SYNTHESIS AND EVALUATION OF N-SUBSTITUTED 1-(5-FLUORO-2-PYRIMIDINYL)PIPERAZINE DERIVATIVES AS POTENTIAL ANTI-ISCHEMIC AGENTS

Joseph P. Yevich*, Pierre Dextraze, Duncan P. Taylor# and Sandra L. Moon

Bristol-Myers Squibb Pharmaceutical Research Institute 5 Research Parkway, Wallingford, CT 06492-7660

Abstract: A number of N-substituted 1-(5-fluoro-2-pyrimidinyl)piperazine derivatives were prepared and evaluated for binding to sigma and serotonin 5-HT_{1A} and 5-HT₂ receptor subtypes as well as for their protection against nitrogen anoxia-induced lethality in rats. Although various compounds exhibited good binding affinity and/or anti-anoxic effects, there was no obvious correlation between their receptor binding and in vivo effects.

We have previously described BMY-14802 (1, also designated BMS-1811001) and analogs as having affinity for sigma binding sites as well as pharmacological properties suggestive of possible antipsychotic utility^{1,2}. Other studies have corroborated the sigma site interaction of 13 or have shown it to be efficacious in animal models of cerebral ischemia^{4,5,6}. Insofar as 1 acts as a partial agonist at the 5-HT_{1A} serotonin receptor subtype^{7,8,9}, the compound's anti-ischemic activty may be ascribed to either its sigma or 5-HT_{1A} component or both. There is a growing body of evidence which indicates that the sigma "receptor" may modulate excitatory amino acid neurotransmission, especially that mediated via the NMDA receptor^{6,7,10,11,12}; the role of NMDA receptor activation in ischemia and neurodegeneration is well-established by an enormous wealth of published empirical data. Although the importance of serotonergic neurotransmission in the pathophysiology of ischemic events such as stroke and the potential value of serotonergic agents in the treatment of neurodegenerative disorders remain to be elucidated, recent investigations have shown 5-HT_{1A} agonists to be as effective as NMDA antagonists and calcium channel blockers in attenuating ischemia-induced neuronal damage in rodents 13.

In order to determine the effects of structural permutations of the BMY-14802 molecule upon both receptor binding and anti-ischemic activity, we have

prepared a number of compounds of type I. While these agents retain the 1-(5-fluoro-2-pyrimidinyl)piperazine pharmacophore, they bear side chains in which structural elements of 1 have been modified or replaced. Among such modifications relative to the BMY-14802 prototype are changing of the 4-fluorophenyl group to another aromatic, heteroaromatic or aliphatic moiety and/or O-acylation of the carbinol or replacement of CHOH by CH2, O, S or CHNHR. The compounds were synthesized by the different routes depicted in Scheme 1. The key step in the preparation of several carbinol derivatives was α -acylation of γ -butyrolactone to afford intermediates II which underwent ring opening and decarboxylation upon treatment with HCl to give the γ -chloroketones III; the latter were elaborated to the target compounds by one of several alternative pathways as shown. Conversion of the carbinols to the corresponding azides was followed by catalytic reduction to the amines, IV, which were acylated or sulfonylated.

Representative compounds were tested for 5-HT $_2$ as well as for sigma and 5-HT $_{1A}$ binding, employing previously cited methods 6 ; IC $_{50}$ values (drug concentration required to inhibit specific binding by 50%) were determined by measuring displacement of radioligand at 5 different test drug concentrations and are reported in Table 1. Values for BMY-14802 are also presented for comparison. Potential neuroprotective activity was assessed by a test compound's ability to block nitrogen (N $_2$) anoxia induced lethality in male Sprague-Dawley rats. Drugs were administered i.p. 15 minutes prior to a one minute exposure to an atmosphere of 100% nitrogen which causes all non-drug treated controls to expire within 4-5 minutes. Table 1 shows the maximal protection against N $_2$ lethality (number of animals surviving 2 hours after N $_2$ exposure/ number in test group (8 or more) X 100) at the lowest drug dose required to achieve it .

Affinity for both sigma and 5-HT_{1A} binding sites was increased ca. 10 fold as the result of replacing the fluorophenyl ring of 1 by a cyclohexyl ring (compound 2) showing that an aromatic group at the terminus of the side chain is not essential for receptor recognition. Affinities for the 5-HT_{1A} and 5-HT₂ receptor subtypes were significantly enhanced in several analogs in which the carbinol moiety of 1 was replaced by a methylene, ether or thioether (7, 8, 9 respectively). These same modifications appeared to increase recognition at the sigma site as well although sigma binding was totally abolished by the introduction of the sulfone moiety (compound 10). The limited data for compound 11 suggests that the effects of combining two structural changes, each of which singularly imparts increased affinity, may be detrimental. O-acetylation of BMY-14802 (5) resulted in contrasting effects, i.e. a two fold drop in sigma binding but increased 5-HT receptor binding whereas both sigma and 5-HT_{1A} binding were

negatively impacted by the bulkier O-benzoyl group (6). In general, the introduction of an N-acetylated or sulfonylated amino functionality caused a marked attenuation in receptor recognition. Within this series of compounds, there is poor correlation between in vitro sigma and/or 5-HT_{1A} binding and in vivo protection against nitrogen lethality. While compounds 2 and 12 which had the highest in vivo potency and efficacy, exhibited good to moderate sigma and 5-HT_{1A} binding, several congeners that bound well at both sites (e.g. 8, 9) showed rather weak in vivo activity. In contrast the benzamide 14 and sulfonamide 15 exhibited very effective anti-anoxic activity despite the fact that both lack sigma site affinity and 15 is also a poor ligand at the 5-HT receptor subtypes. These ambiguous findings raise some doubt as to whether the sigma or 5-HT_{1A} components of BMY-14802 are relevant to its anti-ischemic properties. There are however caveats; although the nitrogen-induced lethality test may be useful as a rapid through-put screen, it may not be a reliable predictor of activity in more stringent in vivo paradigms such as middle cerebral artery occlusion. Moreover, efforts to correlate in vitro data with whole animal test results are often complicated by pharmacokinetic and metabolic parameters. The generally weak 5-HT₂ binding of the compounds in this series suggests that interaction at the 5-HT₂ receptor is not responsible for their in vivo pharmacological effects.

In summary, it was found that both the sigma and 5-HT_{1A} receptors were tolerant toward a number of structural variations in the side chain of the lead compound, BMY-14802. While both the in vitro receptor binding affinities and the in vivo anti-anoxic effects of the latter were surpassed by those exhibited by other (5-fluoro-2-pyrimidinyl)piperazine derivatives, no nexus was clearly established between the in vitro and in vivo activities of these compounds.
