Abstract: B-Nor-4-aza- 5α -androstane derivative 1 was synthesized. The compound 1 showed potent inhibition activity against testosterone 5α -reductase.

Testosterone 5α -reductase plays an important role in the pathology of benign prostatic hypertrophy. It converts testosterone in the prostate to 5α -dihydrotestosterone, whose accumulation is known to cause hypertrophy of the prostate.¹⁾

A series of 4-azasteroid compounds have already been synthesized, and they were found to have 5α -reductase inhibition activity.²⁾ Among them, N-(1,1-dimethylethyl)-3-oxo-4-aza- 5α -androst-1-ene- 17β -carboxamide, MK-906, was recently launched as a drug for benign prostatic hypertrophy. These compounds have a nitrogen at the C-4 position and a backbone structure similar to that of testosterone. In relation to the structure-activity relationship we were interested in modifying the backbone structure, in particular the B-ring. Namely, we focussed attention on synthesizing a B-nor-4-aza- 5α -androstane derivative. The conformation of B-nor-4-aza- 5α -androstane, having a five-membered B ring, is not much different from that of 4-aza- 5α -androstane based on molecular model inspection. In addition, we have already disclosed that the 4-azaandrostane derivative 2, having a 17-benzhydrylcarbamoyl moiety, has highly potent inhibition activity against testosterone 5α -reductase.³⁾ Therefore, the B-nor-4-aza- 5α -androstane derivative 1 with a benzhydrylcarbamoyl moiety at the C-17 position was selected as a target compound. In this report we describe a synthesis of 1 and its 5α -reductase inhibition activity.

The compound 1 was synthesized from 3 by the route described below. First we selected secodicarboxylic acid 12, having a B-nor structure, as a key intermediate. The B-nor structure was constructed according to a method similar to that described by Morisawa et al..⁴⁾ Ester 3^{2a} derived from Pregnenolone was acetylated to provide 4, which was oxidized with ozone to give 5 (81% from 3). Aldehyde 5 was cyclized to 6 with basic alumina, which was oxidized to yield carboxylic acid 7 (75% from 5). Heating 7 with acetic anhydride and triacetin under reflux afforded 8 (66%), via a formation of β -lactone, followed by elimination of carbon dioxide. Deacetylation of 8 afforded ester 9. Oxidation of 9 by the Oppenauer method, followed by hydrolysis gave enone 11 (80% from 8). In order to introduce the 4-aza function, dicarboxylic acid 12 was synthesized. Oxidative cleavage of 11 with NaIO₄ and KMnO₄ in aqueous *tert*-butyl alcohol afforded 12 (28 %).

Next, the cyclization of dicarboxylic acid 12 to 13 was attempted. Upon heating 12 with ammonia, as is described for the synthesis of MK 906, the desired enamido compound 13 was not obtained. Therefore, we investigated preparing the saturated compound 14a directly from 12. Following the Leuckart method, heating 12 with formamide and formic acid, a cyclization occurred, to give B-nor-4-azaandrostane compound 14b (39%). But the compound 14b had undesired 5β-H configuration. This was determined by the presence of Nuclear Overhauser Effect (NOE) between the hydrogen at the C-5 position and the methyl group at the C-19 position.

Then, after introducing a nitrogen function onto the B-ring of compound 16, formation of the A-ring was accomplished. Dicarboxylic acid 12 was esterified to provide 16. Diester 16 was reduced by NaBH₄ in aqueous EtOH, to yield the desired α -alcohol 17a containing lactone 18a together with β -alcohol 17b (major product).⁵⁾ A mixture of compounds 17a and 18a was converted, on treatment with p-TsOH, to a single product 18a⁶⁾ (4% from 16). In order to prepare the 5 β -azide 26, lactone 18a was reduced with LiAlH₄ to triol 19a. Selective silylation of the primary hydroxy group in 19a gave 20a⁷⁾ (53% from 18a). The α -alcohol 20a was mesylated to afford 22. Treatment of 22 with NaN₃ afforded an azide 23 (19%) with the desired β -configuration at the C-5 position. Desilylation and oxidation of 23 gave dicarboxylic acid 25 (82%). Esterification of 25 gave diester 26 and reduction of 26 afforded directly a B-nor-4-aza-5 α -androstane compound 27 (59% from 25).

Finally, the 17-carbamoyl function was introduced. Treatment of 27 with BCl_3 yielded carboxylic acid 28.8) Amidation of 28 with DEPC and benzhydrylamine gave B-nor-4-aza-5 α -androstane derivative 1 (30% from 27).

The *in vitro* inhibition of rat 5α-reductase was determined by using the standard method.⁹⁾ The compound 1 had a 63% inhibition rate at 10⁻⁸M concentration. It was more potent than MK-906 (28% inhibition).

In conclusion, the compound 1, which has a new B-nor-4-aza- 5α -androstane structure, was synthesized, and it showed fairly potent inhibition activity against 5α -reductase.

Scheme 1

Reagents : (a) Ac₂O, pyridine, r.t. \rightarrow 70°C; (b) O₃, CH₂Cl₂-MeOH, -78°C then Zn, AcOH; (c) alumina (grade 3), benzene, r.t.; (d) Jones reagent, acetone, 0°C; (e) Ac₂O, triacetin, reflux; (f) K₂CO₃, MeOH, 60°C; (g) Al(i-PrO)₃, cyclohexanone, toluene, reflux; (h) KOH, MeOH-H₂O, reflux; (i) KMnO₄, NalO₄, Na₂CO₃, t-BuOH-H₂O, reflux; (j) formamide, formic acid, 180°C; (k) CH₂N₂, EtOAc, r.t.; (l) NaBH₄, EtOH-H₂O, r.t.
