. Radical cations are also obtained from aliphatic and aromatic compounds by electron withdrawal when the solutions contain Lewis acids such as aluminum trichloride or antimony pentachloride [24,35,36].

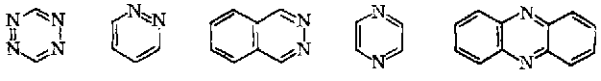


(3)



(4)

Radical-anions containing π-electron systems are usually obtained by the reduction of neutral molecules with alkali metals in dimethoxyethane or tetrahydrofuran. Owing to the low dielectric constants of these solvents, the radical-anions and alkali metal cations are often present as ion pairs at room temperature. Using the small lithium atom, however, the EPR spectra of "free" solvated radical anions, *e.g.* the anions of polyphenyls and polyacenes [37–40], and of their methyl, nitro, cyano, and carbonyl derivatives [41–44], can also be observed at low temperatures. The cyclopropane radical-anion [45], the tropyl and cyclooctatetraenyl radicals [46,47], and the radical-anions of polyazines [*e.g. (5a)–(5e)*] [48,49], phenothiazines *(6)* [50], and cy-



(5a) *(5b)* *(5c)* *(5d)* *(5e)*

[*] Alternant hydrocarbons contain two classes of C-atoms, starred (*) and unstarred (o). Each C-atom of one class possesses only neighbors of the other class. In even alternant hydrocarbons, the number of starred C-atoms is equal to the number of unstarred C-atoms. The odd alternant hydrocarbons contain one extra carbon atom, which is assigned to the starred class.

clazines such as *(7)* [51] have also been obtained with alkali metals. Aromatic free radicals can be obtained in tetrahydrofuran by the addition of butyl-lithium to the solution [52] or by reduction with sodium dithionite in basic media [53] [*]. Radical-anions have been produced from aromatic nitro compounds and ketones by reduction with zinc or glucose in alkaline alcoholic or aqueous solutions [54]. EPR measurements have also been carried out on radical-anions of aromatic hydrocarbons and heterocyclic compounds produced by the action of alkali or alkaline earth metals in liquid ammonia [55].

Using the redox system $TiCl_3 + H_2O_2$, short-lived radicals of organic substances can be produced *via* the radicals $\cdot OH$ and $\cdot O_2H$ [56]. In this way it has been possible, using flow systems in which the solutions are mixed in the microwave resonator itself, to carry out EPR investigations on short-lived radicals, produced during the oxidation of alcohols or during the polymerization of *e.g.* acrylic acid [57]. Many short-lived aryloxy and arylamino radicals, which are formed during the oxidation of phenols or aromatic amines in aqueous solution by cerium(IV) sulfate in sulfuric acid, have been studied with the aid of an EPR mixing chamber [5, 58]. The hydrazine radical-ion $N_2H_4^+$, which is formed on oxidation of hydrazine with cerium(IV) ions, has recently been identified by the flow method [59].

We shall mention only a few of the physical methods of producing free radicals. The pyrolysis of dinaphthyl and diphenyl disulfides leads to the formation of arylsulfenyl radicals Ar–S· [60]; the cyclopentadienyl radical is formed during the pyrolysis of dicyclopentadienyliron (ferrocene) or azo- and hydrazobenzene [61]. Free radicals have been produced by ultraviolet irradiation of solutions of nitrobenzenes [54, 62], nitromethanes [63], benzophenones [54, 64], and the methyl, ethyl, and benzyl derivatives of diquaternary bipyridyl [65], and identified by EPR spectroscopy. EPR measurements on γ-irradiated substances have been mainly confined to high-polymeric plastics such as polyethylene [66, 67] and polypropylene [68]; the identification of the radicals formed was facilitated by the anisotropy of the hyperfine structure of samples oriented by stretching. Free radicals have been produced by the irradiation of oriented polyethylenes [69] and vinyl polymers [70] with electrons, and the kinetics of their recombination were studied. EPR measurements have also been carried out on amino acids irradiated with 1 MeV electrons [71]. The radical produced by the irradiation of benzene with electrons at 77 °K has been identified by EPR measurements as the odd alternant hydrocarbon cyclohexadienyl [72].

Fessenden and *Schuler* [73] have carried out EPR investigations on the structure and reaction kinetics of 21 dissolved alkyl and cycloalkyl radicals as well as on vinyl, methylvinyl, butenyl, allyl, and cyclohexadienyl radicals produced by irradiation with 2.8 MeV electrons.

IV. The Theory of Electron Paramagnetic Resonance

1. Hyperfine Structure

The analysis of EPR hyperfine structure spectra of π-electron radicals is particularly important in organic chemistry. The hyperfine structure of an electron-resonance line is due to interaction between the magnetic momenhet of t unpaired electron and the magnetic moments of neighboring atomic nuclei. The theory of this interaction was developed by *Fermi* [74] and by *Abragam* and *Pryce* [75]. It is necessary to differentiate between anisotropic and isotropic hyperfine interactions. The anisotropic interaction gives a hyperfine structure that depends on the orientation of an axis of the molecule with respect to the external magnetic field [76]. The

[*] Butyl-lithium exists in tetrahydrofuran as the ion pair $C_4H_9^-Li^+$. The butyl anion supplies the electrons for the reduction, being itself converted into octane. In the case of pyrene (R), for example, the redox reaction in which the radical-anion (R^-) is formed by uptake of an electron is as follows:

$$2\ C_4H_9^- \rightarrow C_8H_{18} + 2e$$
$$2\ R + 2e \rightarrow 2\ R^-$$
$$2\ C_4H_9^- + 2\ R \rightarrow 2\ R^- + C_8H_{18}$$

Depending on the temperature, R^- associates more or less strongly with Li^+.

hyperfine splitting due to isotropic interaction, on the other hand, is independent of orientation, and is proportional to the unpaired spin density $|\psi(K)^2$ at the position of the nucleus in question, as given by Eq. (3)

$$a = \frac{8\pi}{3} \frac{|\mu_K|}{I} |\psi(K)|^2 \qquad (3)$$

where μ_K is the magnetic moment and I the total spin quantum number of the nucleus.

The anisotropic hyperfine structure is studied by recording the spectra of radicals in single crystals as a function of the orientation of the crystal axes with respect to the magnetic field [77]. In polycrystalline samples, a statistical average is taken over the hyperfine structure lines. This leads to distortion of the lines to an extent depending on the ratio of the anisotropic interaction. Nevertheless, it is often possible to determine all the isotropic and anisotropic hyperfine structure constants by accurate analysis of the line form [76, 78–84]. Most hyperfine structure investigations on π-electron radicals, however, are carried out in solution. The rotational frequency of the molecules is greater than the frequency of the anisotropic hyperfine interaction, so that, on a time average, only the isotropic hyperfine interaction contributes to the splitting. The positions of the individual components of the spectra obtained for N nuclei are:

$$H_{res}(m_{I_1}, m_{I_2}, \cdots m_{I_N}) = H_0 + a_1 m_{I_1} + a_2 m_{I_2} + \cdots + a_N m_{I_N} \qquad (4)$$

where

$$m_{I_i} = -I_i, -I_i + 1, \cdots + I_i, \; i = 1, \cdots N .$$

In Eq. (4), H_0 is the field strength in the center of the spectrum, a_i is the isotropic splitting constant of the i-th nucleus as given by Eq. (3), and I_i is the total spin of the i-th nucleus (*e.g.* for protons, I = 1/2). The individual m_{I_i} values correspond to the $2I_i + 1$ equally probable orientations of the magnetic dipole of a nucleus with respect to the external field (EPR selection rule: $\Delta m_I = 0$ for a strong field $H_0 \gg a$).

Analysis of the observed spectrum on the basis of Eq. (3) and (4) [1a] gives the unpaired spin densities $|\psi(K_i)|^2$ for all the atomic nuclei in the molecule that make a measurable contribution to the hyperfine splitting. *McConnell* [85] and *Jarrett* [86] have shown that the spin density $|\psi(P)^2$ on a ring proton of an aromatic ring system, and hence also its isotropic splitting factor a_i [in accordance with Eq. (5)], is

$$a_i^H = Q \cdot \rho_i^\pi \qquad (5)$$

proportional to the π-electron spin density ρ^π on the adjacent carbon atom. The proportionality constant Q is about 28 oersted [*]. According to *Colpa* and *Bolton* [87] the effect of an excess charge ε_i^π on the i-th carbon atom of a radical-ion is taken into account by an equation of the form (6) (for values of Q and K, see

$$a_i^H = (Q + K \cdot \varepsilon_i^\pi)\rho_i^\pi \qquad (6)$$

Table 1). Considerable changes in the Q factor can, however, also arise through changes in the hybridization of the atomic orbitals of the C atom in question as a result of steric disturbances [88].

In addition to the hyperfine structure due to protons, hyperfine structure lines due to the isotope ^{13}C (natural abundance about 1 %) have also been observed in the spectra of many organic radicals [89, 90]. In the case of the stable paramagnetic $[NO(SO_3)_2]^{2-}$ ion, in addition to the familiar triplet splitting due to the ^{14}N nucleus (abundance 99.64 %, nuclear spin I = 1), it has also been possible to observe doublet splitting due to ^{15}N-nuclei (abundance 0.34 %, I = 1/2) and quartet splitting due to the sulfur isotope ^{33}S (abundance 0.74 %, I = 3/2) [91].

2. Calculation of π-Electron Spin Densities

π-Electron spin densities can be calculated from measured isotropic splitting constants with the aid of Eq. (5) or (6). A comparison of these "experimental" spin densities with theoretical values not only permits identification of the radical under examination, but also provides information regarding its structure and symmetry properties (deviation from planarity, rotational isomerism, *etc.*). For this reason we shall now give a brief description of the usual methods [92, 93] of calculating theoretical spin densities.

a) The LCAO–MO – Hückel Approximation (HMO Method)

The π-system is treated separately from the σ-system. The π-electrons move in molecular orbitals ψ_j (MO), which can be represented as linear combinations (7) of

[92] *A. Streitwieser jr.*: Molecular Orbital Theory. Wiley, New York 1961.

the atomic orbitals φ_r (AO) of the n carbon $2p_z$ atomic orbitals.

$$\psi_j = c_{j1}\varphi_1 + c_{j2}\varphi_2 + \cdots + c_{jn}\varphi_n \tag{7}$$

The probability of finding a π-electron in the j-th molecular orbital at the r-th C-atom is given by the square of the orbital coefficient c_{jr}. The c_{jr} values are determined such that the total energy of the π-system is a minimum. Neglecting explicit π-electron interactions (Coulomb and exchange interactions) and overlap of the atomic orbitals, this leads to a homogeneous set of equations of the form

$$\begin{aligned} &c_{j1}(\alpha_1 - E_j) + c_{j2}\beta_{12} + \cdots + c_{jn}\beta_{1n} = 0 \\ &\vdots \\ &c_{j1}\beta_{n1} \quad + c_{j2}\beta_{n2} + \cdots\cdots c_{jn}(\alpha_n - E_j) = 0, \end{aligned} \tag{8}$$

in which E_j is the energy of a π-electron in the j-th molecular orbital, α_r is the Coulomb integral (a measure of the electronegativity), and β_{rs} is the bond integral (resonance energy) between the C-atoms (or heteroatoms) in positions r and s. For unsaturated hydrocarbons all the α_r values are assumed to be equal ($a_r = \alpha$). The bond integral β_{rs} is assumed to differ from zero only in the case of bonds between adjacent C-atoms, and is then also assumed to be the same everywhere ($\beta_{rs} = \beta$). The energy E_j can then be represented by

$$E_j = \alpha + m_j\beta \tag{9}$$

and the set of equations (8) simplifies to

$$\begin{aligned} &-c_{j1}m_j + c_{j2}\beta_{12}/\beta + \cdots + c_{jn}\beta_{1n}/\beta = 0 \\ &\vdots \\ &c_{j1}\beta_{n1}/\beta + \cdots\cdots\cdots -c_{jn}m_j = 0. \end{aligned} \tag{10}$$

This set of equations no longer contains the undetermined quantities α and β (β_{rs}/β is equal to either one or zero). For complex systems ($n > 10$), it is desirable to use an electronic computer to solve the equations [92] [*].

After all m_j and c_{jr} values ($j, r = 1, \ldots n$) have been calculated, it is still necessary to arrange the electrons correctly in the various energy levels. The arrangement must obey the aufbau principle (including the Pauli principle), according to which the molecular orbitals are filled in order of increasing energy (*i.e.* decreasing m_j value), each orbital accommodating two electrons with opposite spins. The number M of electrons to be accommodated depends on the number of C-atoms (or heteroatoms) and on the charge of the molecule: M = n + ionic charge (see Fig. 1). An unpaired π-electron is thus placed in a certain level with $m_j = m_o$. The unpaired spin density ρ_r^π on the various C-atoms (*i.e.* the probability of finding the unpaired electron on each C-atom) is given directly by the squares of the corresponding c_{or} values (after normalization to $\sum_r c^2_{or} = 1$), as shown in Eq. (11).

$$\rho_r^\pi = c^2_{or} \tag{11}$$

[*] Computer programs in FORTRAN can be obtained from the authors.

[93] *A. D. McLachlan*, Molecular Physics *3*, 233 (1960).

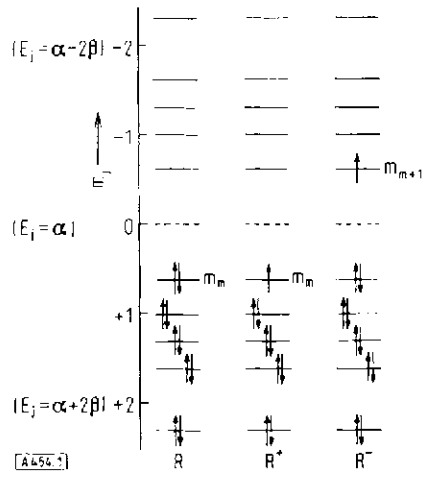

Fig. 1. Arrangement of the π-orbital energy levels and insertion of the π-electrons in naphthalene (10 carbon atoms).

Two or more energy levels (m_j values) often coincide; in these cases, the electrons are inserted in accordance with Hund's rule of maximum spin multiplicity.

It is important for the application of electron paramagnetic resonance to neutral or charged hydrocarbon radicals to differentiate between non-alternant and alternant hydrocarbons. In an even alternant hydrocarbon, the m_j values go in pairs with opposite signs: $m_j = \pm m_1, \pm m_2, \ldots$ The energy levels are therefore symmetrically distributed about the level with $m_j = 0$ ($E_j = \alpha$). The atomic orbital coefficients c_{jr} for $+m_j$ agree, apart from a change of sign on starred positions, with the orbital coefficients for $-m_j$ (pairing theorem [94]). Since, on the basis of the aufbau and Pauli principles, the unpaired electron of the hydrocarbon radical-ions occupies either the highest bonding orbital (smallest positive m_j value; unipositive radical-ion R^+) or the lowest antibonding orbital (smallest negative m_j value; uninegative radical-ion R^-), molecules of this type with opposite charge should have identical spin density distributions. Another consequence of the pairing theorem is the numerical equality of the excess charges ε_r^π for positive and negative ions: $(\varepsilon_r^\pi) = -(\varepsilon_r^\pi)^+$. In Hückel's approximation, moreover, $(\varepsilon_r^\pi)^\pm = \pm\rho_r^\pi$. (For an experimental test of these consequences of the pairing theorem, see Section V.1).

In most odd alternant hydrocarbons, the number of starred C-atoms is one greater than the number of unstarred C-atoms. These molecules are free radicals even in the neutral state. The unpaired electron moves in a molecular orbital with $m_j = m_o = 0$ ($E_o = \alpha$; nonbonding orbital). The corresponding c_{or} values (and spin densities $\rho_r^\pi = c^2_{or}$) can be written directly against the various C positions in the structural formula of the molecule without complicated calculations; in particular, $\rho_r^\pi = 0$ in all the unstarred positions [95].

The effects of different bond lengths, bond deformation, heteroatoms, and hyperconjugation on the spin density distribution can be taken into account in the HMO

[94] *A. D. McLachlan*, Molecular Physics *2*, 271 (1959).

[95] *H. C. Longuet-Higgins*, J. chem. Physics *18*, 265, 275, 283 (1950).

theory by variation of the α and β values for the appropriate positions. The assumption of the HMO theory that β is constant is equivalent to assuming that all the bond lengths are equal. It is known from X-ray studies, however, that the bond lengths in many carbon π-systems vary between 1.33 and 1.52 Å [96,97]. A functional relationship between β_{rs} and the C–C bond length d_{rs} in π-systems has been given by *Longuet-Higgins* and *Salem* [98] in the form (12). In the case of

$$\beta_{rs}/\beta = \exp\left[-(d_{rs}-1.40)/0.311\right] \qquad (12)$$

naphthalene, Eq. (12) gives better results than the simple HMO method [93].

According to *Mulliken* [99] and *Dewar* [100], β_{rs} can be assumed to be related to the torsion angle Θ_{rs} between the 2 p_z orbitals of two adjacent C atoms in positions r and s by:

$$\beta_{rs}/\beta = \cos\Theta_{rs} \qquad (13)$$

By comparing experimental spin densities or m_j values with calculated spin densities or m_j values as a function of Θ_{rs}, it is possible to determine the torsion angle between two or more phenyl rings which cannot lie in the same plane owing to steric hindrance.

Heteroatoms X can be allowed for in the HMO method by suitable modification [Eq. (14)] of the parameters α and β for the appropriate positions. Numerical values

$$\alpha_X = \alpha_C + h_X\beta_{CC}$$
$$\beta_{CX} = k_{CX}\beta_{CC} \qquad (14)$$

of h_X and k_{CX} can be found empirically by fitting the calculated spin densities $\rho^\pi = f(h_X, k_{CX})$ to experimental spin densities [101,102]. However, a number of general principles also apply: for heteroatoms X· that contribute a single electron to the π-system, $h_{X\cdot}$ is approximately equal to the difference in the electronegativities [103] of atoms X· and C [92]. When a heteroatom X: contributes two electrons to the π-system, allowance is made for this by the correction $h_{X:} - h_{X\cdot} \simeq 1$ to 1.5 [92]. Conversely, these rules can also be used to find differences in electronegativity between various atoms in π-systems from empirical h_X values. The numerical values of k_{CX} vary between 0.6 and 1.0 [104].

The EPR spectra of organic free radicals containing substituted methyl groups frequently exhibit hyperfine structure as a result of interaction between the unpaired electron and the methyl protons. This effect is due to direct overlap between the hydrogen 1s-orbitals and the $2p_z$ atomic orbitals of the carbon atoms in the π-system (hyperconjugation), whereby the odd-electron density reaches the protons [92]. The splitting constant of a proton of the i-th methyl group attached to the i-th C-atom of the π-system is given by Eq. (15):

$$a_i^{H(methyl)} = Q\rho_i^\pi \qquad (15)$$

in which $Q \simeq 28$ oersted [105]. The disturbance of the π-electron distribution by a methyl group is allowed for by replacing the three hydrogen atoms of the methyl group by a pseudo-hydrogen atom H_3 and treating the atoms H_3, C_{methyl}, and C_π as heteroatoms [106]. The following h_X and k_{CX} values are generally used: $h_{C_\pi} = 0$ to -0.1; $h_{C_m} = 0.0$ to -0.1; $h_{H_3} = 0.0$ to -0.5; $k_{C_\pi C_m} = 0.7$ to 1.0; and $k_{C_m H_3} = 2.0$ to 2.5 [106–109].

b) McLachlan SCF Approximation

An important disadvantage of the HMO theory is the fact that it disregards the interaction of the π-electrons, although this is partly compensated by the use of effective Coulomb and bond integrals α and β (numerical values of α_{eff} and β_{eff} are not needed for spin density calculations). The π-electron interactions are explicitly taken into account in the self-consistent field (SCF) wave functions [110–116], which permit the removal of spin compensation in the doubly occupied molecular orbitals in free radicals. This depends on exchange energies, which in turn depend on the spin direction. The electrons with α-spin ($\uparrow$) experience on average a weaker repulsion by the unpaired electron than the electrons with β-spin ($\downarrow$); consequently, the two electrons of a Hückel electron pair will move in different molecular orbitals. The unpaired spin density ρ_r^π is then no longer given by the density $(c_{or}^\alpha)^2$ of the unpaired electron alone, but by the excess α-spin density obtained by summation over all the occupied molecular orbitals:

$$\rho_r^\pi = \sum_j^{occ.}\left(c_{jr}^\alpha\right)^2 - \sum^{occ.}\left(c_{jr}^\beta\right)^2 \qquad (16)$$

($\sum^{occ.}$ means summation over all molecular orbitals containing α or β-electrons). This "exchange polarization" of the π-electron core by the unpaired electron makes

possible negative spin densities, when $\sum_{j}^{occ.}(c_{jr}^{\alpha})^2 < \sum_{j}^{occ.}(c_{jr}^{\beta})^2$. However, we still have $\sum_{r=1}^{n}\rho_r^{\pi} = 1$, although we can now have $\sum_{r=1}^{n}|\rho_r^{\pi}| \geq 1$, and hence also $\sum_r' a_r^H = Q\sum_r'\rho_r^{\pi} \geq Q$ (Σ' denotes summation over positions occupied by protons).

According to *McLachlan* [93], the exchange polarization can be accounted for to a first approximation if the Coulomb and bond integrals α and β for the unpaired electron and for the electrons with β-spin are equated again to the corresponding Hückel values, and the Coulomb integral α_r for the other electrons with α-spin are corrected by a quantity given by Eq. (17), in which $\lambda \simeq 1.2$ (constant for all C-atoms). The quantities c_{jr}^{α}

$$\Delta\alpha_r = 2\lambda c_{or}^2\beta \tag{17}$$

for the "paired" electrons with α-spin are thus obtained by solving the eigenvalue problem (10) with $(-m_j + 2.4\, c_{or}^2)$ instead of $-m_j$ in the r-th row, and the spin density ρ_r^{π} is finally found from Eq. (18), in which the summation

$$\rho_r^{\pi} = c_{or}^2 + \sum_j\left[(c_{jr}^{\alpha})^2 - c_{jr}^2\right] \tag{18}$$

must be carried out over all doubly occupied molecular orbitals.

c) Complete SCF Method

The complete SCF method takes into account not only the exchange interaction of the electrons, but also their Coulomb repulsion forces over the whole molecule [117, 118] [*]. No check on the spin densities obtained by this method on the basis of Eq. (6) and covering several molecules has yet been carried out.

V. EPR Parameters and Molecular Properties

1. Spin Densities

In the EPR investigation of aromatic hydrocarbon radicals, interest is centered mainly on checking the various approximations of the LCAO–MO method, and particularly, the procedures of *Hückel* and *McLachlan* (see Section IV). As an example, let us consider the even alternant hydrocarbon tetracene. This hydrocarbon forms both an R^+ and an R^- radical-ion, both of which have been detected by EPR spectroscopy [21]. The measured values of the splitting constants are given in Table 1. There are three groups of four protons with identical splitting constants within the groups, *i.e.* in agreement with the postulated structure, the four protons in each group are equivalent. The pairing theorem, according to which R^+ and R^- should have identical spin density distributions, is also verified, although the spectra are not quite identical, owing to the dependence of the splitting constants on the excess charges [Eq.(6)]. The splitting constants calculated from Hückel spin densities and excess charges show good agreement with the experimental values, and are even slightly better, on average, than results obtained by the McLachlan SCF method [119].

Table 1. Experimental and theoretical splitting constants a^H of the negative and positive tetracene radical-ions.

	Position	exper. a^H [Oe] [21]	ρ^{π} [119]		ε^{π} [119]		$a^H = (Q + K\varepsilon^{\pi})\rho^{\pi}$ [Oe]	
			Hückel	*McLachlan*	*Hückel*	*McLachlan*	*Hückel* Q = 31.7 Oe K = 18 Oe [21]	*McLachlan* Q = 24.4 Oe K = 17 Oe [21]
R^-	α	4.16	0.147	0.196	−0.147	−0.099	4.28	4.46
	β	1.43	0.056	0.067	−0.056	−0.046	1.72	1.58
	γ	1.16	0.034	0.022	−0.034	−0.046	1.05	0.52
R^+	α	4.97	0.147	0.196	+0.147	+0.099	5.05	5.11
	β	1.65	0.056	0.067	+0.056	+0.046	1.84	1.69
	γ	1.01	0.034	0.022	+0.034	+0.046	1.08	0.55

The Hückel theory breaks down, however, in the case of the recently detected allyl radical $\overset{1}{C}H_2{=}\overset{2}{C}H{-}\overset{3}{C}H_2\cdot$ [73]. The experimental spin densities are $|\rho_1^{\pi}| = |\rho_3^{\pi}| = 0.58$ and $|\rho_2^{\pi}| = 0.16$, whereas the Hückel theory gives the values $\rho_1^{\pi} = \rho_3^{\pi} = 0.5$ and $\rho_2^{\pi} = 0.0$. In this case, the McLachlan method is more successful in predicting a high negative spin density of $\rho_2^{\pi} = -0.19$ ($\lambda = 1.06$) on the central C-atom.

With a few exceptions, negative spin densities always occur where the Hückel theory predicts a spin density of zero. The principal positions in which this is the case are the unstarred (inactive) positions in the neutral odd alternant hydrocarbon radicals (*e.g.* allyl, triphenylmethyl, and perinaphthenyl), but

[119] *T. C. Sayetta* and *J. D. Memory*, J. chem. Physics *40*, 2748 (1964).

it also occurs at protonated positions in a few even alternant radical-ions (*e.g.* in biphenyl, pyrene, and phenanthrene) [93].

Whereas the hyperfine structure spectra of condensed aromatic hydrocarbon radicals show a constant overall splitting of approximately 30 oersted, an overall hyperfine splitting of less than 10 oersted was found in the case of the pentaphenylcyclopentadienyl radical [120].

Since the only explanation of this anomaly is that the unpaired spin density is forced onto the unprotonated five-membered ring, it must be assumed that the phenyl rings are largely twisted out of the plane of the five-membered ring. This assumption also seems justified in view of the mutual hindrance of the phenyl rings (interaction of the hydrogen atoms) in the completely planar model.

The steric hindrance of the two phenyl rings of biphenyl by the four ortho hydrogen atoms also leads to twisting about the central C -C bond. Comparison of the measured value of the splitting ratio a_{para}/a_{ortho} with the calculated ratio of the spin densities $\varrho_{para}/\varrho_{ortho} = f(\Theta)$ has shown that the angle between the planes of the two phenyl rings is $38 \pm 2°$ [21].

It has been shown by EPR spectroscopy that rotation of the CHO group in *p*-nitrobenzaldehyde is hindered [121]. If rotation about the C_{ring}–CHO bond were free, there should be at the most three different splitting constants; four different splitting constants are however observed. This is explained by assuming that the two *ortho* ring protons are no longer equivalent, owing to the influence of the CHO group. From the difference in the splitting constants, the rotational frequency of the CHO group is estimated to be, at most, 10^6 sec^{-1}.

The terephthalic aldehyde anion gives a hyperfine structure spectrum [122] that can be reconstructed only if we assume the presence of two types of molecule A and B, each containing three pairs of equivalent protons. The concentration ratio of the two types of molecules has been found, from the intensity ratio of the two superimposed spectra, to be $c_A/c_B = 1.40$. On the basis of spin density calculations with variation of α and β for heteroatoms, A and B have been identified as the planar *trans*- and *cis*-rotamers of the terephthalic aldehyde anion. Since $c_A > c_B$, the *trans*-rotamer is the more stable of the two.

In the case of the phthalic aldehyde anion, three rotamers (*meso*, *endo*, and *exo* forms) are possible. It can be concluded, however, simply from the absence of a central line from the hyperfine structure spectrum, that the *meso* form predominates over the other rotamers by a concentration ratio of at least 16:1 [123].

Geske et al. [32] and *Rieger et al.* [124] have described very detailed EPR studies on the steric effects in anion-radicals of aromatic nitro compounds. When the nitro groups in mononitro and symmetrically substituted dinitro radical-anions are rotated out of the plane of the ring, the nitrogen splitting constants increase considerably, while the splitting constants of the ring protons decrease. In 2,6-dimethyl-1,4-dinitrobenzene, for example, the nitrogen splitting constant of the 1-nitro group, which is hindered by the two methyl groups, is only 0.14 oersted, whereas that of the 4-nitro group is 5.7 oersted.

The theoretical calculation of spin densities and π-orbital energies are valid for isolated molecules. Since, however, the EPR measurements are not generally carried out on gaseous, *i.e.* free organic radicals, environmental factors must be taken into account in comparing theoretical and experimental results. It is known since 1962 [25] that the hyperfine splitting constants of organic radicals in different solvents can vary by up to a few oersted. A survey of the experimental results shows that the solvent-dependence of the splitting constants is particularly pronounced in the case of radicals containing functional groups, whereas unsubstituted aromatic radicals show practically no solvent effects. It is clear from measurements on quinones [25], nitro compounds [125,126], and ketones [127] that the changes in the splitting constants (and hence in the spin densities) are particularly large on passing from aprotic to protonic solvents. In addition to the normal electrostatic interaction, which leads to solvation of the radicals, there is evidently also a much stronger interaction between the radicals and the solvent molecules, involving hydrogen bonds. Thus free solvated radicals are obtained in extremely anhydrous aprotic solvents such as acetonitrile or dimethylformamide. *Gendell*, *Freed*, and *Fraenkel* [128, 128a] have shown that the experimentally observed solvent-dependence of the splitting constants can be theoretically explained by postulating localized complex formation between the solvent and the functional groups in the radical. The redistribution of the spin density is then allowed for if the electronegativity, *i.e.* the Coulomb integral α, of the hydrogen-bonded atom carrying the lone pair of electrons is modified as a matching factor for the particular solvent.

2. g Factors

In addition to the hyperfine structure, a radical is also characterized by the g factor. Since the π electrons are firmly coupled to the plane of the molecule by the strong intramolecular fields, their orbital momentum is almost completely quenched, so that the g factors of all organic radicals differ by at most 1 % from the g factor of the free electron, $g_o = 2.002319$. Within a class of molecules, in fact, the g factors often differ only in

the 5th decimal place; consequently, the identification of radicals demands that the g factors be determined very accurately. The g factors can be found directly in accordance with the resonance condition (2) from the ratio of the microwave frequency ν_0 and the resonance field strengths H_0 found from the proton resonance frequency ν_p [Eq. (19)] [21]; alternatively, they can be

$$g = F \cdot \nu_0/\nu_p;\ (F = 3.042000 \pm 5 \times 10^{-6}) \times 10^{-3} \qquad (19)$$

found in relation to the known g factors of standard samples [129] from the difference in the resonance field strengths [Eq. (20)].

$$g = g_s(1-\delta H/H_{0s}) \qquad (20)$$

The deviations $\Delta g = (g-g_0)$ from the g factor of the free electron are due to a residual spin-orbital coupling, resulting in an admixture of excited states, which contain a triplet state in the σ system, with the ground state. Δg can be represented to a first approximation by an equation of the form (21) [130] in which λ is the

$$\Delta g = \text{const} \cdot \left[-\lambda\left(\frac{1}{\Delta E_1}-\frac{1}{\Delta E_2}\right)\right] \qquad (21)$$

spin-orbital coupling parameter of the atoms of which the molecule is composed. ΔE_1 (< 0) is the energy difference between the π-level containing the unpaired electron and the highest fully occupied bonding σ-level, whilst ΔE_2 (< 0) is the energy difference between this π-level and the first antibonding excited σ^*-level. Depending on whether $|\Delta E_1| < |\Delta E_2|$ or $|\Delta E_1| > |\Delta E_2|$, the measured g factors will be greater or smaller than the g factor of the free electron, so that the sign of Δg can be used for the term analysis. The limitations of the approximation (21) for Δg have been discussed by *Stone* [131]. Eq. (21) predicts a steady increase in the g factor with increasing λ of a substituent (cf. Table 2).

Table 2. Spin-orbital coupling parameters λ [132] and experimental g factors [133] of *p*-benzosemiquinone radicals.

p-Benzosemiquinone radical	Substituent	λ [cm^{-1}]	g
Unsubstituted	O	152	2.00468
Tetrachloro	Cl	587	2.00568
Tetrabromo	Br	2460	2.00875
Tetraiodo	I	5060	2.01217

For hydrocarbons, $\lambda = 28$ cm^{-1}, so that the difference between the g factors of unsubstituted π-electron radicals and the value for the free electron fall in the range $2.0025 \leqslant g \leqslant 2.0027$.

In the $AlCl_3$-catalysed alkylation of benzene (Friedel-Crafts reaction), which had formerly been assumed to proceed by a completely ionic mechanism, EPR spectroscopy has revealed the occurrence of free-radical intermediates [134], the g factors of which were always about 2.0025 ± 0.0001, irrespective of the alkylating agent. The radicals are therefore hydrocarbon radicals, and contain no oxygen or chlorine.

Grignard reactions have also been assumed to proceed by an entirely ionic mechanism. Free radicals have, however, been detected by EPR spectroscopy when Grignard compounds such as C_6H_5MgBr were added to aromatic and aliphatic ketones such as benzophenone and hexamethylacetone in tetrahydrofuran [134a].

The free radical formed during the reaction of diphenylpicrylhydrazyl with t-butyl hydroperoxide has recently been identified, by analysis of the hyperfine structure, as diphenylnitrogen oxide [135]; the large g factor (2.0058) and the fact that it agreed with the g factor of an authentic sample of diphenylnitrogen oxide provided important evidence of the identity of the reaction product.

Stone [131] has shown that the deviation of the g factors of aromatic hydrocarbon radicals from the value g_0 are systematic in nature, and bear a linear relationship to the π-orbital energy of the unpaired electron. If E_π in Hückel's approximation is expressed by constant Coulomb and bond integrals, then

$$\Delta g = A + B \cdot m_o \qquad (A, B = \text{constant}) \qquad (22)$$

Here m_o is the Hückel energy coefficient of the lowest half-occupied orbital, *i.e.* $m_o = m_m > 0$ for even alternant radical-cations, $m_o = m_{m+1} < 0$ for radical-anions, and $m_o = 0$ for neutral odd alternant radicals (cf. Fig. 1). Figure 2 shows the deviations Δg of the g factors (experimental error $\pm 2 \times 10^{-6}$) of some positive and negative aromatic radical-ions as a function of m_o [21]. The required linearity of the relationship between Δg and m_o is satisfactorily fulfilled, the slope and intercept of

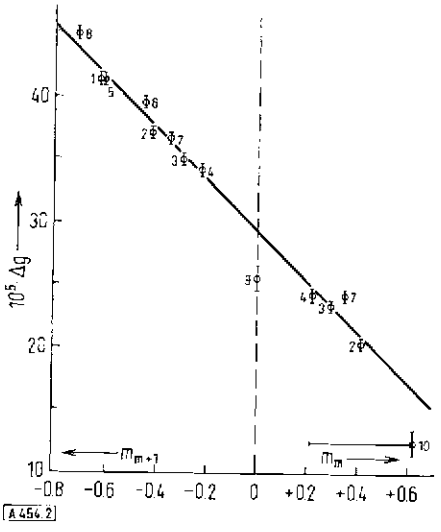

Fig. 2. Change in the g factor of aromatic radicals as a function of the Hückel energy coefficient m_o of the lowest half-occupied π-orbital ($m_o = m_{m+1} < 0$ for R^-, $m_o = m_m > 0$ for R^+).

the fitted line being $-(20.3 \pm 0.7)\times10^{-5}$ and $(29.8 \pm 0.4)\times10^{-5}$ respectively.

A number of the points do not lie on the straight line. In the cases of the biphenyl radical-ion and the pentaphenylcyclopentadienyl radical, this deviation can be explained as resulting from the non-planarity of the molecules. A torsion angle of $31 \pm 8°$ has been found for the biphenyl radical-anion, whereas the five phenyl rings in pentaphenylcyclopentadienyl are almost perpendicular to the plane of the 5-membered ring [21]. (The m_o range shown is bounded on the left by the torsion angle 0° and on the right by the angle 90°). Thus electron paramagnetic resonance offers two methods of finding the torsion angles of radicals in solution: from the hyperfine structure on the one hand, and from the g factor on the other.

All neutral odd alternant hydrocarbon radicals, such as triphenylmethyl, should have the same g-factor deviation $\Delta g = 29.8\times10^{-5}$, since $m_o = 0$. Even after the twisting has been taken into account in the Hückel approximation, the points 9 and 10 still fall well below the fitted line obtained from the values for radical-ions. This confirms what has been found by experience, *i.e.* that the Hückel molecular orbital theory gives practically the same results for radical-ions as the SCF theory, whereas the HMO approximation is too crude for neutral radicals.

It should also be mentioned that Δg can be determined without laborious theoretical calculations by measurement of the polarographic half-wave potential $U_{1/2}$. For aromatic hydrocarbons, Δg bears a linear relationship to $U_{1/2}$, as indicated in Eq. (23) ($U_{1/2}$ measured in volts *versus* a saturated calomel electrode) [21]. It is

$$\Delta g = (27.8 \pm 0.5)\times10^{-5} - (5.6 \pm 0.2)\times10^{-5}\, U_{1/2} \qquad (23)$$

therefore possible to construct a calibration curve which gives the g factors to an accuracy of about 10^{-5} from the known half-wave potentials, even in the case of radical ions, such as the singly charged positive benzene and naphthalene ions, that have not yet been studied by EPR spectroscopy.

3. Line Widths

Absolute line widths and the small line-width variations occasionally observed in hyperfine structure spectra generally give little information regarding structure. In the case of the dinitrodurene anion, however, the marked variation in the line width in the EPR spectrum has been taken to indicate steric hindrance between the methyl groups and the nitro groups [136]. Examples are also known in which anomalous line-width variations are caused by rotational isomerism [137–140].

[140] *A. Carrington*, Molecular Physics *5*, 425 (1962).

4. Intensities

In considering the intensities, it is necessary to distinguish between the relative intensities of individual lines, which are important to the evaluation of the hyperfine structure [1a], and the total intensity of the spectrum. The intensity of the spectrum is measured by the area A under the absorption curve, and is obtained from the recorded curve by double integration. The area depends on the number N_o of absorbing centers, the spin quantum number S, the absolute temperature, and several constants of the apparatus [8] as shown by the proportionality (24). The relative concentrations of radicals in two samples can be found from the ratio A_1/A_2.

$$A \quad N_o S(S+1)/T \qquad (24)$$

In compounds containing paramagnetic ions of transition metals, it is often difficult to establish the valence state of the metal ion. This problem can be solved in many cases with the aid of the EPR spectrum, since the relaxation times of the various valence states are very different. For example, the absorption line for Fe^{2+} is so wide at room temperature that it cannot be detected, whereas Fe^{3+} gives an easily observable spectrum. Even when the relaxation times are approximately equal, however, the valence state can still be calculated from the intensity of the EPR spectrum, since the intensity is proportional to $S(S + 1)$. The spin quantum number of Nb^{4+} is $S = 1/2$, whereas that of Nb^{2+} is $S = 3/2$; at equal Nb concentrations, therefore, the intensities of the spectra are in the ratio of 1:5.

The kinetics of reactions in which radicals are formed or consumed can be studied by the time-dependence of the intensity. This technique has been particularly useful in biological reactions [141], in polymerization [57], and in photochemical reactions [73]. It is possible to measure lifetimes down to a few msec. *Fessenden* [142] has described various experimental methods which can be used to follow fast reactions of this type. This author measured the lifetime at −170 °C (τ = 7.3 to 7.5 msec) of the ethyl radical, which was formed by irradiation of ethane with 2.8 MeV electrons. The activation energy of the recombination reaction was also calculated from the temperature-dependence of τ, the value obtained being 830 cal/mole.

It is often important to know whether free radicals play any part in a given reaction at all. This is the case particularly in biochemical problems in which the course of the reaction has not yet been established. The EPR spectra of free radicals formed during metabolic processes, for example, generally consist of a single wide line at $g \simeq 2$, so that quantitative information can be obtained only from the width and intensity of the line [143].

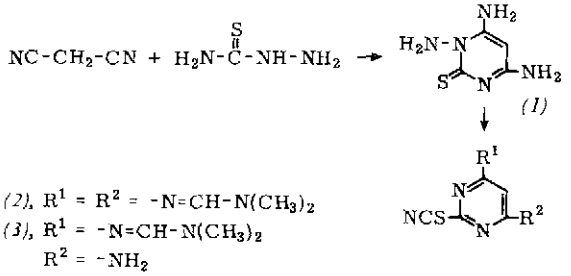
Formation of a 2-Thiocyanatopyrimidine from a 1-Amino-2-thioxo-1,2-dihydropyrimidine and Dimethylformamide/$POCl_3$

By Prof. Dr. E. C. Taylor and Dr. R. W. Morrison, Jr.

Department of Chemistry, Princeton University, Princeton, N.J. (U.S.A.)

Condensation of malonodinitrile with thiosemicarbazide in 2 M ethanolic sodium ethoxide gives 1,4,6-triamino-2-thioxo-1,2-dihydropyrimidine *(1)*, m.p. 261 °C (decomp.), in 34 % yield. Treatment of *(1)* for 2 h at room temperature with the dimethylformamide/$POCl_3$ complex [1] leads to 4,6-bis(dimethylaminomethyleneamino)-2-thiocyanatopyrimidine *(2)* in 65 % yield. This compound melts at 130–131.5 °C and is isolated by addition of the reaction mixture to crushed ice, adjustment of the pH to 10 with 6 N sodium hydroxide, rapid filtration, and recrystallization of the dried precipitate from acetone/hexane.

The structure of *(2)* was indicated by its elemental composition, by a strong infrared absorption band at 2172 cm^{-1} characteristic of the –SCN grouping, and by its chemical reactions. For example, *(2)* was converted by either benzylamine at 95 °C or 1 N sodium hydroxide at room temperature or refluxing 2 M ethanolic ammonia into 4,6-diamino-2-mercaptopyrimidine [2]. Hydrolysis of *(2)* with cold 0.5 N hydrochloric acid gave 4-amino-6-dimethylaminomethyleneamino-2-thiocyanatopyrimidine *(3)*, m.p. 198.5–199 °C, whereas hydrolysis with 6 N hydrochloric acid at 100 °C gave barbituric acid. Hydrolysis with 4 N acetic acid at room temperature afforded 4,6-bisformylamino-2-thiocyanatopyrimidine *(4)*, m.p. 249 °C (decomp.). Treatment of 1.0 g of *(2)* with 4 g of chlorine in 15 ml of acetic acid gave rise to 4,6-diamino-2,5-dichloropyrimidine in 71 % yield [3].



(2), $R^1 = R^2 = -N{=}CH{-}N(CH_3)_2$
(3), $R^1 = -N{=}CH{-}N(CH_3)_2$, $R^2 = -NH_2$
(4), $R^1 = R^2 = -NH{-}CHO$

We consider that the reaction of *(1)* with the dimethylformamide/$POCl_3$ complex involves initial formation of the 1,4,6-tris(dimethylaminomethyleneamino) compound [4]. The $(CH_3)_2N{-}CH{-}N$-group on N-1 could then cyclize with the thioxo sulfur on C-2 to form a thiadiazole ring; loss of dimethylamine followed by cleavage of the N–N bond could then yield *(2)*.

Formation of Phenylcarbenes by Photolysis of Phenyloxiranes

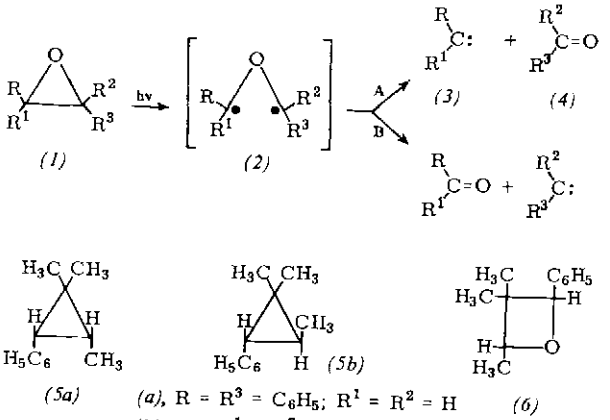
By Dr. H. Kristinsson and Prof. Dr. G. W. Griffin [1]

Department of Chemistry, Tulane University, New Orleans, La.(U.S.A.)

We have found that photolysis [2] of *trans*-stilbene oxide *(1a)* [3] in 2-methylbut-2-ene leads to a 1:1 mixture of *cis*-*(5a)* and *trans*-2,2,3-trimethyl-1-phenylcyclopropane *(5b)* in 90 % yield [4]. In addition, the oxetane derivative *(6)* [5], which is formed by addition of benzaldehyde to the solvent, was isolated.

The cyclopropane derivatives *(5a)* and *(5b)* were also obtained on photolysis [2] of tripbenyloxirane *(1b)* [3] in either 2-methylbut-2-ene/benzene or 2-methylbut-2-ene alone. However, here the main products were tetraphenylethane and the oxetane *(6)*.

These reactions apparently all involve the diradical *(2)*, which decomposes preferentially by Route A to the carbene *(3)* plus the carbonyl compound *(4)*.



(1) *(2)* *(3)* *(4)*

(5a) *(5b)* *(6)*

(a), $R = R^3 = C_6H_5$; $R^1 = R^2 = H$
(b), $R = R^1 = R^2 = C_6H_5$; $R^3 = H$
(c), $R = R^1 = R^2 = R^3 = C_6H_5$

Photolysis of tetraphenyloxirane *(1c)* [3] in methanol/benzene gives benzhydrol methyl ether in almost 100 % yield. *Kirmse* and *Horner* [6] have previously used alcohols to trap aryl carbenes.

All products were separated by gas chromatography and identified by comparison with authentic samples [7].

Preparation of Heavy Metal Halides in Anhydrous Acetic Acid

By Prof. Dr. H. D. Hardt and Dipl.-Chem. R. Bollig

Institut für Anorganische Chemie der Universität Saarbrücken (Germany)

If pure acetyl chloride is added slowly (about 0.2 ml per min) to 100 ml of a 0.1 M solution of lead acetate in anhydrous acetic acid, minima in the specific conductivity of the solution are observed at Pb:Cl molar ratios of 1:1 and 1:2 corresponding to the formation of lead acetate chloride and lead dichloride, respectively.

$$(CH_3COO)_2Pb + CH_3COCl \rightarrow (CH_3COO)PbCl + (CH_3CO)_2O$$

$$(CH_3COO)PbCl + CH_3COCl \rightarrow PbCl_2 + (CH_3CO)_2O$$

Pure lead acetate chloride can he prepared by interrupting the reaction at the first conductivity minimum. The colorless precipitate is filtered off, washed with anhydrous acetic acid, and dried over solid sodium hydroxide in a vacuum desiccator. In this way, lead acetate chloride monoacetic acid-solvate $(CH_3COO)PbCl \cdot CH_3COOH$ is obtained in over 90 % yield. This product releases its acetic acid of crystallization at 120 °C to give lead acetate chloride $(CH_3COO)PbCl$, which decomposes at about 270 °C to basic lead chloride Pb_2OCl_2.

Lead acetate bromide can be obtained similarly at 60 °C and decomposes at about 300 °C to lead oxide bromide. Solvated lead acetate hromide is not formed under these conditions. Lead acetate iodide cannot be made in this way.

The iodides PbI_2, AgI, HgI_2, $Ag_2(HgI_4)$, CuI, and CdI_2 are all highly insoluble in anhydrous acetic acid and can be obtained in quantitative yields by adding a stoichiometric amount of acetone plus the calculated amount of iodine in acetic acid dropwise to solutions of the acetates of these metals in anhydrous acetic acid at 70–80 °C. Silver iodide is precipitated even without addition of acetone.

$$n\,CH_3COCH_3 + n\,I_2 + (CH_3COO)_nM \rightarrow MI_n + n\,CH_3COCH_2I + n\,CH_3COOH$$

The precipitation of lead iodide is very slow at room temperature (30 % conversion after 40 h), but the rate can be almost doubled by passing an alternating current (220 volts between Pt or Ag electrodes) through the solution containing acetic acid, acetone, iodine, and lead(II) acetate. The current density increases to a maximum of 3.3 amp/dm² during the first 3 h and then falls to about 1.6 amp/dm² during the next 30 h.

Thermochromic $Ag_2(HgI_4)$ is obtained at 70–80 °C from a 2:1.3 mixture of silver and mercury acetates. The yellow modification of HgI_2 is formed from mercury(II) acetate alone in anhydrous acetic acid at 118.1 °C. Crystals about 0.5 mm long are obtained which can be kept for a few days (metastable) if quenched rapidly to room temperature.

This new method is especially suitable for the preparation of cadmium iodide. A solution of iodine in acetic acid is added dropwise to a hot solution of $Cd^{2\oplus}$ in acetic acid/acetone until the color of the iodine persists. The yield is quantitative and the product is very pure.

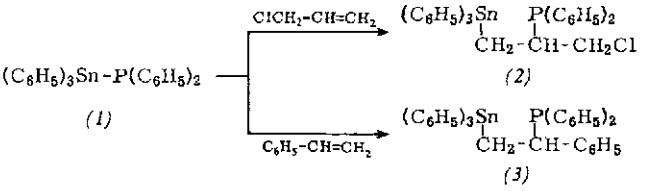
Addition of Diphenyl(triphenylstannyl)phosphine to Multiple Bonds

By Dr. H. Schumann, Dr. P. Jutzi, and Prof. Dr. Max Schmidt

Institut für Anorganische Chemie der Universität Marburg (Germany)

Diphenyltriphenylstannylphosphine *(1)* [1] reacts with allyl chloride or styrene in boiling benzene to afford 3-chloro-2-diphenylphosphino-1-triphenylstannylpropane *(2)*, m.p. 39 °C, or 2-diphenylphosphino-2-phenyl-1-triphenylstannylethane *(3)*, m.p. 59 °C, respectively.



Reaction of phenylacetylene with even a great excess of *(1)* stops at the stage 2-diphenylphosphino-2-phenyl-1-triphenylstannylethylene *(4)*, m.p. 45 °C.

After the solvent has been distilled off, compounds *(2)*, *(3)*, and *(4)* crystallize readily (by scratching) from pentane and can be recrystallized from benzene/pentane. Before this crystallization, unchanged *(1)* is oxidized by prolonged stirring in air to the insoluble triphenyltin diphenylphosphinate which is filtered off.

(4)

We assume a free-radical reaction mechanism, by analogy with hydrostannylation [2]. This is in line with the considerable increases in yield that result on addition of small amounts of azobisisobutyronitrile:

(2): 26 % → 65 %; *(3)*: 16 % → 68 %; and *(4)*: 21 % → 78 %.

Mixtures of isomers were not found in these reactions, even on use of chromatography. The structures given follow from the consideration that the bulky triphenylstannyl group will add preferentially at the terminal-carbon end of the double bond. NMR spectroscopy gave no structural indication. The extraordinarily high solubility of *(2)*, *(3)*, and *(4)* in benzene, pyridine, and carbon disulfide nevertheless did not suffice to permit detection of the Sn- and P-linked protons on aliphatic carbon atoms in ^1H–NMR spectra alongside the 25 or 30 protons of the phenyl nuclei. Moreover, the Sn– and P–NMR spectra were extremely complicated by numerous couplings and could not be interpreted.

N-Methyl-3,4,5-tricyanopyridinium Perchlorate, a Pyridinium Salt of Extremely High Electron Affinity [1]

By Prof. Dr. K. Wallenfels and Dipl.-Chem. W. Hanstein

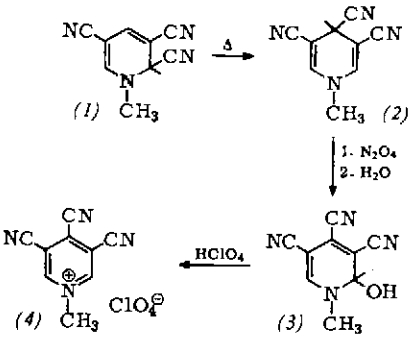
Chemisches Laboratorium der Universität Freiburg (Germany)

The anion affinity of pyridinium salts is greatly increased by the introduction of electron-attracting substituents [2]. The phenomenon is most readily examined by measuring the equilibrium constants of the reaction

$$\overset{\oplus}{Py} + \overset{\ominus}{CN} \rightleftharpoons PyCN$$

for the various pyridinium derivatives. The redox potentials of the pyridinium salt/dihydropyridine system are directly proportional to the logarithms of the cyanide ion affinities. We have synthesized a pyridinium salt *(4)* of extremely high

anion and electron affinity by the following route. 3,5-Dicyanopyridine is fused and methylated with methyl *p*-toluenesulfonate for 4 h at 110 °C. The *N*-methylpyridinium

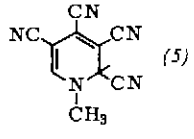


p-toluenesulfonate (90 % yield) is treated with KCN to give the 2-cyanide adduct *(1)* in 80 % yield, which when heated in the melt at 125 °C or in dimethylformamide at 150–160 °C, is converted in 95 % yield into the 4-isomer *(2)*. The latter is suspended in carbon tetrachloride and oxidized for 12 h at 25 °C (90 % yield) with excess N_2O_4. The solvent and reagent are removed in vacuum, the residue is stirred with water, and the *(3)* formed filtered off. Compound *(3)* is then dissolved in acetonitrile, and $HClO_4$ and ether are added. The perchlorate *(4)* crystallizes in the form of long thin needles in 70 % yield.

The *N*-methyl-3,4,5-tricyanopyridinium cation *(4)* is a strong π-acid. It forms intensely colored charge-transfer complexes with anisole (red, λ_{max} = 475 mμ), hexamethylbenzene (red, 505 mμ), and pyrene (green, 620 mμ). The salt *(4)* reacts as a Lewis acid with 2 moles of 9-fluorenol in acetonitrile within 12 h at 25 °C to yield di-9-fluorenyl ether (9 %) and the adduct *(3)*.

Anisole is acetylated in acetonitrile in the presence of the salt *(4)* to give 34 % *p*-methoxyacetophenone, which was isolated as the 2,4-dinitrophenylhydrazone.

The cation *(4)* combines with hydroxide and cyanide ions to form the adducts *(3)*, pK_a = −14.5 [3], and *(5)*, pK_a = −14.9 [3], respectively, which are both extremely resistant to acids.



(5)

The salt *(4)* also acts as an oxidizing agent. In the reaction with 9-fluorenol described above, 8 % fluorenone can be isolated in the form of its 2,4-dinitrophenylhydrazone after 6 days at 25 °C. This is therefore the first model system for the enzymatic dehydrogenation of an alcohol by a pyridinium salt.

When solutions of *(4)* and *p*-bisdimethylaminobenzene in acetonitrile are mixed, a deep blue solution is formed in which Wurster's blue can be detected.

So far the primary reduction product formed from the pyridinium salt has not been isolated from any oxidation; it appears to be readily oxidized by oxygen. The product obtained is *N*-methyl-3,4,5-tricyano-2-pyridone *(6)*, which can also be made by oxidation of *(5)* with nitric oxide. The sensitivity of the primary reduction product towards air suggests that it is a pyridyl radical or the dihydropyridine derivative *(7)*. Compound *(7)*, which can be made by reduction of *(4)* in acidic solution, is also converted to the pyridone *(6)* when its solution in acetonitrile is left standing in air. A free pyridyl radical is formed as an intermediate in this oxidation; the hyperfine structure of its characteristic electron-spin resonance spectrum is being investigated. A free radical with a very similar ESR spectrum is produced on reduction of *(4)* with zinc in acetonitrile. The formation of free radicals of this type during the reduction of pyridinium cations containing substituents capable of mesomerism has already been observed [4].

Synthesis of Tetrakistrifluorophosphinoiridium Hydride and the Proton Magnetic Resonance Spectra of the Hydrides $HM(PF_3)_4$ (M = Co, Rh, Ir) [1]

By Priv.-Doz. Dr. Th. Kruck and Dipl.-Chem. W. Lang

Anorganisch-Chemisches Laboratorium der Technischen Hochschule München (Germany)

Tetrakistrifluorophosphinoiridium hydride, $HIr(PF_3)_4$, has now been made in 86 % yield analogously to the corresponding derivatives of cobalt [2] and rhodium [3], but using a temperature of 260 °C and a PF_3 pressure of 1000 atm. The new compound is a colorless, mobile, extremely volatile liquid with a choking odor and boils at 95 °C/725 mm; the solid melts at −39 °C. It is surprisingly stable towards heat and starts to decompose only above 245 °C; it is unaffected by air. It dissolves to a small extent in water; its solution is acidic.

$HIr(PF_3)_4$ reacts with potassium amalgam in ether to form potassium tetrakistrifluorophosphinoiridate(−I), $K[Ir(PF_3)_4]$, which crystallizes readily to a colorless solid. This salt can be kept for weeks in dry air and decomposes under nitrogen only above 240 °C. It is readily soluble in ether, acetone, tetrahydrofuran, and water; its aqueous solution is slightly alkaline.

The infrared spectrum of $HIr(PF_3)_4$ vapor [4] contains P–F stretching vibrations at 965 (w–m), 925 (vs), 910 (s, shoulder), and 877 (vs) cm^{-1}. In the spectrum of the tetrakistrifluorophosphinoiridate(-I) these bands are shifted to much longer wavelengths on account of the greater π-bond character of the metal-phosphorus bond, which reduces the double-

bond nature of the P–F bonds; absorptions are observed at 830 (vs) and 811 (s, shoulder) cm^{-1} in acetone. The tetrakistrifluorophosphinoiridate anion is isoelectronic and apparently also isosteric (T_d) with tetrakistrifluorophosphinoplatinum(0) [5].

The proton magnetic resonance spectrum of $HIr(PF_3)_4$ [6] is centered around $\delta = 11.93 \times 10^{-6}$ relative to tetramethylsilane as internal standard. As a result of the coupling of the proton spin with the spins of the four ^{31}P and twelve ^{19}F nuclei, the proton signal is split into 65 lines, some of which lie very close together (see Figure); $J_{P-H} = 31.0 \pm 0.1$ cps, and $J_{F-H} = 14.93 \pm 0.04$ cps. Coupling with the ^{191}Ir and ^{193}Ir nuclei does not occur on account of the high quadrupole moment of these isotopes.

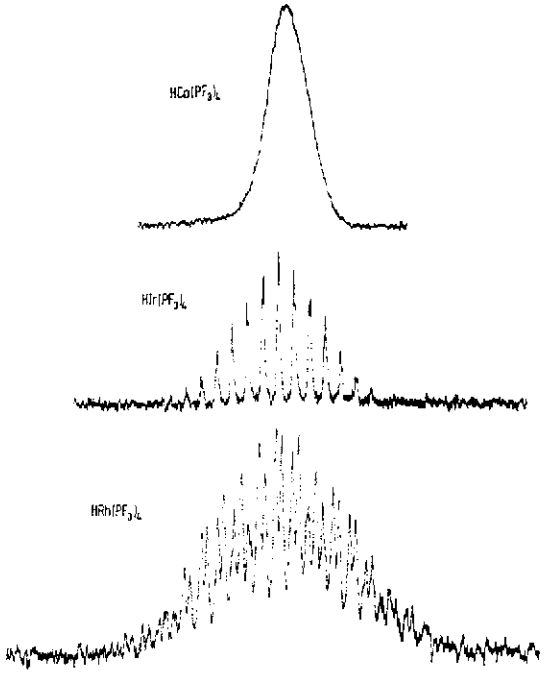

Fig. 1. ^1H—NMR spectra of $HCo(PF_3)_4$, $HRh(PF_3)_4$, and $HIr(PF_3)_4$.

The proton magnetic resonance signal in the NMR spectrum of $HRh(PF_3)_4$ is split into 130 lines since all of the nuclei present in this molecule have a spin quantum number of $^1/_2$. In contrast, despite the comparable quadrupole moments of Ir and Co, the proton signal of $HCo(PF_3)_4$ is merely broadened out over about 130 cps. Measurements at temperatures down to −80 °C gave no indication of any fine structure in the NMR spectrum of $HCo(PF_3)_4$ due to the presence of the P and F nuclei. However, the resemblance of the infrared spectrum of $HCo(PF_3)_4$ and those of $HRh(PF_3)_4$ and $HIr(PF_3)_4$ precludes the possibility that there is any fundamental difference between the structures of these three hydrides.

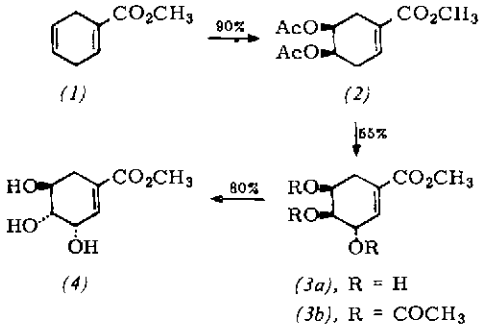
A Simple Synthesis of Shikimic Acid

By Prof. Dr. R. Grewe and Dipl.-Chem. S. Kersten

Institut für Organische Chemie der Universität Kiel (Germany)

Previous syntheses of shikimic acid [1] gave very poor yields. We have now found that the configuration *(3)* is easy to construct and that it can be rearranged to that of methyl shikimate *(4)*. This method constitutes the first preparatively useful synthesis of shikimic acid. No chromatographic purifications are required at any step: the crystalline methyl esters *(3a)* and *(4)* are obtained directly in high purity and are free from isomers.



The starting material *(1)* is readily obtainable by a diene synthesis from butadiene and methyl propiolate [1]. On treatment with silver acetate plus iodine in aqueous acetic acid [2], *(1)* gives a partially acetylated *cis*-diol, which on heating with 4 % methanolic hydrochloric acid and subsequent treatment with acetic anhydride/pyridine is transformed into methyl 4,5-*cis*-diacetoxycyclohex-1-ene-1-carboxylate *(2)*, b.p. 140 °C/0.005 mm. Treatment of *(2)* successively with *N*-bromosuccinimide for 30 min in refluxing carbon tetrachloride, with excess potassium acetate for 3 h in refluxing acetic acid, and with refluxing methanolic hydrochloric acid leads to *(3a)*, m.p. 155 °C from ethyl acetate. Acetylation of *(3a)* with acetic anhydride/pyridine converts it quantitatively into *(3b)*, b.p. 150 °C/0.005 mm. When *(3b)* is hydrolysed with liquid hydrogen fluoride for 24 h [3] and re-esterified with methanolic hydrochloric acid, (±)-methyl shikimate *(4)*, m.p. 172 °C, is formed.

The Mechanism of the Formation of Quinones from Monophenols with Dipotassium Nitrosobissulfate

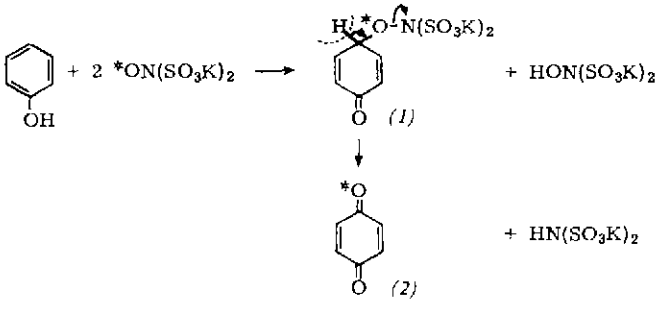
By Prof. Dr. H.-J. Teuber and Dipl.-Chem. K. H. Dietz

Institut für Organische Chemie der Universität Frankfurt/Main (Germany)

Dipotassium nitrosobissulfate $(KSO_3)_2NO$ introduces a new oxygen function in the *ortho*- or *para*-position of phenols. The products formed are a quinone, *e.g. (2)*, plus dipotassium hydroxyimidobissulfate and dipotassium imidobissulfate [1].

If the assumption is correct that quinitrol-like intermediates, *e.g. (1)*, are formed during this reaction, then the new oxygen atom in the quinone *(2)* must be derived from the nitrosobissulfate and not from the solvent (*e.g.* water, alcohol, or acetone) [2]. Oxydation of 2,6-dimethylphenol to 2,6-di-

methyl-1,4-benzoquinone with dipotassium nitrosobissulfate in which the nitroso group was labelled with ^{18}O revealed that the label did in fact recur to 97 % in the new oxygen function of the quinone. The nitroso group does not exchange its oxygen with that of the solvent under the conditions selected. 2,6-Dimethyl-1,4-benzoquinone undergoes a slight, temperature-dependent isotope exchange only above 0 °C.



The formation of *o*-quinones also corresponds to the preceding scheme. However, the labelling, *e.g.* of 3.4-dimethyl-1.2-benzoquinone [3], is somewhat smaller (65–70 %) since the isotope exchange is favored compared with that of *p*-quinones.

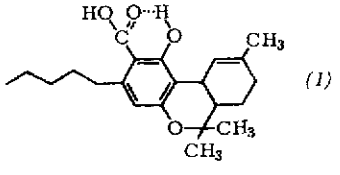
Tetrahydrocannabinolcarboxylic Acid, a Component of Hashish [1]

By Prof. Dr. F. Korte, Dipl.-Chem. M. Haag, and Dr. U. Claussen

Organisch-Chemisches Institut der Universität Bonn (Germany)

Hashish extract [2] was separated into 7 fractions by countercurrent distribution using ligroin/methanol/dimethylformamide/water (10:8:1:2 v/v). Fraction VII was separated by a further 550 transfers with the same solvent system into two components, one of which is tetrahydrocannabinolcarboxylic acid *(1)*. This compound is the missing link in the scheme for the biosynthesis of the active principles of hashish [3].



(1)

The pure acid *(1)* could not be crystallized. Its ultraviolet spectrum in cyclohexane contains three maxima at 308 (ε = 4642), 278 (1426), and 223 mμ (1795). The hydroxyl band in its infrared spectrum is broadened owing to hydrogen bonding and occurs at 3600 cm^{-1} (shoulder) and 3500 cm^{-1} (shoulder); the carbonyl absorption is at 1680 and 1655 cm^{-1}. The specific optical rotation of the acid *(1)* is $[\alpha]_D^{20} = -206.8°$ (c = 5.0 in chloroform).

The NMR spectrum [4] of *(1)* has differences from that of tetrahydrocannabinol which characterize the position of the carboxyl group. The protons of the phenolic hydroxyl and the carboxyl group give a broad signal at τ = −1.15 which disappears on shaking *(1)* with D_2O. The signal for the phenolic proton in the spectrum of *(1)* appears at a lower field than that of the corresponding resonance in the spectrum of tetrahydrocannabinol owing to the hydrogen bond between the two *ortho*-substituents. Integration gives values corresponding to one proton each for the benzene ring (τ = 3.86) and for the double bond in the cyclohexene ring (τ = 3.54). The singlet for the olefinic proton is broadened by slight coupling with the single proton on the neighboring carbon atom.

The position of the carboxyl group is also confirmed by the fact that the n-amyl protons next to the benzene ring give rise to a triplet in the NMR spectrum of tetrahydrocannabinol but appear as a multiplet 30 c.p.s. lower in the spectrum of *(1)*. Otherwise the NMR spectrum of *(1)* is identical with that of tetrahydrocannabinol.

The acid *(1)* is rapidly decomposed by light and heat and instantaneously forms red decomposition products on active surfaces, *e.g.* in thin-layer chromatography. Brief treatment with very dilute alkali at room temperature suffices to convert *(1)* into two cannabiscarboxylic acids.

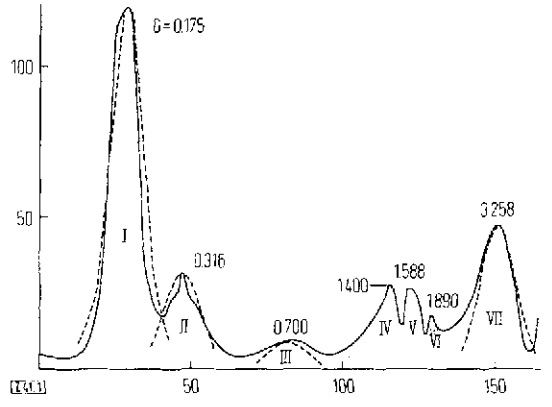


Fig. 1. Distribution of hashish extract: —— experimental curve, –––– theoretical curve. The G-values are the distribution numbers for I: cannabidiolcarboxylic acid, m.p. 45–49 °C, II: cannabidiol, III: cannabinol, IV, V, and VI: tetrahydrocannabinols, VII: tetrahydrocannabinolcarboxylic acid *(1)* and a second substance.
Ordinate: mg of substance; abscissa: fraction number.

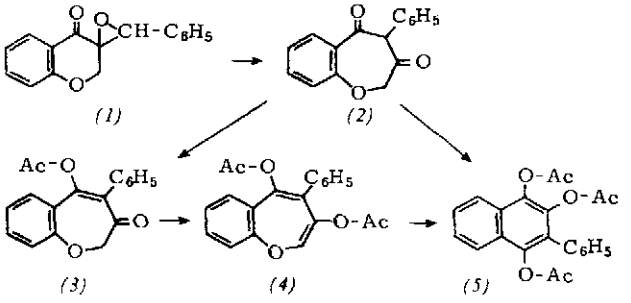
Synthesis of 4-Arylbenzo[b]oxepin Compounds and their Rearrangement to Naphthalene Derivatives

By Dr. Hans Hofmann

Institut für Organische Chemie der Universität Erlangen (Germany)

On treatment of spiro-[4-chromanone-3,2'-(3'-phenyloxirane)] *(1)* [1] with concentrated sulfuric acid or boron trifluoride etherate in benzene or on adsorption on acidic aluminum oxide of activity grade I, a 75 % yield of 4-phenyl-2,3,4,5-tetrahydrobenzo[*b*]oxepin-3,5-dione *(2)*, m.p. 99–101 °C, is formed. This compound is isolated by pouring the mixture into ice-water or removal of the solvents in vacuum, respectively, followed by crystallization from methanol.

The infrared spectrum of *(2)* in KBr or Nujol and its NMR spectrum [2] in $CDCl_3$ indicate that in the solid state and in non-polar solvents it is present in the form of the diketone *(2)* and not as 3,5-dihydroxy-4-phenylbenzo[*b*]oxepin. Acetylation of *(2)* with acetic anhydride in pyridine at *ca.* 20 °C leads to 5-acetoxy-4-phenyl-2,3-dihydrobenzo[*b*]oxepin-3-one *(3)*, m.p. 125–127 °C, which on further acetylation for 24 h at 86–87 °C gives rise to 3,5-diacetoxy-4-phenylbenzo[*b*]-oxepin *(4)*, m.p. 133.5–135 °C.



When *(2)*, *(3)*, or *(4)* are refluxed with sodium acetate in acetic anhydride for 8 h each is converted in good yield into 1,2,4-triacetoxy-3-phenylnaphthalene *(5)* [3].

In view of the oxepin ↔ benzene oxide valence-bond tautomerism [4], it is assumed that a 4,10-epoxy-4,10-dihydronaphthalene is formed by valence-bond tautomerism from *(2)* and *(4)* and by deprotonation of *(3)* and then rearranges to 2,4-diacetoxy-1-hydroxy-3-phenylnaphthalene, which is acetylated to *(5)* [5].

The same reactions were also carried out with spiro{7-methoxy-4-chromanone-3,2′-[3′-(3,4-dimethoxyphenyl)-oxirane]} [1].

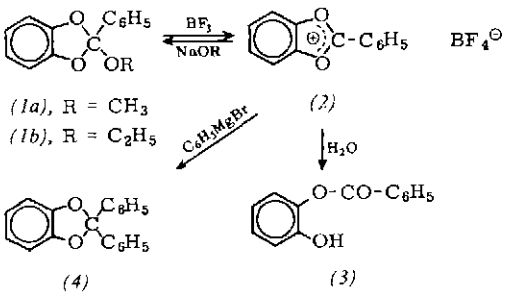
Benzo-1,3-dioxolium Salts

By Prof. Dr. K. Dimroth, Dipl.-Chem. P. Heinrich, and Dr. K. Schromm

Chemisches Institut der Universität Marburg (Germany)

The 1,3-dioxolium cation should as a cyclic 6π-electron system have a certain stability, but in contrast to 1,3-dithiolium salts [1], none of its salts have been reported.

We have now prepared 2-phenylbenzo-1,3-dioxolium fluoroborate *(2)*, the first 1,3-dioxolium salt. The crystalline compound decomposes at 150–160 °C with evolution of gas and formation of a red residue. It is obtained in 60 % yield by treatment of a 2-alkoxy-2-phenylbenzo-1,3-dioxolane *(1a)* or *(1b)* with BF_3 or HBF_4/ether in dichloromethane. The starting material *(1)* is obtained in 68 % yield by heating catechol and a trialkyl orthobenzoate at 170–180 °C. The methoxy compound *(1a)* boils at 112–113 °C/0.5 mm, the ethoxy derivative *(1b)* at 115–116 °C/0.5 mm; both are liquids with an ester-like odor.



Compound *(2)* is readily decomposed by traces of water, which attacks at C-2 and opens the 1,3-dioxolium ring to yield the monobenzoate of catechol *(3)*. Treatment with sodium methoxide or ethoxide reconverts *(2)* into *(1a)* and *(1b)*, respectively, while reaction of *(2)* with phenylmagnesium bromide produces 2,2-diphenylbenzo-1,3-dioxolane *(4)* [2]. The latter reaction can be used to prepare catechol ketals with identical or different residues on C-2.

The NMR spectrum of *(2)* in acetonitrile contains a multiplet at 8.12 ppm and a weakly resolved doublet at 8.70 ppm relative to tetramethylsilane as internal standard. The proton signals in the spectrum of *(2)* are all shifted to lower fields than those in the spectra of *(1)*. The shift is 1.0 ppm for the *ortho*-protons in the 2-phenyl group and about 1.2 ppm for the protons on the benzo moiety, which together with the *meta*- and *para*-protons of the 2-phenyl group give rise to the multiplet.

2-Phenylnaphtho-1,3-dioxolium fluoroborate, m.p. 182 to 187 °C, was prepared analogously to *(2)* and exhibits chemical properties very similar to those of *(2)*.

Synthesis and Reactions of Diarylmethylcarbonium Ions [1]

By Priv.-Doz. Dr. H. Volz and Dipl.-Chem. H. W. Schnell

Institut für Organische Chemie
der Technischen Hochschule Karlsruhe (Germany)

The reaction of diarylmethyl chlorides with antimony pentachloride at room temperature under nitrogen with exclusion of moisture [2] gives the diarylmethylcarbonium salts *(1)*–*(4)* which can be isolated by filtration.

	R	R^1	R^2	Color	Temperature of decomposition [°C]	λ_{max} [mμ] in CH_3NO_2
(1)	H	H	H	canary yellow	97–99	453
(2)	CH_3	H	H	yellow	86–87	459
(3)	CH_3	CH_3	H	carmine red	72–74	465
(4)	CH_3	CH_3	CH_3	red-violet	110–111	522

All the salts give satisfactory C, H, and Cl analyses and react with tropylidene to give the corresponding diarylmethanes and tropylium hexachloroantimonate [3]. The

salts *(1)–(3)* are rapidly decomposed by moisture, but *(4)* can be kept open to the air for several hours since its *ortho*-methyl groups shield the center of the positive charge.

The proton magnetic resonance spectra [4] of *(3)* and *(4)* in dichloromethane with tetramethylsilane as internal standard contain the following signals on the δ-scale: *(3)*, −9.68 (proton on the carbonium carbon), −7.84, −7.69, and −7.33 (benzene ring protons), −7.17 (mesitylene ring protons), and −2.58 (methyl protons); *(4)*, −9.69 (proton on the carbonium carbon), −7.15 (mesitylene ring protons), and −2.50 and −2.43 (methyl protons; relative intensity = 1:2). The methyl proton signals of *(4)* remain unchanged between −60 and +90 °C.

The infrared spectra of *(1)–(4)* in Nujol, Kel–F, or hexachlorobutadiene indicate a strong activation of the C=C vibrations, a reduction in the intensity and shift to higher frequencies in the γ-vibrational region, and a broad and very intense band in the CsBr range at 339 cm^{-1} due to the asymmetric stretching vibrations of the $SbCl_6^{\ominus}$ ion.

The strengths of the carbonium ions as acceptors for chloride ions were determined by reaction with the corresponding di- and triarylmethyl chlorides in carbon tetrachloride and chloroform and measurement of the yields of products. These increase along the series triphenylmethyl$^{\oplus}$<*(4)*<*(1)*,*(2)*<*(3)*. An equilibrium is attained in the reaction of *(4)* with triphenylchloromethane in chloroform which lies to 66–69 % on the side of triphenylmethyl hexachloroantimonate.

The salt *(1)* reacts with ethyl triphenylmethyl ether to yield benzhydryl ethyl ether. The reaction of *(1)* with water or 2 N sodium hydroxide gives mainly dibenzhydryl ether plus some benzhydryl chloride (from internal return of the chloride ion), benzophenone, and diphenylmethane (from hydride transfer between *(1)* and benzhydrol). If the salts are suspended in benzene and shaken with water or 2 N NaOH, *(1)* and *(3)* give diarylchloromethanes as main product together with some bisdiarylmethyl ether by reaction at the interface, but *(4)* yields exclusively dimesitylmethanol.

Aromatic compounds $R-C_6H_5$ are alkylated by *(1)* at room temperature by a Friedel-Crafts reaction *para* to the substituent R; the yields are: R=H, 22–29 %, R=CH_3, 40–42 %, and R=OCH_3, 61–65 %. The reaction of *(1)* with benzhydrol in benzene gives 93 % triphenylmethane, 6 % α,α,α′,α′-tetraphenyl-*p*-xylene, benzophenone, and diphenylmethane. The reaction of the salts with methanol or ethanol produces alkyl diphenylmethyl ethers.

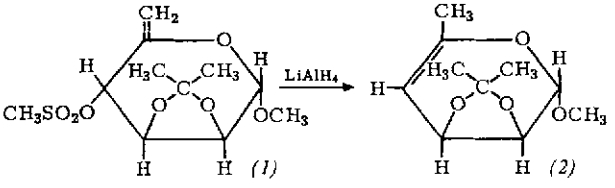
Preparation of α-Methyl 2,3-O,O′-Isopropylidene-4,6-dideoxymannopyranosid-4-ene

By Dr. J. Lehmann

Chemisches Laboratorium
der Universität Freiburg (Germany)

α-Methyl 6-deoxy-2,3-*O*,*O*′-isopropylidenemannopyranosid-5-ene [1] in pyridine was cooled in ice and treated with methanesulfonyl chloride to form the 4-*O*-methanesulfonyl ester *(1)*. The reaction mixture was stirred into a saturated solution of $NaHCO_3$ at 0 °C, and the resultant solution was extracted with chloroform. The organic phase was dried with Na_2SO_4 and the chloroform distilled off. The sirupy residue of *(1)* obtained was processed immediately because it is rather unstable. Reduction with $LiAlH_4$ in ether for 30 min at room temperature gave a mobile oil which contained no sulfur or free hydroxyl groups. The excess $LiAlH_4$ was decomposed with water and the product extracted with chloroform. The extract was washed with water and dried over sodium sulfate, and the chloroform was evaporated off on a water-bath. The residual oil was taken up in low-boiling petroleum ether and the solution washed with water and dried. The solvent was evaporated off and the residue vacuum distilled (b.p. 93–96 °C/13 mm; $[\alpha]_{575}^{25}$ = −193 °, c = 1 in chloroform). The composition and NMR spectrum of the product indicate it to have the structure *(2)*.



The NMR signals for *(2)* at 60 Mc/s in CCl_4 with tetramethylsilane as internal standard are: isopropylidene protons τ = 9.10 ppm (3 H) and 9.02 (3 H); C-6 protons, τ = 8.63 (3 H); C-2 proton, 6.58 (triplet, 1 H); C-3 proton, 6.01 (approximated triplet, 1 H), C-1 proton, 5.90 (doublet, 1 H); C-4 proton, 5.70 (doublet, 1 H) OCH_3 protons, 6.93 (3 H). The coupling constants are $J_{1,2}$ = 5.5 c.p.s., $J_{2,3}$ = 5.5 c.p.s., $J_{3,4}$ = 4 c.p.s., $J_{4,6} \approx 1$ c.p.s., and $J_{3,6} \approx 1$ c.p.s.

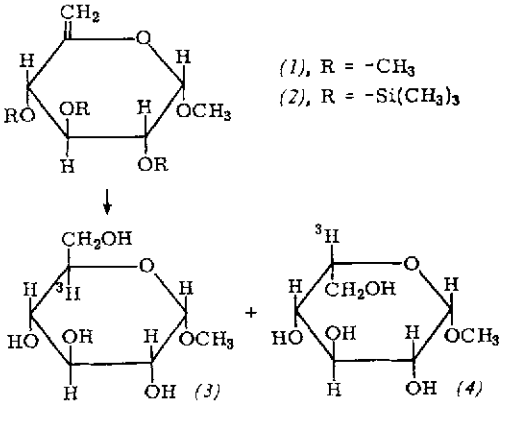
Synthesis of α-Methyl [5-^{3}H]-D-Glucoside and β-Methyl [5-^{3}H]-L-Idoside by Hydroboration of Substituted Methyl Glucosidenes

By Dr. J. Lehmann

Chemisches Institut
der Universität Freiburg (Germany)

The trimethyl ether *(1)* and tristrimethylsilyl ether *(2)* of α-methyl D-glucopyranosid-5-ene [1] can be hydroborated by passing diborane into their solutions in tetrahydrofuran. This method can be used to achieve specific labelling of sugars with tritium or deuterium.

The reaction of *(1)* and *(2)* with [^{3}H]diborane [2] and subsequent removal of the protective groups lead respectively to 1:2 and 1:0.6 mixtures of α-methyl [5-^{3}H]-D-glucoside *(3)* and β-methyl [5-^{3}H]-L-idoside *(4)*.



For example, *(2)* is hydroborated for 2 h at *ca.* 20 °C and the excess diborane is decomposed with methanol. The solution is evaporated in vacuum to a sirup, which is mixed with

tenfold amounts of methanol and 30 % acetic acid and left for 4 h in order to remove the trimethylsilyl groups. This mixture is then shaken with chloroform, and the aqueous phase is evaporated to a sirup in vacuum. The latter is dissolved in five times its weight of 10 % sodium hydroxide. The solution is cooled in ice, and 10 % of its volume of 30 % hydrogen peroxide is added. After 3 h at room temperature, the sodium ions are removed with a Dowex 50 cation exchanger, and a trace of platinum oxide is added to decompose the excess peroxide. The aqueous solution is evaporated to dryness and the boric acid is removed by repeated distillation with methanol. The residue, which begins to crystallize, is taken up in a little hot ethanol; on cooling, *(3)* crystallizes out. The mother liquor is chromatographed on Whatman No. 4 paper with n-butanol/propionic acid/water (142:71:100 v/v, descending), and the zones of *(3)* and *(4)* at R_f 0.50 and 0.65 are cut out and eluted with water. The overall yield of *(3)* plus *(4)* is 85–90 %. The solution containing *(4)* is concentrated to a sirup and heated for 6 h with 1 N sulfuric acid on a steam-bath. Removal of the acid with an Amberlite IR 45 anion exchanger and concentration of the aqueous solution leads to [5-^{3}H]-L-idosan, which has the same paper- and gas-chromatographic properties as D-idosan [3]. It was proved by degradation [4] of *(3)* that the tritium is located on C-5.

Synthesis and Properties of Tantalum Oxide Nitride, TaON

By Prof. Dr. G. Brauer and Dr. J. R. Weidlein

Chemisches Laboratorium
der Universität Freiburg (Germany)

During the preparation of red tantalum nitride Ta_3N_5 [1] from Ta_2O_5 and NH_3, intermediates of various colors are encountered. We have now found that the changes in color are due to the transient formation of tantalum oxide nitride TaON. This compound is also formed in high purity by heating Ta_2O_5 or Ta_3N_5 in a current of ammonia containing a little moisture at about 800 °C.

Tantalum oxide nitride TaON is a yellow-green solid with $d = 10$ g/cm^3. Its monoclinic crystal structure is probably of the Baddeleyite (zirconium dioxide) type [2]; its lattice parameters are $a = 4.966$, $b = 5.034$, $c = 5.185$ Å, and $\beta = 99.65°$.

Infrared Spectroscopic Investigations on Methylenetriphenylphosphoranes

By Prof. Dr. W. Lüttke and Dipl.-Chem. K. Wilhelm

Organisch-Chemisches Institut
der Universität Göttingen (Germany)

For an understanding of the Wittig reaction it is important to know the type of bonding present in methylenetriphenylphosphoranes, and in particular whether the substances are better described by the ylene formula *(1)* or by the ylide formula *(2)*. The type of bonding between the phosphorus and the methylene-carbon should be recognisable on comparison of the P–C stretching frequency in the vibration spectrum with that of methyltriphenylphosphonium ion (P–CH_3 single bond).

$(C_6H_5)_3P{=}CH_2$ *(1)* $\qquad$ $(C_6H_5)_3\overset{\oplus}{P}\ \overset{\ominus}{C}H_2$ *(2)*

We have studied the infrared spectra of methyltriphenylphosphonium iodide *(3)*, methylenetriphenylphosphorane *(4)*, phenacyltriphenylphosphonium bromide *(5)* and phenacylidenetriphenylphosphorane. In order to recognize the P–C stretching frequency among the multiplicity of bands [*(4)* has 37 atoms and thus 105 normal vibrations], we labeled the compounds *(3)*–*(6)* in the methylene group with ^{13}C or D. Thereby the frequencies of those vibrations in which the labeled atoms partake are shifted whereas the frequencies of all the other vibrations of the molecule remain almost unchanged [1]. The labeled compounds were crystallized and were examined spectroscopically as suspensions in Nujol with careful exclusion of air and moisture. Table 1 shows the results. These indicate that the PC bond orders

Table 1. P–C stretching frequencies [cm^{-1}] for compounds *(3)*–*(6)*.

	^{12}C	^{13}C	D
(3) $Ph_3P^{\oplus}CH_3I^{\ominus}$	787	776	763
(4) Ph_3PCH_2	899	884	832
(5) $Ph_3P^{\oplus}{-}CH_2{-}CO{-}PhBr^{\ominus}$	823	–	784
(6) $Ph_3PCH{-}CO{-}Ph$	887	857	?

of the methylenephosphoranes *(4)* and *(6)* are only slightly higher than those of the corresponding quaternary salts *(3)* and *(5)*.

Among P–O and P–N compounds, substantially larger differences are found between compounds with single and double bonds than among the P–C compounds (Table 2).

Table 2. Bond frequencies [cm^{-1}] for compounds with single or double bonds between phosphorus and oxygen, nitrogen, or carbon.

	X = O [2]	X = NH [3]	X = CH_2
P=X	1270–1170	1350–1200	900
	X = OH [4]	X = NH_2 [5]	X = CH_3
P–X	950–1000	870–750	790–775

The remarkably small differences in frequency of the P–C vibrations of methylenephosphoranes and the corresponding quaternary salts show that the bond between phosphorus and methylene-carbon in methylenephosphoranes has only slight double-bond character. With the equation for a diatomic harmonic oscillator, the following force constants were calculated from the P–C frequencies: *(3)*, 3.6 mdyne/Å; *(4)*, 4.9 mdyne/Å. From *H. Siebert*'s rules [6] a rough estimate leads to 1.3 for the bond order in *(4)*. Thus, if one assumes resonance between the ylene form *(1)* and the ylide form *(2)* of methylenephosphoranes, then according to the spectroscopic findings the latter form preponderates.

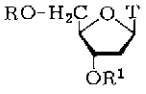
The 2,2,2-Trichloroethyl Group as a Protecting Group for Phosphate in the Synthesis of Mononucleotides

By Dr. F. Eckstein

Max-Planck-Institut für Experimentelle Medizin, Göttingen (Germany)

In order to avoid the formation of diesters during the preparation of mononucleotides, the nucleoside to be phosphorylated is condensed with a primary phosphate whose ester group is readily split off. We found that 2,2,2-trichloroethyl phosphate, $CCl_3CH_2OPO(OH)_2$ *(1)* [1], is stable in acidic and alkaline media and can be cleaved by reduction. This ester is obtained by reaction of 2 moles of 2,2,2-trichloroethanol with 0.1 mole of tristriethylammonium phosphate for 2.5 h at 60 °C in 2 moles of trichloroacetonitrile as condensing agent [2] and isolated by converting the free acid into its cyclohexylammonium salt, which is recrystallized from a 1:1 dioxane/ethanol mixture. The cyclohexylammonium salt of *(1)* melts at 194–199 °C; the yield is 46%.



(2), R = H, $R^1 = CH_3CO-$

(3), R = H, $R^1 = C_6H_5CO-$

(2a), R = $-PO(OH)OR^2$, $R^1 = CH_3CO-$

(3a), R = $-PO(OH)OR^2$, $R^1 = C_6H_5CO-$

(4), R = $-PO(OH)_2$, $R^1 = CH_3CO-$

(5), R = $-PO(OH)_2$, $R^1 = H$

(6), R = $-PO(OH)OR^2$, $R^1 = H$

$R^2 = -CH_2CCl_3$, T = Thymyl

Either 1 mole of 3′-*O*-acetylthymidine *(2)* or 1 mole of 3′-*O*-benzoylthymidine *(3)*, m.p. 96–100 °C, was condensed with 2.5 moles of *(1)* in the presence of 5 moles of dicyclohexylcarbodiimide in pyridine for 72 h at room temperature. Chromatography on a layer of silica gel [PF 254, Merck, Darmstadt (Germany)] 0.2 mm thick with chloroform/methanol (6:4 v/v) yielded the esters *(2a)* and *(3a)* in 90 and 75% yield, respectively. The cyclohexylammonium salt of *(2a)* melts at 120–124 °C, that of *(3a)* at 236–238 °C. The ester *(2a)* is also obtained in 80% yield by condensation of 1 mole of 3′-*O*-acetylthymidine-5′-phosphoric acid *(4)* with 5 moles of trichloroethanol in the presence of 5 moles of dicyclohexylcarbodiimide in pyridine for 72 h at room temperature.

Condensation of 1 mole of thymidine-5′-phosphoric acid *(5)* and 21 moles of trichlorethanol with 10 moles of dicyclohexylcarbodiimide in pyridine for 72 h at room temperature afforded a 52% yield of the ester *(6)*, whose cyclohexylammonium salt melts at 207–210 °C.

The 2,2,2-trichloroethyl nucleoside phosphates are stable in pyridine in the presence of a fivefold molar excess of dicyclohexylcarbodiimide. The protective group can be split off by reduction with Cu/Zn for 5 h in 80% acetic acid at room temperature or for 1 h at 50 °C in dimethylformamide. The free acid is isolated in the form of its pyridinium salt using Merck I ion-exchange resin. Spectrophotometric estimations showed that the compounds *(2a)* and *(6)* give the mononucleotides *(4)* and *(5)* in yields of 80–90%.

Heterosiloxanes of Zinc and Cadmium

By Dr. F. Schindler, Priv.-Doz. Dr. H. Schmidbaur and cand. chem. U. Krüger

Institut für Anorganische Chemie der Universität Marburg (Germany)

We have synthesised compounds containing the hitherto unknown structural units Si–O–Zn and Si–O–Cd by treating dimethylzinc and dimethylcadmium, respectively, with trimethylsilanol. Methane is evolved rapidly and quantitatively from the ethereal solutions, even at room temperature; subsequent vacuum sublimation leads to tetramethylzinc-*(1)* and tetramethylcadmium-siloxane *(2)* in high yields:

$$CH_3ZnCH_3 + HOSi(CH_3)_3 \rightarrow CH_4 + \underset{(1)}{CH_3ZnOSi(CH_3)_3}$$

$$CH_3CdCH_3 + HOSi(CH_3)_3 \rightarrow CH_4 + \underset{(2)}{CH_3CdOSi(CH_3)_3}$$

Compounds *(1)* and *(2)* form colorless crystals which dissolve readily in organic solvents that contain no active proton. Surprisingly they are tetrameric in such solvents. The ^1H-NMR spectrum of *(1)* in CCl_4 contains only two sharp bands, of relative intensity 1:3. In the analogous spectrum of *(2)* the satellites due to $^1H-C-^{111}Cd$ and $^1H-C-^{113}Cd$ coupling can be detected symmetrically around the signal of the Cd-methyl groups. On the basis of these results and of the corresponding infrared data (see Table) a cubane structure of point group 4 is assumed, in which the metal and the oxygen atoms, each having coordination four, occupy the corners of a – perhaps somewhat distorted – cube. *Coates et al.* [1] recently obtained similar results for alkylzinc alkoxides RZnOR. X-Ray investigations to confirm the proposed structure are in progress.

Methyl(trimethylsiloxy)mercury and Dimethyl(trimethylsiloxy)thallium

By Priv.-Doz. Dr. H. Schmidbaur and Dr. F. Schindler

Institut für Anorganische Chemie der Universität Marburg (Germany)

The reaction of diorganylmetals with silanols, which has been used for the synthesis of heterosiloxanes of zinc and cadmium [1], is not suitable for preparation of siloxane derivatives of

bivalent mercury containing the grouping Si–O–Hg. We found, however, that compounds of this type are readily accessible by treatment of organomercury halides with alkali silanolates in tetrahydrofuran (1 h at 65 °C):

$$(CH_3)_3Si{-}O{-}Na + CH_3Hg{-}Cl \rightarrow NaCl + (CH_3)_3Si{-}O{-}HgCH_3 \quad (1)$$

Compound *(1)* forms colorless, sublimable crystals [2], m.p. 52 °C, is very soluble in organic solvents, and is monomeric in benzene, in contrast to the results for $(CH_3)_3Si{-}O{-}ZnCH_3$ and $(CH_3)_3Si{-}O{-}CdCH_3$ for which a four-fold molecular weight has been found. The acceptor strength of mercury is clearly less than that of zinc or cadmium.

Dimethyl(trimethylsiloxy)thallium, the first heterosiloxane with a Si–O–Tl group, has been prepared analogously from $(CH_3)_3SiONa$ and dimethylthallium chloride:

$$(CH_3)_3Si{-}O{-}Na + (CH_3)_2Tl{-}Cl \rightarrow NaCl + (CH_3)_3Si{-}O{-}Tl(CH_3)_2 \quad (2)$$

This compound forms colorless, sublimable crystals *(2)*, m.p. 98–100 °C, that dissolve in organic solvents where they are dimeric. In this respect they resemble the analogous heterosiloxanes of aluminium, gallium, and indium [3–5].

Organometallic Derivatives of Iminotriphenylphosphorane

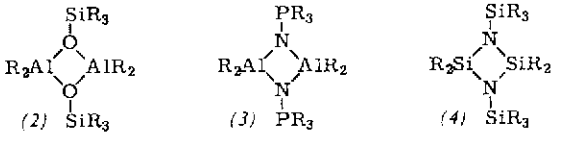
By Priv.-Doz. Dr. H. Schmidbaur, cand. chem. G. Kuhr, and cand. chem. U. Krüger

Institut für Anorganische Chemie
der Universität Marburg (Germany)

Iminotriphenylphosphorane [1] reacts with trimethylaluminum in diethyl ether at room temperature with evolution of methane. (Iminotriphenylphosphorane)dimethylaluminum *(1)* can be isolated in high yield by evaporation of the solvent and recrystallization from cyclohexane.

$$(CH_3)_3Al + HN{=}P(C_6H_5)_3 \rightarrow CH_4 + (CH_3)_2Al{-}N{=}P(C_6H_5)_3 \quad (1)$$

The compound *(1)* forms colorless crystals which slowly disintegrate in moist air. Vapor pressure osmometric determinations of molecular weight show it to be dimeric in benzene solution. Its ^1H–NMR spectrum contains a multiplet for phenyl hydrogen and a singlet due to methyl hydrogen, the ratio of the areas (2.5:1) corresponding with theoretical requirements. In the infrared spectrum, as in the NMR spectrum, analogies to the isoelectronic aluminosiloxanes *(2)* [2] can be seen. Thus structure *(3)* can be assumed for *(1)*, so that now three isostructural isosteres are known, with structures *(2)* [2], *(3)*, and *(4)* [3], respectively. (Iminotriphenylphosphorane)dimethylgallium *(5)* and



(2) *(3)* *(4)*

the indium analogue *(6)* can be prepared similarly from iminotriphenylphosphorane and trimethylgallium or -indium, respectively. Compound *(5)* is also dimeric but *(6)* is less strongly associated. Spectroscopically they resemble the aluminium compound *(1)*.

The isosteres *(7)*–*(9)* which are important for comparative spectroscopic study are all dimeric; they are obtained from the trimethylmetal etherates and triphenylsilanol with evolution of methane:

$$2\,(CH_3)_3M{\cdot}O(C_2H_5)_2 + 2\,HO{-}Si(C_6H_5)_3 \rightarrow 2\,CH_4 + [(CH_3)_2M{-}O{-}Si(C_6H_5)_3]_2$$

Preparation of Pyrimidines from Cyanic Esters and CH-Acidic Compounds

By Dr. E. Grigat and Dr. R. Pütter

Wissenschaftliches Laboratorium der Zwischenproduktenabteilung, Farbenfabriken Bayer AG., Leverkusen (Germany)

The formation of a pyrimidine derivative *(4)* as a by-product was once observed [1] in the reaction of aryl cyanates *(1)* with ethyl β-cyanoacetate *(2)* to make aroxyiminomethylcyanoacetic esters *(3)*. We have now found [2] that *(4)* is ob-

tained as the main product when *(3)* made according to [1] is mixed in acetone at room temperature with 1 mole of *(1)*, 1 mole of triethylamine is then added, and the mixture heated for a short time at 50 °C. If the reaction is carried out in one step, *i.e.* 2 *(1)* + *(2)* → *(4)*, the yield is lower. When two different cyanates are used, two isomeric hydroxypyrimidine derivatives *(4)* are obtained depending on the sequence in which the esters are taken. The products *(4)* precipitate in the form of their triethylammonium salts and can be converted into the free pyrimidines by acidification. The form *(4a)* predominates in the resultant tautomeric mixture; this is indicated by the strong carbonyl bands in the infrared spectra of *(4)*, which are absent in the spectra of their salts.

An analogous cyclization leading to aminopyrimidines *(6)* occurs on treatment of 1 mole of malonodinitrile *(2a)* with 2 moles of ethyl cyanoacetate. Here too *(5)* is first prepared according to [1] and then transformed with *(1)* with addition of triethylamine into *(6)* under conditions similar to those used for the preparation of *(4)*. With two different cyanates *(1)* two isomeric aminopyrimidine derivatives are obtained analogously.

Triscyclopentadienylplutonium

By Prof. Dr. F. Baumgärtner, Prof. Dr. E. O. Fischer, Dr. B. Kanellakopulos, and Dipl.-Chem. P. Laubereau

Kernforschungszentrum Karlsruhe
Anorganisch-Chemisches Laboratorium der Technischen Hochschule München and
Lehrstuhl für Radiochemie der Universität Heidelberg (Germany)

By treatment of plutonium with chlorine and CCl_4 at 880 °C we obtained pure, emerald-green $PuCl_3$ (isolated by sublimation), which reacts further in a melt with $Be(C_5H_5)_2$ at *ca.* 70 °C.

The moss-green compound *(1)* is the first pure cyclopentadienyl complex of a transuranium element. After removal of the excess of $Be(C_5H_5)_2$ by sublimation, *(1)* was isolated in

$$2\ PuCl_3 + 3\ Be(C_5H_5)_2 \rightarrow 2\ Pu(C_5H_5)_3 + 3\ BeCl_2 \qquad (1)$$

more than 60% yield in a high vacuum at 140–165 °C on a water-cooled finger. The product is free from chloride ions and extremely sensitive to air. It is attacked by argon-saturated water with evolution of gas, and by air-free 1 N HCl or by 18% nitric acid with formation of a blue solution of Pu^{3+}.

Compound *(1)* remains unchanged for weeks at room temperature under an inert gas; it begins to sinter at 180 °C and decomposes above 195 °.

Infrared spectra determined for polycrystalline samples in Nujol/polytetrafluoroethylene prove the presence of symmetrical five-membered rings [characteristic bands at 779/793 cm^{-1} (γ_{CH}), 841 cm^{-1}, 1007 cm^{-1} (δ_{CH}), 1447 cm^{-1} (ω_{CC}), 3100 cm^{-1} (ν_{CH})]. From the positions and intensities of the bands, as well as the absence of appreciable absorption at 1100 cm^{-1}, it can be concluded that the linkage between the metal and the cyclopentadienyl ligands has strong ionic character.

Ionization of Benzylmagnesium Chloride

By Dr. H. F. Ebel and Dr. R. Schneider

Organisch-Chemisches Institut der Universität Heidelberg

Triphenylmethylmagnesium chloride [1] and bromide [2] are colorless in ether or in the crystalline state. This contrasts to the triphenylmethyl compounds of the alkali metals which exhibit a red color due to the $(C_6H_5)_3C^-$ anion, thereby showing that they are ionophores. The lack of ionization in $(C_6H_5)_3C$ MgX led to the conclusion [3] that magnesium alkyls are not ionized to any measurable extent.

We have found that benzylmagnesium chloride, prepared from benzyl chloride and magnesium in ether, can be caused to ionize. On addition of tris(dimethylamino)phosphine oxide, $OP(NMe_2)_3$ [4], the colorless ethereal solution assumes the red color of the benzyl anion, which is characteristic of benzylsodium even in the absence of the phosphine oxide [5]. Depending on the concentrations, a white precipitate may be observed before the color develops. The solution can be decolorized, with evolution of heat, by adding an equivalent amount of benzophenone or benzyl chloride [6]. Addition of much water and evaporation of the ether phase then allows isolation of 1,1,2-triphenylethanol (67%) and bibenzyl (65%), respectively. With benzyl-lithium we have also found for the first time [7] a strong solvatochromic effect (red shift on addition of $OP(NMe_2)_3$ [5]). This compound usually is yellow to orange, even in the presence of tetramethylethylenediamine [8], and may be assumed to form contact ion pairs with partial covalent character [9] under normal conditions.

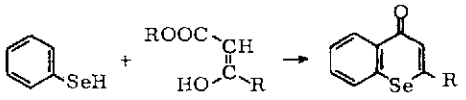
Synthesis of 1-Selenochromones [1]

By Dr. F. Bossert

Pharmazeutisch-Wissenschaftliche Abteilung
der Farbenfabriken Bayer AG., Werk Elberfeld (Germany)

We have prepared 1-selenochromones *(1)* by condensation of selenophenol and β-keto esters with polyphosphoric acid. For example, ethyl acetoacetate yields 2-methylselenochromone *(1)*, R = CH_3, m.p. 100 °C, ethyl benzoylacetate yields



(1)

2-phenylselenochromone *(1)*, R = C_6H_5, m.p. 127–128 °C, and ethyl 4-methoxybenzoylacetate yields 2-(*p*-methoxyphenyl)selenochromone *(1)*, R = *p*-$CH_3OC_6H_4$, m.p. 150 to 152 °C.

A mixture of 0.1 mole of selenophenol and 0.12–0.14 mole of β-keto ester is added dropwise over 1 h to 350 g of polyphosphoric acid at about 90 °C, and the mixture is then heated for about 3 h at 90–100 °C and poured onto ice. The product is extracted with ether, and the ether extract is washed with water, dilute sodium hydroxide, and water and then dried. After evaporation of the ether, the crude product is obtained in 40–50% yield and is purified by recrystallization from methanol, ethanol, or benzene/ligroin. The structures of the products were proved by comparing their infrared and NMR spectra with those of the corresponding thio compounds.

In the title and in the last sentence of this Communication, the name of the compound synthesized should be changed to "3,5-dibromo-1,2,4-triazole".

CONFERENCE REPORTS

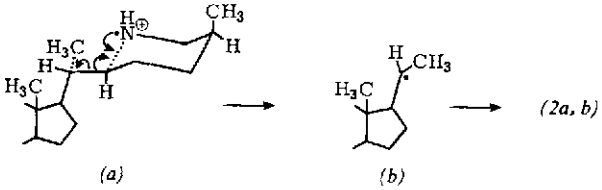
Conference of Chemistry Lecturers in Potsdam

The Conference was held at Potsdam (Germany) on July 5th–8th, 1965. The following is a selection of excerpts from the 108 lectures delivered.

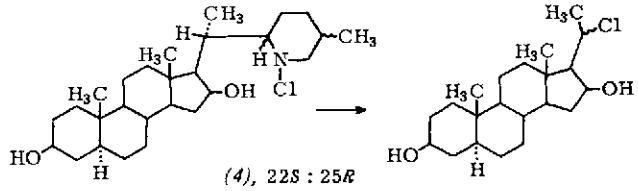
New Photochemical Reactions of Nitrogenous Steroids

G. Adam and *K. Schreiber*, Gatersleben (Germany)

Unlike its (22*R*:25*S*) and (22*S*:25*R*) stereoisomers, (22*S*:25*S*)-*N*-chloro-22,26-imino-5α-cholestan-3β-ol *(1)* does not lead to solanidanol in the Hofmann-Löffler-Freytag reaction induced by ultraviolet irradiation. An unresolvable mixture of the two C-20 stereoisomers of 20-chloro-5α-pregnan-3β-ol *(2a,b)* is obtained instead (in 52% yield) in a degradation reaction taking place when *(1)* is irradiated in trifluoroacetic acid. The same product has also been synthesized from (20*R*)-3β-acetoxy-5α-pregnan-20-ol *(3)*.

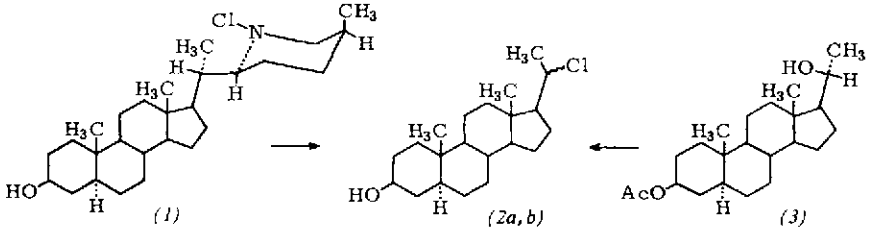


(a) *(b)* *(2a, b)*



(4), 22*S* : 25*R*
(5), 22*S* : 25*S*
(6), 22*R* : 25*S*

(7a,b)



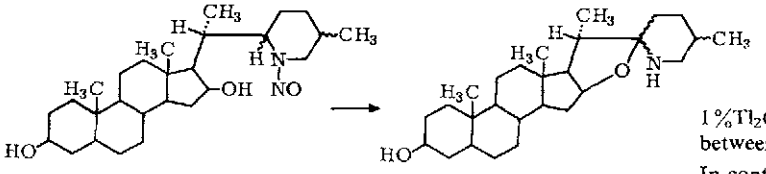
(1) *(2a,b)* *(3)*

According to the free-radical mechanism postulated for this new type of fragmentation, the nitrogen-containing radical ion formed in the photochemical reaction undergoes C–C cleavage *via (a)*, the resulting carbon radical *(b)* being stabilized before it recombines with a chlorine radical to form *(2a,b)*.

When this photolysis is carried out on the 16β-hydroxy-substituted *N*-chloro-22,26-iminocholestanols *(4)–(6)*, degradation is always the principal reaction, leading invariably to the same mixture of C-20 stereoisomeric 20-chloro-5α-pregnan-3β,16β-diols *(7a,b)* in a yield of up to 82%. The resulting mixture can be resolved by column chromatography.

This reaction provides a new route to the degradation of spirosolane alkaloids, leading to the pregnane series in three steps: reduction, *N*-chlorination, and degradation.

Further photochemical investigations with the *N*-nitroso compounds *(8)–(11)* have shown that, instead of degradation, the compounds of this type are cyclized to the corresponding spirosolane alkaloids *(12)–(14)* on ultraviolet irradiation in ethanolic HCl.



(8), 5α, 22*S* : 25*R*
(9), Δ^5, 22*S* : 25*R*
(10), 5α, 22*S* : 25*S*
(11), 5α, 22*R* : 25*S*

(12), 5α, 22*R* : 25*R*
(13), Δ^5, 22*R* : 25*R*
(14), 5α, 22*S* : 25*S*

It has been found in the photolysis of (22*S*:25*R*)-*N*-nitroso-3β,16β-diacetoxy-22,26-imino-5α-cholestane that the photochemical reaction proper consists in the introduction of a $\Delta^{22(N)}$-double bond, followed — in the presence of a free 16β-hydroxyl group — by a spontaneous and stereospecific cyclization to spirosolane.

Preparation and Properties of Silicon Monoxide

H.-H. Emons, Merseburg (Germany)

Vitreous $(SiO)_n$ was prepared [1] from silicon and silicon dioxide. On condensation of SiO vapor on a cold finger, fibrous $(SiO)_n$ is obtained. Even in an atmosphere of argon, the product frequently underwent spontaneous ignition without change in composition, accompanied by lightening of the color. No disproportionation product could be detected in the resulting substance by X-ray analysis.

$(SiS)_n$ was prepared from Si and SiS_2 or CS_2 under vacuum at 850 to 1000 °C. The vitreous substance with a color varying from red to reddish brown obtained on purification by sublimation turns yellow when ground in a mortar, and forms H_2S with water and H_2 with 5% NaOH. The varying appearance of $(SiS)_n$ in metallurgical processes is due to the varying particle size and to impurities.

A three-dimensional, random network structure is assumed for the vitreous $(SiO)_n$ and $(SiS)_n$, the Si atoms or groups of two or more Si atoms being linked *via* oxygen or sulfur by a σ-bond system strengthened by partial $d_\pi p_\pi$ double bonds. An open-chain structure based on rows of Si–Si linkages may be postulated for the fibrous $(SiO)_n$ having unidirectional fracture. The fact that the color of this product becomes lighter on ignition indicates that the chains become detached from each other during this process.

Reactions with Cl_2 and HCl confirm the relative inertness of the vitreous $(SiO)_n$ compared to the more reactive fibrous product.

The "yellow substance" described earlier [1] consists of $(SiO)_n$ and 40 to 50% of silicon and silicon dioxide.

Preparation of Aromatic Nitriles from Alkylaromatic Compounds and Nitric Oxide in the Vapor Phase

E. Fischer, Rostock (Germany)

Alkylaromatic and alkyl-substituted heterocyclic compounds form nitriles with nitric oxide in the presence of catalysts at 650 to 900 °K:

$$2\ RCH_3 + 3\ NO \rightarrow 2\ R{-}CN + 3\ H_2O + 1/2\ N_2$$

(R = aromatic or heterocyclic residue)

The following catalysts were investigated in the reaction with toluene: Ag/carbon, Pd/carbon, Pt/carbon, Re/carbon, $PbSnO_3$, and $PbTiO_3$. The silver catalysts were activated with Tl_2O_3, CaO, or PhO. The highest conversion of toluene into benzonitrile (30 to 42%) was obtained with 7% Ag/1%Tl_2O_3/carbon and $PbTiO_3$/1% Tl_2O_3. The yield varies between 90 and 98%, depending on the temperature.

In contrast to the ammoxidation, the catalytic nitrosation of *p*-xylene into *p*-toluonitrile and of *p*-t-butyltoluene into *p*-t-butylbenzonitrile under suitable conditions leads selectively to the mononitriles.

Benzonitrile is obtained from dialkylaromatics when Pt, Pd, and Ag catalysts containing more than 9% Ag are used above 435 °C.

The concentration of nitric oxide has an important effect. Maximum yields are obtained only when the molar ratio of NO to toluene is 1.5. With a molar ratio of 1.0, the yield amounts at most to 12%, and when the molar ratio is 2.0, the maximum yield falls to 16–25%.

Methyl-substituted heterocyclic compounds, such as 2-methylthiophene or 2-methylfuran can similarly be converted into nitriles. Thus 2-cyanothiophene is obtained in a yield of 85% at 20% conversion of methylthiophene on titanium catalysts at 730 °K.

A residence time of 2.2 to 4.6 sec and a rate of discharge of the liquid products equal to 0.157 to 0.430 h^{-1} represent the best conditions for the vapor phase nitrosation.

Modification of Proteins by the Introduction of Additional Thiol Groups

U. Freimuth and *W. Krüger*, Dresden (Germany)

Thiol groups were introduced into crystalline β-lactoglobulin by the reaction of free ε-amino groups of the latter with acetylmercaptosuccinic anhydride [1] or with *N*-acetylhomocysteine thiolactone [2]. The excess of reagent and the buffer salts can be removed by gel filtration on Sephadex G-25 under milder conditions than by dialysis or ion-exchange chromatography.

Whereas acetylmercaptosuccinyl-β-lactoglobulin appears homogeneous in sedimentation and electrophoresis, *N*-acetylhomocysteinyl-β-lactoglobulin was resolved on Sephadex G-25 into two fractions, one of which was found to be an aggregation product. This result was confirmed by experiments with a reagent labeled with ^{35}S.

The molecules associate rapidly when the thiol groups are removed from acetylmercaptosuccinyl-β-lactoglobulin by deacetylation at pH 10 to 11.

In order to establish whether the introduction of the thiol groups is accompanied by irreversible denaturation, the hydrolysate of the *N*-acetylhomocysteinyl-β-lactoglobulin was tested for lanthionine that may have been formed by disulfide exchange and by nucleophilic attack by the SH^- anions on the disulfide bridges of the protein. However, no lanthionine was detected. The lanthionine analysis was improved considerably by the use of high-voltage electrophoresis, since lanthionine sulfoxide, cysteic acid, homocysteic acid, and methionine sulfone are readily resolved in 1 h in a formic acid/acetic acid buffer (pH 1.9) by the application of about 2000 V.

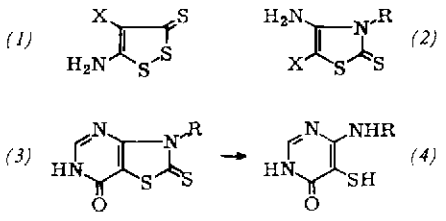
Reactions of Carbon Disulfide and Isothiocyanates with Sulfur and Nitriles Containing an Active Methylene Group

K. Gewald, Dresden (Germany)

In the presence of triethylamine at room temperature, the joint action of sulfur and carbon disulfide on nitriles having an active α-methylene group leads to 4-substituted 5-amino-1,2-dithiol-3-thiones *(1)* [1,2]. If isothiocyanates are used instead of carbon disulfide, 3,5-disubstituted 4-aminothiazoline-2-thiones *(2)* are obtained. These compounds can also be prepared by replacing the isothiocyanate by the corresponding primary amine and by carbon disulfide, and by treating these with sulfur and with the nitrile.



X = CN, CO_2R, $CONH_2$
R = Alkyl, Allyl, Phenyl

The compounds of type *(1)*, which are sensitive to strong bases [2], exhibit "trithione properties" (*e.g. S*-methylation) only when the weakly basic amino group is protected by acylation. When compounds of type *(2)*, which are stable to acids and are similarly very weakly basic, are treated with strong bases, the starting materials are reformed by cleavage. The structure of *(2)* can be ascertained *inter alia* by the following reactions: With ethyl orthoformate, the amido derivative of *(2)* (X = $CONH_2$) gives the thiazolopyrimidone *(3)*, which can be cleaved with dilute NaOH to give the mercaptan *(4)*.

Synthesis of Methylenebisphosphorus Compounds

H. G. Henning, Berlin (Germany)

One-stage reactions of bifunctional methylene compounds with two equivalents of a phosphorus compound are unsuitable for the preparation of methylenebisphosphonates or methylenebisphosphinates. The α-monofunctional methylenephosphonates and methylenephosphinates were therefore tested with a view to forming a (P–C–P) linkage. In some cases α-metallated phosphonates and phosphinates (with Na, Na/K, $MgOC_2H_5$, MgCl) could be acetylated, but reactions with ester chlorides of various acids of phosphorus did not lead to the compounds required.

The Michaelis-Arbuzov and the Michaelis-Becker reactions of alkyl α-halogenomethylphosphonates and alkyl α-halogenomethylphosphinates with trivalent phosphorus compounds lead to derivatives that would be expected to result from a nucleophilic attack (a) on the α–C atom and (b) on the ester alkyl group. In the Arbuzov reaction of ethyl ethyliodomethylphosphinate with diethyl ethylphosphonite between 180 and 200 °C, mechanism (a) leads to methylenebis(ethyl ethylphosphinate) in a yield of 69.9%, and mechanism (b) and the action of ethyl iodide liberated in (a) lead to ethyl diethylphosphinate.

In the Michaelis-Becker reaction of the α-halogenomethylalkyl- or α-halogenomethylarylphosphinic acids, the nature of the alkyl or aryl substituent on the phosphorus is also significant. Positive substituents promote elimination of halogen as the anion in accordance with mechanism (a), and inhibit mechanism (b). Negative substituents, on the other hand, promote the alkylating power of the ester [mechanism (b)] and inhibit mechanism (a). Owing to their (+M)-effect, ethoxy groups oppose the withdrawal of electrons from the neighboring groups by the P=O group. Compounds with aromatic substituents do not react in the required manner. In the reaction of ethyl chloromethylethylphosphinate with sodium diethylphosphite, on the other hand, ethyl O,O-diethylphosphonylmethylphosphinate is formed in a yield of 60.9%.

Solvent Effects on the Stereospecificity of Halogen Addition to cis- and trans-Stilbenes

G. Heublein, Jena (Germany)

The relative amounts of the diastereoisomers in the addition product of halogens to *cis*- and *trans*-stilbenes, as determined by infrared spectroscopy, is regarded as a measure of the stereospecificity of the reaction.

In non-polar solvents, a halogenonium ion *(1)* is formed, which is stabilized by a partial intramolecular charge redistribution. The reaction is therefore largely stereospecific in favor of *trans*-addition.

In polar solvents, on the other hand, the ionic intermediate is stabilized as a carbonium ion *(2)* by solvation. Internal rotation is possible in the intermediate, and the end-product of the addition is determined by the sterically most favorable conformation of the intermediate, which in this case is the one with distant benzene rings leading to the *meso*-form.

(1) *(2)*

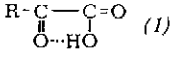
Addition of chlorine to dichloroiodobenzene has shown that, unlike bromine, chlorine is hardly capable of forming a halogenonium ion *(1)* in a non-polar solvent, so that *meso*-dichlorostilbene is formed preferentially with both *trans*- and *cis*-stilbene.

The addition of ICl to *trans*-stilbene in a polar or a non-polar solvent results exclusively in *erythro*-chloroiodostilbene, indicating the formation of an iodonium ion *(1)*.

Intramolecular Acid Catalysis in the Iodination of Keto Acids. Detection of Proton Chelates in Aqueous Solution

G. Hübner, Halle (Germany)

Whereas the halogenation of keto compounds is generally catalysed by acids, the rate of iodination of α-keto acids is independent of the hydrogen-ion concentration [1]. This suggests an intramolecular interaction between the carboxyl and the carbonyl groups, especially since proton chelates of type *(1)* have been detected in non-polar solvents and in



(1)

the vapor phase [2]. In order to separate the inductive effect of the carboxyl group from the hydrogen-bonding effect, aromatic compounds were studied which structurally resemble α-keto acids, but in the *p*-isomers of which the carboxyl or hydroxyl groups have only long-range effects on the carbonyl group. The rates of iodination of *o*-hydroxyacetophenone, *o*-acetophenonecarboxylic acid, and *o*-propiophenonecarboxylic acid were found to be independent of the acid concentration, whereas those of *p*-hydroxyacetophenone and *p*-acetophenonecarboxylic acid were found to be proportional

[1] *A. Schellenberger* and *G. Hübner*, Chem. Ber. *98*, 1938 (1965).

[2] *A. Schellenberger* and *G. Oehme*, Z. physik. Chem. *227*, 112 (1964); *A. Schellenberger*, *W. Beer*, and *G. Oehme*, Spectrochim. Acta *21*, 1345 (1965).

to the acid concentration. It follows that proton chelates can also exist in aqueous solutions, and that the protons protect the carbonyl groups against attack. A certain acidity of the OH groups is probably a prerequisite for such interactions, since phenylacetoin behaves as a simple ketone, although proton chelates can be detected spectroscopically in non-polar solvents. A number of compounds of physiological importance, *e.g.* pyruvic acid, α-ketobutyric acid, and α-ketoglutaric acid exist in the form of proton chelates in aqueous solutions at their spontaneous pH.

Thiocarbamoylphosphines

K. Issleib and *G. Harzfeld*, Halle (Germany)

The formation of thiocarbamoylphosphines depends on the nucleophilicity of the primary or secondary phosphine involved and on the inductive effect of the organic residue of the isothiocynates. Aryl isothiocyanates form thiocarbamoylphosphines $R_2P-C(S)-NHR'$ with aliphatic and aromatic secondary phosphines. Alkyl isothiocyanates, on the other hand, react only with the more strongly nucleophilic aliphatic or cycloaliphatic secondary phosphines to give the corresponding thiocarbamoylphosphines. Being less nucleophilic, diphenylphosphine reacts only with methyl isothiocyanate. Only the use of alkali metal phosphides, MPR_2, provides a general method for the reaction with variously substituted alkyl isothiocyanates. The hydrolysis of such reaction mixtures leads to *N*-alkylthiocarbamoylphosphines, $R_2P-C(S)-NHR'$ with R = C_6H_5-, $C_6H_{11}-$, C_2H_5-, and R' = CH_3-, C_2H_5-, $CH_2=CH-CH_2-$.

Unlike the *N*-arylthiocarbamoylphosphines, the *N*-alkyl derivates form *P*-sulfides$[R_2P(S)-C(S)-NHR']$ with sulfur or by the oxidation of the *P*-oxides.

Whereas the organic groups linked to the phosphorus exert no effect in these reactions, those bound to the nitrogen are highly influential in the reactivity of the lone electron pair on the P-atom. A mesomeric anion *(1)* has now been postulated for the metallated thiocarbamoylphosphines prepared from thiocarbamoylphosphines and phenyl-lithium, or from alkali metal phosphide and isothiocyanate.

$$[R_2P-C(S)-N^{\ominus}R' \longleftrightarrow R_2P-C(S^{\ominus})=NR'] M^{\oplus}$$

(1a) *(1b)*

The existence of this mesomeric anion is indicated by the fact that the reaction with, methanol leads to thiocarbamoylphosphines, pointing to form *(1a)*, whereas the reaction with ethyl iodide results in *S*-ethylisothiocarbamoylphosphines, the substrate being in form *(1b)*.

With secondary phosphines, diisothiocyanates give thiocarbamoylphosphines of the general formula

$R_2P-C(S)-NH-R'-NH-C(S)-PR_2$

R = C_6H_5-, $C_6H_{11}-$; R' = $(C_6H_4)_2-$, $-(CH_2)_6-$

In contrast to methyl isothiocyanate, aryl isothiocyanates react with primary aliphatic and cycloaliphatic phosphines (phenylphosphine does not react), giving bis(thiocarbamoyl)-phosphines, $RP[-C(S)-NHR']_2$, or thiocarbamoylphosphines, $RHP-C(S)-NHR'$. The former are also obtained with dilithium phosphide, Li_2PR, by hydrolysis. The formation of addition compounds between tertiary phosphines and aryl isothiocyanates has not been observed in the case of the biphosphines, R_2P-PR_2, which form thiocarbamoylphosphines in the presence of ethanol.

Preparation and Reactions of Optically Active Aminosilanes

K.-D. Kaufmann and *K. Rühlmann*, Berlin (Germany)

Optically active aminosilanes, $R_3Si^*NR^1R^2$ (R_3Si^* = α-naphthylphenylmethylsilyl, R^1 and R^2 = H, alkyl, or aryl), were prepared from optically active α-naphthylphenylmethylchlorosilane [1,2]. On the basis of optical rotatory dispersion [3], the configuration (−)-R_3Si^*-H has been assigned to the aminosilanes prepared from (−)-R_3Si^*Cl [4].

It follows from this that the nucleophilic substitutions of amines in halosilanes also proceed *via* an S_N2 mechanism, with inversion of configuration at the silicon center. The hydrolysis and the alcoholysis of aminosilanes in polar and non-polar solvents are also accompanied by inversion of configuration. In the conversion of aminosilanes with acid halides into halosilanes and the corresponding amides, inversion of configuration occurs if the steric shielding of the nitrogen atom in the aminosilane is low. Thus the stereochemical yields (inversion) in the reaction of $R_3Si^*NHCH_3$ with *p*-nitrobenzoyl chloride and with phosphorus trichloride are 98 and 83%, respectively. With bulkier substituents at the nitrogen, however, a competing reaction also takes place, accompanied by retention of configuration. Thus the reaction of $R_3Si^*NHC_6H_{11}$ ($C_6H_{11}-$ = cyclohexyl) with *p*-nitrobenzoyl chloride to give R_3Si^*Cl, which is still characterized by the predominance of inversion, leads to a stereochemical yield of only 63%, whereas the reaction of $R_3Si^*N(C_2H_5)_2$ with PCl_3 results in a yield characterized by 61% retention. Similar phenomena have been observed in the reaction of aminosilanes with HCl in non-polar solvents [1].

The reactions of aminosilanes with $LiAlH_4$, giving R_3Si^*H [1], and with solid KOH, giving R_3Si^*OK, proceed predominantly with retention of configuration.

According to these results, inversion of configuration is to be expected in the reactions of aminosilanes if the $d_\pi-p_\pi$ bond between silicon and nitrogen can be ruptured by protons or Lewis acids, whilst retention of configuration occurs whenever this bond can be broken only *via* the formation of a cyclic intermediate.

N-(Iodophenyl)pyridinium Salts

B. Lipke, Berlin (Germany)

In order to study their oxidation reactions, three isomeric *N*-(iodophenyl)pyridinium salts were prepared by *W. König*'s method from cyanogen bromide, pyridine, and the corresponding iodoanilines, and were converted into compounds containing iodine in its higher valence states.

The three isomeric (dichloroiodophenyl)pyridinium salts were prepared by chlorination of the *N*-(iodophenyl)pyridinium salts. Attempts at conversion into the iodoso derivatives were unsuccessful. With the aid of the *N*-(4-iodylphenyl)pyridinium salts, which were prepared from *N*-(iodophenyl)-pyridinium salts by the action of peroxydisulfuric acid, hydroquinone was oxidized to quinone, aniline to azobenzene, and ethanol to acetaldehyde, the reactions being carried out in aqueous acetone at 20 to 50 °C.

At 0 °C, *N*-(4-bromophenyl)pyridinium chloride and *N*-(4-chlorophenyl)pyridinium chloride form adducts with chlorine.

Bonding and Electron Distribution in the I_3^- Ion According to a Three-Dimensional Free-Electron Model

Hans Müller, Jena (Germany)

The three-dimensional free-electron (FE) model suggested earlier [5] can be used for the calculation of bond energies because of the simultaneous treatment of the σ- and π-electrons. In accordance with the $D_{\infty h}$ symmetry group of the

linear I_3^- ion, the 22 valence electrons of the molecule-ion are considered to form a force-free electron gas in a cylindrical potential box. Solution of the Schrödinger equation gives the eigenvalues in closed form and tractable eigenfunctions Ψ_{lpn}. The I_3^- ion is a particularly interesting three-center system, since both I_2 and I^- (which may be considered as the components of I_3^-) have complete octets, so that the additional covalent bond in I_3^- is usually described in terms of hybridization, although the excitation $\ldots(5d)^5 \rightarrow \ldots(5d)^4(6s)$ requires 156 kcal/mole, and the bond energy of I_2 is only 35.6 kcal/mole. In the FE model, on the other hand, the formation of I_3^- can be described without recourse to higher orbitals, thus avoiding this difficulty.

As early as 1951, a MO calculation by *Pimentel* [6] succeeded in excluding the higher states, but arrived at an unsatisfactory qualitative result by taking into account only four electrons and assuming that the other 18 valence electrons occupied non-bonding orbitals.

On the basis of the FE model, the ground state of the I_3^- ion is expressed as (R denotes inner electrons):

$$I_3^-[RRR(1\sigma_g)^2(1\sigma_u)^2(2\sigma_g)^2(2\sigma_u)^2(1\pi_u)^4(1\pi_g)^4(3\sigma_g)^2(2\pi_u)^4]\,{}^1\Sigma \quad (1)$$

Weak σ-bonds are deduced for I_3^- from a balance between the bonding orbitals ($1\sigma_g$, $2\sigma_u$, $1\pi_u$) and the antibonding orbitals ($2\sigma_g$, $2\pi_u$), and a bond energy of 25.8 kcal/mole is obtained for the I–I bond. The corresponding electronic distribution is inferred from an FE molecular diagram:

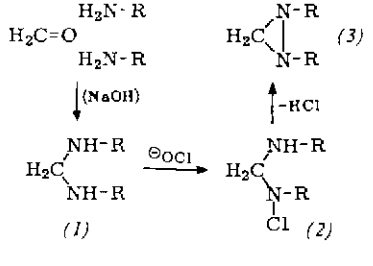
$$1.89\text{–}I\ \underset{3.83}{\overset{1.58}{\underset{1.79}{\quad}}}\ I\text{–}3.38\text{–}I\text{–}1.89 \qquad 3.79$$

whose electronic population $pop_nV = \int g_n D_n(z)dz$ can be calculated from the FE molecular orbitals by the use of the axial density, $D_n(z) = \iint|\Psi_{lpn}|^2\rho d\rho d\varphi$. The aufbau principle following from *(1)* is applicable to linear triisocentric systems, as can be shown on H_3^+, C_3, Si_3, Ge_3, Sn_3, N_3^-, and I_3^-.

Cyclization of 1,1-Diamino Compounds

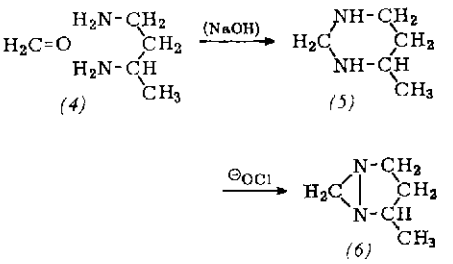
R. Ohme and *P. Dolge*, Berlin (Germany)

Primary aliphatic amines react with formaldehyde leading to hexahydro-1,3,5-triazines. Aminals of formaldehyde are assumed to be the intermediates involved in this well-known reaction. When formaldehyde is condensed with 2 moles of an alkyl amine in a strongly alkaline medium (2N NaOH), the reaction stops at the aminal stage *(1)*.

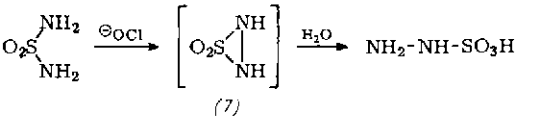


If 1 mole of sodium hypochlorite is then added, *N,N'*-dialkyldiaziridines *(3)* are obtained in good yields *via* the *N*-chloraminals *(2)*. The 1,3-diamine *(4)* can be condensed with formaldehyde in 2 N NaOH, giving a cyclic aminal *(5)*, which is further cyclized into the diaziridine derivative *(6)*, yield 93%, when treated with hypochlorite.

The *N*-substituents in the diaziridine *(6)* are attached in the cis-position, and therefore the compound has a dipole moment of 2.91 D, which is too high for diaziridines.

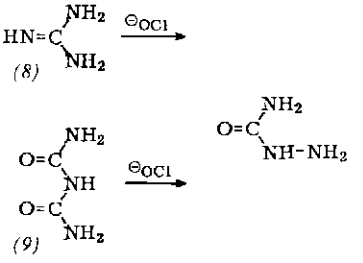


With alkaline hypochlorite, sulfamide forms hydrazinosulfonic acid:



Similarly to the reaction of *N,N'*-dialkylsulfuric acid diamides [1], an S–N–N ring *(7)* may be assumed as intermediate.

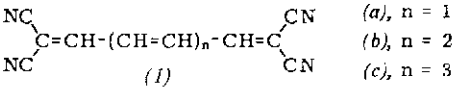
The action of alkaline hypochlorite on guanidine *(8)* and biuret *(9)* leads to semicarbazide (isolated as the *p*-nitrobenzaldehyde semicarbazoen) in a yield of 30–40%.



Synthesis and Properties of Tetracyanopolyenes

Hermann Schmidt and *C. Hamann*, Dresden (Germany)

Tetracyanopolyenes of type *(1)* were prepared, the starting material for *(1a)* and *(1c)* being 1,1,4,4-tetramethoxybut-2-



ene, the bisacetal of maleic dialdehyde. Acid condensation with malononitrile led to *(1a)* in good yield. In the preparation of *(1c)*, the unsaturated bisacetal was first converted by *Kucharov*'s method into 2,4,6-octatriene-1,8-dial, and the latter was then made to react with malononitrile to give *(1c)*. Product *(1b)* was analogously obtained from *trans,trans*-mucondialdehyde bisacetal. Ethyl cyanoacetate, ω-cyanoacetophenone, or barbituric acid can be used as a CH-active compound. Infrared spectroscopy showed all polyenes obtained in this manner to be all-*trans* compounds.

Tetracyanopolyenes behave similarly to tetracyanoethylene in that they form colored π-complexes with aromatic hydrocarbons. In the Diels-Alder reaction, two moles of a diene react with one mole of tetracyanopolyene. They are readily converted into the expected products with nucleophilic reagents (amines, alcohols).

Polycrystalline samples were used to measure the d-c dark conductivity of the polyenes as a function of temperature. This property was found to increase with the number of π-electrons in the compound. The tetracyanopolyenes are n-type semiconductors, their Seebeck coefficients varying linearly with the number of π-electrons in the compound.

[6] *G. C. Pimentel*, J. chem. Physics *19*, 446 (1951).

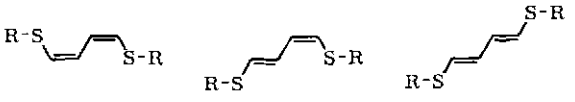
Syntheses and Reactions of 1,4-Dimercaptobutadienes

W. Schroth, F. Billig, and *H. Langguth,* Leipzig (Germany)

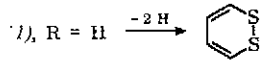
cis,cis-1,4-Bis(dibenzylthio)butadiene *(1)* (R = $-CH_2-C_6H_5$) prepared by the nucleophilic addition of benzyl mercaptan to diacetylene reacts with sodium in liquid ammonia with retention of the double bonds to give the *cis,cis* salt *(1)*, R = Na, which can be *S*-alkylated and *S*-acylated. The multiple bonds



(1) *(2)* *(3)*

also remain intact in the analogous debenzylation of bis-(benzylthio)acetylene into the sodium salt of dimercaptoacetylene (investigations carried out in collaboration with *D. Wallach*). The free dimercaptan *(1)*, R = H, obtained from *(1)*, R = Na, forms the phenylhydrazone of succinaldehyde and thiophene (50% yield) with P_4O_{10}.

The dehydrogenation of *(1)*, R = H, leads to 1,2-dithiin *(4)*, which behaves as an heterocyclic olefin and not as an aromatic compound.



(4)

On ultraviolet irradiation, *(1)*, R = $COCH_3$, undergoes rearrangement, giving the corresponding *cis,trans*-isomer *(2)* and the *trans,trans*-isomer *(3)*, both of which can be hydrolysed and alkylated into sterically uniform derivatives.

Compound *(3)*, R = $COCH_3$, was also obtained from cyclooctatetraene dibromide with potassium thioacetate, by diene synthesis with acetylenedicarboxylic ester, and by the Alder-Rickert fission. Only the *trans,trans*-isomer *(3)*, R = $COCH_3$, reacts with dienophiles under mild conditions because of the possibility of the *cis*-configuration about both double bonds. The diene adducts can be aromatized by the cleavage of thioacetic acid.

The free dimercaptans *(1)*–*(3)*, R = H, exist almost exclusively as enthiols and not as thioaldehydes.

Equilibrium measurements have shown that *cis*-bis(methylthio)ethylene [1] is more stable below 60 °C than the *trans*-isomer (work carried out with *R. Kemmler*).

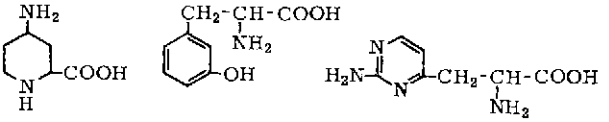
Rare Amino Acids in Plants

H.-R. Schütte, Halle (Germany)

Several non-proteinogenic amino acids have recently been found in plants. The author has investigated 4-aminopipecolinic acid *(1)* extracted from *Strophanthus scandens*, *m*-tyrosine *(2)* extracted from *Euphorbia myrsinitis*, and tingitanin *(3)* obtained from *Lathyrus tingitanus*. The structure of 4-aminopipecolinic acid was established by synthesis and by converting the compound into 4-hydroxypipecolinic acid with sodium nitrite. 4-Aminopipecolinic acid is formed in plants from pipecolinic acid *via* hydroxypipecolinic acid and probably 4-ketopipecolinic acid.

The structure of *m*-tyrosine was elucidated by oxidation reactions, in which *m*-hydroxybenzoic acid was formed together with aspartic acid (on rupture of the benzene ring).

The structure of tingitanin, deduced elsewhere [2] from physical properties, has now been confirmed by synthesis from 2-amino-4-chloromethyl-pyrimidine and ethyl acetaminocyanoacetate. It seems that the biosynthesis of these amino acids proceeds *via* aspartic acid, lysine, homoarginine, and γ-hydroxyhomoarginine.



(1) *(2)* *(3)*

[1] *W. Schroth,* Tetrahedron Letters *1965*, 195, the literature cited therein.

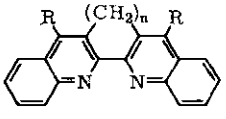
The Complexochemical Properties of Bridged 2,2'-Biquinolyls

E. Uhlemann and *P. Thomas,* Leipzig (Germany)

Several new compounds of the type *(1)* were synthesized and used to prepare complexes of various transition metals. Only 1:1 and 1:2 complexes were formed, similarly to other reagents of the cuproin series. Daylight converts the copper(II) complexes of *(1)* into the copper(I) complexes, the rate of the reaction depending on the temperature, solvent, and the intensity of irradiation.



(1), R = H, CH_3, C_6H_5
n = 1, 2, 3

the copper(II) complexes of *(1)* are converted into the copper(I) complexes, the rate of the reaction depending on the temperature, solvent, and the intensity of irradiation.

The strongly colored copper(I) complexes of compounds of type *(1)*, with n = 2, are suitable for the quantitative photometric determination of copper. They can be extracted with isopentanol.

The complexochemical properties of compounds *(1)* (spectra, basicity constants, and the stability of the complexes) are influenced by substituents in the 4,4'-positions and by the length of the 3,3'-methylene bridge. The polarographic reduction of the copper complexes of *(1)* is irreversible. Therefore, only the relative stabilities of these complexes can be estimated.

Reversed-Phase Paper-Chromatographic Separation of Rare Earths

G. Werner, Leipzig (Germany)

In an organic solvent, dinonylnaphthalenesulfonic acid (DNNSA) acts as a liquid cation-exchanger. Chromatography paper can serve as a support for this organic phase, the mobile phase being an aqueous solution (reversed phases). Paper impregnated with DNNSA can be used for the separation of rare earths. If a non-complexing eluent is used, separation is poor, since the rare earths all have approximately the same affinity for the sulfonic acid. When hydrochloric acid is used as an eluent, the mean separation factor of the adjacent rare earths is 1.04. As in the case of sulfonic acid ion-exchange resins, the lighter elements are more strongly fixed than the heavier ones.

In the application of complexing eluents (lactic acid, α-hydroxybutyric acid), the separation factors are determined by the stability of the rare earth complexes. The R_F-values can be correlated with the distribution coefficients of the DNNSA extraction and of the sulfonic acid ion exchange, as well as with the complexing constants of the rare earths with the eluent.

The rare earths were applied to the paper in 5–20 μg samples, eluted, and the paper was developed by spraying with an ammonical alcoholic solution of 0.1% 1-(2-pyridylazo)-2-naphthol. The spots were marked immediately, since they fade very quickly. With the exception of the Eu/Gd, Tb/Dy, and Dy/Ho pairs, any four adjacent elements chosen from La, Ce, Pr, Nd, Sm, Eu, Gd, Tb, Dy, Ho, Er, and Yb can be separated on a paper chromatogram by the correct selection (in each case) of the concentration and the pH of the eluent, each separation being characterized by constant conditions of elution.

Oxidation in Organic Chemistry

A Symposium on Oxidation in Organic Chemistry was held on March 23rd and 24th, 1965 in the Manchester College of Science and Technology, Manchester (England). Most of the contributions came from scientists in the chemical industry.

From the lectures:

Recent Advances in Metal-Ligand Oxidation Chemistry

J. P. Candlin, G. A. Gamlen, and *J. K. MacKay,*
Runcorn, Cheshire (England)

A necessary condition for electron transfer from or to a metal ion to occur is given by the law of conservation of energy. Thus, for example, the energy absorbed in the rearrangement of a complex so that an electron transfer can occur must be removed again in order to reach the final state. This condition is easy to fulfil in solution owing to the large number of energy levels available. The electron which is transferred must be in a state which is undisturbed by the other electrons in the system, usually an excited state.

If electronegative ligands exert a strong attraction on the electrons of the coordinative σ-bond in a complex, the central atom can take up electrons, and thus a low valence state of the metal atom is stabilized. The withdrawal of electrons into unoccupied or antibonding orbitals is particularly efficient in this respect. The lower the energy of the unoccupied orbital on the ligand, the greater its ability to attract electrons, hence electronegative ligands with vacant orbitals of the π-type, *e.g.* CO and PF_3, stabilize low valence states particularly well.

A third kind of ligand, *e.g.* $OH^{\ominus}$, $F^{\ominus}$, and H_2O, can release sp-electrons into unoccupied orbitals of the metal atom and thus alter the charge density at the metal. The large number of electrons on the central atom then causes the easy release of electrons to oxidizing agents, a process which stabilizes a high oxidation state of the metal.

There are also ligands which stabilize both low and high oxidation states. For instance, $o\text{-}C_6H_4[As(CH_3)_2]_2$ forms complexes with a higher coordination number than that allowed by the rule of the effective atomic number. The excess electrons on the central atom can be readily removed by oxidation. Heterocycles, whose readily polarized π-electron system can both release electrons to and absorb electrons from the central metal atom, are another group of ligands of this type.

The electronic structure of the metal atom also determines in part the occurrence of stable oxidation states. According to the ligand field theory, the five-fold degenerate d-orbitals in octahedral complexes are split under the influence of the ligand field into three orbitals of lower energy and two of higher energy, so that one unpaired electron in Co(II) complexes and two in Ni(II) complexes are in orbitals of higher energy and can therefore be easily released if the ligand field is strong enough. This results in Co(III), Ni(III), and even Ni(IV) as stable oxidation states. Under the influence of the strong ligand field of $CN^{\ominus}$, Fe(III) is a strong oxidizing agent, since the orbitals of low energy are occupied by only five electrons and can readily accomodate one more.

An example of the application of these considerations is the air-drying of a soya oil alkyd film in the presence of a Co(II)-*o*-phenanthroline complex (1:2), which can reduce oxygen to the superoxy stage ($O_2^{\ominus}$), which occupies a free coordination site and initiates the free-radical cross-linking of the oil. The oxygen is reduced to the peroxide stage ($O_2^{2\ominus}$) during this process. The peroxide reduces the Co(III) initially formed back to Co(II). Catalysis by Co(II) is suppressed by a third mole of *o*-phenanthroline. In the presence of a ligand with a lower ligand field, the oxidation of Co(II) to Co(III) with simultaneous formation of superoxide cannot occur. Ligands of higher field strength, *e.g.* $CN^{\ominus}$, prevent the back-reduction to Co(II). The selection of ligands of suitable field strength is therefore of decisive importance for such catalytic processes and even more so for biochemical reactions.

Oxidation of Olefins with Palladium Chloride [1]

J. Smidt, W. Hafner, R. Jira, A. Sabel, J. Sedlmeier, and *R. Sieber,* München (Germany)

The oxidation of olefins to carbonyl compounds by palladium chloride proceeds *via* palladium chloride-olefin complexes. Kinetic investigations showed that the step which initiates the hydrolysis of the complex is an intramolecular reaction of the complexed olefin with a hydroxo ligand on the palladium. Analogous reactions are probably involved in the formation of vinyl acetate and isopropenyl acetate from acetic acid and ethylene or propylene and in the formation of vinyl chloride by thermolysis of $K[C_2H_4PtCl_3]$. Another route that deserves attention is the oxidation *via* π-allyl complexes; sometimes this is the preferred route, *e.g.* with isobutylene or allyl halides. It leads in anhydrous media to allyl compounds, *e.g.* allyl chloride or allyl acetate, but in the presence of water to unsaturated carbonyl compounds, *e.g.* acrolein and its homologues.

Carbonylation of olefins in the presence of palladium chloride also entails olefin or π-allyl complexes. The product composition is not as uniform as in the oxidation of olefins, because carbon monoxide is not a strong nucleophile.

Mechanisms of Oxidation of Organic Compounds by Ions of the Transition Metals

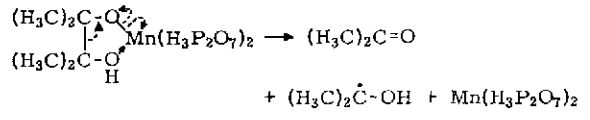
W. A. Waters, Oxford (England)

One prerequisite for many oxidations with ions of transition metals is the intermediate substitution of a ligand of the transition metal ion by the molecule that is to be oxidized in order to make the electron transfer possible or easier. For instance, the oxidation of thiols to disulfides by $K_3[Fe(CN)_6]$ occurs by substitution of a $CN^{\ominus}$ ion by a sulfide residue which releases an electron to the Fe(III), being thereby transformed into a sulfide radical, in preference to a direct transfer of the electron through the hexacyano shell.

$$[RS\text{–}Fe(CN)_5]^{3\ominus} \rightarrow RS\cdot + [Fe(CN)_5]^{3\ominus}$$

[1] Cf. *J. Smidt* et al., Angew. Chem. *71*, 176 (1959); *74*, 93 (1962); Angew. Chem. internat. Edit. *1*, 80 (1962).

Frequently steric factors determine whether a reaction occurs. Simple primary alcohols are not attacked by $Mn[H_3P_2O_7)_3$, but the latter oxidizes pinacol readily to acetone. This reaction proceeds *via* a chelate.



(The broken arrows indicate the transfer of a single electron.)

Some other examples of oxidations by oxometallates in which an intermediate bond between the organic molecule and the metallate ion have been detected are the oxidation of benzaldehyde to benzoic acid and of olefins to glycols by permanganate, the oxidation of alcohols to aldehydes by $HCrO_4^{\ominus}$, and the oxidation of cyclohexanol to cyclohexanone by $[V(OH)_3]^{2\oplus}$. Ester-like intermediates occur during these reactions. When one-electron transfers occur, *e.g.* manganese(VII) → manganese(VI) or vanadium(V) → vanadium(IV), free radicals are often formed as intermediates.

The active form of $Co(ClO_4)_3$ is the cation $[(HO)Co(H_2O)_5]_2^{\oplus}$, which can oxidize primary, secondary, and tertiary alcohols, carboxylic acids, and aromatic hydrocarbons. The products formed are similar to those obtained in other free-radical reactions, *e.g.* the Kolbe synthesis or the Sandmeyer reaction.

Liquid-Phase Oxidation of Organic Compounds with Oxygen

G. H. Twigg, Epsom, Surrey (England)

This reaction has a free-radical chain mechanism; the first products formed usually are hydroperoxides which can react further in various ways.

$$ROO\bullet + RH \rightarrow ROOH + R\bullet$$

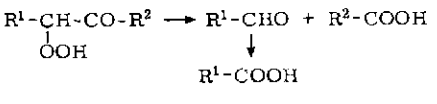
The formation of cumene hydroperoxide in this way is a technically important reaction.

The "hydroperoxide" formed in the oxidation of acetaldehyde is peroxyacetic acid, which reacts with unchanged acetaldehyde to yield a hydroxy peroxyester. The peroxyacetic acid can be isolated from the equilibrium mixture of these three substances. Under the catalytic influence of heavy metal salts, the hydroxy peroxyester rearranges by a non-radical mechanism to two moles of acetic acid. If large amounts of metal salts are present, especially copper salts, the product is acetic anhydride.

$$CH_3{-}CO\bullet + Cu^{2\oplus} \rightarrow CH_3{-}CO^{\oplus} + Cu^{\oplus}$$

$$CH_3{-}CO^{\oplus} + CH_3COOH \rightarrow (CH_3{-}CO)_2O + H^{\oplus}$$

Ketones react more slowly than aldehydes and also yield hydroperoxides according to the same general scheme, but the hydroperoxides often rearrange to acids and aldehydes or ketones. The ketonic products — and even more so the aldehydes — are oxidized further.



Ethers yield hydroperoxides. Alkyl benzyl ethers can be decomposed under the catalytic influence of $Fe^{2\oplus}$ to esters.

When alcohols are oxidized, the carbon atom bearing the hydroxyl group is attacked. The autoxidation of isopropanol to acetone and hydrogen peroxide is a process of technical importance.

$$(CH_3)_2CHOH + HOO\cdot \rightarrow (CH_3)_2\dot{C}{-}OH + H_2O_2$$

$$(CH_3)_2\dot{C}{-}OH + O_2 \rightarrow (CH_3)_2CO + HOO\cdot$$

Numerous products are obtained from the autoxidation of olefins. This is due in part to the resonance of the intermediate allyl radicals formed. 1,4-Diolefins give good yields of hydroperoxides. Epoxides are frequently obtained as the main products when substituted olefins are oxidized.

Under suitable conditions, *e.g.* low oxygen pressures, readily polymerizing olefins such as styrene can yield copolymers with oxygen.

$$ROO\bullet + Ph{-}CH{=}CH_2 \rightarrow ROO{-}CH_2{-}\dot{C}HPh \xrightarrow{O_2} ROO{-}CH_2{-}CHPh{-}O{-}O\bullet\ldots$$

Elevated temperatures are necessary for the oxidation of paraffins because of the absence of activating groups. Tertiary carbon atoms are attacked faster than secondary or primary carbons. The primary products are again hydroperoxides and the major end-products are ketones.

$$R^1OO\bullet + R^2CH{-}OOH \rightarrow R^1OOH + R^2_2\dot{C}{-}OOH$$

$$R^2_2\dot{C}{-}OOH \rightarrow R^2_2C{=}O + HO\bullet$$

$$HO\bullet + R^2_2CH{-}OOH \rightarrow H_2O + R^2_2\dot{C}{-}OOH$$

The amounts of acids formed increase with the time of reaction; the acids are formed by the scheme mentioned above for the oxidation of ketones. The oxidation of butane to acetic acid is an important technical process. Higher paraffins also yield dihydroperoxides, ketonic hydroperoxides, and diketones.

In the presence of boric acid and a limited amount of oxygen, the hydroperoxide is trapped in the form of its peroxyborate, and alcohols can be obtained as reaction products.

Paraffin-Oxygen Reactions at 500–650 °C

R. J. Sampson, Billingham, Durham (England)

The reaction (at low conversions) of ethane with oxygen in a small autoclave at 600–630 °C yielded ethylene (90% of the reacted carbon), H_2O, H_2O_2, H_2, HCHO, CH_4, CO, CH_3CHO, ethylene oxide, and traces of other products. In order to explain these results, a quasi-stationary free-radical chain mechanism was assumed [2]. The main reaction is the abstraction of a hydrogen atom from the ethane by a hydroxyl radical formed from H_2O_2. The oxygen then removes another hydrogen atom from the ethyl radical and converts it into ethylene.

The other products are formed by chain-terminating reactions following chain branching, which includes the formation of the radicals $H\cdot$, $C_2H_5O\cdot$, $H_3O\cdot$, $H_3CO\cdot$, *etc.* Ethylene oxide is formed from ethylene.

Similar autoxidations of propane, n-butane, isobutane, n-pentane, and isopentane were examined at conversions of up to 30%. The principal products were olefins and methane. About 10 moles of oxygenated products such as formaldehyde, acetaldehyde, and methanol plus minor amounts of ethanol, acetone, acrolein, ethylene oxide, propylene oxide, and propionaldehyde and traces of other products were obtained for every 100 moles of paraffin.

The reactivity increases as the number of carbon atoms in the paraffin rises but also depends to a large extent on the structure of the paraffin. At low conversions, propane yields mainly propylene, but as the conversion increases, progressively less propylene but more ethylene and methane are formed. In the same way, n-butane and n-pentane give increasing yields of ethylene, propylene, and methane and decreasing amounts of butylene and pentene. The composition of the mixture of products is considerably different with the iso-paraffins: olefins with one carbon atom less than the initial iso-alkane are the main products, accompanied by olefins with the same number of carbons, methane, ethylene, hydrogen, *etc.*

[2] *R. J. Sampson*, J. chem. Soc. (London) *1963*, 5095.

Oxychlorination

R. B. Richards, Runcorn, Cheshire (England)

Oxychlorination is the reaction of hydrocarbons with hydrogen chloride and oxygen which leads to chlorinated addition and substitution products. Currently it is used mainly for the production of dichloroethane from ethylene, the dichloroethane then being dehydrochlorinated by pyrolysis to vinyl chloride. A modified Deacon catalyst consisting essentially of cupric chloride distributed on pumice as a carrier is used. The rate-determining step in the reaction is:

$$C_2H_4 + 2\,CuCl_2 \rightarrow Cu_2Cl_2 + C_2H_4Cl_2$$

The oxygen mixed with the hydrogen chloride reconverts the cuprous chloride into the cupric salt at 250–300 °C. Free chlorine cannot be detected, and hence the Deacon mechanism, which requires a temperature of 400–450 °C, cannot be in operation with ethylene. However, this mechanism probably does occur during the oxychlorination of paraffins such as ethane, which requires higher temperatures.

Oxidation of Organic Compounds by Sulfur Dioxide under Pressure

A. J. Shipman, Runcorn, Cheshire (England)

Alkylated aromatic compounds are oxidized by excess sulfur dioxide at 250–400 °C and pressures of at least 300 atm to the corresponding aromatic carboxylic acids in 80–90% yield. For example, toluene gives benzoic acid, xylenes give phthalic acids, and pseudocumene gives trimellitic acid. The sulfur dioxide is reduced to sulfur. Aldehydes can be obtained by using smaller amounts of SO_2.

The heat of reaction for the oxidation of a methyl group is about 50 kcal/mole; the activation energy is about 42 kcal/mole. The reaction is accelerated by bromo and iodo compounds but completely suppressed by copper or silver. Solvents exert no effect on the reaction. A free-radical chain mechanism similar to that for the oxidation of hydrocarbons with oxygen is assumed.

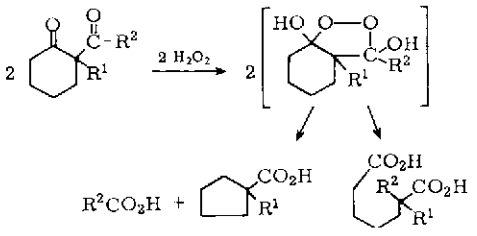
Unsubstituted aromatic compounds, polycyclic hydrocarbons, pyridine, and the picolines do not react with SO_2 under the usual reaction conditions. However, above 450 °C benzene is transformed into biphenyl, diphenyl sulfide, *etc.* Alicyclic compounds are dehydrogenated to aromatics. Non-oxidative reactions occur with other compounds. Olefins copolymerize in the presence of a free-radical sources to yield polysulfones and cyclic sulfones. Alkylene oxides afford cyclic sulfites, and aliphatic alcohols yield ethers.

Some Recent Developments in Organic Oxidations Utilizing Hydrogen Peroxide

G. B. Payne and *J. D. McLure*, Emeryville, Cf. (U.S.A.)

The reactivity of hydrogen peroxide can be augmented by addition to some organic compounds. A suitable adduct is for example peroxyacetic acid. Hydrogen peroxide plus acetonitrile or benzonitrile gives rise to peroxyimidic acids which oxidize olefinic double bonds to epoxides. Since the reactions are carried out in neutral or weakly alkaline solutions, these compounds can be used to make epoxides which are otherwise unobtainable or formed in only low yields, *e.g.* the epoxides of acrolein diethyl acetal, allylcyclohexanone, and 5-hexenone. Unsaturated peroxyimidic acids rearrange to the corresponding epoxy carboxamides.

New, highly effective oxidizing agents for the Baeyer-Villiger reaction are peroxymaleic acid and a reagent consisting of 90% hydrogen peroxide and boron trifluoride etherate. 2-Acylcyclohexanones react with hydrogen peroxide – probably *via* a cyclic peroxide – to yield a cyclopentanecarboxylic acid and a dicarboxylic acid.



Another reaction with activated H_2O_2 is the oxidation of benzene homologues – preferably methyl derivatives have been converted – to phenols and quinones using trifluoroperoxyacetic acid; frequently a shift of the methyl groups is observed.

Polymerization by Oxidative Coupling

A. S. Hay and *J. B. Elliot*, Schenectady, N.Y. (U.S.A.)

Novel polymers with excellent properties are formed by oxidation of 2,6-dimethylphenol with oxygen in the presence of a cupramine complex with the composition, for example, $(R_3N)_2CuCl(OH)$. During the reaction, a phenoxide anion replaces the hydroxyl group in the complex. An electron transfer from the oxygen of the phenoxide ion to the Cu(II) reduces the latter to Cu(I). The resultant phenoxide radical is an intermediate in the formation of the poly(phenylene oxide).

The most suitable amines for the complex are aliphatic tertiary amines containing at least one small alkyl residue, *e.g.* methyl-di-n-octylamine. Other coupling reactions are also possible. When a polymer made from *m*-diethynylbenzene is ignited, its hydrogen burns away with explosive rapidity, but the carbon skeleton remains intact. If a film of the polymer is applied to a solid and then gradually warmed, a conducting carbon film results.

Inhibition of Oxidation

G. Scott, Grangemouth (England)

Inhibition of oxidation is an extension of the induction period of free-radical initiated, mostly autocatalysed oxidation of organic compounds. There are two types of antioxidants. Those which interrupt the oxidation chain are mostly phenols or amines. Their effectiveness is increased by electron-releasing groups (*e.g.* CH_3) and reduced by electron-attracting groups (*e.g.* CN). Their activity is due to their stabilizing or activating effect on the free radicals formed. Steric factors are also important. The second group contains substances which prevent oxidation; here one can differentiate between 1. complexing (chelating) agents which sequester the metal ions that activate peroxides; 2. ultraviolet-light deactivators (2-hydroxybenzophenones), which are rearranged by ultraviolet irradiation to enolic quinones; 3. sulfur compounds such as dithiocarbamic acid, dithiophosphoric acid, and especially dilauryl 3-thiaheptanedioate ("dilauryl thiodipropionate"), which decompose peroxides without giving rise to free radicals. The last compound is used as stabilizer for polypropylene.

German version: Angew. Chem. 77, 867 (1965)

Second Conference of the Federation of European Biochemical Societies

The conference was organized by the Austrian Biochemical Society under the direction of *O. Hoffmann-Ostenhof* and took place in Vienna from April 21st to 24th, 1965. It included three colloquia on "Antibodies to biologically active molecules", "Cyclitols and phosphoinositides", and "Biosynthesis of aromatic compounds", as well as a symposium on the structure and function of ribonucleic acid. Many research papers were also given. About 500 papers were read and some of the results described are reported below.

1. Antibodies to Biologically Active Molecules

M. R. Pollock (England) studied the influence of specific antibodies on the biological activity of bacterial penicillinases produced by wild-type *Bacillus licheniformis* and its mutants. The mutant penicillinase proteins ("muteins") differ from wild-type penicillinase by only one amino acid (point mutation). In the majority of cases, the activity is less than that of natural penicillinase. The "muteins" are precipitated by anti-wild-type penicillinase serum and the activity is then found to have increased almost to that of the precipitate obtained from the wild-type enzyme with the same antiserum. It is thought that the lower activity of the mutein is due to a conformational change resulting from a modification of the primary structure and partly counteracted by reaction with the antibody.

D. Glässer and *M. John* (Germany), by intravenous injection of recrystallized leucine aminopeptidase from bullock's eye lens into mice and rabbits, have produced a several hundredfold increase in the serum level of this enzyme without causing toxic reactions. However, it is impossible to maintain the continuously decreasing level by re-injection. This suggests the formation of antibodies against the active center of the injected leucine aminopeptidase.

An enzyme isolated from mouse salivary gland by *I. Trautschold, E. Werle,* and *A. Schmal* (Germany) was found to resemble kidney renin in its ability to split off Hypertensin I from blood plasma hypertensinogen. Antibodies to this enzyme, produced in the rat, also inactivate mouse kidney renin. Thus the enzymes from the kidney and from the salivary gland have the same specificity range and identical antigen determinants.

2. Cyclitols (Polyhydroxycyclohexanes) and Phosphoinositides

F. Eisenberg, Jr. (U.S.A.) reported on the biosynthesis of inositol in mammals. Experiments on rats point to the testicular tubules as the site of synthesis. The semen contains 1 % inositol, whose function is as yet unknown. Using various forms of ^{14}C-labelled glucose, it was shown that inositol is formed by cyclization from the intact hexose. Glucose-6-phosphate is probably an intermediate product in the biosynthesis and the same is possibly true for *meso*-inositol 1-phosphate.

H. Kindl (Austria) has investigated the biosynthesis of *meso*-inositol in microorganisms and higher plants. Using variously ^{14}C-labelled glucose, he was able to show that *meso*-inositol is formed from intact D-glucose in such a way that C-1 of the glucose becomes C-6 of *meso*-inositol [1]. *Meso*-inositol is possibly metabolized *via* D-glucose 6-phosphate, *meso*-inosose-(2) 1-phosphate and *meso*-inositol 1-phosphate.

[1] *H. Kindl* and *O. Hoffmann-Ostenhof*, Biochem. Z. *339*, 374 (1964).

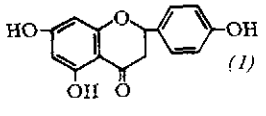
O. Hoffmann-Ostenhof (Austria) reviewed the biosynthesis of other cyclitols. Work carried out to date has shown that the synthesis of all naturally occurring hexahydroxycyclohexanes and their methyl ethers proceeds *via meso*-inositol or a derivative thereof. In *Trifolium incarnatum*, labelled *meso*-inositol is incorporated into D-inositol and the methyl ether D-pinitol. In one species of *Artemisia*, it is incorporated into L-inositol and the methyl ethers L-quebrachitol and L-pinitol, while in *Calicanthus occidentalis*, *meso*-inositol is a direct precursor of scyllitol. An independent biosynthesis for pentahydroxycyclohexanes, *e.g.* L-viburnitol and D-quercitol, cannot be ruled out.

R. M. C. Dawson (England) reported on the metabolism and function of the polyphosphoinositols. Using radioactive phosphorus, it was shown that the phosphate groups of the di- and tri-phosphoinositols, which occur in the brain, are metabolized rapidly. Triphosphoinositols have a greater affinity for calcium than for magnesium. It is suggested that these compounds play a part in controlling the permeation of monovalent ions, especially potassium, across certain regions of the nerve membrane.

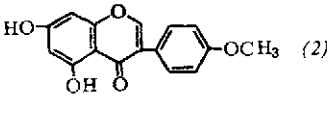
3. Biosynthesis of Aromatic Compounds

S. A. Brown (Canada) reported that over 100 coumarin compounds are known, almost all formed by higher plants. Coumarin itself probably does not exist in the intact cell in the free form but as the phenolic glucoside of *cis-o*-hydroxycinnamic acid. On destruction of the cell this glucoside is hydrolysed by a specific glucosidase and the free phenol is lactonized to coumarin. Using ^{14}C-labelled compounds it was shown that the biosynthesis of coumarin proceeds *via* shikimic acid, phenylalanine, *trans*-cinnamic acid, *trans-o*-hydroxycinnamic acid, *o*-coumaryl glucoside to *o*-coumarinyl glucoside. 7-Hydroxycoumarin and its derivatives also exist in the form of glucosides within the cell. Their biosynthesis takes place *via trans-p*-hydroxycinnamic acid, so that it is necessary to postulate the presence of enzyme systems different from those involved in the synthesis of coumarin itself. This explains why coumarin and 7-hydroxycoumarin are seldom found in association.

H. Grisebach et al. (Germany) found that extracts from chick-pea or parsley can synthesize flavones from cinnamic acid or 7-hydroxycinnamic acid. Using ^{14}C-labelled compounds, it can be shown that in red cabbage plants 5,7,4'-trihydroxyflavanone *(1)* is incorporated unchanged into the cyanidine molecule. In the chick-pea the same compound takes part in



(1)



(2)

the synthesis of biochanin-A (5,7-dihydroxy-4'-methoxyisoflavone) *(2)*. It was shown with *Chaemocyparis obtusa* that the flavanonols are formed by direct oxidation of flavanones and not *via* flavanols. In young tea leaves chalcones are precursors for catechins.

Work by *G. Billek* and *A. Schimpl* (Austria) has confirmed the hypothesis that biosynthesis of all naturally occurring stilbenes proceeds by condensation of a phenylpropane precursor with three acetate groups. These phenylpropane precursors are probably the corresponding cinnamic acids which

are hydroxylated before condensation to form stilbenes. The biosynthesis of 4-hydroxy- and 4-methoxystilbenes remains unsolved. These compounds are said to occur in the Himalayan variety of *Pinus excelsa* but have not been detected in European specimens.

According to *R. Azerad, R. Bleiler-Hill,* and *E. Lederer* (France) the radioactive carbon of [$^{14}CH_3$]-L-methionine is incorporated into position 2 of the naphthoquinone part of vitamin K_2, in cell-free extracts of *Mycobacterium phlei*. ATP and $MgCl_2$ are necessary for this process. [u-^{14}C]-Tyrosine is not incorporated.

M. H. Zenk (Germany) reported on the biosynthesis of C_6–C_1 compounds which are derived from C_6–C_3 compounds such as phenylalanine or cinnamic acid. C_6–C_1 acids result from β-oxidation of C_6–C_3 acids, presumably after these have been hydroxylated or methylated. C_6–C_1 aldehydes, for example vanillin, are also formed from C_6–C_3 compounds and not from the C_6–C_1 acids. Salicyl alcohol is formed particularly readily from *o*-hydroxycinnamic acid with liberation of free acetyl-CoA, which with CO_2 forms malonyl-CoA. This compound forms malonyltryptophan with tryptophan.

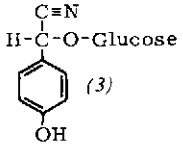
C. Ratledge (Ireland) has shown that in an iron-free medium *Mycobacterium smegmatis* preferentially accumulates salicylic acid. The yield of the latter is increased by addition of shikimic acid. Anthranilic acid, 3,4-dihydroxybenzoic acid, *p*-hydroxybenzoic acid, and *p*-hydroxyphenylacetic acid are also accumulated. Formation of salicylic acid from shikimic acid was postulated. Using cell-free extracts it was, however, possible to establish only the synthesis of anthranilic acid from shikimic acid. A possible mechanism for the anthranilic acid synthesis was put forward, with *N*-pyruvylanthranilic acid as the immediate precursor.

K. Schubert (Germany) was able to show that aromatization of steroids can be brought about with microorganisms. Aromatization is complete with *Mycobacterium smegmatis*, whereas a species of *Norcardia* effects only partial aromatization.

K. Mothes (Germany), in his review of the synthesis of aromatic systems in alkaloids, emphasized that different routes may lead to the same aromatic system in different plants. Thus nicotinic acid may be formed from tryptophan or aspartic acid. The same applies to anabasine and quinoline. Anthranilic acid can arise from shikimic acid but also by degradation of tryptophan. The nitrogen in heterocycles is derived from precursors with amino-acid character and not from ammonia.

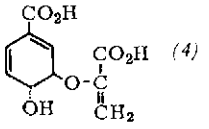
E. W. Underhill and *L. R. Wetter* (Canada) showed that shikimic acid, glucose, and phenylalanine are utilized in the biosynthesis of the aglycone from C_6–C_3 thioglucosides. The maximum incorporation occurred with 3-benzylmalic acid, so that this compound is postulated as an intermediate product in the biosynthesis.

G. H. N. Towers et al. (Canada) suggest that taxiphylline *(3)* (D-*p*-hydroxymandelic nitrile β-D-glucopyranoside) is synthesized from intact tyrosine, since both [^{14}C]- and [^{15}N]-tyrosine are incorporated. β-(*p*-Hydroxyphenyl)lactic acid and smaller quantities of β-(*p*-hydroxyphenyl)serine are also utilized.



(3)

F. Lingens (Germany) demonstrated that accumulation of chorismic acid *(4)* is especially favored when *p*-fluorophenylalanine is added to (try-) mutants of *Saccharomyces cerevisiae* or when 4-methyltryptophan, 6-diazo-5-oxonorleucine, or albizziin (α-amino-β-ureidopropionic acid) are added to (phen$^-$, tyr$^-$) mutants. As a result, the formation of alternative products in other branches of the chain is largely suppressed. [*Phenyl*-^{14}C]-tryptophan was used to investigate the ability of several microorganisms to convert tryptophan into nicotinic acid. In the *phycomycetes*, tryptophan is a starting point for nicotinic acid synthesis when the biosynthesis of lysine proceeds *via* α-aminoadipic acid. However, if lysine is produced from α,ε-*diaminopimelic* acid, tryptophan does not act as a precursor for nicotinic acid.



(4)

P. O. Larsen (Denmark) has studied the biosynthesis of *m*-carboxylated aromatic amino acids in the *Resedaceae*. [1-^{14}C]-Tyrosine was incorporated into L-2-amino-3-(3-carboxy-4-hydroxyphenyl)propionic acid.

4. Ribonucleic Acid – Structure and Function

M. Staehelin (Switzerland) reviewed analytical methods for the elucidation of the structure of transfer-RNA. Preparation of pure t-RNA was accomplished by means of chromatography on Sephadex 200. Isolation of an individual t-RNA can be particularly readily effected by countercurrent distribution. The purity of a fraction is best tested chemically, *viz.* by checking the base composition and by quantitative analysis of the nucleotide sequences, especially of those containing unusual bases.

H. G. Zachau et al. (Germany) have worked out methods for the investigation of the primary structure of serine t-RNA. Fragments formed by degradation of 5–8 mg RNA with pancreas and T_1 ribonuclease were used to elucidate oligonucleotide sequences. The stepwise degradation of RNA with snake venom phosphodiesterase was investigated. Eleven unusual nucleotides were detected in the serine transfer RNA. They are N(2)-dimethyl-Gp, 5-methyl-Cp, rTp, Ip, 2′-*O*-methyl-Gp, 2′-*O*-methyl-Up, three ΨUp and two nucleotides resembling 4,5-dihydro-Up [2].

Sequences of up to 23 nucleotides could he established. Some of the rare nucleotides are closely adjacent in serine t-RNA. Several anticodons were found. The sequences described have little similarity with those of the model proposed by *Cantoni* et al.

D. Grünberger (Czechoslovakia) showed that in growing *Bacillus cereus* cells protein synthesis is inhibited by incorporation of 8-azaguanine into RNA. Incorporation of the different amino acids is not uniformly inhibited; maximum inhibition is found for lysine and glutamic acid. In contrast to findings *in vivo*, the incorporation of amino acids is not inhibited when a ribosomal system from *B. cereus* cells treated with 8-azaguanine is used. However, liberation of the protein formed by the ribosomes into the supernatant is reduced.

S. Ochoa (U.S.A.) showed that hydrogen bonds must be involved in the codon-anticodon interaction, since poly-(5-fluorouridylic acid) or poly-(5-methyluridylic acid) as well as polyuridylic acid bring about polyphenylalanine synthesis in a cell-free system from *E. coli*. In contrast, poly-[*N*(3)-methyluridylic acid] was inactive. This compound does not form a complex with polyadenylic acid.

A further indication of the presence of three nucleotides in one codon was supplied by *H. G. Khorana* (U.S.A.) with the aid

[2] Gp = Guanosine 3′-monophosphate, Cp = Cytidine 3′-monophosphate, rTp = Ribothymidine 3′-monophosphate, Ip = Inosine 3′-monophosphate, ΨUp = Pseudouridine 3′-monophosphate, Up = Uridine 3′-monophosphate.

of a polynucleotide containing a repeating uridylic-cytidylic acid sequence [poly(UC)$_n$]. This polynucleotide induces the cell-free synthesis of a polypeptide with a repeating serine-leucine sequence. Only a codon with an odd number of bases (3,5, *etc.*) is able to form such copolypeptides, since codons with an even number of bases would be identical and could thus produce only homopolypeptides. Even numbers can therefore be ruled out. Experiments with short-chain (poly-A)-nucleotides also lead to formation of polylysine peptides, whose length agrees with the triplet code. Additional experiments showed that messenger-RNA is read from the 5′- to the 3′-end of the chain, while polypeptide formation proceeds from the *N*-terminal to the *C*-terminal end. The polynucleotide

ApApAp · · · · pApApApC

with 17–20 nucleotides brings about synthesis of a polypeptide with 5–6 lysine residues and a *C*-terminal asparagine in a nuclease-free system. Removal of the labelled cytidylic acid residue by periodate oxidation and aminolysis suppresses the incorporation of the asparagine, while that of lysine remains unaffected. This indicates an AAC code for asparagine.

U. Harding and *G. Hartmann* (Germany) recommended a chromatographic technique for the fractionation of transfer-RNA, using a not too fine-grain hydroxyapatite. After adsorption and stepwise elution with phosphate buffer, sharp peaks of the transfer-RNA are obtained. The entire activity is regained in the eluate, with, in the case of phenylalanine, an enrichment of the specific acceptor activity by a factor of 10 to 15.

W. Zillig et al. (Germany) reported on the structure and function of the DNA-dependent RNA polymerase. The enzyme obtained from *E. coli* could be purified by differential ultracentrifugation, chromatography on DEAE cellulose, ammonium sulfate precipitation, and centrifugation in a sucrose density gradient. Electron microscopy leads to a model in which 6 cylindrical sub-units longitudinally surround a central cavity. The enzyme-DNA complex has also been analysed with the electron miscroscope.

M. Bagdasarian and *M. Ombach* (Poland) demonstrated the repression of messenger-RNA synthesis by histidine in (his$^-$) mutants of *Salmonella typhimurium*. Derepressed cultures were obtained by growth in minimal media containing *N*-formylhistidine. On addition of L-histidine one minute before commencement of labelling, a 30–40% decrease in the labelling of the messinger-RNA fraction was observed. An (operator$^-$) mutant of *S. typhimurium* was not repressed by histidine.

5. Miscellaneous

Celina Janion and *D. Shugar* (Poland) reported that hydroxylamine reacts with 5-hydroxymethylcytosine and 5-methylcytosine as well as with cytosine. Since the reaction is accompanied by little change in the ultraviolet spectrum, it has so far been overlooked. The 5,6-double bond is not attacked, but 4-hydroxyamino compounds are formed. In this way the mutagenic action of hydroxylamine on T-phages is explained.

As *D. Yi-Yung Hsia*, *N. Nadler*, and *P. Justice* (Switzerland) were able to show, phenylketonuria patients are able to hydroxylate tryptophan despite their deficiency in phenylalanine hydroxylase. It follows that phenylalanine and tryptophan are not hydroxylated by the same enzyme system, as has been suggested by other authors.

B. Gorzkowski and *Z. Porembska* (Poland) showed that *Helix pomatia* synthesize the pyrimidine ring in the same way as do vertebrates, *i.e.* from carbamyl phosphate and aspartate.

U. Döbereiner and *H. Grisebach* (Germany) showed that the branched sugar apiose [3-*C*-hydroxymethyl-D-glyceroaldotetrose] is metabolically derived from glucose. During synthesis the C-6 atom of glucose is probably split off. The hydroxymethyl group originates from the C-3 or C-4 atom. Decarboxylation of a UDP-4-ketoglucuronic acid and subsequent rearrangement is suggested as the biosynthetic pathway.

T. Klopotowski et al. (Poland) reported on the effect of 3-amino-1,2,4-triazole on *Saccharomyces cerevisiae*. This substance effects accumulation of imidazolylglycerophosphate by inhibition of imidazolylglycerophosphate dehydrase. It is suggested that this inhibitory effect explains the herbicidal action of the compound. [VB 935/247 IE]

German version: Angew. Chem. 77, 921 (1965)

Model Studies on the Mechanism of Microsomal Hydroxylation

Hj. Staudinger and *V. Ullrich*, Gießen (Germany)

In the metabolism of steroids and amino acids and the degradation of foreign substances in organisms, reactions occur involving the substitution of a hydrogen atom by a hydroxyl group. These reactions require molecular oxygen and a reducing agent. Equivalent reactions form the basis of oxidative deamination, dealkylations, *N*-oxidations, and other detoxification reactions. The enzymes which catalyse such reactions are called "mixed-functional oxygenases"; they occur for example in the endoplasmatic reticulum (microsomes) of liver cells.

Model systems were studied to help clarify the mechanism of these oxygenations. A common feature of all such systems is that the oxygen molecule is reduced stepwise with one-electron donors, *e.g.* heavy metal ions such as $Fe^{2\oplus}/P_2O_7^{4\ominus}$, $Fe^{2\oplus}$/EDTA, $Cu^{\oplus}$, $Ti^{3\oplus}$, or $Sn^{2\oplus}$, or organic reducing agents such as reduced flavine, leuco-methylene blue, or the dihydroxyfumarate radical [1]. By examining the hydroxylation products obtained from various substrates it can be shown that two hydroxylation mechanisms can occur simultaneously during the reduction of molecular oxygen [2]. One mechanism proceeds *via* hydroxyl radicals [3], in the other, HOO· radicals are formed first and give rise to an oxygen atom which is inserted directly into the C–H bond in the substrate. By analogy to carbene reactions, this second mechanism might be termed „oxene hydroxylation". This mechanism is operative for example in the hydroxylation of cyclohexane to cyclohexanol and of naphthalene to 1,2-dihydroxynaphthalene. Further reactions typical of the latter mechanism are the oxidative deamination of phenethylamine and the dealkylation of phenacetin. These reactions do not involve hydroxyl radicals. The same products however are also formed by degradation of the compounds by the mixed-functional oxygenases in liver microsomes. These and other parallels make it appear likely that the oxygenations occurring in the microsomes by catalysis with the mixed-functional oxygenases adopt a course similar to that observed in the oxene hydroxylations in the model systems. However, it must be assumed for the enzymatic reactions that some sort of stabilization of the reactive stage of the oxygen atom by iron(III) or copper(II) occurs.

[GDCh-Ortsverband Saar, Saarbrücken (Germany), May 21st, 1965] [VB 936/239 IE]

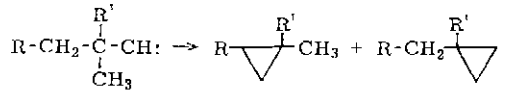
Carbenes and Carbenoid Reactions

W. Kirmse, Marburg/Lahn (Germany)

α-Eliminations [1] and catalytic decomposition of diazo compounds are examples of "carbenoid" reactions [2], which resemble, but are not completely identical with, the reactions of "free" carbenes.

1. The competitive intramolecular insertion reactions of alkylcarbenes, *e.g.*



(1) *(2)*

depend largely on steric and polar effects [3]. They therefore afford a sensitive test for the identity of intermediates which have been made in different ways. Diazo decomposition products were compared with products formed by α-elimination of HCl from primary alkyl chlorides with sodium or sodamide ($R-CH_2Cl \rightarrow R-\ddot{C}H$) and by elimination of iodine from 1,1-diiodoalkanes with methyl-lithium, lithium, or magnesium ($R-CHI_2 \rightarrow R-\ddot{C}H$). The results are qualitatively the same, but the α-elimination reactions are more selective, *i.e.* they give a higher ratio *(2)*:*(1)*.

The reaction of *gem*-diiodoalkanes with zinc (the Simmons-Smith reaction) adopts a different course; here the products are mainly olefins formed by alkyl migration.

2. When carried out in the presence of allyl halides, the decomposition of diazomethane catalysed by copper salts yields information on the behavior of "modified methylene". In addition to a stereoselective addition to the double bond – which excludes the possibility of addition of $XCH_2^{\ominus}M^{\oplus}$ [1] – a chain-lengthening reaction also occurs. Labelling with deuterium or CH_3 shows that the formation of homologous halides occurs *via* an allylic rearrangement.

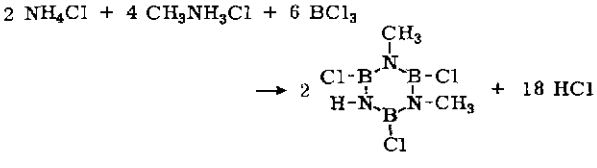
Substitution and Condensation Reactions of Borazines

V. Gutmann, Vienna (Austria)

Although the reactions and properties of borazines are easier to study on unsymmetrically substituted derivatives, so far mainly the symmetrically substituted derivatives have been studied because they are simpler to prepare. However, unsymmetrically substituted borazines can be prepared using known synthetic methods, *e.g.* the chloroborazine synthesis according to *Laubengayer* [1, 2].



1-Methyl-2,4,6-trichloroborazine, 1,3,5-trimethyl-2,4,6-trichloroborazine, and 2,4,6-trichloroborazine are formed as by-products in this reaction. In order to prevent condensation of these products, the borazines must be alkylated on the boron atoms before separating them. On alkylation with Grignard compounds B–N-linked polyborazines are formed as by-products [2, 3].

Cyclopentadienylborazines are obtained by the reaction of cyclopentadienylmetal compounds with *B*-halogenoborazines [4]. In these derivatives the cyclopentadienyl groups are linked to the boron by localized σ-bonds. The compounds exhibit a strong tendency to polymerize, undergo the Diels-Alder reaction with dienophiles, and combine with organotin hydrides.

Little work has been done so far on polyfluoro and perfluoro derivatives of B–N compounds. β-Fluoroalkylmagnesium halides react with *B*-chloroborazines to give *B*-fluoroborazines [5]. The reaction of polyfluoroalkylamines with BCl_3 leads to *N*-polyfluoroalkyl-*B*-trichloroborazines, but the elimination of HCl in the final step of the reaction is difficult. *N*-Trifluoroethyl-*B*-trichloroborazole (earlier data on this compound [6] could not be confirmed) reacts for instance with perfluoroarylmagnesium halides to give borazines in which all of the ring atoms are substituted by perfluoro-organo residues.

New Developments in the Ionic Polymerization of Cyclic Acetals

K. Weissermel, Frankfurt/Main-Hoechst (Germany)

Polymerization of trioxane in the melt with cationically active catalysts leads to high polymers with oxymethylene repeating units. The polymers contain hemiacetal end-groups and are decomposed by heat. Copolymerization of trioxane with oxacycloalkanes leads to stable polymers. Unstable sequences in these copolymers can be removed by treatment with alkali.

The ability of trioxane to copolymerize with cyclic ethers decreases with the ring size of the ethers. If cyclic acetals are used instead of the cyclic ethers, the size of the ring is of only minor importance, since here the oxonium salts formed as intermediates are easy to split. Cyclic acetals derived from higher aldehydes and cyclic ketals react with polymerizing trioxane with elimination of the aldehyde or ketone component. When trioxane is copolymerized with small amounts of ethylene oxide, the latter is almost entirely incorporated into the polymer chains already after small conversions. Nevertheless, at the end of the polymerization, the ethylene oxide is found to be distributed uniformly throughout all the polymer molecules. This result is explained by transacetalizations between polymer molecules and active chain ends, *i.e.* cleavage and recombination of chain segments occurs throughout the course of the polymerization. This principle can be used to copolymerize almost any formal, *e.g.* polydioxolane, poly-*trans*-quinitol formal, or polyethylene glycol formal, with trioxane to give uniform products.

Another peculiarity of trioxane polymerization observed is a hydride shift at the active chain end which causes the for-

mation of formate and methoxyl end-groups and reduces the molecular weights of the polymers to values lower than those expected.

Copolymerization of trioxane with monomers containing a halogeno and/or a carbonyl group leads to products which can be cross-linked. These are characterized by their increased adhesion to metals and their dyeability.

Crystallization and the Microstructure of High Polymers

H. A. Stuart, Mainz (Germany)

Single crystals of polyethylene may contain folded chains. Lamellar single crystals within the bulk of the material have a disordered surface. From this it is concluded that there are both straight and folded chains present in the solid.

Further observations on stretched polyethylene can be represented essentially by an extended Hess-Kiessig model containing both straight and folded chains. Only part of the lamellar single crystals is pulled out on stretching. After stretching, the straight chains in particular are under considerable stress but relax on annealing, as can be seen from the nuclear magnetic resonance signals.

Since some of the chains in the non-crystalline regions are given a fluid-like motion on annealing, the diffusion constant and swelling (coloring capacity) increase considerably, even though the proportion of crystalline material also increases. Analysis of the small-angle X-ray diffraction pattern by the method of *Bonart-Hosemann* shows that the fibrils in cold-stretched polyethylene merge into large blocks on annealing. The crystals of neighboring fibrils form a macrolattice (paracrystalline layer lattice) which can be observed directly in the electron microscope. The chain mobility in the non-crystalline regions and the ratio of straight to folded chains are important structural parameters which must be given due consideration in the interpretation of physical or technological properties of polyethylenes.

Mobility of Molecules Adsorbed on the Surfaces of Solids

R. Haul, Hannover (Germany)

An important property for characterizing the interaction between the surfaces of solids and adsorbed molecules is the residence time of the molecules on the surface. The residence time can be determined from experiments on transient Knudsen molecular flow. For example, the non-stationary flow of argon, krypton, and xenon through a pyrex glass capillary was measured between 80 and 295 °K using ionization manometers. The measurements were made in an ultrahigh vacuum in order to determine the residence times of physisorbed molecules even at a relatively low surface coverage ($\theta = 10^{-3}$ to 10^{-1}).

The adsorption isotherms obtained from the flow experiments are non-linear owing to the energetic heterogeneity of the surface but satisfy the Radushkevich-Dubinin equation. On the basis of these adsorption isotherms, differential residence times $\tau = \tau_0 \cdot e^{E/RT}$ can be calculated. For example, the values found for τ_0 (sec) and E (kcal/mole) at $\theta = 0.01$ were 3×10^{-14} and 3.6 for argon, 1×10^{-13} and 4.4 for krypton, and 1×10^{-13} and 5.5 for xenon. As the coverage of the surface increases, the pre-exponential factor $\tau_0 = 1/\nu_0$ increases by several powers of ten. There is a connection between ν_0 and the activation energy E in the sense of a compensation effect. This phenomenon can be explained by assuming that the molecules do not always leave the surface directly but that some are desorbed only after repeated changes of sites. The same conclusion is arrived at from entropy considerations. The surface mobility of physisorbed molecules can also be derived from studies of material transport in porous media.

The Effect of Particle Size on the Reaction Mechanism of Gases with Solids

W. Feitknecht, Bern (Switzerland)

Finely divided solids react rapidly with gases even at low temperatures. In this way metastable compounds may result, which would not be formed with coarser substances. For reactions of oxygen with metals and metal oxides the following cases were distinguished by X-ray and electron-microscope investigations and kinetic measurements: single-phase reactions I (during the reaction there are no phase boundaries between starting material and product) and two-phase reactions II (the starting material is converted into the end-product along a phase boundary).

Ia. In single-phase surface reactions, only a thin surface layer reacts without phase change.

Example: MnO prepared in a reducing atmosphere at low temperature (particle size 350–1500 Å) takes up considerable amounts of oxygen on careful oxidation at up to 100 °C. The crystal structure (NaCl-type) is not altered since a surface layer (approx. 50 Å) of Mn^{3+} ions with cation defects is formed.

Ib. During single-phase "through" reactions the microcrystals gradually change in composition equally outside and inside. With larger particles a concentration gradient occurs; the mixed phase decomposes to yield starting material and a new phase.

Example: oxidation of Fe_3O_4 to γ-Fe_2O_3 with small particles (< ca. 3000 Å), and to α-Fe_2O_3 with larger particles (> ca. 3000 Å).

IIa. By the layer mechanism, a continuous layer, the growth of which is controlled by diffusion, is formed on the crystal surface. With large specific surface areas, other secondary reactions may take place than occur with small specific surface areas.

Example: finely-divided iron (< ca. 500 Å) + $O_2 \rightarrow Fe_3O_4 \rightarrow \gamma$-$Fe_2O_3$, coarse iron (> ca. 500 Å) + $O_2 \rightarrow Fe$, $Fe_3O_4 \rightarrow Fe$, Fe_3O_4, α-Fe_2O_3.

IIb. By the nucleation mechanism nuclei once formed grow rapidly at the expense of the microcrystal of starting material on which they originated. The reaction is not diffusion-controlled, depends strongly on the pressure of the reacting gas and goes to completion only with finely divided starting material.

Example: oxidation of Mn_3O_4 to Mn_5O_8 with finely divided starting material (size < ca. 1000 Å) and to α-Mn_2O_3 with coarse starting material (particle size > ca. 1000 Å).

German version: Angew. Chem. 77, 870 (1965)

Color and Constitution of Inorganic Solids

O. Schmitz-DuMont, Bonn (Germany)

According to the crystal field theory, the absorption of light by a coloring cation, *e.g.* $Co^{2\oplus}$, $Ni^{2\oplus}$, or $Cr^{3\oplus}$, after isomorphous incorporation into a host lattice is determined by the strength and symmetry properties of the crystal field in the neighborhood of the colored cation. These parameters de-

pend on the coordination number, the symmetry of the coordination polyhedron, and on the distances between the coloring cation and the coordinating ligands.

To investigate this problem experimentally, oxides (MgO, ZnO, spinels, $MgTiO_3$, or silicates) were used as host lattices. It was found that reduction of the coordination number from 6 to 4 causes a red-shift of the main absorption bands. The same effect is observed if the coloring cation is incorporated in a simple host lattice with only one type of cationic lattice site and the lattice is expanded by isomorphous exchange of larger cations [*e.g.* $Ni_{0.01}Mg_{0.99}TiO_3$ (ilmenite lattice, yellow) → $Ni_{0.01}Cd_{0.99}TiO_3$ (ilmenite lattice, red)]. A bathochromic shift is observed with more complicated lattices only when the isomorphous exchange of larger cations expands the coordination polyhedra containing the coloring cation; this is not always the case. Reduction of the point symmetry in the environment of the coloring cation does not produce any significant bathochromic shift. Since the transition from $Ni_{0.1}Mg_{0.9}O_3$ (regular octahedral coordination) to $Ni_{0.1}Mg_{0.9}TiO_3$ (hexagonally distorted coordination octahedron) results in a large red shift of all three main absorption bands, it was at first concluded that this effect was occasioned by the distortion of the coordination polyhedron. However, further studies on phases of the perovskite type revealed that the hathochromic shift of the bands required the presence of both low-charged cations and high-charged cations on coordinatively equivalent lattice sites. This results in a weakening of the field around the low-charged coloring cations.

These findings can be applied conversely in practice by using light absorption to determine unknown types of coordination and to study localized effects in crystal lattices which cannot be investigated by other methods, *e.g.* X-ray techniques. Apart from uses in crystallography (*e.g.* mixed crystal formation), the changes in the light absorption can also be applied to examine changes in bonding types between coloring cation and coordinated ions or atoms.

[GDCh-Ortsverband Düsseldorf, Düsseldorf (Germany), April 12th, 1965] [VB 926/237 IE]

German version: Angew. Chem. 77, 872 (1965)

Advances in Complexometry

R. Pribil, Prague (Czechoslovakia)

Complexometric titrations can be made selective by masking interfering ions. Thus some colored cations can be converted to colorless or almost colorless complexes, *e.g.* $Fe^{3\oplus}$ with triethanolamine, $Cu^{2\oplus}$ with thioglycollic acid, $Mn^{3\oplus}$ with cyanide, and $Co^{3\oplus}$ with triethanolamine or cyanide. $Zn^{2\oplus}$ and $Cd^{2\oplus}$ can be estimated in admixture using β-mercaptopropionic acid.

Triethylenetetraminehexaacetic acid is a new complexometric titrating agent which forms 1:2 complexes M_2Y with bivalent metals M such as Ga, Pb, Cd, or Zn and 1:1 complexes MY with tri- and tetravalent metals. This reagent is used for analysis of gallium/indium mixtures, *etc.* It can also be used to determine thorium in mixtures with rare earths, or thorium alongside scandium. Analyses of mixtures of rare earths (RE) can be carried out using the following displacement reaction:

$$[RE\text{-}EDTA]^{2\ominus} + Zn^{2\ominus} + PO_4^{3\ominus} \rightarrow REPO_4 + [Zn\text{-}EDTA]^{2\ominus}$$

Only La, Ce, Nd, and Pr are precipitated as their phosphates. Holmium and the higher rare earths remain in solution and are titrated complexometrically.

[GDCh-Ortsverband Nordbayern, Erlangen (Germany), May 14th, 1965] [VB 931/234 IE]

German version: Angew. Chem. 77, 871 (1965)

Structures and Reactions in Molten Salts

W. Bues, Tübingen (Germany)

$BO_3^{3\ominus}$ ions with D_{3h} symmetry can be detected in molten Li_3BO_3 by Raman spectroscopy. Melts with the composition $Li_4B_2O_5$ contain $B_2O_5^{4\ominus}$ ions (C_{2v}) plus $BO_3^{3\ominus}$ and $B_3O_7^{5\ominus}$ ions. This means that $B_2O_5^{4\ominus}$ disproportionates by an electron donor-acceptor mechanism to give $BO_3^{3\ominus}$ and $BO_2^{\ominus}$. The $BO_2^{\ominus}$ ion is short-lived and reacts further in the melt either with $BO_3^{3\ominus}$ to give $B_2O_5^{4\ominus}$ or with $B_2O_5^{4\ominus}$ to give $B_3O_7^{5\ominus}$; since the oxygen atoms in $BO_3^{3\ominus}$ and $B_2O_5^{4\ominus}$ are of equal basicity, the $BO_2^{\ominus}$ reacts non-selectively. The $BO_3^{3\ominus}$ ion can also be detected in melts of $Li_5B_3O_7$ and $Li_6B_4O_9$. The spectra of metaborates, borax, and diboron trioxide can be readily interpreted starting from the short-chained anions: in melts, boron has always the coordination number three. This explains for example the great difference in density between B_2O_3 in the molten and crystalline states; in crystals B_2O_3 has the coordination number four.

Molten $ZnCl_2$, like crystalline $ZnCl_2$, has a space lattice structure with the coordination number four for the zinc. K_2ZnCl_4 melts consist of isolated $ZnCl_4$ tetrahedra, while $KZnCl_3$ melts contain chains of $ZnCl_4$ tetrahedra. Molten mixtures of KNO_3 and $ZnCl_2$ contain the ions $NO_3^{\ominus}$, $ZnCl_4^{2\ominus}$, and $Zn^{2\oplus}$.

The TlCl in molten mixtures of TlCl and $CuCl_2$ can be oxidized to $TlCl_3$ with HCl and oxygen. The $TlCl/TlCl_3/CuCl/CuCl_2$ melt catalyses the chlorination of ethylene to 1,2-dichloroethane. At 280 °C and ratios of oxygen:HCl:ethylene of 1:4:2, 3:8:4, and 1:2:1, the purity of the 1,2-dichloroethane obtained is 99.0, 99.0, and 98.0 %, and the conversion (based on the ethylene) is 26.5, 55.7, and 98.6 %, respectively. A glass tube 80 cm long and 2 cm in diameter with a sealed-in Grade 4 sintered-glass filter can be used to achieve 30 seconds contact time of the gases with 150 g of the melt, which foams intensely.

[GDCh-Ortsverband Giessen (Germany), June 14th, 1965] [VB 939/244 IE]

German version: Angew. Chem. 77, 871 (1965)

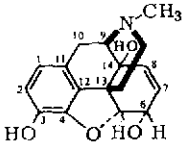
SELECTED ABSTRACTS

The structure of fluorenyl-lithium has studied by *J. A. Dixon, P. A. Gwinner*, and *D. C. Lini* by NMR spectroscopy. When heptane was added to the solutions formed by treating fluorene in tetrahydrofuran (THF) and dimethoxyethane (DME) with lithium, a precipitate of solvated fluorenyl-lithium is formed which does not release its solvent of crystallization even after 48 h at pressure below 1 mm. Solutions of the complexes in perdeuterobenzene give NMR spectra whose integrated signals indicate the compositions RLi·3THF and RLi·1DME (R = 9-fluorenyl). The complexed THF gives signals at higher fields for both the α- and β-protons than free THF. The relative positions of the methyl and methylene proton signals were interchanged in the complexed and free forms. Because of the electron donor/electron acceptor interactions between the cation and the ether molecule, a shift to lower fields would have been expected. The ^7Li resonance occured at higher field strengths (3 ppm for the THF complex) than in aqueous solutions of inorganic lithium salts. It was concluded that the solvated lithium cation lies above the plane of the aromatic carbanion and thus falls within the shielding range of the ring current. / J. Amer. chem. Soc. *87*, 1379 (1965) / -Eb. [Rd 343/552 IE]

The halogenation of aromatic compounds with *N*-bromosuccinimide and *N*-chlorosuccinimide under ionic conditions has been studied by *F. L. Lambert, W. D. Ellis,* and *R. J. Parry*. When 100 ml of the aromatic compound was heated for 1–4 h at 45–90 °C with a mixture of dilute sulfuric acid (200 ml of concentrated H_2SO_4 diluted to 20–66 %) and 0.16 mole of *N*-halogenosuccinimide, nuclearly substituted monohalogeno derivatives are obtained in yields of 64–95 %; practically no higher halogenated or benzyl-substituted products are formed. The use of large amounts of free bromine or chlorine is avoided by this technique. In this way, benzene gives 90 % bromobenzene or 64 % chlorobenzene. Toluene gives 95 % bromotoluene (ratio of *o*-:*m*-:*p*-isomers = 67:2:31) or 93 % chlorotoluene (with similar ratios of isomers). Nitrobenzene yields 70 % bromonitrobenzenes, and chlorobenzene 94 % chlorobromobenzenes, or 80 % dichlorobenzenes. The attacking species may be the protonated *N*-halogenosuccinimide. / J. org. Chemistry *30*, 304 (1965) / –Bi. [Rd 298/507 IE]

A complex with a coordination number of 7 and tungsten-mercury bonds has been made by *M. C. Ganorkar* and *M. H. B. Stiddard*. $HgCl_2$ and $W(CO)_4$(bipy) interact at room temperature in acetone with release of CO [bipy = 2,2′-bipyridyl]; dilution of the reaction mixture with pentane precipitates orange crystals of $W(CO)_3$(bipy)$(HgCl)_2$. The compound is diamagnetic and dissolves in monomeric form in dichloromethane, from which it can be recrystallized. Its solution in nitrobenzene is non-conducting. Its infrared spectrum (in chloroform) contains bands in the C–O stretching frequency range at 2000, 1924, and 1887 cm^{-1}, and is therefore very similar to the spectrum of $W(CO)_3$(bipy)I_2, which compound also contains sevenfold coordinated tungsten(II). The observed shift of the bands to lower frequencies is in accordance with the lower electronegativity of the HgCl ligands. / Chem. Commun. *1965*, 22 / –Gn. [Rd 272/481 IE]

14-Hydroxymorphine and 14-hydroxy-7,8-dihydromorphine, new compounds with analgetic properties, have been synthesized by *U. Weiss*. 14-Hydroxymorphine *(1)* was prepared by reduction of the 6-oxo derivative with $NaBH_4$; its structure



(1)

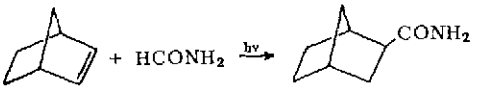
was proved by methylation with diazomethane, which gave the known compound 14-hydroxycodeine. The 14-hydroxy-7,8-dihydromorphine *(2)*, m.p. 249–250 °C, was obtained analogously from 14-hydroxy-7,8-dihydro-6-morphinone. Whereas the analgetic effect of *(1)* is somewhat weaker than that of morphine but of the same duration (*ca.* 2.8 h), *(2)* is twice as effective as morphine (ED_{50} = 1.1 mg/kg in mice) and acts much longer (4 h). / J. med. Chem. *8*, 123 (1965) / –De. [Rd 245/454 IE]

Stable colloids of transition metals in the zerovalent state in ethers (tetrahydrofuran, dimethoxyethane) were prepared by *G. Henrici-Olivé* and *S. Olivé* by slow addition of solutions of VCl_3, $CrCl_3$, $MnBr_2$, $FeCl_3$, $CoCl_2$, or $NiBr_2$ to alkali metal naphthalene ($C_{10}H_8^{\ominus}$ and $C_{10}H_8^{2\ominus}$) solutions (reducing agents) with exclusion of air and moisture. The metallic state is confirmed for Fe and Co by their weak ferromagnetism. The colloid particles are negatively charged. The systems transition-metal colloid/organic halide (*e.g.* CCl_4) are suitable for initiating polymerization of, *e.g.*, methyl methacrylate or styrene. Formally, the radical-producing step is

$$M + CCl_4 \rightarrow M^{\oplus}Cl^{\ominus} + \cdot CCl_3$$

/ Chimia *19*, 46, 47 (1965) / –Ma. [Rd 248/457 IE]

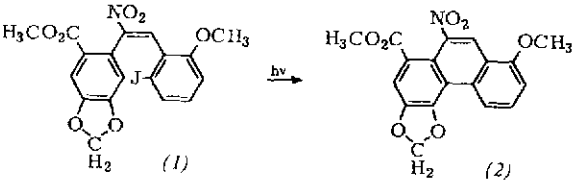
Stereospecific addition of formamide to norbornene was observed by *D. Elad* and *J. Rokach*. Irradiation of a mixture of norbornene, formamide, t-butanol, and acetone for about 1 h with a high-pressure mercury vapor lamp afforded an 87 % yield of norbornane-2-*exo*-carboxamide *(1)*, m.p. 181 to 183 °C; no *endo*-isomer could be detected. Some 2-*exo*-acetonylnorborane was formed in a side reaction, and 2:1 telomers were also produced by the reaction of 2 moles of norbornene with 1 mole of formamide. The photoadduct *(1)*



(1)

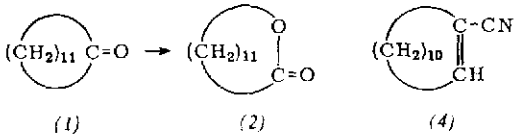
was also formed in sunlight or on prolonged irradiation with ultraviolet light of the mixture without acetone. / J. chem. Soc. (London) *1965*, 800 / –Ma. [Rd 246/455 IE]

A photochemical synthesis of phenanthrene derivatives by photocyclization of substituted 2-iodo-*cis*-stilbenes – similar to the photolysis of aromatic iodo compounds discovered by *Kharasch* – has been described by *S. M. Kupchan* and *H. C. Wormser*. For example, photolysis of 2-iodo-*cis*-stilbene in cyclohexane with ultraviolet light at room temperature leads *via* an intramolecular reaction to phenanthrene in 90 % yield. Analogously, methyl 2′-iodo-*cis*-stilbene-α-carboxylate

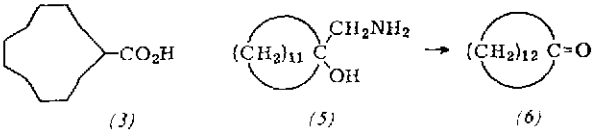


yields 71 % methyl phenanthrene-9-carboxylate, 2′-iodo-α-nitro-*cis*-stilbene affords 40 % 9-nitrophenanthrene, and 2′-iodo-2-methoxycarbonyl-6′-methoxy-4,5-methylenedioxy-α-nitro-*cis*-stilbene *(1)* gives rise to 54 % methyl aristolochiate *(2)*, which on saponification yields the known acid. / Tetrahedron Letters *1965*, 359 / –Ma. [Rd 247/456 IE]

The chemistry of cyclododecanone *(1)* has been studied in detail by *K. Kosswig, W. Stumpf, W. Kirchhoff, W. Dittmann,* and *W. Franke*. Oxidation of *(1)* with peroxyacetic acid in conc. H_2SO_4 at 10 °C leads to the lactone dodecanolide *(2)*, b.p. 130 °C/10–11 mm, in 50 % yield; 1,12-dodecandioic acid is a by-product. H_2O_2 containing 1–2 % SeO_2 transforms *(1)* in t-butanol to cycloundecanecarboxylic acid *(3)*, b.p. 126 to 128 °C, in 32 % yield. Cyclododecanone cyanohydrin can be



(1) *(2)* *(4)*



(3) *(5)* *(6)*

obtained in excellent yield and reacts with $SOCl_2$ in refluxing benzene to give 91 % 1-cyano-1-cyclododecene *(4)*, b.p. 112 to 118 °C, which can be converted into 1-cyclododecene-1-carboxamide, m.p. 84–89 °C, and thence into the free acid, m.p. 120–121 °C. Hydrogenation of *(4)* over acidic catalysts gives 50 % 1-aminomethyl-1-cyclododecanol *(5)*, m.p. 126.6 to 127.7 °C, which rearranges on treatment with HNO_2 to cyclotridecanone *(6)* in 56 % yield. / Liebigs Ann. Chem. *681*, 28, 30, 32 (1965) / –Ma. [Rd 250/459 IE]

An ylide synthesis by pyrolysis is described by *N. E. Miller*. Although ylides normally are made by the reaction of onium salts with strong bases, trimethylsilylmethylenetrimethylphosphorane *(1)*, b.p. 70–75 °C/14 mm, is obtained by heating (trimethylsilylmethyl)trimethylphosphonium chloride to 180 °C *in vacuo*; the product distils off together with

$$(CH_3)_3SI-\overset{\ominus}{C}H-\overset{\oplus}{P}(CH_3)_3 \leftrightarrow (CH_3)_3\overset{\ominus}{Si}=CH-\overset{\oplus}{P}(CH_3)_3 \leftrightarrow (CH_3)_3Si-CH=P(CH_3)_3$$

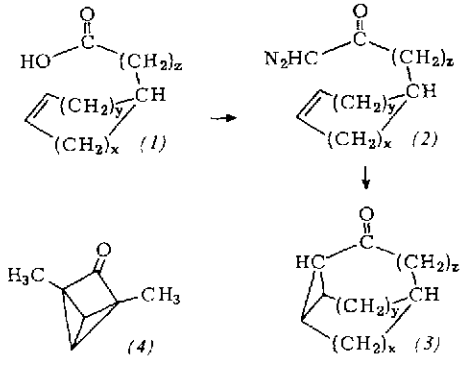
volatile trimethylsilyl chloride, leaving a residue of tetramethylphosphonium chloride. / J. Amer. chem. Soc. *87*, 390 (1965) / –Ma. [Rd 249/458 IE]

Sodium bis-(4-bromophenylsulfonyl)amide is used for identifying organic bases by *E. A. Julian* and *E. M. Plein*. They obtained the amide *(1)* by the reaction of 2 moles of *p*-bromobenzenesulfonyl chloride with NaOH and ammonium chloride. Compound *(1)*, m.p. 232–234 °C, reacts with the

$$Br-C_6H_4-SO_2-\overset{\ominus}{N}-SO_2-C_6H_4-Br\ Na^{\oplus} \qquad (1)$$

salts of primary, secondary, and tertiary amines in ethanol/water (1:1) to give crystalline salts of the sulfonylamide, which can be crystallized from methanol/n-amyl acetate (1:1). These ammonium salts have sharp melting points: for example, the salts of the antihistamines cyclizine, diphenylpyraline, and meclizine melt at 165, 147, and 189 °C, respectively. / J. pharmac. Sci. *54*, 147 (1965) / –De. [Rd 293/502 IE]

Tricyclic ketones *(3)* have been synthesized by *W. v. E. Doering, E. T. Fossel*, and *R. L. Kaye* by copper-catalysed cyclization of cyclo-olefinic diazo ketones *(2)*. Compounds *(2a)–(2f)* are readily obtained from the corresponding carboxylic acids *(1)* by treating the acid chlorides with diazomethane. These diazo ketones *(2)* release nitrogen on warming in inert solvents such as n-hexane or tetrahydrofuran in the presence of copper powder or anhydrous copper salts. Intramolecular cycloaddition of the copper-stabilized keto carbene intermediate onto the olefinic double bond leads to the ketones *(3a)–(3f)*. The reaction could not be conducted photochemically. The method has very broad



Compound	x	y	z	Yield [%]	B.p. [°C/mm] (m.p. [°C])
(3a)	4	0	1	36	82/0.1
(3b)	2	2	0	47	(126–128)

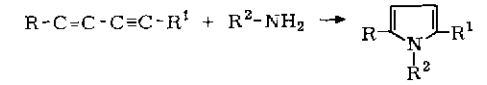
scope and has been used to prepare 2,4-dimethyltricyclo-[1,1,1,$0^{2,4}$]pentan-5-one *(4)*, a compound that is remarkable because of its large ring strain [1]. / Tetrahedron *21*, 25 (1965) / –Bi. [Rd 276/485 IE]

[1] *W. v. E. Doering* and *M. Pomeranz*, Tetrahedron Letters *1964*, 961.

A new pyrrole synthesis starting from butadiyne and its derivatives has been worked out by *K. E. Schulte, J. Reisch*, and *H. Walker*. Pyrrole and 1,2-, 2,5-, and 1,2,5-substituted pyrroles are obtained from butadiyne and mono- or disubstituted butadiynes by reaction with ammonia or primary aliphatic or aromatic amines at 140–160 °C in the presence of catalytic amounts of CuCl; quinoline derivatives are formed as by-products when aromatic amines are used. The reaction proceeds in alcohols, dioxane, or dimethylformamide



R	R^1	R^2	M.p. (B.p.) [°C]	Yield [%]
C_6H_5	C_6H_5	H	143	73
C_6H_5	C_6H_5	CH_3	204	77
C_6H_5	C_6H_5	C_4H_9	113	76

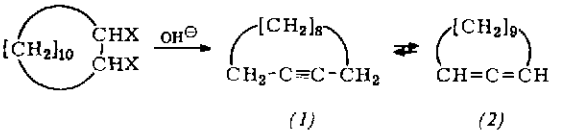
CH_3	CH_3	CH_3	(176–178)	40

or even without solvent. Instead of the butadiyne, 1-methoxybut-1-en-3-yne, which is more stable, can be used. / Chem. Ber. *98*, 99 (1965) / –Ma. [Rd 259/468 IE]

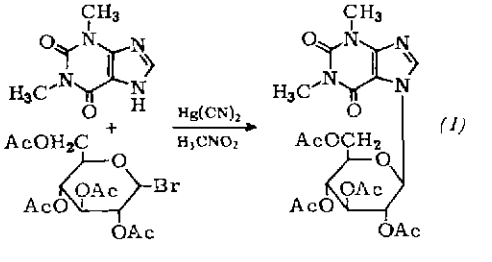
Convenient syntheses of cyclododecyne, cis-cyclododecene, 1,2-cyclododecadiene, and 1,3-cis,trans-cyclododecadiene are described by *W. Ziegenbein* and *W. M. Schneider*. 1,2-Dichlorocyclododecane reacts with alcoholic alkali metal hydroxides at 120–150 °C in an autoclave to give over 70 % cyclododecyne *(1)*. With increasing temperature, 1,2-cyclododecadiene *(2)* is formed in increasing amounts. Hydro-



(1) *(2)*

genation of *(1)* with lithium diisobutylaluminohydride proceeds selectively to *cis*-cyclododecene. 1,3-*cis*,*trans*-Cyclododecadiene is obtained in good yield on pyrolysis of 1,2-bisacetoxycyclododecane at 500 °C/20 mm. It is also formed, together with *cis*- and *trans*-cyclodecene as by-products, from 1,2-dibromocyclododecane and quinoline. / Chem. Ber. *98*, 824 (1965) / –Ma. [Rd 286/495 IE]

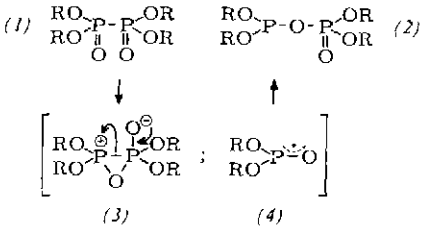
A new synthesis of nucleosides and analogous compounds has been achieved by *N. Yamaoka, K. Aso*, and *K. Matsuda* by condensation of heterocyclic imino compounds such as acylaminopurines, chloropurines, theophylline, *N*(6)-benzoylcytosine, or benzimidazole with acylglycosyl halides in nitromethane in the presence of hydrogen halide acceptors, *e.g.* Ag_2O, $Hg(CN)_2$, $Hg(CN)_2$, $Zn(CN)_2$, AgCN, or KCN. The components are heated for several hours over Drierite with



(1)

exclusion of moisture, and the crystalline acylated nucleosides are obtained directly. For example, 7-(2′,3′,4′,6′-tetra-*O*-acetyl-β-D-glucopyranosyl)theophylline *(1)*, m.p. 167 °C from ethanol, is obtained in 94 % yield. / J. org. Chemistry *30*, 149 (1965) / –De. [Rd 292/501 IE]

Thermal isomerization of a P(V) to a P(III) compound was observed for the first time by *J. Michalski*, W. *Stec*, and *A. Zwierzak*. When tetraalkyl hypophosphates *(1)* are heated for 3–4 h at 190–200 °C, large amounts (up to 60 %) of tetraalkyl esters of mixed anhydrides of phosphoric and



(3) *(4)*

phosphorous acids *(2)* are formed. The isomerization probably occurs *via* a dipolar cyclic phosphonium structure *(3)* or a free radical *(4)*. / Chem. and Ind. *1965*, 347 / –Ma.

[Rd 251/460 IE]

An acidity function H_- in the alkaline region has been set up by *E. C. Steiner* and *J. M. Gilbert* for dimethyl sulfoxide as solvent. The basic medium consisted, for instance, of

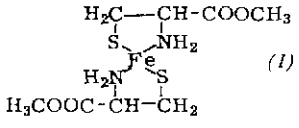
$$H_- = pK_{IH} + \log ([I^\ominus]/[IH])$$

$CH_3SOCH_3/CH_3SOCH_2^\ominus K^\oplus$, sometimes containing water or methanol up to a molarity of 0.4. The equilibrium indicator acid IH/indicator anion $I^\ominus$ was measured by spectrophotometry. The basicity of the medium is defined by

$$H_- = -\log (a_{H^\oplus} \gamma_{I^\ominus}/\gamma_{IH})$$

The H_- function represents an extension of Hammett's acidity function to alkaline, *i.e.* deprotonating, solutions. When pK_{IH} is known, it can be used to determine the value of the H_- function or hence the acidity of a new indicator. By reducing the content of water or methanol, one can advance stepwise to the hitherto unknown acidity constants of less and less acidic indicators. The H_- scale was extended to 12 pK units and is connected to the conventional pH scale by the most acidic indicators used. Precise pK values could be given for the first time for some C–H acids in $(CH_3)_2SO/CH_3OH/CH_3OK$ buffer solutions, *e.g.* indene (pK = 18.2), fluorene (20.5), and triphenylmethane (27.2). / J. Amer. chem. Soc. *87*, 382 (1965) / –Eb. [Rd 274/483 IE]

The iron(II)-cysteine complex in ferredoxin was studied by *E. Bayer*, *W. Parr*, and *B. Kazmeier*. The iron(II) complex *(1)* of methyl cysteinate was prepared as a model compound. The agreement of the spectroscopic data of *(1)* and ferredoxin (λ_{max} = 280 and 390 μm and 285 and 390 mμ, respectively) makes it appear likely that the arrangement of the iron(II) ions in ferredoxin is similar to that in *(1)*. The hydrogen



(1)

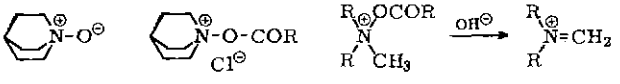
sulfide liberated on acidification of ferredoxin is not linked as inorganic sulfide but is produced by an Fe(II)-catalysed β-elimination of sulfur from the cysteine in the peptide. The methyl *N*-benzoylcysteinate and methyl cysteinate ester used as models behave like ferredoxin in this respect. The benzoyl compound releases H_2S even in the absence of $Fe^{2\oplus}$ on acidification, but methyl cysteinate reacts only in the presence of iron, which therefore exerts a catalytic effect. Pure apoferredoxin was made be splitting off the iron from the complex with α,α'-bipyridyl in a solution containing sodium dithionite. In the presence of $Fe^{2\oplus}$, the apoferredoxin exhibited complete activity in enzymatic tests. / Arch. Pharmaz. *298*, 196 (1965) / –Hö. [Rd 371/580 IE]

Tetrakis-8-hydroxyquinolyltin(IV), a chelate with the coordination number 8, is described by *K. Ramaiah* and *D. F. Martin*. It was made from diphenylbis-8-hydroxyquinolyltin(IV) and excess 8-hydroxyquinoline by cleavage of the phenyl-tin bond at 300 °C. The brick-red substance, m.p. 400 °C, was purified by washing it with ether and toluene and subsequent vacuum sublimation. The properties of the compound are those expected of a chelate with 8-coordinated tin. Conductivity measurements in nitrobenzene preclude an ionic structure $[Sn(Ox)_3]^\oplus Ox^\ominus$. The chelate is present in the monomeric form in its solution in acridine. Polarographic investigations indicate two reduction steps identical with those of diphenyltin dichloride. The infrared spectrum and thermal stability of the compound and the resistance to methylation of its nitrogen atoms make it appear likely that the coordinate bonds occur between the quinoline nitrogens and the tin. / Chem. Commun. *1965*, 130 / –Gn.

[Rd 366/575 IE]

Selective hydrolysis of aspartate bonds in tryptic peptides was achieved by *C. M. Tsung* and *H. Fraenkel-Konrat*. After 16 h in 0.03 N hydrochloric acid at 105 °C, all aspartate residues plus about 50 % of the aspartate residues from asparagine were split off as free aspartic acid. All other amino acids remained practically unaffected. Kinetic measurements revealed that the hydrolysis of peptide bonds involving asparagine is preceded by elimination of ammonia to give aspartate. The rate of hydrolysis of aspartate-peptide bonds is not affected by the nature of the neighboring amino acid. The products of the reaction are ammonium ion, aspartic acid, and peptides that are completely free of aspartate and asparagine. The method should by useful for sequence analysis. / Biochemistry *4*, 793 (1965) / –Hö. [Rd 368/577 IE]

N-Acyloxyammonium salts *(1)* have been made by *R. Huisgen* and *W. Kolbeck*. Anhydrous quinuclidine-*N*-oxide *(2)* and benzoyl chloride or acetyl chloride react in benzene to give the colorless salts *(3a)* or *(3b)* in yields of 89–91 %. The NMR spectra of *(3)* prove that the bicyclic moiety remains intact. Compound *(3a)* is surprisingly stable in acidic or neutral solution but is readily decomposed by alkali. Aniline



(2) *(3a)*: R = C_6H_5 *(1)* *(4)*

(3b): R = CH_3

is benzoylated by *(3a)* in the cold with release of *(2)*. The corresponding *N*-tosylquinuclidinium chloride can be kept in the crystalline state only below –20 °C, but the hexachloroantimonate is stable even at room temperature. The use of a bridgehead amine oxide such as *(2)* suppresses the base-catalysed reaction leading to the immonium ion *(4)* otherwise observed with *(1)*. / Tetrahedron Letters *1965*, 783 / –Ma. [Rd 289/498 IE]

The repressor of the β-galactosidase synthesis in *Escherichia coli* was studied by *J. R. Sadler* and *A. Novick*, who managed to isolate mutants which synthesize a labile repressor. The repression of the β-galactosidase formation in a bacterial culture could be eliminated merely by brief heating. This derepression proceeded like the reaction after addition of an inducer, *e.g.* isopropyl thiogalactoside. In the presence of inducer, the repressor becomes more thermolabile. In agreement with the concepts of *Monod* [1], it is assumed that attachment of the inducer onto the repressor produces a change in the conformation of the latter which inactivates its point of attachment for the Lac-operon. Accordingly, repressors should be classified among the allosteric proteins. / J. molecular Biol. *12*, 305 (1965) / –Hö. [Rd 369/578 IE]

[1] *J. Monod*, *J. P. Changeux*, and *F. Jakob*, J. molecular Biol. *6*, 306 (1963).

A new method of preparing dihalogenocarbenes from organometallic compounds in good yields under mild conditions is described by *D. Seyferth, J. Yick-Pui Mui, M. E. Gordon*, and *J. M. Burlitch*. When $(CH_3)_3SnCF_3$ and NaI are heated with cyclohexene in dimethoxyethane under nitrogen at 80 °C for 12 h, the product is 7,7-difluorobicyclo[4,1,0]heptane in 73 % yield; with tetramethylethylene instead of cyclohexene, 1,1-difluorotetramethylcyclopropane *(1)* is formed (77 % yield).

$$(CH_3)_3SnCF_3 + NaI + (CH_3)_2C{=}C(CH_3)_2 \rightarrow$$

$$(CH_3)_3SnI + (CH_3)_2\overset{CF_2}{\overset{/\backslash}{C}}C(CH_3)_2 + NaF$$

(1)

An analogous reaction between $C_6H_5HgCCl_3$ and cyclohexene affords 7,7-dichlorobicyclo[4,1,0]heptane (72 %) after 48 h at 30 °C. Here a trichloromethide anion, $CCl_3^{\ominus}$, is formed as an intermediate. $C_6H_5HgCCl_2Br$, NaI, and acrylonitrile react at room temperature in 1,2-dimethoxyethane to

$$H_5C_6HgCX_3 + I^- \rightarrow H_5C_6HgI + CX_3^- \quad (2)$$

$$CX_3^- \rightarrow CX_2 + X^-$$

$$CX_2 + (CH_3)_2C{=}C(CH_3)_2 \rightarrow (CH_3)_2\overset{CX_2}{\overset{/\backslash}{C}}C(CH_3)_2$$

yield 1,1-dichloro-2-cyanocyclopropane (16 %), bromodichloromethane (28.5 %), and 4-bromo-4,4-dichlorobutyronitrile (2 %). / J. Amer. chem. Soc. *87*, 681 (1965) / –Ma.
[Rd 288/497 IE]

The reduction of tertiary phosphine oxides with trichlorosilane to tertiary phosphines is reported by *H. Fritzsche, U. Hasserodt*, and *F. Korte*. The reduction can be effected not only with organosilanes alone – as previously thought – but also with trichlorosilane. The Reactions (a) and (b) are carried out in an autoclave or simply in benzene or toluene; both aromatic and aliphatic tertiary phosphine oxides can be re-

$$R_3PO + 2\,SiHCl_3 \rightarrow R_3P + SiCl_4 + H_2 + 1/n\,(Cl_2SiO)_n \quad (a)$$

$$R_3PO + SiHCl_3 + R'_3N \rightarrow R_3P + 1/n\,(Cl_2SiO)_n + HNR'_3Cl \quad (b)$$

duced. The siloxanes formed are dissolved by boiling with 20–30 % sodium hydroxide, and the tertiary phosphines are then isolated from the organic phase. Thus, for example, $(C_6H_5)_3PO \rightarrow (C_6H_5)_3P$, m.p. 80 °C, in 98 % yield without amine, or in 85 % yield with triethylamine; $(p\text{-}CH_3O\text{-}C_6H_4)_3PO \rightarrow (p\text{-}CH_3O\text{-}C_6H_4)_3P$, m.p. 135 °C, in 65 % yield; $(n\text{-}C_4H_9)_3PO \rightarrow (n\text{-}C_4H_9)_3P$, b.p. 111 °C/14 mm, in 92.5 % yield. / Chem. Ber. *98*, 170 (1965) / –Ma.
[Rd 256/465 IE]

Free arylboron radicals have been obtained by *J. E. Leffler E. Dolan*, and *T. Tanigaki*. Dimesitylboron fluoride reacts in 1,2-dimethoxyethane with a Na/K alloy to give the dimesitylboron radical *(1)* which can be kept for at least 4 months in the degassed solvent, as shown by ESR spectra. Trimesitylboron also reacts with alkali metals in dimethoxyethane or tetrahydrofuran to form blue solutions containing free radicals. On further reaction with alkali metal or Na/Hg in

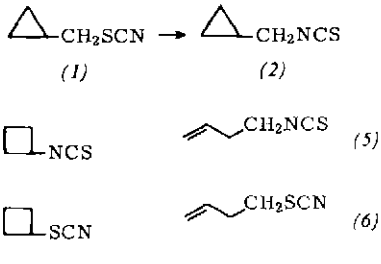
$$R_2BF \xrightarrow{Na\text{-}K} R_2B\cdot \qquad R = \text{2,4,6-trimethylphenyl}$$

(1)

tetrahydrofuran, aryl groups are split off and the ESR spectrum of the resulting product is identical with that of *(1)*. / J. Amer. chem. Soc. *87*, 927 (1965) / –Ma.
[Rd 290/499 IE]

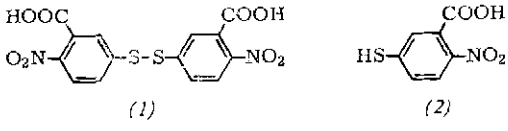
The selective reducing properties of borane carbonyl derivatives have been examined by *R. D. Shoup* and *J. C. Carter*. $[NH_3CH_3]^{\oplus}$ $[H_3BCONHCH_3]^{\ominus}$ can reduce aldehydes, ketones, acyl chlorides, pyridinium salts, and oxides. Suitable solvents are water, tetrahydrofuran, and dimethoxyethane; in the latter the reduction proceeds less intensively but more selectively. The three hydrogens attached to the boron are involved in the reduction. Interesting reactions include the reduction of the pyridinium ring in the 1,4- and 1,2-positions, the stereoselective reduction of 3,3,5-trimethylcyclohexanone to form 3–4 times more *trans*- than *cis*-alcohol, and the 90–95 % selective reduction of an aldehyde in the presence of a ketone. $[NH_2(CH_3)_2]^{\oplus}$ $[H_3BCON(CH_3)_2]^{\ominus}$ is less active than the above reagent but reduces aldehydes very selectively in the presence of ketones. It converts 3,3,5-trimethylcyclohexanone preferentially into the *trans*-alcohol. Nitriles, olefins, and esters are not reduced by this reagent. / Abstracts 149th Meeting Amer. Chem. Soc. *1965*, 49 P / –Ma.
[Rd 328/537 IE]

Thermal isomerization of thiocyanomethylcyclopropane *(1)* was found by *P. E. Newallis* and *L. A. Spurlock* to give rise to compounds *(2)–(6)*. This is the first example of a rear-



rangement of a carbon skeleton coupled with a simultaneous thiocyanate-isothiocyanate isomerization. / Abstracts 149th Meeting Amer. Chem. Soc. *1965*, 29P / –Ma. [Rd 329/538 IE]

A colorimetric micro-assay of glutathione has been developed by *C. W. Owens* and *R. V. Belcher*. Only 30 mg of tissue is required for an estimation. The tissue is homogenized and filtered through a sintered-glass funnel. The filtrate containing the glutathione (GSH) is filled into an absorption cell with phosphate buffer at pH 7.1, bis-(4-nitro-2-carboxyphenyl) disulfide *(1)*, and ethylenediaminetetraacetic acid. When TPNH is added to start the reaction, the disulfide *(1)* is reduced to 5-mercapto-2-nitrobenzoic acid *(2)* by catalytic amounts of GSH. The rate of increase in the optical density of *(2)* at 412 mμ, which is proportional to the concentration of GSH, is recorded. The reduction is probably a cyclic



process: GSH reacts with *(1)* to give a molecule of *(2)* and a mixed disulfide, which reacts with a second molecule of GSH to yield another molecule of *(2)* and GSSG. The GSSG is reduced by TPNH at GSH-reductase with regeneration of the GSH. / Biochemical J. *94*, 705 (1965) / –Hö.
[Rd 319/528 IE]

A radiochemical estimation of terminal lithium in polymers, developed by *D. R. Campbell* and *W. C. Warner*, is based on their reaction with tritium-labelled alcohols. The lithium is exchanged for the tritium of the alcoholic hydroxyl group, and the excess alcohol is washed out with water; the content of labelled end-groups is then determined radiometrically. This process yields results in good agreement with the lithium estimation by carbonation when alcohols containing up to 4 carbon atoms and temperatures of 25–65 °C are used. / Analytic. Chem. *37*, 276 (1965) / –Hl. [Rd 297/506 IE]

Spectroscopy in the far infrared for the analysis of high polymers, resins, monomers, and plasticizers is recommended by *D. Hummel* to supplement the data from spectroscopy in the middle infrared. Spectra in the far infrared (between 700 and 250 cm^{-1}) are particularly sensitive towards alterations in intra- and intermolecular forces and are therefore valuable for examining the conformations and crystallinity of high polymers. Although strongly polar and crystalline materials generally have many relatively strong absorptions in the far infrared, amorphous resins often give spectra with hardly any prominent features. Since light in the far infrared is scattered less by turbid samples than that in the middle infrared, the techniques for measuring far-infrared spectra are ofter much simpler. / Kunststoffe *55*, 102 (1965) / –Hl.

[Rd 296/505 IE]

BOOK REVIEWS

Optical Circular Dichroism. Principles, Measurements, and Applications. By *L. Velluz, M. Legrand*, and *M. Grosjean*, transl. by *J. MacCordick*. Verlag Chemie GmbH., Weinheim/Bergstr. (Germany) and Academic Press, New York-London 1965. XII+247 pp., 149 figs., 10 tables, linen DM 40.– (about $ 10.00).

The measurement of optical circular dichroism, *i.e.* the difference in absorption of left-hand and right-hand circularly polarized light by optically active compounds, is one of the most modern optical methods of investigation. Circular dichroism yields valuable information about the configuration of organic molecules having a chromophore in the vicinity of their center of asymmetry. Some years ago *L. Velluz, M. Legrand*, and *M. Grosjean* developed an apparatus with which dichrograms can be measured as conveniently and rapidly as ordinary absorption spectra, thus making the method accessible to the organic chemist interested in configurational problems. The authors have made a further significant contribution with this first monograph on the subject.

One of the two introductory chapters contains a comparison of circular dichroism and optical rotatory dispersion. The experimentally easier, and therefore previously applied, measurement of the rotation of plane polarized light as a function of wavelength also gives information about the configuration of optically active compounds. Whereas measurable dichroism occurs only in the region of absorption of the responsible chromophore, optical rotation extends well beyond this range, although with diminishing magnitude. This leads to specific differences which makes the two methods complementary. The authors justifiably regard the simpler form of the dichrograms as an advantage in the analysis of the experimental data. In compounds having several chromophores near the asymmetric center, or a chromophore with several absorption bands, a detailed investigation and assignment of the separate effects is often possible only with the aid of circular dichroism. On the other hand, measurement of rotatory dispersion is indispensible for configurational studies on compounds which absorb below 220 mμ and into which no chromophore absorbing at higher wavelengths can be introduced.

Readers primarily interested in the application of the method to structural problems may find the following chapter (58 pp.) somewhat too detailed and theoretical. For circular dichroism it is, however, particularly worthwhile to learn more about the principles and selection of the method of measurement, since considerable difficulties in instrumentation had to be surmouted. It would, however, be desirable if in a later edition a separate chapter could be added here on measuring techniques, cells for kinetic and low-temperature measurements, possibilities to enhance the fine structure, *etc.*

The main part of the book (105 pp.) is devoted to the application of circular dichroism. Optically active compounds containing the ideally suited carbonyl chromophore – mainly steroid ketones – are described first in this section. After a theoretical analysis of the carbonyl chromophore, a clear explanation of the octant rule is given. The application of this rule to determinations of absolute configuration is demonstrated on systematically ordered groups of steroid ketones and extended to compounds in which the keto group is not in a saturated six-membered ring. An advance for the theory and applications of circular dichroism is the introduction by the authors of the normalized dichrograms, in which all ordinate values are divided by the maximum height of the curve. The shape and position of these dichrograms are characteristic for a given combination of chromophore and asymmetric center and independent of the rest of the molecule. – Next alcohols, amines, and carboxylic acids, which do not ahsorb above 220 mμ, and which were investigated after conversion to derivatives absorbing at longer wavelengths, *e.g.* xanthates, nitrosamines, and acylthioureas are discussed. It is then shown with cobalamines, anthracyclinones, peptides, and polynucleotides, that successful configurational investigations of natural products containing a complicated chromophore are possihle with the aid of circular dichroism. The anthracyclinones are also an example of measurements on compounds of low optical activity and very high extinction coefficients. – It is remarkable that most of the numerous measurements puhlished to date have been made on an apparatus described by the authors. The next chapter (10 pp.) describes the effects of concentration, temperature, and solvent on optical circular dichroism in three sections. Some references to application to kinetic measurements, analysis of mixtures, and measurements at low temperatures are also concealed under these headings. The book closes with a brief presentation of the present status of the molecular theory of optical activity and with a valuable appendix listing wavelength and intensity of the dichroism maxima of over 400 compounds.

Configurational analysis using optical circular dichroism is becoming increasingly important through new developments in the elucidation and synthesis of optically active compounds. As the first monograph on the subject, and with the originators of the method as authors, the book hardly needs recommendation. It is very welcome that the publishers have presented it in English and thus made it immediately accessible to a wide range of readers. *B. Franck* [NB 424/269 IE]

Polycyclic Hydrocarbons. Volume I. By *E. Clar*. Academic Press, London-New York, and Springer Verlag, Berlin-Göttingen-Heidelberg 1964. 1st Edit., XXVIII + 488 pp., 80 figures, 8 tables, linen, DM 70. - (about $ 17.50).

Since the appearance of the well known monograph by *E. Clar* on polycyclic aromatic hydrocarbons in 1952, this field has undergone vast material and theoretical developments. Almost 40% of the polycyclic systems known at present have been synthesized within the past 12 years. This new English monograph is therefore much larger than the previous edition and appears in two volumes. The first volume contains general chapters on the chemistry, physics, and biological importance of aromatic hydrocarbons and a systematic discussion of cata-annellated systems.

Although the text covers the synthesis, properties, spectra, and biological activities of all the hydrocarbons described in the literature up to 1963 and thus gains the informational value of a work of reference, *Clar*'s own contributions are placed in the forfront of the theoretical chapters. In the preface, he states that the book is written "... to present the facts in a simple and clear order ... but it does not present a com-

prehensive theory about polycyclic hydrocarbons". By systematic use of simple symbols (Kekulé structures and π-sextets), an attempt is made to achieve a uniform description of the chemical and spectroscopic behavior of aromatic hydrocarbons. These chapters, which contain many new and unconventional proposals, will certainly stimulate discussions.

In addition there is an informative contribution by *Regina Schoental* on the carcinogenic effect of aromatic hydrocarbons.

This book ought to prove an indispensable companion for every chemist, physicist, or physician working directly or indirectly with polycyclic aromatic compounds.

M. Zander [NB 338/196 IE]

Polycyclic Hydrocarbons. By *E. Clar*. Vol. 2. Academic Press, London-New York; Springer Verlag, Berlin-Göttingen-Heidelberg 1964. 1st. edit., LVIII + 487 pp., linen DM 78.40 (about $ 20.00).

The second volume of *E. Clar*'s monograph on polycyclic aromatic hydrocarbons contains descriptions of *peri*-condensed systems, *i.e.* the hydrocarbons derived from perylene, pyrene, fluoranthene, *etc.* A total of about 200 aromatic systems is described. The literature has been completely scanned until the end of 1962 and sometimes up to the end of 1963.

In the chapters on the various hydrocarbons, the well-proved divisions used in *Clar*'s German monograph (1952) on aromatic hydrocarbons has been retained. First the syntheses of the hydrocarbons are described; here many well-printed formulae help to maintain clarity. This is followed by a description of the most important physical properties. Ultraviolet spectra are recorded clearly in illustrations with data on the band maxima and extinction coefficients. On account of its numerous spectra alone, the book should be of great value to the chemist interested in spectroscopy. Furthermore, the most important reactions of the hydrocarbons – substitution, hydrogenation, oxidation, *etc.* – are discussed. Whenever possible, data on their biological activities are given.

This second volume, which now completes the treatise, will also be of great service to anyone working in the field of polycyclic aromatic compounds.

M. Zander [NB 400/258 IE]

The Enzymes. Edited by *P. D. Boyer, H. Hardy*, and *K. Myrbäck*. Vol. 8. Academic Press, New York-London 1963. 2nd completely revised edit., XX + 484 pp., numerous illustrs. and tables, linen $ 16.50.

This volume contains a discussion on the porphyrin enzymes and on the oxidases involved in direct oxygenation. As in the previous volumes, an opening chapter *(Nicholls)* gives an orderly survey of the functions of the cytochromes, whose cofactors are so similar but whose catalytic activities – determined by the protein moiety – are so different. The individual cytochromes are then given due consideration. Although naturally the recently discovered structure of the porphyrin of the respiratory enzyme is not included, the expanse and orderliness of data given are highly impressive, and abundant references are cited covering literature up to 1962. There is only little quantitative information given on the phenol and amine oxidases containing iron or copper. On the other hand, a thorough treatment is given (*Nicholls-Schonbaum, K. G. Paul*) to "the fossil enzymes of unknown function in mammals" – catalase and peroxidase, which played so important a role in the development of the fundamentals of the molecular biochemistry of enzymes, for with them *B. Chance* worked out the methods of kinetic analysis for studying the enzyme-substrate complex and its quantitative dependence on the physico-chemical parameters of the reaction medium. The new field of mixed-function oxidases is discussed with accustomed authority by *O. Hayaishi*, and a clear and poignant description of the interesting topic of phenylalanine hydroxylation is given by its discoverer *S. Kaufman*. The agglomeration of facts in this way awakes reasonable hopes that with their help, the basic principles of enzyme action may soon be recognized, about which, unfortunately, little is said. It is regrettable that here the authors – perhaps in contrast to the earlier edition – have steered clear of hypotheses, which would at least incite discussions. The volume not only completes the description of the oxidizing enzymes, but also closes the entire work and ends with a collective index. The series provides a firm foundation on which molecular biophysical research can continue to build.

L. Jaenicke [NB 382/240 IE]

Analysis of Ancient Metals. By *E. R. Caley*. International Series of Monographs on Analytical Chemistry. Edited by *R. Belcher* and *L. Gordon*. Vol. 19. Pergamon Press, Oxford-London-Edinburgh-New York-Paris-Frankfurt 1964. 1st edit., XI + 176 pp., 64 tables, linen £3.10.0 (about $ 10.–).

After an indication is given of the irregularities caused by weathering processes on various layers of metallic archeological finds, proposals are made for eliminating such interferences, and the most important corrosion products and their analysis are described. This is followed by highly detailed practical procedures for chemical investigations of the metals Au, Ag, Cu, Pb, Sn, Sb, and their historically interesting alloys, and of iron and steel and their weathering products. Mainly classical analytical procedures are applied. More recent assay and separation procedures, and micromethods are not included, although these are probably valuable for rapid series estimations.

The purely chemical section is aptly supplemented by numerous sample analyses and an extensive list of references. The book is well printed and furbished and is of interest to anyone engaged in analyses of ancient metals.

W. Geilmann [NB 365/223 IE]

Recent Progress in Surface Science. Vol. 1. Edited by *J. F. Danielli, K. G. A. Pankhurst*, and *A. C. Riddiford*. Academic Press, New York-London 1964. 1st edit., XII + 414 pp., numerous figs., a few tables, clothbound $ 16.00.

In this book, eleven chapters by several authors give reviews of sections of this very broad field of knowledge, which attracts the interest and research participation of biologists, chemists, physicists, and engineers alike. Subjects dealt with include the viscosity of interfaces, foams, films of free liquids, electrical double layers and electrokinetic phenomena, electrode processes, corrosion of metals, surfactants, the chemistry of semiconductor surfaces, facilitated diffusion through cell membranes, cell contacts, the external surface of cells and intercellular adhesion, and the formation and properties of bimolecular lipid membranes.

Progress reports of this kind are very valuable, for they save the scientist who wants to secure a preliminary survey of the latest results on a certain topic much time that would otherwise be required for studying widely scattered original publications. The encyclopaedic nature of this book makes its purchase recommendable particularly for both large and small libraries.

B. Fell [NB 380/238 IE]

Water and Solute-Water Interactions. By *J. L. Kavanau*. Holden-Day, Inc., San Francisco-London-Amsterdam 1964. 1st edit., 101 pp., 7 figs., linen $ 5.50.

Because of the fundamental significance of its subject, this little book should arouse great general interest. The author briefly treats the following in particular: the structures of water and ice, short- and long-range order in water, proton mobility and proton exchange, and interactions of water with ions and macromolecules. Many advances in these fields have been made so recently that they have not yet found their way into most textbooks. However, many important questions still remain the object of occasionally contradictory speculations and hypotheses. The author's attempt to make his publication as up to date as possible is

illustrated by the fact that he reviews even the latest papers, including some dated 1964. However, the selection of literature reviewed sometimes appears to be a little one-sided, and some relevant matters have been omitted or are only mentioned incidentally, *e.g.* the bonding effect of hydrophobic interactions or the importance of the structure of water to the mechanism of fast reactions.

G. Schwarz [NB 393/251 IE]

The Application of Mathematical Statistics to Chemical Analysis. By *V. V. Nalimov*. Translated from the Russian by *P. Basu*. Pergamon Press, Oxford-London-Edinburgh-New York-Paris-Frankfurt 1963. 1st edit., IX + 294 pp., 54 figs., numerous tables, linen £4.4.0 (about $11.60).

This book is composed as a manual for analytical chemists or physicists. It has obviously been written with a strong background of personal experience and with careful consideration of the pertinent literature. The reader is assumed to possess a fundamental knowledge of higher mathematics and mathematical statistics.

The book is divided into nine chapters. The first three deal with general principles, mathematical statistics in chemical analysis, and random variables. This is followed by chapters on the normal (Gauss) distribution and the distribution functions derived from this and on Poisson and binomial distributions. Chapter 6 deals with the comparative evalution of chemical analyses, and Chapter 7 with variance analysis. The eighth chapter presents a statisical treatment of linear relationships, including a short section on correlation analysis. The closing chapter gives rules and proposals for the planning of statistical experiments. A particularly valuable list of further literature is given: 172 references with short descriptions of the contents of books and papers covering the period up to 1959. This is followed by a most useful appendix with 15 clear tables of the most important statistical functions.

The book contains a wealth of interesting and original thoughts and of step-by-step calculations of numerical examples. The experienced worker in this field will find many suggestions here. The reviewer considers the volume less suitable as an introduction for the beginner, for the main themes cannot he followed well enough. The book adopts a very wide scope, and important conclusions are given unobtrusively in the text; if these had been made more prominent by using italic or bold-faced type, their importance would be more immediately apparent. The symbols used are clear, but the number of concepts introduced could have been reduced. Some definitions are imprecise, and the curves of the Gauss distribution in Figure 11 are poorly reproduced. Some aspects are omitted or given only brief treatment, *e.g.* the question of the distribution of possible true values around a result found by experiment and the definition of the limit of detection.

On the other hand, the book is full of useful ideas and hints. For instance, it is pointed out that decisions reached as a result of statistical criteria are of the nature of agreements. Admirable features of the hook are the applications of Poisson distribution to semiquantitative analysis and of binomial distribution to qualitative analysis. Even the Chebysheff inequality is used in analyses when nothing is known of a distribution function. *Nalimov* himself states in his foreword that he considers his book to be a contribution to the further development of a general statistical theory of chemical analysis. It is certainly a most stimulating and useful contribution.

H. Kaiser [NB 406/264]

Mucopolysaccharides. Chemical Structure, Distribution, and Isolation. By *J. S. Brimacombe* and *J. M. Webber*. B. B. A. Library, Vol. 6. Elsevier Publishing Co., Amsterdam-London-New York 1964. 1st edit., IX + 181 pp., 10 figs. 13 tables, linen DM 31.– (about $8.00).

Although numerous monographs have appeared within recent years on this topic, the present volume is appealing because it brings a careful and comprehensive survey of the more recent literature in clear terms and a systematic order. The authors have attained this their aim firstly by restricting the material covered to the mucopolysaccharides the structures of which have been completely or largely elucidated and secondly by stressing the classical methods of structural analysis in carbohydrate chemistry. There are six chapters given on the individual types of mucopolysaccharides, even blood-group substances being regarded as such (!). Although data are presented on their distribution, preparation, biosynthesis, and enzymatic degradation, the book is not suitable as a work of reference nor for use as a laboratory manual. For example, data on molecular weights and specific optical rotations, which the reader would have preferred in tabular form, are scattered throughout the text, and other physical properties that are of importance especially for the biological function, such as viscosities, electrophoretic mobilities, sedimentation constants, *etc.*, are omitted altogether. In addition, the authors have restricted their discussion in the chapters on quantitative estimation, separation, and purification to a mere reiteration of the methods available without commenting on their usefulness. Despite these shortcomings, the experienced worker in this field will take recourse to this very informative book, especially on account of its reliable bibliography, which encompasses 946 titles.

E. Buddecke [NB 402/260 IE]

Treatise on Analytical Chemistry. Edited by *I. M. Kolthoff*, *P. J. Elving*, and *E. B. Sandell*. Part I: Theory and Practice. Vol. 3 and Vol. 4. Interscience Publishers, a Division of John Wiley & Sons, New York-London-Sydney 1961 and 1963. 1st edit., Vol. 3, Section C (concluded) Separation: Principles and Techniques: XVII + 439 pp., numerous figs. and tables, linen £5.15.0 (about $16.00); – Vol. 4, Section D–1: Magnetic Field Methods of Analysis; Section D–2: Electrical Methods of Analysis: XXV + 953 pp., numerous figs. and tables, linen £9.9.0 (about $26.50).

Fifty-three of the total of 124 sections planned for the first part – Theory and Practice of Analytical Chemistry – of the analytical handbook "Treatise on Analytical Chemistry" have now appeared. The present partial volume I 3 concludes the Section C begun in the partial volume I 2 on separatory methods and their principles and practical techniques; the partial volume I 4 contains section D–1 on magnetic analytical methods and section D–2 on electrical methods of analysis. As for the first two partial volumes, the editors have secured competent specialists to write the individual portions. The fundamentals of the methods are described very carefully and comprehensively, but often the practical aspects receive too little attention. For this reason, the reader will miss a comparitive appraisal of various methods for solving different specific analytical tasks.

In the partial volume I 3, *H. Irving* and *R. J. P. Williams* deal with liquid-liquid extraction, and *J. A. Hermann* and *J. F. Suttle* with methods of separation based on solid-liquid equilibria. Separation and purification by crystallization and precipitation are given much more space than the important new technique of zone melting (only 3 pp.).

The major portion of volume I 3 is devoted to chromatography. The fundamentals of chromatographic methods are discussed by *I. Rosenthal*, *A. R. Weiss*, and *V. R. Usdin*; thereafter individual methods are described: liquid-solid adsorption chromatography by *B. J. Mair*, liquid-solid ion-exchange chromatography by *W. Rieman* and *A. C. Breyer*, paper chromatography by *H. J. Pazdera* and *W. H. McMullen*, and gas chromatography by *C. E. Bennett*, *S. Dal Nogare*, and *L. W. Safranski*. Here too, the 240-odd pages afford far too little space to go beyond the fundamentals and general execution to stress the importance of these methods. Thin-layer chromatography is unfortunately not treated in this partial volume, which appeared in 1961. Electrochromatography could at least have been mentioned in the discussion of the fundamentals of chromatographic processes,

if only for the sake of maintaining the principles of classification.

The measurement of magnetic susceptibility for analytical purposes is reviewed by *L. N. Mulay* to start partial volume I 4. This section gives a good survey of the subject and deals with both fundamentals and experimental methods and applications. The section by *N. F. Chamberlain* on nuclear magnetic and electron paramagnetic resonance conveys the impression that these methods which have been applied so much in analysis within recent years are still in the throes of development; the status reflected in this section is that of 1961, but it is written lucidly and intelligibly. This statement also applies in particular to the following section on mass spectrometry by *F. W. Melpolder* and *R. A. Brown*. The fundamentals, measuring techniques, and applications are described in detail; a further useful addition is a literature review of potential analytical applications of mass spectrometry. The section D–1 on magnetic methods of analysis is then closed by an article on ion scattering by *S. Rubin*. The content of this chapter is good and shows possible analytical applications of this method, which, because of the extensive apparatus required, will at present probably remain restricted to physics laboratories.

The larger portion (over 550 pp.) of partial volume I 4 is allocated to section D–2 on electrical methods of analysis. Following a chapter by *C. N. Reilley* on the fundamentals of electrochemical processes at electrodes and another by *R. W. Murray* on electrochemical techniques, a series of detailed, well-written sections on individual electroanalytical methods is given: chronoamperometry and chronopotentiometry *(P. Delahay)*, potentiometry *(N. H. Furman)*, polarography *(L. Meites)*, coulometric analysis *(D. D. De Ford* and *J. W. Miller)*, stripping analysis *(I. Shain)*, conductometry and oscillometry *(J. W. Loveland)*, and the analytical importance of dielectric constants *(B. W. Thomas* and *R. Pertel)*.

The sections are arranged according to methodical aspects of the subject and frequently – as already pointed out in earlier reviews – overemphasize theory and underestimate practice. Moreover, the presentation often should have followed physico-chemical fundamentals more closely and not the historical developments. Comparisons of the values of different methods in practical analysis are often sadly missed. Despite these shortcomings, the two partial volumes I 3 and I 4 of this series nonetheless represent a valuable addition to the literature on analytical chemistry.

Synthesis of Transcurium Elements by Nuclear Reactions with Heavy Ions

BY PRIV.-DOZ. DR. C. KELLER

LEHRSTUHL FÜR RADIOCHEMIE, TECHNISCHE HOCHSCHULE KARLSRUHE (GERMANY) AND INSTITUT FÜR RADIOCHEMIE, GESELLSCHAFT FÜR KERNFORSCHUNG M.B.H. KARLSRUHE, KERNFORSCHUNGSZENTRUM

Experimental techniques are described for the preparation of transcurium elements. Nuclear reactions with heavy ions appear to be most promising for the preparation of new transcurium elements and isotopes. Since these nuclear reactions have extremely small cross-sections, only few atoms will be produced. Owing to their short half-lives, the heaviest nuclei can presumably be identified only indirectly through the probabilities of their formation and distintegration.

A. Introduction

Although the transmutation of chemical elements had often been attempted, *Becquerel* was the first to succeed in 1896. The new element was however not produced through human agency, but by the spontaneous decay of heavy nuclei. The first true nuclear synthesis was carried out by *Rutherford* in 1919 by the reaction $^{14}_{7}N(\alpha,p)^{17}_{8}O$.

The first artificial element discovered was technetium, which does not occur in nature (*Perrier* and *Segrè*, 1937). The first transuranium element, neptunium, was prepared three years later (*McMillan* and *Abelson*, 1940). The following years witnessed the discovery of the missing element 61 (promethium), and of the transuranium elements up to number 104, the last one being the first transactinide element.

B. Possible Synthesis of the Heaviest Elements

The starting materials for the synthesis of the heaviest elements are either naturally occurring heavy nuclei (*e.g.* ^{238}U and ^{232}Th), or those produced in nuclear reactions (*e.g.* ^{242}Pu and ^{246}Cm). Transurium isotopes can be made in the following two ways:

1. Heavy-ion bombardment of target nuclei of lower atomic number, in the course of which the intermediate compound nuclei emit charged and uncharged particles, as in the reactions

$^{239}_{94}Pu(^{13}_{6}C,4n)^{248}_{100}Fm$

and

$^{238}_{92}U(^{22}_{10}Ne,p3n)^{256}_{101}Md.$

Such nuclear reactions clearly can only be performed with the aid of particle accelerators and yield only unweighable amounts, or even just a few atoms, of the required elements. Apart from a few exceptions, only neutron-deficient isotopes of the heaviest elements can be prepared by this method.

2. Multiple neutron capture followed by β^--decay of the neutron-rich nuclei. This process can take place in three ways:

a) Neutron capture in very high neutron flux densities (10^{23} to 10^{25} neutrons per cm^2), such as those produced for about 10^{-6} to 10^{-8} sec in nuclear explosions. For example, $^{238}_{92}U$ undergoes multiple neutron capture in such high fluxes to give uranium isotopes containing a high excess of neutrons. Thus uranium isotopes up to ^{255}U have resulted from nuclear explosions [1-3]. The number of successive neutron captures depends mainly on the intensity and duration of the neutron pulse. The short-lived, neutron-rich uranium isotopes undergo multiple β^--decays to form the isobars with the longest half-life, *e.g.*

$$^{250}_{92}U \xrightarrow{6\,\beta^-} {}^{250}_{98}Cf$$

$$^{255}_{92}U \xrightarrow{8\,\beta^-} {}^{255}_{100}Fm$$

[1] *H. Diamand, P. R. Fields, C. S. Stevens, M. H. Studier, S. M. Fried, M. G. Inghram, D. C. Hess, G. L. Pyle, J. F. Mech, W. M. Manning, A. Ghiorso, S. G. Thompson, G. H. Higgins, G. T. Seaborg, C. I. Browne, H. L. Smith,* and *R. W. Spence*, Physic. Rev. *119*, 2000 (1960).

[2] *R. W. Hoff* and *D. W. Dorn*, Universtity of California (Berkeley), Radiation Laboratory, Report UCRL-7314 Rev. I (1963).

[3] *R. W. Hoff* and *D. W. Dorn*, University of California (Berkeley), Radiation Laboratory, Report UCRL-7347 (1963).

b) Neutron capture in high-flux nuclear reactors (10^{14} to 10^{16} neutrons per cm^2 per sec). The synthesis of neutron-rich isotopes is in this case limited by the competing radioactive decay of the latter. Consequently, all nuclides synthesized in this manner are near the maximum of nuclear stability. Owing to the short half-life of isotopes with atomic number Z higher than 102, this method is not suitable for the synthesis of such elements. The synthesis of high mass number nuclei is a slow process: four years were required to produce $^{257}_{100}Fm$ in detectable quantities (one α-decay in about 10 min) by irradiating a mixed sample of $^{242}_{92}Pu$-$^{243}_{93}Am$-$^{244}_{94}Cm$ with a neutron intensity of 3×10^{14} neutrons/cm^2/sec [4]. Nuclei with mass number A above 257 have not yet been found.

c) Neutron capture in fluxes of 10^{19} to 10^{21} neutrons/cm^2/sec, the process being similar to that in b) above, but involving nuclei not so close to the maximum in the stability curve. This type of neutron capture is responsible for nuclear syntheses in stars (r-process) [5,6]. It has not yet been possible to carry out such reactions, since they require the maintenance of high neutron flux densities for at least a few seconds. Pulsed reactors may accomplish this aim in the near future.

Fig. 1 shows a scheme for the preparation of fermium isotopes (Z = 100) by the methods 1), 2a), and 2b) above.

C. Reactions of Heavy Nuclei on Bombardment with Heavy Ions

I. The Production of High-Energy Heavy Ions

The first attempts, by *Alvarez* [7] in 1940, to produce accelerated, multiply charged heavy ions resulted in only a trickle of $^{12}_{6}C$ ions (10 ions/sec) with an energy of 50 MeV. Since then, ion beams of higher energy and intensity, but also of better monochromaticity, have been obtained. The conventional ion sources of light-particle cyclic accelerators yield only doubly or triply charged heavy ions, which lose further electrons on collision with the residual gas. The more highly ionized particles are then accelerated more strongly, resulting in a wide energy spread of the particle beam. This can now be avoided in two ways:

1. by the use of a linear accelerator, such as the Heavy-Ion Linear Accelerator (HILAC) at Berkeley, California, in which heavy ions reach an energy of 10.3 MeV per nucleon;

2. by using special ion sources giving a uniformly ionized beam, which is not ionized further in the cyclic accelerator. For example, the maximum energy of the ion beam in the 310 cm cyclotron at Dubna, USSR, is 8.5 MeV per nucleon with a half-width of about 3 MeV for the 100 MeV $^{12}_{6}C$ beam [8,9].

II. Reactions of Heavy Target Nuclei with Heavy Ions

Interactions observed on bombarding heavy (Z > 80) nuclei with heavy ions (Z > 2) can be classified into distance, direct, and fusion reactions [8].

Distance reactions, incorporating all scattering processes, are of no significance in the preparation of heavy elements.

Direct reactions include transfer reactions, in which the projectile carries off some nucleons from the target (pick-up reactions), or donates some to it (stripping reactions) [9, 9a]; *e.g.*

$$^{181}Ta + {}^{14}N \rightarrow {}^{17}N$$
$$^{181}Ta + {}^{20}Ne \rightarrow {}^{17}N$$

Direct reactions involve also those in which the projectile knocks out several nucleons from the target, without absorbing them completely [10, 11]. The daughter products of the residual nuclei formed in such reactions undergo α-decay with energies of 8 MeV or more. Similar decay energies can be expected from the heaviest, α-active nuclei formed in fusion reactions followed by neutron emission from the compound nuclei. Therefore the assignment of mass number on the basis of the energy and the scheme of α-decay, frequently used with the short-lived α-active isotopes of the artificial elements, is rendered very difficult [11a, 11b].

Fusion reactions result in compound nuclei which subsequently decay either by fission or by emitting nucleons. The compound nucleus is characterized by a quasistationary nuclear state, whose lifetime of about 10^{-14} sec is long in comparison with the time needed for a projectile to traverse the length of the nucleus [12].

The term "compound nucleus" will be used in the following to denote the intermediate product of a nuclear reaction, irrespective of whether it is known that the compound nucleus has a finite lifetime and that its excitation energy is distributed equally over all the nucleons [13]. Recent work [14–17] shows that alone the assumption of a compound nucleus is often an oversimplification of the mechanisms of the reactions described in Section III.

III. Types of Disintegration of Compound Nuclei

1. Fission and Neutron Evaporation from the Compound Nucleus

When a heavy target nucleus is bombarded with heavy ions of energy somewhat above the coulomb barrier (*i.e.* the coulombic repulsion energy), the heavy ions will be captured with an effective cross-section corresponding approximately to the geometric cross-section of the nucleus. A compound nucleus is formed having an excitation energy E_A of about half the kinetic energy of the captured projectile. The nucleus then dissipates the excitation energy either by fission, or by emitting nucleons. Fission predominates in heavy nuclei (which have a low threshold energy of fission), so that the cross-sections for the nuclear syntheses are very small. The experimental value of the effective cross-section σ_c for compound-nucleus formation agrees within 15%

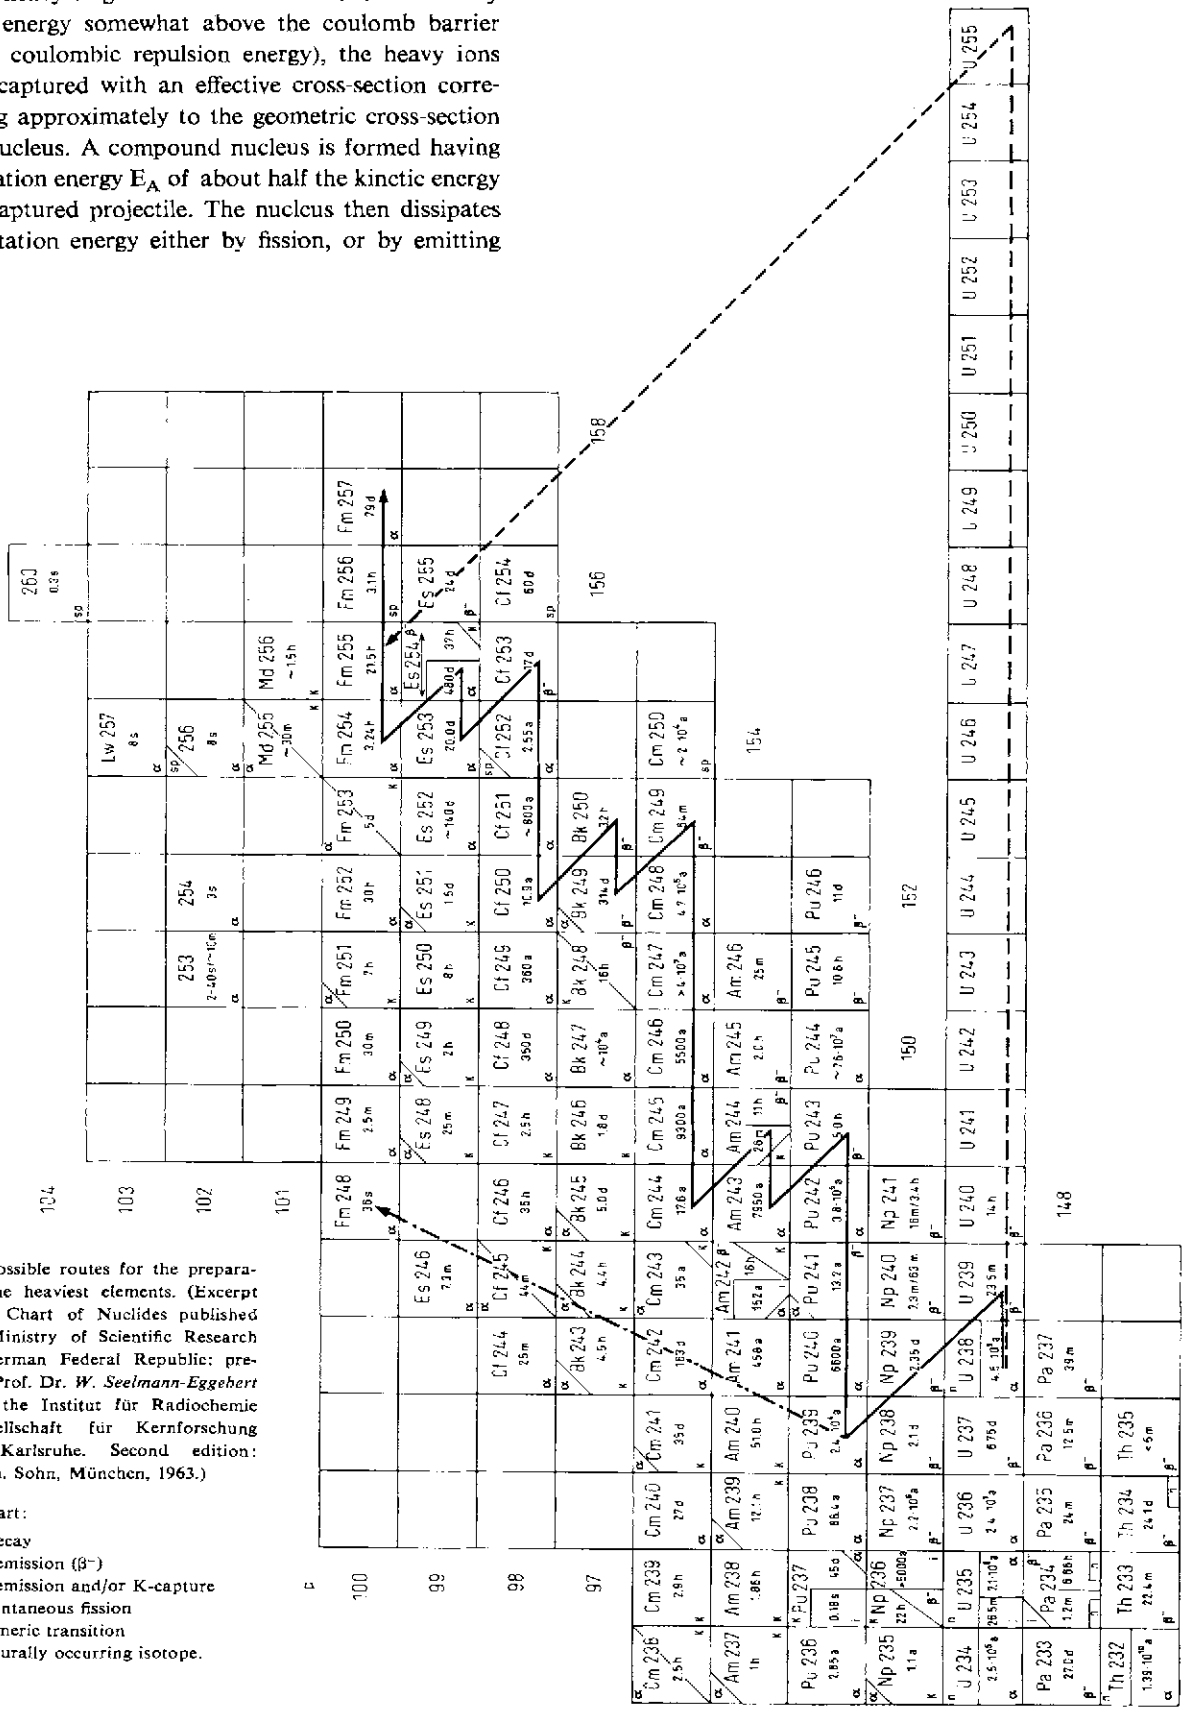

Fig. 1. Possible routes for the preparation of the heaviest elements. (Excerpt from the Chart of Nuclides published by the Ministry of Scientific Research of the German Federal Republic: prepared by Prof. Dr. *W. Seelmann-Eggebert* et al. in the Institut für Radiochemie der Gesellschaft für Kernforschung m.b.H., Karlsruhe. Second edition: Gorbach u. Sohn, München, 1963.)

n	Naturally occurring isotope.

with that calculated by Equation (1), proposed by *Blatt* and *Weisskopf* [19] and modified by *Druin* [18]:

$$\sigma_c = \pi \cdot r_0^2 (A_T^{1/3} + A_P^{1/3})^2 (1 - E_C/E) \quad (1)$$

A_T and A_P are respectively the mass numbers of the target and projectile nuclei, E is the energy of the projectile, and E_C the coulomb barrier for the nuclear reaction under consideration. E_C is calculated from:

$$E_C = \frac{Z_T Z_P e^2}{r_0 (A_T^{1/3} + A_P^{1/3})} \cdot \frac{A_T + A_P}{A_T} \quad (2)$$

Z_T and Z_P denote respectively the nuclear charges of the target and projectile. However, satisfactory agreement of the calculated and measured cross-sections is obtained only for $E > 1.2\ E_C$. The value 1.5×10^{-13} cm is generally used for the radius r_0 of a nucleon.

The relationship between σ_c and the fission cross-section σ_f is

$$\sigma_f = W_f \sigma_c \quad (3)$$

where W_f is the fission probability of the compound nucleus, which rapidly increases both with the nuclear charge of the latter (approximately in proportion to Z^2/A) and with its excitation energy [18, 20, 21]. At mass numbers $A > 220$ and excitation energies as low as about 30 MeV, the value of W_f is practically unity, so that the compound nucleus disintegrates almost exclusively by fission and the cross-sections for the emission of light particles are extremely small. This is shown by Fig. 2 for fermium isotopes [22] formed by bombarding $^{238}_{92}U$ with $^{16}_{8}O$ ions to give the $^{254}_{100}Fm$ compound nucleus, followed by neutron emission from the latter.

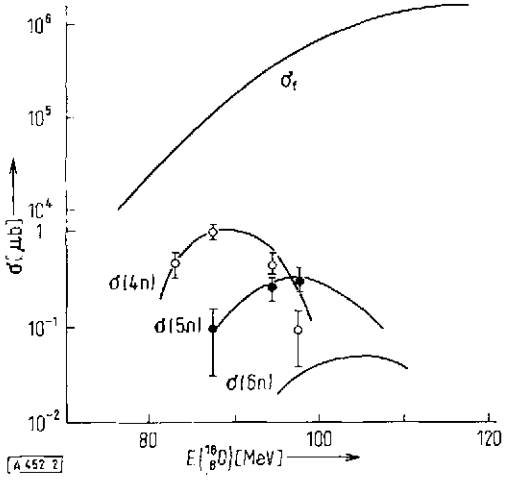

Fig. 2. Cross-sections for ($^{16}_{8}$O,xn) reactions and for fission in the bombardment of $^{238}_{92}U$ with $^{16}_{8}O$ ions, as a function of the projectile energy. (The solid lines denote calculated cross-sections).

Jackson [23] has shown that the experimental cross-sections for (p,xn) reactions of lead and bismuth are in good agreement with the calculated values obtained from a simplified evaporation model assuming constant nuclear temperature. The latter is calculated from the excitation energy E_A of the nucleus with the aid of Equation (4):

$$T = (aE_A)^{1/2} \quad (4)$$

in which the value of 0.1 is generally assigned to the constant a [18]. As shown by a comparison of the calculated and observed cross-sections for the ($^{16}_{8}$O,xn) reactions in Fig. 2, *Jackson*'s nuclear model is also applicable in the case of heavy ion reactions. In the calculation of σ(X,xn), the nuclear temperature T was taken to be 1.6 MeV. It also follows from Fig. 2 that the highest yields of heavy nuclei are obtained when the energy of the projectile exceeds the Coulomb barrier only by a small margin, *i.e.* by 10–20 MeV, according to the type of reaction.

2. Emission of Charged, Light Particles from the Compound Nucleus

Not only W_f but also the probability of the emission of light charged particles from the compound nucleus increases with increasing energy of the projectile, and therefore the fission cross-section becomes comparable to that of the neutron emission. This further complicates the interpretation of experimental results, as shown in the following example.

The bombardment of $^{238}_{92}U$ with $^{22}_{10}Ne$ ions ($E > 100$ MeV) leads to $^{256}_{101}Md$ [24–26], identified by genetic correlation with its daughter nucleus $^{256}_{100}Fm$, which undergoes spontaneous fission [*]. $^{256}_{101}Md$ may be formed in either of two ways:

a) directly in the nuclear reaction:

$$^{238}_{92}U(^{22}_{10}Ne,p3n)^{256}_{101}Md \xrightarrow[1.5\ h]{e} {}^{256}_{100}Fm,$$

b) indirectly as a daughter product of the decay of $^{256}102$ by electron capture:

$$^{238}_{92}U(^{22}_{10}Ne,4n)^{256}102 \xrightarrow[8\ sec]{e} {}^{256}_{101}Md$$

Which of these processes takes place has not yet been determined. However, direct formation is more probable, since the maximum of the yield curve for $^{256}_{101}Md$ corresponds to a projectile energy which is higher by about 15 MeV (relative to the coulomb barrier) than that corresponding to maximum yield in known reactions of the type (b). The maximum yield of $^{256}_{101}Md$ lies at 128 MeV, whereas that of the reaction $^{242}_{94}Pu(^{20}_{10}Ne,4n)^{260}104$ is at 113 MeV. This shift in the maximum effective cross-section is also in good agreement with the probability of the emission of a proton from heavy compound nuclei, for which the potential well is 14 MeV. Further, no decay through electron capture has so

[*] Spontaneous fission is the radioactive autodisintegration of heavy nuclei into two fragments of about equal masses, without external influence, and therefore obeys the statistical laws of radioactivity.

far been detected in the case of $^{256}102$ [27, 28]. It is very difficult to decide which of the routes leads to $^{256}_{101}$Md – which has been isolated in the pure state [26, 29, 29a] – on account of the short half-life of the possible intermediate, product $^{256}102$ ($\tau^1/_2$ = 8 sec) and its small cross-section of formation ($\sigma_{max} \approx 2\times10^{-9}$ barn). An effective cross-section of 2×10^{-9} barn means that only 25 nuclei of $^{256}_{101}$Md are obtained on a three-hour irradiation of a thin uranium foil [*] with a $^{22}_{10}$Ne ion beam of 3 μA, which corresponds to about 2×10^{12} $^{22}_{10}Ne^{8+}$ ions per second. The observed $^{256}_{100}$Fm cannot be formed by ($^{22}_{10}$Ne,α) or ($^{22}_{10}$Ne,2p2n), since the effective cross-sections for these reactions are certainly less than 5×10^{-11} barn.

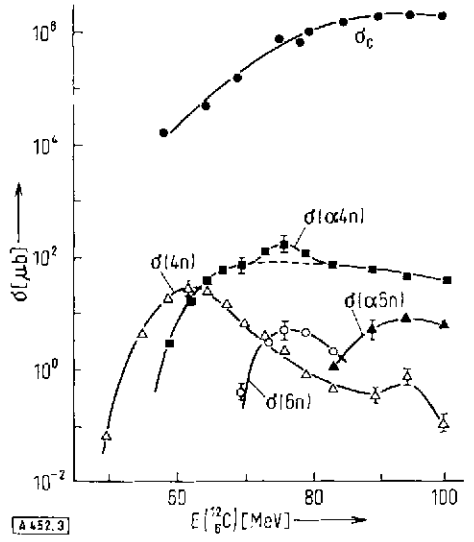

Fig. 3. Cross-sections for the nuclear reactions ($^{12}_{6}$C,xn) and ($^{12}_{6}$C,αxn) of a $^{238}_{93}$U target, as a function of the projectile energy.

Fig. 3 shows the energy-dependence of the cross-section for the reactions ($^{12}_{6}$C,xn) and ($^{12}_{6}$C,αxn) of bombarded $^{238}_{92}$U [30]. Both the form and the position of the maximum of the excitation function for neutron emission are those expected from a reaction proceeding *via* a compound nucleus. On the other hand, the curve for ($^{12}_{6}$C,α4n) is composed of at least two components. The sharp peak at 76 MeV indicates a reaction *via* a compound nucleus; the wide plateau is due to other reactions. The most likely, though unproven, suggestion is that the $^{12}_{6}$C ion is disintegrated by the nuclear forces of the target nucleus to $^{4}_{2}$He + $^{8}_{4}$Be.

Certain internuclear orientations might favor the capture of $^{8}_{4}$Be and impede α-capture, causing the reaction $^{238}_{92}$U(^{8}Be,4n)$^{242}_{96}$Cm. The possibility of the new projectile $^{8}_{4}$Be taking over varying fractions of the total energy of the parent $^{12}_{6}$C might account for the wide maximum of the cross-section for the $^{12}_{6}$(C,α4n) reaction. The fission of $^{12}_{6}$C mentioned here has already been detected on nuclear plates [31].

IV. The Best Combination of Target and Projectile for the Synthesis of Heavy Nuclei

Table 1 lists the transcurium isotopes which have been obtained by heavy-ion bombardment. Evidently most of the nuclides can be obtained by different reactions. For the synthesis of even heavier nuclei, it is important to know which target-projectile combination has the greatest cross-section for the formation of a certain end-product.

Table 1. Transcurium isotopes prepared so far by heavy-ion bombardment (σ_{max} = maximum cross-section).

For example, $^{250}_{100}$Fm is formed by the emission of four neutrons by the compound nucleus $^{254}_{100}$Fm, which is obtainable by any of the reactions $^{232}_{92}$Th + $^{22}_{10}$Ne, $^{238}_{92}$U + $^{16}_{8}$O, and $^{241}_{94}$Pu + $^{13}_{6}$C. Fig. 4 represents the cross-sections for the syntheses of $^{250}_{100}$Fm by these reactions. The highest yield is seen to be ensured by combining a target nucleus of high atomic number with a projectile of low atomic number. This is understandable, since the higher the nuclear charge of the projectile, the greater the kinetic energy required to overcome the Coulomb barrier, resulting in a higher excitation of the compound nucleus. This in turn increases the probability for the fission of the compound nucleus, since – according to *Vandenbosch* and *Seaborg* [51] – an 0.13 MeV increase in the excitation energy of a heavy nucleus is accompanied with a tenfold increase in the fission probability.

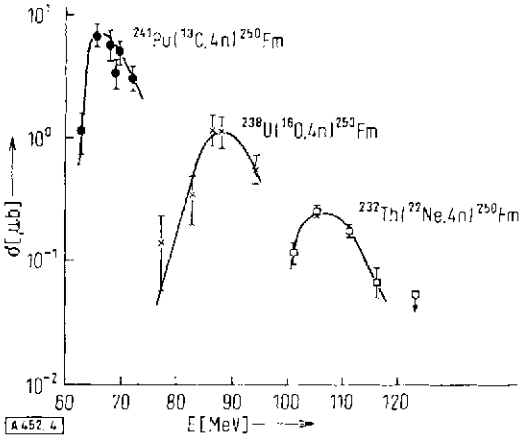

Fig. 4. Cross-sections for the synthesis of $^{250}_{100}$Fm by the reaction (X,4n) as a function of the projectile energy.

In order to show the effect of the target nuclide and the type of the projectile on the yields of the heavy nuclei, the maximum cross-sections of the nuclear reactions are shown in Table 2. Only one variable (either the target or the projectile) is changed at a time in these reactions. These data show that an increase in the nuclear charge of either the target or the projectile reduces the maximum cross-section, this decrease being particularly marked when the nuclear charge of the projectile is increased. A comparison of those nuclear reactions in which only neutrons are emitted reveals that the highest value of the maximum cross-section is usually associated with the (X,4n) reaction (cf. Fig. 2).

Table 2. Maximum cross-sections for the synthesis of heavy nuclei with various target-projectile combinations.

Target nucleus	Projectile	Reaction	Product	σ_{max} [μbarn]	E [MeV]

[54] *G. N. Flerov, S. M. Polikanov, K. A. Gavrilov, V. L. Mikheev, V. P. Perelygin*, and *A. A. Pleve, ibid. 18*, 964 (1964).

with a half-life of $\tau_{s.f.} = 15 \pm 2$ msec, formed by the bombardment $^{241}_{95}$Am and $^{239-242}_{94}$Pu with α-particles, of $^{243}_{95}$Am with α-particles and deuterons, of $^{240-242}_{94}$Pu with deuterons, of $^{238}_{92}$U with $^{22}_{10}$Ne, $^{16}_{8}$O, $^{11}_{5}$B, and $^{10}_{6}$B, of $^{235}_{92}$U with $^{16}_{8}$O, and of $^{232}_{90}$Th and $^{242}_{94}$Pu with $^{22}_{10}$Ne. The spontaneous fission half-life of $^{242m}_{95}$Am is thus seen to be smaller by at least a factor of 10^{20} than that of $^{242}_{95}$Am, indicating an excitation energy of about 3 MeV.

The nuclear reactions of uranium and thorium with heavy ions, leading to $^{242m}_{85}$Am, are stripping reactions and do not proceed *via* a compound nucleus (cf. Section II). The cross-sections of these reactions depend on the type of projectile [$\sigma(^{238}_{92}U + ^{22}_{10}Ne) \approx \sigma(^{238}_{92}U + ^{16}_{8}O)$] to a smaller extent, and on the type of target [$\sigma(^{238}_{92}U + ^{16}_{8}O)/\sigma(^{235}_{92}U + ^{16}_{8}O) \approx 10$] to a greater extent, than is expected for reactions involving a compound nucleus. For projectile energies of 100 to 125 MeV, the maximum cross-sections are only 2×10^{-2} to 4×10^{-2} μbarn, which corresponds to a rate of formation of 10 to 20 $^{242m}_{92}$Am nuclei per μA per h. The bombardment of $^{243}_{95}$Am with fast neutrons also leads to $^{242m}_{95}$Am (σ_{max} = 0.15 mbarn) [55]:

$^{243}_{95}Am(n, 2n)^{242}_{95}Am$

The bombardment of $^{238}_{92}$U with $^{20}_{10}$Ne and $^{16}_{8}$O, and of $^{239}_{94}$Pu with $^{11}_{5}$B has led to two unidentified nuclei decaying by spontaneous fission from isomeric states, with half-lives of 0.9 msec and 3.5 sec respectively [55–57]. All three metastable nuclei were detected by recording their fission with nuclear plates [58] or lithium phosphate glass detectors.

VI. The Discovery of Elements 102 to 104

Elements of atomic number 102, 103, and 104 were first obtained by nuclear reactions with heavy ions. They have so far been identified only by physical methods, and their chemical isolation or enrichment will be possible only when new separation techniques, *e.g.* very fast ion exchange chromatography, are developed.

1. The Discovery of Element 102

The preparation of isotopes of element 102 was first reported in 1957 by a research group working in Stockholm [59], who bombarded a curium sample with $^{13}_{6}$C ions and isolated an α-active nuclide characterized by E_α = 8.5 MeV and τ = 10 min by the recoil method. It was assumed that an isotope with nuclear charge 102 and mass number 251, or 253, or 255 had been formed [60]. The lack of spontaneous fission indicated that no even-even nucleus, *i.e.* one containing an even number of protons and of neutrons, was formed (see Section D). The identification was apparently confirmed by the fact that the α-activity during ion-exchange investigations occurred where it was expected for element 102. The 8.5 MeV α-activity, however, was observed in only 12 out of a total of 50 bombardments, and with only three out of six targets, and even then only on the first bombardment of each target. These results were not confirmed [*] when the above experiments were repeated in the United States [61, 62] and in the Soviet Union [46–48], despite the use of similar experimental conditions and an about ten times stronger ion beam with considerably smaller energy-spread. Further, an α-energy of only 8.0 MeV would be expected for an isotope of element 102 with a half-life of 10 min from the α-decay scheme [11a, 11b].

On bombarding a target containing 4.5 atom-% $^{246}_{96}$Cm with $^{12}_{6}$C ions, *Ghiorso* et al. [40, 49] succeeded in preparing the isotope ^{254}102 by the reaction

$$^{246}_{96}Cm(^{12}_{6}C, 4n)^{254}102 \xrightarrow[3\ sec]{\alpha} {}^{250}_{100}Fm.$$

The daughter element $^{250}_{100}$Fm, used to identify ^{254}102, was isolated by the α-recoil method described below. $^{250}_{100}$Fm is easily detected by its relatively long half-life (30 min) and emission of 7.40 MeV α-radiation.

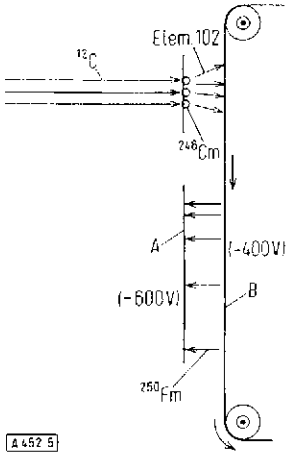

Fig. 5. Explanation of the recoil method (cf. text).

The target used in the above work [61] was a thin nickel foil, on the back of which the curium had been deposited. On irradiation with ^{12}C ions, the atoms of 102 formed are knocked out of the target. Since these are initially highly ionized, they are attracted to the moving metal belt B (Fig. 5) behind the target. About half the recoiling, highly ionized ^{250}Fm atoms formed on α-decay are captured by the more negative collector foil A. In this double recoil separation, relatively pure ^{250}Fm is obtained. The half-life of ^{254}102 can be calculated from the belt speed and the resulting ^{250}Fm activity of the collector.

Flerov et al. [46–48] hombarded $^{241}_{94}$Pu with $^{16}_{8}$O ions, whereupon the reaction

$$^{241}_{94}Pu(^{16}_{8}O, 4n)^{253}102,$$

took place, resulting in the α-active isotope ^{253}102 characterized by an α-energy of 8.9 MeV and a half-life of between 2 and 40 sec. The isotope ^{253}102 was separated from the target by the recoil of the nucleus on

formation, and identified on the basis of the α-decay scheme by determining the energy of the emitted α-particles on nuclear plates. These results have been confirmed (E_α = 8.8 ± 0.1 MeV, half-life between 10 and 20 sec) [63].

2. The Discovery of Element 103 (Lawrencium)

In spring 1961, *Ghiorso* et al. [50] bombarded 3 μg of californium with accelerated $^{10,11}B$ ions, and observed a resulting α-activity of E_α = 8.6 MeV and $\tau \approx 8 \pm 2$ sec. This activity was attributed to an isotope of element 103 having mass number 257. The possibility of the observed α-activity being due to a 101 or 102 isotope was eliminated by repeating the experiment with a different projectile ($^{12}_{6}C$) and a different target ($^{243}_{95}Am$ instead of $^{249-252}_{98}Cf$).

3. The Discovery of Element 104

In the middle of 1964, *Flerov*'s group carried out the reaction $^{242}_{94}Pu$ ($^{22}_{10}Ne$, 4n) (the target contained 97 atom-% of $^{242}_{94}Pu$), and obtained the isotope $^{260}104$, which undergoes spontaneous fission with a half-life of 0.3 ± 0.1 sec [44,45]. Fig. 6 shows the cross-sections of the spontaneously fissile nuclei formed by bombarding $^{242}_{94}Pu$ with high-energy $^{22}_{10}Ne$ ions. The $^{260}104$ was isolated by the recoil method and detected by glass counters.

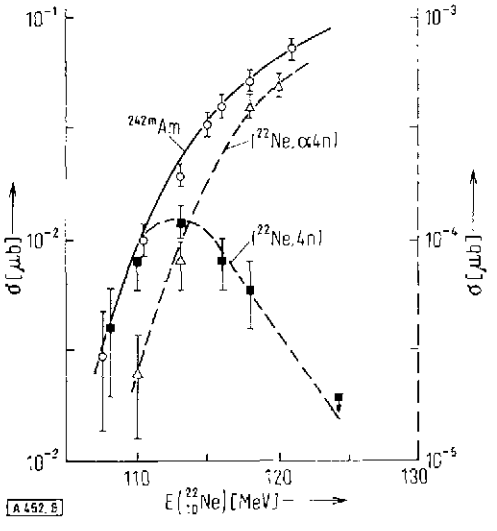

Fig. 6. Cross-sections for the synthesis of spontaneously fissile nuclei by bombarding $^{242}_{94}Pu$ with $^{22}_{10}Ne$ ions.

Element 104 is the first transactinide, and may be regarded as the homologue of hafnium (eka-Hf). This fact should greatly facilitate its chemical separation from the transactinides.

VII. Possible Means of Preparing Neutron-Rich Transcurium Nuclei and Elements with Z > 104

1. Nuclear Reactions with Heavy Ions

Heavy-ion bombardment appears to be the most promising way of preparing further elements. Transuranium elements up to and including einsteinium, which can all be prepared in weighable amounts, may be used as target nuclei. The preparation of the targets might however be rendered very difficult by their high specific activity (*e.g.* 1.06 curie/mg for $^{254}_{99}Es$) and by the high purity required (less than 0.1 ppm of other heavy elements).

The following reactions are suitable for the preparation of element 105 (eka-tantalum): $^{241,243}Am + {}^{22}_{10}Ne$; $^{249}Bk + {}^{16}_{8}O$; $^{249-252}_{98}Cf + {}^{14}_{7}N$; and $^{244}_{99}Es + {}^{12}_{6}C$.

The last reaction will have the highest cross-section. Since however transcurium elements will not be available in sufficient amounts in the next few years, element 105 will probably be first prepared by the reaction $^{241-243}_{95}Am + {}^{22}_{10}Ne$. On the other hand, identification of the sporadically formed 105 nuclei will be very difficult owing to the extremely small cross-section (about 10^{-2} μbarn) of the Am(Ne,xn) reaction. Nevertheless, recent advances in detection techniques make it appear feasible to detect nuclear reaction products characterized by 3 spontaneous fissions per hour, or by an emission of 50 α-particles per hour [18].

If element 105 is assumed to be formed by the reaction

$$^{243}_{95}Am(^{22}_{10}Ne,4n)^{261}105,$$

the product will have a high neutron deficiency, and therefore probably a much shorter half-life than the isotope with mass number 265, which would supposedly be the most stable. It will not however be possible to prepare the latter by any of the reactions discussed, since heavy-ion bombardment can lead only to neutron-deficient isotopes, and accordingly not to the most stable ones. Neutron-rich projectiles such as $^{22}_{10}Ne$, $^{18}_{8}O$, and $^{13}_{6}C$ are often used instead of $^{20}_{10}Ne$, $^{16}_{8}O$, and $^{12}_{6}C$ in order to reduce somewhat the neutron deficiency of the end-products of these reactions. In this case reactions of the types (X,4n), (X,5n), and (X,6n) often have comparable cross-sections. Neutron-rich target isotopes are usually used for the same reason, *e.g.* $^{242}_{94}Pu$ instead of $^{239}_{94}Pu$.

It seems likely that isotopes of elements up to Z = 109 (eka-iridium) will be prepared by similar reactions in the not too distant future. The possible (X,xn) reactions for the synthesis of these elements are as follows (in order of decreasing cross-section):

$$Z = 106 : (^{254}_{99}Es + {}^{14}_{7}N) > (^{252}_{98}Cf + {}^{16}_{8}O) > (^{244-248}_{96}Cm + {}^{22}_{10}Ne)$$

$$Z = 107 : (^{254}_{99}Es + {}^{16}_{8}O) > (^{249}_{97}Bk + {}^{22}_{10}Ne)$$

$$Z = 108 : (^{252}_{98}Cf + {}^{22}_{10}Ne)$$

$$Z = 109 : (^{254}_{99}Es + {}^{22}_{10}Ne)$$

When it becomes possible to accumulate $^{257}_{100}Fm$ in microgram quantities at least – which is not yet the case – the synthesis of element 110 by the reaction $^{257}_{100}Fm + {}^{22}_{10}Ne$ could also be contemplated.

Still unknown neutron-rich fermium and californium isotopes might be prepared by a type of stripping reaction (cf. Section C.II):

$$^{256}_{100}Fm(^{18}_{8}O, {}^{16}_{8}O)^{258}_{100}Fm$$

$$^{254}_{98}Cf(^{22}_{10}Ne, {}^{20}_{10}Ne)^{256}_{98}Cf.$$

63] *A. Ghiorso*, quoted in [40].

In principle it should also be possible to synthesize these nuclei by a ($^3_1$H,p) reaction.

These two isotopes ($^{258}_{100}$Fm and $^{256}_{98}$Cf) cannot be synthesized by multiple neutron capture in nuclear reactors, since the neutron fluxes are too low for this purpose. This is unfortunate, since knowledge of the spontaneous fission half-lives of these nuclei could make an important contribution to our knowledge of the systematics of spontaneous fission. Furthermore, the corresponding values calculated by various authors show large discrepancies [63a].

The prospects of carrying out such processes are promising, since the cross-sections increase with the nuclear charge of the target in the family of reactions:

$$A + {}^{20}_{10}Ne \rightarrow B + {}^{17}_{7}N,$$

in which three protons are captured [9] [*e.g.* in the case of an effective projectile energy of 100 MeV, $\sigma(^{27}_{13}Al)$ = 0.1 mbarn, but $\sigma(^{181}_{73}Ta)$ = 1 mbarn].

2. Nuclear Reactions with Superheavy Ions

In addition to nuclear syntheses using C,N,O, and Ne as projectiles ($^{19}_{9}$F has not been tried), those using even heavier, *i.e.* superheavy ions (*e.g.* $^{24}_{12}$Mg and $^{48}_{20}$Ca) should also be discussed. These ions need very high energies to overcome the potential barrier, so that the resulting compound nuclei will be highly excited. For this reason, the latter will decay almost exclusively by fission (*i.e.* $\sigma_f/\sigma_{(xn)} > 10^{10}$). There is a well-founded hope, however, that cross-sections of at least 10^{-4} μbarn will be found for reactions in which the target captures only part of the projectile, so that detectable numbers of the required nuclei will be formed (detection limit = 10^{-5} μbarn). By capturing only part of the projectile, the compound nucleus will be less excited than after the absorption of the whole ion. Possible reactions of this type are as follows:

$$^{252}_{98}Cf + {}^{36}_{16}S \rightarrow {}^{264-262}104 + (4-6)n + {}^{20}_{10}Ne$$

$$^{752}_{98}Cf + {}^{48}_{20}Ca \rightarrow {}^{276-274}108 + (4-6)n + {}^{20}_{10}Ne.$$

These two reactions are formally equivalent to bombarding $^{252}_{98}$Cf with neutron-rich $^{16}_{6}$C and $^{28}_{10}$Ne ions, respectively. The advantage of such nuclear reactions lies in the possibility of obtaining what are probably the longest-lived isotopes of the elements under consideration. The hope that these reactions have a cross-section of at least 10^{-4} μbarn is based on the assumption that reactions not proceeding *via* compound nuclei, such as

$^{244}_{96}$Cm ($^{13}_{6}$C, $^{8}_{4}$Be3n)$^{246}_{98}$Cf and

$^{244}_{96}$Cm($^{16}_{8}$O, $^{12}_{7}$C3n)$^{245}_{98}$Cf,

have cross-sections which are not smaller (at least not much smaller) than those of the comparable ($^{13}_{6}$C,xn) and (^{16}O,xn) reactions, which do proceed *via* compound nuclei [37].

In addition to the above reactions consisting of partial fusion and subsequent neutron emission, other reactions might also be possible, in which a certain type of interaction with the surface of the nuclei would enable the capture of a larger part of the projectile, without the nuclei becoming highly excited. Such a reaction would be, for example:

$$^{239}_{92}U + {}^{40}_{18}Ar \rightarrow {}^{256}_{100}Fm(^{258}_{100}Fm, {}^{260}_{100}Fm) + {}^{22}_{10}Ne(^{20}_{10}Ne, {}^{18}_{10}Ne).$$

There are several indications that such nuclear reactions are possible, and that they would proceed with measurable cross-sections [64].

3. Capture of Heavy Projectiles without Subsequent Emission of Nucleons

A further possibility of preparing isotopes of the heaviest elements is based on the compound nucleus releasing all its excitation energy by γ-emission (radiative capture) [64], *e.g.*:

$$^{238}_{92}U(^{18}_{8}O,\gamma)^{256}_{100}Fm$$

Cross-sections of about 1 μbarn have been observed [65,66] for the radiative capture of heavy projectiles by light target nuclei (*e.g.* on bombarding $^{27}_{13}$Al or $^{31}_{15}$P with $^{16}_{8}$O ions). Assuming that the radiative capture cross-sections of heavy target nuclei are only five orders of magnitude smaller than the above value, a heavy-ion current of 100 μA should lead to about ten captures per hour. Should spontaneously fissile nuclides be formed, they could be detected even at such a low rate of formation.

4. Secondary Reactions of the Emitted Particles

The possibility of using particles emitted in nuclear reactions as projectiles for further reactions has also been considered [64]. When, for example, $^{232}_{90}$Th nuclei are bombarded with $^{22}_{10}$Ne ions, isotopes of Ra, Ac, and Th with mass numbers ranging from 224 to 227 are known to be formed in a reaction resembling the pick-up process (cf. Section C.II), some of the nucleons released by the target nucleus becoming attached to the projectile. Thus the irradiation of thorium with neon ions results in a secondary beam of Ne, Na, and Mg ions. When the effective cross-section of the pick-up reaction is 1 mbarn, the use of a Ne ion current of 100 μA and a $^{232}_{92}$Th target (10 mg/cm²) leads to about 10^6 secondary ions/sec. Provided their cross-sections are at least 0.1 mbarn, the reactions of these secondary particles are detectable (a few disintegrations per hour). In these reactions, thorium both converts the ion beam and acts as a target for the secondary reaction.

$$^{322}_{90}Th(^{22}_{10}Ne, {}^{28}_{10}Ne)^{226}_{92}Th \quad \text{(primary reaction)}$$

and

$$^{232}_{90}Th(^{28}_{10}Ne, 4n)^{256}_{100}Fm \quad \text{(secondary reaction).}$$

The method under consideration appears promising for the synthesis of neutron-rich isotopes of the heaviest elements, since a cross-section of 0.2 to 0.3 μbarn has been observed

[63a] *N. Feather*, Proc. Roy. Soc. Edinburgh. Sect. A *66*, 20 (1961/62).

[64] *G. N. Flerov, E. D. Donets*, and *V. D. Aruin*, Atomn. Energ. *14*, 18 (1963).

in the formation of astatine (Z = 85) isotopes by the bombardment of lead (Z = 82) with protons, deuterons, and α-particles [67]. This again is a two-stage process: in the first stage the light projectiles generate in a direct process a secondary beam of lithium ions; in the second stage these react with the lead target to form astatine isotopes *via* a compound nucleus.

D. The Stability of Heavy Nuclei

Spontaneous fission and α-decay are the predominant types of disintegration of the heaviest nuclei. As can be seen from Fig. 7, the half-life of the α-activity is about

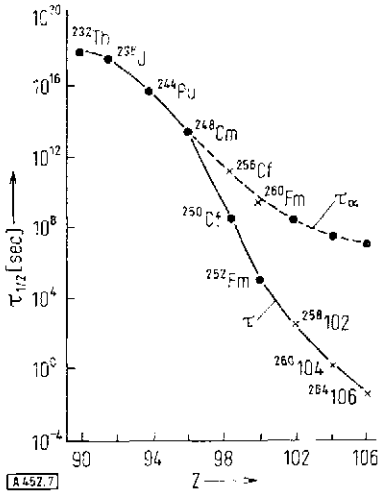

Fig. 7. Half-lives of the longest-lived even-even nuclei of the heaviest elements (×: calculated on the basis of the spontaneous fission scheme or the α-decay scheme; •: determined experimentally). Solid line denotes the overall half-life $\tau_{1/2}$, broken line stands for the α-decay half-life τ_α.

one year for the longest-lived isotopes of elements up to about Z = 106, whereas the half-life of the nuclear disintegration [*] is appreciably shorter. It follows from the liquid drop model of the nucleus that the half-life $\tau_{s.f.}$ of the spontaneous fission of the heaviest nuclei decreases in proportion to increasing Z^2/A [68–70]. However, Fig. 8 shows that this proportionality is merely a rough approximation. The following three deviations occur in the above curve:

1. The half-lives of spontaneous fission do not decrease linearly with increasing Z^2/A even for the longest-lived even-even isotopes of the heaviest elements. Clear deviations occur above $Z^2/A = 37$. The observed $\tau_{s.f.}$ values invariably exceed the calculated ones.

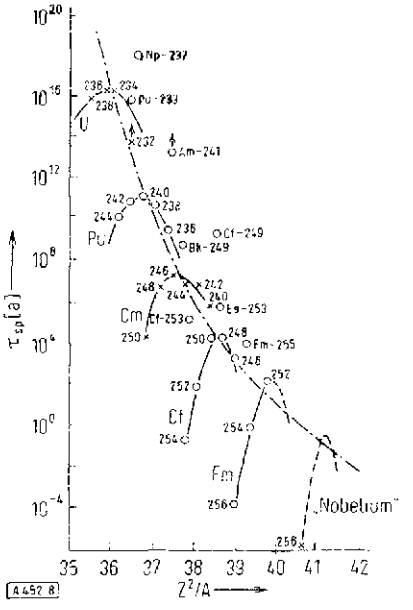

Fig. 8. Spontaneous fission half-lives $\tau_{s.f.}$ of the isotopes of the heavy elements, as a function of Z^2/A (—·—·: calculated curve).

2. As first found by *Huizenga* [71], $\tau_{s.f.}$ values of the isotopes of the same element lie on a parabola.

3. For comparable values of Z^2/A, the values of $\tau_{s.f.}$ are higher by a factor of 10^3 to 10^6 for odd nuclei than for even-even nuclei.

The liquid drop model cannot account for these deviations, and attempts to improve the calculation of $\tau_{s.f.}$ by the introduction of correction terms [72–75] have so far been unsuccessful in the case of most nuclei. In order to predict the spontaneous fission half-lives of unknown nuclei, one still has to resort to extrapolation from experimental values.

Table 3 lists extrapolated decay data of some nuclei with $102 \leqslant Z \leqslant 104$ [76]. It appears, in general, that in the case of the isotopes of elements with Z > 10 the lifetime of the nucleus is determined by α-decay when it is deficient in neutrons, and by spontaneous fission when it has a neutron excess. The half-lives are generally very short, and probably lie somewhere between milli- and microseconds for elements with Z = 106 to 110. However, half-lives of 10^{-2} to 10^{-3} sec can already be determined by recoil methods and nuclear plates. It seems possible to improve detection methods to such an extent as to be able to identify nuclides having half-lives shorter by a further two or three orders of magnitude.

There is a slight hope, derived from the following analogies, that the most stable isotopes of elements with Z = 110 to 112 (from eka-gold to eka-thallium) might have somewhat longer half-lives than expected on the basis of the above discussion (see Fig. 9). Lead and bismuth, which have stable isotopes, are followed by

[*] The partial half-lives τ_x (x = α, β^-, β^+, s.f., ...) of radionuclides with branching decay schemes are inversely proportional to the probabilities W_x of the decay type x. They are related to the (measurable) overall half-life τ by $1/\tau = \Sigma\, 1/\tau_x$. For example, in the decay of Cf (τ = 2.55 years), τ_α = 2.66 years and $\tau_{s.f.}$ = 66 years, so that W_α = 95.9%, $W_{s.f.}$ = 4.1%.

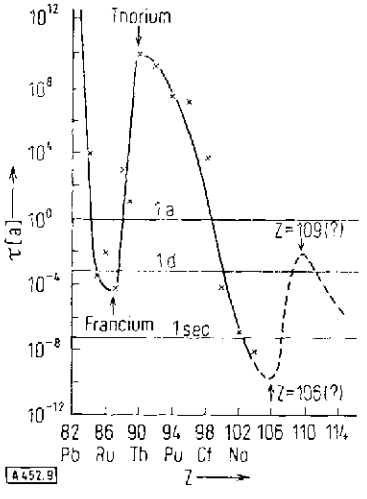

Fig. 9. Stability of the longest-lived transbismuth isotopes, irrespective of the type of decay.

astatine, radon, and francium, with only very short-lived isotopes. The transition period comprising radium and actinium is followed by elements (from thorium to californium) each of which has at least one isotope with a half-life of about a thousand years. The transcalifornium elements again show the same sudden decrease in stability exhibited by the transbismuth elements. Assuming that such an instability-stability sequence occurs again, longer half-lives can once more be expected for elements with Z around 109 to 112, particularly on reaching the next magic neutron number (184). Spontaneous fission has not, however, been taken into account.

The possibility of synthesizing new elements will be exhausted when the rate of decay of the nuclei becomes greater than their rate of formation. It has been suggested [77] that the first "element" characterized by this state of affairs should carry the name "cosmium".

E. The Existence of Superheavy Nuclei

Werner and *Wheeler* [78,79] predicted the possible existence of atomic nuclei up to Z = 147 and A = 500, believed to have half-lives of at least 10^{-4} sec. These authors based their prediction on pre-1957 data concerning the stability of the heaviest elements, and on the binding energies of the individual nucleons of these elements, as derived from *Green*'s semiempirical mass equation. All the assumptions relating to the stability of the superheavy nuclei in the above considerations were derived from extrapolation over a very wide region of the properties of known nuclei. Such extrapolations involve a high degree of uncertainty, but it emerges from these calculations that the capture of peripheral electrons will not determine the stability of the heavy nuclei even with Z > 137. It can be assumed that nuclei with Z > 137 can exist only in stars with neutron fluxes exceeding 10^{30} neutrons per cm² per sec.

F. Neutron Nuclei

Some authors [80–83] do not exclude the possibility of the existence of neutron nuclei, *i.e.* nuclei composed almost exclusively of neutrons, and possessing a lower density than ordinary atomic nuclei. Owing to surface tension, these "neutron drops" can only occur above a certain minimum size. If this assumption is correct, then it is probable that a large range of superheavy neutron nuclei exists, in a region which is either contiguous to that of the known nuclei (Fig. 10b), or not (Fig. 10a).

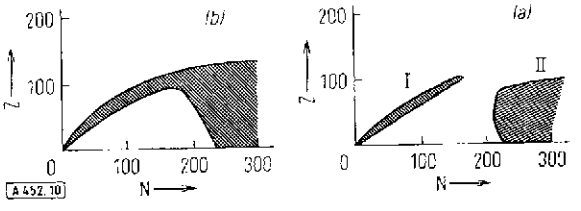

Fig. 10. Possible positions of neutron nuclei in the nuclide field. I: ordinary nuclei; II: neutron nuclei.

G. Outlook

With further improvement in experimental and detection techniques, the next few years may witness the discovery of isotopes of elements up to atomic number 109 (eka-iridium). Since the cross-sections for the reac-

tions in which these nuclei may be formed are very small, yields amounting to only a few atoms can be expected, and the new elements will probably be identified only by physical methods. According to *Ghiorso* [62], it might be possible to determine the mass numbers either by the mass-spectrometric separation of the primary recoil atoms, or by measuring their time of flight. To determine the mass numbers of the heaviest nuclei, we must at present generally resort to the use of analogies. Owing to the short half-lives, the chemical isolation of the heaviest elements will be extremely difficult or even impossible.

Data concerning the syntheses and the stability of the heaviest nuclei are mostly based on extrapolations, and therefore the conclusions derived from them must be regarded as at least partly hypothetical. This, however, leaves a reasonable hope of extending the number of elements known today.

The author wishes to express his gratitude to Prof. Dr. W. Seelmann-Eggebert for numerous suggestions and the benefit of discussions.

The Alkylating Properties of Alkyl Thiophosphates

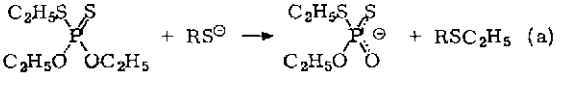
BY PROF. DR. G. HILGETAG AND DR. H. TEICHMANN

INSTITUT FÜR ORGANISCHE CHEMIE DER DEUTSCHEN AKADEMIE DER WISSENSCHAFTEN ZU BERLIN, BERLIN-ADLERSHOF (GERMANY)

Thiophosphate and phosphate esters have been synthesized in great variety since about 1945, and are being produced in increasing quantities, mainly for plant protection. An important property of alkyl phosphates and thiophosphates is their alkylating power, which is comparable with that of dialkyl sulfates and alkyl p-toluenesulfonates. The chemistry of thiophosphates is largely determined by their alkylating properties, since the sulfur, both in the alkyl thiophosphate and in the thiophosphate anion formed on dealkylation, can act as a point of attack for self-alkylation.

I. Introduction

The importance attained over the past two decades by organic thiophosphates in pest control [1] has also promoted sustained interest in the chemistry of this class of compounds. After the discovery of thiophosphates by *Cloez* [2] and *Carius* [3] about the middle of the last century and the fundamental studies carried out around 1910 by *Pistschimuka* [4], very little work was done on the chemical behavior of these compounds. An important property of tertiary thiophosphates with at least one alkoxy group attached to the phosphorus atom is their alkylating power. This had already been recognized by *Carius*, who made use of it in the synthesis of unsymmetrical sulfides in accordance with Eq. (a) [3]. *Kekulé*, who was a friend of *Carius*, and who had himself almost discovered the dithiophosphates [5], included this reaction in his well-known textbook [6]. The knowledge of the alkylating properties of thiophosphates, however, then fell into oblivion for a century.



$R = CH_3, C_5H_{11}$

In 1954, it was found in *Todd*'s laboratory that the method of "anionic dealkylation" developed on trialkyl phosphates could also be used with thiophosphates [7]. Shortly afterwards, *Hilgetag* and co-workers recognized the decisive participation of alkylation reactions in the thermal rearrangements of thionophosphates [8,9], and demonstrated the alkylating properties of thionophosphates and thiolophosphates [10–14]. *Melnikov* began similar investigations [15]. Several groups began studying the isomerism of various thionophosphates in the

middle 1950's [8,9,16–22]. We now understand the tendency of thionophosphates to isomerize as a consequence of their alkylating power, and we know that the ability to lose an alkyl group determines the chemical behavior of the thiophosphates to a much greater extent than that of the corresponding phosphates.

II. Alkyl Phosphates and Thiophosphates as Alkylating Agents

1. General

Sulfur-free trialkyl phosphates have already found many uses as alkylating agents, *e.g.* for the etherification of hydroxyl groups attached to aromatic and heterocyclic rings [23,24], as well as in alcohols [25,26], for the *N*-alkylation of primary aromatic amines [27–32], and for the preparation of isothiuronium salts [33,34], alkyl halides [35], and esters of acetic [36,37] and isocyanic acid [38]. Dialkyl chlorophosphates have also been used to alkylate amines [39,40] and to prepare isothiuronium salts for the synthesis of mercaptans [34].

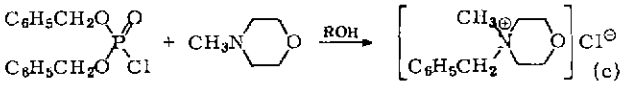
The alkylating properties of thiophosphates are also of general interest, as is shown in Table 1 for the selective monoalkylation of primary amines [cf. Eq. (b)] [41].

Table 1. Alkylation of primary amines with $(RO)_2PO(SC_2H_5)$ according to Eq. (b).

R	R′	Solvent	Time [h]	Temp. [°C]	RR′NH Yield [%]
C_2H_5	C_2H_5	$C_2H_5NH_2$	24	115	42
C_2H_5	c-C_6H_{11}	–	1.5	140	79.7
C_2H_5	C_6H_5	–	5	150	84.3
C_4H_9	C_2H_5	$C_2H_5NH_2$	24	100	45
C_4H_9	c-C_6H_{11}	–	1	150	80.8
C_4H_9	C_6H_5	–	3.5	160	51

$$(RO)_2PO(SC_2H_5) + 2\ R'NH_2 \rightarrow RR'NH + [R'NH_3]^{\oplus}[(RO)(C_2H_5S)PO_2]^{\ominus} \quad (b)$$

The dealkylation of phosphates and thiophosphates, however, is of the greatest importance in phosphate chemistry itself, for the preparation of monobasic dialkyl phosphates and thiophosphates by dealkylation of the triester. Starting from the observation that, during the phosphorylation of alcohols with dialkyl chlorophosphates, tertiary amines, which should bind the hydrochloric acid formed, are quaternized in a competing reaction [Eq. (c)] [42–44], *Todd*'s research group



(c)

$$+\ {}^1/_n\,[C_6H_5CH_2OPO_2]_n$$

developed the technique of "monodealkylation", originally using trialkyl phosphates and tetraalkyl pyrophosphates, as an aid in nucleotide chemistry [44–52].

This monodealkylation has since found general use, particularly since mixed triesters can be synthesized by the introduction of a new alkyl group. A particularly important reaction is the stepwise dealkylation and alkylation of thiophosphates, since the alkylation of an ambident thiophosphate anion such as *(1)* takes

place almost exclusively on the sulfur atom [10, 53–55] unless the conditions used are specially chosen to favor an S_N1 mechanism [55a, b]. This therefore provides an important method of preparing thiol esters of phosphoric acid *(2)*. The nucleophilic agents used for the dealkylation of trialkyl phosphates and thiophosphates, tetraalkyl pyrophosphates, and dialkyl chlorophosphates, chlorothiophosphates, and phosphonates are reviewed in Table 2.

Table 2. List of publications on the dealkylation of esters of pentavalent phosphorus.

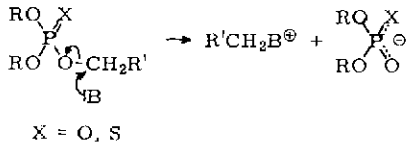
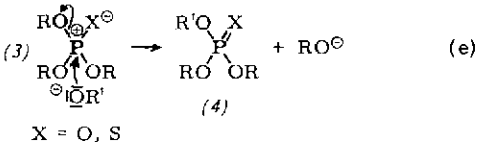
2. Mechanisms of Alkylation and Phosphorylation

There is an important mechanistic difference between the cleavage of esters by alkoxide ions and by the other nucleophilic systems listed in Table 2. Thus nucleophilic agents B generally cause an S_N2 reaction on the α-carbon atom of the ester group, leading to the expulsion of the phosphorus-containing anion, in accordance with Eq. (d) [55c].



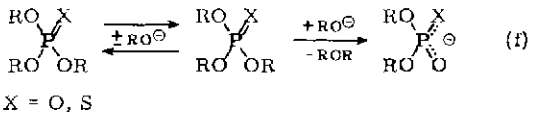
X = O, S (d)

Alkoxide ions, on the other hand, attack preferentially at the phosphorus atom. The transition state *(3)* containing 5-coordinate phosphorus decomposes to form a neutral molecule *(4)*, which can then either react again with the leaving group in the same way, *i.e.* leading to transesterification, or enter into a competing reaction in accordance with Eq. (d). Thus esters of this type have both an alkylating and a phosphorylating action on



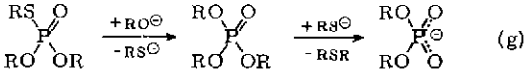
X = O, S (e)

alkoxide ions. Consequently, trialkyl phosphates and thionophosphates can be dealkylated in high yields by means of an alkoxide with the same alkyl group [41,120] [see Eq. (f)], but the same reaction of phosphate esters containing a better leaving group than alkoxy leads to



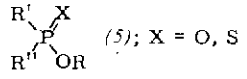
X = O, S (f)

an unwanted modification of the ester molecule. Thus alkyl aryl phosphates lose phenol on reacting with alkoxides [86], and thiolphosphates are largely desulfurized in accordance with Eq. (g) [11,101]. The applicability of alkoxide ions to the dealkylation of esters



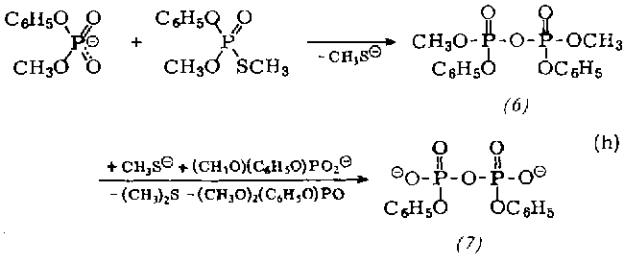
(g)

containing phosphorus is therefore very limited. Hydroxide ions, like alkoxide ions, also react *via* a transition state containing 5-coordinate phosphorus [121]. Phosphates and thiophosphates *(5)* which contain a suitable leaving group R′ or R″ can also react with phosphate ions in accordance with Eq. (e), *i.e.* with phosphorylation of the nucleophile. Suitable phosphorylating agents of this type for the preparation of pyrophosphate and polyphosphate bonds are chlorophosphates (R′ = Cl), amidophosphates (R′ = NH_2), and pyrophosphates [R′ = $OP(O)(OR)_2$] (for further examples see [122]. Thiolphosphates (R′ = SR) can



(5); X = O, S

also have a similar phosphorylating action. Thus *O,S*-dimethyl *O*-phenyl thiophosphate reacts with potassium methyl phenyl phosphate in accordance with Eq. (h) to give high yields of dipotassium *syn*-diphenyl pyrophosphate *(7)*, which is formed by the demethylation of dimethyl diphenyl pyrophosphate *(6)* by the mercaptide and phosphate ions [123].



(h)

The difference in behavior of alkoxide [Eq. (e)] and mercaptide ions [Eq. (d); B = $RS^{\ominus}$] towards phosphates and thiophosphates suggests that a different nucleo-

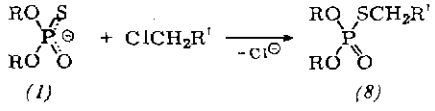
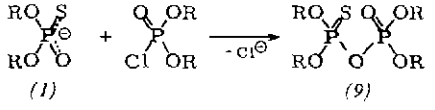
philicity scale [*] applies to phosphorylation, *i.e.* substitution on the phosphorus atom, than to alkylation, *i.e.* S_N2 reactions on the tetrahedral carbon atom [124, 125]. Whereas the nucleophilic constants of anions containing sulfur are particularly high in substitutions on carbon [126], they are lower than those of anions containing oxygen in substitutions on phosphorus, so that in this case there is a closer relationship between nucleophilicity and basicity [125]. The difference in the nucleophilicity scales applying in carbon chemistry and in phosphorus chemistry also explains the fact that the thiophosphate anion *(1)* reacts with alkylating agents to form thiolphosphates *(8)*, and with phosphorylating agents to form thionopyrophosphates *(9)* [127, 138].



(1) *(8)*

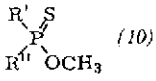


(1) *(9)*

3. Constitution and Alkylating Properties

All the alkylations listed in Table 2 involve the transfer of lower alkyl residues (C_1 to C_4), as well as benzyl and allyl residues. As with other alkylating agents, the heterolysis of benzyl, allyl, and methyl ester linkages proceeds much more readily than that of ethyl and higher alkyl-oxygen bonds.

Since oxygen is more electronegative than sulfur, the phosphorus can be expected to carry a larger positive charge in the phosphates than in the thionophosphates, and the carbon-oxygen bond should therefore be weaker in the former. This is in fact the case, since phosphates are often rather stronger alkylating agents than the isologous thionophosphates, particularly in the absence of solvents and in cases where hydrogen bonding between the substrate and the oxygen of the P=O group occurs [33, 34]. The opposite has, however, been observed in the alkylation of tertiary amines in aprotic solvents [59]. In the heterolysis of carbon-oxygen bonds, however, a much more important factor than the nature of X in a molecule of the type *(5)* is the inductive effect of the substituents R′ and R″. Thus an increase in the attraction of electrons by R′ and R″



(10)

leads to a corresponding decrease in the polarity of the P=O group [128]. The methylating power of the methyl ester *(10)* decreases in the order

R′ p-NO_2-C_6H_4O > C_6H_5O > C_6H_5O > CH_3S > CH_3O > CH_3O > CH_3
R″ p-NO_2-C_6H_4O C_6H_5O CH_3O CH_3O CH_3O CH_3 CH_3

as in the isologous phosphoryl compounds.

It has recently been shown [129a], for the reaction between p-substituted diphenyl methyl phosphates and pyridine, that the effects of substituents on the rate of methylation, as expected, obey the Hammett relation as well as *e.g.* the effects on the dissociation constants of disubstituted phosphoric acids and thiophosphoric acids [129]. Thus the abilities of the esters *(5)* to undergo dealkylation run parallel to the strengths of the parent acids R′R″P(X)OH. Since some disubstituted phosphoric and thiophosphoric acids are stronger acids than phosphoric acid itself, alkyl esters *(5)* with suitable substituents R′ and R″ may be far superior as alkylating agents to the much more commonly used alkyl sulfonates and dialkyl sulfates.

Like dialkyl sulfates, trialkyl phosphates and thiophosphates initially give up only one alkyl cation, since the electron pair remaining in the anion reinforces the other carbon-oxygen bonds. When the dialkyl phosphate anion is protonated, however, the free dialkylphosphoric acid formed can give up another alkyl group [72]. The presence of free dialkylphosphoric and monoalkylphosphoric acids in equilibrium with their salts of weak bases is probably also the reason for the fact that all three alkyl groups can sometimes be used in the alkylation of aromatic amines with trialkyl phosphates under relatively drastic conditions (200 °C and over) [27–30, 119].

In trialkyl phosphates and thiophosphates with only moderate alkylating properties, stronger polarization of the alkyl-ester bond can sometimes be induced artificially by adduct formation with Lewis acids. Esters activated in this way are among the strongest alkylating agents known. Triethyl thiophosphate with antimony (V) chloride, for example, quantitatively alkylates ether to triethyloxonium hexachloroantimonate *(11)* [130].

$(RO)_3PS \rightarrow SbCl_5 + R_2O \rightarrow SbCl_5 \longrightarrow [R_3\overset{\oplus}{O}]SbCl_6^{\ominus} + (RO)_2PSOSbCl_4$

(11)

[*] The reactivity towards tetrahedral carbon decreases in the sequence:

$S_2O_3^{2-} > SH^- > I^- \simeq (CH_3O)_2POS^- > OH^- > Br^- > C_6H_5O^- > Cl^- > F^-$;

for tetrahedral phosphorus the corresponding sequence is:

$F^- > OH^- > C_6H_5O^- > C_6H_5S^- > Cl^-, Br^-, I^-, S_2O_3^{2-}$ [124, 126].

Variously defined nucleophilicity constants, which agree well with one another, have been calculated or experimentally determined for S_N2 reactions on saturated carbon [124, 126]; the sequence for phosphorus follows from the rate constants of comparable reactions [124].

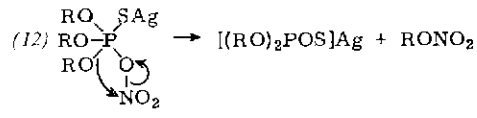
[130] *G. Hilgetag* and *H. Teichmann*, Chem. Ber. *96*, 1446 (1963).

It is possible, however, that the reaction of trialkyl thiophosphates with silver nitrate, silver nitrite, or silver acetate (which proceeds in accordance with Eq. (i), *via* isolable adducts [131], to form high yields of the silver salts of disubstituted thionophosphoric acids [4, 12, 13, 131]) is not a

$$(C_2H_5O)_3PS + AgNO_3 \rightarrow (C_2H_5O)_3PS{\cdot}AgNO_3 \rightarrow [(C_2H_5O)_2POS]Ag + C_2H_5ONO_2 \quad (i)$$

true dealkylation. The fact that the triaryl esters are also readily converted to silver diaryl thionophosphates suggests that the reaction involves the cleavage of a P–O bond in an intermediate *(12)* which contains 5-coordinate phosphorus.



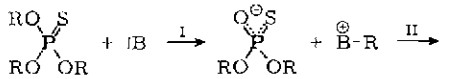
(12) $\rightarrow [(RO)_2POS]Ag + RONO_2$

III. Alkyl Thiophosphates as Unusual Alkylating Agents

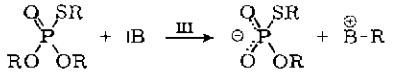
The alkylating behavior of thiophosphates is complicated by the presence of the sulfur atom in two respects. First, the ambident thiophosphate anion *(1)* formed by the dealkylation of a thionophosphate, being a strong nucleophile, can again initiate an S_N2 reaction on the carbon atom of a reaction product, *i.e.* it can be realkylated; the product (see Section II.1) is a thiolphosphate. Second, thiolphosphates can be dealkylated only by the cleavage of carbon-oxygen bonds, but not of carbon-sulfur bonds. Heterolysis of the CS bond is much more difficult than that of the CO bond, since sulfur and carbon have roughly the same electronegativities. As a result of the combination of these two circumstances, thionophosphates frequently isomerize during alkylation. Dealkylations combined in this way with isomerization may occur by the two mechanisms described below.

1. Realkylation

If the transfer of an alkyl residue to the nucleophile B yields a new alkylating agent $\overset{\oplus}{B}$–R, this may realkylate the thionophosphate anion *(1)* [8, 10–14, 77, 132, 133]. The resulting thiol ester *(13)* is a stronger alkylating agent than the thionophosphate *(1a)*, and is immediately dealkylated once more by B. The resultant reaction



(1a) *(1)* (k)



(13) *(14)*

[131] *G. Hilgetag, K.-H. Schwarz, H. Teichmann,* and *G. Lehmann*, Chem. Ber. *93*, 2687 (1960).

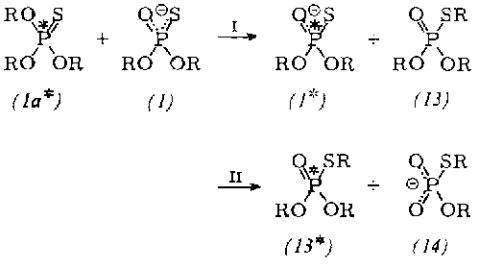
[132] *J. I. G. Cadogan* and *L. C. Thomas*, J. chem. Soc. (London) *1960*, 2248.

[133] *J. I. G. Cadogan*, J. chem. Soc. (London) *1962*, 18.

[Eq. (k)], therefore, is the formation of an *O,S*-dialkyl thiophosphate anion *(14)* from an *O,O,O*-trialkyl thionophosphate *(1a)*; this is the case, for example, when B is $(CH_3)_2S$ or $I^{\ominus}$. The realkylation can be detected *e.g.* when trimethylsulfonium *O,O*-dimethyl thiophosphate is heated in solution; the anion is completely isomerized within a short time. The trimethylphenylammonium salt isomerizes more slowly under the same conditions, whereas the tetramethylammonium salt does so only to a very small extent, and the sodium salt not at all [12]. Trimethylsulfonium *O,O*-diaryl thiophosphates, when heated, form dimethyl sulfide and *S*-methyl *O,O*-diaryl thiophosphates [13]; the realkylation in this case stops at stage II of Eq. (k), since the thiol ester formed is not an alkylating agent.

2. Interaction between Triesters and Diester Anions

If *O,O,O*-trimethyl thiophosphate is treated at room temperature with a nucleophile which is sufficiently strong to bind the methyl group firmly (*e.g.* triethylamine), no realkylation can occur. The product in this case is the *O,O*-dimethyl thiophosphate *(1)* [12]. The same reaction carried out at 80 °C, however, yields only the isomeric *O,S*-dimethyl thiophosphate *(14)* [10]. Since the isomerization of pure tetramethylammonium *O,O*-dimethyl thiophosphate at 80 °C is negligible, so that realkylation can be ruled out, a reaction (l) must have taken place between the *O,O,O*-trimethyl thiophosphate *(1a)* and the *O,O*-dialkyl thiophosphate anion *(1)*.

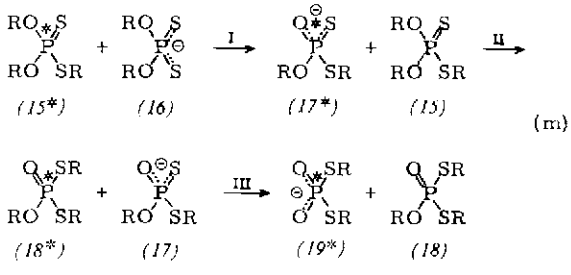


(1a)* *(1)* *(1*)* *(13)* (l)

(13)* *(14)*

In this reaction, the *O,O*-dialkyl thiophosphate anion *(1)* is first alkylated by *(1a)*, with self-regeneration, to form the *S*-ester *(13)*. The latter is then dealkylated by the same anion, with regeneration of the thiol ester *(13*)*, to form the *O,S*-dialkyl thiophosphate anion *(14)* [9, 112]. Eq. (l), together with Equations (k I) and (k II), again gives the overall Eq. (k).

The interaction between a triester *(15)* and an *O,O*-dialkyl dithiophospbate anion *(16)* can even lead to two other isomeric anions *(17)* and *(19)* [114, 115] [Eq. (m)].



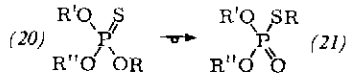
(15)* *(16)* *(17*)* *(15)* (m)

(18)* *(17)* *(19*)* *(18)*

A check on the reaction (m) with R = CH_3 by thin layer chromatography confirms the formation of all the isomers. Reaction (m II) does not go to completion, since the *O,S,S*-trimethyl ester *(18)*, being a stronger alkylating agent, takes over entirely the methylation of the anion *(17)* when the *O,O,S*-triester *(15)* has been about half consumed [115].

IV. The Self-Alkylation of Alkyl Thiophosphates

In the absence of a nucleophile, the alkylating power of tertiary thiophosphates may be directed against the ester molecule itself. The nucleophilic center in the normal case is the thiono sulfur, so that an isomerization *(20)* → *(21)* takes place. Furthermore, if some of the



alkoxy groups in *(20)* are replaced by dialkylaminoalkyl or alkylmercaptoalkyl groups, transalkylation to form ionic products can also take place.

1. Isomerization as a Special Case of Transalkylation

The interpretation of the isomerization of thionophosphates as a self-alkylation explains the following observations:

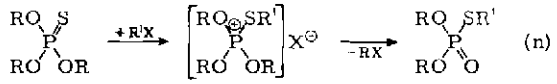
1. Aroxyl groups attached to the phosphorus atom do not take part in isomerizations.

2. The isomerization is favored by the same inductive effects as other alkylations. For an ester $RP(S)(OCH_3)_2$, the rate of isomerization decreases in the following order [14,134]:

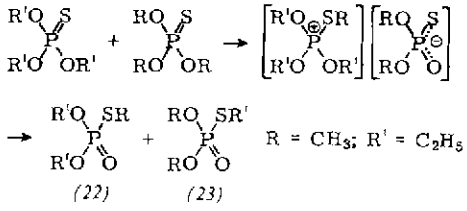
$$R = p\text{-}NO_2\text{-}C_6H_4O > C_6H_5O > CH_3O > CH_3.$$

3. Alkyl esters isomerize extremely slowly. The most readily isomerized trimethyl ester must be heated for 28 h at 130 °C before the thione sulfur disappears completely [8]. Allyl esters react much more rapidly [135].

In general, *O,O,O*-triesters of thiophosphoric acid with no nucleophilic center require temperatures of 120 to 180 °C for isomerization. This isomerization may be regarded as a special case of the Pistschimuka reaction (n) [4], which takes place under similar conditions, and which, like the thermal isomerization [18], is accelerated by polar solvents [77,136]. When a mixture of trimethyl and triethyl thionophosphate is heated, the formation of the two isomeric trialkyl thiolphosphates is accompanied by that of *O,O*-dimethyl *S*-ethyl *(23)* and *O,O*-diethyl *S*- methyl *(22)* thiophosphates. The thiono sulfur in this case is alkylated not only by the thiono esters, but above all by the thiol esters formed [137].



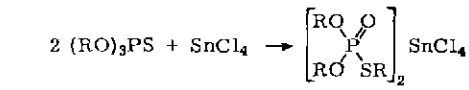
R'≠R; X = Cl, Br, I



(22) *(23)*

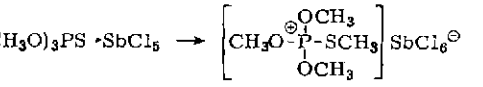
Since ethyl iodide, for example, is a stronger alkylating agent than *O,O,O*-triethyl thiophosphate, the Pistschimuka reaction (n) with alkyl iodides having the same alkyl residue (R′ = R) can sometimes be used to "catalyse" the thermal isomerization [4,138]; the same effect can be achieved by using the isomeric thiolphosphates. The thermal isomerization can also be accelerated by nucleophilic reagents such as dimethyl sulfide or thiourea, since these split off alkyl groups to form thiophosphate ions, which then initiate mechanisms such as that shown in Eq. (l) [8,9,14]. In general, impure thionophosphates isomerize more readily than the purified esters.

A non-catalytic acceleration of the isomerization is also observed with Lewis acids such as $FeCl_3$, $AlCl_3$, or $SnCl_4$, which react quantitatively, even at or below room temperature, to form thiolphosphate adducts such as *(24)* [139,140].



(24)

In contrast to the thermal isomerization, the intermediate *O,O,O,S*-tetraalkyl thiophosphate acidium ions can be isolated in this case. Thus the hexachloroantimonate *(25)* can be quantitatively isolated with $SbCl_5$



(25)

[141]; in the presence of nucleophilic reagents, the cation of *(25)* suffers immediate dealkylation to form *O,O,O*-trimethyl thiophosphate [141,142].

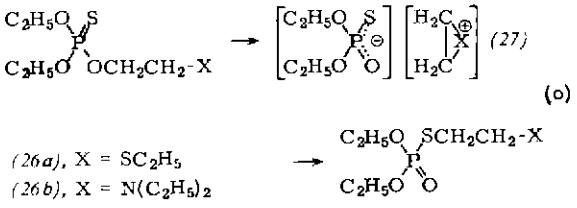
[141] *H. Teichmann* and *G. Hilgetag*, Chem. Ber. *96*, 1454 (1963).

[142] *G. Hilgetag* and *H. Teichmann*, Chem. Ber. *96*, 1465 (1963).

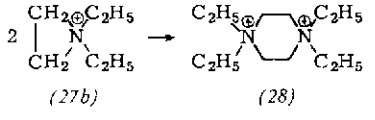
Dialkyl β-alkylthioethyl *(26a)* [17,18] and dialkyl β-dialkylaminoethyl *(26b)* [21,22,62,143] thionophosphates isomerize much more readily than unsubstituted alkyl or alkyl aryl thionophosphates. In this case, owing to a neighboring-group effect, it is not the smallest alkyl residue, but the nucleophilically substituted alkyl residue that migrates onto the sulfur atom, *e.g.* in accordance with Eq. (o).



(o)

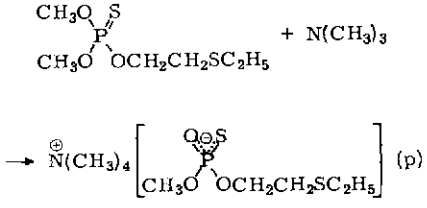
(26a), X = SC_2H_5
(26b), X = $N(C_2H_5)_2$

The first step in this reaction is an intramolecular self-alkylation to form a cyclic sulfonium [17] or immonium *O,O*-dialkyl thiophosphate *(27)* [21,22,62,143], which then undergoes a realkylation similar to reaction (k II), with formation of the thiolphosphate. Tetraethylpiperazinium salts *(28)*, which are formed from the cycloimmonium cation *(27b)* by a side reaction, have occasionally been isolated [62,132].



(27b) *(28)*

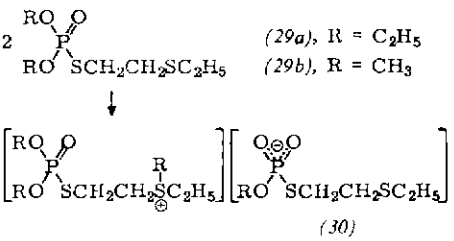
If an ester of the type *(26)* is offered a stronger nucleophile than the nitrogen or sulfur atom in its own molecule, the self-alkylation is suppressed, and once more only the smallest alkyl group is split off [103]; an example is shown in Eq. (p).



(p)

2. Transalkylation

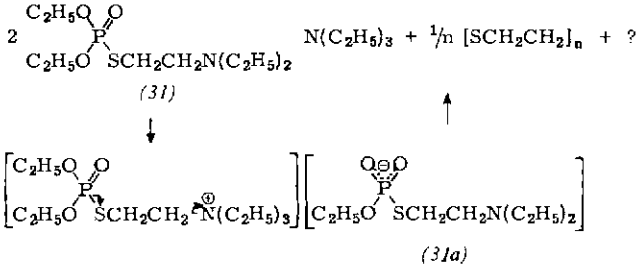
Esters of the type *(26)*, and above all their thiol isomers, tend to change into salt-like products. *O*-Ethyl *O*-β-diethylaminoethyl *O*-methyl thiophosphate, for example changes on standing at room temperature into a substance which is insoluble in ether [62]. This reaction has been investigated in detail in the case of the compounds *(29a)* (Isosystox®) and *(29b)* (Isometasystox®) [144]. It is accelerated by higher temperatures or polar solvents. Oxidation of the thioether group to the sulfone group leads to stable thiolphosphates. According to *Heath* [144], the reaction is essentially a transalkylation with formation of *(30)*.



(29a), R = C_2H_5
(29b), R = CH_3

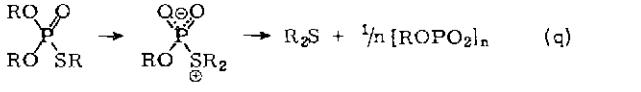
(30)

A similar explanation applies to the formation of triethylamine when the insecticide Amiton® *(31)* is heated [133].



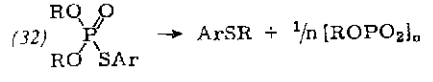
(31) *(31a)*

The sulfur of the thiol ester group in simple alkyl and alkyl aryl thiolphosphates can also become alkyl acceptor for transalkylations at temperatures somewhat higher than 130 °C. Thus considerable quantities of dimethyl sulfide are liberated from *O,O,S*-trimethyl thiophosphate [8] or *O*-aryl *O,S*-dimethyl thiophosphates



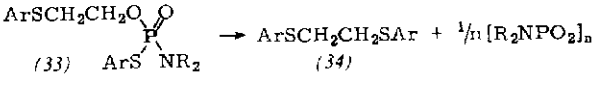
(q)

[134], probably in accordance with Eq. (q). *O,O*-Dialkyl *S*-aryl thiophosphates *(32)* give high to quantitative yields of alkyl aryl sulfide at 170 °C [145]. 1,2-Di-



(32)

arylthioethanes *(34)* can be readily obtained in a similar manner from amido thiophosphates of the type *(33)* [146].



(33) *(34)*

3. Interference in Syntheses

The alkylating properties of thiophosphates are not only of preparative interest, but are equally important in the preparation and use of these compounds.

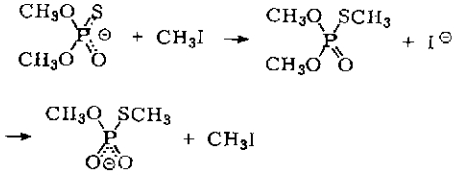
The yields of thiophosphates are considerably reduced if their synthesis involves the formation of *e.g.* iodide

[143] *A. Calderbank* and *R. Ghosh*, J. chem. Soc. (London) *1960*, 637.

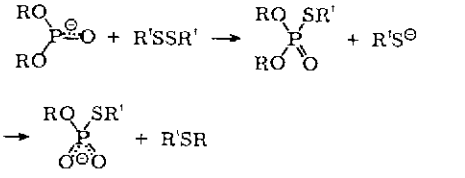
[144] *D. F. Heath*, Nature (London) *179*, 377 (1957); J. chem. Soc. (London) *1958*, 1643; *D. F. Heath* and *M. Vandekar*, Biochem. J. *67*, 187 (1957).

[145] *K. Pilgram* and *F. Korte*, Tetrahedron *21*, 203 (1965).

[11] or mercaptide ions [89–91] which dealkylate the esters according to Eq. (r) and (s).

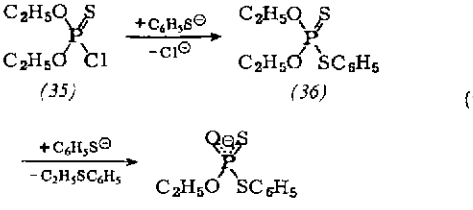


(r)



(s)

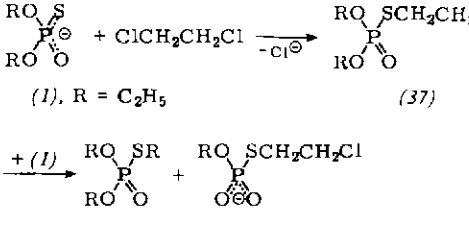
In reactions of chlorophosphates with mercaptides or thiophenolates, the "esterifying reagent" can itself dealkylate the triester formed. Thus the reaction of *O,O*-diethyl chlorothiophosphate *(35)* with sodium thiophenolate [Eq. (t)] [94] yields only 32 % of *O,O*-diethyl *S*-phenyl dithiophosphate *(36)*, whereas the more



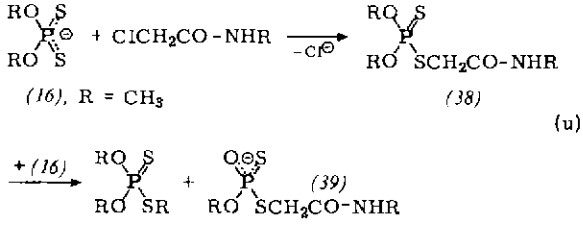
(t)

weakly nucleophilic phenoxide under the same conditions gives 80% of *O,O*-diethyl *O*-phenyl thiophosphate. The dealkylation by tertiary amines during the esterification of alcohols with chlorophosphates has already been mentioned [Eq. (c)]; similar behavior is found with chlorothionophosphates [62, 63].

Another complication is introduced by the interaction between the thiophosphate anion and the triester produced [Eq. (l)]. In the reaction of *O,O*-diethyl thiophosphates *(1)* with ethylene dichloride, for example, instead of the expected *S*-β-chloroethyl ester *(37)*, the

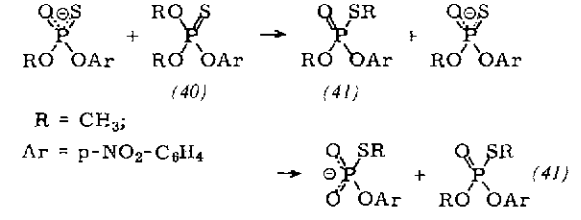


product consists of a mixture of *(37)* with *O,O*-diethyl *S*-ethyl thiophosphate [147]. The anion *(39)* formed by dealkylation in the synthesis of the insecticide Rogor® *(38)* [Eq. (u)] [111, 113–115] can be realkylated to form an isomer of the insecticide which is more toxic to warmblooded animals.



(u)

It is sometimes possible to make preparative use of such generally undesirable reactions. For example, a patent [114] describes the preparation of *O,S*-dimethyl *O*-(*p*-nitrophenyl) thiophosphate *(41)* in high yields by the reaction of the isomeric methyl parathion *(40)* with its dealkylation product.



Thiophosphates can also change as a result of careless storage, formulation, and use, with consequent influence on the pharmacological and insecticidal properties.

The isomerization of thionophosphates of the type *(26)*, which is appreciable on prolonged storage even at room temperature, is generally associated with an increase in toxicity. In particular, the salts *(30)* and *(30a)* formed by transalkylation are very efficient choline esterase inhibitors, whose structural relationship to acetylcholine is obvious. Polar solvents such as water greatly accelerate such transalkylations [144].

The toxicity of phosphate and thiophosphate insecticides has formerly been ascribed mainly to their inhibitory action on choline esterase. It now seems certain that this property does not suffice to explain the toxicity. In this connection, it is probably more than mere coincidence that all toxic phosphoric acid and thiophosphoric acid insecticides are strong alkylating agents [148].

Recent Advances in the Theory of Liquids

BY DR. TERESA S. REE [*], PROF. DR. T. REE, AND PROF. DR. H. EYRING

DEPARTMENT OF CHEMISTRY, UNIVERSITY OF UTAH, SALT LAKE CITY, UTAH (USA)

In this paper, the methods of calculation of liquid properties using cluster integrals or the radial distribution function are not discussed. Rather, the theories using a model approach are presented. The basic principles involved in the cell theory, tunnel theory, and significant structure theory are reviewed, and the merits of the three theories are examined by comparing theoretical and experimental values of the pressures, molar volumes, compressibility factors, and excess entropies of real liquids. – The thermodynamic properties of two- and three-dimensional arrays of hard discs and spheres are also calculated, and compared with the machine calculation. – One finds that the significant structure theory gives the best results in every case.

A. Introduction

The purpose of this paper is to review the lattice theories developed to describe the liquid state. In this category belong the free-volume theory or cell theory [1,2], the tunnel theory [3], which is an improved version of the cell theory, and the significant structure theory of liquids [4]. The first two theories are based more on a fundamental approach [5,6], while the last has more obvious physical significance. All three theories involve assumptions in formulating the partition function, Z_N, which is related to the Helmholtz free energy, A, according to:

$$A = -kT \ln Z_N \tag{1}$$

Thermodynamic properties such as pressure, P, entropy, S, and internal energy, E, can be obtained from the Helmholtz free energy as follows:

$$P = -\left(\frac{\partial A}{\partial V}\right)_T$$

$$S = -\left(\frac{\partial A}{\partial T}\right)_V$$

$$E = -kT^2\left[\frac{\partial}{\partial T}\left(\frac{A}{kT}\right)\right]_V \tag{2}$$

First we shall discuss the formulations of Z_N according to the various theories and the assumptions introduced, and then compare the numerical results obtained with experiment.

B. Theories

I. Cell Theory or Free Volume Theory

This theory was first developed by *Eyring* and *Hirschfelder* [1], and by *Lennard-Jones* and *Devonshire* [2]. They assumed that a molecule in a liquid spends much of its time in the cell which is formed by its neighboring molecules fixed at their equilibrium positions. In order to simplify the calculation of the free volume, they further assumed that the z nearest neighbors can be treated as if uniformly smeared over a spherical surface of radius equal to the nearest neighboring distance, a. Then the partition function (for a system of N molecules) becomes

$$Z_N = \lambda^{-3N} \exp\left[-\frac{z}{2}\frac{N\Psi(a)}{kT}\right] v_f^N \left[J(T)\right]^N \tag{3}$$

where $\lambda = h/(2\pi mkT)^{1/2}$, J(T) is the partition function for the internal degrees of freedom of the molecule, and v_f is the free volume and is given by

$$v_f = \int_{cell} \exp\left[-z\frac{\Psi(\vec{r}) - \Psi(\vec{a})}{kT}\right] d\vec{r} \tag{4}$$

In the above equations, Ψ is a pair interaction potential.

II. Tunnel Theory

The tunnel theory is a one-dimensionally disordered cell theory proposed by *Barker* [3]. Instead of one molecule in a cell, the theory assumes that a whole line of molecules is in a tunnel. The partition function is the product of the partition functions for longitudinal and transverse motions in the tunnel. The partition function for the one-dimensional longitudinal motion can be evaluated exactly, and is

$$Z_M = \lambda^{-M}\left[\frac{1}{M!}\int_0^{lM}\cdots\int_0^{lM}\exp\left[-\frac{U(x)}{kT}\right]dx_1\cdots dx_M\right] \tag{5}$$

where U(x) is the potential energy of the one-dimensional system of M molecules in length *l*M. When there are

K such tunnels in a system, the total partition function will be Z_M^K.

The partition function for the transverse motion can be evaluated in terms of a "free area", a_f, exactly analogous to the "free volume" in the cell model. Therefore, the total partition function is

$$Z_N = \lambda^{-3N}\left[a_f \cdot \exp\left(-\frac{V(a)}{2kT}\right)\right]^N \cdot Z_M^K\,[J(T)]^N \qquad (6)$$

where

$$a_f = \int \exp\left\{-[V(\vec{r})-V(\vec{a})]/kT\right\} d\vec{r} \qquad (7)$$

In the above equation, $V(\vec{r})$ is the potential energy of interaction of a given molecule at a distance $\vec{r}$ from the axis of its tunnel, and this is summed over all molecules except those in the tunnel.

III. The Significant Structure Theory of Liquids [4]

The significant structure theory of liquids was developed in this laboratory, and its concept amounts to picking out *a priori* what one considers to be the regions of phase space that give the major contribution to the partition function and neglecting the rest of phase space. The significant structures that we choose for the liquid state are: (a) solid-like degrees of freedom; (b) a configurational degeneracy associated with the solid-like degrees of freedom; and (c) gas-like degrees of freedom for molecules maneuvering voids through the solid-like regions.

Assuming that the binding energy of the liquid is attributable solely to solid-like degrees of freedom, the fraction of the latter is estimated to be V_s/V, where V_s is the volume of the solid at the melting point and V is liquid volume. Then the partition function is written as:

$$Z_N = \{Z_s[1 + n_h \exp(-\varepsilon_o/kT)]\}^{NV_s/V} Z_g^{N(V-V_s)/V} \qquad (8)$$

where Z_s and Z_g are the partition function for solid and gas, respectively. Presumably n_h is proportional to the total number of holes present in the fluid. Hence,

$$n_h = n(V-V_s)/V_s \qquad (9)$$

The energy necessary to occupy one of the degenerate positions, ε_o, is assumed to be proportional to the potential energy of the lattice, E_c, and inversely proportional to n_h. Thus,

$$\varepsilon_o = a' E_c V_s/(V-V_s) \qquad (10)$$

where a′ is a proportionality constant.

C. Calculations

In order to obtain numerical results, we shall introduce the following two special potential functions into the partition functions:

I. The Lennard-Jones 6-12 Potential

A simple spherical molecule, such as argon, interacts with an identical molecule according to the Lennard-Jones 6–12 potential energy, *i.e.*,

$$\Psi(\vec{r}) = 4\varepsilon\left[\left(\frac{\sigma}{r}\right)^{12} - \left(\frac{\sigma}{r}\right)^{6}\right] \qquad (11)$$

where ε and σ are energy and distance parameters and are listed by *Hirschfelder et al.* [7]. With the 6–12 potential energy, the partition functions of the three theories mentioned above assume the following forms:

1. Cell Theory

When hexagonal close-packing is assumed, then

$$z = 12$$
$$V/N = a^3/\sqrt{2} \qquad (12)$$

With Equations (11) and (12), $\Psi(a)$ and v_f in Equation (3) become, respectively,

$$\frac{z\Psi(a)}{2} = 6\varepsilon\left[\frac{1.0109}{v^{*4}} - \frac{2.4090}{v^{*2}}\right] \qquad (13)$$
$$v_f = 2\sqrt{2}\,(V/N)\,G$$

where

$$v^* = V/N\sigma^3,$$

and

$$G = \int_0^{0.30544} y^{1/2} \exp\{-z[\Psi(y)-\Psi(a)]/kT\}\, dy \qquad (14)$$

The term $\Psi(y)-\Psi(a)$ in Equation (14) is written as

$$z[\Psi(y)-\Psi(a)] = 12\varepsilon\left[\frac{L(y)}{v^{*4}} - 2\,\frac{M(y)}{v^{*2}}\right] \qquad (15)$$

where

$$L(y) = l(y) + \frac{1}{128}\,l\left(\frac{1}{2}\,y\right) + \frac{2}{729}\,l\left(\frac{1}{3}\,y\right)$$

$$M(y) = m(y) + \frac{1}{16}\,m\left(\frac{1}{2}\,y\right) + \frac{2}{27}\,m\left(\frac{1}{3}\,y\right)$$

and

$$l(y) = (1 + 12y + 25.2y^2 + 12y^3 + y^4)\,(1-y)^{-10} - 1$$
$$m(y) = (1 + y)\,(1-y)^{-4} - 1 \qquad (16)$$
$$y = (r/a)^2$$

In Equations (13) and (15), non-nearest neighbor interactions are also counted. Hence, with Equation (1), the pressure equation for the cell theory becomes:

$$\frac{PV}{NkT} = 1 - \frac{12}{T^*}\left[\frac{2.4090}{v^{*2}} - \frac{2.0219}{v^{*4}}\right] - \frac{48}{T^*}\left[\frac{1}{v^{*2}}\cdot\frac{g_M}{G} - \frac{1}{v^{*4}}\cdot\frac{g_L}{G}\right] \qquad (17)$$

where $T^* = kT/\varepsilon$.

[7] *J. O. Hirschfelder, C. F. Curtiss,* and *R. V. Bird*: Molecular Theory of Gases and Liquids. Wiley, New York 1964, pp. 1110 to 1113 and 1212–1215.

The excess of a property is defined as the difference between the real property and the ideal gas property; hence, the excess reduced entropy, S^E/Nk, and the excess reduced energy, $E^E/N\varepsilon$, for the cell theory is derived from Equations (2) by using Equation (3) as:

$$\frac{S^E}{Nk} = \ln\left[2\sqrt{2}\,\pi\frac{G}{e}\right] + \frac{12}{T^*}\left[\frac{1}{v^{*4}}\cdot\frac{g_L}{G} - 2\frac{1}{v^{*2}}\cdot\frac{g_M}{G}\right] \tag{18}$$

and

$$\frac{E^E}{NkT} = \frac{6}{T^*}\left[\frac{1.0109}{v^{*4}} - \frac{2.4090}{v^{*2}}\right] + \frac{12}{T^*}\left[\frac{1}{v^{*4}}\cdot\frac{g_L}{G} - 2\frac{1}{v^{*2}}\cdot\frac{g_M}{G}\right] \tag{19}$$

In the above equations,

$$\left.\begin{aligned} g_L &= \int_0^{0.30544} y^{1/2} L(y)\exp\{-[\Psi(y)-\Psi(a)]/kT\}\,dy \\ g_M &= \int_0^{0.30544} y^{1/2} M(y)\exp\{-[\Psi(y)-\Psi(a)]/kT\}\,dy \end{aligned}\right\} \tag{20}$$

The values of G, g_L, and g_M have been tabulated by *Wentorf et al.* [8].

2. Tunnel Theory

The one-dimensional partition function defined in Equation (5) is written as:

$$-\frac{1}{N}\ln\left(Z_M\lambda^M\right) = \frac{A_1^*}{RT} + \frac{4}{T^*}\left[0.0003\left(\frac{\sigma}{l}\right)^{12} - 0.0173\left(\frac{\sigma}{l}\right)^6\right] \tag{21}$$

The second term on the right in Equation (21) is the Helmholtz free energy due to the non-nearest neighbor interaction, and the first term is that due to nearest neighbor interaction and is

$$A_1^* = -\frac{P_1 l}{kT} - \ln\left[\int_0^\infty \exp\{-[\Psi(x) + P_1 x]/kT\}\,dx\right] \tag{22}$$

Here P_1 is the one-dimensional pressure which is related to the intermolecular distance l by Equation (23):

$$l = \frac{\int_0^\infty x\exp\{-[\Psi(x) + P_1 x]/kT\}\,dx}{\int_0^\infty \exp\{-[\Psi(x)+P_1 x]/kT\}\,dx} \tag{23}$$

The hexagonal close-packed lattice with the lattice distance a is assumed for obtaining V(a) and a_f in Equation (6). Then the following equations are obtained:

$$V/N = (\sqrt{3}/2)a^2 l \tag{24}$$

$$V(a)/kT = 4.652C - 7.925B \tag{25}$$

where

$$B = \frac{4\varepsilon a}{lkT}\left(\frac{\sigma}{a}\right)^6,\quad C = \frac{4\varepsilon a}{lkT}\left(\frac{\sigma}{a}\right)^{12} \tag{26}$$

and a_f is given by

$$a_f = a^2 S \tag{27}$$

where

$$S = 2\pi\int_0^{0.25}\exp-\left[\frac{V(y)-V(a)}{kT}\right]y\,dy \tag{27a}$$

and

$$y = r/a \tag{27b}$$

From Equation (1) with Equations (6) and (21)–(27b), the pressure equation (28) is obtained:

$$\frac{PV}{NkT} = \frac{1}{T^*}\left(\frac{V_o}{V}\right)^4\left(20.938 + 9\frac{S_C}{S}\right) - \frac{1}{T^*}\left(\frac{V_o}{V}\right)^2\left(23.880 + 6\frac{S_B}{S}\right) + \frac{0.3497}{W}\left(\frac{V_o}{V}\right)^{-1/3} + \frac{2}{3} \tag{28}$$

In the above equation the relation $l = a = \sigma(2V/\sqrt{3}\,V_o)^{1/3}$ has been introduced, where

$$S_B = \frac{\partial S}{\partial B};\quad S_C = \frac{\partial S}{\partial C};\quad W = \frac{kT}{P_1\sigma};\quad \text{and } V_o = N\sigma^3 \tag{29}$$

S, S_B, S_C and W have been tabulated by *Barker* [3b].

3. Significant Structure Theory of Liquids

According to the significant structure theory, the partition funktion for simple liquids is written as:

$$Z_N = \left[e^{E_c/RT}\left(\frac{T}{\Theta}\right)^3\left(1 + n_h\cdot e^{-\varepsilon_0/kT}\right)J(T)\right]^{NV_s/V}\left[\left(\frac{2\pi mkT}{h^2}\right)^{3/2}(V-V_s)J(T)\right]^{N(V-V_s)/V}\left[\frac{N(V-V_s)}{V}!\right]^{-1} \tag{30}$$

The first set of brackets represents the solid-like portion of the partition function. The remaining portion is the gas-like part. Here, J(T) is again the partition function for the internal degrees of freedom. E_c is the configurational energy and can be written as

$$E_c = \frac{Z}{2}N\varepsilon\left[2.4090\left(\frac{V_s}{N\sigma^3}\right)^{-2} - 1.0109\left(\frac{V_s}{N\sigma^3}\right)^{-4}\right] \tag{31}$$

At the nearest neighbor distance a in the solid state, the interaction energy, Equation (11), attains the least value. Thus we have the following relation:

$$2^{1/6}\sigma = a \tag{32}$$

By applying equation (32) to hexagonal close packing, one obtains

$$V_s = Na^3/\sqrt{2} = N\sigma^3 \tag{33}$$

In Equation (30), Θ is the Einstein characteristic temperature and is given by

$$\Theta = \frac{h\nu}{k} = \frac{h}{k}\cdot\frac{1}{2\pi}\left(\frac{k_r}{m}\right)^{1/2} \tag{34}$$

where k_r is the force constant which can be approximated using the 6–12 potential as

$$k_r^2/2 \approx Z[\Psi(r)-\Psi(a)] \tag{35}$$

Hence,

$$k_r = 2z\varepsilon\sigma^{-2}\left[22.106\left(\frac{N\sigma^3}{V_s}\right)^4 - 10.559\left(\frac{N\sigma}{V_s}\right)^2\right]\left[1.414\left(\frac{V_s}{N\sigma^3}\right)\right]^{-2/3} \tag{36}$$

The n and a' in Equations (9) and (10) are 10.7 and 0.0052 for simple liquids, respectively, and are derived as follows:

[8] *R. H. Wentorf, R. J. Buehler, J. O. Hirschfelder*, and *C. F. Curtiss*, J. chem. Physics *18*, 1484 (1950).

Near the melting point the fraction of the neighboring positions, z, which are available for occupancy is $z(V_m-V_s)/V_m$, where V_m is the volume of the liquid at the melting point. Therefore, we have the following relation:

$$z(V_m-V_s)/V_m = (zV_s/V_m)(V_m-V_s)/V_s = n(V_m-V_s)/V_s \quad (37)$$

Hence for simple liquids, which expand about 12% on melting, one obtains

$$n = zV_s/V_m = 12/1.12 = 10.7 \quad (38)$$

Next, we calculate the proportionality constant a'. The occupancy of a vacancy in a liquid by neighbors to the vacancy is competitive. One molecule can exclude others from a vacancy providing it is at a higher pressure, *i.e.* if it is at a higher density of translational kinetic energy than its neighbors. Now the average translational kinetic energy of a solid molecule is (3/2)kT. If an average molecule divides its time equally between two neighboring positions, this will cut the energy density in two, and effective pressure will be cut in two. Now if a competing neighbor wants to exclude such average competitors from a vacancy and still hold its old position, it needs (3/2)kT to hold the old position and an additional (1/2) (3/2)kT to preempt the vacancy. Since (3/2)k is very near the entropy of melting of rare-gas solids, and since (3/2)kT is very closely equal to the energy of melting E_m/N, we provide the justification for Equation (39):

$$\frac{a'F_cV_s}{V_m-V_s} = \frac{n-1}{z}\frac{1}{2}E_m \simeq \frac{n-1}{z}\frac{1}{2}\frac{V-V_s}{V_m}E_c \quad (39)$$

Here the factor $(n-1)/z$ comes in from the consideration that there are $n-1$ competitors each contributing $(1/z)$th of the energy (1/2) (3/2)kT to the vacancy; in the second equality of Equation (39), it has been assumed that $E_m \simeq E_c(V_m-V_s)/V_m$. Hence,

$$a' = \frac{n-1}{z}\frac{1}{2}\frac{V_m-V_s}{V_m}\frac{V_m-V_s}{V_s} = 0.0052 \quad (40)$$

By substituting Equations (31) through (39) in Equation (30), and applying Stirling's approximation to $[N(V-V_s)/V]!$, we obtain:

$$Z_N = \left[\frac{(2\pi mkT)^{3/2}}{h^3}\frac{eV}{N}J(T)\right]^N \left[\frac{e\,8.388/T^*}{eV^*}\left(\frac{T^*}{35.01}\right)^{3/2}(1+10.7(V^*-1)\exp\frac{-0.0436}{T^*(V^*-1)}\right]^{N/V^*} \quad (41)$$

Pressure, excess entropy, and excess energy for the significant structure theory of liquids are obtained from the above partition functions as:

$$\frac{PV}{NkT} = 1-\frac{8.388}{V^*T^*}+\frac{\ln V^*}{V^*}-\frac{3}{2V^*}\ln\frac{T^*}{35.01}-\frac{1}{V^*}\ln\left[1+10.7(V^*-1)\exp\frac{-0.0436}{T^*(V^*-1)}\right]$$
$$+\frac{10.7}{T^*(V^*-1)}\frac{0.436+T^*(V^*-1)}{10.7(V^*-1)+\exp[0.436/T^*(V^*-1)]} \quad (42)$$

$$\frac{S_E}{Nk} = \frac{1}{V^*}\ln\left[1+10.7(V^*-1)\exp\frac{-0.0436}{T^*(V^*-1)}\right]$$
$$+\frac{(0.4665/T^*V^*)\exp-0.0436/T^*(V^*-1)}{1+10.7(V^*-1)\exp-[0.0436/T^*(V^*-1)]}+\frac{1.5}{V^*}\ln\left(\frac{T^*}{35.01}\right)+\frac{0.5}{V^*}-\frac{\ln V^*}{V^*} \quad (43)$$

$$\frac{E^E}{Ne} = -\frac{8.388}{V^*}+\frac{15T^*}{V^*}+\frac{[0.4665/V^*]\exp-[0.0436/T^*(V^*-1)}{1+10.7(V^*-1)\exp-[0.0436/T^*(V^*-1)]} \quad (44)$$

4. Results

In Figures 1 and 2, we compare the reduced experimental vapor pressure ($P^* = P\sigma^3/\varepsilon$) and volume ($V^*$) for simple liquids such as Ne [9,10], Ar [11], N_2 [9,12], and CH_4 [11,12] with the calculated values from the three theories.

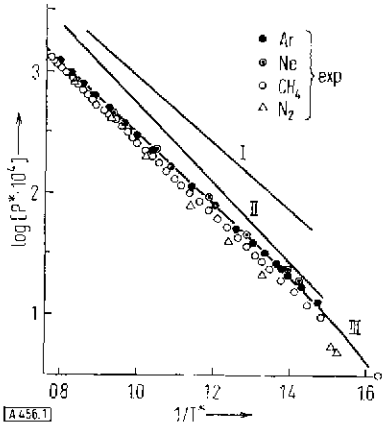

Fig. 1. Logarithm of reduced pressure *versus* the reciprocal of reduced temperature. Curve I, tunnel theory; Curve II, cell theory; Curve III, significant structure theory; points experimental.

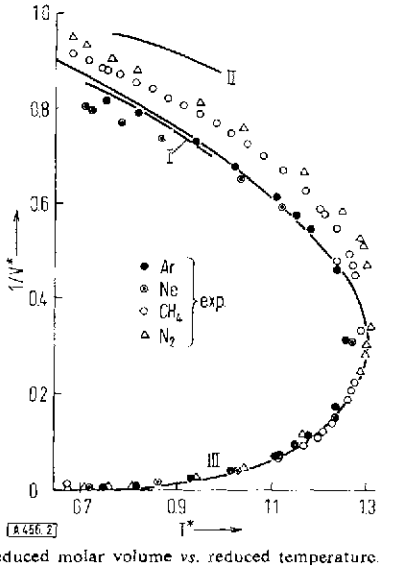

Fig. 2. Reciprocal of reduced molar volume *vs.* reduced temperature. Curve I, tunnel theory; Curve II, cell theory; Curve III, significant structure theory; points experimental.

[10] International Critical Tables. McGraw-Hill, New York 1926.

[11] Thermodynamic Functions of Gases, *F. Din*, ed. Butterworths, London 1961–62.

[12] Landolt-Börnstein, Physikalisch-chemische Tabellen. Springer, Berlin 1923.

One obtains vapor pressure and volume from the cell theory and the tunnel theory as follows: The volume at zero pressure of the liquid phase can be determined by setting P in Equations (17) and (28) equal to zero and solving for V*. In equilibrium between a liquid and its vapor, the Gibbs free energy, F, for the two phases are equal, *i.e.*

$$F_l = F_g \tag{45}$$

where $F_l = A_l + P_l V_l$ and $F_g = A_g + P_l V_g$, and the subscripts l and g indicate the liquid and gas phase, respectively. When the ideal gas law is applicable to the vapor, V_g is expressed by

$$V_g = NkT/P_l \tag{46}$$

With Equations (45) and (46), and the condition $V_g \gg V$ one obtains

$$RT\ln(P_l/kT) = RT\ln\frac{(2\pi mkT)^{3/2}}{h^3} J(T) + A_l \tag{47}$$

The vapor pressure and volume for the significant structure theory of liquids are obtained as follows:

In general, a plot of the Helmholtz free energy against V* by using Equation (1) with Equation (41) yields a curve with two minima for the solid and liquid phases, as shown by the isotherm in Figure 3.

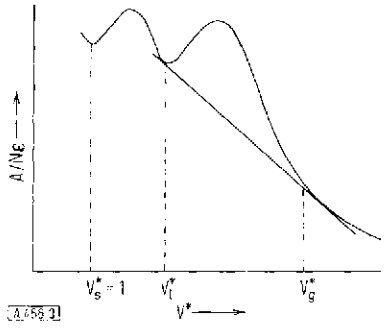

Fig. 3. Reduced Helmholtz free energy *vs.* reduced molar volume (isotherm).

Since the slope gives the pressure, the slope of the common tangent to the curve at the two points corresponding to the liquid and gaseous phases gives the vapor pressure, and the tangential point near the minimum corresponding to the liquid phase yields the liquid volume, while the one at a larger volume indicates the vapor volume. The melting temperature is the temperature at which the slope of the common tangent between the solid and liquid minima is $P^* = \sigma^3/\varepsilon$, *i.e.* P = 1 atmosphere. In Table I, the melting properties for the significant structure theory are compared with experimental data for liquid argon [3a]. The results of the other two theories at $T^* = 0.70$ are also shown. In columns 4 and 5 of Table I, a comparison is made of the calculated reduced excess entropy and excess energy at the melting temperature with the corresponding experimental quantities for liquid argon [3a]. The comparison between the data for the cell theory and for solid argon confirms the fact that the cell theory is a theory of super-heated solids rather than a theory of liquids.

Table 1. Theoretical and experimental properties at the melting point.

	T*	V*	S^E/Nk	$E^E/N\varepsilon$
Significant structure theory	0.711	1.159	−3.89	−6.19
Tunnel theory		1.184	−4.8	−5.9
Liquid argon	0.701	1.178	−3.64	−5.96
Theory of *Lennard-Jones* and *Devonshire*		1.037	−5.51	−7.32
Solid argon	0.701	1.035	−5.53	−7.14

The critical constants are obtained by using the conditions $(\partial P/\partial V)_T = 0$ and $(\partial^2 P/\partial V^2)_T = 0$. In Table II, we compare the critical constants for the three theories and the experimental data for simple liquids [13]. The agreement between experiment and significant structure theory is far better than for the other two theories. The tunnel theory values are in slightly worse agreement with experiment than the cell theory. This is almost certainly due to the approximation of treating the motion in the tunnels as strictly one-dimensional.

II. Hard-Sphere Potential

The potential of interaction between hard spheres of diameter d is

$$\Phi(r) = \infty \qquad r < d$$
$$\Phi(r) = 0 \qquad r \geq d \tag{48}$$

This intermolecular potential is of great theoretical interest because it is amenable to comparatively simple calculations, and the results of extensive machine calculations by the Monte Carlo [14] and the molecular dynamics [15] methods for large systems of hard spheres and hard discs are available. As a result, the hard sphere potential is a very useful test case for a theory of liquids. Hence it is interesting to compare the three theories with the machine calculations.

1. Cell Theory

For a system of hard spheres, the free volume is equal to the volume of a sphere of radius a−d. In obtaining this result the smearing approximation has been used. Hence Equation (3) becomes

$$Z_N = \left[\lambda^{-3}\frac{4}{3}\pi(a-d)^3\right]^N \tag{49}$$

[13] *T. L. Hill*: Statistical Mechanics. McGraw-Hill, New York 1956, p. 389.

[14] *W. W. Wood*, *F. R. Parker*, and *J. D. Jacobson*, Nuovo Cimento Suppl. *9*, 133 (1958).

[15] *B. J. Alder* and *T. E. Wainwright*, J. chem. Physics. *27*, 1208 (1957); *31*, 459 (1959); *33*, 1439 (1960); Nuovo Cimento Suppl. *9* 116 (1958).

The resulting equation of state and the equation for the excess entropy are, respectively:

$$\frac{PV}{NkT} = \frac{1}{1-(V_o/V)^{1/3}} \tag{50}$$

and

$$\frac{S^E}{Nk} = \ln\left\{\frac{4\pi/2}{3}\left[1-\left(\frac{V_o}{V}\right)^{1/3}\right]^3\right\} - 1 + \ln\frac{PV}{NkT} \tag{51}$$

where $V_o = Nd^3/\sqrt{2}$ is the molar volume of hexagonal closest packing.

In parallel with a three-dimensional system, the partition function for two-dimensional hard discs is

$$Z_N = \left[\lambda^{-2}\pi(a-\sigma)^2\right]^N \tag{52}$$

Hence the equation of state and excess entropy are given by:

$$\frac{\Pi}{NkT} = \frac{1}{1-(\mathfrak{A}_o/\mathfrak{A})^{1/2}} \tag{53}$$

$$\frac{S^E}{Nk} = \ln\frac{2\pi}{\sqrt{3}}\left[1-\left(\frac{\mathfrak{A}_o}{\mathfrak{A}}\right)^{1/2}\right]^2 - 1 + \ln\left(\frac{\Pi\mathfrak{A}}{NkT}\right) \tag{54}$$

where $\mathfrak{A}$ is the molar area and $\mathfrak{A}_o = (\sqrt{3}/2)\,Nd^2$ is the molar area of closest packing; Π is the surface pressure.

2. Tunnel Theory

When the rigid sphere potential is applied, Equation (5) becomes

$$Z_M = e^M(l-d)^M \tag{55}$$

and a_f in Z_n [cf. Eq. (6)] together with the smearing approximation gives

$$a_f = \pi(a-d)^2 \tag{56}$$

Hence

$$Z_N = \lambda^{-3N}[\pi(a-d)^2(l-d)e]^N \tag{57}$$

Consequently, the equation of state and excess entropy for the tunnel theory are, respectively:

$$\frac{PV}{NkT} = \frac{1}{1-[\sqrt{3/2}\cdot V_o/V]^{1/3}} \tag{58}$$

and

$$\frac{S^E}{Nk} = \ln\left\{\frac{2\pi}{3}\left[1-\left(\sqrt{\frac{3}{2}}\,\frac{V_o}{V}\right)^{1/3}\right]^2\right\} \tag{59}$$

In Equations (58) and (59), the condition

$$a = l = \left(\frac{2}{\sqrt{3}}\,\frac{V}{N}\right)^{1/3} \tag{60}$$

has been introduced. This equality can be derived by maximizing Equation (57) subject to Equation (24).

3. The Significant Structure Theory of Liquids

Henderson [16] used the cell theory partition function rather than the Einstein partition function for Z_s in Equation (8). This is theoretically permissible, because the cell theory is the theory for metastable solids rather than for liquids, as pointed out previously. Then the partition function for hard spheres becomes:

$$Z_N = \left[\lambda^{-3}\frac{eV}{N}\right]^N\left[0.00967\left(8-11\,\frac{V_o}{V}\right)\right]^{(3/2)NV_o/V} \tag{61}$$

In the above equation, $n = 12$ and $V_s = 1.5\,V_o$ have been introduced, and the value of v_f for $V_s = 1.5\,V_o$ has been obtained by an interpolation of the results tabulated by *Buehler et al.* [17]. The relation $V_s = 1.5\,V_o$ has been observed by *Wood* and *Jacobson* [14] and *Alder* and *Wainwright* [15] by means of machine calculations. Consequently, the equation of state is written as

$$\frac{PV}{NkT} = 1 - \frac{3}{2}\left(\frac{V_o}{V}\right)\ln\left\{0.00967\left[8-11\left(\frac{V_o}{V}\right)\right]\right\} + \frac{3}{2}\,\frac{11(V_o/V)^2}{8-11(V_o/V)} \tag{62}$$

and the excess entropy is given by

$$\frac{S^E}{Nk} = \frac{3}{2}\,\frac{V_o}{V}\ln\left[0.00967\left(8-11\,\frac{V_o}{V}\right)\right] - \ln\left\{1-\frac{3V_o}{V}\ln\left[0.00967\left(8-11\,\frac{V_o}{V}\right)\right] + \frac{3}{2}\,\frac{11(V_o/V)^2}{8-11(V_o/V)}\right\} \tag{63}$$

Wang et al. [18] applied the significant structure theory to two-dimensional discs and obtained

$$Z_N = \left[\lambda^{-2}\frac{e\mathfrak{A}}{N}\right]^N\left[0.02358\,(6-5\,\mathfrak{A}_s/\mathfrak{A})\right]^{N\mathfrak{A}_s/\mathfrak{A}} \tag{64}$$

Here, $\mathfrak{A}$ is the molar area of a liquid of hard discs and $\mathfrak{A}_s$ is the corresponding quantity of solid, and the values $a_f = 0.05552a^2$ and $n = 6$ have been introduced. The equations for pressure Π and excess entropy become:

$$\frac{\Pi\mathfrak{A}}{NkT} = 1 - 1.312\,\frac{\mathfrak{A}_o}{\mathfrak{A}}\ln\left[0.02358\left(6-6.56\,\frac{\mathfrak{A}_o}{\mathfrak{A}}\right)\right] + \left(1.312\,\frac{\mathfrak{A}_o}{\mathfrak{A}}\right)^2\left[\frac{5}{6-6.56\mathfrak{A}_o/\mathfrak{A}}\right] \tag{65}$$

and

$$\frac{S^E}{Nk} = \ln\frac{\Pi\mathfrak{A}}{NkT} + 1.312\,\frac{\mathfrak{A}_o}{\mathfrak{A}}\ln\left[0.02358\left(6-6.56\,\frac{\mathfrak{A}_o}{\mathfrak{A}}\right)\right] \tag{66}$$

In Equations (65) and (66), the relation $\mathfrak{A}_s = 1.312\,\mathfrak{A}_o$ obtained by machine calculation [15], has been introduced.

[16] *D. Henderson*, J. chem. Physics *39*, 1857 (1963).

[17] *R. J. Buehler, R. H. Wentorf, J. O. Hirschfelder*, and *C. F. Curtiss*, J. chem. Physics *19*, 61 (1951).

4. Results

The results of molecular dynamics calculations [15] are compared with the three theories in Figure 4 and 5. For the equation of state, both significant structure theory and tunnel theory agree very well with "experiment".

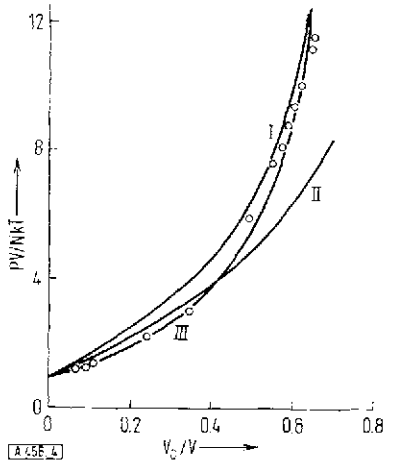

Fig. 4. Compressibility factor *vs.* V_0/V. V and V_0 are the molar liquid volume and the molar volume of closest packing, respectively. Curve I, tunnel theory; Curve II, cell theory; Curve III, significant structure theory; o calculated by the molecular dynamics method.

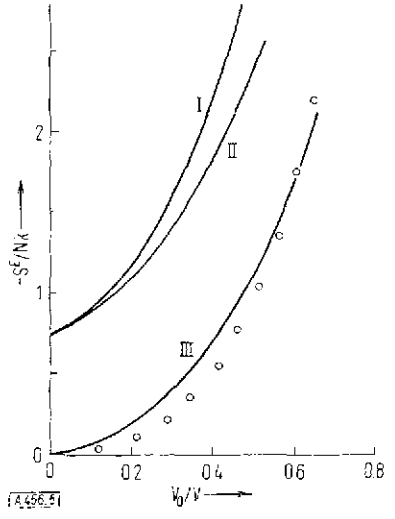

Fig. 5. Excess entropy *vs.* V_0/V. Curve I, tunnel theory; Curve II, cell theory; Curve III, significant structure theory; o calculated by the molecular dynamics method.

For the excess entropy, the tunnel theory agrees with "experiment" slightly less well than the cell theory, while the significant structure theory agrees very well.

In Figures 6 and 7, the theoretical equation of state and the excess entropy for a hard disc system are compared with the results obtained by machine calculations [15].

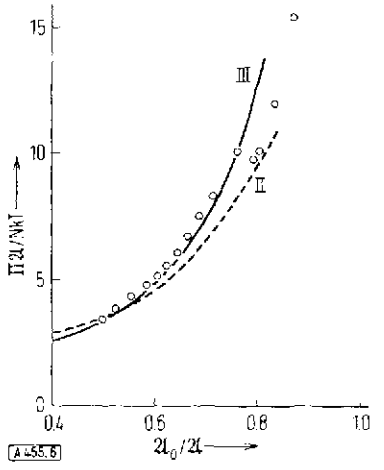

Fig. 6. Compressibility factor of a two-dimensional liquid *vs.* $\mathfrak{A}_0/\mathfrak{A}$. $\mathfrak{A}$ and $\mathfrak{A}_0$ are the molar area of the two-dimensional liquid and the molar area of closest packing, respectively. The data (o) of molecular dynamics calculations at $\mathfrak{A}_0/\mathfrak{A}$ higher than 0.8 correspond to the two-dimensional solid. Curve II, cell theory; Curve III, significant structure theory.

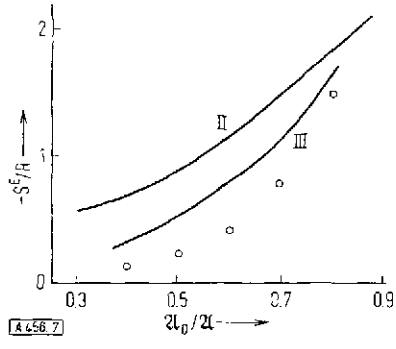

Fig. 7. Excess entropy of two-dimensional liquid versus $\mathfrak{A}_0/\mathfrak{A}$. Curve II, cell theory; Curve III, significant structure theory; o molecular dynamics method.

Here the tunnel theory is omitted because two-dimensional tunnel theory is the same as the cell theory.

The authors express appreciation to the National Science Foundation for support of this work.

Phosphorescence Spectroscopy as an Analytical Method for Aromatic and Heterocyclic Compounds

BY DR. M. ZANDER

RÜTGERSWERKE UND TEERVERWERTUNG AG., CASTROP-RAUXEL (GERMANY)

The phosphorescence of aromatic and heterocyclic compounds at low temperatures can be utilized for their identification and determination. The theoretical and experimental basis of phosphorimetry, which represents a valuable addition to the better-known analytical methods, is described, and examples of its application to coal-tar chemistry are discussed.

A. Introduction

Under suitable conditions, numerous aromatic and heterocyclic compounds exhibit a long-lived phosphorescence after irradiation with ultraviolet light. The spectrum, mean lifetime, and quantum yield of this phosphorescence are characteristic properties of the substance.

Analytical application of phosphorescence spectroscopy has so far been directed to the characterization of some biologically important indole derivatives[1], to the determination of small amounts of aspirin in blood[2], to coal-tar chemistry[3], to the direct determination of inhibitors in polymers[4], and to paper chromatography[5]. Experimental aspects of phosphorimetry have been discussed[6,7].

In the present work, the theoretical and experimental basis of phosphorescence, which is surveyed elsewhere[8], is described insofar as it is needed to appraise and plan phosphorimetric methods of analysis.

B. Theoretical and Experimental Principles

Aromatic and heterocyclic compounds are π-electron systems having a singlet ground state and several singlet and triplet excited states. A general principle of the spectroscopy of unsaturated compounds states that only the lowest excitated state of a given multiplicity is capable of emission[9]. The electronic transition from the lowest singlet excited state to the ground state leads to fluorescence, while the analogous transition from the lowest triplet state leads to phosphorescence[10] (low-temperature phosphorescence).

The long lifetime of the phosphorescence, which may amount to several seconds, is explained by the intercombination selection rule for radiative transitions between terms with different multiplicity. This also explains why the triplet state can be occupied by absorption of radiation to only a very small extent; instead, its occupation occurs predominantly by a radiationless transition from the lowest singlet excitation state.

The relationships can be represented by means of the Jablonski term scheme[11] (Fig. 1). When an aromatic or heterocyclic compound is irradiated with light corresponding to the longest-wavelength absorption band, the electronic transition to the lowest singlet excited state S′ (process 1) takes place. From S′, two competing processes occur: return to the ground state

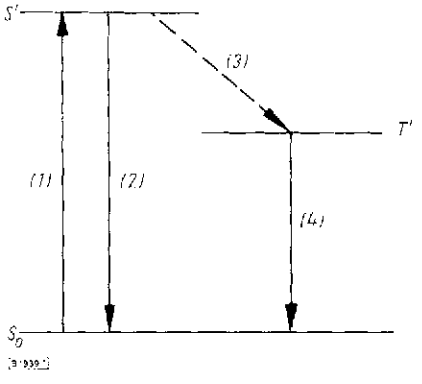

Fig. 1. Jablonski term diagram. (The excitation scheme is somewhat simplified, e.g. by omission of the radiationless transition $S' \rightarrow S_0$). 1. Transition to the lowest singlet excited state S′. 2. Fluorescence emission. 3. Radiationless transition. 4. Spin-forbidden transition (phosphorescence).

with emission of fluorescence (process 2) and radiationless transition to the lowest triplet excitation state T′ (process 3). The spin-forbidden transition T′ → ground state (process 4) leads to emission of phosphorescence. Because of the long lifetime of the triplet state, phosphorescence can usually be observed only under conditions where collisions between molecules and the

associated radiationless deactivation can be substantially eliminated. The most general method is the measurement of phosphorescence spectra in solid solutions at low temperatures. Particularly organic solvents or solvent mixtures which set to a glass at the temperature of liquid nitrogen are used. Only very short-lived phosphorescences have been observed in liquids at room temperature [12].

Many unsaturated compounds exhibit a "delayed" fluorescence under various experimental conditions, in addition to phosphorescence [13]. A special case of delayed fluorescence is the "high-temperature phosphorescence" of organic dyes [8], particularly of the triphenylmethane series. Among aromatic hydrocarbons this phenomenon has so far been observed only with coronene [14]. Delayed fluorescence is unlikely to find important analytical applications [*].

The mean decay period of phosphorescence (= mean lifetime of the triplet state) in aromatic and heterocyclic compounds is of the order of 10^{-3} to several seconds. Because of this longevity, phosphorescence spectra can be measured with a mechanical phosphoroscope, *e.g.* of the Becquerel type, in which exciting radiation and fluorescence are eliminated. The phosphorescence decay process in a solid solution is of the first order. Since the mean decay time at constant temperature in a given solvent is characteristic of the material, *i.e.* independent of concentration [15], it can be used to identify phosphorescent compounds, together with the spectra themselves. Examples are given below. – Table 1 lists the lifetime of the phosphorescence of various compounds. A marked decrease in the lifetime is observed [16] in the series naphthalene, fluoro-, chloro-, bromo-, and iodonaphthalene, *i.e.* with increasing atomic number of the substituent.

In addition to its spectrum and lifetime, the phosphorescence of a particular compound is characterized by the quantum yield. This value varies widely for different compounds (Table 2). A decrease both in the quantum yield and in the lifetime is found with a shift towards longer wavelengths of the phosphorescence spectrum of aromatic hydrocarbons. Phosphorescence spectra in the blue or green regions are generally very intense; in the red or near infrared they are as a rule extremely

the ultraviolet spectrum has been thoroughly investigated, especially for fused polycyclic aromatic hydrocarbons. A red-shift of the ultraviolet absorption is accompanied by a displacement of the phosphorescence spectrum towards longer wavelengths. Since the lowest triplet state has the classification ^{3}La, *i.e.* is coupled with the para-band [*], the positions of the para-absorption and the phosphorescence transition are related. For hydrocarbons with more than five fused benzene nuclei, the difference of the 0, 0 bands [cm^{-1}] of para-absorption and phosphorescence spectrum is constant to a close approximation (10000–11000 cm^{-1}). With hydrocarbons containing less than 5 nuclei the positional difference is found to vary with the size of the molecule [19]. Fig. 2 shows this difference plotted

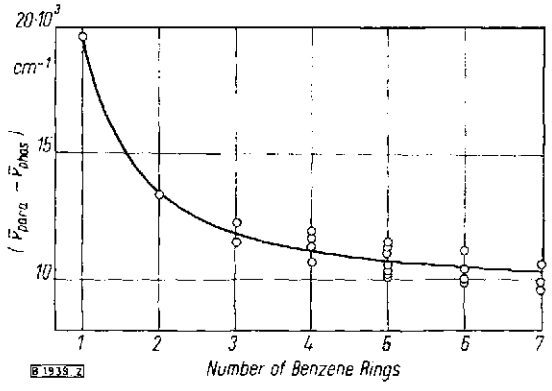

Fig. 2. Relationship between the wavenumber difference of 0,0-bands of the para-absorption and phosphorescence spectrum of aromatic hydrocarbons and the number of fused benzene rings.

against the number of the benzene rings in the hydrocarbons. It is therefore possible to predict the position of the phosphorescence spectrum of an aromatic hydrocarbon from its ultraviolet spectrum with fair accuracy.

Typical phosphorescence spectra (phenanthrene and carbazole) are shown in Fig. 3. In general, the spectra exhibit a symmetry-allowed structure with a strong 0,0-band. Only in a few cases (*e.g.* benzene [20]) is there a symmetry prohibition in addition to the spin prohibition. Position and vibrational structure of the phosphorescence spectra of aromatic hydrocarbons depend only little on the solvent [21].

Phosphorimetric analysis demands a knowledge of the spectra, decay times, and quantum yields of the phosphorescent emissions of the relevant compounds. Complete phosphorescence spectra of polycyclic aromatic hydrocarbons and data concerning the positions of the phosphorescence maxima are given in several publi-

cations [10, 16, 22]. Quantum yields and lifetimes have been measured by various authors (see Tables 1 and 2). The phosphorescence spectra of numerous derivatives of aromatic hydrocarbons are known: methyl homologues [23], halogen compounds [10, 24], phenols [10], nitro compounds [10, 25], amino compounds [10, 25], carboxylic acids [10], *etc.* Among the heterocycles, the phosphorescence spectra particularly of aza-hydrocarbons [26] and of carbazoles [27] have been investigated in some detail; data on sulfur and oxygen heterocycles are also available [28]. Aromatic amino-acids are examples of phosphorescent, biologically important compounds [29].

C. Experimental Details

I. Instrumental

Devices for the measurement of phosphorescence spectra consist of an excitation light source, a low-temperature cell, a phosphoroscope, and a spectrograph or spectrometer. Several constructions have been described [6, 10, 12, 24, 30]. In order to obtain particularly

well-resolved spectra, or for the measurement of extremely weak phosphorescences, spectrographs are the most suitable devices. For routine phosphorimetric analysis, *e.g.* in a control laboratory, recording spectrometers are the recommended instruments. We used an instrument of the latter type, *viz.* an Aminco-Keirs Spectrophosphorimeter [*]. Its construction is shown schematically in Fig. 4.

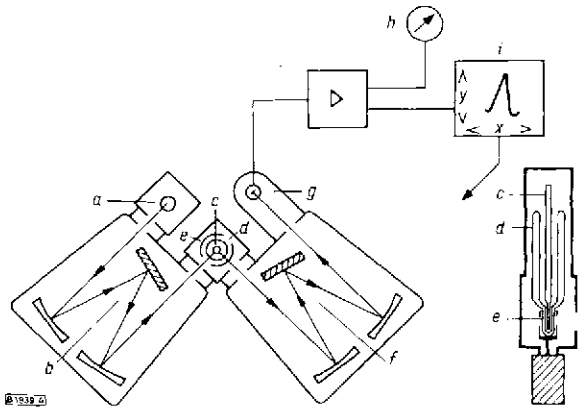

Fig. 4. Schematic view of the Aminco-Keirs spectrophosphorimeter. Right: side-view of the sample cell arrangement.

a = xenon lamp, *b* = grating monochromator (200—800 mμ), *c* = quartz sample cell, *d* = quartz Dewar vessel, *e* = phosphoroscope (eliminates scattered light and fluorescence), *f* = grating monochromator (200—800 mμ), *g* = photomultiplier, *h* = galvanometer, *i* = recorder.

The resulting curves can be evaluated with the aid of calibration measurements on fluorescence standards or light sources of known energy distribution in the form of energy spectra (quantum spectra) [31]. In general, however, this is not necessary for analytical purposes.

Frequently, the knowledge of the phosphorescence lifetime τ of a compound is useful. Phosphorescence lifetimes can be readily determined with the Aminco-Keirs instrument or similar arrangements. For this purpose, the phosphorescence excitation is interrupted, and the change in the intensity of a suitable band of the phosphorescence spectrum is directly recorded as a function of time. An exponential fall in intensity is obtained. To determine τ, the logarithm of the intensity is plotted against time. The slope of the resulting straight line is $2.303\,\tau$.

The two-coordinate recorder fitted with a time base, supplied with the instrument, can measure lifetimes down to about 0.5 sec. For more rapidly decaying phosphorescences, an oscillograph must be employed. The screen picture is conveniently photographed with a Polaroid camera. The reproducibility of the determination of τ (using the two-coordinate recorder) is about 5 %, as found by us in numerous measurements.

II. Solvents

For phosphorescence spectroscopy, solvents or solvent mixtures are required which at low temperature (liquid nitrogen or liquid air) set to a glass, *i.e.* do not crystallize or fracture. Clearly, the solvents used should have no marked intrinsic phosphorescence. The mixture

Table 3. Solvents for phosphorescence spectroscopy [36].

Components	Volume ratio
EPA/chloroform	12:1
Triethylamine/ether/n-pentane	2:5:5
n-Pentane/n-heptane	1:1
Methylcyclohexane/n-pentane	4:1 or 3:2
Di-n-propyl ether/isopentane [30c]	3:1

ethanol/isopentane/ether (2:5:5 by volume) (EPA) [10] is most frequently used. This solvent was employed for all measurements in this work. Other solvent mixtures which are potentially useful for phosphorescence spectra are shown in Table 3. Liquid nitrogen (−196 °C) was used as the coolant in all measurements.

III. Identification of Compounds and Determination of Purity

The phosphorescence spectrum and the mean decay time of the phosphorescence are unique for a given substance, and can therefore be used for identification purposes, similarly to ultraviolet or fluorescence spectra. Identification of individual phosphorescent substances in mixtures is frequently successful provided the phosphorescence spectra are sufficiently different. The choice of exciting wavelength is simplified by the fact that phosphorescence intensity increases with the intensity of absorption at the exciting wavelength. When a mixture is irradiated with a wavelength at which one of the components absorbs appreciably more strongly than the others, predominantly the phosphorescence spectrum of this substance will be obtained. Excitation of phosphorescence of the mixture successively with several wavelengths thus makes it possible to obtain the spectra of the individual components more or less free from interference, provided the ultraviolet spectra of the components present show adequate differences. Recognition of individual components in mixtures is made easier by the fact that the phosphorescence quantum yields of the substances present are generally unequal. For the identification of individual components the lifetimes can be utilized in addition to the spectra, as will be shown later.

To test the purity of a phosphorescent substance, its observed spectrum is compared with its known spectrum in the pure state. This spectrum must be independent of the exciting wavelengths. A frequently useful criterion of purity is the mean decay time. A pure substance alone will show a straight-line plot of log intensity against time. With mixtures, a curved plot is obtained

[36] *J. D. Winefordner* and *P. A. St. John,* Analytic. Chem. *35,* 2211 (1963).

since several decay processes with different rates are superimposed.

Often the impurities in a substance exhibit intense phosphorescence while the substance itself does not phosphoresce or exhibits intensities too low to be measured. In aromatic hydrocarbons it is generally just these impurities which cannot be recognized in the ultraviolet spectrum, because of the superposition of the main component. In this respect, ultraviolet and phosphorescence spectroscopy form excellent complementary methods of testing for purity. Limits of detection of strongly phosphorescent substances are roughly of the same order of magnitude as for strongly fluorescent compounds. Examples are given in Table 4. The values were obtained with the Aminco-Keirs Spectrophosphorimeter at a spectral resolution adequate for the quantitative determination of the compounds. The limits of detection were set largely by the intrinsic phosphorescence of the solvent (EPA, American Instr. Corp.) and the noise in the instrument.

Table 4. Limits of detection by phosphorimetric analysis.

Compound	Excitation wavelength [mμ]	Key band [mμ]	Limit of detection [g/ml]
Phenanthrene	290	500	10^{-8}
Triphenylene	258	463	10^{-9}
1,2-Benzopyrene	332	540	10^{-7}
Carbazole	290	408	10^{-8}
Benzil	285	505	10^{-7}

An interesting method of testing the purity of aromatic and heterocyclic compounds is provided by solid-state spectroscopy. On the basis of theoretical work [32] it can be assumed that unsaturated organic compounds – apart from a few exceptions such as benzophenone – will show no phosphorescence in the crystalline state (even at very low temperatures) when absolutely pure.

It seems therefore that phosphorescence observed in crystalline aromatic and heterocyclic compounds is usually due to impurities. The limits of detection of phosphorescent impurities are extremely low, and the absence of crystal phosphorescence may in many cases well be the most sensitive criterion of purity known today.

IV. Quantitative Determination of Compounds

The basic equations of fluorimetry can be applied to phosphorescence spectroscopy without modification. Phosphorescence intensity P and concentration c are related by the equation [6]:

$$P = \text{const}\ (2.30\ \varepsilon cd - 2.65\ \varepsilon^2 c^2 d^2 + 2.04\ \varepsilon^3 c^3 d^3 - \ldots)$$

where ε is the extinction coefficient of the compound, and d the thickness of the cell. For extinctions $E < 0.01$ ($E = \varepsilon cd$) the higher terms of the series can be neglected, and one obtains:

$$P' = \text{const}' \cdot c \qquad (\text{const}' = \text{const} \cdot 2.30\ \varepsilon d)$$

In sufficiently dilute solutions there is therefore a linear relation between phosphorescence intensity and concentration.

For aromatic hydrocarbons, with irradiation in the relatively low-intensity α-bands ($\varepsilon = 10^2 - 10^3$ l mole^{-1} cm^{-1}) and using the cells of the Amino-Keirs spectrophosphorimeter (d about 0.1 cm) the straight-line region is obtained with dilutions of $c < 10^{-3}$ mole/l. With irradiation in the more intense para and β-bands ($\varepsilon = 10^4 - 10^5$), higher dilutions are necessary ($< 10^{-5}$ mole/l).

The phosphorescence intensity of a solution under otherwise identical conditions depends on the excitation intensity as well as on the concentration of the dissolved, phosphorescent substance. In solutions of a pure substance A, the exciting radiation is absorbed only by this material. When other absorbing substances B, C, D, *etc.*, are present, absorbing part of the exciting radiation, the full intensity is no longer available for the excitation of A. For the same concentration of A, the phosphorescence of A in the presence of B, C, D, *etc.* is therefore less than in a solution of the pure material. This effect is more marked the smaller the ratio of the extinction of A to those of B, C, D, *etc.* at the exciting wavelength, and the higher the concentrations.

For a phosphorimetric analysis, it is initially necessary to construct a phosphorescence intensity *vs.* concentration calibration curve with solutions of known concentrations of the component to be determined. For this purpose, both the key band and the exciting wavelength must be matched to the relevant problem. Where the compounds present in addition to the component to be analysed are known, and where they are available in pure form, they can be added in known amounts during the construction of the calibration curve to eliminate the above effect of a partial absorption of the exciting radiation. This is no longer possible for multicomponent mixtures or where the qualitative composition of the samples is not completely established. In such cases it is necessary to work with dilute samples, in which the above effect is negligible. After calibration, the phosphorescence intensity of the key band in the sample is determined under identical conditions and the relevant concentration is read from the calibration curve. Two examples of such analyses are described below.

The mean relative error of phosphorimetric analyses with present techniques is 5–10 %. This is adequate for many applications, *e.g.* for the determination of impurities in a relatively pure product. Of the possible factors which can affect the reproducibility of determination with the Aminco-Keirs Spectrophosphorimeter, we have found that fluctuations in the lamp brightness, noise in the recording section, and deviations in the adjustment of wavelength have only a slight effect. The greatest error is introduced by non-reproducible changes in the position of the sample cell from one experiment to the next. An improvement in the sample tube holder, which we are attempting, should provide a remedy. The sensitivity of phosphorimetric analyses to such influences is smaller the higher the measured intensities.

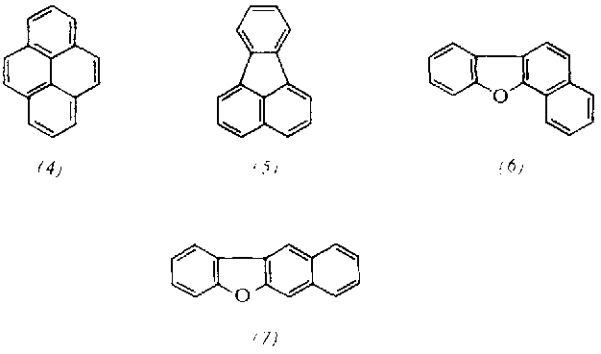
The few results of phosphorimetric analyses so far available already predict a wide field of application for this method. In connection with the present work, special experience in the phosphorimetry of polynuclear aromatic hydrocarbons has been gathered. For this reason, the question of establishing in which cases the phosphorimetric method of analysis can be successfully employed, and where it offers advantages over other methods, will be discussed specially for this class of compounds. In general, weakly fluorescent compounds exhibit strong phosphorescence, and *vice versa*. Therefore weakly fluorescing aromatic compounds such as triphenylene can be determined by phosphorimetry with greater accuracy and with lower limits of detection than by

fluorimetry. In most cases the phosphorescence spectrum of an aromatic hydrocarbon is much more characteristic than its fluorescence spectrum and therefore more suitable for the identification of the compound.

In analyses of mixtures of polynuclear aromatic hydrocarbons, the ultraviolet spectrum is particularly suitable for the identification and determination of the longest-wavelength absorbing components. Thus, for example, very small quantities of anthracene can be determined in phenanthrene. In the short-wavelength region, the ultraviolet spectra of all the substances present in the mixture overlap substantially, and unambiguous identification and quantitative determination of hydrocarbons absorbing at low wavelengths is seldom possible in complex mixtures. Since these hydrocarbons are often strongly phosphorescent, phosphorimetry is particularly suitable for the identification and determination of these components in mixtures. For example, as little as about 50 ppm of phenanthrene can be determined in anthracene, while the ultraviolet-spectroscopic determination encounters difficulties at appreciably higher concentrations. To summarize, it is found that ultraviolet, fluorescence, and phosphorescence spectroscopy are excellent complementary techniques for the analysis of aromatic hydrocarbons. According to the particular problem involved, one or another of the methods is particularly suitable, and offers appreciable advantages over the others.

impurities, the conditions for study by phosphorescence spectroscopy were particularly favorable.

In the ultraviolet spectrum, a single redundant band was found at 288 mμ in addition to those of pyrene.



(4) *(5)* *(6)* *(7)*

This was possibly due to fluoranthene *(5)*. The measurement of phosphorescence on irradiation into a strong absorption band of fluoranthene (360 mμ) gave the almost undisturbed phosphorescence spectrum of this compound. Fig. 5 shows the impurity spectrum (curve 1) next to that of pure fluoranthene (curve 2). As a check, the phosphorescence lifetimes of the pyrene-accompanying substance and of pure fluoranthene were measured (using the 545 mμ band). They agreed (0.8 and 0.9 sec respectively) within the experimental error. Measurement of the phosphorescence of technical

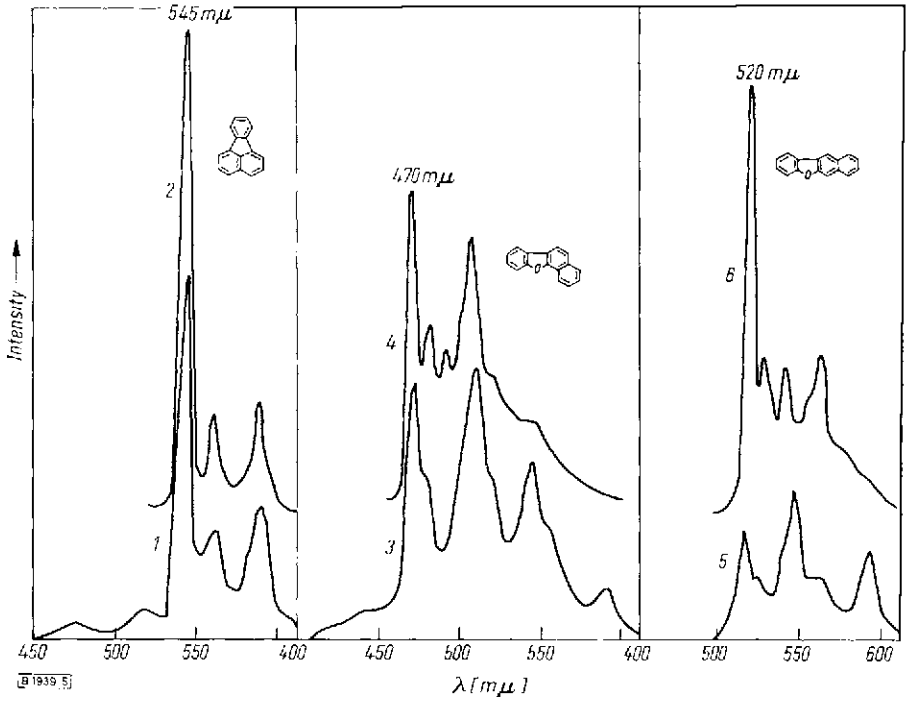


Fig. 5. Phosphorescence spectra (in EPA, 77°K) of technical pyrene on excitation with 360 mμ (curve 1), 290 mμ (curve 3) and 340 mμ (curve 5) radiation and of pure fluoranthene (curve 2), benzo[*b*]naphtho-[1,2-*d*]furan (curve 4) and benzo[*b*]naphtho[2,3-d]furan (curve 6).

D. Some Analytical Applications in Coal-Tar Chemistry

I. Identification of Impurities in Technical Pyrene

Technical (about 95%) pyrene *(4)* was investigated by ultraviolet and phosphorescence spectroscopy to determine the nature of the impurities. Since pyrene itself is appreciably less intensely phosphorescent than its pyrene on irradiation at 290 mμ gave spectrum 3, which belongs to a further impurity. Comparison with the phosphorescence spectra of several tar constituents in the pyrene boiling-point range makes it very likely that this impurity is benzo[*b*]naphtho[1,2-*d*]furan *(6)* (phosphorescence spectrum 4 in Fig. 5). For confirmation, the

lifetimes of both pure *(6)* and of the pyrene impurity were again measured, and agreed within experimental error (3.9 and 4.0 sec respectively). Finally, excitation of the phosphorescence of technical pyrene with 340 mμ radiation gave a third impurity spectrum (curve 5). Since the long-wavelength part of the spectrum is overlapped by that of fluoranthene, only the first two bands could be utilized for identification purposes. It seems probable that this impurity is benzo[*b*]naphtho-[2,3-*d*]furan (β-brazan) *(7)*. The spectrum of the pure substance *(7)* (curve 6) is reproduced for comparison.

To summarize, study of the phosphorescence spectra of technical pyrene *(4)* unambiguously revealed two impurities [fluoranthene *(5)*, benzo[*b*]naphto[1,2-*d*]-furan *(6)*] and very probably a third substance, benzo-[*b*]naphto[2,3-*d*]furan *(7)*. In contrast, ultraviolet investigation gave only a weak indication of a single impurity (fluoranthene).

II. Quantitative Determination of Impurities in Purified Anthracene

Anthracene obtained from coal tar (purity > 97 %) contains carbazole and phenanthrene as principal impurities. Since the ultraviolet spectrum of the main constituent overlaps the spectra of carbazole and phenanthrene over the entire spectral region, their determination by this method is very difficult. In contrast, carbazole and phenanthrene exhibit intense phosphorescence in the blue and green spectral regions, respectively, whereas anthracene phosphoresces very weakly in the red (680 mμ) [10, 33]. Conditions for the phosphorimetric determination of these impurities in pure anthracene are therefore ideal.

The phosphorescence spectra of carbazole and phenanthrene are shown in Fig. 3. The shortest-wavelength carbazole phosphorescence band at 408 mμ is a suitable key band, while for phenanthrene the one at 500 mμ, which is only little overlapped by the carbazole spectrum, can be used. Trial analyses show that, with the proportions encountered in anthracene, no allowance need be made for the carbazole phosphorescence at 500 mμ.

The spectra in Fig. 3 were measured with small slit widths and correspondingly high resolution. For the determination of small concentrations of carbazole and phenanthrene, a lower resolution is acceptable for the sake of increased sensitivity. The following selection of slit widths has proved suitable when the Aminco-Keirs instrument is used for quantitative analysis (see Fig. 4): exit slit of the excitation monochromator *b*: 3 mm; entrance and exit slits of the phosphoroscope housing: 3 and 2 mm, respectively; entrance and exit slits of the emission monochromator *f*: 3 and 2 mm, respectively.

The excitation wavelength for the carbazole and phenanthrene determination is 290 mμ. At this wavelength the extinction coefficients of carbazole and phenanthrene are greater than that of anthracene by a factor of about 40. The concentration of anthracene in the samples is about 50–100 times greater than that of the impurities, so that the extinctions of the three components are of comparable magnitude. Consequently an appreciable part of the exciting radiation is absorbed by the anthracene. It is therefore necessary for the calibration solutions used to contain anthracene as well as carbazole and phenanthrene, in concentrations which approximately match the actual conditions.

To carry out the analysis, calibration solutions containing 0.1–2 % each of phenanthrene and carbazole in EPA are initially prepared from 0.002 M stock solutions. The relative phosphorescence intensities of the key band are then measured, suitably by excitation with 290 mμ radiation. These intensities may then be plotted against concentration (directly as % of the weight taken) to give the calibration curve. Fig. 6 shows such calibration curves for the range 0.1–2 % phenanthrene or carbazole in anthracene. This is followed by a measurement of the relative intensities of the key bands of a

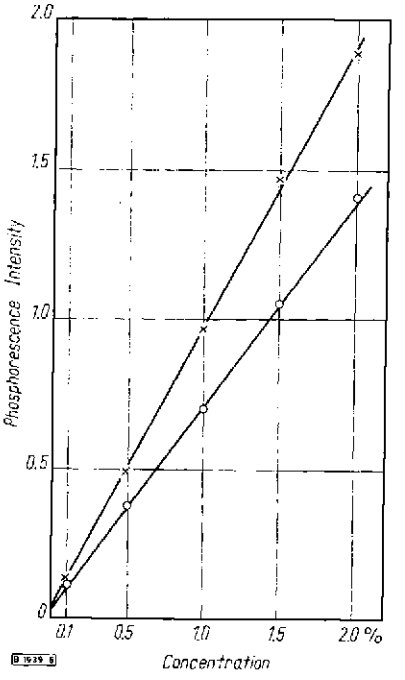

Fig. 6. Phosphorescence calibration curves for the determination of carbazole (×) and phenanthrene (○) in pure anthracene.

likewise 0.002 M solution in EPA of the material to be investigated and the reading-off of the corresponding percentage concentrations of phenanthrene and carbazole.

In highly purified coal-tar anthracene, the impurities amount to less than 0.1 %. As little as about 0.005 % of carbazole and of phenanthrene can be determined by the above procedure. Calibration curves for the range 0.1–0.005 % must be constructed. The required solutions are suitably prepared from 0.002 M anthracene and 2×10^{-5} M carbazole and phenanthrene. Obviously, the carbazole and phenanthrene contents of the anthracene used for the calibration curve must lie below the limit of detection.

Table 5 shows the results of a series of test analyses. The mixtures investigated were prepared from very pure anthracene, carbazole, and phenanthrene, and the anthracene content of the solutions was adjusted to between 99.6 and 96 %. To test the reproducibility of the method, several anthracene samples were each analysed six times for their carbazole and phenanthrene contents. The results are shown in Table 6.

As expected, the mean relative error of the method depends on the concentrations measured. At 0.1 % carbazole or phenanthrene it is about 10 %; at 0.005 % carbazole or phenanthrene it amounts to about 50 %. The procedure is superior to chemical methods of

analysis in regard to sensitivity and precision, and is probably equivalent to gas-chromatographic methods[34].

III. Determination of Triphenylene in Tar Fractions

The number of compounds which occur in coal tar is estimated at about 10000[35]. Evidently even narrow cuts from coal tar still contain a large number of compounds. The determination of individual compounds in coal-tar fractions is therefore often extremely difficult.

Quantitative determination of small amounts of triphenylene in relatively wide cuts was of interest in connection with the processing of higher-boiling tar fractions. While the longest-wavelength absorbing hydrocarbons like tetracene and 1,2-benzanthracene in such fractions can be readily determined in the ultraviolet region, triphenylene, which absorbs at shorter wavelengths, cannot even be detected reliably if present in small concentrations. Gas chromatography is likewise difficult in such cases, because of the overlapping of different constituents, while paper chromatography, which is frequently superior to gas chromatography for the separation and identification of individual hydrocarbons in coal tar fractions, takes longer and is more laborious, (elution of the spots, measurements of the spectra). In contrast, phosphorescence spectroscopy quickly and simply leads to an answer. Triphenylene phosphoresces particularly strongly and has a very characteristic spectrum. When the phosphorescence of a triphenylene-containing coal tar fraction is excited by irradiation in a strong-band region (285 or 258 mμ), the almost undisturbed phosphorescence spectrum of triphenylene is obtained (cf. Fig. 7). Spectrum 1 in Fig. 7 was measured with an excitation at 258 mμ using a tar fraction with boiling range of 470–490 °C. Although this fraction containing largely five-ring compounds contains only about 2 % of triphenylene, its phosphorescence spectrum is substantially identical with that of pure triphenylene (curve 2 in Fig. 7).

For the determination of triphenylene in tar fractions, the intense band at 463 mμ serves as a suitable key band; irradiation with the 258 mμ wavelength, *i.e.* the

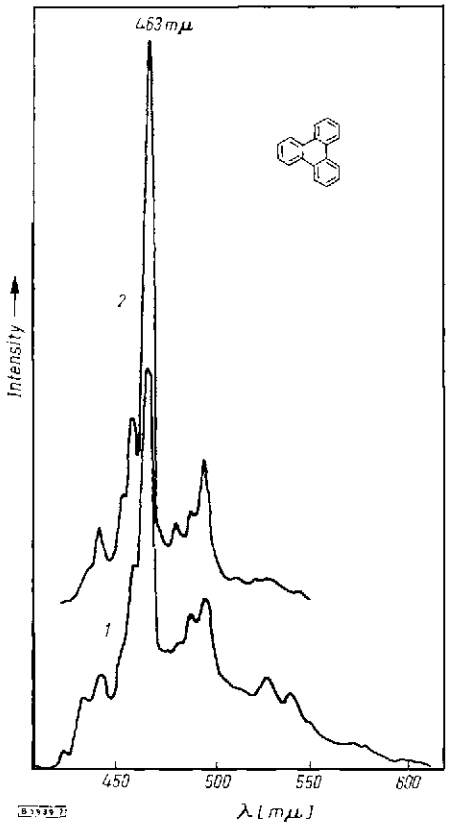

Fig. 7. Phosphorescence spectra (in EPA, 77°K) of a tar fraction containing triphenylene (curve 1) and of pure triphenylene (curve 2)

β-band of triphenylene, is a suitable excitation procedure. In addition to triphenylene, the tar fractions investigated contain numerous other phosphorescing components, but no marked overlapping of the 463 mμ band with other spectra was observed. The partial absorption of excitation radiation by accompanying substances, leading to a weakening of the phosphorescence intensity as compared to calibration solutions of equal concentration, is kept negligibly small by working at concentrations below 10^{-5} mole/l.

Table 7. Phosphorimetric determination of triphenylene in hydrocarbon mixtures.

Thermal Fragmentation and the Determination of the Structure of Organic Compounds [*]

BY PRIV.-DOZ. DR. W. SIMON AND DR. H. GIACOBBO [**]

LABORATORIUM FÜR ORGANISCHE CHEMIE DER EIDGENÖSSISCHEN TECHNISCHEN HOCHSCHULE, ZÜRICH (SWITZERLAND)

A pyrolysis apparatus with high-frequency induction heating has been developed, which, owing to the small dead volume in the pyrolysis zone (≥ 5 μl), can be used for pyrolysis gas chromatography utilizing capillary columns without a sample split system. Thin films of the samples are deposited on ferromagnetic conductors, and can be reproducibly heated in routine operation to an accurately defined temperature (the Curie point) in from 20 to 40 msec. Microgram quantities of natural amino acids can be identified by this method with the aid of standard pyrolysis gas chromatograms. When a thin film of the sample is used on the ferromagnetic conductor, the fragments are closely related to the structure of the original compound.

Introduction

Pyrolysis gas chromatography is used for the qualitative and quantitative analysis of non-volatile organic compounds [1, 2]. The samples are thermally fragmented in a stream of an inert carrier gas, and the reaction products are passed directly into a gas chromatography column where they are separated. The principal methods used for the pyrolysis are the filament method [3–12] and the furnace method [2, 13–18]. In the former the sample is

[*] Lecture delivered at the ACHEMA exhibition in Frankfurt/Main (Germany) on June 24th, 1964 and at the Gas Chromatography Symposium in Basel (Switzerland) on September 21th, 1964. This work was supported by the Schweiz. Nationalfonds zur Förderung der wissenschaftlichen Forschung (Research Project No. 2771).

[**] New address: Gebrüder Sulzer AG., Winterthur (Switzerland).

[1] Reviews on pyrolysis gas chromatography: *J. Dandoy*, Ind. chim. belge *1962*, 355; *Anon:* Pyrolysis-Gas-Chromatography Methods, Supplemental Data Sheet to Bulletin 2382, American Instrument Co., October 1962; *S. G. Perry*, J. Gas-Chromatog. *2*, 54 (1964); *R. W. McKinney*, Pyrolysis-Gas-Chromatography: A Bibliography (1960 to 1963). W.R. Grace & Co., Clarksville 1964.

directly or indirectly brought into contact with a wire situated in a carrier gas stream, and which is rapidly heated by means of an electric current. In the furnace method the pyrolysis is carried out in a heated tube through which carrier gas is flowing. The samples are injected [2, 15, 17], thrown in [19, 20], pushed into the tube in boats [13, 14, 16, 18], or introduced *via* gas-inlet valves [17]. With few exceptions [6, 7, 15–18, 21], the relatively new method of pyrolysis gas chromatography has been studied only in relation to very specific analytical problems. The fundamental relationships are elucidated in only a few papers [7, 10, 17, 22].

Conditions for the Use of Pyrolysis Gas Chromatography

The successful use of pyrolysis gas chromatography in the structural elucidation of organic compounds and in the qualitative and quantitative analysis of mixtures is possible under the following conditions.

a) The fragmentation of the sample must be carried out at such a high dilution, and the fragments must be so quickly stabilized by migration into cooler zones, that no undesirable secondary reactions can occur between the starting materials, between these and the fragments, or between the fragments themselves.

b) The sample must be heated to a constant pyrolysis temperature as quickly and as reproducibly as possible, to ensure that the relative yields of the fragments are not affected by the different reaction rates or mechanisms at different temperatures.

c) The pyrolysis temperature must not be too high, since uncharacteristic fragments (methane, carbon, hydrogen) may otherwise be formed [23–25].

If conditions a) to c) are satisfied, the fragments should be closely related to the structure of the original compound, and the pyrolysis chromatogram of a mixture can be deduced by adding together the signals of the pyrolysis chromatograms of the individual components.

The Pyrolysis Apparatus

A pyrolysis method which combines the advantages of the filament and furnace methods without possessing any of their disadvantages consists in depositing a thin film of the sample on a ferromagnetic conductor, which is heated in a stream of carrier gas by high-frequency induction heating [26–28]. Fig. 1 shows the design of the pyrolysis apparatus, which may be connected to any gas chromatograph.

The power consumption, N [watt/cm], per unit length of a conductor located along the axis of the high-frequency induction coil [29] is

$$N = 2\pi\sqrt{2}\,H^2\rho\frac{r}{s}F(r,s) \qquad (1)$$

where

$$s = \sqrt{\frac{\rho}{\pi\mu_0\mu_r\nu}} \qquad (2)$$

H [oersted] is the magnetic field inside the coil; r [cm] is the radius of the conductor; ρ [Ω cm] is the specific resistance of the conductor; s [cm] is the skin depth of the eddy current; F is a function of s and r; $\mu_0 = 4\pi\times10^{-9}$ V sec/A cm is the permeability of free space; μ_r is the relative permeability ($\gg 1$ for ferromagnetic conductors below the Curie temperature, ~ 1 for non-ferromagnetic conductors); ν [sec^{-1}] is the frequency.

Values of F(s,r) have been tabulated as a function of r/s [29,30]. The relative permeability μ_r of a ferromagnetic conductor suddenly drops when it is heated to the Curie

point [31]. This results in a sudden increase in the skin depth s [cf. Eq. (2)], so that r/s and F(s,r) become smaller, and the heating power supplied to the conductor decreases approximately with the fourth power of the temperature [cf. Eq. (1)].

To illustrate this, Table 1 [32] shows the values of the product ρF(r,s) r/s for various temperatures and radii of the ferromagnetic conductor. This product may be taken as a measure of the heating power supplied. The results are plotted in Fig. 2; if the frequency and the radius of the conductor are suitably chosen, the heating power supplied to the wire decreases very rapidly to a minute fraction when the Curie point is reached.

In order to obtain the greatest possible rate of decrease in power at the Curie point, the radius and the frequency must be matched in such a way that the ratio r/s > 2.5 below the Curie point, but is as small as possible above the Curie point [29, 30]. With a generator (Fig. 3) working at 0.45 Mc/s and equipped with two T 350–1 transmitter triodes (Brown, Boveri & Cie.AG. Baden, Switzerland) having an output of 0.7 kW each, the ferromagnetic conductors listed in Table 2 give the heating curves shown in Fig. 4. For example, iron is heated in approximately 20 msec to a constant temperature which, since it is governed by a constant of the material (the Curie point), is accurately reproducible. Thus from 1 kg of wire, it is possible to produce some

obtained with capillary columns of diameter 0.25 mm without a sample split system (cf. Fig. 5).

Pyrolysis of Sodium Benzoate

As can be seen from Fig. 6, the pyrolysis of 28 ± 5 µg of benzoic acid (deposited from a 5 % solution in 1 N NaOH onto the ferromagnetic conductor [Fe(Zn) 0.6×20 mm] and dried in air at 25 °C) under similar conditions to those described above yields mainly benzene, accompanied by small quantities of substances formed in unwanted secondary reactions. This is not

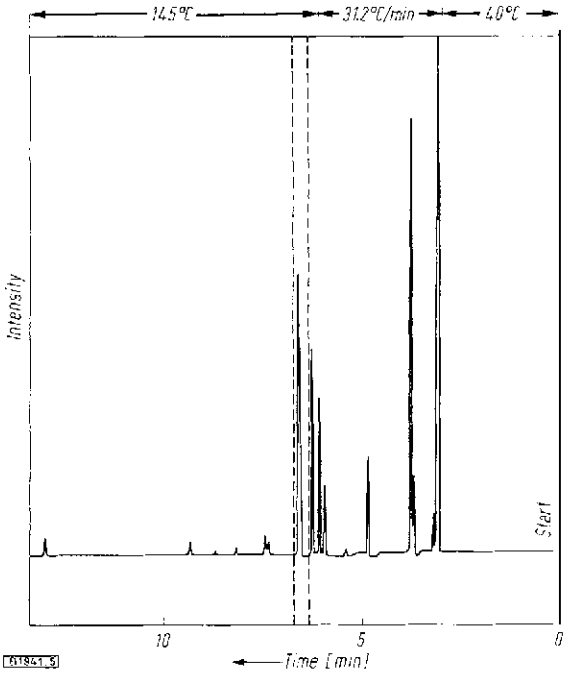

Fig. 5. Temperature-programmed pyrolysis gas chromatogram (5 µg of methionine deposited from a 2 % solution in 1N NaOH) obtained with a capillary column without sample split system. Ferromagnetic conductor: Fe(Zn) (cf. Table 2); gas chromatograph: Perkin-Elmer 226; Golay column K 1540 (150'; 0.01"), 1.2 ml of N_2/min; 3 min at 40 °C; progr. 31.2 °/min; 145 °C. Between the two broken lines the sensitivity was decreased by a factor of 5.

surprising, since even if the distribution of the sample on the surface of the wire were uniform, the thickness of the film would be of the order of 1000 molecules [*].

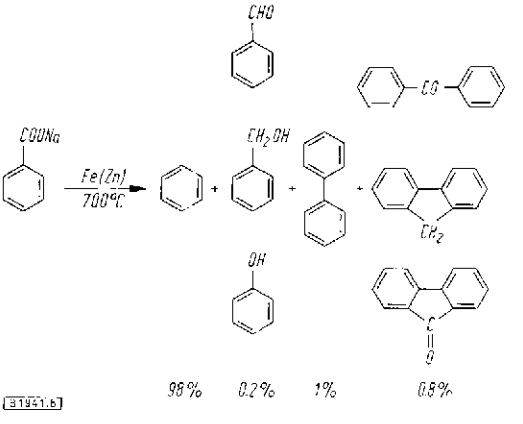

Fig. 6. Fragmentation of sodium benzoate on galvanized iron wire.

The probability for such secondary reactions decreases with decreasing sample size. Thus the relative yield of biphenyl decreases as the quantity of sodium benzoate on the ferromagnetic wire is reduced (cf. Fig. 7). The decrease in the yield of benzene with increasing sample size is probably due to the fact that the hydrogen atom used to form benzene from the benzoate presumably comes from the water retained by excess NaOH on the surface of the conductor after evaporation of the solvent. The relative amount of water present decreases with increasing sample size.

[*] Assuming an area of the of molecule 10×6 Å²; dimensions of the wire: 0.6×20 mm; size of sample: 10 µg, molecular weight: 100.

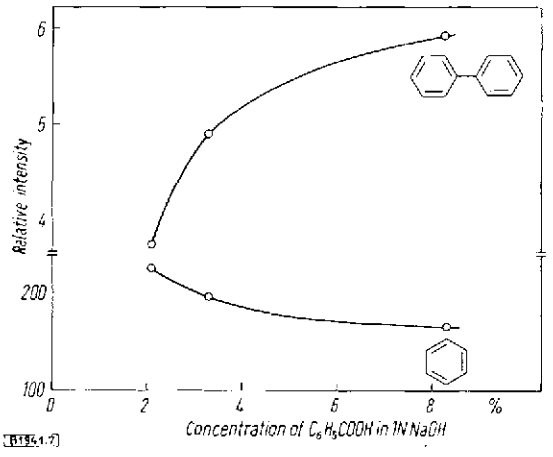

Fig. 7. Dependence of the relative peak heights on the sample size in the pyrolysis of sodium benzoate.

It can be seen from Fig. 8 that the fragmentation is strongly affected by the radius of the metal ion in the salt. This dependence indicates that both simple fragmentations (formation of benzaldehyde) and undesirable secondary reactions (formation of biphenyl) take place in the vicinity of the solid on the surface of the wire.

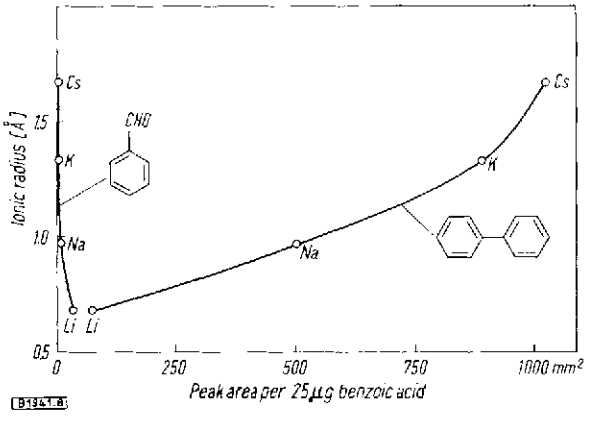

Fig. 8. Yields of biphenyl and of benzaldehyde (expressed as the area of the peak/25 µg of benzoic acid) in the pyrolysis of benzoates, as a function of the cation radius [Å].

Pyrolysis of Amino Acids

For the elucidation of the structures of organic compounds by pyrolysis gas chromatography, it is desirable that the structure of the fragments is closely related to that of the starting material. As expected, this is the case when thin films of the sample are used. The fragmentations of the sodium salts of phenylalanine and of proline, for instance, lead to the products shown in Fig. 9, provided that the salts are deposited on the ferromagnetic conductor as a roughly monomolecular layer [28].

Contrary to *Úlehla*'s opinion [11], naturally occurring amino acids can be identified in samples of about 3 µg by their pyrolysis chromatograms (cf. Fig. 10). As can be shown by chromatography on stationary phases of various polarities, fragments with the same retention data in Fig. 10 are not necessarily indentical.

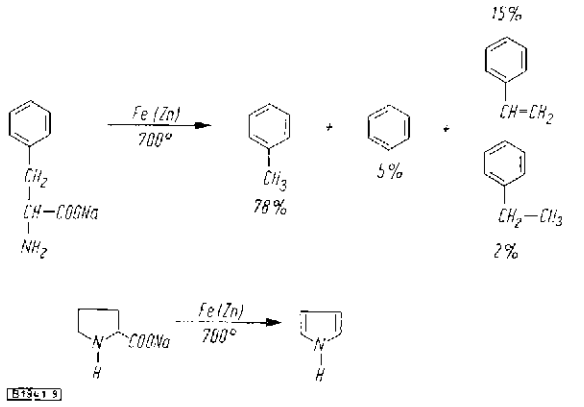

Fig. 9. Fragmentation of the sodium salts of phenylalanine and of proline on a galvanized iron wire.

The fragments found in the pyrolysis of amino acids are also formed in the fragmentation of the corresponding peptides [6, 7, 11, 27, 33] (cf. Fig. 11). However, the relative intensities of the signals seem to be affected by the peptide linkage. The weak signals observed in the pyrolysis of prolylphenylalanine (Fig. 11A), but which are absent in the pyrolysis chromatogram of a 1:1 mixture of proline and phenylalanine (Fig. 11B), are probably due to impurities in the dipeptide.

Extreme Values of the Pressure Coefficient of Viscosity [*]

BY PROF. DR. E. KUSS

INSTITUT FÜR ERDÖLFORSCHUNG, HANNOVER (GERMANY)

The pressure coefficients of viscosity of hydrocarbons and ethers containing two to four phenyl groups linked either directly, via methylene bridges, or via $CH(CH_3)$ bridges, were studied with a view to elucidating the reason for the extreme viscosity-pressure behavior of certain mineral oils. Measurements were made in the range of 1 to 2000 atm at 25, 40, 60, and 80 °C. The results show the existence of a simple relationship between molecular structure and viscosity-pressure coefficient, and suggest applications in control engineering and lubrication technology.

A. Statement of Problem

The viscosity of a liquid generally increases exponentially with pressure [1]. Thus as a first approximation we may write:

$$\eta_p = \eta_0 e^{\alpha p}$$

The quantity α given by

$$\alpha_t = \frac{1}{\eta_p}\left(\frac{\partial \eta_p}{\partial p}\right)_t$$

can then be used to characterize the dependence of the viscosity of the substance on pressure.

On this basis the viscosity-pressure behavior of all liquids is qualitatively the same; quantitatively, however there are substantial differences between various types of substances. Thus for simple substances with low molecular weights, the viscosity at 2000 atm is 3 to 7 times as great as at atmospheric pressure, whereas the corresponding factors for mineral oils and oil extracts are between 30 and 20000.

This strong dependence of viscosity on pressure and the very different behavior of the various oils is important for technical applications in which the oil is subject to very high local pressures [2–5], as in driving gears. It is therefore desirable to establish the reasons for the extreme pressure-dependence of the viscosities of certain oils. For the examination of technical problems it is also desirable to have available series of defined substances having different viscosities and different viscosity-pressure behavior.

Mineral oils are unsuitable for fundamental research, since the structures of the various oil components are in most cases unknown, and since the behavior with pressure may also be influenced by the complexity of the oil mixture. In order to explain the dependence of the viscosity on pressure, therefore, chemically uniform substances with systematically modified molecular structures were studied. It was found that the pressure coefficient of the viscosity depends on the structural characteristics of the molecule in the following ways [6].

a) *Effect of chain length*: In a homologous series, the absolute viscosity increases with chain length, whereas the pressure coefficient remains constant (except for the lower members of the series). By varying the chain length it is therefore possible, within certain limits, to vary the viscosity without affecting the viscosity-pressure coefficient.

b) *Effect of internal mobility of the molecule*: If ether linkages are built into a long-chain molecule, its internal mobility is increased and the dependence of the viscosity on pressure is substantially decreased. In molecules with very long chains, the various molecular segments move almost independently, like the segments of a caterpillar [7].

c) *Effect of side groups*: The pressure coefficient of viscosity depends strongly on the degree of branching in the molecule. In accordance with the predictions of *Eyring*'s hole theory [8,9], α is considerably increased by the introduction of rigid or bulky side groups.

d) *Effect of functional groups*: The pressure coefficient of viscosity can also be raised by the introduction of certain functional groups (*e.g.* Cl or OH).

With a view to the synthesis of compounds having pressure coefficients of viscosity as high as possible, hydrocarbons and ethers containing two and three phenyl groups per molecule were studied. Since substances containing condensed rings are solid under normal conditions, the investigations were carried out on compounds in which the phenyl groups are linked either by C–C bonds, by methylene bridges, or by $CH(CH_3)$ bridges.

Attempts were then made to further increase the pressure coefficient of viscosity by hydrogenation and by cleavage of the ether linkages, and to pass progressively in this way to substances with extremely high pressure-viscosity coefficients.

B. Experimental Techniques

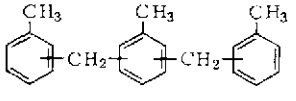
I. The High-Pressure Viscometer

Viscosities were measured at 25, 40, 60, and 80 °C at pressures up to 2000 atm, using a high-pressure falling sphere viscometer described earlier[1].

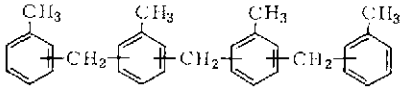
An important improvement was made with respect to the determination of the time of fall. The jacketed induction coils built into the pressure tube and consisting of 2000 turns each are operated at 1.8 kc/s by a two-stage oscillator. The potential differences across the two coils are applied to the two inputs of a bridge amplifier (twice 3 stages), which is detuned when the ball enters one of the coils. This actuates a flip-flop circuit which starts or stops an electronic clock having 6 decimal counters and an output printer[*]. In this way the time of fall can be measured automatically with an accuracy of 0.01 sec.

II. Hydrogenation

Three groups of substances were studied before and after hydrogenation: (a) biphenyl and terphenyls, (b) bis(tolylmethyl)toluene *(1)* and bis(tolylmethyltolyl)methane *(2)*, and (c) substituted methoxybenzenes containing one to three phenyl groups per molecule.



(1)



(2)

Since the pressure coefficient of viscosity is greatly increased on replacement of phenyl groups by cyclohexyl groups, all the substances studied were hydrogenated. This adds considerably to the range of pressure coefficients previously covered.

The hydrogenations were carried out in a rocking autoclave[*] under the mildest possible conditions, *i.e.* in cyclohexane solution with 5 % of Pd on $BaSO_4$ as catalyst at 210 to 240 °C (depending on the substance) and 800 atm. The course of the hydrogenation was always followed by infrared spectroscopy. The characteristic bands between 1490 and 1510, at 1600, and in the region between 1700 and 2000 cm^{-1} disappeared completely in every case. The proportion of unhydrogenated substance was therefore much less than 1 %.

III. Ether Cleavage

In the first two groups of substances, *i.e.* bi- and terphenyl and compounds *(1)* and *(2)*, the pressure coefficient of viscosity could only be increased by hydrogenation. In the phenyl methyl ethers, on the other hand, a substantial increase was obtained on conversion of the methoxy to hydroxy groups.

The first method used to cleave the ether linkage was *Zeisel*'s hydrogen iodide method[10]. This method was specially developed for the determination of CH_3O groups, and is not suitable for preparative purpose, particularly for substances containing three phenyl groups per molecule.

The method developed by *Prey*[11] was found to be suitable for use on the preparative scale, even for complex substances. In this method, freshly prepared pyridinium chloride is used instead of hydrogen iodide for the cleavage of the ether. The substance can be completely converted into the desired alcohol and methyl chloride, which is readily distilled off. The pyridine is removed with water.

C. Viscosity-Pressure Isotherms

I. Bicyclohexane and Tercyclohexanes

Since biphenyl and *o*-, *m*-, and *p*-terphenyl are solid under normal conditions, only the viscosity-pressure isotherms of the hydrogenated substances can be given (Fig. 1). The data for *p*-tercyclohexane have been omitted, since this substance occurs as a mixture of two isomers with very different melting points and unknown difference in conformation.

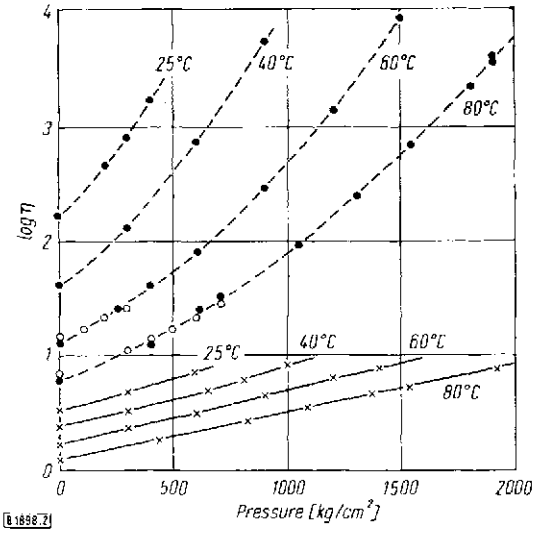


Fig. 1. Viscosity-pressure isotherms of bicyclohexane and tercyclohexanes (η in centipoise).

× Bicyclohexane (m.p. 2.7°C); ● *o*-tercyclohexane (m.p. 38.5–39.0°C); ○ *m*-tercyclohexane (m.p. 66°C).

The curves terminate where the substances solidify.

In the plot of the logarithm of viscosity against pressure (Fig. 1), bicyclohexane gives linear isotherms in accordance with the exponential law. The viscosity changes by a factor of 7 to 10, depending on the temperature, between

[11] *V. Prey*, Ber. dtsch. Chem. Ges. *74*, 1219 (1941); *75*, 350, 445 (1942).

1 and 2000 atm. The pressure coefficient of viscosity increases markedly if the number of cyclohexyl groups per molecule is increased, *i.e.* on passing to the tercyclohexanes.

The absolute value and the pressure-dependence of the viscosity are practically identical for *o*- and *m*-tercyclohexanes. Owing to the high melting point (66 °C) of *m*-tercyclohexane, however, only parts of the 60 °C and 80 °C isotherms can be given. Even at these temperatures *m*-tercyclohexane solidifies at relatively low pressures; consequently, the highest viscosity reached is more than two orders of magnitude lower than that of *o*-tercyclohexane, for which the measurements could be extended well into the supercooled range. At 80 °C the viscosity changes by a factor of 750 between 1 and 2000 atm.

Another striking feature of the viscosity-pressure isotherms of tercyclohexanes is that they are convex towards the pressure axis. Thus the pressure coefficient α increases with pressure. This behavior is observed only for substances with several rings in the molecule.

II. Bis(tolylmethyl)toluene and Bis(tolylmethyltolyl)methane

These substances, which are used as heating and cooling liquids over a very wide temperature range, can be prepared from technical (chloromethyl)toluene and toluene [12]. The *o*-, *m*-, and *p*-isomers were not separated, but were studied as a mixture. In contrast to bi- and tercyclohexanes (Fig. 1), however, the viscosity behavior of both the hydrogenated and the unhydrogenated substances can be studied in this case, since they are liquids under normal conditions.

The effects of both chain length and hydrogenation are clearly visible in Fig. 2. The pressure coefficients α are given for a reference temperature of 40 °C to permit comparisons with other groups of substances. The increase in the chain length of both the hydrogenated and the unhydrogenated substances leads to an increase of 1.6×10^{-3} atm^{-1} in α_{40}, whereas hydrogenation of both starting substances gives an increase of about 2.2×10^{-3}. It was also confirmed that, as had been observed previously [12a], hydrogenation of the phenyl groups leads to a decrease in density and to a considerable increase in the viscosity at atmospheric pressure.

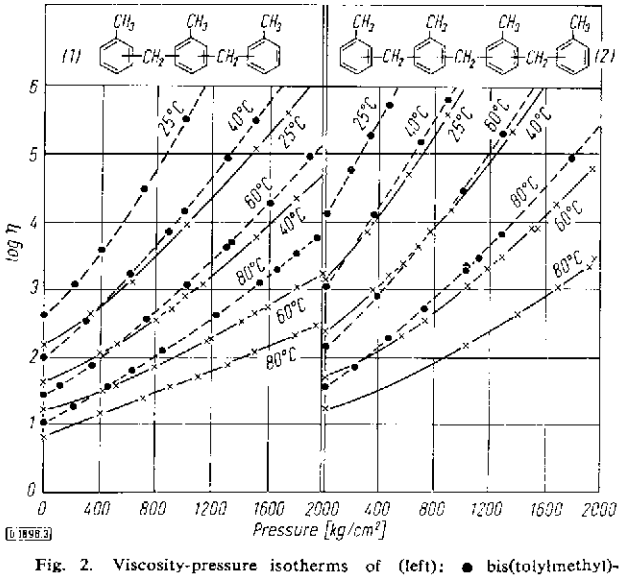

Fig. 2. Viscosity-pressure isotherms of (left): ● bis(tolylmethyl)-toluene *(1)* ($\alpha_{40} = 3.54\times10^{-3}$ atm^{-1}), × perhydro-*(1)* ($\alpha_{40} = 5.77\times10^{-3}$); (right): ● bis(tolylmethyltolyl)methane *(2)* ($\alpha_{40} = 5.18\times10^{-3}$), × perhydro-*(2)* ($\alpha_{40} = 7.35\times10^{-3}$). The α_{40} values refer to a pressure of 1000 atm.

III. Phenylethylphenols and Phenylethylanisoles

By far the widest range of pressure coefficient is found in a group of substituted phenols and anisoles [13]. Data for three anisoles are shown in Fig. 3.

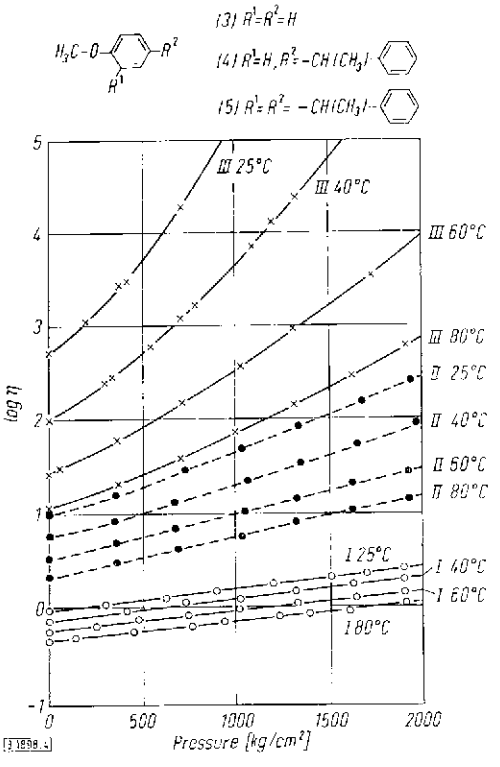

Fig. 3. Viscosity-pressure isotherms of: I anisole *(3)*, II 4-(1-phenylethyl) anisole *(4)*, and III 2,4-bis-(1-phenylethyl)anisole *(5)*.

In the case of anisole (curve I in Fig. 3), $\alpha_{25} = 0.55\times10^{-3}$ atm^{-1}, *i.e.* the viscosity at 2000 atm is 3 times that at 1 atm. Thus $\alpha\times10^3$ falls in the range 0.5–1.0 given above for simple substances with low molecular weights.

To a first approximation, the pressure coefficients are given by:

$$\alpha = \Delta V/RT$$

where ΔV is the local increase in volume required to permit the movement of the molecules past one another in viscous flow. In agreement with this interpretation, α decreases by about 15 % between 25 and 80 °C for methoxybenzene.

[12] *W. Glaß*, Erdöl u. Kohle *17*, 118 (1964).

[12a] *E. Kuss*, Z. angew. Physik *7*, 372 (1955).

[13] German Patent Application C 31800 IV c/23c (Dec. 12th, 1963), Chemische Werke Hüls AG.; inventor: *E. Kuss*.

If another phenyl group is now attached to the molecule *via* a $CH(CH_3)$ bridge, ΔV increases and so also does α. In the case of 4-(1-phenylethyl)anisole *(4)*, the viscosity at 2000 atm is 28 times that at 1 atm ($\alpha_{25} = 1.66 \times 10^{-3}$). The normal viscosity is also about one order of magnitude greater than that of anisole. As can be seen from Fig. 3, the isotherms fan out to a greater extent, *i.e.* α is much more dependent on the temperature.

As in simple substances with low molecular weights, by far the highest pressure coefficients are found for substances having bulky groups in the side chain. A high pressure coefficient can be obtained by the introduction of another phenylethyl substituent to form 2,4-bis-(1-phenylethyl)anisole *(5)*. At 25 °C, the viscosity is so high at pressures above 1000 atm that it could no longer be measured. The pressure coefficient is 5.75×10^{-3} atm^{-1}, corresponding to an extrapolated viscosity at 2000 atm of about 10^5 times that at 1 atm. As can be seen from Fig. 3, the isotherms are convex towards the abscissa; thus this compound exhibits the characteristic behavior of substances containing several rings in the molecule, *i.e.* α increases with pressure. It is also strongly dependent on the temperature.

From the compounds *(3)–(5)* groups of substances were prepared by hydrogenation, ether cleavage, and hydrogenation + ether cleavage, using the methods described above. These groups of compounds should cover the range of pressure coefficients as evenly as possible, and should include substances in which the viscosity is very strongly pressure-dependent.

1. Compounds with One Ring

This group includes methoxybenzene, methoxycyclohexane, phenol, and cyclohexanol. Since phenol melts at 41 °C at atmospheric pressure, only the 60 °C and 80 °C isotherms are given for the two hydroxy compounds (Fig. 4).

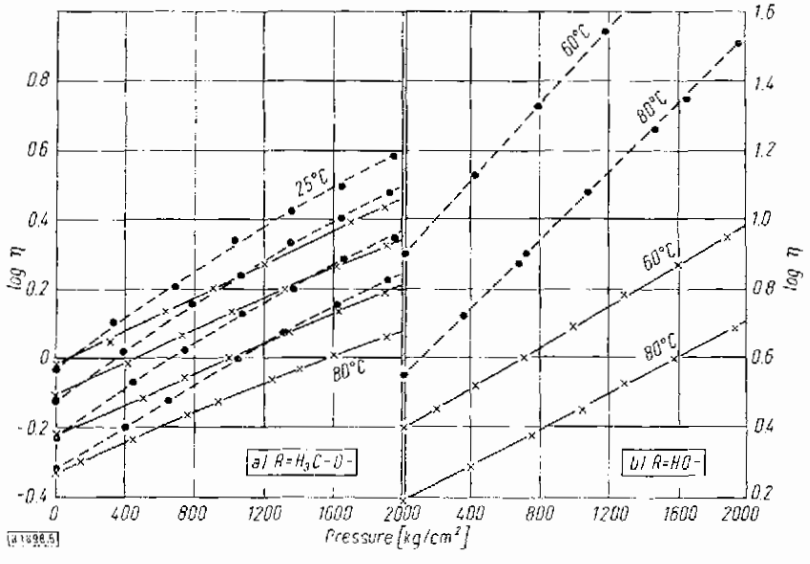

Fig. 4. Viscosity-pressure isotherms of methoxy and hydroxy compounds containing one ring.

(a): Isotherms at 25, 40, 60, and 80°C for: × anisole ($\alpha_{60} = 0.50 \times 10^{-3}$), ● methoxycyclohexane ($\alpha_{60} = 0.66 \times 10^{-3}$); (b): × phenol ($\alpha_{60} = 0.67 \times 10^{-3}$), ● cyclohexanol ($\alpha_{60} = 1.28 \times 10^{-3}$).

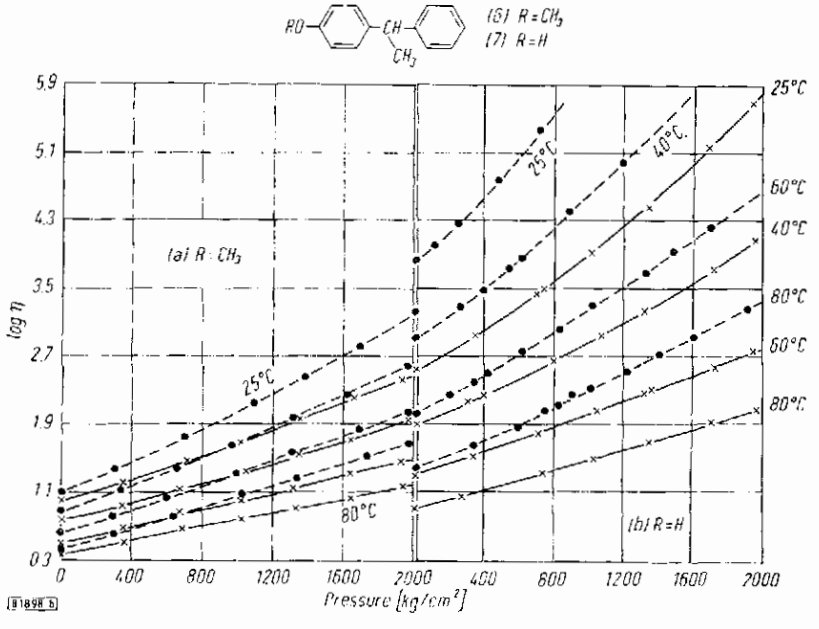

Fig. 5. Viscosity-pressure isotherms at 25, 40, 60, and 80°C of methoxy and hydroxy compounds containing two rings.

(a): × *p*-Phenylethylanisole *(6)*, ● perhydro-*(6)*; (b): × *p*-phenylethylphenol *(7)*, ● perhydro-*(7)*.

Fig. 4 shows that the hydrogenation of the phenyl group of the methoxy compounds has little effect on the viscosity at atmospheric pressure, but leads to a considerable increase in α. The pressure coefficient is also larger for the hydroxy compounds than for the corresponding methoxy compounds. The dependence of the viscosity on pressure is even more strongly affected if hydrogenation is combined with conversion into the hydroxy compound.

2. Compounds with Two Rings

Similar behavior is observed on hydrogenation, ether cleavage, and ether cleavage + hydrogenation of 4-(1-phenylethyl)anisole *(4)*.The viscosity-pressure isotherms of the four substances of this group are shown in Fig. 5. The pressure coefficients α follow on well from those of the compounds containing one ring, covering the wide range of from 1.36×10^{-3} to 3.56×10^{-3} atm^{-1}. Thus at 40 °C the viscosities of these substances increase by factors of 15 to 1250 between 1 and 2000 atm.

The increase in α with increasing content of the phenol in the mixture obtained by partial cleavage of the methoxy groups is faster than linear (Fig. 6). Intermediate values of the pressure coefficient can evidently be obtained by partial cleavage.

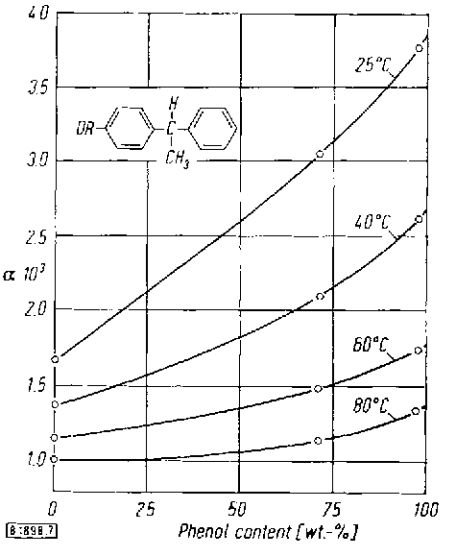

Fig. 6. Pressure coefficient of viscosity α as a function of the degree of conversion of 4-(1-phenylethyl)anisole (R = CH_3) into 4-(1-phenylethyl)phenol (R = H).

The isotherms extend over five decades and are convex towards the pressure axis. They fan out strongly, particularly in the hydroxy compounds, showing that α for these compounds is highly temperature-dependent.

The mean viscosity-pressure coefficient α at 40 °C extends from 3.8×10^{-3} to about 8×10^{-3} atm^{-1} for this group of compounds. The latter value corresponds to an increase in viscosity by a factor of several million between 1 and 2000 atm.

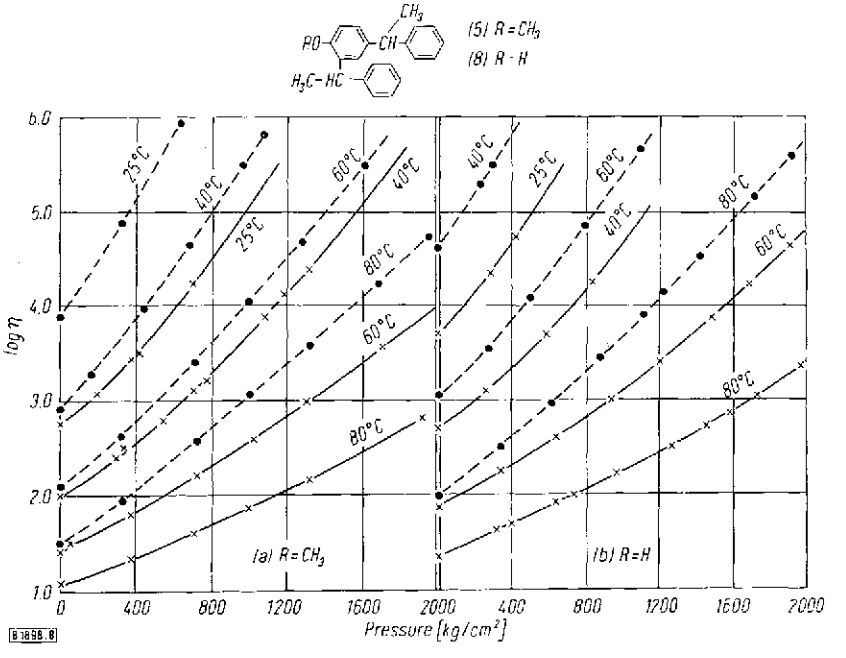

Fig. 7. Viscosity-pressure isotherms of methoxy *(5)* and hydroxy compounds *(8)* containing three rings.
(a): × *(5)*, ● perhydro-*(5)*; (b): × *(8)*, ● perhydro-*(8)*.

3. Compounds with Three Rings

By far the highest pressure coefficients are obtained if another phenylethyl or cyclohexylethyl group is introduced as a side chain. The viscosity-pressure isotherms of 2,4-bis-(1-phenylethyl)anisole and those of the derivatives obtained by hydrogenation, ether cleavage, and ether cleavage + hydrogenation are shown in Fig. 7.

It should also be mentioned that according to Stuart molecular models, 2,4-bis-(1-phenylethyl)anisole *(5)* can exist in a kind of chair form and a kind of boat form (Fig. 8). The model indicates that the interconversion of the two forms is appreciably hindered by the incomplete rotational freedom of the phenylethyl

groups. No evidence for the existence of two forms was, however, found from the viscosity-pressure curve or by infrared spectroscopy.

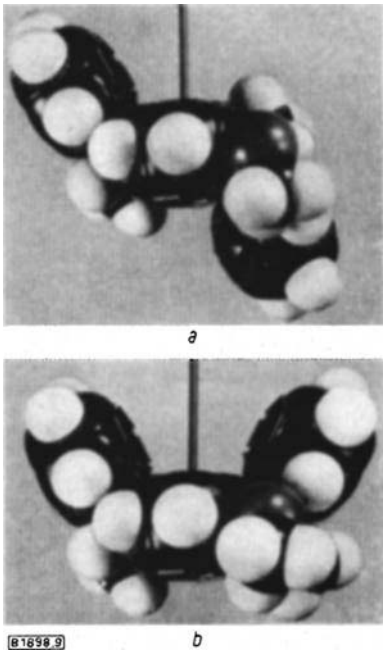

Fig. 8. Stuart models of 2,4-bis-(1-phenylethyl)-anisole *(5)*. *a*: "Chair" form; *b*: "boat" form.

D. Discussion

The data for the methoxy and hydroxy compounds studied are summarized in Table 1. It can be seen that the density decreases on hydrogenation to the extent of 0.10 to 0.12 g/cm³, depending on the number of phenyl groups present. On cleavage of the ether linkage, on the other hand, the density increases, the average increases being 0.084, 0.042, and 0.025 g/cm³ for substances with one, two, and three rings, respectively. The viscosity at atmospheric pressure is increased both by hydrogenation and by cleavage of the ether linkage. The magnitudes of the changes vary by several powers of ten, the strongest effects being observed in the case of compounds with three rings.

Finally, the magnitude of the increase in α on hydrogenation also increases with the number of rings. The conversion of the methoxy group into OH has less effect in substances with three phenyl groups than in substances with one or two rings. The effect of the OH group must obviously be largely screened by the adjacent phenylethyl groups (cf. Fig. 8). According to Table 1, this is also evident to a small extent in the density.

The pressure coefficients of the groups of compounds obtained in this way are much higher than those of mineral oil extracts, which were formerly regarded as very high. Whereas the value of the ratio $\eta_{2000\,atm}/\eta_{1atm}$ in the extreme case is 20000 for oils, factors of up to 8 million are found for the groups of compounds now available. This also shows that the strong pressure-dependence of the viscosities of certain mineral oil extracts is not due to the fact that the oils are mixtures.

Table 1. Densities ρ, viscosities η_i, and pressure coefficients of viscosity α at 40°C for methoxy and hydroxy compounds containing one to three rings.

Compound	ρ_{40} [g/cm³]	η_{40} [cP]	$10^3\,\alpha_{40}$ [atm^{-1}]
Methoxybenzene	0.9757	0.768	0.54
Methoxycyclohexane	0.8479	0.764	0.71
Phenol	1.0586	5.054	(0.81) Solid
Cyclohexanol	0.9339	22.7	1.51
(6)	1.0293	5.86	1.36
Perhydro-*(6)*	0.9191	7.26	2.02
(7)	1.0741	80.0	2.61
Perhydro-*(7)*	0.9583	842	3.56
(8)	1.0441	102.0	3.86
Perhydro-*(5)*	0.9403	859.0	6.09
(5)	1.0719	513	4.15
Perhydro-*(8)*	0.9616	42200	7.95

The values obtained with pure substances raise the question of whether the extremely high pressure coefficients can be explained with the present concepts. To test this question, let us examine the substances containing three cyclohexane rings (Table 1), which have the highest pressure coefficients found so far.

The activation energy for viscous flow E_{visc} is given by the temperature-dependence of the viscosity by

$$E_{visc} = -RT^2 \left(\frac{\partial \ln \eta_i}{\partial T}\right)_{p\,=\,1\ atm}$$

Using the relationships

$$\alpha = \Delta V/RT \quad \text{and} \quad E_{visc} = p_i \Delta V$$

where p_i is the internal pressure of the liquid, we find for the substance with the highest viscosity-pressure coefficient (Table 1) that:

a) the local increase in volume $\Delta V \simeq 0.5$ V.

b) corresponding to the approximations used, the internal pressure of the liquid has a maximum value of $p_i = 6300$ atm.

Both of these values are feasible for an extreme case. The internal pressure p_i is of an order of magnitude that has already been reported [14] for other liquids on the basis of pVT measurements and equations of state. A local volume increase of 50 % during viscous flow is also understandable in view of the molecular structure in question, but this must be regarded as approximately an upper limit.

The results also show a simple relationship between the pressure coefficient α and the molecular structure. In our opinion, however, the extreme pressure-dependence of the viscosity of the compounds studied could also be of interest in technical applications, for the following reasons:

1. In technical processes at low pressures where the influence of the viscosity is not yet known, this could be isolated from other influences by using the substances with high α studied in the present work.

2. The marked changes in viscosity with pressure could be used for control applications.

3. In the lubrication of highly stressed gears, the lubricant can be adapted to special requirements, not only as regards the temperature-dependence of the viscosity, but also as regards its pressure-dependence. In such cases, groups of definite compounds with absolute viscosities and pressure coefficients that cover a wide range would be of value.

E. Summary

Mineral oils and mineral oil extracts differ very markedly from simple substances with low molecular weights in the dependence of their viscosities on pressure. The viscosities of the former group increase by factors of from 30 to 20000 between 1 and 2000 atm, whereas the factors found previously for simple substances are less than 100, and depend on the chain length, intramolecular mobility, the degree of branching, and the presence of functional groups.

In order to find the reasons for this, and with a view to possible technical applications, groups of chemically uniform substances have been made with pressure coefficients of viscosity that cover an extremely wide range. Since substances containing condensed ring systems are solid under normal conditions, the compounds used to obtain the high pressure coefficients were hydrocarbons and ethers in which two to four phenyl groups were linked either by direct C—C bonds, methylene bridges, or $CH(CH_3)$ bridges. The pressure coefficient of viscosity was systematically altered by variation of the number and mutual positions of the rings.

The pressure coefficient could be further increased by hydrogenation of the phenyl groups and by replacement of methoxy groups by hydroxy groups.

The investigations at 25, 40, 60, and 80 °C and at pressures between 1 and 2000 atm were carried out in a high-pressure viscometer with automatic recording of the time of fall. The hydrogenations were carried out at 210 to 240 °C, in an autoclave of our own design, with palladium on barium sulfate as catalyst. The purity of the products was checked by infrared spectroscopy, and in some cases by gas chromatography. The ethers were cleaved by *Prey*'s method. In this way, substances with pressure coefficients up to 8×10^{-3} atm^{-1} were obtained. This corresponds to a viscosity increase of almost 7 powers of ten between 1 and 2000 atm.

Thus by systematic modification of the molecular structure it was possible to find definite groups of chemically uniform substances with pressure coefficients of viscosity that extend far beyond the range covered by mineral oils.

I am grateful to the Chemische Werke Hüls AG. for their generous cooperation, and to the Bergbau-Forschungsgesellschaft GmbH. for some of the samples studied. Thanks are due to Dr. H. Stegemeyer and Dipl.-Chem. P. Pollmann for discussions on chemical questions and in particular for carrying out the preparative work, and to Dr. J. Moos for helpful discussions. I should also like to thank the Hannoversche Hochschulgemeinschaft.

Synthesis of 5-Aryl-1-methyl-[1,2,4]-triazolo[4,3-d] tetrazoles

By Prof. Dr. F. L. Scott, Dipl.-Chem. R. N. Butler, and Dr. D. A. Cronin

Chemistry Department, University College, Cork (Ireland)

We have prepared methyl derivatives of type *(1)*, hitherto unreported, in two ways.

The best method (A) is by the reaction of one equivalent of a benzaldehyde tetrazolylhydrazone [1] in the presence of one equivalent of sodium hydroxide, in 50 % aqueous ethanol solution with 1.2 equivalents of methyl iodide in acetone, the whole mixture being refluxed for 45 minutes. On cooling, the 1-methyl compounds *(1)* precipitate out. A number of other methylated derivatives are formed in small (<10 %) yields in each case.

The second (and unambiguous) method (B) of synthesis involved treating a benzaldehyde 4-methylthiosemicarbazone with lead monoxide and sodium azide in refluxing ethanol under nitrogen [2]. Here, the main products are 1-arylalkylidenecamino-5-methylaminotetrazoles.

When compounds *(1)* were mixed with two equivalents of bromine in glacial acetic acid and the reaction mixtures then stirred for 4 hours at ambient temperatures, careful addition of cold water to the solution precipitated out the bromo derivatives *(2)*. These were dissolved in 50:50 (v/v) dioxane- or acetone-water mixtures with brief heating (10 min at 50 °C) and the resulting solutions were stirred at ambient temperatures for an additional 60–100 minutes. The reaction mixtures were distributed between ether and water. The ethereal layers contained the new 5-aryl-1-methyl-[1,2,4]-triazolo[4,3-*d*]tetrazoles *(3)*. They were dried before removing the ether.

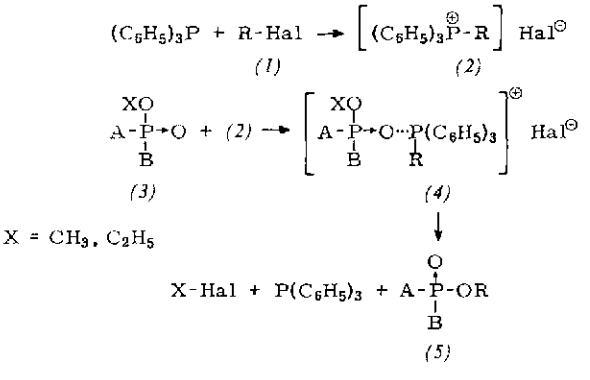
Transesterification of Methyl and Ethyl Phosphates, Phosphonates, and Phosphinates in the Presence of Tertiary Phosphines

By Dr. H. G. Henning and G. Busse

II. Chemisches Institut der Humboldt-Universität, Berlin (Germany)

Methyl and ethyl esters *(3)* of phosphoric, phosphonic, or phosphinic acids react surprisingly readily (140–180 °C, 20 to 120 min) with alkyl or aralkyl halides *(1)* in the presence of small amounts (0·01 mole) of triphenylphosphine, yielding the alkyl or aralkyl esters *(5)* and methyl or ethyl halide. The triphenylphosphine, in whose absence the reaction requires appreciably more vigorous conditions (160–210 °C, 10–25 h, bomb tube) [1], may be replaced by other tertiary phosphines, *e.g.* tri-n-butylphosphine, but not by other tervalent phosphorus compounds (phosphonous esters, triphenyl phosphite) or triphenylphosphine oxide. The tertiary phosphine reacts first with the halide *(1)* to give the quaternary phosphonium salt *(2)*, whose adduct *(4)* with the ester *(3)* immediately loses methyl or ethyl halide, regenerating the tertiary phosphine.



The same results are obtained by direct reaction of the pure phosphonium salts *(2)* with the esters *(3)* in the presence or absence of a solvent (xylene, dimethylformamide, *o*-dichlorobenzene).

R	Hal	A	B	*(5)*, Yield [%] [a]	*(5)*, B.p. [°C/mm]
n-C_7H_{15}	Br	C_2H_5O	C_2H_5O	30.0	85/0.08
		C_2H_5O	n-$C_7H_{15}O$	9.1	133/0.003
		n-$C_7H_{15}O$	n-$C_7H_{15}O$	6.2	172/0.0005
Benzyl	Cl	C_2H_5	C_2H_5O	21.7	174/18.5
		C_2H_5	Benzyl-O	10.8	168/0.6
n-C_9H_{19}	Br	n-C_9H_{19}	n-C_9H_{19}	45.6	149/0.002

[a] Molar proportion of *(1)*:*(3)* used = 1:1. Reaction time: 1 h. The esters *(5)* were isolated by distillation. Unsymmetrical diesters are partly rearranged during the reaction to two symmetrical diesters and partly undergo alkene fission. Yields refer to the amount of *(3)* used.

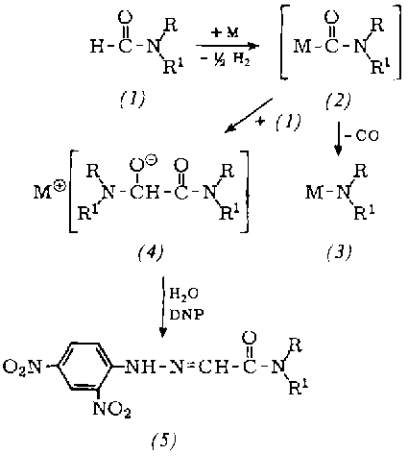
Reactions of N,N-Disubstituted Formamides with Alkali Metals

By Prof. Dr. H. Bredereck, Dr. F. Effenberger, and Dr. R. Gleiter

Institut für Organische Chemie der Technischen Hochschule Stuttgart (Germany)

N,N-Disubstituted formamides *(1)* react with alkali metals (Na, K, or Li) in inert solvents with evolution of hydrogen, yielding alkali dialkylamides *(3)* [1] and glyoxylamide derivatives *(4)*. Both products are formed in finely divided condition, and the amides *(4)* are isolated as 2,4-dinitrophenylhydrazones *(5)* after hydrolysis of the whole reaction mixture (25 °C).

The alkali salt *(2)* of the formamide is probably first formed, then partly decomposes into alkali dialkylamide *(3)* and partly forms the alkali salt *(4)* of the substituted glyoxylamide.



Reaction at a higher temperature (*e.g.* in mesitylene at 140 to 150 °C) gives almost exclusively the sodium dialkylamide, which can be used in this form for further reactions (*e.g.* M = Na, R = R^1 = CH_3 or C_2H_5).

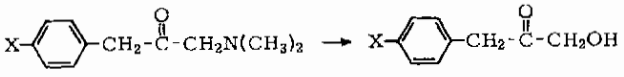
Preparation of α-Hydroxy Ketones by Hydrolysis of α-Amino Ketones

By Doz. Dr. E. F. Jenny and Dipl.-Chem. A. Melzer

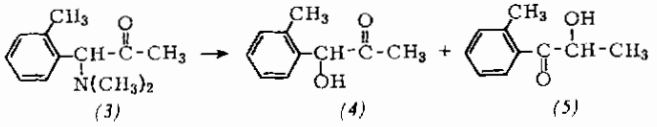
Chemisches Laboratorium der Universität Freiburg (Germany)

We have found that α-amino ketones, which are stable as free bases, are surprisingly easy to hydrolyse to α-hydroxy ketones. Thus the α-dimethylamino ketones *(1)* and *(3)* yield, respectively, the α-hydroxy ketones *(2)* and *(4)* plus *(5)* when

boiled in pyridine [*(1a)* and *(3)* for 20 h, *(1b)* for 1 h] in presence of HCl (1–3 eq.) and water (5–10 eq.). These α-hydroxy ketones are not very stable under the reaction conditions but can be isolated in 30–50 % yield.



(1), *(a)*: X = H
(b): X = NO_2 *(2)*



(3) *(4)* *(5)*

Hydrolysis of the amino ketones *(1a)* and *(1b)* labeled with ^{14}C in the carbonyl group occurs without positional change of the ^{14}C. Thus the carbon skeleton remains intact during the changes *(1a)* → *(2a)* and *(1b)* → *(2b)*, and there is no migration of the aralkyl group [*]. The reaction seems to be related to the rearrangement of α-anilino ketones [1], with water playing the part of the aniline.

The compound *(1b)* was obtained, with its *o*- and *m*-isomers, by nitration of *(1a)* [2]. Labeled *(1a)* was prepared from $(CH_3)_2NCH_2{}^{14}CN$ and benzylmagnesium chloride [2]; compound *(3)* was prepared by hydration of the Sommelet rearrangement product from benzyldimethylpropargylammonium chloride. We confirmed the structure of *(2b)* by synthesis: *p*-nitrophenylacetyldiazomethane [3] afforded *(2b)* when decomposed with aqueous sulfuric acid. For determination of the position of ^{14}C the hydroxy ketones *(2)* were reduced with $NaBH_4$ and the resulting α-glycols were cleaved by sodium periodate to give formaldehyde (dimedone derivative) and phenyl- or *p*-nitrophenylacetaldehyde (semicarbazone or oxime, respectively). All the new compounds and mixtures of isomers gave the expected analytical values, NMR signals, and infrared and ultraviolet bands.

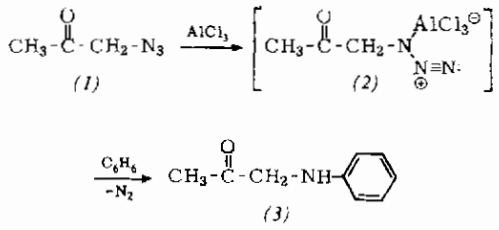
Electrophilic Substitution by α-Azido Ketones [1]

By Dr. R. Kreher and Dipl.-Chem. G. Jäger

Institut für Organische Chemie
der Technischen Hochschule Darmstadt (Germany)

α-Azidoacetone *(1)*, b.p. 53–55 °C/2.5 mm, readily accessible from α-chloroacetone and sodium azide [2], reacts with benzene in the presence of 3 moles of aluminum chloride (5 h at 50 °C) with evolution of nitrogen, yielding α-anilinoacetone *(3)*, m.p. 59–60 °C (hydrochloride, m.p. 140–141 °C), in 35 % yield. α-Azidocyclohexanone, b.p. 70–72 °C/0.3 mm [3], yields α-anilinocyclohexanone, m.p. 84–85 °C (perchlorate, m.p. 190–190.5 °C), analogously in 25 % yield.

Reaction is presumably initiated by electrophilic attack of the aluminum chloride on the N(α) atom of the azide group [4]. The complex *N*-diazonium salt *(2)* assumed as intermediate behaves like a preformed nitrenium ion and on reaction with benzene affords the α-anilino ketone *(3)* with evolution of nitrogen; *i.e.*, *(2)* reacts electrophilically with benzene.



(1) *(2)* *(3)*

In this reaction aliphatic-substituted nitrenium ions have been trapped for the first time with benzene in good yield. These ions are usually stabilized by alkyl or hydrogen migration [5], but these rearrangements are apparently made more difficult in α-azido ketones by the influence of the carbonyl group. Experiments with α-azido carboxylic esters indicate that ester groups have the same effect.

Synthesis of Monodisperse Oligoacrylic Acid by Means of a Template Reaction

By Prof. Dr. H. Kämmerer

Institut für Organische Chemie
der Universität Mainz (Germany)

We have synthesised oligoacrylic acid derivatives of type *(4)* by means of a template reaction. The templates used were monodisperse, structurally homogeneous compounds *(1)* that contain *p*-cresol units linked by methylene groups [1]. Treatment of these compounds with acryloyl chloride (molar ratio 1:6 in aqueous NaOH/benzene; addition of the arcyloyl chloride dropwise during 3 h with stirring and cooling in ice) gave the products *(2)* in which the hydroxy groups are quantitatively esterified (yield 95 %; isolated as usual from the benzene layer). Treatment with an excess of azodiisobutyronitrile initiates "polymerization" of compounds *(2)* [about 2.5 mmoles of *(2)* in 200 ml of benzene and 129 mmoles of azodiisobutyronitrile in 200 ml of benzene were added dropwise to 3 l of benzene in 3 h]. Owing to the high dilution, the polymerization proceeds only for as many propagation steps as there are acyl groups in *(2)*. The product, which in accord with experience in cyclopolymerization probably has structure *(3)*, was isolated in 70 % yield by evaporation of the benzene, treatment with petroleum ether, filtration, and washing with petroleum ether. Hydrolysis of *(3a)* with aqueous NaOH/benzene affords the derivative *(4)* of trimeric acrylic acid in 25 % yield; its structure was proved by conversion into the tetramethyl ester with diazomethane and by isolation and identification of the polynuclear phenol formed on hydrolysis.

The oligomeric template has thus predetermined the molecular size of the product. To our kowledge no other reaction is known in polymer chemistry that gives monodisperse products in a single step. The product *(4)* is a mixture of stereoisomers of unknown composition. A stereospecific oligomerization is being attempted.

Reactions of the kind described above may perhaps be models for protein synthesis in the living cell.

Di-π-cyclopentadienyltitanium Bis(hydrogen sulfide)

By Dr. H. Köpf and Prof. Dr. Max Schmidt

Institut für Anorganische Chemie
der Universität Marburg (Germany)

Di-π-cyclopentadienyltitanium bis(hydrogen sulfide) *(2)* was prepared in almost quantitative yield by the reaction of di-π-cyclopentadienyltitanium dichloride *(1)* [1] with hydrogen sulfide and the stoichiometric amount of triethylamine in anhydrous ether (1 h at 20 °C):

$$\underset{(1)}{(C_5H_5)_2TiCl_2} + 2\ H_2S + 2\ N(C_2H_5)_3 \rightarrow \underset{(2)}{(C_5H_5)_2Ti(SH)_2} + 2\ (C_2H_5)_3N{\cdot}HCl$$

Compound *(2)*, which is surprisingly stable towards oxidation by air and toward hydrolysis, is freed from the accompanying amine hydrochloride by extraction of the mixture with water and is recrystallized from chloroform. The brown-black, malodorous crystals decompose at 150–160 °C. In chloroform solution *(2)* is monomeric [2]. The ^1H-NMR spectrum in $CHCl_3$ [3] contains two sharp signals, at 6.34 (C_5H_5) and at 3.44 (SH) ppm, with an intensity ratio of 5:1. As expected, the proton signal at 3.44 ppm is missing in the spectrum (in $CDCl_3$) of the compound $(C_5H_5)_2Ti(SD)_2$ prepared analogously from D_2S.

The presence of two SH groups was confirmed by iodometric determination of the hydrogen sulfide quantitatively liberated by hydrogen chloride according to

$$(2) + 2\ HCl \rightarrow (1) + 2\ H_2S$$

and by methylation with dimethyl sulfate to di-π-cyclopentydienyltitanium bis(methyl sulfide) [4]. Compound *(2)* does not react with diazomethane. In boiling benzene it slowly eliminates H_2S with the formation of polycrystalline oligomers containing Ti–S–Ti bonds.

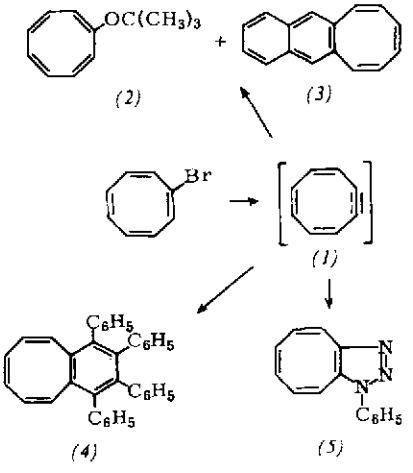
Intermediate Occurrence of 1,2-Dehydrocyclooctatetraene

By Dr. A. Krebs

Institut für Organische Chemie
der Universität Heidelberg (Germany)

The ring strain and reactivity of 1,2-dehydrocyclooctatetraene *(1)* should lie between those of 1,2-dehydrobenzene, a confirmed but non-isolable intermediate, and of cyclooctyne [1] which can be isolated.

After treatment of bromocyclooctatetraene [2] with an ethereal suspension of potassium t-butoxide and subsequent hydrolysis potassium bromide was found in the aqueous phase in a yield of 95 %. Separation of the reaction mixture gave, apart from a high-melting, brown powder insoluble in ether and benzene, t-butoxycyclooctatetraene *(2)* by distillation, b.p. 37–38 °C/0.05 mm, yield 16 %, and naphtho-2,3-cyclooctatetraene *(3)*, m.p. 113–114 °C, yield 9 %, by chromatography of the distillation residue on silica gel with CCl_4.



The structure *(2)* was proved by elemental analysis, the NMR spectrum, acid hydrolysis to cycloocta-1,3,5-trien-7-one (isolated as the 2,4-dinitrophenylhydrazone [3]), and hydrogenation to t-butoxycyclooctane, which was synthesized independently from cyclooctanol. The structure *(3)* was proved by elementary analysis, spectra (particularly NMR), oxidation (by O_3 and CH_3CO_3H) to 1,2,4,5-benzenetetracarboxylic acid, and independent synthesis of 2,3-cyclooctenonaphthalene, which is obtained on hydrogenation of *(3)*.

The probable intermediacy of 1,2-dehydrocyclooctatriene in this reaction of bromocyclooctatetraene was shown by trapping reactions: if the HBr elimination is carried out *e.g.* in the presence of tetraphenylcyclopentadienone or phenyl azide, the adducts *(4)*, m.p. 241–242 °C, yield 72 %, and *(5)*, m.p. 67.5–68 °C, yield 38 %, respectively, are obtained. The con-

stitutional proof for the compounds *(4)* and *(5)* was obtained from elementary analysis, spectra, and hydrogenation to the corresponding known cyclooctyne adducts [4].

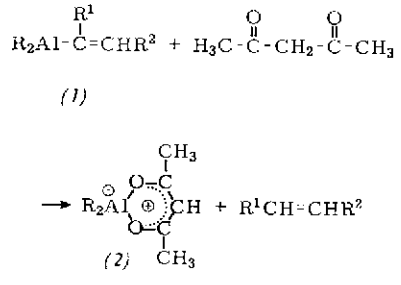
Selective Protolysis of Unsaturated Organoaluminum Compounds

By Dr. B. Bogdanović

Max-Planck-Institut für Kohlenforschung, Mülheim/Ruhr (Germany)

Vinyl groups can be removed preferentially from alkylvinyltin compounds by electrophilic reagents [1]. Similarly vinylboranes are cleaved by acids more easily than alkylboranes [2]. We have found also that organoaluminum compounds of type *(1)*, obtainable by addition of hydridodialkylaluminums to acetylenes, are susceptible to selective protolysis. From compound *(1)* and acetylacetone one obtains exclusively the olefin and acetylacetonatodialkylaluminum *(2)* although Al-alkyl bonds are easily cleaved protolytically.



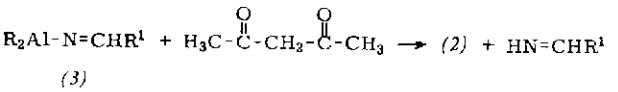
(1)

(2)

R^1 = H, Alkyl
R^2 = Alkyl, Aryl

A solution of acetylacetone in a hydrocarbon, *e.g.* toluene, is dropped slowly at 0° to −30 °C into a solution of the organoaluminum component (molar ratio 1:1). Disappearance of a yellow coloration due to interaction of the compounds *(1)* and *(2)* indicates the end of the reaction. The olefin is separated from the organometallic component by distillation. If this method of cleavage is used in the stereospecific reduction of acetylenes to *cis*-olefins with dialkylaluminum hydrides [2a], the usual hydrolytic cleavage of all metal-carbon bonds can be avoided.

Aluminum imides *(3)*, obtainable by addition of hydridodialkylaluminums to nitriles [3], can also be cleaved selectively at the Al–N linkage by means of acetylacetone, whereby also compound *(2)* and aldimines result. This reaction is significant for the synthesis of aldimines [4], since it can be conducted at very low temperature (−80 °C) where aldimines do not polymerize.



(3)

R^1 = Alkyl

Compounds of the type $R_2Al\text{-}NR_2$ (R = alkyl) are not selectively cleaved at the Al–N linkage, which shows that the H^+ ions attack the π-electron pair of the double bond and not the electron pair of the nitrogen atom. The same is true for compounds *(1)*.

Acetylacetonatodialkylaluminums, which have not been described before [5], are liquids, sensitive to air, monomeric, and almost colorless, and can be distilled in vacuum; their compositions and infrared and H^1–NMR spectra accord with structure *(2)*. Acetylacetonatodiethylaluminum has b.p. 55–56 °C/1–2 mm, and the diisobutyl analogue 40–45 °C/10^{-4} mm.

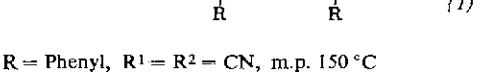
Divinylogous Methylenephosphoranes from Conjugated Diynes, Trialkylphosphines, and Active Methylene Compounds

By Dr. H.-E. Sprenger and Dr. W. Ziegenbein

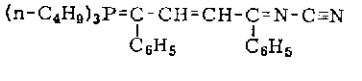
Forschungslaboratorien der Chemischen Werke Hüls AG, Marl (Germany)

Direct preparation of divinylogous methylenephosphoranes can be effected by simultaneous reaction of active methylene compounds and trialkylphosphines with conjugated diynes. For instance, equimolar amounts of diphenyl- or bismorpholinomethyl-1,3-butadiyne with tri-n-butylphosphine and malononitrile, fluorene, or anthrone in ether, tetrahydrofuran, or benzonitrile under reflux afford the methylenephosphoranes *(1a)–(1d)*, which are isolated as follows: After evaporation of the solvent or after mixing the benzonitrile solution with ether [for *(1c)*] the reaction products are washed with ether or quickly recrystallized from methanol, ethanol, dioxane, and benzene [for *(1d)*, *(1a)*, *(1c)*, and *(2)*, respectively].



(1)

(1a), R = Phenyl, $R^1 = R^2 = CN$, m.p. 150 °C
(1b), R = Phenyl, CR^1R^2 = anthromylidene, m.p. 210 °C
(1c), R = Phenyl, CR^1R^2 = fluorenylidene, m.p. 215 °C (decomp.)
(1d), R = Morpholinomethyl, $R^1 = R^2 = CN$, m.p. 200 °C (decomp.)



(2), M.p. = 136 °C

With NH-acidic compounds, *e.g.*, cyanamide, products of type *(2)* are formed.

Structures of the products were proved by elemental analysis and by ultraviolet, infrared, and NMR spectroscopy.

Of the compounds indicated, only *(1c)* reacts with carbonyl compounds and *p*-quinone to give colored, easily crystallizable olefination products of structures *(3)* and *(4)*. Reaction conditions: *(1c)* is heated with exess carbonyl compound or in a solution of an equimolecular amount of carbonyl com-

pound in benzonitrile containing a trace of hydroquinone. Heating is continued until the blue colour of *(1c)* disappears. The products are precipitated with methanol and recrystallized from butanol or tetrahydronaphthalene [preparation of *(4)*].

Synthesis and Reactions of N,N,N′,N′-Tetramethyl-3-methoxy-1-propene-1,3-diamine and N,N,N′,N′,N″,N″-Hexamethyl-2-propene-1,1,3-triamine

By Prof. Dr. H. Bredereck, Dr. F. Effenberger, Dr. R. Gleiter, and cand. chem. K. A. Hirsch

Institut für Organische Chemie
der Technischen Hochschule Stuttgart (Germany)

N,N-Dimethyl-3-dimethylaminoprop-1-enylideneammonium perchlorate or methyl sulfate *(1)* [1,2] react with potassium methoxide, giving the vinylogous aminal ester 3-methoxy-*N,N,N′,N′*-tetramethyl-1-propene-1,3-diamine *(2)*, and with sodium dimethylamide, giving the vinylogous trisdimethylamino compound, *N,N,N′,N′,N″,N″*-hexamethyl-3-propene-1,1,3-triamine *(3)*. Both products are even more reactive than the vinylogous amidacetal, *N,N*-dimethyl-3,3-dimethoxypropenylamine described recently [1] and with CH-acidic compounds gives derivatives *(4)* of butadiene.

Examples:

N,N,N,N′-Tetramethyl-3-methoxy-1-propene-1,3-diamine *(2)*: 19.55 g (0.5 g-atom) of potassium is heated in 200 ml of anhydrous benzene at 75 °C and finely divided with a vibrator. When the suspension has cooled, a solution of 16.01 g (0.5 mole) of anhydrous methanol in 400 ml of anhydrous benzene is added with stirring during 2 h, with heating under reflux for ½ h near the end of the reaction. 113.32 g (0.5 mole) of *N,N*-dimethyl-3-dimethylaminopropenylideneammonium perchlorate is added, and the whole heated for a further 2 h under reflux, allowed to cool, and filtered from the potassium perchlorate that separates. The benzene is distilled off in vacuum and the residue fractionated through a short column. Yield 47.5 g (60 %) of colorless liquid, b.p. 75–76 °C/10 mm.

N,N,N′,N′,N″,N″-Hexamethyl-3-propene-1,1,3-triamine *(3)*: To a suspension of 33.5 g (0.5 mole) of sodium dimethylamide in 500 ml of anhydrous benzene is added 113.32 g (0.5 mole) of the perchlorate *(1)*, and the mixture is heated for 2 h under reflux and processed as described above. Yield 52.5 g (62 %) of colorless liquid, b.p. 75–76 °C/10 mm.

4-Dimethylamino-1-phenyl-1,3-butadienenitrile *(4b)*: 2.34 g (0.02 mole) of benzyl cyanide, 50 ml of anhydrous petroleum ether (b.p. 100–130 °C), and 31.6 g (0.02 mole) of compound *(2)* are heated together at 110 °C for 4 h. The precipitated oil solidifies when kept for a day in a refrigerator. The crystal cake is powdered, filtered off, washed with petroleum ether (b.p. 50–70 °C) (twice with 50 ml), and dried for 24 h in vacuum. The crude product (3.45 g) is recrystallised from *ca.* 300 ml of anhydrous petroleum ether (b.p. 100–130 °C) in presence of basic aluminum oxide and dried for 48 h in vacuum. Yield 2.94 g (74 %) of yellow needles, m.p. 102 °C.

Disubstitution in the Vilsmeyer-Haack Aldehyde Synthesis [*]

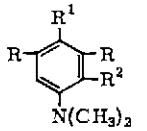
By Prof. Dr. Ch. Grundmann and Judith M. Dean

Mellon Institute, Pittsburgh, Pa. (U.S.A.)

The reaction of an aromatic system with the complex from phosphorus oxychloride and an *N*-formylated secondary amine is known as the Vilsmeyer-Haack aldehyde synthesis. Although it belongs to the most frequently used methods for the preparation of aromatic aldehydes, the introduction of more than one formyl group per aromatic ring has never been achieved [1].

We have, however, found it surprisingly easy to convert *N,N*-dialkylanilines into dialdehydes. Thus from *N,N*-dimethylaniline *(1)* and 2–3 moles of the $POCl_3$-dimethyl-

formamide complex [2], a mixture of 4-dimethylaminobenzaldehyde *(2)* and 4-dimethylaminoisophthaldialdehyde *(3)* is formed from which *(3)* may be isolated with 15–20 % yield. 3,5-Dimethyl-*N*,*N*-dimethylaniline *(4)* is even more easily diformylated. Under conditions which convert *(1)* exclusively to *(2)* [3] a mixture of about equal parts of unchanged *(4)*, 4-dimethylamino-2,6-dimethylbenzaldehyde *(5)*, and 4-dimethylamino-2,6-dimethylisophthaldialdehyde *(6)* is formed. The application of more than two moles of formylating agent results in the exclusive formation of the dialdehyde *(6)* in 60–80 % yield. Monoformylation of *(4)* can only be achieved by adding one mole of the $POCl_3$–DMF complex at 5 °C very slowly to a large excess (5–10 moles) of the amine.



(1), R = R^1 = R^2 = H
(2), R = R^2 = H, R^1 = CHO
(3), R = H, R^1 = R^2 = CHO
(4), R = CH_3, R^1 = R^2 = H
(5), R = CH_3, R^1 = CHO, R^2 = H
(6), R = CH_3, R^1 = R^2 = CHO

The constitution of the aldehydes *(3)*, *(5)*, and *(6)* was ascertained by NMR-spectroscopy: *(5)* displays, beside signals for the *C*-methyl (τ = 7.45) and *N*-methyl (τ = 7.00) groups, only one signal for the two aromatic protons (τ = 3.70) and one signal (unsplit) for the aldehydic proton (τ = −0.08). The dialdehydes *(3)* and *(6)* each give two signals for aldehydic protons (τ = 0.03 and −0.20, resp. τ = 0.10 and −0.28); *(6)* gives furthermore a split signal for the *C*-methyl groups (τ = 7.40 and 7.20). No indication was obtained for the presence of the 2-dimethylaminoisophthaldialdehydes isomeric with *(3)* and *(6)*. The introduction of a third formyl group was not possible even under more rigid conditions.

4-Dimethylaminoisophthaldialdehyde (3) [4]:

N-Dimethylaniline (12.1 g) is added to phosphorus oxychloride (50.0 g) and DMF (81.2 g). The reaction mixture is heated with stirring and exclusion of moisture for 16 hours to 60–65 °C, then poured on ice (600 g), and 33 % NaOH (150 ml) is added at no more than 15 °. After several hours' cooling to 0 °C, the crystalline precipitate, consisting of *(2)* and *(3)*, is filtered off, washed with water and dried in vacuum (11.3 g). Exhaustive ether extraction of the alkaline mother liquor followed by evaporation of the ether yields further 3.5 g. To separate *(3)* from *(2)* the product is distilled with steam until the distillate does not deposit any more crystals of *(2)* on cooling to 0 °C. The crude dialdehyde *(3)* (3.4 g) separates in crystalline form from the aqueous solution (100 ml) remaining in the distillation flask on cooling to 0 °C. After two recrystallizations from ligroine yellowish felted needles of pure *(3)*, m.p. 72 °C, are obtained. Yield: 2.4 g (14 %).

4-Dimethylamino-2,6-dimethylbenzaldehyde (5):

A formylating mixture prepared from phosphorus oxychloride (15.6 g) and dimethylformamide (30.0 g) is added dropwise, with stirring and exclusion of moisture, within 4 hours at 5–10 °C to 3,5-dimethyl-*N*,*N*-dimethylaniline (75.5 g). After keeping the reaction mixture for 16 hours at 25–30 °C, it is decomposed with ice (300 g), made alkaline with 33 % NaOH (75 ml) and extracted with ether. After evaporation of the ether, excess amine *(4)* is distilled off (56.6 g; b.p. 61–62 °C/0.2 mm), and *(5)* is obtained in thick, almost colorless plates (12.5 g, 69 %) from the residue after one recrystallization from ligroine, m.p. 83 °C.

Received: September 15th, 1965 [Z 60/885 IE]
German version: Angew. Chem. 77, 967 (1965)

[*] This work was supported by Public Health Service Research Grant CA 07272-02 of the National Cancer Institute, Bethesda, Md. (U.S.A.).

[1] The only exception – although with a pseudo-aromatic system – seems to be the preparation of azulene-1,3-dialdehyde from azulene; *K. Hafner* and *C. Bernhard*, Angew. Chem. *69*, 533 (1957); Liebigs Ann. Chem. *625*, 108 (1959).

[2] In principle, these syntheses can be carried out as well with *N*-formyl-*N*-methylaniline; however, the separation of the basic aldehydes from the *N*-methylaniline is more difficult.

[3] Org. Syntheses, Coll. Vol. IV, 331 (1963).

[4] Analogously *(6)*, m.p. 79 °C, is obtained in 81 % yield. Steam distillation of the crude product is unnecessary in this case.

Synthesis of Carboxylic Acids with 1,1-Dichloroethylene

By Dr. K. Bott

Forschungslaboratorien der Chemische Werke Hüls AG., Marl (Germany)

Treatment of carbinols, carbinol esters, or olefins obtainable from carbinols by loss of water with 1,1-dichloroethylene in 80 to 100 % sulfuric acid leads to substituted propionic acids *(3)* (cf. Table). The reaction, which takes place at 0 to 15 °C, is greatly accelerated by boron trifluoride and gives particularly good yields when carbonium ions can easily be formed from the carbinols or olefins used.

Carbinol, ester, or olefin	Product *(3)*	Yield [%] of *(3)*
Norbornene	*exo*-Norbornylacetic acid	72
1-Adamantanol	1-Adamantanylacetic acid [1]	93
1-Bromoadamantane	1-Adamantanylacetic acid	86
α-Methylbenzyl alcohol	3-Phenylbutyric acid; carboxylic acids of higher molecular weight [a]	50 20–25
Benzhydrol	3,3-Diphenylpropionic acid	71
t-Butyl chloride	3,3-Dimethylbutyric acid [b]	78
t-Butyl alcohol	3,3-Dimethylbutyric acid	79
Isobutene	3,3-Dimethylbutyric acid	75

[a] These acids (structure not yet clarified) are probably formed by oligomerization of styrene.

[b] Düsobutene (dimerisation product of isobutene, principally 2,4,4-trimethyl-1- and -2-peotene) and isobutyl alcohol yield only 3,3-dimethylbutyric acid.

The principle of this carboxylic acid synthesis consists in addition of a carbonium ion *(1)* to 1,1-dichloroethylene, giving *(2)*, followed by hydrolysis to the acid *(3)*.

Formation of Carbonyl Compounds from Azines or Hydrazones with Active Manganese Dioxide

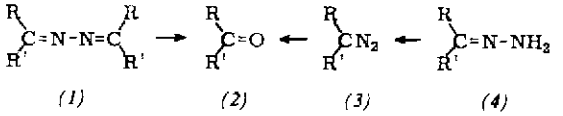
By Priv.-Doz. Dr. G. Maier and cand. chem. U. Heep

Institut für Organische Chemie der Technischen Hochschule Karlsruhe (Germany)

Treatment of 2,5-diphenyl-3,4-diazanorcaradiene with active precipitated manganese dioxide (E. Merck, Darmstadt) gives *cis*-1,2-dibenzoylcyclopropane and nitrogen [1]. We have

tested this reaction for its general applicability and have found that the azines *(1a)* to *(1e)* can be converted smoothly and quantitatively into the carbonyl compounds *(2)* hy stirring them at room temperature with an excess of manganese dioxide in benzene or carhon tetrachloride. We have also studied the hydrazones *(4a)* to *(4d)*. Whereas azines are cleaved relatively slowly (reaction time 2 h to 14 days), hydrazones afford the carbonyl compounds *(2)* more easily (within a few hours), and equally quantitatively, under the same conditions. In the latter case diazo-compounds *(3)* are formed as intermediates, which can be detected spectroscopically. 9-Fluorenone hydrazone is converted analogously into 9-fluorenone by way of 9-diazofluorene.

The carbonyl compounds *(2)* are formed directly from the diazo compounds *(3)* by exchangc of nitrogen for oxygen; thus diphenyldiazomethane gives benzophenone quantitatively. The fact that only acetone arises from acetone



(1) *(2)* *(3)* *(4)*

(a) R = R' = C_6H_5 *(d)* R = R' = CH_3
(b) R = C_6H_5; R' = CH_3 *(e)* R = CH_3; R' = H
(c) R = C_6H_5; R' = H

hydrazone shows that alcohols cannot be intermediates; if they were, isopropyl alcohol would be obtained since it is stable under the reaction conditions.

Benzil dihydrazone gives tolane quantitatively within 30 min, hut no benzil. Moreover, no benzil is obtained from benzil monohydrazone since α-diazo ketones (*e.g.* diazoacetophenone) – and also diazoacetic ester – do not exchange their nitrogen for oxygen. This explains why diazo ketones can be isolated on oxidation of monohydrazones of α,β-dioxo compounds with manganese dioxide [2].

Carboxyhydrazides react with active manganese dioxide with evolution of nitrogen, giving carboxylic acids in quantitative yields.

Ortho-Rearrangement of Metalated Butynyl Benzyl Ether

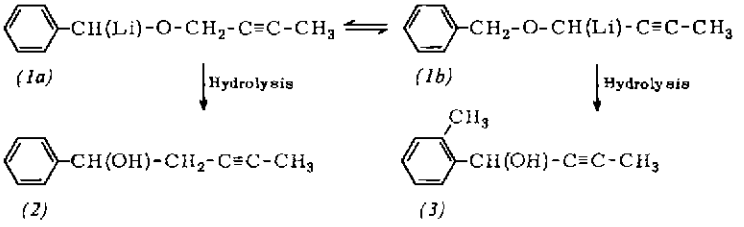
By Prof. Dr. U. Schöllkopf and Dr. M. Rizk

Organisch-Chemisches Institut
der Universität Göttingen (Germany)

Two types of rearrangement are known [1] to compete in the base-induced rearrangement of trialkylbenzylammonium salts, namely, the Stevens rearrangement (1,2-shift) and the Sommelet rearrangement (*ortho*-rearrangement) in which an alkyl group migrates to the *ortho*-position of the benzyl group. Hitherto only the 1,2-shift has been known for alkyl benzyl ethers, for which it is known as the Wittig rearrangement [1].

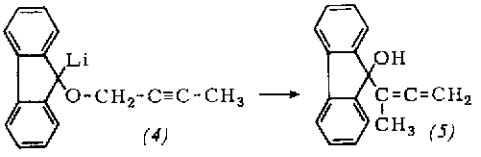
We have now found that an isomerization corresponding to the Sommelet rearrangement is also possible for one of these ethers. For instance, if 2-butynyl lithiobenzyl ether *(1)*, prepared from benzyl 2-butynyl ether and butyl-lithium in tetrahydrofuran at −30 °C, is kept for 14 h in tetrahydrofuran at −60 °C and the mixture is then hydrolysed with CH_3OH/H_2O at 60 °C, 1-(*o*-methylphenyl)-2-butyn-1-ol *(3)* can be isolated in 46 % yield as a result of an *ortho*-rearrangement; 1-phenyl-3-pentyn-1-ol *(2)* is formed also, in 18 % yield, by a Wittig rearrangement [2].

We assume that the rearrangements involve the two metalated ethers *(1a)* and *(1b)*. Whereas the 1,2-shift may occur by a fission-recombination mechanism [3], the course of the *ortho*-rearrangement is unknown.



(1a) *(1b)* *(2)* *(3)*

9-Lithio-9-fluorenyl 2-butynyl ether *(4)*, when similarly treated, yields only 9-(1-methylallenyl)-9-fluorenol *(5)* [4].



(4) *(5)*

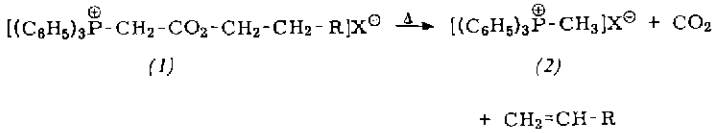
Formation of Ylides on Thermal Decomposition of P-(α-Alkoxycarbonylalkyl)triphenylphosphonium Salts

By Prof. Dr. H. J. Bestmann, Dr. H. Hartung, and I. Pils

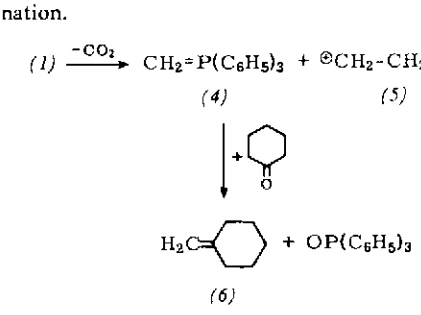
Institut für Organische Chemie der Technischen Hochschule München und der Universität Erlangen-Nürnberg (Germany)

P-(Alkoxycarbonylmethyl)triphenylphosphonium salts *(1)* decompose when heated above the melting point, yielding a methyltriphenylphosphonium salt *(2)*, an olefin *(3)*, and carbon dioxide [1].



(1) *(2)* *(3)*

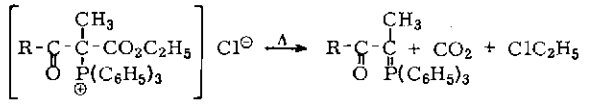
We assume that this reaction begins with the formation of an alkylidenephosphorane *(4)* and a carbonium ion *(5)*, from which the products *(2)* and *(3)* are at once formed by β-elimination.



(1) *(4)* *(5)* *(6)*

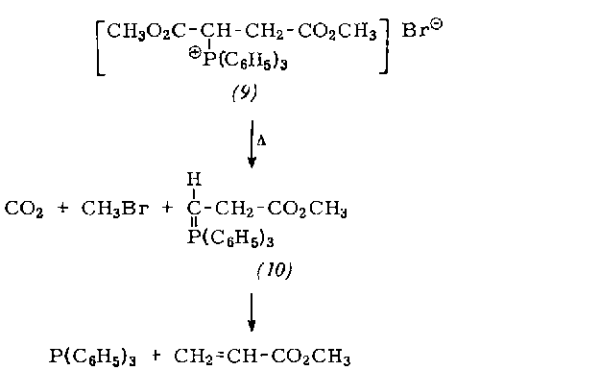
The intermediate occurrence of the phosphorane *(4)* becomes obvious if the decomposition is carried out in boiling cyclohexanone; on subsequent distillation methylenecyclohexanone *(6)* is obtained in 1 % yield.

On thermal decomposition of *P*-(1-acyl-1-ethoxycarbonylethyl)triphenylphosphonium chlorides *(7)* the residues consist of the stable ylides *(8)* (R = C_6H_5, m.p. 172 °C, yield 98 %; R = C_6H_5–CH=CH, m.p. 200 °C, yield 82 %). The compounds *(8)* are weak bases. They attack the carbanions *(5)* (R – H) only slowly, and these ions react preferentially with the chloride ions; one thus obtains ethyl chloride which distils off and can be isolated in a cooled receiver.



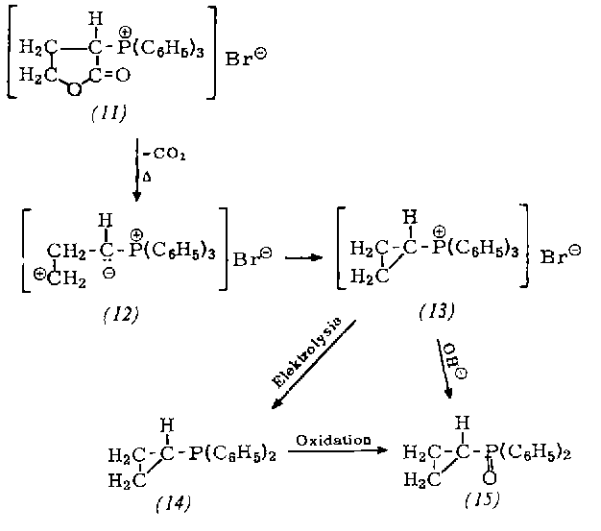
(7) *(8)*

Heating *P*-[1,2-di(methoxycarbonyl)ethyl]triphenylphosphonium bromide *(9)* at 150 °C affords methyl acrylate (75 %) and triphenylphosphine (70 %). We assume that an ylide *(10)* is formed as intermediate in this case also and then decomposes into the products named owing to an intramolecular Hofmann degradation[2]. During the decomposition methyl bromide distils alongside the ester and can be condensed in a cooled receiver.



(9) *(10)*

Carbon dioxide is evolved when the phosphonium salt *(11)* obtained[3] from α-bromo-γ-butyrolactone and triphenylphosphine is heated at 180–190 °C. The carbonium ion *(12)*, assumed to be an intermediate product, passes into cyclopropyltriphenylphosphonium bromide *(13)* by *C*-alkylation of the ylide that is present in the same molecule; this salt *(13)*, which is not otherwise accessible, remains quantitatively as residue in the reaction vessel.



(11) *(12)* *(13)* *(14)* *(15)*

Treating the bromide *(13)* with aqueous sodium hydroxide affords cyclopropyldiphenylphosphine oxide *(15)*, and electrolysis of the aqueous solution[4] affords cyclopropyldiphenylphosphine *(14)* that can be converted into the oxide *(15)* by oxidation. Nuclear magnetic resonance spectra of *(13)*, *(14)*, and *(15)* are in accord with the structures assigned.

A New Ring System Containing Boron

By Prof. Dr. F. Umland and Dr. B. K. Poddar

Anorganisch-Chemisches Institut der Universität Münster
and Institut für Anorganische Chemie
der Technischen Hochschule Hannover (Germany)

In chelates and chelating agents containing short intramolecular hydrogen bonds (2.4–2.6 Å), boron can be introduced in place of the proton [1, 2]. In *N*-salicylidenanthranilic acid *(1)* there are two possibilities for hydrogen bonds to the same N atom. Thus it should be possible to replace two hydrogen atoms by a single boron atom. In fact, when compound *(1)* reacts with diphenylborinic acid, one phenyl residue is removed from the latter with smooth formation of *B*-phenyl-(*N*-salicylideneanthranilato)-*O,O,N*)-boron *(2)*. Reaction with boric acid affords μ-oxobis-(*N*-salicylideneanthranilato)-*O,O,N*-boron *(3)*. The structures of the products were proved by analysis and infrared spectra. Compounds *(2)* and *(3)* have considerable stability towards acids and alkalis. It is surprising that attempts to prepare chelates of compound *(1)* with the bivalent metals Cu, Zn, and Cd led to chelates of anthranilic acid with fission of the azomethine linking.

Preparative methods

One mole each of compound *(1)* and a compound containing a *B*-phenyl group (phenylboronic or diphenylborinic anbydride, Flavognost®, Kalignost®) for preparation of *(2)*, or boric acid for preparation of *(3)*, are refluxed for about 15 min with about one liter of glacial acetic acid. After cooling, compounds *(2)* or *(3)* slowly crystallize. The products are washed first with glacial acetic acid and then with warm water and alcohol and are dried in a vacuum desiccator over sulfuric acid. They are yellow and fluoresce yellowish-green or green in ultraviolet light.

20th International Congress for Pure and Applied Chemistry, Moscow 1965

Between July 12th and 18th, 1965, more than 4000 scientists gathered in Moscow for the 20th IUPAC Congress. More than 650 plenary and short lectures were delivered, dealing with cosmochemistry, inorganic chemistry, analytical chemistry, radiation chemistry, the physical chemistry of surfaces and of disperse systems, and the fundamentals of chemical technology. An international symposium considered the properties and uses of low-temperature plasmas.

In the following, some of the contributions of interest to chemists are summarized.

Owing to the 3rd International Fluorine Symposium in August, only a few lectures were held on the chemistry of fluorine. *N. Bartlett* (Vancouver, Canada) has shown, by magnetic susceptibility measurements, that "PdF_3" should be written $Pd^{2+}[PdF_6]^{2-}$. The complex anion can be isomorphously replaced by $[GeF_6]^{2-}$, $[SnF_6]^{2-}$, and $[PtF_6]^{2-}$. Progress in the chemistry of the rare gases was reported by *J. G. Malm* (Argonne, Ill., U.S.A.). Solutions of XeF_6 can be oxidized with ozone in an alkaline medium to give perxenates, which contain Xe(VIII), and which are themselves extremely powerful oxidizing agents in acidic solutions. SiF_2, which had previously been known only from transport experiments, was isolated by *M. Schmeisser* (Aachen, Germany) by the thermal decomposition of Si_2F_6 and by the reaction of Si with SiF_4. The compound SiF_2 is monomeric below −80 °C, and readily polymerizes to form a white solid $(SiF_2)_\infty$. *R. Hoppe* (Münster, Germany) obtained very pure ternary fluorides by the fluorination of defined intermetallic compounds; *e.g.*, $NaTlF_4$ was obtained from NaTl.

Many contributions dealt with the synthesis of new inorganic compounds. *M. Dratovsky* (Prague, ČSR) prepared iodates containing I(VI), *e.g.*, Na_2IO_4, by the thermal degradation of periodates. In aqueous solution, IO_4^{2-} disproportionates into IO_3^- and IO_4^-; these iodates (IV) exhibit the expected paramagnetism of 1.7 B.M. in the crystalline state. With the aid of transport experiments in a temperature gradient of from 1200 to 1000 °C, *A. V. Novosselova* (Moscow, USSR) obtained single crystals of Be_2SiO_4; the participation of the gaseous substances $NaBeF_3$, $SiOF_2$, SiF_4, and NaF in the transport was explained on the basis of infrared and mass spectrometry. *A. N. Christiansen* (Aarhus, Denmark) prepared $BaMnO_3$ in a hydrothermal synthesis from freshly precipitated δ-$MnO_{1.8}$ in 0.4 M suspension of $Ba(OH)_2$, the synthesis being carried out under oxygen pressure at 200 to 330 °C in a steel autoclave lined with gold foil. *W. Gerrard* (London, U.K.) reported on the synthesis of inorganic polymers of the type $(-O-PO(OR)-O-SiCl_2-)_n$, which can be prepared from $SiCl_4$ and $OP(OR)_3$ by the elimination of RCl. Using the dilution principle and working in the absence of light, *M. Schmidt* and *E. Wilhelm* (Marburg, Germany) obtained the cyclic sulfur species S_6, S_{10}, and S_{12} from H_2S and S_2Cl_2; the reaction also appears to be suitable for the preparation of S_7, S_9, and S_{11}. *K. Dehnicke* and *J. Strähle* (Stuttgart, Germany) found that the azide chlorides $MoCl_5N_3$ and WCl_5N_3, which are obtained by reaction of $MoCl_5$ and WCl_6 with ClN_3, decompose with loss of N_2 and Cl_2 to form the nitride chlorides $MoNCl_3$ and $WNCl_3$ containing triple bonds between nitrogen and the metal. VCl_4N_3, on the other hand, loses only N_2 to form the readily volatile monomeric $Cl_3V{=}NCl$. According to *P. I. Paetzold* (München, Germany) the thermal decomposition of diaryl borazides at 180 °C leads to the formation of dimeric diarylborazenes $(ArN-BAr)_2$, which are extremely sensitive towards acids, but are thermally stable. The behavior of the BN four-membered ring is similar in many respects to that of the cyclobutadiene ring. A promising method for the preparation of ternary oxides was described by *C. C. Addison* (Nottingham, U.K.), who treated metal oxides such as TiO_2 and MoO_3 with a large excess of elementary sodium at 100 to 600 °C, to obtain *e.g.* Na_2TiO_2 and Na_2MoO_3. The excess of sodium, which acted as the reaction solvent, was distilled off in vacuum after the reaction.

Great interest was shown in the problems of semiconductor chemistry. According to *H. Krebs* (Stuttgart, Germany) a deeper understanding of the properties of semiconductors is offered by two factors: the localization of valence electrons on the atom with the greater effective nuclear charge, and the delocalization as a result of eigenfunctions having maxima in several directions, so permitting the establishment of a continuous bond system in the crystal. *A. A. Vypolin* (Leningrad, USSR) studied the semiconducting properties of compounds of the type $A^{II}B^{IV}C_2^V$, *e.g.* $CdSiP_2$ and $ZnSiAs_2$, in relation to their structure. The ternary compounds Ag_3SBr and Ag_3SI, which crystallize in the antiperovskite structure, were obtained in a solid state reaction by *B. Reuter* and *K. Hardel* (Berlin, Germany). The current is transported almost exclusively by Ag^+ ions, which migrate *via* cationic holes. According to *J. Flahaut* (Paris, France), rare earth sulfides of the type M_5S_7 (M = Dy to Tm) are formed by the thermal degradation of the normal sulfides M_2S_3 in vacuum at 1700 °C. These compounds are monoclinic, isomorphous with one another, and paramagnetic, and they possess semiconductor properties. Ternary sulfides of the type $BaTiS_3$ or $BaZrSe_3$ with semiconductor properties were prepared by *L. A. Aslanov* (USSR). The compounds are isotypic with $LiI{\cdot}3H_2O$.

In connection with the electronic structure and periodic properties of the elements, *N. S. Akhmetov* and *G. S. Vozdvizhensky* (Kasan, USSR) suggested, on theoretical and practical grounds, that the zeroth group of the periodic system should be included with the eighth group, and that the triads of the Fe, Co, and Ni groups should be inserted in gaps between Ar and Kr, between Kr and Xe, and between Xe and Rn, respectively.

Only a few of the lectures dealt with the theory and application of nuclear magnetic resonance spectroscopy. The relationships between chemical shifts and coupling constants on the one hand and properties such as electronegativity, bond energy, electron affinity, ionization potential, *etc.* on the other are not yet accessible to a quantitative theoretical treatment. *G. F. Svatos* (St. Louis, Mo., U.S.A.) attempted to treat the chemical shielding and the spin coupling as functions of the ionic and covalent contributions to the bond energy.

R. J. Chuck (London, U.K.), discussed ion-pair effects in the symmetrical ions $[B(CH_3)_4]^-$, $[Al(CH_3)_4]^-$, $[Al(C_2H_5)_4]^-$, $[Sb(CH_3)_4]^+$, $[Sb(C_2H_5)_4]^+$, and $[P(C_2H_5)_n(CH_3)_{4-n}]^+$. A study of the line-widths revealed a close relationship between ion-ion and ion-solvent interactions.

A new application of NMR spectroscopy has been found in the chemistry of gallium. The ^{71}Ga nucleus has a spin number of 3/2 and a resonance frequency of approximately 20 Mc/s at a field strength of 15400 gauss. *N. N. Greenwood* (Newcastle-upon-Tyne, U.K.) described investigations on complex gallium ions. Since the quadrupole moment is large in comparison with the magnetic moment of the nucleus, only symmetrical ions with no electric field at the position of the nucleus could be studied. The chemical shifts obtained were extremely large (> 1000 ppm). Initial investigations provided proof that gallium(II) halides have the structure $Ga[GaX_4]$. Several new ions were found on hydrolysis of gallium halides.

E. Fluck (Heidelberg, Germany) used ^{31}P resonance spectra to study ligand-exchange reactions in phosphorus halide

pseudo-halide systems such as $PCl_3/P(NCS)_3$, $OPCl_3/OP(NCS)_3$ *etc.* A random exchange of the halogen and pseudo-halogen ligands was observed in most cases.

B. F. Scribner (Washington, D.C., U.S.A.) surveyed recent advances in spectrochemical excitation sources. The properties of chemical flames have been greatly improved by the introduction of new fuel-gas compositions. Notable increases in sensitivity are often obtained by the addition of organic solvents to the specimen solutions. Electrical flames, such as the high-frequency torch and the d.c. plasma jet have considerable advantages over conventional excitation sources, such as high reproducibility and insensitivity to "matrix effects". Vaporization of the material with a laser beam combined with excitation of the metal vapor by a spark discharge has been found suitable for the study of small parts of a sample (*e.g.* inclusions, inhomogeneities). *I. A. Voinovitch* (Paris, France) reported that, in addition to 8-hydroxyquinoline, other quinoline derivatives as well as phenol and acetone eliminate the blocking effect of aluminium on the emission of Ca and Sr in the flame. Aliphatic amines and alcohols have little or no effect.

S. W. Webb (London, U.K.) described the use of a plasma jet in the determination of calcium in the presence of elements (*e.g.* aluminium and phosphorus) which seriously interfere with determinations in conventional flames. This interference, which is due to inhibition of evaporation, does not occur in the plasma jet, the temperature of which is approximately 7500 °K; thus with this excitation source, the calibration curves no longer depend on the other substances present in the solution. The spectroscopic determination of the isotopic composition of various substances was discussed by *A. N. Saidel* (Leningrad, USSR). Emission methods were generally used, and calibration samples with accurately known isotope abundances were not required for the semiquantitative analysis often used in routine work. In precision work in which calibration samples are used, ordinary spectroscopic equipment is generally capable of giving a relative accuracy of 1 %, or even 0.1 % in favorable cases.

Spectroscopic methods for the analysis of strongly radioactive materials were described by *C. Feldman* (Oak Ridge, Tenn., U.S.A.). Owing to the greater ease of calibration, solution methods are generally used. For the investigation of trace constituents, these must be separated from the bulk of the sample. In the case of solutions of nuclear fuels (thorium, uranium, *etc.*), extraction with esters of phosphoric acid or with amines has proved a suitable method of separation, while electrolysis may be useful for solutions of alloys (principal components Fe, Cr, Ni, *etc.*). *C. Cherrier* (Antony, France) has determined trace impurities in mercury by mass spectrometry. The sample was cooled to −140 °C at 2×10^{-7} to 3×10^{-7} mm Hg and vaporized with a high-purity graphite counter-electrode. A sensitivity of 0.5 atom per million was obtained with an exposure time of about 30 min. Other substances, such as very pure acids, can also be analysed in this way.

F. Lux (München, Germany) reported on the determination of small quantities of uranium and technetium in small samples of various matrices by X-ray fluorescence analysis. The sample is preferably used in the form of a thin layer (as in the case of samples for β-radiation measurements), the detection limit for uranium then being 10^{-4} %. Even at higher uranium and technetium contents, however, the layer method has a number of advantages over the usual analysis in solution.

According to *Cagnard* (Paris, France), a laser beam can be used to advantage for the excitation of the Raman spectra of unstable or light-sensitive organic compounds. The He-Ne laser emits a monochromatic beam at 6328 Å, which does not produce the photochemical effects observed with ordinary light, and which gives a spectrum without a continuous background.

In the gas-chromatographic analysis of alloys, *R. W. Moshier* (Wright-Patterson Air Force Base, Ohio, U.S.A.), converted the components of the alloys (*e.g.* Fe, Ti, Nb, Ta, W) into volatile β-diketone complexes, either by treating the anhydrous metal chlorides with 1,1,1,5,5,5-hexafluoropentandione in CCl_4 or by extracting the acetate-buffered solution of the sample with 1,1,1-trifluoropentandione in benzene, CCl_4, or $CHCl_3$. The solutions of the complexes were then introduced directly into the chromatograph.

The concentration of trace impurities in very pure metals by zone melting has been studied by *Sh. I. Peisulayev* (Obninsk, USSR). In adapting this originally preparative method of purification, one must bear in mind that appreciable losses occur as a result of evaporation or scorification of the impurities. The optimum velocity of zone travel and the number of passes required must be calculated separately for each individual case. According to *K. Ueno* (Fukuoka, Japan) it may be advantageous to convert the metal into one of its compounds before zone melting. Suitable compounds include chelates that melt without decomposing, particularly acetylacetonates.

In a plenary lecture on radiation chemistry, *F. S. Dainton* (Leeds, U.K.) spoke on "Important Early Stages in the Radiolysis of Solid and Liquid Systems". High-energy radiation is suitable for the ready production and study of radical-ions, solvated electrons, and free radicals.

M. Magat (Orsay, France), reported on "Radiation-Induced Polymerizations in Solids at Low Temperatures", and *M. Steinberg* (Upton, N.Y., U.S.A.) surveyed "Progress in the Industrial Use of High-Energy Radiation". Outside of the plastics field, only one radiation-induced process is used in industry today, *i.e.* the production of ethyl bromide from ethylene and hydrogen bromide; nevertheless, a number of other processes appear to be suitable. These include the reduction of carbon dioxide, the production of nitrogen oxides from nitrogen and oxygen, and the preparation of hydrazine from ammonia.

Many of the lectures dealt with the radiolysis of aqueous solutions and organic liquids and solids. The discussion was centered on the behavior of the electrons liberated by the ionizing radiation. The existence of solvated electrons in polar solvents is now established. The reactions of the solvated electron have been studied with the aid of electron acceptors, and the rate constants were measured by pulse radiolysis. Reactions with reactive substances have rate constants of up to 10^{10} l/mole sec. However, the reaction of the solvated electron with water is particularly slow. The lowest rate constant found so far for this reaction, according to *E. J. Hart* and *S. Gordon* (Argonne, Ill., U.S.A.), is 16 l mole^{-1} sec^{-1}. According to *A. Kupperman* (Pasadena, Calif., U.S.A.), the existing diffusion model for the radiolysis of water can be checked in the light of more accurate data now available for the reaction rates of electrons. The results show that a large proportion of the "primarily" formed H atoms (H-radical yield) result from a reaction of electrons with protons.

The question of the formation and existence of solvated electrons in non-polar solvents has not yet been settled. *G. Scholes* (Newcastle-upon-Tyne, U.K.), found that the irradiation of hexane in the presence of N_2O yields nitrogen, with a G value greater than two, indicating that electrons also exist in non-polar media. Similar results were obtained by *P. J. Dyne* (Chalk River, Canada) by the low-temperature irradiation of samples consisting of layers of hexane and carbon tetrachloride approximately 100 Å thick. In frozen hexane, the electrons have a range of about 200 Å. Using the same layer technique, *Dyne* also detected the transfer of energy between deuterated and undeuterated hexane.

Opposing views as to the mechanisms leading to the formation of solvated electrons were advanced by *G. R. Freeman* (Edmonton, Canada), and *R. Schiller* (Budapest, Hungary). The question of whether the deciding factor is the static or the dynamic behavior of the material, *i.e.* the static dielectric constant or the relaxation, has not yet been settled.

G. E. Adams (Northwood, Middlesex, U.K.), reported investigations on HO_2, O_2^-, OH, O^-, and O_3^- radicals. The rates of reaction of some of these radicals with organic

substances have been measured as functions of the molecular structure by the pulse radiolysis technique. The same technique has been used to determine the position of the acid-base equilibria of a number of radicals. Thus, according to *J. Rabani* (Jerusalem, Israel), the pK value of the equilibrium $\cdot OH + OH^- \rightleftharpoons O^- + H_2O$ is 11.9, and that of the equilibrium $\cdot HO_2 \rightleftharpoons H^+ + O^-_2$, according to *M. S. Matheson* (Argonne, Ill., U.S.A.) is 4.45.

Ch. S. Bagdassaryan (Moscow, USSR), detected the formation of stable radical-cations by a spectroscopic method, when amines were exposed to γ-rays in organic glasses. The quantum yield for the formation of the radical cation can be as high as 3. Thus in certain cases each primary ionization results in the formation of a radical cation. *G. O. Phillips* (Monmouthshire, U.K.), discussed the energy transfer during irradiation of carbohydrates in the presence of aromatic compounds. It can be shown by ESR spectroscopy and by yield measurements that the decomposition of the carbohydrates decreases in the presence of aromatics. The nature of this protection is not yet clear.

Yu. A. Kolbanovsky (Moscow, USSR), demonstrated the formation of polycarboxylic acids in the polymerization of carbonic acid and ethylene with γ-irradiated catalysts. The products (molecular weight ≈ 3000) contain one carboxyl group per 50 ethylene units, and are soluble in dimethylformamide. *A. J. Swallow* (Manchester, U.K.), in collaboration with *D. Hummel* (Cologne, Germany), reported on the radiation-induced addition of hydrogen chloride to olefins, which may proceed as a chain reaction. *D. Schulte-Frohlinde* and *F. Merger* (Karlsruhe, Germany) studied the mechanism of the radiation-induced hydroxylation of nitrophenol. The first step in this reaction is the extremely selective addition of the hydroxy radical to the benzene nucleus to form a cyclohexadienyl radical.

V. N. Kondratyev (Moscow, USSR), in his lecture on "Problems in the Study of Elementary Processes in Low-Temperature Plasmas", reviewed the present position of the theory and the experimental determination of data for the following processes: the thermal dissociation of diatomic and polyatomic molecules, exchange reactions, the excitation and ionization of atoms by electrons, collision ionization, recombinative ionization, electronic excitation, electronic energy transfer and charge transfer in collisions of atoms and molecules, reactions of ionized molecules, dissociative recombination, and associative ionization. Equilibrium constants cannot yet be determined with sufficient accuracy.

W. Lochte-Holtgreven (Kiel, Germany), in his lecture on "Simple Chemical Reactions in Plasmas", dealt with the formation of negative ions. The ions H^-, C^-, N^-, O^-, Cl^-, Ca^-, and Al^- have been detected by their continuous radiation. The preferred temperature range for the formation of these ions is beetwen 3000 and 8000 °K, *i.e.* higher than flame temperatures and lower than luminous-arc temperatures. This temperature range is reached by supplementary electric heating of flames; a quantity of electrical energy that roughly corresponds to the energy of combustion is supplied to the flame. Reaction products can be isolated from a plasma in various ways: by cooling a streaming plasma, by cooling the anode flame of a luminous arc, or by adiabatic cooling in vacuum. The last method in particular was used by *Lochte-Holtgreven* for the reduction of oxides at a high throughput: castings 15 cm long made of the oxide powder, charcoal, and tar when placed in a carbon tube anode, were reduced within a few seconds. The resulting metal was not pure, however, since the carbon anode partly disintegrated.

M. W. Thring (London, U.K.), in his lecture on "Plasma Engineering", surveyed the possible methods of using a plasma as a "commercial reaction system". He discussed *inter alia* the following endothermic processes which, although unable at present to compete with conventional methods of synthesis, may acquire some importance in the future, *e.g.* the preparation of acetylene in a plasma beam by reactions (a) and (b). The best yields of acetylene are ob-

$$2\,C + H_2 \rightarrow C_2H_2;\ \Delta H = -543\ \text{kcal} \quad \text{(a)}$$

$$2\,CH_4 \rightarrow C_2H_2 + 3\,H_2;\ \Delta H = -86\ \text{kcal} \quad \text{(b)}$$

tained if argon or helium is used as the carrier gas. At a plasma temperature of 12000 °K, 80 % of methane could be converted into acetylene.

Dicyanogen is formed in accordance with Equation (c) in a nitrogen plasma which reacts with the graphite cathode; the

$$2\,C + N_2 \rightarrow (CN)_2;\ \Delta H = -71\ \text{kcal} \quad \text{(c)}$$

yield is 15 %, based on the carbon used. Hydrocyanic acid has been obtained by the reaction of a graphite cathode with a hydrogen-nitrogen plasma. In this reaction (d), 50 % of the

$$2\,C + H_2 + N_2 \rightarrow 2\,HCN;\ \Delta H = -60.2\ \text{kcal} \quad \text{(d)}$$

carbon was converted into hydrocyanic acid and acetylene, which is the most important by-product formed.

Uranium carbide can be prepared from uranium dioxide and carbon at a plasma temperature of from 4000 to 5000 °K

$$UO_2 + 3\,C \rightarrow UC + 2\,CO;\ \Delta H = -179\ \text{kcal} \quad \text{(e)}$$

[Equation (e)]. In this case the uranium dioxide and carbon form the rod anode.

M. J. Joncich and *J. W. Vaughn* (Dekalb, Ill., U.S.A.) have prepared iodides, sulfides, halides, and carbides of magnesium and aluminum, as well as nitrides of magnesium, titanium, zirconium, tantalum, and aluminum, by exploding metal wires in the presence of a non-metal (*e.g.* sulfur, iodine). The yields were from 20 to 60 %. The nitrides of iron, rhodium, platinum, copper, zinc, and cadmium could not be obtained by this method. This synthesis of binary compounds has the following advantages: It permits the preparation of very hygroscopic substances; it can also be used to prepare compounds that are not formed under normal laboratory conditions, since the required activation energy is available only in the case of a wire explosion. The experimental arrangement is simple. The reactions are complete in 100 μsec or less, and the products are very rapidly cooled to the ambient temperature, particularly when the reaction is carried out in a liquefied gas. [VB 955/262 IE]

International Congress on Fuel Cells

I. Low and Medium Temperature Cells

The Belgian Société d'Etudes, de Recherches et d'Applications pour l'Industrie organized a meeting in Brussels (Belgium) of scientists working on the development of fuel cells. This meeting was the largest on this subject so far to be held on European soil: 60 lectures were delivered to the 380 participants from June 21st to 24th, 1965.

C. Berger, Newport Beach, Calif. (U.S.A.) reported on organic and inorganic ion-exchange membranes. Single-membrane cells are easy to construct and are compact (representative specifications: 0.72 volt, 75 mA/cm², 110 kW/m³, and 80 W/kg). Their disadvantages are the difficulties encountered in controlling the temperature and moisture. Attempts have

been made to avoid these difficulties with double-membrane cells containing mobile electrolyte between two ion-exchange membranes connected to the electrodes, but the power density falls to 46 kW/m³. All organic exchange membranes are prone to decomposition by high temperatures and oxidative attack. The search for an ion-exchange material stable between 25 and 150 °C led to inorganic exchangers, particularly zirconyl phosphates. Membranes were made either from the pure inorganic material or by embedding it in organic supports. Zeolytes can also be incorporated in order to improve the moisture control. The results of prolonged experiments (300 h) at 150 °C are of interest for the direct conversion of hydrocarbons, which is possible only at high temperatures. Current densities of about 10 mA/cm² at a cell potential of 0.4 V were obtained with propane and butane at platinum electrodes using inorganic ion-exchange membranes. These figures are promising. Attempts were made to economise in the platinum consumption by direct impregnation of the membrane surfaces with the platinum catalyst.

K. Schwabe, Dresden (Germany) discussed the use of oxygen electrodes in fuel cells. Reduction of oxygen with high current densities at catalyst-free carbon electrodes can be achieved only in the strongly alkaline region. A platinum coating is required in the acidic range. Reduction of the Pt content from 10–20 mg/cm² to one-tenth these amounts with maintenance of the activity of the electrodes was achieved by a coating of an Al-V spinel. Satisfactory operation in long-term experiments depends largely on the type and amount of agent used for making the electrodes hydrophobic and on the method of impregnation. Application of a 3% solution of polyethylene in toluene proved to be suitable.

O. Vohler and *R. Martina*, Meitingen near Augsburg (Germany) have adopted a new method for making carbon electrodes for fuel cells with a sharp maximum in the pore distribution curve. Extraneous binding agents can be dispensed with by starting out from cellulose of uniform grain size; after coking, samples of satisfactory rigidity are obtained. The integral pore volume and the pore diameter can be influenced by the pressure used and the nature of the hydraulic fluid, *e.g.* H_2O,C_2H_5OH. The hydraulic press can be used simultaneously to introduce a catalyst into the electrode. This method was used to prepare double-layer carbon electrodes with two layers of different pore sizes. Up to 75% of the pore volume of the sintered carbon is accessible to the electrolyte; the specific surface area lies between 5 and 10 m²/g depending on the conditions used for its preparation.

J. M. Auclair, Marcoussis (France) found that sintered Ni/Ag electrodes can be used without activation on both the oxygen and hydrogen sides of hydrogen fuel cells. Industrial gases give current densities of 50 mA/cm² and cell potentials of 0.7 V at 20 °C. The current density rises to 300 mA/cm² on raising the temperature to 80 °C. CO contents of 1–5% in the gas do not interfere with the operation of the element; the current decrease is still reversible at 20–30% CO. In intermittent operation (current drawn for 10% of the time), the life of the cell is 22 months; in continuous operation at 50 mA/cm² it is 6 months.

H. A. Liebhafsky, Schenectady (U.S.A.) dealt with the problem of direct hydrocarbon combustion cells. Anodic oxidation of hydrocarbons occurs in a series of steps: adsorption, cleavage of C–H and C–C bonds, charge transfer, reaction of intermediates with the solvent, and removal of the reaction products. Since C–H bonds are split much easier on the catalyst than C–C bonds, there is a danger that carbon-rich intermediates accumulate and block the reaction. It was therefore surprising that complete oxidation of unbranched saturated hydrocarbons to carbon dioxide and water was observed. A gauze electrode containing platinum black as catalyst was developed as anode in the General Electric Research Laboratory. A thin porous layer of Teflon on the gas side maintains a stationary position of the three-phase boundary within the electrode. The reactivity increases from methane to propane and butane and then falls with increasing chain length. The same electrode can also be used as cathode. Because of the short diffusion path, operation with air instead of oxygen does not involve any significant reduction in output. Current densities of about 20 mA/cm² at 0.5 V were obtained with methane or propane in complete cells containing 85% phosphoric acid as electrolyte at 150 °C. Attempts to replace the acidic electrolytes with another CO_2-repellant but less corrosive electrolyte have so far remained without success. The major task is now to reduce the platinum content of the electrodes, to augment the activity with additives to the platinum, or to replace the expensive noble metal entirely. At present, about 500 g of Pt would be required to achieve an output of 1 kW.

H. Binder, *A. Köhling*, and *G. Sandstede*, Frankfurt/Main (Germany) studied the anodic oxidation of hydrocarbons in acids. In 3 N sulfuric acid, complete direct oxidation of methane, ethane, and propane can be achieved at 90 °C and +0.5 V (*vs.* a reversible hydrogen electrode). Ethylene is only 90% converted to carbon dioxide and water judging from measurements on porous gold electrodes containing 100 mg/cm² of Raney platinum as catalyst. Ethane and propane are the most reactive alkanes. The polarization potentials in 3 N sulfuric acid are lower at 100 °C than at 120 and 155 °C in 26 N phosphoric acid. When the unit is switched off, a small amount of hydrogen and CO_2 is reformed but no methane can be detected. With ethylene, the back reaction leads to CO_2 and ethane. Propane can displace some of the adsorbed hydrogen from the platinum surface judging from the current *vs.* potential curves determined by the potentiostatic potential method. The oxidation of the hydrocarbon occurs on the free surface, *i.e.* in the double-layer portion.

II. High Temperature Cells

G. H. J. Broers and *M. Schenke*, Amsterdam (Holland) dealt with high temperature cells run with paste electrolyte. The life and load capability of such cells have been considerably improved over the past few years but *Broers* maintains that there is still a long way to go before they will be ready for commercial exploitation. Greater demands are placed on the stability of the electrolyte (alkali metal carbonates + magnesium oxide) and electrodes at the high operating temperatures (about 720 °C) than in low temperature cells. Pulse and impedance measurements were made on cells with porous nickel anodes and silver or copper oxide cathodes. The material transport in the film of electrolyte on the electrodes is the rate-determining step. The ohmic potential drop Ri in the cell represents the major proportion of the total polarization. In prolonged experiments iR increases owing to evaporation losses from the carbonate electrolyte but the remaining polarization becomes constant after two months. Small units could be run for 6 months at 100 mA/cm², but the cell potential decreased from 750 to 480 mV during this period. A battery of ten elements in series utilizes 90% of a 1:1 hydrogen/carbon dioxide fuel mixture when the electrodes are worked at 62 mA/cm². The utilization under the same conditions for the gas at the cathode (2.5 parts air + 1 part CO_2) is 94%.

P. Lovy, La Plaine-St. Denis (France) reported that Gaz de France has worked since 1961 on the development of high temperature cells using fused alkali metal carbonates as electrolyte in attempts to use natural gas as an electrochemical fuel. Corrosion of the porous silver cathode used was suppressed by applying a layer 0.1 mm thick of sintered Al_2O_3. However, the electrodes cannot be piled up as in a filter press because they are so fragile. At present, concentric arrangements are being tested. A carbon tube activated with palladium is used as anode; this is covered with the sintered alumina layer containing the electrolyte and then surrounded by the silver electrode. The fuel gas flows through the carbon tube while the air/carbon dioxide mixture flows around the external cathode. Satisfactory mechanical stability is achieved

with this arrangement but its electrochemical properties are poor. At 600 °C and 20 mA/cm², the life of the cell is only a few days.

III. Cells with Solid Electrolyte

D. W. White, Schenectady (U.S.A.) explained that ZrO_2 doped with 7–10 mole-% Y_2O_3 has a higher conductivity at 800–900 °C than ZrO_2 containing 11–14 mole-% CaO. The gradual drop in conductivity can be reversed by brief heating at 1200–1400 °C. A cell with this electrolyte in the form of a crucible containing molten silver as oxygen cathode was run for 5 months using natural gas as fuel. Methane is pyrolysed at the outer wall, and the pyrolytic carbon is oxidized electrochemically to CO. The carbon monoxide and hydrogen pass out of the cell and must be burnt in another cell.

H. H. Möbius and *B. Rohland*, Greifswald (Germany) proposed the use of a bundle of 2500 tubes, each 1 m long, per m² as a suitable construction for a high temperature fuel element which is supplied on the inside with fuel gas and on the outside with air. Large units are expected to work with high efficiency only when the heat dissipated and remaining heat of combustion can be utilized in a coupled power generator. The production of stable electrodes presents some problems. Addition of cerium, uranium, and praseodymium oxides to the surface regions of the ZrO_2 was proposed in order to augment its electronic conductivity. Connection to the ceramic oxide electrodes could then be made through metallic point contacts.

IV. Nonporous Electrodes

M. A. Vertes and *A. J. Hartner*, New York, found that when fuel reformation is allowed to proceed inside the cell in the gas space of a nonporous palladium/silver foil electrode, the "lost heat" developed in the cell can be used for the endothermic reaction in the gas space. Since the foil electrode works satisfactorily at even low hydrogen partial pressures, temperatures of 200–250 °C are high enough in the reforming space. A nickel carrier catalyst is used for hydrocarbon fuels and a zinc/copper oxide catalyst for methanol as fuel. A limiting current density of 85 mA/cm² was found with hexane at 250 °C. Current densities of 100–200 mA/cm² with very little polarization were observed at temperatures as low as 200 °C with methanol/water vapor mixtures. Bacon electrodes were used as oxygen cathodes in complete cells with 85% KOH as electrolyte. With gasoline and oxygen, the cell can be run at 100 mA/cm² and 0.7 V at 250 °C.

S. M. Chodosh and *H. G. Oswin*, New York, investigated the activation of nonporous Pd/Ag electrodes as hydrogen anodes. The entry of the hydrogen into the Pd phase is known to be kinetically inhibited. Various possibilities for activating the foil surface on the gas side, *e.g.* by etching, oxidative or reductive treatment at high temperature, roughening with alumina powder, or the application of pouros layers of Pd or Pt, were discussed. Activating layers of noble metals were applied by galvanic methods or by immersing the palladium foil charged with hydrogen in solutions of the noble metal salts. Foil anodes 40–400 μ thick activated in this way exhibited diffusion-controlled limiting currents which were inversely proportional to the foil thickness. The stability of the activating layer was studied for several hundred hours at a load of 100 mA/cm² at 250 °C.

A. Küssner, Erlangen (Germany) examined irreversible changes in nonporous palladium/silver foil hydrogen electrodes. The diminution in activity and load capacity of hydrogen foil electrodes in long-term experiments led to the discovery of irreversible processes in the foil. The uptake of hydrogen in the palladium/silver alloy is accompanied by a continuous expansion of the lattice. If the foil electrode is now subjected to sporadic changes in load, pressure gradients arise in the proximity of the foil surface and lead to plastic deformations of the foil material. The diffusion of hydrogen is adversely affected by the resultant lattice defects. The alternating expansions and contractions also result is localized separations of the activated material from the base material. It is hoped that hardening of the material will bring improvements.

V. Electrocatalysis

C. E. Heath, Linden, N.J. (U.S.A.) assumed that the oxidation of methanol on platinum catalysts proceeds *via* surface oxides. Since ordinary platinum black does not sufficiently accelerate the reaction in acidic solution, attempts were made to modify the Pt surface by incorporation of other metals, *i.e.* to increase its specific surface area, and to alter its band structure or introduce defects. The experiments did not have the desired results. On the other hand, the introduction of immobile redox couples into the catalyst surface have an activating effect and determine the potential of the electrode. Methanol/air cells with a platinum/ruthenium catalyst were built which could be loaded with 50 mA/cm² at 50–60 °C and a cell potential of 0.5 V. Slightly lower cell potentials were observed in a battery of 16 cells.

F. P. Dousek, Prague (Czechoslovakia) found that the handling of Raney nickel hydrogen electrodes is complicated by the pyrophoric nature of this catalyst. This difficulty can be avoided by expelling most of the adsorbed hydrogen either by anodic polarization or by treatment with organic compounds that can be hydrogenated. However, the catalytic activity is always depleted by this treatment. *Dousek* observed that when Raney nickel is dissolved out of the Al/Ni alloy with 5 N sodium hydroxide and the solution is subsequently brought to pH 6.5 with tartaric acid, hydrogen is released. The desorption proceeds very rapidly when the nickel is heated to 90 °C with distilled water. After this mild treatment, the catalyst is still active but no longer pyrophoric. Electrodes similar to those of the Bacon type were made from this catalyst by sintering at 450 °C in an atmosphere of hydrogen and gave good current *vs.* voltage curves for the oxidation of hydrogen in long-term experiments, where they remained stable for over 10000 h of operation.

R. Jasinski, Waltham, Mass. (U.S.A.) reported that nickel boride of composition Ni_2B is an active catalyst for the hydrogen and hydrazine electrode. Its activity is greater than that of Pd or Pt for the hydrazine electrode.

The nickel borides NiB, Ni_4B_3, Ni_2B, and Ni_3B were studied by *H. Jahnke*, Stuttgart (Germany) by X-ray and metallurgical methods. When embedded in a nickel or gold support, Ni_3B is the best catalyst for the oxidation of hydrogen and methanol. Ternary Ni/B/Al alloys were made by sintering and activated like Raney alloys. The polarization of the methanol electrode with such a catalyst at 80 °C and 50 mA/cm² is 215 mV compared with 330 mV with Ni_3B. Since Raney nickel alone cannot catalyse the oxidation of methanol, the activity was ascribed to the NiB_{12} and B incorporated in the nickel catalyst.

I. Lindholm, Västerås (Sweden) also tested the suitability of catalytically active nickel borides as hydrogen electrodes. Sodium borohydride precipitates a black nickel boride of sum formula $Ni_{2\cdot35}B$ with a high specific surface area (31.7 m²/g) from solutions of $NiCl_2$. Some of the boron can be dissolved out with potassium hydroxide solution with concomitant increase in the specific surface area. This catalyst was dried *in vacuo* at 100 °C, mixed with nickel powder as an embedding medium, and the mixture was sintered. Hydrogen anodes were also obtained by precipitation of NiB_2 in preformed sintered nickel supports. In operation at 80 °C and 150 mA/cm², these had a polarization of 100 mV. In long-

term experiments with single cells, the cell potential fell from 0.9 to 0.8 volt at a load of 50 m/cm² within 4000 h. Replacement of the noble metals in low temperature cells with the activated nickel boride catalyst produced a significant reduction in costs. However, the total cost of a battery cannot yet be given. [VB 952/256 IE]

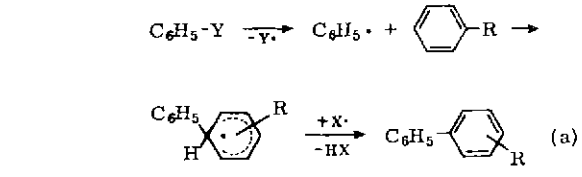
Radical Phenylations with Aromatic Diazo Compounds

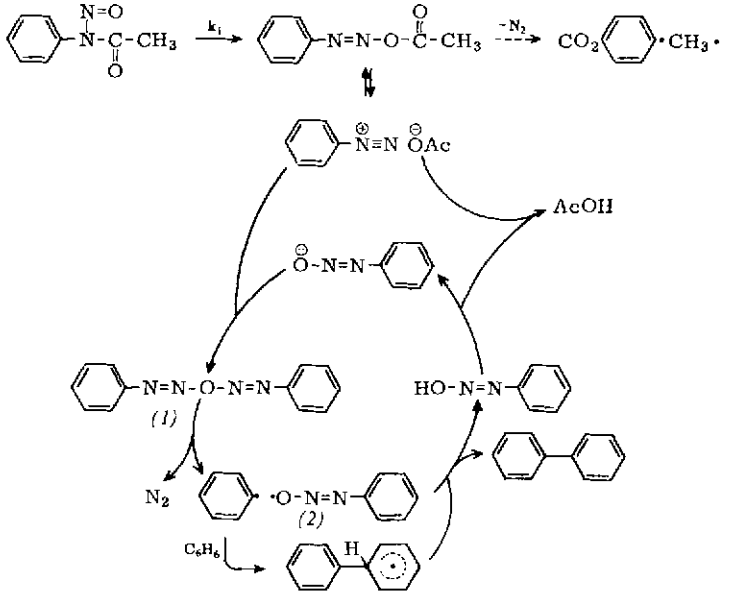
C. Rüchardt, Munich (Germany)

Aromatic radical phenylations occur by the addition-disproportionation mechanism (a). The nature of X· and Y· is essentially clarified for phenylations by dibenzoyl peroxide or

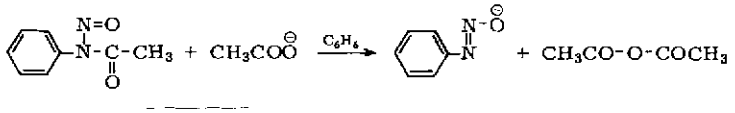


triphenyl(phenylazo)methane, but not for those by aromatic diazo compounds. Assuming that the phenyl radicals are generated from diazohydroxides (Gomberg reaction) or from diazoacetates (thermolysis of *N*-nitrosoacetanilide), or that hydroxyl or acetoxyl radicals constitute X·, contradicts a variety of experimental results [1].

Kinetic investigation of the Gomberg reaction showed that the rate of liberation of nitrogen is proportional to the square of the diazonium salt concentration and is greatest at the pH equal to the pK_a of the diazonium ion-diazotate equilibrium. The results were interpreted as slow formation of diazo anhydrides *(1)* in the aqueous phase and their rapid decomposition in the organic phase. In agreement therewith the formation of biphenyl from benzenediazonium chloride at pH 8.5 is greatly accelerated by addition of *p*-nitrobenzenediazonium chloride, and the yield of 4-nitrobiphenyl under similar conditions increases on addition of benzenediazonium chloride.



Initial reaction



The almost complete absence of evolution of CO_2 on thermolysis of *N*-nitrosoacylanilides, whose acyloxy-radicals must undergo decarboxylation without appreciable activation energy (as, for instance, phenylacetoxyl, phenoxyacetoxyl, or ethoxyoxalyloxy-radicals), is considered a convincing argument against homolytic decomposition of diazo esters formed as intermediates.

Acid anhydrides increase the yield of carbon dioxide from the decomposition of nitrosoacetanilide. The evolution of nitrogen from benzene solutions is first order only in very dilute solutions (0.01 M), and the rate is that of the formation of the diazo ester. The rate of evolution of nitrogen is decreased by the presence of vinylic monomers (acrylonitrile or styrene) and depends greatly on the nature of the solvent. The reaction hardly occurs at all in CCl_4. By reason of these results it was proposed that in the decomposition of diazo esters the formation and decomposition of diazo anhydrides occur in chain reactions. It is known that all steps of this chain reaction proceed rapidly in inert solvents. The diazotate radicals *(2)* were detected and identified by their ESR spectra, which showed them to have a relatively long life, as expected on the basis of chemical results [1].

From 4-chloro-*N*-nitrosobenzanilide in CCl_4 there is formed, besides *p*-chlorobenzoic anhydride and benzenediazonium chloride, a thermolabile compound which, on the basis of its physical and chemical properties, is perhaps the first isolated diazo ester.

The Acid-Base Catalysis of the Mutarotation of Glucose

Hermann Schmid and *Günther Bauer*, Vienna (Austria)

The negative entropy of activation of the water-catalysed mutarotation of glucose is ascribed to the facts that the activating process is the transfer of a proton from the hydroxyl group on the carbon atom adjacent to the ring oxygen to a water molecule and that the electrical field between the ions formed tends to align the solvent dipole in the activated complex.

$$HG_\alpha + H_2O \xrightarrow{H_2O} \text{activated complex } (G^\ominus \ldots H_2O \ldots H_3O^\oplus)$$

HG_α denotes α-glucose and $G^\ominus$ is the glucose anion in the activated complex.

The activation enthalpy of the catalysis with ammonia is almost 4 kcal/mole lower than that of the catalysis with water because the ammonium ion formed in the reaction of glucose with ammonia has a lower tendency to align the solvent dipole in the activated complex than the hydronium ion formed on activation of the α-glucose with water.

The enthalpy of activation for the catalysis with hydronium ions is identical with that for the catalysis with water, but its entropy of activation is less negative. The catalysis with hydronium ions is in fact water catalysis in which the solvent dipole entering the activated complex is "pre-aligned" by the hydronium ions added as catalyst. The activation enthalpies of the mutarotation of glucose catalysed by anions (formate, acetate, α-glucosate, hydroxyl) also correspond to the activation enthalpy of the catalysis with water. These reactions are also water catalyses in which the first step is a reaction of the hydration shell of the ions with the α-glucose.

The rate of mutarotation of glucose in water was measured with and without addition of finely divided copper powder under otherwise identical conditions. The energies of ac-

[1] *C. Rüchardt, B. Freudenberg*, and *E. Merz*: Organic Reaction Mechanisms. The Chemical Society, Special Publication No. 19, London, 1965, p. 168.

tivation were determined by the Arrhenius method; for pure water the value is 17.8 kcal/mole, for "copper catalysis" it is 19.0 ± 1.5 kcal/mole. This heterogeneous catalysis is also a water catalysis by the water molecules which are oriented on the surface of the copper. The mutarotation of glucose does not proceed *via* the open-chain aldehyde; instead, the activated α-glucosate ion inverts to the β-glucosate ion.

Table 1. Catalysis coefficients for the mutarotation of glucose.

Catalyst	Catalysis coefficients [sec^{-1}]		
	5 °C	15 °C	25 °C
NH_3	–	6.26×10^{-2}	0.142
H_2O	–	1.72×10^{-6}	4.90×10^{-6}
$H_3O^{\oplus}$	–	2.23×10^{-3}	6.67×10^{-3}
$HCOO^{\ominus}$	–	3.06×10^{-4}	8.63×10^{-4}
$CH_3COO^{\ominus}$	1.52×10^{-4}	4.88×10^{-4}	1.48×10^{-3}
$C_6H_{11}O_6^{\ominus}$	0.114	0.336	1.00
$OH^{\ominus}$	9.18	27.8	90.7

Table 2. Activation parameters for the mutarotation of glucose.

Catalyst	ΔG* [kcal/mole]			ΔH*	ΔS*
	5 °C	15 °C	25 °C	[kcal/mole]	[cal mole^{-1} deg^{-1}]
NH_3	–	18.4	18.6	13.3	−17.6

Some Reactions of Hydroximic Chlorides

A. Dornow, Hannover (Germany) [1]

Hydroximic chlorides were treated with compounds containing amino groups. The amidoxime derivatives formed react with thionyl chloride to give oxathiadiazole *S*-oxides which on being heated decompose to yield carbodiimides with release of SO_2 [2]. There is an analogy here to the Lossen degradation of hydroxamic acids with thionyl chloride. It also proved possible to cyclize substituted amidoximes with phenylboric anhydride to form oxadiazaboroles.

Ethyl glycinate reacts with ethyl chloroacetohydroxyimate to give ethyl (ethoxycarbonylmethylamino)acetohydroxyimate; with ethyl anthranilate a quinazoline derivative is formed. – *Musante* [3] obtained 1,2,4-oxadiazoles from hydroximic chlorides and amidines. 2-Aminopyridine is similar to the amidines; however, its reaction with the above hydroximic chloride affords a bicyclic compound, a purine analogue, and in contrast to the experiments of *Musante*, here all the nitrogen atoms of the starting components recur in the product.

The reaction of hydroximic hydrazides with carbon disulfide leads by elimination of hydroxylamine to thiadiazoline derivatives, probably *via* the stage of a derivative of hydrazinodithioformic acid. However, when hydroximic chlorides were treated with *S*-methyl hydrazinodithioformate, the cyclization with elimination of hydroxylamine expected did not occur; instead, an amino-1,3,4-thiadiazole was formed. The course of this reaction was clarified by using non-basic components containing the grouping S=C–NH– ⇌ HS–C=N–. The basic hydrazino group is not essential for the reaction to occur, for the initial step is a substitution at the tautomeric mercapto group. This is followed by an intramolecular addition of the oxime group onto the C=N double bond and the intermediate formation of a 1,4,2-oxathiazole. The latter decomposes thermally into the oxygen analogue of the starting material and isothiocyanate, which can react further with basic components. In this way the aminothiadiazole derivative is formed, either unchanged dithio ester or its O-analogue reacting with the isothiocyanate.

The Role of the Nitrosyl Ion in the Dissolution of Metals in Nitric Acid

G. Schmid, Köln (Germany)

There is much controversy about the reactions involved in the dissolution of relatively noble metals such as Ag, Hg, Cu, Bi in nitric acid. The experimental results are contradictory. The autocatalytic effect of nitrous acid is generally acknowledged but is interpreted in various ways.

We examined the reduction of nitrous acid at platinum electrodes in the presence of strong acids (H_2SO_4, $HClO_4$, and H_3PO_4) but in the absence or with stepwise addition of only minute amounts of nitric acid. Measurements of potentiostatic current-time curves [1] and of the stationary current *vs.* potential curves at a rotating disc cathode [2] were made. The results showed that the first step is the discharge of nitrosyl ions to give nitric oxide.

When metals dissolve in nitrous acid, the $NO/NO^{\oplus}$ electrode (standard potential = 1.46 volt [3]) apparently plays the same part as the $H_2/H^{\oplus}$ electrode in the dissolution of ordinary metals in hydrochloric or sulfuric acid. In the latter case, H_2 is formed first, in the former NO is the primary product. In the presence of nitric acid, NO is reoxidized in a homogeneous secondary reaction to nitrous acid, more HNO_2 being formed in this way than is consumed in the primary reaction. Thus the amount of autocatalytic HNO_2 present progressively increases.

The dissolution of a metal in nitric acid (with Ag as an example) can be represented by a scheme proposed by *Abel* [4] (see Scheme 1).

III	II	I		
1	3	2	$Ag \rightarrow Ag^{\ominus} + e^{\ominus}$ (a)	primary reaction of
1	3	2	$NO^{\oplus} + e^{\ominus} \rightarrow NO$ (b)	the corrosion current

tration reaches a limiting value, whereupon the reactions proceed according to Equation II. When the HNO_3 or $NO^{\oplus}$ and $NO_3^{\ominus}$ concentrations are very high, Reaction (e) becomes important and the dissolution proceeds according to the overall Equation III. At the highest HNO_3 concentrations, direct discharge of the $NO_2^{\oplus}$ ion is probably also an important factor in the reaction.

The Chemistry of Polymyxins

K. Vogler, Basel (Switzerland)

The chemistry of polymyxins, a class of basic polypeptide antibiotics, began in 1954 when polymyxin B_1 was first purified by countercurrent distribution *(L. C. Craig)*. Partial hydrolysis with mineral acid led to the conclusion that this was a cyclohepta- or cyclooctapeptide with side-chains containing α,γ-diaminobutyric acid (Dab) *(W. Haussmann)*. An amide linkage of the side chain with a fatty acid – (+)-6-methyloctanoic acid (MOA) or 6-methylheptanoic acid (IOA) – confers the properties of an invert soap on these antibiotics. They are particularly active against Gram-negative bacteria. Difficulties were encountered in elucidating the point of attachment of the side chain and in finding an answer to the question whether the rest of the molecule also contained a D-α,γ-diaminobutyric acid residue. Syntheses with D-Dab led to highly active products which were not however identical with natural polymyxin B_1. Degradation experiments with nagarase *(T. Suzuki)*, which specifically degrades the side chain, revealed that the polymyxins are cycloheptapeptides with α-linked side chains and with a D-amino acid in the ring *(1)*. The α,γ-diaminobutyric acid groupings all have the L-configuration. Structure *(1)* has now been proved by synthesis of polymyxin B_1 and colistin

	R¹	R²	R³	X	Y
Polymyxin B_1	MOA	$-CH_2-C_6H_5$	$-CH_2-CH(CH_3)_2$	Phe	Leu
Polymyxin B_2	IOA	$-CH_2-C_6H_5$	$-CH_2-CH(CH_3)_2$	Phe	Leu
Colistin A (=Polymyxin E_1)	MOA	$-CH_2-CH(CH_3)_2$	$-CH_2-CH(CH_3)_2$	Leu	Leu
Colistin B (=Polymyxin E_2)	IOA	$-CH_2-CH(CH_3)_2$	$-CH_2-CH(CH_3)_2$	Leu	Leu
Circulin A	MOA	$-CH_2-CH(CH_3)_2$	$-CH(CH_3)-C_2H_5$	Leu	Ileu

A, which is identical with polymyxin E_1. Circulin A, which was previously thought to be a cyclodecapeptide, is also a cycloheptapeptide according to the results of new analytical and synthetic experiments.

[GDCh-Ortsverband Aachen (Germany), July 30th, 1965] [VB 951/259 IE]

German version: Angew. Chem. 77, 974 (1965)

General Meeting 1965 of the German Chemical Society and Kekulé Celebration

This year's general meeting of the German Chemical Society in conjunction with the Kekulé Celebration commemorating the 100th anniversary of the benzene formula took place in Bonn (Germany) from 13th to 18th September. The following report contains abstracts of the discussion papers, but is confined to those papers which have not yet been published. Abstracts are arranged alphabetically according to the names of the authors. For a subject index, see page 1003 of this issue.

1

Reactions of "Hot" Carbon Atoms in Nitrogen/Alkane Systems

H. J. Ache and *P. Wolf*, Upton, L.I., New York (U.S.A.)

Reactions of "hot" carbon atoms [generated by $^{14}N(p,\alpha)^{11}C$, $^{12}C(p,pn)^{11}C$, or by $^{11}B(p,n)^{11}C$ processes] in nitrogen/alkane mixtures give rise to ^{11}C-labelled hydrocarbons (*e.g.* acetylene), and $H^{11}CN$ as the only compound containing nitrogen. The reaction of an energetic carbon atom with a nitrogen molecule presumably leads to an $^{11}CN\cdot$ radical, which is stabilized to $H^{11}CN$ in a second rapid step by abstraction of hydrogen from a hydrocarbon molecule.

Further insight into the formation of the second main product, *viz.* [^{11}C]acetylene, was obtained on mixtures of protonated and deuterated hydrocarhons by the "double tracer" technique. The fact that more than 90 % of the [^{11}C]acetylene in 1:1 mixtures of protonated and perdeuterated hydrocarbons is found as $H^{11}C{\equiv}CH$ or $D^{11}C{=}CD$ shows that it is formed by an intramolecular process in which the first step is the insertion of an energy-rich carbon atom into a C–H bond. The highly exited complex formed can decompose to acetylene and other by-products.

In the reaction of hot ^{11}C-atoms with hydrocarbon molecules containing both primary and secondary C–H bonds (*e.g.* propane), preferential formation of [^{11}C]acetylene by C-insertion into C–H bonds of *methyl* groups is observed in the ratio of about 1.3:1.

In mixtures of protonated and perdeuterated hydrocarbons, the acetylene formation shows isotope effects ranging from C_2H_2/C_2D_2 = 1.08 for alicyclic compounds to 1.28 for methane.

2

Radiometric Determination of the Self-Diffusion Coefficient of the Pertechnetate Ion in Aqueous Solutions

L. Astheimer and *K. Schwochau*, Köln (Germany)

In the polarographic determination of electron transfer by the Ilkovič equation, ionic diffusion coefficients calculated from the limiting equivalent conductivity of the ion are generally used. This method assumes the absence of added foreign electrolytes, in disagreement with the conditions used in polarography. Thus at the usual depolarizer concentrations, the self-diffusion coefficient should be used[1]. We determined the self-diffusion coefficient D of the TcO_4^- ion by the capillary method. The long-lived, β^--active ^{99g}Tc was labelled with ^{95m}Tc, which is formed on bombardment of natural molybdenum with deuterons. The equation

$$D = (4l^2/\pi^2 t)\ln[(8/\pi^2)\, A_0/A_t]$$

was used to obtain D from the fraction A_t/A_0 of the activity remaining in the capillary after a time t, where l is the length of the capillary. At 10^{-3} M TcO_4^- in 1 M aqueous NaOH, $D = 1.27\times10^{-5}$ cm²/sec, in 1 M LiCl: 1.24×10^{-5} cm²/sec. In the absence of supporting electrolyte, $D = 1.49\times10^{-5}$ cm²/sec, which almost coincides with the value $D = 1.47\times10^{-5}$ cm²/sec obtained from the limiting ionic conductance. Although the supporting electrolytes noticeably affect the self-diffusion of TcO_4^-, the consequent effects on rate of electron transfer can be neglected. The self-diffusion coefficient of 10^{-3} M perrhenate was also determined in 1 M NaOH and found to be 1.27×10^{-5} cm²/sec, *i.e.* the same as that of TcO_4^- under the same conditions.

Effects in Polarography Attributable to the Specific Adsorption of Reactants

G. C. Barker and *J. A. Bolzan*, Harwell, Berks. (England)

Maxima in d.c. polarography are known to be caused by tangential motion of the surface of the mercury drop and the accompanying streaming of solution near the drop. It has been believed that this tangential motion is due to surface tension gradients connected solely with non-uniformity in the interfacial potential arising from the finite electrical conducitivity of the solution and the non-spherical flow of diffusion current through the solution surrounding the shielded drop. An explanation based on this non-uniformity of potential, however, cannot account for sharp maxima, neither is it consistent with the tendency in many cases for the maximum to increase as the supporting electrolyte concentration is raised. The latter facts become understandable when regard is given to the effect of specific adsorption of a reactant on the electrocapillary curve. If either the oxidized or the reduced form of the depolarizer is strongly adsorbed at the electrode-solution interface, there is a sharp break in the electrocapillary curve at the half-wave potential which greatly affects the rate of change of surface tension with potential in the neighbourhood of this potential. Streaming then tends to be most pronounced close to the half-wave potential and hence a sharp maximum is observed. The height of the maximum may increase along with the supporting electrolyte concentration as the integral adsorption coefficient may be proportional to a power of the anion concentration greater than unity. Although non-uniformity of interfacial potential often plays some part in causing maxima in the presence of specific adsorption, sharp maxima may still occur with solutions of very high conductivity as surface tension gradients may persist due to reactant concentration gradients at the drop surface arising from lack of spherical symmetry in the diffusion systems for the oxidized and reduced forms of the depolarizer.

Specific adsorption of inorganic depolarizers is largely confined to ions of the heavy metals and is most pronounced with halide supporting electrolytes. Approximate values of the adsorption coefficient at potentials close to the half-wave potential can be deduced from changes in wave shape and height produced by specific adsorption in a.c. and pulse polarography. But the most powerful technique for studying specific adsorption of inorganic depolarizers is R.F. polarography as measurements can be made with low depolarizer concentration and with solutions containing insufficient of the adsorption-promoting anion to affect the half-wave potential. Such measurements suggest that lead is adsorbed from perchloric acid solutions containing small amounts of bromide ion in the forms $PbBr^+$ and $PbBr_2$.

4

New Compounds of Lithium Oxide with Europium Oxide

H. Bärnighausen, Freiburg (Germany)

The compound $LiEu_3O_4$ was intensively studied. It is readily prepared by reduction of Eu_3O_4Br with LiH or by treatment of Eu_2O_3 with LiH in a LiCl melt. In the latter procedure evaporation of the LiCl in a high vacuum (600 °C) affords single crystals, examination of which by means of Weissenberg and precession diagrams leads to the following crystal data:

Orthorhombic; a = 11·565 Å, b = 11·535 Å, c = 3·480 Å;
space group Pbnm; Z = 4; ρ_R = 7·539 g/cm³.

According to the formula $LiEu_3O_4$ found analytically, the formula unit must contain two Eu^{2+} ions and this is indirectly confirmed by formation of the isotypic compound $LiSr_2EuO_4$ from the stoichiometric amounts of $LiEuO_2$ and SrO at 700 °C (lattice constants: a = 11·611 Å, b = 11·540 Å, c = 3·4846 Å).

Heating of $LiEu_3O_4$ in air affords the compound $LiEuO_2$, as well as Eu_2O_3 (C form). The new substance occurs in two modifications, which are each obtained in pure form when Eu_2O_3 is treated with Li_2O on slight modification of the reaction conditions. The crystal data of the orthorhombic modification have been reported previously[1]. Crystals of the monoclinic modification belong to space group $P2_1/c$, with lattice constants a = 5·6815 Å, b = 5·9885 Å, c = 5·6211 Å, β = 103·17 ° (Z = 4, ρ_R = 6·807 g/cm³).

5

Ternary Compounds and Solid Solutions in the System Calcium Oxide/Phosphorus(V) Oxide/Boron(III) Oxide

Helmut Bauer, Karlsruhe (Germany)

The ternary system $CaO/P_2O_5/B_2O_3$ has previously been investigated only with regard to the formation and properties of glasses. Investigations confined mainly to the CaO corner show the existence of two compounds with incongruent melting points having the formulae $15CaO\cdot2P_2O_5\cdot3B_2O_3$[1] and $2CaO\cdot P_2O_5\cdot B_2O_3$[2]. The former compound is stable only

between about 1300 and 1400 °C, but can be obtained in a metastable state by rapid quenching. The structure of the compound is not yet known; powder diagrams, however, indicate wide occurrence of the structure type. Thus isostructural phases of wider stability range and a certain range of compositions are found in the systems $SrO/P_2O_5/B_2O_3$ and $BaO/P_2O_5/B_2O_3$, and compounds of the type $6MO \cdot P_2O_5 \cdot B_2O_3$ (M = Mg, Zn, Cd, Cr, Mn, Co, Ni) show similar powder diagrams. $2CaO \cdot P_2O_5 \cdot B_2O_3$ crystallizes in the hexagonal system and is a member of an isotypical series $2MO \cdot X_2O_5 \cdot B_2O_3$, of which the compounds with M = Ca, Sr, Ba, and X = P, As have been prepared.

Besides the ternary compounds, two ranges of solid solutions were found in the system $CaO/P_2O_5/B_2O_3$. These can be assigned structures of the apatite type[1] and the β-tricalcium phosphate type[3]. The solid solutions of apatite structure are based on a combination of substitution (of BO_4^{5-} for PO_4^{3-} groups) and addition (insertion of B^{3+} in interstitial sites and of O^{2-} on the two-fold positions of the apatite lattice); those with the β-tricalcium phosphate structure are formed by pure addition. Both types of solid solutions are also found in other systems $MO/X_2O_5/B_2O_3$: the apatite type in systems with M = Ca, Sr, Ba, and X = P, As, as well as M = Ca, X = V; the β-tricalcium phosphate type in the system $CaO/As_2O_5/B_2O_3$.

Optical Investigations of the Surface Chemistry of Germanium and Silicon

K. H. Beckmann, Hamburg (Germany)

The state of polarization of polarized light reflected from a solid having a thin surface coating depends on the refractive index and the thickness of the film, and can therefore be used to determine these parameters. Thickness measurements on very thin layers (d < 100 Å) can be made with particular accuracy. This method was used to follow the growth of a copper layer on a germanium surface formed by electrode position. It was further shown that during the anodic dissolution of p-germanium in a weakly alkaline electrolyte solution, thin layers of presumably GeO_2 are reversibly formed at certain potentials.

In chemical reactions between a semiconductor surface and the surrounding medium, some of the reaction products often remain on the surface in the form of very thin films. *Harrick*[1] has described a method of determining the infrared spectrum, and thus the composition, of such films in which the radiation is made to traverse the layer 100 times or more by total internal reflections. The infrared spectrum of 15 Å layers of GeO_2 on Ge and the constitution of layers which form on the surface of germanium in various etching solutions were determined by this method.

If in this arrangement the sample in an electrolyte is irradiated with continuous light and an alternating potential is applied between sample and counter electrode at 13 c/s (the modulation frequency of the infrared spectrometer), only the change in the infrared absorption due to the alternating electrochemical polarization is recorded. Such a change occurs, *e.g.*, when the number of absorbing particles changes with the electrochemical polarization. By this means the infrared spectra of free electrons and defect electrons in the space charge zone immediately beneath the semiconductor surface were measured and used to calculate the concentration changes of these charge carriers due to the electrochemical polarization.

7

The Mode of Action of the Antibiotic Chromomycin

W. Behr, K. Koschel, and *G. Hartmann*, Würzburg (Germany)

The antibiotic chromomycin is a very effective inhibitor of DNA-dependent nucleic acid synthesis[1]. Comparative experiments showed that it inhibits the DNA-dependent RNA synthesis as strongly as does actinomycin. The glycosidically bound chromose groups in the chromomycin molecule are essential for this activity. On stepwise cleavage of the sugar residues, a considerable decrease of inhibition efficiency is observed. The sugar-free rest has no effect on RNA synthesis under the conditions used.

As in the case of actinomycin, the reaction of chromomycin with DNA is accompanied by a change in absorption spectrum (red-shift of the maximum in the visible region by about 25 mμ). This indicates that this antibiotic also blocks the DNA. The association indicated by the spectral displacement is, however, significantly slower than that with actinomycin. The apparent enthalpy of activation is about 7 kcal/mole. In the presence of an excess of chromomycin, on the average 29 nucleotides of the DNA bind one molecule of the antibiotic. For actinomycin this ratio is 11:1.

In contrast to actinomycin[2], chromomycin associates not only with DNA and apyrimidinic acid, but also with apurinic acid and transfer-RNA (t-RNA). The spectrum of these associates differs from that of the complex with DNA. With an excess of chromomycin, three t-RNA nucleotides suffice to bind one chromomycin molecule. The antibiotic has no effect on the enzymatic aminoacylation of t-RNA with arginine. Free nucleosides and nucleotides of comparable concentration do not alter the spectrum of chromomycin.

8

Experiments in Chemical Documentation

G. Bergerhoff, Bonn (Germany)

On the bibliography of a very specialized field as an example it is shown that the requirement of completeness increases considerably the number of journals to be scanned. The information material must therefore be condensed. Resolution of publications into words screened with respect to import and redundance can be accomplished by data processing equipment, which can also answer requests for information by logical combination of the stored concepts. The enquirer is led to the original reference without noticing the condensed nature of the stored information.

A randomly selected set of information comprising about 10000 words in 36 publications was processed with a programme of the Deutsches Rechenzentrum. With the aid of a cumulative thesaurus synonyms, foreign words, chemical formulae, and conjugated and declined words can be related to their basic forms, superfluous words can be eliminated, and a reduction to about 10 % is possible. The relatively frequent homonyms are included with all their meanings.

The "ballast" in answers to detailed questions is slight, for general questions stimulating. A logically constructed notation taking into account the expressive power of words would help to reduce ballast and to obtain relations which are not evident in the formalism based on the usual language.

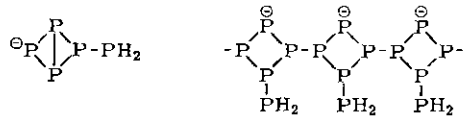
9

Reactions with Potassium Dihydrogen Phosphide

G. Bergerhoff and *F. Knoll*, Bonn (Germany)

Although alkali diorganyl phosphides have become extremely versatile reagents, little is known of the chemistry of the parent compound KPH_2. In oxidation experiments and re-

actions with halides, secondary reactions at the P–H bond always occur. Pure addition reactions can so far be obtained only on elementary phosphorus in dimethylformamide. These can be regarded as nucleophilic cleavage of the P_4 molecule. By following this reaction conductometrically, several intermediate stages were observed, of which the red-brown, amorphous product KP_5H_2 was precipitated with benzene. Attempts to obtain phosphanes by reactions with alkyl halides always resulted in polymers formed by cleavage of P–H bonds as shown by the formation of triphenylmethane from KPH_2 and chlorotriphenylmethane.



(1) *(2)*

Whereas solutions of KPH_2 in dimethylformamide show well-defined ^{31}P- and ^1H-NMR spectra with chemical shifts δ_P = 255.3 ppm (*vs.* 85 % H_3PO_4) and δ_H = 1.12 ppm (*vs.* tetramethylsilane) and coupling constants J_{PH} of 139 and 136.8 cps, the complicated KP_5H_2 gives no ^1H-NMR spectrum and only a poor ^{31}P-NMR spectrum. From the course of the reaction the structure of a monomeric pentaphosphide ion *(1)* or of a polyphosphide ion *(2)* is proposed. The structure *(1)* is supported by molecular-weight determinations. A route to defined polyphosphanes *via* degradation is thus indicated.

10

Reactions at the N=N Double Bond of Azodiphosphoric Acid Derivatives

H. Bock and *E. Kinzel*, München (Germany)

The energy levels of orange azodicarboxylic acid derivatives differ from the corresponding levels of violet azodiphosphoric acid derivatives[1] by up to 20 kcal/mole. Comparison of the reactivity of the two types of compounds was therefore of interest.

Reactions of $Ph_2OP–N=N–POPh_2$ include Diels-Alder cycloadditions, metalation, electrophilic substitution, and addition of proton-active compounds, *i.e.* the same broad reactivity spectrum as the azodicarboxylic ester.

Whereas azodicarboxylic esters oxidize hydroquinones smoothly and without detectable intermediates to quinones the reactions with azobis(diphenylphosphinic acid) gave rise to new 1:1 adducts.

[1] *H. Bock, G. Rudolph, E. Baltin*, and *J. Kroner*, Angew. Chem. *77*, 469 (1965); Angew. Chem. internat. Edit. *4*, 457 (1965).

11

Initiation of Polymerization by Radical Ions and by Dianions

D. Braun and *W. Neumann*, Darmstadt (Germany)

Mono- and disodium adducts of 1,1-diphenylethylene, *trans*-stilbene, and tetraphenylethylene in tetrahydrofuran initiate polymerization of styrene, methyl methacrylate, and acrylonitrile. The corresponding derivatives of benzophenone, *p*-biphenylyl phenyl ketone, bis(*p*-biphenylyl) ketone, and benzophenone anil are initiators for methyl methacrylate and acrylonitrile, but styrene is only initiated by the disodium derivatives. The monosodium adducts of azobenzene, *p*-dimethylaminoazobenzene, azoxybenzene, and nitrosobenzene initiate the polymerization of acrylonitrile; the disodium adducts polymerize acrylonitrile and methyl methacrylate, whereas styrene is not affected. Both the radical ions and the dianions give rise to an anionic polymerization mechanism.

The polymerization of styrene by alkali metal ketyls of benzophenone described by *Smith*[1] is actually initiated by the disodium derivative formed by the addition of two sodium atoms to benzophenone and is not stereospecific, in contrast to earlier reports[1].

Polymers obtained by free-radical polymerization and copolymerization of *p*-vinylbenzophenone, *p*-vinylbenzophenone anil, and *p*-vinyl-1,1-diphenylethylene can be converted into the corresponding poly-radical ions and polydianions; they are suitable for ionic graft polymerization.

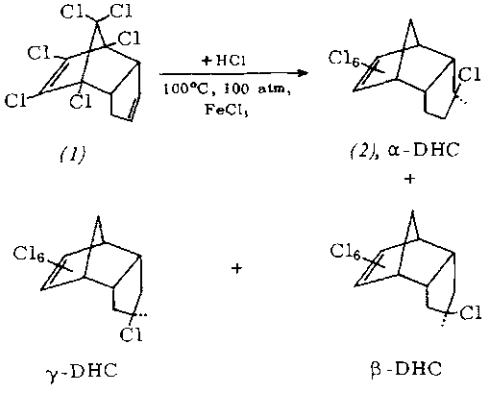
12

Synthesis and Structure of Insecticidal Polychlorotetrahydromethanoindanes

K. H. Büchel, Birlinghoven (Germany)

Little has hitherto been known about the numerous possible stereoisomers in the cyclodiene series of insecticides of the type of heptachlor [1,4,5,6,7,8,8-heptachloro-3a,4,7,7a-tetrahydro-4,7-methanoindene]. The isomeric dihydro-compounds *(2)* of heptachlor seem to be of particular interest because after removal of the double bond from the five-membered ring its biological epoxidation to toxic products cannot come into effect.



(1) *(2)*, α-DHC + γ-DHC + β-DHC

Addition of HCl under pressure and in presence of a Lewis acid catalyst to the unsaturated hexachloro-analogue *(1)* affords α-, β-, and γ-dihydroheptachlor (DHC)[1], whose configuration has been proved by independent syntheses and ^1H-NMR spectra. The addition is an equilibrium reaction. The relative amounts of the isomers produced can be influenced by varying the conditions (solvent, pressure, temperature), so that the synthesis can be caused to yield, for instance, almost homogenous β-isomer. α- and γ-DHC can be isomerised to β-DHC under the conditions of the addition. β-Dihydroheptachlor[1] is an insecticide whose spectrum of activity is comparable with that of chlordane or DDT and which has a very low toxicity to warm-blooded animals (LD_{50} > 9000 mg/kg mouse). Moreover, it has given no sign of possessing chronic toxicity[2].

In the octachlorotetrahydromethanoindane (chlordanes) series *(5)*, *(6)*, the number of possible isomers is still larger. On chlorination of hexachlorotetrahydromethanoindane *(3)* one obtains a crystalline product *(4)* from which, by chromatography on silica gel (n-hexane), have been isolated β-DHC and β-chlordane, the new isomers γ-, δ-, and ε-chlor-

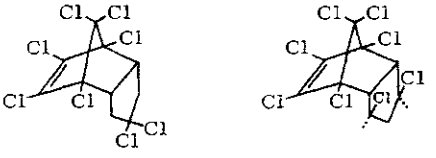
(3) (4)



(5), γ-Chlordane (6), δ-Chlordane

dane, and a nonachloro-derivative. The symmetrical γ- and δ-chlordane have the best insecticidal properties. The structures of all the known chlordane isomers have been confirmed by independent syntheses and ^{1}H-NMR spectra.

13

Automatic Determination of Molecular Weights by Light Scattering

H.-J. Cantow, Freiburg (Germany)

The reciprocal absolute scattering intensity (Rayleigh ratio) R multiplied by the concentration C and the characteristic optical constant K of a dissolved substance can be recorded simultaneously with the measurements versus the angle function $\sin^2\vartheta/2$ + const·C by a combination of analogue computing elements.

The reciprocal Rayleigh ratio is formed by a servo-controlled potentiometer. The geometrical correction factor $\sin\vartheta$ is introduced and the scattering angle is converted to $\sin^2\vartheta/2$ by function potentiometers coupled to the rotating optical system. The solvent scattering is eliminated by an opposing potential.

The weight-average molecular weight $\overline{M}_w$ and the dimensions of the dissolved macromolecules as well as the thermodynamic solution paramters can then be obtained in the usual way from the resulting Zimm diagram. The angular range of 30°–150° can be scanned in 12 sec for each concentration. The recorded curves have the further advantage that errors made in point-by-point measurements are smoothed out.

A system is proposed which instantaneously indicates the molecular weight (at a single concentration in a theta-solvent where the effects of solute-solvent interactions are cancelled) by sacrificing information about the molecular dimensions. The method consists in determining the Rayleigh ratio R_0 at zero angle, which is independent of shape and dimensions of the molecule, by measuring the intensity scattered at two angles in alternation with a rotating-sector system. For monodisperse and polydisperse randomly coiled molecules, angles of 45° and 70° are suitable. The signals are combined so that the alternating component of the resulting signal is $2R_{45}-R_{70}$, which practically equals R_0. Such measurements at fixed angles are possible with an average accuracy (independent of the molecular dimensions) of ±2 % in R_0 or $\overline{M}_w$.

A gas laser with $\lambda = 6328$ Å is a suitable light source. The refractive index increment can be measured simultaneously with the same light source. A simple circuit then allows the direct recording of R_0/CK, which in theta-solvents is equal to $\overline{M}_w$.

It thus appears possible to follow rapid processes as well as continuous fractionations, *e.g.* those using Baker-Williams columns. The method should also be suitable for rapid routine determinations of $\overline{M}_w$.

14

Formation of Ferrocene

H. Cordes, Ludwigshafen (Germany)

The four processes in the formation of dicyclopentadienyliron (ferrocene) from ferrous chloride and cyclopentadiene in presence of alkali alkoxide, *i.e.* the preparation of $FeCl_2$, the reaction with alkoxide, the reaction with monomeric cyclopentadiene, and the isolation of the ferrocene, were investigated.

Anhydrous $FeCl_2$ is formed rapidly and quantitatively by reduction of sublimed $FeCl_3$ in organic solvents, such as alcohols, in which both chlorides are sufficiently soluble, with metals such as Fe, Zn, or Al in the presence of acid, which is essential for the process. Acid is often autogenically produced by partial hydrolysis of the very hygroscopic $FeCl_3$; small amounts of water are removed *via* the insoluble oxide hydrates.

On the addition of methoxide, the remaining acid is neutralized and white to light grey Fe(II) methoxide is then precipitated. An excess of at least 100 % of methoxide should be added to obtain good yields of ferrocene. At 40–50 °C, addition of monomeric cyclopentadiene gives ferrocene in yields of over 80 % within a few minutes. Derivatives such as methylcyclopentadienyl react more slowly.

When a water-soluble solvent is used, hydrolysis of the reaction mixture gives crude ferrocene in better than 95 % purity, particularly if an excess of Fe(II) methoxide is used, since all components except ferrocene are soluble in weakly acidified water. Analytically pure ferrocene is obtained by recrystallization, sublimation, or steam distillation.

The main side reaction is the hydrolysis of the iron salts to oxide hydrates, which, presumably owing to their extreme insolubility (even when freshly precipitated), do not react with cyclopentadiene. Therefore the presence of more than traces of water decreases the ferrocene yield considerably, and even anhydrous alkali hydroxides are not suitable as bases in place of alkali alkoxides.

15

Interpretation of the Spectra of Monoamino-p-benzoquinones

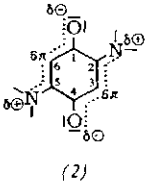
S. Dähne, D. Leupold, H. Paul, and *J. Ranft*, Berlin and Leipzig (Germany)

The spectra of many disubstituted quinone dyes can, like those of indigo dyes, be explained by the assumption that two polymethine elements of the structure *(1)* are coupled within one molecule[1]:

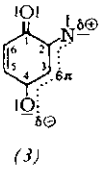
$$\begin{matrix} .....(n+3)\pi..... \\ X\text{-}(CR)_n\text{-}X' \end{matrix} \qquad (1)$$

X,X' = Elements of group IV, V, or VI;
R = any substituents; n = 1,3,5. . . .

For example, 2,5-diamino-*p*-benzoquinones *(2)* can be regarded as coupling products of two trimethinemerocyanines *(1)*, X = NR_2, X' = O, n = 3.



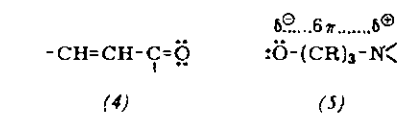
(2)



(3)

[1] *S. Dähne, D. Leupold, H. Paul*, and *J. Ranft*, Mber. dtsch. Akad. Wiss. *7*, 25 (1965); *D. Leupold* and *S. Dähne*, Theoret. chim. Acta *3*, 1 (1965).

Analogously the properties of monosubstituted quinone dyes, *e.g.* 2-amino-*p*-benzoquinone *(3)*, are ascribed to a polyene-polymethine coupling. The term schemes, calculated by a supplemented LCAO–MO method, of the uncoupled polyene *(4)* and the uncoupled polymethine *(5)* can be combined to that of the monoaminoquinone *(3)* by a stepwise approach of the separate molecules, *i.e.* by stepwise increase of the resonance integral of the coupling bonds C(1)–C(2) and C(4)–C(5).



(4) *(5)*

These ideas were confirmed by measurements of infrared and NMR spectra. The C=O stretching frequency of the polyene part of the molecule is higher than that of the polymethine part. The chemical shifts of the protons in *(3)* after correction for the ring current are essentially the same as in the separate polyene and polymethine.

Because of the asymmetry of the polyene-polymethine coupling, the $\pi \rightarrow \pi^*$ transition of longest wavelength of the monosubstituted benzoquinones is allowed. They therefore absorb considerably more strongly in the visible than the centrosymmetric compounds of type *(2)*, in which this symmetry-forbidden transition is only slightly allowed by a Herzberg-Teller mixture [2].

16

Specificity and Mode of Action of Pepsin in the Condensation of Oligopeptides

H. Determann, Frankfurt/Main (Germany)

In the pepsin-catalysed plastein reaction, the terminal amino acids of the peptides play a decisive part. The specificity of pepsin is more marked in condensation than in hydrolysis reactions. Thus pentapeptides with C-terminal L-Leucine, L-phenylalanine, and L-tyrosine can be condensed, whereas those with L-valine, L-isoleucine, and D-phenylalanine are no substrate of the enzyme. The amino-end appears to be less important to the reactivity. Here L-tyrosin can be replaced by L-alanine; the reaction does not take place with D-phenylalanine on either end. A D-amino acid in the peptide interior does not affect the reactivity (experiments with *J. Heuer* and *D. Jaworek*).

The mechanism of pepsin-catalysed peptide hydrolysis is still unknown. The specificity shown by pepsin in our condensation experiments suggests that the carboxy group is activated. Attempts to capture a reactive intermediate by the addition of various acceptors were, however, not successful. Neither inhibition of the plastein reaction, nor inclusion of the additives into the polypeptide, were observed when various amounts of aniline, phenylacetic acid, alanine amide, or acetyltyrosin where present in the reaction mixture.

17

Chelation of Neptunium, Plutonium, and Americium by Derivatives of 8-Hydroxyquinoline

S. H. Eberle and *C. Keller*, Karlsruhe (Germany)

Ter- and quadrivalent ions of the transuranium elements form compounds ML_3 and ML_4 (HL = ligand) with 8-hydroxyquinoline (Hox) and its 5,7-dihalo derivatives. Only basic substances are obtained from aqueous solutions with 2-methyloxine; the neutral neptunium compound is formed in the melt under water. Similarly to $Ce(ox)_3$, $Pu(ox)_3$ is very sensitive to oxidation and is only obtainable under strict exclusion of oxygen. Neptunium(V) forms the neutral chelate $NpO_2(ox)\cdot(H_2O)_2$, difficultly soluble in water and organic solvents, and a water-soluble anion $[NpO_2(ox)_2\cdot aq]^-$. Plutonium(V) gives only chelates of the type $PuO_2(L)(HL)_2\cdot aq$. Both ions give compounds of composition $MO_2(Mox)(Hmox)\cdot aq$ with 2-methyloxine (Hmox). No chelation was observed with 6-valent actinides, since they are reduced by all the ligands used.

The extraction behavior and the stability constants are very similar to those of complexes of the rare earths, thorium, and uranium(IV); the stabilities of the actinide chelates are however always higher than those of the analogous elements. The 5-valent ions stepwise form 1:1 and 1:2 complexes with 8-hydroxyquinolinesulfonic acids, which for neptunium and plutonium have the same stability constants. The measurements show that the tendency to form chelates with oxine derivatives decreases in the sequence M(IV) > M(III) > M(V).

18

Transport and Phase-Boundary Reactions of Defect Electrons in Silver Bromide

E. Eisenmann and *W. Jaenicke*, Erlangen (Germany)

The mobilities of defect electrons as determined by diffusion and Hall-effect measurements, respectively, differ by a factor of about 10^4 at room temperature. To determine whether this discrepancy is caused by reactions at the phase boundary, trapping reactions inside the crystal, or space-charge limited transport, an electrochemical cell with an AgBr single crystal as diaphragm between a bromine and a bromide solution was polarized. The mobility was determined by the rate of migration of the resulting boundary. Current-potential measurements in both directions of polarization allowed the study of rate determining phase-boundary reactions. The mobility from the moving-boundary method agrees with that obtained by diffusion.

Between 0 and 150 °C the mobility has an activation energy of 0.71 eV. At 175 °C it passes through a maximum and maintains a negative temperature coefficient to higher temperatures (measurements to 250 °C). This part of the curve agrees with the curve obtained by extrapolation of the Hall-effect data (measurements to 140 °C). A trapping mechanism is proposed to explain the results.

19

Effect of Ultraviolet Radiation and of Carcinogenic Nitrosamines on Constituents of Nucleic Acids [1]

E. Fahr, *R. Kleber*, and *E. Boebinger*, Würzburg (Germany)

The carcinogenic activity of nitrosamines [2] has been ascribed [3] to a conversion into diazoalkanes. This explanation is supported by the fact that di-t-butylnitrosamine and diphenylnitrosamine, which can give no diazoalkanes, are not carcinogenic.

From the relatively high reactivity of the N–NO group in nitrosamines it may be expected that these can also effect directly chemical reactions in living organisms. We found that in aqueous solution (pH 4.2 and 3.0 at 30 °C, nitrosamine:

[1] For the part of this lecture dealing with the effects of UV-irradiation, cf. Naturwissenschaften *52*, 513 (1965).

[2] *H. Druckrey*, *R. Preussmann*, *G. Blum*, *S. Ivankovic*, and *J. Afkham*, Naturwissenschaften *50*, 100 (1963).

[3] *D. F. Heath*, Nature (London) *192*, 170 (1961); *P. N. Magee* and *E. Farber*, Biochem. J. *83*, 114 (1962); *H. Druckrey*, *R. Preussmann*, *D. Schmähl*, and *M. Müller*, Naturwissenschaften *48*, 134 (1961).

pyrimidine = 200:1) dimethylnitrosamine reacts with cytosine, cytidine, and cytidylic acid, but not with adenosine and guanosine. The reaction is first order with respect to the pyrimidine with half-lives at pH 4.2 of 13000 min (cytosine), 18800 (cytidine), and 6800 (cytidylic acid). The obvious assumption that the reaction is a deamination is incorrect, since the expected products uridine and uridylic acid could not be detected.

Model experiments with the nitrosamines *(1a)–(1e)* and *(2)* showed that the carcinogenic nitrosamines *(1a)*, *(1b)*, and *(2)* react with urea and cytidine, whereas the non-carcinogenic compounds *(1c)–(1e)* do not. These results show that the dialkane hypothesis is not necessary to explain the different behavior of the nitrosamines.

The Electronic Structure of Metal Tri(cyclopentadienyl) Complexes

R. D. Fischer, München (Germany)

The bonding in lanthanide and actinide complexes containing three equivalent, centrally attached C_5H_5 ligands was investigated with a simple LCAO–MO method. The qualitative one-electron approximation already shows that each complex $(C_5H_5)_3M$ has one unoccupied, non-bonding molecular orbital of rotational symmetry along the molecular axis.

This essentially covalent model explains the unexpectedly strong Lewis acidity of most tri(cyclopentadienyl)-lanthanide complexes and the ready formation of many surprisingly stable adducts[1]:

$$(C_5H_5)_3M + :B \rightarrow (C_5H_5)_3MB$$

A satisfactory explanation can also be given for the low magnetic moment and the relatively high dipole moment of $(C_5H_5)_3U$[2]. The MO treatment further enables the U···BH_4 linkage in $(C_5H_5)_3UBH_4$[2] to be understood, as well as the green colour of $(C_5H_5)_3Yb$, which is unusual for Yb(III) complexes.

21

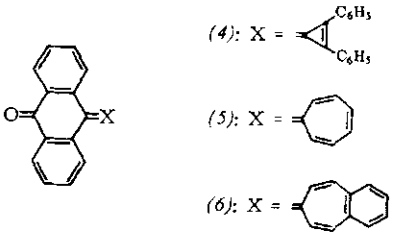
Cyclopropenylium and Tropylium Systems

B. Föhlisch, *P. Bürgle*, and *D. Krockenberger*, Stuttgart (Germany)

The strongly polarized ketones diphenylcyclopropenone, tropone, and 4,5-benzotropone react already at 0–20 °C with phosgene almost quantitatively to 3,3-dichloro-1,2-diphenylcyclopropene *(1)*, 7,7-dichlorocyclohepta-1,3,5-triene *(2)*, and 7,7-dichloro-3,4-benzocyclohepta-1,3,5-triene *(3)*, respectively. ^{1}H-NMR studies show that *(2)* and *(3)* ionize in liquid sulfur dioxide to chlorotropylium chloride and 1-chloro-4,5-benzotropylium chloride, respectively. With $SbCl_5$, *(1)–(3)* form the hexachloroantimonates.

With phenols, *(1)* gives hydroxyarylcyclopropenylium salts[1]. The cyclopropenylium salt formed from *(1)* and anthrone can be deprotonated with triethylamine to the methylenecyclopropene derivative *(4)*. Contrary to previous assumptions[2], the reaction of diphenylcyclopropenylium perchlorate with anthrone in glacial acetic acid/pyridine leads not to *(4)*, but to 10-(2,3-diphenylallylidene)anthrone.

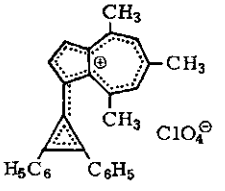
4,6,8-Trimethylazulene is also electrophilically substituted by *(1)*; the isolatable perchlorate *(7)* reacts with ethanol in the presence of bases to 1-(1-ethoxy-2,3-diphenylcyclopropenyl)-4,6,8-trimethylazulene.



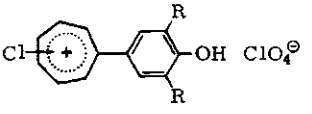
(4): X =

(5): X =

(6): X =



(7)



(8)

Anthrone with *(2)* and *(3)* gives the heptafulvene derivatives *(5)* and *(6)*, respectively, corresponding to *(4)*. With phenol, 2,6-dimethylphenol, and 2,6-diethylphenol, *(2)* reacts in fair yields to x-chloro-(*p*-hydroxyphenyl)tropylium salts *(8)*. Comparison of the $\nu_{C=O}$ frequencies and the dipole moments of *(4)–(6)* [*(4)*: 1630 cm^{-1}, 9.4 D; *(5)*: 1655 cm^{-1}, 3.8 D; *(6)*: 1655 cm^{-1}, 3.7 D] shows that the methylenecyclopropene system is a stronger electron donor than the heptafulvene system.

22

The Influence of the Crystal Field on the Acidity of Protons in the Crystal and on the Surface

F. Freund, Göttingen (Germany)

In hydroxides the proton is situated within the electron cloud of the oxygen ion. When optical excitation is excluded, it vibrates in the zeroth energy level of a potential energy well, the form, position, and connection to neighboring potential wells of which is determined by the gradient of the electric field and the electron density "ρ(H)" at the proton position.

The proton in the electron cloud of the oxygen ion and the cations partly bound covalently to the OH^- group perturb the charge distribution of the oxygen ion: the more covalent the cation-oxygen bond, the weaker the oxygen-proton bond, *i.e.* ρ(H) is decreased and the proton becomes more acidic. The component of the coulomb field of the cation along the O–H direction causes an additional loosening of the O–H bond.

If O^{2-} ions are present as ligands in addition to OH^- groups (as in many oxide hydroxides), the cation is polarized preferably towards the more electronegative O^{2-} ligands, so that

the cation-hydroxyl bond is weakened. This releases electron density from the oxygen ion of the hydroxyl group, which becomes available for firmer binding of the proton: ρ(H) is increased, the proton acidity decreased. The magnitude of this effect increases with increasing polarization of the cations by O^{2-} compared to OH^-.

23

The Interaction of Pigments and Binders in Solid Paint Films

W. Funke, Stuttgart (Germany)

From the dependence of water absorption and water permeability of paint films on the volume concentration of pigment, the behavior of the pigment/binder interface in the presence of water can be determined. If the adhesion of the binder to the pigment is maintained on uptake of water, the water uptake is, relative to the amount of binder, independent of pigment volume concentration, whereas the water permeability decreases with increasing pigment volume concentration. If the adhesion is lost on water uptake, this uptake increases with pigment volume concentration corresponding to the expansion (swelling) of the binder. Since in this case the water vapor need not diffuse through the binder, but can make its way through the crevices on the surface of the pigment particles, the vapor permeability increases with increasing pigment volume concentration.

When soluble substances are present on the pigments or at the interfaces, osmotic processes can lead to increased water absorption if the permeation of these soluble substances through the binder is retarded. As soon as the pigment volume concentration becomes sufficiently large, the binder becomes permeable and the water uptake decreases again.

Electron-microscopic investigations showed that in solid paint films relations exist between both water uptake and permeability to water vapor and the state of agglomeration.

24

Enzymatic Reactions of Isonicotinic Hydrazide

H. W. Goedde, W. Schloot, and *A. Valesky*, Freiburg (Germany)

The tuberculostaticum isonicotinic hydrazide (INH) is converted mainly into acetyl-INH in animals and excreted as such in the urine. Enzyme preparations were made from liver homogenates of *Cercopithecideae* (*C. aethiops sabaeus*). By the use of ^{14}C-labelled acetyl-coenzyme A it was shown according to the reaction

$$\text{INH} + [^{14}\text{C}]\text{-acetyl-S-CoA} \xrightarrow{\text{Acetylase}} [^{14}\text{C}]\text{-acetyl-INH} + \text{CoA-SH}$$

that acetyl-coenzyme A is the acetyl-group donator in this reaction.

The acetylation of INH with acetyl-coenzyme A and with the model substance *N,S*-diacetylcysteamine can be followed spectrophotometrically at 303 mμ and pH 9.0.

The activity of acetylase preparations from liver homogenates of *Macaca mulatta rhesus* can be increased twenty-fold by precipitation with acid and acetone. At 50 °C the enzyme is largely deactivated.

The substrate specificities towards INH, *p*-nitroaniline, *p*-aminosalicyclic acid, and sulfanilamide were studied as a function of acetyl-coenzyme A or *N,S*-diacetylcysteamine concentration, and the inhibition by Hg(II)Cl-benzoate and *N*-ethylmaleinimide were tested.

Further studies with the acetylases of *Macaca mulatta rhesus* and *Cercopithecus aethiops sabaeus* showed a close correlation of the INH concentration in the plasma after injection of INH with the specific activity of the enzyme proteins determined spectrophotometrically in the acetylation reaction, where INH is determined colorimetrically as the coupling product with vanillin.

Differences in the specific activity indicate enzyme variants of INH-acetylase and genetically determined polymorphism for the INH-acetylation in these species similar to that observed in man.

25

Infrared-Spectroscopic Investigation of Barbiturates

S. Goenechea, Bonn (Germany)

The following characteristic absorption bands were found in the infrared spectra of 21 barbiturates:

The N–H stretching vibrations give rise to two strong bands at 3220–3200 and 3100–3080 cm^{-1}. Some of the compounds show a third band in this region; only for Luminal does this band appear at 3310 cm^{-1}.

In all spectra three carbonyl bands are observed: at 1750, 1730, and 1690 cm^{-1} (amide I-band). The derivatives which are not N-methylated show an additional absorption between 1540 and 1515 cm^{-1} (amide II-band). This band is absent from the spectra of N-methylated barbiturates, whereby they can be distinguished.

Substituents at C-5 have the following effects: The asymmetric CH_3 stretching vibration of alkyl groups gives rise to definite absorption at 2975–2960 cm^{-1}. If the substituent is small (*e.g.* ethyl, isopropyl, or n-propyl), then, depending on the nature of a second substituent, additional bands can appear at 2990–2980 cm^{-1} and 2960–2950 cm^{-1}. This splitting occurs when the second substituent is ethyl, allyl, bromoallyl, phenyl, or cycloalkenyl. The symmetric CH_3 stretching vibrations are assigned the absorption at 2875 ± 10 cm^{-1}. The asymmetric CH_2 stretching frequencies (2950–2930 cm^{-1}) become noticeable only when many CH_2 groups are present. The absorptions due to the symmetric CH_2 stretching vibration are generally very weak.

Allyl groups absorb at 1640–1637 cm^{-1}; the bromoallene residue absorbs at 1620 cm^{-1} and can readily be recognized in the presence of the allyl group. Vinyl substituents give a band at 1630–1628 cm^{-1}. Δ^1-Cycloolefins as substituents on C-5, on the other hand, do not absorb between 1680 and 1600 cm^{-1}. In allylcyclopentenylbarbituric acid the allyl absorption also is missing.

Alcoholic OH groups on C-5 give a strong absorption band around 3470 cm^{-1}. Phenyl substitutents can best be recognized by the three sharp bands at 1590, 1575, and 1490 cm^{-1}. In the spectrum of Luminal the band at 1590 cm^{-1} occurs only as an uncharacteristic shoulder.

26

The Charge Distribution in Phosphazines

H. Goetz, Berlin (Germany)

The controversial problem of possible $d_\pi - p_\pi$ conjugation was studied on phosphazines of the type

$$(p\text{-X-C}_6\text{H}_4)(\text{C}_6\text{H}_5)_2\text{P=N-N=(9-fluorenyl)} \qquad (1)$$

with X = H, Cl, Br, OCH_3, and $N(CH_3)_2$, and the corresponding alkyldiphenyl and trialkyl compounds, and on phosphazines of the type

$$(p\text{-X-C}_6\text{H}_4)(\text{C}_6\text{H}_5)_2\text{P=N-N=C}(p\text{-Y-C}_6\text{H}_4)(p\text{-Z-C}_6\text{H}_4) \qquad (2)$$

with Y = Z, Cl, and Y = H, Z = NO_2 by measurements of dipole moments and ultraviolet absorption spectra.

The dipole moments vary between 5 and 10 D, depending on the substituent. This indicates the resonance

$$\geq P{=}N{-}N{=}C\leq \longleftrightarrow \geq \overset{\oplus}{P}{-}N{=}N{-}\overset{\ominus}{C}\leq$$

for the ground state, with high participation of the ionic form, for which in type *(2)* there is a stronger dependence on the substitutents Y and Z than on X. The influence of X cannot be explained purely on the basis of its inductive effect.

The ultraviolet spectra of all the compounds show a $\pi \rightarrow \pi^*$ transition at long wavelengths, which can be assigned to the P=N–N=C chromophore. Solvatochromic effects indicate an isoenergetic point[*], confirming the results of the dipole moment studies. No $n \rightarrow \pi^*$ transitions can be recognized. The $\pi \rightarrow \pi^*$ band is considerably shifted towards the blue with respect to that in symmetrical and asymmetrical diketazines $> C{=}N{-}N{=}C <$. This is however not due to conjugation across the phosphorus, but to a strong decrease of the excitation energy by the resonance of the ground state. The substituents X in type *(2)* have less influence on the position of this $\pi \rightarrow \pi^*$ transition than the substituents Y and Z. The phosphorus atom terminates the conjugation. Further, in the ground state (π) there is an interaction (in the sense of a qualitative LCAO–MO model) of the p_z orbitals of the *p*-phenyl substituents with the d_{xz} or the d_{yz} orbital of the phosphorus atom. No such interactions can be detected in the excited states (π^*).

[*] At the isoenergetic point the participation of the two resonance forms is equal.

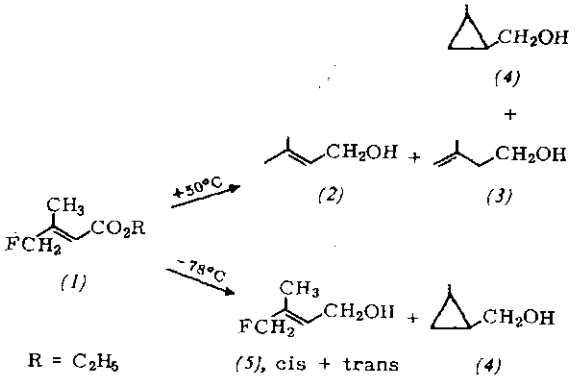
27

Fluoroisoprenols

W. Grell, H. Machleidt, J. Piek, and *H. Schumacher*, Bonn (Germany)

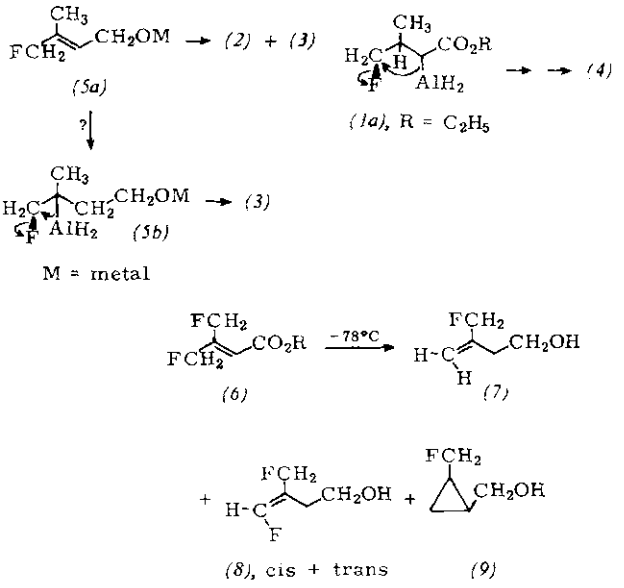
Fluoroisoprenols and their pyrophosphates deserve interest as antimetabolites of squalene and steroid biosynthesis.

$LiAlH_4$ reduces ethyl (3-fluoromethyl)crotonate *(1)* at +50 °C to a mixture of 60–70 % of *(2)*, 20–10 % of *(3)*, and 20 % of *(4)*; at −78 °C to 86 % of *cis/trans*-3-fluoromethyl-2-butenol *(5)*, 14 % of *(4)*, and a trace of *(2)*.

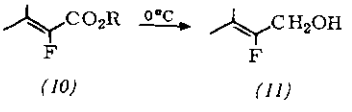


The cyclopropane derivative *(4)* is formed, essentially independently of temperature, *via* the adduct *(1a)* by S_Ni substitution. Compounds *(2)* and *(3)* are probably formed by S_Ni and/or S_N2 reactions from *(5a)*, and *(3)* possibly also *via* the adduct *(5b)*.

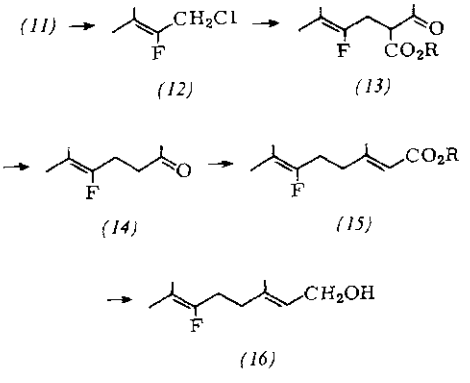
Ethyl 4-fluoro-3-fluoromethylcrotonate *(6)* is reduced by $LiAlH_4$ at −78 °C to 3-fluoromethyl-3-butenol *(7)*, a little *cis/trans-(8)*, and a trace of *(9)*.



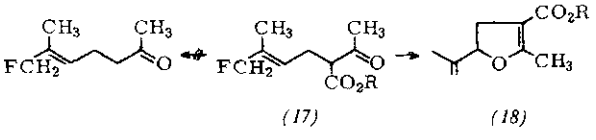
Esters containing olefinic fluorine *(10)* can be reduced without elimination of fluorine[1].



6-Fluorogeraniol *(16)* can be obtained in five stages from *(11)*



In contrast to *(13)*, the acetylacetic ester *(17)* is unstable. It rearranges to the dihydrofuran derivative *(18)* under elimination of HF.



[1] *H. Machleidt* and *R. Wessendorf*, Liebigs Ann. Chem. *674*, 1 (1964).

28

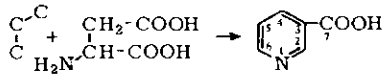
The Biosynthesis of Nicotinic Acid by Mycobacterium tuberculosis

D. Groß, Halle/Saale (Germany)

Nicotinic acid is formed in some fungi and in mammals as a product of tryptophan degradation. This degradation does, however, not occur in most bacteria and in higher plants. In

Mycobacterium tuberculosis (BCG strain), tryptophan is also not a precursor of nicotinic acid. However, here ^{14}C-labelled aspartic acid is incorporated into the nicotinic acid molecule. After application of [4-^{14}C]-aspartic acid, the radioactivity occurs only in the carboxy group of nicotinic acid, whereas on application of [u-^{14}C]-aspartic acid, ^{14}C-activity is found in the ring carbon atoms, too. By application of [1-^{14}C,4-^{15}N]-aspartic acid it was shown that the carboxy group C-1 of aspartic acid is eliminated in the biosynthesis of nicotinic acid, that the carboxy group C-4 of aspartic acid supplies the carboxy group of nicotinic acid, and that the carbon atoms 2,3 and 7 as well as the nitrogen atom of the nicotinic acid are derived from aspartic acid.

After application of ^{14}C-labelled C_3-compounds such as [2-^{14}C]-glycerol, [1,3-$^{14}C_2$]-glycerol, [1-^{14}C]-glyceraldehyde, [1-^{14}C]-glycerate, and [3-^{14}C]-pyruvate, the radioactivity recurs in the pyridine ring of nicotinic acid. [2-^{14}C]-Glycerol and [1,3-^{14}C]-glycerol are preferably incorporated into C-4, C-5, and C-6 of nicotinic acid. These results show the following biosynthesis route for nicotinic acid in *M. tuberculosis*:



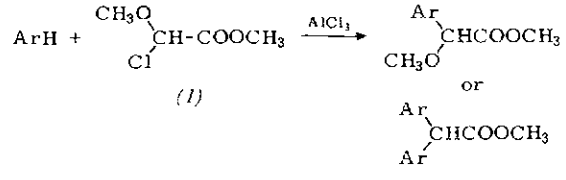
The pyridine ring apparently is synthesized in the same way in higher plants and in other bacteria.

29

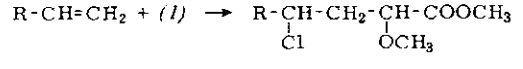
Syntheses with Methyl Methoxychloroacetate

H. Groß and *J. Freiberg*, Berlin-Adlershof (Germany)

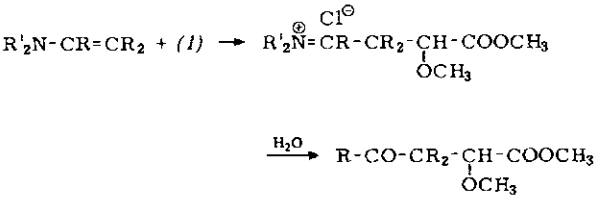
With aromatic compounds in the presence of Friedel-Crafts catalysts, methyl methoxychloroacetate *(1)* gives either methyl methoxyarylacetate or methyl diarylacetate:



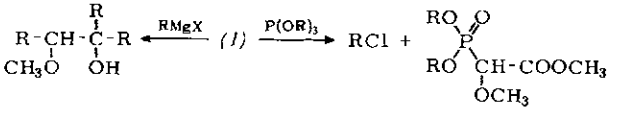
Compound *(1)* adds to unsaturated compounds to give methyl α-methoxycarboxylates:



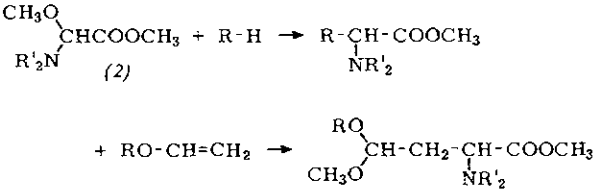
From enamines and *(1)*, methyl α-methoxy-γ-ketocarboxylates are obtained after hydrolysis:



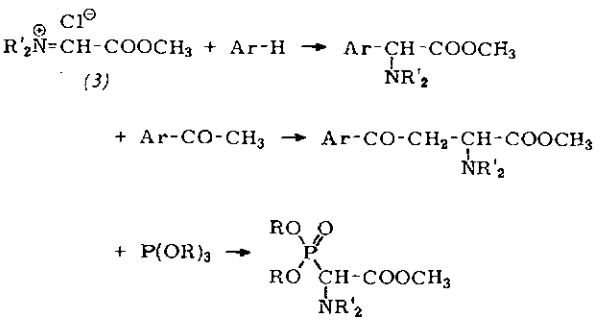
With an excess of Grignard reagents, *(1)* reacts to glycol monomethyl ethers; with trialkyl phosphite *(1)* eliminates alkyl chloride and rearranges to the corresponding dialkyl phosphonate:



Secondary amines or diacylimides react with *(1)* to give *ON*-acetals of type *(2)*, which can be condensed with CH-acidic compounds or added to vinyl ethers.



From *(2)* and acetyl chloride or thionyl chloride, immonium salts of type *(3)* are formed, which give the substituted glycine



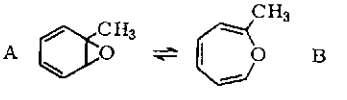
derivatives with aromatic or heterocyclic compounds, and aroylalamine derivatives with ketones. Aliphatic diazo compounds add to *(3)*; trialkyl phosphites react by rearrangement to phosphonic esters as with *(1)*.

30

NMR-Spectroscopic Studies of the Equilibrium and Kinetics of Benzene Oxide — Oxepin Conversions

H. Günther, Köln (Germany)

The hypothesis that substituted oxepins are in equilibrium with the isomeric benzene oxides was confirmed[1] on α-methyloxepin synthesized by *Vogel* and *Schubarth*.



In the NMR spectrum of this compound in CF_3Br solution at about −110 °C, the methyl signal is split into a doublet with chemical shifts τ_A 8.45 and τ_B 8.09. The equilibrium constant K (= γ_B/γ_A) is 4.0 at −90 °C. The temperature-dependence of K between −74 and −123 °C yields the enthalpy difference $\Delta H^\circ = H_B^\circ - H_A^\circ \simeq 0.4$ kcal/mole. The activation energies (9.3 ± 1.0 kcal/mole) of the forward and reverse reaction are the same within the limits of error. The introduction of the methyl group thus lowers the enthalpy difference between monocyclic and bicyclic isomers relative to the unsubstituted compound. The position of the equilibrium at higher temperatures is determined essentially by the entropy term, as in the oxepin case.

[1] In collaboration with *H. Friebolin*, Freiburg.

31

Free-Radical Reactions on Thermolysis of Methyl Oleate in the Absence of Oxygen

A. K. Sen Gupta, Hamburg (Germany)

When methyl oleate is heated to 280 ± 5 °C in an atmosphere of argon, homolytic cleavage of the C–C single bonds adjacent to the double bond occurs as well as dimerization. The

free radicals are stabilized by recombination, hydrogen abstraction, or addition to the chain end of another molecule. The main products isolated were 9-octadecene, 9,17-hexacosadiene, methyl decanoate, methyl 9,17-hexacosadienoate, dimethyl 9-octadecene-1,18-dioate, and dimethyl 9,17-hexacosadien-1,26-dioate.

32

Biochemical Difference Between Fresh and Frozen Meat

R. Hamm and *L. Körmendy*, Kulmbach (Germany)

It could previously not be decided with certainty whether a sample of meat is fresh or had been frozen and thawed. Since there is no reliable histological test, a biochemical method was sought. Previous work[1,2] had shown that two isozymes of glutamate-oxalacetate transaminase occur in the skeletal muscle of beef and pig. One of these (GOT_M) is localized in muscle mitochondria; the other (GOT_S) occurs in the sarcoplasm. The isozymes can be separated by high-voltage electrophoresis on cellulose acetate membranes and determined[2] by spraying the strip with α-ketoglutarate/malate dehydrogenase/NADH/pyridoxal phosphate[3]. The centrifuged juice of fresh meat shows the GOT_S band only. After freezing (−10 to −40 °C) and thawing, however, GOT_M enters the sarcoplasm, evidently because of damage to the mitochondrial structure. A strong GOT_M band is then found in electrophoresis together with the GOTs band. The method is not affected by the duration of the cold storage nor by the normal time of aging of the meat.

[1] *G. Gantner* and *R. Hamm*, Z. Lebensmittel-Unters. u. Forsch. *126*, 1 (1964).

[2] *L. Körmendy*, *G. Gantner*, and *R. Hamm*, Biochem. Z. 342, 31 (1965).

33

Rearrangements of Homoallylic Carbonium Salts

M. Hanack and *H. J. Schneider*, Tübingen (Germany)

From 1-bromo-3-butene and 1-bromo-3-pentene in nitromethane or dichloromethane, the corresponding tetrafluoroborates were prepared with silver tetrafluoroborate, and the rearrangements of the carbonium ions were studied as a function of reaction time and temperature. To this end the solutions were hydrolysed rapidly with an excess of sodium hydrogen carbonate solution, and the alcohols formed were analysed.

Cyclopropylcarbinols, cyclobutanols, homoallylic alcohols, and allyl alcohols were found, the proportions of which depended on the rearrangement time and temperature. The roughly equimolar mixture initially formed from the butenyl tetrafluoroborate of about equal amounts of cyclopropylcarbinyl and cyclobutyl cations first alters its composition in favor of the cyclobutyl cation, which then is converted into the allyl cation. In the rearrangement of the pentenyl system, the cyclopropylcarbinyl cation is found to be the more stable. From this it is concluded that the rearrangements proceed *via* different ionic intermediates. The results give indications of the stabiltities and rearrangement rates of the ions involved.

34

Hydrocyanic Acid in Some Prunoideae Seeds and in their Products such as Marzipan and Marzipan Substitutes

E. Hanssen and *W. Sturm*, Hannover (Germany)

The hydrocyanic acid contents of bitter almonds and of apricot and peach kernels are often higher than has been assumed. On processing of these *prunoideae* seeds to persipan, especially on soaking in water and by the dehydrating process, a stepwise decrease of the HCN content takes place, so that the amounts remaining in the final product are slight and toxicologically insignificant.

When bitter almonds are baked the hydrocyanic acid is only expelled in part (depending on the conditions of baking), and on cooking as well as on burning of bitter almonds practically no HCN is set free. This is because the emulsin required for the liberation of HCN is inactivated by heat.

At the optimum pH-value (4–6) the hydrocyanic acid can be quantitatively liberated at room temperature in 3 hours if it is distilled directly and titrated. It is warned against acid hydrolysis (pH < 3) as well as against acid addition before distillation because the amount of HCN liberated is reduced by lowering pH. – This method of determination also can be used to estimate the amount of bitter almonds mixed with sweet almonds.

35

Non-stationary Processes in the Reduction of Zinc Oxide with Hydrogen

W. Hirschwald, Berlin (Germany)

The kinetics of the reduction of zinc oxide with hydrogen:

$$ZnO(s) + H_2(g) \longrightarrow Zn(g) + H_2O(g)$$

was studied between 280 and 500 °C at hydrogen partial pressures of 0.1–0.01 mm. The rate-determining step then becomes the reaction at the phase boundary instead of diffusion in the gas phase.

On sintered samples of almost the theoretical density, a lag period was observed during which the phase boundary reaction increased to a stationary value. From the temperature dependence, a change in activation energy is found in the non-stationary initial phase of the reaction.

The following relations were obtained for the rate constants k_i and k_{st} of the reduction of fresh samples and those in the stationary period, respectively:

$$k_i = 1 \times 10^6 \, e^{-19500/RT} \text{ [cm/sec]}$$
$$k_{st} = 5 \times 10^4 \, e^{-13900/RT} \text{ [cm/sec]}$$

Although under the conditions used solid zinc is not thermodynamically stable, zinc can remain interstitially in the solid oxide phase and considerably alter the degree of lattice disorder near the surface. Simultaneous measurement of electrical conductivity showed a proportionality of the latter to the reaction rate. On the basis of this result, chemisorption of hydrogen as rate-determining step is excluded by the boundary-layer theory.

The results are interpreted with the assumption of catalytic activity of the interstitial zinc. Pretreatment of the samples in air and with oxygen ions causes an "extraction" of interstitial zinc; this supports the assumption made.

36

Determination of Pilocarpine in the Aqueous Humor of the Eye by Polarographic Adsorption Analysis

O. Hockwin, Bonn (Germany)

Pilocarpine, $C_{11}H_{16}N_2O_2$, an alkaloid occurring in jaborandi leaves (*Pilocarpus pennatifolius*), is used in ophthalmology to decrease the pressure within the eye.

In a study of the influence of pilocarpine on the metabolism of the eye lens, a decrease of oxygen uptake was observed. At a pilocarpine concentration of 10^{-3} M in the nutrient medium of the lens, O_2-uptake was completely inhibited.

The usual methods of determining pilocarpine fail in the study of the aqueous humor because of the small volume (0.1 to

0.15 ml) of the sample. In polarographic adsorption analysis, the diminution or suppression of maxima by surface-active substances is measured. *Von Stackelberg* and *Schütz* measured instead the displacement of the break-off potential, which is directly proportional to the concentration of surface-active agent. This method is suitable for the determination of pilocarpine.

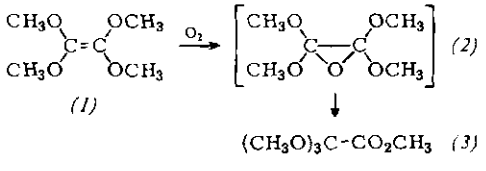
Studies of the aqueous humor of human and rabbits' eyes showed that 20 min after the administration of pilocarpine, $^1/_5$ to $^1/_{10}$ of the amount taken occurs in the aqueous humor. The resulting concentration of pilocarpine is sufficient to completely suppress oxygen uptake by the eye lens.

37

Reactions of Tetramethoxyethylene

R. W. Hoffmann, Heidelberg (Germany)

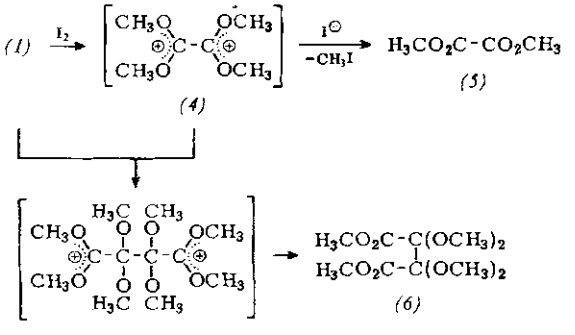
As a particularly electron-rich olefin, tetramethoxyethylene *(1)* is very sensitive to oxidation. With oxygen it gives methyl trimethoxyacetate *(3)* (39 %), as well as dimethyl carbonate (51 %), probably by way of the epoxide *(2)*. Oxidation with iodine affords dimethyl oxalate *(5)* (61 %)



(1) *(2)*

$(CH_3O)_3C\text{-}CO_2CH_3$ *(3)*

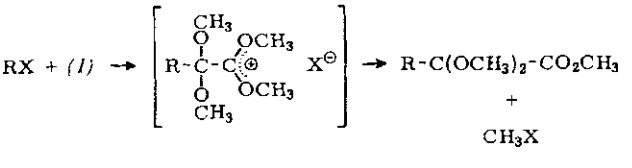
and a small amount of dimethyl tetramethoxysuccinate *(6)*. Occurrence of a radical cation cannot be excluded, but formation of *(5)* and *(6)* is most simply formulated as involving the tetramethoxyethylene dication *(4)*. Attack of iodide on *(4)* gives *(5)*, and attack of *(4)* on *(1)* gives *(6)*. In conformity therewith, oxidation by iodine in the



(4) *(5)* *(6)*

presence of $AgBF_4$, which removes all the iodide as it is formed, leads to a preponderating amount of *(6)*; this compound is also obtained from *(1)* by means of $AgBF_4$ or $HgCl_2$ at a higher temperature.

Compound *(6)* is obtained on alkylation of *(1)* by *(4)*; similar alkylations are readily effected by other cations, *e.g.*, those from tropylium bromide (62 %), benzenediazonium



chloride (88 %), triphenylmethyl chloride (30 %). The larger the partial positive charge on the alkyl group, the easier is alkylation of *(1)*, whereas with, *e.g.*, n-butyl iodide there is no reaction. This shows that *(1)* is readily attacked in an S_N1 reaction but does not function as a nucleophile in S_N2 reactions.

38

Relations between Rotational Isomerism, Hydrogen Bonding, and Substituent Effects

H. Hoyer and *M. Chua*, Bonn (Germany)

Intramolecular hydrogen bonds to rotatable carbonyl groups are supposedly strenthened by the presence of methyl or methylene groups ortho to the carbonyl group by bond deformation [1]. This hypothesis can be tested by measurement of the infrared spectra of solutions (in CCl_4) of compounds in which an OH group is offered a second proton acceptor besides the carbonyl group for the formation of intramolecular hydrogen bonds.

The spectrum of methyl 5,6,7,8-tetrahydro-2-hydroxy-3-nitro-1-naphtoate shows that here the postulated strengthening does not occur, but that the ester group is turned out of the plane of the aromatic system.

In compounds like *N*-(4-methylphenyl)-2-hydroxy-3-methoxycarbonyl-5,6,7,8-tetrahydronaphylideneimine or *N*-(4-methylphenyl)-2-hydroxy-3-methoxycarbonyl-5,6-dimethylbenzylideneimine, however, the hydrogen bond to the azomethine group is favored by the ortho methylene or methyl group. These groups hinder the rotation of the azomethine group and thereby reduce the energy difference between the conformation required for hydrogen bonding and a conformation which is more stable but unfavorable for hydrogen bonding.

The same explanation is given for the facilitation of hydrogen bonding to the aldehyde group in 2-hydroxy-3-nitro-5,6,7,8-tetrahydro-1-naphthaldehyde. The infrared spectrum in CCl_4 shows two carbonyl bands. Their intensities indicate that hydrogen bonding to the aldehyde group is less unfavorable than in the simpler 3-nitrosalicylaldehyde.

39

Preparation of Cyanosilanes

J. Hundeck, München (Germany)

In the presence of chlorotrimethylsilane the yield of cyanotrimethylsilane in the reaction of bis(trimethylsilyl)amine and hydrocyanic acid [1] is approximately doubled.

$$[(H_3C)_3Si]_2NH + (H_3C)_3SiCl + 3\ HCN \rightarrow 3\ (H_3C)_3SiCN + NH_4Cl \quad (a)$$

Adducts of iodosilane with tertiary amines react even at −20 to −70 °C with hydrocyanic acid or cyanogen iodide with the formation of cyanosilanes, possibly according to Eq. (b).

$$R_3SiI\cdot NR_3' + HCN(ICN) \rightarrow R_3SiCN + NR_3'\cdot HI\ (NR_3'\cdot I_2) \quad (b)$$

The action of cyanogen iodide on methyldialkylaminosilanes in bulk or in ether solution at 0 to −20 °C gives methyldialkylaminocyanosilanes according to Eq. (c) (R=CH_3,C_2H_5).

$$(H_3C)_nSi(NR_2)_{4-n} + ICN \rightarrow (H_3C)_nSi(NR_2)_{3-n}CN + [NR_2I] \quad (c)$$

Diethylaminodimethylcyanosilane was also prepared from diethylaminoiododimethylsilane and cyanogen iodide in 28 % yield:

$$(H_3C)_2Si[N(C_2H_5)_2]I + ICN \rightarrow (H_3C)_2Si[N(C_2H_5)_2]CN + I_2 \quad (d)$$

[1] *T. A. Bither, W. H. Knoth, R. V. Lindsey Jr.*, and *W. H. Sharkey*, J. Amer. chem. Soc. *80*, 4151 (1958).

Reaction of organylsilylamines with hydrocyanic acid and cyanogen halide also gives organylcyanosilanes [Eq. (e)]. When organylsilyldialkylamines are used, dialkylcyanamides and organylsilylcarbodiimides are formed as by-products [Eq. (f)].

$$2\ (H_3C)_3Si{-}NR_2 + XCN + 2\ HCN \rightarrow 2\ (H_3C)_3Si{-}CN + NR_2(CN) + NR_2H{\cdot}HX \quad (e)$$

$$2\ [(H_3C)_3Si]_3N + XCN + 4\ HCN \rightarrow 4\ (H_3C)_3Si{-}CN + (H_3C)_3Si{-}N{=}C{=}N{-}Si(CH_3)_3 + NH_3{\cdot}HX \quad (f)$$

Trialkylcyanosilanes $R_3Si{-}CN$ ($R{=}CH_3, C_2H_5$) can further be detected in the reaction of cyanogen with trialkylmethylaminosilanes alongside cyanoformamidine derivatives.

40

Isotope Effects in the Separation of Rare Earths on Ion-Exchangers

H. Ihle, Bonn (Germany)

Equilibria for chemical exchange of isotopes have hitherto been measured mainly for light elements (H, Li, B, C, N, O), where the equilibrium constants are considerably greater or less than unity.

For elements of medium to high mass number the equilibrium constants K for isotope exchange approximate to unity. Values of 10^{-3} to 10^{-4} can be estimated for $\varepsilon = K - 1$.

We have measured the quotients of the distribution coefficients of samarium isotopes between a cation-exchanger and two complex-forming aqueous phases. Because of the high selectivity of the ion-exchange chromatography, microcolumns (length 80 mm, inner diameter 2 mm) suffice in band-elution experiments to give enrichments that are measurable by mass spectrometry. Values of ε have been calculated from the measured relative isotope abundances in the eluted fractions[1]. For two neighboring samarium isotopes, with mass numbers M and M + 1, the following values of ε were obtained at 20 °C:

$$\varepsilon_1 = K_1 - 1 = \frac{[M]_r[M+1]_{w1}}{[M]_{w1}[M+1]_r} - 1 = 3.4\times10^{-5} \pm 10\%$$

$$\varepsilon_2 = K_2 - 1 = \frac{[M]_r[M+1]_{w2}}{[M]_{w2}[M+1]_r} - 1 = 2.4\times10^{-5} \pm 10\%$$

where r denotes cation-exchanger Dowex 50 W X 4, w1 denotes aqueous 0.4 M α-hydroxyisobutyric acid of pH 3.45, and w2 denotes aqueous 0.43 M tartronic acid of pH 2.00.

The results are lower than those estimated from current theory. The discrepancy probably arises because the theory requires a series of simplifying assumptions that cannot be verified experimentally.

41

Alteration of the Barrier-Layer Properties of Oxide-Protected pn-Junctions in Silicon

D. Jahn, Baden (Switzerland)

The rectifying properties of pn-junctions in silicon can be stabilized by covering the crystal surface with an insulating protective coating, particularly at the intersection of the junctions with the surface. If SiO_2 is used as insulator, which can he applied to silicon in thicknesses of several μ by oxydation at high temperatures, this oxidation process often has unfavorable effects on the rectifying properties, *i.e.* redistribution of doping agents at the phase boundary Si/SiO_2 in accord with the distribution coefficients, rapid diffusion of impurities with high temperature coefficients of solubility into the crystal and formation of inclusions on cooling, and formation of inversion layers in the silicon owing to space charges in the SiO_2 layer.

The blocking action of silicon samples with npn structure (P-diffusion in p-Si of 10^3 ohm·cm) and mechanically and chemically exposed pn junctions having a hard characteristic and high blocking voltage (> 1000 volts) was lost on oxidation in dry O_2 at 1000 °C (SiO_2 film thickness 0.1 μ). This change is due partly to a surface effect. When the oxidized samples were polarized for several minutes at 50–200 volts *versus* a platinum cathode in an electrolyte (*e.g.* glycol with 2 % of H_2O and 0.4 % of KNO_3), high blocking voltages were again obtained, although the characteristic remained soft (which indicates defects in the bulk of the material). The same changes are observed when the oxide layer is removed with HF or when the sample is etched with HF/HNO_3. The possibility of changing the effect of the thermally produced SiO_2 layer on the semiconductor by electrolysis supports the assumption[1] that near the Si/SiO_2 interface there are oxygen vacancies in the SiO_2, which represent a strong positive space charge. In the high field prevailing during the electrolysis, migration of ions is evidently possible already at room temperature, which leads to elimination of the space charge.

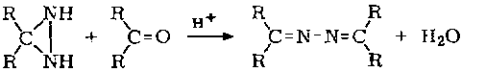
42

Conversion of Diaziridines into Azines

A. Jankowski, Essen (Germany)

Diaziridines *(1)* are isomeric with hydrazones. Like hydrazones they are hydrolysed by acids to a hydrazinium salt and a ketone. In contrast to hydrazones they cannot be hydrolysed in neutral or alkaline media, which limits their applicability in hydrazine synthesis *via* diaziridines.

Diaziridines can be converted into azines *(2)* with a new reaction: Treatment of diaziridines with catalytic amounts of acids, aqueous solutions of acid salts (*e.g.* hydrazine sulfate), or acidic agents (ion exchange resins), in the presence of a carbonyl compound and with the medium kept acidic, opens the ring and an exothermic reaction with the carbonyl compound takes place which yields the azine.



(1) *(2)*

The rate of conversion is strongly temperature-dependent. At 50 °C, *C*-methyl-*C*-ethyldiaziridine is completely transformed after 30 min, whereas at 25 °C the reaction takes 9 h. The reaction rate is also influenced by the substituents R. It increases in the sequence *C,C*-dimethyl- < *C*-methyl-*C*-ethyl- < *C,C*-diethyl-diaziridine.

The optimum pH is 2.5. Below this, the azine is partially cleaved to a hydrazine salt and a ketone; above it an as yet unexplained side reaction occurs with the formation of ammonia and nitrogen, which lowers the azine yields. If instead of acid an aqueous solution of a hydrazine salt is used and the solution is maintained at pH 2.0–2.5, hydrolysis of the azine is prevented and it is obtained in 95 % yield.

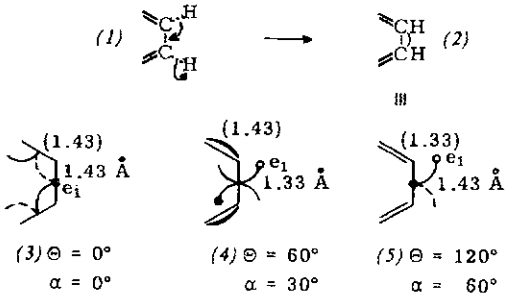
The formation of azines is industrially interesting, since they can be easily hydrolysed to hydrazine hydrate and can be used as starting materials in syntheses.

42a

An Accurate and Simple Calculation of the C-C Distance in Benzene

J. J. Jennen, Mortsel (Belgium)

There is a discrepancy between the observed C–C distance in benzene (1.397 Å [1]) and the average value of C–C single and double bond distances: (1.53 + 1.33)/2 = 1.43 Å. According to *Rogowski* [2] this discrepancy can be attributed to a shortening of the C–C single bond. According to the author a σ-delocalization, due to an electron releasing effect from the three C–H bonds in *m*-position toward the aromatic ring, is responsible for said shortening. Consequently, the Kekulé structure *(1)* changes into a Thiele structure *(2)* with saturated partial valencies. For structure *(2)*, wherein σ-electrons also are involved, the author introduces a segment



notation [3] [see *(3)* to *(5)*]; the segment radius for single and double bonds remains unaltered. In order to describe the bond configurations a segment must rotate around the z-axis of the carbon atom considered (angle Θ) and simultaneously around the segment axis (center of the circle – middle of the arc) (angle α = Θ/2). In this way only three structures result: one Kauffmann *(3)* and two Thiele structures *(4)* and *(5)*; from this it follows that the mean bond length in benzene is (1.33 + 1.43 + 1.43)/3 = 1.397 Å, in agreement with the observed value

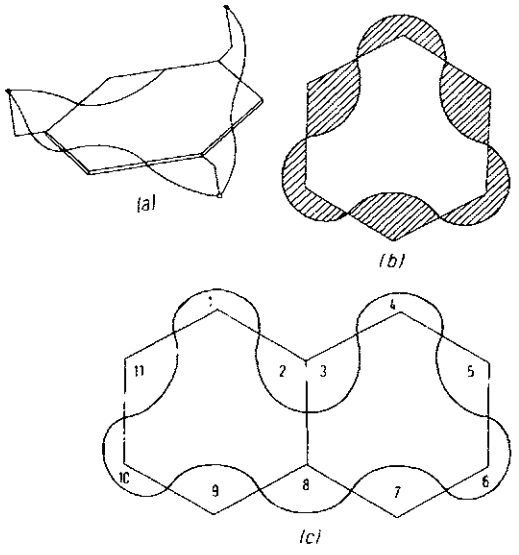
A New Semiquantitative Calculation of the Delocalisation Energy in Benzene and in the Acenes

J. J. Jennen, Mortsel (Belgium)

The ring currents generated by the mobile electrons (six π-electrons and six σ-electrons) in benzene are represented graphically using the segment method [1]. In this way Fig. (a) is obtained, wherein for a mobile electron half of the entire path is represented (the other half is enantiomorphic to the plane of the benzene nucleus). By the segment spin and the exchange in the Kauffmann structure the mobile electrons travel alternatively above and below the ring plane. By projection of the path shown in Fig. (a) the equivalent surfaces of Fig. (b), which are a measure for the delocalisation energies [2], are obtained. With the aid of the segment method delocalisation energies are calculated for the acenes, which agree with those obtained with the MO-method. Fig. (c)



illustrates the situation for naphthalene [surfaces 2, 3 and 8 are equivalent since the segments of the central bond are spinless (α = 0).].

Acene	Delocalisation energies in β: segment method	MO-method
Benzene	6 × 1/3 = 2	2.00
Naphthalene	11 × 1/3 = 3.67	3.68 [3]
Biphenyl	13 × 1/3 = 4.33	4.38 [3]
Anthracene	16 × 1/3 = 5.33	5.32 [3]
Tetracene	21 × 1/3 = 7	6.93 [4]

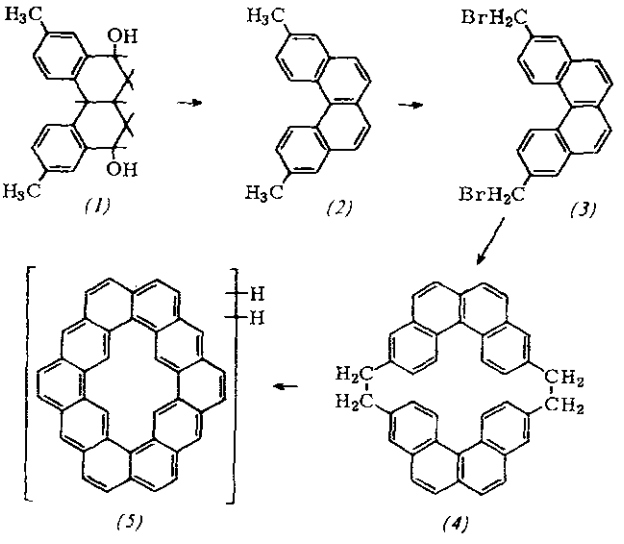
Coronaphenes, a New Group of Cyclic Hydrocarbons

W. Jenny and *R. Peter*, Basel (Switzerland)

The influence of ring fusion on the absorption spectra and reactivity of ortho-fused benzenoid hydrocarbons has repeatedly been studied in the acene and phene series. The empirical rules obtained can be extended only with reserve to angularly fused phenes which are combined in a larger polycyclic ring system. A number of new hydrocarbons was synthesized with the aim of studying these relations. The new polycyclic compounds are related to the circo-hydrocarbons, but in contrast to these they have an "empty" interior. The name coronaphene is proposed for these compounds, with a numerical prefix indicating the number of benzene rings fused in the molecule. All coronaphenes formally contain two concentric annulene systems and are therefore also of theoretical interest.

A synthesis leading to the skeleton of a [10]-coronaphene is described. Starting from 1,1-di-*p*-tolyl-2,2-ethoxycarbonylethane, the diol *(1)* was obtained after several steps. By dehydration and dehydrogenation, this was converted into 3,10-dimethylbenzo[c]phenanthrene *(2)* in 50 % yield. The action of phenyl-lithium on the dibromomethyl derivative *(3)* gave di(benzo[c]phenanthren-3,10-dimethylene) *(4)*, the structure of which was confirmed by NMR and mass spectra. Extensive dehydrogenation of *(4)* was achieved by treatment with $AlCl_3/CS_2$ and subsequent heating in the presence of Pd/C



(1) (2) (3) (5) (4)

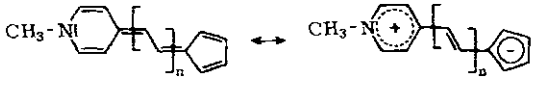
to 320–340 °C in a current of CO_2. A greenish-yellow dihydro derivative *(5)* was isolated by repeated column chromatography.

44

Studies on Azalogous Sesquifulvapolyenes

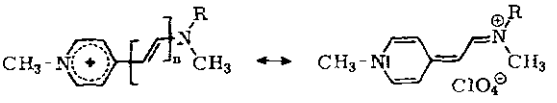
Ch. Jutz, R. Kirchlechner, and *W. Müller*,
München (Germany)

Vinylogous azalogues of sesquifulvalene (with the pyridine or quinoline system instead of the cycloheptatrienylidene group in sesquifulvalene) were previously unknown. For an investigation of bathochromic shifts of the principal absorption when the polyene chain is extended, the set of compounds *(1b)–(1d)* was built up by reaction of the vinylogous 1-methyl-4-aminopyridines *(2a)–(2c)* with cyclopentadienylsodium in tetrahydrofuran.



(1a): n = 0 [1] *(1c)*: n = 2
(1b): n = 1 *(1d)*: n = 3

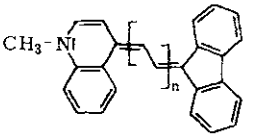
[λ_{max} (log ε) in acetonitrile: *(1a)*, 438 mμ (4.57); *(1b)* 542, 515 mμ (4.69; 4.71); *(1c)* 584 mμ (4.8); *(1d)* 602 mμ].



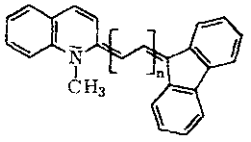
(2a): n = 1, R = CH_3
(2b): n = 2, R = C_6H_5
(2c): n = 3, R = C_6H_5

[λ_{max} (log ε) in acetonitrile: *(2a)* 399.5 mμ (4,96) *(2b)* 483 mμ (4.93); *(2c)* 575 mμ (4.96)].

Compound *(2)* was obtained from *N*-methylpicolinium perchlorate by reaction with dimethylformamide dimethylacetal, *(2a)* and *(2b)* by reaction of 3-(*N*-methylanilino)prop-1-enylidenemethylanilinium and 3-(*N*-methylanilino)penta-1,3-dienylidenemethylanilinium perchlorates, respectively, and sodium methoxide. The betaine-like basic compounds *(1)*, which are poorly soluble in non-polar solvents, are unstable and decompose below their melting points. Only *(1b)* and *(1c)* could be obtained pure; *(1d)* was obtained only in solution. By contrast, the fluorenylidenedihydroquinolines *(3a)–(3d)* and *(4a)–(4d)* are stable, deeply colored compounds of low polarity and basicity.



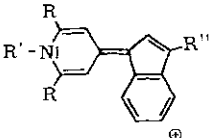
(3a): n = 0 *(3c)*: n = 2
(3b): n = 1 *(3d)*: n = 3



(4a): n = 0 *(4c)*: n = 2
(4b): n = 1 *(4d)*: n = 3

[λ_{max} (log ε) in acetonitrile: *(3a)* (m.p. 220 °C), 541 mμ (4.30); *(3b)* (m.p. 215 °C), 547 mμ (4.60); *(3c)* (decomp. at 229 °C), 562 mμ (4.68); *(3d)* 574 mμ (4.84); *(4a)* (m.p. 181 °C), 523 mμ (4.34); *(4b)* (m.p. 212 °C), 503.5 mμ (4.65); *(4c)* (m.p. 215 °C), 539 mμ (4.79); *(4d)* (decomp. at 214 °C), 552 mμ (4.84)].

Compounds *(3a)*, *(3b)*, *(4a)*, and *(4b)* were obtained by reaction of 4-methoxy- or 2-methoxy-*N*-methylquinolinium perchlorate with fluorene or 9-ethylidenefluorene, respectively, and sodium methoxide; *(3c)*, *(3d)*, *(4c)*, and *(4d)* were prepared from vinylogous *N*-methyl-4- or *N*-methyl-2-aminoquinolines. Electrophilic substitution on the 4-(1-indenylidene)-1,4-dihydropyridine system, *(5)*, R = H, leads to derivatives substituted in the 5-membered ring: The action of dimethylformamide/$POCl_3$ leads *via* the immonium perchlorate *(5a)* (λ_{max} = 475 mμ, log ε = 4.64) to the aldehyde *(5b)* (λ_{max} = 475 mμ, log ε = 4.97); *(5)* with *p*-dimethylaminobenzaldehyde and perchloric acid gives the dye salt *(5c)* (λ_{max} = 515 mμ, log ε = 4.67; methylation of *(5)*, R = H, with dimethyl sulfate gives *(5d)*; coupling of *(5)* with diazonium salts leads *via* a cation to the azo compounds *(5e)* (λ_{max} = 639 mμ, log ε = 4.9).



(5a): R = R' = CH_3; R'' = $-CH=\overset{\oplus}{N}(CH_3)_2ClO_4^{\ominus}$
(5b): R = R' = CH_3; R'' = $-CH=O$
(5c): R = R' = CH_3; R'' = $-CH=p-C_6H_4=\overset{\oplus}{N}(CH_3)_2ClO_4^{\ominus}$
(5d): R = R' = R'' = CH_3
(5e): R = H; R' = n-C_4H_9; R'' = $-N=N-C_6H_5$
(5f): R = H; R' = n-C_4H_9; R'' = $-N=N-p-C_6H_4-NO_2$

45

Ternary Oxides of Seven- and Four-Valent Technetium

C. Keller, B. Kanellakopulos, and *M. Wassilopulos*,
Karlsruhe (Germany)

Tc(VII) and Re(VII) are closely related crystallochemically. Thus the alkali pertechnetates $MTcO_4$ (M = Li to Cs), M_3TcO_5 (M = Na, K), and M_5TcO_6 (M = Li, Na), the alkaline earth pertechnetates $M^{II}(TcO_4)_2$ (M = Ca to Ba), $M_3^{II}(TcO_5)_2$ (M = Ba, Sr), and $M_5^{II}(TcO_6)_2$ (M = Ca to Ba), and the quaternary oxides $M^{II}(M^{I}_{0.5}, Tc^{VII}_{0.5})O_3$ (M^{II} = Ba, Sr; M^{I} = Li, Na) with ordered perovskite structure, largely correspond to the analogous perrhenates. When $Sr(TcO_4)_2$ and $Ca(TcO_4)_2$ are prepared by the evaporation of aqueous solutions, the dihydrates are obtained, which at 90 °C (Sr) and 100 °C (Ca) are transformed to the monohydrates, which are dehydrated at 210 °C (Sr) and 155 °C (Ca), respectively, to the anhydrous compounds. The pertechnetates are generally less stable than the perrhenates. Any

[1] *J. A. Berson* and *E. M. Evleth*, Chem. and Ind. *1961*, 1962; *J. A. Berson, E. M. Evleth, Z. Hamlet*, and *L. Manatt*, J. Amer. chem. Soc. *87*, 2887 (1965).

phase transition temperatures are always lower in the Tc compounds, *e.g.* the transformations of orthorhombic $CsXO_4$ and $TlXO_4$ to the tetragonal Scheelite structure occur at 95 °C ($TlTcO_4$) and 136 °C ($CsReO_4$), respectively. In the compounds of the six-valent elements, the differences in transition temperatures are considerably larger, *e,g.* α-Li_6XO_6 → β-Li_6XO_6 at 310 °C and 620 °C for X = Tc and Re, respectively.

In its solid-state chemistry, TcO_2 shows no similarity to ReO_2. Whereas only one ternary oxide, *viz.* Na_2ReO_3, has so far been prepared with Re(IV) [in most cases disproportionation of Re(IV) occurs in the reaction of ReO_2 with M_2O or MO], TcO_2 reacts to give defined compounds of Tc(IV), *e.g.* Li_2TcO_3(Li_2TiO_3 structure), Na_2TcO_3, Na_4TcO_4, $MTcO_3$ (M = Ba, Sr, Ca; perovskite structure), and M_2TcO_4 (M = Ba, Sr; K_2NiF_4-structure). $BaTcO_3$ was obtained in two modifications: in the direct reaction BaO + TcO_2, $BaTcO_3$ is formed in the $BaTiO_3$-structure (a = 5.763 Å, c = 14.05 Å); in the symproportionation from BaO + Tc + $Ba(TcO_4)_2$, cubic $BaTcO_3$ (a = 8.140 Å) is obtained. Tc(IV) thus is similar to Mn(IV) in its solid-state chemistry.

46

Attempted Preparation of Carbenes, Nitrenes, and Sulfenes

D. Klamann and *K. Ulm*, Hamburg-Harburg (Germany)

Although trihalomethanes and chloromethyl phenyl sulfide form carbenes with ethylene oxide in the presence of tetraalkylammonium halides, alkyl, allyl, and benzyl halides and *p*-toluenesulfonates, as well as halogen compounds activated by neighboring groups, give the corresponding alkyl 2-substituted ethyl ethers smoothly under the same conditions. In these reactions the reactivity, but also the concurrent β-elimination of HX, increases along the series chlorine to iodine and with increasing substitution of the alkyl residue. Dihalomethanes afford bis-(2-halogenoethyl)formals.

On treatment of *N*-halo compounds such as *N*-chloroamines and *N*-haloamides and -urethanes under the same conditions, the nitrene intermediates could not be isolated. Chlorination of the reactant (especially ethylene oxide) and polar addition of the *N*-halo compound to the acceptor double bond occur. On treatment of methane- or benzenesulfonyl chloride with ethylene oxide in the presence of tetraalkylammonium halides and addition to substituted butenynes or butadienes, ethylene oxide is inserted into the SO_2Cl group, yielding 2-halogenated sulfonic esters. This reaction is general for sulfonyl chlorides and epoxides.

47

Preparation and Reactions of Dihalocyclopropanes

D. Klamann and *P. Weyerstahl*, Hamburg-Harburg (Germany)

Dihalocarbenes are formed when trihalomethanes are heated with ethylene oxide in presence of tetraalkylammonium salts at 120–170 °C. By reaction of open-chain and cyclic mono- and di-olefins numerous, mostly new, 1,1-dichloro-, 1,1-difluoro-, and 1-chloro-1-fluorocyclopropanes have been prepared. Diolefins afford various amounts of bis-adducts.

Reaction of chloroform and ethylene oxide with tetrasubstituted ethylenes does not afford the primary product, but the 2-chlorodiene was obtained as a result of elimination of hydrogen chloride and isomerization. One or the other product can be obtained from trisubstituted olefins, depending on the reaction temperature.

1,1-Disubstituted olefins cannot be converted directly into 2-chlorodienes by reaction with chloroform and ethylene oxide, but the resulting dichlorocyclopropanes are smoothly cleaved to the 2-chlorodiene and hydrogen chloride by quinoline at 200 °C or by pyrolysis at about 400 °C.

48

Synthesis of Aliphatic Amines from Carbon Monoxide, Steam, and Ammonia

H. Kölbel and *J. Trapper*, Berlin (Germany)

At 200 to about 270 °C, the equilibrium

$$3n\ CO + n\ H_2O + NH_3 \rightleftharpoons C_nH_{2n+1}NH_2 + 2n\ CO_2$$

favors the products, in which amines with many carbon atoms predominate over those with few. The reaction is exothermic and was studied at 11 atm total pressure of a gas consisting of, *e.g.*, 56 % of CO, 21 % of H_2O, 11 % of NH_3, and 22 % of an inert gas. An iron catalyst containing small amounts of copper and potassium carbonate was used. In continuous operation (for several weeks), a single passage of the gas through the reactor gives conversions of 80 % for CO and 30 % for NH_3 at a gas velocity of 50–60 liters per liter of catalyst per hour.

The liquid products contain, apart from hydrocarbons, up to 23 % of nitrogen-containing compounds, mainly 1-aminoalkanes from methylamine to n-dodecylamine. About 50 % of the non-gaseous products are liquids; the rest have the consistency of soft to hard paraffin waxes. The nitrogen content of the hard paraffin (up to 1.35 %) suggests that more than 50 % of the constituent molecules contain nitrogen. Oxygen compounds are also formed, *e.g.* alcohols, carbonyl compounds, and fatty acids. It is therefore probable that amino acids are also formed, but significant amounts were not found. Since the melting points of the amino acids expected lie in the range of the synthesis temperatures, they probably decompose during the process.

If the yields can be increased, this reaction should be suitable for the technical production of the aliphatic amines mentioned.

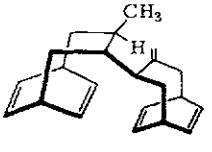
49

A New Photochemical Reaction of Benzene and Some of Its Homologues

G. Koltzenburg and *K. Kraft*, Mülheim/Ruhr (Germany)

Under direct photochemical excitation at 254 mμ, benzene reacts in even dilute solutions (in ether, n-pentane, *etc.*) with isoprene to give at least ten products. The two chief products, a 2:2 adduct (46 %, based on benzene consumed) and a 1:1 adduct (23%), were isolated.

The 2:2 adduct, $C_{22}H_{28}$, forms colorless crystals melting at 164–168 °C. It contains five non-conjugated double bonds; four *cis*-substituted double bonds come from benzene and one *exo*-methylene group from isoprene (shown by comparison of the NMR spectra of $C_{22}H_{28}$ and the analogous adduct of C_6D_6 and isoprene, $C_{22}D_{12}H_{16}$). One of the two methyl groups of the isoprene molecules is retained; it is found on a tertiary carbon atom. The compound can be hydrogenated under pressure. After hydrogenation of the four *cis* double bonds, the *exo*-methylene group is saturated only at 100 atm of H_2.



$C_{22}H_{28}$

The 2:2 adduct isomerizes at 130 °C to a colorless, lower-melting compound (m.p. 82–85 °C) containing a 1,3-cyclohexadiene partial structure (λ_{max} = 38400 cm^{-1}, ε = 3400 in cyclohexane).

The 1:1 adduct, a colorless oil of b.p. 55 °C/6 mm, is probably a mixture of stereoisomers *(1)*.

(1)

Crystalline 2:2 adducts were obtained from toluene (m.p. 132–138 °C), *p*-xylene (m.p. 170–196 °C), *o*-xylene (m.p. 150–170 °C), hexafluorobenzene (m.p. 238–271 °C), and 1,2,4,5-tetrafluorobenzene (m.p. 230–241 °C). Benzene and butadiene also form a 2:2 crystalline adduct which sublimes at 195 °C.

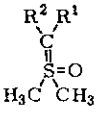
In the presence of sensitizers such as benzophenone and benzil, no crystalline adducts were obtained. Irradiation with electrons or with γ-rays from ^{60}Co also failed to produce adducts.

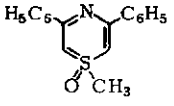
50

Reactions with Sulfur Ylides

H. König, Ludwigshafen (Germany)

Dimethyloxosulfonium methylide *(1)* was acylated in usually very good yield to the crystalline mono- and diacyl derivatives *(2)* and *(3)*.



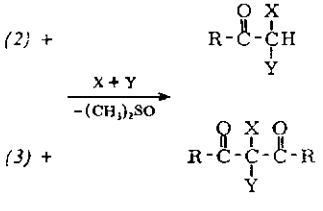


(4)

(1) $R^1 = R^2 = H$
(2) $R^1 = H$; $R^2 = CO\text{-}R$
(3) $R^1 = CO\text{-}R^1$; $R^2 = CO\text{-}R$

The structure elucidation of the new class of compounds is based *inter alia* on the strong displacement of the carbonyl band to longer wavelengths ($\lambda \simeq 6.4\mu$), on the ultraviolet and particularly on the NMR spectrum, which shows a characteristic 6-proton singlet due to the methyl groups on the sulfur atom.

The reaction of excess of benzonitrile with *(1)* gives *inter alia* a crystalline heteroaromatic ylide *(4)*.



Compounds *(2)* and *(3)* react in 40–99 % yield with simultaneous addition of an electrophilic particle X and a nucleophilic partner Y, and elimination of dimethyl sulfoxide, to carbonyl and 1,3-dicarbonyl compounds. Suitable combinations XY are, *e.g.*, formally the ions $X = H^+, CH_3^+, Br^+$, and $Y = Cl^-, Br^-, H^-, C_6H_5S^-, C_6H_5NH^-$.

51

New Syntheses and Reactions of Isoindoles

R. Kreher and *J. Seubert*, Darmstadt (Germany)

Isoindole is formed from 2-benzyloxyisoindoline by base-catalysed elimination; however, it can be recognized only as its adduct with maleic anhydride or *N*-phenylmaleimide[1].

[1] *R. Kreher* and *J. Seubert*, Z. Naturforsch. *20b*, 75 (1965).

2-Alkyl- and 2-Arylisoindoles are obtained from 2-alkyl- or 2-arylisoindoline-2-oxides in the presence of acetic anhydride and triethylamine, even at 0 °C, and can be isolated in pure form by distillation or crystallization[2]. 2-Arylisoindoles can also be obtained from 1,2-dibromobenzocyclobutene and primary aromatic amines.

1-Arylisoindoles are formed on reductive cyclization of 2-cyanobenzophenones with hydrogen and Raney nickel; 1,1'-diaryl-3,3'-dehydrobiisoindoles are by-products which can be regarded as diazafulvalene derivatives.

The substituted isoindoles react like isoindole itself with philodienes as in the Diels-Alder reaction or Michael addition. According to the substituents on the nitrogen, 1:1 or 1:2 adducts are formed; their constitution and configuration have been elucidated in several cases.

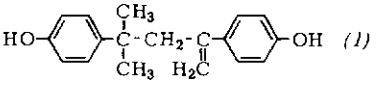
[2] *R. Kreher* and *J. Seubert*, Angew. Chem. *76*, 682 (1964); Angew. Chem. internat. Edit. *3*, 639 (1964).

52

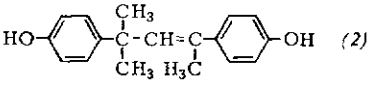
Reactions of p-Isopropenylphenol

H. Krimm, Krefeld-Uerdingen (Germany)

p-Isopropenylphenol dimerizes readily to *(1)*, less easily to *(2)*.

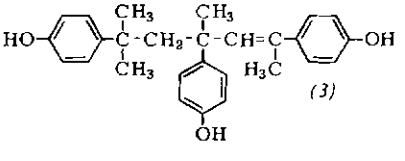


(1)

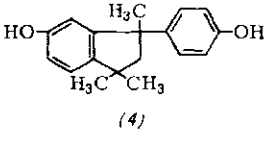


(2)

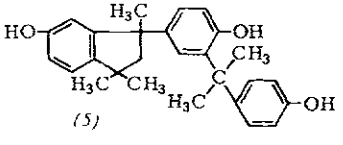
The trimer *(3)* occurs in two geometrically isomeric forms. Two further, saturated oligomers *(4)* and *(5)* have indane structures.



(3)

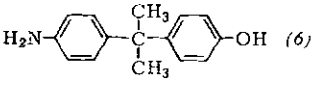


(4)



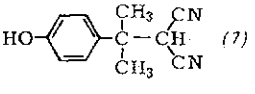
(5)

The reactions of *p*-isopropenylphenol with phenol to 2,2-bis-(*p*-hydroxyphenyl)propane and with aniline to 2,2-(*p*-amino-*p*-hydroxydiphenyl)propane *(6)* are reversible. In *(6)* the hydroxyphenyl and aminophenyl groups are interchangeable. This leads to 2,2-bis-(*p*-hydroxyphenyl)propane and 2,2-bis-(*p*-aminophenyl)propane in good yields.



(6)

CH-active compounds add to *p*-isopropenylphenol; *e.g.*, malonodinitrile gives *(7)*.



(7)

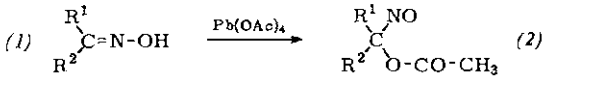
p-Isopropenylphenol can be copolymerized ionically or free-radically with vinyl monomers. Polyfunctional esters of *p*-isopropenylphenol are particularly suitable for radical copolymerization.

53

Geminal Nitrosoacyloxyalkanes and their Dimers

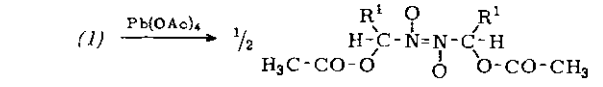
H. Kropf, Hamburg (Germany)

Aliphatic ketoximes *(1a)* to *(1i)* are converted into *gem*-nitrosoacetoxyalkanes *(2)* by lead tetraacetate[1]. Some of the products can be isolated in the monomeric form as deep blue oils (λ_{max} = 660–690 mμ). From aliphatic aldoximes *(1k)* to *(1n)* the nitroso-bridged dimers *(3)* are obtained.



(1) $\xrightarrow{Pb(OAc)_4}$ *(2)*

(a) $R^1 = R^2 = CH_3$ *(d)* $R^1 = CH_3$; $R^2 = C(CH_3)_3$
(b) $R^1 = CH_3$; $R^2 = C_2H_5$ *(e)* $R^1 = CH_3$; $R^2 = CH_2{-}C_6H_5$
(c) $R^1 = R^2 = n\text{-}C_3H_7$ *(f)-(i)* $R^1R^2 = (CH_2)_n$, n = 4,5,6,7

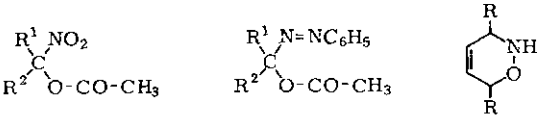


(1) $\xrightarrow{Pb(OAc)_4}$ $\frac{1}{2}$ *(3)*

(k) $R^1 = n\text{-}C_3H_7$ *(m)* $R^1 = n\text{-}C_7H_{15}$
(l) $R^1 = n\text{-}C_5H_{11}$ *(n)* $R^1 = CH_2{-}C_6H_5$

Infrared spectra of *(2)* in tetrachloroethylene: C–O: 1215 to 1240 cm^{-1}; CH_3–(CO): 1360–1370 cm^{-1}; N=O: 1550 to 1570 cm^{-1}; C=O: 1735–1750 cm^{-1}. Infrared spectra of *(3)* in KBr: *trans*-NO–NO: 1185–1200 cm^{-1}; C–O: 1205 to 1220 cm^{-1}; CH_3–(CO): 1360–1375 cm^{-1}; C=O: 1730 to 1750 cm^{-1}.

The structures were confirmed by NMR and mass spectra. The *gem*-nitrosoacetoxyalkanes *(2)* are oxidized to the nitro compounds *(4)* by $H_2O_2/NaNO_2$[1]. Condensation of *(2)* with aniline leads to α-phenylazo-α-acetoxyalkanes *(5)*, Diels-Alder reaction with compounds R–CH=CH–CH=CH–R leads (analogously to the reaction of *gem*-nitrosochloroalkanes[2]) to 3,6-dihydro-1,2-oxazines *(6)*, whereby alcoholysis of the alkyl group takes place.



(4) *(5)* *(6)*

54

Sodium Acetonitriles, Preparation and Reactions

C. Krüger, Mülheim/Ruhr (Germany)

Monosodium acetonitrile *(1)* can be isolated as an insoluble salt, sensitive to air and moisture, by treating sodium bis(trimethylsilyl)amide[1] with acetonitrile in ether at −60 °C.

$$CH_3CN + NaN[Si(CH_3)_3]_2 \rightarrow \underset{(1)}{NaCH_2CN} + HN[Si(CH_3)_3]_2$$

^{1}H-NMR and infrared spectra show all three tautomers

$$NaCH_2CN \quad CH_2{=}C{=}N{-}Na \quad CH{\equiv}C{-}NH{-}Na$$

to be present as a mixture in which the first form predominates. The compound forms a crystalline but unstable adduct with pyridine. It adds to carbonyl compounds according to

$$R_2C{=}O + NaCH_2CN \rightarrow R_2C(ONa){-}CH_2CN$$

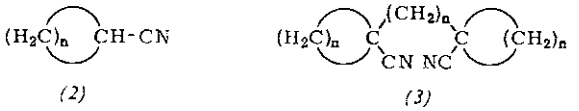
or to nitriles according to

$$R{-}C{\equiv}N + NaCH_2CN \rightarrow R{-}C(NHNa){=}CH{-}CN$$

Compound *(1)* can function as a carbene source particularly in the presence of cyanide acceptors:

$$NaCH_2CN \rightarrow :CH_2 + NaCN$$

The doubly and triply metallated acetonitriles are formed when an excess of metallating agent is used. They can be detected in the reaction mixture[2], but not isolated. Thus the reaction of a multiply metallated acetonitrile with α,ω-dibromoalkanes $Br(CH_2)_nBr$ leads to carbocyclic nitriles *(2)* together with compounds of type *(3)*.



(2) n = 3-6 *(3)*

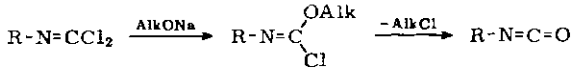
55

Reactions with Isocyanide Dichlorides

E. Kühle and *B. Anders*, Leverkusen (Germany)

Isothiocyanates are obtained in good yields from isocyanide dichlorides with sodium sulfide solution at room temperature or with phosphorus pentasulfide in an inert solvent at a higher temperature

Isocyanates are accessible from isocyanide dichlorides and acid anhydrides. The alkoxy compounds obtained from isocyanide dichlorides and alkoxide solutions also give isocyanates with elimination of alkyl chloride.



Carbodiimides are formed by heating isocyanide dichlorides with primary amine hydrochlorides.

Isonitriles can be prepared from isocyanide dichlorides and organic compounds of trivalent phosphorus.

56

Rheological Properties of Grinding Pastes

W. Liehr, Krefeld-Uerdingen (Germany)

Grinding pastes rich in pigment and containing dilute solutions of binder are usually recommended for high-speed ball mills. The method of flow-point determination of *Daniel* is proposed for finding suitable compositions for the grinding pastes. Pastes compounded in this manner are difficult to use in sand and pearl mills. The addition of binder solution in excess of that required to attain the flow point has been proposed, in order to obtain almost Newtonian behavior. The flow properties of pigment-binder systems have now been studied with a rotation viscometer.

It has previously been observed that the flow properties of grinding pastes change during dispersion. We followed this change with degree of dispersion using the hysteresis method of determining flow curves at various constant concentrations of binder, but with different ratios pigment: binder: solvent, dispersed in a sand mill.

The results obtained were partly expected: the viscosity decreases with increasing proportion of binder solution; it decreases with increasing temperatures; higher structural viscosity is found with higher proportions of pigment. Some peculiar rheological properties were, however, also observed: if the pastes, which become warm during dispersion, are measured immediately, they are found to be thixotropic. With increasing dispersion time and decreasing particle size the initially high viscosities decrease.

If the measurements are made some time later dilatancy is initially observed for the same sample, but on prolonged shearing a structure is destroyed and thixotropy is restored. This time dependence, which is opposite to that of rheopexic systems, might therefore be designated "antirheopexic". The flow anomalies become less pronounced with decreasing proportions of pigment in the pastes, the dilatancy decreases, and Newtonian behavior is approached. Similar observations on polymer solutions of various concentrations have been described.

57

Preparation of Aryl Esters

J. Lorenz, Marienberg (Germany)

When triphenyl phosphite is heated with a carboxylic acid at 150–250 °C, an exothermic reaction takes place to the phenyl ester of the carboxylic acid. The phosphite loses two phenyl groups; excess of acid acts as an "inert" solvent. The best yields are obtained when heating is stopped when the reaction begins, or by working in a diluent such as decalin.

Aliphatic and aromatic monocarboxylic acids can he used, with yields of 70–90 %. Oxalic, fumaric, and acetylenedicarboxylic acid decompose; phthalic acid gives mainly the anhydride. Adipic and terephthalic acid give the diphenyl esters in yields of 72 and 40 %, respectively. Salicylic, *p*-chlorobenzoic, nicotinic, and 4-thiapimelic acid can be converted into the phenyl esters in yields of 68, 50, 38, and 65 %, respectively NH_2- or SH-substituted acids can not. Phosphites made from substituted phenols or thiophenols also give the corresponding aryl or thioaryl esters.

The high activation energy and the exothermic nature of the reaction suggest as high-energy intermediates a mixed anhydride $(C_6H_5O)_2P-O-CO-R$ (in the first stage) and $(C_6H_5O)(O)(H)P-O-CO-R$ (in the second stage). The reaction of potassium acetate with triphenyl phosphite gives phenyl acetate, which would not be expected if the reaction proceeded *via* a phosphonium ion $(C_6H_5O)_2(H)P^+$-O-CO-CH_3. In the presence of one mole of pyridine, the reaction of 2 moles of acetic acid with one mole of triphenyl phosphite gives the phenyl ester (68 %) exothermically already at 100 °C. The fact that only two of the phenyl groups are transferred is due to the high acidity of monophenyl phosphite relative to the carboxylic acids.

58

Evolution of Fission Products from Neutron-Irradiated Uranium Dioxide at High Temperatures

F. Lux, D. Graw, and *J. Vogel*, München (Germany)

The investigations, based on *Hahn*'s emanation method, of the behavior of irradiation products of uranium in heterogeneous reactions of neutron-irradiated uranium compounds with gases or liquids containing a complexing agent[1] have been extended to reactions of solid uranium compounds with solids. The formation of uranium carbide from neutron-irradiated uranium dioxide and graphite in a Tammann furnace under argon was studied. The argon was circulated over copper and uranium turnings at 420 °C to remove any traces of oxygen.

With unirradiated UO_2, UC_2 was formed after 5 min at 1750 °C, as shown by X-ray diffraction. Neutron-irradiated UO_2 was at first heated without admixture of graphite to 1300–1900 °C in alumina or graphite crucibles. Fission products were given off already below the temperature for UC_2 formation (1750 °C), depending on the crucible material (cf. Table 1).

Table 1. Fission products given off from irradiated UO_2 (grain size 1 μ) after 4 h.

T [°C]	Crucible material	Fraction of fission product given off [a] Sr	Ba	Te	Mo	Ru	La	Ce	Nd
1460	Graphite	42.5	41.5	93.7	0	0	0	0	0
	Al_2O_3	0	0	100	95.6	88.7	0	0	0
1620	Graphite	98	99	100	0	0	0	0	0
	Al_2O_3	20	28	100	100	97	0	0	0
1880	Graphite [b]	100	100	100	0	0	74	48	37

[a] Zr, Nb, and Np were not observed in any case.
[b] Here the UO_2 reacts completely with the crucible to UC_2.

The emanation of fission products depends chiefly on whether, owing to "microscopic solid-state reactions" of the products of irradiation with other solids such as the crucible, these products can be immediately removed from the surface of the UO_2 grains, since diffusion from within the grains is sufficiently rapid at the high temperatures employed. In a graphite crucible the BaO, for example, present in the UO_2 is reduced to metallic barium which immediately evaporates. BaO-removal in an alumina crucible occurs only at temperatures where the vapor pressure of BaO is sufficiently high. The oxides of *e.g.* Mo and Ru are however more volatile than the metals themselves. Thus the sequences in which the fission products are removed are found to be in the order of the vapor pressures of the elements in graphite crucibles, and of the oxides in alumina crucibles, except for a shift observed with lanthanum. The rate at which the fission products are given off is inversely proportional to the grain size.

[1] *F. Lux* and *F. Ammentorp-Schmidt*, Radiochim. Acta *4*, 112 (1965); *F. Lux* and *F. Ammentorp-Schmidt*, Angew. Chem. *77*, 732 (1965); Angew. Chem. internat. Edit. *4*, 707 (1965).

59

Preparation and Properties of Diprimary Alkylenediphosphines

L. Maier, Zürich (Switzerland)

Diprimary alkylenediphosphines *(1)* can be easily prepared by reduction of alkylenediphosphonates with $LiAlH_4$.

$$(RO)_2OP(CH_2)_xPO(OR)_2 \rightarrow H_2P(CH_2)_xPH_2$$
(1), x = 1–4

Previous reports[1] that *(1)*, x = 1 and 2, are unstable above −78 °C are incorrect. The infrared spectra of alkylenediphosphines show a P−H absorption band at 2270–2290 cm^{-1}; the ^{31}P-NMR spectrum has a triplet of intensity ratio 1:2:1 which is shifted with increasing x to higher fields; *e.g.* x = 1: +121.8 ppm, x = 2: +130.8 ppm, x = 3: +138.6 ppm. The ^1H-NMR spectrum confirms the structure *(1)* of the alkylenediphosphines.

With strong acids the alkylenediphosphines give phosphonium salts, *e.g. (2)*:

$$H_2P(CH_2)_3PH_2 + H_3PO_4 \rightarrow [H_2P(CH_2)_3PH_3]^+H_2PO_4^- \quad (2)$$

In the presence of free-radical initiators they add onto olefins, forming ditertiary alkylenediphosphines, which can be oxidized with H_2O_2 to the dioxides *(3)* and characterized as such.

$$H_2P(CH_2)_xPH_2 + 4\ CH_2{=}CHR \rightarrow (RCH_2CH_2)_2P(CH_2)xP(CH_2CH_2R)$$
$$\downarrow H_2O_2/\text{Acetone}$$
$$(RCH_2CH_2)_2(O)P(CH_2)_xP(O)(CH_2CH_2R)_2 \quad (3)$$

(3a), x = 3, R = n-C_6H_{13}, m. p. 145–150 °C

(3b), x = 4, R = n-$C_{10}H_{21}$, m.p. 91–91.8 °C

With *N*-hydroxymethyldialkylamines, prepared from formaldehyde and secondary amines, the diprimary alkylenediphosphines *(1)* give alkylenebis(dialkylaminomethylphosphines) *(4)* in excellent yields.

$$H_2P(CH_2)_xPH_2 + 4\ R_2NCH_2OH \rightarrow (R_2NCH_2)_2P(CH_2)_xP(CH_2NR_2)_2$$
$$(4),\ x = 1\text{–}4,\ R = C_2H_5$$

The ^1H-NMR spectrum of alkylenebis(diethylaminomethylphosphines) *(4)* contain three complex bands, quantitative analysis of which proves the structure of the products.

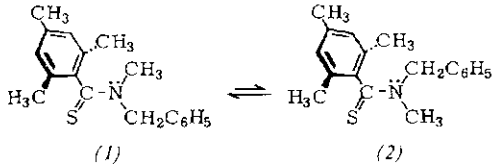
[1] *A. J. Leffler* and *E. G. Teach*, 133rd ACS Meeting, San Francisco, April 1958. Abstracts of Papers, p. 29 N.

60

Separation of Rotational Isomers of Amides, Thioamides, and Nitrosamines

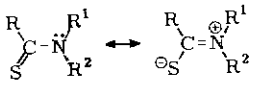
A. Mannschreck, Heidelberg (Germany)

The thioamides, *e.g. (1)* and *(2)*, of mesitylenecarboxylic acid can be separated chromatographically and identified by their NMR spectra; *(1)*: m.p. 58.5–60 °C, *(2)*: m.p. 98–99 °C. The crystalline substances are stable, but in solution an equilibrium mixture containing 68 % of *(1)* at 50 °C is formed. The equilibration is a first order process with a half-life of



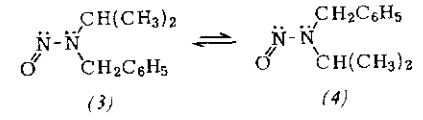
(1) *(2)*

24.7 ± 2.8 h in $CDCl_3$ at 50 °C. The free energies of activation of the isomers were found to be $\Delta G^{\ddagger}_{(1)} = 27.3$ and $\Delta G^{\ddagger}_{(2)} = 26.8$ kcal/mole. For the corresponding oxygen compounds the values are 22.9 and 22.3, respectively[1], *i.e.* they isomerize faster. In the corresponding thioformamides the equilibrium is also established faster than in *(1)* and *(2)*, so that they could not be completely separated[2]. Thus, apart from the thioamide resonance,



the mesityl group contributes to the hindrance of rotation around the C–N bond in *(1)* and *(2)*. This is one of the reasons that isomers of non-sulfur containing formamides, acetamides, and benzamide have so far not been enriched.

For nitrosamines[3], considerable enrichment of isomers was achieved, *e.g.* of *(3)* and *(4)*. The crystals, m.p. 20–22 °C, obtained directly from the synthesis of the compound consist of about 94 % of *(3)*.



(3) *(4)*

The equilibrium [81 % of *(3)*] is attained with a half-life of 8.2 ± 2.0 min in CCl_4 at 36 °C. From an equilibrium mixture of the isomers in CS_2, mainly *(3)* crystallizes out at −60 °C. In the filtrate *(4)* is enriched to 75 % since at this temperature it is converted only slowly into *(3)*.

[2] *W. Walter* and *G. Maerten*, Liebigs Ann. Chem. *669*, 66 (1963); *W. Walter*, *G. Maerten*, and *H. Rose*, Liebigs Ann.Chem., in press.

61

Addition Reactions of Cyanic Esters

D. Martin, Berlin-Adlershof (Germany)

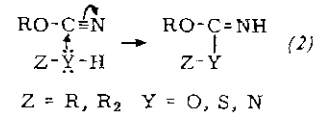
Sterically unhindered esters of cyanic acid give the following reactions:

1. *Isomerization*: On being heated, or on treatment with Lewis acids or H-acidic compounds, alkyl cyanates isomerize to isocyanates, which react further to esters of isocyanuric acid.

2. *Trimerization*: On being heated with acids or tertiary amines, aryl cyanates isomerize to aryl cyanurates.

3. *Nucleophilic Additions*:

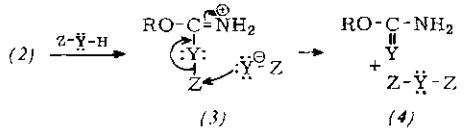
a) At the C-atom: They proceed particularly easily because of the neighboring electron-attracting O and N atoms. The compounds *(2)* obtained by the addition of the nucleophile Z–Y–H *(1)* are stable when the bonding pair of electrons between Z and Y is not available for a secondary reaction.



(1) *(2)*

Z = R, R_2 Y = O, S, N

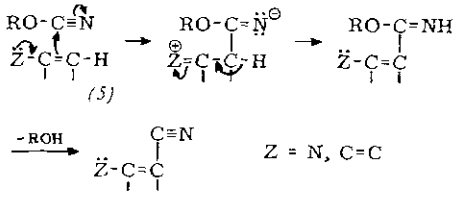
If Z is an acyl group, the primary adduct *(2)* is immediately protonated to *(3)* by another molecule of *(1)*. The bonding electron pair from Z is now available for charge equalization, and *(3)* reacts with $Z{-}Y^{\ominus}$ to *(4)*.



(3) *(4)*

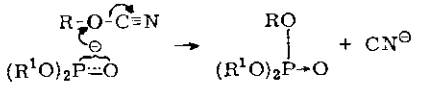
Z = H, Acyl, Sulfonyl, Phosphoryl, Y = O, S

In reactions with compounds *(5)* containing electron-rich double bonds, *i.e.* enamines, pyrroles, aromatic hydrocarbons, carbanions, cyanide ions, CH-acidic compounds, or Grignard reagents, cyanic esters act as nitrile group donors.



(5)

b) At the O-atom: Phosphoric di- and triesters attack cyanates at the O-atom with elimination of cyanide:



4. *Cycloadditions*: In contrast to nitriles, cyanates react smoothly with 1,3-dipoles under cycloaddition. Tetrazoles are formed with azides, 1,2,3-triazoles with diazo compounds, 1,2,4-triazoles with nitrilimines, and 1,2,4-oxadiazoles with nitrile oxides.

5. *Electrophilic Additions*: In the cases studied so far, these are more difficult than with nitriles. *N*-Phenylnitrilium cations add onto aryl cyanates yielding quinazolines. Triethyloxonium tetrafluoroborate yields small amounts of phenetole with phenyl cyanate.

62

Injection and Extraction Processes at Semiconductor Electrodes

R. Memming and *G. Schwandt*, Hamburg (Germany)

Electrons and positive holes participate in reactions at semiconductor electrode surfaces, *i.e.* such reactions can occur *via* various energy bands of the semiconductor (conduction or valence band). Quantitative information on this participation is obtained by the "thin slice method" described below.

On the side opposite the semiconductor surface to be studied there is a pn-junction. When minority carriers are injected into the semiconductor at the phase boundary (*e.g.* electrons in the case of p-germanium), they diffuse into the crystal and thence to the pn-junction. The injected charge carriers are accelerated in the internal electric field of the pn-junction. If the junction is short-circuited, this gives rise to a current. This method has been frequently used to detect qualitatively the injection of charge carriers. It is suitable for quantitative determination of the injection current if the mean free path of the minority carriers in the semiocnductor is known.

The "thin slice" method has been applied to germanium and silicon in various electrolytes. Thus in solutions in methanol (in contrast to aqueous solutions) it can be shown that the reactions occurring at anodically polarized germanium electrodes depend on the nature of the halide ions present.

The method is suited not only to the study of injection and extraction processes during an electrochemical reaction, but also to the observation of the recombination of electrons and holes at the surface. Electron-hole pairs are generated at the surface by illumination and detected by the pn-junction. The short-circuit current is a measure of the rate of recombination *via* surface states. The position of such centers within the forbidden zone can thus be determined.

63

Mechanism of the Electrolytic Reduction of Hydrogen Peroxide on Germanium

W. Mindt and H. Gerischer, München (Germany)

From an analysis of the current-potential curve of the electrolytic reduction of H_2O_2 on germanium it was deduced that the transfer of electrons depends on a free-radical surface state of the germanium. This radical state originates in a transition region between a hydroxide-like and a hydride-like surface structure as a consequence of the surface reaction:

$$\text{GeOH} + 2H^+ + e^- \rightleftharpoons \text{Ge-H} + H_2O + p^+$$

This reaction proceeds *via* the radical form Ge·, which effects the reduction of H_2O_2 according to the reaction:

$$\text{Ge}\cdot + H_2O_2 + e^- \rightleftharpoons \text{Ge-OH} + OH^-$$

It was further shown that only the electrons of the conduction band take part in this reduction.

64

The Determination of Potassium and Argon in Iron Meteorites by Neutron Activation Analysis

O. Müller and *J. Zähringer*, Heidelberg (Germany)

Several iron meteorites were dated using the potassium-argon method. Because of the very low potassium content of these meteorites, potassium and argon were determined by neutron activation analysis:

$$K^{41}(n,\gamma)\ K^{42} \xrightarrow[12.4\ h]{\beta^-,\gamma} Ca^{42} \qquad Ar^{40}(n,\gamma)\ Ar^{41} \xrightarrow[1.8\ h]{\beta^-,\gamma} K^{41}$$

The concentrations found were: argon 10^{-8}–10^{-7} ml/g; potassium 10^{-8}–10^{-7} g/g meteorite.

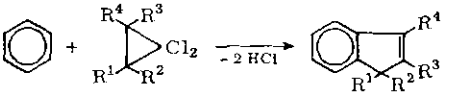
The ages of iron meteorites determined by the potassium-argon method are about 6×10^9–7×10^9 years, *i.e.* they are considerably older than stone meteorites (maximum age 5×10^9 years). This points to a different history of formation of the two types of meteorites.

65

A Simple Indene Synthesis involving Dihalocyclopropanes

F. Nerdel and *J. Buddrus*, Berlin (Germany)

Dihalocyclopropanes *(1)* that carry alkyl or aryl groups condense with aromatic compounds in the presence of strong Lewis acids, affording indenes *(2)*, with concurrent 1,2-migration of an alkyl or aryl group. Ring closure requires a



(1) *(2)*

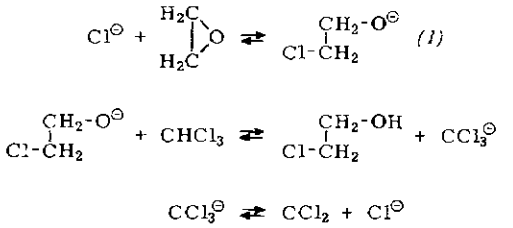
strong Lewis acid ($AlCl_3$ is better than $FeCl_3$), to loosen the halogen (Cl, F) that is fairly firmly retained on the cyclopropane ring. In this way, 1,1-dichloro-2,2-dimethylcyclopropane gives 2,3-dimethylindene. The reactions occur at room temperature. At least 1.1 moles of $AlCl_3$ are used per mole of cyclopropane. Two layers are formed during the reaction: the lower is a complex of indene, $AlCl_3$, HCl (HF), and the aromatic starting compound; the upper contains only the aromatic starting compound. Yields range from 45 to 67 %; they are highest when the aromatic compound and dihalopropane carry several alkyl groups.

66

A New Method of Generating Carbenes

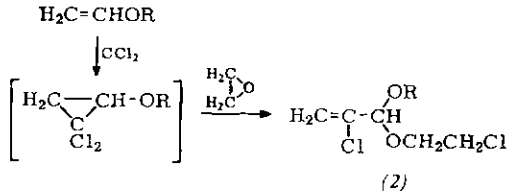
F. Nerdel and *J. Buddrus*, Berlin (Germany)

Epoxide rings can be opened with anions to form "bases"[1]. We found that the pseudobase *(1)* can eliminate hydrogen halide from haloforms, liberating carbenes which can be captured with alkenes.



(1)

Equimolar amounts of ethylene oxide, chloroform, and alkene are heated at 150 °C in an autoclave, and the product is isolated by distillation. No reaction is observed in the absence of alkene. Evidently the formation of carbenes is reversible. With vinyl ethers, α-haloacrolein acetals *(2)* are obtained *via* a cyclopropane, which is unstable at high temperatures.



(2)

67

The Reaction of Iron(III) Chloride with $LiAlH_4$

H. Neumaier, München (Germany)

Iron(III) chloride reacts quantitatively with $LiAlH_4$ in ether solution at −116 °C according to

$$FeCl_3 + 3\ LiAlH_4 \rightarrow Fe(AlH_4)_2 + AlH_3 + 3\ LiCl + 0.5\ H_2$$

Iron(II) aluminum hydride is reasonably stable at room temperature. At higher temperatures it decomposes to the elements, with a significant increase in the rate of hydrogen evolution at 90–100 °C. The P–T diagram of the thermolysis shows no break or region of constant pressure, which makes the existence of the intermediate $FeAl_2H_6$ postulated by *Schaeffer*[1] appear improbable.

[1] *G. W. Schaeffer, J. S. Roscoe,* and *A. C. Stewart*, J. Amer. chem. Soc. *78*, 729 (1965).

68

The Stability of Boron Azides

P. I. Paetzold, München (Germany)

The thermal stability of boron azides L_2BN_3 decreases in the sequence L = NR_2 > OR > R > Cl > Ar. The extent of the rearrangement

$$L_2BN_3 \rightarrow N_2 + {}^1/_n\ (LB{-}NL)_n$$

on thermal decomposition follows the opposite sequence. The rate constants k_1 of the first-order decomposition of the azides Ar_2BN_3 depend on steric and electronic parameters of the aromatic substituents. The yields of rearrangement product, the values of k_1, the derived activation parameters, the migration tendency of the ligands on boron in mixed azides L_2BN_3[1], and the stabilizing influence of Lewis bases allow the following conclusions to be drawn: Boron azides are the more unstable the more electrons are withdrawn from the azide group and the stronger the anchimeric assistance by the migrating ligands during the elimination of nitrogen; the neighboring-group effect becomes weaker with increasing strength of the boron-ligand bond.

[1] *P. I. Paetzold*, Angew. Chem. *7b*, 598 (1964).

69

Carbonato Compounds of Praseodymium(IV) and Terbium(IV)

Sw. Pajakoff, Wien (Austria)

In the thermal decomposition of praseodymium(III) and terbium(III) carbonates in an oxygen atmosphere at 250 to 350 °C, carbonates and oxide carbonates of the quadrivalent metals are formed, which decompose further at higher temperatures:

$$Pr_2(CO_3)_3{\cdot}2\ H_2O \xrightarrow{250-275\,^\circ C} \underset{\text{light green}}{Pr_2(CO_3)_3} \xrightarrow{280-300\,^\circ C} \underset{\text{yellow}}{Pr_2(CO_3)_4}$$

$$\xrightarrow{300-320\,^\circ C} \underset{\text{yellow-brown}}{Pr_2O_4{\cdot}CO_2} \xrightarrow{320-350\,^\circ C} \underset{\text{yellow-brown}}{Pr_2O_4{\cdot}0.5\ CO_2} \xrightarrow{350-380\,^\circ C}$$

$$\underset{\text{brown-yellow}}{Pr_2O_4{\cdot}0{,}5\ CO_2Pr_2O_4} \xrightarrow{380-400\,^\circ C} \underset{\text{light brown}}{Pr_2O_4} \xrightarrow{420-450\,^\circ C} \underset{\text{dark brown}}{Pr_6O_{11}}$$

$$Tb_2(CO_3)_3{\cdot}2\ H_2O\ 250\,^\circ C \xrightarrow{250\,^\circ C} \underset{\text{white}}{Tb_2(CO_3)_3} \xrightarrow{280-300\,^\circ C}$$

$$\underset{\text{yellowish white}}{Tb_2(CO_3)_4} \xrightarrow{300-350\,^\circ C} Tb_2O_4{\cdot}0.5\ CO_2 \xrightarrow{350-400\,^\circ C} \underset{\text{light brown}}{Tb_2O_4}$$

$$\xrightarrow{400-450\,^\circ C} \underset{\text{brown}}{Tb_6O_{11}} \xrightarrow{450-600\,^\circ C} \underset{\text{dark brown}}{Tb_4O_7}$$

In the oxidation of the oxides and hydroxides of praseodymium and terbium in alkali carbonate solutions (>2.5 M K_2CO_3) with ozonized oxygen, hydrogen peroxide, or alkali peroxymonosulfate, yellow, water-soluble carbonato complexes of the quadrivalent metals are formed. From these complexes the following compounds were synthesized:

$K_4[Pr(CO_3)_4]{\cdot}4H_2O$	yellowish-white
$K_6[Pr(CO_3)_5]{\cdot}2H_2O$	light yellow
$K_6[Tb(CO_3)_5]{\cdot}4H_2O$	yellowish-white
$Ba_3[Pr(CO_3)_5]{\cdot}3H_2O$	light yellow
$Ba_3[Tb(CO_3)_5]{\cdot}2H_2O$	yellowish-white

From these compounds new complexes with mixed ligands were prepared:

[Pr-carbonato-oxalato]
[Pr-carbonato-fluoro]
[Pr-carbonato-hydroxo]
[Tb-carbonato-fluoro]
[Tb-carbonato-hydroxo]

The carbonates and oxide carbonates of praseodymium(IV) and terbium(IV) behave differently towards complex-forming aminopolycarboxylic acids and hydroxycarboxylic acids than do carbonates of the tervalent rare earths. This effect can be used to separate praseodymium and terbium from the neighboring rare earths.

70

Action of Hexamethylenetetramine on the Catheptic Endo- and Exopeptidases of Fish Tissues

A. Purr, München (Germany)

Hexamethylenetetramine inhibits the plant endopeptidase papain. Optimum inhibition occurs between pH 4.5 and 5.5. The inhibition is probably due to a reaction of the SH groups of the enzyme with formaldehyde, formed from hexamethylenetetramine in weakly acidic media.

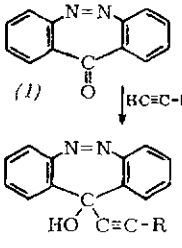
The pH optimum for the inhibition of the catheptic endo- and exopeptidases of fish tissues (*e.g.* carp liver) by hexamethylenetetramine is 4.0, but inhibition is still strong at pH 5.5. Experiments with physiologically harmless substitutes for hexamethylenetetramine show that the peptidases are inhibited particularly by glyoxylic acid, methyl glyoxal, and sorbic acid. The activity of the substances decreases in the sequence glyoxylic acid > methyl glyoxal > formaldehyde > hexamethylenetetramine > sorbic acid.

71

Reactions of Dibenzo[c,f]-1,2-diazepin-11-one

W. Ried and *St. Piesch*, Frankfurt/Main (Germany)

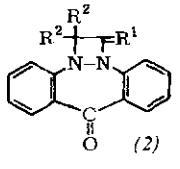
The compound *(1)* [1] undergoes none of the usual carbonyl reactions and does not react with Grignard reagents. It reacts with acetylene in liquid ammonia and with monosubstituted alkynes in dioxanes at 80 °C to give the corresponding ethynols in good yields. Alkynols do not react with *(1)*.



(1)

R = H, $-CH_2N(CH_3)_2$, C_6H_5

The azo chromophore fixed in the *cis*-position in *(1)* reacts with ketenes to *(2)*.

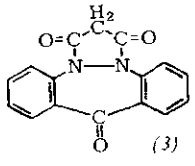


(2)

R^1 = O, N-$C_6H_4CH_3$
R^2 = H, CH_3, C_6H_5

The reaction goes best with diphenylketene, less well with dimethylketene, and in poor yields with unsubstituted ketene. A smooth reaction is also obtained with *p*-tolyldiphenylketenimine.

The azo group in *(1)* can be hydrogenated to the hydrazo group with weakly active Raney nickel. The product reacts with malonoyl chloride to *(3)*, a deep violet substance which gives purple solutions in chloroform and methylene dichloride and blue solutions in acetone and methanol. Addition of ammonia to solutions in acetone or methanol changes the color to orange.



(3)

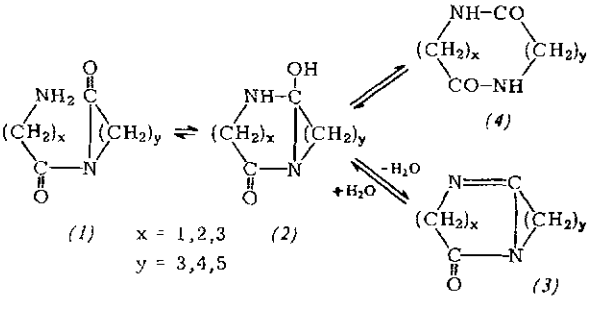
72

Syntheses of Cycloamides and Cyclopeptides with Medium-Sized Rings

M. Rothe, *K.-D. Steffen*, and *J. Rothe*, Mainz (Germany)

N-(Aminoacyl)lactams *(1)* and *N*-(aminoacyl)cyclopeptides cyclize to various products, depending on the length of their side group and the ring size. If a 5-, 6-, or 7-membered ring can be formed, cyclols *(2)* occur as intermediates. α-Aminoacyl-*(1)*, x = 1, and *o*-aminoaroyl-lactams give bicyclic amidines *(3)*; glycyl- and anthranoylcaprolactam give *e.g.* 5-oxopentamethylenimidazoline *(3)*, x = 1, y = 5, and 6-oxopentamethylenedihydroquinazoline, respectively. β-Aminoacyl-lactams *(1)*, x = 2[1] and -cyclopeptides are converted by aminoacyl insertion into macrocyclic peptides *(4)*; after introduction of two β-alanyl groups into the cyclodipeptide of β-alanine and rearrangement, the cyclotetrapeptide is formed. γ-Aminoacyl-lactams *(1)*, x = 3, cyclize by reaction of the free amino group with the carbonyl group in the ring or in the side chain. Medium-sized rings are thus accessible without recourse to the dilution principle, *e.g.* the ten-membered cyclodi-γ-aminobutyryl *(4)*, x = y = 3. δ- and ε-aminoacyl-lactams *(1)*, x = 4 or 5, eliminate the side chain; in compounds with longer aminoacyl groups, polycondensation or, in dilute solution, ring closure occurs.



(1) x = 1,2,3 y = 3,4,5 *(2)* *(4)* *(3)*

The aminoacyl group can be introduced by acylation of free or trimethylsilylated lactams and cyclopeptides with *N*-protected amino-acid chlorides or by lactam formation from activated *N*-protected dipeptides with C-terminal γ- or δ-amino acids.

Diglycylsarcosine dimerizes to cyclo(diglycylsarcosyldiglycylsarcosyl) (decomp. > 350 °C).

73

New Enzymatic Baking Agents

A. Rotsch, Detmold (Germany)

Malt baking agents increase the sugar content of the dough by degradation of the starch, accelerate fermentation, increase the volume of the baked product, and improve color, crust, storage properties, and taste of the products. Fungus amylases have also been used as baking agents. They improve mainly the crumb consistency and usually increase the volume. Doughs treated with these do not tend to relax or to become sticky, and can be readily handled by machines.

Proteolytic enzyme preparations degrade the gluten of excessively strong, gluten-rich flour and can be used particu-

larly in the production of baker's ware for diabetics and sometimes of hard biscuits and crackers. They sometimes have adverse effects, however, when accompanying some malt baking agents in the processing of weak German wheat flour.

After the importance of the cereal gums (water-soluble pentosans) consisting mainly of arabinose and xylose to the rheological behavior of doughs and for the adjustment of the water content in dough and bread had been recognised, pentosanase-containing preparations were developed, which allow the controlled degradation of the gums during fermentation and in the first stage of baking, and effect improved loosening, better crumb consistency, and volume increase. The results obtained with such a pentosanase from *Aspergillus oryzae* in wheat bread and other baked goods show it to be valuable particularly in the processing of rye doughs. The preparation was free from protein- or starch-degrading enzymes.

74

Electrochemical and Direct Fluorination of Substituted Hydrocarbons

P. Sartori, K. P. Ehlers, and *G. Steiner*, Aachen (Germany)

Hydrocarbons can be perfluorinated by the action of elementary fluorine directly or *via* fluorides of metals in high oxidation states, or by electrolysis in anhydrous hydrogen fluoride.

In carboxylic acids and carbonyl fluorides, the carbonyl group impedes substitution of neighboring H atoms to such an extent that the action of fluorine causes almost quantitative chain cleavage to COF_2 and partly and fully fluorinated alkanes, formed by radical recombination.

Chloroalkanes, particularly 1,2-dichloropropane, can be converted into chloroperfluoroalkanes by fluorine in the gas phase. The occurrence of more highly chlorinated products indicates intermediate elimination and readdition of chlorine.

The success of electrochemical fluorination depends decisively on the solubility or the fineness of the dispersion of the starting material in hydrogen fluoride. Thus gaseous alkanes can be perfluorinated by bubbling them through the electrolyte. The carbonyl group in acid fluorides imparts sufficient solubility in HF for a perfluorination with good yield.

Chloroalkanes are poorly soluble in hydrogen fluoride. Electrochemical fluorination in suspension leads to a number of only partially fluorinated compounds, since these are carried out of the mixture by the electrolysis gases before fluorination is complete. The chloro-substituent is retained.

75

Optical Induction in Six-Membered Cycloadditions

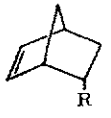
J. Sauer and *J. Kredel*, München (Germany)

The optical induction occuring in six-membered cycloadditions was studied using cyclopentadiene *(1)*, (−)-menthyl acrylate *(2)*, and (−)-menthyl fumarate *(3)*. In various solvents (triethylamine, dioxane, 1,2-dimethoxyethane, acetone, methylene chloride, methanol) *(1)* and *(2)* react to give mixtures of the isomeric Diels-Alder adducts *(4a)* and *(5a)*, which are reduced by $LiAlH_4$ to *(4b)* and *(5b)*, respectively. The ratio *(4a)*:*(5a)* depends on the solvent (Berson scale). Decreasing temperature and increasing polarity of the solvent favor the formation of *(4a)*. At −70 °C, in the presence of catalytic amounts of $AlCl_3{\cdot}O(C_2H_5)_2$ in methylene chloride, practically pure *(4a)* or *(4c)*, respectively, are formed in high yields from *(1)* and *(2)* or from *(1)* and methyl acrylate together with 1 % of the exo-isomers *(5a)* or *(5c)*[1].

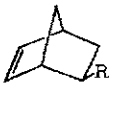
[1] Other Lewis acids, *e.g.* $BF_3{\cdot}O(C_2H_5)_2$, $SnCl_4$, and $TiCl_4$, behave similarly.

Compounds *(4b)* and *(5b)* are obtained in about 8 % and 3–7 % optical purity, respectively, the latter yield depending on the solvent. With decreasing temperature and in the presence of $AlCl_3{\cdot}O(C_2H_5)_2$ the optical yield of *(4b)* increases to about 70 %; the amount of the catalyst has no influence on the degree of optical induction. On reduction, (+)-*(4b)* and (+)-*(5b)* were always obtained; assignments of absolute configurations could be made.

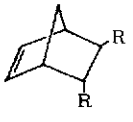
In the system *(1)* + *(3)* the sign of the rotation of the diol *(6b)* obtained by reduction of *(6a)* depends on the solvent in which the diene addition is carried out. In methylene chloride the laevorotatory form of *(6b)* is obtained; in acetone, dioxane, and in methylene chloride in the presence of $AlCl_3{\cdot}O(C_2H_5)_2$ the dextrorotatory enantiomer is obtained. The induction is less marked than for the reaction of *(1)* with *(2)*; it reaches a value of 45 % at −70 °C in methylene chloride [1 equiv. of catalyst]. Chemical determination of the absolute configurations of the pure enantiomers of *(6c)*, obtained by resolution of the racemate, and of the derived pure optically active compounds *(6b)*, *(6d)*, *(7a)*, and *(7c)* was not possible[2].



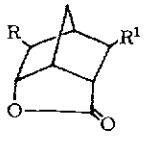
(4a): R = CO_2-Menthyl
(b): R = CH_2OH
(c): R = CO_2CH_3
(d): R = CO_2H



(5a): R = CO_2-Menthyl
(b): R = CH_2OH
(c): R = CO_2CH_3



(6a): R = CO_2-Menthyl
(b): R = CH_2OH
(c): R = CO_2H
(d): R = CO_2CH_3



(7a): R = I; R^1 = CO_2H
(b): R = I; R^1 = CO_3-t-C_4H_9
(c): R = H; R^1 = CO_2H

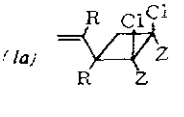
[2] *Note added in proof;* The laevorotatory forms of *(6c)* and *(4d)* have the same configuration.

76

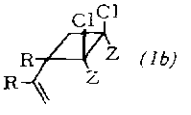
Chemistry and Stereochemistry of the Photocycloadducts of Dichloromaleic Imide and Anhydride with Acyclic 1,3-Dienes

H.-D. Scharf and *F. Korte*, Birlinghoven (Germany)

Dichloromaleimide and dichloromaleic anhydride undergo a Diels-Alder reaction when heated with 1,3-dienes to give derivatives of 1,2-dichloro-1,2,3,6-tetrahydrophthalic acid. Under UV-illumination the same reagents undergo exclusively 1,2-cycloaddition to derivatives of 3-alkenyl-1,2-dichlorocyclobutane-1,2-dicarboxylic acid, *(1a)* and *(1b)*.



(1a)



(1b)

R = H, CH_3 Z = CO_2R

Z-Z = CO-O-CO, CO-NH-CO

In the dehalogenation or *(1a)* or *(1b)*, Z = CO_2CH_3, with Ni $(CO)_4$ in C_6H_6/DMF at 80 °C, the corresponding dimethyl 3-alkenylcyclobutene-1,2-dicarboxylates or (by thermolysis)

the dimethyl 1,3,5-hexatriene-2,3-dicarboxylates would be expected to be formed. Instead, a rearrangement to 4,5-disubstituted 1,4-cyclohexadiene-1,2-dicarboxylates is observed.

This novel formation of Diels-Alder products by rearrangement can also be extented to the photocycloadducts of cyclic 1,3-dienes.

77

Mechanism of C-Nitrosation of Phenol in Various Solvents

Hermann Schmid, *G. Muhr*, and *P. Riedl*, Vienna (Austria)

The initial rate of *C*-nitrosation of phenol by nitrous acid in aqueous solution to *p*-nitrosophenol was determined by stopping the reaction with sodium hydroxide and photometric determination of *p*-nitrosophenol in the resulting solution. The rate equation (at constant ionic strength) is

$$\text{rate} = k[C_6H_5OH][HNO_2]$$

At constant ionic strength the rate is independent of hydrogen-ion concentration in the range 10^{-5}–0.5 mole/l; log k is proportional to the ionic strength.

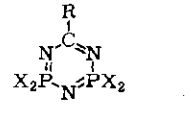
Addition of methanol decreases the rate owing to removal of nitrous acid by the formation of methyl nitrite. This effect was used to determine the position of the methyl nitrite equilibrium. The free energy, entropy, and enthalpy of the *C*-nitrosation in aqueous solution were determined and suggest the following activation process: Phenol, which in the ground state already has a high electron density at the *o*- and *p*-positions, polarizes the nitrous acid, whereby the positive nitrosyl ion adds to the negative carbon atom of the benzene ring. The rearrangement of the activated complex to nitrosophenol takes place by proton shift from the C-atom with the nitroso group to the hydroxide ion.

The nitrosation of phenol by nitrous acid in 70 % sulfuric acid, in which phenol is not oxidized or sulfonated, was followed directly by photometry. Here the nitrite acidium ion acts as the nitrosating agent.

78

Cyclophosphazenes Containing Carbon: Derivatives of a New Heterocyclic System

A. Schmidpeter and *R. Böhm*, München (Germany)



(1a), R = $(CH_3)_2N$, X = C_6H_5

(1b), R = C_6H_5, X = Cl

2,2,4,4-Tetraphenyl-6-dimethylamino-2,4-diphospha-1,3,5-triazine *(1a)* is formed in good yield by cyclocondensation of *N,N*-dimethylguanidine with tetraphenylimidodiphosphinyl trichloride:

$$4\ (CH_3)_2NC(NH)NH_2 + \{N[C_6H_5)_2PCl]_2\}Cl \rightarrow 3[(CH_3)_2NC(NH_2)_2]Cl + \textit{(1a)}$$

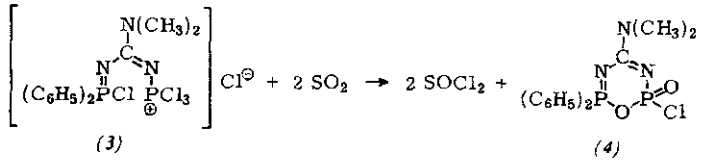
P-chlorinated derivatives *(1b)* are accessible *via* condensation products *(2)* of an amidinium hexachloroantimonate and PCl_5[1].

$$[C_6H_5C(NPCl_3)_2]SbCl_6 + 2\ NH_4Cl \rightarrow 4\ HCl + NH_4SbCl_6 + \textit{(1b)}$$
(2)

[1] *A. Schmidpeter*, *K. Düll*, and *R. Böhm*, Angew. Chem. *76*, 605 (1964).

Compound *(1b)* resembles $(NPCl_2)_3$ in its properties; at 255 °C it polymerizes with elimination of benzonitrile.

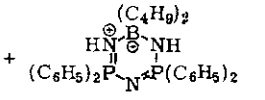
The unexpected reaction of *(3)* with *two* moles of SO_2 can be explained by the formation of the oxygen-containing heterocycle *(4)*.



(3) *(4)*

The transamination of dibutylboramide with tetraphenylimidodiphosphinyl diimide is an example for a ring closure which leads to a "hetero"-cyclophosphazene and which does

$$(C_4H_9)_2BNH_2 + H_2N\text{-}(C_6H_5)_2P{=}N\text{-}(C_6H_5)_2P{=}NH \rightarrow NH_3 +$$



(5)

not occur directly at a phosphorus atom. It yields the borophosphazadiene *(5)*, the ring structure of which is shown by its ^{31}P-NMR spectrum.

79

Exchange Reactions in Solid Co, Rh, and Ir Complexes Initiated Thermally and by the ^{80m}Br Nuclear Transition

G. B. Schmidt, *W. Herr*, and *K. Rössler*, Köln (Germany)

Whereas "activated" exchange reactions occur in crystalline rhodium and iridium pentamminebromo halides as a consequence of the ^{80m}Br nuclear-isomeric transition[1], the thermal exchange of Br atoms in these complex salts is very slow even at 210 °C (about 8 % exchange in 24 hours in $[Rh(NH_3)_5Br]Br_2$). By contrast, there is a rapid exchange of covalent for ionic halogen in solid *cis*- and *trans* $[Co(en)_2Cl_2]Cl$ and *trans*-$[Co(en)_2Br_2]Br$ labelled with ^{36}Cl and ^{82}Br, respectively, between 100 and 170 °C, as well as in solid *trans*-$[Rh(en)_2Cl_2]Cl$ between 170 and 300 °C. The exchange rates in the three cohalt complexes studied were almost the same, *e.g.* $t_{1/2} \approx 4$ h at 150 °C. For *trans*-$[Rh(en)_2Cl_2]Cl$, $t_{1/2} = 13$ h at 250 °C. The activation energies for these exchange reactions were found to be 30 to 34 kcal/mole.

Previous irradiation with ^{60}Co γ-rays or with X-rays does not noticeably affect the exchange rate in *trans*-$[Rh(en)_2Cl_2]Cl$, whereas the rate of exchange of the corresponding cobalt complex increases markedly with the radiation dose: thus $t_{1/2}$ at 150 °C decreases after irradiation with 150 kV X-rays (2×10^4 to 1×10^6 R) to 60 and 6 min, respectively, from 220 min for the unirradiated compound. X-rays are about ten times more effective than γ-rays. The exchange presumably occurs according to a jump mechanism involving lattice defects.

[1] *G. B. Schmidt* and *W. Herr*, Z. Naturforsch. *18a*, 505 (1963).

80

Basic Salts of Bivalent Tin

H. G. Schnering and *H. Pelshenke*, Münster (Germany)

Precipitations from heterogeneous and from homogeneous solution, determinations of halogen[1] and tin, and chemical and X-ray characterization show that the following compounds exist:

$Sn_9Cl_4O_7 = 2SnCl_2 \cdot 7SnO$ *(1)*: pale yellow microcrystalline; isotypic with *(3)*; the compound is the primary hydrolysis product from $SnCl_2$ solutions; when kept in solution it changes completely into compound *(2)*, which regenerates *(1)* when heated at 230 °C (in vacuum); at 525 °C compound *(1)* decomposes endothermally into SnO and $SnCl_2$.

$Sn_4Cl_3(OH)_3O = 3Sn(OH)Cl \cdot SnO$ *(2)*: colorless hexagonal plates; sensitive to light when moist; this is probably the only basic chloro-compound of bivalent tin that is stable in acidic solution; at 230 °C it decomposes endothermally into $SnCl_2$ and *(1)*. Crystals of $Sn_4Cl_3(OH)_3O$ are hexagonal-rhombohedral with a = 10·032 Å and c = 44·092 Å, belonging to space group D_{3d}^5; determination of the complicated structure is not yet complete.

$Sn_9Br_4O_7$ *(3)*: yellow, mostly microcrystalline but also forms six-sided platelets; compounds *(3)* and *(1)* are isotypic and are strongly disordered in some directions; according to a single-crystal photograph, compound *(3)* may be hexagonal, with a = 9·2$_3$ and c = n × 9·55 Å, where the value of n is uncertain.

Attempts to prepare a bromo-compound analogous to *(2)* failed.

[1] Cf. *H. Schäfer* and *K. D. Dohmann*, Z. anorg. allg. Chem. *300*, 1 (1959).

81

Synthesis and Properties of some New Phenyltinarsines, Stibines, and Bismuthines

Herbert Schumann and *Max Schmidt*, Marburg (Germany)

Organotin chlorides or $SnCl_4$ react with sodium diphenylarsine, -stibine, or -bismuthine in liquid ammonia to phenyltinarsines, -stibines, and -bismuthines, which can be crystallized from benzene after removal of the ammonia:

$$(C_6H_5)_nSnCl_{4-n} + 4\text{-}n\ NaX(C_6H_5)_2 \rightarrow (C_6H_5)_nSn[X(C_6H_5)_2]_{4-n} + 4-n\ NaCl$$

X = As, Sb, Bi
n = 0–4

From triphenylstannyl-lithium and phenylchloroarsines, -stibines, and -bismuthines, or with $AsCl_3$, $SbCl_3$, and $BiCl_3$ in tetrahydrofuran, the compounds

$[(C_6H_5)_3Sn]_3X$, $[(C_6H_5)_3Sn]_2XC_6H_5$, and $(C_6H_5)_3SnX(C_6H_5)_2$, X = As, Sb, Bi,

are obtained in pure form after separation from precipitated lithium chloride.

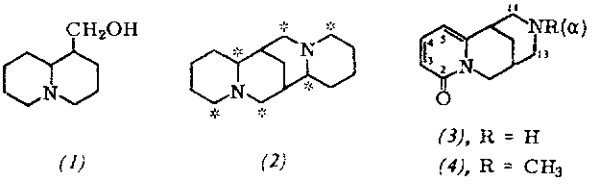
The analogous germanium and lead derivatives are obtained by starting from organogermanium and organolead compounds. Most of the new compounds are very sensitive to air and moisture and are immediately oxidized in air to esters of arsinic acids or to polymers containing Sn–O–Sb or Sn-O-Bi linkages, respectively.

82

Biosynthesis of Lupine Alkaloids

H. R. Schütte, Halle/Saale (Germany)

The lupine alkaloids lupinine and sparteine, as well as the oxygen-containing derivatives of the latter, are formed from two and three molecules of lysine, respectively, *via* cadaverine. The latter, which had previously not been detected in the plant, could be determined by reverse dilution analysis in *Lupinus luteus* after feeding of [2-^{14}C]lysine. We sought the source of the nitrogen in the biosynthesis of lupine alkaloids in *Lupinus luteus* by feeding of [2-^{14}C, ^{15}N]lysine. In the sparteine isolated, the ratio $^{14}C:^{15}N$ was about three times greater than in the lysine used. This is expected if a symmetrical intermediate is assumed, *e.g.* cadaverine, in which the α-nitrogen of lysine is uniformly distributed, and if one takes into account that there are then 6 radioactive carbon atoms [asterisks in formula *(2)*] to two nitrogen atoms. This finding supports previous results that lysine is incorporated into sparteine *via* the symmetrical intermediate cadaverine.



(1) *(2)* *(3)*, R = H *(4)*, R = CH_3

[2-^{14}C]Lysine and [1,5-$^{14}C_2$]cadaverine are incorporated in cytisine *(3)* by *Cytisus laburnum*. Oxidative degradation showed that 20 % of the total radioactivity occurs at C-2, and that C-3, C-4, and C-5 are not radioactive. The radioactivity at C-13 is decisive. In the synthesis of *(3)* from a lupinine-like precursor, this atom should not be radioactive, whereas in biosynthesis by degradation of sparteine *(2)*, 20 % of the radioactivity should be found here also. Oxidation gave a mixture of two isomeric cytisamides, in which the C-atoms 11 and 13 had been converted into carbonyl groups. This mixture was separated. Reaction with phenyl-lithium and subsequent oxidation led to elimination of the carbon atoms 11 and 13 which each contained 20 % of the radioactivity of the original alkaloid.

Labelled cytisine was also obtained by feeding sparteine. The methyl group of methylcytisine *(4)* does not become radioactive after feeding of sparteine or of cadaverine and lysine. This group is therefore introduced subsequently by methylation.

83

Infrared Studies on Hydroxides

E. Schwarzmann, Göttingen (Germany)

In hydroxides containing no hydrogen bonds, the OH stretching vibration occurs in the range 3700–3600 cm^{-1}, and the OH torsional vibration between 300 and 500 cm^{-1}. Hydrogen bonding gives rise to a decrease of the stretching frequency with increasing strength of the bond (*i.e.* decreasing O(H)···O distance) and to an increase in the torsional frequency (provided the bond is linear). A multiplicity of OH bands in the infrared spectrum is therefore often due to hydrogen bonds of various lengths.

Coupling of OH stretching vibrations with each other can also cause a splitting of bands. The same applies to torsional vibrations. Thus the splitting of OH stretching and torsional bands of partially deuterated hydroxides containing a single type of OH^- ion (*i.e.* one hydrogen bond length only) decreases with increasing degree of deuteration and often the bands coalesce to a single band with decreasing coupling. In some hydroxides with very short hydrogen bonds [*e.g.* InO(OH), γ-MnO(OH)], a multiplicity of OH stretching bands is observed, with a splitting of several hundred cm^{-1}, which cannot be explained by vibrational coupling, since it remains in partially deuterated compounds. Resonance effects between neighboring vibrational levels, such as occur in the tunneling motion of a proton in a potential well with a double minimum, and an interaction of the OH stretching vibration with the first overtones of the OH torsional vibration, may be the cause.

84

A Stable Ninhydrin Reagent for Automatic Determination of Amino Acids

E. Schwerdtfeger, Geisenheim/Rheingau (Germany)

In the automatic amino-acid determination according to *Spackmann et al.*[1], difficulty is experienced owing to the sensitivity of the ninhydrin reagent to oxygen and light. These difficulties can be avoided if the partial reduction of ninhydrin is carried out immediately before the color reaction with the amino acids by means of reducing agents added to the eluting buffer. The potassium cyanide first used for this purpose is partly retained by the cation exchange column, so that the color yields of the amino acids first eluted from the column are somtimes too low. The use of ascorbic acid instead of potassium cyanide eliminates these difficulties. The color yields of the reactions with amino acids are constant and correspond to those obtained with the reagent described by *Spackman et al.* The optimum concentration of ascorbic acid in the elution buffer is 0.01–0.02 %. The ninhydrin reagent is a 2 % solution of ninhydrin in a mixture of 37.5 % ethylene glycol, 25.0 % of 4 M acetate buffer (pH 5.5), and 37.5 % of water. It is insensitive to air and diffuse daylight, and forms no insoluble deposits in the tube connections.

85

New Reactions with Trichloromethanesulfenyl Chloride

A. Senning, Aarhus (Denmark)

N-Trichloromethanesulfenyl derivatives can be prepared under mild conditions from amides and CCl_3SCl. For example, in the reaction of benzamide with CCl_3SCl at about 100 °C, 5-phenyl-1,3,4-oxathiazol-2-one is formed (together with benzonitrile), which on pyrolysis decomposes to benzonitrile, CO_2, and sulfur. *N,N',N''*-Trisulfonylguanidines $(RSO_2NH)_2C{=}N{-}SO_2R$ are obtained from sulfonamides and CCl_3SCl. Cyclization attempts with CCl_3SCl and 1,2-diacylhydrazines were unsuccessful. Only the 1,2-bis(trichloromethanesulfenyl)hydrazine derivatives are obtained; the mono-derivatives are accessible from the monopotassium salt of the 1,2-diacylhydrazine.

Depending on the conditions, urotropine and CCl_3SCl give two isomeric 1,3-bis(trichloromethanesulfenyl)hexahydro-1,3,5-triazines. With triethylamine and CCl_3SCl a sequence of substitution and addition-elimination reactions leading to *cis*- or *trans*-1-diethylamino-1,2-bis(trichloromethylthio)-ethylene is observed.

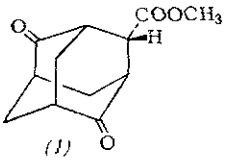
N-(Trichloromethanesulfenyl)ketimines can be prepared by treating the magnesium salt of the ketimine (obtained by addition of a Grignard reagent to a nitrile) with CCl_3SCl. Sulfenimines $(RS)_2NH$ can be substituted with CCl_3SCl and other sulfenyl chlorides to give esters of trithioorthonitrous acid $N(SH)_3$. Nucleophilic substitution of metal acetylacetonates with CCl_3SCl leads to the corresponding fully substituted trichloromethylthioacetylacetonates.

86

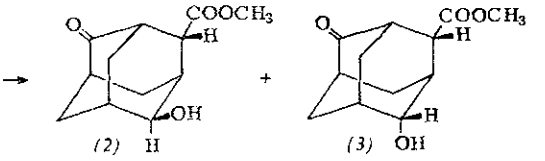
Synthesis of the Two Stereoisomeric β-Adamantanonecarboxylic Acids

G. Snatzke and *D. Marquarding*, Bonn (Germany)

Methyl adamantane-4,8-dione-2-carboxylate *(1)* can be reduced with $NaBH_4$ in isopropanol to two of the four possible hydroxyketo esters.

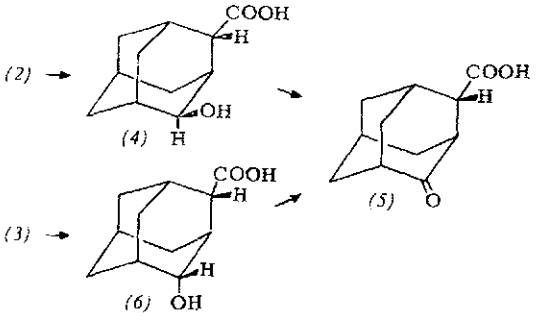


(1)



(2) *(3)*

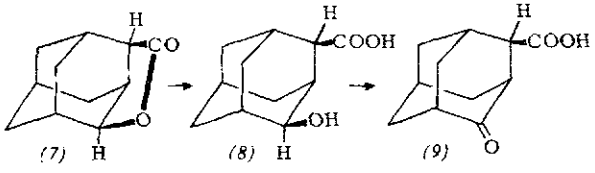
Only the keto group to which the ester group is equatorial is attacked on reduction, since the Clemmensen reduction of the keto group and oxidation of the hydroxy group in *(2)* and *(3)* gives the same β-adamantonecarboxylic acid *(5)*.



(4) *(5)* *(6)*

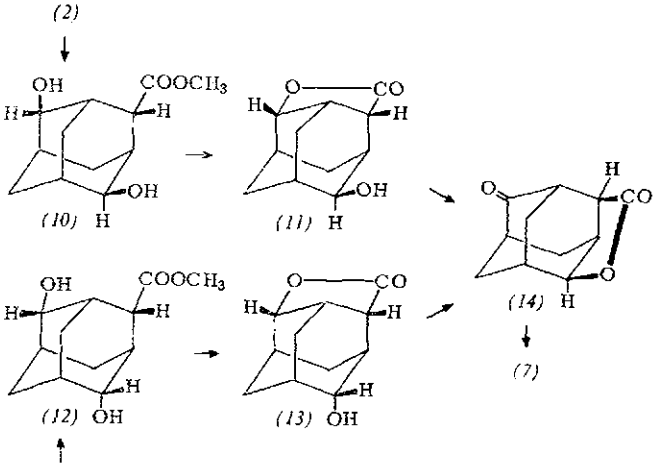
In the ester *(2)* the OH group and the α-hydrogen to the ester group are arranged 1,3-diaxially [as in the compounds *(4)*, *(10)*, and *(11)*], as the low chemical shift of the proton at C-2 in the NMR spectrum shows.

The second β-adamantonecarboxylic acid was prepared *via* the lactone *(7)*, which is formed in 20 % yield in the Clemmensen reduction of *(1)*.



(7) *(8)* *(9)*

Substantially better yields of *(7)* are obtained if the ester *(2)* or *(3)* is reduced in methanol with $NaBH_4$ to *(10)* or *(12)*, respectively. Both compounds form a lactone which can be converted into *(7)* *via* *(14)*.



(10) *(11)* *(12)* *(13)* *(14)*

The esters *(10)* and *(12)* are also obtained directly from *(1)* by reducing the latter in methanol with an excess of $NaBH_4$.

87

Surface Reactions of Gases with Semiconductors

M. J. Sparnaay, Eindhoven (Holland)

Gas adsorption on semiconductor surfaces often effects a change in the surface charge distribution. Thus the negative charge of a pure germanium surface is increased when oxygen at about 10^{-6} mm pressure is admitted. The negative surface charge is compensated by a positive space charge. The free energy of such electrical double layers can be calculated approximately. It is of the order of 1 kcal/mole and depends on the doping.

Surface structures can be investigated by diffraction of slow electrons, as well as by adsorption methods. Thus *Boonstra* found that at room temperature, one HCl or HBr molecule is adsorbed per two germanium atoms at the surface of a powdered germanium crystal. One molecule of H_2O, H_2Se, and H_2Se is adsorbed per four Ge surface atoms, and one molecule of NH_3 or PH_3 per six Ge atoms. Above 100 °C the adsorbed molecules react fairly rapidly with the Ge atoms.

88

Isomerization of Thionophosphates

H. Teichmann, Berlin (Germany)

When trialkyl thionophosphates are heated for several hours at 130 °C or higher they are converted *via* the isomeric trialkyl thiolophosphates into mixtures of sulfur-free trialkyl phosphates, esters of condensed phosphoric acids, their sulfonium salts, and dialkyl sulfides.

The first stage, *viz.* the autocatalytic isomerization of the thionophosphates, is an intermolecular $O \rightarrow S$ transalkylation. From an equimolar mixture of trimethyl and triethyl thionophosphate, the mixed thiol esters $(CH_3O)_2PO(SC_2H_5)$ and $(C_2H_5O)_2PO(SCH_3)$ are formed concurrently with the isomers $(CH_3O)_2PO(SCH_3)$ and $(C_2H_5O)_2PO(SCH_3)$; ligand exchange at the phosphorus atom of the thiolophosphates does not occur under the conditions used. Trimethyl and triethyl thionophosphate decompose about equally fast at 130 °C over *ca.* 70 h, as shown by gas chromatographic analysis; the concentration ratio during this time remains at about 1 $(C_2H_5O)_2PO(SCH_3)$: 0.5 $(CH_3O)_2PO(SCH_3)$: 0.25 $(CH_3O)_2PO(SC_2H_5)$:0.25 $(C_2H_5O)_2PO(SC_2H_5)$. This shows that thiolophosphates participate from the start in the alkylation of the thiono sulfur, preferably the methoxy-containing esters, corresponding to their higher alkylating power.

Methyl diphenyl thionophosphate, in contrast to the trimethyl analogue, is practically stable at 130 °C, although it is a considerably stronger methylating agent. This stability is due to the lack of alkylating properties in the isomeric $(C_6H_5O)_2PO(SCH_3)$; addition of $(CH_3O)_2PO(SCH_3)$ initiates a rapid decrease in thiono sulfur content in methyl diphenyl and trimethyl thionophosphates.

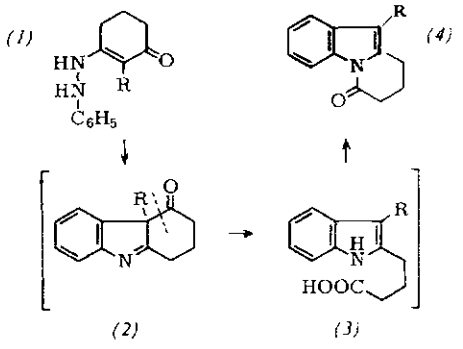
The transformation of trialkyl thionophosphates to their (even less thermostable) thiol isomers, usually described as "isomerization", should be interpreted as a special case of the Pishchimuka reaction, *i.e.* the reaction of thionophosphates with alkylating agents *via* quasi-phosphonium intermediates to thiolophosphates.

89

New Rearrangements in the Indole Series

H.-J. Teuber, Frankfurt/Main (Germany)

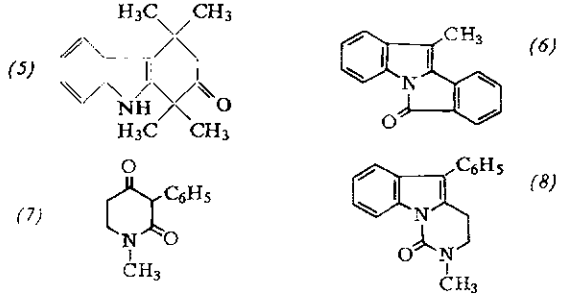
Monophenylhydrazones *(1)* of 2-substituted 1,3-cyclohexanediones, which in accordance with Bredt's rule do not yield pyrazoles, react in the Fischer synthesis by way of 1,2,3,4-tetrahydro-4-oxo-4a*H*-carbazoles *(2)* and 3-alkyl-2-indolebutyric acids *(3)* to afford 3-alkyl-3-indolebutyric acid lactams *(4)*; these can be hydrolysed to *(3)* (*D. Cornelius, E. Worbs*). Dihydro-2,5,5-trimethylresorcinol reacts analogously; the 2,2,5,5-tetramethyl derivative, however, gives *(5)*.



(1) *(2)* *(3)* *(4)*

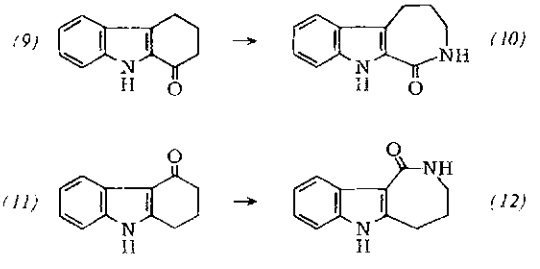
R = CH_3, C_2H_5, C_3H_7, allyl, 2-cyanoethyl, benzyl

2-Methyl-1,3-indanedione affords *(6)*. The β-keto-lactam *(7)* gives *(8)*.



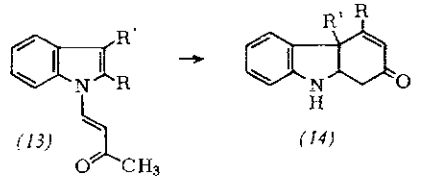
(5) *(6)* *(7)* *(8)*

In the Beckmann or Schmidt rearrangement, tetrahydro-1-, -2-, -3-, or -4-oxocarbazoles[1] afford azepinoindole derivatives [for instance, *(9)* → *(10)*, and *(11)* → *(12)*] (*U. Wölcke*).



(9) *(10)* *(11)* *(12)*

2,3-Disubstituted 1-(3-oxo-2-butenyl)indoles *(13)*[2] are rearranged to *(14)* with opening of the indole ring by methanolic HCl (*U. Reinehr, D. Cornelius*).



(13) *(14)*

R = R' = CH_3

R + R' = $-(CH_2)_4-$

Mechanism of the Reaction of Metal Hexacarbonyls with n- and π-Electron Donors

H. Werner and *R. Prinz*, München (Germany)

The kinetics of the reactions of metal hexacarbonyls of the group VIb elements with n-donors such as amines or phosphines, and with π-donors such as aromatic six-membered rings or oligoolefins were studied spectrophotometrically. The substitutions with n-donors take place according to a two-step dissociation mechanism; in the first, rate-determining step a CO group is eliminated from the hexacarbonyl, and in the second, fast step the resulting pentacarbonyl fragment adds the donor L to form the substituted compound. When polydentate donors (diphosphines, diamines, or triamines) are used, the substitution of further CO groups is also rapid, since the rate constants observed agree very well with those for the reactions of metal hexacarbonyls with monodentate ligands. For the reaction:

$$M(CO)_6 + (C_6H_5)_2PC_2H_4P(C_6H_5)_2 \rightarrow [(C_6H_5)_2PC_2H_4P(C_6H_5)_2]M(CO)_4 + 2\,CO$$

the following activation parameters were obtained: M = Cr: E_a = 38.5 kcal/mole, $\Delta S^{\neq}$ = +17.3 e.u.; M = Mo: E_a = 30.1 kcal/mole, $\Delta S^{\neq}$ = +1.0 e.u.; M = W: E_a = 36.4 kcal/mole, $\Delta S^{\neq}$ = +4.0 e.u.

The reaction of molybdenum hexacarbonyl with π-donors is also first order in $Mo(CO)_6$ and practically independent of the donor concentration. This again suggests a primary dissociation of $Mo(CO)_6$ to $Mo(CO)_5$ and CO. Owing to the low nucleophilicity of the 6-ring aromatic compounds, the reverse reaction

$$Mo(CO)_5 + CO \rightarrow Mo(CO)_6$$

competes in this case with the substitution

$$Mo(CO)_5 + Ar \rightarrow ArMo(CO)_5 \quad (Ar = \text{aromatic compound})$$

so that the rate constants depend on the nature of the aromatic ligand. For example, for the reaction of $Mo(CO)_6$ with benzene at 112 ± 0.2 °C in n-decane/cyclohexane, $k = 1.92 \times 10^{-5}$ sec^{-1}; for the reaction with mesitylene, $k = 2.72 \times 10^{-5}$ sec^{-1} [1].

The rate constant of the reaction with π-donors depends on the initial concentration of $Mo(CO)_6$. With increasing dilution the overall reaction rate increases, which can be explained by the decreasing importance of the reverse reaction, the rate of which depends on the concentrations of $Mo(CO)_5$ and CO. This increase of rate on dilution is evidence against an S_N2 reaction.

[1] *H. Werner* and *R. Prinz*, J. organomet. Chem., in press.

91

The Chemistry of Silyl Azides

N. Wiberg, *K. H. Schmid*, and *Wan-Chul Joo*, München (Germany)

The reactions of silyl azides to be described can be summarized in essence by Equations (a) and (b) (R = methyl, ethyl, n-butyl, phenyl, dimethylamino, methoxy).

$$R_3Si\text{-}\overset{\ominus}{\underset{\cdot\cdot}{N}}\text{-}\overset{\oplus}{N}{\equiv}N: + :X \rightarrow R_3Si\text{-}\overset{\ominus}{\underset{\cdot\cdot}{N}}\text{-}\overset{\oplus}{X} + N_2 \quad (a)$$

$$R_3Si\text{-}N_3 + Y\text{-}Z \rightarrow R_3Si\text{-}Y + Z\text{-}N_3 \quad (b)$$

The elimination of nitrogen [reaction (a)] can be effected either thermally above 300 °C (no group X present) or chemically with trialkylphosphines (X = R_3P) or magnesium salts of organic anions (X = $C_6H_5^{\ominus}$, *o*-, *m*-, or *p*-$CH_3C_6H_4^{\ominus}$, 2,4,6-$(CH_3)_3C_6H_2^{\ominus}$ *etc.*). Thermolysis of silyl azides leads to resin-like, heterogeneous products. *N*-silylphosphazenes are obtained by reaction with phosphines:

$$R'_nSi(N_3)_{4-n} + (4-n)\,R_3P \xrightarrow{100-150\,^\circ C} R'_nSi(NPR_3)_{4-n} + (4-n)\,N_2 \quad (c)$$

The reaction of silyl azides, which are very sensitive to hydrolysis, with Grignard reagents in diethyl ether proceeds by two routes, which yield easily hydrolysable *N*-silyl-*N*-organylmagnesium amide bromide dietherates (d) and tetraalkylsilanes (e).

$$R'_3Si\text{-}N_3 + RMgBr \xrightarrow[C_2H_5OC_2H_5]{100\,^\circ C} \begin{cases} R'_3Si\text{-}N(MgBr)R + N_2 & (d) \\ R'_3Si\text{-}R + MgN_3Br & (e) \end{cases}$$

Reaction (d) is an example of the general reaction (b), *i.e.* replacement of the azide group. This substitution is rapid and quantitative with organic anions as Lewis bases, if they are used as their lithium salts (YZ = RLi), with Brönsted acids (YZ = YH), or according to Eq. (f) with Lewis acids (YZ = Hal–$EHal_n$, E = element).

$$R_3Si\text{-}N_3 + Hal\text{-}EHal_n \rightarrow R_3Si\text{-}Hal + N_3\text{-}EHal_n \quad (f)$$

The following azide-bridged, explosive azide halides were prepared according to reaction (f), among others: $(SbHal_4N_3)_2$ (Hal = F, Cl [1]); $(TiHal_2(N_3)_2)n$ (Hal = Cl, Br); $(BHal_2N_3)_3$ (Hal = Cl, Br) [2]; $SnCl_n(N_3)_{4-n}$ (n = 2,3), and $AlCl_n(N_3)_{3-n}$ (n = 0,1,2).

92

Infrared Spectra of ^{15}N-Labelled Iminophosphoranes

W. Wiegräbe and *H. Bock*, München (Germany)

In the course of investigations of the P=N double bond [1] it proved necessary to make a definite assignment to the P=N stretching frequency, for which conflicting values have been reported. To this end we synthesized the ^{15}N-labelled iminophosphoranes *(1)*–*(3)* by the following method:

$$C_6H_5\text{-}{}^{15}NH_3Br + Br_2P(C_6H_5)_3 \xrightarrow[-3\,HBr]{(C_2H_5)N_3} C_6H_5\text{-}{}^{15}N{=}P(C_6H_5)_3 \quad (1)$$

$$Ts\text{-}{}^{15}NH_2 + Br_2P(C_6H_5)_3 \xrightarrow[-2\,HBr]{(C_2H_5)_3N} Ts{}^{15}N{=}P(C_6H_5)_3 \quad (2)$$

$$Ts\text{-}{}^{15}NH_2 + PCl_5 \xrightarrow[-2\,HCl]{125\,^\circ C} Ts\text{-}{}^{15}N{=}PCl_3 \quad (3)$$

(Ts = *p*-toluenesulfonyl)

The spectra were measured in the range 5000–400 cm^{-1} and complete assignments could be made. P=N stretching bands occur at 1344 *(1)*, 1147 *(2)*, and 1199 *(3)* cm^{-1}. They are easily identified by isotope shifts of 15–20 cm^{-1}. The S–N stretching frequency with Δν = 4–6 cm^{-1}, is found at 784 *(2)* and 762 *(3)* cm^{-1}, compared to 902 cm^{-1} in tosyl amide, which was also studied.

The P=N double bond is reinforced by substituents with (–I) effect at the phosphorus and with (–M) effect at the nitrogen.

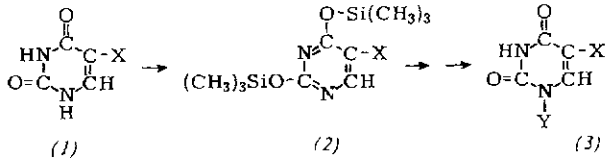
93

Synthesis of Pyrimidine Nucleosides via Silyl Derivatives

E. Wittenberg, Rostock (Germany)

In the reaction of uracil or of its 5-X derivatives *(1)* with hexamethyldisilazane, the bistrimethylsilyl compounds *(2)* are formed quantitatively. Their structures were proved by their ultraviolet and infrared spectra.



(1) *(2)* *(3)*

X = H, CH_3, F, Cl, Br, I, $-CH_2OCH_2C_6H_5$

Y = CH_3, glucopyranosyl, galactopyranosyl, arabinopyranosyl, ribofuranosyl, deoxyribofuranosyl.

The compounds *(2)* react with methyl iodide in benzene in the presence of $AgClO_4$ almost exclusively to *N*(1)-methylpyrimidines *(3)*. In the reaction of *(2)* with acylated halogenosugars (glucopyranose, arabinopyranose, galactopyranose, ribofuranose, 2-deoxyribofuranose), acylated trimethylsilylnucleosides are formed, which are hydrolysed to the acylated nucleosides. The free nucleosides are obtained, usually in good yields, by removing the acyl group with sodium methoxide or ammonia.

94

Formation of Nitrite from Nitrate in Vegetables

W. Wodsak, Hamburg (Germany)

Some vegetables, *e.g.* spinach, are rich in nitrate. The nitrate content depends *inter alia* on nature and amount of fertilizer employed. If there is a deficiency of molybdenum and manganese in the soil, insufficient nitrate reductase is formed; the degradation of nitrate is then inhibited. Manganese favors the formation of vitamin C, which promotes the degradation of nitrate to amino compounds.

Nitrate is harmless even to infants. Nitrite, however, is strongly toxic. It oxidizes hemoglobin to methemoglobin, which cannot transport oxygen. Nitrite is practically never formed in the organism of adults, since the nitrate is absorbed before it can be reduced by the intestinal flora. In the infant dyspepsia which is accompanied by proliferation of the flora of the lower intestinal regions can lead to the reduction of nitrate before it is absorbed.

In fresh spinach, unfavorable storage conditions (dense packing, lack of oxygen) can lead to the formation of up to 40 mg NO_2/100 g. The nitrite content of deep-frozen spinach immediately after thawing is seldom above 1 mg/100 g, provided it is properly prepared. The same applies to tinned spinach. In spinach sold in glass containers as baby food, nitrite was never detected. The nitrite content of spinach which has been prepared for eating may however increase considerably on storage, especially in originally deep-frozen spinach because of the high bacterial count. Up to 15 mg NO_2/100 g were found after 24 h at 20 °C, but very little if the sample had been sterilized.

95

Stereospecific Retention in Nuclear Reactions on cis/trans-Isomeric Cobalt Complexes

G. K. Wolf, Heidelberg (Germany)

Zuber, Rauscher, et al. found some years ago that, after capture of thermal neutrons by isomeric cobalt complexes, retention and subsequent thermal healing are stereospecific, *i.e.* if the neutron-activated atoms recombine with the same ligands after the nuclear reaction, the complexes always have the original configuration.

To elucidate this phenomenon in *cis*- and *trans*-[Co(ethylenediamine)$_2$Cl$_2$]NO$_3$, recoil atoms with different recoil energies were generated by carrying out nuclear reaction with thermal neutrons (0.025 eV) up to 45 MeV neutrons.

The proportion of radioactive cobalt occurring as *trans*-[Co(ethylenediamine)$_2$Cl$_2$]$^{\oplus}$ in the irradiated target material was determined by precipitation as the perchlorate, the *cis*-isomer by precipitation as the nitrate, and Co^{2+} by extraction with 8-hydroxyquinoline in chloroform. Thermal healing was followed for 30 h.

In reactions with cobalt atoms of low recoil energy (10—100 eV), the parent compound is formed stereospecifically together with Co^{2+} and other products. The parent compound is formed exclusively from Co^{2+} on subsequent tempering. At high recoil energies (up to 10^5eV) the other steroisomer is also formed in smaller amounts. All other products are formed from Co^{2+} on subsequent healing.

These results suggest that in nuclear reactions with thermal neutrons the energy transferred locally to the lattice is insufficient for positional exchange processes to occur among the ligands. Such exchange is observed only at higher neutron energies.

96

Structural Studies on Serine-Specific Transfer-RNA

H. G. Zachau, D. Dütting, and *H. Feldmann*, Köln (Germany)

Soluble ribonucleic acid from yeast contains several serine-specific transfer ribonucleic acids (serine t-RNA). The serine t-RNA present in largest amount was purified by repeated countercurrent distribution and split with pancreas and T_1 ribonucleases. The mono- and oligonucleotides were isolated by column chromatography. The composition and base sequence of most of the oligonucleotides could be determined by further enzymatic degradation. Eleven odd nucleotides were found: one each of *N*(2)-dimethyl-Gp, 5-methyl-Cp, rTp, Ip, 2′-O-methyl-Gp, 2′-O-methyl-Up, two of 4,5-dihydro-Up, and three of Ψ-Up. With the aid of these odd nucleotides and the $(Ap)_nGp$ sequences, base sequences up to 23 nucleotides could be determined. Some of the odd nucleotides occur in close proximity in serine t-RNA.

Comparison of the known fragments of serine t-RNA with the base sequence of an alanine t-RNA recently elucidated by *Holley et al.* shows that some of the odd nucleotides and many oligonucleotide sequences are different. There are, however, also some striking similarities, *e.g.* *N*(2)-dimethyl-Gp and Ip are separated by 9 nucleotides in both t-RNA's.

[VB 958/265 IE]

German version: Angew. Chem. 77, 1013 (1965)

The conformations and configurations of complicated organic molecules were examined by *O. Exner* and *V. Jehlička* by measurement of their dipole moments. In order to extend the restricted information obtained from the individual values, the dipole moments of an unsubstituted and a *p*-chloro or *p*-nitro derivative were compared graphically with the dipole moments of the individual configurations and conformations calculated from their bond moments and angles. The method was tested on some simple examples (ω-bromoacetophenone, phenylacetic acid, and ethyl benzimidate) and then applied mainly to determine the steric structure of acylated hydroxylamines (benzhydroxamic acid and its chloride, *N,O*-dibenzoylhydroxylamine, benzamidoxime, and *N,N*-diethylbenzamidoxime). / Coll. czechoslov. chem. Commun. *30*, 639, 652 (1965) / –Hz. [Rd 365/574 IE]

The hydroxylation of proline at the level of microsome-bonded protein was detected by *B. Peterofsky* and *S. Udenfried*. In a cell-free system from chick embryo, the radioactivity from [^{14}C]proline recurred in the hydroxyproline of collagen. Although radioactive proline can be detected in the collagen after only very short incubation times, the radioactive hydroxyproline is found only after about 30 min, when about 70% of the proline is already incorporated. The system consists of microsomes, a soluble enzyme fraction, a non-enzymatic cofactor, which has not yet been identified, and a hydrogen donor, *e.g.* ascorbic acid or 2-amino-4-hydroxydimethylpteridine. The proline hydroxylase is present in the microsomal fraction. Puromycin acts as an inhibitor if added at the start of the incubation but not if added after the 30-min induction period. / Proc. nat. Acad. Sci. USA *53*, 335 (1965) / –Hö. [Rd 372/581 IE]

The interactions among lactic dehydrogenase subunits was studied by *N. O. Kaplan* et al. The occurrence of five isoenzymes in lactic dehydrogenase (LDH) is at present explained by the formation of LDH from two components with different charges, there being four subunits per LDH molecule. Since there are five possible modes of combination, five isoenzymes with different electrophoretic mobilities result. When two isoenzymes with different mobilities – even from different sources – are mixed and the solution is frozen and rethawed several times, a new combination of the subunits is formed which results in new isoenzyme bands. This process is termed hybridization and is dependent on the presence of orthophosphate plus halide or thiocyanate. A decrease of activity is observed in the series $SCN^{\ominus}, I^{\ominus} > Br^{\ominus} > Cl^{\ominus} >>> F^{\ominus}$. The phosphate cannot be replaced by arsenate, pyrophosphate, or sulfate. Inactivation of the enzyme during the process is prevented by DPN, DPNH, or acetylpyridine-DPNH. Acetylpyridine-DPNH is found to inhibit the hybridization. The dissociation and combination steps are thought to be associated with changes in the conformation of the subunits. Hybridizations between LDH isoenzymes from different sources, *e.g.* from chickens and beef, from beef and dogfish, or from chickens and dogfish, lead to products with unreduced enzymatic activity. There must therefore be great similarities between the LDH subunits from these various species. / Biochemistry *4*, 271 (1965 / –Hö.

Dipeptides were made via the phenylhydrazides of N-acyl-α-amino acids by *H. B. Milne* and *W. Kilday*. The hydrazides can be oxidized – preferably in the dark – with *N*-bromosuccinimide in dichloromethane to give red, highly unstable phenyldiimides of the *N*-acyl-α-amino acids. These diimides can acylate nucleophilic coreactants, *e.g.* water, alcohols, or aniline, in a heterolytic reaction with release of nitrogen and benzene to give the free *N*-acylamino acids or their esters or anilides, respectively. Their reaction with amino esters leads to 40.5–71.4% yields of dipeptide esters. For example, carbobenzoxyglycyl phenylhydrazide *(1)* is oxidized in 83% yield to the diimide *(2)*, m.p. 61–62 °C, which when treated with the hydrochloride of glycine ethyl ester *(3)* and diethylamine in dichloromethane affords 61% ethyl carbobenzoxyglycylglycinate *(4)*, m.p. 80–81 °C.

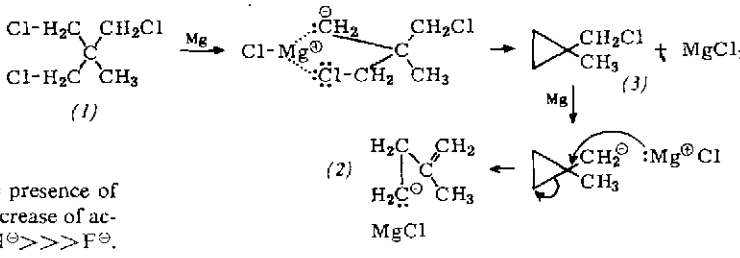
$$\text{Cbo–NHCH}_2\text{CO–NH–NH–C}_6\text{H}_5 \rightarrow \underset{(1)}{\qquad} \underset{(2)}{\text{Cbo–NHCH}_2\text{CO–N=N–C}_6\text{H}_5}$$

$$(2) + \text{H}_2\text{NCH}_2\text{COOC}_2\text{H}_5 \rightarrow \underset{(3)}{\qquad} \underset{(4)}{\text{Cbo–NHCH}_2\text{CO–NHCH}_2\text{COOC}_2\text{H}_5} + \text{N}_2 + \text{C}_6\text{H}_6$$

$\text{Cbo} = \text{C}_6\text{H}_5\text{–CH}_2\text{–OCO–}$

When the amino acids are optically active, a small amount of racemization is observed. The unstable diimides need not be isolated. The progress of the reaction can be followed spectrophotometrically by measuring the disappearance of the red color. / J. org. Chemistry *30*, 64 (1965) / –Bi.
[Rd 299/508 IE]

Polymetallophilic compounds react simultaneously at several positions in the molecule with metals to form organometallic compounds in a direct reaction. *E. L. McCaffery* and *S. W. Shalaby* synthesized 2-methyl-2-chloromethyl-1,3-dichloropropane *(1)* by treating the corresponding trihydroxy compound with thionyl chloride and pyridine. When 1 mole of *(1)* is treated with 2 moles of magnesium, *(1)* rearranges to form the Grignard derivative *(2)*, which reacts with CO_2, water, benzonitrile, and phenyl isocyanate to give the expected products. The rearrangement of *(1)* to *(2)* probably proceeds via a cyclopropane derivative *(3)*. / J. organometallic Chem. *3*, 101 (1965) / –Kr. [Rd 308/517 IE]



n-Propanol increases the virus-inactivating effect of peroxyacetic acid, according to findings of *M. Sprössig* and *H. Mücke*. No fast-acting disinfectants with a broad activity spectrum are known. In addition to its bactericidal and fungicidal properties, peroxyacetic acid has a striking antiviral activity. The activity of Type I poliomyelitis viruses decreases by a factor $\geq 10^4$ within 90 sec in a 0.2% solution of peroxyacetic

acid containing 33 % n-propanol. n-Propanol alone has practically no effect on the viruses even after treatment for 240 sec, and 0.2 % peroxyacetic acid alone produces a decrease of only about 1:10 after 90 sec or about $1:10^3$ after 240 sec. The inactivation is probably accelerated in the presence of the alcohol as a result of better penetration of the peroxyacetic acid into vital centers of the virus. / Acta biol. med. german. *14*, 199 (1965) / –De. [Rd 312/521 IE]

The resynthesis of insulin from *S*-sulfurated insulin A and B chains has been achieved by *D. Yu-cang* and *J. Rong-Qing* with a recovery of activity of 12 I.U. per milligram of protein, *i.e.* 50 % of the activity of crystalline insulin. The insulin A and B chains are obtained in the form of their *S*-sulfonates by cleavage of the native hormone with Na_2SO_3 and $Na_2S_2O_4$ in the presence of urea and can be purified by precipitation at pH 6.4 (B chain) and by zone electrophoresis on cellulose powder at pH 7.0 (A chain). The best yields of regenerated insulin are obtained with a molar ratio of A:B chains of 3:2 by reduction with a 28-fold excess of mercaptoethanol at pH 5.0 for 6 min at 100 °C, precipitation and washing of the reduced insulin chains at pH 3.8, and subsequent re-oxidation at 3–5 °C in glycine buffer at pH 10.6. / Scientia sinica *14*, No. 2 (1965) / –De. [Rd 313/522 IE]

The immunochemical activity of chymotryptic peptides from sperm whale myoglobin has been investigated by *M. J. Crumpton* and *J. M. Wilkinson*. The apomyoglobin was decomposed by chymotrypsin in a dialysis bag, and the fragments were simultaneously removed. The test for immunochemical activity was the inhibition of the precipitation of metmyoglobin and apomyoglobin by two different metmyoglobin antisera. Eight fragments were isolated and purified and their location in the myoglobin was determined. Two of the fragments inhibited the precipitation of metmyoglobin and apomyoglobin by both antisera, five that of apo- and/or metmyoglobin by one antiserum, and six that of the apomyoglobin by one or both antisera. The inhibitory effect of any fragment never went beyond 15 % precipitation; the test with a mixture of all the fragments produced the greatest inhibition of 80 %. These values remained unaltered when the fragments were heated beforehand at 100 °C. In order to achieve half of the strongest inhibition possible, an excess of fragments had to be used. The extent of this excess increased as the molecular weight of the fragments decreases; for example, it was 80:1 for a fragment with a molecular weight of 793 but only 12:1 for a fragment with a molecular weight of 2051. Generally ratios of 2000:1 to 3000:1 are required for haptenes in order to effect 50 % of the maximum inhibition. / Biochemical J. *94*, 545 (1965) / –Hö. [Rd 320/529 IE]

The role of dicyanogen diamide in peptide synthesis during the course of chemical evolution has been studied by *G. Steinman*, *R. M. Lemmon*, and *M. Calvin*. Dicyanogen diamide can be formed under primaeval terrestrial conditions from HCN and is capable of converting orthophosphate into pyrophosphate, glucose and phosphoric acid into glucose-6-phosphate, and adenine and phosphoric acid into adenylic acid. Moreover, in the presence of HCl it transforms alanine into alanylalanine. The yield of alanylalanine after incubation for 20 h at 20 °C and pH 2.0 in the dark was 1.2 %; in addition, a trace of alanylalanylalanine was also found. The course of the condensation corresponds to that of the polymerization of amino acids by carbodiimides. / Science Washington) *147*, 1574 (1965) / –De. [Rd 314/523 IE]

Sex-specific differences in the concentrations of serum amino acids have been observed by *H. Oepen* and *I. Oepen* in the blood of clinically healthy humans. Women generally have a lower level of serum amino acids than men. Cysteic acid and taurine could be detected in larger amounts in women than in men both before and after hydrolysis, but cysteine only before hydrolysis of the serum peptides. The values for free valine, isoleucine, and leucine, and after hydrolysis those for phenylalanine and tyrosine, were much lower in women than in men; less strikingly lower values were found for 13 other amino acids. Since the monoamino monocarboxylic acids (Val, Leu, and Ileu), the cyclic alanine derivatives (Phe and Tyr), and the amino acids containing sulfur (Cy, cysteic acid, and Tau) each occur as distinct groups, these sex-specific differences in concentration must apparently have some function. / Klin. Wschr. *43*, 211 (1965) / –De. [Rd 315/524 IE]

The formation of antibodies against alcohol dehydrogenase has been studied by *H. Werchau* and *H. Kröger*. They examined the influence of protein-synthesis inhibitors on the synthesis of antibodies against the alcohol dehydrogenase (ADH) from rabbit spleen cells *in vitro*. Rabbits were immunized with intravenous injections of ADH. After 10–12 weeks a second injection of ADH was given and the animals were killed 3 days later. Their spleen cells were isolated and maintained in cultures. Incubation with ADH led to the formation of ADH antibodies after about 6 h. After ca. 40 h, the ADH was about 70 % inhibited. The active component of the spleen cell supernatant was found only in the γ-globulin fraction. Additions of puromycin (25 μg/ml) or actinomycin (1 μg/ml) effected complete blockage of the antibody synthesis. Partial blockage was caused by 6-mercaptopurine, 5-iododeoxyuridine, and other nucleic-acid antimetabolites in concentrations around 10^{-3} M. It is therefore assumed that a DNA-dependent RNA synthesis is required for the production of the antibodies and that specific peptide sequences are formed on the RNA following the normal scheme of protein synthesis. / Biochem. Z. *341*, 184 (1965) / –Hö. [Rd 316/525 IE]

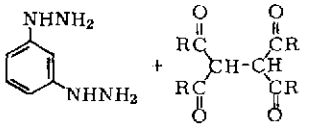
The mode of degradation of isoprenoids by bacteria has been elucidated by *W. Seubert* and *E. Fass*. With geraniol and farnesol the first step is the oxidation of the hydroxymethyl to a carboxyl group, the second the activation of the latter to the corresponding β-methylacyl-CoA. In the third step, the β-methyl group is carboxylated by a biotin enzyme, and in the fourth and fifth steps, hydration of the α,β-double bond and elimination of acetic acid with formation of a β-ketoacyl-CoA occur. The latter compound reacts in the sixth step once again with CoA–SH and is then split into acetyl-CoA and a δ-methyl-acyl-CoA which is then shortened by two carbon atoms in the reaction sequence which corresponds to one turn of the Lynen fatty acid spiral. Thus the starting point of the "isoprenoid spiral", a β-methacrylyl-CoA derivative is again attained and the degradation process starts anew. The spiral ends with dimethylacrylyl-CoA, which yields acetoacetic acid and acetyl-CoA following the scheme of degradation of leucine. Proof of this degradation route was obtained by characterization of the 7-methyl-3-oxo-6-octenoyl-CoA formed from the geranyl-CoA as the dinitrophenylhydrazone of the methylheptenone produced by thioester cleavage and decarboxylation. / Biochem. Z. *341*, 35 (1965) / –Hö. [Rd 317/526 IE]

Polystyrenes with *p*-vinyl and *p*-isopropenyl groups were prepared by *D. Braun* and *H.-G. Keppler*. Their investigations were based on copolymers of styrene and *p*-(β-bromoethyl)-styrene or styrene and *p*-(α-hydroxyisopropyl)styrene. – β-Bromoethyl groups can be converted into vinyl groups by dehydrobromination in methanolic KOH at 130 °C, and isopropenyl groups are produced by dehydration of α-hydroxyisopropyl groups with acetic anhydride at 135 °C in *p*-xylene. Vinyl monomers, *e.g.* styrene, can be grafted onto polymers made from these styrene derivatives by either radical or anionic mechanisms. Cross-linking free-radical copolymerization can be used to make castings with a low degree of cross-linking which do not exhibit orientational

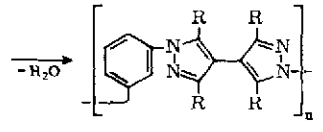
double refraction. The Vicat temperature for a cross-linked polystyrene made from a 5 % solution of a polystyrene with 11.3 mole-% vinyl groups in styrene was 95 °C, while that of a non-cross-linked polystyrene produced under the same conditions was 87.5 °C. / Makromolekulare Chem. *82*, 132 (1965) / –Hl. [Rd 321/530 IE]

The reactivity of methacrylates in radical copolymerization was studied by *J. C. Bevington* and *B. W. Malpass* using ^{14}C and ^{3}H. The polymerization was carried out at 60 °C with azobisisobutyronitrile as initiator. The relative reactivity compared with the poly(methyl methacrylate) radical is greater than 1 for most esters (methyl methacrylate as standard = 1.00) and increases with the possibilities of stabilization of the polymeric free radicals by resonance (ethyl methacrylate 1.09, phenyl methacrylate 1.79). Calculation of the monomer constants using the equation of *Bamford* [1] gives values in agreement with those of *Bamford* and *Jenkins* [2]. The change in monomer reactivity with temperature appears to be of importance for inhibition of growth at higher polymerization temperatures. / European Polymer J. *1*, 19 (1965) / –Hl. [Rd 322/531 IE]

Thermostable polyphenylpyrazoles have been made by *J. P. Schaefer* and *J. L. Bertram*. The starting materials are first precondensed in equimolar amounts at low temperatures under nitrogen and then cured at high temperatures and a pressure of 0.1 mm. For instance, *m*-dihydrazinobenzene *(1)*



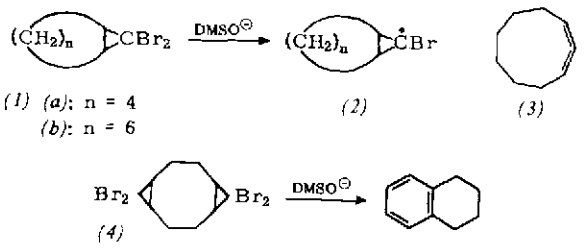
(1) *(2)*



(3)

is heated with tetraacetylethane *(2)* for 1 h at 80–120 °C and then for 10 h at 140–350 °C; the intrinsic viscosity of the resultant polymer in formic acid at 30 °C is 1.5 dl/g. No loss of weight occurs with these polyphenylpyrazoles up to 400 °C. Infrared and mass spectra were used to establish the structure *(3)* for the polymer. / J. Polymer Sci. (Polymer Letters) B *3*, 95 (1965) / –Hl. [Rd 326/535 IE]

Debromination of 1,1-dibromocyclopropanes by sodium methylsulfinylmethide has been studied by *C. L. Osborn, T. C. Shields, B. A. Shoulders, C. G. Cardenas*, and *P. D. Gardner*. Since the $CH_3SOCH_2^{\ominus}$ anion is an effective nucleophile for the elimination of bromine, it seemed likely that it would form carbenes from 1,1-dibromo compounds. 7,7-Dibromobicyclo[4.1.0]-heptane *(1a)* reacts with excess sodium methylsulfinylmethide in dimethyl sulfoxide at room temperature to yield 72 % 7-bromobicyclo[4.1.0] heptane *(2a)*, the *trans*-isomer predominating. Analogous reaction of 9,9-dibromobicyclo-[6.1.0]nonane *(1b)* for 2.5 h affords 71 % *trans*- and *cis*-9-bromobicyclo[6.1.0]nonane *(2b)*. An excess of sodium methylsulfinylmethide converts *(2b)* within 4.5 h in 66 % yield into 1,2-cyclononadiene *(3)*. Similarly, 9,9-dibromobicyclo[6.1.0]-



(1) *(a)*: n = 4 *(b)*: n = 6 *(2)* *(3)* *(4)*

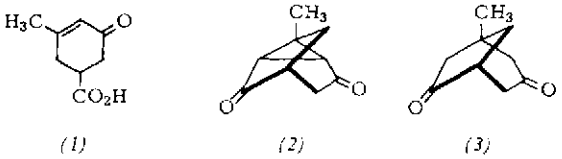
non-4-ene yields 64 % 1,2,6-cyclononatriene, and 5,5,10,10-tetrabromotricyclo[7.1.0.0^{4,6}]decane *(4)* yields 40 % tetralin. / Chem. and Ind. *1965*, 766 / –Ma. [Rd 327/536 IE]

A new method of decarboxylating aliphatic acids to the next lower alkyl halide is given by *J. K. Kochi*. The acids are heated with a metal halide and lead tetraacetate under nitrogen in refluxing benzene, acetonitrile, or hexane/benzene.

$$RCOOH + Pb(OAc)_4 + MX \rightarrow RX + CO_2 + Pb(OAc)_2 + HOAc + MOAc$$

The reaction is complete within a few minutes with LiCl and $CaCl_2$, but KCl and NaCl require prolonged heating because of their low solubility in organic solvents. The decarboxylation is fastest with tertiary and secondary carboxyl groups. The amount of methyl chloride formed from the acetic acid produced as by-product is insignificant in these cases. Acids with primary carboxyl groups also give high yields of chloroalkane but more methyl chloride is formed as by-product. Excess acid must be used to ensure maximum utilization of the lead tetraacetate. The metal halide is consumed in an equimolar amount with the Pb(IV) acetate. Decarboxylation to alkyl bromides and iodides occurs with metal bromides and iodides with simultaneous formation of bromine and iodine. For example, isobutyric acid → 98 % isopropyl chloride [based on $Pb(OAc)_4$]; pivalic acid → 72 % t-butyl chloride; cyclobutanecarboxylic acid → cyclobutyl chloride 98 %; cyclohexanecarboxylic acid → 100 % cyclohexyl chloride. / J. Amer. chem. Soc. *87*, 2500 (1965) / –Ma. [Rd 344/553 IE]

The intramolecular addition of an α-keto carbene onto an alkenone double bond was investigated by *D. Becker* and *H. J. E. Loewenthal*. 3-Methylcyclohex-3-ene-5-one-1-carboxylic acid is converted into the corresponding methyldiazo ketone by treatment with oxalyl chloride in benzene in the presence of pyridine and subsequent reaction with diazomethane. Decomposition of the diazo ketone in boiling



(1) *(2)* *(3)*

cyclohexane in the presence of anhydrous $CuSO_4$ produces the tricyclic diketone *(2)*, m.p. 46.5–47 °C, in 38 % yield. Hydrogenation of *(2)* with Pd/C in methanol leads rapidly to 71 % 1-methylbicyclo[3.2.1]octane-3,6-dione *(3)*, m.p. 64 °C. / Chem. Commun. *1965*, 149 / –Ma. [Rd 337/546 IE]

Tertiary phosphine oxides catalyse the isomerization of epoxides to ketones. This was observed by *D. E. Bissing* and *A. J. Speziale*, who also found that triphenylphosphine oxide is much less effective in this respect than tributylphosphine oxide. *trans*-Stilbene oxide yields 67 % benzyl phenyl ketone and traces of diphenylacetaldehyde and *cis*-stilbene, but the occurrence of *trans*-stilbene as an intermediate during the reaction can be concluded from the transient appearance of

[1] *C. H. Bamford, A. D. Jenkins*, and *R. Johnston*, Trans. Faraday Soc. *55*, 418 (1959).

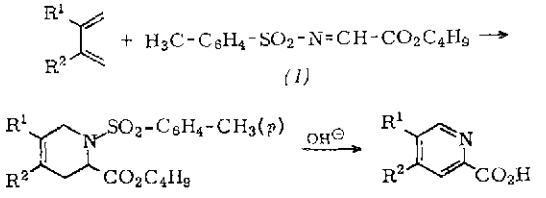
its NMR spectrum. *trans*-4-Octene oxide is converted by heating for 10 days at 160 °C in a sealed tube under nitrogen in the presence of *m*-chlorobenzaldehyde into 4-octanone in 85 % yield. *cis*-4-Octene is isomerized a little more slowly. / J. Amer. chem. Soc. *87*, 1405 (1965) / –Ma. [Rd 333/542 IE]

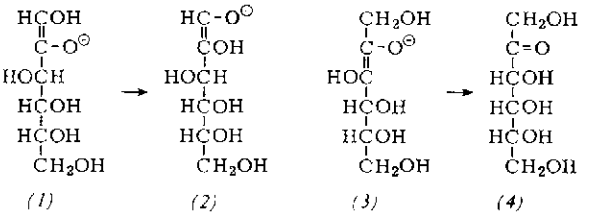
N-Butoxycarbonylmethylene-*p*-toluenesulfonamide is a new dienophile which was found by *R. Albrecht* and *G. Kresze* to be suitable for the preparation of pyridine, piperideine, and piperideine derivatives using the Diels-Alder reaction. The sulfonamide *(1)* is made by heating butyl glyoxylate with *N*-sulfinyl-*p*-toluenesulfonamide in benzene in the presence of $AlCl_3$ and reacts with butadienes to yield piperideine



(1)

derivatives which on hydrolysis with alkali form pyrideine derivatives and *p*-toluenesulfinic acid. Cyclic dienes result in 2-aza bicyclic compounds. / Chem. Ber. *98*, 1431 (1965) / –Ma. [Rd 334/543 IE]

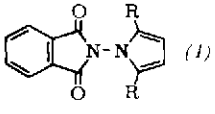
Dicyclohexylcarbodiimide was used as a new reagent for epimerizing and isomerizing sugars in neutral solution by *S. Passeron* and *E. Recondo*. Heating of fructose in anhydrous methanol with dicyclohexylcarbodiimide leads to a mixture of glucose, mannose, and D-psicose *(4)*, the latter in 25 % yield. As a Brønsted base, the diimide probably deprotonates the fructose to give the anion *(1)*, which isomerizes to the anion *(2)*, being then in equilibrium with glucose and



(1) *(2)* *(3)* *(4)*

mannose. The psicose *(4)* can arise analogously from the anion *(3)*. Analogously, D-galactose yields D-tagatose as main product together with a little sorbose. / J. chem. Soc. (London) *1965*, 813 / –Ma. [Rd 255/464 IE]

N-Aminophthalimide has been used for unequivocal syntheses of N-aminopyrroles by *R. Epton*. The phthaloyl group of the reagent can be readily removed. Condensation of *N*-aminophthalimide with acetonylacetone in hot acetic acid yields 96 % *N*-phthalimido-2,5-dimethylpyrrole *(1)*, m.p. 184 to



(1)

184.5 °C. Hydrazinolysis of *(1)* gives 65 % *N*-amino-2,5-dimethylpyrrole, m.p. 51–52 °C. Condensation of *N*-aminophthalimide and 2,5-dimethoxytetrahydrofuran results in 40 % *N*-phthalimidopyrrole, m.p. 223–224 °C, which then yields 70 % *N*-aminopyrrole, b.p. 174–174.5 °C/750 mm. / Chem. and Ind. *1965*, 425 / –Ma. [Rd 287/496 IE]

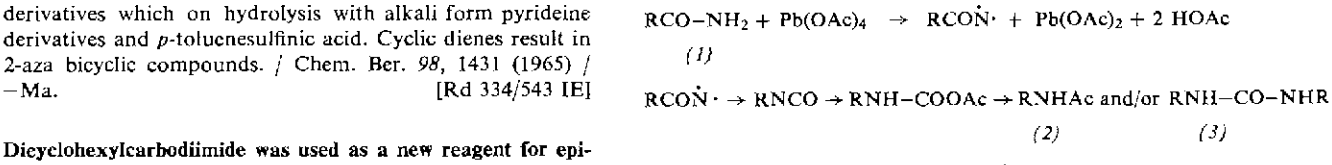
A mass-spectrometric amino-acid sequence analysis enabled *E. Lederer* et al. to establish the structure of the lipoprotein fortuitin. This natural product obtained from *Mycobacterium fortuitum* was already known to have the amino-acid composition $Val_3Thr_2Ala_1Pro_1$ and to contain two *N*-methylleucine residues (MeLeu), a methyl ester group (Me), two acetyl groups (Ac), and a long-chain fatty acid. The mass spectrum revealed that the substance, which was hitherto thought to be homogeneous, consists of two components differing by two methylene groups in the fatty acid moiety. The complete structure is

CH_3-$(CH_2)_n$-CO-Val-MeLeu-Val-Val-MeLeu-Thr(Ac)-Thr(Ac)-
-Ala-Pro-OMe

n = 18 or 20

The amino acids all have the L-configuration; the configuration of the MeLeu is however still unknown. / Biochem. biophysic. Res. Commun. *18*, 469 (1965) / –Hö. [Rd 318/527 IE]

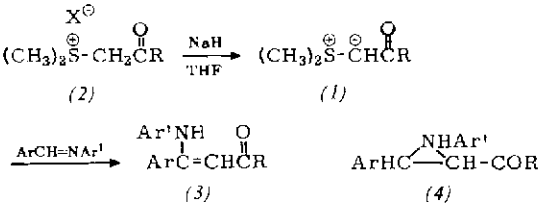
The reaction of lead tetraacetate with unsubstituted primary amides leads to acylamines. On reaction of a primary amide *(1)* with lead tetraacetate in benzene or benzene/acetic acid, *B. Acott* and *A. L. J. Beckwith* obtained a mixture of the *N*-acetylamine *(2)* and a dialkylurea *(3)*. No reaction took place with benzamide.



(1) *(2)* *(3)*

Yields: R = n-butyl: 45 % acylamine/5 % dialkylurea; pentyl 40/5; cyclohexyl 65/8; heptadecyl 61/9; benzyl 67/0; 9-decenyl 53/3; 24-nor-5β-cholanyl 81/0. / Chem. Commun. *1965*, 161 / –Ma. [Rd 338/547 IE]

Carbonyl-stabilized sulfonium ylides *(1)* have been made by *A. J. Speziale, C. C. Tung, K. W. Ratts*, and *A. Yao*. The ylides *(1)* are obtained by treating sulfonium salts *(2)* with NaH in tetrahydrofuran. Their reaction with Schiff bases leads to substituted β-anilinocinnamamides and β-anilinocinnamates *(3)*, which can be identified by their NMR spectra and hydrolysis products. The aziridine *(4)* is proahably an intermediate of the formation of *(3)*. The carbonyl-stabilized



(2) *(1)* *(3)* *(4)*

X = Halogen; R = OC_2H_5

sulfonium ylides are valuable nucleophiles for use in syntheses. / Abstracts 149th Meeting Amer. Chem. Soc. *1965*, 44P / –Ma. [Rd 339/548 IE]

Chloroarsines with t-butyl groups were obtained by *A. Tzschach* and *W. Deylig* by direct synthesis from $AsCl_3$ and t-C_4H_9MgCl in ether with exclusion of air and moisture; the yields were over 50 %.

$$AsCl_3 + t\text{-}C_4H_9MgCl \rightarrow t\text{-}C_4H_9AsCl_2 + MgCl_2$$

$$AsCl_3 + 2\ t\text{-}C_4H_9MgCl \rightarrow (t\text{-}C_4H_9)_2AsCl + 2\ MgCl_2$$

The products are colorless liquids that can be distilled in vacuum and which dissolve in all common organic solvents. The chloroarsines can be reduced with $LiAlH_4$ in diethyl ether at –10 °C to the corresponding arsines, *e.g.* t-$C_4H_9AsH_2$, b.p. 65–67 °C, in 65 % yield or $(t\text{-}C_4H_9)_2AsH$, b.p. 49 to 50 °C/16 mm, in 41 % yield. The arsines are liquids which are extremely sensitive to air and which can be metallated by phenyl-lithium to the corresponding lithium arsides. / Z. anorg. allg. Chem. *336*, 36 (1965) / –La. Paramagnetische Elektronenresonanz (Electron Paramagnetic Resonance). By *S. A. Altschuler* and *B. M. Kosyrew*. Translated from the Russian by *A. Lösche* and collaborators. Verlag Harri Deutsch, Zürich-Frankfurt/Main 1964. 1st edit., VII + 383 pp., 53 figs. linen DM 54.– (about $13.75).

After a brief introduction and a survey of experimental methods, the major part of this book deals with the electron spin resonance spectra of ionic crystals: with the theory in Chapter III (50 pp.), with experimental results in Chapter IV (105 pp.), and with relaxation and line widths in Chapter V (80 pp.).

The remainder of the book deals with the EPR spectra of metals and semiconductors and with defects in crystals (Chapter VI, 37 pp.), and with stable free radicals and radicals produced by radiation (Chapter VII, 28 pp.). The closing chapter (45 pp.) is devoted to allied phenomena such as dynamic nuclear polarization and molecular amplifiers.

In common with all other publications that have appeared on this subject, the present monograph gives a particularly detailed discourse on the particular aspects of electron paramagnetic resonance in which the authors are specialists. Since here the main accent is on ionic crystals, the main attraction should be for solid state physicists; physicochemical applications receive less consideration, and biological aspects none at all. A prominent feature of the book is the tables in Chapters IV and V which take up over eighty pages and which form a work of reference augmented with numerous citations of results published until the appearance of the Russian edition in 1959. In the German edition, which bears the date "January 1962" in the foreword, numerous more recent publications have been cited. It is unfortunate that the long time that has elapsed between this date and the final appearance of the book (1964) has nevertheless resulted in some loss of actuality. In conclusion, attention should be called to the fact that there are almost no original spectra included in the book. The reviewer is of the opinion that the gain in clarity obtained from the printing of typical spectra would justify higher production costs for the book.

K. Hausser [NB 397/255 IE]

Titrationen in nichtwäßrigen Lösungsmitteln (Titrations in Non-aqueous Solvents). By *W. Huber*. Methoden der Analyse in der Chemie (Methods of Analysis in Chemistry). Edited by *F. Hecht*, *H. Kaiser*, and *H. Kriegsmann*. Vol. 1. Akademische Verlagsgesellschaft, Frankfurt/Main 1964. 1st edit., XII + 280 pp., 79 figs., 14 tables, linen DM 35.– (about $ 9.–).

This is the first volume in a new series of monographs on analytical methods in chemistry intended to acquaint their readers with the current status of selected analytical methods. The book deals with the quantitative determination of acids and bases by titration in non-aqueous solvents. In the first – mainly theoretical – section, the general fundamentals, the methods of determining end-points, instrumentation, and reagents are discussed. The second section gives a detailed description of the practical execution of acid-base titrations, arranged mainly according to classes of compounds. The final section contains tables listing mainly dissociation constants measured in water for the most diverse compounds. The author has succeeded in presenting a treatise on acid-base equilibria tailored to suit the practical worker; it is intended to direct the experimenter toward suitable titration techniques even for very strong or very weak acids and bases on the basis of dissociation constants (Section III). Unfortunately the author, allegedly to avoid confusion, has employed the outdated basicity constants K_B as a measure of base strength. For the sake of uniformity, it would have been better to have given data on the acidity constants of the conjugate acids. The book should appeal to the practical worker who has long ago completed his undergraduate chemical studies; it will also offer many an incentive to the expert in this field.

W. Simon [NB 373/231 IE]

Vitamine. Chemie und Biochemie (Vitamins. Chemistry and Biochemistry). Edited by *J. Fragner*. Translated from the Czechoslovakian by *H. Liebster*. Vol. I. VEB Gustav Fischer Verlag, Jena 1964. 1st German edit., 890 pp., 48 figs., 117 tables, linen DM 87.60 (about $22.00).

A group of Czechoslovakian scientists have undertaken the task of writing a monograph on the chemistry and biochemistry of the vitamins. The first volume of the two-volume Czech edition which appeared in 1961 is now available in German. It is divided into a general and a specialized section. In the first part, after a historical introduction, the nomenclature and classification of vitamins, the relationships between their structures and biological activities, their biogenesis, vitamins in biochemical systems, vitamins in the diet, the occurence of vitamins, fundamentals for vitamin assays, and the applications of vitamins are discussed. In the specialized section, which will be continued in the second volume, the individual vitamins are considered, and again the chapters are divided into historical introduction and nomenclature, chemistry, biochemistry, assay, and applications of each vitamin.

The 26 authors who cooperated in compiling the book have considered an astounding number of publications, and patent literature has often been consulted. The tabular summaries given are especially valuable.

The great expectations with which one begins to read the book are however unfortunately disappointed in several parts. The text is often too digressive, the historical development is placed too far in the forefront, and the literature has not been appraised critically enough. Some of the biochemical chapters are particularly unsatisfactory. Here no clear-cut distinction is made between experimentally established results and mere hypotheses, and many inaccuracies and errors have slipped in. For example, in the general chapter on the biogenesis of vitamins, the modern aspects of product inhibition, repression, and induction are not mentioned; instead, inhibition is explained using outdated examples from reaction kinetics. The biogenesis of flavonoids is misrepresented on p. 83 – phloroglucinol is not an intermediate – but is reproduced correctly on p. 531. Despite the reasons presented by the authors, it is still not understandable why "bioflavonoids" and "essential fatty acids" are dealt with in a handbook on vitamins. The participation of lipoic acid (the formula for the dehydro derivative on p. 91 is incorrect) in photosynthesis is presented as a fact, even though *Calvin* considers it as highly dubious. It is stated on p. 94 that the Schiff base is formed non-enzymatically during amino-acid activation. On p. 95, the activation of benzoic acid *via* its CoA ester is reproduced erroneously. The isomerization of isopentenyl pyrophosphate is caused by an enzyme and not by $H^{\oplus}$ ions (see p. 325). The occurrence of lycopersin as an intermediate in carotenoid biosynthesis is strongly disputed (p. 327). In the chapters on the bioflavonoids, the formulae of hesperidin and eriodictin are drawn with D-rhamnose instead of with L-rhamnose, and on p. 534, a "catechin component" of rutin is alleged. In this and in other chapters, little attention is paid to the stereochemistry of the compounds described.

The authors claim that the literature has been reviewed in general until 1961. However, the structure for activated methionine is still given only tentatively (p. 723), and the formula for the vitamin B_{12} coenzyme is lacking.

The print and quality of the book are good, but the reproduction of formulae is sometimes poor and contains many errors. Although the shortcomings outlined above show that the

book is not entirely satisfactory, it will nevertheless be a great help to the specialist in the vitamin field provided he exercises caution in its use. *H. Grisebach* [NB 405/263 IE]

Silicate Science. By *W. Eitel.* Vol. 1: Silicate Structures. Academic Press, New York-London 1964. 1st edit., XII + 666 pp., numerous figs., several tables, price of single volume in linen $ 24.00.

For decades, "Die physikalische Chemie der Silicate" (The Physical Chemistry of Silicates) by *W. Eitel* was the standard textbook in the field of silicate chemistry. It appeared in several German editions and finally in an English edition in 1954. In the meantime, the results of experimental studies of silicates have assumed unprecedented dimensions: over 20000 publications have appeared within the past 15 years alone!

In his new work, "Silicate Science", the author attempts to catch up on this lag in reviews of original publications. The present volume is the first of a planned series of five. Chapters 1–3 correspond to the content of his older monograph and contain a general description of the Si–O bond together with a survey of the crystal structures of silicates, with particular emphasis on isomorphic and isotypical relationships to non-silicate systems. Epitaxic phenomena are also dealt with. The systematic classification is built up on the *Bragg* system and its supplementation by *Zoltai*; however, the work of *Below* and his school is also given due attention. The second section is devoted to clay minerals, particularly their structures. In the last section, which makes up over half the book, the problems of colloid chemistry and the surface properties involved in silicate chemistry are discussed. In this connection, aluminum oxide/silicon dioxide gels and cracking catalysts are described.

The author has managed to review the vast literature in this field in magnificent fashion. It should be emphasized that in all chapters, whenever the views of different research groups do not concur, the different experimental methods and interpretations are presented together. The reader thus has the opportunity of appraising the arguments for himself. For this reason, the book offers a summary of information that is valuable not only for those who wish to acquaint themselves with special topics of this subject but also for experts in this field. It deserves a place in every chemical library. However, it does not provide a modern textbook of silicate chemistry, which is still lacking.

Armin Weiss [NB 384/242 IE]

Colorimetric Determination of Elements. Principles and Methods. By *G. Charlot.* Elsevier Publishing Co., Amsterdam-London-New York 1964. 1st edit., IX + 449 pp., 72 figs., 12 tables, linen DM 56.– (about $ 14.–).

This book is in the main a translation of the second French edition of 1961, a few sections having been revised by the author. In the general section (154 pp.) – somewhat inaptly entitled "Theoretical Background" – Beer's law and the fundamentals of the techniques and equipment used in photometry, fluorimetry, turbidimetry, and nephelometry are discussed. The general physical principles are dealt with only summarily; details concerning apparatus are not given. On the other hand, the author goes further into the sources of error and accuracy of photometric estimations, but again practical aspects are dealt with less thoroughly than the formal mathematical concepts. This section also includes chapters on extraction, ion exchange, chromatography, separations via the gas phase ($1^1/_2$ pages and 2 tables), and electrolytic processes. Although it must be admitted that separations are often intimately connected with photometric estimations, a general reference to paper chromatography and ion-exchange chromatography on about 1 page each are useful only to readers who are totally unfamiliar with these processes. The section on the separation of traces (2 pp.) is also poor. In the second section (280 pp.), procedures for determining 65 elements are described; these are all reliable, well tested methods. However, some methods which might have been preferred by experienced analysts have been omitted. For some elements, several practical procedures are described in detail, but for others, little more than short headings and literature references are given. For the sections on the separation of the elements, this abbreviated style has been used throughout. Occasionally only a literature reference is given for the examination of some natural and synthetic products.

The vast number of literature references given, which are mostly linked with a condensed description of the content of the papers concerned, is the best feature of this book. Some parts could have been improved by more careful editing. Although the book has little hope of ousting the established works on photometric analysis, it is valuable, particularly because of its second section, for rapid reference to the solution to certain problems. *H. Bode* [NB 358/216 IE]

Spectroscopy and Photochemistry of Uranyl Compounds. By *E. Rabinowitch* and *R. L. Belford.* International Series of Monographs on Nuclear Energy, edited by *J. V. Dunworth*, Division XII: Chemistry, Vol. I. Pergamon Press, Oxford - London - Edinburgh - NewYork - Paris - Frankfurt 1964. 1st edit., X + 370 pp., numerous illustrs. and tables, linen £4.0.0 (about $ 11.–).

This monograph reviews the current status of knowledge of the spectroscopy and photochemistry of hexavalent uranium. Chapter 1 deals with the spectroscopy of solid uranyl salts. Following an introductory section on the structure of crystalline uranyl compounds, discussions are given on their fluorescence, absorption, and infrared spectra. Chapter 2 deals with the spectroscopy of uranyl compounds in solution. Chapter 3 describes the intensity and decay of uranyl fluorescence and Chapter 4 the photochemistry of uranyl compounds, while Chapter 5 gives a short presentation of the theory of the electronic structure of the uranyl ion.

The material is presented mainly in chronological order within each section. The main contributions are naturally derived from publications which appeared after 1940. A practically complete list of references is given for the literature from 1833 (!) to 1961; work that appeared after completion of the manuscripts is listed in an appendix covering publications up to the end of 1963.

Naturally, monographs of this type appeal to only a very limited readership. However, they usually are indispensible aids for the experts in their specific fields, and this is particularly true of the present volume. All associated with the chemistry and especially with the spectroscopy of uranium or of actinides in general will he grateful to the authors for their efforts in compiling this book.

G. Koch [NB 364/222 IE]

Inorganic Ion Exchangers. By *C. B. Amphlett.* Topics in Inorganic and General Chemistry. Edited by *P. L. Robinson.* Monograph 2. Elsevier Publishing Co., Amsterdam-London-New York 1964. 1st. edit., XI + 141 pp., 36 figs., 32 tables, linen about DM 23.– (about $ 5.50).

This book has appeared as the second volume of a large series of individual monographs on inorganic and general chemistry. The use of inorganic ion exchangers has acquired increasing importance in recent years on account of their high thermal stability and resistance to radiation.

After a short historical introduction and a general survey, ion exchange on clay minerals, zeolites, and salts of heteropolyacids are dealt with. The major portion of the book is devoted to the exchange properties of zirconium phosphates and related compounds, on which the author has done a considerable amount of research. The exchange equilibria, ion separations and selectivities, suitability for water purification, and the preparation of ion-exchange membranes are discussed for zirconium phosphates. Despite the condensed nature of the text, the author has succeeded in illuminating the problems

concerned and in pointing out the principles. The book can therefore be recommended to anyone who wants to familiarize himself with this field or to have a ready source of information on it. However, the attention of the reader is called in the foreword to the fact that the book is not a comprehensive survey; nonetheless, the chapter on zirconium phosphates covers more than 100 literature references.

Armin Weiss [NB 396/254 IE]

Progress in Boron Chemistry. Edited by *H. Steinberg* and *A. L. McCloskey*. Vol. 1. Pergamon Press, Oxford-London-Edinburgh-New York-Paris-Frankfurt 1964. 1st edit., VII + 487 pp., numerous figs. and tables, linen £7.0.0 (about $ 19.50).

This volume initiates a new series of progress reports dedicated to research on the element boron and its compounds. In the first of the ten chapters in this first volume, *R. J. Brotherton* gives a detailed report on "The Chemistry of Compounds with Boron-Boron Bonds". *T. D. Coyle* and *F. G. A. Stone* then give a critical assay of "Some Aspects of the Coordination Chemistry of Boron", *G. W. Campbell* describes "The Structures of Boron Hydrides", and *H. A. Soloway* the applications of "Boron Compounds in Cancer Therapy". The following contribution by *M. J. S. Dewar* on "Heteroaromatic Boron Compounds" is very short. The evolution of the chemistry of "Organoperoxyboranes" is described by *A. G. Davies*. The interesting and variegated research in the chemistry of "Organoboron Heterocycles" is reviewed authoritatively by *R. Köster*. In their chapter on the "Reactions of Diazoalkanes with Boron Compounds", *C. E. Bawn* and *A. Ledwith* report on the catalytic activity of Lewis acidic boron compounds. The "Chemistry of Boronic and Borinic Acids" is dealt with cursorily by *K. Torsell*, and in conclusion, *R. Schaeffer* gives a convincing demonstration of the value of "Nuclear Magnetic Resonance Spectroscopy of Boron Compounds" in clarifying structural questions.

The quality of the contributions is variable, and it is to be hoped that the editors will be less lenient in the selection of topics and in the coordination of the essays in future volumes. The reports in this first volume will undoubtedly be attractive to all boron chemists, but the book will probably not appeal to a broader readership, *e.g.* advanced students, as suggested on the dustcover. This circumstance is aggravated by the high cost of the volume, which is of de luxe quality. In effect, most of the chapters offer too little information for specialists but too much for others, and thus the question arises whether it is sensible to publish progress reports on individual elements in the form of a series.

H. Nöth [NB 359/217 IE]

The Solvent Extraction of Metal Chelates. By *Jiří Starý*. English edition edited by *H. Irving*. Pergamon Press, Oxford-London-Edinburgh-New York-Paris-Frankfurt 1964. 1st edit. XIV + 240 pp., 46 figs., 31 tables, linen £3.0.0 (about $ 8.30).

The author of this book works in the Department of Nuclear Chemistry of the University of Prague (Czechoslovakia). His book, which is introduced by a foreword by *H. Irving*, Leeds (England), differs in many aspects from other monographs on the analytical applications of extraction of chelates and even supplements them; it is therefore most useful.

The work opens from a very general standpoint, the first few chapters dealing with the theory of metal chelates and their partition between water and an organic solvent (50 pp.); the properties and possible applications of numerous chelating agents are then described (128 pp.), and in conclusion, methods for the selective extraction of about 50 metals are given in highly condensed form (16 pp.).

A long list of publications (25 pp.) contains numerous references which are not easily accessible in the western world. Despite its length, the list is not exhaustive; for instance, no mention is made of the dialkyl phosphates, although the corresponding dithio compounds are discussed. The theoretical section is difficult to read and is not well written from a didactic point of view, for often important premises for derivations, tables, and figures are not mentioned. Apart from these flaws, the worker in this field will find a great many incentives in this book.

Werner Fischer [NB 404/262 IE]

New Biochemical Separations. Edited by *A. T. James* and *L. J. Morris*. van Nostrand, London-Toronto-New York-Princeton, N. J., 1964. 1st edit., IX + 424 pp., numerous illustrs. and tables, linen £4.4.0 (about $ 11.75).

The two editors, who are members of the Unilever research team at Sharnbrook (England), here wish to give a survey of the methods of separating some natural products that have been newly developed or decisively improved in the past decade. The authors generally have participated actively in these advances. The result is a vivid, up-to-date presentation by competent authorities. Obviously the topics dealt with have been stringently limited, and hence a readily surveyable, well organized presentation of the material has resulted.

The work begins with a review of the methods that can be used to detect radioactively labelled substances emerging from gas chromatographic separations. Each of the remaining 16 chapters – of varying length – deals mainly with the application of a method of separation to a single class of substances. The main emphasis is placed on applications of gas chromatography (A), thin-layer chromatography (B), and gel filtration (C) to the separation of steroids (methods A and B), alkaloids (A and B), carbohydrates (A and C), fatty acids (A), gall acids (A and B), amino acids (A, B, and C), proteins and peptides (B and C), triterpenes (B), and lipids (B). New separatory methods have led to great advances in the chemistry of fats and allied compounds, and hence a separate chapter on paper and partition chromatography is devoted to each of these classes of substances. In keeping with the interests of the editors, fats and allied materials receive the closest attention of all the compounds in the book.

The book has 148 figures, including numerous reproductions of original thin-layer chromatograms, and 76 tables and is therefore of exquisite appearance. It contains a wealth of information on the behavior of biologically interesting substances during the separatory operations mentioned above, well expressed in numerical or graphic form. Perhaps only the title of the book is somewhat inaccurate; perhaps it ought to have been called "A Selection of Modern Methods for Separating Natural Products".

H. Determann [NB 371/229 IE]

An Introduction to the Chemistry of Carbohydrates. By *R. D. Guthrie* and *J. Honeyman*. Claredon Press, Oxford 1964. 2nd edit., VI + 144 pp., linen £1.1.0 (about $ 3.–).

This little textbook maintains the aim of its first edition, which appeared 16 years ago, namely to give an introduction to the chemistry of carbohydrates in a highly compact form. The original organization of the material has been preserved, but every chapter has been brought fully up to date. New sections are included on the conformations of monosaccharides and the application of physical methods.

The didactically skillful development of the subject matter and the clear and concise style have resulted in a presentation which is easy to read, despite the vast amount of factual information it contains, particularly because the graphic representation of the formulae given are in accordance with the latest developments in this field. An especially valuable feature of the book is that it deals with the principles of conformation, not as usual in a separate chapter, but by introducing them in the ordinary text whenever they become of importance for the stereochemical interpretation of the course of a reaction.

The book can be recommended not only to students as an introductory text, but also to those who wish to inform themselves rapidly on the latest developments in carbohydrate chemistry.

F. W. Lichtenthaler [NB 376/234 IE]

Comprehensive Biochemistry. Edited by *M. Florkin* and *E. H. Stotz*. Vol. 12: Enzymes. General Considerations. Section III: Chemistry of Biological Compounds. Elsevier Publishing Co., Amsterdam-London-New York 1964. 1st edit., XII + 304 pp., numerous illustrs. and tables, linen DM 47.50 (about $ 12.00).

The third section of this comprehensive textbook [1] contains discussions of the mechanisms of enzymatic reactions. In accordance with the overall planning of the book, here too individual facts are reported only after the regularities derived from them have been outlined. Because of this deductive presentation, many facts may be missed by some readers, but this system has the great advantage that widely dispersed results are dealt with together. This offers great benefits, particularly in the discourse on the relationships between structure and reactivity. The first volume contains fundamental chapters explaining general aspects of enzymatic reactions. However, some of the text requires concentrated study and demands considerable previous knowledge – but not more than may be reasonably expected for use of a text book with the aims of the present series. In addition, the abstract nature of the deductive presentation is comfortably modified by intermittent sections on methods and their biochemical applications, together with instructive examples. in the fundamentals of the modes of reaction of enzymes in The firm foundations of modern enzymology are to be found aspects such as their stereochemistry (*Hirschmann*) and their reactivities, considered from the thermodynamic (*Wurmser-Banerjee*) and kinetic (*Dawes*) viewpoints, which are treated here with equal elegance. Redox potentials (*Wurmser-Banerjee*) and the effects of complex formation with metals on enzymatic activity (*Vallee*) are important topics which are given individual treatment. The connections between enzyme structure and function are particularly well investigated for ribonuclease and chymotrypsin and are reviewed in exemplary fashion by *Hirs*. His chapter simultaneously illustrates the methods of acquiring and interpreting kinetic data, which were discussed on a general basis in the preceding sections. This coordination is particularly fortunate. Although we are still far from knowing any common denominator for enzymatic functions, a few general theories of enzymatic catalysis can be conceived (*Wilson*); these include the hypothesis of induced fit, the formation of a reactive transition state in the enzyme-substrate complex (*Reiner*), and the course of reactions in enzyme-bonded steps. All the sections give a thorough, stimulating interpretation on a high standard and by clever overlapping cover the entirety of this vast field. Both the authors and editors have again done a good job and developed the tools for following the modern developments in molecular and dynamic biochemistry.

New Products of Reaction of Organometallic Compounds with Sulfur, Selenium, Tellurium, and Phosphorus

BY DR. HERBERT SCHUMANN AND PROF. DR. MAX. SCHMIDT

INSTITUT FÜR ANORGANISCHE CHEMIE DER UNIVERSITÄT WÜRZBURG (GERMANY)

Bond fission of molecular sulfur, selenium, and tellurium by lithiotriphenylmetal compounds (of Ge, Sn, Pb) is summarized. The products are suitable as starting materials for synthesis of new "ether analogues". Transphenylation with tetraphenylstannane is interpreted as a high-temperature variant of the usual fission of chalcogen molecules by nucleophilic reagents. In principle, transphenylation can be applied also to other elements, as is illustrated for phosphorus. In the syntheses achieved, many of the tin-phosphorus compounds arising as intermediates can be isolated.

I. Introduction

The strikingly easy fission, by nucleophilic reagents, of sulfur-sulfur bonds in compounds ("modifications") of sulfur with itself and in sulfane chains has been ascribed by us to a marked tendency of the sulfur atom to expand its octet, thereby forming multiple bonds between sulfur atoms. The stability and behavior of such sulfur-sulfur bonds, and the appearance of favored electrophilic centers in sulfur chains, are readily interpreted in terms of this assumption of a delocalized electron system[1]. This hypothesis provides a simple explanation of the formation of fission products of sulfur $(S)_x$ by nucleophilic reagents such as SO_3H^-, SH^-, SR^-, CN^-, $RC\equiv C^-$, NO_2^-, $HAsO_3^{2-}$, NR_2^-, *etc.* Such fission reactions of S–S bonds have not only analytical but also considerable preparative importance; they can be rationally extended to the sulfur homologues selenium and tellurium.

Among the particularly good "thiophilic" reagents are carbanions such as occur in organolithium and Grignard compounds. Molecular sulfur reacts spontaneously with these carbanions, yielding mercaptides or thiophenoxides. We asked ourselves whether analogous reactions could be carried out with compounds that are formally derived from organometallic compounds in that the metalated carbon atom is replaced by germanium, tin, or lead. The expected covalent chalcogen compounds should be very reactive and should open a simple preparative route to the little investigated field of organometallic derivatives (with germanium, tin, or lead) of chalcogens.

II. Chalcogen Fission by Lithiotriphenyl-germane, -stannane, and -plumbane

The formation of formal analogues of triphenylmethyllithium by replacement of the tertiary carbon atom by Ge, Sn, or Pb is illustrated by the well-known lithiotriphenylstannane[2–19]. This is best prepared by treat-

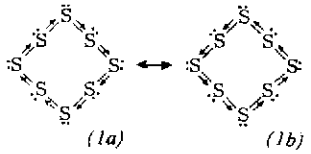
ing chlorotriphenylstannane with an excess of lithium in tetrahydrofuran [18,19]; the primary product, formed according to Eq. (a), is hexaphenyldistannane, which is then more slowly cleaved according to Eq. (b).

$$2\,(C_6H_5)_3SnCl + 2\,Li \rightarrow (C_6H_5)_3Sn{-}Sn(C_6H_5)_3 + 2\,LiCl \quad (a)$$

$$(C_6H_5)_3Sn{-}Sn(C_6H_5)_3 + 2\,Li \rightarrow 2\,(C_6H_5)_3SnLi \quad (b)$$

Germanium [20] and lead compounds [21] can be similarly obtained. These reactive "metal organyls" R_3MLi have not yet been isolated in pure free form. However, their solutions in tetrahydrofuran can be readily obtained on removal of lithium chloride and the excess of lithium under dry nitrogen. Even under mild conditions the compounds R_3MLi (M = Ge, Sn, or Pb) react exactly like carbanions with sulfur, selenium, and tellurium in tetrahydrofuran, moisture being excluded. This reaction [see Scheme (c)] can be illustrated for tin/sulfur. The bonding in the S_8 ring is symbolized as in structures *(1a)* and *(1b)*. One of the electronically equivalent but



(1a) *(1b)*

still electrophilic sulfur atoms in the S_8 ring is attacked by, *e.g.*, the nucleophilic $SnR_3^{\ominus}$ anion (R = C_6H_5), whereby ring cleavage leads to the octasulfane derivative *(2)*. This unsymmetrical anion *(2)* is then degraded

$$R_3Sn{-}S{-}S{-}S{-}S{-}S{-}S{-}S{-}S^{\ominus} \rightarrow R_3Sn{-}S{-}S_5{-}S^{\ominus} + R_3SnS^{\ominus}$$
(2) $+ {}^{\ominus}\overset{\uparrow}{S}nR_3$

$$R_3Sn{-}S{-}S_5{-}S^{\ominus} \rightarrow R_3Sn{-}S{-}S_4{-}S^{\ominus} + R_3SnS^{\ominus}$$
$+ {}^{\ominus}\overset{\uparrow}{S}nR_3$

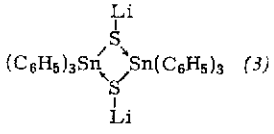
etc. (c)

$$R_3Sn{-}S{-}S^{\ominus} \rightarrow R_3SnS^{\ominus} + R_3SnS^{\ominus}$$
$+ {}^{\ominus}\overset{\uparrow}{S}nR_3$

$$S_8 + 8\,LiSnR_3 \rightarrow 8\,Li{-}S{-}SnR_3$$

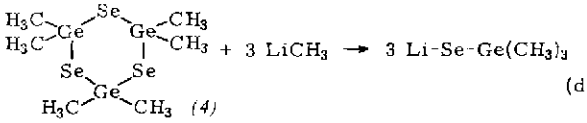
stepwise by an S_N2 mechanism: the ion $SnR_3^{\ominus}$, acting as nucleophile, attacks the electrophilic center, namely the terminal S atom with its formal octet [the negative charge is equally distributed over the $R_3Sn{-}(S)_x{-}$ chain], and ejects the weaker nucleophilic group $R_3SnS_{x-1}^{\ominus}$. In each cleavage step, down to x = 1, a new (terminal) electrophilic center is created. The first step – ring-opening – is rate-determining since it involves a formal electron decet; the further steps involve formal octets.

Selenium and tellurium react in principle like sulfur. Thus, solutions of R_3MXLi (R = C_6H_5; M = Ge, Sn, or Pb; X = S, Se, or Te) [19,21–24] in tetrahydrofuran can be obtained fairly easily. As expected, compounds R_3MXLi are sensitive to solvolysis, oxidation, and elevated temperature (condensation: $2\,R_3MSLi \rightarrow R_3M{-}S{-}MR_3 + Li_2S$) and thus can be isolated only with difficulty, if at all. Up to the present, only triphenyltin-lithium sulfide has been actually isolated [19]; it forms colorless crystals and is dimeric in benzene, probably forming a four-membered ring *(3)*. Isolation is not necessary if the compounds R_3MXLi are to be used for syntheses that can be carried out in tetrahydrofuran (see Section III).



(3)

It has not yet been possible to synthesize trimethylgermanyl-lithium chalcogenides corresponding to t-butyl mercaptides by the above procedure because the lithiotrimethylgermane, $(CH_3)_3GeLi$, needed as starting material is not yet available. *Ruidisch* [25] prepared trimethylgermanyl-lithium chalcogenides in a different way: dichlorodimethylgermane and triethylammonium sulfide in benzene solution afford the cyclic, trimeric dimethylgermanium sulfide; the corresponding selenide, $[(CH_3)_2GeSe]_3$ *(4)*, is formed from sodium selenide [26]. These cyclic inorganic compounds are smoothly and quantitatively cleaved by methyl-lithium, yielding the desired "mercaptides" according to reaction (d).



(d)

(4)

$(CH_3)_3GeSLi$ [25] (decomp. ≈ 85 °C) and $(CH_3)_3GeSeLi$ [27] (decomp. ≈ 65 °C) can be obtained as colorless solids. $(C_6H_5)_2SnCl_2$ reacts with lithium, in principle like

$(C_6H_5)_3SnCl$, yielding $(C_6H_5)_2SnLi_2$ (not isolated), which with sulfur affords the unusually sensitive and reactive $(C_6H_5)_2Sn(SLi)_2$ [28].

III. Condensation of Chalcogen Cleavage Products with Organylmetal Halides

As expected, the organylmetal chalcogenides described above (which, however, were not all isolated in substance) are very reactive. Their interesting properties can be illustrated by their behavior with triorganylmetal chlorides of the germanium, tin, and lead series. In solution they react readily, forming symmetrical and unsymmetrical formal analogues of thio-, seleno-, and telluro-ethers according to reaction (e).

$$R_3MX{-}Li + Cl{-}M'R_3 \rightarrow LiCl + R_3M{-}X{-}M'R_3 \qquad (e)$$

$R = C_6H_5$ or CH_3; M, M' = Ge, Sn, or Pb; X = S, Se, or Te

This reaction opens a simple preparative route to a class of compounds of which only a few representatives have been synthesized, by a considerably more circuitous method. No covalent germanium-, tin-, or lead-tellurium compound has been described previously. Table 1 summarizes the compounds obtained by reaction (e).

Other reactive halogen compounds behave analogously, as shown by the synthesis of *SS*-diphenyltin bis(thiobenzoate) *(5)* [28].

$$(C_6H_5)_2Sn(SLi)_2 + 2\ Cl{-}C(=O){-}C_6H_5 \rightarrow 2\ LiCl + C_6H_5{-}C(=O){-}S{-}Sn(C_6H_5)_2{-}S{-}C(=O){-}C_6H_5 \quad (5)$$

The hexaphenyl compounds listed in Table 1 all crystallize readily; the sulfur compounds are colorless, the selenium compounds have a yellow tinge, and the tellurium compounds are yellow. They are readily soluble in anhydrous organic solvents such as benzene, dioxane, tetrahydrofuran, and chloroform. Particularly noteworthy is their thermal stability and, in many cases, their resistance to solvolysis.

Table 1. "Ether analogues" prepared by double decomposition according to reaction (e).

Final statements cannot yet be made about the bonding in molecules of the type $R_3M{-}X{-}MR_3$. Help should come from X-ray determination, now in progress, of the valence angles at the chalcogen atom, about which information will also be provided by further evaluation of the infrared spectra [34] – these are almost identical in the NaCl region. Skeletal vibrations of the sulfur compounds occur between 250 and 400 cm^{-1} (CsBr region); their assignment is given in Table 2. Corresponding bands are to be expected at still longer wavelengths for the Se and Te compounds.

The stability of Si–O–Si bonds, which is so important in inorganic Nature, is ascribed to a noteworthy contribution by $(p{-}d)_\pi$ bonding between oxygen and

silicon. If the bridging oxygen atom of disiloxanes is replaced by the larger sulfur atom the stability decreases drastically: Si–S bonds are extremely susceptible to hydrolysis. However, study of the new chalcogen derivatives $R_3M–X–MR_3$ of Table 1 shows that the stability increases on simultaneous increase in the size of the bridgehead atom M and the bridging atom X: the grouping Ge–S–Ge is more stable than Ge–O–Ge, although Ge–Se–Ge is, on the contrary, very sensitive to hydrolysis. Again, Sn–Se–Sn compounds do not react with water and can even be recrystallized from alcohol. Thus the relations between Sn–Te–Sn and Sn–Se–Sn groupings are similar to those between Si–S–Si and Si–O–Si groupings. In consequence the Pb–Te–Pb grouping is again very stable; the hexaphenyl derivative is not attacked even by boiling water.

Analogous observations were made for unsymmetrical "ethers." For example, Ge–Se–Pb and Sn–Te–Pb linkages resist hydrolysis, whereas compounds with Ge–Se–Ge and Sn–Te–Sn groups can be handled only in an anhydrous atmosphere. The hexamethyl compounds have similar properties.

Ascribing these findings to the $(p–d)_\pi$ constituents of the M–X–M linkages for the heavier elements (given suitable size relations in M:X), although seeming at first sight a plausible interpretation, is certainly too primitive because d-the very small energy contribution from overlap of of orbitals of the heavier atoms.

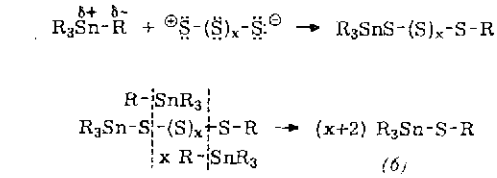
IV. Phenylation of Chalcogens by Tetraphenylstannane

Bond fission of molecular sulfur by nucleophilic reagents occurs under quite mild conditions [1]. Relations are apparently quite different if tetraphenylstannane is treated with sulfur. $Sn(C_6H_5)_4$ is one of the most stable organometallic compounds; it can, for example, be heated for several hours at about 500 °C (b.p. 425 °C/760 mm) without decomposing. Nevertheless it reacts with sulfur at as low a temperature as 200 °C. As early as 1929 *Bost* and *Borgstrom* [35] observed that diphenyl sulfide is thus formed, but, remarkably, they did not study the fate of the tin in this reaction.

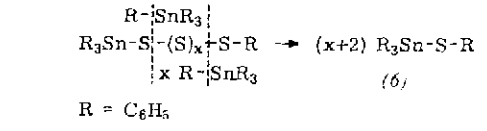
We have found [36] that the reaction takes place in a sealed tube at about 200 °C, according to the overall equation (f). At this temperature, SnR_4 is polarized by

$$3\ Sn(C_6H_5)_4 + 6\ S \rightarrow 3\ S(C_6H_5)_2 + [(C_6H_5)_2SnS]_3 \qquad (f)$$

the "polar solvent" sulfur [*] in such a way ($R_3\overset{\delta+}{Sn}–\overset{\delta-}{R}$) that a phenyl anion is foreshadowed and then, as a nucleophilic reagent, degrades the sulfur chain as shown in reactions (g). The degradation there outlined – without statement of the electron distribution in the sulfur chain – occurs analogously to Scheme (c). The triphenyltin thiophenoxide *(6)* [36] to be expected from reactions (g) is unstable at 200 °C and can therefore not be isolated. The degradation thus proceeds further in accordance with Scheme (h).

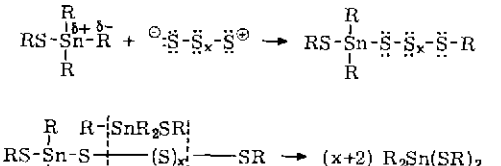


(g)

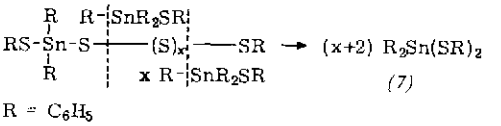


(6)

$R = C_6H_5$



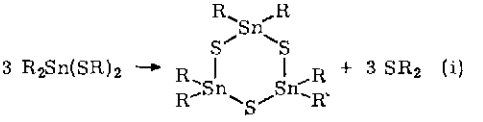
(h)



(7)

$R = C_6H_5$

Diphenyltin dithiophenoxide *(7)*, which has been prepared by a different route [36], decomposes appreciably below the reaction temperature, eliminating diphenyl sulfide to give diphenyltin sulfide (formally analogous to the silico-ketones = silicones) which is not stable as monomer and yields the trimer *(7)*.



(i)

(8)

Good yields can be obtained of the products of sulfur-degradation, during which process the degrading agent is first formed from a reaction partner that has a polarizing action at high temperatures. Tin-sulfur six-membered rings are very stable; they are not attacked by boiling water. These compounds crystallize readily and are soluble in many organic solvents. If $Sn(C_6H_5)_4$ is treated with a sufficient excess of sulfur, further phenyl anions are removed and high-polymeric products are formed in which rings *(8)* are linked by sulfur bridges [37]. A temperature in excess of 220 °C leads – in principle by the same mechanism – to complete dephenylation of the tin compound, with formation of diphenyl sulfide and alloy-like "tin sulfides" which are also obtainable from the cyclic compounds *(8)* and the higher-polymeric subsequent products:

$$(R_2SnS)_3 + 3x\ S \rightarrow 3\ SnS_x + 3\ R_2S$$

(8)

Tetrabutylstannane – and the alkyl derivatives in general – react with sulfur even at lower temperatures. At as low as approximately 150 °C, reaction (k) occurs (for reaction of organyltin chlorides with sulfur see [38]).

$$3\ (C_4H_9)_4Sn + 6\ S \rightarrow [(C_4H_9)_2SnS]_3 + 3\ (C_4H_9)_2S \qquad (k)$$

[35] *R. W. Bost* and *P. Borgstrom*, J. Amer. chem. Soc. *512*, 192 (1929).

[36] *M. Schmidt*, *H. J. Dersin*, and *H. Schumann*, Chem. Ber. *95*, 1428 (1962).

[*] Above the viscosity maximum at *ca.* 160 °C a sulfur melt has clearly a polarizing action, owing to the presence of some $^{\oplus}S–(S)_x–S:^{\ominus}$.

[37] *M. Schmidt* and *H. Schumann*, Chem. Ber. *96*, 462 (1963).

[38] *H. Schumann* and *M. Schmidt*, Chem. Ber. *96*, 3017 (1963).

Because of the lesser polarity of their "metal"-carbon bond, tetraphenyl derivatives of the lighter analogues of tin react only at higher temperatures [*]; the intermediates are no longer stable. $Ge(C_6H_5)_4$ affords GeS_x and diphenyl sulfide above 270 °C [39], and $Si(C_6H_5)_4$ affords SiS_x above 380 °C [39]. The higher reactivity of the n-butyl compounds, on the other hand, still permits isolation of trimeric, cyclic dibutylgermanium sulfide [analogous to *(8)*] and $(C_4H_9)_3Si-S-Si(C_4H_9)_3$, in addition to $(n\text{-}C_4H_9)_2S$, these products being formed by transalkylation [39].

Selenium is also phenylated by tetraphenyltin at about 200 °C. Triphenyltin selenophenoxide *(9)* [**] is isolated in good yield as intermediate [40]. Above 240 °C

$$x\,(C_6H_5)_4Sn + (Se)_x \rightarrow x\,(C_6H_5)_3Sn\text{-}SeC_6H_5 \quad (9)$$

diphenylselenium (and some R_2Se_2) are formed alongside tin selenides, and above 270 °C also selenanthrene [cf. formula *(11)*]. $Sn(C_4H_9)_4$, however, reacts at 200 °C with selenium [40] according to Equation (l), analogously

$$3\ R_4Sn + 6\ Se \rightarrow \text{(10)} + 3\ R_2Se \quad (1)$$

R = C_4H_9

(10)

to sulfur. The corresponding phenyl derivative was obtained on treatment of $R_3Sn-SeLi$ with R_2SnCl_2 [23], in accordance with reaction (m).

$$2\ R_3Sn\text{-}SeLi + R_2SnCl_2 \xrightarrow[-2\ LiCl]{} R_3Sn\text{-}Se\text{-}\underset{\displaystyle R}{\overset{\displaystyle R}{Sn}}\text{-}Se\text{-}SnR_3$$

$$\rightarrow \tfrac{1}{3}\,(R_2SnSe)_3 + R_3Sn\text{-}Se\text{-}SnR_3 \quad (m)$$

R = C_6H_5

Reaction between tellurium and tetraphenyltin sets in, slowly, only above 240 °C; after several days it leads to good yields of diphenyltellurium and tin tellurides [41]. If the temperature is raised above 310 °C, there is formed the previously undescribed and remarkably air-sensitive telluranthrene *(11)* (m.p. 188–190 °C), as well as benzene.

$$(C_6H_5)_4Sn + 2x\ Te \rightarrow SnTe_{2x-2} + 2\ C_6H_6 + \text{(11)}$$

(11)

[*] $Pb(C_6H_5)_4$ probably reacts by a free-radical mechanism [39].

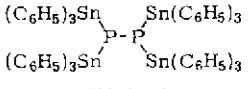
V. Phenylation of Phosphorus by Tetraphenylstannane

The hypothesis developed [1] for element-element bonding in sulfur chemistry is valid equally for other elements from the second Period onwards, and for those of the third and fifth main Group. Compounds of these elements with themselves act electrophilically, as do the chalcogens (cf. the reaction of P_4 with Grignard reagents discovered independently by *Rauhut* and *Semsel* [42] and by us [33]). Thus phosphorus should, like sulfur, react with tetraphenylstannane at high temperatures. The tervalency of phosphorus, of course, complicates matters and makes a direct comparison more difficult. In practice, elementary phosphorus reacts with tetraphenylstannane in a sealed tube above about 235 °C. At higher temperatures the end products are tin phosphide and triphenylphosphine, according to reaction (n) [43, 44].

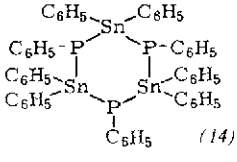
$$3\ Sn(C_6H_5)_4 + 4\ P_n \rightarrow Sn_3P_{n-4} + 4\ P(C_6H_5)_3 \quad (n)$$

(The triphenyl derivatives of As and Sb are also readily available by this process [44].) If the temperature is kept between 235 and 250 °C and the ratio $P:Sn(C_6H_5)_4$ is varied, an intermediate product of the degradation of phosphorus by carbanions can be isolated: *(12)* (m.p. ≈110 °C, yellow, spontaneously inflammable in air), *(13)* (yellow oil, extremely sensitive to oxidation), *(14)* (m.p. 66 °C, colorless).



(12) [45]

(13) [46]



(14) [45]

Covalent tin-phosphorus compounds which, with two exceptions [47, 48], were previously unknown, generally are extremely sensitive to oxidation, which greatly increases the difficulty of isolating them from the complex reaction mixture. The products of oxidation of the tin phosphines occurring in these mixtures can, however, be obtained, cleaved with caustic soda into characteristic fragments, and thus analysed [*]. Table 3 shows the oxidized decomposition products obtained.

[*] Tin was determined [49] by X-ray emission analysis, alongside photometrically determined phosphorus.

Fragments	Structural units of: tin phosphonate	Structural units of: original stannylphosphine
R_2SnO $RP(O)(OH)_2$		$RSn(O)OH$ H_3PO_4		SnO_2 $R_2P(O)OH$ H_3PO_4		$RSn(O)OH$ $R_2P(O)OH$ $RP(O)(OH)_2$		2 $RSn(O)OH$ 3 $RP(O)(OH)_2$		3 $RSn(O)OH$ 3 $RP(O)(OH)_2$ H_3PO_4		
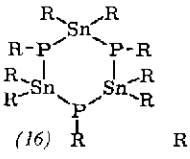
VI. Syntheses of Covalent Tin-Phosphorus Compounds

The above "direct synthesis" having shown that a variety of previously unknown tin-phosphorus compounds can exist, we wished to prepare such compounds systematically. Only phenyl groups were used to render the tin and phosphorus inert. Two series of compounds appeared suitable as models. The first is derived from triphenylphosphine by replacement of one, two, or all three phenyl groups by triphenyltin. The second is derived in the reverse direction from tetraphenylstannane, by replacement of one, two, three, or four phenyl groups by diphenylphosphino groups.

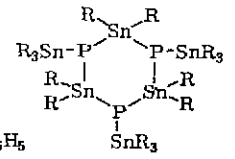
The first series of compounds is formed in tetrahydrofuran in good yield on reaction of lithiotriphenylstannane with appropriate phosphorus chlorides according to reaction (o)[50]. The colorless crystalline products *(15)* dissolve readily in anhydrous organic solvents.

$$n\,(C_6H_5)_3SnLi + (C_6H_5)_{3-n}PCl_n \rightarrow [(C_6H_5)_3Sn]_nP(C_6H_5)_{3-n} + n\,LiCl \quad (o)$$
(15)

However, the products *(15)* arise only if the phosphorus chloride is present in excess until the end of the reaction. Otherwise, the primary reaction products are cleaved by the strongly nucleophilic triphenyltin anion. In this way, although the reaction mechanism is not yet finally clarified, the cyclic compounds *(16)* (m.p. 60 °C)[49,50] and *(17)* (m.p. 101 °C)[50] are obtained in satisfactory yields alongside hexaphenyldistannane, triphenylphosphine, and lithium chloride.



(16) R = C_6H_5



The second series of compounds *(18)*[51] is formed in good yield by reaction (p). (Use of alkali-metal diphenylphosphides in place of the free phosphine leads to complications[52].) The compounds *(18)*, like the tin phosphines described above, crystallize readily and are soluble in organic solvents. Table 4 presents the organylstannylphosphines prepared by reactions (o) and (p) or, in the meanwhile, by other authors analogously[53] or from stannylamines[54].

$$(C_6H_5)_{4-n}SnCl_n + n\,HP(C_6H_5)_2 + n\,(C_2H_5)_3N \rightarrow (C_6H_5)_{4-n}Sn[P(C_6H_5)_2]_n + n\,(C_2H_5)_3N{\cdot}HCl \quad (p)$$
(18)

Table 4. Monomeric organylstannylphosphines.

Organylstannylphosphine	M.p. [°C]	B.p. [°C/mm]	Ref.
$(CH_3)_3Sn-P(C_6H_5)_2$		142/0.7	[53, 54]

$(C_2H_5)_3Sn-P(C_6H_5)C_2H_5$		100/0.2	[53]
$(C_2H_5)_3Sn-P(C_2H_5)_2$		70/0.2	[53]
$(C_3H_7)_3Sn-P(C_6H_5)_2$		177/0.6	[53]
$(C_3H_7)_3Sn-P(C_6H_5)(C_2H_5)$		126/0.3	[53]
$(C_4H_9)_3Sn-P(C_6H_5)_2$	96	192/0.6	[51, 53]
$(C_6H_5)_3Sn-P(C_6H_5)_2$	130		[50, 51, 53]
$(CH_3)_2Sn[P(C_6H_5)_2]_2$	114		[51]
$(C_4H_9)_2Sn[P(C_6H_5)_2]_2$	102		[51]
$(C_6H_5)_2Sn[P(C_6H_5)_2]_2$	80		[51, 53]
$C_6H_5Sn[P(C_6H_5)_2]_3$	117		[51]
$Sn[P(C_6H_5)_2]_4$	107		[51]
$[(C_6H_5)_3Sn]_2P-C_6H_5$	150		[50]
$[(C_6H_5)_3Sn]_3P$	201		[50]

This process is suitable also for the preparation of analogous germanium and lead compounds, *e.g.*, $(C_2H_5)_3Ge-P(C_6H_5)_2$ (b.p. 146 °C/10^{-3} mm)[55], $(C_6H_5)_3Ge-P(C_6H_5)_2$ (m.p. 108 °C)[33], $[(C_6H_5)_3Ge]_3P$ (m.p. 192 °C)[33], and $(C_6H_5)_3Pb-P(C_6H_5)_2$ (decomp. 100 °C)[56].

Covalent tin-phosphorus compounds are sensitive to oxygen (they do not react with oxygen-free water). The degree of this sensitivity depends considerably on the nature of the "shielding" organic radicals. Thus alkyl derivatives are, in general, less stable than the phenyl analogues. Tetrakis(diphenylphosphino)stannane on

[56] *H. Schumann, P. Schwabe,* and *M. Schmidt,* J. organomet. Chemistry *1,* 366 (1963/64).

the one hand and tris(triphenylstannyl)phosphine on the other react only slowly with air. The cyclic compounds are considerably more sensitive to oxygen. Unsymmetrical stannylphosphines can, however, be handled only in an oxygen-free atmosphere [*]. The oxidation occurs, in principle, according to reaction (q), either

$$\gtrless Sn\text{-}P\lessgtr + O_2 \rightarrow \gtrless Sn\text{-}O\text{-}\overset{\overset{O}{\uparrow}}{P}\lessgtr \qquad (q)$$

simply in air or, always quantitatively, with hydrogen peroxide in alcohol [50,51].

Infrared spectra [33] show that, with an excess of oxygen, one O atom first adds to the lone electron pair of phosphorus. Suppositions that this is the only and final reaction step [57] are contradicted by the experimental facts. It seems that the structure *(19a)* rearranges to *(19b)* in a reversal of the Arbusov rearrangement. Then a further oxygen atom adds to the phosphorus according to reaction (r), giving *(19c)*. The oxidation products of monomeric organylstannylphosphines are listed in Table 5.

$$\underset{(19a)}{\overset{\overset{O}{\uparrow}}{\gtrless Sn\text{-}P}} \rightarrow \underset{(19b)}{\gtrless Sn\text{-}O\text{-}\ddot{P}} \xrightarrow{\frac{1}{2}O_2} \underset{(19c)}{\gtrless Sn\text{-}O\text{-}\overset{\overset{O}{\uparrow}}{P}\lessgtr} \qquad (r)$$

Table 5. Oxydation products of organylstannylphosphines.

The new phosphinic esters can be cleaved, like the parent stannylphosphines, by hot sodium hydroxide solution to characteristic, readily detected fragments [50,51].

Questions about the nature of the (certainly covalent) bonding between the metal and phosphorus cannot yet be answered. Physical studies (infrared, Raman, crystal structure) should provide relevant information. Any considerable contribution from $(p{-}d)_\pi$ bonding, as required between Sn and P [53] and indeed between Sn and N [58] (2p and 5d orbitals), seems to us to be excluded by our results and by infrared and N.M.R. investigations. The same applies to the arsenic, antimony, and bismuth compounds [59, 60] listed in Table 6,

Table 6. Organylstannyl-, organogermanyl-, and organylplumbylarsines, -stibines, and bismuthines.

The Chemistry of Silicon-Sulfur Compounds

BY DR. DR. A. HAAS

ANORGANISCH-CHEMISCHES INSTITUT DER UNIVERSITÄT GÖTTINGEN (GERMANY)

The preparations, properties, structures, and chemical reactions of silicon-sulfur compounds are reported. The chain structure of the polymeric silicon disulfide is used as a basis from which the various classes of compounds can be derived: cyclothiasilanes, disilyl sulfides, silanethiols, and organothiosilanes. Infrared data and force constants of the Si–S bond are discussed.

Although silicon disulfide was discovered by *Berzelius* as early as 1824, the chemistry of the silicon-sulfur compounds has never attained the importance of *e.g.* the chemistry of the Si-O compounds (silico esters, silicones). There are several reasons for this. In the first place, no practical use has so far been found for compounds containing the Si-S bond; furthermore, these compounds are characterized by a penetrating odor which offers little encouragement to study them. The main reasons for their lack of practical interest are their chemical instability, particularly their sensitivity towards hydrolysis and oxidation, and their tendency not to form high-molecular weight Si-S chains carrying organic substituents or three-dimensional networks.

1. Silicon Monosulfide

Like silicon monoxide, SiS has been detected with certainty only in the gaseous state. At room temperature "SiS" is probably a mixture of silicon and silicon disulfide. Silicon monosulfide is formed in many industrial processes from silicon and substances containing sulfur. The formation of SiS can be used for the desilicification of ores containing silicon [1, 2], *e.g.*:

$$SiO_2 + C + FeS \xrightarrow{1400-1500\,^\circ C} SiS + CO + FeO \qquad (a)$$

If zinc sulfide is used instead of FeS [1], the reaction must be carried out at 1350 to 1400 °C. The silicon monosulfide formed always contains carbon, so that the process is of little preparative value. A product containing no carbon is obtained when ferrosilicon (80% Si) is treated with FeS at 1500 to 1700 °C; reports differ, however, on the properties of this product [3]. *Cambi* [4] used sulfur instead of FeS, and obtained a product that sublimed at 940 to 980 °C and 20 to 30 mm. The substance was yellow below 980 °C, but on prolonged heating above 980 °C was converted into a black form, perhaps a mixture of Si and SiS_2 produced by disproportionation:

$$2\,SiS \rightarrow Si + SiS_2 \qquad (b)$$

An interesting reaction is the formation of SiS when carbon disulfide [5] is passed over finely powdered silicon at 1000 °C. SiS also occurs as a by-product in the production of SiS_2, particularly in reactions of silicon with sulfur [6, 14], and with hydrogen sulfide [7].

SiS is an amorphous powder, which is unstable at room temperature and whose color is variously reported as being yellow, orange-red [6], dark brown [3], and black [4]; the material existing at room temperature probably is a decomposition product of SiS.

The dissociation energy D, the equilibrium interatomic distance r_o, and the force constant k_e have been determined from the ultraviolet spectrum and provide evidence of the existence of SiS in the gas phase: D = 6.47 eV [9] (ground state); D = 147.4 ± 0.3 kcal/mole [12] (ground state); r_o = 1.929 Å [10]; $k_e = 4.94 \times 10^{-5}$ dyne/cm.

Little is known about the chemical properties of SiS. Its greater volatility as compared with SiS_2 [11] and its extreme sensitivity towards hydrolysis are noteworthy. Water decomposes SiS (sometimes explosively) to H_2S and (through several intermediates) SiO_2 [8]. Hydrogen chloride [4] reacts with SiS at 240 to 260 °C with evolution of H_2S and formation of chlorosilanes (presumably trichlorosilane). SiS is decomposed by 30% KOH in accordance with Equation (c) [6].

$$SiS + 2\,OH^- + H_2O \rightarrow SiO_3^{2-} + H_2 + H_2S \qquad (c)$$

2. Silicon Disulfide

Silicon disulfide is at present the most widely studied silicon-sulfur compound. It was first prepared from its elements by *Berzelius*[13] in 1824. There are two principal methods available for the preparation of fairly large quantities of SiS_2:

a) In the method described by *Hämpel* and *v. Haasy*[14], an intimate mixture of finely ground silicon (200 g; 98% Si + 2% Fe) with three times as much finely ground crystalline sulfur (500 g) and BaO_2 (30 g) is placed in a thin-walled iron tube and ignited with a strip of magnesium. The yield is 74%, and the crude product contains 92 to 95% of SiS_2. Sublimation *in vacuo* at bright-red heat gives a chemically pure silicon disulfide; *Malatesta*[15] used a mixture of 4 g of Fe_2O_3 and 1 g of magnesium powder instead of BaO_2.

b) An elegant method has been described by *Schmeisser*, *Müller*, and *Burgemeister*[16] and confirmed by *Behrens* and *Ostermeier*[17]. The thermal decomposition of a mixture of $(C_2H_5S)_4Si$ and sulfur at 200 °C [Equation (d)] yields a very reactive SiS_2, which is completely free from organic impurities. 46 g of SiS_2 is obtained in

$$(C_2H_5S)_4Si + 2\,S \rightarrow SiS_2 + 2\,C_2H_5{-}S{-}S{-}C_2H_5 \qquad (d)$$

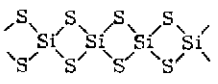
10 min from 136 g of $Si(SC_2H_5)_4$ and 96 g of sulfur. A similar reaction occurs in the absence of sulfur, but the temperatures required in this case are between 250 and 300 °C.

A number of other reactions have also been reported, but these yield only small quantities of SiS_2. They include the reaction of silicon with compounds containing sulfur[11] (*e.g.* H_2S, CS_2) at 1500 °C and the reaction of silicides[18] (*e.g.* Mg_2Si, $CaSi_2$) with sulfur or compounds containing sulfur (*e.g.* H_2S, CS_2, S_2Cl_2). Mg_2Si reacts so vigorously with S_2Cl_2 that this reaction can be used to initiate the reaction of silicon with sulfur. Silicon disulfide is also obtained by the reaction of silicates, carbon, and substances containing sulfur (S, H_2S, CS_2). The addition of carbon is unnecessary when metal sulfides are used[19].

Silverman and *Soulen*[19a] recently treated silicon with sulfur (mixing ratio 1:2.22) at 1430 °C and *ca.* 75000 atm, and obtained a product that appears, from analytical and X-ray studies, to be a new high-pressure modification of SiS_2. However, the authors were unable to rule out the possibility that this is a compound with only approximately the same composition as silicon disulfide[*]. At very high pressures they also obtained yellow and orange to green amorphous glasses which were much more resistant to hydrolysis than SiS and SiS_2.

Physical Properties of SiS_2: M.p. 1090 °C[19]; b.p. 1130 °C[6b]; d^{20} = 2.02 g/cm³[19]; d^{25} = 1.875 ± 0.01 g/cm³[21a].

The X-ray analysis carried out by *Zintl* and *Loosen*[20] showed that silicon disulfide has a fibrous structure, in which each silicon atom is in the center of a distorted tetrahedron formed by four sulfur atoms. The tetrahedra are joined by their edges to form long chains *(1)* in which two silicon atoms are linked *via* two neighboring sulfur atoms, the four atoms together forming a ring.



(1)

The three-dimensional arrangement of the SiS_2 molecules in the lattice is shown in Figure 1. The individual chains are held together by van der Waals forces.

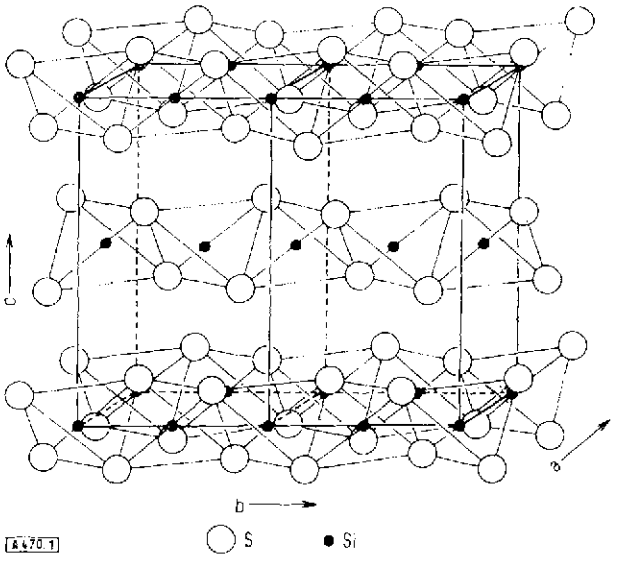


Fig. 1. Two unit cells of polymeric SiS_2 [21].

Space group D_{2h}^{25}-Jcma (Jbma); Z = 4; d_R = 2.066; a = 5.65 ± 0.01; 5.60; b = 5.54 ± 0.01; 5.53; c = 9.57 ± 0.01; 9.55 Å. Distances: Si–Si = 2.765 Å; Si–S = 2.14 Å; S–S = 3.24; 3.5; and 3.62 Å. (These last three values correpond to the S–S distances in the deformed tetrahedra.) The distance between two sulfur atoms in adjacent chains is at least 3.75 Å.

The heat of formation for the reaction

$$Si + 2\,S \rightarrow SiS_2$$

as found from the heat of reaction for the hydrolysis of SiS_2 in 6 N NaOH is $\Delta H_{298} = -59.9 \pm 0.5$ kcal/mole. The value found from the heat of solution of SiS_2 in 20% and 25% hydrofluoric acid is $\Delta H_{298} = -43.2$ kcal/mole.

Phosphorescent SiS_2 was obtained by *Tiede* and *Thimann*[21c] by the sublimation of SiS in an$_2$ atmosphere

of N_2 and in the presence of compounds containing carbon, or directly from SiO_2 and Al_2S_3 in the presence of organic substances (*e.g.* tartaric acid).

The chain structure and the low bond energy of SiS_2 are essential to an explanation of its chemical behavior (cf. Table 1). SiS_2 is stable in dry air, but is hydrolysed

Table 1. Bond energies of various Si—X bonds [21d].

Si—X	E_D [kcal/mole]	Si—X	E_D [kcal/mole]
Si—F	129.3	Si—Br	69.1
Si—O	88.2	Si—S	54.2
Si—Cl	85.7	Si—I	50.9
Si—H	70.4	Si—Si	42.2
Si—C	69.3		

even by traces of moisture. According to *Schwarz* [22], hydrolysis leads to the condensation of four molecules of the initially formed orthosilicic acid to give a cyclic tetrasilicic acid:

$$4\,SiS_2 + 12\,H_2O \rightarrow \left[(HO)_2Si\langle_{O-}\right]_4 + 8\,H_2S \qquad (e)$$

SiS_2 reacts with CO_2 [24] at 350 °C as indicated in Equation (*f*).

$$SiS_2 + 2\,CO_2 \xrightarrow{350\,^\circ C} SiO_2 + 2\,S + 2\,CO \qquad (f)$$

SiS_2 is reduced by carbon monoxide [23] to SiS. SiS_2 is stable towards hydrogen [25] and is insoluble in organic solvents such as CCl_4 or C_6H_6 [20].

The heavy metal thiosilicates Cu_8SiS_6 [25a], Ag_8SiS_6, $Ag_6Si_2S_7$ [*], $Pb_3Si_2S_7$, $Tl_8Si_3S_{10}$, and $Tl_2Si_4S_9$ [25b] have been prepared by the fusion of SiS_2 or silicon and sulfur with metal sulfides. Investigations on the system PbS/SiS_2 showed that only a ternary phase of the composition Pb_2SiS_4 exists between 800 and 1100 °C. The black platelets of this substance have a metallic luster; they are very hygroscopic, and crystallize in a monoclinic structure (space group = C_2^5h–$P2_1$; a = 6.50 Å; b = 6.65 Å; c = 17.68 Å, β = 115 °5′; Z = 4).

The alkali metal [**] and alkaline earth thiosilicates Li_2SiS_3, Li_4SiS_4, Mg_2SiS_4, Ca_2SiS_4, $CaSiS_3$, and $CaSi_2S_5$ were first prepared by *Weiss* and *Rocktäschel* [25d], by the reaction of the corresponding metal silicides with sulfur at high temperatures. They are generally white crystalline powders, which are rapidly hydrolysed in moist air, with the evolution of H_2S. Ca_2SiS_4 is very similar to Mg_2SiS_4: both crystallize in the orthorhombic system and contain isolated SiS_4 tetrahedra [***]. Li_2SiS_3 also crystallizes in the orthorhombic system, but like the corresponding oxygen silicate, consists of infinite one-dimensional SiS_3^{2-} chains.

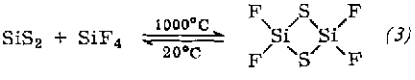
3. 1,3,2,4-Dithiadisiletanes

The 1,3,2,4-dithiadisiletanes are directly derived from the fiber structure of the polymeric silicon disulfide. Partial cleavage of the Si-S bonds in *(1)*, *e.g.* with alcohol, yields low-molecular weight compounds in which the four-membered ring that forms the basic unit in SiS_2 is still retained. The free valences may be saturated by halogens, amino groups, or organic residues.

(2)

a) Tetrafluoro-1,3,2,4-dithiadisiletane

Whereas SiF_4 reacts with SiO_2 to form fluorosiloxanes [26] (main product $F_3SiOSiF_3$), *Gutmann*, *Heilmayer*, and *Utvary* [27] obtained tetrafluoro-1,3,2,4-dithiadisiletane *(3)* by the reaction of SiF_4 with SiS_2 at 1000 °C in a circulating apparatus. Heat of vaporization = 7400 cal/mole; Trouton's constant = 29.02; b.p. −18 °C; m.p. −80 °C. At 20 °C, compound *(3)* decomposes completely into the starting materials.



(3)

b) Tetrachloro-1,3,2,4-dithiadisiletane

Tetrachloro-1,3,2,4-dithiadisiletane *(4)* was obtained by *Besson* [28] on heating S_2Cl_2 and silicon to red heat in a stream of chlorine, or from chlorine and silicon disulfide. Higher yields of *(4)* are obtained if hydrogen sulfide and silicon tetrachloride in constant circulation are

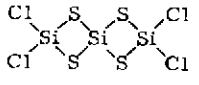
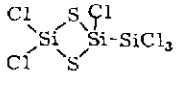
reacted at weak red heat [31]. On cooling, *(4)* crystallizes out as colorless prisms. It can be recrystallized from CS_2 in the absence of moisture.

According to *Etienne* and *Kullmann* [32], $SiCl_4$ condenses with H_2S in the presence of organic bases to form *(4)*. The formula *(4)* given by these authors is based on molecular weight determinations. Doubt has been cast on this conclusion by *Schumb* and *Bernard* [33], who thought that they had isolated an "octachlorocyclotetrasilthiane". *Panckhurst*, *Wilkins*, and *Craighead* [34] repeated the reaction at 700 to 1100 °C and confirmed the structure *(4)* [*]. They also obtained high-molecular weight liquid compounds $(SiSCl_2)_n$ by heating *(4)* to 180 °C, but these products could not be identified. When the reaction of SiS_2 with $SiCl_4$ was carried out at 900 °C, the second member of the homologous series $Si_nS_{2n-2}Cl_4$, *i.e.* $Si_3S_4Cl_4$ *(5)*, was obtained in addition to *(4)* [34a].

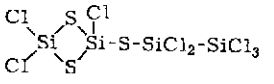


(5)

$(SiCl_2)_x$ reacts with sulfur at 170 to 180 °C to form a mixture from which, in addition to *(4)* and *(5)*, $Si_3S_2Cl_4$ (colorless liquid, b.p. 91.5–93 °C/2.5 mm) and $Si_4S_3Cl_8$ (slightly yellowish oily liquid; b.p. 136–138 °C/0.01 mm) can be isolated. These compounds have the structures *(6)* and *(7)* [34a].



(6)



(7)

Compound *(4)* is sensitive to moisture, and decomposes in accordance with Equation (g).

$$Cl_2SiS_2SiCl_2 + 4\ H_2O \rightarrow 2\ SiO_2 + 4\ HCl + 2\ H_2S \qquad (g)$$

At 220 °C it decomposes into the materials from which it is made. The Si-S bond in *(4)* is cleaved by bromine, with the formation of dibromodichlorosilane, as is expected from the cyclic structure of *(4)*.

$$(4) + 3\ Br_2 \rightarrow 2\ SiCl_2Br_2 + S_2Br_2$$

Tetrachloro-1,3,2,4-dithiadisiletane (m.p. 75 °C, b.p. 92 °C/22.5 mm) forms colorless prisms, which are soluble in $SiCl_4$ and organic solvents (benzene, chloroform, and CS_2).

[34a] *A. Buschfeld*, Dissertation, Technische Hochschule Aachen, 1962.

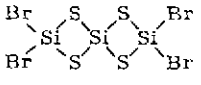
c) Tetrabromo-1,3,2,4-dithiadisiletane

Tetrabromo-1,3,2,4-dithiadisiletane *(8)* is formed by the reaction of $SiBr_4$ with H_2S, but only with $AlBr_3$ as catalyst; the yield reaches approximately 20% after five to six days at 150 °C [35]. Fractional distillation followed by recrystallization from CS_2 gives *(8)* in the form of colorless platelets (m.p. 93 °C; b.p. 150 °C/18 mm). On reaction with water, *(8)* decomposes explosively:

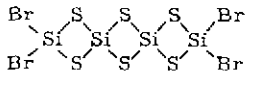
$$\underset{(8)}{Br_2SiS_2SiBr_2} + 4\ H_2O \rightarrow 2\ SiO_2 + 4\ HBr + 2\ H_2S \qquad (h)$$

Investigations on the crystal structure by *Weiss* and *Weiss* [35a] indicated that the molecular structure of *(8)* is similar to that of *(3)* and *(4)*.

In the presence of catalytic amounts of SiS_2, *(8)* reacts with H_2S to form higher sulfide bromides, $Si_nS_{2n-2}Br_4$, with loss of HBr. Compounds *(9)* [m.p. 108 °C, b.p. 164 °C/12 mm] and *(10)* [m.p. 148 °C, decomp., b.p. 171 °C/12 mm] have been isolated from a reaction mixture of this kind by distillation, fractional extraction, or



(9)



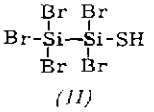
(10)

crystallization from CS_2. The higher homologues (n = 10 and 11), which are sparingly soluble in CS_2, are colorless compounds that do not crystallize well. They lose $SiBr_4$ on heating to form a mixture of higher sulfide bromides. The lower homologues (n = 3, 4) have been isolated by vacuum distillation. They also dismutate partially into $SiBr_4$ and higher homologs.

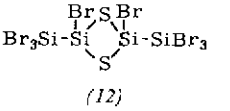
Compound *(8)* can also be obtained from $SiBr_4$ and Na_2S or P_2S_5 if the reaction is catalysed by Al_2Br_6 or $Si_2S_2Br_4$. The reactions of $SiHBr_3$ with sulfur and of SiS_2 with $SiBr_4$ also lead to *(8)*. This last reaction [Equation (i)] is reversible; at high $SiBr_4$ pressures it proceeds to the right, at lower pressures to the left. If Si_2Br_6 is used

$$(SiS_2)_n + n\ SiBr_4 \underset{< 1\ atm}{\overset{200\ °C,\ >1\ atm}{\rightleftharpoons}} n\ Si_2S_2Br_4 \qquad (i)$$

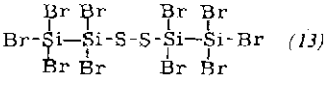
instead of $SiBr_4$, the products include the compounds *(11)*, *(12)*, and *(13)*, but these are even less stable.



(11)



(12)



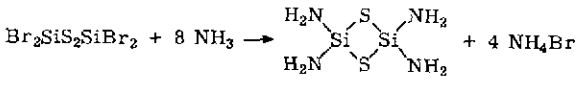
(13)

[35] *M. Blix*, Ber. dtsch. chem. Ges. *36*, 4218 (1903).

[35a] Silicium-Schwefel-Phosphate. Colloquium d. Sektion f. Anorg. Chem. IUPAC, Münster 1954. Verlag Chemie, Weinheim/Bergstr. 1955, p. 41.

d) Tetraamino-1,3,2,4-dithiadisiletane

Tetrahalogeno-1,3,2,4-dithiadisiletanes are very reactive, and the halogen atoms can be replaced by other substituents. Compound *(14)* was first prepared by the reaction of *(8)* with ammonia in dry benzene [35]. On extraction of the NH_4Br, which is soluble in liquid ammonia,

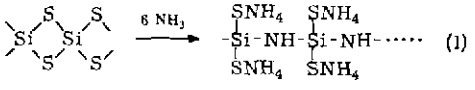


(14)

(14) was obtained as a white amorphous powder. Thermal decomposition begins at temperatures above 0 °C, and the compound is quantitatively hydrolysed by water:

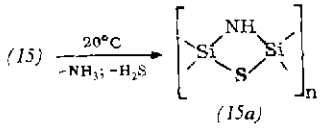
$$(NH_2)_2SiS_2Si(NH_2)_2 + 4\,H_2O \rightarrow 2\,SiO_2 + 2\,H_2S + 4\,NH_3 \quad (k)$$

According to *Behrens* and *Ostermeier* [17], an S atom in the four-membered ring can be replaced by the imino group $-NH-$ [*]. SiS_2 obtained from $(C_2H_5S)_4Si$ and sulfur at 200 °C reacts with liquid ammonia at −33 °C; three moles of NH_3 are consumed per mole of



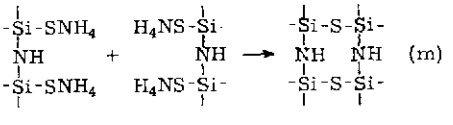
(15)

SiS_2, in accordance with Equation (l). On heating in a high vacuum at 20 °C, *(15)* loses ammonia and hydrogen sulfide, the product presumably being *(15a)*. However, the presence of this ring system has not been conclusively proved. The possibility of an intermolecular



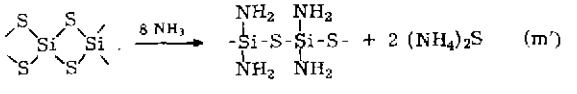
(15a)

condensation [17] in accordance with Equation (m) must also be considered.



By excess NH_3 at 60 °C, *(15)* is quantitatively desulfurized to $[Si(NH)_2]_x$.

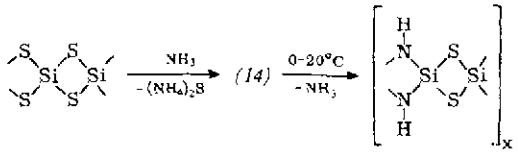
If the $(SiS_2)_n$ obtained from $(C_2H_5S)_4Si$ and sulfur is heated *in vacuo* for two hours at 450 °C, subsequent ammonolysis at −33 °C proceeds not by reaction (l), but by reaction (m'). The product *(16)* loses ammonia above



(16)

[*] According to *M. Becke-Goehring* [35b], the transition $S_8 \rightarrow S_7(NH) \rightarrow S_6(NH)_2 \rightarrow S_4(NH)_4$ is possible.

0 °C and is quantitatively converted into *(15)* at 20 °C. The chain *(16)* must not necessarily be formed, since a cyclic structure *(17)* would also be possible.

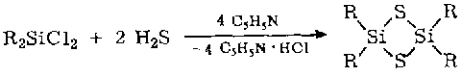


(17)

The formation of *(17)* is indicated by the fact that the properties of substance *(16)* obtained by *Behrens* and *Ostermeier* [17] are similar to those of *(14)* [35]. Moreover, no linear compounds with Si-S chains are known apart from the parent compound $R_3SiSSiR_3$, whereas four-membered rings containing N Si groupings have been described [36].

e) Tetraorgano-1,3,2,4-dithiadisiletanes

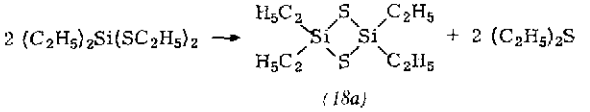
Tetraorgano-1,3,2,4-dithiadisiletanes can be prepared by the reaction of organochlorosilanes with H_2S in petroleum ether and in the presence of an HCl acceptor such as triethylamine or pyridine [37, 38].



(18)

In addition to this generally applicable method, the compounds *(18)* can be obtained by reactions of organodiiodosilanes [37] with Ag_2S in inert solvents.

Compounds of the type $R_2Si(SR)_2$, *e.g.* diethyldi(ethylthio)silane, are decomposed by heat into a tetraorgano-1,3,2,4-dithiadisiletane, *e.g .(18a)*, and a dialkyl sulfide [39]. The alcoholysis of $(SiS_2)_n$ with t-butanol yields tetra-t-butyl-1,3,2,4-dithiadisiletane [40].



(18a)

The compounds *(18)* are thermodynamically [38] unstable and rearrange to form hexaorgano-1,3,5,2,4,6-trithiatrisilin. In the case of the methyl derivative, this rearrangement occurs within a few days, even at room temperature, whereas the ethyl and propyl compounds trimerize at an appreciable rate only above 150 °C. The dimer can be regenerated from the trimer by quenching the vapor.

2 C_3H_7; 2 Cl [a]		261–63/760	
C_4H_9O	121–123.5		colorless crystals insoluble in petroleum ether
C_2H_5S		296/0.1	
C_6H_5	145–147		

[a] Compound *(19)*.

f) Hexaalkyl-1,3,5,2,4,6-trithiatrisilin

In addition to the preparation described above, involving the rearrangement of 1,3,2,4-dithiadisiletanes, the trimer $[(CH_3)_3SiS]_3$ has also been prepared by *Nomura, Yokoi,* and *Yamasaki*[41] by the reaction of $(CH_3)_2SiCl_2$ with hydrogen sulfide at 20 °C (in contradiction of *Etienne*'s findings[37]). On heating for several hours in a current of H_2S, however, it rearranged to the dimer $[(CH_3)_3SiS]_2$.

Physical properties:

$[(CH_3)_2SiS]_3$: b.p. 151.5–153.5 °C/38 mm, 76–78 °C/0.6 mm; m.p. 17–18 °C; dipole moment[42] 1.03 Debye.

$[C_2H_5)_2SiS]_3$: b.p. 111–115 °C/0.2 mm; colorless oil.

$[(n\text{-}C_3H_7)_2SiS]_3$: b.p. 176–180 °C/0.8 mm, 145–148 °C/0.2 mm.

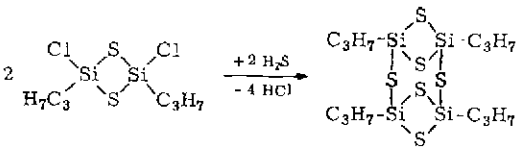
Electron diffraction measurements[43] gave Si-S distances of 2.18 ± 0.03 Å and 2.15 ± 0.3 Å. Assuming a C–S–C angle of 110 °, the following values were found for the bond angles:

	Dimer	Trimer
Si–S–Si	75 °	110 °
S–Si–S	105 °	115 °

In agreement with the results of dipole moment measurements, therefore, the trimer is not planar; instead, like the corresponding oxygen compound, it has a chair structure.

g) 2,4,6,8-Diepithiotetraorgano-1,3,5,7,2,4,6,8-tetrathiatetrasilocanes $(RSiS_{1.5})_4$

The reactions of trichloroorganosilanes with H_2S in the presence of a tertiary amine do not yield high polymers, but only tetramers. *Etienne*[44] obtained methyl, ethyl, and phenyl derivatives in benzene solution. The propyl compound *(20)*[37b] was prepared in a similar manner from *(19)*, so providing chemical evidence for the structure of this compound.



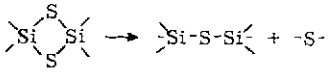
(19) *(20)*

Physical properties:

$(CH_3SiS_{1.5})_4$: m.p. 275 °C;
$(C_2H_5SiS_{1.5})_4$: m.p. 140 °C;
$(C_3H_7SiS_{1.5})_4$: m.p. 86 °C, b.p. 210–215 °C/0.2 mm;
$(C_6H_5SiS_{1.5})_4$: m.p. 216 °C.

4. Disilyl Sulfides

The "desulfurization" of *(2)* formally leads to a new class of compounds, the so-called "disilthianes". These can be produced on the preparative scale by four principal methods:



(2) *(21)*

1. By the reaction of iodosilanes[45–47] with mercury sulfide or silver sulfide, or by the reaction of chlorosilanes with anhydrous sodium sulfide[48] at 250 °C and at a high pressure (60 atm):

$$2\ R_3SiI + HgS\ (Ag_2S) \rightarrow R_3Si\text{-}S\text{-}SiR_3 + HgI_2\ (2\ AgI) \quad (n)$$

$$2\ R_3SiCl + Na_2S \xrightarrow[\text{pressure}]{250\ ^\circ C} R_3Si\text{–}S\text{–}SiR_3 + 2\ NaCl \quad (o)$$

2. By the reaction of chlorosilanes with H_2S in the presence of pyridine[37a]:

$$2\ R_3SiCl + H_2S + 2\ C_5H_5N \rightarrow R_3Si\text{–}S\text{–}SiR_3 + 2\ C_5H_5N\cdot HCl \quad (p)$$

3. A more widely used method is that described by *Larson* and *Marin*[49], who treated trialkylsilylamines with hydrogen sulfide in organic solvents and obtained good yields of disilyl sulfides:

$$R_3SiNHR' + H_2S \rightarrow R_3Si\text{–}S\text{–}SiR_3 + R'NH_2 \quad (q)$$

4. Hexachlorodisilyl sulfide[50,51] was obtained from silicon tetrachloride and hydrogen sulfide at 700 to

1100 °C, in accordance with Equation (r), or from Cl_3SiI and Ag_2S at 250 °C [50].

$$SiCl_4 + H_2S \xrightarrow{700-1100\,^\circ C} Cl_3Si-S-SiCl_3 \qquad (r)$$

Chemical properties: Of the compounds listed in Table 3, $H_5Si_2-S-Si_2H_5$ [46] is thermally the least stable. It decomposes at 157 °C into disilane, hydrogen, and a white, non-volatile substance which has not been identified. Unlike thioethers, the disilyl sulfides do not form sulfonium compounds. They are degraded by iodine and hydrogen iodide to iodosilanes and sulfur or H_2S:

$$R_3Si-S-SiR_3 + I_2\,(HI) \rightarrow 2\,R_3SiI + S\,(H_2S) \qquad (s)$$

Table 3. Disilyl sulfides $R^2R^1_2Si-S-SiR^1_2R^2$.

[a] $(CH_3)_3Si-S-Si(CH_3)_3$ has also been obtained by passing $(CH_3)_3SiCl$ into a melt of $K_2S/LiCl/KCl$ at 400 °C [48a].

The alcoholysis, thioalcoholysis, and aminolysis of bis(trimethylsilyl) sulfide, as well as its reactions with alkyl halides, have been studied [48] (cf. Table 3). $(CH_3)_3Si-S-Si(CH_3)_3$ and $(C_2H_5)_3Si-S-Si(C_2H_5)_3$ react with the silver compounds AgX (X = Cl, Br, NCS) to form $(CH_3)_3SiX$ and $(C_2H_5)_3SiX$ together with silver sulfide, in accordance with *Eaborn*'s conversion series [41]. "Disilthianes" were converted by mercury oxide into disiloxanes. These disilyl sulfides are surprisingly stable to water and to alkaline solutions.

5. Silanethiols

Silanes containing an Si–SH group are generally more stable than the corresponding oxygen compounds, which condense fairly readily to form disiloxanes. Nevertheless, only a few silanethiols have so far been prepared, since the known methods of preparation are not generally applicable. The simplest compound of this class, silanethiol, has not yet been unambiguously identified. It is thought [52] to be formed from SiH_3Cl and H_2S in the presence of $AlCl_3$. It condenses readily to form disilyl sulfide and exists at room temperature in equilibrium with $(SiH_3)_2S$ [53]:

$$2\,H_3SiSH \rightarrow H_3Si-S-SiH_3 + H_2S \qquad (t)$$

Trichlorosilanethiol (b.p. 96 °C; m.p. −57 °C) [29, 30, 34] is much more stable thermally, and has been obtained by passing $SiCl_4$ and H_2S through red-hot porcelain tubes or by passing a mixture of $SiCl_4$ and HCl over SiS_2 at 1000 °C [34]. Trichlorosilanethiol is a colorless liquid that smells strongly of H_2S and $SiCl_4$; it is hydrolysed by water to form SiO_2, HCl, and sulfur, and it reacts with bromine in accordance with Equation (u).

$$2\,Cl_3SiSH + 3\,Br_2 \rightarrow 2\,Cl_3SiBr + S_2Br_2 + 2\,HBr \qquad (u)$$

The condensation [50] to hexachlorodisilyl sulfide [Equation (v)] occurs only at 650 to 700 °C.

$$2\,Cl_3SiSH \rightarrow Cl_3Si-S-SiCl_3 + H_2S \qquad (v)$$

Br_3SiSH [35a] occurs as an intermediate in the synthesis of *(8)*, and has been isolated by *Weiss* and *Weiss*. It forms colorless trigonal prisms, which crystallize tetragonally in the space group D^3_3d–P3ml, with a = 7.84 Å and c = 6.65 Å; m.p. 96 °C. The central silicon atom is tetrahedrally surrounded by bromine and sulfur, the interatomic distances being Si–Br = 2.25 Å and Si–S 2.28 Å. The compound is methylated to Br_3SiSCH_3 by diazomethane in benzene solution. On electrolysis, hydrogen is formed at the cathode, while yellow needles of $Br_3Si-S-S-SiBr_3$ separate out at the anode; this latter product is very unstable and is converted, *inter alia*, into *(8)* if the electrolysis is prolonged.

In addition to these carbon-free silanethiols, a number of organic derivatives have also been prepared:

1. By the reaction [49] of triorganosilylamines with H_2S:

$$R_3Si\,NHR' + H_2S \rightarrow R_3SiSH + R'NH_2 \qquad (w)$$

2. By substitution of the chlorine in organochlorosilanes with Mg, K, Na, Li, or NH_4 hydrogen sulfides in toluene or with H_2S in the presence of pyridine [37a].

3. By careful alcoholysis of SiS_2 with secondary or tertiary alcohols [40, 54].

Method 1) has been used to prepare $(CH_3)_3SiSH$ (b.p. 75–76 °C); $(C_2H_5)_3SiSH$ (b.p. 158 °C), and $(C_3H_7)_3SiSH$ (b.p. 83–84 °C/7 mm). Method 2) has been used to obtain $(CH_3)_3SiSH$ and $(C_6H_5)_3SiSH$ (m.p. 103 °C), the stability of which is comparable to that of triphenyl-

silanol. Method 3) gave $(t\text{-BuO})_3SiSH$ (b.p. 115 °/35 mm; $n_D^{20} = 1.4231$; $d_4^{20} = 0.924$), $(t\text{-AmO})_3SiSH$ (b.p. 109–110 °C/10 mm; $n_D^{20} = 1.4382$; $d_4^{20} = 0.930$); $(i\text{-PrO})_3SiSH$ (b.p. 188 °C; $n_D^{20} = 1.4075$; $d_4^{20} = 0.919$), and $(s\text{-BuO})_3SiSH$ (b.p. 231–233 °C; $n_D^{20} = 1.4200$; $d_4^{20} = 0.916$).

Alcoholysis of $(SiS_2)_n$ was assumed to yield dithiols and trithiols, $R_2Si(SH)_2$ and $RSi(SH)_3$, but attempts to isolate substances of this kind were unsuccessful.

6. Organothiosilanes $R_nSi(SR')_{4-n}$

Organothiosilanes are formally derived from the silanethiols by replacement of the hydrogen attached to the sulfur by alkyl or aryl groups. The number of theoretically possible organothiosilanes is therefore very large; only a few, however, have so far become known. They can be prepared by the following methods:

1. By the reaction of chlorosilanes with lead [39,55], mercury [56], or sodium mercaptides [57, 61–64], *e.g.*:

$$R_nSiCl_{4-n} + n/2\ Pb(SR')_2 \rightarrow R_nSi(SR')_{4-n} + n/2\ PbCl_2 \quad (x)$$

2. By the reaction [39] of chloroorganothiosilanes with lithium aluminum hydride:

$$Cl_nSi(SR)_{4-n} \xrightarrow{LiAlH} H_nSi(SR)_{4-n} \quad (y)$$

3. By the method of *Larson* [49] described above for the preparation of disilyl sulfides, if mercaptans are used instead of H_2S:

$$R_3Si{-}NR_2 + R'SH \rightarrow R_3Si{-}SR' + R_2NH \quad (z)$$

4. By the reaction [59] of triphenylsilyl-lithium with sulfur followed by coupling with organic chlorides:

$$(C_6H_5)_3SiLi + S \rightarrow (C_6H_5)_3Si{-}SLi \xrightarrow[-LiCl]{RCl} (C_6H_5)_3Si{-}SR \quad (a')$$

5. By the reactions of tri(alkylthio)silanes with bromine at 0 to 70 °C. These reactions yield di(alkylthio)dibromosilanes, tri(alkylthio)bromosilanes, or di(alkylthio)bromosilane [58], depending on the ratio of the reactants:

$$(RS)_3SiH \xrightarrow{Br_2} (RS)_3SiBr + (RS)_2SiBr_2 + (RS)_2SiHBr \quad (b')$$

The Si–S bond is generally very sensitive to hydrolysis, the products being mercaptans and the corresponding Si–O compounds [48]. Alcohols react with thiosilanes to form alkoxysilanes and thioalcohols [48]:

$$R_nSi(SR)_{4-n} + n\ R'OH \rightarrow R_nSi(OR')_{4-n} + n\ RSH \quad (c')$$

In the cases of ethanol and 1-butanol, the reactions are exothermic and the yields high. 2-Propanol and t-butanol, on the other hand, react only on heating, and the yields are low [48].

Abel [48] has shown that silylamines can be prepared from thiosilanes and amines.

$$R^1R^2NH + (H_3C)_3SiSC_2H_5 \rightarrow C_2H_5SH + R^1R^2NSi(CH_3)_3$$
$$(R^1 = R^2 = C_4H_9;\ R^1 = C_4H_9,\ C_6H_5;\ R^2 = H) \quad (d')$$

Acetic anhydride has been treated with five tri(alkylthio)silanes [alkyl = CH_3, C_2H_5, C_3H_7, $CH(CH_3)C_2H_5$, $CH(CH_3)_2$] to form alkyl thioacetates and probably di(alkylthio)silyl acetates; the latter, however, lose another

$$HSi(SCH_3)_3 + (CH_3CO)_2O \rightarrow CH_3CO{-}SCH_3 + CH_3CO{-}OSiH(SCH_3)_2$$
$$\xrightarrow{-CH_3CO{-}SCH_3} \left(-O-\overset{H}{\underset{SCH_3}{Si}}- \right)_x \quad (22)$$

molecule of alkyl thioacetate to form polymers *(22)*, the exact composition of which could not be determined [64a].

Organic halides react with thiosilanes at 100 to 250 °C to form alkylhalogenosilanes and the corresponding thioethers, presumably *via* a sulfonium salt intermediate *(23)* [60].

$$(CH_3)_3Si{-}SR' + RX \rightarrow [(CH_3)_3SiSR'R]^{\oplus}X^{\ominus} \rightarrow (CH_3)_3SiX + RSR' \quad (23)$$

The butylmethyltrimethylsilylsulfonium iodide *(24)* has actually been isolated; it is insoluble in petroleum ether

$$(CH_3)_3Si\ SC_4H_9 + CH_3I \rightarrow [(CH_3)_3Si{-}SC_4H_9(CH_3)]^{\oplus}I^{\ominus} \quad (24)$$

and extremely sensitive to hydrolysis. Attempts to prepare sulfones by the oxidation of the Si–S bond have so far been unsuccessful [55]. The Si–S bond always broke to form disulfides and the corresponding Si–O compounds [55]:

$$R_nSi(SR)_{4-n} \xrightarrow{oxid.} R_nSiO_{(4-n)/2} + n/2\ RSSR \quad (e')$$

[64a] *L. Wolinski, H. Tieckelmann*, and *H. W. Post*, J. org. Chemistry *16*, 1134 (1951).

The only evidence for the existence of silyl sulfones was provided by *Wittenberger*, *Wu*, and *Gilman*[65], who detected a phenyl triphenylsilyl sulfone as an intermediate in the reaction of triphenylsilyl-lithium *(25)* with diphenyl sulfone; however, the intermediate reacted immediately to form tetraphenylsilane and lithium phenylsulfinate.

$$(C_6H_5)_3SiLi \xrightarrow{C_6H_5-SO_2-C_6H_5} (C_6H_5)_3Si-SO_2-C_6H_5 + C_6H_5Li$$
$$\rightarrow (C_6H_5)_4Si + C_6H_5SO_2Li \qquad (25)$$

When lead diphenyl disulfide was used instead of lead mercaptide, or when the reaction was carried out at room temperature, complete substitution of the halogen could not be achieved.

A product with the composition $Si_2(SC_2H_5)_6$ was obtained by the reaction of Si_2Cl_6 with $Pb(SC_2H_5)_2$, but this also tended to undergo rearrangement in accordance with reaction (f').

The existence of both forms, *(26a)* and *(26b)*, is also indicated by infrared measurements. Both forms are thermally unstable and decompose into $Si(SC_2H_5)_4$ and $(SiSC_2H_5)_x$.

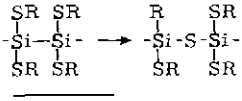
(*o*-Tolyl)$_2$Si(S-*p*-Tolyl)$_2$	112—113	1)		With $KMnO_4$ no sulfone can be isolated.

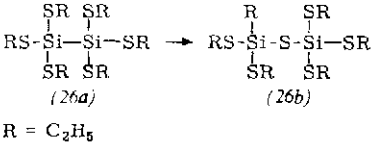
[a] Obtained in 12% yield from $SiCl_4$ and C_6H_5SH [66].

7. Silicon Dimercaptides $[(RS)_2Si]_n$

Attempts to prepare silicon dimercaptides[66a] having the general formula $[Si(SR)_2]_n$ have met with only limited success. $(SiBr_2)_x$ reacts with lead mercaptide at 80 °C complete substitution and subsequent rearrangement:



(f')



(26a) *(26b)*

R = C_2H_5

8. Spectroscopic Investigations

On the basis of infrared and Raman spectroscopic measurements on silanethiols, disilyl sulfides, and 1,3,2,4-dithiadisiletanes, *Goubeau* and *Hirsemann*[67]

[65] *D. Wittenberger*, *T. C. Wu*, and *H. Gilman*, J. org. Chemistry *23*, 1898 (1958).

[66] *H. Jorg* and *J. Stetter*, J. prakt. Chem. [2] *117*, 305 (1927).

[67] *J. Goubeau* and *W. D. Hirsemann*, Z. anorg. allg. Chem. *290*, 292 (1957).

found the force constant of the Si–S bond to be k_{Si-S} = 2.28 mdyne/Å, and the absorption region of the Si–S bond (see also [56] and [60]) was found to be from 520 to 400 cm^{-1}. The force constant was determined for Cl_3SiSH with the aid of the value of k_{Si-Cl} = 2.46 mdyne/Å calculated by *Siebert* [68] for $(CH_3)_3SiSCl$. It was concluded from the close resemblance of the spectra that k_{Si-S} = 2.28 mdyne/Å is valid for all silicon-sulfur compounds, any deviations being only slight. This value agrees closely with the theoretical value of 2.22 mdyne/Å calculated by *Siebert* [69] for the Si-S single bond, showing that Si–S bonds possess no appreciable double-bond character. These results were fully corroborated by subsequent investigations [70–73].

The Si–S distance as found by electron diffraction measurements [74] on Cl_3SiSH is 2.14 ± 0.02 Å, compared with the sum of the covalent radii of 2.338 Å given by *Pauling*. This contraction, however, is not attributed to any double-bond character of the Si–S bond, but to the polarity of the σ-bond. Thus, in agreement with the force constants, p_π–d_π bonds play only a minor part in the chemistry of silicon-sulfur compounds, which is in contrast with the chemistry of silicon-oxygen and silicon-nitrogen compounds. It is still uncertain, however, why the Si–S bond, unlike the C–S bond, cannot form adducts (*e.g.* $[(H_5C_2)_3S]^+I^-$).

I am very grateful to Prof. O. Glemser for encouragement and discussions. I am also deeply indebted to Prof. M. Schmeisser for permission to use unpublished results obtained by his research group.

Heterocycles Containing Phosphorus

BY PRIV.-DOZ. DR. G. MÄRKL

CHEMISCHES INSTITUT DER UNIVERSITÄT WÜRZBURG (GERMANY)

The preparation of heterocycles containing phosphorus is described. The chemical behavior of ring systems containing trivalent phosphorus is mainly determined by their phosphine character; heterocyclic behavior in the ordinary sense is shown by rings containing functional groups. Syntheses and reactions of cyclic compounds of pentavalent and hexavalent phosphorus are particularly interesting.

Introduction

A. General Methods of Preparation

B. Heterocycles Containing One Phosphorus Atom
   1. Phosphacylopropanes and Phosphacyclobutanes
   2. Five-Membered Rings (phospholanes, phospholenes, phospholes, five-membered rings containing pentavalent phosphorus, phosphindolines, isophosphindolines, phosphofluorenes, phosphafluorenes containing pentavalent and hexavalent phosphorus, spiro compounds)
   3. Six-Membered Rings (phosphorinanes, 1,1-diphenyl-1-phosphabenzene, 1,1-diphenyl-1-phosphanaphthalene, tetrahydrophosphinoline, tetrahydroisophosphinoline, spirophosphonium salts, phospha-anthracene and phosphaphenanthrene)
   4. Seven- and Eight-Membered Rings

C. Heterocycles Containing Two or More Phosphorus Atoms
   1. 1,3-Diphosphacyclohexane. Cyclic Phosphacyanins
   2. 1,4-Diphosphacyclohexane. 9,10-Dihydrophosphanthrene
   3. 1,4-Diphosphabicyclo[2.2.2]octane
   4. 1,2-Diphosphacycles and 1,2,3-Triphosphacycles

D. Phosphorus Heterocycles that also Contain Oxygen or Nitrogen Atoms in the Ring
   1. 1-Oxa-3-phosphacyclopentanes
   2. 1,3-Dioxa-5-phosphacyclohexanes
   3. 9-Phosphaxanthene and 9,10-Dihydrophenophosphazine
   4. 1-Aza-4-phosphacyclohexane and 1,2-Diaza-4-phosphacyclohexane

Introduction

Almost 98 % of all papers dealing with heterocycles containing phosphorus were published within the last fifteen years, and more than 80 % since 1959. This development is the result of the rapid progress made in the organic chemistry of phosphorus, which ceased to be a specialized field with the discovery of the phosphorylide olefinations.

What quantitative or qualitative differences should we expect to find between the heterocyclic systems of nitrogen and of phosphorus? The single-bond covalent

radius[1] of phosphorus (1.1 Å) is 0.4 Å greater than that of nitrogen. The greater bulk of the phosphorus atom is shown by the P–C distances of 1.83 to 1.94 Å (as compared with an N–C distance of 1.47 Å in tertiary amines) found by electron-diffraction and X-ray measurements[2] on tertiary phosphines. The C–N–C valence angle in tertiary amines (107 to 108 °) is close to the terahedral angle, whereas the phosphorus atom in tertiary phosphines (valence angle 98.9 to 99.1 °) is situated at the apex of a much more acute trigonal pyramid[2]. The fact that, in contrast to nitrogen, the phosphine pyramid inverts only at bigh temperatures (activation energy 29 to 31 kcal/mole), as is shown by *Horner*'s isolation and racemization of optically active phosphines[3], must have stereochemical consequences for cyclic phosphines. The electronic configurations of nitrogen and phosphorus are $2s^22p^3$ and $3s^23p^3$, respectively. Experimental evidence shows that trivalent phosphorus does not form double bonds either with itself ($3p_\pi-3p_\pi$) or with carbon ($3p_\pi-2p_\pi$) or nitrogen[4].

Thus we cannot to find a branch of phosphorus chemistry corresponding to that of the aromatic N-heterocycles.

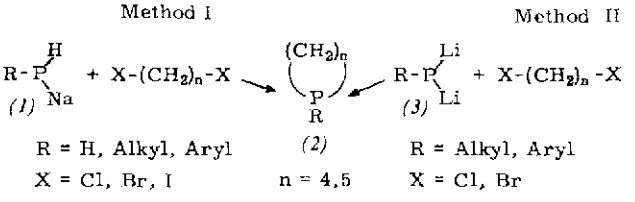
The unique ability of phosphorus to expand its valence shell to include 3d orbitals, *i.e.* to form pentaorganophosphorus compounds, promises new chemical results. In heterocycles in which the phosphorus has five covalent $sd_\sigma-2p_\sigma$ single bonds, it should be possible to observe stereochemical variation, depending on the d-orbitals involved in the hybridization[5]. Finally, ring systems containing pentavalent phosphorus with $3d_\pi-2p_\pi$ double bonds should be obtainable in the form of cyclic methylenephosphoranes.

The difficulties encountered in the nomenclature of organic phosphorus compounds, which have been discussed by *Sasse*[6], are particularly serious in the case of the heterocycles.

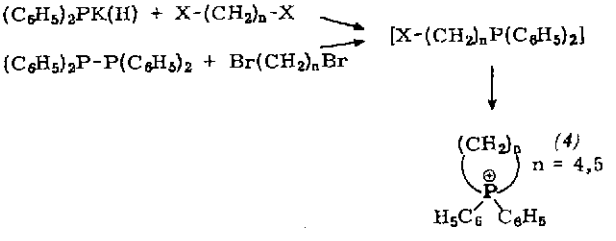
A. General Methods of Preparation

Method I. The monosodium phosphides *(1)*, which result from the reaction of primary phosphines or PH_3 witb sodium (in liquid ammonia[7] or organic solvents[8]), react with dihalogenoalkanes to form cyclic phosphines *(2)*[7,9]. The reaction also (or in some cases even exclusively[9]) yields ω,ω′-diphosphinoalkanes $RHP-(CH_2)_n-PHR$, which can be easily separated by distillation.

Method II. Dilithium phosphides *(3)*, which can be readily obtained by the introduction of the metal into primary phosphines, also react with dihalogenoalkanes (applying the Ruggli-Ziegler dilution principle) to form *(2)*[10]. Even the primary phosphines themselves react slowly at 80 to 130 °C[11].



Method III. Secondary aliphatic phosphines react with dihalogenoalkanes to form bis(dialkylphosphino)alkanes $R_2P-(CH_2)_n-PR_2$[11]. Potassium diphenylphosphide[13], and even diphenylphosphine itself under forcing conditions[11,12], form the cyclic phosphonium salts *(4)*. The reaction of tetraphenyldiphosphine with dihalogenoalkanes[14] is particularly simple.



Method IV. The acid-catalysed nucleophilic addition of secondary phosphines or PH_3 to dialdehydes provides an elegant synthesis of the α,α′-dihydroxyphosphonium salts *(5)*[15a,15b] and spirophosphonium salts *(6)*[15b–16b], respectively.

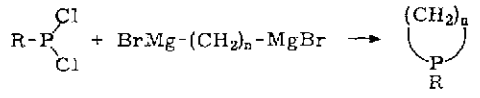
[15b] *M. Grayson*, Chem. Engn. News No. 49, *40*, 90 (1962).

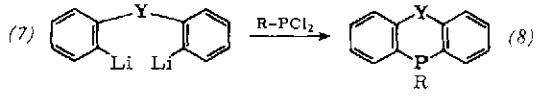
Method V. Reactions of bifunctional Grignard compounds with halogenophosphines (a reversal of Methods I and II) were used by *Grüttner* [17] in the first synthesis of cyclic phosphines. Contrary to earlier belief [20],



R = Alkyl[18], Aryl[17], $N(CH_3)_2$[19] *(2)*, n = 4,5

ring closure evidently does not take place with phosphonic chlorides $R-POCl_2$ [R = $N(C_2H_5)_2$, C_6H_5] or phosphites [21].

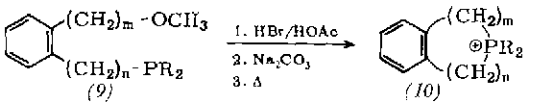
Method VI. The use of bifunctional lithium compounds in reactions corresponding to method V is restricted to the 2,2-dilitbiumdiphenyl derivatives *(7)*, which can be readily obtained by reaction of the 2,2'-dibromides with lithium. This method can, however, be adapted for the synthesis of a very wide range of ring systems *(8)* by variation of the bridging group Y.



Y = -[22a–22c], $(CH_2)_2$[23], PR[24], NR[25a,25b], O[26]; R = Alkyl, Aryl

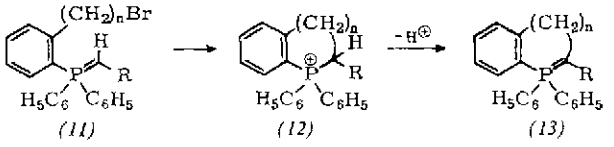
Method VII. Intramolecular formation of quaternary salts *(10)* from ω-bromoalkylphosphines, which are readily available from tertiary phosphines *(9)* containing an ω-alkoxy side chain by cleavage of the ether linkage.

Method VIII. Formation of *(12)* by intramolecular *C*-alkylation of the ylides *(11)* derived from the phosphonium salts, using the ω-bromoalkyl side chain in



n = 0, m = 2,3[27-29]; n=m = 1[30,31]; n = 2, m = 1[32]
R = C_2H_5, C_6H_5

the *o*-position as the alkylating agent [33]. With 2 moles of base, the cyclic methylenephosphoranes *(13)* are formed directly from the open-chain salts.

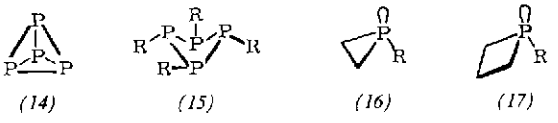


R = C_6H_5, $COOCH_3$; n = 1, 2, 3

B. Heterocycles Containing One Phosphorus Atom

1. Phosphacyclopropanes and Phosphacyclobutanes

As is shown by the examples of the tetrahedral P_4 *(14)* (valence angle 60°) and the cyclotetraphosphines *(15)*, phosphorus forms very stable small rings with itself. The ring strain may be reduced by spd hybridization [34], and stabilization of *(15)* by p_π-d_π double bonds between the phosphorus atoms has been suggested [35].



Small phosphorus-carbon rings are difficult to prepare. 1-Substituted phosphacyclopropanes *(16)* (R = H, CH_3) and unsubstituted phosphacyclobutane *(17)*, R = H, can be synthesized by Method I (for n = 3 and R = alkyl or aryl, only the open-chain phosphines are obtained [7]).

Formation of the four-membered ring is also suppressed in Methods II, III, and VII in favor of polymer formation [10,14] or cyclodimerization [12,29]. An unusual cycloaddition of PCl_3 (as $PCl_2^{\oplus}/AlCl_4^{\ominus}$) to 1,4,4-trimethylpent-2-ene yields the phosphinic acid *(18)* [36].

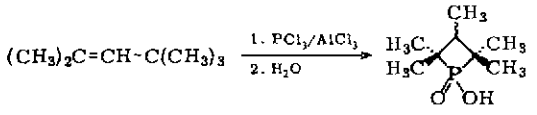
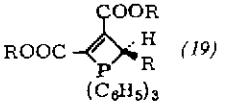
The four-membered ring is not opened even under extreme conditions (*e.g.* boiling conc. HNO_3 or boiling aqueous conc. NaOH), indicating that there is no internal strain.



(18)



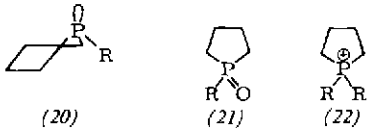
(19)

On the basis of considerations regarding the reaction mechanism, the reaction of alkylidenetriphenylphosphoranes with esters of acetylenedicarboxylic acid [37] or with arynes [38] must proceed *via* 1,1,1-triphenylphosphacyclobut-2-enes *(19)*.

2. Five-Membered Rings

a) Phospholanes

Phospholanes *(20)* have been prepared by Methods I, II, and V. Another interesting preparation is the reduction of dimethylamide *(20)* [R = $N(CH_3)_2$] to 1*H*-phospholane *(20')* by the pyrolysis of the BH_3 adduct *(23)* [19,39].



(20) *(21)* *(22)*

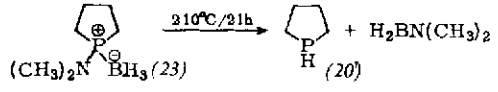


Table 1. Comparison of phospholanes *(20)* with the analogous pyrrolidines *(20a)*.

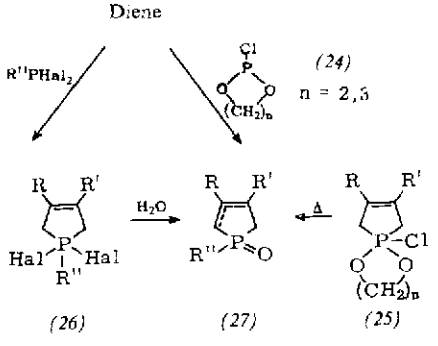
R	*(20)* b.p. [°C/mm]	*(20a)* b.p. [°C/mm]
C_2H_5	145—147/760	107/760
C_6H_5	97/3	124/14

The phospholanes are mostly oily, distillable, unassociated liquids (cf. Table 1) having the characteristic phosphine odor. They are oxidized to the oxides *(21)* by atmospheric oxygen, but the reaction is much slower than that of open-chain phosphines. Like all tertiary phosphines [40], they are strongly nucleophilic and react with alkyl halides, sometimes in an exothermic reaction, to form the phosphonium salts *(22)* (R = alkyl) by an S_N2 mechanism. In accordance with *Ingold*'s rule [41], diaryl-substituted salts (which can be prepared by Method III) are degraded by aqueous alkali to the oxide *(21)* (R = aryl) without suffering ring cleavage.

b) Phospholenes

McCormack [42] discovered in 1955 that, in the presence of polymerization inhibitors (*e.g.* Cu stearate), aryldihalogenophosphines add onto dienes in a quasi-Diels-Alder reaction to form 1-aryl-1,1-dibalogenophospholenes *(26)*, which are readily hydrolysed to 1-arylphospholene oxides *(27)*. Modifications of this synthesis were achieved by the use of PCl_3, PBr_3 [43a–44], and



(26) *(27)* *(25)*

$RO-PHal_2$ [45]. Diene = butadiene, isoprene, 2,3-dimethylbutadiene, chloroprene, dicyclohexylidene, *etc.*; R″ = phenyl, *p*-tolyl, mesityl, CH_3, C_2H_5, OC_2H_5, OC_6H_5, Cl, Br, *etc.*

The diene component must be able to assume a *cisoid* conformation (1,1-disubstituted dienes do not react) and 1-substituted dienes must be in the *trans* form. Phosphorus bromides are more reactive than the chlorides. The average reaction time (1 to 10 days at 25 °C) is increased by bulky and electronegative substituents in the diene. The ring closure probably starts with the nucleophilic addition of the phosphine to the 1-position of the diene.

The use of a dihalide $R''PHal_2$ is not absolutely necessary, as is shown by the addition of cyclic monochlorophosphites *(24)* to dienes to form the spiro intermediates *(25)*, which then undergo rearrangement to *(27)*,

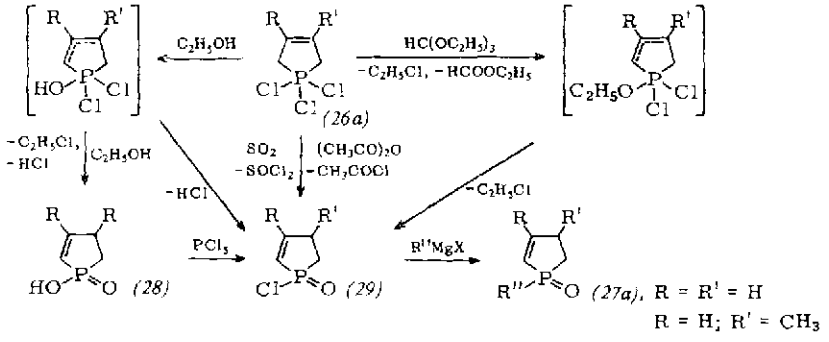
R″ = $O-(CH_2)_2Cl$, $O-(CH_2)_3Cl$, by an intramolecular Michaelis-Arbusow reaction[46,47].

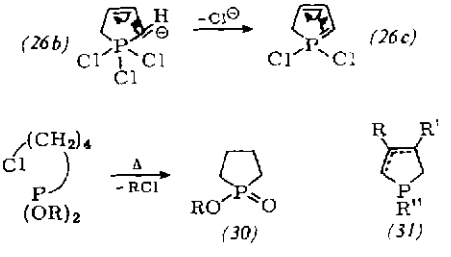
Korte[43b] recognized that the hydrolysis of the primary adduct *(26)* to yield *(27)* may be accompanied by migration of the double bond to the 2-position. The two possible products can be distinguished on the basis of ultraviolet, infrared, and NMR data[48]. The PCl_3 adducts *(26a)* (R = H; R′ = H, CH_3) undergo complete rearrangement in all their reactions, whereas a mixture of both isomers is formed in the case of R = R′ = CH_3. The reactivity of the adducts *(26a)* is similar to that of



PCl_5. Thus alcohols are chlorinated by *(26a)*, which is itself converted into the phosphinic acid *(28)* and the acid chloride *(29)*. Reactions with SO_2, acetic anhydride, and above all, orthoesters of carbocylic acids[49] permit the direct preparation of the acid chlorides *(29)*, which can then be converted into esters, thioesters, amides, and (by reaction with Grignard reagents) tertiary phospholene oxides *(27a)* (R″ = alkyl, aryl). The double bond never migrates in the PBr_3[43b] and CH_3PCl_2 adducts[50].

The tendency of the double bond to migrate is increased by a high concentration of strongly electronegative substituents on the phosphorus, and decreased by the presence of CH_3 groups in positions 3 and 4 (stabilization by hyperconjugation). The first step of the rearrangement is probably the removal of a strongly acidic α-proton to form a carbanion *(26b)* or an ylide *(26c)*.

Partial interconversion of the Δ^2- and Δ^3-phospholene oxides *(27)* occurs on heating at 200 to 300 °C or in the presence of strong bases such as $KOC(CH_3)_3$[43b,50,51].



Oxophospholanes can be obtained by catalytic hydrogenation of the double bond in *(27)* with Raney nickel, Adams' catalyst, or noble metal catalysts[42,43c]. *Helferich*[52] achieved an independent synthesis of 1-alkoxy-1-oxophospholane *(30)* by an intramolecular Michaelis-Arbuzov reaction [R = C_2H_5, $(CH_2)_3CH_3$; yield = 75 %].

The primary adducts *(26)* are dehalogenated by Mg turnings in tetrahydrofuran[53] or by $LiAlH_4$[18,53] to 1-substituted phospholenes *(31)*, [R = R′ = H, CH_3; R″ = CH_3, C_6H_5; yield = 20–40 %], with retention of the double bond (the position of which, however, must be checked). The phosphinic acids and their esters *(27)* [R″ = OH, $O(CH_2)_2Cl$] are reduced to *(31)* by $LiAlH_4$[54].

c) Phospholes

The reason for the great interest shown in the phosphole ring system is the question whether it behaves like pyrrole, *i.e.* whether the phosphorus atom in *(32)* makes its lone electron pair available for the formation of an aromatic system of 6 π-electrons *(33)*. Phosphole oxides *(34)* were obtained by *Howard*[55] (R = R′ = H, CH_3; R = H, R′ = CH_3; R″ = C_6H_5) by dehydrobromination of the bromine adducts of *(27)* with organic bases, and by *Westheimer*[56] (R = R′ = H; R″ = OC_2H_5) from the allyl bromide *(35)* or by Hofmann degradation of the methylphosphonium iodide prepared from *(35)*. As expected, the phosphole oxides *(34)* behave as cyclic

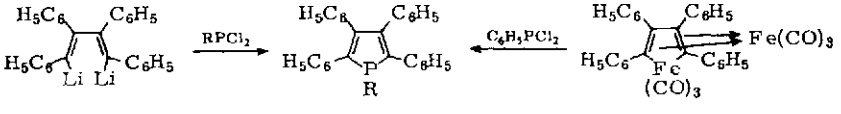
dienes. They form crystalline dimers (for R″ = C_6H_5) on standing at room temperature. The tendency to dimerize is so great in the case of 1-ethoxyphosphole oxide that this compound can only be detected by ultraviolet spectroscopy or by interception as the Diels-Alder adduct.

The phospholes themselves are obtained by a number of syntheses that are both simple and elegant. *Campbell*[57] prepared 1,3,5-triphenylphosphole [yellow needles, m.p. 186.5–187.5 °C] in a single step by the cycloaddition of $C_6H_5PCl_2$ to 1,4-diphenylbutadiene at 226 to 230 °C (thermal dehydrochlorination after migration of the halogen in *(26)* from the phosphorus to the double bond?).

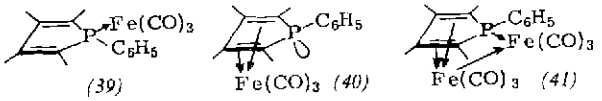
Hübel and *Braye*[58] and *Leavitt*[59] discovered about simultaneously that 1,4-dilithio-1,2,3,4-tetraphenylbuta-1,3-diene *(36)*[60], which is readily obtainable by the dimerization of diphenylacetylene with lithium, is a useful starting material for the synthesis of phospholes. It reacts with dihalogenophosphines to form *P*-alkyl- or *P*-aryl-2,3,4,5-tetraphenylphospholes *(37)*, [R = C_6H_5: light yellow needles; m.p. 255–256 °C; UV: λ_{max} (log ε) = 357.5 mμ (3.945), 320 mμ (3.94), 247.5 mμ (4.51); strong fluorescence with maximum at 480 mμ], while the phosphole oxide is obtained directly by the reaction of *(36)* with $C_6H_5P(O)Cl_2$.



(36) *(37)* R = C_6H_5, CH_3, $C_6H_5CH_2$ *(38)*

Related to this in principle is a second synthesis described by *Hübel*[58]: The $Fe(CO)_3$ complex *(38)* of butadiene[61], which is obtained by the reaction of $[Fe(CO)_4]_3$ with diphenylacetylene in boiling petroleum ether, reacts with $C_6H_5PCl_2$ at 140 °C to form pentaphenylphosphole.

The stability of triphenylphosphole and pentaphenylphosphole towards oxygen is the same as that of tertiary aromatic phosphines; benzylphosphole and methylphosphole are more liable to autoxidation. The diene character of pentaphenylphosphole oxide is shown by the formation of an adduct with maleic anhydride (yield = 67 %); the pentaphenylphosphole itself, on the other hand, gives only a 3 % yield of this adduct, so that prior oxidation appears to be possible and essential. Diethyl acetylenedicarboxylate, however, forces even 1,3,5-triphenylphosphole and *(37)* (R = C_6H_5) into diene reactions, which result in the loss of the C_6H_5P group and formation of the phthalate esters. The availability of the lone electron pair on the phosphorus becomes obvious with the quantitative formation of the σ-complex *(39)* with $Fe(CO)_5$; reaction with $[Fe(CO)_4]_3$ in addition yields the π-complexes *(40)* characteristic of conjugated dienes and *(41)*.



(39) *(40)* *(41)*

Pentaphenylphosphole oxide forms a π-complex corresponding to *(40)*, whereas the sulfide, surprisingly, yields the complex *(39)*. The tendency of the P=S bond to undergo cleavage is observed even in the reaction of *(36)* with $C_6H_5P(S)Cl_2$, which yields 45 % of pentaphenylphosphole together with 1 % of the sulfide.

Using the LCAO and SCFMO methods, respectively, *Brown*[62] calculated conjugation energies of 1.37 and 1.49 β for pyrrole and for the unsubstituted phosphole. The ease of oxidation of 1,3,5-triphenylphosphole and *(37)*, in comparison with pyrrole, can be explained by the fact that the PO bond energy is 70–90 kcal/mole greater than the NO bond energy, so that the loss of conjugation energy is more than compensated.

As is shown by a comparison of the experimental P=O dissociation energies[22a] (Table 2), the conjugation energy in the phosphole, as compared with the corresponding oxide, is much greater than in all other phosphines. The decrease in the D_{PO} value has been explained by increasing participation of the 3pπ-orbital in the conjugation.

Table 2. Dissociation energies of the P–O bonds in some phosphine oxides.

Phosphine oxide	$D_{P=O}$ [kcal/mole]
Pentaphenylphosphole oxide	100.4 ± 9.5
9-Phenyl-9-phosphafluorene oxide	126.0 ± 9.0
Triphenylphosphine oxide	128.4 ± 5.5
Trimethylphosphine oxide	139.3 ± 3.0

Since the D_{PS} values are about 50 kcal/mole lower than the D_{PO} values[2], the formation of the phosphole from the sulfide could also be "financed" by the gain in conjugation energy. The difference of 39 ± 13 kcal/mole in comparison with trimethylphosphine oxide is regarded as a measure of the conjugation energy of the phosphole[22a]. The discussion of the bonding system in the phospholes is not yet closed.

d) Five-Membered Rings Containing Pentavalent Phosphorus

Triphenylphosphine reacts with esters of acetylenedicarboxylic acid at −50 °C to form an unstable yellow 1:2 adduct, which undergoes rearrangement to *(43)*

even at room temperature[63]. On the basis of PMR measurements and the observation that the migration of the phenyl group is catalysed by $H^{\oplus}$, the primary adduct is assumed by *Hendrickson*[64] to possess the structure *(42a)*, in which the phosphorus forms five covalent $3p_\sigma-2p_\sigma$ bonds. The red acetylenedicarbonitrile adduct, for which structure *(42b)* has been postulated by *Reddy* and *Weis*[65], is unusually stable (dec. point 245 °C) in comparison with *(42a)*, as is the 1,1,1-triphenyloctacyanophosphole *(44)* (dec. point 230 °C) obtained in an exothermic reaction with tetracyanoethylene.

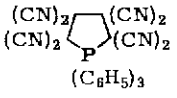
$(C_6H_5)_2$

(43), R = $COOCH_3$



$(C_6H_5)_3$

(44)

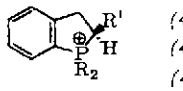
The ^{31}P–NMR spectrum of *(44)* shows a chemical shift δ of −22 ppm[65]. Since according to recent NMR studies, δ-^{31}P values of +25 to +100 ppm are to be expected for compounds of pentavalent phosphorus (phosphoranes) (see Table 3), at least the structure of *(44)* appears uncertain.

Table 3. Chemical shifts of ^{31}P–NMR signals for compounds containing pentavalent phosphorus, based on 85 % H_3PO_4 as external standard.

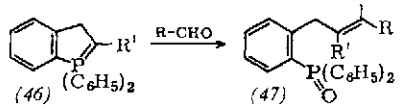
Compound	σ [ppm]	Ref.
(63a)	+97 ± 2	[67]
(63d)	+85 ± 2	[67]
$P(OC_2H_5)_5$	+70.9	[66a]
	+27.9	[66b]
	−16.9	[66b]
$[(C_6H_5)_4P]^{\oplus}Br^{\ominus}$	−22	[65]

e) Phosphindolines and Isophosphindolines

The phosphindolinium salts *(45)* are readily obtainable by methods VII[27,29] and VII[33]. Cyclic ylides *(46)* prepared by the reaction of *(45b)* and *(45c)* with potassium t-butoxide [or directly from *(11)*, n = 1] react with aldehydes in normal Wittig olefinations, with ring cleavage, to form the olefins *(47)*[33].



(45a), R' = H; R = C_2H_5
(45b), R' = H; R = C_6H_5
(45c), R = R' = C_6H_5



(46) *(47)*

As expected[68], 1-ethylphosphindoline *(48)* (b.p. 102 to 104 °C/13 mm) is formed on pyrolysis of *(45a)* at 350 to 375 °C (yield 75 %); 2-phenylisophosphindoline *(49)* is obtained in a similar manner[31]. The phosphine *(49)* possesses the unusual ability to form stable complexes having abnormal coordination numbers with transition metals of group VIII. Whereas the complexes

(48)   *(49)*

formed by aliphatic and aromatic phosphines, as well as by *(48)*, are normal *(50)*, covalent or ionic (depending on the solvent) complexes *(51)* with the coordination number 5 are also formed from *(49)*[69].

$[(Phosphine)_2PdCl_2]$ *(50)* $[A_3MX_2] \rightleftharpoons [A_3MX]^{\oplus}X^{\ominus}$ *(51)*

A = *(49)*; M = Pd, Pt, Ni, Co; X = Cl, Br, I, SCN

The explanation for this is probably the combination of favorable steric (quinuclidine character) and electronic factors (favorable relationship between optimum $P \rightarrow M$ σ-bonding and π-back donation).

f) 9-Phosphafluorenes

Of theoretical interest is the formation of 9-phenyl-9-phosphafluorene *(52)* on thermal decomposition of pentaphenylphosphorane either in the melt or in boiling benzene[22b,70,71]. The ring closure may be initiated by the removal of hydrogen atoms from the *o*-position by phenyl radicals. According to *Razuvaev*[71], the yield of 9-phospha-

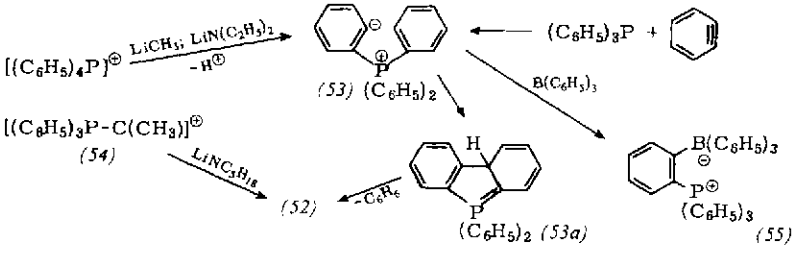
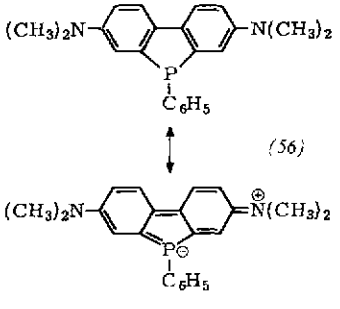
fluorene increases to 60 % if the reaction is carried out in pyridine at room temperature (150 hours) (see also [22b]).

The tetraphenylphosphonium cation reacts with methyl-lithium [22b, 73] or lithium diethylamide (yield 60 %) [72] to form *(52)*. The cyclization, which is facilitated by the inductive and mesomeric effects of the cation, is preceded by the introduction of the metal into the *o*-position to form *(53)*; the ylide *(53a)* then loses benzene to form *(52)*.



The fact that, even in *(54)*, the *o*-attack by the metal is preferred to attack on the β-hydrogen atoms of the t-butyl group is shown by the formation of *(52)* [42 %, together with 8 % of $(C_6H_5)_3P$] on reaction of *(54)* with lithium piperidide [73]. A second route to *(52)* *via* the intermediate *(53)* is the addition of benzene to triphenylphosphine, discovered by *Wittig* and *Benz* [74]; *(53)* was intercepted as the $B(C_6H_5)_3$ adduct *(55)*. This reaction became preparatively important as a result of *Zbiral*'s work [75]. The surprising formation of *(52)* (yield 10 %) from $(C_6H_5)_3P$ and phenylsodium [70] undoubtedly proceeds by an *o*-deprotonation, although this reaction is not favored.

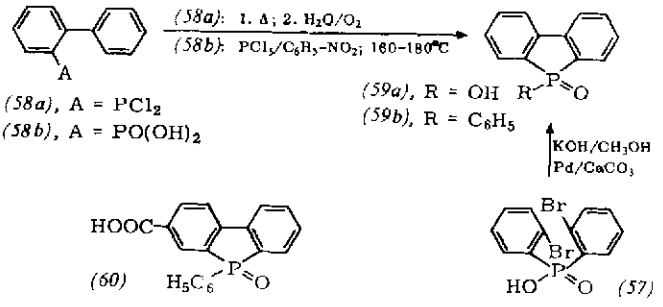
The conventional Method VI [22a–22c] was found to be particularly useful for the synthesis of *(56)* and of 9-(*p*-dimethylaminophenyl)-9-phosphafluorene. The bright



yellow phosphine *(56)* and its orange-red methylphosphonium salt clearly indicate that the phosphorus participates in the conjugation of the biphenyl system.

Many derivatives, particularly containing substituents in the nucleus, have been obtained by the intramolecular electrophilic substitution of substituted biphenyl derivatives *(58a)* and *(58b)* [prepared from the diazonium fluoroborates by reaction with PCl_3 and $C_6H_5P(O)Cl_2$] [76a, 76b, 77]. 2-Carboxy-9-phosphafluorene 9-oxide *(60)* [m.p. 250–251 °C; $[\alpha]_D^{20} = \pm 126 \pm 2°$), which is prepared from the 2-methyl derivative of *(59b)*, has been resolved into its optical antipodes by *Campbell* [77], using the amide of (+)- or (−)-α-phenylethylamine; both antipodes are fully racemized to the phosphine on reduction with $LiAlH_4$.

Finally, another variant is the application of *Busch*'s [78] biphenyl synthesis to phosphinic acids such as *(57)*, particularly for derivatives of the phosphinic acid *(59a)* [79].



g) 9-Phosphafluorenes Containing Pentavalent and Hexavalent Phosphorus. Spiro Compounds

This field was pioneered by *Wittig* and his school. In an adaptation of the synthesis of $(C_6H_5)_5P$ to 9-phosphafluorenes, the salts *(62)* of the latter are treated with phenyl-lithium. For example, 9,9,9-triphenyl-9-phosphafluorene *(61)* [m.p. 155.5–156.5 °C; yield 84 %] is obtained by the addition of phenyl-lithium and displacement (S_N2 reaction) of the methylaniline residue by a second mole of phenyl-lithium; the reaction with 2,2′-dilithiobiphenyl leads to the spiro compound *(63a)* [m.p. 201.5–202.5 °C; yield 68 %], and that with 2,2′-dilithio-4,4′-bis(dimethylamino)biphenyl to *(63b)* [80]. The tosylimines of the 9-phosphafluorenes, too, are suitable starting materials for the synthesis of *(63)* [*(63a)–(63c)* from 9-(*p*-dimethylaminophenyl)-9-phosphafluorene] and are more readily obtainable than

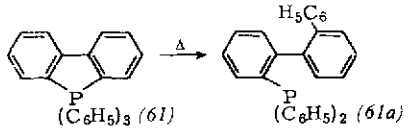
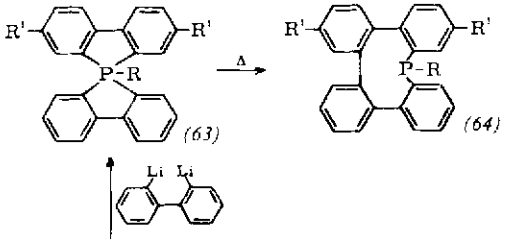
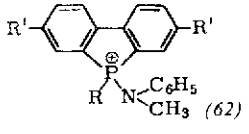
(62)[22b]. Corresponding to the behavior of the phosphole *(42a)*, compound *(61)* rearranges to the tertiary phosphine *(61a)* with migration of the phenyl group, but only at temperatures above the melting point [*i.e.* 250 °C higher than in the case of *(42a)*]. The analogous rearrangement of *(63)* yields derivatives of the 1-substituted phosphacyclononatetraene *(64)*. The stereochemical behavior of *(61)* and *(63)* must be interpreted in accordance with the trigonal-bipyramid arrangement of the phenyl groups in $(C_6H_5)_5P$[81].



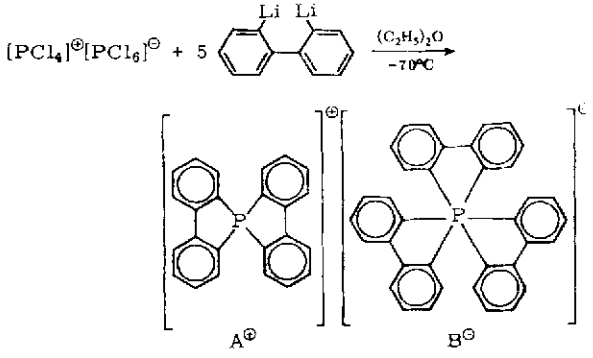


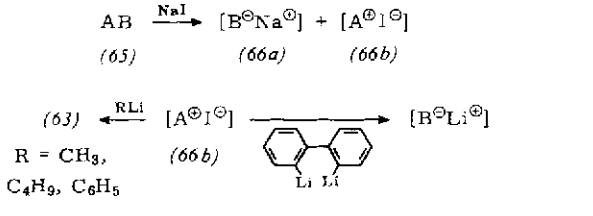


(a): R' = H; R = C_6H_5
(b): R' = $N(CH_3)_2$; R = C_6H_5
(c): R' = H; R = p-$(CH_3)_2N$-C_6H_4
(d): R' = H; R = CH_3
(e): R' = H; R = C_4H_9

Heterocycles containing hexavalent phosphorus were first prepared by *Hellwinkel*[67]. The reaction of 2,2'-dilithiobiphenyl with PCl_5 leads directly to the onium-ate complex $A^{\oplus}B^{\ominus}$ *(65)*, which crystallizes as yellow needles.

The ^{31}P–NMR values are δ = −26.5 ppm for $A^{\oplus}$ (in agreement with the values for other phosphonium salts, cf. Table 3) and δ = +186.5 ppm for $B^{\ominus}$, as compared with +118 ppm and +305 ppm for $PF_6^{\ominus}$ and $PCl_6^{\ominus}$, respectively.





[81] *P. J. Wheatley*, J. chem. Soc. (London) *1964*, 2206.

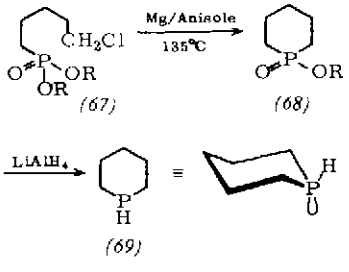
Compound *(65)*, which is stable in boiling ethanol or water, is decomposed by NaI into the sparingly soluble phosphonium iodide *(66b)* and sodium trisbiphenylylenephosphate *(66a)*. The octahedral structure of the anion $B^{\ominus}$ is clearly demonstrated by the resolution of potassium trisbiphenylylenephosphate ($[\alpha]_{578}^{24.5}$ = 1920 ± 30 °).

The iodide *(66b)*, which is directly obtainable (yield 87 %) by the action of 2,2'-dilithiobiphenyl on triphenyl phosphate, is a valuable starting material for the synthesis of the phosphoranes *(63)* and (with dilithiobiphenyl) of the ate-complex itself. Compound *(63)* (R = 2-biphenylyl) is formed by acid cleavage and *(64)* (R = 2-biphenylyl, R = H) by pyrolysis (270 °C) of lithium trisbiphenylylenephosphate.

3. Six-Membered Rings

a) Phosphorinanes

Phosphorinanes (phosphacyclohexanes) and their phosphonium salts, which are synthesized by Methods I, II, III, and V, present no new features in comparison with the phospholanes. The parent compound *(69)* is a readily oxidizable liquid (b.p. 110 °C; m.p. 19 °C) and was prepared by *Howard*[82] by the reduction of *(68)*, which is obtained by an intramolecular Grignard reaction with a phosphonate *(67)*.



Two simple and valuable syntheses of 1-substituted phosphorinan-4-ones were developed by *Welcher*. The bis-(2-cyanoethyl)phosphines *(70)*, which are obtained in good yields by the thermal[83a] or base-catalysed[83b] addition of primary phosphines to acrylonitrile, can be cyclized by the Thorpe-Ziegler method to *(71)* (the enamine structure is confirmed by infrared and PMR spectra); the hydrolysis of *(71)* leads directly to *(72)*[84,85].

After numerous unsuccessful attempts to prepare 1-phenyl-1-phospha-4-tetralone *(73)* by intramolecular

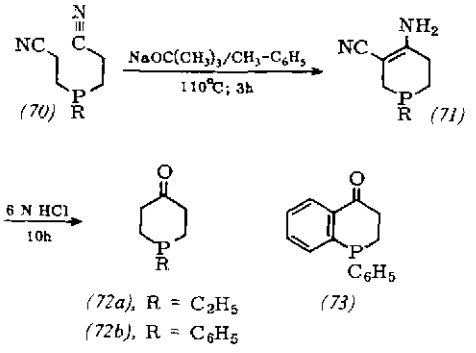
[84] *R. P. Welcher*, *G. A. Johnson*, and *V. P. Wystrach*, J. Amer. chem. Soc. *82*, 4437 (1960); German Pat. 1162840 (Febr. 13th, 1964), inventors: *R. P. Welcher*, *G. A. Johnson*, and *V. P. Wystrach*; Chem. Abstr. *60*, P 14542a (1964).

[85] *M. J. Gallagher* and *F. G. Mann*, J. chem. Soc. (London) *1962*, 5110.

acylation on the benzene nucleus [86], *Mann* succeeded in preparing this compound from the benzonitrile derivative corresponding to *(70)*, which is difficult to obtain [87a]. The formation of phosphonium salts and

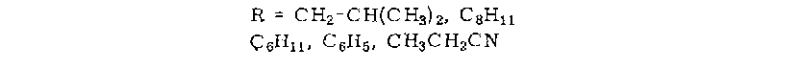


(70) *(71)* *(72a)*, R = C_2H_5 *(72b)*, R = C_6H_5 *(73)*

normal carbonyl derivatives and the position of the C=O band [1695 and 1680 cm^{-1} for *(72b)* and *(73)*, respectively] indicate that there is no interaction between the carbonyl group and the phosphine part of the molecule.

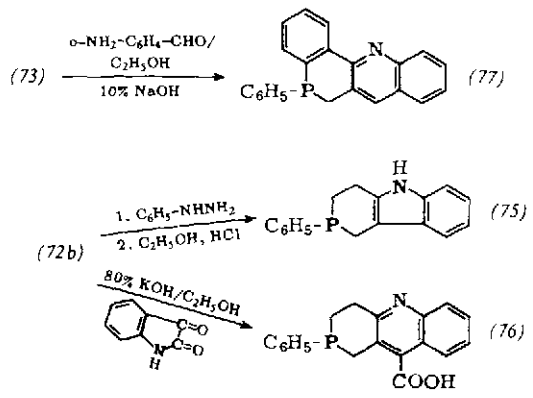
PH_3 and primary and secondary phosphines add onto olefins by a free-radical mechanism; however, the addition can also be catalysed by $H^{\oplus}$ ions or, in the case of strongly polar double bonds, by $OH^{\ominus}$ ions [88]. The possibility of cycloadditions was proved by the preparation of the phosphorinanones *(74)* from primary phosphines and phorone $[(CH_3)_2C{=}CH]_2CO$, dibenzalacetone, *etc.* [89]. In some cases the initial products are open-chain or macrocyclic polymers, which form *(74)* on thermal decomposition (sublimation at 220 °C/0.1 mm).

Reduction of *(74)* with $LiAlH_4$ yields the cyclic alcohols, whereas *Wolff-Kishner* reduction leads to the phosphorinanes. Chemical reactions at the ring became possible for the first time with the phosphorinanones [85, 87a, 87b]. The *Fischer* indole synthesis when applied to the phenylhydrazone of *(72a)* leads to the indole derivative *(75)*; compound *(73)* reacts similarly, in contrast to the formation of the yellow, conjugated Ψ-indoles [*] from the tetralones. The Pfitzinger condensation of *(72b)* yields *(76)*, and the Friedländer condensation of *(73)* yields *(77)*.



(74a) *(74b)*

R = $CH_2{-}CH(CH_3)_2$, C_8H_{11}, C_6H_{11}, C_6H_5, CH_3CH_2CN

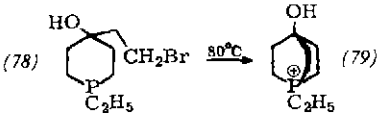


(73) *(77)* *(72b)* *(75)* *(76)*

The yellow color of the hydrochloride of the colorless compound *(77)* has been interpreted by *Mann* as being due to a small contribution by the limiting structure in which phosphorus forms a $p_{\pi}{-}p_{\pi}$ double bond:

$$\overset{\cdot\cdot}{>}P{-}C{=}C{-}CH{=}\overset{\oplus}{N}H{-} \;\leftrightarrow\; \overset{\oplus}{>}P{=}C{-}C{=}CH{-}\overset{\cdot\cdot}{N}H{-}$$

In the corresponding N series, these salts are deep red [87b], owing to the formation of a delocalized π-electron system in a phenylogous trimethinecyanin.



(78) *(79)*

Compound *(72a)* was used for the synthesis of the phosphine *(78)*, which undergoes self-alkylation in boiling benzene to form 1-ethyl-4-hydroxy-1-phosphoniabicyclo[2.2.2]octane bromide *(79)* [90]. The theoretically interesting bicyclic phosphine could not be obtained from *(79)*.

b) 1,1-Diphenylphosphabenzene and 1,1-Diphenylphosphanaphthalene

The trimeric phosphonitrilic chlorides *(80)* are ring systems of pentavalent phosphorus which contain only double bonds of the $p_{\pi}{-}d_{\pi}$ type. MO calculations taking into account only the d_{xz} orbital of the phosphorus *(81)* led *Craig* [91] to postulate the existence of a new type of aromatic system (4n π-rule). *Dewar* [92], on the other hand, believes that each phosphorus atom uses two orthogonal d orbitals, $d_{\pi a}$ and $d\pi b$, *(81)* (from a linear combination of d_{yz} and d_{yz}) in localized three-center π-honds.

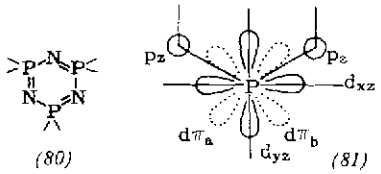
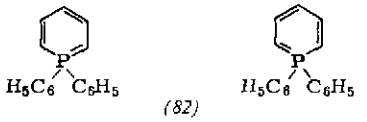
The question of the consequence of replacing one $2p_\pi-2p_\pi$ double bond in benzene with a $2p_\pi-3d_\pi$ double bond led to the synthesis of 1,1-diphenylphosphabenzene *(82)* [29,93]. This compound possesses the structural characteristics of a methylenephosphorane, for which two Kekulé structures can formally be written.

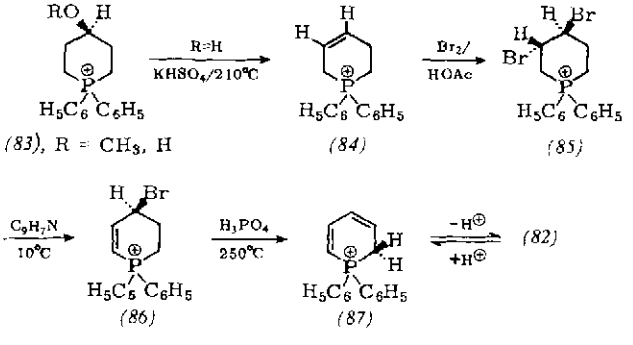


(80) *(81)*



(82)

The ether linkage of 1,1-diphenyl-4-methoxy-1-phosphoniacyclohexane bromide *(83)* (prepared by Method III [13]) can be cleaved to form the alcohol; this is then dehydrated to obtain *(84)*, the double bond being formed in the 3,4-position [$\nu_{C=C}$ = 1637 cm^{-1}]. Intermediate ylide formation permits the ready dehydrobromination of the Br_2 adduct *(85)* to the vinylphosphonium salts *(86)* [$\nu_{C=C}$ = 1596 cm^{-1}]. Since *(86)* is a vinylogous α-bromophosphonium salt [94], both the hydrogen and the bromine at position 4 are active ($H^\oplus$, $Br^\ominus$), and since it is also an allyl bromide, it also possesses S_N1 reactivity. The introduction of the second double bond to form a 1,1-diphenyl-1-phosphoniacyclohexa-2,4-diene salt *(87)* (perchlorate: m.p. 117–119 °C; $\nu_{C=C}$ = 1626, 1572, 1550 cm^{-1}) is possible only with the catalytic action of hot H_3PO_4.



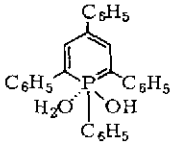
(83), R = CH_3, H *(84)* *(85)*

(86) *(87)* *(82)*

The cation *(87)* is deprotonated by dilute alkalis even in aqueous solution. Compound *(82)* is formed as a yellow (λ_{max} = 409 mμ in ether), non-crystalline precipitate which is stable in water; *(87)* is re-formed in acidic solution. Similar open-chain phosphonium salts, as well as *(84)*, form ylides only with strong bases, and these ylides are extremely readily hydrolysed.

The question of whether this stabilization of *(82)* is due to the formation of a delocalized π-electron system (through conjugation at the phosphorus atom) or to resonance stabilization as postulated by *Dewar* (the phosphorus atom acts as an "insulator" owing to the orthogonality of the d-orbitals) has not yet been settled (see also [95]).

Price [96,97] adapted the classic synthesis of pyridine from pyrilium salts to the preparation of phosphorus heterocycles. $C_6H_5PH_2$ reacts with 2,4,6-triphenylpyrylium fluoroborate in boiling pyridine to form two compounds, one being amorphous and the other crystalline (m.p. 257 °C, colorless). The structure *(88)* has been assigned to the former on the basis of infrared, PMR and ^{31}P–NMR measurements; no protonation of the "quasi-ylide" corresponding to *(82)* ⇌ *(87)* can be observed.



(88)

The deep red ylides of the 3,4-dihydro-1,1-diphenyl-1-phosphanaphthalenes *(90)* [29,33] are formed from the salts *(89)* (obtained by Methods VII and VIII) on treatment with strong bases in aprotic solvents. With these ylides, as with compounds *(46)*, normal Wittig reactions can be carried out. Moreover, *(90)*, R = H, can be methylated or acylated to the stable α-acylylide *(91)*. The bromination of *(89)* to *(92)* with *N*-bromosuccinimide, followed by H_3PO_4-catalysed dehydrobromination, leads to almost quantitative yields of the diene salts *(93)* (perchlorates: R = H, m.p. 173 °C; R = CH_3, m.p. 197–199 °C; R = C_6H_5, m.p. 182–183 °C). In agreement with the structure *(82)*, the ylides *(94)* can be deposited from the aqueous solutions of their salts (R = H; λ_{max} = 439 mμ; strong infrared band at 1550 cm^{-1}; PMR doublet at 4.46 τ, J = 9 c/s, 1 proton; complex spectrum from 2.3 to 3.3 τ). Attempted Wittig olefinations have so far been unsuccessful. Thus *(94)* cannot form betaines with the carbonyl component (by participation of the free electron pair on the ylide carbon atom in a resonance system), but it exhibits nucleophilic behavior towards stronger electrophiles. *(94)*, R = H, is methylated at position 4 (according to infrared and PMR measurements) to give *(95)*; with R = CH_3 or C_6H_5 it couples with diazonium salts to form 4-azo compounds *(96)* and, in the case of R = H, the 2,4-bisazo compounds *(96)*, R = –N–N–R′, is obtained; the cation *(95)* forms the isomeric 2-azo compound [98].

The phosphanaphthalenes with R = H, CH_3 and phosphabenzene *(82)* are extremely susceptible to autoxidation. A mixture of high-molecular weight colored salts (λ_{max} = 460–600 mμ), which are vinylogues of the simplest phosphacyanin $(C_6H_5)_3P{=}CH{-}P(C_6H_5)_3$ [99], are formed, probably *via* free-radical cations such as *(97)*. The ease of formation of *(98)* also indicates a

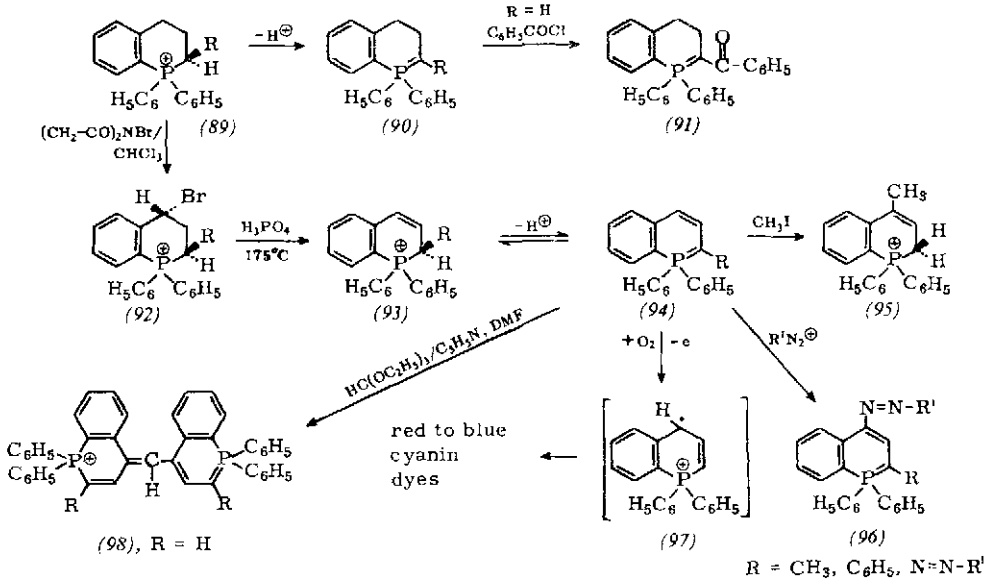
considerable gain in π-electron delocalization energy in the transition from the phosphanaphthalene to a phosphacyanin system[13,93].

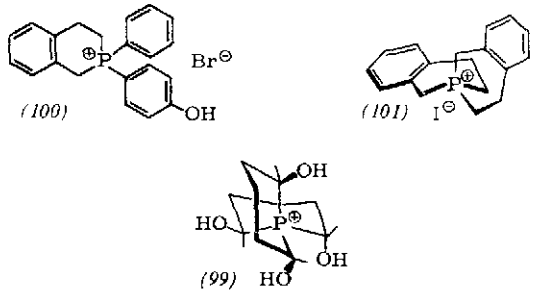
9,9-Diphenyl-9-phosphaphenanthrene[100] is obtained in the same way as *(82)* and *(94)*, from the corresponding phosphonium salt (prepared by Method VII) in aqueous solution. Once again, no Wittig reactions have been observed.

1,5,7,11-Tetrahydroxy-6-phosphoniaspiro[5,5]undecane salts *(99)* and the spiro compound *(6)*, n = 2, with five-membered rings are formed in a single step by Method IV[15b, 16b]. In the paddle-wheel arrangement of the OH groups which is postulated for steric reasons, the molecule has the *meso* structure[103].



c) Tetrahydrophosphinoline, Tetrahydroisophosphinoline, and Spirophosphonium Salts

P-Ethyltetrahydrophosphinoline and *P*-ethyltetrahydroisophosphinoline, like the phosphines *(48)* and *(49)*, can be obtained in good yields as oils which are relatively stable in air, by thermolysis of the diethylphosphonium salts (obtained by Method VII)[28,32,101]. The first optically active phosphonium salt was prepared by *Mann*[32] by the resolution of the camphorsulfonate of the asymmetrically substituted isophosphinolinium salt *(100)* (m.p. 268–270 °C, $[M]_D$ = +32.9 °).



The phosphonium iodide *(101)*[102], which is obtained by twofold intramolecular salt formation (Method VII) exhibits molecular asymmetry, and has been resolved into its optical antipodes by means of the (−)-menthyl acetate (iodide: m.p. 246–248 °C, $[M]_D$ = −65 ° and +66 ° in $CHCl_3$).

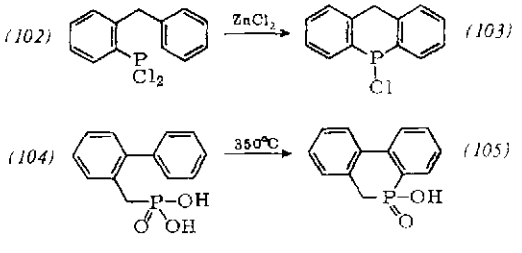
d) Phospha-anthracene and Phosphaphenanthrene

The dichlorophosphine *(102)*, which is prepared in the same way as *(58a)*, undergoes ring closure in the presence of $ZnCl_2$ to form 9-chloro-9-phospha-anthracene *(103)*, which is converted by hydrolysis and oxidation into the phosphinic acid[76]. The acid *(104)*, which can be obtained from 2-bromomethylbiphenyl by an Arbuzov reaction, cannot be cyclized by the usual methods (with P_2O_5, PCl_5, $AlCl_3$); it is, however, cyclized to 9-hydroxy-9-oxo-9-phosphaphenanthrene *(105)* simply on heating at 350 °C[104].



4. Seven- and Eight-Membered Rings

1-Benzyl-1-phosphacycloheptane and 1-phenyl-1-phosphacyclooctane have been synthesized by Method I[7]. Attempted syntheses by other methods led only to polymeric products. The phosphacycloheptadiene *(106)*

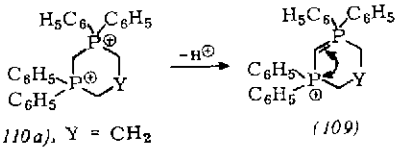
(m.p. 75–75.5 °C) is practically identical to $(C_6H_5)_3P$ in its chemical behavior and in its ultraviolet spectrum[105]. The phosphonium salt *(107)* has been obtained by intramolecular ylide alkylation in accordance with Method VIII[33].

(106)  *(107)* 
C. Heterocycles Containing Two or More Phosphorus Atoms

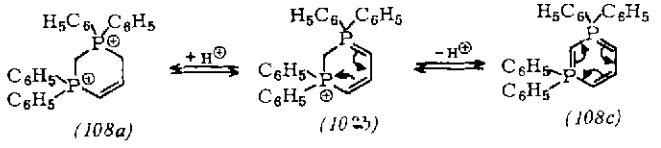
1. 1,3-Diphosphacyclohexane and Cyclic Phosphacyanins

Bisphosphonium salts containing the ring system *(110)* can be readily obtained by the reaction of bis(diphenylphosphino)methane[107] with 1,3-dihalogeno compounds[106]. The salts *(110)* lose a proton in aqueous sodium carbonate solution to give a quantitative yield of the resonance-stabilized phospha-amidinium salts *(109)*. A double bond can be introduced by the dehydration of the alcohol *(110c)* with polyphosphoric acid. The resulting compound *(108)*, like *(110)*, is deprotonated to the resonance-stabilized cyclic trimethinephosphacyanin *(108b)* [perchlorate: m.p. 236–237 °C, $\nu_{C=C}$ = 1620 cm^{-1}, λ_{max} (log ε) = 268 mμ (3.954), 274 mμ (3.967), 340 mμ (4.086)]. A second proton is removed by stronger bases such as aqueous sodium hydroxide, and 1,1,3,3-tetraphenyl-1,3-diphosphabenzene *(108c)* separates out from aqueous solution as a bulky, yellow, non-crystalline precipitate (λ_{max} = 281 and 384 mμ).



(110a), Y = CH_2
(110b), Y = CO
(110c), Y = CHOH

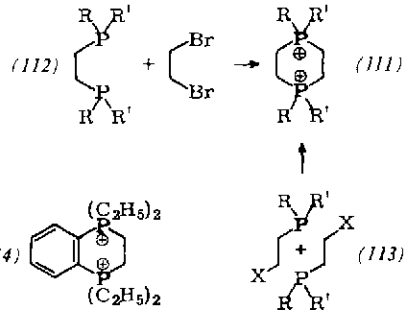
(109)



(108a) *(108b)* *(108c)*

2. 1,4-Diphosphacyclohexane and 9,10-Dihydrophosphanthrene

The bis-quaternary salts *(111)* are again very easy to prepare. One method is by salt formation between 1,2-bis(phosphino)ethanes *(112)*[107] with 1,2-dibromoethane[93, 108–111]; 1,2-bis(diethylphosphino)benzene reacts to form *(114)*. 1,3-Dibromopropane and *o*-bis(bromomethyl)benzene react to form seven- and eight-membered bisphosphonium salts, respectively[112, 113]. A second method is by the free-radical addition of secondary phosphines to vinyl acetate or vinyl bromide at 80 °C. This leads to the phosphines *(113)*. With R = R′ = CH_2CH_2CN and X = OAc, Br, these dimerize even during the preparation to form *(111)*. Temperatures between 120 and 150 °C are required for the dimerization when R = R′ = butyl, isobutyl, or C_6H_{11} (yield = 21–59 %)[109]; linear polymers are first formed at 80 to 120 °C, and these then rearrange at higher temperatures to form *(111)*.



(112) *(111)* *(114)* *(113)*

R = R′ = C_6H_5, $CH_2C_6H_5$, CH_2CH_2CN;
R = C_6H_5, R′ = C_2H_5, $CH_2C_6H_5$

Diphenylvinylphosphine dimerizes quantitatively to *(111)*, R = R′ = C_6H_5, in the presence of proton donors [HOAc, $(C_2H_5)_3NH^{\oplus}Cl^{\ominus}$, α-halogenohydrins]; besides the protonated phosphine, another possible intermediate is the cyclic bis-ylide[114]. On thermolysis of *(111)* (R = C_2H_5, R′ = C_6H_5), ethylene is split off to reform the original phosphine *(112)*.

The reductive debenzylation of phosphonium salts with $LiAlH_4$ was found to be an excellent method of preparing 1,4-diphosphacyclohexanes *(116a)* (m.p. 90–92 °C) and *(116b)* (m.p. 128–130 °C)[108b]. The availability of secondary bis(phosphino)ethanes and their lithium salts *(115)* enabled *Issleib*[115] to develop a direct synthesis of the compound *(116)* without first forming the phosphonium salts. The remarkable octafluoro derivative *(117)* (m.p. 73–73.5 °C, yellowish crystals) is formed, together with a little phospholane *(118)*, in the reaction

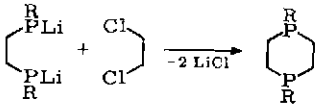
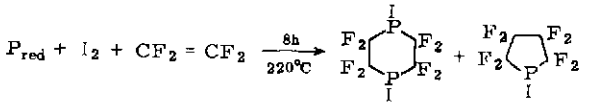
of tetrafluoroethylene with elementary red phosphorus(!) in the presence of stoichiometric quantities of iodine [116].

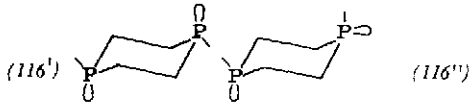


(115) (116a), R = C_6H_5
(116b), R = $CH_2C_6H_5$

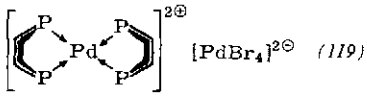


(117) (118)

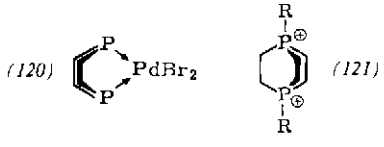
The stability of the phosphines against inversion, as discussed in the Introduction, suggests that *(116)* should exist in two stereoisomeric forms *(116')* and *(116'')*. Compounds *(116a)* and *(116b)* have sharp melting points; they form the complexes *(119)* and *(120)* with $K_2[PdCl_4]$, give bicyclic salts *(121)* with dibromoethane, and form uniform oxides on oxidation [109]. The existence of the *cis* structure *(116'')* thus appears to be certain. On the other hand, the oily product with R = C_6H_5 which was obtained by *Issleib* [115] by distillation at 300 to 310 °C/7 mm was probably the isomer mixture of *(116)*. This also holds for the products with R = C_2H_5, $CH_2C_6H_5$, and cyclo-C_6H_{11}. Since the uptake of oxygen



(116') (116'')



(119)



(120) (121)

or sulfur is not accompanied by inversion of the configuration [117], the formation of two isomeric sulfides and of oxides with very indistinct melting points supports this belief.

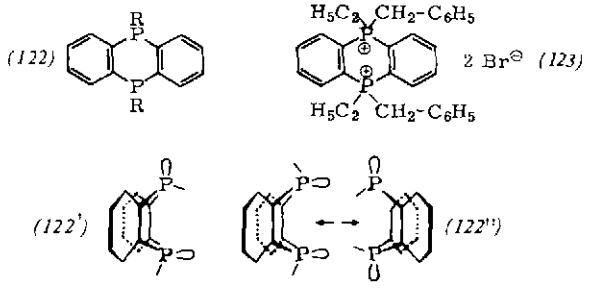
The 9,10-diethyl-9,10-dihydrophosphanthrene *(122)* with R = C_2H_5, which was prepared by *Mann* [118] using Method VI, fulfils these stereochemical expectations. The compound is separated from the reaction mixture by precipitation as the bisbenzylphosphonium bromide *(123)*; the expected salts *(123a)* [m.p. 346 °C] and *(123b)* [m.p. 319 °C] with *cis-trans* isomerism about the tetrahedral phosphorus atom were found.

[116] *C. G. Krespan* and *C. M. Langkammerer*, J. org. Chemistry *27*, 3584 (1962); US.-Pat. 2931803 (Apr. 5th, 1960), inventor: *C. G. Krespan*; Chem. Abstr. *55*, 12436 (1961).

[117] *L. Horner* and *H. Winkler*, Tetrahedron Letters *1964*, 175.

[118] *M. Davis* and *F. G. Mann*, Chem. and Ind. *1962*, 1539; J. chem. Soc. (London) *1964*, 3770.

The debenzylation of *(123a)* gives rise to two phosphanthrenes, *i.e.* *(122a)* [m.p. 52–53 °C] and a little *(122b)* [m.p. 96–97 °C]; the isomerism of these compounds is due to the stable *cis* and *trans* arrangements of the substituents R in the molecule, which is folded about the P–P axis [*(122')* and *(122'')*]. This "butterfly conformation" permits a synchronous oscillation of



(122) (123)

(122') (122'')

the benzene rings about the P–P aixs without loss of isomerism [cf. Formula *(122'')*]. Since *(122a)* readily reacts with dibromoethane and *o*-bis(bromomethyl)-benzene to form bicyclic phosphonium salts, and forms a 1:1 complex with $K_2[PdCl_4]$, for which only a bimolecular *cis* structure is possible, this is probably the *cis* isomer *(122'')*.

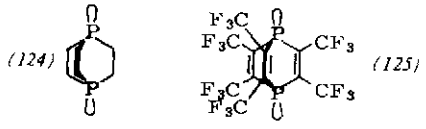
Compound *(122)* with R = C_6H_5 as well as 9,10-diphenyl-9-phospha-10-arsaphenanthrene form only one of the two possible stereoisomers, probably because of the greater bulk of the phenyl group [118].

3. 1,4-Diphosphabicyclo[2.2.2]octane

The first phosphine with the phosphorus in a bridgehead position, *i.e.* 1,4-diphosphabicyclo[2.2.2]octane *(124)* (colorless needles, m.p. 252 °C), was prepared by *Mann* [108b] by the debenzylation of *(121)* (R = $CH_2C_6H_5$) with $LiAlH_4$. Even in boiling benzene, *(124)* is not oxidized by atmospheric oxygen, and quaternization with CH_3I occurs only on heating. The ease of sublimation of this compound is reminiscent of the behavior of quinuclidine and triethylenediamine.

The low nucleophilicity of this compound as compared with normal phosphines may be due to the resistance of the phosphine *(124)* to the widening of the valence angle associated with the change from sp^2 to sp^3 hybridization.

The unexpected formation of the 1,4-diphosphabicyclo-[2.2.2]octatriene derivative *(125)* from hexafluorobut-2-yne and elementary red phosphorus (200 °C, 8 hours, I_2 as catalyst) again shows the special position occupied by perfluorinated compounds, even in the chemistry of phosphorus [119]. The evidence for the structure of the colorless and, like *(124)*, readily sublimable product *(125)* (m.p. 119–120 °C) is based mainly on infrared and ^{19}F–NMR measurements.



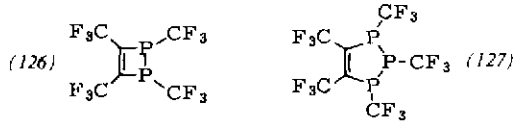
(124) (125)

[119] *C. G. Krespan, B. C. McKusick*, and *T. L. Cairus*, J. Amer. chem. Soc. *82*, 1515 (1960); *C. G. Krespan, ibid. 83*, 3432 (1961); US.-Pat. 2996527 (Aug. 15th, 1961); Chem. Abstr. *56*, 1483 (1962).

The decrease in the basicity and nucleophilicity is even more pronounced in *(125)* than in *(124)*: compound *(125)* is insoluble in concentrated H_2SO_4, does not react with CH_3I or benzyl bromide, and does not add on Br_2. Beside the change in the valence angle, there are other factors that contribute to the decrease in basicity, *i.e.* steric hindrance by the CF_3 groups, electron deficiency on the phosphorus owing to the attraction of electrons by the CF_3 and vinyl groups, and possible stabilization of the trivalent phosphorus by $d_\pi - p_\pi$ overlap with the adjacent double bonds.

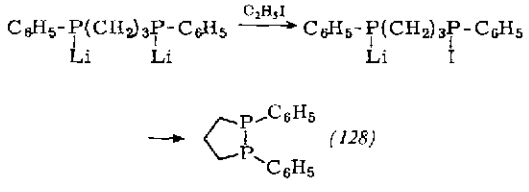
4. 1,2-Diphosphacycles and 1,2,3-Triphosphacycles

Interaction of the d-orbital of the phosphorus with the p_π-orbitals of adjacent double bonds is also indicated by ultraviolet measurements on the 1,2-diphosphacyclobutene and 1,2,3-triphosphacyclopentene derivatives *(126)* and *(127)*, which are formed from hexafluorobut-2-yne and the cyclopolyphosphines $[P(CF_3)]_n$ (n = 4,5)[120]. These phosphines, which are stable in a nitrogen atmosphere, ignite spontaneously on contact with



(126) *(127)*

air. The structurally related 1,2-diphenyl-1,2-diphosphacyclopentane *(128)* (b.p. 184–190 °C) is formed by an exchange reaction[121,122]:

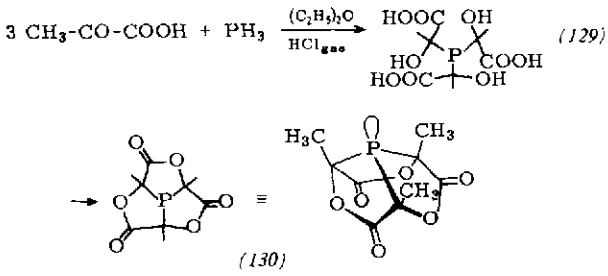


(128)

D. Phosphorus Heterocycles which also Contain Oxygen or Nitrogen as Ring Atoms

1. 1-Oxa-3-phosphacyclopentanes

Unusual phosphorus heterocycles have been obtained by unexpected reactions. An example is the reaction between PH_3 and pyruvic acid, which was carried out as early as 1888[123], and which was shown by *Buckler*[124a–124c] to yield the product *(134)*. The $H^\oplus$ catalysed nucleophilic addition of PH_3 to the C=O groups to form *(129)* is followed by closure of the γ-lactone ring to form *(130)*.

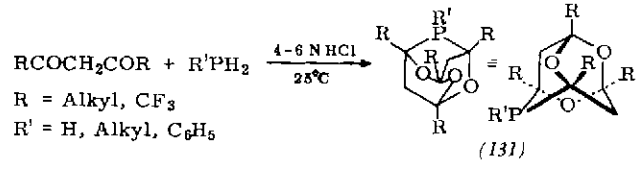


(129)

(130)

Compound *(130)*, which like *(124)* is a tertiary phosphine with a bridgehead phosphorus atom, cannot be protonated even in $HClO_4$/nitromethane, and does not react with CH_3I, H_2O_2, or sulfur. Therefore, the rigid polycyclic system appears to be incapable of tolerating a tetrahedral phosphorus atom at the bridgehead.

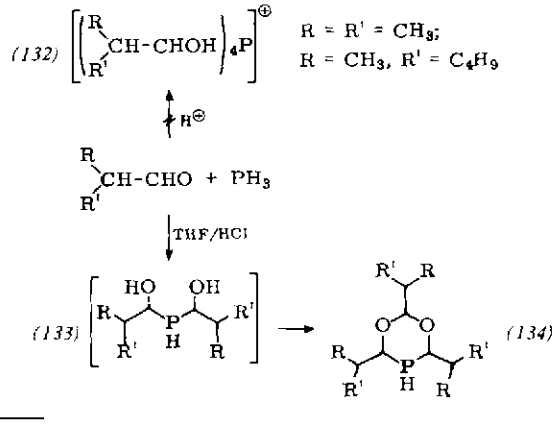
The reaction of acetylacetone with PH_3 has also been known for a long time[123]. *Epstein* and *Buckler* found that the product (as well as the products obtained with other 1,3-diketones and secondary phosphines) has the phospha-adamantane structure *(131)*. These compounds behave as normal phosphines[125].



(131)

2. 1,3-Dioxa-5-phosphacyclohexane

The nucleophilic addition of PH_3 to α-branched aldehydes leads to 2,4,6-trialkyl-1,3-dioxa-5-phosphacyclohexanes[124b,127], and not to the expected[126] phosphonium salts *(132)*. For steric reasons, only the 1:2 adduct *(133)* is formed, and this is then cycloacetalized to *(124)*. The accumulation of bulky substituents favors both the ring closure and the stability of *(134)*, which is



(132) R = R' = CH_3; R = CH_3, R' = C_4H_9

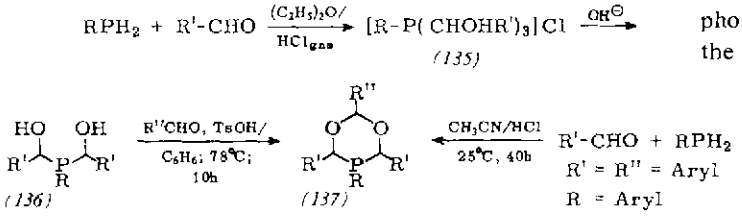
not decomposed even in boiling concentrated HCl. The similarity to normal secondary phosphines is only slight. The 1,3-dioxa-5-phosphacyclohexanes have a mild, not unpleasant odor (!), and are more stable towards oxygen than other secondary phosphines.

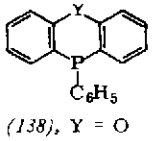
The generally lower sensitivity to oxygen of cyclic as compared with open-chain phosphines indicates that autoxidation is probably hindered by the conformational change accompanying the P → PO transition, as well as by steric shielding of the σ-orbital of the phosphorus.

The α-hydroxyalkylphosphonium salts *(135)* obtained from primary phosphines (R = alkyl, aryl) and aliphatic aldehydes can be readily degraded by bases to the α,α'-dihydroxyphosphines *(136)*, the acetalization of which with any aldehyde (R'' = alkyl, aryl) also leads to cyclic compounds *(137)* [128]. Aromatic aldehydes also react directly with aryl-substituted secondary phosphines (benzaldehyde even reacts with PH_3 [124b, 130]) to give *(137)* (R' = R'') [129].

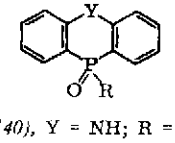


3. 9-Phosphaxanthene and 9,10-Dihydrophenophosphazine

9-Phenyl-9-phosphaxanthene *(138)* (m.p. 94–94.5 °C) has been prepared from 2,2'-dibromodiphenyl ether by Method VI [26]. 2,2'-Dibromodiphenylamine, which is difficult to prepare, gives only polymerization products, owing to metalation of the NH group [25a]. The alkylation of the amine *via* the Li compound [131] led to *(139)* [R = CH_3: pale yellow crystals, m.p. 154 to 157 °C] [25b]. Compounds *(138)* and *(139)* are almost identical in their chemical behavior and in their ultraviolet spectra to $(C_6H_5)_3P$. The valence angles (C–O–C: 116 ± 4 °; C–N–C: 107 °) indicate a folded structure, as in *(122)*.



(138), Y = O
(139), Y = NR



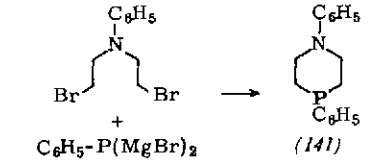
(140), Y = NH; R = H
(140a), Y = O; R = OH

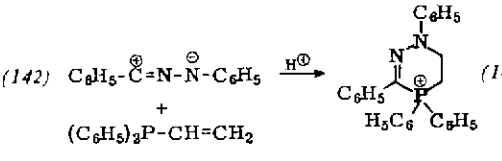
Michaelis and *Schenk* [132] reported a phenophosphazine derivative, *i.e.* the secondary phosphine oxide *(140)* (m.p. 214–216 °C, yield 40 %), which they had prepared by the reaction of diphenylamine with $PCl_3/ZnCl_2$ (in a sealed tube) followed by hydrolysis. This was later confirmed, in particular by *Häring* [133]. Compound *(140)* is oxidized to the phosphinic acid by atmospheric oxygen, whereas the reaction with bromine surprisingly leads to a dibrominated product in which no attack on the phosphorus has taken place. Whereas di-*p*-tolyl ether reacts in a similar manner with ring closure [76b], the unsubstituted phosphinic acid *(140a)* is obtainable only by the cyclization of dichloro-*o*-phenoxyphenylphosphine, which proceeds on heating [76a].

4. 1-Aza-4-phosphacyclohexane

The applicability of Method II in cases in which the dibromoalkane chains also contain heteroatoms is shown by the synthesis of 1,4-diphenyl-1-aza-4-phosphacyclohexane *(141)* (colorless crystals; m.p. 89 to 90 °C) [134]. CH_3Br and C_2H_5Br attack only on the phosphorus atom, due to the greater nucleophilicity of the phosphine; a bis-salt of *(141)*, which is thermally very unstable, is formed only in boiling methyl iodide. Compound *(141)* is stable towards oxygen at room temperature, *i.e.* substantial deactivation has taken place in comparison with 1-phenylphosphorinane, owing to the presence of the nitrogen atom in the ring.

Cycloadditions onto vinylphosphines promise interesting methods for the preparation of phosphorus heterocycles. The 1,3-dipolar nitrilimine *(142)* adds onto triphenylphosphine to form the azophosphorus ylide; with diphenylvinylphosphine, on the other hand, *(142)* undergoes ring closure to the 1,3,4,4-tetraphenyl-1,2-diaza-4-phosphoniacyclohex-2-ene cation *(143)* [114].





The author's own investigations mentioned in this review have been supported by the Deutsche Forschungsgemeinschaft and by the Fonds der Chemischen Industrie.

Electronic Structure and Properties of Non-Alternant Hydrocarbons [*]

BY DR. R. ZAHRADNIK

INSTITUTE OF PHYSICAL CHEMISTRY OF THE CZECHOSLOVAK ACADEMY OF SCIENCES, PRAGUE (CZECHOSLOVAKIA)

The present paper is concerned mainly with studies on the electronic structure of non-alternant hydrocarbons by quantum-chemical methods. The references to original publications are by no means exhaustive, but an attempt has been made to cover the entire field. (Analogues and derivatives of non-alternant hydrocarbons are only touched.) The intention is to outline the present situation with regard to quantum-mechanical studies on non-alternant hydrocarbons, and to indicate to the chemist the use of the theoretical characteristics obtained by various approximations of the MO-LCAO method [**].

I. The Classification of Non-Alternant Hydrocarbons

The terms "alternant" and "non-alternant" hydrocarbons were coined by *Coulson* and *Rushbrooke* [1]. A conjugated unsaturated hydrocarbon is non-alternant if the carbon atoms cannot be divided into two groups such that all the atoms of the first group have only atoms of the second group as immediate neighbors, and *vice versa*. Thus all fully conjugated hydrocarbons that contain rings with an uneven number of carbon atoms are non-alternant. There is no simple relationship between the energies and the orbital coefficients of the bonding and antibonding molecular orbitals in non-alternant hydrocarbons, as there is in the case of alternant hydrocarbons.

The results of studies on non-alternant hydrocarbons by *B.* and *A. Pullman*, *Berthier*, *Bergmann*, *Fischer*, *Ginsburg*, *Mayot*, and *Pontis* are discussed in a monograph [1a]. Considerable attention is paid to non-alternant hydrocarbons in a book by *Ginsburg* [2] and in a monograph by *Streitwieser* [3] (see also [4,5]). HMO data for a few dozen hydrocarbons are given in tables published by *Coulson* and *Daudel* [6], which also contain many references (for numerical data see also [1a,7,7a]). The reader is also referred to early papers [8–15]; the reviews [16,17] concentrate mainly on experimental aspects.

The present review makes use of a classification [18] which takes into account the number of condensed rings in a carbon skeleton (benzenoid rings with even numbers of carbon atoms and sharing only two atoms with non-alternant rings are not counted). Non-alternant hydrocarbons have also been classified on the bases of rings with even and odd numbers of carbon atoms and of rings containing only odd numbers of carbon atoms [19].

Thus we regard the tropylium cation *(1)* and the fluorenyl anion *(2)*, for example, as monocyclic compounds, whereas s-indacene *(3)* is tricyclic, and indeno[2,1-*a*]-

[*] Based on a lecture delivered to a colloquium in the Organic Chemistry Laboratory of the ETH Zurich (Switzerland) on October 26th, 1964.

[**] The simplest modification of the MO–LCAO method is the Hückel approximation (HMO), in which the molecular orbitals ψ_i are expressed as linear combinations of the atomic orbitals φ_j; in the π-electron approximation only the $2p_z$ atomic orbitals are considered. For the interaction of n orbitals we have:

$$\psi_i = \sum_{j=1}^{n} c_{ij}\,\varphi_j \qquad (a)$$

The π-electron densities and the bond orders can be calculated from the coefficients c_{ij} of the molecular orbitals. The energies E_i of the molecular orbitals are found by solving the determinantal equation; the n permitted levels are given by:

$$E_i = \alpha + k_i\beta, \qquad (b)$$

where α is the Coulomb integral of the $2p_z$ orbital of carbon and β is the resonance integral of the C–C π-bond (and also the unit of energy in the HMO theory). The occupied molecular orbital with the highest energy is denoted by k_1 (normal state), and the unoccupied level with the lowest energy by k_{-1} (valence state). The transfer of an electron from k_1 to k_{-1} is called $N \rightarrow V_1$ excitation.

The main difference between the HMO method and the more accurate MO–LCAO methods is that electronic interactions are explicitly taken into account in the latter; these methods are *Pople*'s SCF (self-consistent field) method and *Pariser* and *Parr*'s LCI (limited configuration interaction) method.

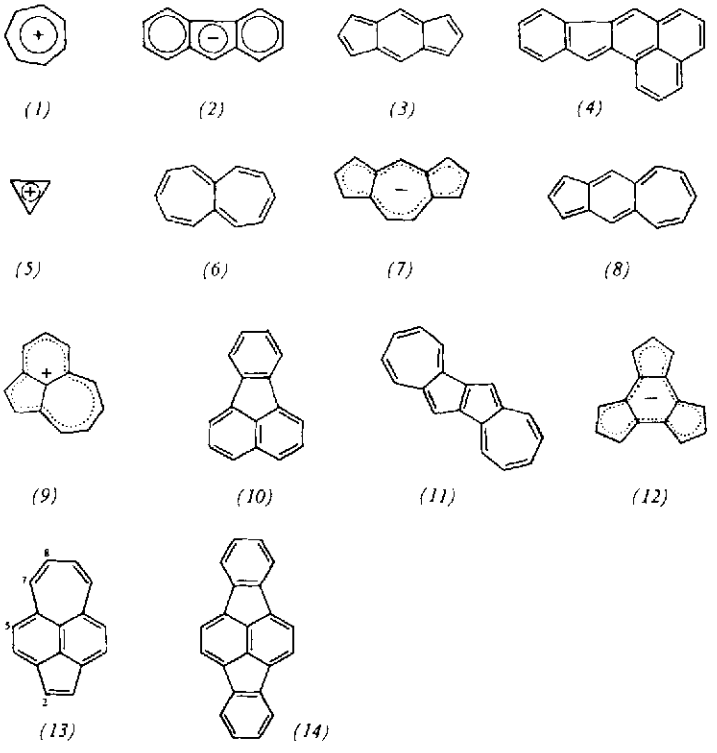
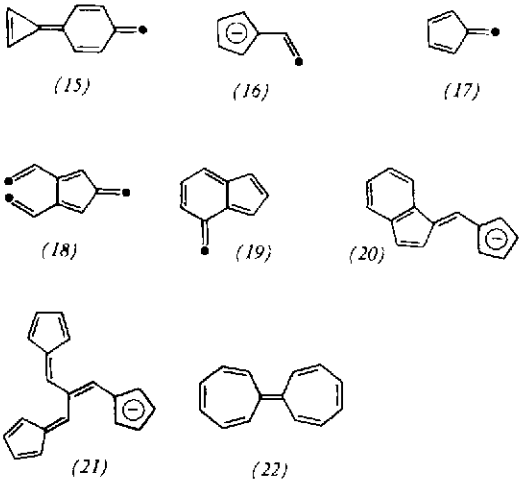
phenalene *(4)* (in which one benzene ring is not counted) is tetracyclic. In the conjugated system phenalene, which has an odd number of carbon atoms, the benzene rings cannot be disregarded.



We distinguish between the basic types of skeletons shown in Figure 1 [examples are given in formulae *(1)* to *(14)*]. This formal classification is important to a systematic treatment, and can be readily applied to larger systems. Skeletons of Group A contain an uneven number of carbon atoms, those of Group B are even, while those of Groups C and D are subdivided into even and odd.

The basic skeletons contain no exocyclic bonds. Skeletons such as *(16)* to *(19)* are derived by the introduction of one or more polyene chains or residues such as *(15)*; furthermore, several basic skeletons may be linked by a polyene chain as in *(20)* and *(21)*, or directly, as in *(22)*.



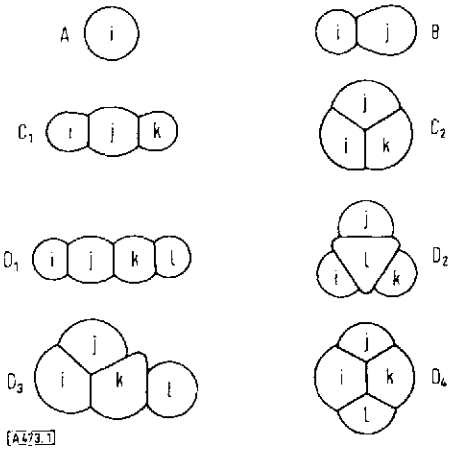


Fig. 1. Basic skeletons of conjugated unsaturated hydrocarbons. i, j, k, and l denote the numbers of carbon atoms in the rings. Each number may be even or odd, unless otherwise indicated. Each skeleton must contain at least one odd ring.

A: monocyclic, i = odd [*e.g. (5)*]
B: bicyclic, i, j = odd [*e.g. (6)*]
C_1: tricyclic, kata-fused, i, j, k = odd [*e.g. (7)*]
j = even, indenoid [*e.g. (8)*]
C_2: tricyclic, peri-fused [*e.g. (9)*]. Benz[*a*]acenaphthylene (= fluoranthene) *(10)* and its benzo derivatives form an independent sub-group: fluoranthenoid hydrocarbons.
D_1,D_2: tetracyclic, kata-fused, i, l = odd or i, j, k = odd [*e.g. (11)* or *(12)*].
D_3: tetracyclic, kata-peri-fused, l = odd.
D_4: tetracyclic, peri-fused [*e.g. (13)*]. Dibenzo[*a*,*g*]pyracylene *(14)* and its benzo derivatives are regarded as fluoranthenoid hydrocarbons.

II. Physical Properties of Non-Alternant Hydrocarbons

1. Electronic and Charge-Transfer Spectra

Electronic spectrocscopy is an important tool for the study of the electronic structures of conjugated organic compounds. The energies corresponding to the maxima of the various absorption bands (electronic bands) are the energies required to raise the molecule from the ground state to the various excited singlet or triplet states.

The spectra of non-alternant hydrocarbons, unlike those of alternant hydrocarbons (particularly benzenoid), cannot be classified empirically. In order to be able to interpret or predict these spectra, it is therefore necessary to use the LCI method. Only in special cases (vinylogous series, ions) is it possible to correlate the energies of the maxima of the intense longest-wavelength bands with the energies of the $N \rightarrow V_1$ transitions, which are calculated by the HMO method.

Various authors [20–23] have used the LCI method in the theoretical treatment of the electronic spectra of non-alternant hydrocarbons; it was only recently, however, that systematic studies have been undertaken [24,25].

[20] *R. Pariser*, J. chem. Physics *25*, 1112 (1956).

[21] *J. N. Murrell* and *H. C. Longuet-Higgins*, J. chem. Physics *23*, 2347 (1955).

[25] *J. Koutecký*, *P. Hochman*, and *J. Michl*, J. chem. Physics *40*, 2439 (1964).

Satisfactory agreement has been found between the calculated and experimental values of the singlet excitation energies of 45 hydrocarbons (cf. *e.g.* Fig. 2, in which calculated values for the absorption maxima were plotted together with the absorption curves). The advantage of comparing the experimental and theoretical values as in Figure 2 [24] is that it is not necessary therefore, that series of non-alternant hydrocarbons and their derivatives have been found in which the longest-wavelength bands lead to a satisfactory correlation between the HMO energies and the experimental excitation energies (see Table 1 and Fig. 3). The values for the ions lie on a regression line which is different from that for neutral hydrocarbons.

Table 1. Regression coefficients (a,b) and correlation coefficients (r) for the relationship between the experimental wavenumbers $\tilde{\nu}$ of the longest-wavelength bands and the theoretical values $E(N \rightarrow V_1)$.
(N: normal spectra; CT: charge-transfer spectra; n: number of compounds that belong to one type.)

N: $\tilde{\nu}\,[cm^{-1}\cdot 10^{-3}] = a\cdot E\,(N \rightarrow V_1)\,[\beta] + b$
CT: $\tilde{\nu}\,[cm^{-1}\cdot 10^{-3}] = a\cdot k_1(_{-1})\,[\beta] + b$

Benzenoid hydrocarbons + tropylium cation	CT	5	22.45	8.37	0.997	[40, 41]

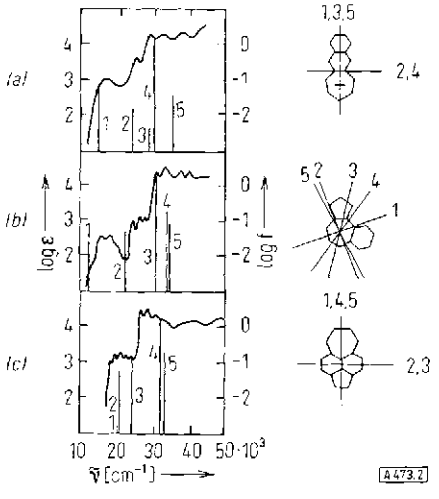

Fig. 2. Comparison of experimental and calculated electronic spectra of non-alternant hydrocarbons [25] for the five longest-wavelength transitions. The theoretical polarization directions are shown in the formulae (f = oscillator strength).

to select that band in the spectrum which corresponds to a vertical electronic excitation (the geometry remains unchanged), since this can be particularly difficult in the case of non-alternant hydrocarbons. It was found [25] that nearly all the hydrocarbons studied have an excited state in which the configuration $\chi_{1\rightarrow -1}$ predominates as a result of the excitation of the electron from k_1 to k_{-1}; the contribution of this configuration, in fact, is frequently about 90 %. The transition in question is evidently similar to *Clar*'s p-transition in benzenoid hydrocarbons [26]. Thus within the various classes (*e.g.* tropylium and its benzo or naphtho derivatives), there is a relationship between these LCI excitation energies for the first transitions and the HMO energies of the $N \rightarrow V_1$ transitions. It is not surprising,

A perturbation calculation [42] within the framework of the simple HMO method shows that the replacement of a carbon atom j in the skeleton by a hetero-atom causes a change in the excitation energy δE_j which is given by

$$\delta E_j = \left(c^2_{-1,j} - c_{1,j}\right)\delta\alpha_j \qquad (c)$$

[$c_{1,j}$ and $c_{-1,j}$ are the orbital coefficients of φ_j in the k_1 and k_{-1} orbitals, and α_j is the Coulomb integral of the hetero-atom (in β units)]. If $\delta\alpha_j$ is positive, a positive value of the expression in brackets corresponds to a bathochromic shift of the first band.

This method has been used in particular in the study of alkyl-substituted azulenes, in which only an inductive effect of the alkyl groups was considered. In many systems containing one hetero-atom, it was found that

Table 1).
I, II, and III: regression lines for polyenes, benzenoid hydrocarbons, and ions respectively.

there is a close relationship between the quantities δE_i found by perturbation calculations and the energies of the $N \rightarrow V_1$ transitions, which were obtained by solving the secular equations.

The charge-transfer spectra of many complexes containing non-alternant hydrocarbons have been studied. Neutral hydrocarbons and in particular anions act as π-electron donors, and cations as acceptors. It was found that the excitation energies of the charge-transfer bands of complexes of the tropylium cation with benzenoid hydrocarbons and of fluoranthenes with trinitrofluorenone can be correlated with the HMO energies of the corresponding frontier orbitals [*] (see Table 1).

2. Polarographic Behavior

Attempts (see *e.g.* [3]) to correlate the half-wave potentials for the reduction of conjugated unsaturated hydrocarbons have so far been based on the assumption that the process determining the potential of the first step is the reversible uptake of an electron; unfortunately, however, there is no convincing experimental proof. The reduction to the free radical may be preceded or followed by interfering reactions (preceded by molecular association, the formation of solvated complexes, *etc.*, or followed by dimerization, free-radical reactions, *etc.*). Interference with the establishment of the polarographic potential is least likely to occur in aprotic solvents. A remarkably good agreement has been found between the cathodic and anodic half-wave potentials and energies of the k_1 and k_{-1} levels in the case of alternant hydrocarbons and their derivatives [42a]. The only unsubstituted non-alternant hydrocarbons that have been systematically studied are fluoranthene and its benzo, naphtho *etc.* derivatives [43]. It was found that their half-wave potentials lie almost on the same regression line as the values for benzenoid hydrocarbons [30]. The data for α-(2,2′-biphenylylene)polyenes and for α,ω-bis(biphenylylene)polyenes also correspond to this regression line [44].

The half-wave potential of azulene, on the other hand, does not fall on the line. A perturbation calculation leads only to an explanation of the increasing difficulty of reduction as we pass from azulene to monomethylazulene and dimethylazulene. The HMO theory cannot explain the order of the cathodic half-wave potentials of azulene, benz[*a*]azulene and benz[*b*]azulene, just as it cannot explain the order of the excitation energies of the absorption bands in the visible region [19].

The polarographic half-wave potentials of the esters of fluoranthenecarboxylic acid are related to the energies of the k_{-1} orbitals in exactly the same way as those of the esters derived from alternant hydrocarbons [45].

3. Possibilities of Radio-Frequency Spectroscopy

In NMR spectroscopy [46], the linear relationship between the chemical shift and the π-electron densities on the carbon atoms in the cyclopentadienyl anion, benzene, and the tropylium cation can be used to estimate the π-electron densities in other systems. ESR spectroscopy, on the other hand, gives the distribution of the unpaired electrons in the k_1 or k_{-1} orbital in the radical cation or radical anion. The agreement of the HMO theory with experiment regarding the hyperfine structure constants is remarkably good.

III. Chemical Properties of Non-Alternant Hydrocarbons

1. Aromaticity

The concept of "aromaticity" has undergone a far-reaching change, and the use of the term is by no means uniform [47]. It is more convenient, therefore, to speak of chemical stability, and to base the estimation of this stability on the theoretical values of the specific delocalization energy and on the theoretical reactivity indices (atom and ortho-localization energies or superdelocalizability [*]). It is also important to characterize the ability of the molecule as a whole to give up or accept a π-electron (energies of the frontier orbitals k_1 and k_{-1}).

At the moment, only the relative stabilities of substances can be given, on the basis of a comparison with struc-

[*] The frontier orbitals are the highest occupied (k_1) and the lowest unoccupied (k_{-1}) molecular orbitals.

turally related substances whose properties have been determined experimentally and theoretically (keeping in mind that the medium also has some effect)[48].

The specific delocalization energy $E_{d,s}$ is defined as the ratio of the HMO delocalization energy to the number m of C–C σ-bonds in a conjugated system, m also being a measure of the size of the conjugated system. Only in the case of polyacenes is $E_{d,s}$ almost independent of m; in polyenes and cyclopolyenes $E_{d,s}$ increases or decreases as the conjugated system increases in size and approaches the value of 0.273 β, which is the value for an infinitely long polyene (see Fig. 4)[48]. In

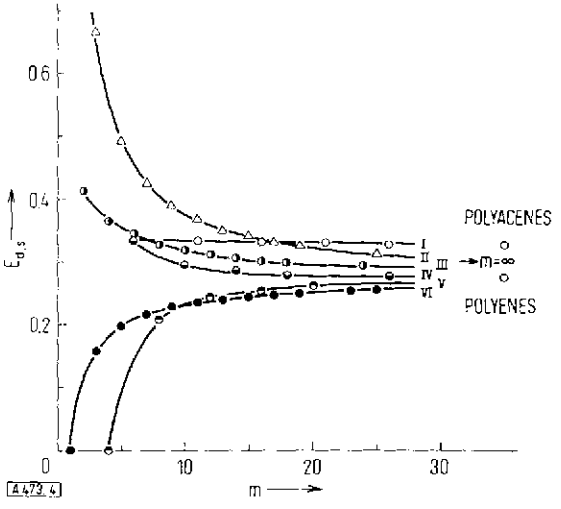

Fig. 4. Relationship between the specific delocalization energy ($E_{d,s}$) and the number m of C–C σ-bonds.
I: polyacene; II: odd cyclopolyenes (cations and anions); III: odd polyenes; IV: even cyclopolyenes with (4n − 2 π-electrons; V: even cyclopolyenes with 4n π-electrons; VI: even polyenes.

practice, the values of $E_{d,s}$ are plotted in a diagram containing the $E_{d,s}$ values for a number of substances of various types (Fig. 4), and the thermochemical stability of the compound in question is estimated by comparison. A similar method, *i.e.* comparison of the reactivity indices with those of structurally related substances, is used to predict the chemical properties of compounds that have not yet been synthesized[33, 49, 50].

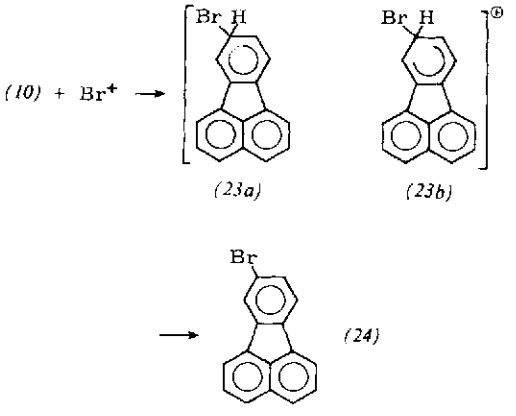
If the delocalization energies found by experiment are plotted against those obtained by the HMO method, the points for some non-alternant hydrocarbons (*e.g.* heptafulvene, fulvalene)[3] lie on a straight line whose slope is smaller than that found for other compounds (*e.g.* benzenoid hydrocarbons)[48]. The reason for this appears to be that the delocalization in compounds of the fulvalene type *(32)* is overestimated by the HMO method.

2. Chemical Reactivity

a) Kinetic Processes

The estimation of the reactivities of non-equivalent positions and bonds in conjugated hydrocarbons should at least be based on calculations of the π-electron contributions to the activation energy, assuming that there is a linear relationship between the activation energy and the entropy of activation, and that the σ-electron contribution is constant for all members of the series in question.

The π-electron contribution is easily found, *e.g.* in the 8-bromination of fluoranthene *(10)*, as the difference between the π-electron energy of the activated complex



(23a) and that of the reacting compound *(10)*. It is nearly always assumed, in fact, that the model of type *(23a)* can be replaced by a Wheland model *(23b)*. In the activated complex *(23a)* the substituted position is assumed to exhibit reduced interaction with the conjugated system, whereas in the model *(23b)* it is assumed that the substituted position is completely excluded from the conjugation. In the case of alternant hydrocarbons it was found that the reactivity is theoretically the same whether model *(23a)* or model *(23b)* is used[51]. In the case of non-alternant hydrocarbons it was shown only for the benzofluoranthenes[37] that the difference between the π-electron energies of the complex *(23b)* and of the reacting substance (*i.e.* Wheland's localization energy A_e) is linearly related to a similar quantity M_e for the complex *(23a)* (see Fig. 5). The localization energy A for electrophilic and nucleophilic reactions

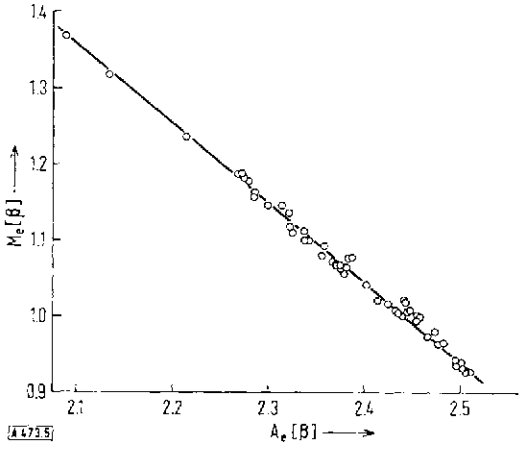


Fig. 5. Relationship between the electrophilic reactivity indices M_e of fluoranthene complexes in accordance with model *(23a)* and the localization energy A_e for model *(23b)*. The values for substituted fluoranthenes, benzo[*a*]-, -[*b*]-, -[*j*]-, and -[*k*]-fluoranthenes, are included.

[49] *R. Zahradnik* and *J. Michl*, Collect. czechoslov. chem. Commun. *30*, 520 (1965).

[50] *R. Zahradnik*, *J. Michl*, and *J. Pancíř*, Collect. czechoslov. chem. Commun. *30*, 2891 (1965).

[51] *R. Zahradnik* and *J. Koutecký*, Collect. czechoslov. chem. Commun. *28*, 904 (1963).

shows a linear dependence on the superdelocalizability S, not only for the fluoranthenes, but also for other classes of non-alternant hydrocarbons (*e.g.* azulene).

Thus any of the quantities M_e, A_e, or S_e can be used for correlation with the experimental values. However, the localization energy and the π-electron density are not related; on the other hand, the dynamic (A_r, S_r) and static (F = free valence) indices of the free-radical reactivity are generally linearly related to one another. Separation was observed into three groups, depending on the nature of the substitution site; these groups are the benzene type, the α-naphthalene type, and the meso-anthracene type (corresponding to class 0, 1, and 2 positions [52]). The linear relationship between the bond order and the ortho-localization energy found in the case of benzenoid hydrocarbons [53] is also valid for fluoranthene-like hydrocarbons (Fig. 6).

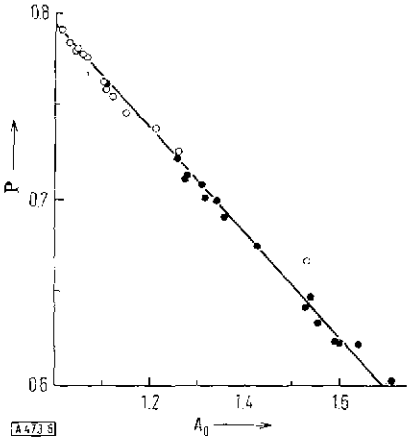

Fig. 6. Relationship between the bond orders p and the ortho-localization energy (A_0) [β units] for benzenoid (○) (benzene, naphthalene, anthracene, phenanthrene, and some benzo derivatives of these) and fluoranthenoid (●) hydrocarbons (fluoranthene *(10)* and four of its benzo derivatives: [*a*], [*b*], [*j*], and [*k*]).

The π-electron densities of the hetero-analogues of non-alternant hydrocarbons, as found by perturbation calculations from the atom-atom polarizabilities, are approximately linearly related to similar quantities calculated by the HMO method (except for positions α to the hetero-atom). However, a completely satisfactory linear relationship was found only in the case of fluoranthene [54].

The results of experimental studies are still unsatisfactory, since data on the reactivities of large groups of structurally related substances are lacking. By analogy with alternant hydrocarbons we conclude that, when the rate constants of polar substitutions are plotted against the theoretical indices (A_e, S_e), the values group themselves according to the class of the substitution site. In this respect the rate constants for the nitration of fluoranthene *(10)* [55], for example, must be regarded as inhomogeneous, since two positions that can be substituted are of class 0, while the other three are of class 1 (two of these belonging to the sterically unfavorable sub-class 1* of the 4-phenanthrene type). This may be the reason for the disagreement between the theoretical and experimental results.

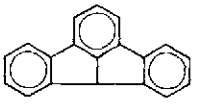
b) Equilibrium States

Acid-base equilibria have been most thoroughly studied in the case of C-acids, both in alternant and in non-alternant systems [3]. The equilibrium constants can in many cases be estimated from the contribution of the π-electrons to the dissociation energy, which is proportional to the difference in the π-electron energies of the forms occurring in the reaction. Some of the non-alternant hydrocarbon anions are extremely weak bases, so weak, in fact, that they can exist even in solutions of alkali metal hydroxides in aqueous alcohol. These include the anion derived from fluoradene *(25)* [56], as



(25)

well as a number of anions, such as *(40)*, which have been studied by *Kuhn* [31] and *Jutz* [32]; the pK values of the conjugated acids in extreme cases are about 12, whereas the acidity of a hydrocarbon such as cyclopropene or toluene is extremely low. Thus the total range covered by the pK values of these acids is of the order of several decades. Although there is a relationship between the pK values of many C-acids and the corresponding localization energies (*e.g.* [3]), points which still remain unsettled include the influence of the class of the reacting site, the difference between alternant and non-alternant hydrocarbons, and the influence of the solvent.

The situation found in the case of hetero-analogues and protonatable or ionizable derivatives is also interesting. For example, the basicity of an aromatic amine increases with the π-electron density at the position in the parent hydrocarbon to which the amino group is bound, and *vice versa*. Thus 1-aminoazulene [57] is a strong base; the pK value of 3-aminofluoranthene is 2.6 (the amino group is attached at a position for which q = 0.959), while that of the 8-isomer is 4.0 (the q value for this position in the hydrocarbon is 1.008) [58].

A satisfactory agreement between the theoretical and experimental values is also found in the case of the pseudo-basicity (loss of the OH^- group in strongly acidic media: $ROH \rightarrow R^+ + OH^-$) of the carbinols [3]; the experimental pK_{R^+} [58a] values are linearly related to the difference in the π-electron energies of the carbonium ion and of the adduct formed by the combination of OH^-

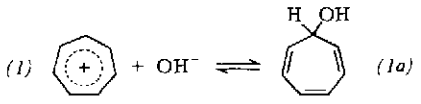
with the cation, *i.e.* in the case of the tropylium cation *(1)*, to the difference between the π-electron energy of *(1)* and that of the hexatriene derivative *(1a)*.



IV. Classification of Conjugated Unsaturated Cyclic Hydrocarbons

1. Monocyclic Systems

Two groups of non-alternant monocyclic systems can be distinguished: (a) "Hückel" systems, which contain $4n+2$ π-electrons, and in which all the bonding orbitals are occupied, and (b) "anti-Hückel" systems, which contain $4n$ π-electrons, and in which not all the bonding orbitals are occupied, or antibonding orbitals are also occupied. Out of the group *(26a)* to *(30a)*, the systems *(27a)* to *(29a)* have been prepared [2,59]. The dipropyl derivative of *(26a)* is the simplest cyclopropenylium cation known [60]. Many aryl and aralkyl derivatives of the systems *(26a)* to *(29a)* have been prepared. It can be seen from curve II in Fig. 4 that $E_{d,s}$ rapidly approaches the value characteristic for polyenes, as the ring size increases. The spectra of the benzo derivatives of the anion *(27a)* [29] and of the cation *(28a)* [27,28] have been studied. The spectra and reactivities of many analogues of tropylium compounds containing sulfur, *e.g.* the thiapyrylium and dithiolium ions and their derivatives [61], have also been studied.

The "anti-Hückel" ions *(26b)* to *(30b)* are interesting. The fluorenyl cation *(31)* [62] and its four benzo-derivatives ([*a*], [*b*], [*c*], [*def*]) have been studied most thoroughly [58, 63]. These compounds absorb at the edge of

(31)

the near infrared region (*ca.* 13000 cm^{-1}). This is understandable, since the absorption is due to a $\pi \rightarrow \pi$ transition, and not to a $\pi \rightarrow \pi^*$ transition, as is the case in "Hückel" ions and in most neutral molecules. However, even if the extension of the conjugated system is taken into account, the wavelength of the first absorption band is still extremely high, even in the case of the anion. For

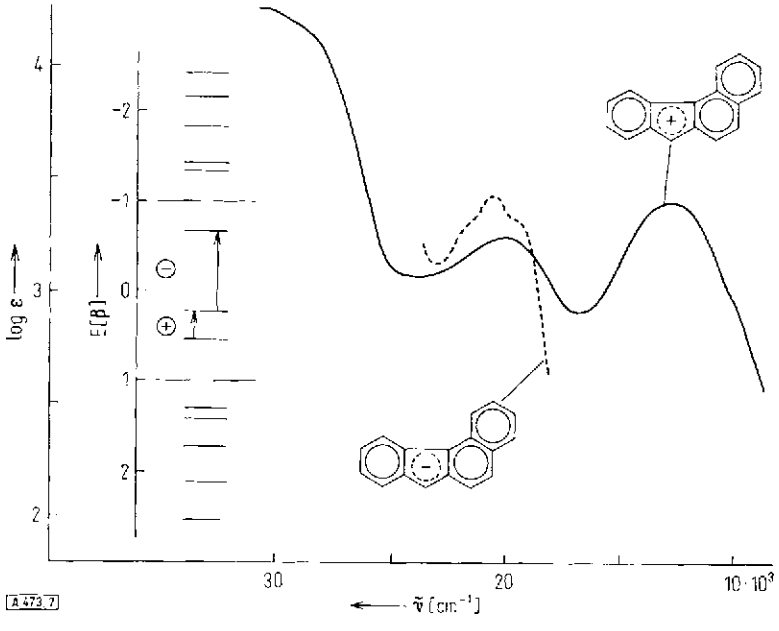


Fig. 7. Absorption curve of the benzo[*c*]fluorenylium cation [58] and the longest-wavelength absorption band of the benzo[*c*]fluorenyl anion [29], together with the HMO energy levels.

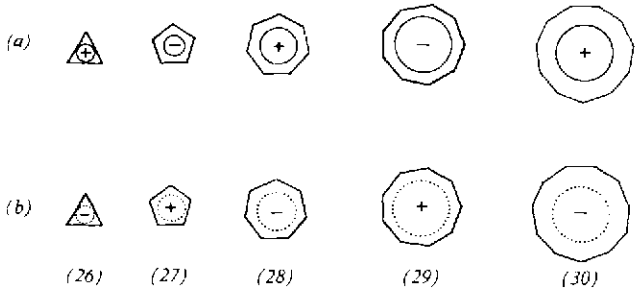
example, benz[*a*]anthracene which is isoelectronic with the benzo[*c*]fluorenyl anion (see Fig. 7), absorbs at 26000 cm^{-1}. The explanation for this behavior appears to be that, in the case of ions, the part of the total excitation energy which is due to the mutual repulsion of



[59] *T. J. Katz* and *P. J. Garratt*, J. Amer. chem. Soc. *85*, 2852 (1963); *E. A. LaLancette* and *R. E. Benson*, *ibid.* *85*, 2853 (1963).

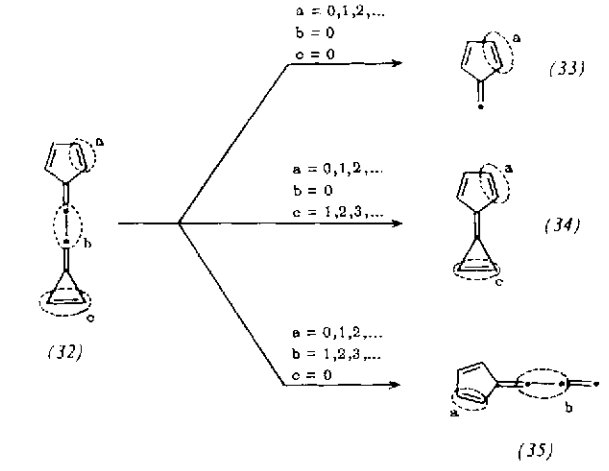
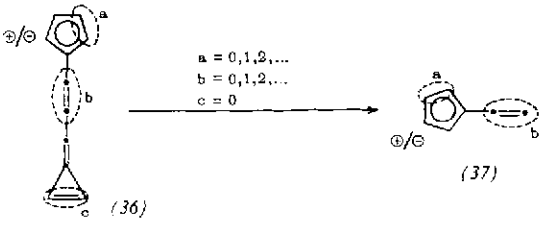
the electrons, and which is not taken into account in the HMO method, is approximately 5000 cm^{-1}, *i.e.* appreciably less than in the case of conjugated neutral hydrocarbons (approximately 10000 cm^{-1})[64].

By combining rings with polyene chains, systems of the type *(32)* are obtained [special cases of which are fulvenes *(33)*, fulvalenes *(34)*, and compounds *(35)* consisting of a ring with an odd number of carbon atoms and a polyene chain with an odd number of carbon atoms], as well as compounds *(36)* and *(37)*. The systems *(32)* to *(35)* possess only one Kekulé structure, and their delocalization energies are very low[65]; in these cases, therefore, the results of the HMO method can only be regarded as rough approximations. It was only recently that fulvene *(33)*, with a = 1, has been prepared in high yields[66,66a]; heptafulvene *(33)*, with a = 2, has only been prepared in solution and is stable only at −60 °C for a short time[67].

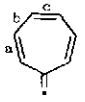


(32) *(33)* *(34)* *(35)*

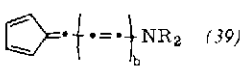


(36) *(37)*

It is worth noting that the fusion of a benzene ring onto fulvene *(33)* causes a hypsochromic shift of the first band in the electronic spectrum; this shift is correctly predicted by the HMO theory[1a]. A similar increase is found in the energies of the $N \rightarrow V_1$ transitions in benzo derivatives of heptafulvene *(38)* in which the benzene ring is attached in position *a* or *c*. On the other hand, a significant bathochromic shift is to be expected if a benzene ring is fused in position *b*[7]. The exocyclic carbon atom in fulvene (heptafulvene) and its vinylogues *(35)* carries a large positive (negative) charge; the molecule should therefore be stabilized by the attachment of a substituent with a −M (+M) effect, *e.g.* an NH_2 or OH (NO_2 or CN) group to this carbon. The dimethylaminofulvenes of the type *(39)* are, in fact, relatively stable[34].



(38)

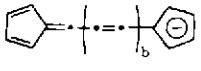


(39)

As predicted by theory, substances of the type *(39)* have been found to be strong π-bases; their ease of polarographic oxidation was to be expected[35]. 8,8-Dicyanoheptafulvene and its vinylogues are also stable for the same reasons[68–69]. It is interesting to note that the energy of the $N \rightarrow V_1$ transitions of fulvapolyenes *(32)* (a = 1; b = 0, 1, 2; c = 2) increases with increasing chain length[1a]; it should be added that these are $\pi \rightarrow \pi$ transitions, since the highest bonding molecular orbital is unoccupied.

Two compounds of the type *(34)* are known, namely fulvalene and heptafulvalene *(22)*[67,70]. Judging from MO theory[1a] it should also be possible to synthesize the sesquifulvalene *(34)* (a = 1, c = 3). The use of improved MO methods is particularly important for compounds of the type *(32)*[71]. It should be noted, that these substances are strongly olefinic in character. The spectra of fulvene and heptafulvene as calculated by the LCI method do not agree with the experimental findings[25]; the use of SCF orbitals would be desirable[72]. It is interesting to note that the energies of the $N \rightarrow V_1$ transitions as calculated by the HMO method and by a method that takes the alternation into account are linearly related[73].

Anions of the type *(40)* with a five-membered ring at each end of the odd polyene chain have been studied both experimentally and theoretically. Their dibenzo and tetrabenzo derivatives[31–33], however, show that the corresponding "anti-Hückel" cations can also be prepared[74]. The very large differences in the delocalization energies of the anion and the cation of the system



(40), b = 0,1,2

(40) with b = 0 are predicted by the theory; the difference decreases with increasing chain length and above all with ring fusion. The most remarkable property of

anions of the type *(40)* is their unusually low basicity; for this reason, their conjugate acids are called "highly acidic hydrocarbons".

2. Bicyclic Systems

Of the basic bicyclic systems two are known at present, namely azulene [20] and heptalene *(6)* [75]. Since the synthesis of other bicyclic hydrocarbons seems possible, we shall consider systems that are formally derived by the fusion of rings containing from three to eleven carbon atoms (Figure 8). System containing $4n+2$ π-electrons will be referred to as azulenoid (A) and systems

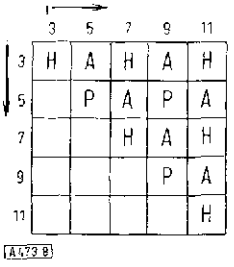

Fig. 8. Combination of monocyclic systems to give azulenoid (A), pentalenoid (P), and heptalenoid (H) bicyclic systems.

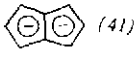
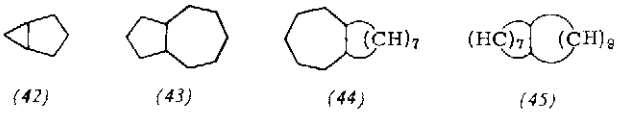
with $4n$ π-electrons as pentalenoid (P) or heptalenoid (H), depending on whether they contain an occupied (H) or unoccupied (P) non-bonding π-molecular orbital in the ground state. Pentalenoid systems should show some tendency to form dianions and heptalenoid systems to form dications, which again contain $4n+2$ π-electrons. The pentalene dianion *(41)* has in fact been prepared [76].



(41)

Energy data and extreme values of the π-electron density (q_{max}, q_{min}) of various azulenoid systems are given in Table 2. It can be concluded from these results that a system such as *(44)* consisting of a seven-membered ring and a nine-membered ring should be reasonably stable. It is found that the maximum (minimum) π-electron density always occurs on a carbon atom adjacent to the common bond, and in a ring containing $4n+1$ $(4n+3)$ carbon atoms. The probability that it will be possible to prepare substances *(42)* and *(45)* is considerably lower.



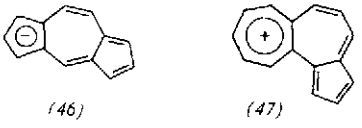
(42) *(43)* *(44)* *(45)*

The spectra, the electrochemical and other physical properties (*e.g.* infrared frequencies, thermodynamic quantities), and the reactivities of azulene and its alkyl derivatives were studied by *Heilbronner* [19]. Considerable attention was paid to pentalene and heptalene *(6)* [71, 77]. Heptalene possesses alternating bonds (olefinic character), and the same will probably also be true of pentalene, which has not yet been prepared in spite of numerous attempts. In agreement with this, it has been found [78, 79] that the pentalene and heptalene structures with an axis of symmetry (C_{2h}) are energetically more favorable than structures containing two planes of symmetry (D_{2h}).

3. Tricyclic Systems

a) Kata-Fused Systems

Of the nine odd structures that can be constructed from five-membered and seven-membered rings (Fig. 1, type C_1; i, j, k = odd), six contain a plane of symmetry. Symmetrical ions with occupied bonding orbitals are negatively or positively charged, depending on whether the outer rings are five- or seven-membered. Compound *(46)* is an example of an ion that should be relatively stable, the energies of its frontier orbitals being k_1 $0.275\,\beta$ and $k_{-1} = -0.494\,\beta$. Unsymmetrical compounds, such as *(47)* [$k_{-1} = -0.07\,\beta$] always have a molecular orbital that is almost non-bonding. This means that these unsymmetrical compounds will not be very stable;



(46) *(47)*

Table 2. Energy data of some azulenoid bicyclic hydrocarbons (in β units). W: total π-electron energy; $E_{d,s}$: specific delocalization energy; k_2, k_1, k_{-1}, k_{-2}: energies of the two highest occupied and of the two lowest unoccupied molecular orbitals; $E(N \rightarrow V_1)$: energy of the $N \rightarrow V_1$ transition; q: π-electron density.

Compound	W	$E_{d,s}$	k_2	k_1	k_{-1}	k_{-2}	$E(N \rightarrow V_1)$	q_{max}	q_{min}
(42)	8.390	0.341	1.139	0.618	−0.820	−1.618	1.438	1.215	0.700
(43)	13.364	0.306	0.887	0.477	−0.400	−0.738	0.878	1.173	0.855
(44)	18.410	0.294	0.543	0.295	−0.335	−0.618	0.630	1.110	0.877

it should, however, be possible to prepare both their anions and cations [137].

Kata-fused hydrocarbons of the type C_1 (i, k = odd, j = even) are characterized by the fact that they contain two non-alternant rings fused to a central alternant ring.

[75] *H. J. Dauben Jr.* and *D. J. Bertelli*, J. Amer. chem. Soc. *83*, 4656, 4657 (1961).

[76] *T. J. Katz* and *M. Rosenberger*, J. Amer. chem. Soc. *84*, 865 (1962).

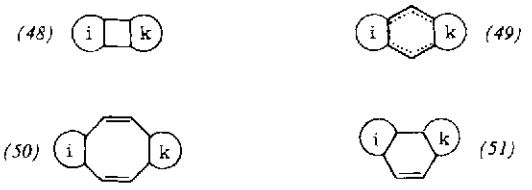
[79] *L. C. Snyder*, J. physic. Chem. *66*, 2299 (1962).

These hydrocarbons *(48)* to *(51)* are referred to as indacenoid. Great interest is being devoted at present



to hydrocarbons of the type *(49)*. The HMO calculations for three substances of this type (i, k = 5, 7) and for three isomeric compounds of the type *(51)* [80,81], as well as the fact that s-indacene *(3)* has been prepared [16], indicate that compounds that are formally derived from azulene will be relatively stable. According to Fig. 9,

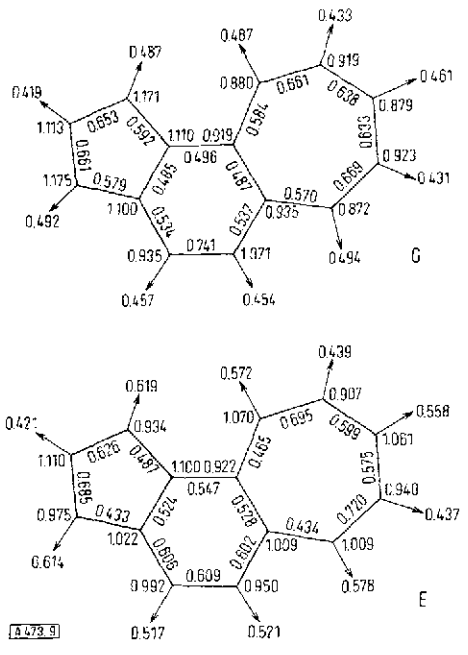


Fig. 9. Molecular diagrams of dehydrocycloheptatrieno[*e*]indene in the ground state (above) and in the excited state ($N \rightarrow V_1$) (below) [80].

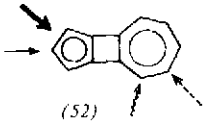
the properties of the angular isomer are rather favorable. It has been found that the insertion of one or two benzene rings between the five-membered and the seven-membered rings of azulene (linear condensation) has no effect on the positions of the centers of electrophilic and nucleophilic reactivity of the latter. On the other hand, in the non-alternant isomer *(52)* of biphenylene, which has not yet been prepared, a change in the positions of these centers is to be expected [80]. (The arrows $\longrightarrow$, $\dashrightarrow$, and $\rightsquigarrow$ indicate the theoretical centers of electrophilic, nucleophilic, and free-radical reactivity; the bond which is most likely to undergo an addition is marked by a bold arrow.)



(52)

[80] *R. Zahradnik, J. Michl,* and *J. Kopecký,* Collect. czechoslov. chem. Commun., in the press.

[81] *D. Peters,* J. chem. Soc. (London) *1958,* 1028, 1039.

In the case of pentalene and heptalene derivatives, type *(49)* is theoretically more favorable than type *(51)*. This difference is so pronounced that angularly fused compounds can probably only be obtained in the form of the dianion.

b) Peri-Fused Systems

Nine non-alternant peri-fused hydrocarbons can be derived by the combination of five-membered, six-membered, and seven-membered rings, three of them being odd.

System *(9)* is an interesting case, since it contains a non-bonding molecular orbital [37,*] and should therefore be stable both as the anion and as the cation (Fig. 10).

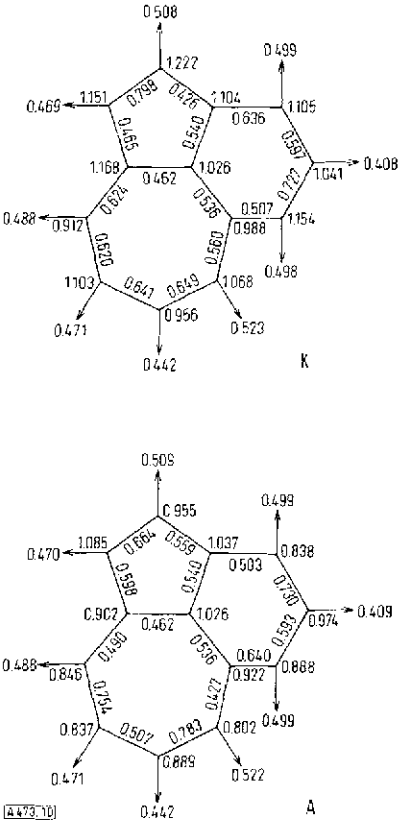


Fig. 10. Molecular diagrams of the anion (above) and the cation (below) of benz[*cd*]indene [37].

Both forms have actually been prepared as the methyl derivatives [83,84]. Dimethyl derivatives have also been prepared [84,85] of the hydrocarbons *(53)* and *(54)*, which can be derived from pentalene and heptalene. The theoretically expected centers of reactivity are marked in these formulae in the same way as in formula *(52)* [86].

[*] This is remarkable, since the system is odd and non-alternant. The absolute term in the determinantal equation is equal to zero, as can be shown by an analysis of the graphical representation of the molecule [82].

[82] *J. Čížek,* personal communication.

[83] *K. Hafner* and *H. Schaum,* Angew. Chem. *75,* 90 (1963); Angew. Chem. internat. Edit. *2,* 95 (1963).

[84] *K. Hafner* and *H. Schaum,* unpublished work.

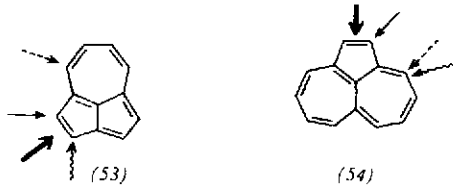
[86] *M. A. Ali* and *C. A. Coulson,* Molecular Physics *4,* 5 (1961).

The hydrocarbon *(54)*, unlike *(53)*, possesses some aromatic character [85]. The properties of the ions *(55)*



(53) *(54)*

(55) *(56)*

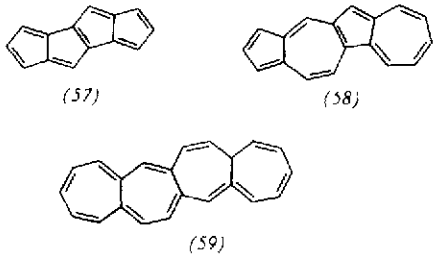
and *(56)* are theoretically promising, and the possibility of a synthesis of the anion *(55)* appears to be very good [37].

Theoretical studies have been carried out on acenaphthylenes, their hetero-analogues and derivatives [58], benz[*a*]acenaphthylene (= fluoranthene) *(10)*, and a few dozen benzo derivatives of fluoranthene, including compounds of the type *(14)* [26, 30, 58, 87]. The half-wave potentials, electronic spectra, and reactivities found can be satisfactorily explained by theory. It appears that the fluoranthenes have the character of real non-alternant hydrocarbons [87a].

4. Tetracyclic Systems

a) Kata-Fused Systems

Only a few kata-fused tetracyclic systems have been subjected to a theoretical study [37]. It appears that azulenoazulene *(58)* should be the most stable of the compounds *(57)* to *(59)*.

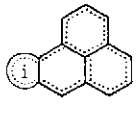


(57) *(58)*

(59)

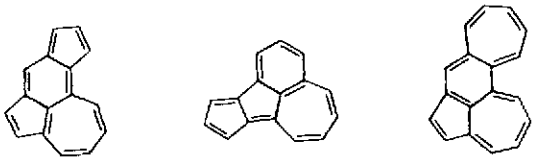
b) Kata-Peri-Fused Systems

The extremely interesting kata-peri-fused hydrocarbons include the Reid hydrocarbons [49, 88]. Reid hydrocarbons of the type *(60)* are formally analogues of azulene, which may be regarded as the "fusion products" of the cyclopentadienyl anion and the tropylium cation. Replacement of one of these structural units by phenalenyl [*], which is stable both as a cation and as an anion (presence of a non-bonding MO) leads to other interesting compounds.



(60), i = 5, 7

By definition, Reid hydrocarbons are formally derived by kata-fusion of the cyclopentadienyl anion or the tropylium cation with an oppositely charged odd peri-fused tricyclic hydrocarbon with an HMO energy of zero. This definition fits henz[*cd*]azulenyl *(9)* as well as



(61) *(62)* *(63)*

the phenalenyl system. The theoretical values indicate that, of the eight hydrocarbons studied (none of which has yet been prepared), *(61)* and *(62)* should be most stable; the hydrocarbon *(63)*, on the other hand, should be very unstable.

The agreement between the theoretical and experimental values of the excitation energy is satisfactory in the case of the benzo derivative *(60′)* of *(60)*, i = 5 (Fig. 11).

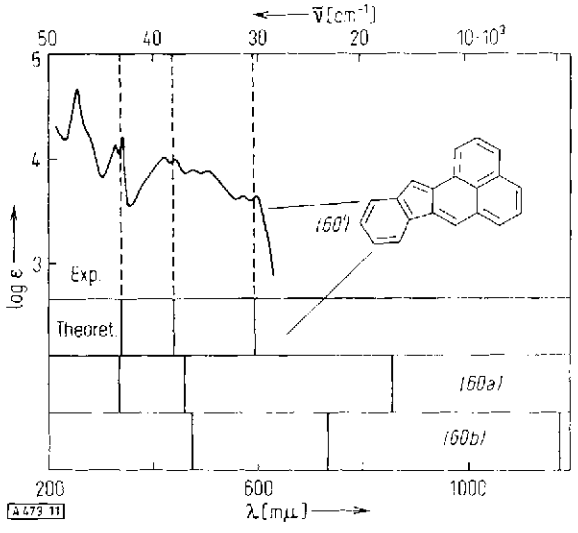


Fig. 11. Results of calculations of the absorption bands of Reid hydrocarbons and experimental curve of a compound of this type [49].

The chemistry of this hydrocarbon [88] has been interpreted in terms of the HMO theory [49]. The excitation energies of the two parent substances *(60a)* and *(60b)* [*(60)*, i = 5, 7] which have not yet been synthesized have been calculated by the LCI method; the results show that the longest-wavelength absorption bands will lie in the near infrared region. It should be pointed out that a close linear relationship has been found between the energies of the $N \rightarrow V_1$ transitions for hetero-analogues of the Reid hydrocarbons, as obtained by perturbation calculations from the data for the parent substances, and the energies obtained by accurate calculation from the secular determinants [49].

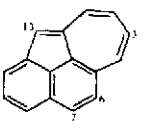
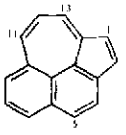
c) Peri-Fused Systems

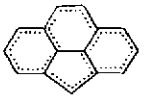
Of the 35 possible hydrocarbons of this type, the neutral compounds *(13)* [89], *(64)* [90], and *(65)* [91], as well as the anion [29] and the cation [58] derived from the skeleton *(66)*, have been synthesized. The electronic spectra of *(13)*, *(64)*, and *(65)* have been successfully interpreted. The reactivity indices of the most reactive positions in these hydrocarbons are given in Table 3.



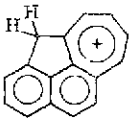
(64)



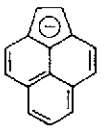
(65)



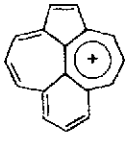
(66)



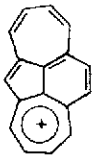
(67)



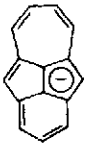
(68)



(69)



(70)



(71)

Table 3. Chemical reactivity indices of selected positions in the hydrocarbons *(13)*, *(64)*, and *(65)*. q: π-electron density; F: free valences; A_E, A_N, A_F: Wheland localization energies for electrophilic, nucleophilic, and free-radical substitution (β units).

Compound	Position	q	F	A_E	A_F	A_N
(13)	2	1.095	0.470	2.081	2.205	2.329
	5	1.055	0.449	2.164	2.323	2.482
	8	0.938	0.438	2.431	2.296	2.161
	7	0.934	0.488	2.234	2.130	2.026
(64)	1	1.113	0.465	2.065	2.200	2.336
	5	1.060	0.458	2.105	2.277	2.450
	11	0.849	0.509	2.351	2.079	1.806
	13	0.832	0.498	2.543	2.188	1.833
(65)	13	1.198	0.542	1.732	2.010	2.287
	6	1.005	0.448	2.294	2.294	2.294
	7	0.946	0.458	2.471	2.290	2.109
	3	0.924	0.437	2.443	2.289	2.135

Protonation of *(65)* apparently yields the cation *(67)*, the π-electron arrangement of which corresponds to that of the naphtho[1,2]tropylium cation; the ultraviolet spectra of both substances are in fact very similar [48].

Most of the 35 possible hydrocarbons have not yet been prepared. On the basis of the HMO charcteristics, we believe [91a,92] that the ions *(68)* to *(71)* and the hydrocarbons *(72)* to *(74)* should be reasonably stable. A methyl derivative of the hydrocarbon *(74)* has recently been synthesized [93]. Calculated absorption maxima (LCI method) [94] and experimental findings agree well. The three molecules *(75)*, *(76)*, and *(77)* appear to be very unstable. The hydrocarbon *(75)* possesses a non-bonding molecular orbital; according to Craig's rule it is non-aromatic, and its chemical reactivity indices are unfavorable. The stability of the hydrocarbon *(76)* would undoubtedly be adversely affected by ring strain; the corresponding dication, however, has a favorable π-electron distribution.

Sequence Distribution in Copolymers

Physical Property Studies

BY PROF. DR. H. JAMES HARWOOD

INSTITUTE OF RUBBER RESEARCH, UNIVERSITY OF AKRON, AKRON, OHIO (U.S.A.)

The physical properties of copolymers are determined by their compositions and by the distribution of monomeric sequences in their chains. In some cases, sequence distributions can be determined from or correlated with physical properties observed for copolymers. Such determinations or correlations are relatively simple when calculations are based on run numbers.

A. Introduction

Knowledge of the detailed structure of copolymers can be valuable in studies on copolymerization mechanism and on the physical and chemical properties of copolymers. Chemical methods for characterizing sequence distribution in copolymers were surveyed in an earlier review [1] and the use of run numbers [2] in such studies was illustrated.

Physical methods for characterizing sequence distribution in copolymers will be reviewed in this article. The techniques covered are also used to characterize stereoregular polymers [4, 5].

B. General Methods for Correlating Physical Properties with Copolymer Structure

If the magnitude of a physical property (extinction coefficient, molar polarization, specific volume, *etc.*) associated with an A unit in a copolymer containing A and B units is dependent upon the nature of its neighbors, then measurements of the property can provide information about sequence distribution in the copolymer. Assuming that only nearest neighbors influence A units, the average value of the property, $P_{A,av.}$, observed for the copolymer is given by Equation (a), where f_{AAA},

$$P_{A,av.} = f_{AAA} \cdot P_{AAA} + f_{BAA} \cdot P_{BAA} + f_{BAB} \cdot P_{BAB} \qquad (a)$$

f_{BAA}, and f_{BAB} refer to the fractions of A units centered in $\overset{*}{A}AA$, $A\overset{*}{A}B$ (and $B\overset{*}{A}A$), or $B\overset{*}{A}B$ triads, respectively, and where P_{AAA}, P_{BAA}, and P_{BAB} represent the values of the property associated with A groups centered in these triads. (More terms are needed when copolymer stereochemistry must be considered or where the properties of A units depend on pentadic, *etc.*, environment).

Since f_{AAA}, f_{BAA}, and f_{BAB} are related, through Equations (b), (c), and (d), to copolymer composition and run number [1, 3], experimentally determined $P_{A,av.}$ values can be used for the evaluation of run numbers, provided P_{AAA}, P_{BAA}, and P_{BAB} are known. Unfortunately, suitable reference models for evaluating P_{BAA} and P_{BAB} are difficult to obtain and

$$f_{AAA} = \frac{(\%\,A - R/2)^2}{\%\,A^2} \qquad (b)$$

$$f_{BAA} = \frac{R\,(\%\,A - R/2)}{\%\,A^2} \qquad (c)$$

$$f_{BAB} = \frac{R^2}{4\,(\%\,A)^2} \qquad (d)$$

it is at present not possible to calculate these quantities theoretically. They can, however, be estimated in some cases from investigations on appropriate copolymers. The quantity P_{AAA} can be obtained from studies on the homopolymer of A, and P_{BAB} from studies on copolymers containing only small amounts of A. In such copolymers ($R \simeq 2\ \%A$), the A units are essentially isolated ($f_{BAB} \simeq 1.0$). The quantity P_{BAA} can be estimated from the properties of copolymers having low B contents ($R \simeq 2\ \%B$). In such copolymers, A units are present in both $A\overset{*}{A}A$ and $B\overset{*}{A}A$ triads and the measurements must be corrected for the contribution of A units in $\overset{*}{A}AA$ triads before the properties of A units in $B\overset{*}{A}A$ triads can be assessed. The correction is easily made, however, for the proportions of A units centered in $\overset{*}{A}AA$ and $B\overset{*}{A}A$ triads are $(1 - \%B/\%A)^2$ and $2\,(\%B/\%A)\,(1 - \%B/\%A)$, respectively, when $R \simeq 2\ \%B$.

In some copolymerizations, one of the monomers (B) is reluctant to combine with itself (*e.g.*, styrene-maleic anhydride); run numbers of copolymers obtained from such systems are directly proportional to composition ($R = 2\ \%B$) at even high B contents and the above approximations are

[1] *H. J. Harwood*, Angew. Chem. *77*, 405 (1965); Angew. Chem. internat. Edit. *4*, 394 (1965).

[2] The run number, R, is defined as the average number of monomer sequences (or blocks) which are present per one hundred monomer units in a copolymer chain. This quantity is related by simple equations to copolymer composition and measurable aspects of copolymer structure [1, 3]. The run number is a convenient parameter for characterizing sequence distribution in copolymers.

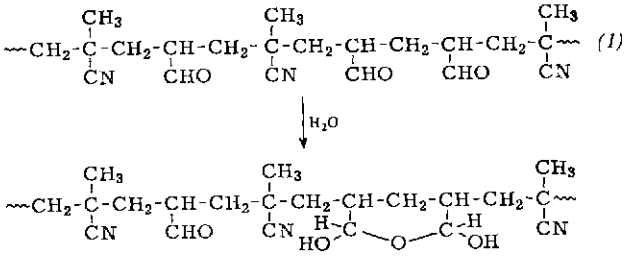
[5] *W. R. Krigbaum* in *B. Ke* (ed.): Newer Methods of Polymer Characterization. Interscience ,New York 1964, Chapter 1.

quite reliable. In other systems, the best that can be accomplished, at present, is an empirical assignment of values to P_{BAA} and P_{BAB} which allow $P_{A,av.}$ to be correlated with calculated sequence distributions.

C. Infrared Absorption Studies

The ideal situation for measuring sequence distribution in copolymers by physical methods is obtained when the property measured is due only to monomer units in a specific environment (*e.g.*, $P_{AAA} = 0$, $P_{BAA} = 0$, $P_{BAB} \neq 0$).

Schulz, *Kaiser*, and *Kern* [6] noted that the carbonyl absorption of acrolein-methacrylonitrile or methacrolein-methacrylonitrile copolymers is directly proportional to the concentration of isolated acrolein or methacrolein units (only methacrylonitrile neighbors) in copolymers containing less than 66 mole-% acrolein or methacrolein. The results were attributed to the tendency of acrolein and methacrolein units to form cyclic acetal or hemiacetal units when present in sequences of two or more units. Such cyclic units do not absorb in the carbonyl



(1)

region. Furthermore, the carbonyl absorption of copolymers containing up to 95 % methacrolein could be correlated with calculated sequence distributions if 20 % of the methacrolein units in sequences containing four or more such units were assumed to be in the free state.

Ang and *Harwood* [7] noted that phenyl absorption at 700 cm^{-1} in styrene (S)-maleic anhydride (M) copolymers is independent of sequence distribution ($P_{SSS} = P_{MSS} = P_{MSM}$) and hence useful for determining copolymer compositions. Phenyl absorption occurring at 760 cm^{-1} is not independent of sequence distribution, however; the relative intensities of the 700 and 760 cm^{-1} bands ($\varepsilon_{760}/\varepsilon_{700}$) decrease as the styrene content of the copolymers decreases (Fig. 1). In relating the relative absorbances observed for these bands to copolymer structure, Equation (e) was used (a, b, and c represent the extinction coefficients of the 760 cm^{-1} band for styrene units centered respectively in SSS, MSS, and MSM triads divided by the extinction coefficient of the 700 cm^{-1} band).

$$\frac{\varepsilon_{760}}{\varepsilon_{700}} = a \cdot f_{SSS} + b \cdot f_{MSS} + c \cdot f_{MSM} \qquad (e)$$

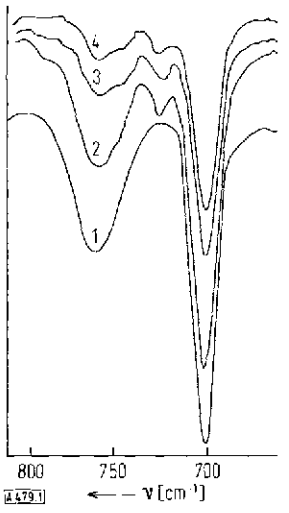

Fig. 1. Infrared spectra of styrene-maleic anhydride copolymers. Styrene contents: Curve 1: 100; 2: 64.6; 3: 59.4; 4: 50 mole-% [7].

Coefficient a was evaluated from the spectrum of polystyrene. Investigation of copolymers having low M contents ($f_{MSM} \simeq 0$) showed that $b \simeq a$. From the spectra of copolymers in which the styrene units were essentially isolated ($f_{MSM} \simeq 1.0$), it was found that $c \simeq a/2$. These results and the requirement that f_{SSS}, f_{MSS}, and f_{MSM} total unity lead to Equation (f).

$$f_{MSM} = \frac{a - \varepsilon_{760}/\varepsilon_{700}}{a - c} = \frac{0.295 - \varepsilon_{760}/\varepsilon_{700}}{0.144} \qquad (f)$$

Assuming maleic anhydride units to be essentially isolated in all the copolymers ($r_M \simeq 0$), run numbers ($R = 2\,\%M$) and f_{MSM} values [Eq. (g)] can be calculated from their compositions (Table 1).

$$f_{MSM} = \frac{R^2}{4\,(\%S)^2} = \left(\frac{\%M}{\%S}\right)^2 \qquad (g)$$

Table 1. Sequence distribution in styrene-maleic anhydride copolymers [7].

Mole-% of styrene		$\varepsilon_{760}/\varepsilon_{700}$	$f_{MSM(obs.)}$	f_{MSM} (calc.)

50.1	(50)	0.151	—	—	—
21.3	(50)	0.153	—	—	—
12.3	(50)	0.150	—	—	—

[a] Calculated from copolymer composition [Eq. (g)].

[b] Calculated for low conversion copolymers from feed compositions ($\%S_f$ and $\%M_f$) according to Equations (d) and (g'). The reactivity ratios of the monomers S and M are $r_S = 0.019$ and $r_M = 0.0$ respectively. If ——M· and ——S· denote growing copolymer chains, we have the following reactions and corresponding rates.

——M· + M → ——M·	k_{MM}[——M·][M]
——M· + S → ——S·	k_{MS} [——M·][S]
——S· + M → ——M·	k_{SM} [——S·][M]
——S· + S → ——S·	k_{SS} [——S·][S]

The reactivity ratios are defined as

$$r_S = \frac{k_{SS}}{k_{SM}} \qquad r_M = \frac{k_{MM}}{k_{MS}}$$

$$R = 200/(2 + r_S \cdot \%S_f/\%M_f + r_M \cdot \%M_f/\%S_f) \qquad (g')$$

$$\frac{\%S}{\%M} = \frac{\%S_f}{\%M_f} \cdot \frac{r_S\,(\%S_f/\%M_f) + 1}{r_M\,(\%M_f/\%S_f) + 1}$$

Enomoto[8] noted that the tertiary C–H deformation mode of vinyl chloride units in vinyl chloride (VC)-vinylidine dichloride (VDC) copolymers shifts to lower frequencies as the proportion of vinylidine chloride in the copolymers increases. He concluded that the C–H deformation of vinyl chloride units occurs at 1247, 1235, and 1197 cm^{-1} when these units are centered, respectively, in VC–$\overset{*}{V}$C–VC, VDC–$\overset{*}{V}$C–VC, and VDC–$\overset{*}{V}$C–VDC triads. The three absorptions overlap considerably and it is necessary to evaluate absorption coefficients for VC units in the various environments at each wavelength (cf. Section B).

By measuring the absorption of copolymers at the three wavelengths, and by using three simultaneous equations of form (a), *Enomoto* calculated the quantities of VC units present in the various triadic environments in the copolymers. His results, expressed according to our terminology, are shown in Table 2. The results are in reasonably good agreement with calculated sequence distributions, even though his treatment ignores the head-head linkages subsequently suggested (see Section E) to be present in such copolymers. The C–H deformation mode of vinyl bromide units in vinyl bromide-vinylidine chloride copolymers is also sensitive to environment[8].

Germar recently studied methylene absorption (1390 to 1440 cm^{-1}) in vinyl chloride (VC) – vinylidine dichloride (VDC) copolymers[8a]. Absorption at 1405, 1420, and 1434 cm^{-1} provides a measure of methylene units in $-CCl_2-CH_2-CCl_2-$, $-CHCl-CH_2-CCl_2-$, and $-CHCl-CH_2-CHCl-$ environments, respectively. The relative intensities of these bands thus provide a measure of the relative amounts of VDC–VDC, VDC–VC, and VC–VC linkages in the polymers. These were in excellent agreement with calculated values (see Equations (a), (b), and (c) in Ref.[1]), based on monomer feed composition data and on r_{VC} and r_{VDC} values of 0.20 and 3.2, respectively. *Germar* found no evidence for the presence of head-head structure in these copolymers.

In a related study, *Oswald* and *Kubu*[9] used infrared analysis to characterize chlorinated polyethylene samples. Bands in the 1400–1475 cm^{-1} region (CH_2 bending) were used to determine the proportions of methylene groups centered in $-CH_2CH_2CH_2-$, $-CH_2CH_2CHCl-$, and $-CHClCH_2CHCl-$ triads.

By considering the chlorinated polymers to be terpolymers of ethylene, vinyl chloride, and 1,2-dichloroethylene, glass transition temperatures of the copolymers can be predicted from the infrared results with considerable accuracy. No evidence for the presence of $-CCl_2-$ units in the copolymers was obtained, in agreement with the results of *Nambu*[10] and of *Fuchs* and *Louis*[11] who studied chlorinated poly(vinyl chloride) samples. *Germar* has also published an infrared study of the microstructure of chlorinated poly(vinyl chloride)[11a].

The infrared absorption of ethylene copolymers in the 700–850 cm^{-1} region can provide information about their sequence distributions. Studies on model hydrocarbons[12–14] have shown that the absorption of methylene groups in this region is dependent on the size of methylene sequences in the compounds. Methylene absorptions observed in this region and their relation to structures occurring in ethylene copolymers are shown in Table 3.

Table 2. Sequence distribution in vinyl chloride-vinylidine chloride copolymers [8].

Natta and coworkers [15] cited the intense absorption shown by such copolymers at 751 cm^{-1} (13.29 μ) as evidence for their highly alternating structures.

The absorption at 724 and 731 cm^{-1} of several ethylene (E)–propylene (P) copolymers have been assigned [16] to structures *(6)* and *(4)*, respectively. The relative intensities observed were qualitatively consistent with sequence distributions calculated for the copolymers, assuming reactivity ratios of 7.08 and 0.088 for ethylene and propylene, respectively. *Veerkamp* and *Veermans* [17] subsequently developed a technique to measure the intensities of these absorptions accurately. By assuming similar extinction coefficients for the two bands, the ratio of methylene units in $(CH_2)_3$ and larger methylene sequences in a number of copolymers was determined. The results agreed reasonably well with theoretical values based on *Natta*'s calculations.

More recently, the presence of $(CH_2)_2$ sequences in ethylene-propylene copolymers has been considered in studies of their structure [18]. Such sequences could result from the tail-head incorporation of propylene units into the copolymers [structure 3a]. By measuring absorption at 815, 752, 733, and 727 cm^{-1}, *Bucci* and *Simonazzi* [19] were able to quantitatively account for methylene groups present in the copolymers. Their results are shown in Fig. 2.

Copolymers of tetrafluoroethylene with ethylene [19], propylene [20], or isobutylene [21], prepared at low temperatures in the presence of ionizing radiation, show infrared absorption which is significantly different from that observed for the corresponding homopolymers, indicating that they do not have block or polyblend structures. The tetrafluoroethylene-isobutylene copolymer was believed to have an alternating structure.

Yanagisawa [22] investigated the absorption of a series of styrene copolymers in the 1000–1300 cm^{-1} and 500–650 cm^{-1} regions and concluded that strong phenyl absorption (coupled with skeletal vibrations) occurs at 543 cm^{-1} only when the average styrene sequence length is greater than three. Copolymers having shorter average styrene sequences absorb at higher frequencies. These results suggest that the 543 cm^{-1} band might provide a measure of $\overset{\blacktriangle}{S}SS$ structure and that bands at higher frequencies might be found for other styrene-centered triads. Similarly, the absorption observed at 1068 cm^{-1} in polystyrene shifts to about 1075 cm^{-1} in copolymers having low styrene contents. Shifts of bands observed at 1191 and 1148 in poly(methyl methacrylate) to higher and lower frequencies, respectively, in styrene-methyl methacrylate copolymers were also noted. The magnitude of the shifts depends on the average sequence length of the methyl methacrylate units in the copolymers. Similar results were obtained with styrene-ethyl methacrylate copolymers.

Shirakawa, *Yamazaki*, and *Kambara* [23] used ionic polymerization techniques to prepare α-methylstyrene-methylene block copolymers *(7)* having controlled sequence lengths. Many bands in the infrared spectra

$$[\text{-}(\alpha\text{-methylstyrene})_m\text{-}(CH_2)_x\text{-}]_n \qquad (7)$$

(600–1300 cm^{-1}) of these copolymers were noted to increase or decrease in intensity with increasing length of the α-methylstyrene sequences. The spectra of α-methylstyrene blocks in the copolymers are essentially identical to those of poly(α-methylstyrene) samples of comparable size. These workers concluded that planar C–H deformations of monosubstituted benzene rings increase in intensity as the number of α-methylstyrene units in a sequence increase. The opposite seems to hold for out of plane deformations.

D. Ultraviolet Absorption Studies

When poly(methyl vinyl ketone) is heated *in vacuo* at 250 °C, it slowly develops color due to the formation of condensed structures *(9)–(11)* in the polymer chain. From the kinetics of this process, *Hay* concluded [24] that the cyclization occurs randomly, and predicted the relative amounts of cyclized sequences which should be present in the polymers after various extents of cyclization. These predictions are compared with values obtained by absorption measurements at 235, 285, and 335 mμ according to Equation (g″) in Table 4. A_{235}, A_{285}, and A_{335} are the absorbance values (log I_0/I) observed at the indicated wavelengths for a cyclized sample.

(The molar extinction coefficient was assumed to be inversely proportional to the number of conjugated double bonds present in the absorbing structure.)

$$\%\ (9) = 100 \cdot A_{235}/(A_{235} + \tfrac{1}{2} A_{285} + \tfrac{1}{3} A_{335})$$

$$\%\ (10) = 100 \cdot (\tfrac{1}{2} A_{285})/(A_{235} + \tfrac{1}{2} A_{285} + \tfrac{1}{3} A_{335}) \qquad (g'')$$

$$\%\ (11) = 100 \cdot (\tfrac{1}{3} A_{335})/(A_{235} + \tfrac{1}{2} A_{285} + \tfrac{1}{3} A_{335})$$

E. Nuclear Magnetic Resonance Studies

Nuclear magnetic resonance has become a powerful tool for characterizing the structures of polymers [25–27]. The use of NMR for quantitative analysis is relatively easy, since the area under a given resonance peak is directly proportional to the number of nuclei responsible for the resonance.

Ferguson [28] was the first to use NMR to study sequence distribution in copolymers. By studying F^{19} resonance in vinylidine fluoride (VF)-hexafluoropropylene (HFP) copolymers, he established that no HFP–HFP linkages are present in the copolymers and that a small proportion (5–7%) of both VF and HFP units are present in head-head arrangements. By comparing appropriate resonance areas, the fraction, n, of vinylidene fluoride CF_2 groups in $-CH_2\dot{C}F_2CH_2CF_2-$ and $-CH_2\dot{C}F_2CF_2CH_2-$ environments was determined. This fraction is approximately equal to the number of VF–VF linkages in the copolymer divided by the number of VF units present:

$$n = \frac{\%\,VF - VF\ linkages}{\%\,VF} = \frac{\%\,VF - R/2}{\%\,VF} \qquad (h)$$

Since HFP units are isolated in the copolymers, R = 2·%HFP and n can be expressed in terms of copolymer composition, as follows:

$$n = 1 - \%\,HFP/\%\,VF \qquad (h')$$

Table 5 compares values of n determined by *Ferguson* (taken from his graph) with those calculated from Eq. (h').

Table 5. Fraction (n) of vinylidine fluoride CF_2 groups in $-CH_2CF_2CH_2CF_2-$ and $-CH_2CF_2CF_2CH_2-$ environments in vinylidine fluoride-hexafluoropropylene copolymers [28].

% VF	n	
	found	calc. [Eq. (h')]
85	0.81	0.82
78	0.68	0.72
70	0.56	0.57
61	0.38	0.36

Chujo and coworkers [29] reported the NMR spectrum of a vinyl chloride–vinylidine chloride copolymer. Separate resonance areas were observed for methylene protons centered in $-CHClCH_2CHCl-$ and $-CCl_2CH_2CCl_2-$ environments. From the relative resonance areas observed, they calculated the percentages of vinyl-vinyl, *etc.*, linkages present in the copolymers. This spectrum has been reinterpreted [30] in terms of head-head linkages in vinylidine chloride sequences, these linkages occurring only at sequence junctions. This new interpretation is based on a comparison of the copolymer spectrum with that of partially chlorinated poly(2,3-dichlorobutadiene). Other model systems should be studied before this interpretation is accepted. *Okuda* [31] observed reasonably intense $-CHClCH_2CHCl-$ type resonance in copolymers having high vinylidine chloride contents and concluded that the copolymers have block structures. This result is inconsistent with the relatively low reactivity ratio observed for vinyl chloride (0.3) in this system.

Nishioka and coworkers [32, 33] and also *Bovey* [34] measured the NMR spectra of styrene–methyl methacrylate and *p*-xylylene–methyl methacrylate copolymers in chloroform and carbon tetrachloride solution. They observed three types of methoxy resonance and concluded that this resonance might be used to characterize sequence distribution and possibly also tacticity in the copolymers. Similar results [35] have been obtained for styrene–methyl methacrylate copolymers in thionyl chloride solution. *Bovey* [34] correlated the methoxy resonance patterns of styrene (S)-methyl methacrylate (M) copolymers ($CHCl_3$ solution) with calculated distributions of M centered triads by considering the

resonance of methoxy protons in SMM and SMS triads to be distributed among several methoxy resonance areas, rather than being associated with a given area. This was attributed to triad configurational effects. According to a recent interpretation [35a], the highest-field, methoxy resonance is due to SMS triads in which *both* styrene units have the same configuration (co-isotactic) as the central methyl methacrylate unit. The central methoxy resonance area is due to methoxy protons of methyl methacrylate units centered in SMM and SMS triads, where *one* of the styrene units has the same configuration as the central methyl methacrylate unit. The upfield shift of the resonance of such methoxy protons is probably due to shielding by diamagnetic regions of neighboring phenyl units. The resonance of the remaining methoxy protons (MMM and SMM or SMS where *none* of the styrene units has the same configuration as the central methyl methacrylate unit) occurs in the lowest-field resonance area.

On the basis of this interpretation, which permits the methoxy resonance patterns to be accounted for quantitatively, the probability that adjacent styrene-methyl methacrylate units have the same configuration (co-isotactic) in their copolymers is 0.48. The probability that adjacent styrene-methyl acrylate units have the same configuration in their copolymers was estimated to be much higher (0.80).

Ito and *Yamashita* [35a] and also *Overberger* and *Yamamoto* [35b] have studied the NMR spectra of styrene-methyl methacrylate copolymers prepared by anionic polymerization. They conclude that there are very few styrene-methyl methacrylate linkages in the copolymers (or polyblends).

Harwood and *Ritchey* [36] obtained spectra of the type shown in Fig. 3 for styrene-methyl methacrylate copolymers in deuteriobenzene solution. As in the other studies, methoxy resonance was observed in three general areas. For copolymers containing less than 50 mole percent styrene, the methoxy patterns observed were correlated with calculated distributions of M centered *pentads*; the fraction of methoxy resonance observed in the lowest-field peak is equal to the fraction of M units centered in $\overset{*}{M}MM\overset{*}{M}M$, $\overset{*}{M}MM\overset{*}{M}S$, $\overset{*}{S}M\overset{*}{M}MS$, and $\overset{*}{S}M\overset{*}{M}SM$ pentads, for example, and the fraction of methoxy resonance observed in the highest-field peak to the fraction of M units centered in $\overset{*}{M}S\overset{*}{M}SM$ pentads. Copolymers containing higher amounts of styrene have appreciable quantities of M units centered in SSMSS and SSMSM pentads and these units seem to be responsible for resonance in more than one general area. This phenomenon was attributed to pentad configurational effects.

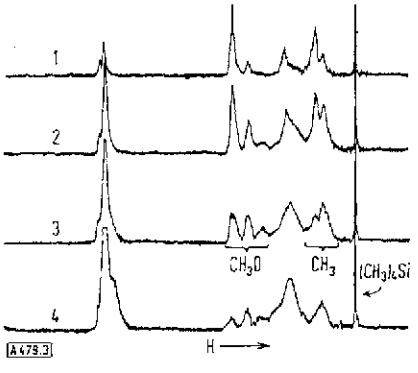

Fig. 3. NMR spectra of styrene-methyl methacrylate copolymers. Styrene contents, Spectrum 1, 16.8; 2, 33.3; 3, 50.2; 4, 72.6 mole-% [36].

α-Methyl resonance was observed for these copolymers in two general areas, the higher-field area being about the intensity expected for α-methyl protons centered in SMM and SMS triads. By combining Equation (b) with an expression (i) for the percentage, P′, of all copolymer resonance occurring in the high field α-methyl peak, Equation (j) relating run numbers to P′ values can be derived. Table 6 compares experimentally determined P′ and R values with those calculated from monomer feed compositions and monomer reactivity ratios.

$$P' = (3/8)\,(\%\,M)\,(1-f_{MMM}) \qquad (i)$$

$$R = 2\,(\%\,M)\,(1-\sqrt{1-8\,P'/(\%\,M)}/3) \qquad (j)$$

Table 6. Results of studies on high-field α-CH_3 resonance in styrene-methyl methacrylate copolymers [36].

10.0	16.8	10.5	10.9	30	32

Nuclear magnetic resonance has not been used to characterize sequential structure in organic polycondensates, but *Van Wazer* and coworkers [37–39] have made good use of this technique in characterizing low molecular weight inorganic polymers, *e.g.* linear and branched polyphosphates, polyarsenites, and polysiloxanes having Cl, $N(CH_3)_2$, OCH_3, or F end groups, obtained through equilibration experiments. Equilibrium constants for the various exchange reactions were also established.

F. Electrical Polarization Studies

The application of dielectric measurements to the study of sequence distribution in copolymers is rather straightforward, especially if one of the monomers is nonpolar. In most cases, only nearest-neighbor interactions need be considered. The average molar polarization, $P_{av.}$, of a polar monomer unit A can be related to triad

distributions and the molar polarizabilities, P, of monomer units centered in various triadic environments, by Equation (k).

$$P_{av.} = f_{AAA} \cdot P_{AAA} + f_{BAA} \cdot P_{BAA} + f_{BAB} \cdot P_{BAB} \qquad (k)$$

A six-term expression, in which each term is weighted according to copolymer composition, would be required to describe the average molar polarization of units in a copolymer containing two polar monomers. Even more terms, appropriately weighted, would be needed to treat differences in triad configurations. Fortunately, the three-term expression proved adequate for most studies. Styrene has been used as a relatively nonpolar comonomer in these studies and its molar polarization has been considered constant.

Work and *Trehu* [40] developed a general expression for the average dipole moments of polar-polar and polar-nonpolar copolymers in terms of sequence distribution, the dipole moments of equivalent isolated units present, and the average cosines of the angles between neighboring dipoles in the copolymers. The dielectric polarization of *p*-chlorostyrene-styrene copolymers was then correlated *via* this expression with calculated sequence distributions, and the average cosines of the angles between various dipoles in the copolymers were estimated. Excellent agreement is obtained between theory and experiment when only nearest-neighbor dipolar interactions are treated.

Shima [41a] subsequently determined the molar polarizations and average dipole moments of a series of styrene-methyl methacrylate copolymers. The effective dipole moment of methyl methacrylate units in the copolymers increases as the percentage of styrene increases; the limiting value is close to that observed for simple esters. The results were correlated by a least squares procedure with calculated sequence distributions, through use of Equation (k). The fit obtained is shown in Table 7. Similar results have also been obtained for copolymers of styrene with *p*-chlorostyrene [41b], *p*-methoxystyrene [41b], methyl acrylate [42, 43] and methyl vinyl ketone [43].

Table 7. Results of dielectric studies on styrene-methyl methacrylate copolymers [41].

Mole-% styrene in copolymer	Temp. [°C]	$P_{av.}$ [cm³]	μ [Debye] obs.	μ [Debye] calc. [a]
0	10	64.3	1.36	—
	40	63.3	1.41	—

	40	66.4	1.46	1.46
21.3	10	72.4	1.49	1.48
	40	70.9	1.54	1.54
45.7	10	79.4	1.59	1.60
	40	76.2	1.63	1.64
54.4	10	82.5	1.64	1.63
	40	79.9	1.68	1.67

[a] The copolymers were prepared in total conversion from given monomer feeds. These calculated values are averages.

Although good correlations are obtained in these studies, this approach to sequence distribution measurement has limited sensitivity. The molar polarizability of methyl methacrylate units centered in SMS triads in styrene-methyl methacrylate copolymers is only about 20 % higher than that of units centered in MMM triads. The difference is even less for methyl acrylate units in styrene-methyl acrylate copolymers.

G. Thermochemical Measurements

1. Heats of Copolymerization

Alfrey and *Lewis* [44] suggested that four separate heats of reaction (ΔH_{AA}, ΔH_{AB}, *etc.*), one for each propagation step shown below, contribute to heats of copolymerization. Since equal numbers of A–B and B–A linkages

$$\sim\!\!\sim A\bullet + A \xrightarrow{-\Delta H_{AA}} \sim\!\!\sim AA\bullet$$

$$\sim\!\!\sim A\bullet + B \xrightarrow{-\Delta H_{AB}} \sim\!\!\sim AB\bullet$$

$$\sim\!\!\sim B\bullet + A \xrightarrow{-\Delta H_{BA}} \sim\!\!\sim BA\bullet$$

$$\sim\!\!\sim B\bullet + B \xrightarrow{-\Delta H_{BB}} \sim\!\!\sim BB\bullet$$

are established in copolymers, the cross-propagation reactions occur to equal extents and the corresponding heats of reaction (ΔH_{AB} and ΔH_{BA}) can be treated collectively. Equation (l) can then be written for the molar heat of copolymerization, $\Delta H_{cop.}$ (expressed per mole of repeating units).

$$\Delta H_{cop.} = \frac{1}{100}[\%\,AA \cdot \Delta H_{AA} + \%\,(AB + BA) \cdot (\Delta H_{AB} + \Delta H_{BA})/2 + \%\,BB \cdot \Delta H_{BB}] \qquad (l)$$

Following *Alfrey* and *Lewis*' treatment and a more recent treatment by *Sawada* [45], this equation can be written in terms of copolymer composition and run number, as follows [46].

$$\Delta H_{cop.} = \frac{1}{100}[\%\,A \cdot \Delta H_{AA} + \%\,B \cdot \Delta H_{BB} + R/2(\Delta H_{AB} + \Delta H_{BA} - \Delta H_{AA} - \Delta H_{BB})] \qquad (m)$$

Of the quantities in Equation (m), only R and ($\Delta H_{AB} + \Delta H_{BA}$) are not assessible independently (although R can be calculated from kinetic parameters). In most studies, a value is assigned to ($\Delta H_{AB} + \Delta H_{BA}$) which permits measured heats of copolymerization to be related to calculated sequence distribution parameters, such as R. For example, in Fig. 4 heats of copolymerization determined [47] for styrene–methyl methacrylate and for vinyl acetate–methyl methacrylate copolymerizations are plotted against the methyl methacrylate con-

[46] The expression m_2P_{21} used by *Alfrey* and *Lewis* and the expression X_BP_1 used by *Sawada* can be shown to equal R/200. $\Delta H_{cop.}$ in these treatments is, of course, corrected for heat changes due to initiator decomposition, monomer mixing, solution of polymer in monomer mixtures, *etc.*

[47] *M. Suzuki, H. Miyama*, and *S. Fujimoto*, J. Polymer Sci. *31*, 212 (1958).

tent of the copolymers. Plots of Equation (m), in which calculated[1,3] values of R and assigned (ΔH_{AB} + ΔH_{BA}) values are employed, fit the experimental results reasonably well. Similar results[48] were obtained for copolymerizations of acrylonitrile with styrene, methyl methacrylate, and vinyl acetate.

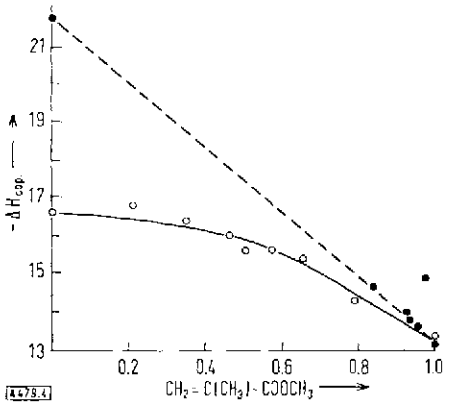

Fig. 4. Heats of copolymerization, $\Delta H_{cop.}$, for methyl methacrylate-styrene (○) and methyl methacrylate-vinyl acetate (●) copolymerizations [47].
– — Calculated for (ΔH_{SM} + ΔH_{MS}) = −32.7 kcal/mole;
---- calculated for (ΔH_{VM} + ΔH_{MV} − ΔH_{VV} − ΔH_{MM}) = 0.
Abscissa: Mole fraction of methyl methacrylate in the copolymer.

The sensitivity of $\Delta H_{cop.}$ to R depends on the magnitude of the expression (ΔH_{AB} + ΔH_{BA} − ΔH_{AA} − ΔH_{BB}); when this expression is zero, $\Delta H_{cop.}$ becomes independent of sequence distribution and linearly dependent on copolymer composition. This is almost the case with styrene-vinyl acetate copolymerization (Fig. 4). Values of (ΔH_{AB} + ΔH_{BA} − ΔH_{AA} − ΔH_{BB}) obtained for a number of copolymerization systems[47–50] range from 0 to 9 kcal/mole.

In copolymerizations where one of the monomers (B) fails to homopolymerize (r_B = 0; R = 2 %B), $\Delta H_{cop.}$ is related to copolymer composition by Equation (n). In such situations, $\Delta H_{cop.}$ varies linearly with copolymer composition and

$$\Delta H_{cop.} = \Delta H_{AA} + \frac{\%B}{100}(\Delta H_{AB} + \Delta H_{BA} - 2\Delta H_{AA}) \qquad (n)$$

(ΔH_{AB} + ΔH_{BA}) can be obtained from the value of $\Delta H_{cop.}$ when %B = 50. Results of this type were obtained by *Tong* and *Kenyon*[51] in studies on copolymerizations of vinyl acetate with diethyl maleate and diethyl fumarate.

2. Entropies of Copolymerization

Entropy changes associated with copolymerization reactions can be related to run numbers by an equation similar to (m), except that an additional term, C, must be included to account for the entropy of arranging monomer sequences in the copolymer chains. Calcula-

$$\Delta S_{cop.} = \frac{1}{100}[\%A \cdot \Delta S_{AA} + \%B \cdot \Delta S_{BB} + R/2(\Delta S_{AB} + \Delta S_{BA} - S_{AA} - S_{BB})] + C \qquad (o)$$

tions by *Orr*[52] and by *North* and *Richardson*[53] indicate C to be 0.5 to 1.5 cal deg^{-1} mole^{-1} of repeating units, so this term will seldom be responsible for more than 5 % of $\Delta S_{cop.}$. In what appears to be the only experimental study on copolymerization entropy, *Orr* noted that (ΔS_{SB} + ΔS_{BS}) is about 5 cal deg^{-1} mole^{-1} smaller than (ΔS_{SS} + ΔS_{BB}) in the copolymerization of styrene (S) with butadiene (B) at 30 °C.

H. Crystalline Contents and Melting Points of Copolymers

The melting points and crystalline contents of copolymers containing crystallizable (A) and non-crystallizable units (B) can provide information about sequence distribution. The simplest approach to take in correlating the crystalline content of such copolymers with their sequence distributions is to assume that all A units in sequences larger than a critical length m* are crystalline, whereas A nnits in shorter sequences and all B units are noncrystalline. The weight fraction of crystalline material, W_c, in a copolymer can then be calculated from Equation (p), where $\%A_w$ is the weight percentage of A units in the copolymer and f_{BA_mB}

$$W_c = \frac{\%A_w}{100} \cdot \sum_{m^*}^{\infty} m \cdot f_{BA_mB} = \frac{\%A_w}{100} \cdot \sum_{m^*}^{\infty} m \cdot (p_{AB})^2 \cdot (p_{AA})^{m-1} \qquad (p)$$

represents the fraction of A units in *each* position of sequences containing m A units[54]. Summations of Equation (p) have been evaluated algebraically[55,56] and a relationship similar to (p) has been used to predict W_c for various ethylene-propylene copolymers, assuming m* = 7[57].

In correlating W_c with calculated or measured sequence distributions, the critical sequence length, m*, is selected empirically. Ideally, m* corresponds to the sequence length which melts just above the temperature employed in determining W_c, but the value selected probably also corrects for incomplete crystallization due to kinetic or steric factors. Values of m* selected[55–60] in various studies on ethylene copolymers and stereoregular polymers range from 8 to 13. *Ring*[55] obtained a good correlation between calculated and observed W_c values for

[48] *H. Miyama* and *S. Fujimoto*, J. Polymer Sci. *54*, S33 (1961); *M. Suzuki*, *H. Miyama*, and *S. Fujimoto*, Bull. chem. Soc. Japan *35*, 57, 60 (1962).

[52] *R. J. Orr*, Polymer *2*, 74 (1961).

[53] *A. M. North* and *D. Richardson*, Polymer *5*, 227 (1964).

[54] Consider ~~BAAAAB~~ (1 2 3 4) sequences. The fraction of A units in positions 1 *or* 4 is $p_{AB} \cdot p_{AA} \cdot p_{AA} \cdot p_{AA} \cdot p_{AB}$ (*i.e.*, ~~BAAAAB~~ or BAAAAB). The fraction of A units in positions 3 *or* 4 is also $(p_{AB})^2(p_{AA})^3$. The fraction of A units in positions 1, 2, 3, *and* 4 is therefore $4(p_{AB})^2(p_{AA})^3$ and this corresponds to the fraction of A units in tetrameric sequences. The expression for the general case, $m(p_{AB})^2(p_{AA})^{m-1}$, can be obtained similarly; p_{AB}, for example, denotes the probability that an A unit in the copolymer is followed by a B unit.

[60] *J. F. Jackson*, J. Polymer Sci. A *1*, 2119 (1963).

random ethylene–propylene copolymers by assuming m* to be 11, whereas *Jackson*[60] assumed m* to be about 8 in studies on a series of ethylene–propylene copolymers having block, random, or alternating type structure ($r_E r_P$ ranged from 0.09 to 1.73).

Should a reliable relationship of m* to temperature be available, the melting curve of a copolymer (W_c *vs.* T) can be used to construct a curve representing the integral weight distribution of A sequence lengths. *Gubler* and *Kovacs*[61] based assignments of m* at various temperatures on melting points reported for linear hydrocarbons. From melting curves observed for various polyethylene samples, they calculated the distributions of crystalline sequences present. By assuming one methyl (branch) unit to be associated with each amorphous sequence present, they calculated methyl contents for the polymers which where in fairly good agreement with those determined by infrared spectroscopy. *Flory*[62] has derived a theoretical relationship for m*. *Miller*[56] used *Flory*'s relationship and expressions analogous to (p) to construct melting curves for polypropylene fractions. The curves are in excellent agreement with experimental results.

Flory's treatment of copolymer crystallization[62], which was subsequently extended to treat stereoregular polymer crystallization[63], is more elaborate than the treatments outlined above. In addition to providing an expression for m* at various temperatures, his theory corrects W_c for the "solubility" of crystallizable sequences in the amorphous melt. Melting curves predicted by his theory are in reasonably good agreement with experimental results at temperatures somewhat removed from maximum copolymer melting points, T_m[*], but predicted W_c values are too high at very low temperatures and also in the vicinity of T_m[64].

According to *Flory*, the maximum melting point, T_m, of a copolymer is given by Equation (q), where T_m^o and ΔH_f are the melting point and enthalpy of fusion (per mole of repeating units) of the homopolymer of A, where $\Re$ is the molar gas constant and where P_{AA} is the probability ($1 - R/2\ \%A$) that an A unit is followed by another A unit in the copolymer chain. P_{AA} equals the mole fraction of A units present in random copolymers

$$\frac{1}{T_m} - \frac{1}{T_m^o} = \frac{-\Re}{\Delta H_f} \ln P_{AA} \qquad (q)$$

and it approaches unity in block copolymers. In the former case, the expression becomes identical with that which describes the melting points of low molecular weight mixtures.

Flory's melting point equation has been used extensively in studies on the melting behavior of copolymers[65] and for estimating the concentration of non-crystallizable units present in stereoregular polymers and in branched polyethylene samples. Unfortunately, the broad melting characteristics of copolymers preclude the accurate determination of T_m; the last 0.1 % of crystalline material in a copolymer can melt over a 5 or 10 degree range, for example. Experimentally determined T_m values are necessarily low and melting point depressions observed are consequently too large. Copolymer melting points can provide qualitative information about sequence distribution in many copolymers, however. Recently proposed extrapolation procedures[66] may be useful for obtaining reliable T_m values and hence reliable sequence distribution determinations may result from such procedures. When T_m observed for a copolymer is very close to T_m^o, the presence of a block copolymer or a polyblend is almost certain[31, 67, 68].

Wunderlich[69] has derived expressions for the melting points and crystalline contents of random copolymers crystallized by a "cold crystallization" process. Cold crystallization is an extreme case of nonequilibrium crystallization in which A units are assumed to crystallize only with adjacent A units; chain movement and the selective crystallization of large A sequences do not occur during this process. As most copolymer crystallizations occur under conditions which lie between the extremes of equilibrium and cold crystallization, the melting points and crystalline contents observed for copolymers are dependent on their thermal history. Differential thermal analysis[70–72] is a powerful tool for studying the influence of crystallization conditions on T_m and W_c.

Wunderlich and *Poland*[72] suggested that T_m^o in *Flory*'s melting point equation (q) be replaced by T_m^f, the melting point of homopolymer crystallized under the same conditions as the copolymer. By comparing the melting points of linear polyethylene and ethylene-propylene copolymer samples, these workers estimated the mole fraction of crystallizable units, X_a (P_{AA}), present in the copolymers. The fraction of noncrystallizable units ($1 - X_a$) proved to be twice the fraction of methyl carbon atoms in the copolymers. The authors concluded that both CH_3 and CH groups are noncrystallizable units[73].

Many physical properties of copolymers (tensile strength, elasticity, permeability, equilibrium swelling, *etc.*) are dependent upon their crystalline contents. Determinations of W_c, in fact, are often based on

measurements of copolymer density or specific heat [74, 75].

When W_c can be correlated with copolymer composition and sequence distribution, then density, specific heat, or other properties can also be related to sequence distribution. The fraction of insoluble material in stereoregular polymers has been used as a qualitative index of stereoregularity [76, 77]. The solubility of block ethylene-propylene copolymers prepared by *Bier* and coworkers [78] increased as the average lengths of the blocks and the crystallinity decreased.

By using the kinetic theory of elasticity to describe the behavior of amorphous chains connecting crystalline regions in copolymer samples, *Flory* [62] derived an expression relating the elastic modulus of a copolymer to thermodynamic and sequence distribution parameters. Elastic moduli determined for copolymers recently [79] are an order of magnitude larger than values predicted by the theory. By correcting for the reinforcing action of crystallites, *Nielsen* and *Stockton* [80] obtained improved agreement between experimental and theoretical results, although calculated moduli were still too low.

I. Other Physical Properties

Glass transition temperatures of copolymers and solution properties of copolymers are dependent on intermolecular forces involving A and B units and on the flexibility of A–A, A–B, and B–B linkages. Glass transition temperatures, T_g, of copolymers have been related to copolymer compositions in most theoretical treatments [81]. *Kanig*'s recent treatment [82], which assumes that T_g is determined by intermolecular interactions between similar and dissimilar monomer units, can explain positive and negative deviations from linearity noted in many [83] T_g *vs.* copolymer composition plots. Recent work [83–85] indicates that the relative stiffness of A–A, A–B, and B–B bonds may also have an important effect on T_g in certain copolymers. In such cases, T_g will be sensitive to sequence distribution as well as copolymer composition.

Solution properties of random copolymers differ significantly from those of block copolymers. Attempts to treat the solution properties of copolymers theoretically have been made [86, 87], but only one attempt to correlate measured properties of copolymers in solution with their sequence distributions has been reported [88]. In this work, the apparent specific volume of vinyl acetate-vinyl chloride copolymers in dioxane was related to their compositions and sequence distributions through an equation analogous to (a). Unfortunately the author used an incorrect expression for P_{AA} and his calculations seem to account only for the properties of A units in various environments. Due to the difficulty of separating effects due to intermolecular forces and bond flexibilities, the correlation of T_g or solution properties of copolymers with the distribution of their sequences will be very difficult.

The preparation of this paper was supported, in part, by grants from the National Science Foundation and the National Institutes of Health, U. S. Public Health Service.

The Structural Chemistry of Condensed Inorganic Phosphates [*]

BY PROF. DR. E. THILO

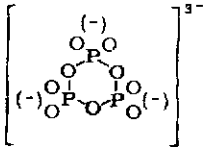
INSTITUT FÜR ANORGANISCHE CHEMIE DER DEUTSCHEN AKADEMIE DER WISSENSCHAFTEN ZU BERLIN (GERMANY)

After it had become known that three types of condensed inorganic phosphates, i.e. metaphosphates, polyphosphates, and ultraphosphates, exist, attempts were made to elucidate their formation, properties, and mutual relationships. Metaphosphates and polyphosphates containing up to eight or ten monomer units can be separated chromatographically. In the melts, equilibria exist between the various types of phosphate anions. Annealing of the glasses leads to crystalline products, sometimes containing only one type of anion. The glass-crystal transition proceeds via monomeric XO_3^- anions. This has been shown in the case of polyarsenatophosphates, in which the As atoms are randomly distributed over the chains in the vitreous state, but are located at preferred positions in the crystalline state. The maximum degree of dissociation of polyphosphates and polyphosphoric acids in water is 30 %, which accounts for the ion exchange and the chelating effects. The cation-catalysed decomposition of polyphosphates can take place either by hydrolytic degradation from the chain ends, or by rearrangement within the chains to form metaphosphates.

Introduction

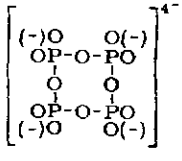
It has been known since 1955 [1a,1b] that condensed phosphates fall into the following three groups:

1. Metaphosphates, $M_n^I(PO_3)_n$ with cyclic anions, *e.g.* *(1)* and *(2)*.



(1)

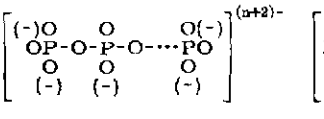
$[P_3O_9]^{3-}$
Trimetaphosphate anion



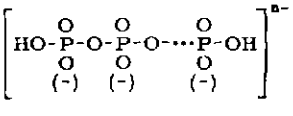
(2)

$[P_4O_{12}]^{4-}$
Tetrametaphosphate anion

2. Polyphosphates, $M_{n+2}^I(P_nO_{3n+1})$ or $M_n^IH_2(P_nO_{3n+1})$, with open-chain anions, *e.g.* *(3)* and *(4)* in which each of the n PO_4 tetrahedra (except those at the chain ends) is linked to each of its neighbors by an oxygen atom.

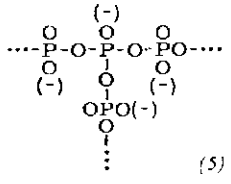


(3)



(4)

3. Cross-linked phosphates or ultraphosphates *(5)* containing "tertiary" P atoms which are linked to three other P atoms by three O atoms.



(5)

Since 1955, the first two types of phosphates in particular have been investigated by preparative and analytical methods, in order to elucidate their mutual relationships and their chemical properties [2a,2b], and by physicochemical methods, in order to explain the properties of their solutions and their complexing power [2b,3]. The present paper is concerned mainly with investigations of the former type, without giving a comprehensive survey of the literature. Whenever the cations of the salts are not explicitly named, sodium salts are to be understood.

A. Metaphosphates

Metaphosphates are always present in Graham's salt $Na_nH_2P_nO_{3n+1}$ [4a,4b], which is obtained by heating NaH_2PO_4 above 620 °C and rapidly cooling the resulting melt. The melt solidifies to form a glass, about 90 % of which consists of a mixture of high-molecular weight polyphosphates, the remainder being metaphosphates

with cyclic anions of various degrees of polymerization. When this glass is annealed at 400 to 550 °C, it is converted into pure trimetaphosphate.

Trimetaphosphates of K, Rb, and Cs are obtained by the dehydration of potassium, rubidium, and cesium dihydrogen phosphates in the melts of the corresponding nitrates[5]. Pure tetrametaphosphates are formed when the dihydrogen phosphates of Al^{3+}, Cu^{2+}, Mg^{2+}, Ni^{2+}, Co^{2+}, Mn^{2+}, Fe^{2+}, Zn^{2+}, and Cd^{2+} are dehydrated at 400 to 500 °C, or when the glasses resulting on cooling of the melts are annealed at 400 to 500 °C[6a,6b]. The tetrametaphosphate $Na_4(P_4O_{12})$ can be prepared by the reaction of the copper salt with Na_2S, or by the reaction of the zinc and cadmium salts with Na_2CO_3. The same product is obtained in good yields by the alkaline hydrolysis of the volatile form of phosphorus(V) oxide[7].

The existence of higher metaphosphates, $Na_n(P_nO_{3n})$ with $n \geqslant 5$, was first observed by *van Wazer* and *Karl-Kroupa*[8a] in the chromatograms of hydrolysates of Graham's salt, and was confirmed by *Rudy* and *Ruf*[8b]. The stepwise addition of acetone to a solution of Graham's salt at first results in the precipitation of high-molecular weight polyphosphates. Subsequent treatment of the mother liquor with a large quantity of acetone leads to the separation of an oily substance in which metaphosphates are present in such a high concentration that they can be easily identified and quantitatively determined up to the octamers by two-dimensional paper chromatography (see Fig. 1)[9a,9b].

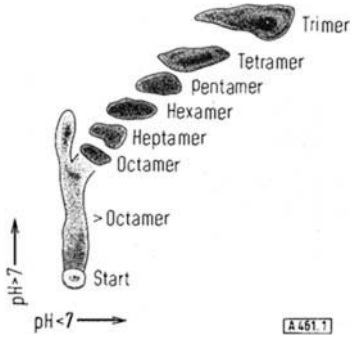

Fig. 1. Two-dimensional paper chromatogram of a metaphosphate fraction obtained from a solution of Graham's salt in water at 16 °C. Paper: Schleicher and Schüll 2043b mgl; Eluent: alkaline, after *Biberacher* [46f], and acidic, after *Pfrengle* [46g].

The concentrations of the individual metaphosphates in Graham's salt decrease exponentially as the number of atoms in the ring increases (cf. Fig. 2), indicating an equilibrium distribution. Only the pentamer content is lower than predicted by the exponential curve (see Fig. 2). The monomeric and dimeric metaphosphates are absent, being apparently incapable of existence at least at room temperature. The fact that monomeric metaphosphate $[PO_3]^{1-}$ with an electron deficiency on the P atom is isoelectronic with sulfur trioxide SO_3

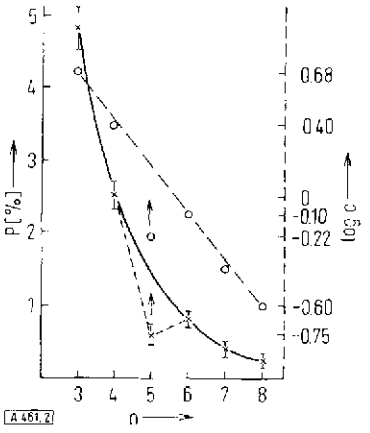

Fig. 2. The quantitative distribution of the individual metaphosphates in Graham's salt (see also Fig. 1).

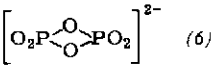
and like this species is formed as an intermediate at higher temperatures will be discussed below (cf. Section B.2). No evidence has yet been found for the existence of a dimeric anion *(6)*. In fact, such an anion having two XO_4 tetrahedra

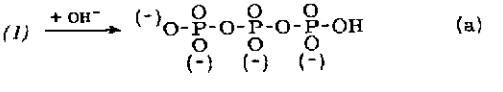


(6)

joined through a common edge should be incapable of existence, according to *Pauling*'s rules for the stability of tetrahedra chains in crystals[84]. The only exception to this rule is an unstable modification of SiO_2, in which SiO_4 tetrahedra are linked in this way to form high-molecular weight chains[10].

Pentametaphosphates and hexametaphosphates of Na, Ag, and Ba containing water of crystallization have been prepared on the gram scale by the fractionation of the metaphosphate components of Graham's salt *via* the silver and hexamminecobalt(III) salts[9b].

The proof of the structure of the metaphosphates is based on their ability to undergo ring cleavage to form the corresponding polyphosphates when attacked by nucleophilic reagents, such as OH^- ions. Thus trimetaphosphate *(1)*, for example, yields pure triphosphate[11]:



(a)

Tetrametaphosphate can be converted in a similar manner into tetraphosphate[12]. On the other hand, pentaphosphate and hexaphosphate cannot be pre-

pared in this way, since the polyphosphates formed on cleavage of the anion rings are largely degraded to lower phosphates, even before all the metaphosphate has reacted. The kinetics of the metaphosphate ring cleavage are first order with respect to the metaphosphate, and the rate constants depend on the size of the anion ring. It can be seen from Table 1 that the stability of the metaphosphates increases rapidly as the number n of the ring

Table 1. Half-lives of metaphosphates $Na_n(PO_3)_n$ and of methylcyclosiloxanes $(CH_3)_{2n}(SiO)_n$ on ring cleavage with NaOH and HI, respectively.

n	$Na_n(PO_3)_n$ using 0.1 N NaOH [9b] τ ½ [hours]	$(CH_3)_{2n}(SiO)_n$ using 0.01 N HI in CH_3OH [13] τ ½ [hours]
3	4.5	0.44
4	150	175
5	≈ 200	310
6	≈ 1000	1000

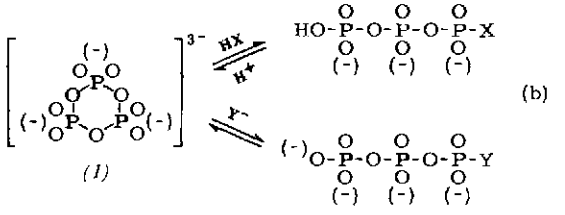
members increases. This observation is in contrast to the fact that the concentrations of these metaphosphates in the equilibrium melt of Graham's salt decrease with increasing ring size, but finds an analogy in the stability of the methylcyclosiloxanes towards cleavage with HI in methanol [13].

The ring structures of the following metaphosphate anions have been established by X-ray analysis: $Na_3P_3O_9$, $Na_3P_3O_9 \cdot H_2O$ [14], $LiK_2P_3O_9 \cdot H_2O$ [15], $(NH_4)_4P_4O_{12}$ [16], $Na_4P_4O_{12} \cdot 4H_2O$ [17], $Al_4(P_4O_{12})_3$ [18], $Na_2H_2P_4O_{12}$ [19], and $Na_6P_6O_{18} \cdot 6H_2O$ [20]. The compound $Al_4(P_4O_{12})_3$ is isomorphous with $Ti_4(P_4O_{12})_3$ [21]. The P–O bond lengths in the P–O–P linkages of the cyclic anions vary between 1.589 and 1.631 Å, when the phosphorus atoms of the rings lie in the same plane. No connection has, however, been found between the bond length and the ease of cleavage. In the case of extra-annular oxygen atoms, the P–O distance is between 1.457 and 1.493 Å. The P–O–P angles vary between 124.0 and 137.6°, while the O–P–O bond angles are between 97.5 and 123.5° (see Table 2).

Table 2. Mean bond lengths and bond angles in condensed phosphates [22].

P–O (in P–O–P)	1.62 Å
P–O (not in P–O–P)	1.49 Å
∢ POP	129°
∢ OPO	109°

Whereas ring cleavage of the metaphosphate anions with NaOH proceeds relatively slowly and practically quantitatively, the reactions with NH_3, alkylamines, H_2O_2, and F^- ions, which have been studied in detail for trimetaphosphate (although tetrametaphosphate behaves analogously), proceed to equilibrium [$N(CH_3)_3$ does not react]:



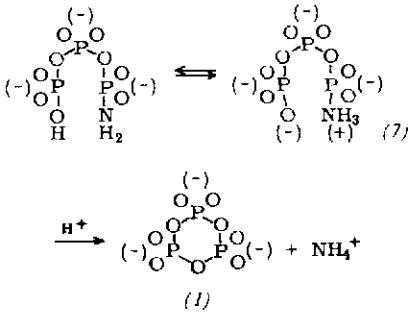
(b)

(1)

X = NH_2, $NHCH_3$, NHC_2H_5, $N(CH_3)_2$

$Y^- = O_2H^-$, F^-

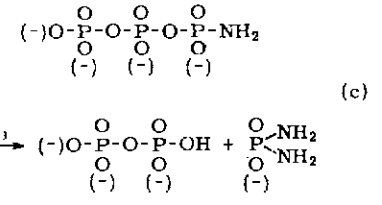
The products are amidotriphosphate, *N*-alkylamidotriphosphate [23], peroxotriphosphate [24], and fluorotriphosphate [25] anions, of which, with the exception of the peroxo derivative, various stable salts (Na, K, NH_4, Ag, and Ba) have been isolated [23, 25]. Acidification of solutions of the amido derivatives results in the quantitative re-formation of the trimetaphosphate, the reaction proceeding *via* betaine-like intermediates *(7)*. The fluoro derivatives can also be recyclized, but in alkaline



(7)

(1)

solutions. In excess ammonia or amine, the amido derivatives are degraded to the diphosphate with elimination of the corresponding diamidomonophosphates [Equation (c)], whereas in the presence of an excess of fluoride



(c)

ions, fluorotriphosphate is converted by a similar reaction [Equation (d)] into the diphosphate and difluoromonophosphate, minor quantities of fluorodiphosphate and fluoromonophosphate also being formed. Similarly,

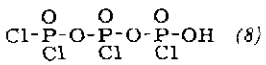
the peroxo derivatives lose peroxomonophosphate to form diphosphate or triphosphate [24]. Acetyl triphosphate (which is obtained when triphosphate is treated with acetic acid/acetic anhydride) is cyclized to trimetaphosphate [26], and tetrachlorotriphosphoric acid *(8)* to trimetaphosphoric acid trichloride $(ClPO_2)_3$ [27a]. This tendency to cyclize, which is not observed with



(8)

pure triphosphate and which is found only if at least one terminal group is substituted, is explained by the shape of the anions in the two crystalline modifications of sodium triphosphate, $Na_5P_3O_{10}$, and in that of the amidotriphosphate $K_4P_3O_9NH_2$ (see Figures 3 and 4). The anions are linear in both forms of the triphosphate [27b], and angular in the amidotriphosphate [27c].

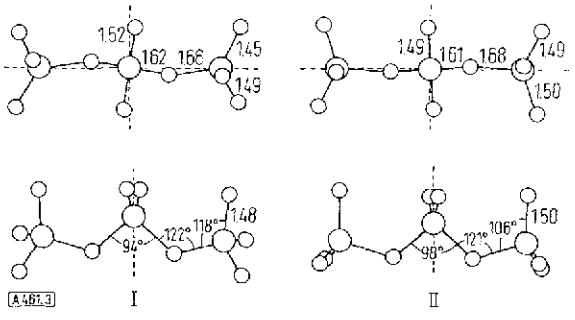


Fig. 3. Bond lengths and bond angles in the $[P_3O_{10}]^{5-}$ anions in the crystalline modifications I and II of sodium triphosphate $Na_5[P_3O_{10}]$ [27b].

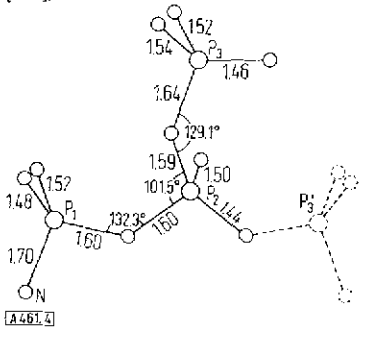

Fig. 4. The shape of the amidotriphosphate anion $[P_3O_9NH_2]^{4-}$ in potassium amidotriphosphate $K_4[P_3O_9NH_2]$ (see [27c]). The position of the third PO_4 tetrahedron P_3' in the triphosphate anion is shown for comparison by broken lines (cf. Fig. 3).

The cleavage of P–O–P bonds is catalysed by any cation (cf. Section B 4). This also applies to the ring cleavage of metaphosphates [28], which is generally accompanied by the degradation of the resulting polyphosphates. With uranyl ions, however the trimetaphosphate is quantitatively converted into the sparingly soluble uranyl triphosphate [29].

Most alkali metal metaphosphates crystallize with water of crystallization. On thermal dehydration, side reactions generally begin when only part of the water of crystallization has been eliminated. The elimination of the remaining water is usually accompanied by ring cleavage to form acid polyphosphates. In the case of the sodium derivatives, heating of the acidic intermediates above 350 °C invariaby leads to anhydrous sodium trimetaphosphate. On the oher hand, when the potassium and lithium metaphosphates containing water of crystallization are heated, the reaction proceeds *via* hydrolysis products to yield high-molecular weight polyphosphates [30a–30c]. Some anhydrous alkali metal metaphosphates react similarly. $Na_4(P_4O_{12})$ and $K_4(P_4O_{12})$, for example, are converted *via* free-radical intermediates into $Na_3(P_3O_9)$ and high-molecular weight potassium polyphosphate $(KPO_3)_x$ [31].

The acids corresponding to the metaphosphates can be easily prepared in solution by the use of ion exchangers. They behave as strong monobasic acids when titrated with alkalis [32]. Even in the case of hexametaphosphoric acid containing six OH groups per molecule, only one dissociation constant has been found [9a,9b]. Unlike the corresponding polyphosphates, the metaphosphates show only a very low tendency to bind ions. The electrical conductivity of metaphosphate solutions and the solubility data indicate the formation of charge-carrying "ion pairs" such as $[M^{II}(P_3O_9)]^{\ominus}$ in small amounts [33].

B. Polyphosphates

There are two types of polyphosphates: low-molecular weight oligophosphates with chain-lengths of up to n = 12, which can be separated by chromatography, and high-molecular weight polyphosphates with chain lengths up to and above $n = 10^3$. Glassy and crystalline forms are known in both groups. The glasses always contain mixtures of salts with anions of different chain lengths. The crystalline oligophosphates contain only one anionic species. It is doubtful whether this is also true of the high-molecular weight crystalline polyphosphates.

1. Oligophosphates

When mixtures of NaH_2PO_4 and Na_2HPO_4 are heated until they lose their water of constitution, rapid cooling of the resulting melts yields glasses; the average chain-length $\bar{n}$ of the anions in these glasses can be calculated from the Na:P ratio in the initial mixture with the aid of the formula $Na_{n+2}P_nO_{3n+1}$. As long as the Na:P

ratio is between 1 and 2, the glasses contain no monophosphate, hut only anions with $n > 1$, the distribution

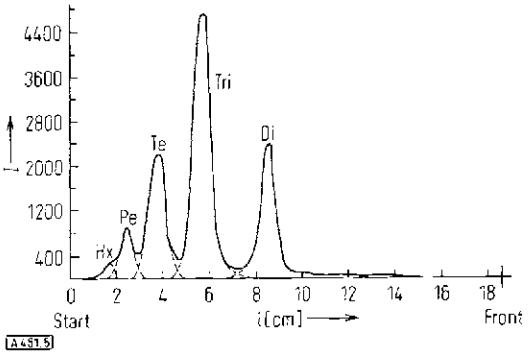

Fig. 5. Distribution of oligophosphate anions in a triphosphate (Na: P = 5:3) glass labelled with ^{32}P. The area under each peak in the curve gives the concentration of the corresponding oligophosphate in % phosphorus of the total phosphorus content. (Di = diphosphate, Tri = triphosphate, Te = tetraphosphate, Pe = pentaphosphate, Hx = hexaphosphate). Abscissa: Distance from start *l*. Ordinate: I = counts/min.

of which depends on the Na:P ratio, and can be determined by paper chromatography (Fig 5.) [4b, 34a–35]. Assuming that PO_3^- and $P_2O_7^{4-}$ or combinations of these are the only low-molecular weight anions present in the melts, the equilibrium distribution of the $(P_nO_{3n+1})^{(n+2)-}$ anions of various chain-lengths in the glasses can be calculated to a good approximation by a statistical method [36]. The result of the calculation for a glass in which $\bar{n} = 6$ is shown in two approximations (curves I and II) in Figure 6, together with experimental values

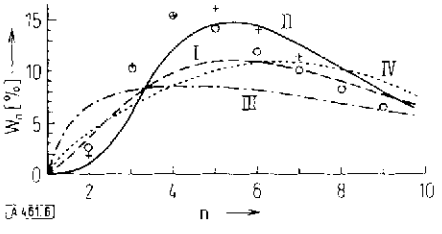

Fig. 6. The percentage W_n of phosphorus present in chains of length n in a "sodium hexaphosphate" glass ($\bar{n} = 6$). Experimental values after *Westman* [34a] (o) and after *Grunze* [34b] (+). Theoretical values by *Jost* [36] (curve I: first approximation; curve II: second approximation), and by *Van Wazer* [1b] (curve III: flexible chains; curve IV: rigid chains).

found by *Westman* and by *Grunze* [34]. Curves III and IV were obtained by calculation, assuming that more highly charged units such as PO_4^{2-} and PO_3^{2-} are present in the anion chains as well as PO_3^- [37]. These calculations refer to sodium phosphate glasses. Somewhat different distribution curves were obtained for glasses with other cations and mixtures of cations [38], indicating that the chain-length distribution in the oligophosphate glasses depends on the nature of the cation.

Oligophosphates of uniform chain length are only occasionally obtained directly from the melts. In the case of the sodium salts, this is possible only for the monophosphate and diphosphate (= pyrophosphate), and for the triphosphate by the tempering of melts with an Na:P ratio of 5:3 [Equation (e)]. This reaction involves various intermediates, depending on the water content [2b].

$$2\,Na_2HPO_4 + NaH_2PO_4 \rightarrow Na_5P_3O_{10} + 2\,H_2O \qquad (e)$$

The resulting triphosphate decomposes on remelting to give a mixture of high- and low-molecular weight polyphosphates containing a high proportion of diphosphate (= pyrophosphate). As the temperature of the melt is raised, the equilibrium distribution is established slowly at first, and then rapidly at temperatures above 900 °C. This equilibrium distribution is retained in the glass on quenching. When the glass is annealed, pure triphosphate is slowly re-formed at a rate that depends on the temperature, and also to a large extent on the rate of dissolution of the initially formed $Na_4P_2O_7$ crystallites, *i.e.* on the rate with which the Na:P ratio in the glass rises again to 5:3 [34b, 39].

Pure tetraphosphates are obtained directly by heating mixtures of Pb or Bi monophosphates with the correct M:P ratio to over 550 °C (elimination of water [40]). The ring opening of sodium tetrametaphosphate by NaOH leads to sodium tetraphosphate [12]:

$$Na_4[P_4O_{12}] + 2\,NaOH \rightarrow Na_6[P_4O_{13}] + H_2O \qquad (f)$$

The compound obtained is amorphous, and can be used to prepare the crystalline tetraacridinium dihydrogen salt and the neutral hexaguanidinium salt [41]. The treatment of $Pb_3P_4O_{13}$ with solutions of $(NH_4)_2S$ leads to the formation of crystalline $(NH_4)_6P_4O_{13}\cdot 6H_2O$ [42]. When glasses with the composition $4CaO:3P_2O_5$ are annealed they are converted into trömelite [43], which has recently been identified as calcium hexaphosphate $Ca_4P_6O_{19}$ [44]. Pure crystalline hexamminecobalt hexaphosphate has been prepared from calcium hexaphosphate which was solubilized by means of sodium ethylenediaminetetraacetate [44]. Besides sodium hexaphosphate, pure sodium pentaphosphate, heptaphosphate, and octaphosphate have also been prepared in milligram quantities from aqueous solutions of octaphosphate glass using anion exchange columns (Dowex 1 X 10) [45–46b].

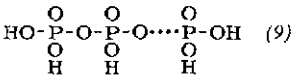
These substances are identified and their purity determined by means of paper chromatography. Their chain-lengths (or the average chain lengths in the case of glasses) are determined by alkalimetric techniques based on the fact that the terminal OH groups in the polyphosphoric acids *(9)* are weakly dissociated, whereas the non-terminal groups are strongly dissociated.



(9)

The dissociation constants of polyphosphoric acids, as reported by *Watters* [46c,46d] and by *Irani* and *Callis* [46e], are listed in Table 3.

Table 3. The dissociation constants pK_a of polyphosphoric acids $H_{n+2}P_nO_{3n+1}$ in solutions of ionic strength = 1 [$N(CH_3)_4Hal$], starting with the n-th proton (the values in brackets are uncertain).

Proton	pK_a n	n-1	n-2	n-3	n-4	Ref.
H_3PO_4	11.1	6.61	2.36			[46g]
$H_4P_2O_7$	8.74	5.98	1.75	(1.7)		[46g]
$H_5P_3O_{10}$	8.56	5.69	2.04	1.15	(0.5)	[46g]
	8.81	5.83	2.11	1.06		[8a]
$H_6P_4O_{13}$	8.34	6.63	2.23	1.36		[46f]
	8.13	5.98	2.19	(2.1)		[46g]
$H_{n+2}P_nO_{3n+1}$ ($\bar{n}$ = 40)	8.17	7.22	?	?		[46g]

The alkali metal salts of the oligophosphoric acids dissolve readily in water, whereas the corresponding salts of silver and of polyvalent cations are only sparingly soluble. From the triphosphate onwards, the oligophosphates exhibit a strong tendency to bind cations (see Section B.3).

As in the metaphosphates containing water of crystallization, only part of the water is generally eliminated without side reactions from oligophosphates containing water of crystallization. The anions are hydrolysed to fragments of shorter chain-lengths by the last parts of the water of crystallization. Thus the dehydration of *e.g.* sodium triphosphate hexahydrate initially yields the diphosphate and dihydrogen monophosphate:

$$Na_5P_3O_{10}\cdot 6\,H_2O \rightarrow Na_4P_2O_7 + NaH_2PO_4 + 5\,H_2O \qquad (g)$$

Monophosphate that has already been formed is then phosphorylated to the diphosphate in a side reaction with as yet unchanged triphosphate. Consequently, the dehydration product of the triphosphate hexahydrate contains more diphosphate than is expected from Equation (g), the actual quantity depending on the temperature and the water vapor pressure [47a–47d]. The dehydration of acidic oligophosphates is also complex [6b, 47e–47i].

2. High-Molecular Weight Polyphosphates

The most important of the glassy polyphosphates with $n \gtrsim 20$ is Graham's salt which is formed when NaH_2PO_4 is melted and then rapidly cooled; the melt solidifies as a glass. Similar glasses are formed with other cations. (Only in the case of the potassium salt a crystalline substance, *i.e.* Kurrol's potassium salt $(KPO_3)_x$, is formed, unless small amounts are quenched very rapidly.) These glasses also contain mixtures of salts with anions of different chain-lengths, always including metaphosphates and small quantities of cross-linked phosphates [6a,4b, 48,49a].

The average chain-length in Graham's salt depends on several factors: it increases with increasing temperature and with decreasing water vapor pressure of the parent melt (Fig. 7).

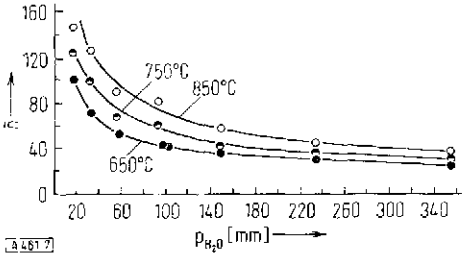


Fig. 7. The variation of the average chain length $\bar{n}$ in aqueous solutions of Graham's salt with the temperature and the water vapor pressure at which the NaH_2PO_4 melts were annealed for 20 h.

An equilibrium distribution of the various chain lengths is established in these melts in the course of about 20 hours, independently of whether the starting material is hydrated NaH_2PO_4 or anhydrous trimetaphosphate $Na_3P_3O_9$ (see Fig. 8). Whereas the former loses water, the latter takes up water vapor from the atmosphere to form the terminal free OH groups. The average chain

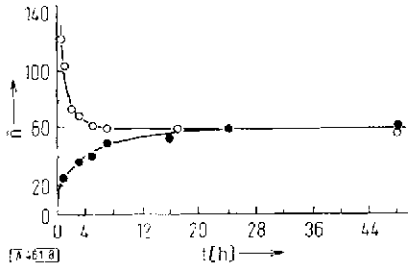

Fig. 8. The variation of the average chain length $\bar{n}$ of the polyphosphates with the duration of melting at 650 °C and p_{H_2O} = 55.3 mm Hg; Starting material: NaH_2PO_4 (●) and $Na_3[P_3O_9]$ (○).

length $\bar{n}$ of the glass at equilibrium is given by Equation (h), where p_w is the water vapor pressure in mm Hg [49a].

$$\bar{n} = \exp[8.87 - (5100/RT) - 0.5 \ln p_w] \qquad (h)$$

Graham's salt is soluble in water, and the anions have strong binding properties, particularly for polyvalent cations (see Section B.3). When glassy Graham's salt is annealed, it is converted into one of the two forms of the high-molecular weight Kurrol's sodium salt $(NaPO_3)_x$, into Maddrell's salt, or into one of the three forms [49b, 49c] of sodium trimetaphosphate $Na_3[P_3O_9]$, depending on the temperature and the water vapor pressure. The stable form of sodium trimetaphosphate is obtained as a pure product at about 400 °C when the Na:P ratio is exactly 1:1 (see Fig. 9).

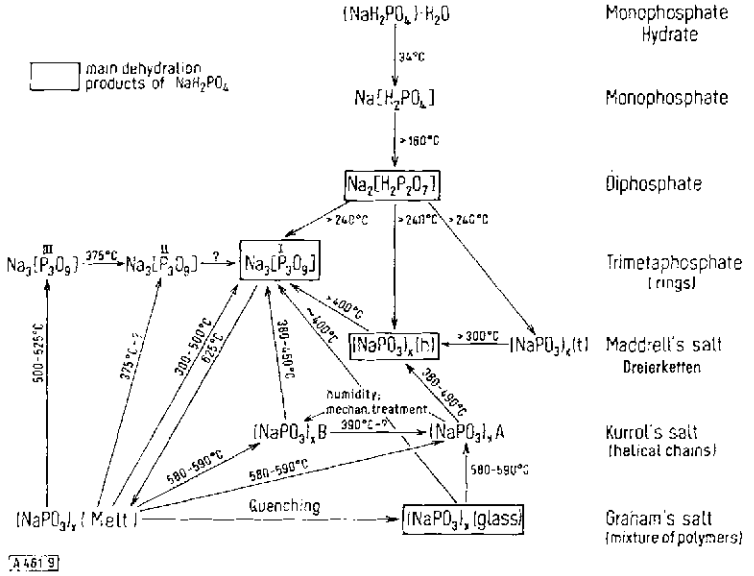

Fig. 9. Condensed phosphates obtained from NaH_2PO_4 by heating, and their mutual relationships.

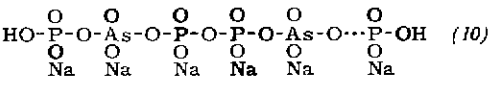
The glasses obtained from dihydrogen monophosphates of the bivalent cations of Cu, Mg, Ni, Co, Fe, and Mn are ultimately converted to tetrametaphosphates on annealing, whereas the glasses of the salts of Li, K, Rb, Cs, Be, Hg^{2+}, Ca, Sr, Ba, Pb, Cr^{3+}, Fe^{3+}, and Bi^{3+} are converted into crystalline high-molecular weight polyphosphates, which generally occur in various polymorphic modifications. The glasses of Zn, Cd, and Al polyphosphates yield tetrametaphosphates or polyphosphates, depending on the conditions [6a, 6b].

The fact that the high-molecular weight polyphosphates form open-chain anions has been established by the investigation of the corresponding arsenatophosphates, which are obtained from the melts of NaH_2PO_4/NaH_2AsO_4 mixtures. The P–O–As and the As–O–As linkages in arsenatophosphates $Na_nH_2(P,As)_nO_{3n+1}$ *(10)* can be readily hydrolysed, the salts then being converted into monoarsenate/polyphosphate mixtures. The



(10)

distribution of the As atoms in the chains can be found from the chromatographic determination of the quantities of oligophosphates formed on hydrolysis. It is approximately random, though with a slight preference for As–O–P bonds [50]. The presence of larger quantities of oligophosphates with $n \geqslant 5$ in the hydrolysate shows that the high-molecular weight arsenatophosphate anions exist in the form of open chains. However, in the cases of potassium trimetaarsenatophosphate, which contains the anions *(1)* to *(1c)* in a statistical distribution [51], and magnesium tetrametaarsenatophosphate, which contains mixed tetrameric cyclic anions [52], the hydrolysates contain (apart from trimetaphosphate and tetrametaphosphate) only oligophosphates with a maximum of two and three phosphorus atoms, respectively, *i.e.* the number of P atoms in each case is one less than the number of P and As atoms in the ring.

The fact that the anions form long chains of PO_4 tetrahedra has also confirmed by the X-ray analysis of Maddrell's salt

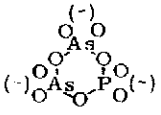
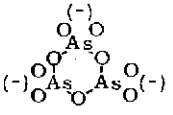
(1a)



(1b)



(1c)

Six types of chains have so far been distinguished (see Fig. 10). The Rb, Cs, and K polyphosphates and the low-temperature form of lithium polyphosphate

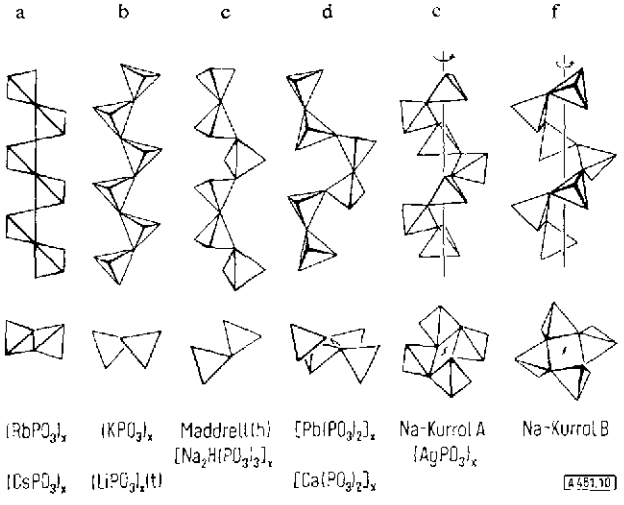


Fig. 10. The six known types of anion chains present in high-molecular weight crystalline polyphosphates. Above: vertical projections; below: projections along the chain axis.

$(LiPO_3)_x$(t), contain "Zweierketten"[62] with two PO_4 tetrahedra as the repeating unit, while the high-temperature form of Maddrell's salt $(NaPO_3)_x$(h), contains "Dreierketten" and the polyphosphates of Pb and Ca contain "Viererketten". The anion chains in Kurrol's sodium salts and in silver polyphosphate form different helices. The length of the P–O bridges in the chains is 1.57 to 1.64 Å, that of the non-bridging P=O bonds 1.44 to 1.52 Å. The P–O–P angles are between 124 and 134° and the O–P–O angles between 98 and 120°. The averages of these values are practically the same as those for the metaphosphates (cf. Table 2).

The transition from the melts to high-molecular weight crystalline polyphosphates does not take place by ordering of the chains present in the amorphous phase, as in the case of organic polymers, but by cleavage into monomeric $XO_3^{\ominus}$ anions, followed by the formation of new chains in the crystalline arrangement. This is shown by the fact that the As atoms in the arsenatophosphate glass of the Graham's salt type are approximately statistically distributed over the anion chains, whereas in crystalline sodium arsenatophosphate, which crystallizes with the structure of Maddrell's salt when the glass is annealed, the As atoms preferentially occupy the centers of the XO_4 tetrahedra forming the "noses" of the "Dreierketten" [cf. Fig. 10, third column from the left].

X-ray crystallographic investigations were carried out on a crystalline arsenatophosphate with an As:P ratio of 1:2.7. This ratio was selected since salts with higher arsenic contents are highly hygroscopic, whereas those with higher phosphorus contents are too difficult to dissolve. The results show that about 43% of the central positions in the projecting tetrahedra [see Fig. 10, third column] and only about 19% of the central positions in each of the two other tetrahedra are occupied by arsenic atoms[49b]. In a statistical distribution, on the other hand, 37% of the central positions of all the tetrahedra should be occupied by As. The non-statistical distribution in the crystals can also be seen if the chromatograms of the hydrolysates of the glasses are compared with those of the hydrolysates of the crystals (see Fig. 11).

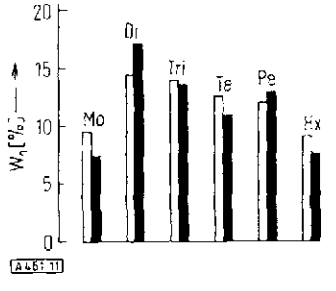

Fig. 11. The percentage distribution W_n of oligophosphates in the hydrolysates of high-molecular weight sodium arsenatophosphates. Hydrolysates of the glass (□) and of the crystalline phase of the same composition (■).

The latter contain more di- and pentaphosphates and less of the other oligophosphates than the hydrolysates of the glasses. This must be the case if the arsenatophosphate chains are preferentially cleaved at the bonds leading to the "nose tetrahedra" [cf. Fig. 10, third column], since this must favor the formation of oligophosphates with chain lengths $n = 2, 5, 8, \ldots (2 + 3x)$. This result also shows that monomeric PO_3^- anions or $NaPO_3$ groups occur as intermediates in the polyphosphate melts. The existence of these species at higher temperatures was postulated previously to explain the chain-length distribution in oligophosphate glasses.

3. The Ability of the Polyphosphates to Bind Cations

The technical importance [*] of the oligophosphates and high-molecular weight polyphosphates is mainly due to the ability of these substances to combine with polyvalent cations and to keep them in solution, so that they can no longer be detected by means of the common precipitants. In view of the large number of papers already published on this topic [63], only the essential features are discussed here.

Schindewolf and *Bonhoeffer* [64] have found that the maximum degree of dissociation of the polyphosphates in aqueous solutions is only 30%. This also applies to the free polyphosphoric acids, although all the OH groups present, with the exception of the two terminal groups [cf. Formula *(9)*], behave as strong acids on titration. If salts of any cation are added to solutions of the acids corresponding to Graham's salts, the H^+ concentration in the solutions will increase. An ion exchange takes place between the previously non-dissociated H^+ ions and the added cations, which is described by the Rothmund equation [65,66]:

$$K\cdot([H^+]^n/[M^{n+}])_P^\sigma = ([H^+]^n/[M^{n+}])_L \qquad (i)$$

In this equation, n is the number of charges on the cation, P and L respectively denote ions bound to the polyphosphate and those moving freely in the solution. The concentration of the latter can be calculated from the pH of the solution and from the known concentrations of the polyphosphate and of the cations. σ is an empirical exponent denoting the deviation of the solutions from ideal behavior; K is the constant for the exchange of the individual cations for the proton of the polyphosphoric acid.

The exchange constant K and the values of σ for ions of alkali metals (M^+) and alkaline earth metals (M^{2+} = Ba^{2+}, Sr^{2+}, Ca^{2+}, and Mg^{2+}), as well as for NH_4^+, are listed in Table 4. These data show that the bivalent ions

Table 4. Exchange constant K and values of σ for the exchange between protons and cations in an 0.1 base-molar [*] aqueous solution of the acid $H_{n+2}P_nO_{3n+1}$ corresponding to Graham's salt.

	M^{2+}	Li^+	Na^+	NH_4^+	K^+
K	2.5	5.13	5.75	7.6	13.8
σ	0.5	0.79	1.43	(0.77)	2.3

[*] The concentration is based on the $(PO_3)^-$ units.

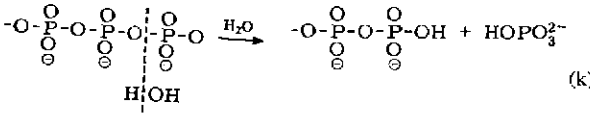
are much more tenaciously bound than the alkali metal ions, and that the bond strength of the latter decreases in the order $Li^+ > Na^+ > NH_4^+ > K^+$. This suggests at first that the low degree of dissociation of the polyphosphates, which is obvious even in the triphosphate $Na_5[P_3O_{10}]$, is due to the fact that the anionic charge increases with the number of dissociated cations to such an extent as to prevent the dissociation of the remaining cations on purely electrostatic grounds. However, this cannot be the only reason, since the soluble hexametaphosphates are almost fully dissociated, and show no tendency to bind counter-ions (see Section A). It is more probable that the ion-exchange tendency of polyphosphates is also caused by the ability of the PO_4 tetrahedra to rotate freely about the P–O–P bonds, the resulting mobility of the polyphosphate chains making possible the formation of relatively stable chelates [67a], in which the cations are linked to more than one PO_3^- group. This is supported by the observation that several phosphorus atoms bound in polyphosphates are always required for firm combination with Ca^{2+} ions [1a, 2a, 2b, 63, 67a].

High-molecular weight crystalline polyphosphates also act as ion-exchangers [67b]. This is shown, *inter alia*, by the fact that the crystalline alkali metal polyphosphates, which are practically insoluble in water, can be solubilized by solutions of salts containing other cations, and by the fact that 1:1 mixtures of Maddrell's salt $(NaPO_3)_x$ and Kurrol's potassium salt $(KPO_3)_x$, both of which are insoluble by themselves, dissolve when shaken with water [2b].

4. The Degradation of Polyphosphates

Polyphosphates are stable in aqueous solutions at pH *ca.* 7 and 25 °C. However, they are degraded at higher temperatures, higher hydrogen ion concentrations, and in the presence of cations. The reaction proceeds in two ways [68a–68d]:

The first type of degradation [Equation (k)] is of zero order with respect to the total polyphosphate. Mono-



(k)

phosphate units are removed, one at a time, from the chain ends, and a new OH group, which can be directly titrated, is formed at the chain end. The reaction appears to be of zero order kinetics, since no change in the number of terminal groups can be detected chromat-

[*] For example, in the softening of boiler water and cooling water, for washing liquids and dye baths, and in the food industry.

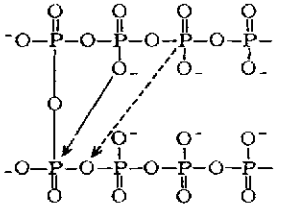
ographically, at least until the long chains have been degraded to oligomers. The latter are also degraded by the stepwise removal of monophosphate units from the chain ends, but this reaction is of first order [46a,46b,68a].

A second route of degradation becomes increasingly important as the chain length increases beyond the pentaphosphate stage. It leads to metaphosphates, and in particular to trimetaphosphate [46a,46b,68b–68d], which can also be obtained from tetraphosphate at pH 1, *i.e.* when the substrate is present in the form of hydrogen tetraphosphate [68c]. The cyclic metaphosphate anions are formed from the internal units of the chains, the reaction being of the first order and proportional to the concentration of the P–O–P bonds still present. The metaphosphates are not formed as a result of hydrolysis; when the degradation is carried out in water labelled with ^{18}O, the latter is not detected in the metaphosphates. Anhydrous polyphosphates containing long-chain alkylammonium ions are converted in anhydrous benzene in 90% yield into trimetaphosphate in three days at 60 °C. The formation of the trimetaphosphate must therefore proceed as a rearrangement [Scheme (I)], *i.e.*



(I)

the folded polyphosphate chains give rise to the metaphosphate and to an anion chain, which is shorter by three (or four) PO_3 units. The effect of the pH shows that both reactions, contrary to an earlier interpretation [68a–68d], proceed independently of each other and are not coupled (see Fig. 12).

The increase in the rate of zero-order formation of monophosphates at the chain ends is particularly large at pH 10 to 7. Here the weakly acidic terminal groups of the chains are converted into undissociated POH groups. The increase in the rate of first-order formation of metaphosphates is particularly large at pH 3 to 5, at which the non-terminal, strongly acidic "side groups" of the polyphosphates are also converted into undissociated POH groups.

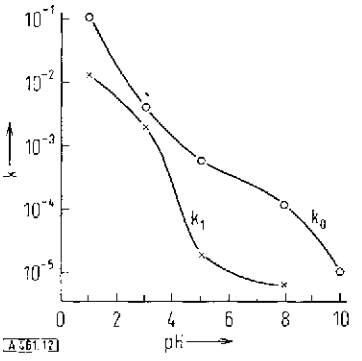


Fig. 12. The variation of the constants k_0 (zero order) and k_1 (first order) with the pH in the degradation of high-molecular weight polyphosphates.

Both reactions are also accelerated by the cations of added salt solutions, but at higher salt concentrations the formation of metaphosphates is accelerated more than the degradation from the chain ends. This is a further indication that the two reactions are not coupled. In general, the higher the ionic charge and the smaller the ionic radius, the more effective are the cations.

It can be seen from the analogous catalytic effect of cations on the hydrolysis of disulfate ions [69] (see Fig. 13) that even ions which are equal in radius and charge, *e.g.* Mg^{2+} and Ni^{2+}, differ in catalytic activity, and that the latter increases with the tendency of the ions to complex formation (*i.e.* the stability constant), *e.g.* with EDTA. The effect of the

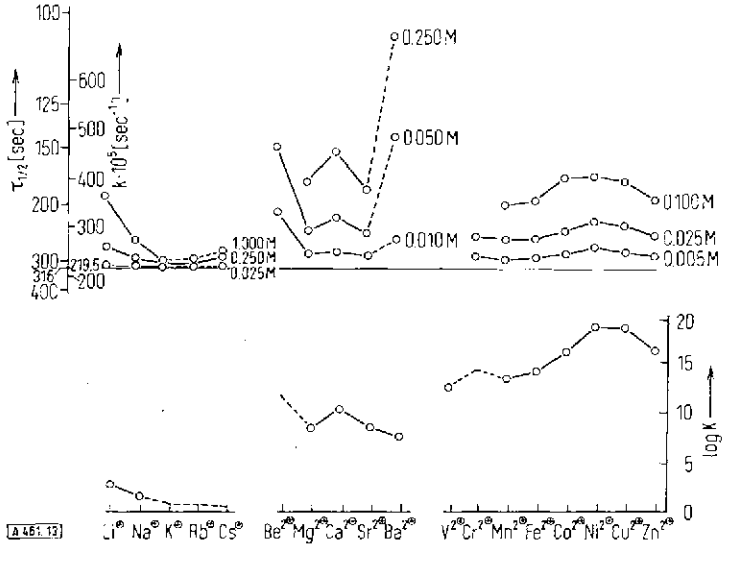

Fig. 13. Above: half-lives $\tau_{1/2}$ and rate constants k for the hydrolysis of 0.01 M solutions of $K_2[S_2O_7]$, catalysed by cations at various concentrations. (The line parallel to the abscissa denotes solutions free from foreign salts.)

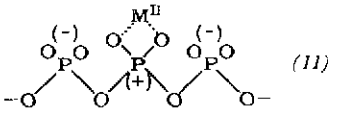
Below: the stability constants K of the EDTA complexes of cations. (The dotted lines denote the means of the stability constants of other similar complexes.)

[69] *E. Thilo* and *F. von Lampe*, Chem. Ber. *97*, 1775 (1964).

cations on the degradation of polyphosphates is also due to chelate formation [see Formula *(11)*], as a result of which the P atoms of the PO_4 tetrahedra in question become positive, and hence more ready to combine with PO groups situated elsewhere in the same anion chain, or with OH^- ions or water molecules.

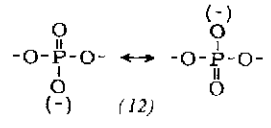


(11)

The fact that cations accelerate the formation of metaphosphates more than the degradation from the chain ends is probably due to the greater ease of chelation within the chains. This is supported by the observation that the cations promote coiling of the chains. For this reason the rate of degradation of polyphosphates also depends on the chain length. Other conditions being equal, the rate of degradation of sodium polyphosphates increases with the chain length, reaching a maximum at about the decaphosphate. The effect of the chain length can no longer be observed when $\bar{n} > 100$ [70]. This is a further indication that the cations must interact with more than one PO_3 group of the anion chain at time.

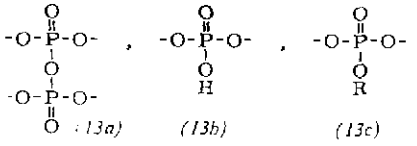
C. Cross-Linked Phosphates

Cross-linked phosphates are obtained by heating a mixture of phosphates, in which the cation:phosphorus ratio is smaller than 1 (*e.g.* by the thermal dehydration of a mixture of dihydrogen monophosphates and free phosphoric acid). The processes involved are complex and depend on the nature of the cation, as well as on the temperature and the water vapor pressure [71]. Even free phosphoric acid is converted into polymers *(5)* with tertiary PO_4 groups, after first forming linear polymers [72] which, unlike the oligophosphates, contain free water and monophosphoric acid [73]. The polymers *(5)* contain a varying number of PO_4 tetrahedra which are



(12)

resonance stabilization



(13a) *(13b)* *(13c)*

no resonance stabilization

linked to other PO_4 tetrahedra through three oxygen atoms. These groups *(13a)*, which also occur to a small extent in Graham's salt and its analogues [74], are easily hydrolysed, since they are not stabilized by resonance, unlike the polyphosphates *(12)* formed from them by hydrolysis. Furthermore, nucleophilic attack on the tertiary PO_4 tetrahedra is favored in comparison with that on the negatively charged PO_4 tetrahedra. The same is true of the free polyphosphoric acids *(13b)* and their esters *(13c)*, in which the P–O–P bonds are again easily cleaved by hydrolysis, more easily in fact than the P–O–R linkages, as is particularly noticeable in the products of the reaction of phosphorus pentoxide (P_4O_{10}) with ether [30c, 75].

D. The Analysis of Condensed Phosphates

The quantitative separation and the accurate quantitative determination of the components of mixtures of condensed polyphosphates is rendered impossible by the ability of the latter to bind cations [76]. The only practicable method is paper chromatography, which was extended to phosphate chemistry by *Ebel* [77] and by *Westman* [78], and which has since been modified [35] for special purposes and quantitative determinations, aided also by the use of ^{32}P [26, 8a, 46f, 46g]. The migrating components have been found to be free acids or acidic anions [79]. Thin-layer chromatography [80] and (for high-molecular phosphates) paper electrophoresis [81] can also be used. Polyvalent cations, however, must first be replaced by alkali metal ions with the aid of ion exchangers if unambiguous results are to be obtained [82]. Quantitative separations, even for preparative purposes, have also been achieved on anion-exchange columns (*e.g.* Dowex IX 10) by eluting with solutions of alkali metal salts [45, 46a, 46b, 83].

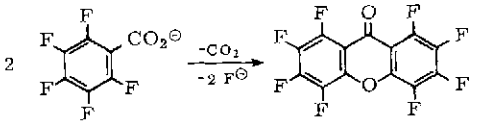
Pyrolysis of Sodium and Silicon Pentafluorobenzoates [1]

By Dr. P. Sartori and Dipl.-Chem. M. Weidenbruch

Institut für Anorganische Chemie und Elektrochemie der Technischen Hochschule Aachen (Germany)

Pyrolysis of sodium pentafluorobenzoate at 275 °C leads to removal of CO_2 and formation of a pale brown powder, from which white needles of composition $C_{13}F_8O_2$ *(1)* with m.p. 250 °C can be isolated in a yield of 35 % by sublimation at 110 °C/10^{-3} mm and recrystallization of the sublimate from benzene. The substance has infrared absorption bands at 1670 ($\nu_{C=O}$), 1645, 1620, 1510, and 1480 cm^{-1} (fluorinated aromatic ring).

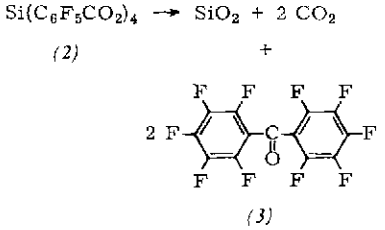


(1)

Its chemical behavior and mass spectrum [2] (molecular ion at m/e = 339.97380 and fragments at m/e = 320.97982, 311.98376, and 292.98926) indicate the structure of an octafluoroxanthone. Compound *(1)* behaves chemically to a large extent analogously to xanthone. In conc. sulfuric acid it affords a yellow solution with a green fluorescence, showing ultraviolet and visible absorption bands at 2630, 3420, and 4200 Å. The positions and structures of these bands correspond to those for xanthone. Dilution with water regenerates compound *(1)* unchanged from its solution in conc. H_2SO_4 or 70 % $HClO_4$. The basicity of the carbonyl group characteristic of 4-pyrones is shown by the ready formation, in anhydrous benzene, of an intensely yellow adduct with $AlBr_3$ that crystallizes from the solution as $C_{13}F_8O_2 \cdot AlBr_3 \cdot C_6H_6$.

Silicon tetrakis(pentafluorobenzoate) *(2)*, m.p. 200 °C, $\nu_{C=O}$ = 1755 cm^{-1}, can be obtained in almost quantitative yield by reaction of silicon tetrachloride with pentafluorobenzoate in boiling anhydrous benzene for 24 hours. It is purified by recrystallization from anhydrous benzene.

When heated at 290 °C it decomposes slowly to yield decafluorobenzophenone *(3)*, $C_{13}F_{10}O$, m.p. 94 °C, $\nu_{C=O}$ = 1720



(2) *(3)*

cm^{-1} with further bands at 1650, 1535, and 1510 cm^{-1} (fluorinated aromatic ring). The yield of pure *(3)* amounts to 80 %. Hitherto this compound was accessible only in poor yield, by chromic acid oxidation of bis(pentafluorophenyl)-methanol [3].

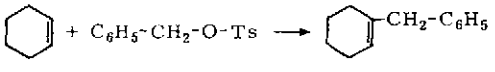
Benzylation of Olefins

By Prof. Dr. D. Klamann, Dr. P. Weyerstahl, and Dr. M. Fligge

Esso-Forschungslaboratorien, Hamburg-Harburg (Germany)

Benzyl *p*-toluenesulfonate can decompose spontaneously and exothermally into *p*-toluenesulfonic acid and resins having the composition $(C_7H_6)_n$ [1]. We were interested in the mode of reaction of compounds of the type $R-CH_2X$ (R = aryl or a heterocyclic group; X = RSO_3– or halogen) in presence of an excess of olefin.

Benzyl *p*-toluenesulfonate (0.2 mole) was refluxed for 8 h with 300 ml of cyclohexane and a catalytic amount of acid, or the mixture was heated without acid in a bomb tube at 120 °C for 3 h; reaction occurred with discoloration and separation of *p*-toluenesulfonic acid. The liquid was decanted from the acid and shaken with sodium hydrogen carbonate solution, the excess of cyclohexane was distilled off in a vacuum, and the residue chromatographed on aluminum oxide (neutral, activity II) in pentane. The eluate was distilled. The main fraction, distilling between 48 and 60 °C at 0.2 mm, consisted of 1-cyclohexylcyclohexene (formed by acid-catalysed dimerization of cyclohexene) together with a 67 % yield of an approximately 8:1 mixture of 1-benzylcyclohexene *(1)* and 3-benzylcyclohexene. Three further products formed in much smaller amounts were not identified.



(1)

A similar mixture was obtained on fission of *endo-exo*-7-phenylnorcarane by *p*-toluenesulfonic acid in cyclohexene at 120 °C.

This benzylation of olefins, which has not previously been observed, can also be carried out with isobutene, 2-methyl-1-pentene, and 2-ethyl-1-hexene. It has not so far been possible to separate the mixtures of isomeric benzylated products.

Partial Synthesis of Some Cocarcinogens from Croton Oil

By Prof. Dr. E. Hecker, Dr. H. Kuhinyi, Dipl.-Chem. H. U. Schairer, Dipl.-Chem. Ch. v. Szczepanski, and Dr. H. Bresch

Biochemisches Institut des Deutschen Krebsforschungszentrums, Heidelberg (Germany)

Dedicated to Professor Richard Kuhn on the occasion of his 65th birthday

The eight compounds A1 and B1 to B7 that have been obtained pure from croton oil are toxic, inflammatory, and highly active cocarcinogens; they are fatty acid diesters of the polyfunctional diterpene phorbol for which the structure *(1)* is proposed [1]. Of the three esterifiable hydroxy groups of phorbol, the primary one on C-20 is free in the isolated compounds; the secondary one on C-5 and the tertiary one

on C-8 carry, respectively, a short- and a long-chain fatty acid residue [1]. Thus two series of isomers are possible.

[a] From silica gel HF_{254} (Merck, Darmstadt). Solvent CH_2Cl_2/acetone (3:1), saturated atmosphere.

[b] Light red modification.

[c] Inflammation unit (see ref. [2]).

For the synthesis of 8-*O*-acetyl-5-*O*-acylphorbols, phorbol was converted by partial acetylation with acetic anhydride into phorbol 8,20-diacetate *(2)*, m.p. 181–182 °C, $[\alpha]_D^{26}$ = +78° (0.5 % in dioxane), γmax = 203, 233, 335 mμ, ε_{max} = 12000, 5200, 70 (in ethanol). With long-chain acyl chlorides this diacetate gave the 5,8,20-triesters. Liberation of the primary hydroxyl group by acid-catalysed partial transesterification led to 8-*O*-acetylphorbol 5-decanoate *(3)*, 5-laurate *(4)*, and 5-myristate *(5)*. These compounds, which were homogeneous on thin-layer chromatography, are colorless, non-crystallizing resins whose Rf values and ultraviolet, infrared, and NMR spectra could not be differentiated; they were characterized as their crystalline 4-(4-nitrophenylazo)benzoates (NPAB).

For preparation of 5-*O*-acetyl-8-*O*-acylphorbols, phorbol triacetate was converted by base-catalysed partial transesterification into resinous 5-*O*-acetylphorbol *(6)*, $[\alpha]_D^{25}$ = +128° (*ca.* 2.5 % in dioxane), γ_{max} = 231 and 333 mλ, ε_{max} = 5000 and 70 (CH_3OH). With long-chain acyl chlorides *(6)* gives triesters from which the primary hydroxy group can be liberated by acid-catalysed partial transesterification. 5-*O*-Acetylphorbol 8-decanoate *(7)*, 8-laurate *(8)*, and 8-myristate *(9)* were homogeneous on thin-layer chromatography, forming colorless, non-crystallizing resins whose Rf and $[\alpha]_D$ values as well as ultraviolet, infrared, and NMR spectra could not be differentiated; the same applies to the melting points of their NPAB esters, which gave no mixed m.p. depression.

Three of the synthetic phorbol esters are identical with active components of croton oil: B4 [3] is identical with 5-*O*-acetylphorbol 8-decanoate *(7)*, B7 [3] with 5-*O*-acetylphorbol 8-laurate *(8)*, and A1 [4] with 8-*O*-acetylphorbol 5-myristate *(5)*. Representatives of both series are thus present in croton oil and biologically active.

The partial synthesis of *(5)* has been described earlier [5] and meanwhile confirmed [6].

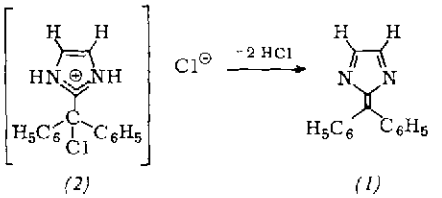
Synthesis of a 1,4-Diazafulvene

By Dr. W. Rohr and Prof. Dr. H. A. Staab

Institut für Organische Chemie
der Universität Heidelberg (Germany)

The dependence of the "aromatic" character of fulvenes on the electron-donating properties of substituents at C-6 of the fulvene system has been intensively studied [1]. However, little is yet known about how a change in the charge distribution in the five-membered ring affects the bonding system of fulvenes. Azafulvenes are of particlar interest in this respect.

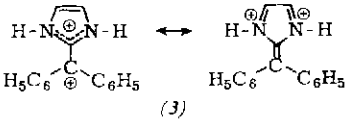
We have prepared 6,6-diphenyl-1,4-diazafulvene *(1)* [2], the first representative in the diazafulvene series, by elimination of HCl from 2-(chlorodiphenylmethyl)imidazolium chloride *(2)* with triethylamine in tetrahydrofuran (65–70 % yield); the product *(1)* is isolated by filtering off the triethylammonium chloride and evaporating the solvent and is recrystallized from tetrahydrofuran. Compound *(2)* was obtained by the action of thionyl chloride on 2-(hydroxydiphenylmethyl)imidazole (m.p. 189–190 °C, prepared from 2-benzoylimidazole and phenylmagnesium bromide in 75–80 % yield).



(2) *(1)*

The product *(1)* forms yellow crystals, m.p. 150–152 °C (decomp.). Its molecular weight was determined mass-spectrometrically as 232. Its NMR spectrum in $CDCl_3$ (tetramethylsilane as internal standard) shows the two five-membered-ring protons as a sharp singlet of intensity 2 at τ = 1.72 and the protons of the two phenyl residues as a multiplet of intensity 10 at τ = 2.52.

The most intense ultraviolet band for *(1)* (λ_{max} = 361 mμ, ε = 18700, in cyclohexane) is at distinctly longer wavelengths than is the corresponding absorption of 6,6-diphenylfulvene [3]. This band is shifted hypsochromically in acetonitrile with a slight decrease in intensity (λ_{max} = 356 mμ, ε = 17400). A second absorption maximum is observed at 241 mμ (ε = 9000, in cyclohexane). In conc. H_2SO_4 compound *(1)* gives the same spectrum as 2-(hydroxydiphenylmethyl)imidazole in the same solvent (λ_{max} = 438 mμ, ε = 36300). We assume that the mesomeric dication *(3)* is present in these solutions.



(3)

With sodium borohydride in tetrahydrofuran/ethanol (5:1), the product *(1)* gives a 75% yield of a compound, m.p. 233 °C, that is identical with the recently prepared 2-(diphenylmethyl)imidazole[4]. When product *(1)* is boiled for 2 h in tetrahydrofuran/water (2:1) it affords 2-(hydroxydiphenylmethyl)imidazole in 72% yield. Addition of the calculated amount of ethereal hydrogen chloride to a solution of product *(1)* in tetrahydrofuran regenerates the starting material *(2)* almost quantitatively.

Synthesis of 1,2,3-Triazolo[1,5-a]quinoxalinium and 1,2,3-Triazolo[5,1-c]-benzo-1,2,4-triazinium Salts [1]

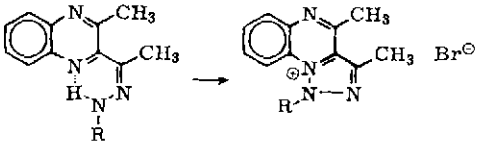
By Dr. A. Messmer and Dipl.-Chem. O. Szimán

Central Research Institute for Chemistry of the Hungarian Academy of Sciences, Budapest (Hungary)

By a generalization of the method of preparation of pyridine-condensed triazolium[2] and tetrazolium[3] salts, 2-acetyl-3-methylquinoxaline phenylhydrazone *(1a)*[4] is converted by four moles of *N*-bromosuccinimide in glacial acetic acid at room temperature into 3,4-dimethyl-1-phenyl-1,2,3-triazolo[1,5-*a*]quinoxalinium bromide *(2a)*. A 1:1 complex, m.p. = 128 °C, of *(2a)* and *N*-bromosuccinimide is first precipitated from the solution. The compound *(2a)* is isolated from this complex by precipitation from nitromethane with diethyl ether.

The analogue *(2b)* is obtained similarly from the *p*-methoxyphenylhydrazone (m.p. = 186 °C).

Compounds *(2)* are water-soluble and give 90–95% yields of tetrafluoroborates and perchlorates that crystallize well. The structure of compounds *(2)* corresponds with their elemental analyses and infrared spectra (no NH bands). Sodium dithionite in alkaline solution regenerates the hydrazones *(1)* from the compounds *(2)* in 70% yield.



(1) *(2)*

R	M.p. [°C]	Yield [%]	$BF_4^{\ominus}$-salt m.p. [°C]	$ClO_4^{\ominus}$-salt m.p. [°C]
(2a), C_6H_5	171	60	213	214
(2b), p-CH_3O—C_6H_4	163	92	206	212

Further, the phenylhydrazone *(3a)* and the *p*-methoxyphenylhydrazone *(3b)*, m.p. = 151 °C, of 3-acetylbenzo-1,2,4-triazine[5] are cyclodehydrogenated to 3-methyl-1-phenyl-1,2,3-triazolo[5,1-*c*]benzo-1,2,4-triazinium bromide *(4a)* and the 1-(*p*-methoxyphenyl) derivative *(4b)*, respectively, by *N*-bromosuccinimide under the above-mentioned conditions. The product *(4a)* is precipitated as tribromide, which is converted into the monobromide by boiling ethanol/ether (1:1). Both products *(4)* form tetrafluoroborates and perchlorates that crystallize well.

Synthesis and Properties of Allyl Hydroperoxide

By Dr. H. E. Seyfarth, J. Henkel (deceased), and Prof. Dr. A. Rieche

Institut für Technische Chemie der Universität Jena (Germany)

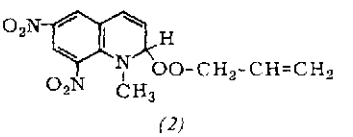
Allyl hydroperoxide *(1)* has been synthesized in preparative quantities by peroxygenation of allylzinc chloride. Very small amounts were previously obtained from allyl methanesulfonate and H_2O_2 by *S. Dykstra* and *H. S. Mosher*[1] who described the substance as very sensitive (synthesis under red light).

Allylzinc chloride is accessible from allylmagnesium chloride and zinc chloride in ether at 25 °C (molar ratio 1:1, 2 hours' stirring under argon). Its 0.3 M solution is saturated with oxygen at −75 °C. Hydrolysis[2] with 2 N HCl liberates the hydroperoxide *(1)* (crude yield 50%) which is found in the ether phase. Extraction with 2 N NaOH and removal of the ether by distillation leads to a liquid product of 98% purity (determined by iodimetric titration).

$$CH_2{=}CH{-}CH_2{-}MgCl \xrightarrow{ZnCl_2} CH_2{=}CH{-}CH_2{-}ZnCl$$

$$\xrightarrow{O_2} CH_2{=}CH{-}CH_2{-}OOZnCl \xrightarrow{H_2O} CH_2{=}CH{-}CH_2{-}OOH \quad (1)$$

Reduction of the product *(1)* with Na_2SO_3 gives allyl alcohol quantitatively. Treatment with 2-ethoxy-1,2-dihydro-1-methyl-6,8-dinitroquinoline, a specific precipitant for hydroperoxides[3], affords 2-allylperoxy-1,2-dihydro-1-methyl-6,8-dinitroquinoline *(2)* as yellow needles, m.p. 101.5–103 °C.



(2)

The hydroperoxide *(1)* is stable below 0 °C but can also be kept for considerable periods at room temperature and is not decomposed to a notable extent in 2 N KOH or 2 N

H_2SO_4 at 0 °C. Heating a drop in a test tube over a free flame leads to detonation; sensitivity to shock is notable only after admixture of a few grains of sand. Addition of bromine affords 2,3-dibromopropyl hydroperoxide (solvent: ether; Br_2 added dropwise at 15 °C). The isomer, 2-bromo-1-bromomethylethyl hydroperoxide, was recently[4] obtained by simultaneous action of oxygen and bromine on allyl bromide. Addition of chlorine to compound *(1)* is also possible.

The hydroperoxide *(1)* is perhaps an intermediate product of the oxygenation of propene to acrolein[5] or glycerol[6]. In accord with this suggestion acrolein can be detected on thermal decomposition of compound *(1)*.

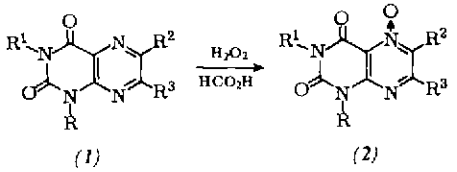
Synthesis of Pteridine N-Oxides [1]

By Prof. Dr. W. Pfleiderer and W. Hutzenlaub

Institut für Organische Chemie
der Technischen Hochschule Stuttgart (Germany)

Pteridine *N*-oxides have so far been obtained only by cyclization of 4-amino-5-nitrosopyrimidines with phenacyl- or acetonyl-pyridinium salts[2]. The product obtained by *G. B. Brown et al.*[3] is probably a 1-hydroxy-6,7-dimethyl-lumazine (analogous to 3-hydroxy-4-pteridinone[4]) rather than a pteridine oxide.

We have found that pteridines can be converted into *N*-oxides by direct oxidation with 30 % H_2O_2 in concentrated formic acid at room temperature. In this way lumazine *(1a)* and its *N*- and *C*-methyl derivatives *(1b)–(1f)* give lumazine 5-oxides *(2a)–(2f)*, which separate either at once or on concentration of the reaction mixture. Yields are between 20 and 70 %.



(1) *(2)*

	R	R¹	R²	R³		R	R¹	R²	R³
a)	H	H	H	H	*(f)*	CH_3	CH_3	CH_3	CH_3
b)	CH_3	H	H	H	*(g)*	CH_3	H	C_6H_5	C_6H_5
c)	H	H	CH_3	CH_3	*(h)*	CH_3	CH_3	C_6H_5	H
d)	CH_3	H	CH_3	CH_3	*(i)*	CH_3	CH_3	H	C_6H_5
e)	H	CH_3	CH_3	CH_3					

The structure of the product *(2a)* was proved by rearrangement (refluxing with acetic anhydride for 10 h) to 2,4,6-pteridinetrione. Reduction of *(2a)* by Pt/H_2 gave 5,6,7,8-tetrahydrolumazine which was isolated and characterized as its 5-acetyl derivative. The *N*-oxides are stable to acid hydrolysis (1 N H_2SO_4). Alkaline hydrolysis (1 N NaOH) of *(2d)* and *(2f)* occurs with opening of the pyrimidine ring and affords 5,6-dimethyl-3-methylamino-2-pyrazinecarboxylic acid 1-oxide and 3-methylamino-5,6-dimethyl-2-methylcarbamoyl-pyrazine 1-oxide, respectively. For further characterization the pK_a values and ultraviolet spectra of the *N*-oxides were determined (see Table).

Steric factors have a strong influence on the formation of *N*-oxides. While 1-methyl-6,7-diphenyl- *(1g)* and 1,3-dimethyl-6-phenyl-lumazine *(1h)* could not be oxidized, 1,3-dimethyl-7-phenyl-lumazine affords the 5-oxide *(2i)* in 65 % yield. In accord with these findings we formulate the oxidation product of 3-methyl-2-methylthio-6-phenyl-4(3*H*)-pteridone as the 8-oxide *(3)* or its tautomer, the 8-hydroxy-derivative *(4)*.

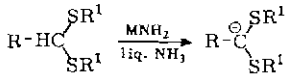
Carbanions of 1,3-Dithianes. Reagents for C–C Bond Formation by Nucleophilic Displacement and Carbonyl Addition

By Prof. Dr. E. J. Corey and Dr. D. Seebach

Department of Chemistry, Harvard University,
Cambridge, Massachusetts (U.S.A.)

The temporary modification of a carbonyl group so that the carbon atom behaves as a nucleophile in displacement and addition reactions would be of great utility in organic

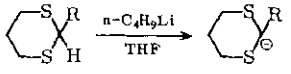
synthesis. A simple way of accomplishing this objective is suggested by the work of *Arens et al.*[1a] which established that mercaptals of type *(1)* can be converted into carbanions *(2)* using alkali metal amides in liquid ammonia. However, these anions are not of general synthetic applicability. For example, the anion *(2)*, R = CH_3, can only be alkylated using an excess of primary halide (30–70 % yield) and does not add onto ketones.



(1) *(2)*

R = H, CH_3, C_6H_5
R^1 = C_2H_5, C_6H_5

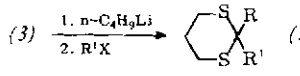
Carbanions of type *(4)* can be generated from dithianes *(3)*[1b,2] by the action of n-butyl-lithium (1 equiv.). As reagents they are superior to the carbanions *(2)*, because of ease of preparation, relative stability, and excellent reactivity especially in those cases where the carbanion carries an alkyl or other electron-repelling-substituent.



(3) *(4)*

A variety of carbanions *(4)* have been generated including R = prim., sec., and tert. alkyl, allyl, benzyl, aryl, and oxygen-containing groups such as $-CH_2CH(OC_2H_5)_2$ and $C_6H_5-CH(O^{\ominus})-$.

The anion *(4)*, R=H, undergoes alkylation in excellent yields (70–90 % of purified product) with a wide variety of alkyl halides (highest yields with iodides). The efficiency of introduction of a second alkyl group is also good, as can be seen in Table 1. Starting from *(3)*, R=H, by two successive



(5)

Table 1.

R	R'X	Yield of *(5)* [%]	B.p. (bath temp.) [°C/mm]
CH_3	i-C_3H_7I	84	60/0.3
CH_3	$C_6H_5CH_2Br$	90	113/0.08
CH_3	$ClCH_2CON(C_2H_5)_2$	50	undist. oil
t-C_4H_9	i-C_3H_7I	45	
n-C_5H_{11}	n-$C_5H_{11}Br$	82	100/0.05
n-C_5H_{11}	i-C_3H_7Br	85	84/0.03

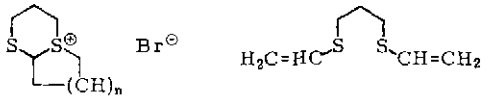
C_6H_5	i-C_3H_7Br	90	m.p. 50.5–51.5 °C
H	$(C_2H_5O)_2CHCH_2Br$	77	115/0.3

additions of butyl-lithium and alkyl halide, two alkylations can be performed in a single reaction mixture without isolation of intermediates to give 2,2-dialkyldithianes in good yields, *e.g.* 70 % yield for *(5)*, R=R'=i-C_3H_7, using *(3)*, R=H, and isopropyl iodide.

Although the alkylation reaction fails with some halides, *e.g.* cyclohexyl iodide, due to competing elimination, the tendency for elimination is surprisingly low with other halides, *e.g.* $(C_2H_5O)_2CHCH_2Br$, which normally lead to much elimination with carbanionic reagents.

One or two bromide ions may be displaced from 1,3-dibromopropane or 1,4-dibromobutane by the carbanion *(4)*, R=H, depending on the relative amounts used; with equivalent amounts the sulfonium bromides *(6)* are obtained and, interestingly, *(6a)* undergoes internal elimination with base to form *(7)* cleanly[3].



(6a), n = 1
(6b), n = 2

(7)

The carbanions *(4)* also react readily with 1,2-oxides to form mercaptals of β-hydroxy ketones or -aldehydes, *e.g.* *(8)*, from styrene oxide and *(4)*, R=CH_3, (70 % yield). Compound *(8)* is an undistillable oil which yields benzylideneacetone on hydrolysis and dehydration.

(8) *(9)*

(10) *(11)*

Ketones and aldehydes combine with anions of type *(4)* generally and in good yields to give mercaptals *(9)* of α-hydroxy aldehydes and -ketones (Table 2). The products of

Table 2.

(4), R =	Aldehyde or ketone	Yield of *(9)* [%] [a]	B.p. (bath temp.) [°C/mm] (m.p. [°C])
H	propionaldehyde	80	–
H	benzaldehyde	91	(70.5–71.6)
H	cyclopentanone	70	113/0.02

H	benzophenone	80	(136–136.5)
CH_3	cyclohexanone	80	165/1.2
CH_3	benzophenone	83	(136–137.5)
n-C_5H_{11}	benzophenone	78	(94–95.5)
i-C_3H_7	benzophenone	52	(144–145.2)

[a] The yields given are generally those obtained in the first experiment and are not necessarily optimal.

addition of *(4)*, R=H, to ketones can be dehydrated either by treatment with *p*-toluenesulfonic acid in benzene or by sequential reaction with thionyl chloride and potassium t-butoxide to give ketene mercaptals *(10)*.

Imines are also susceptible to addition as shown by the formation of *(11)*, m.p. 102.5–103.8 °C, from benzylideneaniline and *(4)*, R=CH_3, in 70 % yield.

The conversion of dithianes to carbonyl compounds can be accomplished by a variety of procedures[4].

On reaction of the anions *(4)* with oxygen and subsequent hydrolysis carboxylic acids R–CO_2H are formed[5].

Preparation of the carbanions (4) from 1,3-dithianes:

A 0.2–0.5 M solution of the dithiane at −30 °C under nitrogen is stirred and treated with one equivalent of 1.5 M n-butyl-lithium in hexane at the rate of 3–5 ml/min. The mixture is stirred at −30 to −20 °C for 1.5 h for *(3)*, R=H, CH_3, C_2H_5, i-C_3H_7, n-C_5H_{11}, C_6H_5, or 8 h for *(3)* R=t-C_4H_9. The clear, colorless solutions thus obtained can be stored at −20 °C under N_2 for at least three weeks. The content of anion *(4)* can be checked by treatment with deuterium oxide followed by NMR analysis of the isolated [2-D]-dithiane.

2,2-Diisopropyl-1,3-dithiane by sequential alkylation of 1,3-dithiane:

To a solution containing 30 mmoles of the anion *(4)*, R=H, in tetrahydrofuran at −5 °C were added 5.60 g (33 mmoles) of isopropyl iodide, and the mixture was maintained at 0 °C for 14 h under nitrogen. The resulting solution of 2-isopropyl-1,3-dithiane was treated at −30 °C with 35 mmoles of n-butyl-lithium in hexane and after 1.5 h 5.85 g (35 mmoles) of isopropyl iodide were added. After a reaction period of 70 h at 0 °C under nitrogen the reaction mixture was poured into three times its volume of water, acidified to pH 5–6 and extracted with five portions (30 ml each) of pentane. After washing successively with 3 % aqueous sodium bisulfite, 5 % aqueous KOH, and water the extract was dried (K_2CO_3) and concentrated to give 5.82 g (95 %) of a nearly colorless oil which contained 15 % of 2-isopropyl-1,3-dithane and 85 % of 2,2-diisopropyl-1,3-dithiane (NMR analysis). Fractionation through a small (5 cm) column gave 4.30 g (70 %) of pure 2,2-diisopropyl-1,3-dithiane *(5)*, R=R'=i-C_3H_7, b.p. 95 °C/0.5 mm, n_D^{25} = 1.5392.

Synthesis of 1,n-Dicarbonyl Derivates Using Carbanions from 1,3-Dithianes

By Prof. Dr. E. J. Corey and Dr. D. Seebach

Department of Chemistry, Harvard University, Cambridge, Massachusetts (U.S.A.)

The preceeding note[1] reports the utility of bisthiocarbanions of type *(1)* as reagents for displacement and addition reactions at electrophilic carbon atoms to form derivatives of aldehydes and ketons. This communication deals with the application of these carbanions to the synthesis of 1,2-, 1,3-, and other dicarbonyl derivatives.

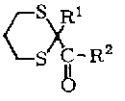
Treatment of the anions *(1)* of 1,3-dithianes[1] with CO_2 at −70 °C affords the mercaptals *(2)* of α-keto carboxylic acids in 70–75 % yield. With a large excess of ethyl chloroformate (instead of CO_2) at −70 °C the ethyl carboxylates *(3)* are obtained [yields: *(3a)* 60 %, *(3b)* 78 %] which can be saponified ($CH_3OH/H_2O/KOH$) to the dithianecarboxylic acids.

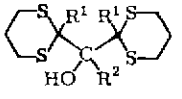
(1)

(2a), R^1 = CH_3, R^2 = CO_2H, m.p. 133–135 °C
(2b), R^1 = t-C_4H_9, R^2 = CO_2H, m.p. 98.5–99 °C
(3a), R^1 = CH_3, R^2 = $CO_2C_2H_5$
(3b), R^1 = $CH_2C_6H_5$, R^2 = $CO_2C_2H_5$
(4), R^1 = CH_3, R^2 = CHO

Reaction of *(1)*, R^1=CH_3, with one equivalent of dimethylformamide or a large excess of ethyl formate at ca. −10 °C leads to the dithioketal *(4)* of α-oxopropionaldehyde (m.p. of the 2,4-dinitrophenylhydrazone of *(4)*: 167.5–168.5 °C). The yield is 50–60 %. *N,N*-Dimethylacetamide, however, does not react with *(1)*, R^1 = CH_3, under similar conditions, and this seems to be true for higher homologues in general.

Monomercaptals *(5)* of 1,2-diketones can be made from anions of type *(1)* and carboxylic acid derivatives. In some cases, but not generally, esters are satisfactory starting materials. Thus, the reaction of *(1)*, R^1=CH_3, (2 equiv.) with ethyl cyclohexanecarboxylate gives *(5a)* in 60 % yield, whereas the reaction with ethyl benzoate under the same conditions leads to the dimercaptal *(6a)*, m.p. 156.5–158 °C, in 95 % yield. The results obtained in a particular case depend on the relative reactivities of the starting ester and the ketone derivative *(5)* and the tendency of this derivative to undergo enolate formation *vs.* addition in further reaction with the anion *(1)*. The synthesis of *(5b)* is not feasible by reaction of *(1)*, R^1=CH_3, with ethyl acetate even when the anion is added slowly to a thirty-fold excess of the ester. The chief product is invariably the 2:1 adduct *(6b)*. However, the 1:1 adduct *(5b)* can be obtained in about 50 % yield by slow addition of the anion *(1)*, R^1=CH_3, to excess acetyl chloride at −70 °C. Presumably the zinc or cadmium salts of *(1)* would be more satisfactory reagents for the synthesis of structures of type *(5)* from acid chlorides and this point is under investigation. The reaction of nitriles with the lithium salts *(1)* produces the monomercaptals *(5)* usually without complication; for example, *(5d)* was readily obtained (80 % yield) from the anion *(1)*, R^1=CH_3, and benzonitrile at low temperatures.



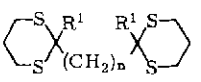


(5a), R^1 = CH_3, R^2 = C_6H_{11}
(5b), R^1 = CH_3, R^2 = CH_3
(5c), R^1 = H, R^2 = CH=CH-C_6H_5
(5d), R^1 = CH_3, R^2 = C_6H_5

(6a), R^1 = CH_3, R^2 = C_6H_5
(6b), R^1 = CH_3, R^2 = CH_3
(6c), R^1 = H, R^2 = CH=CH-C_6H_5

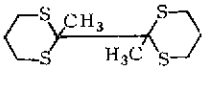
With α,β-unsaturated carbonyl compounds reaction occurs preferentially by 1,2- rather than 1,4-addition. For example, ethyl cinnamate and *(1)*, R^1=H, (in equimolar amounts) afford a mixture of *(5c)* (m.p. 99–100 °C) and a 1:2 adduct *(6c)* (m.p. 176.5–177.5 °C). Alkylation of carbanions *(1)* by ketals of α- and β-halocarbonyl compounds[1] [*e.g.* $XCH_2CH(OR)_2$] represents an approach to 1,3- and 1,4-dicarbonyl structures.

Alkylation reactions furnish another route to derivatives of 1,n-dicarbonyl compounds. The 1,6-diketone derivatives *(7a)* and *(7b)* were prepared from 1,4-dibromobutane in 84 and 89 % yield, respectively, and the 1,5-diketone derivative *(7c)* was obtained from 1,3-dibromopropane (66 % yield).



(7a), R^1 = H, n = 4, m.p. 102.5–103.5 °C
(7b), R^1 = CH_3, n = 4, m.p. 108.5–109 °C
(7c), R^1 = H, n = 3, m.p. 101.5–102 °C

Finally, carbanions of type *(1)* undergo coupling under the influence of oxidizing agents such as 1,2-dibromomethane, Cu(II), or iodine to afford 1,2-dicarbonyl derivatives such as *(8)*, m.p. 184–186 °C.



(8)

2-Methyl-2-benzoyl-1,3-dithiane (5d):

To a cold (−78 °C) solution of 10 mmoles of the lithium derivative *(1)*, $R^1=CH_3$, in tetrahydrofuran[1] was added with stirring 1.06 g (10 mmoles) of benzonitrile. The resulting bright orange mixture was kept at −78 °C for 40 min, after which the bath was removed and stirring was continued for an additional 40 min. The reaction mixture was then poured onto ice and extracted with ether. The extracts were washed with dilute base, dried over Na_2SO_4 and concentrated to give 2.22 g (95 %) of crude imine which was hydrolysed with 150 ml of 4 % hydrochloric acid at 70 °C for 45 min. The product, which partially separated as colorless crystals, was removed by extraction with ether. After washing, drying, and concentration the extract yielded 1.95 g (82 %) of *(5d)*, m.p. 97.8–98.7 °C. After recrystallization from methanol the m.p. is 98.4–98.8 °C.

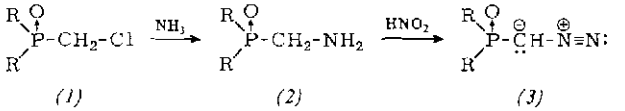
Diazomethylphosphine Oxides

By Prof. Dr. N. Kreutzkamp, Dr. E. Schmidt-Samoa, and K. Herberg

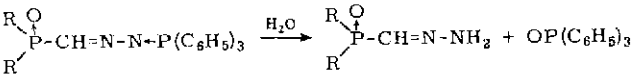
Institut für Pharmazeutische Chemie
der Universität Hamburg (Germany)

The first preparation of diazomethylphosphine oxides *(3)* has been achieved by the following reactions:



(1) *(2)* *(3)*

For synthesis of the intermediates *(2)*, methanolic solutions of the chloromethyl compounds *(1)* were saturated with NH_3 at 0 °C and heated for 5 h in an autoclave at 130 °C. The residues were taken up in chloroform and extracted several times with dilute sulfuric acid. The compounds *(2)* were precipitated from the extracts by alkali and recrystallized several times from benzene/ether. Their conversion into *(3)* was effected by adding sodium nitrite to their solutions in glacial acetic acid, with ice-cooling, whereupon the diazomethylphosphine oxides separated. Thus, *P,P*-dibenzyl-*P*-diazomethylphosphine oxide *(3)*, R = C_7H_7, m.p. 99 °C, was formed immediately in 90 % yield from *P*-aminomethyl-*P,P*-dibenzylphosphine oxide *(2)*, R = C_7H_7, m.p. = 112 °C, and 1 mole of sodium nitrite in glacial acetic acid; *P*-diazomethyl-*P,P*-diphenylphosphine oxide *(3)*, R = C_6H_5, m.p. = 56 °C, was obtained analogously in 70 % yield from *P*-aminomethyl-*P,P*-diphenylphosphine oxide *(2)*, R = C_6H_5, m.p. = 101 °C. Both the diazomethyl compounds are very stable and intensely yellow. On addition of hydrochloric acid to their methanol solutions they are converted into the chloromethylphosphine oxides *(1)*, and they react with triphenylphosphine to give phosphazines *(4)* which crystallize from the solution.



(4) *(5)*

These products *(4)* are hydrolysed when heated with 80 % ethanol, affording the phosphinylformaldehyde hydrazones *(5)* which, after removal of the alcohol, are separated by means of chloroform/water from the triphenylphosphine oxides that are formed simultaneously.

Of preparative interest are the addition reactions of the diazomethylphosphine oxides to unsaturated compounds, which lead to phosphine oxides of the pyrazoline series not accessible in other ways. For instance, by warming *P*-diazomethyl-*P,P*-diphenylphosphine oxide *(3)*, R = C_6H_5, with methyl vinyl ketone or dimethyl maleate in dioxane or toluene, removal of the solvent in a vacuum, and recrystallization of the residue from methanol we obtained the pyrazolines *(6)*, m.p. = 169 °C, and *(7)*, m.p. 153 °C, in about 70 % yield.

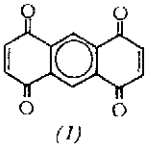
Synthesis and Properties of 1,4,5,8-Anthradiquinone

By Priv.-Doz. Dr. P. Boldt and Dipl.-Chem. F. Vardakis

Organisch-Chemisches Institut
der Universität Göttingen (Germany)

1,4,5,8-Anthradiquinone *(1)*, which is of interest in connection with M.O. calculations of redox potentials of quinones[1] is obtained in good yield by shaking a dioxane solution of 1,4,5,8-anthratetrol with freshly precipated silver oxide and calcium sulfate (as drying agent) for a short time. Small



(1)

amounts of 5,8-dihydroxy-1,4-anthraquinone formed at the same time can be removed chromatographically (chloroform/ethyl acetate, neutral silica gel).

The constitution of the diquinone *(1)* (yellow needles from dioxane/cyclohexane; decomp. at 170 °C) follows from elemental analysis, the ultraviolet spectrum (λ_{max} = 353 mμ; ϵ_{max} = 3750 in dimethylformamide), the NMR spectrum (2 singlets at −7.22 and −8.80 ppm, relative intensity 2:1[2]), and the simple infrared spectrum (strong bands at 1667, 1600, 1271, 1124, and 849 cm^{-1} in KBr). The compound *(1)* has a higher redox potential (+736 mV in 90 % acetic acid containing 3 % of dimethylformamide) than 1,2,5,6-anthradiquinone[3], decomposes in aqueous alkali (in contrast to the 1,2,5,6-diquinone), and reacts readily with nucleophiles. Repeated treatment with aziridine and subsequent dehydrogenation with silver oxide affords 2,7-di- and 2,6,7-tri-aziridino-1,4,5,8-anthradiquinone (proof of structure by elemental analysis and NMR spectroscopy).

On oxidation with *one* equivalent of silver oxide, 1,4,5,8-anthratetrol, which is accessible by alkaline hydrolysis of its acetate[4] with exclusion of air, affords 5,8-dihydroxy-1,4-anthraquinone[5] (colorless leaflets from butanol; decomp. at 300 °C) as main product. By oxidation of 1,4,5-anthratriol (yellow prisms from acetone; decomp. at 230 °C), accessible from its acetate[4], with silver oxide in acetone we obtained 5-hydroxy-1,4-anthraquinone (red needles from chloroform/ethyl acetate; decomp. at 220 °C).

Trifluoroacetates of Silicon, Germanium, and Tin [1]

By Dr. P. Sartori and Dipl.-Chem. M. Weidenbruch

Institut für Anorganische Chemie und Elektrochemie der Technischen Hochschule Aachen (Germany)

Treatment of silicon tetrachloride with trifluoroacetic acid in anhydrous benzene (250 h at 70 °C, molar ratio 1:2), followed by removal of all the substances distilling up to 100 °C/760 mm and fractional distillation of the residue in a vacuum, affords silicon tetrakis(trifluoroacetate) *(1)*, b.p. 51 °C/1 mm[2], in 25 % yield. There remains a residue, also in 25 % yield, of a highly viscous, colorless liquid that cannot be distilled without decomposition, even in a high vacuum; on the grounds of analysis ($Si:CF_3COO$ = 1.0:2.0), insolubility in proton-inactive solvents, and extremely low volatility, the structure of a polymeric silicon oxide bis(trifluoroacetate) must be ascribed to this compound; molecular-weight determinations were not possible because of the insolubility and involatility of the substance.

When heated for a short time at 200 °C under dry nitrogen, compound *(1)* yields hexakis(trifluoroacetoxy)disiloxane *(2)*, b.p. 120 °C/1 mm, with loss of trifluoroacetic anhydride:

$$2\ Si(OCOCF_3)_4 \xrightarrow{\Delta} [Si(OCOCF_3)_3]_2O + (CF_3CO)_2O$$

(1) *(2)*

On account of the low reactivity of the metal-halogen linkage the trifluoroacetates of germanium and tin cannot be prepared by direct reaction of their tetrahalides with trifluoroacetic acid. These trifluoroacetates are obtained in *ca.* 25 % yield on reaction of germanium or tin tetrachloride with mercury(II) trifluoroacetate in anhydrous trifluoroacetic acid at 0 °C for 8 h. After separation from mercury(II) chloride, germanium tetrakis(trifluoroacetate) *(3)* can be isolated by fractional distillation in a vacuum, forming a colorless liquid of b.p. 20 °C/0.1 mm; this product *(3)* decomposes slowly even at room temperature, with removal of trifluoroacetic anhydride and formation of solid polymeric germoxanes. For isolation of tin tetrakis(trifluoroacetate) *(4)*, m.p. 112 °C, the mercury(II) chloride is filtered off and the liquid concentrated at 20 °C/15 mm until copious crystallization occurs, and the crystal mass is filtered off with exclusion of air; fractional sublimation at 70 °C/10^{-3} mm then affords *(4)* as pure white crystals.

A further route to the compound *(4)* consists of fission of tetraphenyltin by trifluoroacetic acid at 40 °C. The small yield (7 %) in this and the preceding reaction is ascribed to simultaneous formation of a stannoxane. Although the analogous treatment of tetraphenylgermanium with trifluoroacetic acid alone gives no appreciable yield, reaction in anhydrous benzene at 80 °C gives triphenylgermanium trifluoroacetate quantitatively; this can be purified by sublimation at 120 °C/10^{-3} mm and then forms white needles of m.p. 122 °C.

Largely non-polar linkages in the structure M–O–CO can be assumed for all the trifluoroacetates of the fourth main group of the Periodic System, including the well-known lead tetrakis(trifluoroacetate)[3], because of their volatilities and the high-frequency carbonyl absorptions [$\nu_{C=O}$ = 1815 (Si), 1770 (Ge), and 1750 (Sn) cm^{-1}].

Stereospecific Synthesis of D-Hydroxynitriles and Optically Active Ethanolamines

By Dr. W. Becker, H. Freund, and Prof. Dr. E. Pfeil

Chemisches Institut der Universität Marburg (Germany)

In the presence of the enzyme D-hydroxynitrile lyase (4.1.2.10)[1] aldehydes and hydrocyanic acid afford D-hydroxynitriles of high optical purity in excellent yields.

D-(+)-*Mandelonitrile*: 40 ml (42 g; 0.4 mole) of benzaldehyde and 80 mg of D-hydroxynitrile lyase are placed in a 1000 ml measuring vessel and the mixture is made up to 980 ml with 0.05 M 50 % alcoholic acetate buffer (pH 5.4). The liquid is covered with a layer (20 ml; 14 g; 0.52 mole) of anhydrous hydrocyanic acid, and the whole is shaken and then kept until the optical rotation is constant (*ca.* 20 min). The D-(+)-mandelonitrile is removed from the aqueous alcoholic layer by shaking with chloroform. After drying and evaporation of the extraction medium in vacuum there remains 51 g of a clear, pale yellow oil of specific rotation $[\alpha]_D^{20} = +39°$ (c = 5, $CHCl_3$). This solidifies to colorless crystals in a refrigerator. The crude product has an optical purity of 90 % and is obtained in 96 % yield.

Aldehyde used	Yield of crude D-hydroxynitrile [%]	$[\alpha]_D^{20}$ of crude product
Benzaldehyde	96	+39.0° (c=5, $CHCl_3$)
m-Methylbenzaldehyde	100	+25.9° as oil
p-Methylbenzaldehyde	98	+30.0° (c=5, benzene)
m-Hydroxybenzaldehyde	94	+21.5° (c=5, CH_3OH)
m-Methoxybenzaldehyde	96	+32.0° (c=5, $CHCl_3$)
Heliotropine	98	+39.5° (c=5, $CHCl_3$)
Thiophene-2-carbaldehyde	88	+38.9° (c=5, $CHCl_3$)
Furfural	85	+30.6° as oil
Crotonaldehyde	69	−22.0° (c=5, $CHCl_3$)
Acetaldehyde	28	+8.2° (c=5, $CHCl_3$)
Propanal	45	+14.0° (c=5, $CHCl_3$)
n-Butanal	88	+6.7° (c=5, $CHCl_3$)
iso-Butanal	84	+3.2° (c=5, $CHCl_3$)
n-Pentanal	86	+6.5° (c=5, $CHCl_3$)

The syntheses can be made continuous if the enzyme is adsorbed on a high-molecular carrier (*e.g.*, ECTEOLA cellulose) and the product is placed in a column. The enzyme is stable in the form of the enzyme-carrier complex that is insoluble in the reaction medium (water or aqueous alcohol according to the solubility of the aldehyde)[2].

Substituted optically active ethanolamines can be obtained from the dextrorotatory D-hydroxynitriles by reduction with $LiAlH_4$ in ether.

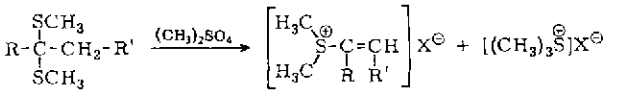
Preparation of 1,2-Disubstituted Vinylsulfonium Salts and Alkyl Vinyl Sulfides, and of Ethynylsulfonium and Ethynylselenonium Salts

By Priv.-Doz. Dr. J. Gosselck, Dipl.-Chem. L. Béress, Dipl.-Chem. H. Schenk, and Dipl.-Chem. G. Schmidt

Institut für Organische Chemie
der Universität Gießen (Germany)

We have found a simple approach to dialkylvinylsulfonium salts disubstituted at the 1,2-positions of the vinyl group in the reaction of dimethyl dithioacetals *(1)* with an excess of acid-free dimethyl sulfate. In the reaction conditions used (1–2 h at 90–100 °C), alkylating cleavage of the thioacetals occurs, with formation of an equimolar mixture of dimethylvinylsulfonium methyl sulfate *(2)* and trimethylsulfonium methyl sulfate *(3)*. The yields of *(2)* amount to 60–80 % [1]. The products *(2)* are isolated by washing the reaction mixture several times with anhydrous ether, dissolving the residue in water, and precipitating the salts *(2)* with picric acid, perchloric acid, or sodium tetraphenylborate [2]. The salts *(3)* then remain in solution.



(1) *(2)* *(3)*

$X^{\ominus} = CH_3SO_4^{\ominus}$

	R	R'	Analysed as	M.p. [°C]
(2a)	Methyl	1-Pyridyl	Picrate	152
(2b)	Phenyl	*p*-Nitrophenoxy	Picrate	199
(2c)	Methyl	2,4-Dinitrophenyl	Perchlorate	178
(2d)	Phenyl	Phenyl	Picrate	161
(2e)	*p*-Nitrophenyl	*p*-Nitrophenyl	Picrate	184
(2f)	Phenyl	$-COOC_2H_5$	Tetraphenylborate	134–135
(2g)	β-Naphthyl	$-COOC_2H_5$	Picrate	138–139

Methylation of methyl vinyl sulfides by dimethyl sulfate under the above conditions also leads to dialkylvinylsulfonium salts *(2h)–(2l)* (yield 60–80 %).

	R	R'	Analysed as	M.p. [°C]
(2h)	H	Phenyl	Picrate	127
(2i)	Phenyl	Benzoyl	Picrate	150
(2k)	Benzoyl	*p*-Chlorophenyl	Methyl sulfate	158
(2l)	Benzoyl	*p*-Nitrophenyl	Perchlorate	202

In contrast to the stable trimethylsulfonium salts *(3)*, the dialkylvinylsulfonium salts *(2)* are very reactive. If their aqueous solution is boiled for 10–15 min with aqueous hot-saturated NaCl solution, removal of methyl chloride leads smoothly to the 1,2-disubstituted methyl vinyl sulfides *(4)*, which are isolated by extraction with ether and distillation or crystallization (yields 40 to 70 %).

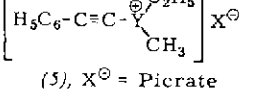
Phenyl	Phenylthio	142/0.01
Phenyl	Phenyl	130/0.01

[a] As *N*-methyl perchlorate. [b] As picrate.

Methyl vinyl sulfides *(4)* are also obtained directly from the thioacetals *(1)* and dimethyl sulfate by heating them only to 40–50 °C, extracting the solution with ether, and destroying the excess of alkylating agent with ammonia.

Alkylation of methyl phenylethynyl sulfide or selenide with triethyloxonium fluoroborate without a solvent gave the colorless, very hygroscopic ethynylsulfonium and ethynylselenonium salts *(5)*, which were isolated as picrates.



(5), $X^{\ominus}$ = Picrate

Received: October 13th, 1965 [Z 85a/923 IE]
German version: Angew. Chem. 77, 1140 (1965)

[1] Exceptionally, the yield of *(2a)* was only 30 %.

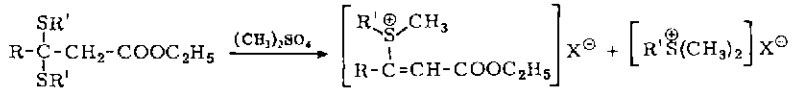
[2] When sodium tetraphenylborate is used, separation from *(3)* by fractional crystallization from acetonitrile is necessary.

Ethynylation with Vinylsulfonium Salts

By Priv.-Doz. Dr. J. Gosselck, Dipl.-Chem. L. Béress, Dipl.-Chem. H. Schenk, and Dipl.-Chem. G. Schmidt

Institut für Organische Chemie
der Universität Gießen (Germany)

On warming alkyl dithioacetals *(1)* of β-oxocarboxylic acids in an excess of acid-free dimethyl sulfate at 90–100 °C we obtained an equimolar mixture of the dialkylvinylsulfonium methyl sulfate *(2)* and the trialkylsulfonium methyl sulfates *(3)* [1].



(1) *(2)* *(3)*

$X^{\ominus} = CH_3SO_4^{\ominus}$

Addition of an excess of alkali to an aqueous solution of such a dialkylvinylsulfonium salt *(2)* furnishes, even at 0 °C, the corresponding acetylenecarboxylic ester *(4)*, with loss of dialkyl sulfide; the esters are readily hydrolysed to the acids under the reaction conditions, whereas the trialkylsulfonium salts are stable under these conditions.

(2) $\xrightarrow[0°C]{\text{Aqueous alkali}}$ R-C≡C-COOC$_2$H$_5$ + CH$_3$SR'

(4)

+ H$_2$O + CH$_3$SO$_4$Na

R	M.p. [°C]	Yield of acid [%] based on (1)
Phenyl	136–137	80
4-Nitrophenyl	203–204	70
3-Nitrophenyl	143–144	50
4-Chlorophenyl	192–193	75
α-Naphthyl	140–141	55
β-Naphthyl	145–146	77
2-Thienyl	139–140	25

Double ethynylation can also be achieved by this process. Thus the bis(methyl thioacetal) of terephthaloyldiacetic ester gives *p*-phenylenedipropiolic acid

HOOC–C≡C–C$_6$H$_4$–C≡C–COOH

(decomp. 280 °C) in 65 % yield. *m*-Phenylenedipropiolic acid (m.p. 209 °C; yield 70 %) was obtained in the same way.

Received: October 13th, 1965 [Z 85b/924 IE]

[1] Cf. *J. Gosselck, L. Béress, H. Schenk*, and *G. Schmidt*, Angew. Chem. 77, 1140 (1965); Angew. Chem. internat. Edit. 4, 1080 (1965).

Trimethylsilyl as Protecting Group for Nitrogen in Organometallic Syntheses Involving Halogenoanilines

By Prof. Dr. W. Broser and Dipl.-Chem. W. Harrer

Institut für Organische Chemie
der Freien Universität Berlin (Germany)

The amino hydrogen atoms of aniline can be relatively easily replaced by trimethylsilyl groups[1]:

$$\text{Ar-NH}_2 \xrightarrow[\text{or 2 n-C}_4\text{H}_9\text{Li}]{\text{2 C}_6\text{H}_5\text{Li}} \text{Ar-NLi}_2 \xrightarrow[-2\ \text{LiCl}]{\text{2 TMS-Cl}} \text{Ar-N(TMS)}_2$$

TMS = $(CH_3)_3Si$

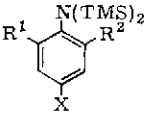
Since the halogen atoms of halogenoanilines are not replaced if stoichiometric amounts of the lithium reagent are used, and since the trimethylsilyl groups can be easily removed by hydrolysis, the latter groups are suitable for use as protecting groups in organometallic syntheses involving halogenoanilines. Thus the following compounds can be synthesized in 80–85 % yield by dropping the organometallic reagent (2 moles) into an ethereal solution of the halogenoaniline (1 mole), then adding a mole of trimethylsilyl chloride, replacing the ether by means of ligroin, adding a second mole (+ 20 % excess) of trimethylsilyl chloride, and refluxing the mixture for 8–10 h:

p-bromo-*N,N*-bis(trimethylsilyl)aniline *(1a)*, a yellow oil, b.p. 86–87 °C/1 mm;

4-bromo-2-methoxy-*N,N*-bis(trimethylsilyl)aniline *(1b)*, a colorless oil, b.p. 99–100 °C/1 mm; and

4-bromo-2,6-dimethoxy-*N,N*-bis(trimethylsilyl)aniline *(1c)*, colorless crystals, b.p. 112–113 °C/1 mm; m.p. = 73 °C.

The halogen of compounds *(1a)–(1c)* can also be replaced by lithium, if metallic lithium or n-butyl-lithium in ether under nitrogen at 25–35 °C is used. The products *(2a)–(2c)* resemble phenyl-lithium in chemical behavior. For instance, addition of an ethereal solution of *(2a)–(2c)* slowly to a rapidly stirred suspension of solid carbon dioxide in ether at −80 °C affords the lithium benzoates *(3a)–(3c)*, from which the corresponding *p*-aminobenzoic acids are obtained on removal of the protecting groups (short heating with dilute mineral acid or 10 % acetic acid). The lithium benzoates *(3a)–(3c)* are converted by trimethylsilyl chloride in boiling ligroin into the trimethylsilyl esters *(4a)–(4c)* [*(4a)*: b.p. 129–131 °C/1 mm, *(4b)*: 134–135 °C, 1 mm, *(4c)*: 136–137 °C/1 mm; pale yellow, viscous oils that crystallize



(1), X = Br
(2), X = Li
(3), X = COOLi
(4), X = COOTMS

(a), $R^1 = R^2 = H$
(b), $R^1 = H$, $R_2 = OCH_3$
(c), $R^1 = R^2 = OCH_3$

slowly]. On treatment of the lithio derivatives *(2a)–(2c)* with diethyl carbonate in boiling ether and subsequent hydrolysis with dilute hydrochloric acid at 40–60 °C, the corresponding triarylmethanol derivatives are formed. Further, all the *m*-methoxylated parafuchsins have been synthesized by combinations of the compounds *(2a)–(2c)* with the esters *(4a)–(4c)*.

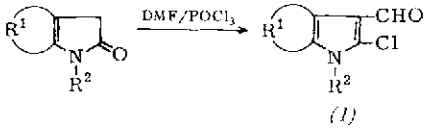
Institut für Pharmazeutische Chemie
der Universität Münster (Germany)

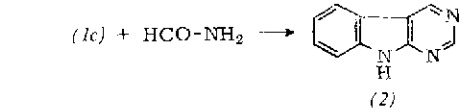
α,β-Unsaturated β-chloroaldehydes can be prepared by chloroformylation[1,2] of isocyclic ketones. We found that α-pyrrolones also undergo this reaction, affording the corresponding chloroaldehydes *(1)* in 50–60 % yield (for products see the Table).



(1)

	R^1	R^2	M.p. [°C]
(1a)	$-(CH_2)_4-$	$-H$	162
(1b)	$-(CH_2)_4-$	$-C_6H_5$	156
(1c)	$-(CH)_4-$	$-H$	223–225

A solution of 0.02 mole of the pyrrolone in 40 ml of chloroform is added dropwise at 0–10 °C to a Vilsmeier reagent prepared from 0.06 mole of dimethylformamide and 0.05 mole of phosphorus oxide chloride. The mixture is heated for 5–6 h at the boiling point. After removal of the solvent by distillation, the residue is treated with ice-water, neutralized, and extracted with chloroform. The organic phase is dried and freed from solvent, and the residue is recrystallized from alcohol.



(2)

Compounds *(1)* can also be used for preparation of condensed heterocycles. For instance, 9*H*-pyrimido[4,5-*b*]indole *(2)* (m.p. 235–237 °C, yield 80 %) is formed when 2-chloroindole-3-carbaldehyde *(1c)* is heated for several hours in an excess of formamide.

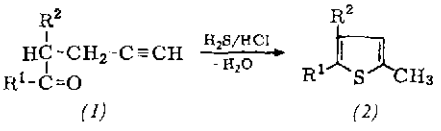
Thiophenes from 5-Oxo Derivatives of 1-Alkynes

By Prof. Dr. K. E. Schulte, Doz. Dr. J. Reisch, and D. Bergenthal

Institut für Pharmazeutische Chemie der Universität Münster (Germany)

β-Dicarbonyl compounds in the 1-alkyne series can yield furans by intramolecular ring closure[1]. *Baumann* and *Fromm*[2] obtained thioketones by treating ketones with H_2S and HCl, and *Mitra*[3] found that β-dicarbonyl compounds can be converted into monounsaturated thiols if hydrogen sulfide is passed into their alcoholic solution previously saturated with hydrogen chloride. In similar conditions thiophenes *(2)* are obtained from 5-oxo derivatives *(1)* of 1-alkynes (for products see Table).



(1) *(2)*

	R^1	R^2	B.p.[°C/mm Hg]	n_D (at °C)	Yield [%]
(2a)	CH_3	$CO_2C_2H_5$	108–109/8	1.5152 (20)	69
(2b)	C_6H_5	$CO_2C_2H_5$	129–130/2	1.5833 (21)	65
(2c)	CH_3	C_6H_5	109/1.5	1.6044 (19)	50
(2d)	C_6H_5	H	(M.p. 49 °C)		71

0.3 mole of H_2S is passed at −20 °C, and then 1 mole of HCl at between −20 and −10 °C, into a solution of 0.1 mole of the unsaturated ketone in about 100 ml of ethanol. After several hours at room temperature the solvent is removed and the mixture is fractionated in a vacuum.

On the Existence of Metal Carbonyl Carbene Complexes

By O. S. Mills and Dr. A. D. Redhouse[1]

Department of Chemistry, University of Manchester, England

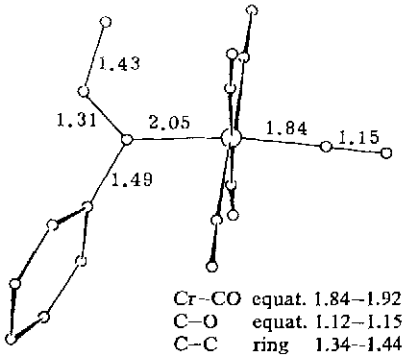
In a recent paper[2], *Fischer* and *Maasböl* have described the preparation of complexes of stoichiometry $(CO)_5W(RCOCH_3)$ *(1)*, where $R=CH_3$ or C_6H_5. From a study of infrared and proton magnetic resonance spectra the possibility that *(1)*, $R=CH_3$, was methoxymethylcarbene-pentacarbonyltungsten was considered.

We have analysed, by x-ray diffraction, single crystals of *(1)*, $R=C_6H_5$, and also of the corresponding chromium complex[3]. We find that the compounds are isomorphous, with the following unit cell dimensions:

	$(CO)_5W(C_6H_5COCH_3)$	$(CO)_5Cr(C_6H_5COCH_3)$
a	10.00 Å	9.91 Å
b	21.90 Å	21.70 Å
c	6.45 Å	6.34 Å
β	96° 12′	96° 35′
Z	4	4
Space group	Cc	Cc

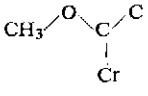
The analysis of these complexes is complicated since the symmetry of the heavy atoms alone corresponds to the higher symmetry of space group C2/c with the metal atoms in special positions on two-fold axes. The pseudo-symmetry introduced into the resulting electron density calculation corresponds to the superimposition of the molecule and its two-fold rotation image.

Crystals of both complexes yielded relatively few diffraction spots, consistent with large thermal vibrations. The structure of the chromium complex was determined from 565 three-dimensional data collected on precession photographs taken with molybdenum Kα radiation. The structure as given in



the figure clearly shows that the molecule does correspond to a "carbene-metal complex". The structure shows the following features:

(i) The phenyl group is roughly perpendicular to the



plane so that the π-electron system of the phenyl group presumeably does not interact with the empty p orbital on the carbene carbon atom. The carbene-phenyl distance (1.49 ± 0.03 Å) corresponds to bonding between two sp^2 hybridized carbon atoms.

(ii) The carbene – oxygen and methyl-oxygen distances (1.31 ± 0.02 Å and 1.43 ± 0.03 Å, respectively) are similar to those found in methyl esters of carboxylic acids.

(iii) The individual Cr–CO distances do not differ from the average (1.88 Å) by more than one standard deviation (0.03Å)
(iv) The Cr-carbene distance (2.05 ± 0.03 Å) is significantly longer than the Cr–CO distances.

(v) The normal to the "carbene plane", *i.e.* the direction of the empty p-orbital, does not align parallel to a principal axis of the Cr octahedron. Indeed, it lies at approximately 45 ° to the x,y axes (with the carbene carbon on the z axis). This arrangement could be caused by steric requirements.

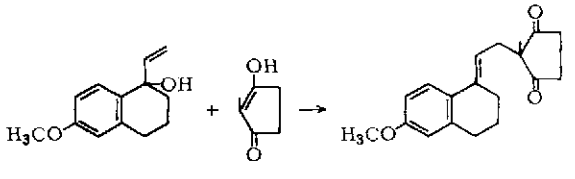
The Condensation of 6-Methoxy-1-vinyl-1,2,3,4-tetrahydro-1-naphthol with 2-Methylcyclopentane-1,3-dione

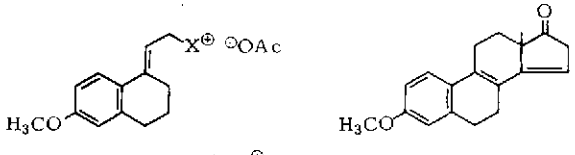
By C. H. Kuo, M. Sc., Dr. D. Taub, and Dr. N. L. Wendler

Merck Sharp & Dohme Research Laboratories,
Rahway, New Jersey (U.S.A.)

The condensation of *(1)* with *(2)* to give *(3)* has achieved considerable importance recently in the total synthesis of estrone and related substances. The condensation, as reported, is effected in hot alcoholic media in the presence of strong bases[1], but proceeds at best in only fair yield (50–60 %).



(1) *(2)* *(3)*



(4), $X^{\oplus}$ = $-S-C(NH_2^{\oplus})NH_2$

(5), $X^{\oplus}$ = $-\overset{\oplus}{P}(C_6H_5)_3$

(6)

We have found that this condensation does not occur in the presence of a mole of base and is, in fact, catalysed by acid and by the 1,3-dione *(2)*. Thus, when *(1)* and *(2)* are warmed together in alcohol solution coupling to give *(3)* occurs smoothly in 65–70 % yield. This finding suggested an ion-pair intermediate arising from acid-base interaction of *(2)* and *(1)*, respectively. In pursuance thereof it was found that *(1)* in acetic acid in the presence of thiourea produced the crystalline thiuronium salt *(4)* in nearly quantitative yield (m.p. 125–127 °C; λ_{max} = 275 mμ, ε = 19500 in methanol). The latter, in turn, coupled with *(2)* in aqueous solution at room temperature to yield crystalline *(3)* in 80–85 % yield.

The reaction of *(1)* and *(2)* (pK_a 4.5) is essentially unaffected by triphenylphosphine, although *(1)* itself in acetic acid solution (pK_a 4.7) rapidly forms a stable but non-crystalline salt *(5)* (λ_{max} = 270 and 276 mμ, ε = 13000 and 13500 in methanol) with triphenylphosphine[2]. From this it would follow that the ion-pair involved in the coupling of *(1)* and *(2)* is intimate in character.

Finally it was observed that *(1)* and *(2)* in acetic acid-xylene (1:2) at 120 °C afford 8,14-bisdehydroestrone methyl ether *(6)* in one operation in 60–65 % yield.

CONFERENCE REPORTS

Conference of North-West German Chemistry Lecturers

The conference took place on June 11th and 12th, 1965 at Clausthal-Zellerfeld (Germany). A total of 74 papers was read partly in three parallel sessions. To avoid duplication, the following review contains abstracts of only those papers whose contents have not yet been published or submitted for publication. The abstracts are arranged in alphabetical order of authors' names. A subject index to this Report is on p. 1097 of this issue.

1

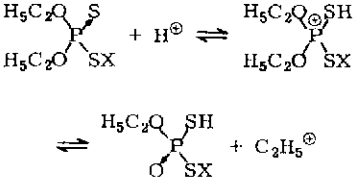
Thermal Decomposition of Zinc Dialkyldithiophosphates

E. Baumgarten and *H. Luther,* Clausthal-Zellerfeld (Germany)

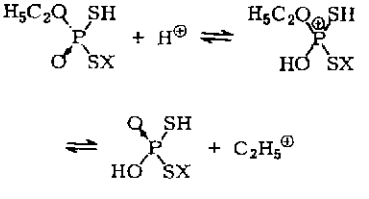
Zinc dialkyldithiophosphates are used, *inter alia*, in lubricants as oxidation and corrosion inhibitors. To obtain an insight into their mode of action, we have investigated their thermal decomposition kinetically. It was found from thermo-gravimetric measurements and from gas-chromatographic and infrared spectroscopic analyses that zinc dialkyldithiophosphates decompose in an autocatalytic reaction. An initial reaction, the nature of which is not yet elucidated, is followed by several steps catalysed by acidic compounds formed as intermediates, for which the following scheme is proposed (X = metal).

A. Formation of Alkyl Ions

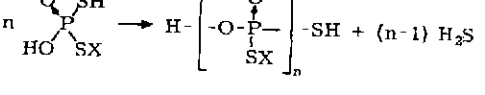
1. Decomposition of the diester



2. Decomposition of the monoester



B. Decomposition of the monometal dithiophosphate



C. Recombination steps

1. Formation of olefin

$$C_2H_5^{\oplus} \rightleftharpoons H_2C{=}CH_2 + H^{\oplus}$$

2. Formation of mercaptan and dialkyl sulfide

$$C_2H_5^{\oplus} + H_2S \rightleftharpoons C_2H_5\text{-}\overset{\oplus}{\underset{H}{\overset{H}{S}}} \rightleftharpoons C_2H_5\text{-}SH + H^{\oplus}$$

$$C_2H_5^{\oplus} + C_2H_5\text{-}SH \rightleftharpoons C_2H_5\text{-}\overset{\oplus}{\underset{H}{S}}\text{-}C_2H_5 \rightleftharpoons (C_2H_5)_2S + H^{\oplus}$$

The volatile decomposition products (dialkyl sulfides, mercaptans, olefins, hydrogen sulfide) arise in approximately the calculated amounts.

2

Separation of Enzymes of Pancreatic Fluid

W. Berndt and *W. Thorn*, Hamburg (Germany)

Rabbit pancreatic fluid, dialysed against 5×10^{-3} M phosphate buffer was chromatographed on DEAE-cellulose with 0.005 M phosphate buffer (pH 8.0). Lipase, procarboxypeptidase-K_1, trypsinogen, and chymotrypsinogen were eluted as cationic proteins with the solvent, followed by amylase. The separation of trypsinogen, still containing procarboxypeptidase-K_2, and chymotrypsinogen, was effected by gradient elution (phosphate buffer, pH 8.0, 0.005 M → 0.2 M). The other enzymes eluted with the solvent front were fractionated on CM-cellulose.

The enzymes of the pancreatic juice of the cat precipitate easily at low salt concentrations. Procarboxypeptidase, trypsinogen, and in particular lipase precipitate on dialysis against 5×10^{-3} M tris(hydroxymethyl)aminomethane buffer (pH 8.0). In this case, because of the necessary high salt concentration, ion-exchange chromatography is less suitable. Gel filtration on Sephadex G-100 (0.1 M tris buffer, pH 7.2, containing 1 M NaCl) gave a sharp separation of lipase, procarboxypeptidase, chromotrypsinogen + trypsinogen, trypsin inhibitor, and amylase. Under these conditions, the molecular weights of the procarboxypeptidase and trypsin inhibitor are about 57,000 and 8000. Lipase, with a molecular weight of about 100,000, migrated with the solvent front. A molecular weight of 24,500 was found for trypsinogen and chymotrypsinogen. Less pronounced separation effects are found with Sephadex G-200.

Characteristic species-dependent differences were observed on electrophoresis on cellulose acetate foils in 0.056 M veronal buffer (pH 8.6). The pancreatic juices of cats and rabbits were separated into several fractions.

3

Resonance of 1,2-Dithiacyclopenten-3-ones

F. Boberg, Hannover (Germany)

Infrared carbonyl bands and dipole moments provide information about electron displacements in 1,2-dithiacyclopenten-3-ones. The direction of the C–O bond moment can be determined by comparing the moments of halogenated 1,2-dithiacyclopentenones (Cl in the 4- and 5-positions). 4-Chloro-5-amino-1,2-dithiacyclopenten-3-ones possess extraordinarily high moments (up to 10 D), ascribed to the importance of the resonance structures with nitrogen as electron donor and oxygen as electron acceptor. The structures of the benzoylation products [1] of 4-chloro-5-anilino-1,2-dithiacyclopenten-3-one are confirmed by the dipole moments.

4

Microwave Spectrum and Structure of $(CH_3)_3C{-}C{\equiv}C{-}Cl$ [1]

H. K. Bodenseh, R. Gegenheimer, J. Mennicke, and *W. Zeil*, Kiel (Germany)

Rotational transitions of the following compounds have been measured (isotopes in natural abundance):

$(CH_3)_3C{-}C{\equiv}C{-}^{35}Cl$, $(CH_3)_3C{-}C{\equiv}C{-}^{37}Cl$, $(CH_3)_3C{-}C{\equiv}{}^{13}C{-}^{35}Cl$; $(CH_3)_3{}^{13}C{-}C{\equiv}C{-}^{35}Cl$, and $(CH_3)_2({}^{13}CH_3)C{-}C{\equiv}C{-}^{35}Cl$.

Lines of $(CH_3)_3C{}^{13}C{\equiv}C{-}^{35}Cl$ are only 0.2–0.5 Mc/s from the ^{12}C lines of the compounds $(CH_3)_3C{-}C{\equiv}C{-}^{35}Cl$ and $(CH_3)_3C{-}C{\equiv}C{-}^{37}Cl$, since the corresponding C-atom is very close to the center of gravity of the molecule, and they could therefore not be found. Because of the large number of excited vibrational states, every rotational transition gives very many lines. The absorption line corresponding to the vibrational ground state was determined by intensity comparisons at various temperatures. The following distances could be calculated directly from the measured rotational constants: $r_{\equiv C-Cl} = 1.638$ Å; $r_{\overline{C-C\equiv C}-} = 2.671$ Å. Even on the assumption of a short triple-bond distance of 1.205 Å, a value of only 1.466 Å is obtained for the length of the sp^3-sp single bond. This is about 0.03 Å less than in the analogous compounds t-butylacetylene and t-butyl cyanide [2]. No accurate information could be obtained on the position of the methyl C-atoms, since the lines of the transitions with $K_{-1} = 0$ and $K_{-1} \geqslant 2$ of the asymmetric molecules $(CH_3)_2({}^{13}CH_3)C{-}C{\equiv}C{-}^{35}Cl$ form an irresolvable group, and of the two lines with $K_{-1} = 1$, the one at higher frequency is masked by lines of excited vibrational states of the group mentioned, whereas the one at lower frequency could not be detected with certainty because of its low intensity.

[1] Previous investigations: *W. Zeil* et al., Z. Naturforsch. *15a*, 1011 (1960).

5

Alkali-Metal Thioferrates(III)

W. Bronger, Münster (Germany)

$RbFeS_2$ and $CsFeS_2$ [1] were first prepared, by a process known from the preparation of $KFeS_2$ [2], by the reaction of iron powder with a mixture of sulfur and rubidium and cesium carbonates, respectively, at 800 °C in an atmosphere of nitrogen, followed by purification with water. $NaFeS_2$ could not be obtained pure in this way, but could be so obtained by the reaction of iron powder with Na_2S_2 and sulfur at 800 °C under nitrogen. The compounds are produced as analytically pure, well-formed needle-shaped crystals with metallic luster.

For $RbFeS_2$, X-ray investigations on single crystals showed a structure isotypical with that of $KFeS_2$ [3] (space group C_{2h}^6-$C_{c/2}$; lattice constants $a = 7.22$ Å, $b = 11.70$ Å, $c = 5.42$ Å, $\beta = 112.0°$). For $CsFeS_2$, a hitherto unknown rhombic type of structure was found (space group D_{2h}^{25}-Immm; lattice constants $a = 7.13$ Å, $b = 11.92$ Å, $c = 5.42$ Å).

In the previously known alkali-metal thioferrates(III), the Fe atoms are surrounded tetrahedrally by the S atoms.

The tetrahedra are always linked through edges, so that relatively short Fe-Fe distances occur. In the $KFeS_2$ type, the alkali-metal ions have a coordination number of 8 with respect to the sulfur, and in $CsFeS_2$ they have a coordination number of 10.

Between 90 and 700 °K, $KFeS_2$, $RbFeS_2$, and $CsFeS_2$ have a slight, substantially temperature-independent paramagnetism, which indicates pronounced Fe-Fe interactions. Mixed crystals of the composition $K(Fe_{1-x}Al_x)S_2$ with $x \leq 0.08$ show a transition to normal paramagnetism, the Fe-Fe interactions being perturbed.

6

Quantitative Separation of RNA and DNA Structural Units on Cation-Exchangers

E. W. Busch and *N. Takriti*, Hamburg (Germany)

The cation-exchanger Dowex 50W, X 4 (400 mesh, Na^+ form) was used. On a column 60 cm long (diameter 1 cm) it was possible to separate the ribomononucleotides with the exception of thymidine and uridine monophosphates from the deoxyribomononucleotides. With a 10^{-3} M HCl solution and 10^{-2} M NaCl, or an ammonium formate buffer (pH 3.0, 0.05 M NH_3), the nucleotides were eluted in the sequence thymidine, guanosine, deoxyguanosine, cytidine, deoxycytidine, adenosine, and deoxyadenosine monophosphates. The small elution volumes (averaging about 15 ml) of individual substances were surprising. A small part (about 10 % of the amount added) of the purine derivatives of deoxyribose phosphate was hydrolysed on the column at room temperature. For quantitative determinations, it was therefore necessary to cool the column to 10 °C.

With a column 20 cm long, it was possible to separate the bases thymine, hypoxanthine, guanine, cytosine, methylcytosine, 6-methylaminopurine, and adenine with an ammonium formate buffer (pH 3.5, 0.06 M NH_3) and 0.35 M NaCl. The process is suitable for quantitative determination of the bases in acid hydrolysates of the DNA from mammalian organs in contrast to the well-known Cohn method, in which 2 N HCl is used as eluent.

The corresponding nucleosides can be separated with the same arrangement, except that the ammonium formate buffer has a lower pH (3.1).

It was possible to separate a mixture of bases and nucleosides on a column 50 cm long. The individual substances appeared in the sequence uridine, thymine, hypoxanthine, guanosine, cytidine and guanine (together), adenosine, cytosine, methylcytosine, adenine. The eluent consisted of an ammonium formate buffer (pH 3.5, 0.06 M NH_3) and 0.35 M NaCl. Cytine and guanine were distinguished photometrically by measurements at two different wavelengths.

7

Representation of Diffusion Coefficients by Melting Parameters

G. Döge, Braunschweig (Germany)

The temperature-dependence of self-diffusion coefficients is frequently described by the Arrhenius relation

$$D = D_0 \exp(-A/RT)$$

A rule, first found for liquid metals, that the constant A in this equation is proportional to the Gibbs free energy at the melting point, also applies to liquid alloys, liquid rare gases, and compounds whose molecules are approximately spherical and not highly polar. The proportionality factor is about 1.3. For the above substances and at low pressures, the coefficient of self-diffusion D_{Tm} at the melting point T_m is between 1.5×10^{-5} and 2.0×10^{-5} cm² sec^{-1}. This range is not greater than the error of most measurements in the liquid phase.

The Arrhenius relation can be rewritten in terms of D_{Tm} and T_m:

$$D = D_{Tm} \cdot \exp[(A/R)(T_m^{-1} - T^{-1})]$$

With this equation, it is possible to calculate very satisfactorily the unknown self-diffusion coefficients of the class of substances mentioned.

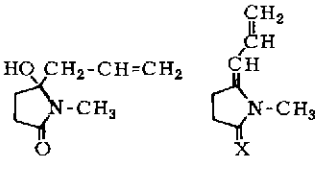
Theoretical consideration of this rule leads to the assumption that liquid phase at the melting point is to be regarded as a corresponding state. Reduction of the diffusion data of liquids to critical constants does not lead to a relation applicable to different classes of substances.

8

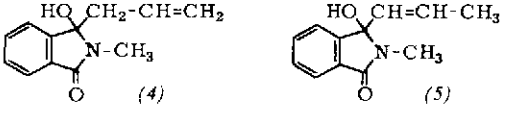
Anomalous Reactions of Imides with Grignard Compounds

W. Flitsch and *R. Heidhues*, Münster (Germany)

With excess of allylmagnesium bromide, cyclic imides form basic products that have not so far been obtained in the pure state. To elucidate the reaction, equimolar amounts of imides and Grignard compounds were allowed to react, and definite primary products of the reaction were obtained. Of these, the 2-allyl-2-hydroxy-1-methyl-5-pyrrolidone *(1)* arising from *N*-methylsuccinimide eliminates water on heating with the formation of 1-methyl-2-propenylidene-5-pyrrolidone *(2)*. This can be reduced to the pyrrolidine *(3)* with $LiAlH_4$.



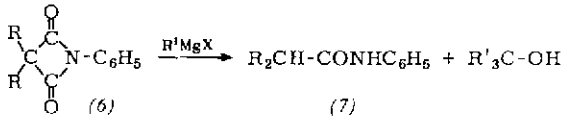
(1) *(2)*, X = O; *(3)*, X = H_2



(4) *(5)*

The 1-allyl-1-hydroxy-2-methyl-3-oxo-2,3-dihydro-1*H*-isoindole *(4)* formed from *N*-methylphthalimide does not, however, split out water but isomerizes on heating to *(5)*.

Malonimides *(6)* react with Grignard compounds with the formation of monocarboxylic anilides *(7)*:



(6) *(7)*

9

Investigations on Tetrathiopercarbonic Acid

G. Gattow and *J. Wortmann*, Göttingen (Germany)

The stoichiometric amount of gaseous HCl was passed slowly into a suspension of $(NH_4)_2CS_4$ in dimethyl ether cooled to about −78 °C. The liquid phase was filtered at about −78 °C

and the dimethyl ether was distilled off in vacuum. A yellow compound having the composition H_2CS_4 crystallized. The fact that this was not a solution of sulfur in H_2CS_3 was shown by investigations on the H_2CS_3/S system, by comparison of the infrared spectra and the spectra in the visible and ultraviolet regions, and by paper-chromatographic analysis. H_2CS_4 melts at −36 °C; the heat of fusion is 2.7 ± 0.5 kcal/mole. By determining the H_2S pressure over H_2CS_4 (isoteniscopic method) the enthalpy of formation of tetrathiopercarbonic acid was determined as $\Delta H_f = +9.7 \pm 0.8$ kcal/mole. In aqueous solution, H_2CS_4 decomposes according to first-order kinetics with a half-life of 14 sec at 0 °C. The acid dissociation constants at 0 °C were found to be $K_1 = 2.89 \times 10^{-4}$ and $K_2 = 1.4 \times 10^{-8}$. It can be concluded from the results that tetrathiopercarbonic acid must be formulated as SC(SSH)(SH).

10

Substrate Supply and Inhibition of the Metabolism of Rabbit Heart Perfused In Situ

G. Gercken and *P. Hürter*, Hamburg (Germany)

Because of the multiplicity of substances that the heart takes up from the flowing blood, it is difficult to determine the significance of individual substrates for cardiac metabolism. We have perfused rabbit hearts in the heart-lung preparation with a simplified blood consisting of washed and dialysed bovine erythrocytes in phosphate Ringer solution with 3 % of Haemaccel [*]. The effects of individual substrates supplied and of metabolism inhibitors on the function and metabolism of the heart were determined by the pressure-volume work and the content of ATP, ADP, AMP, creatine phosphate, inorganic phosphate, glycogen, glucose, glucose-1-phosphate, glucose-6-phosphate, fructose 1,6-diphosphate, dihydroxyacetone phosphate, lactate, and pyruvate in the muscle. The heart was kept capable of functioning by glucose, pyruvate, and fatty acids, in contrast to mannose, fructose, and metabolites of the citric acid cycle. If no nutrient was supplied, acute heart failure set in at an ATP content of 75 % and a creatine phosphate content of less than 50 % of the normal figure. A similar decrease in the glycogen content with a reduction in the energy-rich phosphate compounds was found with insufficiencies after disturbance of the oxidative metabolism (CO and KCN poisoning). Here, however, glycogen can be degraded only to lactic acid. After poisoning with NaF or monoiodoacetate, the hearts failed with a normal glycogen content and a concentration of energy-rich phosphate compounds reduced as with other insufficiences. Monoiodoacetate increased the concentration of dihydroxyacetone phosphate and fructose diphosphate to 100 and 50 times the normal values, respectively. The insufficiency due to inhibition of glycogenolysis indicates that the substrate chain phosphorylation in the cytoplasm is important for the contraction. The various insufficiencies due to inadequate availability of energy are in contrast with the insufficiency due to inhibition of the contractile proteins in which the energy-rich phosphate compounds and the glycogen increase above their normal amount.

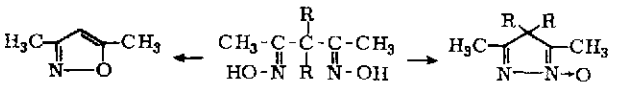
4H-Pyrazole N-Oxides from 1,3-Dioximes

H. Gnichtel and *H. Schönherr*, Berlin (Germany)

We have investigated the formation of heterocycles from the dioximes of acetylacetone *(1a)* and 3,3-dimethyl- *(1b)* and 3,3-diethylacetylacetones *(1c)*.

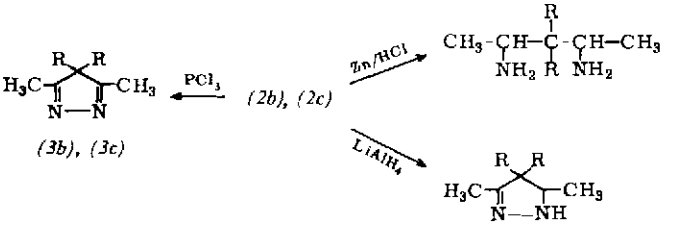
The action of thionyl chloride in liquid SO_2 on *(1a)* gives 3,5-dimethylisoxazole *(2a)*, while *(1b)* and *(1c)* gives 3,4,4,5-



(2a) *(1)* *(2b), (2c)*

(a), R = H; *(b)*, R = CH_3; *(c)*, R = C_2H_5

tetramethylpyrazole 1-oxide *(2b)* and 3,5-dimethyl-4,4-diethylpyrazole 1-oxide *(2c)*, respectively. In the reaction of *(1b)*, 3,4,4,5-tetramethylpyrazole *(3b)* and *N*-methyl-*N'*-acetylaminoisobutyramide were isolated as by-products. The *N*-oxide *(2c)* forms a very hygroscopic hydrochloride, the hydroxyl band of which is at 2100 cm^{-1}. The high dipole moment (6.8 D) is in harmony with the hypsochromic displacement of the ultraviolet absorption with increasing dielectric constant of the solvent.



(3b), (3c) *(2b), (2c)*

The presence of a 4*H*-pyrazole *N*-oxide is also proved by the deoxygenation of *(2b)* and *(2c)* with PCl_3 to the pyrazoles *(3b)* and *(3c)*, respectively. In contrast to other cyclic nitrones, the reduction of *(2b)* or *(2c)* with $LiAlH_4$ leads to pyrazoline.

The formation of *(2b)* and *(2c)* permits the conclusion that the dioximes *(1b)* and *(1c)* exist in the α-form *(4)*.

12

Resorption and Metabolism of cis-Octadec-12-enoic Acid in Man and Rat

G. Grimmer, Hamburg (Germany)

cis-Octadec-12-enoic acid is possibly a biosynthetic precursor of the octadeca-9,12-dienoic acids (*e.g.* linoleic acid).

Some hours after the administration of *cis*-octadec-12-enoic acid triglyceride to an experimental subject, samples of intestinal lymph and blood were taken and the lipids were isolated from them. After separation into cholesterol esters, triglycerides, phosphatides, and free fatty acids, the fatty acid composition of these fractions was determined by gas chromatography. Besides unchanged *cis*-octadec-12-enoic acid in all the fractions, the content of the octadecadienoic acids in all fractions with the exception of the phosphatides increased in the first 3 hours after the administration of the cis-octadec-12-enoic acid triglyceride. Six hours after the administration of the triglyceride, the content of octadecadienoic acids had fallen below the initial value. If, on the other hand, the experimental subject was given linoleic acid, the concentration of the octadecadienoic acids increased further even after six hours.

By oxidative degradation, it was possible to identify the bulk (85 %) of the octadecadienoic acid which occurred in the triglyceride fraction after the administration of *cis*-octadec-12-enoic acid as linoleic acid.

After the feeding of [^{14}C]-*cis*-octadec-12-enoic acid triglyceride to rats, approximately the same specific activities were found in the cholesterol esters, triglycerides, and free fatty acids, but only a quarter of this figure in the phosphatides. Under these

conditions the specific activity of the dienoic acids is only slightly less than that of the monoenoic acids (unchanged *cis*-octadec-12-enoic acid). It was found, however, that the dienoic acids consisted of equal parts of unlabeled linoleic acids (from the depot fat) and strongly labeled octadeca-12,15-dienoic acid. Consequently, *cis*-octadec-12-enoic acid is not a precursor of linoleic acid in the rat. In contrast to previous ideas, the second double bond is introduced nearer to the methyl end than to the carboxyl end of the acid.

13

Comparison of Calculated and Measured Line Intensities in X-Ray Fluorescence Analysis

K. H. Grothe and *G. Krause*, Hannover (Germany)

In the calculation of the intensity of X-ray fluorescence lines, monochromatic exciting radiation is generally assumed. For more accurate calculations, therefore, the intensity distribution of the Bremsspectrum of a tungsten tube was determined, including the characteristic lines.

The spectrum was subdivided into 600 equal, almost monochromatic sections, and for each of these sections the intensities of the K lines of cobalt and nickel were calculated with all correction factors taken into account. The sum of all the part-intensities gives the total fluorescence intensity. The calculations were carried out for mixtures of cobalt and nickel (Co:Ni = 0.01:1 to 60:1).

Although the strong tungsten lines in the exciting spectrum were only slightly below the cobalt and nickel absorption edges, the fluorescence lines were 50 % excited by the Bremsspectrum. Even regions of the Bremsspectrum with very much shorter wavelengths than the absorption edges still contributed considerably to the excitation.

It was possible to determine the secondary excitation of the cobalt line by the Kβ line of Ni by comparing the measured intensities with those in the calculation of which the secondary excitation was not taken into account. It amounted to about 8 % for a cobalt-nickel ratio of 1:1 and about 20 % for higher concentrations of nickel. This method is generally applicable to the determination of the secondary excitation.

14

New Phases Near the Composition $NbO_{2.5}$)

R. Gruehn, *D. Bergner*, and *H. Schäfer*, Münster (Germany

With M = (Nb^{IV}, Nb^{V}) and (Nb^{V}, W^{VI}) ten independent phases are observed in the range from $MO_{2.4}$ to $MO_{2.6}$; the numerous modifications of Nb_2O_5 are not included in this number.

The Nb/O system was investigated with an arrangement with which the heterogeneous equilibrium could be measured simultaneously. At 1300 °C, Nb_2O_5 or NbO_2 was heated in definite mixtures of H_2O and H_2 (method A). Under these conditions, all the NbO_x phases mentioned below can be obtained.

The narrow phase $NbO_{2.482}$ and the homogeneity region $NbO_{2.479-2.467}$ are available by chemical transport (method B) as well as by method A [1, 2]. Compounds of the same type arise in the heating of mixed precipitates (method C) in the TiO_2-Nb_2O_5 system [1]. The upper phase boundary at $MO_{2.479 \pm 0.001}$ is identical with the compound $TiNb_{24}O_{62}$ ($MO_{2.480}$) the structure of which was determined by *Roth* and *Wadsley* [3a]. The high stability of the lower phase boundary $MO_{2.467}$ is surprising; this can be obtained as (Nb^{IV}, Nb)$O_{2.467}$ (methods A, B), (Ti^{IV}Nb)$O_{2.467}$ (method C), and by heating the oxide mixture (method D) as (Al, Nb)$O_{2.467}$[4], (Ga, Nb)$O_{2.467}$ and (Fe^{III}, Nb)$O_{2.467}$.

Method A gives two other phases: $NbO_{2.453}$, which is identical with *Norin*'s $Nb_{22}O_{54}$ ($NbO_{2.454}$) [5], and $NbO_{2.460-2.466}$. The latter gives Guinier diagrams very similar to those of the new compound (Nb, W)$O_{2.506-2.512}$ (method D). The upper limits of the two phases possibly correspond to the members of a new structurally related series $M_{3n+2}O_{8n-1}$ with n = 10 and n = 13.

As the lowest phase, $NbO_{2.417}$(I) arises at 1100 °C and $NbO_{2.417}$(II) at 1300 °C by method A; both can also be obtained by method B [1].

In the Nb_2O_5/WO_3 system (method D), we found a further new compound (Nb,W)$O_{2.567}$. The Guinier diagram shows a close relationship to the neighboring phases (Nb,W)$O_{2.538}$ and (Nb,W)$O_{2.589}$, the structures of which were determined by *Roth* and *Wadsley* [3b]. However, (Nb,W)$O_{2.567}$ is obviously not to be assigned to one of the structural series $M_{3n+1}O_{8n+1}$ and $M_{4n+3}O_{11n}$ to which these and other phases belong [3b].

The composition of the phase (Nb,W)$O_{2.653 \pm 0.005}$ (method D, 1000–1100 °C) differs from the ratio $Nb_2O_5 \cdot WO_3 (= MO_{2.667})$. A previously described "$Nb_2O_5 \cdot WO_3$" [6] should probably be described as (Nb,W)$O_{2.653}$. The corresponding (Ta, W)$O_{2.653}$ has also been found.

15

Mass-Spectrometric Sequence Analysis of Acetylated Peptides of Aromatic Amino Acids

H. Grützmacher, Hamburg (Germany)

In the mass spectra of simple aliphatic *N*-acetylpeptides, aminoacylium or iminium ions are formed preferentially by cleavage of the CO–NH or the –CHR–CO– bonds. These reactions can be explained by the removal of an electron from the electron-rich peptide group on electron impact. Aromatic systems are also readily ionized by electron impact. When phenylalanine, tyrosine, tryptophan, or histidine is present in the petide chain, the positive charge in the molecule ion can also be taken over by the aromatic side-chain, which leads to the frequent formation of "side-chain" ions $Ar-CH_2^{\oplus}$. The intensity of the lines due to these ions is particularly high with an *N*-terminal position of the aromatic amino acid. It increases in the sequence phenylalanine < histidine < tyrosine < tryptophan. The same sequence is found from the mass spectra of simple amino acid derivatives. The relative intensities of the otherwise common aminoacylium and iminium ions decrease in the same sequence. A second reaction typical of the mass spectra of the *N*-acetylpeptides of aromatic amino acids is the elimination of the amino group together with the adhering acyl residue as a neutral amide molecule from the molecular and fragment ions.

The nature and the position of the aromatic amino acid in the peptide can be determined from the mass number of these characteristic ions.

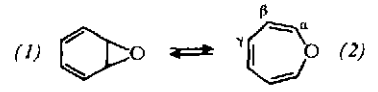
16

NMR-Spectroscopic Investigations of the Kinetics of the Benzene Oxide-Oxepin Equilibrium

H. Günther, Köln (Germany)

Oxepin [1] exhibits a proton-resonance spectrum at room temperature which agrees neither with the structure of benzene oxide *(1)* nor with the valence-tautomeric monocyclic

structure *(2)*. The absorption of the γ-, β-, and α-protons at 3.9, 4.4, and 4.8 τ and the temperature-dependent changes of the spectrum are however satisfactorily explained by the assumption of a valence-tautomeric equilibrium *(1)* ⇌ *(2)* with comparable concentrations of the two forms.



The existence of valence-tautomerism has now been confirmed by NMR measurements in CF_3Br/pentane (2:1) between −87 and −127 °C. After broadening of all the signals, an incipient splitting of the α-proton signal is observed at *ca.* −113 °C. At −127 °C, the spectrum corresponds to a superposition of the spectra of the two compounds. On the basis of the intensity ratio found, the following assigment was made:

$$\tau^{\alpha}_{(1)} = 6.0;\ \tau^{\beta}_{(1)} = 3.7;\ \tau^{\gamma}_{(1)} = 3.7;\ \tau^{\alpha}_{(2)} = 4.3;\ \tau^{\beta}_{(2)} = 4.3;\ \tau^{\gamma}_{(2)} = 3.7.$$

The relative chemical shift between the α-protons in *(1)* and *(2)* is 100.8 ± 5.1 cps. The mole fractions of the two forms are obtained from the intensity ratios of the signals below the coalescence temperature and from the chemical shift of the α-protons in the averaged spectrum ($\nu^{\alpha} - p_{(1)}\nu^{\alpha}_{(1)} + p_{(2)}\nu^{\alpha}_{(2)}$) above −110 °C, and the equilibrium constants are obtained from $K = p_{(2)}/p_{(1)}$. The temperature-dependence of K gives the heat of the reaction *(1)* → *(2)* as $\Delta H^{\circ} = 1.7 \pm 0.4$ kcal/mole. The life-time $\tau_{(1)}$ of benzene oxide was determined from the half-width of the α-proton signal in the region of slow exchange below the coalescence temperature and of fast exchange above −110 °C. The line width was corrected for field inhomogeneity and spin-spin coupling with the β-protons. Using 10 measured points, the Arrhenius equation gives an activation energy of $E_a = 9.1 \pm 0.8$ kcal/mole and a frequency factor $A = 2.5 \times 10^{14}$ for the reaction *(1)* → *(2)*. For the reverse reaction $E_a = 7.2 \pm 1.0$ kcal/mole and $A = 1.3 \times 10^{12}$. The ratio of the frequency factors gives the entropy change for the reaction *(1)* → *(2)* as $\Delta S^{\circ} = 10$ cal. deg.$^{-1}$ mole^{-1}.

17

Sulfophthalein Ethers

H. Haeussler, Seelze (Germany)

Alcoholic solutions of some sulfophthaleins bleach on long standing, owing to the formation of ethers. This reaction has been investigated with Phenol Red as an example, using *Stahl*'s gradient thin-layer technique [1].

Phenol Red first forms the yellow monomethyl ether and then a colorless dimethyl ether in the sultone form. The sultone dissolved in dioxane migrates to the solvent front on a thin-layer plate. At pH 1.7, it forms the pink cation when the developed plate is dried. Above pH 2, the sultone adds on water when the starting spot is dried, to form the dimethyl ether of the carbinol form; partial hydrolysis to the monomethyl ether also occurs. If the sultone is applied in methanolic solution, above pH 8 the trimethyl ether of the carbinol form is formed as well, by the addition of methanol to the sultone of the dimethyl ether.

Phenol Red reacts with higher alcohols in a substantially similar manner. The reaction rate decreases considerably with increasing chain length. However, the dimethyl ether of Phenol Red adds alcohols instantaneously. This reaction is proposed for the identification of alcohols, because of the distinct R_f-values of the mixed trialkyl ethers formed. The dimethyl ether also reacts instantaneously with ammonia and with primary and secondary amines.

Alcoholic solutions of Chlorophenol Red, Bromophenol Red, and Thymol Blue also form ethers readily. On the other hand, solutions of Bromophenol Blue and Bromocresol Green are stable on storage.

18

Acid-Catalysed Rearrangements of N-Halogenoguanidines

A. Heesing, H. Schulze, and *U. Wernicke,* Münster (Germany)

The thermal stability of alkylated *N*-chloroguanidines depends markedly on the position of the alkyl groups. Symmetrically disubstituted guanidines give the most stable *N*-halogeno derivatives. Explanation of this effect is difficult because of the large number of possible isomers and tautomers.

Arylguanidines can be converted into *N*-halogeno compounds only if oxidation to intensely colored quinoid by-products is inhibited by substitution. This oxidation does not take place with arylated amides, ureas, and amidines.

On thermal decomposition of *N*-halogenoguanidines, most of the guanidine is re-formed; in addition, alkyl and arylalkyl side-chains are split off as aldehydes or acids. Chlorinations in the sense of a thermally induced Orton rearrangement [1] play no part.

Aralkylated *N*-chloroguanidines rearrange almost instantaneously in concentrated sulfuric acid to products chlorinated in the nucleus. Trapping experiments show the intermolecular character of the rearrangement. The high velocity and the high *o*/*p* ratio show that the reaction takes place through Cl^+ (or the protonated *N*-chloroguanidine). The reaction therefore corresponds only formally to the Orton rearrangement.

The same isomer ratio (*o*:*m*:*p* = 7: *ca.* 0:3) is obtained in the chlorination of alkylguanidines with other *N*-chloro compounds (*e.g.*, *N*-chlorosuccinimide, -phthalimide, and -acetamide) in concentrated sulfuric acid. The guanidinium group, which is separated by one or two CH_2 groups from the phenyl group, thus exerts no directing effect on the substitution despite its charge. *N*-Phenyl-*N*-methylguanidine also gives also gives very little of the *meta* isomer in the rearrangement of its *N'*-chloro-derivative and in the chlorination with the very active *N*-chloro-*N'*-butylguanidine (*o*:*m*:*p* = 1:1:4). The reactions are significantly slower. The small amount of *o*-isomer must be ascribed to the repulsion of the attacking cation by the charge of the guanidinium group. The small extent of the *m*-directing effect, which is surprising when compared with all other positively charged first substituents that have so far been investigated [2], can be explained by mesomerism between the phenyl and the guanidine groups, as a result of which the phenyl residue is made negative in the *o*- and *p*-positions.

19

Reactions of Alkylaluminum Compounds with Diazomethane

H. Hoberg, Mülheim/Ruhr (Germany)

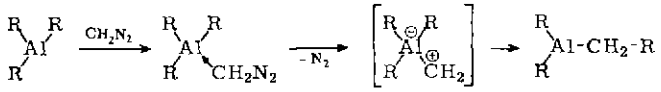
The action of CH_2N_2 at room temperature on organoaluminum compounds R_2AlX (X = R,H, halogen, or OR) gives rise to the evolution of N_2. Reactions are rapid when X = Cl, Br, or I, the corresponding halogenomethylaluminum compounds $R_2Al\text{-}CH_2X$ being formed [1]. When X = H or R, the products *(1)* are immediately produced.

$$R_2AlX + 3m\ CH_2N_2 \longrightarrow Al\text{-}(CH_2)_{m_1}\text{-}R\ (CH_2)_{m_2}\text{-}R\ (CH_2)_{m_3}\text{-}X + 3m\ N_2$$

(1), $m_1 + m_2 + m_3 = 3m$

Aluminum compounds with X = H are more reactive with respect to diazomethane than those with X=R, whereas those with X = CH_3 react less readily than those with X = CH_2–R. This agrees with the situation in the reaction between 1-alkenes and the corresponding Al compounds [2]. With diazomethane, R_2AlX with X = F or OR forms exclusively polymethylene with slow elimination of N_2. CH_2N_2 does not react at room temperature with dialkyl-*N*-dialkylaminoaluminum $R_2Al\text{-}NR_2$. The same applies to salt-like organoaluminates, *e.g.* $Na[Al(C_2H_5)_4]$.

While the formation of compounds *(1)* is explained by the intermediate formation of an "inverse Al-ylide" *(2)*, the



(2)

formation of polymethylene must be regarded as a catalytic reaction of the organoaluminum compounds.

20

Coordination Chemistry of Organometallic Compounds of Group IVb Elements

F. Huber, Aachen (Germany)

8-Hydroxyquinoline (HOx) reacts with R_2PbHal_2 in alcoholic solution on addition of NH_3 to give yellow, crystalline dioxinates $R_2Pb(Ox)_2$ (R = CH_3, decomp. p. > 135 °C; C_2H_5, decomp. p. > 120 °C; n-C_4H_9, decomp. p. > 120 °C; C_6H_5, decomp. p. > 167 °C), while on addition of water, crystalline, yellow complexes of the composition $R_2PbHal(Ox)$ precipitate, which can be recrystallized from methanol. Analogous compounds arise when alcoholic solutions of HOx and R_2PbA_2 (A = NO_3; carboxylate) are mixed. Some representatives of this new kind of compound $R_2MX(Ox)$ have also been prepared with M = Sn and Ge (see Table).

	R	X	Decomp. p. > °C
$R_2PbX(Ox)$	CH_3	CF_3CO_2	190
	C_2H_5	Br	110 m.p.
	n-C_4H_9	Cl	122
		CH_3CO_2	180
	C_6H_5	Cl	187
		NO_3	228
		$C_2H_5CO_2$	212
		$ClCH_2CO_2$	204
		CF_3CO_2	240
$R_2SnX(Ox)$	CH_3	Cl	157 m.p.
	n-C_4H_9	Cl	50
		CH_3CO_2	142
	C_6H_5	Cl	147 m.p.
$R_2GeX(Ox)$	C_6H_5	Cl	34

Molecular weight determinations show that some of these compounds (particularly the halogenooxinates) are monomeric in solution, while others are polymeric. In agreement with the result of conductivity measurements, this excludes a salt-like structure $[R_2M(Ox)]X$ with a coordination number of 4; it is assumed that in the monomeric compounds the metal has a coordination number of 5 and in the polymers a coordination number of 6.

In the dioxinates $R_2M(Ox)_2$ [$(C_6H_5)_2Ge(Ox)_2$, decomp. p. > 140 °C has also been prepared] and in the benzoylacetonates [*e.g.* $(C_6H_5)_2Pb(Bzac)_2$, m.p. 160 °C], as in the donor-acceptor complexes $R_2MX_2{\cdot}2D$ (*e.g.* D = pyridine) there is a coordination number of 6 (prepared for the first time: M = Pb; R = C_2H_5, n-C_4H_9, C_6H_5 [1]; X = Cl, Br; – M = Sn; R = n-C_4H_9, C_6H_5; X = Cl, CH_3COO; D/2 = 1,10-phenanthroline, 2,2′-dipyridyl; – M = Ge; R = n-C_4H_9, C_6H_5; X = Cl; D/2 = 1,10-phenanthroline). The tendency of R_2PbX_2 to form coordination compounds is more pronounced than was previously assumed. The reaction of R_4Pb (R = CH_3, C_2H_5, C_6H_5) with dry SO_2 gives $R_2Pb(SO_2R)_2$, a sulfinate which is insoluble in all the usual solvents and is, on the basis of infrared spectra, a coordination polymer with sixfold-coordinated Pb.

[1] $(C_6H_5)_2PbCl_2$·phenanthroline and $(C_6H_5)_2PbCl$ 2,2′-dipyridyl have recently also been prepared by *K. Hills* and *M. C. Henry*, J. organomet. Chemistry *3*, 159 (1965).

21

Metabolite Content and Function of the Substrate-Free Perfused Rabbit Brain

P. Hürter and *G. Gercken*, Hamburg (Germany)

According to *Geiger et al.* [1], cat's brain remains capable of functioning on artificial perfusion with nutrient-free solution for more than one hour. This raises the question of what materials are degraded when glucose is not available for the production of energy.

We have investigated the influence of a substrate deficiency on the rabbit brain with the help of an arrangement in which the head, separated from the circulation of the body, was perfused with a Sigma-pump. The natural blood flow was then completely prevented, and the circulation was independent of regulation by the brain centers. The perfusion solution used was a simplified blood consisting of bovine erythrocytes and phosphate Ringer solution with the addition of Haemaccel. The contents of adenosine triphosphate, creatine phosphate, glycogen, glucose, and lactate were determined enzymatically in brain tissue taken after various times, and were fixed in liquid air. With a low supply of glucose (1 mmole/l of the perfusion solution), spontaneous electric potentials of the brain were also recorded after 60 min from the beginning of perfusion. The contents of ATP and creatine phosphate in the brain remained unchanged. On the other hand, with complete absence of glucose, the functioning of the brain ceased after about 7 min. After 10 min the intracellular content of free glucose was only 0.3 µmole/g of fresh tissue and after 30 minutes 0.05 µmole/g. The concentration of energy-rich phosphate compounds had already fallen after only 10 minutes. Within 30 minutes, the ATP content fell from 2.0 to 0.32 µmole/g of fresh tissue and the content of creatine phosphate from 2.1 to 0.29 µmole/g. In contrast to experiments on oxygen deficiency [2], the glycogen content of the brain with substrate deficiency and a sufficient supply of oxygen fell only slowly. Since the signs of an energy deficit appeared even in the first few minutes, under these conditions the rate of degradation of glycogen is obviously not sufficient to cover the lack of free glucose.

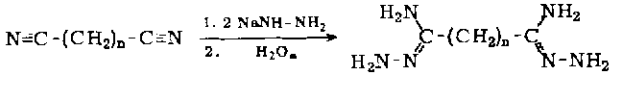
22

Uses of Sodium Hydrazide for the Synthesis and Degradation of Organic Compounds

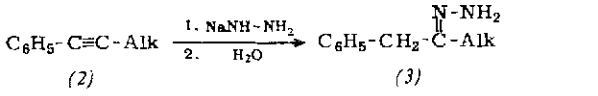
Th. Kauffmann, L. Bán, W. Burkhardt, E. Rauch, and J. Sobel, Münster and Darmstadt (Germany)

The hitherto unknown diamidrazones *(1)*, which undergo interesting polymerization reactions, are obtained conveniently and in good yield by treating the corresponding dinitriles in boiling ether with sodium hydrazide in the presence of free hydrazine. Under conditions (excess of sodium hydrazide without the addition of hydrazine, ether at 0 °C) which lead almost quantitatively to amidrazones in the case of mononitriles, aliphatic dinitriles remain substantially unaffected.



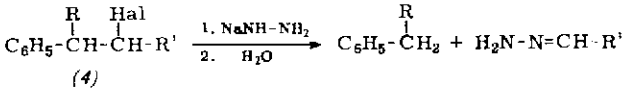
(1)

With alkyl groups other than CH_3 (for which metallation takes place), acetylenes *(2)* react with sodium hydrazide in boiling ether to give good yields of hydrazones *(3)* from which the corresponding ketones, amines, and azines can be conveniently prepared.



(2) *(3)*

Halides of type *(4)* (Hal = Cl, Br, I; R and R′ = H or alkyl) are split by sodium hydrazide in boiling diethyl or diisopropyl ether. As a rule, the yields of toluene are higher than 75%. On the other hand, halides of types *(5)* and *(6)* give only a small amount of toluene in corresponding reactions. Here the main reaction is the substitution of the halogen by hydrogen [halides *(5)*] or by the hydrazino group [halides *(6)*].



(4)

(5) *(6)*

In the splitting of ethylenes *(7)* with sodium hydrazide [1], in accordance with *M. S. Newman*'s "rule of six" [2], the rate of decomposition fails suddenly when the unbranched alkyl residue, extended from 4 to 5 and more C-atoms, is capable of sterically screening the olefinic double bond.

(7)

Aromatic sulfonic acids are smoothly converted into the corresponding arylhydrazines by treatment with sodium hydrazide in ether at 35 °C. Thus *p*-toluenesulfonic acid *(8)* gives *p*-tolylhydrazine *(9)* in 98% yield; since no *m*-tolylhydrazine forms, the substitution takes place by the addition/elimination mechanism. This surprising reaction opens up a new route to arylhydrazines.

23

Reactions of Trithiocarbonic Acid

B. Krebs and *G. Gattow*, Göttingen (Germany)

Trithiocarbonic acid $SC(SH)_2$ is a versatile reagent for the introduction of the CS_3 group: because of its ready decomposition into H_2S and CS_2, it is often a preparatively more convenient substitute for H_2S in the preparation of R^1-S-R^2 bonds (R^1,R^2 = inorganic or organic groups) or for the preparation of inorganic sulfides sensitive to hydrolysis. The reaction of $SC(SH)_2$ with mono- or polyfunctional halogen compounds takes place particularly smoothly.

In particular, the following compounds have been prepared by the reaction of stoichiometric amounts in chloroform or benzene:

1. chemically very stable, yellow to orange-brown solid polymers of uniform composition $(CS_3)_n$ and $(CS_{2.5})_n$ (n = 8 to 12) by the reaction of $SC(SH)_2$ with Br_2 or from Na_2CS_3 + S + thiophosgene [1];

2. 1,3-dithiolan-2-thione-4,5-dione $C_3O_2S_3$ in the form of lustrous red crystals by the reaction of $SC(SH)_2$ with oxalyl chloride [2];

3. dimeric thiomalonic anhydride $(C_3H_2O_2S)_2$ as colorless crystals by reaction with malonyl chloride;

4. thiosuccinic anhydride $C_4H_4O_2S$ from $SC(SH)_2$ and succinyl chloride;

5. a yellow, chemically very stable polymer of composition $(S-CO-CH=CH-CO)_n$ (n = 4 or 5) from $SC(SH)_2$ and fumaroyl dichloride;

6. a very stable, yellow polymer insensitive to hydrolysis, of uniform composition $[SP(C_{0.5}S_{1.5})_3]_n$ from PCl_5 and $SC(SH)_2$, as well as a similar compound from $SC(SH)_2$ and PCl_3;

7. solid white addition compounds $BX_3 \cdot SC(SH)_2$ stable below −20 °C by the reaction of the boron halides BF_3, BCl_3, and BBr_3 with $SC(SH)_2$; and

8. Al_2S_3 by the reaction of $SC(SH)_2$ with $AlCl_3$.

Other new products were obtained in the reaction of $SC(SH)_2$ with Se_2Cl_2, $SeCl_4$, and BrCN at low temperatures. The compounds prepared were characterized by chemical, infrared spectroscopic, and X-ray methods.

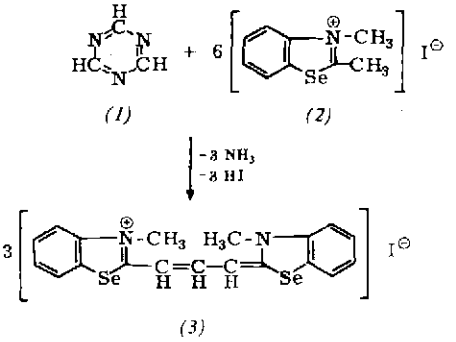
24

Ring Opening of 6-Membered Heterocycles by Nucleophilic Reagents

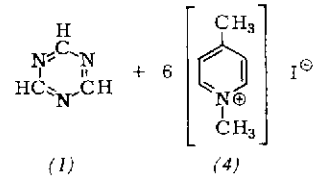
A. Kreutzberger, Münster (Germany)

1,3,5-Triazine *(1)* and 2,3-dimethyl-1,3-benzoselenazolium iodide *(2)* in anhydrous pyridine give bis[methylbenzoselenazole-(2)]-trimethinecyanine iodide *(3)* in a smooth reaction and with good yield. In contrast to the condensation of *(2)* with orthoformic ester, the 1,3,5-triazine method permits the use of lower temperatures and shorter reaction times.



(1) *(2)* *(3)*

This method is also applicable to quarternary bases which cannot be condensed with orthoformic ester. While *N*-methyl-γ-picolinium iodide *(4)* reacts with chloroform only in the presence of a large excess of caustic potash and with strong heating, with 1,3,5-triazine it forms bis-[1-methyl-pyridine-(4)]-trimethinecyanine iodide *(5)* even on moderate heating of the reaction mixture.



(1) *(4)*

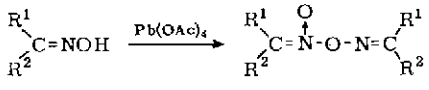
25

The Oxidation of Aromatic and α,β-Unsaturated Oximes with Lead Tetraacetate

H. Kropf, Hamburg (Germany)

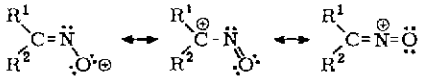
Whereas the reaction of aliphatic and alicyclic oximes with lead tetraacetate gives *gem*-acetoxynitrosoalkanes or their dimers [1], these can be detected only for a very short time or not at all in the oxidation of aromatic and α,β-unsaturated oximes. In solvents such as ether, tetrahydrofuran, benzene, and methyl chloride, in addition to the carbonyl compounds, the corresponding oxime anhydride *N*-oxides *(1)* are obtained [2].



(1)

Examples: α- or β-benzaldoxime → benzaldoxime anhydride *N*-oxide; α- or β-cinnamaldoxime → cinnamaldoxime anhydride *N*-oxide; α- or β-furfuraldoxime → furfuraldoxime anhydride *N*-oxide; benzophenone oxime → benzophenone oxime anhydride *N*-oxide; benzil α- or β-dioxime → diphenylfuroxan.

The formation of these compounds is explained as a trapping reaction of the mesomeric cations *(2)* arising as primary products by unconverted oxime.



(2a) *(2b)* *(2c)*

Since in no case were sterically individual isomers isolated after the oxidation of unsymmetrically substituted oximes, in particular of aldoximes, participation of the limiting structure *(2c)* cannot be excluded.

The carbonyl compound corresponding to the oxime used probably arises from the *gem*-acetoxynitrosoalkane formed as an intermediate *via* a *gem*-diacetoxy compound. This is also indicated by the appearance of nitrous gases in the reaction in glacial acetic acid, in which it was also not possible to detect any oxime anhydride *N*-oxide. Benzaldoxime anhydride *N*-oxide can be disproportionated with HCl/glacial acetic acid to the oxime and the nitroso compound.

[1] *D. C. Iffland* and *G. X. Criner*, Chem. and Ind. *1956*, 176; *H. Kropf* and *R. Lambeck*, unpublished work.

[2] Some of these compounds have also been prepared from the oximes with nitrous gases, nitrous acid, Na hypochlorite, or I_2/Na_2CO_3, and have been called oxime peroxides: *J. L. Smith*, Chem. Rev. *22*, 239 (1938); *J. H. Boyer* and *H. Alul*, J. Amer. chem. Soc. *81*, 4237 (1959).

26

Coordination Polymers of Dialkylphosphinic Acids

W. Kuchen and *H. Hertel*, Aachen (Germany)

Phosphinic acids occur in metal complexes in various ways as bridge ligands. The dialkyldithiophosphinato complexes $[R_2PSS]_2M$ of Zn(II), Cd(II), and Hg(II) are associated through ligand bridges. The corresponding Zn(II)-complexes of the acids $(C_2H_5)_2PSSeH$ and $(C_2H_5)_2PSeSeH$ exhibit a slight association in benzene solution. On the other hand, molecular weights of up to about 15,000, depending on the pretreatment of the preparations, have been found for the dialkylphosphinate complexes $[R_2POO]_2Co$ ($R = C_3H_7$, C_4H_9) in benzene. Coordination polymers also arise in the reaction of diethyldithiophosphinic acid or its sodium salt with metal carbonates or the corresponding halides in organic solvents:

$$\begin{matrix} 2\ (C_2H_5)_2PSOH + MCO_3 \\ \text{or} \\ 2\ (C_2H_5)_2PSONa + MX_2 \end{matrix} \xrightarrow[-\ 2\ NaX]{-H_2O,\ \ CO_2} [(C_2H_5)_2PSO]_2M$$

The colorless bis(diethylthiophosphino)-zinc(II) and the corresponding deep blue Co(II) complex are powders which melt without decomposition and dissolve in organic solvents after previous swelling. On evaporation, their very viscous benzene solutions leave smooth highly adherent films. Osmometric molecular weight determinations in benzene have shown a marked concentration-dependence of the molecular weights; for example, the molecular weight of the Zn complex varies between 3000 and 12,000 (at 10–65 g/l, 25 °C). A molecular weight of 60,000 (± 20%) was found for the Co complex with a Zellophan-600 membrane, which proved to be permeable to small amounts of low-molecular weight components of the polydisperse substance. The reduced viscosities, which increase strongly with increasing concentration of the benzene solutions of the two complexes, and also the concentration- and temperature-dependences of the molecular weights, indicate that weakly aggregated threadlike molecules are present.

27

Structure and Thermodynamics of Molten Halides

H. Kühnl, Giessen (Germany)

When halides of multivalent metals are dissolved in molten alkali-metal halides, halogeno complex ions are formed. Information on the coordination and association of the dissolved salts is given by a comparison of the liquidus lines on the alkali-metal chloride side of the phase diagram with curves calculated theoretically. The latter were obtained by a method due to *Flood* and *Urnes* [1] based on the Temkin model of salt melts.

According to this model, in melts of KCl the chlorides of bivalent Cr, Mn, Fe, Co, Cu, Zn, Cd, and Mg form complexes of the type $[MCl_4]^{2-}$. On the other hand, $TiCl_2$ and VCl_2 associate to form complicated mixtures of polynuclear complex ions. Solutions of $TiCl_3$, VCl_3, $CeCl_3$, and $PuCl_3$ in a KCl melt show that the chlorides of the trivalent ions are present predominantly as $[MCl_6]^{3-}$ complexes. $AlCl_3$ and $FeCl_3$ are

exceptions; with these substances the existence of ions of the type $[M_2Cl_8]^{2-}$ must be assumed.

Analogous statements apply to solutions in molten RbCl. Because of the higher charge density of the Na^+, lower mean coordination numbers are obtained in a melt of NaCl than in molten KCl or RbCl.

The influence of the composition of mixed melts of alkali-metal halides, sometimes with added alkaline-earth metal halides, on the enthalpies of solution of $FeCl_2$ and $FeBr_2$ was investigated by EMF measurements. In this case the solvent can be described by the mean charge density of the cations or anions. A bend in the plot of the enthalpy of solution against cation charge density indicates that in solutions of $FeCl_2$, complex anions change into cationic units at a charge density of 1.2.

A change in the mean charge density of the anions in solutions of $FeBr_2$ in bromide melts affects the excess Gibbs free energy of solution 10–15 times more strongly than a corresponding change in the cations, since the Fe^{2+} ions are affected by the anions from the first coordination sphere and by the cations of the second coordination sphere.

28

Metabolite Content and Protein-Synthesizing Capacity of Cat Pancreas Before and After Interruption of the Circulation for Two Hours

F. Liemann and *W. Berndt*, Hamburg (Germany)

We have investigated the synthesis of protein in cat pancreas as a function of the energy metabolism. For this purpose, the protein synthesis was stimulated by infusion of the hormones pancreozymin and secretin, and, with continuation of the infusion, the flow of blood through the gland was interrupted for 2 hours. The metabolites of the energy metabolism and the protein synthesis were determined before the infusion, after 2 hours of infusion, after interruption of the circulation for 2 hours, and 2 hours after restoring the circulation. The results show: 1) the infusion brings about a considerable increase in the rate of metabolism, 2) the ADP-content of the pancreas is not increased after interruption of the circulation for 2 h; 3) the cellular components responsible for the synthesis of protein withstand an interruption of the circulation for 2 h; 4) after interruption of the circulation, less protein is secreted per unit time, but it contains all enzymes in the same ratio as before.

29

New Compounds of the $CaFe_2O_4$ Type

Hk. Müller-Buschbaum, Münster (Germany)

Compounds of the composition $M^{2+}M_2^{3+}O_4$ (where M^{2+} is, for example, Mg, Ca, Sr, Ba, and M^{3+} is Sc, Y, La) have been obtained in a plasma furnace above 2000 °C in well-crystallized form. So far, $CaSc_2O_4$, SrY_2O_4, and $MgSc_2O_4$ have been investigated by X-ray analysis. The compounds, which are colorless, stable to air, and soluble in hot mineral acids, crystallize orthorhombically in the space group D_{2h}^{16}-Pnam and are isotypical with $CaFe_2O_4$ [1, 2] (lattice constants $CaSc_2O_4$: a = 9.65, b = 11.20, c = 3.16 Å; SrY_2O_4: a = 10.08, b = 11.91, c = 3.40 Å; $MgSc_2O_4$: a = 9.51, b = 10.83, c = 3.11 Å). M^{3+} is always surrounded octahedrally by oxygen, whereas M^{2+} has six O-neighbors in the form of a trigonal prism with other O-particles arranged over the prism surfaces, two of these belonging to the coordination sphere [3]. The distribution of metal in $MgSc_2O_4$, which no longer corresponds to $CaSc_2O_4$, is remarkable. Calculations of structure factors and $(F_o - F_c)$ syntheses show that Mg and Sc are statistically distributed over the metal positions. This result is in accord with the mean distances between the positions of M^{3+} and oxygen, which are smaller than the sum of the ionic radii (2.10 Å instead of 2.14 Å), or the mean Sc^{3+}–O distances in other scandium compounds. The prismatic environment present for the M^{2+} particles is "too large" for the relatively "small" Mg^{2+} ions. It is true that this discrepancy is moderated by partial replacement of the Mg by Sc particles, but it is not eliminated. $MgSc_2O_4$ must therefore, in contrast to the metallates $CaSc_2O_4$ and SrY_2O_4, be regarded as a mixed oxide.

Distance calculations on compounds of the $CaFe_2O_4$ type show that the $[M^{3+}{}_2O_4]^{2-}$ anion skeleton is immobile and rigid. The existence of such compounds therefore depends strongly on the size of the cation. The margin for the existence of stable compounds with small M^{2+} ions is greater than that for stable compounds with large cations. The fact that it has not so far been possible to prepare $CaSc_2O_4$ is due to this effect.

The holes for the M^{2+} ions become greater with increasing size of the octahedra of M^{3+} ions. However, the compound BaY_2O_4 can be prepared because of the larger $[Y_2O_4]^{2-}$ skelton as compared with Sc.

Colloid Chemical Investigations on Asphaltenes

H. J. Neumann, Braunschweig (Germany)

Asphaltenes are bituminous substances which are soluble in carbon disulfide and insoluble in paraffins. For analytical determination, they are precipitated by the addition of a 40-fold volume of standard gasoline or n-pentane. The asphaltenes have been separated completely from various petroleum oils by four-stage ultrafiltration. Like the petroleum resins, they are dispersed colloidally in the crude oils. Since they precipitate on the addition of a large excess of (non-polar) paraffins, but remain colloidally dispersed on the addition of (slightly polar) naphthenic, aromatic, or chlorinated hydrocarbons, and precipitate together with other substances with more highly polar non-solvents (*e.g.* diethyl ether, ethyl acetate, acetone, isopropanol), the precipitations cannot be explained simply by solubility considerations. The asphaltenes are polydisperse, spherical, resoluble, oleophilic micellar colloids which are solubilized in the naphthenic hydrocarbons of petroleum oils. The addition of large amounts of paraffinic hydrocarbons abstract their solubilizing agents by dilution, and they coagulate. Such a precipitation of polydisperse colloids is unsuitable as an analytical method, since the solubility depends on the amount of the substrate and the past history of the sol. The asphaltenes contain almost all the inorganic constituents of the petroleum oils, and almost all the polar groups (carboxyl, aldehyde, and phenolic groups). These polar groups are responsible for aggregation to micelles (dipole forces). Hydrocarbon residues responsible for the solvation of the micelles are turned outwards. If such micelles arrive at water-oil boundaries, the molecules are oriented in such a way that the polar groups are turned towards the water, and the hydrocarbon residues project into the oil phase. This irreversibly destroys the micelles, and mechanically stable surface skins form, which stabilize water-in-oil emulsions. These emulsions can be broken by colloids dissolved in the aqueous phase and possessing a hydrophilic and an oleophilic end. This is important for secondary recovery and for the demulsifying of the emulsions obtained. Breaking the emulsion by destruction of the boundary skin brings about a reduction in viscosity.

31

Chemical Problems of Lead Poisoning

H. Rüssel, Hannover (Germany)

In order to elucidate the question of the binding of lead to liver constituents in chronically lead-poisoned cattle and sheep, liver homogenates were analysed, with the following results: 1) The lead is non-dialysable and is therefore bound to high-molecular weight substances. 2) With physiological saline, the lead passes partially into the solution and is included in the substances stable up to 80 °C. These consist of ferritin or ferritin-like compounds. 3) Lead contained in cattle liver is more than 50% insoluble in neutral aqueous solution. By solubility experiments with acids and complexing agents, it was possible to show the linkage of this lead component to iron-containing compounds. These differ from hemosiderin by their solubility in phenol, and are probably iron hydroxide-protein colloids with different particle sizes.

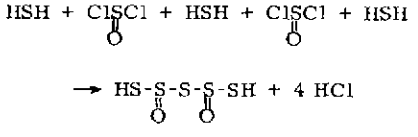
32

Synthesis of Sulfane Oxides

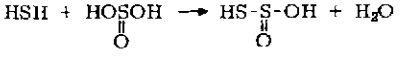
P. W. Schenk, W. Kretschmer, R. Ludwig, R. Steudel, and *M. Töpert*, Berlin (Germany)

Sulfane oxides are chain-like sulfur compounds of the type $H(S_2O)_xSH$. The structure follows from the synthesis, for which three routes have been found:

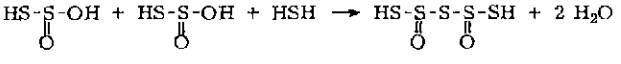
1. Condensation of $SOCl_2$ with H_2S in ether at −10 °C:



2. Polycondensation of thiosulfurous acid, which is formed from H_2S and H_2SO_3 in organic solvents at low temperatures and can be isolated[1]:



Further condensation takes place spontaneously, and in the presence of H_2S occurs according to the scheme



H_2S and SO_2 in CCl_4 at −10 °C give a yellow precipitate of the composition S:O:H ≈ 2.6:1:0.5. Even without an organic solvent, the liquid compounds give a poly(sulfane oxide) at −65 °C. SO_2Cl_2 (in CCl_4/ether at −10 °C) can also be used instead of SO_2, being reduced by H_2S to SO_2, after which the components of the Wackenroder reaction are again present together.

3. Careful hydrolysis of S_2Cl_2 in CCl_4/dioxane at −10 °C leads to a poly(sulfane oxide) of the composition S:O:H ≈ 2.6:1:1.0. The primary product is probably again thiosulfurous acid:

Because of their thermal sensitivity, the sulfane oxides often contain more sulfur than the value corresponding to the ideal formula. They decompose above 70 °C with vigorous evolution of gases; in vacuum S_2O is evolved as well as SO_2.

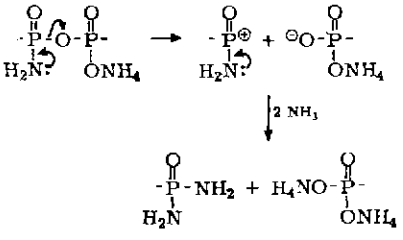
33

The Ammonolysis of Diphosphorus Pentoxide

P. W. Schenk and *K. Scheffler*, Berlin (Germany)

Hexagonal-rhombohedral P_4O_{10} (H-form) and anhydrous liquid ammonia do not react with one another at atmospheric pressure. In the presence of small amounts of water or ammonium chloride (of the order of a few ppm), on the other hand, a reaction sets in which has been followed by measuring the proton magnetic resonance and by analysis of the reaction products insoluble in liquid ammonia. Water is not consumed in the reaction – on the contrary, its content in the liquid ammonia increases during the ammonolysis. While the ammonolysis of the H-form of P_4O_{10} takes place rapidly, the orthorhombic modifications of phosphorous pentoxide do not react, or react only very slowly, with liquid ammonia. The first step of the ammonolysis is the addition of an NH_4^+ ion to the oxygen of the $\geqslant P{=}O$ group. Subsequently NH_3 is added to the phosphorus atom, which has become positive. The main products of the reaction were found to be phosphoric triamide, ammonium phosphorodiamidate, and various ammonium oligophosphoroamidates, by one- and two-dimensional thin-layer chromatography. No diammonium phosphoromonoamidate is produced. The sizes and intensities of the spots in the chromatogram were compared with those from solutions of known concentrations. The yields of the ammonolysis products are independent of the water content of the liquid ammonia, provided that this is between 10^{-4} and *ca.* 8%. The directive influence of the NH_2 group leads to an accumulation of NH_2 groups on the same phosphorus atom:



34

Investigations on Triarylphosphines with Substituents of the Second Kind

G. P. Schiemenz, Kiel (Germany)

According to the classification of organic groups into (+M) and (−M) substituents, phosphine phosphorus should be classed as an electron donor while, if it is desired to retain the octet rule, the phosphorus in aromatic phosphine oxides and sulfides should exert no mesomeric effect. Ultraviolet spectra show, however, that the phosphorus in tris-(*p*-dimethylaminophenyl)phosphine, and its oxide and sulfide, and in similar compounds, probably through d-orbital participation, behaves as a (−M) substituent [1]. This finding is opposed by no convincing evidence of a 3p-donor effect of the phosphine phosphorus. The electronic effect of the phosphine phosphorus has been investigated by several independent methods on triarylphosphines $(C_6H_5)_2PC_6H_4A$ with electron-accepting substituents (A = COOH, $COOCH_3$, $CONH_2$, $CON(CH_3)_2$, $COCH_3$, CHO, CN, NO_2) in the *p*-position to the phosphorus, in which the conditions for a p-orbital participation should be particularly favorable. The pK values of the acids, and hence the Hammet constants, and the ν(C=O) frequencies, show that with respect to a phenyl residue having weak acceptor substituents in the *p*-position (A = COOH,

$COOCH_3$, $CON(CH_3)_2$, $COCH_3$, disturbed by strong intermolecular interactions in the amides) and also with respect to the unsubstituted phenyl residue, the phosphine phosphorus always behaves as a weak, and the phosphine oxide and sulfide phosphorus as a relatively strong, (−M) substituent. Intensification of the (−M) effect of *p*-substituents (A = CHO, CN, NO_2) diminishes the acceptor effect of the phosphorus in the phosphine oxides and sulfides, while the phosphine phosphorus behaves in the aldehyde as a substituent without an M effect (by NMR spectroscopy: position of the signal of the formyl proton), but in the nitrile [IR-spectroscopy: position and intensity of $\nu(C\equiv N)$] and in the nitro compound [by IR-spectroscopy: position of $\nu_{as}(NO_2)$] as a (+M) substituent having donor properties of the magnitude of a methyl group. On the other hand, the $(C_6H_5)_2N$ group is always a strong electron-donor and the phosphonium phosphorus is still a fairly strong acceptor even with respect to a *p*-nitrophenyl residue.

Consequently, both donor properties of the phosphine phosphorus and the earlier postulated reversal of the M-effect in phosphine phosphorus have been experimentally confirmed. If the measured effect is regarded as the difference between a 3d-acceptor and a 3p-donor effect, the difference between the phosphines and the phosphine oxides and sulfides (with pure 3d-orbital participation) leads to a considerable 3p-orbital participation also for those phosphines in which an acceptor effect results. The idea of an acceptor effect of phosphine phosphorus, together with a recalculation of the electronegativity of sp^2 carbon, allows for the first time an explanation of the well-known fact that the phosphorus in aromatic phosphines forms the negative end of the P–C partial dipole. The special role of the phosphorus in the series of the triaryl compounds of group Va elements and the deficient tendency of the elements of the 2nd octet to form p_π to p_π double bonds is also possibly due to d-orbital participation.

35

Investigations on the Constitution of Hydroxo Complexes [1]

H. G. v. Schnering, Münster (Germany)

$Na[Zn(OH)_3]$ contains discrete planar $[Zn(OH)_3]$ groups linked to one another in pairs by strong hydrogen bonds (tetragonal needles; a = 10.86, c = 5.35 Å; D_{4H}^{13}) [2, 3].

$Na_2[Cu(OH_4)]$ shows the (4+2) coordination typical of Cu^{2+}. The plane $[Cu(OH)_4]$ groups are not completely isolated, since the OH^- particles of the complex ion should be regarded as more distant partners of neighboring Cu-atoms (orthorhombic; a = 6.75, b = 6.78, c = 9.02 Å; D_2^4; marked pseudosymmetries.

$Ba_2[Zn(OH)_6]$ contains isolated $[Zn(OH)_6]$ groups with a markedly distorted quasi-octahedral (4+2) coordination for Zn. This is a deformed K_2PtCl_6 structure, the deformation of which is obviously not due to hydrogen bonds but to the diminution in the size of the "holes" for the Ba particles (monoclinic; a = 6.11, b = 6.37, c = 10.46 Å, β = 125.7°; C_{2h}^5) [3].

According to the powder diagrams, $Ba_2[Cu(OH)_6]$ is isotypical with $Ba_2[Zn(OH)_6]$ (a = 6.09, b = 6.50, c = 10.45 Å, β = 126.0°) [3].

$Ba_2[Mg(OH)_6]$ is isostructural with $Ba_2[Zn(OH)_6]$ and $Ba_2[Cu(OH)_6]$, and is therefore a true complex compound. It crystallizes pseudotetragonally, with a' = 8.72 and c' = 8.49 Å, in a distorted K_2PtCl_6 lattice. The exact symmetry of the anisotropic "octahedral" crystals is still not quite certain because of high pseudo-symmetries.

In the preparation of $NaSn(OH)_3$ (orthorhombic needles with a = 14.55, b = 16.79, c = 5.89 Å; D_2^4), a complete rearrangement in about 48 hours of this phase into a different, morphologically very similar phase was observed (monoclinic needles; with a = 17.35, b = 8.23, c = 22.20 Å, β = 101°). It is difficult to decide by analysis whether this is a second form of $NaSn(OH)_3$ or a compound containing less water.

The infrared spectra of the complex hydroxides are disturbed by the small amounts of carbonate always present. Nevertheless, they show characteristic absorptions in the region from 700–1200 cm^{-1}. Comparisons of hydroxides and fluorides of the same type of formula gave an increment of 13 cm^3/mole for the space requirement of the OH^- group. Otherwise, there are hardly any examples of isostructural pairs of compounds.

A calculation in which the electrostatic potential profiles in the environments of proton-bearing particles were determined gives very satisfactorily the positions of the H-atoms if the positions of the other particles are known [3]. The process was checked on a number of compounds with known positions of the hydrogen [LiOH, $Ca(OH)_2$, $AlO(OH)$, KH_2PO_4].

[1] The samples were prepared according to *R. Scholder* et al., cf. Z. anorg. allg. Chem. *241*, 76 (1939); *216*, 138 (1934); *215*, 355 (1933); *317*, 113 (1962); *216*, 176 (1933).

36

Raman Spectra of Colored Crystal Powders Obtained by Excitation with Laser Radiation

B. Schrader and *M. Stockburger*, Dortmund (Germany)

The red radiation of the ruby (6943 Å) and the He-Ne gas lasers (6328 Å) is suitable for the excitation of Raman frequencies. The spectra of colored fluorescing and light-sensitive substances, in which the customary excitation by Hg-lines is unsuccessful, are particularly interesting. Colored substances are generally solid at room temperature and often sparingly soluble. They were investigated as layers of powder or as polycrystalline tablets. The radiation leaving the rear (unirradiated) side of the sample was observed. The unshifted scattered radiation was greatly weakened by twofold reflection at an interference filter of narrow bandwidth with practically no weakening of the Raman radiation. Raman lines in the neighborhood of the exciting lines were therefore still observable. The amount of substance required was 10 to 50 mg.

Colorless substances can also be excited by laser radiation. Here however, as the energy balance shows, the Hg low-pressure lamp is superior to the He-Ne and the ruby lasers. The argon laser with a radiation output of 350 mw at each of the wavelengths 4880 and 5145 Å is highly promising as a universal source of Raman lines, but it is still too expensive.

37

Comparative Investigations on the Stability of the Hexabalogenotechnetates(IV) and -rhenates(IV)

K. Schwochau, Köln (Germany)

We have determined complex-formation constants and ligand-exchange rates of the hexachloro- and hexabromotechnetates(IV) and -rhenates(IV). The formation constants k_6, determined by potentiometric measurements of the equilibrium concentration of the free ligand ions in 3 M $HClO_4$ at 15.0 °C, were 4.6×10^4 for $[TcCl_6]^{2-}$, 2.2×10^6 for $[ReCl_6]^{2-}$, 3.8×10^3 for $[TcBr_6]^{2-}$, and 1.8×10^5 l/mole for $[ReBr_6]^{2-}$. The constants of the Tc complexes are smaller than those of the corresponding Re complexes by a factor of about

50. The greater stability of the halogenorhenates can be explained qualitatively by their different ligand field stabilization energies.

To measure the rates of exchange, the complex ions were labeled with ^{36}Cl or ^{82}Br. Here again, the chloro- and bromotechnetates were found to be considerably more labile; their exchange rates are approximately 20 and 50 times larger, respectively, than those of the analogous Re compounds. The activation energies of the exchange reactions were found to be 28.4 kcal/mole for $[TcCl_6]^{2-}$, 30.3 for $[ReCl_6]^{2-}$, 22.8 for $[TcBr_6]^{2-}$, and 27.5 for $[ReBr_6]^{2-}$.

38

C_{26}-Hydrocarbons as Model Substances for Lubricating Oils

P. Studt, Berlin (Germany)

The following hydrocarbons were prepared:

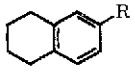
(1), $R^1 = -C_2H_5$, $R^2 = -C_{18}H_{37}$
(2), $R^1 = -C_4H_9$, $R^2 = -C_{16}H_{33}$
(3), $R^1 = -C_6H_{13}$, $R^2 = -C_{14}H_{29}$
(4), $R^1 = -C_8H_{17}$, $R^2 = -C_{12}H_{25}$

(5), $R^1 = R^2 = -C_{10}H_{21}$

(6), $R^1 = R^2 = -HC(CH_3)(C_8H_{17})$

(7), $R^1 = R^2 = -HC(C_3H_7)(C_6H_{13})$

Compounds *(6)* and *(7)* contain two equivalent asymmetric C-atoms. From *(6)* it was possible to isolate the racemate in pure form by fractional crystallization. It was impossible to separate *(7)* into the racemic and meso-forms. Catalytic hydrogenation of compounds *(3)* *(5)* and subsequent fractional crystallization gave the *trans*-disubstituted cyclohexane derivatives.



(8), $R = -C_{16}H_{33}$

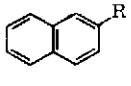
(9), $R = -CH(C_5H_{11})(C_{10}H_{21})$

(10), $R = -CH_2-CH(C_5H_{11})(C_8H_{19})$

(11), $R = -(CH_2)_2-CH(C_5H_{11})(C_8H_{17})$

(12), $R = -(CH_2)_4-CH(C_5H_{11})(C_6H_{13})$

(13), $R = -(CH_2)_5-CH(C_5H_{11})(C_5H_{11})$



(14), $R = -C_{16}H_{33}$

(15), $R = -CH(C_5H_{11})(C_{10}H_{21})$

(16), $R = -(CH_2)_5-CH(C_5H_{11})(C_5H_{11})$

The compounds with unbranched side chains are crystalline substances at room temperature, but have low melting points. Branching of the side-chains leads to a marked lowering of the melting points (so that the compounds are liquid at room temperature), to a lowering of the boiling points, and to an increase in the viscosities, branching in the vicinity of the ring system having a particularly marked effect. The boiling points can be explained qualitatively on the basis of a steric effect: branching hinders the mutual approach of the molecules and leads to a decrease in the cohesion energy and therefore to a lowering of the boiling point. The marked influence of the structure on viscosity cannot yet be satisfactorily explained. It is striking that a decrease in the cohesion energy runs parallel with an increase in viscosity.

39

Separation and Detection of Glucuronides

N. Takriti and *W. Thorn*, Hamburg (Germany)

Formation of glucuronides occupies the foremost position among the possibilities available to an organism for the conversion of sparingly soluble substances belonging to the body or foreign to it into a more soluble form capable of secretion. The properties of the glucuronides are substantially determined by the properties of the aglycones. The development of a generally applicable method of determination has hitherto been prevented by the variability of the aglycones. In most cases, one of the components has been determined after hydrolytic splitting of the glucuronides.

We have separated mixtures of glucuronides without hydrolysis by means of ion-exchange and thin-layer chromatography. Model substances and samples of urine with and without the addition of model substances could be separated on silica gel with chloroform/methanol/glacial acetic acid (8:1:1) as the eluent. A spraying reagent used consisted of anisaldehyde conc. sulfuric acid/glacial acetic acid (100:2:1). The method was demonstrated on pregnanediol glucuronide. Good separation of the urine components is achieved in a short time without hydrolysis or previous purification. 5β-Pregnane-3α,20α-diol glucuronide is readily identified as a blue spot.

40

Oxidation Reactions of α-Substituted Thiocarboxamides

W. Walter, *K.-D. Bode*, and *P. Hell*, Hamburg (Germany)

The oxidation of α-ketothioamides with hydrogen peroxide leads to stable thioamide *S*-oxides only in the case of primary thioamides; α-ketothioamides substituted on the nitrogen are oxidatively desulfurized, the *S*-oxide stage being passed through very rapidly. The stability of the *S*-oxides of amides of purely aliphatic or purely aromatic thiocarboxylic acids is affected substantially less by substitution on the nitrogen.

Tertiary compounds are the only series in which thiourethanes give no *S*-oxides [1].

The reaction of thioamides with sulfenyl chlorides also takes place with electrophilic attack on the sulfur and leads to unsymmetrical disulfides. The thioamides which give no *S*-oxides also react in this way.

[1] *W. Walter* and *K.-D. Bode*, Liebigs Ann. Chem. *681*, 64 (1965).

41

Investigations in the Titanium/Hydrogen System

G. Wedler and *H. Strothenk*, Hannover (Germany)

The phase diagram of the titanium/hydrogen system is known above 300 °C. The heats of reaction have generally been determined from the temperature-dependence of the absorption isotherms and occasionally from heats of combustion. The figures have a pronounced scatter even at the same composition of the system. Direct calorimetric measurements of the heat of reaction are not yet available.

In order to determine the ranges of existence of the individual phases and heats of reaction at 273 °K, titanium films about 150 Å thick, vapor-deposited in ultrahigh vacuum were investigated. These films could be charged with hydrogen at

room temperature, even at an equilibrium pressure of $< 10^{-5}$ mm, up to a composition of $TiH_{1.9}$.

With very small amounts of hydrogen, the differential heats of absorption amount to 35 kcal/mole of hydrogen, but they fall sharply with increasing concentration of hydrogen and reach a minimum of 22 kcal/mole of H_2 at $TiH_{0.06}$. From about $TiH_{0.3}$ upwards, they are almost independent of the hydrogen concentration with an average value of 27.5 kcal/mole of H_2.

The electrical resistance of the titanium films first increases with increasing content of hydrogen, the increase being 2.4% with respect to the resistance of the pure titanium film at $TiH_{0.07}$. When the hydrogen concentration is increased further, the resistance decreases, first linearly and then faster, being only 64% of the value for the pure titanium film at $TiH_{1.9}$.

The ranges of existence of the individual phases can be determined from the behavior of the electrical resistance. The upper limiting concentration of the hexagonally close-packed α-phase is found in $TiH_{0.07}$, and the lower limiting concentration of the face-centered cubic γ-phase in $TiH_{0.6}$. The intermediate range is characterized by a linear relationship between hydrogen concentration and electrical resistance.

Consequently, in the range of existence of the pure α-phase the differential heats of absorption fall sharply with increasing hydrogen content, while in the region of the γ-phase they depend only slightly on the hydrogen concentration.

42

Preparation and Reactions of Chloro(chloromethyl)dimethylgermane

M. Wieber and *C. D. Frohning*, Marburg (Germany)

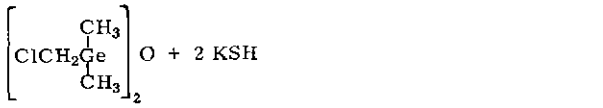
Chloro(chloromethyl)dimethylsilane $(ClCH_2)(CH_3)_2SiCl$ is a starting material for the synthesis of siloxanes with functional groups. The analogous germanium compound has been prepared in accordance with Equations (a)–(c):

$$Ge + 3\,CH_3Cl \rightarrow CH_3GeCl_3 + C_2H_6 \quad (a)$$

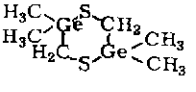
$$CH_3GeCl_3 + CH_2N_2 \rightarrow CH_3(CH_2Cl)GeCl_2 + N_2 \quad (b)\ [1]$$

$$CH_3(CH_2Cl)GeCl_2 + LiCH_3 \rightarrow (CH_3)_2(CH_2Cl)GeCl + LiCl \quad (c)$$

For reaction (a), a method has been evolved to obtain pure methylgermanium trichloride with a yield of 70% (based on the germanium used). The reaction of the dichlorochloromethylmethylgermane with methyl-lithium according to Eq. (c) takes place with a yield of about 50% at −30 °C.



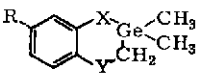
(1)



(2)

Hydrolysis of the chlorochloromethyldimethylgermane gives 1,3-bis(chloromethyl)tetramethyldigermoxane *(1)* which, in turn, can be converted with potassium hydrogen sulfide into 2,2,5,5-tetramethyl-2,5-digerma-1,4-dithiane *(2)*.

The reaction of chloro(chloromethyl)dimethylgermane with aromatic 1,2-diols in the presence of triethylamine as hydrogen chloride acceptor gives binuclear germanium-containing heterocycles having the structure *(3)*.



(3)

X = Y = O, R = H, CH_3
X = Y = S, R = CH_3
X = O, Y = NH, R = H

43

Phosphorus, Antimony, Sulfur, and Selenium Compounds in the Liquid-Liquid Extraction of Transition-Metal Ions

M. Ziegler, Göttingen (Germany)

Substituted onium compounds $[R_nM]X$ *(1)*, substituted amides $(R_2N)_3MO$ *(2)* and substituted oxides R_nMO *(3)* (M = P, Sb, S, or Se) are suitable for the liquid-liquid extraction of the transition metals. Phosphoric hexamethyltriamide $[(CH_3)_2N]_3PO$ (PHT) gives the crystalline coordination compounds:

$Fe(SCN)_3 \cdot 3(PHT)$ *(4)*	$Th(NO_3)_2 \cdot (PHT)$
$Zn(SCN)_2 \cdot 2(PHT)$ *(5)*	$BiCl_4 \cdot 2(PHT)$
$VO(SCN)_2 \cdot 2(PHT)$	$FeCl_3 \cdot (PHT)$ *(6)*
$UO_2(NO_3)_2 \cdot 2(PHT)$	

Iron can be separated from various transition metals and zinc in the form of compound *(4)*. Zinc isolated in the form of compound *(5)* can be determined volumetrically with EDTA. Iron extracted in the form of compound *(6)* can be determined photometrically in amounts of from 5 μg upwards. Tetraphenylantimonates *[(1), M = Sb]* permit the selective extraction of small amounts of molybdate and the extraction and photometric determination of iron *via* the ferron complex.

Among the substituted sulfoxides *[(3), M = S]*, dibenzyl sulfoxide permits the extraction and photometric determination of small amounts of iron as $Fe(SCN)_3 \cdot 3\,OS(CH_2\text{-}C_6H_5)_2$. With thioxane (thiox), palladium can be extracted and photometrically determined in the form of $Pd(thiox)_2Cl_2$. Triphenylsulfonium salts *(1)*, M = S, permit the selective extraction of $[Co(SCN)_4]^{2-}$.

Diphenyl selenoxide permits the selective extraction of rhodium as $RhCl_3 \cdot 3\,OSe(C_6H_5)_2$, and triphenylselenonium salts permit the isolation of small amounts of ReO_4^-.

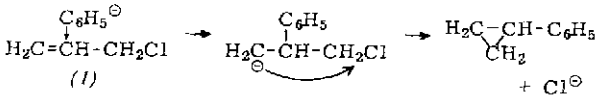
SELECTED ABSTRACTS

A new synthesis of phenylcyclopropanes is reported by *S. Wawzonek, B. Studnicka, H. J. Bluhm,* and *R. E. Kallio*. Addition of phenyl-lithium onto allyl chloride in ether yields allylbenzenes plus phenylcyclopropanes in a ratio which depends on the substitution of the allyl chloride, *e.g.* 13:87, 19:81, and 40:60 for addition onto allyl chloride *(1)*, crotyl chloride, and 1-chloro-5,5,7,7-tetramethyl-2-octene, respectively. The cyclopropanes can be isolated after oxidation of the olefins with potassium permanganate. The reaction is proba-



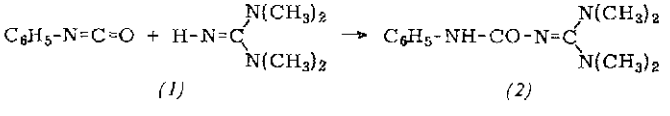
(1)

bly equivalent to an S_N2' reaction in which the phenyl carbanion attacks at the β-carbon atom instead of at the γ-carbon. The resultant anion undergoes an intramolecular reaction with elimination of the chloride ion. / J. Amer. chem. Soc. *87*, 2069 (1965) / – Ma. [Rd 361/570 IE]

The chemical shifts and the π-electron densities of ring protons in aromatic nitrogen heterocycles were compared by *A. H. Gawer* and *B. P. Dailey*. The π-electron densities were calculated using the SCF–MO method of *Roothaan*. The compounds studied were pyridine, the diazines, quinoline, isoquinoline, and the 1,2-, 1,3-, 1,4-, 1,5-, and 2,3-diazanaphthalenes. The chemical shifts and the calculated electron densities correspond only approximately; particularly large differences are observed with the protons attached to the carbon atoms next to the nitrogens. Factors which contribute to these irregularities are the influence of the low molecular symmetry on the calculated electron densities, the magnetic anisotropy due to the lone pair of electrons on the nitrogen, and the interaction of δ- and π-electrons. / J. chem. Physics *42*, 2658 (1965) / –Hz. [Rd 362/571 IE]

The spin multiplicity of difluorocarbene is discussed by *J. Heicklen, N. Cohen,* and *D. Saunders* in connection with the rate constants of its reaction with ethylene, tetrafluoroethylene, and oxygen. CF_2 made by photolysis from C_2F_4, CF_2HBr, CF_2Br_2, or CF_2N_2 is in the singlet state, but CF_2 made by a glow discharge from CF_4 or by the reaction of C_2F_4 with atomic oxygen was recognized to be in the triplet state because of its much faster rates of reaction. The singlet state is probably of lower energy than the triplet state. / *J.* physic. Chem. *69*, 1774 (1965) / –Hz. [Rd 363/572 IE]

The catalytic effect of 1,1,3,3-tetramethylguanidine on the polymerization of isocyanates was studied by *J. T. Gerkegan* and *R. W. Roth*. Tetramethylguanidine *(1)* is a better catalyst than triethylamine or 1,4-bisdimethylaminobutane but is less active than diazobicyclooctane (based on equal concentrations). It combines with phenyl isocyanate to form the urea derivative *(2)*, which also has good catalytic properties. Com-

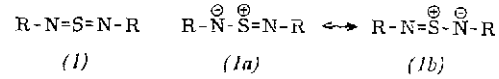


(1) *(2)*

pound *(1)* exerts two functions during the preparation of polyurethanes. Apart from its catalytic effect on the isocyanate reaction, some of it is incorporated into the polyurethane. Thus, in contrast to the t-amine catalysts, it does not remain unchanged in the polymers. / J. appl. Polymer Sci. *9*, 1089 (1965) / –Hl. [Rd 380/589 IE]

α-Phenylethylpotassium as initiator for the polymerization of styrene leads, according to *S. S. Yen*, to almost monodisperse polystyrene (M_w/M_n = 1.06). When chain termination by a proton occurs, no foreign end groups are introduced, for the initiator is identical with the repeating unit of polystyrene. The reaction of polystyrylpotassium with 1,2,4,5-tetrakis-chloromethylbenzene was used to produce a "star" branched polystyrene which also had a very narrow distribution of molecular weights (M_w/M_n = 1.05). The lengths of the rays of the stars can be readily controlled by the ratio of monomer to starter taken. The sedimentation pattern in the ultracentrifuge gives a direct indication of the high uniformity of the branched polystyrene. / Makromolekulare Chem. *81*, 152 (1965) / –Hl. [Rd 325/534 IE]

A new synthesis of stable aliphatic sulfur diimines *(1)* is described by *D. H. Clemens, A. J. Bell,* and *J. L. O'Brien*. If the group R in *(1)* is a bulky t-alkyl group, the sulfur diimines can be obtained from the t-alkylamines and SCl_2, which yield a condensation product $(RNS)_x$ which is then heated in vacuum. Sulfur di-t-butylimine, b.p. 60–62 °C/15 mm, and sulfur di-t-octylimine, b.p. 88–90 °C/0.15 mm, were made in this way. The same sulfur diimines are also obtained in somewhat lower yields by pyrolysis of the product formed by reaction of sulfur monochloride and excess t-alkylamine. The diimines are hydrolysed slowly by water but rapidly by dilute hydrochloric acid. Oxidation of *(1)* with dilute H_2O_2 produces *N,N'*-di-t-alkylsulfamides. The sulfur diimines *(1)* probably have structures with large contributions from the resonance forms *(1a)* and *(1b)*. Its structure has an ylide character



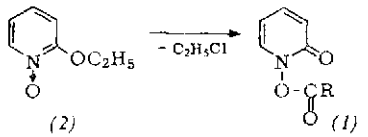
(1) *(1a)* *(1b)*

which opens a large range of possibilities for reactions, *e.g.* with carbonyl compounds, isocyanates, isothiocyanates, and thioureas. / Tetrahedron Letters *1965*, 1487, 1491 (1965) / –Ma. [Rd 348/557 IE]

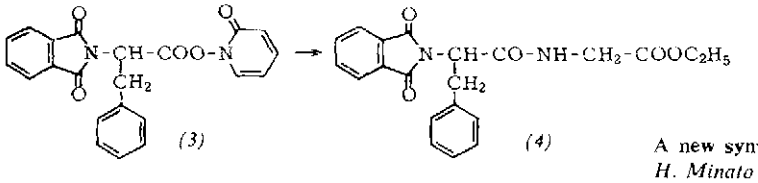
The redox potentials of alkyl-substituted quinone/hydroquinone systems were measured by *O. Ryba, J. Petranek,* and *J. Pospisil*. Since the quinones decompose readily, the redox potentials can be determined only by measurement of the polarographic half-wave potentials. The half-wave potentials of hydroquinones substituted by methyl, ethyl, isopropyl, t-butyl, 3,3-dimethylpropyl, and 2,2,4,4-tetramethylbutyl groups in the 2- or 2- and 5-positions can be represented as a linear function of the sum of the steric substitution constants E_S. The additivity of the effects of individual substituents is not valid for 2,6-dialkylated hydroquinones. / Coll. czechoslov. chem. Commun. *30*, 843 (1965) / –Hz. [Rd 360/569 IE]

Preparation of metal fluorides by the fluidized bed process was achieved by *H. W. Roesky, O. Glemser,* and *K. H. Hellberg*: 0.5–1.0 g of metal powder (Mn, Pb, Bi, or Re) reacted quantitatively with elemental fluorine within a few minutes in a vertical electrically heated tube 15 mm in diameter and 600 mm long made of pure nickel. Metal powder with a grain diameter of 0.062–0.075 mm is placed in a nickel sieve below the reaction zone and gas is then passed in from below at a rate fast enough to give a fluidized bed 10 cm long. The temperature above the fluidized bed is 700–800 °C. The fluorides formed are collected in cold traps made of silica or teflon and characterized by chemical analysis or infrared spectroscopy. MnF_4, PbF_4, BiF_5, and ReF_7 were made in this way. / Chem. Ber. *98*, 2046 (1965) / –Gn. [Rd 367/576 IE]

1-Acyloxy-2(1*H*)-pyridones *(1)*, a new class of activated esters, are described by *L. A. Paquette*. Electrophilic attack by acyl halides on 2-ethoxypyridine-1-oxide *(2)* at room temperature causes an exothermic reaction with release of ethyl halide and formation of *(1)*. For example, with acetyl chloride, the resultant pyridone *(1)* has R = CH_3 and m.p. 93–94 °C, and the yield is 86 %; with benzoyl chloride, R in *(1)* = C_6H_5, the m.p. is 140 °C, and the yield is 93 %. The



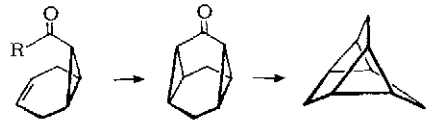
(2) *(1)*



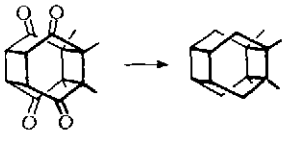
(3) *(4)*

acetyl derivative *(1)* is hydrolysed quantitatively by water to 1-hydroxy-2(1*H*)-pyridone; transacetylation occurs with butanol and butylamine. The high reactivity of *(1)* can be used for synthesizing peptides. The ester *(3)* is obtained in quantitative yield from phthaloyl-L-phenylalanyl chloride and *(2)* and condenses with glycine ethyl ester to give optically pure ethyl phthaloyl-L-phenylalanylglycinate *(4)*. / J. Amer. chem. Soc. *87*, 1407 (1965) / –Ma. [Rd 332/541 IE]

The synthesis of asteranes is reported by *U. Biethan, U. von Gizycki*, and *H. Musso*. In the asteranes, cyclohexane rings are fixed in the boat form. Triasterane, *i.e.* tetracyclo-[3.3.1.$0^{2,8}$.$0^{4,6}$]nonane *(4)*, m.p. 110 °C, was prepared from *endo*-Δ^3-norcarene-7-carbonyl chloride *(1)* *via* the diazo ketone *(2)*, which was decomposed in boiling hexane with copper powder to give the ketone *(3)*, which on Wolff-Kishner reduction affords *(4)*. Tetramethyltetraasterane *(6)*, *i.e.* 1,2,7,8-tetramethylpentacyclo[6.4.0.$0^{2,7}$.$0^{4,11}$.$0^{5,10}$] dodecane, m.p. 283–286 °C, was synthesized from the cage dimer *(5)* of



(1) R = Cl *(3)* *(4)*
(2) R = CHN_2

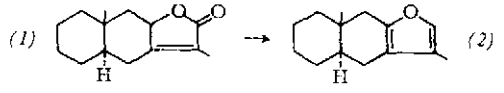


(5) *(6)*

2,3-dimethylbenzoquinone *via* its tetrahydrazone, which on heating with KOH in ethylene glycol gave a mixture of hydrocarbons that were separated by gas chromatography. Analogously, the hydrazone of the cage dimer of 2,5-dimethylbenzoquinone gives rise to a tetramethyltetraasterane, m.p. 106–108 °C; the positions of the methyl groups in this compound are not yet known with certainty. / Tetrahedron Letters *1965*, 1477 / –Ma. [Rd 350/559 IE]

The reaction of sodium and potassium with dimethyl sulfoxide (DMSO) has been examined by *D. E. O'Connor* and *W. L. Lyness*. Na and K react with excess DMSO to form a mixture of the salts of methanesulfenic acid and methylsulfinylmethide $CH_3SOCH_2^{\ominus}$ plus some methane and dimethyl sulfide. Two primary reactions occur with almost equal rate with Na: reductive cleavage of the C–S bond to yield sodium methanesulfenate and methylsodium, and cleavage of the S–O bond to give dimethyl sulfide and Na_2O. The strong bases $NaCH_3$ and Na_2O react with more DMSO to produce sodium methylsulfinylmethide, methane, and NaOH. The C–S fission predominates in the reaction with K. Both sodium and potassium methanesulfenates are stable for several days at room temperature in the reaction mixture. Alkylation of the methanesulfenates with alkyl bromides or iodides gives the corresponding methyl alkyl sulfoxides in good yields. No *O*-alkylated products can be detected. / Abstracts 149th Meeting Amer. Chem. Soc. *1965*, 45P / –Ma. [Rd 336/545 IE]

A new synthesis of furan compounds has been published by *H. Minato* and *T. Nagasaki*. A solution of dialkylaluminum hydride or tri-isobutylaluminum in tetrahydrofuran is added to a solution of an α,β-unsaturated γ-lactone derivative such as *(1)* and stirred for about an hour at room temperature

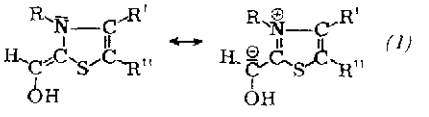


(1) *(2)*

under nitrogen. The solution is then acidified and the furan derivative is extracted: *e.g.*, *(2)* is obtained in 74 % yield. / Chem. and Ind. *1965*, 899 / –Ma.

[Rd 349/558 IE]

"Activated formaldehyde" is 2-hydroxymethylthiamine pyrophosphate *(1)*, according to *G. Kohlhaw, B. Deus*, and *H. Holzer*. This is an intermediate of the degradation of glyoxylic acid in *Escherichia coli* by glyoxylate carboligase. Glyoxylate is activated by condensation with thiamine pyrophosphate (TPP) and then decomposes into *(1)* and carbon dioxide. The *(1)* then reacts with another molecule of glyoxylate to give



(1)

TPP-activated tartronmonoaldehyde, which is reduced to glyceric acid by the corresponding reductase and DPNH. Compound *(1)* was isolated by chromatography on acetylated Dowex 2 of incubation mixtures containing pyruvate oxidase from pig heart, TPP, and glyoxylate and detected by cleavage of [2–^{14}C]-labelled *(1)* with hydroxylamine to give glycolhydroxamic acid or by oxidation with 2,6-dichlorophenylindophenol to [^{14}C]formate. / J. biol. Chemistry *240*, 2135 (1965) / –Hö. [Rd 370/579 IE]

The formation of streptococcal proteinase from cymogen was investigated by *W. H. Stein, S. Moore, et al.* This conversion is catalysed by trypsin, subtilisin, or the proteinase itself (autocatalysis). A polypeptide containing about 100 amino acids is split from the cymogen (molecular weight 44000). An intermediate with 17 amino acids fewer than cymogen can be isolated; after liberation of its sole mercapto group, this intermediate exhibits proteolytic activity. The removal of the 17 amino acids therefore exposes the active center. The peptide containing about 100 amino acids released during the activation is the carrier of the immunochemical specificity of cymogen. The free proteinase does not react with cymogen antiserum. / J. biol. Chemistry *240*, 1138 (1965) / –Hö. [Rd 376/585 IE]

Organikum. Organisch-Chemisches Grundpraktikum (Practical Organic Chemistry). Edited by a group of authors from the Technische Universität Dresden (Germany). VEB Deutscher Verlag der Wissenschaften, Berlin 1964. 3rd revised Edition, XII + 596 pp., Appendix, 106 illustrations, imitation leather, DM 36.–.

The reform in the study of chemistry that is currently the subject of so much discussion in Germany obviously cannot be achieved without a well-grounded change in our practical courses in chemistry. A new textbook of practical organic chemistry that leaves the beaten track to follow new paths is therefore particularly interesting at the present time. The "Organikum", first published in 1962 and now in its fourth edition, appeared at just the right time, and its authors – a group of young lecturers and assistants at the Technische Universität Dresden – are to be congratulated on their outstanding and well-deserved success.

The book begins with an introduction to laboratory practice (approx. 100 pp.), which is both good and complete as far as conventional laboratory methods are concerned. Better treatment could have been accorded to more recent developments, such as thin-layer chromatography. In the section on the determination of the physical properties of organic compounds, no mention is made of proton magnetic resonance and mass spectrometry, although the importance of these two methods in the routine work of the organic chemist is as great as that of electronic and infrared spectroscopy, which are discussed at some length.

The real interest in this book is to be found in the section dealing with preparations (approx. 400 pp.), in which it is attempted, more consistently than in any other practical textbook, to synchronize the teaching of preparative techniques with the learning of the mechanistic principles of the reactions treated. As a logical consequence of this program, the material is arranged not according to classes of compounds, but according to reaction types. The didactic advantage of this arrangement is obvious, although it must not be overlooked that not all reactions of practical importance can be forced with the same ease into the "Procrustes bed" of a system of reaction mechanisms. This may be the reason for the accentuation, in this book, of certain reactions whose inclusion cannot be explained solely on the basis of preparative importance.

The isolation and purification of natural products is completely neglected in the "Organikum"; this is regrettable, since it means that the important extraction and partition techniques are also omitted. The chemistry of natural products could also be allowed more space in the discussion of the preparative methods. For example, the remarks on peptide syntheses (p. 378) are rather insufficient. Other desirable improvements in the next edition would be a better account of organometallic reactions and the inclusion of the most important new types of reactions such as hydroboration, the Wittig reaction, and reductions with diimide, which are not mentioned in the present edition. Criticism could be made of some details of the treatment of reaction mechanisms, but this is unimportant in comparison with the success achieved by this book in the dovetailing of theoretical knowledge with practical laboratory arts.

Another new interesting and remarkable feature of the book is that it does not give detailed recipes for the preparation of individual compounds, but contains instead general procedures for certain reactions, together with brief notes on special points to be observed in the preparation of particular compounds. This is to prevent the student from carrying out a preparation mechanically, as frequently happens when very detailed instructions are given. Moreover, the number of preparations that can be covered by the "Organikum" is greatly increased (to about 1000). Since these general, standardized procedures can also be used for the corresponding reactions of new compounds or compounds that are not mentioned, the "Organikum" is also valuable as a small handbook on methods for graduate students and advanced chemists.

In the basic organic practical course, however, the almost exclusive use of general procedures also has certain disadvantages. In Heidelberg we have found that, especially at the beginning of the laboratory course, the student often experiences difficulties as a result of the generalized, and hence necessarily less precise, instructions; this is aggravated by the fact that, for some incomprehensible reason, the "Organikum" begins the section on preparations with free radical reactions, which are not altogether simple from the point of view of method. Furthermore, since special procedures are not given, no mention can be made of special phenomena (intermediate coloration, formation of precipitates, *etc.*) observed during the reaction in particular cases, the observation and interpretation of which can teach the student a great deal. The complete absence of small-scale experiments with the compounds prepared does not exactly help to improve the student's power of observation or to increase his interest in experimenting, and this, after all, is the principal purpose of the practical organic chemistry course. It may be possible in a later edition to find a compromise that takes these points more satisfactorily into account.

The last chapter, which deals with the identification of organic compounds, is without a doubt the weakest part of the book. It is disappointing to find that this book, which is so progressive in other respects, does not also follow new paths in organic analysis by the use of modern separation processes and physico-chemical methods of analysis to supplement the conventional methods.

The presentation of the book is good, and the quality of the paper is much better than in the earlier editions. With a few exceptions, the formulae are clear and contain no errors. Unfortunately, even in the new editions, the index is still bound separately.

Even those who, like the reviewer, find some fault with the conception and details of this book will recognize that the "Organikum" must be regarded as one of the most significant innovations in German literature on organic chemistry in the last few years. This book has set a standard against which other present and future laboratory books must and will be measured.

H. A. Staab [NB 420/281 IE]

Organische Chemie. Ein Lehrbuch für Naturwissenschaftler, Mediziner und Techniker (Organic Chemistry. A Textbook for Science, Medicine, and Technology Students). By *F. Nerdel*, in collaboration with *B. Schrader*. Verlag Walter de Gruyter & Co., Berlin 1964. 2nd completely revised and extended edit., XII + 209 pp., 48 figs., linen DM 18.– (about $4.50).

This revised and expanded second edition is intended, as the subtitle and the size of the book indicate, for students taking chemistry as a minor subject. The content is divided into six sections: I. Fundamentals of theoretical organic chemistry; II. Systematic organic chemistry; III. Macromolecular organic materials; IV. Solvents, plasticizers, and surfactants; V. Biochemistry; VI. Analytical methods in organic chemistry.

It is very welcome that the attempt is made to convey a complete survey of organic chemistry on only 200 pages, for a book of this length can in fact be mastered by the readers for whom it is intended. One can be of different opinions concerning the selection of material dealt with and one must ask whether the

structure of the atom should be examined here and whether terpenes are a suitable class of compounds with which to demonstrate the variability of organic compounds to medical or engineering students.

Parts III–VI of the book (by *Schrader*) do in fact serve its purpose; they record an abundance of interesting facts and relationships which are presented clearly but sometimes very tersely and schematically (*e.g.* ion exchangers on p. 136). However, the presentation given to many fundamentals in Parts I and II (by *Nerdel*) is unsatisfactory (*e.g.* mesomerism on p. 16). On p. 81 it is stated that the anions derived from keto and enol forms of ethyl acetoacetate differ only in the distribution of their charge. Apart from the fact that the polar limiting structure of the carbonyl group is said to be very important for understanding its reactions (p. 50), reaction mechanisms frequently are discussed, apparently without a proper knowledge of the issues at stake, in the most primitive manner, *e.g.* the Wurtz synthesis (p. 41), the aldol condensation (p. 54), and the Hofmann elimination (p. 62). The print in the formulae is not always very good, *e.g.* the formula for acetylene on p. 56. Printing errors are few, *e.g.* at the center of p. 71 it should read "Seite 113" and not "Seite 13".

Before this book – the arrangement of which must be acknowledged to be most useful – can be recommended without reservations to students, the first two chapters must be thoroughly revised. *H. Musso* [NB 399/257 IE]

Chelating Agents and Metal Chelates. Edited by *F. P. Dwyer* and *D. P. Mellor*. Academic Press, New York-London 1964. 1st edit., XV + 530 pp., numerous figs. and tables, linen $ 17.–.

This volume contains ten chapters written by different authors on metal chelates. Nevertheless, the content and arrangement of the chapters give the book the character of a textbook, for first bonding relationships are discussed, followed by descriptions of the types of metal chelates, their stereochemistry, and some special facets of the subject such as redox potentials, complexes with ethylenediamine-tetraacetic acid and related substances, and some naturally occurring chelates. Overlapping has been largely avoided. However, a uniform symbol for the metal-ligand bonds would have been better. For example, different formulations are given for acetylacetonates on pp. 34 and 100.

D. P. Craig and *R. S. Nyholm* have contributed a very original presentation of the nature of the metal-ligand bond. The authors did not wish to deal with the ligand field theory in this connection, and this restriction must be accepted. However, their mention of this theory could at least have been coupled with a few references for those interested. The sections on bi- and polydentate ligands by *H. A. Goodwin*, *C. M. Harris*, and *S. E. Livingstone* and on optical phenomena with metal chelates by *A. M. Sargeson* are well written. In the specialized section, the selection of topics is typical for the research sphere of the editors. The reviews of "Metal Chelates in Biological Systems" (*F. P. Dwyer*) and of "Metal Activation by Enzymes and the Catalytic Effect of Metal Complexes" (*A. Shulman* and *F. P. Dwyer*) are undoubtedly profitable and up-to-date undertakings; however, both chapters are so fragmentary and apparently so much tailored to the interests of the authors that they cannot claim to be of general interest. The problems discussed are almost all very difficult to approach experimentally: for example, metal ion activation of proteolytic enzymes, the toxic effect of metal ions, and even the effect of metal ions on microorganisms. It would have been better to include a discourse on the chemistry of the known naturally occurring metal chelates and to use this as a basis to discuss the mechanisms of their biochemical action instead of introducing these somewhat vague concepts. Enzymes containing copper or molybdenum are not mentioned, for example, and iron complexes not containing porphyrins and the vitamin B_{12} coenzymes are omitted; this shows clearly how unfortunate the selection is. An attractive chapter on porphyrin complexes by *J. E. Falk* and *J. N. Phillips* is included.

Since the biochemical aspects of metal chelates receive too little attention here, the book cannot be recommended to biochemists, microbiologists, enzymologists, or medical researchers. *E. Bayer* [NB 368/226 IE]

Peroxidase. The Properties and Uses of a Versatile Enzyme and of Some Related Catalysts. By *B. C. Saunders*, *A. G. Holmes-Siedle*, and *P. B. Stark*. Butterworths, London 1964. 1st edit., X + 271 pp., numerous illustrs. and tables, linen £ 3.0.0 (about $ 8.30).

In his foreword, *Lord Todd* remarks that monographs of this type are very valuable and provide incentives to advanced students and scientists, and one can certainly second his statement. All the authors have once been members of *Todd*'s research group and they have succeeded here in reproducing the current status of our knowledge of peroxidase and the hemin enzymes generally in a concise and concentrated form. Fourteen sections are given dealing with diverse aspects of this group of enzymes such as their occurrence, purification, properties, detection and assay, and particularly their behavior in kinetic spectroscopy and EPR measurements. A valuable feature for the non-specialist is the section in which the modern concepts of the electronic configuration of hemin-iron enzymes and the structure of coordination compounds are used to interpret the optical and catalytic (or enzymatic) properties. This excellent presentation makes it obvious that modern enzymology has become an exact science.

The main stress in the book is laid on the chemistry of peroxidases, and it is therefore understandable that biological aspects are somewhat neglected. For this reason, some of the applications of peroxidase that have become so important (*e.g.* for the specific detection of glucose in combination with notatin) receive only brief reference. As a special case, catalase receives a separate section; however, the question of the biological function of this enzyme is only touched upon.

These remarks do in no way deprecate the value of this book as an extremely welcome source of information. This is due in no small extent to the lists of the oxidation products identified to date which arise on treatment of various substrates with peroxidase and to the spectra of all known hemin compounds, including data on their optical and magnetic properties. *H. Aebi* [NB 387/245 IE]

The Chemistry of Beryllium. By *D. A. Everest*. Topics in Inorganic and General Chemistry. Edited by *P. L. Robinson*, Vol. 1. Elsevier Publishing Co., Amsterdam-London-New York 1964. 1st edit., IX + 151 pp., several figs. and tables, linen DM 25.– (about $ 6.25).

Here the author attempts to give a summarical presentation of the chemistry of beryllium, deliberately omitting some aspects such as beryllium ceramics and intermetallic compounds; the material otherwise covered does indeed review the whole of beryllium chemistry.

Chapter 1 is an introduction to beryllium chemistry, and Chapter 2 reviews the solution chemistry of the element. Chapter 3 deals with simple oxygen salts of Be and Chapter 4 with its halides. Chapter 5 describes the complex compounds of Be and Chapter 6 its simple binary compounds. Chapter 7 then deals with organoberyllium compounds, and the production of beryllium from its ores is discussed in Chapter 8. The analytical chemistry of beryllium forms the topic of Chapter 9. The toxicity of beryllium and safety measures are dealt with in Chapter 10, and the nuclear properties of Be are discussed in the last chapter.

The material covered is very extensive; however; some striking faults are observed, especially with regard to the presentation of the material. The sequence of the chapters suffices to show that there is a lack of coherence in the treatment. The sequence 1-11-8-9-6-4-3-2-5-7-10 would have been more reasonable. Without exception, the text is a conglomeration of fragmentary data placed one after the other and conveys the general impression of a poor set of lecture notes. No signs of strict organization can be detected. It is noticeable that although many structural data are given, only few lattice constants are recorded in text. It would certainly have been easy to have included highly condensed tables of physical data. Similarly, there are no illustrations of lattice models, which would have been quite in place in such a book. Although intermetallic compounds have been disregarded, a detailed discussion of the element itself at least ought to have been given. In the chapter on the extraction of Be from its ores, although many individual processes are described, not a single flow sheet is given, even though such flow sheets serve well to convey a clear understanding of technical processes. Some important facts are completely overlooked, *e.g.* the preparation of $BeCl_2$ and $BeBr_2$ for atomic weight determinations (according to *Hönigschmid*) and the very instructive health precautions used at Oak Ridge (Report Y-868). In Chapter 11 it is not mentioned that ^{10}Be has been electromagnetically enriched (Report Y-577, Oak Ridge) or that $RaBeF_4$ and BePo have been used as homogeneous neutron sources.

These shortcomings, particularly the lack of clarity in the arrangement of the material, make the book difficult to work through. The reader is confronted with a vast number of facts, some of which are incompletely reported, without being able to recognize any clear principles. Purchase of the volume can be recommended only with restrictions.

F. Weigel [NB 385/243 IE]

Tetracyclic Triterpenes. By *G. Ourisson, P. Crabbé*, and *O. R. Rodig*. Editions Scientifiques Hermann, Paris; Hermann Publishing Ltd., Huddersfield, Yorkshire 1964. 2nd edit., 237 pp., linen £ 2.19.0 (about $ 8.25).

This monograph is a translation and extension of the older French edition of 1961 [1]. The authors deal first with the chemistry of the tetracyclic triterpenes (including methyl steroids and nor-compounds such as limonin); they do not discuss the individual compounds in sequence but describe general reactions which can occur in the various rings and in the side chain. These general reactions are then contrasted with the anomalous behavior of certain representatives of a given group, particular attention being directed to stereochemical effects in this connection. This system provides an excellent didactic approach to the subject. Rather unusual is the extension of *Ruzicka*'s convention of writing a large dot to designate the stereochemistry at ring junctions also to hydrogen atoms not in an angular position. This formulation is however not applied consistently throughout the book. Two chapters on the total synthesis and the biochemistry of the title compounds close the general section.

In the "catalogue", the formulae, melting points, and specific optical rotations of all the known tetracyclic triterpenes are given in summary. A particularly valuable appendix follows in which the infrared and ultraviolet absorption bands and the amplitudes of the Cotton effects of the most frequently occurring chromophores are tabulated.

Ourisson and his coauthors have succeeded in presenting the interesting chemistry of the tetracyclic triterpenes in a masterly, comprehensive form. Their book can be recommended highly to anyone seeking detailed information in this field.

SUBJECT INDEX

FP = Full paper (review article) CR = Conference report
SC = Short communication LA = Literature abstract
G.E. = Reference to the German Edition of Angewandte Chemie. References are given for Review Articles, Short Communications, and Conference Reports only.

ACENES, New semiquantitative calculation of the delocalization energy in benzene and in the ~ (CR) 979 [G.E. 77, 1026 (1965)]

Acetals, Reacns. of amide ~ with isothiocyanates (SC) 523 [G.E. 77, 507 (1965)]

Synth. of *O,N*- and *N,N*-~ of α-ketonitriles (SC) 523 [G.E. 77, 508 (1965)]

New developments in the ionic polymerizn. of cyclic ~ (CR) 891 [G.E. 77, 871 (1965)]

Acetexa, Therapy congress and pharmaceutical exhibition (CR) 157 [G.E. 77, 174 (1965)]

Acetic acid solvates of Ni and Cu salts (CR) 703 [G.E. 77, 727 (1965)]

Acetonitrile, Sodium ~-s, prepn. and reacns. (CR) 983 [G.E. 77, 1030 (1965)]

Acetoxylation, Anodic ~ of aromatic compds. (LA) 607

Acetylacetonates, Reacns. of metal ~ (FP) 132 [G.E. 77, 154 (1965)]

Metal chelate complexes as polymerizn. initiators (CR) 531 [G.E. 77, 512 (1965)]

Acetylene, Photocatalysed cycloaddn. of dihalogenomaleimides and dihalogenomaleic anhydrides onto olefins and ~-s (SC) 429 [G.E. 77, 452 (1965)]

Stereochemistry of addns. to acetylenic triple bonds (SC) 689 [G.E. 77, 679 1965)]

Thiophenes from 5-oxo derivs. of 1-alkynes (SC) 1082 [G.E. 77, 1141 (1965)]

Microwave spectrum and structure of $(CH_3)_3C-C\equiv C-Cl$ (CR) 1084 [G.E. 77, 1080 (1965)]

Diaryl-~-s and 1-alkyl-2-aryl-~-s (LA) 611

Acetylides, Complex ~ of transition metals (CR) 366 [G.E. 77, 352 (1965)]

Acid-base catalysis of the mutarotation of glucose (CR) 964 [G.E. 77, 973 (1965)]

Acid-base titrations, Potentiometric ~ in fused salts (LA) 371

Acid bromides, Reduction of ~ to aldehydes by irradiation in a hydrogen donor (SC) 146 [G.E. 77, 169 (1965)]

Acid chlorides, Reacns. of carbodiimides with ~ (CR) 703 [G.E. 77, 727 (1965)]

Acidity function, An ~ H_- in the alkaline region (LA) 896

Acrylonitrile copolymers, Protecting effects in styrene-~ during the action of ionizing radiation (CR) 704 [G.E. 77, 728 (1965)]

Actinide elements, Anayltical chemistry of the ~ (Book Review) 268

Actionomycin, Binding of ~ on apyrimidinic acid (CR) 707 [G.E. 77, 731 (1965)]

Acylamines, Reacn. of lead tetraacetate with unsubstd. prim. amides (LA) 999

N-Acylaziridines, β-Aminoethylation of CH-acidic compds. with ~ (SC) 524 [G.E. 77, 546 (1965)]

N-Acylcarbodiimides, Synth. of ~ and *N*-sulfonylcarbodiimides (LA) 449

Acyl migration, 1,4-N → N'-~ in a diamino steroid (SC) 74 [G.E. 77, 94 (1965)]

N-Acyloxyammonium salts (LA) 896

Acyloxynitrosoalkanes, Gem. ~ and their dimers (CR) 983 [G.E. 77, 1030 (1965)]

Acyl radicals, Substitution reacns. with photochemically produced ~ (SC) 239 [G.E. 77, 216 (1965)]

Adamantane, New synth. of the ~ ring system (SC) 153 [G.E. 77, 171 (1965)]

β-Adamantanonecarboxylic acids, Synth. of the two stereoisomeric ~ (CR) 992 [G.E. 77, 1040 (1965)]

Addition compds., Complexes and ~ of main group elements (CR) 251 [G.E. 77, 266 (1965)]

Adsorption, Mobility of molecules adsorbed on the surfaces of solids (CR) 892 [G.E. 77, 924 (1965)]

Effects in polarography attributable to the specific ~ of reactants (CR) 967 [G.E. 77, 1014 (1965)]

Ageing of precipitates by Ostwald ripening (CR) 444 [G.E. 77, 431 (1965)]

Air chemistry and radioactivity (Book Review) 176

Albizziin, The action of diazooxonorleucine and ~ on the biosynth. of aromatic amino acids in *Saccharomyces cerevisiae* and *Escherichia coli* (CR) 707 [G.E. 77, 731 (1965)]

Alchemy, Lexicon alchemiae sive dictionarum alchemisticum (Lexicon of alchemy and alchemical dictionary) (Book Review) 611

Alcohol dehydrogenase, Amino-acid sequence around the active site in liver ~ (LA) 374

Formation of antibodies against ~ (LA) 997

Alcohols, Association of isomeric hydroxyalkane derivs. (CR) 367 [G.E. 77, 352 (1965)]

Asymmetric synth. of optically active ~ from carbonyl compds. (LA) 98

Characterization of prim. and sec. ~ (LA) 719

Aldehydes, Reduction of acid bromides to ~ by irradiation in a hydrogen donor (SC) 146 [G.E. 77, 169 (1965)]

Prepn. of 1,3-oxazolidines from isonitriles and ~ by a multicomponent reacn. (SC) 596 [G.E. 77, 591 (1965)]

Disubstitution in the Vilsmeier-Haack ~ synth. (SC) 955 [G.E. 77, 967 (1965)]

Five-membered heterocycles from hydrazomethane, aromatic ~, and dipolarophiles (CR) 701 [G.E. 77, 725 (1965)]

Conversion of aromatic ~ into alkyl aryl ketones (LA) 795

Algae, Chloramphenicol can serve as sole source of nitrogen for ~ (LA) 718

Alkali halide, Formation of negative ions in ~ vapors (LA) 100

Alkaloids, Synth. of heterocyclic compds. and model reacns. of ~ biogenesis (CR) 260 [G.E. 77, 224 (1965)]

Biosynth. of lupine ~ (CR) 991 [G.E. 77, 1039 (1965)]

Tecomine and tecostanine, two antidiabetic ~ (LA) 608

Die Mutterkorn-Alkaloide (Ergot ~) (Book Review) 612

Alkoxides, Hydrolysis of metal ~ – a new method for studying polyacids (CR) 368 [G.E. 77, 386 (1965)]

~ oxidn. involving hydride transfer to dichlorocarbene, and group migration during carbene reacns. (LA) 451

Alkylaluminum compds., Reacns. of ~ with diazomethane (CR) 1088 [G.E. 77, 1084 (1965)]

7-Alkylamino-7-phenyl-8-thioxo-1,2,3,4-5,6-hexathiocanes, Synth. and elucidation of the structures of ~ (SC) 71 [G.E. 77, 41 (1965)]

Alkyl aryl ketones, Conversion of aromatic aldehydes into ~ (LA) 795

Alkylating properties of alkyl thiophosphates (FP) 914 [G.E. 77, 1001 (1965)]

Alkylation, Introduction of tert. alkyl groups into aliphatic compds. (CR) 369 [G.E. 77, 386 (1965)]

~ of phosphine chalcogenides and phosphinylamines (CR) 712 [G.E. 77, 737 (1965)]

Alkyl halides, Isotopic exchange reacns. of ~ (CR) 699 [G.E. 77, 723 (1965)]

Alkylidenephosphoranes, New Methods in preparative organic chemistry. New reacns. of ~ and their preparative uses (FP) 583, 645, 830 [G.E. 77, 609, 651, 850 (1965)]

Alkylenediphosphines, Prepn. and properties of diprim. ~ (CR) 984 [G.E. 77, 1032 (1965)]

Alkyl sulfates, Addn. of sodium ~ to water alters the chem. shift of the proton signals (LA) 100

Alkyl thiophosphates, Alkylating properties of ~ (FP) 914 [G.E. 77, 1001 (1965)]

Alkyl vinyl sulfides, Prepn. of 1,2-disubstd. vinylsulfonium salts and ~, and of ethynylsulfonium and ethynylselenonium salts (SC) 1080 [G.E. 77, 1140 (1965)]

Allocystathionine, New synth. of cystathionine and ~ (SC) 599 [G.E. 77, 591 (1965)]

Alloys, Structures and chem. properties of nitrides in ternary iron ~ (CR) 256 [G.E. 77, 268 (1965)]

Crystallographic data on metal and alloy structures (Book Review) 380

Selected values of thermodynamic properties of metals and ~ (Book Review) 452

Allyl halides, Reacn. of ~ with diazomethane catalysed by Cu salts (SC) 691 [G.E. 77, 679 (1965)]

Allyl hydroperoxide, Synth. and properties of ~ (SC) 1074 [G.E. 77, 1078 (1965)]

Alpha-radiation, Influence of ~ on metal surfaces (CR) 445 [G.E. 77, 431 (1965)]

Aluminosiloxanes, Recent developments in the chemistry of heterosiloxanes (FP) 201 [G.E. 77, 206 (1965)]

Aluminum-arene complexes (SC) 600 [G.E. 77, 623 (1965)]

Aluminum compds., Heterosiloxanes and t-butoxy compds. of aluminum, gallium and indium (SC) 152 [G.E. 77, 169 (1965)]

Trimethylaluminum trimethylphosphorus oxide and trimethylarsenic trimethylgallium oxide (SC) 153 [G.E. 77, 170 (1965)]

Amide acetals, Synth. and reacns. of vinylogous ~ and vinylogous amidines (SC) 242 [G.E. 77, 219 (1965)]

Reacns. of ~ with isothiocyanates (SC) 523 [G.E. 77, 507 (1965)]

Selective protolysis of unsatd. organo-~ (SC) 954 [G.E. 77, 1010 (1965)]

Reacns. of alkyl-~ with diazomethane (CR) 1088 [G.E. 77, 1084 (1965)]

Americium, Chelation of neptunium, plutonium, and americium by derivs. of 8-hydroxyquinoline (CR) 971 [G.E. 77, 1018 (1965)]

Amides, Production of mixed dicarbox-~ from cyclic sec. amines and cyclic dicarboximides. Products of the reacn. of aziridine with maleimide (SC) 693 [G. E. 77, 718 (1965)]

Mechanism of catalysed reactions of formaldehyde with amines and ~ (CR) 440 [G.E. 77, 459 (1965)]

Reduction of vinylogous ~ with $LiAlH_4$ (CR) 710 [G.E. 77, 735 (1965)]

Sepn. of rotational isomers of ~, thioamides, and nitrosamines (CR) 985 [G.E. 77, 1032 (1965)]

Synth. of cyclo-~ and cyclopeptides with medium-sized rings (CR) 988 [G.E. 77, 1036 (1965)]

Addn. of formamide onto terminal olefins (LA) 171

Connections between the structures and long-wave infrared spectra of aliphatic ~ (LA) 721

Sodium bis-(4-bromophenylsulfonyl)-~ is used for identifying organic bases (LA) 895

Reacn. of lead tetraacetate with unsubstd. prim. ~ (LA) 999

Amidines, Synth. and reacns. of vinylogous amide acetals and vinylogous ~ (SC) 242 [G.E. 77, 219 (1965)]

Amination, Dialkylamination – a new aromatic substitution reacn. (SC) 783 [G.E. 77, 807 (1965)]

Amines, Addn. of ~ to cyanic esters (SC) 430 [G.E. 77, 452 (1965)]

Production of mixed dicarboxamides from cyclic sec. ~ and cyclic dicarboximides. Products of the reacn. of aziridine with maleimide (SC) 693 [G.E. 77, 718 (1965)]

Synth. and reacns. of *N,N,N',N'*-tetramethyl-3-methoxy-1-propene-1,3-diamine and *N,N,N',N',N'',N''*-hexamethyl-2-propene-1,1,3-triamine (SC) 955 [G.E. 77, 1010 (1965)]

Mechanism of catalysed reacn. of formaldehyde with ~ and amides (CR) 440 [G.E. 77, 459 (1965)]

Reduction of vinylogous amides with $LiAlH_4$ (CR) 710 [G.E. 77, 735 (1965)]

Nucleophilicity and basicity of ~ (CR) 715 [G.E. 77, 739 (1965)]

Detecn. and determination of ~ on the 10^{-10} molar scale. Sepn. of 5-dimethylamino-1-naphthalenesulfonamides on thin-layer chromatograms (CR) 716 [G.E. 77, 684 (1965)]

Cyclization of 1,1-diamino compds. (CR) 883 [G.E. 77, 919 (1965)]

Synth. of aliphatic ~ from carbon monoxide, steam and NH_3 (CR) 981 [G.E. 77, 1028 (1965)]

Condensation of formaldehyde with bis-(2-halogenoethyl)-~ (LA) 372

Amino acids, *N*-(2,4-Dinitrophenyloxycarbonyl)amino esters – new *N*-activated ~ derivs. (SC) 790 [G.E. 77, 813 (1965)]

VIth International congress of biochemistry (CR) 75 [G.E. 77, 97 (1965)]

New synth. of β-hydroxy-α-~ (CR) 365 [G.E. 77, 381 (1965)]

Action of diazooxonorleucine and albizziin on the biosynthesis of aromatic ~ in *Saccharomyces cerevisiae* and *Escherichia coli* (CR) 707 [G.E. 77, 731 (1965)]

Rare ~ in plants (CR) 884 [G.E. 77, 920 (1965)]

Stable ninhydrin reagent for automatic determin. of ~ (CR) 992 [G.E. 77, 1039 (1965)]

Mass-spectrometric sequence analysis of acetylated peptides of aromatic ~ (CR) 1087 [G.E. 77, 1083 (1965)]

Di- and tripeptides from ~ esters and hydroxamic acid derivs. (LA) 171

New method for resolving D,L-~ (LA) 793

Sex-specific differences in the concentration of serum ~ (LA) 997

Amino-acid sequence, of ferredoxin (LA) 536

Mass-spectrometric ~ analysis (LA) 999

Amino alcohols, New synth. of aziridines, carbamates, oxazolidones and *cis*- or *trans*-2-~ (LA) 370

Aminoalkenes, α-Dithiopyrones from ~ and CS_2 (SC) 246 [G.E. 77, 261 (1965)]

α-Formyl ketones from ~ by Vilsmeier formylation (SC) 358 [G.E. 77, 380 (1965)]

Synth. of iminopyrrolidones and iminothiopyrrolidones from ~ and isonitriles plus isocyanates or isothiocyanates (SC) 519 [G.E. 77, 544 (1965)]

Synth. of 1,3-thiazolidin-2-ones from ~, isocyanates, and sulfur (SC) 519 [G.E. 77, 544 (1965)]

Cycloaddn. of diphenylcyclopropenone onto ~ (LA) 795

α-Aminoalkylation of white phosphorus (SC) 527 [G.E. 77, 549 (1965)]

Aminoboranes, Infrared spectra and frequency assignment of some ~ containing ^{10}B (CR) 698 [G.E. 77, 722 (1965)]

β-Aminoethylation of CH-acidic compds. with *N*-acylaziridines (SC) 524 [G.E. 77, 546 (1965)]

~ of malonic esters and of β-keto esters with aziridines (CR) 714 [G.E. 77, 738 (1965)]

β-Aminoisobutyric acid, Quantitative determin. of ~ by thin-layer chromatography (CR) 716 [G.E. 77, 683 (1965)]

α-Amino ketones Prepn. of α-hydroxy ketones by hydrolysis of ~ (SC) 951 [G.E. 77, 964 (1965)]

New synth. of ~ from olefins (LA) 372

3'-Aminonucleosides, Synth. of ~ (CR) 706 [G.E. 77, 731 (1965)]

Amino peptidase, New ~ from kidney particles (LA) 536

N-Aminophthalimide has been used for unequivocal synth. of *N*-aminopyrroles (LA) 999

N-Aminopyrroles, *N*-Aminophthalimide has been used for unequivocal synth. of ~ (LA) 999

Aminosilanes, Prepn. and reacns. of optically active ~ (CR) 882 [G.E. 77, 918 (1965)]

Ammonia, Function of the promotors in the technical ~ catalyst (FP) 341 [G.E. 77, 333 (1965)]

Enrichment of deuterium by countercurrent isotope exchange between hydrogen and ~ in a hot-and-cold plant (SC) 597 [G.E. 77, 620 (1965)]

Photolysis of ~ in the vacuum-ultraviolet (CR) 370 [G.E. 77, 387 (1965)]

Ammoniates of uranium trichloride and tetrachloride (SC) 431 [G.E. 77, 453 (1965)]

Ammonium salts, *N*-Acyloxy-~ (LA) 896

Ammonolysis, High-temperature ~ of uranium trichloride and tetrachloride (SC) 433 [G.E. 77, 428 (1965)]

~ of diphosphorus pentoxide (CR) 1093 [G.E. 77, 1089 (1965)]

Amphoteric oxides, Chemistry of ~ (CR) 534 [G.E. 77, 551 (1965)]

α-Amylase, Enzymatic method for kinetic investigations of endohydrolases: assay of the activity of ~ (CR) 529 [G.E. 77, 510 (1965)]

Analgetics, Alcoholic derivs. of tetrahydro-6,14-endoethenothebaine have a high analgetic affect (LA) 262

Analysis, Symposium on radiochem. methods of ~ (CR) 254 [G.E. 77, 220 (1965)]

Modern methods of inorg. ~ (CR) 255 [G.E. 77, 267 (1965)]

Modern analytical methods in the chemistry of foodstuffs and in biological chemistry (CR) 716 [G.E. 77, 683 (1965)]

Treatise on analytical chemistry (Book Review) 381, 900

Reagents and reactions for qualitative inorganic ~ (Book Review) 453

Comprehensive analytical chemistry (Book Review) 541

~ of ancient metals (Book Review) 899

The application of mathematical statistics to chemical ~ (Book Review) 900

Anaplerotic sequences in microbial metabolism (FP) 558 [G.E. 77, 601 (1965)]

Anesthetics, The effect of sodium γ-hydroxybutyrate on the activity of ~ (LA) 98

1,6-Anhydroidose derivs. with rings containing nitrogen (SC) 592 [G.E. 77, 589 (1965)]

Anion-exchangers, Use of chromatography on ~ for determin. of low phosphate contents (CR) 717 [G.E. 77, 683 (1965)]

Aolan, Therapy congress and pharmaceutical exhibition (CR) 157 [G.E. 77, 174 (1965)]

Annulene trisulfide, Structure of [18]-~ (LA) 97

Anthracene, Deriv. of Dewar ~ (LA) 448

Anthradiquinone, Synth. and properties of 1,4,5,8-~ (SC) 1078 [G.E. 77, 1137 (1965)]

Anthranilic acid, Incorporation of ~ into peganine (vascine) (LA) 448

Antibodies, to biologically active molecules (CR) 888 [G.E. 77, 921 (1965)]

Formation of ~ against alcohol dehydrogenase (LA) 997

Antidiabetic alkaloids, Tecosine and tecostanine are two ~ (LA) 608

Antimony compds., Phosphorus ~, sulfur, and selenium compds. in the liquid-liquid extraction of transition-metal ions (CR) 1096 [G.E. 77, 1092 (1965)]

Apyrimidinic acid, Binding of actinomycin on ~ (CR) 707 [G.E. 77, 731 (1965)]

Aromatic compds., Phosphorescence spectroscopy as an analytical method for ~ and heterocyclic compds. (FP) 930 [Chemie-Ing.-Techn. 37, 1010 (1965)]

Biosynth. of ~ (CR) 888 [G.E. 77, 921 (1965)]

Aromaticity, Cyclopropenylium compds. and cyclopropenones (FP) 10 [G.E. 77, 10 (1965)]

Arsenic compds., Trimethylaluminum trimethylphosphorus oxide and trimethylarsenic trimethylgallium oxide (SC) 153 [G.E. 77, 170 (1965)]

Arsenic radical, Mesomeric free ~ (LA) 450

Arsines, Synth. and properties of some new phenyltin-~, -stibines, and -bismuthines (CR) 991 [G.E. 77, 1039 (1965)]

Chloro-~ with t-butyl groups (LA) 999

Arsinosiloxanes, Recent developments in the chemistry of heterosiloxanes (FP) 201 [G.E. 77, 206 (1965)]

Aryl iminomethyl disulfides, Synth. of ~ (SC) 696 [G.E. 77, 720 (1965)]

Arynes, The Hetarynes (FP) 543 [G.E. 77, 557 (1965)]

Aspartate, Selective hydrolysis of ~ bonds (LA) 896

Aspartate transcarbamylase, Mechanism of the end-product inhibition of ~ (LA) 264

Asphaltenes, Colloid chemical investigations on ~ (CR) 1092 [G.E. 77, 1088 (1965)]

Association of isomeric hydroxyalkane derivs. (CR) 367 [G.E. 77, 352 (1965)]

Intermolecular ~ of liq. nitriles (LA) 98

Asteranes, Synth. of ~ (LA) 1099

Asymmetric synth. of optically active alcohols from carbonyl compds. (LA) 98

Azeotropy and polyazeotropy (Book Review) 380

Azenes. Pyrolysis of alkyl azidoformates in the gas phase (SC) 69 [G.E. 77, 42 (1965)]

Azides, Thermal analysis of inorganic ~ (CR) 602 [G.E. 77, 593 (1965)]

Reacns. of organic ~ under the conditions of the Friedel-Crafts reacn. (CR) 706 [G.E. 77, 730 (1965)]

Azido complexes of manganese(II) and palladium(II) (SC) 439 [G.E. 77, 458 (1965)]

Azidoformates, Pyrolysis of alkyl ~ in the gas phase (SC) 69 [G.E. 77, 42 (1965)]

α-Azido ketones, Electrophilic substitn. by ~ (SC) 952 [G.E. 77, 963 (1965)]

Azines, Synthesis of bis(diaziridin-1-ylmethylene)hydrazine (SC) 521 [G.E. 77, 506 (1965)]

Formation of carbonyl compds. from ~ or hydrazones with active manganese dioxide (SC) 956 [G.E. 77, 967 (1965)]

Reacns. of triethyl orthoformate with some nitrogen compds. (CR) 702 [G.E. 77, 726 (1965)]

Conversion of diaziridines into ~ (CR) 978 [G.E. 77, 1026 (1965)]

Aziridines, Synthesis of bis(diaziridin-1-ylmethylene)hydrazine (SC) 521 [G.E. 77, 506 (1965)]

β-Aminoethylation of CH-acidic compounds with *N*-acyl-~ (SC) 524 [G.E. 77, 546 (1965)]

Production of mixed dicarboxamides from cyclic sec. amines and cyclic dicarboximides. Products of the reacn. of ~ with maleimide (SC) 693 [G.E. 77, 718 (1965)]

β-Aminoethylation of malonic esters and of β-keto esters with ~ (CR) 714 [G.E. 77, 738 (1965)]

New synth. of ~, carbamates, oxazolidones, and *cis*- or *trans*-2-amino alcohols (LA) 370

~ from cyclic olefins (LA) 449

~ and Schiff bases from picryl azide and olefins (LA) 608

~ by photolysis of 1,2,3-triazolines (LA) 794

Aziridinium salts, Experiments with bridged cyclic systems containing nitrogen (CR) 536 [G.E. 77, 550 (1965)]

Aziridinium tetrafluoroborate, Synthesis of imidazolines and imidazolidines by the reacn. of ~ with nitriles and benzylideneaniline (SC) 518 [G.E. 77, 505 (1965)]

Azobenzenes, Symmetrically substituted ~ (LA) 609

Azobisphosphoric acid, Color and constitution of azo compds. (FP) 457 [G.E. 77, 469 (1965)]

Azo compds., Color and constitution of ~ (FP) 457 [G.E. 77, 469 (1965)]

Prepn. of ~ from *N,N'*-dialkylsulfamides (SC) 433 [G.E. 77, 429 (1965)]

Azocyanines, Synthesis of γ-phenylazopentamethinecyanine dyes (SC) 524 [G.E. 77, 508 (1965)]

Azodiphosphoric acid, Reacns. at the N=N double bond of ~ derivs. (CR) 969 [G.E. 77, 1016 (1965)]

Azulene, Polyazomethines with ~ residues inserted in the main chain (LA) 719

BACTERIOPHAGES, Protein components of the tail of T2 ~ (LA) 173

Baking agents, New enzymatic ~ (CR) 988 [G.E. 77 1036 (1965)]

Barbiturates, Infrared-spectroscopic investign. of ~ (CR) 973 [G.E. 77, 1020 (1965)]

Basazol dyes, New cotton dyes (FP) 312 [G.E. 77, 303 (1965)]

Bases, Sodium bis-(4-bromophenylsulfonyl) amide is used for identifying organic ~ (LA) 895

Basicity, Nucleophilicity and ~ of amines (CR) 715 [G.E. 77, 739 (1965)]

Benzaldehydes, Synth. of ~ by diazotization of benzylamines in dimethyl sulfoxide (SC) 787 [G.E. 77, 811 (1965)]

Benzene, Formula of ~ (FP) 729 [G.E. 77, 750 (1965)]

Valence-bond isomers of substituted ~ (FP) 746 [G.E. 77, 768 (1965)]

Accurate and simple calculation of the C–C distance in ~ (CR) 979 [G.E 77, 1026 (1969)]

New semiquantitat. calculation of the delocalization energy in ~ and in the acenes (CR) 979 [G.E. 77, 1026 (1965)]

New photochem. reacn. of ~ and some of its homologues (CR) 981 [G.E. 77, 1029 (1965)]

Friedel-Crafts reacn. of isocyanates and ~ derivs. (LA) 98

Benzene oxide, NMR-Spectroscopic studies of the equilibrium and kinetics of ~-oxepin conversns. (CR) 975 [G.E. 77, 1022 (1965)]

NMR-Spectroscopic investigations of the kinctics of the ~-oxepin equilibrium (CR) 1087 [G.E. 77 1083 (1965)]

Benzimidazoles, Uncoupling of the oxidative phosphorylation in mitochondria by NH-acidic ~ (SC) 788 [G.E. 77, 814 (1965)]

Inhibition of photosynth. reacns. by NH-acidic imidazoles and ~ (SC) 789 [G.E. 77, 911 (1965)]

Benzoazaboraoxacyclohexadienes, Benzoboradioxacyclohexadienes and ~ (SC) 432 [G.E. 77, 426 (1965)]

Benzoboradioxacyclohexadienes and benzoazaboraoxacyclohexadienes (SC) 432 [G.E. 77, 426 (1965)]

Benzo-1,3-dioxolium salts (SC) 873 [G.E. 77, 863 (1965)]

Benzo[b]oxepin, Synth. of 4-aryl-~ compounds and their rearr. to naphthalene derivs. (SC) 872 [G.E. 77, 864 (1965)]

Benzo[c]phenanthrene, Cyclic hydrocarbons of the ~ series (LA) 794

Benzoquinone, Interpretation of the spectra of monoamino-*p*-~-s (CR) 970 [G.E. 77, 1017 (1965)]

Three-dimensionally bonded dimer of ~ (LA) 99

Action of light on a Diels-Alder system (LA) 173

Benzosesquifulvalene, 1,2,3,4-Tetrachlorobenzo[g]sesquifulvalene (SC) 353 [G.E. 77, 345 (1965)]

Benzothiadiazole, Decomposition of 1,2,3-~ 1,1-dioxide (CR) 704 [G.E. 77, 728 (1965)]

Benzo-1,2,3-triazines, Photolysis of 3,4-dihydro-4-oxobenzo-1,2,3-triazines substd. in the 3-position (CR) 699 [G.E. 77, 723 (1965)]

Benzoylphosphonates, Synth. of *N*-phenyliminobenzylphosphonates and ~ by Michaelis-Arbusow reacn. of aromatic imidoyl chlorides (SC) 247 [G.E. *77*, 261 (1965)]

Benzoyl radicals, Isoln. of ~ (SC) 355 [G.E. *77*, 378 (1965)]

Benzvalene, Valence-bond isomers of substd. benzenes (FP) 746 [G.E. *77*, 768 (1965)]

Benzylamines, Synth. of benzaldehydes by diazotization of ~ in dimethyl sulfoxide (SC) 787 [G.E. *77*, 811 (1965)]

Benzylation of olefins (SC) 1072 [G.E. *77*, 1137 (1965)]

Benzyl butynyl ether, Ortho-rearr. of metalated ~ (SC) 957 [G.E. *77*, 1012 (1965)]

Benzylchloride, Oxidn. of transition elements by organic halides; detecn. of radicals by polymerizn. kinetics (CR) 533 [G.E. *77*, 514 (1965)]

Benzylideneaniline, Synth. of imidazolines and imidazolidines by the reacn. of aziridinium tetrafluoroborate with nitriles and ~ (SC) 518 [G.E. *77*, 505 (1965)]

Benzylmagnesium chloride, Ionization of ~ (SC) 878 [G.E. *77*, 914 (1965)]

Benzyne, see Dehydrobenzene

Beryllium, Chemistry of ~ (Book Review) 1101

Betaines, Reversibility of ~ formation during the Wittig reacn. (SC) 689 [G.E. *77*, 682 (1965)]

Formation of nucleophilic carbenes from heterocyclic *N*-methyl ~ (SC) 691 [G.E. *77*, 680 (1965)]

Bicyclo[5.4.1]dodecapentaenylium cation, Synth. of the ~ – a carbonium ion with 10 π-electrons (SC) 354 [G.E. *77*, 348 (1965)]

Bicyclo[2.2.1]hept-5-ene, Cycloaddn. of 1,1-dichloro-2,2-difluoroethylene onto dienes (LA) 172

Bicyclo[3.1.0]hex-2-ene, Unusual valence-bond isomerism (LA) 718

2,2'-Biindenyl, Synth. and properties of ~ (LA) 449

Binders, Interaction of pigments and ~ in solid paint films (CR) 973 [G.E. *77*, 1020 (1965)]

Biochemistry, VIth International congress of ~ (CR) 75 [G.E. *77*, 97 (1965)]

Second Conference of the Federation of European Biochemical Societies (CR) 888 [G.E. *77*, 921 (1965)]

Allgemeine Biochemie (General ~) (Book Review) 266

Bioenergetics, VIth International congress of biochemistry (CR) 75 [G.E. *77*, 97 (1965)]

2,2'-Biquinolyls, Complexochemical properties of bridged ~ (CR) 884 [G.E. *77*, 920 (1965)]

Biradical intermediates (LA) 172

Bis(diaziridin-1-ylmethylene)hydrazine, Synth. of ~ (SC) 521 [G.E. *77*, 506 (1965)]

Bismuthines, Synth. and properties of some new phenyltinarsines, -stibines, and -~ (CR) 991 [G.E. *77*, 1039 (1965)]

Bistrifluoromethyldiazomethane (LA) 719

Blood cells, Structure and function of the red ~ (CR) 165 [G.E. *77*, 138 (1965)]

Bond angles in metal carbonyl and metal nitrosyl compds. (SC) 692 [G.E. *77*, 719 (1965)]

Bond character in aromatic phosphorus compds. – a contribution to the problem of the existence and properties, of p_{π}–d_{π} bonds (CR) 603 [G.E. *77* 593 (1965)]

Character of the C–N bond between the benzene ring and the nitroso group (LA) 609

Bonding, Modern theoretical views on the chemical bond (FP) 660 [G.E. *77*, 666 (1965)]

Techniques for the use of radioisotopes in analysis. A laboratory manual 725

Ring index. A list of ring systems used in organic chemistry 725

Surface properties of silicate glasses 726

Spectrometric identification of organic compounds 726

Practical optical crystallography 726

Carbene chemistry 795

Handbook of chemistry and physics 795

Organic experiments 796

Physikalische Chemie (Physical chemistry) 796

Vanadium, toxicology and biological significance 797

Optical circular dichroism, principles, measurements, and applications 898

Polycyclic hydrocarbons 898, 899

Water and solute-water interactions 899

Analysis of ancient metals 899

Recent progress in surface science 899

The enzymes 899

The application of mathematical statistics to chemical analysis 900

Mucopolysaccharides. Chemical structure, distribution, and isolation 900

Treatise on analytical chemistry 900

Vitamine, Chemie und Biochemie (Vitamins, chemistry and biochemistry) 1000

Paramagnetische Elektronenresonanz (Electron paramagnetic resonance) 1000

Titrationen in nichtwäßrigen Lösungsmitteln (Titrations in non-aqueous solvents) 1000

Colorimetric determin. of elements. Principles and methods 1001

Silicate science 1001

Spectroscopy and photochemistry of uranyl compds. 1001

Inorg. ion exchangers 1001

Progress in boron chemistry 1002

Solvent extraction of metal chelates 1002

New biochem. separations 1002

Introduction to the chemistry of carbohydrates 1002

Comprehensive biochemistry 1003

Organische Chemie. Ein Lehrbuch für Naturwissenschaftler, Mediziner und Techniker (Organic chemistry. A textbook for science, medicine, and technology students) 1100

Organikum. Organisch-Chemisches Grundpraktikum (Practical organic chemistry) 1100

Chelating agents and metal chelates 1101

Peroxidase. Properties and uses of a versatile enzyme and of some related catalysts 1101

Chemistry of beryllium 1101

Tetracyclic triterpenes 1102

1-Bora-2,5-dioxa-3-aza-4-cyclopentene, New heterocyclic ring systems containing boron and nitrogen (SC) 151 [G.E. 77, 169 (1965)]

Boradioxacyclohexadienes, Benzo-~ and benzoazaboraoxacyclohexadienes (SC) 432 [G.E. 77, 426 (1965)]

1-Bora-2,5-dioxa-3,4-diaza-4-cyclopentene, New heterocyclic ring systems containing boron and nitrogen (SC) 151 [G.E. 77, 169 (1965)]

Borane carbonyl derivs., Selective reducing properties of ~ (LA) 897

Boranes, Prepn. of triphenylphosphine from triphenylphosphine oxide by reducn. with ~ (SC) 593[G.E. 77, 589 (1965)]

Boraoxacyclohexadienes, Benzoboradioxacyclohexadienes and benzoaza-~ (SC) 432 [G.E. 77, 426 (1965)]

1-Bora-2-oxa-3,4,5-triaza-4-cyclopentene, New heterocyclic ring systems containing boron and nitrogen (SC) 151 [G.E. 77, 169 (1965)]

Bora-5-phosphabicyclo[3.3.0]octane, 1,5-Diphenyl-1-~ (LA) 536

1-Bora-2,3,4,5-tetraza-4-cyclopentene, New heterocyclic ring systems containing boron and nitrogen (SC) 151 [G.E. 77, 169 (1965)]

Borazines, Substitution and condensation reacns. of ~ (CR) 891 [G.E. 77, 872 (1965)]

Borazole, 1,2:3,4:5,6-Tris-(2,2'-biphenylylene)-~ — a trimer of 9,10-azaborophenanthrene (SC) 695 [G.E. 77, 719 (1965)]

Boron, Diffusion of ~ in graphite (LA) 718

Boron azides, Stability of ~ (CR) 987 [G.E. 77, 1035 (1965)]

Boron compds., New heterocyclic ring systems containing boron and nitrogen (SC) 151 [G.E. 77, 169 (1965)]

Synthesis of a 2,5-diaza-1,3,4-triborolidine (SC) 522 [G.E. 77, 506 (1965)]

New ring system containing boron (SC) 958 [G.E. 77, 1012 (1965)]

Progress in boron chemistry (Book Review) 1002

Boron halides, Curtius reacn. with ~ (SC) 595 [G.E. 77, 591 (1965)]

Boron heterocycles, Production and properties of boron heterocycles containing sulfur (LA) 263

Boron oxide, Ternary compds. and solid solutions in the system calcium oxide/phosphorus(V) oxide/boron(III) oxide (CR) 967 [G.E. 77, 1014 (1965)]

Boron radicals, Free aryl-~(LA) 897

Bradykinine, Biological activity of ~ (LA) 607

Brain metabolism, Metabolite content and function of the substrate-free perfused rabbit brain (CR) 1089 [G.E. 77, 1085 (1965)]

Brinaldix, Therapy congress and pharmaceutical exhibition (CR) 157 [G.E. 77, 174 (1965)]

1-Bromo-2-chloroethane, Prepn. of ~ and 1-chloro-2-iodoethane (SC) 241 [G.E. 77, 218 (1965)]

N-Bromohexamethyldisilazane (SC) 73 [G.E. 77, 130 (1965)]

Bullvalene, Molecules undergoing fast, reversible valence-bond isomerizn. (FP) 752 [G.E. 77, 774 (1965)]

Synth. and properties of phenyltricyclo[3.3.2.0^{4,6}]decatriene (phenyl-~) (SC) 695 [G.E. 77, 682 (1965)]

Butadiene, Recent results in the catalytic oligomerization and co-oligomerization of ~ (FP) 327 [G.E. 77, 318 (1965)]

Synth. and reacns. of 1,4-dimercapto-~ (CR) 884 [G.E. 77, 919 (1965)]

1,2-Polybutadiene from ~ (LA) 262

Vulcanization of styrene/~ copolymers with maleimides (LA) 721

Butadiyne, New pyrrole synthesis starting from ~ (LA) 895

Butenolides, New synth. of ~ (SC) 783 [G.E. 77, 808 (1965)]

γ-Butyrolactone, Photoinduced addn. of ~ onto terminal olefins (LA) 607

CADMIUM, Heterosiloxanes of zinc and ~ (SC) 876 [G.E. 77, 865 (1965)]

Cadmium halides, Prepn. of heavy metal halides in anhydrous acetic acid (SC) 869 [G.E. 77, 860 (1965)]

Calcium oxide, Ternary compds. and solid solutions in the system ~/phosphorus(V) oxide/boron(III) oxide (CR) 967 [G.E. 77, 1014 (1965)]

Calicene, 5,6-Dimethylbenzo[*a*]-~ (SC) 242 [G.E. 77, 258 (1965)]

Synth. and properties of 5,6-dimethyldibenzo[*a,c*]-~ (SC) 598 [G.E. 77, 621 (1965)]

Canal inclusion compds., Importance of ~ for polymerizn research (CR) 367 [G.E. 77, 353 (1965)]

ε-Caprolactam, Oligomers obtained in cationic and anionic polymerizn. of ~ (CR) 531 [G.E. 77, 512 (1965)]

Caradrin, Therapy congress and pharmaceutical exhibition (CR) 157 [G.E. 77, 174 (1965)]

Carbamates, New synth. of aziridines, ~, oxazolidones, and *cis*- or *trans*-2-amino alcohols (LA) 370

Carbanions, of 1,3-dithianes. Reagents for C–C bond formation by nucleophilic displacement and carbonyl addn. (SC) 1075 [G.E. 77, 1134 (1965)]

Synth. of 1,n-dicarbonyl derivs. using ~ from 1,3-dithianes (SC) 1077 [G.E. 77, 1135 (1965)]

Stability and reactivity of α-halogen ~ (CR) 706 [G.E. 77, 730 (1965)]

Carbazole, Dehydrobenzene condenses with nitrobenzenes to form the ~ ring system (LA) 610

Carbenes, Intermediates of α-eliminations (FP) 1 [G.E. 77, 1 (1965)]

Formation of nucleophilic ~ from heterocyclic *N*-methyl betaines (SC) 691 [G.E. 77, 680 (1965)]

Rearr. of β-alkoxyalkyl-~ (SC) 692 [G.E. 77, 681 (1965)]

Formation of phenyl-~ by photolysis of phenyloxiranes (SC) 868 [G.E. 77, 859 (1965)]

Existence of metal carbonyl ~ complexes (SC) 1082 [G.E. 77, 1142 (1965)]

~ and carbenoid reactions (CR) 891 [G.E. 77, 923 (1975)]

Attempted prepn. of ~, nitrenes, and sulfenes (CR) 981 [G.E 77, 1028 (1965)]

New method of generating ~ (CR) 987 [G.E. 77, 1034 (1965)]

Alkoxide oxidation involving hydride transfer to dichloro-~, and group migration during ~ reacns. (LA) 451

New method of preparing dihalogeno-~ from organometallic compds. (LA) 897

Intermolecular addn. of an α-keto carbene onto an alkenone double bond (LA) 998

Spin multiplicity of difluoro-~ (LA) 1098

Carbene chemistry (Book Review) 759

Carbodiimides, Sulfonyl isocyanide dichlorides and sulfonyl ~ (SC) 430 [G.E. 77, 430 (1965)]

(1,3,4,6-Tetra-*O*-acetyl-β-D-glucos-2-yl)-~ (SC) 435 [G.E. 77, 454 (1965)]

Synth. of 2-imino-4-thioxo-1,3-diazetidine derivs. by cycloaddn. of isothiocyanates onto ~ (SC) 520 [G.E. 77, 545 (1965)]

Reacns. of ~ with acid chlorides (CR) 703 [G.E. 77, 727 (1965)]

Synthesis of *N*-acyl- and *N*-sulfonyl-~ (LA) 449

Carbohydrates, Chemistry of ~ (CR) 166 [G.E. 77, 135 (1965)]

Dicyclohexylcarbodiimide as a new reagent for epimerizing and isomerizing ~ (LA) 999

Methods in carbohydrate chemistry (Book Review) 266

Introduction to the chemistry of ~ (Book Review) 1002

Carbonato compds. of praseodymium(IV) and terbium(IV) (CR) 987 [G.E. 77, 1035 (1965)]

Carbon dioxide, Rapid determin. of ~ (LA) 97

Carbonic acid, Prepn. of "free ~" (SC) 149 [G.E. 77, 132 (1965)]

Carbonium ion, Synth. of the bicyclo[5,4,1]dodecapentaenylium cation – a ~ with 10 π-electrons (SC) 354 [G.E. 77, 348 (1965)]

Synth. and reacns. of diarylmethyl-~-s (SC) 873 [G.E. 77, 864 (1965)]

Rearr. of homoallylic ~-s (CR) 976 [G.E. 77, 1023 (1965)]

Carbon monoxide, Reacn. of sodium bistrimethylsilylamide with ~ and metal carbonyls (SC) 438 [G.E. 77, 457 (1965)]

Synth. of aliphatic amines from ~, steam, and NH_3 (CR) 981 [G.E. 77, 1028 (1965)]

Carbon tetrachloride, Oxidn. of transition elements by organic halides; detecn. of radicals by polymerizn. kinetics (CR) 533 [G.E. 77, 514 (1965)]

Carbonyl complexes, Reacn. of sodium bistrimethylsilylamide with carbon monoxide and metal carbonyls (SC) 438 [G.E. 77, 457 (1965)]

Bond angles in metal carbonyl and metal nitrosyl compds. (SC) 692 [G.E. 77, 719 (1965)]

Existence of metal carbonyl carbene complexes (SC) 1082 [G.E. 77, 1142 (1965)]

Carbonyl compds. (CR) 250 [G.E. 77, 265 (1965)]

Isomerism of complexes of the type [π-$C_5H_5M(CO_2)_2$] (CR) 700 [G.E. 77, 724 (1965)]

Mechanism of the reacn. of metal-hexacarbonyls with n- and π-electron donors (CR) 994 [G.E. 77, 1041 (1965)]

Covalent metal-metal bonds in mixed metal carbonyls (LA) 97

Production of carbonyls of transition metals (LA) 172

Carbonyl compds., Formation of ~ from azines or hydrazones with active manganese dioxide (SC) 956 [G.E. 77, 967 (1965)]

Asymmetric synth. of optically active alcohols from ~ (LA) 98

Carbonyl groups, NADH model which reduces ~ almost quantitatively and non-enzymatically (LA) 171

Carboranes, Organo-~ from alkyldiboranes (SC) 439 [G.E. 77, 457 (1965)]

Carboxylic acids, Light-induced formation of ~ from cyclic ketones (FP) 211 [G.E. 77, 229 (1965)]

Gas-chromatographic sepn. and estimation of aliphatic mono-~ with 1–5 carbon atoms (SC) 71 [G.E. 77, 95 (1965)]

Synth. of ~ with 1,1-dichloroethylene (SC) 956 [G.E. 77, 967 (1965)]

Association of isomeric hydroxyalkane derivs. (CR) 367 [G.E. 77, 352 (1965)]

New aspects of the Koch ~ synth. (CR) 535 [G.E. 77, 551 (1965)]

Aliphatic ~ formed by a Friedel-Crafts synth. (LA) 372

Extension of the chains of ~ by three carbon atoms (LA) 450

New method of decarboxylating aliphatic acids to the next lower alkyl halide (LA) 998

Carvomenthylamines, NMR-Spectroscopic conformational analysis of menthylamines and ~ (CR) 699 [G.E. 77, 723 (1965)]

Catalase, Quaternary structure of ~ from beef liver (SC) 597 [G.E. 77, 621 (1965)]

Isoenzyme pattern of maize ~ has been determined genetically (LA) 609

Catalyst, Function of the promotors in the technical ammonia ~ (FP) 341 [G.E. 77, 333 (1965)]

Novel chelated ~ systems for polymerizing ethylene (LA) 610

Cell division, Zeatine a factor which induces ~ (LA) 99

Cellulose, Model concepts of ~ synth. and of the formation of plant cell walls (CR) 530 [G.E. 77, 510 (1965)]

Kinetic studies on the biosynth. of ~ (CR) 530 [G.E. 77, 510 (1965)]

Cell walls, Model concepts of cellulose synth. and of the formation of plant ~ (CR) 530 [G.E. 77, 510 (1965)]

Chain extension of carboxylic acids by three carbon atoms (LA) 450

Charge-transfer complexes, Reactivity of dienophiles and ability to form ~ (CR) 711 [G.E. 77, 736 (1965)]

~ of biochemically important substances (LA) 371

~ between rhodane and aromatic hydrocarbons (LA) 537

Chelates, Metal ~ as polymerizn. initiators (FP) 322 [G.E. 77, 313 (1965)]

Tetrahedral and octahedral cationic ~ of main group elements (CR) 248 [G.E. 77, 264 (1965)]

Opening of the four-membered ~ ring of the tetraamminecarbonatocobalt-(III) ion (CR) 443 [G.E. 77, 462 (1965)]

Polychelated siloxanes (CR) 530 [G.E. 77, 511 (1965)]

Metal ~ complexes as polymerizn. initiators (CR) 531 [G.E. 77, 512 (1965)]

Intermolecular acid catalysis in the iodination of keto acids. Detection of proton ~ in aqueous solution (CR) 881 [G.E. 77, 917 (1965)]

Solvent extraction of metal ~ (Book Review) 1002

Chelating agents and metal ~ (Book Review) 1101

Chemical bond, Modern theoretical views on the ~ (FP) 660 [G.E. 77, 666 (1965)]

Die chemische Bindung. Drei Vorlesungen für Chemiker (The chemical bond – three lectures for chemists) (Book Review) 265

Chemical technology, Ullmanns Encyklopädie der technischen Chemie (Ullmann's Encyclopaedia of ~) (Book Review) 173

Encyclopedia of ~ (Book Review) 378

Chemiluminescence in org. compds. (FP) 566 [G.E. 77, 572 (1965)]

Chemistry lecturers, Meeting of South-West German ~ (CR) 697 [G.E. 77, 684 (1965)]

Conference of ~ in Potsdam (CR) 879 [G.E. 77, 915 (1965)]

Conference of North-West German ~ (CR) 1083 [G.E. 77, 1079 (1965)]

Chemotherapy, Therapy congress and pharmaceutical exhibition (CR) 156 [G.E. 77, 174 (1965)]

Chloramphenicol can serve as sole source of nitrogen for algae (LA) 718

Chlorates, Behavior of alkali metal ~ on heating (LA) 606

Chlorination, Synth. of *N*-phenyl-*S*-chloroisothiocarbamoyl chlorides by ~ of isothiocyanates (SC) 432 [G.E. 77, 427 (1965)]

Isomer formation in the mono-~ of n-heptane with PCl_5 and with PCl_3/Cl_2 (SC) 522 [G.E. 77, 506 (1965)]

Chlorinated poly(vinyl chloride) (CR) 533 [G.E. 77, 514 (1965)]

Chloroarsines with t-butyl groups (LA) 999

Chloroaurate, Standard potentials of the gold/~ system (LA) 608

Chloroform, Proton magnetic resonance measurements on hydrogen-bond associates of ~ (CR) 700 [G.E. 77, 724 (1965)]

1-Chloro-2-iodoethane, Prepn. of 1-Bromo-2-chloroethane and ~ (SC) 241 [G.E. 77, 218 (1965)]

Chlorometalates, Stability and coordination of alkali ~-(II) of the light transition elements (CR) 713 [G.E. 77, 738 (1965)]

Chloromethoxyacetate, Synth. with methyl ~ (CR) 975 [G.E. 77, 1022 (1965)]

5-Chloromethylcytosine, Synth. and properties of ~ (SC) 245 [G.E. 77, 260 (1965)

5-Chloromethyl-2,2-dinitrotetrahydrofuran, Synth. of ~ (SC) 433 [G.E. 77, 427 (1965)]

S-Chloro-*N*-phenylisothiocarbamoyl chlorides, Synth. of ~ by chlorination of isothiocyanates (SC) 432 [G.E. 77, 427 (1965)]

Chromates, Simultaneous thermogravimetric and differential thermal analysis of the decomposition of ~ and dichromates (CR) 601 [G.E. 77, 593 (1965)]

Chromatography, Fractionation of high molecular-weight materials on silica gels having a defined cavity structure (CR) 530 [G.E. 77, 511 (1965)]

Fractionation of polystyrene by gel ~ (CR) 698 [G.E. 77, 723 (1965)]

Quantitative detrmin. of β-aminoisobutyric acid by thin-layer ~ (CR) 716 [G.E. 77, 683 (1965)]

Detecn. and determination of amines on the 10^{-10} molar scale. Sepn. of 5-dimethylamino-1-naphthalenesulfonamides by thin-layer ~ (CR) 716 [G.E. 77, 684 (1965)]

Use of ~ on anion-exchangers for determin. of low phosphate contents (CR) 717 [G.E. 77, 683 (1965)]

Reversed-phase paper-chromatographic sepn. of rare earths (CR) 884 [G.E. 77, 920 (1965)]

Ionenaustausch-Chromatographie (Ion-exchange ~) (Book Review) 722

3,4-Chromene, Novel general synth. of heterocyclic and carbocyclic compds. (LA) 265

Chromium oxide trichloride, Synth. of ~ (LA) 262

Chromomycin, Mode of action of the antibiotic ~ (CR) 968 [G.E. 77, 1015 (1965)]

Circular dichroism, Progress in optical ~ (FP) 838 [G.E. 77, 842 (1965)]

Optical ~, principles, measurements, and applications (Book Review) 898

Claisen rearrangement, Geometry of the transition state of the ~ (CR) 443 [G.E. 77, 461 (1965)]

Cobaloximes, Organometallic derivs. of ~ and of vitamin B_{12} (SC) 146 [G.E. 77, 130 (1965)]

Cobalt compds., Synth. of tetrakis(trifluorophosphine)cobalt hydride and hexakis(trifluorophosphine)tungsten(0) (SC) 148 [G.E. 77, 132 (1965)]

Synthesis of tetrakistrifluorophosphinoiridium hydride and the proton magnetic resonance spectra of the hydrides $HM(PF_3)_4$ (M = Co, Rh, Ir) (SC) 870 [G.E. 77, 860 (1965)]

Opening of the four-membered chelate ring of the tetraamminecarbonatocobalt(III) ion (CR) 443 [G.E. 77, 462 (1965)]

Trifluorophosphine complexes of nickel, cobalt, and iron (CR) 706 [G.E. 77, 731 (1965)]

Exchange reacns. in solid Co, Rh, and Ir complexes initiated thermally and by the ^{80m}Br nuclear transition (CR) 990 [G.E. 77, 1038 (1965)]

Stereospecific retention in nuclear reacns. in *cis/trans* isomeric Co complexes (CR) 995 [G.E. 77, 1043 (1965)]

Cocarcinogens, Partial synth. of some ~ from croton oil (SC) 1072 [G.E. 77, 1076 (1965)]

Code for the classification of the ultraviolet spectra of org. compds. (FP) 516 [G.E. 77, 541 (1965)]

Colloids, Stable ~ of transition metals in the zerovalent state in ethers (LA) 894

Color and constitution of azo compds. (FP) 457 [G.E. 77, 469 (1965)]

~ and constitution of inorg. solids (CR) 892 [G.E. 77, 872 (1965)]

Colorimetric determin. of elements. Principles and methods (Book Review) 1001

Combustion, Oxidn. of org. compds. by ~ in a *jet* (CR) 447 [G.E. 77, 463 (1965)]

Complexes, Exchange rates of ligands in complex ions (FP) 281 [G.E. 77, 361 (1965)]

Nitryl nitrato ~ of indium and thorium (SC) 436 [G.E. 77, 456 (1965)]

Gold ~ of cycloalkenes and cycloalkadienes (SC) 438 [G.E. 77, 456 (1965)]

Azido ~ of manganese(II) and palladium(II) (SC) 439 [G.E. 77, 458 (1965)]

Aluminum-arene ~ (SC) 600 [G.E. 77, 623 (1965)]

~ of iminophosphoranes with metal salts (SC) 785 [G.E. 77, 809 (1965)]

Phosphine sulfide/tin halide ~ (SC) 785 [G.E. 77, 809 (1965)]

Structure and properties of coordination compds. (CR) 89 [G.E. 77, 44 (1965)]

Coordination chemistry (CR) 248 [G.E. 77, 263 (1965)]

New approaches to the theory of complex ions and their physical foundations (CR) 248 [G.E. 77, 263 (1965)]

Intermediates in the electrode reacns. of coordination compds. (CR) 249 [G.E. 77, 264 (1965)]

The role of organometallic compds. in the development of coordination chemistry (CR) 249 [G.E. 77, 264 (1965)]

π- and σ-~ with aromatics and olefins (CR) 250 [G.E. 77, 265 (1965)]

~ and addn. compds. of main group elements (CR) 251 [G.E. 77, 266 (1965)]

Symposium on coordination chemistry (CR) 359 [G.E. 77, 349 (1965)]

Opening of the four-membered chelate ring of the tetraamminecarbonatocobalt(III) ion (CR) 443 [G.E. 77, 462 (1965)]

Fulminato-metal ~ (CR) 698 [G.E. 77, 722 (1965)]

Isomerism of ~ of the type [π-C_5H_5M-$(CO_2)_2$] (CR) 700 [G.E. 77, 724(1965)]

Trifluorophosphine ~ of Ni, Co, and Fe (CR) 706 [G.E. 77, 731 (1965)]

The behavior of neptunium and various uranium fission products in heterogenous reactions of neutron-irradiated uranium compds. with complexing agents (CR) 707 [G.E. 77, 732 (1965)]

Cis-trans-isomeric mixed-ligand ~ of Ir and Os (CR) 710 [G.E. 77, 734 (1965)]

Prepn. and structure of a monophenyl isocyanate of Ni$(HN_2S_2)_2$ (CR) 715 [G.E. 77, 740 (1965)]

Novel ~ of metallocenes (LA) 96

~ of trivalent silver (LA) 172

Triple decker sandwich ~ (LA) 263

Charge-transfer ~ of biochemically important substances (LA) 371

Complexation in analytical chemistry (Book Review) 267

Coordination chemistry, Essays on ~ (Book Review) 722

Complexometry, Advances in ~ (CR) 893 [G.E. 77, 871 (1965)]

Configurational models, Cyclic compds. as ~ for stereoregular polymers (FP) 107 [G.E. 77, 149 (1965)]

Configurational research, Recent results of ~ (FP) 139 [G.E. 77, 161 (1965)]

Configurations, Conformations and ~ of complicated org. molecules (LA) 996

Conformational analysis in mobile cyclohexane systems (FP) 761 [G.E. 77, 784 (1965)]

~ of cyclohexane derivs. by NMR spectroscopy (FP) 774 [G.E. 77, 798 (1965)]

Conformations and configurations of complicated org. molecules (LA) 996

Congressane, Synth. of pentacyclo-[7.3.1.$1^{4,12}$.$0^{2,7}$.$0^{6,11}$]tetradecane (CR) 169 [G.E. 77, 180 (1965)]

Contergan, Mutagenic activity of thalidomide (~) (LA) 606

Coordination compds., see Complexes

Copolymers, Sequence distribution in ~ (FP) 394, 1051 [G.E. 77, 405, 1124 (1965)]

Copper halides, Prepn. of heavy metal halides in anhydrous acetic acid (SC) 869 [G.E. 77, 860 (1965)]

Copper salts, Acetic acid solvates of nickel and ~ (CR) 703 [G.E. 77, 727 (1965)]

Coronaphenes, a new group of cyclic hydrocarbons (CR) 979 [G.E. 77, 1027 (1965)]

Cyclic hydrocarbons of the benzo[c]-phenanthrene series (LA) 794

Cotton dyes, New ~ (FP) 312 [G.E. 77, 303 (1965)]

Coulometric analysis, Die coulometrische Analyse (~) (Book Review) 101

Crepenynic acid, *cis*-9-Octadecen-12-ynoic acid (~) (LA) 172

Croton oil, Partial synth. of some cocarcinogens from ~ (SC) 1072 [G.E. 77, 1076 (1965)]

Crystal field, Influence of the ~ on the acidity of protons in the crystal and on the surface (CR) 972 [G.E. 77, 1020 (1965)]

Crystallographic data on metal and alloy structures (Book Review) 380

Crystallography, Practical optical ~ (Book Review) 726

Crystal powders, Raman spectra of colored ~ obtained by excitation with laser radiation (CR) 1094 [G.E. 77, 1090 (1965)]

Crystal structure, Melting and ~ – some current problems (FP) 587 [G.E. 77, 614 (1965)]

~ of nitrogen compds. (SC) 72 [G.E. 77, 96 (1965)]

~ of a phosphacyanine (SC) 150 [G.E. 77, 134 (1965)]

~ of dipotassium periodate hydrate (SC) 523 [G.E. 77, 507 (1965)]

~ of methyllithium (LA) 538

Cubane, Strained polycyclic systems consisting of three- and four-membered rings (FP) 121 [G.E. 77, 119 (1965)]

"Octaphenyl-~" is actually octaphenylcyclooctatetraene (LA) 606

Cumulenes, Tetrabenzylbutatriene (1,6-diphenyl-2,5-dibenzylhexa-2,3,4-triene) (SC) 74 [G.E. 77, 95 (1965)]

Curtius reaction with boron halides (SC) 595 [G.E. 77, 591 (1965)]

Cyanamide formation under primeval conditions (LA) 718

Cyanates, Synth. of aliphatic ~ (LA) 538

Cyanic esters, Addn. reacns. of ~ (SC) 73 [G.E. 77, 96 (1965)]

On the addn. of amines to ~ (SC) 430 [G.E. 77, 452 (1965)]

Prepn. of pyrimidines from ~ and CH-acidic compds. (SC) 877 [G.E. 77, 913 (1965)]

Synth. of heterocycles containing sulfur and ring opening with formation of ~ (CR) 365 [G.E. 77, 381 (1965)]

Addn. reacns. of ~ (CR) 985 [G.E. 77, 1033 (1965)]

Cyanine dyes, Synthesis of γ-phenylazopentamethine-~ (SC) 524 [G.E. 77, 508 (1965)]

Photochemical *trans-cis* rearr. of simple polymethine dyes. Determination of the quantum yield and establishment of the configuration using the oscillator strength (SC) 525 [G.E. 77, 545 (1965)]

Photochemical rearr. of a trimethinecyanine dye from the all-*trans* form to a mono-*cis* and a di-*cis* form (SC) 526 [G.E. 77, 546 (1965)]

~ and related compds. (Book Review) 453

Cyanogen azide, Synth. of ~ (LA) 448

Cyanogen fluoride, Monomeric ~ (LA) 262

Cyanogen halides, Reacns. of silylamines with hydrocyanic acid and ~ (CR) 704 [G.E. 77, 729 (1965)]

Cyanosilanes, Prepn. of ~ (CR) 977 [G.E. 77, 1025 (1965)]

Cyclitols (polyhydroxycyclohexanes) and phosphoinositides (CR) 888 [G.E. 77, 921 (1965)]

Cycloadditions, Photocatalysed ~ of dihalogenomaleimides and dihalogenomaleic anhydrides onto olefins and acetylenes (SC) 429 [G.E. 77, 452 (1965)]

Chemistry and stereochemistry of the photocycloadducts of dichloromaleic imide and anhydride with acyclic 1,3-dienes (CR) 989 [G.E. 77, 1037 (1965)]

Optical induction in six-membered ~ (CR) 989 [G.E. 77, 1037 (1965)]

~ of 1,1-dichloro-2,2-difluoroethylene onto dienes (LA) 172

Transannular free-radical ~ of *cis,cis*-1,5-cyclooctadiene (LA) 449

~ of diphenylcyclopropenone onto aminoalkenes (LA) 795

Cycloalkadienes, Gold complexes of cycloalkenes and ~ (SC) 438 [G.E. 77, 456 (1965)]

Cycloalkanones, Thermolysis of cycloalkyl esters yielding ~ (SC) 355 [G.E. 77, 346 (1965)]

Cycloalkenes, Gold complexes of ~ and cycloalkadienes (SC) 438 [G.E. 77, 456 (1965)]

Cycloalkyl esters, Thermolysis of ~ yielding cycloalkanones (SC) 355 [G.E. 77, 346 (1965)]

Cyclobutane, Photocatalysed cycloaddn. of dihalogenomaleimides and dihalogenomaleic anhydrides onto olefins and acetylenes (SC) 429 [G.E. 77, 452 (1965)]

Cyclopropane and ~ derivs. by rearr. of unsaturated compds. (CR) 603 [G.E. 77, 624 (1965)]

Cyclodisilazane, Synthesis of *N,N'*-bis-(chlorodimethylsilyl)tetramethyl-~ (SC) 592 [G.E. 77, 618 (1965)]

Cyclododecadiene, Synth. of cyclododecyne, *cis*-cyclododecene, 1,2-~, and 1,3-*cis,trans*-~ (LA) 895

Cyclododecanone, Chemistry of ~ (LA) 894

Cyclododecene, Synth. of cyclododecyne, *cis*-~, 1,2-cyclododecadiene, and 1,3-*cis,trans*-cyclododecadiene (LA) 895

Cyclododecyne, Syntheses of ~, *cis*-cyclododecene, 1,2-cyclododecadiene, and 1,3-*cis,trans*-cyclododecadiene (LA) 895

Cyclohexane, Conformational analysis in mobile ~ systems (FP) 761 [G.E. 77, 784 (1965)]

Conformational analysis of ~ derivs. by NMR spectroscopy (FP) 774 [G.E. 77, 798 (1965)]

Cyclohexanethiols, Existence of two isomeric ~ (LA) 608

Cyclohexyl isonitrile, Reacn. of triphenylaluminum with ~ (SC) 355 [G.E. 77, 380 (1965)]

Cyclooctane, Stable episulfonium salts in the ~ series (LA) 607

Cyclooctatetraene, Molecules undergoing fast, reversible valence-bond isomerizn. (FP) 752 [G.E. 77, 774 (1965)]

Cyclooligoamides, Isoln. of higher ~ from polyamides (SC) 696 [G.E. 77, 720 (1965)]

Cyclooctadiene, Transannular free-radical cycloaddns. of *cis,cis*-1,5-~ (LA) 449

Cyclooctatriene, Valence tautomerism of unsatd. ring systems (CR) 368 [G.E. 77, 353 (1965)]

Cyclopentadiene, Gravimetric procedure for estimating ~ (LA) 97

Cyclopentadienyl complexes, Isonitrilo-~ of lanthanides (SC) 246 [G.E. 77, 261 (1965)]

Triscyclopentadienylplutonium (SC) 878 [G.E. 77, 866 (1965)]

Di-π-cyclopentadienyltitanium bis-(hydrogen sulfide) (SC) 953 [G.E. 77, 965 (1965)]

Isomerism of complexes of the type [π-$C_5H_5M(CO)_2$] (CR) 700 [G.E. 77, 724 (1965)]

Reacn. of triethylaluminum with bis-cyclopentadienyltitanium(IV) and -zirconium(IV) compds. (CR) 713 [G.E. 77, 738 (1965)]

Electronic structure of metal tri-~ (CR) 972 [G.E. 77, 1019 (1965)]

Cyclophosphazenes containing carbon: derivs. of a new heterocyclic system (CR) 990 [G.E. 77, 1038 (1965)]

Cyclopropane, Synth. of ~ compds. from triethyl phosphoenolpyruvate or α-halogenoacrylic esters (SC) 238 [G.E. 77, 216 (1965)]

Tri(isopropylidene)-~ (SC) 594 [G.E. 77, 590 (1965)]

Reacn. of allyl halides with diazomethane catalysed by Cu salts (SC) 691 [G.E. 77, 679 (1965)]

~ and cyclobutane derivs. by rearr. of unsatd. compds. (CR) 603 [G.E. 77, 624 (1965)]

Prepn. and reacns. of dihalo-~-s (CR) 981 [G.E. 77, 1028 (1965)]

Simple indene synth. involving dihalo-~-s (CR) 986 [G.E. 77, 1034 (1965)]

Thermal isomerization of thiocyanomethyl-~ (LA) 897

Debromination of 1,1-dibromo-~-s by sodium methylsulfinylmethide (LA) 998

Cyclopropanols, Synth. of ~ from β-chloroethyl cyclopropyl ethers (SC) 246 [G.E. 77, 262 (1965)]

Cyclopropenylium compds., and cyclopropenones (FP) 10 [G.E. 77, 10 (1965)]

Cyclopropenylium and tropylium systems (CR) 972 [G.E. 77, 1019 (1965)]

Cyclotetrasilazanes, Inorganic ring systems with silicon and nitrogen atoms as ring members (CR) 605, 717 [G.E. 77, 626, 746 (1965)]

Cyclotri-L-prolyl, Synth. of ~, a cyclotripeptide having a nine-membered ring (SC) 356 [G.E. 77, 347 (1965)]

Cyclotrimethine dyes derived from squaric acid (SC) 694 [G.E. 77, 680 (1965)]

Cyclotripeptide, Synth. of cyclotri-L-prolyl, a ~ having a nine-membered ring (SC) 356 [G.E. 77, 347 (1965)]

Cyclotrisilazanes, Inorganic ring systems with silicon and nitrogen atoms as ring members (CR) 605, 717 [G.E. 77, 626, 746 (1965)]

Cymogen, Formation of streptococcal proteinase from ~ (LA) 1099

Cystathionine, New synth. of ~ and allocystathionine (SC) 599 [G.E. 77, 591 (1965)]

~ is absent from the brains of patients suffering from homocystinuria (LA) 99

Cysteine, The iron(II)-~ complex in ferredoxin (LA) 896

DAKIN-West reacn., Mechanism of the ~ (CR) 705 [G.E. 77, 729 (1965)]

Debromination of 1,1-dibromocyclopropanes by sodium methylsulfinylmethide (LA) 998

Decafluorobenzophenone, Pyrolysis of sodium and silicon pentafluorobenzoates (SC) 1072 [G.E. 77, 1076 (1965)]

Decarboxylation, New method of decarboxylating aliphatic acids to the next lower alkyl halide (LA) 998

Dehydration of hydroxides (CR) 445 [G.E. 77, 431 (1965)]

Dehydrobenzene, The Hetarynes (FP) 543 [G.E. 77, 557 (1965)]

1,2-~ (FP) 731 [G.E. 77, 752 (1965)] Synth. of *o*-dihalogenobenzenes from benzenediazonium-2-carboxylate (SC) 239 [G.E. 77, 217 (1965)]

Decomposition of 1,2,3-benzothiadiazole 1,1-dioxide (CR) 704 [G.E. 77, 728 (1965)]

~ condenses with nitrobenzenes to form the carbazole ring system (LA) 610

1,2-Dehydrocyclooctatetraene, Intermediate occurrence of ~ (SC) 953 [G.E. 77, 966 (1965)]

Deseril, Therapy congress and pharmaceutical exhibition (CR) 157 [G.E. 77, 174 (1965)]

Detergents, 4th International congress on ~ (CR) 161 [G.E. 77, 140 (1965)]

Deuterium, Enrichment of ~ by countercurrent isotope exchange between hydrogen and ammonia in a hot-and-cold plant (SC) 597 [G.E. 77, 620 (1965)]

Dewar anthracene, Deriv. of ~ (LA) 448

Dewar benzene, Strained polycyclic systems consisting of three- and four-membered rings (FP) 121 [G.E. 77, 119 (1965)]

Valence-bond isomers of aromatic systems (FP) 738 [G.E. 77, 759 (1965)]

Valence-bond isomers of substituted benzenes (FP) 746 [G.E. 77, 768 (1965)]

Dextrans, Molecular weights of native ~ (CR) 529 [G.E. 77, 510 (1965)]

Dialkylamination – a new aromatic substitution reacn. (SC) 783 [G.E. 77, 807 (1965)]

α-Dialkylamino ethers, New cleavage reacns. of methylenediamine derivs. and ~ (CR) 603 [G.E. 77, 594 (1965)]

Dialkyldithiophosphates, Thermal decomposition of zinc ~ (CR) 1083 [G.E. 77, 1079 (1965)]

N,N-Dialkylhydroxylamines (LA) 263

Dialkylphosphinic acids, Coordination polymers of ~ (CR) 1091 [G.E. 77, 1087 (1965)]

N,N'-Dialkylsulfamides, Prepn. of azo compds. from ~ (SC) 433 [G.E. 77, 429 (1965)]

1,1-Diamino compds., Cyclization of ~ (CR) 883 [G.E. 77, 919 (1965)]

1,5-Diaminonaphthalene, Herz reacn. with ~ (CR) 711 [G.E. 77, 735 (1965)]

Diamino steroid, 1,4-N → N'-Acyl migration in a ~ (SC) 74 [G.E. 77, 94 (1965)]

Diamonds, Surface compds. on ~ (CR) 698 [G.E. 77, 722 (1965)]

Diarylmethylcarbonium ions, Synth. and reacns. of ~ (SC) 873 [G.E. 77, 864 (1965)]

Diazabicyclooctadiene, Attempts to prepare compds. with the 3,4-diazabicyclo-[4.2.0]octa-2,4-diene and 3,4-diazabicyclo[4.2.0]octa-2,4,7-triene ring structure (CR) 708 [G.E. 77, 732 (1965)]

Diazafulvene, Synth. of a 1,4-~ (SC) 1073 [G.E. 77, 1077 (1965)]

2,5-Diaza-1,3,4-triborolidine, Synth. of a ~ (SC) 522 [G.E. 77, 506 (1965)]

1,3-Diazetidine, Synth. of 2-imino-4-thioxo-1,3-~ derivs. by cycloaddn. of isothiocyanates onto carbodiimides (SC) 520 [G.E. 77, 545 (1965)]

Diaziridines, Conversion of ~ into azines (CR) 978 [G.E. 77, 1026 (1965)]

Diazo compds., Ring opening of cyclic ~ (CR) 364 [G.E. 77, 381 (1965)]

Radical phenylations with aromatic ~ (CR) 964 [G.E. 77, 974 (1965)]

Diazo group transfer, Synth. of v-triazolo-[3.4-a]pyridines and 1,2,3-triazoles by

~ with tosyl azide (SC) 431 [G.E. 77, 428 (1965)]

Synth. of 1,2,3-triazoles and isomeric α-diazoimines by ~ with tosyl azide (CR) 710 [G.E. 77, 735 (1965)]

α-Diazoimines, Synth. of 1,2,3-triazoles and isomeric ~ by diazo group transfer with tosyl azide (CR) 710 [G.E. 77 735 (1965)]

Diazomethane, Reacn. of allyl halides with ~ catalysed by Cu salts (SC) 691 [G.E. 77, 679 (1965)]

Reacns. of alkylaluminum compds. with ~ (CR) 1088 [G.E. 77, 1084 (1965)]

Bistrifluormethyl-~ (LA) 719

Diazomethyl ketones, Synth. of ~ without using diazomethane (SC) 688 [G.E. 77, 678 (1965)]

Diazomethylphosphine oxides (SC) 1078 [G.E. 77, 1138 (1965)]

8a,10a-Diazoniaphenanthrene cation, 9-Methyl-~ (LA) 538

Diazonium salts, Synth. of ~ from sulfinyl imides and nitrosyl salts (SC) 148 [G.E. 77, 132 (1965)]

N-~ of iminophosphoranes (SC) 695 [G.E. 77, 683 (1965)]

Diazooxonorleucine, The action of ~ and albizziin on the biosynthesis of aromatic amino acids in *Saccharomyces cerevisiae* and *Escherichia coli* (CR) 707 [G.E. 77, 731 (1965)]

Dibenzocycloheptatriene, Intramolecular mobility of ~ and tribenzocycloheptatriene derivs. (CR) 715 [G.E. 77, 739 (1965)]

Dibenzodiazepinone, Reacns. of dibenzo-[*c,f*]-1,2-diazepin-11-one (CR) 988 [G.E. 77, 1035 (1965)]

2,5-Dibenzyl-1,6-diphenylhexa-2,3,4-triene, Tetrabenzylbutatriene (~) (SC) 74 [G.E. 77, 95 (1965)]

Dibenzo[a,c]calicene, Synth. and properties of 5,6-dimethyl-~ (SC) 598 [G.E. 77, 621 (1965)]

3,5-Dibromo-1,2,4-triazole, Synth. of ~ by bromination of 1,2,4-triazole (SC) 434 [G.E. 77, 429 (1965)]

Dichloroborazide (CR) 710 [G.E. 77, 734 (1965)]

Dichlorocarbene, Alkoxide oxidation involving hydride transfer to ~, and group migration during carbene reacns. (LA) 451

1,1-Dichloro-2,2-difluoroethylene, Cycloaddn. of ~ onto dienes (LA) 172

1,1-Dichloroethylene, Synth. of carboxylic acids with ~ (SC) 956 [G.E. 77, 967 (1965)]

Dichlorogallane, Synth. of ~ (SC) 152 [G.E. 77, 170 (1965)]

4,5-Dichloropyridazones, New methods in the chemistry of pyridazones (FP) 292 [G.E. 77, 282 (1965)]

Dichlorotrinitrosylvanadium [$V(NO)_3Cl_2$] (SC) 151 [G.E. 77, 134 (1965)]

Dichromates, Simultaneous thermogravimetric and differential thermal analysis of the decomposition of chromates and ~ (CR) 601 [G.E. 77, 593 (1965)]

Dictionary, Fachwörterbuch der Chemie (einschließlich Verfahrenstechnik u. den Grundlagen der verwandten Wissenschaften) [Dictionary of chemistry (including chemical engineering and fundamentals of allied sciences)] (Book Review) 376

1-Dicyanomethylenephenalene, Synth. of ~ and 1-(ethoxycarbonylcyanomethylene)phenalene (SC) 243 [G.E. 77, 346 (1965)]

Dicyclohexylcarbodiimide as a new reagent for epimerizing and isomerizing sugars (LA) 999

Dienes, Cycloaddn. of 1,1-dichloro-2,2-difluoroethylene onto ~ (LA) 172

Dienophile, Reactivity of ~s and ability to form charge-transfer complexes (CR) 711 [G.E. 77, 736 (1965)]

N-Butoxycarbonylmethylene-*p*-toluenesulfonamide as a ~ (LA) 999

Diethyldiselenophosphinic acid, Synth. of ~ and its salts and esters (SC) 244 [G.E. 77, 259 (1965)]

Diffraction methods, Fortschritte der Strukturforschung mit Beugungsmethoden (Advances in structural analysis using ~) (Book Review) 175

Diffusion coefficient, Radiometric determin. of the self-~ of the pertechnetate ion in aqu. solution (CR) 967 [G.E. 77, 1013 (1965)]

Representation of the ~ by melting paramcters (CR) 1085 [G.E. 77, 1080 (1965)]

Difluoroboranes, Pure ~ (LA) 96

Difluorocarbene, Spin multiplicity of ~ (LA) 1098

Difluorodiazine, Recent investigations of covalent inorg. fluorides (CR) 446 [G.E. 77, 463 (1965)]

1,1-Difluoroolefins, One-step synth. of ~ from ketones (LA) 606

Dihalocyclopropanes, Prepn. and reacns. of ~ (CR) 981 [G.E. 77, 1028 (1965)]

Simple indene synth. involving ~ (CR) 986 [G.E. 77, 1034 (1965)]

o-Dihalogenobenzenes, Synth. of ~ from benzenediazonium-2-carboxylate (SC) 239 [G.E. 77, 217 (1965)]

Dihalogenocarbenes, New method of preparing ~ from organometallic compds. (LA) 897

Dihalogenomaleic anhydrides, Photocatalysed cycloaddn. of dihalogenomaleimides and ~ onto olefins and acetylenes (SC) 429 [G.E. 77, 452 (1965)]

Dihalogenomaleimides, Photocatalysed cycloaddition of ~ and dihalogenomaleic anhydrides onto olefins and acetylenes (SC) 429 [G.E. 77, 452 (1965)]

2,5-Dihydro-2,3-dimethylfuran, Synth. of heterocyclic and carbocyclic compds. (LA) 265

9,10-Dihydronaphthalene, Valence-bond isomers of aromatic systems (FP) 738 [G.E. 77, 759 (1965)]

Dihydropyran-2-carboxaldehyde, High molecular-weight, soluble polymers from 2*H*-3,4-~ (LA) 372

Dihydroresorcinol, Synth. with ~ (CR) 366 [G.E. 77, 381 (1965)]

Diimide, Synth. and properties of *N*'-fluorodiimide *N*-oxides (LA) 608

Diimine, Chemistry of ~ (FP) 271 [G.E. 77, 368 (1965)]

Diketones, 1,4- and 1,5-~ (LA) 263

1,4-Dimercaptobutadienes, Synth. and reacns. of ~ (CR) 884 [G.E. 77, 919 (1965)]

5,6-Dimethylbenzo[a]calicene (SC) 242 [G.E. 77, 258 (1965)]

2,3-Dimethyl-1,3-butadiene, Action of light on a Diels-Alder system (LA) 173

5,6-Dimethyldibenzo[a,c]calicene, Synth. and properties of ~ (SC) 598 [G.E. 77, 621 (1965)]

2,5-Dimethyl-2,3:4,5-dioxidohexanes, Stereoisomeric ~ as the main products of the pyrolysis of polymeric 2,5-dimethyl-2,4-hexadiene peroxide (SC) 149 [G.E. 77, 133 (1965)]

Dimethylsulfoxide, Synth. of benzaldehydes by diazotization of benzylamines in ~ (SC) 787 [G.E. 77, 811 (1965)]

Base-catalysed addn. of ~ onto olefins (LA) 610

Reacn. of sodium and potassium with ~ (LA) 1099

2,4-Dinitrophenyl glycosides, Synth. of 2,4-dinitrophenyl α- and β-*O*-glycosides (SC) 601 [G.E. 77, 623 (1965)]

N-(2,4-Dinitrophenyloxycarbonyl)amino esters, new *N*-activated amino-acid derivs. (SC) 790 [G.E. 77, 813 (1965)]

1,3-Dioxacycloheptane, Copolymerizn. of formaldehyde with cyclic formals (CR) 532 [G.E. 77, 513 (1965)]

1,3-Dioxacycloheptene, Copolymerizn. of formaldehyde with cyclic formals (CR) 532 [G.E. 77, 513 (1965)]

1,3-Dioxane, Copolymerizn. of formaldehyde with cyclic formals (CR) 532 [G.E. 77, 513 (1965)]

1,5-Dioxaspiro[2.4]heptane, Synth. and polymerizn. of ~ (SC) 437 [G.E. 77, 455 (1965)]

Dioxidohexanes, Stereoisomeric 2,5-dimethyl-2,3:4,5-~ as the main products of the pyrolysis of polymeric 2,5-dimethyl-2,4-hexadiene peroxide (SC) 149 [G.E. 77, 133 (1965)]

Dioximes, 4*H*-Pyrazole *N*-oxides from 1,3-~ (CR) 1086 [G.E. 77 1082 (1965)]

1,3-Dioxolane, Copolymerizn. of formaldehyde with cyclic formals (CR) 532 [G.E. 77, 513 (1965)]

Dioxolium salts, Benzo-1,3-~ (SC) 873 [G.E. 77, 863 (1965)]

Dipeptide phosphates as intermediates of enzymatic tripeptide synth. (LA) 720

1,5-Diphenyl-1-bora-5-phosphabicyclo-[3.3.0]octane (LA) 536

Diphenylcyclopropenone, Cycloaddn. of ~ onto aminoalkenes (LA) 795

Diphenyl ketene, Acid-catalysed oxidative solvolysis of ~ (LA) 373

Diphenylphosphide anion (LA) 374

3,4-Diphenyl-1,2,5-thiadiazole, Synth. of 3-phenyl-, 3,4-diphenyl-, and 3-(β-naphthyl)-1,2,5-thiadiazole (SC) 239 [G.E. 77, 262 (1965)]

Diphosphorus pentoxide, Ammonolysis of ~ (CR) 1093 [G.E. 77, 1089 (1965)]

Dipolarophiles, Five-membered heterocycles from hydrozamethane, aromatic aldehydes, and ~ (CR) 701 [G.E. 77, 725 (1965)]

Dipole moments, Tables of experimental ~ (Book Review) 268

Dipotassium periodate hydrate, Crystal structure of ~ (SC) 523 [G.E. 77, 507 (1965)]

Diriboside, New ~ synth. (LA) 100

Dissociation constants of acidic hydrocarbons (LA) 718

Distraneurin, Therapy congress and pharmaceutical exhibition (CR) 158 [G.E. 77, 174 (1965)]

Distyrylmethanol, Prepn. and rearr. of ~ derivs. and a new route to reductones (CR) 535 [G.E. 77, 550 (1965)]

Dithiaborolane, Production and properties of boron heterocycles containing sulfur (LA) 263

Dithiacyclopenten-3-ones, Resonance of 1,2-~ (CR) 1084 [G.E. 77, 1079 (1965)]

Dithianes, Carbanions of 1,3-~. Reagents for C–C bond formation by nucleophilic displacement and carbonyl addn. (SC) 1075 [G.E. 77, 1134 (1965)]

Synth. of 1,n-dicarbonyl derivs. using carbanions from 1,3-~ (SC) 1077 [G.E. 77, 1135 (1965)]

1,3-Dithiolium system, Proton activity of the ~ (SC) 435 [G.E. 77, 453 (1965)]

1,2-Dithiol-3-thiones, Reacns. of carbon disulfide and isothiocyanates with sulfur and nitriles containing an active methylene group (CR) 881 [G.E. 77, 916 (1965)]

Dithioperoxodiphosphoric acid, Free ~ (LA) 793

Dithiophosphates, Alkylation and isomerizn. reacns. of ~ (CR) 365 [G.E. 77, 381 (1965)]

Thermal decomposition of zinc dialkyl-~ (CR) 1083 [G.E. 77, 1079 (1965)]

α-Dithiopyrones from enamines and carbon disulfide (SC) 246 [G.E. 77, 261 (1965)]

Diuretics, Chemistry and pharmacology (Book Review) 539

Documentation, Mechanization of chemical ~ (FP) 347 [G.E. 77, 340 (1965)]

Experiments in chem. ~ (CR) 968 [G.E. 77, 1015 (1965)]

Double bond, Location of a ~ in an olefinic chain by mass spectrometry (LA) 450

Drug research, Fortschritte der Arzneimittelforschung (Progress in ~) (Book Review) 103, 376

Dyes, New cotton ~ (FP) 312 [G.E. 77, 303 (1965)]

Organic ~ as photoelectric semiconductors (FP) 619 [G.E. 77, 633 (1965)]

Synthesis of γ-phenylazopentamethinecyanine ~ (SC) 524 [G.E. 77, 508 (1965)]

Photochemical *trans,cis*-rearr. of simple polymethine ~. Determination of the

quantum yield and establishment of the configuration using the oscillator strength (SC) 525 [G.E. 77, 545 (1965)]

Photochemical rearr. of a trimethinecyanine ~ from the all-*trans* form to a mono-*cis* and a di-*cis* form (SC) 526 [G.E. 77, 546 (1965)]

Cyclotrimethine ~ derived from squaric acid (SC) 694 [G.E. 77, 680 (1965)]

ELECTROCHEMICAL reacns., Control of ~ by means of foreign sorbates (CR) 446 [G.E. 77, 459 (1965)]

Electrochemistry, Anodic acetoxylation of aromatic compds. (LA) 607

~ (Book Review) 455

Electrode reacns., Intermediates in the ~ of coordination compds. (CR) 249 [G.E. 77, 264 (1965)]

Electrodes, Injection and extraction processes at semiconductor ~ (CR) 986 [G.E. 77, 1033 (1965)]

Electrolyte solutions, Equilibrium and transport properties of conc. ~ (FP) 485 [G.E. 77, 517 (1965)]

Electron diffraction, Structure determination of free molecules by ~ (FP) 819 [G.E. 77, 877 (1965)]

Electron distribution, Bonding and ~ in the I_3^- ion according to a three-dimensional free-electron model (CR) 882 [G.E. 77, 918 (1965)]

Electronic charges of bonds in organic compds. (Book Review) 178

Electronic spectra, Theory of the ~ of org. molecules (Book Review) 269

Electronic structure and properties of non-alternant hydrocarbons (FP) 1039 [G.E. 77, 1097 (1965)]

Electronic theory of organic reacns., Einführung in die Elektronentheorie organisch-chemischer Reaktionen (Introduction to the ~) (Book Review) 376

Electron microscopy, Advances in ~ (CR) 158 [G.E. 77, 179 (1965)]

Electron paramagnetic resonance, The use of ~ in org. chemistry (FP) 856 [G.E. 77, 888 (1965)]

Paramagnetische Elektronenresonanz (~) (Book Review) 1000

Electron resonance, Symposium on magnetic nuclear and ~ (CR) 256 [G.E. 77, 269 (1965)]

Electrons, Transport and phase-boundary reacns. of defect ~ in silver bromide (CR) 971 [G.E. 77, 1018 (1965)]

Behaviour of ~ in atoms. – Structure, spectra, and photochemistry of atoms (Book Review) 377

Electron-transfer, Hydrogen- and ~ in reacns. with molecular oxygen (CR) 442 [G.E. 77, 461 (1965)]

Electrophoresis, Improved apparatus for continuous ~ without a support (LA) 722

Zone ~ in blocks and columns (Book Review) 454

Eliminations, Intermediates of α-~ (FP) 1 [G.E. 77, 1 (1965)]

~ from olefins (FP) 49 [G.E. 77, 75 (1965)]

Influence of the nucleophile on competing β-~ and S_N2 substitution (CR) 441 [G.E. 77, 460 (1965)]

Elimination reactions (Book Review) 178

Emdabol, Therapy congress and pharmaceutical exhibition (CR) 156 [G.E. 77, 174 (1965)]

Endohydrolases, Enzymatic method for kinetic investigations of ~: assay of the activity of α-amylase (CR) 529 [G.E. 77, 510 (1965)]

Enterobacteria, Specific polysaccharides of ~ (CR) 529 [G.E. 77, 509 (1965)]

Enzymatic reactions, Mechanismen enzymatischer Reaktionen (Mechanisms of ~) (Book Review) 451

Enzymes, Effect of steroids on the activity of DNA-dependent RNA polymerase (SC) 155 [G.E. 77, 172 (1965)]

The quaternary structure of catalase from beef liver (SC) 597 [G.E. 77, 621 (1965)]

VIth International congress of biochemistry (CR) 75 [G.E. 77, 97 (1965)]

Oligomerizn. of peptides by enzymatic catalysis (CR) 529 [G.E. 77, 509 (1965)]

Investigations on oxidases and peroxidases (CR) 534 [G.E. 77, 549 (1965)]

Oscillating fermentation system from yeast (CR) 535 [G.E. 77, 550 (1965)]

Sepn. of ~ of pancreatic fluid (CR) 1084 [G.E. 77, 1079 (1965)]

The repressor for the alkaline phosphatase in *E. coli* (LA) 99

β-Galactosidase subunits have no enzymatic activity (LA) 100

The mechanism of the end-product inhibition of aspartate transcarbamylase (LA) 264

Amino-acid sequence around the active site in liver alcohol dehydrogenase (LA) 374

Isoenzyme pattern of maize catalase (LA) 609

Enzymatic ω-oxidation of long-chain fatty acids (LA) 609

Sepn. of lactic dehydrogenase isoenzyme bands into sub-bands (LA) 719

The repressor of β-galactosidase synthesis (LA) 896

Comprehensive biochemistry (Book Review) 379

The enzymes (Book Review) 899

Comprehensive biochemistry (Book Review) 1003

Epimerization, Dicyclohexylcarbodiimide as a new reagent for epimerizing and isomerizing sugars (LA) 999

Episulfones, Synth. of olefins from sulfenes and diazoalkanes *via* ~ (SC) 70 [G.E. 77, 41 (1965)]

Episulfonium salts, Stable ~ in the cyclooctane series (LA) 607

Epoxides, New cyclization reacn. leading to ~ of aromatic hydrocarbons (LA) 720

Ergot alkaloids, Die Mutterkorn-Alkaloide (~) (Book Review) 612

Erythrocytes, Structure and function of the red blood cells (CR) 165 [G.E. 77, 138 (1965)]

ESR spectroscopy, The use of electron paramagnetic resonance in org. chemistry (FP) 856 [G.E. 77, 888 (1965)]

^{17}O-Hyperfine structure in the ESR spectrum of [^{17}O]-2,4,6-triphenylphenoxyl (SC) 240 [G.E. 77, 217 (1965)]

ESR-Spectroscopic detection of a [^{33}S]-sulfur radical (SC) 243 [G.E. 77, 220 (1965)]

Esterification, Protonic states and the mechanism of acid-catalysed ~ (FP) 40 [G.E. 77, 65 (1965)]

Esters, Prepn. of aryl ~ (CR) 984 [G.E. 77, 1031 (1965)]

Ethanolamines, Stereospecific synth. of D-hydroxynitriles and optically active ~ (SC) 1079 [G.E. 77, 1139 (1965)]

Ethers, New cleavage reacns. of methylenediamine derivs. and α-dialkylamino ~ (CR) 603 [G.E. 77, 594 (1965)]

1-(Ethoxycarbonylcyanomethylene)phenalene, Synth. of 1-dicyanomethylenephenalene and ~ (SC) 243 [G.E. 77, 346 (1965)]

2-Ethoxyindole, Formation of indirubin and 2-ethoxy-3-(indol-2-yl)indole from ~ (SC) 520 [G.E. 77, 505 (1965)]

Ethylene, Novel chelated catalyst systems for polymerizing ~ (LA) 610

Ethyl nitrodiazoacetate (SC) 358 [G.E. 77, 379 (1965)]

Ethynylation with vinylsulfonium salts (SC) 1080 [G.E. 77, 1141 (1965)]

Ethynylselenonium salts, Prepn. of 1,2-disubstd. vinylsulfonium salts and alkylvinyl sulfides, and of ethynylsulfonium and ~ (SC) 1080 [G.E. 77 1140 (1965)]

Ethynylsulfonium salts, Prepn. of 1,2-disubstd. vinylsulfonium salts and alkyl vinyl sulfides, and of ~ and ethynylselenonium salts (SC) 1080 [G.E. 77, 1140 (1965)]

Ethynylsulfur pentafluoride (LA) 448

European Biochemical Societies, Second Conference of the Federation of ~ (CR) 888 [G.E. 77, 921 (1965)]

Europium, New ~ isotopes ^{142}Eu and ^{143}Eu (CR) 708 [G.E. 77, 732 (1965)]

Europium oxide, New compds. of lithium oxide with ~ (CR) 967 [G.E. 77, 1014 (1965)]

Exchange rates of ligands in complex ions (FP) 281 [G.E. 77, 361 (1965)]

Exosalt, Therapy congress and pharmaceutical exhibition (CR) 156 [G.E. 77, 174 (1965)]

Extraction, Synergic effects in solvent ~ (CR) 95 [G.E. 77, 57 (1965)]

Phosphorus, antimony, sulfur, and selenium compds. in the liquid-liquid ~ of transition-metal ions (CR) 1096 [G.E. 77, 1092 (1965)]

Liquid ~ (Book Review) 453

FATTY acids, The protein carrier responsible for the biosynth. of ~ (LA) 98

Enzymatic ω-oxidation of long-chain ~ (LA) 609

Fermentation, Oscillating ~ system from yeast (CR) 535 [G.E. 77, 550 (1965)]

Ferrates, New compds. of the $CaFe_2O_4$ type (CR) 1092 [G.E. 77, 1088 (1965)]

Ferredoxin, Model for the active center of ~ (LA) 171

Amino-acid sequence of ~ (LA) 536

The iron(II)-cysteine complex in ~ (LA) 896

Ferrocene, Prepn. and polyaddn. reacns. of ~ derivs. with two dimethylsilyl groups (CR) 530 [G.E. 77, 511 (1965)]

Silicon-organic polymers containing ~ (CR) 701 [G.E. 77, 726 (1965)]

Formation of ~ (CR) 970 [G.E. 77, 1017 (1965)]

Triple decker sandwich complexes (LA) 263

Ring migration and transalkylation in alkylated ~ (LA) 537

Fibers, Formation of free radicals in polyamide ~ during drawing (FP) 332 [G.E. 77, 323 (1965)]

Fish, Action of hexamethylenetetramine on the catheptic endo- and exopeptidases of ~ tissues (CR) 988 [G.E. 77, 1035 (1965)]

Flavins, Progress in the chemistry and molecular biology of ~ and flavocoenzymes (FP) 671 [G.E. 77, 699 (1965)]

Flavocoenzymes, Progress in the chemistry and molecular biology of flavins and ~ (FP) 671 [G.E. 77, 699 (1965)]

Flow birefringence, New aspects for the quantitat. interpretation of ~ (CR) 533 [G.E. 77, 514 (1965)]

Fluorenyl-lithium, Structure of ~ (LA) 893

Fluorescence analysis, Comparison of calculated and measured line intensities in X-ray ~ (CR) 1087 [G.E. 77, 1082 (1965)]

Fluorides, Recent investigations of covalent inorg. ~ (CR) 446 [G.E. 77, 463 (1965)]

Prepn. of metal ~ by the fluidized bed process (LA) 1098

Fluorinated imines (LA) 97

Fluorination, Electrochem. and direct ~ of substd. hydrocarbons (CR) 989 [G.E. 77, 1036 (1965)]

Fluorinating agent, Fluorosulfuric acid as a reacn. medium and ~ in inorg. chem. (FP) 641 [G.E. 77, 695 (1965)]

Fluorosulfuric acid as a reacn. medium and ~ (CR) 368 [G.E. 77, 387 (1965)]

Fluorine chemistry (Book Review) 613

Fluoroamines, *N*-Fluoro compds. of the types RNF_2, HNF–COOR, and RFN–CO–NHR (LA) 371

Fluoro compds., Synth. and reacns. of org. ~ (CR) 605 [G.E. 77, 625 (1965)]

N'-Fluorodiimide *N*-oxides, Synth. and properties of ~ (LA) 608

Fluoroisoprenols (CR) 974 [G.E. 77, 1021 (1965)]

Fluorophosphoranes, Chemistry and stereochemistry of ~ (FP) 496 [G.E. 77, 530 (1965)]

Fluorosulfonylfluoroamines, Synth. of FSO_2NF_2 and $(FSO_2)_2NF$ (LA) 371

Fluorosulfuric acid as a reacn. medium and fluorinating agent in inorg. chemistry (FP) 641 [G.E. 77, 695 (1965)]

~ as a reacn. medium and a fluorinating agent (CR) 368 [G.E. 77, 387 (1965)]

~ as an acid-base system (LA) 606

Fluoroxenates, Synth. of alkali ~-(VI) (LA) 371

Food additives, Analytical methods for pesticides, plant growth regulators, and ~ (Book Review) 377

Foodstuffs, Modern analytical methods in the chemistry of ~ and in biological chemistry (CR) 716 [G.E. 77, 683 (1965)]

Formaldehyde, Mechanism of catalysed reacns. of ~ with amines and amides (CR) 440 [G.E. 77, 459 (1965)]

Polymeric products made from ~ and nitriles containing activated methylene groups (CR) 531 [G.E. 77, 511 (1965)]

Polymerizn. of ~ by adsorbed water (CR) 532 [G.E. 77, 512 (1965)]

Copolymerizn. of ~ with cyclic formals (CR) 532 [G.E. 77, 513 (1965)]

Synth. and polymerizn. of *S*-vinylmercaptals of ~ (CR) 701 [G.E. 77, 725 (1965)]

Condensation of ~ with bis-(2-halogenoethyl)amines (LA) 372

New thermostable copolymer of ~ (LA) 795

"Activated ~" is 2-hydroxymethylthiamine pyrophosphate (LA) 1099

Formals, Copolymerizn. of formaldehyde with cyclic ~ (CR) 532 [G.E. 77, 513 (1965)]

Formamides, New methods in preparative organic chemistry. Isonitrile syntheses (FP) 472 [G.E. 77, 492 (1965)]

Reacns. of *N,N*-disubstd. ~ with alkali metals (SC) 951 [G.E. 77, 964 (1965)]

Addn. of ~ onto terminal olefins (LA) 171

Stereospecific addn. of ~ to norbornene (LA) 894

Formamidines, Reacns. of carbodiimides with acid chlorides (CR) 703 [G.E. 77, 727 (1965)]

Formulas, From vital force to structural ~ (Book Review) 103

Formylation, α-Formyl ketones from aminoalkenes by Vilsmeier ~ (SC) 358 [G.E. 77, 380 (1965)]

α-Formyl ketones from aminoalkenes by Vilsmeier formylation (SC) 358 [G.E. 77, 380 (1965)]

Fragmentation, Thermal ~ and the determin. of the structure of org. compds. (FP) 938 [Chemie-Ing.-Techn. 37, 709 (1965)]

Mechanism and stereochemistry of ~ reacns. (CR) 440 [G.E. 77, 459 (1965)]

Freeze-drying, Degradation of linear macromolecules during ~ (LA) 610

Friedel-Crafts reacn., Reactions of organic azides under the conditions of the ~ (CR) 706 [G.E. 77, 730 (1965)]

~ of isocyanates and benzene derivs. (LA) 98

Aliphatic carboxylic acids formed by a ~ (LA) 372

Friedel-Crafts and related reactions (Book Review) 177, 178

Fuel cells, International congress on ~ (CR) 961 [G.E. 77, 971 (1965)]

Fulminato-metal complexes (CR) 698 [G.E. 77, 722 (1965)]

Fungicidal compds., *N*-Substituted tetrahydro-1,4-oxazines – a new class of ~ (FP) 336 [G.E. 77, 327 (1965)]

Furan, New synth. of ~ compds. (LA) 1099

Fusarinic acid, Synth. of ~ and its isomers and homologues (LA) 450

Fused salts, and their use as reacn. media (FP) 222 [G.E. 77, 241 (1965)]

Structures and reacns. in ~ (CR) 893 [G.E. 77, 871 (1965)]

Les réactions chimiques dans les solvants et les sels fondus (Chemical reacns. in solvents and ~) (Book Review) 724

GADOLINIUM corner, Mixed-crystal formation of lithium indium oxide with magnesium oxide, and a contribution to the "~" (CR) 713 [G.E. 77, 737 (1965)]

β-Galactosidase subunits have no enzymatic activity (LA) 100

The repressor of ~ synthesis (LA) 896

Gallates, Chemistry of amphoteric oxides (CR) 534 [G.E. 77, 551 (1965)]

Gallium compds., Synth. of dichlorogallane $HGaCl_2$ (SC) 152 [G.E. 77, 170 (1965)]

Heterosiloxanes and t-butoxy compds. of aluminum, gallium, and indium (SC) 152 [G.E. 77, 169 (1965)]

Trimethylaluminum trimethylphosphorus oxide and trimethylarsenic trimethylgallium oxide (SC) 153 [G.E. 77, 170 (1965)]

Gallosiloxanes, Recent developments in the chemistry of heterosiloxanes (FP) 201 [G.E. 77, 206 (1965)]

Gas analysis, Detection and analysis of minute amounts of gas in metals using the mass filter (CR) 255 [G.E. 77, 267 (1965)]

Gas-chromatography, Gas-chromatographic sepn. and estimation of aliphatic monocarboxylic acids with 1–5 carbon atoms (SC) 71 [G.E. 77, 95 (1965)]

Vth International symposium on ~ (CR) 85 [G.E. 77, 104 (1965)]

Gas analysis by ~ (Book Review) 540

Gas reacns., The effect of particle size on the reacn. mechanism of gases with solids (CR) 892 [G.E. 77, 870 (1965)]

Chem. kinetics of ~ (Book Review) 267

Gastrins, Structure of ~ I and II (LA) 606

Gel chromatography, Fractionation of polystyrene by ~ (CR) 698 [G.E. 77, 723 (1965)]

Gene, Protein as the product of a regulator ~ (LA) 100

Regulator ~ determines a protein (LA) 538

Genetic code, Chemical synth. and biosynth. of coding nucleic acids (CR) 528 [G.E. 77, 509 (1965)]

Genetics, VIth International congress of biochemistry (CR) 75 [G.E. 77, 97 (1965)]

German Academy of Sciences, Tenth anniversary of the institute for organic chemistry of the ~ (CR) 364 [G.E. 77, 381 (1965)]

German Chemical Society, General meeting 1965 of the ~ and Kekulé celebration (CR) 966 [G.E. 77, 1013 (1965)]

Germane, Prepn. and reacns. of chloro-(chloromethyl)dimethyl-~ (CR) 1096 [G.E. 77, 1092 (1965)]

Germanium, Optical investigations of the surface chemistry of ~ and Si (CR) 968 [G.E. 77, 1015 (1965)]

Mechanism of the electrolytic reducn. of hydrogen peroxide on ~ (CR) 986 [G.E. 77, 1034 (1965)]

Germanium(IV) chloride, Determin. of traces of impurities in highly purified ~ and germanium(IV) oxide (CR) 256 [G.E. 77, 268 (1965)]

Germanium compds., Hydrogermylation of aromatic compds. (SC) 352 [G.E. 77, 345 (1965)]

Trifluoroacetates of Si, Ge, and Sn (SC) 1079 [G.E. 77, 1138 (1965)]

Coordination chemistry of organometallic compds. of group IVb elements (CR) 1089 [G.E. 77, 1084 (1965)].

Germanium(IV) oxide, Determn. of traces of impurities in highly purified germanium(IV) chloride and ~ (CR) 256 [G.E. 77, 268 (1965)]

Germanosiloxanes, Recent developments in the chemistry of heterosiloxanes (FP) 201 [G.E. 77, 206 (1965)]

Glasses, Structure and crystallization behavior of ~ (FP) 112 [G.E. 77, 109 (1965)]

Glucose, Acid-base catalysis of the mutarotation of ~ (CR) 964 [G.E. 77, 973 (1965)]

Glucoside, Synthesis of α-methyl [5-^{3}H]-D-~ and β-methyl [5-^{3}H]-L-idoside by hydroboration of substituted methyl glucosidenes (SC) 874 [G.E. 77, 863 (1965)]

Glucuronides, Sepn. and detecn. of ~ (CR) 1095 [G.E. 77, 1091 (1965)]

Glutathione, Colorimetric micro-assay of ~ (LA) 897

Glycolipids, Glycosaminoglycans, glycoproteins and ~ (CR) 160 [G.E. 77, 176 (1965)]

N-Glycolylneuraminic acid, Synthesis of ~ and the biochemistry of glycoproteins containing neuraminic acid (CR) 445 [G.E. 77, 432 (1965)]

Glycoproteins, Glycosaminoglycans, ~ and glycolipids (CR) 160 [G.E. 77, 176 (1965)]

Synthesis of *N*-glycolylneuraminic acid and the biochemistry of ~ containing neuraminic acid (CR) 445 [G.E. 77, 432 (1965)]

Glycosaminoglycans, glycoproteins and glycolipids (CR) 160 [G.E. 77, 176 (1965)]

Glycosides, Synthesis of 2,4-dinitrophenyl α- and β-*O*-~ (SC) 601 [G.E. 77, 623 (1965)]

Synth. of heterocyclic *O*- and *N*-~ (CR) 261 [G.E. 77, 273 (1965)]

Glyoxylate cycle, Anaplerotic sequences in microbial metabolism (FP) 558 [G.E. 77, 601 (1965)]

Gold, Standard potentials of the system ~/chloroaurate (LA) 608

Gold complexes of cycloalkenes and cycloalkadienes (SC) 438 [G.E. 77, 456 (1965)]

Graft polymerizn. of vinyl compds. onto ethylene/vinyl acetate copolymers (CR) 532 [G.E. 77, 512 (1965)]

Graphite, Diffusion of boron in ~ (LA) 718

Graphite electrodes, Radioactive nuclides for investigating physicochem. processes in ~ during excitation in an electric arc (CR) 256 [G.E. 77, 268 (1965)]

Grignard compds., Anomalous reacns. of imides with ~ (CR) 1085 [G.E. 77, 1081 (1965)]

Grignard reacns., Free-radical intermediates of ~ (LA) 263

Grignard reagents, Ionization of benzylmagnesium chloride (SC) 878 [G.E. 77, 914 (1965)]

Grinding pastes, Rheological properties of ~ (CR) 983 [G.E. 77, 1031 (1965)]

Guanine, Selective labelling of ~ in polynucleotides (LA) 609

HALIDES, Structure and thermodynamics of molten ~ (CR) 1091 [G.E. 77, 1087 (1965)]

Halogen addition, Solvent effects on the stereospecificity of ~ to *cis*- and *trans*-stilbenes (CR) 881 [G.E. 77, 917 (1965)]

Halogenation, The ~ of aromatic compds. (LA) 894

α-Halogen carbanions, Stability and reactivity of ~ (CR) 706 [G.E. 77, 730 (1965)]

Halogenoalkyl hydroperoxides, Synth. of ~ by "bromine-induced autoxidation" of allyl halides (SC) 244 [G.E. 77, 219 (1965)]

Halogenoanilines, Trimethylsilyl as protecting group for nitrogen in organometallic synth. involving ~ (SC) 1081 [G.E. 77, 1141 (1965)]

N-Halogenoguanidines, Acid-catalysed rearrs. of ~ (CR) 1088 [G.E. 77, 1084 (1965)]

Handbook, Taschenbuch für Chemiker und Physiker (D'Ans-Lax), Vol. II: Organische Verbindungen (~ for chemists and physicists, vol. II: org. compds.) (Book Review) 612

~ of chemistry and physics (Book Review) 795

Hashish, Tetrahydrocannabinolcarboxylic acid, a component of ~ (SC) 872 [G.E. 77, 862 (1965)]

Isoln., structure, and partial synth. of an active constituent of ~ (marihuana) (LA) 99

Heart metabolism, Substrate supply and inhibition of the metabolism of rabbit heart perfused *in situ* (CR) 1086 [G.E. 77, 1081 (1965)]

n-Heptane, Isomer formation in the monochlorination of ~ with PCl_5 and with PCl_3/Cl_2 (SC) 522 [G.E. 77, 506 (1965)]

Herz reacn. with 1,5-diaminonaphthalene (CR) 711 [G.E. 77, 735 (1965)]

Hetarynes (FP) 543 [G.E. 77, 557 (1965)]

Heterocyclic chemistry, Advances in ~ (Book Review) 451

Physical methods in ~ (Book Review) 613

Heterocyclic compds., Phosphorescence spectroscopy as an analytical method for aromatic and ~ (FP) 930 [Chemie-Ing.-Techn. 37, 1010 (1965)]

~ containing phosphorus (FP) 1023 [G.E. 77, 1109 (1965)]

Synth. of ~ and model reacns. of alkaloid biogenesis (CR) 260 [G.E. 77, 224 (1965)]

Ring opening of 6-membered ~ by nucleophilic reagents (CR) 1090 [G.E. 77, 1086 (1965)]

Heterosiloxanes, Recent developments in the chemistry of ~ (FP) 201 [G.E. 77, 206 (1965)]

~ and t-butoxy compds. of aluminum, gallium, and indium (SC) 152 [G.E. 77, 169 (1965)]

Methyl(trimethylsiloxy)mercury and dimethyl(trimethylsiloxy)thallium (SC) 876 [G.E. 77, 865 (1965)]

~ of zinc and cadmium (SC) 876 [G.E. 77, 865 (1965)]

Hexachlorodihydrofuran, Synth. of ~ (SC) 787 [G.E. 77, 811 (1965)]

Hexakis(trifluorophosphine)tungsten(0), Synth. of tetrakis(trifluorophosphine)-cobalt hydride and ~ (SC) 148 [G.E. 77, 132 (1965)]

Hexamethylenetetramine, Action of ~ on the catheptic endo- and exopeptidases of fish tissues (CR) 988 [G.E. 77, 1035 (1965)]

Hexathiocanes, Synth. and elucidation of the structures of 7-alkylamino-7-phenyl-8-thioxo-1,2,3,4,5,6-~ (SC) 71 [G.E. 77, 41 (1965)]

History of chemistry (Book Review) 379

L-Homocystine, Optically pure ~ (LA) 171

Homocystinuria, Cystathionine is absent from the brains of patients suffering from ~ (LA) 99

Homotropilidene, Molecules undergoing fast, reversible valence-bond isomerizn. (FP) 752 [G.E. 77, 774 (1965)]

Hormone, Lipotropin, a new hypophyseal ~ (LA) 171

Hydrazide, Uses of sodium ~ for the synth. and degradn. of organic compds. (CR) 1090 [G.E. 77, 1085 (1965)]

Hydrazine, Chemistry of diimine (FP) 271 [G.E. 77, 368 (1965)]

Thermal decomposition of ~ (CR) 369 [G.E. 77, 385 (1965)]

Hydrazomethane, Five-membered heterocycles from ~, aromatic aldehydes, and dipolarophiles (CR) 701 [G.E. 77, 725 (1965)]

Hydrazones, Formation of carbonyl compds. from azines or ~ with active manganese dioxide (SC) 956 [G.E. 77, 967 (1965)]

Hydride transfer, Alkoxide oxidn. involving ~ to dichlorocarbene and group migration during carbene reacns. (LA) 451

Hydroboration, Synth. of α-methyl[5-^{3}H]-D-glucoside and β-methyl [5-^{3}H]-L-idoside by ~ of substd. methyl glucosides (SC) 874 [G.E. 77, 863 (1965)]

Hydrocarbons, Electronic structure and properties of non-alternant ~ (FP) 1039 [G.E. 77, 1097 (1965)]

C_{26}-~ as model substances for lubricating oils (CR) 1095 [G.E. 77, 1091 (1965)]

Charge-transfer complexes between rhodane and aromatic ~ (LA) 537

Dissociation constants of acidic ~ (LA) 718

Radiolysis of ~ (Book Review) 615

Polycyclic ~ (Book Review) 898, 899

Hydrocarboxylation, Photo-initiated ~ of mono-olefins (SC) 790 [G.E. 77, 813 (1965)]

Hydrocyanic acid in prunoideae seeds and in their products (CR) 976 [G.E. 77, 1023 (1965)]

Hydrodemethylation, Catalytic cleavage and formation of C–C bonds in aromatic compds. in the gas phase (CR) 366 [G.E. 77, 381 (1965)]

Hydroformylation, Synth. of lactones by ~ of unsaturated esters (LA) 371

Hydrogen, Advances in the determn. of oxygen, ~, and nitrogen in metals (CR) 255 [G.E. 77, 267 (1965)]

Investigations in the titanium/~ system (CR) 1095 [G.E. 77, 1091 (1965)]

Hydrogenations, Steric course of catalytic ~ (CR) 369 [G.E. 77, 387 (1965)]

Hydrogen bonds, Investigation of steric features by proton magnetic resonance (SC) 697 [G.E. 77, 721 (1965)]

Proton magnetic resonance measurement on ~ associates of chloroform (CR) 700 [G.E. 77, 724 (1965)]

Relations between rotational isomerism, hydrogen bonding, and substituent effects (CR) 977 [G.E. 77, 1024 (1965)]

OH···N bridges in pyridine/methanol mixtures (LA) 537

Hydrogen fluoride, The chemistry of nitrous acid and of its derivs. in liq. HF (FP) 635 [G.E. 77, 689 (1965)]

Hydrogen peroxide, Addn. of ~ onto Schiff bases (SC) 524 [G.E. 77, 548 (1965)]

Some recent developments in organic oxidations utilizing ~ (CR) 887 [G.E. 77, 870 (1965)]

Mechanism of the electrolytic reducn. of ~ on Ge (CR) 986 [G.E. 77, 1034 (1965)]

Adduct of triphenylphosphine and ~ (LA) 374

Hydrogen-transfer and electron-transfer in reacns. with molecular oxygen (CR) 442 [G.E. 77, 461 (1965)]

Hydrogermylation of aromatic compds. (SC) 352 [G.E. 77, 345 (1965)]

Hydroperoxides, Synth. of halogenoalkyl ~ by "bromine-induced autoxidation" of allyl halides (SC) 244 [G.E. 77, 219 (1965)]

Association of isomeric hydroxyalkane derivs. (CR) 367 [G.E. 77, 352 (1965)]

Hydroplumbation of unsatd. organic compds. (SC) 784 [G.E. 77, 809 (1965)]

Hydroquinone, Redox potentials of the alkyl-substd. quinone/~ system (LA) 1098

Hydroxamic acid, Di- and tripeptides from amino esters and ~ derivs. (LA) 171

Hydroxides, Dehydration of ~ (CR) 445 [G.E. 77, 431 (1965)]

Infrared studies on ~ (CR) 991 [G.E. 77, 1039 (1965)]

Hydroximic chlorides, Reacns. of ~ (CR) 965 [G.E. 77, 975 (1065)]

Hydroxo complexes, Investigations on the constitution of ~ (CR) 1094 [G.E. 77, 1090 (1965)]

β-Hydroxy-α-amino acids, New synth. of ~ (CR) 365 [G.E. 77, 381 (1965)]

γ-Hydroxybutyrate, The effect of sodium ~ on the activity of anesthetics (LA) 98

α-Hydroxy ketones, Prepn. of ~ by hydrolysis of α-amino ketones (SC) 951 [G.E. 77, 964 (1965)]

Hydroxylation, Model studies on the mechanism of microsomal ~ (CR) 890 [G.E. 77, 924 (1965)]

14-Hydroxymorphine and 14-hydroxy-7,8-dihydromorphine, new compds. with analgetic properties (LA) 894

Hydroxynitriles, Stereospecific synth. of D-~ and optically active ethanolamines (SC) 1079 [G.E. 77, 1139 (1965)]

8-Hydroxyquinoline, Tetrakis-8-hydroxyquinolyltin(IV) (LA) 896

Hypophyseal hormone, Lipotropin, a new ~ (LA) 171

IDOSE DERIVS., 1,6-Anhydro-~ with rings containing nitrogen (SC) 592 [G.E. 77, 589 (1965)]

Idoside, Synth. of α-methyl [5-^{3}H]-D-glucoside and β-methyl [5-^{3}H]-L-~ by hydroboration of substd. methyl glucosidenes (SC) 874 [G.E. 77, 863 (1965)]

Imidazoles, Inhibition of photosynth. reacns. by NH-acidic ~ and benzimidazoles (SC) 789 [G.E. 77, 911 (1965)]

New synth. of ~ (LA) 173

Imidazolidines, Synth. of ~ and imidazolines by the reacn. of aziridinium tetrafluoroborate with nitriles and benzylidineaniline (SC) 518 [G.E. 77, 505 (1965)]

Imidazolidones, New *N*-silyl-~ (SC) 438 [G.E. 77, 456 (1965)]

Imidazolines, Synth. of ~ and imidazolidines by the reacn. of aziridinium tetrafluoroborate with nitriles and benzylideneaniline (SC) 518 [G.E. 77, 505 (1965)]

Imides, Anomalous reacns. of ~ with Grignard compds. (CR) 1085 [G.E. 77, 1081 (1965)]

Imines, Fluorinated ~ (LA) 97

Iminophosphoranes, *N*-Diazonium salts of ~ (SC) 695 [G.E. 77, 683 (1965)]

Complexes of ~ with metal salts (SC) 785 [G.E. 77, 809 (1965)]

Infrared spectra of ^{15}N-labelled ~ (CR) 994 [G.E. 77, 1042 (1965)]

Iminopyrrolidones, Synth. of ~ and iminothiopyrrolidones from aminoalkenes and isonitriles plus isocyanates or isothiocyanates (SC) 519 [G.E. 77, 544 (1965)]

Iminothiopyrrolidones, Synthesis of iminopyrrolidones and ~ from aminoalkenes and isonitriles plus isocyanates or isothiocyanates (SC) 519 [G.E. 77, 544 (1965)]

2-Imino-4-thioxo-1,3-diazetidine, Synthesis of ~ derivs. by cycloaddn. of isothiocyanates onto carbodiimides (SC) 520 [G.E. 77, 545 (1965)]

Iminotriphenylphosphorane, Organometallic derivs. of ~ (SC) 877 [G.E. 77, 866 (1965)]

Inclusion compds., Importance of canal ~ for polymn. research (CR) 367 [G.E. 77, 353 (1965)]

Indanes, Synth. and structure of insecticidal polychlorotetrahydromethano-~ (CR) 969 [G.E. 77, 1016 (1965)]

Indenes, Simple synth. of ~ involving dihalocyclopropanes (CR) 986 [G.E. 77, 1034 (1965)]

Ion-pair mechanism for the tautomerization of substd. ~ (LA) 720

Optically active ~ (LA) 720

Indirubin, Formation of ~ and 2-ethoxy-3-(indol-2-yl)indole from 2-ethoxyindole (SC) 520 [G.E. 77, 505 (1965)]

Indium compds., Heterosiloxanes and t-butoxy compds. of aluminum, gallium and indium (SC) 152 [G.E. 77, 169 (1965)]

Nitryl nitrato complexes of indium and thorium (SC) 436 [G.E. 77, 456 (1965)]

Mixed-crystal formation of lithium indium oxide with magnesium oxide (CR) 713 [G.E. 77, 737 (1965)]

Indole, New ~ synth. (CR) 711 [G.E. 77, 735 (1965)]

New rearr. in the ~ series (CR) 993 [G.E. 77, 1041 (1965)]

New route from ~-s to oxindoles (LA) 450

Infrared spectroscopy, Infrared spectroscopic investigations on methylenetriphenylphosphoranes (SC) 875 [G.E. 77, 867 (1965)]

Infrared spectra and frequency assignment of some aminoboranes containing ^{10}B (CR) 698 [G.E. 77, 722 (1965)]

Activation of molecular vibration bands by lattice disorders (CR) 714 [G.E. 77, 738 (1965)]

Infrared studies on hydroxides (CR) 991 [G.E. 77, 1039 (1965)]

Infrared spectra of ^{15}N-labelled iminophosphoranes (CR) 994 [G.E. 77, 1042 (1965)]

Prismatic samples can give wrong transparency values (LA) 96

Spectra in the far infrared (LA) 173

Connections between the structures and long-wave infrared spectra of aliphatic amides (LA) 721

Spectroscopy in the far infrared for the analysis of high polymers (LA) 898

Infrared band handbook (Book Review) 179

~ of high polymers (Book Review) 539

~ and molecular structure. An outline of the principles (Book Review) 616

Infrared spectra of inorg. and coordination compds. (Book Review) 616

Introduction to ~ and Raman spectroscopy (Book Review) 724

Inorg. Chemistry, Advances in ~ and radiochemistry (Book Review) 102

Anorganische Chemie (~) (Book Review) 176

Lehrbuch der anorganischen Chemie (Textbook of ~) (Book Review) 265

Progress in ~ (Book Review) 453

Anorganische Chemie (~) (Book Review) 539

Insecticides, Synth. and structure of insecticidal polychlorotetrahydromethanoindanes (CR) 969 [G.E. 77, 1016 (1965)]

Die Entwicklung neuer insektizider Phosphorsäureester (Development of new insecticidal phosphoric esters) (Book Review) 174

Insulin, Chemistry of the recombination of ~ chains to give biologically active ~ (CR) 528 [G.E. 77, 509 (1965)]

Resynth. of ~ from S-sulfurated ~ A and B chains (LA) 997

Interfacial energy, Influence of the ~ of org. solvents on the photochemical dimerization of thymidylyl-(3′ → 5′)-thymidine (SC) 150 [G.E. 77, 133 (1965)]

Interfacial phenomena (Book Review) 267

Iodides, New method for preparing org. ~ (LA) 100

Iodination, Intermolecular acid catalysis in the ~ of keto acids. Detection of proton chelates in aqueous solution (CR) 881 [G.E. 77, 917 (1965)]

Mechanism of the ~ of aromatic compds. with iodine/peroxyacetic acid (LA) 721

Iodine, Bonding and electron distribution in the I_3^- ion according to a three-dimensional free-electron model (CR) 882 [G.E. 77, 918 (1965)]

N-(Iodophenyl)pyridinium salts (CR) 882 [G.E. 77, 918 (1965)]

Ion exchange, Analytische Anwendungen von Ionenaustauschern (Analytical applications of ion exchangers) (Book Review) 452

~ separations in analytical chemistry (Book Review) 724

Inorg. ion exchangers (Book Review) 1001

Ionizing radiation, Protecting effects in styrene-acrylonitrile copolymers during the action of ~ (CR) 704 [G.E. 77, 728 (1965)]

Ion-pair formation in aqueous solns. (LA) 100

Ions, Formation of negative ~ in alkali halide vapors (LA) 100

Iridium compds., Synth. of tetrakistrifluorophosphinoiridium hydride and the proton magnetic resonance spectra of the hydrides $HM(PF_3)_4$ (M = Co, Rh, Ir) (SC) 870 [G.E. 77, 860 (1965)]

Cis-trans-isomeric mixed-ligand complexes of Ir and Os (CR) 710 [G.E. 77, 734 (1965)]

Exchange reacns. in solid Co, Rh, and Ir complexes initiated thermally and by the ^{80m}Br nuclear transition (CR) 990 [G.E. 77, 1038 (1965)]

Isolation of some aquo and hydroxochloro complexes of Rh(III), Ir(III) and Pt(IV) (LA) 793

Iron alloys, Structures and chem. properties of nitrides in ternary ~ (CR) 256 [G.E. 77, 268 (1965)]

Iron compds., Trifluorophosphine complexes of Ni, Co, and Fe (CR) 706 [G.E. 77, 731 (1965)]

Reacn. of iron(III) chloride with $LiAlH_4$ (CR) 987 [G.E. 77, 1035 (1965)]

New Landoldt reacn. (LA) 97

The iron(II)-cysteine complex in ferredoxin (LA) 896

Irreversible processes, Thermodynamik der irreversiblen Prozesse (Thermodynamics of ~) (Book Review) 265

3-Isoadenosine derivs. (LA) 794

Isocyanates, Synth. of 1,3-thiazolidin-2-ones from aminoalkenes ~ and sulfur (SC) 519 [G.E. 77, 544 (1965)]

Synth. of iminopyrrolidones and iminothiopyrrolidones from aminoalkenes and isonitriles plus ~ or isothiocyanates (SC) 519 [G.E. 77, 544 (1965)]

The Friedel-Crafts reacn. of ~ and benzene derivs. (LA) 98

Isocyanates, Catalytic effect of 1,1,3,3-tetramethylguanidine on the polymerizn. of ~ (LA) 1098

Isocyanide dichlorides, Reacns. with ~ (CR) 983 [G.E. 77, 1031 (1965)]

Isoenzyme pattern of maize catalase (LA) 609

Sepn. of lactic dehydrogenase ~ bands into subbands (LA) 719

Isoindoles, New synth. and reacns. of ~ (CR) 982 [G.E. 77, 1029 (1965)]

Isomerization, Thermal ~ of a P(V) to a P(III) compd. (LA) 896

Isonicotinic hydrazide, Enzymatic reacns. of ~ (CR) 973 [G.E. 77, 1020 (1965)]

Isonitriles, New methods in preparative organic chemistry. ~ syntheses (FP) 472 [G.E. 77, 492 (1965)]

Synth. of iminopyrrolidones and iminothiopyrrolidones from aminoalkenes and ~ plus isocyanates or isothiocyanates (SC) 519 [G.E. 77, 544 (1965)]

Prepn. of 1,3-oxazolidines from ~ and aldehydes by a multicomponent reacn. (SC) 596 [G.E. 77, 591 (1965)]

Reacns. of triethyl orthoformate with some nitrogen compds. (CR) 702 [G.E. 77, 726 (1965)]

Syntheses and reacns of *N*-acyl- ~ (CR) 708 [G.E. 77, 733 (1965)]

Isonitrilocyclopentadienyl complexes of lanthanides (SC) 246 [G.E. 77, 261 (1965)]

Isoprene, Polymerizn. of ~ initiated by organolithium compds. (CR) 697 [G.E. 77, 721 (1965)]

Isoprenoids, Mode of degradn. of ~ by bacteria (LA) 997

p-Isopropenylphenol, Reacns. of ~ (CR) 982 [G.E. 77, 1030 (1965)]

Isoquinuclidines, Experiments with bridged cyclic systems containing nitrogen (CR) 536 [G.E. 77, 550 (1965)]

Isothiocyanates, *N*-Sulfonyl ~ (SC) 430 [G.E. 77, 429 (1965)]

Synth. of *N*-phenyl-*S*-chloroisothiocarbamoyl chlorides by chlorination of ~ (SC) 432 [G.E. 77, 427 (1965)]

Synth. of iminopyrrolidones and iminothiopyrrolidones from aminoalkenes and isonitriles plus isocyanates or ~ (SC) 519 [G.E. 77, 544 (1965)]

Synth. of 2-imino-4-thioxo 1,3-diazetidine derivs. by cycloaddn. of ~ onto carbodiimides (SC) 520 [G.E 77, 545 (1965)]

Reacns. of amide acetals with ~ (SC) 523 [G.E. 77, 507 (1965)]

Symposium on ~ (CR) 258 [G.E. 77, 271 (1965)]

Reacns. of carbon disulfide and ~ with sulfur and nitriles containing an active methylene group (CR) 881 [G.E. 77, 916 (1965)]

Isotope effect, in the sepn. of rare earths on ion-exchangers (CR) 978 [G.E. 77, 1025 (1965)]

An unusually high H/D ~ (LA) 264

Isotope exchange, Enrichment of deuterium by counter-current ~ between hydrogen and ammonia in a hot-and-cold plant (SC) 597 [G.E. 77, 620 (1965)]

~ reacns. of alkyl halides (CR) 699 [G.E. 77, 723 (1965)]

Itaconic acid, Radical polymerizn. of ~ (CR) 531 [G.E. 77, 512 (1965)]

IUPAC, 20th International Congress for Pure and Applied Chemistry, Moscow 1965 (CR) 959 [G.E. 77, 963 (1965)]

JUDOLOR, Therapy congress and pharmaceutical exhibition (CR) 158 [G.E. 77, 174 (1965)]

KEKULÉ celebration, General meeting 1965 of the German Chemical Society and ~ (CR) 966 [G.E. 77, 1013 (1965)]

Keto acids, One-step synth. of γ-~ (SC) 785 [G.E. 77, 810 (1965)]

Intermolecular acid catalysis in the iodination of ~. Detection of proton chelates in aqueous solution (CR) 881 [G.E. 77, 917 (1965)]

β-Keto esters, New synth. of α-branched ~ (SC) 596 [G.E. 77, 620 (1965)]

β-Aminoethylation of malonic esters and of ~ with aziridines (CR) 714 [G.E. 77, 738 (1965)]

Ketones, Light-induced formation of acids from cyclic ~ (FP) 211 [G.E. 77, 229 (1965)]

Synth. of β-thioxo ~ by condensation of ~ with thionic esters (SC) 154 [G.E. 77, 172 (1965)]

Synth. of diazomethyl ~ without using diazomethane (SC) 688 [G.E. 77, 678 (1965)]

Prepn. of α-hydroxy ~ by hydrolysis of α-amino ~ (SC) 951 [G.E. 77, 964 (1965)]

Electrophilic substitution by α-azido ~ (SC) 952 [G.E. 77, 963 (1965)]

New synth. of methyl ~ (LA) 371

New synth. of α-amino ~ from olefins (LA) 372

One-step synth. of 1,1-difluoroolefins from ~ (LA) 606

Conversion of aromatic aldehydes into alkyl aryl ~ (LA) 795

Tricyclic ~ (LA) 895

α-Ketonitriles, Synth. of *O,N*- and *N,N*-acetals of ~ (SC) 523 [G.E. 77, 508 (1965)]

Kidney, New amino peptidase from ~ particles (LA) 536

Kinetics at solid phase boundaries (CR) 447 [G.E. 77, 463 (1965)]

~ of proton transfer processes (CR) 791 [G.E. 77, 814 (1965)]

Progress in reaction ~ (Book Review) 454

Kinetics of precipitation (Book Review) 725

LABORATORY manual, Chemisches Praktikum für Mediziner und Studierende sonstiger an Chemie interessierter Wissenschaften (Practical chemistry for medical students and students of other sciences affiliated to chemistry) (Book Review) 539

Einführung in das anorganisch-chemische Praktikum (einschließlich der quantitativen Analyse) [Introduction to practical inorganic chemistry, including quantitative analysis] (Book Review) 612

Organic Experiments (Book Review) 796

Organikum. Organisch-Chemisches Grundpraktikum (Practical organic chemistry) (Book Review) 1100

Lactic dehydrogenase, Sepn. of ~ isoenzyme bands into subbands (LA) 719

Interactions among ~ subunits (LA) 996

Lactones, Synth. of ~ by hydroformylation of unsaturated esters (LA) 371

Landoldt reacn., New ~ (LA) 97

Lanthanides, Isonitrilocyclopentadienyl complexes of ~ (SC) 246 [G.E. 77, 261 (1965)]

Laser, Raman spectra of colored crystal powders obtained by excitation with ~ radiation (CR) 1094 [G.E. 77, 1090 (1965)]

Emission-spectrometric analysis using intermittent beams from a ~ (LA) 263

Lasix, Therapy congress and pharmaceutical exhibition. (CR) 157 [G.E. 77, 174 (1965)]

Lattice disorders, Activation of molecular vibration bands by ~ (CR) 714 [G.E. 77, 738 (1965)]

Lead compds., Recent developments in the chemistry of heterosiloxanes (FP) 201 [G.E 77, 206 (1965)]

Hydroplumbation of unsaturated organic compds. (SC) 784 [G.E. 77, 809 (1965)]

Lead compds., Coordination chemistry of organometallic compds. of group IVb elements (CR) 1089 [G.E. 77, 1084 (1965)]

Lead halides, Prepn. of heavy metal halides in anhydrous acetic acid (SC) 869 [G.E. 77, 860 (1965)]

Lead poisoning, Chemical problems of ~ (CR) 1093 [G.E. 77, 1088 (1965)]

Lead tetraacetate, Oxidn. of aromatic and α,β-unsatd. oximes with ~ (CR) 1091 [G.E. 77, 1087 (1965)]

Reacn. of ~ with unsubstd. prim. amides (LA) 999

Liebig, Justus von ~ in eigenen Zeugnissen und solchen seiner Zeitgenossen (Justus von ~ in his own memoirs and those of his contemporaries) (Book Review) 101

Light scattering, Automatic determin. of molecular weights by ~ (CR) 970 [G.E. 77, 1017 (1965)]

Lignin, Chemistry and biochemistry of ~ (CR) 93 [G.E. 77, 56 (1965)]

Structure of beech ~ (CR) 709 [G.E. 77, 733 (1965)]

Lipids, VIth International congress of biochemistry (CR) 75 [G.E. 77, 97(1965)]

α-Lipoic acid, Chemistry and biochemistry of ~ (FP) 846 [G.E. 77, 900 (1965)]

Lipotropin, a new hypophyseal hormone, (LA) 171

Liquid-liquid extraction, Phosphorus, antimony, sulfur, and selenium compds. in the ~ of transition-metal ions (CR) 1096 [G.E. 77, 1092 (1965)]

Liquid extraction (Book Review) 453

Liquids, Recent advances in the theory of ~ (FP) 923 [G.E. 77, 993 (1965)]

Nuclear magnetic relaxation times and the microdynamic structure of liquid mixtures (CR) 446 [G.E. 77, 463 (1965)]

Lithium, Radiochemical estimation of terminal ~ in polymers (LA) 897

Lithium bismuthide, Solution of an intermetallic compd., Li_3Bi, in a molten salt (LA) 171

Lithium compds., Reacn. of organo-~ with silicon dioxide (SC) 600 [G.E. 77, 622 (1965)]

Polymerizn. of isoprene initiated by organo-~ (CR) 697 [G.E. 77, 721 (1965)]

Crystal structure of methyllithium (LA) 538

Lithium indium oxide, Mixed-crystal formation of ~ with magnesium oxide, and a contribution to the "gadolinium corner" (CR) 713 [G.E. 77, 737(1965)]

Lithium oxide, System ~/uranium(V) oxide (CR) 705 [G.E. 77, 729 (1965)]

New compds. of ~ with europium oxide (CR) 967 [G.E. 77, 1014 (1965)]

Liver alcohol dehydrogenase, Amino-acid sequence around the active site in ~ (LA) 374

Locacorten, Therapy congress and pharmaceutical exhibition (CR) 158 [G.E. 77, 174 (1965)]

Lubricants, Extreme values of the pressure coefficient of viscosity (FP) 944 [Chemie-Ing.-Techn. 37, 465 (1965)]

C_{26}-hydrocarbons as model substances for ~ (CR) 1095 [G.E. 77, 1091 (1965)]

Lupine alkaloids, Biosynth. of ~ (CR) 991 [G.E. 77, 1039 (1965)]

Lysozyme, Positions of the disulfide bridges in ~ (LA) 100

MACROMOLECULAR compds., Symposium on ~ (CR) 251 [G.E. 77, 221 (1965)]

Macromolecular chemistry, Colloquium on ~ (CR) 528 [G.E. 77, 509 (1965)]

Macromolecules, Degradation of linear ~ during freeze-drying (LA) 610

Magnesium oxide, Mixed-crystal formation of lithium indium oxide with ~, and a contribution to the "gadolinium corner" (CR) 713 [G.E. 77, 737 (1965)]

Magnetic susceptibility, Effect of ~ on proton resonance; magnetic measurements on new organic radicals (CR) 170 [G.E. 77, 181 (1965)]

Maleic anhydrides, Photocatalysed cycloaddn. of dihalogenomaleimides and dihalogeno ~ onto olefins and acetylenes (SC) 429 [G.E. 77, 452 (1965)]

Maleimides, Photocatalysed cycloaddn. of dihalogeno-~ and dihalogenomaleic anhydrides onto olefins and acetylenes (SC) 429 [G.E. 77, 452 (1965)]

Production of mixed dicarboxamides from cyclic secondary amines and cyclic dicarboximides. Products of the reacn. of aziridine with ~ (SC) 693 [G.E. 77, 718 (1965)]

Chemistry and stereochemistry of the photocycloadducts of dichloromaleic imide and anhydride with acyclic 1,3-dienes (CR) 989 [G.E. 77, 1037 (1965)]

Vulcanization of styrene/butadiene copolymers with ~ (LA) 720

Malonic esters, β-Aminoethylation of ~ and of β-keto esters with aziridines (CR) 714 [G.E. 77, 738 (1965)]

Manganese, Azide complexes of ~-(II) and palladium(II) (SC) 439 [G.E. 77, 458 (1965)]

Manganese compds., Covalent metal-metal bonds in mixed metal carbonyls (LA) 97

Mannopyranosid-4-ene, Prepn. of α-methyl 2,3-O,O'-isopropylidene-4,6-dideoxy-~ (SC) 874 [G.E. 77, 863 (1965)]

Marihuana, The isoln., structure, and partial synth. of an active constituent of hashish (~) (LA) 99

Mass spectrometry, Relationships between structures and mass spectra of organic compds. (FP) 383 [G.E. 77, 393(1965)]

Mass-spectrometric investigation of rhenium trichloride (SC) 148 [G.E. 77, 131 (1965)]

Detection of non-metals in metals by ~ (CR) 255 [G.E. 77, 267 (1965)]

Mass-spectrometric sequence analysis of acetylated peptides of aromatic amino acids (CR) 1087 [G.E. 77, 1083 (1965)]

Location of a double bond in an olefinic chain by ~ (LA) 450

Table of the masses of molecules and molecular fragments (LA) 717

Regularities in the field-ion mass spectra of organic molecules (LA) 793

Mass-spectrometric amino-acid sequence analysis (LA) 999

~ of organic ions (Book Review) 176

Interpretation of mass spectra of org. compds. (Book Review) 267

Massenspektrometrie (~) (Book Review) 374

Structure elucidation of natural products by ~ (Book Review) 382

Computation of molecular formulas for ~ (Book Review) 540

Mathematics, Mathematik für Naturwissenschaftler und Chemiker (~ for Scientists and Chemists) (Book Review) 175

Meat, Biochem. difference between fresh and frozen ~ (CR) 976 [G.E. 77, 1023 (1965)]

Mechanisms, Symposium on reaction ~ (CR) 440 [G.E. 77, 459 (1965)]

Medicine, Medizin und Chemie, Vol. VII (~ and chemistry) (Book Review) 101

Melting and crystal structure ~ some current problems (FP) 587 [G.E. 77, 614 (1965)]

Melting points, Schmelzpunkttabellen organischer Verbindungen (Tables of the ~ of org. compds.) (Book Review) 375

Melts, Fused salts and their use as reacn. media (FP) 222 [G.E. 77, 241 (1965)]

Structures and reacns. in molten salts (CR) 893 [G.E. 77, 871 (1965)]

Structure and thermodynamics of molten halides (CR) 1091 [G.E. 77, 1087 (1965)]

Menthylamines, NMR-Spectroscopic conformational analysis of ~ and carvomenthylamines (CR) 699 [G.E. 77, 723 (1965)]

C-Mercuration of an alkenylamine (LA) 264

Mercuric chloride, Structural relationships between basic ~, $HgCl_2 \cdot 4\,HgO$, and the modifications of mercuric oxide HgO (CR) 708 [G.E. 77, 732 (1965)]

Mercuric oxide, Structural relationships between basic mercuric chloride, $HgCl_2 \cdot 4\,HgO$, and the modifications of ~, HgO (CR) 708 [G.E. 77, 732 (1965)]

Mercury compds., Methyl(trimethylsiloxy)mercury and dimethyl(trimethylsiloxy)thallium (SC) 876 [G.E. 77, 865 (1965)]

A complex with a coordination number of 7 and tungsten-mercury bonds (LA) 894

Mercury halides, Prepn. of heavy metal halides in anhydrous acetic acid (SC) 869 [G.E. 77, 860 (1965)]

Messenger RNA, Organic solvents alter the coding properties of synthetic ~ (LA) 373

Metabolism, Anaplerotic sequences in microbial ~ (FP) 558 [G.E. 77, 601 (1965)]

VIth International congress of biochemistry (CR) 75 [G.E. 77, 97(1965)]

Metallocenes, Novel complexes of ~ (LA) 96

Metallophilic compds., Poly-~ (LA) 996

Metal-metal compds. (CR) 250 [G.E. 77, 265 (1965)]

Metal-metal bonds, Covalent ~ in mixed metal carbonyls (LA) 97

Metal-metal interactions in coordination compds. (CR) 248 [G.E. 77, 263 (1965)]

Metals, Detecn. and analysis of minute amounts of gas in ~ using the mass filter (CR) 255 [G.E. 77, 267 (1965)]

Detection of non-~ in ~ by mass spectroscopy (CR) 255 [G.E. 77, 267 (1965)]

Advances in the determn. of oxygen, hydrogen, and nitrogen in ~ (CR) 255 [G.E. 77, 267 (1965)]

Role of the nitrosyl ion in the dissolution of ~ in nitric acid (CR) 965 [G.E. 77, 975 (1965)]

Oxydation des métaux (Oxidation of ~) (Book Review) 179

Selected values of thermodynamic properties of ~ and alloys (Book Review) 452

Analysis of ancient ~ (Book Review) 899

Metal surfaces, Influence of alpha-radiation on ~ (CR) 445 [G.E. 77, 431 (1965)]

Methacrylate, Oxidation of transition elements by organic halides; detecn. of radicals by polymerizn. kinetics (CR) 533 [G.E. 77, 514 (1965)]

Reactivity of ~-s in radical copolymerization (LA) 998

1,6-Methanocyclodecapentaene, Aromatic character of systems with ten π-electrons: ^{1}H–NMR-spectra of ~ and 1,6-oxidocyclodecapentaene (CR) 702 [G.E. 77, 726 (1965)]

Methanol, OH···N bridges in pyridine/~ mixtures (LA) 537

Methionine, Biological *C*-methylation by ~ (LA) 719

β-Methoxy-α-nitropropionate, Synth. of methyl ~, a protected α-nitracrylic ester (SC) 788 [G.E. 77, 812 (1965)]

Methylation, Biological *C*-~ by methionine (LA) 719

Methylenebisphosphinates, Synth. of methylenebisphosphorus compds. (CR) 881 [G.E. 77, 916 (1965)]

Methylenebisphosphonates, Synth. of methylenebisphosphorus compds. (CR) 881 [G.E. 77, 916 (1965)]

Methylenediamine, New cleavage reacns. of ~ derivs. and α-dialkylamino ethers (CR) 603 [G.E. 77, 594 (1965)]

Methylenephosphoranes, Divinylogous ~ from conjugated diynes, trialkylphosphines, and active methylene compds. (SC) 954 [G.E. 77, 1011 (1965)]

Methylenetribenzocycloheptatriene, Optically active derivatives of ~ (SC) 156 [G.E. 77, 173 (1965)]

Methylenetriphenylphosphoranes, Infrared spectroscopic investigations on ~ (SC) 875 [G.E. 77, 867 (1965)]

Methyl ketones, New synth. of ~ (LA) 371

Methyllithium, Crystal structure of ~ (LA) 538

N-Methyl-3,4,5-tricyanopyridinium perchlorate, a pyridinium salt of extremely high electron affinity (SC) 869 [G.E. 77, 861 (1965)]

Micelle formation, Entropy of ~ (LA) 99

Microbial metabolism, Anaplerotic sequences in ~ (FP) 558 [G.E. 77, 601 (1965)]

Microcalorimetry, Recent progress in ~ (Book Review) 540

Microsomal hydroxylation, Model studies on the mechanism of ~ (CR) 890 [G.E. 77, 924 (1965)]

Microwave spectrum and structure of $(CH_3)_3C-C\equiv C-Cl$ (CR) 1084 [G.E. 77, 1080 (1965)]

Mineralogical society, Annual conference of the German ~ (CR) 94 [G.E. 77, 45 (1965)]

Mitochondrion, The ~ (Book Review) 382

Molecular weights, Automatic determin. of ~ by light scattering (CR) 970 [G.E. 77, 1017 (1965)]

Molybdenum compds., Arylazo deriv. of molybdenum (LA) 720

Monosaccharides, The ~ (Book Review) 723

Morphine, 14-Hydroxy-~ and 14-hydroxy-7,8-dihydro-~, new compds. with analgetic properties (LA) 894

2-Morpholino-5-phenylthiophene, Formation of ~ in the Willgerodt-Kindler reacn. (SC) 788 [G.E. 77, 812 (1965)]

Mucochloric acid, New methods in the chemistry of pyridazones (FP) 292 [G.E. 77, 282 (1965)]

Mucopolysaccharides, Chemical structure, distribution, and isolation (Book Review) 900

Mutagenic activity of thalidomide (contergan) (LA) 606

Mutarotation, Acid-base catalysis of the ~ of glucose (CR) 964 [G.E. 77, 973 (1965)]

Myoglobin, Reversible changes in the conformation of ~ (LA) 718

Immunchemical activity of chymotryptic peptides from sperm whale ~ (LA) 997

NAPHTHALENE, Synth. of thieto-[2.3.4-ij]-~ 1,1-dioxide, a 1,8-bridged ~ deriv. (SC) 786 [G.E. 77, 810 (1965)]

Synth. of 4-arylbenzo[b]oxepin compds. and their rearr. to ~ derivs. (SC) 872 [G.E. 77, 864 (1965)]

1,2,5-Naphto[2.3-c]thiadiazole, Synthesis of ~ (LA) 449

3-(β-Naphthyl)-1,2,5-thiadiazole, Synth. of 3-phenyl-, 3,4-diphenyl-, and ~ (SC) 239 [G.E. 77, 262 (1965)]

Natural products, Fortschritte der Chemie organischer Naturstoffe (Advances in the chemistry of org. ~) (Book Review) 266

Neptunium, The behavior of ~ and various uranium fission products in heterogenous reactions of neutron-irradiated uranium compds. with complexing agents (CR) 707 [G.E. 77, 732 (1965)]

Chelation of ~, plutonium, and americium by derivs. of 8-hydroxyquinoline (CR) 971 [G.E. 77, 1018 (1965)]

Neuraminic acid, Synth. of *N*-glycolyl-~ and the biochemistry of glycoproteins containing ~ (CR) 445 [G.E. 77, 432 (1965)]

Neutron activation, Neutronenaktivierung als analytisches Hilfsmittel (~ as an analytical tool) (Book Review) 103

Neutron diffraction, Applications of ~ in chemistry (Book Review) 105

Neutron irradiation, Sensitivity of pyrimidines and purines towards ~ (SC) 434 [G.E. 77, 428 (1965)]

Nickel, Estimation of metallic ~ and nickel oxide in metallurgical products (CR) 255 [G.E. 77, 267 (1965)]

Nickel compds., Trifluorophosphine complexes of Ni, Co, and Fe (CR) 706 [G.E. 77, 731 (1965)]

Prepn. and structure of a monophenylisocyanate of $Ni(HN_2S_2)_2$ (CR) 715 [G.E. 77, 740 (1965)]

Nickelocene, Triple decker sandwich complexes (LA) 263

Nickel oxide, Estimation of metallic nickel and ~ in metallurgical products (CR) 255 [G.E. 77, 267 (1965)]

Nickel salts, Acetic acid solvates of ~ and Cu salts (CR) 703 [G.E. 77, 727 (1965)]

Nicotine adenine dinucleotide, NADH model which reduces carbonyl groups almost quantitively and non-enzymatically (LA) 171

Nicotinic acid, Biosynth. of ~ by *Mycobacterium tuberculosis* (CR) 974 [G.E. 77, 1022 (1965)]

Ninhydrin, Stable ~ reagent for automatic determin. of amino acids (CR) 992 [G.E. 77, 1039 (1965)]

Niobium oxide, New phase near the composition $NbO_{2.5}$ (CR) 1087 [G.E. 77, 1082 (1965)]

α-Nitracrylic ester, Synth. of methyl α-nitro-β-methoxypropionate, a protected ~ (SC) 788 [G.E. 77, 812 (1965)]

Nitrate, Formation of nitrite from ~ in vegetables (CR) 995 [G.E. 77, 1043 (1965)]

Nitrenes, Pyrolysis of alkyl azidoformates in the gas phase (SC) 69 [G.E. 77, 42 (1965)]

Attempted prepn. of carbenes, ~, and sulfenes (CR) 981 [G.E. 77, 1028 (1965)]

Nitric acid, Role of the nitrosyl ion in the dissolution of metals in ~ (CR) 965 [G.E. 77, 975 (1965)]

Nitric oxide, Prepn. of aromatic nitriles from alkylaromatic compds. and ~ in the vapor phase (CR) 880 [G.E. 77, 916 (1965)]

Nitrides, Structures and chem. properties of ~ in ternary iron alloys (CR) 256 [G.E. 77, 268 (1965)]

Nitriles, Synth. of imidazolines and imidazolidines by the reacn. of aziridinium tetrafluoroborate with ~ and benzylideneaniline (SC) 518 [G.E. 77, 505 (1965)]

Polymeric products made from formaldehyde and ~ containing activated methylene groups (CR) 531 [G.E. 77, 511 (1965)]

Prepn. of aromatic~ from alkylaromatic compds. and nitric oxide in the vapor phase (CR) 880 [G.E. 77, 916 (1965)]

Reacns. of carbon disulfide and isothiocyanates with sulfur and ~ containing an active methylene group (CR) 881 [G.E. 77, 916 (1965)]

Synth. and properties of tetracyanopolyenes (CR) 883 [G.E. 77, 919 (1965)]

Intramolecular association of liq. ~ (LA) 98

Synth. of ~ from α-chloro ethers and NaCN (LA) 264

Nitrite, Formation of ~ from nitrate in vegetables (CR) 995 [G.E. 77, 1043 (1965)].

Nitrodiazoacetate (SC) 358 [G.E. 77, 379 (1965)]

Nitrogen, Advances in the determn. of oxygen, hydrogen, and ~ in metals (CR) 255 [G.E. 77, 267 (1965)]

Inorg. chemistry of ~ (Book Review) 377

Nitrogen compds., New heterocyclic ring systems containing boron and nitrogen (SC) 151 [G.E. 77, 169 (1965)]

Inorganic ring systems with silicon and nitrogen atoms as ring members (CR) 605, 717 [G.E. 77, 626, 746 (1965)]

Nitrogen selenide, Crystal structure of nitrogen compds. (SC) 72 [G.E. 77, 96 (1965)]

Nitrogen trifluoride, Recent investigations of covalent inorganic fluorides (CR) 446 [G.E. 77, 463 (1965)]

Nitroguanylation, New reagent for nitroguanylating proteins (LA) 718

Nitromethane, Cyclization of "nucleoside dialdehydes" with ~ (SC) 147 [G.E. 77, 131 (1965)]

Nitrosamines, Effect of ultraviolet radiation and of carcinogenic ~ on constituents of nucleic acids (CR) 971 [G.E. 77, 1019 (1965)]

Sepn. of rotational isomers of amides, thioamides, and ~ (CR) 985 [G.E. 77, 1032 (1965)]

Nitrosation, Mechanism of *C*-~ of phenol in various solvents (CR) 990 [G.E. 77, 1037 (1965)]

Nitroso compds., The free-radical nature of ~ (SC) 688 [G.E. 77, 717 (1965)]

Nitroso group, Character of the C-N bond between the benzene ring and the ~ (LA) 609

p-Nitroso-*N*,*N*-dimethylaniline, Character of the C-N bond between the benzene ring and the nitroso group (LA) 609

Nitrosyl compds., Bond angles in metal carbonyl and metal ~ (SC) 692 [G.E. 77, 719 (1965)]

Nitrosyl fluoride, The chemistry of nitrous acid and of its derivs. in liq. HF (FP) 635 [G.E. 77, 689 (1965)]

Nitrosyl ion, Role of the ~ in the dissolution of metals in nitric acid (CR) 965 [G.E. 77, 975 (1965)]

Nitrosyl salts, Synth. of diazonium salts from sulfinyl imides and ~ (SC) 148 [G.E. 77, 132 (1965)]

Nitrous acid, Chemistry of ~ and of its derivs. in liq HF (FP) 635 [G.E. 77, 689 (1965)]

Nitryl nitrato complexes of indium and thorium (SC) 436 [G.E. 77, 456 (1965)]

NMR spectroscopy, Exchange rates of ligands in complex ions (FP) 281 [G.E. 77, 361 (1965)]

Conformational analysis of cyclohexane derivs. by ~ (FP) 774 [G.E. 77, 798 (1965)]

Investigation of steric features by proton magnetic resonance (SC) 697 [G.E. 77, 721 (1965)]

Effect of magnetic susceptibility on proton resonance; magnetic measurements on new organic radicals (CR) 170 [G.E. 77, 181 (1965)]

Symposium on magnetic nuclear and electron resonance (CR) 256 [G.E. 77, 269 (1965)]

Elucidation of the microstructure of polymers by ~ (CR) 534 [G.E. 77, 514 (1965)]

NMR-Spectroscopic conformational analysis of menthylamines and carvomenthylamines (CR) 699 [G.E. 77, 723 (1965)]

Proton magnetic resonance measurement on hydrogen-bond associates of chloroform (CR) 700 [G.E. 77, 724 (1965)]

^{1}H-NMR-Investigations of organic Pt and Rh compds. (CR) 700 [G.E. 77, 724 (1965)]

NMR-spectroscopic studies of the equilibrium and kinetics of benzene oxide-oxepin conversions (CR) 975 [G.E. 77, 1022 (1965)]

NMR-spectroscopic investigations of the kinetics of the benzene oxide-oxepin equilibrium (CR) 1087 [G.E. 77, 1083 (1965)]

Addn. of sodium alkyl sulfates to water alters the chem. shift of the proton signals (LA) 100

Chem. shifts and π-electron densities (LA) 1098

Noble gases and their compds. (Book Review) 381

Nobel lectures, Physiology or medicine 1942–1962 (Book Review) 617

Non-stoichiometric compds. (Book Review) 103

Norbornene, Stereospecific addn. of formamide to ~ (LA) 894

Nortrilen, Therapy congress and pharmaceutical exhibition (CR) 157 [G.E. 77, 174 (1965)]

Nuclear magnetic relaxation times and the microdynamic structure of liquid mixtures (CR) 446 [G.E. 77, 463 (1965)]

Nuclear reacns., Synth. of transcurium elements by ~ with heavy ions (FP) 903 [G.E. 77, 981 (1965)]

Chem. effects associated with ~ and radioactive transformations (CR) 362 [G.E. 77, 383 (1965)]

Reactions of "hot" carbon atoms in nitrogen/alkane systems (CR) 966 [G.E. 77, 1013 (1965)]

Stereospecific retention in ~ on *cis*/*trans*-isomeric Co complexes (CR) 995 [G.E. 77, 1043 (1965)]

Nucleic acids, Influence of the interfacial energy of org. solvents on the photochemical dimerization of thymidylyl-(3′ → 5′)-thymidine (SC) 150 [G.E. 77, 133 (1965)]

Effect of steroids on the activity of DNA-dependent RNA-polymerase (SC) 155 [G.E. 77, 172 (1965)]

VIth International congress of biochemistry (CR) 75 [G.E. 77, 97 (1965)]

Chemical synth. and biosynth. of coding ~ (CR) 528 [G.E. 77, 509 (1965)]

Binding of actinomycin on apyrimidinic acid (CR) 707 [G.E. 77, 731 (1965)]

Ribonucleic acid – structure and function (CR) 889 [G.E. 77, 922 (1965)]

Effect of ultraviolet radiation and of carcinogenic nitrosamines on constituents of ~ (CR) 971 [G.E. 77, 1019 (1965)]

Structural studies on serine-specific transfer-RNA (CR) 995 [G.E. 77, 1043 (1965)]

Quantitat. sepn. of RNA and DNA structural units on cation-exchangers (CR) 1085 [G.E. 77, 1080 (1965)]

Size of the binding site of messenger RNA on ribosomes (LA) 99

Organic solvents alter the coding properties of synthetic messenger RNA (LA) 373

Die Nucleinsäuren (~) (Book Review) 722

Nucleophile, Influence of the ~ on competing β-elimination and S_N2 substitution (CR) 441 [G.E. 77, 460 (1965)]

Nucleophilic substitution at a saturated carbon atom (Book Review) 540

Nucleophilicity and basicity of amines (CR) 715 [G.E. 77, 739 (1965)]

Nucleoside dialdehydes, Cyclization of ~ with nitromethane (SC) 147 [G.E. 77, 131 (1965)]

Nucleoside monophosphates, Complete sepn. of ~ (LA) 263

Nucleosides, Synth. of 3′-amino- ~ (CR) 706 [G.E. 77, 731 (1965)]

Synth. of pyrimidine ~ *via* silyl compds. (CR) 995 [G.E. 77, 1043 (1965)]

3-Isoadenosine derivs. (LA) 794

New synth. of ~ and analogous compds. (LA) 895

The chemistry of ~ and nucleotides (Book Review) 266

The 2,2-trichloroethyl group as a protecting group for phosphates in the synthesis of mono- ~ (SC) 876 [G.E. 77, 912 (1965)]

Selective labelling of guanine in poly- ~ (LA) 609

The chemistry of nucleosides and ~ (Book Review) 266

cis-OCTADEC-12-ENOIC ACID, Resorption and metabolism of ~ in man and rat (CR) 1086 [G.E. 77, 1082 (1965)]

cis-9-Octadecen-12-ynoic acid (crepenynic acid) (LA) 172

Octafluoroxanthone, Pyrolysis of sodium and silicon pentafluorobenzoates (SC) 1072 [G.E. 77, 1076 (1965)]

Octaphenylcubane is actually octaphenylcyclooctatetraene (LA) 606

Octaphenylcyclooctatetraene, "Octaphenylcubane" is actually ~ (LA) 606

Oleate, Free-radical reacns. on thermolysis of methyl ~ in the absence of oxygen (CR) 975 [G.E. 77, 1023 (1965)]

Olefins, Eliminations from ~ (FP) 49 [G.E. 77, 75 (1965)]

Alkylidenephosphoranes and reagents containing multiple bonds (FP) 830 [G.E. 77, 850 (1965)]

Synth. of ~ from sulfenes and diazoalkanes *via* episulfones (SC) 70 [G.E. 77, 41 (1965)]

Photocatalysed cycloaddn. of dihalogenomaleimides and dihalogenomaleic anhydrides onto ~ and acetylenes (SC) 429 [G.E. 77, 452 (1965)]

Prepn. of oxaziridines from ~ (SC) 525 [G.E. 77, 548 (1965)]

Photo-initiated hydrocarboxylation of mono- ~ (SC) 790 [G.E. 77, 813 (1965)]

Addn. of diphenyl(triphenylstannyl)-phosphine to multiple bonds (SC) 869 [G.E. 77, 912 (1965)]

Benzylation of ~ (SC) 1072 [G.E. 77, 1137 (1965)]

Oxidn. of ~ with palladium chloride (CR) 885 [G.E. 77, 868 (1965)]

Addn. of formamide onto terminal ~ (LA) 171

New synth. of ~ (LA) 373

Conversion of thiols into homologous α- ~ (LA) 448

Azirdines from cyclic ~ (LA) 449

Location of a double bond *in* an olefinic chain by mass spectrometry (LA) 450

Photoinduced addn. of γ-butyrolactone onto terminal ~ (LA) 607

Aziridines and Schiff bases from picryl azide and ~ (LA) 608

Base-catalysed addn. of dimethylsulfoxide onto ~ (LA) 610

Ozonolysis of cyclo- ~ in ammonia (LA) 611

Oligoacrylic acid, Synth. of monodisperse ~ by means of a template reacn. (SC) 952 [G.E. 77, 965 (1965)]

Oligomerization, Recent results in the catalytic ~ and co-oligomerizn. of butadiene (FP) 327 [G.E. 77, 318 (1965)]

~ of peptides by enzymatic catalysis (CR) 529 [G.E. 77, 509 (1965)]

Optical circular dichroism, Progress in ~ (FP) 838 [G.E. 77, 842 (1965)]

~, principles, measurements, and applications (Book Review) 898

Organic chemistry, Methoden der organischen Chemie (Methods in ~) (Book Review) 104

Techniques of ~ (Book Review) 178
Physical methods in ~ (Book Review) 378

Progress in physical ~ (Book Review) 541

Progress in ~ (Book Review) 613

Advances in ~, methods and results (Book Review) 614, 725

Physical ~ (Book Review) 614

Basic principles of ~ (Book Review) 614

Organocarboranes from alkyldiboranes (SC) 439 [G.E. 77, 457 (1965)]

Organofluorine compds., Chemie und Technologie aliphatischer fluororganischer Verbindungen (Chemistry and technology of aliphatic ~) (Book Review) 175

Organolithium compds., Reacn. of ~ with silicon dioxide (SC) 600 [G.E. 77, 622 (1965)]

Organometallic chemistry, Advances in ~ (Book Review) 452

Organometallic compds., Role of ~ in the development of coordination chemistry (CR) 249 [G.E. 77, 264 (1965)]

Organophosphorus compds., Reacns. of *N*-sulfinylsulfonamides with ~ (SC) 357 [G.E. 77, 379 (1965)]

Orthoformate, Reacns. of triethyl ~ with some nitrogen compds. (CR) 702 [G.E. 77, 726 (1965)]

Osazones, Structure of sugar phenyl- ~ (FP) 574 [G.E. 77, 580 (1965)]

Oscillating fermentation system from yeast (CR) 535 [G.E. 77, 550 (1965)]

Osmium compds., *Cis-trans*-isomeric mixed-ligand complexes of Ir and Os (CR) 710 [G.E. 77, 734 (1965)]

New Landoldt reacn. (LA) 97

Ostwald ripening, Ageing of precipitates by ~ (CR) 444 [G.E. 77, 431 (1965)]

Ovulen, Therapy congress and pharmaceutical exhibition (CR) 158 [G.E. 77, 174 (1965)]

Oxazines, *N*-Substd. tetrahydro-1,4- ~ – a new class of fungicidal compds. (FP) 336 [G.E. 77, 327 (1965)]

Oxazinium salts, *N*-Substd. 4*H*-1,3- ~ (SC) 241 [G.E. 77, 218 (1965)]

Oxaziridines, Addn. of hydrogen peroxide onto Schiff bases (SC) 524 [G.E. 77, 548 (1965)]

Prepn. of ~ from olefins (SC) 525 [G.E. 77, 548 (1965)]

Oxazolidines, Prepn. of 1,3- ~ from isonitriles and aldehydes by a multicomponent reacn. (SC) 596 [G.E. 77, 591 (1965)]

Oxazolidones, New synth. of aziridines, carbamates, ~ and *cis*- or *trans*-2-amino alcohols (LA) 370

Oxepin, Synth. of 4-arylbenzo[b]- ~ compds. and their rearr. to naphthalene derivs. (SC) 872 [G.E. 77, 864 (1965)]

NMR-spectroscopic studies of the equilibrium and kinetics of benzene oxide- ~ conversions (CR) 975 [G.E. 77, 1022 (1965)]

NMR-spectroscopic investigations of the kinetics of the benzene oxide- ~ equilibrium (CR) 1087 [G.E. 77, 1083 (1965)]

Oxidases, Investigations on ~ and peroxidases (CR) 534 [G.E. 77, 549 (1965)]

Oxidation of org. compds. by combustion in a jet (CR) 447 [G.E. 77, 463 (1965)]

~ of transition elements by org. halides; detecn. of radicals by polymerizn. kinetics (CR) 533 [G.E. 77, 514 (1965)]

~ in org. chemistry (CR) 885 [G.E. 77, 867 (1965)]

Recent advances in metal-ligand ~ chemistry (CR) 885 [G.E. 77, 867 (1965)]

Mechanisms of ~ of org. compds. by ions of the transition metals (CR) 885 [G.E. 77, 868 (1965)]

~ of olefins with palladium chloride (CR) 885 [G.E. 77, 868 (1965)]

Liquid-phase ~ of org. compds. with oxygen (CR) 886 [G.E. 77, 868 (1965)]

Paraffin-oxygen reactions at 500–650 °C (CR) 886 [G.E. 77, 869 (1965)]

~ of org. compds. by sulfur dioxide under pressure (CR) 887 [G.E. 77, 869 (1965)]

Some recent developments in org. ~-s utilizing H_2O_2 (CR) 887 [G.E. 77, 870 (1965)]

Inhibition of ~ (CR) 887 [G.E. 77, 870 (1965)]

~ of aromatic and α,β-unsatd. oximes with lead tetraacetate (CR) 1091 [G.E. 77, 1087 (1965)]

~ reacns. of α-substd. thiocarboxamides (CR) 1095 [G.E. 77, 1091 (1965)]

Enzymatic ω- ~ of long-chain fatty acids (LA) 609

~ mechanisms, Applications to organic chemistry (Book Reviw) 380

Mechanisms of oxidation of organic compds. (Book Review) 380

Oxidative coupling, Polymerizn. by ~ (CR) 887 [G.E. 77, 870 (1965)]

Oxidative phosphorylation, following addn. of inorg. phosphate onto compds. with a $C{=}N^{\oplus}$ double bond (SC) 240 [G.E. 77, 259 (1965)]

Uncoupling of the ~ in mitochondria by NH-acidic benzimidazoles (SC) 788 [G.E. 77, 814 (1965)]

Oxides, Chemistry of amphoteric (CR) 534 [G.E. 77, 551 (1965)]

Thermogravimetric analysis of ~ (CR) 602 [G.E. 77, 593 (1965)]

High-melting metal ~ (LA) 370

Oxide halides, Syntheses of ~ (FP) 22 [G.E. 77, 23 (1965)]

Oxidizing agent, The system trifluoroperoxyacetic acid/borontrifluoride is a strong ~ (LA) 373

1,6-Oxidocyclodecapentaene, Aromatic character of systems with ten π-electrons: ^{1}H-NMR-spectra of 1,6-methano- and ~ (CR) 702 [G.E. 77, 726 (1965)]

Oximes, Association of isomeric hydroxyalkane derivs. (CR) 367 [G.E. 77, 352 (1965)]

Oxidn. of aromatic and α,β-unsatd. ~ with lead tetraacetate (CR) 1091 [G.E. 77, 1087 (1965)]

Oxime tosylates, The reacn. of ~ with phenylmagnesium bromide (LA) 264

Oxindoles, New route from indoles to ~ (LA) 450

Oxiranes, Formation of phenylcarbenes by photolysis of phenyl ~ (SC) 868 [G.E. 77, 859 (1965)]

Oxogallates, Chemistry of amphoteric oxides (CR) 534 [G.E. 77, 551 (1965)]

Oxychlorination (CR) 887 [G.E. 77, 869 (1965)]

Oxygen, Advances in the determn. of ~, hydrogen, and nitrogen in metals (CR) 255 [G.E. 77, 267 (1965)]

Estimation of ~ in uranium carbides by hot extraction (CR) 256 [G.E. 77, 268 (1965)]

Hydrogen and electron-transfer in reactions with molecular ~ (CR) 442 [G.E. 77, 461 (1965)]

Liquid-phase oxidation of organic compounds with ~ (CR) 886 [G.E. 77, 868 (1965)]

Paraffin- ~ reacns. at 500–650 °C (CR) 886 [G.E. 77, 869 (1965)]

Oxythiamine, Mode of action of the thiamine antagonists pyrithiamine and ~ in rat brain (CR) 717 [G.E. 77, 684 (1965)]

Ozone is stabilized by strong bases (LA) 98

Ozonolysis of cyclo-olefins in ammonia (LA) 611

PAINT FILMS, Interaction of pigments and binders in solid ~ (CR) 973 [G.E. 77, 1020 (1965)]

Palladium, Azido complexes of manganese(II) and ~-(II) (SC) 439 [G.E. 77, 458 (1965)]

Palladium chloride, Oxidation of olefins with ~ (CR) 885 [G.E. 77, 868 (1965)]

Palladium complexes, Synth. of tetrakis-(trifluorophosphine)platinum(0) and tetrakis(trifluorophosphine)palladium(0) (SC) 521 [G.E. 77, 505 (1965)]

Pancreas, Sepn. of enzymes of pancreatic fluid (CR) 1084 [G.E. 77, 1079 (1965)]

Metabolite content and protein synthesizing capacity of cat ~ before and after interruption of the circulation for two hours (CR) 1092 [G.E. 77, 1088 (1965)]

Paraffin-oxygen reactns. at 500–650 °C (CR) 886 [G.E. 77, 869 (1965)]

Particle size, Effect of ~ on the reacn. mechanism of gases with solids (CR) 892 [G.E. 77, 870 (1965)]

Peganine, Incorporation of anthranilic acid into ~ (vascine) (LA) 448

Penicillin, Mode of action of ~ (LA) 794

Pentacyclo[7.3.1.1^{4,12}.0^{2,7}.0^{6,11}]tetradecane, Synth. of ~ (CR) 169 [G.E. 77, 180 (1965)]

Pentafluorobenzoate, Pyrolysis of sodium and silicon ~ (SC) 1072 [G.E. 77, 1076 (1965)]

Pentaleno[2.1.6-def]heptalene, a non-benzenoid isomer of pyrene (SC) 69 [G.E. 77, 43 (1965)]

Pepsin, Oligomerizn. of peptides by enzymatic catalysis (CR) 529 [G.E. 77, 509 (1965)]

Specificity and mode of action of ~ in the condensation of oligopeptides (CR) 971 [G.E. 77, 1018 (1965)]

Peptidases, Action of hexamethylenetetramine on the catheptic endo- and exo-~ of fish tissues (CR) 988 [G.E. 77, 1035 (1965)]

Peptides, Progress in optical circular dichroism (FP) 838 [G.E. 77, 842 (1965)]

Synth. of cyclotri-L-prolyl, a cyclotripeptide having a nine-membered ring (SC) 356 [G.E. 77, 347 (1965)]

Prepn. of ~ with 3-pyridyl esters (SC) 594 [G.E. 77, 619 (1965)]

VIth International congress of biochemistry (CR) 75 [G.E. 77, 97 (1965)]

VIIth European ~ symposium (CR) 90 [G.E. 77, 53 (1965)]

Oligomerizn. of ~ by enzymatic catalysis (CR) 529 [G.E. 77, 509 (1965)]

Specificity and mode of action of pepsin in the condensation of oligo-~ (CR) 971 [G.E. 77, 1018 (1965)]

Synth. of cycloamides and cyclo-~ with medium-sized rings (CR) 988 [G.E. 77, 1036 (1965)]

Mass-spectrometric sequence analysis of acetylated ~ of aromatic amino acids (CR) 1087 [G.E. 77, 1083 (1965)]

Di- and tri-~ from amino esters and hydroxamic acid derivs. (LA) 171

Dipeptide phosphates as intermediates of enzymatic tripeptide synth. (LA) 720

Selective hydrolysis of aspartate bonds (LA) 896

Perfluoroallene, Reactions of ~ which proceed *via* ionic intermediates (LA) 172

Synth. of di-~ *via* phenylhydrazides of *N*-acyl-α-amino acids (LA) 996

Role of dicyanogen diamide in ~ synth. (LA) 997

Peroxidases, Investigations on oxidases and ~ (CR) 534 [G.E. 77, 549 (1965)]

~. The properties and uses of a versatile enzyme and of some related catalysts (Book Review) 1101

Peroxides, Formation of ~ from heterocyclic compds. containing nitrogen (CR) 366 [G.E. 77, 381 (1965)]

Induced decomposition of acyl and alkyl ~ (CR) 709 [G.E. 77, 733 (1965)]

Pertechnetate, Radiometric determin. of the self-diffusion coefficient of the ~ ion in aqu. solution (CR) 967 [G.E. 77, 1013 (1965)]

Pesticides, Analytical methods for ~, plant growth regulators, and food additives (Book Review) 377

pH, An apparatus for maintaining the ~ of unbuffered solns. (LA) 96

Pharmaceutical exhibition, Therapy congress and ~ (CR) 156 [G.E. 77, 174 (1965)]

Pharmaceuticals, Einführung in die Arzneibereitung (Introduction to the preparation of ~) (Book Review) 174

Phase boundaries, Kinetics at solid ~ (CR) 447 [G.E. 77, 463 (1965)]

Phenalene, Synth. of 1-dicyanomethylene-~ and 1-(ethoxycarbonylcyanomethylene)-~ (SC) 243 [G.E. 77, 346 (1965)]

Phenanthrene derivs., Photochemical synth. of ~ (LA) 894

Phenanthridine derivs., Synth. with dihydroresorcinol (CR) 366 [G.E. 77, 381 (1965)]

Phenol-phenoxyl systems, Redox potentials of ~ (SC) 354 [G.E. 77, 378 (1965)]

Phenols, Mechanism of the formation of quinones from mono-~ with dipotassium nitrosobissulfate (SC) 871 [G.E. 77, 913 (1965)]

Mechanism of *C*-nitrosation of ~ in various solvents (CR) 990 [G.E. 77, 1037 (1965)]

Phenylations, Radical ~ with aromatic diazo compds. (CR) 964 [G.E. 77, 974 (1965)]

Phenylbullvalene, Synth. and properties of phenyltricyclo[3.3.2.0^{4,6}]decatriene (~) (SC) 695 [G.E. 77, 682 (1965)]

Phenylcarbenes, Formation of ~ by photolysis of phenyloxiranes (SC) 868 [G.E. 77, 859 (1965)]

Phenylcyclopropanes, New synth. of ~ (LA) 1098

Phenyldifluorophosphine, $C_6H_5PF_2$ (LA) 719

α-Phenylethylpotassium, as initiator for the polymerizn. of styrene (LA) 1098

N-Phenyliminobenzylphosphonates, Synth. of ~ and benzoylphosphonates by Michaelis-Arbusow reacn. of aromatic imidoyl chlorides (SC) 247 [G.E. 77, 261 (1965)]

Phenylmagnesium bromide, The reacn. of oxime tosylates with ~ (LA) 264

Phenylosazones, The structure of sugar ~ (FP) 574 [G.E. 77, 580 (1965)]

Phenylphosphinidene, Detecn. of atomic sulfur and ~ (C_6H_5P:) in solution (SC) 437 [G.E. 77, 455 (1965)]

3-Phenyl-1,2,5-thiadiazole, Synth. of ~, 3,4-diphenyl-, and 3-(β-naphthyl)-1,2,5-thiadiazole (SC) 239 [G.E. 77, 262 (1965)]

Phosphacyanine, Crystal structure of a ~ (SC) 150 [G.E. 77, 134 (1965)]

Phosphanes, Recent developments in the chemistry of phosphorus (CR) 443 [G.E. 77, 433 (1965)]

Phosphatase, The repressor for the alkaline ~ in *E. coli* (LA) 99

Regulator gene determines a protein (LA) 538

Phosphates, Structural chemistry of condensed inorg. ~ (FP) 1061 [G.E. 77, 1056 (1965)]

The 2,2-trichloroethyl group as a protecting group for ~ in the synth. of mononucleotides (SC) 876 [G.E. 77, 912 (1965)]

Transesterification of methyl and ethyl ~, phosphonates, and phosphinates in the presence of tert. phosphines (SC) 951 [G.E. 77, 963 (1965)]

Use of chromatography on anion exchangers for determin. of low ~ contents (CR) 717 [G.E. 77, 683 (1965)]

Quant. sepn. of inorg. ortho-~ from pyro-~ and org. ~ (LA) 99

Phosphazenes, Cyclo-~ containing carbon: derivs. of a new heterocyclic system (CR) 990 [G.E. 77, 1038 (1965)]

Phosphazines, Charge distribution in ~ (CR) 973 [G.E. 77, 1021 (1965)]

Phosphide, Reacns. with potassium dihydrogen ~ (CR) 968 [G.E. 77, 1016 (1965)]

Phosphinates, Transesterification of methyl and ethyl phosphates, phosphonates, and ~ in the presence of tert. phosphines (SC) 951 [G.E. 77, 963 (1065)]

Phosphine, Addn. of diphenyl(triphenylstannyl)-~ to multiple bonds (SC) 869 [G.E. 77, 912 (1965)]

Divinylogous methylenephosphoranes from conjugated diynes, trialkylphosphines, and active methylene compds. (SC) 954 [G.E. 77, 1011 (1965)]

Thiocarbamoyl-~ (CR) 882 [G.E. 77, 917 (1965)]

Prepn. and properties of diprimary alkylenedi-~-s (CR) 984 [G.E. 77, 1032 (1965)]

Investigations on triaryl-~-s with substituents of the second kind (CR) 1093 [G.E. 77, 1089 (1965)]

Adduct of triphenyl-~ and hydrogen peroxide (LA) 374

Phosphine chalcogenides, Alkylation of ~ and phosphinylamines (CR) 712 [G.E. 77, 737 (1965)]

Phosphine oxide, Prepn. of triphenylphosphine from triphenyl-~ by reducn. with boranes (SC) 593 [G.E. 77, 589 (1965)]

Diazomethyl-~ (SC) 1078 [G.E. 77, 1138 (1965)]

Reduction of tert. ~ with trichlorosilane (LA) 897

Tert. ~-s (LA) 998

Phosphine sulfide-tin halide complexes (SC) 785 [G.E. 77, 809 (1965)]

Phosphinic acid, Synth. of diethyldiseleno-~ and its salts and esters (SC) 244 [G.E. 77, 259 (1965)]

Coordination polymers of dialkyl-~ (CR) 1091 [G.E. 77, 1087 (1965)]

Phosphinoalkanoic acids (SC) 155 [G.E. 77, 172 (1965)]

Phosphinylamines, Alkylation of phosphine chalcogenides and ~ (CR) 712 [G.E. 77, 737 (1965)]

Phosphoinositides, Cyclitols (polyhydroxycyclohexanes) and ~ (CR) 888 [G.E. 77, 921 (1965)]

Phosphonic esters, Bis-(*p*-hydroxyphenyl)-alkyl-~ and derived polycarbonates (SC) 592 [G.E. 77, 618 (1965)]

Transesterification of methyl and ethyl phosphates, phosphonates, and phosphinates in the presence of tertiary phosphines (SC) 951 [G.E. 77, 963 (1965)]

Phosphonium salts, Formation and reactivity of ~ in the vitamin A series (FP) 287 [G.E. 77, 277 (1965)]

New methods in preparative organic chemistry. New reacns. of alkylidenephosphoranes and their preparative uses (FP) 583, 645, 830 [G.E. 77, 609, 651, 850 (1965)]

New synth. of α-branched β-keto esters (SC) 596 [G.E. 77, 620 (1965)]

Formation of ylides on thermal decomposition of P-(α-alkoxycarbonylalkyl)triphenyl-~ (SC) 957 [G.E. 77, 1011 (1965)]

Phosphoranes, Chemistry and stereochemistry of fluoro-~ (FP) 496 [G.E. 77, 530 (1965)]

New methods in preparative org. chemistry. New reacns. of alkylidene-~ and their preparative uses (FP) 583, 645, 830 [G.E. 77, 609, 651, 850 (1965)]

Complexes of imino-~ with metal salts (SC) 785 [G.E. 77, 809 (1965)]

Infrared spectroscopic investigations on methylenetriphenyl-~ (SC) 875 [G.E. 77, 867 (1965)]

Organometallic derivs. of iminotriphenyl-~ (SC) 877 [G.E. 77, 866 (1965)]

Divinylogous methylene-~ from conjugated diynes, trialkylphosphines, and active methylene compds. (SC) 954 [G.E. 77, 1011 (1965)]

Infrared spectra of ^{15}N-labelled imino-~ (CR) 994 [G.E. 77, 1042 (1965)]

Phosphorescence spectroscopy as an analytical method for aromatic and heterocyclic compds. (FP) 930 [Chemie-Ing.-Techn. 37, 1010 (1965)]

Phosphoric acids, Recent developments in the chemistry of phosphorus (CR) 443 [G.E. 77, 433 (1965)]

Phosphoric monoesters, Structure and properties of some salts of ~ (CR) 703 [G.E. 77, 727 (1965)]

Phosphonium halides, Thermal decomposition of alkoxycarbonylmethyltriphenyl-~ (CR) 704 [G.E. 77, 728 (1965)

Phosphorus, New product of reacn. of organometallic compds. with S, Se, Te, and ~ (FP) 1007 [G.E. 77, 1049 (1965)]

α-Aminoalkylation of white ~ (SC) 527 [G.E. 77, 549 (1965)]

Recent developments in the chemistry of ~ (CR) 443 [G.E. 77, 433 (1965)]

Phosphorus compds., Color and constitution of azo compds. (FP) 457 [G.E. 77, 469 (1965)]

Heterocycles containing phosphorus (FP) 1023 [G.E. 77, 1109 (1965)]

Trimethylaluminum trimethylphosphorus oxide and trimethylarsenic trimethylgallium oxide (SC) 153 [G.E. 77, 170 (1965)]

Reacns. of *N*-sulfinylsulfonamides with organo-~ (SC) 357 [G.E. 77, 379 (1965)]

Synth. of phosphoryl and thiophosphoryl compds. from sulfur dioxide and ~ with a coordination number of three (SC) 359 [G.E. 77, 381 (1965)]

Polar reacns. at covalent tin-phosphorus bonds (SC) 787 [G.E. 77, 812 (1965)]

Bond character in aromatic ~ - a contribution to the problem of the existence and properties of p_π–d_π bonds (CR) 603 [G.E. 77, 593 (1965)]

Synth. of methylenebis-~ (CR) 881 [G.E. 77, 916 (1965)]

Ternary compds. and solid solutions in the system calcium oxide/phosphorus (V) oxide/boron(III) oxide (CR) 967 [G.E. 77, 1014 (1965)]

Ammonolysis of diphosphorus pentoxide (CR) 1093 [G.E. 77, 1089 (1965)]

~, antimony, sulfur, and selenium compds. in the liquid-liquid extraction of transition-metal ions (CR) 1096 [G.E. 77, 1092 (1965)]

The hydridotetrafluoro(trifluoromethyl)phosphate anion (LA) 97

Synth. of organo-~ (LA) 538

Synth. of polyamides containing phosphorus by interfacial polycondensation (LA) 721

Thermal isomerization of a P(V) to a P(III) compd. (LA) 896

Phosphorus halides, Cleavage of the Si–N bond of silazanes by ~ (CR) 709 [G.E. 77, 734 (1965)]

Phosphorylation, Oxidative ~ following addn. of inorg. phosphate onto compds. with a $C{=}N^{\oplus}$ double bond (SC) 240 [G.E. 77, 259 (1965)]

Uncoupling of the oxidative ~ in mitochondria by NH-acidic benzimidazoles (SC) 788 [G.E. 77, 814 (1965)]

Photochemistry, Light-induced formation of acids from cyclic ketones (FP) 211 [G.E. 77, 229 (1965)]

Reduction of acid bromides to aldehydes by irradiation in a hydrogen donor (SC) 146 [G.E. 77, 169 (1965)]

Substitution reacns. with photochemically produced acyl radicals (SC) 239 [G.E. 77, 216 (1965)]

Photocatalysed cycloaddn. of dihalogenomaleimides and dihalogenomaleic anhydrides onto olefins and acetylenes (SC) 429 [G.E. 77, 452 (1965)]

Photochemical isomerization of the tricyclo[3.2.1.$0^{2,4}$]octene system – a homovinylcyclopropane system (SC) 436 [G.E. 77, 453 (1965)]

Photo-initiated hydrocarboxylation of mono-olefins (SC) 790 [G.E. 77, 813 (1965)]

Org. ~ (CR) 81 [G.E. 77, 47 (1965)]

New photochemical reacns. of nitrogenous steroids (CR) 879 [G.E. 77, 915 (1965)]

New photochem. reacns. of benzene and some of its homologues (CR) 981 [G.E. 77, 1029 (1965)]

Chemistry and stereochemistry of the photocycloadducts of dichloromaleic imide and anhydride with acyclic 1,3-dienes (CR) 989 [G.E. 77, 1037 (1965)]

Action of light on a Diels-Alder System (LA) 173

Photoinduced addn. of γ-butyrolactone onto terminal olefins (LA) 607

Photochem. synth. of phenanthrene derivs. (LA) 894

Photolysis, Formation of phenylcarbenes by ~ of phenyloxiranes (SC) 868 [G.E. 77, 859 (1965)]

~ of ammonia in the vacuum-ultraviolet (CR) 370 [G.E. 77, 387 (1965)]

~ of 3,4-dihydro-4-oxobenzo-1,2,3-triazines substd. in the 3-position (CR) 699 [G.E. 77, 723 (1965)]

Photosynthesis, Analysis of ~ by flash-light techniques (FP) 799 [G.E. 77, 821 (1965)]

Inhibition of ~ reacns. by NH-acidic imidazoles and benzimidazoles (SC) 789 [G.E. 77, 911 (1965)]

Physical chemistry, Physikalische Chemie (~) (Book Review) 796

Picryl azide, Aziridines and Schiff bases from ~ and olefins (LA) 608

Pigments, Interaction of ~ and binders in solid paint films (CR) 973 [G.E. 77, 1020 (1965)]

Pilocarpine, Determin. of ~ in the aqu. humor of the eye by polarographic adsorption analysis (CR) 976 [G.E. 77, 1024 (1965)]

Piperidinoses, 1,6-Anhydroidose derivs. with rings containing nitrogen (SC) 592 [G.E. 77, 589 (1965)]

Plant growth regulators, Analytical methods for pesticides, ~, and food additives (Book Review) 377

Plasticizers, Interactions of ~ with poly(vinyl chloride) (CR) 604 [G.E. 77, 625 (1965)]

Platinum compds., Synthesis of tetrakis(trifluorophosphine)platinum(0) and tetrakis(trifluorophosphine)palladium(0) (SC) 521 [G.E. 77, 505 (1965)]

^1H-NMR-Investigations of org. ~ and rhodium compds. (CR) 700 [G.E. 77, 724 (1965)]

Isolation of some aquo and hydroxochloro complexes of Rh(III), Ir(III) and Pt(IV) (LA) 793

Plumbosiloxanes, Recent developments in the chemistry of heterosiloxanes (FP) 201 [G.E. 77, 206 (1965)]

Plutonium, Triscyclopentadienyl-~ (SC) 878 [G.E. 77, 866 (1965)]

Chelation of neptunium, ~, and americium by derivs. of 8-hydroxyquinoline (CR) 971 [G.E. 77, 1018 (1965)]

Polarity, Empirical parameters of the ~ of solvents (FP) 29 [G.E. 77, 30 (1965)]

Polarography, Effects in ~ attributable to the specific adsorption of reactants (CR) 967 [G.E. 77, 1014 (1965)]

Determin. of pilocarpine in the aqu. humor of the eye by polarographic adsorption analysis (CR) 976 [G.E. 77, 1024 (1965)]

Polyacids, Hydrolysis of metal alkoxides – a new method for studying ~ (CR) 368 [G.E. 77, 386 (1965)]

Polyamide fibers, Formation of free radicals in ~ during drawing (FP) 332 [G.E. 77, 323 (1965)]

Polyamides, Isoln. of higher cyclooligoamides from ~ (SC) 696 [G.E. 77, 720 (1965)]

Synth. of ~ containing phosphorus by interfacial polycondensation (LA) 721

Polyazomethines with azulene residues inserted in the main chain (LA) 719

Poly-(*m*-aminostyrene), Thermal analysis of ~ and related polymers (CR) 602 [G.E. 77, 593 (1965)]

Polybutadiene, Investigations on the molecular-weight jump reacn. of 1,4-*cis*-~ (CR) 533 [G.E. 77, 513 (1965)]

1,2-~ from butadiene (LA) 262

Polycarbonates, Bis-(*p*-hydroxyphenyl)-alkylphosphonic esters and derived ~ (SC) 592 [G.E. 77, 618 (1965)]

Poly-α-cyanostyrene, Polymeric products made from formaldehyde and nitriles containing activated methylene groups (CR) 531 [G.E. 77, 511 (1965)]

Polycyclic systems, Strained ~ consisting of three- and four-membered rings (FP) 121 [G.E. 77, 119 (1965)]

Poly-(2,5-dimethyl-2,4-hexadiene) peroxide, Stereoisomeric 2,5-dimethyl-2,3:4,5-dioxidohexanes as the main products of the pyrolysis of ~ (SC) 149 [G.E. 77, 133 (1965)]

Polyesters, Crystalline compds. of poly(ethylene oxides) and ~ with urea and thiourea (CR) 533 [G.E. 77, 514 (1965)]

Polyethylene, Differential thermal analysis of polymer dissolution (CR) 601 [G.E. 77, 592 (1965)]

Novel chelated catalyst systems for polymerizing ethylene (LA) 610

Poly(ethylene oxides), Crystalline compds. of ~ and polyesters with urea and thiourea (CR) 533 [G.E. 77, 514 (1965)]

Polymerase, Effect of steroids on the activity of DNA-dependent RNA polymerase (SC) 155 [G.E. 77, 172 (1965)]

Polymer chemistry, Inorg. ~ (Book Review) 105

Polymerization, Oligomers obtained in cationic and anionic ~ of ε-caprolactam (CR) 531 [G.E. 77, 512 (1965)]

Radical ~ of itaconic acid (CR) 531 [G.E. 77, 512 (1965)]

~ of formaldehyde by adsorbed water (CR) 532 [G.E. 77, 512 (1965)]

Co-~ of formaldehyde with cyclic formals (CR) 532 [G.E. 77, 513 (1965)]

~ of isoprene initiated by organolithium compds. (CR) 697 [G.E. 77, 721 (1965)]

Synth. and ~ of *S*-vinylmercaptals of formaldehyde (CR) 701 [G.E. 77, 725 (1965)]

~ by oxidative coupling (CR) 887 [G.E. 77, 870 (1965)]

New developments in the ionic ~ of cyclic acetals (CR) 891 [G.E. 77, 871 (1965)]

Initiation of ~ by radical ions and by dianions (CR) 969 [G.E. 77, 1016 (1965)]

Vinyl ~ coupled with ~ by acetal ring opening (LA) 608

Reactivity of methacrylates in radical co-~ (LA) 998

Catalytic effect of 1,1,3,3-tetramethylguanidine on the ~ of isocyanates (LA) 1098

Chemistry of cationic ~ (Book Review) 452

Polymerization initiators, Metal chelates as ~ (FP) 322 [G.E. 77, 313 (1965)]

Metal chelate complexes as ~ (CR) 531 [G.E. 77, 512 (1965)]

α-Phenylethylpotassium as ~ for the polymerizn. of styrene (LA) 1098

Polymers, Cyclic compds. as configurational models for stereoregular ~ (FP) 107 [G.E. 77, 149 (1965)]

Sequence distribution in co-~ (FP) 394, 1051 [G.E. 77, 405, 1124 (1965)]

Synth. of molecularly uniform ~ (CR) 170 [G.E. 77, 181 (1965)]

Thermal analysis of poly-(*m*-aminostyrene) and related ~ (CR) 602 [G.E. 77, 593 (1965)]

Silicon-organic ~ containing ferrocene (CR) 701 [G.E. 77, 726 (1965)]

Crystallization and the microstructure of high ~ (CR) 892 [G.E. 77, 871 (1965)]

Coordination ~ of dialkylphosphinic acids (CR) 1091 [G.E. 77, 1087 (1965)]

High molecular-weight, soluble ~ from 2*H*-3,4-dihydropyran-2-carboxaldehyde (LA) 372

"Living" ~ from tetrahydrofuran (LA) 794

New thermostable co-~ of formaldehyde (LA) 795

Radiochemical estimation of terminal lithium in ~ (LA) 897

Spectroscopy in the far infrared for the analysis of high ~ (LA) 898

Infrared spectroscopy of high ~ (Book Review) 539

Polymethine dyes, Synthesis of γ-phenylazopentamethinecyanine dyes (SC) 524 [G.E. 77, 508 (1965)]

Photochemical *trans,cis* rearr. of simple ~. Determination of the quantum yield and establishment of the configuration using the oscillator strength (SC) 525 [G.E. 77, 545 (1965)]

Photochemical rearr. of a trimethinecyanine dye from the all-*trans* form to a mono-*cis* and a di-*cis* form (SC) 526 [G.E. 77, 546 (1965)]

Polymyxins, Chemistry of ~ (CR) 966 [G.E. 77, 974 (1965)]

Polynucleotides, Labelling of terminal groups in ~ (LA) 537

Selective labelling of guanine in ~ (LA) 609

Poly-oxadiazoles, Polymers with 1,2,4-oxadiazole and 1,2,4-oxadiazoline rings (CR) 700 [G.E. 77, 725 (1965)]

Poly-oxadiazolines, Polymers with 1,2,4-oxadiazole and 1,2,4-oxadiazoline rings (CR) 700 [G.E. 77, 725 (1965)]

Polyoxymethylene, Polymerizn. of formaldehyde by adsorbed water (CR) 532 [G.E. 77, 512 (1965)]

Transfer reacns. during the cationic polymerization of trioxane (CR) 532 [G.E. 77, 513 (1965)]

Polysaccharides, Specific ~ of enterobacteria (CR) 529 [G.E. 77, 509 (1965)]

Polystyrene, Fractionation of ~ by gel chromatography (CR) 698 [G.E. 77, 723 (1965)]

~-s with *p*-vinyl and *p*-isopropenyl groups (LA) 997

Poly(vinyl chloride), Chlorinated ~ (CR) 533 [G.E. 77, 514 (1965)]

Elucidation of the microstructure of polymers by NMR spectroscopy (CR) 534 [G.E. 77, 514 (1965)]

Interactions of plasticizers with ~ (CR) 604 [G.E. 77, 625 (1965)]

Polyvinylcyclobutane, Crystalline ~ and polyvinylcloheptane (LA) 173

Polyvinylcycloheptane, Crystalline polyvinylcyclobutane and ~ (LA) 173

Poly-(4-vinylpyridine), Two molecular-weight ranges in ~ (LA) 374

Poly(vinylthiol), Synth. and autoxidn. of ~ (CR) 532 [G.E. 77, 513 (1965)]

Potassium dihydrogen phosphide, Reacns. with ~ (CR) 968 [G.E. 77, 1016 (1965)]

Praseodymium, Carbonato compds. of ~-(IV) and terbium(IV) (CR) 987 [G.E. 77, 1035 (1965)]

Precipitates, Ageing of ~ by Ostwald ripening (CR) 444 [G.E. 77, 431 (1965)]

Precipitation, Kinetics of ~ (Book Review) 725

Precipitation crystallization, Theory and technique of ~ (CR) 361 [G.E. 77, 351 (1965)]

Preparative organic chemistry, New methods of ~. The use of silylation in org. synth. (FP) 417 [G.E. 77, 414 (1965)]

~. Isonitrile synth. (FP) 472 [G.E. 77, 492 (1965)]

~. New reacns. of alkylidenephosphoranes and their preparative uses (FP) 583, 645, 830 [G.E. 77, 60, 651, 850 (1965)]

Pressure coefficient, Extreme values of the ~ of viscosity (FP) 944 [Chemie-Ing.-Techn. 37, 465 (1965)]

Primazin P dyes, New cotton dyes (FP) 312 [G.E. 77, 303 (1965)]

Prismane, Strained polycyclic systems consisting of three- and four-membered rings (FP) 121 [G.E. 77, 119 (1965)]

Valence-bond isomers of substd. benzenes (FP) 746 [G.E. 77, 768 (1965)]

Prismatic samples can give wrong transparency values (LA) 96

Proline, Hydroxylation of ~ at the level of microsome-bonded protein (LA) 996

Promotors, Function of the ~ in the technical ammonia catalyst (FP) 341 [G.E. 77, 333 (1965)]

Propanol, n-~ increases the virus-inactivating effect of peroxy-acetic acid (LA) 996

Prostaglandins (FP) 410 [G.E. 77, 445 (1965)]

Protecting group, The 2,2,2-trichloroethyl group as a ~ for phosphates in the synth. of mononucleotides (SC) 876 [G.E. 77, 912 (1965)]

Trimethylsilyl as ~ for nitrogen in organometallic synth. involving halogenoanilines (SC) 1081 [G.E. 77, 1141 (1965)]

Proteinase, Formation of streptococcal ~ from cymogen (LA) 1099

Proteins, VIth International congress of biochemistry (CR) 75 [G.E. 77, 97 (1965)]

Intermolecular interactions in the heat-induced aggregation of globular ~ in solution (CR) 705 [G.E. 77, 729 (1965)]

Modification of ~ by the introduction of additional thiol groups (CR) 880 [G.E. 77, 916 (1965)]

Metabolite content and ~ synthesizing capacity of cat pancreas before and after interruption of the circulation (CR) 1092 [G.E. 77, 1088 (1965)]

Protein carrier responsible for the biosynth. of fatty acids (LA) 98

Repressor for the alkaline phosphatase in *E. coli* (LA) 99

~ as products of regulator genes (LA) 100

~ components of the tail of T 2 bacteriophages (LA) 173

Regulator genes determine ~ (LA) 538

New reagent for nitroguanylating ~ (LA) 718

The ~. Composition, structure, and function (Book Review) 723

Protein synthesis, Inhibition of ~ by puromycin (LA) 538

One peptide chain is formed at every protein-synthesizing ribosome (LA) 607

Protonic states and the mechanism of acid-catalysed esterification (FP) 40 [G.E. 77, 65 (1965)]

Proton transfer, Kinetics of ~ processes (CR) 791 [G.E. 77, 814 (1965)]

Protons, Influence of the crystal field on the acidity of ~ in the crystal and on the surface (CR) 972 [G.E. 77, 1020 (1965)]

Pteridine *N*-oxides, Synth. of ~ (SC) 1075 [G.E. 77, 1136 (1965)]

Purines, 8,8-Disubstituted xanthines – a novel group of ~ derivs. (SC) 146 [G.E. 77, 129 (1965)]

Sensitivity of pyrimidines and ~ towards neutron irradiation (SC) 434 [G.E. 77, 428 (1965)]

Puromycin, Inhibition of protein synthesis by ~ (LA) 538

4*H*-Pyrazole *N*-oxides from 1,3-dioximes (CR) 1086 [G.E. *77*, 1082 (1965)]

Pyrazoles, Thermostable polyphenyl-~ (LA) 998

Pyrene, Pentaleno[2.1.6-def]heptalene – a non-benzenoid isomer of ~ (SC) 69 [G.E. *77*, 43 (1965)]

Pyridazones, New methods in the chemistry of ~ (FP) 292 [G.E. *77*, 282 (1965)]

Pyridine, OH···N bridges in ~/methanol mixtures (LA) 537

Pyridinium salt, N-Methyl-3,4,5-tricyanopyridinium perchlorate, a ~ of extremely high electron affinity (SC) 869 [G.E. *77*, 861 (1965)]

N-(Iodophenyl)-~-s (CR) 882 [G.E. *77*, 918 (1965)]

Pyridones, 1-Acyloxy-2(1*H*)-~ (LA) 1099

4-Pyridyl phosphate, Synth. and properties of ~ (CR) 714 [G.E. *77*, 739 (1965)]

Pyrimidines, Sensitivity of ~ and purines towards neutron irradiation (SC) 434 [G.E. *77*, 428 (1965)]

Formation of a 2-thiocyanato-~ from a 1-amino-2-thioxo-1,2-dihydro-~ and dimethylformamide/$POCl_3$ (SC) 868 [G.E. *77*, 859 (1965)]

Prepn. of ~ from cyanic esters and CH-acidic compds. (SC) 877 [G.E. *77*, 913 (1965)]

Synth. of ~ nucleosides *via* silyl compds. (CR) 995 [G.E. *77*, 1043 (1965)]

Pyrithiamine, Mode of action of the thiamine antagonists ~ and oxythiamine in rat brain (CR) 717 [G.E. *77*, 684 (1965)]

Pyrolysis of alkyl azidoformates in the gas phase (SC) 69 [G.E. *77*, 42 (1965)]

γ-Pyrones, New synth. of ~ (SC) 527 [G.E. *77*, 547 (1965)]

Pyrophosphate, Quant. sepn. of inorg. orthophosphate from ~ and org. phosphates (LA) 99

Pyrrole, New ~ synth. starting from butadiyne (LA) 895

N-Aminophthalimide has been used for unequivocal synth. of *N*-amino-~-s (LA) 999

Pyrrolidones, Synth. of imino-~ and iminothio-~ from aminoalkenes and isonitriles plus isocyanates or isothiocyanates (SC) 519 [G.E. *77*, 544 (1965)]

QUASI-AROMATIC compds., New results in the chemistry of ~ (CR) 261 [G.E. *77*, 224 (1965)]

Quinol-2-ones, *N*-Alkyl-3,4-dihydro-3,4-Methylene-~, derivs. of a new ring system (LA) 372

Quinoline, The origin of the nitrogen in ~ made by the Skraup synth. (LA) 721

Quinone, Mechanism of the formation of ~-s from monophenols with dipotassium nitrosobissulfate (SC) 871 [G.E. *77*, 913 (1965)]

New reacns. in the ~ and heterocycle series (CR) 604 [G.E. *77*, 624 (1965)]

Redox potentials of the alkyl-substd. ~/hydroquinone system (LA) 1098

RACEMIZATION, VIIth European peptide symposium (CR) 90 [G.E. *77*, 53 (1965)]

Radicals, Formation of free ~ in polyamide fibers during drawing (FP) 332 [G.E. *77*, 323 (1965)]

The use of electron paramagnetic resonance in org. chemistry (FP) 856 [G.E. *77*, 888 (1965)]

Stable tri-~ (SC) 72 [G.E. *77*, 43 (1965)]

Substitution reacns. with photochemically produced acyl ~ (SC) 239 [G.E. *77*, 216 (1965)]

^{17}O-Hyperfine structure in the ESR spectrum of [^{17}O]-2,4,6-triphenylphenoxyl (SC) 240 [G.E. *77*, 217 (1965)]

ESR-Spectroscopic detection of a [^{33}S]-sulfur radical (SC) 243 [G.E. *77*, 220 (1965)]

Isoln. of benzoyl ~ (SC) 355 [G.E. *77*, 378 (1965)]

1,3,5-Tris(di-*p*-biphenylylmethyl)benzene, a new triradical (SC) 596 [G.E. *77*, 619 (1965)]

Reinvestigation of the assumed homopolar dissociation of the Sn–Sn bond (SC) 599 [G.E. *77*, 622 (1965)]

The free-radical nature of nitroso compds. (SC) 688 [G.E. *77*, 717 (1965)]

Effect of magnetic susceptibility on proton resonance; magnetic measurements on new organic ~ (CR) 170 [G.E. *77*, 181 (1965)]

Oxidation of transition elements by organic halides; detecn. of ~ by polymerizn. kinetics (CR) 533 [G.E. *77*, 514 (1965)]

Induced decomposition of acyl and alkyl peroxides (CR) 709 [G.E. *77*, 733 (1965)]

Initiation of polymerizn. by ~ ions and by dianions (CR) 969 [G.E. *77*, 1016 (1965)]

Free-~ reacns. on thermolysis of methyl oleate in the absence of oxygen (CR) 975 [G.E. *77*, 1023 (1965)]

Biradical intermediates (LA) 172

Free-radical intermediates of Grignard reacns. (LA) 263

Novel radical trianion (LA) 264

Transannular free-radical cycloaddns of *cis,cis*-1,5-cyclooctadiene (LA) 449

Mesomeric free arsenic radical (LA) 450

Free arylboron ~ (LA) 897

Reactivity of methacrylates in ~ copolymerizn. (LA) 998

Radioactive transformations, Chem. effects associated with nuclear reacns. and ~ (CR) 362 [G.E. *77*, 383 (1965)]

Radioactivity, Apparent prolongation of the half-life of radioactive nuclides (LA) 173

Air chemistry and ~ (Book Review) 176

Radiochemistry, Symposium on radiochem. methods of analysis (CR) 254 [G.E. *77*, 220 (1965)]

Advances in inorg. chemistry and ~ (Book Review) 102

Radioisotopes, Techniques for the use of ~ in analysis. A Laboratory manual (Book Review) 725

Radiolysis of hydrocarbons (Book Review) 615

Raman spectroscopy, of colored crystal powders; excitation with laser radiation (CR) 1094 [G.E. *77*, 1090 (1965)]

Introduction to infrared and ~ (Book Review) 724

Rare earths, Reversed-phase paper-chromatographic separation of ~ (CR) 884 [G.E. *77*, 920 (1965)]

Isotope effects in the sepn. of rare earths on ion-exchangers (CR) 978 [G.E. *77*, 1025 (1965)]

Progress in the science and technology of the ~ (Book Review) 104

Reaction mechanisms, Symposium on ~ (CR) 440 [G.E. *77*, 459 (1965)]

Reactive dyes, New cotton dyes (FP) 312 [G.E. *77*, 303 (1965)]

Rearrangement, New ~ of ar-tetrafols with perchloric acid (SC) 690 [G.E. *77*, 717 (1965)]

Ortho-~ of metalated butynyl benzyl ether (SC) 957 [G.E. *77*, 1012 (1965)]

The mechanism of anionic ~-s. – A Stevens-1,3-~ (CR) 441 [G.E. *77*, 460 (1965)]

Geometry of the transition state of the Claisen ~ (CR) 443 [G.E. *77*, 461 (1965)]

Cyclopropane and cyclobutane derivs. by ~ of unsatd. compds. (CR) 603 [G.E. *77*, 624 (1965)]

~ of β-alkoxyalkylcarbenes (SC) 692 [G.E. *77*, 681 (1965)]

~ of *homoallylic* carbonium salts (CR) 976 [G.E. *77*, 1023 (1965)]

New ~ in the indole series (CR) 993 [G.E. *77*, 1041 (1965)]

Acid-catalysed ~ of *N*-halogenoguanidines (CR) 1088 [G.E. *77*, 1084 (1965)]

Red blood cells, Structure and function of the ~ (CR) 165 [G.E. *77*, 138 (1965)]

Redox potentials of phenol-phenoxyl systems (SC) 354 [G.E. *77*, 378 (1965)]

~ of the alkyl-substd. quinone/hydroquinone system (LA) 1098

Redox titrations, Microanalytical ~ (CR) 602 [G.E. *77*, 626 (1965)]

Reductones, Prepn. and rearr. of distyrylmethanol derivs. and a new route to ~ (CR) 535 [G.E. *77*, 550 (1965)]

Synth. of ~ and their "ketals" (CR) 712 [G.E. *77*, 736 (1965)]

Redul, Therapy congress and pharmaceutical exhibition (CR) 156 [G.E. *77*, 174 (1965)]

Regulator gene, Protein as the product of a ~ (LA) 100

~ determines a protein (LA) 538

Repressor, The ~ for the alkaline phosphatase in *E. coli* (LA) 99

The ~ of the β-galactosidase synth. (LA) 896

Resorcinol, Structures of macrocyclic condensation products obtained from veratrole and ~ with aldehydes (LA) 96

Rhenates, Comparative investigations on the stability of the hexahalogenotechnetates(IV) and -~-(IV) (CR) 1094 [G.E. *77*, 1090 (1965)]

Rhenium trichloride, Mass-spectrometric investigation of ~ (SC) 148 [G.E. *77*, 131 (1965)]

Rhodane, Charge-transfer complexes between ~ and aromatic hydrocarbons (LA) 537

Rhodium compds., Synth. of tetrakistrifluorophosphinoiridium hydride and the proton magnetic resonance spectra of the hydrides $HM(PF_3)_4$ (M=Co, Rh, Ir) (SC) 870 [G.E. *77*, 860 (1965)]

^1H-NMR-Investigations of organic Pt and ~ (CR) 700 [G.E. *77*, 724 (1965)]

Exchange reacns. in solid Co, Rh, and Ir complexes initiated thermally and by the ^{57m}Ir nuclear transition (CR) 990 [G.E. *77*, 1038 (1965)]

Isolation of some aquo and hydroxo-chloro complexes of Rh(III), Ir(III) and Pt(IV) (LA) 793

Riboside, New di-~ synth. (LA) 100

Ribosomes, Size of the binding site of messenger RNA on ~ (LA) 99

One peptide chain is formed at every protein-synthesizing ~ (LA) 607

Ring index, A list of ring systems used in organic chemistry (Book Review) 725

Ring migration and transalkylation in alkylated ferrocenes (LA) 537

Ring opening of 6-membered heterocycles by nucleophilic reagents (CR) 1090 [G.E. 77 1086 (1965)]

Vinyl polymerizn. coupled with polimerizn. by acetal ~ (LA) 608

Rotational isomerism, Relations between ~ hydrogen bonding, and substituent effects (CR) 977 [G.E. 77, 1024 (1965)]

Sepn. of rotational isomers of amides, thioamides and nitrosamines (CR) 985 [G.E. 77, 1032 (1965)]

SCANDATES, New compds. of the $CaFe_2O_4$ type (CR) 1092 [G.E. 77, 1088 (1965)]

Scheele, Carl Wilhelm ~, Apotheker-Chemiker-Entdecker (Book Review) 175

Schiff bases, Addn. of hydrogen peroxide onto ~ (SC) 524 [G.E. 77, 548 (1965)]

Reacn. of oxime tosylates with phenylmagnesium bromide (LA) 264

Aziridines and ~ (LA) 608

Selenium, New products of reacn. of organometallic compds. with S, ~, Te, and P (FP) 1007 [G.E. 77, 1049 (1965)]

Selenium compds., Crystal structure of nitrogen compds. (SC) 72 [G.E. 77, 96 (1965)]

Phosphorus, antimony, sulfur, and ~ in the liquid-liquid extraction of transition-metal ions (CR) 1096 [G.E. 77, 1092 (1965)]

1-Selenochromones, Synth. of ~ (SC) 879 [G.E. 77, 913 (1965)]

Selenophene, Prepn. of tetrachlorotelluro-phene and tetrachloro-~ (SC) 245 [G.E. 77, 260 (1965)]

Selenophosphinic acid, Synth. of diethyl-di-~ and its salts and esters (SC) 244 [G.E. 77, 259 (1965)]

Semiconductors, Organic dyes as photo-electric ~ (FP) 619 [G.E. 77, 633 (1965)]

Org. ~ and inorg. ~ with molecular lattices (CR) 163 [G.E. 77, 177 (1965)]

Injection and extraction processes at ~ electrodes (CR) 986 [G.E. 77, 1033 (1965)]

Surface reacns. of gases with ~ (CR) 993 [G.E. 77, 1040 (1965)]

Separations, New biochemical ~ (Book Review) 1002

Sequence distribution in copolymers (FP) 394, 1051 [G.E. 77, 405, 1124 (1965)]

Sesquifulvalene, 1,2,3,4-Tetrachloro-benzo[g]-~ (SC) 353 [G.E. 77, 345 (1965)]

Sesquifulvapolyenes, Studies on azalogous ~ (CR) 980 [G.E. 77, 1027 (1965)]

Shikimic acid, Simple synth. of ~ (SC) 871 [G.E. 77, 859 (1965)]

Silanes, Prepn. and reacns. of optically active amino-~ (CR) 882 [E.G. 77, 918 (1965)]

Prepn. of cyano-~ (CR) 977 [G.E. 77, 1025 (1965)]

Reduction of tert. phosphine oxides with trichloro-~ (LA) 897

Silazane, Synth. of *N,N'*-bis(chlorodi-methylsilyl)tetramethylcyclodi-~ (SC) 592 [G.E. 77, 618 (1965)]

Cleavage of the Si–N bond of ~-s by phosphorus halides (CR) 709 [G.E. 77, 734 (1965)]

Inorganic ring systems with silicon and nitrogen atoms as ring members (CR) 605, 717 [G.E. 77, 626, 746 (1965)]

Silica gels, Fractionation of high molecular-weight materials on ~ having a defined cavity structure (CR) 530 [G.E. 77, 511 (1965)]

Silicate glasses, Surface properties of ~ (Book Review) 726

Silicate structures, Silicate science (Book Review) 1001

Silicon, Optical investigations of the surface chemistry of Ge and ~ (CR) 968 [G.E. 77, 1015 (1965)]

Alteration of the barrier-layer properties of oxide-protected pn-junctions in ~ (CR) 978 [G.E. 77, 1025 (1965)]

Silicon compds., The chemistry of sulfur-~ (FP) 1014 [G.E. 77, 1066 (1965)]

N-Bromohexamethyldisilazane (SC) 73 [G.E. 77, 130 (1965)]

Resolution of the silicon complex with 2-hydroxypyridine *N*-oxide into its enantiomers – evidence for octahedrally coordinated silicon (SC) 357 [G.E. 77, 347 (1965)]

Trifluoracetates of Si, Ge and Sn (SC) 1079 [G.E. 77, 1138 (1965)]

Inorganic ring systems with silicon and nitrogen atoms as ring members (CR) 605, 717 [G.E. 77, 626, 746 (1965)]

Volatile ~ (Book Review) 454

Silicon dioxide, Reacn. of organolithium compds. with ~ (SC) 600 [G.E. 77, 622 (1965)]

Silicon monoxide, Prepn. and properties of ~ (CR) 880 [G.E. 77, 915 (1965)]

Silicon-organic polymers containing ferrocene (CR) 701 [G.E. 77, 726 (1965)]

Siloxanes, Recent developments in the chemistry of hetero-~ (FP) 210 [G.E. 77, 206 (1965)]

Hetero-~ and t-butoxy compds. of aluminum, gallium and indium (SC) 152 [G.E. 77, 169 (1965)]

Hetero-~ of zinc and cadmium (SC) 876 [G.E. 77, 865 (1965)]

Methyl(trimethylsiloxy)mercury and dimethyl(trimethylsiloxy)thallium (SC) 876 [G.E. 77, 865 (1965)]

Polychelated ~ (CR) 530 [G.E. 77, 511 (1965)]

Silver compds., Complexes of trivalent silver (LA) 172

Silver bromide, Transport and phase-boundary reacns. of defect electrons in ~ (CR) 971 [G.E. 77, 1018 (1965)]

Silver halides, Prepn. of heavy metal halides in anhydrous acetic acid (SC) 869 [G.E. 77, 860 (1965)]

Silylamide, Reaction of sodium bistrimethyl-~ with carbon monoxide and metal carbonyls (SC) 438 [G.E. 77, 457 (1965)]

Silylamine, Chemistry of bis(trimethylsilyl)halogenoamines (CR) 715 [G.E. 77, 740 (1965)]

Silylation, New methods of preparative organic chemistry. The use of ~ in org. synth. (FP) 417 [G.E. 77, 414 (1965)]

Silyl azides, Chemistry of ~ (CR) 994 [G.E. 77, 1042 (1965)]

Silyl compds., Synth. of pyrimidine nucleosides *via* ~ (CR) 995 [G.E. 77, 1043 (1965)]

Silylferrocene, Prepn. and polyaddn. reacns. of ferrocene derivs. with two dimethylsilyl groups (CR) 530 [G.E. 77, 511 (1965)]

N-Silylimidazolidinones, New ~ (SC) 438 [G.E. 77, 456 (1965)]

Single crystals, Einkristalle. Wachstum, Herstellung und Anwendung (~ – growth, production, and use) (Book Review) 105

Skraup synth., Origin of the nitrogen in quinoline made by the ~ (LA) 721

Sodium hydrazide, Uses of ~ for the synth. and degradn. of org. compds. (CR) 1090 [G.E. 77, 1085 (1965)]

Solid phase boundaries, Kinetics at ~ (CR) 447 [G.E. 77, 463 (1965)]

Solute-water interactions, Water and ~ (Book Review) 899

Solutions, Equilibrium and transport properties of conc. electrolyte ~ (FP) 485 [G.E. 77, 517 (1965)]

Solvates, Acetic acid ~ of Ni and Cu salts (CR) 703 [G.E. 77, 727 (1965)]

Solvent effects on the stereospecificity of halogen addition to *cis*- and *trans*-stilbenes (CR) 881 [G.E. 77, 917 (1965)]

Solvent extraction, Synergic effects in ~ (CR) 95 [G.E. 77, 57 (1965)]

~ of metal chelates (Book Review) 1002

Solvents, Empirical parameters of the polarity of solvents (FP) 29 [G.E. 77, 30 (1965)]

Influence of the interfacial energy of org. ~ on the photochem. dimerizn. of thymidylyl-(3′ → 5′)-thymidine (SC) 150 [G.E. 77, 133 (1965)]

Les réactions chimiques dans les solvants et les sels fondus (Chemical reactions in ~ and molten salts) (Book Review) 724

Sorbates, Control of electrochem. reacns. by means of foreign ~ (CR) 446 [G.E. 77, 459 (1965)]

Spectroscopy, Code for the classification of the ultraviolet spectra of org. compds. (FP) 516 [G.E. 77, 541 (1965)]

Emission-spectrometric analysis using intermittent beams from a laser (LA) 263

Filter solution for the mercury resonance line at 1849 Å (LA) 371

Infrared band handbook (Book Review) 179

Anleitung zum Messen von Absorptionsspektren im Ultraviolett und Sichtbaren (Directions for measuring absorption spectra in the ultraviolet and visible regions) (Book Review) 375

Chem. applications of infrared ~ (Book Review) 377

Experimental ~ (Book Review) 615

Infrared ~ and molecular structure. An outline of the principles (Book Review) 616

Spectrometric identification of org. compds. (Book Review) 726

Squaric acid, Cyclotrimethine dyes derived from ~ (SC) 694 [G.E. 77, 680 (1965)]

Stannosiloxanes, Recent developments in the chemistry of heterosiloxanes (FP) 201 [G.E. 77, 206 (1965)]

Stannyl radicals, Reinvestigation of the assumed homopolar dissociation of the the Sn–Sn bond (SC) 599 [G.E. 77, 622 (1965)]

Induced decomposition of acyl and alkyl peroxides (CR) 709 [G.E. 77, 733 (1965)]

Statistics, Application of mathematical ~ to chemical analysis (Book Review) 900

Stereochemistry, Cyclic compds. as configurational models for stereoregular polymers (FP) 107 [G.E. 77, 149 (1965)]

Steroids, Recent advances in the total synth. of ~ (FP) 181 [G.E. 77, 185 (1965)]

1,4-N → N'-Acyl migration in diamino ~ (SC) 74 [G.E. 77, 94 (1965)]

Effect of ~ on the activity of DNA-dependent RNA-polymerase (SC) 155 [G.E. 77, 172 (1965)]

Condensation of 6-methoxy-1-vinyl-1,2,3,4-tetrahydro-1-naphthol with 2-methylcyclopentane-1,3-dione (SC) 1083 [G.E. 77, 1142 (1965)]

VIth International congress of biochemistry (CR) 75 [G.E. 77, 97 (1965)]

New photochemical reacns. of nitrogenous ~ (CR) 879 [G.E. 77, 915 (1965)]

~ reactions: an outline for organic chemists (Book Review) 179

~ chromatography (Book Review) 378

Stevens-1,3-rearrangement, Mechanism of anionic rearr. - ~ (CR) 441 [G.E. 77, 460 (1965)]

Stibines, Synth. and properties of some new phenyltinarsines, -~, and -bismuthines (CR) 991 [G.E. 77, 1039 (1965)]

Stilbenes, Solvent effects on the stereospecificity of halogen addition to *cis*- and *trans*- ~ (CR) 881 [G.E. 77, 917 (1965)]

Strained polycyclic systems consisting of three- and four-membered rings (FP) 121 [G.E. 77, 119 (1965)]

Strontium disilicide, Crystal structure of ~ (SC) 245 [G.E. 77, 258 (1965)]

Structural analysis, Automation of X-ray ~ (FP) 508 [G.E. 77, 484 (1965)]

~ of free molecules by electron diffraction (FP) 819 [G.E. 77, 877 (1965)]

Fortschritte der Strukturforschung mit Beugungsmethoden (Advances in ~ using diffraction methods) (Book Review) 175

Styrene, α-Phenylethylpotassium as initiator for the polymerizn. of ~ (LA) 1098

Styrene-acrylonitrile copolymers, Protecting effects in ~ during the action of ionizing radiation (CR) 704 [G.E. 77, 728 (1965)]

Styrene/butadiene copolymers, Vulcanization of ~ with maleimides (LA) 721

Substitution reacns. with photochemically produced acyl radicals (SC) 239 [G.E. 77, 216 (1965)]

Influence of the nucleophile on competing β-elimination and S_N2 substitution (CR) 441 [G.E. 77, 460 (1965)]

Sugar phenylosazones, Structure of ~ (FP) 574 [G.E. 77, 580 (1965)]

Sulfamides, Prepn. of azo compds. from *N,N'*dialkyl- ~ (SC) 433 [G.E. 77, 429 (1965)]

Sulfane oxides, Synth. of ~ (CR) 1093 [G.E. 77, 1089 (1965)]

Sulfenes, Synth. of olefins from ~ and diazoalkanes *via* episulfones (SC) 70 [G.E. 77, 41 (1965)]

Attempted prepn. of carbenes, nitrenes, and ~ (CR) 981 [G.E. 77, 1028 (1965)]

Sulfinylimides, Synth. of diazonium salts from ~ and nitrosyl salts (SC) 148 [G.E. 77, 132 (1965)]

N-Sulfinylsulfonamides, Reacns. of ~ with organophosphorus compds. (SC) 357 [G.E. 77, 379 (1965)]

Sulfonamides, Synth. of *N*-(alkylthiohalogenomethylene)- ~ (SC) 521 [G.E. 77, 549 (1965)]

Sulfones, Formation of cyclic ~ from dialkylaminobutadienes and methanesulfonyl chloride (SC) 786 [G.E. 77, 811 (1965)]

Sulfonium ylides, New stable ~ (LA) 607

Carbonyl-stabilized ~ (LA) 999

Sulfonylcarbodiimides, Sulfonyl isocyanide dichlorides and ~ (SC) 430 [G.E. 77, 430 (1965)]

Synth. of *N*-acyl- and *N*- ~ (LA) 449

Sulfonyl isocyanide dichlorides and sulfonyl carbodiimides (SC) 430 [G.E. 77, 430 (1965)]

N-Sulfonyl isothiocyanates (SC) 430 [G.E. 77, 429 (1965)]

Sulfophthalein ethers (CR) 1088 [G.E. 77, 1083 (1965)]

Sulfoxides, Stereochemistry of ~ (CR) 717 [G.E. 77, 684 (1965)]

Sulfur, Detection of atomic ~ and phenylphosphinidene (C_6H_5P:) in solution (SC) 437 [G.E. 77, 455 (1965)]

Synth. of 1,3-thiazolidin-2-ones from aminoalkenes, isocyanates, and ~ (SC) 519 [G.E. 77, 544 (1965)]

Sulfur compds., New products of reacn. of organometallic compds. with sulfur, selenium, tellurium, and phosphorus (FP) 1007 [G.E. 77, 1049 (1965)]

The chemistry of silicon- ~ (FP) 1014 [G.E. 77, 1066 (1965)]

Org. ~ (CR) 87 [G.E. 77, 51 (1965)]

Sulfur diimines, New synth. of stable aliphatic ~ (LA) 1098

Sulfur dioxide, Oxidn. of org. compds. by ~ under pressure (CR) 887 [G.E. 77, 869 (1965)]

Sulfur hexafluoride, Quantitative analysis of ~ and its derivs. (LA) 447

Sulfur oxides, New findings in the chemistry of the lower ~ (FP) 402 [G.E. 77, 437 (1965)]

Sulfur ylides, Reacns. with ~ (CR) 982 [G.E. 77, 1029 (1965)]

Surface area estimations (LA) 609

Surface chemistry, Optical investigations of the ~ of Ge and Si (CR) 968 [G.E. 77, 1015 (1965)]

Surface compds. on diamonds (CR) 698 [G.E. 77, 722 (1965)]

Surface reacns. of gases with semiconductors (CR) 993 [G.E. 77, 1040 (1965)]

Surfaces, Influence of alpha-radiation on metal ~ (CR) 445 [G.E. 77, 431 (1965)]

Mobility of molecules adsorbed on the ~ of solids (CR) 892 [G.E. 77, 924 (1965)]

Influence of the crystal field on the acidity of protons in the crystal and on the ~ (CR) 972 [G.E. 77, 1020 (1965)]

Recent progress in surface science (Book Review) 899

Surfactants, Colloidal ~. Some physicochemical properties (Book Review) 614

Synthetic methods of org. chemistry (Book Review) 541

TALUSIN, Therapy congress and pharmaceutical exhibition (CR) 157 [G.E. 77, 174 (1965)]

Tantalum nitride, Synth. and properties of red ~ Ta_3N_5 (SC) 241 [G.E. 77, 218 (1965)]

Tantalum oxide nitride, Synth. and properties of ~, TaON (SC) 875 [G.E. 77, 913 (1965)]

Taxonomy, Chemotaxonomie der Pflanzen (Chemical ~ of plants) (Book Review) 723

Technetates, Comparative investigations on the stability of the hexahalogeno- ~- (IV) and -rhenates(IV) (CR) 1094 [G.E. 77, 1090 (1965)]

Technetium, Ternary oxides of seven- and four-valent ~ (CR) 980 [G.E. 77, 1028 (1965)]

Tecomine and tecostanine, two antidiabetic alkaloids (LA) 608

Tecostanine, Tecomine and ~, two antidiabetic alkaloids (LA) 608

Tellurium, New products of reacn. of organometallic compds. with sulfur, selenium, ~, and phosphorus (FP) 1007 [G.E. 77, 1049 (1965)]

Tellurophene, Prepn. of tetrachloro- ~ and tetrachloroselenophene (SC) 245 [G.E. 77, 260 (1965)]

Template reacn., Synth. of monodisperse oligoacrylic acid by means of a ~ (SC) 952 [G.E. 77, 965 (1965)]

Terbium, Carbonato compds. of praseodymium(IV) and ~-(IV) (CR) 987 [G.E. 77, 1035 (1965)]

Terpene biosynth., Hydrolysis of terpenyl phosphates, model reacns. of ~ (CR) 444 [G.E. 77, 432 (1965)]

Terpenyl phosphates, Hydrolysis of ~, model reacns. of terpene biosynth. (CR) 444 [G.E. 77, 432 (1965)]

Tetrabenzylbutatriene (1,6-diphenyl-2,5-dibenzylhexa-2,3,4-triene) (SC) 74 [G.E. 77, 95 (1965)]

1,2,3,4-Tetrachlorobenzo[g]sesquifulvalene (SC) 353 [G.E. 77, 345 (1965)]

Tetrachlorotellurophene, Prepn. of ~ ~ and tetrachloroselenophene (SC) 245 [G.E. 77, 260 (1965)]

Tetrachloroselenophene, Prepn. of tetrachlorotellurophene and ~ (SC) 245 [G.E. 77, 260 (1965)]

Tetrachloro-*p*-xylylene, Synthesis and reacns. of α,α,α',α'- ~ (SC) 598 [G.E. 77, 592 (1965)]

Tetracyanopolyenes, Synth. and properties of ~ (CR) 883 [G.E. 77, 919 (1965)]

Tetrahedrane, Strained polycyclic systems consisting of three- and four-membered rings (FP) 121 [G.E. 77, 119 (1965)]

Tetrahydrocannabinol, Isoln., structure, and partial synth. of an active constituent of hashish (marihuana) (LA) 99

Tetrahydrocannabinolcarboxylic acid, a component of hashish (SC) 872 [G.E. 77, 862 (1965)]

Tetrahydro-6,14-endoethenothebaine, Alcoholic derivs. of ~ have a high analgetic effect (LA) 262

Tetrahydrofuran, Synth. of 5-chloromethyl-2,2-dinitro-~ (SC) 433 [G.E. 77, 427 (1965)]

"Living" polymer from ~ (LA) 794

Tetrahydromethanoindanes, Synth. and structure of insecticidal polychloro-~ (CR) 969 [G.E. 77, 1016 (1965)]

Tetrahydro-1,4-oxazines, *N*-Substd. ~ – a new class of fungicidal compds. (FP) 336 [G.E. 77, 327 (1965)]

Tetrakis(trifluorophosphine)cobalt hydride, Synth. of ~ and hexakis(trifluorophosphine)tungsten(0) (SC) 148 [G.E. 77, 132 (1965)]

Tetralols, New rearr. of ar-~ with perchloric acid (SC) 690 [G.E. 77, 717 (1965)]

Tetramethoxyethylene, Reacns. of ~ (CR) 977 [G.E. 77, 1024 (1965)]

Tetramethylguanidine, Catalytic effect of 1,1,3,3-~ on the polymerizn. of isocyanates (LA) 1098

Tetrathiopercarbonic acid, Investigations on ~ (CR) 1085 [G.E. 77, 1081 (1965)]

Tetrazines, Five-membered heterocycles from hydrazomethane, aromatic aldehydes, and dipolarophiles (CR) 701 [G.E. 77, 725 (1965)]

Tetrazoles, Synth. of 5-aryl-1-methyl-[1,2,4]-triazolo[4,3-d]-~ (SC) 950 [G.E. 77, 963 (1965)]

Reacns. of triethyl orthoformate with some nitrogen compds. (CR) 702 [G.E. 77, 726 (1965)]

Novel conversion of 3-diazoaminoisoxazoles into ~ (LA) 173

Tetrazolo[5,1-a]isoquinolinium bromide, Synth. of 3-phenyltetrazolopyridinium bromides and 3-phenyl-6-bromo-~ (SC) 154 [G.E. 77, 171 (1965)]

Tetrazolopyridinium bromides, Synth. of 3-phenyl-~ and 3-phenyl-6-bromotetrazolo[5,1-a]isoquinolinium bromide (SC) 154 [G.E. 77, 171 (1965)]

Thalidomide, Mutagenic activity of ~ (Contergan) (LA) 606

Thallium, Methyl(trimethylsiloxy)mercury and dimethyl(trimethylsiloxy)-~ (SC) 876 [G.E. 77, 865 (1965)]

Therapy congress and pharmaceutical exhibition (CR) 156 [G.E. 77, 174, (1965)]

Thermal analysis, Differential ~ of polymer dissolution (CR) 601 [G.E. 747 592 (1965)]

Simultaneous thermogravimetric and differential ~ of the decomposition of chromates and dichromates (CR) 601 [G.E. 77, 593 (1965)]

~ of inorg. azides (CR) 602 [G.E. 77, 593 (1965)]

~ of poly-(*m*-aminostyrene) and related polymers (CR) 602 [G.E. 77, 593 (1965)]

Thermal fragmentation and the determin. of the structure of org. compds. (FP) 938 [Chemie-Ing.-Techn. 37, 709 (1965)

Thermodynamics, Classical ~ of non-electroiyte solns. (Book Review) 105 Thermodynamik der irreversiblen Prozesse (~ of irreversible processes) (Book Review) 265

Thermogravimetric analysis of oxides (CR) 602 [G.E. 77, 593 (1965)] Inorg. ~, (Book Review) 616

Thermolysis, of cycloalkyl esters yielding cycloalkanones (SC) 355 [G.E. 77, 346 (1965)]

Free-radical reacns. on ~ of methyl oleate in the absence of oxygen (CR) 975 [G.E. 77, 1023 (1965)]

Thiadiazole, Synth. of 3-phenyl-, 3,4-diphenyl-, and 3-(β-naphthyl)-1,2,5-~ (SC) 239 [G.E. 77, 262 (1965)]

Synth. of heterocycles containing sulfur and ring opening with formation of esters of cyanic acid (CR) 365 [G.E. 77, 381 (1965)]

Synthesis of 1,2,5-naphtho[2,3-c]-~ (LA) 449

Thiamine, "Activated formaldehyde" is 2-hydroxy-methyl-~ pyrophosphate (LA) 1099

Thiatriazole, Bis-(1,2,3,4-thiatriazol-5-yl)-thio compds. with high-explosive properties (SC) 357 [G.E. 77, 348 (1965)]

Synth. of heterocycles containing sulfur and ring opening with formation of esters of cyanic acid (CR) 365 [G.E. 77, 381 (1965)]

Thiadiazolidine, Five-membered heterocycles from hydrazomethane, aromatic aldehydes, and dipolarophiles (CR) 701 [G.E. 77, 725 (1965)]

Thiamine antagonists, Mode of action of the ~ pyrithiamine and oxythiamine in rat brain (CR) 717 [G.E. 77, 684 (1965)]

1,3-Thiazolidin-2-ones, Synth. of ~ from aminoalkenes, isocyanates, and sulfur (SC) 519 [G.E. 77, 544 (1965)]

Thiazolo[3,2-*a*]pyridinium ion (LA) 372

Thieto[2.3.4-ij]naphthalene 1,1-dioxide, Synth. of ~, a 1,8-bridged naphthalene deriv. (SC) 786 [G.E. 77, 810 (1965)]

Thin-layer chromatography, Quantitative determin. of β-aminoisobutyric acid by ~ (CR) 716 [G.E. 77, 683 (1965)]

Detecn. and determin. of amines on the 10^{-10} molar scale. Sepn. of 5-dimethylamino-1-naphthalenesulfonamides by ~ (CR) 716 [G.E. 77, 684 (1965)]

Thioamides, Sepn. of rotational isomers of amides, ~, and nitrosamines (CR) 985 [G.E. 77, 1032 (1965)]

Oxidn. reacns. of α-substituted ~ (CR) 1095 [G.E. 77, 1091 (1965)]

Thiocarbamoyl chlorides, Synth. of *N*-phenyl-*S*-chloroiso-~ by chlorination of isothiocyanates (SC) 432 [G.E. 77, 427 (1965)]

Thiocarbamoylphosphines (CR) 882 [G.E. 77, 917 (1965)]

3-Thiochromones, New synth. of ~ (LA) 794

Thiocyanates, Arylsulfonyl ~ (LA) 537

Thiocyanatopyrimidine, Formation of a 2-~ from a 1-amino-2-thioxo-1,2-dihydropyrimidine and dimethylformamide/$POCl_3$ (SC) 868 [G.E. 77, 859 (1965)]

Thiocyanomethylcyclopropane, Thermal isomerization of ~ (LA) 897

Thioferrates, Alkali-metal ~-(III) (CR) 1084 [G.E. 77, 1080 (1965)]

Thiol groups, Modification of proteins by by the introduction of additional ~ (CR) 880 [G.E. 77, 916 (1965)]

Thiols, Conversion of ~ into homologous α-olefins (LA) 448

Thionophosphates, Isomerizn. of ~ (CR) 993 [G.E. 77, 1041 (1965)]

Thiophene, Formation of 2-morpholino-5-phenyl-~ in the Willgerodt-Kindler reacn. (SC) 788 [G.E. 77, 812 (1965)]

~ from 5-oxo derivs. of 1-alkynes (SC) 1082 [G.E. 77, 1141 (1965)]

Thiophosphates, Alkylating properties of alkyl ~ (FP) 914 [G.E. 77, 1001 (1965)]

Thiophosphoryl compds., Synth. of phosphoryl and ~ from sulfur dioxide and phosphorus compds. with a coordination number of three (SC) 359 [G.E. 77, 381 (1965)]

Thiopyrrolidones, Synth. of iminopyrrolidones and imino-~ from aminoalkenes and isonitriles plus isocyanates or isothiocyanates (SC) 519 [G.E. 77, 544 (1965)]

Thiourea, Crystalline compds. of poly(ethylene oxides) and polyesters with urea and ~ (CR) 533 [G.E. 77, 514 (1965)]

β-Thioxo ketones, Synth. of ~ by condensation of ketones with thionic esters (SC) 154 [G.E. 77, 172 (1965)]

Thorium, Nitryl nitrato complexes of In and ~ (SC) 436 [G.E. 77, 456 (1965)]

Thymidylyl-(3′ → 5′)-thymidine, Influence of the interfacial energy of org.

solvents on the photochemical dimerization of ~ (SC) 150 [G.E. 77, 133 (1965)]

Tin compds., Reinvestigation of the assumed homopolar dissociation of the Sn–Sn bond (SC) 599 [G.E. 77, 622 (1965)]

Addn. of diphenyl(triphenylstannyl)-phosphine to multiple bonds (SC) 869 [G.E. 77, 912 (1965)]

Trifluoroacetates of Si, Ge and Sn (SC) 1079 [G.E. 77, 1138 (1965)]

Basic salts of bivalent Sn (CR) 990 [G.E. 77, 1038 (1965)]

Synth. and properties of some new phenyltinarsines, -stibines, and -bismuthines (CR) 991 [G.E. 77, 1039 (1965)]

Coordination chemistry of organometallic compds. of group IVb elements (CR) 1089 [G.E. 77, 1084 (1965)]

Covalent metal-metal bonds in mixed metal carbonyls (LA) 97

Tetrakis-8-hydroxyquinolyltin(IV) (LA) 896

Tin halide, Phosphine sulfide/~ complexes (SC) 785 [G.E. 77, 809 (1965)]

Tin-phosphorus bonds, Polar reacns. at covalent ~ (SC) 787 [G.E. 77, 812 (1965)]

Titanium, Investigations in the ~/hydrogen system (CR) 1095 [G.E. 77, 1091 (1965)]

Titanium compds., Di-π-cyclopentadienyl-titanium bis(hydrogen sulfide) (SC) 953 [G.E. 77, 965 (1965)]

Reacn. of triethylaluminum with bis-cyclopentadienyl-titanium(IV) and -zirconium(IV) compds. (CR) 713 [G.E. 77, 738 (1965)]

Titrations, Microanalytical redox ~ (CR) 602 [G.E. 77, 626 (1965)]

Titrationen in nichtwäßrigen Lösungsmitteln (~ in non-aqu. solvents) (Book Review) 1000

Toluene, Catalytic cleavage and formation of C–C bonds in aromatic compds. in the gas phase (CR) 366 [G.E. 77, 381 (1965)]

Tosyl azide, Synth. of v-triazolo[3,4-a]pyridines and 1,2,3-triazoles by diazo group transfer with ~ (SC) 431 [G.E. 77, 428 (1965)]

Synth. of 1,2,3-triazoles and isomeric α-diazoimines by diazo group transfer with ~ (CR) 710 [G.E. 77, 735 (1965)]

Trace elements, Biochemie der Mineral- und Spurenelemente (Biochemistry of mineral and ~) (Book Review) 375

Transalkylation, Ring migration and ~ in alkylated ferrocenes (LA) 537

Transcurium elements, Synth. of ~ by nuclear reacns. with heavy ions (FP) 903 [G.E. 77, 981 (1965)]

Transesterification of methyl and ethyl phosphates, phosphonates, and phosphinates in the presence of tert. phosphines (SC) 951 [G.E. 77, 963 (1965)]

Transfer reacns. during the cationic polymerizn. of trioxane (CR) 532 [G.E. 77, 513 (1965)]

Transition metals, Mechanism of oxidation of org. compds. by ions of the ~ (CR) 885 [G.E. 77, 868 (1965)]

Production of carbonyls of ~ (LA) 172

Stable colloids of ~ in the zerovalent state in ethers (LA) 894

Transparency, Prismatic samples can give wrong ~ values (LA) 96

Triarylphosphines, Investigations on ~ with substituents of the second kind (CR) 1093 [G.E. 77, 1089 (1965)]

1,4a,8,8a-Triazaboradecalin (LA) 447

Triazine, Photolysis of 3,4-dihydro-4-oxobenzo-1,2,3-~-s substd. in the 3-position (CR) 699 [G.E. 77, 723 (1965)]

2-Methyl-2*H*-naphtho[1,8-*de*]-~, a blue ~ (LA) 374

Triazoles, Synth. of v-triazolo[3,4-a]-pyridines and 1,2,3-~ by diazo group transfer with tosyl azide (SC) 431 [G.E. 77, 428 (1965)]

Synth. of 3,5-dibromo-1,2,4-~ by bromination of 1,2,4-~ (SC) 434 [G.E. 77, 429 (1965)]

Synth. of 1,2,3-~ and isomeric α-diazoimines by diazo group transfer with tosyl azide (CR) 710 [G.E. 77, 735 (1965)]

Triazolidine, Five-membered heterocycles from hydrazomethane, aromatic aldehydes, and dipolarophiles (CR) 701 [G.E. 77, 725 (1965)]

Triazolines, Five-membered heterocycles from hydrazomethane, aromatic aldehydes, and dipolarophiles (CR) 701 [G.E. 77, 725 (1965)]

Aziridines by photolysis of 1,2,3-~ (LA) 794

Triazolobenzotriazinium salt, Synth. of 1,2,3-triazolo[1,5-*a*]quinoxalinium and 1,2,3-triazolo[5,1-*c*]benzo-1,2,4-triazinium salts (SC) 1074 [G.E. 77, 1077 (1965)]

v-Triazolo[3,4-a]pyridines, Synth. of ~ and 1,2,3-triazoles by diazo group transfer with tosyl azide (SC) 431 [G.E. 77, 428 (1965)]

Triazoloquinoxalinium salt, Synth of 1,2,3-triazolo[1,5-*a*]quinoxalinium and 1,2,3-triazolo[5,1-*c*]benzo-1,2,4-triazinium salts (SC) 1074 [G.E. 77, 1077 (1965)]

Triazolotetrazoles, Synth. of 5-aryl-1-methyl-[1,2,4]-triazolo[4,3-*d*]tetrazoles (SC) 950 [G.E. 77, 963 (1965)]

Tribenzocycloheptatriene, Intramolecular mobility of di- and ~ derivs. (CR) 715 [G.E. 77, 739 (1965)]

2,2,2-Trichloroethyl group, The ~ as a protecting group for phosphates in the synth. of mononucleotides (SC) 876 [G.E. 77, 912 (1965)]

Trichloromethanesulfenyl chloride, New reacns. with ~ (CR) 992 [G.E. 77, 1040 (1965)]

Trichlorosilane, Reducn. of tert. phosphine oxides with ~ (LA) 897

Tricyclo[3.2.1.0^{2,4}]octene, Photochem. isomerizn. of the ~ system – a homovinylcyclopropane system (SC) 436 [G.E. 77, 453 (1965)]

Trifluoroperoxyacetic acid, The system ~/boron trifluoride is a strong oxidizing agent (LA) 373

Trifluorophosphine complexes, Synth. of tetrakis(trifluorophosphine)platinum(0) and tetrakis(trifluorophosphine)-palladium(0) (SC) 521 [G.E. 77, 505 (1965)]

Synth. of tetrakistrifluorophosphino-iridium hydride and the proton magnetic resonance spectra of the hydrides $HM(PF_3)_4$ (M = Co, Rh, Ir) (SC) 870 [G.E. 77, 860 (1965)]

~ of Ni, Co, and Fe (CR) 706 [G.E. 77, 731 (1965)]

Tri(isopropylidene)cyclopropane (SC) 594 [G.E. 77, 590 (1965)]

Trimethylsilylamide, Reacn. of sodium bis-~ with carbon monoxide and metal carbonyls (SC) 438 [G.E. 77, 457 (1965)]

Trimethylsilylation, New methods of preparative organic chemistry. The use of silylation in org. synth. (FP) 417 [G.E. 77, 414 (1965)]

Trimethylsilyl as protecting group for nitrogen in organometallic synth. involving halogenoanilines (SC) 1081 [G.E. 77, 1141 (1965)]

1,3,6-Trioxacyclooctane, Copolymerizn. of formaldehyde with cyclic formals (CR) 532 [G.E. 77, 513 (1965)]

Trioxane, Transfer reacns. during the cationic polymerizn. of ~ (CR) 532 [G.E. 77, 513 (1965)]

Triphenylaluminum, Reacn. of ~ with cyclohexyl isonitrile (SC) 355 [G.E. 77, 380 (1965)]

[^{17}O]-2,4,6-Triphenylphenoxyl, ^{17}O-Hyperfine structure in the ESR spectrum of ~ (SC) 240 [G.E. 77, 217 (1965)]

Triphenylphosphine, Prepn. of ~ from ~ oxide by reducn. with boranes (SC) 593 [G.E. 77, 589 (1965)]

Adduct of ~ and hydrogen peroxide (LA) 374

Triple bonds, Stereochemistry of addns. to acetylenic ~ (SC) 689 [G.E. 77, 679 (1965)]

Triradical, Stable ~ (SC) 72 [G.E. 77, 43 (1965)]

1,3,5-Tris(di-*p*-biphenylylmethyl)benzene, a new ~ (SC) 596 [G.E. 77, 619 (1965)]

Trisbiphenylenephosphates, Optically active ~ (SC) 356 [G.E. 77, 378 (1965)]

1,3,5-Tris(di-*p*-biphenylylmethyl)benzene, a new triradical (SC) 596 [G.E. 77, 619 (1965)]

Trisilyl compds., New ~ (LA) 171

Tris(trifluoromethanesulfenyl)amine, Prepn. and properties of ~ (SC) 440 [G.E. 77, 458 (1965)]

Triterpenes, Tetracyclic ~ (Book Review) 1102

Trithiocarbonic acid, Reacns. of ~ (CR) 1090 [G.E. 77, 1086 (1965)]

Tropone, One-stage synth. of ~ (LA) 373

Tropylium systems, Cyclopropenylium and ~ (CR) 972 [G.E. 77, 1019 (1965)]

Tungsten compds., Synth. of tetrakis-(trifluorophosphine)cobalt hydride and hexakis(trifluorophosphine) tungsten (0) (SC) 148 [G.E. 77, 132 (1965)]

Complex with a coordination number of 7 and tungsten-mercury bonds (LA) 894

ULTRAVIOLET SPECTRA, Code for the classification of the ~ of org. compds. (FP) 516 [G.E. 77, 541 (1965)]

Uranium, The behavior of neptunium and various ~ fission products in heterogenous reacns. of neutron-irradiated ~ compds. with complexing agents (CR) 707 [G.E. 77, 732 (1965)]

Analytical chemistry of ~ (Book Review) 617

Uranium carbides, Estimation of the oxygen in ~ by hot extraction (CR) 256 [G.E. 77, 268 (1965)]

Uranium dioxide, Evolution of fission products from neutron-irradiated ~ at high temperatures (CR) 984 [G.E. 77, 1032 (1965)]

Uranium(V) oxide, The system lithium oxide/~ (CR) 705 [G.E. 77, 729 (1965)]

Uranium tetrachloride, Ammoniates of uranium trichloride and ~ (SC) 431 [G.E. 77, 453 (1965)]

High-temperature ammonolysis of uranium trichloride and ~ (SC) 433 [G.E. 77, 428 (1965)]

Uranium trichloride, Ammoniates of ~ and uranium tetrachloride (SC) 431 [G.E. 77, 453 (1965)]

High-temperature ammonolysis of ~ and tetrachloride (SC) 433 [G.E. 77, 428 (1965)]

Uranyl compds., Spectroscopy and photochemistry of ~ (Book Review) 1001

Uranyl vandate, Uvanite, a swelling ~ with a layer structure (SC) 353 [G.E. 77, 347 (1965)]

Urea, Crystalline compds. of poly(ethylene oxides) and polyesters with ~ and thiourea (CR) 533 [G.E. 77, 514 (1965)]

Uvanite, a swelling uranyl vandate with a layer structure (SC) 353 [G.E. 77, 347 (1965)]

VALENCE-BOND ISOMERS of aromatic systems (FP) 738 [G.E. 77, 759 (1965)]

~ of substd. benzenes (FP) 746 [G.E. 77, 768 (1965)]

Molecules undergoing fast, reversible valence-bond isomerizn. (FP) 752 [G.E. 77, 774 (1965)]

Unusual valence-bond isomerism (LA) 718

Vanadium, toxicology and biological significance (Book Review) 797

Vanadium compds., Dichlorotrinitrosylvanadium $[V(NO_3Cl_2)]_n$ (SC) 151 [G.E. 77, 134 (1965)]

New Landoldt reacn. (LA) 97

Vasicine, Incorporation of anthranilic acid into peganine (~) (LA) 448

Vegetables, Formation of nitrite from nitrate in ~ (CR) 995 [G.E. 77, 1043 (1965)]

Ventrinerval, Therapy congress and pharmaceutical exhibition (CR) 158 [G.E. 77, 174 (1965)]

Veratrole, Structures of macrocyclic condensation products obtained from ~ and resorcinol with aldehydes (LA) 96

Vilsmeier formylation, α-Formyl ketones from aminoalkenes by ~ (SC) 358 [G.E. 77, 380 (1965)]

Disubstitution in the Vilsmeier-Haack aldehyde synth. (SC) 955 [G.E. 77, 967 (1965)]

Vinyl acetate/ethylene copolymers, Graft polymerizn. of vinyl compounds onto ~ (CR) 532 [G.E. 77, 512 (1965)]

Vinylcyclohexa-1,3-diene, Prepn. of ~ from 5,6-diacetoxycyclooctene (SC) 77 [G.E. 77, 42 (1965)]

Vinyl polymerization, Metal chelate complexes as polymerizn. initiators (CR) 531 [G.E. 77, 512 (1965)]

~ coupled with polymerizn. by acetal ring opening (LA) 608

Vinylsulfonic acid, Chemistry of ~ (FP) 300 [G.E 77, 291 (1965)]

Vinylsulfonium salts, Prepn. of 1,2-disubstd. ~ and alkyl vinyl sulfides, and of ethynylsulfonium and ethynylselenonium salts (SC) 1080 [G.E. 77, 1140 (1965)]

Ethynylation with ~ (SC) 1080 [G.E. 77, 1141 (1965)]

Virus, n-Propanol increases the ~-inactivating effect of peroxy-acetic acid (LA) 996

Viscosity, Extreme values of the pressure coefficient of ~ (FP) 944 [Chemie-Ing.-Techn. 37, 465 (1965)]

Vitamin A, Formation and reactivity of phosphonium salts in the ~ series (FP) 287 [G.E. 77, 277 (1965)]

Vitamin B_{12}, Organometallic derivs. of cobaloximes and of ~ (SC) 146 [G.E. 77, 130 (1965)]

Vitamins, Vitamine, Chemie and Biochemie (~, chemistry and biochemistry) (Book Review) 1000

Vulcanization of styrene/butadiene copolymers with maleimides (LA) 721

WATER, Addn. of sodium alkyl sulfates to ~ alters the chem. shift of the proton signals (LA) 100

~ and solute-~ interactions (Book Review) 899

Willgerodt-Kindler reacn., Formation of 2-morpholino-5-phenylthiophene in the ~ (SC) 788 [G.E. 77, 812 (1965)]

Wittig reacn., Formation and reactivity of phosphonium salts in the vitamin A series (FP) 287 [G.E. 77, 277 (1965)]

Reversibility of betaine formation during the ~ (SC) 689 [G.E. 77, 682 (1965)]

Stereoselective ~ (CR) 712 [G.E. 77, 736 (1965)]

XANTHINES, 8,8-Disubstd. ~ – a novel group of purine derivs. (SC) 146 [G.E. 77, 129 (1965)]

Xenon hexafluoride, Production of pure ~ (LA) 170

X-Ray fluorescence analysis, Comparison of calculated and measured line intensities in ~ (CR) 1087 [G.E. 77, 1082 (1965)]

X-Ray structural analysis, Automation of ~ (FP) 508 [G.E. 77, 484 (1965)]

Xylonest, Therapy congress and pharmaceutical exhibition (CR) 157 [G.E. 77, 174 (1965)]

YEAST, Oscillating fermentation system from ~ (CR) 535 [G.E. 77, 550 (1965)]

Ylides, New reacns. of alkylidenephosphoranes and their preparative uses (FP) 645 [G.E. 77, 651 (1965)]

Formation of ~ on thermal decomposition of *P*-(β-alkoxycarbonylalkyl)-triphenylphosphonium salts (SC) 957 [G.E. 77, 1011 (1965)]

Reacns. with sulfur ~ (CR) 982 [G.E. 77, 1029 (1965)]

Carbonyl-stabilized sulfonium ~ (LA) 999

~ synth. by pyrolysis (LA) 895

ZEATINE, a factor which induces cell division (LA) 99

Zinc, Heterosiloxanes of ~ and cadmium (SC) 876 [G.E. 77, 865 (1965)]

Zinc dialkyldithiophosphates, Thermal decomposition of ~ (CR) 1083 [G.E. 77, 1079 (1965)]

Zinc oxide, Non-stationary processes in the reduction of ~ with hydrogen (CR) 976 [G.E. 77, 1023 (1965)]

Zirconium(IV) compds., Reacn. of triethylaluminum with biscyclopentadienyltitanium(IV) and -~ (CR) 713 [G.E. 77, 738 (1965)]

Zirconium(IV) oxide chloride, Prepn. of anhydrous ~ (LA) 448

Zone electrophoresis in blocks and columns (Book Review) 454

Zone melting, Zonenschmelzen (~) (Book Review) 101
