Hongo, Bunkyo-ku, Tokyo 113  
(Received March 23, 1987)

Highly active Mo catalysts for mixed alcohol synthesis were prepared using Fuji Davison ID silica gel as a carrier. KCl promoted the selectivity to alcohols but reduced CO conversions in particular to hydrocarbons. Productivity of alcohols was largely affected by the reaction conditions. High pressure and short contact time enhanced space-time yield of alcohols, i.e. 420 g (kg-catalyst)<sup>-1</sup> h<sup>-1</sup> at 5.0 MPa, 573 K, and W/F=1.4 g-catalyst h mol<sup>-1</sup>. The presence of K effectively prevented the complete reduction of Mo to metal, resulting in the increase in the production of alcohols. The study on addition of ethene and ethanol to synthesis gas revealed that the other roles of K are to retard dehydration of alcohols to alkenes and their hydrogenation to alkanes.

The development of a selective catalyst for co-production of methanol and C<sub>2</sub>+ higher alcohols remains as one of the main goals of C<sub>1</sub> chemistry. The principal use of the alcohol mixtures is for blending in automotive fuel to meet the octane requirement raised by the global trend to lead phase-down. Blending methanol with gasoline requires the addition of cosolvent to mitigate the problems due to phase separation and high volatility. The C<sub>2</sub>+ higher alcohols have proved effective as cosolvent.

It is well-known that appropriate modifications of the methanol synthesis catalyst and also of the reaction conditions result in the production of higher alcohols together with methanol.<sup>1,2)</sup> The conventional Fischer-Tropsch catalysts based on iron, ruthenium, and cobalt have been also reported to give long chain alcohols. Institut Francias du Petrole patented catalysts for the synthesis of mixed alcohols, consisting of methanol synthesis catalysts (Cu) and Fischer-Tropsch catalysts (Co).<sup>3)</sup>

Molybdenum catalysts have long been recognized as being effective for the Fischer-Tropsch synthesis of light hydrocarbons.<sup>4,5)</sup> In our previous study, however, the supported molybdenum catalysts were found to be active in the synthesis of mixed alcohols, which was significantly influenced by support and additive.<sup>6)</sup> Moreover, the successive impregnation method, in which addition of K to silica gel was followed by impregnation with molybdenum solution, was found to give higher activity and selectivity for alcohol formation.<sup>7)</sup> Dow and Union Carbide have claimed a number of patents of the catalysts based on MoS<sub>2</sub>, promoted by CoS and alkali metal salts for higher alcohol synthesis.<sup>8–10)</sup>

Here we report the improved design of catalyst and reaction conditions for the production of mixed alcohols. High activity and selectivity for alcohols were attained on the KCl-promoted, ID silica-gel-supported Mo catalyst at high pressure and short contact time; alcohol yield exceeded 420 g (kg-catalyst)<sup>-1</sup> h<sup>-1</sup> with 68 C-atom% selectivity.

### Experimental

Catalysts were prepared by impregnating various silica gels (Fuji Davison ID, RD, and B) with an aqueous solution of KCl first, followed by air calcination at 673 K for 1 h and impregnation with (NH<sub>4</sub>)<sub>6</sub>Mo<sub>7</sub>O<sub>24</sub> solution. The Mo metal loading was 10 and 20 wt% and the K/Mo ratio was varied in the range of 0–0.4. The impregnates were dried overnight at 393 K and treated in the He stream at 673 K for 1 h and then reduced by H<sub>2</sub> 773 K for 12 h.

The synthesis reaction was carried out in a flow reactor made of stainless steel tube with 0.6 cm inside diameter, containing 1.0 g catalyst. The synthesis gas (H<sub>2</sub>/CO=1) was supplied to the reactor through the stainless-steel tube heated at 473 K for decomposition of carbonyl impurities. Hydrogen was purified to remove oxygen by passage through a DEOXO unit (Engelhard), followed by a molecular sieve trap. Activity and selectivity of the catalyst were observed over a reaction period of 50–130 h until their steady states were attained. Products were analyzed by gas chromatographs. Concentrations of CO, CO<sub>2</sub>, and CH<sub>4</sub> in the off-gas were determined by a TCD gas chromatograph with an active carbon separation column at 323 K using H<sub>2</sub> as a carrier gas. The organic compounds were analyzed by an FID gas chromatograph with the following separation column using N<sub>2</sub> as a carrier gas; 2 m Porapak Q for C<sub>1</sub>–C<sub>5</sub> hydrocarbons, 2 m polyethylene glycol 1500 for oxygenates, 2 m Silicone SE-30 for C<sub>6</sub>+ hydrocarbons, and 8 m VZ-7 for isomers of C<sub>3</sub>, C<sub>4</sub>, and C<sub>5</sub>.

The catalytic surface areas of reduced Mo catalysts were measured by O<sub>2</sub> adsorption at 195 K. X-Ray powder diffraction measurements were performed using a Rigaku Denki diffractometer RU-200A with Cu K $\alpha$  radiation.

### Results and Discussion

As previously reported, excellent activity for alcohol synthesis activity was obtained by the use of KCl as a promoter in preparing silica-supported Mo catalysts. Three kinds of silica gel were investigated as a carrier for Mo-KCl catalyst and the results are summarized in Table 1. With all of the catalysts, both alcohol selectivity and CO conversion gradually increased with time on stream and therefore the data were

obtained after 50–130 h on stream when the catalytic activity reached the nearly steady state. As is expected from the shift activity of the molybdenum catalysts,<sup>4,5)</sup> these catalysts yielded CO<sub>2</sub>, instead of water, almost exclusively. Hence the product selectivities (carbon atom%) in this work are given on a CO<sub>2</sub>-free basis. Alcohol synthesis activity is represented by space-time yield of alcohols, STY, which stands for the total weight of alcohols produced per unit weight of catalyst per unit time on stream.

The alcohol formation activity over the KCl-promoted silica-supported Mo catalysts increased in the following order; B<RD<ID. Apparent average oxidation number, estimated from O<sub>2</sub> consumption from 195 to 773 K, increased in the order; B<RD<ID. This sequence conforms to the order of alcohol formation activity. This suggests that Mo species with a relatively high oxidation state participates in the key step of alcohol formation.

Alcohols/hydrocarbons ratio in space-time yield increased in the order; RD<B<ID. This order is in accordance with the sequence of pore diameter of support. The silica-supported Mo catalysts have moderate activity for alcohol dehydration as described

below. Therefore, if the pores are smaller, product alcohols would have more chance to be readsorbed and dehydrated to hydrocarbons before leaving the catalysts. RD-silica-supported catalyst gave the highest C<sub>2</sub>+ alcohol/methanol ratio. The C<sub>2</sub>+ hydrocarbons/methane ratio was in the same order but less dependent on the kind of silica gel than C<sub>2</sub>+ alcohols/methanol ratio.

Total activities increased in the order; B<ID<RD. This order is not consistent with the order of O<sub>2</sub> uptake.<sup>11)</sup> Na<sub>2</sub>O impurity (0.25 wt%) in B-silica gel might have the effect of poison on CO hydrogenation activity.<sup>1)</sup> ID-silica-supported Mo catalysts were employed for further investigation.

Table 2 shows the influence of Mo loading on the activity for alcohol synthesis, with the K/Mo ratio kept constant at 0.4. The selectivity for alcohols increased with increasing Mo loading. The C<sub>2</sub>+ alcohols/methanol ratio and the olefin content also increased. Total activities, however, increased in the order: 5% Mo<20% Mo<10% Mo. In view of the effect of K content on catalyst performance as is described below, this change in activity and selectivity could be accounted for by the K content proportional to the Mo content.

The influence of K content on activities of 20 wt% Mo catalysts is shown in Fig. 1. The addition of KCl reduced CO conversion and also hydrocarbon yield in particular. The selectivity for alcohols increased with KCl content and reached 70 C-atom% at K/Mo=0.4. The yield of alcohols, however, reached a maximum at K/Mo=0.2. With the increase in K/Mo ratio the C<sub>2</sub>+ alcohols/methanol ratio largely increased. It

a) Reaction conditions; 573 K, 1.6 MPa, W/F=10 g-catalyst h mol<sup>-1</sup>.

should be noted that  $C_2+$  hydrocarbons/methane ratio remained almost unchanged.

Table 3 represents the  $O_2$  uptakes for the 20 wt% Mo catalysts. Without KCl addition,  $O_2$  uptake for the fresh (reduced) Mo catalyst amounted to  $532 \mu\text{mol g}^{-1}$ .  $O_2$  uptake was significantly reduced by addition of KCl and was at virtually constant level beyond  $K/Mo \geq 0.2$ . The decrease in CO conversion by addition of K should be partly due to the decrease in  $O_2$  uptake. Concha and Bartholomew reported a linear correlation between CO hydrogenation activity and  $O_2$  uptake for unsupported  $MoS_2$ .<sup>13</sup>

Figure 2 shows X-ray diffractograms of reduced Mo (20 wt%) catalysts with K/Mo ratio changed. Lines corresponding to metallic Mo and  $MoO_2$  appeared on all the catalyst. With increase in K/Mo ratio, the intensity of  $MoO_2$  lines increased at the expense of metallic Mo.<sup>12</sup> The productivity of alcohols is supposed to depend significantly upon the oxidation state of Mo;  $MoO_2$ -like species are responsible for alcohol synthesis while metallic Mo is associated with

carbon chain growth and hydrocarbon formation.<sup>13</sup> Thus the presence of K could retard the reduction of Mo, resulting in increase in the production of alcohols.

The influence of the time factor (W/F) on CO conversion, the yields of alcohols and hydrocarbons, the selectivity to alcohols and  $C_2+$  alcohols/methanol ratio over  $Mo(20 \text{ wt}\%) + KCl(K=1.63 \text{ wt}\%)/SiO_2(ID)$  at 573 K and 1.6 MPa are illustrated in Figs. 3 and 4.

Fig. 1. Effect of K content (K/Mo ratio) on space-time yields of alcohols (○) and hydrocarbons (●), and  $C_2+OH/CH_3OH$  ratio (△) over  $Mo(20 \text{ wt}\%) + KCl/SiO_2(ID)$  at  $W/F=10 \text{ g-catalyst h mol}^{-1}$ , 573 K, and 1.6 MPa.

Fig. 2. X-Ray diffractograms of reduced Mo catalysts with K/Mo ratio changed.

Fig. 3. Effect of time factor on CO conversion (▲) and space-time yields of alcohols (○) and hydrocarbons (●) over  $Mo(20 \text{ wt}\%) + KCl(K=1.63 \text{ wt}\%)/SiO_2(ID)$  catalyst at 573 K and 1.6 MPa.

Short contact time enhanced the selectivity for alcohols. The CO conversion vs. W/F plot displayed a convex curvature, which might suggest that the rate of intrinsic surface reaction is not the rate controlling step. At short contact time, the selectivity for alcohols was markedly improved. C<sub>2</sub>+ alcohols/methanol ratio was independent of the time factor, ruling out the significant contribution of alcohol homologation, e.g., methanol conversion to ethanol. The alcohol yield tended to be more influenced by W/F with lower K/Mo ratios, indicating that there is a route from alcohols to hydrocarbons promoted by acid sites of the catalysts.

The influence of the addition of ethanol and ethene to CO-H<sub>2</sub> feedstock was investigated on unpromoted and KCl-promoted Mo catalysts. Pertinent data are given in Table 4. Over the unpromoted catalyst, added ethanol momentarily converted to ethene and ethane. This alcohol dehydration activity of Mo/SiO<sub>2</sub> indicates that Mo/SiO<sub>2</sub> has significant acidity, in agreement with the observation by Maruyama et al.<sup>10</sup>

Fig. 4. Effect of time factor on alcohol selectivity (O) and C<sub>2</sub>+alcohols/methanol ratio (Δ) over Mo(20 wt%)+KCl(K=1.63 wt%)/SiO<sub>2</sub>(ID) catalyst at 573 K and 1.6 MPa.

| 1.63               | 12                                                                                                                | 105                                                                                                   |

a) Increase in ethene and/or ethane on addition of ethanol and ethene to synthesis gas. b) Reaction conditions; 523 K, 1.6 MPa, W/F=10 g-catalyst h mol<sup>-1</sup> C<sub>2</sub>H<sub>5</sub>OH=1.0 mol(kg-catalyst)<sup>-1</sup>h<sup>-1</sup>. c) Reaction conditions; 473 K, 1.6 MPa, W/F=10 g-catalyst h mol<sup>-1</sup>, C<sub>2</sub>H<sub>4</sub>=1.3 mol(kg-catalyst)<sup>-1</sup> h<sup>-1</sup>.

The addition of KCl led to the considerable decrease in ethene and ethane. This is supposed to be due to the K-induced decrease in acidity. It can be seen in Table 4 that addition of KCl to Mo/SiO<sub>2</sub>(ID) remarkably suppressed the ethene conversion rate to ethane. Thus the additional role of K in improving alcohol selectivity is to retard dehydration of alcohol to alkenes and to slow hydrogenation of the alkenes to alkanes.

The yield of alcohols was considerably influenced by raising the total pressure. The effect of total pressure on the product distribution over Mo(20 wt%)+KCl(K=1.63 wt%)/SiO<sub>2</sub>(ID) at 573 K and W/F=1.4 g-catalyst h mol<sup>-1</sup> was indicated in Fig. 5 and Table 5. Raising the pressure, the yield of alcohols was greatly improved. The C<sub>2</sub>+C<sub>1</sub> ratios of hydrocarbons and alcohols were independent of the pressure. It should be noted that at 5.0 MPa STY of alcohols as large as 420 g(kg-catalyst)<sup>-1</sup> h<sup>-1</sup> was obtained in 68 C-atom% selectivity. This STY is comparable with those reported so far with Cu-Co based catalyst<sup>15)</sup> and MoS<sub>2</sub>-Co-K<sub>2</sub>CO<sub>3</sub> catalyst.<sup>11)</sup> At 6.5 MPa the selectivity for alcohol formation was deteriorated, while the yield of hydrocarbons was greatly increased. This would also result from the successive reaction of alcohols to hydrocarbons owing to the increase in the contact time under the high pressure. Xie et al. recently claimed that alcohol

Fig. 5. Effect of total pressure on product distribution over Mo(20 wt%)+KCl(K=1.63 wt%)/SiO<sub>2</sub>(ID) catalyst at W/F=1.4 g-catalyst h mol<sup>-1</sup> and 573 K.

a) Reaction conditions; see footnote in Fig. 6.

yields were very sensitive to total pressure over MoS<sub>2</sub> based catalysts.<sup>16)</sup>

Figure 6 and Table 6 show the effect of reaction temperature on the product distribution over Mo(10 wt%)+KCl(K=1.63 wt%)/SiO<sub>2</sub>(ID) at 1.6 MPa and W/F=10 g-catalyst h mol<sup>-1</sup>. With the decrease in temperature, the selectivity to alcohols was greatly

improved. At 513 K, 76 C-atom% of the alcohol selectivity was obtained. A maximum yield of alcohols was attained at 573 K. At temperatures above 573 K, the yield of alcohols was decreased while that of hydrocarbons was strongly promoted. C<sub>2</sub>+ alcohols/methanol ratio gradually increased with the increase in temperature.

In the Mo catalyst system, water, the primary product, is rapidly converted to CO<sub>2</sub>. This makes the alcohol separation simple and less energy consuming as there is no problem due to azeotrope formation.<sup>17)</sup> Moreover, it is feasible to utilize a synthesis gas with a low H<sub>2</sub>/CO ratio produced from coal gasifiers without a separate shift converter.<sup>18)</sup>
