**Synopsis.** The  $\text{OH}(^2\Sigma)$  emissions from shock-heated mixtures of  $\text{C}_2\text{H}_2/\text{O}_2$ ,  $\text{C}_2\text{H}_2/\text{C}_2\text{H}_6/\text{O}_2$ , and  $\text{C}_2\text{H}_6/\text{O}_2$  diluted in Ar were observed and the mixture dependences of the emissions were obtained.  $\text{OH}(^2\Sigma)$  production, depending on the test gas mixture, could be in accordance with the view-point that the two oxidations of  $\text{C}_2\text{H}_2$  and  $\text{C}_2\text{H}_6$  progress by influencing each other.

The reaction on  $\text{OH}(^2\Sigma)$ , hereafter abbreviated as  $\text{OH}^*$ , at high temperatures (above 1000 K) has been studied for many reaction systems using shock-tube techniques.<sup>1,2</sup> As for  $\text{OH}^*$  in hydrocarbon oxidation, only single hydrocarbon/ $\text{O}_2$  systems, excepting multi-hydrocarbon/ $\text{O}_2$  systems, have been investigated.<sup>3</sup>

The temperature reached by hydrocarbon combustion is high due to their large exothermicity. The hydrocarbons used for fuels therefore decay to smaller species, thermally, as well as by oxidation processes. Acetylene is one of the primary products given by such thermal decay. Thus, at high temperatures acetylene could be present from the beginning of combustion; hydrocarbon combustion seems to proceed by self decay, as mentioned above, influenced by acetylene combustion.

We paid attention to the  $\text{OH}^*$  produced in a  $\text{C}_2\text{H}_2+\text{C}_2\text{H}_6$  systems, studying it in comparison with those in the  $\text{C}_2\text{H}_2$  and  $\text{C}_2\text{H}_6$  systems. The time parameters and intensities of  $\text{OH}^*$  emission were investigated in relation to the test gas compositions

used. The production of  $\text{OH}^*$  could be understood by considering that the two oxidations of  $\text{C}_2\text{H}_2$  and  $\text{C}_2\text{H}_6$  progress by influencing each other.

### Experimental

The rectangular shock tube used in the present study for incident shock waves was detailed in previous papers.<sup>3,4</sup>

$\text{OH}^*$  emission at 306.4 nm was observed using a monochromator (Jarrell-Ash, JE-25) and a photomultiplier (Hamamatsu, R-208). The output signal of the photomultiplier was fed into an operational amplifier and then recorded on a digital-oscilloscope (Iwatsu, DS-6121).

The purities of the element gases used for the test gas were;  $\text{C}_2\text{H}_2$ , 99.5% pure;  $\text{C}_2\text{H}_6$ , 99.3% pure;  $\text{O}_2$ , 99.999% pure; and Ar, 99.999% pure. The compositions of the test gas mixture are shown in the footnote of Fig. 1.

### Results and Discussion

The obtained oscillograms show that after shock arrival at the observation window of the shock tube,  $\text{OH}^*$  emission can not be observed for a reaction period (induction time), but increases abruptly to a maximum value and finally decays. Although the time profile and intensity of  $\text{OH}^*$  emission changes depending on the temperature and the test gas mixture examined (as shown below), such profiles of  $\text{OH}^*$  emission are common for the three mixtures, as well as for other hydrocarbons.<sup>1,3</sup>

We evaluated three parameters from these oscillograms: (1) induction time( $\tau$ ),<sup>3</sup> (2) reaction time at which the emission intensity reaches a maximum ( $t_m$ ), (3) the maximum emission intensity ( $I_m$ ).<sup>3</sup> The time parameters,  $\tau$  and  $t_m$ , were evaluated on the laboratory time base. The  $I_m$  values are proportional to  $[\text{OH}^*]$ .

Figure 1 shows the relation between  $\tau$  and  $10^4/T$ . Except for high temperatures (around 2000 K), the dependence of  $\tau$  on the test gas mixture was found to be  $\tau(\text{C}_2\text{H}_6) > \tau(\text{C}_2\text{H}_2+\text{C}_2\text{H}_6) > \tau(\text{C}_2\text{H}_2)$ , where the species in parenthesis identifies the hydrocarbons contained in the test gas mixtures used. Such a mixture dependence on  $\tau$  is in accord with the experimental results reported for both  $\text{C}_2\text{H}_2$  and  $\text{CH}_4$  oxidation:<sup>3,5</sup> that  $\tau(\text{CH}_4) > \tau(\text{C}_2\text{H}_2+\text{CH}_4) > \tau(\text{C}_2\text{H}_2)$ . Since  $\text{C}_2\text{H}_2$  and  $\text{CH}_4$  oxidation was confirmed to progress by influencing each other in a  $\text{C}_2\text{H}_2+\text{CH}_4$  mixture,<sup>5</sup> in a  $\text{C}_2\text{H}_2+\text{C}_2\text{H}_6$  mixture the  $\text{C}_2\text{H}_2$  and  $\text{C}_2\text{H}_6$  oxidation are also expected to proceed similarly and to affect the production of  $\text{OH}^*$ .

It should be pointed out here that the values of  $\tau$  evaluated at high temperatures are not accurate as those evaluated at lower temperatures, since  $\tau$  at high temperatures becomes small and is hard to estimate from each oscillogram with sufficient precision. In contrast to such a time parameter as  $\tau$ , both the  $t_m$  and

Symbols used are;  $\square$ :  $\text{C}_2\text{H}_2/\text{O}_2/\text{Ar}=1/2.5/96.5$ ,  $\circ$ :  $\text{C}_2\text{H}_2/\text{C}_2\text{H}_6/\text{O}_2/\text{Ar}=1/1/6/92$ ,  $\triangle$ :  $\text{C}_2\text{H}_6/\text{O}_2/\text{Ar}=1/3.5/95.5$ . Lines through each data point show least squares fit.

Fig. 2. Reaction times,  $t_m$ , vs.  $10^4/T$ . Symbols used are the same as those in Fig. 1.

$I_m$  values could be evaluated precisely even at high temperature.

Figure 2 shows the relation between  $t_m$  and  $10^4/T$ . The difference of the  $t_m$  values between the three mixtures is not so clear and, thus, the influential relation between  $C_2H_2$  and  $C_2H_6$  oxidation to produce  $OH^*$  seems to proceed much more.

Figure 3 shows the relation between  $I_m$  vs.  $10^4/T$ . In accordance with the former experimental results regarding  $I_m$  for  $C_2H_2$  and  $CH_4$  oxidation,<sup>3)</sup> that  $I_m(C_2H_2) > I_m(CH_4)$ , the mixture dependence  $I_m(C_2H_2) > I_m(C_2H_6)$  can be seen. If  $C_2H_2$  and  $C_2H_6$  oxidation could progress independently in a  $C_2H_2 + C_2H_6$  mixture, the relation  $I_m(C_2H_2 + C_2H_6) \approx I_m(C_2H_2) + I_m(C_2H_6)$  would be expected, since  $t_m$  is almost same for all three mixtures. The result is that the  $I_m(C_2H_2 + C_2H_6)$  values lie between those in the other two mixtures.

Taking into account the temperature dependences of the time parameters,  $\tau$  and  $t_m$ , and the  $I_m$  values, the production of  $OH^*$  can be seen to proceed rapidly and violently at high temperature. Such results may support the viewpoint that the difference in the heat of combustion between the two oxidations affects the production of  $OH^*$  much more than does the difference of the generated radicals between them. As for the reaction temperature in the  $C_2H_2 + C_2H_6$  mixture, it must reach the highest value among the three mixtures, and the observed  $I_m$  values in the mixture could be largest. The result shown in Fig. 3 does not seem to be in accord with these hypotheses. Therefore, it can be concluded that in  $OH^*$  production the two oxidations of  $C_2H_2$  and  $C_2H_6$  in the  $C_2H_2 + C_2H_6$  mixture proceed with any influence other than the thermal effect.<sup>5)</sup> Such influences could arise due to chemical coupling of the generated radicals in each oxidation.

It is also informative regarding the existence of chemical coupling that the time variation of  $OH^*$

emission is also very smooth in a test gas mixture of  $C_2H_2 + C_2H_6$ . If  $C_2H_2$  and  $C_2H_6$  oxidation could proceed independently, two peaks of maximum emission, attributed to the two oxidations, should appear.

Although the producing step of  $OH^*$  in hydrocarbon oxidation is still controversial, the fate of  $OH^*$  is mentioned here briefly. If  $OH^*$  is produced by the process  $CH + O_2 = OH^* + CO$ , as proposed by Gaydon,<sup>6)</sup> the  $I_m$  values should be proportional to the concentration product of  $[CH][O_2]$ .<sup>1,3)</sup> It was, however, found that the  $I_m$  does not increase simply with increasing  $[O_2]$  in the mixture used. We can thus say that the producing step of  $OH^*$  depends greatly on the value of  $[CH]$ .

Shock tube studies concerning the production of  $OH^*$  in other hydrocarbon mixtures are in progress and the results may appear elsewhere.

The present author wishes to thank Professor Kihei Morinaga, National Defense Academy, for many helpful discussions and also the reviewer for a comment on the  $OH^*$  production in the present reaction system.
