Each 2 ml. of reagent and metal solution (both 10^{-3} M) was pipetted into a separatory funnel having the mark of 20 ml., in which had been contained approximately 15 ml. of the buffer solution having the desired pH and was then diluted to the mark with water. Red or reddish orange precipitate was immediately formed by mixing. After standing for 20 min. or more to digest the precipitate, 10.0 ml. of freshly distilled chloroform was added, and the vessel was vigorously shaken for 2 min. or more. The extraction seemed to be complete, when the lower chloroform layer colored, but the aqueous layer became completely colorless. The organic extract was then transferred into a little Erlenmayer flask containing about 1 g. of anhydrous sodium sulfate. Absorbance was measured for the dried chloroform solution over a range of 300~600 mμ using chloroform as a reference solvent. The pH was measured for the aqueous phase which remained after extraction. Spectra are shown in Fig. 3, and the wavelength of maximum absorption is also listed in Table II. Quite similar experiments were made for the reagent solution, and the results are also shown in Fig. 3 and Table II. In the following experiments, all the extraction procedures are followed as above, unless otherwise indicated. It is seen that a specific absorption band for each chelate appears in the visible region at which the reagent does not show appreciable absorbance.

1-Hydroxyacridine	341	358		386	
Copper chelate	353	358		368	502
Cobalt chelate	341	358		388	480
Nickel chelate	340	350		357	468
Zinc chelate	341	350	358	389	478

Effect of pH on Extraction.—To obtain optimum range of pH for the extraction of each element and reagent, the absorbance was measured for the organic extract from aqueous solution, the pH values of which had been adjusted to various values with respective buffer. The pH measurements were made for the aqueous phase after extraction and the absorbance was measured at wavelength of the respective peak of the metal chelate.

The results are shown in Fig. 4. The pH range of optimum extraction for the four metals is somewhat narrow, as compared with the metal chelate of oxine reported by several workers[9], contrary to the expectation. In order to obtain higher selectivity in a solvent extraction using chelate reagents, various masking reagents are extensively used. The effects of some complexing agents as cyanide, ethylenediaminetetraacetic acid and tartaric acid

④ Cobalt chelate
⑤ Zinc chelate

were thus investigated. It was found that these complexing agents inhibit the reaction of all metals with 1-hydroxyacridine. When a complexing agent is present in the concentration of 10^{-1} M, the precipitate does not form and the organic extract also does not show appreciable absorbance in the visible region.

Stability of the Metal Chelates.—The effects of time of standing were investigated for the organic extracts of the metal chelates. Standing the dried extract in the transmission cell with a stopper, the absorbance was measured at several intervals. Results are shown in Table III. The result is that the absorbance decreases slightly during the initial several minutes and then remains almost constant during 60~180 min. But when the solution was kept for 1 day, the absorbance had considerably decreased.

TABLE III. EFFECT OF STANDING TO ABSORBANCE

Time min.	Copper 502 mμ	Nickel 468 mμ	Cobalt 480 mμ	Zinc 478 mμ
0	0.554	0.448	0.330	0.305

1 day	.280	.231	.140	.102

Per Cent Extracted.—The per cent extracted at optimum pH in Fig. 4 was determined for the four elements. For zinc and cobalt, radioactive isotope was used as tracer, and for the other two, the amount of metal ion in aqueous or organic layer was determined by spectrophotometric method using sensitive organic reagents. The procedures are as follows and the results are listed in Table IV.

TABLE IV. PER CENT EXTRACTED

Element	%	pH
Copper	99.71	8.7
Cobalt	99.19	11.7
Nickel	99.10	9.1
Zinc	99.93	11.7

Copper.—Ten milliliters of cupric solution (10^{-3} M) and 5 ml. of the reagent solution (10^{-2} M) were pipetted into a 100 ml. volumetric flask. The solution was then diluted to the mark with the buffer solution. After standing, the red precipitate was extracted with 50 ml. of freshly distilled chloroform. The remaining aqueous solution was then evaporated to about 5 ml. on a sand bath. After cooling, the pH was readjusted to 5.5 with hydrochloric acid and about 1 g. of hydroxylamine hydrochloride was added in order to reduce cupric ion to cuprous. The cuprous ion was then extracted with 10.0 ml. of amyl alcohol containg 0.01% of cuproine[7]. The absorbance was measured at 540 mμ for the reddish violet organic extract. For the standard cupric solution (10^{-5} M), the same extraction procedure with amyl alcohol containing cuproine was done after reduction, and the absorbance was obtained similarly. The per cent of extraction was calculated from the two absorbance values.

Nickel.—The extraction was done under the same condition, except pH, as described above. The organic extract was destroyed by adding proper amount of concentrated perchloric acid and heating to fumes. After destroying organic matter completely, the solution was evaporated to dryness. The residue was dissolved and diluted with water and the amount of nickel ion was determined by dimethylglyoxime following the method described by Sandell[8].

8) E. B. Sandell, "Colorimetric Determination of Traces of Metals", Interscience Publishers, New York (1950), p. 470.

Cobalt.—Two milliliters cobalt (10^{-3} M), 1.0 ml. of the reagent (10^{-2} M) and 1.0 ml. of Co^{60} (carrier free) solution were taken and, after adjusting the pH and diluting to 20 ml., cobalt chelate was extracted as above. A 2.0 ml. of aqueous layer was then pipetted out into a small stainless dish. The solution was evaporated completely to dryness and the counts were determined using Geiger Counter. The per cent extraction was obtained by comparing the counts with that of the standard which was determined similary before extraction.

Zinc.—Zn^{65} was used as tracer. The method of determination for the per cent extracted was quite similar to that for cobalt.

It was found that per cent extracted is more than 99% in all cases under the optimum pH.

Summary

The absorption spectra of 1-hydroxyacridine were obtained both in aqueous and chloroform solution, and the pK_a and the pK_b were determined. The pK_a is slightly greater than that of oxine, and it is suggested that the stability of metal chelate with 1-hydroxyacridine will have values of the same or larger order as that of oxine chelate, because there is a direct relation between the basicity of a chelating agent, as measured pK_a values, and the stability of the chelates it forms, as cited in the literature of Morrison and Friser[9].

The various aspects of solvent extraction using chloroform were then investigated. The optimum pH range on extraction for each element was determined and it was found that the range is narrow as compared with that of the oxine chelate. The per cent extracted was determined and it was found that copper, nickel, cobalt and zinc were almost completely extracted under the conditions investigated.

The authors thank the Ministry of Eduction for the financial support granted for this research.

Enzymic Preparation of Guanosine-2′, 3′-cyclic Phosphate, Inosine-2′, 3′-cyclic Phosphate and Xanthosine-2′, 3′-cyclic Phosphate

By Kimiko SATO-ASANO, Yoshiko FUJII and Fujio EGAMI

(Received February 14, 1959)

Our previous studies have shown that ribonuclease T_1(RNase T_1) in Takadiastase hydrolyzes the secondary phosphate ester bonds of guanosine-3′ phosphate in ribonucleic acid (RNA)[1-3]. During the digestion, guanosine-2′, 3′-cyclic phosphate (G-cyclic-p) is accumulated in the reaction mixture as an intermediary product.

It has been also found that RNase T_1 hydrolyzes *deamino*-ribonucleic acid (*deamino*-RNA) splitting preferentially the secondary phosphate ester bonds of inosine-3′ phosphate with an intermediary formation of inosine-2′, 3′-cyclic phosphate (I-cyclic-p). With higher amounts of RNase T_1, the secondary phosphate ester bonds of xanthosine-3′ phosphate is also hydrolyzed with an intermediary formation of xanthosine-2′, 3′-cyclic phosphate (X-cyclic-p)[4].

Nucleoside-2′, 3′-cyclic phosphate

It has so far been difficult to synthesize G-cyclic-p by a chemical method with good yield and in high purity[5]. Markham et al. prepared G-cyclic-p and adenosine-2', 3'-cyclic phosphate (A-cyclic-p) by mild alkaline hydrolysis of "RNase I core"[6]; however, the yield was far from satisfactory. On the other hand, I-cyclic-p and X-cylic-p have been neither separated from the natural source nor synthesized.

We succeeded in preparing these purine nucleoside cyclic phosphates with good yield by the enzymic reactions. So the method of preparation of these nucleoside-2', 3'-cyclic phosphates and the properties of new compounds will be reported.

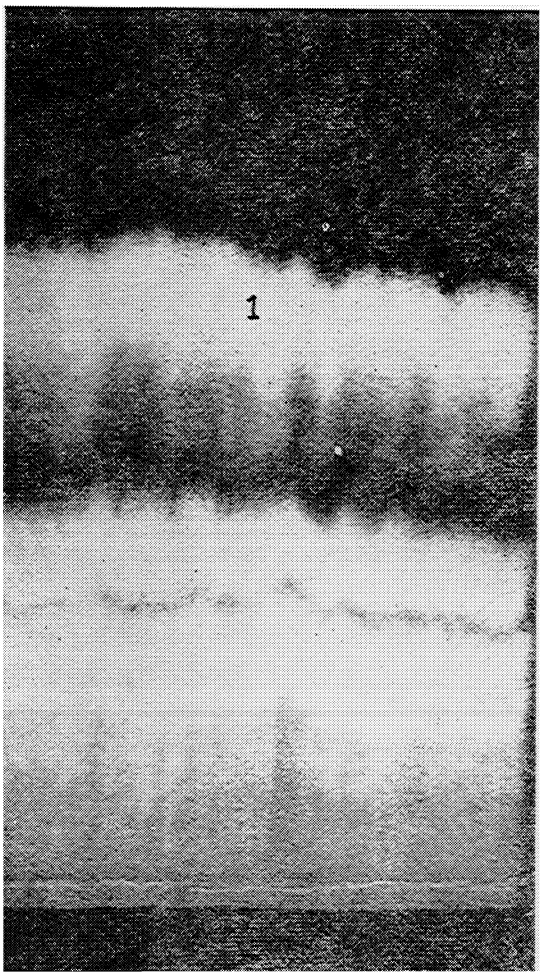

Fig. 1. Paper chromatogram of the dialyzate of the digestion mixture of yeast RNA by RNase T_1. Reaction mixture contains 100 mg. of yeast RNA and 10 μg. of RNase T_1 at pH 7.5. The band 1 is that of G-cyclic-p. Solvent I was used.

Experimental

RNA.—A commercial yeast RNA (Schwarz Laboratories) was deproteinized with chloroform gel formation, dialyzed in a cellophane tubing against distilled water and precipitated with alcohol.

Deamino-RNA.—Yeast RNA was deaminated by the method of Takemura[7]. Details of the preparation and properties of deamino-RNA will be reported elsewhere.

RNase T_1.—The purest sample extracted and prepared from Takadiastase according to the method of Sato and Egami[1] was used.

Paper Chromatography.—*Solvent I*: isopropanol: water (7 : 3) with concentrated aqueous ammonia in the bottom of the vessel (0.5 ml. for each liter of gas phase)[8], descending for 18 to 19 hr.

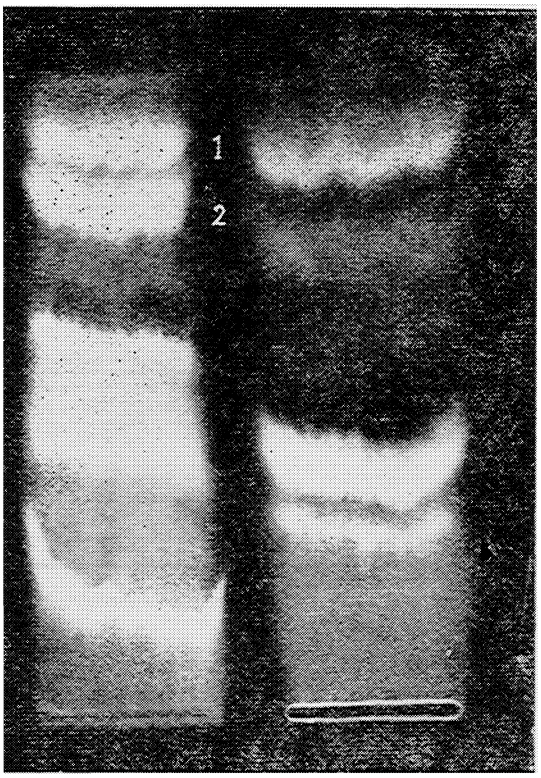

Fig. 2. Paper chromatograms of the dialyzate of the digestion mixture of *deamino*-RNA by RNase T_1. Solvent I was used. The bands are: 1, I-cyclic-p; 2, X-cyclic-p.
a) 20 mg. *deamino*-RNA, 2 μg. RNase T_1/ml.
b) 200 μg. RNase T_1 was added to the nondialyzable fraction in a).

Solvent II: saturated ammonium sulfate : water: isopropanol (79 : 19 : 2)[9], ascending for 9 hr. Tôyôroshi No. 51 paper was used throughout the studies and the bands on the chromatogram were located by the usual photographic methods.

Organic Phosphorus.—It was measured by the method of Allen[10].

Preparation of G-cyclic-p.—Yeast RNA (100 mg.) was dissolved in 5 ml. of distilled water and pH was adjusted to 7.5. To the solution 10 μg. of RNase T_1 was added. The reaction mixture was incubated at 37°C for 2 hr., then dialyzed against distilled water in a cold room under stirring overnight. The dialyzate was concentrated and subjected to paper chromatography (15~20 cm./100 mg. RNA) using solvent I. As is shown in Fig. 1 the wide intensive band 1 was found, this was identified with that of G-cyclic-p[3]. The band was eluted and lyophilyzed. G-cyclic-p was obtained in an almost pure state by chromatography. After the preparation was rechromatographed with the same solvent, it was proved by another paper chromatography test, paper electrophoresis and its U. V. absorption spectrum that it became completely free from other nucleotides except for a trace amount of guanylic acid (Gp).

Preparation of I-cyclic-p. — One hundred milligrams of *deamino*-RNA was dissolved in 5 ml. of distilled water at pH 7.5 and 10 μg. of RNase T_1 was added, then the reaction mixture was incubated for 5 hr. at 37°C. The reaction mixture was dialyzed against 50 ml. of distilled water in a cold room under stirring, then the dialyzate was concentrated and subjected to paper chromatography (solvent I, descending for 18 hr.). After drying, the paper was rechromatographed with the same solvent for 19 hr. (Fig. 2a). The broad band 1 moving rapidly was identified with that of I-cyclic-p[11]. Band 2 which is that of X-cyclic-p[11] also appeared sightly. Band 1 was eluted with distilled water, the eluate was concentrated and subjected to paper chromatography using solvent I. There was nothing except for a large amount of I-cyclic-p and a trace of inosinic acid (Ip). It was also proved by another paper chromatography test using solvent II that the band was pure I-cyclic-p. The purest preparation was used for the following experiments.

Preparation of X-cyclic-p.—After the pH of the reaction mixture, which remained in the cellophane tubing in the experimental for I-cyclic-p, was adjusted to 7.5, 1.0 ml. of RNase T_1 (1.3 mg./ml.) was added and the reaction mixture was incubated for 5 hr. at 37°C. Then it was dialyzed against 60 ml. of distilled water in a cold room under stirring, then the dialyzate was concentrated and subjected to paper chromatography (solvent I, descending for 18 hr.). After drying, the paper was rechromatographed with the same solvent for 19 hr. (Fig. 2b). The broad band 2 was identified with that of X-cyclic-p[11]. To purify the sample completely, band 2 was eluted with distilled water, the eluate was concentrated and subjected to rechromatography with the same solvent. There was nothing but large amounts of X-cyclic-p and a trace of xanthylic acid (Xp). Moreover, this band 2 was proved to be pure X-cyclic-p by another paper chromatography test with solvent II. This sample was used in the following studies.

Results and Discussion

Yields.—The yields were calculated from the optical density. Five milligrams G-cyclic-p from 100 mg. of yeast RNA ; 2 mg. of I-cyclic-p from 100 mg. of *deamino*-yeast RNA ; 2.5 mg. of X-cyclic-p from 100 mg. of *deamino*-yeast RNA.

Absorption Spectra of I-cyclic-p and X-cyclic-p.—Using the purest preparation, their ultraviolet absorption spectra were measured at various pH ranges, and their molar extinction coefficients were determined by measuring phosphate (Figs. 3 and 4).

Rf values were calculated in two solvent systems.

TABLE 1. *Rf* VALUES OF PREPARED CYCLIC NUCLEOTIDES AND OF MONONUCLEOTIDES

	Solvent I	Solvent II
G-cyclic-p	0.28	0.29
I-cyclic-p	0.43	0.33
X-cyclic-p	0.35	0.19
A-cyclic-p	0.48	0.13
C-cyclic-p, U-cyclic-p	0.50	0.54
Gp	0.13	0.45 (3') 0.54 (2')
Ip	0.16	0.52
Xp	0.15	0.33
Ap	0.21	0.23 (3') 0.33 (2')
CP, Up	0.21	0.73

These cyclic nucleotides, especially G-cyclic-p, were rather labile in diluted solution and were hydrolyzed to nucleotides. So all procedures had to be carried out as rapidly as possible.

If two or more cyclic nucleotides were produced from RNA at the same time, the separation might be very difficult. So the stepwise enzymic preparation seems to be a better method. After the preparation of G-cyclic-p from the dialyzate of the digestion mixture of yeast RNA by RNase T_1, the nondialyzable fraction which remained in the cellophane tubing was treated in 0.1 N hydrochloric acid to split the residual cyclic phosphate[2], neutralized and dialyzed completely. What may be

called "RNase T_1 core" thus obtained was useful for the preparation of pyrimidine nucleosidecyclic phosphates by RNase I.

Pyrimidine nucleosidecyclic phosphates were prepared from the dialyzate of yeast RNA digests by RNase I and the residues were further completely digested and dialyzed, and thus the well known "RNase I core" was obtained. It was also a good source for the preparation of G-cyclic-p by RNase T_1.

It was rather difficult to separate a large amount of I-cyclic-p and X-cyclic-p. To solve this difficulty RNase T_1 digestion was divided into two steps: at the first step with a small quantity of RNase T_1, the greater part of I-cyclic-p was separated and at the second step by addition of more RNase T_1, the remaining I-cyclic-p and X-cyclic-p were obtained separately.

Summary

By RNase T_1 digestion, guanosine-2′,3′-cyclic phosphate was obtained with good yield from yeast RNA, and two new compounds, inosine-2′,3′-cyclic phosphate and xanthosine-2′,3′-cyclic phosphate were obtained from *deamino*-yeast RNA. The properties of the new compounds were studied.

Recombination of Hydrogen, Nitrogen and Oxygen Atoms on Copper and Silver Single Crystal Surfaces

By Kazuo NAKADA

(Received March 4, 1959)

Hoping to get information about the bond strength of the chemisorption of hydrogen, the author et al.[1] carried out the recombination of hydrogen atoms on various metal surfaces including single crystal surfaces of copper. In the present work, experiments have been extended to cases of nitrogen and oxygen atoms on single crystal surfaces of copper and silver, considering the fact that comparatively simple electronic band structures of copper and silver will render the theoretical treatment of results possible in future. With regard to oxygen atoms, experiments were conducted only on single crystal surfaces of silver, because the probable formation of relatively thick oxide layers on copper surfaces might complicate the subject for consideration.

Since relatively much information about physical and physico-chemical properties of single crystal surfaces of metals with definite crystal indices are available, execution of any surface reaction on these surfaces seems to be advantageous in considering the mechanism of surface reaction through the comparison of catalytic activity with physical properties. With regard to the research along this line, the works of Gwathmey et al.[2], Sosnovsky[3] and Crocker et al.[4] are noteworthy.

However, few works have yet been undertaken except for the work of Gwathmey et al. in which detailed structures of surfaces during the course of and after the completion of the reaction are fully followed. In the work of Sosnovsky, where the decomposition of formic acid on single crystal surfaces of silver was dealt with, the natural free

surface frozen from the melt was used as a reaction surface. The work of Crocker et al. in which the decomposition of formic acid on single crystal surfaces of copper was dealt with and that of Nakada et al. in which the recombination of hydrogen atoms on the same was dealt with were only concerned with the electropolished surfaces. Although the flatness of these surfaces on the atomic scale was ensured by Rhodin[5] through the adsorption experiment by the use of microbalance technique, there seems still to be doubtful whether or not the electro-polishment would really give such an extreme flatness.

Accordingly, it is highly desirable to know detailed structures of surfaces on which the experiments were made. In the present work, the author devotes himself to the detection of the effect of various kinds of surface pre-treatments on catalytic activity. It seems probable that surfaces subject to such a treatment as chemical etching, which possibly roughen them, will comply with the purpose of this work better than the flattened surfaces, because for such a roughened electron diffraction technique may give the most detailed information on its surface structure. Conversely, it may be expected that from the change in activity resulting from various surface treatments, unknown surface structures lying beyond the limit of the power of the present scientific method, like electron microscopy or electron diffraction technique, would be made clear.

Experimental

An effusion method used in the preceding report* for determining the recombination activity of different transition metals was also adopted this time.

Apparatus. — The apparatus (not shown) described in the above was used without modification, but the sample metal slice was hung only with a Pt/Pt-Rh thermocouple (0.1 mm. in diameter) without any other lead.

Sample Gases.—The hydrogen, oxygen and nitrogen used were all commercial cylinder gases. Hydrogen or oxygen was allowed to bubble through a saturated sodium hydroxide solution and further to diffuse over the platinized asbestos (ca. 400°C) to remove oxygen and hydrogen included in hydrogen and oxygen as an impurity, respectively, but for nitrogen this procedure was not done. They were sent to the discharge tube through a capillary from a reservoir in which the gases were allowed to stay over the saturated sodium hydroxide solution to keep the humidity constant.

Sample Metal Slices.—Single crystals of copper and silver were produced by means of a slow cooling method from electrolytic copper and standard silver for analysis respectively. The single crystals thus obtained were of a cylindrical form (12 mm. in diameter and about 6 cm. long). Single crystal slices (generally in an elliptical form, about 2 to 3 mm. thick) were cut from a cylindrical single crystal in order that their macroscopic-cut planes might coincide with the three principal planes (100), (110) and (111), but in the case of silver only the (110) and (100) slices were prepared.

Pre-treatment of Surfaces.—Two surfaces of a sample slice were generally subjected to two different kinds of pre-treatments, e.g., one pre-treatment was electro-polishment and another, chemical etching with nitric acid or the like. The main conditions of pre-treatment adopted in this work were as follows:

1) Chemical etching was carried out a) in the nitric acid solution (1 : 1 by volume) for 3 min. and b) in the saturated ammonium persulfate solution for 15 min.

2) Electro-polishment of copper was done in the bath of phosphoric acid (90%) at the current densities of 6 to 8 amp./dm^2 for 10 min. and that of silver in the mixed solution of potassium cyanide (10%) and potassium ferrocyanide (10%) at the current densities of 1 to 3 amp./dm^2 for 3 min.

3) For the electric plating, solutions of potassium cuprous cyanide, potassium silver cyanide and ammonium aurocyanide were used as baths of copper-, silver- and gold-plating, respectively.

Procedure.—All free atoms were produced in a discharge tube by use of alternating currents. A sputtering of the electrode material (aluminum) occurred more markedly in the case of nitrogen than in oxygen. Since such a sputtering was localized within the neighborhood of electrodes even in the case of nitrogen, they did not become a serious obstacle to the present experiments.

In the reaction chamber, which was strongly pumped off, the sample metal slice was hung only by a Pt/Pt-Rh thermocouple (0.1 mm.) serving as the temperature measurements at the front of a small hole provided at the end of a side tube of the discharge tube. The temperature of a sample can be followed by measuring the electro-motive force by use of a K-type potentiometer. The electro-motive force was read at intervals of 5 min. The slice was allowed to turn over every twenty or thirty minutes. Before and after this procedure, the temperature was usually shifted from one value to another. From such a shift of the temperature the difference in activities of two surfaces of the same sample subjected to different treatments could readily be detected.

Results

In Fig. 1 is given a plot of temperature, expressed in terms of electro-motive force

18	Ag(110)	ditto	ditto	(110)>Cu, Au	O

In this table the following abbreviations were adopted. For example, chemical etching in a nitric acid solution was abbreviated as Chem. etch. :HNO_3, electrolytic polishing as El. pol. :H_3PO_4 and electrical plating of silver as Ag-plating.

(μV), against the time (min.) for the case of Ag(110) slice, one side of which is the one electrically plated with silver, while the other side is electrolytically polished. Arrows in Fig. 1 show times when the sample slice was let turn over. From this plot the electrolytically polished Ag(110) surface is found to be more active than the electrically plated silver surface.

Inequality relations thus determined are shown en bloc in Table I. The first column shows species of macroscopic-cut planes of sample slices. In the second and the third columns are shown methods of pre-treatments applied to each side of the surfaces. In the fourth column are given the inequality relations about recombination activities of two surfaces. The last column shows kinds of atoms used.

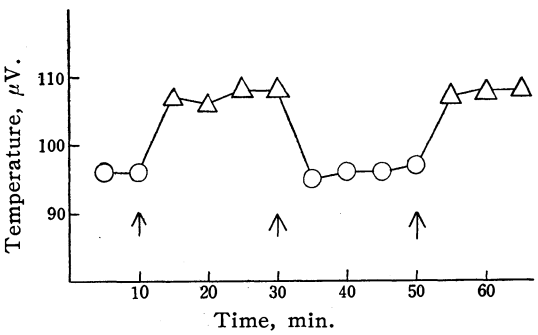

Fig. 1. The shift of the sample slice temperatures on the alternative exposure of two side planes to the reacting gas. This is an example about silver slice corresponding to Table I, No. 15.

Some Remarks on the Surface Structures

Since the main purpose of the present work is to make clear the effect of different surface structures on catalytic activity, several bits of information available to date concerning the surface structures of single crystals of some metals will be reviewed below in a little detail.

Among the works along this line the work of Yamaguchi[6] on single crystals of nickel is noteworthy. He made clear their detailed structures when they were etched by a mixed solution of ethyl alcohol and liquid bromine (1 : 1 by volume) by the cooperative uses of electron microscope and electron diffraction technique. In a similar way, structures of the single crystal of copper etched with ammonium

6) S. Yamaguchi, *J. Appl. Phys.*, **22**, 983 (1951).

persulfate was made clear by Ueda et al.[7] According to their result, the surface of a single crystal of copper etched by the saturated solution of ammonium persulfate exposes composite small facets, but all the faces of such facets have (110) family index irrespective of their directions.

Chalmers et al.[8] examined the surface thermally etched in the presence of oxygen or nitrogen. According to their results, the surface heated to 500°C in oxygen was found to show a zonal orientation which should be ascribed to the exposition of (111) face, while surfaces heated in nitrogen show a flat surface having all desired orientations. Pashley[9] examined the single crystal surfaces of silver parallel to the (100), (111), (110) and (311) plane when they were subjected to the electrolytic etching, electrolytic polishing and chemical etching by nitric acid (35%). In this work the electrolytic polishing was found to give very smooth surfaces, while the electrolytic etching or the chemical etching to give well-developed facets which were always of the (100), (110), (210) and (310) types and did not include (111) facets.

Less detailed and less reliable information can be drawn from the optical back reflection image obtained when a very intense light beam is spotted on the single crystal surfaces etched by chemical agents. This optical back reflection method was used in determining the crystal axes of single crystals in this work. Several pieces of information obtained by the use of this method can be found in old works of physicists who were engaged in the study of the anisotropy of work functions of metal single crystals. Farnsworth[10] found that the electrolytic etching of a single crystal of copper at low current densities developed a (111) face and the same treatment at high current densities a (100) face. In the work of Rose[11] the electrolytic etching of the (111) surface in a copper sulfate solution was stated to expose a (111) face and the chemical etching of the (100) surface in a nitric acid solution (65%) to produce a smooth (100) surface with very few undesired faces.

Discussion

In Fig. 2 is given only a part of the electron micrographs of single crystal surfaces of copper and silver with different crystal indices. From Figs. 2b, c and d, it was clearly recognized that slices with different crystal indices were subjected to corrosion in a considerably different

Fig. 2. Electron micrographs of copper and silver single crystal surfaces subjected to various kinds of pre-treatment.

manner on the attack of the same etching agent. As known from Figs. 2e and f, it seems rather reasonable that the electrolytical polishing of silver surfaces in the bath used in the present work is considered as the electrolytical etching in an electron-microscopic scale. In spite of the significance of determining crystallographic planes of the small facets exposed to the reacting gas, further approach to the true surface structures could not be attained without getting an opportunity to use the electron diffraction method.

No results were obtained in which inequality relations of relative activities for hydrogen atoms and nitrogen atoms disagreed with each other. This suggests that the recombination of hydrogen atoms and nitrogen atoms may proceed probably through the similar mechanism.

In the case of both Cu(100) and Cu(110) slices, the mechanically polished surfaces were more active than electrolytically polished surfaces (Table I, No. 1 and 4). It is supposed that this difference in activity might have originated in strains of Beilby layers formed on the surface. Experiments of No. 7 and 8 were made about the special sample of the Cu(110) slice, the back side of which was changed to a polycrystal state by rapid cooling of only one side after re-heating, while another side remained to be the original single crystal state. From the comparison of activities of these two surfaces for the recombination of nitrogen atoms, both of which are subjected to the attack of the same reagent (nitric acid or ammonium persulfate), were obtained results showing that the polycrystal surface was always more active than the single crystal surface. It seems, however, to be premature to accept the existence of the effect of the crystal boundaries on the catalytic activity.

Bearing in mind the statement of Rose, an experiment of No. 11 was done to know whether the Cu(111) surface electrolytically polished in a copper sulfate solution may be more flat (accordingly less active) than the electrolytically polished surface in phosphoric acid, but any difference in these two treatments could not be detected.

In the previous work of the present author et al. about the recombination of hydrogen atoms on single crystal surfaces of copper which was electrolytically polished, it was made clear that the (110) face is the most active, the (100) face less active than this, and the (111) face the least active. In view of Ueda's work cited above, in which single crystal surfaces of copper etched by ammonium persulfate were shown to be composed of only the (110) family facets, it may be expected that surfaces etched by ammonium persulfate will be more active than those etched by nitric acid which was known to develop the (100) face. Present results show that with the Cu(100) slice this is certainly the case (No. 3), whereas with the Cu(110) slice the reverse order of activity has been obtained (No. 6). These results show that copper surfaces subjected to the chemical etching by nitric acid or ammonium persulfate seem to have more complex structures than expected from the information given above.

Throughout every three slices (100), (110) and (111), electrolytically polished surfaces were found always to be more active than chemically etched surfaces (No. 2, 5 and 9). This suggests that there may exist some other faces with relatively high activity than these principal faces. It is instructive that chemically etched surfaces having a rather complex micro-topography are less active than flat surfaces electrolytically polished. This implies that the recombination does not proceed on the corners or edges of small crystal facets, but rather mainly on plane faces. This has probably originated in such a special circumstance as that reactants are only composed of free atoms which need not be activated further.

Next, let us examine the results on single crystal surfaces of silver. As for the Ag(100) slice, surfaces chemically etched by nitric acid are also less active than those electrolytically polished in accord with the experiment of No. 2 (No. 12), whereas between surfaces chemically etched by ammonium persulfate and those electrolytically polished, no difference in activity was observed (No. 13). Combining the result of the experiment No. 12 with that of No. 13, the surface etched by ammonium persulfate is known to be more active than the one etched by nitric acid in accord with experiment No. 3 about copper. Consequently, it may be said that these chemical agents will have, to some extent, a similar corrosive action against both copper and silver.

For both the recombination of hydrogen atoms and that of nitrogen atoms, Ag(100) and Ag(110) surfaces electrolytically

polished were together more active than the electrically plated surfaces of copper, silver and gold (No. 14 and 15). This shows firstly that activities of these three kinds of metals do not show any wide diversity and secondly that the character of surfaces plays a significant role when the activities of these metals were compared. From the combination of No. 14 and 15, no conclusion could be drawn as to which of the Ag(110) slice and the Ag(100) slice would be more active. With reference to the earlier results of the present author et al. about the recombination of hydrogen atoms on single crystal surfaces of copper, the author has been inclined to ascribe the higher activity to the (110) face.

For the recombination of oxygen atoms on single crystal surfaces of silver subjected to the electro-polishment, inequality relations

$$\text{Ag(110)} > \text{Cu or Au plated surface} > \text{Ag(100)}$$

were obtained (No. 17 and 18). The relation Ag(110)>Ag(100) is in good accordance with the case of the recombination of hydrogen atoms on single crystal surfaces of copper so far as the order is concerned. This accordance seems, however, to be fortuitous in view of the considerably larger nuclear distance of an oxygen molecule, 1.20 Å, than that of a hydrogen molecule, 0.75 Å, even though the larger lattice constant of silver, 4.08Å, compared to that of copper, 3.61 Å, would work favorably for this reaction.

With the recombination of oxygen atoms it was noticed that a kind of polishing action becomes appreciable in repeated runs. Comparing the micro-photograph of Fig. 2a with Fig. 2i, it is immediately perceived that such an aged surface under the contact with oxygen atoms resembles the electrolytically polished surface of copper in its micro-topographic appearance, except that the former possesses somewhat worse flatness than the latter. Experiments No. 17 and 18 are obtained with respect to such aged surfaces, while experiments No. 12 to No. 15 with respect to surfaces polished afresh.

Though it appears probable that this kind of polishing will come from any particular property of oxide layers, such changes of surface structures were not studied further, because this problem is not concerned with the main theme of the present work.

Summary

Recombination of hydrogen atoms, nitrogen atoms and oxygen atoms was carried out on single crystal surfaces of copper and silver subjected to various surface pre-treatments.

With both the recombination of hydrogen atoms and that of nitrogen atoms, copper surfaces electrolytically polished have always higher activity than those chemically polished. The Cu(100) surface chemically etched by ammonium persulfate was more active than that etched by nitric acid for both hydrogen atoms and nitrogen atoms, whereas with the Cu(110) the opposite order of activity was obtained. For both silver and copper, no evidence was found to show the different order of activity between the recombination of hydrogen atoms and that of nitrogen atoms. Concerning the recombination of oxygen atoms on single crystal surfaces of silver, the (110) face was found to be more active than the (100) face in accord with the result of our earlier work about the recombination of hydrogen atoms on single crystal surfaces of copper.

The author wishes to express his gratitude to Professor S. Shida for his help and encouragement during the course of this study.

Polymerization of Methyl Methacrylate Initiated by the System of p-Toluenesulfinic Acid, Dimethylaniline and Oxygen

By Ryoichi UEHARA

(Received December 17, 1958)

Polymerization of vinyl monomers initiated by some sulfinic acids was first reported by Hagger[1]. The present author[2] has reported a self-curing method of methyl methacrylate by the combined action of *p*-toluenesulfinic acid and dimethylaniline in the presence of air. Hagger considered that sulfinic acids by themselves could initiate the polymerization of vinyl monomers and reported an equation representing a relation between the initial rate of polymerization of methyl methacrylate and the concentration of *p*-toluenesulfinic acid.

Recently, Bredereck and others[3] found that absolutely pure *p*-toluenesulfinic acid could not initiate the polymerization of methyl methacrylate, and that for the initiation of the polymerization, the coexistence of oxygen and an "oxygen-acceptor" such as amines or chloide ions was necessary. The polymerization-initiating action of sulfinic acid found by Hagger was explained by Bredereck to be due to the combined action of the sulfinic acid, oxygen in air, and chloride ions containd in the sulfinic acid as an impurity. Moreover, Bredereck[4] has postulated a mechanism for the initiation of the polymerization of methyl methacrylate with an initiating system consisting of oxygen, *p*-toluenesulfinic acid, and an "oxygen-acceptor"; i.e., a peroxide was formed from oxygen and the sulfinic acid, and then a radical was produced from the peroxide and the "oxygen-acceptor" to initiate the polymerization. But no experimental evidence was given by him for this mechanism.

The present author has studied the polymerization of methyl methacrylate initiated by the system of *p*-toluenesulfinic acid, oxygen in air and dimethylaniline from the standpoint of chemical kinetics. In the present paper, correlations of the initial rate of polymerization of methyl methacrylate with the concentration of the components of the inititating system are given, and the initial step of the polymerization is discussed.

The polymerization was carried out in open test tubes under atmospheric pressure of air for the study of the dependence of the initial rate (R) of polymerization upon concentrations of *p*-toluenesulfinic acid (TSA), dimethylaniline (DMA), and methyl methacrylate (MMA). When the effect of the initial pressure of oxygen was tested, the polymerization was carried out in sealed test tubes under various initial pressures of air.

When the concentration of *p*-toluenesulfinic acid was held constant and that of dimethylaniline was varied under atmospheric pressure of air, the initial rate of the bulk polymerization of methyl methacrlate

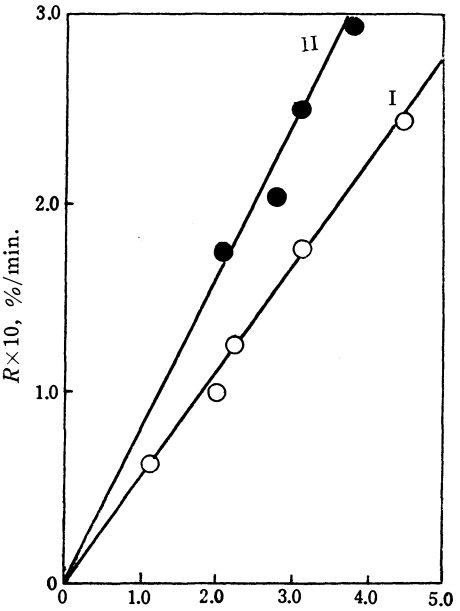

Fig. 1. Correlations of R with [TSA]$^{1/2}$ and [DMA]$^{1/2}$ at 30°C in air.
Line I. [TSA]$=5.1\times10^{-2}$ mol./l.
Line II. [DMA]$=10.0\times10^{-2}$ mol./l.

1) O. Hagger, *Helv. Chim. Acta.*, **31**, 1629 (1948).
2) R. Uehara, *Dental Practice* (*Rinsho Shika*), **196**, 24 (1952).
3) H. Bredereck et al., *Ber.*, **89**, 731 (1956).
4) H. Bredereck et. al., *Angew. Chem.*, **68**, 306 (1956).

was linearly proportional to the square root of the concentration of dimethylaniline. This correlation is shown by line I in Fig. 1, in which 5.01×10^{-2} mol./l. of *p*-toluenesulfinic acid was used at 30°C.

When the concentration of dimethylaniline was kept constant and that of *p*-toluenesulfinic acid was varied, the initial rate of polymerization was linearly dependent upon the square root of the concentration of *p*-toluenesulfinic acid. This relationship is shown by line II in Fig. 1, in which 10×10^{-2} mol./l. of dimethylaniline was used at 30°C. Straight lines I and II in Fig. 1 are brought to a focus at the origin. This fact indicates that neither *p*-toluenesulfinic acid nor dimethylaniline alone can initiate the polymerization in combination with oxygen in air.

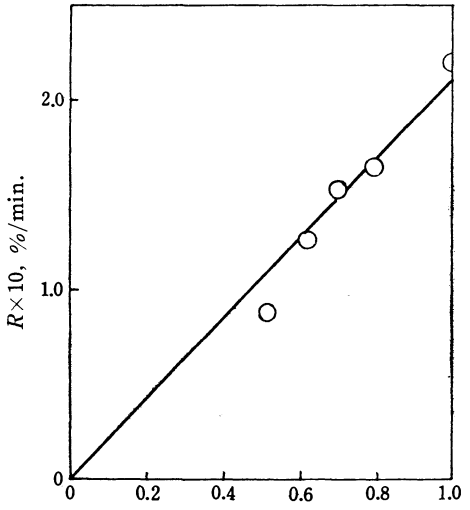

Fig. 2. Correlation of R with the initial pressure of air at 30°C
[TSA] = [DMA] = 8.8×10^{-2} mol./l.

In Fig. 2 the correlation of the initial rate of polymerization with the initial pressure of air in the sealed test tubes is shown. The initial rate of polymerization is linearly proportional to the square root of the initial pressure of air. In this case 8.8×10^{-2} mol./l. of both *p*-toluenesulfinic acid and dimethylaniline were used. The straight line in Fig. 2 gose through the origin. This fact indicates that the polymerization can not be initiated without air. The pressure of air is proportional to that of oxygen, so Fig. 2 shows that the initial rate of polymerization is linearly dependent upon the square root of the initial pressure of oxygen.

In the case of the solution-polymerization in benzene, the initial rate of polymerization was linearly dependent upon the concentration of methyl methacrylate. This correlation is shown in Fig. 3, in which 5.10×10^{-2} mol./l. of both *p*-toluenesulfinic acid and dimethylaniline were used at 40°C, under air of atmospheric pressure.

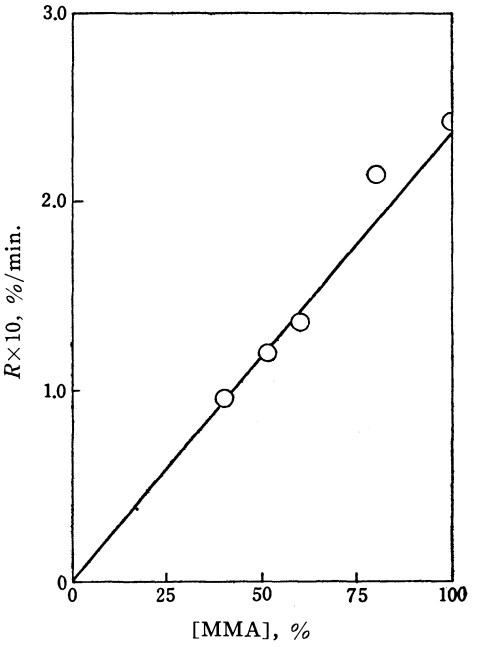

Fig. 3. Relationship between R and [MMA] in case of solution-polymerization in benzene at 40°C.
[TSA] = [DMA] = 5.10×10^{-2} mol./l.

Correlations shown in Figs. 1—3 can be represented by the following equation:

$$R=k[O_2]^{1/2}[TSA]^{1/2}[DMA]^{1/2}[MMA] \quad (1)$$

where k is a constant.

Eq. 1 suggests that oxygen, *p*-toluenesulfinic acid and dimethylaniline, all three, take part in the formation of a radical to initiate the polymerization, but methyl methacrylate is not concerned in the radical formation at the initiation reaction. Moreover, Eq. 1 suggests that there may be several reactions forming the radical from the initiating system. As mentioned above, Bredereck[4] has postulated the formation of a peroxide from oxygen and *p*-toluenesulfinic acid as the first step of the initiation. In another paper, however, Bredereck[3] has reported very briefly without any details of experiments that salts of *p*-toluenesulfinic acid and some aromatic amines initiated the polymerization of methyl methacrylate under air. In addition, it has been reported by

Bredereck[5] and Brauer[6] that salts of the sulfinic acid and amines were efficient accelerators for the polymerization of methyl methacrylate initiated with benzoyl peroxide. Formation of a salt from an amine and *p*-toluenesulfinic acid takes place very smoothly in organic solvent[6]. So, in the case of the combination of *p*-toluenesulfinic acid and dimethylaniline, formation of a salt from the sulfinic acid and the amine is more probable than the formation of a peroxide from the sulfinic acid and oxygen in air. The initiating system, *p*-toluenesulfinic acid-oxygen-chloride ions, must be considered separately from the initiating system under discussion.

To get support for this idea from another point of view, the present author has examined the effects of anhydride, and methyl and ethyl esters of *p*-toluenesulfinic acid for the initiation of the polymerization. The per cent conversions of bulk polymerization by means of equimolar mixtures of these compounds and dimethylaniline are shown in Table I.

TABLE I. THE PER CENT CONVERSIONS OF THE BULK POLYMERIZATION OF METHYL METHACRYLTE UNDER ATMOSPHERIC PRESSURE OF AIR

Initiator*	Conversions, %			
	at 30°C		at 70°C	
	3 hr.	6 hr.	1 hr.	3 hr.
p-Toluenesulfinic acid	22.1	98.7	43.8	96.2
Anhydride	0	0	trace	3.8
Methyl ester	0	0	trace	8.4
Ethyl estr	0	0	trace	4.3

* 5.0×10^{-2} mol./l. of each was used together with equimolar amount of dimethylaniline

Polymerizations were carried out at 30 and 70°C under atomospheric pressure of air. At 30°C, *p*-toluenesulfinic acid was the only material which was responsible for the initiating action. At 70°C, the effect of *p*-toluenesulfinic acid was much greater than those of its derivatives. Namely, the polymerization-initiating action of the sulfinic acid was lost by changing it to its anhydride or esters. Therefore, it appears to be conclusive that the formation of a salt from the sulfinic acid and dimethylaniline is the first step of the polymerization.

By considering the formation of the salt, the following reactions of polymerization are derived:

$$\mathrm{TSA}+\mathrm{DMA}\overset{K}{\rightleftarrows}\mathrm{S}$$

$$\mathrm{S}+\mathrm{O_2}\overset{k_1}{\rightarrow}\mathrm{R}\cdot$$

$$\mathrm{MMA}+\mathrm{R}\cdot\overset{k_2}{\rightarrow}\mathrm{P_1}\cdot$$

$$\mathrm{P}_m\cdot+\mathrm{MMA}\overset{k_3}{\rightarrow}\mathrm{P}_{m+1}\cdot$$

$$\mathrm{P}_m\cdot+\mathrm{P}_n\cdot\overset{k_4}{\rightarrow}\mathrm{P}_{m+n}\ \text{or}\ \mathrm{P}_m+\mathrm{P}_n$$

where S is the salt, R· the radical formed from the salt and oxygen, $P_1\cdot$, $P_m\cdot$, $P_n\cdot$, $P_{m+1}\cdot$ are polymer radicals, P_m, P_n, P_{m+n} polymer molecules, K is the euqilibrium constant, and k_1, k_2, k_3, k_4 are respectively rate constants for each of the reactions.

From these reactions the follwing equation can be deduced by the usual method of chemical kinetics for radical polmerization:

$$R=k_3(Kk_1/k_4)^{1/2}[\mathrm{O_2}]^{1/2}[\mathrm{TSA}]^{1/2}[\mathrm{DMA}]^{1/2}[\mathrm{MMA}] \qquad (2)$$

Eq. 2 completely coincides with Eq. 1.

Experimetal

Materials.—Purification of methyl methacrylate, dimethylaniline and benzene have been reported in a previous paper by the present author[7]. *p*-Toluenesulfinic acid was prepared from *p*-toluenediazonium sulfate by using sulfur dioxide and copper[8]. The crude product was washed with distilled water until ions of heavy metals, chloride and sulfate were not detected in the washing then recrystallized from benzene and methanol, and dried under reduced pressure, m.p. 81°C. The crystallization and the drying of the sulfinic acid were carried out as rapidly as possible, and the purified sulfinic acid was used immediately after drying to avoid deterioration. Anhydride of the sulfinic acid was obtained by treating the acid with acetic anhydride in the presence of a small amount of sulfuric acid, m.p. 75.0°C[9]. Methyl and ethyl esters of the sulfinic acid were prepared from sodium *p*-toluenesulfinate and metyl or ethyl chlorocarbonate, respectively[10]. The esters were used without any purification because of their instability.

Polymerization.—Polymerization under atmospheric pressure of air was carried out in test tubes, each of which was open to the atmosphere

through a capillary at the top. The test tubes were 15 mm. in diameter and 20 cm. in height, and the capillary was 1 mm. in inner diameter and 4 cm. in length, and fitted to the test tube with a ground glass joint. When the effect of the initial pressure of the air was examined, sealed test tubes, each of which was 20 cc. in capacity, were used in place of the above mentioned open tubes. *p*-Toluenesulfinic acid and dimethylaniline were dissolved separately in methyl methacrylate. Both solutions were chilled in a dry ice-methanol bath for 30 min. Measured amounts of each chilled solution were placed in a test tube and mixed. The polymerization was effected by shaking the tubes in a thermostat. The yield of the polymer was measured at intervals of 10 min. Details of the procedures of polymerization and the determination of the initial rate of polymerization have been reported previously[7].

Summary

Initiation of the polymerization of methyl methacrylate with the initiating system, *p*-toluenesulfinc acid-oxygen-dimethylaniline, has been investigated from the standpoint of chemical kinetics. The initial rate of polymerization of methyl methacrylate was linearly proportional to the square roots of the concentrations of each component of the initiating system, and methyl methacrylate. The polymerization initiating action of the initiating system is lost by changing the sulfinic acid to its anhydride or esters. The formation of a salt from the sulfinic acid and dimethylaniline was suggested as the first step of the initiation of the polymerization.

The present author wishes to express his hearty thanks to Professor Osamu Simamura of the University of Tokyo for his interest in this work.

Polymerization of Methyl Methacrylate Initiated by a Combined Action of p-Tolyl Methyl Sulfone, Dimethylaniline and Oxygen in Air

By Ryoichi UEHARA

(Received December 25, 1958)

p-Tolyl methyl sulfone first reported by Knoevenagel[1] is a compound prepared from sodium *p*-toluenesulfinate and methyl iodide, and an isomer of methyl *p*-toluenesulfinate. The effect of *p*-toluenesulfinic acid for the polymerization of methyl methacrylate has been noted by several authors[2] and that of *p*-tolyl hydroxymethyl sulfone has been reported by Bredereck[3], but about the effect of *p*-tolyl methyl sulfone nothing has been reported up to the present.

It has been found by the present author that the polymerization of methyl methacrylate was initiated by a combined action of *p*-tolyl methyl sulfone, dimethylaniline and oxygen in air. The fact that the system of *p*-toluenesulfinic acid, dimethylaniline and oxygen lost the ability to initiate the polymerization by changing the sulfinic acid to its esters has been reported in a previous paper by the present author[4]. So, it appears of interest that the isomer of the methyl ester initiates the polymerization in combination with dimethylaniline and oxygen. In the present paper, some experimental results concerning the relation between the per cent conversion of the polymerization and the concentrations of the initiating reagents, and effects of various amines on the initiating ability of the system are given. In Fig. 1, per cent conversions versus time of the bulk polymerization of methyl methacrylate in air at 70°C are shown. The concentrations of *p*-tolyl methyl sulfone (TMS) and dimethylaniline (DMA) were respectively 3.01×10^{-2} and 2.98×10^{-2} mol./l. In the case when *p*-tolyl methyl sulfone alone was used

1) E. Knoevenagel, *Ber.*, **21**, 1349 (1888).
2) For example, H. Bredreck et. al., ibid., **89**, 731 (1956).
3) H. Bredereck et. al., *Makromol. Chem.*, **12**, 100 (1954).

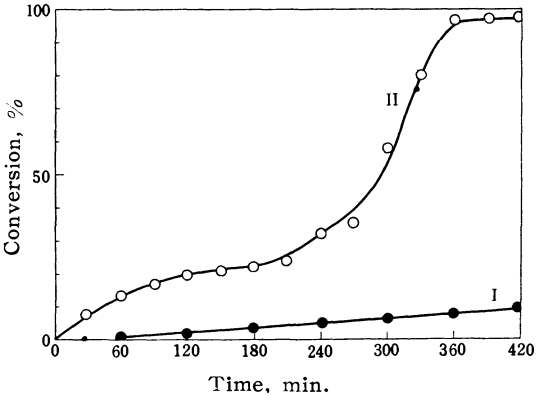

Fig. 1. Conversion versus time relationships of the bulk polymerization at 70°C in air.
([TMS]$=3.01\times10^{-2}$, [DMA]$=2.98\times10^{-2}$ mol./l., I. TMS alone, II. TMS and DMA).

under air, an induction period appeared and then the polymerization took place at a very small rate. When dimethylaniline was used alone, trace of polymethyl methacrylate was formed after 3 hr. By means of *p*-tolyl methyl sulfone and dimethylaniline, the polymerization proceeded at a fairly rapid rate under air. In that case, the time-conversion curve shows an *S*-form which appears usually in the bulk polymerization of methyl methacrylate. The polymerization was completely inhibited by the addition of 0.10×10^{-2} mol./l. of hydroquinone. Under nitrogen the polymerization did not take place.

When equimolar mixture of *p*-tolyl methyl sulfone and dimethylaniline were used in air, per cent conversion after 1 hr. at 60°C were linearly proportional to the initial concentration of *p*-tolyl methyl sulfone or dimethylaniline. At 70°C, the linear dependence of the per cent conversion upon the concentration of *p*-tolyl methyl sulfone can be seen in case the initial concentration of *p*-tolyl methyl sulfone is less than 3.0×10^{-2} mol./l. Those correlations are shown in Fig. 2.

In Table I, per cent conversions after 1 hr. (at 70°C) in the bulk polymerization of methyl methacrylate initiated by equimolar mixtures of *p*-tolyl methyl sulfone and various amines are shown. The mixtures containing heterocyclic, aliphatic, primary and secondary amines were not responsible for the initiation of the polymerization. Only aromatic tertiary amines were effective as the component

of the polymerization-initiating system. *p*-Substitution in dimethylaniline influenced significantly its efficiency as a component of the initiating system. Electron-donating groups such as methyl and methoxy increased the yield of the polymer, while electron-withdrawing groups such as chlorine and bromine reduced the yield. When a strongly electron-withdrawing group such as nitro, nitroso, or phenylazo

was present in the para position of dimethylaniline, no polymerization occurred even after 3 hr. The nature of the effects of dimethylaniline will be discussed in future.

Copolymerization of styrene and methyl methacrylate with this initiating system has been examined. To an equimolar mixture of styrene and methyl methacrylate 3.0×10^{-2} mol./l. of each of *p*-tolyl methyl sulfone and dimethylaniline were added, and the polymerization was carried out in air at 70°C for 2 hr. A portion (5.7% by weight) of the copolymer was obtained. *Analysis* found: C, 76.09 and H, 8.13%, calculated for the copolymer in the molar ratio of 1:1, $(C_{13}H_{16}O_2)_n$: C, 76.47 and H, 7.84%, respectively. It was evident that a copolymer containing styrene and methyl methacrylate in a molar ratio of approximately 1:1 was obtained.

Experimental results mentioned above suggest that the polymerization is initiated by a combined action of *p*-tolyl methyl sulfone, dimethylaniline, and oxygen. The facts that the polymerization is inhibited with hydroquinone, and a copolymer in a molar ratio of 1:1 is formed from styrene and methyl methacrylate indicate that the polymerization proceeds through a free radical mechanism[5]. So, it is probable that radicals to initiate the polymerization are produced from *p*-tolyl methyl sulfone, dimethylaniline and oxygen, though the details of the reaction forming the radical are not made clear at present.

Experimental

p-Tolyl methyl sulfone was prepared from sodium *p*-toluenesulfinate and methyl iodide in aqueous methanol[1]. The crude product was carefully washed with 10% aqueous solution of sodium carbonate and distilled water, then recrystallized from ethanol, m. p. 87°C. Purification of methyl methacrylate, dimethylaniline, and hydroquinone were given in a previous paper[6]. Styrene was washed with 10% aqueous solution of sodium hydroxide and pure water, dried over anhydrous sodium sulfate and carefully distilled under a reduced pressure in nitrogen through a fractionating column, b. p. 46°C/20 mmHg. Amines were distilled under reduced pressure of 3 mmHg, or recrystallized from ethanol.

Polymerization was carried out in open test tubes as mentioned in the preceding paper[4]. The procedures of the polymerization and the determination of per cent conversions have been reported in a previous paper[6].

Summary

The polymerization of methyl methacrylate is initiated by a combined action of *p*-tolyl methyl sulfone, dimethylaniline, and oxygen. The efficiency of the initiating system is increased by using dimethylanilines substituted with electron-donating groups in the para position. The fact that the 1:1 copolymer of styrene and methyl methacrylate is formed by means of this initiating system suggests the formation of radicals to initiate the polymerization from the initiating system.

The present author wishes to express his thanks to Professor Osamu Simamura of the University of Tokyo for his interest and also Mr. Tsurahide Cho, the President of Tama Kagaku Kogyo Co., for permission to publish this work.

Polymerization of Methyl Methacrylate Initiated by a Combined Action of Di-p-tolylsulfonylhydroxylamine and Oxygen in Air

By Ryoichi UEHARA

(Received January 13, 1959)

Di-*p*-tolylsulfonylhydroxylamine was first prepared by Koenigs[1] through the reaction of nitrous acid on *p*-toluenesulfinic acid:

$$2CH_3C_6H_4SO_2H + HNO_2 = H_2O + (CH_3C_6H_4SO_2)_2NOH$$

It has been found by the present author that di-*p*-tolylsulfonylhydroxylamine initiates the polymerization of methyl methacrylate by a combined action with oxygen in air, and this effect is accelerated by the addition of dimethylaniline[2]. Although some compounds related to di-*p*-tolylsulfonylhydroxylamine such as *p*-toluenesulfinic acid[3] and di-*p*-tolylsulfonylmethylamine[4] are noted as components of the initiating system for the polymerization of methyl methacrylate, nothing has been reported up to the present about the effect of di-*p*-tolylsulfonylhydroxylamine for the polymerization.

In the present paper, experimental results concerning the polymerization of methyl methacrylate intiated by the combined action of di-*p*-tolylsulfonylhydroxylamine and oxygen in air, with or without dimethylaniline, are given.

Fig. 1 shows the per cent conversion versus time of the bulk polymerization of methyl methacrylate in air. The polymerization proceeded at a moderate rate by means of 1.86×10^{-2} mol./l. of di-*p*-tolylsulfonylhydroxylamine (DTSH) alone. By the addition of 2.0×10^{-2} mol./l. of dimethylaniline (DMA) the polymerization proceeded fairly rapidly. 3.1×10^{-2} mol./l. of hydroquinone (HQ) retarded the polymerization initiated with 1.86×10^{-2} mol./l. of di-*p*-tolylsulfonylhydroxylamine, i.e., the rate of polymerization was not affected until the conversion reached approximately 5%, but after that the reaction hardly proceeded at all. In the atmosphere of nitrogen, the polymerization occured with difficulty by means of di-*p*-tolylsulfonylhydroxylamine and dimethylaniline. So, it is evident that oxygen is necessary for the initiation of the polymerization.

Copolymerization of methyl methacrylate

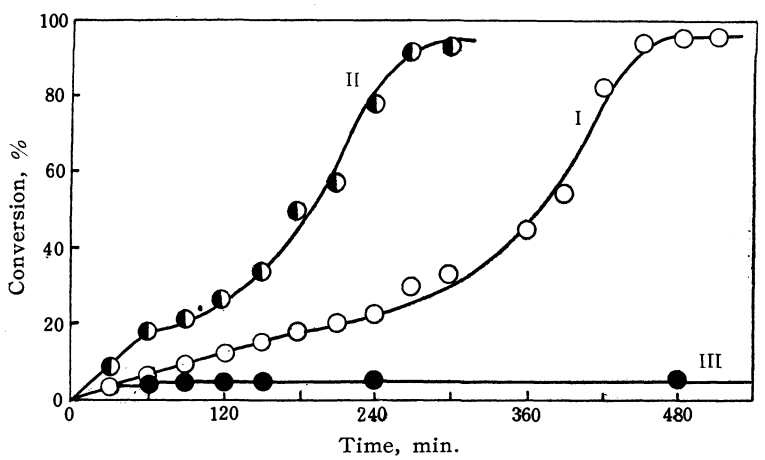

Fig. 1. Per cent conversion versus time of bulk polymerization of methyl methacrylate at 70°C in air. I. DTSH 1.86×10^{-2} mol./l., II. DTSH 1.86×10^{-2} and DMA 2.0×10^{-2} mol./l., III. DTSH 1.86×10^{-2} and HQ 3.1×10^{-2} mol./l.

and styrene was examined by the initiating system of di-*p*-tolylsulfonylhydroxylamine, oxygen and dimethylaniline. An equimolar mixture of methyl methacrylate and styrene containing 1.7×10^{-2} mol./l. each of di-*p*-tolylsulfonylhydroxylamine and dimethylaniline was heated at 70°C in air. After 2 hr., 9.1% by weight of the copolymer was obtained. Analysis of the copolymer shows that a copolymer in the molar ratio of 1 : 1 has been formed; i. e., found: C, 76.31 and H, 8.03%, calculated for the copolymer in the molar ratio of 1 : 1, $(C_{13}H_{16}O_2)_n$: C, 76.47 and H, 7.84%, respectively. This fact indicates that the polymerization proceeds through a free radical mechanism[5].

Average degrees of polymerization of polymethyl methacrylate formed by means of the initiating system are shown in Table I. In a course of the bulk polymerization by means of 1.86×10^{-2} mol./l. of di-*p*-tolylsulfonylhydroxylamine, the average degrees were approximately constant until the conversion reached 20% (after about 240 min.), while, after that period, they increased gradually corresponding to the extent of the polymerization. Fig. 2 shows the correlation of the average degree of polymerization of

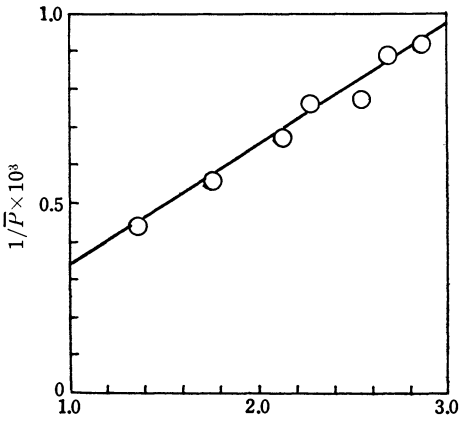
5) C. Walling, F. R. Briggs, W. Cummings and F. R. Mayo, *J. Am. Chem. Soc.*, 72, 48 (1950).



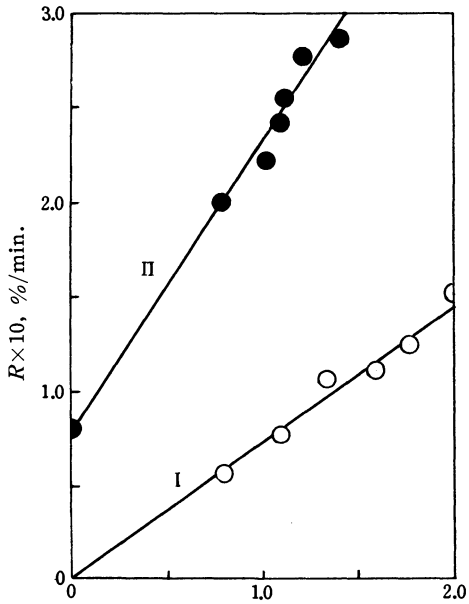


Fig. 2. Correlation of the average degree of polymerization of polymethyl methacrylate with the initial concentration of DTSH at 70°C in air.

polymethyl methacrylate formed during the course of the first 30 min. of the polymerization with the initial concentration of di-*p*-tolylsulfonylhydroxylamine. It is seen that the reciprocal of the average degree of polymerization is linearly dependent upon the square root of the intial concentration of di-*p*-tolylsulfonylhydroxylamine. This fact also indicates the radical character of the polymerization.

The relation between the initial rate of polymerization and concentrations of di-*p*-tolylsulfonylhydroxylamine and dimethylaniline has been investigated. The correlation of the initial rate of polymerization in air with the concentration of di-*p*-tolylsulfonylhydroxylamine is shown in Fig. 3 by line I. The initial rate of polymerization is linearly proportional to the square root of the initial concentration of di-*p*-tolylsulfonylhydroxylamine. When the concentration of di-*p*-tolylsulfonylhydroxylamine was kept constant and various amounts of dimethylaniline were added, the initial rate of polymerization was linearly dependent upon the square root of the initial concentration of dimethylaniline. Line II in Fig. 3 shows this relation in a case when 1.2×10^{-2} mol./l. of di-*p*-tolylsulfonylhydroxylamine was used. It is evident that the so-called square root dependence which is typically seen in the radical polymerization of vinyl monomers holds between the initial rate of polymerization and the initial concentration of both di-*p*-tolylsulfonylhydroxylamine and dimethylaniline. This fact can be regarded as supporting the

[DTSH]$^{1/2}\times 10$ for I
[DMA]$^{1/2}\times 10$ (with 1.20×10^{-2} of DTSH) for II
mol./l.

Fig. 3. Correlations of the initial rate of polymerization with concentrations of DTSH and DMA at 70°C in air.

radical character of the polymerization reaction.

The accelerating effect of dimethylanilne is significantly influenced by groups substituted in its para position. The per cent conversions of the polymerization after 1 hr. at 70°C accelerated by using various amines are compared in Table II. Electron-donating groups such as methyl and methoxy promote, and electron-withdrawing groups such as chloro and bromo reduce the efficiency of the initiating system. By strongly electron-withdrawing groups such as nitro and nitroso, the polymerization-initiating action of the initiating system is completely lost.

TABLE II. EFFECTS OF *p*-SUBSTITUTED DIMETHYLANILINE ON THE EFFICIENCY OF THE INITIATING SYSTEM

CH_3O	30.4
CH_3	23.5
H	16.0
Cl	8.1
Br	7.3
NO	0
NO_2	0

Di-*p*-tolylsulfonylhydroxylamine (1.86×10^{-2} mol./l.) and the amine (2.0×10^{-2} mol./l.) were used at 70°C in air.

From the above mentioned experimental results, it is evident that the polymerization of methyl methacrylate initiated by a combined action of di-*p*-tolylsulfonylhydroxylamine and oxygen, with or without dimethylaniline as an accelerator, proceeds through a free radical mechanism. Therefore, it is very probable that a radical to initiate the polymerization is produced from the initiating system, though the nature of the initiating reactions will be the subject of further investigations.

Experimental

Purification of methyl methacrylate, dimethylaniline, and hydroquinone have been reported in a previous paper by the present author[6]. Di-*p*-tolylsulfonylhydroxylamine was prepared from sodium *p*-toluenesulfinate, sodium nitrite, and hydrochloric acid at 0°C[1]. The crude product was washed with distilled water until no ions of chloride and heavy metals were detected in the washing to eliminate water soluble impurities, and recrystallized from benzene and methanol, m. p. 127°C, with decomposition.

Polymerizations were carried out in open test tubes which have been mentioned in a previous paper by the author[7]. Di-*p*-tolylsulfonylhydroxylamine and dimethylaniline were dissolved in methyl methacrylate cooled in an ice-salt bath. The solution (2 cc.) was placed in each of the tubes and heated in a thermostat bath with shaking. The procedures of the polymerization and determination of the initial rate of polymerization have been given previously[6]. The initial rate was expressed in unit of per cent per minute. The average degree of polymethyl methacrylate was estimated from its intrinsic viscosity in chloroform by using the equation of Sakurada[8].

Summary

The polymerization of methyl methacrylate is initiated by a combined action of di-*p*-tolylsulfonylhydroxylamine and oxygen. The polymerization is accelerated with dimethylaniline and retarded with hydroquinone. The initial rate of polymerization is linearly dependent upon the square roots of concentrations of di-*p*-tolylsulfonylhydroxylamine and dimethylaniline in air. The reciprocal of the average degree of polymerization of the

polymethyl methacrylate formed by means of the present initiating system is proportional to the square root of the initial concentration of di-*p*-tolylsulfonylhydroxylamine. A copolymer (1 : 1) is obtained from an equimolar mixture of styrene and methyl methacrylate. These facts suggest that the polymerization is initiated by a radical produced from the initiating system.

On the Phase Transition of Hexamethyldisilane

By Hiroshi SUGA* and Syûzô SEKI

(Received March 7, 1959)

So-called plastic crystal was first defined by Timmermans[1] in 1938 as a class of crystals which have the entropy of fusion less than about 5 e.u., being miscible together regardless of the difference in the molecular shape, and show much larger plastic flow than the ordinary crystals. This kind of crystal usually undergoes phase transition with much larger entropy change than that at the melting point and the phase just below the melting point possesses a peculiar nature such as that mentioned above. Since then, a number of crystals were found to belong to this category. In general, most of these crystals were composed of more or less globular molecules and these molecules having methyl or methylene groups at the molecular peripheries are the typical case; i.e., $C(CH_3)_4$[2], $C(SCH_3)_4$[3], cyclohexane[4], $Be_4O(CH_3COO)_6$[6], camphor[6], etc. These kinds of molecules in the lattice are considered to be held together mainly by the weak van der Waals force in respect of the rather small heat of sublimation, and the molecules are characterized by the violent thermal motions such as statistical randomness of molecular orientation or, moreover, by such a factor as self-diffusion which was revealed by recent investigations with nuclear magnetic resonance absorption[7] or in other ways.

In the previous paper[8], the present authors and others have reported the results of preliminary investigations of the phase transition of hexamethyldisilane by thermal and X-ray methods and found that this material really belongs to the category of the plastic crystal. We have also published already the result of the investigation by use of the nuclear magnetic resonance method on the present crystal[9]. So, in the present paper we should like to confine ourselves to reporting mainly the results obtained by the thermal method.

Experimental

Material.—The hexamethyldisilane used in this investigation was prepared by the courtesy of Dr. Nozakura from hexachlorodisilane and the methyl Grignard reagent[10] and purified by

fractional distillation under ordinary pressure, b.p. 112.8~113.0°C. After repeated fractional crystallizations, the sample obtained was finally purified by vacuum distillation, m. p. 14.2~14.4°C. It has been found in the course of purification that this crystal showed remarkably the so-called "vapor snake" phenomenon[11] which seemed to be characteristic of the crystal having low heat of fusion and high triple-point pressure.

Procedure and Apparatus.—For the reaffirmation of the occurrence of the phase transition, the method of the differential thermal analysis (DTA) was employed by using alumina powder as a reference substance. The sample was distilled into a DTA test tube and then sealed off in vacuo. After cooling down to the liquid nitrogen temperature, the sample was heated at a nearly constant rate 0.75°C/min. The apparatus was similar to that[12] used hitherto in our laboratory except for the automatic controller device for the constant heating rate with the reference substance and also the automatic recording of the temperature difference between the sample and the reference substance. The details of the automatic controller and recorder will be reported elsewhere in the near future. In order to determine the accurate temperatures and enthalpy changes associated with the polymorphic transition and fusion, respectively, the heat capacity was determined over the temperature range from −80 to +40°C with the conduction calorimeter which was the same one[13] used in our laboratory with a slight modification. The sample-containing cell was made anew of eighteen-carat gold plate with a wall thickness of 0.03 cm. and was approximately 2.5 cm. in height and 1.5 cm. in diameter. Eight radial fines of thin platinum sheet were silver-soldered inside the calorimeter to aid in establishing good heat distribution. In order to ensure thermal equilibrium, the heating rate employed was 0.25~0.30°C/min. except for around the transition and fusion points where a much slower heating rate was necessary. The vapor pressure measurements were carried out below and above the melting point of this crystal by using a simple glass-made mercury manometer with a sufficiently degassed sample.

Results and Discussion

Fig. 1. gives the result of the differential thermal analysis. The heat effect accompanied by the phase transition (at about −52°C) was three times as large as that corresponding to the fusion and consistent with the previous preliminary result[8]. The high temperature phase looks uniformly transparent, to a glassy mass, and always accompanies the vapor snake phenomenon as far as the air is absent. The microscopic observation indicates that this phase is optically isotropic. On cooling this phase, it is observed to be converted into a polycrystalline, opaque mass at the transition point where the appearance of the birefringence was observed under the microscopic observation.

The heat capacity data are tabulated in Table I and their variation with temperature is plotted in Fig. 2. Table II gives enthalpy and entropy changes accompanying the transition and fusion processes, respectively. In order to determine the true melting point of hexamethyldisilane and also to test the amout of impurity

involved in the used sample, the well-known thermodynamic equation[14]

$$T = T_1^* - (\boldsymbol{R}T_1^{*2}/\Delta H_f)(N/y)$$

was used. Here, T and T_1^* are the apparent and true melting points of the material, respectively; $\boldsymbol{R}$, gas constant; ΔH_f, the enthalpy of fusion; N, the number of moles of impurity; and y, the number of moles of material melted. Fig. 3 represents a plot of equilibrium temperatures against the various amounts melted. As is shown, the observed T versus $1/y$ relationship gives a straight line whose slope makes it possible to determine the value of N, by using the measured value of ΔH_f. As the result, we have determined the true melting point of hexamethyldisilane to be 14.5_6°C and the purity of the sample was 99.87% pure (the m. p. reported in the literature is 14.0~14.4°C[15]).

Table III gives the vapor pressure data of the liquid and solid states. The observed values in the liquid range are in good agreement with those of Brockway and Davidson[15]. By applying the method of least squares, good linear relations are obtained between $\log P$ and $1/T$ in both phases. The table also includes the changes of free energy, enthalpy and entropy accompanying the vaporization and sublimation processes, respectively. As the difference between the heat of vaporization and of sublimation, one can obtain the heat of fusion 697±41 cal./mol. which agrees within their experimental errors with the calorimetric value mentioned above.

We summarize in Table IV the entropies

of the transition and of the fusion of the present substance together with those of the related compounds. As is evident for all compounds except for C_2Me_6, the sum of both entropies of the transition and fusion is nearly equal to 13.0 e. u., the value predicted from the Walden rule[16], which holds for the entropy of fusion of usual organic compounds. Accordingly, the transition phenomenon of these compounds may be reckoned as the beginning of the melting process. In other words, the total amount of entropy change which ordinarily should be gained at the melting point is divided between the transition and the melting processes. In the case of hexamethyldisilane, the observed entropy of fusion is very close to the value 2.0 e. u. calculated theoretically for a communal entropy of fusion[17], which comes from the communal sharing of free volume in the liquid state. Considering the reverse (freezing) process, it may be reasonable to infer that the liquid of hexamethyldisilane freezes only with respect to the translational motion** of the molecule at the freezing point and does not do so with respect to the rotational or orientational motion until the transition point is reached. And, even at the transition point, it seems that the stopping of the rotational motion of the methyl group about the Si–C axis does not take place yet. This is because the sum of the entropies of fusion and of transition for hexamethyldisilane is almost equal to that for hexachlorodisilane which is isoelectronic with the former and possesses no corresponding rotational group. This thermodynamical conclusion coincides with the result obtained from the nuclear magnetic resonance experiment[9] which revealed that the rotational motion of the methyl group about the Si–C axis was already excited even at temperatures far below the transition point.

In the X-ray investigation[8] of hexamethyldisilane, it was found that the high temperature phase belongs to body-centered cubic lattice with the cell constant of 8.47Å (at 0°C) containing two molecular units and that the molecular axis (Si–Si axis) is orientated randomly among the four body-diagonals. The observed reflection lines were also interpreted semi-quantitatively by assuming a D'_{3h} model (internal free rotation about the Si–Si axis), or alternatively assuming either a D_{3d} or a D_{3h} model combined with overall rotation of the molecule about the molecular axis, by using the value 18 for the temperature factor in all cases. On the other hand, the crystal structure of the low temperature phase was not yet determined, owing to the difficulty of preparing a single crystal available for the X-ray analysis (it may be hexagonal or orthorhombic crystal system[8]). The anomalously large value of the temperature factor in the high temperature phase is qualitatively in accordance with the large value of the entropy of transition. In passing it may be added here that the studies of Raman and infrared spectra[18] of hexamethyldisilane revealed that the molecule in the liquid state has a D_{3h} or a D'_{3h} equilibrium configuration, excluding a D_{3d}-type.

Now, we shall infer from the entropy consideration what sorts of molecular motions will be excited on passing through the transition point from the ordered low-temperature phase to the plastic crystal phase. Referring to the results of X-ray and spectroscopic investigations mentioned above, the following model may be assumed reasonably. In the high temperature phase, the molecular orientation (motion 1) is randomly distributed among the four body-diagonals and the two kinds of internal rotation (motion 2, about Si–Si axis ; motion 3, about Si–C axis) combined with the overall molecular rotation about the molecular axis (motion 4) are fully excited, whereas the motions are highly hindered except for motion 3 in the low temperature phase though not so below the transition point[9]. Then each contribution from the enhancement of such a kind of motion to the entropy of transition can be estimated in terms of statistical mechanics. The contribution from the increase of the orientational freedom (motion 1) is $R \ln 4$ which amounts to 2.54 e. u. The contribution from motion 2 is calculable by use of Pitzer's table[19], assuming the symmetry number 3 and the potential barrier hindering the internal rotation in the low temperature phase 5.7 kcal./mol.[9] In this case, the moment of inertia is computed

** It may be noted that even in the plastic crystal phase a kind of self-diffusion process seems to occur (see Ref. 9).

using tetrahedral angle for ∠Si–Si–C and the interatomic distance of Si–C, 1.88 Å[20], and also assuming that the three rotating hydrogen atoms in methyl group lie at the position of the carbon atom. This contribution amounts approximately to 2.58 e. u. The sum of both entropies, 5.1 e. u., is only half of the observed entropy of transition, 10.5 e. u., so the remaining contribution from motion 4 seems to amount to nearly equal magnitude. Although the precise estimation of the latter is difficult at the present stage owing to the lack of knowledge about the crystal structure of the low temperature phase and also about the heights of the potential barrier hindering this motion in both phases, we assume tentatively that the rotation is fully excited in the high temperature phase whereas the motion is entirely fixed in the low temperature phase. Then the contribution can be calculated with the following equation

$$\Delta S = \boldsymbol{R}\left[\ln\frac{1}{\pi\sigma}\left(\frac{8\pi^3 I_m \boldsymbol{k} T}{\boldsymbol{h}^2}\right)^{1/2} + \frac{1}{2}\right]$$

where I_m is the moment of inertia about the molecular axis, and σ the symmetry number. The calculated value becomes 5.50 e. u. with the values of $T=222$°K and $\sigma=3$. Thus, the calculated total amount of these three entropies, 10.6 e. u., comes out to be nearly equal to the observed one, 10.5 e.u. Here it may be noticed that we have not completely ignored the overall rotational motions about the other two principal axes, since these motions were partly involved already in motion 1. Probably this fortuitous agreement arises from the situation that the over-estimated entropy value of motion 4 might be canceled by the under-estimaton of motion 1.

In conclusion, we may say that although our discussion on the mechanism of the phase transition in hexamethyldisilane from the point of view of entropy is of semi-quantitative nature, its main feature was explained by combining our thermodynamical study with those of the X-ray crystal analysis and the nuclear magnetic resonance.

Summary

Measurements of the heat capacity (200~300°K) and the vapor pressure (274~310°K) were carried out covering the transition and melting points of hexamethyldisilane. The following results were obtained; T_{tr} 221.8°K, ΔH(transition) 2330 cal./mol., ΔS(transition) 10.5 e. u.; T_f 287.7$_2$°K, ΔH(fusion) 721 cal./mol., ΔS (fusion) 2.51 e. u.; vapor pressure equations,

$$\log P(\text{mmHg}) = -2105.4/T + 8.5503 \quad (274.5\sim286.6\text{°K})$$

$$\log P(\text{mmHg}) = -1953.1/T + 8.0105 \quad (287.6\sim310.4\text{°K});$$

ΔH_{sub} 9640±25 cal./mol., ΔS_{sub} 26.0±0.17 e.u., $\Delta G°_{298.16}$(sub.) 1900±76 cal./mol.; ΔH_{vap} 8943±16 cal./mol., ΔS_{vap} 23.5±0.05 e. u., $\Delta G°_{298.16}$(vap.) 1940±31 cal./mol.

These data showed that the present crystal belongs to the class of plastic crystal. We have discussed the qualitative nature of the phase transition in the present crystal from the point of view of entropy, referring to the X-ray and the nuclear magnetic resonance studies. The remarkable "vapor snake" phenomenon was also observed on this material.

In conclusion, the authors wish to express their sincere thanks to Professor I. Nitta for his valuable advice and continued interest in the present study. The cost of this research has been defrayed from the Scientific Research Encouragement Grant from the Ministry of Education to which the authors' thanks are due.

*Stereoregular Polymers. I. Polymerization of Styrene by Triethylaluminum-Titanium Tetrachloride Catalysts**

By Shunsuke MURAHASHI, Shun'ichi NOZAKURA, Masao SUMI and Kōichi HATADA

(Received November 17, 1958)

Much information is now accumulating in regard to the isotactic polymerization of α-olefins. In particular, the reports of Natta and his collaborators[1] are very instructive about the mechanisms of stereospecific polymerization of propylene. These experiments, however, are mainly based on the heterogeneous catalysts composed of triethylaluminum ($AlEt_3$) and titanium trichloride ($TiCl_3$) (Natta's type). Catalysts derived from $AlEt_3$ and $TiCl_4$ (Ziegler's Type) have not been examined in detail mainly because of their poor reproducibility. Recently, Yamazaki has reported some aspects of polymerization of styrene with this type of catalysts[2].

The authors carried out the polymerization of styrene with the heterogeneous catalysts prepared from $AlEt_3$ and $TiCl_4$, and found that the stereospecificity of the catalysts varied very much with the method of preparation of catalytic mixtures.

The object of the present work is to investigate the relationship between property and stereospecificity of the catalysts.

Results and Discussion

Effect of Preparative Conditions of Triethylaluminum-Titanium Tetrachloride Catalysts upon the Stereospecificities of the Catalysts.— Even in the catalysts of the same ratio of $AlEt_3$ to $TiCl_4$ the stereospecificities of the catalytic mixtures varied intensively according to the method of mixing the two components. Some of the experimental data are listed in Table I.

When $AlEt_3$ and the monomer were charged before the introduction of $TiCl_4$, the stereospecificity was very low, and this is probably due to the cationic polymerization with $TiCl_4$. There was only a small difference between two kinds of catalysts that were prepared under the reverse orders of addition of $AlEt_3$ and $TiCl_4$. A very pronounced effect was observed when the catalysts were prepared with or without stirring. In some cases ultrasonic wave was applied in order to effect an efficient agitation. The catalyst that was prepared without stirring had an appearance of solid mass and was colored orange-brown. Such a catalyst yielded a high stereospecificity. When, on the other hand, the catalyst was prepared under mixing, it was a fine black powder and showed a poor stereospecificity. An explanation for this difference will be given later.

Influence of the Ratio of Triethylaluminum to Titanium Tetrachloride. — Preparation of catalysts and polymerization were carried out under stirring by magnetic stirrer. Yields of the atactic and the isotactic polystyrene polymerized on varying the ratios of $AlEt_3$ to $TiCl_4$ are shown in Fig. 1.

The yield of atactic polystyrene decreased rapidly up to the molar ratio (r) of unity and remained almost constant at

7	〃	Stirring	70	4	7.9	64
8	〃	Stirring and ultrasonic wave[b]	70	4	13.3	4.4

a) Stirring was carried out by a magnetic stirrer.
b) After mixing by a magnetic stirrer, ultrasonic wave (450 KC, ca. 2W./cm^2) was applied for about ten minutes.
c) The percentage fraction of extraction residue with hot methylethylketone in total polymer.

increasing ratios. On the other hand, the yield of isotactic polymer showed a small but gradual increase over the whole range examined.

The high content of atactic polymer that was formed in a condition $r<1$ may reasonably be ascribed to the existence of remaining $TiCl_4$. Furthermore, the appearance of a break on the atactic curve in Fig. 1 seems to indicate the disappearance of $TiCl_4$ and the appearance of another kind of catalyst which also promotes the atactic polymerization of styrene with minor activity, and this kind of catalyst may probably be soluble complex compounds containing titanium and aluminum.

Valency States of Titanium in Catalytic Mixtures.—The reaction between $AlEt_3$ and $TiCl_4$ may be considered to be analogous to that of Grignard's reagent on alkyl orthotitanate[3]. Therefore, the reaction scheme may be written in the following manner:

Alkylation (fast)

$$Et_3Al+TiCl_4\rightarrow EtTiCl_3+Et_2AlCl \quad (1)$$

$$Et_3Al+EtTiCl_3\rightarrow Et_2TiCl_2+Et_2AlCl \quad (2)$$

Decomposition (slow)

$$EtTiCl_3\rightarrow Et\cdot+TiCl_3 \quad (3)$$

$$Et_2TiCl_2\rightarrow 2Et\cdot+TiCl_2 \quad (4)$$

The alkylation reaction may be fast and the decomposition which yields titanium of lower valencies may be comparatively slow.

3) D. F. Herman, W. K. Nelson, *J. Am. Chem. Soc.*, 75, 3877,3882 (1952).

In order to elucidate the results obtained above, the distribution of the valency states of titanium in catalysts was examined. When $AlEt_3$ and $TiCl_4$ was mixed to produce a heterogeneous catalyst, a gas evolved. According to the gas chromatographic analysis, the gas consisted of a large portion of ethane and small portions of butane and hydrogen. Ethane might be derived from the disproportionation reaction of ethyl radical which occurred in reactions 3 and 4. Ethylene, which is another procuct of disproportionation, was not found. It probably had polymerized in this condition.

On the other hand, the gas, which evolved when the solid catalyst was decomposed by dilute sulfuric acid, was found to be composed mainly of ethane and hydrogen, a small amount of butane, and a trace of ethylene. Ethane might be derived from the hydrolysis of ethyl-metal bond in the catalyst mixture. Hydrogen can be assumed to evolve according to the following reaction[3]:

$$Ti^{2+}+H_2O\rightarrow Ti^{3+}+\frac{1}{2}H_2+OH^- \quad (5)$$

Therefore, the amount of hydrogen was measured volumetrically by absoption with colloidal palladium and one mole of hydrogen was assumed to be equivalent to two moles of divalent titanium. The total trivalent titanium in the hydrolyzate was then determined by redox titration with ceric sulfate. The results are given in Table II. As expected, the catalyst which was prepared in a condition $r=1$

TABLE II. VALENCY STATES OF TITANIUM IN SOLID CATALYSTS

The catalysts were prepared at 70°C in 15 ml. of *n*-heptane from 0.37 g. of $AlEt_3$ and the appropriate amount of $TiCl_4$.

$AlEt_3/TiCl_4$ molar ratio	Preparation of catalyst	Gas evolved		Ti(IV) %	Ti(III) %	Ti(II) %
		When catalyst was prepared, ml.	When catalyst was decomposed, ml.[c]			
1.09	Stirring[a]	41	65	2	98	0
2.44	Stirring[a]	30	116	0	35	65
2.74	Stirring[a]	30	113	0	23	77
2.51	Without stirring[b]	13	133	4	80	16

a) $TiCl_4$ and $AlEt_3$ were added in this order under stirring by a magnetic stirrer.
b) Catalyst components were added in the order of $AlEt_3$ and $TiCl_4$ without stirring.
c) Decomposition was carried out about half an hour after preparation of the catalyst, when evolution of gas had almost entirely ended.

TABLE III. POLYMERIZATION AFTER WASHING THE SOLID CATALYSTS

Styrene (5.00 ml.) was polymerized for 3.0 hr. at 70°C without stirring.

No.	Preparation of catalyst[a]			$AlEt_3$ added after washing, g.	Conversion, %	Insoluble part in M.E.K. %
	$TiCl_4$, g.	$AlEt_3$, g.	Temp., °C			
1	0.44	0.33	70	0.33	28.7	91
2[b]	0.45	0.33	b. p. of *n*-heptane	0.34	33.3	90
3	0.45	0.13	b. p. of xylene[c]	0.33	27.3	92
4	0.40	0.33	b. p. of *n*-heptane	0	79.4	Trace
5	0.23	0.33	b. p. of *n*-heptane	0	45.5	17
6[d]	0.44	0.32 0.32	b. p. of *n*-heptane	Without washing	32.7	86
7[e]	0.44	0.67	70	0.32	2.4	65

a) Generally heterogeneous catalysts were prepared in 15 ml. of *n*-heptane under stirring by a magnetic stirrer. $TiCl_4$ and $AlEt_3$ were added in this order.
b) Polymerization time was 3.2 hr.
c) Xylene wae used as solvent for preparing the catalyst. The catalyst was washed with *n*-heptane as usual, and then the polymerization was carried out in *n*-heptane.
d) $AlEt_3$ (0.32 g.) was added dropwise into the solution of $TiCl_4$ at the boiling temperature of *n*-heptane and the mixture was refluxed for ten minutes and kept for one hour at room temperature, and then the remaining half (0.32 g.) of $AlEt_3$ and monomer was added at 70°C.
e) The order of adding two components was reversed. Into 0.67 g. of $AlEt_3$ was added $TiCl_4$ rapidly under stirring at 70°C and the black, fine precipitate was washed with *n*-heptane and the polymerization was carried out as usual with the secondary addition of $AlEt_3$ and monomer.

contained a small amount of tetravalent titanium, which is responsible for a relatively large amount of atactic polymer. The catalyst, in which *r* is more than unity, was found to be mainly composed of divalent and trivalent titanium. The reduction of titanium over trivalent state does not seem to have a marked effect upon stereospecificity. In fact, the catalyst that was prepared without agitation, although it included a certain amount of tetravalent titanium and a large amount of trivalent titanium, showed a good stereospecificity and a good catalytic activity.

Influence of Washing the Solid Catalyst.—In order to remove the soluble catalysts which were considered to be responsible for the atactic polymerization, catalyst mixtures were washed with *n*-heptane by decantation and then polymerizations were carried out with or without addition

of further $AlEt_3$. Experimental data are summarized in Table III.

Without the secondary addition of $AlEt_3$ after washing only amorphous polystyrene was obtained, while with its addition the catalyst acquired a very high stereospecificity and also good catalytic activity. However, when $TiCl_4$ was reduced gradually by an equivalent amount of $AlEt_3$ and then an additional equivalent amount of $AlEt_3$ and styrene was added, a good result was obtained (Table III, No. 6).

The catalyst which was prepared by adding $TiCl_4$ to 2.5 times on molar base of $AlEt_3$ under stirring showed a very poor catalytic activity even after washing (Table III, No. 7).

The results seem to suggest the importance of the physical nature of solid catalyst. This subject will be discussed in detail in the later part of this paper.

Recently similar experiments were described in a patent publication where the catalyst was filtered through a glass filter and the effect of filtration was explained there to be due to the removal of the finely dispersed parts of the catalyst[4].

X-ray Study of Solid Catalysts.—The solid catalysts, which were prepared in similar manners to those of Tables I and II, were washed with *n*-heptane and sealed in a small ampoule with a thin wall (Fig. 2), and then exposed to X-ray. It was found in general that the more stereospecific and active catalyst showed the sharper diffraction pattern. X-ray photographs of the catalysts prepared under various conditions are shown in Fig. 3. In the case of the catalyst that was prepared by dropping $TiCl_4$ quickly into the solution

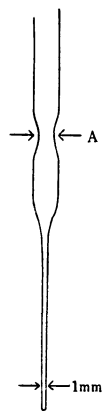

Fig. 2. A capillary ampoule for the X-ray study.

4) S. G. Montecatini and K. Ziegler, Irish Pat., 66,855 (1955).

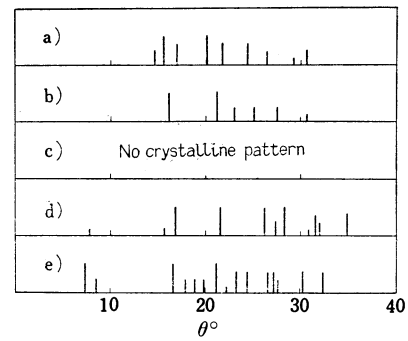

Fig. 3. X-ray powder patterns of catalytic masses (CuKα radiation).
a) $TiCl_4$ (1 mol. equivalent) was added into $AlEt_3$ (2.3 mol. equivalents) at 70°C without agitation.
b) $AlEt_3$ (1 mol. equivalents) was added to $TiCl_4$ 1 mol. equivalent) at 70°C under agitation.
c) $AlEt_3$ (2.3 mol. equivalents) was added quickly into $TiCl_4$ (1 mol. equivalent) at 70°C under agitation.
d) $TiCl_3$, the product of Stauffer Chem. Co.
e) $TiCl_2$[6].

of 2.5 mol. equivalents of $AlEt_3$ at 70°C under agitation, there was found no crystalline reflection but a diffuse halo. Such a catalyst had a poor stereospecificity and catalytic activity.

On the contrary, when either (a) 1 mol. equivalent of $TiCl_4$ was added into 2.4 mol. equivalents of $AlEt_3$ without agitation or (b) 1 mol. equivalent of $AlEt_3$ into the solution of 1 mol. equivalent of $TiCl_4$ under agitation, the solid mass showed moderately crystalline reflections. These reflections are rather diffuse as compared with that of commercial $TiCl_3$, indicating an imperfect growth of the crystals. The reflections coincide with neither that of $TiCl_3$[5] nor that of $TiCl_2$[6]. This fact might suggest the existence of some crystalline complex compound containing Al and Ti or another modification of $TiCl_3$ and $TiCl_2$[7].

The solid mass prepared by method a showed a good stereospecificity and catalytic activity. But in the case of the catalyst b, also good results were obtained

5) W. Klemm and E. Krose, *Z. anorg. u. allgem. Chem.*, **253**, 218 (1947).
6) M. Farber, A. J. Darnell and F. Brown, *J. Chem. Phys.*, **23**, 1556 (1955).
7) F. Böck and L. Moser, *Monatsch.*, **34**, 1825 (1913). The existence of two modifications of $TiCl_3$ was first suggested by Böck and Moser in the study of the heat of solution. Two kinds of $TiCl_3$ were described by them to be violet colored and brown. The violet is the one that is obtaind by reduction of $TiCl_4$ at high temperture and is now available commercially.

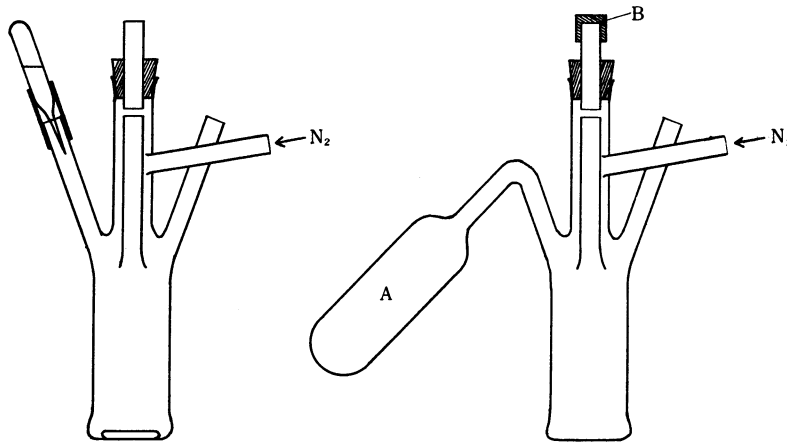

Fig. 4. Vessels for the polymerization.

by washing with *n*-heptane. (Table III, No. 1—3). Although both the catalysts (a and b) gave the crystalline patterns, they showed some differences in details of X-ray diagram. Further study of this point would be necessary, but was not pursued.

Conclusion

Titanium tetrachloride, ethylaluminum chlorides, soluble aluminum-titanium complex compounds, and amorphous insoluble solid are conceivable for the formation of atactic polymer. Titanium tetrachloride is the one that remained unreacted when the molar ratio of $AlEt_3$ to $TiCl_4$ did not exceed unity. The others are considered to be formed by the reaction between $AlEt_3$ and $TiCl_4$. Although the first three can be removed by washing with *n*-heptane, the last one can not.

The content of the crystalline component in solid mass depends upon the condition of reaction between $AlEt_3$ and $TiCl_4$. If the alkylation of $TiCl_4$ proceeded beyond the stage of $EtTiCl_3$ (or Et_2TiCl_2), the sufficient growth of the crystallites of the compound containing $TiCl_3$ (or $TiCl_2$) could not be expected. Moreover, it is a factor to be considered that some amorphous titanium compound would be produced if the alkylation of the unstable compound containing titanium chlorides occurred preferentially before the sufficient growth of crystallites was permitted.

In order to prepare a crystalline catalytic mass, therefore, it is preferable to use $AlEt_3$ in an amount not more than an equivalent of $TiCl_4$. As shown in the experiments, it may be a convenient method for obtaining a crystalline catalytic mass to combine the solutions of two reactants without agitation.

It is noteworthy that the crystalline component of the effective solid catalyst is neither $TiCl_3$ nor $TiCl_2$, and is probably some complex compound containing Al and Ti or the other modification of $TiCl_3$ (or $TiCl_2$). The fact seems to be one of the important differences between catalysts of Ziegler's type (i. e., $AlEt_3$ and $TiCl_4$) and Natta's type (i. e., $AlEt_3$ and $TiCl_3$).

Experimental

Meterials. — Commercial styrene was washed with 10% solution of sodium hydroxide and water, dried over calcium chloride, and distilled in a nitrogen stream before use[8].

n-Heptane was shaken with fuming sulfuric acid, washed with water and dilute alkali, dried over calcium chloride, distilled and stored over sodium chips.

$AlEt_3$ was the product of Mitsui Chem. Ind. Co. and was used as 30% solution in *n*-heptane. Concentration was checked by the amount of ethane evolved when the solution was hydrolyzed.

$TiCl_4$ was the product of Osaka Titanium Co. and used as 21% solution in *n*-heptane. The concentration was checked by determining titanium by redox titration with ceric solution after reduction with zinc amalgam.

Polymerization.—The polymerization vessel is shown in Fig. 4a. *n*-Heptane was placed in the vessel of about 100 ml. capacity and the ampoules of monomer, $TiCl_4$, $AlEt_3$, and a thermometer if necessary were mounted on it through rubber tubings. The air in the apparatus was replaced by dry nitrogen by repeated evacuation and introduction of nitrogen. Then the lower half

8) E. R. Blout and H. Mark, "Monomers", Interscience Publishers, Inc., New York (1949).

of the apparatus was immersed in the thermostat and the contents of the ampoules were dropped in by breaking the top of the ampoule which was previously scratched at the capillar part in order to ease the breaking.

Polymerization was stopped by the introduction of 2 ml. of methanol and 0.3 ml. of concentrated hydrochloric acid and then all the contents were poured onto a large amount of methanol. After standing overnight, the polymer was collected and washed with methanol, and dried.

If the washing of the solid catalyst with *n*-heptane was needed the vessel shown in Fig. 4b was used. The supernatant liquid was decanted into the side flask (A) and 15 ml. of *n*-heptane was injected through a silicone rubber cap (B). The decantation and the injection were repeated three times. The ampoule of $AlEt_3$ now emptied was exchanged with another one in the stream of nitrogen and charged, and then the monomer was dropped in.

Extraction of the Atactic Polymer from the Crude Polymer.—About 0.4 g. of polymer was refluxed with 40 ml. of methylethylketone for several hours. After standing overnight at room temperature, the remaining isotactic polymer was collected, washed with methylethylketone, dried in vacuo at 100°C.

Valency States of Titanium in Catalytic Mixtures.—A gas buret was connected to the reaction vessel of Fig. 4a and an ampoule containing 8 ml. of 10% sulfuric acid was mounted in place of styrene. After the mixing of the catalyst components, 30 to 40 min. was required for almost complete evolution of gas. The reaction vessel was cooled to 0°C and the gas in the vessel was replaced by nitrogen by repeated evacuation and filling. Then the catalyst mixture was hydrolyzed by dropping the aqueous sulfuric acid and the amount of the gas evolved was measured by the gas buret.

An aliquot of the mixed gas was analyzed for hydrogen using colloidal palladium as absorbent.

The hydrolyzed aqueous layer was separated from the organic layer in an atmosphere of carbon dioxide and analyzed for Ti(III) by titration with ceric standard solution using diphenylamine as an indicator. The amount of Ti(III) thus measured was taken as the sum of Ti(II) and Ti(III) in the catalyst mixture. Some of the results are given in Table III.

X-ray Study of Solid Catalyst—The solid catalytic mass was washed with *n*-heptane by decantation, and the slurry of catalyst was brought into a small thin-walled ampoule made of Terex glass (Fig. 2). All the operations were carried out in a nitrogen atmosphere. The ampoule was sealed at A. The solid powder was packed down to the bottom by a centrifuge and exposed to X-ray.

Summary

Styrene was polymerized by the heterogeneous catalysts of Ziegler's type which were prepared under various conditions. The important factors which have pronounced effects on the stereospecificity and the catalytic activity of the mixture are concluded to be the existence of the remaining titanium tetrachloride, ethylaluminum chlorides and some soluble aluminum-titanium complex compounds, and the crystalline nature of the solid catalytic mass. The first three are considered to be responsible for the atactic polymerization of styrene and can be removed by washing with *n*-heptane. The crystallinity of the solid catalyst seems to be necessary for its high stereospecificity and catalytic activity.

The solid catalyst was examined by X-ray. It was found that the crystalline component of the catalyst did not correspond to $TiCl_3$ or $TiCl_2$, and thus it was suggested that some crystalline complex compounds containing Al and Ti or some other modifications of $TiCl_3$ (or $TiCl_2$) would be responsible for the effective catalytic component of Ziegler catalyst. The authors also suggested that the fact might be one of the important differences between the heterogeneous catalysts of Ziegler's type and Natta's type.

The authors wish to thank Mitsui Chem. Ind. Co. for the generous supply of triethylaluminum and Osaka Titanium Co. for titanium tetrachloride. We are also very grateful to Mr. Y. Chatani of Nitta Laboratory who helped us in the experiment of X-ray.

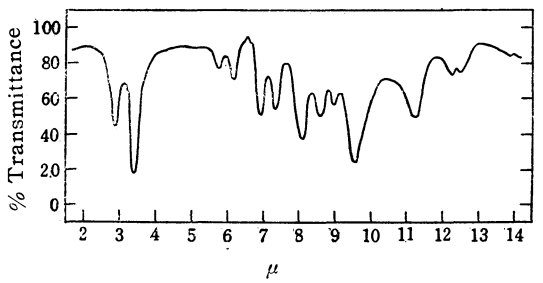
Derivatives of 1,8(9)-p-Menthadien-10-yl-carbinol

By Kyoichi SUGA and Shoji WATANABE

(Received February 10, 1959)

In the previous paper[1], the preparation of a limonenylcarbinol and the determination of its structure as 1,8(9)-*p*-menthadien-10-yl-carbinol (I) were reported. The present paper describes various derivatives of the limonenylcarbinol.

When a mixture of I and paraformaldehyde was heated at 130~150°C for several hours, a pale yellow viscous oil was obtained. Analysis ($C_{12}H_{20}O_2$) and the molecular weight (192) indicated that the product was an adduct of one mole of formaldehyde to I. The presence of a primary hydroxyl group was proved by a qualitative analysis and an infrared absorption spectrum (9.6 μ). Quantitative acetylation with pyridine and acetic anhydride[2] showed that it was a monohydric alcohol. The infrared absorption spectrum showed characteristic absorption bands of the acetal type at 8.05, 8.6 and 9.0 μ (Fig. 1). From the above results, it was concluded that the structure of the substance is formaldehyde mono-1,8(9)-*p*-menthadien-10-yl-carbinyl acetal (II).



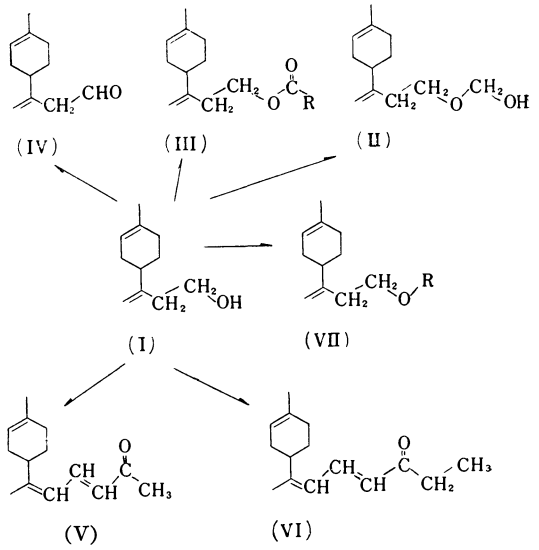


Fig. 1. Infrared absorption spectrum of II.

Various esters (III) were prepared from I. The monoesters of maleic acid, phthalic acid and succinic acid were prepared. The sodium salt of the acid maleate shows remarkable surface activity, and the foaming force is equal to that of the cetylsulfate (Table I). By the action of palmitoyl chloride, capryloyl chloride, isovaleryl chloride, phenylacetyl chloride and cinnamoyl chloride, I gave the esters of the corresponding acids (Table II). The caprylate and the phenylacetate are fragrant.

TABLE I. THE FOAMING FORCE OF SODIUM LIMONENYLCARBINYL MALEATE

%	Numbers of foams after (min.) 2	5	Quantities of foams after (min.) 2	5
Na limonenylcarbinyl maleate				
0.50	25.5	13.8	216	184
0.25	19.8	12.3	195	173
0.10	14.0	10.0	114	90
Na laurylsulfate (SO_3: 27.2%)				
0.24	7.4	2.2	857	852
0.15	8.4	2.7	758	753
Na cetylsulfate (SO_3: 22.1%)				
0.30	24.8	16.2	265	256
0.15	19.8	13.4	180	173

By the action of chromic anhydride in glacial acetic acid, a limonenylformaldehyde, 3-(4-methyl-3-cyclohexen-1-yl)-3-buten-1-al (IV) was obtained. Its odor is more fragrant than that of I. It gives positive reactions with Schiff's reagent and Tollen's reagent. The composition was confirmed from those of the 2,4-dinitrophenylhydrazone and semicarbazone.

TABLE III. LIMONENYLCARBINYL ETHERS

	Boiling point °C/mmHg	Refractive index	Specific gravity	Molecular refraction Found	Calcd.	Yield %
Methyl	85~86/12	n_D^{25} 1.4870	$d_4^{24.5}$ 0.9317	55.39	52.61	80
Ethyl	96~97/4~5	n_D^{23} 1.4921	d_4^{23} 0.9353	59.98	59.64	90
Allyl	115~118/17	n_D^{23} 1.4927	$d_4^{24.5}$ 0.9293	64.26	63.79	80
Benzyl	175~179/10	n_D^{23} 1.5300	d_4^{23} 0.9885	80.17	79.13	90

Action of a large excess of acetone and aluminum isopropoxide on I gave a limonenylmethyleneacetone, as a viscous oil with burning odor. The structure of 6-(4-methyl-3-cyclohexen-1-yl)-3,5-heptadien-2-one(V) was demonstrated as follows: The substance gave a 2,4-dinitrophenylhydrazone and a positive iodoform reaction, which showed that it was a methyl ketone. The major absorption peaks at 295 and 223 mμ in the ultraviolet spectrum (Fig. 2) suggested the presence of a conjugated dienone grouping.

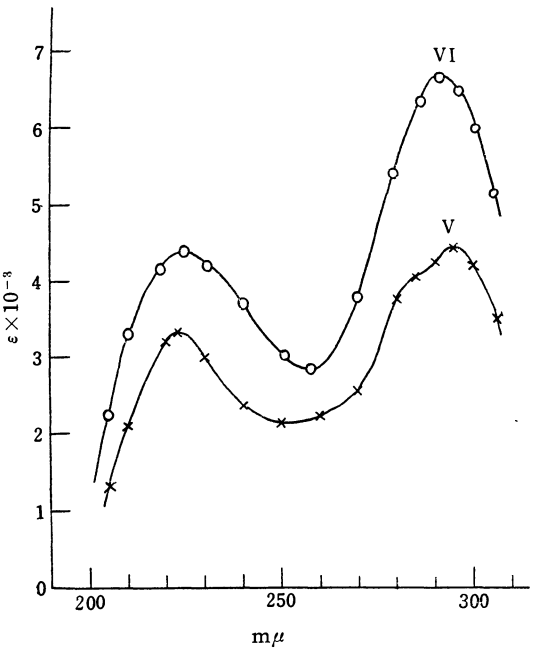

Fig. 2. Ultraviolet absorption spectra of V and VI.

Similarly, 7-(4-methyl-3-cyclohexen-1-yl)-4,6-octadien-3-one(VI) was prepared from I and methyl ethyl ketone. It is more viscous than V and also possesses a burning odor. The composition was confirmed by an elementary analysis of its 2,4-dinitrophenylhydrazone. It showed absorption peaks at 291 and 225 mμ (Fig. 2) corresponding to the conjugated dienone structure(VI). The iodoform reaction was negative.

Some ethers of I were also prepared. I was converted into the sodium compound by the action of sodamide in benzene. The ethyl limonenylcarbinyl ether VII ($R=C_2H_5$) was obtained in a yield of 90% from ethyl bromide and the sodium compound. Its ethoxyl radical was detected by Zeisel's method[3]. Similarly, methyl, ethyl, benzyl and allyl ethers were prepared (Table III).

Experimental

1,8(9)-*p*-Menthadien-10-yl-carbinol(I). — Prepared from *d*-limonene and paraformaldehyde as reported previously[1]: b. p. 102~106°C/4 mm.; d_4^{17} 0.9603; n_D^{17} 1.5020; $[\alpha]_D^{10}$+37.2; phenylurethan, m. p. 56~57°C.

Formaldehyde Mono-1,8(9)-*p*-menthadien-10-yl-carbinyl Acetal.—In a glass tube, 4 g. of I and 0.8 g. of paraformaldehyde were sealed and heated

3) R. L. Shriner, R. C. Fuson and D. Y. Curtin, "The Systematic Identification of Organic Compounds", 4th Ed., John Wiley & Sons, Inc., New York; Maruzen Co., Ltd., Tokyo (1956), p. 116.

at 150~170°C for 6 hr. By fractional distillation, 1.5 g. of II was given: b. p. 155~162°C/5 mm.; $n_D^{20.5}$ 1.5066; $d_4^{20.5}$ 1.0306; molecular refraction 56.64 (calcd. for $C_{11}H_{17}OCH_2OH$: F_2, 57.65); hydroxyl group, 6.03% (calcd. for monohydric alcohol, 8.68%); molecular weight, 192 (calcd. for $C_{12}H_{20}O_2$: 196.2).

Anal. Found: C, 72.17; H, 9.41. Calcd. for $C_{12}H_{20}O_2$: C, 73.40; H, 10.27%.

The Limonenylcarbinyl Monoesters of Dibasic Acids.—*1,8(9)-p-Menthadien-10-yl-carbinyl hydrogen maleate.*—A mixture of 2 g. maleic anhydride and 2 g. of I was heated at 100°C for 3 hr. The reaction mixture was thoroughly washed with water of 60°C, dried in vacuo, and 3 g. of a pale yellow monoester was obtained, n_D^{12} 1.4921. Molecular weight, 264.25[4] (calcd. for $C_{15}H_{20}O_4$: 264.2). The silver salt was prepared by adding silver nitrate solution to the sodium salt of the acid maleate.

Anal. Found: Ag, 29.75; Calcd. for $C_{15}H_{19}O_4Ag$: Ag, 29.08%.

The foaming force of the sodium salt solution was measured by Nakajima's method[5] (Table I).

Acid phthalate and acid succinate of I.—They were prepared similarly.

The Limonenylcarbinyl Esters of Monobasic Acids. — *1, 8(9)-p-Menthadien-10-yl-carbinyl palmitate.*—To a mixture of 1.5 g. of I and 20 cc. of anhydrous ether, a dry ethereal solution of 3.0 g. of palmitoyl chloride was added with stirring. The reaction mixture was left overnight at room temperature. The crude palmitate was extracted with ether and the extract was washed three times with 30% aqueous methanolic solution containing 5% potassium hydroxide, and several times with water, and dried over anhydrous sodium sulfate. The crude palmitate, obtained by evaporation of the solvent, was chromatographed on active alumina and the pale yellow part in the middle of the chromatogram was eluted with methanol. By removing the methanol, 2.0 g. of the palmitate was obtained.

Caprylate, phenylacetate and cinnamate.—They were prepared similarly (Table II).

3-(4-Methyl-3-cyclohexen-1-yl)-3-buten-1-al (IV).—To a mixture of 4 g. of chromic anhydride, 5 cc. of water and 100 cc. of glacial acetic acid, a mixture of 9 g. of I, 30 cc. of acetone and 20 cc. of glacial acetic acid was added in 25 min. at 50~55°C with vigorous agitation, and the mixture was stirred for 4.5 hr. Then this was poured into a large amount of water and extracted with ether. The extracts were washed with water and dried over anhydrous sodium sulfate. By fractional distillation, 3.5 g. of IV was obtained: b. p. 88°C/4 mm.; n_D^8 1.5045. It gave a positive reaction with Schiff's reagent and reduced an ammoniacal silver nitrate solution.

2, 4-Dinitrophenylhydrazone.—It was prepared as usual and recrystallized twice from a mixture of pyridine and methanol. Fine red crystals, m. p. higher than 220°C.

Anal. Found: N, 16.14. Calcd. for $C_{17}H_{20}O_4N_4$: N, 16.27%.

Semicarbazone.—A mixture of IV, semicarbazide hydrochloride, sodium acetate and methanol was allowed to stand for about a month, and the crystals produced were collected and recrystallized twice from methanol. Colorless needles, m. p. 192°C.

Anal. Found: N, 18.35. Calcd. for $C_{12}H_{19}ON_3$: N, 18.98%.

6-(4-Methyl-3-cyclohexen-1-yl)-3, 5-heptadien-2-one (V).—A mixture of 5 g. of I, 18.5 g. of aluminum isopropoxide, 150 g. of refined acetone and 150 g. of anhydrous benzene was refluxed for 40 hr. Then 300 g. of benzene was added to the reaction mixture, and the benzene solution was separated, washed with 30% sulfuric acid three times and with water several times, and dried over anhydrous sodium sulfate. After benzene was evaporated, 1.0 g. of V was obtained by fractional distillation: b. p. 125~133°C/3 mm.; n_D^{10} 1.5271; λ_{max} 295 mμ, ε 4480; λ_{max} 223 mμ, ε 3340. The substance gave a positive iodoform reaction.

2, 4-Dinitrophenylhydrazone.—This was prepared as usual and recrystallized from ethylacetate. Red needles, m. p. 179~180°C.

Anal. Found: N, 14.50. Calcd. for $C_{20}H_{24}O_4N_4$: N, 14.50%.

7-(4-Methyl-3-cyclohexen-1-yl)-4, 6-octadien-3-one (VI).—A mixture of 7 g. of I, 24 g. of aluminum isopropoxide, 200 g. of refined methyl ethyl ketone and 200 g. of dry benzene was refluxed for 60 hr. It was poured into 30% sulfuric acid and extracted with ether. The extracts were washed with water and dried over anhydrous sodium sulfate. By fractional distillation, 2.0g. of VI was obtained: b. p. 125~132°C/2 mm.; n_D^{23} 1.4806; λ_{max} 291 mμ, ε 6650; λ_{max} 225 mμ, ε 4340. It did not give a positive iodoform reaction.

2, 4-Dinitrophenylhydrazone.—This was prepared as usual and recrystallized twice from a mixture of ethyl acetate and ethanol. Red needles, m. p. 203°C.

Anal. Found: N, 14.11. Calcd. for $C_{21}H_{26}N_4O_4$; N, 13.99%.

The Ethers of the Limonenylcarbinol (VII).—*Ethyl 1, 8(9)-p-menthadien-10-yl-carbinyl ether* (R=C_2H_5).—To a benzene solution (100 cc.) of 4.3 g. of sodamide, 12.4 g. of I was added gradually at 60~65°C with vigorous agitation. When ammonia gas was no more generated, 13.3 g. of ethyl bromide was added in drops and the mixture was stirred for three hours. After leaving it overnight, the benzene solution was washed with water, and dried over anhydrous sodium sulfate. By fractional distillation 13.1 g. of VII was given.

Anal. Found: C, 80.04; H, 11.61. Calcd. for $C_{13}H_{22}O$: C, 80.34; H, 11.41%.

The ethoxyl radical was detected by Zeisel's method.

Methyl, benzyl and allyl ethers.—These were prepared similarly.

Absorption Spectra. — Infrared absorption spectra were measured by using a Perkin-Elmer spectrophotometer and ultraviolet absorption

4) It was measured by using 0.3971 N sodium hydroxide solution.

5) H. Nakajima, *J. Chem. Soc. Japan, Ind. Chem. Sec.* (*Kogyo Kagaku Zasshi*), **56**, 611 (1953).

spectra by a "Shimadzu" photometric spectrophotometer Type QB-50 using isopropyl alcohol as a solvent.

Modified Bond Eigenfunction Method of Constructing Potential Energy Surface of Reaction. I. Theory and General Remarks

By Iwao YASUMORI

(Received February 28, 1959)

In order to evaluate the chemical reaction rates theoretically, it is necessary to know the detailed feature of the interaction potential between the reacting species, i. e., the potential energy surfaces of the reaction. These surfaces are formed, in principle, from the eigenvalues of the wave equation for all electrons in the system at all orientations of atomic nuclei. Because of mathematical difficulties, however, which are the same as those in the calculation of "molecular energy", it is extremely difficult to construct the surface with the required accuracy, e. g., 0.1 kcal.

This situation of the problem has been a main cause of the fact that there is no available method for this purpose except Eyring's semi-empirical one[1] which is based on London's formula. Also it has been frequently pointed out by several investigators[2] that this approximate procedure contains many inadequacies, for instance, neglect of non-orthogonality between the orbitals of different atoms, introduction of *s*-electron approximation disregarding the direction of valence and the arbitrary choice of coulombic fraction ρ, etc. Nevertheless, this method has the distinctive character of giving an interpolation formula utilizing the experimental bond energies of component species.

Based on the idea of making use of the observed data for the component species, Moffitt[3] recently developed the "atoms-in-molecules" method in the field of "molecular theory" and succeeded in improving the calculated energy values for oxygen, ethylene, allyl radical, etc. If we regard the reacting system as a "complex molecule" and take molecular species as components, instead of atoms in Moffitt's method, it is possible to develop the corresponding "molecules-in-molecules" or "modified bond eigenfunction" method of constructing potential energy surfaces[4].

According to this idea, the author presents an improved method which stands on a firm basis and has wider applicability. The outline of the method and remarks on its application are given in this paper. The practical application and the inspection of the availability of the method will be made in relation to the hydrogen atom-molecule reaction in the following paper[5].

Theory

Elementary chemical reaction

$$A_1+B_1 \rightarrow A_2+A_2$$

is here considered, where A_1, B_1, A_2 and B_2 denote component molecular species. The potential energy surfaces of this reaction are constructed by the eigenvalues E of the wave equation for all n electrons,

$$\boldsymbol{H}\Psi(1,2,\cdots,n)=E(R_1,R_2,\cdots,R_N)\Psi(1,2\cdots,n) \quad (1)$$

2) H. M. James and A. S. Coolidge, *J. Chem. Phys.*, **1**, 825 (1933).

3) W. Moffitt, *Proc. Roy. Soc.*, **A210**, 224, 245 (1951); ibid., **A218**, 464, 486 (1953).

4) Also this idea has been independently found by Dr. P. Lykos, Argonne National Laboratory, U. S. A., private communication.

5) This series of papers contains the detailed account of the communication which was presented in *J. Chem. Phys.*, **23**, 1566 (1955).

at every set of fixed orientation of all N nuclei, $R_1, R_2, \cdots R_N$ in the system. Total Hamiltonian $\boldsymbol{H}$ has the usual form as

$$\boldsymbol{H}=-\sum_i \frac{1}{2}\Delta_i+\sum_{i>j}\frac{1}{r_{ij}}+\sum_{p>q}\frac{Z_pZ_q}{R_{pq}}-\sum_p\sum_i\frac{Z_p}{r_{pi}} \tag{2}$$

where p, q, and i, j, denote atomic nuclei and electrons, respectively; Z, nuclear charge, R and r, mutual distances between nuclei and electrons, respectively.

It is almost impossible to solve this equation in general; we must, therefore, be contented with merely some approximate solution. Now, when the distances between each species in the system become infinitely large, the wave function will have the following asymptotic form for any set of reactant or of any product, i. e., A_m+B_m, A_n+B_n, $\cdots$,

$$\Psi=\boldsymbol{A}\phi_{A_m^\mu}\cdot\phi_{B_m^\nu} \tag{3}$$

or

$$\Psi=\boldsymbol{A}\phi_{A_n^{\mu'}}\cdot\phi_{B_n^{\nu'}} \tag{3'}$$

$\phi_{A_m^\mu}$ and $\phi_{B_m^\nu}$ are the exact eigenfunctions of species A_m and B_m in the states μ and ν, respectively, and satisfy the equations

$$\boldsymbol{H}_{A_m}\phi_{A_m^\mu}=E_{A_m^\mu}\phi_{A_m^\mu} \tag{4}$$

and

$$\boldsymbol{H}_{B_m}\phi_{B_m^\nu}=E_{B_m^\nu}\phi_{B_m^\nu} \tag{4'}$$

where $\boldsymbol{H}_{A_m}$ and $\boldsymbol{H}_{B_m}$ are partial Hamiltonians for A_m and B_m, respectively, having the form of

$$\boldsymbol{H}_{A_m}=-\frac{1}{2}\sum_i\Delta_i+\sum_{i>j}\frac{1}{r_{ij}}+\sum_{p>q}\frac{Z_pZ_q}{R_{pq}}-\sum_p\sum_i\frac{Z_p}{r_{pi}} \tag{5}$$

and

$$\boldsymbol{H}_{B_m}=-\frac{1}{2}\sum_k\Delta_k+\sum_{k>l}\frac{1}{r_{kl}}+\sum_{r>s}\frac{Z_rZ_s}{R_{rs}}-\sum_s\sum_k\frac{Z_s}{r_{sk}} \tag{5'}$$

The nuclei p, q, and electrons i, j, belong to A_m and the nuclei r, s, and electrons k, l, to B_m. Also the eigenvalues $E_{A_m^\mu}$ and $E_{B_m^\nu}$ are those for the states of species, respectively. $\boldsymbol{A}$ in Eq. 3 is an antisymmetrizer[3] which makes the product functions $\phi_{A_m^\mu}\cdot\phi_{B_m^\nu}$ totally antisymmetrical for the exchange between any pair of electrons in the system, and has the form

$$\boldsymbol{A}=\{n!/n_A!\cdot n_B!\}^{1/2}\sum_t P_tv_t \tag{6}$$

where n_A, n_B and n are the numbers of electrons in A_m, B_m and their total respectively, P_t is any operator for inter-species exchange of electrons and $v_t=\pm1$ according to whether P_t gives an even or odd permutation.

Corresponding to all sets of species in their respective electronic states, $A_m^\mu+B_m^\nu$ $(m, \mu, \nu=1, 2, \cdots)$, we take the "composite functions" defined by

$$\phi_{m\mu\nu}=\boldsymbol{A}\phi_{A_m^\mu}\cdot\phi_{B_m^\nu} \tag{7}$$

and we assume that the total wave function is constructed approximately from these sets of composite functions,

$$\Psi=\sum_{m,\mu,\nu}C_{m\mu\nu}\cdot\phi_{m\mu\nu} \tag{8}$$

The eigenvalues $E(R_1, R_2, \cdots, R_N)$ for each orientation of nuclei are given by

$$E=\int\bar{\Psi}\boldsymbol{H}\Psi\,\mathrm{d}\tau\Big/\int\bar{\Psi}\Psi\,\mathrm{d}\tau \tag{9}$$

When the usual variation method is adopted, the above relations are converted into the secular determinant,

$$\mathrm{Det.}\,|H_{m\mu\nu,n\mu'\nu'}-ES_{m\mu\nu,n\mu'\nu'}|=0 \tag{10}$$

where

$$H_{m\mu\nu,n\mu'\nu'}=\int\bar{\phi}_{m\mu\nu}\boldsymbol{H}\phi_{n\mu'\nu'}\,\mathrm{d}\tau \tag{11}$$

and

$$S_{m\mu\nu,n\mu'\nu'}=\int\bar{\phi}_{m\mu\nu}\phi_{n\mu'\nu'}\,\mathrm{d}\tau \tag{12}$$

Moreover, when we take an assumption of neglecting the contribution of spin angular momentum to the energy, the whole electronic state is classified with their total spin S and its component S_z values and the determinant is factorized into several smaller ones in which all the elements of H and S are those for the same electronic states $\kappa(S, S_z)$'s,

$$\mathrm{Det.}\,|H^\kappa_{m\mu\nu,n\mu'\nu'}-E^\kappa S^\kappa_{m\mu\nu,n\mu'\nu'}|=0 \qquad \kappa=1, 2, \cdots \tag{13}$$

Next, let us divide the total Hamiltonian into the partial Hamiltonians $\boldsymbol{H}_{A_n}+\boldsymbol{H}_{B_n}$ for the composite species A_n+B_n and the remaining interaction term $\boldsymbol{I}_n$, that is,

$$\boldsymbol{H}=\boldsymbol{H}_{A_n}+\boldsymbol{H}_{B_n}+\boldsymbol{I}_n \tag{14}$$

where

$$\boldsymbol{I}_n=\sum_i\sum_k\frac{1}{r_{ik}}+\sum_p\sum_s\frac{Z_pZ_s}{R_{ps}}-\sum_p\sum_k\frac{Z_p}{r_{pk}}-\sum_s\sum_i\frac{Z_s}{r_{si}} \tag{15}$$

the nuclei p's and electrons i's belong to A_n and the nuclei s's and electrons k's to B_n. $\boldsymbol{H}_{A_n}$ and $\boldsymbol{H}_{B_n}$ have forms similar to $\boldsymbol{H}_{A_m}$ and $\boldsymbol{H}_{B_m}$, Eqs. 5 and 5'. Accordingly, $H^\kappa_{m\mu\nu,n\mu'\nu'}$ is rewritten as

$$H^{\kappa}_{m\mu\nu,\, n\mu'\nu'} = (E_{A^{\mu'}_n} + E_{B^{\nu'}_n})\, S^{\kappa}_{m\mu\nu,\, n\mu'\nu'} + I^{\kappa}_{m\mu\nu,\, n\mu'\nu'} \quad (16)$$

where

$$I^{\kappa}_{m\mu\nu,\, n\mu'\nu'} = \int \bar{\psi}_{m\mu\nu} \boldsymbol{I}_n \psi_{n\mu'\nu'} \mathrm{d}\tau \quad (17)$$

The number of bonds which take part in the reaction is usually one or two in each species and if we take an energy scale in which the bond energy of the composite state $A^{\mu'}_n + B^{\nu'}_n$, $\varepsilon_{n\mu'\nu'}$ is measured from the state where all these "reacting bonds" break down and the species A_n and B_n are separated into several fragments (radicals), then the eigenvalues for the composite state is described as a sum of "fragment-state energy" $E_{n\mu'\nu'}$ and "bond energy" $\varepsilon_{n\mu'\nu'}$

$$E_{A^{\mu'}_n} + E_{B^{\nu'}_n} = E_{n\mu'\nu'} + \varepsilon_{n\mu'\nu'} \quad (18)$$

Further, we take conveniently one of these "fragment-states" as a standard state and define its energy, E^{κ}_0. For this standard, the energies of the whole system E and of any composite state which belongs to the same $\kappa(S, S_z)$, $E_{A^{\mu'}_n} + E_{B^{\nu'}_n}$, are rewritten as follows:

$$E^{\kappa} = E^{\kappa}_0 + \varepsilon^{\kappa} \quad (19)$$

and

$$E_{A^{\mu'}_n} + E_{B^{\nu'}_n} = E^{\kappa}_0 + \varepsilon^{\kappa}_{n\mu'\nu'} = E^{\kappa}_0 + (\varepsilon_{A^{\mu'}_n} + \varepsilon_{B^{\nu'}_n}) \quad (20)$$

ε^{κ}, $\varepsilon^{\kappa}_{n\mu'\nu'}$, $\varepsilon_{A^{\mu'}_n}$ and $\varepsilon_{B^{\nu'}_n}$ in Eqs. 19 and 20 are respective "bond energies" of the system, of the composite state and of the species A_n and B_n newly measured from the level E_0. Substituting Eqs. 16, 19 and 20 into 10,

$$\mathrm{Det.}\,|I^{\kappa}_{m\mu\nu,\, n\mu'\nu'} + (\varepsilon^{\kappa}_{n\mu'\nu'} - \varepsilon^{\kappa}) S_{m\mu\nu,\, n\mu'\nu'}| = 0 \quad (21)$$

is obtained finally. Since $\varepsilon_{A^{\mu'}_n}$ and $\varepsilon_{B^{\nu'}_n}$ in Eq. 20 are bond energies[6] for molecules, we can frequently utilize their observed values[7]. The remaining unknown quantities, $S_{m\mu\nu,\, n\mu'\nu'}$ and $I_{m\mu\nu,\, n\mu'\nu'}$ can be evaluated, in principle, if we know the exact forms of the composite functions. Unfortunately, this is not the case except for a few states of hydrogen molecule and also the direct use of the function in exact form for the present purpose is unsuitable because of complicated calculations. Therefore, we may use their values calculated by the use of approximate composite functions with a simple analytic form[8].

Some Limitations for the Composite Functions

According to the above considerations the reactions proceed "adiabatically" on each surface. It is expected that this adiabatic condition brings some limitations on the character of states (wave functions) of species to be combined. Furthermore, when the reacting system has some symmetrical configurations during the reaction, the limitations become finer. This correlation between limited states of species was recently studied by Shuler and Laidler for the polyatomic system by the use of spin and orbital correlation rules[9,10].

Their conclusion shows that three or four atomic systems lie frequently on a

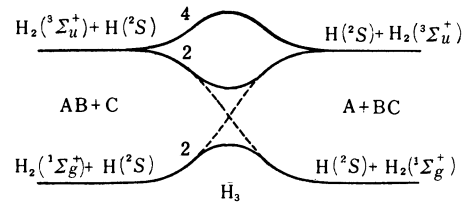

Fig. 1a. Lower potential energy surfaces of H-H-H system.

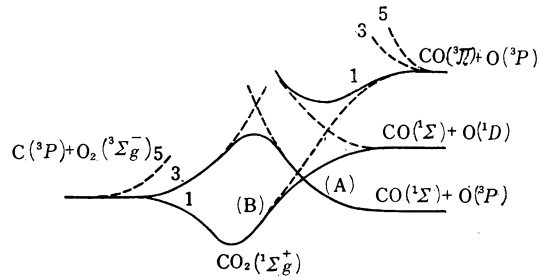

Fig. 1b. Lower potential energy surfaces of C-O-O system.

6) Here, the definition of "bond energy" is used also for the energy of the repulsive state of a molecule.

7) For example, when A_n is a diatomic molecule, some of its bond energies are given as functions of nuclear distance based on the spectroscopic data. (Morse function etc.)

8) The matrix, $\boldsymbol{H} = \boldsymbol{I} + \boldsymbol{ES}$, is not always Hermitian in this case. In order to avoid this theoretial defect, adoption of approximation for the elements such as

$$\bar{H}_{m\mu\nu,\, n\mu'\nu'} = \bar{H}_{n\mu'\nu',\, m\mu\nu} = \frac{1}{2}[H_{m\mu\nu,\, n\mu'\nu'} + H_{n\mu'\nu',\, m\mu\nu}]$$

may be required. Similar cosideration also has been given by Moffitt. See Ref. 3.

9) K. E. Shuler, *J. Chem. Phys.*, **21**, 624 (1953).

10) K. J. Laidler, ibid., **22**, 1740 (1954).

straight line or a plane where the orbital correlation may have an important part, while the general polyatomic system scarcely has these constraints at all as long as special symmetry does not exist. These results and the correlation tables given by Shuler[9] are available for the present consideration. Typical examples of correlation for the lower energy surfaces are shown in Fig. 1. In the figure, the numbers on the curves representing adiabatic surfaces are for spin multiplicity, $2S+1$, and the states of reactants and resultants are shown in both ends of each curve. Relative orientation and shapes of the curves are arbitrary.

Some explanations are added to the system H_3 (Fig. 1a). The lowest surface of this reaction is clearly one of doublet. When all the nuclei are orientated on a line, the system has a symmetry of $C_{\infty v}$ and so the lowest state will be classified to $^2\Sigma^+$. Then the states of composite species which satisfy this designation are confined

$$H_2(^{1,3}\Sigma^+)+H(^2S_g),\quad H_2(^{1,3}\Sigma^+)+H(^2P_u)$$
$$H_2(^{1,3}\Pi)+H(^2P_u),\ \text{etc.}$$

However, it is known that elements, $S_{m\mu\nu,\,n\mu'\nu'}$ and $I_{m\mu\nu,\,n\mu'\nu'}$ which relate to states of higher energy hardly contribute to the lowest state, so we can conveniently neglect these composite states of high energy and can reduce the order of the determinant. Further, when this system has higher symmetries such as equidistance-on-a-line ($D_{\infty h}$) or equilateral triangle (D_{3h}), new relations appear among the coefficients of composite functions $C_{m\mu\nu}$'s, so as to reduce the order of determinant[11].

As for the C-O-O system, the reaction, $CO_2(^1\Sigma^+)\rightarrow CO(^1\Sigma)+O(^3P)$ is a forbidden process in the present treatment. The intersection of the surfaces A and B in Fig. 1b will give, however, the zeroth approximation for the surface of this reaction.

Approximate Estimation of $S_{m\mu\nu,\,n\mu'\nu'}$ and $I_{m\mu\nu,\,n\mu'\nu'}$ for the Three-atom System

Discussion is focused here on the reaction, as an example,

$$AB+C\rightarrow A+BC \quad \text{or} \quad AC+B$$

which is composed of three atoms having one valence electron. One of composite functions which express its lowest state with $S=1/2$ and $S_z=1/2$ is

$$\psi_1=\boldsymbol{A}\psi_{AB}(1,2)\cdot\psi_C(3)$$
$$=\sum_n P_c^n\varphi_{AB}(1,2)\cdot\varphi_C(3)$$
$$\times\frac{1}{\sqrt{2}}\{\alpha(1)\beta(2)-\alpha(2)\beta(1)\}\cdot\alpha(3) \quad (22)$$

where P_c means cyclic exchange of electrons 1, 2 and 3 in this order; φ's are the orbital parts and the bond orbital, $\varphi_{AB}(1,2)$, is symmetrical for the exchange of electrons 1 and 2. Analogous forms are taken for the functions ψ_2 and ψ_3 of other composite states, BC+A and CA+B, respectively.

Now, we neglect the contributions from all higher composite states and assume φ_{AB}, $\varphi_{BC},\cdots$, and φ_A, $\varphi_B,\cdots$, to be the ones of their lowest states, and then the order of determinant can be reduced to three. We take, furthermore, the simplest form of these functions by the use of atomic orbital approximation,

$$\varphi_{AB}(1,2)=a(1)b(2)+a(2)b(1) \quad (23)$$

and

$$\varphi_C(3)=c(3) \quad (24)$$

and so on. In these functions, $a(1)$, $b(2)$ and $c(3)$ express the valence orbitals of atom A, B and C, respectively. By the use of these expressions, the formulae of S_{mn} and I_{mn} (m, $n=1$, 2, 3) are described as shown in the Appendix.

Since the numerical values of molecular integrals including atomic orbitals with the principal quantum number $n=1,2,3$ are available at present[12], it is possible to evaluate the formulae directly except for several multiple-center integrals. Also these integrals are estimated exactly for some simple systems and also are approximately given by, e.g., Rudenberg-Mulliken's procedure[13].

Here, it is interesting to examine the simplification neglecting all these multiple-center integrals in the formulae. In this case, I_{mn} can be described as the function of coulombic energies Q_{AB}, $Q_{BC},\cdots$, and exchange energies J_{AB}, $J_{BC},\cdots$, of respective bonds, AB, $BC,\cdots$, for example,

$$I_{11}=2Q_{CA}+Q_{BC}-J_{CA}-J_{BC}$$

where

$$Q_{CA}=\bar{R}_{CA}^{-1}+(c^2|a^2)-(c^2|A)-(a^2|C)^{14}$$

11) See, for example, H. Eyring, J. Walter and G. E. Kimball, "Quantum Chemistry", John Wiley & Sons, Inc., New York (1949), Chap. X, p. 172; Chap. XIII, p. 252.

12) M. Kotani, A. Amemiya, E. Ishiguro and T. Kimura, "Table of Molecular Integrals", Maruzen Co., Ltd., Tokyo (1955).

13) K. Rudenberg, *J. Chem. Phys.*, **19**, 1433 (1951); R. S. Mulliken and R. G. Parr, ibid., **18**, 1338 (1950).

and

$$J_{CA}=(ac)^2\bar{R}_{CA}^{-1}+(ac|ac)-(ac)(ac|A+C),$$

etc.

Moreover, when the non-orthogonality between orbitals of different atoms is disregarded in S_{mn}'s, the expressions for I_{mn}'s and S_{mn}'s exactly correspond to those obtained by the well-known method of bond eigenfunction[15].

Eyring's semi-empirical method is derived readily by the use of these expressions and by taking the values of Q_{AB}, $J_{AB},\cdots$, from the assumption,

$$\varepsilon_{AB}=Q_{AB}+J_{AB},\quad \varepsilon_{BC}=Q_{BC}+J_{BC},\cdots, \tag{25}$$

and

$$\rho_{AB}=Q_{AB}/\varepsilon_{AB},\quad \rho_{BC}=Q_{BC}/\varepsilon_{BC},\cdots, \tag{26}$$

where ε_{AB}, $\varepsilon_{BC},\cdots$ and ρ_{AB}, $\rho_{BC},\cdots$ are bond energies and coulombic fractions of bonds AB, $BC,\cdots$. Therefore, this procedure may be regarded as one of the methods for estimating the elements I_{mn}'s conveniently by the use of ε_{AB}'s and ρ_{AB}'s.

Another basis of the present method will be examined below with respect to this reaction example. It is known theoretically that the wave functions which express the doublet states with $S_z=1/2$ are written as follows, by the use of orbital approximation;

$$\Phi_1=\sum_n P_c^n\{\psi(1,2,3)+\psi(2,1,3)\}\times\frac{1}{\sqrt{2}}\{\alpha(1)\beta(2)-\alpha(2)\beta(1)\}\alpha(3) \tag{27}$$

and

$$\Phi_2=\sum_n P_c^n\{(\psi1,2,3)-\psi(2,1,3)\}\times\frac{1}{\sqrt{6}}[\{\alpha(1)\beta(2)+\alpha(2)\beta(1)\}\alpha(3)-2\alpha(1)\alpha(2)\beta(3)] \tag{28}$$

where $\psi(1,2,3)$ is the orbital function[16]. When we take the simplest form of ψ's, $\psi(1,2,3)=a(1)b(2)c(3)$, etc., Φ_1 is identified with the composite function $\boldsymbol{A}\psi_{AB}\cdot\psi_C$ and Φ_2 is also rewritten as

$$\Phi_2=\sum_n P_c^n\{a(1)b(2)-a(2)b(1)\}c(3)\times\frac{1}{\sqrt{6}}[\{\alpha(1)\beta(2)+\alpha(2)\beta(1)\}\alpha(3)-2\alpha(1)\alpha(2)\beta(3)] \tag{29}$$

or

$$=\sum_n P_c^n[\{b(1)c(2)+b(2)c(1)\}a(3)+\{c(1)a(2)+c(2)a(1)\}b(3)]\times\frac{1}{\sqrt{6}}\{\alpha(1)\beta(2)-\alpha(2)\beta(1)\}\alpha(3) \tag{29'}$$

These expressions correspond apparently to the state composed of AB in a triplet state and C in a doublet state or the combination of composite states, BC in a singlet state and A in a doublet state, and CA and B in the analogous states.

Since the eigenvalues of these doublet states of the whole system are determined from the wave function,

$$\Psi=c_1\Phi_1+c_2\Phi_2 \tag{30}$$

the utilization of Φ_1 and Φ_2 as the basic functions is equivalent to the adoption of the set of composite functions, $\boldsymbol{A}\psi_{AB}\cdot\psi_C$, $\boldsymbol{A}\psi_{BC}\cdot\psi_A$ and $\boldsymbol{A}\psi_{CA}\cdot\psi_B$.

The conclusion from the above consideration and also the method of bond-eigenfunction shows that one of these three functions is linearly dependent on the others. But, in the present method, such a relation does not always hold, for the present choice of a functional set is effectively to make use of the observed values of bond energies, ε_{AB}, ε_{BC} and ε_{CA}.

Remarks on the Application to the General System

In several reactions, bonds have frequently a directional character such as p-, d- orbitals or their hybridization. Also other important cases are the reactions in multielectronic systems with inner-shell and incompleted shell electrons. Any polyatomic system is comprised in the combination of these cases. Some remarks will be made on the application to these systems.

System with Directed Valence Bond. — A typical example is the hydrogen-halogen reaction

$$X(^2P)+H_2(^1\Sigma^+)\rightarrow HX(^1\Sigma^+)+H(^2S)$$

For simplicity, the halogen atom is assumed to have only a p-valence electron. This system has been studied only by Magee with crude approximation[17].

Denoting two independent p-orbitals of halogen, which lie on the plane involving three atoms, by p_x and p_y, we can readily see that these p-orbitals and s-orbitals of two hydrogen atoms form a basis for an

14) For these notations, see the definitions given in Appendix.
15) Ref. 11, Chap. XIII, p. 232.
16) Ref. 12, p. 15.
17) J. L. Magee, *J. Chem. Phys.*, 8, 677 (1940).

irreducible representation of the group of surface symmetry C_s. Accordingly, the p-bonding orbital on the plane is expressed by linear combination of p_x and p_y,

$$p_\sigma = \lambda p_x + \mu p_y \tag{31}$$

Since the total wave function is described as

$$\Psi = C_1 A\psi_{XH_A}\cdot\psi_{H_B} + C_2 A\psi_{XH_B}\cdot\psi_{H_A} + C_3 A\psi_{H_2}\cdot\psi_X \tag{32}$$

respective bond functions are given by

$$\psi_{XH_A} = \lambda_1\psi(p_x - h_A) + \mu_1\psi(p_y - h_A)$$

$$\psi_{XH_B} = \lambda_2\psi(p_x - h_B) + \mu_2\psi(p_y - h_B)$$

and $\psi_X = \lambda_3\psi(p_x) + \mu_3\psi(p_y)$

where h's are the valence orbitals of the hydrogen atom.

Even if all states of higher energy are neglected, the determinant is still so great. But when the ratios λ_i/μ_i's are fixed so as to minimize the energy of each composite state, the order of determinant can be reduced to three and the bond energy of HX is utilized effectively, for the p_σ orbital lies along the line joining H and X in this case[18].

System with Inner-shell Electrons. — The simplest example is the reaction including alkali metal,

$$LiH(^1\Sigma^+) + H(^2S) \rightarrow Li(^2S) + H_2(^1\Sigma^+)$$

of which one of the composite functions is

$$\phi_1 = A\phi_{LiH}(1,2,3,4)\cdot\phi_H(5)$$

The orbital part of molecular function, ϕ_{LiH} may be factorized by the use of the inner shell orbital ϕ_i[19] and the bond orbital ϕ_{LiH} which are symmetrical for exchange of electrons, respectively. Expressing these orbitals by the introduction of atomic orbital approximation, it is found that I_{mn}'s consist of two parts, (1) integrals with exchange of electrons between inner-shell and bond orbitals of other species and (2) integrals in which inner-shell electrons remain un-exchanged.

Now, we take a simplification neglecting the former because of the small overlapping between inner-shell and valence orbital of different species. The electrons in closed shell distribute almost spherically round the Li nucleus and then contribute to energy only by coulombic repulsion. Since this effect is estimated effectively by adjusting the nuclear charge of Li atom, the system is regarded as the one consisting of three valence electrons only.

The effect of an incomplete shell, lone pair and even that of radicals which are not concerned directly with the reaction, are similar in principle to the above case. However, an important difference between them is that the charge distributions in these cases are not spherically symmetrical for the nuclei noticed. Therefore, it may be necessary to take such an approximation as the replacement of these distributions to several point charges distributed around the nucleus.

Finally, a remark is briefly made on the system having multiple bond. When the bond breaks completely or is newly formed as a result of reaction, all electrons relating to the bond must be taken into the treatment. On the other hand, when the bond is partially subjected to reaction, electrons in the remaining part of the bond behave in the same manner as those of the incompleted shell stated above and then are treated in a similar way too. The above consideration has been taken for the displacement reaction $A+BC \rightarrow AB+C$. Conclusions obtained here, however, are readily extended to other types of reaction, for instance, double decomposition, $AB+CD \rightarrow AC+BD$.

If the ground states of molecules are all singlet in this case, the lowest surface will also belong to singlet and composite functions, which can be constructed in a way quite analogous to that shown in the previous sections.

The author wishes to thank Professor S. Shida of Tokyo Institute of Technology and Professor K. Hirota of Osaka University for their valuable suggestions and kind encouragement. Also the author is indebted to Mr. Y. Mori for many helpful discussions.

Appendix

Formulae of S_{mn} and I_{mn} for the System of Three Atoms with One Valence Electron. — In a way similar to ϕ_1 of Eq. 22, ϕ_2 and ϕ_3 for the other composite states are described as follows:

18) When the direction of the valence orbital is fixed during the reaction for some reason, for example, the hindrance of atoms or radicals attached to the noticed atom, and it does not accord with the joining line, some correction may be required for full insertion of observed bond energies.

19) This orbital almost coincides with inner shell orbital of Li atom.

$$\psi_2=\boldsymbol{A}\psi_{BC}(1,2)\cdot\psi_A(3)$$

and $$\psi_3=\boldsymbol{A}\psi_{CA}(1,2)\cdot\psi_B(3)$$

Total Hamiltonian operator and wave function are

$$\boldsymbol{H}=-\frac{1}{2}\sum_{i=1}^{3}\Delta_i+\sum_{i>j}\frac{1}{r_{ij}}+\sum_{p>q}\frac{Z_pZ_q}{R_{pq}}-\sum_p\sum_i\frac{Z_p}{r_{pi}} \tag{A.1}$$

and

$$\Psi=C_1\psi_1+C_2\psi_2+C_3\psi_3 \tag{A.2}$$

Accordingly, the determinant to be solved is

$$\text{Det.}\,|I_{mn}+(\varepsilon_{mn}-\varepsilon)S_{mn}|=0 \quad m,n=1,2,3 \tag{A.3}$$

I_{mn}'s are further resolved into several terms for convenience,

$$I_{mn}=K_{mn}-J_{mn}+R_{mn}\cdot S_{mn} \tag{A.4}$$

The formulae of ε_{mn}, S_{mn}, R_{mn}, K_{mn} and J_{mn} are shown below. The notation of integrals used in the expressions is as follows:

$$(ab)=\int a(1)b(1)\,d\tau_1$$

$$(a^2|b^2)=\int a^2(1)\frac{1}{r_{12}}b^2(2)\,d\tau_1d\tau_2$$

$$(ab|ab)=\int a(1)b(1)\frac{1}{r_{12}}a(2)b(2)\,d\tau_1d\tau_2$$

$$(a^2|B)=\int a^2(1)\cdot\frac{Z_B}{r_{B1}}\,d\tau_1 \qquad \text{etc.}$$

Also, in the expressions below, ε_{m1} $(A\rightleftarrows C)$ means the exchange of letters "A" and "C" in that of ε_{m1} and so on.

(1) ε_{mn}; $\varepsilon_{m1}=\varepsilon_{AB}$

$\varepsilon_{m2}=\varepsilon_{m1}(A\rightleftarrows C)$ $\quad m=1,2,3$

$\varepsilon_{m3}=\varepsilon_{m1}(B\rightleftarrows C)$

(2) R_{mn}; $R_{m1}=\bar{R}_{BC}^{-1}+\bar{R}_{AC}^{-1}$ $\quad \bar{R}_{BC}^{-1}=Z_BZ_C\cdot R_{BC}^{-1}$ etc.,

$R_{m2}=R_{m1}(A\rightleftarrows C)$ $\quad m=1,2,3$

$R_{m3}=R_{m1}(B\rightleftarrows C)$

(3) S_{mn}; $S_{11}=2+2(ab)^2-(bc)^2-(ac)^2-2(ab)(bc)(ca)$

$S_{22}=S_{11}(a\rightleftarrows c)$

$S_{33}=S_{11}(b\rightleftarrows c)$

$S_{12}=S_{21}=-1+2(ac)^2-(ab)^2-(bc)^2$
$+(ab)(bc)(ca)$

$S_{13}=S_{31}=S_{12}(a\rightleftarrows b)$

$S_{23}=S_{32}=S_{12}(b\rightleftarrows c)$

(4) K_{mn}; $K_{11}=2(a^2|c^2)+2(b^2|c^2)$
$+4(ab)(ab|c^2)-(ac|ac)$
$-(bc|bc)-(bc)\cdot\{(a^2|bc)+(ab|ac)\}$
$-(ac)\{(b^2|ac)+(ab|bc)\}$
$-2(ab)(ac|bc)$

$K_{22}=K_{11}(a\rightleftarrows c)$

$K_{33}=K_{11}(b\rightleftarrows c)$

$K_{12}=2[(ac|ac)+(ac)(b^2|ac)]$
$+(bc)(ab|ac)+(ab)(bc|ac)$
$-[(a^2|c^2)+(b^2|a^2)+(ab|ab)$
$+(ab)(c^2|ab)+(ac)(bc|ab)$
$+(bc)\{2(bc|a^2)+(ab|ac)\}]$

$K_{32}=K_{12}(b\rightleftarrows c)$

$K_{21}=K_{12}(a\rightleftarrows c)$

$K_{31}=K_{21}(a\rightleftarrows b)$

$K_{13}=K_{12}(a\rightleftarrows b)$

$K_{23}=K_{13}(a\rightleftarrows c)$

$J_{23}=J_{13}(a\rightleftarrows c,\ A\rightleftarrows C)$

Modified Bond Eigenfunction Method of Constructing Potential Energy Surface of Reaction. II. Application to the Hydrogen Atom-Molecule Reaction

By Iwao YASUMORI

(Received March 3, 1959)

A new method of constructing the potential energy surface of a chemical reaction was presented in the previous paper and some remarks on the procedure of application were also given. In order to examine its availability, the method is effectively applied to the hydrogen atom-molecule reaction, since much theoretical and experimental knowledge has been accumulated on its component species, H_2 and H.

As is well known, the potential energy surfaces of this reaction have been evaluated by Hirschfelder et al.[1] in a purely theoretical manner and by Eyring et al.[2] semi-empirically. Also, recently several investigators[3] have given some considerations about this system from the standpoint of molecular orbital method.

In this paper, besides the examination of the applicability of the method, surface properties obtained here are discussed comparing them with those obtained in the previous works. Calculation of reaction rate based on the surface is carried out also.

Composite Wave Functions

We denote three hydrogen atoms in the systems, A, B and C, and, for simplicity, confine ourselves to the lowest surface of linear configuration. Therefore, it is assumed that the reaction proceeds by the equation

$$H_AH_B+H_C \rightarrow H_A+H_BH_C$$

on a straight line.

According to the considerations given in Paper 1, the total wave function which expresses the state with the total spin $S=1/2$ and its component $S_z=1/2$ is described as follows:

$$\begin{aligned}\Psi=\sum_{m=1}^{3} C_m\psi_m &= C_1\boldsymbol{A}\varphi_{AB}(1,2)\varphi_C(3)\\ &\times\frac{1}{\sqrt{2}}\{\alpha(1)\beta(2)-\alpha(2)\beta(1)\}\alpha(3)\\ &+C_2\boldsymbol{A}\varphi_{BC}(1,2)\varphi_A(3)\\ &\times\frac{1}{\sqrt{2}}\{\alpha(1)\beta(2)-\alpha(2)\beta(1)\}\alpha(3)\\ &+C_3\boldsymbol{A}\varphi_{CA}(1,2)\varphi_B(3)\\ &\times\frac{1}{\sqrt{2}}\{\alpha(1)\beta(2)-\alpha(2)\beta(1)\}\alpha(3)\end{aligned} \tag{1}$$

where each term represents the composite functions for bond structures $AB+C$, $BC+A$ and $CA+B$, respectively. In the equation, $\varphi_{AB}(1,2),\cdots$ are ${}^1\Sigma^+_g$ orbital functions of H_2 and $\varphi_c(3),\cdots$ are atomic $1s$ orbital functions of hydrogen. Spin functions $\frac{1}{\sqrt{2}}\{\alpha(1)\beta(2)-\alpha(2)\beta(1)\}$ and $\alpha(3)$ correspond to singlet state of molecule and doublet state of atom, respectively. There are many higher energy states which correlate to the lowest surface such as $H_2({}^{1,3}\Sigma^+)+H({}^2S_g,{}^2P_u)$, $H_2({}^1{}^3\Pi)+H({}^2P_u)$, etc. But all these composite states were excluded in the present calculation[4], since, apart from the simplification of procedure, their contributions to the energy of the lowest state are rather small and also some of them are hardly available because of the lack of experimental data.

By the operation of antisymmetrizer,

$$\boldsymbol{A}=\frac{1}{\sqrt{3}}\Sigma_t P_t v_t \tag{2}$$

each composite function is expressed as

$$\begin{aligned}\psi_1=&\frac{1}{\sqrt{6}}\varphi_{AB}(1,2)\cdot\varphi_C(3)\{\alpha(1)\beta(2)-\alpha(2)\beta(1)\}\alpha(3)\\ &+\frac{1}{\sqrt{6}}\varphi_{AB}(2,3)\cdot\varphi_C(1)\{\alpha(2)\beta(3)-\alpha(3)\beta(2)\}\alpha(1)\\ &+\frac{1}{\sqrt{6}}\varphi_{AB}(3,1)\cdot\varphi_C(2)\{\alpha(3)\beta(1)-\alpha(1)\beta(3)\}\alpha(2)\end{aligned} \tag{3}$$

and so on. The determinant, from which energy values for all configurations of atoms are deduced, is described as

$$\text{Det.}\,|I_{mn}+(\varepsilon_{mn}-\varepsilon)S_{mn}|=0 \qquad m,n=1,2,3 \tag{4}$$

1) J. O. Hirschfelder, N. Rosen and H. Eyring, *J. Chem. Phys.*, **4**, 121 (1936).

2) J. O. Hirschfelder, H. Eyring and B. Topley, ibid., **4**, 170 (1936).

3) J. M. Walsh and F. A. Matsen, ibid., **19**, 526 (1951); V. Griffing and J. T. Vanderslice, ibid., **23**, 1035 (1955); G. E. Kimball and J. G. Trulio, ibid., **28**, 493 (1958).

4) However, the composite states $H_2({}^3\Sigma^+_u)+H({}^2S_g,1s)$, are automatically included in the wave function. See Paper I.

where $$S_{mn}=\int \bar{\psi}_m \psi_n d\tau \quad (5)$$

$$I_{mn}=\int \bar{\psi}_m \boldsymbol{I}_n \psi_n d\tau \quad (6)$$

When we take the lowest state of free atoms 3H as a standard of energy of system, bond energies of species are given by

$$\varepsilon_{m1}=\varepsilon_{H_2}(AB),\quad \varepsilon_{m2}=\varepsilon_{H_2}(BC),\quad \varepsilon_{m3}=\varepsilon_{H_2}(CA)$$
$$m=1,2,3$$

and interaction operators $\boldsymbol{I}_n$'s are also defined as

$$\boldsymbol{I}_1=\boldsymbol{H}-\boldsymbol{H}_{AB}-\boldsymbol{H}_C \quad (7)$$
$$\boldsymbol{I}_2=\boldsymbol{H}-\boldsymbol{H}_{BC}-\boldsymbol{H}_A \text{ and } \boldsymbol{I}_3=\boldsymbol{H}-\boldsymbol{H}_{CA}-\boldsymbol{H}_B$$

where $\boldsymbol{H}$ is the total Hamiltonian of three electrons in the system and $\boldsymbol{H}_{AB}$ and $\boldsymbol{H}_C$ are the partial ones for molecule AB and atom C, respectively, and so on.

Molecular functions taken into the calculation are as follows:

(a) Heitler-London type function,

$$\varphi_{AB}(1,2)=a(1)b(2)+a(2)b(1)$$

where $a(1)$ and $b(2)$ are 1s orbital functions of hydrogen,

$$a(1)=(1/\pi)^{1/2}\exp(-r_{A1})$$

and $$b(2)=(1/\pi)^{1/2}\exp(-r_{B2}),\text{ etc.}$$

(b) Wang type function obtained by introduction of effective nuclear charge z into the atomic orbitals of the function a,

$$a(1)=(z^3/\pi)^{1/2}\exp(-zr_{A1})\quad \text{etc.}$$

(c) Weinbaum type function composed of the above functions, that is, the covalent term, and the ionic term,

$$\varphi^{ion}{}_{AB}(1,2)=a(1)a(2)+b(1)b(2)$$

Since these functions are described by the use of atomic orbital approximation, formulae of elements I_{mn} and S_{mn} given in the Appendix of Paper I are available for the present calculation. In addition to this, it is to be noted that when we estimate the values of ε_{H_2} also by the use of these approximate functions, the results are reduced to those of Hirschfelder et al.[1] The present method differs from theirs in the point that the interaction energies are evaluated by making use of approximate functions, while the observed values, that is, those deduced from the exact functions, are utilized for the bond energies of H_2.

Details of Calculation and Results

Detailed procedure of energy calculations which were performed by the use of approximate functions are shown below for the respective cases.

(a) Calculation of Symmetrical Linear Configuration with Heitler-London Type Function of H_2.—Making use of the formulae in the Appendix of Paper I, we can express the elements S_{mn} and I_{mn} as the sum of several molecular integrals, i. e., two-center and three-center ones. The values of two-center integrals were obtained from the tables by Kotani et al.[5] and by Hirschfelder and Linnett[6] (being abbreviated to L.-H. hereafter). For the three-center integrals, values of one electron integrals such as

$$(bc\mid A)=\int b(1)c(1)\frac{1}{r_{A1}}d\tau_1$$

were taken from the table by Hirschfelder and Weygandt[7] and values of two electron ones, for example,

$$(bc\mid a^2)=\int b(1)c(1)\frac{1}{r_{12}}a^2(2)\,d\tau_1 d\tau_2$$

were calculated in a similar way as those of Hirchfelder's[1].

Also some of their values were taken from the table in the paper of Baker et al.[8] Therefore, such an approximate calculation as Rudenberg-Mulliken's procedure[9],

$$(bc\mid a^2)\cong\frac{1}{2}(bc)\cdot[(b^2\mid a^2)+(c^2\mid a^2)]\quad \text{etc.},$$

was not required in this case.

(b) Calculation with Heitler-London-plus-Ionic Type Function.—Strictly speaking, the coefficient of ionic term added to covalent function must be taken so as to minimize the energy value, since the ionic term is another function contributing $^1\Sigma^+$ state of molecule. However, the coefficient was fixed to the value, $C_{ion}=0.1607$ take from L.-H.'s work, in order only to examine the effect of electronic distribution in hydrogen molecular function. In this case, the ionic integrals of two-center type, for example,

$$(ac\mid a^2)=\int a(1)c(1)\frac{1}{r_{12}}a^2(2)\,d\tau_1 d\tau_2\quad \text{etc.},$$

newly appear. The values were obtained also from the table by Kotani et al.

(c) Calculation with Wang Type Function.—At the values of effective nuclear charge in atomic orbital function, the following values were used for the calculation; (i) the values from original Wang function, $z=1.166$[10] and (ii) the values from L.-H.'s work shown in Table I.

When we adopt these functions for the strict procedure of calculation, the molecular integrals which appear, are of unsymmetrical type including the atomic orbital functions with effective nuclear charge, z and $z=1$. The values of these

unsymmetrical integrals were estimated accurately by James[11] for 1s and 2s orbitals of lithium atom and approximately be Mulligan[12] for carbon dioxide calculation. Here, for simplicity, the effective nuclear charges in all orbitals were assumed to be equally z, so as to utilize the results of calculations a) and b). The effect of this approximation will be discussed later.

(d) Calculation with Wang-plus-Ionic Type Function.—Used values of effective nuclear charge and coefficients of ionic term are as follows: (i) the values used in original Weinbaum's function[13], $z=1.193$ and $C_{ion}=0.256$ and (ii) the values obtained from L.-H's treatment of H_2 which are shown in Table II.

TABLE II. VARIATION OF z AND C_{ion} IN THE WANG-PLUS-IONIC TYPE FUNCTION OF H_2

zR(a. u.)	1.0	1.5	1.75	2.0	2.5	3.0
z	1.3976	1.2411	1.1746	1.1195	1.0472	1.0000
C_{ion}	−0.01603	0.1361	0.1664	0.1780	0.1681	0.1200

Further calculations were performed for the following cases.

(e) Effect of Varying Nuclear Charge z.—For the linear configuration of equi-distance, calculation was carried out varying z in Wang type function as $z=1.0$, 1.166, 1.3, 1.4 and 1.5, respectively.

(f) Comparison of Energy Values on Various Stages of Approximation.—The effects of various approximations such as (i) use of three-center integral values calculated by Rudenberg-Mulliken type approximation, (ii) neglect of these integrals and (iii) ii plus neglect of non-orthogonality of orbitals in S_{mn}'s, were examined utilizing Heitler-London type function for the same configuration as described in e).

(g) Variaton of Energy by Bending.—Increase of energy owing to bend of R_{BC} to R_{AB} was calculated for several equi-distant configurations by the use of Heitler-London and Wang type functions.

(h) Energy Values of Some Unsymmetrical Configuration. — Three-center integrals which appear in this case have need of complicated calculations. However, it is possible that, by an analogy of Mulligan approximation for the unsymmetrical integrals with different z's, these integrals are expressed approximately in terms of symmetrical configurations.

For example, denoting $R_{AB}=R_1$ and $R_{BC}=R_2$, we have

$$(ab \mid bc)_{R_1,R_2}=(ab)_{R_1}\cdot(bc)_{R_2}\times\frac{1}{2}\left[\left(\frac{(ab\mid bc)}{(ab)(bc)}\right)_{R_1}+\left(\frac{(ab\mid bc)}{(ab)(bc)}\right)_{R_2}\right]$$

Otherwise, these integrals may be resolved into the sum of several two-center integrals by the use of Rudenberg-Mulliken type approximation. Calculation was carried out for the configurations of

$R_{AB}=1.5$ a. u., $R_{BC}=2.0$ a. u.
$R_{AB}=1.75$ a. u., $R_{BC}=2.0$ a. u.
$zR_{AB}=2.00$ a. u., $zR_{BC}=2.50$ a. u.
and $zR_{AB}=2.25$ a. u., $zR_{BC}=2.50$ a. u.

by the use of Heitler-London and Wang ($z=1.4$) type functions and of approximate values of integrals.

Discussion

Activation energies obtained by the present method (Table V) are not always satisfactory compared with the observed value[14] or the previous ones by Hirschfelder et al.[1], except the result with Wang

type function in which $z=1.4$. However, marked improvements from their work are found in the absolute energy values of H_3 complex state, that is, the lowering 15~30 kcal. Besides, it is apparent that the activation energies estimated by them are of relative character; the use of improved function of H_2 brings, on the contrary, large increase for the values.

Interesting results are seen for the influence of an added ionic term. The introduction of this term lowers energies of H_3 complex slightly in the case of Hirschfelder et al., while it has almost no effect in the present treatment. These results are owing partly to the small contribution of ionic state to the lowest one and partly to the use of fixed coefficient of that term.

Also the results are explained phenomenally as that addition of this state brought an increase of interaction energy allowing superposition of electrons on the same atom. Considerations shall be done again later relating to the distribution of electrons in the system.

Next, the effect of nuclear charge z is examined. The lowering of energy and the contraction of the dimension of activated complex with increase of z are shown in Fig. 2. When z is increased to 1.4 or larger, the activation energy calculated attains the observed one. This effect may be explained qualitatively as that the use of atomic orbital shrunk by larger z diminishes the interaction between species and then energy of complex and nuclear distance decrease to those of the initial molecule.

If the energies of molecular species are estimated by the use of the same approximate function, this decrease of interaction energy will be compensated by the increase of molecular energy, and then an optimum value of z will be obtained. Accordingly, the variational principle does not always hold in the present method which makes use of the experimental value of molecular energy. However, this "half-theoretical" character of the present method gives an advantage of taking the nuclear charge z as an arbitrary parameter. According to this idea, it becomes possible to choose the z value from such a different point of view as will be discussed below.

When the atom C is separated infinitely from the molecule AB, the energy of the lowest state is apparently equal to that of molecule AB and that of the next higher state belonging to another doublet is expressed, by the use of Wang type function, as follows:

$$E_1=\frac{1}{R_{AB}}+\frac{Q-J}{1-S^2} \tag{8}$$

where

$$S=(ab) \tag{9}$$

$$Q=(a^2 \mid b^2)-(a^2 \mid B)-(b^2 \mid A) \tag{10}$$

and

$$J=(ab \mid ab)-(ab)(ab \mid A+B) \tag{11}$$

This equation corresponds clearly to the theoretical expression of the repulsive ${}^3\Sigma_u^+$ state of H_2.

Since the energy of this state was evaluated accurately by James, Coolidge and Present[15] by the aid of the variation method, we can choose the parameter z so as to coincide the energy by Eq. 8 with the calculated value by them.

The result is satisfactory as shown in Fig. 5; when the nuclear distances R_{AB} and R_{BC} come near the configuration of activated state, z value approaches 1.4. This

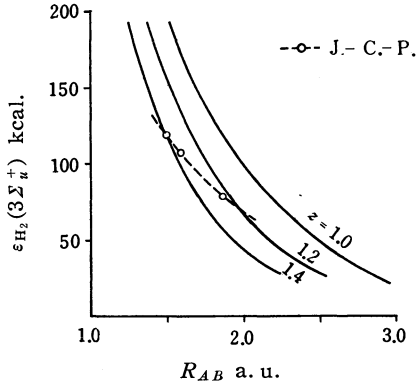

Fig. 5. Energy of triplet state of H_2.

fact suggests that the use of a composite function which gives better value for the energy of the state correlating strongly to the noticed one, improves the result markedly. Another qualitative reason of taking a larger value of z is in its effect upon the electronic distribution in the molecule. The present results will be improved if we make use of exact molecular function, e. g., James-Coolidge type one[16]. The distinction of J.-C. function from usual orbital ones is in its electronic distribution in which the overlapping of electrons is diminished by the introduction of inter-electronic coordinate r_{12}. This effect is

15) H. M. James, A. S. Coolidge and R. D. Present, *J. Chem. Phys.*, 4, 187 (1936).
16) H. M. James and A. S. Coolidge, ibid., 1, 825 (1933).

attained to some extent by the use of orbital functions with increasing z value. Also the addition of an ionic term, on the contrary, estranges the distribution from J.-C.'s. It is expected, therefore, that the utilization of larger z takes in partly the energy of electronic correlation in molecules, and then in the reacting system. It goes without saying that this correlation is partly included by the use of experimental data for the component species.

Potential Energy Basin

Here, the existence of so-called "potential energy basin" is briefly discussed.

By applying straightforwardly Eyring's semi-empirical method to the H_3 system of linear configuration, the obtained surface has two distinct basins[17], i.e., (a) a markedly deep one occurring where the distances between neighboring atoms, R_{AB} and R_{BC} are smaller than 1.0 a.u. and (b) a shallow one near the activated state.

Neither the results of the present calculation nor that of Hirschfelder et al.[1] show such basins as those above. The fact that these basins are apparent ones, being induced from the assumption of constant coulombic fraction, is explained as follows; for the shrunken configuration where both R_{AB} and R_{BC} are nearly equal to those giving zero bond energies, ε_{AB}, $\varepsilon_{BC}\simeq 0$, the coulombic and exchange parts of these bonds, Q_i and J_i $(i=AB, CB)$ are in the relation as

$$Q_i \simeq -J_i \gg 0 \tag{12}$$

while their values by Eyring's procedure are

$$(1-\rho)Q_1=\rho\cdot J_i\simeq 0 \tag{12'}$$

Therefore, the energy value which is obtained from London's formula,

$$E=Q_{AB}+Q_{BC}+Q_{CA}-[J_{AB}^2+J_{BC}^2+J_{CA}^2 - J_{AB}J_{BC}-J_{BC}J_{CA}-J_{CA}J_{AB}]^{1/2} \tag{13}$$

and these Q's and J's, is underestimated extremely as

$$E'=\varepsilon_{AC}=Q_{AC}+J_{AC} \tag{14'}$$

instead of exact value,

$$E=\varepsilon_{AC}+3Q_{AB}\gg E' \tag{14}$$

This situation is apparently the cause of basin a).

Next, the origin of basin b) is examined. For the equi-distant configuration "P" as shown in Fig. 7, the energy change ΔE,

17) S. Sato, This Bulletin, 28, 450 (1955).

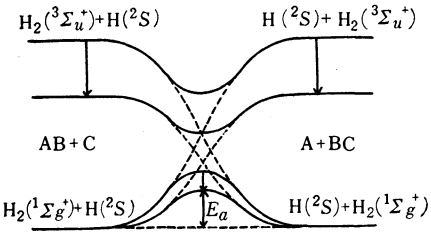

Fig. 6. Variation of activation energy with lowering of upper surface.

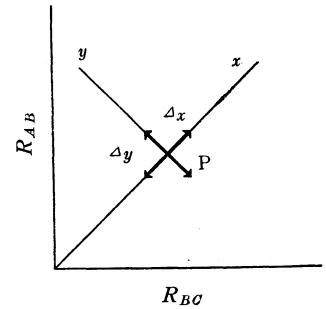

Fig. 7. Displacements around P.

induced from the small displacements around P is expressed as

$$\begin{aligned}\Delta E_x &\simeq \sqrt{2}\left[\left(\frac{\partial Q_{AB}}{\partial R_{AB}}\right)+\frac{1}{2}\left(\frac{\partial J_{AB}}{\partial R_{AB}}\right)\right.\\ &\quad\left.+\left(\frac{\partial Q_{AC}}{\partial R_{AC}}\right)-\left(\frac{\partial J_{AC}}{\partial R_{AC}}\right)\right]\cdot(\Delta x)\\ &\quad+\left[\frac{1}{2}\left(\frac{\partial^2 Q_{AB}}{\partial R_{AB}^2}\right)+\frac{1}{4}\left(\frac{\partial^2 J_{AB}}{\partial R_{AB}^2}\right)\right.\\ &\quad\left.+\left(\frac{\partial^2 Q_{AC}}{\partial R_{AC}^2}\right)-\left(\frac{\partial^2 J_{AC}}{\partial R_{AC}^2}\right)\right]\cdot(\Delta x)^2\\ &=A_1(\Delta x)+A_2(\Delta x)^2\end{aligned}$$

along the x axis and

$$\begin{aligned}\Delta E_y &\simeq \left[\frac{1}{2}\left(\frac{\partial^2 Q_{AB}}{\partial R_{AB}^2}\right)+\frac{1}{4}\left(\frac{\partial^2 J_{AB}}{\partial R_{AB}^2}\right)\right.\\ &\quad\left.-\frac{3}{4}\cdot\frac{1}{|J_{AB}-J_{AC}|}\cdot\left(\frac{\partial J_{AB}}{\partial R_{AB}}\right)^2\right]\cdot(\Delta y)^2\\ &=B_2(\Delta y)^2\end{aligned}$$

along the y axis. According to Eyring's assumption of constant ρ, the minimum point appears at the position where the coefficient of (Δx), A_1, is equal to zero and the nuclear separation $R_{AB}^*(=R_{BC}^*)$ is slightly larger than the equilibrium distance r_e of H_2 (1.40 a.u.), for example, $R_{AB}^*=1.6$ and 1.9 a.u. for $\rho=0.2$ and 0.1, respectively. In the case of large coulombic fraction, therefore, this point is apparently in a basin, for $A_2>0$ and B_2, the coefficient of $(\Delta y)^2$, estimated approximately by the

use of equation

$$B_2 \simeq \frac{1}{4}\left(\frac{\partial^2 J_{AB}}{\partial R_{AB}^2}\right) - \frac{3}{4}\cdot\frac{1}{|J_{AB}-J_{AC}|}\cdot\left(\frac{\partial J_{AB}}{\partial R_{AB}}\right)^2$$

$$J_{AB} = (1-\rho)\cdot\varepsilon_{H_2}(R_{AB})$$

and of Morse function of H_2, is positive where

$$R_{AB}^{*} < 1.74 \text{ a. u.}$$

Alternatively, when we give up this assumption of constant ρ, the nuclear distances at the minimum point are somewhat extended. The value of B_2 estimated by making use of the following expression of J_{AB},

$$J_{AB} = D'\left[e^{-2a(r-r_e')} - 2e^{-a(r-r_e')}\right]$$ [18]

where $D' = 0.9\, D_{H_2} = 98.51$ kcal./mol.

$r_e' = 0.9\, r_e = 1.261$ a. u.

and $a = 1.0298$,

is negative where

$$R_{AB}^{*} > 1.60 \text{ a. u.}$$

This result shows that the surface near the activated state is a saddle-like one or, at least, has not such a depression as was expected by Eyring et al.

Computation of Reaction Rate

Now, we shall evaluate the rate of the reaction on the knowledge of the surface derived here. Such a detailed calculation has been done only by Eyring et al.[19] According to the activated complex theory, the rate v and rate constant k of the elementary reaction $H_2(AB) + H(C) \rightarrow H(A) + H_2(BC)$ are expressed by

$$v = kC_{H_2}\cdot C_H \qquad (20)$$

and

$$k = \kappa\frac{I_{H_3}\sigma_{H_2}}{I_{H_2}\sigma_{H_3}}\cdot\frac{h^2}{(4\pi m_H/3)^{3/2}\cdot(kT)^{1/2}} \times\frac{1}{4}\cdot\frac{\sinh\left(\frac{1}{2}h\nu_{H_2}/kT\right)e^{-E_c/kT}}{\sinh\left(\frac{1}{2}h\nu_s/kT\right)\cdot\sinh^2\left(\frac{1}{2}h\nu_\phi/kT\right)} \qquad (21)$$

The notations in these equations are as follows:

C; concentration of species.
κ; the transmission coefficient.
I; a moment of inertia.
σ; symmetry number.
m_H; mass of hydrogen atom.
ν_{H_2}; vibrational frequency of H_2.
ν_s and ν_ϕ; stretching and bending vibrational frequencies of activated complex respectively.
E_c; classical energy of activation.

The quantities belonging to molecule or complex are distinguished by the addition of subscripts, e. g., "H_2" or "H_3". Since the complex in the present result is a symmetrical linear one, $\sigma_{H_2} = \sigma_{H_3} = 2$ holds. Constants deduced from the surface constructed by the use of Wang type function ($z = 1.4$) are shown in Table VI with Eyring's ones.

TABLE VI. CONSTANTS FOR THE HYDROGEN ATOM-MOLECULE REACTION

	Present result*	Eyring et al.**
R_{AB}^{*} (Å)	0.88 (0.91)	1.354

TABLE VII. RATE CONSTANTS OF HYDROGEN ATOM-MOLECULE REACTION, k (cc. mol^{-1} sec^{-1})

Temperature °K	300	600	1000
Observed values	9.0×10^7	—	2.2×10^{12}
Present results a.	3.6×10^6	1.0×10^{10}	0.4×10^{12}
〃 b.*	3.9×10^7	3.5×10^{10}	0.7×10^{12}
Eyring et al.	7.3×10^7	7.3×10^{10}	1.5×10^{12}

* Values obtained by the use of constants in parentheses, Table VI.

The evaluated rate values are given in Table VII, with the observed ones by Geib and Harteck and Farkas et al.[14] and also with the calculated ones by Eyring et al. Although detailed comparison is rather difficult because of few experimental data, the agreement with the evaluated ones is reasonably good. The reason why Eyring's values are slightly large compared with the present ones is in the use of larger moment-of-inertia value of the complex deduced from its unsymmetrical form. Accordingly, when we give up the assumption of constant ρ, the moment-of-inertia and therefore rate

18) The corresponding coulombic fractions obtained from this function are 0.13, 0.18 and 0.20 at $R_{AB} = 1.5$, 2.0 and 2.5 a. u., respectively.
19) H. Eyring et al., "The Theory of Rate Processes", McGraw-Hill Book Co. Inc., New York, (1941), p. 203.

also are reduced to those near the present ones.

Besides, it is necessary to use corrected values of transmission coefficient for this reaction consisting of light atoms in low temperatures.

Since it is known that the bending of the reaction path scarcely affects the extent of transmission at all, the evaluation of κ is confined to that through potential energy barrier[20]. Now taking Wigner's correction, $\kappa=1-\frac{1}{24}\left(\frac{h\nu_t}{kT}\right)^2$, where ν_t is the imaginary vibrational frequency of complex along the reaction path, we obtain κ's values to be 6.3, 2.3 and 1.5 at 300, 600 and 1000°K respectively from the value $ih\nu_t=6.8$ kcal. The rate values are then corrected to

$$2.5\times10^8,\ 8.1\times10^{10} \text{ and } 1.1\times10^{12}$$

at respective temperatures. Since Wigner's correction may give upper limit of κ, it is sure that the rate in lower temperatures were well improved.

Conculusion

The method of modified bond eigenfunction was applied to construct the potential energy surface of the hydrogen atom-molecule reaction. Also it was shown that the reaction rates estimated on this surface were in agreement with the observed ones.

In the calculation of surface, we took effective nuclear charge z in orbital function as an arbitrary parameter and showed the propriety of employing a larger z value than unity. Accordingly, it is to be noted that the functions of component species near the configuration of activated state are different from those of "free species" and that, by the use of these deformations, some parts of electronic correlation energy are taken into calculation.

Recently, Arai et al.[21] have developed, in the field of "molecular theory", the method of "deformed-atoms-in-molecules" which differs from the original Moffitt's method by taking deformed atomic orbitals in the molecule. Then, it may be said that the method by the present author corresponds to a further extension of theirs for the reacting system.

Although, the electronic correlation is considered partly in the above-mentioned manner, its full inclusion by the device of more valid approximation for wave function will be the important problem to be studied hereafter.

The author wishes to thank Professor S. Shida of Tokyo Institute of Technology and Professor K. Hirota of Osaka University for their valuable suggestions and kind encouragement. Also the auther is indebted to Mr. Y. Mori for helpful discussion.

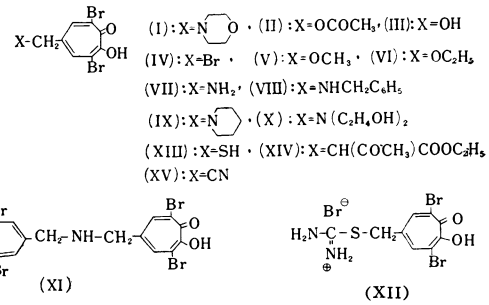
The Mannich Base of Troponoid and its Application. II. On 5-Bromomethyltropolone Derivative



By Shuichi SETO and Kyozo OGURA

(Received March 26, 1959)

In the preceding paper[1], the authors reported on the derivation of 5-hydroxymethyl- and 5-formyltropolones from 3,7-dibromo-5-morpholinomethyltropolone, and on their reactions. In the present series of experiments, the 5-hydroxymethyl derivative was further led to 5-bromomethyl derivative and examination of this reaction showed some interesting results which are described herein.

Warming of 3,7-dibromo-5-hydroxymethyltropolone(III), obtained from 3,7-dibromo-5-morpholinomethyltropolone (I), in hydrobromic acid affords 3,7-dibromo-5-bromomethyltropolone(IV) as colorless needless, m. p. 140°C, in a good yield. IV is very reactive and reacts with various anionoid reagents to undergo substitution of bromine in the bromomethyl group as *p*-bromomethylphenol does[2].

Under some conditions, for example, treatment with sodium hydroxide solution, it forms a bis(tropolonyl)methane derivative. When IV is heated in methanol or ethanol, 5-methoxymethyl-(V) or 5-ethoxymethyltropolone derivative(VI) is obtained. These substances are the same as the compounds obtained on refluxing 5-acetoxymethyltropolone derivative(II) in methanol or ethanol. Reaction of IV with sodium acetate afforded II. Reaction with amines occurs easily at room temperature to afford the corresponding aminoalkyltropolone derivatives. Treatment with liquid ammonia, benzylamine, morpholine, piperidine and diethanolamine, respectively, affords 5-aminomethyl-(VII), 5-benzylaminomethyl-(VIII), 5-morpholinomethyl-(I), 5-piperidinomethyl-(IX), and 5-bis (β-hydroxyethyl) aminomethyltropolone (X) derivatives. I and IX are also obtained by the Mannich reaction of 3,7-dibromotropolone, and VII is also obtained in some cases by treatment of II with liquid ammonia. Reaction of IV with concentrated ammonium hydroxide gives bis (3,7-dibromotropolon-5-ylmethyl) amine (XI). All these aminoalkyltropolone derivatives form a water-soluble green iron complex with ferric chloride. IV undergoes reaction with thiourea in *tert*-butanol at room temperature to form *S*-(3,7-dibromotropolon-5-ylmethyl) isothiuronium bromide(XII) whose treatment with alkali affords 3,7-dibromo-5-mercaptomethyltropolone (XIII). IV forms a bis(tropolonyl)-methane derivative in strong alkali and its reaction with carbanions is not possible by the conventional method. Application of a large excess of the reagent to a dilute solution of IV gives the desired compound. For example, dropwise addition of a dilute solution of IV in ethyl acetoacetate with stirring, into a solution of a large excess of potassium compound of ethyl acetoacetate affords the anticipated 5-(β-acetyl-β-ethoxycarbonyl)tropolone derivative(XIV). Application of a large excess of potassium cyanide to a solution of IV in dioxane and water gives 5-cyanomethyltropolone derivative(XV).

Experimental[3]

3,7-Dibromo-5-bromomethyltropolone (IV). — A mixture of 2 g. of 3,7-dibromo-5-hydroxymethyltropolone(III) and 40 ml. of hydrobromic acid (sp. g., 1.38) was warmed for 15 min. and the colorless needle crystals that separated out were recrystallized from a benzene-cyclohexane mixture: m. p. 139~140°C. Yield, 2 g.

Anal. Found: C, 25.91; H, 1.89. Calcd. for $C_8H_5O_2Br_3$: C, 25.73; H, 1.34%. U. V. λ_{max}^{MeOH} mμ (log ε): 265(4.53), 350(4.21), 428(421).

1) S. Seto and K. Ogura, This Bulletin, **32**, 493 (1959).
2) K. Auwers, *Ber.*, **34**, 4264 (1901).
3) All melting points are not corrected.

3, 7-Dibromo-5-methoxymethyltropolone (V). — A solution of 10 mg. of IV in 1 ml. of methanol was heated on a water bath for about 10 minutes and the removal of methanol left colorless needles, m. p. 135°C, which showed no depression on admixture with the substance[1] obtained by refluxing II in methanol.

Anal. Found: C, 33.98; H, 2.73. Calcd. for $C_9H_8O_3Br_2$: C, 33.33; H, 2.47%. U. V. λ_{max}^{MeOH} mμ (log ε): 267(4.63), 346(4.29), 428(4.30).

3, 7-Dibromo-5-ethoxymethyltropolone (VI). — In exactly the same manner as in the cases of V and IV was heated in ethanol and colorless needles, m. p. 100°C, were obtained. These showed no depression on admixture with the substance[1] obtained by the refluxing of II in ethanol.

Anal. Found: C, 35.62; H, 2.91. Calcd. for $C_{10}H_{10}O_3Br_2$: 35.54; H, 2.96%.

3, 7-Dibromo-5-aminomethyltropolone (VII).—(a) A solution of 100 mg. of IV dissolved in ca. 5 ml. of liquid ammonia was allowed to stand at room temperature for 4 days. The yellowish brown residue which was obtained by removal of liquid ammonia was extracted with 1.5 N hydrochloric acid. The extract was neutralized to pH 2.5 and the precipitate thereby formed was collected. Washing of this precipitate with water and methanol afforded yellow powder, m. p. 225°C (decomp.).

b) A solution of 100 mg. of II dissolved in ca. 100 ml. of liquid ammonia was allowed to stand for a week. VII was obtained by treating the residue in the same manner as in the case of a).

Anal. Found: C, 29.62; H, 3.27; N, 4.04. Calcd. for $C_8H_7O_2NBr_2 \cdot H_2O$: C, 29.35; H, 2.75; N, 4.28%. U. V. λ_{max}^{MeOH} mμ (log ε): 268(4.44), 345 (3.95), 430(3.98).

3,7-Dibromo-5-benzylaminomethyltropolone(VIII). —About 30 mg. of IV was dissolved in one drop of benzylamine and the solution was warmed at 50°C for a few minutes. By this process yellow crystals separated out. About 1 ml. of acetic acid-water was added to this mixture, the crystals were collected by filtration, and recrystallized from ethanol; m. p. 180°C. Yield, ca. 30 mg.

Anal. Found: C, 43.94; H, 3.57; N, 3.10. Calcd. for $C_{15}H_{13}O_2NBr_2 \cdot 2H_2O$: C, 43.17; H, 3.59; N, 3.35%. U. V. λ_{max}^{MeOH} mμ (log ε): 267(4.32), 347 (3.95), 430(3.87).

3, 7-Dibromo-5-piperidinomethyltropolone (IX).— a) The addition of 0.5 ml. of piperidine to 50 mg. of IV resulted in excessive generation of heat and a solution was effected. Addition of water to this solution produced a yellow precipitate. This mixture was adjusted to pH 5 with hydrochloric acid, the precipitate was collected, and washed with water and ethanol. m. p. 189~190°C (decomp.). Yield, ca. 20 mg.

b) A mixture of 400 mg. of 3,7-dibromotropolone(I) in 0.6 ml. of acetic acid and 0.4 ml. of piperidine was heated at 100°C and when in solution, 0.2 ml. of formaldehyde solution (37%) was added dropwise, with stirring. After about 10 min. of stirring and heating, the yellow precipitate that formed was collected and washed with water and ethanol, m. p. 190°C (decomp.). Yield, 490 mg. This substance showed no depression of melting point on admixture with the substance obtained by method a).

Anal. Found: C, 41.69; H, 3.95; N, 3.74. Calcd. for $C_{13}H_{15}O_2NBr_2$: C, 41.38; H, 3.98; N, 3.72%. U. V. λ_{max}^{MeOH} mμ (log ε): 268(4.02), 350 (3.71), 425(3.71).

3, 7-Dibromo-5-bis(β-hydroxyethyl)aminomethyltropolone (X). — A solution of 30 mg. of IV dissolved in 3 drops of diethanolamine was neutralized with 2 N hydrochloric acid and the yellow precipitate that formed was collected, washed with water and methanol; m. p. 160°C.

Anal. Found: C, 35.60; H, 3.89; N, 3.69. Calcd. for $C_{12}H_{15}O_4NBr_2$: C, 36.27; H, 3.78; N, 3.52%. U. V. λ_{max}^{MeOH} mμ (log ε): 267(4.21), 350 (3.90), 430(3.87).

Bis(3, 7-dibromotropolon-5-ylmethyl)amine (XI). —A mixture of ca. 30 mg. of IV in 0.5 ml. of concentrated ammonium hydroxide was stirred for a few minutes at room temperature. By this process yellow crystals precipitated out. This mixture was neutralized with 2 N hydrochloric acid, the yellow powder so formed was collected, and washed with water and methanol; m. p. 196°C.

Anal. Found: C, 31.31; H, 1.98; N, 2.59. Calcd. for $C_{16}H_{11}O_4NBr_4$: C, 31.94; H, 1.83; N, 2.31%. U. V. λ_{max}^{MeOH} mμ (log ε): 268(4.40), 345 (4.06), 425(4.00).

S-(3,7-Dibromotropolon-5-ylmethyl)isothiuronium Bromide (XII).—A solution of 40 mg. of IV and 20 mg. of thiourea dissolved in 3 ml. of *tert*-butanol was stirred at room temperature for a few minutes and the colorless crystals that separated out were collected, and washed with ethanol; m. p. 223~224°C (decomp.). Yield, 50 mg.

Anal. Found: C, 24.59; H, 2.42; N, 6.51. Calcd. for $C_9H_9O_2N_2SBr_3$: C, 24.05; H, 2.00; N, 6.24%. U. V. λ_{max}^{MeOH} mμ (log ε): 268(4.59), 335 (3.88), 387(3.71), 420(3.58).

3, 7-Dibromo-5-mercaptomethyltropolone (XIII). —A mixture of 50 mg. of XII in 0.5 mol. of 45% sodium hydroxide solution was heated for a few minutes on a water bath and neutralized by pouring this mixture into 6 N hydrochloric acid containing cracked ice. The precipitate that formed was collected and recrystallized from ethanol to give pale yellow needles, m. p. 128°C. Yield, 20 mg.

Anal. Found: C, 30.10; H, 1.84. Calcd. for $C_8H_6O_2Br_2S$: C, 29.45; H, 1.82%. U. V. λ_{max}^{MeOH} mμ (log ε): 267(4.46), 350(4.01), 430(3.86).

3, 7-Dibromo-5-(β-acetyl-β-ethoxycarbonylethyl)-tropolone (XIV). — A solution of 500 mg. of IV dissolved in 50 ml. of ethyl acetoacetate was added dropwise into a solution of 1 g. of potassium dissolved in 50 ml. of ethyl acetoacetate, with stirring at room temperature. The solution was further stirred for 2 hr. at room temperature,

neutralized with 6 N sulfuric acid to pH 5, and the ethyl acetoacetate layer was separated. The acetate layer was washed with water and evaporated under reduced pressure to remove the acetate. The dark red, oily residue crystallized on addition of ether, the crystals were collected, washed with ether, and recrystallized from a mixture of benzene and petroleum ether; m. p. 114~115°C. Yield, 350 mg.

Anal. Found: C, 39.83; H, 3.74. Calcd. for $C_{14}H_{14}O_5Br_2$: C, 39.81; H, 3.32%. U. V. λ_{max}^{MeOH} mμ (log ε): 268(4.55), 345(4.07), 430(3.96).

3, 7-Dibromo-5-cyanomethyltropolone (XV). — A solution of 150 mg. of IV dissolved in 3 ml. of dioxane was added dropwise, with stirring, into a solution of 150 mg. of potassium cyanide dissolved in 6 ml. of dioxane and 1 ml. of water at room temperature, the drops causing a transitory red color to appear. After completion of addition, the mixture was stirred for 1 hr., the solvent was removed under reduced pressure at room temperature, and the residue was acidified with hydrochloric acid. The brown precipitate that formed was collected and recrystallized from benzene; m. p. 148~151°C. Yield, 100 mg. During recrystallization, bis(3,7-dibromotropolon-5-yl)-methane formed as a benzene-insoluble by-product.

Anal. Found: C, 34.04; H, 1.80; N, 3.82. Calcd. for $C_9H_5O_2NBr_2$: C, 33.86; H, 1.57; N, 4.39%. U. V. λ_{max}^{MeOH} mμ (log ε): 267(4.50), 345(4.04), 430(3.98).

Summary

Reaction of 3,7-dibromo-5-hydroxymethyltropolone with hydrobromic acid affords 3, 7-dibromo-5-bromomethyltropolone, which has a high reactivity and reacts with various anionoid reagents to undergo substitution of bromine in the bromomethyl group. In this manner it is possible to extend the substituent by forming C–O, C–N, C–S and C–C bonding at the tip of the methyl group in position 5 of the tropolone ring.

A part of the expense for the present research was defrayed by Sankyo Co., Ltd. The microanalyses were carried out by Messrs. S. Oyama and S. Azumi and Miss A. Iwanaga. The authors wish to express their sincere gratitude to the above-mentioned people.

Synthesis of Polyanhydride. I. Mixed Anhydride of Aromatic and Aliphatic Dibasic Acids*

By Naoya YODA and Akihisa MIYAKE

(Received February 4, 1959)

The polyanhydride of aromatic dibasic acid was first prepared by Bucher and Slade[1], who reported that the crystalline polymer of the melting point above 300°C was obtained by heating isophthalic acid or terephthalic acid with acetic anhydride. Aliphatic polyanhydride was synthesized in 1932 by Hill and Carothers[2] who have investigated the preparation of polyanhydride from sebacic acid. Although possessing fiber-forming properties, it was reported that the aliphatic polyanhydride melted at too low a point to be of practical interest and the polymer gradually disintegrated in the presence of moisture due to hydrolytic degradation. On account of these unfavorable properties, the study of polyanhydride has not been taken into consideration since then. In 1957, however, Conix[3] reported that aromatic polyanhydride prepared from di-(*p*-carboxyphenoxy)-α,ω-alkane has shown excellent film and fiber-forming properties. This might be ascribed to the hydrophobic nature of polymer molecules, caused by the accumulation of phenylene nuclei along the polymer chain to form a regular molecular structure very closely packed as observed in polyethylene terephthalate.

The present investigation has been undertaken in order to study the synthesis

* Presented before the 4th Autumnal Meeting of the Chemical Society of Japan, held in Tokyo, November 23, 1958.

of mixed polyanhydrides of aromatic and aliphatic dibasic acids. As described herein, the mixed polyanhydrides of random structure were obtained when the calculated amount of aromatic and aliphatic dibasic acids had been mixed and treated with acetic anhydride which caused them to polymerize by heating in vacus. When suitable amounts of aromatic and aliphatic dibasic acids were used, it was possible to obtain mixed polyanhydrides of practical interest having their melting points in the range of 200 to 250°C. Using terephthalic acid as aromatic dibasic acid and adipic acid or sebacic acid as aliphatic dibasic acid, the mixed dibasic acids can be transformed into mixed anhydride with acetic anhydride. These mixed anhydrides polymerize by splitting off acetic anhydride. The diagram of composition versus melting point was obtained. From this the composition of mixed polyanhydride having its melting point in the range of 200°C to 250°C has been obtained for terephthalic acid-adipic acid, and terephthalic acid-sebacic acid copolymers.

Furthermore, the preparation of aromatic and aliphatic mixed polyanhydrides of regular structure have been investigated by the polycondensation reaction of diacid halide with dibasic acid in organic solvent pairs such as pyridine-benzene and pyridine-ether. The mixed polyanhydrides of regular structure having their melting points at 225°C (adipic acid) and 215°C (sebacic acid) have been synthesized, and the influence of chemical structure on the physical properties of these polymers was discussed[4].

Experimental and Results

Materials.—Commercially available sebacic acid and adipic acid were recrystallized from ethanol. The melting point was 133°C and 151~153°C, respectively. The purified terephthalic acid was obtained by converting it into dimethyl ester, followed by vacuum distillation and alkaline hydrolysis. Thus, carefully purified aliphatic and aromatic dibasic acids were used as a starting material for each polymerization.

Mixed Polyanhydride of Random Structure.—The mixed polyanhydride of terephthalic acid and adipic acid was obtained by polycondensation reaction using the excess of acetic anhydride. The detailed procedure is described as follows.

A 13.3 g. (0.08 mol.) portion of terephthalic acid and 17.5 g. (0.12 mol.) of adipic acid were mixed together and 415 ml. of acetic anhydride (b. p. 130°C) were added to the mixture. The combined solution was refluxed on an oil bath at 150~160°C for 8 hr. After the dibasic acids were completely dissolved into acetic anhydride, reflux was continued for an additional one hour and the excess of acetic anhydride was distilled off under water jet pump pressure to form mixed anhydride of low melting crystalline solid. The prepolymer thus formed was heated under dry nitrogen atmosphere in vacuo at 240°C for 1.5 hr. The resulting polyanhydride has its melting point at 235°C and possesses fiber-forming property. The intrinsic viscosity of polymer measured in 1,4-dioxane at 30°C was 0.130. However, it becomes brittle shortly after spinning due to its hydrolytic degradation by absorbing moisture. When purified terephthalic acid and adipic acid were used, it was possible to avoid coloration by impurities on heating.

The relationship between the melting point and the composition of terephalic acid and adipic acid was measured and its mole fraction was plotted against the melting point of copolymer as shown in Fig. 1. It gives the minimum melting point at 47~48°C where the composition of copolymer

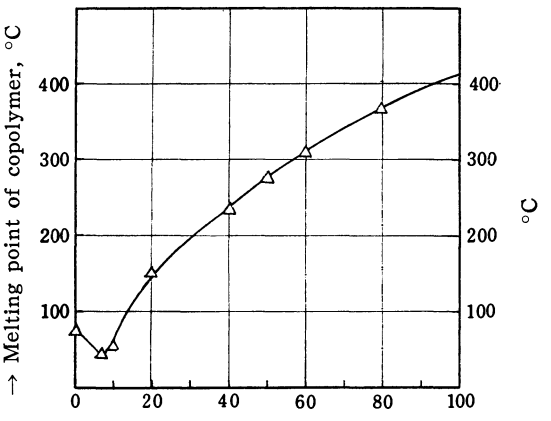

Fig. 1. Relation between composition and melting point of adipic acid-terephthalic acid anhydride copolymer.

is 93 mol. % of adipic acid. Polyanhydride of terephthalic acid itself has its melting point above 410°C. Two acids, e. g., terephthalic acid and aliphatic acid, furnish a series of copolymers in which the melting point and degree of crystallinity increase as the proportion of terephthalic acid is increased over 10 mol. %.

The experimental results are summarized in Table 1. The infrared spectrum of the polymerization product has absorption bands of anhydride carbonyl group at 5.56 and 5.78 μ as illustrated in Fig. 2[5].

The polycondensation proceeds smoothly upon heating in vacuo to obtain a linear polymer and

the infrared data support the fact that the chains link with each other by anhydride groups and are terminated by acetyl groups derived from the reagent used in bringing about the anhydride formation.

The polymerization is started even by simple heating at 220～250°C at atmospheric pressure. A much faster reaction, leading to the formation of polyanhydride of higher molecular weights is observed, however, on heating the mixed anhydrides in vacuo under dry nitrogen atmosphere at elevated temperatures in order to facilitate the removal of acetic anhydride.

In the same manner, the mixed polyanhydride of terephthalic acid and sebacic acid was prepared by polycondensation of purified sebacic acid and terephthalic acid. The detailed procedure is illustrated below.

A 17 g. portion (0.10 mol.) of terephthalic acid and 40 g. (0.20 mol.) of sebacic acid were pulverized and 1000 ml. of acetic anhydride was added to the mixture. The solution was refluxed at 150～160°C for 8 hr. After distilling off the excess of acetic anhydride, a mixed anhydride of low melting crystalline solid was obtained. The prepolymer was heated under dry nitrogen atmosphere in vacuo at 230°C for 1.5 hr. to form polyanhydride having its melting poing at 220°C. This possesses a fiber-forming property and it is somewhat elastic. It becomes brittle shortly after spinning due to its hydrolytic degradation by absorbing moisture. The intrinsic viscosity of polymer measured in *p*-dioxane at 30°C immediately after spinning was 0.162.

The relationship between the melting point versus the composition of terephthalic acid and

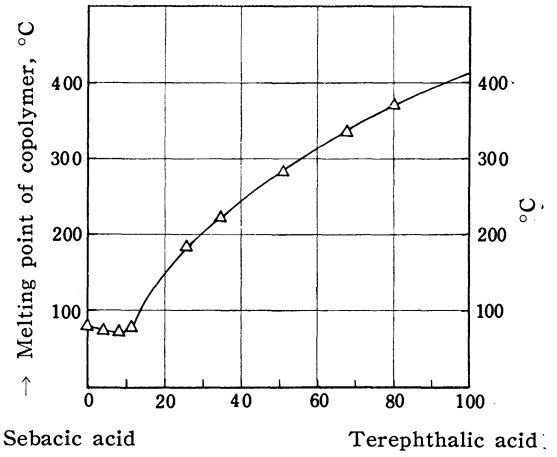

Fig. 3. Relation between composition and melting point of sebacic acid-terephthalic acid anhydride copolymer.

sebacic acid was obtained and its mole fraction was plotted against the melting point of copolymer as shown in Fig. 3. It was found that the minimum melting point was at 75°C where the composition of copolymer was 95.6 mol. % of sebacic acid and 4.4 mol. % of terephthalic acid. The experimental results are summarized in Table II. The infrared spectrum of copolymer has carbonyl absorption bands at 5.56 and 5.78 μ as shown in Fig. 4[5].

Infrared spectra indicate that polyanhydride before hydrolysis has two carbonyl absorption

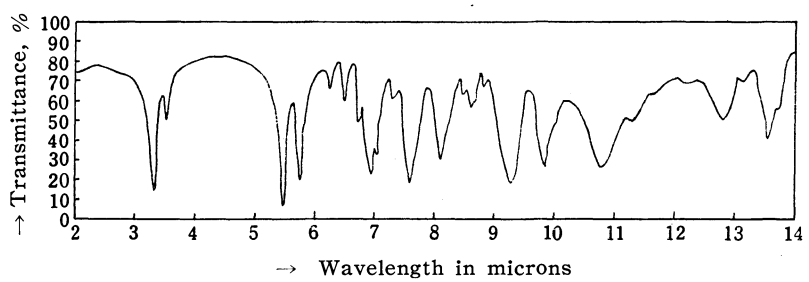

Fig. 4. The infrared spectrum of polyanhydride of sebacic acid-terephthalic acid system (KBr)

bands of the anhydride group at 5.56 and 5.78 μ. In addition to the carbonyl absorptions, the anhydride group also shows a strong band due to the C-O-C stretching vibration at 9.56 μ. When the polymer is exposed to moisture, the carbonyl absorption band at 5.86 to 5.95 μ appears. This indicates the existence of aliphatic and aromatic carboxylic acid carbonyl groups. The absorption bands at 3.71 and 3.95 μ are also observed. These can be taken as a strong evidence for the presence of dimeric carboxylic acid by taking account of bands existing in the carbonyl region.

When polyanhydrides of random structure are exposed to alkaline solution, it leads to the complete hydrolysis of anhydride to form aromatic and aliphatic dicarboxylic acids. An infrared spectrum shows neither anhydride carbonyl bands at 5.56 and 5.78 μ nor an ether band at 9.56 μ. On the contrary, the typical carboxylic acid bands appear at 3.71 and 3.95 μ of dimeric carboxylic acid bands and the strong carbonyl band at 5.86 μ[5].

The mixed anhydride of three components of dibasic acid such as the terephthalic acid, the adipic acid and the sebacic acid system was prepared by polycondensation reaction using the excess of acetic anhydride. The polymerization procedure is described as follows.

A 8.3 g. portion (0.05 mol.) of terephthalic acid, 7.3 g. of adipic acid (0.05 mol.) and 10.1 g. (0.05 mol.) of sebacic acid were thoroughly mixed in a mortar and refluxed with 550 ml. of acetic anhydride at 150~160°C for 8 hr. After all the acids were completely dissolved into acetic anhydride, the excess of acetic anhydride was distilled off under reduced pressure to form a mixed anhydride which was a low-melting crystalline solid. Then the prepolymer was heated under dry nitrogen atmosphere in vacuo at 250°C for 1.5 hr. to form a polyanhydride having a melting point at 245°C, which possesses a fiber-forming property.

Polymerization with acetyl chloride was also studied for dibasic acid anhydride of terephthalic acid and adipic acid or sebacic acid. In this case, the fiber-forming copolymer having a melting point at 210~230°C was also obtained with the mole fraction of 40 mol. % of terephthalic acid and 60 mol. % of adipic acid or sebacic acid.

Mixed Polyanhydride of Regular Structure.— Attempting to prepare the polyanhydride in which aromatic dibasic acid and aliphatic dibasic acid link with each other in a regularly bonded form, the polycondensation reaction of dibasic acid and dibasic acid chloride by dehydrochorination was studied in organic solvent pairs such as pyridine-ether, pyridine-benzene and dimethyl formamide-dimethyl aniline. Furthermore, the reaction of dibasic acid chloride with dimethyl ester of dibasic acid was investigated. In this case, terephthalic acid was again used for aromatic dibasic acid, and adipic acid or sebacic acid was chosen for aliphatic dibasic acid.

Preparation of Dibasic Acid Chloride.— Terephthalic acid chloride was prepared by the action of phosphorus pentachloride on terephthalic acid. After extraction with ether, it was dried over anhydrous sodium sulfate and the ether was evaporated off. The recrystallizations from ligroin after decolorization with activated charcoal

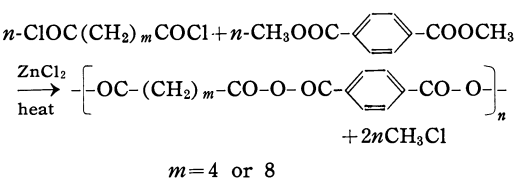
gave colorless needles, m.p. 83.0°C (yield, 67%).

Adipic acid chloride was also obtained by refluxing adipic acid with the excess of thionyl chloride on a water bath for 4 hr. After evaporating off the excess of thionyl chloride, it gave adipic acid chloride which boiled at 112~115°C/10 mmHg (yield, 60%). Sebacic acid chloride was prepared in the same manner mentioned above with thionyl chloride to obtain a product boiling at 161°C/14 mmHg (yield, 45%). In order to avoid hydrolysis, the solvents used for the polymerization were carefully purified each time before use. Pyridine (C. P. grade) was refluxed with barium oxide and distilled, and the fraction at 115.5°C was taken. Benzene and ether were dried over metallic sodium and distilled immediately before use.

Polymerization in Pyridine-Ether Medium —A 4.5 g. portion (0.03 mol.) of terephthalic acid was dissolved into 120 ml. of pyridine and 5 g. (0.03 mol.) of adipic acid chloride dissolved into 100 ml. of ether were added dropwise into the reaction system with ice cooling under dry nitrogen atmosphere.

When acid chloride is added into pyridine, the pyridine complex is formed[6]. The reaction temperature was gradually raised to 25~30°C and stirring was continued for 4 hr. at this temperature. The resulting polymer was filtered, washed and dried to obtain polyanhydride having a melting point at 250°C. The existence of the anhydride group was confirmed by the infrared spectrum which showed acid anhydride absorption bands in a carbonyl region[5].

Polyanhydride of sebacic acid-terephthalic acid obtained under the same reaction condition has its melting point at 240°C, and the infrared spectrum has acid anhydride absorption bands in a carbonyl region[5].



On the contrary, polyanhydride of terephthalic acid chloride and aliphatic acid forms a white crystalline solid, melting at 300°C with decomposition. The infrared spectrum shows acid anhydride and carboxylic acid absorption bands in a carbonyl region.

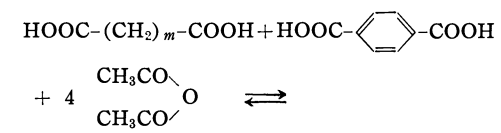
Polymerization in Pyridine-Benzene Medium.— When a pyridine-benzene solvent pair is used for the dehydrochlorination of terephthalic acid and aliphatic dibasic acid chloride, it was observed that the reaction proceeded more smoothly than in a pyridine-ether medium to form a white crystalline solid having its melting point at 225°C. The infrared spectrum shows carbonyl absorption band at 5.50 and 5.70 μ.

The reaction of sebacic acid chloride and terephthalic acid was also studied under the same reaction conditions, and white crystalline polymer melting at 215°C was obtained. The percent conversion of polyanhydrides in pyridine-benzene was found to be higher than that of polyanhydrides in pyridine-ether. The infrared spectrum indicates the existence of the acid anhydride group in a carbonyl region.

Polymerization of Dibasic Acid Chloride with Dibasic Acid Methyl Ester in the Presence of Zinc Chloride Catalyst.—As one of the processes to prepare polyanhydrides of regular structure, the polymerization reaction of dibasic acid chloride with dibasic acid methyl ester in the presence of zinc chloride was studied. The polyanhydrides of regular structure having their melting points at 203°C (adipic acid-terephthalic acid) and at 195°C (sebacic acid-terephthalic acid) were obtained.

Kyrides and Dvornikoff[7] reported the reaction of dialkyl phthalate and phthalyl chloride to give anhydride and the alkyl chloride. The improved method of the reaction of diacid chloride and diacid ester was employed in the presence of zinc chloride as a catalyst. The following reaction takes place for the polymerization in this case.

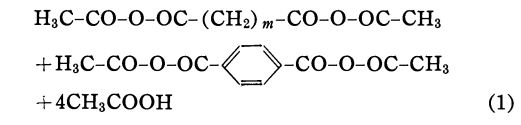
$m=4$ or 8



Although it is relatively stable against hydrolytic degradation, coloration of the polymer was observed when it was heated above 200°C.

In the same manner, polyanhydride obtained from sebacic acid chloride melts at 195°C and coloration occurs when it is heated above 200°C. It was found that the polymer thus obtained was relatively stable towards hydrolysis and it has a melting point with thermal decomposition. The polycondensation in dimethyl formamide medium was also studied and the polymers thus obtained failed to show good hydrolytic and thermal stability. It was found from the experimental results obtained above that the dehydrochlorination reaction of acid chloride and dibasic acid in pyridine-benzene medium gave the most satisfactory results.

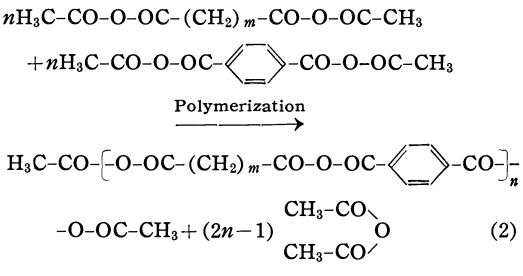
Infrared Absorption Measurements. — The spectra were recorded with a Perkin-Elmer Model 21 spectrophotometer using an NaCl prism. Potassium bromide disks were used. The die and handpress were those supplied by the Shimadzu Co., Ltd.



Discussion

The polycondensation reaction of aromatic and aliphatic dibasic acids with acetic anhydride proceeds through the following equations; firstly, the dibasic acids are converted into mixed anhydrides with acetic anhydride as shown in Eq. 1.

6) E. C. Harning, "Organic Syntheses", Col. Vol. III, John Wiley & Sons, Inc., New York (1955), p. 28.



7) L. P. Kyrides and M. N. Dvornikoff, *J. Am. Chem. Soc.*, **55**, 4630 (1933).

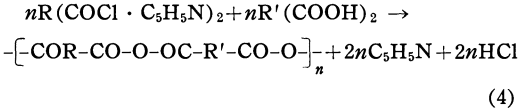
(1)

$m=4$ or 8

Secondly, these mixed anhydrides thus formed, which bear terminal acetyl end-groups and are low-melting crystalline solids, polymerize upon heating by splitting off acetic anhydride to form polyanhydride with high molecular weights as indicated in the following Eq. 2.

(2)

$m=4$ or 8

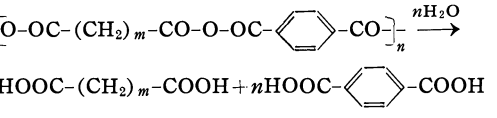


As to the mixed polyanhydride of random structure from aliphatic and aromatic dibasic acids, it was observed that the melting point and the degree of crystallinity increase with an increase in the proportion of aromatic dibasic acid. Presumably this can be explained by the fact that the introduction of aromatic nuclei into the polymer chain results in the formation of the polymer having rigid molecular structure due to the accumulation of phenylene nuclei along the polymer chain.

In the polymerization of polyanhydride of regular structure in pyridine-ether and pyridine-benzene media, the pyridine complexes of diacid chloride are first formed as shown in the following scheme:

(3)

The pyridine complexes thus formed react with dibasic acid to obtain polyanhydride of regular structure as follows:



(4)

A. R; $-(CH_2)_4-$, $-(CH_2)_8-$, R'; 

B. R;  , R'; $-(CH_2)_4-$, $-(CH_2)_8-$

There are possibilities that anhydride interchange reaction takes place during the dehydrochlorination process at an elevated temperature to be transformed into the polyanhydride of random structure. This can be avoided, however, when the polymerization is performed at room temperature or at slightly elevated temperature under atmospheric pressure.

It is reasonably presumed that acid anhydride groups in a less closely packed polymer chain (e. g., polyanhydride of random structure) are easily hydrolyzed in the presence of moisture[8], and the polyanhydride chain is disintegrated into low molecular weight dicarboxylic acid, as shown below:

(5)

The authors have further given their attention to the application of interfacial polycondensation[9] for the polymerization of polyanhydride, which involves a similar concept already mentioned in the case of polymerization in solvent pairs, using diacid chloride for one component in such organic solvent as chloroform or benzene, and sodium or potassium salt of dibasic acid or dimethyl ester of dibasic acid for another in aqueous alcohol phase at room temperature under nitrogen atmosphere[10]. Much room is left for the detailed study of polyanhydride synthesis in this field, and further investigation is necessary before it can be applied for general purposes.

Summary

Copolymerization reactions of mixed anhydrides of aliphatic and aromatic dibasic acids have been investigated. It has been shown that a polyanhydride of regular structure was obtained from diacid chlorides and dibasic acids in organic medium, and that polyanhydrides of random structure were obtained from the mixed aromatic and aliphatic dibasic acids. A polyanhydride having its melting point at 225°C was prepared for terephthalic acid and adipic acid copolymer of regularly linked structure and that having its melting point at 215°C for terephthalic acid and sebacic acid copolymer. It was found that the stability of copolymer towards hydrolytic and thermal degradations was greater for those with regularly

linked structure than for a polyanhydride of random structure. The mixed polyanhydrides of random structure were prepared and the diagram of composition versus melting point was obtained. The mole fractions of the two acid components were found to be 35~40 mol. % of terephthalic acid and 60~65 mol. % of aliphatic dibasic acid for copolymers melting at 220 to 240°C. It has further been shown that aliphatic and aromatic dibasic acids furnish a series of copolymers in which the solubility decreases and the melting point and the degree of crystallinity increase as the proportion of aromatic dibasic acid is increased.

The authors wish to express their gratitude to Dr. K. Hoshino, the Director of the Research Department, and Dr. M. Watanabe for their interest in this research and the permission for its publication. Sincere thanks are also due to Professor Y. Ishii of Nagoya University for helpful discussion. The authors are indebted to Messrs. S. Tanaka and Y. Bamba for their cooperation in carrying out the experiments.

The Isolation of Technetium by Coprecipitation or Anion Exchange

By Fujio ICHIKAWA

(Received January 17, 1959)

1. Coprecipitation of Technetium with Molybdate. — Technetium-99 having a long half-life is usually separated from fission products of uranium-235 after a long irradiation and cooling time. But technetium-99m is easily prepared as a decay product of molybdenum-99 from neutron irradiated molybdenum. Articles[1-3] on the coprecipitation of technetium mainly refer to that with sulfide, perrhenate and perchlorate. In this paper, the coprecipitation behavior in connection with the separation of technetium from molybdenum is reported.

Experimental. — Technetium-99m is not a β emitter but a γ emitter, whereas molybdenum-99 is a β and γ emitter. Accordingly the γ-ray spectrum peak of technetium-99m (0.140 MeV.) is measured with 256 channel pulse height analyzer, whereas molybdenum-99 is simply determined by measurement of β-ray activity with G-M counter.

Fifty milligrams of ammonium molybdate is irradiated in a J. R. R.-1 Reactor for 2 hr. at a flux of 10^{11} neutrons/cm^2/sec. Since the half-life of molybdenum-99 is 67 hr. and that of technetium-99m is 6.04 hr., radioactive equilibrium is reached after 23.08 hr. The irradiated sample is dissolved in 10 ml. of water after a day.

Two milliliters each of various precipitants is added to 1 ml. portion of this sample solution. A 5% solution of lead nitrate, calcium chloride, barium chloride, silver nitrate or uranyl nitrate is used as the precipitant. When calcium chloride is used, 1 ml. of 3 M aqueous ammonia is required for the complete precipitation of calcium molybdate. The precipitate formed is separated

TABLE I-1. COPRECIPITATION RATIO OF TECHNETIUM-99 m WITH SOME MOLYBDATES

Form of precipitate	Precipitation ratio of Mo-99 %	Precipitation ratio of Tc-99m %
$PbMoO_4$	99.2	99.6
	96.0	99.6
	86.4	87.5
$CaMoO_4$	94.4	23.1
	93.3	12.3
	96.5	20.1
	97.7	33.7
$BaMoO_4$	96.3	10.9
	94.7	41.4
	75.1	39.6
Ag_2MoO_4	85.5	51.6
	95.9	67.8
	96.7	41.8
UO_2MoO_4	85.0	35.2

from the supernatant solution by the aid of a centrifuge, a filter tube or an usual filtering funnel. The β and γ-ray activities of precipitates and supernatant solutions are measured by comparing them with the activities of the sample solution to which no precipitant was added. The separation ratio is calculated from those data and is shown in Table I-1.

Results. — A 99.6% portion of technetium-99m is coprecipitated with lead molybdate. About 70% of technetium-99m remains in the solution after calcium molybdate is precipitated, but a few per cent of molybdenum also remains by single precipitation. Seventy per cent of technetium-99m is not precipitated with barium molybdate or uranyl molybdate. J. A. Swartout[4] used silver molybdate in order to isolate technetium from molybdenum, but in the present study 50~60% of technetium is coprecipitated with silver molybdate.

The results mentioned above, are applied in two ways. One is an easy preparation of technetium-99m solution from irradiated calcium molybdate, and the other is an isolation of technetium-99m and molybdenum-99 from fission products by coprecipitation with lead molybdate.

(1) Fifty milligrams of calcium molybdate irradiated in J. R. R.-1 Reactor for 2 hr. is washed on a Toyo 5B filter paper with 10 ml. of water or 1% ammonium hydroxide and the β and γ activities of washings are measured. The results are shown in Table I-2.

The absorption curve of β-ray shows that calcium-45 coexists in the washings. This solution is passed through a cation-exchange column and almost all of the β contaminations are removed by this treatment.

TABLE I-2. SEPARATION OF TECHNETIUM-99m FROM IRRADIATED $CaMoO_4$

Washing	γ Activity of Tc-99m cpm/ml.	β Activity of impurities cpm/ml.	β Activity after resin treatment cpm/ml.
H_2O	129000	6240	691
1% NH_4OH	74565	12250	—

(2) Twenty milligrams of uranyl nitrate is irradiated in J. R. R.-1 for 2 hr. Neptunium-239 is separated by nitrate form anion exchanger[5]. Then the solution containing uranium and fission products is neutralized with ammonium hydroxide and ammonium biuranate formed is removed by filtering. A few milligrams of ammonium molybdate and lead nitrate are added to this solution. Lead moybdate is separated and washed with water. This precipitate shows a γ-ray spectrum of technetium-99m free from other fission products. (Fig. 1-1)

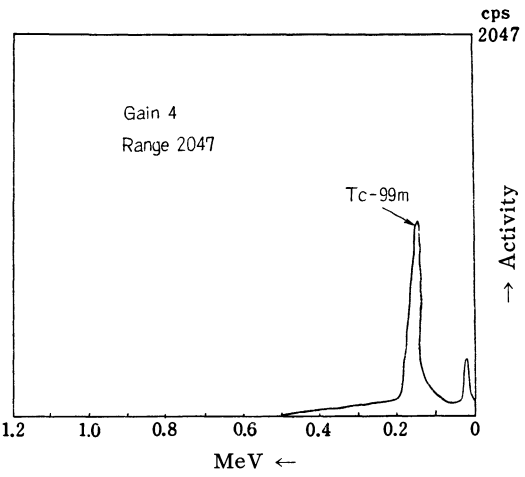

Fig. 1. γ-Ray spectrum of $PbMoO_4$ precipitation.

2. Isolation of Technetium from Fission Products by Anion Exchanger. — Several methods[1,2,6,7] were reported on the separation of technetium-99m from irradiated uranium. These were mainly based on the coprecipitation with sulfide or the solvent extraction. Hall and Johns[8] reported an anion-exchange separation of molybdenum and technetium. According to their results, molybdenum is eluted from a perchlorate form anion exchanger with 10% sodium hydroxide solution, and the technetium is then washed out with 2.0 M ammonium thiocyanate solution. This is a good separation method but thiocyanate solution is unfavorable for further treatment. In another report[9], the dependence of distribution coefficient of technetium on the nitric acid and hydrochloric acid concentrations was measured, and it is known that technetium forms a chloride complex anion within the 0.1~12 N hydrochloric acid concentration range and that it is strongly absorbed at lower nitric acid concentrations, but eluted easily with nitric acid of higher acidity. In the

present paper, the separation of technetium from irradiated uranium by anion exchangers is studied, following the papers mentioned above.

Experimental.—Fifty milligrams of ammonium molybdate is irradiated as mentioned in section 1. The sample is dissolved into 1 or 2 ml. of water and poured on the top of hydroxide form anion exchanger Dowex 1 column (100~200 mesh, 1 cm.×5 cm.). The column is washed with 100 ml. of 10% sodium hydroxide and then technetium is eluted with nitric, hydrochloric or sulfuric acid of various concentrations. Results are shown in Fig. 2-1. From these data, it is shown that technetium is not eluted with 10% sodium hydroxide or 0.7 N nitric acid, but easily eluted with 7 N nitric acid. Then these behaviors are applied to the following experiment.

** Tc-99m found in NaOH fraction may be a decay product of Mo-99.

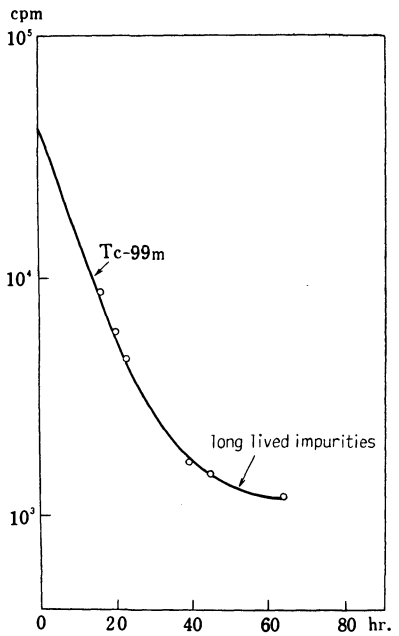

Fig. 2-7. γ-Ray decay curve of 7.5 N HNO_3 fraction.

Twenty milligrams of irradiated uranyl nitrate is used as a starting material. Neptunium-239 is removed by a nitrate form anion exchanger[5]. Thus, about 50 ml. of 7.5 N nitric acid solution of fission products is obtained. This solution is dried up and redissolved in 1 ml. of water and poured onto the hydroxide form anion exchanger. The column is washed with 150 ml. of 10% sodium hydroxide, with 200 ml. of 0.7 N nitric acid and finally with 20 ml. of 7.5 N nitric acid. γ-ray spectra of each fraction are measured by a 256 channel pulse height analyzer. They are shown in Figs. 2-2~5. As Fig. 2-5 shows, the pure spectrum of technetium-99m is found in 7.5 N nitric acid fraction. Decay of β and γ activities are shown in Figs. 2-6 and -7. After 3 days technetium 99m is disintegrated away almost completely, leaving impurities of long half-life.

Results.—Technetium is not eluted with 10% sodium hydroxide and eluted with 3~7 N nitric acid. But with other kinds of acid or dilute nitric acid, the elution of technetium is very slow or unpredictable. This is probably due to the complex formation. Some species of fission products may behave as an anion, and some others may form insoluble hydroxides in these chemical circumstances. These will be caught on a hydroxide form anion exchanger. Species which may form insoluble hydroxide will be eluted with 0.7 N nitric acid. Molybdenum-99 is washed out with sodium hydroxide and other anionic species will be removed with sodium hydroxide and 0.7 N nitric acid.

Recovery of technetium is calculated and shown in Table II. About 40~45% of technetium-99m is recovered in 7.5 N nitric acid solution. Purity in γ-ray activity is about 95% at the separation time.

Thanks are due to Dr. T. Ishimori for his advice and also to Miss S. Uruno, for her able assistance.

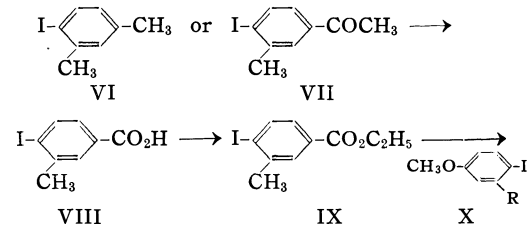
Estrogenic Biphenyls. V[1]. *Steric Effect in 2,2'-Dialkyl-4-methoxybiphenyl-4'-carboxylic Acids*

By Takeo SATO

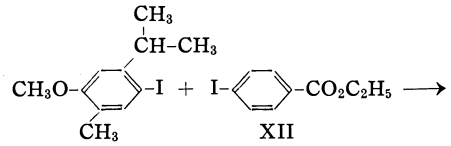
(Received February 17, 1959)

Enhancement in the estrogenic activity of the 2- or 2'-alkyl homologs of 4-methoxybiphenyl-4'-carboxylic acid (I) in comparison with the parent compound I was attributed to the increase in the interplanar angle of the two benzene nuclei to attain a favorable conformation[2] for the development of the activity[3].



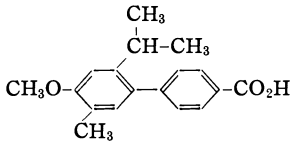
I: R=R'=H
II: R=CH_3, R'=H
III: R=H, R'=CH_3
IV: R=R'=CH_3
V: R=C_2H_5, R'=CH_3

The present author and Ōki also pointed out in the part III[4] of this series that the increase in the chain-length of the alkyl group at position 2 has little effect, as was deduced from the ultraviolet absorption spectra, and, consequently, essentially the same estrogenic potency was found in those compounds.



Since the minimum active dose in mice of the most potent compound of this series was found to be 100 γ, compared with 2.5 γ of stilbestrol dimethyl ether, it is considered that the methylene group at position 2 affords a steric effect which is not optimum for the development of the estrogenic potency as far as the biphenyl derivatives are concerned. Then the author sought higher estrogenic activity in more sterically hindered biphenyl derivatives.

4-Methoxy-2'-methylbiphenyl-4'-carboxylic acid (III) should have a similar conformation with 4-methoxy-2-methylbiphenyl-4'-carboxylic acid (II)[4], as was proved in 2,3'-diethyl-4-methoxybiphenyl-4'-carboxylic acid and 2',5'-diethyl-4-methoxybiphenyl-4'-carboxylic acid[5], because the steric interference by the methyl group must be equivalent at positions 2 and 2'. It is expected that the introduction of another alkyl group into position 2 of the compound III will give more steric interference and will result in a greater rotation of the benzene rings toward each other to relieve the steric hindrance. Thus the thicker models will be given.



The method of preparation is illustrated in the following chart. Although 4-iodo-3-methylbenzoic acid (VIII) was obtained by Klingel[6] through a sequence of reactions starting from *o*-toluidine, the present author largely modified the method as is described in *Experimental Part*. The compound VIII is also obtainable through nitric acid oxidation[7] of 4-iodo-*m*-xylene (VI). The Ullmann reaction between appropriate 4-iodoanisoles (X) and ethyl 4-iodo-3-methylbenzoate (IX) followed by alkaline hydrolysis gave the desired biphenyls.

As a reference compound 2-isopropyl-4-methoxy-5-methylbiphenyl-4'-carboxylic acid (XIII) was prepared from ethyl 4-iodobenzoate (XII) and 4-iodo-3-isopropyl-6-methylanisole (XI). The compound XIII is expected to involve greater rotation of the benzene nuclei toward each other than the corresponding straight-side-chain compounds because of the greater steric interference of the isopropyl group.

XIII

The ultraviolet absorption maxima with the estrogenic activities in mice of the compounds I, II, III, IV, V and XIII are given in Table I.

TABLE I. ULTRAVIOLET ABSORPTION MAXIMA AND ESTROGENIC ACTIVITIES OF 4-METHOXY-BIPHENYL-4'-CARBOXYLIC ACID DERIVATIVES

Compound	K-Band maxima λ, mμ	log ε	Active dose in mice, γ (%)
I	289	4.36	1000 (50)
II	280	4.17	200 (100)
III	271	4.21	
IV			100 (80)
V			100 (60)
XIII	273	4.06	

The ultraviolet absorption maximum of the compound III is located at 271 mμ and the curve is similar with that of compound II. The hypsochromic shift in the type of the compound III compared with the compound II is always observed and may be attributed to the hyperconjugation of the methyl group[8]. The compound XIII, even though the bulkiness of the isopropyl group is expected to exert a greater steric interference and to cause a greater deterioration in conjugation, still possesses a strong K-band of the biphenyl system. The hypsochromic shift of the absorption maximum of the compound XIII, which can be compared with the compound II in term of hyperconjugation, can be attributed to the deterioration in conjugation, since the methyl group at position 5 is known to have little effect on the ultraviolet absorption[9]. On the other hand, the compounds IV and V show weak absorption at about 280 mμ, possess instead the strong absorption at about 230 mμ, indicating the two moieties of the biphenyl system absorb the light almost independently. Thus the two benzene nuclei in the compounds IV and V are considered nearly perpendicular to each other.

The estrogenic activity in ovariectomized mice was determined by the vaginal smear test. It is striking to find out that the estrogenic potency is not greatly altered by the introduction of the alkyl groups into position 2 and/or posititon 2', but it is evident that the estrogenic action is enhanced by the introduction of the alkyl groups.

Experimental[10]

4-Amino-3-methylacetophenone. — To a well stirred mixture of 115 g. (0.77 mol.) of *o*-acetotoluidide, 70 g. (0.89 mol.) of acetyl chloride and 700 ml. of carbon disulfide, was added 350 g. (2.62 mol.) of anhydrous aluminum chloride in small portions in the course of one hour, during which time the whole was gently refluxed on a bath. The refluxing was continued for one hour and the viscous oil at the bottom, after cooling, was decomposed with an excess of concentrated hydrochloric acid. The acidic mixture was hydrolyzed by refluxing for two hours without isolation of the acetamido compound. The solution was made alkaline with sodium hydroxide and the organic material was extracted with ether. The ethereal solution was washed as usual and evaporated to give 44 g. (38% of the theoretical) of 4-amino-3-methylacetophenone, colorless needles, which melted at 110°C on recrystallization from benzene-petroleum ether. The reported melting point is 102°C[5].

Anal. Found: N, 9.52. Calcd. for $C_9H_{11}NO$: N, 9.39%.

4-Iodo-3-methylacetophenone (VII).—To a diazonium solution obtained from 16 g. (0.11 mol.) of 4-amino-3-methylacetophenone, 30 ml. of concentrated sulfuric acid, 100 ml. of water and 7 g. (0.10 mol.) of sodium nitrite in minimum quantity of water, was added a solution of 17 g. (0.1 mol.) of potassium iodide in 20 ml. of water in the course of 10 min. Stirring was continued for thirty minutes below 10°C and then at 50°C for one hour. The mixture was extracted with ether and the ethereal extract was successively washed with aqueous sodium hydroxide, aqueous sodium thiosulfate and water. The iodo-acetophenone boiled at 146~148°C/8 mm. and solidified on standing. Pale yellow crystals, m.p. 42~43°C. Yield, 15.5 g. or 60% of the theoretical. It was prepared by Klingel[6] in the same way and the reported melting point was 39°C.

4-Iodo-3-methylbenzoic acid (VIII).—A solution of 45 g. (0.17 mol.) of iodoketone VII in 170 ml. of dioxane was dropped slowly into a sodium hypobromite solution, made from 56 g. (1.4 mol.) of sodium hydroxide, 82 g. (0.51 mol.) of bromine and 450 ml. of water, at the temperature below 10°C. After the excess of sodium hypobromite was decomposed with sodium bisulfite and bromoform was removed by steam distillation, the solution was acidified to give a crystalline substance, which was recrystallized from ethanol-water. Colorless needles, m.p. 198~199°C. Yield, 39 g. (88% of the theoretical). According to

8) Private communication from Dr. M. Ōki, the University of Tokyo.
9) T. Sato and M. Fujii, unpublished work.
10) All melting and boiling points are uncorrected. The microanalyses were carried out by Mr. Mizushima to whom the author's thanks are due.

Klingel[6] the same acid, m. p. 203~204°C, was obtained by chromic acid oxidation of the iodoketone VII.

Anal. Found: C, 36.72; H, 2.72. Calcd. for $C_8H_7O_2I$: C, 36.66; H, 2.69%.

Ethyl 4-iodo-3-methylbenzoate (IX).—The iodobenzoate was obtained as a colorless oil boiling at 145~147°C/8 mm. by usual esterification of the acid VIII.

Anal. Found: C, 41.21; H, 3.79. Calcd. for $C_{10}H_{11}O_2I$: C, 41.41; H, 3.82%.

4-Methoxy-2'-methylbiphenyl-4'-carboxylic acid (III).—As a general procedure of the Ullmann reaction, the preparation of 4-methoxy-2'-methylbiphenyl-4'-carboxylic acid (III) is described. To a well-stirred mixture of 3 g. (0.010 mol.) of ethyl 3-methyl-4-iodobenzoate (IX) and 10 g. (0.043 mol.) of 4-iodoanisole (X, R=H), 10 g. (0.16 atom) of copper bronze, activated by Kleiderer and Adams' method[11], was added in 20 min. at 220~230°C. The reaction mixture was then heated to 270~280°C for 25 min. and extracted with acetone after cooling. The extract was hydrolyzed by refluxing with a mixture consisting of 50 ml. of 10% sodium hydroxide solution and 100 ml. of ethanol for about two hours. The solvent was evaporated and the residue was diluted with water. Insoluble dimethoxybiphenyl was removed by filtration. On acidification, the filtrate afforded an acid mixture, which was purified by chromatography on alumina. Repeated recrystallizations from ethanol gave 500 mg. of colorless needles, m. p. 183~184°C.

Anal. Found: C, 73.92; H, 5.59. Calcd. for $C_{15}H_{14}O_3$: C, 74.36; H, 5.83%.

2, 2'-Dimethyl-4-methoxybiphenyl-4'-carboxylic acid (IV).—The dimethylbiphenyl was prepared from compound IX and 4-iodo-3-methylanisole (X, R=CH_3)[4]. It was necessary to remove unchanged starting materials in vacuo before hydrolysis for the easier purification of the product. The acid was obtained as colorless prisms on recrystallization from ethanol-water, m. p. 142~144°C.

Anal. Found: C, 74.99; H, 6.39. Calcd. for $C_{16}H_{16}O_3$: C, 74.98; H, 6.29%.

2-Ethyl-4-methoxy-2'-methylbiphenyl-4'-carboxylic acid (V).—It was prepared from IX and 3-ethyl-4-iodoanisole (X, R=C_2H_5)[3]. Removal of the unchanged materials in vacuo was required and the distillate up to 180°C/5 mm. was discarded. Colorless needles, m. p. 139~140°C were obtained on recrystallization from benzene-petroleum ether.

Anal. Found: C, 75.55; H, 6.75. Calcd. for $C_{17}H_{18}O_3$: C, 75.53; H, 6.71%.

2-Isopropyl-5-methyl-4-iodoanisole (XI). — To a solution of 80 g. (0.49 mol.) of carvacrol methyl ether in 100 ml. of ethanol were alternatively added 130 g. (0.51 mol.) of iodine and 130 g. (0.60 mol.) of yellow mercuric oxide in small portions in the course of 30 min., while the mixture was well stirred and cooled in ice-water below 20°C. Stirring was continued for an additional 30 min. The mixture was heated on a water bath for 10 min. and filtered with suction. After the filtrate was diluted with water, the heavy oil was extracted with ether. The ethereal solution was washed with aqueous potassium iodide and dried over calcium chloride. The product boiling at 130~150°C/6~7 mm. was collected and then refractionated. The pure compound was obtained as brown oil, b. p. 135~137°C/6 mm.

Anal. Found: C, 46.16; H, 5.21. Calcd. for $C_{11}H_{15}OI$: C, 45.53; H, 5.21%.

2-Isopropyl-4-methoxy-5-methylbiphenyl-4'-carboxylic acid (XIII). — It was prepared from the compound XI and ethyl 4-iodobenzoate (XII). After hydrolysis the acidic portion was extracted with ethanol and the extract was recrystallized from ethanol to give colorless plates, m. p. 227.5~229°C.

Anal. Found: C, 76.06; H, 6.98. Calcd. for $C_{18}H_{20}O_3$: C, 76.03; H, 7.09%.

Ultraviolet absorption spectra. — They were measured with a Hitachi photoelectric spectrophotometer Model EPU-2, the compounds being in dissolved 95% ethanol.

The author wishes to express his hearty thanks to Professor Y. Urushibara, the University of Tokyo, Professor K. Hata, Tokyo Metropolitan University, and Dr. M. Ōki for their kind guidance and encouragement throughout this study and to the members of the Research Department, Teikoku Hormone Manufacturing Co., Ltd., Kawasaki, for bioassays. The author is also indebted to the Ministry of Education for the Grant in Aid for Fundamental Scientific Research.

The Aconite Alkaloids. XXXII[1]. *On Lucidusculine. Part II*[2]

By Takashi AMIYA

(Received March 2, 1959)

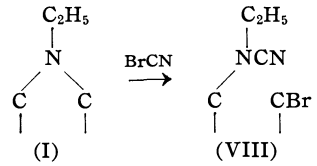
In the previous report[2] the extended formula of lucidusculine (I) has been proposed as follows:

$$C_{18}H_{23}\begin{cases}(OH)_2\\ OCOCH_3\\ >N-C_2H_5\\ >C=CH_2\end{cases}$$

Some new derivatives of lucidusculine are described in the present paper.

Catalytic hydrogenation[3] of I with platinum oxide in glacial acetic acid yielded dihydrolucidusculine(II), $C_{24}H_{37}O_4N$, m. p. 192~198°C, $[\alpha]_D^{18}$ −58.6°. On acetylation with acetic anhydride in pyridine, II gave dihydrolucidusculine diacetate(III), $C_{28}H_{41}O_6N$, m. p. 140~144°C, $[\alpha]_D^{18}$ −55.5°.

The infrared absorption spectrum of compound I gave two peaks at 6.06 and 11.26 μ and that of lucidusculine diacetate (IV)[4,5], $C_{28}H_{39}O_6N$, gave peaks at 6.08 and 11.32 μ due to presence of a terminal methylene group. Compounds II and III, on the other hand, showed no peak near the above-mentioned wavelengths. Therefore, it seems very probable that the hydrogenation of compound I proceeds as:



$$>C=CH_2 \xrightarrow{2H} >\overset{*}{C}H-CH_3$$

On account of a newly formed asymmetric carbon atom (asterisked) the formation of an epimer of compound II might be suspected[6].

Luciculine(V), $C_{22}H_{33}O_3N\cdot H_2O$, obtained from compound I upon hydrolysis with alcoholic potassium hydroxide[5], also showed two peaks in the infrared spectrum at 6.09 and 11.27 μ characteristic of a terminal methylene group.

Hofmann degradation of luciculine methiodide(VI) yielded a basic substance, named isomesoluciculine[7](VII), $C_{21}H_{31}O_3N\cdot H_2O$, m. p. 123~127°C (decomp.), $[\alpha]_D^{19}$ −17.0°. Compound VII showed peaks in the infrared spectrum at 6.08 and 11.28 μ characteristic of a terminal methylene group.

On treatment of compound I with cyanogen bromide, two reaction products were obtained. One of them was easily isolated because of its high solubility in water; it was named bromolucidusculine cyanamide (VIII), $C_{24}H_{35}O_4N(CN)Br\cdot 2H_2O$, m. p. 157~162°C (decomp.), $[\alpha]_D^{17}$ −76.0°, in which cleavage of the N-containing ring was noticed. It showed a peak in the infrared spectrum at 4.74 μ due to presence of a cyano group. The other was easily soluble in acetone but found to crystallize with difficulty. This cyanogen bromide degradation may proceed as follows:

(I) (VIII)

The ultraviolet absorption spectra of all these compounds showed only end absorptions and are reminiscent of those of aconite alkaloids, i. e., atisine, dihydroatisine, aconine, delphonine[8] and lycoctonine[9].

Experimental

Lucidusculine (I).—The ultraviolet absorption spectrum of this compound in methanol showed end absorption and no maximum. The infrared absorption spectrum in Nujol showed the presence of hydroxyl groups (2.95 μ), an acetoxyl group (5.82 and 8.10 μ) and a terminal methylene group (6.06 and 11.26 μ).

Dihydrolucidusculine (II).—Lucidusculine (1 g.)

was dissolved in 16 cc. of glacial acetic acid and hydrogenated with 0.5 g. of platinum oxide for six hours. After removal of platinum, the solution was evaporated to dryness. On treatment of the residue with water and then with aqueous ammonia, a precipitate was obtained. On recrystallization from ethyl acetate, crystals were yielded, which melted at 192~198°C. $[\alpha]_D^{18}$ −58.6° (methanol). Yield, 0.5 g. The ultraviolet absorption spectrum of this compound in methanol showed end absorption and no maximum. The infrared absorption spectrum in Nujol showed the presence of hydroxyl groups (2.96 μ) and an acetoxyl group (5.80 and 8.12 μ).

Anal. Found: C, 70.61; H, 9.15. Calcd. for $C_{24}H_{37}O_4N$: C, 71.43; H, 9.24%.

Dihydroluciduscuiline Diacetate (III). — A mixture of dihydroluciduscuiline (0.6 g.), acetic anhydride (1 cc.) and pyridine (4 cc.) was allowed to stand in a sealed tube at room temperature for two days. After removal of the solvents, the residue was dissolved in water and then precipitated with aqueous ammonia. The precipitate was recrystallized from ethanol. Crystals melted at 140~144°C. $[\alpha]_D^{18}$ −55.5° (methanol). Yield was quantitative. The ultraviolet absorption spectrum of this compound in methanol showed end absorption and no maximum. The infrared absorption spectrum in Nujol had no peak attributable to a hydroxyl group but showed the presence of acetoxyl groups (5.82 and 7.95 μ).

Anal. Found: C, 68.45; H, 8.84. Calcd. for $C_{28}H_{41}O_6N$: C, 68.96; H, 8.48%.

Luciduscuiline Diacetate (IV). — A mixture of luciduscuiline (0.6 g.), acetic anhydride (1 cc.) and pyridine (4 cc.) was allowed to stand in a sealed tube at room temperature for two days. After removal of the solvents, the residue was dissolved in water and then precipitated with aqueous ammonia. The precipitate was recrystallized from ethanol. Crystals melted at 159~167°C alone and on admixture with luciduscuiline diacetate prepared according to the direction of Majima and Morio[4,5]. Yield was quantitative. The ultraviolet absorption spectrum of this compound in methanol showed end absorption and no maximum. The infrared absorption spectrum in Nujol showed the presence of acetoxyl groups (5.82 and 8.01 μ) and a terminal methylene group (6.08 and 11.32 μ).

Luciculine (V). — The ultraviolet absorption spectrum of this compound in methanol showed end absorption and no maximum. The infrared absorption spectrum in Nujol showed the presence of hydroxyl groups (2.98 μ) and a terminal methylene group (6.09 and 11.27 μ).

Luciculine Methiodide (VI). — The ultraviolet absorption spectrum of this compound in methanol showed end absorption and no maximum. The infrared absorption spectrum in Nujol had a peak at 2.98 μ attributable to hydroxyl groups and peaks at 6.11 and 11.22 μ attributable to a terminal methylene group.

Isomesoluciculine (VII). — The base was prepared from luciculine methiodide (0.5 g.) by Hofmann degradation. Recrystallization from acetone gave crystals, which melted at 123~127°C (decomp.). $[\alpha]_D^{19}$ −17.0° (methanol). The ultraviolet absorption spectrum of this compound in methanol showed end absorption and no maximum. The infrared spectrum in Nujol showed the presence of hydroxyl groups (2.98 μ) and a terminal methylene group (6.08 and 11.28 μ).

Anal. Found: C, 68.79; H, 9.31; (N)CH_3, 4.52; H_2O, 5.04. Calcd. for $C_{21}H_{31}O_3N \cdot H_2O$: C, 69.39; H, 9.15; (N)$CH_3$, 4.13; H_2O, 4.95%.

Bromoluciduscuiline Cyanamide (VIII). — To cyanogen bromide (0.25 g.) dissolved in 7.5 cc. of benzene, luciduscuiline (0.45 g.) dissolved in benzene (16 cc.) was added. The reaction mixture, which became turbid after 10 min., was allowed to stand at room temperature for 24 hr. and then was filtered. The crystalline precipitate collected by filtration was hygroscopic and then treated with water. The residue, obtained from the water-soluble portion, was crystallized from acetone and melted at 157~162°C (decomp.). $[\alpha]_D^{17}$ −76.0° (methanol). The ultraviolet absorption spectrum of this compound in methanol showed end absorption and no maximum. The infrared absorption spectrum in Nujol showed the presence of hydroxyl groups (2.94 and 3.10 μ), a cyano group (4.74 μ), an acetoxyl group (5.88 and 7.97 μ) and a terminal methylene group (6.06 and 11.23 μ).

Anal. Found: C, 55.92; H, 7.89; N, 4.52; Br, 13.66; (N)C_2H_5, 4.94; H_2O, 5.5. Calcd. for $C_{24}H_{35}O_4N(CN)Br \cdot 2H_2O$; C, 55.23; H, 7.23; N, 5.13; Br, 14.70; (N)C_2H_5, 5.34; H_2O, 6.62%.

The water-insoluble portion did not crystallize from acetone. These portions were nearly equal in amounts.

The author wishes to express his sincere thanks to Professor Harusada Suginome, President of Hokkaido University, for his kind guidance throughout this work and to Mr. Mineo Yakushiji for the determination of *N*-alkyl groups.

Intramolecular Interaction between Hydroxyl Group and π-Electrons. VI[1]*. Electronic Effect on the Interaction in ω-Arylalkanols*

By Michinori Ōki and Hiizu Iwamura

(Received March 17, 1959)

In connection with the intramolecular interaction between hydroxyl group and π-electrons, the authors have measured the ν_{O-H} absorption of various substituted benzyl alcohols and concluded that the hydrogen atom of the hydroxyl group interacts with the π-electron on the carbon atom to which the hydroxymethyl group is attached. On the other hand, Goldman and Crisler[2] examined three phenethyl alcohol derivatives on the O–H stretching absorption and concluded that the hydrogen atom of the hydroxyl group interacts with the π-electron on the carbon atom to which the 2-hydroxyethyl group is attached. Meanwhile, the present authors predicted[3], by comparison of the two band intensities of the interacting forms in allyl alcohol and 3-buten-1-ol, that the interaction occurring in them might be different in nature, since allyl alcohol gives a larger band intensity of the interacting form than 3-buten-1-ol in spite of the fact that $\Delta\nu_{max}$ is smaller in allyl alcohol than in 3-buten-1-ol. Moreover, it is reasonable to consider that allyl alcohol with benzyl alcohol and 3-buten-1-ol with phenethyl alcohol possess the same type of interaction. Therefore, it may be thought that there is a contradiction between the conclusion by Goldman and Crisler and that by the present authors. Since it is dangerous to draw a conclusion from a small number of examples, the ν_{O-H} absorptions of various ω-arylalkanols have been re-examined.

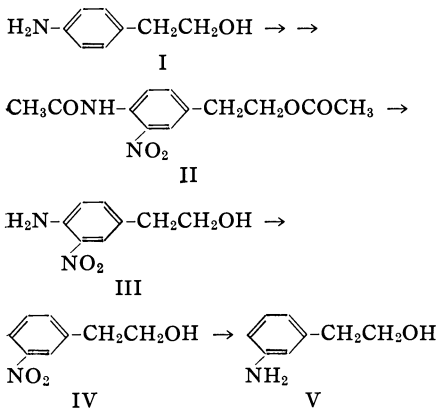
Experimental

Measurement.—It was performed similarly as described previously[3]. When a small peak was present (3-arylpropanols) or the presence of a peak was suspected (4-arylbutanol), the measurement was carried out with a quartz cell of 5 cm. length without alteration of concentration.

Calculation of Integrated Intensities.—It was carried out similarly as reported previously[3], when only two bands were present. However, the presence of three bands, two of which were derived from the presence of the rotational isomers and the third by the internal interaction, required modification to some extent. The two stronger bands were first obtained in the usual manner and the summation of the bands was subtracted from the apparent curve. This procedure usually gave rise to an unsymmetric band. The process was repeated through the trial-and-error method until the third band became symmetric.

Materials. — The compounds used for the measurement are known compounds, unless otherwise stated, and their physical constants well agree with those in the literature.

Preparation of ω-Arylalkanols by Lithium Aluminum Hydride Reduction of Esters.—To a slurry prepared from 2.5 g. (0.07 mol.) of lithium aluminum hydride and 100 ml. of ether, was added 0.1 mol. (0.05 mol. for amino-esters) of the corresponding ester[4]. After stirring for two hours at the room temperature, the excessive lithium aluminum hydride was decomposed by adding ethyl acetate in ether and then dilute sulfuric acid (aqueous sodium hydroxide in the case of aminoalcohols) was added. The aqueous layer was extracted with ether and ethereal extract was washed with aqueous sodium hydroxide. After drying over potassium carbonate followed by evaporation, the residue was either fractionally distilled or recrystallized from an appropriate solvent. Compounds with low melting points were once distilled and then recrystallized. The results are summarized in Table I.



Preparation of 2-(*m*-Aminophenyl)-ethanol.—2-(*m*-Aminophenyl)-ethanol (V) was prepared as illustrated in the following chart.

1) Part V of this series: This Bulletin, **32**, 955 (1959).
2) I. M. Goldman and R. O. Crisler, *J. Org. Chem.*, **23**, 751 (1958).
3) M. Ōki and H. Iwamura, This Bulletin, **32**, 567 (1959).
4) Amino-esters were conveniently prepared by hydrogenation of the corresponding nitro-esters or alkyl nitrocinnamates in the presence of U-Ni-A catalyst [Y. Urushibara, S. Nishimura and H. Uehara, This Bulletin, **28**, 466 (1955)]. Substituted cinnamic acids were also reduced with the same catalyst in excellent yields, when their sodium salts in water were used. The authors are grateful to Dr. S. Nishimura for hydrogenation.

a) The starting material, methyl *m*-chlorophenylacetate, was conveniently prepared through the modified Wilgerodt reaction[5] using morpholine and *m*-chloroacetophenone followed by hydrolysis and then esterification. The over-all yield of the ester was 70%.
b) The melting point has not been reported[6].
c) Recrystallized from benzene containing a small amount of alcohol.
d) Refractive index was reported as 1.5424 (21°C) for substance obtained by the chlorination of 3-phenylpropanol[7].
e) This compound is rather unstable and discolors quickly in the air. Benzene was used as the recrystallization solvent.

2-(p-Acetamido-m-nitrophenyl)-ethyl acetate (*II*). To 102 g. (1 mol.) of acetic anhydride, 118 g. (0.86 mol.) of 2-(*p*-aminophenyl)-ethanol[8] was added and the mixture was heated on a water bath for thirty minutes. After cooling, 79 g. (1 mol.) of acetyl chloride was slowly added, and the mixture was heated under reflux on a water bath for one hour. Hydrogen chloride and the excessive reagents were removed in vacuo and the residue was dissolved in 400 ml. of acetic anhydride. The solution was cooled in an ice-salt bath and 106.5 ml. (1.7 mol.) of nitric acid (d=1.42) was carefully added at 10～20°C with good stirring. The mixture was stirred for further fifteen minutes at that temperature and then poured into 3 l. of ice-water. The crystals were collected and the major portion was submitted to the subsequent hydrolysis. The analytical sample was obtained by recrystallization from benzene-petroleum ether. It was obtained as yellow needles, m. p. 77°C.

Anal. Found: C, 53.95; H, 5.48. Calcd. for $C_{12}H_{14}N_2O_5$: C, 54.15; H, 5.25%.

2-(p-Amino-m-nitrophenyl)-ethanol (*III*). — The crude compound II was heated with 500 ml. of 6 N hydrochloric acid under reflux for three hours. The cooled reaction mixture was basified with aqueous sodium hydroxide and organic material was extracted with ether. The ethereal extract was dried over potassium carbonate and evaporated. The residue solidified on standing and was recrystallized from benzene. Orange flat needles, m. p. 85～87°C. Over-all yield, 88 g. (56%).

Anal. Found: C, 52.86; H, 5.63. Calcd. for $C_8H_{10}N_2O_3$: C, 52.74; H, 5.53%.

2-(m-Nitrophenyl)-ethanol (*IV*).—To a solution of 54.6 g. (0.2 mol.) of compound III in 80 ml. of concentrated hydrochloric acid and 20 ml. of water, was added 20.7 g. (0.3 mol.) of sodium nitrite in a minimal quantity of water at −5～−3°C. The mixture was stirred at 0°C for ten minutes and then 325 g. (1.5 mol.) of 30% hypophosphorus acid precooled to 0°C was added, the temperature being maintained at 0～3°C. The mixture was stirred for another hour and then allowed to stand in an ice-bath containing ca. 5 kg. of ice which melted in about twelve hours. After twenty-four hours, the mixture was extracted with ether and the ethereal extract was washed with aqueous sodium hydroxide. Drying with potassium carbonate followed by fractional distillation afforded 25.0 g. (50%) of an orange-yellow oil, b. p. 141～146°C/4 mm., which set to needles. The analytical sample was obtained through recrystallization from benzene-petroleum ether. It was obtained as faintly yellow needles, m. p. 50～51°C.

Anal. Found: C, 57.58; H, 5.55. Calcd. for $C_8H_9NO_3$: C, 57.38; H, 5.43%.

2-(m-Aminophenyl)-ethanol (*V*)[9].—To a solution

8) H. M. Woodburn and C. F. Stuntz, *J. Am. Chem. Soc.*, **72**, 1362 (1950).

9) This compound has been prepared by lithium aluminum hydride reduction of *m*-aminophenylacetic acid [J. B. Dickey and E. B. Towne, Brit. Pat., 722,367; *Chem. Abstr.*, **49**, 9935 (1955)]. They reported only the boiling point as 135～138°C/2 mm. but no melting point.

of 90 g. (0.36 mol.) of 90% stannous chloride in 80 ml. of concentrated hydrochloric acid, was added 20 g. (0.12 mol.) of compound IV and the mixture was stirred, when the spontaneous reaction set in. After the reaction subsided, the mixture was heated on a water bath for thirty minutes, cooled and decomposed with an excess of aqueous sodium hydroxide. When the mixture was chilled, the aminoalcohol solidified and was collected by filtration. It was recrystallized from benzene, m. p. 68~69°C. It sometimes forms needles and sometimes plates. Yield, 13 g. (80%).

Anal. Found: C, 70.00; H, 7.98. Calcd. for $C_8H_{11}NO$: C, 70.04; H, 8.08%.

Results and Discussion

2-Arylethanols. — The apparent O–H stretching absorption curves are divided into three, assuming that they are the overlap of the three symmetric bands which are expressed by Lorentz function. The apparent curves refuse to be divided into two to fit in, as was pointed out in the earlier paper[3]. The results are shown in Table II.

The actual features of division are shown in Fig. 1 and Fig. 2, 2-(*p*-aminophenyl)-ethanol and 2-(*p*-nitrophenyl)-ethanol being taken as the examples because of the extremity of Hammett's σ-values of the substituents.

Two (bands II and III) of the three ν_{O-H} absorption bands are derived from the rotational isomers of primary alcohols and their positions (3635 cm^{-1} and 3625 cm^{-1}) are in good agreement with the previous assignment[10]. The third band (band I) must be attributed to the presence of the intramolecular interation between the hydroxyl group and the π-electrons as

10) M. Ōki and H. Iwamura, This Bulletin, **32**, 950 (1959).

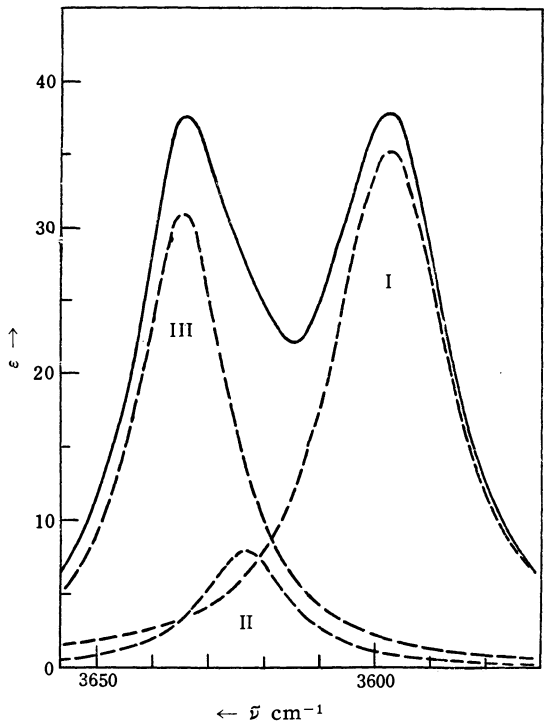

Fig. 1. ν_{O-H} absorption of 2-(*p*-aminophenyl)-ethanol.

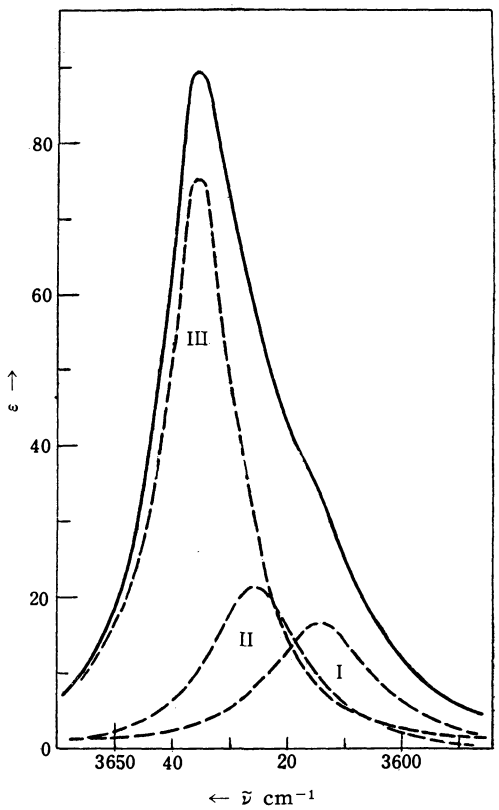

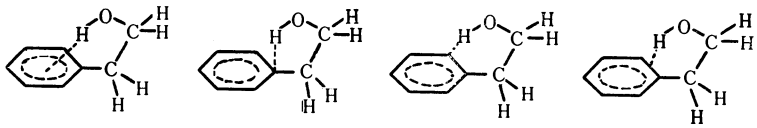

Fig. 2. ν_{O-H} absorption of 2-(*p*-nitrophenyl)-ethanol.

Trifan and his coworkers[11,12], Anet and Bavin[13] and Goldman and Crisler[2] have assigned. Since the error involved in dividing the original band into three is rather great, especially for band II, it is not allowable to use the integrated intensity of band II for discussion, although molecular scale models tell that band II is derived from the only rotational form that makes the interaction possible. Hence, the difference of the wave numbers is shown by $\nu_{III}-\nu_I$ rather than by $\nu_{II}-\nu_I$ and the ratio of the integrated intensities is also exemplified by $A_I/(A_{II}+A_{III})$ rather than by A_I/A_{II}.

As clearly understood from Table II, the electronic effect from the substituent is observed. The wave number of the ν_{O-H} absorption maximum (band I) of the interacting form shifts to a lower wave number as the substituent becomes more electron-releasing, and the electron-attracting substituent causes the wave number of band I to shift and approach to the absorption of normal primary alcohols, this phenomenon having not been observed in benzyl alcohol derivatives. The integrated intensity of band I also increases as the electron-releasing group is introduced.

As to the molecular structure of the internally interacting form, the authors pointed out four possibilities as shown in Fig. 3[1]. Structure VI indicates the interaction between the hydroxyl group and the benzene nucleus as a whole, the case having been suggested by Trifan and his coworkers[11]. Structure VII, representing the interaction which includes C_1 of the benzene nucleus, was deduced by Goldman and Crisler[2] by comparison of three ν_{O-H} curves of 2-phenylethanol, 2-(*p*-methoxyphenyl)-ethanol and 2-(*p*-nitrophenyl)-ethanol. Structure VIII with the participation of C_2 of the benzene nucleus was suggested by Lüttke and Mecke[14], and structure IX, in which C_1 and C_2 take part, by Baker and Shulgin[15].

VI VII VIII IX

Fig. 3.

Structure VII is first excluded on the basis of the experimental results given in Table II, because compounds with the same substituent in the meta and in the para positions to the 2-hydroxyethyl group give similar curves. Structure VII expects a favored interaction in the 2-phenylethanol with a strongly electron-donating group in the para position over the compound possessing the same substituent in the meta.

Structure VI is rather improbable because it has no orbital which would couple with that of the hydrogen atom. If such interaction took place, further lengthening of the O–H bond should be expected, which would give rise to further lowering of the wave number of band I because of a weaker force constant. Structure VI is made improbable also by the theoretical treatment of the complex of benzene with hydrogen ion or silver ion as discussed below. The structure should not be hexagonally symmetrical, nor should the positive ion be on the plane of the benzene nucleus[16].

Thus, there are two possibilities left for the structure. It seems that structure VIII is more convincing when Hammett's σ values[17] of the ortho position in respect of 2-hydroxyethyl group is taken for the ordinate and $\log\frac{A_I/(A_{II}+A_{III})}{[A_I/(A_{II}+A_{III})]_0}$, where $[A_I/(A_{II}+A_{III})]_0$ is the ratio obtained with 2-phenylethanol, for the abscissa (Fig. 4), because they are nearly in linear relation. However, the defect of this structure can be pointed out immediately because of the far deviation of 2-(*p*-methoxyphenyl)-ethanol from a straight line, or, in other words, because 2-(*p*-methoxyphenyl)-ethanol and 2-(*m*-methoxyphenyl)-ethanol show almost the same internal interaction in spite of the great distance between σ constants ($\sigma_m=+0.115$, $\sigma_p=-0.268$). Even the correction which will be discussed in the following paragraph modifies only σ_m but does not affect σ_p. The deviation of 2-(nitrophenyl)-ethanols can be attributed to the error in dividing the apparent curves into three, since the bands I of these compounds are the smallest comprising no maxima nor distinct shoulders.

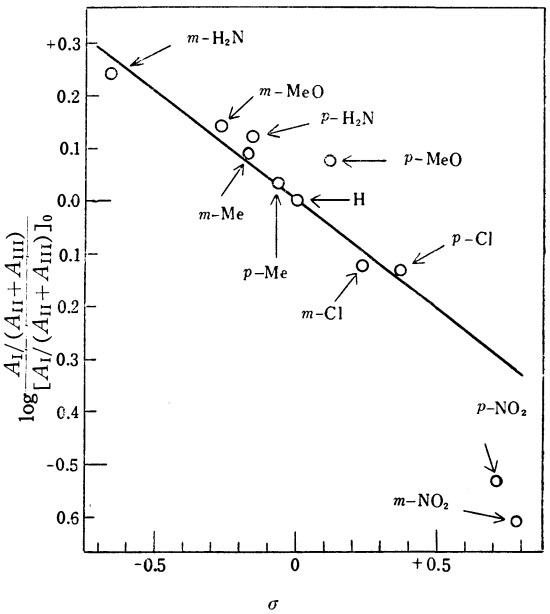

Fig. 4. Relation between $\log\frac{A_I/(A_{II}+A_{III})}{[A_I/(A_{II}+A_{III})]_0}$ in 2-arylethanol and σ constants for structure VIII.

The relation between the σ constants and $\log\frac{A_I/(A_{II}+A_{III})}{[A_I/(A_{II}+A_{III})]_0}$ for structure IX is shown in Fig. 5. The σ constants for the para-substituted compounds should be the mean values of those for meta and for para and those for the meta-substituted compounds should be expressed by $\left(\frac{\sigma_o+\sigma_p}{2}+\sigma_m\right)\Big/2$. Unfortunately, however, few σ values for ortho-substitution have been known, the only example having been provided by Shulgin and Baker[18]

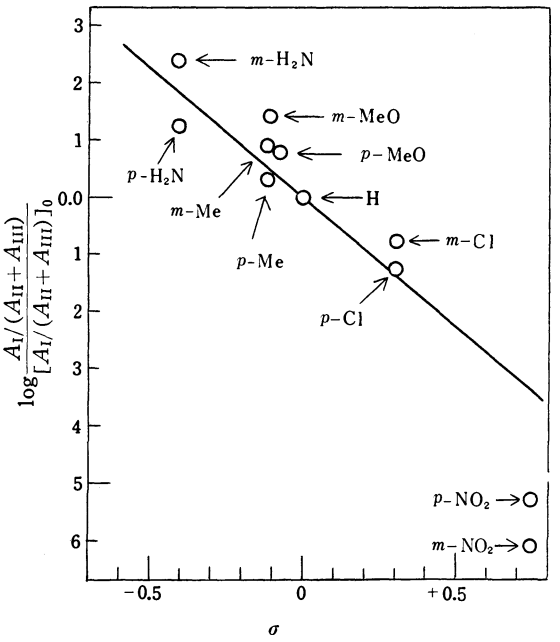

Fig. 5. Relation between $\log\frac{A_I/(A_{II}+A_{III})}{[A_I/(A_{II}+A_{III})]_0}$ in 2-arylethanol and σ constants for structure IX.

who found the same values for ortho-chloro and para-chloro within the experimental error and a slightly more negative value for ortho-methoxyl than for para-methoxyl. Electron densities computed by the molecular orbital method have been reported in some instances and slight differences between ortho- and para-position have been reported, although they do not cover all the substituents used in the present work. Hence, $(\sigma_m+\sigma_p)/2$ is used as an approximation for the substituents in the meta-position except the methoxyl group for which respective values for ortho and for para are available.

There are deviations from a straight line, even though the results are better than those considered from structure VIII. In other words, the meta-substituted 2-phenylethanol is always favored in the internal interaction over the para-substituted, or the former always gives a greater integrated intensity of band I, when an electron-releasing group is introduced. The deviations may be caused by neglecting the electron density of the ortho-position and/or by the contribution of structure VIII to some extent, which favors 2-phenylethanols with an electron-donating group in the meta-position for the interaction. The deviation may be also caused by using $A_{II}+A_{III}$ instead of A_{II} as the integrated intensity of the free form, since the scale model indicates that the free form capable of producing such an interaction is only one, of which integrated intensity is given by A_{II}.

If the intramolecular interaction between the hydroxyl group and the π-electrons is considered as a complex formation between a cation and an aromatic nucleus, structure IX can be supported. Namely, Rundle and Goring[19] observed on the basis of diffraction data that the silver ion in the complex with benzene is bonded equally with the two carbon atoms of the benzene nucleus and is located above the surface. Judged from the present results shown in Table II, the wave number of the ν_{O-H} absorption of the interacting form can be said just the same for a given substituent irrespective of its position. This fact strongly supports structure IX as the internally interacting form of 2-phenylethanol.

Strictly speaking, however, structure VIII can not be totally rejected, because it is one of the possibilities that favor the meta-substituted compounds in the internal interaction more than the para-substituted. Doering et al.[20] studied the structure of the heptamethylbenzenonium compound and postulated the 1,1,2,3,4,5,6-heptamethylbenzenonium ion with C_1 of the tetrahedral structure, without totally rejecting another with the methyl ion located between the two carbon atoms of the benzene nucleus and out of the plane. On the contrary, the present conclusion is that structure IX is the main contribution[21].

3-Arylpropanols.—As the representatives of 3-arylpropanols the ν_{O-H} absorption curves of 3-(*p*-aminophenyl)-propanol and 3-(*p*-chlorophenyl)-propanol and the corresponding divided values are shown in Figs. 6 and 7, respectively. The results are summarized in Table III.

It may be suspected that the lowest

20) W. von Doering, M. Saunders, H. G. Boyton, H. W. Earhart, E. F. Wadley, W. R. Edwards and G. Laber, *Tetrahedron*, **4**, 178 (1958).

21) It may be pointed out that another possibility exists in which either structure VII or VIII contributes. Namely, the direction of the hydroxyl group points to either C_1 or C_2 depending on the favorable electron density on the carbon atom. This is improbable, however, since interacting forms of both meta- and para-substituted compounds absorb at nearly the same wave number, while, in O-H···O hydrogen bonding, ν_{O-H} absorption generally appears at lower wave numer in the formation of a six-membered ring than of a five-membered ring.

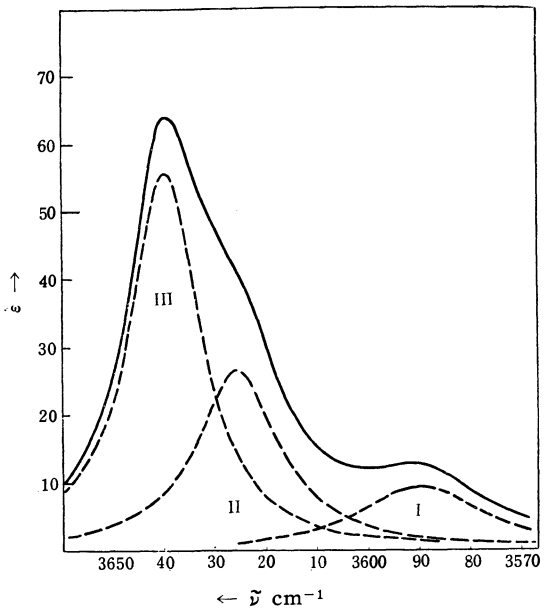

Fig. 6. ν_{O-H} absorption of 3-(*p*-aminophenyl)-propanol.

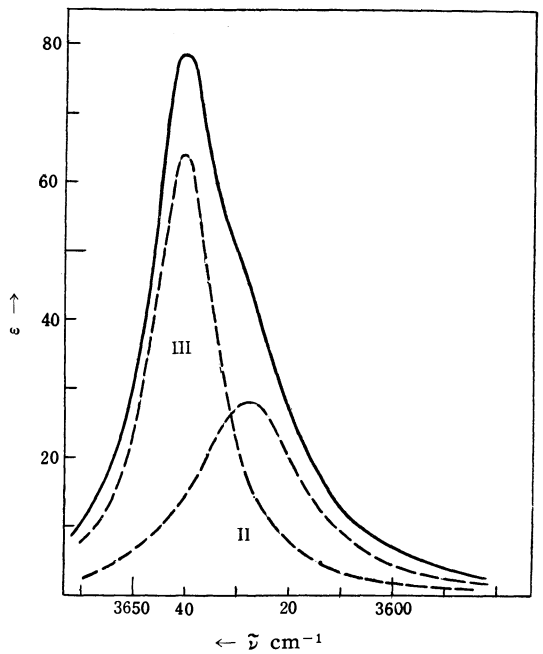

Fig. 7. ν_{O-H} absorption of 3-(*p*-chlorophenyl)-propanol.

ν_{O-H} absorption (band I) of 3-(aminophenyl)-propanols might be the ν_{N-H} absorption, but actually ν_{N-H} absorptions are found at 3479 cm^{-1} and 3393 cm^{-1} for 3-(*m*-aminophenyl)-propanol. The shift in the wave numbers of the ν_{O-H} absorption of the interacting form is consistent with the results obtained with 2-arylethanols. Namely, the methoxyl and the methyl groups give bands I at nearly the same wave number and the amino group further lowers the wave number. The difference between the meta- and the para-substituted compounds can not be taken as an

TABLE IV. ν_{O-H} ABSORPTIONS OF 4-ARYLBUTANOLS (p-$RC_6H_4CH_2CH_2CH_2CH_2OH$)

R	OH	ν_{max} (cm^{-1})	$\Delta\nu^a_{1/2}$ (cm^{-1})	$A\times10^{-3}$ ($mol^{-1}\cdot l.\cdot cm^{-2}$)	$\Delta\nu_{max}$ (cm^{-1})
H_2N	II	3626.1	19.8	2.21	13.0
	III	3639.1	17.4	3.26	
H	II	3626.6	23.2	2.36	13.3
	III	3639.9	17.6	3.43	

important indication, because bands I constitute the smallest peaks and errors involved in dividing the apparent absorption do not allow to discuss such a small difference.

It is apparent that the interaction is less favored in 3-arylpropanols than in 2-arylethanols, because even 3-(aminophenyl)-propanols give the smaller integrated intensities of band I. 3-Phenylpropanol itself does not show any absorption corresponding to band I of the other compounds with an electron-releasing group. However, the close examination of band II reveals that band II of 3-phenylpropanol is located at a rather low wave number, $\Delta\nu_{III-II}$ being as large as 16.7 cm^{-1}, in comparison with 12~15 cm^{-1} of others. It may be attributed to the fact that the peak corresponding to band I of 3-phenylpropanol is too small to be separated from others by the present technique. The above assumption seems verifiable because 3-(p-chlorophenyl)-propanol gives bands II and III in the normal positions for primary alcohols, $\Delta\nu_{III-II}$ being 12.6 cm^{-1}. In this case, the electron-attracting power of the chlorine atom seems to prohibit the interaction from taking place.

It is rather strange that 3-arylpropanols possess smaller numbers of internally interacting molecules even though the interacting form seems to be more stabilized than that in 2-arylethanol, because the wave numbers of bands I of 3-arylpropanols are lower than those of 2-arylethanols[22]. It must be attributed either to the unfavorable change in entropy and energy or to the difference in nature, as the authors pointed out for allyl alcohol and 3-buten-1-ol[3]. In this case, however, the present authors will choose the former for the following reasons. Firstly, the electronic effect in 3-arylpropanols shows the same trend as that in 2-arylethanol, and, secondly, the interacting form in 3-arylpropanol requires the all-*gauche* form including two carbon and one oxygen atoms, while that in 2-arylethanol requires the *gauche* form including one each of carbon and oxygen atoms. Hence, even though the interacting form of 3-arylpropanols will be more stabilized, if once formed, the unfavorable change in entropy and energy will limit the number of the molecules.

As to the nature of the interaction, 3-arylpropanols do not provide further information. The authors again come to a difficulty because of the weakness of bands I, but would like to assign tentatively the same structure as 2-arylethanols, because the meta- and the para-substituted compounds give nearly the same ν_{O-H} absorptions.

4-Arylbutanols.—The results of 4-arylbutanols are shown in Table IV.

From Table IV, it is obvious that 4-phenylbutanol does not possess any intramolecular interaction between the hydroxyl group and the π-electrons, since its ν_{O-H} absorption is normal for primary alcohols. Even 4-(p-aminophenyl)-butanol shows the normal absorption for primary alcohols in spite of the favorable electron density on the aromatic nucleus due to the presence of the strongly electron-releasing amino group. And again, this fact must be attributed to the unfavorable change in both entropy and energy.

Thus, it can be concluded that the internal interaction between the hydroxyl group and the π-electrons of the benzene nucleus occurs, when the hydroxyl group is an alcoholic O-H and the carbon chain is not fixed, up to 3-phenylpropanol in the series of ω-arylalkanols.

Summary

The electronic effect on the intramolecular interaction between the hydroxyl group and the π-electrons of the benzene nucleus was studied with various ω-arylalkanols. In 2-arylethanols, introduction of an electron-releasing group into the benzene nucleus gives rise to the shift of the ν_{O-H} absorption maxima to a lower wave number and to greater integrated

22) For example, see R. M. Badger and S. H Bauer, *J. Chem. Phys.*, 5, 839 (1937).

intensities of the band due to the interacting form, and introduction of an electron-attracting group to a higher wave number and smaller integrated intensities. However, the wave number of the band due to the interacting form is not affected by the position of the substituent, as far as the substituent is the same. Thus, the structure represented by IX is favored. On the other hand, a compound with an electron-releasing group in the meta position always shows greater integrated intensities of the band due to the interacting form than the para-substituted isomer and this fact saves structure VIII from entire rejection. Hence, the authors tentatively assign structure IX as the most favorable with participation of structure VIII to some extent.

In 3-arylpropanols the interaction is observed only in the compounds with an electron-releasing group and 3-(*p*-chlorophenyl)-propanol shows the normal ν_{O-H} absorption for primary alcohols. The phenomenon that 3-arylpropanols show smaller interaction in spite of the appearance of the band due to the interacting form at a lower wave number is attributed to the unfavorable change in both energy and entropy.

In 4-arylbutanol no interaction is observed, even though a strongly electron-donating group is introduced.

Thus, as the authors predicted, it has been proved that the intramolecular interaction occurring in 2-phenylethanol is different in nature from that in benzyl alcohol.

The authors wish to express their hearty thanks to Professor Y. Urushibara and Professor T. Shimanouchi for their valuable suggestions and discussions. The authors are also indebted to the Ministry of Education for a Grant in Aid for Fundamental Scientific Research.

Self-diffusion of Iodide Ion and Strontium Ion in Strontium Iodide Solutions

By Ryohei MATUURA and Yasushi KOGA

(Received April 3, 1959)

Self-diffusion coefficients of iodide ion in hydrogen iodide, sodium iodide, potassium iodide and rubidium iodide solutions were measured by Mills and Kennedy[1]. They showed that in every iodide solution studied the product of self-diffusion coefficient of iodide ion and relative viscosity of the solution, i.e., $D\eta/\eta_0$, was linear against the square root of the concentration, $\sqrt{c}$, up to considerably high concentrations. In the case of self-diffusion of sodium, potassium, chloride and sulfate ions, however, no such linear relations were found. Matuura and Shimozawa[2] showed that the self-diffusion of calcium and strontium ions in chloride solutions was very complicated with respect to the concentration of the solution and found that the $D\eta/\eta_0$ vs. $\sqrt{c}$ curves had two minima and one maximum. The important difference of iodide ion from the other ions cited above in connection with the kinetic behaviors in aqueous solutions may be in its large size and poor hydration. A simple picture of the self-diffusion process for such "unhydrated" ions was suggested by Mills and Kennedy, which, in the case of monovalent counter ions, seems to explain the iodide ion self-diffusion satisfactorily. It is very interesting to investigate whether or not the same picture could be extended to the iodide of the divalent counter ions. The present work has been performed with the solution of strontium iodide in order to check this point and to obtain further knowledge

of the behavior of ions in electrolyte solutions.

Experimental

Apparatus. — The diffusion apparatus was essentially the same as that proposed by Anderson and Saddington[3] and modified by Wang[4]. The schematic diagram of the apparatus is shown in Fig. 1. A three-necked flask of one liter capacity

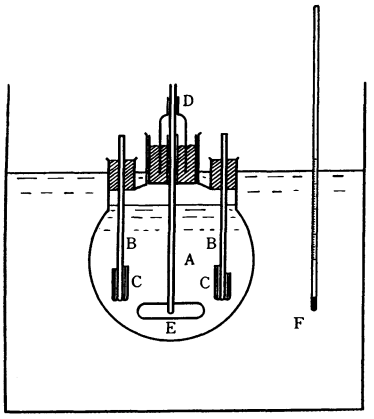

Fig. 1. Diffusion apparatus.

(A) was fitted with capillary holders (B) and a mercury seal stirrer (D). A plastic paddle (E) was turned slowly by an electric motor. The flask and contents were immersed in a thermostat (F) of 25±0.01°C. The capillary diffusion cells (C) were prepared as follows. The different diameter capillaries of Pyrex glass were used and the inside diameter was calibrated by filling with pure mercury. They were 0.0612 and 0.0780 cm. The capillaries were cut to different lengths and the top end of each capillary was ground flat with fine carborundum. The other end was sealed with glass to make a flat bottom. The length of each capillary was measured precisely with a micrometer caliper. These lengths varied from 2.97 to 5.19 cm.

Procedure.—Capillaries were filled with a radiotracer solution of known concentration by using a fine pipette drawn from a glass tubing. They were then held vertically in a flask containing one liter of inactive strontium iodide solution of the same concentration as the capillary solution. The air above the solution in the flask had been replaced by nitrogen gas so that the strontium iodide solution might not be decomposed by oxygen in air. Also, in order to avoid the effect of light, the outer surface of the flask had been coated with black paint. Each capillary was immersed in the flask solution up to just below the upper end of the capillary and left standing for about 30 min. in order to secure thermal equilibrium between the solution inside and outside of the capillary. Then the capillaries were dipped completely into the flask solution and the diffusion was allowed to start. The nitrogen gas in the flask was renewed after setting the capillary cells in it. During the diffusion period the flask solution was stirred by turning a paddle (see Fig. 1) at a constant rate 90 r. p. m. This turning rate was chosen in order to minimize the Δl correction according to Mills and Kennedy[1]. After each diffusion period (3 to 7 days) the capilliaries were taken out of the flask and the radioactivity of the solution in each capillary was measured by a counter. The radioactivity of the original solution was also measured at the same time and two values of radioactivity, that is, before and after diffusion corrected for natural decay, was compared on the same volume unit.

The viscosity of the solution was measured with an Ostwald viscometer at 25°C.

Materials. — The tracers used in the present experiment were ^{131}I and ^{89}Sr. ^{131}I (half-life 8.0 days) was obtained in the form of chloride in weak basic sodium bisulfite solution. The bisulfite was removed by titration with hydrogen iodide to a pH of about 5. A drop of this solution was added to a quantity of strontium iodide solution. The concentration of iodide in this solution was measured volumetrically. Since the concentration of cations other than strontium in this solution was negligibly small, this was used as a tracer solution for iodide ion diffusion in strontium iodide solutions. The radioactivity of ^{131}I in the solution was measured by a proportional gas counter.

^{89}Sr (half-life 54 days) was obtained as a carrier-free chloride. This contained less than 10% ^{90}Sr (half-life 25 years) which decays into ^{90}Y (half-life 65 hr.). A drop of the original solution was dried up and dissolved in the strontium iodide solution of known concentration to make a capillary solution. After diffusion the solution was drawn out of a capillary by means of a fine pipette. The capillary was washed several times with a large excess of distilled water. The sample solution, together with all washings, was evaporated to dryness and its radioactivity (c_{av}) was measured by a G. M. counter. The radioactivity (c_0) of the original solution was also measured at the same time. It was found that the ratio c_{av}/c_0 depended upon the duration after the diffusion had been stopped, because of the destruction of equilibrium between ^{90}Sr and ^{90}Y caused by the difference in the diffusion rate of the two species. So the measurement of c_{av} and c_0 was made week by week until the constant value of c_{av}/c_0 was obtained. It took two to four weeks to attain the complete equilibrium between ^{90}Sr and ^{90}Y. From this constant value of c_{av}/c_0 the diffusion coefficient of strontium ion in strontium iodide solutions was calculated.

It was found that strontium iodide decomposes gradually in air and by light, resulting in the liberation of iodine which makes the solution colored. So it was necessary to use a fresh sample for each experiment. The strontium

3) J. S. Anderson and K. Saddington, *J. Chem. Soc.*, **1949**, S 381.
4) J. H. Wang, *J. Am. Chem. Soc.*, **73**, 4181 (1951).

iodide solution was prepared from strontium carbonate and hydrogen iodide just before each run of diffusion and viscosity measurement. Rigorous precautions were made for the solution not to change by air and light during the experiment, as already mentioned. The solution was slightly acidic. Its concentration was determined gravimetrically as strontium sulfate and also volumetrically as silver iodide. Both methods agreed well.

Calculations

Under the present experimental conditions the Fick's diffusion equation is solved as follows[5].

$$\frac{c_{av}}{c_0}=\frac{8}{\pi^2}\sum_{n=0}^{\infty}\frac{1}{(2n+1)^2}\exp\left[-(2n+1)^2\pi^2Dt/4l^2\right] \tag{1}$$

where, c_{av} is the average concentration of the tracer ion in the capillary solution after diffusion, c_0 is its initial concentration, l is the length of the capillary, t is the diffusion time and D is the self-diffusion coefficient. For the value of Dt/l^2 greater than 0.2 the series in the Eq. 1 converges so rapidly that all terms following the first can be neglected with an error smaller than 0.2%. This condition was always kept in the present experiment. Thus the equation

$$2.303\log\frac{\pi^2}{8}\cdot\frac{c_{av}}{c_0}=-\frac{\pi^2Dt}{4l^2} \tag{2}$$

was always used for the calculation of the self-diffusion coefficient of iodide ion and strontium ion in the strontium iodide solutions.

Discussion

In the dilute solution the self-diffusion of an ion is mainly controlled by the relaxation of ionic atmosphere around the ion. On the basis of Onsager's limiting law for the diffusion coefficient[6], Gosting and Harned[7] derived an equation for the variation of self-diffusion coefficient of the ion with its concentration, which in the case of self-diffusion of the ion (chemical

7) L. J. Gosting and H. S. Harned, *J. Am. Chem. Soc.*, **73**, 159 (1951).

species 1) in its binary electrolyte (chemical species 1 and 2) solutions, may be put into the following form.

$$D_1=\frac{\boldsymbol{R}T\lambda^0{}_1}{|Z_1|\boldsymbol{F}^2}-2.694\times10^{16}\frac{\lambda^0{}_1|Z_1|\boldsymbol{F}}{3\boldsymbol{N}\varepsilon}\sqrt{\frac{4\pi}{\varepsilon\boldsymbol{R}T}}\times\left(1-\sqrt{d(\omega_1)}\right)\sqrt{\sum_i c_i Z_i{}^2} \quad (3)$$

where, D_1 is the self-diffusion coefficient of the ion (in cm²/sec.), Z_1 and $\lambda^0{}_1$ are its number of the charge and limiting equivalent conductance (in coulomb/sec.×cm²/V.), respectively, c_i is the concentration of the i-th ion (in mol./l.), ε is dielectric constant of the solvent, and $\boldsymbol{R}$, $\boldsymbol{F}$, $\boldsymbol{N}$ and T are gas constant (in joule/deg. mol.), Faraday constant (in coulomb), Avogadro number and absolute temperature, respectively. $d(\omega_1)$ in Eq. 3 is given by

$$d(\omega_1)=\left(\frac{|Z_1|}{|Z_1|+|Z_2|}\right)\left(\frac{1}{2}+\frac{|Z_2|\lambda^0{}_2}{|Z_2|\lambda^0{}_1+|Z_1|\lambda^0{}_2}\right) \quad (4)$$

For the self-diffusion of iodide ion and strontium ion in strontium iodide solutions we use[8]

$$\lambda_{I^-}=76.8$$
$$\lambda_{Sr^{2+}}=59.46$$

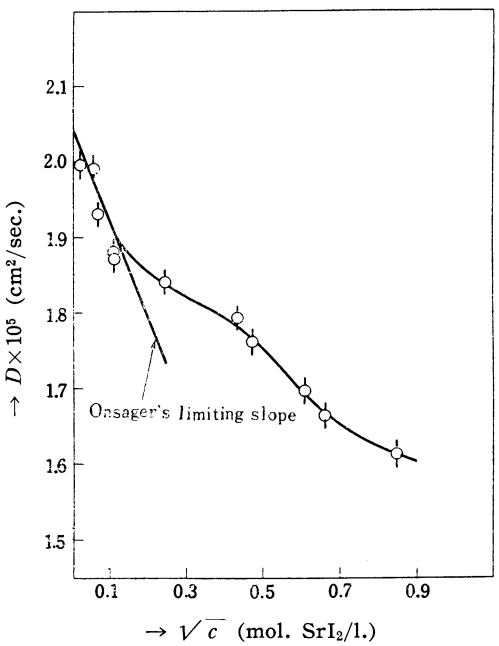

Fig. 2. Self-diffusion coefficient of I^- in SrI_2 solutions against square root of the concentration at 25°C.

8) D. A. McInnes, "The Principles of Electrochemistry", Reinhold Publishers Corp., New York (1950), p. 342.

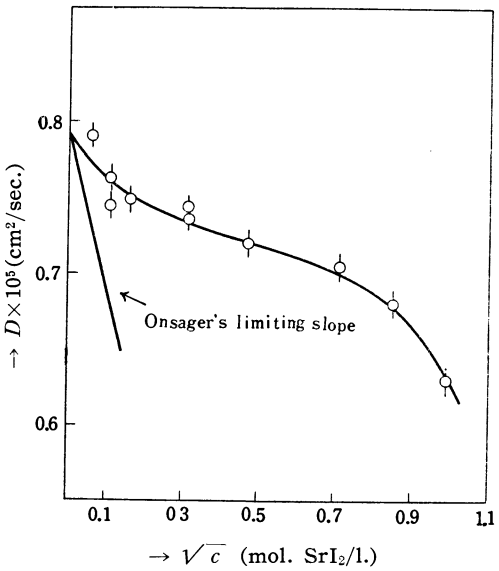

Fig. 3. Self-diffusion coefficient of Sr^{2+} in SrI_2 solutions against square root of the concentration at 25°C.

and we obtain the following equations by inserting the numerical values in Eq. 3:

$$D_{I^-}\times10^5=2.045-1.12\sqrt{c} \quad (5)$$

$$D_{Sr^{2+}}\times10^5=0.792-1.04\sqrt{c} \quad (6)$$

where, c is expressed in mol. SrI_2/l. These are limiting laws for the self-diffusion in the present case. In Figs. 2 and 3 are shown measured D_{I^-} and $D_{Sr^{2+}}$ against $\sqrt{c}$, respectively. It is seen that the experimental data fit the limiting law fairly well.

At higher concentrations the situation is much more complicated. Of various factors which control the ionic self-diffusion three may be considered most important, i.e., the viscosity of the solution, the hydration of the diffusing ion (i.e., the interaction between ion and solvent) and the state of ionic atmosphere (i.e., the interaction between ions). The correction for viscosity of the solution is usually made simply by multiplying D with η/η_0. In Fig. 4 $D\eta/\eta_0$ for iodide ion is plotted against $\sqrt{c}$. The curve for iodide ion is approximated by two straight lines. The straight line of lower concentrations can be extrapolated exactly to the Nernst limiting value, D_0, while that of higher concentrations gives a lower value by extrapolation to the zero concentration. Mills and Kennedy[1] showed that the $D\eta/\eta_0$ vs. $\sqrt{c}$ relation for iodide ion in the solution of iodide of monovalent

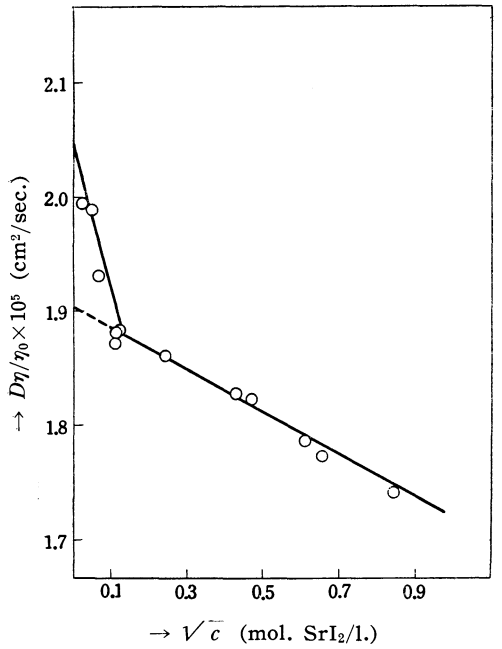

Fig. 4. $D\eta/\eta_0$ vs. $\sqrt{c}$ relation for I^- in SrI_2 solutions at 25°C.

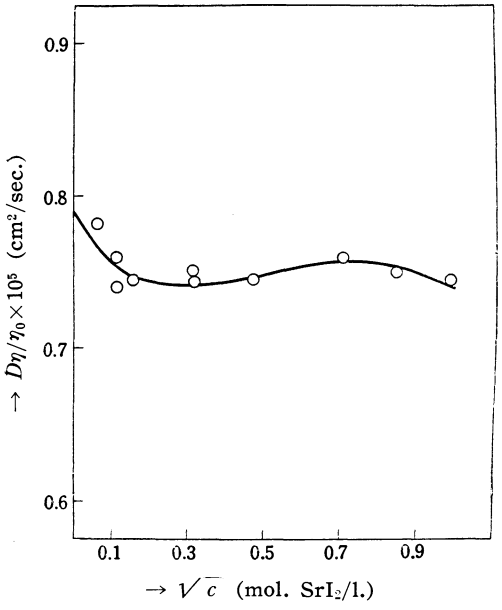

Fig. 5. $D\eta/\eta_0$ vs. $\sqrt{c}$ relation for Sr^{2+} in SrI_2 solutions at 25°C.

metal or hydrogen is linear all through from low to considerably high concentrations and extrapolated to the Nernst limiting value. It is not perfectly evident why the self-diffusion of iodide ion in strontium iodide is markedly different from that in the iodides which Mills and Kennedy studied, but one might ascribe it to the difference in the state of ionic atmosphere around the diffusing iodide ion.

The $D\eta/\eta_0$ vs. $\sqrt{c}$ relation for strontium ion in the solution of strontium iodide is shown in Fig. 5. This curve is much more complicated than and quite different in nature from the curve for iodide ion. It is well known that strontium ion is strongly hydrated, while iodide ion is "unhydrated". Matuura and Shimozawa[2] applied an empirical equation to the self-diffusion of strongly hydrated ions, which is

$$D\eta/\eta_0 = D_0 - k_1\sqrt{c} + k_2 c \log c + k_3 c \qquad (7)$$

where, k_1, k_2 and k_3 are constants. Of these k_1 is a limiting slope $D\eta/\eta_0$ vs. $\sqrt{c}$ relation and can be calculated from Fig. 5. Eq. 7 may be checked by plotting

$$F(D) \equiv \frac{D\eta/\eta_0 - D_0 + k_1\sqrt{c}}{c} \qquad (8)$$

against $\log c$. In Fig. 6 this plot is shown. It is seen that Eq. 7 is a fair expression for the self-diffusion of strontium ion in strontium iodide solutions.

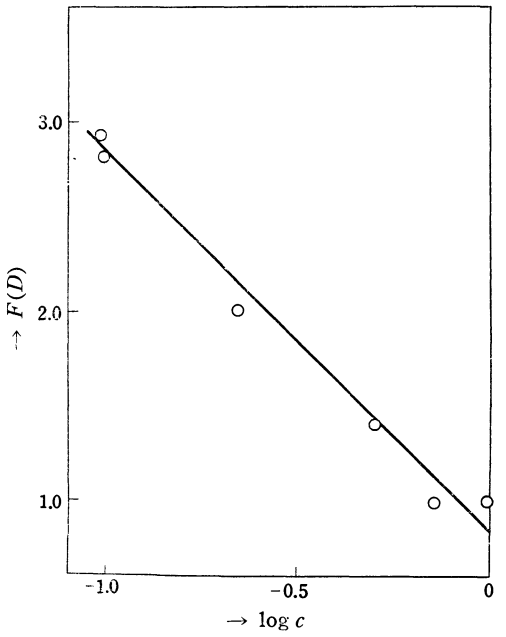

Fig. 6. $F(D)$ vs. $\log c$ relation for Sr^{2+} in SrI_2 solutions.

From the straight line in Fig. 6 the values of k_2 and k_3 are calculated as shown in Table IV. In the same table the data are given for the self-diffusion of strontium ion in strontium chloride

solutions and of sodium ion in sodium iodide and sodium chloride solutions[2].

TABLE IV. VALUES OF k_2 AND k_3 FOR STRONTIUM AND SODIUM ION

System	k_2	k_3
Sr^{2+} in SrI_2	−1.98	0.84
Sr^{2+} in $SrCl_2$	−1.54	0.93
Na^+ in NaI	−0.67	0.24
Na^+ in NaCl	−0.51	0.35

It is clear from Table IV that the absolute values of both k_2 and k_3 are larger for strontium ion than for sodium ion. Since Eq. 7 is an empirical one, the physical meaning of k_2 and k_3 is not definitely given, but one may conclude that k_2 and k_3 are mainly concerned with the charge (and of course also with the hydration) and size of the diffusing ion.

Summary

The self-diffusion coefficient of iodide ion and strontium ion in aqueous strontium iodide solutions has been measured by a capillary method. It has been found that the Onsager's limiting equation can be applied to the self-diffusion of both ions. The $D\eta/\eta_0$ vs. $\sqrt{c}$ relation for iodide ion has been represented by two straight lines, while that for strontium ion has been shown by a much more complicated curve. The latter has been represented successfully by an empirical equation for strongly hydrated ions presented by Matuura and Shimozawa.

SHORT COMMUNICATIONS

*Infrared Spectra of Polyvinyl Chloride**

By Akihiro KAWASAKI, Shigeo SHIOTANI, Junji FURUKAWA and Teiji TSURUTA

(Received June 10, 1959)

There exist many reports on infrared spectra of polyvinyl chloride, but are found only a few studies[1-5] which deal with crystalline and amorphous bands in the infrared spectra of this polymer.

With respect to some samples of polyvinyl chloride, we have examined correlation between the specific gravity and the optical density in the absorption bands ranging from 4,000 to 700 cm^{-1}.

Polyvinyl chloride was prepared at room temperature with a binary mixture of triethylaluminum and di-*tert*-butyl peroxide as catalyst. The viscosity average molecular weight of the polymer was 32,000. The samples were in the form of thin solid films, which were prepared from tetrahydrofuran solution of the polymer. By heat treatment in the Wood alloy, the specific gravity, d_4^{30}, of the sample was controlled from 1.3887 to 1.4022.

The examination of the infrared spectra of the polymer having various specific gravity has made clear that the ratios of any two of the optical densities at 2920, 1375 and 1092 cm^{-1} remain almost unchanged irrespective of the change in the specific gravity of the samples. Since it was considered, from this result, that each of the bands mentioned above varied in the same way with the specific gravity, the band at 2920 cm^{-1} was taken as standard and the ratio of optical densities at every absorption band to 2920 cm^{-1} band was calculated.

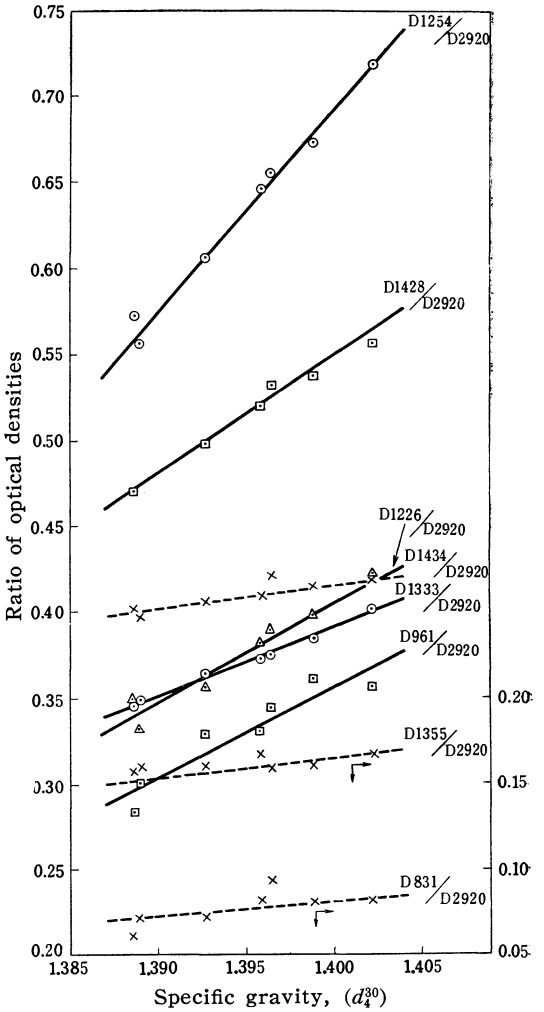

Fig. 1. Relation between optical density and specific gravity.

The liner relationship in Fig. 1 between the specific gravity and the optical density at bands 1428, 1333, 1254, 1226 (distinct parallel band) and 961 cm^{-1}, and the differential absorption band between two polymers having different specific gravity in Fig. 2 lead to the conclusion that these five absorption bands correlate with the specific gravity or crystallinity of the sample. A similar relation was observed

also in the absorption bands at 1434, 1355 and 831 cm^{-1} but its dependency upon the specific gravity was much smaller than the above case.

The analysis of these results is under study in our laboratory. Full dentails will be reported in this bulletin.

Infrared Spectra of Crystalline and Amorphous Polystyrene

By Masatami TAKEDA, Kazuyoshi IIMURA
Akira YAMADA and Yoshio IMAMURA

(Received June 30, 1959)

It has been reported[1] that crystalline polystyrene (CPS) prepared by Ziegler type catalyst shows a quite different infrared spectrum from that of amorphous polystyrene (APS) prepared by radical catalyst. It has been also suggested[2] that some bands in the spectrum of CPS could be associated with the three fold herical structure[3] of isotactic polystyrene.

We have studied the infrared spectrum of CPS-I* in the solid state, in the solution of carbon disulfide***, and in the molten state, and have compared them with the corresponding spectra of APS**. Another

** Commercial polystyrene, "Styron-666".

*** The solution was prepared by extraction of CPS-I at the boiling point of carbon disulfide.

crystalline polystyrene, CPS-II****, prepared by Alfin catalyst has been studied in the solid state.

The spectra of these samples in various states are shown in Fig. 1. The most remarkable differences between CPS-I and APS in solid are found in the bands at 1085, 1054 and 567 cm^{-1}. These absorption bands of CPS-I in solution are very similar to those of solid CPS-I, but some of the other bands observed in the solid state disappear.

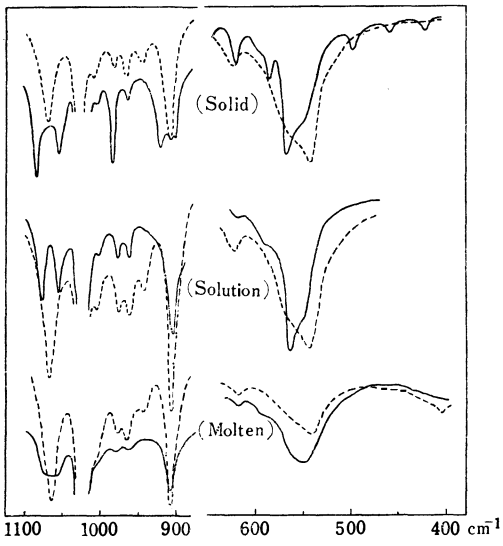

Fig. 1. Infrared spectra of CPS-I and APS in various states.
—— CPS-I ---- APS

In the molten state, the spectrum of CPS-I is almost similar to the spectrum of APS, except for the following points: the doublet at 1085 and 1054 cm^{-1} of solid CPS-I changes into a single and broad band with the maximum at 1070 cm^{-1} with melting, whereas molten APS shows a rather sharp absorption at 1070 cm^{-1}.

The asymmetric band with the maximum at 567 cm^{-1} of solid CPS-I becomes a symmetric and broad band with the maximum at 552 cm^{-1}, while the absorption maximum of molten APS at 543 cm^{-1} remains unchanged.

The observed absorption frequencies are shown in Table I. Complete assignment of the bands at 1085, 1054 and 567 cm^{-1} in both polystyrenes in various states are not yet obtained.

However, the differences between the spectra of CPS-I in various states can be used to classify the observed bands in three groups.

TABLE I. FREQUENCIES IN VARIOUS STATES OF CPS AND APS

CPS-I			APS		Classification of the band
solid	soln.	molten	solid, soln., molten		
1364	1364	1370 w	1370		B
1314	1314	1314 w	1312		B
1297	1297	1295 w	1295		B
1185	1190	1185 w	1182		B

		552 b			C
			543		C
499					A
465					A
426					A

s: sharp
b: broad
w: weak in solution and in molten state

(A) Under the first group come the bands at 984, 923, 901, 620, 587, 499, 465 and 426 cm^{-1}. They disappear instantly or are very much weakened when CPS-I dissolves in solution or melts. These bands, which are not observed in the spectrum of APS, may be assigned to the vibrational bands caused by the perturbation by rather long range intra- and intermolecular interactions in the CPS-I crystal. The band at 984 cm^{-1} is considered as a typical crystalline band by Tadokoro et al[4].

(B) Under the second group come the bands at 1365, 1314, 1297 and 1185 cm^{-1}. They are stronger in crystallized CPS-I than in quenched one, and persist in the spectrum of the solution. These bands have been assigned[2] to the CH or CH_2 deformation vibrations, which are closely associated with the intramolecular interaction in the herical chain having a three-fold screw axis.

(C) The doublet at 1085~1054 cm^{-1} and

**** Separated from insoluble parts in cold methyl ethyl ketone after treating with *n*-heptane.

4) H. Tadokoro et al., Symposium of High Polymer, Osaka, Oct., 1958.

the asymmetric bands at 567 cm^{-1} in solid CPS-I and at 543 cm^{-1} in APS could form the third group, because they appear differently in the spectra of molten CPS-I and APS.

The band at 567 cm^{-1} is tentatively assigned by the following reason: The Raman band at 558 cm^{-1} of APS has been assigned to the ν_{6A} mode, an in-plane vibration of benzene nuclei of A_1 mode, by Liang and Krimm[5], which derives from a Raman active and infrared inactive mode of benzene. If all the phenyl radicals in the herical conformation of a polystyrene molecule vibrate in the same phase in the ν_{6A} mode, the dipole moment of the molecule changes along the screw axis of the conformation. It is possible in this case that the ν_{6A} mode is infrared active and shows parallel dichroism which is actually found in our experimental data shown in Fig. 2. Thus we may expect that the band at 567 cm^{-1} is an *X*-sensitive vibration of monosubstituted benzene[6], and sensitive to the short range interaction between the phenyl group and the herical C–C main chain which has alternate *trans* and *gauche* conformations[7].

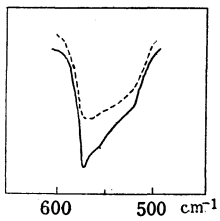

Fig. 2. Dichroism of the 567 cm^{-1} band in solid CPS-I.
—— Electric vector parallel to elongation
---- Electric vector perpendicular to elongation

The band at 543 cm^{-1} of APS is assigned to an *X*-sensitive vibration which is affected by another short range interaction between the phenyl group and the C–C main chain of APS which may have mainly *trans-trans* conformation sequence in their syndiotactic parts.

The doublet at 1085~1054 cm^{-1} of CPS-I and singlet at 1070 cm^{-1} of APS are probably assigned also to the same type of vibration.

On the basis of the above empirical classification of characteristic bands of CPS-I and APS, as a possible interpretation of the origin of these absorption bands, the following tentative conclusions are drawn.

Based on the behavior of C class band, the conformation of CPS-I along the C–C main of a few monomer units seems to differ from that of APS in their molten states. This may lead us to expect that the change of the bands at 1085, 1054 and 567 cm^{-1} must be connected with the content of the isotactic configuration of CPS-I. If this is assumed, it should be suggested that the isotactic contents in the chain configuration of CPS-II is smaller than that of CPS-I, since the C band of CPS-II in the solid state is quite similar to that of molten CPS-I as is shown in Fig. 3.

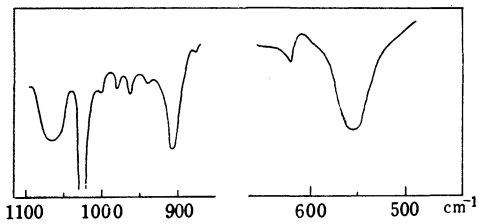

Fig. 3. Infrared spectrum of solid CPS-II.

In solution, it is interesting to note that the herical conformation of isotactic polystyrene is partly reserved, because the persistence of the bands at 567, 1085, 1054 and also 1364, 1314, 1297, 1185 cm^{-1} of crystallized CPS are well recognized.

The authors are grateful to Professor T. Shimanouchi of the University of Tokyo for his discussion and kind cooperation in the measurement of dichroism.

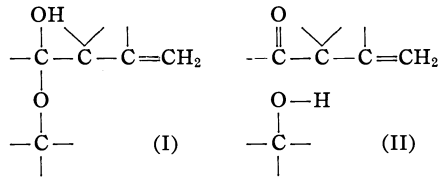
On Miyaconitine and Miyaconitinone

Shichiro KAKIMOTO, Nobukatsu KATSUI and Yoshiyuki ICHINOSE

(Received August 7, 1959)

In an earlier paper[1], the extended formulae of miyaconitine(I) $C_{23}H_{29}O_6N$ and miyaconitinone(II) $C_{23}H_{27}O_6N$ were given respectively as follows:

(I) $C_{19}H_{20}(OAc)(OH)(=O)_3(N\text{-}Et)$



(II) $C_{19}H_{19}(OAc)(=O)_4(N\text{-}Et)$

The present communication presents further consideration of the empirical and extended formulae of I and II:

(I) $C_{24}H_{31}O_6N$: $C_{20}H_{22}(OAc)(OH)(-O-)\cdot(=O)_2(N\text{-}Et)$. λ_{max}^{EtOH} 295 mμ (log ε 1.6), ν_{max}^{KBr} 3470(OH), 1726, 1678(CO), 3090, 1648, 877 cm^{-1} ($\rangle C=CH_2$)

(II) $C_{24}H_{31}O_6N$: $C_{20}H_{22}(OAc)(OH)(=O)_3\cdot(N\text{-}Et)$. pK_a' 6.5 λ_{max}^{EtOH} 290 mμ(log ε 2.6), ν_{max}^{KBr} 3410(OH) 1728, 1715, 1676(CO), 3090, 1648, 883 cm^{-1} ($\rangle C=CH_2$)

The presence of the terminal methylene group was confirmed not only by the observation of infrared spectra, but also by ozonolysis and novel Lemieux oxidation[2] to give formaldehyde. Compound I showed extreme susceptibility to aldehyde reagents (viz., Fehling, Tollens and TTC, etc.), but II did not. The oxidation of I with bismuth oxide in refluxing acetic acid yielded II. The infrared spectrum of II showed a band at 3410 cm^{-1} probably due to a tertiary hydroxyl group. These observations are explained by the consideration that the conversion of I to II is not a simple oxidation of a secondary hydroxyl group to a carbonyl group but is an oxidation of a hemiketal moeity existing in I. Ultraviolet absorption of II and its alkamine, miyaconinone(III), $C_{22}H_{25}O_5N$ showed abnormal intensity due to a β,γ-unsaturated carbonyl group[3]: λ_{max}^{EtOH} 294 mμ (log ε 2.6), ν_{max}^{Nujol} 3460, 3310 (OH) 1724, 1673 (CO) 1649, 888 cm^{-1} ($\rangle C=CH_2$). Therefore, the partial structures of I and II may be represented by the following schemata.

Alkaline hydrolysis of II gave ψ-miyaconinone*(IV), m. p. 254~256°C, $[\alpha]_D^{20}$ −1.0°, pK_a 4.2, λ_{max}^{EtOH} 284 mμ(log ε 1.2). ν_{max}^{Nujol} 3600, 3510 (OH) 1783, 1727(CO) 1648, 889 cm^{-1} ($\rangle C=CH_2$) (*Anal.* Found: C, 68.58, H, 7.48. Calcd. for $C_{22}H_{25}O_5N$: C, 68.19; H, 7.54%). This compound was obtained also by alkaline treatment of III. In the ultraviolet absorption of IV, the maximum displayed no longer the abnormal intensity as shown in those of II and III. On the other hand, the infrared spectrum of IV showed three peaks due to hydroxyl group although that of III had two peaks. Then it is considered that the reaction of II to IV involves the base-catalyzed conversion of the carbonyl group to a hydroxyl group. A plausible explanation of this reaction is that the carbonyl group showing abnormal intensity in II or III has undergone an internal aldol condensation. It has been previously reported that an α-diketone group adjacent to the nitrogen atom is present[4]. Accordingly, the condensation must have occurred in the methylene group adjacent to the α-diketone. The lower basicity of IV also supports these considerations.

In the titrations of periodate and lead tetraacetate, III and IV took up rapidly one mole more than II in one hour. It is suggested then that III and IV have a vicinal glycol system.

The composition of the fundamental base, $C_{20}H_{31}N$, and the exsistence of terminal methylene group suggest that I and II may be belonged to atisine or garryine type alkaloids.

Furthermore, it has been already reported that songorine[3b,5], one of aconite alkaloids, has the same β,γ-unsaturated ketonic system with II. And so it is considered tentatively that I and II have

5) K. Wiesner, S. Itô and Z. Valenta, *Experientia*, **14**, 167 (1958).

closely related ring structures with these alkaloids.

Above all, it has been reported that selenium dehydrogenation of II gives phenanthrene and anthracene[6]. If anthracene ring occurred without rearrangement in the course of dehydrogenation, this fact, above consideration and the partial structures may lead possible structures for I and II as follows:

(I) R=O R'=H₂ (II)

As for the α-diketone system, R=O is more probable than R'=O**. The infrared absorption of I or II is similar*** to that of kobusine diacetate which has an allylic acetate function[7]. It is suggested that the acetyl group in I and II covers an allylic hydroxyl group which is observed generally in alkaloids of the atisine group. Some experimental studies in order to confirm the above considerations are in progress.

The authors wish to express their deep thanks to Professor Harusada Suginome, President of Hokkaido University, for his exceedingly kind direction throughout this work.

The Structure of Matatabilactone

By Takeo Sakan, Akira Fujino, Fujio Murai, Akio Suzui and Yasuo Butsugan

(Received August 18, 1959)

In the preceding communication[1], the authors presented the structural formula of dihydronepetalactone for matatabilactone which was isolated as one of the physiologically active components for the Felidae animals from the leaves of *Actinidia polygama* Miq. (Matatabi). This estimation was principally based on the fact that two known epimeric nepetalinic acids were obtained by the oxidation of the corresponding hydroxy acid with potassium permanganate. It was pointed out that the alternative formula, i. e., that of isoiridomyrmecin(Ia)[2] or iridomyrmecin (Ib)[2] was unlikely to be the case because of the quite clear differences among the $\nu_{C=O}$ values in the infrared spectra of these substances. The examination thereafter has, however, led to some new informations in regard to the structural problem.

Ia $R_1=CH_3$, $R_2=H$

Ib $R_1=H$, $R_2=CH_3$

A hydroxy acid, $C_{10}H_{18}O_3$(II) of m. p. 109~110°C (*Anal.* Found: C, 63.86; H, 9.72. Calcd: C, 64.49; H, 9.74%) was isolated when I (*Anal.* Found: C, 71.54; H, 9.88. Calcd. for $C_{10}H_{16}O_2$: C, 71.39; H, 9.59%) was, after alkali hydrolysis, treated carefully with acetic acid. By vacuum sublimation II was converted into a lactone, m. p. 60°C, $[\alpha]_D^{21}-67.6°$ (c 0.10, carbon tetrachloride)(III), from which the hydrazide(IV) of II, m. p. 119~120°C (*Anal.* Found: N, 14.11. Calcd. for $C_{10}H_{20}O_2N_2$: N, 13.99%) was derived. The physical properties of II—IV are respectively very similar to those of the compounds of Ia series. The mixed fusion tests and the

comparisons of the infrared spectra of the samples of III and IV proved their identities with those that have been found by the Australian chemists. The authors are deeply indebted to Dr. G. W. K. Cavill for his kind offers.

It was difficult to seperate II completely from I, and accordingly, the residual part is as yet non-crystalline. Although attempts to obtain the other component in a pure state have been up to now without success, it is likely that matatabilactone is a mixture of Ia and Ib.

Calcd. for $C_{10}H_{13}O_2N$: C, 67.02; H, 7.31; N, 7.82%) was obtained. Chlorination of IV with phosphorus oxychloride and successive catalytic hydrogenation of the dechloro-compound (oil) afforded DL-actinidine(V), b.p. 100~103°C/12 mmHg (picrate: m. p. 142~143°C). V was then resolved into an optically active form through the mono-salt of dibenzoyltartaric acid. The less soluble salt in absolute ethanol yielded, on regeneration of the base, a laevorotatory oil(VI), $[\alpha]_D^{21}$ −8.01° (c 2.17, chloroform), the infrared spectrum of which was in all respects identical with that of natural actinidine. Identity between the picrates of VI, m.p. 146~147°C, and of I, was also established through the mixed melting point determination and the comparison of the infrared spectra.

The Synthesis of Actinidine

By Takeo SAKAN, Akira FUJINO, Fujio MURAI, Akio SUZUI and Yasuo BUTSUGAN

(Received August 18, 1959)

Actinidine(I)[1], a basic effective component for the Felidae animals in *Actinidia polygama* Miq. (Matatabi), was synthesized from ethyl α-(3-methyl-2-oxo-cyclopentyl)-propionate(II)[2] as follows.

(I) (II)

The cyanohydrin of II was dehydrated to a cyanoester(III), b. p. 106~120°C/2 mmHg by the action of thionyl chloride in the presence of pyridine. The position of the double bond in III is not conclusive, and both possible isomers seem to have been actually produced. Attempts to separate them with alkali or ethoxide solution resulted in failure. On acid or alkali hydrolysis of III, the dihydroxy-pyridine derivative(IV), m. p. 167~168°C (*Anal.* Found: C, 66.71; H, 7.32; N, 7.77.

Dialkylthioboronates

By Nobuyuki ASHIKARI

(Received September 7, 1959)

Many organo boron compounds are known to be effective catalysts for vinyl-polymerization[1-3]. Accordingly, several dialkylthioboronates have been prepared for testing the catalytic activity. It was found that though the activites of the compounds as polymerization catalysts were low, they reacted in a characteristic manner with ammonia. These compounds are new substances, and the synthetic method and some properties of them are described in this paper.

The only known dialkylthioboronate is dimethylthioboronate[4], $(CH_3)_2BSCH_3$, which was prepared by the interaction of methylmercaptan and tetramethyl diborane.

$$2CH_3SH + B_2H_2(CH_3)_4 = 2(CH_3)_2BSCH_3 + 2H_2$$

In the present studies, the dialkylthioboronates have been prepared by reaction between dialkylboron chloride and the sodium salt of mercaptan. While alcohols react readily with dialkylboron chloride to produce dialkylboronous esters[5], mercaptans do not react at least at room temperature. Dialkylthioboronate reacts readily with ammonia to produce a white solid at about $-60°C$, which appears to be an unstable 1 : 1 addition product. This product easily decomposes to dialkylamino borine, R_2BNH_2, on distillation. The reaction is considered to be as follows:

$$R_2BSR' \xrightarrow{\text{liq. } NH_3} R_2BSR' : NH_3$$
$$\xrightarrow{\text{distill.}} R_2BNH_2 + R'SH$$

The details of this aspect will be reported in the near future.

Experimental and Results. — In a 300 cc. three necked round-bottomed flask, fitted with a mechanical stirrer with a mercury seal, a reflux condenser, and a dropping funnel, were placed about 100 cc. of anhydrous ether and the various amonts of sodium shown in Table I. To the mixture,

TABLE I. YIELDS OF R_2BSR'

R in R_2BCl	Wt., g.	R in $R'SH$[a]	Na, g.	Product, g.	Yield, %[b]
iso-C_3H_7	33	C_2H_5	10	18	30.0
n-C_4H_9	45	C_2H_5	10	30	40.0
n-C_4H_9	30	*iso*-C_3H	7	16	36.6
n-C_4H_9	31	*n*-C_4H_9	6	34	38.0

a) The amount of R'SH is 25 g. in each experiment.
b) The yield was calculated from R'SH employed.

25 g. of mercaptan was dropped slowly, with stirring. After completion of addition, the system was heated for about three hours, and the mixture was cooled to room temerature. The unchanged sodium was removed, and about 100 cc. of ethereal solution containing a certain amount of dialkylboron chloride (shown in Table I) was added slowly from the dropping funnel. The reaction proceeds as follows:

$$R_2BCl + R'SNa = R_2BSR' + NaCl$$

After the dropping had been completed, the mixture was heated for about four hours. The solvent was distilled off, and further distillation was carried out under reduced pressure. The products were redistilled for measurements of physical constants. The results are shown in Table II.

Calculated Thermodynamic Properties of Trimethylchlorosilane

By Kazuhiro Shimizu and Hiromu Murata

(Received September 10, 1959)

The vibrational assignment of trimethylchlorosilane has been revised, based on a normal coordinate treatment as a fourteen body problem[1]. The probable values of the wave numbers of the normal vibrations were used to calculate the values of the heat content, free energy, entropy and heat capacity for the ideal gaseous state at 1 atmospheric pressure (rigid rotator, harmonic oscillator approximation). The bond distances and the interbond angles in the previous Table I[1] and the Hirschfelder formula[2] were used to calculate the product of the principal moments of inertia, $I_aI_bI_b=3.85961\ 10^{-113}$ g^3 cm^6. The molecular weight used was 108.652 and the symmetry number was 3. The three torsional vibrational frequencies of the methyl groups belong to the species a_2 and e. No information about their frequencies has been given. Therefore, the total contributions of the translational, rotational and vibrational frequencies are listed in Table I, except those of the three unknown methyl torsional modes. When the contributions of the three ones are evaluated, they have to be added.

Polarographic Studies on the Rare Earths. II. Europium

By Seizo MISUMI and Yasushi IDE

(Received March 22, 1959)

Europium has the stable dipositive oxidation state similar to samarium and ytterbium among the rare earth elements. It is also clearly recognized that this intermediate dipositive oxidation state exists during the reduction process of the tripositive europium ions on dropping mercury electrode and this fact has already been studied by some investigators. Laitinen and Taebel[1], and also Noddack and Brukl[2] obtained only a single wave having the half-wave potential of −0.77 V. vs. S. C. E. in acidic solution and −0.67 V. vs. S. C. E. in neutral solution. On the other hand, Holleck[3] obtained double wave for europium. Namely, the half-wave potential of the first wave was −0.78 V. vs. S. C. E. and that of the second wave, −2.14 V. vs. S. C. E. with lithium chloride as the supporting electrolyte, and −0.82 V. and −2.14 V. vs. S. C. E. respectively when with tetramethylammonium iodide. Many other polarographic studies on the europium complexes with various complex-forming agents were reported by Holleck[4], Onstott[5] and Vlček[6].

In this paper, the authors have reported the behaviors of europium ion in the process of reduction on the dropping mercury electrode. The reduction waves were studied in detail under various conditions, especially in order to know the electrode reactions.

Experimental

All current-voltage curves were recorded by the Yanagimoto photographic polarograph PEL-Model 3 Type. All potentials were corrected and referred to saturated calomel electrode (S. C. E). The capillary used had the flowing weight of mercury, $m=0.789$ mg./sec. at the height of 58.5 cm. (corr.) Hg and the drop time, $t=5.20$ and 3.10 sec./drop at the applied potentials of −0.8 V. and −2.0 V. vs. S. C. E. respectively (the factor $m^{2/3}\,t^{1/6}$ was from 1.021 to 1.135 $mg^{2/3}\,sec^{-1/2}$ in the same potential range). pH value of the solution was measured with the Hitachi glass electrode pH meter EHM-1 Type for micro amount. All experiments were carried out in a thermostat of 25.0±0.1°C.

Europium solution was prepared by dissolving pure europium oxide (Eu_2O_3: more than 99.9%), purified with ion exchange resin. The concentration of the stock solution was 0.01 M/l. Lithium chloride and lithium perchlorate used as supporting electrolytes were guaranteed grade pure Shikajirushi. The concentrations of these stock solutions were 1 mol./l. The gelatin solution used as maximum suppressor, was prepared freshly in every experiment.

To the sample solution of europium, certain quantities of the supporting electrolyte and of gelatin were added to be the final concentrations, 0.1 M/l. and 0.01%, respectively. And then a micro amount of 0.01 N sulfuric acid was added to prevent the hydrolysis of the aquo europium ion and to adjust pH at the same time. The total volume of the solution was made up to 5 ml. with distilled water. The concentration of europium ion was in the range from 0.5 to 1.6 mM/l. and pH of the solution was varied from 2.75 to 3.90. Dissolved oxygen was removed by passing purified nitrogen gas through the solution for at least 20 min. Then polarograms were recorded.

Results and Discussion

1) The Reduction Wave of Aquo Tripositive Europium Ion. — Typical reduction waves of aquo tripositive europium ion are shown in Fig. 1. At pH less than 3.9, three stepped waves were obtained and the first and the third waves are due to the

reduction of aquo europium ion and the second wave is the hydrogen wave. In this paper hereafter, the first step is called "the first wave" and the third step "the second wave" of europium.

Owing to the variation in pH and the concentration of europium, the differences between the forms of the reduction waves were indicated. From the polarograms obtained, the following results were derived as the common characteristics, i. e., 1) at pH more than 3.2, independent of concentration, the second wave had a small maximum, but as the pH decreased, this maximum usually disappeared; 2) at pH less than 2.7, a well defined second wave could not be obtained. It is supposed that the large diffusion current of the hydrogen wave probably disturbed the second wave. The effect of various supporting electrolytes on the forms of the reduction waves were rather small and negligible, giving polarograms of similar types.

2) Dependence of Limiting Current of the First and the Second Waves on the Pressure of Dropping Mercury and Influence of Temperature on the Diffusion Current. — The relation between limiting currents and various heights of the mercury column is shown in Table I. The results obviously indicate the fact that the limiting current is proportional to the square root of the height of the mercury column, corrected for the back pressure. Accordingly, the limiting current is diffusion controlled.

The temperature coefficient of the half-wave potential of the first wave at 20~30°C, was 0.4 mV./deg. and that of the limiting current 1.9%/deg., which would be expected in the case of diffusion controlled process for the reduction of tripositive ion.

3) Reversibility. — The reduction waves were analyzed by logarithmic plot. The results are shown in Table II. As the reciprocal slope of the first wave was nearly constant, the average value 0.087 V., in the range of pH 3.50 to 2.75, the first reduction wave was irreversible and due to one electron transfer. The value of $\alpha_1 n_1$, was about 0.68 on the average. The transfer coefficient α was equal to 0.68 if the number of electrons associated with the electrode reaction was assumed to be one (α is a transfer coefficient in the equation of potential on irreversible wave, $E=E_{1/2}-\boldsymbol{RT}/\alpha n\boldsymbol{F}\cdot\ln(i/i_d-i)$. The plots of E against $\log(i/i_d-i)$ indicated an almost straight line. The reciprocal slope of the second wave decreased gradually with decrease of pH and approached a constant value, about 0.030 and the value of $\alpha_2 n_2$ increased reversely up to about 2.0. The plots of E against $\log(i/i_d-i)$ for the second wave indicated the slightly curved line near a pH about 3.50, but with decrease of pH it approached a straight line. Therefore, it is considered that the electrode reaction of the second wave was irreversible or quasi-reversible and according to the decrease of pH, it approached the reversible wave and the reaction was accompanied with two electron transfer. Many investigators have reported the reduction process of aquo tripositive europium ion as reversible except Vlček[6] who suggested that it was irreversible. The results in this experiment were also in good agreement with those of Vlček's report on the confirmation of irreversibility in the reduction process of the aquo europium ion.

TABLE II. THE RECIPROCAL SLOPE OF E VS. $\log(i/i_d-i)$ AND THE VALUE OF αn

pH	Reciprocal slope, V.		$\alpha_1 n_1$	$\alpha_2 n_2$
	1st wave	2nd wave		
3.50	0.087	0.045	0.63	1.3
3.15	0.085	0.045	0.78	1.7
3.05	0.086	0.034	0.69	1.7
2.95	0.087	0.030	0.68	2.0
2.75	0.090	0.030	0.66	2.0
(Eu^{3+} ion: 1.104 mM in 0.1 M LiCl and 0.01% gelatin medium)				
2.90	0.090	0.048	0.65	1.2
2.80	0.082	0.036	0.71	1.6
(Eu^{3+} ion: 1.000 mM in 0.1 M $LiClO_4$ and 0.01% gelatin medium)				

The oxidation wave of aquo dipositive europium ions (Eu^{2+} aq.), which were obtained by the reduction of aquo tripositive europium ions (Eu^{3+} aq.) with John's reductor, was studied. The half-wave potential of the oxidation wave of aquo dipositive europium ions was −0.292 V. vs. S. C. E. at pH 2.55 and this value did not coincide with the half-wave potential of the reduction wave of aquo tripositive europium ions under the same conditions. Thus, from this fact, the electrode reaction of the first wave was shown evidently to be irreversible (the potential difference of anodic and cathodic waves was about 0.440 V.).

4) The Effects of Variation in pH Value on the Reduction Waves.—The results of variation in pH value are shown in Table III, by which the effects on half-wave potentials and diffusion currents were studied. Both the half-wave potential of the first wave $(E_1)_{1/2}$ and the second wave $(E_2)_{1/2}$ shifted all to the more negative side as pH values were decreased. The extent of the shift for the first wave was somewhat greater especially in the range of pH 3.50 to 3.15 than at pH less than 3.15. This fact is probably due to the existence of various hydroxo europium complex ions, produced by hydrolysis of aquo europium complex ions in each step of variation in pH of solution, owing to the basicity of europium. The diffusion currents were independent of pH, almost constant at the same concentration in the range of pH, given in Table III.

5) The Effects of Variation in Concentration on the Reduction Wave. — In the various concentrations of europium ion, i. e., 0.552, 1.104 and 1.656 mM/l. at the constant pH (adjusted to ca. 2.95), the reduction waves were recorded. These effects of variations in concentrations of europium ions on half-wave potentials and diffusion currents were studied. Results are shown in Table IV.

The half-wave potentials of the first and the second wave, $(E_1)_{1/2}$ and $(E_2)_{1/2}$, were constant, independent of concentrations. The diffusion current of the first wave i_d, increased proportionally to concentration and thus the ratio i_{d_1}/c (c : concentration of europium ion) indicated constant value too, i. e., there exists a linear relationship between diffusion current and concentration, which can be used for determination of europium. Especially, since in the potential range where the first wave of tripositive europium ion appears, the reduction waves of all other rare earth ions are absent, it is possible to determine polarographically the contents of europium in a mixture of several kinds of rare earth elements. The diffusion current constant of the first wave, I_{d_1}, was also constant. The diffusion current of the second wave, i_{d_2}, however, increased anomalously with the increase of the concentration and the value of the ratio i_{d_2}/c and the diffusion current constant of the second wave, I_{d_2}, decreased gradually

(pH: 2.95, 0.1 M LiCl, 0.01% gelatin)

with rise of concentration. These anomalies may be attributed to precipitation or adsorption of the basic substances of europium on the electrode surfaces.

6) The Effects by the Kinds of Anions Contained in the Supporting Electrolytes.—The reduction process of aquo europium ion on dropping mercury electrode, often depends on its ionic states. These ionic states show considerably different dependence upon the kinds of electrolytes dissolved in the solution. Therefore, the kinds of supporting electrolytes added, are frequently able to cause remarkably different results to the reduction wave. Particularly, by the anion species of supporting electrolytes and further by the differences of their concentrations, the reversibility of the electrode reaction and the rate-determining step are influenced. From this standpoint, under the same conditions, by varying the anion species of the supporting electrolytes, the effects on the reduction waves were studied. The results are shown in Table V.

At the same concentration, somewhat large effects by the species of anions in the supporting electrolytes on the reduction wave could be seen as shown in Table V. Although pH was not kept strictly the same, the trend of the effects on the reduction wave could be seen. The half-wave potential of the second wave shifted to the more negative side in the order of $I^- < Cl^- < ClO_4^-$. Since the ionic strength was kept always constant, the half-wave potential should have the same value under the same conditions, but owing to the kinds of the anion species the different values were indicated. It is considered that the aquo europium ion forms the halogeno aquo complex ion with halogen ion, which takes part in the electrode reaction. However, as the perchlorate ion is the anion which does not form complex generally with the metal ions, it is also considered that the aquo europium ion exists in the same ionic state (single ion) in the solution with lithium perchlorate as the supporting electrolyte. If the halogeno aquo europium complex ion exists in the solution with the halides as the supporting electrolytes, it is known that this complex ion becomes more reducible than the aquo europium ion (single ion) and as the results of the electrode reaction approaches the reversible one from the irreversible. These facts were recognized from the reciprocal slope and the half-wave potential in this experiment. That is to say, in the presence of the halogen ions, the half-wave potential of the second wave shifted to the positive side and the reversibility increased at the same time. The value of the diffusion current constant of the first wave, I_{d_1}, was nearly constant in the case of the halide ions, but in the case of the perchlorate ions, the diffusion current constant of the second wave, I_{d_2}, was greater, which means the irreversible reaction. Thus, the aquo complex ion (single ion) is more difficult to be reduced than the halogeno aquo complex ion. This fact

(Concn. of the gelatin: 0.01%, concn. of Eu^{3+} ion: 1.000 mM, pH: 3.10)

was in good agreement with the values of the reciprocal slopes for the second waves.

The results concerning the variation in the concentration of lithium chloride as supporting electrolyte are given in Table VI, in which effects of the chloride ion on the reduction wave are shown.

The half-wave potential of polarography is generally represented by the term containing activity coefficients and diffusion coefficients. If either the activity coefficient or the diffusion coefficient is varied, the half-wave potential will probably indicate a different value. With increasing ocncentratoins of total electrolytes the activity coefficient tends to decrease and as the result, the half-wave potential is likely to shift to the more negative potential. Moreover the stability of halogeno aquo europium complex ion is thermodynamically greater than the aquo europium ion and the negative shift will probably take place.

But, on the contrary, as shown in the results of Table VI, there can be seen a tendency for the half-wave potential to shift apparently to the more positive side according to the increase of the concentration of lithium chloride as the supporting electrolyte. At the concentration of 0.5 to 0.7 mmol., the extent of the shift was considerably great. With the increase of chloride ions, the increased chloro aquo complex ions caused the overpotentials to decrease and this large decrease in this overpotential, i. e., the easiness of reduction, outweighed the shift in the equilibrium relation. Thus the half-wave potential seems to shift apparently to the more positive side. In spite of these facts, the value of the reciprocal slope increased with the increase of the concentration of lithium chloride, that is, the irreversibility in the electrode reaction increased too.

7) The Effects of Concentration of Gelatin as Maximum Suppressor, on the Reduction Wave. — By the variation in concentration of gelatin from 0 to 0.05%, the effects on the reduction waves were studied. With the increase of the concentration of gelatin, the half-wave potentials of both the first and the second waves shifted to the more negative side respectively and the values of the reciprocal slopes increased. At pH less than 3.2, without gelatin, a large maximum appeared in the second wave, but with the increase of concentration of gelatin added as maximum suppressor, the maximum decreased gradually and, when 0.01% concentration of gelatin was added, it disappeared completely. At pH more than 3.2, even at concentration of gelatin 0.01%, the maximum could be seen slightly.

8) The Electrode Reduction and the Relation between Reduction Process and Electronic Structure of Aquo Europium Ion.—The reduction of aquo europium ion on dropping mercury electrode, proceeds irreversibly or quasi reversible as described in section 3. In the equation of the current-voltage curve for the irreversible reaction, $E=E_{1/2}-0.0591/\alpha n\cdot\log(i/i_d-i)$ $(0<\alpha<1)$, it was derived that n_1 was equal to 1 and n_2 to 2, by using the results given in Table II. Consequently, the electrode reaction for the first wave was one electron change and that for the second wave two electrons. As the limiting current was diffusion controlled, with Ilkovic's equation, the following relation could be held theoretically between diffusion currents of the first wave and of the second wave, i. e., $i_{d_1} : i_{d_2}=1 : 2$. Therefore, the ratio of the diffusion current constants for the first and the second wave, $I_{d_1} : I_{d_2}=1 : 2$ is obtained.

The experimental average values of diffusion current constants were as follows, namely, $(I_{d_1})_{av}=1.57$ and $(I_{d_2})_{av}=3.46$. Hence, the ratio $(I_{d_1})_{av} : (I_{d_2})_{av}=1 : 2.2$ was obtained, which was in fairly good agreement with the value of the theoretical ratio. Thus, it is considered that the electrode reaction in the reduction of aquo tripositive europium ion proceeds as follows:

The first wave,

$$Eu^{3+}\,aq.+\,e^-\rightarrow Eu^{2+}aq.$$

The second wave,

$$Eu^{2+}\,aq.+\,2e^-\rightarrow Eu^0$$

For the rate determining steps of the irreversible electrode reaction, the following main factors are supposedly considered.

a) The overpotential required for dehydration of the coordinated water molecules.

b) The stepwise dissociation of the aquo complex ion.

c) The overpotential required for the changes of the inner electronic configuration (in some $(n-2)f$ orbitals).

d) The stability in the oxidation state of the aquo complex ion.

e) The others.

The results of the irreversible reduction process of the aquo europium complex ion at the dropping mercury electrode, was

TABLE VII. POLAROGRAPHIC REDUCTION (ELECTRON TRANSFER AND ELECTRONIC CONFIGURATION)

Electrode reaction	Electronic configuration (Oxidized form) 1st wave	(Reduced form) 2nd wave	
Eu^{3+} aq. → Eu^{2+} aq. Irreversible	$f^6s^2p^6d^0d^0d^0[d^2sp^3]+e^-$		
		→ $f^6s^2p^6d^1d^0d^0[d^2sp^3]$	(2 step electron transfer)
		→ $f^7s^2p^6d^0d^0d^0[d^2sp^3]+2e^-$	
Eu^{2+} aq. → Eu^0 Irreversible			→ $f^7s^2p^6d^1d^1d^0[d^2sp^3]$
			→ $f^7s^2p^6s^2$—ligand

(Eu: $4f^75s^25p^66s^2$)

in good agreement with the conclusions of Vlček's rule[7], concerning the mechanism of the electron transfer by polarographic reduction. The dipositive stable oxidation state of europium is already known in solution. As Vlček pointed out, the true two step reduction wave as *f*-transition element was seen for the aquo europium complex ion. Generally, the rate of the electrode reaction is determined always by the slowest of the processes and the change by the electron transfer in reduction processes may always have a tendency to produce the most stable electronic configuration. The aquo europium complex ion is assumed to have simply the coordination number 6 and to be $Eu(H_2O)_6^{3+}$ complex ions. The probable relation between electron transfer and electronic configuration is shown in Table VII.

Summary

The double reduction waves of pure aquo tripositive europium ion, under various conditions, at dropping mercury electrode were studied. The effects of the variations in pH, the concentration of europium ion, the anion species of supporting electrolytes, and the concentration of gelatin as maximum suppressor, etc. were examined. The electrode reaction of the first wave was irreversible and one electron reduction, and that of the second wave was the irreversible or quasi reversible two electrons reduction. The half-wave potentials of the first wave and the second wave at pH 2.95 were as follows.

$(E_1)_{1/2}$: −0.767 V. vs. S. C. E.

$(E_2)_{1/2}$: −1.971 V. vs. S. C. E.

where concentration of Eu^{3+} ion: 1.104 mM in 0.1 M LiCl and 0.01% gelatin medium.

Aminosäure-Synthese aus Nitromalonester. IV[1]. *Eine neue Synthese von Tryptophan mit Hilfe der Alkylierung des Indols mit 1, 1, 5, 5-Tetracarbalkoxy-1, 5-dinitro-3-azapentan**

Von Tôru OKUDA

(Eingegangen am 25. März 1959)

Seitdem Hopkins und Cole[2] zum erstenmal im Jahre 1901 Tryptophan aus dem Caseinhydrolysat isolierten, sind bisher zahlreiche Untersuchungen über die synthetische Darstellung dieser Aminosäure gemacht worden, von denen nur die praktischen im folgenden angeführt seien: (1) Umsetzung von Gramin mit Acylaminomalonestern[3-5], Nitroessigester[6] bzw. Nitromalonester[7]; (2) Umsetzung von Indol mit Dialkylaminomethyl-acylaminomalonestern[8]; (3) Fischer-Indol-Ringschluß des aus Acetamino-malonester, Acrolein und Phenylhydrazin dargestellten Phenylhydrazons[9]; (4) reduzierende Aminierung von α-Keto-β-(3-indolyl)propionsäure[10]; (5) Decarboxylierung von 2-Carboxytryptophan, welches von γ-Butyrolacton[11], Acetessigester[12] bzw. α-Ketoglutarsäure[13] abgeleitet wird; (6) Addition von Indol zu α-Acetaminoacrylsäure[14]. Es bleibt trotzdem noch die einfachere Synthese dieser Aminosäure in besserer Ausbeute wünschenswert.

* Auszugsweise vorgetragen an der XI. Versammlung der Japanischen Chemischen Gesellschaft, Tokio, 4. April 1958.

1) III. Mitteil.: T. Okuda, Dieses Bulletin, **32**, 931 (1959).

2) F. G. Hopkins und S. W. Cole, *Proc. Roy. Soc. (London)*, **68**, 21 (1901); *J. Physiol.*, **27**, 418 (1902).

Wie das oben angegebene Reaktionsschema zeigt, stellt die vorliegende Arbeit eine neue Synthese des Tryptophans dar, in der, Nitromalonester als Ausgangsstoff dient. In früheren Mitteilungen haben wir über Synthesen von Ornithin[15], Prolin[16], Glutaminsäure-γ-semialdehydacetal[16] und Glutaminsäure[1] aus dem gleichen Ester (I) berichtet.

Wie schon zitiert, haben Weisblat und Lyttle ein Verfahren zur Darstellung des Tryptophans mittels Nitromalonesters entdeckt[7], indem sie zunächst I in siedendem Toluol mit Gramin zur Reaktion brachten und anschließend das Kondensationsprodukt reduzierten und verseiften.

Unsere Synthese geht auch von dem gleichen Nitromalonester (I) aus, aber, wie aus dem Reaktionsschema ersichtlich ist, unterscheidet sich dieser von dem von ihnen entdeckten Verfahren darin, daß bei uns eine bisher unbekannte, neuartige Alkylierungsreaktion mittels 1,1,5,5-Tetracarbalkoxy-1, 5-dinitro-3-azapentans (III), einer Art bis-substituierten Amins, welches durch eine Mannich-Reaktion von Nitromalonester (I), Formaldehyd und Ammoniak gewonnen wird, angewandt ist.

Mannich-Reaktion von Nitromalonester mit Formaldehyd und Ammoniak. — Durch Einwirkung von wässriger Formaldehyd-

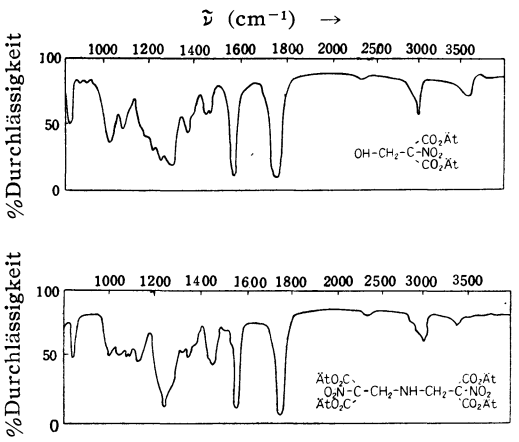
Lösung auf Nitromalonester (I) in Gegenwart einer katalytischen Menge Natronlauge als Kondensationsmittel konnten wir Hydroxymethyl-nitromalonsäure-dimethylester (IIa) als weiße Kristalle vom Schmp. 90~91°C und den Äthylester (IIb) als farblose Flüssigkeit vom Sdp 1 mm. 120~125°C in guten Ausbeuten erhalten. Versuche, α-Carbalkoxy-α-nitro-β-(3-indolyl)-propionsäureester (III) direkt durch Umsetzung von Indol mit Hydroxymethyl-nitromalonester (II) oder mit dessen acetyliertem Derivate darzustellen, waren alle ohne Erfolg, was uns einen andern Weg einschlagen ließ.

Kürzlich haben Feuer und Mitarb.[17] sowie Fränkel und Mitarb.[18] gefunden, daß 2, 2-Dinitroalkanole, die aus *gem*-Dinitroparaffinen und Formaldehyd gewonnen wurden, unter Bildung von Bis-(2, 2-dinitroalkyl)-aminen mit Ammoniak in wässriger Essigsäure-Lösung kondensieren.

Auch für die Mannich-Reaktion von Hydroxymethyl-nitromalonester (II) mit Ammoniak galten die Bedingungen, unter denen Bis-(2, 2-dinitroalkyl)-amine dargestellt wurden. Wenn man also II mit 2 Mol. Ammoniumacetat in Wasser auf etwa 60°C behandelte, so erhielt man leicht das Kondensationsprodukt. Anderseits gelang es uns, auch durch Versetzung von Nitromalonester (I) mit Ammoniumacetat und Formaldehyd das gleiche Mannich-Kondensationsprodukt direkt zu gewinnen.



Im Jahre 1903 erhielten Ulpiani und Mitarb.[19] durch Umsetzung von Ammoniumsalz des *aci*-Nitromalonsäure-diäthylesters mit einem großen Überschuß von Formaldehyd ein kristallinisches Produkt vom Schmp. 46°C, das vermutlich mit dem von uns dargestellten als identisch anzusehen ist. Sie gaben aber aus falschen experimentellen Daten die Formel VII an. Bald darauf wurde diese

VII

auf Grund der ebullioskopischen und kryoskopischen Molekulargewichtsbestimmung derart korrigiert, daß dieser Verbindung statt der Formel VII wohl eher die Formel IIIb zukommen sollte[20].

Zur endgültigen Entscheidung der

Abbild 1. IR-Spektren von Hydroxymethyl-nitromalonsäure-diäthylester (IIb) und 1,1, 5,5-Tetracarbäthoxy-1,5-dinitro-3-azapentan (IIIb). (in Flüssigkeit)

Konstitution des Kondensationsprodukts, dessen Formel trotz der Battagliaschen Berichtigung im Beilsteins Handbuch mit dem Wort "vielleicht" aufgeschrieben ist[21], wiederholten wir die Elementaranalyse und die Molekulargewichtsbestimmung nach der Rast-Methode und konnten dabei bestätigen, daß die von Battaglia angegebene Formel III als ein bis-substituierten Amin richtig ist. Die Struktur von III ergibt sich auch aus folgenden Befunden: das Infrarot-Spektrum (Abbild. 1) zeigt lediglich eine NH-Bande (3300 cm^{-1}), aber keine NH_2-Doppelbande (3300~3500 cm^{-1}).

Alkylierung des Kohlenstoffatoms in β-Stellung von Indol mit 1, 1, 5, 5-Tetracarbalkoxy-1, 5-dinitro-3-azapentan. — An der Molekularstruktur von 1, 1, 5, 5-Tetracarbalkoxy-1, 5-dinitro-3-azapentan (III) ist anzunehmen, daß durch die Einflüsse der Carbalkoxyl- und Nitro-Gruppen, welche elektronenanziehend wirken können, an beiden Enden des Moleküls die Bindungen zwischen dem mittelständigen Stickstoffatom und den benachbarten Kohlenstoffatomen aufgelockert genug seien, um sich unter gewissen Bedingungen abzuspalten. Es wäre daher denkbar, das Ziel der Substitution eines Wasserstoffatoms von nucleophilen oder potentiell nucleophilen Verbindungen durch Dicarbalkoxy-nitroäthyl-Gruppe $\left(\begin{matrix}RO_2C\\O_2N\end{matrix}\!\!>\!C\!-\!CH_2\!-\right)$ mittels dieses bis-substituierten Amins anzustreben.

Es ist wohl bekannt, daß im allgemeinen

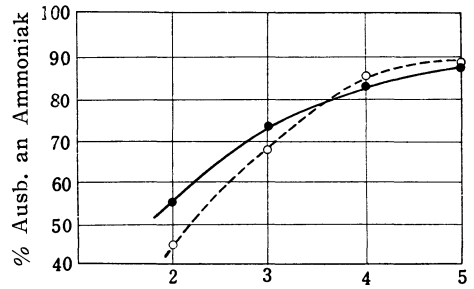
die *C*-Alkylierungsreaktion von *H*-aciden Verbindungen mittels tertiärer Mannich-Basen oder quartärer Ammoniumsalze in Anwesenheit von Natriumhydroxyd als Kondensationsmittel mit Erfolg durchgeführt werden kann[22].

Aber bisher ist unseres Wissens keine Literaturangabe über die *C*-Alkylierungsreaktion mittels sekundärer Aminen bekanntgeworden.

Bei den Vorversuchen beobachteten wir, daß beim Erhitzen von Indol und 1, 1, 5, 5-Tatracarbalkoxy-1, 5-dinitro-3-azapentan (III) in Xylol unter Stickstoff-Strom auf 130~140°C die Entwicklung des Ammoniaks eintrat. Diese und andere Versuche, die hintenan beschrieben sind, deuten auf die Umsetzung von 2 Mol. Indol mit 1 Mol. Azapentan (III) unter Abspaltung von 1 Mol. Ammoniak hin (s. das Reaktionsschema).



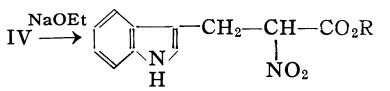
Beim Arbeiten mit äquivalenten Mengen von beiden Reagenzien war jedoch die Entwicklungsmenge des Ammoniaks ziemlich gering (etwa 50% d. Theorie), was uns zur Bestimmung optimaler Bedingungen auf dieser Reaktionsetappe veranließ. In Tabelle I sind einige typische Versuchsergebnisse mit verschiedenen Molenverhältnissen von Indol zu Azapentan (III) in An- oder Abwensenheit von Kondensationsmitteln zusammengestellt.

TABELLE I. VERGLEICH DER AMMONIAKENTWICKLUNGSMENGE BEI DER ALKYLIERUNG VON INDOL MIT AZAPENTAN UNTER VERSCHIEDENEN BEDINGUNGEN

Mol.-Verhältnis von Indol zu III	Lösungsmittel	Katalysator	Reaktionsdauer Std	Ausb. %
2	Xylol	kein	4	45
2	Xylol	K_2CO_3	2	6
2	kein	kein	5	52
5	Xylol	kein	8	89
4	Xylol	kein	6	84

Die Kurven auf Abbild. 2 zeigen Einflüsse von Molenverhältnissen auf die Ammoniakentwicklung ohne Zusatz von einem Katalysator.

Wie aus Tabelle I und Abbild. 2 ersichtlich ist, sind die befriedigenden Ausbeuten (über 80% d. Theorie) durch Verwendung von über 4 Mol. Indol zu 1 Mol. Azapentan (III) erreicht worden**. Hierbei ist auch berichtenswert, daß die Anwesenheit einer



Abbild. 2. Einfluß des Molenverhältnisses von Indol zu Azapentan auf die Ammoniakentwicklung.
—●— IIIa, ---○--- IIIb

katalytischen Menge Alkali die Entwicklung von Ammoniakgas erheblich verhinderte, während die Abwesenheit des Lösungsmittels wenigstens auf die Gasentwicklung keinen wesentlichen Einfluß ausübte.

Das Kondensationsprodukt (IV) war zwar nicht zur Kristallisation zu bringen, sondern immer als zähflüssiges Öl zu erhalten, dessen Konstitution jedoch durch die weiteren Umsetzungen gesichert wurde.

Eine von den günstigen Voraussetzungen für Gelingen dieser Alkylierungsreaktion scheint die bereits erwähnte Auflockerung der *N-C*-Bindungen im alkylierenden Amin (III) zu sein. Zugleich dürfte dabei eine sterische Assistenz[23] eine Rolle spielen, die dem großen Umfang der Amino-Gruppe zuzuschreiben ist. Auch die Flüchtigkeit des dabei abgespalteten Ammoniaks begünstigt vermutlich den Verlauf der Reaktion; denn das Kondensationsprodukt (IV) ist gegen Alkali sehr empfindlich.

Auch in Gegenwart von Indol wurde die Eliminierung einer Carbalkoxy-Gruppe von IV mit Natriumalkoholat ebenso[7] bequem

V

durchgeführt. Bei Zugabe von Eiswasser in das Reaktionsgemisch ging das entstandene Natriumsalz des *α-aci*-Nitro-*β*-(3-indolyl)propionsäureester (V) in wässrige

22) Vgl. J. H. Brewster und E. L. Eliel, "Organic Reactions", Vol. VII, John Wiley & Sons, Inc., New York (1953), S. 99.

** Unter ähnlichen Bedingungen wurden Phenol und Azapentan zur Reaktion gebracht, wobei heftige Ammoiakgasentwicklung beobachtet wurde. Die Chromatographie einer Probe des Hydrolysats ergab, daß es Tyrosin und wahrscheinlich 2-Oxyphenylalanin enthält. Die Reaktion wurde präparativ nicht weiter untersucht, zeigt aber an, daß sich auch Phenol in *o*- und *p*-Stellung alkylieren läßt.

23) G. L. Shoemaker und R. W. Keown, *J. Am. Chem. Soc.*, **76**, 6374 (1954).

Schicht über, während das an der Alkylierungsreaktion nicht beteiligte Indol in ätherischer Schicht zurückblieb, womit das Ziel der Trennung von V aus Indol einfach erreicht werden konnte. Der beim Ansäuern der Natriumsalz-Lösung gewonnene, freie Nitroester (V) wurde unter Druck hydriert. Die Gesamtausbeute an Tryptophan, bezogen auf Nitromalonester (I), war 50～60%.

Beschreibung der Versuche

Hydroxymethyl-nitromalonsäure-dimethylester (IIa).—Ein Gemisch von 8.5 g (0.105 Mol, 3.15 g Formaldehyd) 37 proz. Formalin und 17.7 g (0.1 Mol) Nitromalonsäure-dimethylester in 20 ccm Methanol wurde in Gegenwart von 0.5 ccm 1 N NaOH unter gelindem Rühren 2 Stdn auf 40°C erwärmt. Dabei entstand anfangs eine klare gelbliche Lösung, aus der sich im Verlauf der Reaktion weiße Kristalle des Kondensationsproduktes abschied. Nach Erkalten wurde die Reaktionsmischung mit 200 ccm eisgekühltem Wasser verdünnt und über Nacht im Eisschrank stehengelassen. Man saugte die Kristalle ab, wusch mit wenig kaltem Wasser und trocknete. Die Ausbeute an Hydroxymethyl-nitromalonsäure-dimethylester (IIa) vom Schmp. 83～84°C betrug 20.5 g (nahezu quantitativ). Der durch Umkristallisation aus Methanol-Wasser analysenrein erhaltene Ester schmolz bei 92～93°C.

Hydroxymethyl-nitromalonsäure-diäthylester (IIb).—Ein Gemisch von 82.0 g (0.4 Mol) Nitromalonsäure-diäthylester, 34 g (12.6 g Formaldehyd, 0.42 Mol) 37% Formalin in 60 ccm Methanol wurde in Gegenwart von 3 ccm 1 N Natronlauge unter Schüttelung 3 Stdn auf 35～45°C erwärmt. Nach Erkalten und Neutralisierung des als Kondensationsmittel verwendeten Natriumhydroxyds mit Salzsäure wurde die gelblich klare Lösung in 500 ccm Eiswasser gegossen, wobei sich ein Öl ausschied. Die obere wässrige Schicht wurde dreimal mit je 200 ccm Benzol extrahiert. Die Auszüge und das ausgeschiedene Öl wurden vereinigt, die benzolische Lösung wurde mit Wasser gewaschen und auf Natriumsulfat getrocknet. Nach dem Abdampfen des Benzols destillierte man *i. Vak.* den Rückstand. 83 g Hydroxymethyl-nitromalonsäure-diäthylester(IIb) wurden als farblose Flüssigkeit vom Sdp $_{1\,mm}$. 120～125°C erhalten. Ausbeute 94%.

Bestimmung optimaler Bedingung für Alkylierung des Indols mit Azapentan (III).—Da sich bei dieser Alkylierungsreaktion Ammoniakgas entwickelte, wurde seine Menge durch Rücktitrierung mit Natronlauge bestimmt, nachdem es sich in Schwefelsäure absorbieren ließ. Der unten geschilderte Versuch stellt ein typisches Beispiel für solche Bedingungsbestimmung dar.

Zu 4 ccm trocknem Xylol, welches sich im langen 20 ccm-Kolben mit einem Stickstoff-Einleitungsröhrchen und einem Kühler befindet, wurden 395 mg (0.001 Mol) 1, 1, 5, 5-Tetracarbomethoxy-1, 5-dinitro-3-azapentans (IIIa) und 468 mg (0.004 Mol) Indol gegeben. Der Kolben wurde im Ölbade von 140°C gehalten; während des Erhitzens wurde durch das in die Lösung eintauchendes Glasröhrchen ein lebhafter Strom des mit Calciumchlorid getrockneten Stockstoffs geleitet, welcher zusammen mit dem abgespalteten Ammoniakgas zu verd. Schwefelsäure mit bekannter Normalität geführt wurde. Nach 6 stdg. Kochen wurde die Reaktion abgebrochen. Aliquote der Schwefelsäure-Lösung wurden aufgenommen und mit N/50 NaOH rücktitriert. Molzahl des abgespalteten Ammoniaks während der Reaktion war 0.000840. Also 84% der Theorie. Über andere Versuchsergebnisse siehe Tabelle I und Abbild. 2.

α-Nitro-α-carbomethoxy-β-(3-indolyl)propionsäure-methylester (IVa). — 3.95 g (0.01 Mol) 1, 1, 5, 5-Tetracarbomethoxy-1, 5-dinitro-3-azapentan (IIIa) und 5.85 g (0.015 Mol) Indol wurden in 20 ccm trocknem Xylol gelöst und unter kräftigem Rühren 8 Stdn lang auf 130°C erhitzt. Während des Erhitzens wurde ein lebhafter Strom des Stickstoffs geleitet. Schon bei einer Temperatur von 110°C begann eine Entwicklung des Ammoniaks und war auf dem Siedepunkt von Xylol sehr lebhaft. Nach beendeter Reaktion verdampfte man Xylol unter vermindertem Druck und unterwarf dann den Rückstand einer kontinuierlichen Extraktion mit Petroläther. Nach 36 stdg. Extraktion wurde das hinterbliebene rote Öl in 80 ccm Äther aufgenommen und die ätherische Lösung wurde zweimal mit je 10 ccm 10 proz. Salzsäure, zweimal mit 15 ccm Wasser, dann zweimal mit je 10 ccm 5 proz. Na_2CO_3 und schließlich dreimal mit je 15 ccm Wasser ausgeschüttelt und über Natriumsulfat getrocknet. Das nach dem Abdampfen des Äthers erhaltene Öl wurde auf 100°C unter 1 mmHg gehalten. α-Nitro-α-carbomethoxy-β-(3-indolyl)propionsäure-methylester (IVa) war ein viskoses rotes Öl, das weder kristallisierbar noch unzersetzt destillierbar war. Ausb. 4.2 g.

$C_{14}H_{14}O_6N_2$(306.3) Ber. N 9.15 Gef. N 9.64.

α-Nitro-α-carbäthoxy-β-(3-indolyl)propionsäure-äthylester (IVb).—Nach der oben bei der Darstellung von IVa beschriebenen Methode. Zähflüssiges, rotes Öl.

α-Nitro-β-(3-indolyl)propionsäure-methylester (Va). — Der Ester (Va) kann nach dem bekannten Verfahren[7] aus IVa gewonnen werden. Wir konnten auch aus IIIa den Ester(Va) direkt darstellen, ohne daß man IVa isolierte. Denn bei unsrer Synthese wurde ein Überschuß Indol verwendet und dessen Entfernung nahm zur Gewinnung von IVa, wie bereits erwähnt, viel Zeit in Anspruch.

Eine Lösung von 11 g (0.0279 Mol) rohem 1, 1, 5, 5-Tetracarbomethoxy-1, 5-dinitro-3-azapentan (IIIa) und 13 g (0.111 Mol) Indol in 50 ccm trocknem Xylol wurden in einen 200 ccm-Vierhalskolben gesetzt, welcher mit Rührer, Einleitungsrohr und Rückflußkühler versehen war. Die Lösung wurde unter kräftigem Rühren und lebhaftem Strom des Stickstoffs 5 Stdn lang auf 130~140°C erhitzt. Nach Erkalten fügte man zum Reaktionsgemisch 50 ccm Äther hinzu, schüttelte die Lösung mit 5 proz. HCl, H_2O, 5 proz. Na_2CO_3 und H_2O aus und trocknete diese über Natriumsulfat. Die getrocknete Lösung wurde unter Feuchtigkeitsausschluß und Rühren mit einer Lösung von 1.3 g Natrium in 40 ccm absol. Alkohol im Verlauf von 40

min. tropfenweise versetzt. Nach 5 stdg. Weiterrühren ließ man die Reaktionsmischung im Eisschrank stehen, sodann ließ man 100 ccm eiskaltes Wasser unter kräftigem Rühren hinzufließen, wodurch das Natriumsalz von *α-aci*-Nitro-*β*-(3-indolyl)propionsäure-methylester in die wässrige Phase überging, während das an der Reaktion nicht beteiligte Indol im organischen Lösungsmittel blieb. Man trennte die beiden Schichten voneinander, extrahierte die organische Schicht dreimal mit je 30 ccm eiskaltem Wasser, und vereinigte die Auszüge mit der wässrigen Schicht. Die wässrige Lösung wurde dann mit wenig Chloroform ausgezogen, mit 100 ccm Äther überschichtet und mit 10 ccm 10 proz. HCl unter kräftiger Schüttelung angesäuert, wobei der freie Ester (Va) in Äther überging. Nach dreimaliger Extraktion der wässrigen Lösung mit 30 ccm Äther wurde die vereinigte ätherische Lösung zweimal mit je 30 ccm Wasser gewaschen und auf Natriumsulfat getrocknet. Nach der Abdestillation des Äthers erhielt man 11.2 g *α*-Nitro-*β*-(3-indolyl)-propionsäuremethylester(Va) als ein zähflüssiges rotes Öl. Ein Teil des rohen Produktes wurde *i. Vak.* destilliert und das Destillat erstarrte kristallinisch beim Stehenlassen. $Sdp_{0.04\ mm}$. 160～165°C. Schmp. 44～46°C.

Das Kaliumsalz zersetzte sich unter Aufschäumung bei 218～219°C.

Zusammenfassung

1. Es wird eine neue Synthese des Tryptophans aus Nitromalonester in einer Gesamtausbeute von rund 50-Prozent beschrieben.

2. Die Schlüsselreaktion, die auf diese Synthese angewandt ist, ist eine neue Alkylierung des Indols mit 1, 1, 5, 5-Tetracarbäthoxy-1, 5-dinitro-3-azapentan, einem bis-substituierten Amin, welches leicht erhältlich ist durch Mannich-Reaktion von Nitromalonester, Ammoniak und Formaldehyd. Die optimale Bedingung für die Alkylierungsreaktion wurde auch untersucht.

Meinem verehrten Lehrer, Herrn Prof. Dr. S. Akabori bin ich für die Förderung dieser Arbeit zu großem Dank verpflichtet. Ebenso danke ich Herren Dr. S. Sakurai und Dr. Y. Izumi für freundliche Unterstüzung.

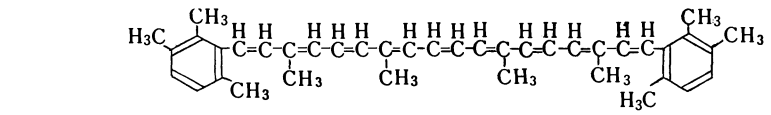
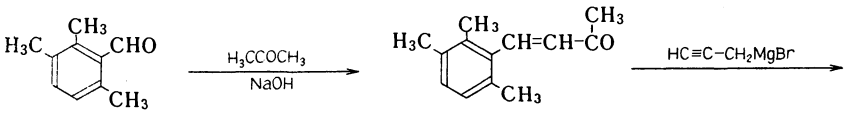
*Total Synthesis of Isorenieratene**, **



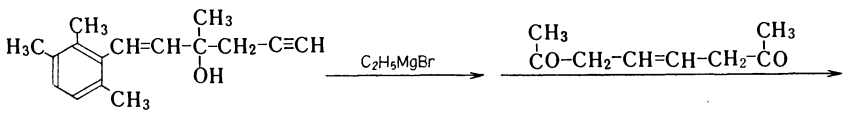
By Masaru YAMAGUCHI

(Received April 3, 1959)



It has been shown by degradative oxidation that isorenieratene, one of the C_{40}-carotenoid hydrocarbons discovered in a sea-sponge, *Reniera japonica*[1], has a remarkable constitution I[2], in which substituted benzene rings are present as terminal groups in place of ionone rings. As the natural carotenoids have so far been aliphatic or alicyclic compounds, the above finding is very significant, and, therefore, it is of importance to make a further confirmation of this exceptional structure of isorenieratene by a synthetic study.

Recently, several routes involving many interesting intermediates have been developed for the total syntheses of carotenoids[3], some of these routes giving considerably good yields. For the present study, however, a method established by Karrer et al.[4] has been applied for the reason of the simplicity of the method, though the overall yields attained by them are not so satisfactory.



The starting material, 2,3,6-trimethylbenzaldehyde (II), was condensed with acetone to give 2,3,6-trimethylbenzalacetone (III), which corresponds to β-ionone, a starting material in the β-carotene syntheses. The ketone (III) was converted into an acetylenic alcohol (IV), which by condensation with 4-octene-2,7-dione gave a C_{40}-diynetetraol (V). Partial hydrogenation of V followed by dehydration gave

isorenieratene (I) in a small yield.

Isorenieratene thus obtained forms purplish-red fine needles, m. p. 199~200°C, and is indistinguishable in the appearance from the specimen isolated from the sea-sponge. Furthermore, a mixed melting point, a mixed chromatography, and UV- and IR-spectra established perfect identity. (IR-spectra : Fig. 1).

Experimental

Solutions were evaporated under diminished pressure unless otherwise mentioned. Anhydrous sodium sulfate was employed for drying solutions.

4-(2, 3, 6-Trimethylphenyl)-3-buten-2-one (III).—A 10% aqueous sodium hydroxide solution (3.1 cc.) was added dropwise during five minutes to a stirred mixture of 2, 3, 6-trimethylbenzaldehyde (14 g.), acetone (16 g.) and water (10 cc.) at room temperature. After stirring for eight hours, the upper layer was separated, combined with the extract (benzene, 20 cc.) of the lower aqueous layer, washed successively with water, 3% hydrochloric acid and water, dried and evaporated. Distillation of the residue gave at first trimethylbenzaldehyde (2.5 g.) and then 4-(2, 3, 6-trimethylphenyl)-3-buten-2-one (11 g.) as an almost colorless oil, b.p. 127~132°C/6 mmHg.

Anal. Found: C, 82.98; H, 8.67. Calcd. for $C_{13}H_{16}O$: C, 82.93; H, 8.57%.

The semicarbazone, colorless needles, m.p. 223~225°C.

Anal. Found: C, 68.37; H, 7.83. Calcd. for $C_{14}H_{19}ON_3$: C, 68.54; H, 7.81%.

The 2, 4-dinitrophenylhydrazone, red plates, m.p. 178~180°C.

Anal. Found: C, 61.79; H, 5.37. Calcd. for $C_{19}H_{20}O_4N_4$: C, 61.95; H, 5.47%.

The residue of the distillation solidified on cooling, which on recrystallization from benzene-ethanol gave 1, 5-bis(2, 3, 6-trimethylphenyl)-1, 4-pentadien-3-one (1.9 g.) in pale yellow plates, m.p. 153~154°C.

Anal. Found: C, 86.67; H, 8.15. Calcd. for $C_{23}H_{26}O$: C, 86.74; H, 8.23%.

The 2, 4-dinitrophenylhydrazone, red needles from acetic acid, m.p. 166~168°C.

Anal. Found: C, 70.11; H, 5.95. Cacld. for $C_{29}H_{30}O_4N_4$: 69.86; H, 6.07%.

1-(2, 3, 6-Trimethylphenyl)-3-methyl-1-hexen-5-yn-3-ol (IV).—A Grignard solution was prepared by dropwise addition (1.5 hr.) of propargyl bromide (5.9 g.) in dry ether (20 cc.) to magnesium (1.5 g.) covered with dry ether (60 cc.) under vigorous stirring. Magnesium was previously activated with a 1% aqueous solution of mercuric chloride. The excess of magnesium was removed by filtration and the solution was added during a half hour to a well stirred solution of the above C_{13}-ketone (III) (9 g.) in dry ether (20 cc.). The mixture was refluxed under stirring for additional one hour, and then decomposed with ice and 5% aqueous sulfuric acid. The ethereal layer was washed with water, dried and evaporated. The oily residue was dissolved in absolute ethanol (80 cc.), a solution of Girard reagent P (6 g.) in acetic acid (6.3 g.) was added, and the mixture was refluxed for an hour. The cooled solution was poured into ice water (300 cc.) containing sodium hydrogen carbonate (7.95 g.) and extracted with ether (3×50 cc.). The ethereal solution was washed, dried and evaporated. Distillation of the residue gave 1-(2, 3, 6-trimethylphenyl)-3-methyl-1-hexen-5-yn-3-ol (4.3 g.) as a faint colored viscus oil, b.p. 110~115°C/0.04 mmHg.

Anal. Found: C, 83.92; H, 9.05. Calcd. for $C_{16}H_{20}O$: C, 84.16; H, 8.83%.

C_{40}-diyntetraol (V).—A solution (ca. 30 cc.) of ethylmagnesium bromide prepared from ethyl bromide (3.9 g.) was filtered, and added dropwise during one and a half hour to a well stirred mixture of above acetylenic alcohol (4.1 g.), cuprous chloride (50 mg.) and dry ether (16 cc.). The mixture was refluxed for an additional one hour. A solution of 4-octene-2, 7-dione[5] (840 mg.) in dry ether (18 cc.) was then added dropwise during thirty minutes under efficient stirring. After refluxing for one hour, the mixture was allowed to stand overnight, and decomposed with 1 N sulfuric acid under ice-cooling. Ether (30 cc.) was added, and the ethereal layer was washed with dilute sulfuric acid, an aqueous solution of sodium hydrogen carbonate and water, dried and evaporated. The yellow brown oily residue was adsorbed on alumina (95 g., standardized according to Brockmann), from a benzene solution (15 cc.). The column was washed successively with benzene (115 cc., the elute gave an oily residue, 1.7 g.), with ether (100 cc., it gave 1.4 g. of residue), and with ether-methanol (10:1, 180 cc.). The last fraction contained C_{40}-tetraol, which is obtained by evaporation of the solvent as a yellowish colored glasslike mass (1.8 g.).

Anal. Found: C, 79.39; H, 8.82. Calcd. for $C_{40}H_{52}O_4$: C, 80.50; H, 8.78%.

It showed somewhat low C-value, and was employed for the next step without further purification.

Isorenieratene (I).—A solution of tetraol (300 mg.) in ethyl acetate (10 cc.) was agitated with active charcoal (100 mg.) for 10 min., filtered, and shaken with palladium barium sulfate catalyst (1%, 20 mg.) in an atmosphere of hydrogen. Occasional additions of the catalyst (ca. 5 mg.) were necessary until 2 mol. (23.6 cc., 13°C/760 mmHg) of hydrogen was adsorbed (2.5

5) P. Karrer and C. H. Eugster, ibid. ,32, 1934 (1949).

hr.). The catalyst was removed and the solution was evaporated to give a glassy residue. A boiling solution of toluene-*p*-sulfonic acid (40 mg., dehydrated by melting in vacuo) in toluene (5 cc.) was added at a time to a boiling solution of the above residue in toluene (10 cc.) and the mixture was boiled for ca. eighty seconds, the water which formed being removed by azeotropic distillation. The greenish brown solution was cooled and poured into a mixture of a saturated aqueous solution of sodium hydrogen carbonate and petroleum ether (50 cc.). On shaking, the color changed into deep red. The petroleum ether solution was then washed once with water and thrice with 90% methanol, dried and evaporated. The reddish brown residue was dissolved in petroleum ether and chromatographed on alumina (2×20 cm.). The chromatogram was developed with petroleum ether, giving (i) a diffuse faint yellow band (least strongly adsorbed); (ii) an orange zone which is somewhat heterogeneous due to the presence of *cis*-isomer; (iii) a small orange brown zone; (iv) a small brown zone. The orange zone (ii) was eluted with benzene-methanol (10:1). The residue of the elute was treated with a mixture of petroleum ether and ethanol (1 : 1, 3 cc.), and left to stand overnight in an ice chamber to giv a red precipitate (4.5 mg.). From the mother liquor was obtained an additional quantity of the pigment (1 mg.) after isomerization with iodine. In this way, 900 mg. in total of the tetraol was worked up giving 14 mg. of the pigment. Several recrystallizations from benzene-methanol gave the analytically pure pigment (9 mg.), in purplish red fine needles, m.p. 199～200°C. The mixed melting point with isorenieratene (m.p. 199～200°C) which was isolated from the sea-sponge, *Reniera japonica*, was 199～200°C. A mixed chromatography of the synthetic and the natural pigments showed no separation. They gave the same UV-curves with maxima at 492 ($\varepsilon=12.3\times10^4$) and 463 m$\mu$ ($\varepsilon=10.4\times10^4$) (in benzene, spectrophotoelectric method). IR-curves: Fig. 1.

Anal. Found: C, 90.58; H, 9.24. Calcd. for $C_{40}H_{48}$: C, 90.85; H, 9.15%.

The author wishes to express his thanks to Professor Tokuichi Tsumaki for his exceedingly kind direction throughout this work. The author also thanks Mr. Ryoichi Shimada for UV-spectra measurement and Mr.Michio Shido for microanalysis. *Magnetochemical Investigation on Thermal Decomposition of Silver Oxide**

By Shōtaro TOBISAWA

(Received April 20, 1959)

The thermal decomposition of silver oxide in oxygen under atmospheric pressure, was investigated by Lewis[1], and was found to follow the equation $dx/dt = kx(1-x)$, where x is the fraction of silver produced. His result was confirmed by Hood and Murphy[2]. On the other hand, it was found by Garner and Reeves[3] that the decomposition in vacuo did not hold Lewis' equation but gave the equation $\sqrt[3]{p} = kt - C$ for the initial part of the decomposition, where p is the pressure of oxygen evolved with the progress of decomposition. The rates of thermal decompositions of the type A (solid)→B (solid) + C (gas) have been interpreted in terms of the formation and growth of nuclei by many investigators[4]. It may, therefore, be considered that the formation and growth of nuclei depend on the origins of silver oxide and also on the experimental conditions under which the decompositions are carried out.

All the previous work on the kinetics of the decomposition of silver oxide had been carried out by measuring the pressures of the oxygen gas evolved. Although this pressure-method is the most common for kinetic measurements of solid decomposition, it is undesirable for an accurate

measurement of the reaction rate on account of the existence of a considerable space from a reaction chamber to a piece of equipment for pressure measurement. The present author has constructed a recording magnetic balance of Hirone's type[5] with many improvements. This balance has been used continuously with very high sensitivity for many hours and as a thermal balance without magnetic field. By using it as the magnetic balance, the kinetics of the decomposition of silver oxide can be investigated by the measurement of change in magnetic susceptibility, due to the oxygen gas evolved. By using it as the thermal balance, the kinetics can be studied by the measurement of the loss in weight with the progress of decomposition. In the case of magnetic balance, silver oxide was charged into a small bulb and was sealed after being evacuated. The pressure of oxygen in contact with the undecomposed silver oxide became higher as the reaction proceeded. However, in the case of thermal balance, the sample was packed in an open bulb and the decomposition was carried out under costant reduced pressure.

The purpose of the present work is to show the results of kinetic measurements obtained under the above two experimental conditions, together with the measurements of the magnetic susceptibility of silver oxide and of metallic silver produced by the complete decomposition of silver oxide.

Experimental

Materials.—In the present work, four samples were used. Samples A and B were guaranteed reagents of the Kanto Chemical Co. Ltd., and of Kahlbaum, respectively. Silver carbonate contained in the above samples could easily be converted into silver oxide by heating under vacuum according to the equation, $Ag_2CO_3 = Ag_2O + CO_2$. Samples C and D were obtained by heating the samples A and B at 250°C for an hour under the vacuum of 10^{-5} mmHg, respectively. This treatment was carried out before each measurement.

Apparatus.—The magnetic balance was operated by the Faraday method, because this method is convenient to measure the change in magnetic susceptibility of the reaction system at high temperatures. As indicated in Fig. la, a small bulb of fused quartz was suspended in the position giving the maximum value of $H \cdot \partial H/\partial x$, which was determined from Fig. 2. Here H is the field strength and $\partial H/\partial x$ is its gradient along the vertical line passing through the center of the gap between the pole pieces. The bulb 4 mm. high could be held within the error of about one per cent of the maximum value of $H \cdot \partial H/\partial x$.

The recorder used here could plot three values, the magnetic forces acting on a bulb containing a sample, the temperatures of a sample, and the currents supplied to an electromagnet, on a chart at regular intervals of 15 sec., respectively. The

5) T. Hirone, S. Maeda and N. Tuya, *Rev. Sci. Instr.*, **25**, 516 (1954); *Sci. Rep. Res. Inst. Tohoku Univ.*, **A6**, 67 (1954).

magnetic force could be indicated by the current which was proportional to the force, and was calibrated by the magnetic susceptibility of the empty bulb of fused quartz in each measurement. The susceptibility of the fused quartz was -0.46×10^{-6} units per gram[6], and it scarcely depended on temperature at all. The full scale of the recording chart was 10 milliamp. The apparatus was modulated to make it possible to indicate changes of 0.1 milliamp. corresponding to -0.58×10^{-6} e. m. u. in magnetic susceptibility, on a recording chart. The temperature scale of the recorder was calibrated by using the freezing points of four Kahlbaum reagents: tin, zinc, antimonium and silver. Each measurement was carried out in the constant magnetic field of 8250 Oersteds.

When the balance was used as a thermal balance, the recorder could give the losses in weight and the corresponding temperatures of the sample. One millimeter on the recording chart corresponded to 0.015 mg. A sample was packed in the bulb shown in Fig. 1b and was thermally decomposed under the constant pressure of 50 mmHg.

Results

Decomposition Temperature.—The decomposition temperature of silver oxide was determined by the above two methods by raising the temperature at constant rate, 200°C per hour. The results obtained by means of the thermal balance, are shown in Figs. 3 (for the samples A and B) and 4 (for the samples C and D). The first losses in weight for the samples A and B occur at 148°C and the second ones at 372°C. The first losses in weight for the samples C and D are negligibly small and the second ones occur at 354°C.

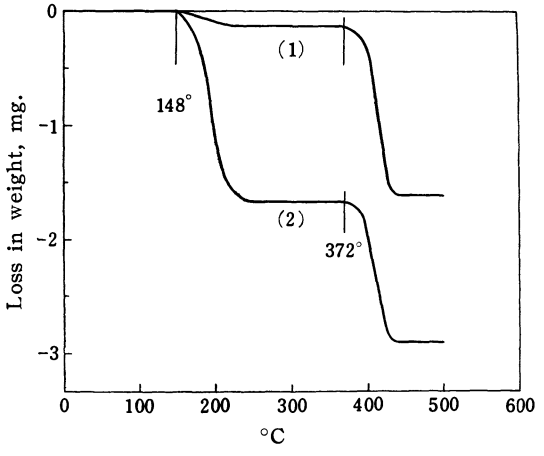

Fig. 3. Loss in weight-temperature curves. (1) Sample A (wt. 20.0 mg.); (2) Sample B (wt. 20.0 mg.).

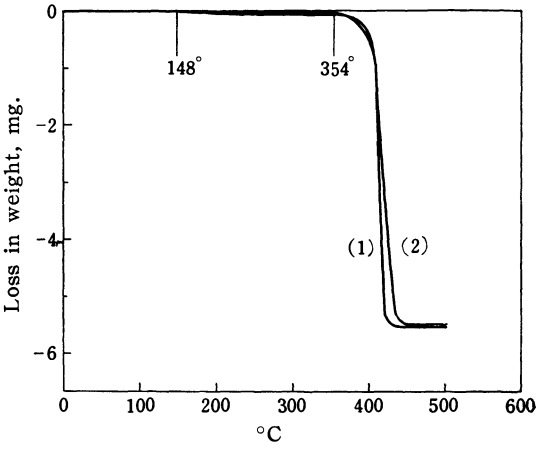

Fig. 4. Loss in weight-temperature curves. (1) Sample C (wt. 80.0 mg.); (2) Sample D (wt. 80.0 mg.).

The curves of magnetic susceptibility against temperature for the reaction system are given in Fig. 5. The sample used in each measurement was about 50 mg. and was sealed in a bulb after being evacuated for several hours under a vacuum of 10^{-5} mmHg. The curves for the samples A and B deflect obviously toward the paramagnetic sides owing to the paramagnetism of oxygen gas evolved at the decomposition at 372°C. The curve of the sample C shown in a broken line in Fig. 5, indicates that the silver oxide decomposes at 354°C. All the samples treated with heating under evacuation, decomposed at the same temperature. It is apparent from the magnetic measurements that the first losses at 148°C are not due to oxygen gas.

Moisture had no responsibility for the loss in weight at 148°C, because each sample was freed from moisture by evacuation. A preliminary qualitative analysis of carbon dioxide with barium hydroxide solution, showed that the silver oxide was partly converted into silver carbonate. The first loss in weight at 148°C in Fig. 3 is, therefore, due to the thermal decomposition of silver carbonate contained in the sample. The negligibly small amount of loss in weight in Fig. 4 can be ascribed to the decomposition of silver carbonate which had been formed by combining the silver oxide with carbon dioxide in air, within two hours or so before the beginning of the measurement. From the above experimental results, it

is found that the decomposition temperature of silver oxide is apparently affected by silver carbonate contained in the oxide.

Magnetic Susceptibilities of Metallic Silver and Silver Oxide.—In order to know whether paramagnetic or ferromagnetic impurity was present in the samples A and B, the magnetic susceptibilities of metallic silver obtained by the complete decomposition, were measured. In addition, the susceptibility of Kahlbaum silver was measured. The curves obtained are shown in Fig. 6. The magnetic susceptibilities of metallic silver produced by the decomposition of the samples A and B were -0.21×10^{-6} units per gram and that of Kahlbaum silver was -0.20×10^{-6} units per gram at room temperature. The curves in Fig. 6 show that the magnetic susceptibility of metallic silver is independent of temperature below 1100°C, except for a slight increase at the melting point. These facts indicate that no magnetic impurities are involved in either sample, and that the metallic silver is normally diamagnetic and takes no supercooling. The curve obtained by Honda[7] shows that the magnetic susceptibility of metallic silver increases with increasing temperature. On the other hand, Selwood[8] mentioned that the magnetic susceptibility of metallic silver was almost independent of temperature.

The magnetic susceptibility of silver oxide from which carbon dioxide was removed, was -0.48×10^{-6} units per gram at room temperature. It was less than the value of -0.58×10^{-6} units per gram[9], reported previously.

Kinetic Measurements.—(1) Photo. 1 is an example of the chart obtained by means of the thermal balance, showing the losses in weight and the corresponding temperatures. In each measurement a required constant temperature could be obtained within a few minutes. Curves of the loss in weight (x) against time (t) at 380, 390, 400 and 410°C for 80 mg. of the sample D are shown in Fig. 7. It was ascertained that the rate of decomposition held neither

Lewis' equation nor that of Prout-Tompkins[10]. The validity of the equation, $\sqrt[3]{x}=kt-C$, presented by Garner et al. for the initial part of the decomposition, was examined by plotting $\sqrt[3]{x}$ against t in Fig. 8. The values of k were obtained from the figure. The activation energy of 29.4 kcal. per mole was estimated from the slope of line which was obtained by plotting $\log k$ against $1/T$. The activation energies reported for this decomposition are as follows: 31.8[1] 35~36[11], 10.5[12] and 45.6~46.2 kcal. per mole[2].

(2) Examining in detail the plots in Fig. 8, it is seen that these plots show the curves with several inflection points. The plots of dx/dt against t are shown in Fig. 9. The time was calculated by setting zero time at the point where the half of

TABLE I. VALUES FOR α AND β

Stage	380°C		390°C		400°C		410°C	
	α	β	α	β	α	β	α	β
1	1.72×10^{-2}	0.39	1.74×10^{-2}	0.52	1.75×10^{-2}	0.83	1.79×10^{-2}	1.44
2	0.09×10^{-2}	1.65	0.16×10^{-2}	1.65	0.42×10^{-2}	1.65	1.32×10^{-2}	1.65
3	0.81×10^{-2}	0.91	0.79×10^{-2}	1.09	2.29×10^{-2}	0.95	3.76×10^{-2}	1.13
4	1.77×10^{-1}	0	2.45×10^{-1}	0	3.30×10^{-1}	0	4.42×10^{-1}	0
5	1.44×10^{12}	− 7.50	3.69×10^{11}	− 7.50	1.61×10^{7}	− 5.00	6.63×10^{4}	− 3.64
6	1.35×10^{23}	−14.14	2.95×10^{28}	−18.14	1.15×10^{20}	−14.14	1.95×10^{16}	−12.00

silver oxide was decomposed. All the curves in Fig. 9 indicate that the rate of decomposition varies discontinuously, and that the period constant rate is recognized in the curve. The plots of dx/dt against t obtained for 20, 50 and 80 mg. of the sample D at the same temperature, 380°C, are given in Fig. 10. The figure shows that the period of constant rate is not affected by the difference in weight of sample. By plotting $\log dx/dt$ against $\log t$ in Fig. 11, the breaking points become very distinctive. The curve for the whole course of the decomposition can be divided into several linear parts. Each linear part can be represented by the equation $\log dx/dt = \log\alpha + \beta\log t$ or $dx/dt = \alpha t^{\beta}$. The estimated values for α and β from Fig. 11 are listed in Table I. The value of α depends on temperature except in the case of the first stage, and β also varies with temperature except in the cases of the certain stages.

As indicated in Fig. 12, the curves of

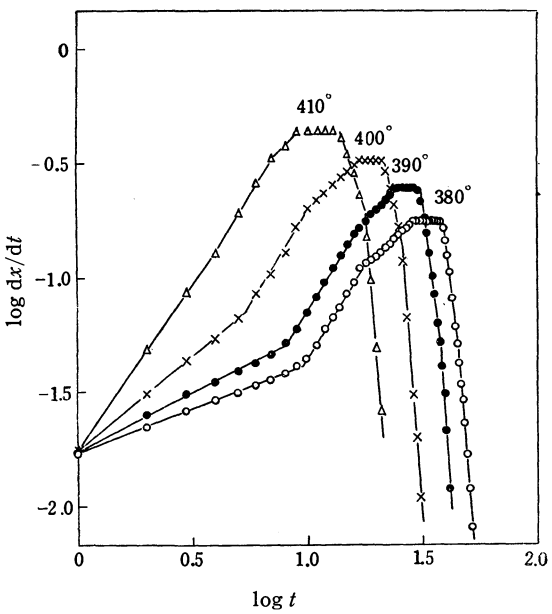

Fig. 11. Plots of $\log dx/dt$ against $\log t$ for sample D.

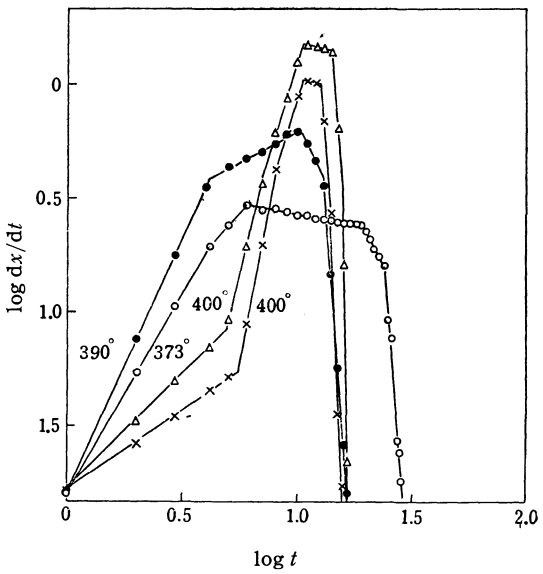

Fig. 12. Plots of $\log dx/dt$ against $\log t$ for sample C (wt. 80.0 mg.).
—△—: wt. 150.0 mg.

$\log dx/dt$ against $\log t$ for the sample C can also be divided into several linear parts for the whole course of the decomposition, as found in the case of sample D.

(3) In the magnetic measurements, the balance was modulated to make it possible to indicate only the change of paramagnetic nature with very high sensitivity. Thus, the small values of diamagnetic susceptibilities of silver oxide and of metallic silver produced by decomposition could be neglected. To determine the weight of oxygen gas evolved in the bulb, the value of paramagnetic susceptibility obtained under a constant temperature was compared with the theoretical value calculated from Van Vleck's equation[13]. In each experiment, the estimated weight of oxygen gas evolved in the bulb at the end of the experiment, was in good agreement with the difference between an initial

13) J. H. Van Vleck, "The Theory of Electric and Magnetic Susceptibilities", Oxford University Press, London (1932), p. 266.

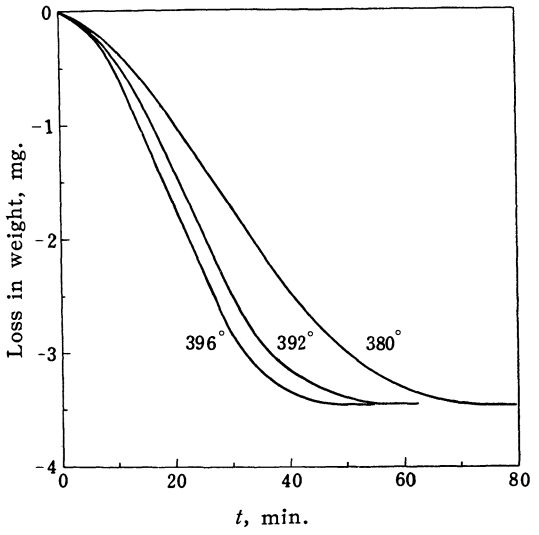

Fig. 13. Loss in weight-time curves for sample D.

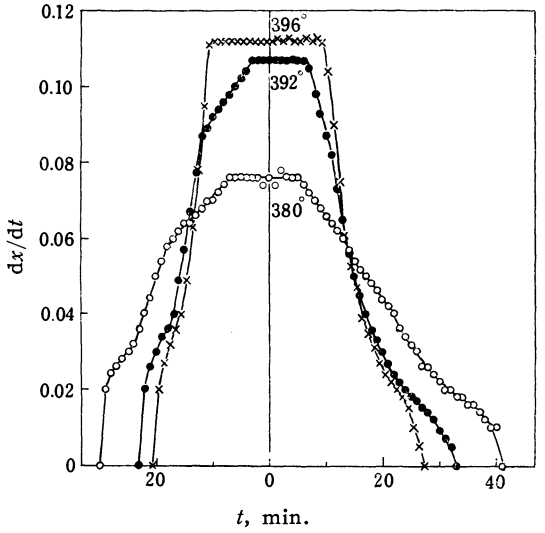

Fig. 14. Plots of dx/dt against time for sample D.

weight of bulb containing a sample and the one containing the residue obtained by removing the oxygen gas evolved in the bulb. In every measurement, the sample used was about 50 mg., and the temperature of the sample was controlled similarly as in the case of the thermal balance. The curves of x against t for the sample D at 380, 392 and 396°C, and the curves of dx/dt against t are shown in Figs. 13 and 14, respectively. The rate of decomposition is represented by the curves with the period of constant rate, as found in the case of the thermal balance. From the plots of $\log dx/dt$ against $\log t$ in Fig. 15, it is apparent that the curves can be divided into the several linear parts. The equation $dx/dt=\alpha' t^{\beta'}$ can, therefore, be applied to the result obtained under the condition in which the sample is decomposed in contact with the evolved gas. The estimated values for α' and β' are given in Table II. The value of α' depends on temperature except for the first stage, β' also varies with temperature except for certain stages. These features are similar to those found in the

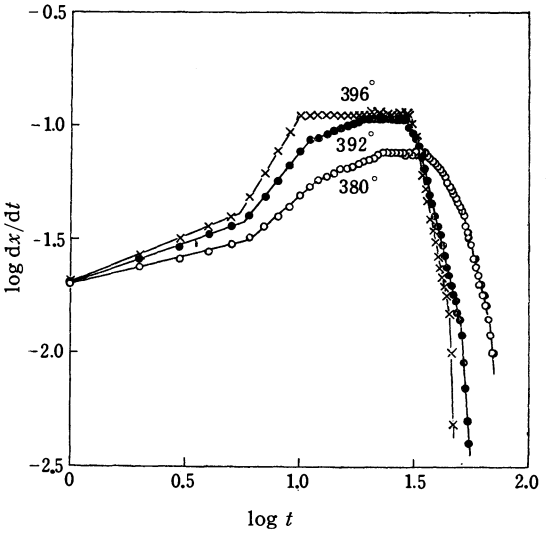

Fig. 15. Plots of $\log dx/dt$ against $\log t$ for sample D.

TABLE II. VALUES FOR α' AND β'

Stage	380°C		392°C		396°C	
	α'	β'	α'	β'	α'	β'
1	2.00×10^{-2}	0.26	2.03×10^{-2}	0.35	2.04×10^{-2}	0.42
2	0.65×10^{-2}	0.88	0.42×10^{-2}	1.26	0.29×10^{-2}	1.61
3	2.04×10^{-2}	0.42	3.80×10^{-2}	0.34	0.29×10^{-2}	1.61
4	0.76×10^{-1}	0	1.07×10^{-1}	0	1.12×10^{-1}	0
5	4.10	−1.12	7.95×10	−1.95	3.93×10^{7}	−5.09
6	9.04×10	−1.95	3.76×10^{6}	−4.35	3.93×10^{7}	−5.09
7	4.34×10^{6}	−4.10	3.76×10^{6}	−4.35	3.93×10^{7}	−5.09
8	5.01×10^{18}	−10.70	1.10×10^{22}	−13.40	3.38×10^{39}	−24.40

experimental results obtained by the thermal balance.

It was noteworthy that several breaking points appear on the curve in each constant temperature, in spite of the entirely different origins and experimental conditions. This fact shows that fresh potential sites at which nuclei can be formed, are created at intervals as the reaction proceeds. It may be considered that the formation of fresh potential sites is due to a strain which is induced by the reaction product at a surrounding undecomposed portion when the reaction product grows to a certain magnitude.

Summary

(1) It was found, by means of the thermal and magnetic balance, that the decomposition temperatures of silver oxide and of silver oxide containing silver carbonate are 354 and 372°C, respectively.

(2) The magnetic susceptibilities of metallic silver obtained by the decomposition and of silver oxide are -0.21×10^{-6} and -0.48×10^{-6} units per gram at room temperature, respectively. Metallic silver is normally diamagnetic from room temperature to 1100°C.

(3) Under the present experimental conditions, the rate of decomposition is represented by the equation $dx/dt=a_i t^{b_i}$ for the whole course of the decomposition, where i is the subscript for each stage, and generally both a_i and b_i depend on the temperature. It is considered that nuclei are created at intervals as the reaction proceeds.

The author wishes to express his sincere gratitude to Professor Y. Nomura for his suggestions regarding this work and for his helpful advice during the course of the construction of the apparatus.

The Kinetic Study of Surface-chemical Reactions at Extremely Low Pressures. IV. The Thermal Reaction between Water Vapor and a Tungsten Filament. Part IV

By Takuya HAMAMURA

(Received April 21, 1959)

Tungsten compound formed by the reaction of water vapor with tungsten at high temperatures has been studied by some investigators. Smithells[1] has studied the reaction by using a gas-filled electric bulb and reported that tungsten was removed from the hotter part of the filament as WO_2 and deposited as W on the colder part. Alterthum[2] assumed the formation of WO_2 in their estimation of equilibrium constants of the system W-H_2O at high temperatures, and Dushman[3] showed thermodynamically that water vapor could oxidize W to WO_2 or W_2O_5. In the previous experiments[4-6] concerning the heating of a tungsten filament in water vapor at low pressures, however, it was found that a blue deposit was formed on the wall of the reaction vessel as the reaction proceeded.

Since WO_2 is brown, this deposit seemed to correspond to another compound. This difference may come from the fact that other authors' results are those at the equilibrium state and not applicable to the present case. It is the aim of the present work to identify the blue deposit and to explain the process of its formation.

Experimental

The tungsten compound formed by the reaction vaporizes from the filament at high temperatures to produce the deposit on the wall of the vessel. The composition of deposit was determined by means of an electron diffraction method and an indirect method mentioned below.

Electron Diffraction Method. — A film of formval attached on a sheet mesh was placed in the reaction vessel to deposit the product on it; and after the reaction ended, it was taken out of the vessel and a diffraction pattern was taken with a micro-diffraction apparatus.

Indirect Method. — Composition of the deposit was determined from the weight loss of the filament and the amount of hydrogen produced. Since no layer of the product was formed on the filament above 1200°K and the evaporation of tungsten was negligible below 2400°K, the weight loss of filament gave the weight of tungsten converted to the product. On the other hand, if one molecule of hydrogen was assumed to be formed from one molecule of water vapor, the quantity in moles of hydrogen was equal to twice that of oxygen combined with tungsten. Therefore, the mean apparent composition was determined from the weight loss of filament and the amount of hydrogen produced.

Apparatus. — The experimental apparatus was the same as that described in the previous papers, except that the filaments were made removable from the lead wires for weighing, i. e., they were clamped at both ends by nickel strips welded to the leads. The filaments used were taken from the same spool as that used in the previous experiments and pretreated in a similar manner. Six filaments, 0.114 mm. in diameter and 75 mm. long each, were mounted perpendicular to the axis of the reaction vessel at a distance of 5 cm. from each other. One of them was used for a standard to compensate all the weight changes that were not caused by the reaction itself; for example, the change caused by the oxidation and adsorption during the weighing process and the evaporation during the degassing process and so on. The filament was degassed in a similar manner as the others, but not heated in water vapor. The other five filaments were used for the determination of the composition. A glass balloon of 10.278 l. was used to introduce hydrogen into it and the pressure was measured with a McLeod manometer.

Procedure.—Prior to the mounting, each filament was weighed with a micro-balance and mounted in the vessel in a manner such as that mentioned above. The procedures of evacuating the apparatus, degassing the filaments and introducing water vapor into the vessel were similar to those of the previous experiments, except that the filaments were degassed at 2200°K for 6 hr. When the flow of water vapor became stationary, one of the filaments was heated at a definite temperature and the hydrogen liberated was carried by the diffusion pump into the balloon. After a certain interval of time, the filament was cooled and the pressure of the balloon was measured to obtain the amount of hydrogen. Thus, five filaments were heated one by one under different filament temperatures and pressures of water vapor. After five filaments had been heated, all the filaments were heated again in high vacuum at 2000°K for twenty minutes. Then the filaments were taken out of the vessel, removed from the leads and weighed again with a micro-balance. The net weight loss was obtained as a difference of weight loss of the respective filament and the weight change of the standard filament.

The experiments were made at temperatures from 1480 to 1950°K and initial pressures of water vapor from 63×10^{-5} to 200×10^{-5} mmHg. The hydrogen pressure in the vessel was controlled whenever it was necessary. The temperature of the vessel remained at room temperature throughout the experiments.

The hydrogen in the balloon was compressed by a diffusion pump into a sampling bulb of one liter up to about 0.1 mmHg and analyzed with a Consolidated Electrodynamics Corporation mass-spectrometer model 21-401.

Results and Discussion

Electron Diffraction Method. — All the diffraction patterns obtained consisted of diffused lines, presumably because the deposits were too fine crystalline or amorphous. Therefore, this method was not used for identification of the products.

Indirect Method. — Results obtained are given in Table IV*, representing the composition in form of WO_x. It is evident from this table that the compositions are about $WO_{2.80}$ independent of filament temperatures, pressures of water vapor and hydrogen pressures. The colors of all the deposits were blue by transmitted light.

From the color and composition the deposits seem to be composed of some of the following oxides[7,8] or hydroxides[9-11] of tungsten, e. g., β-($WO_{2.9}$) and γ-($WO_{2.72}$) for oxide and $H_{0.1}WO_3$, $H_{0.33}WO_3$ and $H_{0.5}\cdot WO_3$ for hydroxide. These are blue or violet, respectively, and have compositions close to those of the blue deposits, (hydroxide has the apparent composition of $WO_{2.95}$, $WO_{2.83}$ and $WO_{2.75}$ respectively, if determined by means of the indirect

method). It is known that these oxides are formed by reduction of WO_3 with hydrogen and the hydroxides by reduction of WO_3 with atomic hydrogen.

The following two processes may be considered for the production of the blue deposit:

1) the product vaporizes from the filament as a blue compound to make a blue deposit on the wall.

2) the product vaporizes from the filament as trioxide and its colorless deposit is secondarily reduced on the wall to form a blue deposit.

The process, by which the deposit was, produced was studied by vaporizing γ-oxide from the filament in high vacuum. When a tungsten filament was heated at 700°C in about 0.01 mmHg pressure of oxygen, a dark violet layer of γ-oxide[12] was formed on the filament. After forming a certain thickness of the layer, excess oxygen was evacuated and the filament was heated above 1500°K. Then the oxide layer vaporized from the filament and made a deposit on the wall of the vessel. The experiments were carried out at various thicknesses of deposit up to about 1000 Å and vaporizing temperatures up to about 2200°K. It was found that the deposits produced were always colorless regardless of the thickness of the deposit and the vaporizing temperature and the blue deposit was not formed at all. The thickness was estimated from the amount of oxygen combined with the filament to make γ-oxide. It was found experimentally that deposit of about 100 Å thick was detectable as a blue film when it was formed by the reaction of water vapor with tungsten. Blackburn[13] has found that WO_2 decomposed completely to W and WO_3 above 1300°K and made WO_3 deposit on the wall. γ-Oxide and probably β-oxide, too, would behave similarly. Hydroxides are not likely to vaporize from the filament as they are. $H_{0.5}WO_3$ is known[9] to decompose into $WO_{2.9}$, hydrogen and water vapor above 60°C. Other hydroxides seem to behave in a similar manner, although their thermal stability is not known. As a result, it is probable that the blue deposit was formed not primarily by the deposition of blue compounds, but secondarily by the reduction of a colorless deposit of WO_3 with hydrogen on the wall.

As for the reduction, the following facts are known in the present stage of research. It is evident that the reduction was not carried out with hydrogen in gas phase, because the composition of the deposit and the reaction rate[6] were independent of the hydrogen pressure in the vessel. Accordingly, the reduction should be carried out with hydrogen liberated by the reaction of water vapor with tungsten. The hydrogen would contain the molecules excited in the electronic or the vibrational energy and even the atoms, if generated. These will be discussed in a subsequent paper.

The independence of the composition $WO_{2.80}$ of deposit upon the filament temperatures and others mentioned above may be due to the fact that the reduction rate becomes smaller at the lower oxidation state. The reduction rate was studied by means of a static method by heating

12) H. Hashimoto, K. Tanaka and E. Yoda, *J. Electron-Microscopy*, **6**, 8 (1958).

13) P. E. Blackburn, M. Hoch and H. L. Johnston, *J. Phys. Chem.*, **62**, 769 (1958).

a tungsten filament in hydrogen within a reaction vessel whose wall had been covered with WO_3 deposit formed by heating the filament in a definite amount of oxygen. The hydrogen pressure was measured as a function of the heating time of the filament and the extent of reduction was determined from the pressure decrease of hydrogen. Two examples are shown in Fig. 10, where the filament

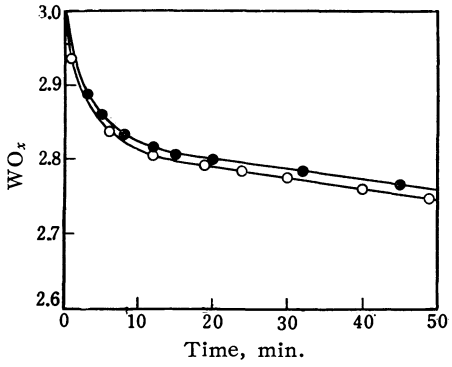

Fig. 10. Reduction of WO_3 with atomic hydrogen.
● 100 Å, 100×10^{-4} mmHg
○ 50 Å, 50×10^{-4} mmHg

temperature was 1740°K and the thickness of WO_3 was about 50 and 100 Å, respectively, and the initial pressure of hydrogen was 50×10^{-4} and 100×10^{-4} mmHg each. It is evident from the figure that the reduction proceeds swiftly down to about $WO_{2.80}$ but the rate slows down appreciably at the lower oxidation state. It is obvious in these experiments that the reduction is carried out mainly with atomic hydrogen formed from the molecules by the dissociation in contact with the filament, and not with hydrogen molecules which rebound from the filament, because the mean temperature of rebounding molecules is about 280°C (for the filament temperature of 1740°K) which is too low to reduce WO_3, since the accomodation coefficient of hydrogen on tungsten surface is 0.19[14].

Result of analysis of hydrogen is shown in Table IV. Only a small amount of gas of mass number 28, presumably carbon monoxide formed from carbon in the filament and water vapor, is contained. The fact that oxygen was not detected in hydrogen suggests that WO_3 was formed by a direct reaction of water vapor with tungsten and not by the reactions through the thermal decomposition of water vapor

$$2H_2O \rightarrow 2H_2 + O_2$$
$$W + 3/2O_2 \rightarrow WO_3$$

If oxygen was liberated, a part of it would leave the vessel without reacting with the filament and be introduced into the balloon, and a part would react with the filament to form WO_3 deposit. The ratio of the former oxygen to the latter can be evaluated by the kinetic theory of gases as follows; the quantity in moles of oxygen which leaves the vessel per second is given similar to Eq. 12 by

$$A'\bar{B}''P'' \qquad (13)$$

where $A'\bar{B}''$ is a constant determined experimentally and P'' the partial pressure of oxygen in the vessel. While the quantity which reacts with the filament per second is given similar to Eq. 2 by

$$k''SB''P'' \qquad (14)$$

where k'' is the reaction probability of oxygen with tungsten. From these formulae, the ratio is calculated as a function of filament temperature as shown in Table V, where values of k'' are determined experimentally by using a filament taken from the same spool. It is evident that if WO_3 was formed by a reaction of gaseous oxygen with tungsten at 1700°K, oxygen had to be detected by the mass spectrometer which was able to detect 0.1% oxygen in hydrogen.

TABLE V

Temp. of filament °K,	1600	1700	1800	1900
Ratio	1.7	1.1	0.64	0.51

Summary

1) Reaction product vaporizes from the filament as tungsten trioxide and its colorless deposit is reduced with hydrogen liberated by the reaction. Consequently, the blue deposit having the mean apparent composition of $WO_{2.80}$ can be obtained.

2) The WO_3 deposit is reduced readily with atomic hydrogen down to $WO_{2.80}$, but the reduction rate becomes appreciably slower at the lower oxidation state.

3) Oxygen is not contained in hydrogen. This suggests that WO_3 is not formed by a reaction of tungsten with gaseous oxygen liberated by thermal decomposition of water vapor, but is formed directly by a reaction of tungsten with water vapor.

Crystallinity Studies of Polychlorotrifluoroethylene by the Infrared Method. II. Kinetics of the Crystallization

By Hiroshi MATSUO

(Received April 30, 1959)

The isothermal rate of spherulitic growth of polychlorotrifluoroethylene (PCTFE) was studied by Price[1] by direct microscopic observation. He observed, however, that there was an ordering process, detectable by X-rays, which developed much more rapidly than did the spherulites. Allen[2] also suggested that there would be no necessary simple connection between the rate of growth of a spherulite and the rate of change of density. On the other hand, Morgan[3] and Flory[4] demonstrated that spherulitic growth was a true measure of the crystallization rate in the cases of polyethylene terephthalate and polydecamethylene sebacate, respectively.

In the preceding paper[5] it was shown that the infrared method was available for reliable estimates of crystallinity in PCTFE, completely independent of other methods. Furthermore, this method is responsive to crystallinity changes taking place rapidly. The investigation reported in the present paper was undertaken with the objective of measuring the isothermal rate of crystallization and to understand the crystallization kinetics of PCTFE by employing this technique. These results were discussed, comparing them with those obtained by other methods.

Experimental

The crystalline band at 440 cm^{-1} of the infrared spectrum was used to follow the production of crystalline material as the crystallization proceeded.

To determine the isothermal rate of crystallization, a procedure was used similar to that used by Reding and Brown[6] to measure the rate of crystallization of polyethylene. Two ovens, one directly over the other, were mounted on a Perkin-Elmer Model 112 infrared spectrometer with potassium bromide optics. The ovens were separately controlled; the upper oven was heated to 230°C of melting temperature and the lower one was heated to any desired growth temperature between 190 and 170°C by circulating a rapid stream of air through an insulated duct from the heaters. A calibrated thermocouple inserted in the lower oven very close to the sample led to a recorder-controller. The controller served to keep the growth temperature within the accuracy of ±0.5°C.

A thin film (0.03~0.06 mm. thick) of commercial PCTFE (NST 270) was clamped in a thin metal holder and placed in the upper oven. After five minutes at 230°C the sample holder was dropped into the lower oven so that it was in the path of the infrared radiation. The melt sample was estimated to reach the desired growth temperature in less than ten seconds. Since the spectrometer was responsive to changes taking place in three seconds or more, this technique proved adequate to follow the crystallization at high rates.

Results

The crystallized fraction of the sample was calculated from the experimental curves. Measurements of the rate of crystallization were carried out at temperatures between 174 and 190°C. Fig. 1 is

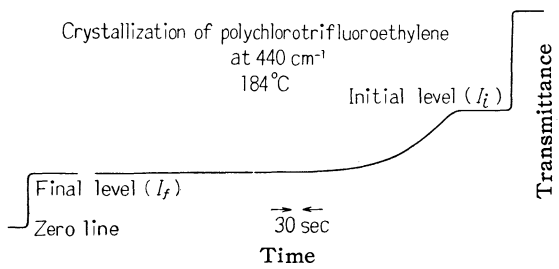

Fig. 1. Typical experimental record.

a typical experimental record obtained in this manner at 184°C. The optical density at time t is defined as

$$D_t \log = (I_i/I_t)$$

Similarly, obtical densities at final and initial states of the crystallization process are obtained by

$$D_f = \log(I_i/I_f), \quad \text{and} \quad D_i = 0$$

The continuously determined data for one curve at each growth temperature were plotted to form Fig. 2. The sigmoid-shaped curves seem to indicate that the crystallization process consists of an induction period, an intermediate period of accelerating rate of crystallization, and a final period to approach an equilibrium state. The degree of crystallinity of the sample, which completed the crystallization process, was measured by the infrared method[5] at room temperature. It is shown in Fig. 3.

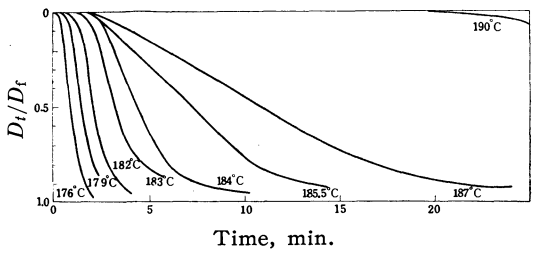

Fig. 2. Ratio of optical density at time t to that at completion of the process, plotted against t at various growth temperatures.

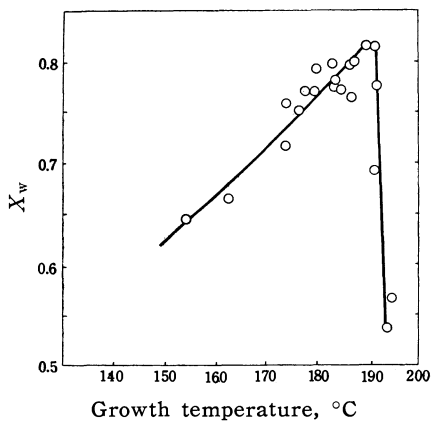

Fig. 3. Degree of crystallinity at completion of crystallization vs. growth temperature.

Discussion

In general, it is found[7] that

$$\ln(V_f - V_t)/(V_f - V_i) = (-1/X_w)kt^n \quad (1)$$

where V_t, V_f and V_i denote the specific volumes at time t, final and initial states of the crystallization process, respectively. X_w is the degree of crystallinity at the completion of the process, and k is the crystallization rate constant. Since the proportionality between the optical density of 440 cm^{-1} and the specific volume for the crystallization process of the polymer is known[5], Eq. 1 becomes

$$\ln(D_f - D_t)/D_f = (-1/X_w)kt^n \quad (2)$$

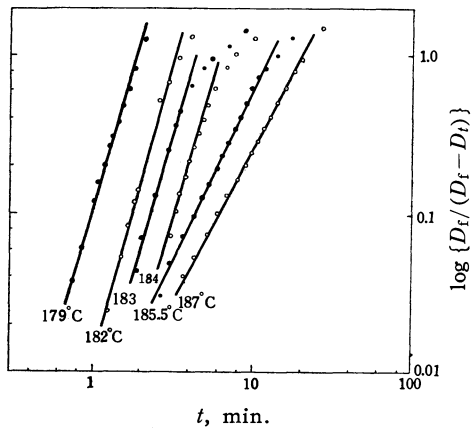

Fig. 4. Plot of log log $[D_f/D_f - D_t)$ vs. log t.

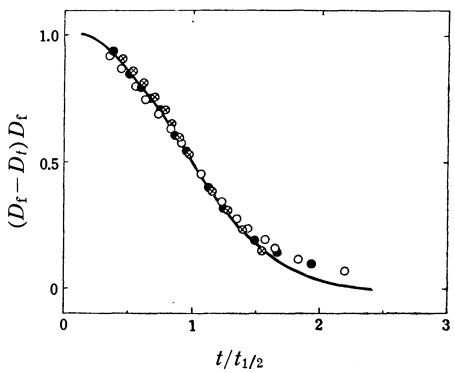

Fig. 5a. Superposition of isotherms at 188°C (⊗); 187°C (○); 185.5°C (●) to Eq. 2 for $n=2.2$.

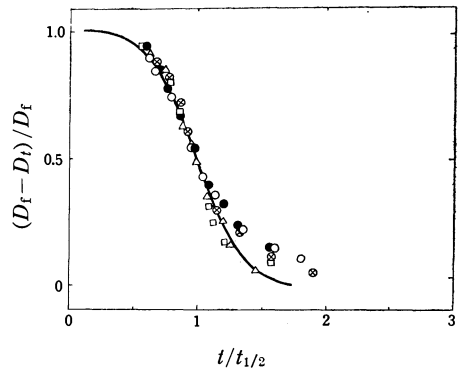

Fig. 5b. Superposition of isotherms at 184°C (●); 183°C (○); 182°C (⊗); 179°C (△); 178°C (□) to Eq. 2 for $n=3.4$.

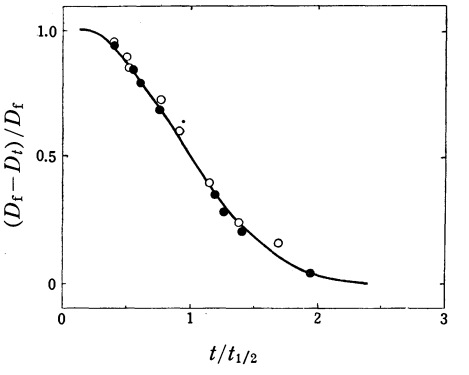

Fig. 5c. Superposition of isotherms at 176°C (●); 174°C (○) to Eq. 2 for $n=2.2$.

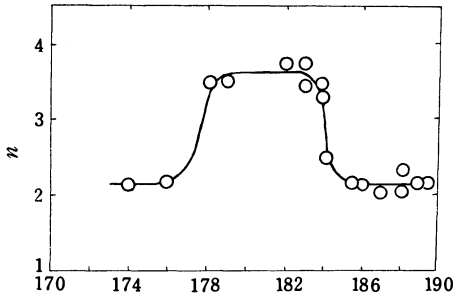

Fig. 6. Values of n at various growth temperatures.

By plotting ln $\ln(D_f-D_t)/D_f$ against ln t, the value of n can be obtained from the slope of the resultant straight line in Fig. 4. In Fig. 5 typical isotherms are plotted according to Eq. 2, where the half time $t_{1/2}$ indicates that the time at $D_t=1/2\,D_f$. The solid lines represent the theoretical isotherms. Good agreement can be obtained for the early stages of the process, but as the crystallization proceeds, the calculated amount of crystallinity is systematically greater than the observed.

The experimental values of n at various growth temperatures are plotted in Fig. 6. The value of n in Avrami's analysis[8] is dependent upon the type of crystallites in nucleation and growth as Table I shows.

TABLE I

Type of growth	Type of nucleation	n
spherical	homogeneous	4
disk	homogeneous	3
spherical	heterogeneous	3
disk	heterogeneous	2

It is, therefore, conceivable that at the growth temperature between 190 and 185°C the nucleation process will be promoted by any heterogeneities which are present in the melt. A fixed number of stable nuclei are present and subsequent transformation is a consequence only of the disk-type lineal growth of these centers. At the growth temperature between 184 and 178°C the nucleation process will be mainly governed by homogeneous nucleation. Price[1] observed by the microscopic method that at temperatures between 190 and 175°C the spherulites are heterogeneously nucleated, and at 170°C and below they are both heterogeneously and homogeneously nucleated. The difference in the results obtained by Price and the present method will be mainly due to the differences in molecular weight, thickness, form of the sample, and in the melting temperature and time, just as has been pointed out in the case of polyethylene terephthalate[3]. In this experiment samples could not be preserved physically as films at higher melting temperatures for a long time prior to the initiation of the crystallization process. Therefore, it will be difficult to say whether the variation of the exponent n with growth temperature is an inherent property of the polymer or not. Very recently, Hoffman[9] indicated that crystallization of the polymer is a results of one-dimensional growth of primary nuclei that are born at later and later dates, and that no obvious relation exists between the growth of primary nuclei and that of spherulites. Furthermore, he pointed out that the polymer has to be heated to the vicinity of 305°C prior to crystallization so as to destroy virtually all of the embryos in the crevices of the heterogeneities.

8) M. Avrami, *J. Chem. Phys.*, **7**, 1103 (1939); **8**, 212 (1940); **9**, 177 (1941).

Next, the temperature coefficient of the crystallization rate was examined. In the vicinity of $T_m(\Delta T=25-30°C)$ the growth rate of crystallites shows a great negative temperature coefficient, in contradiction to the concept of growth controlled by diffusion. The fact leads to the concept of growth governed by secondary nucleation at the spherulite surface[4]. Accurate measurement of the rate of crystallization in the lower growth temperature range was prevented by the rapid onset of crystallization as the material was cooled from the melt through the temperature region of the maximum rate of crystallization, however short the time spent there. It will be, however, expected by Fig. 7 that the maximum rate of crystallization of the polymer locates at a lower temperature near 170°C[9].

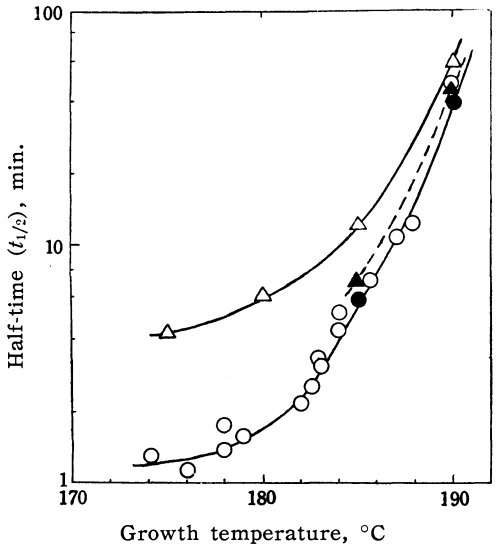

Fig. 7. Half-time vs. growth temperature.
(○) obtained by the infrared method (NST 270);
(●) obtained by the density method (NST 270);
(▲ and △) obtained by the microscopic method (NST 240 and 300).

Considering the formation of disk nuclei of fixed thickness which possess only lateral surface energy, the free energy, ΔF_d, can be expressed as

$$\Delta F = 2\pi rl\sigma - \pi r^2 l\Delta f_0 \qquad (3)$$

where σ is the interfacial free energy per unit area for the cylindrical surface, and Δf_0 is the bulk free energy of fusion per unit volume. Maximizing Eq. 3 with respect to r and equating Δf_0 to $(\Delta T/T_m)\Delta h_u$, where Δh_u is the heat of fusion per unit volume of repeating unit, there is obtained

$$\Delta F^* = (\pi l\sigma^2/\Delta h_u)(T_m/\Delta T) \qquad (4)$$

The rate of nucleation in condensed systems may be expressed by

$$A = A_0 \exp(-E/kT - \Delta F^*/kT) \qquad (5)$$

Furthermore, assuming the growth to be mainly diffusion controlled, then

$$G = G_0 \exp(-E/kT) \qquad (6)$$

Therefore, the rate constant may be expressed[10]

$$k = k_0 \exp\{-3E/kT - (\pi l\sigma^2/H_u)T_m/\Delta T \cdot kT\} \qquad (7)$$

Over the small temperature range of the present experiments the pre-exponential factor may be considered to remain constant, then

$$\log k = A - B(T_m/\Delta T \cdot T) \qquad (8)$$

The plot of $\log k$ against $T_m/T \cdot T$ is shown in Fig. 8. Here the melting point of the polymer is taken as 215°C and the values of k in the microscopic method[1] are calculated by

$$k = \frac{4}{3}NS^3$$

where N is the number density and S is the growth rate of spherulites. In this

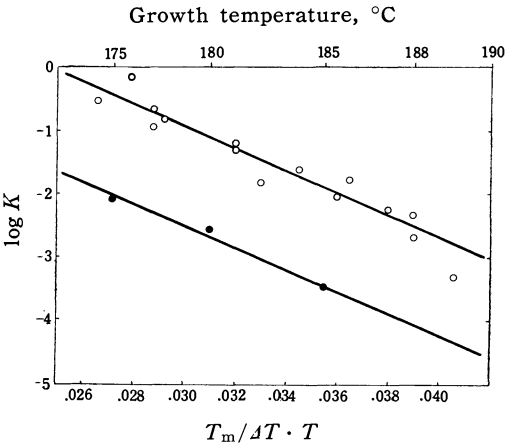

Fig. 8. Plot of $\log k$ vs. $T_m/\Delta T \cdot T$.

figure the results obtained by both the microscopic and the infrared methods can be approximated by straight lines which indicate the same negative temperature coefficient.

Finally, the effect of melting temperature on the rate of crystallization of the polymer was examined by the present method. After samples had been maintained at different melting temperatures (273~210°C) for five minutes, the half-times of crystallization at 188, 187 and 183°C were measured. They are shown in Fig. 9. The increase in the rate of

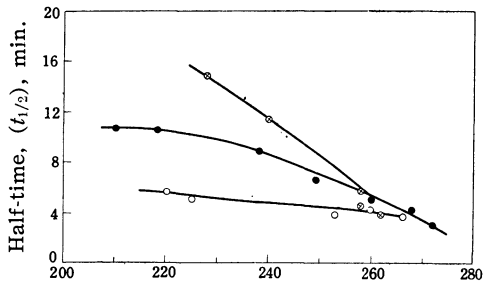

Fig. 9. Half-times as a function of melting temperature for crystallizations at 188°C (⊗), 187°C (●), and 183°C (○).

crystallization with an increase of the melting temperature was indicated contrary to the cases of Nylon 66[2] and polyethylene terephthalate[3]. The fact had been explained by Price[1] as due to degradation of the polymer at a higher melting temperature. Recently, thin films of the polymer of NST 300 and 290 were supplied. The average molecular weight of the polymers were estimated to be approximately 81,000 and 78,000, respectively. Using these samples the half-time of crystallization at 183°C and the degree of crystallinity at the completion of the crystallization process were measured. The half-times were 4.6 and 7.4 min., respectively; the degree of crystallinity at the completion of the crystallization process were 74 and 64%, respectively. It will be expected that both the rate of crystallization and the degree of crystallinity at the completion of the crystallization process increase as the molecular weight of the polymer decreases.

Summary

The isothermal rate of crystallization in polychlorotrifluoroethylene was measured at temperatures ranging from 172 to 190°C below the melting point by following the change of observed absorbance of crystalline band at 440 cm^{-1}. The isothermal rate of crystallization and apparent induction time are dependent on temperature. The data on the kinetics of the crystallization are compared with the result of Avrami's analysis. At temperatures between 190 and 185°C the nucleation process will be promoted by heterogeneities which exist in the melt. Between 184 and 178°C it will be mainly governed by homogeneous nucleation.

Ultraviolet Absorption Spectra of Substituted Phenylureas

By Yojiro TSUZUKI, Shinichi MOTOKI and Kazuko MIGITA

(Received April 30, 1959)

Dulcin(*p*-ethoxypenylurea) has been a well known substance as one of the strongest sweetening agents, whereas the ortho isomer is tasteless and the *m*-ethoxyphenylurea rather bitter.

In an earlier work on the sweetness of organic compounds one of the authors has pointed out that the sweetness of aromatic compounds is closely related to the resonance structures, and has shown that the greater the sweetness of the compound, the greater is the resonance energy[1]; thus, the resonance energy in dulcin isomers decreases in the order of $p>o>m$.

Since the ethoxy group, being associated with the carbamide group, would contribute to the resonance stabilization of the molecule in different ways to cause electronic effects according to the relative position of the two groups, the mode of the resonance in these compounds could be analyzed, provided the electronic nature of the carbamide group is elucidated. The purpose of this paper is to obtain whatever information is possible on these problems.

As is well known the ultraviolet absorption spectrum of benzene exhibits the characteristic peaks at 203.5 mμ (K-band, $\varepsilon=7400$) and 240~260 mμ (B-band, $\varepsilon=250$). When a substituent is introduced into the nucleus, both of the absorption bands are displaced towards the region of longer wavelengths owing to the resonance attributed to the conjugation of the substituent with the nucleus. In disubstituted benzenes the following semiquantitative relations have been established by Doub and Vandenbelt[2,3] between the absorption displacement and the electronic properties of the two groups, thus:

1. In the absorption spectrum of the disubstituted benzenes, one substituent of which is electron-attracting and the other electron-releasing.

a) The absorption shift of the 203.5 mμ band of benzene is, in the case of *p*-compounds ($\Delta\lambda$), considerably greater than the sum of those of the corresponding monosubstituted compounds ($\Delta\lambda_1+\Delta\lambda_2$), namely,

$$\Delta\lambda \gg \Delta\lambda_1+\Delta\lambda_2$$

Example:

	p-$H_2N\cdot C_6H_4\cdot NO_2$		$C_6H_5NO_2$		$C_6H_5NH_2$
λ_{max} (mμ)	381		268.5		230
$\Delta\lambda$ (mμ)	177.5	$\gg$	65	+	26.5
	$\Delta\lambda$		$\Delta\lambda_1$		$\Delta\lambda_2$

b) As to the orientation effect, the following order of red-shift is observed:

$$\lambda_{max}\ p>o>m$$

Example:

$H_2N\cdot C_6H_4\cdot NO_2$	p	o	m
K-band	381	282.5	280
B-band	—*	412	358

2. In the spectra of disubstituted benzenes the groups of which are both electron-attracting or both electron-releasing.

a) In the case of *p*-compounds:

$$\Delta\lambda<\Delta\lambda_1+\Delta\lambda_2$$

Example:

p-$NO_2\cdot C_6H_4\cdot CO_2H$	$C_6H_5NO_2$		$C_6H_5\cdot CO_2H$
$\Delta\lambda$ (mμ) 55	<	65	+ 26.5

b) In the case of nuclear isomers:

$$\lambda_{max}\ p>m>o$$

Example:

$H_2N\cdot C_6H_4\cdot NH_2$	p		m		o
K-band	245	>	240	>	233
B-band	320	>	289	$\geqq$	289

3. In the spectra of disubstituted benzenes, one substituent of which is a halogen atom or a methyl radical.

a) In the case of *p*-compounds:

$$\Delta\lambda \geqq \Delta\lambda_1+\Delta\lambda_2$$

This relation always holds, regardless of whether the electronic property of the other substituent be electron-attracting or electron-releasing.

b) In the case of three isomers:

$$\lambda_{max}\ p>m>o$$

1) Y. Tsuzuki, S. Kato and H. Okazaki, *Science [Japan] (Kagaku)*, **24**, 523 (1954).
2) L. Doub and J. M. Vandenbelt, *J. Am. Chem. Soc.*, **69**, 2714 (1947).
3) L. Doub and J. M. Vandenbelt, ibid., **71**, 2414 (1949).

* The absorption corresponding to the B-band often disappeared with *p*-compounds.

Few exceptions have been, however, found in this case.

On the basis of these empirical rules, one might determine, by means of spectroscopy, the stabilization due to resonance in disubstituted benzenes and the electronic effect of the substituent.

In the present investigation several substituted phenylureas containing various substituents of typical electronic nature such as NO_2, EtO, CH_3, Br were prepared and the spectra of these compounds were measured for the purpose of determining the electronic effect of the carbamide group and comparing with each other the magnitudes of the resonance of the nuclear isomers of dulcin.

Results and Discussion

The experimental results are shown in Table I.

TABLE I. ULTRAVIOLET ABSORPTION SPECTRA OF SUBSTITUTED PHENYLUREAS ($R \cdot C_6H_4 \cdot NHCONH_2$)

Substituent R	K-band		B-band	
	λ_{max}	ε_{max}	λ_{max}	ε_{max}
o-NO_2	275	4350	365	3260
m-NO_2	270	5130	338	1660
p-NO_2	322	13200	—	—
o-EtO	241	15400	281	3830
m-EtO	240.5	13500	280	2550
p-EtO	242	18200	290	1980
o-CH_3	236	10400	270	660
m-CH_3	240	17600	277	770
p-CH_3	240	18400	281	1090
p-Br	247	25300	276	1370

Table II is given to see how the above stated relations are applicable to the present results. It is seen from this table that the absorption maxima of the three isomers $EtO \cdot C_6H_4 \cdot NHCONH_2$ appear in the order of $p>o>m$ for both K- and B-bands. The results may be interpreted as indicating the resonance energy decreasing in the order $p>o>m$, which shows that the carbamide group is electron-attracting. The conclusion is well in accordance with the tentative theory of the relation between the sweetness and the resonance. On the other hand, the slight resemblance of the spectra of nitrophenylureas to those of nitroaniline rather leads us to a somewhat opposite conclusion that the carbamide group is slightly electron-releasing.

TABLE II. ANALYSIS OF ABSORPTION DATA

a) *p*-Substituted phenylureas

p-$R \cdot C_6H_4 \cdot NHCONH_2$

Substituent R	Relation				
	$\Delta\lambda$	>	$\Delta\lambda_1$**	+	$\Delta\lambda_2$
NO_2	118.5	>	33.5	+	65
	$\Delta\lambda$	<	$\Delta\lambda_1$	+	$\Delta\lambda_2$
EtO	38.5	<	33.5	+	16
	$\Delta\lambda$	=	$\Delta\lambda_1$	+	$\Delta\lambda_2$
CH_3	36.5	=	33.5	+	3
	$\Delta\lambda$	>	$\Delta\lambda_1$	+	$\Delta\lambda_2$
Br	43.5	>	33.5	+	6.5

b) Nuclear isomers of substituted phenylureas

Substituent R	Relation	
	K-band	B-band
NO_2	$p>o>m$	$o>m$
EtO	$p>o>m$	$p>o>m$
CH_3	$p=m>o$	$p>m>o$

It follows therefore that this group is to be regarded as electronically amphoteric, behaving in an electron-attracting or releasing manner, depending on the other group.

Since such a peculiar organic group has never been known in the chemical literature, further investigation is now being made to ascertain the new interpretation of these structural problems, the results of which will be published in the near future.

Experimental

Preparation of Samples. — Commercial dulcin was used after purification by repeated recrystallization from water.

o-Nitrophenylurea was synthesized according to the direction of Arndt[4] with slight modification.

$$o\text{-}NO_2C_6H_4NH_2HCl \xrightarrow[NaOH]{Pb(SCN)_2} (o\text{-}NO_2C_6H_4NHCSNH_2)$$

$$\xrightarrow[-H_2S]{} o\text{-}NO_2C_6H_4NHCN \xrightarrow[HCl]{H_2O} o\text{-}NO_2C_6H_4NHCONH_2$$

The other substituted phenylureas were prepared from potassium cyanate and the corresponding nuclear substituted anilines by the methods given in "Organic Syntheses"[5].

o-Nitrophenylurea, m. p. 183~184°C, the *m*-isomer, m. p. 189°C, the para, m. p. 235°C.

o-Ethoxyphenylurea, m. p. 134°C, the *m*-isomer, m. p. 112°C, the para, m. p. 175°C.

o-Methylphenylurea, m. p. 195°C, the *m*-compound, m. p. 145°C, the para, m. p. 183°C.

p-Bromophenylurea m. p. 220°C.

** Phenylurea has two absorption peaks at 237 mμ (ε=17700) and 266~275 mμ (ε=1100) corresponding to K-band and B-band, respectively. W. A. Schroeder et al., *Anal. Chem.*, **23**, 1740 (1951).

4) F. Arndt, *Ber.*, **46**, 3528 (1913).

5) F. Kurzer, "Organic Syntheses", Vol. 31, John Wiley & Sons, Inc., New York (1951), p. 8.

Absorption Spectra.—The absorption spectra were measured in the region of 200~350 mμ by means of a Beckman Model DU Quartz spectrophotometer with the above samples dissolved in absolute ethanol to the concentration of ca. 1/10,000 mol./l.

Summary

Ultraviolet absorption spectra of several nuclear substituted phenylureas have been measured with the attempt to study the electronic effect of the carbamide group, and the resonance stabilization in three dulcin isomers.

Analysis of Non-Newtonian Flow by Falling-Sphere Method

By Sadao HIROTA and Masao TAKADA

(Received May 12, 1959)

Thixotropic solution must be handled without any strong agitation in order to obtain so-called "virgin-state viscosity". Neither the capillary nor the rotating cylinder viscometer is suitable for this purpose, while the falling-sphere method is applicable, because (a) the agitation of the sample in this measunement is far less compared with that in other methods, and (b) the sphere always falls contacting with a new, so-called "virgin-state" solution.

In order to devise the falling-sphere method for this purpose it is necessary to obtain general flow curves by this method because the fluidity of these solutions normally shows shear dependence as well as time dependence.

Shear stress S_R at the equator of a sphere was given[1] by

$$S_R = R\Delta\rho g/3 \tag{1}$$

where R is the radius of the sphere and $\Delta\rho$ is the density difference between sphere and fluid. Eq. 1 was later proved to be applicable also to non-Newtonian flow. And a necessary shear stress could be obtained by selecting a sphere of suitable radius.

For Newtonian flow, the shear rate at the equator of the sphere $(du/dr)_R$ followed immediately from Stokes' equation.

$$(du/dr)_R = 3U_0/2R \tag{2}$$

Sheppard[2], however, pointed out that Eq. 2 fails to express the true shear rate in a non-Newtonian nitrocellulose solution. Phipps[3] claimed the necessity of non-Newtonian correction for Eq. 2. Many attempts[4-9] have been made to utilize the falling-sphere method for non-Newtonian systems without success establishing the corrected equation for Eq. 2 so far. The aim of this paper is to find it and to examine its applicability.

In the previous study[10] we obtained empirically

$$(du/dr)_R = (3U_0/2R) \times [1 + 2.4(d\log U_0/d\log R - 2)] \tag{3}$$

adopting the capillary viscometer method as the standard for which a standardized treatment of data had been proposed by Krieger and Maron[11]. In the present study, a similar result has been obtained theoretically.

Theoretical

In Newtonian Flow. — Consider a steady flow around a sphere of radius R falling

slowly at the velocity U_0 in a Newtonian fluid. The rate of flow U at the distance r from the center is given[12] by

$$U = -R^3 \Delta\rho g(3+R^2/r^2)\phi/18r \quad (4)$$

Where ϕ = fluidity = 1/viscosity

Differentiating Eq. 4 by r, we obtain the shear rate.

$$du/dr = R^3 \Delta\rho g(1+R^2/r^2)\phi/6r^2 \quad (5)$$

Shear stress S is then

$$S = (du/dr)/\phi = R^3 \Delta\rho g(1+R^2/r^2)/6r^2 \quad (6)$$

At $r=R$, Eq. 6 becomes Eq. 1. Eq. 1 has also been obtained directly from the calculation based on the balance between shear force and gravity without being confined to the Newtonian flow[9]. And Eq. 1 is also applicable to the non-Newtonian flow.

In Non-Newtonian Flow. — Non-Newtonian fluidity $P(S)$ is a function of S. Since the latter is a function of R and r, $P(S)$ may be regarded as a function of R and r.

$$(du/dr)/S \equiv P(S) = F(R, r) \quad (7)$$

If we assume that only the shear rate is responsible for the non-Newtonian anomaly, and that Eq. 6 is still applicable* to the non-Newtonian flow, we may introduce Eq. 6 into Eq. 7.

$$du/dr = R^3 \Delta\rho g(1+R^2/r^2)\cdot F(R, r)/6r^2 \quad (8)$$

Though the form of $F(R, r)$ or du/dr is unknown, the following functional equation holds.

$$U_0 = \int_R^\infty (du/dr)dr = \int_R^\infty R^3 \Delta\rho g(1+R^2/r^2) \times F(R, r)/6r^2 \cdot dr \quad (9)$$

Since non-Newtonian fluidity increases with increasing S in many cases, it increases with increasing R and decreases with increasing r. Therefore, if we assume

$$P(S) \equiv F(R, r) = f(R)\cdot g(r) \quad (10)$$

$f(R)$ is an increasing function of R and $g(r)$ is a decreasing function of r.

Defining apparent fluidity, F_a, analogous to Stokes' equation, as

$$F_a = 9U_0/2R^2 \Delta\rho g \quad (11)$$

and substituting Eqs. 10 and 11 into Eq. 9, we obtain

$$4F_a/3R^3 \cdot f(R) = (1/R^2)\cdot \int_R^\infty g(r)/r^4 \cdot dr + \int_R^\infty g(r)/r^4 \cdot dr \quad (12)$$

which may be differentiated by R to become

$$2F_a/3R \cdot f(R) \cdot [(d\log F_a/d\log R) - (d\log f(R)/d\log R) - 3] = -g(R)/R - \int_R^\infty g(r)/r^2 \cdot dr \quad (13)$$

At $r=R$, since $F(R, R) \propto F_a$**

$$d\log F(R, R)/d\log R = d\log F_a/d\log R = H \quad (14)$$

From Eq. 10

$$\log F(R, R) = \log f(R) + \log g(R) \quad (15)$$

$$H = (d\log f(R)/d\log R) + G \quad (16)$$

where

$$G = d\log g(R)/d\log R \quad (17)$$

Introducing Eq. 16 into Eq. 13 and differentiating it again by R

$$F(R, R) = 2F_a[(G-1)(G-3) + dG/d\log R]/3(2-G) \quad (18)$$

From Eq. 10

$$(\partial \log P(S)/\partial \log r)_R = (d\log P(S)/d\log S)\cdot(\partial \log S/\partial \log r)_R = d\log g(r)/d\log r \quad (19)$$

where, from Eq. 6

$$\partial \log S/\partial \log r = [2r^2/(r^2+R^2)] - 4 = -3 \quad (\text{at } r=R) \quad (20)$$

and from Eq. 1, $d\log S_R = d\log R$, then

$$d\log P(S)/d\log S = d\log F(R, R)/d\log R = H \quad (21)$$

$$d\log g(r)/d\log r = d\log g(R)/d\log R = G \quad (22)$$

Substituting Eqs. 20—22 into Eq. 19,

$$\left.\begin{aligned} G &= -3H \\ dG &= -3dH \end{aligned}\right\} \quad (23)$$

Thus, Eq. 18 becomes

$$F(R, R) = F_a(1+4H+3H^2-dH/d\log R) \times [1-(3H/2)+(3H/2)^2\cdots\cdots] \quad (24)$$

There is an empirical fact that, for many non-Newtonian fluids, the slope of a plot of $\log F_a$ vs. $\log R$ is constant over a wide range of shear stress and is usually small as compared with unity. For example, $H=0.143$ in 1% NaCMC aq. (MW.$=8\times10^4$, Deg.Eth.$=0.654$) as in Fig. 1.

12) Derived from, for example, B. Fujimoto, "Ōyō Ryutairikigaku (Applied Fluid Dynamics)", Maruzen Co., Ltd., Tokyo (1941), p. 340.

* Discussion on the applicability will be given in another paper.

** This proportionality follows from Krieger-Maron's relation, $P(S)=F_a[1+\Delta(S)]$, where $\Delta(S)$ has been known to be constant over a wide range of S[11].

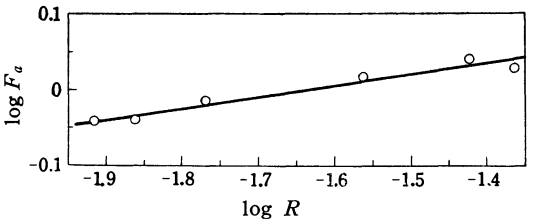

Fig. 1. Plot of $\log F_a$ vs. $\log R$ for 1% NaCMC. aq. (MW.$=8\times10^4$, Deg. Eth.$=$ 0.654) by falling sphere method at 25°C.

Thus,

$$\left.\begin{aligned} &\mathrm{d}\log F_a/\mathrm{d}\log R = H = \text{const.} < 1 \\ &\mathrm{d}H/\mathrm{d}\log R = 0,\ H^3 \fallingdotseq 0,\ H^4 \fallingdotseq 0, \cdots \end{aligned}\right\} \quad (25)$$

Substituting Eq. 25 into Eq. 24, we have

$$F(R,R) \fallingdotseq F_a[1+2.5(\mathrm{d}\log F_a/\mathrm{d}\log S_R) - (3/4)(\mathrm{d}\log F_a/\mathrm{d}\log S_R)^2] \quad (26)$$

or

$$(\mathrm{d}u/\mathrm{d}r)_R \fallingdotseq (3U_0/2R) \times [1+2.5(\mathrm{d}\log U_0/\mathrm{d}\log R-2) - (3/4)(\mathrm{d}\log U_0/\mathrm{d}\log R-2)^2] \quad (27)$$

which agrees very well with the empirical equation (Eq. 3).

Now, using Eqs. 1 and 27, we can obtain the exact flow curve, and hence the true viscosity by the falling-sphere method.

Experimental

For the measurement a glass tube about 20 cm. long and of 2.0 cm. in inside diameter was used, fixed in a thermostat regulated to 25±0.1°C. Glass spheres were made in the manner reported previously[10]. The fall of the sphere (density 2.50) was measured by a stop-watch over a definite distance in the sample. From these data, S_R and $(\mathrm{d}u/\mathrm{d}r)_R$ were calculated by means of Eqs. 1 and 27. Table I gives some examples of data and calculations. Values of $\mathrm{d}\log F_a/\mathrm{d}\log R$ in Table I were obtained from the slope in Fig. 1. The resulting flow curve is shown in Fig. 2.

Results

From Fig. 3 it is seen that the flow curves from the proposed falling-sphere method coincide very well with those from Krieger and Maron's capillary method. The difference between the empirical equation (Eq. 3) and the theoretical one (Eq. 27) is also negligibly small. These results seem to indicate the validity of our formula.

Capillary method ·····●○

Summary

A procedure to obtain a general flow curve by falling-sphere method is presented. The shear stress S_R and shear rate $(du/dr)_R$ at the equator of the sphere are given as

$$S_R = R\Delta\rho g/3$$

$$(du/dr)_R = (3U_0/2R) \times [1+2.5(d\log U_0/d\log R-2) - (3/4)(d\log U_0/d\log R-2)^2]$$

where $\Delta\rho$ is the density difference between sphere and fluid, R the radius and U_0 the falling velocity of the sphere.

The authors wish to express their hearty thanks to Dr. Tsurutaro Nakagawa and Dr. Hirotaro Kambe of the University of Tokyo for their valuable suggestion and discussion and also to Dr. Junzo Shinoda and Dr. Kazuo Miyatake of Daiichi Pharmaceutical Company, Limited for their kind encouragement and permission to publish this paper.

The Preparation and Properties of N-Salicylideneglycinato-aquo-copper(II), Sodium N-Salicylideneglycylglycinato-cuprate(II) and Related Compounds

By Akitsugu NAKAHARA

(Received May 13, 1959)

It was demonstrated by Eichhorn and Marchand[1] that the coordination of copper(II) ion with the Schiff base produced from salicylaldehyde and glycine results in a stabilization of the >C=N-double bond under conditions that would promote its rupture in the absence of the metal. However, the formation of the copper(II) chelate of salicylideneglycine was observed only in a solution on the basis of a spectroscopic investigation; and the composition of the complex was deduced from an extension of the method of continuous variation to a three component system, copper : salicylaldehyde : glycine. In the present work the same compound, *N*-salicylideneglycinato-aquo-copper(II), **A**, was isolated in the crystalline state and investigated as to its properties. Sodium *N*-salicylideneglycylglycinato-cuprate(II), **B**, was also prepared and investigated as to its structure.

Experimental

Preparation of Copper(II) Chelates.—*N-Salicylideneglycinato-aquo-copper(II).*— To a solution of 6 g. of glycine in 100 ml. water was added 10 g. of salicylaldehyde. The resulting mixture was stirred and heated at about 60°C.

Upon the addition of 16 g. of crystalline cupric acetate, a dark-green solution was formed. A yellowish-green crystalline solid of *N*-salicylideneglycinato-aquo-copper(II) was then gradually deposited within half an hour. The reaction mixture was allowed to cool and filtered by suction. The additional crude product was also obtained by evaporating the filtrate. The yield, in total, was almost quantitative. Recrystallization from a large amount of water gave acicular crystals which decomposed at 240°C.

Anal. Found: C, 32.46; H, 5.39; N, 4.21; H_2O, 26.9. Calcd. for tetrahydrate of **A**: C, 32.60; H, 5.14; N, 4.23; H_2O, 27.2%.

In the above procedure cupric sulfate in place of acetate was observed to give the same result. Furthermore, the same compound was prepared also by reactions between: (1) bis-glycinato-copper(II) and bis-salicylaldehyde-copper(II) in 1:1 molar ratio; (2) bis-glycinato-copper(II) and salicylaldehyde in 1:2 molar ratio; (3) glycine and bis-salicylaldehyde-copper(II) in 2:1 molar ratio.

However, the yield of reaction 2) or 3) was only half of that of 1), since the copper was not sufficient to give the same amount of the product.

The compound is soluble in water, methanol and ethanol, though the solubility is comparatively small, especially in the latter two solvents.

Sodium N-salicylideneglycylglycinato-cuprate(II).— To a solution of 5.3 g. of glycylglycine and 3.2 g. of sodium hydroxide in 100 ml. water was added 8 g. of crystalline cupric acetate. After heating the resulting mixture on a water bath, a deep-blue solution characteristic of copper(II) chelates of peptides was gradually formed. Upon the addition of 5 g. of salicylaldehyde the color of the solution changed to violet. The solution was stirred and heated for thirty more minutes, and was then filtered. The filtrate was concentrated to a small volume and allowed to stand, whereupon beautiful violet needles were obtained. These were recrystallized from their concentrated aqueous solution by adding alcohol or acetone.

Anal. Found: C, 30.69; H, 5.02; N, 6.32; H_2O, 25.8. Calcd. for hexahydrate of **B**: C, 30.81; H, 4.91; N, 6.54; H_2O, 25.2%.

A complete dehydration of the compound was performed by heating the crystals in vacuo at 56°C.

Anal. Found: C, 41.00; H, 3.04; N, 8.89. Calcd. for **B**: C, 41.2; H, 2.81; N, 8.75%.

As described above, an aqueous solution of the compound is violet, but reversibly changes to green in an acid solution.

Potassium salt of the same copper(II) chelate was also obtained in the same way by employing potassium hydroxide instead of sodium hydroxide.

In order to identify the potassium salt, a precipitation of potassium hexanitro-cobaltate(III) was ascertained.

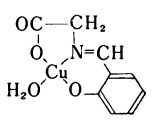
Copper(II) chelate of N-salicylideneglycineethylester.—This compound, **F**, was prepared according to the direction of Pfeiffer et al.[2] by treating the copper(II) complex of salicylaldehyde with hydrochloride of glycineethylester in the presence of sodium acetate in alcohol. It was also confirmed that a reaction in an aqueous suspension between bis-salicylaldehyde-copper(II) and hydrochloride

1) G. L. Eichhorn and N. D. Marchand, *J. Am. Chem. Soc.*, **78**, 2688 (1956).

2) P. Pfeiffer, W. Offermann and H. Werner, *J. prakt. Chem.*, **159**, 313 (1942).

of glycineethylester in the presence of sodium hydroxide is more convenient than the previously reported one[2]. After recrystallization from pyridine or ethanol olive-green crystals were obtained, which decomposed at 200°C, showing a good agreement with the previous datum[2].

Glycylglycinato-aquo-copper(II)[3]. — Freshly precipitated cupric hydroxide was treated in an aqueous suspension with a slight excess of glycylglycine. The resulting deep-blue solution was filtered and concentrated to a small volume, and was then filtered again. The filtrate was allowed to stand for several days over sodium hydroxide, whereupon deep-blue prisms were obtained. These were recrystallized from their concentrated aqueous solution by adding alcohol.



Anal. Found: C, 20.99; H, 4.53; N, 12.09; H_2O, 14.73. Calcd. for monohydrate of **C**: C, 20.85; H, 4.35; N, 12.18; H_2O, 15.65%.

Measurements. — The visible and ultraviolet absorption spectra were determined with a Beckman DU Spectrophotometer at room temperature. The concentration of the solutions varied from 10^{-2} to 10^{-5} F/l.

The infrared spectra were obtained by a Hilger H 800 Infrared Spectrophotometer using a sodium chloride prism. The potassium bromide disk method was employed.

Discussion

The result of analyses and other small tests described in the preceding section afford good reasons to assign structures **A** and **B** for the copper(II) chelate of *N*-salicylideneglycine and that of *N*-salicylideneglycylglycine, respectively. Structure **A** is exactly the same as that postulated by Eichhorn and Marchand[1] on the basis of a spectroscopic investigation. Though they reported also on the formation of 1 : 2 : 2 copper : salicylaldehyde : glycine complex at pH 5, no such compound was isolated in the present investigation even under conditions that would favor its formation. For example, in the case of the reaction between bis-glycinato-copper(II) and salicylaldehyde or between glycine and bis-salicylaldehyde-copper(II) a 1 : 2 : 2 ratio of copper, salicylaldehyde and glycine was employed in a neutral solution, but the reaction product was only the 1 : 1 : 1 complex, **A**. The disagreement might be understood by taking the low solubility of **A** into consideration, since there might be an equilibrium between 1 : 1 : 1- and 1 : 2 : 2-complex in the system.

A

Inspection of the chemical quations of the reactions used in this work reveals that the formation of **A** is accompanied by a liberation of acid:

$$CuSO_4 + C_6H_4\langle^{OH}_{CHO} + NH_2CH_2COOH \rightarrow \mathbf{A} + H_2SO_4$$

$$Cu(CH_3COO)_2 + C_6H_4\langle^{OH}_{CHO} + NH_2CH_2COOH \rightarrow \mathbf{A} + 2CH_3COOH$$

In fact, it was ascertained that the solution was considerably strong acid when the reaction was over. Thus, the present work supports the previous conclusion[1] that the cordination of copper(II) with salicylideneglycine stabilizes >C=N- double bond to such an extent that the Schiff base complex is capable of existence even in acid media, where the uncomplexed Schiff base is dissociated.

It may further be speculated that the tremendous effect of this kind, of metal, may play an important role also in the case of the non-enzymatic transamination reaction of pyridoxal[4-6].

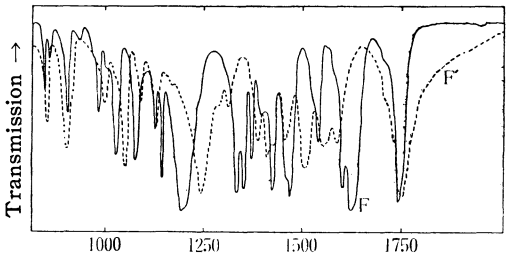

Fig. 2. Infrared absorption spectra of: **F**, copper(II) chelate of *N*-salicylideneglycineethylester; **F'**, hydrochloride of glycineethylester.

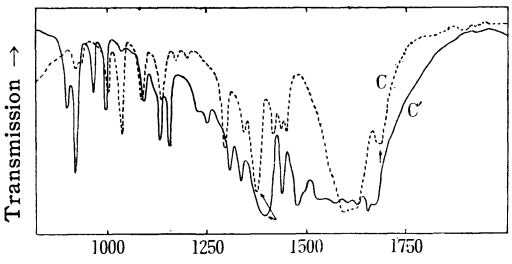

Fig. 3. Infrared absorption spectra of: **C**, glycylglycinato-aquo-copper; **C'**, glycylglycine.

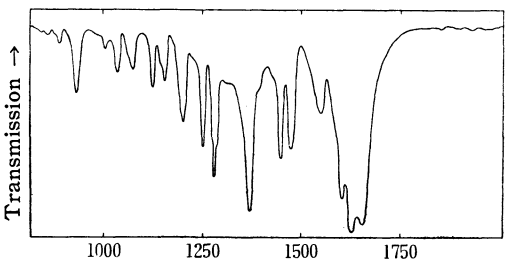

Fig. 4. Infrared absorption spectrum of *N*-salicylideneglycinato-aquo-copper(II), **A**.

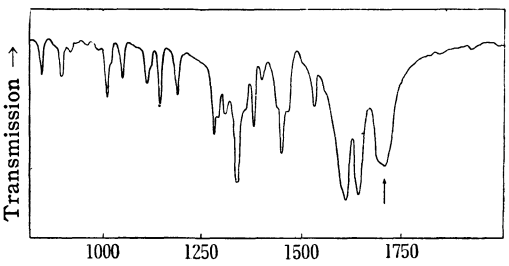

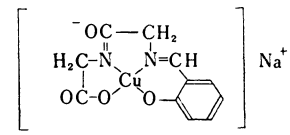

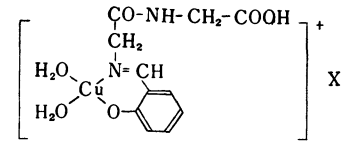

Fig. 5. Infrared absorption spectrum of sodium *N*-salicylideneglycylglycinatocuprate(II), **B**.

Contrary to the case of *N*-salicylideneglycine which is coordinated to copper(II) ion as a terdentate chelate ligand even at a low pH value, *N*-salicylideneglycylglycine behaves as a quadridentate ligand in neutral or basic media and perhaps as a bidentate in acid media.

Formula **B** corresponds to the structure of the copper(II) chelate in neutral or basic media, while **D** would correspond to that in acid media.

B

D

Though there is no decisive reason for the latter the fact that it is green in acid media seems to favor the formula, **D**, in which the peptide nitrogen and carboxylate oxygen are detached from the copper.

As to the process of the formation of **A** the first step may be the coordination of copper(II) with glycinate ion, since a deep-blue solution characteristic of copper(II) chelates of amino acids was first observed before any other marked change occurred, regardless of the methods of preparation employed in this investigation. A chelate ligand in coordination very often increases its reactivity on account of the effect of the metal[7]. Therefore, it may be considered that the glycinate ligand in coordination gains greater activity and becomes easier to form the Schiff base with salicylaldehyde. In contrast with this type of reactions, Sato et al.[8] already reported that bis-glycinato-copper(II) reacts with acetaldehyde in a basic solution to give threonine in a very good yield. The difference between the above two reactions may be attributed to the effect of the -OH group in the molecule of salicylaldehyde.

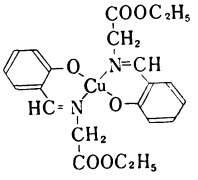
* Reported by H. Ito[9].

a) Ammonium hexa-molybdato-cuprate(II).

b) Di-α-methylamino-isobutyrato-copper(II).

Absorption curves of **A** and **B**, and of the copper(II) chelate of glycine, **E**, and glycylglycine, **C**, are shown in Fig. 1. The curves of **C** and **E** consist of two each



C

of typical absorption bands, whereas both **A** and **B** contain some additional absorption bands in the ultraviolet region. These additional bands apparently belong to the specific absorption bands, being due to the salicylaldimino group of the ligand in coordination. On the other hand, the small absorption bands on each curve in the visible region are the characteristic band of copper(II) complexes. Their numerical data together with those of some other copper(II) complexes are tabulated in Table I. Inspection of Table I reveals that the absorption maximum of **B** is hypsochromically shifted to a considerable degree compared with those of the same type of complexes with respect to the kind of donor atoms. In fact, the color of **B** rather resembles that of bis-ethylenediamine-copper(II) complex, in which all the four donor atoms are nitrogens. From this point of view, it may be supposed[9] that *N*-salicylideneglycylglycinato-cuprate-(II), **B**, belongs to a typical dsp^2-type complex.

Infrared Absorption Spectra. — Infrared absorption curves of **A**, **B**, **C**, and of the copper(II) chelate of *N*-salicylideneglycine-ester, **F**, are shown in Figs. 2—5.

From a comparison of the spectrum of **A** with that of **F**, in which two carboxylate groups of the ligand are protected from coordination by being bound to ethyl groups, it may be concluded that the carboxylate group of **A** is apparently coordinates to copper(II). This is owing to the fact that there is no very strong absorption band in the region of 1700~1740 cm^{-1} on the curve of **A**, contrary to the case of **F**.

E

The carbonyl peak of the carboxylate groups is usually shifted toward lower frequencies upon coordination[10,11]. In the present case, however, the carbonyl peak which is expected to shift toward lower frequencies can not be assigned, since there are some very strong absorptions of salicylaldimino group of the ligand in the expected region.

In the case of the curve, **C**, the carbonyl peak of the coordinated carboxyl group

10) D. H. Busch and J. C. Bailar, Jr., *J. Am. Chem. Soc.*, **75**, 4574 (1953).

11) S. Kirschner, ibid., **78**, 2372 (1956).

is observed at about 1600 cm^{-1}. Not only the anti-symmetric C–O stretching band, but also the shifting of the symmetric stretching band from 1400 to 1370 cm^{-1} affords an additional evidence for the structure with a coordinated carboxyl group[12].

Of interest is a weak absorption at 1680 cm^{-1}, which is supposed to be concerned with the carbonyl group of the peptide link. The concerned band in the free peptide molecule normally appears at about 1655 cm^{-1} [13].

However, the coordination of copper(II) with the nitrogen atom of peptide may shift the band to some extent. Richard and Thompson[14] have pointed out, for example, that electrophilic substituents on the nitrogen atom can give rise to an increase in the frequency up to 1680 cm^{-1}.

The same kind of shifting of the peptide carbonyl band is more effectively presented in **B**. In this case, however, the absorption band is much stronger than that of **C**; and the degree of shifting is even greater. This fact may indicate that the linkage between copper(II) and peptide nitrogen is stronger in **B** than in **C**, and is consistent with the conclusion that **B** might be a typical dsp^2-type complex.

Summary

The two new compounds, *N*-salicylideneglycinato-aquo-copper(II) and sodium *N*-salicylideneglycylglycinato-cuprate(II) were prepared and investigated as to their structure.

Their infrared, visible and ultraviolet absorption spectra together with those of some related compounds were measured and discussed.

The author wishes to express his sincere thanks to Professor R. Tsuchida for his encouragement throughout the course of this work, and to Dr. S. Yamada and Mr. Y. Yamamoto for their valuable discussion.

Polymerization of Methyl Methacrylate Initiated by Phenylazo p-Tolyl Sulfone

By Ryoichi UEHARA

(Received May 15, 1959)

Phenylazo *p*-tolyl sulfone was first prepared by Koenigs[1] through the reaction of benzenediazonium chloride with sodium *p*-toluenesulfinate:

$$C_6H_5N_2Cl + CH_3C_6H_4SO_2Na = C_6H_5N_2SO_2C_6H_4CH_3 + NaCl$$

Copolymerization of butadiene and styrene (GR-S rubber) by the use of various arylazo aryl sulfones as initiators have been carried out by Brown[2]. It has been reported by Theobold[3] that solution-polymerization of acrylonitrile in ethanol takes place very smoothly at 40°C by means of phenylazo *p*-tolyl sulfone and a very small amount of cupric chloride. The present author has examined the effect of phenylazo *p*-tolyl sulfone upon the polymerization of methyl methacrylate. Phenylazo *p*-tolyl sulfone was an efficient initiator of the polymerization, but it was not suitable for use in manufacture of polymethyl methacrylate, because the polymer formed was dark orange in color. On the other hand, it appears of interest that dimethylaniline acted as an accelerator for this polymerization. In the present paper, results of experiments about the

1) P. Koenigs, *Ber.*, **10**., 1531 (1877).
2) R. S. Brown, U. S. Pat., 2,527,393 (1950); *Chem. Abstr.*, **45**, 383 (1951).
3) C. W. Theobold, U. S. Pat., 2,584,306 (1952); *Chem. Abstr.*, **46**, 3798 (1952).

relation between the initial rate of polymerization and the concentrations of phenylazo *p*-tolyl sulfone, dimethylaniline and methyl methacrylate are given, and the nature of the initiating reaction is discussed from the standpoint of the reaction kinetics.

The dependence of the initial rate of polymerization (R) upon the concentration of phenylazo *p*-tolyl sulfone ([AZS]) in the solution-polymerization in benzene (concentration of methyl methacrylate, 30%) were studied at 41, 51 and 60°C. As are shown in Fig. 1, the square root dependence of the rate upon the concentration was observed at each temperature. When the logarithms of the initial rates

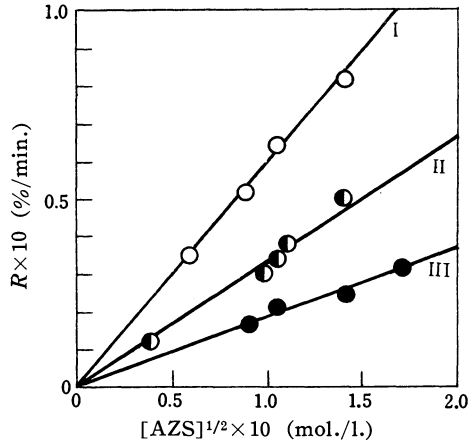

Fig. 1. Dependences of R upon $[AZS]^{1/2}$ at 60 (I), 51 (II) and 41°C (III) ([MMA]=30% in benzene).

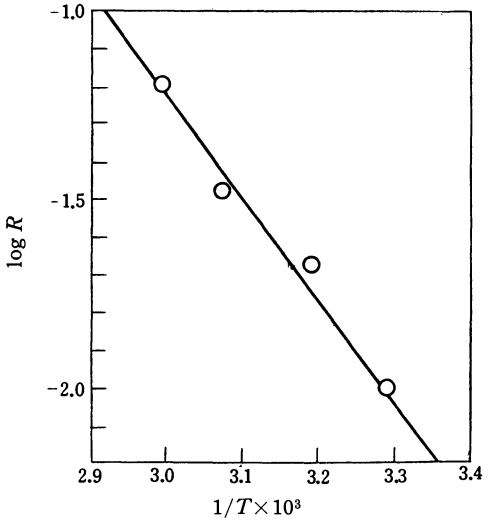

Fig. 2. Relationship between $\log R$ and $1/T$ ([AZS]=1.1×10^{-2} mol./l. and [MMA]=30% in benzene).

(phenylazo *p*-tolyl sulfone 1.1×10^{-2} mol./l.) were plotted against the reciprocals of the temperatures, a straight line was obtained (Fig. 2). The overall activation energy of the polymerization calculated from the slope of the straight line in Fig. 2 was found to be 12.2 kcal./mol.

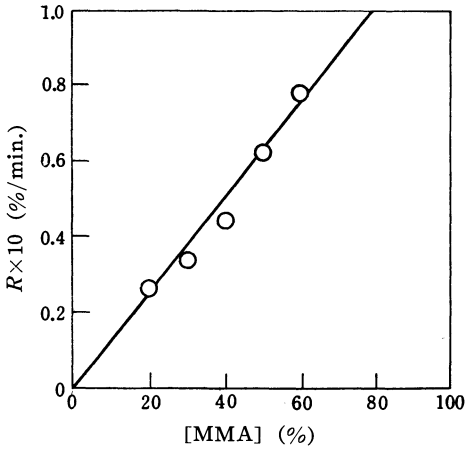

Fig. 3. Correlation of R with [MMA] at 51°C ([AZS]=1.1×10^{-2} mol./l.).

Fig. 3 shows a relationship between the initial rate and the concentration of methyl methacrylate ([MMA]) in benzene (at 51°C and phenlazo *p*-tolyl sulfone 1.1×10^{-2} mol./l.). The rate was linearly proportional to the concentration of methyl methacrylate.

Relationships shown in Figs. 1 and 3 are represented by Eq. 1:

$$R=k_0[AZS]^{1/2}[MMA] \quad (1)$$

where k_0 is a constant. This equation is quite similar to that which is usually known to hold in the polymerization of vinyl monomers initiated by benzoyl peroxide or α,α'-azo-bis-isobutyronitrile[4]. Eq. 1, therefore, suggests a unimolecular first order decomposition of phenylazo *p*-tolyl sulfone as the initiating reaction of the polymerization.

The polymerization of methyl methacrylate initiated by phenylazo *p*-tolyl sulfone is accelerated by addition of dimethylaniline. When the concentration of phenylazo *p*-tolyl sulfone was kept constant and various amounts of dimethylaniline were added, the initial rate of polymerization was linearly dependent upon the square root of the concentration of dimethylaniline ([DMA]). Fig. 4 shows

4) P. J. Flory, "Principles of Polymer Chemistry", Cornell University Press, Ithaca, N. Y. (1953), p. 116.

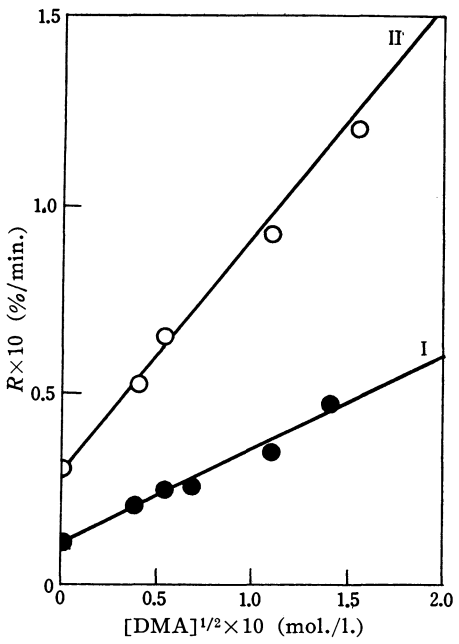

Fig. 4. Correlations of R with $[DMA]^{1/2}$ at 51°C ($[MMA]=30\%$, $[AZS]=0.15\times10^{-2}$ for line I and 0.96×10^{-2} mol./l. for line II).

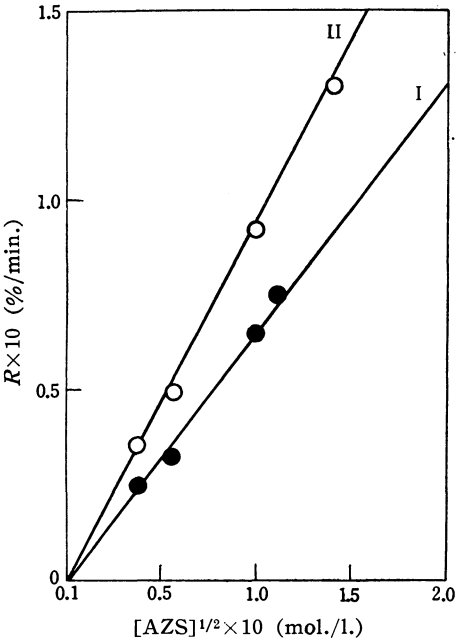

Fig. 5. Correlations of R with $[AZS]^{1/2}$ at 51°C ($[MMA]=30\%$, $[DMA]=0.29\times10^{-2}$ for line I and 1.2×10^{-2} mol./l. for line II).

examples of this relationship (concentration of methyl methacrylate 30%; concentration of phenylazo *p*-tolyl sulfone 0.15×10^{-2} and 0.95×10^{-2} mol./l. at 51°C). In the case when the concentration of dimethylaniline was held constant and that of phenylazo *p*-tolyl sulfone was varied, the initial rate of polymerization was proportional to the square root of the concentration of phenylazo *p*-tolyl sulfone. Examples of this correlation are shown in Fig. 5 (methyl methacrylate 30%, and dimethyl- aniline 0.29×10^{-2} and 1.2×10^{-2} mol./l. at 51°C). It is evident from Figs. 1 and 4 that the polymerization takes place at measurable rates at 51°C by means of phenylazo *p*-tolyl sulfone alone. Therefore, in the case where the concentration of methyl methacrylate is kept constant, the correlations shown in Figs. 4 and 5 can be represented by the following equation:

$$R=k[AZS]^{1/2}+k'[AZS]^{1/2}[DMA]^{1/2} \quad (2)$$

where k and k' are constants.

Eq. 2 suggests that the polymerization of methyl methacrylate by means of phenylazo *p*-tolyl sulfone and dimethylaniline is initiated by two reactions, i. e., a unimolecular first order decomposition of phenylazo *p*-tolyl sulfone and a bimolecular reaction between phenylazo *p*-tolyl sulfone and dimethylaniline, k and k' being the rate constants respectively. From Eq. 2, the following equation is derived:

$$R=k[AZS]^{1/2}(1+k'/k[DMA]^{1/2}) \quad (3)$$

k'/k, the ratio of the rate constants of the two initiating reactions of the polymerization, can be calculated from the slops of the straight lines in Fig. 4. It was found to be 2.00 from line I and 2.18 from line II (at 51°C and methyl methacrylate 30% in benzene).

Imoto and others[5] have reported a rate-concentration equation similar to Eq. 2 or 3 for the polymerization of methyl methacrylate initiated with benzoyl peroxide and dimethylaniline, and suggested a similar mechanism to that mentioned above.

Experimental

Materials.—Purification of methyl methacrylate, dimethylaniline and benzene have been mentioned in a previous paper by the present author[6]. Phenylazo *p*-tolyl sulfone was obtained by addition of sodium *p*-toluenesulfinate (21 g.) into an aqueous solution of benzenediazonium chloride which was prepared from aniline (10 g.), 30%

5) M. Imoto et al., *J. Chem. Soc. Japan, Ind. Chem. Sec.* (*Kogyo Kagaku Zasshi*), **58**, 451 (1955).
6) R. Uehara, This Bulletin, **31**, 685 (1958).

aqueous HCl (40 cc.) and $NaNO_2$ (8 g.). The crude product was recrystallized three times from pure methanol, giving pure phenylazo *p*-tolyl sulfone (17.5 g.), m. p. 87.5°C with decomposition (83.5°C by Brown[2]). This compound was not quite stable at room temperature under sunlight. In a colorless, transparent glass vessel, it changed into a resinous meterial during several weeks in summer.

Polymerization. — Polymerization was carried out in sealed test tubes which were 15 mm. in diameter and 10 cm. in height and made of brown-colored glass so as to reduce the effects of sunlight upon the polymerization. Phenylazo *p*-tolyl sulfone was dissolved in benzene. Methyl methacrylate was cooled in an ice-salt bath. Measured amounts of the benzene-solution and methyl methacrylate were placed in a test tube and mixed. The test tube was immersed in a dry ice-methanol bath and flushed with nitrogen and sealed. The extent of the polymerization was estimated from the weight of polymethyl methacrylate, and the rate of polymerization was expressed in unit of per cent per minute. Details of the procedures of the polymerization and the determination of the initial rate of polymerization have been reported previously[6].

Summary

The effects of phenylazo *p*-tolyl sulfone upon the polymerization of methyl methacrylate were examined. In the solution-polymerization in benzene, the initial rate of polymerization was linearly dependent respectively upon the square root of the concentration of phenylazo *p*-tolyl sulfone and upon the concentration of methyl methacrylate. A unimolecular first order decomposition of phenylazo *p*-tolyl sulfone is suggeted as the initiating reaction of the polymerization. Dimethylaniline acted as an accelerator for this polymerization. In this case, the initial rate of polymerization was linearly proportional to the square root of each of the concentrations of phenylazo *p*-tolyl sulfone and dimethylaniline. A bimolecular reaction between phenylazo *p*-tolyl sulfone and dimethylaniline has been proposed for the acceleration of the polymerization.

The author wishes to express his hearty thanks to Professor Osamu Simamura of the University of Tokyo for his interests in this work and Mr. Tsurahide Cho, the President of Tama Kagaku Kogyo Co. for permission to publish this work.

*Synthesis of 3, 6-Dimethyl-2, 3-dihydro-1H-cyclopent[a]anthracene. A Possible Dehydrogenation Product of Anthranoid Rearrangement Product of Steroids**

By Masao NAKAZAKI and Sachihiko ISOE

(Received February 11, 1959)

A number of works have been accumulated on the dienone-phenol rearrangement of the steroid A ring, and there can be found scrupulous studies on the structures of the products of this rearrangement[1], the relation between the products and the reaction conditions[2], and the effects of the structures on the rearrangement course[3]. Stimulated by these studies on steroids, various model compounds were synthesized and the same pattern of reaction was demonstrated[4].

* A preliminary note appeared in *Chem. & Ind.*, **1958**, 43.

1) H. Minlon, *Naturwissenschaften*, **36**, 765 (1938); R. B. Woodward, H. H. Inhoffen, H. O. Larson and K. H. Menzel, *Chem. Ber.*, **86**, 594 (1955); and Inhoffen's preceeding papers, **1940—1953**.

3) A. L. Wilds and C. Djerassi., ibid., **68**, 1715 (1946); and numerous studies by Djerassi, ibid., **70**, 1911, 3962 (1948); **72**, 4540 (1950); **73**, 990, 1523 (1951); **76**, 1741 (1954); and *J. Org. Chem.*, **15**, 896 (1950).

4) R. B. Woodward and T. Singh, *J. Am. Chem. Soc.*, **72**, 494 (1950); R. T. Arnold, ibid., **71**, 1781 (1949); **69**, 2322 (1947); **72**, 3153 (1950); F. M. Marbell and E. Magoon, ibid., **77**, 2542 (1955); **76**, 5118 (1954).

But, as to the dienone-phenol rearrangement of the steroid B ring[5], thorough study is still lacking and the structures of the rearrangement products have remained obscure. Tsuda's group[6] was the first to carry out the structural study of a dienone-phenol rearrangement product of the steroid B ring. Namely, 7-keto-5,8(9)-cholestadien-3β-yl acetate (I)[6,7], prepared by chromic acid oxidation of 5,8(9)-cholestadien-3β-yl acetate in acetic acid, was treated with concentrated sulfuric acid in acetic anhydride to give phenol acetate(IIa). After hydrolysis of IIa with ethanolic potassium hydroxide to a phenol IIb, m. p. 261~265°C, they submitted this phenol to selenium dehydrogenation to obtain, among other products, a hydrocarbon (oil) $C_{19}H_{18}$ in the form of picrate, m. p. 133.5~134°C. The ultraviolet absorption which showed an anthracene type pattern, was attributed by them to the structure IV, and consequently structure IIb was assumed for the phenol, m. p. 261~265°C.

This type of rearrangement is not the only one which can convert the perhydrophenanthrene skeleton of steroids into the perhydroanthracene skeleton, but a smooth "anthrasteroid" rearrangement studied by Mosettig and coworkers[8] can be counted as another type of conversion leading to the anthracene skeleton. Tsuda and coworker[9] also carried out a modification of "anthrasteroid" rearrangement of $\Delta^{5,8}$-cholestadien-3β-ol to the product III, in the presence of mercuric acetate and toluenesulfonic acid in ethanol under the influence of strong irradiation[10]. Dehydrogenation of product III with selenium afforded the same hydrocarbon $C_{19}H_{18}$, which they obtained from II previously. Since 3,6-dimethyl-2,3-dihydro-1-*H*-cyclopent[*a*]anthracene (IV) is a dehydrogenation product to be expected from the "anthranoid rearrangement" product and corresponds to Diels' hydrocarbon usually obtained by the dehydrogenation of steroids, the synthesis of this compound IV is considered to be important[11]. In this paper we report the synthesis of compound IV.

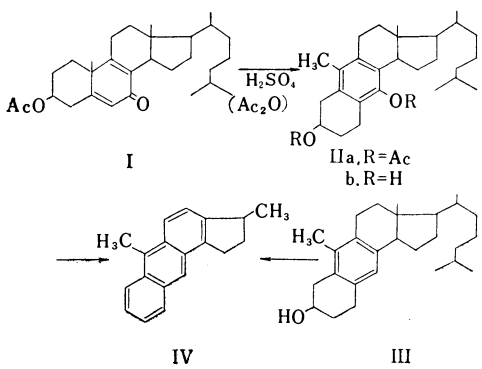

Fig. 1

Whereas the synthetic routes to the phenanthrene type dehydrogenation products of steroids have been well explored[12], there have been few to prepare the anthracene type like IV. Compound VII appears to be the most promising starting material which could be transformed into IX by Johnson's modification of Stobbe condensation[13](Fig. 2). 1-Methyl-2-naphthoic acid (VIa), prepared either

5) D. H. R. Barton and B. R. Thomas, *J. Chem. Soc.*, **1953**, 1842, converted 7-ketolanosta-5,8-dien-3β-yl acetate into "isomeric phenol" by bolling with acetic acid and zinc dust. P. Bladon, *J. Chem. Soc.*, **1955**, 2176, obtained a phenol from 3β-acetoxylumista-5,8 (9), 20-trien-7-one (λ_{max} 246 mμ, ε 11,800) by the action of acetic acid and zinc dust, and discussed the structure. They also pointed out another possible route of dienone-phenol rearrangement by methyl migration.

6) K. Tsuda, K. Arima and R. Hayatsu, *J. Am. Chem. Soc.*, **76**. 2933 (1954). Compound I shows ultraviolet absorption at λ_{max} 238 mμ (log ε 4.475), $[\alpha]_D^{22}$ −67.3°. m. p. 151~152°C. Semicarbazone: m. p. 210~212°C (decomp.). The same compound prepared by Inhoffen by another route has m. p. 169~170°C $[\alpha]_D^{20}$ −9°, λ_{max} 248 mμ, ε 12,800 (methanol). H. H. Inhoffen and W. Menzel, *Chem. Ber.*, **87**, 146 (1954).

7) Other steroids possessing 5,8(9)-dien-7-one structure show maxima of ultraviolet absorption as follows: 3β-hydroxy-5,8(9), 20-ergostatrien-7-one, λ_{max} 247 mμ (ε 21,000) (D. C. Burke, J. H. Turnbull and W. Wilson, *J. Chem. Soc.*, **1953**, 3237); 3β-acetoxy-5,8(9). 20-ergostatrien-7-one, λ_{max} 245 mμ (ε 11,800) (J. Elks, R. M. Evans, A. G. Long and G. H. Thomas, ibid., **1954**, 451); λ_{max} 246 mμ (ε 12,800) (J. Elks, R. M. Evans, J. F. Oughton and G. H. Thomas, ibid., **1954**, 463).

8) E. Mosettig and I. Scheer, *J. Org. Chem.*, **17**, 764 (1952); W. R. Nes and E. Mosettig, *J. Am. Chem. Soc.*, **75**, 2787 (1953); **76**, 3182, 3186 (1954); W. R. Nes, ibid., **78**, 193 (1956); I. Scheer, W. R. Nes and P. B. Smeltzer, ibid., **77**, 3300 (1955); W. R. Nes, R. B. Kostic and E. Mosettig, ibid., **78**, 36 (1956). We would like to propose the general term "anthranoid rearrangement" for all rearrangements of steroids to the compounds possessing an anthracene skeleton, and to restrict the term "anthrasteroid rearrangement" to the type of Mosettig's reaction.

9) K. Tsuda and R. Hayatsu, *J. Am. Chem. Soc.*, **77**, 3089 (1955).

10) Being a photochemical reaction accompanied by simultaneous dehydrogenation, the mechanism appears complicated. But the product is in sharp contrast to the product of Mosettig's rearrangement in maintaining the 3-hydroxyl group unattacked.

11) After we completed the synthesis of IV, A. W. Burgstahler, *J. Am. Chem. Soc.*, **79**, 6047 (1957), published a paper in which he described an elegant proof of the structure of anthracholestatetraene proposed by Mosettig et al.

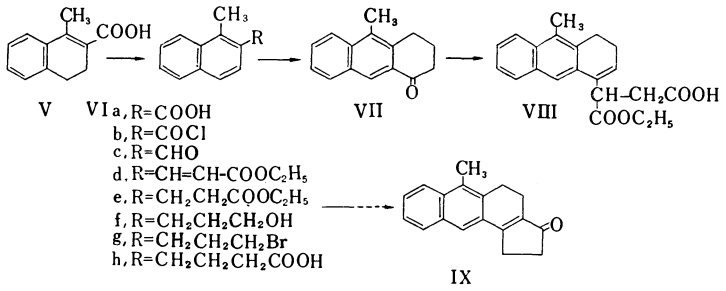

Fig. 2.

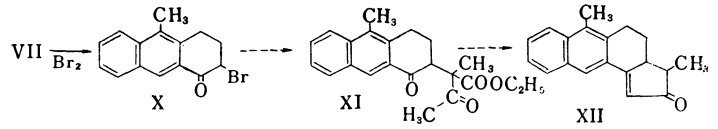

Fig. 3.

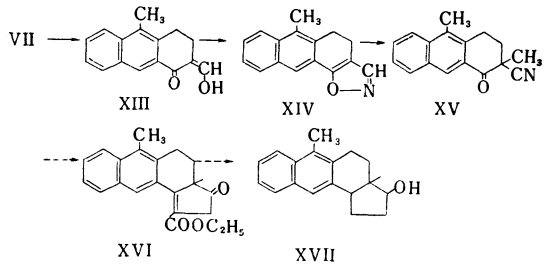
by dehydrogenation[14] of V by means of bromine or by the Grignard synthesis from α-(chloromethyl)naphthalene, was converted into the aldehyde VIc via the aicd chloride VIb by means of the Rosenmund reduction with Pd-$BaSO_4$. By the Claisen condensation with ethyl acetate, VIc gave the unsaturated ester VId, which in turn was catalytically hydrogenated to VIe. The alcohol VIf, obtained by lithium aluminum hydride reduction of VIe, was treated with phosphorus tribromide to afford the bromide VIg, which gave the acid VIh by the usual nitrile synthesis and hydrolysis.

The Stobbe condensation of the ketone VII, easily accessible from the acid VIh by Wilds' method[15], led to the formation of VIII, but the ring closure to IX by Johnson's method[16] using zinc chloride was unsuccessful, probably owing to the vulnerability of the α-position of the naphthalene nucleus to the cationoid attack which would direct the ring closure in an undesired direction. Although the plan to build up the D ring by Johnson's method failed, various synthetic routes which can be carried out in a basic medium so as to avoid the complicated side reaction encountered above, were tried with the ketone VII to secure the D ring.

Condensation of the bromoketone X, provided by the bromination of the ketone VII in ether, with potassium ethyl methylacetoacetate[17] in *tert*-butanol failed to give XI, which was expected to afford XII by ring closure.

Another route tried was an indirect one (Fig. 4). The alcohol XVII which would be prepared following the scheme whereby Johnson achieved his brilliant equilenine synthesis[18], might give IV on dehydrogenation accompanied by the simultaneous migration of the angular methyl group to the position originally occupied by the hydroxyl group.



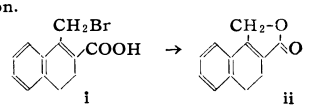


Fig. 4.

The process leading to XV was carried out smoothly, but again the Stobbe condensation of the α-cyanomethylketone to afford XVI was fruitless, probably owing to the ready opening of the ketone XV with the base. The sequence of the steps which finally led to IV is shown in Fig. 5.

14) When dehydrogenation was carried out in acetic acid, the bromination product i was the main product, which could be converted into the lactone ii by hydrolysis with methanolic potassium hydroxide followed by acidification.

16) W. S. Johnson and J. W. Peterson, ibid., **67**, 1367 (1945).
17) Wilds succeeded in the same type of condensation using ethyl acetoacetate, *J. Am. Chem. Soc.*, **64**, 1421 (1949).
18) W. S. Johnson et al., ibid., **69**, 2942 (1947).

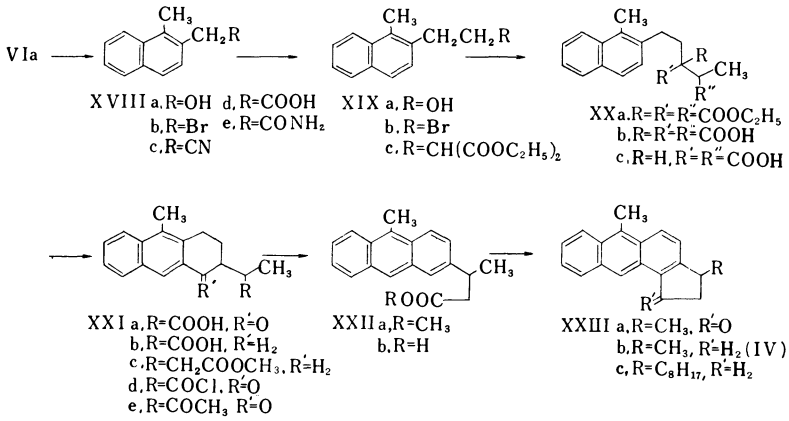

Fig. 5.

1-Methyl-2-naphthoic acid (VIa) was reduced with lithium aluminum hydride to give the alcohol XVIIIa, and its side chain was extended to the homologous alcohol XIXa by the usual sequence of reactions (bromide XVIIIb→cyanide XVIIIc →acid XVIIId→alcohol XIXa). The alcohol XIXa was treated with phosphorus tribromide in benzene to yield the bromide XIXb, which gave the condensation product XIXc with ethyl sodiomalonate.

Condensation of XIXc with ethyl α-bromopropionate in the presence of potassium *tert*-butoxide led to the triester XXa. The tricarboxylic acid XXb obtained by the hydrolysis of XXa with methanolic potassium hydroxide was decomposed to the dicarboxylic acid XXc, which was cyclized to the ketocarboxylic acid XXIa by PCl_5-$SnCl_4$ method of Wilds[15,19], whereas the ring closure using polyphosphoric acid[20] resulted only in the recovery of the starting material.

After the carbonyl group of XXIa was removed by the Clemensen-Martin reduction, the resulting acid XXIb[21] was transformed into the methyl ester of the homologous acid XXIc by the Arndt-Eistert method. Heating with 30% Pd-C at 290~300°C, followed by hydrolysis, converted the ester XXIc into the anthracene derivative XXIIb, m. p. 160~160.5°C, which showed an ultraviolet absorption spectrum characteristic of an anthracene type (see *Experimental*).

The appearance of new bands in the infrared absorption spectrum (11.90 and 12.30 μ) which can be attributed to the 1,2,4-trisubstituted benzene structure[22], together with the characteristic absorption in ultraviolet region, leaves no doubt about the anthracene structure of the compound. The ring closure[23] of the acid XXIIb by PCl_5-$SnCl_4$ method accomplished the ketone XXIIIa, which exhibited infrared absorption band at 5.93 μ (indanone)[24] and 12.2 μ (two adjacent hydrogens on aromatic hydrocarbon). The ultraviolet absorption spectrum which is very close to α-acetylanthracene (see Table I) also confirms the structure of the ketone.

The final stage to IV was the Clemensen-Martin reduction of the ketone XXIIIa. The oily product was purified by chromatography on alumina column to provide colorless crystals, m. p. 78~79.5°C after recrystallization from methanol. The picrate melted at 128~128.5°C (the picrate of Tsuda's hydrocarbon, m. p. 133~134°C), and the 2,4,6-trinitrobenzolate at 142~142.5°C. The ultraviolet absorption spectrum of the hydrocarbon XXIIIb (IV) could in almost every detail be overlapped on the spectrum of Mosettig's hydrocarbon XXIIIc (dehydroanthracholesterol), whereas Tsuda's hydrocarbon showed an anomalous absorption in the long wavelength, presumably owing to impurity[25].

19) To get the methyl ketone XXIe, which would give a five membered D ring was tried in vain. Cf. A. L. Wilds et al., *J. Am. Chem. Soc.*, **69**, 3079 (1947); **66**, 1688 (1944).

20) D. D. Gardner and W. J. Horton, ibid., **74**, 4976 (1953).

21) Two racemates of compound XXIb can be expected, but no attempt was made to separate them.

22) H. Dannenberg, U. Shiedt and W. Sheidle, *Z. Naturforsh.* **B8**, 269 (1953).

23) The reactivity to cationoid attack is much greater at α-position on anthracene than at β-position. Cf. L. F. Fieser and H. Heymann, *J. Am. Chem. Soc.*, **63**, 2333 (1941) and W. S. Johnson, "Organic Reactions", Vol. 2, John Wiley & Sons, Inc., New York (1946). p. 114.

24) H. Dannenberg and D. D. Dannenberg, *Ann.*, **585**, 1 (1954), reported the absorption at 5.92 μ in the similar system.

25) The selenium dehydrognation of IIb may lead, although it is highly unlikely, to another structure than IV, but in the case of dehydrogenation of III to IV, there is no reason to expect serious change of the skeleton.

Experimental**

Ethyl α-Aceto-γ-phenylbutyrate.—To a stirred and cooled solution of sodium ethoxide prepared from 450 cc. of absolute ethanol and 23 g. of sodium, 143 g. of ethyl acetoacetate was added in an atmosphere of nitrogen, and the reaction mixture was warmed to 60~70°C. After the addition of 197 g. of phenethyl bromide (b. p. 96~98°C/11 mmHg) over a period of 2 hr., the mixture was heated at 70~75°C for 5 hr., 80~85°C

** All ultraviolet spectra were measured with a Beckmann spectrophotometer DK 2, and infrared spectra with a Perkin Elmer Model 12 C. The anlyses were performed in the Microanalytical Laboratory of the Institute of Polytechnics, Osaka City University, Osaka.

for an additional 5 hr., and refluxed for 6 hr. on a water bath. After the solvent was removed, the residue was poured into water, made sligitly acidic with hydrochloric acid, and extracted with ether. The organic layer was washed with water and dried over anhydrous sodium sulfate, and the ether was removed.

The ester distilled at 124~127°C/1 mmHg, and weighed 163 g. (Yield, 69.5%).

1-Methyl-3, 4-dihydro-2-naphthoic Acid.—Ninety grams of ethyl α-aceto-γ-phenylbutyrate was added dropwise to 375 cc. of concentrated sulfuric acid chilled at −4°C with stirring more than 40 min., and the mixture was kept at this temperature for 2 hr. After the reaction mixture was poured on crushed ice, the crystals were collected and washed thoroughly with water. After being dried, they weighed 64.5 g. (yield, 84.2%), and were used in dehydrogenation without further purification. A small portion was recrystallized from petroleum ether, m. p. 127~130°C. (literature[26]: m. p. 129~130°C).

1-Methyl-2-naphthoic Acid (VIa).—*Dehydrogenation of V.*—To a solution of 58 g. of V in 300 cc. of carbon tetrachloride, 54 g. of bromine was added at 65~70°C over a period of 2 hr. with stirring. After additional heating (70~75°C) for 2 hr. with stirring, the mixture was cooled to deposite crystals.

The crude crystalline product (55.6 g.) was dissolved in a solution of 40 g. of sodium hydroxide in 750 cc. of water and the solution was heated on a water bath for 2 hr., and treated with Norit. The alkaline solution was freed from Norit, and made acidic with 1 N hydrochloric acid to afford 34.5 g. of crude VIa (yield, 44.1%), which was recrystallized, m. p. 177.5~178°C (literature[26]: 177~178°C).

Grignard synthesis from α-(chloromethyl)naphthalene.—To a suspension of 35 g. of magnesium in 360 cc. of absolute ether, was added 85 g. of α-(chloromethyl) naphthalene in 200 cc. of ether with stirring for more than 5 hr., and the mixture was refluxed for 1 hr.

The Grignard solution was filtered through glass wool to remove excessive magnesium, and added to a chilled solution of 215 g. of ethyl chlorocarbonate in 160 cc. of ether taking more than 40 min. After being kept at room temperature for 30 min., the mixture was decomposed with dilute sulfuric acid and ice, and the organic layer was washed in turn with water and dilute sodium carbonate solution. Romoval of the solvent gave a liquid, which boiled at 140~143°C/2~3 mmHg and weighed 46.6 g. Hydrolysis of the ester with 20 g. of potassium hydroxide, 25 cc. of water and 50 cc. of methanol gave 28.6 g. of VIa, m. p. 160~170°C. Recrystallization from benzene raised the m. p. to 175~176°C.

1-Bromomethyl-3, 4-dihydro-2-naphthoic Acid (i).—To a solution of 15 g. of V (m. p. 127~130°C) in 60 cc. of glacial acetic acid, a mixture of 13.8 g. of bromine and 20 cc. of acetic acid was added with stirring for more than 1.5 hr. The color of bromine disappeared rather rapidly. The solution was warmed at 55°C for 30 min., and a small amount of sodium sulfite was added to discharge the bromine color.

Crystals, precipitated by the addition of water, were collected and washed with water to give 20 g. of the bromide i, which was recrystallized from benzene to give prismatic crystals, m. p. 177°C (decomp.).

Anal. Found: C, 54.44; H, 4.23; Br, 29.96. Calcd. for $C_{12}H_{11}O_2Br$: C, 53.50; H, 4.15; Br, 29.93%.

The Lactone (ii).—Five grams of i was dissolved in a solution of 5 g. of potassium hydroxide in 1 cc. of water and 30 cc. of methanol, and the solution was refluxed on a water bath for 40 min. After the addition of 30 cc. of water, the alkaline solution was made acidic to precipitate an oil, which was decanted from superfluous liquid. The viscous oil could be crystallized by trituration with a cold dilute sodium hydroxide solution.

Recrystallization from petroleum ether gave the lactone ii melting at 112~113°C.

Anal. Found C, 77.48; H, 5.68. Calcd. for $C_{12}H_{10}O_2$: C, 77.42; H, 5.38%.

1-Methyl-2-naphthoyl Chloride (VIb).—A mixture of 35.0 g. of VIa and 44.5 g. of thionyl chloride was refluxed on a water bath for 2 hr. The excess of thionyl chloride was removed to give an oil, which distilled at 136~138°C/2 mmHg, m. p. 79~80.5°C and weighed 36.5 g. The anilide was recrystallized from ethanol m. p. 212~214°C.

Anal. Found: C, 82.75; H, 6.04; N, 5.55. Calcd. for $C_{18}H_{15}ON$: C, 82.73; H, 5.79; N, 5.36%.

1-Methyl-2-naphthaldehyde (VIc).—A stream of hydrogen was introduced into a stirred mixture of 36.5 g. of VIb and 3.4 g. of 5% Pd/$BaSO_4$[27] in 330 cc. of xylene at 110°C. When the evolution of hydrogen chloride ceased (in about 2 hr.), the reaction mixture was cooled and freed from the catalyst. Removal of the solvent in vacuo followed by distillation gave 15.4 g. of an oil (yield, 50.6%), which solidified gradually on standing. The semicarbazone was recrystallized from dilute acetic acid, m. p. 227~231°C (decomp.).

Anal. Found: C, 69.16; H, 5.61. Calcd. for $C_{13}H_{13}ON_3$: C, 68.70; H, 5.77%.

Ethyl β-(1-Methyl-2-naphthyl)acrylate (VId).—A mixture of 42 cc. of ethyl acetate and 0.3 cc. of absolute ethanol was added all at once to the cooled powdered sodium[28] provided by vigorous stirring of 2.7 g. of molten sodium under refluxing xylene followed by decantation from the xylene. After stirring for 10 min. at −5°C, a solution of 15.2 g. of the aldehyde VIc in 30 cc. of ethyl acetate was added over a period of 1.5 hr. and the mixture was stirred for 1.5 hr. at −6°C. The dark red reaction mixture was decomposed by adding 9 cc. of acetic acid and then 200 g. of ice, and the aqueous layer was extracted with ethyl acetate twice. The combined extract was washed

with water, 5% sodium bicarbonate solution and water. After drying, the solvent was removed to afford a pale yellow liquid, which was distilled to give 10.1 g. of a colorless liquid, b. p. 167~173°C/2 mmHg, (yield, 47%), which solidified on standing and recrystallized from petroleum ether, m. p. 62~63°C.

Anal. Found: C, 80.25; H, 6.97. Calcd. for $C_{16}H_{16}O_2$: C, 79.97; H, 6.71%.

Ethyl β-(1-Methyl-2-naphthyl)propionate (VIe).—Catalytic hydrogenation of 15.3 g. of the unsaturated ester VId with 0.4 g. of 10% Pd/C in 180 cc. of ethanol gave an oil which boiled at 161~162°C/2 mmHg and weighed 11.4 g. (yield, 75%).

Anal. Found: C, 79.59; H, 7.71. Calcd. for $C_{15}H_{18}O_2$: C, 79.31; H, 7.49%.

3-(1-Methyl-2-naphthyl)-1-propanol (VIf).—To a slurry of 0.95 g. of lithium aluminum hydride in 40 cc. of ether, a solution of 5.4 g. of the ester VIe in 20 cc. of ether was added with stirring. After refluxing for 1 hr., the excess of the reducing reagent was decomposed by adding 4 cc. of ethyl acetate and then 25 cc. of water and 15 cc. of concentrated hydrochloric acid. The organic layer was washed with water, 5% sodium bicarbonate solution and water again. After drying over anhydrous magnesium sulfate, the solvent was removed to give an oil, which was purified by distillation in vacuo, b. p. 173~174°C/3 mmHg. 4.1 g. (yield, 91.9%). The phenylurethane was recrystallized from benzene-petroleum ether, m. p. 113~114°C.

Anal. Found; C, 78.96; H, 7.03. Calcd. for $C_{21}H_{21}O_2N$: C, 78.97; H, 6.63%.

1-Bromo-3-(1-methyl-2-naphthyl)-propane (VIg).—A solution of 5.0 g. of the alcohol VIf in 19 cc. of benzene was added dropwise to a stirred mixture of 5.0 g. of phosphorus tribromide and 125 cc. of benzene. After heating at 70~75°C for 4 hr., the mixture was poured into ice water and saturated with sodium chloride. The benzene layer was separated, and the aqueous layer was extracted with ether. The combined benzene solution and ether were washed with water and dried over anhydrous magnesium sulfate. The residue freed from the solvent was distilled at 135~136°C/0.002 mmHg, to give the bromide VIg weighing 5.2 g. (yield, 80.4%).

3-(1-Methyl-2-naphthyl)-1-propanecarboxylic Acid (VIh).—A mixture of 5.2 g. of the bromide VIg, 89 cc. of ethanol, 5.0 g. of potassium cyanide and 20 cc. of water was refluxed for 26 hr. After removal of the ethanol, the mixture was poured onto ice, acidified with 20 cc. of concentrated hydrochloric aicd, and extracted with ether.

After removal of the ether the residual oil was hydrolyzed by boiling with 59 cc. of acetic acid and 33 cc. of concentrated hydrochloric acid for 7 hr., while 1.2 cc. of concentrated hydrochloric acid was added every hour. The crystals deposited on cooling melted at 123~125°C and weighed 4.3 g. (yield, 94.6%). Recrystallization from benzene-petroleum ether raised the melting point to 126~127°C.

Anal. Found: C, 79.62; H, 7.05. Calcd. for $C_{15}H_{16}O_2$: C, 78.92; H, 7.06%.

1-Oxo-10-methyl-1, 2, 3, 4-tetrahydroanthracene (VII).—To a solution of 5.1 g. of the carboxylic acid VIh in 44 cc. of dry benzene, 9.2 g. of phosphorus pentachloride was added. After stirring at room temperature for 1 hr., the mixture was heated for 10 min. at 45~50°C, and then a solution of 28.6 g. of stannic chloride in 22 cc. of benzene was added to the chilled solution. The orange-red solution was stirred for 50 min. with cooling in an ice bath, and was decomposed with 200 cc. of water. Addition of 22 cc. of concentrated hydrochloric acid was followed by extraction with ether, and the organic layer was washed with water, 1 N sodium hydroxide solution and water. After drying over anhydrous magnesium sulfate, the solvent was removed to give a solid weighing 4.3 g. (yield, 91.7 g.), which was recrystallized from methanol, m. p. 99.5~100.5°C, 4.0 g. An infrared absorption spectrum indicated a peak at 5.97 μ.

Anal. Found: C, 85.95; H, 7.62. Calcd. for $C_{15}H_{14}O$: C, 85.68; H, 6.71%.

The Stobbe Condensation of VII.—In a stream of nitrogen, 1.2 g. of potassium was dissolved in 22 cc. of *tert*-butanol. To the solution was added a mixture of 5.4 g. of the ketone VII, 7.2 g. of diethyl succinate and 7.5 g. of *tert*-butanol and the mixture was heated at 110°C for 50 min. To the cooled solution, 8.5 cc. of concentrated hydrochloric acid and 50 cc. of water was added, the separated brown oil was extracted with ether. After being washed with water, the ether layer was extracted with three portions of 160 cc. of 1 N ammonia water to separate the half ester VIII. The turbid solution was cleared with Norit, and was acidified with 4 N hydrochloric acid to precipitate an oil, which was extracted with ether. The ether extract was washed with water and dried over anhydrous magnesium sulfate. To the brown residue (5.3 g.) was added 50 cc. of acetic acid and then a solution of 25 cc. of acetic acid and 1.5 g. of zinc chloride. The solution was heated on a free flame for 5 hr. The reaction mixture turned blue-black in color, and was filled with a voluminous amorphous solid, from which no traceable material was isolated.

1-Oxo-2-bromo-10-methyl-1, 2, 3, 4-tetrahydroanthracene (X).—To a chilled suspension of 2.6 g. of the ketone VII in 20 cc. of ether, a solution of 2.0 g. of bromine in 10 cc. of ether was added over a period of 10 min. with stirring. After stirring at room temperature for 2 hr., precipitated crystals were collected and recrystallized from methanol-acetone (3 : 1), m. p. 136~137°C. Yield, 2.7 g.

Anal. Found: C, 62.46; H, 4.71. Calcd. for $C_{15}H_{13}OBr$: C, 62.28; H, 4.50%.

The Condensation of the Bromoketone X with Ethyl Methylacetoacetate.—To a cold solution of potassium *tert*-butoxide prepared from 0.33 g. of potassium and 11 cc. of *tert*-butanol, 1.35 g. of ethyl methylacetoacetate was added and the mixture was stirred for 5 hr. at room temperature in an atmosphere of nitrogen. After a solution

of 2.4 g. of the bromoketone X in 28 cc. of dry benzene was added taking more than 10 min., the reaction mixture was stirred at room temperature for 5 min., and refluxed for 1.5 hr. The solution was acidified with 10 cc. of 1 N hydrochloric acid and ice, and the organic layer was in turn washed with water and 2% sodium hydroxide solution. Removal of the solvent gave a brown oil (3.4 g.) from which no traceable material was isolated by chromatographic adsorption on alumina.

1-Oxo-2-oxymethylene-10-methyl-1,2,3,4-tetrahydroanthracene (XIII).—To pulverized sodium methoxide prepared from 0.82 g. of sodium and 20 cc. of methanol, a solution of 2.64 g. of ethyl formate in 30 cc. of benzene was added with stirring and cooling in a gentle stream of nitrogen. A mixture of 3.7 g. of the ketone VII and 40 cc. of benzene was added dropwise with stirring for more than 17 min. The color of the solution changed from yellow-green to green-yellow. After heating at 8~20°C for 6 hr., ice water was added to precipitate the sodium salt of the oxymethylene ketone XIII, which was separated and washed with water. A reddish brown oil, separated on addition of hydrochloric acid to the aqueous solution of the sodium salt, was extracted with ether and the extract was washed with water and dried. Removal of the solvent gave 3.9 g. of a viscous oil, which showed a violet color reaction with ferric chloride and was used directly to prepare the isoxazole XIV.

The Isoxazole XIV.—To a solution of 3.90 g. of the crude oxymethylene ketone XIII in 144 cc. of acetic acid, was added 1.67 g. hydroxylamine hydrochloride and the mixture was heated at 75~80°C for 7 hr. After the solvent (about 120 cc.) was removed by evaporation in vacuo, 100 cc. of water was added to the mixture to precipitate an oil, which solidified upon standing. The crude isoxazole (3.65 g.) was recrystallized from diluted methanol to give needles melting at 111~112°C.

Anal. Found: C, 81.61; H, 5.67; N, 6.46. Calcd. for $C_{16}H_{13}ON$: C, 81.68; H, 5.57; N, 5.94%.

The Cyanoketone XV.—To a solution of potassium *tert*-butoxide provided from 1.68 g. of potassium and 47 cc. of *tert*-butanol, was added 3.15 g. of the isoxazole XIV, and the mixture was heated for 10 min. at 70°C. To the orange-red solution, 13.5 cc. of methyl iodide was added taking more than 7 min. at 70~73°C. After heating at 75°C for 25 min. the solvent was removed and water was added to precipitate crystals. They were collected and washed with water, m. p. 141~142°C. Yield, 3.25 g. The melting point was raised by recrystallization from ethanol to 142~143°C.

Anal. Found: C, 82.21; H, 6.16; N, 5.93. Calcd. for $C_{17}H_{15}ON$: C, 81.90; H, 6.06; N, 5.62%.

The Stobbe Condensation of the Cyanoketone XV.—To a solution of potassium *tert*-butoxide prepared from 0.75 g. of potassium and 30.5 cc. of *tert*-butanol, was added 6.8 cc. of diethyl succinate taking more than 5 min. with stirring and cooling, and then 2.15 g. of the cyanoketone XV. The mixture was stirred for 2 hr. at room temperature, heated at 50°C for 1 hr., and then stirred for 5 hr. at room temperature. After being kept overnight, 20 cc. of 2 N hydrochloric acid solution was added with cooling, when carbon dioxide was evolved. After removal of the solvent in vacuo at 40°C, the aqueous layer was extracted with ether, from which the acidic material was transferred into 5% potassium hydroxide solution. Upon evaporation of the ether, the organic layer gave a small amount of a solid melting at 220~221°C after recrystallization from benzene.

Anal. Found: C, 81.22; H, 6.90%.

This was not investigated further because of the small amount available. The alkaline solution which contained the acidic material was acidified with hydrochloric acid to afford a very viscous oil, which was not studied further.

1-Methyl-2-hydroxymethyl-naphthalene (XVIIIa).—To a slurry of 5.75 g. of lithium aluminum hydride in 120 cc. of ether, a solution of 16 g. of 1-methyl-2-naphthoic acid in 340 cc. of ether was added taking more than 30 min., and the mixture was refluxed for 1 hr. on a water bath. After the excess of the reducing reagent was destroyed with ethyl acetate, the white voluminous precipitate was dissolved in dilute hydrochloric acid, and extracted with ether. The ether extract was washed with water, sodium bicarbonate solution and water. Removal of the solvent gave 14.0 g. of crystals melting at 124~126°C, which were recrystallized from benzene, m. p. 126~126.5°C.

Anal. Found: C, 83.88; H, 7.26. Calcd. for $C_{12}H_{12}O$: C, 83,69; H, 7.02%.

1-Methyl-2-bromomethyl-naphthalene (XVIIIb).—To a solution of 25.3 g. of the alcohol XVIIIa in 90 cc. of acetic acid, 63 g. of acetic acid saturated with hydrobromic acid was added for more than 15 min. After the solution was heated at 50~52°C for 20 min., the precipitate was collected (35.1 g.). Recrystallization from acetic acid afforded crystals melting at 68~69°C, 41.3 g. (yield, 90.6%).

For analysis this was further recrystallized from ligroin to give crystals melting at 69~70°C.

Anal. Found: C, 61.37; H, 4.97. Calcd. for $C_{12}H_{11}Br$: C, 61.28; H, 4.68%.

1-Methyl-2-cyanomethyl-naphthalene (XVIIIc).—A mixture of 10 g. of the bromide XVIIIb, 100cc. of ethanol, 5.0 g. of potassium cyanide and 20 cc. of water was refluxed for 5.5 hr. After the ethanol was removed, 300 cc. of water was added to the solution to precipitate a solid which showed m. p. at 75.5~76.5°C after recrystallization from ligroin, and weighed 7.2 g. (yield, 93.5%).

Anal. Found: C, 85.97; H, 6.24; N, 7.98. Calcd. for $C_{13}H_{11}N$: C, 86.16; H, 6.12; N, 7.73%.

(1-Methyl-2-naphthyl)-acetic Acid (XVIIId) and its Amide (XVIIIe).—A mixture of 6.8 g. of the cyanide XVIIIc, 10 cc. of acetic acid, 10 cc. of concentrated hydrochloric acid and 10 cc. of water was refluxed for 30 min. After cooling, crystals (m. p. 146~158°C) were collected and washed with 5% sodium hydroxide solution to remove the acid XVIIId. The amide could be further hydrolyzed with concentrated hydrochloric acid and acetic acid to give the acid

XVIIId.

Anal. Found: C, 78.36; H, 6.60; N, 7.05. Calcd. for $C_{13}H_{13}ON$: C, 78.36; H, 6.58; N, 7.03%.

The alkaline extract was acidified to precipitate the acid XVIIId which was recrystallized from benzene to afford prisms, m. p. 165~166°C, weighed 5.7 g.

Anal. Found: C, 78.00; H, 6.03. Calcd. for $C_{13}H_{12}O_2$: C, 77.98; H, 6.04%.

When an attempt was made to hydrolyze the crude cyanide XVIIIc directly, the overall yield of the acid was 83%.

2-(1-Methyl-2-naphthyl)-ethanol (XIXa).—To a slurry of 5.03 g. of lithium aluminum hydride in 120 cc. of ether, was added a solution of 14 g. of the acid XVIIId in 300 cc. of ether with stirring for more than 30 min., and the mixture was refluxed for 3 hr. The excess of the reducing reagent was destroyed with 20 cc. of ethyl acetate, and the mixture was decomposed with dilute hydrochloric acid.

The organic layer was separated and the aqueous layer was extracted with ether. After drying, removal of the ether gave an oil, which was distilled to give a liquid boiling at 140~143°C/1 mmHg and weighing 11.7 g. (yield, 90.0%). For analysis a small sample was recrystallized from ligroin, m. p. 54~55°C.

Anal. Found: C, 83.95; H, 7.63. Calcd. for $C_{13}H_{14}O$: C, 83.83; H, 7.58%.

1-Bromo-2-(1-methyl-2-naphthyl)-ethane (XIXb).—To a solution of 17.5 g. of the alcohol XIXa in 60 cc. of benzene, 19 g. of phosphorus tribromide in 24 cc. of benzene was added taking more than 25 min., and the mixture was stirred for 3 hr. at 60~70°C. The reaction mixture was poured onto crushed ice, and the bromide was taken into ether. After the ether layer was washed with saturated sodium chloride solution and water, it was dried over anhydrous sodium sulfate. Removal of the solvent gave a liquid, which was distilled to afford the bromide XIXb, boiling at 124~126°C/0.006 mmHg and weighing 14.4 g. (yield, 61.5%).

Anal. Found: C, 63.10; H, 5.50. Calcd. for $C_{13}H_{13}Br$: C, 62.60; H, 5.23%.

Diethyl 1-(1-Methyl-2-naphthyl)-3, 3-propanedicarboxylate (XIXc).—Under 40 cc. of xylene, 2.52 g. of sodium was pulverized, and the xylene was decanted off and replaced by 18 cc. of benzene. To this mixture, 16.2 cc. of absolute ethanol was added for more than 5 min., and heated for 5 min. After 25.2 cc. of diethyl malonate was added over a period of 10 min., the solution was heated for 10 min. on a water bath, and a solution of 14.3 g. of the bromide XIXb in 118 cc. of benzene was added taking more than 20 min. Then the mixture was heated at 60~63°C for 8 hr. at 70°C for 2 hr., and refluxed for an additional 4 hr. The solution was poured onto ice, acidified with diluted hydrochloric acid, and extracted with ether. The ether extract was washed with water and dried. The residue, obtained by evaporation of the solvent, was distilled to give an oil, b. p. 160~165°C/0.005 mmHg. Yield, 18.1 g. (96.3%).

Anal. Found: C, 72.00; H, 7.41. Calcd. for $C_{20}H_{24}O$: C, 73.14; H, 7.37%.

Triethyl 5-(1-Methyl-2-naphthyl)-2, 3, 3-pentanetricarboxylate (XXa).—To a solution of potassium *tert*-butoxide in *tert*-butanol, provided from 1.1 g. of potassium and 26 cc. of *tert*-butanol in an atmospher of nitrogen, 8.0 g. of the diethyl ester XIXc was added, the mixture was stirred for 3 min. at room temperature, and 5.4 g. of ethyl α-bromopropionate was added for more than 10 min. The solution was stirred for an additional 30 min. After the *tert*-butanol was removed, the residue was poured into ice water and extracted with ether. After washing with water and drying, the solvent was removed to leave an oil, which was distilled at 195~200°C/0.006~0.008 mmHg. Yield, 9.5 g. (91.5%).

Anal. Found: C, 70.08; H, 7.59. Calcd. for $C_{25}H_{32}O_6$: C, 70.07; H, 7.53%.

5-(1-Methyl-2-naphthyl)-2, 3-pentanedicarboxylic Acid (XXc).—A solution of 11.7 g. of the ester XXa in 40 cc. of methanol was added to a solution of 26.5 g. of potassium hydroxide in 93 cc. of methanol and the mixture was refluxed for 1hr., to precipitate the potassium salt. Water (34 cc.) was added and the mixture was refluxed for 2 hr. After the addition of 30 cc. of water, the methanol was removed and 50 cc. of water was added to the solution. Unsaponified material was removed with ether, and the aqueous layer was acidified with 6 N hydrochloric acid. The tricarboxylic acid was extracted with ether. The ether was removed to give a semisolid which was decarboxylated by heating at 180~185°C. The acid was taken into 10% sodium hydorxide solution, precipitated with 6 N hydrochloric acid, and then extracted with ether. Removal of the ether gave 8.5 g. of tan-yellow semisolid, which was cyclized to XXa without further purification.

α-2-(10-Methyl-1-oxo-1, 2, 3, 4-tetrahydroanthryl)-propionic Acid (XXIa).—To a solution of 3.8 g. of the dicarboxylic acid XXc in 30 cc. of benzene, 9.7 g. of phosphorus pentachloride was added with stirring, and the mixture was heated at 20°C for 1 hr., and at 45°C for 5 min. To the cold stirred solution, a solution of 37.0 g. of stannic chloride in 15 cc. of benzene was added taking more than 5 min., and the mixture was stirred for 1 hr. at room temperature. The mixture was poured onto a mixture of 200 g. of ice and 30 cc. of concentrated hydrochloric acid, and extracted with ether. The ether extract was washed with water and shaken with 10% sodium hydroxide solution to extract the acid XXIa. The ketoacid (1.15 g., m.p. 179.5~181.5°C) was obtained by acidification followed by extraction with ether, and recrystallized from benzene to give needles melting at 181~182°C.

Anal. Found: C, 76.58; H, 6.59. Calcd. for $C_{18}H_{18}O_3$: C, 76.57; H, 6.45%.

The infrared spectrum indicated peaks at 6.00 and 5.90 μ.

α-2-(10-Methyl-1, 2, 3, 4-tetrahydroanthryl)-propionic Acid (XXIb).—A mixture of 1.0 g. of the ketoacid XXIa, 5 g. of zinc amalgam, 6 cc. of acetic acid and 6 cc. of concentrated hydrochloric acid was covered with a layer of 4 cc. of toluene

and the whole was refluxed for 24 hr., while 1 cc. of concentrated hydrochloric acid was added to the solution every four hours (5 cc. in total). The solution, freed from excessive zinc, was diluted with water and extrated with ether. After the ether layer was washed with water and dried over anhydrous sodium sulfate, the solvent was removed to give crystals melting at 133~154°C and weighing 0.48 g. From mother liquor the second crop (0.28 g.) was obtained, m. p. 133~138°C. The combined material was recrystallized from dilute methanol to give a mixture of stereoisomers of the acid XXIb. The infrared spectrum showed peaks at 5.85 μ and lacked the carbonyl band at 6.00 μ of the ketocarboxylic acid XXIa.

Anal. Found: C, 80.87; H, 7.66. Calcd. for $C_{18}H_{20}O_2$: C, 80.56; H, 7.51%.

Methyl β-2-(10-Methyl-1, 2, 3, 4-tetrahydroanthryl)-butyrate (XXIc).—To a solution of 1.58 g. of the carboxylic acid XXIb in 19 cc. of benzene, 5 cc. of thionyl chloride was added and the mixture was heated on a water bath for 1 hr. After removal of the thionyl chloride and benzene in vacuo, 10 cc. of benzene was added and the solvent was evaporated so as to remove the excess of the thionyl chloride completely, and the residue was dissolved in 20 cc. of cold benzene. This solution of the acid chloride was added to a dried etheral solution of diazomethane provided from 6.3 g. of nitrosomethylurea. The reaction mixture was allowed to stand in an ice bath for 50 min., and at room temperature for 3 hr., while vigorous effervescence was observed. After the solvent was evaporated below 25°C, the residue was dissolved in 20 cc. of methanol and the solution was added to a slurry of 0.4 g. of silver oxide in 40 cc. of methanol and the mixture was refluxed for 2 hr.[29] The solution was filtered, and 0.2 g of silver oxide was added. After refluxing for 30 min., again 0.2 g. of silver oxide was added and the mixture was refluxed for an additional 30 min. After filtering off the silver and silver oxide, the solvent was removed to give a viscous liquid weighing 1.38 g., which was directly dehydrogenated to the ester XXIIa.

β-(10-Methyl-2-anthryl)-butyric Acid (XXIIb).—A mixture of 1.35 g. of the methyl ester XXIc and 0.2 g. of 30% Pd/C[30] was heated in an atmosphere of nitrogen at 250~280°C for 12 min. at 290~300°C for 1 hr. and at 310°C for 30 min. The reaction mixture was taken into boiling benzene, and freed from the catalyst. Removal of the solvent afforded a viscous orange oil possessing violet-green fluorescence. Beside the carbonyl band at 5.75 μ, the infrared spectrum showed peaks at 12.3 and 11.9 μ which are characteristic of the 1, 2, 4-trisubstituted benzene nucleus. The methyl ester was directly hydrolyzed. The mixture of 1.11 g. of the ester, 3 cc. of 40% potassium hydroxide solution, 5 cc. of water and 5 cc. of methanol was refluxed for 2 hr. in an atmosphere of nitrogen. After cooling, water was added and the solution was washed with ether to remove unsaponified material. The aqueous layer was acidified with hydrochloric acid, and extracted with ether. The ether extract was washed with water and dried. Removal of the solvent left an oil, which could be brought to crystallization by trituration with a small amount of benzene. The crystals collected weighed 0.60 g. and melted at 148~153°C. These were recrystallized from benzene to yield 0.5 g. of the acid XXIIb, m. p. 154~157°C. From mother liquor, the second crop (0.28 g., m. p. 157~158°C) was obtained by sublimation at 0.5 mmHg. The combined crystals were recrystallized from benzene, m. p. 160~160.5°C. The infrared spectrum showed peaks at 5.90 μ (carboxyl group) and 12.3 μ (1, 2, 4-trisubstituted benzen nucleus). The ultraviolet spectrum in ethanol indicated the following maxima: λ_{max} mμ (log ε): 258 (5.20), 332 (3.41), 347 (3.66), 365 (3.80), 385 (3.75).

Anal. Found: C, 82.07; H, 6.74. Calcd. for $C_{19}H_{18}O_2$: C, 81.98; H, 6.52%.

1-Oxo-3,6-dimethyl-2, 3-dihydro-1*H*-cyclopent[*a*]-anthracene (XXIIIa).—To a solution of 0.68 g. of the carboxylic acid XXIIb in 20 cc. of benzene, 0.9 g. of phosphorus pentachloride was added and the mixture was stirred for 30 min. at 0°C and 1 hr. at room temperature. To the well chilled and stirred solution, a solution of 0.6 g. of stannic chloride in 2 cc. of benzene was added and the mixture was stirred for 30 min. at 0°C and 1 hr. at room temperature. The reaction mixture was decomposed with a cold solution of 7 cc. of concentrated hydrochloric acid in 30 cc. of water, and extracted with ether. The ether extract was washed with 6 N hydrochloric acid, water, 5% sodium carbonate solution, and water. After drying, the solvent was removed to yield a residue which gave 0.41 g. of crystals, m. p. 135~141.5°C, upon trituration with methanol. For analysis they were recrystallized from methanol to afford needles, m. p. 142~143.5°C. The infrared spectrum indicated peaks at 5.93 μ, and the ultravioled spectrum is shown in Table I.

Anal. Found: C, 87.47; H, 6.23. Calcd. for $C_{19}H_{16}O$: C, 87.66; H, 6.17%.

3, 6-Dimethyl-2, 3-dihydro-1*H*-cyclopent[*a*]-anthracene (IV).—A mixture of 0.32 g. of the ketone XXIIIa, 5 g. of zinc amalgam, 5 cc. of concentrated hydrochloric acid, 5 cc. of acetic acid and 5 cc. of toluene was refluxed for 22 hr., while 7.5 cc. in total of concentrated hydrochloric acid was added from time to time. After the solution was cooled, the toluene layer was separated and the aqueous layer was extracted with ether. The combined toluene solution and ether were washed with water and dried over anhydrous sodium sulfate. Removal of the solvent yielded 0.265 g. of an orange oil with blue green fluorescence, which was dissolved in 40 cc. of benzene and chromatographed on 15 g. of alumina. Elution with 40 cc. of benzene gave 216 mg. of a pale yellow liquid. This was dissolved in 15 cc. of petroleum ether, and chromatographed again on

Spectrophotometric Study of the Iodine-Complexes of cis- and trans-Stilbene

By Shigeru YAMASHITA

(Received March 25, 1959)

Results of the experiments[1], carried out recently in this laboratory, on the iodine-catalyzed *cis-trans* isomerization of stilbene in *n*-hexane led to the suggestion that the molecular complex formed between iodine and stilbene may play an important role in the photochemical as well as in the thermal isomerization at low temperatures around room temperature. It seemed then desirable to investigate the equilibria in the formation of iodine-complexes of both *cis-* and *trans*-stilbene quantitatively, since only limited information was available about these equilibria and related thermodynamic quantities. The present paper reports a spectrophotometric study of these complexes. The equilibrium constants, the heats and the entropy changes for the formation of iodine-complexes of *cis*-stilbene in *n*-hexane and of *trans*-stilbene in *n*-hexane and in carbon tetrachloride have been determined.

Experimental

Materials.—*Iodine.*—The commercial reagent of special grade was used without any further purification.

cis-Stilbene.—The preparation described in "Organic Syntheses"[2] was followed. After several repetitions of vacuum distillation, the product (b. p. 114~119°C/3.5~4.0 mmHg) was stored in the dark under reduced pressure. The absorption curve was in good agreement with that previously reported[3].

trans-Stilbene.—The commercial reagent (m. p. 119~120°C) was used without any further purification. The absorption curve was again in good agreement with that previously reported[3].

n-Hexane.—The commercial reagent of chemically pure grade was treated with fuming sulfuric acid, concentrated sulfuric acid and an aqueous solution of potassium permanganate, successively. After drying over anhydrous calcium chloride, the product was fractionally distilled.

Carbon tetrachloride.—The commercial reagent was successively treated with potassium hydroxide and anhydrous calcium chloride and then fractionally distilled.

Methods.—The absorption spectra were measured with an EPB-U type Hitachi-spectrophotometer. A quartz cell with a glass stopper (10.0 mm. light path) was used for the measurement in all wavelength regions.

The temperature of the absorption cell was kept constant in a water-circulating thermostat equipped with windows, as described by Bell[4].

4) P. H. Bell, *Science*, **105**, 15 (1947).

All the operations were carried out in a dark place in order to avoid the occurrence of iodine-catalyzed *cis-trans* photoisomerization of stilbene.

Results and Discussion

Visible Absorption Bands of Iodine-Stilbene Complexes.—Iodine has an absorption maximum at 520 mμ in *n*-hexane, its absorbance over the range from 430 to 270 mμ being very weak. *cis*-Stilbene shows no absorbance in the range longer than 350 mμ in the same solvent. As *cis*-stilbene is added in increasing amounts to a dilute solution of iodine in *n*-hexane, the absorption peak at 520 mμ characteristic of the free iodine diminishes and is replaced by a new peak at 420 mμ as shown in Fig. 1. This new peak at 420 mμ may, therefore, be interpreted as a blue shift of iodine such as is frequently observed for iodine-complexes[5]. The charge-transfer band of the complex which may also be expected to appear in a still shorter wavelength region has not been studied in this work on account of difficulties due to the overlapping intense absorption of *cis*-stilbene.

Preliminary experiments in which the ratio of concentration of iodine to that of *cis*-stilbene was varied, keeping the sum of these constant, showed that the optical density at the absorption maximum was greatest in the equimolar mixture,

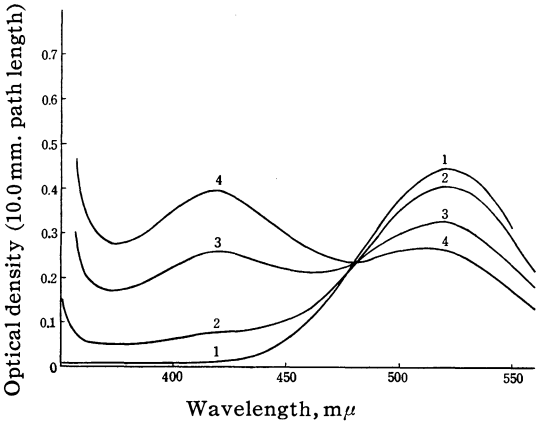

Fig. 1. Variation of the absorption band of iodine with increasing concentration of *cis*-stilbene: solvent, *n*-hexane; temperature, 24°C; concentration of I_2, 5.0×10^{-4} M; concentrations of *cis*-stilbene, 0, 2.0×10^{-2}, 1.0×10^{-1}, and 1.9×10^{-1} M for curves 1—4, respectively.

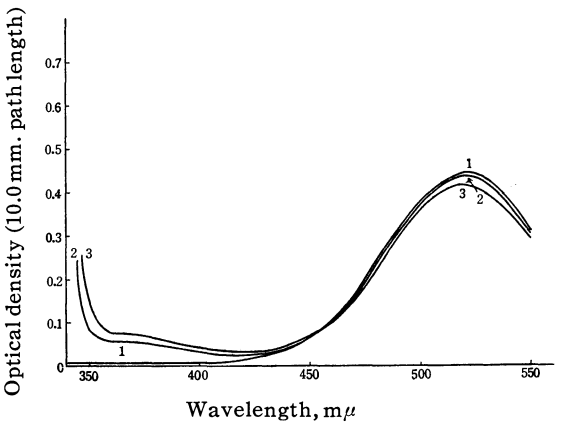

Fig. 2. Variation of the absorption band of iodine with increasing concentration of *trans*-stilbene: solvent, *n*-hexane; temperature, 24°C; concentration of I_2, 50×10^{-4} M; concentrations of *trans*-stilbene, 0, 5.0×10^{-2}, 9.5×10^{-2} M for curves 1—3, respectively.

indicating that the composition of the complex formed is 1 : 1. Isosbestic points such as those seen in Fig. 1 and less clearly in Fig. 2 have frequently been observed for 1 : 1 complexes.

Results obtained with *trans*-stilbene in the same solvent were, on the whole, similar to those with *cis*-stilbene. Here, however, the equilibrium constant for the complex formation has a lower value than for *cis*-stilbene as shown below. Consequently, the new maximum at 365 mμ which may again be taken as a blue shift of iodine is, as seen in Fig. 2, less sharp than that for *cis*-stilbene.

Andrews and Keefer[6a] reported an absorption maximum at 373 mμ, and a molar extinction coefficient of 7140 at this wavelength for the iodine-complex of *trans*-stilbene in carbon tetrachloride. In order to compare them with these results[6], measurements in carbon tetrachloride have been traced for the iodine-complex of *trans*-stilbene. The results obtained, together with those in *n*-hexane, are given in Table I where molar extinction coefficients determined as described below are included. As for the *trans*-stilbene complex in carbon tetrachloride, the values of λ_{max} obtained by the present author and by Andrews and Keefer agree with each other, but those of ε_{max} differ considerably from each other. Though the reason for the discrepancy in ε_{max} is not

5) H. A. Benesi and J. H. Hildebrand, *J. Am. Chem. Soc.*, **71**, 2703 (1949); C. Reid and R. S. Mulliken, ibid., **76**, 3869 (1954); S. Nagakura, ibid., **80**, 520 (1958); P. A. D. de Maine, *J. Chem. Phys.*, **26**, 1192 (1957).

6) (a) L. J. Andrews and R. M. Keefer, *J. Am. Chem. Soc.*, **74**, 4500 (1952); see also (b) R. Bhattacharya and S. Basu, *Trans. Faraday Soc.*, **54**, 1286 (1958).

clear yet*, Table I shows that all the values of ε_{max} found in this work for the iodine-stilbene complexes are nearly equal to each other and are of the same order of magnitude as those for free iodine. This is consistent with the interpretation that the observed absorption maxima are caused by the blue shifts of iodine since ε_{max} of the blue shift does not differ much from that of free iodine for many iodine-complexes, while far greater values, around 10000, have been reported for charge-transfer bands[5,7].

Equilibrium Constants.—Equilibrium constants for the iodine-stilbene complexes were determined, as usual, by a series of experiments in which the concentration of the donor component was varied, keeping that of iodine constant. As the latter concentration was relatively low in this work, the following equation[8,9] was applied to the optical densities obtained at respective absorption maxima.

$$1/(\varepsilon_A-\varepsilon_F) = 1/(\varepsilon_C-\varepsilon_F)(1/K_C)(1/C_D) + 1/(\varepsilon_C-\varepsilon_F) \quad (1)$$

n this equation ε_F and ε_C are, respectively, the molar extinction coefficients for free iodine and the complex in the mixture, and $\varepsilon_A = d/[(I_2)l]$, where d is the measured optical density of the solution containing the complex, (I_2) is the total concentration of iodine (free and complexed) and l is the path length of the absorption cell (1 cm.); C_D is actually the concentration of donor left free in the mixture but can be equated to its total concentration when an amount much greater than that of iodine is employed, as was the case in the present work; K_C is the equilibrium constant for the formation of the 1:1 complex.

Figs. 3 and 4 show that the linear relation required by Eq. 1 between $1/(\varepsilon_A-\varepsilon_F)$ and $1/C_D$ holds for *cis*- as well as for *trans*-stilbene in *n*-hexane, indicating that the compositions of these complexes are equally 1:1, as already inferred for

cis-stilbene. Silmilar results were obtained with *trans*-stilbene in carbon tetrachloride. Values of ε_C calculated from intercepts of these straight lines have already been

* Andrews and Keefer determined ε_{max} from the intercept of a Benesi-Hildebrand plot at 25°C using the optical densities corrected for free iodine. Their extrapola tion at a single temperature is liable to produce a considerable error; however, it is not clear whether this is the sole reason for the large discrepancy in question. In the present work, as seen in Figs. 3 and 4, extrapolations at five different tempertures gave a constant intercept, making the value of ε_{max} thus determined much more reliable.

given in Table I as ε_{max}'s and those of K_C obtained from the slopes are listed in Table II.

Heats and Entropy Changes.—Fig. 5 shows plots of $\log K_C$ against the reciprocal temperature for the three systems investigated. The heats of the complex formation obtained from these plots are given in Table III, together with free energy and entropy changes calculated at 25°C. As seen in the table, the change of solvent from *n*-hexane to carbon tetrachloride produces only slight changes, as would usually be expected, while there exist significant differences between the values for *cis*- and *trans*-stilbene. Apparently, *cis*-stilbene forms a more stable and rigid complex with iodine than *trans*-stilbene. A plausible explanation for such a difference may be given as follows. Since the molecule of stilbene is planar in the *trans*-form and also nearly planar in the *cis*-form[10], iodine will attach to either form of stilbene on either side of its molecular plane to form a molecular complex.

trans-Stilbene has, however, two phenyl groups projected almost in the opposite direction, while *cis*-stilbene has a bent and therefore much more compact structure. Hence the complex of *cis*-stilbene may have a more rigid structure than that of *trans*-stilbene, and, at the same time, the former complex may be more stable owing primarily to a greater van der Waals attraction.

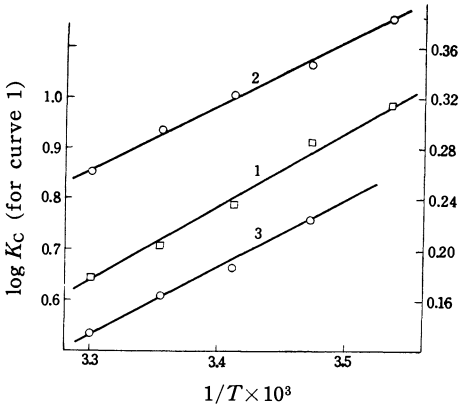

Fig. 5. Plots of $\log K_C$ vs. $1/T$:
1, I_2+*cis*-stilbene in *n*-hexane;
2, I_2+*trans*-stilbene in *n*-hexane;
3, I_2+*trans*-stilbene in carbon tetrachloride.

The author is particularly indebted to Professor O. Toyama of the College of Engineering and to Dr. T. Hayakawa for their discussions and encouragement during this investigation. The author wishes also to thank Mr. Y. Hayashibara for his assistance. A part of the expense of this study has been defrayed by the Scientific Research Grant from the Ministry of Education.

The Crystal Structure of Bis(glutaronitrilo)copper(I) Nitrate

By Yukio KINOSHITA, Ikuo MATSUBARA and Yoshihiko SAITO*

(Received April 2, 1959)

In a previous paper[1] the authors have reported the crystal structure of bis-(succinonitrilo)copper(I) nitrate. As a continuation of our crystallographic study of a series of complexes prepared from nitriles of aliphatic dibasic acids and univalent copper, the present paper reports the determination of the crystal structure of bis(glutaronitrilo)copper(I) nitrate, $[Cu(NC\text{-}CH_2\text{-}CH_2\text{-}CH_2\text{-}CN)_2]NO_3$. This work was undertaken to elucidate the mechanism of cuprous ion dyeing of polyacrylonitrile fibers[2], and the structure of bis(glutaronitrilo)copper(I) nitrate may be particularly interesting in this complex series, because, as Rath et al.[3] have suggested, it is considered to be most suitable as the model substance of the polyacrylonitrile fibers dyed with cuprous ion technique.

Experimental

Bis(glutaronitrilo)copper(I) nitrate was prepared according to the directions of Rath et al.[3] similar to those described in the previous paper[1].

Anal. Found: C, 38.15; H, 4.08; N, 22.12; Cu, 20.27. Calcd. for $C_{10}H_{12}N_5O_3Cu$: C, 38.28; H, 3.86; N, 22.32; Cu, 20.25%.

Minute prismatic crystals were chosen for X-ray study in order to minimize the effects of absorption.

Rotation and Weissenberg photographs, taken with Cu $K\alpha$ radiation ($\lambda=1.542$ Å), showed the crystals to be tetragonal with $a=8.25\pm0.01$ Å, and $c=9.71\pm0.01$ Å.

The observed extinction, $(h\,h\,l)$ with $l=2n+1$ and $(h\,0\,0)$ with $h=2n+1$, is characteristic of the space group $P\bar{4}2_1c$–D_{2d}^4.

The observed density of the crystals, measured by flotation, is 1.587 g./cc., while the density calculated on the basis of two formula units in each unit cell is 1.577 g./cc.

Complete intensity data for the $(h\,k\,0)$ and $(0\,k\,l)$ zones were obtained from Weissenberg photographs in conjunction with the multiple film technique. The $(h\,k\,0)$ data comprise 41 different reflections out of a total of 48 that are accessible, and the $(0\,k\,l)$ data represent 95 forms out of all 106 forms available.

All intensities were estimated visually. After being corrected for the Lorentz and polarization factors, the intensities were reduced to relative F_o values which were later converted into absolute values by comparison with calculated ones.

Determination of Atomic Positions

In the space group $P\bar{4}2_1c$ there are two independent sets of twofold positions: 000; $\frac{1}{2}\frac{1}{2}\frac{1}{2}$ and $00\frac{1}{2}$; $\frac{1}{2}\frac{1}{2}0$. Since there are two formula units of $[Cu(NC\text{-}CH_2\text{-}CH_2\text{-}CH_2\text{-}CN)_2]NO_3$ in each unit cell, the copper atoms and the nitrogen atoms of nitrate ions must occupy these positions; the copper atom may be placed arbitrarily at the origin and the nitrogen atoms at $00\frac{1}{2}$. The point symmetry of these twofold positions is $\bar{4}$. This is in accordance with the expected tetrahedral coordination of a univalent copper atom. The nitrate ions thus centered at $00\frac{1}{2}$ are also required to have the same symmetry. However, trigonal nitrate ions could have the apparent symmetry $\bar{4}$ only if disorder exists in the crystal. The central carbon atom of each glutaronitrile molecule must occupy one of the two sets of fourfold positions and all other atoms probably lie on general positions. Consequently a glutaronitrile molecule must have a twofold axis of symmetry. Patterson projections upon (001) and (100) were calculated. These served to confirm the arrangement of heavy atoms. Both Patterson projections could be readily solved on the basis of the knowledge of interatomic distances and bond angles obtained for crystals of bis(succinonitrilo)copper(I) nitrate[1], and the orientation of the glutaronitrile molecule in the crystal could be successfully deduced. In this way, all the coordinates of atoms except those of oxygen atoms were approximately fixed. It is almost evident that the phase angles of the structure factors for a complete set can be determined on the

basis of these parameters. Fourier projections of electron density, $\rho(xy)$ and $\rho(yz)$ were then evaluated, the phase angles of which were calculated from the above mentioned parameter values. The projections so obtained showed the heavy copper atoms as well as ligand molecules clearly resolved, together with rather faint outlines of oxygen atoms in the nitrate ions. From the distribution of peaks around the nitrogen atoms, statistical orientations of nitrate ions were deduced. Calculation of structure amplitudes including the contribution of oxygen atoms improved the agreement

between calculated and observed intensities. The best agreement is found if the nitrate ions lie perpendicularly to the *c*-axis, taking four different azimuthal orientations in such a way that the direction of one N–O bond coincides with one of the *a*-axis. Thus the apparent symmetry of the nitrate ions becomes $\bar{4}$, in accordance with the requirement of the space group. Although structure factors were also calculated under the assumption of free rotation of nitrate ions, the result gave a slightly greater *R*-value.

By the usual method of successive approximation the final projections were obtained. The final Fourier projections upon (001) and (100) are shown in Figs. 1 and 2, respectively. The final atomic coordinates are listed in Table I. Observed and calculated structure factors as well as phase angles are listed in Table II. The agreement on the whole is quite good and values of $R=\sum||F_o|-|F_c||/\sum|F_o|$ are 0.106 and 0.117 for $(h\,k\,0)$ and $(0\,k\,l)$, respectively. In the calculation of the structure factors, the atomic scattering curves calculated by Berghuis et al.[4] were employed. A temperature correction, $\exp -B(\sin\theta/\lambda)^2$, was applied with $B=3.0$ Å^2.

Interatomic distances and bond angles calculated on the basis of the atomic parameters listed in Table I are given in Table III.

TABLE III. INTERATOMIC DISTANCES AND BOND ANGLES

Calculation of the structure factors as well as that of the electron density was carried out with a Remington Rand UNIVAC 120 electronic computer quite effectively.

Description of the Structure

The projections of the structure of bis-(glutaronitrilo)copper(I) nitrate upon (001) and (100) are shown in Figs. 3 and 4, respectively. It consists of infinite two-dimensional networks of the complex ion $[Cu(NC-CH_2-CH_2-CH_2-CN)_2]_n^{n+}$ and nitrate ions. A copper atom is tetrahedrally surrounded by four nitrogen atoms at a distance of 1.98 Å. Each glutaronitrile molecule is coordinated to two different copper atoms with nitrogen atoms at both ends. As a consequence, all the copper atoms in a plane perpendicular to the *c*-axis are linked together with ligand molecules, forming a two-dimensional network of complex ions. A glutaronitrile molecule possesses a twofold axis of symmetry and takes a *gauche-gauche* configuration with respect to the C_2–C_3 and C_3–$C_{2'}$ bonds. The angles of internal rotation were found to be 115° with the *trans* position taken as the origin. The carbon-carbon distances and bond angles agree well with those usually found in other organic crystals. The carbon-nitrogen bond distance is 1.14 Å and the Cu–N–C–C group is close to linear, which is similar to the case of bis(succinonitrilo)copper(I) nitrate. These facts indicate that the bond character of the carbon-nitrogen bond may be expressed as C≡N. Because of the rigidity of the triple bond and the tetrahedral coordination of copper atoms, the network of the complex ion is puckered. Nevertheless, the mode of packing of each layer is considered to be satisfactory with reasonable van der Waals distances between successive sheets. At the center of each mesh of the network of the complex ion a nitrate ion is located perpendicularly to the *c*-axis. The trigonal nitrate ion seems to have statistical azimuthal orientations and its apparent symmetry becomes $\bar{4}$. Just above and below the nitrate ion lie two copper atoms of adjacent layers at a distance of 4.86 Å, which should be compared with the corresponding distance of 4.77 Å found for the crystals of bis(succinonitrilo)copper(I) nitrate. That is to say, there is a cavity in the packed layers of the two-dimensional complex ions and a nitrate ion is at the center of the cavity. The interatomic distances between oxygen atoms of nitrate ions and the carbon atoms of the nearest methylene groups in the complex ion are longer than 3.14 Å. This is to be compared with the distance of 3.12 Å found between the carbon atom of a methylene group and the oxygen atom of a water molecule in the crystals of $[Co\,en_3]Cl_3\cdot 3H_2O$[5].

Further discussions of the structure will be made after the crystal structure of bis(adiponitrilo)copper(I) nitrate[6] has been determined.

Summary

The crystal structure of bis(glutaronitrilo)copper(I) nitrate has been determined by the two-dimensional Fourier method. It is tetragonal $P\bar{4}2_1c$ with two formula units in a cell of dimensions: $a=8.25\pm0.01$ Å and $c=9.71\pm0.01$ Å.

The crystal consists of infinite two-dimensional networks of complex ion $[Cu(NC-CH_2-CH_2-CH_2-CN)_2]_n^{n+}$ and nitrate ions. A copper atom is tetrahedrally surrounded by four nitrogen atoms at a distance of 1.98 Å. Each glutaronitrile molecule is coordinated to two different copper atoms with nitrogen atoms at both ends and takes a *gauche-gauche* configuration with respect to the two C–C bonds. The nitrate ions lie perpendicularly to the *c*-axis. The trigonal nitrate ions seem to have statistical azimuthal orientations in the crystal and the apparent symmetry of the nitrate ion is $\bar{4}$.

All the atoms in the group Cu–N–C–C lie approximately on a straight line. This fact and the observed carbon-nitrogen distance of 1.14 Å suggest that the bond character in the carbon-nitrogen group may essentially be expressed as C≡N.

The authors wish to express their hearty thanks to Dr. K. Hoshino and Dr. K. Kato of the Central Research Laboratories of Toyo Rayon Co., Ltd. for their kind encouragement in the course of this study. They also wish to thank Mr. K. Yoshida of Toyo Rayon Co., Ltd. for carrying out the mechanical computations.

The Crystal Structure of Bis(adiponitrilo)copper(I) Nitrate

By Yukio KINOSHITA, Ikuo MATSUBARA, Taiichi HIGUCHI* and Yoshihiko SAITO*

(Received April 27, 1959)

We have previously reported on the crystal structures of some complexes prepared from nitriles of aliphatic dibasic acids and univalent copper[1,2], which may be of interest in relation to the mechanism of cuprous ion dyeing of polyacrylonitrile fibers. In the course of our study on crystal structures of this series of complexes, the crystal structure of bis(adiponitrilo)copper(I) nitrate, $[Cu(NC-CH_2-CH_2-CH_2-CH_2-CN)_2]NO_3$, has been determined by means of two-dimensional Fourier methods.

The crystal structure will be discussed together with those of homologues reported in the previous papers, and some remarks will be made on the mechanism of dyeing polyacrylonitrile fibers.

Experimental

Bis(adiponitrilo)copper(I) nitrate was prepared according to the method of Rath et al.[3] by dissolving silver nitrate into adiponitrile at 60°C and adding an excess of copper powder. After some black spongy silver was deposited, the mixture was filtered. On cooling, the clear filtrate deposited yellowish crystals.

Anal. Found: C, 42.05; H, 4.70; N, 20.54; Cu, 18.52. Calcd. for $C_{12}H_{16}N_5O_3Cu$: C, 42.16; H, 4.72; N, 20.49; Cu, 18.59%.

The crystals are orthorhombic and the unit cell dimensions, as determined from rotation and Weissenberg photographs taken with Cu $K\alpha$ radiation ($\lambda=1.542$ Å), are $a=9.41\pm0.02$ Å, $b=13.73\pm0.02$ Å and $c=5.85\pm0.01$ Å. Systematic extinctions occur only for $(h\,k\,0)$ with $h+k$ odd, $(0\,k\,l)$ with $k+l$ odd and $(h\,0\,l)$ for $h+l$ odd. The space group is therefore $Pnnn-D_{2h}^2$.

Assuming two formula units in the unit cell, the calculated density is 1.502 g./cc., in good agreement with the measured density 1.516 g./cc.

The intensities of the spectra recorded on multiple-film zero-layer Weissenberg photographs were estimated visually and corrected for Lorentz and polarization factors. In view of the small size of the crystals no corrections were made

for the absorption effect. The resulting F^2's were correlated so that all observed data were on the same relative intensity scale. They were later converted into an absolute scale by comparison with calculated values.

Determination of Atomic Positions

Since the general point position in the space group *Pnnn* is eightfold, and since there are only two formula units of $[Cu(NC-CH_2-CH_2-CH_2-CH_2-CN)_2]NO_3$ in the unit cell, it follows that the copper atom must occupy one of the four sets of special positions; 0, 0, 0; 1/2, 1/2, 1/2, etc. All these positions are the intersecting points of three twofold axes which are parallel to the three principal axes respectively. Should the copper atoms occupy a set of these positions, the $(h\,k\,l)$ intensities should conform approximately to the extinction condition of body centered lattice. Equi-inclination Weissenberg photographs revealed that this condition was actually fulfilled. The positions of the copper atoms are, therefore, arbitrarily chosen as 0, 0, 0; 1/2, 1/2, 1/2.

Similarly the nitrogen atoms of nitrate ions must lie on a set of these special positions. The point symmetry of these twofold positions is 222. This is not in accordance with the trigonal symmetry of the nitrate ion. The nitrate ion could have apparent symmetry 222 only if disorder exists in the crystal.

The Patterson projections onto (001), (010) and (100) are very similar to the corresponding Fourier projections, since copper atoms at the origin and the center of the unit cell make all signs of zero-layer reflections positive and moreover the plane group symmetry of the Patterson projections are similar to that of Fourier projections. Therefore, preliminary Fourier projections were computed with all signs positive. Because the *c*-axis is as short as 5.85 Å, the extended chain form of methylene groups in the adiponitrile molecule, which apparently connects the copper atom at the origin with that at the center of the unit cell, is clearly shown on $P(uv)$ and $\rho(xy)$. Further, it has been found from $(0\,k\,l)$ data that the atoms in adiponitrile molecules are concentrated in (031) planes, because the orders of reflection from (031) are exceptionally intense and the intensity decreases through four orders according to a normal decline. Consideration of the above facts with the aid of the Patterson projection upon (100) has led to the conclusion that an adiponitrile molecule is coordinated with the nitrogen atoms of both ends to two copper atoms at 0, 0, 0 and at 1/2, 1/2, 3/2, taking a planar zigzag configuration. Thus the approximate coordinates of all the atoms in the ligand molecule could be fixed. However, from the Patterson projections and the preliminary Fourier maps of electron density only, locations of the atoms in the nitrate ions could not be fixed unequivocally. As a consequence, the approximate parameters of these atoms were determined by trial calculations of structure amplitudes. The best agreement between observed and calculated structure amplitudes was obtained when the nitrate ion was placed perpendicularly to the *a*-axis, taking four different azimuthal orientations as shown in Table I. Thus, the apparent symmetry of the nitrate ion becomes 222 in accordance with the requirement of the space group. Determination of the more precise atomic parameters was achieved by successive

TABLE I. FINAL ATOMIC COORDINATES

$C_3-C_{3'}$	1.53		
N_2-O	1.24		

A mean isotropic temperature factor with $B=3.0$ Å^2 was found to be satisfactory for the three principal zones. Calculation of electron density as well as that of structure factors were carried out on a Remington Rand UNIVAC 120 electronic computer quite effectively.

Description of the Structure

The projections of the structure of bis(adiponitrilo)copper(I) nitrate upon (001) and (100) are shown in Figs. 3 and 4, respectively.

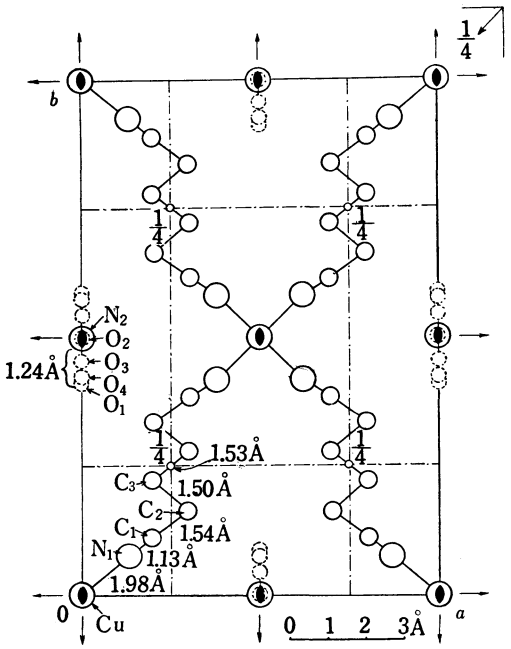

Fig. 3. Projection of the structure upon (001).

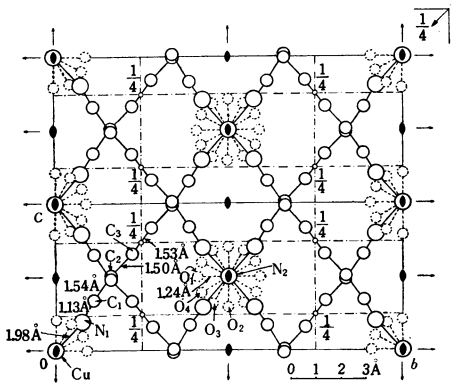

Fig. 4. Projection of the structure upon (100).

It is evident from the figures that the structure consists of infinite three-dimensional networks of the complex ion $[Cu(NC-CH_2-CH_2-CH_2-CH_2-CN)_2]_n^{n+}$ and nitrate ions. A copper atom is surrounded tetrahedrally by four nitrogen atoms at a distance of 1.98 Å, which is in good agreement with the corresponding values observed for the related compounds reported previously[1,2]. Each adiponitrile molecule is coordinated to two different copper atoms, resulting in a complicated three-dimensional network of the complex ion. A copper atom at the origin is linked to four copper atoms belonging to different unit cells at 1/2, 1/2, 3/2; −1/2, −1/2, 3/2; 1/2,

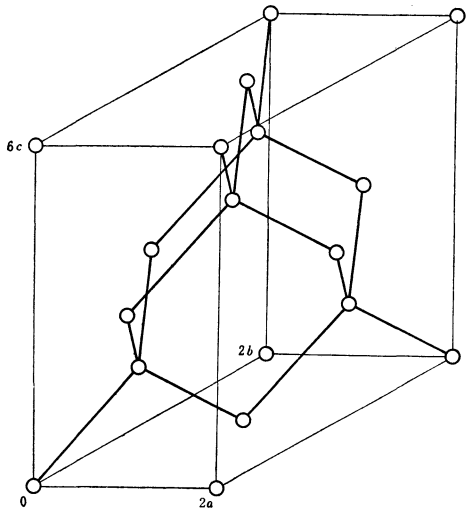

Fig. 5. Schematic diagram of a single 4-connected network in the crystal of bis(adiponitrilo)copper(I) nitrate.

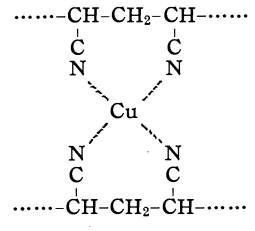

$-1/2, -3/2; -1/2, 1/2, -3/2$. In this way the copper atoms and the ligand molecules form a three-dimensional 4-connected network[4], in which all the copper atoms are arranged on a distorted diamond lattice and are linked by the ligand molecules with each other. Fig. 5 schematically illustrates the constitution of the network. The figure shows a single 4-connected network. For simplicity, adiponitrile molecules are drawn as straight lines connecting two copper atoms. The structure of bis(adiponitrilo)copper(I) nitrate consists of a superposition of six sets of this 4-connected network displaced through c with respect to each other.

Each adiponitrile molecule has a center of symmetry between the two central carbon atoms. All the carbon atoms of the adiponitrile molecule are less than 0.06 Å from the plane (031) and constitute a planar zigzag chain configuration, while the nitrogen atoms of nitrile groups are 0.10 Å distant from that plane. All the carbon-carbon bond lengths and bond angles in the methylene groups are close to normal values. The carbon-nitrogen bond distance is 1.13 Å and the Cu-N-C-C group is close to linear as in the cases of the related compounds reported previously[1,2]. These facts indicate that the bond character of the carbon-nitrogen bond may be expressed as C≡N.

The nitrate ions lie perpendicularly to the a-axis. The trigonal nitrate ion seems to have statistical azimuthal orientations in the crystal and its apparent symmetry becomes 222. The interatomic distances between the oxygen atoms of the nitrate ions and the carbon atoms of the nearest methylene groups in the complex ion are longer than 3.19 Å. This is to be compared with the corresponding value of 3.14 Å found in the crystals of bis(glutaronitrilo)-copper(I) nitrate[2].

Remarks on the Mechanism of Cuprous Ion Dyeing of Polyacrylonitrile Fibers

As pointed out in the previous paper[1], cuprous ion is readily absorbed by polyacrylonitrile fibers which then acquire an almost unlimited affinity for anionic dyes, which ordinarily can not be applied to this class of fibers. Blaker et al.[5] and Rath et al.[3] have suggested that the high affinity of cuprous ion for polyacrylonitrile is due to the inherent capability of nitrile groups in the fibers to absorb cuprous ion through formation of complexes, which may act as positive sites for fixation of dye anions. It has been established by the present investigations that, in the complexes prepared from univalent copper and nitriles of aliphatic dibasic acids, four nitrogen atoms of nitrile groups enter into combination with a cuprous ion, forming a stable tetrahedral complex. This fact strongly indicates that there may exist a strong interaction of the same kind between cuprous ions and nitrile groups of polyacrylonitrile molecules in the dyeing of fibers with cuprous ion technique. However, by analogy with the structures of these complexes it is very unlikely that stable chelate rings of the type,

are formed between cuprous ions and polyacrylonitrile molecules. In fact, it can easily be understood that such a chelate ring with reasonable bond distances and bond angles can never be obtained, owing to the rigidity of the Cu-N-C-C

4) For the definition of the term, see A. F. Wells, *Acta Cryst.*, **7**, 545 (1954).

5) R. H. Blaker, S. M. Katz, J. F. Laucius, W. R. Remington and H. E. Schroeder, *Discussions Faraday Soc.*, No. **16**, 210 (1954).

group. Therefore, Blaker and Rath's suggestion is only valid in the sense that the nitrile groups of polyacrylonitrile molecules are involved in the formation of complexes similar to those of simple nitriles as described in this and the preceding papers.

In the structures of these complexes, nitrate ions are located in cavities which are formed in the polymeric chain or network of complex ions owing to the rigidity of the Cu–NC–CH_2– group and the tetrahedral nature of the Cu–N bonds. This fact may suggest that in the polyacrylonitrile-Cu(I) complex the dye anions are trapped in cavities analogous to those mentioned above and are fixed by electrostatic interactions with the positive cuprous ions.

Summary

The crystal structure of bis(adiponitrilo)-copper(I) nitrate has been determined by the two-dimensional Fourier method. It is orthorhombic *Pnnn* with two formula units in a cell of dimensions: $a=9.41\pm0.02$ Å, $b=13.73\pm0.02$ Å and $c=5.85\pm0.01$ Å.

The crystal consists of infinite three-dimensional networks of complex ion $[Cu(NC-CH_2-CH_2-CH_2-CH_2-CN)_2]_n^{n+}$ and nitrate ions. A copper atom is tetrahedrally surrounded by four nitrogen atoms at a distance of 1.98 Å. Each adiponitrile molecule is coordinated to two different copper atoms with nitrogen atoms of both ends, forming a planar zigzag configuration of methylene groups. Thus the copper atoms and the ligand molecules form a complicated three-dimensional 4-connected network. The nitrate ions lie perpendicularly to the *a*-axis. The trigonal nitrate ion seems to have statistical azimuthal orientations in the crystal and its apparent symmetry becomes 222.

All the atoms in the group Cu–N–C–C lie approximately on a straight line. This fact and the observed carbon-nitrogen distance of 1.13 Å suggest that the bond character in the carbon-nitrogen group may essentially be expressed as C≡N.

On the basis of the structures of this and the other related complexes, some remarks have been made on the mechanism of cuprous ion dyeing of polyacrylonitrile fibers.

The authors wish to express their hearty thanks to Dr. K. Hoshino and Dr. K. Kato of the Central Research Laboratories of Toyo Rayon Co., Ltd. for their kind encouragement in the course of this study. They also wish to thank Mr. K. Yoshida of Toyo Rayon Co., Ltd. for carrying out the mechanical computations.

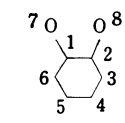
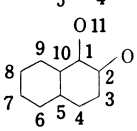
π-Electronic Structures of o-Quinones

By Akira KUBOYAMA



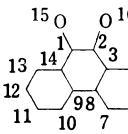
(Received April 17, 1959)

Previously[1], we studied the π-electronic structures of *p*-quinones (*p*-benzoquinone, α-naphthoquinone and anthraquinone) by the aid of the simple LCAO MO method and succeeded in explaining the following problems concerning the near UV absorption bands of the *p*-quinones: 1) a similarity among the $\pi-\pi$ transition bands of these *p*-quinones, 2) a relative magnitude of the $n-\pi$ transition energy of *p*-benzoquinone, α-naphthoquinone, and anthraquinone, 3) the effect of the electron-donating group on the $\pi-\pi$ transition bands of α-naphthoquinone and anthraquinone. In the present paper, similar theoretical studies have been extended to absorption spectra of *o*-quinones such as *o*-benzoquinone, β-naphthoquinone, and phenanthrenequinone. The calculations on β-naphthoquinone and phenanthrenequinone by the MO method have never been carried out. The obtained results are now reported.



1) A. Kuboyama, This Bulletin, 31, 752 (1958).

Method of Calculation

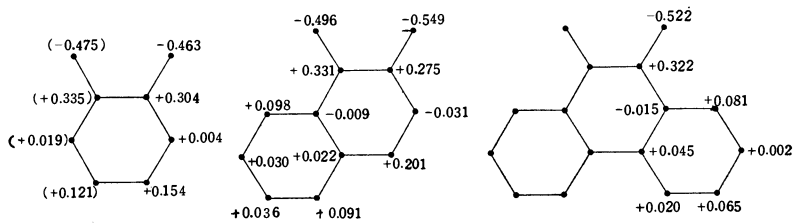


The method employed in the present calculation is exactly the same as that used in the case of *p*-quinones. The coulomb (α_i) and exchange (β_{ij}) integrals were determined on the basis of the same principles as described in the previous paper. They are as follows:

$\alpha_7=\alpha+1.3\beta$, $\alpha_1=\alpha+0.2\beta$
$\alpha_3=\alpha_4=\alpha$
$\beta_{17}=\beta_{34}=\beta$, $\beta_{12}=0.8\beta$
$\beta_{23}=\beta_{45}=0.9\beta$

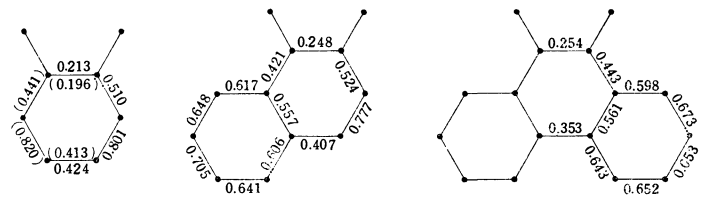
$\alpha_{11}=\alpha_{12}=\alpha+1.3\beta$
$\alpha_1=\alpha_2=\alpha+0.2\beta$
$\alpha_3=\alpha_4=\cdots\cdots=\alpha_9=\alpha_{10}=\alpha$
$\beta_{1-11}=\beta_{2-12}=\beta_{34}=\beta_{56}=\beta_{67}$
$=\cdots\cdots=\beta_{9-10}=\beta_{5-10}=\beta$
$\beta_{12}=0.8\beta$,
$\beta_{23}=\beta_{45}=\beta_{1-10}=0.9\beta$

$\alpha_{15}=\alpha+1.3\beta$, $\alpha_1=\alpha+0.2\beta$
$\alpha_3=\alpha_4=\alpha_5=\alpha_6=\alpha_7=\alpha_8=\alpha$
$\beta_{1-15}=\beta_{34}=\beta_{45}=\beta_{56}=\beta_{67}$
$=\beta_{78}=\beta_{38}=\beta$
$\beta_{12}=0.8\beta$, $\beta_{23}=\beta_{89}=0.9\beta$



Among these values, those concerning the quinone nuclei were set equal to the values evaluated for *o*-benzoquinone by the self-consistent method[2].

Results



The obtained molecular diagrams are given below.

In the above diagram, the unpaired electron densities are the ones in the lowest unfilled orbitals[3]. In the molecular diagram for *o*-benzoquinone the values in brackets are the ones previously calculated by the self-consistent method. The agreement between these two molecular diagrams for *o*-benzoquinone is substantially good. Further, the energy levels of *o*-benzoquinone calculated by the two methods mentioned above are in good agreement with each other. The energy levels evaluated with these quinones are given in Fig. 1. Furthermore, the dependence* of the energy levels upon the coulomb integral of the oxygen atom was

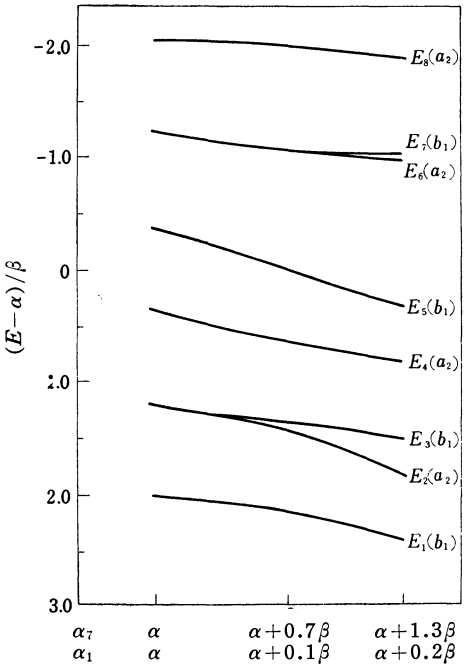

Fig. 2.

studied with *o*-benzoquinone. The result is shown in Fig. 2. The energy levels are classified according to the symmetry properties of the corresponding orbitals in the symmetry groups of these *o*-quinones (C_{2v}), taking the molecular symmetry axis as the x-axis and the molecular plane as the xy plane. For β-naphthoquinone which has no molecular symmetry axis, the symmetry properties of the orbitals are considered in relation to the quinone nucleus. The letters x and y attached to the arrow showing the transition between the energy levels denote the directions of the polarization in the allowed transitions. In phenanthrenequinone, the E_2 and E_6 orbital energies are a little lower than the E_3 and E_7 orbital energies, respectively.

Discussion

Molecular Diagrams. — The molecular diagrams of the three *o*-quinones are also similar in many points as well as those of the *p*-quinones. As for charge distributions, the negative charges of oxygen atoms slightly increase in the order of *o*-benzoquinone < β-naphthoquinone < phenanthrenequinone. In β-naphthoquinone, the carbonyl group (C_1–O_{11}) is relatively electronically more negative than the one (C_2–O_{12}). Positions 3 and 4 of β-naphthoquinone are relatively electronically more negative and positive, respectively, than the corresponding positions of *o*-benzoquinone. The result that position 3 of β-naphthoquinone is electronically somewhat negative explains the remarkable fact[4] that at this position the nitro group substitution reaction occurs. The calculated dipole moments of *o*-benzoquinone, β-naphthoquinone, and phenanthrenequinone are ca. 8.1, 11.0, and 9.9 D, relatively. If the contribution of the inductive effect between two large dipoles belonging to adjacent carbonyl bonds (ca. 1.5 D)** is in every case subtracted from these values, the final values are 6.6, 9.5 and 8.4 D, respectively, which are considerably greater than the experimental values (5.1[2], 5.6[2] and 5.6 D[5], respectively). These differences between the calculated and the experimental values are commonly observed in the simple MO calculations. As for bond orders, in β-naphthoquinone the value for the C_2–C_3 bond is greater than the one for the C_{10}–C_1 bond and the value for the C_3–C_4 bond is nearly equal to the corresponding one of *o*-benzoquinone. The diagrams also show that the six-membered carbon rings attached to the quinone nuclei of β-naphthoquinone and

** The contribution of the inductive effect was calculated by the same method as that described in the following reference: H. M. Smallwood and K. F. Herzfeld, *J. Am. Chem. Soc.*, **52**, 1919 (1930).

5) C. C. Caldwell and R. J. W. LeFèvre, *J. Chem. Soc.*, **1939**, 1614.

phenanthrenequinone are correctly approximated by the benzene nucleus. Free valence values for position 4 of *o*-benzoquinone and β-naphthoquinone are great, particularly in the case of the latter. The unpaired electron densities in the lowest unfilled orbitals are thought to be roughly equal to the unpaired electron densities in the corresponding semiquinone ions[3]. In the three *o*-quinones, the parts greater than seventy per cent of the total unpaired electron densities exist at the carbonyl groups. Previously, McConnell[3] reported that between the splitting constant, α_i, in the hfs in the electron paramagnetic resonance absorption of semiquinone ions and the unpaired electron density, ρ_i (i denotes the position of a carbon atom to which a proton bonds), the following relationship can be formulated.

$$\alpha_i = 34\,\rho_i \qquad (1)$$

Recently M. Adams[6] reported the measured values of the splitting constants of various semiquinone ions. In *o*-benzoquinone, the values calculated following formula 1 (3.44 and 1.07 gauss) are in good agreement with the measured values (3.65 and 0.95 gauss). In β-naphthoquinone, the unpaired electron density of position 4 is considerably great and the value calculated by formula 1 is 4.48 gauss. As in β-naphthoquinone the measured values are 1.3 and 0.24 gauss, a doublet with a large splitting constant is probably overlooked. In accordance with the experimental result that in phenanthrenequinone 5 quintets resulting from the two sets of four equivalent protons were found, the calculated results show that the unpaired electron densities at positions 4, 6, 11, 13 and positions 5, 7, 10, 12 are mutually nearly equal in each group, respectively.

The Energy Levels. — From the energy levels given above, the following two points are noticeable, as in the *p*-quinones. First, the differences between the high filled and the lowest vacant orbitals are similar in these *o*-quinones. In the region 300 ~ 400 mμ, *o*-benzoquinone has one $\pi-\pi$ transition band, and β-naphthoquinone and phenanthrenequinone have two $\pi-\pi$ transition bands and all these bands are relatively weak***. Further, these three *o*-quinones have one $\pi-\pi$ transition band near 250 mμ***. Those of β-naphthoquinone and phenanthrenequinone are strong, and the one of *o*-benzoquinone is relatively weak. In the above energy levels all the transitions are allowed. Now, it is thought that the longest wavelength $\pi-\pi$ bands are assigned as $E_4 \rightarrow E_5$ (*o*-benzoquinone), $E_6 \rightarrow E_7$ (β-naphthoquinone) and $E_8 \rightarrow E_9$ (phenanthrenequinone), and the second long wavelength $\pi-\pi$ transition bands as $E_5 \rightarrow E_7$ (β-naphthoquinone) and $E_6, E_7 \rightarrow E_9$ (phenanthrenequinone), and the bands near 250 mμ as $E_3 \rightarrow E_5$ (*o*-benzoquinone), $E_4 \rightarrow E_7$ (β-naphthoquinone), and $E_5 \rightarrow E_9$ (phenanthrenequinone), respectively. Though there remains a π unfavorable point that the band near 250 mμ of *o*-benzoquinone alone is relatively weak, the above assignments are thought to be reasonable, considering the similarity of the energy levels among the three *o*-quinones. Second, the energy levels are as a whole a little elevated as the size of the *o*-quinone molecule becomes larger. Now, the lone-pair orbital energies of the oxygen atoms in the three *o*-quinones are thought to be nearly equal. Thus, as was previously reported[1], this result explains the fact that the $n-\pi$ transition energy becomes greater as the size of the *o*-quinone molecule becomes larger. The average value of the highest filled and the lowest vacant orbital energies of each *o*-quinone as a measure of the elevation of the energy levels is $\alpha+0.628\beta$, $\alpha+0.514\beta$ and $\alpha+0.469\beta$ for *o*-benzoquinone, β-naphthoquinone and phenanthrenequinone, respectively.

The Effect of the Electron-Donating Substituent on the $\pi-\pi$ Transition Bands. — As was previously reported[7,1], the greater the C_{mi}^2 value is, and the smaller the C_{ni}^2 value, the greater the extent of the red-shift of the band corresponding to the transition ($m \rightarrow n$) is, and the C_{mi}^2 value has a much greater effect than the C_{ni}^2 value, where C_{mi} and C_{ni} are the coefficients of the i-th atomic orbital in the LCAO MO, m and n, respectively. Now, let us examine this rule for *o*-benzoquinone and β-naphthoquinone. In Figs. 3[8] and 4[9], the absorption spectra of some methyl group substituted *o*-benzoquinones and methoxyl group substituted β-naphthoquinones are given, respectively. All the π-orbitals of the three *o*-quinones are intrinsically non-degenerate and we can reasonably assume that the quasi-π-orbital energy of the methyl group and the lone-pair orbital

$E_7(b_1)$	0.003	0.132

energy of the oxygen atom in the methoxyl group as a substituent are lower than the E_3 (*o*-benzoquinone) and the E_4 (β-naphthoquinone) orbital energies, respectively. Thus, the above method can be applied to these cases. In Fig. 3, the longer and the shorter wavelength $\pi-\pi$ transition bands of *o*-benzoquinone largely shift toward longer wavelengths for 3- and 4-substitutions, respectively. The data in Table I clearly fit these facts. In Fig. 4, the band near 400 mμ and the band near 250 mμ of β-naphthoquinone largely shift toward longer wavelengths for 3- and 4-substitutions, respectively. The data in Table II clearly explain these facts. In addition, the absorption spectra of some hydroxyl group substituted at the benzene nucleus attached to the quinone nucleus of β-naphthoquinones are also generally explained by the calculated results. Thus, in general, the effect of the electron-donating substituent on the $\pi-\pi$ transition bands in the near UV region of *o*-benzoquinone and β-naphthoquinone can be clearly explained by the above method as well as in the case of the *p*-quinones.

The good agreements between the results calculated by the simple MO method and the experimental results, concerning the near UV absorption spectra in the *o*- and the *p*-quinones, are thought to be due to the quinoid field****, characteristic of quinone compounds, which differs from the round fields, characteristic of the aromatics, presented by J. R. Platt[10].

Summary

Electronic structures of *o*-benzoquinone, β-naphthoquinone and phenanthrenequinone were studied with the simple MO method, using the same integral values as those adopted in the self-consistent MO calculation for *o*-benzoquinone. As for charge distributions, the negative charges of oxygen atoms slightly increase in the order of *o*-benzoquinone, β-naphthoquinone, and phenanthrenequinone. The calculated dipole moments (6.6, 9.5 and 8.4 D for *o*-benzoquinone, β-naphthoquinone and phenanthrenequinone, respectively) seem a little greater than the experimental values. As for bond orders, reasonable results were obtained. The calculated results predict the existence of a doublet with a large splitting constant (ca. 4.5 gauss) in the hfs of the electron paramagnetic resonance absorption of β-naphtho-semiquinone ion. Three problems

**** The similar discussion was given in J. W. Sidman's work: *J. Am. Chem. Soc.*, 78, 4567 (1956).

10) J. R. Platt, *J. Chem. Phys.*, 18, 1168 (1950).

concerning the near UV absorption bands [1) the similarity among the $\pi-\pi$ transition bands of the three *o*-quinones, 2) the relative magnitude of the $n-\pi$ transition energy of *o*-benzoquinone, β-naphthoquinone, and phenanthrenequinone, 3) the effect of the electron-donating group on the $\pi-\pi$ transition bands of *o*-benzoquinone and β-naphthoquinone] can be clearly explained by the calculated results, as in the cases of the *p*-quinones.

*Behavior of Surface Active Molecules at an Interface. II. Statistical Thermodynamics of Monolayers of Rod-Like Molecules**

By Masayuki NAKAGAKI

(Received May 20, 1959)

A monolayer is often considered to be a two-dimensional system. However, this standpoint is not acceptable in detailed discussions, because a monolayer has a certain thickness and has a thermodynamic freedom in the direction perpendicular to the monolayer as well as in the two directions along the interface. An effort to consider the monolayer as a three-dimensional existence has been made in the preceding paper of this series[1] by considering the possibility that the end groups of the molecules in a monolayer are not necessarily on one plane, in order to explain the shape of the pressure-area curves of condensed monolayers.

Another example that definitely requires the three-dimensional consideration comes out from rather expanded monolayers in which molecules are supposed to be inclined to the normal of the interface so that the collision diameter of the molecules in the monolayer depends on the degree of the inclination of the molecules. This will be discussed in the present paper.

As for the equation of the state of the monolayer insoluble in the substrate, it has already been pointed out by Akamatsu and the present author[2] that the two dimensional analogue of the van der Waals equation can be used. Then, the equation applicable, at least empirically, is:

$$(F+a/A^2)(A-A_0)=kT \qquad (1)$$

where F is the surface pressure, A is the area per one molecule, k is the Boltzmann constant, T is the absolute temperature and a and A_0 are constants. A_0 corresponding to the constant b in the van der Waals equation is given by

$$A_0=(\pi/2)d^2 \qquad (2)$$

if the molecules are spherical and the diameter is d. However, fatty acid molecules and substances of much interest in surface chemistry is not spherical but is rod-like. If all the rod-like molecules are vertical to the interface and thickness of each molecule is d in diameter, it is then obvious that Eq. 2 can be used. Generally the rod-like molecules are, however, inclined to the interface or lying flat on the interface, so that Eq. 2 can not be used. For the molecules inclined to the interface, theoretical equations to be used instead of Eq. 2 will be derived, and the equations will be applied to experimental data already known in literature.

Theoretical Calculation of the Constant A_0

Principle of the Calculation. — For three-dimensional solutions, Zimm[3] calculated the van der Waals constant b for rod-like

* Presented before the 11th Symposium on Colloid Chemistry, the Chemical Soeiety of Japan, Sendai, Sept. 5, 1958.

3) B. Zimm, *J. Chem. Phys.*, **14**, 164 (1946).

molecules by using the method of McMillan and Mayer[4]. This method is to obtain the second virial coefficient from the value of the phase integral over the entire range of the overlapping of two molecules. By analogy with the three-dimensional osmotic pressure equation in the above mentioned papers, the second virial coefficient A_2 in the expression of the surface pressure F as a power series of surface concentration c:

$$F=\boldsymbol{R}T\{(1/M)c+A_2c^2+\cdots\cdots\} \quad (3)$$

is given by the equation,

$$A_2=-(\boldsymbol{N}_0/2SM^2)\int g_2\{2\}\,\mathrm{d}\,\{2\} \quad (4)$$

where $\boldsymbol{N}_0$ is the Avogadro number, M is the molecular weight of the surface active substance, S is the area of the interface. The integral will be explained later on. Since the surface concentration c is related to the area per one molecule A by the equation:

$$c = M/\boldsymbol{N}_0A \quad (5)$$

Eq. 3 is rewritten as

$$FA/\boldsymbol{k}T=1+(A_2M^2/\boldsymbol{N}_0)(1/A)+\cdots\cdots \quad (6)$$

On the other hand, Eq. 1 expanded in a power series of $(1/A)$ is

$$FA/\boldsymbol{k}T=1+(A_0-a/\boldsymbol{k}T)(1/A)+\cdots\cdots \quad (7)$$

where the term A_0 comes from the repulsion due to the overlapping of two molecules and the term $(a/\boldsymbol{k}T)$ comes from the intermolecular attraction.

On comparing Eqs. 6 and 7, two methods will be suggested for further calculations. The one, which is theoretically accurate but difficult to put in practice, is to calculate the integral in Eq. 4 by taking both the overlapping and the attraction into account, and to assign the value of $(A_2M^2/\boldsymbol{N}_0)$ thus obtained to $(A_0-a/\boldsymbol{k}T)$. The other method, which is theoretically rather arbitrary but easy to put in practice, is to calculate the integral in Eq. 4 by taking only the overlapping into account and neglecting the intermolecular attraction, and to assign the value of $(A_2M^2/\boldsymbol{N}_0)$ thus obtained to A_0. The latter method is adopted in the present paper because the term A_0 is of main interest and because the calculation of the integral is very complicated if the first method is used. Therefore,

$$A_0=-(1/2S)\int g_2\{2\}\,\mathrm{d}\,\{2\} \quad (8)$$

4) McMillan and Mayer, *J. Chem. Phys.*, **13**, 376 (1954).

The g-function of two molecules g_2 is calculated from distribution functions F_n by the equation

$$g_2(1,2)=F_2(1,2)-F_1(1)F_1(2) \quad (9)$$

where the suffix of both g- and F-functions designates the number of molecules in the system considered, and $\{n\}$ means the assembly of all the coordinates of n molecules, while (i) means the coordinates of the i-th molecule. The distribution function $F_2(1,2)$ must be zero in the region where the two molecules overlap. On the other hand, in the region where the molecules do not overlap, the function must be a constant, since the intermolecular attraction is to be neglected in the present method of the calculation. The value of the constant is determined by a normalization equation,

$$(1/S^n)\int F_n\{n\}\,\mathrm{d}\,\{n\}=1 \quad (10)$$

This equation can be rewritten as

$$F_n\{n\}=S^n/\int \mathrm{d}\,\{n\} \quad (11)$$

if $F_n\{n\}$ is a constant.

The Case in which All Molecules are Vertical to the Interface ($\theta=0°$).—Since all the rod-like molecules are assumed to be vertical to the interface, the overlapping of two circles of diameter d in one plane is to be considered. Therefore, the result must be identical with the case of spherical molecules given by Eq. 2. The calculation will be described in some detail for this simplest case in order to explain the process followed repeatedly in the later part of this paper.

As shown in Fig. 1a, the location of the axis of rod 1 is given by the coordinates X and Y, and that of rod 2 relative to rod 1 is given by the coordinates r and φ. Then,

$$\mathrm{d}\{2\} = \mathrm{d}X\mathrm{d}Y r\mathrm{d}r\mathrm{d}\varphi \quad (12)$$

By using Eq. 11,

$$F_2(1,2)=\begin{cases}1 & \text{when rods 1 and 2 do not overlap}\\ 0 & \text{when rods 1 and 2 overlap}\end{cases} \quad (13)$$

$$F_1(1)=F_1(2)=1$$

Now, rods 1 and 2 overlap when $0<r<d$, so that by Eq. 9,

$$\begin{aligned} &g_2(1,2)=-1 \quad \text{when } 0<r<d\\ &g_2(1,2)=0 \quad \text{in all other ranges of coordinates}\end{aligned} \quad (14)$$

Therefore,

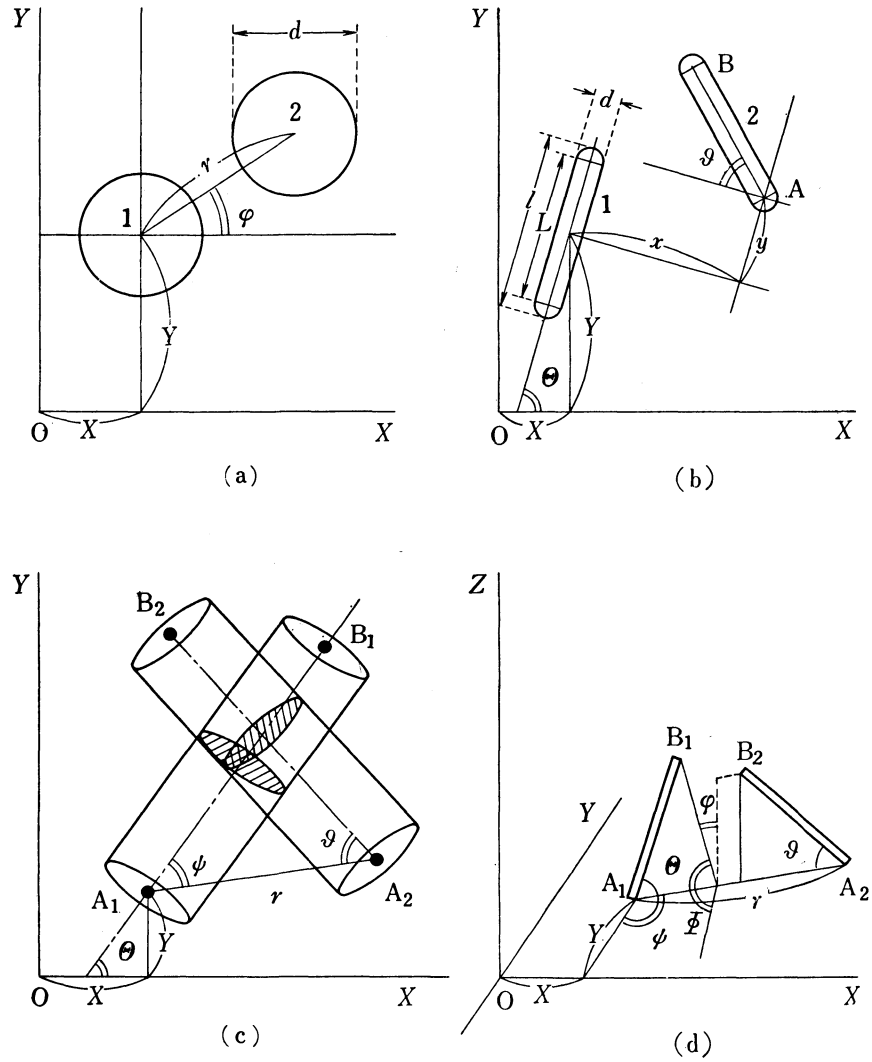

Fig. 1. Coordinate systems used in the cases of (a) $\theta=0°$; (b) $\theta=90°$; (c) $\theta=\theta_0$; and (d) θ is indefinite.

$$\int g_2\{2\}\,\mathrm{d}\{2\} = -\int_S \mathrm{d}X\mathrm{d}Y\int_0^{2\pi}\mathrm{d}\varphi\int_0^d r\,\mathrm{d}r$$
$$= -\pi S d^2 \qquad (15)$$

By combining this with Eq. 8, an equation exactly identical with Eq. 2 is obtained.

The Case in which All Molecules are Lying Flat upon the Interface ($\theta=90°$).—In order to avoid the complication arising from the overlapping of the edges of the rods, and to make the results of the present calculation comparable to the preceding results, the molecules are assumed to have round edges. To describe this shape of the molecule, it is assumed that a rod is composed of a circular cylinder of length L and diameter d and two hemispheres of diameter d at both ends of the circular cylinder, the center of the hemispheres being A and B, as shown in Fig. 1b.

When all rods are lying flat on the interface, the position and the orientation of a rod are designated by using three coordinates. For the three coordinates of rod 1, Cartesian coordinates X and Y of the center of gravity and the angle Θ between the X-axis and the axis of the rod may be used. For rod 2, the Cartesian coordinates x and y of the center of a hemisphere A (the origin of which is the center of gravity of rod 1 and the direction of the coordinate axes is perpendicular and

parallel to the direction of the axis of rod 1), and the angle ϑ between the axis of rod 2 and the coordinate axis $(-x)$ may be used as shown in Fig. 1b.

Then, $d\{2\}$ is $dXdYd\Theta dxdyd\vartheta$, $F_2\{2\}$ is $(1/4\pi^2)$ when two rods do not overlap with each other and is zero when they overlap, and $F_1\{1\}$ is $(1/2\pi)$. Therefore, the value of $g_2(1,2)$ is equal to $(-1/4\pi^2)$ when the rods overlap and is equal to zero when they do not. Therefore, the value of the integral calculated over the entire range of the coordinates corresponding to the overlapping of the rods is

$$\int g_2\{2\}d\{2\} = -(2S/\pi)(L^2+2\pi dL+\pi^2d^2/2) \tag{16}$$

This agrees with Eq. 15 if $L=0$. If the total length of the rod (that is $L+d$) is designated by l, and the value of A_0 is calculated from Eq. 8 by the aid of Eq. 16, then,

$$A_0=(1/\pi)l^2+2(1-1/\pi)dl+(\pi/2-2+1/\pi)d^2 \tag{17}$$

This agrees with Eq. 2 if $d=l$. Now, if the rods are very thin, $(d \ll l)$,

$$A_0 = (1/\pi)l^2 \tag{18}$$

The Case in which All Molecules are Inclined by the Same Angle($\theta=\theta_0$). — When all rods are inclined to the normal of the surface by the same angle θ_0, the position and the orientation of a rod may be specified by three coordinates. Fig. 1c shows the projection of rod 1 (A_1B_1) and of rod 2 (A_2B_2) onto the plane XY parallel to the interface. The three coordinates of rod 1 may be X and Y to give the location of the lower end A_1 of the axis and angle Θ to give the direction of the rod. The three coordinates of rod 2 may be r and ψ to give the location of A_2 and ϑ to give the direction. Then, $d\{2\}$ is $dXdYd\Theta rdrd\psi d\vartheta$, and $g_2\{2\}$ is $(-1/4\pi^2)$ when two rods overlap and is zero when they do not.

The calculation of the range of overlapping is rather complicated in this case and needs some approximation. If the rods are sufficiently thin, rods 1 and 2 overlap with each other when $\vartheta=\psi$, and the height of the intersection h from the surface is $r/2\cos\psi\tan\theta_0$. Now, considering the rods of some thickness, the cross section of the rods will be an ellipse when the cross section is parallel to the interface. The range of the angle ϑ to give the overlapping of the ellipses at the hight of h will give the condition of the overlapping of the rods. It is not easy, however, to estimate this range of ϑ, because the mutual orientation of the ellipses depends on the value of r and ψ. To avoid this mathematical complication, the ellipses will be replaced in this approximate calculation with circles of the same area. Then, the diameter of the equivalent circles d_0 will be $(d/\sqrt{\cos\theta_0})$ where d is the diameter of the rods. If the rods are sufficiently thin and long, that is, $2\sin\theta_0 > d_0/l$, the rods overlap approximately when

$$\psi-(2d_0/r)\cos\psi<\vartheta<\psi+(2d_0/r)\cos\psi \tag{19}$$

The final results thus obtained and applicable when $d/2l<\theta_0<\pi/2-d/l$ are

$$A_0=(\pi-4/\pi)d^2/2\cos\theta_0 + (\sin\theta_0/\sqrt{\cos\theta_0})dl \tag{20}$$

If $d \ll l$,

$$A_0=(\sin\theta_0/\sqrt{\cos\theta_0})dl \tag{21}$$

The Case in which Molecules can be Inclined at Any Angle with Equal Probability ($0<\theta<\pi/2$). — In this case, the position and the orientation of two rods 1 and 2 are defined by eight coordinates, X, Y, r, ψ, Θ, ϑ, Φ and φ. As is shown in a perspective, Fig. 1d, X and Y give the position of A_1. r gives the distance between A_1 and A_2. ψ gives the direction of A_1A_2. Θ gives the angle $B_1A_1A_2$. ϑ gives the angle $B_2A_2A_1$. Φ gives the angle between the plane $B_1A_1A_2$ and the plane XY. φ gives the angle between the plane $B_1A_1A_2$ and $B_2A_2A_1$. Here A_1 and A_2 are the lower end of rods 1 and 2, respectively, and B_1 and B_2 are the upper ends of rods 1 and 2. If the rods are sufficiently thin and $d \ll l$, the two rods overlap in the following three cases:

(1) $0<\Theta<\pi/2$, $0<\vartheta<\pi/2$,
$0<r<l(\cos\Theta+\cos\vartheta)$ and
$-(d/r)(1/\tan\Theta+1/\tan\vartheta)$
$<\varphi<(d/r)(1/\tan\Theta+1/\tan\vartheta)$;

(2) $\pi/2<\Theta<\pi$, $0<\vartheta<\pi-\Theta$,
$0<r<l(\cos\vartheta+\sin\vartheta/\tan\Theta)$ and
$-(d/r)(1/\tan\Theta+1/\tan\vartheta)$
$<\varphi<(d/r)(1/\tan\Theta+1/\tan\vartheta)$;

(3) $\pi/2<\vartheta<\pi$, $0<\Theta<\pi-\vartheta$,
$0<r<l(\cos\Theta+\sin\Theta/\tan\vartheta)$ and
$-(d/r)(1/\tan\Theta+1/\tan\vartheta)$
$<\varphi<(d/r)(1/\tan\Theta+1/\tan\vartheta)$.

Then, by using the value of a definite integral, $\int_0^1(\tan^{-1}x/x)dx=0.9160$, the following equation can be obtained under the

assumption that $d \ll l$.

$$A_0 = 1.7014\, dl \qquad (22)$$

Eq. 22 corresponds to Eq. 21 with $\theta_0 = 71.8°$. This value of θ_0 is considered to be the statistically averaged value of θ for freely orienting molecules.

Applications for Gaseous Films of Fatty Acids

The theoretical equations derived above are to be applied to gaseous films and not to condensed films because multiple collisions, important in condensed films, are not taken into account in the derivations of these theoretical equations.

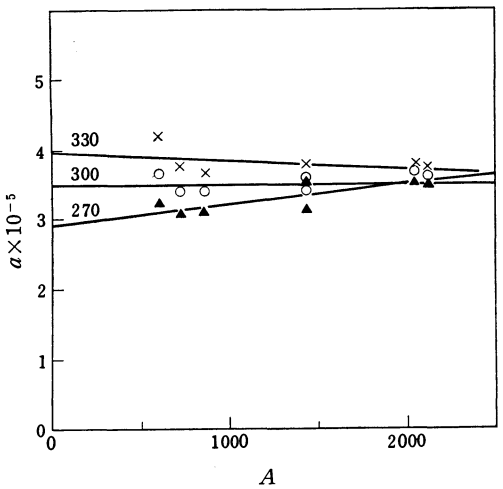

Fig. 2. The dependence of a on A for tridecylic acid, the parameter being A_0.

Therefore, the equations are applied to gaseous films of fatty acid using the experimental data given by Adam and Jessop[5]. In order to obtain the values of the constants a and A_0 of the van der Waals type equation, Eq. 1 was rewritten in the following form:

$$a = [kT/(A - A_0) - F]\, A^2 \qquad (23)$$

and the value of a for systematically varied values of A_0 are calculated by using experimental values of A and F given by Adam and Jessop. The value of a thus calculated for tridecylic acid are shown in Fig. 2. It is seen that the value of a is independent of A if the value of A_0 is assumed to be 300 Å^2. The values of a and A_0 thus obtained for tridecylic acid and myristic acid are shown in Table I.

TABLE I. CONSTANTS OF GASEOUS FILMS

	A_0	$a\times10^{-5}$	M	a/M^2	
Myristic acid	320	4.02	228	7.74	7.71
Tridecylic acid	300	3.52	214	7.68	

The data used for these calculations are shown in Fig. 3 with ○ for myristic acid and with △ for tridecylic acid. Curves in the figure shows the values calculated by Eq. 1, using the values of constants given in Table I. These curves explain well the experimental plots. Horizontal lines in the figure show where a two-dimensional phase change occurs. It is obvious that Eq. 1 does not hold over the pressure of the phase change.

As for the constant a, it is often said

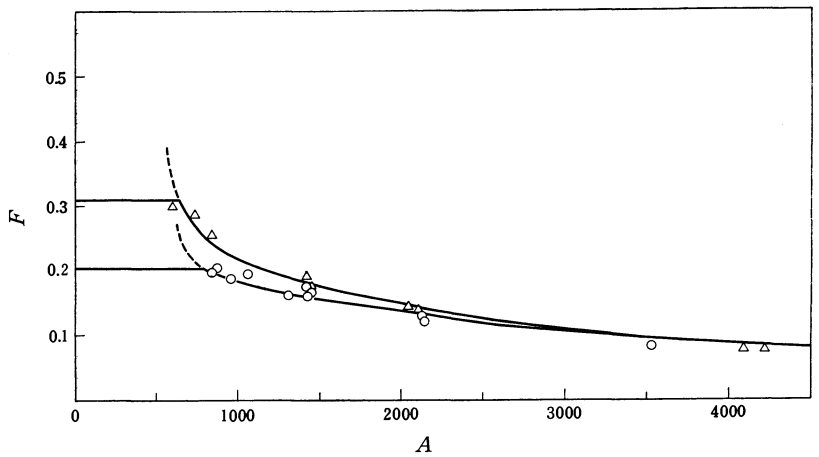

Fig. 3. Gaseous films of myristic acid and tridecylic acid.
○: Myristic acid △: Tridecylic acid

5) N. K. Adam and G. Jessop, *Proc. Roy. Soc.* (*London*), **A110**, 423 (1926).

that its value is proportional to the square of the molecular weight. This is valid in this case since the value of a/M^2 in Table I gives the relation,

$$a = 7.71 \times M^2 \qquad (24)$$

In order to compare the values of A_0 given in Table I with the theoretical equations derived above, the molecules are assumed to be rods of 5.0 Å in diameter and of $(6.0+1.3m)$ Å in length, where m is the number of carbon atoms in the hydrocarbon chain of the molecule. The values thus assumed are cited in Table II.

TABLE II. THE CONSTANT A_0 FOR GASEOUS FILMS

	d Å	l Å	A_0 $\theta=0°$ Å^2	A_0 $\theta=71.8°$ Å^2	A_0 $\theta=90°$ Å^2
Myristic acid	5.0	22.9	39.3	270	320
Tridecylic acid	5.0	21.6	39.3	258	294
Lauric acid	5.0	20.3	39.3	247	267

These values seem reasonable on the basis of various surface chemical studies and are compatible with the values already used by the present author[6]. Using these values of d and l, values of A_0 are calculated for vertical orientation, $\theta=0°$, by Eq. 2; for free orientation by Eq. 20 with $\theta_0=71.8°$; and for horizontal orientation, $\theta=90°$, by Eq. 17. The values thus calculated are shown in Table II. Comparing these with those in Table I, it may be concluded that the molecules of myristic acid and tridecylic acid are lying flat upon the interface.

In the case of lauric acid, the F–A curve obtained experimentally by Adam and Jessop is different from those of myristic and tridecylic acid, because lauric acid does not show any definite phase transition at the range of some hundred Å^2, as shown with ○ in Fig. 4. If it is assumed that the molecules of lauric acid are rods of $d=5.0$ Å and $l=20.3$ Å, and lying flat on the interface, A_0 should be 267 Å^2 as shown in Table II. On the other hand, a should be 3.08×10^5 for lauric acid according to Eq. 24. By using these values with Eq. 1, the solid curve in Fig. 4 is obtained. The curve can explain the experimental data to some extent in the region of larger A values, but the experimental data for smaller A values neither coincide with the van der Waals equation shown by the solid curve nor show any phase transition. The data will be explained by the assumption that the molecules at first lying flat on the interface gradually stand up according to the compression of the monolayer.

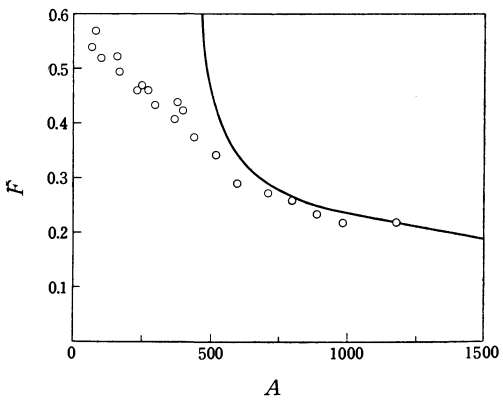

Fig. 4. Gaseous film of lauric acid.

Assuming that the molecules of lauric acid are rods of the above described dimensions, the value of A_0 is calculated as a function of the angle θ, that is the angle between the normal of the interface and the axis of the molecule. The curve in Fig. 5 is thus obtained by using Eqs. 2, 17 and 20. The point f in the figure shows the value of A_0 for the case in which the molecules can take any value of θ with equal likelihood.

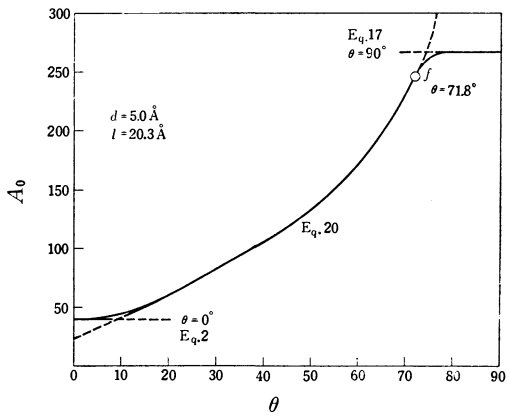

Fig. 5. The relationship between A_0 and θ for lauric acid.

By using, on the other hand, Eq. 1 together with the value of $a=3.08\times10^5$, the value of A_0 can be calculated as a function of the area A from the experimental data shown in Fig. 4. From this value of A_0, the value of θ can be obtained on the basis of Fig. 5. The relation between θ and A thus obtained are shown in Fig. 6. The horizontal line in the

6) M. Nakagaki, *J. Chem. Soc. Japan, Pure Chem. Sec.* (*Nippon Kagaku Zasshi*), **72**, 113 (1951).

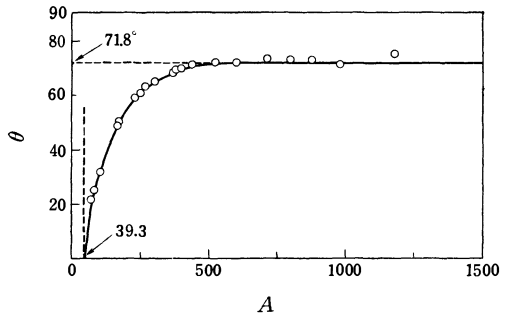

Fig. 6. The orientation of lauric acid molecules as a function of A.

figure shows the case of free orientation, in which the statistically averaged value of θ is 71.8°, and the vertical line shows the case in which all molecules are vertical to the interface. Molecules of lauric acid are in free orientation when the area A is very large, but the molecules interfere with each other and θ becomes smaller when A is les than about 500 Å^2. At last, all the molecules are vertical when A is 39.3 Å^2.

Summary

On the basis of the two-dimensional analogy of the method of McMillan and Mayer, the van der Waals constant A_0 for monolayers of rigid rod-like molecules is calculated theoretically for the cases in which all molecules are (1) vertical to the interface; (2) lying flat upon the interface; (3) inclined by a constant angle θ_0; and (4) orienting freely.

The theoretical equations thus obtained are used to discuss the orientation of molecules in gaseous films of myristic acid, tridecylic acid and lauric acid. As the results, it is concluded that the molecules of myristic acid and tridecylic acid are lying flat upon the interface in the gaseous film until the phase transition to a condensed film occurs. On the other hand, molecules of lauric acid are freely orienting when the area per one molecule is large, and the orientation becomes the more vertical, the more the monolayer is compresssed. The molecular orientations during this compression process were described quantitatively.

Dielectric Constants of Binary Mixtures; 1,2-Dichloroethane and Nonpolar Solvents

By Ryoichi FUJISHIRO and Ko KIMURA

(Received May 25, 1959)

The molecular structure of 1,2-dichloroethane has been studied in detail by many authors[1]. This molecule has steric isomers arising from the internal rotation and the equilibrium between these isomers in solutions is determined by the intramolecular interaction in the dichloroethane molecule and by the intermolecular interaction with solvent molecules. For example, the greater part of the dichloroethane molecules exists as the *gauche* form in the liquid state, whereas the dilution by adding nonpolar solvents causes decrease of the fraction of the *gauche* form. This is particular interest and worth being examined from various standpoints, that is, the dielectric and the thermodynamic behaviors of mixtures.

The thermodynamic behavior of such mixtures has already been discussed from the measurements of heats of mixing[2], and the excessive enthalpy was explained to some extent by considering the equilibrium between the steric isomers. The dielectric behavior of mixtures of dichloroethane with nonpolar solvents, however, has not been studied in detail except in the low concentration range of dichloroethane.

In this report the dielectric properties of mixtures of dichloroethane with nonpolar solvents such as carbon tetrachloride,

1) S. Mizushima, "Structure of Molecules and Internal Rotation", Academic Press, New York (1954).

2) K. Amaya and R. Fujishiro, This Bulletin, **31**, 90 (1958).

cyclohexane, benzene and carbon disulfide, will be examined experimentally over all the concentrations and discussed on the basis of the Onsager theory and the theory extended by Fujishiro[3] and Scholte[4].

Outlines of the Theory

According to Onsager, we select the spheroidal cavity of the molecular dimension and put a point dipole in the center of this cavity. The surroundings of the spheroidal cavity are replaced by the continuum of the macroscopic dielectric constant. When the long and the short axes of the spheroid are $2a$ and $2b$, respectively, and the dipole is located along the long axis, the local field $\vec{f}$[5] is given by

$$\vec{f}=\vec{G}+\vec{R}=\varepsilon/[\varepsilon+(1-\varepsilon)A]\vec{E}+g\vec{m} \qquad (1)$$

where $\vec{G}$, $\vec{R}$ and $\vec{E}$ express the cavity, the reaction and the external fields, respectively, and $\vec{m}$ is the electric dipole moment in dielectrics in the presence of an external field. A is the constant determined by the geometric shape of the cavity and has the following expression[6],

$$A=\frac{ab^2}{2}\int_0^\infty \frac{\mathrm{d}\xi}{(\xi+a^2)^{3/2}(\xi+b^2)}$$

g is called the factor of the reaction field and is given by

$$g=\frac{3}{ab^2}\cdot\frac{A(1-A)\cdot(\varepsilon-1)}{\varepsilon+(1-\varepsilon)A}$$

When we assume the optical polarizability of dichloroethane to be isotropic, $\vec{m}$ is generally related to both $\vec{\mu}$ and $\vec{f}$ by the formula,

$$\vec{m}=\vec{\mu}_v+\alpha\vec{f} \qquad (2)$$

μ_v and α being the electric dipole moment and the optical palarizability of the *gauche* form of dichloroethane, respectively. From Eqs. 1 and 2, we obtain

$$\vec{f}=\frac{g}{1-\alpha g}\vec{\mu}_v+\frac{\varepsilon}{\varepsilon+(1-\varepsilon)A}\cdot\frac{\vec{E}}{1-\alpha g} \qquad (3)$$

Then the average dipole moment $\bar{m}$ is written as follows:

$$\begin{aligned}\bar{m}&=<\vec{m}\cdot\vec{e}>\\&=\int_\Omega(\vec{m}\cdot\vec{e})e^{-U/kT}\mathrm{d}\Omega\Big/\int_\Omega e^{-U/kT}\cdot\mathrm{d}\Omega\\&=\frac{\varepsilon}{\varepsilon+(1-\varepsilon)A}\left\{\frac{\alpha}{1-\alpha g}+\frac{1}{(1-\alpha g)^2}\cdot\frac{\mu_v^2}{3kT}\right\}E\end{aligned} \qquad (4)$$

The symbols $\vec{e}$ and U are a unit vector in the direction of the external field and the potential energy of the system in the presence of the external field, respectively. Then the dielectric constant of a mixture containing N_1 molecules of 1-compound, N_2 molecules of 2-compound and so on per cc., is given by the following formula,

$$\varepsilon-1=4\pi\textstyle\sum_z\cdot N_z\bar{m}_z/E \qquad (5)$$

If we take the mixture containing N_g molecules of the *gauche* form of dichloroethane, N_t molecules of the *trans* form ($N_d=N_g+N_t$) and N_s molecules of a non-polar solvent per cc., we obtain from Eqs. 4 and 5

$$\begin{aligned}\varepsilon-1=4\pi\Bigg[&N_g\cdot\frac{\varepsilon}{\varepsilon+(1-\varepsilon)A}\left\{\frac{1}{(1-\alpha g)^2}\cdot\frac{\mu_v^2}{3kT}\right\}\\&+N_d\cdot\frac{\varepsilon}{\varepsilon+(1-\varepsilon)A}\cdot\frac{\alpha}{1-\alpha g}\\&+N_s\frac{\varepsilon}{2\varepsilon+n_s^2}a_s^3(n_s^2-1)\Bigg]\end{aligned} \qquad (6)$$

In the derivation of this equation, we used the following assumption and relation:

(i) A or α for the *trans* form is equal to that for the *gauche* from, though this assumption is not strictly correct.

(ii) Assuming that a solvent molecule is spherical, A for the solvent molecule may be substituted by the value 1/3 for the spherical cavity, and the polarizability of the solvent molecule is replaced by the Lorentz-Lorenz relation,

$$\frac{n_s^2-1}{n_s^2+2}=\frac{\alpha}{a^3}$$

n and a being the refractive index and the radius of the spherical solvent molecule, respectively. Strictly speaking, as there is the contribution of atomic polarization to α, it is expressed by the Clausius-Mossotti relation instead by that of Lorentz-Lorenz. However, the atomic polarization is generally equal to only a few per cent of the electronic polarization. Hence we have conventionally used the latter relation.

Now, as the dielectric constant of the

6) C. G. Bötter, "Theory of Electric Polarisation", Elsevier Publishing Co., Houston (1952).

mixture itself is concerned not only with N_d, but also with N_g in the mixture as already shown in Eq. 6, we need to know the ratio N_g/N_d in the equilibrium state of the mixture. Factors determining the equilibrium are the intramolecular energy difference ΔE between the *gauche* and the *trans* forms of dichloroethane, the free energy ΔG for the electrostatic stabilization of the polar *gauche* form in the dielectrics, and the intermolecular dispersion energy between dichloroethane and solvent molecules. As is well known, ΔG is given by

$$\Delta G=\frac{1}{2}\cdot\frac{g}{1-\alpha g}\mu_v^2 \tag{7}$$

So far as the dispersion energy is concerned, it is natural to consider that the interaction of the *gauche* form of dichloroethane with a solvent molecule is approximately equal to that of the *trans* form. Thus, one interaction parameter w instead of two may be introduced as follows:

$$w=w_{ds}-\frac{1}{2}(w_{dd}+w_{ss})$$

where w_{ij} is the ordinary dispersion energy between i and j molecules and d or s expresses dichloroethane or a solvent. Then the configurational partition function[7] may be written as

$$Z=2^{N_g}\phi_d^{N_d}\phi_s^{N_s}\frac{(N_d+N_s)!}{N_t!\,N_g!\,N_s!}\exp\left(\frac{-Xw}{kT}\right)\times\exp\left\{\frac{-N_g(\Delta E-\Delta G)}{kT}\right\} \tag{8}$$

where ϕ_d and ϕ_s represent the internal partition functions of dichloroethane and a solvent molecule respectively, and X is the number of dichloroethane solvent pairs. As the chemical potential of the *gauche* form of dichloroethane is equal to that of the *trans* form in the equilibrium state, we write

$$\frac{\partial \ln Z}{\partial N_g}=\frac{\partial \ln Z}{\partial N_t} \tag{9}$$

Hence the ratio of N_g/N_t is easily derived by using Eqs. 8 and 9 as follows:

$$N_g/N_t=2\exp\left\{\left(-\Delta E+\Delta G+N_g\cdot\frac{\partial \Delta G}{\partial N_g}\right)\Big/kT\right\} \tag{10}$$

The value ε and at the same time the ratio N_g/N_t are determined at any composition and temperature by the method of "trials and errors" from Eqs. 6, 7 and 10.

7) The detailed description was given in a previous paper. See reference 2.

Experimental

In order to compare the theoretical results with the experimental ones, we measured the dielectric constants of the mixture of dichloroethane and nonpolar solvents such as carbon tetrachloride, cyclohexane, benzene and carbon disulfide. The apparatus[8] for the measurement of the dielectric constant was already described and the capacity of a dielectric cell used in this experiment was about 5 pf. All materials were purified according to the standard method[9].

Comparison of the Theoretical Results with the Observed Values

Fig. 1 shows the theoretical curves of the dielectric constants plotted against the mole fraction of dichloroethane for the dichloroethane-carbon tetrachloride mixture at 25 and 60°C. In this calculation the following values are used;

$\mu=2.55$ D, $\alpha=0.838\times10^{-23}$ cc.
E[10]$=1.27$ kcal./mol.

	n_s^2	v_d (molecular volume of dichloroethane)	v_s (molecular volume of carbon tetrachloride)
25°C	2.124	1.325×10^{-22}	1.612×10^{-22}
60°C	2.072	1.375×10^{-22} cc.	1.676×10^{-22} cc.

All the calculations were carried out on the assumption that there is no volume change on mixing, i.e., $N_dv_d+N_sv_s=1$. This

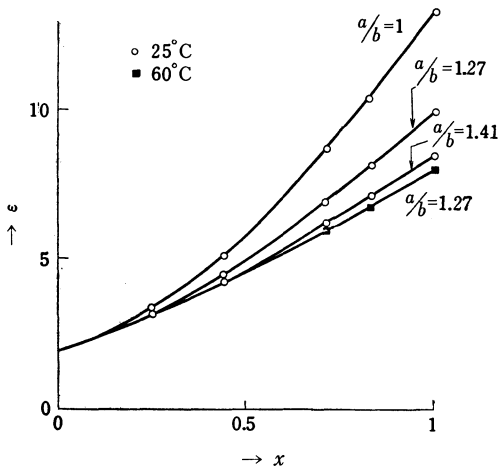

Fig. 1. The calculated dielectric constants of the mixture; dichloroethane-carbon tetrachloride.

8) I. Nakagawa, *J. Chem. Soc. Japan, Pure Chem. Sec.* (*Nippon Kagaku Zasshi*), **79**, 1353 (1958); K. Kimura and R. Fujishiro, This Bulletin, **32**, 433 (1959).

assumption was confirmed to be reasonable by the measurements of densities of the mixture.

The ratio a/b of the *gauche* form of dichloroethane is to be estimated by the use of the atomic distances and van der Waals radii of component atoms of the dichloroethane molecule. But the dichloroethane molecule is not strictly spheroidal. Only the long axis along which the dipole

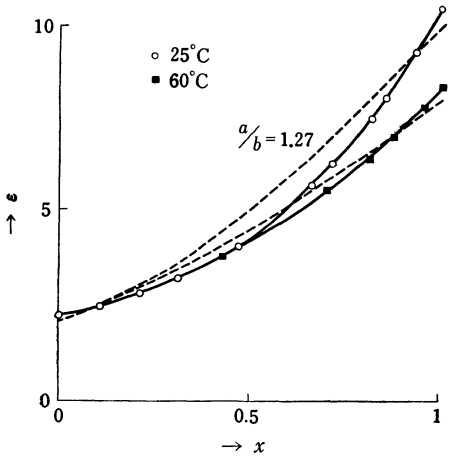

Fig. 2. Comparison of the calculated dielectric constants of the mixture, dichloroethane - carbon tetrachloride, with the observed dielectric constants. ------ Calculated, —— Observed

is located is determined uniquely, whereas the selection of the short axis is arbitrary. The ratio a/b, therefore, can take any value from 1.27 in the case of the maximum short axis to 1.57 of minimum short axis. Values of a/b used in the actual calculation are 1.27 and 1.41, the latter of which is the geometric mean of 1.27 and 1.57. For the sake of comparison the theoretical results in the case of $a/b=1$ are also shown in Fig. 1. From this figure, we may infer that the modification of the shape of the cavity leads to considerable variation of the calculated values of the dielectric constants. This means that the reaction field is overestimated in the Onsager model, i. e., $a/b=1$ and underestimated in the case of $a/b=1.41$. Fig. 2 shows the experimental results corresponding to those of Fig. 1. As seen from these figures, the most satisfactory agreement with experiments is obtained when we adopt as a/b a value 1.27 which corresponds to the allowed maximum of the short axis. This result is of particular interest from the viewpoint of the selection of the short axis. Moreover, the experimental curves representing the dielectric constants of the mixture against the mole fraction x of dichloroethane are more concave than the theoretical curves. The curvatures of the experimental curves themselves are different for different solvents as is seen later, and for different temperatures.

When we compare the theoretical values with the observed ones at 25 and 60°C, we find a better agreement with the experimental results at 60°C than at 25°C as is

TABLE I. THE OBSERVED DIELECTRIC CONSTANTS OF THE MIXTURE; DICHLOROETHANE-CARBON TETRACHLORIDE AT 25° AND 60°C

shown in Fig. 2 and Table I. This result is the same as that deduced from the equation for the dielectric constants of polar liquids proposed by Yasumi-Komooka[11]. Their conclusion was that a better agreement with the experimental data is obtained near the boiling point than near the melting point.

On the other hand, when we examine the calculated ratio N_g/N_d, we find that it decreases more gradually in the spheroidal model than in the spherical, as is shown in Fig. 3. The calculated ratio N_g/N_d in $x=1$ at 25°C is about 0.75 which

is somewhat larger than the value 2/3 measured by the spectroscopic method, but the apparent dipole moment calculated from N_g/N_d when $x \to 0$ agrees fairly well with that estimated experimentally by the use of Debye's equation for dilute solutions.

Finally, the experimental results on mixtures of dichloroethane with other nonpolar solvents at 25°C are summarized in Fig. 4 and Table II. By comparing the experimental curves representing the dielectric constants of mixtures against x with one another, it will be found that the curvatures of the curves are different for different mixtures, and diminish in the following order; cyclohexane and carbon tetrachloride > benzene > carbon disulfide. The excess enthalpy[2] of each mixture decreases in the same order, that is, cyclohexane > carbon tetrachloride > benzene, although the heats of mixing for the carbon disulfide solution have not been measured as yet. Now, the actual calculation of the dielectric constants was carried out only for the mixture dichloroethane-carbon tetrachloride. However, the concentration dependence of the dielectric constants in other mixtures may be inferred to some extent from the calculated results for the mixture dichloroethane-carbon tetrachloride. The case in which the best agreement of the theoretical results with experiments is obtained is the carbon disulfide solution, and next to it, the satisfactory agreement of the theoretical values with the experimental ones is found in the case of benzene solution. The reason why the better agreement even in this simple model is obtained in the case of the carbon disulfide and the benzene solutions is not clear, but some specific interaction may be responsible for this coincidence, considering that the thermodynamic and the spectroscopic[12] measurements suggest the anomalous behavior in the benzene solution. This interesting point may be elucidated partly by examining in detail the temperature dependence of the dielectric constants of the mixtures.

Summary

The dielectric constant for the mixture dichloroethane-carbon tetrachloride was calculated by making use of a model proposed by Onsager, Fujishiro and Scholte. The calculated values agree rather well with the experimental. The higher the temperature is, the better is the agreement. The dielectric constants of other mixtures such as dichloroethane-cyclohexane, dichloroethane-benzene and dichloroethane-carbon disulfide were also measured only at 25°C and compared with one another. The coincidence of the theoretical values with the experimental was obtained in the following order; carbon disulfide, benzene, carbon tetrachloride and cyclohexane.

The cost of this research has been partly defrayed by a grant from the Ministry of Education.

Estimation of the Energy of Hydrogen Bonds Formed in Crystals. I. Sublimation Pressures of Some Organic Molecular Crystals and the Additivity of Lattice Energy

By Ariyuki AIHARA

(Received May 25, 1959)

A considerable number of investigations have been done on the problem of hydrogen bonds from both experimental and theoretical points of view, especially since the introduction of the infrared technique in this field of study. Thus, it may safely be said that there is little left to be studied on these topics, so far as they are concerned with hydrogen bondings in solutions of, e. g., phenols, amides and amines in appropriate solvents. One of the questions, however, which is not completely solved as yet, is how to estimate the strength of hydrogen bonds when they are formed in the crystalline state. In this connection, the author has been engaged in the measurement of sublimation pressures of a number of amides and amines with the hope of getting knowledge concerning the relation between the energy of hydrogen bonds in crystals and the heat of sublimation[1].

The principle of estimating the energy of hydrogen bonds in crystals, which has hitherto been adopted by several investigators[1-3], is first to measure the heat of sublimation of a substance in question and then to subtract from it the amount of contribution to the lattice energy due to dispersive and dipolar interaction between molecules in the lattice. Here, the interaction energy due to dispersive force can be calculated theoretically by the Slater-Kirkwood formula[4] if the crystal structure is fully analyzed by X-ray diffraction or by any other methods, while the dipolar interaction can be estimated by the usual procedure or by assuming point charge models.

In case the crystal structure is too complicated to permit theoretical calculation of lattice energy or if it is not analyzed yet, a conventional method has been used in which one assumes the heat of sublimation of a substance, isoelectronic with that in question, as equivalent to the portion of lattice energy due to dispersive and dipolar interaction between molecules in the crystal of a substance forming a hydrogen bond, thereby estimating the energy of the hydrogen bond according to the method already mentioned. A trouble is that an appropriate isoelectronic molecule is not always available to follow the above procedure.

To overcome this difficulty the author has tried first to establish the approximate method of estimating the lattice energy of molecular crystals empirically, assuming its additivity, and then to make use of this method to estimate the energy of hydrogen bonds in crystals of phenols, amides and amines. In this paper, the additivity rule for lattice energy of organic molecular crystals will be examined together with experimental results of sublimation pressure measurement for a number of molecular crystals.

Experimental

Sublimation pressures were measured with a viscosity gauge of the type first designed by Haber[5], Langmuir[6] and later modified by Sasaki[7]. It consists of a Λ shaped fine quartz fiber mounted on a piece of a quartz rod and set in a measuring cell. The diameter of the fiber is 0.1 mm. and the length of the isosceles side of the triangle formed is nearly 10 cm. To facilitate the setting of vibration of the fiber from outside of the cell by a small magnet, a piece of iron wire is attached to the top of the fiber. Samples are fractionally sublimed or distilled under high vacuum and are introduced directly into the cell without allowing them to

make contact with air. The device is shown in Fig. 1[1].

Like most of other vapor pressure measuring gauges, the viscosity gauge must be calibrated with an absolute manometer, such as the McLeod or Knudsen gauge. Here, the calibration was made by subjecting the gauge to saturated vapor of carefully purified benzophenone at several temperatures at which the vapor pressure of benzophenone was already known[8]. According to Haber and Kerschbaum[5], the relation between the pressure in the gauge, P, and the damping time rebuired for the amplitude of the vibration of the fiber to decrease to its half value, t, can be expressed as follows; $P\sqrt{M}=b/t-a$. Here a and b are constants of the gauge and M is the molecular weight of the vapor in it. Thus by observing the damping time, t, at several temperatures and putting the corresponding values of vapor pressures into the above equation, the values of a and b can be determined by the method of least squares. An example of the above procedure is shown in Table I. The values of vapor pressure in the last column of the table were calculated by an equation obtained by Nitta and Seki[8]: $\log P = 12.434-4654.3/T$. The constants, a and b, thus obtained are the average values at 30°C, and correction must be made as they vary with $\sqrt{T}$ when measurements are made at different temperatures.

Most of the materials used are commercial products of high grade and are purified several times by fractional sublimation or distillation under high vacuum. Their melting points are shown in the following tables together with sublimation pressure obtained.

Some of the results of the measurements of sublimation pressure of biphenyl, published previously by several investigators[9-11], are compared in Fig. 2 with the author's. As can be seen in the figure, the author's result is in good agreement with that of Seki and Suzuki, while the others show considerable deviations from the author's, Bradley's data being too high and Bright's too low. The fact that the results obtained by different methods, i. e., a method using viscosity gauge by the

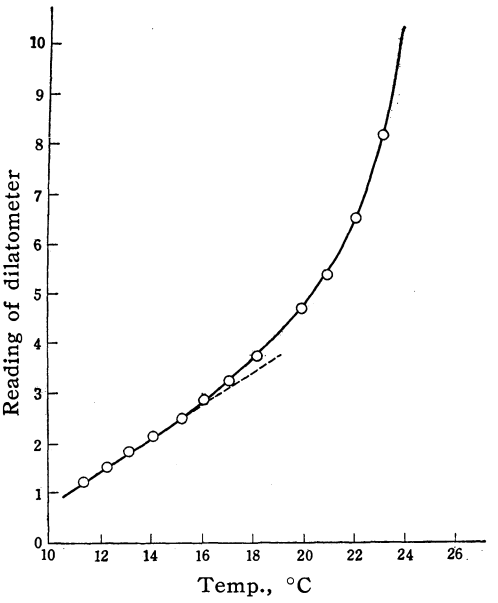
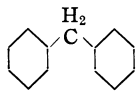
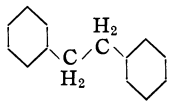
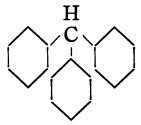
author and an effusion method by Seki and Suzuki, give a good agreement, clearly shows the reliability of these data.

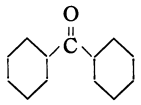
The sublimation pressure of diphenylmethane measured by Bright[9] is again lower than the author's result, the linear relation between $\log P$ and T^{-1} showing a smaller inclination compared with the author's. (Fig. 3). Plotting the experimental values of $\log P$ against T^{-1}, it is noticed in the author's measurement that there occurs a change in the linear relation between $\log P$ and T^{-1} at about 15°C and upward. Roughly speaking, the relation between $\log P$ and T^{-1} after this change goes almost parallel with that of Bright's. Also a simple dilatometric measurement revealed the occurrence of a change in the expansion coefficient of diphenylmethane at about 15°C. (Fig. 4). Although the nature of this transitional change is not clear as yet, it is likely that Bright missed it, putting too much weight on observed values of sublimation pressure above 15°C. The vapor pressure equation shown in Table III is, thus, valid for the temperature range below 15°C.

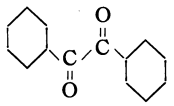


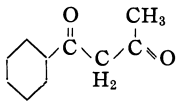


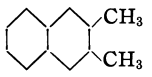


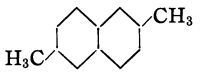


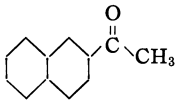


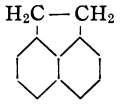












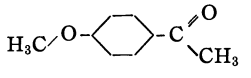


Fig. 4. Dilatometry of diphenylmethane. Reading of dilatometer is in an arbitrary scale.

Bright's[9] result on the sublimation pressure of dibenzyl deviates similarly from the author's as was seen in the two cases mentioned above: the vapor pressure equation and the heat of sublimation obtained by Bright are, $\log P=9.86-3783/T$, $\Delta H=17.3$ kcal./mol., while the author's are $\log P=12.194-4386.0/T$ and $\Delta H=20.07$ kcal./mol.

Of the other substances dealt with in this paper, mention should be made of the

result of sublimation pressure of naphthalene. There are plenty of data on the sublimation pressure of naphthalene published already in literatures[11-13], but strangely none of them coincide with one another. The author's value of sublimation pressure lies between those of Bradley[11]* and Andrews[13], while $\Delta H=15.84$ kcal./mol. by the author agrees well with Zilberman-Granovskaya's[12] value, $\Delta H=15.7$ kcal./mol., and Wolf's[14] value, $\Delta H=15.9$ kcal./mol. The differences between the various results must be due to different degrees of purity of the samples with which the determinations were made, and also due to the inaccuracy of the methods of determination.

The values of some thermodynamic functions of the substances derived from vapor pressure equations are shown in Table XIV.

Additivity of Lattice Energy

Inspection of the relation between the heats of sublimation and the molecular structures of the compounds listed in Table XIV suggests that an additivity rule may be applied to the lattice energies of these crystals, at least as a first approximation. Now let it be assumed that each constituent group of a molecule, such as methyl, carbonyl, phenyl, etc., makes a contribution to the lattice energy independently. Then, if we allot an appropriate energy to each group, it should be possible to get a "calculated lattice energy" of a compound in question. The third column of Table XIV shows the values of lattice energies thus calculated for compounds dealt with in this paper, with the following values of allotted lattice energies for constituent groups. (Table XV). Notwithstanding the approximate nature of the method of calculation, the agreement between observed and calculated values of lattice energies, i. e., ΔH_{obs} and ΔH_{calc}, is quite satisfactory, as can be seen in Table XIV. Disagreement noticed in a few cases, such as dibenzyl, triphenylmethane and benzil, can be ascribed to the bulky structure of the molecules which prevents the close approach of constituent groups to each other, thus decreasing the amount of contribution to the lattice energy to some extent.

Table XV. Allotment of lattice energies to groups

Groups	Energy kcal./mol.	Groups	Energy kcal./mol.
CH, CH_2, CH_3	2.0	O-CH_3	4.0
NH, NH_2	2.0	C_6H_5	9.0
OH	2.0	$C_{10}H_7$	15.5
C=O	3.5	*t*-Butyl	5.5

In Table XV, the value for phenyl group, 9.0 kcal./mol., was determined by dividing the heat of sublimation of biphenyl, 18.1 kcal./mol., by two: this value is very close to the heat of sublimation of benzene obtaind by Trieschmann, 9.2 kcal./mol.[15] The value for naphthyl group, 15.5 kcal./mol. is close to the average of the heat of sublimation of naphthalene determined by the author, Wolf[14], and Zilberman-Granovskaya[12]. As to the increment of lattice energy due to a methyl (or methylene) group, several investigators have published the following values: 2.3 kcal./mol. by Müller[16], 1.5 kcal./mol. by Inokuchi[17], 1.7~2.2 kcal. mol. by Moelwyn-Hughes[18], 1.1~1.7 kcal./mol. by Davies[19]. The author's value, 2.0 kcal./mol., is the average of the above values and those obtained by analyzing the data in Table XIV. The same value is assigned to amino and hydroxyl groups as that of a methyl group, because these molecules are all isoelectronic. The validity of assigning the same value to these groups will be confirmed in succeeding papers where the lattice energies of phenols, amides and amines will be discussed. Also Bondi and Simkin[20] have discussed this problem. The value for a carbonyl group, 3.5 kcal./mol., was obtained by analyzing the heats of sublimation of benzophenone, benzoylacetone, 2-acetylnaphthalene and some other compounds having a carbonyl group. The value for a *tert*-butyl group was derived from the heat of sublimation of 1, 4-di*tert*-butylbenzene[21]. 4.0 kcal./mol. for

a methoxyl group was determined by subtracting the allotted lattice energies for methyl and carbonyl groups from the heat of sublimation of *p*-acetylanisole.

It must be admitted that the treatment of lattice energies of organic molecular crystals discussed above is quite rough and could not be applied to more complicated cases without further refinement. Still, an orthodox way of calculating lattice energies, such as by Slater-Kirkwood formula[4] or by other ways, does not necessarily give a satisfactory agreement between calculated and observed lattice energies, as has been pointed out by Seki and his collaborators[22]. Therefore, it would be helpful, at the present stage, to have an approximate way of estimating lattice energies of molecular crystals empirically, as is proposed in this paper. This procedure will be used later to get the energy of hydrogen bond in crystals of phenols, amides and amines.

Summary

Sublimation pressures of a number of organic molecular crystals were measured by a viscosity gauge. The heats of sublimation of these compounds were examined in relation to their molecular structures, and it was concluded that an additivity rule could be applied to the lattice energies of these crystals as a first approximation.

The author wishes to thank Professor M. Davies, the University of Wales, for informing the author about some of his results prior to publication. The cost of the work was partly defrayed by the financial support of the Ministry of Education to which the author's thanks are due.

Stress Relaxation of Thermo-Reversible Gels. Polyvinyl Alcohol—Congo Red—Water System

By Kiyoshi ARAKAWA

(Received June 1, 1959)

In the previous paper the author reported the result of the stress relaxation experiment made on the gel of the polyvinyl alcohol-glycerin-water system[1]. As another example of thermo-reversible gels of polymeric nature, the gel of the polyvinyl alcohol-congo red-water system is known, and several studies on the properties of the gel have been reported[2].

As a part of the series of rheological studies of thermo-reversible gels[1,3] a stress relaxation experiment has been attempted on the gel, and the result is reported in the present paper.

Experimental

Apparatus. — The apparatus to measure the relaxing stress produced in the specimen under a given strain is the same one as that used previously[1,3]. The chainomatic balance part of the apparatus is shown in Fig. 1. A specimen is compressed between a plate attached to a bar and a bottom plate connected to a screw gauge by the rotation of the gauge, which is graduated to 0.01 mm. The stress in the specimen is calculated from the vertical length of the suspended chain which is balancing automatically with the stress. The specimen is dipped in liquid paraffin, as was done in the preceding studies[1,3].

Sample. — A commercial sample of polyvinyl alcohol was purified by precipitation from aqueous solution. The amount of residual acetate groups in the sample was 1.5% by mole. The intrinsic viscosity $[\eta]_{30}$ was 0.96 100 cc./g., which was determined by a capillary viscometer. The viscosity-average molecular weight M_V was calculated to be 8.5×10^4 according to the formula by

A. Nakajima et al.[4] Congo red used was Merck's analytical grade chemical.

The preparation of specimens was as follows. A definite quantity of dried polyvinyl alcohol was mixed with dried congo red powder, the amount of which was adjusted to be accurately 1/10 of polyvinyl alcohol by weight (this weight ratio of congo red and polyvinyl alcohol was taken to be the same for all specimens used in the present study), and a calculated quantity of water was added to the mixture in a conical beaker. After being covered with liquid paraffin, the mixture was dissolved slowly by heating in a water bath. After complete dissolution the solution was poured into cylindrical moulds kept at about 85°C in a thermostat and was cooled down slowly to 50°C (the rate of temperature decrease: 5°C per hour), and then was aged at room temperature. After several days the specimens (diameter, 2 cm.; height, about 3 cm.) were taken out from the moulds, and were aged moreover at room temperature in liquid paraffin for about a month. The composition of the prepared specimens is described in Table I.

TABLE I. THE COMPOSITION OF GELS

Sample	Polyvinyl alcohol wt. %	Congo red wt. %
A	17.5	1.75
B	15.0	1.50

Samples A and B have typical rubber-like elasticity at ordinary temperature and make the sol-gel transition reversibly at about 80°C.

Results and Discussion

Stress Relaxation Data.—The data of stress relaxation of samples A and B are plotted in the form $(298/T)E_r$ vs. $\log t$, where $E_r=f/\gamma$ is relaxation Young's modulus; t time, and f stress, in Figs. 2a and 2b. The strain γ applied in the present experiment was 15% for all specimens. This value was in the range where the linear relation between stress and strain was almost maintained. These data are reduced to 25°C by multiplying E_r by a factor $298/T$.

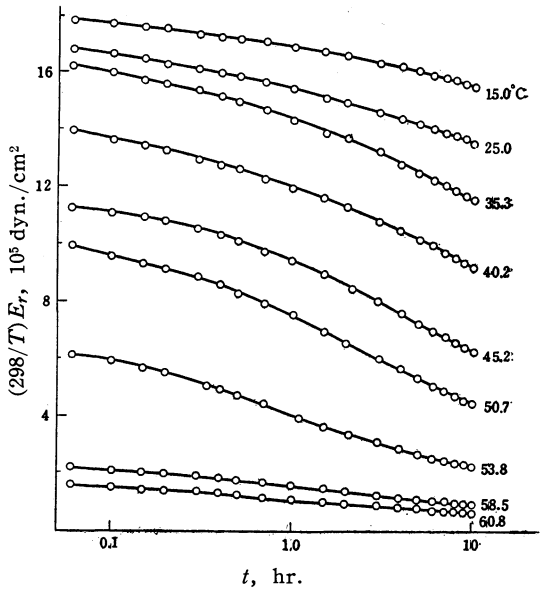

Fig. 2a. Reduced relaxation Young's modulus of 17.5% gel.

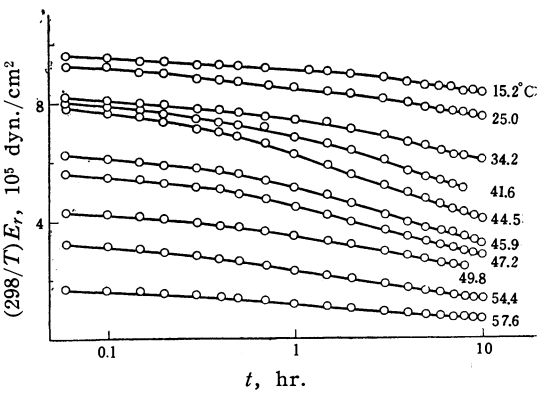

Fig. 2b. Reduced relaxation Young's modulus of 15% gel.

The master relaxation curve[5] at 25°C for each sample is obtained by means of arbitrary shift factors a_T. The curves,

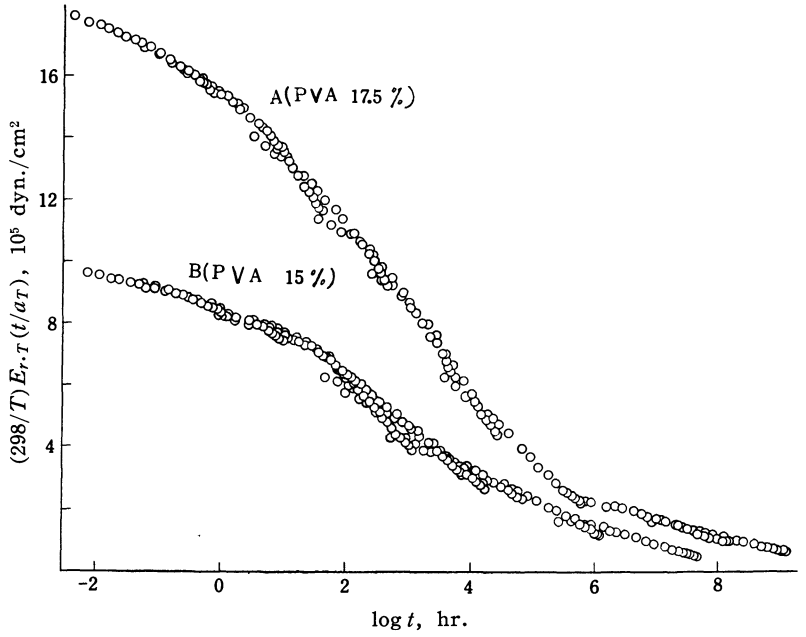

Fig. 3. Master relaxation curves at 25°C.

thus obtained, are plotted in Fig. 3. The superposition of each relaxation curve is seen to be fairly good.

Shift factors $\log a_T$ are plotted against $1/T$ in Fig. 4. It seems the $\log a_T$ vs. $1/T$ curve is approximately linear in the low temperature region, and that the deviation from linearity occurs at about 43°C. The apparent activation energy H_a which is calculated from the $\log a_T$ vs. $1/T$ curve is a constant value, 42 kcal., below 43°C. This value of H_a is smaller than that of the gel of polyvinyl alcohol, glycerin, and water system. The value of H_a increases with temperature above 43°C. This tendency differs from that observed in the polyvinyl alcohol-glycerin-water gel, but is similar to that observed in the hydrogel of agar-agar in which the deviation from linearity appears at about the same temperature, but the value of H_a below the temperature is much smaller*,[3].

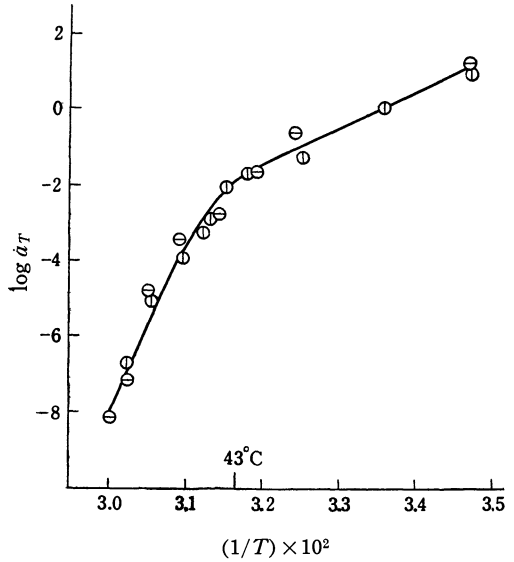

Fig. 4. Log a_T vs. $1/T$ relation.
⊖ Sample A
⊕ Sample B

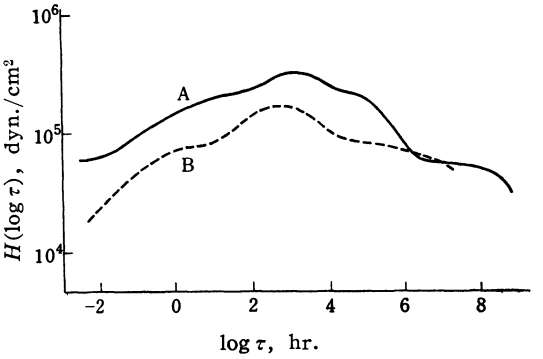

Fig. 5. Relaxation spectra

* In the hydrogels of agar-agar the superposition of each relaxation curve is not so good, except in the case of 2.6% gel, above ca. 40°C. The mechanical behavior of 2.6% gel was as described in the text. In the gels of the other concentration a similar tendency was seen, though exact master curves were not obtained.

As seen in the fact described above, the $\log a_T$ vs. T relation does not obey the equation of WLF form[6].

Distribution Functions of Relaxation Times.— The relaxation spectra $H(\log \tau)$ are shown in Fig. 5, which were calculated from the master relaxation curves shown in Fig. 3 by the second order approximation[7].

$$H\left(\log\frac{\tau}{2}\right)=2.303\left[E_r\left\{-\frac{\mathrm{d}\log E_r}{\mathrm{d}\log t}+\frac{1}{2.303}\frac{\mathrm{d}^2(\log E_r)}{\mathrm{d}(\log t)^2}+\left(\frac{\mathrm{d}\log E_r}{\mathrm{d}\log t}\right)^2\right\}\right]_{t=\tau}$$

Each curve in Fig. 5 is seen to exhibit the character of the box type region of the whole spectrum, which corresponds to the rubbery and fluid state of materials.

Each spectrum is similar in shape except at the long time end, and the spectrum for 15% gel is seen to conform to that for 17.5% gel when slid upwards and to the right.

From the above facts it seems to be possible that two curves shown in Fig. 3 are composed to a single curve approximately, but this reduction on concentration has turned out to need the multiplication factor $(C_0/C)^n$, where the value of n is 3.5~4 and C_0 is a reference concentration. This value of n is too large, being compared with the value, 2, reported previously by DeWitt et al.[8] on the solution of polyisobutylene. More data are required.

Summary

Stress relaxation curves were obtained for the gels of the polyvinyl alcohol-congo red-water system in the temperature range, 15~60°C, by means of a chainomatic relaxometer. The molecular weight of polyvinyl alcohol was 8.5×10^4, and gels of 15.0 and 17.5% were used, where the concentration of congo red was adjusted to be 1/10 of that of polyvinyl alcohol. Master relaxation curves were obtained for each concentration over the range, 10^{-2}~10^9 hr, and relaxation spectra were calculated by the second order approximation. The following results were obtained.

1) The $\log a_T$ vs. T relation gives a single curve for two concentrations, and does not obey the equation of WLF form. Also it has characteristics similar to that of agar-agar gels.

2) The apparent activation energy is kept constant to be 42 kcal. below about 43°C, and above this temperature it sharply increases with temperature.

3) The reduction on concentration to a single composite relaxation curve seems to be possible in rough approximation.

The author is indebted to Mr. Morio Kamisho and Mr. Yoshio Daicho for their cooperation in carrying out the experiment.

Infrared Studies of Polyvinyl Alcohol by Deuteration of its OH Groups

By Hiroyuki TADOKORO

(Received May 29, 1959)

In the previous paper[1] we have studied the density, the sorption of water vapor, and the infrared absorption spectrum of polyvinyl alcohol (PVA) films subjected to heat-treatments at different temperatures from the point of view of crystallinity, and have concluded as follows: (1) the degree of crystallinity determined by these methods is parallel unless the thermal decomposition is considerable, and (2) the 1141 cm^{-1} (8.76 μ)* band is a so-called "crystallization-sensitive" band[2-4]. Succeeding the previous work, we have carried out further studies on PVA by means of infrared spectrum, X-ray diffraction and density measurements in the hope of making some contribution to the studies of the crystallinity and fine texture[3] of high polymers.

The purpose of the present paper is to report some new information obtained by the results of deuteration of the OH groups of PVA.

We have made the infrared spectroscopic measurements of the deuterated PVA for the following purposes. The first is for the elucidation of the nature of the crystallization-sensitive band at 1141 cm^{-1}. As to the crystallization-sensitive band, a considerable number of reports have been published during these several years on polyethylene and many other polymers. Although some reasonable interpretations on the absorption mechanism of the crystallization-sensitive bands have been proposed in the cases of polyethylene, there is no conclusive one for the 1141 cm^{-1} band of PVA. The second purpose is for the assignments of the absorption bands in the region of 1500~800 cm^{-1}. There are already many publications on this problem[5-8], but it is not yet settled at all. The third is to test whether we can determine the crystallinity (or accessibilty) of PVA by means of the deuterium exchange method or not. In the case of cellulose, for instance, it is well known that the velocity of deuterium exchange reaction of the hydroxyl group in the amorphous region is much faster than it is in the crystalline region[9-11]. The fourth is to examine the fine structure of the OH stretching bands of the spectrum arising from the crystalline region, if the amorphous region is to be exclusively deuterated. Marrinan and Mann[11] have investigated the fine structure of the OH bands of various kinds of cellulose by the use of this method.

As to the infrared absorption spectrum of deuterated PVA, Ukita, Nishino and Kominami[12] and also Krimm, Liang and Sutherland[8] have reported quite independently. Ukita and his coworkers have recognized no appreciable change of the spectrum, except the new appearance of the broad band at 4.01 μ due to the OD stretching vibration, because of the low degree of deuteration in their case. Krimm and his coworkers have measured the spectrum of PVA-*d* (degree of deuteration: about 90%) in the region of 3600~400 cm^{-1}, and have obtained experimental results similar to ours. As the assignments of the absorption bands of polymers are generally very complicated problems, we have carried out other experiments such

as infrared spectroscopic measurements of oriented PVA-*d* and of doubly oriented PVA[13,14], density measurements[15], etc., to get some useful data for this purpose.

Experimental

a) Polyvinyl Alcohol Samples.—Film specimens were prepared from the same starting material (PVA of average degree of polymerization: 1650) by the same method as that described already in the previous papers[1,16]. (See Table I). In the present work the films were cast on a polystyrene plate instead of a glass plate, because the most suitable thickness of the film for infrared measurements is about 7~10 μ, and it is difficult to strip off such a thin film from a glass plate.

The oriented film was prepared by stretching it by hand in one direction over a small flame until it could be stretched no more. Examination of the film between crossed polaroid sheets confirmed the orientation in the direction of stretching.

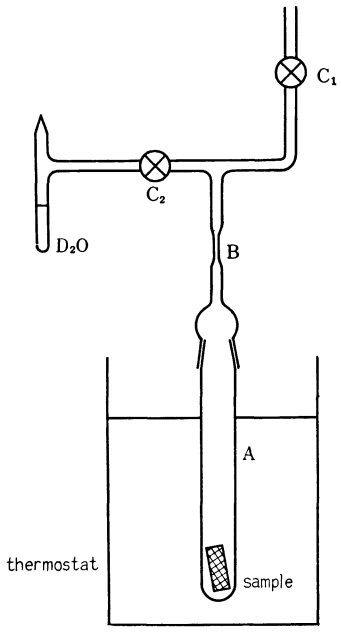

Fig. 1. Apparatus for deuteration.

b) Deuteration, Formalization and Infrared Measurements.—The deuteration of PVA was carried out by using 99.7% heavy water** in a vessel shown in Fig. 1. A PVA film (ca. 20 mm. ×30 mm.) put between the parts of folded stainless steel wire gauze (350 mesh), was inserted in a glass tube A, and was dried at 60°C for about 48 hr. under high vacuum (10^{-4} mmHg or below) by using a liquid air trap (stopcock C_1 being open, and C_2 being closed). After the drying was over, C_1 was closed, the temperature was lowered to room temperature, and then by opening C_2, the sample was equilibrated to the saturated vapor pressure of heavy water. After "being allowed to stand" for about 24 hr., the sample was dried again, and such procedures were repeated several times. At last the glass tube was sealed off at B. The measurements were carried out by putting the films between rock salt plates, with or without polychlorotrifluorocarbon oil (Difloil #3, kindly supplied by Osaka Kinzoku Kôgyô Co., Ltd.).

The oriented and deuterated PVA film for the measurement of dichroism could be prepared by successive procedures in a series of stretching, heat-treatment and deuteration.

Samples I and III were also subjected to formalization and then to deuteration. The formalization was carried out in an aqueous solution of sulfuric acid (200 g./l.), sodium sulfate (250 g./l.) and formaldehyde (40 g./l.) at about 50°C for 15 min. and 2 hr. for each sample. During the formalization treatment the film was held between the parts of a folded wire gauze of bronze (300 mesh) to be free from deformation.

Infrared absorption spectra were taken by using a Hilger H800 Recording Infrared Spectrophotometer with sodium chloride prism, and a Perkin-Elmer Model 21 Double Beam Recording Infrared Spectrophotometer with sodium chloride prism and silver chloride polarizer.

Results and Discussion

a) Deuteration.—The obtained spectra of PVA and of deuterated PVA are shown in Fig. 2a and Table II. The possible errors of the wave number are $\pm 10\,cm^{-1}$ and $\pm 5\,cm^{-1}$ in the regions of $4000 \sim 2000\,cm^{-1}$ and $2000 \sim 700\,cm^{-1}$, respectively. Thus, our spectral data shown in Fig. 2 and Table II are in substantial agreement with those obtained by Krimm et al.[8]

It is well known that OH or NH groups are easily converted into OD or ND by exchange reaction with heavy water, but CH groups are not converted easily unless

a) The ν(OH) band at about 3340 cm^{-1} shows no appreciable dichroism at the band maximum, but perpendicular and parallel nature at the higher frequency and lower frequency side, respectively, agreeing with the descriptions of Glatt et al.[19] and Krimm et al.[8] The ν(OD) band at about 2470 cm^{-1} was also found to show the same behavior.

b) The band at about 1430 cm^{-1} splits to 1440 and 1420 cm^{-1} in the polarized spectra because of the difference of their dichroism.

c) The band at about 1325 cm^{-1} has its absorption maximum at 1326 and 1315 cm^{-1} in the case of perpendicular and parallel radiation, respectively.

d) T: Thompson and Torkington[5], E: Elliott, Ambrose and Temple[7], B: Blout and Karplus[6], K: Krimm, Liang and Sutherland[8], Ni: Nishino, Ukita and Kominami[17], Na: Nagai and Kuribayashi[18].

e) ν: stretching, ν_a: antisymmetric stretching, ν_s: symmetric stretching, δ: bending, w: wagging, r: rocking.

f) The data in the region lower than 640 cm^{-1} was reproduced from the paper by Krimm et al.[8]

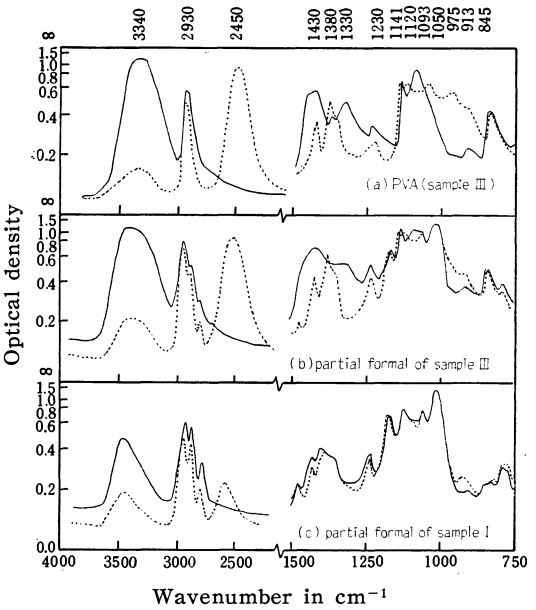

Fig. 2. Infrared spectra of (a) PVA, (b) partial formal of sample III and (c) that of sample I and their deuterated samples (broken line).

under some special conditions[20]. Thus, when PVA is brought into contact with heavy water, the following reaction will take place and the change of the structure will be detected in the infrared spectrum of the sample.

$$-(-CH_2-\underset{\displaystyle OH}{\underset{|}{CH}}-)_{\bar{p}} \xrightarrow{D_2O} -(-CH_2-\underset{\displaystyle OD}{\underset{|}{CH}}-)_{\bar{p}}$$

As a result of the deuteration, the intensity of the ν(O–H) band at 3340 cm^{-1} decreases and at the same time a new intense band appears at 2450 cm^{-1}. This latter band evidently corresponds to the ν(O–D) band. While the ν(C–H) band at 2940 cm^{-1} is not affected appreciably by deuteration, this band could be used as the standard for the intensity measurements. The diminution of the optical density of the ν(O–H) band referred to this C–H band, may be used as a measure of degree of deuteration. The extent of deuteration of the sample shown in Fig. 2a is found to be about 90% by this method of estimation.

Now, the deuterations for samples I and III of Table I were studied under various conditions. When the procedures of drying and of exposure to heavy water vapor were repeated alternately several times, both the samples were deuterated up to about 90% regardless of the degree of crystallinity. On the contrary, the extent of deuteration of nylon 6 which had undergone the same procedure as the PVA sample, was much lower than that of PVA. Moreover, the lower the degree of crystallinity of the sample of nylon 6 is, the higher is the extent of deuteration as is shown in Fig. 3. The same results have been reported on the celluloses as mentioned above[9-11].

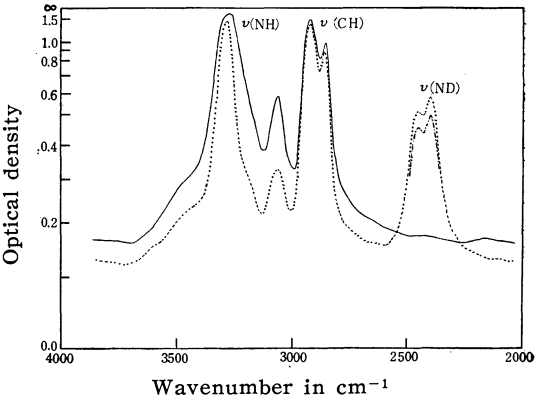

Fig. 3. Infrared spectra of nylon 6 (——) and deuterated nylon 6 (------): ———— sample subjected to heat-treatment.

In relation to these evidences, it will be quite interesting to examine whether the crystalline region of PVA, which is considered to be inaccessible to formalization[21,22], could be deuterated or not. The solid lines of Figs. 2b and 2c show the infrared spectra of samples I and III subjected to formalization. For sample I, the remarkable decrease of the intensity of the OH stretching band at 3340 cm^{-1} and its shift to the shorter wavelength side on formalization may indicate the high degree of formalization. However, for sample III the intensity of the OH stretching band decreases only to a slight extent. This result reconfirmed the fact that the crystalline region is not formalized appreciably as was reported previously by some authors[21,22]. The spectra of these partial formals after deuteration were also shown in the same figure with broken lines. This result indicates that the residual OH groups of the formal of sample III were

20) For example, M. Koizumi, Organic Deuterocompounds, "Advances in Organic Chemistry (Yûkikagaku no Shimpo)" Vol. II. Edited by M. Kotake and S. Akabori, Kyôritsu Shuppan Co. Ltd., Tokyo (1939), p. 27.

21) K. Hirabayashi and N. Fujimoto, *Chem. High Polymers (Kobunshi Kagaku)*, **7**, 159 (1950).

22) Y. Yoshioka and M. Nagano, ibid., **9**, 36 (1952).

deuterated up to about 84%. Thus, the crystalline region of sample III, which was not accessible to formalization, was found to be highly deuterated. These facts seem to show that the difference between the velocity of deuterium exchange in the crystalline region and that in the amorphous region, is considerable in the cases of nylon 6 and cellulose, while this difference is negligibly small in PVA. In this respect, the mechanism of the deuteration reaction of the crystalline region of PVA seems to be a very interesting problem.

b) Interpretation of the Spectra. — The infrared dichroism of the deuterated PVA is shown in Fig. 4, together with that of ordinary PVA for the purpose of comparison. This sample could be prepared by the successive procedures of stretching, heat-treatment and finally deuteration. This method of preparation is based upon the aforementioned remarkable fact that the crystalline region of PVA film even after subjected to heat-treatment can be easily deuterated by exposing it to D_2O vapor.

Although we can not make conclusive assignments of the absorption bands in the region of 1500~700 cm^{-1} at present, we may give here our tentative assignments on the main bands in this region. The band at about 1430 cm^{-1} was assigned by Thompson and Torkington[5] and also by Blout and Karplus[6] to a deformation mode of CH_2 group. On the other hand, Elliott, Ambrose and Temple[7] considered this band to be the δ(O–H), or to be the superposition of the δ(O–H) and the $\delta(CH_2)$ modes. However, this band should be a superposition of the CH_2 bending and some other band connected with hydroxyl group, or probably the O–H deformation, since the intensity of this band decreases sensitively on deuteration and there remains a sharp band which is certainly attributed to the CH_2 bending mode, because of its perpendicular nature. The perpendicular band at 1325 cm^{-1} should also be related to the hydroxyl group because of the intensity decrease on deuteration, whereas Elliott and his coworkers[7] merely referred this band to a hydrogen deformation mode. Just at the middle of the above-mentioned two bands, i.e., at 1380 cm^{-1}, a new intense and sharp band appears on deuteration. We have already suggested[23] that this fact is well interpreted by assuming that these two bands (1430 and 1325 cm^{-1}) are associated with the coupling of the δ(OH) and some other mode such as the CH deformation, and the coupling is removed on deuteration. Krimm and his coworkers[8] independently made a more or less similar interpretation on the results of deuterated PVA (no orientation), and concluded that these two bands come from the interaction between the δ(OH) and δ(CH) modes. However, we have found from the dichroic data with the oriented PVA-*d* that the new band at 1383 cm^{-1} has the nature of distinguished parallel dichroism, and there appear also two perpendicular bands at 1376 and 1361 cm^{-1}, superposed with the 1383 cm^{-1} band. Thus Krimm and his coworkers' assignment of the 1383 cm^{-1} band to δ(CH) can not explain the parallel dichroism of this band. The problem of the assignments of the bands in this region is very complex, but our suggestion in the previous paper[21] does not contradict the present experimental results***.

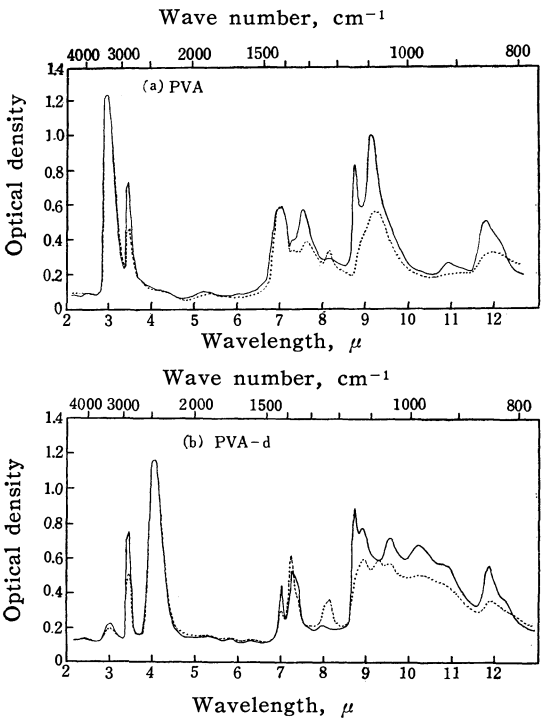

Fig. 4. Infrared dichroism of (a) PVA and (b) PVA-*d* (degree of deuteration ca. 92%): —— electric vector perpendicular to elongation: ------ electric vector parallel to elongation.

23) H. Tadokoro, S. Seki and I. Nitta, *J. Chem. Phys.*, **23**, 1351 (1955).

*** Possibile assignments will be that the 1383 cm^{-1} band is the w(CH) or the $w(CH_2)$[24], and 1376 cm^{-1} band the δ(CH).

24) I. Nakagawa, *J. Chem. Soc. Japan, Pure Chem. Sec.* (*Nippon Kagaku Zasshi*), **76**, 540 (1955).

The parallel band at 1230 cm^{-1} was reported to be associated with the residual acetyl group by Thompson et al.[5] and Elliott et al.[7] But later this assignment was shown to be inadequate by Blout and Karplus[6] from the experimental fact that this band is not removed by acid hydrolysis, although the 1256 cm^{-1} band in unpurified samples is removed simultaneously with the 1710 cm^{-1} band. From the facts that this band is not affected by deuteration and that it becomes intense on formalization with preserving the parallel dichroic nature, this band may be supposed to be $w(CH_2)$, although Krimm and his coworkers' assignment[8] to w(CH) is also undeniable.

The 1148 cm^{-1} band of PVA-*d* is supposed to correspond to the 1141 cm^{-1} band of PVA, because of the distinct perpendicular dichroism. As to the assignment of this band, various interpretations have been proposed, and this seems to be one of the most interesting problems in the infrared studies of this substance. Detailed discussions of this band will be reported in subsequent paper.

The 1093 cm^{-1} band may be mainly associated to the ν(C–O) mode from its location, perpendicular dichroism and the reasonable wave number shift by deuteration, in accordance with the interpretations of Blout et al.[6], Elliott et al.[7], and Krimm et al.[8] The parallel band at 1083 cm^{-1}, superposing the 1093 cm^{-1} band, seems not to be affected by deuteration. On deuteration the 1093 cm^{-1} band disappears and three perpendicular bands appear at 1122, 1049 and 977 cm^{-1}. Of these three bands, the 1049 cm^{-1} band may be assigned to the ν(C–O), and 977 cm^{-1} band to the δ(O–D) tentatively from the consideration of the wave number ratios of the shifts on deuteration.

The perpendicular bands at 913 and 845 cm^{-1} are considered not to be directly associated with the OH group, because of the negligibly small effect of deuteration.

Finally, we wish to refer to the results of our infrared microspectroscopic measurement on the highly doubly oriented PVA sample[14]. In this experiment the measurements were made so that the direction of the polarized infrared beam was parallel to the direction of rolling (the same as that of the carbon zigzag chain). The spectra obtained in this experiment were partly reproduced in Fig. 5. The solid line represents the spectrum with the electric vector parallel to the rolled plane (i. e., the plane of the carbon zigzag chain), and the broken line that with the electric vector perpendicular to the rolled plane. It was found that the 913 and 845 cm^{-1} bands have weak pleochroism, and the latter is a superposition of two bands. The direction of the transition moment of the $r(CH_2)$ mode is perpendicular to the plane of the carbon zigzag chain. The 835 cm^{-1} band, the transition moment of which is in this direction as is evident from the curves in Fig. 5, may be considered as assigned to this mode. The assignment of the 913 cm^{-1} band to $r(CH_2)$ by Krimm et al.[8] is not consistent with our experimental result that the transition moment of this band is parallel to the plane of the carbon zigzag chain.

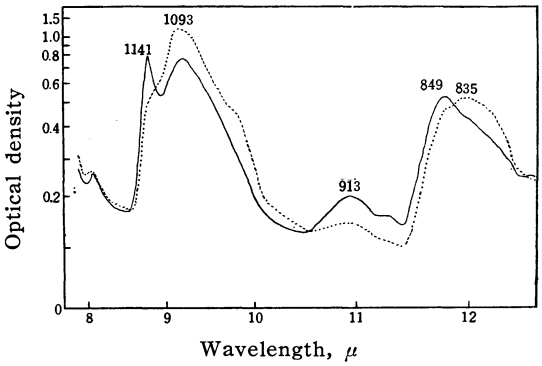

Fig. 5. Infrared spectra of highly doubly oriented PVA specimen[14]. The direction of the infrared beam is parallel to that of rolling.
—— electric vector ∥ rolled plane.
------ electric vector ⊥ rolled plane.

The author wishes to express his gratitude to Professor I. Nitta and Assistant Professor S. Seki, under whose guidance this research was carried out. He also expresses his sincere thanks to Professor T. Shimanouchi of the University of Tokyo for helpful advice and criticism, to Dr. T. Kanzawa and Mr. H. Kamio of Takeda Pharmaceutical Industries Co., Ltd. for preparing part of the charts of the infrared absorption spectra, and to Kurashiki Rayon Co., Ltd. for kindly giving him the PVA samples.

Heats of Combustion and Formation of Lower Members of Methyl- and Ethyl-methoxypolysiloxanes

By Toshio TANAKA

(Received May 29, 1959)

The heats of combustion of lower members of polydimethylsiloxanes were measured by Thompson[1], and with the aid of the results, average values of bond energy terms for Si–O and Si–C bonds were found to be 117 and 64 kcal./mol., respectively. Of these energy values, the former seems to be too great and the latter somewhat too small, in comparison with those calculated from heats of formation of silica and carborundum. In fact, the Si–O bond energy term has been calculated to be 102 kcal./mol. as the reasonable value, from the heats of formation of methoxy-polysilanes and -polysiloxanes in the preceding paper[2].

In the present work, the heats of combustion of lower members of methyl- and ethyl-methoxypolysiloxanes represented by L_n and L'_2 have been measured, and thermal data derived therefrom have been discussed.

$$L_n:\ CH_3O\left[\begin{array}{l}CH_3\\ |\\ Si\cdot O\\ |\\ OCH_3\end{array}\right]_n\cdot CH_3,\quad n=1\sim3$$

$$L'_2:\ CH_3O\left[\begin{array}{l}C_2H_5\\ |\\ Si\cdot O\\ |\\ OCH_3\end{array}\right]_2\cdot CH_3$$

Experimental

Materials. — The preparation and the physical constants of the members of L_n [3] and L'_2 [4] used in the present work were already reported.

Calorimetry. — The apparatus and procedure used in the combustion experiment have been similar to that described elsewhere[2,5]. The calibration experiment of the calorimeter was carried out at 20°C using benzoic acid (39f) supplied from National Bureau of Standards, Washington, and its energy equivalent value was determined to be 2459 cal./deg. (relative mean deviation ±0.1%).

A thin walled glass ampoule[5] has been used for the purpose of making possible complete combustion of each member of L_n. The completeness of combustion has been ascertained by the method as described in the previous paper[5]. A few other techniques which cause organosilicon compounds to burn completely was reported[1,6]. It seems, however, that satisfactory combustion is not always attained even when these techniques are employed. In the experiment of L'_2, the techniques which are troublesome about the procedure have not been applied; a sample of about 0.4 g. has been weighed in a gelatine capsule, with a known heat of combustion, and the capsule has been vertically supported on a platinum combustion vessel by a platinum ignition wire, a piece of cotton being tied to it, which passes through two small holes at the top of capsule. The evaporation of L'_2 through the very small holes on the capsule has been neglected in quantity, because of its high boiling point (97°C/20 mmHg). This neglect has no influence on the experimental results of L'_2. After burning the sample by electrical ignition, carbon monoxide has not been identified by Winkler's reagent[7] in gaseous phase of bomb contents, and a bulky product, consisting of silica and an incomplete combustion product in a part, has been yielded on the combustion vessel. The incomplete combustion product contains amorphous carbon and, sometimes, a trace of carborundum, and these have been determined in quantity by the procedure described elsewhere[8]. Thermal corrections for carbon and carborundum have been calculated using the values of 7.84 cal./mg. (=32.8 joules/mg.)[9] and 6.86 cal./mg. for their heats of combustion, respectively. The latter value has been calculated from the figures of −26.7 kcal./mol. for the heat of formation of carborundum[10], and is that at standard constant volume process. The completeness of combustion in L'_2 has been found to be 98.5~99.7% by the analysis of incomplete combustion product.

Results and Discussion

Four to six combustion experiments have been made with each liquid sample, and the results are shown in Table I.

TABLE I. HEAT OF COMBUSTION AT CONSTANT VOLUME, cal./g.

Compound							Mean
L_1	5632	5629	5617	5609	—	—	5622
L_2	5213	5228	5221	5212	5219	—	5219
L_3	5083	5055	5074	5072	—	—	5071
L'_2	5875	5865	5903	5856	5891	5868	5876

The relative mean deviation in each run is somewhat high compared with modern precision measurements, but of sufficient precision for bond energy term purpose in view of the other uncertainties involved.

Table II is the summary of important thermal data of four organosilicon compounds, calculated from the results of combustion experiments. Notations in Table II are as follows: $-\Delta U_R$, the heats of combustion at standard constant volume process where the reactants are one atmospheric pressure; $-\Delta H_c$, the heats of combustion in isobaric process at one atmospheric pressure; $-\Delta H_f$, the heats of formation of liquid compounds under consideration from standard elements (gaseous H_2 and O_2, graphitic carbon and metallic silicon); $-\Sigma E$, the heats of formation of the gaseous compounds from monoatomic gases. These energy values, except that in the last column of Table II, have been calculated by the same method as that used in the preceding paper[2], and in the calculation of $-\Sigma E$, heats of vaporization have been estimated to be 7.9, 9.1, 10.3 and 9.5 kcal./mol. for L_1, L_2, L_3 and L'_2, respectively, from Trouton's rule.

Bond Energy Term. — According to the additive law of bond energy, the value ΣE obtained experimentally in such a way may also be expressed by the formula

$$\Sigma E = pE_{Si-O} + qE_{Si-C} + rE_{C-O} + sE_{C-H} + tE_{C-C} \quad (1)$$

where E represents the energy value of bond corresponding to each suffix, and the factors p, q, r, s and t the number of bonds in the molecule under consideration. The energy terms of C–O, C–H and C–C bonds are well known, and if it is assumed that each value is not varied with the change of molecule, the bond energy values of bonds concerning the silicon atom may be estimated by formula 1. The value of $-E\left[\begin{smallmatrix} & C & \\ & | & \\ O-Si-O & & \end{smallmatrix}\right]$ presented in the last column of Table II has been estimated in this manner, using 98.8, 83.2 and 83.2 kcal./mol. for C–H, C–C and C–O bond energy terms, respectively. The former two values have been calculated by the method of least squares from heats of formation of lower members (from ethane to hexane) in normal paraffin[11], other than methane, and the latter from the heat of formation of dimethylether[10] using the C–H bond energy obtained there. Two kinds of Si–O bond are contained in the molecules of L_n and L'_2; that of Si–O–CH_3 linkage and of Si–O–Si linkage. However, no energy difference between the two kinds of Si–O bond were observed in the preceding work on methoxy-polysiloxanes[2], and so these bonds will not be distinguished in the following discussion.

The $-E\left[\begin{smallmatrix} & C & \\ & | & \\ O-Si-O & & \end{smallmatrix}\right]$ in L_2 and L'_2 is in good agreement. However, this value increases with the polymer size of L_n, and further its energy difference between L_2 and L_3 is not so large as that between L_1 and L_2. This tendency has also been found in our recent investigation on heats of formation of methoxy end-blocked dimethylpolysiloxanes[12], and suggests that the $-E\left[\begin{smallmatrix} & C & \\ & | & \\ O-Si-O & & \end{smallmatrix}\right]$ may be close to a constant value as the polymer size increases*.

TABLE II. HEATS OF COMBUSTION AND FORMATION, AND BOND ENERGY, kcal./mol.

Compound	Mol. wt.	$-\Delta U_R$	$-\Delta H_c$	$-\Delta H_f$	$-\Sigma E$	$-E\left[\begin{smallmatrix} & C & \\ & | & \\ O-Si-O & & \end{smallmatrix}\right]$
L_1	136.23	766	767	227	1799	364
L_2	226.38	1181	1183	412	2847	368
L_3	316.54	1605	1608	589	3887	370
L'_2	254.43	1495	1498	422	3408	368

12) T. Tanaka, to be published in *J. Inorg. Nuclear Chem.*

* Such a tendency for bond energy will always be found in lower members of a homologous series; for example, in calculation of C-C bond energy from heats of formation of normal paraffin, assuming that C-H bond energy is constant in the members.

The heats of combustion of various alkylsilanes were already measured by Tannenbaum[6], and Si-C bond energy estimated therefrom[13]. There was found an interesting tendency; namely, that the Si-C bond energy decreased as the size of the alkyl group joined to the silicon atom increased. It will here be assumed for the convenience of discussion that Si-O bond energy in $Si(OCH_3)_4$ (103 kcal./mol.**), which is 1 kcal. lower than that in amorphous silica, is the normal value for its bond energy. Similarly, if Si-C bond energy calculated from the heat of formation of $Si(CH_3)_4$ [6] is assumed to be its normal value, it may be estimated to be 71 kcal./mol. using the heats of atomization and the C-H bond energy adopted in the present work. This value for Si-C bond energy is 1 kcal. lower than that*** in carborundum, and seems to be reasonable for its normal bond energy. If such assumptions are accepted for the normal bond energies of Si-O and Si-C bonds, the calculated value for $-E\left[\begin{array}{c} C \\ | \\ O\text{-}Si\text{-}O \\ | \\ O \end{array}\right]$ results in 380 kcal./mol. under the additive law of bond energy, and is considerably higher than the observed value in L_3, not to speak of L_1, L_2 and L'_2. Such a deviation from the additive law of bond energy may be attributed to all of the bonds in the molecule under consideration. However, silicon atom has small electronegativity (1.8)[14] and its covalent radius is considerably larger than that of the carbon atom. Also it is well known that the silicon atom is, frequently, able to form a partially double bonding character with other atoms having lone-pair electron or electron donating power, by accepting the electron in its vacant *d*-orbital[15]. Considering these characteristics, the bonding orbital of the silicon atom seems to be liable to undergo any sort of distortion by the effect of neighboring groups.

The observed atomic distance of Si-O bond[16] is abnormally shorter than that (1.91 Å) expected from covalent radii, and this shortening has been considered to be due to the contribution of d_π-p_π bond character[17]. The π-bond character of each Si-O bond in structural unit, $\begin{array}{c} C \\ | \\ O\text{-}Si\text{-}O \\ | \\ O \end{array}$, of the molecules considered in this paper will be undoubtedly less than that in $\begin{array}{c} O \\ | \\ O\text{-}Si\text{-}O, \\ | \\ O \end{array}$ being the structural unit of methoxypolysiloxanes, considering the numbers of resonance structures between Si-O bonds in both the structural units. As the result, the energy value of Si-O bond in L_n and L'_2 will be supposed to be lower than that in methoxy-polysiloxanes. In this manner, the considerable lowering of bond energy should be expected in the case of methoxy end-blocked dimethylpolysiloxanes, $CH_3O[Si(CH_3)_2 \cdot O]_n \cdot CH_3$, the structural unit being $\begin{array}{c} C \\ | \\ O\text{-}Si\text{-}O \\ | \\ C \end{array}$, and this expectation has been ascertained in the recent investigation on their lower members. This supposition on Si-O bond energy will correspond to the shortening of the silicon-halogen bond distance with the decrease of the number of halogen atoms attached to silicon[18].

Summary

1. The heats of combustion of lower members of methyl- and ethyl-methoxypolysiloxanes have been measured at 20°C and constant volume, and the corresponding heats of combustion and formation in isobaric process have been calculated.

2. The bond energy term in structural unit of $\begin{array}{c} C \\ | \\ O\text{-}Si\text{-}O \\ | \\ O \end{array}$ has been calculated from the heat of formation, and it has been found that its value increases with the polymer sizes of the members. Finally, the $-E\left[\begin{array}{c} C \\ | \\ O\text{-}Si\text{-}O \\ | \\ O \end{array}\right]$ has been compared with

Studies on the State of Formic Acid Adsorbed on Silica and Alumina by a Combined Method of Nuclear Magnetic Resonance and Infrared Absorption

By Kozo HIROTA, Kenji FUEKI, Kotaro SHINDO and Yasuo NAKAI

(Received June 6, 1959)

As reported already[1], formic acid is chemisorbed as the formate ion on several metallic powders (Ag, Cu, Ni, Rh, Pd, Pt and Zn), while the acid chemisorbed on silica does not dissociate[2]. However, it was found in the present study that the conclusion obtained in the case of silica can not be applied to alumina, especially in the case of low coverage of adsorption. Such a conclusion may be worthy to be reported, considering the fact[3] that the catalytic role of alumina is similar to that of silica rather than that of metals, e. g., these oxides have dehydrating activity in addition to dehydrogenating activity, contrary to the case of metals which have only dehydrogenating activity.

Experimental

Formic Acid.—The reagent of C. P. grade made by Edogawa Kagaku Kogyo Co. was repeatedly dehydrated by crystallization and then vacuum-distilled in the presence of anhydrous copper sulfate.

Silica—Silica gel for chromatographic use made by Mallinkrodt Chemical Works was dehydrated at 300°C for 150 hr. It was confirmed by X-ray analysis that the amorphous structure of silica was not changed by dehydration. The specific surface area of the silica was found to be 520 m^2/g. by the BET method (adsorbate: nitrogen).

Alumina.—Alumina gel, precipitated by the reaction between aluminum nitrate and ammonia in aqueous solution, was dehydrated at 300°C for 50 hr. The specific surface area was found to be 310 m^2/g.

Measurement.—Formic acid was adsorbed on each adsorbent which was enclosed in a glass sample tube in vacuo. In the case of nuclear magnetic resonance measurement, a capillary tube filled with water as a standard substance was put in the center of the sample tube. The proton resonance spectra were obtained with a high resolution spectrometer (Varian V-4300B)* at a fixed frequency of 40 Mc/sec. The tube was always rotating around its axis during the measurement. The infrared spectra were obtained using the paste method[4], in which the sample was quickly mulled with Nujol, and a part of the sample was held between the plates of sodium chloride and then offered for measurement (apparatus: Hilger H800). During this procedure a small amount of formic acid may be lost in the atmosphere, but it was checked that this amount was small enough not to alter the conclusion. Taking such a situation into account, the coverage was conventionally designated by θ' instead of the true coverage θ in the case of samples used in infrared absorption measurement. Measurements were made at room temperature.

Results and Discussion

Proton Magnetic Resonance Absorption.—The proton resonace spectrum of formic acid

4) G. C. Pimentel, C. V. Gerland and G. Jura, *J. Am. Chem. Soc.*, **75**, 803 (1953).

adsorbed on silica is quite different from that in the liquid state, especially when the amount of adsorption is small, (e. g., $\theta=0.5$); only one signal**, corresponding to the hydrogen atom bonded to the carbon atom, appears as a broad one and, moreover, its position shifts by 33 cps to a higher magnetic field. However, as the coverage is increased up to 2.7, the signal becomes narrower in width and that of the hydrogen atom bonded to the oxygen atom also appears as a very broad one. Thus it may be concluded that the motion of hydrogen in the carboxyl group is fixed in the state of monomolecular adsorption, and such a restriction of the motion is relaxed gradually according as the adsorption layer is the upper. Furthermore, it is pointed out that the observed shifts may be mainly of apparent nature, and therefore, the effect of the magnetic susceptibility of bulk substance was taken into consideration. The chemical shifts, corrected for this effect[5], are shown in the last column of Table I. Though it seems that there is a relation between the amount of adsorbed formic acid and the chemical shift, it is too small for the meaning to be discussed in detail.

TABLE I. CHEMICAL SHIFT OF FORMIC ACID ADSORBED ON SILICA***
(Unit: cps)

δ_{ads}: Shift from reference (water)
δ_{meas}: Shift from liquid formic acid
δ_{cor}: Value to be corrected for bulk magnetic susceptibility
$\delta=\delta_{meas}-\delta_{cor}$: Chemical shift

θ	δ_{ads}	δ_{meas}	δ_{cor}	δ
0.5	97	33	26	7
1.1	100	30	25	5
1.7	103	27	23	4
2.7	109	21	19	2

On the other hand, we could not detect any appreciable signal for the formic acid adsorbed on alumina in the monomolecular state. This is probably due partly to the small amount of adsorption and partly to stronger interaction with alumina than with silica.

Furthermore, the difference in the adsorbed state between silica and alumina could be made clear by the infrared absorption measurement as shown below.

Infrared Absorption.—*Silica.*—In the case of silica two adsorption bands are observed at 3450 (broad) and 1620 cm^{-1}. Both bands may be ascribed to associated water on the surface[6]. However, the stretching band due to the isolated hydroxyl group on the silica surface[7] does not appear at 3749 cm^{-1}, probably being masked by the broad band at 3450 cm^{-1} [8].

Now, when formic acid is adsorbed on silica, new absorption bands appear at 1714 and 960 cm^{-1} in addition to the band near 3520 cm^{-1} (Fig. 1, Table II). The absorption band at 1714 cm^{-1} can be ascribed to

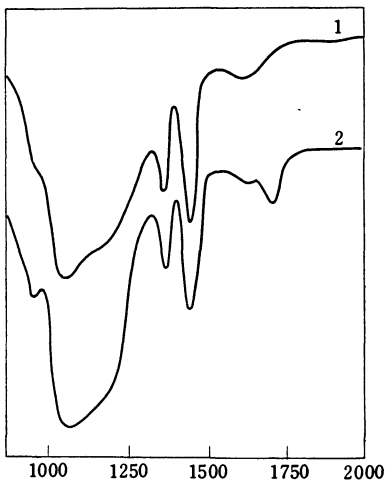

Fig. 1. Infrared spectrum of formic acid adsorbed on silica.
1: silica, 2: $\theta'=0.7$

the C=O stretching vibration, while the band at 960 cm^{-1} to the OH out-of-plane deformation vibration. Thus, it may be said that formic acid is adsorbed on silica in a non-dissociated state. The C=O stretching band shifts to lower frequency as compared to that of the monomer and also of the dimer. This band is rather similar in frequency to that of formic acid in the crystalline state. The same situation holds for the OH deformation band[9]. Considering these facts, it seems that the adsorbed formic acid forms hydrogen bonding not only to the silica surface, but also to each other, forming thus a two-dimensional net structure. Such a model

** The assignment of the signal was made by the use of deuteroformic acid HCOOD.

was already proposed in the case of the adsorption of water and ethanol on silica from the results of the dielectric measurement of these systems[10,11].

Alumina. — In the infrared spectrum of alumina, not only the absorption bands (3450 and 1620 cm^{-1}) of associated water on the surface, but also that (3760 cm^{-1}) of the isolated hydroxyl group are observed. When formic acid is adsorbed in a monomolecular layer, new absorption bands appear at 1344 and 1402 cm^{-1} besides 1620 cm^{-1} (strong), while the intensity of the band at 3450 cm^{-1} does not vary (Fig. 2, Table II). As the bands at 1344, 1402 and 1620 cm^{-1} can be assigned to the fundamental modes of vibration, ν_2, ν_5 and ν_4, of the formate ion[12], respectively, the state of formic acid adsorbed on alumina is similar to that on metals. However, when the amount of adsorbed formic acid is increased and a monomolecular layer is completed, new absorption bands appear at 1733 and 1124 cm^{-1}, and the band near 3520 cm^{-1} increases in intensity. These results show that non-dissociated formic acid can exist in the upper layer of adsorption on alumina.

TABLE II. SUMMARIZED RESULTS OF INFRARED ABSORPTION****

Adsorbent	θ' 0.3	0.7	1.3	2.4
Silica	1714	1714	1714	—
	960	960	960	—
Alumina			1733 (1705)	1733 (1705)
	1620 (1602)	1620 (1602)	1620 (1602)	1620 (1602)
	1402 (1377)	1402 (1377)	1402 (1377)	1402 (1377)
	1344 (1329)	1344 (1329)	1344 (1329)	1344 (1329)
			1124 (1100)	1124 (1100)

In short, it has been found that the adsorbed formic acid in a monomolecular layer exists as a dissociated or non-dissociated state, according as the adsorbent is alumina or silica. Such difference of state may be noteworthy, in the light of the fact that the catalytic activity of both oxides is similar, i. e., formic acid is dehydrated rather than dehydrogenated, in contrast with the overwhelmingly dehydrogenating activity of metallic powders. It seems, therefore, that there is no direct relation between the adsorbed state and the activated state of decomposition. Concerning this result further research is in progress.

Summary

The state of formic acid adsorbed on silica and alumina has been studied by a combined method of nuclear magnetic resonance and infrared absorption. The adsorbed formic acid in a monomolecular layer has been found not to be dissociated in the case of silica, but to be dissociated in the case of alumina.

A part of the expense for the present investigation has been defrayed from a grant given by the Ministry of Education, to which the authors' thanks are due.

Study on the Reductive Spinel—A New Spinel Formula AlN-Al_2O_3 instead of the Previous One Al_3O_4

By Goro YAMAGUCHI and Hiroaki YANAGIDA

(Received March 4, 1959)

It was proposed in the previous papers[1-3] that a lower valent aluminum ion Al^+ or Al^{2+} may exist in a spinel form Al_2O-$5Al_2O_3$ or Al_3O_4. L. M. Foster, however, suggested[4] that the spinel-like material contains nitride as its component and, therefore, the reducing ability is probably due to the nitride component.

In order to determine whether the reducing ability is due to the lower valent aluminum ion or to the nitride component, the chemical behaviors, the conditions of the formation, the magnetic susceptibility, the cell constant, and the density of the reductive spinel have been investigated.

Experimental

Synthesis of the Reductive Spinel.—Alumina and the reducing agent, aluminum or graphite, were mixed together and heated in the Tammann furnace (Fig. 1).

The X-ray diffraction patterns of the products were investigated at first, and the formation of the reductive spinel was confirmed with a number of methods as shown in Table I. The purity was confirmed also with the slow scanning X-ray diffraction recording.

Chemical Behaviors (Analysis of Nitrogen).—

The decomposition of the reductive spinel was tried by using the following reagents: (1) alkali or acid at room temperature; (2) PbO 90: B_2O_3 glass as a flux at 800°C in vacuo (Fig. 2); (3) air above 1000°C. The spinel employed in these experiments was confirmed not to show any X-ray diffraction pattern originating in crystalline aluminum nitride. The evolved gases in the

decomposition process were analyzed by a mass-spectrometer.

Other Properties of the Spinel.—The magnetic susceptibility was measured by the Gouy method. The applied magnetic field was 8500 or 13000 gauss.

The mean dielelectric constant of the system of the spinel and air was measured. The frequency applied was 1 MC. The size of the spinel was 60~80 in Tyler mesh. Its packing ratios were from 0.48 to 0.53.

Results

Formation of the Reductive Spinel.—The reductive spinel can be formed through reduction of alumina in a reductive atmosphere above 1650°C, but in vacuo, alumina evaporates. The best procedure in the present study is as follows: (1) mixing 0.2 g. of graphite with 5 g. of γ-alumina thoroughly; (2) heating it at 1700°C for 2 hr. in the Tammann furnace through which only a little air can pass; (3) quenching it. When the reduction of alumina is insufficient α-alumina remains, whereas crystalline aluminum nitride is isolated when the reduction has proceeded too far.

Chemical Behaviors. — The decomposition of the reductive spinel by acid or alkali can not be noticed at room temperature. Products of the reaction between the reductive spinel and the glass as a flux were lead metal and nitrogen gas. The volume of the emitted nitrogen gas corresponds to 85% of the calculated value from the formula of $AlN-Al_2O_3$. The volume of nitrogen gas was fluctuated because of the difficulties of complete fusing. The emitted gas moved the flux to a lower temperature part. The sample increased in weight by 6.90% when it was kept in air above 1000°C, and turned into α-alumina.

Other Properties.—The observed magnetic susceptibility was $\chi = -0.34\times10^{-6}$/g. The dielectric constant was calculated to be 23.8. The refractive index 1.80 was also calculated from data[3]. Then, the ionic refraction of nitrogen N^{3-} in the reductive spinel should be 4.30. This calculation was made by the Lorentz-Lorenz equation. The unit cell dimension is 7.940 Å (in spinel structure *Fd3m*), and the density is 3.78 g./cc.

Discussion

The synthetic experiments show that the presence of nitrogen is inevitable in the conditions of the formation of the reductive spinel, and alumina turns into aluminum suboxide and evaporates in vacuo[5]. Emission of nitrogen gas and the weight increase of the reductive spinel through oxidation lead us to conclude that the reducing ability is due to the nitride component. The weight increase by 6.90% corresponds approximately to that of $AlN-Al_2O_3$ by 6.95%. The magnetic susceptibility shows an absence of lower valent aluminum ion Al^{2+}. The ionic refraction of nitrogen ion 4.30 in the spinel structure is only 1.14 times larger than that of oxygen ion 3.77[3]. This shows that the ionic radii of nitrogen ion is not much greater than that of oxygen ion. The density 3.78 g./cc. and the cell dimension 7.940Å are coincident with a spinel formula $AlN-Al_2O_3$.

Summary

A compound between aluminum oxide and aluminum nitride can be produced in a reductive atmosphere above 1650°C.

A new spinel formula $AlN-Al_2O_3$ should be adopted instead of the previous one $Al_2O-5Al_2O_3$ or Al_3O_4.

The physical constants of $AlN-Al_2O_3$ are as follows: crystal structure *Fd3m*, $Z=8$, $a=7.940$ Å; density 3.78 g./cc.; dielectric constant 23.8; refractive index 1.80; magnetic susceptibility -0.34×10^{-6}/g.

*The Molecular Structure of the Monomer and the Dimer of Acrylic Acid**

By Takeshi UKAJI

(Received June 2, 1959)

Acrylic acid is known as an important source of some highly polymeric products, however its molecular structure has been left unsolved.

Recent electron diffraction study[1] of the monomer of formic and acetic acids has indicated that the two distances between the carbon atom and oxygen atoms in carboxyl group are not the same. This result essentially agreed with the structure of the monomer of formic acid of the electron diffraction sector-photometer method proposed by Karle and Karle[2]. Furthermore, various data[3] on the conjugated system show that the C–C single bond distance between two double bonds is shorter than its normal distance of 1.54 Å.

The present investigation was undertaken for the purpose of clarifying the stereochemical structure of acrylic acid, and also to elucidate the question as to what changes may occur on association of the monomer of the acid.

Experimental

Acrylic acid was prepared by hydrolysis of commercial grade methyl acrylate. On careful distillation of the acid, a fraction boiling at 50~51°C/20 mmHg was collected.

Electron diffraction photographs were taken according to the usual manner using a camera reported in the previous paper[4] (camera distance, ca. 9 cm., electron wavelength, 0.056~0.063 Å, determined by gold foil). The diffraction pattern were visually measured to the extent of ca. 70 of q-values.

Interpretation of Diffraction Patterns and Results

The well known formula for the calculation of the theoretical intensity curves are as follows:

$$I_{(q)}=\sum_i\sum_j \frac{Z_iZ_j}{r_{ij}} \exp(-a_{ij}q^2) \sin\frac{\pi}{10}qr_{ij}$$

$$q=(40/\lambda)\sin(\theta/2), \quad a_{ij}=(\pi^2/200) \ <\Delta r_{ij}^2>$$

where r_{ij} is the distance between the i-th and j-th atom, λ the electron wavelength, θ the scattering angle, Z_i the atomic number of i-th atom, and $<\Delta r_{ij}>$ the mean square amplitude of r_{ij}. The exponential term is omitted as a first approximation, i.e., $\exp(-a_{ij}q^2)=0$.

Monomer of Acrylic Acid. — To obtain the monomer of the acid, a fine nozzle through which its vapor flowed out was heated at 170~200°C by a spiral nichrome wire. No available data concerning the thermal equilibrium between the dimer and monomer of the vapor of this acid have appeared in literature. Also the temperature of the nozzle was controlled to obtain diffraction patterns different from those of the dimer. Some photographs were taken and these were then carefully compared with that of the dimer of the acid. In the regions of 20~30 of q-values, a remarkable change was observed in these patterns. Eight satisfactory photographs were obtained.

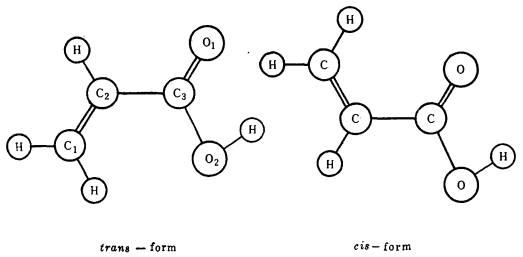

Fig. 1. Schematic model showing the *trans*- and *cis*-forms of acrylic acid.

It is assumed that all the atoms in this molecule are coplanar, and that the C–H distance and ∠CCH are 1.08 Å and 120°, respectively. The hydrogen atom in OH group was neglected, because its contribution to the total theoretical intensity curve was small. The parameters C_1=C_2, C_2–C_3, C_3=O_1 and C_3–O_2 used in the calculation of theoretical intensity curves, were varied from 1.32 to 1.45 Å, from 1.40 to 1.54 Å, from 1.18 to 1.24 Å and from 1.32 to 1.50 Å in steps of 0.02 or 0.03 Å, respectively, while the angles of $C_1C_2C_3$, $C_2C_3O_1$ and $O_1C_3O_2$ were varied from 110 to 130°, from 110 to 130° and from 110 to 135° in steps of 2 or 3°, respectively. In Fig. 2, the solid lines are the theoretical intensity curves of *trans*-form, and the chain lines are of *cis*-form.

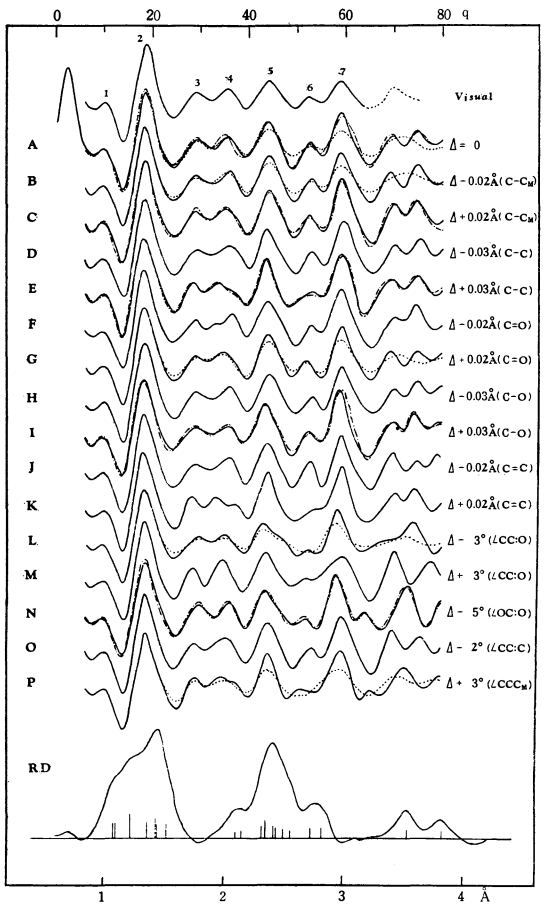

Fig. 2. Visual, theoretical intensity curves and radial distribution curve for acrylic acid. The notations on the right hand side of this figure show that the models deviate from the most probable model, for example, $\Delta=0$ is the most probable model which has the parameter as follows: C-H, 1.08; C=C, 1.36; C-C, 1.44; C=O, 1.22; C-O, 1.43 Å; $\angle$C : CH=$\angle$C : CC=$\angle$CC : O, 120° and $\angle$OC : O, 125°.

The effect of thermal vibration on the theoretical curves was examined, the vibration factors a's listed in Table I being used, and the curves including these effects were shown in the dotted lines in the same figure.

A careful comparison was made between the visual and theoretical intensity curves. Curve A is in the best agreement with the visual one. The curves of several other models resemble the visual one, but they differ from it in some features. The 4th, 5th and 6th maxima of curve B shift outward, while in curve C the 3rd and 4th maxima shift inward. Curves D and E are taken for the purpose of ascertaining the limit of acceptability for C=O distance, both curves being in good agreement with the visual one in all respects, except for the small displacement of the positions of the 3rd, 4th and 6th maxima. Likewise curves F and G are used to show the limit for C-O distance. These curves are also rejected because of the disagreement with the visual curve in the range $q>45$. In curve H, the 4th and 6th maxima shift outward, while in curve I the 3rd and 5th maxima shift outward, while in curve I the 3rd and 5th maxima shift inward. Curves J and K are taken as typical ones for models which have values accepted as borderline: the features of these curves in the range $q>50$ disagree with the visual curve. In curve L, the 4th minimum and the 7th maxima both shift inward, while the 4th and 5th maximum shift outward. Curves M and N are shown as the acceptable limit for the angle $C_1C_2C_3$. In curve M, the 6th and 7th maxima shift outward greatly, on the other hand, in curve N the positions of the 5th maximum and minimum shift inward.

As shown in Fig. 2, the theoretical curves of the *trans*- and *cis*-forms remain almost unchanged in all features. Therefore, we could not distinguish the difference between the *trans*- and *cis*-configurations of this molecule.

From the above considerations, model A is regarded as the most acceptable one, while the others are all accepted as borderline fits. Seven models are selected from them, and their q_C/q_O values are summarized in Table II.

The radial distribution curve for this molecule (RD curve in Fig. 2) was calculated using the following equation:

$$rD_{(r)}=\sum_{q=1}^{q_{max}} I_{(q)O} \exp(-bq^2) \sin\frac{\pi}{10}qr$$

where $I_{(q)O}$ is the intensity read from the visual curve. The value of b was determined by setting the $\exp(-bq^2) = 0.1$ at $q=70$. The curve shows that the first peak corresponds to the C–H, C_1=C_2, C_2–C_3, C_3=O_1 and C_3–O_2 distances, the second to the C′···H, C_1′···C_3, O_1′···O_2, O_1′···C_2 and O_2′···C_2 distances, the third to the O_2″···C_1 and fourth to the O_1″···C_1 distance, respectively. Owing to the complex nature of the peaks, no attempt was made to resolve them. It is found, however, that the positions determined from the most probable model agree fairly well with the peaks observed in this radial distribution curve.

The following values are obtained for the structure of the monomer of acrylic acid: C_1=C_2=1.36±0.02 Å; C_2–C_3=1.44±0.03 Å; C_3=O_1=1.22±0.02 Å; C_3–O_2=1.43±0.03 Å; ∠$C_1C_2C_3$=120±2°; ∠$C_2C_3O_1$=120±3°; ∠$O_1C_3O_2$=125±5°.

Dimer of Acrylic Acid. — It was assumed that the association of acrylic acid was the hydrogen bond coupling of two single molecules of the same type as in the case of formic and acetic acids, that the two planar acrylic acid molecules were coplanar, and also that the C_2, C_3, C_2′ and C_3′ atoms were laid on the same axis (as shown in Fig. 3). Many parameters were involved, so that the complete analysis on the molecular structure of the dimer of this acid would be very laborious. Therefore, some of the parameters of the most probable model obtained from

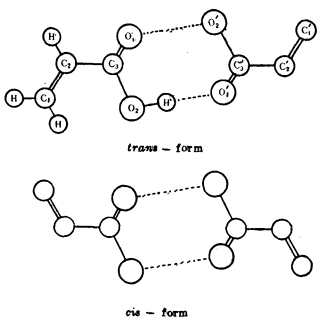

Fig. 3. Schematic model showing the skeletons and the numbering of atoms of the dimer of acrylic acid.

the above-mentioned analysis of monomer of this acid were assumed to be as follows: C–H, C_1=C_2, ∠C_2C_1H and ∠$C_1C_2C_3$ are assumed to be 1.08, 1.36 Å, 120 and 120°, respectively. Then the other parameters determining the structure C_2–C_3, C_3=O_1 and C_3–O_2 distances were varied from 1.40 to 1.50 Å, from 1.18 to 1.24 Å and from 1.30 to 1.43 Å in steps of 0.02 or 0.03 Å and O–H···O separation was varied from 2.65 to 2.80 Å with the same increment, while the angles of ∠$C_2C_3O_1$ and ∠$O_1C_3O_2$ were varied from 110 to 130° and from 120 to 135° in steps of 2 or 3°, respectively.

Some of the intensity curves are shown in Fig. 4. In this figure, the solid lines are the theoretical intensity curves of the *trans*-form, and the chain lines are of the *cis*-form. The effect of thermal vibration factors listed in Table I being used, the curves including these effects are shown in a dotted line in the same figure.

Curve E is in the best agreement with the visual one. In curve A, the 3rd and 4th maxima shift inward, while in curve B these maxima shift outward. A comparison of curves C and D, which possess 0.02 Å longer and shorter parameters, respectively, for C_3=O_1 distance, show that there are remarkable changes of the features

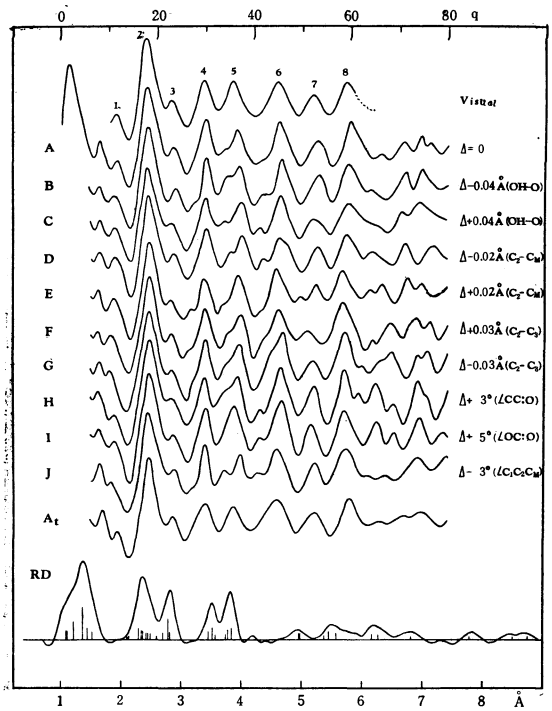

Fig. 4. Visual, theoretical intensity curves and radial distribution curve for the dimer of acrylic acid.
The notations on the right hand side of this figure show that the models deviate from the most probable model, for example, $\Delta=0$ is the most probable model which has the parameter as follows; C-H, 1.08; C=C, 1.36; C-C, 1.44; C=O, 1.22; C-O, 1.36 Å; ∠C:CH=∠C:CC=∠CC:O, 120°; ∠OC:O, 1.25° and OH···O distance, 2.76 Å.

in the region of 20 to 30 q-values. Curve F differs from E, the former possessing a parameter of an OH···O distance which is 0.04 Å longer than in the latter; and curve G differs from E, the former possessing the same distance by 0.04 Å shorter. These curves disagree with the visual one in the positions of the 3rd and 4th maxima. In curves H and I, remarkable differences from the visual one are found in features between 20 and 30 of q-values and in positions of 3rd and 4th maxima. Curves J and K were examined for the purpose of ascertaining the limit of acceptability for C_2–C_3 distance, both curves being in good agreement with the visual one in all respects, except the 3rd and 6th maxima.

The radial distribution curve for the dimer of acrylic acid is shown in Fig. 2 (RD curve). The positions determined from the most acceptable model (shown in vertical lines in this curve) fairly well agree with the peaks observed in this radial distribution curve. A relatively small peaks is found at 2.76 Å corresponding to the separation across the bridge O–H···O.

The structure determined for the dimer of acrylic acid, which is in agreement with the quantitative results (q_C/q_O values in Table III), is as follows: C_1=C_2=1.36 Å (assumed); C_2–C_3=1.44±0.03 Å; C_3=O_1=1.22±0.02 Å; C_3–O_2=1.36±0.03 Å; ∠$C_1C_2C_3$=120° (assumed); ∠$C_2C_3O_1$=120±3°; ∠$O_1C_3O_2$=125±5°; O–H···O=2.76±0.04 Å.

Discussion

The C=O and C–O distances in acrylic acid are the same as those observed in several interesting structural studies of the carboxyl group on formic and acetic acids. Therefore, no differences between a saturated and an unsaturated substituent attached to the carboxyl group could be found in this work.

Moreover, the C=C, C–C and C=O distances and the valence angles in this

molecule generally agree with the corresponding bond lengths and valence angles of acrolein[5] and acrylyl chloride[6] which are obtained by electron diffraction studies. Bond shortening and bond elongation of C–C and C=C bonds in conjugated molecules were plausibly explained by the delocalization of π-electron. As a matter of fact, it may be considered that the order of conjugation in this molecule is the same as that calculated on acrolein by C. A. Coulson[7].

In the dimer, the C–O bond becomes 0.07 Å shorter than that in the monomer, while the C=O bond remains unchanged. Within the limits of accuracy of this work, the circumstances are the same as in the case of association of formic and acetic acids. Several investigations show that the heat of dimerization of some carboxylic acids is of the order of 13~18 kcal./mol. The C–O bond shortening may be attributed for considerable part to the formation of a ring by two carboxyl groups across the hydrogen bridges.

The author wishes to express his sincere gratitude to Professor A. Kotera and Mr. M. Igarashi of Tokyo University of Education for their kind guidance and encouragement throughout this work, and for the free use of the apparatus located at their university. Thanks are also due to Professor J. Kurahashi and Dr. T. Takeshima of this university for their helpful advice.

*The Molecular Structure of the Monomer and the Dimer of Methacrylic Acid**

By Takeshi UKAJI

(Received June 2, 1959)

It has been commonly recognized that the derivatives of acrylic acid which have a methyl group on the α-carbon atom are reactive than the one having no substituent. Theoretical and structural explanation of this chemical fact seems not yet to have been given. The present work is directed to clarifying the stereochemical structure of methacrylic acid, and also to elucidate the question concerning the changes which may occur on the introduction of the methyl group into the α-position of the acid and on the association of the monomeric acid.

Experimental

Methacrylic acid was prepared by hydrolysis of commercial grade methacrylate. On careful distillation of the acid, a fraction boiling at 75~76°C/20 mmHg was collected. It was stocked over hydroquinone.

The electron diffraction photographs were taken according to the usual manner using a camera reported in the previous paper[1] (camera distance, ca. 9 cm.; electron wavelength, 0.053~0.061 Å, determined by calibration with gold foil). The experimental technique concerning the photographs of the monomer of this acid was essentially the same in the case of the monomer of acrylic acid. The diffraction pattern was visually measured to an extent of ca. 70 of q-values.

Interpretations of Diffraction Patterns and Results

For the calculation of theoretical intensity curves, the authorized formula[3b] was used. The thermal vibration factor is omitted as a first approximation.

Monomer of Methacrylic Acid.—To examine if the temperature of the present experiment is sufficient for the thermal dissociation of the acid, some photographs were taken and these were carefully compared with that of the dimer of this acid. A remarkable change was observed.

* Presented partly at the Symposium on Structural Chemistry, Fukuoka, Nov. 22, 1957.

1) T. Yuzawa and N. Yamaha, This Bulletin, **26**, 414 (1953).

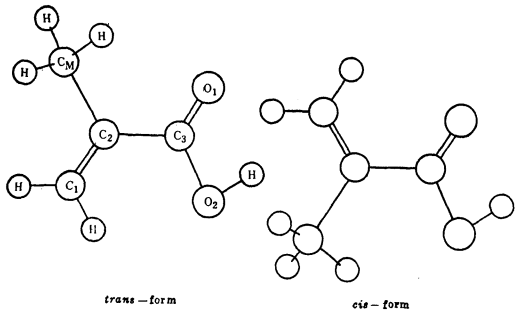

Fig. 1. Schematic model showing the *trans*- and *cis*-forms of methacrylic acid.

in the feature at about 23 of q-values in these patterns. Six satisfactory photographs were obtained.

On the basis of foregoing information[2,3], it is assumed that all the carbon and oxygen atoms in this molecule are coplanar, and that the C-H bond distance in the methyl group is 1.10 Å, in which each hydrogen atom forms tetrahedral configuration, and the C-H distance and ∠CCH in methylene group are 1.08 Å and 120°, respectively. The hydrogen atom in the hydroxyl group was neglected for the same reason as that described in the previous paper[3b]. The parameters C_1=C_2, C_2-C_3, C_3=O_1, C_3-C_2 and C_2-C_M (in methyl group), used in the calculation of theoretical intensity curves, were varied from 1.32 to 1.45 Å, from 1.40 to 1.54 Å, from 1.18 to 1.24 Å, from 1.32 to 1.50 Å and from 1.40 to 1.54 Å in steps of 0.02 or 0.03 Å, while the angles of $C_1C_2C_3$, $C_3C_2C_M$, $C_2C_3O_1$ and $O_1C_3O_2$ were varied from 110 to 130°, from 110 to 130°, and from 110 to 135° in steps of 2 or 3°, respectively.

In Fig. 2, the solid lines are descriptive of the theoretical intensity curves of the *trans*-form, and the chain lines those of the *cis*-form. The effect of thermal vibration (the factors are listed in Table I) was then examined and the curves including these effects were shown in the dotted lines in the same figure.

A careful comparison was made between the visual and theoretical intensity curves. Curve A is in the best agreement with the visual one. The curves of several other models quoted in this figure also resemble the observed intensity curve, but they differ from it in the features of some maxima and minima. Curves B and C agree with the visual one in all features, except for the position of the 4th maximum. While in curves D and E, the positions of the 3rd minimum and the 4th maximum and minimum, and the feature of the 6th peak differs from the visual curve. Curves F, G, H and I are taken for the purpose of ascertaining the limit of acceptability for C_3=O_1 and C_3-O_2 distances; these curves are in good agreement with the observed one in all features, except for the positions of the 4th and

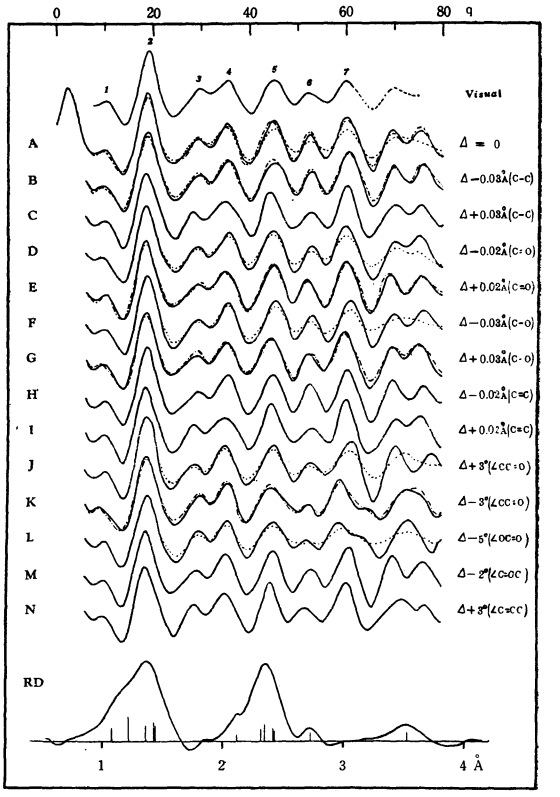

Fig. 2. Visual, theoretical intensity curves and radial distribution curve for methacrylic acid. The notations on the right hand side of this figure show that the models deviate from the most probable model, for example, Δ=0 is the most probable model which has the following parameters; C-H=1.08, C_M-H (in methyl group)=1.10, C=C=1.36, C-C=1.44, C=C=1.22, C-O=1.43 Å, $\angle CC_MH$=109.5°, $\angle$C:CH=$\angle$C:CC=$\angle$CCC=$\angle$CC:O=120° and $\angle$OC:O=125°.

6th maxima. In curves J and K, the positions of the 4th maximum and the intensity relations of the 6th peak are different from those of the visual one. Curves L and M are used to examine the limit of angle $C_2C_3O_1$. These curves are rejected because of the disagreement with the visual one in the range of q>45. Curves from N to P show the acceptable limit of the angles of $O_1C_3O_2$, $C_1C_2C_3$ and $C_2C_3C_M$, respectively. These curves have small differences in the positions and features of the 3rd minimum, the 4th and the 6th maximum.

The theoretical intensity curves of the *trans*- and the *cis*-forms remain almost unchanged throughout all the features. Therefore, we could not distinguish between the *trans*- and *cis*-configuration of this molecule.

From the above considerations, model A is regarded as the most acceptable one, while others are all accepted as on the borderline.

Seven models are selected from them, and their q_C/q_O values are summarized in Table II. The structural information deduced from the values of averages and the average deviations of q_C/q_O ratios is consistent with the above correlation analyses.

The RD curve in Fig. 2 is the radial distribution curve for this molecule. In this curve, the first peak corresponds to the C–H, C_M–H (in methyl group), C_1=C_2, C_2–C_3, C_2–C_M, C_3=O_1 and C_3–O_2 distances, the second, third and fourth to the C'$\cdots$H, $C'_2\cdots$H, $O'_1\cdots C_2$, $O'_2\cdots C_2$, $C'_1\cdots C_M$, $C'_3\cdots C_M$, $C'_1\cdots C_3$, $O''_2\cdots C_1$ and $O''_1\cdots C_M$, the fifth to the $O''_1\cdots C_1$ and the sixth to the $O''_2\cdots C_M$ distances, respectively. The interatomic distances determined from the most probable model (shown in vertical lines in this RD curve) are in good agreement with the peaks observed in this radial distribution curve.

The following values are obtained for the structure of the monomer of methacrylic acid: C_1=1.36±0.02 Å; C_2–C_3=1.44±0.03 Å; C_2–C_M=1.52±0.02 Å; C_3=O_1=1.22±0.02 Å; C_3–O_2=1.43±0.03 Å; $\angle C_1C_2C_3$=120±2°; $\angle C_3C_2C_M$=120±3°; $\angle C_2C_3O_1$=120±3°; $\angle O_1C_3O_2$=125±5°.

Dimer of Methacrylic Acid.—The circumstances of the association of methacrylic acid is assumed to be the same as in the case of the dimer of acrylic acid. The complete analysis on the molecular structure of the dimer of this acid may be very laborious because of the inclusion of so many parameters. Therefore, some parameters of the most probable model of the

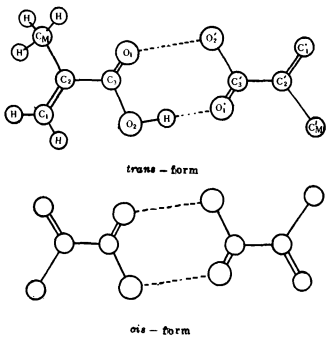

Fig. 3. Schematic model showing the skeletons and the numbering of atoms of the dimer of methacrylic acid.

monomer of this acid obtained from the above analysis were assumed to be as follows: C-H (in methyl group), C_M-H (in methyl group), C_1=C_2, C_3=O_1, $\angle C_2C_1H$, $\angle C_2C_MH$, $\angle C_1C_2C_3$, $\angle C_2C_3O_1$ and $\angle O_1C_3O_2$ were taken to be 1.08 Å, 1.10 Å, 1.36 Å, 1.22 Å, 120°, 109.5°, 120°, 120° and 125°, respectively. In the thirty models examined in this analysis, the parameters C_2-C_3, C_2-C_M and $C_1C_2C_M$ were varied from 1.40 to 1.50 Å, from 1.45 to 1.54 Å and from 110 to 130°, respectively.

Some of the theoretical intensity curves are shown in Fig. 4. These curves are representative of the theoretical intensity curves of the *trans*-form, and those of the *cis*-form are omitted in this figure for the reason that few differences are found between them. Curve A is in the best agreement with the visual one, and has parameters described in the notations of Fig. 4. In curves B and C, the 5th and 6th maxima have some different features from the visual curve; the position of the 7th maximum shifts outward in the former curve and the same maximum

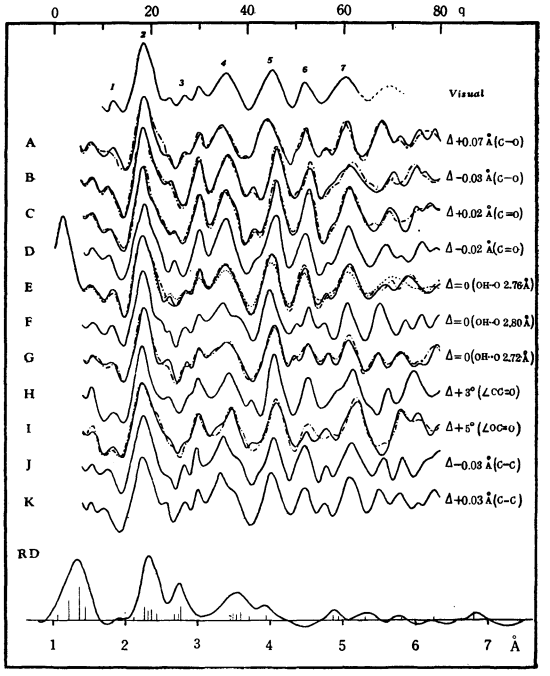

Fig. 4. Visual, theoretical intensity curves and radial distribution curve for the dimer of methacrylic acid. The notations on the right hand side of this figure show that the models deviate from the most probable model, for example, $\Delta=0$ is the most probable model which has the following parameters; C-H=1.08, C_M-H (in methyl group)=1.10, C=C=1.36, C-C=1.44, C=O=1.22, C-O=1.36 Å, $\angle$C : CH=$\angle$C : CC=$\angle CCC_M$=$\angle$CC : O=120°, $\angle CC_MH$=109.5°, $\angle$OC:O=125° and OH···O=2.75Å.

shifts inward in the latter. Curves D and F are taken for the purpose of ascertaining the limit of acceptability for C_2–C_M distance, both curves being in good agreement with the visual one in all the positions of maxima and minima; however, small peaks and shoulders appear among them. In curve F, the 3rd minimum and 7th and 8th maxima shift inward and the 5th maximum outward, while in curve G, the 5th and 6th maxima shift outward. In curves H and I, the 4th and 5th minima and 6th maximum have different positions, but in curve J small peaks appear between the 4th and 5th and 6th maxima. Curve A shows the effect of thermal vibration on curve A, using the vibration factors listed in Table I.

The radial distribution curve for the dimer of methacrylic acid is shown in Fig. 4 (RD curve). The curve shows that the positions and their relative height of peaks determined from the most probable model (as shown in vertical lines) agree fairly well in general with the peaks observed in this radial distribution curve.

The structure of the dimer of methacrylic acid, which is in agreement with the quantitative results in Table III, is determined as follows: C_2–C_M=1.52±0.02 Å, $\angle C_1C_2C_M$=120±3° and O_1–H···O_2 separation 2.75±0.04 Å; and all other parameters are the same as in the dimer of acrylic acid.

Discussion

The C_1=C_2, C_2–C_3, C_3=O_1 and C_3–O_2 distances and the valence angles of $C_1C_2C_3$, $C_2C_3O_1$ and $O_1C_3O_2$ in this molecule are essentially the same as the corresponding bond lengths and valence angles of acrylic acid which is obtained in a previous paper[2]. The C_2–C_M distance in this molecule is shorter than the normal C–C single bond distance 1.54 Å. This bond shortening is explained by the term hyperconjugation. The result of the theoretical calculation by Coulson and Crawford[4] shows that the bond compression energy of C–C single bond, from 1.54 to 1.52 Å, is 0.13 kcal./mol. In our preliminary calculation by a simple MO method** (neglecting overlap integral) acrylic and methacrylic acid, the values of bond order and free valence are shown schematically as follows:

When the values obtained here of the bond order and the bond lengths were treated following the method of Mulliken and others[5], the results compared favorably with the criterion regarding the bond order and the bond lengths which included the idea of hyperconjugation of them (the values concerned with C=C and C–C of acrylic acid, C=C, C–C and C–C_M (in methyl group) of methacrylic acid). In the above figure, the comparison of free valence shows that methacrylic acid has a tendency to possess somewhat greater sensibility than acrylic acid in radical reaction.

In the dimer of this acid, the circumstances are the same as in the case of the association of acrylic acid.

The author wishes to express his sincere gratitude to Professor A. Kotera, Mr. M. Igarashi and Mr. M. I'Haya of Tokyo University of Education for their kind guidance and encouragement throughout this work, and for the free use of the

4) C. A. Coulson and V. A. Crawford, *J. Chem. Soc.*, **1953**, 2052.

** The well-known LCAO molecular orbital treatment is conducted as follows: the effect of the σ electron, assumed to be constant, is neglected, and the π-electrons are considered, as an approximation, to occupy the molecular orbital formulated below.

$$\Psi_i=\sum_{r=1}^{n} c_{ir}\phi_r$$

Then, we have the equatin:

$$(\alpha_r-E)C_r+\sum_{s\neq r}(\gamma_{rs}-S_{rs}E)C_s=0 \qquad (r=1,2,\cdots\cdots,n)$$

in which α is the coulomb integral, E's the energies of LCAO MO's, γ_{rs} the exchange integral and S_{rs} the overlap integral. The details of the calculations of the lower energy levels of these molecules and the empirical parameters adopted are essentially the same as in the case of the calculation of hyperconjugation by I'Haya except for the parameters assigned of oxygen atoms which are: α_O(carbonyl oxygen)=α_C+2.0 and α_O(carboxyl oxygen)=α_C+1.5. Here α_C is the coulomb integral of the carbon atom. According to Coluson's*** definition, the charge density (q_r) of π-electron on the atom r and the bond order (p_{rs}) of the bond between atoms r and s are given by the following equations:

$$q_r=2\sum_i C_{ir}^2$$

$$q_{rs}=2\sum_i C_{ir}\cdot C_{is}$$

where the summations are taken overall occupied MO's.

The calculation of the free valence F_r at atom r in a molecule followed the definition formulated by Coulson****

$$F_r=N_{max}-N_r$$

The values of N_{max} is $3+\sqrt{3}$ and the N_r is

$$N_r=3+\sum_i p_{rs}$$

in which p_{rs} is the π-bond order of the r-s bond, where s is adjacent to r atom.

*The Molecular Structure of Methyl Acrylate and Methyl Methacrylate**

By Takeshi UKAJI

(Received June 2, 1959)

Investigations of methyl formate and methyl acetate by electron diffraction have been reported[1], but no information seems to have been proposed regarding the stereochemical structure of methyl acrylate and methyl methacrylate which are important materials for high polymeric products.

In the present work, structural studies on methyl acrylate and methyl methacrylate by the electron diffraction method are undertaken to determine the most probable location of the methyl group of ester in these two compounds and to inspect the effect of hyperconjugation on the C-C single bond between the methyl group and the α-carbon atom in methyl methacrylate.

Experimental

Samples were purified by careful distillation. Methyl acrylate, b. p. 84.5~85.5°C. Methyl methacrylate, b. p. 100~101°C. These were stocked over hydroquinone.

The electron diffraction photographs were taken in the usual manner using a camera similar to the one reported in the previous paper[2] (camera distance, ca. 9 cm., electron wavelength, 0.059~0.063 Å, determined by calibration with gold foil). Fifteen satisfactory photographs were obtained in the case of methyl acrylate and eight in the case of methyl methacrylate. The diffraction patterns were visually measured to an extent of about $q=80$ in both cases.

Interpretation of Diffraction Patterns and Results

For the calculation of theoretical intensity curves, the authorized formula[3] was used. The exponential term of the formula is omitted as a first approximation.

Methyl Acrylate.—In the models of this molecule only four parameters are changed. In these the C_3-O_2 distance in carboxyl bond is varied from 1.32 to 1.45 Å in steps of 0.02 or 0.04 Å, and the O_2-C_4 distance in methoxyl bond from 1.40 to 1.50 Å with the same increments. The angle of $C_3O_2C_4$ of methoxyl group varied from 105 to 130° in steps of 5° and the angle between $C_3O_2C_4$ plane and the plane composed of the other atoms in the molecule is varied from 0 to 60°. The other parameters of this molecule were assumed to be those of the most probable model of acrylic

acid[4]. Careful comparison was made between the visual intensity curve and the theoretical ones.

Fig. 2 shows the parameter chart for this molecule. The groupings of the models in the following discussions are made according to the qualitative similarity of the theoretical intensity curves. Groups D, E and F correspond to the models of which methyl groups are inclined by 20, 25 and 30°, respectively, to the molecular plane, and others are all rejected because of the disagreement with the visual curve.

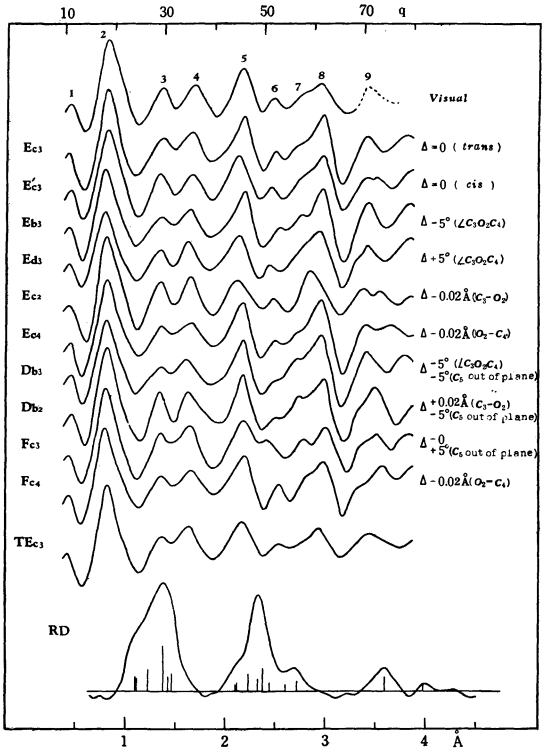

Fig. 3. Visual, theoretical intensity curves and radial distribution curve for methyl acrylate. The notations on the right hand side of this figure show that the models deviate from the most probable model, for example, $\Delta=0$ is the most probable model which has the following parameters; C_1–H $=1.08$, C_5–H (in methyl geoup) $=1.10$, C_1=C_2 $=1.36$, C_2–$C_3=1.44$, C_3=$O_1=1.22$, C_3–$O_2=1.36$, O_2–$C_4=1.46$ Å, $\angle C_2C_1H=\angle C_1C_2C_3=\angle C_2C_3O_1$ $=120°$, $\angle O_2C_4H$ (in methyl ester group) $=$ $109.5°$, $\angle O_1C_3O_2=125°$, $\angle C_3O_2C_4=115°$ and C_4 atom is 25° out of plane configuration.

Of curves of the *trans*-form of the models E_{c2}, E_{b3}, E_{c3}, E_{d3} and E_{c4}, curve E_{c3} is in excellent agreement with the visual curve in all respects (Fig. 2). Curve E'_{c3} is taken as the typical one of which the model has a *cis*-configuration as regards C_1=C_2 and C_3=O_1. No remarkable discrepancies in the positions of maxima, minima and their intensity relations of the theoretical intensity curves are found throughout this work between the *trans*- and *cis*-configurations. Therefore, that of the *cis*'s of all the other models are omitted in Fig. 3. Curves E_{c3}, E_{b3}, E_{d3} and E_{c4} are given in order to show the limits of acceptability for the positions and relative intensities of the 5th, 6th and 8th maxima, and of the acceptable range of shapes of the 7th shelf. All curves with 4th maximum and minimum shifting inward and with the resolution of the 7th shelf greater than that in curve E_{b3} were rejected. Curve E_{d3} was the lower limit of acceptability for the 4th, 5th and 6th maxima shifting inward and for the prominence of the 7th shelf.

Curves D_{b2} and D_{b3} are given as acceptable curves of the D group. The height of the 5th maximum is slightly increased in both curves, and that of the 3rd maximum in the D_{b2} curve decreased, but that in D_{b3} increased. These discrepancies are not regarded as sufficient to justify the rejection of these models, and both models are considered to be acceptable borderline ones.

Of models in the F group, curves F_{c3} and F_{c4} are taken as representative ones. The features of the 6th maximum and the 7th shelf are both accepted as the limit of permission.

The effect of the thermal vibration on the theoretical curve was then examined. The vibration factor is listed in Table I. Curve TE_{c3} is a representative one showing this effect on the theoretical curve calculated from model E_{c3}. This curve has the same feature in all respects as the visual one has.

From the above considerations, model E_{c3} may be regarded as the most acceptable one, while the others are all accepted as borderline cases. The q_C/q_O values of these eight models are summarized in Table II. The weighing for each feature is indicative of its reliability in comparison with theoretical curves. Low weighing is given to the inner features, because these have generally been found to give less satisfactory agreement than do those at somewhat greater q values. Features for which reproducible measurements could not be obtained are also given lower weights. To the features farther out are assigned relatively low weights.

The radial distribution function for this molecule is calculated by the use of the following equation, (RD curve in Fig. 3):

$$rD_{(r)}=\sum_{q=1}^{q_{max}} I_{(q)_O}\exp(-bq^2)\sin\frac{\pi}{10}qr$$

where $I_{(q)_O}$ is the intensity read from the visual curve. The value b is determined by setting $\exp(-bq^2)=0.1$ at $q=80$. The curve shows that the first peak corresponds to the C–H, C_3–O_1, C_2–C_3, C_3–O_2 (in carboxyl) and O_2–C_4 (in methoxyl) distance, the second and the third to the nonbonding atom pairs, i. e., $C'\cdots H$, $O'_2\cdots H$, $O_1'\cdots O_2$, $O_1'\cdots C_2$, $O_2'\cdots C_2$, $C_1'\cdots C_3$, $C_1'\cdots O_2$ and $C_2''\cdots C_4$, the fourth to the $C_1''\cdots O_1$, and the fifth to the $C_1'''\cdots C_4$, respectively. Owing to the complex nature of the peaks, no attempt was made to resolve the distances. It may be noted, however, that the position determined from the most acceptable model agrees fairly well with the peaks observed in this radial distribution curve.

The results obtained from the examination of theoretical intensity curves and the visual ones are as follows.

Assumption: C–H=1.08 Å, C–H (in methyl group)=1.10 Å, C_1=C_2=1.36 Å, C_2–C_3=1.44 Å, C_3=O_1=1.22 Å, $\angle CCH=\angle C_1C_2C_3=\angle C_2C_3O_1=120°$, $\angle O_1C_3O_2=125°$ and $\angle O_2C_4H=109.5°$ (in methyl group).

Results: C_3–O_2 (in carboxyl)=1.36±0.02 Å, O_2–C_4 (in methoxyl)=1.46±0.02 Å, $\angle C_3O_2C_4=115\pm5°$ and out-of-plane angle of methyl group is 25±5°.

Methyl Methacrylate.—On account of the many parameters involved, a complete analysis on the molecular structure of methyl methacrylate may be very laborious. The present analysis was based upon the following assumption: C–H (in methylene group)=1.08 Å, C–H (in methyl group)=1.10 Å, the hydrogen atoms in two methyl groups have tetrahedral configuration, C_1=C_2=1.36 Å, C_2–C_3=1.44 Å, C_3=O_1=1.22 Å, C_3–O_2 (in carboxyl)=1.36 Å, O_2–C_4 (in methoxyl)=1.46 Å, $\angle C_2C_1H=\angle C_1C_2C_3=\angle C_2C_3O_1=120°$, $\angle O_1C_3O_2=125°$, $\angle C_3O_2C_4=115°$ and the C_4 atom is inclined by 25° to the molecular plane. Therefore, in the models examined in this work, only two parameters are changed; the C_2–C_5 distance between C_5 atom of methyl group and α-carbon atom is varied from 1.45 to 1.54 Å in steps of 0.02 or 0.03 Å and the angle of $C_5C_2C_3$ from 110 to 130° in steps of 2 or 3°.

The theoretical intensity curves which are calculated through the above mentioned equation are carefully compared with the visual one. In Fig. 5, visual and theoretical intensity curves and also the radial distribution curve are shown. Curve B is the most acceptable one, and curves A and from C to E can be considered to show the limit of acceptability for the resolution and

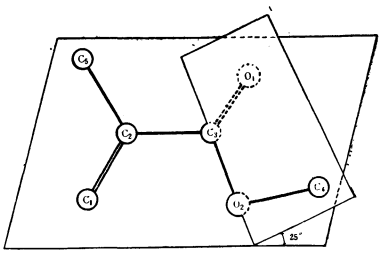

Fig. 4. Schematic model showing the skeleton and the numbering of atoms of methyl methacrylate. This model shows the *trans*-form.

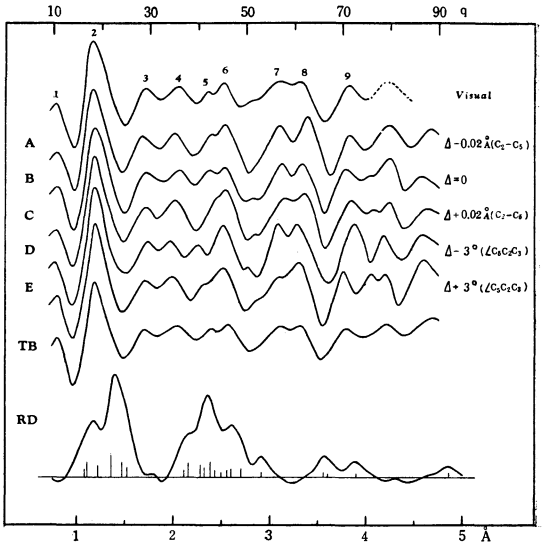

Fig. 5. Visual, theoretical intensity curves and radial distribution curve for methyl methacrylate. The notations on the right hand side of this figure show that the models deviate from the most probable one, for example, $\Delta=0$ is the most probable model which has the following parameters; C_1–H=1.08, C_4–H=C_5–H=1.10, C_1=C_2=1.36, C_2–C_3=1.44, C_3=O_1=1.22, C_3–O_2=1.36, O_2–C_4=1.46 Å, $\angle C_2C_1H=\angle C_1C_2C_3=\angle C_2C_3O_1=120°$, $\angle C_2C_5H=\angle O_2C_4H=109.5°$, $\angle O_1C_3O_2=125°$, $\angle C_3O_2C_4=115°$ and C_4 atom is 25° out of plane configuration.

for the relative intensities of the 7th and 8th maxima and the feature of the 5th shelf. Curve TB shows the effect of thermal vibration. The thermal vibration factors examined in this case are listed in Table III. The q_C/q_O values of these models are summarized in Table IV. The weighing of these features followed the same consideration as in the case of methyl acrylate.

The radial distribution curve (RD curve in Fig. 5) is drawn according to the above equation. The value of b is determined by setting $\exp(-bq^2)=0.1$ at $q=90$. The curve shows that the positions determined from the most acceptable model agree

well with the peaks observed in this radial distribution curve.

The results obtained from the above analyses in this molecule are as follows.

Assumption: All parameters of the most probable model of methyl acrylate were assumed, and the C_5 atom in the methyl group was coplanar, H atoms in this group were of tetrahedral configuration and C_5–H bond lengths were 1.10 Å.

Results: C_2–C_5 = 1.52±0.02 Å and $\angle C_5C_2C_3$ = 129±3°

Discussion of the Results

The results obtained from electron diffraction investigation of acrylic acid generally agree with the corresponding bond lengths and valence angles of acrolein and acetic acid which were obtained by electron diffraction study by Sutton et al.[5] and by Brockway et al.[6] On the basis of the above reason, it was assumed that the skeletons of methyl acrylate and methyl methacrylate were of the same dimension as in the case of acrylic acid.

Unfortunately, no data have appeared which make possible the valid comparison of the C=C, C–C and C=O distances in these esters with those in other compounds. However, the configuration of the methyl group in methyl acrylate agrees with that of methyl acetate. The values for the $C_3O_2C_4$ angle (115±5°) and for the out-of-plane configuration (25±5°) obtained in this work do not differ significantly from the values reported for methyl acetate.

Regarding methyl methacrylate, the value of C_2–C_5 distance obtained here is comparable with the recent value obtained by Keidel and Bauer[7] in the case of toluene, and with the results of I'Haya's theoretical calculation on hyperconjugation[8] of the methyl group in ethylacetylene.

The author wishes to express his sincere thanks to Professor A. Kotera and Mr. M. Igarashi of Tokyo University of Education for their kind guidance and encouragement throughout this work. Thanks are also due to Dr. T. Takeshima of this university for his helpful advice.

SHORT COMMUNICATIONS

The Glass Transition Temperatures of Various Kinds of Polyethylenes

By Kōji TANAKA

(Received August 18, 1959)

It is well known that various physical properties of polyethylene are considerably affected by the chain branching. According to C. A. Sperati et al.[1], for instance, short chain branching controls crystallinity, and long chain branching the viscoelastic properties of the molten polymer and the ultimate strength of the solid.

The author performed an experiment in order to know whether chain branching affects the glass transition temperature or not.

Samples used in this investigation are Marlex 50, Ziegler type polyethylene, and eight kinds of high-pressure polyethylene which are different in their molecular weights, melt index and numbers of short and long chain branchings. These high-pressure samples were provided by courtesy of E. I. du Pont de Nemours and Company. Marlex 50 and Ziegler were commercial polymers. In Table I are shown molecular parameters for these high-pressure polyethylenes. For Marlex 50 and Ziegler these data were not available hitherto, but since the number of short chain branchings was found for

1) C. A. Sperati, W. A. Franta and H. W. Starkweather, Jr., *J. Am. Chem. Soc.*, **75**, 6127 (1953).

the two materials in the paper by R. C. Rempel et al.[2], those were adopted for reference. These are 0.15 and 0.25 for Marlex 50 and Ziegler, respectively. Prior to a series of measurements these ten samples were sufficiently crystallized by thermal treatment.

TABLE I. MOLECULAR PARAMETERS[a] FOR HIGH-PRESSURE POLYETHYLENES

Sample	Melt index	$Mn \times 10^{-3}$	Nc[b]	Nw[c]
A	0.2	34	1.6	20
B	2.1	32	1.6	18
C	2.1	21	2.2	27
D	2.1	18	3.0	34
E	3.8	20	1.6	13
F	2.0	50	2.0	18
G	1.8	27	0.6	10
H	1.6	12	3.2	29

a) These data were determined at E. I. du Pont de Nemours and Company according to the method described in *J. Am. Chem. Soc.*, **75**, 6110 (1953).

b) Short chain branching index in CH_3 groups per 100 CH_2 groups.

c) Long chain weight average number of branch points per molecule[3].

Measurements were carried out by volume dilatometry[4]. As confining liquid mercury and absolute alcohol were used for the run above −40°C and for that from −70°C to room temperature, respectively. A Dewar vessel containing toluene was used as a bath. Cooling and heating of the bath were conducted at the rate of 0.3°C per min. by throwing dry ice and inserting nichrom wire into the bath.

Glass transition temperature, T_g, was determined from intersection of two straight lines on the volume-temperature curve and from discontinuity of the curve obtained by plotting the volume-temperature derivatives as a function of temperature.

Glass transition temperatures obtained from this experiment were plotted as a function of the short chain branching index (Fig. 1). From the figure it seems that the glass transition temperature of these samples lowers proportionally with the increase of the short chain branchings, though Marlex and Ziegler appear to deviate somewhat from this tendency. Then the relation between the glass

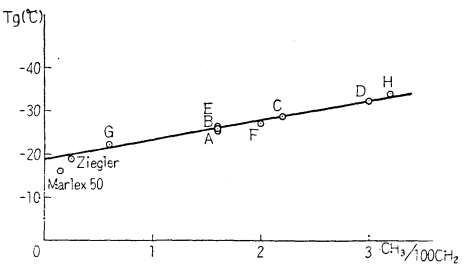

Fig. 1. Glass transition temperatures of various polyethylene samples different in their short chain branching index.

transition temperature and the short chain branching index of these high-pressure polyethylenes was led to the following equation:

$$T_g = -4.6\ \mathrm{Nc} - 18.7$$

On the other hand, long chain branching does not appear to affect the glass transition temperature so much as short chain branching does.

The author thanks Professor M. Takeda for many helpful suggestions and discussion.

Studies on Organic Catalytic Reactions. I

By Ken-ichi WATANABE

(Received October 3, 1959)

It is interesting to study the application of metallic catalysts to new organic reactions beyond the customary catalytic reactions. Various reactions of organic compounds may be accelerated with the aid of catalysts and subsequently some new catalytic reactions are expected to be found. In this paper, general aspects of hydrolysis of aromatic nitriles and esters with nickel catalysts—mainly the Urushibara nickel catalyst[1]— are reported, and reactions of aromatic halogen compounds with the catalyst are also described.

When aromatic nitriles were refluxed with water in the presence of the catalyst, they were found to be hydrolyzed to the

1) Y. Urushibara and S. Nishimura, This Bulletin, 27, 480 (1954).

TABLE I. HYDROLYSIS OF BENZONITRILE WITH URUSHIBARA NICKEL CATALYST

Benzonitrile g.	U-Ni-B g.	Solvent cc.	Time hr.	Products, g. Amide	Amine	acid	Remarks
5	4	Water 80	11	4.2 (73%)	0.4	+

corresponding acid amides in fairly good yields even though the reaction medium was neutral to litmus. The hydrolysis was generally stopped at the amide stage and very small amounts of acids were obtained. Further hydrolysis of amides to acids could not be observed even when the amides were treated again with a newly prepared catalyst. Small quantities of nitriles were hydrogenated to amines by hydrogen absorbed on the nickel catalyst. Some factors, effective for the reaction, were examined in regard to the kind of catalyst, promoter or poison, solvent and duration of refluxing. In most of the reactions, the Urushibara nickel was used as the catalyst, and representative results of the experiments with benzonitrile are shown in Table I. Stabilized nickel catalysts (K. S. Y. Catalysts)[2] were also used in some experiments, and similar results could be observed.

Among the varieties of the Urushibara catalyst, U-Ni-B was the most advantageous for the hydrolysis; U-Ni-A[3], BA[4], AA[5] and U-Cu-B were not so admirable because some undesirable side reactions were induced. When precipitated nickel prepared from nickel chloride and zinc dust was used in place of the Urushibara catalyst, the product was found to be a complex of a primary amine and zinc, which can be decomposed to the amine by treating with alkali. Zinc powder by itself did not show any catalytic activity for hydrolysis.

As for the reaction solvents, water, ethanol, dioxane and *n*-butanol were used, and water was proved to be the most excellent of all as shown in Table I. A small quantity of thiophene or pyridine was added to the U-Ni-B catalyst in order to examine specific behavior as a promoter for the catalyst. However, they were of no use but rather gave an unfavorable effect.

The hydrolysis of the nitrile group was also observed in *p*-tolunitrile, *o*-nitrobenzonitrile and benzyl cyanide, yielding the appreciable amounts of the corresponding amides. On the contrary, hydrolysis of ethyl benzoate hardly proceeded with the same method, and benzoic acid could scarcely be obtained.

On the other hand, some aromatic halogen compounds were treated with the nickel catalyst in the same procedure mentioned above. Chlorobenzene, bromobenzene and iodobenzene were mainly dehalogenated to bezene along with a small quantity of biphenyl, although the reaction velocity of chlorobenzene was very slow compared with those of the others. When a small quantity of thiophene was added to the catalyst in the reaction of bromobenzene, alternative obscure reaction occurred yielding an unidentifiable oily product of a high boiling point. Reactions of nitro or amino derivatives of halogenobenzenes were more complicated. Among the reactions of this series, remarkable result was obtained with benzyl chloride. When benzyl chloride was refluxed with U-Ni-B in ethanol, a Wurtz type reaction was observed and bibenzyl was obtained in a good yield (above 70%). However, when the mixture was refluxed for a long time, the production of bibenzyl was accompanied with the formation of a highly boiling oil.

As the results of the studies on these catalytic reactions, it was found that amides are obtained from nitriles without acidic or alkaline hydrolysis, and that bibenzyl is obtained from benzyl chloride without sodium metal. These reactions are simple in procedure, and the yields of products are fairly good when the reactions are carried out under suitable conditions. The details of these experiments and discussion will be published in a following paper.

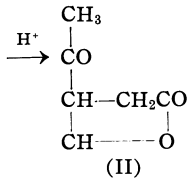
The New Synthetic Method of β-Acetyl-butyrolactone



By Yoshihiko NISHIZAWA

(Received October 3, 1959)

B. R. Baker[1] has prepared β-acetyl-butyrolactone (II) from itaconic acid half ester or dimethyl methoxy-succinate. This method, however, gave a very poor yield and β-acetyl-butyrolactone (II) was only isolated as 2,4-dinitrophenylhydrazone derivative.

The present author found that β-acetyl-butyrolactone (II) is synthesized in a smooth way from diethyl acetyl-succinate[2] (I) according to the following equation[3].

(II)

One hundred and eight grams (0.5 mol.) of diethyl acetyl-succinate (I) (b. p. 140~ ~142°C/14 mmHg, n_D^{16} 1.4380) were added to 480 ml. of 10% sodium hydroxide aqueous solution at 0°C and left for twenty four hours at room temperature (ca. 15~20°C). After the oil was dissolved completely, the aqueous solution was neutralized with 30% sulfuric acid to pH 8~8.2 and then 20 g. of sodium bicarbonate and 54 ml. of 37% formaline were added. After the mixture was allowed to stand overnight at room temperature, acidified with 30% sulfuric acid and extracted continuously with ether. The ether layer was dried with anhydrous sodium sulfate and then ether was evaporated. The residual oil was distillated under the diminish pressure; yield, 28.0 g. (43.8%), b. p. 140~143°C/6 mmHg, n_D^{31} 1.4600.

Anal. Found: C, 55.98; H, 6.41. Calcd. for $C_6H_8O_3$: C, 56.24; H, 6.29%.

2,4-Dinitrophenylhydrazone; m. p. 191~ 192°C (recrystallized from acetic acid).

Anal. Found: C, 46.61; H, 3.70; N, 18.20. Calcd. for $C_{12}H_{12}O_6N_4$: C, 46.76; H, 3.92; N, 18.18%.

The 2,4-dinitrophenylhydrazone was soluble in sodium bicarbonate aqueous solution and the mixed melting point with the authentic 2,4-dinitrophenylhydrazone[1] was not depressed.

The author is much indebted to Mr. S. Kitamura for his earnest assistance and wishes to express his thanks to his coworkers for the microanalysis.

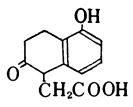
*Abnormal Reduction of 2-Methoxy-5-hydroxy-1-naphthylacetic Acid**



By Takeshi MATSUMOTO and Akira SUZUKI

(Received February 20, 1959)

In the previous paper[1] the synthesis of 2-methoxy-5-hydroxy-1-naphthylacetic acid (I) was described. The present work was undertaken in an attempt to prepare 1,2,-3,4-tetrahydro-2-oxo-5-hydroxy-1-naphthylacetic acid (II), a potential intermediate for building up the diterpenoid alkaloid framework, by reduction I.

(I)

(II)

It is well known that the reduction of a variety of 2-methoxynaphthalene derivatives by alkali metal in alcohol[2] or in alcohol-liquid ammonia[3] yields the corresponding 2-oxotetralins. At first sight, therefore, it seemed easy to prepare tetrahydro-2-oxo-5-hydroxy-1-naphthylacetic acid (II). However, attempted reduction along this line led to unusual results. Depending upon the procedure employed, tetrahydro-5-hydroxy-1-naphthylacetic acid (III) or a mixture of compound III and tetrahydro-2-oxo-4,5-dihydroxy-1-naphthylacetic acid (IV) has been obtained.

At first, the reduction was effected by employing a large excess of sodium (ca. 0.03 mol. per 0.001 mol. of I) in butanol. Product A, which was obtained in good yield, unexpectedly did not react with dinitrophenylhydrazine. The elemental composition corresponded to $C_{12}H_{14}O_3$ rather than to that of the expected product II, $C_{12}H_{12}O_4$. The tests for a methoxyl group (Zeisel) and for a secondary alcohol group (Nessler) were both negative. The infrared spectrum in nujol mull possessed a single sharp band at 1700 cm^{-1} (carboxyl group) and a broad absorption band at 3200~3400 cm^{-1}. Of three oxygen atoms, two have thus been shown to be present in a carboxyl group, and one probably as a hydroxyl group. The presence of a hydroxyl group was confirmed by the formation of monoacetate, $C_{14}H_{16}O_4$. The ultraviolet spectrum (Fig 2. curve b) of product A could be superimposed upon that of 1,2,3,4-tetrahydro-5-naphthol (curve c). These results clearly indicate that product A should be expressed by formula III. So far as the authors are aware, the ready conversion of methoxynaphthalenes to desoxygenated tetralins has not hitherto been reported[4]. The formation of the abnormal reduction product must be attributed, at least in part, to the presence

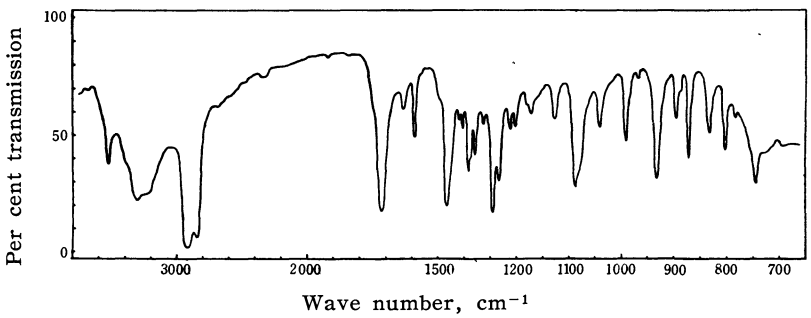


Fig. 1. Infrared spectrum of 1,2,3,4-tetrahydro-2-oxo-4,5-dihydroxy-1-naphthylacetic acid (IV).

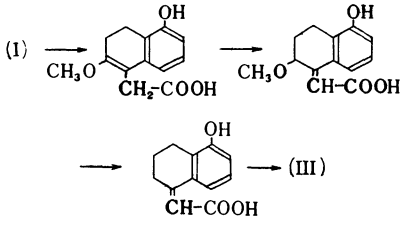
3) A. J. Birch and H. Smith, *Quart. Revs.*, **12**, 17 (1958).



4) A. L. Wilds et al., *J. Am. Chem. Soc.*, **95**, 5360 (1953), have obtained Δ^{9-10}-octahydronaphthalene as a by-product (10~16%) from 5,6,7,8-tetrahydro-1-methoxynaphthalene by reduction with lithium in alcohol-liquid ammonia.

of a carboxyl group, since 1-methyl-2-methoxy-5-hydroxynaphthalene is reported to give smoothly tetrahydro-1-methyl-2-oxo-5-hydroxynaphthalene[5]. On the other hand, Jacobs and Scott[6] have observed that $\beta\gamma$-unsaturated-γ-lactones are susceptible to catalytic hydrogenolysis to form saturated acids, whereas $\alpha\beta$-isomers give saturated lactones on catalytic hydrogenation. The authors are not aware of any example of reductive cleavage of $\beta\gamma$-unsaturated-γ-lactone by means of sodium and alcohol. Nevertheless, it seemed likely at that time that the abnormal reduction proceeds under the participation of the carboxyl group through a $\beta\gamma$-unsaturated-γ-lactone such as V as shown below:

(III)

According to this assumption, treatment of methyl ester of I, rather than I itself, under the same conditions was expected to afford methyl ester of the desired tetralone (II). However, reduction of the methyl ester of I with subsequent hydrolysis gave again the tetralin derivative III as a main product. The above assumption therefore became improbable; the tetralin derivative III might be formed through a process which involves reductive elimination of the allylic methoxyl group as outlined below, but further evidence is required to elucidate the pathway.

The authors next examined the reduction employing sodium and boiling ethanol as well as sodium and ethanol-liquid ammonia (Birch's conditions). In both

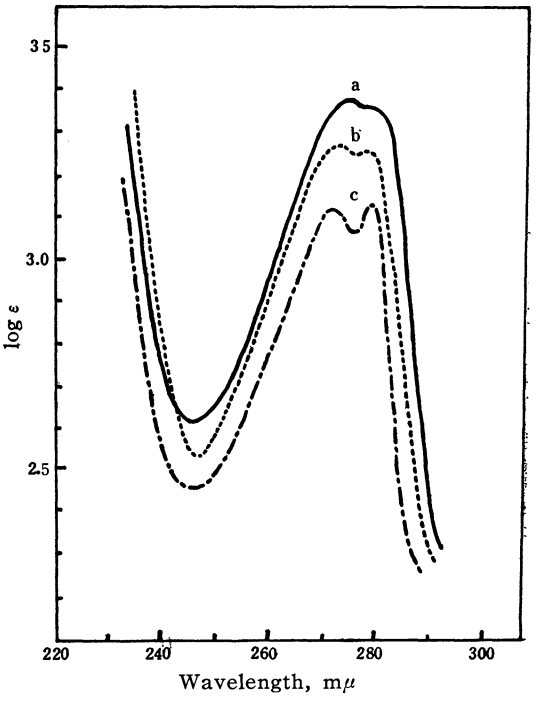


Fig. 2. Ultraviolet spectra.

b (------): 1,2,3,4-Tetrahydro-5-hydroxy-1-naphthylacetic acid (III) in methanol.
c (-----): 1,2,3,4-Tetrahydro-5-naphthol in cyclohexane.

cases most of the starting material was recovered, in the former case, probably because of the low reaction temperature and in the latter case, probably owing to the extreme low solubility[7] of the naphthylacetic acid in liquid ammonia. Attempts to reduce I by means of lithium in ethanol-liquid ammonia-dimethoxyethane (Wild's procedure) led to the formation of tetrahydro-5-hydroxy-1-naphthylacetic acid (III) in good yield, even when only 4.7 g. atoms per mol. of lithium was used[8].

Since all efforts to prepare III were thus unsuccessful, attention was turned again to the first method. The reduction was carried out at this time employing a smaller amount than before (8 atoms per mol.) of sodium. From the resulting reaction mixture, an appreciable amount of a carbonyl compound B, m. p. 121.5~123°C was isolated through its triethylamine salt, together with tetrahydro-5-hydroxy-1-naphthylacetic acid (III) and the

8) In this case a portion of the starting material was recovered; see *Experimental Section* below.

unchanged starting material I. Elemental analysis of the carbonyl compound B indicated the formula $C_{12}H_{14}O_6$. The infrared spectrum (Fig. 1) of this compound exhibited absorption bands at 3550 and 1635 cm^{-1} (solvated water), which disappear in a sample dried at 80°C in high vacuum, a broad band extending from 3400 to 3200 cm^{-1} (associated OH) and a single broad band at the carbonyl region (probably superimposed carboxyl and carbonyl bands). The ultraviolet spectrum (Fig. 2, curve a) of the hydrated substance showed almost the same shape as those of 1,2,3,4-tetrahydro-5-naphthol (curve c) and 1,2,3,4-tetrahydro-5-hydroxy-1-naphthylacetic acid (III) (curve b).

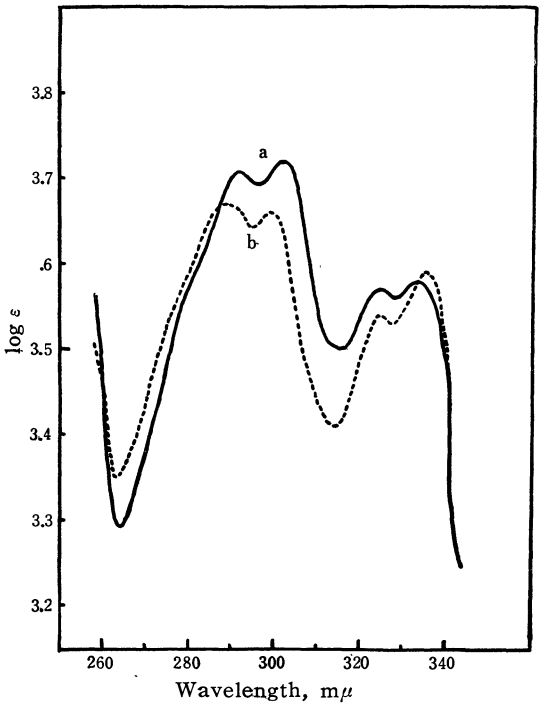

Fig. 3. Ultraviolet spectra in methanol.
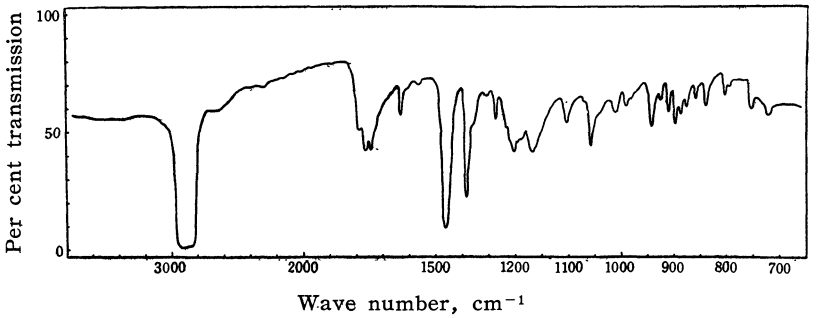
a (——): 2-Methoxy-5-hydroxyl-1-naphthylacetic acid (I).
b (------): Methyl 2,5-dihydroxy-1-naphthylacetate (VI).

At this stage the authors supposed that they had the desired product II ($C_{12}H_{12}O_4$) with two moles of water of crystallization at hand, although analytical values for carbon and hydrogen agreed better with $C_{12}H_{14}O_6$. Drying at 80°C in high vacuum was accompanied by decomposition of product B and an analytically pure anhydrous sample could not be obtained. To confirm the above hypothesis, preparation of the methyl ester was then attempted. Contrary to the expectation, treatment with methanolic hydrogen chloride led to two naphthalene derivatives. Presence of the 1-naphthol chromophore in both the products was clearly demonstrated by their ultraviolet spectra. One of the products, $C_{14}H_{14}O_4$, m. p. 155.5~156.5°C, ν_{max}^{nujol} 3420(OH) and 1735 cm^{-1} (ester) exhibited positive Zeisel test and was readily identified with methyl 2-methoxy-5-hydroxy-1-naphthylacetate (VII)[1], which was obtained separately by esterification of I. The other product, $C_{13}H_{12}O_4$, m. p. 183~184°C, ν_{max}^{nujol} 3480 (OH) and 1740 cm^{-1} (ester) was formulated as methyl 2,5-dihydroxy-1-naphthylacetate (VI) on the basis of analytical and spectral data (ultraviolet spectrum; Fig. 3, curve b). Formation of these naphthalene derivatives suggests strongly that product B, $C_{12}H_{14}O_6$, is actually a monohydrate of tetrahydro-2-oxo-5-hydroxy-1-naphthylacetic acid with an additional hydroxyl group on the aliphatic portion. Presence of two hydroxyl groups was proved by the formation of a diacetate, $C_{16}H_{14}O_6$. The infrared spectrum (Fig. 4) of the diacetate showed complete absence of a hydroxyl function and presence of the following groups: $\beta\gamma$-unsaturated-γ-lactone (1795 cm^{-1}), phenyl acetate (1765 cm^{-1}) and saturated ester (1745 cm^{-1}). Therefore, a structural formula like VIII is concluded for this



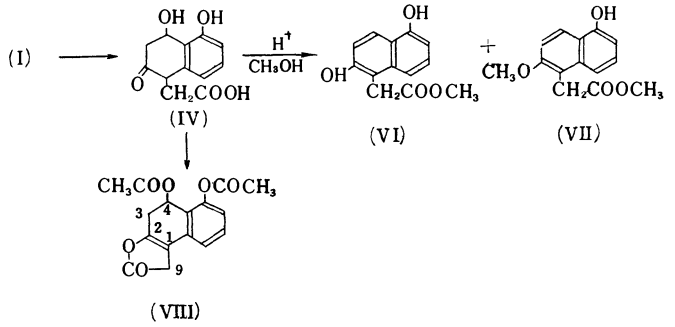


Fig. 4. Infrared spectrum of VIII.

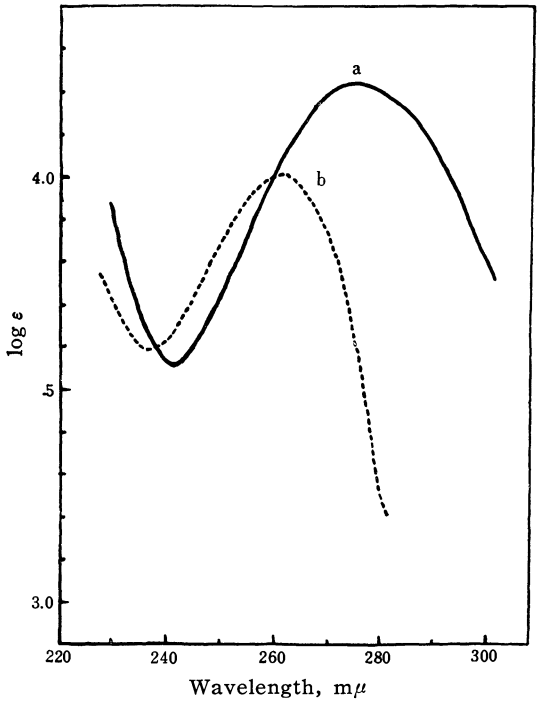

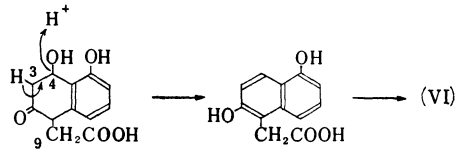

Fig. 5. Ultraviolet spectra.
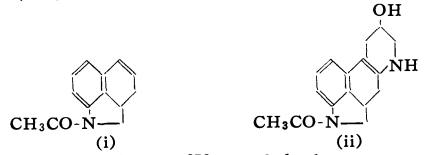
a (——): VIII in methanol.
b (------): 1,2-Dihydronaphthalene in *n*-hexane.

compound*. The ultraviolet spectrum[9] (Fig. 5, curve a) seems also to agree with this formula. There is a bathochromic shift and an increase in absorption intensity as compared with the spectrum (curve b) of the parent hydrocarbon, 1,2-dihydronaphthalene; these changes can be reasonably ascribed to the presence of an enolic and of a phenolic acyloxy group on the conjugated system.

From formula VIII thus assigned to the diacetate, it follows that two hydroxyl groups (except one hydroxyl group of water of crystallization) are present in product B, and moreover, the hydroxyl group does not occupy the 1-position.



Concerning the position of the aliphatic hydroxyl group in compound B, there remain possibilities of its presence at C_3, C_4 and C_9 positions, of which the C_4 position is the most likely one, since the formation of the naphthalene derivatives[10] is readily explained by a β-elimination reaction:

However, the possibilities of C_3 and C_9 positions can not be conclusively excluded at this stage, since substituents at these positions, being placed respectively at $\alpha\beta$-position to the phenyl and carbonyl groups, are expected to be also susceptible to undergoing an elimination reaction. In the case of C_9 position, subsequent rearrangement of the resultant unsaturated compound would lead to the naphthalene derivatives. The presence of the hydroxyl group at the C_4 position, however, has been demonstrated by the following evidence: product B does not reduce triphenyltetrazolium chloride and hence does not contain an α-ketol system, and moreover, the fact that p*K*a value (6.20) of the product is very close to that (6.12)

* At this stage the position of the alicyclic acetoxyl group is uncertain.

9) Compound i has been reported to possess bands at 241, (ε 22500), 254 (ε 23000), 307 (ε 1600) and 316 (ε 1300) mμ; absorption bands at 252 (ε 2060) and 328 (ε 1500) mμ are recorded for compound ii. E. C. Kornfeld, E. J. Kornfeld, G. B. Kline, M. T. Mann, D. E. Morrison, R. G. Jones and R. B. Woodward, *J. Am. Chem. Soc.*, 78, 3087 (1956).

Low ε max value at 252 mμ of the latter compound is quite unusual.

10) 2-Naphthols are readily methylated by methanol in the presence of acidic catalysts; W. A. Davis, *J. Chem. Soc.*, 77, 33 (1900).

of the tetrahydro-5-hydroxy-1-naphthylacetic acid (III), clearly indicates that the hydroxyl group is not located at the α-position (C_9) relative to carboxylic function. Although the structure of product B has thus been shown to be IV, the mechanism of conversion I→IV is quite obscure. No example of this kind of reaction seems ever to have been recorded. Although it is out of the scope of the authors' immediate purpose to study in detail the reaction process, it may be noted that the effective reagent which causes the conversion seems not to be sodium butoxide, but to be sodium itself; IV could not be obtained by a mere boiling of I in butanolic sodium butoxide solution.

Experimental[11]

Reduction of 2-Methoxy-5-hydroxy-1-naphthylacetic Acid (I) with Sodium and *n*-Butanol.—A solution of I (230 mg.; 0.001 mol.) in butanol (7 cc.) was boiled under reflux in an oil-bath at 120～130°C with stirring, sodium (730 mg.; 0.032 g. atom) was added in small pieces during 15 min. A further quantity of butanol (3 cc.) was then added to dissolve precipitated sodium butoxide. When the sodium had completely dissolved, the mixture was poured into an equal volume of water. The alkaline aqueous layer was separated, extracted twice with ether, acidified with concentrated hydrochloric acid and allowed to stand overnight. The crude reduction product, which separated out, was collected by filtration. When the filtrate was extracted three times with ether and the ether was evaporated, an additional amount of the above product was obtained. Total yield, 130 mg. (63%). After recrystallization from water, product A (tetrahydro-5-hydroxy-1-naphthylacetic acid) had m. p. 144～145°C and exhibited ν_{max}^{nujol} 3200～3400 (OH) and 1700 cm^{-1} (CO_2H). Ultraviolet absorption bands at 272 (log ε 3.27) and 278 mμ (log ε 3.26).

Anal. Found: C, 69.79; H, 6.98. Calcd. for $C_{12}H_{14}O_3$: C, 69.88; H, 6.84%.

1, 2, 3, 4-Tetrahydro-5-acetoxy-1-naphthylacetic Acid.—The above acid (III) (100 mg.) was dissolved in absolute pyridine (1.5 ml.). Pure acetic anhydride (0.5 ml.) was added with shaking and the reaction mixture was set aside overnight. The most of pyridine and excess of acetic anhydride was then evaporated. To the residue was added 2 N hydrochloric acid and the mixture was extracted three times with ethyl acetate. The extract was washed twice with water, dried and evaporated. The solid residue on being crystallized from ligroin afforded 100 mg. (83.5%) of the acetoxy acid. Recrystallization from ligroin gave an analytical sample as colorless needles, m. p. 125～126.5°C, ν_{max}^{nujol} 1750 (phenylacetate) and 1700 cm^{-1} (CO_2H).

Anal. Found: C, 67.74; H, 6.60. Calcd. for $C_{14}H_{16}O_4$: C, 67.73; H, 6.50%.

1, 2, 3, 4-Tetrahydro-2-oxo-4, 5-dihydroxy-1-naphthylacetic Acid (IV).—To a boiling solution of I (1.84 g.; 0.008 mol.) in 40 cc. of butanol, sodium (1.47 g.; 0.064 g. atom) was added rapidly in small pieces during 10 min. with stirring. After the sodium had completely dissolved, the mixture was treated with 40 cc. of water, and the two layers were separated. After the aqueous layer had been washed twice with ether, 8 cc. of concentrated hydrochloric acid was added under ice cooling and the solution was warmed in a water bath at 70～80°C for 30 min. When the mixture had cooled, an oily substance was separated out; the aqueous layer was then extracted three times with ethyl acetate. The oil and the ethyl acetate extract were combined and the whole was washed twice with water, dried with sodium sulfate, and evaporated to dryness. The oily residue (1.82 g.) was then dissolved in 50 cc. of ethyl acetate; to this solution an excess of triethylamine was added in small portions and the solution was allowed to stand for 5 days. At the end of this period, a considerable amount of triethylamine salt and viscous gum precipitated on the bottom of the flask. The solvent was removed by decantation and the viscous gum was removed by washing the residue quickly with a small amount of cold absolute ethanol. The crystalline triethylamine salt thus obtained melted at 152°C with decomposition.

The salt was then dissolved in 5 cc. of water; the solution was acidified with 6 N hydrochloric acid and extracted with ethyl acetate; the extract was washed with water, dried and evaporated. On being triturated with ether, the residue crystallized to furnish crude tetrahydro-2-oxo-4, 5-dihydroxy-1-naphthylacetic acid (IV), which was recrystallized from water as colorless solvated prisms (0.3 g.; 15%), m. p. 121.5～123°C. Ultraviolet absorption band at 274 mμ (log ε 3.38).

Anal. Found: C, 56.92; H, 5.75. Calcd. for $C_{12}H_{12}O_5 \cdot H_2O$: C, 56.69; H, 5.55%.

The viscous part, which was separated from the triethylamine salt of IV, on being acidified with hydrochloric acid afforded a mixture of the starting material and III, which was separated by virtue of higher solubility of the latter compound in water.

Reduction of I by Nelson-Wild's Method.—Sample of compound I (920 mg.; 0.004 mol.) was placed in a three-necked flask equipped with stirrer, dropping funnel and drying tube (soda-lime). To the vessel was added enough anhydrous dimethoxyethane (20 ml.) to dissolve I. The flask was cooled to −40～−50°C. Liquid ammonia (45 ml.) was added to the solution and then lithium (0.5 g.; 0.072 g. atom) in small pieces during 2 min. After stirring for 10 min. absolute

11) All melting points are uncorrected. Infrared spectra were taken on a Koken model DS-301 infrared spectrophotometer with sodium chloride optics. Ultraviolet spectra were measured by means of a Beckman model DK-2 spectrophotometer. The authors are indebted to Mr. O. Yonemitsu of the Pharmaceutical Institute of Hokkaido University for infrared spectra data and to Miss Noriko Fujino for microanalyses.

ethanol was added dropwise for a period of 15 min. When the blue color of the solution had disappeared, ammonia was expelled, the residue was then treated with cold water and acidified with 6 N hydrochloric acid. The acidic aqueous solution was extracted three times with ethyl acetate. After the combined extracts had been washed with saturated sodium chloride solution and dried over sodium sulfate, the solvent was evaporated and the residue was crystallized from water. A yield of 500 mg. (61%) of 1, 2, 3, 4-tetrahydro-5-hydroxy-1-naphthylacetic acid (III) was obtained. Recrystallization from water gave a pure material of m. p. 144~145°C as colorless needles. No depression at the melting point was observed on admixture with the product obtained by the use of sodium and butanol.

When reduction had been effected employing 0.92 g. (0.004 mol.) of compound I, 20 cc. of dimethoxyethane, 50 cc. of ammonia, 0.13 g. (0.0188 mol.) of lithium and 1.2 cc. of ethanol, there were obtained 310 mg. of III and 560 mg. of I. Presence of a small amount of carbonyl compound in the crude reaction product was indicated by the dinitrophenylhydrazine test, but the compound could not be isolated.

Aromatization of Product B.—Sample of product B (210 mg.) was suspended in 5% methanolic hydrogen chloride (10 cc.). The reaction mixture was refluxed on a steam bath for a period of 2 hr. After it had cooled, the solution was evaporated to dryness in vacuo. To the viscous residue were added water and ethyl acetate; the aqueous layer was separated and was re-extracted with ethyl acetate. The combined extracts were washed successively with water, 5% sodium bicarbonate and saturated sodium chloride solution, and dried over anhydrous sodium sulfate. After removal of the solvent, 192 mg. of a solid product was obtained. Crystallization of the product from benzene gave 50 mg. of methyl 2,5-dihydroxy-1-naphthylacetate (VI) with a melting point 180~183°C, which raised to 183~184°C (decomp.) on recrystallization from benzene. Ultraviolet absorption bands at 288 (log ε 3.67), 299 (log ε 3.66), 324 (log ε 3.54) and 335 mμ (log ε 3.59). Infrared spectrum (nujol): 3480 (OH) and 1740 cm^{-1} (ester group).

Anal. Found: C, 67.46; H, 5.51. Calcd. for $C_{13}H_{12}O_4$: C, 67.23; H, 5.21%.

From the above benzene filtrate, after removal of the solvent and crystallization from aqueous methanol, 100 mg. of methyl 2-methoxy-5-hydroxy-1-naphthyl acetate (VII), m. p. 146~149°C, was obtained. An analytical sample, obtained by recrystallization from a small amount of benzene, had m. p. 155.5~156.5°C.

Infrared spectrum[12]: 3400 (OH) and 1720 cm^{-1} (ester group).

Anal. Found: C, 68.15; H, 5.95. Calcd. for $C_{14}H_{14}O_4$: C, 68.28; H, 5.73%.

Acetylation of the Tetralon Derivative (IV).—The keto acid (IV) (47 mg.) was added to a solution of acetic anhydride (0.5 cc.) in anhydrous pyridine (1.5 cc.) and the mixture was allowed to stand overnight. After concentration of the reaction mixture to a small volume, water and 2 N hydrochloric acid were added. The mixture was then shaken three times with ethyl acetate. The organic layers were combined, washed twice with water and dried over sodium sulfate. Removal of the solvent in vacuo left 33 mg. of an oily residue from which on trituration with petroleum ether, 24 mg. of crystalline material was obtained. For analysis the product was recrystallized from benzene, m. p. 176~176.5°C.

Ultraviolet absorption band at 276 mμ (log ε 4.22).

Anal. Found: C, 63.86; H, 4.67. Calcd. for $C_{16}H_{14}O_6$: C, 63.57; H, 4.67%.

Dissociation constants of III and IV were measured at 25°C in 50% ethanol using HRL model M-3 pH meter.

Summary

1,2,3,4-Tetrahydro-5-hydroxy-1-naphthylacetic acid has been obtained from 2-methoxy-5-hydroxy-1-naphthylacetic acid by reduction either with sodium and *n*-butanol, or with lithium and liquid ammonia-ethanol. In the former case, under moderate conditions, 1,2,3,4-tetrahydro-2-oxo-4,5-dihydroxy-1-naphthylacetic acid has been isolated as a by-product.

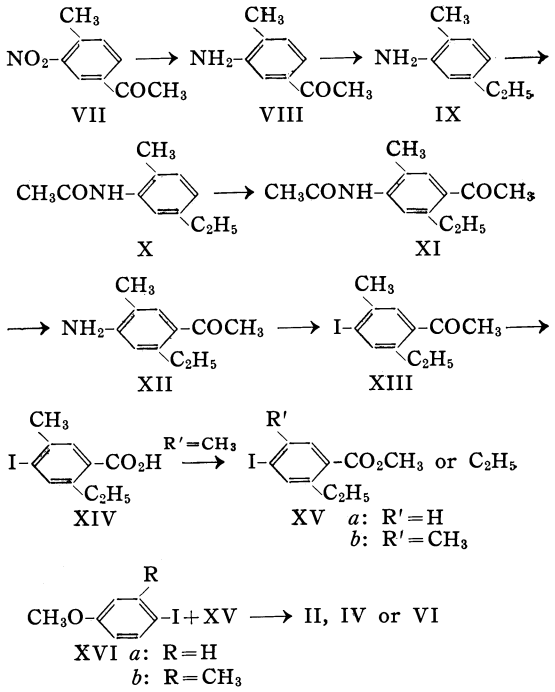
12) In the 1650~1500 cm^{-1} region, the dihydroxynaphthylacetate (VI) absorbs at 1630, 1608, 1590, 1524 cm^{-1}. See Ref. 1.

Estrogenic Biphenyls. VI[1]. *2- and 6'-Alkyl Derivatives of 3'-Ethyl-4-methoxy-biphenyl-4'-carboxylic Acid*

By Takeo SATO and Michinori ŌKI*



(Received March 16, 1959)

It was reported[2] that 3'-ethyl-4-methoxybiphenyl-4'-carboxylic acid (I) was fully estrogenic at the dose of 250 γ when injected subcutaneously to ovariectomized mice. Introduction of an additional ethyl group into position 2 or 6' of compound I increased the activity to a minimum active dose of 100 γ, thus 2,3'-diethyl-4-methoxybiphenyl-4'-carboxylic acid (III)[3] and 2',5'- (for 3',6')-diethyl-4-methoxybiphenyl-4'-carboxylic acid (V)[4] being the most active members of this series hitherto known. Enhancement of the estrogenic activity in compounds III and V in comparison with compound I was taken as an indication of a favorable molecular conformation in III and V as had already been observed in dialkylstilbestrol dimethyl ethers and related compounds[5]. The ethyl group introduced into position 2 or 6' was found to force the two benzene rings to a non-planar arrangement from the ultraviolet absorption spectra.

II	CH_3	H	V	H	C_2H_5
III	C_2H_5	H	VI	CH_3	CH_3

The present communication deals with further studies on the effect of the 2- and 6'-alkyl substituents on the conformation and on the estrogenic activity of compound I and with the discussion on the relation between the physiological activity and the molecular structure in this series. 3'-Ethyl-4-methoxy-2-methylbiphenyl-4'-carboxylic acid (II) was prepared from 4-iodo-3-methylanisole (XVIb)[6] and ethyl 2-ethyl-4-iodobenzoate (XVa)[3] through the Ullmann reaction. The 6'-methyl isomer, namely, 5'-ethyl-4-methoxy-2'-methylbiphenyl-4'-carboxylic acid (IV), and the 2,6'-dimethyl derivative, namely, 5'-ethyl-4-methoxy-2,2'-dimethylbiphenyl-4'-carboxylic acid (VI), were prepared from methyl 2-ethyl-4-iodo-5-methylbenzoate (XVb) and the corresponding iodoanisoles (XVIa or b). The preparation of the ester XVb is shown in the accompanying diagram.

Modified Wolff-Kishner reduction[7] of 3-amino-4-methylacetophenone (VIII)[8] afforded 5-ethyl-2-methylaniline (IX) in an excellent yield which was acetylated in the usual manner to give 5-ethyl-2-methylacetanilide (X). The acetanilide was treated with acetyl chloride and aluminum chloride in carbon disulfide and resulting 4-acetamido-2-ethyl-5-methylacetophenone (XI) was refluxed with dilute hydrochloric acid to give 4-amino-2-ethyl-

5-methylacetophenone (XII). Diazotization of the aminoketone XII followed by treatment of the diazonium salt with potassium iodide yielded 2-ethyl-4-iodo-5-methylacetophenone (XIII), which was oxidized with sodium hypobromite to 2-ethyl-4-iodo-5-methylbenzoic acid (XIV). Esterification of compound XIV gave the desired ester XVb.

The ultraviolet absorption data of compounds II, IV and VI are recorded in Table I together with those of compounds I[6], III[4] and V[4]. Compounds II and IV showed the K-band at 272 and 270 mμ, respectively, approximately in the regular intensities characteristic of this system. Hypsochromic shift of some 15 mμ caused by the introduction of the methyl substituent into an ortho position to the pivot bond is the result of an increase in the interplanar angle of the two benzene nuclei to relieve the steric hindrance. The shift is, however, smaller by 2 mμ than in the corresponding compounds with the ethyl group (III and V), and it agrees with the data of the present authors[6] and others[9]. It is noteworthy that the 6′-alkyl derivative of compound I gives an absorption maximum at a shorter wavelength than the 2-alkyl derivative whether the alkyl is methyl or ethyl. The result is in good agreement with the idea of hyperconjugation of the alkyl group with the carboxyl group through the benzene nucleus, with which the 2-alkyl derivative is favored[10]. In the 2,6′-dimethyl derivative (VI), no K-band maximum was found in the region examined but a shoulder at ca. 270 mμ was noticed. This is undoubtedly caused by further deterioration in conjugation of the biphenyl skeleton.

TABLE I. ULTRAVIOLET ABSORPTION MAXIMA[a] AND ESTROGENIC ACTIVITIES OF 2- AND 6′-ALKYL DERIVATIVES OF 3′-ETHYL-4-METHOXYBIPHENYL-4′-CARBOXYLIC ACID

Compound	λ, mμ	log ε	Active dose in mice, γ
I	286	4.36	250
II	272	4.13	100
III	270	4.09	100
IV	270	4.17	100[c]
V	268	4.14	100
VI	~270[b]	3.92	500

a) In 95% ethanol. b) ~: Indicates a shoulder. c) Active in 80% animals.

9) E. A. Braude, F. Sondheimer and W. F. Forbes, *Nature*, **173**, 117 (1954).
10) M. Ōki and H. Iwamura, unpublished work; also see Ref. 1.

The physiological data in Table I were obtained by the usual vaginal smear test with ovariectomized mice. The activities of the compounds with a methyl group were nearly the same as those with an ethyl group at the same position. The estrogenic potency is surely raised by the introduction of an alkyl group into position 2 or 6′, but again no difference due to the change in the alkyl group was observed. Although the minimum active dose of compound VI to produce estrus in 100% animals was found to be 500 γ, it is not certain whether the excessive thickness of the molecule as indicated by the greater deterioration in conjugation really weakened the estrogenic activity of this compound, because it was active in 80% animals at 100 γ.

Experimental[11]

5-Ethyl-2-methylacetanilide (X).—A mixture of 149 g. (1 mol.) of 3-amino-4-methylacetophenone (VIII), obtained from 3-nitro-4-methylacetophenone (VII) according to Rinkes[8], 69 g. (1.1 mol.) of 80% hydrazine hydrate, 280 g. of potassium hydroxide and 1 kg. of diethylene glycol, was heated under reflux for two hours. Then the low boiling fraction was distilled off until the pot temperature reached 180°C. After the remaining mixture was refluxed for further three hours, the whole was steam-distilled and the distillate was combined with the low boiling fraction collected previously. The combined distillate was extracted with ether and the extract was dried over potassium carbonate. 5-Ethyl-2-methylaniline (IX) was obtained as a colorless liquid boiling at 78~79°C/3 mm. in 90% yield. The acetanilide X was obtained by acetylation with acetic anhydride, m. p. 136~137°C. The reported melting point is 138°C[8].

4-Acetamido-2-ethyl-5-methylacetophenone (XI).—To a well stirred suspension of 165 g. (0.93 mol.) of compound X in 78 g. (1 mol.) of acetyl chloride and 750 ml. of carbon disulfide, was added 415 g. (3.1 mol.) of anhydrous aluminum chloride in small portions in the course of one hour, while the mixture was gently refluxed. It was refluxed for another hour and then allowed to stand for two hours. The upper layer was decanted off and the viscous oil was decomposed with ice water and hydrochloric acid. The crystals were collected and recrystallized from aqueous ethanol to give 170 g. (79% yield) of colorless needles, m. p. 139~140°C.

Anal. Found: N, 6.56. Calcd. for $C_{13}H_{17}NO_2$: N, 6.39%.

4-Amino-2-ethyl-5-methylacetophenone (XII).—The acetamido compound XI was hydrolyzed with 1:1 aqueous hydrochloric acid. Colorless needles, m. p. 105~106°C, were obtained on recrystallization from benzene-petroleum ether.

11) All melting and boiling points are uncorrected.

Anal. Found: N, 8.22. Calcd. for $C_{11}H_{15}NO$: N, 7.91%.

2-Ethyl-4-iodo-5-methylacetophenone (XIII).—To a diazonium salt solution obtained from 32 g. (0.18 mol.) of compound XII, 39 ml. of concentrated sulfuric acid, 54 ml. of water and 13 g. (0.19 mol.) of sodium nitrite in a minimum quantity of water, was added a solution of 31 g. (0.19 mol.) of potassium iodide in a small amount of water. Stirring was continued for 30 min. at a low temperature and then at 50~60°C for two hours. The mixture was extracted with ether and the extract was washed with aqueous sodium hydroxide, aqueous sodium thiosulfate and water. The iodoacetophenone was obtained in a 50% yield as a brown oil boiling at 127~128°C/2.5 mm. On standing it solidified and colorless needles melting at 51~52°C were obtained on recrystallization from petroleum ether.

Anal. Found: I, 43.88. Calcd. for $C_{11}H_{13}IO$: I, 44.08%.

2,4-Dinitrophenylhydrazone.—It was obtained as orange needles, m. p. 165~166°C, on recrystallization from ethyl acetate.

Anal. Found: N, 11.54. Calcd. for $C_{18}H_{19}IN_4O_4$: N, 11.62%.

2-Ethyl-4-iodo-5-methylbenzoic Acid (XIV).—To a well stirred sodium hypobromite solution prepared from 28 g. (0.18 mol.) of bromine, 20 g. (0.50 mol.) of sodium hydroxide and 120 ml. of water, was added a solution of 17 g. (0.057 mol.) of compound XIII in 60 ml. of dioxan in one hour. The temperature was kept below 10°C during the addition and then at 50~60°C for one hour. After excessive hypobromite was decomposed with sodium sulfite, the whole was steam-distilled. The remaining solution was acidified with hydrochloric acid and the product was recrystallized from aqueous ethanol. Colorless needles, m. p. 157~158°C, were obtained in 90% yield.

Anal. Found: I, 44.41. Calcd. for $C_{10}H_{11}IO_2$: I, 43.77%.

Methyl 2-Ethyl-4-iodo-5-methylbenzoate (XVb).—The acid XIV was esterified in the usual manner. The ester, b. p. 125°C/2.5 mm., was obtained in a 78% yield.

Anal. Found: I, 42.08. Calcd. for $C_{11}H_{13}IO_2$: I, 41.76%.

3'-Ethyl-4-methoxy-2-methylbiphenyl-4'-carboxylic Acid (II).—With vigorous stirring 15 g. (0.24 atom) of copper bronze activated by Kleiderer and Adams' method[12] was added in small portions to a mixture of 9 g. (0.036 mol.) of 4-iodo-2-methylanisole (XVIb) and 5 g. (0.016 mol.) of ethyl 2-ethyl-4-iodobenzoate[3] over a period of 30 min., while the temperature was maintained at 215~220°C. The mixture was then heated to 280~285°C and was stirred for 30 min. at that temperature. After cooling, the whole was extracted with boiling acetone and the extract was refluxed with 40 ml. of 10% aqueous sodium hydroxide and 70 ml. of ethanol for two hours. A part of ethanol was removed by distillation and the residue was diluted with water to make up 500 ml. and an insoluble oil was removed by extraction with ether. The aqueous layer was acidified with hydrochloric acid and the acid mixture thus collected was extracted with hot benzene. On concentration of the solution it afforded a crude product, which on repeated recrystallization from aqueous ethanol gave 500 mg. of colorless needles melting at 150.5~151°C.

Anal. Found: C, 75.32; H, 6.80. Calcd. for $C_{17}H_{18}O_3$: C, 75.53; H, 6.71%.

5'-Ethyl-4-methoxy-2'-methylbiphenyl-4'-carboxylic Acid (IV).—The Ullmann reaction was carried out in the same way as described above with 15 g. (0.064 mol.) of 4-iodoanisole (XVIa), 9 g. (0.030 mol.) of methyl 2-ethyl-4-iodo-5-methylbenzoate (XVb) and 20 g. (0.32 atom) of activated copper bronze. The temperature for the addition of copper bronze was 230~240°C and then raised to 280~290°C. The acidic portion was digested with ether and the ethereal solution was passed through an alumina column. The elute was evaporated and repeated recrystallization of the residue from ethanol gave colorless needles melting at 188~189°C. It weighed 900 mg.

Anal. Found: C, 75.35; H, 6.51. Calcd. for $C_{17}H_{18}O_3$: C, 75.53; H, 6.71%.

5'-Ethyl-4-methoxy-2,2'-dimethylbiphenyl-4'-carboxylic Acid (VI).—The reaction was carried out in the same way as described for the preparation of II, with 18 g. (0.073 mol.) of compound XVIb, 10 g. (0.033 mol.) of compound XVb and 30 g. (0.47 atom) of activated copper bronze. The reaction temperatures were the same as in the preparation of IV. The acetone extract was distilled under reduced pressure to remove any unchanged materials, and the distillate up to 190°C/5 mm. was discarded. Colorless plates, melting at 127~128°C after recrystallization from ethanol-water, were obtained by handling the residue of vacuum distillation as described before. It weighed 600 mg.

Anal. Found: C, 76.27; H, 7.39. Calcd. for $C_{18}H_{20}O_3$; C, 76.03; H, 7.09%.

Ultraviolet Absorption Spectra.—The ultraviolet absorption spectra were measured with a Hitachi photo-electric spectrophotometer Model EPU-2. The samples were dissolved in 95% ethanol.

The authors wish to express their hearty thanks to Professor Y. Urushibara, the University of Tokyo, and Professor K. Hata, Tokyo Metropolitan University, for encouragement throughout this work, and to the Research Department of Teikoku Hormone Manufacturing Co., Kawasaki, for bioassays. The authors' thanks are also due to the Ministry of Education for the Grant in Aid for Fundamental Research.

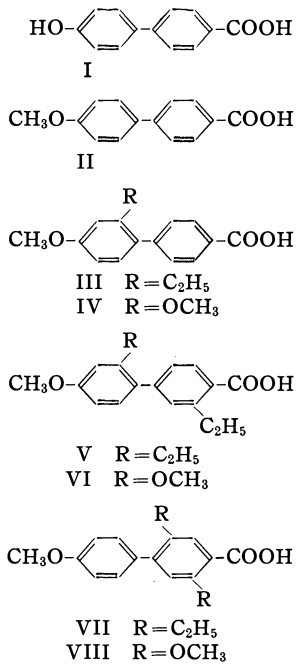
Estrogenic Biphenyls. VII. Preparation and Estrogenic Action of Methoxyl Derivatives of 4-Methoxybiphenyl-4'-carboxylic Acid



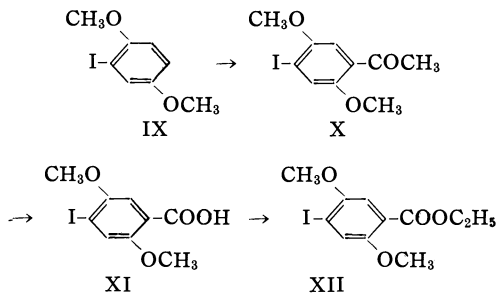
By Takeo SATO

(Received April 20, 1959)

In the study on the relation between the estrogenic activity and the molecular structure it has been found that in 4-hydroxybiphenyl-4'-carboxylic acid (I) and its methyl ether (II) the introduction of alkyl groups into suitable positions of the biphenyl skeleton increases the activity[1-6]. That the introduction of alkyl groups into position 2 or 2' of 4-methoxybiphenyl-4'-carboxylic acid (II) largely modifies the otherwise planar conformation of the biphenyl skeleton is apparent from the ultraviolet absorption spectra. The enhancement of the activity caused by the alkyl groups is explained on the basis of the steric effect of the alkyl groups, which makes the molecular structure or the conformation more suitable for the development of the physiological activity.

The minimum active doses of typical compounds of this series were found to be as follows: The parent compound II[3] was active only in 50% of ovariectomized mice at the dose of 1 mg., while full estrus was produced in 100% animals by a dose of 500 γ of compound III[3] and by 100 γ of either compound V[1] or compound VII[2]. The substances with a methyl or a propyl group in place of the ethyl group in compound III showed an activity similar to that of compound III in contrast to the case of the stilbene series[7]. This may be understood, when the similar ultraviolet absorption spectra of these homologous compounds are interpreted as the indication of their similar basic biphenyl skeletons which are not altered by the chain length of the straight-chain alkyl groups at position 2[2,3,8].

It was not explained, however, that the estrogenic activity of 2,2'-disubstituted



derivatives[5,6], whose ultraviolet spectra differed markedly from those of the monoalkyl derivatives in missing the characteristic K-band in the region examined, was nearly the same as that of the monoalkyl derivatives. The fact was striking because the physiological activity such as estrogenic activity is considered to be very sensitive even to a slight deformation of the structure.

In this connection it is interesting to prepare the alkoxyl analogues in which the alkoxyl group will take the same arrangement as alkyl groups but will produce less steric hindrance. The present communication describes the preparation of three such methoxyl analogues, IV, VI and VIII. The effect of the replacement of the alkyl group by the methoxyl group on the estrogenic activity may be compared with the case of the methoxyl analogues of hexestrol. Takahashi reported that 1, 2-dimethoxy-1,2-bis-(*p*-hydroxyphenyl)-ethane was fully active at 0.5 γ while the ethoxyl analogue was so at

10 γ[9]. The compound in which only one of the ethyl groups of hexestrol was replaced by a methoxyl group was less active than the dimethoxyl compound[10].

2,4-Dimethoxybiphenyl-4'-carboxylic acid (IV) was prepared by the Ullmann reaction of 2,4-dimethoxyiodobenzene and ethyl 4-iodobenzoate. The 2-methoxyl analogue (VI) of 2,3'-diethyl-4-methoxybiphenyl-4'-carboxylic acid (V), one of the most active members of the alkyl series, was prepared from 2,4-dimethoxyiodobenzene and ethyl 2-ethyl-4-iodobenzoate[1] through the same method. 2',4,5'-Trimethoxybiphenyl-4'-carboxylic acid (VIII), the totally methoxylated analogue of the diethyl compound VII, was obtained from 4-iodoanisole and ethyl 4-iodo-2,5-dimethoxybenzoate (XII), which was prepared by the following reaction sequence:

2,5-Dimethoxyiodobenzene (IX), prepared either from hydroquinone dimethyl ether by direct iodination or from 2,5-dimethoxyaniline by diazo reaction, was treated with acetyl chloride and aluminum chloride in carbon disulfide. 4-Iodo-2,5-dimethoxyacetophenone (X), thus produced, was oxidized with sodium hypobromite to give the corresponding benzoic acid XI, which was esterified to XII in the usual manner. Attempted Friedel-Crafts reaction of 2,5-dimethoxyacetanilide in carbon disulfide with the aim of obtaining 4-acetamido-2,5-dimethoxyacetophenone, which might be another intermediate for the preparation of XII, failed and the starting material was recovered.

The estrogenic activities were determined by the vaginal smear test with ovariectomized mice, substances in oil solution being injected subcutaneously. Compound IV was found active at 400 γ, while the corresponding ethyl compound (III) at 500 γ, as stated above. Compound VI was active only to 20% of the test animals at 100 γ, while the corresponding diethyl compound (V) was fully estrogenic at this level. The same situation is also observed in 2',5'-disubstituted compounds. Namely, while the 2',5'-diethyl compound (VII) was active equally to compound V, the 2',5'-dimethoxyl analogue (VIII) was active to 40% of the animals even at 200 γ. Although these 2-methoxyl compounds may be represented by thinner structural models than the corresponding alkyl compounds, the weaker activities of the former may be attributed to the thinner structures only with a reserve, since the direct physiological effect of the methoxyl group itself is obscure.

Experimental*

2,4-Dimethoxybiphenyl-4'-carboxylic Acid (IV).—With good stirring, 15 g. (0.057 mol.) of 2,4-dimethoxyiodobenzene, prepared by iodination of resorcinol dimethyl ether with iodine and yellow mercuric oxide according to Kauffmann and Kieser[11], and 5 g. (0.018 mol.) of ethyl 4-iodobenzoate were heated to 230°C and 15 g. (0.24 atom) of activated copper bronze[12] was added in small portions over a period of twenty minutes, while the temperature was maintained at 230~250°C. When the addition was over, the reaction mixture was heated to 280~290°C and kept at that temperature for thirty minutes. The acetone extract was subjected to vacuum distillation and the distillate up to 120°C/5 mm. was discarded. The residue was hydrolyzed with aqueous-alcoholic alkali and tetramethoxybiphenyl was removed by filtration. Acidification of the aqueous solution gave a crude product, which was extracted with hot acetic acid, and the substance obtained from the extract was recrystallized from ethanol to yield 1 g. of colorless plates melting at 199~200°C.

Anal. Found: C, 69.39; H, 5.99. Calcd. for $C_{15}H_{14}O_4$: C, 69.75; H, 5.46%.

3'-Ethyl-2,4-dimethoxybiphenyl-4'-carboxylic Acid (VI).—In the same way as described for the preparation of compound IV, 11 g. (0.042 mol.) of 2,4-dimethoxyiodobenzene and 5.5 g. (0.018 mol.) of ethyl 2-ethyl-4-iodobenzoate[1] were condensed with 15 g. (0.24 atom) of activated copper bronze. The acetone extract was concentrated until the temperature of the distilling vapor reached 152°C at 5 mm. The crude acid, obtained by hydrolysis of the product, was extracted with hot benzene. Repeated recrystallization from ethanol gave 200 mg. of colorless needles melting at 187~187.5°C.

Anal. Found: C, 71.24; H, 6.10. Calcd. for $C_{17}H_{18}O_4$: C, 71.31; H, 6.34%.

2,5-Dimethoxyiodobenzene. — Hydroquinone dimethyl ether was iodinated with iodine and mercuric oxide[13]. It was also prepared[14] from 2,5-dimethoxyaniline by diazotization followed by decomposition in the presence of potassium iodide.

4-Iodo-2, 5-dimethoxyacetophenone (X).—To a well stirred mixture of 100 ml. of carbon disulfide and about one fifth of 33 g. (0.25 mol.) of powdered aluminum chloride was added dropwise a solution consisting of 16 g. (0.20 mol.) of acetyl chloride and 50 g. (0.19 mol.) of 2, 5-dimethoxyiodobenzene in the course of thirty minutes, while the rest of the aluminum chloride was added occasionally through another opening of the flask. The reaction mixture was gently refluxed for one hour and then poured into ice water containing hydrochloric acid. The carbon disulfide layer was concentrated and the residue was extracted with ether. The ethereal solution was successively washed with water, aqueous alkali, sodium thiosulfate and again water. Evaporation of the solution afforded 15 g. (26% of the theoretical) of light brown needles melting at 98～99°C on recrystallization from ethanol.

Anal. Found: C, 39.28; H, 3.60. Calcd. for $C_{10}H_{11}O_3I$: C, 39.23; H, 3.62%.

The 2, 4-Dinitrophenylhydrazone was obtained as deep-orange plates, m. p. 210～212°C, on recrystallization from ethyl acetate.

Anal. Found: N, 11.72. Calcd. for $C_{16}H_{15}O_6N_4I$: N, 11.53%.

4-Iodo-2, 5-dimethoxybenzoic Acid (XI).—To a sodium hypobromite solution, prepared by dropping 21 g. (0.13 mol.) of bromine into 15 g. (0.38 mol.) of sodium hydroxide in 130 ml. of water below 0°C, was added 14 g. (0.046 mol.) of compound X dissolved in 50 ml. of dioxan over a period of one hour, the temperature being kept below 20°C. After the excessive hypobromite was decomposed with sodium bisulfite, the whole was steam-distilled and the remainder was acidified with hydrochloric acid. Colorless needles melting at 175～177°C were obtained on recrystallization of the product from ethanol. Yield, 10 g. or 71% of the theoretical.

Anal. Found: C, 35.25; H, 3.00. Calcd. for $C_9H_9O_4I$: C, 35.09; H, 2.94%.

Ethyl 4-Iodo-2, 5-dimethoxybenzoate (XII).—A solution of 5 g. (0.016 mol.) of compound XI in 50 ml. of ethanol, saturated with dry hydrogen chloride, was heated under reflux for five hours. After the solvent was removed the residue was diluted with water and extracted with ether. The ethereal solution was successively washed with water, sodium bicarbonate solution, sodium thiosulfate solution and again water. Colorless plates melting at 65～66°C were obtained on recrystallization from petroleum ether. Yield, 5 g. or 93% of the theoretical.

Anal. Found: C, 39.30; H, 3.95. Calcd. for $C_{11}H_{13}O_4I$: C, 39.30; H, 3.90%.

2', 4, 5'-Trimethoxybiphenyl-4'-carboxylic Acid (VIII).—The Ullmann reaction was carried out in the same way as described for the preparation of compound IV, using 8 g. (0.034 mol.) of 4-iodoanisole, 5 g. (0.015 mol.) of compound XII and 15 g. (0.24 atom) of activated copper bronze. The acidic part was extracted with hot benzene and the extract was concentrated to yield 200 mg. of colorless plates melting at 142～143°C.

Anal. Found: C, 66.84; H, 5.48. Calcd. for $C_{16}H_{16}O_5$: C, 66.66; H, 5.59%.

The author wishes to express his hearty thanks to Professor K. Hata, Tokyo Metropolitan University, and Professors Y. Urushibara and M. Ōki, the University of Tokyo, for their kind guidance and encouragement and to the Research Department of Teikoku Hormone Manufacturing Co., Ltd., Kawasaki, for bioassays. The author's thanks are also due to the Ministry of Education for the Grant in Aid for Fundamental Scientific Research.

Synthesis and Physical Properties of Normal Higher Alcohols. I. Synthesis of Normal Higher Primary Alcohols of Odd Carbon Numbers from Undecanol to Pentacosanol

By Akira WATANABE*

(Received March 17, 1959)

As part of a broad program of investigating the synthesis and physical properties of long chain compounds, the present author has taken up normal primary alcohols. Since Müller[1] reported an X-ray investigation of a series of normal paraffins, a phenomenon of phase transitions in the solid state of long chain compounds has drawn much attention of chemists and physicists.

Although several communications dealing with the transition phenomenon of long chain compounds have appeared in the literature, higher alcohols have not been studied as fully as paraffins and consequently the results are rather fragmentary and somewhat ambiguous. Moreover, only few reports are found on the alcohols with odd carbon numbers and more than eighteen carbon atoms[2]. A reason for this may have been the difficulty of obtaining a series of higher alcohols in high purity. Therefore, it is desirable to investigate in more detail and more systematically the synthesis and the physical properties of the series of alcohols. From this point of view, the author has undertaken to synthesize alcohols having more than ten carbon atoms and in this paper the preparation of higher alcohols of odd carbon numbers from undecanol $C_{11}H_{23}OH$ to pentacosanol $C_{25}H_{51}OH$ is reported.

Until recently, all the alcohols up to hexatriacontanol $C_{36}H_{73}OH$ have been synthesized by other workers for the purpose of making comparison with naturally occurring products. In the present investigation, the three synthetic routes were chosen depending upon the availability of starting materials and close attention was paid to obtain the products having sufficient purity for physical studies.

(A) $RCO_2H \rightarrow RCO_2Ag \xrightarrow[(\text{in } CCl_4)]{Br_2} RBr \xrightarrow{CH_3CO_2Ag} CH_3CO_2R \xrightarrow{H_2O} ROH$

(B) $RCO_2H \xrightarrow{SOCl_2} RCOCl \xrightarrow{CH_2N_2} RCOCHN_2 \xrightarrow[(\text{in } CH_3OH)]{Ag_2O} RCH_2CO_2CH_3 \xrightarrow{LiAlH_4} RCH_2CH_2OH$

(C) $C_2H_5O_2C(CH_2)_5Br \xrightarrow{\text{Ethyl malonate}}$

(I)

$C_2H_5O_2C(CH_2)_5CH(CO_2C_2H_5)_2 \xrightarrow[Na]{C_6H_5CH_2OH}$

(II)

(VI) (VII)

$\xrightarrow{LiAlH_4} R(CH_2)_8OH$

(VIII)

Undecanol $C_{11}H_{23}OH$, tridecanol $C_{13}H_{27}OH$, pentadecanol $C_{15}H_{31}OH$, heptadecanol $C_{17}H_{35}OH$ and heneicosanol $C_{21}H_{43}OH$ were prepared by method A. The process of degradative bromination of silver salts of fatty acids is the well known Hunsdiecker reaction[3]. The alkyl bromides obtained by this method were heated with silver acetate at 150°C without a solvent to yield the acetyl compounds which were converted into the desired alcohols by hydrolysis with alcoholic potassium hydroxide. Overall yields were about 40%.

Nonadecanol $C_{19}H_{39}OH$ was prepared by the Arndt-Eistert reaction (method B) from stearic acid. Stearoyl chloride, obtained from stearic acid and thionyl chloride, and diazomethane in ether gave

* Ethyl ester.

diazononadecanone which had been synthesized by Grundmann previously[4]. The conversion of the diazoketone into methyl nonadecanoate with silver oxide in methanol was carried out easily. The ester was reduced with lithium aluminum hydride to nonadecanol in almost quantitative yield.

Method C which was used for the synthesis of tricosanol $C_{23}H_{47}OH$ and pentacosanol $C_{25}H_{51}OH$ is analogous to that of Bowman's ketone synthesis[5]. Ethyl *n*-hexane-1,1,6-tricarboxylate (II) which served as the starting material was prepared from ethyl malonate and ethyl bromocaproate which was obtained from cyclohexanone by the method of Brown[6]. Benzyl *n*-hexane-1,1,6-tricarboxylate derived from the ethyl ester by transesterification with benzyl alcohol was condensed with palmitoyl chloride or stearoyl chloride, to give, after hydrogenation and decarboxylation, 8-ketotricosanoic acid or 8-ketopentacosanoic acid. Reduction to the corresponding fatty acid by Huang-Minlon's method[7] was efficient. Ethyl tricosanoate and ethyl pentacosanoate were readily reduced to the desired alcohols with lithium aluminum hydride.

The physical constants and analytical data of the alcohols are given in Table I together with those reported by other workers who had previously synthesized them by different methods. The transition points of C_{19}, C_{21}, C_{23}, C_{25} alcohols were unknown.

Since it is known that sometimes minor impurities, especially homologues, have a marked influence on the transition behavior of long chain compounds, it was felt necessary to obtain the starting fatty acids in high purity. Commercial fatty acids such as lauric, myristic, palmitic, stearic,

and behenic acids were obtained in a pure state by fractionation of the methyl ester through four feet Fenske column followed by saponification and recrystallization. Physical constants and analytical data of these fatty acids are given in Table II.

Experimental

Undecanol, Tridecanol, Pentadecanol, Heptadecanol and Heneicosanol.—These alcohols were prepared from the corresponding fatty acids by method A involving Hunsdiecker's reaction[3]. A typical example is given for the preparation of heneicosanol.

Silver behenate: $C_{21}H_{43}CO_2Ag$—A solution of 20 g. of potassium behenate in 200 ml. of ethanol was stirred on a steam bath while a solution of 13 g. of silver nitrate in 50% aqueous ethanol was added dropwise. The resulting bulky white precipitate was collected on a filter, thoroughly washed four times by suspension in 500 ml. of hot water, air-dried, and brought to complete dryness at 150°C under reduced pressure (2 mm.). The yield was almost quantitative.

Heneicosyl bromide: $C_{21}H_{43}Br$—The reaction was carried out under strict exclusion of moisture. To a suspension of 12 g. of silver behenate in 80 ml. of carbon tetrachloride was added a solution of 10 g. of bromine in 50 ml. of carbon tetrachloride which had previously been dried over phosphorus pentoxide. Reaction began immediately, with the evolution of carbon dioxide. When the reaction almost ceased, the reaction mixture was heated at the boiling point for a short period to complete the reaction. Silver bromide formed was filtered off and the solution was washed successively with water, sodium thiosulfate solution, 5% sodium hydroxide solution, and water, and dried over sodium sulfate. Evaporation of the solution gave 8.5 g. of an oily product, which solidified on standing at room temperature. Recrystallization from ethanol yielded the pure bromide which melted at 44.5~45°C and weighed 5.3 g. (53%).

Anal. Found: C, 67.5; H, 11.49. Calcd. for $C_{21}H_{43}Br$: C, 67.2; H, 11.47%.

The melting point is higher than that of docosyl bromide $C_{22}H_{45}Br$ (44°C)[8]. This is consistent with the fact that the melting points of normal alkyl bromides of odd carbon numbers are slightly higher than those of next higher homologue.

Heneicosanol: $C_{21}H_{43}CH$ — An intimate mixture of 5 g. of heneicosyl bromide and 2.3 g. of silver acetate was kept at 150°C for 3 hr. The reaction mixture was extracted three times with hot benzene. The benzene solution free from silver bromide was washed with water and dried over sodium sulfate. Evaporation of the solution gave 4.2 g. of a residue which was saponified without purification. The crude ester was refluxed for 3 hr. with 10 ml. of 30% alcoholic potassium hydroxide. The resulting alcohol was recrystallized twice from ethanol and twice from benzene to give heneicosanol in platelets, m. p. 68.5~69°C. Overall yield was 40% (3 g.).

Nonadecanol. — The intermediate diazoketone was prepared by the method of Grundmann[4]. The melting point of this compound was 69~70°C (reported 69°C).

Methyl nonadecanoate: $C_{18}H_{37}CO_2CH_3$—A slurry of freshly prepared silver oxide in methanol was added portionwise to a stirred solution of 18 g. of 1-diazo-2-nonadecanone in 160 ml. of methanol which was heated beforehand at 65°C. The addition required about 4 hr. and the temperature of the reaction mixture was kept at 60~65°C during the course of the reaction. At the end of this period a 2 ml. portion was taken from the solution and added to concentrated hydrochloric acid. An evolution of nitrogen was not observed, and then the solution was cooled and filtered. Partial removal of the methanol and subsequent cooling gave a white solid which was recrystallized from methanol, m. p. 42~43°C. The yield was 17 g. (95%). It was identified by the mixed melting point with an authentic sample.

Reduction of methyl nonadecanoate.—To a stirred suspension of 0.2 g. of lithium aluminum hydride in 25 ml. of dry ether was added a solution of 3 g. of methyl nonadecanoate in 15 ml. of ether dropwise at such a rate that a gentle reflux of the solvent was maintained. After the addition was complete, the solution was refluxed for 15 min. The excess of lithium aluminum hydride was decomposed by cautious addition of water and the reaction mixture was acidified with dilute sulfuric acid. The ether layer was removed, and washed with water to neutral reaction. The solid residue, obtained by removal of the solvent from the dried solution, was recrystallized four times from benzene to give nonadecanol in platelets, m. p. 62~62.5°C. Yield was 90% (2.3 g.).

Tricosanol. — The preparation of intermediate ethyl ε-bromocaproate (I) was modelled after that of Brown and Partridge[6]. From 50 g. of purified cyclohexanone 52 g. of the bromoester was obtained, b. p. 118°C/14 mm. or 98°C/4.5 mm., n_D^{32} 1.4561 (reported: b. p. 120~125°C/14 mm., n_D^{21} 1.4566).

Ethyl n-hexane 1,1,6-tricarboxylate (II).—The bromoester (33 g.) was refluxed with a solution of 48 g. of sodiomalonic ester in 150 ml. of absolute ethanol for 8 hr. After removal of the solvent the cooled mixture was treated with dilute solfuric acid and the triethylester was isolated in a usual manner as a colorless liquid, b. p. 150~151°C/1 mm. Yield, 28 g. (63%). n_D^{28}, 1.4360.

Anal. Found: C, 59.91; H, 9.01; Calcd. for $C_{15}H_{26}O_6$: C, 59.58; H, 8.67%.

8-Ketotricosanoic acid (V): $CH_3(CH_2)_{14}CO(CH_2)_6CO_2H$—In a 200 ml. three-necked flask equipped with a mechanical stirrer, a dropping funnel and a reflux condenser fitted with a calcium chloride tube, were placed 0.75 g. of finely powdered sodium sand and 70 ml. of dry benzene. To the mixture was added from the dropping funnel 11.3 g. of ethyl *n*-hexane-1,1,6-tricarboxylate.

8) V. Braun et at., *Ann.*, **472**, 132 (1929).

The mixture was refluxed with stirring until the sodium sand disappeared. It required about 8 hr. After 7.5 g. of benzyl alcohol (purified by oximation followed by distillation: b. p. 79~80°C/7 mm., odorless) was added, the reflux condenser was replaced by a Fenske column and the mixture was heated to distill off ethanol as the benzene-ethanol azeotrope. Then the Fenske column was again replaced by the reflux condenser. Palmitoyl chloride (9 g.) b. p. 148°C/1.5 mm. was added with stirring, and the resulting solution was refluxed for 1 hr. The neutral solution obtained was distilled under reduced pressure to give a yellow oil which could not be crystallized and was subjected to hydrogenation without purification. A solution of 25 g. of tribenzyl compound IV in 50 ml. of ethyl acetate was shaken with Pd-C (0.5 g.) and Pd-$SrCO_3$ (0.5 g.) in a hydrogen atmosphere of slightly positive pressure. After 10 hr. the absorption of hydrogen ceased, but during this period the fresh catalyst was added from time to time because of its poisoning, the total amount of catalyst being 4 g. The solution freed from the catalyst was refluxed for 30 min. to decarboxylate the product. After the solvent was partially removed, white small crystals separated out from the cooled solution. Repeated recrystallization from acetone gave white crystals having the constant melting point of 93.5~94°C. Yield was 23% (2.8 g.).

Anal. Found: C, 75.16; H, 12.00. Calcd. for $C_{23}H_{44}O_3$: C, 74.94; H, 12.03%.

Tricosanoic acid (VI): $C_{22}H_{45}CO_2H$—To a solution of 2.5 g. of potassium hydroxide in 30 ml. of diethylene glycol was added 2.5 g. of the ketonic acid and 2.5 ml. of hydrazine hydrate. The mixture was heated to 165°C in an oil bath. After 1 hr. of heating the water formed distilled off through a take-off condenser. The contents of the flask were held at 200°C for 6 hr., and cooled. The fatty acid was isolated by pouring the reaction mixture into an equal volume of water followed by acidification with dilute sulfuric acid. Recrystallization from benzene gave 2.2 g. of platelets, m. p. 78.5°C (reported: 79~79.3°C[9]). The ethyl ester of the acid was obtained by the usual method and purified by vacuum distillation followed by recrystallization from benzene, m. p. 51~52°C (reported: 51.2~51.4°C[9]), b. p. 207°C/1.5 mm.

Tricosanol: $C_{23}H_{47}OH$ — From 2 g. of ethyl tricosanoate, 0.15 g. of lithium aluminum hydride in absolute ether was obtained 1.3 g. of the pure alcohol which melted at 72.5°C.

Pentacosanol.—It was prepared analogously to tricosanol stearic acid, being used in place of palmitic acid. The experimental results are given briefly.

Condensation product of benzyl n-hexane-1,1,6-tricarboxylate with stearoyl chloride. — From 17 g. of the tribenzyl compound and 11 g. of stearoyl chloride (b. p. 169°C/1.5 mm.) were obtained 24 g. of a crude product in a state of viscous brown liquid.

8-Ketopentacosanoic acid: $CH_3(CH_2)_{16}CO(CH_2)_6CO_2H$—From 24 g. of the above benzyl compound, 2.5 g. of the ketonic acid was obtained. The product was recrystallized from acetone and then from benzene to a constant melting point of 97°C.

Anal. Found: C, 75.91; H, 12.05. Calcd. for $C_{25}H_{48}O_3$: C, 75.70; H, 12.20%.

Pentacosanoic acid: $C_{24}H_{49}CO_2H$ — The Huang-Minlon reduction of 2.5 g. of the ketonic acid gave 2.2 g. of pentacosanoic acid, m. p. 83.1°C (reported: 83.2~83.4°C[9]). Ethyl pentacosanoate, m. p. 57~58°C (reported: 57.1~57.4°C[9]), b. p. 215°C/0.7 mm.

Pentacosanol: $C_{25}H_{51}OH$ — By use of lithium aluminum hydride (0.15 g.), 1.7 g. of the pure product was obtanied from 2.1 g. the ethyl pentacosanoate. m.p. 77.5°C (from ligroin).

Competitive Hydrogenation of Acetylenic Compounds

By Tosao FUKUDA

(Received March 18, 1959)

1, 4-Butynediol can be partially hydrogenated on the Pd-$CaCO_3$ catalyst, with quinoline as a poison, and also on the Pd-$BaCO_3$ catalyst poisoned by lead acetate and quinoline, but not on the ordinary palladium catalyst[1,2]. The effect of lead acetate on the Pd-$CaCO_3$ catalyst was different from that of quinoline. It was explained that lead acetate is adsorbed more strongly than 1, 4-butynediol or 1, 4-butenediol, while quinoline is adsorbed in competition with 1, 4-butynediol and 1, 4-butenediol[3].

It seems to be an interesting problem to study in more detail how the properties of the Pd-$CaCO_3$ catalyst are affected by such an additive as quinoline. Thus, the properties of the catalyst for the hydrogenation of phenylacetylene and propargyl alcohol were studied.

Experimental

Procedure. — The hydrogenation experiments were carried out with Pd-$CaCO_3$ catalyst[4] (Pd-content, 5% by wt.), at 25°C and at the atmospheric pressure in methyl alcohol. Phenylacetylene was prepared according to J. C. Hessler[5], and propargyl alcohol was a commercial product[6]. These were purified by distillation. The hydrogenation products were analyzed by gas chromatography.

The gas chromatography experiments were carried out at 100°C by a glass gas chromatography apparatus[7]. Polyethyleneglycol-400 column (P.E.G.-column) and polyethyleneglycol-400-dinonyl phthalate column (P.E.G.-D.N.P-column) were used. With P.E.G.- and P.E.G.-D.N.P.-columns, phenylacetylene, styrene, ethylbenzene, propargyl alcohol, allyl alcohol, and propyl alcohol eluted as shown in Fig. 1.

Results

The hydrogenation of phenylacetylene and propargyl alcohol on the Pd-$CaCO_3$ catalyst took place as shown in Fig. 2. It was shown that phenylacetylene and propargyl alcohol could not be partially hydrogenated in the presence of quinoline.

When 20 millimol. of phenylacetylene or propargyl alcohol in a concentration of 2 millimol./ml. was used, the reaction products were shown in Fig. 3. In these experiments, a mixture of methyl alcohol

and *n*-butyl alcohol (an internal standard for the gas chromatographic analysis) was used as a solvent. The hydrogenation of phenylacetylene took place with simultaneous hydrogenation of about 20 mol. % of styrene. On the other hand, in the hydrogenation of propargyl alcohol, allyl alcohol was scarcely hydrogenated.

The competitive hydrogenation took place as shown in Fig. 4. When the concentration of the each acetylenic compound was 2 millimol./ml., the reaction products came out as shown in Figs. 5—7, with the absorbed amount of hydrogen. In these experiments, a mixture of methyl alcohol and *n*-butyl alcohol was used as a solvent. The peak of 1,4-butynediol, 1,4-butenediol, and 1,4-butanediol did not appear under the experimental conditions of the gas chromatography. However, the contents of these substances in the product could be roughly estimated from the absorbed amount of hydrogen as shown by the dotted lines, assuming that 1,4-butynediol and 1,4-butenediol were hydrogenated selectively.

● Styrene ○ 1,4-Butenediol
▲ Ethylbenzene △ 1,4-Butanediol

It was shown that, in the competitive hydrogenation of 1,4-butynediol and phenylacetylene, the latter was hydrogenated first and the former was then hydrogenated, and both steps were accompanied by the hydrogenaion of a small amount of styrene.

The hydrogenation of 1,4-butenediol took place after that of styrene was completed. In the competitive hydrogenation of 1,4-butynediol and propargyl alcohol, the latter was hydrogenated first, and the hydrogenation of 1,4-butynediol with a small amount of allyl alcohol followed. The remaining allyl alcohol was hydrogenated with 1,4-butenediol. In the competitive hydrogenation of phenylacetylene and propargyl alcohol, the latter was hydrogenated with about 35 mol. % of the former. The remaining phenylacetylene was hydrogenated with a small amount of styrene and allyl alcohol. Styrene was hydrogenated with allyl alcohol.

Even when 0.2 millimol./ml. of phenylacetylene (or propargyl alcohol) and 1.8 millimol./ml. of 1,4-butynediol were used, the competitive hydrogenation took place similarly as explained above.

It was observed that an appreciable amount of allyl alcohol was consumed by

the side reaction, and its hydrogenation was interrupted with the occurrence of the side reaction. The product from the side reaction was mainly propionaldehyde. However, it was found that propionaldehyde could not retard the hydrogenation of allyl alcohol, a mixture of methyl alcohol and propionaldehyde being used as a solvent.

Consideration

It is interesting to note that, when phenylacetylene has been absorbed on the catalyst surface, styrene is hydrogenated more easily than 1,4-butynediol, but, when the hydrogenation of phenylacetylene has been completed, 1,4-butynediol is hydrogenated more easily than styrene. Allyl alcohol is hydrogenated more easily than 1,4-butenediol. However, 1,4-butenediol is hydrogenated, even when the hydrogenation of allyl alcohol has been interrupted.

These results show that the catalyst properties are affeced by the adsorption of 1,4-butynediol, phenylacetylene, propargyl alcohol and so on. It is generally admitted that the catalyst properties are changed by the adsorbed substance[8]. When phenylacetylene or propargyl alcohol is adsorbed on the catalyst surface, the catalyst properties may be different from those when 1,4-butynediol is adsorbed. Accordingly, the partial hydrogenation of 1,4-butynediol might have been achieved on the Pd-$CaCO_3$ catalyst, with quinoline as a beneficial poison, but not phenylacetylene and propargyl alcohol.

It was shown that the gas chromatography is very useful to study the reactions.

The author is grateful to Professor T. Kusama, Yokohama National University, for his unfailing kindness in encouraging this work. The author is also indebted to Professor K. Tamaru, Yokohama National University, for his valuable advice, and Mr. Y. Suzuki, for his assistance.

Dehydration of Bile Acids and their Derivatives. VII. Isomerization of Methyl 3α-Hydroxy-Δ^7-cholenate to Methyl 3α-Hydroxy-Δ^{14}-cholenate

By Ryuzaburo OSAWA and Kazumi YAMASAKI

(Received April 3, 1959)

Yamasaki[1] reported previously that the action of concentrated hydrochloric acid on chenodeoxycholic acid gave three isomeric 3α-hydroxycholenic acids, but the localization of their double bonds has not yet been settled. In order to obtain any further information about these acids, the authors have attempted to isomerize 3α-hydroxy-Δ^7-cholenic acid derived from chenodeoxycholic acid and to compare the product obtained with the isomers reported by Yamasaki[1]. Methyl 3α-ethoxycarbonyloxy-7α-hydroxycholanate (Ib) was prepared from methyl chenodeoxycholate (Ia) according to Fieser et al.[2] and dehydrated with phosphorus oxychloride in pyridine[3] to give methyl 3α-ethoxycarbonyloxy-Δ^7-cholenate[4] in a fairly good yield, m. p. 136°C, $\alpha_D^{24} = +81.20°$ (Chf.) [Herz[5]: m. p. 126°C, $\alpha_D^{21} + 80 \pm 2°$ (Di)].

Methyl 3α-hydroxy-Δ^7-cholenate (IIc)

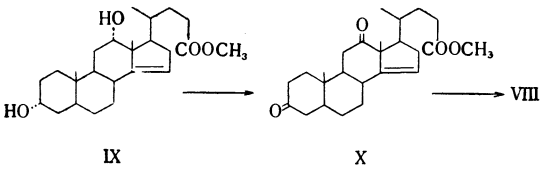
3) E. Berner, A. Lardon and T. Reichstein, *Helv. Chim. Acta*, **30**, 1542 (1947).



4) Although the proposed position (Δ^7) of the double bond of this acid has not yet been studied, the position is highly probable, because the C_7 OH-group of chenodeoxycholic acid is apt to be dehydrated (*trans*-dehydration) exactly like cholic acid[3], and any possible shift of the double bond then formed can be excluded under the condition here described.

TABLE I. 3α-HYDROXYCHOLENIC ACIDS DERIVED FROM CHENODEOXYCHOLIC ACID

3α-Hydroxy-cholenic acid	m. p. °C	$[\alpha]_D$	Methyl ester, m. p., °C	Methyl ester acetate, m. p. °C
β-Apochenodeoxycholic acid[1]	195～196	+83.67° (alc.)	—	83～84
γ-Apochenodeoxycholic acid[1]	182～183	+101.73° (MeOH)	—	77～78
Chenocholenic acid[1]	211～213	+30.0° (MeOH)	—	—
3α-Hydroxy-Δ^7-cholenic acid	189～190	+62.0° (Di.)	108～109	127
3α-Hydroxy-Δ^{14}-cholenic acid	160	+62.8° (Chf.)	140～141	110

was subjected to isomerization by the action of dry hydrogen chloride gas[6], and a crystalline mixture was obtained. A fraction melting higher than the starting material was purified to afford crystals of m. p. 140～141°C, $\alpha_D^{20}=+55.8°$ (Chf.). The isomerized ester showed a distinct depression of the melting point on admixture with the starting substance and gave a negative selenium dioxide test, while the latter did a positive test, contrary to Fieser's report[7].

The corresponding free acid dissolved in ethanol showed an absorption maximum at 211 mμ with an extinction coefficient of ε_{max}^{EtOH} 2390, while $\Delta^{8(14)}$-cholenic acid as a reference substance, obtained from apocholic acid[8], showed an extinction coefficient of $\varepsilon_{max}^{EtOH}=6170$. According to Bladon et al.[9], this finding suggests that the new 3α-hydroxycholenate possesses either a tri- or a disubstituted ethylenic grouping. As was expected, the ester absorbed one mole of hydrogen on catalytic hydrogenation to give methyl lithocholate (VI) (m.p. 130°C). These results provide a strong evidence for the Δ^{14}-structure (V) of the new acid.

In order to ascertain the structure, the 3-hydroxy-ester (Va) was transformed into a cholenic acid by the Huang-Minlon reduction[10] of the corresponding 3-keto-ester (VII). The cholenic acid obtained was identified with Δ^{14}-cholenic acid (VIII) which was derived from 3α,12α-dihydroxy-Δ^{14}-cholenic acid[11] (IX) through its dehydro-acid (X).

Thus it is concluded that the isomerized product from methyl 3α-hydroxy-Δ^7-cholenate (IIc) is methyl 3α-hydroxy-Δ^{14}-cholenate (Va), but, as shown in Table I, the 3α-hydroxy-Δ^{14}-cholenic acid (Vb) was found to be different from any of the three 3α-hydroxycholenic acids obtained by Yamasaki[1]. The expected presence of the isomeric 3α-hydroxy-$\Delta^{8(14)}$-cholenate together with the Δ^{14}-ester in the isomerization product is now under investigation.

Experimental

Preparation of 3α-Hydroxy-Δ^7-cholenic Acid and Derivatives. — *Methyl 3α-ethoxycarbonyloxy-7α-hydroxycholanate (Ib).* — Two grams of methyl chenodeoxycholate (Ia) (the free acid, m.p. 140°C, was prepared according to Fieser and Rajagopalan[12] from cholic acid and the non-crystalline methyl ester was prepared with diazomethane as ususl) dissolved in 20 ml. of dioxane containing 3.2 ml. of pyridine was treated with 4 ml. of ethyl chloroformate with cooling in ice water. After standing at room temperature for 2 hr., the mixture was diluted with water, and extracted twice with ether. The combined extract was washed with dilute hydrochloric acid and with water, dried over sodium sulfate, and evaporated to dryness in vacuo. The residue was treated with a small quantity of methanol, warmed and allowed to stand at room temperature to crystallization. Recrystallization from methanol gave the ethoxycarbonyl derivative (Ib) in colorless blades, m. p. 136°C, $\alpha_D^{20}=+30.55°$ (Chf.).

Methyl 3α-ethoxycarbonyloxy-Δ^7-cholenate (IIa).— The above ester (Ib) (1.8 g.) was dissolved in 20 ml. of pyridine, 6 ml. of phosphorous oxychloride was added, and the mixture was kept at room temperature overnight. The reaction mixture was poured cautiously into 300 ml. of ice water, and extracted 3 times with ether. The combined ethereal extract was washed with water, dilute hydrochloric acid, aqueous sodium hydroxide solution and again water, successively, and dried over sodium sulfate. Removal of the solvent gave a crystalline residue, to which was added a small quantity of methanol, and the solution was warmed and allowed to stand at room temperature to give a crystalline product, m.p. 120~121°C. Yield, 1.65 g. Recrystallization from acetone gave the product in blades, m. p. 132~133°C, $\alpha_D^{24}=+81.2°$ (Chf.).

Anal. Found: C, 73.00; H, 9.63. Calcd. for $C_{28}H_{44}O_5$ (460.32): C, 73.01; H, 9.89%.

3α-Hydroxy-Δ^7-cholenic acid (IIb). — The above ester (IIa) (1.5 g.) was dissolved in 20 ml. of methanol containing 10 ml. of 10% aqueous potassium hydroxide and the solution was refluxed for 1.5 hr. The hydrolyzate was diluted with water and acidified with dilute hydrochloric acid. The precipitates were collected, washed with water and dried to give the free acid, m. p. 183~184°C. Yield, 1.17 g. Recrystallization from ethyl acetate and methanol gave the substance in needles, m. p. 189~190°C, $\alpha_D^{21}=+62.0°$ (Di). The selenium dioxide test was positive.

Anal. Found: C, 76.64; H, 10.05. Calcd. for $C_{24}H_{38}O_3$ (374.54): C, 76.94; H, 10.23%.

Methyl 3α-hydroxy-Δ^7-cholenate (IIc).—The above acid (IIb) (m. p. 190~191°C, 0.5 g.) was refluxed with 10 ml. of methanol containing two drops of concentrated hydrochloric acid for 1/2 hr., and the solution was concentrated by passing a stream of air to crystallization. After completion of crystallization, the crystals were collected and washed with a small volume of methanol, m. p. 104~105°C. Yield, 0.49 g.

Recrystallized twice from aqueous methanol, the substance was obtained in glistening leaflets, m. p. 108~109°C, $\alpha_D^{24}=+61.8\pm1.4°$ (Chf.).

Methyl 3α-acetoxy-Δ^7-cholenate (IId).—The above ester (IIc) (200 mg.) in 4 ml. of pyridine was treated with 2 ml. of acetic anhydride. After standing for 24 hr., water and concentrated hydrochloric acid (3.5 ml.) were added and the mixture was warmed for 20 min. on a steam bath. The solid was collected, and weighed 200 mg. Recrystallized once from methanol, the substance was obtained in glistening plates, m. p. 126~127°C, $\alpha_D^{23}=+86.0°$ (Chf.), λ_{max} 211 mμ, ε_{max}^{EtOH} 2075.

Anal. Found: C, 74.80; H, 9.64. Calcd. for $C_{27}H_{42}O_4$ (430.61): C, 75.30; H, 9.85%.

Methyl 3-keto-Δ^7-cholenate (III). — Methyl 3α-hydroxy-Δ^7-cholenate (IIc) (800 mg.) was oxidized in acetone with the chromic acid-H_2SO_4 mixture according to Baldon et al.[13] When the reaction was completed, the solution was diluted with water. After completion of crystallization in an ice box, the crystals were collected, m. p. 123~124°C. Yield, 770 mg. Recrystallized once, the substance was obtained in a pure state, m. p. 125°C, $\alpha_D^{23}=+53.3$ (Chf.).

Anal. Found: C, 77.22; H, 9.77. Calcd. for $C_{25}H_{38}O_3$ (386.55): C, 77.67; H, 9.91%.

Methyl Δ^7-cholenate (IVa). — Methyl 3-keto-Δ^7-cholenate (III) (0.51 g.) was heated with a mixture of triethylene glycol (30 ml.), hydrazine hydrate (1.5 ml.) and potassium hydroxide (1 g.) by the modified Wolff-Kishner method (Huang-Minlon[10] reduction).

The reaction mixture was diluted with water and acidified with dilute hydrochloric acid. The solid was collected, washed with water, and dried. The crude acid in methanol was treated with an ether solution of diazomethane and concentrated. The first crop (0.37 g.) showed m. p. 95.5~97°C, and the second (0.05 g.), m. p. 85~86°C.

Recrystallization of the combined crops from methanol-acetone gave thin rectangular plates of m. p. 98~99°C, undepressed by the sample obtained by the phosphorous oxychloride dehydration of methyl 7-hydroxycholanate (Herz[5]); $\alpha_D^{23}=+53\pm3°$ (Chf.) [$\alpha_D^{21}=+56\pm2°$ (Di.) (Herz[5])].

Anal. Found: C, 80.25; H, 10.58. Calcd. for $C_{25}H_{40}O_2$ (372.57): C, 80.62; H, 10.82%.

13) P. Bladon, J. M. Fabian, H. B. Henbest, H. P. Koch and G. W. Wood, *J. Chem. Soc.*, **1951**, 2402.

Δ^7-Cholenic acid (IVb).—The above ester (IVa) (100 mg.) was refluxed for 1 hr. with 7 ml. of methanol and 3 ml. of 10% aqueous potassium hydroxide, and the reaction mixture was diluted with water and acidified with dilute hydrochloric acid. The crystalline solid was collected. Recrystallized twice from methanol, Δ^7-cholenic acid was obtained in a pure state, m. p. 150~151°C, undepressed on admixture with the specimen (m. p. 151°C) prepared by Herz[5].

Anal. Found: C, 80.78; H, 10.47. Calcd. for $C_{24}H_{38}O_2$ (558.54): C, 80.80; H, 10.68%.

Isomerization of Methyl 3-Hydroxy-Δ^7-cholenate.—*Methyl 3α-hydroxy-Δ^{14}-cholenate (Va).*—A stream of dry hydrogen chloride gas was passed into a solution of methyl hydroxy-Δ^7-cholenate (IIc) (1.0 g.) in anhydrous chloroform (20 ml.) for 2 hr. at 0°C. The solution was diluted with chloroform with cooling in ice water, washed with water, soda solution and again with water, successively, and dried over sodium sulfate. Removal of the solvent gave a crystalline residue. This was dissolved in 1 ml. of benzene, passed throngh a Brockmann-alumina column and eluted with petroleum ether, benzene, ether and methanol, successively. The first portions of the elute contained the original substance, and a substance of higher melting point was obtained from the fractions eluted with ether. Rechromatography of the fractions of the higher melting point gave an ester of m. p. 139°C, and recrystallization from ethanol-water afforded crystals of m. p. 140~141°C, $\alpha_D^{20}=+55.8°$ (Chf.), which showed a depression in the melting point on admixture with the starting substance and was negative in the selenium dioxide test.

Anal. Found: C, 77.40; H, 10.13. Calcd. for $C_{25}H_{40}O_3$ (388.32): C, 77.69; H, 9.91%.

Methyl 3α-acetoxy-Δ^{14}-cholenate (Vc).—Methyl 3α-hydroxy-Δ^{14}-cholenate (Va) (m. p. 141°C, 100 mg.) in 2 ml. of pyridine was treated with 1 ml. of acetic anhydride. After standing for 24 hr., water and concentrated hydrochloric acid (3.5 ml.) were added to the reaction mixture, and the whole was warmed for 20 min. on a steam bath. The solid was collected. Yield, 100 mg. Recrystallized once from methanol, the product was obtained in glistening leaflets of m. p. 110°C, $\alpha_D^{20}=+86.7°$ (Chf.).

Anal. Found: C, 75.30; H, 9.85. Calcd. for $C_{27}H_{42}O_4$ (430.61): C, 75.30; H, 9.85%.

3α-Hydroxy-Δ^{14}-cholenic acid (Vb).—Methyl 3α-hydroxy-Δ^{14}-cholenate (Va) (100 mg.) was dissolved in 7 ml. of methanol containing 3 ml. of 10% aqueous potassium hydroxide and the mixture was refluxed for 1 hr. The solution was acidified with dilute hydrochloric acid. The crystalline solid was collected. Recrystallized twice from methanol containing ethyl acetate, the substance was obtained in a pure state, m. p. 161°C, $\alpha_D^{24}=+62.8°$ (Chf.), λ_{max} 211 mμ, ε_{max}^{EtOH} 2390.

Anal. Found: C, 76.27; H, 10.37. Calcd. for $C_{24}H_{38}O_3$ (374.54): C, 76.94; H, 10.23%.

Methyl lithocholate (VI).—Methyl 3α-hydroxy-Δ^{14}-cholenate (Va) (m. p. 141°C, 50 mg.) in 10 ml. of glacial acetic acid was shaken for 3 hr. with 10 mg. of PtO_2 (Adams) and hydrogen, 3.1 ml. of hydrogen being absorbed (the calculated amount: 3.07 ml.). Concentration of the solution, addition of a small amount of methanol and heating gave needles. Recrystallization from methanol afforded a sample of m. p. 130°C, $\alpha_D^{20}=+24.2°$ (Chf.). This showed no depression in the melting point on admixture with authentic methyl lithocholate (m. p. 129~130°C).

Anal. Found: C, 77.48; H, 10.17. Calcd. for $C_{25}H_{42}O_2$ (375.58): C, 76.78; H, 10.83%.

Methyl 3-keto-Δ^{14}-cholenate (VII).—Methyl 3α-hydroxy-Δ^{14}-cholenate (Va) (m. p. 141°C, 200 mg.) in 20 ml. of acetone was oxidized with the chromic acid-H_2SO_4 mixture according to Bladon et al.[13] After completion of oxidation, the excess of the oxidant was destroyed by addition of a small quantity of methanol. The solution was diluted with water and extracted with ether. The ether extract was washed with water, soda solution and again with water, successively, dried over sodium sulfate and evaporated. The residue was triturated with a small quantity of methanol, and kept at room temperature. The yield of colorless needles, m. p. 78~79°C, was 155 mg. Recrystallized twice from aqueous methanol, the substance was obtained in a pure state, m. p. 89~90°C, $\alpha_D^{24}=+38.8°$ (Chf.).

Anal. Found: C, 77.40; H, 10.13. Calcd. for $C_{25}H_{38}O_3$ (386.55); C, 77.69, H. 9.09%.

Δ^{14}-Cholenic acid (VIII).—Reduction of methyl 3-keto-Δ^{14}-cholenate (VII) (100 mg.) was conducted according to the modified Huang-Minlon procedure[10] with a mixture of triethylene glycol (10 ml.), hydrazine (1 ml.) and potassium hydroxide (1 g.). The reaction mixture was diluted with water and acidified with dilute hydrochloric acid. The solid was collected, washed with water, dried over sodium sulfate, and evaporated. Recrystallization from ethyl acetate and then from aqueous methanol afforded colorless needles of m. p. 143~144°C, $\alpha_D^{22}=+61.8°$ (Chf.), ε_{max}^{EtOH} 3404.

Anal. Found: C, 80.44, H, 10.71. Calcd. for $C_{24}H_{38}O_2$ (358.54): C, 80.39; H, 10.68%.

Derivation of Δ^{14}-cholenic Acid from 3,12-Dihydroxy-Δ^{14}-cholenic Acid.—*Methyl 3,12-diketo-Δ^{14}-cholenate (X).*—Methyl 3,12-dihydroxy-Δ^{14}-cholenate (IX) (200 mg.) was oxidized with the chromic acid-H_2SO_4 mixture according to Bladon et al.[13] Recrystallization from methanol gave fine needles of m. p. 134°C, $\alpha_D^{22}=+60.3$ (Chf.). Yield, 0.175 g.

Anal. Found: C, 75.18; H, 9.15. Calcd. for $C_{25}H_{36}O_4$ (400.56): C, 74.96; H, 9.06%.

Δ^{14}-Cholenic acid (VIII).—The above diketoester (X) (200 mg.) was reduced by the Huang-Minlon procedure[10] (25 ml. of triethylene glycol, 2 ml. of hydrazine hydrate, 2 g. of potassium hydroxide). Recrystallization from acetone and then from acetic acid gave crystals of m.p. 142~143°C, $\alpha_D^{20}=+62.1°$ (Chf.). This acid showed no depression of the melting point on admixture with the specimen obtained above from 3α-hydroxy-Δ^{14}-cholenic acid.

Anal. Found: C, 79.59; H, 10.75. Calcd. for $C_{24}H_{38}O_2$ (358.54): C, 80.39; H, 10.68%.

The preparation of methyl Δ^7-cholenate from methyl 3α-hydroxy-Δ^7-cholenate was carried out, when Yamasaki was working in L. F. Fieser's Laboratory, Harvard University. The elementary analyses were carried out by Mr. Okada of the Analysis Room of Shionogi Laboratory, to whom the authors' gratitude is due.

The authors are greatly indebted to Professor Itô of the Pharmaceutical Institute, the University of Tokyo, for his valuable suggestion and encouragement.

The Silver Catalyzed Oxidation of Arsenious Acid by Persulfate

By Yugul Kishore GUPTA and Deen Dayal MISRA

(Received April 13, 1959)

The uncatalyzed oxidation of arsenious acid by persulfate has been studied by Gupta & Ghosh[1] and Gupta[2] has found the specific influence of several ions in this oxidation. The oxidation is similar to other uncatalyzed oxidations such as those of thiosulfate[3] and oxalate[4,5] ions. Catalysis by silver ion has been reported by Gupta and Ghosh, but no systematic study was made by them. Silver catalyzed oxidations by persulfate are reported to be of three types. Hence a detailed study of this silver catalyzed reaction was made to evaluate a possible mechanism and to compare the results with those of other silver catalyzed oxidations.

Experimental

Persulfate oxidations are very susceptible to impurities of the solutions and the nature of the glass vessel, and hence all the vessels and apparatus used in this investigation, were of Jena glass. The medium of reaction was redistilled water.

All the chemicals used were of B.D.H.A.R. or E. Merck G.R. quality. A stock solution of 0.20 N arsenious acid was prepared. For this, a requisite amount of arsenious oxide, sufficient to give a little more than 0.20 N acid, was dissolved by boiling in redistilled water. After allowing it to cool, it was filtered and standardized against permanganate solution. Persulfate solution was always freshly prepared and its concentration checked by Eckardt's method[6]. All other solutions were prepared in the usual way.

The reaction was studied at 24°C in a thermostat and silver nitrate was added at the end. A preliminary study indicated that there was practically no reaction between persulfate and arsenious acid at 24°C for about 30~40 min., the time for which they were kept together in the reaction vessel. The reaction speed becomes measurable only at higher temperatures. Gupta and Ghosh studied the uncatalyzed reaction at 45°C.

Five milliliters of the reaction mixture were pipetted out at suitable intervals of time, in a beaker containing 3 ml. of pure and concentrated hydrochloric acid and 10~15 ml. of distilled water. One drop of 0.0025 M KIO_3 added and the contents were titrated against 0.01 N $KMnO_4$ from a microburette. Persulfate did not interfere with this titration. The reaction was completely checked by inhibiting chloride ions[2].

Results and Discussion

The oxidation is of the first order in persulfate and the constants have been calculated from the relation,

$$k = (2.303/t) \times (1/C_{Ag^+}) \times \log [a/(a-x)]$$

where 'a' and '$a-x$' are the concentrations of the persulfate initially and after time 't', respectively, and C_{Ag^+} is the concentration of the silver ions. The reaction is in fact bimolecular, but has a first order rate constant because the concentration of the catalyst Ag^+ does not change during the course of the reaction. Hence k, though a first order constant, has the units of l. equi^{-1} min^{-1}.

△ Sample 2; k=31.49
× Sample 3; k=36.77

Gupta and Ghosh[1] obtained different results with different samples of arsenious acid solution. It was, therefore, imperative to study also the catalyzed reaction with different samples of acid solution. Three experiments out of 20 are shown in Fig. 1 where the average k varied within appreciable limits.

However, the results are quite reproducible with the same sample of arsenious acid solution and hence in order to compare the results amongst themselves, it was necessary to use the same stock solution of arsenious acid as was done by Gupta and Ghosh. Efforts were made to eradicate the cause of this trouble, but without any success. The present paper reports the results of experiments using sample 1 of Fig. 1. The reaction is specifically influenced by the ions and hence no electrolyte was added to keep the ionic strength constant. Nor was there any need for it, because in any particular experiment no change in k was observed as the reaction progressed.

Table I shows the results using different concentrations of the reactants.

It may be seen that the reaction is independent of the concentration of arsenious acid — a fact found in other persulfate oxidations where it is independent of the concentration of the reductant. The rate of reaction increases with the increase in the concentration of the persulfate, but the constants decrease, probably due to the inhibition by potassium ions. The inhibiting character of the potassium ions have been reported in the oxidation of formate[7], oxalic acid[8] and oxalate[9], and the decomposition of persulfate[10]. Alkali metal ions, in general, inhibit many persulfate oxidations.

TABLE I

$K_2S_2O_8$, N	H_3AsO_3, N	k
0.005	0.0102	25.80
0.01	0.0102	23.96
0.02	0.0102	19.80
0.04	0.0102	13.82
0.01	0.0051	24.01
0.01	0.0102	23.96
0.01	0.0204	24.59

Specific Effect of the Ions.—Table II gives the average values of k for the kinetics of this reaction in the presence of several electrolytes.

TABLE II

$K_2S_2O_8$=0.01 N; H_3AsO_3=0.0102 N; $AgNO_3$=0.001 M

Electrolyte	Concn., M	k
—	—	23.96
K_2SO_4	0.25	7.49
K_2SO_4	0.125	8.49
$(NH_4)_2SO_4$	0.25	11.22
$(NH_4)_2SO_4$	0.125	11.71
$MgSO_4$	0.25	7.93
$MgSO_4$	0.125	9.88
KNO_3	0.50	10.72
KNO_3	0.25	11.44
$NaNO_3$	0.25	16.50
$NaNO_3$	0.125	18.96
NH_4NO_3	0.50	13.80
NH_4NO_3	0.25	18.21

There is no regular variation in k with the change in the ionic strength of the reaction mixture and hence no conclusion regarding the salt effect could be obtained. A comparison of the results shows that the inhibiting action is in the order $K^+ > Na^+ > NH_4^+$——a conclusion similar to that of uncatalyzed oxidation[2]. When the results for nitrates and sulfates are compared, it may be seen that either sulfate ion inhibits or the nitrate ion accelerates. However, the possibilty of both is also considered. In any reaction a sulfate ion is gradually produced, but no increase or decrease in the constants was observed as the reaction progressed. Hence the sulfate ion seems to have no effect or little effect in this reaction and the reaction rate is higher in presence of nitrates than

of sulfates, due to the acceleration by nitrate ions.

Reaction in Presence of CH_3COONa, CH_3COONH_4 and CH_3COOH.—Five concentrations of CH_3COONa were investigated and it was found that there exists an optimum concentration of sodium acetate for which the reaction is fastest. Fig. 2 shows the average constants for different concentrations of sodium acetate.

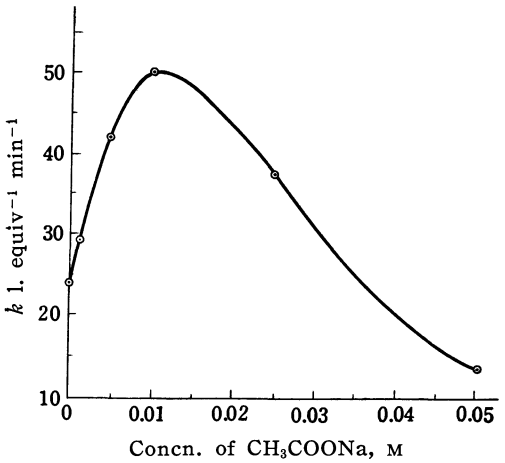

Fig. 2. Effect of CH_3COONa in the silver catalyzed oxidation of H_3AsO_3 by $K_2S_2O_8$.

The sodium ion has been found to inhibit and hence the acetate ion must catalyze the reaction. It appears that at lower concentrations of CH_3COONa, the catalyzing influence of acetate ions predominates over the inhibiting action of sodium ions; whereas the reverse is true at higher concentrations of sodium acetate. The accelerating action of acetate ions may further be seen in Table III where the results with acetic acid and ammonium acetate are shown.

TABLE III

$K_2S_2O_8$=0.01 N; H_3AsO_3=0.0102 N; $AgNO_3$=0.001 M

Electrolyte	Concn., M	k
CH_3COOH	0.40	40.27
CH_3COOH	0.10	39.70
CH_3COONH_4	0.50	4.94
CH_3COONH_4	0.25	6.16

Higher concentrations of sodium acetate could not be employed because a precipitate of possibly sodium arsenite formed. This, however, disappeared as the reaction progressed. Results with ammonium acetate are quite as expected.

Reaction in Presence of Sulfuric Acid.—Seven

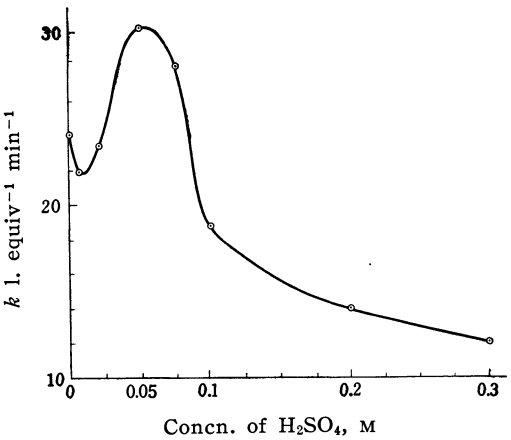

Fig. 3. Effect of H_2SO_4 in the silver catalyzed oxidation of H_3AsO_3 by $K_2S_2O_8$.

concentrations of sulfuric acid were employed and the results are graphically shown in Fig. 3.

There is a concentration of sulfuric acid for which the reaction is fastest. The rate decreases below or above that concentration. The rate constant is 30.26 l. $equi^{-1}$ min^{-1} at this concentration. It may appear from Fig. 3 that hydrogen ions inhibit and sulfate ions slightly accelerate, although the latter have been found to be without any effect. The actual mechanism is not clear. In fact, it is difficult to explain the behavior of sulfuric acid in persulfate oxidations. In the silver catalyzed oxidations of oxalic acid[11] and hydrogen peroxide[12], sulfuric acid retards the rate, whereas it accelerates the rate in the uncatalyzed oxidation of oxalic acid[8] and silver catalyzed oxidation of potassium oxalate[9].

Action of Nitrate, Aluminum and Manganous Ions.—When nitric acid is used, the reaction is very slow in the initial stages, but the rate increases quickly with time. The average constants as shown in Table IV, are found to increase till the end of the reaction.

It seems that there is some impurity in nitric acid which helds up the reaction in the beginning. Further on comparing these results with those in the presence of sulfuric acid, it is evident that the rate is higher in the presence of nitric acid. Hence nitrate ions accelerate the rate.

The results with aluminum nitrate and

aluminum sulfate are shown in Table V. The reaction is very fast in the presence of aluminum nitrate. The rate only slightly increases in the presence of aluminum sulfate.

From this it appears that nitrate ions greatly catalyze the reaction and sulfate does so only slightly, whereas aluminum is without any effect. It may, however, be mentioned that the rate constants gradually decreased in the case of aluminum nitrate and increased in the case of aluminum sulfate till the end of the reaction, and that the above table gives only the average constants. The increase or decrease was 15 to 20%.

Manganous sulfate was used because it has been found to act as a catalyst or an anticatalyst in many of the persulfate oxidations. The authors believe that Mn(II) has a specific inhibiting effect.

Energy and Entropy of Activation.—The energy of activation has been calculated from the results of experiments at three different temperatures. Table VI gives the constants at these temperatures.

The average energy of activation was 18941 cal. The frequency factor[13] and the entropy[14] calculated from this, are 1.55×10^6 l. equiv^{-1} sec^{-1} and -31.06 E.U., respectively. These values correspond to the overall reaction and they may be quite different for the rate determining step. Also these values may vary from sample to sample of arsenious acid, but their nature and order of magnitude do help us to arrive at a possible mechanism.

TABLE VI

$K_2S_2O_8=0.01$ N; $H_3AsO_3=0.0102$ N; $AgNO_3=0.001$ M

Temp. °C	k
24	23.96
29	30.54
39	50.00

The rate is the first order in persulfate and independent of the concentration of arsenious acid. No conclusion regarding the salt effect could be obtained. The authors propose the following mechanism for the silver catalyzed oxidation of arsenious acid by persulfate.

$$S_2O_8^{2-} \rightleftarrows 2SO_4^- \quad \text{rapid (1)}$$

$$2SO_4^- + Ag^+ \rightarrow 2SO_4^{2-} + Ag^{3+} \quad \text{slow (2)}$$

$$Ag^{3+} + 2H_2O \rightarrow Ag^+ + 2H^+ + 2OH \quad \text{fast (3)}$$

$$H_3AsO_3 + 2OH \rightarrow H_3AsO_3 + H_2O \quad \text{fast (4)}$$

The existence of free radicals[15] SO_4^- and OH, and higher valent silver, Ag^{3+} is now beyond doubt. Gupta and Ghosh[16] have discussed the possibilty of higher valent silver in a paper on the silver catalyzed oxidation of Mn(II) by persulfate. The rate determining step 2 is preceded by an equilibrium which has a very small equilibrium constant K, of the order of 10^{-8} or even less. Step 2 is really bimolecular or rather termolecular, but has a first order dependence on the concentration of the persulfate as shown below.

$$-dc/dt = k_2[Ag^+][SO_4^-]^2$$

but $K[S_2O_8^{2-}] = [SO_4^-]^2$ from reaction 1.

Hence $-dc/dt = k_2K[S_2O_8^{2-}][Ag^+]$

$= k_r[S_2O_8^{2-}]$ where $k_r = k_2K[Ag^+]$

The silver ion concentration remains constant and hence the slow step is the first order in persulfate. Experimentally determined k is equal to $k_r/[Ag^+]$. Hence

13) Calculated from the relation $k=A\times e^{-E/RT}$ where A is the frequency factor.

14) Calculated from the relation $k=(KT/h)\cdot e^{\Delta S/R}\cdot e^{-\Delta H/RT}$ where ΔS the entropy change and ΔH is not much different than E.

15) N. Uri, *Chem. Revs.*, **50**, 375 (1952).

16) Y. K. Gupta and S. Ghosh, *J. Inorg. & Nuclear Chem.*, **9**, 178 (1959).

$k=k_2K$ or $k_2=k/K=23.96/10^{-8}$ or 23.96×10^8 l. equiv^{-1} min^{-1}. Based on this value of k_2, the entropy change for the slow step is +5.47 E.U. Absolute entropy values have no meaning. Reactions are faster or slower according as their entropy changes are positive or negative as compared to standard values. A standard value for comparision for bimolecular reactions is about −12 E.U. (calculated for the frequency factor, 10^{11}). There is an entropy increase[17] if the reactants are oppositely charged ions and hence the slow step 2 is supported by a positive entropy change. The generally accepted mechanism is, $S_2O_8^{2-}+Ag^+=2SO_4^{2-}+Ag^{3+}$. If this were the rate determining step, entropy change for the overall reaction should directly support this. The overall entropy change is negative and hence the authors disapprove the slow step between $S_2O_8^{2-}$ and Ag^+. With a prior equilibrium, the entropy change for the slow step 2 is positive and hence step 2 must be preferably between oppositely charged ions, i. e. the reaction is between positively charged silver ion and a negative ion from persulfate, but not persulfate itself.

Gupta and Ghosh[1] have proposed two mechanisms for the uncatalyzed oxidation of arsenious acid by persulfate.

$$S_2O_8^{2-} \rightleftarrows SO_4+SO_4^{2-} \quad \text{slow}$$

or

$$S_2O_8^{2-}+2H_2O \rightleftarrows 2HSO_4^-+2OH \quad \text{slow}$$

Since the silver catalyzed oxidation of arsenious acid is very similar to the uncatalyzed oxidation, particularly in so far as the specific effect of the ions is concerned, it is reasonable to conclude that reaction mechanisms must also be similar. Hence it is believed that OH is preferably the radical responsible for oxidation in the uncatalyzed reaction.

This silver catalyzed oxidation is comparable to the fast oxidation of oxalate[9], and is much faster than the other type of catalyzed reactions wherein the specific rate constant lies between 0.2 and 0.3 at 25°C. Such oxidations are those of Cr(III)[18], VO(II)[19], Mn(II)[20], Ce(II)[21] and many other ions.

17) A. A. Frost and R. G. Pearson, "Kinetics and Mechanism", John Wiley & Sons, Inc., New York (1953), p. 132.

Summary

The kinetics of silver catalyzed oxidation of arsenious acid has been followed by estimating the acid with the permanganate. The results are reproducible only with the same stock solution of arsenious acid. This oxidation is much faster than other silver catalyzed oxidations, such as those of Cr^{3+}, VO^{2+}, Mn^{2+}, Ce^{2+}, etc. The oxidation is of the first order in persulfate and independent of the concentration of the acid. The entropy of activation has been calculated and a mechanism has been suggested. No conclusion regarding the salt effect could be obtained due to the specific effect of the ions. K^+, Na^+, NH_4^+ and Mg^{2+} inhibit in the order given. Nitrate ion accelerates the rate and sulfate ion seems to have no effect.

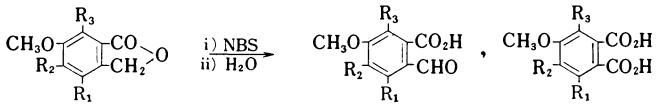
Zur Darstellung von Polymethoxy-o-phthalaldehydsäuren

Von Eturô MAEKAWA und Seiko NAN'YA



(Eingegangen am 18. Mai 1959)

Polymethoxyphthalaldehydsäuren sind von Bedeutung, weil sie durch Grignardreaktion mit Methylmagnesiumjodid 3-Methylphthalide geben, die als Ausgangsprodukte zur Darstellung von Seeigelfarbstoffen interessant sind[1]. Edwards, Perkin und Stoyle[2] oxydierten Mekonin mit Braunstein in verdünnter Schwefelsäure zur Opiansäure. Es ist aber schwierig, die Oxydation genau zu kontrollieren. Stevens und Robertson[3] versuchten, 5.6-Methylendioxyphthalid mit Bleidioxyd oder Chromsäure zu 4.5-Methylendioxyphthalaldehydsäure zu oxydieren, konnten jedoch keine günstigen Ergebnisse bekommen. Da der Phthalidring im alkalischen Medium geöffnet wird, kann man die Oxydation besser alkalisch durchführen. Obgleich in den stark alkalischen Lösungen die durch Oxydation zuerst entstandene Phthalaldehydsäure sogar die Neigung zeigt[4], durch Cannizarosche Reaktion zu Phthalsäure und Phthalalkoholsäure, nämlich dem Ausgangsprodukt, zu disproportionieren, scheinen die Phthalide in schwach alkalischen Medien leicht zu Phthalaldehydsäuren oxydiert zu werden. Blair, Brown und Newbold[5] erhielten z. B. aus Mekonin bzw. 5.6.7-Trimethoxyphthalid (XIII) und Dimethylamin in Alkohol bei Raumtemperatur 2-Hydroxymethyl-5.6-dimethoxy- bzw. 2-Hydroxymethyl-4.5.6-trimethoxybenzoesäuredimethylamid, das durch Chromsäureoxydation in Eisessig in der Kälte und durch anschließende Verseifung mit verdünnter Salzsäure Opiansäure bzw. 4.5.6-Trimethoxyphthalaldehydsäure (XIV) in etwa 40%-iger Ausbeute ergab. Andererseits wird aus 3-Bromphthalid durch Hydrolyse mit Wasser *o*-Phthalaldehydsäure leicht hergestellt[6], welcher man aus Phthalid durch direktes Bromieren bei erhöhter Temperatur[6] oder durch Versetzen mit *N*-Bromsuccinimid (abgekürzt NBS) nach Hirshberg, Lavie und Bergmann[7] in guten Ausbeuten erhalten kann. Zur Darstellung der Polymethoxyphthalaldehydsäuren scheint sich das direkte bromieren schlechter zu eignen als das Verfahren mit NBS, weil die Gefahr darin besteht, daß der, während der Reaktion der Phthalide mit Brom entwickelte Bromwasserstoff bei der Reaktionstemperatur, nämlich bei 130~150°C, die Methoxygruppe abspaltet. Brown und Newbold[8] erhielten durch die Methode mit NBS *m*-Opiansäure und 4.5-Methylendioxyphthalaldehydsäure aus den entsprechenden Phthaliden in guten Ausbeuten, erwähnten jedoch, daß diese Reaktion auf die Phthalide, die, wie Mekonin, am Benzolkern leicht substituierbare Stelle besitzen, im allgemeinen nicht anwendbar ist[5]. Nach der in der Literatur beschriebenen Vorschrift[7,8] mit etwa doppelter molekularer Menge an NBS konnte in der früheren Arbeit[1] aus 4.5.6-Trimethoxyphthalid (I) keine erwartete Aldehydsäure (II) erhalten werden, wobei die Reaktion aber nicht weiter probiert wurde. Unter Verwendung von äquimolekularer Menge an NBS wird jedoch 3.4.5.6-Tetramethoxyphthalaldehydsäure (V) aus 4.5.6.7-Tetramethoxyphthalid (IV) in 85%-iger Ausbeute hergestellt[1]. Um optimale Bedingungen zur Darstellung der Polymethoxyphthalaldehydsäuren aus den entsprechenden Phthaliden zu finden, wird deren Reaktion mit NBS weiter untersucht.

IV ergibt durch Behandeln mit doppelter molekularer Menge an NBS und durch anschließende Hydrolyse des Produktes mit Wasser in nah-quantitativer Ausbeute 3.4.5.6-Tetramethoxyphthalsäure(VI), deren Konstitution durch Elementaranalyse sowie durch die Bildung des Anhydrids beim Erhitzen und durch IR-Absorptionsspektrum* festgestellt wurde.

Aus I konnte durch Behandeln mit äquimolekularer Menge an NBS und durch anschließende Hydrolyse 3.4.5-Trimethoxyphthalaldehydsäure (II) in einer Ausbeute von 77% hergestellt werden. Unter Verwendung von doppelter molekularer Menge an NBS bildete sich nach der Hydrolyse als Hauptprodukt 3. 4. 5-Trimethoxyphthalsäure (III) und daneben auch eine kleine Menge II. Die auf diese Weise hergestellte Aldehydsäure II fällt aus Wasser zum größten Teil als Nadeln aus, die bei 129°C schmelzen, und aus Äthanol oder Chloroform zum größten Teil als Nadeln, die bei 135°C schmelzen. Beide Kristalle unterscheiden sich durch ihr Aussehen sowie durch die Geschwindigkeit der Auflösung in verschiedenen Lösungsmitteln, wobei der höherschmelzende Kristall sich im allgemeinen langsamer löst, ergeben jedoch identisches 2. 4-Dinitrophenylhydrazon. Phthalaldehydsäuren können bekanntlich nicht nur als Aldehydsäuren sondern unter Umständen auch als 3-Oxyphthalide reagieren. Opiansäure reagiert z. B. sowohl mit den Aldehydreagenzien als auch mit Alkoholen unter Bildung von 3-Alkoxymekoninen[9,10], die in die normalen Ester der Opiansäure übergehen können. Buu-Hoï stellte fest[11], daß *o*-Phthalaldehydsäure und ihre kernsubstituierten Derivate nach UV-Spektren in Wasser fast ausschließlich als echte Aldehydsäure, in Chloroform zum größten Teil als 3-Oxyphthalid und in Alkoholen als ein Gleichgewichtsgemisch aus beiden Isomeren existieren. Die IR-Spektren der beiden Kristallarten von II in KBr (Abb. 1 u. 2) unterscheiden sich durch Absorptionen bei 1700~1800 cm^{-1}, sind beide jedoch sehr ähnlich dem der *o*-Phthalaldehydsäure in KBr[12], während das IR-Spektrum der Chloroformlösung von II (Abb. 3) eine dem Phthalidring typische Bande bei 1768 cm^{-1} zeight und keine Bande, die der echten Phthalaldehydsäure zuzuordnen ist. Daher wird angenommen, daß der Unterschied zwischen beiden Kristallarten von der Säure II, die im kristallinischen Zustand als echte Phthalaldehydsäure existiert, auf den der Kristallstruktur zurückzuführen ist, obgleich, wie unten erwähnt, der niedrigerschmelzende Kristall nicht fähig ist, durch Grignardreaktion mit Methylmagnesiumjodid 3-Methyl-4. 5. 6-trimethoxyphthalid zu ergeben.

Die oben beschriebenen Polymethoxyphthalsäuren, nämlich III und VI, reagieren mit 2. 4-Dinitrophenylhydrazin viel schneller als Phthalsäure selbst unter Bildung der 2. 4-Dinitrophenylhydrazone ihrer Anhydride.

Gegen die Meinung von Blair u. a.[5] ergibt Mekonin (VII) Opiansäure in relativ guter Ausbeute unter Verwendung von äquimolekularer Menge an NBS und 3. 4-Dimethoxyphthalsäure (IX) mit doppelter Menge an NBS. Zur Darstellung von *m*-Opiansäure (XI) aus X ist auch unsere Vorschrift mit äquimolekularer Menge an NBS besser geeignet als die von Brown u. a.[8] mit überschüssigem NBS, nach welcher sich beim Nachprüfen in unserem Laboratorium *m*-Hemipinsäure in erheblicher Menge ergab. Auch der aus *m*-Mekonin nach McRae u. a.[13] hergestellte 5. 6. 7-Trimethoxyphthalid (XIII) gibt 4. 5. 6-Trimethoxyphthalaldehydsäure (XIV) bzw. 3. 4. 5-Trimethoxyphthalsäure (III) je nach der Menge an verwendetem NBS. 4. 5. 6-Trimethoxy-7-chlormethylphthalid, der aus Gallussäuretrimethyläther nach King und King[14] hergestellt wurde, ergibt durch Reduktion mit Zinkstaub und Essigsäure 4. 5. 6-Trimethoxy-7-methylphthalid (XV), der durch Versetzen mit äquimolekularer Menge an NBS 3. 4. 5-Trimethoxy-6-methylphthalaldehydsäure (XVI) ergab. XVI kristallisierte wieder in zwei verschiedenen

a) In Klammern Ausbeute; b) G. Bargellini u. a., *Atti Acad. Lincei*, **21 II**, 146 (1912), Fp. 174°C; c) Daten aus Lit. 1 zitiert; d) Lösungsmittel Benzol u. CCl_4 (1 : 2 in Volumen); e) Lit. 2, Fp. 150°C; f) Lit. 2, Fp. 187°C; g) Lit. 8, Fp. 187~188°C; h) R. G. Fargher u. a., *J. Chem. Soc.*, **119**, 1724 (1921), Fp. 202°C; i) Lit. 8, Fp. 136°C, Mischprobe mit der höher schmelzenden II zeigte eine Depression von ca. 10°C.

Derivaten, besonders bie Opiansäure, nimmt die Ausbeute ab, offenbar weil die Löslichkeit von Polymethoxyphthalaldehydsäuren in Äther viel geringer ist. Es gelang uns also 3-Methyl-4.5.6-trimethoxyphthalid aus der ätherischen Suspension der höherschmelzenden Aldehydsäure II herzustellen. Die niedrigerschmelzende II war unter allen Bedingungen—soweit versucht—nicht fähig, mit Methylmagnesiumjodid zu reagieren. Der Unterschied der Reaktivität beider Kristallarten, der auch auf dem der Kristallstruktur beruhen mag, ist jedoch noch nicht völlig aufgeklärt.

Organische Bromide können auch aus den entsprechenden um ein Kohlenstoffatom höheren Carbonsäuresilbersalzen durch Behandeln mit Brom hergestellt werden[17,18]. Um andere Möglichkeiten zur Darstellung der 3-Bromphthalide und dadurch die der Darstellung der Phthalaldehydsäuren zu finden, wurde nun die Reaktion des Silbersalzes der aus 3-Trichlormethyl-4.5.6-trimethoxyphthalid hergestellten 4.5.6-Trimethoxyphthalid-3-carbonsäure (XVII)[19] mit Brom probiert. Obgleich XVII in einer äquimolekularen Kalilauge beim Versetzen mit Silbernitrat kein Silbersalz ausfallen läßt, ergibt sie jedoch in einer wässerigen Lösung, die die zweifach-molekulare Menge Kaliumhydroxyd enthält, beim Zusatz des Silbernitrats Disilbersalz der 2-(Hydroxy-carboxy-methyl)-3.4.5-trimethoxybenzoesäure. Da Silbersalze aromatischer Carbonsäuren nach unseren Versuchen im allgemeinen langsamer als Salze aliphatischer Säuren mit Brom unter Decarboxylieren reagieren und da Salze der α-Hydroxycarbonsäuren Aldehyde geben[20], wird das Disilbersalz mit einer äquimolekularen Menge Brom in Tetrachlorkohlenstoff behandelt, wobei 4.5.6-Trimethoxy-7-bromphthalid-3-carbonsäure (XVIII) statt der erwarteten Aldehydsäure II erhalten wird. XVIII enthält ein Molekül Kristallwasser und gibt das Wasser beim Schmelzen ab. Eine andere Konstitutionsmöglichkeit, nämlich 2-(Hydroxy-carboxy-methyl)-3.4.5-trimethoxy-6-brombenzoesäure, wird aber nach dem IR-Absorptionsspektrum, wegen des undeutlichen Schmelzpunktes sowie auf Grund der Tatsache, daß die wasserfreie Säure XVIII viel höher schmilzt als die wasserhaltige, verneint. Die kristallwasserfreie Säure XVIII geht beim Erhitzen in 4.5.6-Trimethoxy-7-bromphthalid über. Die Totalausbeute beträgt auf XVII bezogen ca. 50%. Derselbe Bromphthalid wird auch aus 4.5.6-Trimethoxy-7-aminophthalid, der aus XVII über 4.5.6-Trimethoxyphthalid und 4.5.6-Trimethoxy-7-nitrophthalid hergestellt wurde[1], nach Sandmeyer hergestellt, wobei die Ausbeute auf XVII bezogen höchstens 5% beträgt.

Beschreibung der Versuche

1. 4.5.6-Trimethoxyphthalid (I)[14].—Ein Gemisch aus 10 g Gallussäuretrimethyläther, 33 ccm 30%-igem Formalin und 9 ccm konz. Salzsäure wurde 20 Min. am Rückfluß erhitzt, 5 g (47%) farblose Nadeln, Fp. 136°C** (aus Äthanol) (Lit.[14] 135~136°C).

2. 4.5.6.7-Tetramethoxyphthalid (IV)[1]. — Eine Lösung von 10 g 3.4.5.6-Tetramethoxyphthalalkohol in 60 ccm Eisessig wurde mit einer Lösung von 8 g Natriumbichromat in 60 ccm Eisessig bei 60°C tropfenweise oxydiert, 3,5 g

** Schmelzpunkte wurden mikroskopisch bestimmt, aber nicht korrigiert.

(36%) leicht gelbe Nadeln, Fp. 52°C (aus Äther) (Lit.[1] 52°C).

3. Mekonin (VII)[2].—Ein Gemisch aus 8 g 2.3-Dimethoxybenzoesäure, 35 ccm konz. Salzsäure und 30 ccm 30%-igem Formalin wurde 15 Min. am Rückfluß erhitzt, 2 g (24%) farblose Nadeln, Fp. 101～103°C (aus Wasser) (Lit.[2] 102°C).

4. *m*-Mekonin (X)[13]. — 50 g Veratrumsäure wurden in 250 ccm Eisessig mit 80 ccm 40%-igem Formalin und 200 g konz. Salzsäure 10 Std. auf 90～95°C und noch 3 Std. auf 100°C erhitzt. 25 g (47%) farblose Nadeln, Fp. 155°C (aus Wasser) (Lit.[13] 155°C).

5. 5.6.7-Trimethoxyphthalid (XIII)[13]. — 20 g X wurden durch Versetzen mit 10 ccm konz. Schwefelsäure und 140 ccm konz. Salpetersäure zu 8 g 7-Nitro-*m*-mekonin nitriert, dessen Reduktion in Essigester mit Raney-Nickel 6,5 g 5.6-Dimethoxy-7-aminophthalid [Fp. 181～182°C (aus Äthanol)] ergibt. 5,9 g des Hydrochlorids dieses Amins geben durch Diazotieren mit Natriumnitrit und durch anschließendes Versetzen mit Kaliumjodid 3,5 g 5.6-Dimethoxy-7-jodphthalid [Fp. 169°C (aus Essigsäure)], dessen 3,2 g bei 12-stündigem Kochen in einer methanolischen Lösung von 0,8 g Kalium in Gegenwart von wenig Kupferbronze (Merck) in 2,0 g XIII übergehen, Fp. 136～136,5°C (aus Wasser) (Lit.[13] 136,6～137°C). Mischprobe mit I zeigte eine Depression von ca. 10°C.

6. 4.5.6-Trimethoxy-7-chlormethylphthalid[14].—Ein Gemisch aus 10 g Gallussäuretrimethyläther, 33 ccm 30%-igem Formalin und 40 ccm konz. Salzsäure 20 Min. am Rückfluß erhitzt, 6,5 g (51%) farblose Nadeln, Fp. 85°C (aus Äthanol) (Lit.[14] 85°C).

7. 4.5.6-Trimethoxy-7-methylphthalid (XV).—5 g der vorstehenden Chlormethylverbindung wurden in 70 ccm Eisessig mit 13,5 g Zinkstaub 30 Min. am Rückfluß gekocht, das Filtrat nach dem Erkalten im Vakuum eingeengt und dann mit Wasser versetzt. Der ausgeschiedene Niederschlag wurde aus verdünnter Essigsäure umkristallisiert, 4,4～4,5 g (ca. 90%) farblose Nadeln, Fp. 80～82°C.

*Anal.**** Gef.: C 58,07; H 5,88. Ber. für $C_{12}H_{14}O_5 \cdot 1/2CH_3CO_2H$ (268,2): C 58,20; H 6,01.

8. 3.4.5-Trimethoxyphthalaldehydsäure (II). — 4 g I wurden in 350 ccm Tetrachlorkohlenstoff mit 3,2 g NBS in Gegenwart von einer Messerspitze Dibenzoylperoxyd (abgekürzt BPO) unter Bestrahlung mit einer 500W-Wolframlampe 1 Std. am Rückfluß gekocht. Das gebildete Succinimid wurde abgesaugt und das Filtrat eingeengt. Der Rückstand wurde mit ca. 150 ccm Wasser unter mechanischem Rühren 2 Std. auf dem siedenden Wasserbad erwärmt, das Reaktionsgemisch abfiltriert und die Lösung langsam abdunsten gelassen. Dabei fielen gelbe Nadeln aus, Ausbeute 3,4 g (77%), Fp. 128,5～129°C (aus Wasser) und Fp. 134～135°C (aus Äthanol oder Chloroform).

Anal. Gef.: C 55,13; H 5,11. Ber. für $C_{11}H_{12}O_6$ (240,2): C 55,00; H 5,04.

2.4-Dinitrophenylhydrazon.—Orange Nadeln, Fp. 235～236°C (aus 95%-igem Äthanol).

Anal. Gef.: C 48,73; H 4,13; N 13,28. Ber. für $C_{17}H_{16}N_4O_9$ (420,4): C 48,58; H 3,84; N 13,33.

9. 3.4.5-Trimethoxyphthalsäure (III).—11,2 g I wurden in 1000 ccm Tetrachlorkohlenstoff mit 18 g NBS und wenig BPO 1 Std. unter Bestrahlung am Rückfluß gekocht, das gebildete Succinimid abgesaugt und das Filtrat eingeengt. Der Rückstand wurde mit 150 ccm Wasser 2 Std. auf dem siedenden Wasserbad erwärmt und das Gemisch noch heiß abfiltriert. Es fielen zuerst 1,3 g (16%) II beim Abkühlen der Lösung und dann 6,6 g (51%) III beim Einengen der Mutterlauge in Prismen aus, Fp. 173,5～174,5°C (aus Wasser) (Lit.[10] 174°C), IR-Absorption in KBr: 1680～1720 cm^{-1} (breite Bande).

Anhydrid.—Nadeln, Fp. 143～144°C (aus Benzol) (Lit.[10] 143°C), IR-Absorptionen in KBr: 1724 u. 1831 cm^{-1}.

2.4-Dinitrophenylhydrazon des Anhydrids.—Gelbe Nadeln, Fp. 254,5～256°C (aus Äthanol).

Anal. Gef.: C 49,00; H 3,73; N 13,79. Ber. für $C_{17}H_{14}N_4O_9$ (418,3): C 48,81; H 3,37; N 13,39.

10. 3.4.5.6-Tetramethoxyphthalsäure (VI).—1,5 g IV wurden in 30 ccm Tetrachlorkohlenstoff mit 2,1 g NBS und wenig BPO unter Bestrahlung 1 Std. am Rückfluß gekocht und das Gemisch wie vorstehend aufgearbeitet, wobei 1,3 g (86%) VI in farblosen Nadeln erhalten wurden. Fp. 191,7～192,3°C (aus Wasser), IR-Absorption in KBr: 1690～1710 cm^{-1} (breite Bande).

Anal. Gef.: C 50,43; H 5,00. Ber. für $C_{12}H_{14}O_8$ (286,2): C 50,35; H 4,93.

Anhydrid bildete sich beim Schmelzen von VI quantitativ, Fp. 137,5～138°C (aus Benzol).

Anal. Gef.: C 53,50; H 4,75. Ber. für $C_{12}H_{12}O_7$ (268,2): C 53,73; H, 4,51.

2.4-Dinitrophenylhydrazon des Anhydrids.—Gelbe Nadeln, Fp. 220,5～221°C (aus Äthanol).

Anal. Gef.: C 48,58; H 3,86; N 12,41. Ber. für $C_{18}H_{16}N_4O_{10}$ (448,4): C 48,22; H 3,60; N 12,50.

11. 3.4.5-Trimethoxy-6-methylphthalaldehydsäure (XVI).—Eine Lösung von 2 g XV in 150 ccm Tetrachlorkohlenstoff wurde mit 2 g NBS und wenig BPO unter Bestrahlung 2 Std. am Rückfluß erhitzt und das Gemisch wie vorstehend aufgearbeitet, 0,98 g (50%) farblose Nadeln, Fp. 114°C (aus Wasser), IR-Absorptionen in KBr: 1690 u. 1703 cm^{-1}, und Fp. 122°C (aus Chloroform), IR-Absorptionen in KBr: 1689 u. 1703 cm^{-1}.

Anal. Gef.: C 56,44; H 4,88. Ber. für $C_{12}H_{14}O_6$ (254,2): C 56,69; H 4,55.

2.4-Dinitrophenylhydrazon. — Rote Nadeln, Fp. 214°C (aus 95%-igem Äthanol und Essigester).

Anal. Gef.: C 50,02; H 3,86; N 12,84. Ber. für $C_{18}H_{18}N_4O_9$ (434,4): C 49,72; H 4,12; N 12,89.

12. 3-Methyl-4.5.6-trimethoxyphthalid.—Einem Grignardreagens aus 0,50 g Magnesiumspänen und 3,0 g Methyljodid wurde eine Suspension von 1,5 g II vom Fp. 135°C in 500 ccm absolutem Äther unter Eiskühlung zugetropft. Es wurde 1 Std. unter Eiskühlung und noch 1 Std. am Rückfluß umgerührt. Das Reaktionsgemisch wurde auf Eis gegossen und mit 2 N Schwefelsäure angesäuert. Die wässerige Schicht wurde mehrmals mit Äther ausgezogen, die ätherische Lösung mit verdünnter Natriumhydrogencarbonatlösung

*** Für Mikroanalysen der Verbindungen sind wir der Zentralen Mikroanalysenstelle der Univ. Kyôto sehr dankbar.

gewaschen, mit Natriumsulfat getrocknet und eingeengt. Es blieb ein gelbes Fett zurück, das aus Wasser kristallisiert wurde, 0,75 g (49%) farblose Nadeln, Fp. 52°C, IR-Absorption in KBr: 1765 cm^{-1}.

Anal. Gef.: C 60,56; H 5,98. Ber. für $C_{12}H_{14}O_5$ (238,2): C 60,50; H 5,92.

13. 2.4-Dinitrophenylhydrazon des Phthalsäureanhydrids. — Gelbe Nadeln, Fp. 280~282°C (aus 95%-igem Äthanol und Essigester).

Anal. Gef.: C 51,09; H 2,62; N 17,65. Ber. für $C_{14}H_8N_4O_6$ (328,2): C 51,23; H 2,46; N 17,07.

14. 4.5.6-Trimethoxyphthalid-3-carbonsäure (XVIII)[20]. — 5 g 3-Trichlormethyl-4.5.6-trimethoxyphthalid wurden in einer Natronlauge aus 5 g Natriumhydroxyd und 20 ccm Wasser 45 Min. erhitzt und das abgekühlte Gemisch mit Salzsäure angesäuert, 3,5 g (90%) farblose Nadeln, Fp. 147~148°C (aus Wasser) (Lit.[20] 147~148°C).

15. Disilbersalz der 2-(Hydroxy-carboxy-methyl)-3.4.5-trimethoxybenzoesäure. — Eine Lösung von 2,68 g XVII in einer Kalilauge aus 1,12 g Kaliumhydroxyd und 100 ccm Wasser wurde mit 3,4 g Silbernitrat in 100 ccm Wasser versetzt. Der Niederschlag wurde mit Methanol gewaschen und im Vakuumexsikkator getrocknet, 3,04 g (76%).

Anal. Gef.: Ag 42,75. Ber. für $C_{12}H_{12}Ag_2O_8$ (499,8): Ag 43,18.

16. 4.5.6-Trimethoxy-7-bromphthalid-3-carbonsäure (XVIII).—Eine Suspension von 3,0g vorstehenden Silbersalzes in 100 ccm Tetrachlorkohlenstoff wurde bei ihrem Siedepunkt mit 1,2 g Brom in 20 ccm Tetrachlorkohlenstoff tropfenweise versetzt, das Gemisch mit 150 ccm 0,1 N Brom-Wasserstoffsäure 10 Min. umgerührt und das Silberbromid abfiltriert (2,70 g). Beim Einengen des Filtrats fielen farblose Nadeln aus, 3,50 g (90%), Fp. 75~90°C (aus Wasser). IR-Absorptionen in KBr: 1721 cm^{-1} (COOH) u. 1761 cm^{-1} (Phthalid).

Anal. Gef.: C 39,81; H 3,84; Br 22,04. Ber. für $C_{12}H_{11}BrO_7 \cdot H_2O$ (365,1): C 39,49; H 3,59; Br 21,89.

Beim Schmelzen bildete sich die wasserfreie XVIII, Fp. 137~138°C.

Anal. Gef.: C 41,40; H 3,32; Br 23,27. Ber. für $C_{12}H_{11}BrO_7$ (347,1): C 41,55; H 3,19; Br 23,02.

17. 4.5.6-Trimethoxy-7-bromphthalid (XIX).— 2,92 g der wasserfreien XVIII wurden auf 185°C erhitzt, 1,91 g (76%) (nach einer Umkristallisation aus Methanol), Fp. 103~104°C.

18. XIX aus 4.5.6-Trimethoxy-7-aminophthalid. —Eine Lösung von 4 g 4.5.6-Trimethoxy-7-aminophthalid[1] in 3 ccm konz. Schwefelsäure und 20 ccm Wasser wurde mit 2 g festem Natriumnitrit diazotiert, die überschüssige salpetrige Säure mit Harnstoff zersetzt, das Gemisch mit 2,4 g Kupfer(I)-bromid mit überschüssiger Bromwasserstoffsäure versetzt und dann erhitzt. Das dabei getrennte Öl wurde nach dem Erkalten aus Methanol kristallisiert, 1,5 g (29%), farblose Nadeln, Fp. 103~104°C. Mischschmelzpunkt mit dem obenstehenden Präparat 103~104°C.

Zusammenfassung

Polymethoxyphthalaldehydsäuren wurden aus den entsprechenden Phthaliden durch Bromieren mit äquimolekularer Menge an NBS und durch anschließende Hydrolyse der Produkte in guten Ausbeuten hergestellt, während die Verwendung von überschüssigem Reagens Phthalsäuren ergab. 3.4.5-Trimethoxyphthalaldehydsäure existiert in Chloroformlösung als 3-Hydroxy-4.5.6-trimethoxyphthalid und fällt aus den Lösungen als echte Phthalaldehydsäure in zwei verschiedenen Kristallarten aus, von denen nur die höher schmelzende durch Grignardreaktion mit Methylmagnesiumjodid 3-Methyl-4.5.6-trimethoxyphthalid ergeben konnte. Das aus 4.5.6-Trimethoxyphthalid-3-carbonsäure hergestellte Disilbersalz ergab durch Versetzen mit Brom statt der erwarteten Phthalaldehydsäure das 7-Bromderivat.

Herrn Prof. Dr. F. Weygand, München sagen wir an diesser Stelle unseren aufrichtigsten Dank für seine Anleitung und Anregung zu vorstehender Arbeit. Dem Unterrichtsministerium Japan sind wir für seine Unterstützung dieser Arbeit durch eine Beihilfe für individuelle Forschung 1958 zum Dank verpflichtet.

Studies on the Cobalt(III) Complexes of Monothiophosphate Ion

By Jinsai HIDAKA, Junnosuke FUJITA, Yoichi SHIMURA and Ryutaro TSUCHIDA

(Received June 11, 1959)

Recently, Yasuda and Lambert[1] reported that the monothiophosphate ion shows an interesting color reaction with the cobalt-(II) ion in aqueous solution. Except for this report there has been no description heretofore about the coordinative nature of the monothiophosphate ion. In the present paper, the syntheses of di-monothiophosphato - bis - ethylenediamine and monothiophosphato - bis - ethylenediamine cobalt(III) complexes will be reported. Furthermore, their visible and ultraviolet and also the infrared absorption spectra will be discussed mainly in comparison with those of the known thiosulfato complexes of cobalt(III).

Experimental

Preparation.—*1) Dark green complex*: $Na_3[Co\,en_2(SPO_3)_2]\cdot 8H_2O$. — This complex was prepared as follows: 3.2 g. anhydrous sodium monothiophosphate[1,2], was completely dissolved in 80 ml. of water, and the solution was added to the aqueous solution (20 ml.) of 2.5 g. *trans*-$[Co\,en_2Cl_2]Cl$. The color of the mixture changed from dark red to dark greenish red. To complete the reaction the mixture was preserved for one hour. The resulting solution was filtered quickly, and ethanol was added carefully to the clear filtrate on cooling. Dark greenish crystalline powder was obtained. The crude product was recrystallized from a small quantity of cold water by the addition of ethanol. The fine crystals obtained were dried in a desiccator over sulfuric acid.

Anal. Found: Co, 9.58; P, 9.72; N, 8.97; C, 7.67; H, 5.05; H_2O, 23.66. Calcd. for $Na_3[Co\,en_2(SPO_3)_2]\cdot 8H_2O = C_4H_{16}O_6S_2N_4P_2Na_3Co\cdot 8H_2O$: Co, 9.59; P, 10.10; N, 9.12; C, 7.82; H, 5.25; H_2O, 23.46%.

2) Dark red complex: $[Co\,en_2(SPO_3)]\cdot 2H_2O$.— To the aqueous solution (30 ml.) of 5 g. *trans*-$[Co\,en_2Cl_2]Cl$, was added on cooling an aqueous solution (70 ml.) of 3.2 g. of anhydrous sodium monothiophosphate. The resulting solution was dark red. A large amount of ethanol was added carefully to the solution. The desired complex was obtained as dark reddish crystalline powder.

Anal. Found: Co, 17.8; P, 9.35; N, 16.93; C, 14.37; H, 6.51; H_2O, 11.82. Calcd. for $[Co\,en_2(SPO_3)]\cdot 2H_2O = C_4H_{16}O_3SN_4PCo\cdot 2H_2O$: Co, 18.07; P, 9.5; N, 17.18; C, 14.73; H, 6.19; H_2O, 11.05%.

Measurements. — The visible and ultraviolet absorption measurements were made by a Beckman DU spectrophotometer in cold aqueous solutions to prevent the aquation of the complexes. The concentration of the solutions varied from $1/2\times10^{-2}$ to $1/8\times10^{-3}$ F. The infrared spectra were obtained by a Parkin-Elmer Model 21 (double beam) and a Hilger H-800 infrared spectrophotometer using sodium chloride prisms. The potassium bromide disk method and nujol mull technique were employed.

Materials.—Thiosulfato-pentammine cobalt(III) chloride, $[Co(NH_3)_5(SSO_3)]Cl$[3], and sodium dithiosulfato - bis - ethylenediamine cobaltate(III), $Na[Co\,en_2(SSO_3)_2]$[4], were obtained as dark red and green crystals, respectively, in the usual way as done by Rây and his coworker. The visible and ultraviolet absorption curves of these compounds are shown in Figs. 1 and 2. These absorption curves were in good agreement with those obtained by Kiss et al.[5,6].

Results and Discussion

Dark green complex: $Na_3[Co\,en_2(SPO_3)_2]\cdot 8H_2O$.—The visible and ultraviolet absorption curve of this compound is shown in Fig. 1, in which the spectrum of the corresponding thiosulfato-complex, $Na[Co\,en_2(SSO_3)_2]$, is also plotted for comparison. These two absorption curves are similar to each other on the whole. The frequencies of the absorption maxima for each complex are listed in Table I.

The first absorption bands of these complexes are shifted towards longer wavelengths than those of complexes of $[Co^{III}N_4O_2]$ type[7,8] and distinctly split into two components. Moreover, the type of these splittings differ from those of $[Co^{III}N_4O_2]$ and $[Co^{III}N_5O]$ type complexes.

TABLE I. THE FIRST, SECOND AND THE CHARGE-TRANSFER BANDS OF MONOTHIOPHOSPHATO AND THIOSULFATO Co(III) COMPLEXES
(in frequency unit 10^{13}/sec.)

Complex salt	First band ν_{max} (log ε)	Second band ν_{max} (log ε)	Charge-transfer band ν_{max} (log ε)
$[Co(NH_3)_5(SSO_3)]Cl$	58.8 (1.82)	ca. 82 (2.3)	103.4 (4.9) 126 (3.6)
$Na[Co\,en_2(SSO_3)_2]$	54.9 (1.93)		89.6 (4.28)
$Na_3[Co\,en_2(SPO_3)_2]$	53.9 (2.10)		87.0 (4.36) 108 (3.83)
$[Co\,en_2(SPO_3)]$	56.0 (2.31)	ca. 82 (2.6)	107.3 (4.16)

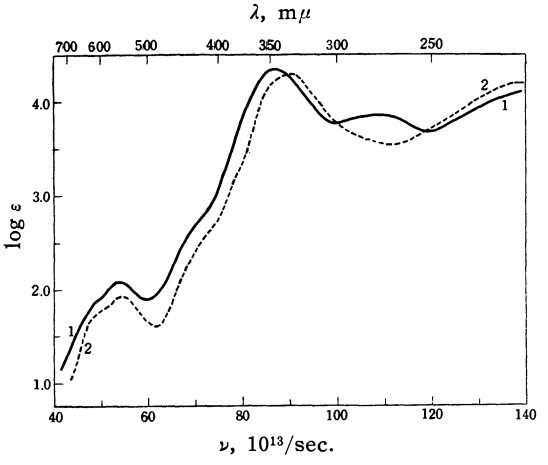

Fig. 1. Absorption spectra of:
1, $Na_3[Co\,en_2(SPO_3)_2]\cdot 8H_2O$;
2, $Na[Co\,en_2(SSO_3)_2]$.

These facts indicate that the cobalt(III) ion in these complex ions coordinates monothiophosphate or thiosulfate ions by their sulfur atoms. This conclusion is also supported by the fact that these complexes show intense absorption bands in the near ultraviolet, which are probably originated from charge transfer between the central cobalt(III) ion and the coordinated monothiophosphate or thiosulfate ion. As to the charge transfer band of di-thiosulfato-bis-ethylenediamine cobalt(III) ion, it is located at a longer wavelength than that of thiosulfato-pentammine cobalt(III) ion. Judging from the position of the thiosulfate ion in the spectrochemical series, it is evident that $[Co\,en_2(SSO_3)_2]^-$ has *trans* structure with regard to two thiosulfate ions in coordination[8]. It may be concluded, therefore, that the structure of $[Co\,en_2(SPO_3)_2]^{3-}$ is also *trans*, since its absorption curve is quite similar to the corresponding thiosulfato-complex.

Structure of the Dark Red Complex.—From the result of the chemical analysis, there was two possibilities of the structure of the "dark red complex". The one is $[Co\,en_2(OH_2)(SPO_3)]\cdot H_2O$ in which the monothiophosphate ion is coordinated as a monodentate ligand, and the other, $[Co\,en_2(SPO_3)]\cdot 2H_2O$ in which the monothiophosphate ion is coordinated as a chelate ligand.

Being heated for dehydration, sodium di-monothiophosphato-bis-ethylenediamine cobaltate(III) is rather unstable and changes into black sulfide of cobalt at about 110°C with evolution of hydrogen sulfide. On the contrary, the dark red complex is more stable against heating. Even after the two molecules of water were expelled at 110°C, the dark red color of the complex was well preserved and no indication of the decomposition of the complex was observed. These facts suggest that the structure of the dark red complex is $[Co\,en_2(SPO_3)]\cdot 2H_2O$ and not $[Co\,en_2(OH_2)(SPO_3)]\cdot H_2O$.

The visible and ultraviolet absorption curve of the dark red complex is shown in Fig. 2, in which the spectrum of thiosulfato-pentammine cobalt(III) ion is also plotted for comparison.

The trend that the two absorption curves resemble each other on the whole, is similar to the case of Fig. 1. There are, however, a few important differences between the two curves in Fig. 2. In the

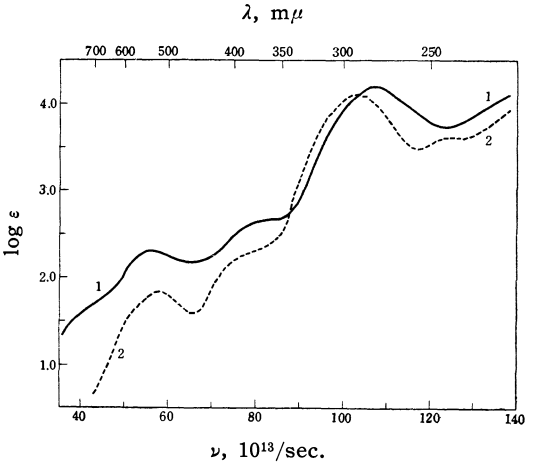

Fig. 2. Absorption spectra of:
1, $[Co\,en_2(SPO_3)]\cdot 2H_2O$;
2, $[Co(NH_3)_5(SSO_3)]Cl$.

first place, the charge transfer band of the dark red complex ($\nu=107.3\times10^{13}$/sec.) is in a shorter wavelength than that of the thiosulfato-pentammine complex. The second difference is seen in the first and the second absorption bands. In this region, the absorption of the dark red complex is stronger in intensity than that of the thiosulfato-pentammine complex. These phenomena may be considered as a proof for the structural difference between the two complexes, especially the difference in the type of coordination of the sulfur-containing ligands.

Infrared Absorption Spectra. — Fig. 3 indicates the infrared spectra of the thiosulfato cobalt(III) complexes and of sodium thiosulfate pentahydrate in 1250~850 cm^{-1} region. Except for the absorption bands which are due to the vibration of ethylenediamine, two absorption bands appear in this region, which are assigned as the S–O vibration[9].

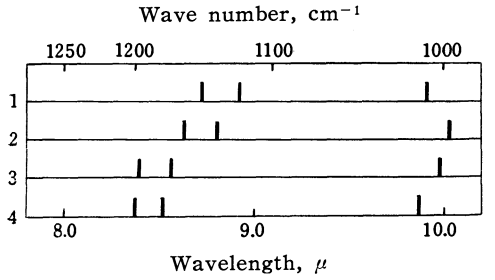

Fig. 3. Infrared absorption bands of:
1, $Na_2S_2O_3\cdot5H_2O$ (KBr disk);
2, $[Co(NH_3)_5(SSO_3)]Cl$ (nujol mull);
3, $Na[Co\,en_2(SSO_3)_2]$ (nujol mull);
4, $K_4[Co(CN)_5(SSO_3)]$ (KBr disk).

The free thiosulfate ion has the symmetry of C_{3v}, and the symmetry is not altered by coordination, because the central cobalt(III) ion is attached to the sulfur atom of the monodentate thiosulfate ion in these complexes. As is seen in Fig. 3, although the band at 1000 cm^{-1} is hardly shifted by coordination, the bands at 1120 cm^{-1} are shifted to higher frequencies by coordination. A similar trend is seen in the cobalt(III) complex which contains monothiophosphate ions as monodentate ligand (Fig. 4).

These facts will be explained from the assumption that the free ligand (SPO_3^{3-}) and the coordinated ligand have the same symmetry C_{3v}. The two sharp bands of the free ligand are due to the PO_3 group

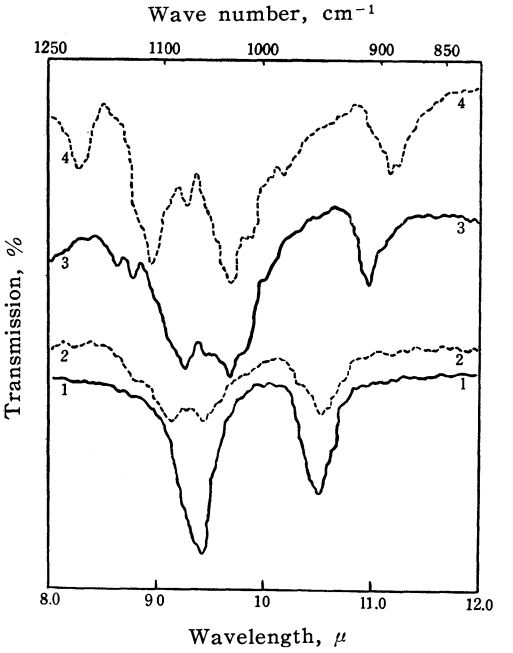

Fig. 4. Infrared absorption spectra of:
1, Na_3SPO_3 (KBr disk);
2, $Na_3[Co\,en_2(SPO_3)_2]\cdot8H_2O$ (KBr disk);

4, $[Co\,en_2(SPO_3)]$ (nujol mull).

and the vibrations are assumed to be symmetric PO_3 stretching vibration (950 cm^{-1}) and degenerate PO_3 asymmetric vibration (1064 cm^{-1}), respectively[10]. In the di-monothiophosphato-bis-ethylenediammine cobalt(III) ion, the band at 950 cm^{-1} is hardly shifted, but the band at 1064 cm^{-1} is shifted to a higher frequency and splits into two peaks. This trend is in good accordance with that of the thiosulfato complexes mentioned above. These relationships led us to the conclusion that the cobalt(III) ion in this complex coordinates the monothiophosphate ion by the sulfur atom, in good agreement with the conclusion from the visible and ultraviolet spectra. On the contrary, in the spectra of the dark red complex, the symmetric PO_3 stretching vibration of the monothiophosphate ion is shifted to a lower frequency by coordination. If it is assumed that the dark red complex has the structure containing the monodentate monothiophosphate ligand, namely, $[Co\,en_2(OH_2)(SPO_3)]\cdot H_2O$, the symmetry of the coordinated SPO_3^{3-} ions is C_{3v}, but if the chelate structure in $[Co\,en_2(SPO_3)]\cdot2H_2O$, is assumed, the symmetry of the ligand is lowered to C_s. It is presumed, therefore,

10) M. Tsuboi, ibid., **79**, 1351 (1957).

that the shift of the band at 950 cm^{-1} is caused by the chelate coordination. Furthermore, in the spectra of the dehydrated complex (Fig. 4), no new band by degradation symmetry appears, though the bands are more or less shifted. These shifts probably result from the vanishing of the hydrogen-bond between the water molecules and the SPO_3^{3-} group. Similar shifts were reported for some inorganic phosphorus compounds[11].

Summary

Two new complexes, sodium di-monothiophosphato-bis-ethylenediamine cobaltate(III) octa-hydrate and monothiophosphato-bis-ethylenediamine-cobalt(III) dihydrate, have been synthesized by the reaction of *trans*-dichloro-bis-ethylenediamine cobalt(III) chloride with anhydrous sodium monothiophosphate in cold aqueous solution. The infrared and the visible and ultraviolet absorption spectra of these compounds and of the corresponding thiosulfato-Co(III) complexes have been measured and discussed in relation to the structures of the complexes.

This study was supported by a grant from the Ministry of Education.

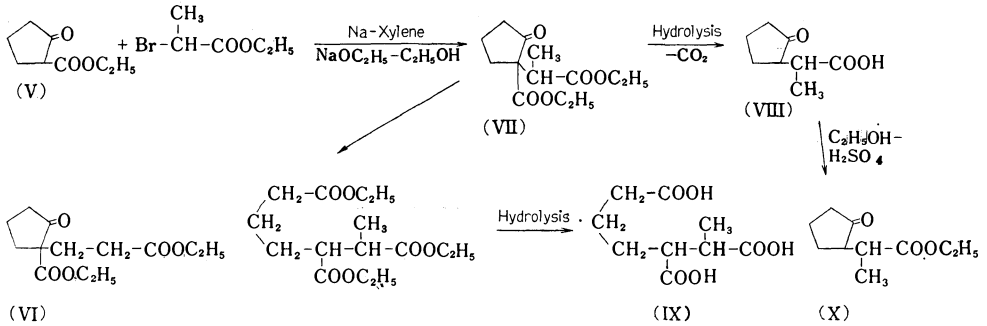
The Synthesis of Cyclopentane Derivatives. I

By Tsuguo TANAKA

(Received April 11, 1959)

Recently, several methylcyclopentane derivative from natural sources have been reported. Among them, nepetalic acid (I) and nepetalactone (II) from the oil of cat-nip (Nepeta cataria)[1], matatabilactone (III) from the oil of the wormseed of matatabi (Actinidia poligama Miq.,)[2] and iridolactone (IV) from ant (Iridomyrmex species)[3] are particularly interesting because of their close relationship concerning both physiological activities and chemical structures.



(I) (II) (III) (IV)

The determination of conformations of these compounds[4] in relation to their physical and chemical properties seems worthy of further considerations. Now, synthesis of several cyclopentane derivatives was attempted with a view to obtain some informations about conformational problems and to find out a new synthetic route.

In the present experiment, *cis*- and *trans*-lactones of 2-α-carboxyethylcyclopentanol were prepared as the first step in a series of this investigation attempted, which lead to the compounds having no methyl substituent in the ring, and thus alleviating stereochemical difficulties. The condensation of carbethoxycyclopentanone (V) with ethyl α-bromopropionate, reported by Šorm et al.[5] and Sen et al.[6], respectively, was re-examined and some new results were obtained. The condensation was conducted by use of either sodium metal in toluene[5,7] or sodium ethoxide in absolute alcohol[8]. 2-Carbethoxy-2-α-carbethoxyethyl cyclopentanone (VII) was obtained

in 70 and 60% yield, respectively. Here, in the latter case, an acid, m.p. 147°C, was newly detected as the by-product of the cleavage of the ring in VII[9,8b] followed by hydrolysis of the ester group. The acid was identified as hexane-tricarboxylic acid-1,4,5 (IX) obtained by Sen et al.[10] from 2-methyl-2,3-dicarbethoxy-cyclohexanone; the formation substantiates structure VII for the condensation product.

2-Carbethoxy-2-β-carbethoxyethyl-cyclopentanone (VI) which might be the product of dehydrobromination and Michael addition[11] of ethyl α-bromopropionate to carbethoxycyclopentanone (V) could not be detected. The ketoester (VII) was converted into 2-α-carboxyethyl-cyclopentanone (VIII), m.p. 66°C, which on esterification yielded ethyl ester (X), as indicated in the formulation.

On the other hand, VIII was treated with sodium borohydride, when a selective reduction of the keto group[12] was realized;

from the reduction product a lactone of possibly *cis*-2-α-carboxyethyl-cyclopentanol (*cis*-lactone) (XI) and a hardly lactonized one, possibly *trans*-hydroxyacid (XII) were obtained. Structure XII was ascertained by analysis and also by the comparison of the absorption spectrum of the reduction product with that of keto-acid (VIII). 288 mμ band in the ultraviolet spectrum and 5.80 μ peak in the infrared spectrum of the keto-acid were not observed in the spectrum of the reduction product as illustrated in Figs. 1 and 2, respectively.

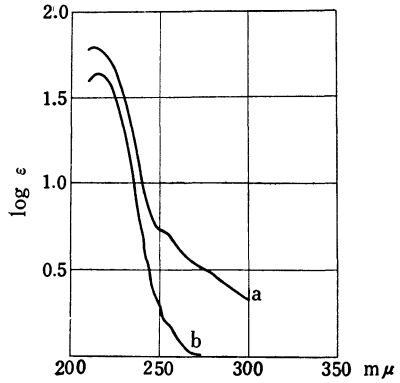

Fig. 3. Ultraviolet spectra of *trans*-lactone (a) and *cis*-lactone (b) in alcoholic solutions.

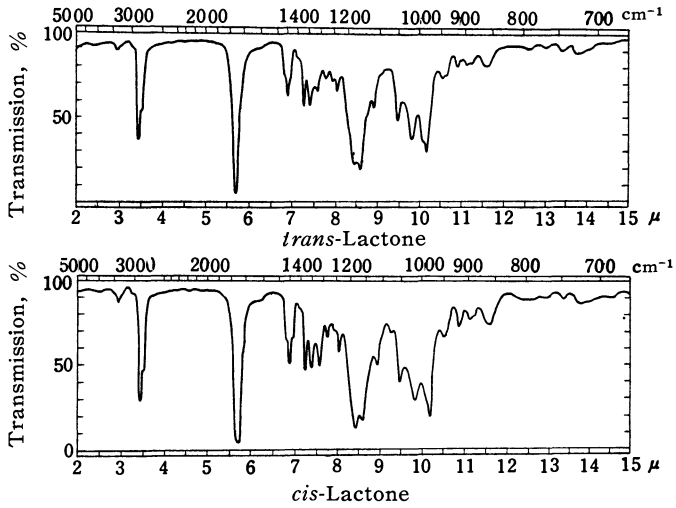

Fig. 4. Infrared spectra of *trans*-lactone and *cis*-lactone.

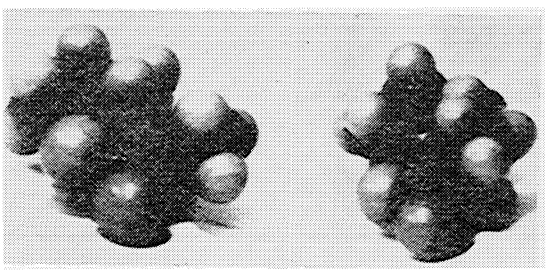

The reduction of 2-carboxymethyl-cyclopentanone with sodium amalgam in sodium hydroxide solution was reported by Linstead et al.[13] to yield *cis*-lactone in 28% yield. The lactonization of XII gave a sweet smelling *trans*-lactone (XIII) (heated under diminished pressure); a trace of concentrated sulfuric acid facilitated the reaction. In this way the reduction of keto-acid (VIII) yielded 37% of *cis*-lactone and 38% of *trans*-lactone (consult Table I).

TABLE I. PHYSICAL CONSTANTS OF *cis*- AND *trans*-LACTONES

	Density $d_4^{13.5}$	Refractive index $n_D^{13.5}$	b. p., °C
cis-Lactone	1.08462	1.4712	73~74/2 mm.
trans-Lactone	1.09688	1.4725	67/2 mm.

Some differences between these lactones were also revealed in the ultraviolet (Fig. 3) and infrared (Fig. 4) spectra of them. In the ultraviolet spectra, the extinction coefficient of *trans*-lactone is a little higher than that of *cis*-lactone particularly at longer wavelengths.

In the infrared spectra, comparison of relative intensity of absorption peaks 8.44 μ (a) and 8.60 μ (b) (C–O stretching) gives a convenient method of characterizing these lactones. In the spectra of *cis*- and *trans*- lactones, a>b and b>a are recognized, respectively. And the singlet absorption peaks 10.50 μ, 11.13 μ in the spectrum of *cis*-lactone, appear as doublet peaks 10.50, 10.64 μ; 11.13, 11.25 μ respectively in that of *trans*-lactone. By the examination of the molecular models in Fig. 5, it is ascertained that *cis*-lactone is a staggered molecule having *cis*-orientation at C_1 and C_2, while *trans*-lactone is a planar molecule having a *gauche*-orientation at C_1 and C_2.

trans-Lactone *cis*-Lactone

TABLE II. PHYSICAL CONSTANTS OF 2-α-CARBOXYETHYL-CYCLOPENTANONE AND ITS DERIVATIVES

	b. p., °C	m. p., °C	Melting point of semi-carbazone °C	Melting point of 2,4-dinitro-phenylhydrazone °C	Boiling point of ethylester °C
Šorm et al.	154/15 mm.	—	188	—	81～83/0.5 mm.
Sen et al.	150/3 mm.	—	—	220	—
Experiment	118～119/0.4 mm.	66	189	220	93.5～94/3 mm.

pentanone was gently refluxed with 100 ml. of concentrated hydrochloric acid for sixteen hours at 135～145°C in an oil bath. The reaction mixture was cooled and extracted with ether. Benzene was added to the ether solution and the solvents were evaporated and the residue was vacuum-distilled. A portion (18.4 g.) of the acid b. p. 118～119°C/0.4 mm. was obtained. Yield, 64%. On standing in the ice box, it gradually crystallized; m. p. 45°C. Recrystallized from benzene-petroleum ether as feathery needles; m. p. 66°C, λ_{max} 214 mμ log ε 1.86, 288 mμ log ε 1.34; ν_{max} 5.80 μ, 5.90 μ (C=O).

Anal. Found: C, 60.72; H, 7.84. Calcd. for $C_8H_{12}O_3$: C, 61.52; H, 7.75%.

An additional amount (ca. 1 g.) was obtained by evaporating the hydrochloric acid solution in vacuum and extracting the residual tar with ether. Physical constants by three different authors are listed in Table II.

(b) To a solution of 7.6 g. of sodium in 120 ml. of absolute alcohol was added 54 g. of carbethoxy-cyclopentanone in twenty minutes at 20°C with efficient stirring. Sixty-four grams of ethyl α-bromopropionate was added to the mixture and refluxed for four hours. A clear red solution resulted. Fifty milliliters of alcohol was distilled off from it and the residue was diluted with 250 ml. of ice water and extracted with ether. The ether solution, after washing with water, dried with sodium sulfate and the ether was evaporated and the residue vacuum-distilled. Fifty and a half grams of fraction boiling 126.5～130°C/2.5 mm. was obtained. Yield, 60%.

2-α-Carboxyethyl-cyclopentanone and Hexane-tricarboxylic Acid-1, 4, 5.—Hydrolysis was effected in the same way as in a) by using 47.5 g. of ketodiester b. p. 126.5～130°C/2.5 mm. and 105 ml. of concentrated hydrochloric acid. On evaporation of ether and redissolving the residue in a small amount of dry ether, 850 mg. of colorless crystals which were difficult to solve in ether, separated, which on crystallization from ethyl acetate-petroleum ether melted at 147°C. Analysis and titration conformed to hexane-tricarboxylic acid-1, 4, 5.

Anal. Found: C, 49.40; H, 6.71. Calcd. for $C_9H_{14}O_6$: C, 49.54; H, 6.47%. Titration. 9.00 mg. required 12.4 ml. of 0.010 N sodium hydroxide. Calcd. for $C_6H_{11}(COOH)_3$: 12.4 ml. From the ether solution after distillation in vacuum was obtained 14 g. of 2-α-carboxyethyl-cyclopentanone b. p. 119～120°C/0.4 mm. Yield, 46%.

2-α-Carbethoxyethyl-cyclopentanone. — Seven grams of 2-α-carboxyethyl-cyclopentanone was dissolved in 20 ml. of absolute alcohol containing 0.7 ml. of concentrated sulfuric acid and refluxed for six hours in a water bath. Twelve milliliters of ethanol was distilled off from the reaction mixture and the residue was poured into 120 ml. of ice water.

The product was extracted with ether and the ether solution was washed with 5% aqueous sodium carbonate solution and with water successively, and dried with sodium sulfate. Evaporation of ether and vacuum-distillation of the residue produced 5.8 g. of 2-α-carbethoxyethyl-cyclopentanone b. p. 93.5～94°C/3 mm. Yield, 70%. λ_{max} 214 mμ log ε 2.02, 288 mμ log ε 1.36; ν_{max} 5.80 μ (C=O).

Anal. Found: C, 64.91; H, 9.21. Calcd. for $C_{10}H_{16}O_3$: C, 65.19; H, 8.75%.

***cis*-Lactone, *trans*-2-α-Carboxyethyl-cyclopentanol and *trans*-Lactone.**—The aqueous sodium hydroxide solution (4.2 g. of sodium hydroxide in 94 ml. of water) of 14.4 g. of 2-α-carboxyethyl-cyclopentanone was gradually (in one hour) added to a solution of 2.3 g. of sodium borohydride in 35 ml. water. The mixture was well shaken after each addition and left to stand for two days at room temperature after the addition was over. It was cooled in an ice bath, and 50 ml. of concentrated hydrochloric acid was added to it with stirring. After the addition was over, it was warmed on a water bath for fifteen minutes, cooled in an ice bath and extracted three times with benzene followed by four times with ether. The combined benzene solution after washing three times with water was dried with sodium sulfate. Benzene was evaporated under reduced pressure and the residue vacuum-distilled. Four and four-fifth grams of *cis*-lactone (3.8 g. of fraction b. p. 73～74°C/2 mm., 1 g. of fraction b. p. 71～72.5°C/2 mm.) was obtained. The latter fraction was also used for further work. Yield, 37%. λ_{max} 215 mμ log ε 1.65; ν_{max} 5.70 μ (C=O) 8.44 μ, 8.60 μ (C-O).

Anal. Found: C, 67.96; H, 8.89. Calcd, for $C_8H_{12}O_2$: C, 68.54; H, 8.63%.

To the combined ether solution was added 100 ml. of benzene. Ether and moisture were azeotropically distilled. And the residue was vacuum-distilled. *trans*-2-α-Carboxyethyl-cyclopentanol b. p. 125～126°C/0.4 mm., m. p. 58°C, was obtained. λ_{max} 215 mμ log ε 1.93; ν_{max} 5.90 μ (C=O).

Anal. Found: C, 61.37; H, 9.21. Calcd. for $C_8H_{14}O_3$: C, 60.74; H, 8.92%.

***trans*-Lactone Prepared from *trans*-2-α-Carboxyethyl-cyclopentanol.** — In the usual pro-

cedure the residue of the ether extract was directly lactonized by heating it at 180~195°C under 30 mm. pressure from thirty minutes to three hours. *trans*-Lactone mixed with water slowly distilled out. But when one drop of concentrated sulfuric acid was added to the hydroxyacid, lactonization was completed in a few minutes. The product was dissolved in benzene, dried with sodium sulfate. Benzene was evaporated and the residue vacuum-distilled. Four and nine-tenths grams of *trans*-lactone b. p. 67°C/2 mm. was obtained. Yield, 38%. λ_{max} 213.5 mμ log ε 1.81; ν_{max} 5.70 μ (C=O) 8.44 μ, 8.60 μ (C-O).

Anal. Found: C, 68.52; H, 8.80. Calcd. for $C_8H_{12}O_2$: C, 68.54; H, 8.63%.

The author is grateful to Mr. H. Kotsuma* for infrared spectra and Mr. M. Shito and Miss S. Indo for the microanalysis.

Characteristics of Alginic Acid as a Cation Exchanger and its Application to the Separation of Thorium(IV) and Cerium(III) Ions

By Takeo TAKAHASHI and Shingo MIYAKE

(Received June 6, 1959)

Alginic acid belongs to one of the polyacids with carboxylic groups as the dissociation group. It is generally soluble in water, either neutral or basic, but can maintain a solid state in an acidic salt solution, showing an excellent cation exchange property[1] and although its analytical and industrial applications have also been investigated[2], the characteristics as cation exchanger or situation in cation exchangers have not yet been explained clearly. It is the principle object of the present research to discuss the cation exchange property of alginic acid from the viewpoint of acidity. Alginic acid indicates somewhat stronger acidity in the aqueous solution than acetic acid[3] and polyacrylic acid which is also one of the polycarboxylic acids. From the viewpoint of the acidity, it is expected that the characteristics of alginic acid as cation exchanger would be placed between a strongly acidic and a weakly acidic exchanger. Thus it may be used advantageously for the ion-exchange separation of some multivalent cations, which are separated with difficulty with conventional exchangers, either strongly or weakly acidic. For example, the separation of thorium(IV) and cerium(III) with alginic acid as exchanger was briefly described in the previous communication[4]. The present paper discusses the characteristics of alginic acid as cation exchanger and the same subject was described in a previous paper in some detail.

Experimental

Alginic acid employed for the measurement of the ion exchange equilibrium was prepared by the following procedure. A commercial sodium alginate was dissolved in water to make about 0.5% solution. The insoluble residue was congelated by warming the solution to 50~60°C on a water bath, and removed by filtering through a filter bed composed of Toyo filter paper No. 2 and No. 5c. Alginic acid, coagulated by the addition of hydrochloric acid to the filtrate, was, after a few hours, collected on a piece of silk gauze of about 60 mesh, and washed with about 50% methanol until the absence of chlorine ions in the washing was confirmed. After the methanol was pressed out, the swelled alginic acid was stored in a closed container with water in the bottom.

Amberlite IR-120, a strongly acidic exchanger and IRC-50, a weakly acidic one were similarly stored in a wet state. Table I shows the properties of these exchangers available for the experiment.

TABLE I. THE PROPERTIES OF THE EXCHANGERS

Exchanger	Humidity %	0.1 N NaOH (ml.) for neutralization of 1 g. of exchanger
IR-120	43.1	23.56
H alg.	66.6	18.96
IRC-50	48.5	53.70

The alginic acid used in the column (1.5 cm. in diameter and 20 cm. in length) for the separation of thorium (IV) and cerium (III) ions was prepared from calcium alginate thread* by the procedure described in the previous paper[4].

Other reagents were all of the special grade (G. R.) available commercially.

Spectrophotometric methods were used for the analysis of thorium(IV) and cerium(III) ions, using Neo-thorone for thorium(IV) (580 mμ) and hydrogen peroxide for cerium(III) (320 mμ).

Results and Discussion

Characteristics of Alginic Acid as an Exchanger.—*Apparent dissociation constant.*—IR-120 (0.22 g.), IRC-50 (0.10 g.) and alginic acid (0.28 g.) weighed exactly within a deviation of 1 mg. were immersed in 10 ml. of the mixed solution containing $(10-x)$ ml. of 1 N potassium chloride and x ml. of potassium chloride and potassium hydroxide mixture (1 N KCl–0.1 N KOH), respectively. After the ion exchange equilibrium was achieved by allowing the mixed solution to stand for 24 hr. (for 3 days in the case of IRC-50) with occasional agitation, the pH of each supernatant solution was measured by means of Toa Denpa Model HM-3 glass electrode pH meter. Fig. 1 shows the relationship between the pH of the supernatant solution in its equilibrium state and the volume of 0.1 N potassium hydroxide added.

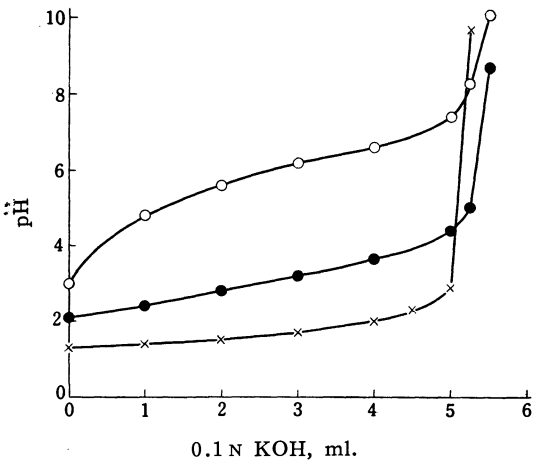

Fig. 1. Titration curves of exchangers.
○: IRC-50, ●: H alg., ×: IR-120

Such curves as those shown in Fig. 1 correspond to the titration curves of the exchangers as polyacids, and have been used for a mean in the characterization of the dissociation group of ion exchangers. For the purpose of expressing the apparent dissociation constant, pK, in the case of a weak polyacid, it is useful to take the value of pH at which half of the polyacid is exactly neutralized.

From Fig. 1, the values of pK for the exchangers are found to be 1.6 for IR-120, 3.1 for alginic acid and 6.0 for IRC-50. Now, attention must be paid to the fact that the values of pH cited above are of the external solution with which the exchangers are in equilibrium, and the true pH[5] in the internal body of the exchangers may show lower values. However, it is concluded that alginic acid is situated between the strongly acidic and the weakly acidic exchangers from the viewpoint of acidity. In fact, it is well known that alginic acid is one of the strongest acids among all the weak polyacids with the carboxylic group. The most valuable characteristic of alginic acid is that it has an intermediate acidity as cation exchanger.

On the other hand, in a cation exchange reaction under a given condition, the difference between the selectivity of different cations is independent in principle of the kind of functional group of exchangers, with the exception of some special exchangers, but the effect of the kind of functional group upon the property of the exchanger is due to the difference of their acidities. When the exchangers have the same functional group and different acidities, a difference in property as ion exchanger should be found. Accordingly, it is expected that alginic acid would have an intermediate property for cations, and that it may be available for the separation of several cations, which are separated with difficulty by means of conventional exchangers.

Distribution constant of thorium(IV) and cerium(III) ions.—Each exchanger, weighed in the same manner as that described above, is immersed in 20 ml. of 3.8×10^{-3} M thorium nitrate solution or 7.1×10^{-3} M cerous nitrate solution, with nitric acid of various concentrations. After equilibrium is reached through the same procedure as

* The alginate thread was supplied from Kamogawa Kato Co., Ltd., to whom the authors are indebted and to whom they express their thanks.

5) M. Honda, *J. Am. Chem. Soc.*, **73**, 2943 (1951).

that described above, thorium(IV) or cerium(III) ions in an aliquot of the supernatant solution were determined.

The distribution constant, K_d, for thorium(IV) and cerium(III) ions in regard to each exchanger was calculated from the following equation.

$$K_d = \frac{\text{Concn. of cation in the exchanger (dry base) (mg./g.)}}{\text{Concn. of cation in the supernatant soln. (mg./ml.)}}$$

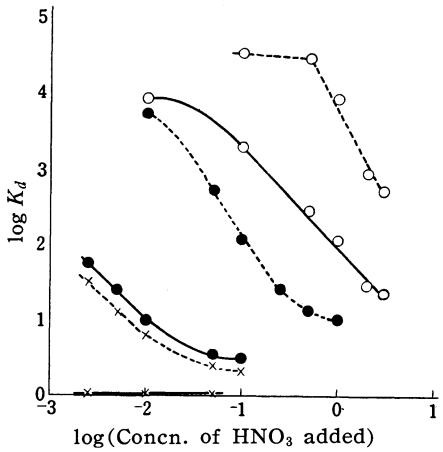

Fig. 2. Effect of concentration of nitric acid upon K_d of thorium(IV) and cerium(III).
------: Th, ——: Ce
○: IR-120, ●: H alg., ×: IRC-50

Fig. 2 shows the relationship between log K_d and logarithm of concentration of nitric acid in the solution. Now, for the concentrations of nitric acid, the stoichiometrical concentrations in the initial periods of the reaction were used instead of pH at the equilibrium, because of the difficulty of the measurement of pH in a concentrated nitric acid.

It is clear that IRC-50 adsorbs these cations little or not at all from an acid solution which keeps them without hydrolysis, and that these cations are adsorbed by IR-120 too tightly to be eluted fractionally with a dilute solution of conventional mineral acid. The values of K_d for thorium(IV) and cerium(III) ions in regard to alginic acid is placed between those in regard to IR-120 and IRC-50.

For the separation of thorium(IV) and cerium(III) ions by cation exchanger, it has been, heretofore, usual to use strongly acidic exchangers such as Amberlite IR-120 or Dowex-50 and to use complex reagents such as EDTA[6,7], citrate[8] and oxalate[9] for the fractional elution. This is because of the difficulty with which these cations are eluted from strongly acidic exchangers with a dilute acid solution. On the other hand, it is not always easy to convert the complex ions into simple metallic ions. However, it seems likely that thorium(IV) and cerium(III) ions can be easily eluted fractionally with a conventional mineral acid as shown in Fig. 2, provided that alginic acid is used as exchanger. It has never been suggested that an intermediately acidic exchanger such as alginic acid be used for the separation of thorium(IV) and cerium(III) ions.

Separation of Thorium(IV) and Cerium(III) Ions by the Use of Alginic Acid Column.—*Synthetic solution.*—The synthetic solutions containing thorium(IV) and cerium(III) ions in various concentrations were made pH 2 to 2.5 with aqueous ammonia and poured over the top of the column. Thorium(IV) and cerium(III) ions are adsorbed on alginic acid. After the column is washed with 100 ml. of water, cerium(III) ion is eluted with nitric acid of a concentration below 0.1 N at a flow rate of about 1 ml./min., and then the thorium(IV) ion is eluted with 1 N nitric acid. An example of the elution diagram has been shown in the previous paper[4]. Some analytical results are given in Table II.

TABLE II. SEPARATION OF THORIUM(IV) AND CERIUM(III) IONS FROM THEIR SYNTHETIC SOLUTION

It is shown that the present method can be feasible for the quantitative separation of thorium(IV) and cerium(III) ions and that the column employed in this experiment has a dimension suitable for the adsorption of the cerium(III) ion below 45 mg.

Application to monazite. — The monazite employed in this experiment was mined in 1940 at Ishikawa-yama, Fukushima-ken. Monazite ore was digested with concentrated sulfuric acid in the usual way. Mixed oxalates of thorium(IV) and rare earth metals were separated from other metallic ions through reprecipitation with oxalic acid. The oxalate mixture was converted into hydroxide by immersing into a warm sodium hydroxide solution and then dissolved in nitric acid. After the ceric ion contained in the mixed solution was reduced with a small amount of sodium nitrite to the cerous ion, and after the pH was adjusted with nitric acid to about 1, an aliquot of the solution was poured over the top of the column, which then was washed with 250 ml. of 0.1 N nitric acid at a flow rate of about 1 ml./min. Thus, the thorium(IV) ion is adsorbed entirely on alginic acid in the column, while all rare earth metal ions pass through the column. The results are shown in Table III.

TABLE III. SEPARATION OF THORIUM(IV) AND RARE EARTH IONS FROM MONAZITE

Mixed oxide	ThO_2 found in the column	Oxides of R.E. found in the effluent	Other oxides eluted with 1 N H_2SO_4
mg.	mg.	mg.	mg.
298	42.5	237.1	18.3
〃	42.8	237.3	17.8
〃	43.1	236.8	19.1

The "other oxides" shown in the last column of Table III are the oxides not eluted with 1 N nitric acid but eluted with 1 N sulfric acid. They seem to be composed of the oxides of titanium, zirconium and hafnium. In this experiment, the mixed oxide, the oxides of rare earth elements and "other oxides" were precipitated with aqueous ammonia from respective solutions and determined gravimetrically.

Summary

The apparent dissociation constant of alginic acid was measured by means of the neutralization with 0.1 N potassium hydroxide in 1 N potassium chloride solution and found to have a value of 3.1. This value is between that of IR-120 and of IRC-50, which is obtained by the same manner of measurement. The values of K_d for thorium(IV) and cerium(III) ions in regard to these three exchangers were measured, showing that the value in regard to alginic acid is also situated between the other two.

The application of alginic acid to the fractional separation of thorium(IV) and cerium(III) ions gave a satisfactory result.

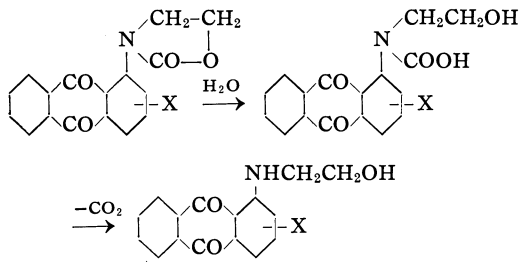
*Studies on 3-(Anthraquinon-1-yl)oxazolidin-2-ones. II. 3-(Bromoanthraquinon-1-yl)oxazolidin-2-ones and their Related Compounds**



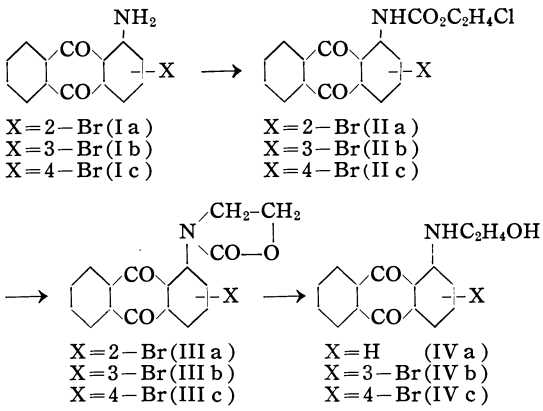
By Kō Naiki

(Recieved June 10, 1959)

It was shown in a previous paper[1] that an introduction of a methyl group into an anthraquinone nucleus of 3-(anthraquinon-1-yl)oxazolidin-2-one decreases the reactivity with an aqueous solution of potassium hydroxide. In other words, the existence of a steric hindrance of the 2-methyl group plays an important part in the hydrolysis process (Scheme I), inhibiting the conversion of the anthraquinon-1-yl-oxazolidin-2-ones into the 1-*N*-2-hydroxyethylamino-anthraquinones to a certain extent.

* Presented at the 12th Annual Meeting of the Chemical Society of Japan, Kyoto, April, 1959.

1) K. Naiki, This Bulletin, **32**, 361 (1959).



Scheme I

Furthermore, it was shown that in the case of the spectra of 2-chloroethyl methylanthraquinon-1-ylcarbamates the steric inhibition of the $\pi-p$ conjugation, i. e. interaction between an anthraquinone ring and an unshared electron pair of the nitrogen atom, plays an important role. Thus the introduction of the 2-methyl group into the anthraquinone ring results in the lowering of the intensity of the band near 400 mμ ascribed to the Aq-N̈ chromophore, where Aq represents the anthraquinone ring, and results in the displacement by 43 mμ towards shorter wavelength as compared with 2-chloroethyl 4-methylanthraquinon-1-ylcarbamate. In 3-(methylanthraquinon-1-yl) oxazolidin-2-ones, the steric inhibition of the $\pi-p$ conjugation due to a bulky *N*-substituent, oxazolidin-2-onyl, results in the lowering of the intensity of the band near 400 mμ to a greater extent, and the introduction of the 2-methyl group into the anthraquinone ring weakens the band associated with Aq-N̈ chromophore.

In the present study, 3-(bromoanthraquinon-1-yl)oxazolidin-2-ones, 2-chloroethyl bromoanthraquinon-1-ylcarbamates and 1-*N*-2-hydroxyethylamino-bromoanthraquinones were synthesized and the effect of the bromine atom according to its position on absorption spectra of 2-chloroethyl bromoanthraquinon-1-ylcarbamates and 3-(bromoanthraquinon-1-yl) oxazolidin-2-ones was discussed in terms of the steric hindrance. None of them has yet been prepared. Furthermore, the effect of the bromine atom according to its position on the reactivity of bromoanthraquinon-1-yloxazolidin-2-ones with potassium hydroxide was investigated.

Preparation and Results

The syntheses of the compounds were carried out according to the following processes (Scheme II).

Scheme II

2-Chloroethyl 2-bromoanthraquinon-1-ylcarbamate(IIa), 3-bromoanthraquinon-1-ylcarbamate(IIb) and 4-bromoanthraquinon-1-ylcarbamate(IIc) were obtained from the corresponding 1-amino-bromoanthraquinones (Ia, Ib and Ic, respectively) by the action of 2-chloroethyl chloroformate in the presence of sodium carbonate in boiling xylene.

3-(2-Bromoanthraquinon-1-yl)oxazolidin-2-one(IIIa) was prepared from 2-chloroethyl 2-bromoanthraquinon-1-ylcarbamate by the action of a 20% aqueous solution of potassium hydroxide at 98~99°C for 1 hr. The mixture of 1-*N*-2-hydroxyethylaminoanthraquinone(IVa) and 3-(2-bromoanthraquinon-1-yl)oxazolidin-2-one(IIIa) was obtained from 2-chloroethyl 2-bromoanthraquinon-1-ylcarbamate by the action of a 20% aqueous solution of potassium hydroxide at 105~107°C for 1 hr. Each of the constituents was separated by a column chromatography from benzene on alumina.

The mixture of 1-*N*-2-hydroxyethylamino-3-bromoanthraquinone(IVb), 3-(3-bromoanthraquinon-1-yl)oxazolidin-2-one(IIIb) and 2-chloroethyl 3-bromoanthraquinon-1-ylcarbamate was obtained from 2-chloroethyl 3-bromoanthraquinon-1-ylcarbamate by the action of a 20% aqueous solution of potassium hydroxide at 98~99°C for 1 hr. and each of the constituents was separated by a column chromatography from benzene on alumina. In the same way, 1-*N*-2-hydroxyethylamino-4-bromoanthraquinone(IVc) and 3-(4-bromoanthraquinon-1-yl)oxazolidin-2-one(IIIc) were obtained from 2-chloroethyl 4-bromoanthraquinon-1-ylcarbamate.

The proportion of constituents of the reaction mixture from the corresponding 2-chloroethyl bromoanthraquinon-1-ylcarbamates by the action of a 20% aqueous

TABLE I. THE PROPORTIONS OF THE CONSTITUENTS OF THE REACTION PRODUCTS OBTAINED FROM 2-CHLOROETHYL BROMOANTHRAQUINON-1-YLCARBAMATES AND A 20% AQUEOUS SOLUTION OF POTASSIUM HYDROXIDE

2	0	100	0
3	29	7	64
4	44	26	30

solution of potassium hydroxide at 98~99°C for 1 hr. was determined.

The results are shown in Table I. The reaction mixture obtained from the chloroethyl bromoanthraquinon-1-ylcarbamate and potassium hydroxide can be separated into the constituents by a column chromatography from benzene on alumina, but it is observed that the 2-chloroethyl bromoanthraquinon-1-ylcarbamate is gradually converted into the corresponding bromoanthraquinon-1-yloxazolidin-2-one on alumina. For this reason, the determination of the proportion of constituents was carried out by a spectrophotometry. Since the absorption bands of the constituents are separated from each other, the determination was carried out exactly. The absorption spectra of 2-chloroethyl bromoanthraquinon-1-ylcarbamates, 3-(bromoanthraquinon-1-yl)oxazolidin-2-ones and 1-*N*-2-hydroxyethylamino-bromoanthraquinones are shown in Figs. 1—3, respectively.

Discussion

Effect of the Bromine Atom according to its Position on Absorption Spectra.—In the case of the spectra of 2-chloroethyl anthraquinon-1-ylcarbamates, the introduction of the 2-bromine atom into an anthraquinone ring results in the lowering of an intensity of the band near 400 mμ ascribed to Aq-N̈ chromophore and the displacement by 53 mμ towards a shorter wavelength as compared with 2-chloroethyl 4-bromoanthraquinon-1-ylcarbamate. This fact may be explicable in terms of the steric hindrance of the $\pi-p$ conjugation, between the anthraquinone ring and an unshared electron pair of the nitrogen atom, due to a repulsion between the carbonyl group and the 2-bromine atom which arises from the overlapping of the van der Waals radii. It is pointed out that $\varepsilon_2/\varepsilon_4$ is considerably smaller for 2-chloroethyl bromoanthraquinon-1-ylcarbamates than for 2-chloroethyl methylanthraquinon-1-ylcarbamates. Projection diagrams (Fig. 4) of uniplanar

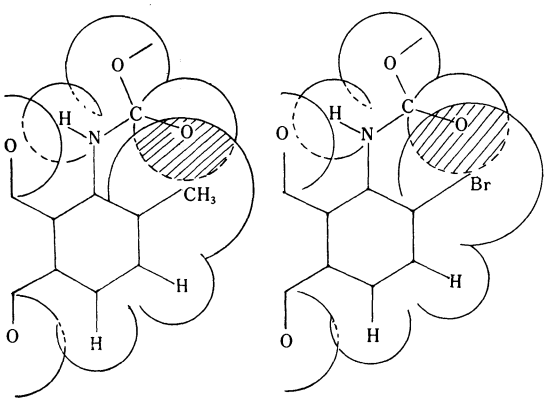

Fig. 4. Projection diagrams of 2-chloroethyl 2-bromo- and 2-methyl-anthraquinon-1-yl-carbamates.

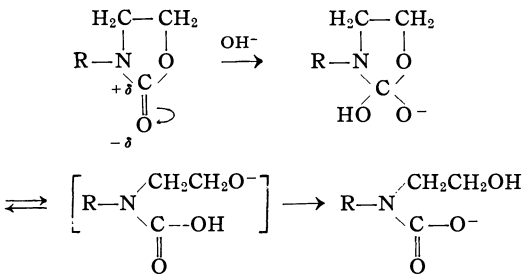
structures, employing van der Waals radii, indicate only a slightly larger overlapping for 2-chloroethyl 2-bromoanthraquinon-1-ylcarbamate than for 2-chloroethyl 2-methylanthraquinon-1-ylcarbamate. Hence additional effects, i. e. the coulombic interaction of the carbonyl group with the 2-bromine atom and the hydrogen bonding between the carbonyl group and the 2-methyl group, must be considered in an explanation of the spectral diffrence between 2-chloroethyl 2-bromoanthraquinon-1-ylcarbamate and 2-methylanthraquinon-1-ylcarbamate (Table III).

Table III. Absorption maxima and extinction coefficients of the primary bands of 2-chloroethyl anthraquinon-1-ylcarbamates

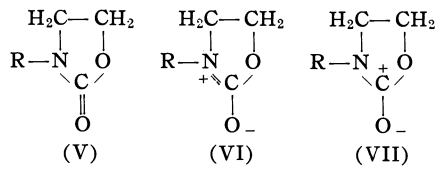


Substituent of anthraquinone nucleus	λ_{max} mμ	$\varepsilon\times10^{-4}$	$\varepsilon_2/\varepsilon_4$
2-Methyl	378	0.520(ε_2)	0.84
4-Methyl	421	0.618(ε_4)	
2-Bromo	370	0.346(ε_2)	0.60
4-Bromo	423	0.580(ε_4)	

In the spectra of 3-(anthraquinon-1-yl)-oxazolidin-2-ones, it is expected that an absence of intermolecular hydrogen bonding possibility results in the lowering of the intensity of the band near 400 mμ as compared with the compounds which have intermolecular hydrogen bonding possibility, 2-chloroethyl anthraquinon-1-ylcarbamates. It is further expected that the introduction of a bulky group, such as oxazolin-2-onyl, into the 1-position of the anthraquinone ring increases the extent of steric inhibition of the $\pi-p$ conjugation, between the anthraquinone ring and the unshared electron pair of the nitrogen atom, and results in the lowering of the intensity of the band near 400 mμ ascribed to Aq-N̈ chromophore. If the 2-bromine atom is introduced into the anthraquinone ring, the steric hindrance inhibits the $\pi-p$ conjugation between the ring and the unshared electron pair of the nitrogen atom to a greater extent. This is illustrated in Table II.

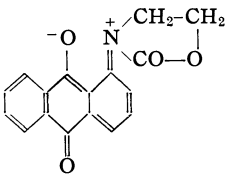
The Effect of the 2-Bromine Atom on the Reactivity of 3-(Bromoanthraquinon-1-yl)-oxazolidin-2-ones with the Hydroxide Ion.—On account of an aqueous dispersion of solid material, various difficulties may be introduced in the discussion when the reactivities are compared with each other. Nevertheless, it may be probable that some close relation exists between the reactivity and factors such as electronic and steric effects of groups in the anthraquinone nucleus. Table I shows clearly that the 2-bromine atom decreases the reactivity of the 3-(bromoanthraquinon-1-yl)-oxazolidin-2-ones with potassium hydroxide to a considerable extent. In other words, it shows the existence of a steric hindrance of the 2-bromine atom in the hydrolysis, this effect inhibiting the conversion of 3-(2-bromoanthraquinon-1-yl)oxazolidin-2-one into 1-*N*-2-hydroxyethylamino-2-bromoanthraquinone.

In the basic hydrolysis of 3-substituted oxazolidin-2-ones, there is a carbonyl carbon atom at which attack would be



expected to occur. A mechanism of the hydrolysis reaction may be illustrated as follows (Scheme III).

Scheme III



The addition complex has a more or less tetrahedral configuration at the site of substitution. Its formation controls the rate of the reaction. It may be probable, therefore, that the steric hindrance to the formation of the addition complex, due to overlapping of the van der Waals radii and the coulombic interaction of the 2-bromine atom with the hydroxide ion, inhibits the conversion of 3-(2-bromoanthraquinon-1-yl)-oxazolidin-2-one into 1-*N*-2-hydroxyethyl-amino-2-bromoanthraquinone. Further effects must, however, be considered in an explanation of the experimental results.

3-Substituted oxazolidin-2-ones may be described as a resonance hybrid of structures V—VII.

(V) (VI) (VII)

If the -N̈-C=O system is planar, there will be a flow of a charge away from the nitrogen atom into the carbonyl oxygen atom; in other words, structure VI is much more important than structure VII, in which the positive charge is on the carbonyl carbon atom. In 3-anthraquinon-1-yloxazolidin-2-ones, an additional structure VIII contributes to the resonance hybrid. This means that if the Aq-N̈ system is planar, there will be a flow of a charge away from the nitrogen atom into the anthraquinone ring, this resulting in a decrease of the contribution of structure VI to the resonance hybrid. The steric hindrance of the 2-bromine atom to the planar configuration of the Aq-N̈ system decreases the contribution of structure VIII, increasing the contribution of structure VI to the resonance hybrid.

(VIII)

On the other hand, a nucleophilic attack occurs readily at the position at which an open sextet of electrons can be provided readily. It is therefore reasonable to suppose that the contribution of structure VI is unfavorable for the formation of an addition complex in the reaction of 3-(anthraquinon-1-yl)oxazolidin-2-ones with the hydroxide ion. The steric hindrance of the 2-bromine atom to the planar configuration of the Aq-N̈ system inhibits the conversion of 3-(2-bromoantraquinon-1-yl)-oxazolidin-2-one into 1-*N*-2-hydroxyethyl-amino-2-bromoanthraquinone.

It is also expected that the introduction of electron attracting groups into the anthraquinone ring results in the decrease of contribution of strueture VI to the resonance hybrid and the formation of the addition complex will be facilitated, increasing the rate of conversion of 3-(anthraquinon-1-yl)oxazolidin-2-ones into 1-*N*-2-hydroxyethylaminoanthraquinones. This is illustrated by the comparison of reactivities of 3-(bromoanthraquinon-1-yl)-oxazolidin-2-ones with those of 3-(methyl-anthraquinon-1-yl)oxazolidin-2-ones (Table IV).

2) F. Ullmann and O. Fisher, *Ber.*, **49**, 2154 (1956).

1-Amino-4-bromoanthraquinone (Ic)[3].—The compound was separated by a column chromatography from benzene on alumina and recrystallized from ligroin, giving red needles, m. p. 179~180°C.

Anal. Found: N, 4.69. Calcd. for $C_{14}H_8O_2NBr$: N, 4.64%.

2-Chloroethyl 2-Bromoanthraquinon-1-ylcarbamate (IIa)[4].—Yellow needles (ethyl alcohol), m. p. 188~189°C.

Anal. Found: N, 3.48. Calcd. for $C_{17}H_{11}O_4NBrCl$: N, 3.42%.

2-Chloroethyl 3-Bromoanthraquinon-1-ylcarbamate (IIb).—A mixture of 2.00 g. of 1-amino-3-bromoanthraquinone (m. p. 240~241°C), 1.20 g. of 2-chloroethyl chloroformate (b. p. 150~151°C), 0.90 g. of sodium carbonate and 30 ml. of xylene was refluxed with stirring for 8 hr. The insoluble material was removed by hot filtration and the filtrate was evaporated to a volume of about 15 ml. for crystallization. Yield, 2.65 g. (99% of the theory) of yellow needles, m. p. 215~216°C. It was recrystallized from ethanol, giving yellow needles, m. p. 220~221°C.

Anal. Found: N, 3.53. Calcd. for $C_{17}H_{11}O_4NBrCl$: N, 3.42%.

2-Chloroethyl 4-Bromoanthraquinon-1-ylcarbamate (IIc).—A mixture of 2.00 g. of 1-amino-4-bromoanthraquinone (m. p. 175~176°C) 1.20 g. of 2-chloroethyl chloroformate (b. p. 150~151°C), 0.90 g. of sodium carbonate and 20 ml. of xylene was refluxed with stirring for 2 hr. The insoluble material was removed by hot filtration and the filtrate was evaporated to a volume of about 10 ml. for crystallization. Yield, 2.55 g. (94% of the theory) of yellow needles, m. p. 201~202°C. It was recrystallized from ethanol, giving yellow needles, m. p. 203~204°C.

Anal. Found: N, 3.67. Calcd. for $C_{17}H_{11}O_4NBrCl$: N, 3.42%.

3-(2-Bromoanthraquinon-1-yl)oxazolidin-2-one (IIIa)[4].—Pale brown plates (toluene), m. p. 284°C (decomp.).

Anal. Found: N, 4.09. Calcd. for $C_{17}H_{10}O_4NBr$: N, 4.11%.

3-(3-Bromoanthraquinon-1-yl)oxazolidin-2-one (IIIb) and 1-*N*-2-Hydroxyethylamino-3-bromoanthraquinone (IVb).—A mixture of 1.00 g. of finely powdered 2-chloroethyl 3-bromoanthraquinon-1-ylcarbamate and 30 g. of a 20% aqueous solution of potassium hydroxide was heated with vigorous stirring in a boiling water bath for 1 hr. After being diluted with water, the precipitate was collected, washed with water, and dried. Yield, 0.92 g. of reddish brown powder. The product, consisting of 1-*N*-2-hydroxyethylamino-3-bromoanthraquinone, 3-(3-bromoanthraquinon-1-yl)oxazolidin-2-one and 2-chloroethyl 3-bromoanthraquinon-1-ylcarbamate, was dissolved in benzene and chromatographed on alumina. 1-*N*-2-Hydroxyethylamino-3-bromoanthraquinone is most strongly adsorbed and 3-(3-bromoanthraquinon-1-yl)oxazolidin-2-one is more strongly adsorbed than 2-chloroethyl 3-bromoanthraquinon-1-ylcarbamate, which is gradually converted into 3-(3-bromoanthraquinon-1-yl)oxazolidin-2-one on alumina in the column. The red band, containing 1-*N*-2-hydroxylamino-3-bromoanthraquinone, was eluted by the use of ethanol. Yield, 0.15 g. of red needles, m. p. 213~214°C. It was recrystallized from toluene, giving red needles, m. p. 213~214°C.

Anal. Found: N, 4.08. Calcd. for $C_{16}H_{12}O_3NBr$: N, 4.11%.

The pale brown band, containing 3-(3-bromoanthraquinon-1-yl)oxazolidin-2-one, was eluted by the use of ethanol. Yield, 0.07 g. of pale brown crystalline powder, m. p. 215~229°C. It was recrystallized from ethanol, giving pale brown needles, m. p. 243~244°C.

Anal. Found: N, 3.73. Calcd. for $C_{17}H_{10}O_4NBr$: N, 3.76%.

The yellow elute, containing 2-chloroethyl 3-bromoanthraquinon-1-ylcarbamate, was evaporated for crystallization. Yield, 0.70 g. of yellow needles, m. p. 212~215°C.

3-(4-Bromoanthraquinon-1-yl)oxazolidin-2-one (IIIc) and 1-*N*-2-Hydroxyethylamino-4-bromoanthraquinone (IVc).—A mixture of 1.00 g. of finely powdered 2-chloroethyl 4-bromoanthraquinon-1-ylcarbamate (m. p. 201~202°C) and 30 g. of a 20% aqueous solution of potassium hydroxide was heated with vigorous stirring in a boiling water bath for 1 hr. After being diluted with water, the precipitate was collected, washed with water and dried. Yield, 0.88 g. of reddish brown powder. The product was treated as in the foregoing experiment. The red band, containing 1-*N*-2-hydroxyethylamino-4-bromoanthraquinone, was eluted by the use of ethanol. Yield, 0.45 g. of red needles, m. p. 176~177°C. It was recrystallized from ethanol, giving red needles, m. p. 181~182°C.

Anal. Found: N, 4.09. Calcd. for $C_{16}H_{12}O_3NBr$: N, 4.11%.

The pale brown band, containing 3-(4-bromoanthraquinon-1-yl)oxazolidin-2-one, was eluted by the use of ethanol. Yield, 0.20 g. of pale brown needles, m. p. 197~202°C. It was recrystallized from ethanol, giving pale brown needles, m. p. 208~209°C.

Anal. Found: N, 3.98. Calcd. for $C_{17}H_{10}O_4NBr$: N, 3.76%.

The yellow elute, containing 2-chloroethyl 4-bromoanthraquinon-1-yl-carbamate, was evaporated for crystallization. Yield, 0.10 g. of yellow needles, m. p. 184~190°C.

1-*N*-2-Hydroxyethylaminoanthraquinone (IVa).—A mixture of 0.50 g. of 2-chloroethyl 2-bromoanthraquinon-1-ylcarbamate (m. p. 191~192°C) and 15 g. of a 20% aqueous solution of potassium hydroxide was refluxed with vigorous stirring for 1 hr. After being diluted with water, the precipitate was collected, washed with water and dried. Yield, 0.40 g. of brownish red powder. It was treated as in the foregoing experiment. The red band, containing 1-*N*-2-hydroxyethylaminoanthraquinone, was eluted by the use of ethanol. Yield, 0.05 g. of red needles, m. p. 169~171°C. A mixed m. p. with authentic 1-*N*-2-hydroxyethylaminoanthraquinone[5] (m.p. 172°C) was 170~171°C.

3) Ger. Pat., 266,563 (1913).

4) K. Naiki, *J. Soc. Org. Syn. Chem., Japan* (*Yūki Gōsei Kagaku Kyōkaishi*), **14**, 84 (1954).

5) K. Naiki, ibid., **12**, 401 (1954).

The pale brown band, containing 3-(2-bromoanthraquinon-1-yl)oxazolidin-2-one, was eluted by the use of ethanol. Yield, 0.30 g. of pale brown plates, m. p. 265°C (decomp.).

Determination of the Proportion of the Constituents of the Reaction Product Obtained from 2-Chloroethyl Bromoanthraquinon-1-ylcarbamate and a 20% Aqueous Solution of Potassium Hydroxide.—A mixture of 0.20 g. of finely powdered 2-chloroethyl bromoanthraquinon-1-ylcarbamate and 6.0 g. of a 20% aqueous solution of potassium hydroxide was heated with vigorous stirring in a boiling water bath for 1 hr. After being diluted with water, the precipitate was colleted, washed with water and dried. Yield, 0.18 g. of brownish red powder from 2-chloroethyl 2-bromoanthraquinon-1-ylcarbamate; 0.18 g. of brownish red powder from 2-chloroethyl 3-bromoanthraquinon-1-ylcarbamate; 0.18 g. of brownish red powder from 2-chloroethyl 4-bromoanthraquinon-1-ylcarbamate. The proportion of the constituents of the products obtained above was determined by a Shimadzu QB-50 electrophotometer. Optical densities (D) of the toluene solution of the products are shown in Tables V—VII. It was found by simple calculation that the reaction product obtained from 2-chloroethyl 2-bromoanthraquinon-1-ylcarbamate contains 174 mg. of 3-(2-bromoanthraquinon-1-yl)oxazolidin-2-one; the product obtained from 2-chloroethyl 3-bromoanthraquinon-1-ylcarbamate contains 10 mg. of 3-(3-bromoanthraquinon-1-yl)oxazolidin-2-one, 106 mg. of 1-*N*-2-hydroxyethylamino-3-bromoanthraquinone and 57 mg. of 2-chloroethyl 3-bromoanthraquinon-1-ylcarbamate; the product obtained from 2-chloroethyl 4-bromoanthraquinon-1-ylcarbamate contains 46 mg. of 3-(4-bromoanthraquinon-1-yl)oxazolidin-2-one, 49 mg. of 1-*N*-2-hydroxyethylamino-4-bromoanthraquinone and 86 mg. of 2-chloroethyl 4-bromoanthraquinon-1-ylcarbamate.

Crystallization-sensitive Band of Polyvinyl Alcohol

By Hiroyuki TADOKORO

(Received June 11, 1959)

So-called "crystallization-sensitive bands" in the infrared absorption spectra have recently been found with various kinds of high polymers, such as polyethylene[1-5], polyethylene terephthalate[6-8], polychlorotrifluoroethylene[9], rubber hydrochloride[10], neoprene[11], polyamides[12-14], polyethylene glycol[15], polyvinylidene chloride[16], gutta percha[17], etc. Bands of this kind have at present interested many investigators as one of the powerful measures of the degree of crystallinity, or as a useful clue for the elucidation of the fine structure of the crystalline high polymers[12].

As to the 1141 cm^{-1} band in the infrared spectrum of polyvinyl alcohol (PVA), Elliott, Ambrose and Temple[18] reported that this band shows strong dichroism, and Nagai and his coworkers[19] found that this band becomes more and more intense as heat-treatment proceeds, up to the temperature at which the sample becomes colored. In a previous paper[20] they have concluded that degrees of crystallinity determined by density, sorption of water vapor and infrared absorption methods are approximately in linear relationship unless the thermal decomposition is considerable, and that the 1141 cm^{-1} band is recognized as a so-called crystallization-sensitive band. The nature of this band has been discussed by several authors as will be described below, but is still in a stage of speculation. Accordingly it is highly desirable that further new experimental facts should be accumulated. In the present paper the author will report the experimental results obtained on the proposed crystallization-sensitive band of PVA.

Experimental

a) Samples.—Film specimens were prepared by the same procedures as those described in the previous paper[21].

b) Measurements of the Pleochroism.—A doubly oriented specimen was prepared as follows. A uniaxially oriented PVA film* was rolled with a hot roller at about 90°C (to about four times its length compared with the original one) by holding it between two sheets of nylon 610**. In this procedure the direction of rolling was the same as that of stretching. The double orientation of the sample prepared in this way was ascertained by taking an X-ray Sauter photograph.

Fig. 1 shows schematically the relation between the cross-section perpendicular to the direction of rolling (the direction of the molecular chain axis) of the doubly oriented PVA film and the incident polarized infrared radiation***. As is shown in this figure, both the electric vector and the direction of propagation of the polarized infrared beam are perpendicular to the direction of rolling which is normal to the plane of the figure. The infrared spectra were observed at various angles of the incident beam, namely, 0, 45, 60, 70 and 75°. These infrared measurements were carried out by using a Perkin-Elmer Model 21 Infrared Spectrophotometer with AgCl polarizer.

*** It may be noticed that the angle β of the crystal lattice given in the text of Bunn's paper[22] is different from that of the figure. Fig. 1 in the present paper was reproduced according to the text of Bunn's paper.

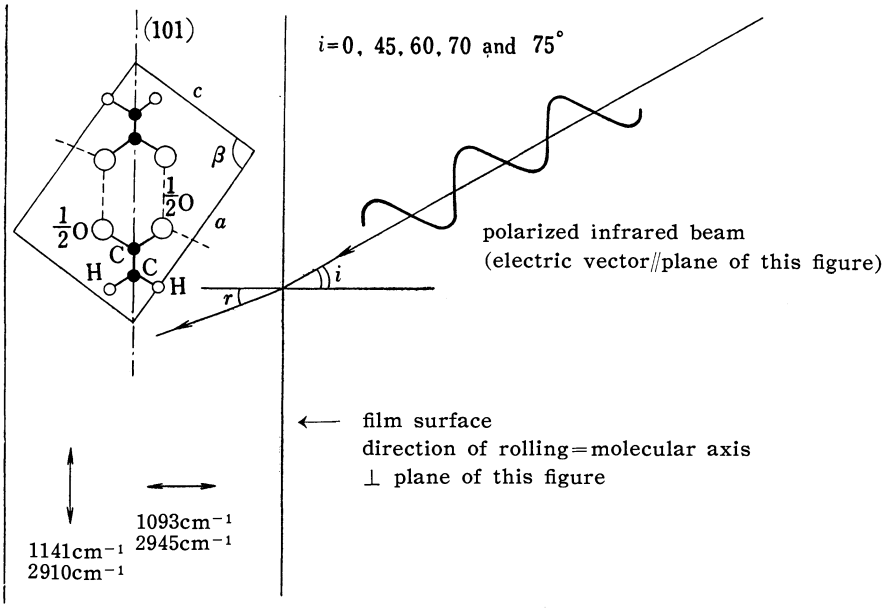

Fig. 1. The relation between the cross-section of the doubly oriented PVA film and the incident polarized infrared beam.

c) Formalization and Swelling in Water.—The PVA samples used for the experiments of formalization and swelling in water, were the same as samples I and III described in the previous papers[20,21]. The details of the experimental condition of the formalization was also given in the previous paper[22]. Those samples were also subjected to swelling in water at room temperature for 2 days. The degrees of swelling for samples I and III in this experimental condition are about 4.7 and 0.7, respectively. The infrared absorption spectra and X-ray diffraction photographs were taken by using a Hilger H800 Infrared Spectrophotometer and an ordinary Laue camera, respectively, before and after the treatment of formalization and swelling in water. During the X-ray measurements the swollen samples were held between aluminum foils in order to prevent the vaporization of water from the samples.

Results and Discussion

a) Pleochroism of the 1141 cm^{-1} Band.—When a polymer is stretched, the crystallites (or molecular chains) are so oriented that the molecular chain axes will be arranged parallel to the stretched direction, but the orientation of the molecular plane in the cross-section perpendicular to the direction of stretching remains completely random. Such a kind of orientation is called a "uniaxial orientation" and the usual fibers have more or less this kind of orientation. When the uniaxially oriented film is rolled in an adequate condition, a certain plane parallel to the molecular axis (in the case of PVA, the plane of carbon zigzag chain) is oriented further parallel to the rolled plane. Such a mode of orientation is called "double orientation". This possibility of double orientation was found for the first time by Bunn et al. on polyethylene[23] and nylon 66[24] by the use of X-ray diffraction, and afterwards this procedure was applied to the infrared studies of nylon 66, PVA and polyethylene by Ambrose and his coworkers[25] in the 3 μ region, and of polyethylene terephthalate by Miller and Willis in the 5~15 μ region[26].

The infrared studies of the doubly oriented PVA sample were carried out in the 3 μ region by Glatt et al.[27] and Elliott et al.[25] By the use of the pleochroism of the CH_2 stretching modes, they found that the plane of the carbon zigzag chain is parallel to the rolled plane of the film.

If the transition moment of an absorption band is perpendicular to the direction of rolling and exists in the rolled plane of

the doubly oriented film, the intensity of the band must be strongest when the angle of incidence, $i=0°$, and must be weaker as i increases (see Fig. 1). On the contrary, in the case when the direction of the transition moment is normal to the rolled plane, the intensity of the band should behave in the reverse manner. Utilizing this fact, it is possible to know the appoximate direction of the transition moment from the results of the absorption measurements on the doubly oriented sample.

The spectra taken with the doubly oriented specimen at different inclinations to the incident polarized beam is partly reproduced in Fig. 2. The relation between the optical density of the bands and the angle of incidence i is also given in Fig. 3.

From these measurements, it was possible to draw the following experimental conclusions: (1) the directions of the transition moments of the CH_2 symmetric stretching band at 2910 cm^{-1} and of the band at 1141 cm^{-1} are preferentially parallel to the surface of the rolled film, and (2) that of the CH_2 antisymmetric stretching band at 2945 cm^{-1} and of the band at 1093 cm^{-1} are more or less normal to the film surface, while (3) those of the other bands do not show any remarkable polarization**** (see Fig. 3).

Prior to the discussion on the nature of 1141 cm^{-1} band, it should be liked to make

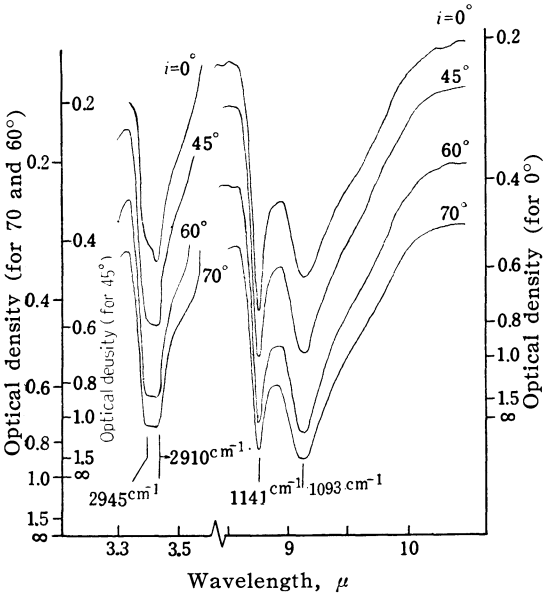

Fig. 2. Infrared spectra of doubly oriented PVA film taken at different inclinations (i means the angle of incidence).

a short comment on the modes of vibrations of CH_2 group. As shown in Fig. 4, there are two kinds of C-H stretching vibrations of the CH_2 group of PVA[25]. The transition moment of the symmetric stretching mode at 2910 cm^{-1} should be parallel to the bisector of the angle H-C-H, and that of the antisymmetric mode at 2945 cm^{-1} perpendicular to it. The results on the CH_2 stretching modes inform us of the fact that the plane of the zigzag chain of carbon atoms is parallel to the surface of the film, in agreement with the observation of Ambrose and his coworkers[25].

Krimm, Liang and Sutherland[27] assigned this 1141 cm^{-1} band to the stretching of

**** Of the other bands, 913, 849 and 835 cm^{-1} bands were found to have weak pleochroism by the infrared microspectroscopic measurements on a highly and doubly oriented PVA sample[28].

28) H. Tadokoro, S. Seki, I. Nitta and R. Yamadera, *J, Polymer Sci.*, 28, 244 (1958).

ether linkage produced by heat-treatment and they stated that the authors' conclusion[20] that this 1141 cm^{-1} band is the crystallization-sensitive band, is open to question. However, the experimental fact presented here together with the following sections b), c) and d) are believed to support the authors' conclusion.

b) Density Consideration. — Of the four samples (Table I) studied in the previous paper[20], sample IV subjected to heat-treatment in air at highest temperature (at 193°C for 2.5 min.) showed a deviation from the linear relationship between the optical density of the 1141 cm^{-1} band and the density of the samples, and this was interpreted as the result of a chemical change on the basis of the ultraviolet absorption spectrum. This deviation was pointed out by Krimm et al.[27] as one of the evidences for their objection to the authors' view[20]. Here, the author wishes to refer to the results of the authors' density measurements by the density gradient tube method on PVA films[29]. The samples for the measurements were treated in silicone oil for various durations at various temperatures as shown in the explanation of Fig. 5. The density of the samples was determined at 25°C by using the mixture of xylene and carbon tetrachloride as flotation medium. The ultraviolet absorption spectra of these samples were also measured with a Beckman Model DU Quartz Spectrophotometer in order to examine whether or not some chemical change occurs. Fig. 5 shows the correlation between the optical density of the 1141 cm^{-1} band and the density of the samples. As the thicknesses of the films were not the same in each case, the relative intensity of the 1141 cm^{-1} band of the samples was obtained by adjusting the intensities of the other bands to fit one another as closely as possible. This procedure was based upon the fact that the intensity of the 1141 cm^{-1} band is very sensitive to heat-treatment, whereas those of others are not. In Fig. 5 the samples denoted by △ show two strong absorption bands (280 and 330 mμ) in the ultraviolet region similarly to that for sample IV in the previous paper[20]. Twelve samples denoted by ○ clearly satisfy the linear relationship, while the samples denoted by △ deviate downwards from this. This fact indicates that this deviation is to be attributed to the thermal decomposition, and so it is less significant in the discussion of the crystallinity of PVA. Thus the observed linear relationship between the intensity of the 1141 cm^{-1} band and the density of the samples is in good agreement with the previous conclusion that the 1141 cm^{-1} band is a crystallization-sensitive band.

c) Formalization and Swelling in Water. — Fig. 6 shows infrared spectra of dry and swollen PVA samples I and III, and their partial formals. The curves below the swollen samples are for those of the drying process, and were measured successively about 7 min. after the measurement on the swollen sample was done, and so on. In the case of sample I, the 1141 cm^{-1} band was observed to disappear on formalization. On the other hand, for sample III the 1141 cm^{-1} band is not affected remarkably. The 1141 cm^{-1} band of the partial formal of sample III is identified with that of sample III by its similar behavior to deuteration, namely, this band shifts slightly to a shorter wavelength side on deuteration in both cases of PVA and the partial formal of

29) H. Tadokoro, K. Kôzai, S. Seki and I. Nitta, ibid., **26**, 379 (1957).

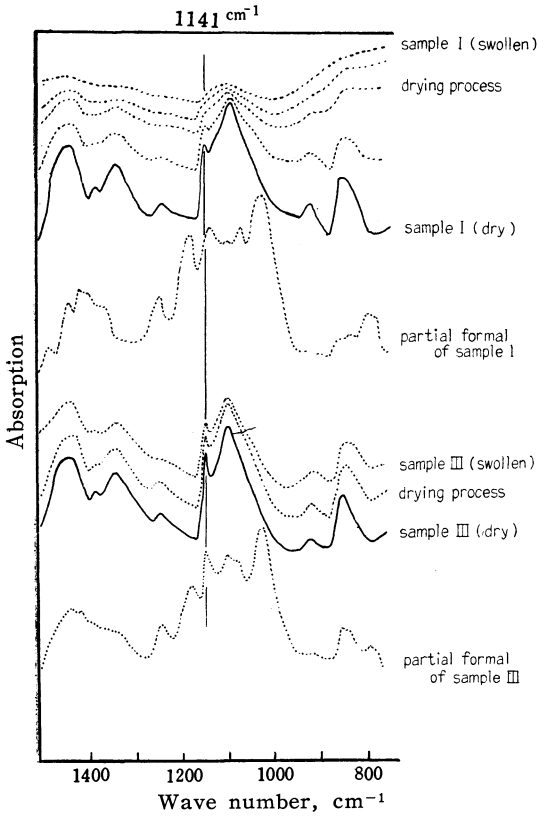

Fig. 6. Infrared spectra of dry and swollen PVA samples I and III and of their partial formals. The curves below the swollen one were measured successively ca. 7 min. after the measurement of the swollen sample was done, and so on.

sample III[30]. The 1141 cm^{-1} band is hardly found in the spectra of the swollen sample I, but appears progressively as the samples are being dried. On the other hand, in the case of sample III this band seems not to be influenced strongly by swelling.

Fig. 7 shows the X-ray photographs of the samples in Fig. 6. In Fig. 7, a) is for dried sample I, b) swollen sample I, c) partial formal of sample I, d) dried sample III, e) swollen sample III, and f) partial formal of sample III. The spots in the photographs a), b) and e) arise from the aluminum foil used for sealing the samples in order to prevent vaporization of water from the samples. The spots in c) and f) are due to the residual sodium sulfate being used for formalization. The haloes in b) and e) are due to liquid water. The diffraction rings due to PVA disappear in photograph b) of the swollen sample I, but the rings seem not to be affected remarkably in the case e) of sample III. In photograph c) of the partial formal of sample I, the intense diffraction rings of PVA give place to a new halo of smaller diffraction angle. This change corresponds to the increase of the apparent lattice distance from 4.51 to 4.72 Å.

The authors' previous observations by use of the infrared absorption and X-ray photographs indicate evidently that the 1141 cm^{-1} band behaves in parallel with the diffraction rings due to the crystalline region of PVA on formalization and swelling in water; namely, both the band and the rings disappear in the case of sample I, but are not affected remarkably in the case of sample III. This fact may also be considered to support the conclusion that this band is a crystallization-sensitive band.

d) On the Assignment of the 1141 cm^{-1} Band.—As to the assigment of the 1141 cm^{-1} band, various interpretations have already been proposed. Elliott and his coworkers[18] explained that this band is connected with the presence of the oxygen atom because of the lack of this band in the case of polyvinyl chloride. Nishino and his coworkers[31] as well as Nagai and his coworkers[32] considered this band to be associated with the formation of hydrogen bond. Krimm and his coworkers[27] suggested that this band may be the stretching of C–O–C linkage produced as the result of the heat-treatment of the sample.

It is considered to be necessary that the assignment of this band should satisfy the following experimental facts:

(1) The strongly perpendicular dichroism of this band (Fig. 4 of Ref. 21).

(2) The fact that the transition moment of the band is nearly parallel to the plane of the zigzag chain (Fig. 2).

(3) The parallel relationship between the intensity of the band and the density of the sample (Fig. 5).

(4) The location of the band in the observed spectrum.

(5) The only slight shift of this band on deuteration (about 7 cm^{-1} or 0.994 in wave number ratio, to higher frequency).

(6) The crystal structure of this substance[22], etc.

As the shift of this band on deuteration is so small, this band seems to be not

30) See Fig. 2 of Ref. 21.

directly associated with the motion of the hydrogen atom of hydroxyl group such as O–H deformation. The assignment of this band to the stretching of C–O–C linkage does not seem to be able to explain the experimental facts mentioned above [sections a), b) and c)] and the fact that this band exists distinctly even in the spectrum of the sample with no heat-treatment (such a sample is hardly considered to contain ether linkage). In this respect, Haas[33] has recently concluded that (1) the suggestion by Krimm et al.[27] relating this band to C–O–C vibration must be rejected, and (2) a hypothesis which relates the band with some vibrational modes associated only with crystallization is favored.

At the present stage it is still difficult to make the final assignment of this band from the present experimental data, but this band is undoubtedly due to the crystalline arrangements of the molecules and is thought to be intimately related to the regular repetition of the *trans*-configuration of the zigzag chains. For further elucidation of the nature of this band the total syntheses of $-(-CD_2-\underset{\underset{OH}{|}}{CD}-)_p-$ are now being carried out. (D)

The author wishes to express his gratitude to Professor I. Nitta and Assistant Professor S. Seki, under whose guidance this research was carried out. He also expresses his sincere thanks to Professor T. Shimanouchi of the University of Tokyo for helpful advice and criticism, to Dr. T. Kanzawa and Mr. H. Kamio of Takeda Pharmaceutical Industries, Ltd. for preparing part of the charts of the infrared absorption spectra, and to Kurashiki Rayon Co., Ltd. for kindly giving him the PVA samples.

Relations between Electronic Absorption Spectra and Spatial Configurations of Conjugated Systems. I. Biphenyl

By Hiroshi SUZUKI

(Received June 12, 1959)

A twist of a "single" bond in a conjugated system caused by steric effects affects the electronic absorption spectrum of the molecule. Since the interaction of the π-orbitals across the bond and hence the conjugation of the system are maximal when the system is planar, as is well known, any deviation from the planarity of the molecular configuration reduces the degree of conjugation to the corresponding extent, and consequently alters the spectral feature.

The relation between the spatial configuration and the electronic absorption spectrum of a conjugated system may conveniently be divided into the following three kinds; (A) that between the spatial configuration and the shape of the absorption curve (mainly an appearance of fine structure), (B) that between the spatial configuration and the intensity of the conjugation band, and (C) that between the spatial configuration and the position of the conjugation band.

Concerning the relation of A, Merkel and Wiegand[1] proposed the hypothesis that the appearance of fine structure depended on the planarity of the molecular configuration. Thus, the spectra of fluorene and of carbazole, for example, which are thought to be planar, and also that of biphenyl in the crystalline state exhibit fine structures. On the basis of this hypothesis, Merkel and Wiegand suggested that the lack of structure in the spectrum of biphenyl in solution might indicate the non-planarity of the molecule in solution. However, this hypothesis has been denied by Kortüm and Dreesen[2]. According to their opinion, the appearance of fine structure does not depend on planarity of the molecular configuration, but depends rather on its rigidity. However, whether there is an unconditional relation between the molecular configuration and the appearance of fine structure or not has not yet been clarified, since this problem is considerably complicated, and since an appearance of fine structure depends on techniques of measurement, on solvents, etc.

A change in spatial configuration about a "single" bond in a conjugated system has conventionally been thought to affect the position and the intensity of the conjugation band in any of the following three ways, depending on the degree of deviation from the coplanarity[3]: (1) No change in the position of the absorption maximum but a decrease in the intensity. This effect is caused by relatively small twists. (2) A shift of the absorption maximum to shorter wavelengths in addition to a decrease in the intensity. This effect is caused by larger twists than the first effect. (3) When the twist is large enough to eliminate almost completely the $\pi-\pi$ interaction across the twisted bond, the spectrum is similar to the sum of the spectra of the component parts of the molecule on either side of the bond.

On the basis of such a classification, Braude and his coworker[4] assumed the following relation between the angle of twist θ and the molar extinction coefficient ε of the absorption maximum of the conjugation band for the cases of type 1, namely the cases in which the steric effect changes the absorption intensity alone;

$$\varepsilon/\varepsilon_0 = \cos^2\theta$$

where ε_0 is the molar extinction coefficient of the corresponding absorption maximum of the planar reference compound. Braude and his coworkers applied this postulated relation to some sterically hindered derivatives of benzaldehyde[4], of acetophenone[4], of styrene[5], and of biphenyl[6],

and stated that the satisfactory value of the angle of twist θ was obtained for each of the compounds. However, it can not be recognized that only a change of the intensity of the conjugation band occurs without any significant displacement of the position in each of the systems of compounds cited by Braude and others, in spite of their assumption. And further, it seems that the derivation of their equation and its basic theory are open to considerable criticism.

However, independently from Braude and others' works, a relation bearing a close similarity to the one mentioned above has been proposed. Thus, Klevens and Platt[7] have stated that the oscillator strength of the conjugation band is linearly related to the van der Waals radius of the interfering group and to the $\cos^2$ of the calculated angle of the C–N bond twist in some ortho-substituted dimethylanilines. In addition, Beale and Roe[8] have found that the changes in oscillator strength of the conjugation band for substitution with methyl groups in stilbene are additive, and that the ortho-substitution reduces the oscillator strength.

Regarding the relation of C, that is, the relation between the spatial configuration of a molecule and the position of the conjugation band, the following examples may be cited: *trans*-Stilbene has the conjugation band at about 294 mμ, which is progressively shifted toward shorter wavelengths with the concurrent decreases in the intensity as one, and then two methyl groups are introduced into the α- and α'-positions of the molecule[9,10]. Biphenyl has the conjugation band at about 247 mμ, which is markedly shifted toward shorter wavelengths in the spectrum of o,o'-dimethylbiphenyl[11]. Further, bimesityl does not exhibit the characteristic conjugation band, but absorbs as two molecules of mesitylene[11,12]. These hypsochromic wavelength displacements are explained in terms of the steric interference of the substituents which prevents the molecule from assuming a coplanar configuration.

Although these phenomena had been known for a considerably long time as the references cited show, no theoretical explanation had been established satisfactorily, and consequently, the quantitative relation between the dimensions of the spatial configuration of the molecule, especially the angle of twist, and the position of the conjugation band had not been clarified[13]. Thus, the prevailing explanations were rather unsatisfactory or unreasonable ones such as, for example, the following: The appearance of the conjugation band is related to the conjugation, and therefore requires the coplanarity of the molecular configuration. On the basis of such an assumption, the hypsochromic shifts observed in, for example, the spectra of α- and α,α'-substituted stilbenes as well as in that of *cis*-stilbene as compared with that of *trans*-stilbene needed to be explained by a rather implausible hypothesis based on a concept of "partial chromophore"[14]. The alternative prevailing explanation was as follows: The extent of the contribution of the dipolar structure in the electronic excited state is larger than in the ground state. Since the dipolar structure requires a coplanarity of the molecular configuration, steric hindrance to such a configuration will raise the potential energy of the excited state more than that of the ground state, and hence, the transition energy will be increased[15].

Previously, the present author calculated the quantitative relations between the degree of deviation from coplanarity of the molecular configuration and the position of the conjugation band as well as the extent of conjugation for stilbenes[16] and also for biphenyls[17,18], by the method based on the simple LCAO molecular orbital method. By the results of the calculations he clarified the fact that the perfect coplanarity is not prerequisite to the occurrence of conjugation and to the appearance of the characteristic conjugation band, and that the conjugation band is gradually shifted toward shorter wavelengths as the degree of deviation from the coplanarity increases. Further he showed that the values of the angle of

twist as well as the effective resonance energy can be satisfactorily computed from the observed position of the conjugation band.

Although these previous treatments seem fairly satisfactory in principle, it was found afterwards that they included an inadequate assumption. Thus, the choice of the absorption maximum corresponding to the planar molecule of biphenyl in the previous paper[17] was found to be probably inadequate. In addition, it seems that there are some aspects which were not given adequate consideration in the previous papers. Thus, first, the spectrum of *trans*-stilbene in solution was assumed to be that of the planar molecule of the compound without sufficient consideration. Strictly speaking, there is no evidence to indicate that *trans*-stilbene in the solution state has the planar configuration. Secondly, the electronic bathochromic effects of substituents such as methyl groups were ignored, and this ignoring seems to be an over-simplification. These electronic effects of substituents should not be ignored particularly when the substituents are on the benzene nuclei. Lastly, the position of absorption maximum varies more or less with the solvent, so the solvent effect should also be taken into account.

In this series of papers, the erroneous assumption mentioned above being corrected, and the aspects which were not given sufficient consideration being re-examined, a method similar to the previous one is applied to the greater range of conjugated compounds, and the relation between the spatial configuration of the molecule and the electronic absorption spectrum, especially the position of the conjugation band, is discussed more comprehensively and more fully. The relation of the intensity of the band and that of the appearance of fine structure to the spatial configuration of the molecule will also be referred to at suitable places in this series.

The present series is concerned mainly with the spatial configurations and the electronic states of the molecules in solution. This subject is certain to be very important in studying the relations between molecular structures and reactivities of organic compounds. In this connection, it seems that there is no precise and direct means to determine the spatial configurations of molecules in solution, such as the X-ray analysis for the crystalline states or the electron diffraction analysis for the vapor states. Therefore, information from the analysis of the electonic absorption spectra is conceivably important and useful in this respect. From this point of view, in this series the spatial configurations of the compounds inferred from the electronic absorption spectra are correlated as much as possible with the other properties, especially the reactivities of the compounds.

In this part of series, the ultraviolet absorption spectra of biphenyl in the various states, i.e. the crystalline, the solution, and the vapor state, and their relations to the spatial configurations of the molecule are discussed in detail as the basis of the present treatment.

Calculation

Although the procedures of calculation were already outlined in the previous papers[16,17], those for biphenyl are shown below in somewhat more refined form.

(1) Correlation of a Parameter for the Resonance Integral for the Pivot Bond with the Bond Length and the Interplanar Angle. — The π—π resonance integral for the 1-1′ bond, namely the co-annular or pivot bond, is denoted by $\mu\beta$, in which β is the π—π resonance integral for the C-C bond in the benzene ring and μ is a parameter by which allowance is made for changes of the resonance integral with the bond length and the angle of twist, i.e. the angle between the planes of the two benzene rings, which is subsequently referred to also as the interplanar angle. (The symbol α in the previous papers was replaced by μ.)

The π—π resonance integral for C-C bond can be taken to be approximately proportional to the π—π overlap integral[19], and, as easily verified, the π—π overlap integral $S(R, \theta)$ in the case where the bond length is R and the angle of twist is θ is equal to the overlap integral $S(R, 0°)$ in the case where the bond length is R and the angle of twist is 0°, multiplied by $\cos\theta$. Accordingly, the parameter μ can approximately be expressed by the following equation;

$$\mu = S(R, 0°)\cos\theta / S(1.39, 0°) \qquad (1)$$

where $S(1.39, 0°)$ represents the π—π overlap integral for the C-C bond in the benzene ring, the length of which is 1.39 Å.

The relation between the bond length R and the corresponding overlap integral $S(R, 0°)$ can be obtained from Mulliken's Tables[20]. According to results of calculation based on the tables, the values of $S(R, 0°)$ and hence of $S(R, 0°)/S(1.39, 0°)$ vary linearly with R, at least in the range of R

19) (a) R. S. Mulliken, C. A. Rieke and W. G. Brown, *J. Am. Chem. Soc.*, **63**, 41 (1941). (b) J. van Dranen and J. A. A. Ketelaar, *J. Chem. Phys.*, **17**, 1338 (1949).
20) R. S. Mulliken, C. A. Rieke, D. Orloff and H. Orloff, ibid., **17**, 1248 (1949).

between 1.44 and 1.54 Å, and the relations can approximately be expressed as follows:

$$S(R,0°)=0.1920+(1.54-R)\times 0.36 \quad (2)$$

$$S(R,0°)/S(1.39,0°)=0.77108+(1.54-R)\times 1.4458 \quad (3)$$

where the value of $S(1.39,0°)$ is 0.249.

According to the result of X-ray crystal analysis by Dhar[21], R is 1.48 Å and θ is 0° in biphenyl in the crystalline state. Consequently, the corresponding value of μ is evaluated at 0.858.

Any deviation from the coplanar configuration must inevitably reduce the π—π interaction across the co-annular bond to the corresponding extent, and consequently must be accompanied by change in the bond length. Thus, the value of R will vary from 1.48 Å in the planar biphenyl molecule to 1.54 Å, i. e. the length of the normal C-C single bond, as θ varies from 0° to 90°. Therefore, the following relation may tentatively be assumed between R and θ:

$$\{S(R,0°)-S(1.54,0°)\}/\{S(1.48,0°)-S(1.54,0°)\}=S(R,\theta)/S(R,0°)=\cos\theta \quad (4)$$

Hence, evidently from Eq. 2,

$$R=1.54-(1.54-1.48)\times\cos\theta \quad (5)$$

Then, from Eqs. 1 and 4 one obtains;

$$\mu=\cos\theta\times S(1.54,0°)/S(1.39,0°)+\cos^2\theta\times\{S(1.48,0°)/S(1.39,0°)-S(1.54,0°)/S(1.39,0°)\} \quad (6)$$

And further, from Eqs. 3 and 6

$$\mu=\cos\theta\times 0.77108+\cos^2\theta\times(1.54-1.48)\times 1.4458 \quad (7)$$

It is evident that the value of μ becomes gradually smaller as the value of θ becomes larger and that μ becomes 0 when θ is 90°.

(2) Solution of the Secular Equation for the Determination of the Molecular Orbitals. — By solving the secular equation for the determination of the molecular orbitals as linear combinations of $2p\pi$ atomic orbitals, one can obtain the values of energies of the molecular orbital corresponding to the value of the parameter μ. Consequently, the values of the extra-resonance energy (subsequently referred to as *R.E.*), of the coefficients of the $2p\pi$ atomic orbitals in the molecular orbital functions, and of the quantities such as the π-bond orders corresponding to the molecular configuration prescribed by the value of μ can also be obtained by the usual procedures[22].

The biphenyl molecule can be considered as belonging to the symmetry group D_2. Then, the highest occupied π-orbital (π_1) in the biphenyl molecule belongs to the representation B_3, and coincides with the φ_1 orbital in benzene when μ is 0. On the other hand, the lowest vacant π-orbital (π_1*) belongs to A_1, and coincides with the φ_2 orbital in benzene when μ is 0. (The notation for orbitals in benzene is according to Sklar[23].) Transitions from orbitals belonging to B_2 to those belonging to A_1 are allowed by absorption of light polarized along the direction of the long-axis of the molecule. Accordingly, the energy difference (referred to as ΔE_A) between the lowest vacant orbital π_1* and the highest occupied orbital π_1 is considered to be the transition energy corresponding to the conjugation band (the A-band) in the spectrum of biphenyl.

In addition to the eight orbitals belonging to B_1 and B_3, energies of which vary with μ, there are two sets of doubly degenerate orbitals belonging to A_1 and B_2, energies of which do not vary with μ. These orbitals may be considered as ones localized in the benzene rings. Thus, the two of these orbitals whose energy is $+\beta$ (φ) correspond to the φ_{-1} orbital in benzene, and another two whose energy is $-\beta$ (φ*) correspond to the φ_{-2} orbital in benzene. In other words, it can be considered that one orbital of each of the two sets of doubly degenerate orbitals in each benzene ring interacts with the neighboring π-orbitals to give whole-molecular orbitals when two benzene rings are linked with each other, whereas the other orbital of each set remains isolated. The intense bands observed at about 200 mμ in the spectra of biphenyl and its related compounds are presumably due to transitions between the orbitals localized in the benzene rings.

The results of calculations are shown in Table I. In this table, $\Delta E_A(-\beta)$ and $R.E.(-\beta)$ are values obtained by ignoring the π—π overlap integral, and $\Delta E_A(-\gamma)$ and $R.E.(-\gamma)$ are values obtained by taking the overlap integral into account, assuming the value of the overlap integral for the C-C bond in benzene as 0.25. The symbol $p_{1-1'}$ represents the π-bond order of the 1-1' bond.

It is evident that the values of ΔE_A increase as the value of μ decreases, and agree with the values for benzene when μ is 0. This means that the conjugation band is gradually shifted toward shorter wavelengths as the value of μ decreases, and therefore as the value of θ increases, and that the band will coincide with that of benzene when μ is 0 and therefore θ is 90°.

It appears that there is no simple quantitative relation between μ and ΔE_A, or between ΔE_A and *R.E.* On the other hand, examination of the data in Table I reveals that *R.E.* $(-\beta)$ is almost completely proportional to μ^2 and can approximately be expressed as $0.385\times\mu^2$, a fact which coincides with the qualitative generalization by Dewar[24]. In addition, $p_{1-1'}$ is roughly proportional to μ and can roughly be expressed as

$0.375\times\mu$. The value of $p_{1-1'}$ is 0.319 when μ is 0.858.

(3) Correlation of the Calculated Transition Energy with the Observed Position of the Conjugation Band. — The present calculations are concerned with the vertical excitations according to the Franck-Condon principle, namely, to electron jumps without change in the configuration of the molecular skeleton.

In general, the most probable spatial configuration of a conjugated compound and its stability are believed to be determined mainly by the combined effect of the resonance stabilization and the steric repulsion. The steric repulsion will raise the potential energy of the molecule in the ground state. Accordingly, in the problem which is concerned with, for example, the difference of stability between the geometrical isomers, the steric repulsion energy must be taken into account in principle.

On the other hand, since the spatial configuration of the molecule is assumed not to change between in the ground state and in the electronic excited state, the magnitudes of the steric repulsion energies involved in both the states may be the same at least approximately, and therefore, it seems that the electronic transition energy must not contain any significant contribution of the steric repulsion energy itself, and must be determined as a function of the spatial configuration of the molecule alone. That is, the values of ΔE_A shown in Table I may be correlated directly with the observed wave numbers of the absorption maxima of the conjugation bands. (In this connection, the interpretations by Braude and others on the relation between the steric effect and the position of the conjugation band are highly questionable. This will be referred to in detail in later parts of this series.)

The correlation of the calculated transition energy ΔE_A with the observed position ν_A (in wave number) of the conjugation band is accomplished as follows. When there are two compounds whose spatial configurations are already known and whose corresponding electronic absorption spectra are already observed, the linear relation of ΔE_A to ν_A is assumed between the two points prescribed by the two reference compounds.

As one of the two reference compounds, the planar compound is chosen in most cases. This is subsequently referred to as the longer-wavelength-side reference compound. The corresponding ΔE_A and ν_A are denoted by ΔE_L and ν_L, respectively. On the other hand, as the shorter-wavelength-side reference compound the one which corresponds to the value 0 of the parameter μ or the analogous one is chosen in most cases. The corresponding ΔE_A and ν_A are denoted by ΔE_S and ν_S, respectively. Then, the value of ΔE_A for a given compound of the type under consideration is obtained from the observed value of ν_A by the following equation:

$$\Delta E_A = \Delta E_S - (\Delta E_S - \Delta E_L)(\nu_S - \nu_A)/(\nu_S - \nu_L) \quad (8)$$

Consequently, the corresponding value of μ and then the values of θ, R, $R.E.$, etc. can be calculated in turn.

In the case of biphenyl, biphenyl in the crystalline state is chosen as the longer-wavelength-side reference compound. In this molecule, θ is 0°, and R is 1.48 Å as mentioned already, and consequently, the corresponding values of μ and of ΔE_A (i.e. ΔE_L) are computed to be 0.858 and $1.482(-\beta)$, respectively. On the other hand, as the shorter-wavelength-side reference compound, benzene is chosen, which corresponds to the case where the values of μ and of ΔE_A (i.e. ΔE_S) are 0 and $2(-\beta)$, respectively. However, it requires sufficient consideration to determine what values of ν are to be taken as ν_L and ν_S, corresponding to ΔE_L and ΔE_S, respectively. Therefore, these choices of the references are discussed in detail in the next sections.

The Shorter-wavelength-side Reference

When the value of the parameter μ is 0, the energy levels in biphenyl coincide with those in benzene, and the value of ΔE_A (i.e. ΔE_S) is $2(-\beta)$. According to Platt[25], the "center of gravity of singlets", 48000 cm^{-1} in the absorption spectrum of benzene, that is, the weighted mean of the energies of the three singlet-singlet transitions at 48000 cm^{-1} (208.3 mμ, B_{1u}), at 38200 cm^{-1} (261.8 mμ, B_{2u}), and at 53000 cm^{-1} (188.7 mμ, E_{1u}) measured in solution[26], corresponds to the energy

25) J. R. Platt, *J. Chem. Phys.*, 18, 1168 (1950).
26) H. B. Klevens and J. R. Platt, ibid., 17, 470 (1949).

difference of $2(-\beta)$ calculated by the molecular orbital method of the same order of approximation as the present treatment. Therefore, the value of 48000 cm^{-1} was taken as ν_S in the previous papers.

The same assumption is used also in the present treatment, since this assumption seems to be supported by the following facts. First, Dewar[27] has used the value of 208 mμ for the wavelength of the band of benzene in his application of the NBMO method to spectra of catacondensed aromatic compounds. Secondly, Dale[28] has used a value of about 205 mμ for benzene in his attempt to correlate the wavelength positions of the main bands of linear polyphenyls with the numbers of linked chain benzene nuclei. Furthermore, according to Wenzel[29], the intense conjugation band at about 250 mμ in the spectrum of biphenyl corresponds to the band at about 210 mμ of benzene. All these values for benzene are closely similar to the "center of gravity of singlets" mentioned above.

The Longer-wavelength-side Reference

Spectra of Biphenyl in the Crystalline State.— The value of ΔE_A (i.e. ΔE_L), $1.482(-\beta)$, calculated by using the values of the dimensions of the spatial configuration of biphenyl in the crystalline state is to correspond to the wave number of the absorption maximum of the conjugation band of the "isolated" planar molecule of biphenyl. The spectrum of biphenyl in solution has the conjugation band at about 247 mμ, but this band should not be taken as the band corresponding to ΔE_L, because there is no evidence to indicate that the molecule of biphenyl in solution would have the same spatial configuration as in the crystalline state. In the earlier paper[17], the wave number 36306 cm^{-1} of the first absorption maximum in the spectrum of biphenyl in the crystalline state measured by Deb[30] was taken as ν_L, i.e. the wave number corresponding to ΔE_L. According to Deb, the characteristic (conjugation) band in the spectrum of biphenyl in the liquid state is split up into two broad bands at 36306 cm^{-1} (2754 Å) and at 37386 cm^{-1} (2675 Å) in the spectrum of the solid at 30°C, and the band at 36306 cm^{-1} was presumed to be the intrinsic band. This assignment of the band is evidently inadequate, in view of the studies by Wenzel[29] and by Dale[28].

Wenzel[29] has proposed the hypothesis that the intense transition at about 250 mμ in biphenyl in solution is interpreted as a superposition of a strong and a weak transition corresponding to the 210 mμ and the 260 mμ transition in benzene, respectively. According to her, the weak transition is hidden by the strong one in the spectrum of biphenyl in solution. From comparison of spectra of some 3- and 3,3'-substituted biphenyl derivatives with pairs of spectra of benzene and the correspondingly substituted benzene derivatives and with pairs of spectra of naphthalene and its correspondingly substituted derivatives, she has inferred that the "hidden transition" of biphenyl may be located at about 275 mμ or at about 271 mμ, and that the intensity of this transition may be of the same order as the weak transitions in benzene and naphthalene.

The existence of the hidden transition in biphenyl has experimentally been corroborated by Dale[28]. He has measured the spectrum of biphenyl in the crystalline state by the pressed KCl-disk technique, and found that the spectrum is very similar to the solution spectrum. Thus, the spectrum of the solid showed an intense, structureless band with a maximum at 253 mμ, which is to be compared with the band at about 246 mμ in the solution spectrum. On the other hand, the spectra measured on thin films of solidified melt, on those by evaporation of a thin layer of solution, and on those of sublimed crystals of biphenyl revealed a band showing fine structure with a maximum at about 275 mμ. The molar extinction coefficient of the absorption maximum has been very roughly estimated to be about 1000~2000. In addition, whereas the spectra of *p*-terphenyl and of *p,p'*-quaterphenyl either in solution or in the crystalline states measured by the pressed KCl-disk technique showed the intense bands without structure at considerably longer wavelengths than that of biphenyl, the spectra of solidified melts or sublimed crystals of these compounds showed bands with structure at about 275 mμ, similarly to the corresponding one of biphenyl. These weak bands at about 275 mμ are probably due to the transversely polarized transitions normally hidden by the stronger conjugation bands. This revelation of the hidden transitions in biphenyl and *p*-polyphenyls has been interpreted as follows. Since the incident light is almost parallel to the long molecular axes in the thin films of crystals prepared by solidification of melts, by evaporation of solutions, or by sublimation, owing to the orientation of molecules in these samples, the conjugation bands due to transitions polarized along the long molecular axes are so reduced that the weak hidden transitions are revealed.

In view of the evidences mentioned above, the band at about 275 mμ in the spectrum of the solid biphenyl measured by Deb[30] is probably the "hidden transition". In this connection, Merkel and Wiegand[1] reported that the spectrum of biphenyl in the crystalline state exhibited a band showing fine structure in sharp contrast with that in the solution, and assumed this fact as one of the bases for their hypothesis concerning the relation between the appearance of fine structure and the coplanarity of the molecular configuration. Probably they compared impertinently the "hidden transition" revealed in the solid spectrum with the conjugation band in the solution spectrum.

Besides the bands at about 275 mμ and at 267 mμ mentioned above, Deb[30] found a very feeble band at about 290 mμ with structure in spectra

of biphenyl measured on the liquid films and on the solid films of larger thickness. This feeble band was resolved as sharp absorption peaks when the temperature of the solid film was reduced to −180°C. Deb has assumed that this feeble band at about 290 mμ belongs to a system different from the one to which the bands at 275 mμ and at 267 mμ belong, and that this feeble system is due to the transition in one of the two benzene rings in biphenyl when the second one is in the excited state. Perhaps the same feeble band at about 290 mμ was recently found by Coffman and McClure[31] and by Broude and his collaborators[32] in the spectrum of a single crystal of biphenyl at 20°K with polarized light, and also by Kanda[33] in the spectrum of the solution at low temperature. In addition, biphenyl appears to have a very feeble band at longer wavelengths than 300 mμ. Although the assignments of these feeble bands have not yet been established with certainty, it may be safe to say that these bands are to be excluded from the present consideration.

Although it may be somewhat open to criticism that the state of biphenyl in the pressed KCl-disk is the same as that in the crystal, it is assumed to be so. Then, from the above considerations, the intense band detected by the pressed KCl-disk technique may be taken as the conjugation band of the planar molecule of biphenyl in the crystalline state. Consequently, one would assume that the wave number 39526 cm^{-1} (253 mμ) of the position of the maximum might be ν_L, corresponding to the calculated transition energy $1.482(-\beta)$, ΔE_L, for the planar molecule of biphenyl. However, there is the possibility that interactions between the molecules in the crystal may affect the energy levels in the molecule and consequently the absorption spectrum of the compound. Accordingly, although such intermolecular interactions are supposed to be weak in nonpolar aromatic crystals[34], it is necessary to make allowances for this effect in the choice of the references for the correlation between ν_A and ΔE_A.

Normal Red-shift.—According to the results of measurements by Dale[28], the absorption maximum in the spectrum measured by the pressed KCl-disk technique is always at longer wavelengths than the corresponding one in the spectrum of the solution. The magnitude of the wavelength displacement of a band of a rigid molecule due to the change of the state from the solution in hexane to the solid state, which was referred to as the "normal red-shift", was found to vary regularly with the wavelength of the corresponding band, by measuring the spectra of naphthalene and of anthracene in both the states. Thus, the normal red-shift increases regularly from about 2 mμ at 220 mμ to 8 mμ at 300 mμ, and to 19 mμ at 400 mμ, with increasing wavelength of the position of the band. This normal red-shift is supposed to be due to the effect of interactions between the molecules in the crystals. From the analogy of the solvent effect[35] and of the Davydov effect[36-41] in a single crystal, it would be expected that the magnitude of the normal red-shift might be related to the intensity of the band. But, in fact, it is not so. The band cited by Dale includes the bands of considerably different intensity from each other, and no regularity between the magnitude of the normal red-shift and the intensity of the band can be found. Thus, the logarithms of the molar extinction coefficients of the bands of naphthalene at about 275 mμ and at about 221 mμ are 3.82 and 5.02, respectively[42], and the oscillator strengths of these bands are 0.11 and 1.7, respectively[41]. The logarithms of the molar extinction coefficients of the bands of anthracene at about 376 mμ and at about 252 mμ are 3.88 and 5.25, respectively[42], and the oscillator strengths of these bands are 0.1 and 2.3, respectively[37]. And further, according to Craig and others, the band of naphthalene[41] at about 275 mμ and that of anthracene[37-39] at about 380 mμ are assigned as "short-axis transitions", and that of naphthalene at about 220 mμ and that of anthracene at about 250 mμ are assigned as "long-axis transitions". From these considerations, the regular relation between the magnitude of the normal red-shift and the wavelength of the position of the absorption band seems to hold regardless of kinds of compounds, of characters of bands, and of intensities of bands. Accordingly, by application of this relation, the magnitude of the normal red-shift corresponding to the wavelength 253 mμ of the maximum of the conjugation band in the spectrum of biphenyl in the crystalline state (measured by the pressed KCl-disk technique) may be estimated to be about 3.5 mμ. (The oscillator strength of the conjugation band of biphenyl is 0.411 in solution, according to Almasy and Laemmel[43].)

On the other hand, according to the results of the measurements by the present author, which will be reported in detail in Part V of this series, the intense bands at 294.1 mμ and at 306.9 mμ in the spectrum of *trans*-stilbene in *n*-heptane are shifted toward longer wavelengths by about 4.5 mμ and by about 5.5 mμ, respectively, in the spectrum measured by the pressed KCl-disk

	λ_{max}	ε	λ_{max}	ε	λ_{max}	ε
n-Heptane	247.0	16450	(205.0)	41400	200.5	45100
Methanol	247.2	17300	—		—	
95% Ethanol	247.7	18050	(204.5)	42000	201.5	43000
Chloroform	249.5	16700	—		—	
Carbon tetrachloride	256.5	16450	—		—	

Wavelengths (mμ) in parentheses denote inflections.

technique. (The oscillator strength of the conjugation band in the spectrum of *trans*-stilbene in solution is 0.745, according to Beale and Roe[8].) These values, probably corresponding to the normal red-shifts of the conjugation band of *trans*-stilbene, are considerably smaller than those (about 8 and 9 mμ) anticipated from the relation mentioned above between the shift and the position of the band.

The crystals of naphthalene[41], anthracene[37], biphenyl[44], and *trans*-stilbene[44,45] all belong to the monoclinic space group C_{2h}^5, and bear a certain similarity to each other. However, whereas in each of these compounds except for the last the number of molecules in a unit cell is 2, in the crystal of *trans*-stilbene the number of molecules in a unit cell is 4. On the other hand, the molecular structure of biphenyl may be said to have greater similarity to that of *trans*-stilbene than to those of naphthalene and anthracene. From such considerations, it seems that there may be a possibility that the magnitude of the normal red-shift of the conjugation band of biphenyl is smaller than the value estimated above and is probably about 2 mμ, on the analogy of the case of *trans*-stilbene.

Since the estimation of the magnitude of the normal red-shift of the conjugation band of the "planar" molecule of biphenyl, at any rate, includes inevitable uncertainty, the alternative values of 3.5 and 2 mμ are assumed in the present calculation. After being corrected for the normal red-shift by these values, the position of the absorption maximum of the conjugation band of the "isolated" planar biphenyl molecule is assumed to be 249.5 mμ (a) or alternatively 251 mμ (b), and the corresponding wave numbers, (a) 40080 cm^{-1} and (b) 39841 cm^{-1}, are assumed to be ν_L.

The difference between the above assumed position of the conjugation band of the "isolated" planar biphenyl molecule, 249.5 or 251 mμ, and the corresponding one of biphenyl in solution, 247 mμ (in *n*-heptane, the present work) or 246 mμ (in hexane[28]), is assumed to be due to the difference in the most probable spatial configuration of the molecule between in the solution state and in the crystalline state.

Spectra of Biphenyl in Solution

The ultraviolet absorption spectra of biphenyl in various solvents measured by the present author on a Cary recording spectrophotometer Model 14 M-50 are shown in Table II and Fig. 1. In Fig. 1, the spectra of biphenyl in the crystalline state and in the vapor state found in the literature are also shown for comparison.

The band represented as A-band in Table II is the conjugation band (the so-called K-band). The C-band is the one presumably due to transitions between the orbitals localized on each of the benzene rings, as already mentioned. The B-band (inflection) is probably the vestigial band due to transitions from the highest

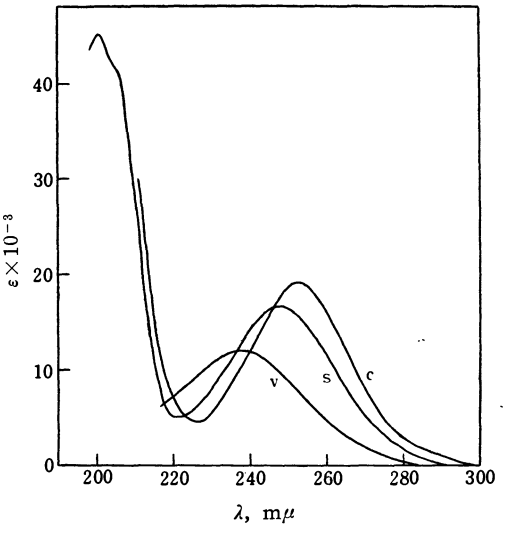

Fig. 1. Ultraviolet absorption spectra of biphenyl in various states.
c. The crystal spectrum measured by Dale[28] by the pressed KCl-disk technique. (The extinction scale is arbitrary for the reliable absolute extinction value could not be obtained.)
s. The solution spectrum (solvent: *n*-heptane).
v. The vapor spectrum measured by Almasy and Laemmel[43] at 170°C.

occupied orbital $\pi_1(B_2)$ to the orbitals φ^* belonging to A_1 or B_2 whose energy is $-\beta$, or from the orbitals φ belonging to A_1 or B_2 whose energy is $+\beta$ to the lowest vacant orbital $\pi_1^*(B_1)$.

It is seen that the spectrum is affected more or less by the solvents. Thus, the conjugation band at 247 mμ in the spectrum of the solution in *n*-heptane is shifted more or less toward longer wavelengths in the spectra in other solvents. The magnitude of the bathochromic shift by the solvent effect is small in methanol and in ethanol, is considerably larger in chloroform, and is extraordinarily large in carbon tetrachloride. In view of these solvent effects, data of spectra in the same solvent should in principle be compared at least in each of the systems of compounds in the treatment. In this part, the data of the spectra in non-polar hydrocarbon solvents being taken as the basis for comparison, and being corrected for the wavelength displacements of the band resulting from changes in phase (i. e. the normal red-shift mentioned above for the crystalline state and the solvent effect for the vapor state which will be mentioned later), the data of the spectra of biphenyl in the various states are compared.

Since the difference of the solvent effect between that of *n*-heptane and of *n*-hexane is supposed to be very small, the difference between the result of the measurement by the present author using *n*-heptane as solvent and that by Dale[28] using *n*-hexane as solvent may be ascribed to experimental errors. At any rate, the position of the maximum of the conjugation band in the spectra of biphenyl in the non-polar hydrocarbon solvents is located at slightly shorter wavelengths than that assumed above for the "isolated" planar molecule of biphenyl. This fact may be supposed to indicate that the most probable conformation of the molecule of biphenyl in solution is slightly non-planar, agreeing with the inference by Dale[46] from comparison of the results of measurements of the infrared absorption spectra of biphenyl in the solutions and in the pressed KBr-disk.

Spectra of Biphenyl in Vapor State

The spectra of biphenyl in the vapor state were studied thoroughly by Almasy and Laemmel[43]. They measured the spectra of biphenyl vapor at the various temperatures from 170 to 520°C and investigated also effects of various foreign gases.

It is noteworthy that the spectrum of pure biphenyl vapor is not largely affected by temperature at least in the range mentioned above, and that whereas the intensity ε of the absorption maximum of the conjugation band decreases gradually from 12050 at 170°C to 9400 at 520°C when the temperature is raised, the oscillator strength of the band is maintained almost constant regardless of the temperature. (The oscillator strength at 170°C is 0.316. The average of the values at 170, 260, 360 and 520°C is 0.311±0.0035.)

The position of the absorption maximum is gradually shifted toward longer wavelengths from 42000 cm^{-1} at 170°C to 41750 cm^{-1} at 520°C, as the temperature is raised. From these results, the position of the maximum at 20°C was inferred by extrapolation as 42100 cm^{-1} (ε, 19000).

Whereas these spectra of the vapor, showing no fine structure, resemble in shape the spectra of the solutions and that of the crystal by the pressed KCl-disk technique, the absorption maximum is considerably shifted toward shorter wavelengths in the vapor spectra than in the solution spectra, and further than the assumed position of the maximum for the "isolated" planar molecule. This fact is supposed to indicate that the degree of deviation from the planarity of the molecular configuration is larger in the vapor state than in the solution state.

Correction for Solvent Effect.—In order to compare the position of the absorption maximum in the vapour spectrum with that in the solution spectrum and with that for the "isolated" planar molecule, the solvent effect must be taken into account.

According to Bayliss[35], the magnitude of the displacement $\Delta\nu$ (in cm^{-1}) of the absorption maximum of a nonpolar molecule to lower frequencies by a nonpolar solvent is related to the refractivity of the solvent, and is expressed as the following equation:

$$\Delta\nu = \frac{3e^2}{8\pi^2c^2m}\cdot\frac{f}{\nu a^3}\cdot\frac{n^2-1}{2n^2+1}$$

$$= 10.71\times10^9\frac{f}{\nu a^3}\cdot\frac{n^2-1}{2n^2+1}$$

where n is the refractive index of the solvent at the frequency concerned, f is

** Values corrected for the solvent effect.

the oscillator strength of the band, ν is the wave number of the position of the absorption maximum, and a is the radius of the (spherical) solute molecule. This relation was experimentally verified by Coggeshal and Pozefsky[47] in their study on the spectra of naphthacene and some other cata-condensed aromatic hydrocarbons. By application of this equation, the magnitude of the shift toward lower frequencies of the maximum of the conjugation band of biphenyl resulting from change in the state from the vapor to the solution in *n*-hexane is computed to be about 134 cm^{-1}, the following values being used; f=0.316 (the value at 170°C); ν=42000 cm^{-1} (the absorption maximum at 170°C); n=1.438 (the refractive index of *n*-hexane[48] at 42000 cm^{-1}); a=5 Å (as the radius a of the molecule, the round value of the half length of the long molecular axis of biphenyl along which the transition is polarized was provisionally taken by consulting the study by Lippert[49] on *p,p'*-disubstituted stilbenes, although this evaluation is inevitably still somewhat arbitrary).

This calculated value of $\Delta\nu$ may approximately apply to the inferred position of the maximum at 20°C and also to the case where the solvent is *n*-heptane instead of *n*-hexane. Accordingly, being corrected for this solvent effect, the wave number of the position of the maximum of the conjugation band of biphenyl in the vapor state, which is to be compared with the corresponding ones in the spectra of the solutions of biphenyl in *n*-hexane and in *n*-heptane, is evaluated to be 41866 cm^{-1} (at 170°C) or 41966 cm^{-1} (at 20°C).

49) E. Lippert, *Z. Naturforsch.*, **10a**, 541 (1955).
50) O. Bastiansen, *Acta Chem. Scand.*, **4**, 926 (1950).

Application of Calculation

On the basis of the above considerations, from the observed positions of the absorption maxima in the solution spectra and the positions in the vapor spectra corrected for the solvent effect, the respectively corresponding values of ΔE_A can be evaluated according to the assumption that ΔE_A varies linearly with μ_A from ΔE_L [1.482$(-\beta)$] for ν_L (40080 or 39841 cm^{-1}) to ΔE_S [2$(-\beta)$] for ν_S (48000 cm^{-1}). Consequently, the corresponding values of μ, θ, R and $R.E.$ can be evaluated in turn. The results are summarized in Table III.

It is shown that the values calculated for the interplanar angles in the most probable conformations of biphenyl in the solution state and in the vapor state are about 20° and about 40~43°, respectively. These values coincide fairly well with those estimated by other workers on different grounds. Thus, Bastiansen[50] deduced the value of 45±10° for the angle in the vapor state from the result of his study by the electron diffraction sector method. This value agrees almost completely with the present one. On the other hand, Samoilov and Dyatkina[51] inferred the value to be about 30° from calculations of resonance energy and steric repulsion energy between the nearest hydrogen atoms by the molecular orbital method. Recently, Adrian[52] concluded, from calculations somewhat similar to those by Samoilov and Dyatkina, that the angle is probably between 20° and 30°. In addition, calculations by Coulson and Longuet-Higgins[53] are said to indicate that

52) F. J. Adrian, *J. Chem., Phys.*, **28**, 608 (1958).
53) C. A. Coulson, presented at a Conference on Quantum-Mechanical Methods in Valence Theory, Washington, 1951. (According to Refs. 6 and 52.)

the decrease in repulsion energy between the ortho-hydrogen atoms and the decrease in resonance energy resulting from non-planarity are practically balanced for interplanar angles of up to about 20°. All these values are compatible with the values calculated here for the solution state.

Summary

1) The ultraviolet absorption spectra of biphenyl in the crystalline state, in the solution state, and in the vapor state have been discussed in detail.

2) The relation between the position of conjugation band in the spectra of biphenyl and the spatial configuration of the molecule has been clarified by calculations based on the simple LCAO molecular orbital method.

3) By using the results of the calculations, it has been inferred from the analysis of the absorption spectra that the angles between the planes of the two benzene rings in the most probable conformations of biphenyl in the solution state and in the vapor state are about 20° and about 40~43°, respectively. These values coincide fairly well with the values estimated by other workers on different grounds.

The author thanks Professor Kengo Shiomi for his encouragement and for reading the manuscript, Professor Osamu Simamura for his encouragement, and Dr. Yoshiya Kanda of Kyushu University for helpful advice and especially for drawing his attention to Dale's papers which furnished one of the important bases for the present work.

Relations between Electronic Absorption Spectra and Spatial Configurations of Conjugated Systems. II. o-Alkyl- and o, o'-Dialkylbiphenyls

By Hiroshi SUZUKI

(Received June 22, 1959)

In the preceding part[1] of this series the relation between the ultraviolet absorption spectra and the most probable spatial configurations of biphenyl in the various states has been discussed in detail on the basis of the calculation carried out by the simple LCAO molecular orbital method. In the present part, the same method is applied to some ortho-alkyl substituted biphenyl derivatives, and the relation between the spectra and the most probable spatial configurations of these compounds is discussed.

It is well known that atrop-isomerism occurs when two or more, especially when all, of the four ortho hydrogen atoms in biphenyl are replaced by larger atoms or groups. This phenomenon is explained as being due to steric hindrance caused by the substituents which prevents rotation about the central 1—1′ bond, namely the co-annular bond, in the biphenyl derivatives. Therefore, the most probable configurations of these compounds must be non-coplanar.

This inference is supported by information from the electronic absorption spectroscopy. Thus, for example, the spectrum of bimesityl does not exhibit the conjugation band characteristic of biphenyl-type compounds, but is closely similar to the sum of the spectra of two mesitylene molecules[2]. This fact is considered to indicate that the twist of the co-annular bond is large enough to eliminate almost completely the $\pi-\pi$ interaction across the

1) H. Suzuki, This Bulletin, **32**, 1340 (1959).

2) (a) L. W. Pickett, G. F. Walter and H. France, *J. Am. Chem. Soc.*, **58**, 2296 (1936). (b) M. T. O'Shaughnessy and W. H. Rodebush, ibid., **62**, 2906 (1940). (c) E. Marcus, W. M. Lauer and R. T. Arnold, ibid., **80**, 3742 (1958).

bond in this compound. That is, it is inferred that the two benzene rings in this compound are almost perpendicularly oriented, as suggested by Guy by means of calculations of the energy associated with the tortion about the central linkage in 2, 2', 6, 6'-tetramethylbiphenyl[3].

In either *o*- or *o*, *o*'-substituted biphenyls, the substituents do not confer, unless they are exceptionally large, measurable optical stability on the rotational enantiomorphs at room temperature[4], but contrariwise, they affect markedly the spectral feature. Thus, for example, the conjugation band of *o*-methylbiphenyl is at a considerably shorter wavelength and of considerably lower intensity than that of biphenyl. This hypsochromic shift is believed to indicate that the interplanar angle θ, i. e. the angle of twist of the co-annular bond, in the most probable spatial configuration of *o*-methylbiphenyl is considerably larger than the corresponding one of biphenyl itself. Further, the spectrum of *o*, *o*'-dimethylbiphenyl exhibits no distinct maximum of the conjugation band, but exhibits only an inflection at a further shorter wavelength than the position of the conjugation band of *o*-methylbiphenyl (Fig. 1.).

It is to be noted here that the effect of the substituents upon the spectra of these biphenyl derivatives must include not only the hypsochromic effect due to steric interference of the substituents, but also the electronic (probably bathochromic) effect of the substituents. As is seen in Fig. 1, the absorption maximum of the conjugation band of *p*, *p*'-dimethylbiphenyl

from which the steric interference of the substituents is absent is at a considerably longer wavelengths as compared with the corresponding one of biphenyl. This bathochromic displacement of the band is probably due to the hyperconjugation effect of methyl groups. The similar bathochromic effect due to hyperconjugation must operate also in the spectra of ortho-substituted biphenyl derivatives such as *o*-methyl- and *o*, *o'*-dimethylbiphenyl. Accordingly, in order to clarify the relation between the spectra and the spatial configurations of *o*-alkyl- and *o*, *o*-dialkylbiphenyls, it is necessary to make allowance for the electronic bathochromic effect of the substituents.

Spectra of Alkylbiphenyls

The data of the ultraviolet absorption spectra of some alkylbiphenyls are summarized in Table I, in which that of biphenyl is included for comparison. Of the spectra measured by the present author, those of biphenyl and of *p*, *p'*-dimethylbiphenyl were measured with a Cary recording spectrophotometer Model 14 and those of *o*-methyl- and of *o*, *o'*-dimethylbiphenyl with a Beckman quartz spectrophotometer Model DU. These spectra are shown also in Fig. 1[13].

***o*-Alkylbiphenyls.**—The absorption maximum of the conjugation band of *p*-methylbiphenyl is at 253 mμ. The bathochromic effect due to the hyperconjugation effect of a *p*-methyl group and that of an *o*-methyl group are considered to be approximately of the same magnitude, as supported by the comparison of the results of calculations of the energy levels in *p*-terphenyl and in *o*-terphenyl, which will be reported in Part IV of this series.

Accordingly, if the steric effect of the ortho methyl substituent were absent, *o*-methylbiphenyl would exhibit the conjugation band at approximately the same position as that of the *p*-isomer. Hence *p*-methylbiphenyl may reasonably be taken as the longer-wavelength-side reference compound in this case.

It was reported in the preceding part that the value of the parameter μ in the $\pi-\pi$ resonance integral $\mu\beta$ for the 1–1′ bond in biphenyl in solution is 0.780 and that the corresponding calculated transition energy ΔE_A is 1.523 $(-\beta)$ (cf. Table III in Ref. 1). From the above consideration, these values are assumed here to correspond approximately to the position of the maximum of the conjugation band of *p*-methylbiphenyl. That is, the values of ΔE_L and of ν_L in the present treatment of *o*-methylbiphenyl are assumed to be 1.523 $(-\beta)$ and 39526 cm^{-1} (253 mμ), respectively.

On the other hand, as the value of ν_S corresponding to ΔE_S $[2(-\beta)]$ when μ is 0, analogously to the choice of the "center of gravity of singlets" 48000 cm^{-1} of benzene[14] in the case of biphenyl itself[1], the corresponding value of toluene may be taken here.

In Table II, a collection of the relevant data of the spectra of benzene and of several alkylbenzenes is assembled. In this table also the data of *m*-xylene and of mesitylene which are not needed in the present part are conveniently included for the sake of reference in the later parts (probably VIII and XI) of this series.

It is seen in Table II that each of the bands of toluene is at a longer wavelength by about 5 mμ than the corresponding band of benzene. Therefore, as the value of toluene corresponding to the center of gravity of singlets 48000 cm^{-1} (208.3 mμ) of benzene, the value of 46882 cm^{-1} (213.3 mμ) may be taken. Accordingly, the value of ν_S is assumed here to be 46882 cm^{-1}.

In this manner, the allowance for the electronic bathochromic effect of the substituent is made by the choice of the

references for correlation between the observed position of the conjugation band and the calculated transition energy. Thus, quite analogously to the treatment in the preceding part, the value of the transition energy ΔE_A corresponding to the wave number of the absorption maximum of the conjugation band of *o*-methylbiphenyl can be computed (cf. Eq. 8 in Ref. 1). In this case, it is assumed that ΔE_A varies linearly with ν_A in the range of ΔE_L [1.523 $(-\beta)$] to ΔE_S [2$(-\beta)$]. By the way, ΔE_L and ΔE_S correspond to ν_L (39526 cm^{-1}) and ν_S (46882 cm^{-1}), respectively. Then, one can obtain the corresponding values of μ, θ, R, etc. in turn according to the relation between ΔE_A and μ (cf. Table I in Ref. 1), and to the relation between μ and θ as well as R (the length of the 1–1′ bond) (cf. Eqs. 1—7 in Ref. 1), which were postulated in the preceding part.

The absorption maxima of ethyl-, *n*-propyl- and *n*-butylbenzene are located at about the same wavelength, 260~261 mμ, as that of toluene. On the other hand, *o*-ethyl- *o*-*n*-propyl-, *o*-isopropyl-, and *o*-*n*-butylbiphenyl all exhibit the maxima of the conjugation bands at about the same wavelength, 233 mμ. Hence it is obvious that these *o*-alkylbiphenyls can be approximately treated also by application of the relation between ΔE_A and ν_A assumed above for the case of the *o*-methyl analogue.

o, o′ - Dialkylbiphenyls. — The absorption spectra of *o*, *o*′-dimethyl-, *o*, *o*′-diethyl-, and *o*, *o*′ - diisopropylbiphenyl are markedly different from those of the corresponding *o*-monoalkylbiphenyls. Each of the spectra of these *o*, *o*′-dialkylbiphenyls shows no distinct absorption maximum of the conjugation band, but merely an inflection at about 227 mμ, which is regarded as the vestigial or submerged conjugation band. According to Everitt and his coworkers[12], the spectra of these *o*, *o*′-dialkylbiphenyls exhibit feeble bands at about 263.5 mμ and at about 270~271 mμ (the molar extinction coefficients are lower than 1000) in addition to the vestigial conjugation band mentioned above. These feeble bands are believed to correspond to the "hidden transition" in biphenyl[19], and this revelation is probably due to the marked hypsochromic shift and the reduction in the intensity of the conjugation band caused by larger deviation from coplanarity of the configuration in these sterically hindered biphenyl derivatives, as compared with biphenyl itself.

In order to infer the most probable spatial configurations of these *o*, *o*′-dialkylbiphenyls by application of the present

TABLE III. RESULTS OF CALCULATION

Biphenyl derivative	λ_{max}, mμ	ν_A, cm^{-1}	ΔE_A, $-\beta$	μ	θ	R, Å
o-Methyl-	235	42553	1.719	0.438	58°	1.508
o-Ethyl-, *o*-*n*-propyl, *o*-isopropyl-, *o*-*n*-butyl-	233	42918	1.743	0.399	60.7	1.5105
o,*o*'-Dimethyl-	(227)	44053	1.826	0.267	70	1.5193
o,*o*'-Diethyl-, *o*,*o*'-diisopropyl-	(227)	44053	1.829	0.262	70.3	1.5195

method, allowance for the electronic bathochromic effects of the substituents is made analogously to the case of *o*-monoalkylbiphenyls by choice of the references for correlation between the calculated transition energy and the observed position of the conjugation band. Thus, as ν_L corresponding to ΔE_L 1.523 $(-\beta)$, the wave number 39124 cm^{-1} (255.6 mμ) of the maximum of the conjugation band of *p*,*p*'-dimethylbiphenyl is taken in the case of *o*,*o*'-dimethylbiphenyl, and the wave number 38986 cm^{-1} (256.5 mμ) of the maxima of the conjugation bands of *p*,*p*'-diethyl- and *p*, *p*'-diisopropylbiphenyl is taken in the case of the corresponding *o*,*o*'-isomers. On the other hand, as ν_S corresponding to ΔE_S $2(-\beta)$, the value of monoalkylbenzene 46882 cm^{-1} (213.3 mμ) corresponding to the center of gravity of singlets of benzene is taken, quite similarly to the case of *o*-monoalkylbiphenyls.

Results of Calculations and Discussion

The results of the calculations are shown in Table III. The calculated value of the angle of twist in *o*-methylbiphenyl is in considerably good agreement with the value 62° deduced from the scale model in which the length of the 1–1' bond is 1.51 Å, the lengths of C_6H_5–H bond and of the C_6H_5–CH_3 bond are 1.08 and 1.54 Å, respectively, the radii of hydrogen atom and of methyl group are 0.9 and 2.0 Å, respectively, and an ortho hydrogen atom just touches the ortho methyl group.

It is noteworthy that the values of the angle of twist in *o*-ethyl-, *o*-*n*-propyl-, *o*-isopropyl-, and *o*-*n*-butylbiphenyl are equal to each other, and that they are merely slightly larger than that in the methyl analogue. This fact may be considered to indicate that all but the methylene group attached directly to the phenyl ring can adopt conformations such that they cause little or no additional interference, as suggested already by Braude and Forbes[6].

The calculated value of the interplanar angle in *o*,*o*'-dimethylbiphenyl is eventually closely similar to the value estimated in the earlier paper[7], 70.5°. Therefore, the discussion in the earlier paper may apply also to the present result. Thus, this value 70° of the interplanar angle in *o*,*o*'-dimethylbiphenyl coincides almost exactly with the corresponding value, 70.6°, found for 2,2'-dimethylbenzidine dihydrochloride by the X-ray crystal analysis[20], and it is inferred that the preferred configuration of the former is similar to the configuration of the latter which has been found to have the two ortho methyl groups in the *cis*-disposition. This inference of the *cis*-configuration of *o*,*o*'-dimethylbiphenyl seems to be supported also by the fact that the interplanar angle in gaseous 2,2'-dichlorobiphenyl found by the electron diffraction method[21] and that in crystalline 2,2'-dichlorobenzidine found by the X-ray crystal analysis[22] are 74° and 72°, respectively, and that both these compounds have been found to have *cis*-configurations.

If the molecule of *o*,*o*'-dimethylbiphenyl assumed the *trans*-configuration in which the ortho hydrogen atoms just contact with the ortho methyl groups, the configuration of the biphenyl skeleton would be similar to that in *o*-methylbiphenyl, and consequently *o*,*o*-'dimethylbiphenyl would show a closely similar spectrum to that of *o*-methylbiphenyl. In fact it is not so. Thus, as already mentioned, the hypsochromic shift of the conjugation band is observed to be markedly larger in the spectrum of *o*,*o*'-dimethylbiphenyl than in that of *o*-methylbiphenyl.

This fact has been interpreted by Braude and Forbes[6] as follows: "The hypsochromic shift from 2500 to 2350 Å due to one *o*-methyl substituent actually corresponds to an increase in transition energy of 7 kcal./mol., which is the amount by which the energy level of the electronic excited

20) (a) F. Fowwether and A. Hargreaves, *Acta Cryst.*, **3**, 81 (1950); *Chem. Abstr.*, **44**, 7118 (1950). (b) A. Hargreaves and W. H. Taylor, *J. Sci. Instruments*, **18**, 138 (1941); *Chem. Abstr.*, **35**, 7261 (1941).

state has been raised relative to that of the ground state and it is obviously reasonable that the effect of two such substituents should be about twice as great". It seems that they have attributed the hypsochromic shift, viz. an increase in transition energy, to an increase in the difference between the steric repulsion energy in the electronic excited state and that in the ground state.

However, as mentioned already in the preceding part[1] of this series, since the transition is considered to be an electron jump without change in nuclear configuration according to the Franck-Condon principle, the steric repulsion energy in the electronic excited state and that in the ground state must be at least approximately of the same magnitude. Therefore, whereas the steric repulsion energy is a contributing factor to the stability of the molecule and hence to determination of the most probable spatial configuration of the molecule, the electronic transition energy must not depend directly on the steric repulsion energy in the ground state, but on the spatial configuration itself. And further, of course, there should be no direct relation between the electronic transition energy and the height of the energy barrier to rotation about the co-annular bond which depends mainly on the difference between the steric repulsion energy in the coplanar configuration and that in the most probable configuration.

From such considerations, the difference between the spectrum of *o*-methylbiphenyl and that of *o*, *o'*-dimethylbiphenyl should be ascribed to the difference of the most probable spatial configurations of the biphenyl skeleton in these compounds. It is obvious that the interpretation by Braude and his coworker is quite unreasonable.

o, *o'*-Diethyl- and *o*, *o'*-diisopropylbiphenyl are inferred to have configurations similar to that of *o*, *o'*-dimethylbiphenyl, although the estimation of the interplanar angle in these compounds is inevitably somewhat uncertain since the conjugation bands of these compounds are vestigial, the positions of the maxima of which can not accurately be determined.

o, *o'*-Di-*tert*-butylbiphenyl exhibits no trace of a discrete conjugation band. This fact may be considered to indicate that the interplanar angle in this compound is so large owing to the bulkiness of the substituents that the $\pi-\pi$ interaction across the co-annular bond is almost completely eliminated.

23) W. Theilacker and W. Ozegowski, *Ber.*, **73**, 33 (1940).

Relation of Spatial Configurations with Other Properties

The difference of the spatial configurations of the compounds must undoubtedly affect also certain physical and chemical properties of the compounds besides the electronic absorption spectra. Accordingly, the spatial configurations of the biphenyls inferred above on the basis of the absorption spectra may be correlated with various other properties of the compounds. A few examples are given below.

Theilacker and Ozegowsky[23] found that 2, 2'-dimethyl-4, 4'-biphenylene-bis-diphenylmethyl has properties closely similar to those of the 2, 2', 6,6'-tetrachloro analogue which is known to be a true biradical[24]. In addition, Müller and Hertel[25] concluded from the result of measurement of the magnetic susceptibility that this 2, 2'-dimethyl compound is paramagnetic and hence a true biradical in contrast to its parent compound, Chichibabin's hydrocarbon, which had been found to be completely diamagnetic and not a biradical[26]. Although the latter compound was found afterwards by application of the paramagnetic resonance absorption method to contain about 4% of the biradical form in solution in benzene[27], it may be safe to state that in the equilibrium between the diphenoquinone form and the biradical form the latter form is more favorable in the 2, 2'-dimethyl compound than in the parent compound, and that this fact is to be related to the reduced $\pi-\pi$ interaction across the co-annular bond in the former compound as compared with the latter compound.

According to Sherwood and Calvin[28], in *p*-amino-*p'*-nitrobiphenyl the *p'*-nitro group exerts a marked effect upon the basicity of the *p*-amino group and this effect is diminished by ortho substitution by two methyl groups. This effect of ortho methyl groups has been ascribed to the blocking of nitro-amino resonance by the forced non-coplanarity of the configuration of the biphenyl skeleton.

Castro, Andrews and Keefer[29] recently measured the equilibrium constants and the heats of formation of 1 : 1 complexes of a series of methylbiphenyls with 1, 3, 5-trinitrobenzene. According to their results, whereas the complexes increase in stability as the number of *p*-methyl substituents on the biphenyl nucleus is increased, the complex stability decreases in the order

biphenyl> *o*-methylbiphenyl > *o*, *o*'-dimethylbiphenyl>bimesityl, as the number of *o*-methyl substituents is increased. This fact is indicative of the dependence of the complex stability on the factors which prevent coplanarity of the two benzene rings in the biphenyl derivatives, and supports the present conclusion that the degree of deviation from planarity of the configuration of biphenyl skeleton increases as the number of *o*-methyl substituents is increased.

Furthermore, Brownstein[30] measured the nuclear magnetic resonance absorption spectra of some 2-halo- and 4-halobiphenyls and attributed shifts in proton resonance absorption toward a higher field observed for some of the protons in 2-halobiphenyls to steric effects of the halogen upon the ortho protons of the unsubstituted benzene ring. In addition, he explained the melting points of these compounds by the twisting of the benzene rings as the size of the 2-substituent is increased. Thus, whereas a heightening of melting point is observed with increasing molecular weight for the 4-halobiphenyl as would be expected, the melting point of the 2-halobiphenyl is lowered as the molecular weight increases. This was believed to be caused by the decreasing symmetry of the molecule as the benzene rings are twisted further out of plane by the steric effect of the *o*-substituent.

Although the melting point is a very complex property, it may be sure that the spatial configuration of the molecule is an important factor to govern the melting point. A somewhat similar phenomenon to the one mentioned above is observed in the series of methylbiphenyls. Thus, whereas the melting points of biphenyl and of *p*-methylbiphenyl are 69 and 49~50°C (47~48°C), respectively, *o*-methylbiphenyl is liquid at room temperature. In addition, whereas the melting point of *p*, *p*'-dimethylbiphenyl is 125°C (121°C), that of the *o*, *o*'-isomer is 18°C. (Data of the melting points are according to Dictionary edited by Heilbron[31]). The fact that the melting point of the *o*-isomer is invariably markedly lower than that of the corresponding *p*-isomer may be at least partly due to the non-planarity of the configuration of the *o*-isomer.

Summary

The method described in the preceding part of this series has been applied with allowance for the electronic bathochromic effect of the substituents to *o*-alkyl- and *o*, *o*'-dialkylbiphenyls, and the relation between the ultraviolet absorption spectra and the most probable spatial configurations of these compounds has been clarified, resulting in the conclusion that the interplanar angle in *o*-methylbiphenyl as well as its analogues is about 60° and that *o*, *o*'-dimethylbiphenyl as well as its analogues has the *cis*-configuration in which the interplanar angle is about 70°.

On the basis of the result, the interpretation by Braude and Forbes of the spectra of *o*-methyl- and *o*, *o*'-dimethylbiphenyl has been criticized.

In addition, the inferred spatial configurations of these biphenyl derivatives have been correlated with some physical and chemical properties of these and some related compounds.

The author thanks Professor Kengo Shiomi for reading the manuscript and for valuable advice.

Relations between Electronic Absorption Spectra and Spatial Configurations of Conjugated Systems. III. o,o'-Bridged Biphenyls

By Hiroshi SUZUKI

(Received June 22, 1959)

The method developed in the earlier parts[1,2] of this series is applied to some *o,o'*-bridged biphenyls, and the relation between the ultraviolet absorption spectra and the spatial configurations of these compounds is discussed.

A collection of the data of the spectra of some *o,o'*-bridged biphenyls is assembled in Table I.

o,o'-One-atom-bridged and Two-atom-bridged Biphenyls

The spectra of fluorene and of 9,10-dihydrophenanthrene exhibit besides the intense bands at about 260 mμ lower bands at about 300 mμ. The former bands are probably the conjugation bands characteristic of the biphenyl-type compounds. The

latter, which are absent from biphenyl, are difficult to interpret. Braude[8,9] seems to have attempted to explain these feeble bands by means of an assumption of C–C hyperconjugative interaction of the two benzene rings through the methylene bridge. Perhaps these bands may be considered to correspond to the "hidden transition" in biphenyl[10].

The spectrum of fluorene and that of 9,10-dihydrophenanthrene resemble each other considerably on the whole[11]. However, while the latter shows no fine structure, the former shows a remarkably well-resolved fine structure (Table II and Fig. 1). This may be related to the fact that fluorene has probably a strained or forced coplanar or near-coplanar configuration.

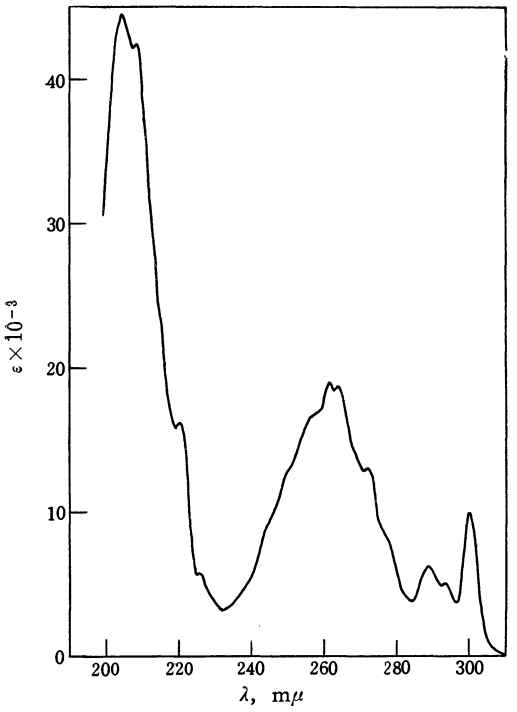

Fig. 1. The ultraviolet absorption spectrum of fluorene in *n*-heptane (cf. Table II).

The conjugation band of fluorene is at considerably longer wavelengths than that of biphenyl. This bathochromic shift of the band may be partly due to the forced coplanarity or near-coplanarity of the molecular configuration of fluorene, and partly to the hyperconjugation of the methylene group. When the relation postulated for biphenyl[1] between the calculated electronic transition energy ΔE_A and the observed position ν_A (in wave number) of the maximum of the conjugation band is provisionally applied without allowance for the bathochromic (hyperconjugation) effect of the substituent to fluorene, the value of the parameter μ in the π—π resonance integral $\mu\beta$ for the co-annular bond in fluorene is estimated to be about 1.060 from the position 261.5 mμ (in *n*-heptane) of the most intense maximum of the conjugation band. This value is to be compared with the corresponding value 0.780 or 0.762 for biphenyl in solution, although this value for fluorene should be considered as a measure of the degree of "conjugation" in fluorene including hyperconjugation of the methylene group as well as intrinsic conjugation which depends on the spatial configuration of the biphenyl skeleton. The fact that the degree of conjugation in fluorene is considerably larger than in biphenyl may explain at least partly the extraordinarily larger reactivity of fluorene as compared with biphenyl in some kinds of reactions. A few examples are given below.

The reactivity of fluorene to nitration is much higher than that of biphenyl. Thus, while the "partial rate factor" (the rate constant of separate nuclear position of the compound relative to one nuclear position of benzene being taken as unity) at *p*-position and that at *o*-position in biphenyl are 38 and 41, respectively[12], or 11.0 and 18.5, respectively[13], the values at the corresponding positions (i. e. the 2- or 7- and the 4- or 5-positions) in fluorene are 2040 and 944, respectively[14].

14) M. J. S. Dewar and D. S. Urch, ibid., **1958**, 3079.

Berliner and Shieh[15] have correlated the rate constants of solvolysis of α-arylethyl chlorides with the atom localization energies calculated by Dewar and others for the aryl radicals, and found that the reactivity of 2-fluorenyl compound is extraordinarily higher than expectation.

In addition, Sandin and coworkers[16] have compared the carcinogenic activities of 2-acetylaminofluorene, 4-acetylaminobiphenyl, and their related compounds, and found the fact that 2-acetylaminofluorene has a much higher activity as compared with 4-acetylaminobiphenyl and especially its *o*-methyl substituted derivatives. They have ascribed this fact to the greater planarity of the configuration of the biphenyl skeleton in 2-acetylaminofluorene than in the other compounds.

The interplanar angle in 9,10-dihydrophenanthrene has been estimated by Beaven and coworkers[4] to be about 20° by means of a model in which the saturated carbon atoms maintain their tetrahedral valency angle. Accordingly the bathochromic displacement of the conjugation band of this compound relative to that of biphenyl may be due mainly to the normal electronic substituent effect (probably hyperconjugation effect) of the alkyl group.

The maximum of the conjugation band of 4,5-methylene-9,10-dihydrophenanthrene is at even longer wavelengths than those of fluorene and 9,10-dihydrophenanthrene. In this compound the conflicting steric requirements of the two bridges would appear to be most favorably compromised in an approximately planar configuration. Accordingly the bathochromic shift of the conjugation band of this compound relative to those of fluorene and of 9,10-dihydrophenanthrene may be ascribed partly to the planarity or nearer-planarity of the configuration, and partly to the electronic substituent effect of the additional dimethylene or methylene bridge.

o, *o'*-Three-atom-bridged and Four-atom-bridged Biphenyls

Each of the spectra of the compounds in which the *o*,*o'*-positions of biphenyl are bridged by a 7-membered ring (which are subsequently referred to as the *o*,*o'*-three-atom-bridged biphenyls) (entries 4—9, Table I) shows the conjugation band at considerably shorter wavelengths than those of fluorene and of 9,10-dihydrophenanthrene. The corresponding band of each of the compounds in which the *o*,*o'*-positions of biphenyl are bridged by an 8-membered ring (the *o*,*o'*-four-atom-bridged biphenyls, entries 10 and 11) is further shifted toward shorter wavelengths.

These *o*,*o'*-three-atom-bridged and four-atom-bridged biphenyls are considered to have non-planar configurations. Accordingly, the hypsochromic displacements of the conjugation band observed in these compounds with respect to fluorene or 9,10-dihydrophenanthrene are probably ascribed to the non-planarity of the configurations, and therefore, their configurations may be inferred from their spectra by application of the method described in the earlier parts of this series.

In application of the method to these compounds, 9,10-dihydrophenanthrene is taken as the longer-wavelength-side reference compound. The justification for taking this compound rather than fluorene as the reference compound is that this makes a pertinent allowance for the bathochromic effect of two methylene groups attached at the *o*- and the *o'*-positions of biphenyl, and further justification is found in the fact that the molecule of fluorene is presumed to contain a considerably large strain.

The previously assumed relation between the length of the co-annular bond R and the interplanar angle θ (Eqs. 4 and 5 in Part I of this series) may not be pertinent to this case. However, a slight change in the value of R does not substantially affect the calculated value of the interplanar angle θ, as suggested by the results of calculations in the case of terphenyls which will be described in the next part of this series. Hence the relation is applied to the present case for simplification. Then, adopting the value (about 20°) estimated by Beaven and coworkers from the scale model for the interplanar angle in 9,10-dihydrophenanthrene, the corresponding value of R is computed to be 1.4837 Å, and the parameter μ in the $\pi-\pi$ resonance integral $\mu\beta$ for the co-annular bond is evaluated to be 0.801. Consequently, the value of the calculated transition energy $1.5115(-\beta)$, viz. ΔE_L, when μ is 0.801 is assumed to correspond to the wave number 37879 cm^{-1} (264 mμ),

15) E. Berliner and N. Shieh, *J. Am. Chem. Soc.*, **79**, 3849 (1957).
16) R. B. Sandin, R. Melley, A. S. Hay, R. N. Jones, E. C. Miller and J. A. Miller, ibid., **74**, 5073 (1952).

viz. ν_L, of the position of the maximum of the conjugation band in the spectrum of 9,10-dihydrophenanthrene in ethanol. (In the present treatment the data of the spectra of the solutions in ethanol are compared in principle.)

As the shorter-wavelength-side reference, quite similarly to the previous treatment of *o*-alkyl- and *o,o'*-dialkylbiphenyls[2], the value of toluene, 46882 cm^{-1} (213.3 mμ), corresponding to the "center of gravity of singlets" of benzene is taken, because the effect of a methylene group upon the positions of the bands of benzene is considered to be approximately of the same magnitude as that of a methyl group (cf. Table II in Part II of this series). That is, the value of 46882 cm^{-1} (viz. ν_S) is assumed to correspond to the value of the calculated transition energy $2(-\beta)$ (viz. ΔE_S) when μ is 0.

On the basis of the above assumptions, the value of ΔE_A, μ, θ, R, etc. for each of the *o,o'*-three-atom-bridged and the *o,o'*-four-atom-bridged biphenyls can be computed by the usual procedure from the position of the conjugation band in its spectrum. The results of calculations are summarized in Table III.

TABLE III. RESULTS OF CALCULATION

Compound	λ_{max} mμ	ν_A cm^{-1}	$\Delta E_A/-\beta$	μ	θ	R Å

9	248	40323	1.644	0.565	47.3	1.499
(Average)	249	40161	1.635	0.579	46.0	1.498
o,o'-Four-atom-bridged biphenyls						
10	239.5	41754	1.722	0.434	58.0	1.508
11	236.5	42283	1.751	0.387	61.5	1.511
(Average)	238	42017	1.736	0.411	59.8	1.510

Compounds are represented by the entry numbers in Table I.

Beaven and coworkers have estimated the interplanar angle in *o,o'*-three-atom-bridged biphenyls as about 50°[4], and that in *o,o'*-four-atom-bridged biphenyls as about 60~65°[6] from models. The values have been computed here to be 44.5~47.3° average, 46°) and 58.0~61.5° (average, 59.8°), respectively, which agree fairly well with the values estimated from models.

From the close similarity between the spectrum of 2,7-dihydro-3,4-5,6-dibenzoxepin (entry 4,Table I)and that of biphenyl Beaven and others[4] have presumed that "in the oxepin the phenyl groups are no less conjugated and hence no less coplanar than in biphenyl", and concluded that "the biphenyl-type spectrum does not provide sure evidence for a coplanar configuration" "since the oxepin can not be coplanar". In addition, the present author considered in the previous paper[17] that the estimation of the value of the interplanar angle in biphenyl as about 50° was supported by this spectral similarity. A common flaw in these considerations is that the bathochromic effect of the substituents was not sufficiently taken into account.

On the other hand, Braude and Forbes[18] have estimated the interplanar angles in ortho-bridged biphenyls and their related compounds by applying the equation $\cos\theta = \varepsilon/\varepsilon_0$, assuming that ε_0 is equal to the molar extinction coefficient of the conjugation band of fluorene, and obtained the following values; 21° for 2,7-dihydro-3,4-5,6-dibenzoxepin (entry 4, Table I), 41° for its *o,o'*-dimethyl derivative, 47° for its *o,o'*-dimethoxy-derivative, and 27° for 2,7-dihydro-3,4-5,6-dibenzazepinium-1-*spiro*-1'''-piperidinium bromide (entry 9).

Their equation mentioned above has been assumed to be true on the basis of the hypothesis of transitions from the non-planar ground state to the uniplanar or near-planar excited state, and the starting point of their theory is the assumption that the absorption intensity is determined by the transition probability which is in turn governed mainly by the probability in which the molecule in the ground state assumes the uniplanar or near-planar configuration[19]. However, this probability must be governed by the shape of the potential energy curve for the tortional vibration, and hence mainly by the energy difference between the uniplanar or near-planar configuration and the most probable configuration. In spite of the hypothesis by Braude and others, it seems to be very questionable whether or not there is any direct relation between this probability, namely, the height of the energy barrier to the rotation about the pivot bond and the interplanar angle in the most probable configuration.

Furthermore, according to its basic theory, the equation mentioned above

17) H. Suzuki, This Bulletin, **27**, 597 (1954).
18) E. A. Braude and W. F. Forbes, *J. Chem. Soc.*, **1955**, 3776.
19) E. A. Braude and F. Sondheimer, ibid., **1955**, 3754.

should be applied only to the case in which the so-called steric effect of type 1 is exerted, that is, to the case in which a reduction in the intensity of the conjugation band occurs alone without any significant hypsochromic shift. Nevertheless, it is evident that in the spectra of the compounds cited by Braude and Forbes remarkable hypsochromic shifts are involved. The application of the equation to these compounds is, therefore, inconsistent with its basic theory itself.

The introduction of two *o*-methyl groups or of two *o*-methoxyl groups into dihydrodibenzoxepin (entry 4, Table I) causes a remarkable decrease in the intensity of the "biphenyl-type" conjugation band. Considering this effect as being mainly due to the steric effect, Braude and Forbes[18] have stated that the assumption by Beaven and others of an angle of 50° between the benzene rings in the parent oxepin is questionable. Thus, adopting the assumption of Beaven and others, since the benzene rings in this compound are already at an angle of about 50°, the introduction of the *o*-substituents should have no steric consequences. On the other hand, Beaven and others[4] have attempted to explain this effect of the substituents by electronic interaction between the substituents and the separate benzene rings to which they are attached.

However, in the preceding part of this series, the interplanar angle in *o,o'*-dimethylbiphenyl was estimated to be about 70°, and this compound was inferred to have the *cis*-configuration. This value of the interplanar angle is considerably larger than that for dihydrodibenzoxepin, 50°, estimated by Beaven et al., or 44.5°, by the present author. Therefore, even when the value, 50° or 44.5°, is adopted as the interplanar angle in dihydrodibenzoxepin, the introduction of the substituents into the ortho positions can evidently increase the interplanar angle, and hence a decrease in the intensity and the hypsochromic shift caused by the introduction of two *o*-methyl groups can be explained sufficiently, contrary to the opinion of Braude and others. A decrease in the intensity of the band caused by the introduction of two *o*-methoxyl groups may be similarly explained by steric effect, but the fact that the band of *o,o'*-dimethoxy-derivative is at, though slightly, longer wavelengths than that of the parent compound may be attributed to the electronic effect of the substituents.

Finally, in connection with the spatial configuration of the *o,o'*-bridged biphenyls, it is noteworthy that recently Iffland and Siegel[7] succeeded first in preparing an optically active biphenyl derivative whose optical activity is due to non-planarity of the biphenyl skeleton as a consequence of the requirement of a three-carbon-atom-bridge across the *o,o'*-positions. According to them, this compound, *d*-6,6-dicarbethoxy-dibenzo-[a, c] [1, 3]-cycloheptadiene (entry 6, Table I), is optically stable in the crystalline state, and loses half of its activity ($[\alpha]_D^{32.5}$ +2.25° in cyclohexane) in 80 min. in cyclohexane solution.

Summary

The ultraviolet absorption spectra of some *o,o'*-bridged biphenyls and their relations to the spatial configurations have been discussed. The method developed in the earlier parts of this series has been applied to these compounds, especially *o,o'*-three-atom-bridged (*o,o'*-7-membered-ring-bridged) and *o,o'*-four-atom-bridged (*o,o'*-8-membered-ring-bridged) biphenyls, and the interplanar angles have been calculated to be about 44.5~47.3° (average, 46°) for the former compounds and about 58.0~61.5° (average, 59.8°) for the latter.

The author thanks Professor Kengo Shiomi for reading the manuscript and for valuable advice.

The Relation between the Deformation of Substrate of PVA Sheet by Stretching and the Stretch Ratio R_s

By Yoshié TANIZAKI, Teruaki KOBAYASHI and Noboru ANDO

(Received June 24, 1959)

In the hope of analyzing relative directions of transition moments of dyes by their dichroism in stretched polyvinyl alcohol (PVA) sheets, the following equation has been derived previously in reference to the relation between the observed optical density ratio R_d and the stretch ratio R_s[1],

$$R_d=\frac{2+2(2r^2-1)\,T(R_s)}{(2r^2+1)-(2r^2-1)\,T(R_s)} \qquad (1)$$

where

$$\left.\begin{aligned} T(R_s)&=\frac{R_s^2}{R_s^2-1}\\ &\times\left\{1-\frac{N(R_s)}{\sqrt{R_s^2-1}}\ln(R_s+\sqrt{R_s^2+1})\right\}\\ N(R_s)&=2\\ &\times\left\{\frac{1}{\sqrt{R_s^2-1}}\ln(R_s+\sqrt{R_s^2-1})+R_s\right\}^{-1}\\ R_s&>1 \end{aligned}\right\} \qquad (2)$$

and the angle between the orientation axis of a molecule and the direction of its transition moment is given by $\cot^{-1}r$. When Eq. 1 was derived, it was assumed that an imaginary sphere in substrate of PVA sheet changes into a spheroid, keeping its volume constant, with the stretching of the PVA sheet. The relation between R_d and R_s expressed by Eq. 1, which was derived on the basis of such an assumption, coincided well with the experimental results of the dyes which the authors used. However, it has become necessary to ascertain whether the assumption is practically correct or not. This inspection was carried out by a very simple check measurement. Therefore, the method and the results obtained will be reported.

The object of this paper is to confirm the following subjects: 1) whether the width and the thickness of a PVA sheet decrease in the same ratio, when the sheet is stretched; 2) whether the relation between two quantities used when R_s was defined—namely the lengths of both long and short axes of an ellipse deformed from a circle drawn on the sheet by stretching it—coincides with the theoretical relation derived by assuming an ellipsoid of constant volume as just mentioned; 3) and whether if the two facts are just as expected, the relation between R_d and R_s of poly-iodine ions in PVA sheet[2], which seem to have both their transition moment and orientation axis in the same direction, must have the same behavior both experimentally and theoretically.

The Change in Width and Thickness of PVA Sheet When It Is Stretched.—The width and the thickness of PVA sheet were measured with a caliper and a micrometer. Let w_0 be the initial length of PVA sheet perpendicular to the stretching direction (the width), t_0 be the initial thickness, and w and t be their respective values corresponding to any R_s. Values of $(w/w_0)/(t/t_0)$ are plotted in Fig. 1, in which the white circles mean values when the ratio of the initial lengths of sheet parallel and perpendicular to the stretching direction is about 1 : 1, and the black circles those corresponding to the ratio of about 1 : 3. The figure shows clearly that the width and the thickness decrease in the same ratio at least in the former case (which has the same condition as the others which the authors have reported).

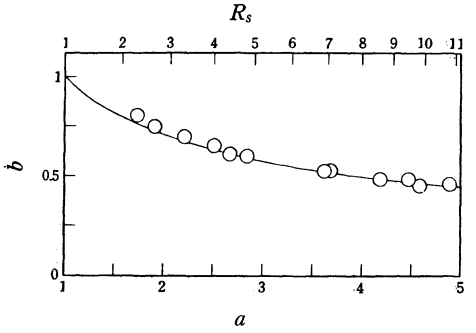

Fig. 2

The Relation between Lengths of Long and Short Axes. — Let a be the length of the long axis and b that of the short one of an ellipsoid, and then its volume is proportional to ab^2 and R_s is defined by a/b, with $a=b$ before stretching. Now, taking up a case in which the width decreases in proportion to the thickness as shown in Fig. 1, the authors searched for the following relation, to see whether the values of R_s actually used were correct. If an assumed sphere in a PVA sheet changes into ellipsoids, keeping its volume constant, when it is stretched, then the theoretical relation of $b-a$ or $b-R_s$ will be expressed by the curve shown in Fig. 2. Observed values corresponding to the curve are also shown in the figure, and they fit it satisfactorily.

The Relation between R_d and R_s of Poly-iodine Ions in PVA Sheet. — The absorption at about 600 mμ of iodine in PVA is due to linear poly-iodine ions constituted by many iodine atoms[3]. Therefore, in such a polyatomic molecule, its orientation axis coincides with the direction of its transition moment, and then the value of r mentioned above becomes infinity and Eq. 1 has the simple form of

$$R_d = [2T(R_s)] / [1 - T(R_s)] \qquad (3)$$

In Fig. 3 a curve drawn by Eq. 3 is shown, and corresponding observed values are also shown by white circles. This experiment was performed as follows.

Iodine was adsorbed by PVA sheets in solutions containing boric acid ~5 g.%, potassium iodide 1~2 g.%, ammonium iodide 1~2 g.% and iodine 0.2~0.5 g.%. The sheets, which were swollen beforehand in water, were dehydrated in alcohol to be put back in a hard state, in order to

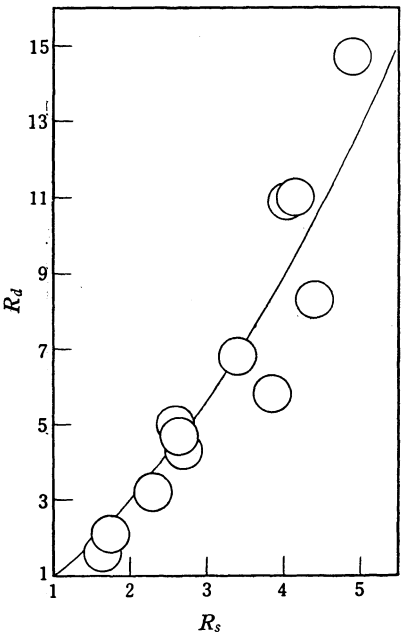

Fig. 3

prevent adsorbed iodine from fleeing from the sheets. However, even by this method, iodine could not be adsorbed in a satisfactorily uniform manner. The PVA sheets which adsorbed iodine were stretched after they were dried well at room temperature. The absorption spectra by polarized light of any stretched iodine-PVA sheet did not always show the same values at corresponding angles, when the sample sheet was rotated (0° to 360°); that is, $D_{\parallel}$ (or $D_{\perp}$) of a sample was measured at two angles, but the two observed values did not always coincide with each other. Therefore, it is their average values that are shown in Fig. 3.

The agreement between the curve drawn by Eq. 3 and the observed values is a direct verification of the propriety of distribution function which was used when Eq. 1 was derived. Therefore, if only samples which are sufficiently long as compared with their width are used, when PVA sheets are stretched, it may be considered that the deformation of their substrate occurs with a constant volume (at least when $R_s<15$). This shows that the fundamental assumption employed for the derivation of the equation was proper.

Effect of Dry Grinding on Gibbsite

By Goro YAMAGUCHI and Kenichi SAKAMOTO

(Received May 26, 1959)

The crystal structure of gibbsite, one of the aluminum-trihydroxides, is a double-layered structure, and the binding force between layers is a rather weak hydrogen bond. So, when gibbsite is ground, it is supposed that the dimension of crystal particles is reduced and the stacking disorder of layers may occur. The authors examined the structural change of ground gibbsite, and confirmed the fact that very fine gibbsite (diameter of the particles is less than 1 micron) decomposes to χ-alumina directly, and in this process boehmite is not produced. The authors also studied the thermal decomposition of ground gibbsite and checked the difference of thermal properties between unground and ground gibbsite.

Experimental

Material. — Gibbsite employed in this study is a commercial product. It consists of aggregates of small crystals of a few microns and the dimension of the aggregates is 20~30 microns. Impurities are shown in Table I.

TABLE I. IMPURITIES IN GIBBSITE

Na_2O	0.35 %
Fe_2O_3	0.009
SiO_2	0.008

Procedure. — This gibbsite was ground in a ball mill and sampled. The samples were examined by X-ray methods, including X-ray small-angle diffraction procedure, and also by differential thermal analysis (DTA). Also their ignition loss was determined.

Results

Gibbsite was ground for 100 hr., and sampled at a definite time during grinding. The ignition loss was nearly constant through this process (Table II). The result of X-ray analysis was shown in Fig. 1. It is seen from this result that

TABLE II. IGNITION LOSS OF GROUND GIBBSITE

Time of grinding	Igniton loss
0 hr.	34.4 %
1	34.4
3	34.7
6	33.9
10	34.1
20	33.7
40	34.2
100	35.0

e) Ground for 100 hr.

the intensities of diffracted lines decreased gradually, and only two lines (002) and (110) were observed after 40 hr. On the contrary, the result of the small-angle scattering suffered little change (Fig. 2). From this, the authors can calculate the diameter of gibbsite by using Warren's formula[1]. Diameters of unground gibbsite and of that ground for 100 hr. are about 3500 and 2000 Å respectively. The diameter of gibbsite, ground less than 100 hr., lies between 3500 and 2000 Å. Microscopic observation reveals that an aggregate was released into some single particles, and a single particle was broken to a few fragments which have the size of about a micron. From above facts, it may be said that a particle of gibbsite which seems to be a single crystal is not continuous in the sense of X-ray crystallography. This continuous domain which is sensible for small-angle diffraction remained almost unchanged during grinding. The result of DTA was shown in Fig. 3. When the grinding time is within a few hours, ground gibbsite decomposes similarly as unground gibbsite does, that is, it reveals three endothermic peaks. But after a longer period of grinding, the DTA-curve of gibbsite changes gradually from the normal curve. The first peak becomes smaller and

only a knob is seen at this point. Parallel with this, the third peak becomes smaller. After the grinding of 40 hr., only the main peak is observed. This leads us to the conclusion that ground gibbsite decomposes directly into alumina; diffracted lines of alumina at 700~900°C were different from each other according to their grinding times. The diffraction of 1.99 Å became weaker and the diffraction of 2.12 Å became relatively intense (Fig. 4).

Consideration

There are many minerals, such as clay minerals, which have layered structures. In these substances the binding force within the layer is covalent and very rigid, but the interlayer force is rather weak. Lately it has been reported that there are many disordered clay minerals and theoretical calculation has been made by many authors[2].

Gibbsite, which has a composition of aluminum-trihydroxide and does not contain silicon oxide, may be said to be one of the most simple layered minerals. Therefore, it is possible to anticipate the fact that the various types of stacking along *c*-axis will occur in aluminum-trihydroxide. Thus it can also be anticipated that gibbsite, one of aluminum-trihydroxide-polytypes, is naturally supposed to be easily disordered by grinding. In this study, the authors can indicate that the properties of ground gibbsite are as follows: 1) gibbsite retains its composition during grinding; 2) the X-ray small-angle diffraction behavior suffers little change by grinding and appears within a very narrow range; 3) the intensities of diffracted lines become weak gradually with grinding; 4) (002) reflection does not diminish at first but becomes weak after a grinding of about 10 hr.; 5) (110) reflection still exists with (002) reflection after the disappearence of other lines.

From the facts mentioned above, it is clear that the disintegration of crystal occurred by grinding and the intensity of diffracted lines became weak. It may be said that only a slipping of layers took place so long as (002) reflection did not change, and after that the order along *c*-axis began to be lost with the diminution of (002) intensity. But the fact that (110) reflection remained as well as (002) after the other reflections had vanished indicates the direction of the slipping of the layers. The crystal structure of gibbsite is shown in Fig. 5 and Table III[3]. As explained already the packing of (OH) is an unusual packing of 1—2 2—1, so the direction of the slipping of layers would be [110]. In fact, it is proved that $F(110)$ is unchanged so long as the slipping of layers proceeds in the direction [110].

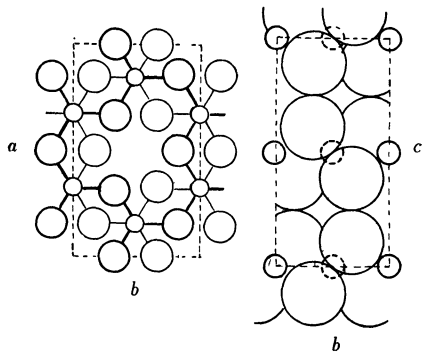

Fig. 5. Crystal structure of gibbsite.

TABLE III. CRYSTAL STRUCTURE OF GIBBSITE

Crystal class	Monoclinic
Space group	$P\,2_1/n$ (C_{2h}^5)
Unit cell	$a=8.6236$ Å, $b=5.0602$ Å
	$c=9.699$ Å, $\beta=85°26'$
Z	8 $Al(OH)_3$
Atomic coordinates	$4(e)$; $\pm(X,Y,Z;\ 1/2-X,$ $Y+1/2,\ 1/2-Z)$

As seen from Fig. 5, there are two layers with a distance of $c/2$ in a unit cell and the structure within the layer is unchanged. Thus F is separated to parts F_1 and F_2, each of which is an F-factor of its own layer. Also it is assumed that a lower layer keeps its position and an upper layer slips by $\Delta r(\Delta X+\Delta Y)$. So the displacement of any atom of an upper layer is equal to Δr. Thus

$$\begin{aligned} F(110)_{\text{slipped}} &= F_1(110)+F_2(110) \\ &= \Sigma\, 2f\cdot\cos 2\pi(X+Y) \\ &\quad +\Sigma\, 2f\cdot\cos 2\pi[(1/2-X-\Delta X) \\ &\quad +(1/2+Y+\Delta Y)] \\ &= \Sigma\, 2f\cdot\cos 2\pi(X+Y) \\ &\quad +\Sigma\, 2f\cdot\cos 2\pi[(Y-X) \\ &\quad +(\Delta Y-\Delta X)] \end{aligned}$$

Zachariasen, *Phys. Rev.*, **71**, 715 (1947); C. R. Houska and B. F. Warren, *J. Appl. Phys.*, **25**, 1503 (1954).

3) H. D. Megaw, *Z. Krist.*, **A87**, 185 (1934).

$$= \Sigma 2f \cdot \cos 2\pi (X+Y) + \Sigma 2f \cdot \cos 2\pi (Y-X) \quad (\Delta X = \Delta Y) = F(110)_{\text{original}}$$

In a disordered structure, the magnitude of the slipping is not constant but it is natural that (OH) of disordered gibbsite has nearly hexagonal close stacking in short range.

Many reports about the thermal decomposition of gibbsite have been published[4]. Brown and coworkers proposed the dual decomposition hypothesis of gibbsite as follows[5].

$$\begin{array}{l} \text{Gibbsite} \rightarrow \chi \rightarrow \kappa \rightarrow \alpha \\ \quad\downarrow \qquad\qquad\qquad\uparrow \\ \text{Boehmite} \rightarrow \gamma \rightarrow \delta \rightarrow \theta \end{array}$$

Also Tertian and coworker showed that very fine gibbsite decomposed directly to χ-alumina without being contaminated with boehmite[6].

$$\text{Gibbsite} \rightarrow \chi \rightarrow \kappa \rightarrow \alpha$$

When the authors were writing this report, Dr. Tertian sent us kindly very fine gibbsite which had the diameter of about 0.5 micron. So the thermal transformation of this gibbsite was checked and, consequently, it could be recognize that Tertian's result was correct. (Fig. 6)

In reference to the above facts, it is expected that after long grinding, it is possible to get fine gibbsite which does not decompose into boehmite but is transformed directly into χ-alumina. The result of DTA shows that the first peak and the third peak which indicate respectively formation and decomposition of boehmite become smaller with the duration of grinding. Parallel to this, the dimension of ground crystal decreased to a micron. After 40 hr. grinding, gibbsite decomposed to alumina which did not contain boehmite. This alumina exhibited the characteristic diffraction of 2.12 Å for χ-alumina and was transformed to κ-alumina. So it may be concluded that the ground gibbsite has the same properties as the fine gibbsite. But there are some questions in this explanation. This ground gibbsite shows only two diffraction lines and is no longer true gibbsite. But it may be supposed that this

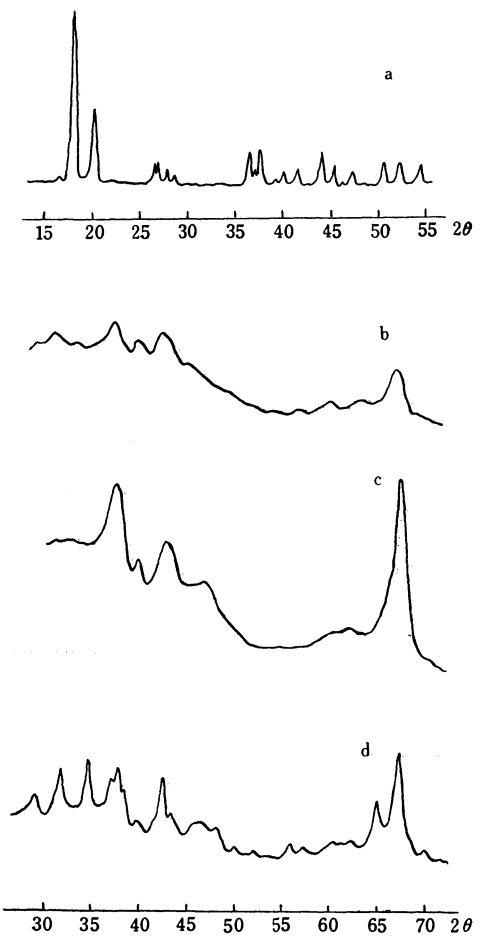

Fig. 6. X-ray diffraction diagrams of fine gibbsite.
a) Original gibbsite
b) Calcined at 350°C
c) Calcined at 800°C (χ-alumina)
d) Calcined at 1000°C (κ-alumina)

gibbsite retains the essential property and structure after being ground, so the thermal property of this gibbsite would have the true character of gibbsite.

The difference of thermal property between large and small particles of gibbsite is explained as follows. When large particles of gibbsite is heated to about 200°C, the hydrothermal reaction begins to form interior crystals and dissolution of gibbsite and crystallization of boehmite occur[7]. But in the case of fine particles, the small crystal can not keep the vapor pressure in it, and the vapor evaporates, so the formation of boehmite ceases. Then the gibbsite decomposes to χ-alumina. That is, the formation

6) R. Tertian and D. Papee, *Compt rend.*, **241**, 1575 (1955).
7) G. Yamaguchi and K. Sakamoto, This Bulletin, **32**, 696 (1959).

of boehmite is not the result of direct decomposition but the result of hydrothermic reaction as in an autoclave, while the small particles of gibbsite can not keep the vapor pressure in it. Thus the hydrothermic reaction does not occur and boehmite is not produced from this gibbsite.

Summary

The effect of dry grinding on gibbsite was examined by X-ray diffraction, X-ray small angle diffraction and differential thermal analysis. It has been found that there are two sorts of structural change in the process of dry grinding. One, which occurs early in this process, is the slip of layers. In this stage (002) reflection retains its intensity. The other, which takes place after grinding of about 10 hr., is the three-dimensional disintegration of the crystal structure and the intensities of all diffractions become weak. Since only two reflections (002) and (110) are observed after 40 hr., it can be known that the direction of the slipping of layers is [110].

DTA-curve of gibbsite exhibits three endothermic peaks in the beginning of grinding but comes to exhibit only one peak which indicates the decomposition of gibbsite to alumina. This means that ground gibbsite decomposes directly to χ-alumina as fine gibbsite and boehmite is not produced in this process.

The authors wish to express hearty thanks to Dr. R. Tertian of Pechiney for his favor.

Sur la dissolution des minerais sulfurés en divers milieux. I. Dissolution d'un minerai sulfuré de fer en milieu acide

Par Masami ICHIKUNI et Hiroshi KAMIYA

(Reçu le 29 mai 1959)

La désagrégation des minerais sulfurés a été étudiée au point de vue de prospection géochimique par Ohashi[1], qui s'est préoccupé à la dissolution du fer, cuivre, zinc et plomb dans les conditions des eaux naturelles. Garrels en a développé une discussion se basant sur les notions thermodynamiques d'équilibre des reactions[2]. La connaissance du comportement du soufre n'est pas pourtant satisfaisante pour l'explication complète de la désagrégation. D'ailleurs l'influence des facteurs de milieu sur ce phénomène reste encore peu claire. L'examen détaillé du phénomène, par voie de cinétique de la réaction, serait d'une importance particulière dans la géochimie.

On pourrait désigner le pH, le potentiel d'oxydo-réduction, la température, la concentration en ion sulfate et d'autres comme facteurs de milieu participant à la désagrégation. Dans ce rapport on présentera une étude fondamentale sur l'influence du pH et de l'air, celui-ci se rapportant avec le pH au potentiel d'oxydoréduction.

Expérience

Généralité. — On pulvérise du minerai sulfuré de fer frais, en traite en milieu acide ou neutre en conduisant de l'air dans la suspension du minerai et poursuit la concentration de composants dissous en fonction du temps.

Echantillon.—Un minerai siliceux (nom populaire donné à un minerai sulfuré consistant en

TABLEAU I. RÉSULTAT D'ANALYSE DU MINERAI

Composant	Teneur, %
SiO_2	71,0
Fe	13,3
S combiné	15,0
S libre	0,15
Cu	0,048
Total	99,5

sulfure de fer et en acide silicique qui se produit autour d'un filon de minerai sulfuré chalcophile) produit à la mine de Kosaka, département d'Akita. On l'a pulvérisé de manière à ce que la poudre passe par un tamis avec un nombre de maille à 100. Le tableau I en montre le résultat d'analyse et révèle que le minerai consiste presque entièrement en pyrite et en acide silicique.

La présence du soufre libre dans le minerai pulvérisé suggère la décomposition du minerai provoquée par l'oxydation lors de la pulvérisation. Il y a donc une possibilité d'altération partielle du minerai sulfuré en d'autres composés que le sulfure, tels que l'oxyde, le sulfate.

Traitement. — On prend 200 ml. d'acide chlorhydrique à une concentration connue ou d'eau bidistillée dans un ballon à fond plat à 300 ml. et le met sur un bain-marie. On en attache à l'entrée un tuyau de verre qui a 4 mm. de diamètre et qui sert à introduire de l'air dans la liqueur et un condensateur à reflux dont la sortie est reliée à une trompe, réglée de manière à ce que l'air barbote dans la liqueur à un débit constant. La température de la liqueur est réglée à 80°C. On y ajoute 5 g. de minerai pulvérisé et effectue le prélèvement d'une petite quantité de liqueur, à peu près 10 ml., à 10 min., une, deux, trois et quatre heures à partir du moment de l'addition du minerai. Le dosage du cuivre, fer et sulfate s'effectue sur la liqueur filtrée.

Conditions du traitement.—Les facteurs à examiner sont le débit de l'air et le pH. Etant donné que la désagrégation des minerais sulfurés donne de l'acide sulfurique, les essais de la dissolution en milieu acide sulfurique se conformeraient aux conditions dans la nature. Mais le dosage du sulfate formé par le traitement rencontrera une difficulté, l'augmentation de la concentration en sulfate devant être très légère. Par suite de cette considération, on s'est permis d'employer l'acide chlorhydrique. On maintient la température constamment à 80°C sur toute la série des expériences, afin de supprimer l'effet de la température lors de la comparaison des résultats.

Les essais du débit de l'air s'effectuent en milieu acide chlorhydrique 0,1 N. Le débit de l'air est varié d'une façon suivante: 1) sans introduction de l'air, 2) 0,5 l./min., et 3) 1,5 l./min. Le premier essai ne signifie pas l'exclusion entière de l'air, mais la diminution la plus possible de contact avec l'air. On a recours en même temps à un agitateur mécanique dans le but de maintenir l'efficacité constante de l'agitation.

Les essais du pH s'effectuent sous un débit de l'air de 1,5 l./min., en milieu acide chlorhydrique: 1) 0,1 N, 2) 0,01 N, 3) 0,001 N, et 4) dans l'eau bidistillée.

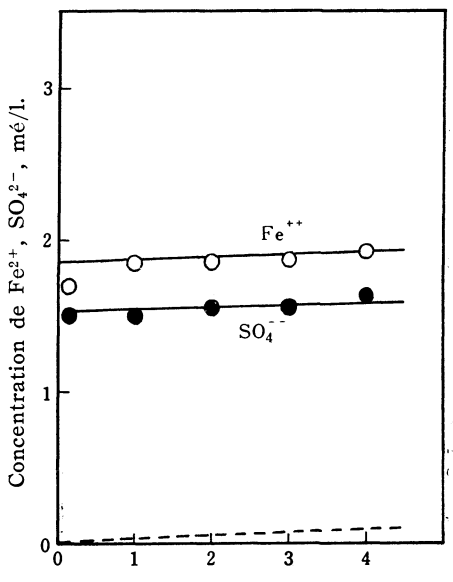
Analyse. — Une quantité limitée de liqueur prélevée ayant empêché d'effectuer une analyse complète, on se borne à faire le dosage du cuivre, fer divalent, fer total et sulfate. Le cuivre et le fer sont dosés par la colorimétrie, avec la dithizone et l'*o*-phénanthroline, respectivement. Le sulfate, par la turbidimétrie après la formation du sulfate de baryum.

On ne décèle pas dans la liqueur d'autres composants de soufre que le sulfate.

Résultats et discussion

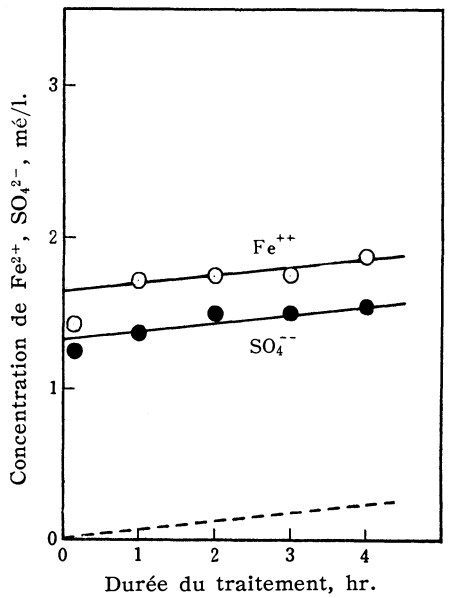
Le tableau II montre le résultat obtenu. Lors du traitement avec de l'eau bidistillée ou de l'acide très dilué, on a remarqué la formation de l'acide sulfurique dont la quantité est estimée par la soustraction du fer du sulfate, les deux étant exprimés en mé/l. Par des essais effectués à part, on a constaté que la somme du fer et de l'acidité s'accorde bien avec la quantité de sulfate dans la limite d'erreur du dosage.

D'autre part, la teneur en fer trivalent est donnée par la différence entre le fer total et le fer divalent.



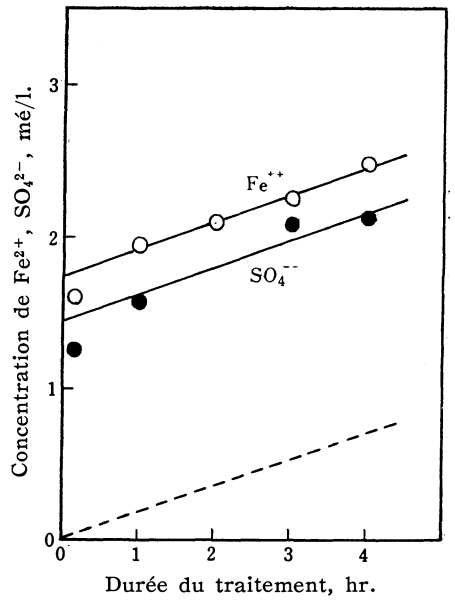
Interprétation des données. — Le minerai utilisé pour ces essais a subi une décomposition partielle par la pulvérisation, ce qui cause quelques irrégularités de dissolution au début du traitement. On développera la discussion en tenant compte de la quantité de composants dissous provenant de la partie préalablement décomposée du minerai.

Les figures sont dessinées avec les données du tableau II. La figure 1 représente la dissolution du fer et du sulfate, et la figure 2, celle du cuivre.

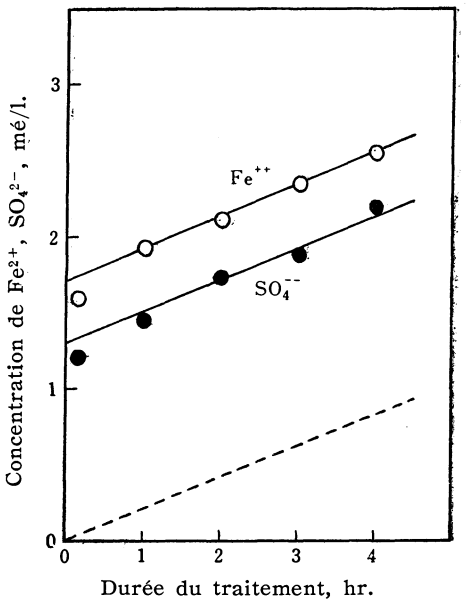


Dans les figures, le trait plein représente la concentration de composants telle qu'on l'a trouvée, et le trait discontinu, tracé de l'origine parallèlement à celui-là, en montre la concentration correspondant à la dissolution par le traitement. La pente du trait discontinu permet de comparer la vitesse de dissolution d'un composant avec celle d'autres.

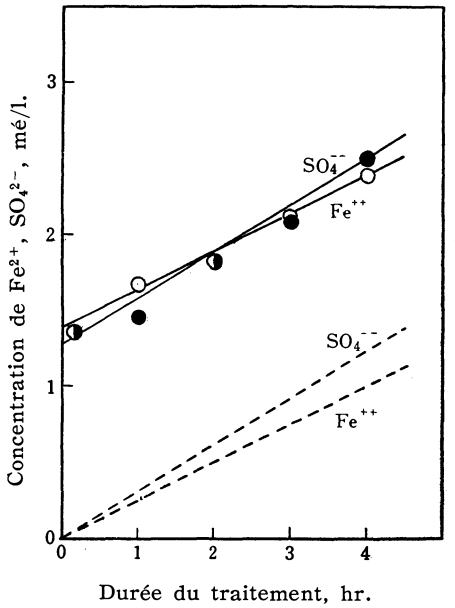
Influence du débit de l'air. — Ces essais, effectués en milieu acide chlorhydrique 0,1 N, montrent que la dissolution du cuivre en subit peu d'influence, tandis que celle du fer et du soufre est favorisée par l'augmentation du débit de l'air.



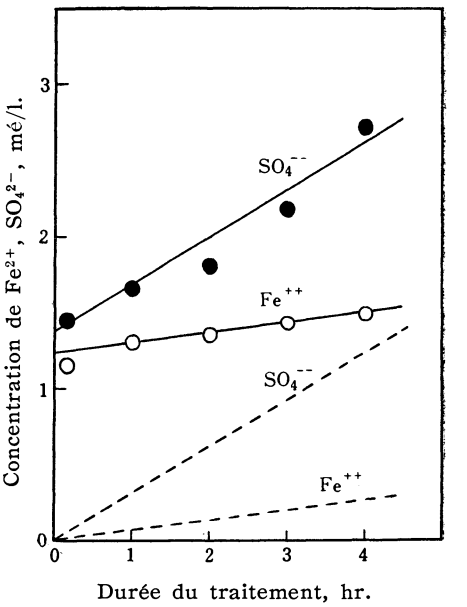
Influence du pH.—La vitesse de dissolution du fer est la même dans l'acide chlorhydrique 0,1 N que dans l'acide 0,01 N. Il en est de même du cuivre et du soufre. L'élévation du pH empêche la dissolution du cuivre et du fer, et accélère celle du soufre.



(a) HCl 0,1 N; Air 0 l./min.



(b) HCl 0,1 N; Air 0,5 l./min.



(c) HCl 0,1 N; Air 1,5 l./min.

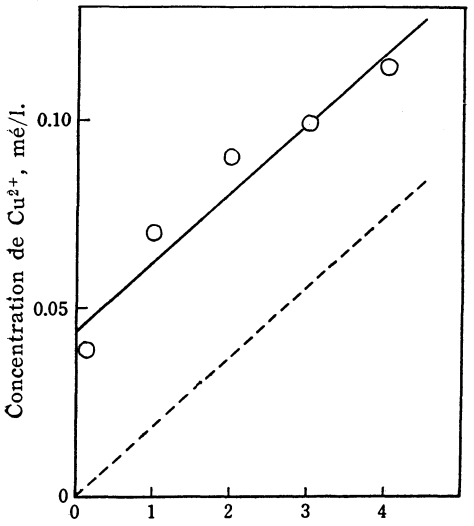
(e) HCl 0,001 N; Air 1,5 l./min.

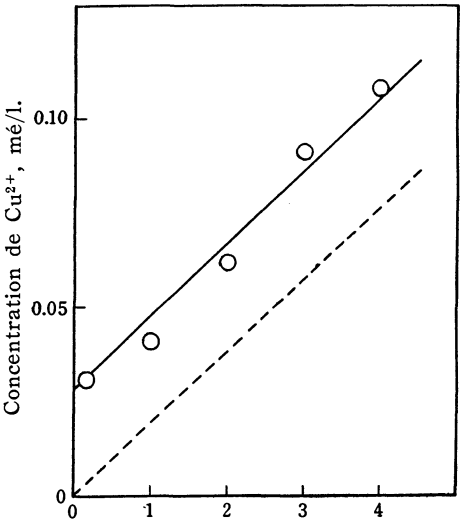
(f) Eau bidistillée; Air 1,5 l./min.

Fig. 1. Dissolution du fer et du sulfate.
Trait plein: concentration totale.
Trait discontinu: concentration correspondant à la dissolution par le traitement.



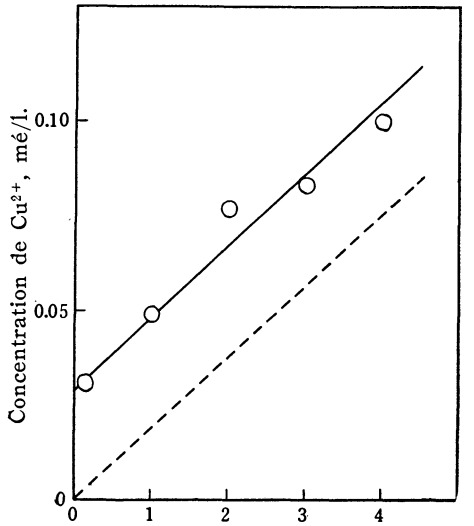
Aucune variation de pH n'a été trouvée pour les expériences effectuées en milieu acide 0,1 N et 0,01 N. Cependant on a remarqué l'abaissement du pH au cours du traitement dans l'acide 0,001 N et l'eau bidistillée. Dans le premier cas, le pH de la liqueur était de 3,0 avant l'addition du minerai, et de 2,8 après quatre heures du traitement. On discutera plus loin le dernier cas, dissolution du minerai par l'eau.

Composition de composants dissous. — La quantité de cuivre dissous étant très petite par rapport à celle de fer et de sulfate,

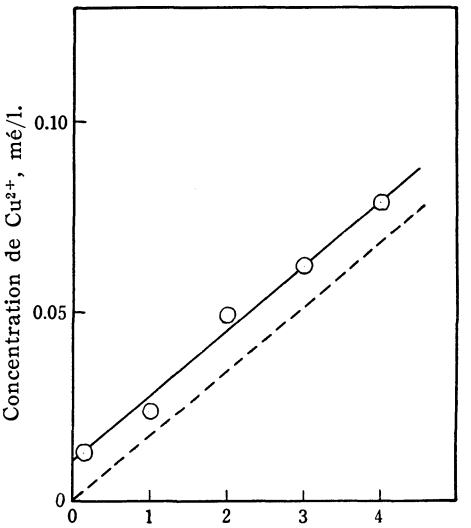


on étudie ici simplement la relation entre le fer et le sulfate. La concentration de fer trivalent ne dépassant pas quelques pourcents de celle de fer divalent, on ne prend pas non plus celui-là en considération. Comme l'indique la figure 1, le rapport de la quantité de fer divalent sur celle de sulfate est l'unité, tous deux étant produits par le traitement et exprimés en unité de mé. On voit bien que l'oxydation du minerai sulfuré par l'air donne le sulfate de fer(II). La présence du fer trivalent serait attribuable à l'oxydation du fer divalent sous forme duquel le fer contenu dans le minerai se dissout dans l'eau.

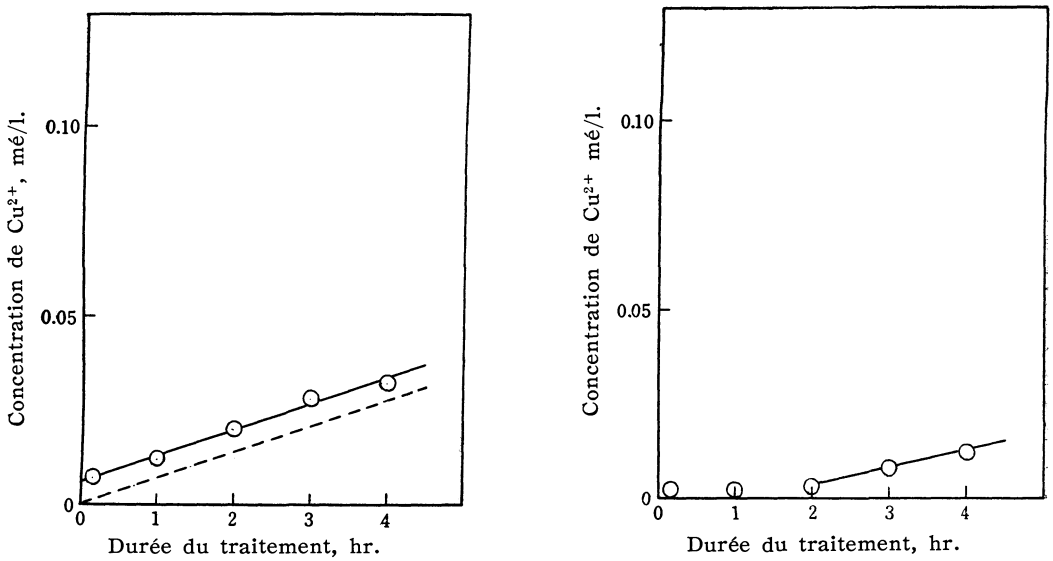
Si la réaction a lieu dans un milieu à pH relativement grand, le sulfate se dissout plus que le fer. Cela s'explique par la formation de l'acide sulfurique. Ce phénomène devient plus remarquable lors du traitement avec de l'eau bidistillée.



Dissolution du minerai par l'eau.—Le résultat de cet essai, considéré comme reproduction de la désagrégation du minerai sulfuré par les eaux naturelles de caractère normal, serait indispensable pour la connaissance des réactions qui ont lieu dans la nature. La dissolution du fer devient



(a) HCl 0,1 N; Air 0 l./min.



(b) HCl 0,1 N; Air 0,5 l./min.

(c) HCl 0,1 N; Air 1,5 l./min.

(d) HCl 0,01 N; Air 1,5 l./min.

(e) HCl 0,001 N; Air 1,5 l./min. (f) Eau bidistillée; Air 1,5 l./min.

Fig. 2. Dissolution du cuivre
Trait plein: concentration totale.
Trait discontinu: concentration correspondant à la dissolution par le traitement.

extrêmement petite, et on ne décèle presque pas de cuivre. Celle du sulfate, au contraire, s'accélère dans ce milieu.

Pourtant on n'arrive pas à différer si une faible concentration en fer est causée par la précipitation du fer hydrolysé ou par la prédominance de la réaction de formation de l'acide sulfurique.

La liqueur devient acide avec la durée du traitement, et au bout de quatre heures, le pH en est inférieur à 3. La dissolution du cuivre augmente avec l'abaissement du pH. Cette tendance est prévue par des essais décrits ci-dessus.

Comportements des composants.—*Cuivre.*—Le facteur règnant sur la dissolution du cuivre contenu dans le minerai sulfuré est vraisemblablement le pH du milieu. Dans un milieu à pH inférieur à 2, la vitesse de dissolution reste constante, indépendamment du pH. Elle est peu influencée par le débit de l'air introduit dans la liqueur.

Fer. — Le débit de l'air exerce une influence considérable sur la dissolution de ce métal. Le résultat des essais fait présumer que la pyrite est relativement stable, même en milieu acide, s'il s'agit des conditions non-oxydantes.

Soufre. — Cet élément se dissout sous forme de sulfate, en milieu acide ou neutre, et en présence de l'air. Sous ces conditions oxydantes, le sulfate est toujours le plus stable parmi les espèces de composés de soufre[3]. La vitesse de dissolution en est d'autant plus grande que le pH est grand, mais le mécanisme de la formation de l'acide sulfurique restera comme un problème à résoudre. Le comportement du soufre résiduel après la dissolution du sulfate de fer, $FeSO_4$, à partir de la pyrite, FeS_2, exigera une étude plus approfondie.

Les auteurs expriment leurs remerciements profonds à Monsieur le professeur K. Noguchi qui leur a permis l'exécution de cette étude et qui leur a accordé toutes les aides possibles, et à Monsieur le professeur T. Hanya qui a bien voulu leur donner des conseils utiles.

The Infrared Spectrum of Dimethyl Sulfone

By Kuniaki FUJIMORI

(Received June 5, 1959)

In the preceding paper[1] normal vibrations and force constants of the methanesulfonate ion were determined empirically. In this paper the infrared spectrum of dimethyl sulfone was measured, the normal vibrations of this molecule were calculated using force constants of the methanesulfonate ion, and they were compared with the experimental values.

Calculation of Normal Vibrations

The calculation was done by means of Wilson's method[2] and treated as a five-body problem assuming the methyl radical to be one particle. As the intramolecular potential, Urey-Bradley field[3] was assumed as done in the case of the methanesulfonate ion[1]. By assuming all the valence angles of sulfur to be tetrahedral, the following elements of G and F materices were obtained[4].

Elements of G matrix for A_1 type vibrations

$$g_{11}=\frac{2}{3}\mu_S+\mu_{Me}$$

$$g_{12}=-\frac{2}{3}\mu_S$$

$$g_{13}=\frac{2}{\sqrt{3}}(\sigma'-1)\mu_S$$

$$g_{14}=-\frac{\sqrt{8}}{3}(\sigma'+1)\mu_S$$

$$g_{22}=\frac{2}{3}\mu_S+\mu_O$$

$$g_{23}=-\frac{2}{\sqrt{3}}(\sigma'-1)\mu_S$$

$$g_{24}=\frac{\sqrt{8}}{3}(\sigma'+1)\mu_S$$

$$g_{33}=\frac{3}{2}(\sigma'^2\mu_{Me}+\mu_O)+2(\sigma'-1)^2\mu_S$$

$$g_{34}=-\frac{1}{\sqrt{6}}\{3(\sigma'^2\mu_{Me}-\mu_O)+4\sigma'(\sigma'-1)\mu_S\}$$

$$g_{44}=\sigma'^2\mu_{Me}+\mu_O+\frac{4}{3}(\sigma'+1)^2\mu_S$$

Elements of F matrix for A_1 type vibrations

$$f_{11}=K_{SMe}+2(s^2_{Me}F_{Me}+t^2_{MeO}F'_{MeO}+s^2_{MeO}F_{MeO})$$

$$f_{12}=-2(t_{MeO}t_{OMe}F'_{MeO}+s_{MeO}s_{OMe}F_{MeO})$$

$$f_{13}=\sqrt{\frac{2}{3}}\{(t_{MeO}s_{OMe}F'_{MeO}+t_{OMe}s_{MeO}F_{MeO})+\sigma t_{Me}s_{Me}(F'_{Me}+F_{Me})\}$$

$$f_{14}=\sigma t_{Me}s_{Me}(F'_{Me}+F_{Me})$$

$$f_{22}=K_{SO}+2(t^2_{OMe}F'_{MeO}+s^2_{OMe}F_{MeO}+s^2_OF_O)$$

$$f_{23}=\sqrt{\frac{2}{3}}(t_{OMe}s_{MeO}F'_{MeO}+t_{MeO}s_{OMe}F_{MeO})-t_Os_O(F'_O+F_O)\}$$

$$f_{24}=-t_Os_O(F'_O+F_O)$$

$$f_{33}=\frac{1}{3}\{\sigma^2(H_{Me}-s^2_{Me}F'_{Me}+t^2_{Me}F_{Me})+(H_O-s^2_OF'_O+t^2_OF_O)\}$$

$$f_{34}=\frac{1}{\sqrt{6}}\{-\sigma^2(H_{Me}-s^2_{Me}F'_{Me}+t^2_{Me}F_{Me})+(H_O-s^2_OF'_O+t^2_OF_O)\}$$

$$f_{44}=\frac{1}{2}\{\sigma^2(H_{Me}-s^2_{Me}F'_{Me}+t^2_{Me}F_{Me})+(H_O-s^2_OF'_O+t^2_OF_O)\}+\frac{3}{\sqrt{8}}\kappa/r^2_{SO}$$

Elements of G and F matrices for A_2 type vibration

$$g=\frac{3}{2}\sigma'^2\mu_{Me}+\frac{3}{2}\mu_O+\frac{1}{3}(5\sigma'^2+2\sigma'+5)\mu_S$$

$$f=\sigma(H_{MeO}-s_{MeO}s_{OMe}F'_{MeO}+t_{MeO}t_{OMe}F_{MeO})-\frac{1}{\sqrt{8}}\kappa/r^2_{SO}$$

Elements of G matrix for B_1 type vibrations

$$g_{11}=\frac{4}{3}\mu_S+\mu_{Me}$$

$$g_{12}=-\frac{2}{3}(\sigma'+3)\mu_S$$

$$g_{22}=\frac{1}{2}\sigma'^2\mu_{Me}+\frac{3}{2}\mu_O+\frac{1}{3}(\sigma'+3)^2\mu_S$$

$$f_{12}=\sqrt{2}\,(t_{MeO}s_{OMe}F'_{MeO}+t_{OMe}s_{MeO}F_{MeO})$$

$$f_{22}=\sigma(H_{MeO}-s_{OMe}s_{MeO}F'_{MeO}+t_{MeO}t_{OMe}F_{MeO})+\frac{3}{\sqrt{8}}\kappa/r^2_{SO}$$

Elements of G matrix for B_2 type vibrations

$$g_{11}=\frac{4}{3}\mu_S+\mu_O$$

$$g_{12}=-\frac{2}{3}(3\sigma'+1)\mu_S$$

$$g_{22}=\frac{3}{2}\sigma'^2\mu_{Me}+\frac{1}{2}\mu_O+\frac{1}{3}(3\sigma'+1)^2\mu_S$$

Elements of F matrix for B_2 type vibrations

$$f_{11}=K_{SO}+2(t^2_{OMe}F'_{MeO}+s^2_{OMe}F_{MeO}+t^2_{O}F'_{O})$$

$$f_{12}=\sqrt{2}\,\sigma(t_{OMe}s_{MeO}F'_{MeO}+t_{MeO}s_{OMe}F_{MeO})$$

$$f_{22}=\sigma(H_{MeO}-s_{OMe}s_{MeO}F'_{MeO}+t_{MeO}t_{OMe}F_{MeO})+\frac{3}{\sqrt{8}}\kappa/r^2_{SO}$$

where, K is the stretching force constant, H is the bending force constant and F and F' are repulsive force constants. And μ is the reciprocal of the atomic weight of sulfur, oxygen or the methyl radical.

The following notations are also used:

$$s_{ij}=(r_i-r_j\cos\alpha_{ij})/q_{ij},$$

$$s_{ji}=(r_i-r_j\cos\alpha_i)/q_{ij},\quad t_{ij}=r_j\sin\alpha_{ij}/q_{ij},$$

$$t_{ji}=r_i\sin\alpha_{ij}/q_{ij},\quad \sigma=r_{SMe}/r_{SO},\quad \sigma'=1/\sigma,$$

κ (intramolecular tension)

$$=-(K'_i r_{ij}^2+H'_{ij}r_{ij}q_{ij}\sqrt{t_{ij}t_{ji}}),$$

where r denotes S–O or S–Me bond length, q_{ij} denotes distance between non-bonded atoms, α_{ij} denotes valence angle and $r^2_{ij}=r_ir_j$.

For the S–O and S–Me bond length, the following values were assumed. S–O= 1.43 Å, S–Me=1.80 Å[5].

Force constants were transferred from methanesulfonate ion[1], diethyl sulfide[6], tetramethyl silane[7] and sulfur dioxide[8]. Their values are given in Table I.

TABLE I. FORCE CONSTANTS

F.C.	10^5 dyn./cm.	Ref.	F. C.	10^5 dyn./cm.	Ref.
K_{SMe}	3.05	1)	F'_{Me}	−0.020	7)

H_{MeO}	0.250	1)	F'_{MeO}	−0.035	1)
F_{Me}	0.200	7)	κ	0.328*	1)

* Unit is 10^{-11} dyn./cm.

Results and Discussion

The calculated normal vibrations are given in Table II. The infrared spectrum of dimethyl sulfone in a solid state is shown in Fig. 1. The absorption frequencies are compared with the observed values and their assignments are made as shown in Table III.

TABLE II. CALCULATED NORMAL VIBRATIONS (in cm^{-1})

Type	Wave number	Assignment
A_1	741	S-Me stretching
	314	$S(Me)_2$ bending
	1252	S-O stretching
	521	SO_2 bending
A_2	408	twisting
B_1	795	S-Me stretching
	472	$S(Me)_2$ rocking SO_2 wagging
B_2	1345	S-O stretching
	428	$S(Me)_2$ wagging SO_2 rocking

TABLE III. ABSORPTIONS AND ASSIGNMENTS (in cm^{-1})

Wave number	Assignment	Calcd.
3024 (m), 2962 (w)	C-H stretching	
1430 (m), 1412 (m)	CH_3 degenerated bending	
1337 (s)	CH_3 symmetric bending	
1315 (s), 1290 (s)	S-O stretching	1345
1130 (s)	S-O stretching	1252
938 (s)	Me rocking	
761 (s)	S-Me stretching	795
695 (m)	S-Me stretching	741

C-H stretching frequencies have higher wave numbers than those of hydrocarbons because of strong electronegativity of $-SO_2-$ group. This phenomenon was also found in the case of lower sulfonates[9]. Methyl rocking vibration at 938 cm^{-1} has lower wave number than that of methanesulfonate ion. The reason may be attributed to the coupling with S–O stretching vibration.

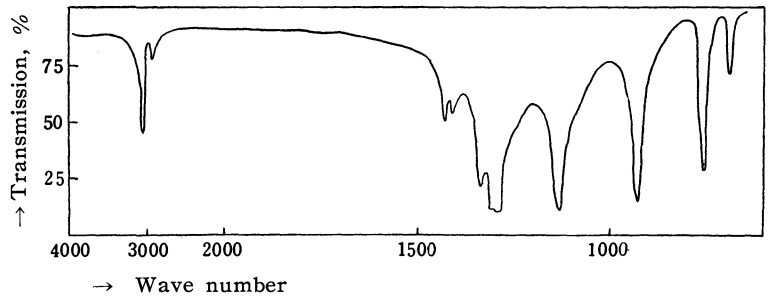

Fig. 1. Infrared spectrum of dimethyl sulfone.

The deviation between the observed and calculated frequencies may be attributed to the high value of S–O stretching force constant and the low value of O–O repulsive force constants.

Experimental

The infrared spectrum was obtained by a Perkin-Elmer Model 21 double-beam infrared spectrophotometer using NaCl prism. The KBr disk method was employed to obtain the spectrum in solid state.

Dimethyl sulfone was prepared by oxidation of dimethyl sulfoxide with hydrogen peroxide in acetic acid solution[10]. After the reaction mixture was treated with acetaldehyde and the solvent was removed, dimethyl sulfone was recrystallized from ethanol. The melting point of this compound is 108.5°C and the referenced value is 109°C[11].

The author wishes to express his indebtedness to Dr. A. Kotera, Professor of Tokyo University of Education, and Dr. T. Shimanouchi, Professor of the University of Tokyo, under whose kind direction this work was performed. The author also wishes to thank Mr. Y. Ikegami, Fellow of Tohoku University, for his co-operation in obtaining infrared spectrum, and to Mr. Y. Akai, Chief of Research Section of Funakawa Refinery, for his encouragement of this research.

The Kinetics of Substitution Reactions Involving Metal Complexes. II. Effect of Acetate Ions on the Reaction between Copper(II) and Lead-Ethylenediaminetetraacetate Complexes

By Nobuyuki TANAKA and Kiyoko KATO*

(Received July 3, 1959)

In the previous paper[1], the substitution reaction of copper(II) ions and lead-ethylenediaminetetraacetate(EDTA) complexes was reported. The rate of the reaction was followed by measuring the change of the polarographic diffusion current of copper(II) ions with time in acetate buffer solutions. The reaction was found to proceed, under the experimental conditions, simultaneously through three different reaction paths, and the rate constants of the elementary reactions of those reaction paths were determined.

Although the reaction rate was measured in acetate buffer solutions, the effect of acetate ion concentration was not taken into consideration, all measurements being

* Present address: The Women's Department, Tokyo College of Pharmacy, 31, Uenosakuragi-cho, Taito-ku, Tokyo.

1) N. Tanaka, K. Kato and R. Tamamushi, This Bulletin, 31, 283 (1958).

carried out at 0.1 M of acetate in concentration. Ackermann and Schwarzenbach[2] found that the overall reaction rate of the substitution reaction of copper(II) ions and cadmium-EDTA complexes increased with the decreasing concentration of acetate ions, but they gave no quantitative explanation of this phenomenon. The increase of the reaction rate with the decrease of the acetate ion concentration was also found by the present authors in the case of the substitution reaction of copper(II) ions and lead-EDTA complexes.

In this paper, the effect of acetate ions on the rate of the substitution reaction of copper(II) ions and lead-EDTA complexes is investigated. The experimental results reported in the previous paper[1] are treated on the basis of the formation of acetato complexes of metal ions in acetate media and on the assumption that the substitution reaction proceeds through the hydrated metal ions which are in equilibrium with the acetato complexes. The rate constants of the elementary reactions reported previously are recalculated with the equations newly derived.

Derivation of the Rate Equation

Let us consider the acetate buffer solution which contains copper(II) ions and lead-EDTA complexes. In the solution containing acetate ions less than 0.2 M in concentration, copper(II) and lead(II) form mono- and diacetato complexes[3]. Therefore, the overall substitution reaction is represented by the equations

$$Cu^{2+}+2\ OAc^- \rightleftarrows CuOAc^+ + OAc^- \rightleftarrows Cu(OAc)_2 \quad (1)$$

$$Cu^{2+}+PbY^{2-} \rightleftarrows CuY^{2-}+Pb^{2+} \quad (2)$$

$$Pb^{2+}+2\ OAc^- \rightleftarrows PbOAc^+ + OAc^- \rightleftarrows Pb(OAc)_2 \quad (3)$$

where Y^{4-} means a completely dissociated EDTA anion. Under the condition that lead ions and lead-EDTA complexes are present in a large excess over copper(II) ions, the substitution reaction 2 can be simplified to

$$Cu^{2+} \underset{k^-}{\overset{k^+}{\rightleftarrows}} CuY^{2-}$$

In the polarographic measurement in acetate media, it is impossible to determine separately either the concentration of hydrated copper(II) ions or that of acetato-copper(II) complexes. On the contrary, the diffusion current of copper(II) obtained in acetate media corresponds to the sum of the diffusion current of the hydrated copper(II) ions and that of the acetato-copper(II) complexes. In other words, the concentration that can be determined polarographically is $[Cu^{2+}]_{app}$ given by the equation[4]

$$[Cu^{2+}]_{app} = [Cu^{2+}] + [CuOAc^+] + [Cu(OAc)_2] \quad (5)$$

The rate equation for reaction 4, therefore, is expressed as

$$-\frac{d[Cu^{2+}]_{app}}{dt} = k^+[Cu^{2+}]_{app} - k^-[CuY^{2-}] \quad (6)$$

Integrating Eq. 6,

$$\ln\{[Cu^{2+}]_{app} - [Cu^{2+}]_{e,app}\} = -(k^+ + k^-)t + \ln\{[Cu^{2+}]_{0,app} - [Cu^{2+}]_{e,app}\}$$

is obtained. At the equilibrium of the reaction, the relation

$$\frac{k^+}{k^-} = \frac{[CuY^{2-}]_e}{[Cu^{2+}]_{e,app}} \doteqdot K^{Cu}_{Pb,app}\frac{[PbY^{2-}]_0}{[Pb^{2+}]_{0,app}}$$

may be satisfied, where $K^{Cu}_{Pb,app}$ represents the apparent equilibrium constant expressed as

$$K^{Cu}_{Pb,app} = \frac{[Pb^{2+}]_{e,app}[CuY^{2-}]_e}{[Cu^{2+}]_{e,app}[PbY^{2-}]_e}$$

Subscripts e and 0 mean equilibrium and zero time, respectively. The value of $K^{Cu}_{Pb,app}$ must be determined polarographically as the same concentration of acetate as the reaction rate is observed.

In the previous study[1], it was found that the substitution reaction between copper(II) and lead-EDTA complexes proceeds through the simultaneous reaction paths

$$\text{(i)}\quad Cu^{2+}+PbY^{2-} \underset{k_1^-}{\overset{k_1^+}{\rightleftarrows}} CuY^{2-}+Pb^{2+} \quad (7)$$

$$\text{(ii)}\quad PbY^{2-}+H^+ \rightleftarrows PbHY^- \quad (8a)$$

$$Cu^{2+}+PbHY^- \underset{k_{II}^-}{\overset{k_{II}^+}{\rightleftarrows}} CuHY^- + Pb^{2+} \quad (8b)$$

$$CuHY^- \rightleftarrows CuY^{2-}+H^+ \quad (8c)$$

$$\text{(iii)}\quad PbY^{2-}+H^+ \rightleftarrows Pb^{2+}+HY^{3-} \quad (9a)$$

$$Cu^{2+}+HY^{3-} \underset{k_{III}^-}{\overset{k_{III}^+}{\rightleftarrows}} CuY^{2-}+H^+ \quad (9b)$$

and the rate equation

2) H. Ackermann and G. Schwarzenbach, *Helv. Chim. Acta*, **35**, 485 (1952).

3) N. Tanaka and K. Kato, unpublished work.

4) Cf., N. Tanaka and K. Kato, This Bulletin, **32**, 516 (1959).

$$-\frac{d[Cu^{2+}]}{dt}=\left\{k_1^{+}+k_2^{+}[H^+]+k_3^{+}\frac{[H^+]}{[Pb^{2+}]}\right\}\times[Cu^{2+}][PbY^{2-}]-\left\{k_1^{-}+k_2^{-}[H^+]+k_3^{-}\frac{[H^+]}{[Pb^{2+}]}\right\}[Pb^{2+}][CuY^{2-}] \quad (10)$$

was derived, where

$$\left.\begin{aligned} k_2^{+}&=k_{II}^{+}K_{PbHY}^{H}, & k_2^{-}&=k_{II}^{-}K_{CuHY}^{H}\\ k_3^{+}&=k_{III}^{+}/(K_{PbY}K_{HY}), & k_3^{-}&=k_{III}^{-}\end{aligned}\right\} \quad (11)$$

As has been mentioned above, the concentration which was actually measured polarographically was not the concentration of hydrated copper(II) ions in Eq. 10, but the sum of the concentrations of hydrated ions and acetato complexes. If it is assumed that the substitution reaction proceeds through only the hydrated ions which are in equilibrium with the acetato complexes, the apparent rate of the reaction ($=-d[Cu^{2+}]_{app}/dt$) which is determined polarographically is expressed as

$$-\frac{d[Cu^{2+}]_{app}}{dt}=\left\{k_1^{+}+k_2^{+}[H^+]+k_3^{+}\frac{[H^+]}{[Pb^{2+}]}\right\}\times[Cu^{2+}][PbY^{2-}]-\left\{k_1^{-}+k_2^{-}[H^+]+k_3^{-}\frac{[H^+]}{[Pb^{2+}]}\right\}[Pb^{2+}][CuY^{2-}] \quad (12)$$

From Eq. 5, the concentration of the hydrated copper(II) ions is given as

$$[Cu^{2+}]=\frac{[Cu^{2+}]_{app}}{1+\sum_{n=1}^{2}K_{Cu(OAc)_n}[OAc^-]^n} \quad (13)$$

where $K_{Cu(OAc)_n}$ represents the overall formation constant of acetatocopper(II) complexes expressed with

$$K_{Cu(OAc)_n}=\frac{[Cu(OAc)_n^{(2-n)+}]}{[Cu^{2+}][OAc^-]^n}$$

Similarly the concentration of the hydrated lead(II) ions is given as

$$[Pb^{2+}]=\frac{[Pb^{2+}]_{app}}{1+\sum_{n=1}^{2}K_{Pb(OAc)_n}[OAc^-]^n}$$

where $K_{Pb(OAc)_n}$ means the overall formation constant of acetatolead(II) complexes.

Introducing Eqs. 13 and 14 into Eq. 12, Eq. 15 is obtained. Eq. 15 is now considered to be a general formula which expresses the rate of the substitution reaction between copper(II) and lead-EDTA complexes in acetate media.

Determination of the Rate Constants

From Eqs. 6 and 15, the relations given by Eqs. 16 and 17 are obtained, where the initial concentrations, $[Pb^{2+}]_0$ and $[PbY^{2-}]_0$, are substituted for $[Pb^{2+}]$ and $[PbY^{2-}]$, respectively. Since both $[Pb^{2+}]$ and $[PbY^{2-}]$ are present in the reaction mixture in a large excess over the concentration of copper(II), the changes of their concentrations during the reaction can be neglected.

$$-\frac{d[Cu^{2+}]_{app}}{dt}=\left\{\frac{k_1^{+}+k_2^{+}[H^+]+k_3^{+}[H^+]\dfrac{1+\sum_{n=1}^{2}K_{Pb(OAc)_n}[OAc^-]^n}{[Pb^{2+}]_{app}}}{1+\sum_{n=1}^{2}K_{Cu(OAc)_n}[OAc^-]^n}\right\}[Cu^{2+}]_{app}[PbY^{2-}]-\left\{\frac{k_1^{-}+k_2^{-}[H^+]+k_3^{-}[H^+]\dfrac{1+\sum_{n=1}^{2}K_{Pb(OAc)_n}[OAc^-]^n}{[Pb^{2+}]_{app}}}{1+\sum_{n=1}^{2}K_{Pb(OAc)_n}[OAc^-]^n}\right\}[Pb^{2+}]_{app}[CuY^{2-}] \quad (15)$$

$$\frac{k^{+}}{[PbY^{2-}]_0}\equiv\frac{k_1^{+}+k_2^{+}[H^+]+k_3^{+}[H^+]\dfrac{1+\sum_{n=1}^{2}K_{Pb(OAc)_n}[OAc^-]^n}{[Pb^{2+}]_{0,app}}}{1+\sum_{n=1}^{2}K_{Cu(OAc)_n}[OAc^-]^n} \quad (16)$$

$$\frac{k^{-}}{[Pb^{2+}]_{0,app}}\equiv\frac{k_1^{-}+k_2^{-}[H^+]+k_3^{-}[H^+]\dfrac{1+\sum_{n=1}^{2}K_{Pb(OAc)_n}[OAc^-]^n}{[Pb^{2+}]_{0,app}}}{1+\sum_{n=1}^{2}K_{Pb(OAc)_n}[OAc^-]^n} \quad (17)$$

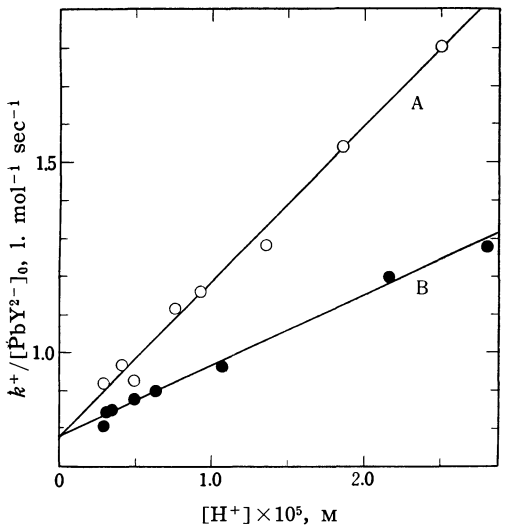

Fig. 1. $k^+/[PbY^{2-}]_0$ as a function of the hydrogen ion concentration in acetate buffer—potassium nitrate solutions of ionic strength 0.2 at 25°C. Initial concentrations are: $[Cu^{2+}]_{0,app}=1.86\times10^{-4}$ M; $[PbY^{2-}]_0=4.05\times10^{-3}$ M; $[Pb^{2+}]_{0,app}=3.95\times10^{-3}$ M (curve A) and 9.97×10^{-3} M (curve B). Concentratrations of free acetate are: 0.095 M(A) and 0.088 M (B).

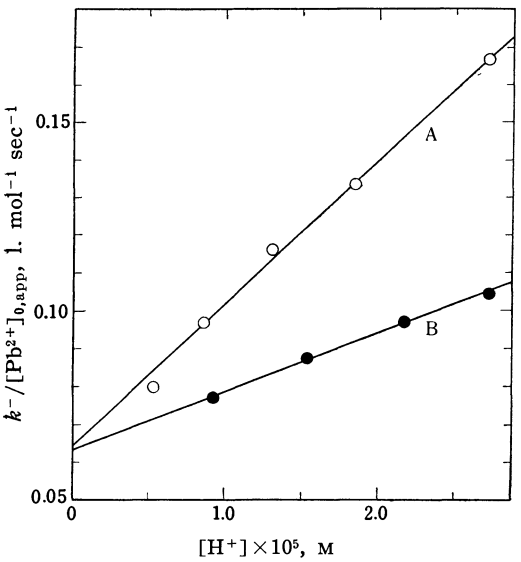

Fig. 2. $k^-/[Pb^{2+}]_{0,app}$ as a function of the hydrogen ion concentration in acetate buffer—potassium nitrate solutions of ionic strength 0.2 at 25°C. Initial concentrations are: $[CuY^{2-}]_0=4.65\times10^{-4}$ M; $[PbY^{2-}]_0=4.05\times10^{-3}$ M; $[Pb^{2+}]_{0,app}=3.95\times10^{-3}$ M (curve A) and 9.97×10^{-3} M (curve B). Concentrations of free acetate are: 0.095 M (A) and 0.088 M (B).

The experimental results which were reported in the previous paper[1] were utilized for the calculation of the rate constants in Eq. 15. The relations of $k^+/[PbY^{2-}]_0$ vs. $[H^+]$ and $k^-/[Pb^{2+}]_{0,app}$ vs. $[H^+]$ are plotted in Figs. 1 and 2. The values of the rate constants calculated are given in Table I. The formation constants of acetatocopper(II) and acetatolead(II) complexes which were used in the calculation are those which were determined polarographically at ionic strength 0.2 at 15, 25 and 35°C[3]. They are given in Table II. The concentration of uncomplexed acetate in the solution was calculated by successive approximation.

The rate constants of both elementary reactions 8b and 9b can be calculated from the relations given in Eqs. 11, using the values of K^{H}_{PbHY}, K_{PbY} and K_{HY} which are given in Table III. The values of K_{PbY} at 15, 25 and 35°C were obtained by dividing the values of K_{CuY} by those of K^{Cu}_{Pb}. The

Reaction	Rate constant, expressed in l. mol^{-1} sec^{-1}	$\Delta H^{\ddagger}$, kcal. mol^{-1}	$\Delta S^{\ddagger}$, e. u.
$Cu^{2+}+PbY^{2-} \rightarrow CuY^{2-}+Pb^{2+}$	$k_1^+=2.7\times10^{15}\ \exp(-20{,}000/\boldsymbol{RT})$	19	10
$Cu^{2+}+PbHY^{-} \rightarrow CuHY^{-}+Pb^{2+}$	$k_{II}^+=2.5\times10^{22}\ \exp(-28{,}000/\boldsymbol{RT})$	27	42
$Cu^{2+}+HY^{3-} \rightarrow CuY^{2-}+H^+$	$k_{III}^+=3.2\times10^{15}\ \exp(-\ 8{,}200/\boldsymbol{RT})$	7.6	10

formation constants of CuY^{2-}, K_{CuY}, at 15, 25 and 35°C at ionic strength 0.2 were calculated, from the value obtained by Schwarzenbach et al.[5] at 20°C at ionic strength 0.1, with the aid of the Debye-Hückel equation and the heat of formation of CuY^{2-}, −8.2 kcal./mol., reported by Charles[6]. The equilibrium constants of reaction 2 at zero acetate concentration, K_{Pb}^{Cu}, used in this calculation are those determined by the present authors[3]. The rate constants of three elementary reactions 7, 8b and 9b thus calculated are summarized in Table IV.

Discussion

Linear relations were found between the logarithm of rate constant and the reciprocal of absolute temperature for three elementary reactions 7, 8b and 9b.

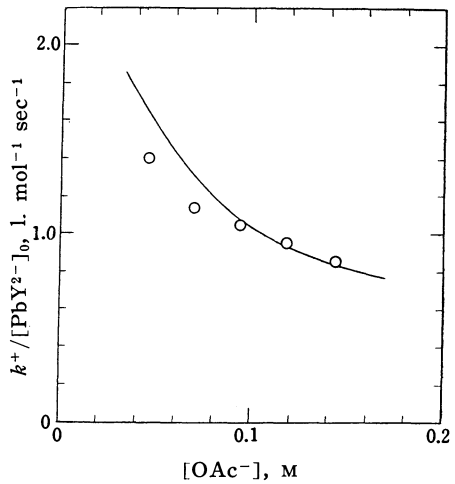

Fig. 3. $k^+/[PbY^{2-}]_0$ as a function of the acetate concentration in acetate buffer—potassium nitrate solutions of pH 5.14 and ionic strength 0.2 at 25°C. Initial concentrations are: $[Cu^{2+}]_{0,app}=1.96\times10^{-4}$ M; $[PbY^{2-}]_0=4.90\times10^{-3}$ M; $[Pb^{2+}]_{0,app}=4.90\times10^{-3}$ M. — indicates the theoretical curve and ○, the experimental value.

5) G. Schwarzenbach, R. Gut and G. Anderegg, *Helv. Chim. Acta*, **37**, 937 (1954).
6) R. G. Charles, *J. Am. Chem. Soc.*, **76**, 5854 (1954).

This made it possible to express the rate constants in the form of the Arrhenius equation and to calculate the heat of activation and the entropy of activation. The results are given in Table V.

From Eq. 15, it is predicted that the reaction rate decreases with the increase of acetate concentration. Using Eq. 16, the values of $k^+/[PbY^{2-}]_0$ were calculated at various acetate concentrations with the rate constants given in Table I and the formation constants of the acetato complexes. They are plotted against acetate concentration as shown in Fig. 3. The reaction rates were experimentally measured at various acetate concentrations, keeping the other conditions constant, with the same procedure as given in the previous paper[1]. Those values are also shown in Fig. 3, which are in fair agreement with the calculated ones. The deviation of the expermental values from the calculated ones is apparent at lower acetate concentration. This has not been clearly understood, but is considered to be due to a contribution of the reactions in which acetatocopper(II) complexes participate.

Summary

The effect of acetate ions on the rate of the substitution reaction of copper(II) and lead-EDTA complexes is explained quantitatively on the basis of the formation of acetato complexes of copper(II) and lead(II) in acetate media and on the assumption that the substitution reaction proceeds only through the hydrated metal ions. The rate constants, the heats of activation and the entropies of activation for three elementary reactions are recalculated with the experimental results obtained previously.

Infrared Spectra of Glycols Coordinated to Metal Ions

By Akihisa MIYAKE

(Received October 12, 1959)

Ethylene glycol has received attention in discussion of the infrared spectrum of polyethylene glycol[1]. Certain problems with regard to the rotational isomerism of this molecule still remain to be solved. It has been known that ethylene glycol forms coordination compound with cobalt or nickel ion[2]. In an attempt to provide some new information on the vibrational assignments for this molecule, the infrared spectra of these coordination complexes were investigated.

Cobalt(II) chloride or nickel(II) chloride was dehydrated by heating at about 150°C. The coordination complexes were prepared by adding ethylene glycol to these dehydrated salts. There is a marked spectral difference between the free molecule and the molecule coordinated about a metal ion (Fig. 1). The coordinated ligand shows two kinds of spectra according to the water content of the dehydrated salts, both for cobalt and nickel. When the water contents of the salts exceed a value of about 15%, the complexes obtained from them (complex I) exhibit the spectrum shown in Fig. 1B. When the water contents are lower than this value, the complexes obtained (complex II) exhibit the spectrum shown in Fig. 1C. On the other hand, there is no difference between the cobalt and nickel complexes.

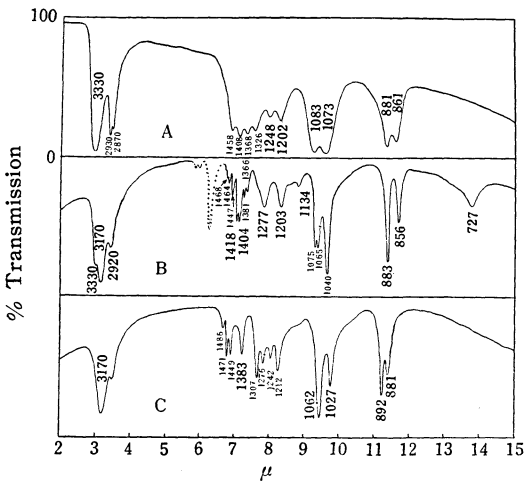

Fig. 1. Infrared spectra of ethylene glycol: (A) Liquid, (B) (C) metal complex (Nujol and polytrifluoroethylene mull, ---- water).

Two bands at 881 and 861 cm^{-1} in liquid ethylene glycol are undoubtedly assigned to the CH_2 rocking vibrations, because no other fundamental vibrations are expected in this region. The appearance of two CH_2 rocking bands indicates that ethylene glycol is present in the *gauche* form, because two CH_2 rocking bands (A and B types) are expected for the *gauche* form but only one (A_u type) for the *trans* form. The other CH_2 rocking vibration (B_g type) of the *trans* form is forbidden to appear in an infrared spectrum. An alternative interpretation is possible, however, assuming that two vibrations coalesce into a single band. In this way Kuroda and Kubo[1] have assigned the band at 881 cm^{-1} to the *gauche* form and the band at 861 cm^{-1} to the *trans* form, considering that the two *gauche* vibrations overlap. Experimental results obtained in the present work provide data as to which one of these contradictory interpretations is more reasonable.

The number of absorption bands observed in the spectra of the complexes is a little larger than that observed for the liquid state. This indicates that the number of molecular forms present in the complex is at least not smaller than that present in the liquid. Thus, if the *trans* and *gauche* forms coexist in the liquid, they must also coexist in the complexes. Then the bands at 887 cm^{-1} (complex I) and 892 cm^{-1} (complex II) must be assigned to the *gauche* form, and the bands at

1) Y. Kuroda and M. Kubo, *J. Polymer Sci.*, **26**, 323 (1957).
2) A. Grün and E. Boedecker, *Ber.*, **43**, 1051 (1910).

856 cm^{-1} (complex I) and 881 cm^{-1} (complex II) to the *trans* form. Relative intensities of these two bands attributed to different molecular forms do not change appreciably through the three states, liquid, complex I and complex II. Therefore, the assignment based on the coexistence of both *trans* and *gauche* forms leads to a very improbable conclusion that the equilibrium ratio of the two kinds of molecular form and hence the energy difference between them do not change through the three different states.

All the bands change their positions more or less on going from liquid to complex I and from complex I to complex II, indicating that some small differences in the molecular form are present among the three states. If the band at 881 cm^{-1} in liquid ethylene glycol is composed of two *gauche* vibrations, it is reasonably expected that these two separate from each other in the complexes because the CH_2 rocking frequencies are particularly sensitive to conformation[3]. Although the bands of the complexes at 887 and 892 cm^{-1} are much sharper than the band of the liquid at 881 cm^{-1}, there is no indication of such a separation. It is too accidental that the two *gauche* frequencies coincide through the three states.

From these considerations it is more reasonable to assign both the CH_2 rocking bands to the *gauche* form than to assign one of them to the *gauche* and the other to the *trans* form. The presence of only the *gauche* form is sufficient to account for the number of observed bands in the region 1500~800 cm^{-1}, ten for the liquid, fifteen for complex I, and thirteen for complex II. The number of fundamental frequencies expected to appear in this range are thirteen for the *gauche* form and six for the *trans* form.

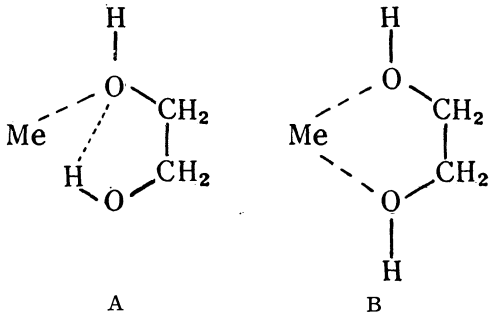

Fig. 2. Two types of coordination.

3) I. Nakagawa and S. Mizushima, This Bulletin, 28, 589 (1955).

The ligand in complex I can be considered to coordinate in a manner shown in Fig. 2A. This is based on the existence of two OH bands (3330 and 3170 cm^{-1}) indicating the presence of two kinds of OH groups. [The OH frequencies of the coexisting water are higher (ca. 3400 cm^{-1}) even if they appear.] The ligand in complex II shows a single OH band and probably coordinates in a manner shown in Fig. 2B. Spectral features of the liquid ethylene glycol, especially the positions of the CH_2 rocking frequencies, are more close to those of complex I than to those of complex II. Thus one of the OH groups of ethylene glycol molecule seems to form an intramolecular hydrogen bond in the liquid state.

Besides ethylene glycol, diethylene glycol and triethylene glycol were also investigated. Again, there are significant changes of the spectra on passing from

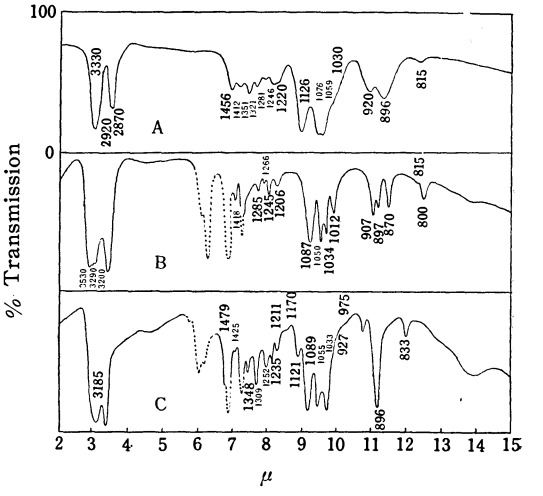

Fig. 3. Infrared spectra of diethylene glycol: (A) Liquid, (B) cobalt complex, (C) nickel complex (Nujol mull, ---- water and Nujol).

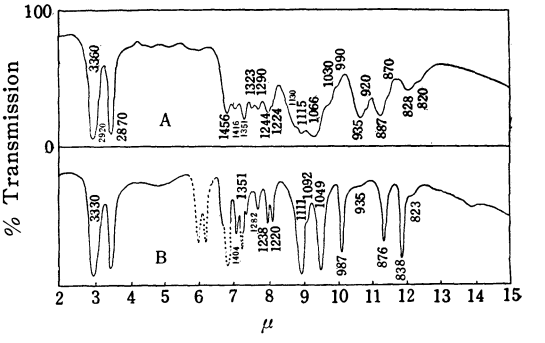

Fig. 4. Infrared spectra of triethylene glycol: (A) Liquid, (B) metal complex (Nujol mull, ---- water and Nujol).

liquid to complex compound. In the case of triethylene glycol, there is no difference between the spectra of nickel and cobalt complexes. On the other hand, in the case of diethylene glycol, the spectrum of the nickel complex differs profoundly from that of the cobalt complex (Fig. 3).

Permeability of Amino Acid across Ion Exchange Membranes

By Takeo YAMABE, Manabu SENŌ and Nobuharu TAKAI

(Received October 17, 1959)

The bulk of experimental work[1] has published on the separation of amino acids by ion exchange resins and a few studies[2], which dealt with electro-chemical desalting of amino acid solution using ion exchange membranes, have recently been presented. These electrodialyses of amino acids using ion exchange membranes were carried out in the range of pH higher than the isoelectric point of the amino acids and deep concerns were not paid for hydrogen ion concentration of sample solution by these authors. Since the charge carried by an ion of amino acid in its aqueous solution is greatly affected by pH of the medium, it is natural to expect that pH of sample solution is one of the greatest factors in the electrodialysis operation of amino acid.

In the present study, permeability of amino acid across ion exchange membranes was examined in the whole range of pH and some interesting results were found.

The apparatus consisted mainly of five-compartment cell which is shown shematically in Fig. 1. Into the center compartment, 0.05 N aqueous solution of glutamic acid containing sodium chloride (0.1 N), whose pH was adjusted with hydrochloric acid or sodium hydroxide beforehand, was fed at the flow-rate of 500 ml./hr. The two adjacent compartments, which are filled with 0.1 N sodium chloride, are separated from the center compartment by cation and anion exchange membranes, respectively. Amino acid transferred across each of these ion exchange membranes was measured.

2) J. D. Blainey and H. J. Yardley, *Nature*, **177**, 83 (1956); A. T. Di Benedetto and E. N. Lightfoot, *Ind. Eng. Chem.*, **50**, 691 (1958); A. M. Peers, *J. Appl. Chem.*, 8, 59 (1958).

All the electrodialysis experiments were carried out for one hour at four fixed current densities. Ion exchange membranes used are heterogeneous and strongly dissociated ones are prepared in the authors' laboratory.

The results were given in Fig. 2. As seen in this figure, the permeability of amino acid depends greatly on the pH of medium and it is the lowest at the isoelectric point, pI 3.2, of glutamic acid. In the range of pH higher than pI, the larger parts of glutamic acid migrate through the anion exchange membrane to the anode-side and the permeation across the cation exchange membrane is predominant in the lower pH range. This behavior becomes more remarkable with the rise of current density. This result is reasonable in view of amphoteric nature of amino acid.

It must be pointed out that some parts of amino acid migrate in the direction unexpected and some amounts of amino acid permeate across the anion and the cation exchange membranes at the isoelectric point. It appears that both positively and negatively charged molecules of amino acid may exist in the moderate pH range, since it is clear that such a permeation of amino acid does not always take place only by the simple diffusion process through membranes as revealed by the experimental data when no electric current runs*. Further investigation must be done on this behavior.

The similar results were also obtained concerning the electro-chemical permeation of glycine and lysine. The full data will be presented in the near future.

From these results, the optimum pH in the separation of amino acids and the demineralization of amino acid solution by ion exchange membranes may be predicted. These experiments are now under study.

Yayoi-cho, Chiba

* When no electric current is passed, the total amounts of glutamic acid transferred across ion exchange membranes are as follows:

pH	Total amounts of glutamic acid transferred across A. M.	C. M.
1.0	0	15.1×10^{-4} g.
3.2	0	0
12.0	95×10^{-4} g.	0

Absorption Spectra of 1,4-Diaminoanthraquinone in Mixed Solvents of Carbon Tetrachloride and Ethyl Alcohol

By Yoshio SUDA

(Received October 21, 1959)

It was previously discussed by Arban[1,2] that the absorption spectra of methylene blue in mixed solvents of water and organic solvents showed characteristic shifts which might be attributed to the change in aggregation states of the dye ion in the mixed solvents.

In this paper, characteristic changes in spectra of 1,4-diaminoanthraquinone (DAA) in mixed solvents are reported. The spectra were measured by means of a Hitachi recording spectrophotometer model EPR and all the measurements were carried out with the 1.0×10^{-4} mol./l. solution of DAA. As shown in Fig. 1, the spectrum of DAA in carbon tetrachloride has one absorption peak I at

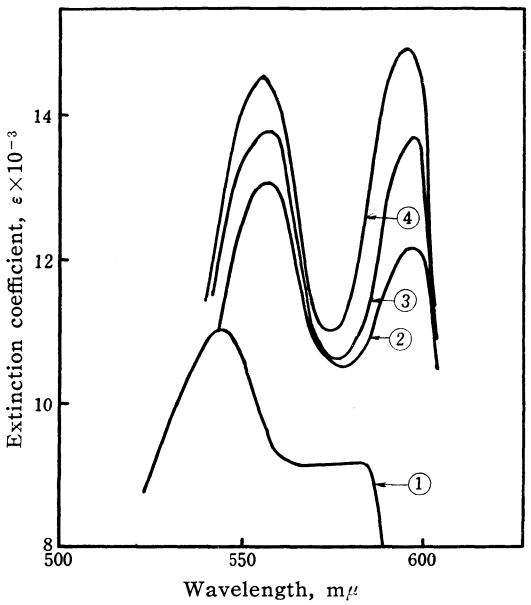

Fig. 1. Absorption spectra of 1,4-diaminoanthraquinone in mixed solvents; in CCl_4 ①, in CCl_4 80%: C_2H_5OH 20% ②, in CCl_4 40%: C_2H_5OH 60% ③, and in C_2H_5OH ④.

544 mμ and one horizontal shoulder at 565~584 mμ. On addition of ethanol to the solution, the latter changes to the second peak II, and simultaneously a shift of the peak location occurs. With the increasing ethanol concentration, the extinction coefficient at peak II increases rapidly as compared with that at peak I, and consequently, the ratio of both coefficients $r=\varepsilon_{II}/\varepsilon_{I}$ increases. The spectral data of DAA in various organic solvents are given in Table I. Solvents which belong to the first group are non-polar and the spectra in these solvents show one maximum and one shoulder, and a small value of r. In contrast to this, the spectra in solvents of the second group which are polar and have hydrogen-bonding ability, show the two absorption peaks and a large value of r.

TABLE I. ABSORPTION SPECTRA DAA IN VARIOUS SOLVENTS

Solvents	Refractive Index	Absorption peak I mμ	r
The first group			
n-Hexane	1.38	534	0.83
Cyclohexane	1.43	539	0.82
Carbon tetrachloride	1.46	544	0.83
Benzene	1.50	545	0.85
The second group			
Methanol	1.33	551	0.98
Ethanol	1.36	554	1.03
Acetic acid	1.37	552	1.03
Glycerine	1.47	557	1.05
Pyridine	1.51	558	0.94

An addition of ethanol to pure solvent exerts another effect on the spectrum. When the concentration of ethanol is increased, the location of the peak shifts to longer wavelengths at first and via the point of the maximum shift return back to shorter wavelengths. Similar shifts are also observed with methanol and others. As examples, absorption curves in mixed solvents of carbon tetrachloride with methanol and ethanol are shown in Fig. 2.

This characteristic change can not be explained by the simple solvent-effect (Kundt's law) alone, because the law says only that the larger the refractive index of solvent is, the larger the degree of shift to longer wavelengths becomes. DAA satisfies Beer's law both in ethanol and in carbon tetrachloride, and disperses as the monomer or a uniformly aggregated

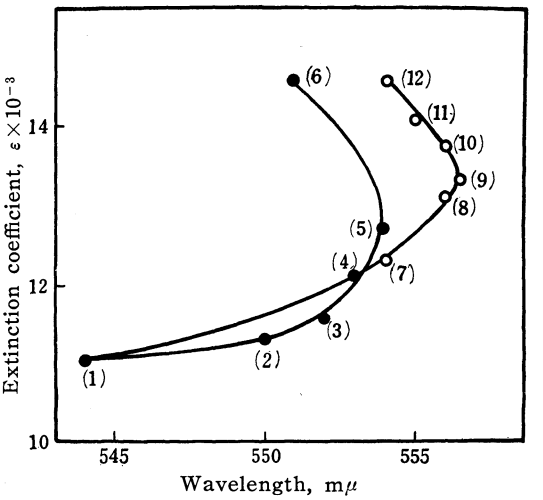

Fig. 2. Effects of solvent composition on wavelength and extinction coefficient at peak I.

particle. Arban's suggestion for methylene blue does not explain the case of DAA, if it can be assumed that dispersed particles are monomers in both solutions.

Spectral differences such as a number of peaks, the ratio of extinction coefficients and characteristic changes of locations of peaks indicate that mutual interaction between DAA and carbon tetrachloride (the first group) differs from that between DAA and ethanol (the second group). The essential difference in the interaction has been studied by the present author from the view points of solubility. The detailed discussion on the results will be reproted elsewhere.

The author wishes to express his sincere thanks to Mr. H. Uedaira for helpful discussion and for a gift of copies of Arban's papers.

Detection of Atomic Oxygen in the Decomposition Products of Nitrous Oxide by the Platinum Catalyst at Low Pressures

By Kazuo MITANI and Yoshio HARANŌ

(Received November 4, 1959)

Nitrous oxide is decomposed by platinum catalyst into oxygen and nitrogen. It is generally accepted that the first step of this reaction is $N_2O \rightarrow N_2+O$; and that the nitrogen is given off from the surface, while the oxygen atom remains adsorbed. The authors have investigated to find whether this oxygen atom is given off in the atomic state into the gas phase at low pressures.

The main part of the apparatus is shown in Fig. 1.

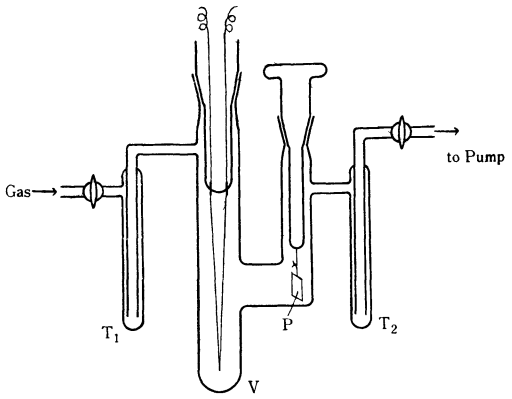

Fig. 1.

In the reaction vessel V, a platinum ribbon ($0.024\times0.28\times363$ mm.) is stretched, which can be heated by electric current. Atomic oxygen is detected by the change of color of molybdenum trioxide from pale yellow to deep blue according to the following equation[1]:

$$3\,MoO_3+O=Mo_3O_8+O_2$$

Molybdenum trioxide is deposited on a glass plate P, which is hung in the side tube of the reaction vessel. All the apparatus can be evacuated by a diffusion pump through a trap cooled by dry ice.

After decomposing nitrous oxide, it was found that atomic oxygen is given off from the platinum surface heated in vacuo for a long time[2]. Therefore, the following preliminary treatment of the platinum ribbon is necessary before every experiment. The platinum ribbon is heated in hydrogen first, and then in vacuo, to a high temperature. Subsequently oxygen is admitted, and the ribbon is heated again. Finally the ribbon is heated once more in vacuo to 1400°C for an hour. After this treatment, the platinum ribbon does not give off atomic oxygen. Now, nitrous oxide is conducted from the reservoir to the pump through the reaction vessel, the pressure in the reaction vessel being kept at $1\times10^{-3}\sim5\times10^{-4}$ mmHg. When the platinum ribbon is heated to 1400°C, molybdenum trioxide changes its color distinctly from plale yellow to deep blue within 30 min. From this experiment it is certain that atomic oxygen is given off when nitrous oxide is decomposed by the platinum catalyst at low pressures. When the pressure of nitrous oxide is higher (0.1~0.03 mmHg), no atomic oxygen is detected in a similar experiment. In the latter experiment, oxygen atoms given off from the platinum surface may recombine to form molecular oxygen before reaching the detector of atomic oxygen. But it is also probable that nitrous oxide molecules collide from the gas phase to the adsorbed oxygen atoms very frequently when the pressure of nitrous oxide is higher, and that consequently adsorbed oxygen atoms are given off as molecular oxygen according to the following reaction:

$$O_{ads}+N_2O \rightarrow N_2+O_2$$

In order to decide which mechanism is true, further investigations are necessary.

Electrometric Estimation of Bismuth

By V. D. Anand, B. N. Prasad and Aqil Ahmed Amani

(Received June 8, 1959)

Thiourea and its derivatives, which are good sulfur coordinators[1], have been used for the detection and determination of a number of ions. Bismuth ion forms a yellow compound on the addition of thiourea[2]. Recently an electrometric study of the bismuth complexes with thiourea and substituted thioureas employing the bimetallic electrode system has been communicated by the anthors' laboratories[3]. During the course of this work it was observed that the method can be easily adopted for the quantitative determination of bismuth. The present communication reports in detail the application of the bimetallic electrode system to the estimation of bismuth with thiourea, substituted thioureas and urea.

B.D.H. reagent grade bismuth trichloride was recrystallized twice from acetone and its solutions of varying concentrations in anhydrous methanol, ethanol and acetone were prepared. The strength of these solutions was determined by the oxychloride method[4]. Thiourea solutions were standardized by the Volhard procedure[5] as modified by Cuthil and Atkins[6].

The bimetallic electrode system was used, employing the Pt : W bimetallic couple, first proposed by Furman and Wilson[7]. The Bi : W electrode system was also used. An aliquot of the bismuth chloride solution was taken in a pyrex cell fitted with the platinum and tungsten (or the bismuth and tungsten) electrodes. The electrical circuit was similar to that used by Gay[8], and consisted of a 1.5 V. cell with its negative pole connected to the tungsten electrode, a 1 kΩ fixed resistance, a 200 Ω variable rheostat and a suitably shunted galvanometer, all connected in series. Galvanometer deflections were noted after successive additions, from the burette, of small amounts of standard thiourea solution and thorough stirring.

The addition of the titrant near the end point was dropwise. Maxima in the galvanometric deflection mark the equivalence points, corresponding to the formation of different complexes.

A representative curve from an actual determination of bismuth against thiourea in acetone medium, using the Pt : W bimetallic electrode system, is shown in Fig. 1. The curve shows two peaks corresponding to the two complexes of bismuth with thiourea reported in the earlier communication[3].

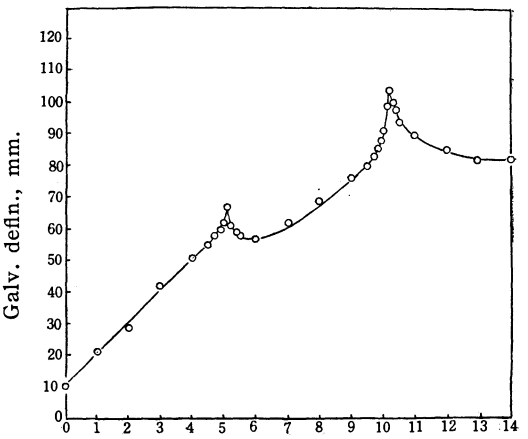

Fig. 1. Titration of bismuth against thiourea in acetone medium, using Pt: W bimetallic electrode system.

Table I shows the results of determination of bismuth against thiourea, phenyl thiourea, *p*-toluyl thiourea and urea in different non-aquous media using the Pt: W bimetallic system.

The estimation of bismuth against the same ligands was also done with the Bi: W bimetallic electrode couple. The results are recorded in Table II. The titrations with urea had to be restricted to methanol and ethanol medium only because of the low solubility of urea in acetone.

The two peaks in the titration curve correspond to the two end points in these titrations. This agrees with the formation of the two complexes viz., $2BiCl_3 \cdot 3X$ and

* X denotes the complexing ligand.

$BiCl \cdot 3X$ (Where X stands for the complexing group). The two end points afford a convenint internal check on the accuracy of the procedure. The titration may, however, be stopped at either stage, since both equivalence points give accurate values within the limits of experimental error and results are easily reproducible.

It is evident from an examination of Tables I and II that the error is generally small and far less than is usually met with in the ordinary estimations. This is indicative of the fact that the electrometric determination is a simple, convenient and rapid procedure, easily applicable to the quantitative determination of bismuth.
