A tandem reaction ...

... for the construction of β -ester- γ -amino ketones combines a carbene radical, an organoradical, and an ionic Kornblum–DeLaMare reaction into a single catalytic cycle. In their Communication on page 1231 ff., X. Wan and co-workers show that once the cobalt-based carbene radical intermediate has been generated, it can be intercepted with α -aminoalkyl radicals instead of simply adding to an olefin.
