means the angle graduated on the disk of the sheet-rotation apparatus (see Figure 1 of Ref. 1). In Fig. 1, $D_\theta$ for a given angle $\theta$ coincides with $D_{(\theta+180°)}$ for $(\theta+180°)$. When the angle of the middle point of equivalent densities on both sides of the maximum is denoted as $\parallel$ and that for the minimum as $\perp$, the angle scale difference between $\parallel$ and $\perp$ is equal to just 90°. The optical densities for $\parallel$ and $\perp$ are indicated by $D_{\parallel}$ and $D_{\perp}$, respectively. A revolution of the disk gives two $D_{\parallel}$'s and two $D_{\perp}$'s. Two $D_{\parallel}$'s ought to be equivalent to each other, and the same must be said with two $D_{\perp}$'s, but sometimes they were not. These differences, however, were small, so that the mean value of each was used for the purpose of analysis.

## Results

Absorption spectra of pinacyanol in the non-stretched PVA sheet are shown by solid lines in Figs. 2 and 3. In these figures, spectra in ethanol are also shown by broken lines for the comparison. Pinacyanol reveals absolutely corresponding absorption bands in both media, where every band in the sheet only shifts more or less to the longer side (200~300 cm$^{-1}$) compared with that in ethanol.

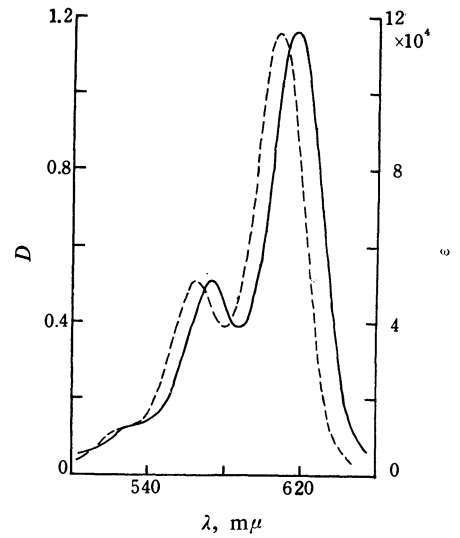

Fig. 2. Absorption spectra both in visible region of pinacyanol in the non-stretched ($R_s=1.0$) PVA sheet (solid line) and in an ethanolic solution of $2.79\times10^{-5}$ mol./kg. (broken line).

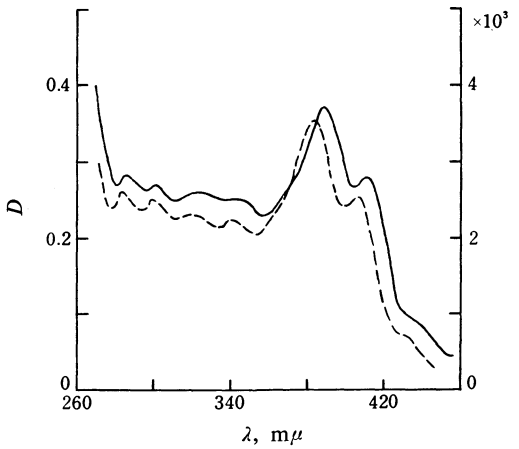

Fig. 3. Absorption spectra both in the near ultraviolet region of pinacyanol in the non-stretched ($R_s=1.0_4$) PVA sheet (solid line) and in ethanolic solution of $2.79\times10^{-5}$ mol./kg. (broken line).

Curves indicated in Figs. 4 and 5 corresponding to respective ones of Figs. 2 and 3 are obtained by stretching the sheet and then observing it with polarized light. None of the bands in Fig. 4 nor those around 400 m$\mu$ in Fig. 5 have any change either in shape or in maximum position, with the change of angle $\theta$, and they have the same order of the optical density ratio $R_d$, with a considerably large value compared with the rest of the bands.

The rest, on the other hand, change in shape and maximum position, together with $\theta$. The behavior with $\theta$ of the absorption curves near

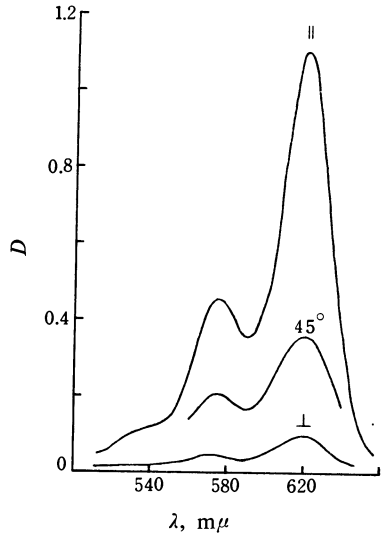

Fig. 4. Dichroism of pinacyanol in the stretched sheet at $R_s=8.2$, corresponding to Fig. 2. The sheet reflection is already corrected. ∥, 45° and ⊥ mean the absorptions for the polarized light of which the direction of the electric vector is parallel, 45° and right angles to the stretch direction of the sheet, respectively.

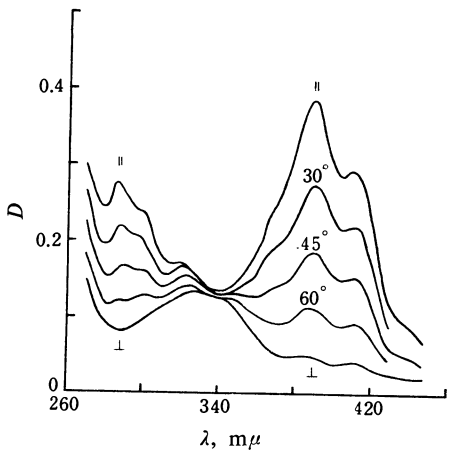

Fig. 5. Dichroism of pinacyanol in the stretched sheet at $R_s=8.0$, corresponding to Fig. 3. Corrected as for the absorption and reflection of the sheet. ∥, 30°, 45°, etc. have the same meaning as these in Fig. 4.

340 mμ is especially noticeable in the point that the absorption intensity has no great change with $\theta$.

Expansion of observation from the first bands to the long wavelength found out a weak but single band at 700 mμ. This is as shown in Fig. 6 and has similar behavior as other visible bands. Moreover, there were noticed weak absorptions at about 470 mμ and at 440 mμ,

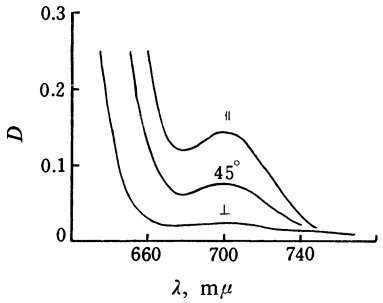

Fig. 6. Dichroism of the pinacyanol weak band at 700 mμ. $R_s=11$.

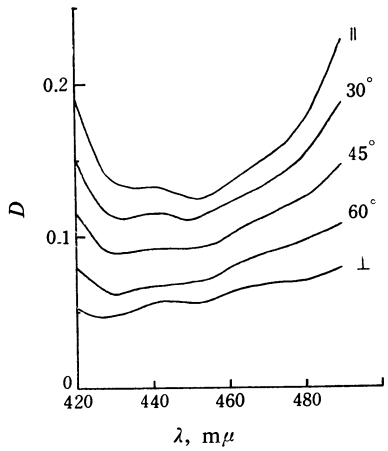

Fig. 7. Dichroism of the Pinacyanol weak band at about 470 mμ and at 440 mμ. $R_s=6.0$.

but their properties could not be judged owing to the nearby strong absorptions (Fig. 7).

The polarization degree of the polaroid used decreases in short region of 300 mμ and follows a curve as shown in Fig. 8. That is to say, the incident light in this region is a partially polarized light. Absorption spectra by this light are indicated by solid lines in Fig. 8. Curves in this figure show an obvious absorption band at 240 mμ and a shoulder at 260 mμ. The absorption at 240 mμ becomes more indistinct as it moves from $D_{\parallel}$ to $D_{\perp}$ curve, and that of 260 mμ stands just on the reverse.

All the absorption bands that could be recognized by the measurement are summarized in Table I, being numbered in order from high to low wavelength. These bands in Table I were distinguished by their shape in this way as follows. The number, wavelength and wavenumber of a band have no mark when it indicated a distinct maximum at least in one of $D_{\parallel}$ and $D_{\perp}$ (in general $D_{\theta}$) curve, are put in parentheses when it indicated distinct shoulder, and are put in brackets when it showed indistinct shoulder or curvature.

Experimental relations between each $R_d$ and

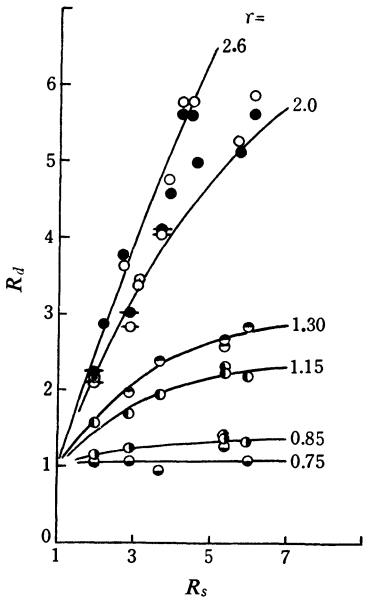

Fig. 9. Relations of $R_d$ to $R_s$ of absorption bands. Circles represent the observed values; ○: 620 m$\mu$ (Band II), ●: 570 m$\mu$ (III), -○-: 410 m$\mu$ (VII), -●-: 388 m$\mu$ (VIII), ◓: 286 m$\mu$ (XIII), ◒: 344 m$\mu$ (X), ◐: 300 m$\mu$ (XII), ◑: 328 m$\mu$ (XI). Curves are the calculated ones for respective *r*-value from the $R_d$ expression of Ref. 1.

$R_s$ of Bands II, III, VII, VIII and X—XIII are shown in Fig. 9. Curves in the figure are theoretical ones corresponding to respective *r*-values[1),*2]. Observed values of each Band II, III, VII and VIII approximately fall between these curves which have peculiar *r*-values. Angles between transition directions and an orientation axis of the molecule are evaluated from the *r*-values and indicated in Table I.

**Assignment of Transition Direction.**—As shown in Figs. 2—8, all the absorption bands in visible region and around 400 m$\mu$ had so large $R_d$ values that they were distinguished from others. It is considered that the double bond system which runs through over the molecular axis responsible for the first band of cyanines of this kind (here Band II)[4]. If

*2 Cot$^{-1}r$ gives the angle between the direction of orientation and that of transition of the absorption.

4) For example, H. Kuhn, *J. Chem. Phys.*, 17, 1198 (1949); G. S. Levinson, W. T. Simpson and W. Curtis, *J. Am. Chem. Soc.*, 79, 4314 (1957).

this is the case, it must be expected that such an absorption band gives the maximum $R_d$ when the longitudinal axis of the molecule meets the stretching direction of the sheet. In effects, the fact that the $R_d$-value of the first band is always larger than that of any band in the region below 360 m$\mu$, means that this molecular axis approaches most completely its orientation axis. Accordingly, it is concluded that a group of bands, of which $r$-values fall between 2.0~2.6, as indicated in Fig. 9, is all due to transitions parallel to the long axis of molecule.

When two transition directions are at right angles to each other in a molecule, a product of these $r$-values must be unity. Namely,

$$r_{\parallel} \times r_{\perp} = 1 \quad (1)$$

According to Table I, the following two pairs are approximately unity*3.

$$r_{\mathrm{X}} \times r_{\mathrm{XIII}} = 0.975 \quad (2)$$

$$r_{\mathrm{XI}} \times r_{\mathrm{XII}} = 0.978 \quad (3)$$

Moreover, Table I indicates $r_{\mathrm{X}} < r_{\mathrm{XI}}$ and $r_{\mathrm{XIII}} > r_{\mathrm{XII}}$. If they lie in a common absorption plane[1] (made of an orientation axis and a transition direction) and if Relation 1 is held, relations $r_{\perp} = r_{\mathrm{X}} = r_{\mathrm{XI}}$ and $r_{\parallel} = r_{\mathrm{XIII}} = r_{\mathrm{XII}}$ must be kept. These disagreements would be due to the following reason. Because there are two bands XI and XII of opposite character existing close to each other, as is clarified in Fig. 5, $R_d$ of Band XI might be elevated by might be elevated by XII, while that of XII might be lowered by XI. For this reason, concerning $r$-values in this case, $r_{\mathrm{X}}$ and $r_{\mathrm{XIII}}$ are believed to be a most reliable $r_{\perp}$ and $r_{\parallel}$ respectively. From the above discussion, it may be concluded that the product of each pair of $r$-values in Relations 2 and 3 is in fact unity and therefore satisfies Relation 1 in itself, and that the relations $r_{\perp} = r_{\mathrm{X}} = r_{\mathrm{XI}}$ and $r_{\parallel} = r_{\mathrm{XII}} = r_{\mathrm{XIII}}$ should come into existence.

If Bands XV (240 m$\mu$) and XIV (260 m$\mu$) in Fig. 8 were measured by perfect polarized light*4, $R_d$ for XV would perhaps be found to be larger and for XIV smaller. Consequently, it can be expected that $r$-values for these bands approach $r_{\mathrm{XIII}}$ and $r_{\mathrm{X}}$, respectively. In this case, therefore, $r_{\mathrm{XV}}$ presumably corresponds to $r_{\parallel}$ and $r_{\mathrm{XIV}}$ to $r_{\perp}$. Moreover, the weak band XVI (230 m$\mu$) is not thought of conclusively.

According to the above discussion, the absorptions of Pinacyanol will be distinguished into the following three groups. One of these groups is such that the transition direction runs along the molecular axis. And to this groups Bands I—IX belong, although it is not certain regarding Bands V and IX. The other two groups contain the bands of which any two transition directions taken from each group separately are orthogonal. Let us decide to make "$\parallel$" represent those near to the molecular axis and make "$\perp$" represent the others; then Bands XII, XIII and XV become "$\parallel$" and X, XI, XIV and XVI become "$\perp$".

The transition direction assigned above was based on an analysis of the observed $R_d$—$R_s$ relation. However, when we compare again the dichroic behavior of the band in the curves of Figs. 4—8 with their transition directions indicated in Table I, we see that the direction can well be decided only by an inspection of the dichroic behavior without the help of the $R_d$—$R_s$ relation: for instance, absorption bands which have the maximum $R_d$ for the same $R_s$ in the whole region with no change in shape and in $\lambda_{\max}$ can be decided as "longi." (bands shown in Fig. 2 and around 400 m$\mu$ in Fig. 3). Others in general change in their shape of absorption and in $\lambda_{\max}$ for $D_\theta$: this fact suggests the superposition of absorptions with different directions. $R_d$-values of these bands are so small as to be easily distinguished from "longi.". This absorption group is considered to be formed of $\parallel$ $\perp$ absorptions. Accordingly, of these absorptions the ones with the larger $R_d$ may be decided as $\parallel$ and the others with the smaller $R_d$ as $\perp$.

## Discussion

It is evident from Figs. 2 and 3 that pinacyanol shows the identical absorption both in PVA sheet and in ethanol. Therefore, the following discussion on the light absorption in PVA sheet may be thought to apply to that in ethanol.

In the last section, the absorption bands have been classified only from the standpoint of their transition directions. Now, turning attention to the absorption position and intensity, we can roughly divide them again into four groups (Table I and Figs. 2—8): the first group includes Bands I—IV, the second group Bands V*5—IX, the third group Bands X—XIII,

*3 In fact, however, these products are slightly smaller than unity. This may be interpreted by the following reason. From the polarization degree curve in Fig. 8, it is noticed that Bands XIII and XII were observed by the light of 93% and 97% polarization respectively. In this case, therefore, $R_d$ becomes smaller than when observed by 100% polarization light, and $r$-value might be estimated to be exceedingly small.

*4 From Fig. 8, it is estimated, $R_d$(XV)=2.0 and $R_d$(XIV)=1.5 at $R_s$=5.4. As for $r$-values, $r_{\mathrm{XV}}$=1.1 and $r_{\mathrm{XIV}}$=0.9, and the former is smaller than 1.3 of $r_{\mathrm{XIII}}$ and latter is larger than 0.75 of $r_{\mathrm{X}}$. But the product is again approximately unity.

*5 According to the apparent shape of the curve in Fig. 7, it seems plausible that Band V belongs to the 1st group. But, from the standpoint of band distance, as will be seen later, it will reasonably be put into the 2nd group.

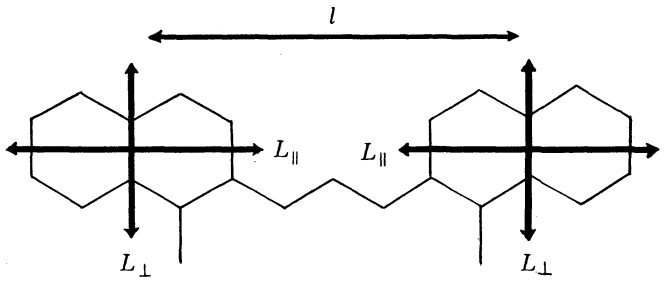

Fig. 10. The molecular skeleton of pinacyanol.

and the fourth groups Band XIV—XVI.

As already mentioned, the absorptions of the first and the second group lie on the long axis of the molecule. Accordingly, if the molecular skeleton of Pinacyanol cation is just as shown in Fig. 10, the direction of these absorptions may correspond to *l*-direction of the figure. And again as mentioned, the ∥ and the ⊥ transition are normal to each other in the same plane. This is visually understood from the fact that the sum of angles between the transition direction and orientation axis in Table I, for example, Band X(⊥) and XIII (∥), is approximately 90 degrees. Thus, it may conclusively be said that the ∥ and the ⊥ transition coinside with the long and the short axis of the quinoline nucleus, respectively.

The absorption bands of the 3rd and the 4th groups, therefore, are attributed to the localized $\pi$ electron system in the quinoline nuclei: those of the 3rd group would be derived, for example, from the weak 320 and 310 m$\mu$ absorption of 2-methyl-*N*-ethyl-quinolinium cation, and those of the 4th group from the strong 240 and 220 m$\mu$ absorption.

Now, if the molecule is planar in the shape of Fig. 10, the direction of the long axis ($L_{\parallel}$) of quinoline nucleus and *l*-direction become parallel, hence these two directions must take any identical angle toward the orientation axis of the molecule. Table I actually shows, however, rather great difference between the two angles*[6]. This means that two quinolines are to a large extent off the common plane*[7].

Absorptions of the 1st and the 2nd group apparently resemble each other in shape (cf. Figs. 2 and 3). Further, the fact that the latter is weaker than the former in intensity and that their directions are the same suggests that the 2nd goup corresponds to an overtone of the 1st group. In this connection, the following fact is of interest: the distances of the adjacent bands in the 1st group are $1500\pm300\,cm^{-1}$ and those in the 2nd group are also $1500\pm200\,cm^{-1}$, indicating a constant space of band-distribution. It is from the standpoint of band distance that we have put Band V into the 2nd group, in the above group classification.

As is already well known, the first group absorption is very sensitive to the solvent nature[5,6]. A correspondence of complexes of monomer, dimer, etc. with absorptions were attempted[6], with the help of the fact that the pinacyanol cation is easily aggregated. At the present stage, however, it can not be decided whether respective absorption bands correspond to those intrinsic to respective complexes possibly considered, e. g. such new absorptions as revealed by a Davidov splitting[7], or transitions originally existing are intensified by coupling with vibration[8] on some account involving complex formation.

## Summary

1. Dichroism of pinacyanol iodide in the PVA sheet was observed in the region higher than 220 m$\mu$, and at least sixteen absorption bands were recognized.

2. The relation of $R_d$ to $R_s$ was analyzed concerning some absorption bands, and it was verified that there are two groups of transitions,

*[6] Namely, if two absorption planes of "longi". and "∥" (Band XIII) were coincident, the angle between these transitions would be about 64 degrees. The difference is about 14 degrees, indicating that the molecule is almost planar. That this is not correct would be shown by constructing the structural model corresponding to Fig. 10. Besides, the assumption that the absorption planes coincide with each other has no grounds.

*[7] Concerning the double bond character, this is not inconsistent with the concept of the usual planar molecule. Because, if the rotation of quinoline planes is equally shared by the polymethine bonds (here 4 bonds) the double bond character of each bond will be roughly lowered only by about 10 percent of that in case of planar, even though the inclined angle of the planes is 80 degrees.

one existing along the long axis of the molecule, the other being at right angles to one another in geometry.

3. The absorption group at right angles to one another appears in the shorter wavelength region than about 340 m$\mu$, and it was shown that this is due to the two orthogonal electronic transitions localized in the quinoline nuclei of the molecule.

4. The absorptions of the long axis of the pinacyanol molecule consist of two groups, each involving several bands and it was pointed out that the bands are distributed with nearly constant distance of 1500 $cm^{-1}$ between adjacent one.

5. It was deduced that the molecule is not a planar and both quinoline planes are far from planar.

6. Sixteen absorptions mentioned above were reasonably classified in their relation to the transition direction or in their correspondence to the molecular structure.

The author wishes to express his thanks to Professor N. Ando and I. Tana kain this laboratory for their encouragement throughout this work, also to Mr. Y. Mori in our laboratory for his useful discussion and helpful advice, and to Mr. H. Ono of the Laboratory of Fuji Photo Film Co. for his kind supply of the dye sample used in this investigation.

# *On Some Dark-colored Chlorocuprates(I, II) and Related Compounds. I. The Method of Preparation and Some Properties**

By Masayasu MORI

(Received September 14, 1959)

A considerable amount of data has now been accumulated concerning the characteristic properties of "mixed valence" compounds, i. e. compounds containing atoms of the same element in different valence states. Mixed valence compounds having a comparatively covalent character have been fairly well studied and are now utilized in the field of semiconductors. One of the most characteristic features of such mixed valence semiconductors is that the ratio of atoms in two valence states can often be changed arbitrarily, thus resulting in a change in the properties of the substance, as if the valence of the metal could take a continuous non-integral number. Such a technique of preparing semiconductors, termed *valence control*, is often useful for giving desired electrical properties to these substances[1]. On the other hand the properties of the mixed valence compounds of ionic character containing halometallate ions have scarcely ever been elucidated. Most of these mixed valence halometallates show an "interaction color" due to an abnormal light absorption[2].

The interaction color of copper(I) and copper(II) chlorides in hydrochloric acid solution has been known from an early date. Doehlemann and Fromherz measured the absorption spectrum of this system and found a broad interaction absorption in the visible region[3]. However, the present-day knowledge of the structure of chlorocuprate ions is very meager, and it is not known what kinds of chlorocuprate ion are responsible for the interaction color. This is mainly due to the fact that the phenomenon has hitherto been observed only in aqueous solution. It occurred, therefore, to the present author that an investigation on crystalline compounds showing an interaction color of copper(I) and copper(II) might be helpful in throwing light on the nature of this problem and he succeeded in obtaining dark brown chlorocuprates(I, II) of hexamminechromium(III) and hexamminecobalt(III) cations. For comparison the chlorocuprates(I) and chlorocuprates(II) of these

complex cations were also prepared and they were found to form yellow or orange crystals. In the following paragraphs the methods of preparation and some properties of these compounds will be described.

## Experimental

**Methods of Preparation.**—*Hexamminechromium(III) Chlorocuprate(I, II) and Hexamminecobalt(III) Chlorocuprate(I, II).*—Five tenths grams of copper(I) chloride was dissolved in 100 ml. of hot water containing 15 g. of ammonium chloride and 40 ml. of concentrated hydrochloric acid. When the color of the solution was found to be greenish yellow, a dilute solution of titanium(III) chloride was added dropwise, until the very moment when the yellow color disappeared. The solution was quickly filtered and the filtrate was poured into a solution of 2.7g. of hexamminechromium(III) chloride mono-hydrate and 3 g. of copper(II) chloride di-hydrate in 100 ml. of water. The same amount of hexamminecobalt-(III) chloride was used in preparing the corresponding cobalt compound. It seemed preferable to heat both solutions to about 60°C before mixing, for the precipitate formed in the cold solution was very fine and liable to decomposition. The mixture was cooled in a cold water bath for 30 min. with occasional stirring. The dark brown or almost black crystalline precipitate thus formed was filtered off, washed with 2 N hydrochloric acid and then with ethanol, and dried in air. (Samples No. 3 and 8 in Table I.)

Found for the chromium compound: Cr, 14.2, 13.8, 13.6; N, 21.5, 21.7, 21.8; total Cu, 16.8, 15.7; Cl, 42.3; loss in wt. at 110°C, 1.05, 1.23. Calcd. for $[Cr(NH_3)_6]_2Cu_2Cl_9(H_2O)_{1/2}$: Cr, 13.6; N, 22.0; Cu, 16.6; Cl, 41.8; $H_2O$, 1.14%.

Found for the cobalt compound: Cu, 15.2; N, 21.3; total Cu, 16.5, 16.9; Cl, 41.1; loss in wt. at 110°C, 1.15. Calcd. for $[Co(NH_3)_6]_2Cu_2Cl_9(H_2O)_{1/2}$: Co, 15.2; N, 21.6; Cu, 16.4; Cl, 41.1; $H_2O$, 1.13%.

The total copper content in the above analytical data was determined gravimetrically. The content of bivalent copper was determined iodometrically in 3 N acetic acid using finely powdered sample. The chromium compound gave a fairly sharp end point of titration and it was found to contain about a half of the total copper in the bivalent state (Found, 8.4; calcd., 8.3). In the cobalt compound the end point of the iodometric titration was very obscure, and the results were less reproducible (Found, 8.7, 9.0, 9.1, 9.3. Calcd., 8.2). It was found, however, that the composition of the chlorocuprate(I, II) depends on the quantity of copper(I) and copper(II) chlorides and used in the preparation. An outline of this relationship is given in Table I. Samples Nos. 1—6 are chromium compounds and Nos. 7—11 cobalt compounds. The procedure adopted in preparing these samples was the same as that given above except the difference in the quantities of the copper chlorides used.

*Hexamminechromium(III) Chlorocuprate(I) and Hexamminecobalt(III)Chlorocuprate(I).*—One gram of copper(I) chloride and 15 g. of ammonium chloride were dissolved in a mixture of 100 ml. of hot water, 20 ml. of 15% titanium(III) chloride solution in hydrochloric acid and 40 ml. of concentrated hydrochloric acid. The solution was quickly filtered and the filtrate was poured into a solution at 60°C of 2.7 g. of hexamminechromium(III) chloride mono-hydrate in 100 ml. of water. The same amount of hexamminecobalt(III) chloride was used in preparing the corresponding cobalt compound. The mixture was cooled in a cold water bath for 30 min. with occasional stirring. The yellow or orange precipitate was filtered off and washed with 2 N hydrochloric acid and ethanol, and then it was

TABLE I. THE RELATIONSHIP BETWEEN THE QUANTITIES OF THE STARTING MATERIALS AND THE CHEMICAL COMPOSITION OF THE CHLOROCUPRATE

| Sample No. | Starting Material[a] | | Product | | |
|---|---|---|---|---|---|
| | CuCl (in g.) | $CuCl_2 \cdot 2H_2O$ (in g.) | Total Cu (in %) | Bivalent Cu (in %) | Color |
| 1 | 0 | 3 | 16.1 | 16.1 | yellow |
| 2 | 0.2 | 3 | 17.0 | 12.7 | brownish black |
| 3 | 0.5 | 3 | 16.8 | 8.4 | black |
| 4 | 1 | 3 | 19.5 | 2.0 | grayish brown |
| 5 | 1 | 1 | 20.0 | 1.0 | brown |
| 6 | 1 | 0 | 20.4 | 0 | yellow |
| 7 | 0 | 3 | 15.8 | 16.8[b] | orange |
| 8 | 0.5 | 3 | 16.4 | 9.2[b] | black |

| 11 | 1 | 0 | 19.8 | 0 | orange |

a) For samples Nos. 1—6 the complex cation used was hexamminechromium(III) ion and for samples Nos. 7—11 hexamminecobalt(III) ion.

b) The end point of the iodometry of the cobalt compound is very obscure.

dried in vacuo over potassium hydroxide. (Samples No. 6 and No. 11 in Table I.)

Found for the chromium compound: Cr, 13.6; N, 21.7; Cu, 20.4; Cl, 39.2. Calcd. for $[Cr(NH_3)_6]_4 \cdot Cu_5Cl_{17}$: Cr, 13.5; N, 21.9; Cu, 20.7; Cl, 39.2%.

Found for the cobalt compound: Co, 15.4; N, 20.8; Cu, 19.8; Cl, 38.5. Calcd. for $[Co(NH_3)_6]_4 \cdot Cu_5Cl_{17}$: Co, 15.1; N, 21.5; Cu, 20.3; Cl, 38.5%.

*Hexamminechromium(III) Chlorocuprate(II).*—Two grams of hexamminechromium(III) chloride monohydrate and 2 g. of copper(II) chloride di-hydrate were dissolved in 60 ml. of water. The solution was filtered and the filtrate was heated to 60°C and mixed with 20 ml. of concentrated hydrochloric acid. The mixture was cooled in a cold water bath for 30 min. with occasional stirring and the precipitated complex was filtered and washed with ethanol. (Sample No. 1, Table I.)

Found: Cr, 13.8; N, 21.5; Cu, 16.1; Cl, 44.9. Calcd. for $[Cr(NH_3)_6]CuCl_5$: Cr, 13.2; N, 21.3; Cu, 16.1; Cl, 44.5%.

The corresponding cobalt compound had already been prepared by Levi[4]. (Sample No. 7, Table I).

*Hexamminechromium(III) Bromocuprate(II).*—Two grams of hexamminechromium(III) bromide, 2.4 g. of copper(II) sulfate penta-hydrate, 10 g. of sodium bromide, 20 ml. of water and 20 ml. of 48% hydrobromic acid were mixed and the mixture was occasionally stirred. After 1 hour the resulting black crystals were filtered off through a glass filter under strong suction, washed quickly with fuming hydrobromic acid (ca. 66%) and dried in vacuo over sulfuric acid.

Found: Cr, 9.0; N, 13.9; Cu, 9.6; Br, 65.1. Cacld. for $[Cr(NH_3)_6]CuBr_5$; Cr, 8.4; N, 13.6; Cu, 10.3; Br, 64.7%.

An attempt to prepare the corresponding cobalt compound was unsuccessful.

**Absorption Spectrum Measurement.**—The absorption spectrum of copper sulfate dissolved in 48% hydrobromic acid was measured with a Beckman spectrophotometer, model DU. The result is given in Fig. 1. The concentration of copper sulfate was 0.0000870 M and the extinction coefficient is expressed on the basis of g. ion of copper.

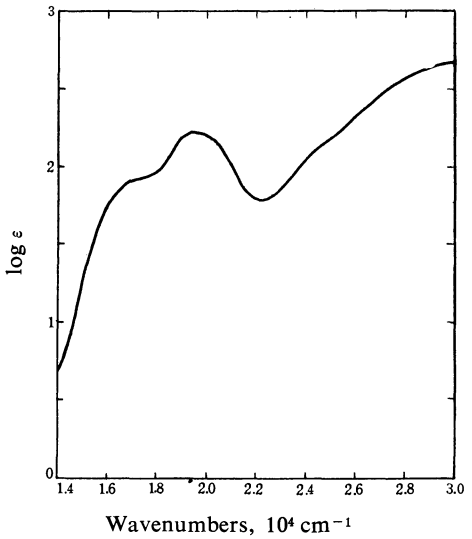

Fig. 1. Absorption spectrum of copper(II) sulfate in 48% hydrobromic acid.

**Measurement of Magnetic Susceptibility.**—Dr. Saburo Fujii* of the Tokyo Institute of Technology kindly measured the magnetic susceptibility of hexamminecobalt(III) chlorocuprate(I, II) by Weiss-Foex's zero point compensation method.

## Results and Discussion

All the foregoing chlorocuprates crystallize in regular octahedra. As has been pointed out in the preceding section, the composition of the chlorocuprate(I, II) depends on the quantities of copper(I) and copper(II) chlorides used in the preparation (Table I). Observation under a microscope as well as with the naked eye shows that the color changes from sample to sample as the chemical composition changes, although it is uniform in a given sample. This fact indicates that the product is not a mixture of two chemical species, but a nearly uniform chemical compound whose composition can change continuously. As far as is known to the present author, this series of chlorocuprates form the only known typical ionic crystals consisting of well-defined cations and anions in which the valence control is possible.

From the total copper content given in Table I it will be seen that the atomic ratio of chromium to copper is 1 : 1 when more than a half of the total copper is bivalent, and that this ratio gradually decreases to the limiting value of 4 : 5 when the bivalent copper is less than a half. In this extreme case the product is a pure chlorocuprate(I) (samples No. 6 and No. 11 in Table 1). The reason why compounds having such different chemical formulae belong to one series of compounds would be made clear only by a crystallographic investigation with X-rays. A research along this line is now in progress and the results will be published shortly.

An interesting phenomenon is observed when crystals of hexamminecobalt(III) chlorocuprate-(I, II) are digested in the mother liquor at 30~40°C for many hours. The crystals reach 0.1~1 mm. in size and often present a tortoise-shell appearance. The black or dark brown crystals are spotted with yellow transparent portions although the crystals as a whole are well developed octahedra. This may be explained as follows. By the oxidation of the mother liquor in the air the quantity of univalent copper therein is gradually decreased. The portions of the crystals that grow at later stages, therefore, have a poorer content of

4) G. R. Levi, *Atti Accad. Lincei*, (5) 32 I, 633 (1923).

* The present address: Toho Rayon Co., Ltd., Kitajima-cho, Itano-gun, Tokushima-ken.

univalent copper and consequently the interaction color is feeble in these portions.

Hexamminechromium(III) bromocuprate(II) is black in contrast to yellow chlorocuprate(II). This difference of color is probably due to the strong absorption band of bromocuprate(II) ion with a peak at $1.95\times10^4\,cm^{-1}$ as is observed in the spectrum of copper(II) sulfate in hydrobromic acid in Fig. 1. An investigation of hexamminechromium(III) bromocuprate(II) may give some information about the ionic species to which this absorption band belongs.

Magnetic study on $[Co(NH_3)_6]_2Cu_2Cl_9(H_2O)_{1/2}$ showed, after a correction being made for the presence of diamagnetic groups, a magnetic moment of 1.9 Bohr magnetons per each formula unit. This value may be considered quite reasonable as the magnetic moment ascribed to the bivalent copper atom present in the crystals. The magnetic moment of the bivalent copper atom, therefore, seems to be little affected even when an interaction color is observed.

**Summary**

A series of dark-colored chlorocuprates(I, II) of hexamminechromium(III) and hexamminecobalt(III) have been prepared. The chemical composition and the color of these compounds have been found to change continuously with the composition of the mother liquor in which they were crystallized.

The author wishes to express his sincere thanks to Professor Yuichi Nakatsuka under whose kind guidance the present work was carried out. He is also grateful to Dr. Saburo Fujii for the magnetic measurement. A part of the expenses of the present study was defrayed by a grant-in-aid of the Ministry of Education.

# *Diffusion Coefficients for Amorphous Polymer and Water Systems*

By Akira KISHIMOTO, Etsuji MAEKAWA and Hiroshi FUJITA

(Received December 29, 1959)

Recent studies of absorption and desorption of low-molecular-weight substances in amorphous polymers olids have demonstrated a sharp distinction between organic solvents and water. In systems of amorphous polymer + organic vapor the processes are of the Fickian type[1-4], usually with a diffusion coefficient which depends appreciably on penetrant concentration, when the systems are well above the glass transition temperatures, $T_g$, of respective polymers. At temperatures below $T_g$ they exhibit various non-Fickian features[5-8]. No definite information has as yet been obtained about the behavior at temperatures slightly above $T_g$[9]. On the other hand, the processes of water are Fickian both above and below $T_g$, if in the latter region the system is not greatly removed from $T_g$[10]. In addition, the diffusion coefficients for amorphous polymer +water systems are practically independent of water concentration at any given temperature in the region mentioned above[10-13]. It is also reported that while the apparent activation energies, $\Delta H_d$, for diffusion of organic solvents in amorphous polymers increase as the temperature is lowered toward $T_g$[3,4], the $\Delta H_d$ for aqueous systems are constant in the corresponding temperature region[10-12]. Furthermore, there are some experimental data[13] which show that plots of $\log D$ vs. $1/T$ for a water system

are represented by two straight lines intersecting at $T_g$, where $D$ is the mutual diffusion coefficient of the system and $T$ is the absolute temperature. This implies that the $\Delta H_d$ of such a system changes discontinuously to another constant value when the temperature is lowered through $T_g$. These features suggest that the molecular mechanism responsible for the diffusion of water in amorphous polymers must be different from that for the diffusion of organic solvents in the same polymers. No adequate explanation has yet been presented concerning this problem.

In a recent publication[4] we have shown that the dependence on temperature and also on concentration of diffusion coefficients for systems of amorphous polymer+organic solvent above $T_g$ can be interpreted quite satisfactorily in terms of a simple theory based on the free volume model of polymer network. One will find it natural that in view of this previous success we were interested in examining the extent to which our free volume theory can account for data of diffusion coefficients for polymer + water systems. One of the purposes of the study reported in this paper is to obtain experimental data pertinent to this problem. The other purpose is concerned with the re-examination of the previously reported variation of $D$ for polymer + water systems with temperature. This arose from a close inspection of existing data and also from the prediction that if the free volume of the polymer network is the controlling factor for the diffusion of water, the linear relation between $\log D$ and $1/T$ should be only approximate.

## Experimental

**Materials.**—Two amorphous polymers, polyvinyl acetate (PVAc) and polymethyl acrylate (PMA), were chosen for the present study. These were purified, unfractionated materials obtained from the Institute for Chemical Research, University of Kyoto. The number-average molecular weight of the PVAc, determined osmotically in a mixture of methanol (80) and ethanol (20) at 17°C, was $8.3\times10^4$. According to Naito[14], this is a thata solvent for PVAc. In fact, our osmotic measurements gave a second virial coefficient which was zero within the accuracy of the experiment. The films for sorption experiments were prepared in the same manner as described previously[15]. Their thicknesses were varied from $1.0\times10^{-2}$ to $4.1\times10^{-2}$ cm., depending upon the rate of absorption or desorption in respective cases.

The PMA used was identical to that used for obtaining the data reported in reference (4) and had a number-average molecular weight of $3.1\times10^5$ (determined osmotically in acetone at 25°C). Films of this polymer prepared for sorption measurements were $1.1\times10^{-2}$ to $4.9\times10^{-2}$ cm. thick.

**Apparatus and Procedure.** — Our sorption apparatus has been described previously[15]. Integral absorption from and integral desorption to zero pressure were measured for several external pressures of water vapor at a number of temperatures in the range 10 to 60°C for PMA and in the range 5 to 60°C for PVAc. In each experiment the temperature of the system was controlled to within ±0.1°C. According to the literature[16], the glass transition temperatures, $T_g$, of dry PMA and PVAc are about 3°C and about 28°C, respectively. Thus the present study for PVAc covered the temperature range both above and below $T_g$, and that for PMA treated the range above $T_g$ only. Pressures of water vapor in the sorption tube were measured to ±1 mm. on a dioctyl phthalate manometer. This corresponded to an accuracy of ±0.07 mmHg. At every temperature studied, especially at temperatures below $T_g$, it was essential to use well-annealed specimens in order to obtain reproducible results.

For PVAc we performed steady-state permeation measurements at three temperatures, 10, 30 and 40°C, by using the cup method.

## Results and Discussion

**Diffusion Coefficients.**—It was found that for both PVAc and PMA the equilibrium water concentrations, $Q_\infty$ (grams of water sorbed per gram of dry polymer), at given relative humidities are independent of the temperature, over the ranges studied, within the accuracy of the present measurements. Those isotherm data are not shown here.

All the absorption and desorption data obtained were plotted in the form of $Q_t/Q_\infty$ against $(t)^{1/2}$, where $Q_t$ denotes the amount (in grams) of water absorbed or desorbed per gram of dry polymer for a time $t$ from the start of a particular run. For all the external pressure and temperature measured, these plots had shapes expected from the normal Fickian diffusion mechanism. Furthermore, in each case, the absorption curve and the corresponding desorption curve coincided with each other over the entire range of time-scale of the experiment. According to theory[17], these features indicate that the mutual diffusion coefficient, $D$, of such a system should be independent of the penetrant concentration and may be evaluated from the initial slope, $I$, of the coincident absorption-desorption plot by means of the equation:

$$D=\pi I^2X^2/16 \qquad (1)$$

where $X$ is the thickness of the sample film.

Fig. 1 illustrates how well a pair of absorption and desorption curves coincided with each other. The solid line in the figure represents the curve which has been calculated from the Fick diffusion equation by using for $D$ the value determined by Eq. 1. A similar agreement between observed and calculated values was found for almost all the experimental data obtained. In Fig. 2 the values of $D$ calculated by Eq. 1 from the data for the PVAc system are semi-logarithmically plotted against the equilibrium water concentration $Q_\infty$. It is seen that the $D$ values for each temperature are independent of $Q_\infty$, and hence of the penetrant concentration, within errors of experiment. In the figure the filled circles give results from the steady-state permeation measurements. There are good agreements between the $D$ values from the two different types of measurement at all temperatures where comparison can be made. It is of interest to note that this agreement was obtained even at 10°C, a tempetature about 20°C below $T_g$ of PVAc. The indication from these results is that the diffusion of water into PVAc is controlled by the purely Fickian mechanism not only above $T_g$ but also below $T_g$, provided that in the latter region the temperature is not too low from $T_g$. In this connection it is of significance to recall that the sorption processes of organic vapors in amorphous polymers generally exhibit marked deviations from the behavior expected from the normal Fickian mechanism when the systems are studied at temperatures below $T_g$ of respective polymers.

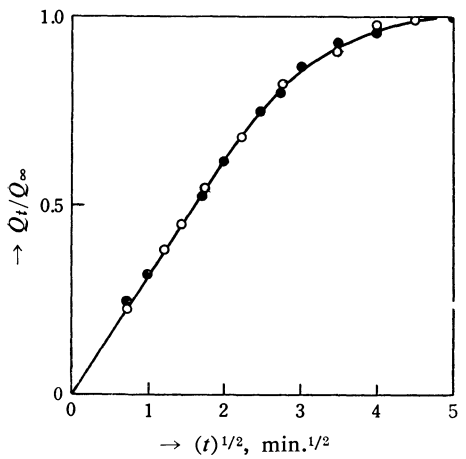

Fig. 1. Absorption and desorption curves for water in PMA. Water vapor pressure =17.2 mmHg; thickness of film=$1.83\times10^{-2}$ cm; temperature=30°C; concentration of water at sorption equilibrium=$0.99\times10^{-2}$ g./g. Open circles, absorption; filled circles, desorption; solid line, theoretical.

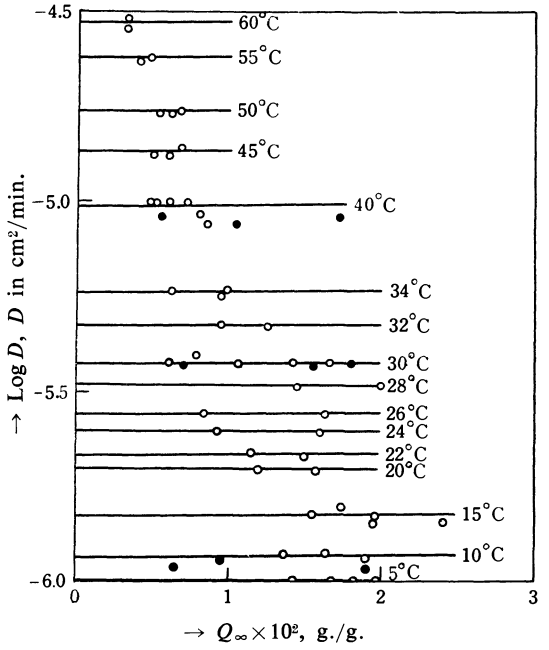

Fig. 2. Mutual diffusion coefficient vs. concentration relations on the system PVAc+water.
○ sorption studies;
● steady-state permeation studies.

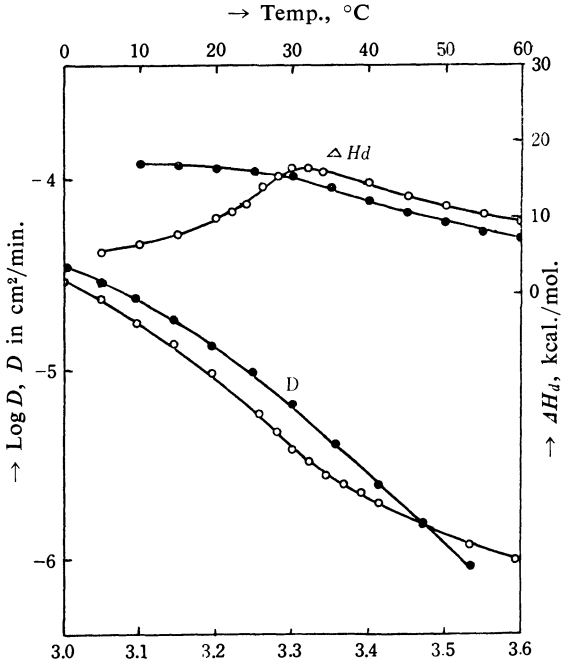

Fig. 3. Mutual diffusion coefficient vs. reciprocal absolute temperature (lower part); Apparent activation energies for diffusion, $\Delta H_d$, vs. temperature (upper part).
○ PVAc; ● PMA.

The data for the PMA system were exactly similar to those for the PVAc system described above, although the behavior below $T_g$ could not be studied on this polymer in the present work.

In Fig. 3 the values of $D$ for the two systems are semi-logarithmically plotted against the reciprocal of absolute temperature $T$. First it will be seen that the plots for the two systems are not linear but curved. Of special interest is the inflection point which appeared on the plot for PVAc at a temperature near $T_g$ of the polymer. Values of $\Delta H_d$, the activation energy for diffusion of water in a polymer, were calculated from the smooth $\log D$ vs. $1/T$ curves drawn in Fig. 3, and are plotted against $T$ in the upper part of the same figure. One finds that for both systems $\Delta H_d$ increases as the temperature is lowered toward $T_g$ of respective polymers, and for PVAc it reaches a maximum at a temperature near $T_g$ and then decreases gradually with further decrease in temperature. This appearance of a maximum $\Delta H_d$ is the reflection of the fact that the corresponding $\log D$ vs. $1/T$ plot has an inflection point. We wish to emphasize that this is the first experimental demonstration of a $\Delta H_d$ vs. $T$ curve which goes through a maximum at a temperature in the vicinity of which the system undergoes glass transition. It should also be mentioned that our data for PVAc do not conform to the previous finding[13] for the system polymethyl methacrylate+water where the plots for $\log D$ vs. $1/T$ were represented by two straight lines intersecting at a temperature near $T_g$.

By employing the steady-state permeation method Meares[18,19] measured diffusion coefficients of several gases in PVAc and found that the slope of the plots for $\log D$ vs. $1/T$ showed distinct discontinuities at two temperatures, about 10°C apart from one another, in the region encompassing $T_g$ of the polymer. Then he suggested that the glass transition of PVAc must take place over a range of temperature, rather than at a particular temperature. Although our PVAc data do not show any break in the temperature region studied, it appears that the occurrence of a broad maximum in $\Delta H_d$ has some correlation with Meares' suggestion on the "glass transition region". Recently, there are similar arguments from measurements of viscoelastic properties of dry polymers[20].

**Comparison with Amorphous Polymer+Organic Solvent Systems.**—Fig. 4 compares the

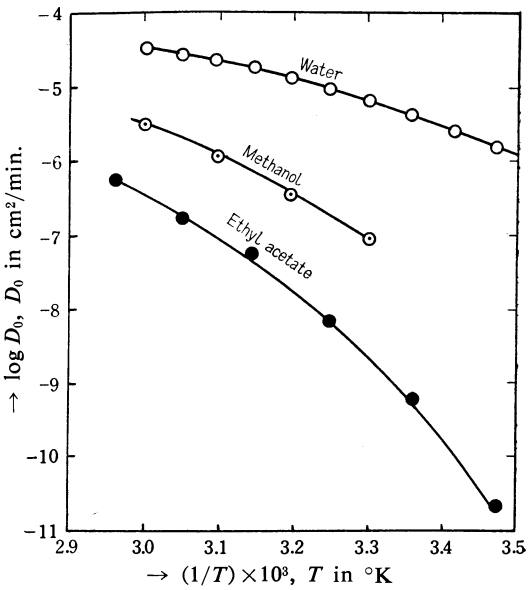

Fig. 4. Mutual diffusion coefficients at the limit of zero penetrant concentration as a function of reciprocal absolute temperature.

temperature dependence of $D_0$ (the value of $D$ at the limit of zero penetrant concentration) for systems PMA+ethyl acetate, PMA+methanol, and PMA+water. The data for the first two systems were taken from our previous publication[4]. The graph shows that with increasing molecular size as well as chemical affinity to PMA of the penetrant the values of $\log D_0$ at fixed temperatures decrease and their temperature dependence becomes more pronounced. This latter fact implies that more activation energy for diffusion into PMA is required at any given temperature (above $T_g$) for organic solvents than for water.

As noted in the introduction to this article, we have recently shown that the dependence on temperature and also on penetrant concentration of diffusions coefficients for amorphous polymer+organic solvent systems (above $T_g$ of respective polymers) can be accounted for satisfactorily by a simple free volume theory[4]. According to this theory, the thermodynamic diffusion coefficient, $\mathfrak{D}_T$, of a penetrant in an amorphous polymer at a temperature $T$ is represented by the equation:

$$\ln\ (\mathfrak{D}_T/\mathfrak{D}_0) = B_d\beta'(T)/[f(T,0)^2 + \beta'(T)f(T,0)v_1] \qquad (2)$$

Here $\mathfrak{D}_0$ is the value of $\mathfrak{D}_T$ at the limit of zero penetrant concentration, $f(T,0)$ is the average fractional free volume in the dry polymer at temperature $T$, $v_1$ is the volume fraction of the penetrant in the mixture, $B_d$ is

18) P. Meares, *J. Am. Chem. Soc.*, 76, 3415 (1957).
19) P. Meares, *Trans. Faraday Soc.*, 53, 101 (1957).

a constant characteristic of the system, and $\beta'(T)$ is a parameter representing the plasticizing effect of the penetrant. The value of $\mathfrak{D}_T$ can be calculated from $D$ when the corrections for the volume expansion of the polymer by the addition of penetrant and for the thermodynamic non-ideality of the mixture are applied. The former correction can be made under the assumption that no volume change on mixing occurs and the latter correction may be derived from the analysis of the isotherm curve of the system.

We examined the applicability of Eq. 2 to the present data, by assigning to $\beta'(T)$ the values which we had previously deduced from measurements of stress-relaxation on these systems[15]. It was found that in order that Eq. 2 may fit the concentration dependence data obtained, the values of $B_d$ have to be chosen as almost equal to zero for both PVAc and PMA systems. On the other hand, as shown previously[4], the constant $B_d$ may also be determined from the ratio of $\Delta H_d$ to $\Delta H_v$, where $\Delta H_v$ is the apparent activation energy for the steady-flow viscosity of the pure polymer. Comparison of the $\Delta H_d$ data given in Fig. 3 with the $\Delta H_v$ values calculated from the equation of Williams, Landel and Ferry[16] yielded $B_d=0.16$ for PVAc and 0.25 for PMA. These $B_d$ values are inconsistent with those derived above from the analysis of concentration dependence data, indicating that Eq. 2 is no longer applicable to the polymer+water systems investigated here. This result leads us to the conjecture that the amount of free volume must not be a major controlling factor for the diffusion of small molecules, such as water, through amorphous polymers. Previously we have inferred[4] that for penetrants very small in size and less soluble in the given polymer only a very local cooperation of the solid-like vibrations of two or three monomer units on the polymer chain would be sufficient to give a cross-section for the penetrant molecules to pass. This cooperative motion is so local that the probability of its occurrence, and hence the rate of diffusion of the penetrant molecule in the mixture, may be, in a first approximation, independent of how large the free volume in the mixture is. This will explain why the $D$ values for the polymer+water systems studied did not exhibit measurable variation with water content. If the above is the case, then we would have to ascribe the observed temperature dependence of $D$ for these systems to a temperature variation of solid-like vibration of monomer units, rather than to the temperature dependence of the free volume which is thought to be associated with larger-scale cooperative motions of several polymer segments.

We wish to thank Mr. Kinya Matsumoto of this Laboratory who carried out the steady-state permeation experiments on PVAc.

# *On the Assignment of a Band at 727 cm$^{-1}$ in Polyethylene Terephthalate*

By Akihisa MIYAKE

(Received December 17, 1959)

Some controversy surrounds the assignment of a strong band at 727 cm$^{-1}$ in polyethylene terephthalate. It was first assigned to a C–O–C bending mode[1]. This assignment is now believed to be incorrect[2,3] because it seems much too high for a C–O–C bending mode. The most generally favored explanation is that the band arises from an aromatic C–H out-of-plane bending mode[4-6] and therefore that it is similar in origin to a band at 875 cm$^{-1}$. The removal of the band in question, on going from polyethylene terephthalate to polyethylene deuteroterephthalate[2,5], has been considered as strong evidence for this explanation. On the other hand, the present author has proposed an alternative interpretation that two bands at

6) M. C. Tobin, *J. Phys. Chem.*, **61**, 1392 (954).

875 $cm^{-1}$ and 727 $cm^{-1}$ arise from coupled C–H out-of-plane bending and $CO_2$ out-of-plane bending vibrations[3].

This problem is of interest because the band mentioned above is in close relation with the so-called extra-bands[7] present in aromatic acids, esters, amides and nitro compounds, the origin of which has yet been unexplained. In order to ascertain whether the author's interpretation is correct or not, some additional observations have been carried out, infrared investigations of polyethylene terephthalate below NaCl region and examinations of thiol esters as model compounds.

## Experimental

**Material.** — 1) *Polyethylene Terephthalate, Polyethylene-$d_4$ Terephthalate.*—The film samples used are the same as those used in previous researches[3,8].

2) *1,2-Ethanedithiol Dibenzoate.* — Benzoyl chloride (20 g.) was added dropwise with agitation to an ice-cooled solution of 1,2-ethanedithiol (7.5 g.) in pyridine (40 g.). The reaction mixture was allowed to stand overnight and poured into cold dilute sulfuric acid. The solid resulted was collected by filtration and washed successively with aqueous sodium carbonate and water. Repeated recrystallization from ethanol gave white crystals, m. p. 94.5°.

Found: C, 63.18; H, 4.61; O, 10.72. Calcd. for $C_{16}H_{14}O_2S_2$: C, 63.59; H, 4.64; O, 10.59%.

3) *1,2-Ethanedithiol Bis-(4-methoxycarbonylbenzoate).* — A solution of 4-methoxycarbonylbenzoyl chloride (10 g.) in chloroform (50 ml.) was added dropwise with agitation to an ice-cooled solution of 1,2-ethanedithiol (3 g.) in pyridine (40 g.). The reaction mixture, after standing overnight, was poured into cold dilute sulfuric acid with stirring. The solid product obtained as a suspension in the chloroform layer was recrystallized after the addition of ethanol. The resulting crystals were collected by filtration and washed with aqueous sodium hydroxide. Recrystallization from a mixture of ethanol and benzene (1 : 2) gave white crystals, m. p. 208~210°.

Found: C, 57.20; H, 4.35; O, 22.68. Calcd. for $C_{20}H_{18}O_6S_2$: C, 57.40; H, 4.33; O, 22.94%.

**Infrared Spectra*.** — The infrared spectra were obtained by means of Perkin-Elmer spectrometers model 21, 13 and 321 with NaCl, KBr and CsBr prisms respecively.

The polymer films were investigated in the KBr and CsBr regions. The two thiol esters were investigated in the NaCl and KBr regions as Nujol mulls and KBr disks. Dichroic measurements for the polymer were made in the KBr region on drawn films. Dichroic measurements for 1,2-ethanedithiol dibenzoate were made in the NaCl region on oriented crystal film obtained by differential cooling of a melt between rock-salt plates.

## Results

**Polyethylene Terephthalate.**—Infrared spectra of polyethylene terephthalate and polyethylene-$d_4$ terephthalate in the range 10~32 $\mu$ are shown in Fig. 1. The frequencies of the bands observed below 750 $cm^{-1}$ together with those reported by Tobin[6] are listed in Table I. Two bands at 575 and 422 $cm^{-1}$ reported by Tobin were not observed though a band at 631 $cm^{-1}$ which was reported as a weaker band than the above two was detected. None of the bands between 700~400 $cm^{-1}$ showed perpendicular dichroism. Tentative assignments for some of the bands are given in the last column of Table I. The assignment of the $CO_2$ rocking vibrations is supported by the fact that corresponding bands are found in ethylene glycol dibenzoate (480 $cm^{-1}$) and 1,2-ethanedithiol bis-(4-methoxycarbonylbenzoate) (488 $cm^{-1}$) but not in 1,2-ethanedithiol dibenzoate.

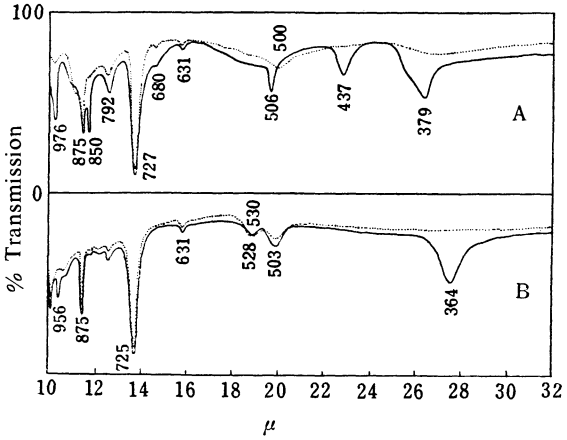

Fig. 1. Infrared spectra of polyethylene terephthalate (A) and polyethylene-$d_4$ terephthalate (B). ····· quenched sample; —— annealed sample.

**Thiol Esters.** — Infrared spectra of the two thiol esters in the NaCl region are shown in Fig. 2 together with that of ethylene glycol bis-(4-methoxycarbonylbenzoate) previously reported[8]. It is apparent that the strong band at 727 $cm^{-1}$ observed in ethylene glycol bis-(4-methoxycarbonylbenzoate) disappears in 1,2-ethanedithiol bis-(4-methoxycarbonylbenzoate), while the bands at 1502, 1408 and 1021 $cm^{-1}$ in the former which are attributable to the vibrations of *p*-phenylene group by analogy with polyethylene terephthalate[3] also appear in the latter at substantially the same frequencies (1502, 1403, and 1016 $cm^{-1}$). Most of the strong bands observed in the latter can be attributed to the ester or thiol ester groups (Table II). The bands which arise from the thiol ester group are easily identified by their distinguished intensities in 1,2-ethanedithiol dibenzoate. The assignments for the vibrations of the thiol ester group given in Table II are consistent with the results of dichroic measurement which will be described next.

**Dichroic Measurement for 1,2-Ethanedithiol Dibenzoate.** — Fig. 3 shows the spectra of an oriented crystalline film of 1,2-ethanedithiol dibenzoate. The solid curve was run with the polarizer setting so that the electric vector of the polarized beam was perpendicular to the direction of the crystal growth of the sample.

TABLE II. VIBRATION OF ESTER AND THIOL ESTER GROUPS ($cm^{-1}$)

| $(CH_3O_2CC_6H_4CO_2CH_2-)_2$ | $(CH_3O_2CC_6H_4COSCH_2-)_2$ | $(C_6H_5COSCH_2-)_2$ | Assignment |
|---|---|---|---|
| 1724 | 1730 | | C=O stretching |
| | 1664 | 1658 | C=O stretching |
| 1279, 1266 | 1277 | | C-O-C asym. stretching |
| | 1205 | 1203 | C-S-C asym. stretching |
| 972 | 1109 | | C-O-C sym. stretching |
| | 921 | 915 | C-S-C sym. stretching |
| | 776 | 773 | COS out-of-plane bending |
| | 717 | | $CO_2$ in-plane bending |
| | 699 | 684 | COS in-plane bending |

The dotted curve was run with the sample in the same position but with the polarizer rotated 90° from the first position. The C=O stretching (1652 cm$^{-1}$) and C–S–C antisymmetric stretching (1197 cm$^{-1}$) bands whose assignments are certain, show perpendicular and parallel dichroisms respectively. Further, a band at 1450 cm$^{-1}$ attributable to $CH_2$ bending vibrations shows perpendicular dichroism and a band at 1300 cm$^{-1}$ attributable to $CH_2$ wagging vibrations shows parallel dichroism. From these facts, it follows that the chain CO–S–$CH_2$–$CH_2$–S–CO is essentially parallel to the direction of crystal growth. On the other hand, bands attributable to in-plane vibrations of the phenyl group by analogy with toluene and monodeutero benzene show perpendicular dichroism, while bands attributable to out-of-plane vibrations show parallel dichroism (Table III). This indicates that the plane of the phenyl group is approximately normal to the direction of crystal growth. Based on these results, the probable configuration and arrangement of the molecule** are shown in Fig. 4. The dichroisms observed for the three strong bands at 917, 772 and 684 cm$^{-1}$ which were assigned, respectively, to the C–S–C symmetric stretching, COS out-of-plane bending, and COS in-plane bending vibrations are in agreement with those expected from the above arrangement.

TABLE III. VIBRATION OF PHENYL GROUP (cm$^{-1}$)

| Out-of-plane | 5 | 995 | 943 | 994 ($\pi$) |
| | 17 a | 970 | (985) | 971 ($\pi$) |
| | 17 b | 922 | 890 | 890 ($\pi$) |
| | 10 b | 850 | 730 | 723 ($\pi$) |
| | 4 | 698 | 695 | 706 ($\pi$) |

a) We owe the numbering of vibrational modes to Wilson [E. B. Wilson, Jr., *Phys. Rev.*, **45**, 706 (1934)].

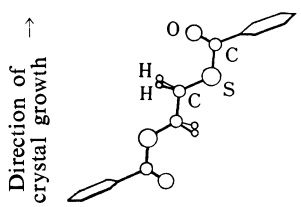

Fig. 4. Probable configuration of 1,2-ethane dithiol dibenzoate.

## Discussion

Although a good deal of work has been done on the characteristic stretching frequencies of the ester group, no systematic study of the deformation frequencies has been carried out. Our knowledge of the factors influencing the frequency and intensity of the deformation vibrations is still relatively meager. Nevertheless, it is possible to predict the approximate position for some of them. Thompson and Torkington[11] have found two characteristic bands of fair intensities at about 600 cm$^{-1}$ for acetates and propionates (612 and 640 cm$^{-1}$ for acetates and 590 and 610 cm$^{-1}$ for propionates). Later, Wilmshurst[12] has assigned the bands at 639 and 615 cm$^{-1}$ in methyl acetate to $CO_2$ in-plane bending and $CO_2$ out-of-plane bending vibrations, respectively. In a number of $\alpha,\beta$-unsaturated esters, Walton and Hughes[13] have found strong bands at 850~750 cm$^{-1}$, which have been reasonably assigned to the $CO_2$ out-of-plane vibration by their dichroic behaviors. A band of similar nature falls at 781 cm$^{-1}$ in methyl oxalate[13]. In the light of these results, the $CO_2$ out-of-plane bending vibration of aromatic esters is reasonably expected to appear above 600 cm$^{-1}$.

In either polyethylene terephthalate or polyethylene-$d_4$ terephthalate, however, no band attributable to the $CO_2$ out-of-plane bending vibration is observed in the range 700~550 cm$^{-1}$. The bands at 680 and 631 cm$^{-1}$ are too weak to be assigned to a $CO_2$ out-of-plane vibration, and moreover their dichroisms are inconsistent with that expected for an out-of-plane vibration. The polymer chain in a drawn sample of polyethylene terephthalate has been known to orient parallel to the direction of drawing[1,4,14] and hence an out-of-plane vibration is expected to exhibit perpendicular dichroism. Since the absorption bands above 750 cm$^{-1}$ in this polymer have been assigned with fair certainty[3] to vibrations other than the $CO_2$ out-of-plane bending vibration, the only band left assignable to it is the strong and perpendicular band at 727 cm$^{-1}$.

There are three infrared-active out-of-plane

TABLE IV. INFRARED-ACTIVE OUT-OF-PLANE VIBRATIONS ($cm^{-1}$)

| Mode | $C_6H_6$[15] | $p$-$C_6H_4D_2$[16] | $p$-$C_6H_2D_4$[16] | $C_6D_6$[15] | $p$-$C_6H_4(CH_3)_2$[10] |
|---|---|---|---|---|---|
| 16 b | 405 | 367 | 383 | 350 | 389 |
| 11 | 673 | 597 | 548 | 496 | (170) |
| 17 b | 975 | 876 | 925 | 793 | 796 |

vibrations for $p$-disubstituted benzenes (point group $V_h$). Some authentic frequencies for these vibrations are listed in Table IV together with those of benzene. Based on these frequencies, modes 16b and 11 in polyethylene terephthalate can be reasonably assumed to appear below 500 $cm^{-1}$. Hence, the only aromatic out-of-plane vibration expected to appear above 700 $cm^{-1}$ is the mode 17b. It is unlikely that both the perpendicular bands (875 and 727 $cm^{-1}$) observed in polyethylene terephthalate can be assigned to aromatic out-of-plane vibrations.

It thus seems logical to consider that the band at 727 $cm^{-1}$ is related to the $CO_2$ out-of-plane bending vibration. It should be noted that similar bands called the extra bands[7] are found in aromatic esters, acids, amides, and nitro compounds, all of which have out-of-plane bending vibrations of the substituents.

The band at 727 $cm^{-1}$, however, cannot be described as a pure $CO_2$ out-of-plane bending vibration, because it is removed by the deuteration of terephthalic acid residue[2,5]. This removal can be explained by assuming that the $CO_2$ out-of-plane bending mode and the 17b mode referred to above couple between each other. These two modes are similar in their frequencies and symmetry types. Therefore it is very probable that the perpendicular band at 875 and 727 $cm^{-1}$ in polyethylene terephthalate arise from these coupled vibrations. The assumption of the coupling between the $CO_2$ and aromatic C–H out-of-plane bending vibration can also explain the anomalous shift of the latter in certain aromatic esters[7]. For example, the appearance of two bands at 809 and 711 $cm^{-1}$ in methyl benzoate[8] may be explained as a consequence of this coupling, considering that pure frequencies for phenyl C–H and ester $CO_2$ out-of-plane bending vibrations fall at 770～730 $cm^{-1}$ and 800～750 $cm^{-1}$, respectively. Furthermore, similar anomalies of C–H out-of-plane bending frequencies in some $\alpha, \beta$-unsaturated esters seem also to result from an analogous coupling. The ethylenic C–H out-of-plane bending frequencies of acrylates and methacrylates fall outside the normal range, while those of crotonates lie close to the normal range (Table V). Based on the assumption that the ethylenic C–H and ester $CO_2$ out-of-plane bending vibrations in crotonates are substantially free of coupling and hence that the frequency of a pure out-of-plane vibration of an ester group attached to an ethylenic bond falls at about 840 $cm^{-1}$, the shifts in acrylates and methacrylates can be easily explained as the result of coupling between the ethylenic C–H and ester $CO_2$ out-of-plane bending vibrations. The frequency difference between the two pure modes is about 50 $cm^{-1}$ in acrylates and methacrylates, while it amounts to about 120 $cm^{-1}$ in crotonates.

TABLE V. C–H AND $CO_2$ OUT-OF-PLANE BENDING FREQUENCIES ($cm^{-1}$) FOR $\alpha, \beta$-UNSATURATED ESTERS

| Compound | $\pi$(C–H) | $\pi$($CO_2$) | Normal position[17] for $\pi$(C–H) |
|---|---|---|---|
| Crotonates[13] | 982～970 | 842～833 | 970～960 |
| Acrylates[13,18] | 988～981<br>967～960 | 813～808 | 995～985<br>915～905 |
| Methacrylates[13,18] | 943～935 | 817～813 | 895～885 |

All these facts indicate the general occurrence of the coupling between $CO_2$ and C–H out-of-plane bending vibrations in aromatic esters. This coupling is, of course, destroyed when any one of the following conditions is not satisfied; first, similarity of frequencies of pure vibrations for the two modes, and second, coplanarity of the aromatic ring and the ester group.

1, 2-Ethanedithiol dibenzoate and 1, 2-ethanedithiol bis-(4-methoxycarbonylbenzoate) investigated in the present work provide further evidence for the interpretation developed above. As was shown in the section of experimental results, phenyl and thiol ester groups of the former compound are not present in the same plane, and hence no coupling is expected between the out-of-plane vibrations of the two groups. Therefore the perpendicular band at 773 $cm^{-1}$ can be considered as an essentially pure COS out-of-plane bending vibration. Since the out-of-plane bending frequency of an ester group is expected not to be very different from that of a thiol ester group, the appearance of the latter at 773 $cm^{-1}$ supports

15) F. A. Miller, *J. Chem. Phys.*, **24**, 996 (1956).
16) S. C. Carson, R. R. Gordon and C. K. Ingold, *J. Chem. Soc.*, **1946**, 288.
17) L. J. Bellamy, "The Infrared Spectra of Complex Molecules", 2nd Ed., Methuen, London (1958), p. 34.

the assumption adopted in the foregoing discussion that a pure out-of-plane bending vibration of an aromatic ester group falls at about 800 $cm^{-1}$. The aromatic out-of-plane vibration of this compound (721 and 709 $cm^{-1}$) falls close to the normal positions for phenyl groups (see Table III). In ethylene glycol dibenzoate[8], however, three bands were observed at 804, 695 and 683 $cm^{-1}$, but no band was observed in the normal range (770~720 $cm^{-1}$) for the mode 10b. This difference between the thiol ester and the ester can be again explained by the coupling between the out-of-plane vibrations. If one assumes that the $CO_2$ vibration couples with phenyl vibration, the lowering of the phenyl out-of-plane frequency in ethylene glycol dibenzoate is readily explained.

Two bands at 873 and 727 $cm^{-1}$ in ethylene glycol bis-(4-methoxycarbonylbenzoate) undoubtedly correspond to the two perpendicular bands at 875 and 727 $cm^{-1}$ in polyethylene terephthalate. The latter disappears and the former shifts to 865 $cm^{-1}$ on going from ethylene glycol bis-(4-methoxycarbonylbenzoate) to 1, 2-ethanedithiol bis-(4-methoxycarbonylbenzoate). This change seems also to be accounted for by assuming that the aromatic ring and thiol ester group in the latter are not coplanar. The C–H out-of-plane vibration of the *p*-phenylene group and the $CO_2$ out-of-plane vibrations of the two ester groups in the former compound couple amoung each other giving rise to two bands at 873 and 727 $cm^{-1}$. On the other hand, in the latter compound, at least the vibration of the thiol ester group may not be coupled with the aromatic vibration, and hence their frequencies are different from those of the former compound. It is not known whether the ester and *p*-phenylene groups in 1, 2-ethanedithiol bis-(4-methoxycarbonylbenzoate) are coplanar or not, but in any case the bands at 865 and 778 $cm^{-1}$ (shoulder) are attributable to the out-of-plane vibrations of these two groups. It is difficult to explain the spectral difference between the two model compounds on the basis of assigning both the bands at 873 and 727 $cm^{-1}$ cited above to aromatic out-of-plane vibrations.

In conclusion, the bands at 875 and 727 $cm^{-1}$ in polyethylene terephthalate can be reasonably assigned to coupled vibrations of aromatic C–H and ester $CO_2$ out-of-plane bending modes which provide a consistent explanation for several aromatic esters and thiol esters.

Finally, mention should be made of the $CO_2$ in-plane bending frequency. Since this is expected not to be very different from that of the COS in-plane bending vibration, that band at 717 $cm^{-1}$ in 1, 2-ethanedithiol bis-(4-methoxycarbonylbenzoate) can probably be assigned to this mode. It is possible that this vibration in polyethylene terephthalate lies buried under the band at 727 $cm^{-1}$.

## Summary

Infrared spectra of polyethylene terephthalate and polyethylene-$d_4$ terephthalate were investigated in the KBr and CsBr regions. No band attributable to a $CO_2$ out-of-plane bending vibration was found below 700 $cm^{-1}$. The only band assignable to this mode is a strong and perpendicular band at 727 $cm^{-1}$. This fact together with the disappearance of the 727 $cm^{-1}$ band in polyethylene deuteroterephthalate, indicates that two bands at 875 and 727 $cm^{-1}$ in polyethylene terephthalate can be assigned to coupled vibrations of aromatic C–H and ester $CO_2$ out-of-plane bending modes. This interpretation provides a consistent explanation for the spectral differences between ethylene glycol dibenzoate and 1, 2-ethanedithiol dibenzoate and between ethylene glycol bis-(4-methoxycarbonylbenzoate) and 1, 2-ethanedithiol bis-(4-methoxycarbonylbenzoate) as well as for the anomalous shifts of C–H out-of-plane frequencies and the appearances of " extra bands " in several aromatic esters.

*Central Research Laboratories*
*Toyo Rayon Co.*
*Otsu, Shiga*

*Note Added in Proof*:

Recently, perpendicular bands at about 820 $cm^{-1}$ have been found in polyethylene terephthalate-$d_4$ and polyethylene $d_4$ terephthalate-$d_4$ [C. Y. Liang and S. Krimm, *J. Mol. Spectroscopy*, 3, 554 (1959).]. These bands can be assigned to the $CO_2$ out-of-plane vibration in these deuteroterephthalates. If this assingnment is correct, it seems better to consider that the 17b vibration of the terephthalates has a lower frequency than the $CO_2$ out-of-plane vibration. Then, for the band at 727 $cm^{-1}$ in polyethylene terephthalate, the contribution of the 17b vibration may exceed that of the $CO_2$ vibration, and vice versa for the band at 875 $cm^{-1}$[9].

# *Application of the Theory of Regular Solutions to Binary Phase Equilibria. I. Method of Application to Binary Liquid Equilibria*

By Kiyoharu ISHIDA

(Received January 7, 1960)

Accurate prediction of phase relationships over a wide range of temperatures from some data determined at several temperatures is difficult in general. It seems that if the theory of strictly regular solutions developed by Guggenheim[1] is applicable to mixtures for most binary systems, the behavior of solutions may be more satisfactorily interpreted by the theory than by the semi-empirical equations according to van Laar or Margules. However, exceedingly few systems satisfy all the conditions for forming regular mixtures in which the molecules are assumed to be sufficiently alike in size and shape to be interchangeable on a lattice or quasi-lattice.

The author has shown that the theory of regular solutions can apply to a much wider class of mixtures by assuming the formation of stable 'clusters' consisting of each component in its liquid phases[2]. This paper will be concerned with the derivation of the relationship between the compositions in two conjugate liquid phases on which the application of the theory of regular solutions is based and with the method of representing the solubility curves for most binary systems symmetrically. Detailed consideration referring to the estimation of interchange energy from mutual solubility data and its dependency upon temperature will be given in a subsequent paper.

## 1. Thermodynamic Aspects on the Coexistence Curve of Binary Liquid Mixtures

The rigorous thermodynamic equations of the form

$$\ln(a_{\mathrm{I}}/a_{\mathrm{II}}) = \ln(x_{\mathrm{I}}/x_{\mathrm{II}}) + \ln(\gamma_{\mathrm{I}}/\gamma_{\mathrm{II}}) \qquad (1,1)$$

are applicable to any binary mixtures, where $a$'s, $x$'s and $\gamma$'s denote activities, mole fractions and activity coefficients of the component designated by subscripts I and II at a given temperature, respectively. (The pure component is taken as standard state). When the solution is separated into two liquid phases by the increase of the deviation from Raoult's law, designating the I-component rich phase by one prime and the II-component rich phase by two primes,

$$a_{\mathrm{I}}' = a_{\mathrm{I}}'', \quad a_{\mathrm{II}}' = a_{\mathrm{II}}'' \text{ and } x_{\mathrm{I}}' = 1 - x_{\mathrm{II}}'.$$

It therefore follows

$$\ln\{(1-x_{\mathrm{II}}')/x_{\mathrm{II}}'\} - \ln\{(1-x_{\mathrm{II}}'')/x_{\mathrm{II}}''\} = \ln(\gamma_{\mathrm{I}}''\gamma_{\mathrm{II}}'/\gamma_{\mathrm{I}}'\gamma_{\mathrm{II}}'') \qquad (1,2)$$

In cases where mutual solubilities are not so great, both values of $\gamma_{\mathrm{I}}'$ and $\gamma_{\mathrm{II}}''$ are near unity.

The temperature dependence of the activity coefficient can be related to the heat of mixing by the following equation

$$\frac{\mathrm{d}\ln\gamma_{\mathrm{I}}}{\mathrm{d}T} = -\frac{\Delta\bar{H}_{\mathrm{I}}}{\boldsymbol{R}T^2} \qquad (1,3)$$

where $\Delta\bar{H}_{\mathrm{I}}$ is the partial molal heat of solution of component I, $\boldsymbol{R}$ the gas constant and $T$ the absolute temperature. Then, Eq. 1,2 may be transformed into

$$\frac{\mathrm{d}\ln\{(1-x')/x'\}}{\mathrm{d}T} - \frac{\mathrm{d}\ln\{(1-x'')/x''\}}{\mathrm{d}T} = -\frac{\Delta H}{\boldsymbol{R}T^2} \qquad (1,4)$$

where

$$\Delta H = \Delta\bar{H}_{\mathrm{I}}'' - \Delta\bar{H}_{\mathrm{II}}'' - (\Delta\bar{H}_{\mathrm{I}}' - \Delta\bar{H}_{\mathrm{II}}') \qquad (1,5)$$

In Eq. 1,4 $x_{\mathrm{II}}$ is represented as $x$ for the sake of simplicity.

For most binary liquid mixtures with a few exceptions, it is observed that the solubilities of one component in one phase increase as the corresponding values in the other conjugate phase decrease with changing temperatures, and then the signs of $(\Delta\bar{H}_{\mathrm{I}}'' - \Delta\bar{H}_{\mathrm{II}}'')$ and $(\Delta\bar{H}_{\mathrm{I}}' - \Delta\bar{H}_{\mathrm{II}}')$ are opposite. The absolute values of these two quantities are equal in particular systems where the solubility curves are symmetrical with respect to the mole fraction as it is for a regular mixture. If the absolute value of the latter of these two quantities is $m$ times the former and $m$ is assumed to be independent of temperature, then

$$\Delta\bar{H}_{\mathrm{I}}' - \Delta\bar{H}_{\mathrm{II}}' = -m(\Delta\bar{H}_{\mathrm{I}}'' - \Delta\bar{H}_{\mathrm{II}}'') \qquad (1,6)$$

1) E. A. Guggenheim, "Mixtures", Oxford University Press, London (1952).
2) K. Ishida, *Nature*, **184**, 814 (1959).

Using these assumptions, Eq. 1, 4 may be written in the form

$$\frac{d\ln\{(1-x')/x'\}}{dT} - \frac{d\ln\{(1-x'')/x''\}}{dT} = (1+m)\frac{d\ln(\gamma_I''/\gamma_{II}'')}{dT} \qquad (1,7)$$

In the following Eq. 1, 8, which is obtained by setting the value of the first derivative of the molal free energy of mixing at a given temperature and pressure, $g(x)$, with respect to $x$ equal to zero,

$$\ln(\gamma_I/\gamma_{II}) = -\ln\{(1-x)/x\} \qquad (1,8)$$

values of $x$ represent the mole fractions of component II along the coexistence curve in cases of symmetrical systems. However, in cases of ordinary unsymmetrical systems, values of $x$ do not represent the mole fractions along the consolute curve, but they represent those at the extreme values on the $g(x)$ curve in the neighborhood of the compositions in mutual equilibrium of two phases such as $x'$ and $x''$, which are the two points of contact of the common tangent on the $g(x)$ curve. If the dependency of the logarithms of mole ratio of two components at the compositions in two coexisting phases upon temperature is assumed to be scarcely different from that at the compositions corresponding to the extreme values on the $g(x)$ curve, the following simple relation can be obtained

$$\ln\{(1-x')/x'\} = -m\ln\{(1-x'')/x''\} + B \qquad (1,9)$$

for the values of $x'$ and $x''$ on the coexistence curves, where $B$ is a constant independent of temperature.

As will be clear from Figs. 1—3* in which plots are made of the logarithms of the mole ratios of two components in one phase against the corresponding values in the other conjugate phase for several systems described in the literature, fair straight lines whose slopes are near minus unity are obtained from these plots over the considerably wide range of temperatures not only for systems with virtually symmetrical solubility curves, but also for systems with extremely unsymmetrical ones. Even for the systems showing the closed solubility curve, the linear relationships between the functions $\log\{(1-x')/x'\}$ and $\log\{(1-x'')/x''\}$ hold for temperatures within 30° of a critical solution temperature, $T_c$. This fact indicates that the value of $m$ is near unity for most systems and the deviations due to two assumptions involved in the derivation of Eq. 1, 9 from actual behavior of solutions are almost cancelled, and that when the logarithm of the mole ratio of two components in one phase increases with the change in temperature, the corresponding value in the other phase decreases in proportion to the increase of that in the former phase and the proportional factor is a constant over a wide range of temperature. It is clear that the form of Eq. 1, 9 is independent of whether weight, mole or volume fractions are used for the unit of concentration.

It is reasonable that Eq. 1, 9 holds for temperatures within 30°C of a critical solution temperature for most binary liquid systems, since this formula is immediately derived from the empirical relations 1, 10 shown by Cox and Herington[14].

$$T-T_c=[A'\log\{(1-x')/x'\}+B']^3 \qquad (1, 10a)$$

$$T-T_c=[A''\log\{(1-x'')/x''\}+B'']^3 \qquad (1, 10b)$$

## 2. Method of Representing the Solubility Curve Symmetrically

At the critical solution temperature $T_c$, the two coexisting phases become identical having the composition $x'=x''=x_c$. Eq. 1, 9 may be transformed into

$$\frac{1-x'}{x'}\cdot\frac{x_c}{1-x_c}=\left[\frac{1-x''}{x''}\cdot\frac{x_c}{1-x_c}\right]^{-m} \qquad (2, 1)$$

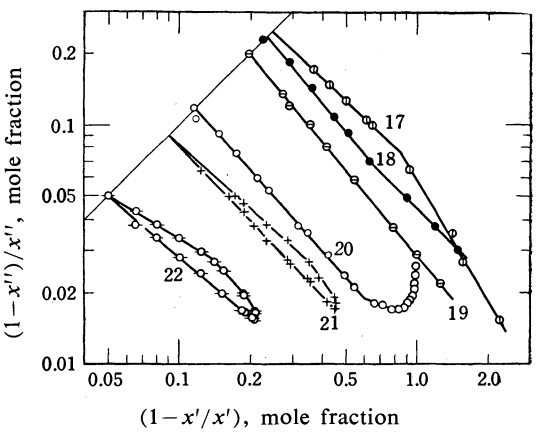

Fig. 3. Plot on double logarithmic coordinates of $(1-x'')/x''$ against $(1-x')/x'$.

| No. | Symbol | Component I | Component II | Ref. |
|---|---|---|---|---|
| 17 | ⓘ | Octene— | Liquid sulfur dioxide | 16 |
| 18 | ● | *m*-Xylene— | Liquid ammonia | 11 |
| 19 | ⊖ | Isopropylbenzene— | Liquid ammonia | 11 |
| 20 | ○ | *n*-Butanol— | Water | 13 |
| 21 | + | 1-Propoxypropane-2-ol— | Water | 17 |
| 22 | -○- | Ethylene glycol *n*-butyl ether— | Water | 18 |

It is possible to represent the solubility curve for a binary liquid system symmetrically with respect to the composition by plotting properly selected units. When the following units $\varphi$, which are the variation of volume fractions, are used for the concentrations, the resulting solubility curve will be symmetrical with respect to $\varphi$ as for regular binary mixtures, since $\varphi'+\varphi''=1$.

$$\varphi'=\frac{x'/x_c}{x'/x_c+(1-x')/(1-x_c)}$$

$$\varphi''=\frac{(x''/x_c)^m}{(x''/x_c)^m+\{(1-x'')/(1-x_c)\}^m} \qquad (2, 2)$$

Therefore, the interchange energy $w$ between two kinds of cluster may be obtained from the theory of regular solutions by assuming that each component forms clusters consisting of each component in its liquid phase, the number of moles being $(1-x')x_c$ and $x'(1-x_c)$ respectively, and that two kinds of cluster are stable and sufficiently alike in size and shape to satisfy all the conditions for forming strictly regular solutions on mixing[2]. In this case, by the definition of Eq. 2, 2 the molecular

18) H. L. Cox and L. H. Cretcher, ibid., **48**, 451 (1926).

ratio, $r'$, becomes

$$r'=\frac{1-\varphi'}{\varphi'}=\frac{1-x'}{x'}\cdot\frac{x_c}{1-x_c} \qquad (2,3)$$

Sometimes values of the interchange energy estimated from the compositions in one phase, $x'$, differ a little from those estimated by the use of the compositions in the other phase, $x''$, since a constant $m$ is not always exactly equal to unity as shown in Figs. 1—3. Of course, both values should coincide with each other when they are calculated by $\varphi'$ and $\varphi''$ using the value of $m$ estimated from the mutual solubility data determined at two temperatures by Eq. 1, 9, but calculations are considerably tedious.

It is convenient to introduce a variable $x_k$ defined by

$$\frac{x_k}{1-x_k}=\left(\frac{x'}{1-x'}\cdot\frac{x''}{1-x''}\right)^{1/2} \qquad (2,4)$$

and to use the variable $x_k$ instead of critical composition $x_c$ setting the value of $m$ equal to unity. Then,

$$\varphi'=\frac{\{x'/(1-x')\}^{1/2}}{\{x'/(1-x')\}^{1/2}+\{x''/(1-x'')\}^{1/2}}$$
$$=\frac{\{(1-x'')/x''\}^{1/2}}{\{(1-x')/x'\}^{1/2}+\{(1-x'')/x''\}^{1/2}}\equiv\varphi$$

and Eq. 2, 3 is replaced by Eq. 2, 6

$$r=\frac{1-\varphi}{\varphi}=\left(\frac{x''}{1-x''}\cdot\frac{1-x'}{x'}\right)^{1/2} \qquad (2,6)$$

Thus, by using $x_k$ instead of $x_c$ and putting $m=1$, the solubility curve can always be represented symmetrically with respect to $\varphi$ and the molecular ratio and the interchange energy at a given temperature can be evaluated by simpler calculation.

The value of $x_k$ may be dependent of the temperature and different from $x_c$ to a certain extent when $m$ is not unity, but $x_k$ corresponds to $x_c$ at the critical solution temperature. It may be easily proved by further algebraic arguments that there are straight line relationships between the functions $\log\{x_k/(1-x_k)\}$ and $\log\{x'/(1-x')\}$ and between the functions $\log\{x_k/(1-x_k)\}$ and $\log\{x''/(1-x'')\}$, and that $x_c$ is given by the following equation

$$\log\frac{x_c}{1-x_c}=\left[\log\frac{1-x_2'}{x_2'}\log\frac{x_1''}{1-x_1''}-\log\frac{1-x_1'}{x_1'}\log\frac{x_2''}{1-x_2''}\right]\Big/\left[\log\left(\frac{x_1'}{1-x_1'}\cdot\frac{1-x_2'}{x_2'}\right)-\log\left(\frac{x_1''}{1-x_1''}\cdot\frac{1-x_2''}{x_2''}\right)\right] \qquad (2,7)$$

where subscripts 1 and 2 denote the values at temperatures $T_1$ and $T_2$, respectively.

Thus it should be possible to predict the solubility relationships of the system from mutual solubility data, determined at more than one temperature, when the dependence of the interchange energy estimated from mutual solubility data in terms of $\varphi$-fractions upon temperature is known.

## Summary

The same expression for the correlation of compositions in mutual equilibrium of two liquid phases as that which is immediately obtained from the empirical relations used by Cox and Herington was derived thermodynamically. The method has been given in such a manner as to represent the solubility curve for a binary liquid system symmetrically and to estimate the interchange energy from the mutual solubility data by applying the theory of regular solutions.

# *Application of the Theory of Regular Solutions to Binary Phase Equilibria. II. Dependency of the Interchange Energy upon Temperature*

By Kiyoharu ISHIDA

(Received January 7, 1960)

A few examples[1] have been shown for the comparison of the theories of strictly regular solutions with experiments, since there are few suitable systems for which measurements necessary to adequate comparison have been made. In cases of many systems in which mixtures of two components show so great deviations from Raoult's law that the solutions separate into two liquid phases, the solutions are generally formed from chemically dissimilar constituents which are different in molecular size, chemical structure, polarity and so on, these conditions being far from those for forming regular mixtures. It, therefore, was impossible that the comparisons of the theories with experimental results obtained for such mixtures with great deviations from ideal behavior were made in order to verify the validity of theories and to extend their application to the field of the chemical engineering design, but now the application of the theories of strictly regular solutions to most partially miscible liquid systems and the estimation of the interchange energy from the mutual solubility data have become possible as described in the previous paper[2]. It is interesting and desirable from a practical viewpoint to study what relations are obtained between the interchange energy or the co-operative energy and the temperature for such systems.

## 3. Theoretical Expressions for Estimating Co-operative Energy from Compositions in Two Coexisting Phases

It has been shown that the problem of the phase transition for the regular mixtures of two components is mathematically identical with that of the so-called Ising model of ferromagnetism and that there is an equivalent relation between the compositions in mutual equilibrium of two liquid phases and the intensity of spontaneous magnetization in the absence of a magnetic field[3,4]. No exact results for the three-dimensional problems are available at present that could be applied to phase equilibria, but exact closed form expressions of the free energy in the absence of a magnetic field[5], which corresponds to the theory of regular solutions with equal ratio of constituents, and of the spontaneous magnetization[6] are available for the two-dimensional model, particularly the square net, though it has been found that there is a marked difference in behavior between two- and more realistic three-dimensional model[7].

The intensity of spontaneous magnetization per spin at zero magnetic field for a two-dimensional ferromagnetic Ising square lattice is given by

$$I=\left[\frac{1+\zeta^2}{(1-\zeta^2)^2}(1-6\zeta^2+\zeta^4)^{1/2}\right]^{1/4} \quad \text{for } \zeta\leqq\sqrt{2}-1 \tag{3,1}$$

$$\zeta=\exp(-\varepsilon/\boldsymbol{k}T) \tag{3,2}$$

where $\varepsilon$ is the interaction energy between each pair of nearest neighbor antiparallel spins assuming the interaction energy between pairs of parallel spins to be zero, and $\boldsymbol{k}$ is the Boltzmann constant.

By the correspondence of the theory of regular solutions to the Ising model, the interchange energy or one half of the energy increase of the whole system when a pair of two molecules of type I and a pair of two molecules of type II are converted into two pairs of a molecule of type I and a molecule of type II, $w$, will be obtained in terms of the mole fractions of component II in two coexisting phases, $x$, by the relation

$$\exp(w/\boldsymbol{k}T)=\left[\frac{1+[1+\{1-(1-2x)^8\}^{1/2}]^{1,2}}{\{1-(1-2x)^8\}^{1\,4}}\right]^4 \tag{3,3}$$

for the square lattice. At the critical solution temperature,

$$x=1/2, \qquad \exp(w/\boldsymbol{kT})_c=[1+\sqrt{2}]^4 \quad (3,4)$$

The information on the behavior of the model has been provided by exact series expansion of the partition function to any desired degree of accuracy[4,7-9]. In the rigorous expansion of the partition function by Bethe-Kirkwood's method of moments[8], the molar free energy of mixing in the notation used by Guggenheim[1] is given by

$$\frac{\Delta mF}{\boldsymbol{RT}}=(1-x)\ln(1-x)+x\ln x+x(1-x)\frac{w}{\boldsymbol{kT}} -\frac{z}{2}\left[\frac{l_2}{2!}\left(\frac{2w}{z\boldsymbol{kT}}\right)^2+\frac{l_3}{3!}\left(\frac{2w}{z\boldsymbol{kT}}\right)^3+\frac{l_4}{4!}\left(\frac{2w}{z\boldsymbol{kT}}\right)^4+\cdots\right] \quad (3,5)$$

where $z$ is the coordination number and

$$l_2=x^2(1-x)^2 \quad (3,6)$$

$$l_3=x^2(1-x)^2(1-2x)^2 \quad (3,7)$$

$$l_4=x^2(1-x)^2(1-6x+6x^2)^2 +6\left(\frac{y}{z}-1\right)x^4(1-x)^4 \quad (3,8)$$

$$l_5=x^2(1-x)^2(1-2x)^2(1-12x+12x^2)^2 +60\left(\frac{y}{z}-1\right)x^4(1-x)^4(1-2x)^2 \quad (3,9)$$

$$l_6=x^2(1-x)^2\{1-60x(1-x)(1-2x)^2\} +30\left(13\frac{y}{z}+17\right)x^4(1-x)^4 +120\left(\frac{\gamma_1}{z}-30\frac{y}{z}-28\right)x^5(1-x)^5 +120\left(\frac{\gamma_2}{z}-4\frac{\gamma_1}{z}+66\frac{y}{z}+42\right)x^6(1-x)^6 \quad (3,10)$$

$y$, $\gamma_1$ and $\gamma_2$ are parameters depending on the lattice and defined by

$$y=\sum_{a'} z^2_{aa'}-z(z-1) \quad (3,11)$$

$$\gamma_1=\sum_{a'} z^3_{aa'}-3\sum_{a'} z^2_{aa'}+2z(z-1) \quad (3,12)$$

$$\gamma_2=\sum_{a'a''} z_{aa'}z_{a'a''}z_{a''a}-3(z-2)\sum_{a'} z^2_{aa'} +2z(z-1)(z-2) \quad (3,13)$$

where $z_{aa'}$ is another coordination number denoting the number of first neighbors common to the sites $a$ and $a'$.

The compositions in two coexisting phases are given by the points where the value of the first derivative of the free energy of mixing is zero, owing to the symmetry of the solubility curve. To obtain the value of $w/\boldsymbol{kT}$ it is convenient to introduce an abbreviation $u$ defined by

$$u=\ln\frac{1-x}{x}\Big/(1-2x) \quad (3,14)$$

Differentiating Eq. 3, 5 with respect to $x$ and setting $\mathrm{d}(\Delta_m F/\boldsymbol{RT})/\mathrm{d}x$ equal to zero, the expression for $u/z$ as a power series in $2w/z\boldsymbol{kT}$ is obtained, which can be inverted into an expression for $2w/z\boldsymbol{kT}$ as a power series in $u/z$ as follows:

$$\frac{w}{\boldsymbol{kT}}=u\left[1+x(1-x)\frac{2u}{z}+\frac{x(1-x)}{3}\left(\frac{2u}{z}\right)^2 +\frac{x(1-x)}{12}\left\{1+2x(1-x) +12x^2(1-x)^2\frac{y}{z}\right\}\left(\frac{2u}{z}\right)^3 +\frac{x(1-x)}{60}\left\{1+8x(1-x) +120x^2(1-x)^2(1-2x+2x^2)\frac{y}{z}\right\}\left(\frac{2u}{z}\right)^4 +\frac{x(1-x)}{360}\left\{1+22x(1-x) +4x^2(1-x)^2\left(4+195\frac{y}{z}\right) +30x^3(1-x)^3\left(10\frac{\gamma_1}{z}-104\frac{y}{z}\right) +360x^4(1-x)^4\left(\frac{\gamma_2}{z}-4\frac{\gamma_1}{z} +10\frac{y}{z}\right)\right\}\left(\frac{2u}{z}\right)^5+\cdots\cdots\right] \quad (3,15)$$

And

$$(w/\boldsymbol{kT})_c=2\left[1+\frac{1}{z}+\frac{4}{3}\frac{1}{z^2}+\left(2+\frac{y}{z}\right)\frac{1}{z^3} +\left(\frac{16}{5}+4\frac{y}{z}\right)\frac{1}{z^4} +\left(\frac{16}{3}+10\frac{y}{z}-\frac{2}{3}\frac{\gamma_1}{z}+\frac{\gamma_2}{z}\right)\frac{1}{z^5}+\cdots\cdots\right] \quad (3,16)$$

The evaluation of the series of coefficients is increasingly tedious and complicated as the series is ascended.

Since the series converges to the exact value extremely slowly, and the presence of a magnetic field, which corresponds to regular solutions of varying concentrations, is difficult to deal with by an exact method even in

two-dimensions, several approximate solutions have been derived in closed form[1,10,11].

In the first (pairs) approximation[1] treated according to the quasi-chemical equilibrium conditions which is equivalent to Bethe approximation, $w$ is given by

$$\exp(w/zkT)=(1-r)/(r^{1/z}-r^{(z-1)/z}) \qquad (3,17)$$

where $r$ is the molecular ratio. At the critical solution temperature

$$\exp(w/zkT)_c=\frac{z}{z-2} \qquad (3,18)$$

In the zeroth approximation[1] which corresponds to the limiting form taken by the first approximation when the coordination number is made infinite, and is equivalent to Bragg-Williams approximation,

$$\frac{w}{kT}=\ln\frac{1-x}{x}\Big/(1-2x)=u \qquad (3,19)$$

Eq. 3,19 is only the first term in the Eq. 3,15 of rigorous series expansion. At the critical solution temperature

$$(w/kT)_c=2 \qquad (3,20)$$

Several methods which are capable of yielding successively higher approximations in the quasi-chemical method have been developed[1,10,12], but the use of a large group introduces troublesome calculations in practical applications of these higher approximations. In the higher approximation for the case of the simple square lattice with the tetrahedra as basic figure[1,10], which is the simplest case treated by the method of a logical extention to larger groups of the quasi-chemical approximation for pairs, the method being equivalent to an approximation developed by Kikuchi, $w/kT$ is obtained from

$$\exp\left(\frac{w}{kT}\right)=\left[\frac{(\sqrt{r}+1)^2+\{(\sqrt{r}+1)^4+4r\}^{1/2}}{2\sqrt{r}}\right]^2 \qquad (3,21)$$

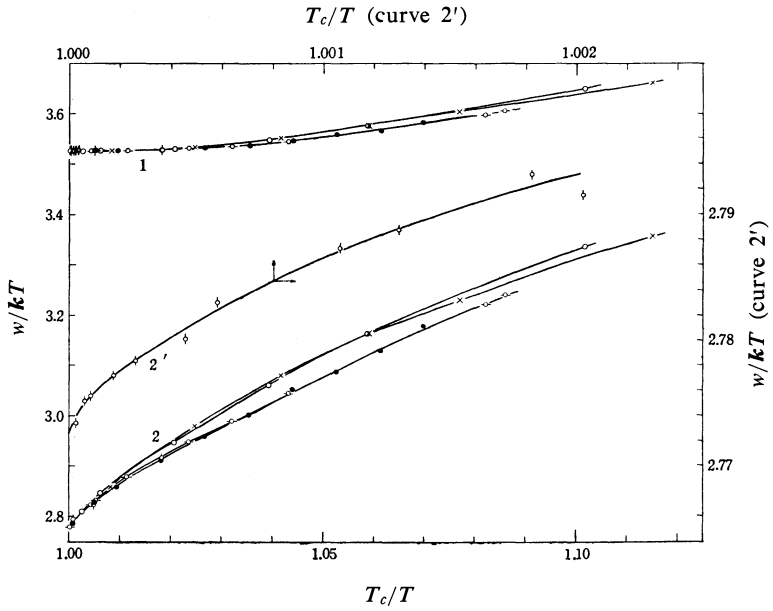

Fig. 4. Relations between $w/kT$ and $T_c/T$ for several systems. Values of $w/kT$ along curve 1 are obtained from Eq. 3,3. Corresponding values along curves 2 and 2' are obtained from Eq. 3,17 assuming $z=4$.

At the critical solution temperature

$$\exp(w/kT)_c = (2+\sqrt{5})^2 \qquad (3,22)$$

When the value of $w/kT$ is less than the value given by Eqs. 3,4, 3,16, 3,18, 3,20 or 3,22, the separation into two liquid phases does not occur.

## 4. Dependency of $w/kT$ upon Temperature

All formulae described in the above section contain the co-operative energy $w$ in the form of the ratio $w/kT$ or in particular $\exp(w/kT)$. It is convenient to compare the theories with the experiment, regarding either of these quantities as a single parameter whose value determines all the thermodynamic properties at a given temperature. Using $\varphi$ defined by Eq. 2,5 in the preceding paper instead of $x$, similar results between the functions $w/kT$ according to each theoretical formula and $T_c/T$ were obtained from the mutual solubility data for most binary liquid systems described in the literature as shown in Fig. 4. Accordingly, it may be sufficiently shown by the results for some representative systems how values of $w/kT$ are affected by such various theoretical

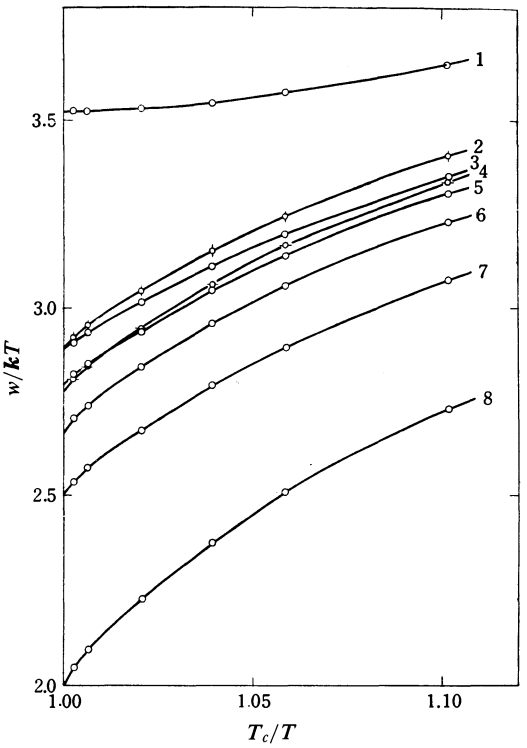

Fig. 5. Plot of values of $w/kT$ obtained from several theoretical expressions against $T_c/T$ for the system ethylbenzene—liquid ammonia.

Curve 1 is obtained from Eq. 3,3; curve 2 is obtained from Eq. 3,21; curve 3 is the expansion to terms of order $(2u/z)^4$ as given by Eq. 3,15 assuming $z=4$; curve 4 corresponds to Eq. 3,17 assuming $z=4$; curves 5, 6 and 7 are the expansions to terms of order $(2u/z)^3$, $(2u/z)^2$ and $(2u/z)$ as given by Eq. 3,15 assuming $z=4$, respectively; curve 8 is obtained from Eq. 3,19.

$\Delta T_c$ indicates the difference between observed and calculated values.
* These are systems which show a lower critical solution temperature.

expressions. Fig. 4. shows the relations between $w/kT$ by Eqs. 3, 3 and 3, 17 in which $z$ is assumed to be 4 and $T_c/T$ for systems of ethylbenzene—liquid ammonia[13], carbon tetrachloride—perfluoromethylcyclohexane[14,15], *n*-butane—perfluoro-*n*-butane[16] and *n*-hexane—methanol[17]. Plots are made of values of $w/kT$ obtained from formulae according to several approximations for square lattice against $T_c/T$ for the system ethylbenzene—liquid ammonia in Fig. 5, compared with results obtained from Eq. 3, 3. As will be clear from these figures, simple uninflected curves convex downward are obtained by exact solution for the two dimensional model, while similar curves convex upward by several approximate solutions, and it is observed that $w$ can be represented by neither a linear function of $T$ nor a constant since no linear relationships are observed in these figures.

Inspection of literature data on partially miscible binary liquid systems reveals that $w/kT$ is satisfactorily expressed by the following exponential functions

$$w/kT-(w/kT)_c=K(|T_c/T-1|)^n \qquad (4,1)$$

where $K$ and $n$ are constants. When values of $|T_c/T-1|$ are small, using the abbreviation $\eta$ for the quantity $\exp(w/zkT)$, this formula may be transformed into

$$\eta-\eta_c=K\eta_c(|T_c/T-1|)^n/z \qquad (4,2)$$

by expanding $\eta/\eta_c$ in terms of $K(T_c/T-1)^n/z$ and neglecting higher than square.

Plots of $\log(\eta-\eta_c)$ against $\log(|T_c/T-1|)$ for several binary liquid systems are shown in Fig. 6 where values of $\eta$ are evaluated from the mutual solubility data described in the literature according to Eqs. 3, 17 and 3, 18 assuming $z=4$. It will be seen from Fig. 6 that fair straight lines are obtained from these plots over a wide range of temperatures.

## 5. Prediction of the Critical Solution Temperature

It has been observed that the quasi-chemical approximation is considerably more accurate than the zeroth approximation and the results given by the first approximation differ little from those given by the higher approximations. Considering the possibility of the application of the theory of regular solutions to the vapor-liquid equilibria, it will be convenient at present to estimate $w/\boldsymbol{kT}$ by the Eqs. 3, 17 and 3, 18 according to the first approximation.

Since two empirical constants $K$ and $n$, besides the critical solution temperature $T_c$, are involved in Eqs. 4, 1 or 4, 2, three pairs of data are required for the estimation of the critical solution temperature. However, it is observed in Fig. 6 that the average value of $n$ for many systems is about 5/7 in the first approximation when $z$ is assumed to be 4. When the approximate value of five seventh is used for $n$ in Eq. 4, 2, it is possible to estimate the critical solution temperature and the solubility relationships at any other temperature from two pairs of the mutual solubility data.

In Table I are given critical compositions estimated by Eq. 2, 7 from the solubility data at temperatures $T_1$ and $T_2$ and critical solution temperatures calculated according to the expression

$$T_c=\frac{T_1T_2\{(\eta_1-\eta_c)^{7/5}-(\eta_2-\eta_c)^{7/5}\}}{T_1(\eta_1-\eta_c)^{7/5}-T_2(\eta_2-\eta_c)^{7/5}} \qquad (5,1)$$

which is derived from Eq. 4, 2 by the use of approximate value of five seventh for $n$ and the notation of $\eta_1$ and $\eta_2$ for the respective values of $\exp(w/z\boldsymbol{kT})$ at temperatures $T_1$ and $T_2$, compared with experimental values and the calculated values of critical solution temperature according to Eq. 1, 10.

It will be seen that with few exceptions in which $m$ in Eq. 1, 9 is not a constant over a wide range of temperatures, showing two straight lines having different slopes on plots of $\log\{(1-x')/x'\}$ against $\log\{(1-x'')/x''\}$ such as shown in Figs. 1—3 in the preceding paper, the agreement between the experimental and calculated values of $T_c$ by Eq. 5, 1 is about as good as the experimental accuracy even though the approximation of $n=5/7$ is used, better than the results given by Eq. 1, 10 which has been proposed by Cox and Herington[27].

## Summary

Theoretical expressions for estimating the interchange energy $w$ were given in such form as to be obtained from the mutual solubility data. It has been found that the dependency of the interchange energy estimated from mutual solubility data in terms of $\varphi$-fractions upon temperature is satisfactorily expressed by the form of equations $w/\boldsymbol{kT}-(w/\boldsymbol{kT})_c=K(|T_c/T-1|)^n$. The method of predicting the critical solution point was described as an example of the application of the theory of regular solutions.

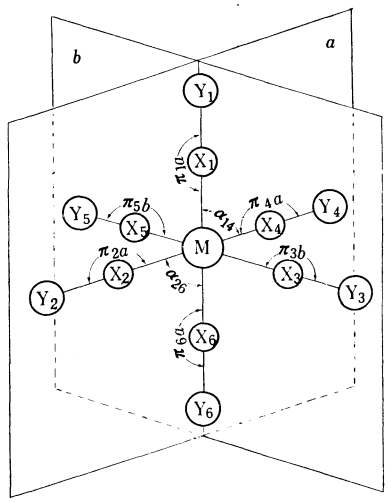
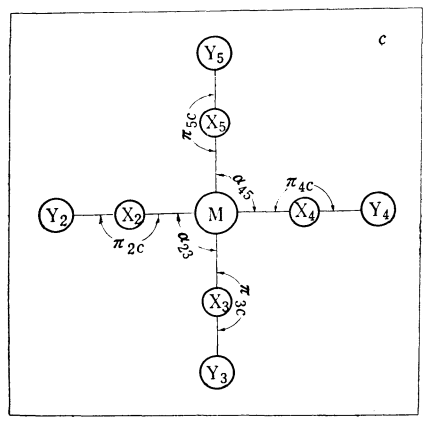
# *Normal Vibrations and Thermodynamic Properties of Chromium and Molybdenum Hexacarbonyls*

By Kiyoyasu KAWAI and Hiromu MURATA



(Received December 4, 1959)

Hawkins, Mattraw, Sabol and Carpenter[1] have observed successfully infrared spectra of chromium and molybdenum hexacarbonyls in gaseous state and have made an attempt to obtain Raman spectra of molybdenum hexacarbonyl. Recently, Danti and Cotton[2] have reported Raman spectra of those and tungsten hexacarbonyls using chloroform as solvent. The molecular structure by electron diffraction has been reported by Brockway, Evens and Lister[3], and by X-ray diffraction by Rudorf and Fofmann[4], and it has been clear for the molecule to have $O_h$-symmetry. The assignments of the observed frequencies have been made by these investigators and the thermodynamic properties have been calculated by Hawkins, Mattraw, Sabor and Carpenter[1].



Out of thirteen fundamental vibrations resulting from the $O_h$-symmetry of the $M(XY)_6$ type of molecule only four fundamental vibrations are infrared active, and the lowest frequency of them, which has considerably great contribution to thermodynamic properties is out of the region of the observation by a usual spectrometer. In connection with the other metal carbonyls previously reported[5] and now proceeding*, the present paper** deals with a normal coordinate analysis for chromium and molybdenum hexacarbonyls to establish the more reliable assignments of vibrational frequencies and to compute the potential constants which may afford some information concerning the nature of the metal-carbonyl and carbonyl bonds in those compounds. The thermodynamic properties based on these assignments were calculated.

## Normal Coordinate Treatment

The method of group theory shows that, as explained by Hawkins, Mattraw, Sabol and Carpenter[1], thirty-three normal modes of vibration of the octahedral $M(XY)_6$ type molecule are reduced to two of $a_{1g}$, two of $e_g$, one of $f_{1g}$, four of $f_{1u}$, two of $f_{2g}$ and two of $f_{2u}$, and $a_{1g}$, $e_g$ and $f_{2g}$ species are active in Raman and $f_{1u}$ species in infrared. The $f_{1g}$ and $f_{2u}$ species are inactive in both.

* A normal coordinate treatment of iron pentacarbonyl is being carried out in our laboratory. A part of the study has already been reported by H. Murata and K. Kawai, *J. Chem. Phys.*, **28**, 516 (1958).

** A part of this work has been reported by H. Murata and K. Kawai, *J. Chem. Phys.*, **27**, 605 (1957).

The general secular equation may be obtained by means of the Wilson's method[6]. The internal coordinates of $M(XY)_6$ molecule of this type are as follows:

$$d(M-X_i)=x_i \qquad d(X_i-Y_i)=y_i$$
$$\angle(M-X_i-Y_i)_{\text{lying in } j\text{th plane}}=\pi_{ij}$$
$$\angle(X_i-M-X_j)=\alpha_{ij}$$

Fig. 1 illustrates the above internal coordinates.

The symmetry coordinates were set up from these internal coordinates as follows:

For $a_{1g}$ species:

$$R_1=1/\sqrt{6}\,(\Delta y_1+\Delta y_2+\Delta y_3+\Delta y_4+\Delta y_5+\Delta y_6)$$
$$R_2=1/\sqrt{6}\,(\Delta x_1+\Delta x_2+\Delta x_3+\Delta x_4+\Delta x_5+\Delta x_6)$$

For $e_g$ species:

$$R_{3a}=1/\sqrt{12}(2\Delta y_1-\Delta y_2-\Delta y_3-\Delta y_4-\Delta y_5+2\Delta y_6)$$
$$R_{4a}=1/\sqrt{12}(2\Delta x_1-\Delta x_2-\Delta x_3-\Delta x_4-\Delta x_5+2\Delta x_6)$$

For $f_{1g}$ species:

$$R_{5a}=1/2(\Delta\pi_{1a}-\Delta\pi_{2a}+\Delta\pi_{4a}-\Delta\pi_{6a})$$

For $f_{1u}$ species:

$$R_{6a}=1/2(\Delta y_1+\Delta y_2-\Delta y_4-\Delta y_6)$$
$$R_{7a}=1/\sqrt{8}\,(\Delta\pi_{1a}+\Delta\pi_{2a}+\Delta\pi_{3b}-\Delta\pi_{3c}+\Delta\pi_{4a}+\Delta\pi_{5b}+\Delta\pi_{5c}+\Delta\pi_{6a})$$
$$R_{8a}=1/2(\Delta x_1+\Delta x_2-\Delta x_4-\Delta x_6)$$
$$R_{9a}=1/4(2\Delta\alpha_{12}+\Delta\alpha_{13}+\Delta\alpha_{15}+\Delta\alpha_{23}+\Delta\alpha_{25}-\Delta\alpha_{34}-\Delta\alpha_{36}-\Delta\alpha_{45}-\Delta\alpha_{56}-2\Delta\alpha_{46})$$

For $f_{2g}$ species:

$$R_{10a}=1/2(\Delta\pi_{1a}+\Delta\pi_{2a}-\Delta\pi_{4a}-\Delta\pi_{6a})$$
$$R_{11a}=1/2(\Delta\alpha_{12}-\Delta\alpha_{14}-\Delta\alpha_{26}+\Delta\alpha_{46})$$

For $f_{2ua}$ species:

$$R_{12a}=1/\sqrt{8}\,(\Delta\pi_{1a}+\Delta\pi_{2a}-\Delta\pi_{3b}+\Delta\pi_{3c}+\Delta\pi_{4a}-\Delta\pi_{5b}-\Delta\pi_{5c}+\Delta\pi_{6a})$$
$$R_{13a}=1/4\,(2\Delta\alpha_{12}-\Delta\alpha_{13}-\Delta\alpha_{15}-\Delta\alpha_{23}-\Delta\alpha_{25}+\Delta\alpha_{34}+\Delta\alpha_{36}+\Delta\alpha_{45}+\Delta\alpha_{56}-2\Delta\alpha_{46})$$

Using the table of Decius[7] and for the M−X−Y bending the method by Ferigle and Meister[8] **G** matrices were evaluated. In therms of the abbreviations $\rho$ and $\tau$ for reciprocal of the bond lengths $x$ and $y$, respectively, and $\mu_M$, $\mu_X$ and $\mu_Y$ for the reciprocals of the atomic masses, the following **G** matrix elements were obtained***:

For $a_{1g}$ species:

$$G_{11}=\mu_X+\mu_Y,\quad G_{12}=-\mu_X,\quad G_{22}=\mu_X$$

For $e_g$ species:

$$G_{33}=G_{11}(a_{1g}),\quad G_{34}=G_{12}(a_{1g}),\quad G_{44}=G_{22}(a_{1g})$$

For $f_{1g}$ species:

$$G_{55}=(\rho+\tau)^2\mu_X+\tau^2\mu_Y$$

For $f_{1u}$ species:

$$G_{66}=G_{11}(a_{1g}),\quad G_{67}=G_{69}=0,$$
$$G_{68}=G_{12}(a_{1g}),$$
$$G_{77}=4\rho^2\mu_M+(\rho+\tau)^2\mu_X+\tau^2\mu_Y,$$
$$G_{78}=\sqrt{8}\,\rho\mu_M,$$
$$G_{79}=-\sqrt{2}\{4\rho^2\mu_M+(\rho^2+\rho\tau)\mu_X\},$$
$$G_{88}=2\mu_M+\mu_X,\quad G_{89}=-4\rho\mu_M,$$
$$G_{99}=2\rho^2(4\mu_M+\mu_X)$$

For $f_{2g}$ species:

$$G_{1010}=G_{55}(f_{1g}),$$
$$G_{1011}=-2(\rho^2+\rho\tau)\mu_X,\quad G_{1111}=4\rho^2\mu_X$$

For $f_{2u}$ species:

$$G_{1212}=G_{55}(f_{1g}),$$
$$G_{1213}=-\sqrt{2}\,(\rho^2+\rho\tau)\mu_X,$$
$$G_{1313}=2\rho^2\mu_x$$

Following the method of Shimanouchi[9], the Urey-Bradley type quadratic potential energy function for octahedral $M(XY)_6$ molecule may be written as:

$$2V=\sum_{i=1}^{6}\{K(M-X)+2[F(X\cdots X)+F'(X\cdots X)]\}(\Delta x_i)^2$$
$$+\sum_{i=1}^{6}K(X-Y)(\Delta y_i)^2$$
$$+\sum_{i<j=1}^{6}\{H(X-M-X)+1/2[F(X\cdots X)-F'(X\cdots X)]\}(x_0\Delta\alpha_{ij})^2$$
$$+\sum_{i=1}^{6}\sum_{l=a}^{c}H(M-X-Y)(\sqrt{x_0y_0}\Delta\pi_{il})^2$$
$$+2\sum_{i<j=1}^{6}1/2[F(X\cdots X)$$

$$-F'(\mathrm{X}\cdots\mathrm{X})]\,(\Delta x_i)(\Delta x_j)$$
$$+2\sum_{i<j=1}^{6} 1/2\,[F(\mathrm{X}\cdots\mathrm{X})$$
$$+F'(\mathrm{Y}\cdots\mathrm{X})]\,(\Delta x_i)(x_0\Delta\alpha_{ij})$$
$$+2\sum_{i\neq j\neq k=1}^{6} 1/(2x_0^2)\kappa(x_0\Delta\alpha_{ij})(x_0\Delta\alpha_{ik})$$

where $x_0$ and $y_0$ are the equilibrium M−X and X−Y bond distances respectively; $K$, $H$, $F$ and $F'$ are the potential constants and $\kappa$ the intramolecular tension whose definition and physical meaning were expressed by Shimanouchi[9].

The intra-molecular tension for the octahedral $MX_6$ type molecule can easily be derived from the following relation obtained for the octahedral geometrical structure

$$\Sigma(\Delta\alpha_{ij})+1/2\Sigma(\Delta\alpha_{ij})(\Delta\alpha_{ik})=0$$

where the first summation extends for all of the twelve angles and the second for all the forty-eight sets of adjacent angles.

The potential energy matrix elements evaluated from the above potential function are as follows:

For $a_{1g}$ species:

$$\boldsymbol{F}_{11}=K(\mathrm{X}-\mathrm{Y}),\quad \boldsymbol{F}_{12}=0,$$
$$\boldsymbol{F}_{22}=K(\mathrm{M}-\mathrm{X})+4F(\mathrm{X}\cdots\mathrm{X})$$

For $e_g$ species:

$$\boldsymbol{F}_{33}=\boldsymbol{F}_{11}(\mathrm{a_{1g}}),\quad \boldsymbol{F}_{34}=0,$$
$$\boldsymbol{F}_{44}=K(\mathrm{M}-\mathrm{X})+0.7F(\mathrm{X}\cdots\mathrm{X})$$

For $f_{1g}$ species:

$$\boldsymbol{F}_{55}=x_0y_0H(\mathrm{M}-\mathrm{X}-\mathrm{Y})$$

For $f_{1u}$ species:

$$\boldsymbol{F}_{66}=\boldsymbol{F}_{11}(\mathrm{a_{1g}}),\quad \boldsymbol{F}_{77}=\boldsymbol{F}_{55}(\mathrm{f_{1g}}),$$
$$\boldsymbol{F}_{88}=K(\mathrm{M}-\mathrm{X})+1.8F(\mathrm{X}\cdots\mathrm{X}),$$
$$\boldsymbol{F}_{89}=0.9x_0F(\mathrm{X}\cdots\mathrm{X}),$$
$$\boldsymbol{F}_{99}=x_0^2\,[H(\mathrm{X}-\mathrm{M}-\mathrm{X})+0.55F(\mathrm{X}\cdots\mathrm{X})]+\kappa,$$
$$\boldsymbol{F}_{67}=\boldsymbol{F}_{68}=\boldsymbol{F}_{69}=\boldsymbol{F}_{78}=\boldsymbol{F}_{79}=0$$

For $f_{2g}$ species:

$$\boldsymbol{F}_{1010}=\boldsymbol{F}_{55}(\mathrm{f_{1g}}),\quad \boldsymbol{F}_{1011}=0,$$
$$\boldsymbol{F}_{1111}=x_0^2\,[H(\mathrm{X}-\mathrm{M}-\mathrm{X})+0.55F(\mathrm{X}\cdots\mathrm{X})]$$

For $f_{2u}$ species:

$$\boldsymbol{F}_{1212}=\boldsymbol{F}_{55}(\mathrm{f_{1g}}),\quad \boldsymbol{F}_{1213}=0,$$
$$\boldsymbol{F}_{1313}=x_0^2\,[H(\mathrm{X}-\mathrm{M}-\mathrm{X})+0.55F(\mathrm{X}\cdots\mathrm{X})]-\kappa$$

In the above elements it was assumed experimentally that $F'=-1/10F$, and consequently six potential constants are used here.

b Inferred from combination or overtone bands.
c Obtained by the method of high-frequency separation.

To evaluate numerically the above elements, the bond lengths listed in Table I and the atomic masses on a physical scale were used.

## Discussion

A comparison of the normal frequencies calculated from the set of potential constants in Table II with those observed by Hawkins, Mattraw, Sabol and Carpenter[1] are summarized in Table III. The numbering of the frequencies is the same as that used by Hawkins et al.[1]

The agreement between the calculated and the observed frequencies is satisfactory except for the M—C—O bending vibrations. The present results from the Urey-Bradley type potential function in which all the M—C—O bending interaction constants are not included indicated that 213 and 310 $cm^{-1}$ bands assigned to $\sigma_{10}$ and $\sigma_{12}$ respectively by Hawkins, Matraw, Sabol and Carpenter[1] and 137.1 $cm^{-1}$ band to $\sigma_{10}$ by Danti and Cotton[2] for chromium hexacarbonyl and 230 and 327 $cm^{-1}$ bands by the former[1] and 135.7 $cm^{-1}$ band by the latter[2] for molybdenum hexacarbonyl are too small for M—C—O bending vibrational frequencies. Based on this point of view, all of the observed bands by Hawkins, Matraw, Sabol and Carpenter[1] except for only three strong bands which may be designated as fundamentals, were reassigned as shown in Table IV for chromium hexacarbonyl and Table V for molybdenum hexacarbonyl.

In order to obtain better agreement with the observed frequencies of $a_{1g}$ and $e_g$ species some other sets of values of diagonal terms in **F** matrix were used, but as long as proper values with physical meaning were used the calculated values were not close to the observed ones. This, therefore, may suggest that the

interaction terms between X−Y and M−X or X—Y stretching internal coordinates in the Urey-Bradley type potential function are not negligibly small.

Though, as explained above, there are contained a few quetionable points and the limits of error are uncertain, we may be allowed to conclude that the assignments in Table III and the potential constants in Table II are reasonable.

As the carbon-oxygen stretching potential constant $K$(C−O), that of nickel carbonyl[5], 16.02 mdyn./Å, was employed. For this selection the metal-carbon stretching potential constants $K$(M−X) were obtained to be 1.83 and 1.77 mdyn./Å for chromium and molybdenum hexacarbonyls respectively. These metal-carbon stretching potential constants are a little smaller than that of nickel carbonyl[5], 2.12 mdyn./Å, and this fact is in agreement with the study by Giacometti[10] who suggested that the shortening of chromium-carbon bond is smaller than that of nickel-carbon bond in the metal carbonyls. The values of the metal-carbon stretching potential constant, although many authors[10,11] have discussed the evidence of partial double bond caracter in such coordination compounds of various symmetry as these metal carbonyls, are nearly equal to those of Si—C and Cr—Cl bonds of tetramethylsilane[12] and chromyl

chloride[13] (2.72 and 2.56 mdyn./Å respectively), which are considered as single bonds.

The **L** matrices, whose components give the transformation from normal to symmetry coordinates, were calculated and listed in Table VI for chromium hexacarbonyl and Table VII for molybdenum hexacarbonyl.

## Thermodynamic Properties

The heat content, free energy, entropy and heat capacity at constant pressure were calculated for seven temperatures from 273.15 to 1000°K in the rigid rotator-harmonic oscillator approximation using the probable values of the observed wave numbers listed in Table III. The molecular constants used in these computation and the symmetry number are given in Table I, while Table VIII lists the thermodynamic properties.

The authors express their sincere appreciation to Professor R. Tsuchida of Osaka University for helpful suggestions and valuable advice.

# SHORT COMMUNICATIONS

## *Glumamycin, A New Peptide-type Antibiotic**

By Michitaka INOUE, Hiroshi HITOMI, Komei MIZUNO, Masahiko FUJINO, Akira MIYAKE, Koiti NAKAZAWA, Motoo SHIBATA and Toshihiko KANZAKI

(Received May 13, 1960)

A Streptomyces strain isolated in March, 1954 from a sample collected in Osaka Prefecture resembled the Zaomycin producing strain, S. zaomyceticus[1], in morphological and cultural characteristics and the utilization of carbon source, and therefore it was named S. zaomyceticus No. 7548 tentatively. The strain, when cultivated on a medium containing 3.0% of starch, 1.0% of polypepton, 0.2% of potassium phosphate 0.3% of soybean oil, and 2.0% of rice bran for 96 hr., produced an antibiotic, but the potency lowered abruptly thereafter.

The antibiotic inhibited the growth of Gram-positive bacteria such as Micrococcus aureus 209p and B. subtilis and was especially active against the bacteria resistant to known antibiotics. Although this antibiotic was similar to Amphomycin[2,3], Zaomycin[1] and Crystallomycin[4,5], it differed from them clearly. The authors, having found it to be a new antibiotic, named it Glumamycin and investigated its constituents.

The antibiotic was isolated pure from the broth by Craig's counter current distribution method 300 plates; chloroform- methanol-0.02 N hydrochloric acid (2 : 2 : 1), and it gave only one spot in paper chromatography and paper ionophoresis at various pH's. M. p. 230°C (decomp.). Found: C, 51.71; H, 7.20; N, 12.99%. From its dissociation constant, the molecular weight was estimated to be about 1800. The antibiotic had its isoelectric point at pH 3.4, and though it showed the typical infrared-spectrum characteristic of peptides, it exhibited no peculiar absorption in the ultraviolet-region.

The antibiotic was not hydrolized by any hydrolyrase such as pepsin, trypsin and carboxypeptidase, but it was completely hydrolized by heating with 6 N hydrochloric acid at 110°C for 20 hr. When the hydrolysate was subjected to two dimensional paper chromatography *n*-butanol-acetic acid-water (4 : 1 : 5) or 80% phenol containing 0.5 N ammonia, six amino acids were detected, four of which were aspartic acid, glycine, valine and proline and the other were unknown. Of the two unknown amino acids, one was a basic amino acid differing from lysine, histidine and arginine on paper chromatogram, and the other was a neutral amino acid which was characterized by a violet blue color with ninhydrin and a blue color with isatin. The six amino acids were separated from each other in crystalline form when chromatographed first on ion-exchange resin (IR-4B, Dowex 50×8) and then on cellulose powder.

After recrystallization from 75% methanol, the unknown basic amino acid showed m. p. 202°C (decomp.), $[\alpha]_D^{22} = +16°$ (c, 1 : $H_2O$), Pk <2, 6.6, 9.6, and gave the values of 1.0 mol. of C-$CH_3$ (Kuhn-Roth) and 1.8 mol. of amino nitrogen (Van Slyke), and it was different from authentic $\alpha,\gamma$-diaminobutyric acid on paper chromatogram. From these facts it was presumed to be $\alpha,\beta$-diaminobutyric acid. On the other hand, the unknown neutral amino acid, when recrystallized from methanol·ether, melted at 240°C (decomp.), showed $[\alpha]_D^{21} = +10°$ (c, 1 : $H_2O$) and accorded with $C_6H_{11}O_2N$·HCl, but no amino nitrogen (Van Slyke) and C-$CH_3$ (Kuhn-Roth) were detected. This compound was in complete agreement with synthetic DL-pipecolic acid in paper chromatography with various solvent systems, and the optical rotations of its hydrochloride and tartarate were $[\alpha]_D^{25} = +10°$ (c, 1 : $H_2O$) and $[\alpha]_D^{25} = +20°$ (c, 1 : $H_2O$), respectively. As the sign of optical activity of the neutral amino acid was opposite to that of the natural pipecolic acid it belongs to the D-series; the aspartic acid, valine, and proline derived from the antibiotic belong to the L-series.

The hydrolysate mentioned before contained about 10% of a substance soluble in ether, which was found to ba a monobasic unsaturated fatty acid, b. p. 139°C (1 mmHg), $[\alpha]_D^{21} = +4°$

(c, 1 : $C_2H_5OH$), $C_{13}H_{24}O_2$. Oxidation of the substance with ozone afforded a compound $C_9H_{18}O_2$, b. p. 154°C (25 mmHg), $[\alpha]_D^{21} = +12°$ (c. 1 : $C_2H_5OH$), and from this and other results, a 4-isotridecenoic acid structure, $C_8H_{17}CH=CHC_2H_4$–COOH, was assigned to the unsaturated fatty acid.

Thus Glumamycin was assumed to be composed of 4-isotridecenoic acid, L-aspartic acid, glycine, L-valine, L-proline, D-pipecolic acid, and $\alpha$, $\beta$-diaminobutyric acid combined through peptide linkages. Full details of this work will be reported shortly.

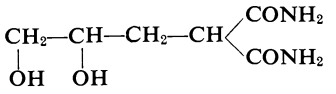
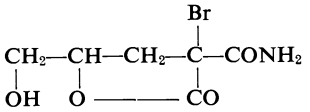
# *Eine Neue Synthese des cis- und trans D, L-Desmethylmuscarins*

Von Takeshi MATSUMOTO
und Akitami ICHIHARA



(Eingegangen am 4. Juni, 1960)

In früheren Mitteilungen[1,2] haben wir die Synthese und pharmakologische Wirkung von stereoisomeren Muscarinen beschrieben. Hier soll nun über die Synthese der einfacher gebauten Desmethylmuscarine berichtet werden. Zu ihrer Herstellung haben wir die Reaktionsfolge, die bei der Durcharbeitung der Muscarinsynthesen erprobt wurde, übertragen.



Als Ausgangsmaterial bot sich Allylmalonsäure-äthylester (I). Durch Hydroxylierung dieses Esters mittels Perameisensäure und darauf folgende Ammonolyse wurde Dihydroxydiamid (II)[3] erhalten. Das letztere wurde dann nach der bekannten Methode von W. Traube[3] über Bromlacton (III) in Tetrahydrofurandicarbonsäure (IV) übergeführt. Erhitzte man die wässrige Lösung von Dicarbonsäure (IV) auf 150～160°C, so entstanden erwartungsgemäss zwei stereoisomere Monocarbonsäuren (V) ($\alpha$, Schmp. 143.5°C, Ber. C 45.45 H 6.10 Gef. C 45.59 H 5.99%; $\beta$, Schmp. 129°C, Ber. C 45.45 H 6.10 Gef. C 45.50 H 6.10, die sich durch Chromatographie an Alumina-Säule

# *Formation of Isoxazolecarboxylic Acids from α, β-Unsaturated α-Nitroesters*[1]

By Sumio UMEZAWA and Shōnosuke ZEN

(Received April 15, 1960)

We wish to report the synthesis of new members of isoxazolecarboxylic acids. When treated with *n*-butylamine (2.0 g.) in ligroin at room temperature overnight, diethyl α-nitroglutaconate[2] (I) (1.0 g.) produced 3, 5-bis(*n*-butylcarbamoyl) - 4 - (*n*-butylcarbamoylmethyl)-isoxazole (III) (crude product 0.6 g.). We have found that the cyclization is generally applicable to the synthesis of 4-substituted isoxazole-3, 5-dicarboxylic acids. Thus, 4-phenyl-3, 5-bis(*n*-butylcarbamoyl)isoxazole (VI) (crude product 0.22 g.) and 4-methyl-3, 5-bis (*n*-butylcarbamoyl)isoxazole (IX) have been obtained from ethyl α-nitrocinnamate[3] (V) (1.0 g.) and ethyl α-nitrocrotonate[4] (VIII) by refluxing with *n*-butylamine in absolute ethanol for three hours, respectively (Tables I and II).

By mild alkaline hydrolysis with 10% sodium hydroxide in 50% aqueous ethanol at about 60°C for two hours, III (1.12 g.) and VI (1.0 g.) were converted into isoxazole-3, 5-dicarboxylic-4-acetic acid (IV) (crude product 0.56 g.) and 4-phenylisoxazole-3, 5-dicarboxylic acid (VII) (crude product 0.45 g.), respectively (Table I).

Drastic alkaline hydrolysis of VI by refluxing with 28% potassium hydroxide in 50% aqueous ethanol resulted in the formation of phenylacetic acid and oxalic acid, the fact indicating that the above-mentioned cyclization forms a 4-substituted isoxazole-3, 5-dicarboxylic acid derivative.

It seems reasonable to suggest that the initial step involves base-catalyzed cleavage of α, β-unsaturated α-nitroester to liberate nitroacetic ester moiety which may be in equilibrium

1) Presented in part at the Division of Organic Chemistry of the Annual Meeting of the Chemical Society of Japan, Kyoto, April 2, 1959.

2) Prepared by the condensation of sodium salt of ethyl formylacetate with ethyl nitroacetate in the presence of diethylamine or *n*-butylamine; b. p. 125~130°C/0.2 mmHg.

3) Prepared by the method of A. Dornow and H. Menzel, [*Ann.*, **580**, 43 (1952)]. They obtained carbethoxy-diethylcarbamoyl-4-phenylisoxazoline *N*-oxide by refluxing an ethanol solution of diethylamine and diethylamine salt of ethyl 1,3-dinitro-2,3-diphenylbutyrate which was prepared from ethyl α-nitrocinnamate and phenylnitromethane. This result is closely related to the method reported in the present paper, whereby, however, isoxazole derivatives are obtained.

4) Prepared from ethyl α-nitro-β-acetoxybutyrate by heating with anhydrous sodium carbonate in dry benzene by a variation of the method of H. B. Hass, A. G. Susie and R. L. Heider, (*J. Org. Chem.*, **15**, 8 (1950)).

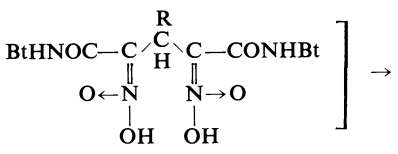
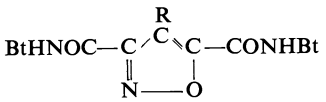
| VI | —[b] | 3338, | 1678, | 1535 |
| IX | 246 (10100)[c] | 3290, | 1664, | 1555 |

a) Methanol solution.
b) No characteristic maximum in the range of 220~340 m$\mu$.
c) Ethanol solution.



with the original unsaturated nitroester, followed by the addition of the former to the latter to give a key intermediate II, which may cyclize by elimination of water and nitrous acid to form isoxazole derivatives, as outlined in the following scheme:



I, R=$CH_2CO_2Et$
V, R=$C_6H_5$
VIII, R=$CH_3$

II

Bt=*n*-Butyl

III, R=$CH_2CONHBt$
VI, R=$C_6H_5$
IX, R=$CH_3$

The validity of the above mechanism has been supported by the experimental observation that, if ethyl nitroacetate is added to the above-mentioned reaction system as an external source of nitroacetate moiety, the yield of isoxazole derivative is significantly increased. As a typical result: When a mixture of ethyl $\alpha$-nitrocinnamate (5.0 g.) and ethyl nitroacetate (3.0 g.) was caused to react with *n*-butylamine (10 g.) under similar conditions, VI (crude product 4.7 g.) was obtained in a 60% yield.

Further studies on the related reactions are in progress.

The authors are grateful to Mr. S. Nakada and Miss S. Taguchi for helping their experiments.

## *Genesis of Sulfate in Acid Hot Spring*

By Iwaji IWASAKI and Takejiro OZAWA

(Received March 18, 1960)

Acid hot springs contain generally large amounts of sulfate ion, and it has been usually considered that most of them are formed by the oxidation of hydrogen sulfide or other sulfides with oxygen from the air at or near the ground surface[1].

However, this explanation is not always acceptable, when their high discharges and the chemical composition of gases accompanied with the acid hot springs are taken into consideration.

Fumarolic gases from active volcanoes contain usually hydrogen sulfide, sulfur dioxide,

TABLE I

| Silicate rock | Condition | $H_2SO_3$(mM) Residual | $H_2SO_4$(mM) Found | S(mM) Found | $H_2SO_4$/S |
|---|---|---|---|---|---|
| None | A | 6.51 | 2.36 | 1.10 | 2.1 |
| | B | 3.43 | 3.79 | 1.80 | 2.1 |
| Basalt | A | 0.69 | 5.96 | 2.38 | 2.5 |
| | B | 0.36 | 5.68 | 2.69 | 2.1 |
| Andesite | A | 0.26 | 5.89 | 2.75 | 2.1 |
| | B | 0.14 | 5.25 | 2.95 | 2.1 |
| Granite | A | 1.03 | 5.60 | 2.70 | 2.1 |
| | B | 2.68 | 3.89 | 1.72 | 2.3 |

hydrogen chloride and carbon dioxide in the same order of amounts, and nitrogen in a smaller amount, but scarcely any oxygen and sulfur trioxide.

On the other hand, gases from region of the acid hot springs consist of carbon dioxide and hydrogen sulfide as the major components, and of nitrogen as the minor components, and of sulfur dioxide, hydrogen chloride and oxygen as the trace components. Therefore, the most important chemical species for the formation of sulfate would not be hydrogen sulfide, but sulfur dioxide.

When volcanic gases are condensed by cooling under the ground, hydrogen chloride and sulfur dioxide would dissolve into the condensed water to form hydrochloric and sulfurous acids. Then sulfuric acid may be formed from this sulfurous acid, liberating sulfur by the following self oxidation-reduction reaction.

$$3H_2SO_3 = 2H_2SO_4 + S + H_2O \qquad (1)$$

In order to confirm this new hypothesis, some experiments were carried out as follows. Two grams of the powdered silicate rock were taken into an ampoule (50 ml.) and 20 ml. of 0.5 M sulfurous acid solution (condition A) or 20 ml. of the mixed solution consisting of 0.5 M sulfurous acid and 0.5 M hydrochloric acid (condition B) were added. Then each ampoule was sealed in the atmosphere of carbon dioxide and kept at 105°C. After about three days, some droplets of sulfur were observed on the surface of the solution into which andesite or granite was added. After a week, all ampoules were cooled to room temperature and the amount of each reaction product was determined (Table I).

It is clear that, as shown in Table I, the self oxidation-reduction reaction of sulfurous acid is mainly based on Eq. 1 under these conditions and this reaction proceeds easily in the presence of hydrochloric acid or silicate rock. Under natural circumstances where higher pressure and temperature are expected, this reaction would proceed more easily and the sulfur formed may contribute to the formation of some ores such as pyrite and native sulfur impregnated with wall rocks.

It is concluded that the principal source of sulfate in the acid hot spring may be sulfur dioxide from volcanic gas and the formation of sulfate may be based on the self oxidation-reduction of sulfurous acid.

# *A Research on Isotopic Composition of Evolved Hydrogen Molecules with Special Reference to the Mechanism of Nickel Cathode*

By Kozo HIROTA and Takeo HISANO*

(Received May 2, 1960)

Although a number of research has been published on the separation factor of hydrogen evolved at the electrolysis of aqueous solutions, no attention has been paid on the composition of isotopically different molecules, i.e., $H_2$ HD and $D_2$. However, by the following reasoning, it seems very important to investigate if the composition coincides with the one expected by the gaseous equilibrium:

$$H_2 + D_2 \rightleftarrows 2HD \qquad (1)$$

In the case of the discharge mechanism (A), evolved hydrogen must be equilibrated by the practical equilibrium of the recombination step of statistically independent hydrogen atoms formed by the rate-determining step $H^+ + e \rightarrow H$ of this mechanism. On the other hand, in the case of the catalytic (B) or the electrochemical (C) mechanism the evolved hydrogen need not be equilibrated, inasmuch

* Research fellow from the Engineering Faculty, Tokushima University (1959-1960).

TABLE I. SEPARATION FACTOR AND ISOTOPIC COMPOSITION EVOLVED AT THE NICKEL ELECTRODE AT 0°C

| Exp. no. | Current density mA/cm² | D atom% | Separation factor $\alpha$ | $K(\text{obs}) = \frac{[HD]^2}{[H_2][D_2]}$ |
|---|---|---|---|---|
| 41 | 25.3 | 30.3 | 4.3 | 2.8 |
| 42 | 50.6 | 25.1 | 5.6 | 2.7 |
| 43 | 84.3 | 21.6 | 6.6 | 2.7 |
| 44 | 147.3 | 20.5 | 7.3 | 2.7 |
| 45 | 190 | 21.4 | 7.4 | 2.8 |

* a) All the data of the columns 3,4 and 5 are the means of two measurements except for No. 41.
b) D atom% of the original solution: 65.2%.

as the rate is governed in either case by the step of formation of the hydrogen molecule itself, which is not of course in equilibrium.

It is interesting therefore to demonstrate the above consideration experimentally on some cathode. As the first example, nickel electrode has been taken up, because the mechanism of this electrode is not yet determined in spite of the effort of many researchers. The electrolysis was carried out on 1 N sodium carbonate solution with the cathode of nickel plate (surface area, 0.48 cm²) and the anode of platinum wire. Deuterium content in the original solution was 65.2% (atom%). The ratio $H_2$ : HD : $D_2$ of the hydrogen evolved at the cathode as well as the separation factor $\alpha$, defined by $(H/D)_{gas}/(H/D)_{sol}$, were determined mass-spectrometrically.

The result obtained at 0°C is summarized in Table I. It is shown that $\alpha$ increases with current density and approaches to the value of 7.4 which is nearly equal to that hitherto obtained by the electrolysis of aqueous solution of low deuterium concentration in the case of nickel cathode[1]. It is noteworthy on the other hand that the factor $K(\text{obs.}) = [HD]^2/[H_2][D_2]$ is 2.7 or 2.8 which is less than the $K$ (equil.), i. e., 3.25 at 0°C[2].

Such being the situation, the discharge mechanism (A) can not be accepted so far as nickel cathode is concerned. Although the mechanism (B) or (C) is reasonable, some other experimental fact must be resorted to for the discussion between the mechanisms. From the reason that no positive proof for the mechanism (C) has been found until now, the catalytic mechanism (B)[1,3] may be accepted.

Detailed research on other electrodes is now in progress.

We express sincere thanks to Professor J. Horiuti, Hokkaido University, for his kind advice and discussions on this research.

# *The Assignment of Infrared Absorption Bands of p-Dichlorobenzene*

By Shinnosuke SAËKI*

(Received December 27, 1959)

Many works have been published by a number of investigators concerning the vibrational spectra of *p*-dichlorobenzene (for example Ref. 1 and 2). But all of these measurements were done in solid state or in solution, and we have not yet any molecular spectrum of this substance in gaseous state. Since the spectrum of *p*-dichlorobenzene in solid or solution shows many strong overtones and combination liable to lead to an erroneous assignment, we have measured the gaseous spectra of deuterated and non-deuterated *p*-dichlorobenzenes to obtain the correct assignment.

## Experimental

The measurements were carried out using Perkin-Elmer model 112 spectrometer, for the region from 5,000 to 2,000 $cm^{-1}$ with a LiF prism, from 2,000 to 700 $cm^{-1}$ with an NaCl prism and from 700 to 400 $cm^{-1}$ with a KBr prism.

As the boiling points of these substances are considerably high (173.4°C for $C_6H_4Cl_2$), it was necessary to use a high temperature cell to obtain their gaseous spectra. An ordinary gas cell 85 mm. thick with pyrex bracelets of 15 mm. height on the KBr windows was coiled by a fine nichrome wire, then covered by a thick layer of asbestos for the sake of thermal insulation. The bracelets prevented the sample gas from condensing on the KBr windows and made sure to obtain the real gas phase spectra. This cell was usable at any temperature below 300°C by the aid of a slide wire resistor. We did not use any binding agent either to fix the KBr windows to the cell body, or to attach the pyrex rings to the windows, in order to avoid introduction of any impurity which might result from the thermal decomposition of the binding agent. The design of the cell is shown in Fig. 1. The inequality of the diameters at both ends of the cell might cause an inhomogeneity of the temperature in the cell to some extent, but it was not considered to have any effect on the spectra obtained.

The powder of the substance was put in the cell which was previously heated to a temperature sufficiently higher than its boiling point, and the measurement was carried out for the mixture of the vapor and the air at one atmospheric pressure.

## Results

The spectra obtained are shown in Fig. 2, and the observed frequencies of the absorption bands are shown in Table I. The spectra of deuterated *p*-dichlorobenzene were not so clear as those of ordinary *p*-dichlorobenzene because of the small available quantity of the substance. Thus we could detect no overtone nor combination band of deuterated *p*-dichlorobenzene

in the LiF region, and further it is necessary to mention here that the shapes of bands of deuterated *p*-dichlorobenzene in the figure are not so precise as those of ordinary *p*-dichlorobenzene.

Several measurements were repeated for non-deuterated *p*-dichlorobenzene to observe the correct shapes of the absorption bands, but were not successful except for those in the lower frequency part of NaCl region, that is, for the bands at 1013 $cm^{-1}$ and at 819 $cm^{-1}$ which were found to be type B and type C (or A) bands respectively. The other bands did not show any definite feature of the envelopes by which the types of the bands might be decided.

## Assignment

The molecular structure of *p*-dichlorobenzene has the $V_h$ symmetry, and we can expect for the molecule thirteen infrared active fundamental vibrations which are shown in Table II. Among those vibrations the frequencies of the C–Cl deformation vibrations are obviously too low to be measured under our experimental conditions, and it is possible that the frequencies of the ring deformation vibrations are also too low to be observed. Consequently only from nine to eleven bands are expected to be observed by our measurements.

| | 544 | 526 | ring deformation |
| | — | — | C–Cl deformation |

N. B. Concerning the notations for symmetry species, we remark that we have chosen x-axis to be perpendicular to the plane of molecule and z-axis in the direction of the line combining two chlorine atoms.

* The mean value of 1395 and 1417 $cm^{-1}$ in Table I.

We can easily assign the absorption bands at 3094 $cm^{-1}$ (2290 $cm^{-1}$ for $C_6D_4Cl_2$) and 3035 $cm^{-1}$ (2283 $cm^{-1}$ for $C_6D_4Cl_2$) to the two C–H (or C–D) stretching frequencies. The absorption band at 819 $cm^{-1}$ of $C_6H_4Cl_2$ (695 $cm^{-1}$ for $C_6D_4Cl_2$) is assigned to the out-of-plane vibration of C–H (or C–D) by many authors (for example, by D. H. Whiffen[1] and Y. Kakiuchi[3]). We have assigned a strong band at 544 $cm^{-1}$ of $C_6H_4Cl_2$ (526 $cm^{-1}$ for $C_6D_4Cl_2$) to the out-of-plane vibration of benzene ring. This band might be assigned to the in-plane deformation vibration of the ring,

3) Y. Kakiuchi, *J. Chem. Soc. Japan, Pure Chem. Sec.* (*Nippon Kagaku Zasshi*), 77, 1572 (1956).

but, as shown later, this assignment does not satisfy the product rule.

As for the other normal frequencies, we measured seven strong bands between 1000 and 2000 $cm^{-1}$ in the spectrum of $C_6H_4Cl_2$ (six bands for $C_6D_4Cl_2$), while there remain six normal vibrations to assign them. As there were too many absorption bands in the spectrum of $C_6H_4Cl_2$, we assumed that the two bands at 1417 and at 1395 $cm^{-1}$ are caused by a Fermi resonance between a fundamental and a combination* near by it. Taking into account of the fact that the intensities of these two bands were nearly equal, we estimated that the position of the fundamental would be 1405 $cm^{-1}$ (mean value of these two observed frequencies) if it were not for the Fermi resonance. We assigned the highest two of these six bands to the stretching vibrations of the ring, and the next two frequencies (one of which is the above-mentioned 1405 $cm^{-1}$) to the in-plane bending vibrations of C–H, and 1015 $cm^{-1}$ and 1091 $cm^{-1}$ to the deformation vibration of the ring and the stretching vibration of C–Cl respectively. As for the C–Cl stretching vibration, we could easily imagine from its abnormal frequency that this mode might be extremely mixed with some other modes. Although assignments of the last two frequencies seem to be mutually exchangeable, the exchange would result the larger deviation from the product rule.

In addition to the above-mentioned bands, we observed a strong band at 483 $cm^{-1}$ in the spectrum of the $C_6H_4Cl_2$. This band corresponds to the band at 414 $cm^{-1}$ in the spectrum of the $C_6D_4Cl_2$. We assigned these bands to the skeletal vibration of the molecule, i. e., the mixed vibration of ring deformation and C-Cl stretching.

Thus we assigned eleven of thirteen fundamental vibrations, and the remaining two fundamentals are the vibrations of C-Cl deformation, the frequencies of which are expected to be too low to be measured. The present assignments are shown in Table III.

## Discussion

According to the product rule, the ratio of the products of the frequencies of non-deuterated and deuterated *p*-dichlorobenzene is 1.972 for the species $B_{1u}$ and $B_{2u}$, and 1.388 for the species $B_{3u}$. In the case of the species $B_{1u}$ we found that the ratio calculated from the observed frequencies was 1.970 which is in good accordance with the theoretical value. But in the case of the other species, the unobserved bands of low frequencies prevented us from applying the product rule perfectly, and all that we were able to do was to verify that the ratios calculated from the observed frequencies alone did not exceed the theoretical value. Actually these ratios were calculated as 1.917 and 1.219 for species $B_{2u}$ and $B_{3u}$ respectively, and these were quite plausible values.

As for the band envelopes, as mentioned in the previous chapter, for non-deuterated *p*-dichlorobenzene the band at 1014 $cm^{-1}$ was found to be a type B band showing an apparent absorption minimum at the center of the band, while the band at 819 $cm^{-1}$ was found to be type A or C band showing a prominent Q branch accompanied by P and R branches at its both sides. Considering that the axis of the largest moment of inertia of this molecule is perpendicular to the molecular plane, and that the axis of the smallest moment of inertia combines the two chlorine atoms, it would be easily shown that the type A, B and C bands belong to the species $B_{1u}$, $B_{2u}$ and $B_{3u}$ respectively, and that the band at 1014 $cm^{-1}$ belongs to species $B_{2u}$ and the band at 819 $cm^{-1}$ belongs to the species $B_{1u}$ or $B_{3u}$. The assignment shown in Table III is in good accordance with these results. The observed envelopes of the other bands were not adequately clear to give some suggestions for their assignments. Further for the spectra of deuterated *p*-dichlorobenzene we could not find any absorption band which showed a clear band envelope. The band at 819 $cm^{-1}$ the envelope of which showed a clear feature of type A or C band was apparently to be considered as the extremely strong band of ordinary *p*-dichlorobenzene contained in deuterated *p*-dichlorobenzene as a slight impurity.

We had tried many other assignments which seemed to be compatible with the empirical knowledge. But they did not satisfy the product rule so well as the one shown in Table III.

The present assignment is different at some points from those given by other authors for their spectra in solid state or in solution. Comparing our gaseous spectra with those spectra of solid or solution, we saw that many strong bands in the latter spectra disappeared entirely or partially in the former. Thus we believe that the spectrum measured in solid state or in solution is not suitable for the assignment of the absorption bands.

## Summary

The infrared absorption spectra of deuterated and non-deuterated *p*-dichlorobenzene were measured in the vapor state using a high

* We observed a strong Raman line at 331 $cm^{-1}$. The combination of this vibration with the infrared active vibration at 1090 $cm^{-1}$ would appear in the neighborhood of 1405 $cm^{-1}$. We shall present a paper on the Raman spectra of *p*-dichlorobenzene in near future.

temperature cell. The results obtained by the measurements permitted us the assignment of the observed fundamental bands with the aid of the product rule. For some frequencies which we could not measure under our experimental conditions, we used the frequencies observed by other workers in the solid state which enabled us to apply the product rule.

This work was done at the laboratory of Professor J. Lecomte of the Laboratoire des Recherches Physiques, Faculté des Sciences de Paris. The author acknowledges gratefully his encouragement and advice. He also wishes to thank Dr. Leitch of the National Research Council at Ottawa for kindly sending us deuterated *p*-dichlorobenzene prepared by him.

# The Assignment of Infrared Absorption Bands of 1, 3, 5-Trichlorobenzene

By Shinnosuke SAËKI*

(Received January 23, 1960)

Several works have been published concerning the infrared spectra of 1, 3, 5-trichlorobenzene (for example, Ref. 1 and 2). However, all of these spectra were measured in solid state or in solution and we have no spectrum of this substance in vapor state. As we pointed out in our previous paper[3] chlorobenzenes show strong bands of overtones and combinations in solid state or in solution. So, one must be very cautious in trying the assignment of infrared bands of these substances using the spectra in these states. For this reason, we measured the infrared absorption spectra of deuterated and non-deuterated 1, 3, 5-trichlorobenzenes in vapor state to make the assignment of the absorption bands of these substances.

## Experimental and Results

Spectral data were obtained by means of a Perkin-Elmer 112 spectrometer equipped with LiF, NaCl and KBr prisms. The measurements were carried out under ordinary pressure at high temperature. In these measurements we used the high temperatures cell which we described in detail in our previous paper[3]. The non-deuterated 1, 3, 5-trichlorobenzene used in our experiments was the "extra pure" one on the market, and the deuterated one was kindly provided by Dr. Leitch in Canada.

For the non-deuterated substance we made several measurements in various concentrations to obtain the correct frequencies and shapes of the strong bands and also to ascertain the existence of very weak bands. But, for the deuterated substance, we could not measure its spectra so attentively because of the smallness of the quantity, and it is possible that some weak bands were missed in our measurements. However, as we are going to assign only the fundamental bands of these spectra, this missing would not be very serious.

The spectra obtained by our measurements are shown in Fig. 1, and the frequencies of the observed bands are shown in Table I.

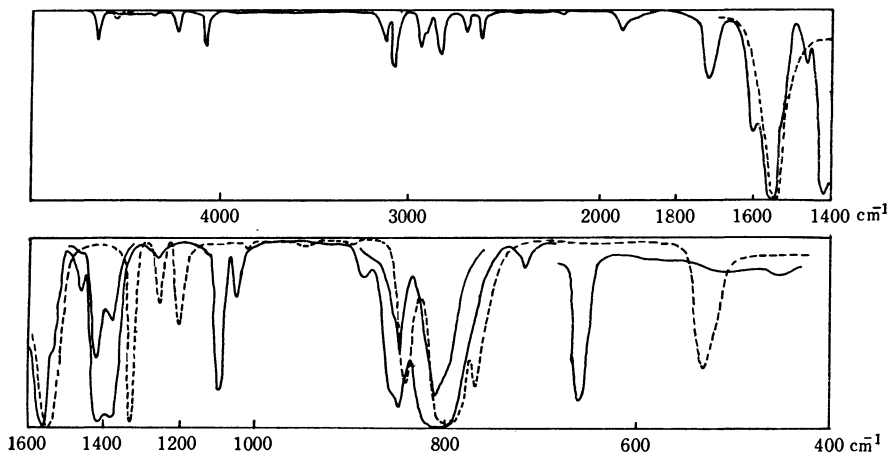

Fig. 1. Infrared absorption spectra of 1,3,5-trichlorobenzene.
—— non-deuterated ---- deuterated

## Assignments

Assuming the molecular structure of 1,3,5-trichlorobenzene to be of $D_{3h}$ form, it has ten infrared active fundamental frequencies, of which seven are doubly degenerate (species E′, in-plane) and three are non-degenerate (species $A_2''$, out-of-plane). The modes of these vibrations are shown in Table II. Of course we can not expect to observe all of these ten normal frequencies under our experimental conditions, because two C–Cl deformation frequencies (E′ and $A_2''$) are evidently too low to be measured, and two ring deformation frequencies might also exist below the observable region. Thus only from six to eight fundamental frequencies might be observed by our experiments. However, as is shown in Fig. 1 and Table I, there were too many strong bands in the spectra, but we could eliminate some of them by comparing the spectrum of non-deuterated substance with that of deuterated one.

Table II. Normal vibrations of 1,3,5-trichlorobenzene

| E′ (in-plane) | $A_2''$ (out-of-plane) |
|---|---|
| C–H stretching | C–H deformation |
| ring stretching | ring deformation |
| ring stretching | C–Cl deformation |
| C–H deformation | |
| ring deformation | |
| C–Cl stretching | |
| C–Cl deformation | |

We could easily assign the band at 3089 $cm^{-1}$ of $C_6H_3Cl_3$ to the C–H stretching vibration (E′). The C–D stretching vibration of $C_6D_3Cl_3$ was not observed. It might be because of the unfortunate overlapping with the strong band of carbon dioxide near 2200 $cm^{-1}$. In solid state, it was observed at 2310 $cm^{-1}$ [4].

We assigned two strong bands at 1565 and 1419 $cm^{-1}$ of $C_6H_3Cl_3$ (1549 and 1333 $cm^{-1}$ of $C_6D_3Cl$) to the ring stretching fundamental vibrations of species E′, and the strong band at 1380 $cm^{-1}$ of $C_6H_3Cl_3$ to the C–H deformation vibration of E′ (in-plane). However, for the corresponding band of $C_6D_3Cl_3$, we observed two bands of considerable intensity at 1257 and 1206 $cm^{-1}$. These two bands were considered to be brought about by a Fermi resonance between a fundamental and an overtone or combination of species E′, and their nearly equal relative intensities suggested to us that the proper frequency of the concerned fundamental band might be about 1230 $cm^{-1}$. As for the overtone or combination band which interacts with the fundamental, we can say little of it because of the lack of data in the low frequency region and also of the lack of the Raman spectrum* of this substance.

We observed another strong band at 1100 $cm^{-1}$ in the spectrum of $C_6H_3Cl_3$ but in the spectrum of $C_6D_3Cl_3$ we did not find any strong band corresponding to it. Although the intensity of the band at 1100 $cm^{-1}$ of $C_6H_3Cl_3$ was very remarkable, this lack of corresponding band in the spectrum of $C_6D_3Cl_3$ kept us from assigning the band to a fundamental one.

The band at 853 $cm^{-1}$ of $C_6H_3Cl_3$, was hitherto pointed out by many investigators[5] as an out-of-plane fundamental vibration band of C–H

4) J. Lecomte, unpublished.

* We have not yet succeeded in observing the Raman lines of this substance. For, when this substance was resolved in the solvents, the solution was slightly colored, and it prevented us from measuring the Raman spectrum.

5) For example, Y. Kakiuchi, *J. Chem. Soc. Japan, Pure Chem. Sec.* (*Nippon Kagaku Zasshi*), **80**, 356 (1959) and A. R. H. Cole and H. W. Thompson, *Trans. Faraday Soc.*, **46** 103 (1950).

bond. But, as is shown in our spectrum of Fig. 1, this band corresponds to the band at 843 $cm^{-1}$ of $C_6D_3Cl_3$. That means, the frequency shift caused by the substitution of hydrogen atoms by deuterium atoms was only 10 $cm^{-1}$. If this is a band principally concerning the vibration of C–H bond, the frequency shift might be much greater than 10 $cm^{-1}$. Even if we dare to consider that it is the band at 769 $cm^{-1}$ of $C_6D_3Cl_3$ that corresponds to 853 $cm^{-1}$ of $C_6H_3Cl_3$, another difficulty would be caused. As we shall show later, we have a band in a lower frequency region which showed a large frequency shift by the substitution of hydrogen atoms, that is, the band at 662 $cm^{-1}$ of $C_6H_3$ (532 $cm^{-1}$ of $C_6D_3Cl_3$). If we assign the band at 853 $cm^{-1}$ to the out-of-plane C–H vibration, there should be no way to explain the band at 662 $cm^{-1}$ which was shifted widely to 532 $cm^{-1}$ by the introduction of deuterium atoms. Therefore we did not assign this band at 853 $cm^{-1}$ (at 843 $cm^{-1}$ in the case of $C_6D_3Cl_3$) to the out-of-plane C–H (or C–D) vibration. One might also assign it to the in-plane ring deformation fundamental vibration (E′). But it is generally known that the frequency of this mode is very variable over a wide region, especially when there is a large possibility of coupling with other modes. So we are not sure that we could assign this band to the ring deformation fundamental vibration. After all we assigned it to no normal vibraton. After all we assigned it to no normal vibration, considering it as an overtone or combination band which was brought about by the Fermi resonances with a fundamental band at 813 $cm^{-1}$ and which borrowed the intensity from the fundamental band. Thus we could get over the superabundance of the strong bands in the observed spectra.

We assigned the very strong bands at 813 $cm^{-1}$ of $C_6H_3Cl_3$ and at 795 $cm^{-1}$ of $C_6D_3Cl_3$ to the C–Cl stretching vibration. But it should be mentioned here that this designation of the vibrational mode is used just as a convention. For, as we showed in our previous paper[3], the mixing of the vibrational modes is extreme in this region of frequency, and it might not be very correct to designate the modes of these normal vibrations by simple terms as C–Cl stretching vibration and so forth.

We observed only one strong band in KBr region in each spectrum of $C_6H_3Cl_3$ and $C_6D_3Cl_3$, that is, the bands at 662 $cm^{-1}$ and at 532 $cm^{-1}$ respectively. As there was no other strong absorption band, it is quite certain that these two bands correspond to each other. Further, the fact that the ratio of their frequencies is considerably apart from 1 (1.24) suggests to us that these vibrational bands are concerned with the hydrogen and deuterium atoms respectively. For the spectrum of mesitylene Whiffen[6] assigned the band at 928 $cm^{-1}$ to the out-of-plane vibration of C–H bond. In the case 1, 3, 5-trichlorobenzene, since no appropriate strong band was found in the neighbourhood of 900 $cm^{-1}$, we assigned the band at 662 $cm^{-1}$ (at 532 $cm^{-1}$ for $C_6D_3Cl_3$) to the C–H (C–D) out-of-plane vibration. The above-mentioned assignment is shown in Table III.

TABLE III. THE ASSIGNMENT OF THE INFRARED BANDS OF 1,3,5-TRICHLOROBENZENE

| Type | $C_6H_3Cl_3$ | $C_6D_3Cl_3$ | Mode |
|---|---|---|---|
| E′ | 3089 | (2310) | C–H stretching |
| | 1565 | 1549 | ring stretching |
| | 1419 | 1333 | ring stretching |
| | 1380 | 1230* | C–H deformation |
| | 813 | 795 | C–Cl stretching |
| | — | — | ring deformation |
| | — | — | C–Cl deformation |
| $A_2''$ | 662 | 532 | C–H deformation |
| | — | — | ring deformation |
| | — | — | C–Cl deformation |

* This is the average value of the two observed frequencies, i.e., 1257 and 1206 $cm^{-1}$.

## Discussion

The theoretical values of the ratios of products of normal frequencies of each substance (deuterated and non-deuterated) are 1.972 for the species E′ and 1.402 for the species $A_2''$. For the species $A_2''$ we could observe only one frequency of each substance, and it was impossible to apply the product rule to this species. The only one observed frequency of species $A_2''$ was 662 $cm^{-1}$ of $C_6H_3Cl_3$ (532 $cm^{-1}$ of $C_6D_3Cl_3$) which we assigned to the out-of-plane C–H (or C–D) fundamental vibration by reason of the large shift of frequency accompanying the substitution of hydrogen atoms by deuterium atoms. As was mentioned in the previous section, this assignment is quite different from that which is generally admitted now. We can not get to a definite conclusion on this point at present, but if we succeed in measuring the spectra of these substances in the far infrared region, and if we observe the other two out-of-plane fundamental bands, we shall be able to determine the correct assignment.

For the species E′ too, there were some frequencies that were left unobservable under our experimental conditions, and it is also impossible to apply the product rule perfectly. But, in this case, five or six normal frequencies (seven in all) were observed, so it is not

6) D. H. Whiffen, *Spectrochim. Acta*, 7, 253 (1955–6).

completely meaningless to calculate the ratio of products of observed frequencies alone. This calculated ratio was 1.650, when we excluded the pair of frequencies at 853 $cm^{-1}$ (for $C_6H_3Cl_3$) and at 843 $cm^{-1}$ (for $C_6D_3Cl_3$) from this calculation. It means that the ratio of products by the other two unobserved frequencies is to be about 1.19, and this is quite an appropriate value. But if we include the above-mentioned pair of frequencies into this calculation, the ratio increases only a little and becomes 1.670. It requires that the ratio of the last unobserved frequency of each substance is 1.18. This value seems to be too great to attribute to the ratio of only one pair of frequency. This is another reason why we have not dared to assign this pair of bands to the fundamental ones.

## Summary

The infrared absorption spectra of deuterated nd non-deuterated 1,3,5-trichlorobenzenes were measured in the vapor state from 5,000 to 400 $cm^{-1}$. The results of our measurements allowed us the assignment of the fundamental bands of this substance by the aid of the product rule. As we could not observe all of the fundamental bands of this substance, the perfect application of the product rule was not possible. But we proved that our assignment did not conflict with the product rule.

This work was done at the laboratory of Professor J. Lecomte of the laboratoire des Recherches Physiques, Faculté des Sciences de Paris. # *The $n$—$\pi^*$ Transition Band of Acenaphthenequinone*

By Akira KUBOYAMA

(Received January 26, 1960)

In a previous paper[1], Nagakura and the present author measured the weak visible bands of *o*- and *p*-quinones in various solvents. From the result on the solvent effect these bands were ascribed to an $n-\pi^*$ transition, namely, the transition from the non-bonding electron orbital of oxygen atom to the excited $\pi$-electron orbital. However, the $n-\pi^*$ transition band of acenaphthenequinone has never been studied. Thus, the present author measures the $n-\pi^*$ transition band of acenaphthenequinone in various solvents. Further, for the purpose of comparison, the absorption spectra of various *o*- and *p*-quinones are newly measured. The obtained results are now reported.

## Experimental

**Measurements.** — The absorption spectra were measured with a Cary recording spectrophotometer 14 M. Quartz cylindrical cells with path lengths of 1, 2 and 5 cm. were used. A thermostated cell jacket was used for measurements at 35°C.

**Materials.** — Acenaphthenequinone[2] (AQ) was prepared through the oxidation of acenaphthene with potassium bichromate and was recrystallized from benzene, m. p. 256°C. *p*-Benzoquinone[3] was prepared through the oxidation of hydroquinone with potassium bichromate and was purified by sublimation, m.p. 114°C. $\alpha$- And $\beta$-naphthoquinones and phenanthrenequinone were prepared according to L. F. Fieser's method[4]. $\alpha$-Naphthoquinone was purified by charcoal treatment in ether solution, m. p. 124°C. $\beta$-Naphthoquinone was used without further purification, according to Fieser's note[4], m. p. with decomp. 145~147°C. Phenanthrenequinone was recrystallized from ethanol, m. p. 208°C. All the solvents used in the present study were of special grade. Benzene and ethyl ether were distilled after being dried over sodium metal. Dioxane was distilled from sodium metal, after being dried with it. Carbon disulfide was distilled after being dried over calcium chloride, and was

kept in the dark. Chloroform was washed successively with concentrated sulfuric acid and with aqueous sodium hydroxide, and was distilled after being dried over calcium chloride. *n*-Heptane was distilled after being treated as in the case of chloroform and being dried over sodium metal.

## Results

The obtained absorption spectra are given in Figs. 1—6. The spectra of AQ in various solvents are given in Figs. 1* and 2 and those of β-naphthoquinone, phenanthrenequinone, *p*-benzoquinone, and α-naphthoquinone are given in Figs. 3**, 4, 5 and 6, respectively.

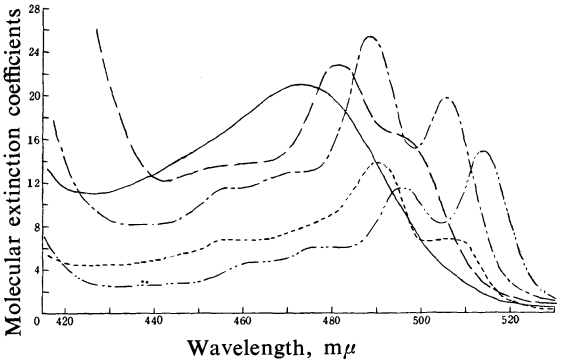

Fig. 1. Absorption spectra of acenaphthenequinone, solvent, —— benzene, —— chloroform, —— dioxane, —— carbon disulfide, ---- ethyl ether (in case of the latter two*, the scale of the ordinate is arbitrary).

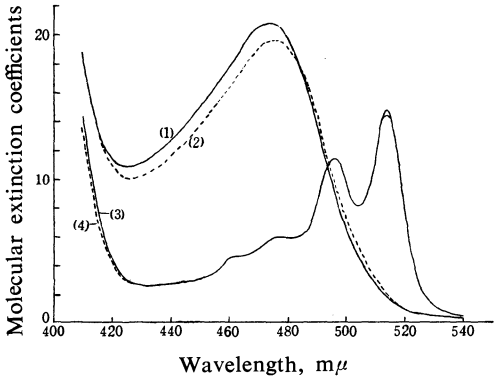

Fig. 2. Absorption spectra of acenaphthenequinone, solvent, (1), (2) dioxane, (3), (4) carbon disulfide; temperature, (1), (3) room temperature (17°C), (2), (4) 37°C (in case of carbon disulfide, the scale of the ordinate is arbitrary).

*1 AQ is sparingly soluble in carbon disulfide and ethyl ether. Thus, the molecular extinction coefficient of the α-band in these solvents could not be determined.

*2 The longest wavelength π-π* transition band of β-naphthoquinone in chloroform largely shifts towards longer wavelengths as in AQ.

## Discussion

In the visible and near UV regions, AQ has three main peaks at 225 mμ, 300 mμ, and 500 mμ. It is thought that strong peaks at 225 mμ and 300 mμ correspond to the $\beta$ and the $p$ bands of naphthalene[5], respectively, while a weak peak at 500 mμ which is given in Fig. 1 is assumed to be an $n-\pi^*$ transition band from the consideration of its intensity and position. Hereafter, this band will be called the α-band. As for the solvent effect on the α-band, which is shown in Fig. 1, two points are noticeable. First, the α-band in dioxane and chloroform largely shifts towards shorter wavelengths and almost completely loses vibrational structures. Secondly, the relative height of the two main peaks of the α-band markedly depends upon solvents such as carbon disulfide, benzene, ethyl ether etc. As for the first point, the blue-shift of the α-band in chloroform is attributed to hydrogen bond formation[6]. This fact verifies the assignment of the α-band to the $n-\pi^*$ transition band. The large blue-shift of the α-band in dioxane may be attributable to molecular complex formation. Here, dioxane is an $n$-type donor[7]. The blue-shift of an $n-\pi^*$ transition band due to molecular complex formation has never been pointed out. The mechanism of this blue-shift is thought to be similar to the one[8] due to the substitutions of electron-donating groups to a $\pi$-electronic system containing carbonyl groups. The fact that such a large blue-shift of the α-band as in dioxane is not seen in ethyl ether, may be attributable to the large steric hindrance caused by the side chains of ethyl ether in the molecular complex formation. As is seen from Figs. 1, 3, 4, 5 and 6, the blue-shift of the α-band in dioxane is much larger in the ortho-type quinones than in the para-type quinones***. This fact may be explained as follows. The oxygen atoms of dioxane are expected to coordinate themselves to carbon atoms of carbonyl groups of the quinones by the electrostatic interaction as well as by the charge transfer interaction. The electrostatic interaction is thought to be caused by the interaction between the atomic dipoles of the oxygen atoms of dioxane and the positive charges of the carbon atoms of the carbonyl groups. Hence, the magnitude of the electrostatic interaction is determined by the amount of the positive charges of the carbon atoms. The charge transfer interaction can be approximately represented by the interaction between the lowest unfilled orbitals of the quinones and the lone pair orbitals of the oxygen atoms of dioxane. Therefore, the magnitude of the charge transfer interaction is roughly determined by the coefficients of the atomic orbitals of the carbonyl carbon atoms in the lowest unfilled orbitals of the quinones. The greater those coefficients are, the greater is the charge transfer interaction. From our previous calculations[9] for $o$- and $p$-quinones, it is seen that the above two requirements are best fulfilled by the carbon atoms of the carbonyl groups of the quinones. The above requirements are also expected to be satisfied for AQ, which may be regarded as one of the $o$-quinones. Since in $o$-quinones the two carbon atoms of the two carbonyl groups are jointed with each other, the interaction between the oxygen atoms of dioxane and the carbonyl carbon atoms of $o$-quinones**** is expected to be larger than that of $p$-quinones. It is naturally expected that the above fact is ascribed to this point.

As for the second point previously described, there occurs a question whether the two main peaks of the α-band are ascribed to the vibrational structure of the one $n-\pi^*$ transition

*3 Previously, L. S. Forster found that the weak visible absorption band of biacetyl in dioxane shows relatively large shift towards shorter wavelengths (*J. Am. Chem. Soc.*, 77, 1417 (1955)). But this blue-shift is not so large as the ones of ortho-type quinones, here found.
9) a) A. Kuboyama, This Bulletin, 31, 752 (1958); b) A. Kuboyama, ibid., 32, 1226 (1959).

band, to the two different $n-\pi^*$ transition bands of the one form of AQ or to the two different $n-\pi^*$ transition bands belonging to the two different forms of AQ. As is seen in Fig. 2, the $\alpha$-band in dioxane and in carbon disulfide are almost independent of temperature. Thus, the third possibility is probably denied. As is seen in Fig. 3, the behaviors of the two peaks in the longer wavelength side of $\beta$-naphthoquinone are, though less marked, similar to the ones of the two main peaks of the $\alpha$-band of AQ and the distance (ca. 700 $cm^{-1}$) between the two peaks of $\beta$-naphthoquinone is almost equal to that of the $\alpha$-band*****. Previously, J. W. Sidman[10] experimentally concluded that *p*-benzoquinone in crystalline state has two distinct singlet-singlet $n-\pi^*$ transition bands in the wave number region of 20000 $cm^{-1}$ to 25000 $cm^{-1}$. In that case, the wave number difference between the two 0—0 bands corresponding to these two transitions was determined to be 797 $cm^{-1}$. In connection with Sidman's conclusion mentioned above, it[11] may safely be assumed that the two main peaks of the $\alpha$-band may be due to the two $n-\pi^*$ transitions whose energy difference is ca. 700 $cm^{-1}$.

As is seen in Figs. 3, 5 and 6, in carbon disulfide the intensities of the $n-\pi^*$ transition bands of the quinones, especially of *p*-benzoquinone, are considerably larger than the ones in the other solvents. This fact is probably attributed to the large refractive index of carbon disulfide[12].

*4 The signs of the two atomic orbitals of the two carbonyl carbon atoms in the lowest unfilled orbitals of *o*-quinones[9b] are equal.

*5 Forster*[3] found the fact, similar to the one of $\beta$-naphthoquinone, for the $n$-$\pi^*$ transition band of biacetyl, where the distance between the two peaks is ca. 1300 $cm^{-1}$. He thought that these two peaks respectively result from two electronic transitions.

**Summary**

The weak absorption band ($\alpha$-band) ($\varepsilon_{max}\sim$ 20) near 500 m$\mu$ of acenaphthenequinone was measured in various solvents. This band was determined as the $n-\pi^*$ transition band on the basis of the observed results on intensity and solvent effect. In dioxane, the $n-\pi^*$ transition bands of the *o*-quinones, including the $\alpha$-band, largely shift towards shorter wavelengths. This fact, which is thought to be due to molecular complex formation, was discussed from the qualitative point of view. The relative height of the two main peaks of the $\alpha$-band markedly depends upon solvents. The similar, though less marked, fact is seen in $\beta$-naphthoquinone. The two main peaks of the $\alpha$-band were assumed to be due to the two $n-\pi^*$ transitions, whose transition energy difference is ca. 700 $cm^{-1}$. It was found that the $n-\pi^*$ transition bands of the quinones, especially of *p*-benzoquinone, are markedly intensified in carbon disulfide. This fact is probably attributed to the large refractive index of this solvent.

# *The Stochastic Model for Unimolecular Gas Reaction*

By Kenji ISHIDA

(Received July 13, 1959)

According to the probabilistic representation for the deterministic theory of the "true" unimolecular gas reaction[1], in which it is assumed that the reactant molecules are independent of the coexisting resultant molecules, i. e., the distribution of each reactant molecule is not correlated to the distribution of each resultant molecule, and that the reverse reaction is not taking place, the fraction of the reactant molecules which react during time $dt$ can be set equal to the probability $k_1 dt$;

$$-\frac{dn}{n}=k_1 dt \tag{1}$$

1) Jen-Yuan Chien, *J. Chem. Phys.*, **16**, 426 (1948). See, e. g., A. A. Frost and R. G. Pearson, "Kinetics and Mechanism", John Wiley & Sons, Inc., New York (1953), p. 67.

where the rate constant $k_1$ denotes the probability that one molecule reacts during unit time, $n$ is the number of reactant molecules at time $t$ and $-dn$ the number reacting during time $dt$. It should be emphasized, however, that in Eq. 1 the probabilistic notions are not manifested in a precise form, and that the number of molecules predicted for various times is not precise, but the reaction proceeds at random at an average rate[2]. In order to formulate this on the basis of the mathematically exact laws of the theory of probability, Bartholomay[3] has recently presented a method to construct the stochastic model for the true unimolecular gas reaction by starting from the deterministic theory as represented by Eq. 1. But the chemical and mathematical foundations on which the theory of the stochastic process can be applied to this chemical reaction do not appear to have been exactly mentioned. Therefore it is instructive to formulate definitely the probabilistic properties of the chemical reaction.

If the number of resultant molecules produced during the time interval $(0, t)$ is denoted by $n_p(t)$, the function $n_p(t)$ itself is a random variable for all arbitrary but fixed periods of duration $t$. Since the function $n_p(t)$ which assumes only the integers and is nondecreasing becomes the aggregate of random variables with continuous parameter when $t$ varies, this represents a possible development of the chemical reaction. Consequently the course of the chemical reaction is a stochastic process. It has been acknowledged, in general, that under the given temperature and external parameters the rate of a chemical reaction is determined only by the composition of the reaction system at the time and does not depend on its previous history, so that it is concluded that the course of chemical reaction is a Markov process[4]. It has been recognized for many years that by its very nature a chemical reaction must disturb the equilibrium distribution of the reactant species[5]. If, however, we assume that the rate of the chemical reaction is sufficiently small compared with the rate of energy exchange and the disturbance of the equilibrium distribution of energy during the course of the chemical reaction can be approximately neglected, the reaction system can be discussed on the assumption that it is at thermal equilibrium. By "temporally homogeneous"[6] for the course of chemical reaction we mean that the thermal equilibrium remains absolutely unchanged throughout the process. Accordingly, we obtain the conclusion that *the theory of temporally homogeneous Markov process can be applied to the course of chemical reaction* for such reaction systems at thermal equilibrium that the reactant molecules do not interact mutually with the coexisting resultant molecules and the reverse reaction does not occur, and such conditions permit us to calculated the average rate of the chemical reaction at a time.

Although the one-dimensional stochastic process for the total number of reactant molecules has been studied by Bartholomay who, from the macroscopic point of view, has given a rate constant to the whole reaction, we shall be able to calculate the average rate constant by constructing microscopically the multi-dimensional stochastic process[7] for the number of reactant molecules in various states of energy, on the assumption that the stochastic model is conformable also to the "true" unimolecular reaction concerning the reactant molecules in each state of energy.

## One-dimensional Stochastic Model

In general the Chapman-Kolmogorov equation for temporally homogeneous Markov processes[8] is given by

$$P_{i,n}(t+\tau)=\sum_{\nu}P_{i,\nu}(t)\cdot P_{\nu,n}(\tau) \qquad (2)$$

where $P_{i,\nu}(t)$ is the transition probability from any state $E_i$ to any other state $E_\nu$ during the time interval of length $t$ and for the process of chemical reaction $i$, $\nu$ and $n$ represent the numbers of reactant molecules, respectively. If the initial probability $P_i(0)$ is known, then the probability $P_n(t)$ of finding the system at time $t$ in the state $E_n$ is set equal to the quantity $\sum_{i=0}^{n_0}P_i(0)P_{i,n}(t)$ according to the theorem of total probability[9], that is, $P_n(t)=\sum_{i=0}^{n_0}P_i(0)P_{i,n}(t)$, where $n_0$ is the total number of reactant molecules at time $t=0$. Hence this probability $P_n(t)$ is related to both $t$ and $P_i(0)$. In our case, however, it may be provided that one of the probabilities $P_i(0)$ $(i=0, 1, 2, \cdots\cdots, n_0)$ is equal to one, and the others to zero;

$$\text{if} \qquad i=n_0, \quad P_i(0)=1 \qquad (3)$$

9) A. N. Kolmogorov. "Foundations of the Theory of Probability" (Translation edited by Nathan Morrison), Chelsea Publishing Co., New York (1950). p. 7.

otherwise, $P_i(0)=0$

Multiplying both sides of Eq. 2 by $P_i(0)$ and summing over all values of $i$, we get

$$\sum_{i=0}^{n_0} P_i(0)P_{i,n}(t+\tau)=\sum_{\nu}\left(\sum_{i=0}^{n_0} P_i(0)P_{i,\nu}(t)\right)P_{\nu,n}(\tau)$$

which is reduced to, according to the theorem of total probability,

$$P_n(t+\tau)=\sum_{\nu} P_\nu(t)P_{\nu,n}(\tau) \qquad (4)$$

where $P_\nu(t)$ denotes the probability of finding $\nu$ reactant molecules at time $t$ in the reaction system. This is the fundamental equation for the application of the stochastic process to the chemical reaction.

If at time $t$ the reaction system is in the state $E_n$, the probability that any one of $n$ reactant molecules will undergo a reaction during the infinitely small time interval of length $(t, t+\tau)$ is equal to $P_{n,n-1}(\tau)=k_1 n\tau+o(\tau)$, where $k_1$ is a constant and $o(\tau)$ denotes the probability that more than one reaction occurs is of smaller order of magnitude than $\tau$. Similarly the transition probability $P_{n+1,n}(\tau)$ from the state $E_{n+1}$ to the adjacent state $E_n$ is equal to $k_1(n+1)\tau+o(\tau)$, and the probability of staying in the state $E_n$ is given by $P_{n,n}(\tau)=1-P_{n,n-1}(\tau)=1-(k_1 n\tau+o(\tau))$. Rewriting $P_\nu(t)$ in the alternative form $P(\nu, t)$, we have, according to Eq. 4,

$$\begin{aligned}P(n, t+\tau)&=P(n+1, t)P_{n+1,n}(\tau)+P(n, t)P_{n,n}(\tau)\\&=k_1(n+1)\tau P(n+1, t)\\&\quad+(1-k_1 n\tau)P(n, t)+o(\tau)\end{aligned}$$

From this we obtain

$$\begin{aligned}\frac{P(n, t+\tau)-P(n, t)}{\tau}&=-k_1 nP(n, t)\\&\quad+k_1(n+1)P(n+1, t)+o(1)\end{aligned}$$

Thus if we let $\tau\to 0$ for fixed $t$, we have

$$\frac{\mathrm{d}}{\mathrm{d}t}P(n, t)=-k_1 nP(n, t)+k_1(n+1)P(n+1, t) \qquad (5)$$

In particular, by assuming $P(n+1, t)=0$ for $n=n_0$, we obtain $\frac{\mathrm{d}}{\mathrm{d}t}P(n_0, t)=-k_1 n_0 P(n_0, t)$ in place of Eq. 5, and for $n=0$, Eq. 5 is reduced to $\frac{\mathrm{d}}{\mathrm{d}t}P(0, t)=k_1 P(1, t)$. Hence Eq. 5 holds for all values of $n$. Solving Eq. 5 under the conditions (3), we obtain the binomial distribution

$$P(n, t)=\binom{n_0}{n}\{\exp(-k_1 t)\}^n\{1-\exp(-k_1 t)\}^{n_0-n} \qquad (6)$$

whose derivation will be shown later. Of course, the equation $\sum_{n=0}^{n_0} P(n, t)=1$ holds certainly.

In order to reduce Eq. 5 to the equation of the mean value for the number of reactant molecules, if we multiply both sides of Eq. 5 by $n$ and summing over all values of $n$, we get

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}t}\sum_{n=0}^{n_0} nP(n, t)&=-k_1\sum_{n=0}^{n_0} n^2P(n, t)\\&\quad+k_1\sum_{n=0}^{n_0} n(n-1)P(n, t)\end{aligned}$$

that is,

$$\frac{\mathrm{d}\langle n\rangle}{\mathrm{d}t}=-k_1\langle n\rangle \qquad (7)$$

where $\sum_{n=0}^{n_0} nP(n, t)=\langle n\rangle$ denotes the mean value for the number of reactant molecules at time $t$. This equation is consistent "in the mean" with the deterministic rate equation $\frac{\mathrm{d}n}{\mathrm{d}t}=-k_1 n$, excepting the chance fluctuations* which arise inherently in the reaction itself and are not associated with random experimental errors.

We have so far discussed the stochastic model for such a true unimolecular reaction as the rate constant $k_1$ is invariable with time, but we can easily extend this to the more general cases in which the rate constants are variable with time. Using in place of $k_1$ the "instantaneous" value $k(t)$ of the rate constant which is able to take different values at different points on the time axis, we have, instaed of Eq. 5,

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}t}P(n, t)&=-k(t)nP(n, t)\\&\quad+k(t)(n+1)P(n+1, t) \qquad (8)^*\end{aligned}$$

In order to solve this equation, we introduce the generating function $\varphi(t, x)=\sum_{n=0}^{n_0} x^n P(n, t)$, which is convergent for $|x|\leq 1$ and defined so that the coefficient of $x^n$ is the probability of finding $n$ reactant molecules at time $t$ in the reaction system. Multiplying both sides of Eq. 8 by $x^n$ and summing from $n=0$ to $n=n_0$, we have

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}t}\sum_{n=0}^{n_0} x^n P(n, t)&=-k(t)\sum_{n=0}^{n_0} nx^n P(n, t)\\&\quad+k(t)\sum_{n=0}^{n_0} nx^{n-1}P(n, t)\end{aligned}$$

Substituting $\frac{\partial\varphi}{\partial t}=\frac{\mathrm{d}}{\mathrm{d}t}\sum_{n=0}^{n_0} x^n P(n, t)$ and $x\frac{\partial\varphi}{\partial x}=\sum_{n=0}^{n_0} nx^n P(n, t)$ into this equation, we obtain the first-order partial differential equation

* cf. Eq. 22.

** This equation refers to non-stationary process with $k(t)$ depending on time. Since, however, Eq. 5 has the purely "localized" property, the method by which we have derived Eq. (5) is completely applicable to such Markov processes as are not temporally homogeneous.

$$\frac{\partial\varphi}{\partial t}=k(t)(1-x)\frac{\partial\varphi}{\partial x} \tag{9}$$

The auxiliary differential equation of Eq. 9 is given by

$$\frac{dx}{k(t)(1-x)}=\frac{\mathrm{d}t}{-1}$$

Solving this, we obtain

$$(1-x)\exp\left(-\int_0^t k(t)\mathrm{d}t\right)=\text{constant}$$

According to the theory of partial differential equation the general solution of Eq. 9 is then given by

$$\varphi(t,x)=f\left((1-x)\exp\left(-\int_0^t k(t)\mathrm{d}t\right)\right) \tag{10}$$

where $f$ is an arbitrary function which is to be determined by the initial condition; the function $f$ is led to the form $f(1-x)=x^{n_0}$ by $\varphi(0,x)=f(1-x)$ and $\varphi(0,x)=\sum_{n=0}^{n_0}x^nP(n,0)=x^{n_0}$, where the initial condition (3) has been used. If we replace $1-x$ by $\xi$, we obtain the relation $f(\xi)=(1-\xi)^{n_0}$. Again, replacing $\xi$ by $(1-x)\exp\left(-\int_0^t k(t)\mathrm{d}t\right)$, we can transform Eq. 10 into the form

$$\varphi(t,x)=\left\{\left(1-\exp\left(-\int_0^t k(t)\mathrm{d}t\right)\right)+x\exp\left(-\int_0^t k(t)\mathrm{d}t\right)\right\}^{n_0} \tag{11}$$

which satisfies the condition $\varphi(t,1)=1$, i. e., $\sum_{n=0}^{n_0}P(n,t)=1$. Hence expanding the r. h. s. of Eq. (11), we obtain the binomial distribution by the definition of the generating function,

$$P(n,t)=\binom{n_0}{n}\left(\exp\left(-\int_0^t k(t)\mathrm{d}t\right)\right)^n\times\left(1-\exp\left(-\int_0^t k(t)\mathrm{d}t\right)\right)^{n_0-n} \tag{12}$$

Since the mean value for the number of reactant molecules at time $t$ is given by $\langle n\rangle=\left(x\frac{\partial\varphi}{\partial x}\right)_{x=1}$, we can easily find

$$\langle n\rangle=n_0\exp\left(-\int_0^t k(t)\mathrm{d}t\right) \tag{13}$$

If $k(t)$ is set equal to $k_1$ invariable with time, the above equation becomes $\langle n\rangle=n_0\exp(-k_1t)$, which agrees with the integral of Eq. 7. Such stochastic processes with the variable parameter $k(t)$ can be applied to such various cases as will be described below.

**Example 1. Bimolecular Reaction.** — The deterministic rate of the bimolecular reaction $2A\rightarrow A_2$ is expressed in the form

$$\frac{\mathrm{d}(2n)}{\mathrm{d}t}=-k_2(2n)^2 \tag{1, 1}$$

where $2n$ denotes the number of reactant molecules at time $t$ and $k_2$ the rate constant. Solving Eq. 1, 1 under the initial condition that $2n=2n_0$ at $t=0$, we obtain

$$2n=\frac{2n_0}{1+k_2(2n_0)t} \tag{1, 2}$$

or if we set $2n=N$, this becomes

$$N=\frac{N_0}{1+k_2N_0t} \tag{1, 3}$$

From Eq. 1, 2 the probability that any one of $n$ reactant molecules undergoes a chemical transformation during the time interval $(t, t+\Delta t)$ is given by

$$\frac{|\Delta n|}{n}=\frac{k_2N_0}{1+k_2N_0t}\Delta t+o(\Delta t) \tag{1, 4}$$

If we set $\frac{k_2N_0}{1+k_2N_0t}=k(t)$, then we have according to Eq. 8

$$\frac{\mathrm{d}}{\mathrm{d}t}P(n,t)=-\frac{k_2N_0}{1+k_2N_0t}nP(n,t)+\frac{k_2N_0}{1+k_2N_0t}(n+1)P(n+1,t) \tag{1, 5}$$

Multiplying both sides of Eq. 1, 5 by $n$ and summing over all values of $n$, we obtain as the differential equation concerning the mean value for the number of reactant molecules

$$\frac{\mathrm{d}\langle n\rangle}{\mathrm{d}t}=-\frac{k_2N_0}{1+k_2N_0t}\langle n\rangle \tag{1, 6}$$

or

$$\frac{\mathrm{d}\langle N\rangle}{\mathrm{d}t}=-\frac{k_2N_0}{1+k_2N_0t}\langle N\rangle \tag{1, 7}$$

whose solution is given by

$$\langle N\rangle=\frac{N_0}{1+k_2N_0t} \tag{1, 8}$$*

---

* In general we have as the stochastic model for the bimolecular reaction $2A\rightarrow A_2$

$$\frac{\mathrm{d}}{dt}P(2n,t)=-k_2\frac{(2n)(2n-1)}{2}P(2n,t)+k_2\frac{\{2(n+1)\}\{2n+1)-1\}}{2}P(2(n+1),t) \tag{1}$$

Transforming this into the differential equation of the mean value, we obtain

$$\frac{\mathrm{d}\langle 2n\rangle}{\mathrm{d}t}=-k_2(\langle(2n)^2\rangle-\langle 2n\rangle) \tag{2}$$

If we set $2n=N$, we have in place of Eq. 2

$$\frac{\mathrm{d}\langle N\rangle}{\mathrm{d}t}=-k_2(\langle N^2\rangle-\langle N\rangle) \tag{2}'$$

Solving this under the initial condition that $N=N_0$ at $t=0$, we obtain

$$\langle N\rangle=\frac{N_0}{1+k_1N_0t+k_2N_0\int_0^t\frac{\sigma^2(t)-\langle N\rangle}{\langle N\rangle^2}\mathrm{d}t} \tag{3}$$

where $N_0$ is the initial number of reactant molecules and $\sigma^2(t)=\langle N^2\rangle-\langle N^2\rangle$ denotes the variance.

for the initial condition that $N=N_0$ at $t=0$. It should be here noted that Eq. 1, 8 agrees "in the mean" with the result derived by the deterministic theory. If we multiply both sides of Eq. 1, 5 by $n^2$ and sum over all values of $n$, we obtain as the differential equation for the second moment $\langle n^2\rangle$

$$\frac{d\langle n^2\rangle}{dt}=-2\frac{k_2N_0}{1+k_2N_0t}\langle n^2\rangle+\frac{k_2N_0}{1+k_2N_0t}\langle n\rangle \tag{1, 9}$$

which is transformed into the form, according to $2n=N$ and Eq. 1, 8,

$$\frac{d\langle N^2\rangle}{dt}+2\frac{k_2N_0}{1+k_2N_0t}\langle N^2\rangle=2k_2\left(\frac{N_0}{1+k_2N_0t}\right)^2 \tag{1, 10}$$

Solving Eq. 1, 10 under the initial condition that $N=N_0$ at $t=0$, we obtain

$$\langle N^2\rangle=\left(\frac{N_0}{1+k_2N_0t}\right)^2+2k_2t\left(\frac{N_0}{1+k_2N_0t}\right)^2 \tag{1, 11}$$

Substituting Eq. 1, 8 into this equation, we have as the variance $\sigma^2(t)=\langle N^2\rangle-\langle N\rangle^2$

$$\sigma^2(t)=2k_2t\langle N\rangle^2 \tag{1, 12}$$

and consequently the coefficient of variation $\delta(t)=\frac{\sigma(t)}{\langle N\rangle}$ is expressed in the form

$$\delta(t)=\sqrt{2k_2t} \tag{1, 13}$$

For sufficiently large values of $t$, the coefficient of variation, which is independent of the initial number of reactant molecules, is considerably large, so that the statistical fluctuation arising inherently in the bimolecular reaction itself may become large compared with the random experimental errors incidental to the observed value $\langle N\rangle$.

**Example 2. Lindemann's Mechanism.** — Let us consider the collision theory for the unimolecular reaction which is usually associated with the name of Lindemann[10].

$$\begin{array}{ccc} A+A & \rightleftarrows & A^*+A \\ & & \downarrow \\ & & B \end{array}$$

The reaction $A+A\rightarrow A^*+A$ is the activation process by the collision between two inert reactant molecules, the reverse reaction $A+A^*\rightarrow A+A$ is the deactivation process by the collision between an inert reactant molecule and an activated molecule and the spontaneous reaction $A^*\rightarrow B$ is the "true" unimolecular reaction. If we denote by $P(n_a, n_a^*, n_b, t)$ the probability that $n_a$ inert reactant molecules, $n_a^*$ activated molecules and $n_b$ resultant molecules coexist in the reaction system at time $t$, then we have

$$\begin{aligned}\frac{d}{dt}P(n_a, n_a^*, n_b, t)&=-k^*(t)n_aP(n_a, n_a^*, n_b, t)\\&\quad+k^*(t)(n_a+1)P(n_a+1, n_a^*-1, n_b, t)\\&\quad-k'(t)n_a^*P(n_a, n_a^*, n_b, t)\\&\quad+k'(t)(n_a^*+1)P(n_a-1, n_a^*+1, n_b, t)\\&\quad-kn_a^*P(n_a, n_a^*, n_b, t)\\&\quad+k(n_a^*+1)P(n_a, n_a^*+1, n_b-1, t)\end{aligned} \tag{2, 1}$$

where $k^*(t)$ and $k'(t)$ denote the instantaneous values of the rate constants for the reactions $A+A\rightarrow A^*+A$ and $A+A^*\rightarrow A+A$ respectively and $k$ the rate constant for the true unimolecular reaction $A^*\rightarrow B$. Thus the differential equations for the mean values $\langle n_a\rangle$ and $\langle n_a^*\rangle$ are given by

$$\frac{d\langle n_a\rangle}{dt}=-k^*(t)\langle n_a\rangle+k'(t)\langle n_a^*\rangle \tag{2, 2}$$

and

$$\frac{d\langle n_a^*\rangle}{dt}=k^*(t)\langle n_a\rangle-(k'(t)+k)\langle n_a^*\rangle \tag{2, 3}$$

respectively, which are consistent "in the mean" with Fowler's equations[11].

## Multitdimensional Stochastic Model

In comparing the probabilistic theory with the deterministic theory, we have so far considered the one-dimensional stochastic process for the "true" unimolecular gas reaction on the macroscopic point of view. Now consider microscopically the multi-dimensional stochastic process for a reaction system, such that at time $t$ the numbers of reactant molecules in the states of internal energies $\varepsilon_1, \varepsilon_2, \cdots\cdots, \varepsilon_i, \cdots\cdots$ are $n_1, n_2, \cdots\cdots, n_i, \cdots\cdots$, respectively, under the same conditions as in the previous section. Then if we denote the probability for this reaction system by $P(n_1, n_2, \cdots\cdots, n_i, \cdots\cdots, t)=P(\{n_i\}, t)$, we have

10) F. A. Lindemann, *Trans. Faraday. Soc.*, 17, 599 (1921).

11) R. H. Fowler, "Statistical Mechanics", Cambridge University Press (1936), p. 712.

* The internal energy $\varepsilon_i$ of reactant molecule changes continually into the enregy $\varepsilon$ with various values by the random energy transfer between molecules. Expressing the distribution of such energy $\varepsilon$ by $F_i(\varepsilon)$, we have as the averaged specific reaction rate $\langle k_1(\varepsilon_i)\rangle$

$$\langle k_1(\varepsilon_i)\rangle=\int_0^\infty k_1(\varepsilon/\varepsilon_i)dF_i(\varepsilon),$$

where we may take such distribution function that $F_i(0)=0$ and $F_i(\infty)=1$, and $k_1(\varepsilon/\varepsilon_i)=0$ if $\varepsilon$ is smaller then the value necessary for a chemical reaction to occur. The $k_1^{(\varepsilon)}$ in Eq. 14 denotes such $\langle k_1(\varepsilon_i)\rangle$.

$$\begin{aligned}
&\frac{d}{dt}P(n_1, n_2, \cdots\cdots, n_i, \cdots\cdots, t)\\
&= -k_1^{(1)}n_1P(n_1, n_2, \cdots\cdots, n_i, \cdots\cdots, t)\\
&\quad +k_1^{(1)}(n_1+1)P(n_1+1, n_2, \cdots\cdots, n_i, \cdots\cdots, t)\\
&\quad -k_1^{(2)}n_2P(n_1, n_2, \cdots\cdots, n_i, \cdots\cdots, t)\\
&\quad +k_1^{(2)}(n_2+1)P(n_1, n_2+1, \cdots\cdots, n_i, \cdots\cdots, t)\\
&\quad \vdots\\
&\quad -k_1^{(i)}n_iP(n_1, n_2, \cdots\cdots, n_i, \cdots\cdots, t)\\
&\quad +k_1^{(i)}(n_i+1)P(n_1, n_2, \cdots\cdots, n_i+1, \cdots\cdots, t)\\
&\quad \vdots
\end{aligned} \tag{14}$$

or

$$\begin{aligned}
\frac{d}{dt}P(\{n_i\}, t) &= -\sum_i k_1^{(i)}n_iP(\{n_j\}_{j\neq i}, n_i, t)\\
&\quad +\sum_i k_1^{(i)}(n_i+1)P(\{n_j\}_{j\neq i}, n_i+1, t)
\end{aligned} \tag{14}'$$

where $P(\{n_j\}_{j\neq i}, n_i+1, t) = P(n_1, n_2, \cdots\cdots, n_{i-1}, n_i+1, n_{i+1}, \cdots\cdots, t)$ and the rate constant $k_1^{(i)}$* which is the function of energy $\varepsilon_i$ denotes the transition probability that a molecule in the internal state with an energy $\varepsilon_i$ is transformed into a resultant molecule during unit time. Let the total number of reactant molecules at time $t$ be $n=\sum_i n_i$ and the initial number of reactant molecules with the internal energy $\varepsilon_i$ be $n_i^0$. If we multiply both sides of Eq. 14 by $\sum n_i$ and sum from 0 to $n_i^0$ $(i=1, 2, \cdots\cdots)$ with respect to each energy state, we obtain

$$\begin{aligned}
\frac{d}{dt}\langle\sum_i n_i\rangle &= -\langle k_1^{(1)}n_1\sum_i n_i\rangle + \langle k_1^{(1)}n_1(\sum_i n_i - 1)\rangle\\
&\quad -\langle k_1^{(2)}n_2\sum_i n_i\rangle + \langle k_1^{(2)}n_2(\sum_i n_i - 1)\rangle\\
&\quad \vdots\\
&\quad -\langle k_1^{(i)}n_i\sum_i n_i\rangle + \langle k_1^{(i)}n_i(\sum_i n_i - 1)\rangle\\
&\quad \vdots\\
&= -\langle\sum_i k_1^{(i)}n_i\rangle
\end{aligned}$$

that is,

$$\frac{d\langle n\rangle}{dt} = -\langle\sum_i k_1^{(i)}n_i\rangle \tag{15}$$

Here if we set

$$\frac{\sum_i k_1^{(i)}n_i}{\sum_i n_i} = \bar{k}_1 \tag{16}$$

Eq. 15 becomes, according to $\sum_i k_1^{(i)}n_i = \bar{k}_1 n$,

$$\frac{d\langle n\rangle}{dt} = -\bar{k}_1\langle n\rangle \tag{17}$$

which formally agrees with Eq. 7. The rate constant $\bar{k}_1$ denotes the "average" probability that one molecule undergoes a chemical transformation during unit time. On comparing Eq. 17 with the conventional rate equation

$$\frac{dn}{dt} = -\bar{k}_1 n, \tag{18}$$

which is statistical only with respect to the rate constant but deterministic with respect to the number of reactant molecules, it should be noticed that the application of the multi-dimensional stochastic model to the "true" unimolecular gas reaction presents us with an excellent method for calculating statistically the rate constant together with the number of reactant molecules.

In order to calculate the variance of the total number of reactant molecules, if we multiply both sides of Eq. 14′ by $(\sum_i n_i)^2$ and sum over all values of each $n_i$ we obtain as the differential equation of the mean value for $(\sum_i n_i)^2$

$$\begin{aligned}
\frac{d}{dt}\langle(\sum_i n_i)^2\rangle &= -2\langle(\sum_i k_1^{(i)}n_i)(\sum_i n_i)\rangle\\
&\quad +\langle\sum_i k_1^{(i)}n_i\rangle
\end{aligned}$$

Using $\sum_i n_i = n$ and $\sum_i k_1^{(i)}n_i = \bar{k}_1 n$, we can transform this to

$$\frac{d\langle n^2\rangle}{dt} = -2\bar{k}_1\langle n^2\rangle + \bar{k}_1\langle n\rangle \tag{19}$$

When we rewrite Eq. 17 by the alternative equation

$$\frac{d\langle n\rangle^2}{dt} = -2\bar{k}_1\langle n\rangle^2 \tag{20}$$

and subtract Eq. 20 from Eq. 19, we obtain, using $\langle n\rangle = n_0\exp(-\bar{k}_1 t)$,

$$\begin{aligned}
&\frac{d}{dt}(\langle n^2\rangle - \langle n\rangle^2) + 2\bar{k}_1(\langle n^2\rangle - \langle n\rangle^2)\\
&\quad = \bar{k}_1 n_0\exp(-\bar{k}_1 t)
\end{aligned} \tag{21}$$

Solving Eq. 21 with respect to the variance $\langle n^2\rangle - \langle n\rangle^2$, we obtain

$$\langle n^2\rangle - \langle n^2\rangle = n_0\exp(-\bar{k}_1 t)\{1-\exp(-\bar{k}_1 t)\} \tag{22}$$

which agrees with the variance in Bartholomay's macroscopic treatment if we use $k_1$ in place of $\bar{k}_1$. We observe, however, that $\bar{k}_1$ is estimated by the method to be shown below.

In the reaction system at thermal equilibrium the equilibrium fraction of reactant molecules in the energy state $\varepsilon_i$ is given by

$$n_i = n\frac{g(\varepsilon_i)\exp(-\varepsilon_i/\boldsymbol{kT})}{\sum_i g(\varepsilon_i)\exp(-\varepsilon_i/\boldsymbol{kT})} \tag{23}$$

where $g(\varepsilon_i)$ denotes the quantum statistical weight for the state of energy $\varepsilon_i$. Substituting Eq. 23 into Eq. 16, we find

$$\bar{k}_1=\frac{\sum_i k_1^{(i)}(\varepsilon_i)g(\varepsilon_i)\exp(-\varepsilon_i/\boldsymbol{kT})}{\sum_i g(\varepsilon_i)\exp(-\varepsilon_i/\boldsymbol{kT})} \tag{24}$$

If we differentiate logarithmically with respect to $T$, we obtain

$$kT^2\frac{\partial \ln \bar{k}_1}{\partial T}=\frac{\sum_i \varepsilon_i k_1^{(i)}(\varepsilon_i)g(\varepsilon_i)\exp(-\varepsilon_i/\boldsymbol{kT})}{\sum_i k_1^{(i)}(\varepsilon_i)g(\varepsilon_i)\exp(-\varepsilon_i/\boldsymbol{kT})}$$
$$-\frac{\sum_i \varepsilon_i g(\varepsilon_i)\exp(-\varepsilon_i/\boldsymbol{kT})}{\sum_i g(\varepsilon_i)\exp(-\varepsilon_i/\boldsymbol{kT})} \tag{25}$$

where the first term on the r. h. s. is the average internal energy, not of the existing energized molecules, but of those which react during unit time and the second term is the average internal energy for all molecules[12]. If all reacting molecules that possess energy exceeding $\varepsilon_0$ have the same probability $\lambda_0$ for the "true" unimolecular reaction during unit time, then we have the following relations;

$$k_1^{(i)}=0 \quad \text{for} \quad \varepsilon_i<\varepsilon_0,$$
$$k_1^{(i)}=\lambda_0 \quad \text{for} \quad \varepsilon_i\geq\varepsilon_0.$$

Eq. 24 is therefore transformed into

$$\bar{k}_1=\frac{\lambda_0\sum_{\varepsilon_i\geq\varepsilon_0} g(\varepsilon_i)\exp(\varepsilon_i/\boldsymbol{kT})}{\sum_i g(\varepsilon_i)\exp(-\varepsilon_i/\boldsymbol{kT})} \tag{26}$$

If we treat the internal vibration of molecule as consisting of linear harmonic oscillators whose energy levels are continuous, we have $g(\varepsilon)\propto\varepsilon^{s-1}\Delta\varepsilon$ within a certain range of $\Delta\varepsilon$ and can approximate the r. h. s. of Eq. 26 by the distribution function of $\Gamma$-type

$$\frac{\lambda_0}{\Gamma(s)}\int_{\varepsilon_0}^{\infty}\left(\frac{\varepsilon}{\boldsymbol{kT}}\right)^{s-1}\exp(-\varepsilon/kT)\frac{d\varepsilon}{\boldsymbol{kT}}$$

where $\Gamma(s)=(s-1)!$. Hence we have in place of Eq. 26

$$\bar{k}_1\simeq\lambda_0\exp(-\xi_0/\boldsymbol{kT})\sum_{r=0}^{s-1}\frac{1}{r!}\left(\frac{\varepsilon_0}{\boldsymbol{kT}}\right)^r \tag{27}$$

where $\varepsilon_0$ denotes the minimum energy required for reaction. But if $\varepsilon_0\gg s\boldsymbol{kT}$, the overall rate constant $\bar{k}_1$ is approximately given by

$$\bar{k}_1\simeq\frac{\lambda_0}{\Gamma(s)}\left(\frac{\varepsilon_0}{\boldsymbol{kT}}\right)^{s-1}\exp(-\varepsilon_0/\boldsymbol{kT}) \tag{27}'$$

And more generally, if we denote the probability for the distribution of higher energy levels than $\varepsilon_0$ by $g(\varepsilon_i-\varepsilon_0)/g(\varepsilon_i)$, $k_1^{(i)}$, the specific reaction rate for molecules of energy $\varepsilon_i\geq\varepsilon_0$, is proportional to this probability. We then have the relations

$$k_1^{(i)}=0 \quad \text{for} \quad \varepsilon_i<\varepsilon_0$$
$$k_1^{(i)}=Ag(\varepsilon_i-\varepsilon_0)/g(\varepsilon_i) \quad \text{for} \quad \varepsilon_i\geq\varepsilon \tag{28}$$

where $A$ is the proportional coefficient and we define $g(\varepsilon_i-\varepsilon_0)=0$ for $\varepsilon_i\leq\varepsilon_0$. Thus substituting Eq. 28 into Eq. 24, we obtain

$$\bar{k}_1=A\exp(-\varepsilon_0/\boldsymbol{kT})$$
$$\times\frac{\sum_{\varepsilon_i\geq\varepsilon_0} g(\varepsilon_i-\varepsilon_0)\exp\{-(\varepsilon_i-\varepsilon_0)\boldsymbol{kT}\}}{\sum_i g(\varepsilon_i)\exp(-\varepsilon_i/\boldsymbol{kT})}$$
$$=A\exp(-\varepsilon_0/\boldsymbol{kT})\frac{\sum_{\varepsilon_i'} g(\varepsilon_i')\exp(-\varepsilon_i'/\boldsymbol{kT})}{\sum_i g(\varepsilon_i)\exp(-\varepsilon_i/\boldsymbol{kT})}$$

where $\varepsilon_i'=\varepsilon_i-\varepsilon_0$. If, however, we use the same model molecule composed of a set of simple harmonic oscillators of equal frequency as in Kassel's theory[13], $\sum_{\varepsilon_i'} g(\varepsilon_i')\exp(-\varepsilon_i'/\boldsymbol{kT})$ is equal to $\sum_i g(\varepsilon_i)\exp(-\varepsilon_i/\boldsymbol{kT})$, and consequently we obtain the Arrhenius' equation

$$\bar{k}_1=A\exp(-\varepsilon_0/\boldsymbol{kT}) \tag{29}$$

And from Eqs. 28 and 29 $k_1^{(i)}$ is given by

$$k_1^{(i)}=\bar{k}_1\exp(-\varepsilon_0/\boldsymbol{kT})\frac{g(\varepsilon_i-\varepsilon_0)}{g(\varepsilon_i)} \tag{30}$$

where $\varepsilon_i\geq\varepsilon_0$.

## Conclusions

We have clarified the probabilistic foundations for the application of the theory of the stochastic process to the "true" unimolecular reaction. By extending Bartholomay's method to the more general stochastic process having the parameter $k(t)$ variable with time, we have shown that the theory of stochastic process can be applied to any chemical reaction other than the unimolecular reaction. We have also noticed that the averaged rate constant $\bar{k}_1$ of the "true" unimolecular reaction is legitimately calculated by the application of the multi-dimensional stochastic process to the chemical reaction.

# *The Functional Groups of Sachaconitine*

By Nobukatsu KATSUI and Gen HASEGAWA

(Received December 25, 1959)

In a previous paper[1] the extended formula of sachaconitine (I) ($C_{23}H_{37}O_4N$), one of the alkaloids of *Aconitium miyabei* Nakai, was given as follows:

$$C_{19}H_{24}\begin{cases}(OH)_2\\(OCH_3)_2\\N\text{-}C_2H_5\end{cases}$$

Experiments for characterizing the functional groups of "compound I" have been carried out, and the results are here comunicated.

Oxidation of "compound I" with potassium permanganate in acetone gave a mixture of (a) a neutral compound (II), m. p. 194~196°C, $[\alpha]_D$ −37.8 (EtOH) (Found: C, 67.92; H, 8.71; N, 3.51. Calcd. for $C_{23}H_{35}O_5N$: C, 68.12; H, 8.70; N, 3.45%), and (b) a basic compound (III), m. p. 230~231°C, $[\alpha]_D$ +17.1° (EtOH), p$K_a$ 9.8, $\nu_{max}$ 3545, 3447 $cm^{-1}$ (OH), 3230 $cm^{-1}$ (NH) (Found: C, 69.30; H, 8.97; N, 4.04. Calcd. for $C_{21}H_{33}O_4N$: C, 69.39; H, 9.15; N, 3.85%).

"Compound II" was characterized as the lactam, oxosachaconitine, by its infrared spectrum, $\nu_{max}$ 3537, 3447 $cm^{-1}$ (OH), 1635 $cm^{-1}$ (lactam), and by treatment with lithium aluminum hydride, which converted it into "compound I".

"Base III" was shown to be *N*-desethylsachaconitine by treatment with ethyl iodide, which also reverted to "compound I", thus firmly establishing the presence of an *N*-ethyl group in the alkaloid. Treatment of "compound II" with acetylchloride gave diacetyloxosachaconitine, m. p. 149~151°C, $\nu_{max}$ 1725 $cm^{-1}$ (ester carbonyl), 1625 $cm^{-1}$ (lactam) (Found: C, 64.15; H, 8.00; N, 3.01. Calcd. for $C_{27}H_{39}O_7N$: C, 64.49; H, 8.44; N, 3.01%). On the same treatment, "compound III" gave a neutral product in very poor yield, which could not be purified. Hence "compound III" was treated with acetic anhydride in pyridine at room temperature, and then a neutral product, m. p. 175~176°C, was yielded. In the infrared spectrum this product showed an amide band at 1635 $cm^{-1}$, hydroxyl bands at 3487 and 3331 $cm^{-1}$, but no ester carbonyl band. With the same reagent "compound I" or "II" were recovered without change, and thus it was suggested that the hydroxyls of the alkaloid resisted acetylation with acetic anhydride at room temperature. Oxidation of "compound I" with chromic acid—pyridine complex or with potassium permanganate in acetone-acetic acid produced again two products: one was a neutral compound (IV), m. p. 237~239°C, $[\alpha]_D$ +35.7° (EtOH), $\lambda_{max}$ 290 m$\mu$ ($\varepsilon$ 40) (Found: C, 68.46; H, 8.25; N, 3.62. Calcd. for $C_{23}H_{35}O_5N$: C, 68.46; H, 8.24; N, 3.47%), the second was a base (V), m. p. 275~277°C, $[\alpha]_D$ +107° (EtOH), p$K_a$ 8.3 (Found: C, 70.35; H, 8.00; N, 4.04. Calcd. for $C_{21}H_{29}O_4N$: C, 70.17; N, 8.13; N, 3.90%). "Compound IV", also obtainable from "compound II" by oxidation with chromic acid in acetone, showed a hydroxyl band at 3470 $cm^{-1}$ a lactam band at 1619 $cm^{-1}$ and a five-membered carbonyl band at 1745 $cm^{-1}$ in infrared. Reduction of "compound IV" with sodium borohydride produced "compound II", and with lithium aluminium hydride gave back "compound I". Thus "compound IV" is a keto-lactam, oxosachaconitinone, and also it is indicated, that one of the two hydroxyls in "compound I" or "II" is a secondary one in a five-membered ring.

"Base V" showed a band at 1741 $cm^{-1}$ due to the five-membered ketone carbonyl, a band at 3300 $cm^{-1}$ and no double bond band in infrared, and in ultraviolet spectrum this base contained two maxima at 290 m$\mu$ ($\varepsilon$ 70) and 250m$\mu$ ($\varepsilon$ 210) due to ketone carbonyl respectively. Confirmation of base V as a *N*-desethyl base was supported by the facts that the base gave "compound III" on reduction with sodium borohydride and was obtained also from "compound III" by oxidation with chromic acid in acetone; accordingly the above noted band at 3300 $cm^{-1}$ may be due to N–H group. Thus the results of ultraviolet and infrared absorptions give the assumption, that in "base V" two hydroxyls of "compound III" were oxidized to diketo groups both being five-membered cyclic ketones without more free hydroxyl present.

This consideration was further tested by treatment of "base V" with acetic anhydride in pyridine at room temperature, which as above mentioned, is not capable of acetylating the hydroxyls of the alkaloid. The neutral product obtained, m. p. 222~224°C, showed

1) H. Suginome, N. Katsui and G. Hasegawa, This Bulletin 32, 604 (1959).

a band at 1755 $cm^{-1}$ (carbonyl) and 1616 $cm^{-1}$ (amide), but no hydroxyl band in infrared. On the other hand, one maximum(290 m$\mu$, $\varepsilon$ 70) in ultraviolet of "base V" is normal and may be caused by the same carbonyl as that of "compound IV", but the second (250 m$\mu$, $\varepsilon$ 210) is abnormal. The same abnormality in ultraviolet has been already shown in dehydrodelpheline[2] (250 m$\mu$, $\varepsilon$ 200), obtainable by oxidation of the delphinium alkaloid, delpheline, having the same skeletal formula ($C_{21}H_{33}N$) as sachaconitine.

Furthermore the decrease of p$K_a$ in the conversion from "compound I" (p$K_a$ 9.7) or "compound III" (p$K_a$ 9.8) to "compound V" (p$K_a$ 8.3) has been also observed analogously in the change of parent alkaloid to a dehydroderivative. Then it may be assumed, that in "compound V" a carbonyl is present at the analogous position with dehydrodelpheline. Thus "compound V" is assigned the name, *N*-desethyldehydrosachaconitinone; the environment of the ring containing nitrogen in "compound I" is considered to resemble that of delcosine[3], one of the delphinum alkaloids, because the *N*-ethyl group of the former is more readily oxidized as well as the latter to a *N*-desethyl derivative than the other delphinum or aconitum alkaloids.

But it may be more plausible to assume, that the position of a carbonyl in "compound V" is not the same with didehydrodelcosine[4] but with dehydrodelpheline[5], since the carbonyl is a five-membered ring ketone.

Investigation concerning the methoxyl functions of the alkaloid is in progress and will be reported later.

The authors are grateful to Professor Harusada Suginome, President of Hokkaido University, for his exceedingly kind direction throughout this work.

# *Inorganic Extraction Studies on the System between Bis(2-ethyl hexyl)-orthophosphoric Acid and Hydrochloric Acid (I)*

By Kan KIMURA

(Received January 26, 1960)

During the last decade, alkyl esters of orthophosphoric acid as liquid-liquid solvent extraction reagents have been investigated widely for both chemical and chemical engineering purposes. A number of review articles on this subject[1,2] have been published. Among the esters, tributyl phosphate is beneficially used in several processes of the recovery of uranium and plutonium as well as in many other chemical separation techniques.

Bis(2-ethyl hexyl)-orthophosphoric acid, commonly abbreviated as HDEHP or D2EHPA, has been employed as a liquid-liquid extraction reagent primarily for uranium by Blake et al.[3] at Oak Ridge National Laboratory, and furthermore by Peppard et al. for berkelium-(IV)[4] and lanthanides[5]. Some physicochemical studies have also been performed by Peppard[6,7], Baes and others[8]. Recently, some metal complexes of this reagent were prepared by Peppard and Ferraro[9] and their infrared spectra were also surveyed.

However, no comprehensive study on the

extraction from a given mineral acid solution has been reported. In the present paper, the influence of acid concentration is presented and discussed when the extraction is carried out from hydrochloric acid solution containing each of about fifty elements.

## Experimental

**Solvent.**—The bis(2-ethyl hexyl)-orthophosphoric acid received from Virginia Chemicals, Co. was purified according to the method of Peppard[7,10]. All treatments were manually performed using two separatory funnels. The purity of the solvent was checked by the determination of the distribution ratio, $K_d$, for lanthanum and iron[1,6]. The work reported here was carried out using HDEHP diluted to 50 volume percent with toluene of chemically pure grade.

**Determination of Distribution Ratios.** — The distribution ratio, $K_d$, of a given nuclide (or nuclides), defined as the concentration of nuclide in the organic layer divided by that in the aqueous layer, was determined radiometrically. In the determination, a portion of an aqueous acid solution of a given concentration containing the radioactive tracer was shaken with a portion of the solvent which had been previously equilibrated with the corresponding barren aqueous acid.

Details of the method of the determination were as follows. Two millilitres each of aqueous acid and pre-equilibrated HDEHP were placed in a 5 ml. glass-stoppered measuring-cylinder, and shaken vigorously. After the two layers were transferred together into a centrifuge tube, the content was centrifuged at 4000 rpm for 1 min. Nearly all of the aqueous layer was transferred with a transfer pipette to a new centrifuge tube. Both tubes were centrifuged for 1 min. again. Aliquots of each layer were taken into two glass-stoppered tubes for the radioassay. The quantity of the aliquots taken was usually 1 ml.

In several cases, a portion of the organic extract obtained was transferred to a new 5-ml. cylinder, shaken with an equal volume of fresh aqueous acid, and treated again as mentioned above. Further scrubbings were made in a few cases. By these scrubbings and the following redetermination of $K_d$ values, difficulties caused by the undesired metal hydrates were obviated.

The greater part of the data was obtained by $\gamma$-ray scintillation counting. The counter was a Philips Model PW 4022-52-32 counting unit and the scintillator was a well-type Na(Tl)I crystal "7F8" made by Harshow Chemicals Co. In cases of $\beta$- and $\alpha$-ray emitters aliquot portions from both layers were carefully dried up on small stainless steel or platinum disks, under an infrared lamp or in an induction furnace avoiding any loss of activity and dissolution of stainless steel in hydrochloric acid. $\beta$-Counting was performed with a G-M counter having a mica window of 2.1 mg./cm$^2$ thick made by Rikagaku Kenkyujo, and $\alpha$-rays with a proportional counter of Nuclear Measurement Corp. or with an $\alpha$-ray scintillation counter of Nihon-Musen Irigaku Kenkyujo.

**Remarks on the Determination.**—Almost all data in this experiment were obtained after shaking the two layers for two minutes. According to Peppard and his co-workers[7], the equilibrium of extraction of $^{147}$Pm was attainable in a mixing period of less than 30 sec. Thus the equilibrium might be attained within two minutes for almost all elements. The $K_d$ values for magnesium, aluminum, titanium, vanadium and silver were obtained by one minute shaking, because their half-lives are short.

The range of acidity of the aqueous hydrochloric acid solution covered mainly from 0.01 to 2 N. In some cases, it was extended to 12 N. The acidity was determined volumetrically, when necessary. Although the amount of the elements in the initial 2 ml. of the hydrochloric acid solutions was made as small as possible, it varied from tracer amount to about 1 mg. Details are shown in Table I. In all cases, the specific activity was higher than $10^4$ cpm/mg. under a given condition of measurement.

All experiments were carried out at $21\pm3$°C. Within this range, the variations in $K_d$ values have been shown to be within experimental error.

**Radioisotopes Used.** — The radioactive isotopes used in this experiment were mainly prepared by irradiation of high purity targets in a water-boiler type reactor (Japan Research Reactor I, (neutron flux: $5\times10^{11}$ n/sec. cm$^2$), whereas some of the isotopes were imported from Oak Ridge National Laboratory, U.S.A. or Radiochemical Centre, U.K.

The radiochemical purity of the isotopes was checked by their half-lives, $\gamma$-ray spectra, and/or $\beta$-ray absorption curves with aluminum foils. The $\gamma$-ray spectrograms were obtained with an RCL 256 channel $\gamma$-ray spectrometer or a single channel spectrometer made by Tokyo Shibaura Denki Co.

Table I[14-21] shows the radio-isotopes used[11], together with their half-lives and mass numbers, the target materials or sources, the method of checking the radiochemical purity, and the weight of the materials added in the initial 2 ml. of hydrochloric acid solutions.

Usually the irradiated targets were dissolved in hydrochloric acid and used without further treatment. For example, lanthanum oxide, magnesium

metal, sodium nitrate and barium carbonate were simply dissolved in hydrochloric acid after irradiation. Some of the irradiated targets were dissolved in nitric acid, aqua regia or sodium hydroxide solution and converted into hydrochloric acid solution. For example, rhenium and silver were primarily dissolved in nitric acid, platinum and gold in aqua regia, and arsenous oxide was dissolved in sodium hydroxide solution.

It is likely that the $K_d$ values for arsenic were not largely affected by sodium chloride resulting from sodium hydroxide, for only one drop of tracer solution was added into 2 ml. of the aqueous phase.

Chromium and tungsten tracers were prepared by Yoshihara and Ebihara[12,13], Radioisotope Production Group, Japan Atomic Energy Research Institute. Both were of a high specific activity. On the other hand, most of the imported tracers were used as received.

Some special precautions taken both for the preparation of tracers and for the measurement of distribution ratios are given below in detail:

*Vanadium.*—Irradiated ammonium metavanadate was dissolved in hot 5 N hydrochloric acid and used without any further treatment. Hence, the chemical form of the vanadium tracer was not clearly known. It might have remained in the V(V) state. *Selenium.*—Irradiated selenium was dissolved in nitric acid containing bromine water, and then converted into a hydrochloric acid solution. The resultant solution was used without heating, as selenic tracer, whereas selenous tracer was obtained by heating the solution in 3 N hydrochloric acid. *Molybdenum.*—Irradiated ammonium molybdate showed a pale purple tint, and the hydrochloric acid solution colored blue-green. It was likely that this color came from a certain reduced chemical form. However, the solution was used without any further treatment, e.g., oxidation. *Antimony.*—Irradiated antimony was dissolved in hydrochloric acid containing a small volume of nitric acid. In an acid range below 2 N, obvious hydrolysis occurred. As the $K_d$ values for 3 N acid is fairly high, being as high as 0.2, the HDEHP solution of antimony that had been prepared by extracting antimony(III) from 3 N hydrochloric acid solution was used as the organic phase. *Tantalum.*—Tantalum-182 solution was acidified with hydrochloric acid, and hydrated tantalum precipitate was centrifuged off. The supernatant solution was used as the tracer solution. *Iridium.*—Fusion with sodium peroxide was more rapid and complete than sodium nitrate-carbonate fusion. *Mercury.*—A dilute nitric acid solution of imported mercury tracer was dropped into hydrochloric acid of known concentration, and used without any further treatment. Both phases were clear after the contact. *Thallium.*—Thallic chloride solution was prepared by oxidation of Tl(I) solution with ceric ammonium nitrate or potassium bromate. *Uranium.*—$K_d$ values for uranium were obtained photometrically[21].

## Results and Discussion

The results are summarized in Fig. 1 as a series of graphs of $\log K_d$ vs. $\log N$, where $K_d$ is the distribution ratio and $N$ the acidity in normality. Fig. 1 was compiled from some published and unpublished results. Data for lead, bismuth and americium were taken from the observation of Ishimori[22]. Data for neptunium were taken from the work of Nakamura[23].

Peppard and his coworkers reported that the $K_d$ values for selected lanthanide and actinide cations (III) in the system of HDEHP—perchloric acid are inverse third power dependent on the hydrogen ion concentration in the aqueous phase (0.15 M HDEHP—toluene solution) and direct third power dependent on

22) T. Ishimori, unpublished.
23) E. Nakamura, unpublished.

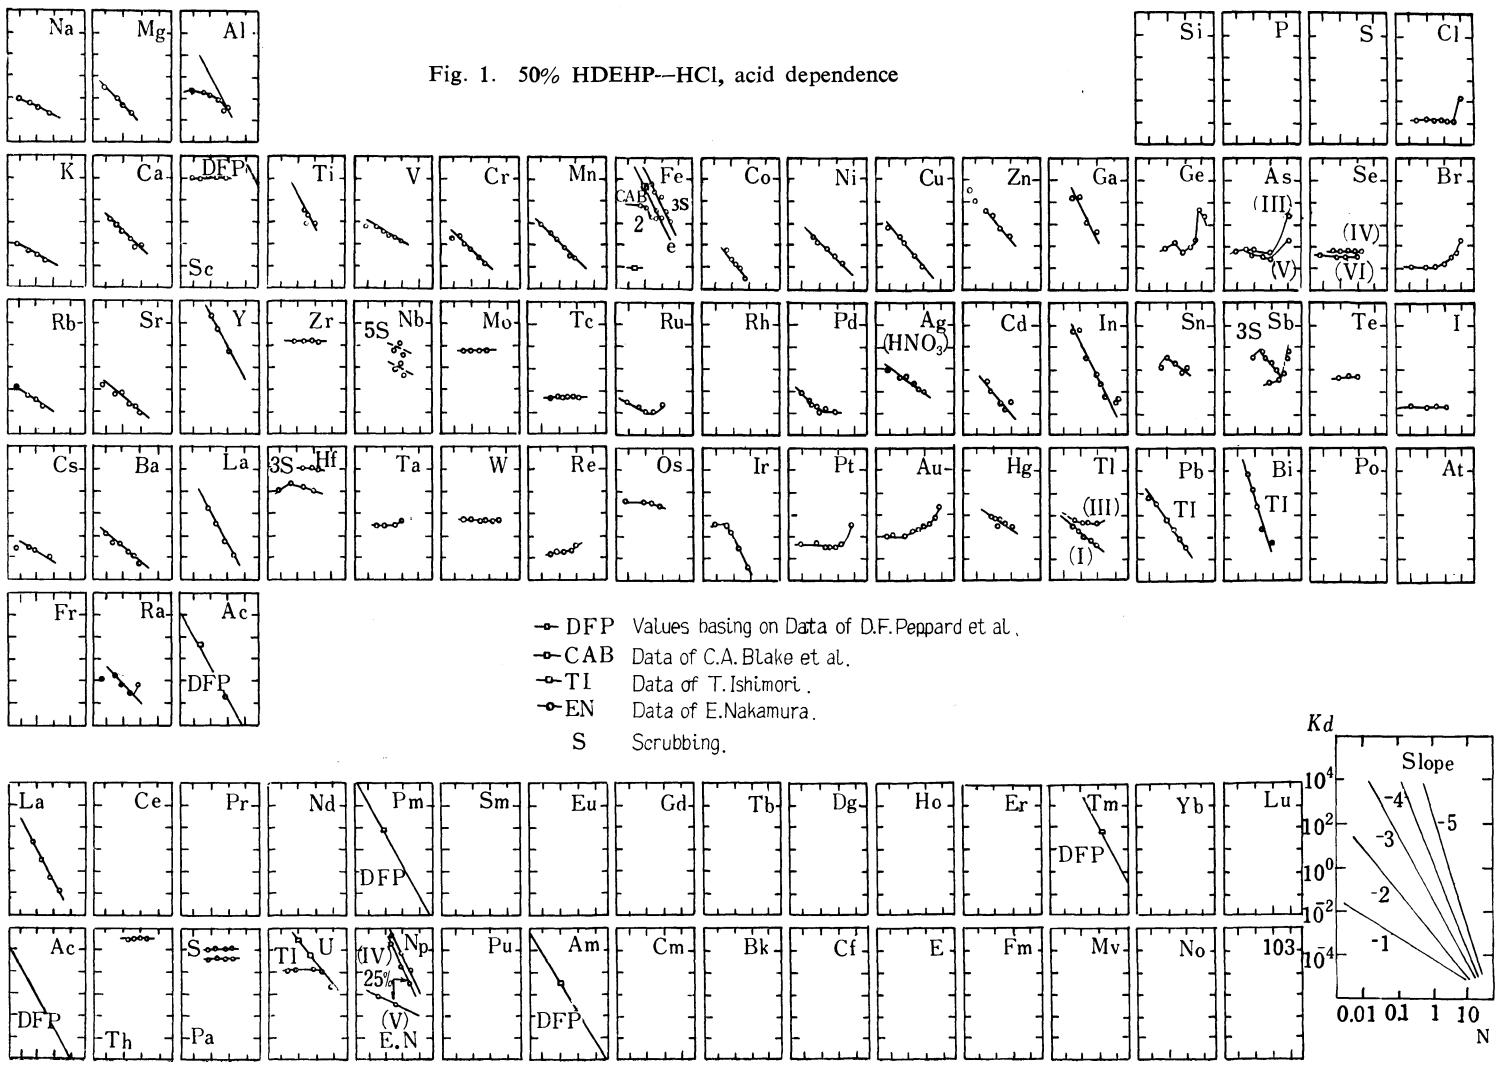

Fig. 1. 50% HDEHP–HCl, acid dependence

the solvent concentration. The results for yttrium and lanthanum of the present author agree with those of Peppard in $K_d$ values. Therefore, $K_d$ values for thulium, promethium, actinium and americium were taken from their data corrected for 50% HDEHP (1.5 M) assuming that the solvent dependence remains unchanged at this high concentration.

According to Peppard and his coworkers[6,9] and Baes et al.[8], the $K_d$ values for scandium, thorium and uranium for diluted HDEHP solution are inverse third, fourth and second power dependent on the hydrogen ion concentration in the aqueous phase, respectively. However, the concentration of HDEHP is so high in this experiment that the $K_d$ values for these elements show almost horizontal curves. It is caused by the limitation of the method of determination. The fact that the horizontal $K_d$ curve for uranium is lower than those for thorium and scandium is mainly brought about by the difference in the method of $K_d$ determinations. The same can be said for protactinium, zirconium and hafnium, whereas the fourth power acid dependence of $K_d$ values is obtained for titanium. Ishimori's data for uranium in the system of 0.75 M HDEHP solution and hydrochloric acid solution are also added after correction for the concentration of HDEHP. The $K_d$ values show inverse second power dependence on the hydrogen ion concentration in the aqueous phase.

As Fig. 1 shows, the shape of the curves is roughly divided into two types. The first type consists of those in which the absolute figures of the slope are identical with the ionic charges or at least the figures are below minus one. On the other hand, the $K_d$ values of the second type are unaffected by the hydrogen ion concentration in the aqueous phase in the acid range below about 2 N.

The $K_d$ values for alkali metals, alkaline earth metals and lanthanide elements are characteristic of the first type, showing first, second and third power dependence on the hydrogen ion concentration in the aqueous phase, respectively. A similar relationship holds for the elements of Ib, IIb and IIIb group in the periodic table except in the case of gold.

The extraction of metal cation with HDEHP is expressed generally in the following equation[1,6]:

$$M^{m+}_{(aq)} + m(HDEHP)_{2\,(org)} \rightleftarrows MH_m(DEHP)_{2m\,(org)} + mH^+_{(aq.)}$$

$$K_d = K \cdot [(HDEHP)_{2\,(org)}]^m \cdot [H^+_{(aq)}]^{-m} \quad (1)$$

where, $K$ is the constant of the above equilibrium. In this equation, $(HDEHP)_{2\,(org)}$ represents the dimer of HDEHP in the organic phase[24]. Eq. 1 indicates that an ion with $+m$ charge shows a curve of $-m$ slope. It appears as if an element giving a $K_d$ curve of the first type behaves as a cation in the given system.

On the other hand, the $K_d$ curves for chlorine, bromine and iodine are typical of the second type. Germanium, arsenic, platinum and gold give curves of a similar shape. Almost all of these elements give higher $K_d$ values in an acid solution over 2 N than in 1 N. It is likely that the extraction of these elements is not based on the chelation mentioned above, but on partition, as is found in the case of extraction with TBP[25].

Although the three light elements of Va, VIa and VIIa group, vanadium, chromium and manganese, show the characteristic curves of the first type, the heavy elements of the groups, niobium, molybdenum, technetium, tantalum, tungsten and rhenium, show those of the second type. This appears to be in accord with the fact that Cr(III) and Mn(II) are apt to behave in cationic state in hydrochloric acid media, whilst niobium, molybdenum, technetium, tantalum, tangsten and rhenium are not. The present $K_d$ values for vanadium were relatively low. Vanadinyl(IV) ion in the system HDEHP-sulfate solution, however, shows high $K_d$ values which depend on the hydrogen ion concentration with a slope of ca. $-2$[1].

Chromium resembles manganese more than it does molybdenum or tungsten as regards the type of acid concentration-$K_d$ value relation. Besides, the slope of ca. $-2$ for chromium gives a suggestion that chromium exists as a mixture of hydrated chloro-complexes. $K_d$ values for molybdenum and niobium are relatively high, while those for technetium and rhenium are very low.

In contrast with the Va, VIa and VIIa groups, the light elements of IVb, Vb and VIb group, germanium, arsenic and selenium, show $K_d$ curves of the second type, while heavy elements, lead and bismuth, show that of the first type.

It is known that iron(III) and aluminum require a long time to attain extraction equilibrium[1]. In graph "Fe" in Fig. 1, curve 2 shows $K_d$ values for 2 min. shaking, line 3s those for three times scrubbing, line e those for thirty hours shaking. Line e has a slope of $-3$. In all three cases, iron gives high $K_d$ values, while cobalt and nickel give low values throughout the acidity range. For aluminum,

24) D. F. Peppard, J. R. Ferraro and G. W. Mason, *J. Inorg. Nucl. Chem.*, **4**, 371 (1957).
25) D. Dyrssen and F. Krasovec, *Acta Chem. Scand.*, **13**, 568 (1959).

the $K_d$ values for the equilibrium were not obtained, because the aluminum tracer used was short-lived.

It is difficult to account for the difference in the behavior of the platinum elements because the methods used in preparing the tracers were quite different. The $K_d$ values for osmium are relatively high, those for iridium show $-4$th power acid dependence, and those for others are low.

Indium gives a straight line of slope ca. $-3$ over the acidity range from 0.05 to 10 N. Copper, silver, zinc, cadmium and gallium also behave similarly giving the slope of $-m$. It is generally accepted that these elements form chloro-complexes easily. However, the absolute figures of the slopes for these are nearly equal to those of ionic charges in such condition that the elements do not form chloro-complexes.

As was mentioned by Peppard and his coworkers[6], Eq. 1 is principally analogous to that of the equilibrium found for the extraction of metals with thenoyl trifluoroacetone, HTTA. Figs. 2 and 3 show the comparison between HDEHP and HTTA extraction for

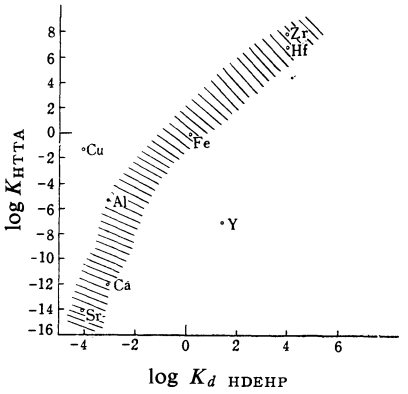

Fig. 2. Relation between $K_{d\ HDEHP}$ and $K_{HTTA}$ values.

○ 0.5 M HTTA; △ 0.25 M HTTA

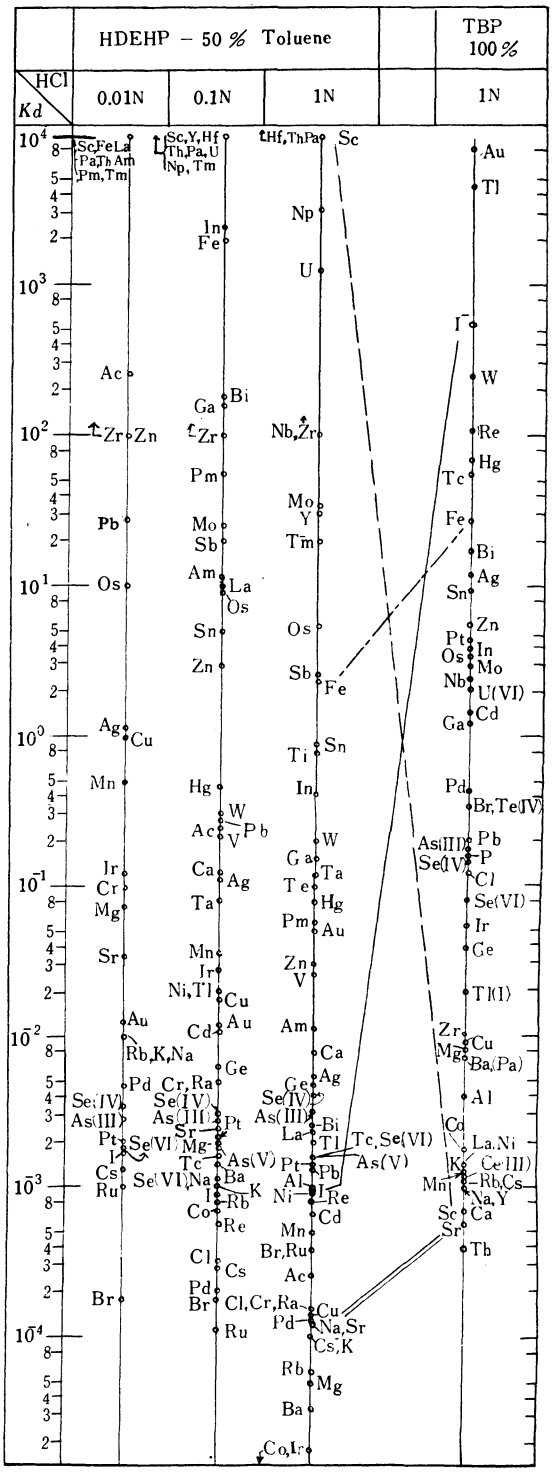

Fig. 4. $K_d$ values in 50% HDEHP—0.01 ~1 N HCl and comparison with 100% TBP—1 N HCl.

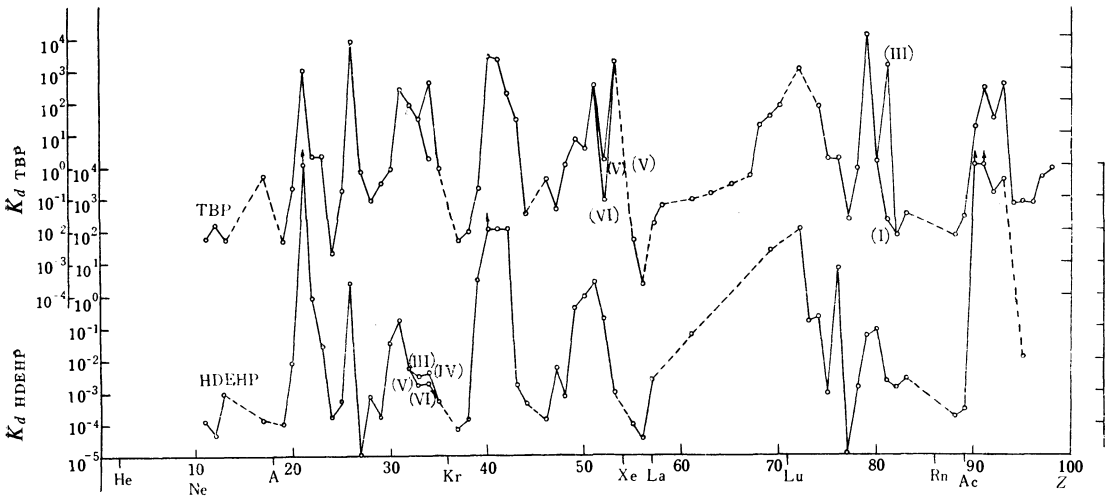

Fig. 5. Relation between $K_d$ values and $Z$.

some cations. The $K_d$ values for 50% HDEHP at 1 N hydrochloric acid are plotted against $K_{HTTA}$ values*[26,27]. In Fig. 3, the acidity given by $\log K_d = 0$ with HDEHP are plotted against the pH values giving 50% extraction with HTTA[27-29]. As Fig. 2 shows, the plots for zirconium, hafnium, iron, aluminum, calcium and strontium appear in the hatched band. Besides, as seen in Fig. 3, Fe-Bi-Pb-Tl and Np-In-La-lines show a straight line of slope ca. +2, showing that mutual difference of the values for these elements are larger in the HTTA system rather than in the HDEHP system. The Sc-Y-Tm-Pm-La-Ac-line of Fig. 3, however, gives a slope of +1. In all cases, it is found that these cations extractable into HTTA phase are also readily extracted into HDEHP.

Fig. 4 gives $K_d$ values in 50% HDEHP (toluene) vs. 1, 0.1 and 0.01 N HCl systems together with $K_d$ values in 100% TBP—1 N hydrochloric acid system. Alkali and alkaline earth metals are situated in a range of low $K_d$ values both for the systems of HDEHP and TBP—1 N hydrochloric acid. It is very interestingthat $K_d$ values for scandium, thorium and protactinium are very high for HDEHP, but very low for TBP. In contrast with this fact $K_d$ values for zinc, cadmium and gold are very high for TBP, but relatively low for HDEHP. However, it is found that iron and indium have relatively high $K_d$ values both for HDEHP and TBP.

$K_d$ values between 50% HDEHP and 1N hydrochloric acid are plotted against the atomic number, $Z$, in Fig. 5. The figure shows that the $K_d$ values vary regularly to some extent, giving two peaks in a given long period of the periodic table. A similar regularity is also found in the system of 50% HDEHP vs. 0.1 N and 0.01 N hydrochloric acid. Although an obvious exception for this regularity is the peak for iron(III), this peak may become low by adopting the $K_d$ value for iron(II) which is more suitable for this consideration from the viewpoint of the electron configuration. Blake et al.[1] mentioned that iron(II) is less extractable. In Fig. 5, $K_d$ values at 12 N hydrochloric acid and 100% TBP are also plotted on the same scale for comparison. It is clear and somewhat noticeable that the readily extractable ions are almost common for systems 100% TBP-12 N hydrochloric acid and 50% HDEHP-1 N hydrochloric acid. It appears as if the extraction of ions with HDEHP is not only based on chelation, but also based on partition as in the extraction with TBP. A notable exception is the case of iodine. Iodine shows remarkably high $K_d$ values for TBP, but low for HDEHP.

As can be seen in Figs. 1 and 5, the $K_d$ values for Ia, IIa and IIIa groups in low acidity region decrease according to the following sequence: Sc > Ca > K, Y > Sr > Rb and La > Ba > Cs. These are analogous to the sequence of relative affinity $K^*$ for cation exchange resin Dowex 50 or Diaion SK:

$$M^{4+} > M^{3+} > M^{2+} > M^{+}$$

However, the order of the extractability with HDEHP for cations of the same valence is

* $K_{HTTA} = (MT_m)_{org} \cdot (H^+)^m_{aq} \cdot (M^{m+})^{-1}_{org} \cdot (HT)^{-m}_{org}$.

* $K = [MR_m]_{resin} \cdot [H^+]^m_{aq.} \cdot [HR]^{-m}_{resin} \cdot [M^{m+}]^{-1}_{aq.}$

# *Coloration and Decarboxylation of the Aniline Salts of 2, 4, 6-Trinitrobenzoic Acid in Ketones and Other Solvents*

By Minoru HIROTA

(Received February 15, 1960)

Molecular compounds of aromatic polynitro compounds with aromatic hydrocarbons and with aromatic amines have been reported by many authors[1] and a number of molecular compounds of 1, 3, 5-trinitrobenzene[2-4], 2, 4, 6-trinitrotoluene[5], 2, 4, 6-trinitroanisole[6], picric acid[7,8], etc., have been investigated, but little has been known of 2, 4, 6-trinitrobenzoic acid (TNBA) complexes. So the present author studied TNBA complexes and found that, while several aromatic hydrocarbons and phenols form normal molecular complexes with TNBA, aniline, as expected, forms salts when one mole of aniline is added to one mole of TNBA.

The TNBA salts of anilines decompose into the complexes of 1, 3, 5-trinitrobenzene (TNB) with anilines and carbon dioxide on heating in solution or in the crystalline state, and the decarboxylation is extremely fast in ketonic solvents even at low temperatures. Moreover, a striking dark red color is produced in ketonic solvents. From the investigation of the relation

between the coloration and the rates of decarboxylation in various solvents it has been found that there are two types of coloration. The color of the first type occurs immediately after the dissolution of a salt in a pure ketone, accompanying very rapid decarboxylation, its intensity decreasing rather rapidly. The color of the other type occurs some time after the dissolution of the salt in an alcohol or in a mixed solvent containing an alcohol, when the decarboxylation is completed and almost all the TNBA has decomposed, its intensity increasing gradually. The spectra of the colors of both types resemble each other in shapes but differ in the locations of the absorption maxima. The measurments of the rates of the decarboxylation of the complexes of TNBA with anilines also showed that the decarboxylation in ketones is extremely rapid.

**2, 4, 6-Trinitrobenzoates of Aniline and Substituted Anilines and their Decomposition into Corresponding Trinitrobenzene Complexes on Fusion.** — A colorless crystalline substance was obtained when one mole of aniline and one mole of TNBA, both in cold acetone solution, were mixed, while a red mass was obtained from one mole of TNBA and two moles of aniline. The colorless substance was proved to be a 1 : 1 compound by analysis (Found: N, 18.09%, Calcd: N, 18.30%). The infrared absorption spectrum indicated that this compound is a salt[9]; namely it showed no absorption near 1725 $cm^{-1}$ (carbonyl stretching frequency of the carboxyl group), and 1270 $cm^{-1}$, but absorption bands at 1600 $cm^{-1}$ and 1380 $cm^{-1}$ (antisymmetric and symmetric stretching frequencies of the carboxylate ion). (See Fig. 1 for the infrared spectra of the TNBA salts of aniline and pyridine.) The molecular compounds[10] of TNBA with benzene, naphthalene and chrysene have acid type carbonyl absorptions near 1730 and 1270 $cm^{-1}$. The 2 : 1 compound also showed no absorption near 1730 $cm^{-1}$ but more experiments are required for further information.

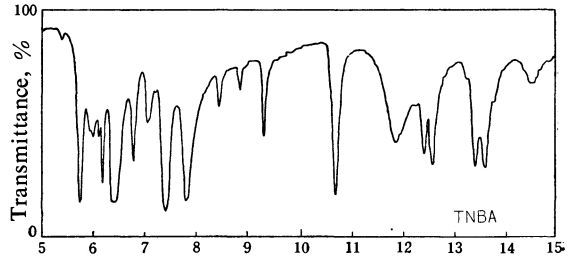

Fig. 1a.

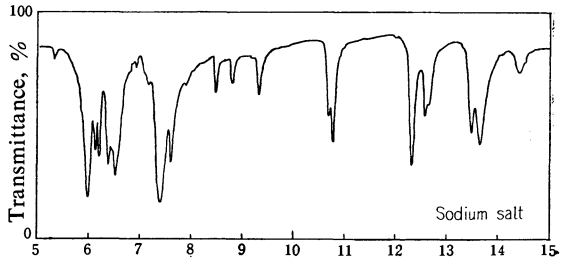

Fig. 1b.

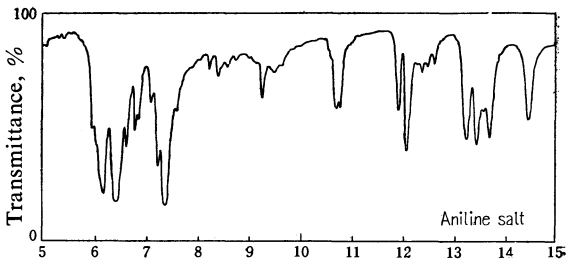

Fig. 1c.

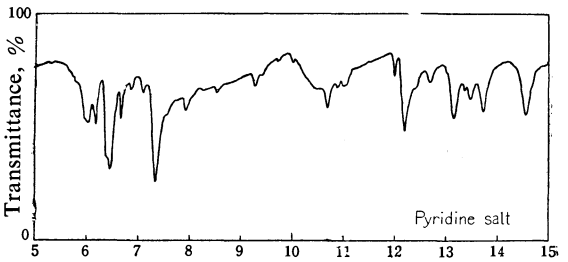

Fig. 1d.

Fig. 1. Infrared spectra of 2, 4, 6-trinitrobenzoates.

9) The salt form is proved mainly by the absence of the bands at 1730 and 1270 $cm^{-1}$, because the bands at 1600 and 1360 $cm^{-1}$ overlap with the strong bands of the nitro group.

10) These molecular compounds will be described later.

2, 4, 6-Trinitrobenzoates of substituted anilines were also prepared and compared in the infrared spectra with the sodium and ammonium salts of TNBA (Table I and Fig. 1), which showed that all of these colorless 1 : 1 compounds are salts.

The 2, 4, 6-trinitrobenzoates decomposed at their melting points and changed into an orange-yellow or red liquid. The orange-yellow crystalline substance melting at 127°C, obtained from the melt of the aniline salt, was identified with the TNB-aniline complex. Other salts also gave the corresponding TNB complexes.

** The color is much paler than in ketonic solvents.

The sign + is for rapid coloration, the sign ± is for slow coloration (about one hour after heating) and the sign − is for no coloration.

**Coloration and Decarboxylation of the Aniline Salts of TNBA in Various Solvents.** — The aniline salt of TNBA could be recrystallized from boiling benzene without coloration, but a dark red color appeared when boiling acetone was used as the solvent for recrystallization, an orange crystalline substance being obtained from the colored solution after spontaneous evaporation of acetone and was again identified with the TNB-aniline complex by the melting point and by the X-ray diffraction pattern (Table IV). On the other hand, the free TNBA could be recrystallized from boiling acetone without decomposition; and, therefore, the aniline salt form is essential for the unusual

facility of decarboxylation of TNBA in ketones.

In order to investigate what kind of solvent produces the particular red color, 5 mg. of a salt was added in 2 ml. of a solvent (if insoluble, the salt was suspended in the solvent), and then the whole was heated for 5 sec. on a water bath of 60°C. If the red did not appear markedly immediately after heating, the

as the solvent. Some alcohols and ethers also produced a red color on longer heating. The color in ketones is so intense immediately after heating that very small amounts of a ketone and the aniline salts are needed for the color reaction and it gives a method for the qualitative detection of ketones. Nevertheless, this method requires ketones of high purity, so the utilization is limited. Some nitro compounds, ethers and alcohols also produced coloration, but the greenish red color in ketones and nitro compounds seemed to be different from the red color in alcohols. Results of the color reaction in various solvents are summarized in Table II.

Then, the absorption spectra of the aniline salts in various solvents were measured. Some of the spectra are illustrated in Fig. 2 and the locations of the absorption maxima are given in Table III. The spectra of the aniline salt of TNBA in a pure ketone or nitromethane, measured immediately after dissolution and warming, had absorption maxima at 447.5 and 595 m$\mu$, and their intensities (extinction coefficients) decreased as time passed. On the other hand, the spectra of the salt in alcohols had absorption maxima at 465 and 565 m$\mu$ and their intensities gradually increased as time passed. From these experimental results it was certain that there were two types of coloration, so the time dependence of the absorption intensity was measured with the results given below.

**Relation between the Rate of Decarboxylation and Coloration of the Aniline Salts of TNBA in Various Solvents.**—The relation between the decarboxylation and the coloration of the TNBA salt of aniline was investigated by measuring the rate of decarboxylation and the change of

absorption intensity. The decarboxylation is extremely fast in ketones (Fig. 5). The rate of decarboxylation is in the order: acetone> methyl ethyl ketone>ethanol>methanol> dioxane. Measurements of the change of absorption intensity revealed that the intensity in pure ketones is reduced fast, while the color in the acetone-ethanol mixture, though not very intense at the beginning, becomes intense gradually. The more acetone the mixed solvent contains, the more promptly the coloration occurs, while, the more ethanol is present in the solvent, the more intense the absorption of the solution becomes. However the coloration is hardly observed in pure ethanol. On the other hand, since the decarboxylation of the aniline salt proceeds without any coloration in many other solvents at higher temperatures, the color is not essential for the decarboxylation, but the unusual facility of decarboxylation with simultaneous coloration in ketones suggests different mechanisms of the two types of decarboxylation.

The decarboxylation of the TNBA salts of substituted anilines were also examined with the results shown in Fig. 6.

To examine the nature of the intermediate compounds of the decarboxylation, the TNBA salts of some *p*-substituted anilines were prepared and the rates of decarboxylation were measured. The order of the decarboxylation rates is almost parallel to that of the coloration rates. Namely, ammonium salt $\ll$*p*-nitroaniline salt $<$*p*-bromoaniline salt $<$ aniline salt $<$*p*-anisidine salt for the coloration, and *p*-bromoaniline salt $<$*N*, *N*-dimethylaniline salt $<$*p*-nitroaniline salt $<$*N*-methylaniline salt $<$*p*-toluidine salt $<$ aniline salt $<$*p*-anisidine salt for the decarboxylation.

The order of the decarboxylation rates is not simply in the order of basicity of the anilines.

## Experimental

**Qualitative Tests for the Coloration.** — To examine a solvent in the coloration, about 5 mg. of the aniline salt of TNBA was dissolved in 2 ml. of the solvent and the solution was heated for 30 seconds in a water bath of 60°C. If the salt was not completely dissolved, a suspension was used. All solutions in ketones produced dark red color instantly on heating. When no coloration occurred, the solution was examined after heating at 50°C for 3 minutes and 60 minutes. To test a solution in ether or other volatile solvents, the solution was heated under reflux on a water bath.

**Visible Spectra of the Color.** — Visible spectra were measured in the range of wavelength from 420 to 625 m$\mu$. with a Beckman DU type quartz spectrophotometer. Determination of the band envelopes and locations of the absorption maxima were the main purpose of the spectral measurements, while the exact determination of the absolute values of intensities was less important and only relative intensities were needed for the present discussions, since the intensities of the absorption bands changed rather rapidly.

**Infrared Spectra of the Salt.** — The infrared spectra were determined with an Infracord infrared spectrophotometer or with a Baird Model B infrared spectrophotometer. All measurements were made in solid state; the potassium bromide pellet method was employed in most measurements, and the mull method in a few measurements. Nujol and hexachlorobutadiene were used as mulling agents, because they compensate each other, the whole wavelength region between 2.5 and 15 $\mu$ thus being covered without interference of the absorption bands of the mulling agents.

**Preparation of the Materials and Determination of the Rates.**—All salts were prepared by the following procedure: TNBA[12] in acetone and an equivalent amount of a base in the same solvent were mixed in an ice bath and the precipitated salt was collected by filtration as rapidly as possible, washed first with a small amount of cold acetone and then with benzene, and dried in a vacuum desiccator. The salts prepared in this way were analytically pure (Table V) and can be used in the spectral and other measurements. The rate of decarboxylation was determined by titrating the unchanged acid with a standard alkali in aqueous solution, methyl red being used as the indicator without interference by the anilines.

**X-ray Diffraction Measurements.**—Powder X-ray diffraction patterns were obtained with a Norelco X-ray diffractometer. Diffraction angles and relative intensities of the diffracted beams are listed in Table IV.

The author wishes to express his hearty thanks to Professor Y. Urushibara, and to Professor M. Ōki for their helpful advice and to Mr. Masuda for elementary analyses.

# *Sur la Dissolution des Minerais Sulfurés en Divers Milieux. II. Dissolution de la Pyrite et de la Chalcopyrite*

Par Masami ICHIKUNI

(Reçu le 22 octobre 1959)

La décomposition ou l'altération des minerais sulfurés dépend, d'une part, de leur propre caractère, composition chimique, propriété minéralogique, structure cristalline, et d'autre part, des facteurs du milieu, température, pression, pH, potentiel d'oxydo-réduction, présence d'autres substances. Ayant exécuté des essais préliminaires, on a déjà signalé dans le rapport précédent[1] des rôles importants que jouent le pH et l'air dans la dissolution des minerais. Dans le but d'élargir et de généraliser ce résultat, on reprend l'expérience de la dissolution de la pyrite et de la chalcopyrite, classées parmi les plus importants des minéraux sulfurés primaires. L'expérience s'effectue sous les conditions oxydantes et non-oxydantes à divers pH. Les premières conditions sont caractérisées par la présence de l'air, les dernières par l'absence de l'oxygène. On met en évidence le mécanisme de la dissolution des minerais et montre sa signification géochimique. L'application du résultat du présent rapport aux phénomènes naturels sera utile pour l'éclaircissement de ces derniers.

## Expérience

**Généralité.** — Le dispositif et les conditions de l'expérience sont les mêmes que ceux décrits dans le rapport précédent. On prend 200 ml. d'acide chlorhydrique de concentration connue ou la même quantité d'eau bidistillée dans un ballon à 300 ml., l'apporte sur un bain-marie, chauffe la liqueur à la température de 80 à 85°C, y ajoute 1 g. de minéral pulvérisé et traite pendant quatre heures, en y introduisant l'air ou l'azote avec un débit constant de 1,5 l./min. Chaque prélèvement de portion de 10 ml. doit être effectué avec l'interval d'une heure. Le dosage du fer divalent, du cuivre et du sulfate sont fait sur la liqueur filtrée.

L'interféromètre ayant indiqué 0,05% comme teneur en oxygène de l'azote, celui-ci est lavé à une solution de pyrogallol, afin d'éliminer l'oxygène.

**Echantillons.**—La pyrite s'est produite à la mine de Kanaborizawa, département d'Aomori, la chalcopyrite, à la mine d'Ani, department d'Akita. La dernière a été examinée par voie diffractométrique à rayons X pour qu'on vérifie qu'elle est exempte d'autres impuretés minéralogiques. Le résultat d'analyse chimique est porté sur le Tableau I. La composition chimque des échantillons se conforme approximativement à la formule chimique idéale des minéraux, $FeS_2$ et $CuFeS_2$. Une petite quantité d'impuretés qu'on a décelées par la spectrographie ne présentera aucun inconvénient pour l'expérience.

TABLEAU I. RÉSULTAT D'ANALYSE DES MINÉRAUX

| Elément | Pyrite | Chalcopyrite |
|---|---|---|
| Fe | 46,50% | 30,40% |
| Cu | — | 34,35 |
| S | 53,36 | 34,86 |
| Total | 99,86 | 99,61 |

Tout en évitant l'oxydation provoquée par la pulvérisation, on arrête cette opération lorsque toutes les poudres passent par un tamis à nombre de maille de 100.

**Considérations.** — (1) *Diminution du Volume de Liqueur par l'Evaporation.* — Entraînée par l'air ou l'azote introduit dans la liqueur, une portion de liqueur s'évapore. L'augmentation apparente de quantité dissoute de composants, si elle était calculée par la différence des concentrations trouvées tout en négligeant la diminution du volume, doit être supérieure à son augmentation véritable. Cela nécessite donc une correction pour la diminution du volume causée par l'évaporation. Cette correction a une importance particulière dans le cas d'un composant qui ne se dissout que très peu. Elle s'effectue par la division des concentrations trouvées par le taux de concentration, rapport du volume initial sur la somme du volume final et du volume prélevé. Toutes les concentrations trouveées ont été ainsi recalculées pour qu'on puisse éliminer l'influence de l'évaporation. Si le minéral pulvérisé contient une certaine quantité de sulfate ou d'oxyde, qui dépasse la quantité dissoute par le traitement, cela empêchera de déterminer précisément la quantité véritable de dissolution, car la correction ne se fait pas très rigoureusement. On est obligé de prendre une grande précaution pour la préparation des échantillons. On peut effectuer la correction avec une erreur inférieure à 5%.

(2) *Variation du pH.*—Lorsqu'on traite les minerais sulfurés en présence de l'oxygène, il se produit toujours une certaine quantité d'acide sulfurique et le pH de la liqueur diminue. L'effet de l'évaporation qui concentre la liqueur, par conséquent l'ion hydrogène, participe également à l'abaissement du pH. Il n'est que de 0,2, en milieu acide, avant et après le traitement, tandis que le pH descend de 6 à 3 environ par le traitement effectué avec de l'eau bidistillée. Lorsqu'on examine la relation

1) M. Ichikuni et H. Kamiya, Ce Bulletin, 32. 1368 (1959).

entre la dissolution et le pH, on prend la valeur moyenne de pH au cours du traitement, et elle est de 3,2 et de 4,2 pour le traitement effectué avec l'eau de la pyrite et de la chalcopyrite, respectivement. Pour maintenir le pH du milieu à une valeur donnée, on pourrait utiliser une solution tampon, mais son emploi offre en même temps un inconvénient, car la présence des sels étrangers exerce une influence considérable sur la dissolution des minéraux; on aura donc de la difficulté à interpréter le résultat obtenu.

(3) *Efficacité de l'Agitation.*—La réaction ayant lieu entre la phase solide et la phase liquide, l'agitation donne une influence considérable sur la vitesse de réaction. On maintient le débit du gaz à une valeur constante de 1,5 l./min., afin d'égaliser, pour toute la série d'expériences, l'efficacité de l'agitation.

(4) *Suppression du Dosage du Fer Trivalent.*—Comme la concentration de fer trivalent ne dépasse que très rarement 1% de celle de fer divalent, on a supprimé le dosage de celui-là.

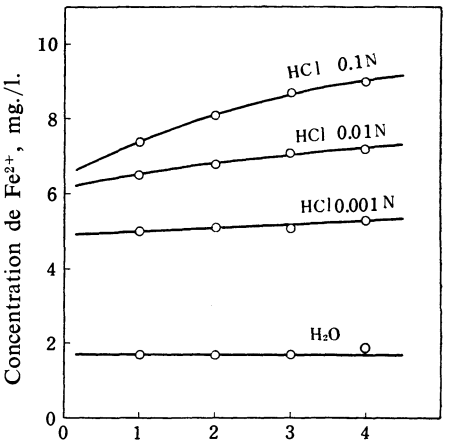

Fig. 1 Dissolution du fer à partir de la pyrite en milieu exempt d'oxygène

## Résultats et Discussion

**Expérience de Dissolution de la Pyrite Effectuée à l'Exclusion de l'Oxygène.**—L'exclusion de l'oxygène a été réalisée par l'introduction de l'azote dans le dispositif.

Le Tableau II montre la concentration de composants qui a été correctionnée pour la diminution du volume, et qui correspond à l'heure du prélèvement et aux conditions d'expérience. L'absence de l'oxygène ne provoque presque pas la formation du sulfate, tandis que celle-ci est remarquée légèrement lors du traitement avec l'eau. Comme la pyrite est très sensible à l'oxydation en milieu à pH élevé, la formation du sulfate est attribuable à des traces d'oxygène contenu dans l'azote. Comme l'indique la Figure 1, la dissolution du fer s'accélère à mesure que le pH s'abaisse. Toutefois la courbe de concentration a une tendance à s'aplanir.

Par ces résultats, on peut exprimer la décomposition de la pyrite en milieu acide et en l'absence de l'oxygène par l'équation (1)

$$(1) \quad FeS_2 + 2H^+ \rightarrow Fe^{2+} + H_2S + S$$

L'hydrogène sulfuré étant chassé par le barbotage de l'azote, la réaction peut avancer.

Tableau II. Variation de concentration de fer divalent et de sulfate au cours de la dissolution de la pyrite

TABLEAU III. VITESSE DE DISSOLUTION DU FER DIVALENT ET DU SULFATE À PARTIR DE 1 g. DE PYÉITE EN PRÉSENCE DE L'AIR

| Milieu | Valeur moyenne de pH | $Fe^{2+}$ m mol./hr. ($\times 10^{-2}$) | $SO_4^{2-}$ m mol./hr. ($\times 10^{-2}$) | $SO_4^{2-}/Fe^{2+}$ |
|---|---|---|---|---|
| HCl 0,1 N | 1,1 | 1,53 | 1,03 | 0,67 |
| HCl 0,01 N | 2,0 | 1,78 | 2,80 | 1,57 |
| HCl 0,001 N | 2,9 | 1,70 | 4,58 | 2,70 |
| $H_2O$ | 3,2 | 1,12 | 5,35 | 4,78 |

La présence de l'hydrogène sulfuré, au contraire, empêche la réaction. Pour cette raison, la pyrite reste stable en milieu acide, si le milieu est caractérisé par la présence de l'hydrogène sulfuré. Ainsi s'expliquent la stabilité et la formation de la pyrite dans la nature.

**Expérience de Dissolution de la Pyrite Effectuée en Présence de l'Air.**—Dans le Tableau II, on trouve que la présence de l'air favorise une dissolution considérable du fer divalent et du sulfate, et on peut constater que le potentiel d'oxydo-réduction est un facteur important pour la décomposition de la pyrite. La vitesse de dissolution du fer et du soufre dépend du pH et du potentiel d'oxydo-réduction du milieu. Il est bien connu que l'oxydation de l'hydrogène sulfuré par l'oxygène libre donne génénralement le soufre libre et non l'acide sulfurique en milieu acide[2].

En partant de l'équation (1), on a deux équations suivantes:

$$(2)\quad FeS_2 + 2H^+ + O \rightarrow Fe^{2+} + H_2O + 2S$$

où la pyrite se décompose en fer divalent et soufre libre,

$$(3)\quad FeS_2 + H_2O + 7O \rightarrow Fe^{2+} + 2H^+ + 2SO_4^{2-}$$

où tous les soufres sont oxydés en sulfate. Ces deux équations correspondent aux deux cas extrêmes de la décomposition de la pyrite, et le rapport de $SO_4^{2-}/Fe$ peut varier de 0 à 2. Cependant au-dessus de pH 3, le fer trivalent, formé par oxydation du fer divalent, précipitant sous forme de l'hydroxyde, le rapport de $SO_4^{2-}/Fe$ est toujours suppérieur à 2. Dans le Tableau III, on montre la vitesse de formation du fer divalent et du sulfate par la dissolution de la pyrite.

La Figure 2 montre la relation entre le pH et le rapport de $SO_4^{2-}/Fe^{2+}$. A un petit pH, la réaction exprimée par l'équation (2) est prédominante. Au-dessus de pH 2,5, on remarque déjà l'hydrolyse du fer trivalent, et la précipitation de l'hydroxyde devient très rapide au delà du pH 3.

Que la vitesse de formation du fer divalent et du sulfate soit variable selon le pH du milieu

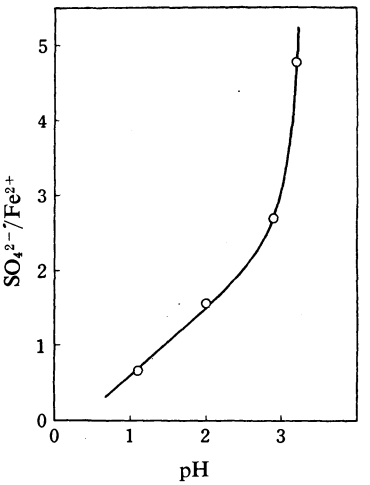

Fig. 2 Relation entre le pH et le rapport de $SO_4^{2-}/Fe^{2+}$, qui se trouve dans la dissolution de la pyrite.

a une signification très importante au point de vue géochimique. La variation du rapport de $SO_4^{2-}/Fe$ en fonction du pH est influencée par les conditions d'expérience, toutefois elle garderait toujours la même tendance. Dans la nature, l'acidité forte à pH inférieur à 1 étant exceptionnelle, la désagrégation de la pyrite donne simplement l'acide sulfurique et le sulfate de fer(II). La neutralisation de la solution ainsi formée provoque la précipitation du fer, notamment l'hydroxyde de fer(III) par l'intervention de l'oxygène. L'oxydation du sulfure en sulfate se produit d'autant plus vite que le pH est plus élevé.

**Expérience de Dissolution de la Chalcopyrite Effectuée à l'Exclusion de l'Oxygène.** — Le Tableau IV montre le résultat de la dissolution du minéral dont l'expérience est effectuée en présence de l'azote et de l'air. Le traitement du minéral, effectué en milieu exempt d'oxygène et avec l'acide chlorhydrique, ne donne que du fer divalent et rien d'autres composants. La décomposition proposée par l'équation (4) explique bien l'indissolution du cuivre:

$$(4)\quad CuFeS_2 + 2H^+ \rightarrow CuS + Fe^{2+} + H_2S$$

On comprend que la dissolution du fer divalent est d'autant plus rapide que le pH du milieu est plus petit. D'après le Tableau

TABLEAU V. VITESSE DE DISSOLUTION DU FER DIVALENT, DU CUIVRE ET DU SULFATE À PARTIR DE 1 g. DE CHALCOPYRITE EN PRÉSENCE DE L'AIR

| Milieu | Valeur moyenne de pH | $Fe^{2+}$ m mol./hr. ($\times 10^{-2}$) | Cu m mol./hr. ($\times 10^{-2}$) | $SO_4^{2-}$ m mol./hr. ($\times 10^{-2}$) | $Cu/Fe^{2+}$ |
|---|---|---|---|---|---|
| HCl 0,1 N | 1,1 | 16,3 | 5,31 | 0,4 | 0,33 |
| HCl 0,01 N | 2,0 | 0,80 | <0,63 | 0,2 | $\leq$0,79 |
| HCl 0,001 N | 3,0 | 0,37 | 0 | 0,2 | 0 |
| $H_2O$ | 4,2 | 0,11 | 0 | 0 | 0 |

IV, la vitesse de dissolution du fer est de 0,26 mg. à l'heure, dans l'acide 0,1 N, et de 0,13 mg. à l'heure, dans l'acide 0,01 N. Le fer ne se dissout aucunement dans l'eau.

**Expérience de Dissolution de la Chalcopyrite Effectuée en Présence de l'Air.** — Dans le Tableau IV, on voit que l'expérience effectuée en présence de l'air donne approximativement le même résultat que celle qui a été effectuée en milieu exempt d'oxygène, d'autant que le pH soit supérieur à 2. A un pH supérieur à 3, aucune dissolution du cuivre n'est remarquée, et celle du sulfate est très limitée. De ce fait on peut conclure que l'oxygène n'exerce pas une grande influence sur la dissolution de la chalcopyrite à un pH supérieur à 2. Cela se conforme au résultat du rapport précédent que la dissolution du cuivre est soumise à l'influence du pH et non du débit de l'air qu'on introduit dans la liqueur contenant du minerai pulvérisé.

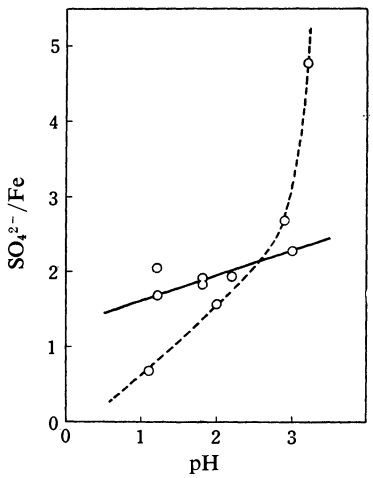
Une vitesse très limitée de formation du sulfate en milieux neutre et faiblement acide attire notre attention. Pour cette raison, le traitement de la chalcopyrite avec l'eau ne diminue que modérément le pH de la liqueur. La pyrite, au contraire, diminue considérablement le pH de la liqueur, lorsqu'elle est traitée avec de l'eau, d'ailleurs chez la pyrite, la vitesse de formation du sulfate est d'autant plus grande que le pH du milieu est plus élevé. Cependant la dissolution de la chalcopyrite augmente énormément en milieu acide 0,1 N, ce qui n'est pas pareil au cas de la pyrite.

Le Tableau V montre la vitesse de formation du fer divalent, du cuivre et du sulfate par la dissolution de la chalcopyrite.

Dans le Tableau V, on trouve que la quantité dissoute de cuivre est toujours inférieure à celle de fer, quoique le rapport de Cu/Fe soit de l'unité dans le minéral. La dissolution du soufre, sous forme du sulfate, est très faible par rapport à celle du fer et du cuivre. Alors on remarque que le soufre libre se forme abondamment au cours de l'expérience effectuée en milieu acide 0,1 N. On présente donc les équations (5) et (6) qui conviendront à l'explication de ce résultat :

(5) $CuFeS_2 + 2H^+ + O \rightarrow CuS + Fe^{2+} + H_2O + S$

(6) $CuFeS_2 + 4H^+ + 2O \rightarrow Cu^{2+} + Fe^{2+} + 2H_2O + 2S$



D'après ce résultat, on peut déduire qu'une grande dissolution du cuivre à partir de la chalcopyrite est peu possible, d'autant que le minéral se trouve indépendamment des autres minéraux, et que le milieu en question ne soit pas très acide et oxydant. Cependant on trouve souvent une dissolution rapide du cuivre à partir du gisement des minerais sulfurés. On ne pourra pas éclaircir ce phénomène sans avoir recours aux effets de la co-présence d'autres minéraux, notamment de la pyrite, et de l'action de l'acide sulfurique ou du fer, qui sont produits par la désagrégation des minerais sulfurés. D'après Ohashi[3], la présence de la pyrite ne favorise pas particulièrement la dissolution du cuivre à partir de la chalcopyrite, toutefois le fer trivalent contribue à sa dissolution, en réagissant sur le minéral.

Les effets de la co-présence d'autres minéraux sur la dissolution de la chalcopyrite présentent un problème intéressant, car on a déjà désigné la présence d'autres substances comme un des facteurs importants déterminant le milieu géochimique.

### Désagrégation de la Pyrite dans la Nature

L'acide sulfurique et le sulfate de fer se forment en grande quantité par la désagrégation des minerais sulfurés. C'est ainsi que les eaux d'une forte acidité, souvent de pH inférieur à 3, jaillissent au fond de mine. Ces eaux se jettent dans une rivière, et abaissent dans une grande mesure le pH des eaux de rivière. Il est d'un intérêt particulier de comparer le résultat de ces expériences avec celui d'analyse des eaux de mine.

On a choisi donc à partir des résultats d'analyses des eaux de mine de Kamikita, département d'Aomori,[4] les eaux contenant simplement de l'acide sulfurique et du sulfate de fer. Le résultat d'analyse des dernières est indiqué par le Tableau VI.

Fig, 3 Relation entre le pH et le rapport de $SO_4^{2-}/Fe$, qui se trouve dans les eaux de mine de Kamikita (courbe discontinue correspondant à celle de la Fig. 2).

Avec les chiffres du Tableau VI, on examine la relation entre le pH et le rapport de $SO_4^{2-}/Fe$, et la compare avec celle obtenue par les expériences décrites ci-dessus. La Figure 3 montre cette comparaison. On en a constaté que:

1. A mesure que le pH s'abaisse, le rapport de $SO_4^{2-}/Fe$ a une tendance à diminuer, mais il n'est pas très inférieur à 2, même à pH 1.
2. Cela souligne que la réaction exprimée par l'équation (3) est toujours prédominante dans la nature, même à un petit pH, par conséquent la formation abondante du soufre libre par la désagrégation de la pyrite serait peu possible.

La relation entre le pH et le rapport de $SO_4^{2-}/Fe$, qui se trouve dans les données du Tableau VI, ne se conforme pas à celle obtenue par les expériences. Cette discordance peut s'expliquer par le fait que dans la nature, la manière de contact des minerais avec l'air est entièrement différente de celle effectuée au laboratoire, et que la dissolution des minerais est soumise à l'influence des substances

TABLEAU VI. QUELQUES RELEVÉS DES DONNÉES D'ANALYSE DES EAUX DE MINE DE KAMIKITA, DÉPARTEMENT D'AOMORI (D'APRÈS T. HAMACHI ET H. GOTO)

| pH | $Fe^{2+}$ m mol./l. | $Fe^{3+}$ m mol./l. | $SO_4^{2-}$ m mol./l. | $SO_4^{2-}/Fe$ total |
|---|---|---|---|---|
| 1,2 | 107 | 95,8 | 340 | 1,68 |
| 1,2 | 182 | 80 | 535 | 2,04 |
| 1,8 | 15,0 | 9,5 | 46,4 | 1,89 |
| 1,8 | 22,7 | 0 | 42,2 | 1,86 |
| 2,2 | 9,3 | 0,7 | 19,4 | 1,94 |
| 3,0 | 5,0 | 3,8 | 20,1 | 2,28 |

3) S. Ohashi, *J. Chem. Soc. Japan, Pure Chem. Sec.* (*Nippon Kagaku Zasshi*), **74**, 845 (1953).

4) T. Hamachi et H. Goto, *Bull. Geol. Survey Japan*, **6**, 265 (1955).

co-existantes. Au laboratoire on effectue le barbotage de l'air, mais une agitation violente de solution est plutôt rare dans la nature, par conséquent l'hydrogène sulfuré ne sera pas chassé hors de solution, même s'il s'est formé. D'ailleurs la relation entre le pH et le rapport de $SO_4^{2-}$/Fe peut varier selon la manière d'introduction de l'air.

Dans le Tableau VI, on trouve qu'il y a une quantité considérable de fer trivalent dans les eaux, et que l'acidité des eaux consiste en acide sulfurique, ce qui n'est pas pareil aux conditions d'expérience où l'acidité consiste en acide chlorhydrique. Il faut qu'on tienne compte de la présence du fer trivalent et de l'acide sulfurique pour l'explication complète du phénomène de désagrégation des minerais sulfurés. Toutefois il est d'une signification particulière qu'on a pu ici reproduire d'une façon réduite le phénomène de désagrégation.

L'auteur exprime ses remerciements sincères à Monsieur le professeur K. Noguchi qui a bien voulu lire cet essai et lui donner des conseils utiles, et particulièrement à Monsieur H. Kamiya dont le concours aimable et l'encouragement étaient indispensables pour la réalisation de ce travail. Il remercie également Monsieur le professeur T. Watanabe et Monsieur le docteur A. Kato, à l'Université de Tokyo, pour l'examen diffractométrique à rayons X de la chalcopyrite.

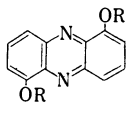
# *The Constitution of the Pigments of Brevibacterium Crystalloiodinum, Sasaki, Yoshida et Sasaki*

By Tosi Irie, Etsuro Kurosawa and Iwao Nagaoka



(Received January 14, 1960)

Sasaki, Yoshida and Sasaki[1] isolated a deep purple, antibiotic pigment and a yellow pigment from the culture medium of *Brevibacterium crystalloiodinum*, Sasaki, Yoshida et Sasaki*, and named them crystalloiodinine A and B, respectively. The name of crystalloiodinine was proposed on account of the purple pigment resembling to iodinine[2].

The present paper is concerned with the study on the structure of these pigments, which were sent by Professor Yuji Sasaki, to whom the authors' thanks are due. It has been established that crystalloiodinine A is identical with iodinine, *i.e.*, 1, 6-dihydroxyphenazine di-*N*-oxide (I), and crystalloiodinine B is 1, 6-dihydroxyphenazine (II: R=H).

(I)

(II)

The purple pigment, isolated from the culture medium, was purified by repeated recrystallizations from chloroform or dioxane; its homogeneity was indicated by the fact, that it gives a single blue band on alumina chromatogram. Crystalloiodinine A, $C_{12}H_8O_4N_2$, was thus obtained in deep purple prisms with coppery lustre, m. p. 230°C (decomp.). It dissolves in aqueous sodium hydroxide to a blue solution, and separates in purple crystals when the alkaline solution is acidified. It shows greenish coloration in ethanol with ferric chloride. The ultraviolet spectrum in chloroform shows maxima at 291 m$\mu$ ($\log \varepsilon = 5.1$) and 355 m$\mu$ ($\log \varepsilon = 3.9$) (Fig. 1); and the infrared spectrum exhibits absorptions due to a bonded hydroxyl group at 3400 $cm^{-1}$ and that of *N*-oxide group at 1285, 1160 and 1025 $cm^{-1}$ (Fig. 2). The infrared spectrum and certain chemical properties[1] indicated, that the pigment closely resembles iodinine[2-6]. Accordingly, crystalloiodinine A

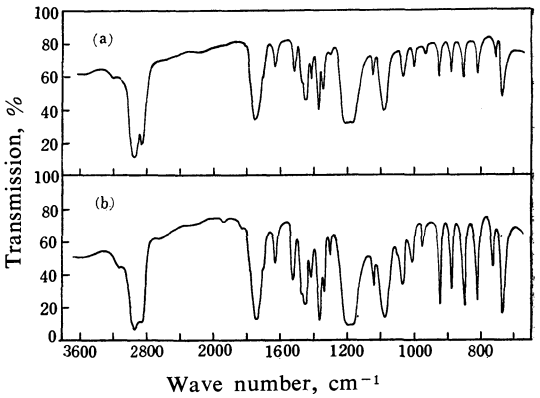

Fig. 4. IR spectra in nujol of (a) diacetate of crystalloiodinine B and (b) 1, 6-diacetoxyphenazine.

material has been identified as 1, 6-dihydroxyphenazine[7] as described below.

The yellow pigment, isolated from the culture medium, was also purified by the chromatographical method and recrystallization from benzene or sublimation under reduced pressure. Crystalloiodinine B, $C_{12}H_8O_2N_2$, was obtained in golden yellow plates, m. p. 273~4°C. It dissolves in aqueous sodium hydroxide to a purplish-red solution and separates in yellow crystals on acidification of the alkaline solution. It shows greenish coloration in ethanol with ferric chloride. The ultraviolet spectrum in ethanol shows maxima at 274 mμ (log ε=5.1) and 370 mμ (log ε=3.6) (Fig. 1); and the infrared spectrum exhibits absorption due to a

** The ultraviolet spectrum does not agree with that shown in the literature.[2]

7) I. Yoshioka and Y. Kidani, ibid., 72, 847 (1952).

hydroxyl group at 3390 $cm^{-1}$, but does not exhibit an *N*-oxide band (Fig. 3). Diacetate of this pigment, $C_{16}H_{12}O_4N_2$, was obtained in pale yellow needles, m. p. 234°C (the ultraviolet and infrared spectra are shown in Figs. 1 and 4, respectively). Thus, by the mixed melting point method and by comparison of the absorption spectra of the pigments and of their diacetates, it has been established that crystalloiodinine B is identical with the above reduction product of crystalloiodinine A and with 1, 6-dihydroxyphenazine.

It is possible to assume that 1, 6-dihydroxyphenazine, which has not hitherto been isolated from any natural source, plays the role of a precursor of iodinine[1].

## Experimental

**Isolation of the Pigments. (1) Purple Pigment, Crystalloiodinine A.**—The bacteria were incubated in the broth containing 1% glycerine. The cultures were shaken at 30°C for 5 days, during which deep purple crystals developed. Water was added to the cultures and shaken, and the washings were allowed to stand. After 24 hr. the suspension of bacteria was decanted from precipitated pigment. Several treatments were sufficient to remove the pigment. The crude pigments were filtered and extracted in a Soxhlet apparatus with chloroform. On concentration, the pigment separated as purple prisms with coppery lustre; it was recrystallized from chloroform or dioxane, m. p. 230°C (decomp.). Qualitative tests showed the pigment to contain nitrogen; sulfur and metals were absent.

Found: C, 58.61; H, 3.43; N, 11.42. Calcd. for $C_{12}H_8O_4N_2$: C, 59.02; H, 3.30; N, 11.48%.

It was slightly soluble in chloroform, carbon disulfide, petroleum ether, glacial acetic acid, acetone, dioxane and benzene, but not soluble in water, ethenol, nor ether. It was soluble in concentrated sulfuric acid with blue-greenish coloration, and also in aqueous sodium hydroxide with blue coloration. It showed greenish coloration in ethanol with ferric chloride. It dissolved in glacial acetic acid to give a red solution, which on warming with the addition of 10% potassium iodide liberated iodine.

This compound was found to be identical with 1,6-dihydroxyphenazine di-*N*-oxide, which was synthesized after Yoshioka and Kidani[6], by the mixed melting point method and by comparison of their absorption spectra.

(2) **Yellow Pigment, Crystalloiodinine B.**—The water layer obtained by decantation to remove crystalloiodinine A, was acidified by hydrochloric acid and extracted with ether. After evaporation of the ether, black gruel was obtained. This was treated with a small amount of chloroform and filtered. Dark brown crystals were boiled with benzene and filtered. Evaporation of the solvent afforded yellow crystals, which were recrystallized from benzene or sublimated under reduced pressure. Golden yellow plates were obtained, m. p. 273~4°C.

Found: C, 67.98; H, 3.53; N, 13.12. Calcd. for $C_{12}H_8O_2N_2$: C, 67.97; H, 3.80; N, 13.28%.

This material was soluble in benzene, alcohol, and ether. It was soluble in concentrated sulfuric acid with greenish coloration and also in aqueous sodium hydroxide with purplish-red coloration. It showed greenish coloration in ethanol with ferric chloride.

This compound was identified as 1,6-dihydroxyphenazine[7] by the mixed melting point method and by comparison of absorption spectra with an authentic specimen.

**Reduction of Crystalloiodinine A.**—The pigment (0.6 g.), platinum oxide (0.6 g.) and absolute ethanol (50 cc.) were shaken in hydrogen (1 atm.) for 24 hr., during which the pigment completely dissolved. Catalysts were then filtered off. On being exposed to air, the color of the filtrate changed soon from pale orange to yellow. This meant, that the hydrogenation yielded the dihydrophenazine compound and it was oxidized by air to the corresponding phenazine derivative. After evaporation of the solvent under reduced pressure, dark brown crystals were obtained. On purification by recrystallization from benzene or sublimation under reduced pressure, golden yellow plates were yielded, m. p. 273~4°C. This material was found to be identical with 1,6-dihydroxyphenazine and crystalloiodinine B, by the mixed melting point method and by comparison of the absorption spectra.

Found: C, 67.48; H, 3.45; N, 13.08. Calcd. for $C_{12}H_8O_2N_2$: C, 67.97; H, 3.80; N, 13.28%.

**Acetylations of the Reduction Product and Crystalloiodinine B.**—The compound (50 mg.), pyridine (5 cc.), and acetic anhydride (1 cc.) were refluxed for 2 hr. The solvent was removed under reduced pressure and the residue was recrystallized from ethanol. Pale yellow needles were obtained, m. p. 234°C. This compound was found to be identical with an authentic specimen of 1,6-diacetoxyphenazine (II: $R=COCH_3$) by the mixed melting point method and by comparison of the absorption spectra.

Found: C, 64.58; H, 3.86; N, 9.50. Calcd. for $C_{16}H_{12}O_4N_2$: C, 64.86; H, 4.06; N, 9.46%.

The authors are indebted to Mr. Y. Ichinoe for measurements of absorption spectra and to Mr. H. Homma of the Institute of Physical and Chemical Research, Tokyo, for microanalyses.

# *Dilatometric Study on Transition Phenomena of Various Polyethylenes with Different Degree of Chain Branching*

By Kōji TANAKA

(Received January 26, 1960)

Much interesting work has been done about the effect of chain branching of polyethylene on its physical and chemical properties. It is well known that branches in ordinary high-pressure polyethylene are of two types, short chain and long chain branchings. According to Roedel[1] short chain branching has the most marked effect on such properties as melting point, yield point, bending modulus, hardness, and vapour permeability, while long chain branching has a marked effect on melt flow and viscoelastic properties. Richards[2] presented data on the relation between the degree of crystallinity and the degree of short chain branching in a series of polyethylenes, and Sperati et al.[3] gave quantitative relations between density, degree of chain branching, and degree of crystallinity, and also between density and many other physical properties.

An early study of polyethylene by volume dilatometry was carried out by Boyer and Spencer[4]. They found melting points at 103°C and in the neighborhood of 115°C for different polyethylenes. Hunter and Oakes[5] reported from the volume measurement of a number of polyethylenes in the range from 0° to 170°C that the percentage of crystalline part did not change up to about 70°C, but thereafter fell more and more rapidly until the substances became wholly amorphous at a temperature depending on the nature of the specimen and that density of molten polyethylene showed little dependence on average molecular weight, but the temperature at which crystalline material first appeared on cooling was raised by increase in molecular weight. Mandelkern and his co-workers[6] presented the results of a study of volume-temperature behavior and melting temperatures of linear polymethylene and highly branched polyethylene. For polymethylene a well defined first order transition or melting temperature was found at 136.5±0.5°C and 70% of melting occurred in only a three to four degree interval, while for branched polyethylene the melting temperature was 115°C and the melting range considerably extended in comparison with the linear polymethylene. Similar results were reported by Nielsen[7] and recently by Marker[8] as for the melting of polyethylene. Grams and Gaube[9] showed that melting temperature existed between 124° and 133°C for low-pressure polyethylene and between 104° and 111°C for high-pressure polyethylene. According to the results by Hunter and Oakes, and by Nielsen, specific volumes above melting point were equal for various polyethylenes at the same temperature, but according to Grams and Gaube high-pressure polyethylene had higher specific volume than low-pressure polyethylene. Gubler and Kovacs[10] determined the specific volume of three samples (high-pressure, Ziegler and Marlex) dilatometrically between −38.8° and 170°C after various heat treatments, and showed the variation of the degree of crystallinity with temperature, the size of the polyethylene crystal and the state of the distribution of the crystal. About the specific volume above melting point they also showed that all the polyethylenes had the equal specific volumes at the same temperature regardless of the properties of polyethylenes. Moreover they showed that the cubic expansion coefficient changed at the temperature between −20° and −25°C for high-pressure polyethylene and Ziegler polyethylene, which was well consistent with the result presented by Danusso et al.[11]

Now, according to Hunter and Oakes as is mentioned already, molecular weight is given as a factor affecting the properties such as melting point, crystallizing temperature, that is, the temperature at which crystalline material first appears on cooling, and premelting phenomenon. However, by the appearance of polyethylene made by the low-pressure process and from the

several reports above quoted, it seems that chain branching must be regarded as a more significant factor affecting those properties. But at present detailed data about this point are not yet available.

Therefore a series of measurements were performed in the present paper about melting point, crystallizing temperature, premelting phenomenon, glass transition temperature, and degree of crystallinity at 25°C for various polyethylenes with different degrees of short chain and of long chain branchings. The results obtained showed that the temperature and degree crystallinity were raised with the increase of short chain branching. About the effect of long chain branching, no remarkable result could be found, since the amount of long chain branching contained in the sample used was very small.

**Sample.**—Samples used in this investigation were Marlex 50-9, Ziegler polyethylenes, and eight kinds of high-pressure polyethylenes. These high-pressure samples were provided by the courtesy of Dr. Hammer of E. I. du Pont de Nemours and Company. These samples, the molecular parameters of which are listed in Table I, were different in molecular weight, melt index, degree of short chain branching and that of long chain branching. Marlex 50-9 and Ziegler polyethylene were commercially available polymers made by Phillips Petroleum Company and The Dow Chemical Company, respectively. As the molecular parameters for these samples were not available, the degree of short chain branching was determined by the infrared method by using the 1370 and 1378 $cm^{-1}$ bands according to Slowinski[12]. It was found to be 0.25 for Marlex 50-9 and 0.4 for Ziegler polyethylene.

TABLE I. THE MOLECULAR PARAMETERS[a] FOR POLYETHYLENE SAMPLES

| Sample | Melt index | $M_n \times 10^{-3}$ | $N_c$[b] | $N_w$[c] |
|---|---|---|---|---|
| A[d] | 0.2 | 34 | 1.6 | 20 |
| B | 2.1 | 32 | 1.6 | 18 |
| C | 2.1 | 21 | 2.2 | 27 |

d) These (A to H) are high-pressure polyethylenes.
e) This was determined here by the infrared method.

## Experimental

An experiment was carried out by volume dilatometry on which there was detailed description by Bekkedahl[13].

The dilatometer used in this experiment was made of Pyrex glass (as the volume expansion coefficient 0.00001/deg. was used) and consisted of three parts (Fig. 1, a). They were connected together tightly

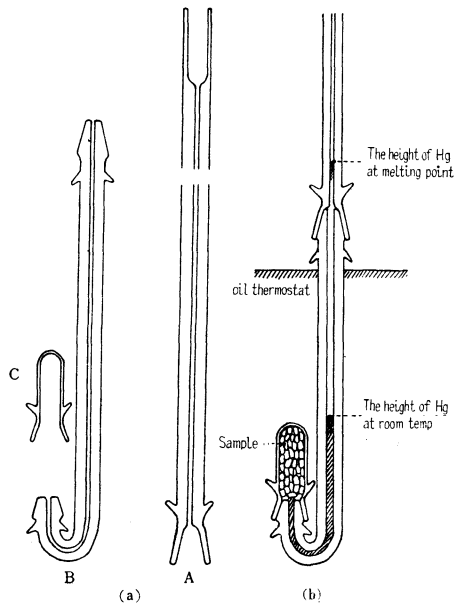

Fig. 1. Dilatometers: (a) for the measurements from about −40° to 150°C. (b) for the measurements above melting point.

with springs and in the case of measurement the dilatometer was immersed into the bath up to the height a little below the ground joint connecting the parts A and B. Prior to the experiment the capillary of part A was calibrated. After the dried and weighed sample was put in part C and this part was combined with part B, they were weighed, and then they were connected to the apparatus shown in

12) E. J. Slowinski, Jr., H. Walter and R. L. Miller, ibid., **19**, 353 (1956).
13) N. Bekkedahl, *J. Research Natl. Bur. Standards*, **42**, 145 (1949).

Fig. 2 and all the ground parts greased with silicone grease. Mercury as the confining liquid was inserted by distillation under vacuum of $10^{-3}$ mmHg and finally the total weight was weighed again in order to known the amount of mercury. As this amount of mercury was insufficient for the measurement, the adequate amount of mercury was weighed and added after parts A and B were combined together. The specific volume of the sample at the fixed temperature was calculated from the weights of the sample and of mercury and the total volume of parts B and C of the dilatometer which had been determined by using mercury in advance. In the case of calculation, corrections for the emergent stem and the expansion or contraction of the glass of the dilatometer were made according to Bekkedahl.

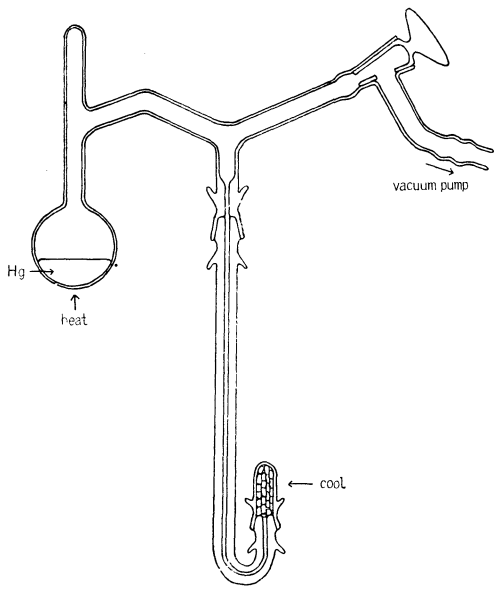

Fig. 2. The apparatus for insertion of Hg by vacuum distillation.

As is well known, the specific volume of polyethylene is dependent on temperature, as well as on its crystallinity and the amorphous region may have the possibility of further crystallization at temperature above its glass transition temperature, if the sample is not sufficiently crystallized. Therefore it is naturally expected that the volume-temperature curve above the glass transition temperature obtained by heating such a specimen contains both effects of the increase of volume by thermal expansion and the decrease of volume by further crystallization, which will obstruct the reproducibility of the curve and complicate the analysis of it. In order to eliminate such disadvantages, volume-temperature curves were taken for sufficiently crystallized samples. Sufficient crystallization of samples was carried out as follows. (1) The height of mercury in the capillary of the dilatometer containing the untreated polyethylene and mercury was recorded at 25°C exactly to 0.001 cm. (2) The dilatometer was gradually heated in the oil thermostat up to 150°C and kept at that temperature for about three hours to melt the sample in the dilatometer. (3) It was then cooled down slowly at the rate of 1/5°C per min. to 25°C. (4) The height of the mercury column was again recorded at 25°C. In this case the height was lower than that in the former case, which showed that the volume of the sample decreased by further crystallization by this treatment. Similar operations were performed, the time of melting being lengthened or shortened and the cooling rate being slower or faster, and also the dilatometer being kept for several hours at the temperature where crystallization occurred, on the way back to 25°C from 150°C at the rate of 1/5°C per min. The height of the mercury column thus obtained at 25° was equal to or higher than that obtained by the already mentioned way. As the result it is considered that the polyethylene sample can be crystallized to the highest degree by this procedure, and all the most highly crystallized specimens of polyethylene used for this investigation were obtained in this way. Volume temperature measurements were repeatedly performed in two temperature ranges, from 40°C to around freezing point of mercury and from 20° to 150°C. For measurements below 40°C a Dewar vessel containing toluene was used as a bath. The bath temperature was lowered about 5°C at a time by throwing pieces of dry-ice into the bath and it was kept at constant temperature for 15 min. by controlling the fluctuation of temperature $\pm 0.05$°C. After that the bath temperature and the height of mercury column which corresponded to the volume change by cooling of the dilatometer contents, polyethylene and mercury, were recorded. It was confirmed that 15 min. was sufficient for polyethylene to attain the equilibrium temperature within the experimental error. Similar operations were taken down to the melting point of mercury. After the measurement at the lowest temperature was finished, the bath temperature was raised by inserting nichrom wire into the bath and measurements were performed in quite the same way up to 40°C. The temperature control of the bath was carried out by letting toluene chilled below the bath temperature run through the cooling pipe immersed in the bath. The current of chilled toluene was regulated so that it might be turned off or on automatically according to the change of the bath temperature.

The measurements from 20° to 150°C were performed in the oil thermostat which was used for thermal treatment of the sample and carried out in the same way as the measurements below 40°C except in the case of the temperature range around melting point of polyethylene. In the vicinity of the melting point of the specimen the height of mercury column abruptly increased owing to the expansion of the sample by premelting or melting, so the bath temperature was raised 1°C at a time and a sufficiently long time was taken until the sample ceased to expand. When the measurement was finished at 150°C, the dilatometer was kept at the temperature for three hours, and then cooled slowly down to 25°C at the rate of 1/5°C per min. to crystallize sufficiently the sample again, and the experiment was repeated. In this case the measurements were carried out around the melting point of the sample at a one degree intervals, in order to

know exactly the crystallizing temperature. Experiments of these kinds were repeated two or three times for each sample.

## Result and Discussion

The specific volume-temperature curves from around −40° to 150°C for the most highly crystallized polyethylenes are shown in Fig. 3.

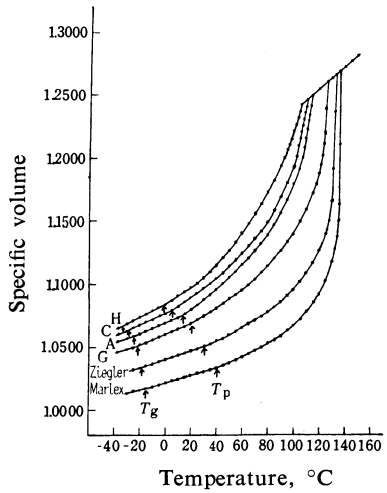

Fig. 3. Specific volume-temperature curves of the most highly crystallized polyethylenes from about −40° to 150°C. Those of samples B, D, E and F are omitted to avoid confusion.

As was mentioned already, the volume-temperature measurements were performed separately, covering two temperature ranges, below 40°C and above 20°C. The two curves obtained in these temperature ranges coincided perfectly between 20° and 40°C.

As is shown in the figure, the sample having the higher degree of short chain branching has the higher specific volume in the temperature range below melting point. Samples A, B and E which are equal in degree of short chain branching have almost equal values of specific volume at each measured temperature. This results shows that the highest degree of crystallinity of polyethylene is dependent upon the degree of short chain branching as was reported already by Richards. By inferring from the fact that when they are annealed, the unbranched linear polymethylene gets a considerably high degree of crystallinity and the more or less branched polyethylene has a lower one, it is considered that most of the amorphous regions of the most highly crytsallized polyethylene arises from the existence of short chain branching and branch point of long chain branching which disturb the regularity of molecules and keep the molecules from being

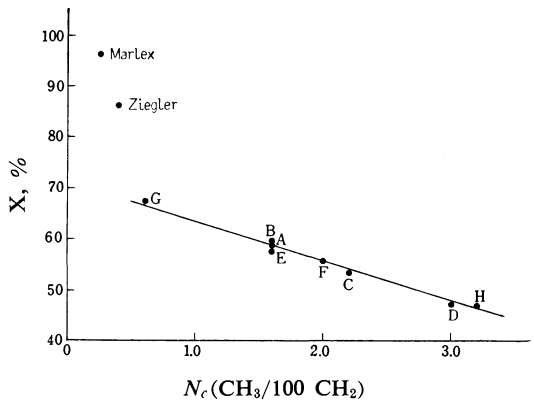

Fig. 4. The relation between degree of short chain branching and degree of crystallinity.

arranged in good order in proportion to their number. Therefore polyethylene containing the larger amount of chain branching is considered to have the poorer degree of crystallinity, even if it has the highest degree of crytallinity.

The highest degree of crystallinity of polyethylene samples at 25°C are illustrated in Fig. 4 as a function of short chain branching. They were obtained transforming the following equation, as was done by Kuroda et al.[14],

$$X=\frac{V-V_l}{V_c-V_l} \qquad (1)$$

where $V$ was the specific volume of the sample directly obtained from the volume-temperature measurement, $V_l$ the specific volume of purely amorphous region, and $V_c$ that of the entirely crystalline region. According to Gubler and Kovacs, $V_l$ and $V_c$ are expressed as follows;

$$V_l=1.170+9\times10^{-4}(T-25) \qquad (2)$$

and

$$V_c=1.0255+3\times10^{-4}(T-25) \qquad (3),$$

where $T$ shows temperature in °C. The relation between $V$ and $T$ at any degree of crystallinity is shown by a straight line by putting $V_l$, $V_c$ above presented and optional value for $X$ into the equation (1). For the values 0.0, 0.1, 0.2, ..... 0.9 and 1.0 of $X$, a series of $V$—$T$ line was obtained (Fig. 5) and from these straight lines and specific volume-temperature curve of polyethylene the degree of crystallinity was estimated.

A curve similar to that shown by Richards was obtained as a whole between the degree of crystallinity and the degree of short chain branching. According to the equations presented by Sperati et al. which showed the relation

14) T. Kuroda et al., given out in the symposium on polyethylene in Tokyo, November 1959.

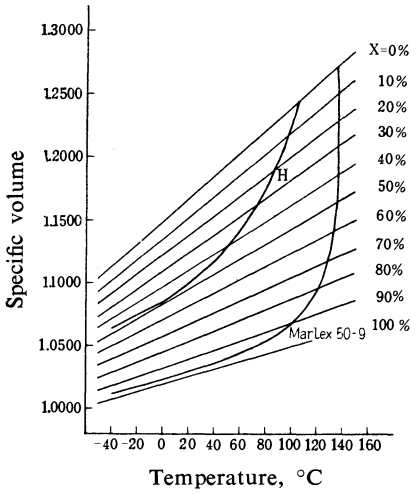

Fig. 5. The relationship between specific volume and temperature in various degree of crystallinity from which the degree of crystallinity of polyethylene was estimated.

between the density and the degree of crystallinity and that between the density and short chain branching, the linear relation is formed between the degree of crystallinity and the degree of short chain branching in the range of $CH_3$/100C from 0.4 to 5.0 and within the accuracy of $\pm 1.0\%$. In this experiment the linear relation was also obtained in the range of degree of short chain branching within the same accuracy shown by Sperati et al., though the slope of the straight line differed from that obtained by them. Marlex and Ziegler polyethylenes have a remarkably high degree of crystallinity in comparison with high-pressure polyethylene, which is probably due to the difference in the nature of their short chain branching reported by Willbourn[15]; that is, according to him short chain branches of high-pressure polyethylene are ethyl and butyl branches and those of Marlex and Ziegler polyethylene are methyl, and methyl and ethyl, respectively, which are shorter than butyl. Therefore these low-pressure polyethylenes are considered to have a higher degree of crystallinity. As is mentioned already it is expected that the increasing amount of branch point of long chain branching lowers the degree of crystallinity. In this experiment, however, no appreciable result was obtained in this respect. This is probably due to the very small amount of long chain branching.

Above the melting point the values of specific volume of all samples at each temperature were equal within the experimental error. The calculation of specific volume by volume dilatometry is accompanied by a larger error as the difference between bath temperature and room temperature becomes larger. In order to reduce the error, volume-temperature measurements were performed in the temperature range from the melting point to 150°C by using a larger amount of the sample than that previously used. For this experiment the bulb (part C in Fig. 1, a) and the inside diameter of the capillary in part B were made large. As part A, the capillary of the equal diameter as previous was used, so as not to reduce the accuracy of the measurement. The amount of mercury inserted was adjusted so that its top might be at the middle part of part B at room temperature, and measurements were started after the bath temperature was raised and the top of the mercury column reached a height a little above the joint connecting parts A and B at around the melting point of the sample (Fig. 1, b). The total volume up to a height a little above the joint was measured by using mercury in advance and in the case of calculation, corrections were made in quite the same way as previously. Results thus obtained for low-pressure and high-pressure polyethylenes were almost equal and well consistent with the result shown by Gubler and Kovacs in specific volume and the degree of cubic expansion, and also with those by Danusso et al.[16] for a polyethylene and a polypropylene which has methyl branch every second carbon. From these results it was confirmed that the volume-temperature relation above melting point was equal regardless of the kind of polyethylene. These results

|---|---|---|---|---|---|---|
| Marlex 50-9 | 0.25 | 135.5 | 125.0 | 40.5 | −16.0 | 2.5 |
| Ziegler | 0.4 | 132.1 | 122.0 | 30.8 | −19.0 | 6.1 |
| G | 0.6 | 122.8 | 113.7 | 21.5 | −22.2 | 11.8 |
| A | 1.6 | 113.2 | 106.8 | 13.3 | −25.2 | 19.3 |
| B | 1.6 | 113.5 | 108.5 | 10.9 | −25.8 | 21.0 |
| E | 1.6 | 113.5 | 105.6 | 11.7 | −26.3 | 19.8 |
| F | 2.0 | 111.6 | 102.9 | 4.5 | −27.3 | 22.1 |
| C | 2.2 | 109.8 | 103.2 | 5.5 | −28.8 | 22.8 |
| D | 3.0 | 108.1 | 100.8 | −1.8 | −32.5 | 30.7 |
| H | 3.2 | 105.1 | 94.1 | −2.0 | −34.0 | 32.1 |

led to the following equation by using the method of least square;

$$V_{sp}=9\times10^{-4}T+1.1480$$

As is shown in Fig. 6 for Marlex 50-9 and high-pressure polyethylene H as examples, the specific volume-temperature curve of polyethylene has several transition points peculiar to the kind of polyethylene, that is, a melting point $T_m$, a crystallizing point $T_c$, a glass transition temperature $T_g$, and a premelting point $T_p$, at which the volume-temperature relation above $T_g$ deviates from the straight line and polyethylene crystals are considered to begin to melt. Their temperatures became higher with the decrease of degree of short chain branching. They are listed in Table II in the order of degree of short chain branching. The curvature of the curve between premelting point and melting point which showed the premelting process grew larger and the curve came to show almost typical first order transition as the amount of short chain branching became smaller. The premelting phenomenon is considered to be due to the variety of the size of crystalline regions in polyethylene which have different melting points according to their size. According to Gubler and Kovacs the crystalline region of low-pressure polyethylene is on the whole considerably larger than that of high-pressure polyethylene. Therefore it is considered that low-pressure polyethylene begins and finishes melting at the higher temperature and sharply at that. In order to show quantitatively the difference of curvature of these curves, $\Delta T$ was given in Table II for each sample. Here, $\Delta T$ represents the temperature difference beween the melting point and the point at which half of the difference between specific volume at the premelting point and that at the melting point is shown (Fig. 6). The values of $\Delta T$ were plotted as a function of short chain branching in Fig. 7. Among high-pressure polyethylenes it seems that these values increase with the increasing amount of short chain branching and between these two quantities

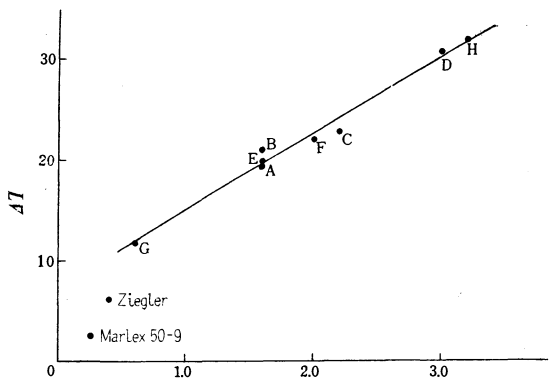

Fig. 7. The relation between short chain branching and the temperature difference between $T_m$ and the point where half of the difference in specific volumes at $T_p$ and $T_m$ are shown.

the following linear relationship is obtained approximately;

$$\Delta T=7.7N_c+7.3$$

According to Hunter and Oakes, melting point, crystallizing temperature and premelting phenomenon were dependent upon the molecular weight of the sample. In this experiment the values of $T_m$, $T_c$, $T_p$ and $T_g$ apparently rose with the increase of molecular weight on the whole. But sample E showed almost equal values of these temperatures to those of samples A and B, though it had lower molecular weight by about 10,000 than samples A and B, and it was the same with samples C and F, that is, sample F which is almost equal in the amount of short chain branching to sample C and in molecular weight more than double that of sample C, showed almost equal values of these temperatures to those of sample C. Therefore it seems that molecular weight has almost no or a very small effect on these temperatures in comparison with short chain branching.

The glass transition temperature appears at

present to be considered −21°C regardless of molecular weight, degree of crystallinity and degree of chain branching from the experimental results by Danusso et al., though there had been presented different values by other researchers previously. The results obtained in this experiment, however, showed that the glass transition temperature of polyethylene was dependent upon the degree of short chain branching. The details about this will be presented later.

As quenched polyethylene has a very low degree of crystallinity and crystalline regions of rather small size are considered to be distributed in it, it is expected that quenched low-branched polyethylene melts in the process similar to that of highly-branched polyethylene. Therefore volume temperature measurements were carried out by using quenched Marlex 50–9. Quenching of the sample was performed by immersing the dilatometer containing the sample and mercury into the toluene-bath cooled at −40°C after it was kept at 150°C for about three hours. The volume-temperature curve for Marlex 50–9 treated in this way is shown in Fig. 8 with the curve for the most highly crystallized Marlex 50–9. This quenched sample had a low degree of crystallinity of 38.6% at 25°C. The result as expected, however, was not obtained, but the curve showing sharp melting phenomenon was obtained, which is probably due to further crystallization which is occurring slowly on raising temperature. Similar

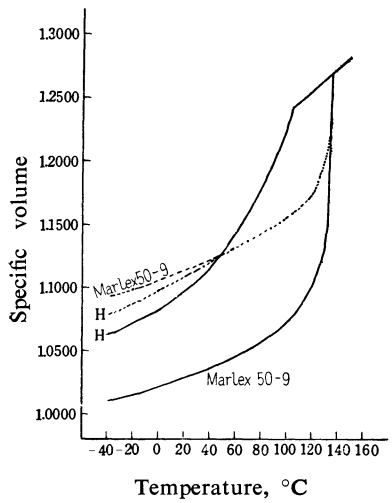

Fig. 8. Volume-temperature curves of Marlex 50–9 and high-pressure polyethylene H obtained for the most highly crystallized and quenched samples.

measurements were performed by using sample H quenched in the same way. The volume-temperature curve was also illustrated in Fig. 8 with the curve for the most highly crystallized sample H. The degree of crystallinity of this quenched sample was 40.0% at 25°C. The curve for quenched and the most highly crystallized Marlex 50–9 do not overlap with each other up to just below melting point, while the curve for quenched sample H falls on the curve for the most highly crystallized sample at around 50°C. From these results it is considered that further crystallization of the quenched sample occurs at a lower temperature and more easily in highly-branched polyethylene than in low-branched polyethylene. Probably short chain branchings of polyethylene expand the average intermolecular distances in the amorphous regions and weaken the intermolecular interaction, and as a result the molecules can begin to move easily at low temperature.

## Summary

The specific volumes of various kinds of polyethylenes with the different degrees of short chain and long chain branchings were measured by volume dilatometry in the temperature range from −40° to 150°C, and volume-temperature curves were determined. Polyethylene having the higher degree of short chain branching had the higher specific volume at any temperature below the melting point. Above the melting point specific volumes of all the polyethylenes were equal at the same temperature. Melting point, crystallizing temperature, premelting point, and glass transition temperature were raised with the decrease of degree of short chain branching. The curvature of the curve showing premelting process grew large as the amount of short chain branching contained in the sample became small, and came to show the typical first order transition phenomenon.

The author is indebted to Professor Masatami Takeda for his helpful suggestions and discussion. He also thanks Dr. C. F. Hammer of E. I. du Pont de Nemours and Company for providing the samples of polyethylene. It is also a pleasure to aknowledge the assistance in experimental work given by Miss Masako Yoshida.

# *Stability of Complexes of Several Carboxylic Acids Formed with Bivalent Metals**

By Motoo YASUDA, Kazuo YAMASAKI and Hitoshi OHTAKI**

(Received February 4, 1960)

Numerous reports have been published on the stability of various complexes formed between bivalent metals and carboxylic acids; however, no extensive study regarding these complexes has ever been performed in any one laboratory under identical experimental conditions. Experiments under identical conditions are of primary importance because the respective values of the stability of these complexes and the differences between these values are quite small; therefore, a precise comparison of these stability constants is possible only when the values determined under the same conditions are available.

In this report the stability of various complexes formed between carboxylic acids and bivalent metals having the ratio of 1 : 1 was determined by using the pH titration method. The monobasic and dibasic acids containing the COOH groups alone were studied, i. e. the acids containing the OH groups in addition to the COOH group were excluded. Thus tartaric acid or similar acids were not studied because of their rather complicated bahavior in a solution.

## Experimental

**Materials.**—The nitrates of lead, copper, cadmium, zinc and nickel were chemicals of the analytical grade. The carboxylic acids used are listed in Table I. They were reagents of the analytical or highest grade available.

**Procedure.**—The pH values were measured with a pH meter having a glass electrode made by Horiba and Co. The temperature of the measurement was 25°C and the ionic strength of the solution was maintained at 0.1 by the addition of sodium perchlorate; however, in some cases where the stability of the complex was small such as in the nickel benzoate complex the ionic strength of the solution was kept at 0.1 by nickel nitrate itself without the addition of sodium perchlorate.

The concentration of the metal nitrate was kept generally higher than that of the carboxylic acid to prevent the formation of a complex having the metal to ligand ratio of 1 : 2. The concentrations used were as follows:

Monobasic acids

| | | | |
|---|---|---|---|
| Lead nitrate | 0.004~0.02M | Acid | 0.004~0.009M |
| Copper nitrate | 0.006~0.015 | 〃 | 0.004~0.009 |
| Cadmium nitrate | 0.03 | 〃 | 0.012 |
| Zinc nitrate | 0.034 | 〃 | 0.012 |
| Nickel nitrate | 0.026 | 〃 | 0.009~0.012 |

Dibasic acids except diglycolic and thiodiglycolic acids

| | | | |
|---|---|---|---|
| Lead nitrate | 0.004M | Acid | 0.002M |
| Copper nitrate | 0.003 | 〃 | 0.002 |
| Cadmium nitrate | 0.006 | 〃 | 0.01 |
| Zinc nitrate | 0.007 | 〃 | 0.01 |
| Nickel nitrate | 0.01 | 〃 | 0.01 |

Diglycolic and thiodiglycolic acids

| | | | |
|---|---|---|---|
| Lead nitrate | 0.002M | Acid | 0.001M |
| Cadmium nitrate | 0.002 | 〃 | 0.001 |
| Zinc nitrate | 0.002 | 〃 | 0.001 |
| Copper nitrate | 0.0015 | 〃 | 0.001 |
| Nickel nitrate | 0.0026 | 〃 | 0.001 |

To convert the hydrogen ion activity into its concentration in the solution, the value 0.83 suggested by Kielland[1] was used.

## Results

**Acid Dissociation Constant.**—If the dibasic acid is represented as $H_2A$, the acid dissociation constants to be determined may be expressed as

$$K_1 = \frac{[H^+]\,[HA^-]}{[H_2A]} \qquad (1)$$

and

$$K_2 = \frac{[H^+]\,[A^{2-}]}{[HA^-]} \qquad (2)$$

where [ ] expresses the concentration in mole per litre. The values of the dissociation constant were determined by titration with alkali and they are given in Table I[2]. For some dicarboxylic acids such as succinic, itaconic, glutaric, adipic, diglycolic and thiodiglycolic acids the first and second dissociation occurred simultaneously and the method of successive approximation was used to calculate their dissociation constants.

**Stability Constant.**—The values of the stability constant of the complexes formed are expressed by

* Presented at the XVIIth International Congress of Pure and Applied Chemistry held at Munich in 1959.

| 13 | Thiodiglycoic acid | 3.15 | 4.13 |

$$k_1=\frac{[MA]}{[M^{2+}]\,[A^{2-}]} \tag{3}$$

Under the conditions in the present experiments, the formation of complexes having a metal to ligand ratio of 1:2 is negligible. Therefore the species present in the solutions are $H^+$, $M^{2+}$, MA, $A^{2-}$, $HA^-$, $H_2A$ and $OH^-$ except in the case of sodium and perchlorate ions which were added in order to keep the ionic strength of the solution constant. Then the following relations exist between the total concentrations of acidic hydrogen, acid and metal for which the symbols $C_H$, $C_A$ and $C_M$ are used respectively.

The concentration of $OH^-$ is negligible in acid solutions.

Thus

$$C_H=[H^+]+[HA^-]+2[H_2A] \tag{4}$$

$$C_A=[A^{2-}]+[HA^-]+[H_2A]+[MA] \tag{5}$$

$$C_M=[M^{2+}]+[MA] \tag{6}$$

By substituting Eqs. 1 and 2 into 4, Eq. 7 may be obtained

$$C_H-[H^+]=\frac{[H^+]\,[A^{2-}]}{K_2}+\frac{2[H^+]^2[A^{2-}]}{K_1K_2} \tag{7}$$

From the pH measurements of the solutions $[H^+]$ was calculated. By substituting $[H^+]$ into 7 $[A^{2-}]$ was found and then [MA] and $[M^{2+}]$ were obtained from 5 and 6 combined with 1 and 2 and finally $k_1=[MA]/[M^{2+}]\,[A^{2-}]$ was found. The logarithmic values of the stability constant thus obtained are given in Table II. For monobasic acids the calculations are more simple than for dibasic acids shown above.

The stability of these complexes under somewhat different experimental conditions of temperature and ionic strength have been previously determined by several other authors, as listed in Table III:

If the differences in temperature and ionic strength of the solution are taken into consideration, their results agree fairly well with the results of the present study.

From the results shown in Table II the acids studied are divided into three groups:

1) Dibasic acids forming a seven membered or a larger chelate ring and having no double bonds in the chelate ring. Monobasic acids also belong to this group.

2) Dibasic acids forming a six membered ring such as malonic acid and those having double bonds in the chelate ring such as maleic and citraconic acids.

3) Dibasic acids seeming to act as tridentate chelating agent. Diglycolic and thiodiglycolic acids belong to this group.

It is obvious from Table II that the acids of the first group form complexes whose stability constants follow the order

$$Pb>Cu>Cd>Zn>Ni$$

and that lead shows the highest stability. The values for monobasic acids are nearly

TABLE II. STABILITY CONSTANTS ($\log k_1$)

| | Acids | Pb | Cu | Cd | Zn | Ni |

the same and show only small differences between them. The dibasic acids show higher values than monobasic acids. Both succinic and itaconic acids form seven membered rings, but the stability constants are a little larger for the latter, which has a double bond in the side chain.

The empirical stability order for bivalent metals was proposed by various authors and the order

$$Cu > Ni > Pb > Co,\ Zn$$

found by Mellor and Maley[13] holds with some variations for many O and N type ligands. Irving and Williams[14] pointed out that the order

$$Zn < Cu > Ni > Co > Fe > Mn$$

for the metals of the first transition series held irrespective of the nature of the ligands involved. However, generally the order of stability depends on the nature of ligands, especially when metals of non-transition series are concerned.

The stability constants of more than five hundred ligands have so far been determined, but no example of a ligand showing a high stability for lead has been found except in the case of $\beta$-(*S*-ethyl)mercaptopropionic acid as determined by Irving and Fernelius[15] in a water-dioxane mixture. The order of stability found by them is the same as the present one, i. e. lead showed the highest stability. The highest stability found in the lead complexes of carboxylic acids is, therefore, quite remarkable. The exact reason for the large stability of lead is rather difficult to explain at present.

The above mentioned order in the first group does not hold for the acids in the second group. The complexes of malonic acid which form six membered chelate rings follow the stability order

$$Cu > Ni > Pb > Zn > Cd$$

However, with the other two acids, maleic and citraconic acids which form seven membered chelate rings, copper is the highest in the stability order,

$$Cu > Pb > Cd > Zn > Ni$$

Citraconic acid has a methyl group and its effect seems to decrease somewhat the stability, perhaps due to steric hindrance.

If the size of the chelate ring for one metal is compared, for example, for copper, the stability is highest for malonic acid and it decreases in the following order as the size of the chelate ring increases,

| | |
|---|---|
| malonic acid | six membered ring, |
| succinic acid | seven membered ring, |
| glutaric acid | eight membered ring, |
| adipic acid | nine membered ring. |

If we could determine the stability of oxalic acid complexes which form a five membered ring, it might be interesting. However, under the experimental conditions of the present study, precipitation occurred instantaneously. The stability of oxalic acid complexes given in the literature are few and no data for lead are available.

For the acids in the third group the order of metals are

$Pb > Cu > Zn > Cd > Ni$ for diglycolic acid

and

$Cu > Ni > Pb > Zn > Cd$ for thiodiglycolic acid.

These two acids have rather small values for their acid dissociation constants. On the other hand, the values of their stability constant are large and it seems that they form tridentate complexes with O and S atoms participating in the chelation as Tichane and Bennett[12] pointed out.

In connection with this point, *o*-methoxybenzoic acid was studied to ascertain whether the O atom of the methoxy group participates in the chelation. The values for *o*-methoxybenzoic acid complexes were nearly the same as those of the benzoic acid complexes. This appears to mean that the O atom of the methoxy group has very little relation to the chelation.

Concerning the chelating tendency of various bivalent metals for O and S atoms of similar ligands, several studies have been made on *o*-aminobenzenethiol[16], *β*-mercaptopropionic acid[17], *β*-(*S*-ethyl)mercaptopropionic acid[15] and purine derivatives[18], and zinc was found to form a stronger complex than nickel when sulfur is involved in the metal-ligand bond. However, this is not the case for thiodiglycolic acid, and a more detailed study on ligands containing sulfur is desirable to elucidate this problem.

Finally the use of these dicarboxylic acids as the eluting agent of the metal ions adsorbed on ion exchange resins was investigated. As the acid, adipic acid was chosen, as it showed suitable differences of stability for various metals.

Metal ions were adsorbed on the resin Dowex 50, H-form. Sodium adipate solution of pH 5.2 (0.1 molar solution) was poured into the column. Lead was omitted as it formed a precipitate in the 0.1 molar solution of sodium adipate. The metals in the eluted solution were determined by titration with ethylenediaminetetraacetate. The vertical axis of the graph (Fig. 1) indicates the values proportional to the metal concentration in each fraction (5 ml.) and the horizontal axis the fraction number. The separation between copper, cadmium and zinc is complete, but the separation between zinc and nickel is not. Diglycolic acid was also tested for the eluting agent, but in this case the tailing of each metal was remarkable and the complete separation was difficult.

## Summary

Stability constants of the bivalent metal complexes formed with several mono- and dicarboxylic acids were determined at 25°C and ionic strength of 0.1. For monocarboxylic acids and several dicarboxylic acids having no double bond or forming larger chelate rings than six membered rings the following stability order held: Pb>Cu>Cd>Zn>Ni. It is very remarkable that lead showed the highest stability among bivalent metals.

A part of the expense of the present study was defrayed by a Grant-in-aid for Fundamental Scientific Research from the Ministry of Education.

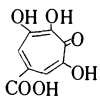
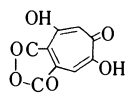
# *Synthesis of Puberulonic Acid*[1]

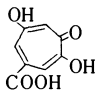


By Tetsuo NOZOE, Kozo DOI* and Tokuro HASHIMOTO**

(Received January 16, 1960)



Puberulonic acid (I) was first isolated, together with puberulic acid (II), by Birkinshaw and Raistrick[2] from cultures of the moulds *Penicillium puberulum* Bainer and *P. aurentio-virens* Biourge. These mould tropolones (I and II) have been reported to have a significant antibiotic activity against various Gram-positive organisms[3]. The structure I for puberulonic acid has been accepted reasonably by the presence of a dicarboxylic anhydride grouping evidenced from the data of the infrared spectrum[4], ultraviolet spectrum[5] and titration[6], and by the decarboxylation of it to puberulic acid[6,7] (II). As other mould tropolones, stipitatonic acid[8] (III) and stipitatic acid[9] (IV) have been isolated from culture of *P. stipitatum* Thom. Of the above four mould tropolones, puberulic acid[10] (II) and stipitatic acid[11,12] (IV) have already been synthesized by Johnson and his collaborators from 1, 2, 4-trimethoxybenzene and diazoacetate.



I

II

III

IV

The present authors have been able to synthesize puberulonic acid (I), the details of which will be reported in this communication.

The starting material used was tropolone-3, 4-dicarboxylic anhydride[13] (V), which had been obtained in a poor yield by alkaline hydrogen peroxide oxidation[14] of purpurogallin, of which synthesis[15] had been completed by Haworth and his co-workers. The structure of the anhydride V had been proved by the conversion of it to benzene-1, 2, 3-tricarboxylic acid with alkali-fusion.

As an approach to the synthesis of puberulonic acid (I), it was adopted, that an introduction of bromine, followed by replacing of the bromine with the hydroxyl group, into the anhydride V, was carried out and that a further brominationhydroxylation process were repeated in the resulted hydroxytropolone-dicarboxylic anhydride (XIII). To the reaction for replacing bromine atom with the hydroxyl group, the Rosenmund method[16], in which *o*-bromobenzoic acid was converted into salicylic acid, was satisfactorily applied.

When 3-bromotropolone (VI) was heated with sodium $\beta$-naphthalenesulfonate in dilute alkaline solution, 3-hydroxytropolone (VII) was obtained in a 40% yield. This fact proves that a normal nucleophilic substitution of the bromine into the hydroxyl group took place in the above reaction, contrary to formation of 4-hydroxytropolone, a *ciné* (abnormal) substitution product, in high temperature hydrolysis of 3-bromotropolone (VI) with 75% potassium hydroxide[17]. Application of similar reaction to 3, 7-dibromotropolone (VIII) afforded in less yield 3, 4-dihydroxytropolone (IX), which was proved to be identical with the compound known as "decarboxylated puberulic acid"[6,18].

Bromination of tropolone-3, 4-dicarboxylic anhydride (V) in acetic acid gave easily 7-bromotropolone-3, 4-dicarboxylic anhydride (X) in a good yield. Heating of the anhydride X in

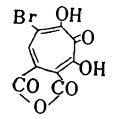
water at 180°C afforded 3-bromo-6-carboxytropolone[19] (XI), a bromination product of 4-carboxytropolone (XII). This fact, together with derivation of 3-hydroxytropolone (VII) from the compound XIII described below, appears to determine the position of the bromine-atom in the molecule X.

V : X=H X : X=Br XIII : X=OH

VI : X=Br VII : X=OH

VIII : X=Br IX : X=OH



XI : X=Br XII : X=H XIV : X=OH

Reaction of the bromo derivative X with sodium β-naphthalenesulfonate in weak alkaline solution for four hours gave 3-hydroxytropolone-4, 5-dicarboxylic anhydride (XIII) in a good yield. The replacement of the bromine-atom in the compound X with hydroxyl group appeared to be more facile than in the cases of 3-bromotropolone (VI) and 3, 7-dibromotropolone (IX), the fact of which indicates probably, that the bromine-atom in the former X is activated by the dicarboxylic anhydride grouping situated at the *p*-position.

It was found, that stipitatonic acid[8a] (III) gives stipitatic acid (IV) under the same condition as that[6] of formation of puberulic acid (II) from puberulonic acid (I). On the contrary, 3-hydroxytropolone derivative XIII did not decarboxylate under the same condition, but caused decarboxylation under heating with water in a sealed tube at 180°C to 5-carboxy-3-hydroxytropolone (XIV), which corresponds to "isostipitatic acid"[10,12], synthesized already by Johnson and others. Subsequent heating of the compound (XIV) at its melting point gave 3-hydroxytropolone (VII). 3-Hydroxytropolone-4, 5-dicarboxylic anhydride (XIII) was also obtained by treatment of the corresponding bromo derivative X with 75% potassium hydroxide or by persulfate oxidation of the anhydride V, the details of which will be reported elsewhere.

It was found, that the monobromination of the hydroxy compound XIII was unexpectedly difficult. Addition of bromine to XIII in acetic acid appeared to result in consumption of about one-half of the calculated amount of bromine, and the successive isolation procedure of the product left only charred matter. This fact recalls an observation of Johnson and others on bromination of isostipitatic acid[10] (XIV). In this series of experiments, however, 7-bromo-3-hydroxytropolone-4, 5-dicarboxylic anhydride (XV) could be obtained by the bromination of XIII in the presence of sodium hydrogen sulfite in a 50% yield.

XV

Fig. 1 shows the ultraviolet absorption spectra of the foregoing four intermediates (V, X, XIII and XV). The absorption maximum near 350 mμ in curves (1) and (2) is respectively split into three absorption peaks in curves (3) and (4), the fact of which is probably characteristic of those of 3-hydroxytropolones[20].

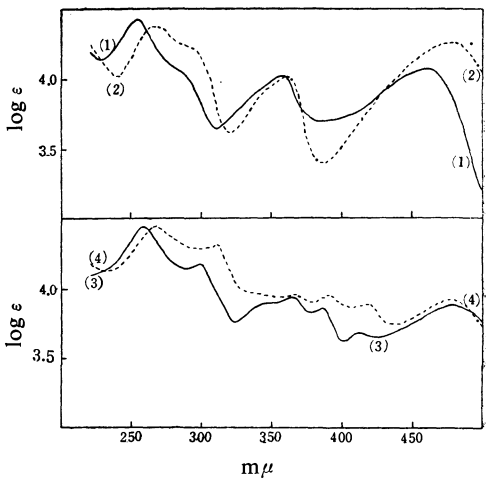


Fig. 1. Ultraviolet absorption spectra in methanol.
(1) : Tropolone-3, 4-dicarboxylic anhydride (V)
(2) : 7-Bromotropolone-3, 4-dicarboxylic anhydride (X)
(3) : 3-Hydroxytropolone-4, 5-dicarboxylic anhydride (XIII)
(4) : 7-Bromo-3-hydroxytropolone-4, 5-dicarboxylic anhydride (XV)

Treatment of the bromo derivative XV with sodium β-naphthalenesulfonate in slightly alkaline solution resulted in formation of puberulonic acid (I) in a 35% yield. The nucleophilic reactivity of the bromine atom in XV seemed to be distinctly smaller than that of the bromine in X. Puberulonic acid (I) synthesized as above did not show any depression of the melting point on admixture with a natural one[21].

19) Y. Kitahara, *Science Repts. Tohoku Univ., Ser.* I, **40**, 74 (1956).

20) T. Nozoe et al., ibid., **37**, 191 (1953); **40**, 121 (1957).

21) It was separated from a mixture of puberulonic and puberulic acids, m. p. 275°C (decomp.), which Professor J. H. Birkinshaw had kindly sent to us.

Puberulic acid (II), obtained by decarboxylation of the synthesized puberulonic acid, also showed no depression of the melting point on admixture with a natural one[21].

In Fig. 2 are shown the comparisons of the ultraviolet absorption spectra of synthetic puberulonic and puberulic acids with natural ones, and in Table I is shown, that of the infrared absorptions (6 $\mu$ bands) of synthetic and natural puberulonic acid.

(——) : Synthetic products
(------) : Natural products

TABLE I. COMPARISON OF THE INFRARED ABSORPTION OF SYNTHETIC AND NATURAL PUBERULONIC ACID

| Puberulonic acid | M.p. | Main strong bands $cm^{-1}$ | | | | |
|---|---|---|---|---|---|---|
| Synthetic[22] | 293°C | 1830 | 1765 | 1618 | 1545 | KBr |
| Natural[22] | 293°C | 1830 | 1765 | 1618 | 1545 | KBr |
| Johnson et al.[4] | 298°C | 1830 | 1770 | 1615 | 1544 | Nujol |

## Experimental[23]

**3-Hydroxytropolone (VII).**—A mixture of 3-bromotropolone (VI, 0.60 g.), sodium $\beta$-naphthalenesulfonate (0.76 g.), sodium hydroxide (0.4 g.), copper bronze (60 mg.) and water (45 cc.) was heated under reflux for 4 hr. The filtrate, from which copper was removed, was acidified with dilute sulfuric acid to Congo-red and extracted with ethyl acetate (100 cc.). The evaporated residue of the extract, after sublimation in vacuo followed by crystallization from cyclohexane, gave 3-hydroxytropolone (VII, 0.14 g., 44%), m. p. 136°C, undepressed on admixture with an authentic specimen[20].

**3, 4-Dihydroxytropolone (IX).**—A mixture of 3, 7-dibromotropolone (VIII, 0.28 g.), sodium $\beta$-naphthalenesulfonate (0.7 g.), sodium hydroxide (0.2 g.), copper powder (10 mg.) and water (30 cc.) was heated under reflux for 8 hr. The similar procedure as above described, after sublimation in vacuo and subsequent crystallization from ethyl acetate, yielded 3, 4-dihydroxytropolone (IX, 35 mg., 22%), colorless prisms, m. p. 237°C (reported 233~235°C[18], 237~238°C[6]).

Found : C, 54.58 ; H, 4.00. Calcd. for $C_7H_6O_4$ : C, 54.55 ; H, 3.92%.

The ultraviolet absorption, having maxima at 272 m$\mu$ (log $\varepsilon$ 4.64) and 355 (3.95) in water, was identical with that of the reported decarboxylated puberulic acid[6].

**7-Bromotropolone-3, 4-dicarboxylic Anhydride (X).**—To a stirred mixture of the dicarboxylic anhydride (V, 2.5 g.), sodium acetate trihydrate (1.8 g.) and acetic acid (40 cc.) was added, dropwise, bromine (2.1 g.) in acetic acid (5 cc.). After being stirred for 2 hr. at room temperature, the mixture was diluted with water, acidified with dilute sulfuric acid to Congo-red, and then extracted with methyl ethyl ketone. The concentrated residue of the extract was crystallized from acetic acid to form 7-bromotropolone-3,4-dicarboxylic anhydride (X, 3.0 g., 86%), yellow needles, m. p. 197~198°C. The analytical sample, m. p. 198°C, was obtained after sublimation in vacuo following recrystallization from acetic acid.

Found : C, 39.73 ; H, 1.42. Calcd. for $C_9H_3O_5Br$ : C, 39.85 ; H, 1.11%.

$\lambda_{max}^{MeOH}$ m$\mu$ (log $\varepsilon$) : 265 (4.38), 362 (4.03), 480 (4.27).

**Decarboxylation of X.**—A mixture of the bromotropolonedicarboxylic anhydride (X, 70 mg.) and water (3 cc.) was heated in a sealed tube at 180°C for 2 hr. The evaporated residue, after sublimation in vacuo and successive crystallization from methanol, afforded 3-bromo-6-carboxytropolone (XI, 20 mg.), pale yellow prisms, m. p. 233~234°C, alone or mixed on admixture with an authentic specimen[17].

**3-Hydroxytropolone-4, 5-dicarboxylic Anhydride (XIII).**—A mixture of the bromo derivative (X, 0.5 g.), sodium $\beta$-naphthalenesulfonate (0.42 g.), sodium hydroxide (0.3 g.), copper powder (10 mg.) and water (6 cc.) was heated on a boiling water bath for 4 hr. The filtrate, after copper was removed from the mixture, was acidified with dilute sulfuric acid to Congo-red and extracted with ether for 48 hr. continuously. The evaporated residue of the extract, after being washed with a small volume of methanol, gave 3-hydroxytropolone-4, 5-dicarboxylic anhydride (XIII), yellow prisms, m. p. 254~255°C. Yield, 0.32 g. (83%). The analytical sample melted at 258°C was obtained by sublimation in vacuo and by successive recrystallization from acetic acid.

22) The infrared spectra were measured by a Perkin-Elmer Model 21 Infrared Spectrometer with a rock salt prism.
23) All melting points are uncorrected.

Found: C, 51.74; H, 2.02. Calcd. for $C_9H_6O_6$: C, 51.93; H, 1.94%.

$\lambda_{max}^{MeOH}$ mμ (log ε): 258 (4.44), 300 (4.14), 365 (3.94), 385 (3.88), 410 (3.69), 475 (3.90).

**Decarboxylation of XIII.** — A mixture of XIII (100 mg.) and water (4 cc.) was heated in a sealed tube at 180°C for 2 hr. The reaction mixture was evaporated and the residual solid was washed with ethyl acetate. The soluble part in the same solvent afforded 3-hydroxytropolone (VII, 15 mg.), undepressed on admixture with an authentic specimen[20]. The less soluble part, after crystallization from water, gave 5-carboxy-3-hydroxytropolone (XIV, 40 mg.), m. p. 279°C (decomp.), of which further heating at its decomposition point yielded 3-hydroxytropolone. The product XIV is assumed to correspond to impure "isostipitatic acid"[10,12], having m. p. of 282°C.

**7-Bromo-3-hydroxytropolone-4, 5-dicarboxylic Anhydride (XV).**—To astirred mixture of the hydroxytropolone-dicarboxylic anhydride (XIII, 0.21 g.), sodium acetate trihydrate (0.14 g.) and acetic acid (4 cc.), was added dropwise a solution of bromine (0.16 g.) in acetic acid (1 cc.) at room temperature. At the point of dropping of about one-half volume of bromine, sodium hydrogen sulfite (20 mg.) was added, further bromination being followed. Then, the reaction proceeded smoothly and the reaction mixture became a transparent solution, which was allowed to evaporate in vacuo over an alkali-desiccator. The residue was diluted with water, acidified with dilute sulfuric acid to Congo-red, and extracted with methyl ethyl ketone. The residue obtained after removal of the solvent crystallized from acetic acid to give the bromo derivative (XV, 0.16 g.), yellow needles, m. p. 236~237°C (decomp). The analytical sample melted at 240°C (decomp.) was obtained by sublimation in vacuo followed by recrystallization from acetic acid.

Found: C, 38.00; H, 1.27. Calcd. for $C_9H_3O_6Br$: C, 37.66; H, 1.05%.

$\lambda_{max}^{MeOH}$ mμ (log ε): 266 (4.44), 310 (4.31), 365 (3.96), 390 (3.96), 420 (3.89), 480 (3.92).

**Puberulonic Acid (I).**—A mixture of the above bromo compound (XV, 0.57 g.), sodium β-naphthalenesulfonate (0.7 g.), sodium hydroxide (0.56 g.), copper powder (20 mg.) and water (7 cc.) was heated on a boiling water-bath for 8 hr. The solution obtained by removal of copper was acidified with dilute sulfuric acid to Congo-red and extracted wih ether for 48 hr. continuously. The evaporated residue of the extract crystallized to give yellow solids, m. p. 265~270°C (decomp.), of which washing with a small volume of methanol, sublimation in vacuo and subsequent recrystallization from methanol gave puberulonic acid (I, 15 mg., 35%), yellow crystals, m. p. 293°C (decomp.), undepressed on admixture with natural puberulonic acid[21].

Found: C, 48.04; H, 1.62. Calcd. for $C_9H_4O_7$: C, 48.23; H, 1.80%.

The ultraviolet absorption (in water) of the synthesized puberulonic acid (I) has maxima at 275 (4.54), 317 (4.00) and 447 mμ (log ε 3.94), identical with those of the authentic specimen[6].

**Puberulic Acid (II).**—A mixture of the above synthesized puberulonic acid (I, 80 mg.) and water (2 cc.) was heated under reflux for one hour. The evaporated residue of the mixture was dissolved in sodium hydrogen carbonate solution and treated with active charcoal. The solution obtained by removal of the charcoal crystallized by acidification with dilute sulfuric acid to give puberulic acid (II, 45 mg.), colorless crystals, m. p. 317~318°C, not depressed on admixture with natural puberulic acid[21].

Found: C, 48.37; H, 2.96. Calcd. for $C_8H_6O_6$: C, 48.49; H, 3.05%.

The ultraviolet absorption spectrum (in water), having maxima at 274 (4.54) and 352 mμ (log ε 3.84), was identical with that of the authentic specimen[6]. Heating of the synthesized puberulic acid (II) at 350°C and subsequent sublimation in vacuo afforded 3,4-dihydroxytropolone (IX), undepressed on admixture with an authentic specimen.

The authors express their sincere thanks to the Ministry of Education for a monetary assistance from the Grant in Aid for Scientific Research, to Professor J. H. Birkinshaw for his kind gift of natural puberulonic and puberulic acids, to Mr. Yusaku Ikegami for the infrared spectral measurements and to Messrs. Ohyama, Kato, Iwanaga and Azumi for microanalyses.

# *Studies on Antibiotics and Related Substances. X. Syntheses of Some Unsaturated Ketocarboxylic Acids, Anti-tumor Substances**

By Mitsuhiro KINOSHITA and Sumio UMEZAWA

(Received December 26, 1959)

The anti-tumor activities of sarkomycin[1] (2-methylenecyclopentanone-3-carboxylic acid), 5-methylenecyclopentanone-3-carboxylic acid[2] and its esters prompted us to investigate some related aliphatic compounds. The present paper presents the syntheses of two isomeric methylenelevulinic acids, 4-keto-5-hexene-1-carboxylic acid and 4-keto-3-methylenepentane-1-carboxylc acid, which have been found to possess significant anti-tumor and antibacterial activities. In addition, we have described here two rare illustrations of the Mannich reaction where the formation of two isomers respecting to the methylene groups at either side of the ketone-group has been demonstrated.

**δ-Methylene- and β-Methylene-levulinic Acid.** —Ethyl 5-dimethylamino-3-keto-pentane-1-carboxylate hydrochloride (II) was prepared by the esterification of 5-dimethylamino-3-keto-pentane-1-carboxylic acid hydrochloride (I) which was synthesized from levulinic acid as reported by Mannich[3]. Thermal degradation of II afforded a 61% yield of ethyl δ-methylene-levulinate (III). Structural proof of II was obtained by hydrogenation of III with platinum catalyst to give a 83% yield of ethyl γ-keto-*n*-caproate (V). Mild hydrolysis of the ester III with dilute sulfuric acid afforded a crude product of δ-methylenelevulinic acid (IV), which resisted attempts to purify it. The analytically pure product of IV has been prepared by thermal degradation of 5-dimethylamino-3-keto-pentane-1-carboxylic acid hydrochloride I.

The ultraviolet absorption of III in methanol solution showed peaks at 211 and 315 mμ, suggesting the presence of an α, β-unsaturated ketone group. The absorption of IV prepared directly from I also showed peaks at 212 and 305 mμ in aqueous solution (Fig. 1). The infrared absorption characteristics of IV was just as expected, showing the presence of double bond, conjugated carbonyl and carboxyl groups

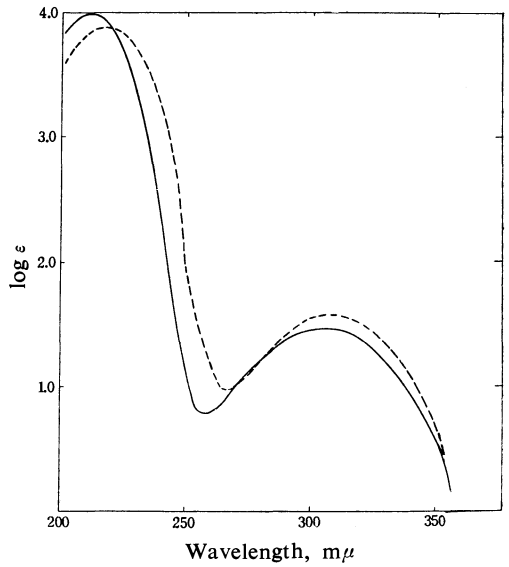

Fig. 1. Ultraviolet absorption spectra of δ-methylenelevulinic acid (——) and β-methylenelevulinic acid (----) in water.

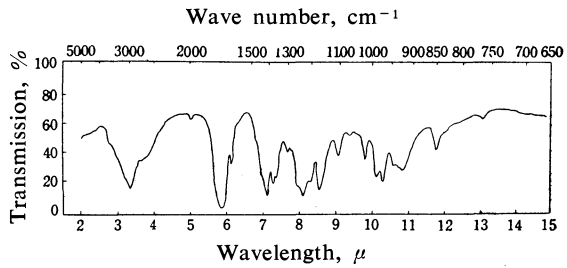

Fig. 2. Infrared absorption spectrum of δ-methylenelevulinic acid in Nujol.

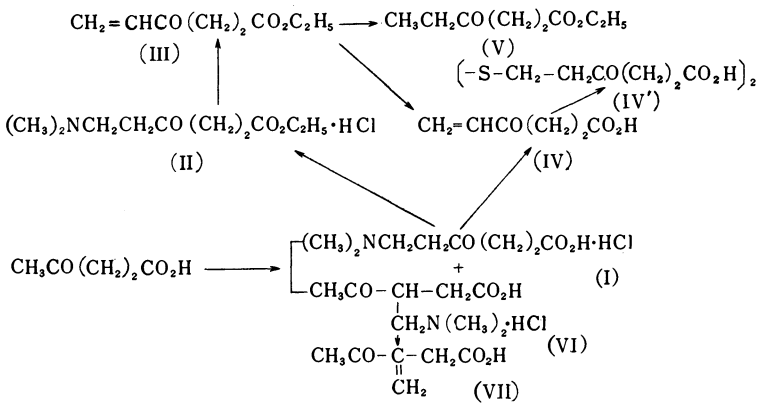
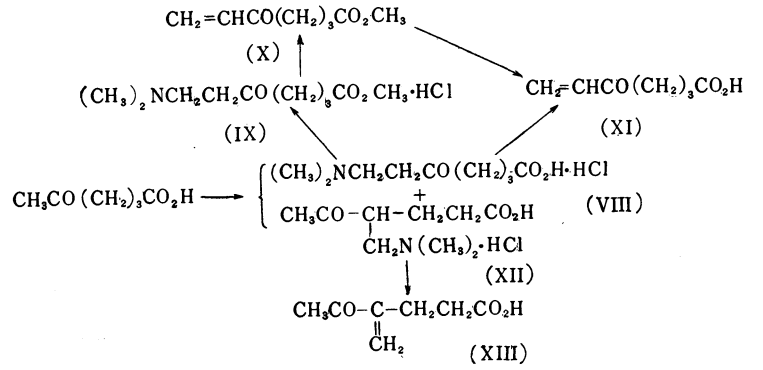
(Fig. 2).



By adding a large quantity of acetone to the mother-liquor which was separated from I, the hydrochloride (VI) of 2-(dimethylamino-methyl)-3-ketobutane-1-carboxylic acid, a Mannich base isomer of I, has been obtained. Thermal degradation of VI afforded β-methyl-enelevulinic acid (VII), an isomer of IV. β-Methylenelevulinic acid (VII) has been found to be stable, while, δ-methylene isomer (IV) polymerized gradually on standing.



* Presented at the Division of Organic Chemistry of the Annual Meeting of the Chemical Society of Japan, Kyoto, April 2, 1959.

1) H. Umezawa, T. Yamamoto, T. Takeuchi, T. Osato, Y. Okami, S. Yamaoka, T. Okuda, K. Nitta, K. Yagishita, R. Utahara and S. Umezawa, *Antibiotics a. Chemotherapy*, **4**, 514 (1954).

2) S. Umezawa and M. Kinoshita, This Bulletin, **30**, 268 (1957).

3) C. Mannich and M. Bauroth, *Ber.*, **57**, 1108 (1924).

Addition of hydrogen sulfide to IV afforded ε, ε-dithio-di-γ-keto-*n*-caproic acid (IV'), which has been found to have a strongly inhibitory effect only for the growth of *Micrococcus flavus*.

**4-Keto-5-hexene-1-carboxylic Acid and 4-Keto-3-methylenepentane-1-carboxylic Acid.**—Methyl 4-keto-5-hexene-1-carboxylate (X) has been prepared from δ-ketocaproic acid by an analogous series of reactions as described above in the synthesis of ethyl δ-methylenelevulinate (III).

Structural proof for 6-dimethylamino-4-keto-hexane-1-carboxylic acid hydrochloride (VIII) was obtained by paper chromatographic confirmation of the spot of glutaric acid as well as that of succinic acid as the oxidation products of VIII with nitric acid[3]. VIII was esterified to yield methyl ester hydrochloride IX, which was degraded by pyrolysis to yield a crude product of methyl 4-keto-5-hexene-1-carboxylate (X). Mild hydrolysis of X with dilute sulfuric acid afforded a crude product of 4-keto-5-hexene-1-carboxylic acid (XI) in a low yield, while thermal degradation of VIII gave better result, yielding XI in a 31% yield. Unexpectedly, XI was very hygroscopic and easily crystallized as its monohydrate which was stable, showing almost no tendency to polymerize.

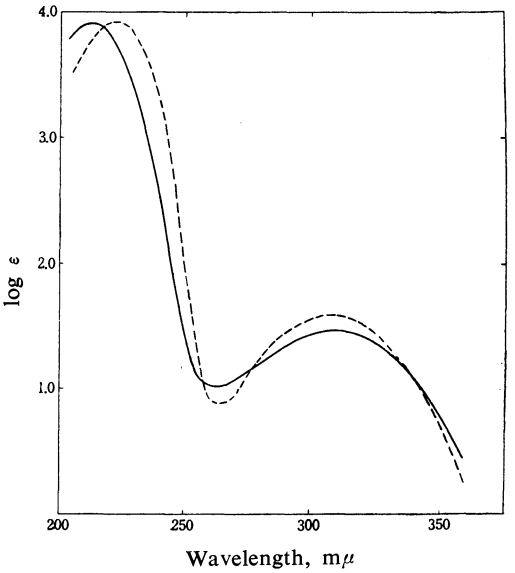


Fig. 3. Ultraviolet absorption spectra of 4-keto-5-hexene-1-carboxylic acid (——) and 4-keto-3-methylenepentane-1-carboxylic acid (----) in water.

Ozonolysis of XI gave formaldehyde as one of the products, indicating the presence of a terminal methylene group. The ultraviolet and

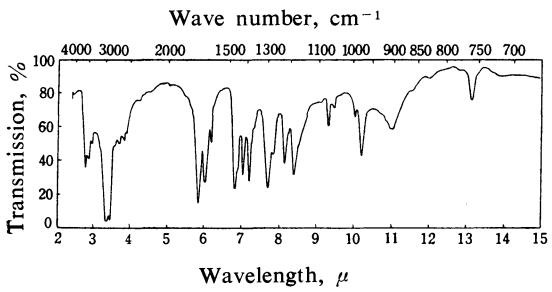

Fig. 4. Infrared absorption spectrum of 4-keto-5-hexene-1-carboxylic acid in Nujol.

infrared absorption spectra of XI presented in Fig. 3 and 4 indicated that XI is an $\alpha,\beta$-unsaturated ketocarboxylic acid.

When the mother liquor separated from VIII was stored in a refrigerator for two weeks, the hydrochloride (XII) of 3-(dimethylaminomethyl)-4-ketopentane-1-carboxylic acid separated in a crystalline mass. The product showed a positive test for iodoform reaction, suggesting that the product still contained a terminal acetyl group. Thermal degradation of XII afforded 4-keto-3-methylenepentane-1-carboxylic acid (XIII) in 71% yield. From the fact that ozonolysis of XIII yielded formaldehyde and succinic acid in reasonable yields, the structure of XIII has been confirmed and it has been further concluded that the structure of XII is 3-(dimethylaminomethyl)-4-ketopentane-1-carboxylic acid. The ultraviolet spectrum of XIII presented in Fig. 3 indicated that XIII is an $\alpha,\beta$-unsaturated ketocarboxylic acid.

## Experimental

**Separation of 5-Dimethylamino-3-ketopentane-1-carboxylic Acid Hydrochloride (I) and 2-(Dimethylaminomethyl)-3-ketobutane-1-carboxylic Acid Hydrochloride (VI) from Mannich Reaction Product.**—A mixture of levulinic acid (25 g.) and dimethylamine hydrochloride (17.6 g.) was heated to 105°C in an oil bath. To the resulting melt was added paraformaldehyde (6.45 g.) and then the mixture was stirred at 105~110°C for 30 min. After evaporation under reduced pressure, the resulting syrup was dissolved in absolute ethanol (22 cc.) by warming. To the cooled solution was added acetone (93 cc.) and the mixture was allowed to stand overnight in a refrigerator to precipitate a first crystalline crop (17.5 g.); m. p. 94~104°C. Recrystallization from ethanol gave a pure sample of I (12.9 g.), m. p. 119.5~120.5°C. An additional crop (0.9 g.) of I was obtained from the recrystallization mother liquor. The total yield of I was 31%.

Acetone (135 cc.) was added to the mother liquor of the above mentioned first crop and the mixture was stored in a refrigerator for several days to give the second crystalline crop, which was collected and washed with absolute ethanol (15 cc.); yield 7.3 g., m. p. 102~115°C. Recrystallization from ethanol gave colorless short prisms of VI, yield 3.3 g., m. p. 121~122°C. By the treatment of the recrystallization mother liquor of the second crop, additional crystals (0.5 g.) of VI (m. p. 121~122°C) were recovered. Further storage of the mother liquor of the second crop at room temperature for 3 months afforded the third crop which was recrystallized from ethanol to yield short prisms of VI (1.9 g.), m. p. 121~122°C. The total yield of VI was 12.6%. On admixing with a sample of I, the m. p. of VI was depressed.

Found: C, 45.77; H, 7.50; N, 6.42. Calcd. for $C_8H_{16}O_3NCl$: C, 45.82; H, 7.69; N, 6.68%.

**Ethyl 5-Dimethylamino-3-ketopentane-1-carboxylate Hydrochloride (II).**—A mixture of I (2.0 g.) and absolute ethanol (80 cc.) was saturated with dry hydrogen chloride and allowed to stand overnight. The ethanol was removed by distillation at about 40°C under reduced pressure and the residue was dried in a desiccator over phosphorous pentoxide. The resulting crystals were dissolved in a small quantity of ethanol by gentle warming and the solution was diluted with absolute ether, whereupon there separated a crystalline precipitate of ethyl 5-dimethylamino-3-ketopentane-1-carboxylate hydrochloride (II); yield 1.8 g. (80%). On recrystallization from absolute ethanol-absolute ether, colorless plates of m. p. 105~107°C were obtained and found to be hygroscopic.

Found: N, 6.02. Calcd. for $C_{10}H_{20}O_3NCl$: N, 5.89%.

**Ethyl δ-Methylenelevulinate (III)*.**—A sample of 1.5 g. of II was placed in a round-bottom flask and heated at 150°C in an oil bath under highly reduced pressure (0.002 mmHg). Colorless liquid with the characteristic smell of III was obtained in a receiver cooled in a dry ice-methanol bath; yield 0.6 g. (61%), $\lambda_{max}^{MeOH}$ 210 (ε 10650) and 315 mμ (ε 27).

Found: C, 61.58; H, 7.14. Calcd. for $C_8H_{12}O_3$: C, 61.52; H, 7.75%.

**Hydrogenation of III to Ethyl γ-Keto-*n*-caproate (V).**—A sample (III) (440 mg.) in ethanol (3 cc.) absorbed hydrogen (75 cc. at 11°C, 753.7 mmHg) in the presence of platinum oxide (40 mg.). The reduced product was purified by fractional distillation in vacuo to give 370 mg. of ethyl γ-keto-*n*-caproate (V), b. p. (bath temp.) 122~126°C/18 mmHg This was identified by formation of semicarbazone and 2, 4-dinitrophenylhydrazone by the usual procedure. Semicarbazone was recrystallized from ethyl acetate-petroleum ether; m. p. 105~106.5°C. The reported m. p. 106°C[4].

Found: N, 19.25. Calcd. for $C_9H_{17}O_3N_3$: N, 19.52%. 2,4-Dinitrophenylhydrazone was recrystallized twice from ethanol; long, orange-yellow needles, m. p. 69.5~71.0°C.

Found; N, 16.67. Calcd. for $C_{14}H_{18}O_6N_4$: N, 16.56%.

**δ-Methylenelevulinic Acid (IV).**—A mixture of

* Methyl ester of the same acid was reported by I. N. Nazarov and S. I. Zavyalov, *Izvest, Akad, Nauk S. S. S. R., Otdel. Khim. Nauk*, **1952**, 289; *Chem. Abstr.*, **47**, 5364 (1953) and by C. Grundmann and W. Ruske, *Chem. Ber.*, **86**, 939 (1953).

4) M. Maire, *Bull. Soc. chim. France*, [4] 3, 285 (1908).

370 mg. of III and 7.5 cc. of 1.5 N sulfuric acid was stirred at 30°C for 3 hr. The reaction mixture was cooled with ice and adjusted to pH 8 with a saturated solution of sodium bicarbonate and washed with three 5 cc. portions of ethyl acetate. The water-layer was adjusted to pH 2.0 and extracted with three 6 cc. portions of ethyl acetate. After the extract has been dried over sodium sulfate, the ethyl acetate was removed by distillation under reduced pressure at 30°C to yield crude $\delta$-methylenelevulinic acid, a colorless viscous liquid which is soluble in water; yield 50 mg. (17%). Ultraviolet spectrum of this compound in water showed the presence of a $\alpha,\beta$-unsaturated ketone group at 212 m$\mu$. However, purification of the product was unsuccessful. The analytically pure sample of IV has been obtained directly by thermal degradation of 5-dimethylamino-3-ketopentane-1-carboxylic acid hydrochloride (I) as described below.

A sample of 5 g. of I was heated (bath temp. 185°C/0.0075 mmHg) as described in the preparation of III to give a solid mass of crystals intermixed with oil in a receiver cooled in a dry ice-methanol bath. The crystals were drained on porous porcelain to remove the oily part; yield 1.26 g. (41.2%), m. p. 34.0~42.5°C*. The product was soluble in methanol, ether and water. Recrystallization from ether gave an analytical sample of $\delta$-methylenelevulinic acid (IV), m. p. 44.0~45.5°C, $\lambda_{max}^{H_2O}$ 212 m$\mu$ ($\varepsilon$ 9870) and 305 m$\mu$ ($\varepsilon$ 30.3), $\nu_{max}^{Nujol}$ 1701 (conjugated carbonyl), 1644 (C=C), 2700~2500 (carboxyl OH) and 1724 cm$^{-1}$ (carboxyl C=O).

Found: C, 55.97; H, 6.24. Calcd. for $C_6H_8O_3$: C, 56.24; H, 6.29%.

**Semicarbazone.** — m. p. 152~153°C (decomp.), $\lambda_{max}^{MeOH}$ 262 m$\mu$ ($\varepsilon$ 16200).

Found: C, 45.27; H, 5.98; N, 22.67. Calcd. for $C_{17}H_{11}O_3N_3$: C, 45.40; H, 5.99; N, 22.69%.

**$\varepsilon,\varepsilon'$-Dithio-di-$\gamma$-keto-*n*-caproic Acid (IV').**—$\delta$-Methylenelevulinic acid (IV) (760 mg.) was added to a 4.12 M aqueous solution (1.45 cc.) of sodium tetrasulfide with stirring. The reaction was exothermic and the resulting orange-red solution was allowed to stand overnight at room temperature, and then adjusted to pH 7.4 with concentrated hydrochloric acid. After removal of the separated sulfur, the filtrate was shaken with three 10 cc. portions of ethyl acetate. The water-layer was adjusted to pH 4.0 and extracted with five 10 cc. portions of ethyl acetate. The dried extract was concentrated in vacuo to afford a crystalline mass (820 mg.). A mixture of the crude product and water was adjusted to pH 7.0 with sodium bicarbonate, filtered off the precipitated sulfur and then acidified to pH 4.0. The resulting precipitate was collected and washed with water, yield 429 mg. (45%). Recrystallization from ethyl acetate and then absolute ethanol resulted pure $\varepsilon,\varepsilon'$-dithio-di-$\gamma$-keto-*n*-caproic acid; yield 180 mg., m. p. 131~131.5°C.

Found: C, 44.50; H, 5.48. Calcd. for $C_{12}H_{18}O_6S_2$: C, 44.73; H, 5.60%.

**Ozonolysis of IV.** — (a) A solution of IV (200 mg.) in ethyl acetate (10 cc.) was treated with an approximately 3% by weight ozone-oxygen mixture at 0°C at a rate of 500 cc./min. for 30 min. To the resulting solution was added water (10 cc.) and zinc dust (300 mg.). The mixture was refluxed on a water bath for 30 min. The reaction mixture was filtered, while hot, into a solution of methone (300 mg.) in 10 cc. of ethanol. Dilution with water (20 cc.) afforded needless of (200 mg., 44%), m. p. 185~187°C. Recrystallization from aqueous methanol gave pure crystals of m. p. 188~189.5°C. The m. p. was undepressed on admixing with an authentic sample of formaldehyde methone. This established the presence of the terminal methylene group in IV. (b) A solution of IV (300 mg.) in ethyl acetate (15 cc.) was treated with 3% ozone-oxygen at −20°C at a rate of 400 cc./min. for 2 hr. The resulting yellow solution was concentrated to about 0.8 cc. in vacuo below 10°C, then 30% hydrogen peroxide (1.7 cc.) was added. After gentle warming of the mixture at 60°C for a little while, the resulting solution was kept at room temperature overnight. The colorless solution was evaporated under reduced pressure. Addition of water to the residue followed by evaporation was repeated to remove exess of hydrogen peroxide as much as possible. The final crystalline residue (320 mg.) gave only the distinct spot of succinic acid on paper chromatography[5] using xylene-phenol-85% formic acid (7:3:1) as a solvent. Recrystallization from ethanol gave 194 mg. (70%) of a pure sample of succinic acid, m. p. 183~184°C; mixed m. p. determination showed no depression.

**$\beta$-Methylenelevulinic Acid (VII).**—A sample of 4 g. of VI was heated (bath temp. 180°C/0.002 mmHg) as described in the preparation of III to give a crystalline product in a receiver cooled in a dry ice-methanol bath. A small amount of oily material was removed by treatment on a porous porcelain; yield 1.7 g. (69.5%), m. p. 62~66°C. Recrystallization from ether followed by fractional vacuum sublimation (60°C/0.06 mmHg) afforded an analytical pure sample; m. p. 67.0~68.5°C; $\lambda_{max}^{H_2O}$ 218~219 ($\varepsilon$ 7520) and 309 m$\mu$ ($\varepsilon$ 38.5); $\nu_{max}^{Nujol}$ 1682 (conjugated carbonyl), 1640 (C=C), 2800~2500 (carboxyl OH), and 1715 cm$^{-1}$, (carboxyl C=O).

Found: C, 56.29; H, 6.11. Calcd. for $C_6H_8O_3$: C, 56.24; H, 6.29%.

**Ca Salt.**—Found: C, 48.70; H, 4.72; Ca, 13.83. Calcd. for $C_{12}H_{14}O_8Ca$: C, 48.91; H, 4.80; Ca, 13.62%.

**Semicarbazone.**—M. p. 184°C (decomp.). Found: C, 45.38; H, 5.71; N, 22.44. Calcd. for $C_7H_{11}O_3N_3$: C, 45.40; H, 5.99; N, 22.69%.

**2, 4-Dinitrophenylhydrazone.** — M. p. 210°C (decomp.)[6]. Found: C, 46.66; H, 4.15; N, 18.25. Calcd. for $C_{12}H_{12}O_6N_4$: C, 46.76; H, 3.92; N, 18.18%.

Ozonolysis of VII was carried out in the same manner as described in the ozonolysis of IV: (a) The compound VII (99 mg.) gave formaldehyde methone (96 mg., 42.5%), indicating the presence

* B. p. of this compound was reported by H. T. Taylor, *J. Chem. Soc.*, 1958, 3922.

5) N. F. Holyer and B. C. L. Weedon, *Chem. and Industry*, (1955), 1219. H. Kalbe, *Z. physiol. Chem.*, 297, 19 (1954).

6) The same m. p. was reported by L. Birkofer and L. Storch, *Chem. Ber.*, 87, 571 (1954).

of terminal methylene group. (b) The compound (346 mg.) gave a crude crystalline product (250 mg.) which gave only the distinct spot of malonic acid on paper chromatography. Pure malonic acid was obtained by fractional vacuum sublimation, m. p. and mixed m. p. 134~135°C (decomp.).

**Separation of 6-Dimethylamino-4-ketohexane-1-carboxylic Acid Hydrochloride (VIII) and 3-(Dimethylaminomethyl)-4-ketopentane-1-carboxylic Acid Hydrochloride (XII) from Mannich Reaction Product.**—A mixture of 5-ketocaproic acid[7] (30 g.) and dimethylamine hydrochloride (20.2 g.) was heated to 114°C in an oil bath. To the resulting melt was added paraformaldehyde (7 g.) and then the mixture was stirred at 114°C for 1.5 hr. After evaporation under reduced pressure, the resulting syrup was dissolved in absolute ethanol (35 cc.) by warming. To the cooled solution was added acetone (100 cc.) and some seeds of pure VIII, and the mixture was allowed to stand in a refrigerator for 3 days to give the first crystalline crop, which was separated and washed with a mixture of acetone-ethanol (14 : 5); yield 15.8 g., m. p. 98~108°C. Recrystallization from ethanol (18 cc.) gave a pure sample of VIII; yield 13.9 g. (27%), m. p. 116~117°C.

Found: C, 48.49; H, 7.90; N, 6.18. Calcd. for $C_9H_{18}O_3NCl$: C, 48.32; H, 8.11; N, 6.26%.

A sample of VIII (50 mg.) was added by bits to 1 cc. of fuming nitric acid. The reaction mixture was heated on a water bath until the evolution of nitrogen oxide ceased. After concentration, the reaction mixture was diluted with water and evaporated to dryness. The residue was dissolved in water. Aliquots of the solution were used for paper chromatography in the same manner as described above to give the spots of glutaric acid and succinic acid.

The mother liquor of the above mentioned first crop was stored in a refrigerator for 2 weeks to afford the second crop, which was collected and washed with acetone-ethanol and dried; yield 7.6 g. Recrystallization from ethanol gave a pure sample of XII; yield 6.6 g. (11.3%), m. p. 131~132°C. Iodoform test was positive.

Found: C, 48.53; H, 8.00; N, 6.44. Calcd. for $C_9H_{18}O_3NCl$: C, 48.32; H, 8.11; N, 6.26%.

**4-Keto-5-hexene-1-carboxylic Acid (XI).**—A sample of 5 g. of VIII was heated (bath temp. 185~190°C/0.005 mmHg) in the same manner as described in the preparation of III to give a crystalline product (2 g.) in a receiver in a dry ice-methanol bath. The product melted at room temperature into a colorless viscous liquid which was very hygroscopic and, on standing in atmosphere, formed a crystalline monohydrate. To the liquid product (2 g.) was added water (0.27 cc.) and the resulting crystalline monohydrate of XI was collected by filtration under ice-cooling, dried on a porous sheet; yield 1.4 g. (39%), m. p. 43~45°C. Cautious recrystallization from water gave a pure sample of monohydrate of XI; yield 1.2 g. (31%), m. p. 45.0~46.5°C. $\lambda_{max}^{H_2O}$ 212~3 ($\varepsilon$ 8190) and 310~3 m$\mu$ ($\varepsilon$ 29.6), $\nu_{max}^{Nujol}$ 1692 (conjugated carbonyl), 1617 (C=C), 2700~2500 (carboxyl OH), 1746 (carboxyl C=O) and 3600~3350 $cm^{-1}$ (crystalline water).

(a) Crystalline monohydrate; Found: C, 52.46; H, 7.52. Calcd. for $C_7H_{10}O_3 \cdot H_2O$: C, 52.49; H, 7.55%. (b) Anhydrous acid (dried at 100°C/10 mmHg for 4 hr.); Found: C, 59.57; H, 7.35. Calcd. for $C_7H_{10}O_3$: C, 59.14; H, 7.09%. (c) Calcium salt* (dried at 125~130°C/10 mmHg for 4 hr.); Found: C, 51.71; 5.87; Ca, 12.42. Calcd. for $C_{14}H_{18}O_6Ca$: C, 52.16; H, 5.62; Ca, 12.43%.

**Semicarbazone.**—M. p. 156~157°C (decomp.), $\lambda_{max}^{MeOH}$ 260 m$\mu$ ($\varepsilon$ 17100).

Found: C, 47.62; H, 6.33; N, 21.18. Calcd. for $C_8H_{13}O_3N_3$: C, 48.23; H, 6.58; N, 21.09%.

Ozonolysis of XI was carried out in the same manner as described in the ozonolysis of IV: (a) The monohydrate (200 mg.) gave formaldehyde methone (148 mg., 40.5%). (b) The monohydrate (426 mg.) gave a crude crystalline product (245 mg., 70%) which gave only the distinct spot of glutaric acid on paper chromatography. Recrystallization from benzene gave pure glutaric acid; m. p. and mixed m. p. 95~96°C.

**4-Keto-3-methylenepentane-1-carboxylic Acid (XIII).**—A sample of 2 g. of XII was heated (bath temp. 175~180°C/0.002 mmHg) as described in the preparation of III to give a crystalline product; yield 0.9 g. (71%), m. p. 56~62°C. Three recrystallizations from ether gave a pure sample of XIII, m. p. 66~67°C, $\lambda_{max}^{H_2O}$ 222 ($\varepsilon$ 8270) and 308 m$\mu$ ($\varepsilon$ 39.5), $\nu_{max}^{Nujol}$ 1648 (conjugated carbonyl), 1631 (C=C), 2800~2500 (carboxyl OH) and 1738 $cm^{-1}$ (carboxyl C=O).

Found: C, 59.22; H, 6.92. Calcd. for $C_7H_{10}O_3$: C, 59.14; H, 7.09%.

**Semicarbazone.**—M. p. 164~165°C (decomp.), long needles.

Found: C, 48.30; H, 6.38; N, 21.13. Calcd. for $C_8H_{13}O_3N_3$: C, 48.23; H, 6.58; N, 21.10%.

Ozonolysis of XIII was carried out in the same manner as described in the ozonolysis of IV: (a) The compound (100 mg.) gave formaldehyde methone (84 mg., 46%). (b) The compound (300 mg.) gave a crude crystalline product (295 mg.) which gave only the distinct spot of succinic acid on paper chromatography. Recrystallization from ethanol afforded 150 mg. (65%) of pure succinic acid, m. p. and mixed 183~184°C.

**Methyl 6-Dimethylamino-4-ketohexane-1-carboxylate Hydrochloride (IX).**—A mixture of VIII (3 g.) and absolute methanol (75 cc.) was saturated with dry hydrogen chloride and after-treatment was carried out just as described in the preparation of II. Recrystallization from absolute methanol-absolute ether gave long needles of IX (3 g., 95%), m. p. 91~93°C, very hygroscopic.

Found: N, 5.73. Calcd. for $C_{10}H_{20}O_3NCl$: N, 5.90%.

**Methyl 4-Keto-5-hexene-1-carboxylate (X).**—A sample of 2 g. of IX was heated (bath temp. 140~148°C/0.001 mmHg) in the same manner as described in the preparation of III. Yield 0.34 g. (26%), b. p.

7) H. Fittig and L. Wolff, *Ann.*, **216**, 129 (1883); W. H. Bentley and W. H. Perkin, *J. Chem. Soc.*, **69**, 1510 (1896).

* Prepared by Mr. T. Soga of Nikken Kagaku Co.

(bath temp.) 36~38°C/0.002 mmHg, $\lambda_{max}^{MeOH}$ 209 mμ (ε 9570) and 320 mμ (ε 27.2), $\nu_{max}^{CCl_4}$ 1692 (conjugated carbonyl), 1617 (C=C) and 1746 $cm^{-1}$ (ester C=O).

Found: C, 61.04; H, 7.56. Calcd. for $C_8H_{12}O_3$: C, 61.52; H, 7.75%.

Hydrolysis of X with dilute sulfuric acid in the same manner as described in the preparation of IV resulted a low yield of oily product, the ultraviolet absorption of which showed the presence of α,β-unsaturated ketone at 213 mμ in water. However, the product resisted an attempt to obtain a pure sample of 4-keto-5-hexene-1-carboxylic acid (XI).

**Biological Activities.**—δ-Methylenelevulinic acid (IV), β-methylenelevulinic acid (VII), 4-keto-5-hexene-1-carboxylic acid (XI) and 4-keto-3-methylenepentane-1-carboxylic acid (XIII) showed a potency of 0.6, 0.9, 0.4 and 1.3 units/mg. (in terms of sarkomycin potency) against *M. pyogenes var. aureus* 209-P, respectively. The ethyl ester III of IV and the methyl ester X of XI showed much higher potency than the original acids, but had higher toxicity than the original acid. $LD_{50}$ of IV, VII, XI, XIII and III were 1.0, 3.7, 2.0, 4.7 and 0.78 mg./mouse, respectively. ε,ε'-dithio-di-γ-keto-*n*-caproic acid (IV') exhibited a curious activity; it inhibited strongly the growth of *Micrococcus flavus*, but had almost no activity against tested bacteria and fungi.

It is very interesting to find, that all these compounds possess antitumor activities against Ehrlich cells and HeLa cells[9]. The minimum necessary concentrations of IV, VII, XI and XIII for anti-HeLa cell effect were 62.5, 62.5, 12.5 and 62.5 mcg./cc. Against cells of Ehrlich carcinoma, IV, VII, XI and XIII had a potency of 1.56, 3.8, 2.2 and 3.4 units/mg. (in terms of sarkomycin potency) by cylinder plate method. The daily intraperitoneal injection of 0.5 mg./mouse/day of IV inhibited the ascites increase and prolonged the survival period of mice (highly inbred) bearing ascites type of Ehrlich carcinoma by intraperitoneal route. Especially, calcium salt of 4-keto-5-hexene-1-carboxylic acid (XI) showed an excellent results; daily intraperitoneal injection of 0.125, 0.25 or 0.5 mg./mouse/day which was continued for 52 days showed significant inhibition. The control mice all died in 14~22 days. Mice of the group treated with 0.5 mg. daily all survived 52 days. Moreover, toxicity of the calcium salt of XI was $LD_{50}$=4.0 mg./mouse.

A detailed report on the biological activities of the above-mentioned compounds will be published elswhere.

9) Private communicaiton from Professor H. Umezawa of National Institute of Health, Tokyo.

## Summary

1) 2-(Dimethylaminomethyl)-3-ketobutane-1-carboxylic acid hydrochloride (VI) as well as 5-dimethylamino-3-ketopentane-1-carboxylic acid hydrochloride (I) has been obtained from levulinic acid, paraformaldehyde and dimethylamine hydrochloride by means of the Mannich reaction. Thermal degradation of I and VI afforded δ-methylenelevulinic acid (IV) and β-methylenelevulinic acid (VII), respectively.

2) 3-(Dimethylaminomethyl)-4-ketopentane-1-carboxylic acid hydrochloride (XII) as well as 6-dimethylamino-4-ketohexane-1-carboxylic acid hydrochloride (VIII) has been obtained from 5-ketocaproic acid, paraformaldehyde and dimethylamine hydrochloride by means of the Mannich reaction. Thermal degradation of XII and VIII afforded 4-keto-5-hexene-1-carboxylic acid (XI) and 4-keto-3-methylenepentane-1-carboxylic acid (XIII), respectively.

3) The structures of IV, VII, XI and XIII have been proven.

4) Some derivatives of above-mentioned carboxylic acids have been described.

5) It has been found that IV, VII, XI and XIII possess significant antitumor and antibacterial activites; especially calcium salt of 4-keto-5-hexene-1-carboxylic acid (XI) gave an excellent result in animal experiments.

A part of expenses for this work was defrayed by the Grant-in-Aid for Scientific Research from the Ministry of Education, which is gratefully acknowledged. The authors are indebted to Professor H. Umezawa, National Institute of Health, Tokyo, for antitumor assays.

# *The Reaction of Tropoids and Quinone Derivatives. I. Reaction of Several Tropolones and p-Benzoquinone-dibenzenesulfonimide**

By Shuichi SETO, Hiromi YAMAZAKI and Yukio NISHIYAMA

(Received January 28, 1960)

Several processes have been reported for the synthesis of tropolones having an aryl group[1]. For example, as a method of introducing an aryl group into the 5-position of the tropolone ring, one by the decomposition of the diazonium salt obtained from 5-aminotropolone in benzene, anisole or allied compounds has been described, but the yield is generally not good.

Based on the work of Admas and others[2] that aryl phenylenediamide derivatives are obtained in good yields from quinonimide derivatives by their reactions with aromatic compounds, an attempt was made to apply this reaction to tropolones.

This reaction appears to be the action of quinonimide, acting as a kind of a cationoid reagent, on the aromatic compounds and it seems possible to apply this to tropoids other than tropolones.

Mixing of the chloroform solutions of tropolone and *p*-benzoquinonedibenzenesulfonimide (I) results in orange red solution. Addition of a small amount of triethylamine to this solution results in change of color of the solution to yellow and after some time, a colorless solid (II) separates.

This behavior is similar to the formation of 2-(4′-hydroxyphenyl)-*p*-phenylenedibenzenesulfonamide from phenol and I[3].

It is clear from its ultraviolet absorption spectrum, and coloration with ferric chloride that II possesses a tropolone ring, and its analytical values agree with those calculated for 2′,5′-dibenzenesulfonamidophenyltropolone.

From an analogy, to the reaction of phenol, the 2′, 5′-dibenzenesulfonamidophenyl-group is considered to have entered the *para*- or 5-position of the tropolone ring and the experimental results described below supports this assumption.

The same reaction carried out with 3-bromotropolone and 3, 7-dibromotropolone in place of tropolone respectively affords colorless crystals (III) and pale yellow crystals (IV), although the reaction velocity is somewhat slower than that in the case of tropolone itself. The analytical values of III and IV agree respectively with those for the monobromo and dibromo derivatives of II.

Hydrogenolysis of III and IV in the presence of palladium-charcoal affords II, and bromination of II and III in chloroform affords IV. These fact can be understood by assuming that the 2′, 5′-dibenzenesulfonamidophenyl group in II, III and IV is situated in the 5-position of the tropolone ring.

The reaction of I and 4-isopropyltropolone (hinokitiol) is likely to be affected by steric hindrance of the isopropyl group in the 4-position, but the reaction actually progressed smoothly, giving colorless crystals (V). Further, reaction of I with 3-bromo-6-isopropyltropolone and 3, 7-dibromo-4-isopropyltropolone respectively afforded colorless crystals (VI) and pale yellow crystals (VII).

Hydrogenolysis of VI and VII gave V.

From the foregoing experimental facts, and from analytical values and ultraviolet absorption spectra of V, VI and VII, it is clear, that V is 4-isopropyl-5-(2′, 5′-dibenzenesulfonamidophenyl)tropolone, and VI and VII are respectively its monobromo and dibromo derivatives. The fact, that the aryl group enters the 5-position without interference of such a bulky group in 4-position suggests, that this reaction might be applied to the syntheses of tricyclic tropolone derivatives.

3-Isopropyltropolone ($\alpha$-thujaplicin) also reacts easily with I to form 3-isopropyl-5-(2′, 5′-dibenzenesulfonamidophenyl)tropolone (VIII).

The reaction of tropolone derivatives with a substituent in the 5-position with I was then carried out. Addition of triethylamine to the chloroform solution of 5-methyltropolone and I resulted in gradual blackening of the solution. This color change is different from that observed, when the reaction is progressing as anticipated.

Colorless crystals separated on standing this reaction mixture and this substance was found to be the reduction product of I, i. e. *p*-phenylenedibenzenesulfonamide.

A part of the starting 5-methyltropolone was recovered from the filtrate.

*) Presented at the 49th Tohoku Local Meeting of the Chemical Society of Japan, Yamagata, June, 1959.

TABLE I. SOME PROPERTIES OF THE REACTION PRODUCTS

| | $R_1$ | $R_2$ | $R_3$ | M. p. °C (decomp.) | UV $\lambda_{max}^{MeOH}$ m$\mu$(log $\varepsilon$) |
|---|---|---|---|---|---|
| II | H | H | H | 233~235 | 241(4.49), 345(4.15), 390(3.79) |
| III | Br | H | H | 210~213 | 257(4.65), 351(4.29), 418(3.99) |
| IV | Br | Br | H | 211~213 | 272(4.60), 356(4.31), 435(4.18) |
| V | H | H | isoPr | 254~256 | 250(4.60), 344(4.24) |
| VI | Br | H | isoPr | 242~243 | 263(4.58), 349(4.24), 413(3.93) |
| VII | Br | Br | isoPr | 195~197 | 265(4.44), 355(4.06), 430(3.84) |
| VIII | isoPr | H | H | 207~215 | 243(4.58), 340(4.28), 390(3.84) |

The reaction of 5-bromotropolone and I also took the same course. It is known, that when the *para* position of phenol is blocked, as in *p*-cresol, the same reaction affords the reduction product, *p*-phenylenedibenzenesulfonamide[3,4].

I specifically attacks the *para* position of phenols and it is interesting, that it also attacks the 5-position of tropolones, corresponding to the *para* position, showing the similarity of phenols and tropolones.

## Experimental[5]

**5-(2′, 5′-Dibenzenesulfonamidophenyl) tropolone (II).**—To a solution of 1 g. of *p*-benzoquinonedibenzenesulfonimide (I) dissolved in 25 ml. of chloroform, a solution of 0.8 g. of tropolone in 2 ml. of chloroform was added, by which the color of the solution changed to orange red. Addition of 3 drops of triethylamine to it further changed the color of the solution to yellow and colorless crystals began to separate after a few minutes. The mixture was allowed to stand for 1 hr. and the crystals were collected by filtration to 1.27 g. of the first crop of crystals, m. p. 228~232°C (decomp.). The filtrate was evaporated under a reduced pressure, 5 ml. of benzene and 2 ml. of 1 N sulfuric acid were added to the residue, and the crystals that separated out were collected by filtration. The crystals were washed with benzene and water, and amounted to 70 mg. of the second crop of m. p. 228~230°C (decomp.). The combined first and second crops of crystals were recrystallized from a mixture of chloroform and benzene to yield 1.30 g. of II of m. p. 233~235°C (decomp.).

Found: C, 59.20; H, 3.64; N, 5.30. Calcd. for $C_{25}H_{20}O_6N_2S_2$: C, 59.02; H, 3.97; N, 5.51%.

The filtrate left after separation of the second crop of crystals was combined with the washings, the benzene layer was separated, and evaporated under a reduced pressure. The residue was sublimed at 1 mmHg in a bath of 60°C, and 0.46 g. of tropolone was recovered.

II was dissolved in ethyl acetate and aqueous solution of ferric chloride was added by which the organic layer colored red.

**2-Acetoxy-5-(2′, 5′-dibenzenesulfonamidophenyl)-tropone.**—A mixture of 100 mg. of II and 0.5 ml. of acetic anhydride was heated at 140°C for 20 min., by which II dissolved completely. The mixture was evaporated under a reduced pressure and the crystalline residue was recrystallized from chloroform to 60 mg. of crystals melting at 200~201°C.

Found: C, 58.85; H, 4.18; N, 5.03. Calcd. for $C_{27}H_{22}O_7N_2S_2$: C, 58.87; H, 4.03; N, 5.09%.

U. V. $\lambda_{max}^{MeOH}$ m$\mu$ (log $\varepsilon$): 231(4.56), 330(4.11).

**2-Methoxy-5-(2′, 5′-dibenzenesulfonamidophenyl)-tropone.**—An ether solution of diazomethane was added to 100 mg. of II suspended in 4 ml. of methanol by which an active reaction set in with evolution of nitrogen. After standing the mixture over night, the crystals were collected and recrystallized from methanol, affording 70 mg. of colorless needles, m. p. 190~191°C.

Found: C, 60.36; H, 4.36; N, 5.27. Calcd. for $C_{26}H_{22}O_6N_2S_2$: C, 59.73; H, 4.24; N, 5.36%.

U. V. $\lambda_{max}^{MeOH}$ m$\mu$ (log $\varepsilon$): 226(4.47), 330(4.11).

**3-Bromo-5-(2′, 5′-dibenzenesulfonamidophenyl)-tropolone (III).**—One drop of triethylamine was added to the solution of 130 mg. of 3-bromotropolone and 100 mg. of I dissolved in 5 ml. of chloroform and the mixture was allowed to stand for 2 days. The first crop of crystals that separated was collected by filtration to 50 mg. of crystals of m. p. 210~213°C (decomp.). The filtrate was evaporated under a reduced pressure, 2 ml. of benzene and 1 ml. of 1 N sulfuric acid were added and 90 mg. of the second crop of crystals, m. p. 205~212°C (decomp.), was obtained. The first and second crops of crystals were combined and recrystallized from chloroform-ethanol mixture to 135 mg. of crystals of m. p. 210~213°C (decomp.).

Found: C, 50.76; H, 3.26; N, 4.70. Calcd. for $C_{25}H_{19}O_6N_2BrS_2$: C, 51.08; H, 3.26; N, 4.77%.

The benzene layer was separated from the filtrate left after removal of the second crop of crystals, the solvent was evaporated, and the residue was sublimed at 1 mmHg in a bath of 100°C, by which 70 mg. of 3-bromotropolone was recovered.

4) R. Adams and K. R. Eilar, ibid., 73, 1149 (1951).

5) All melting points are uncorrected. The microanalyses were carried out by Mr. S. Ohyama and Miss Y. Endo of this Institute.

**3, 7-Dibromo-5-(2′, 5′-dibenzenesulfonamidophenyl)tropolone (IV).**—One drop of triethylamine was added to the solution of 180 mg. of 3,7-dibromotropolone and 100 mg. of I dissolved in 5 ml. of chloroform and the mixture was allowed to stand for 5 days. The first crop of 160 mg. of crystals, m. p. 207~210°C (decomp.), was collected by filtration, the filtrate was evaporated, and 5 ml. of benzene and 1 ml. of 1 N sulfuric acid were added to its residue. The second crop of 10 mg. of crystals, m. p. 206~210°C (decomp.), thereby obtained was collected by filtration, combined with the first crop, and recrystallized from ethanol-chloroform mixture, affording 165 mg. of pale yellow crystals, m. p. 211~213°C (decomp.).

Found: C, 45.48; H, 2.71; N, 3.97. Calcd. for $C_{25}H_{18}O_6N_2Br_2S_2$: C, 45.03; H, 2.72; N, 4.20%.

The benzene layer was separated from the filtrate left after removal of the second crop of crystals, the solvent was evaporated, and the residue was sublimed at 1 mmHg and 120°C, from which 85 mg. of 3,7-dibromotropolone was recovered.

**Hydrogenolysis of III.**—A solution of 90 mg. of III dissolved in 20 ml. of 0.1 N sodium hydroxide, added with 200 mg. of 5% palladium-charcoal, was shaken in hydrogen atomsphere at ordinary temperature. After the absorption of hydrogen ended, the catalyst was filtered off, the filtrate was acidified, and the precipitate thereby formed was crystallized from a mixture of ethanol and chloroform to 25 mg. of crystals, m. p. 230~233°C (decomp.), undepressed on admixture with II. The ultraviolet absorption spectra of these two substances were also in complete agreement.

**Hydrogenolysis of IV.**—A solution of 50 mg. of IV dissolved in 20 ml. of 0.1 N sodium hydroxide was added with palladium-charcoal. The mixture was treated as in the foregoing example. Recrystallization of the precipitate gave 15 mg. of crystals of m. p. 233~234°C (decomp.), undepressed on admixture with II. The ultraviolet absorption of this product was also in agreement with that of II.

**Bromination of II.**—A mixture of 60 mg. of bromine added to a suspension of 70 mg. of II in 5 ml. of chloroform was allowed to stand for 2 days and crystals were collected. This substance was found to be the unreacted II. The filtrate was evaporated under a reduced pressure and the oily residue solidified on being added with methanol. This solid was recrystallized from a chloroform-ethanol mixture to 10 mg. of pale yellow crystals, m. p. 207~210°C (decomp.), undepressed on admixture with IV. The ultraviolet absorption spectra of these two substances were also in good agreement. Admixture of this product with III melted at 195~200°C.

**Bromination of III.**—A suspension of 50 mg. of III in 5 ml. of chloroform, added by 60 mg. of bromine, was allowed to stand for 2 days. The reaction mixture was filtered to collect 30 mg. of crystals which was proved to be the unreacted III. The filtrate was treated as in the foregoing example and 10 mg. of pale yellow crystals, m. p. 207~209°C (decomp.), was obtained. This showed no depression of m. p. on admixture with IV.

**4-Isopropyl-5-(2′,5′-dibenzenesulfonamidophenyl)-tropolone (V).**—One drop of triethylamine was added to the reddish orange solution formed by dissolving 110 mg. of 4-isopropyltropolone and 100 mg. of I in 4 ml. of chloroform and the color of the solution changed immediately to yellow, gradually separating colorless crystals. After allowing the mixture to stand for 30 minutes, the crystals were collected by filtration, affording 130 mg. of colorless crystals, m. p. 253~256°C (decomp.). The filtrate was evaporated under a reduced pressure, 5 ml. of benzene and 1 ml. of 1 N sulfuric acid were added to the residue, and 10 mg. of the second crop of crystals, m. p. 247~251°C (decomp.), was collected. The first and second crops of crystals were combined and recrystallized from a chloroform-ethanol mixture to 135 mg. of crystals, m. p. 254~256°C (decomp.).

Found: C, 60.36; H, 4.67; N, 4.90. Calcd. for $C_{25}H_{26}O_6N_2S_2$: C, 61.06; H, 4.76; N, 5.09%.

The benzene layer was separated from the filtrate left after removal of the second crop of crystals, the solvent was evaporated from it, and the residue was sublimed under a reduced pressure, from which 60 mg. of 4-isopropyltropolone was recovered.

**3-Bromo-6-isopropyl-5-(2′, 5′-dibenzenesulfonamidophenyl)tropolone (VI).**—An orange solution formed on dissolving 170 mg. of 3-bromo-6-isopropyltropolone and 100 mg. of I in 4 ml. of chloroform was added with one drop of triethylamine and the solution turned yellow but there was no precipitation of crystals. After allowing this mixture to stand for 7 days, the solvent was evaporated under a reduced pressure, leaving a mixture of crystals and oil. To this residue, 5 ml. of benzene and 1 ml. of 1 N sulfuric acid were added and crystals that separated out were collected to 150 mg. of colorless crystals, m. p. 242~243°C (decomp.).

Found: C, 53.21; H, 3.67; N, 4.10. Calcd. for $C_{28}H_{25}O_6N_2BrS_2$: C, 53.39; H, 4.00; N, 4.45%.

The benzene layer was separated from the filtrate left after removal of crystals, the solvent was evaporated from this layer, and sublimation of the residue under a reduced pressure gave 85 mg. of the recovered 3-bromo-6-isopropyltropolone.

**3,7-Dibromo-4-isopropyl-5-(2′,5′-dibenzenesulfonamidophenyl)tropolone (VII).**—To the yellow solution formed on dissolving of 400 mg. of 3,7-dibromo-4-isopropyltropolone and 200 mg. of I in 8 ml. of chloroform, one drop of triethylamine was added and the solution changed transitrally red but returned immediately to the original yellow color. There was no precipitation of crystals after standing the mixture for 10 days. The solvent was evaporated under a reduced pressure from this mixture, 6 ml. of benzene and 1 ml. of 1 N sulfuric acid were added to the residue, and the crystallized residue was recrystallized from a chloroform-ethanol mixture to 330 mg. of pale yellow crystals, m. p. 195~197°C (decomp.).

Found: C, 47.62; H, 3.26; N, 3.73. Calcd. for $C_{28}H_{24}O_6N_2Br_2S_2$: C, 47.44; H, 3.42; N, 3.96%.

Evaporation of the benzene layer separated from the filtrate and low-pressure sublimation of its residue afforded 210 mg. of recovered 3,7-dibromo-4-isopropyltropolone.

**Hydrogenolysis of VI.**—Hydrogenolysis of 50 mg. of VI in the same manner as for III afforded 30

mg. of crystals, m. p. 251~253°C (decomp.), undepressed on admixture with V.

**Hydrogenolysis of VII.**—Treatment of 100 mg. of VII as in the foregoing examples afforded 50 mg. of crystals of m. p. 251~253°C (decomp.), undepressed on admixture with V.

**3-Isopropyl-5-(2',5'-dibenzenesulfonamidophenyl)-tropolone (VIII).**—Treatment of 110 mg. of 3-isopropyltropolone and 100 mg. of I in the same manner as for V afforded 140 mg. of crystals of m. p. 207~215°C (decomp.).

Found: C, 61.92; H, 4.59; N, 4.84. Calcd. for $C_{28}H_{26}O_6N_2S_2$: C, 61.05; H, 4.76; N, 5.09%.

There was recovered 60 mg. of 3-isopropyltropolone.

**Reaction of 5-Methyltropolone and I.**—One drop of triethylamine was added to the solution of 40 mg. of 5-methyltropolone and 50 mg. of I dissolved in 2 ml. of chloroform by which the solution turned dark brown and crystals began to form after some time. The mixture was allowed to stand for 2 hr. and 20 mg. of colorless crystals, m. p. 240~241°C, were obtained. This showed no depression of m. p. on admixture with *p*-phenylenedibenzenesulfonamide and the ultraviolet absorption spectra of the two substances were identical.

Evaporation of the filtrate left an oily substance to which benzene and 1 N sulfuric acid were added, and the benzene layer was separated. The benzene solution was chromatographed over silica gel and 20 mg. of 5-methyltropolone was recovered from it.

**Reaction of 5-Bromotropolone and I.**—One drop of triethylamine was added to the solution of 30 mg. of 5-bromotropolone and 20 mg. of I dissolved in 2 ml. of chloroform by which the color of the solution changed through dark green to dark brown. The reaction mixture was treated as above, and 15 mg. of *p*-phenylenedibenzenesulfonamide and 15 mg. of 5-bromotropolone were obtained.

## Summary

The reaction of tropolones with *p*-benzoquinonedibenzenesulfonimide was carried out and the following points were observed.

1) The 2', 5'-dibenzenesulfonamidophenyl group enters the 5-position of the tropolone ring, similar to the case of phenol.

2) The reaction proceeds in the same way in the case of 4-isopropyltropolone, without interference of the isopropyl group.

3) In the case of tropolones with a substituent in 5-position, reduction of *p*-benzoquinonedibenzenesulfonimide takes place.

A part of the expenses for the present work was supported by a fund from the Sankyo Co., Ltd., which is gratefully acknowledged.

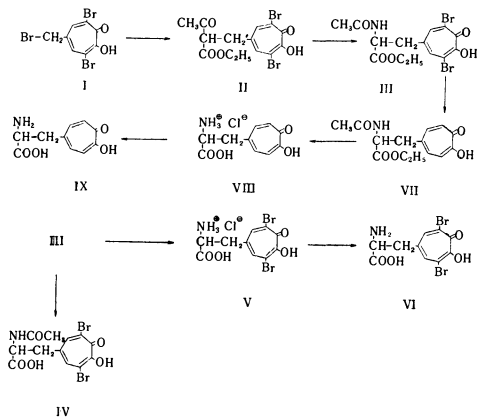
# *The Mannich Base of Troponoid and its Application. IV. The Synthesis of Tropolon-5-ylalanine*

By Shuichi SETO and Kyozo OGURA



(Received February 13, 1960)

It was shown in previous reports[1,2] that 5-hydroxymethyl-, 5-formyl- and 5-bromomethyl-tropolone derivatives were derived from 3, 7-dibromo-5-morpholinomethyltropolone and that 3, 7-dibromo-5-formyltropolone and 3, 7-dibromo-5-bromomethyltropolone (I) were important starting materials for the synthesis of various tropolone derivatives possessing a substituent in the 5-position of the tropolone ring. The present paper describes the synthesis of tropolone derivative possessing an amino acid residue in the 5-position of tropolone ring, i. e. tropolon-5-ylalanine, and related compounds from I.

Application of a large excess of ethyl potassioacetoacetate to I affords 3, 7-dibromo-5-(β-acetyl-β-ethoxycarbonylethyl)tropolone (II)[2] whose Schmidt reaction gives 3, 7-dibromo-5-(β-acetamido-β-ethoxycarbonylethyl)tropolone (III), m. p. 198°C. Hydrolysis of III with dilute alkali produces 3, 7-dibromo-5-(β-acetamido-β-carboxyethyl)tropolone (IV), m. p. 217°C (decomp.), but the treatment of III with concentrated hydrochloric acid with boiling gives 3, 7-dibromotropolon-5-ylalanine hydrochloride (V), m. p. 223~230°C (decomp.). Neutralization of V liberates 3, 7-dibromotropolon-5-ylalanine (VI), m. p. 216°C (decomp.). Hydrogenolysis of III over palladium-carbon as a catalyst, in methanol affords 5-(β-acetamido-β-ethoxycarbonylethyl)tropolone (VII), m. p. 176°C. Treatment of VII with concentrated hydrochloric acid by boiling produces

1) S. Seto and K. Ogura, This Bulletin, 32, 493 (1959).
2) S. Seto and K. Ogura, ibid., 32. 1118 (1959).

tropolon-5-ylalanine hydrochloride (VIII), m. p. 215~220°C (decomp.), which liberates tropolon-5-ylalanine (IX), m. p. 240°C (decomp.), by neutralization. The amino acids so obtained, VI and IX, color reddish violet to ninhydrin and the aqueous layer turns green with ferric chloride. The infrared spectra of these compounds show absorption bands[3] originating in the zwitter ion structure characteristic of amino acid[4], by the presence of marked absorption at 3030, 1631 and 1575 $cm^{-1}$ in VI and at 3020 and 1640 $cm^{-1}$ in IX.

## Experimental[5]

**3, 7-Dibromo-5-(β-acetamido-β-ethoxycarbonylethyl)tropolone (III).**— To a solution of 500 mg. of II dissolved in 25 ml. of benzene, 10 ml. of conc. sulfuric acid was added and the mixture was stirred under ice-cooling. To this mixture, 180 mg. of sodium azide was added and the stirring was continued for a further 1 hr. period, during which vigorous evolution of nitrogen gas occurred and the reaction product transited to the conc. sulfuric acid layer. The benzene layer was discarded, ca. 20 g. of cracked ice was added to the sulfuric acid layer, and the colorless precipitate thereby formed was collected by filtration. After washing the precipitate with water and drying, it was recrystallized from methanol and III was obtained as colorless needles, m. p. 197~198°C. Yield, 500 mg. The aqueous layer colored green to ferric chloride.

U. V. $\lambda_{max}^{MeOH}$ mμ (log ε): 268 (4.50), 345 (3.99), 430 (3.88).

**3, 7-Dibromo-5-(β-acetamido-β-carboxyethyl)tropolone (IV).** — A solution of 50 mg. of III dissolved in 0.5 ml. of 10% sodium hydroxide solution was heated on a water bath for about 10 min. and cooled to room temperature when yellow crystals of the sodium salt separated out. The salt was neutralized with 6 N hydrochloric acid, the colorless crystals that formed were collected, and recrystallized from ethanol. Yield, 20 mg. of m. p. 216~217°C (decomp.).

Found: C, 35.10; H, 2.61; N, 3.44. Calcd. for $C_{12}H_{11}O_5NBr_2$: C, 35.21; H, 2.69; N, 3.42%.

U. V. $\lambda_{max}^{MeOH}$ mμ (log ε): 268 (4.48), 345 (4.00), 425 (3.80).

**3, 7-Dibromotropolon-5-ylalanine Hydrochloride (V).** — A mixture of 150 mg. of III and 5 ml. of conc. hydrochloric acid was heated on a water bath for 2 hr. when the crystals dissolved completely. The solution was evaporated to dryness and residual colorless prismatic crystals were collected after addition of ethanol. Yield, 100 mg. of m. p. 223~230°C (decomp.).

Found: C, 30.11; H, 2.59; N, 3.38. Calcd. for $C_{10}H_{10}O_4NBr_2Cl$: C, 29.78; H, 2.48; N, 3.46%.

U. V. $\lambda_{max}^{MeOH}$ mμ (log ε): 267 (4.47), 340 (3.88), 425 (3.66).

**3, 7-Dibromotropolon-5-ylalanine (VI).** — Adjustment of 50 mg. of V to pH 6 by addition of diluted ammonia water produced a pale yellow precipitate which was collected, washed with water, and recrystallized from ethanol to colorless crystals, m. p. 215~216°C (decomp.). Yield, 30 mg.

Found: C, 32.70; H, 2.45; N, 3.82. Calcd. for $C_{10}H_9O_4NBr_2$: C, 32.91; H, 2.76; N, 3.25%.

U. V. $\lambda_{max}^{MeOH}$ mμ (log ε): 270 (4.85), 348 (4.09), 435 (4.90).

**5-(β-Acetamido-β-ethoxycarbonylethyl)tropolone (VII).**—A suspension of 1.5 g. of III in a solution of 0.6 g. of potassium hydroxide in 200 ml. of ethanol was shaken in hydrogen atmosphere after the addition of palladium-carbon catalyst. After absorption of 2 molar equivalents of hydrogen, the catalyst was filtered off and ethanol was evaporated completely from the filtrate. The residual, yellow potassium salt was dissolved in a small quantity of water and neutralized with 6 N hydrochloric acid, by which a yellow precipitate was produced. The mother liquor left after removal of the precipitate also afforded a small quantity of VII, m. p. 171~173°C, by extraction with ethyl acetate. Yield, 0.6 g.

Found: C, 59.42; H, 5.90; N, 5.01. Calcd. for $C_{14}H_{17}O_5N$: C, 60.20; H, 6.14; N, 5.02%.

U. V. $\lambda_{max}^{MeOH}$ mμ (log ε): 231 (4.37), 228 (4.05).

**Tropolon-5-ylalanine Hydrochloride (VIII).**—A solution of 100 mg. of VII dissolved in 0.5 ml. of conc. hydrochloric acid was heated on a water bath for 1 hr. and the solution was evaporated to dryness, leaving a syrupy residue. The addition of ethanol to this residue resulted in crystallization, the crystals were collected, and recrystallized from ethanol. Yield, 50 mg. of m. p. 220°C (decomp.).

Found: C, 48.76; H, 5.27; N, 5.45. Calcd. for $C_{10}H_{12}O_4NCl$: C, 48.40; H, 4.84; N, 5.70%.

U. V. $\lambda_{max}^{MeOH}$ (log ε): 229 (4.37), 326 (4.01).

**Tropolon-5-ylalanine (IX).** — A solution of 100 mg. of VIII dissolved in a small quantity of water was adjusted to pH 6 by addition of dilute ammonia water, the precipitate formed was collected, and recrystallized from ethanol. Yield, 40 mg. of m. p. 240°C (decomp.).

Found: C, 52.20; H, 5.77; N, 5.83. Calcd. for $C_{10}H_{11}O_4N \cdot H_2O$: C, 52.86; H, 5.77; N, 6.17%.

U. V. $\lambda_{max}^{MeOH}$ mμ (log ε): 230 (4.31), 330 (4.00).

# *Infrared Spectra of Diacetyl Monoxime and Isonitrosoacetone*

By Masao KIMURA, Yoko KURODA, Hitoshi TAKAGI*
and Masaji KUBO

(Received February 17, 1960)

Oximes are known to be subject to association, which has hampered the elucidation of the molecular structures of this type of compounds by means of physical methods such as dipole moment measurement, etc. The association through hydrogen bonding is an interesting problem in its own right and extensive studies have been made on these compounds by means of infrared spectroscopy[1] and Raman effect and also by the freezing point depression[2] of solutions, X-ray analysis[3-6] on crystals, etc. For this purpose, it is desirable and even necessary to carry out as complete assignments as possible of observed frequencies to various modes of vibrations of characteristic groups. Two oximes having conjugated double bonds were chosen in the present study anticipating the possible increase of the effect of hydrogen bonding due to conjugation.

## Materials

**Diacetyl Monoxime.**—A commerical preparation was purified by recrystallization from an aqueous solution (m. p. 74.5°C).

**Isonitrosoacetone.**—A commercial sample was purified by extraction from an ether solution with petroleum ether (m. p. 64.5°C).

## Experimental

The infrared spectra were recorded with a Hilger H-800 infrared spectrophotometer equipped with a rock-salt prism as well as with a fluorite prism. Both these compounds were studied in carbon tetrachloride and in carbon bisulfide, no appreciable dependence of frequencies upon the kind of solvents being observed. For isonitrosoacetone, which was sparingly soluble in carbon tetrachloride and carbon bisulfide, also chloroform solutions were employed. The results are shown in Tables I and II.

The spectra of solutions of various concentrations, solid samples, and some of the deuterated compounds, $CH_3$-CO-CR-NOD ($R=CH_3$ or H), were also studied whenever they were required for carrying out assignments.

## Discussion

The spectra of diacetyl monoxime and isonitrosoacetone in the wave number range from 3200 to 3600 $cm^{-1}$ are reproduced in Figs. 1 and 2. They show a very strong sharp band at about 3570 $cm^{-1}$ and a broad band at about 3330 $cm^{-1}$. The intensity of the former decreases, whereas that of the latter increases with increasing concentration. The former disappears completely in the solid state. These bands are absent in the spectra of the corresponding deuterated compounds, which display a new strong sharp band at about 2620 $cm^{-1}$ along with a broad band at about 2470 $cm^{-1}$. These facts indicate that the band of diacetyl monoxime at 3577 $cm^{-1}$ and that of isonitrosoacetone at 3574 $cm^{-1}$ can be unequivocally assigned to the OH stretching vibration of free OH groups, while the band of the former compound at about 3345 $cm^{-1}$ and that of the latter at about 3325 $cm^{-1}$ can be assigned to the OH stretching vibration of hydrogen-bonded OH groups. These wave numbers suggest that

intermolecular hydrogen bondings are involved in association, because the stretching vibration of OH groups forming a chelate ring is known[7] to absorb at a frequency much lower than 3300 $cm^{-1}$.

The value of about 3570 $cm^{-1}$ for the wave number of stretching vibration of free OH groups is fairly low compared with those of alcohols ranging in 3600~3650 $cm^{-1}$ and is rather close to those of carboxylic acids at about 3600 $cm^{-1}$. Oximes having no conjugate double bonds, such as acetaldoxime, acetoxime, cyclohexanoxime, etc.[8] absorb at about 3600 $cm^{-1}$ in solutions, while those containing conjugate double bonds show absorptions at lower frequencies. For instance, benzaldoxime and its derivatives absorb in the wave number range 3500~3560 $cm^{-1}$ in solutions,* and quinone monoxime[10] at 3540 $cm^{-1}$. The present results are consistent with this relation. On the other hand, the values of 3345 $cm^{-1}$ and 3325 $cm^{-1}$ for the wave numbers of stretching vibrations of hydrogen-bonded OH groups of the two compounds under investigation are higher than those of the oximes mentioned above, most of which absorb at a wave number lower than 3300 $cm^{-1}$**.

Three types of hydrogen bonds can be presumed, namely –OH···N=C, –OH···O–N= and –OH···O=C–. The type of association will be discussed below in connection with other absorption bands. As can be anticipated, Raman spectra show no line corresponding to OH stretching vibration or only a very weak line[11,12].

The weak broad bands at 3065 and 2945 $cm^{-1}$ of diacetyl monoxime were assigned to the degenerate and symmetric stretching vibrations of methyl groups, respectively. The appearance of these bands observed in solutions were not altered appreciably on solidification or on deuteration. The corresponding bands and the CH stretching vibration of isonitrosoacetone were too weak to be observed with certainty. Therefore, they are not listed in Table II.

The spectra in the wave number range covering 1600~1700 $cm^{-1}$ are shown in Figs. 3 and 4. Diacetyl monoxime has a very strong band at 1698 $cm^{-1}$ with a shoulder at 1686 $cm^{-1}$. The corresponding band of isonitrosoacetone split into two peaks, a main peak being found at 1703 $cm^{-1}$ and a subsidiary one at 1674 $cm^{-1}$. Besides, a relatively weak band appeared at 1630 $cm^{-1}$ in the spectrum of diacetyl monoxime and at 1614 $cm^{-1}$ in that of isonitrosoacetone. The general features of these bands were not affected by deuteration, except for slight changes taking place in the

position of absorption bands. In general, saturated open chain ketones absorb in the range of 1705~1725 $cm^{-1}$, while compounds having a C=N bond show an absorption in the range of 1640~1690 $cm^{-1}$, provied that the compounds have an open chain or that they have a ring system involving no conjugation. Although the frequencies of CO and CN stretching vibrations may shift to some extent in conjugate systems, it is still reasonable to presume that the CO stretching vibration has a higher frequency than that of the CN stretching vibration. In addition, a band due to the CO stretching vibration is, in general, very strong, whereas a band due to the CN stretching is not always so. For these reasons, the bands at about 1700 $cm^{-1}$ were assigned to the CO stretching vibration and those at about 1620 $cm^{-1}$ to the CN stretching mode.

Kahovec and Kohlrausch[12] observed two Raman frequencies, 1679 and 1632 $cm^{-1}$, of diacetyl monoxime in the crystalline state. They tentatively assigned these frequencies to the CO stretching and the CN stretching vibration, respectively, with due precaution to the low value of the latter frequency compared with those of acetaldoxime, etc.[11,13,14] at about 1670 $cm^{-1}$. Their assignments seem to be adequate, because strong conjugation in a molecule will lower the characteristic frequency associated with a double bond. In fact, Hadži[10] observed the CO band of 1, 4-benzoquinone monoxime at 1628 $cm^{-1}$ in the solid state and at 1648 $cm^{-1}$ in solutions and also the CN band at 1555 $cm^{-1}$ in the solid state. Palm and Werbin[9] have made observations on the CN frequencies of benzaldoxime and its derivatives in the solid state, the observed values ranging from 1614 to 1650 $cm^{-1}$.

The CO bands mentioned above showed a decrease in intensity of the main peak and an increase in that of the subsidiary peak or the shoulder with increasing concentration. The effect of association on the CO stretching frequency is presumed to cause a shift towards a lower frequency owing to the increased single bond character of the C=O bond due to hydrogen bond formation. Accordingly, the main peaks were assigned to the stretching vibration of free CO groups while the subsidiary peak and the shoulder were assigned to that of hydrogen-bonded CO groups. This suggests that hydrogen bonds of the -OH··· O=C- type are present in solutions.

The absorption spectrum of diacetyl monoxime in the wave number range 1300~1500 $cm^{-1}$ is shown in Fig. 5. A band at about

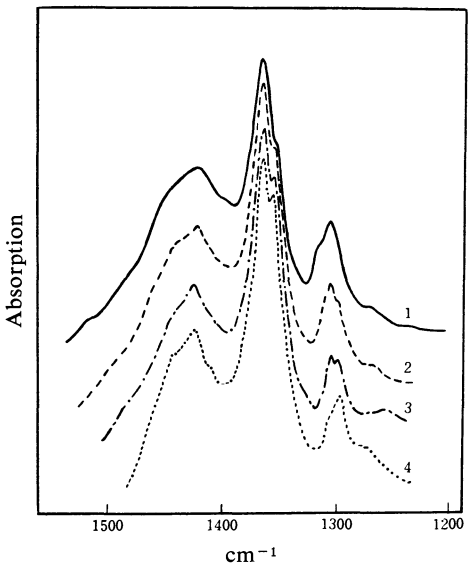

Fig. 5. Diacetyl monoxime in carbon tetrachloride.

The concentrations and the cell lengths are the same as given in Fig. 3.

1424 $cm^{-1}$ is a broad one of medium intensity. A strong band 1365 $cm^{-1}$ had a shoulder, which changed into a distinct maximum at 1355 $cm^{-1}$ with increasing dilution. The same compound in the solid state showed a broad band at about 1430 $cm^{-1}$ and a sharp one at 1365 $cm^{-1}$, no peak or shoulder being observed at about 1355 $cm^{-1}$. The change of spectral features taking place on deuteration was inappreciable, except that the band at 1355 $cm^{-1}$ disappeared and a new band appeared at about 1000 $cm^{-1}$, although it overlapped with other bands. Based on these experimental facts, the band at 1355 $cm^{-1}$ was assigned to the bending vibration of free OH groups. Palm and Werbin[15] proposed to assign a band of $\alpha$(*syn*)-benzaldoxime at 1265 $cm^{-1}$ to the OH in-plane bending vibration, Hadži[10] assigned a band of quinone oxime near 1450 $cm^{-1}$ to the OH bending vibration, and Bratož et al.[16] found the values of 1460 and 1078 $cm^{-1}$ for the OH and OD bending vibrations, respectively. These results suggest the adequacy of the present assignments.

Two bands at 1424 and 1365 $cm^{-1}$ mentioned above were assigned to the $CH_3$ degenerate and symmetric deformation vibrations, respectively, because they showed no concentration change and also because they were not affected by deuteration. The slight decrease of these frequencies below those of hydrocarbons is presumed to be a result of the presence of a C=O or C=N group in the molecule. In fact,

acetone[17] shows absorptions at 1430 and 1363 $cm^{-1}$ and diacetyl at 1426 and 1362 $cm^{-1}$ in the vapor state and at 1420 and 1352 $cm^{-1}$ in the liquid state[18,19]. The Raman frequencies of diacetyl monoxime observed by Kahovec and Kohlrausch[12] correspond to these vibrational modes. The OH bending frequency of hydrogen-bonded OH groups was not observed clearly but, as suggested also by Califano and Lüttke[20] in their studies on formaldoxime and acetoxime, is expected to be masked by the band at 1424 $cm^{-1}$. In fact, this band became relatively weak and sharp with decreasing concentration as well as on deuteration.

Another band at about 1300 $cm^{-1}$ appeared to consist of two component peaks at 1304 and 1298 $cm^{-1}$. The former was stronger than the latter in concentrated solutions, whereas the intensity relation was reversed in dilute solutions. Accordingly, by taking into account the weak intensity of the band and the value of the wave number, the former was assigned to the C–C(central) stretching vibration of associated molecules, while the latter was assigned to that of unassociated ones. The increase of frequency displayed by associated molecules over that of unassociated ones can be readily explained, since the C–C bond in an associated molecule has a greater double bond character than the bond has in an unassociated molecule. This rather weak band due to the C–C stretching vibration has its counterpart in the Raman spectra observed by Kahovec and Kohlrausch[12], who observed a very strong Raman band at 1310 $cm^{-1}$ in a chloroform solution and at 1315 $cm^{-1}$ in the crystalline state. The value of 1300 $cm^{-1}$ is fairly large for a C–C stretching vibration, but is nearly equal to 1284 $cm^{-1}$ observed in the Raman spectra of diacetyl involving also the conjugation of double bonds[18,19].

In this wave number range, isonitrosoacetone absorbed in much the same way as diacetyl monoxime did. The spectra of the former differed from that of the latter only in that the absorption frequency due to the OH bending vibration at 1398 $cm^{-1}$ and that due to the $CH_3$ degenerate deformation vibration overlapped each other. Accordingly, the latter was evaluated from the spectra of the solid or of the deuterated sample. The same precaution was also taken for the C–C stretching vibration, because it was very weak.

The vibrational modes expected to appear in the wave number range 800~1250 $cm^{-1}$ are $CH_3$ in-plane and out-of-plane rocking vibrations, an NO stretching vibration, a C–$CH_3$ stretching vibration and an OH out-of-plane bending vibration. Isonitrosoacetone will show additional bands due to the CH in-plane and out-of-plane bending motions. Only a band arising from the NO stretching vibrations is possibly subject to an intensity change with concentration. A band having such a character was observed at 963~970 $cm^{-1}$ for diacetyl monoxime (See Fig. 6.) and at 972~990 $cm^{-1}$ for isonitrosoacetone.

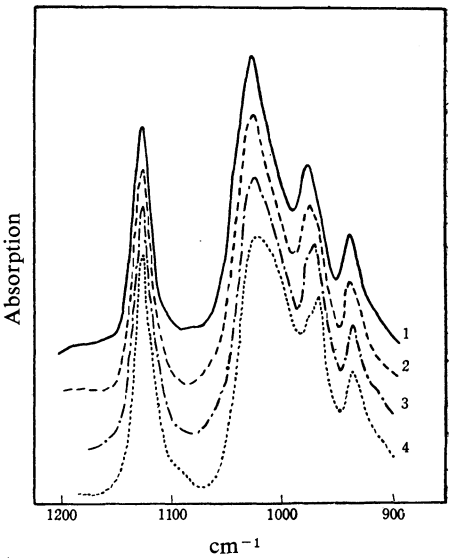

Fig. 6. Diacetyl monoxime in carbon tetrachloride.
1) 0.397 mol./1., 0.008 cm. cell. 2) 0.198 mol./1., 0.016 cm. cell. 3) 0.099 mol./1., 0.032 cm. cell. 4) 0.060 mol./1., 0.053 cm. cell.

The double bond character of the N–O bond will be greater in associated molecules than in unassociated ones. Accordingly, the increase in the amount of associated molecules with increasing concentration will give rise to an increase in the intensity of the component peak of higher frequency. This explains adequately the results of observations that with increasing dilution the maximum of these composite bands shifted towards the longer wavelength side. Hadži[10] assigned a band of 1, 4-benzoquinone monoxime at 1025 $cm^{-1}$ while Palm and Werbin[15] assigned the bands of various oximes at about 940 $cm^{-1}$ to the NO stretching vibration. The present assignment is in agreement with theirs.

A weak band of diacetyl monoxime at 933 $cm^{-1}$ and that of isonitrosoacetone at 920 $cm^{-1}$ were assigned to the C–$CH_3$ stretching vibration, reference being directed to a similar band of diacetyl at 945 $cm^{-1}$.

20) S. Califano and W. Lüttke, *Z. physik. Chem.* (neue Folge), **6**, 83 (1956).

Isonitrosoacetone showed an absorption at 833 $cm^{-1}$, which had no counterpart in the spectrum of diacetyl monoxime. For this reason and also because the frequencies of out-of-plane vibrations are known to be lower than those of in-plane vibrations, this band was assigned to the CH out-of-plane bending vibration.

Bands still left to be assigned are those of diacetyl monoxime at 1124 and 1022 $cm^{-1}$ and of isonitrosoacetone at 1226 and 1016 $cm^{-1}$. Since CH in-plane bending vibrations usually absorb at higher frequencies than $CH_3$ in-plane rocking vibrations do, the band at 1226 $cm^{-1}$ was assigned to the CH in-plane bending mode and others to the $CH_3$ rocking modes.

For both diacetyl monoxime and isonitrosoacetone, the band near 1020 $cm^{-1}$, which was sharp in the solid state, showed a hump on the lower frequency side especially in dilute solutions. This suggests the presence of another band capable of being assigned to the OH out-of-plane bending vibration of unassociated molecules.

In this way, all major observed bands have been interpreted in terms of the molecular form of an oxime type, $CH_3$–CO–CR=NOH (R=$CH_3$ or H). If the molecules exist in a nitroso form, $CH_3$–CO–CHR–NO, bands ascribed to hydroxyl groups in the present investigation could hardly be explained adequately. In addition, the presence of a C–N bond and an N=O bond in a molecule of the nitroso form in place of a C=N bond and an N–O bond as in that of the oxime form will render proper assignments almost impossible. The coexistence of the two forms is also ruled out, because the spectra are simpler than might be expected for the presence of the two forms. This conclusion affords at least an element of simplification in dealing with these molecules by means of other physical methods of attack.

## Summary

The infrared absorption spectra of diacetyl monoxime and isonitrosoacetone in solutions were recorded in the rock-salt region. The assignment of observed bands was carried out, taking into account the concentration dependence of the spectra, the effect of deuteration, and the absorptions in the solid state. All the observed frequencies could be interpreted in terms of the molecular form of an oxime type, the presence of molecules in a nitroso form being presumed to be unlikely.

# *Spectroscopic Study on the Living Polymers of Styrene, Butadiene and their Derivatives*

By Keiji KUWATA

(Received October 29, 1959)

Recently the living polymers of styrene[1-3,5-7], its derivatives, butadiene[4] and isoprene have been an object of investigation, in view of their interesting property as an initiator of polymerization of vinyl monomers.

Their structure which seems to be the origin of the red color and the reactivity has been the subject of considerable discussion[1,2,5]. For the living polymer of styrene Szwarc proposed a structure of polymer anion having two groups of benzyl anion type at both ends of the polymer chain[2]. However, no direct evidence has been shown for this structure.

In the present paper, comparing the spectra of the living polymers of styrene and its derivatives with that of alkali benzyl, the

author is to report that their structure is a polymer anion with the end of benzyl anion type.

The existence of the living polymers of butadiene and isoprene was asserted by Szwarc et al.[4] In this paper, their structure and reactivity are to be discussed from the spectroscopic data on the living polymers prepared by the direct reaction of butadiene and isoprene with metallic sodium, and on the block polymerization of isoprene with the living polymers of styrene.

## Experimental

**Materials Used.**—Since the living polymers have an extreme reactivity toward water, oxygen, and carbon dioxide, special precautions on purifications of the starting materials are required[5,7]. In addition to the ordinary method of purification the monomers (styrene, $\alpha$-methyl styrene, *p*-methyl styrene and *p*-divinyl benzene) were dried over metallic sodium for several hours and then distilled into storage vessels under reduced pressure. The solvents, tetrahydrofuran (THF), dioxane and toluene, were refluxed over metallic sodium or potassium for several hours, and also distilled under reduced pressure into a glass ampoul containing a piece of sodium and a small amount of anthracene. The blue color appeared instantly and stayed permanently. The solvents were distilled under reduced pressure into the reaction vessel as required. For toluene, however, styrene was used instead of anthracene, since toluene is a poor solvent for sodium adduct of anthracene. Mercury dibenzyl, prepared by the Grignard reaction[8] between benzylmagnesium chloride with mercuric chloride, was purified by recrystallization from toluene. Diallyl ether of GR grade, dried over metallic sodium for a short time, was purified by distillation under reduced pressure.

**Preparation of the Samples.**—All the processes of preparations and measurements were carried out in the glass vessels which were previously degassed as much as possible. A typical method of preparation was as follows: Alkali metal was distilled under reduced pressure from an ampoul A into an ampoul B (see Fig. 1). Monomer or solvent was distilled into B from an ampoul C. Then the vessel was sealed off from the vacuum system. The reaction proceeded gradually and an intensely colored solution of the living polymer formed. This solution was filtered through a glass filter G and stored in an ampoul D. The solution of the living polymer or the anion formed was poured into the measuring cell E and was diluted by the solvent distilled from D until an appropriate concentration was obtained. The concentration of the living polymers of styrene and isoprene were determined by the flame spectroscopy of alkali metal contained in the solutions, and the molar extinction coefficients of the living polymers were estimated.

8) P. Wolff, *Ber.*, **46**, 64 (1913).

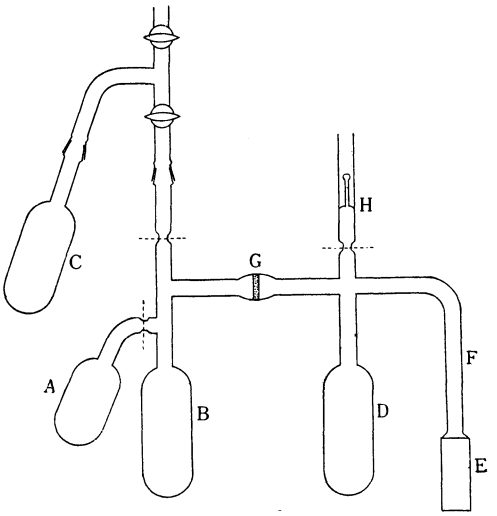

Fig. 1. Apparatus for preparation of the living polymers.
A, B, C and D: Glass ampoul, E: quartz cell, F: Gradual joint, G: Glass filter, H: Breakable joint.

**Measurement of Absorption Spectra.** — Absorption spectra of the living polymers and the anions were measured from 300 m$\mu$ to 2 $\mu$ with a Beckman DU type spectrophotometer equipped with an additional cover on the cell holder. After the measurement of the spectra, the vacuum was broken off and the spectra of the product were again measured.

## Experimental Results

A spectrum between 300 m$\mu$ and 2 $\mu$ for the toluene solution of the living polymer of styrene is shown in Fig. 2. In addition to the characteristic absorption at 510 m$\mu$ which had already been reported[1,5] another absorption at 450 m$\mu$ and an end absorption at longer wavelength were also observed. On the THF and dioxane solutions the absorptions were observed at 520 and 535 m$\mu$ respectively, shifting

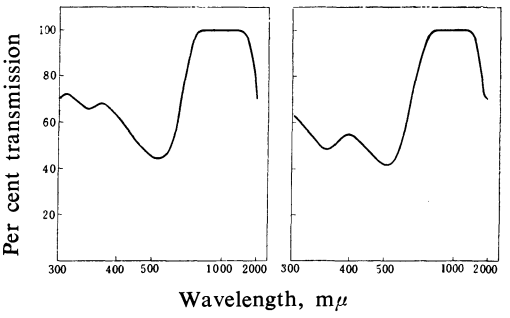

Fig. 2. Spectrum of the toluene solution of the living polymer of styrene.

Fig. 3. Spectrum of the THF solution of benzyl anion sodium.

toward longer wavelength according as the solutions were diluted.

The near infrared spectrum for the filmy state of the living polymer of styrene from 2 to 3.5 $\mu$ was the same as that of polystyrene, but its intensity was stronger than that of "dead polymer"* throughout this region. Therefore a very broad absorption in this region may exist. In the cases of the living polymers of styrene with potassium, rubidium and cesium in toluene solution, the corresponding absorptions were observed at 518, 525 and 535 m$\mu$ respectively.

For the living polymer of 1, 1-diphenyl ethylene in THF solution, the absorption at 525 m$\mu$ and two other absorption at 450 m$\mu$ and the end one at longer wavelength were also observed.

In cases of $\alpha$-methyl styrene and $p$-methyl styrene of toluene solution the absorption at 515 m$\mu$ was observed in addition to two other absorptions.

The absorptions at 550 and 1650 m$\mu$ were observed in case of divinyl benzene, and the latter seems to correspond to the end absorptions at longer wavelength for the living polymers of styrene etc.

A spectrum of the red THF solution of alkali benzyl is shown in Fig. 3. A maximum absorption which is characteristic of alkali benzyl at 505 m$\mu$ was observed in addition to two other absorptions. The shift of the maximum absorption at 505 m$\mu$ which originated from the alteration of alkali metal was very small. This absorption obeyed the law of Beer-Lambert within a concentration range of $10^{-2}\sim10^{-3}$ moles per litre.

Isoprene and butadiene reacted with sodium film, forming yellow adducts of high molecular weight. Dissolving these adducts into THF, slightly yellow and very reactive solutions were obtained. These solutions showed the maximum absorptions at 375 and 357 m$\mu$ respectively, and could initiate the polymerization of styrene and isoprene. These absorptions quickly disappeared upon exposure to air. A spectrum for the living polymer of isoprene in THF solution is shown in Fig. 4.

A yellow solution of allyl sodium containing sodium allylate, which was a byproduct[9] of the reaction, had a maximum absorption at 375 m$\mu$ and an end absorption at longer wavelength as shown in Fig. 5. The maximum absorption at 375 m$\mu$ was unaltered on dilution within the concentration range of $10^{-2}\sim10^{-3}$ moles per litre.

* The reaction product of the living polymer with air, and such product has no more reactivity to initiate the polymerization of styrene etc.

9) R. L. Letsinger and J. G. Traynham, *J. Am. Chem. Soc.*, **70**, 3342 (1948).

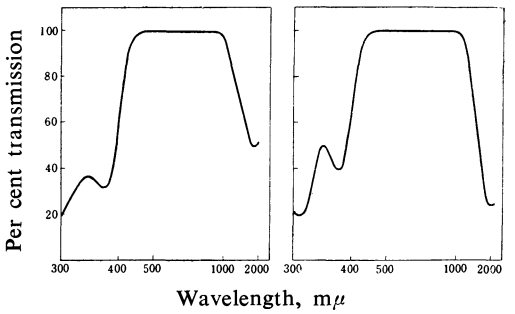

Fig. 4. Spectrum of the THF solution of the living polymer of isoprene.

Fig. 5. Spectrum of the THF solution of allyl sodium.

Block polymerization of isoprene with styrene was carried out, by use of the living polymer of styrene as the initiator, as follows: A constant amount of purified isoprene monomer was added by distillation through a breakable joint into the THF solution of styrene living polymer contained in ampoul D (Fig. 1). The absorption at 510 m$\mu$ of the living polymer of styrene (Fig. 6a) decreased by addition of isoprene and the absorption at 375 m$\mu$ of the living polymer of isoprene appeared as shown in Fig. 6b. The latter increased by further addition of isoprene as shown in Fig. 6c.

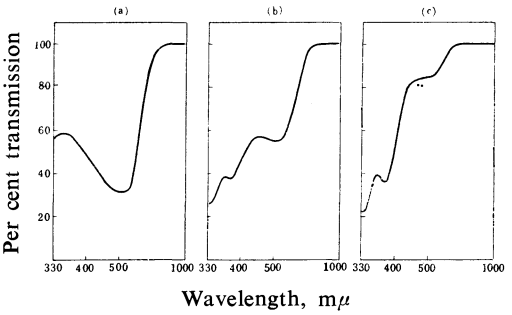

Fig. 6. Change of spectrum in the block polymerization of isoprene by the living polymer of styrene.

## Discussion

**Absorption Spectra of Benzyl Anion Type.**— Since the two maximum absorptions and the end absorption observed for the living polymer of styrene disappeared quickly upon exposure to air, they seem to be characteristic of the living polymer. However, when the starting materials used were not perfectly purified, yellow solutions were obtained. They had the maximum absorption only at 430 m$\mu$ besides the end absorption, and could not initiate polymerization. These two absorptions, therefore, may have originated from the decomposition product of the living polymer.

It seems that the temperature dependence of the absorption at 510 mμ of the living polymer of styrene may indicate the behaviour of association, but further study is necessary to confirm the conjecture.

The other absorption at 510 mμ, which may be a characteristic measure of the living polymer of styrene varied according as the kind of alkali metal was altered. The intermolecular charge-transfer spectra shown by a large number of molecular complexes in solution were found to exhibit certain regularities in regard to wavelength[10]. The wavelength of these transitions shows an excellent correlation i.e. a linear relation between frequency $\nu$ and ionization potential $I_p$ of the electron donor partners of the complexes :

$$h\nu = 0.61 I_p - 1.8 \text{ (in eV.)}$$

In case of the living polymer of styrene, the similar relation seems to exist as shown in Fig. 7, but the decrease of wavelength with the increase of ionization potential was small as compared with those of the molecular complexes, and also no donor-acceptor complexes such as a type containing alkali metal as the donor or aromatic hydrocarbon as the acceptor has been known. The change of absorption, therefore, would be caused by the change of solvation or dissociation of the polymer anion.

Considering the facts that the position of the maximum absorption near 505 mμ of THF solution of benzyl sodium is constant on dilution and that ether solution of benzyl sodium is conductive as shown by previous investigators[11], it is believed that alkali benzyl

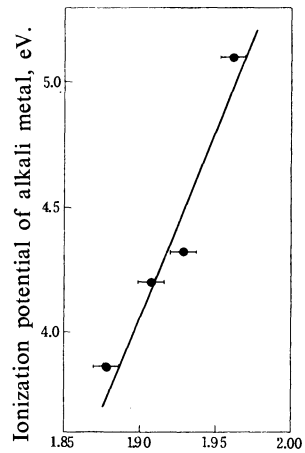

Fig. 7. Ionization potential of alkali metal versus the frequency of the absorption maximum.

in dilute THF solution is completely ionized. The absorption curve of alkali benzyl is the same as that of the living polymer of styrene. It seems evident, therefore, that the end group of benzyl anion type exists in the solution.

The theoretical investigations on the electronic states of benzyl anion and allyl anion were already carried out by several researchers[12-14]. Theoretically calculated wavelength of absorption for benzyl anion, shown in Table I are shorter than that of the observed absorption. The cause of this difference is partly due to the solvation of anion, but this effect may not be so much. Therefore,

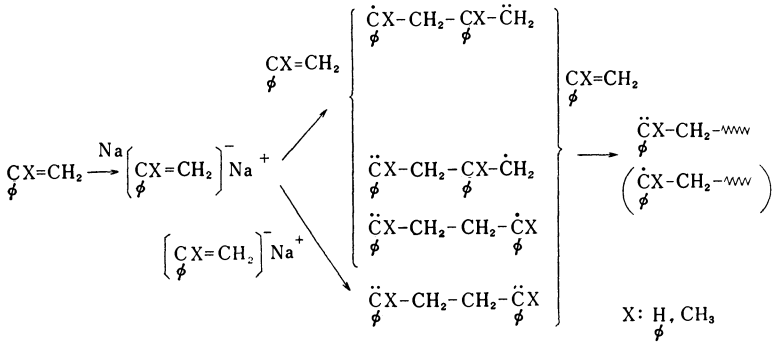
it may be attributed to oversimplification of the theory or to inadequate estimation of the electron interaction integrals used, as will be discussed later in the case of allyl anion.

The small difference of the absorption maximum between the solution of alkali benzyl and the living polymer of styrene may be ascribed to the effect of substitution of $\alpha$-hydrogen of benzyl anion by the polymer chain of polystyrene, since no difference was observed between the solution of alkali benzyl-polystyrene mixture and that of alkali benzyl.

As an effect of substitutions in anionic group of the living polymer of styrene, it was observed that the maximum absorption shifted toward a longer wavelength as the $\pi$-electronic conjugation in anionic group became larger. This effect was approximately interpreted by the Hückel treatment on the $\pi$-electronic structure of the anions as shown in Table II.

**Absorption Spectra of Allyl Anion Type.**—By comparing the maximum absorptions of the living polymers of butadiene and isoprene at 375 and 357 m$\mu$ with that of allyl sodium, they seem to be characteristic of allyl anion. Extinction coefficient of the absorption for the living polymer of isoprene was the order of $3\times10^3$ corresponding to the calculated oscillator strength of the order of 0.036 for allyl anion. Two other absorptions for the solution of the living polymers and that of anion may be attributed to the decomposition product or the byproduct. A typical value[14] of the longest wavelength calculated semi-empirically for allyl anion is shown in Table I, where considerable discrepancies between calculated and experimental values exist. This may be ascribed to the solvation of the anion in solution to some extent, but should rather be attributed to other causes: for example, rough approximation in the theory or inadequate estimation of the integrals used. If the Coulomb electronic repulsion integral for the two electrons on adjacent two carbon atoms in the method of Pople or of Pariser and Parr is decreased, a better approach to the observed value will be obtained*. Such a correction seems to be reasonable since the abnormally partial distribution of electronic charge, which resulted from the calculation, diminishes at the same time. A value corrected on this line is listed in Table I, showing that the partial distribution of charge diminishes to that of the Hückel method. It may be reasonable to consider that the structure of the living polymers of butadiene and isoprene are the polymer anion having the group of allyl anion type at the end of a polymer chain.

Both benzyl sodium and allyl sodium were known to have a reactivity as the initiators of polymerization of styrene[15] etc. Therefore, it may be plausible to attribute the reactivity of the living polymers to their anionic groups. Such a presumption was justified by the change of spectrum for the living polymer of styrene to that for isoprene, in the block polymerization of isoprene by the use of the living polymer of styrene as the initiator; the alteration of end group of benzyl anion type with that of allyl anion type may occur as follows:



**Mechanism of Polymerization.**—The existence of the radical anion of styrene and its derivatives in the living polymers of low molecular weight was shown by the paramagnetic resonance absorption measurements[6,17]. Then the first step of the polymerization of styrene and its derivatives may be the formation of the radical anion which can play the role of the initiator of polymerization. The next step is the successive addition of monomers to the radical anion which will convert into the polymer anion making the polymerization reaction proceed. The end groups of radical type did not remain in the solution of the living polymers except the relatively stable diphenylmethyl radical type formed from the radical anion of 1, 1-diphenyl ethylene[16,17]. The general reaction scheme may be as follows:

* Since the electronegativities of the carbon atoms of the anions should be different from these of the neutral molecule, the correction on this line is also necessary.

15) A. A. Morton, *J. Am. Chem. Soc.*, **68**, 93 (1946).

16) K. Kuwata, K. Morigaki, K. Hirota and J. Itoh, *Annual Reports of the Institute for Fibre Research (Sen-i Kagaku Kenkyu-jo Nen-po)*, **12**, 9 (1959).

17) K. Kuwata, S. Ishida and K. Hirota, *J. Chem. Soc. Japan Pure Chem. Sec. (Nippon Kagaku Zasshi)*, **80**, 25 (1959).

This scheme is more general than that of Szwarc, because the formation of radical anions is considered in addition to the bivalent dimer anion proposed by Szwarc.

In cases of butadiene and isoprene the situation is the same, but the existence of monomer radical anion has been confirmed experimentally only with isoprene[18].

## Summary

The absorption spectra of the living polymers of styrene and its derivatives as well as of alkali benzyl have been measured from near infrared region to near ultra violet region, and they were compared. It has been concluded that these living polymers are the polymer anions having the groups of benzyl anion type at the end of a polymer chain.

The living polymers of butadiene and isoprene have been separated as the intermediates of polymerization by metallic sodium, and their spectra have been measured. Comparing these spectra with that of allyl sodium, it has been concluded that the living polymer of butadiene and isoprene are the polymer anions having the groups of allyl anion type at the end of a polymer chain. The spectroscopic study on the block polymerization of isoprene with the living polymer of styrene has been carried out. The mechanism of polymerization has been discussed.

The author wishes to express his sincere thanks to Professor Kozo Hirota of Osaka University for his guidance and encouragement throughout this work, and is also indebted to Professor Saburo Nagakura of Tokyo University for his helpful discussions.

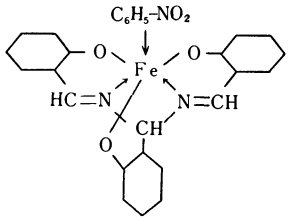
# *Coördinate Valency Rings. XXIV.*[1] *On Some Inner Complex Ferric Salts of Hydrosalicylamide and its Derivatives**

By Tokuichi TSUMAKI, Shigetoshi ANTOKU and Michio SHITO

(Received February 12, 1960)

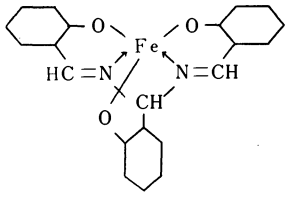
It is well known that salicylaldehyde reacts readily with ammonia in an alcoholic solution to form hydrosalicylamide, which consists of 3 molecules of salicylaldehyde and 2 molecules of ammonia, involving elimination of 3 molecules of water. When hydrosalicylamide is treated with divalent metallic salts, such as

(1)



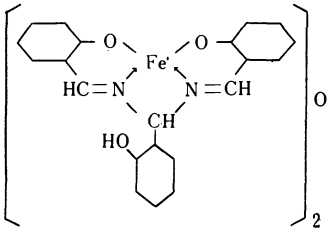
1) Part XXIII: T. Tsumaki, K. Katsuta and S. Okada, *J. Chem. Soc. Japan, Pure Chem. Sec.* (*Nippon Kagaku Zasshi*), **78**, 1086 (1957).

* Presented at the Joint Meeting of the Chugoku-Shikoku Branch and Kyushu Branch of the Chemical Society of Japan, Matsuyama, June 7, 1958.



copper or nickel salts, metal chelates of salicylaldimine (formula 1) instead of those of hydrosalicylamide are obtained[2].

In the chelate-forming reactions, therefore, hydrosalicylamide splits by metallic salts giving one molecule of salicylaldehyde.



An attempt was made in 1934, by one of the authors[3], to obtain an analogous ferrous complex salt, that is, bis-salicylaldimine-iron-(II) by the reaction between hydrosalicylamide and ferrous sulfate. But the obtained chelate recrystallized from nitrobenzene was trisalicylaldehyde-diimine-iron(III), which contained one molecule of nitrobenzene coördinated to iron atom (formula 2). During the reaction, therefore, ferrous complex salt was oxidized to ferric by atmospheric oxygen.

(2)

(3)

(4)

Later, by using ammonium ferric sulfate, instead of ferrous sulfate, the same product was obtained as had been expected[4].

In the above-mentioned reactions, the main product, before recrystallization from nitrobenzene, consists of reddish brown powder. In the present paper are described the method of preparation of this compound in pure state and the comfirmation of its chemical structure. The structure of the compound, in recognition of the structure of nitrobenzene-containing chelate indicated by formula 2, is considered as a rarely known penta-coördinated ferric complex (formula 3). Besides formula 3, another formula, 4, may be taken into consideration for the ferric complex, on the basis of the results of elementary analysis and of the route of preparation of the complex. Of these two formulae, the latter should be excluded for reasons described below.

1) The complex salt does not react with diazomethane. The presence of a phenolic hydroxyl group must be denied.

2) It is known that the ferric complexes of oxide-form, for example, bis-salicylaldehyde-ethylenediimine-ferric oxide, react with a number of weak organic acids to give their salts (formula 5)[5]. Our complex, however, does not show such behavior.

3) If the hydroxyl group of the central salicylidene group does not take part in the complex formation as in the case of formula 4, the synthesis of a complex salt having formula 6, which has a benzylidene group in place of a salicylidene group in formula 4, may be possible by the action of a ferric salt on 2, 2′-dihydroxyhydrobenzamide. The complex salt of formula 6, however, could not be obtained by such attempts, and only a complex salt of hydrosalicylamide having formula 3 was obtained. Therefore, it can be considered that benzaldehyde splits off from the ligand and salicylaldehyde takes its place in the course of the reaction. This fact indicates that three hydroxyl groups of hydrosalicylamide may all be used for the complex formation.

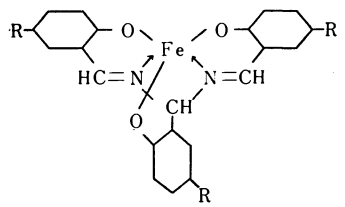
4) The infrared spectra indicate the absence of phenolic hydroxyl groups (Figs. 1 and 2).

Because of the above-mentioned experimental facts, the pentadentate formula 3 should be given to the ferric complex in question and the structure (formula 2) of its nitrobenzene-containing adduct has been proved to be correct.



For some of the so-called tri-coördinated copper complexes, the presence of dimeric molecules has been suggested because of their abnormally low magnetic moments[6]. In the case of our pentadentate ferric complex, it has been shown by the measurement of magnetic susceptibilities that it has a normal magnetic moment (5.82 B. M.) and O–Fe bonds are essentially ionic. Therefore, the complex does not exist in the form of dimers.

(5)

(6)

(7)

As the penta-coördinated complex is coördinatively unsaturated, it will be expected that the complex will have a strong tendency to become a hexa-coördinated one, by the addition of a ligand molecule. The nitrobenzene adduct is a good example. Further, we succeeded in obtaining some such adducts, which contain pyridine, quinoline, bromobenzene, $\alpha$-chloronaphthalene, ethylene chloride and methyl benzoate. Each of the ligand molecules, except ethylene chloride, is bound firmly to the complex. The expelling of them is completed only by heating the adducts at 150~170°C for 8~10 hr. under 10 mmHg. It is well known that tertiary amines such as pyridine or quinoline enter very often into the complexes as ligands, but the examples of adducts which contain nitro-compounds or halogenated hydrocarbons have been rarely known.

Starting from benzene-substituted methyl-, chloro-, bromo- and nitro-derivatives of hydrosalicylamide, corresponding penta-coördinated iron complexes and their hexa-coödinated adducts were obtained (formula 7). In the case of methyl derivative, however, it formed no addition compound.

All these complexes decompose hydrogen peroxide catalytically and for that reason show strong chemi-luminescence in the presence of luminol in an alkaline solution.

## Experimental

**Trisalicylaldehyde - diimine - iron(III).** — Hydrosalicylamide (2 g.) is dissolved in absolute alcohol (300 cc.) in a three necked round-bottomed flask (500 cc.) fitted with a glass filter, a stirrer and a reflux condenser protected by calcium chloride. The solution is stirred and heated to 70~75°C on a water bath. A solution of anhydrous ferric chloride (0.6 g.) in absolute alcohol (50 cc.) is allowed to flow into the flask through a glass filter. The solution changes at once from yellow to orange red. After about two hours the reaction product is filtered off, washed with hot alcohol several times and dried at 90°C. Yield 1.5 g., black needles.

Found: C. 62.71; H, 4.18; N, 6.76; Fe, 13.78. Calcd. for $C_{21}H_{15}N_2O_3Fe$: C, 63.18; H, 3.78; N, 7.02; Fe, 13.99%.

**Reaction between 2,2'-Dihydroxyhydrobenzamide and Ferric Chloride.**—The reaction is carried out by essentially the same method as described above, using 2,2'-dihydroxyhydrobenzamide and ferric chloride. The resulting black crystals are recrystallized from nitrobenzene.

Found: N, 8.25; Fe, 10.52; drying loss, 23.66. Calcd. for $C_{21}H_{15}N_2O_3Fe \cdot C_6H_5NO_2$: N, 8.05; Fe, 10.69; nitrobenzene, 23.57%.

Since the description in the literature regarding 2,2'-dihydroxyhydrobenzamide had been only briefly given in the U. S. patent[7], a sample synthesized by the authors was ascertained by elementary analysis. m. p. 117°C. Pale yellow needles.

Found: C, 76.48; H, 5.52; N, 8.35. Calcd. for $C_{21}H_{18}N_2O_2$: C, 76.34; H, 5.49; N, 8.48%.

**Magnetic Susceptibility.**—The magnetic susceptibilities of trisalicylaldehyde-diimine-iron(III) and its nitrobenzene adduct were measured by the Curie method at room temperature (17°C). Cupric sulfate pentahydrate (further purified by the recrystallization of an extra pure reagent thrice from water) was used as the standard sample. The results are presented in Table I, where $\chi$ is the magnetic susceptibility per gram of the complex.

Neglecting the diamagnetic contribution of the ligand and assuming the validity of Curie-Langevin's law, the effective magnetic moments $\mu$ per one mole of the complex were calculated (see also Table I).

6) M. Kishita, Y. Muto and M. Kubo, *Austral. J. Chem.*, **10**, 386 (1957).

7) J. A. Chenicek, U. S. Pat. 2,533,205 (1950).

TABLE I.

| | $\chi$ (c. g. s., e. m. u.) | $\mu$ (B. M.) |
|---|---|---|
| Trisalicylaldehyde-diimine-iron(III) + nitrobenzene | $28.5\times10^{-6}$ | 5.90 |
| Trisalicylaldehyde-diimine-iron(III) | $36.3\times10^{-6}$ | 5.82 |

The theoretical moment of iron(III) (calculated from "spin-only" formula) is 1.73 B. M. for covalent bonds and 5.92 for the ionic ones.

**Infrared Spectra.**—They were taken in a hexachlorobutadiene mull, with an Oyo-Koken double beam instrument equipped with a sodium chloride prism (Figs. 1 and 2).

**Addition Compounds of Trisalicylaldehyde-diimine-iron(III).**—These compounds were prepared by the recrystallization of trisalicylaldehyde-diimine-iron (III) from various organic solvents. They are dried in a vacuum desiccator, because the coördinated solvent molecules are partially removed on heating or by washing with alcohol. All of them form black plates and their appearance or colors are almost unaltered by desolvation.

**Trisalicylaldehyde-diimine-iron(III)+Pyridine.** Found: N, 8.88; Fe, 11.51; drying loss, 16.90. Calcd. for $C_{21}H_{15}N_2O_3Fe\cdot C_5H_5N$: N, 8.79; Fe, 11.68; pyridine, 16.54%.

**Trisalicylaldehyde-diimine-iron(III)+Quinoline.** Found: C, 67.94; H, 4.46; N, 7.82; Fe, 10.42; drying loss, 24.63. Calcd. for $C_{21}H_{15}N_2O_3Fe\cdot C_9H_7N$: C, 68.18; H, 4.17; N, 7.95; Fe, 10.57; quinoline, 24.43%.

**Trisalicylaldehyde-diimine-iron(III)+α-Chloronaphthalene.** Found: C, 65.95; H, 4.26; N, 4.78; Fe, 9.60. Calcd. for $C_{21}H_{15}N_2O_3Fe\cdot C_{10}H_7Cl$: C, 66.27; H, 3.95; N, 4.99; Fe, 9.33%.

**Trisalicylaldehyde-diimine-iron(III)+Ethylene Chloride.** Found: C, 57.35; H, 4.13; N, 5.72; Cl, 12.35; Fe, 11.65; drying loss, 16.40. Calcd. for $C_{21}H_{15}N_2O_3Fe\cdot 0.8\ C_2H_4Cl_2$: C, 57.12; H, 3.86; N, 5.90; Cl, 11.94; ethylene chloride, 16.00%. The complex salt desolvates at room temperature. The analytical results shown above are the average values of several analyses.

**Trisalicylaldehyde-diimine-iron(III)+Methyl Benzoate.** Found: Fe, 10.32; drying loss, 25.92. Calcd. for $C_{21}H_{15}N_2O_3Fe\cdot C_8H_8O_2$: Fe, 10.43; methyl benzoate, 25.43%.

**Tri(5-substituted-salicylaldehyde)-diimine-iron-(III).**

**Tri(5-methylsalicylaldehyde)-diimine-iron(III).**—By a method similar to that mentioned above for the synthesis of trisalicylaldehyde-diimine-iron(III), a solution of ferric chloride (0.4 g.) in absolute alcohol (10 cc.) is added to a solution of 5, 5′, 5″-trimethylhydrosalicylamide (1 g.) in absolute alcohol (70 cc.). But in this case, in order to avoid the decomposition of the ligand at high temperature, the reaction is carried out at 45~50°C. The product was purified by reprecipitation from pyridine with water. Black needles.

Found: C, 64.87; H, 4.98; N, 6.36; Fe, 12.40. Calcd. for $C_{24}H_{21}N_2O_3Fe$: C, 65.32; H, 4.80; N, 6.35; Fe, 12.66%.

**Tri(5-bromosalicylaldehyde)-diimine-iron(III)+Nitrobenzene.**—A solution of 5, 5′, 5″-tribromohydrosalicylamide (1 g.) (or 5-bromosalicyladehyde and ammonia) in alcohol (30 cc.) is warmed on a water bath and a solution of ammonium ferric sulfate (dodecahydrate; 0.7 g.) in water (7 cc.) is added to it. After about half an hour, the black brown precipitates are filtered off, washed with hot alcohol and dried on a tone plate. Yield 0.7 g.

The powder is recrystallized from nitrobenzene to give the black plates which are dried in vacuo.

Found: C, 42.87; H, 2.48; N, 5.37; Fe, 7.27; drying loss, 16.17. Calcd. for $C_{21}H_{12}N_2O_3Br_3Fe\cdot C_6H_5NO_2$: C, 42.67; H, 2.25; N, 5.37; Fe, 7.36: nitrobenzene, 16.20%.

**Tri(5-bromosalicylaldehyde)-diimine-iron(III)+Bromobenzene.**—The black brown powder obtained above is recrystallized from bromobenzene. Dark violet needles.

Found: N, 3.64; Fe, 6.90; drying loss, 19.81. Calcd. for $C_{21}H_{12}N_2O_3Br_3Fe\cdot C_6H_5Br$: N, 3.54; Fe, 7.05; bromobenzene, 19.81%.

**Tri(5-chlorosalicylaldehyde)-diimine-iron(III)+Nitrobenzene.**—The reddish brown powder is obtained by the same treatment as in the case of the bromoderivative, using a solution of 5, 5′, 5″-trichlorohydrosalicylamide (3.5 g.) (or 5-chlorosalicylaldehyde and ammonia) in alcohol (60 cc.) and a solution of ammonium ferric sulfate (dodecahydrate; 4 g.) in water (20 cc.). Yield 3 g. This powder is recrystallized from nitrobenzene. Black plates.

Found: N, 6.88; Fe, 9.05; drying loss, 19.49. Calcd. for $C_{21}H_{12}N_2O_3Cl_3Fe\cdot C_6H_5NO_2$: N, 6.72; Fe, 8.93; nitrobenzene, 19.67%.

**Tri(5-chlorosalicylaldehyde)-diimine-iron(III)+Bromobenzene.**—This is prepared by the recrystallization of the powder from bromobenzene. Dark violet needles.

Found: N, 4.01; Fe, 8.64; drying loss, 23.55. Calcd. for $C_{21}H_{12}N_2O_3Cl_3Fe\cdot C_6H_5Br$: N, 4.24; Fe, 8.47; bromobenzene, 23.80%.

**Tri(5-nitrosalicylaldehyde)-diimine-iron(III)+Nitrobenzene.**—A Solution of 5, 5′, 5″-trinitrohydrosalicylamide (1 g.) in alcohol (50 cc.) is warmed on a water bath and a solution of ammonium ferric sulfate (dodecahydrate: 0.7 g.) in water (10 cc.) is added to it. The resulting reddish brown precipitates are treated as before. This powder is insoluble in common organic solvents and slightly soluble in nitrobenzene. When the powder is recrystallized from nitrobenzene, a small amount of crystals is obtained after about two days.

Found: N, 12.41; Fe, 8.43; drying loss, 18.48. Calcd. for $C_{21}H_{12}N_5O_9Fe\cdot C_6H_5NO_2$: N, 12.79; Fe, 8.50; nitrobenzene, 18.70%.

The authors wish to express their thanks to Miss S. Indo for N-analysis, to Dr. K. Hirakawa (Department of Physics) for the measurement

of magnetic susceptibilities, and to Assistant Professor Dr. Y. Ueda, Dr. H. Yoshimura and Mr. H. Yano (Department of Pharmacy, Faculty of Medicine) who kindly took the infrared spectra.

# *Studies on Leucomycin. II. Preparative Chromatography of Macrolides on Amberlite IRC-50**

By Tetsuo WATANABE

(Received January 16, 1960)

As shown in the previous paper[1], leucomycin, a basic antibiotic produced by *Streptomyces kitasatoensis* Hata[2-4], was proved by the paper-chromatographic and -electrophoretic analysis, to be a mixture composed of at least six biologically active components, $A_1$, $A_2$, $B_1$, $B_2$, $B_3$ and $B_4$. Preliminary experiments on the chromatographic separation of these components in a preparative scale showed, that both leucomycin groups, A and B, were able to be absorbed on a column of alumina or silisic acid from the benzene solution and to be separately eluted with the same solvent containing methanol in this order. Using this or similar chromatographic systems, however, recoveries of the antibiotics was markedly low (50~70 per cent in weight, less than 40 per cent in biological activity; presumably accompanied with decomposition) and a more minute resolution into each component, was unsuccessful.

In course of our studies, it was found that leucomycin absorbed on a column of carboxylic resin, such as Amberlite IRC-50 in H-cycle, could be eluted quantitatively with sodium citrate buffer, and that all six components in the leucomycin complex were separately eluted with a mixture of citrate buffer and ethanol, in such a high concentration as the chromatographic system could be used for a preparative separation of these components. Using this method, not only leucomycin complex, but also some derivatives of leucomycin $A_1$ and other macrolides such as erythromycin[5], magnamycin[6] and spiramycin[7], having dimethylamino sugar as the basic moiety[8], could be purified from the contaminated minor components, which had been separated only with difficulties by counter current distribution. In this paper, we propose to report these results. In addition some properties of purified leucomycin components $B_1$, $B_2$, $B_3$ and $B_4$ and the composition of these components in leucomycin complex will be reported.

## Experimental

**Materials.**—Leucomycin complex (I)** and the fractionated antibiotics (II, III, IV) were kindly prepared for this study by J. Abe et al., at the Research Institute, Toyo Jozo Co. Ltd., according to the methods summarized in Table I. Erythromycin, magnamycin and spiramycin were the samples furnished as "standard antibiotics" through the National Institute for Preventive Medicine, Tokyo. Diacetylleucomycin $A_1$ ($C_{50}H_{85}O_{19}N$, m. p. 127~129°C)[9], propionylleucomycin $A_1$ ($C_{49}H_{85}O_{18}N$, m. p. 123~126°C)[10], tetrahydroleucomycin $A_1$ ($C_{46}H_{85}O_{17}N$, m. p. 162~164°C)[11], and a basic moiety derived from leucomycin $A_1$ with the methanolysis ($C_{34}H_{59}O_{13}N$, m. p. 154~155°C; corresponding to carimbose fragment in magnamycin)[12], were prepared from leucomycin $A_1$ by the present author, according to the methods which will be published soon.

TABLE I. FRACTIONATION OF LEUCOMYCIN

**Chromatography on Amberlite IRC-50.** — One hundred grams of the resin (XE-64) of approximately 150 mesh, was suspended in 500 cc. of 1 N sodium hydroxide and the suspensions were heated on a water bath at 60°C for 3 hours under occasional stirring. After the decantation of brown colored supernatant, the resin of the Na-cycle was washed with distilled water thoroughly, then suspended in 1 N hydrochloric acid at room temperature. After 30 minutes, the resin was washed with distilled water until the washing became free from acid. Forty grams of so purified resin of H-cycle, was added as thick suspension in water to a column of 1 cm. in the diameter, to a hight of 45 cm. To the column, 10 mg. of sample to be analyzed was added as 1 per cent solution in N/100 hydrochloric acid. As soon as the applied sample solution had been allowed to flow into the column, washing with 150 ml. of distilled water, then elution with a mixture of 96 per cent ethanol and M/5 sodium citrate buffer ($Na^+$ 1.6 g. ion per liter, pH 5.0) in an equal volume, was initiated at a flow rate of 9 cc. per $cm^2$ per hour at 15°C. The effluent was collected in 4.5 cc. fraction by means of automatic fraction collector. For the chromatography in a preparative scale (15 g. of sample), a column of 3×180 cm. was used.

**Chemical Assay of Leucomycin in the Effluent.** —The concentration of leucomycin in each effluent fraction was determined photocolorimetrically with sulfuric acid as follows. An aliquot of sample solution was mixed with an equal volume of concentrated sulfuric acid under adequate shaking, and the resulting red brown color was measured between 10 and 30 minutes after the addition of sulfuric acid, with Kotaki photometer Model D2 using filter 470. Experiments showed, that the readings were strictly proportional to leucomycin concentration up to an optical density of about 1.1 equivalent to approximately 500 μg per cc. of leucomycin complex (I) and they were not affected by the presence or absence of M/5 citrate and of 50 per cent ethanol. As the color developed per unit weight of leucomycin components, were not just the same, the correction was made for the calculation of weight composition of each component. This method could be also applied with success for the assay of leucomycin derivatives and other macrolides, except erythromycin which with sulfuric acid colored only slightly. The fact, however, did not prevent the determination of an approximate elution position of erythromycin with this coloration.

**Paper Chromatography of Leucomycin.**—Leucomycin components contained in each fraction of chromatographic effluent, were identified from the chromatographic $R_f$ values, A and B groups could be easily distinguished from the $R_f$ developed with *n*-butyl acetate containing M/15 sodium phosphate (pH 6) ; while $A_1$ and $A_2$ ; $B_1$, $B_2$, $B_3$ and $B_4$ from the $R_f$ developed with M/15 sodium phosphate containing *n*-butyl acetate (pH 8) on a liquid paraffin-treated filter paper. The position of the leucomycin component migrated on the filter paper, was detected as a growth-inhibited zone of *Bacillus subtilis* on the bioautogram[1].

**Isolation of Leucomycin Components.**—Fractions corresponding to each peak on the elution diagram, were combined and cocentrated to about one third volume under reduced pressure. The basic antibiotics in the aqueous concentrates, after adjusting the pH to 8, were extracted with *n*-butyl acetate. From the acid re-extract of the ester layer, leucomycin was crystallized by adjusting the pH to 7. For the recrystallization benzene-cyclohexane solvent for A group and hot benzene for the B group were used.

**Assay of Antibacterial Activity.**—The assay of the antibacterial activity of the so purified components, was kindly done by the Bioassay Division, Toyo Jozo Co. Ltd., according to the usual cup method against *Bacillus subtilis* No. 209 as the test organism.

## Results

**Chromatography of Leucomycin.**—Fig. 1-A represents a typical elution diagram of a leucomycin complex (I) from a column of Amberlite XE-64 (H-cycle) with a mixture of ethanol and M/5 sodium citrate buffer (pH 5.0) in an equal volume. Fig. 1-B illustrates the paper-chromatograms of the above-mentioned effluent fractions detected by the growth-inhibition of

Fig. 1-A. *Bacillus sabtilis*. These results indicated that leucomycin components, $B_1$, $B_2$, $B_3$, $B_4$, $A_1$ and $A_2$ were eluted from the column in this order and these components could be separated from each other under the conditions used, except the last two components $A_1$ and $A_2$, which could be only partially separated***. A minor component $B_0$ eluted at the hold-up volume, colored with concentrated sulfuric acid but showed no antibacterial activity (less than 10 unit per mg.). Some discrepancies occasionally observed between both of the amounts of leucomycin complexes, assayed photocolorimetrically and biologically, might be due in part to the presence of this component. The recovery of leucomycin from the column assayed both photocolorimetrically and biologically, was more than 90 per cent and the rechromatography of each component showed an elution of only one component at the same position, indicating that no appreciable degradation occurred for this antibiotic.

*** Recently, however, both of the components were found to be completely separated on a longer column (1.5~2.0 m.), if the amount of the sample added to the column was limited.

The reproducibility of this chromatography was fairly good and the position of the elution of each component varied only within 5 per cent, so far as the chromatographic conditions mentioned rather in detail in the experimental part were exactly maintained. The flow rate of 9 cc./$cm^2$/hr. seemed to be an upper limit for the elution without any broadening of each peak. The pH of buffer should be selected between 4 and 8, as the more acidic or alkaline pH caused slight degradation of leucomycin even at room temperature. In this region, the higher the pH, the less the spreading of the elution peak but also lesser than the separation of the components among each other. Most important in this chromatographic method is the temperature. At higher temperature than 25°C, all components were eluted very rapidly, while at a lower than 10°C very slowly, and both of the extremes resulted into a poor resolution. For a precise analysis, a device to maintain the temperature of the column at a constant (15~20°C) might be profitable.

**Leucomycin Components.**—From the elution diagram as shown in Fig. 1, the composition of the leucomycin complex (I) was estimated to be composed of 11 per cent of $B_1$, 7 per cent of $B_2$, 8 per cent of $B_3$, 13 per cent of $B_4$, 32 per cent of $A_1$ and 24 per cent of $A_2$, in weight respectively. These values were by no means inconsistent with those estimated from the counter current distribution diagram of the same sample[13].

Using the same chromatographic technique, another sample of leucomycin complex (I) produced by a new strain (seed No. L 149-373) and some fractionated leucomycin samples (II, III and IV) from the original strain, were analyzed. The results indicated, that a new strain of *Streptmyces kitasatoensis* produced mainly A components; B components produced by the original strain were much more absorbed on a column of active carbon from the *n*-butyl acetate solution and were precipitated at higher pH from the aqueous solution than A components did; and the crystallization of B components from benzene was effective for the separation of $B_2$ and $B_4$ from less active components $B_1$ and $B_3$. Four leucomycin components, $B_1$, $B_2$, $B_3$ and $B_4$ and partially purified $A_1$ (contaminated small amount of $A_2$) were actually isolated from the preparations which had been previously fractionated (see Table I) according to the above mentioned method by the use of preparative column (3×180 cm.).

The antibacterial activity of $A_1$, though still contaminated with a small amount of $A_2$, was as much as 1000 unit per mg. This value was

* Leucomycin complex (I) ; 560 unit/mg.

approximately 1.8~1.9 times as much as that of leucomycin complex (I) produced by the original strain, and was the highest one as far as known on leucomycin samples. These facts will be explained by the contamination of less active B components. It may be of interest that the activity of B components varied from 700 units to 100 units. According to J. Abe slight undesirable properties observed in the leucomycin complex (produced by the original strain) was mainly due to the presence of B components and their action increased in the following order; $B_4$, $B_3$, $B_2$ and $B_1$, thus with the decrease of the antibacterial activity. These results are summarized in Table II, together with some analytical data of purified B components.

**Chromatography of Leucomycin Derivatives.**—Under the same condition as used for the separation of leucomycin complex, some leucomycin derivatives, acetyl-[9], propionyl-[10], tetrahydroleucomycin $A_1$[11], and a basic moiety derived from $A_1$ by methanolysis[12], were also eluted quantitatively, but at a different position, which are summarized in Table III. The results indicated that this chromatography was effective for the purification of these derivatives from the unreacted leucomycin $A_1$. Less-retardation of the basic moiety derived from $A_1$ by methanolysis and more retardation of the two acyl derivatives on a column of carboxylic acid resin, will be related to their different $pK'_a$ values ($pK'_a$ 5.0 for acyl derivatives; $pK'_a$ 8.1 for basic moiety derived from $A_1$ by methanolysis) from the original leucomycin $A_1$ ($pK'_a$ 7.1)****, but the different chromatographic behaviors of $A_1$ and of the tetrahydro-derivative and of other leucomycin components ($pK'_a$ 6.8~7.1) indicated that " Weiss's effect " would play a predominant rôle in these separations.

**Chromatography of Other Macrolides.**—Table III lists the elution position of several macrolides, including erythromycin, magnamycin, and spiramycin, from a column of Amberlite XE-64 (H-cycle) with an equi-volume mixture of ethanol and M/5 sodium citrate buffer (pH 5.0). These results, together with the results of the paper-chromatographic and -electrophoretic analysis[1], indicated that all six antibiotics contained in leucomycin complex different from one another well-known macrolides, namely: erythromycin, magnamycin and spiramycin. As reported already by the other authors, antibiotics belonging to macrolides were usually produced as a complex composed of a main and a few minor components, the latter of which could be fairly separated with some difficulties. In these experiments,

TABLE III. THE ELUTION POSITION OF SOME LEUCOMYCIN DERIVATIVES AND MACROLIDES UNDER THE SAME CONDITIONS AS USED FOR THE SEPARATION OF LEUCOMYCIN COMPLEX (I)

| Antibiotics | | | Volume cc. |
|---|---|---|---|

**** Basicity of leucomycin is due to the presence of 3-dimethylamino sugar, so the $pK'_a$ was fairly affected by the 2, 4-*O*-substitution.

too, some commercial samples of the above-mentioned antibiotics, though considered to be fairly purified, showed the presence of these minor antibiotics. Such minor components of usual macrolides, however, had been limited to only two or three kinds. The presence of many minor components, as much as five in leucomycin seemed to belong to the first case.

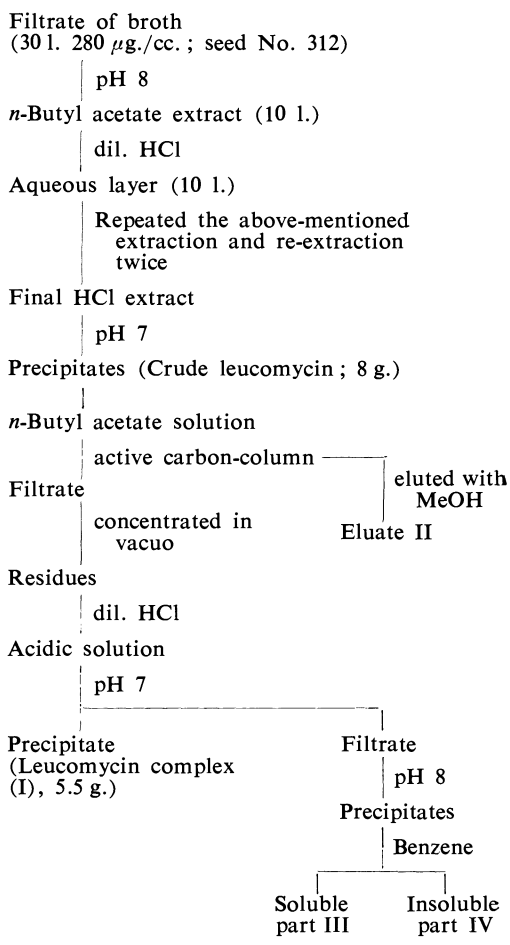
# *Studies on Leucomycin. III. Isolation*[1] *and Properties of Six Antibacterial Components in Leucomycin Complex*



By Tetsuo WATANABE, Hisao NISHIDA, Jinnosuke ABE and Kazuo SATAKE

(Received February 4, 1960)

Leucomycin[2], a basic antibiotic obtained from the broth-filtrate of *Streptomyces kitasatoensis* Hata[3,4], has been presumed to be a macrolides on its physical, chemical[3,5] and antibacterial[3,6] properties. In the previous papers of this series[7,8] it was reported that the antibiotic was a mixture of six biologically active components, $A_1$, $A_2$, $B_1$, $B_2$, $B_3$ and $B_4$ and that the last four minor components, though in a minute amount, could be purified by fractional precipitation[8] of the mixture from aqueous and from benzene solutions (see Table I), followed by the further minute resolution of the resulting fractions by chromatography on a column of Amberlite IRC-50[8]. The main component $A_1$ which seemed to have the highest activity[8], however, had been scarcely separated from $B_4$ and another minor component $A_2$, by this method.

For the resolution of macrolides complex in preparative scale, counter current distribution has been reported to be effective[9-12]. Using this technique, leucomycin complex was also

TABLE I. FRACTIONATION OF LEUCOMYCIN

analyzed[13]. The distribution diagram, though after only 30 transfers, seemed to suggest a partial resolution. These facts prompted us to study the counter current distribution of leucomycin complex (I) (see Table I) in more detail. In this paper we wish to report on these results. In addition, some properties of such purified antibacterial components as $A_1$, $A_2$, $B_1$, $B_2$, $B_3$ and $B_4$, will be described.

**Solvent System for the Distribution of Leucomycin Complex.** — The marked difference observed among the solubilities of each of the components of leucomycin complex in aqueous solution at pH 7~8 and in benzene[8], seemed to suggest the use of both solvents for the counter current distribution. Preliminary experiments showed that the addition of methanol to this binary system further improved the resolution. Fig. 1 presents the distribution diagram of leucomycin complex (I), after 150 transfers between the two layers which resulted from a mixture of five parts of benzene, two parts of M/15 sodium phosphate buffer at pH 6.5, and five parts of methanol (Solvent system 1); together with a composite paper chromatogram of leucomycin components in each distribution tube. The results suggested that system 1 could be used for the isolation of $A_1$, $A_2$ and $B_1$.

A solvent system which gave a more minute resolution of leucomycin complex, could be obtained by using much more acid citrate buffer and by adding a sufficient amount of choroform to the triple-system composed of benzene, citrate buffer and methanol. Differing from solvent system 1, the quartet-system separated into two layers very rapidly, though the volume-ratio of these two layers differed to some extent by a slight change of temperature. Fig. 2 illustrates the distribution diagram

of leucomycin complex (I), after 210 transfers between the two layers which resulted from a mixture of ten parts of benzene, nine parts of M/15 sodium citrate buffer of pH 4.9, eight parts of chloroform and twenty parts of methanol (Solvent system 2); together with a composite paper chromatogram of leucomycin components in each distribution tube. From the appropriate tubes after this distribution, five kinds of antibacterial component could be isolated completely free from other components though the yields of $B_2$ and of $B_3$ were not so excellent as that of $A_1$ $A_2$ or $B_1$ due to the partial resolution of the former two.

For the resolution of B components, especially of $B_2$ and $B_4$ which were only slightly soluble in benzene, another system composed of chloroform and acid buffer seemed to be promising, as B components showed a moderate solubility in both solvents. In this case, too, the resolution was improved by adding an appropriate amount of a third solvent which could be mixed with upper and lower layers at any ratio, and the effect of acetone seemed to be superior to that of methanol in this solvent system. Fig. 3 shows the distribution diagram of antibiotic IV (see Table I) present in the filtrate fraction from leucomycin complex (I) precipitated at pH 7, after 250 transfers between the two layers which resulted from a mixture of one part of chloroform, two parts of M/15 sodium acetate buffer of pH 4.5, and two parts of acetone (Solvent system 3), together with a composite paper chromatogram of leucomycin components in each distribution tube. From the appropriate fractions after this distribution, all B components, $B_1$, $B_2$, $B_3$ and $B_4$, could be isolated in a good yield, respectively. The results suggested that the counter current distribution with "Solvent system 3" was the most suitable method for the isolation of four B components; if the most part of $A_1$ which was the main component of leucomycin complex, had been previously removed.

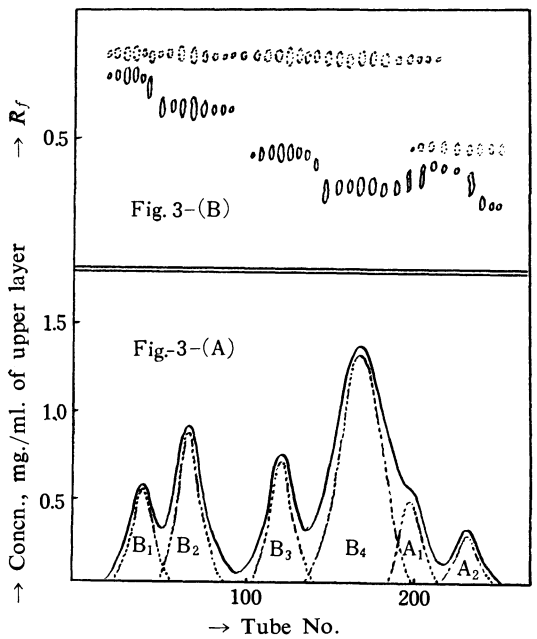

Fig. 3—(A). ---- Counter current distribution of fraction IV (See Table I, B components rich fraction) using "Solvent system 3".

Fig. 3—(B). ---- Composite paper chromatogram in each distribution tube; ○ developed with *n*-butyl acetate containing phosphate buffer (pH 6). ○ developed with phosphate buffer (pH 8) containing *n*-butyl acetate.

**Leucomycin $A_1$ and $A_2$.**—As shown in Fig. 2, the observed distribution curves of $A_1$ and of $A_2$, showed no serious disagreement with the theoretical ones calculated from the maximum peak position[14], nor with the distribution of $A_1$ and $A_2$ estimated by paper chromatography. The facts seemed to indicate the homogeneity of both the components resolved by counter current distribution. The presumption was verified by the identity of the observed and the calculated re-distribution

curves (using "Solvent system 1 or 2" for the samples isolated with "Solvent system 2 or 1", respectively).

In Table II, are summarized the analytical data and some properties of leucomycin $A_1$ and $A_2$. There have been reported several macrolides, from picromycin ($C_{25}H_{43}NO_7$)[15] up to magnamycin ($C_{42}H_{67}NO_{16}$)[16]. Minor components $A_2$ ($C_{65}H_{111}NO_{22}$) seemed to be a macrolide of highest molecular weight, as far as we know. Main component $A_1$ ($C_{46}H_{81}NO_{17}$), on the other hand, was similar to magnamycin in the molecular weight and $pK'_a$, though the former had an antibacterial activity higher than that of the latter. In Table II, are also presented the contents of $A_1$ and $A_2$, in leucomycin complex and in several fractions derived during the preparation of fraction I. These values calculated from the distribution diagram with "Solvent system 2" were not inconsistent with the $A_1$- and $A_2$-content estimated from the elution diagram from a column of Amberlite IRC-50 with a mixture of ethanol and M/15 sodium citrate buffer at pH 5[8]. The results also indicated that both the components were less soluble in aqueous solution at pH 7, less absorbed on a column of active carbon, and more soluble in benzene than B components. Fig. 4 represents infrared spectra of $A_1$. The presence of OH, C=O (ester) and C=C was presumed from the characteristic absorption at 3450 $cm^{-1}$, 1750 $cm^{-1}$ and 1680 $cm^{-1}$, respectively. A shoulder at 1710 $cm^{-1}$ seemed to be due to the presence of the second C=O (lactone).

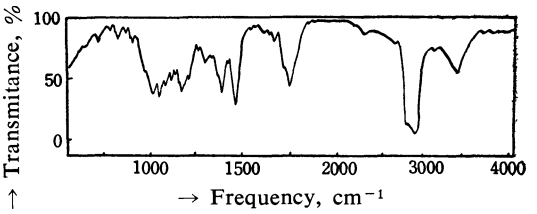

Fig. 4. Infrared spectrum of leucomycin $A_1$. (in Nujol)

Infrared spectrum of $A_2$ was extremely close to that of $A_1$.

**Leucomycin $B_1$, $B_2$, $B_3$ and $B_4$.** — Four components, $B_1$, $B_2$, $B_3$ and $B_4$, found in leucomycin complex as minor components, could be isolated by counter current distribution using "Solvent system 3" from the filtrates III and IV of leucomycin complex (I) precipitated at pH 7[8], from the mother liquid of the recrystallization of leucomycin complex (I); and from the methanol-eluate II of the carbon-column previously treated with *n*-butyl acetate solution of leucomycin[7,8]. As shown in Fig. 3, the distribution curves of these components agreed with the corresponding theoretical curve. The homogeneity of the component so isolated was further verified by analytical chromatography on a column of Amberlite IRC-50[8].

Leucomycin B components ($C_{34}$—$C_{38}$) had a molecular weight similar to that of erythromycin A[18], but the $pK'_a$ value (6.8) was similar to those of leucomycin A and magnamycin. The antibacterial activity was considerably lower than that of $A_1$. In Table III,

are summarized the analytical data, some properties and the content in leucomycin complex (I) and in several fractions II, III and IV. The last data indicated that B components could be fractionated, and that the fractions thus obtained could be further separated into two groups, $B_1$ and $B_3$ rich III, and $B_2$ and $B_4$ rich group IV. It seems to be interesting that the original strain of *Streptomyces kitasatoensis* produced as many as six kinds of macrolide, while the mutant (strain No. L-149-373) gave only $A_1$ and $A_2$ without any decrease of the weight of total antibiotics. The elucidation and comparison of the structure of these components might give valuable information on the biosynthesis of macrolides.

## Experimental

**Materials.**—Leucomycin complex (I) and the fractionated antibiotics II, III, IV were prepared by the methods summarized in Table I.

**Counter Current Distribution.** — The procedure was achieved at 15~20°C in an automatic "Craig-type" apparatus having 300 transfer tubes No. 555 F, Mitamura Shoten, Tokyo). The sample (1~10 g.) was added as a concentrated solution in the lower solvent layer (5~10%) into the first few tubes. The volume of the upper and the lower layer in each distribution tube was 10 cc. each. The partition coefficient of distributed components was calculated from the peak position on the distribution diagram and the total transfer-number. The theoretical distribution curve was calculated from the partition coefficient so obtained, according to Craig's method[14].

**Determination of the Concentration of Leucomycin.** — The concentration was assayed by the photometry of red brown color which was produced by mixing 0.5 cc. of the sample (aqueous layer in the distribution tube) with 2.0 cc. of concentrated sulfuric acid[8]. The concentration in organic-solvent rich layer, was calculated from the above-mentioned concentration in aqueous layer and the calculated partition coefficient.

**Paper Chromatography of Leucomycin Components.**—Paper chromatography of leucomycin in each distribution tube was achieved by the method already reported[7], using 0.02 cc. of the organic-solvent rich phase as the sample.

**Crystallization of Each Component.**—The leucomycin components separated by counter current distribution, was crystallized from the aqueous solution by adjusting the pH to 8 according to the method reported already[8].

**Antibacterial Activity.** — The assay of the antibacterial activity of the components so purified, was done by the Bio-assay Division, Toyo Jozo Co. Ltd., according to the usual cup assay method with the use of *Baccillus subtilis* No. 209 as the test organism.

**Absorption Specta.** — Absorption spectra were measured by Hitachi Spectrophotometer Model DUP-2.

**p$K'_a$.**—p$K'_a$ was measured on the sample solution in a dimethylformamide (60%) at a concentration of 0.05 per cent, by titrating with 1 N hydrochloric acid with the use of Toa-denpa pH meter HM-5.

We are greatly indebted to Mr. S. Suda for his assistance in paper chromatographic analysis of the distributed fractions.

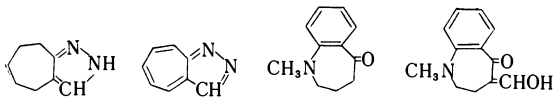
# *Studies on Seven-Membered Heterocyclic Compounds Containing Nitrogen. IV. Hexahydro-1, 2, 5-Triazazulene*



By Shiro MOROSAWA

(Received February 6, 1960)

It has been found that hexahydro-1, 2-diazazulene (I)[1-3] was prepared from 2-hydroxymethylenecycloheptanone. Buchta[4] has made only a simple statement that W. Treibs succeeded in dehydrogenation of the hydroazazulene by chloranil to yield 1, 2-diazazulene (II), but no further detailed report was given. The present author has synthesized hitherto unknown hexahydro-1, 2, 5 (or 1, 2, 6)-triazazulene (XIa or XIb), having one nitrogen atom in the seven-membered ring in satisfying yield. Spectral studies have shown that the former

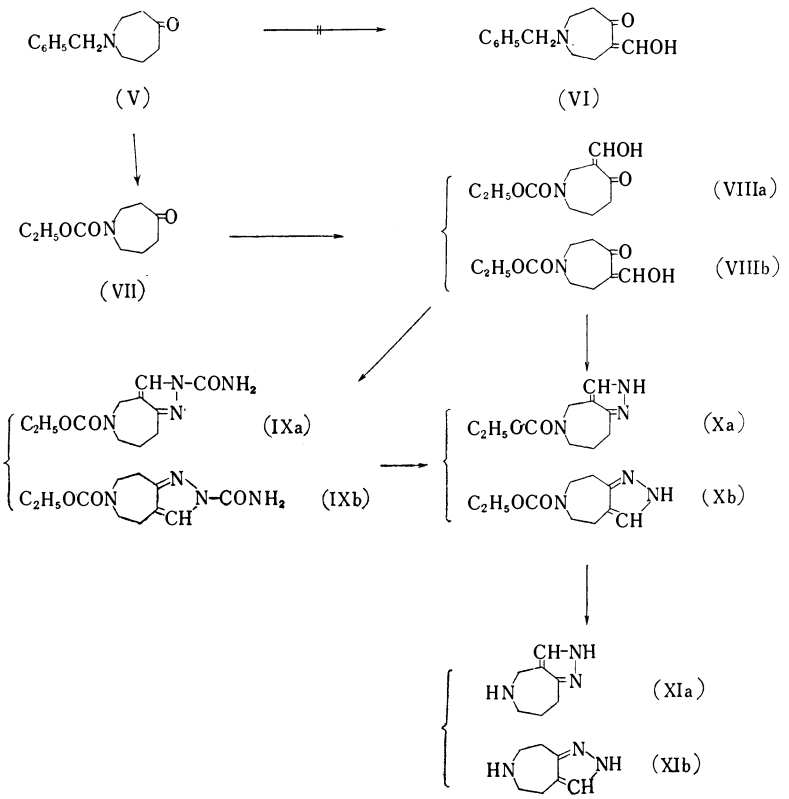
4) E. Buchta et al., *Angew. Chem.*, **67**, 77 (1955).



structure is more reasonable. A preliminary test of dehydrogenation was quite unsuccessful, but further attempts are in progress.

(I) (II) (III) (IV)

*N*-Methyl type azasuberenone, 1-methyl-2, 3, 4, 5-tetrahydro-5-keto-1-benzazepine (III)[5] has been reported to afford 4-hydroxymethylene derivative (IV) in 72% yield by the reaction with ethyl formate in the presence of sodium methoxide in benzene. Under the same condition, however, *N*-benzyl type azasuberone, 1-benzyl-1-azacycloheptan-4-one (V)[6] gave only a trace of hydroxymethylene compound, which certified as bis-2, 4-dinitrophenylhydrazone, leaving much residue on distillation. 1-Ethoxycarbonyl-1-azacycloheptan-4-one (VII) derived from V was subjected to the similar treatment and 1-ethoxycarbonyl-3 (or 5)-hydroxymethylene-1-azacycloheptan-4-one (VIIIa or VIIIb)*, b. p. 127~130°C/0.7 mmHg was obtained in 72.5% yield as a colorless oil. Reaction of hydrazine hydrate with VIII in ether gave a stable pyrazole derivative (Xa or Xb), b. p. 183~185°C/0.3 mmHg in 87.6% yield. X was also derived from VIII cyclic semicarbazone (IXa or IXb), m. p. 159~159.5°C by hydrolysis. X afforded a picrate of m. p. 136.5~137.5°C and a chloroplatinate of m. p. 184°C (decomp.) respectively. Deethoxycarbonylation of X by hydrogen bromide in glacial acetic acid gave hydrobromide of XIa or XIb in 84% yield as hygroscopic colorless long prisms which softened at above 260°C. Free base, XIa or XIb, was liberated almost quantitatively from the hydrobromide with alkali as hygroscopic, colorless hexagonal prisms of m. p. 155.5~156.5°C. XI formed a picrate of m. p. 220~221°C (decomp.), which was unstable to light and turned brown on standing.

As a preliminary examination of dehydrogenation 4, 5-cyclohepteno-7-methylthiazole (XIV), b. p. 109~111°C/15 mmHg which was prepared from cycloheptanone** (XII) by NBS bromination and condensation with thioacetamide was subjected to the dehydrogenation

** The author wishes to thank Professor Tetsuo Nozoe (Tohoku University) for donating the sample.

(XII) (XIII) (XIV) (XV) (XVI) (XVII)

with 10% palladium on carbon at elevated temperature. Thus 4, 5-cycloheptatrieno-7-methylthiazole (XV) was obtained as a colorless oil, b. p. 104°C/12 mmHg, XV gave a picrate of m. p. 147~148°C. XI, however, was decomposed under the same condition with evolution of hydrogen. Ultraviolet absorption spectra of XI, XIV and XV are given in Fig. 1, together with that of the condensation product of XIV ethiodide with *p*-dimethylaminobenzaldehyde.

It appeared of interest to obtain a unique product in the formation of the hydroxymethylene compound (VIII) from the asymmetrical ring ketone (VII). The structure of the pyrazole derivative (XI) was estimated by the following spectral studies. It has already been recognized[7] that the band arising from the hydrogen bending vibrations of methylene appeared near the 1450 $cm^{-1}$ region and shifted in some degree higher when attached to the nitrogen atom and somewhat lower to carbon-carbon or carbon-oxygen double bond. As shown in Fig. 2, 1-azacyclohexane-4-one (XVI)[8],* gave rise to only two bands near the region at 1469 and 1428 $cm^{-1}$, presumably arising from 2 (or 6)- and 3 (or 5)-methylene of the ring respectively. 1-Azacycloheptan-4-one (XVII)**, on the other hand, indicated at least three bands at 1464, 1452 and 1431 $cm^{-1}$, probably due to 2 (or 7)-, 6- and 3 (or 5)-methylene respectively. Hydrochlorides of XVI and XVII also gave rise to two and three bands respectively, corresponding to the above absorption bands. XV was expected to show two bands near the region arising from methyl*** at 2-position of the thiazole ring and methylene in the seven-membered ring, and in fact two bands at 1457 and 1437 $cm^{-1}$ were observed. From a consideration of these facts it became clear that the methylenes in the nitrogen containing ring ketone were distinguishable from each other in the infrared

8) E. Königs and L. Neumann, *Ber.*, **48**, 956 (1915).

* Prepared from 1-benzyl-1-azacyclohexan-4-one[6b] by catalytic reduction in the presence of palladous oxide, b. p. 56~57°C/6 mmHg. It began to polymerize into a white solid within an hour after distillation.

** Liberated by potassium carbonate from its hydrochloride[6a], b. p. 95~96°C/15 mmHg.

*** According to Bellamy[7], the band arising from the methyl group adjacent to the carbon atom appeared near 1450 $cm^{-1}$ in relatively low intensity.

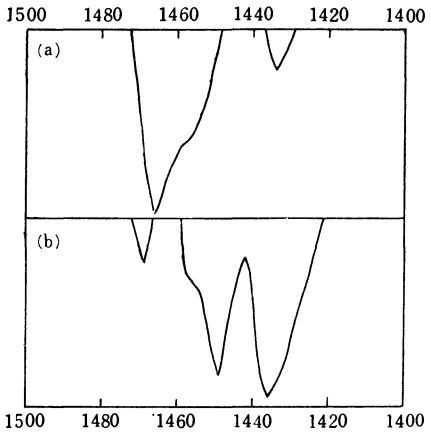

Fig. 3.
(a) XI; (b) XI hydrobromide

absorption spectra. The pyrazole derivative (XI) indicated, as seen in Fig. 3, three bands at 1466, 1458 (shoulder) and 1434 $cm^{-1}$. It may be assumed that the former band is due to 6-methylene and the latter to 8, the shoulder being due to overlapping of bands arising from 4- and 7-methylene. Hydrobromide of XI distinctly showed three principal bands at 1469, 1449 and 1436 $cm^{-1}$ together with a shoulder at 1456 $cm^{-1}$ which probably arose from 4-methylene. From these spectral data it may be concluded that XI has an angular form (XIa) rather than a linear one (XIb) and therefore the hydroxymethylene compound is in the form of VIIIa.

## Experimental

**1-Ethoxycarbony-1-azacycloheptan-4-one (VII).**—A solution of 15 g. of V hydrochloride[6a,b] in 200 cc. of water was shaken with hydrogen in the presence of 0.2 g. of palladous oxide under normal temperature and pressure. After the theoretical amount of hydrogen was consumed the catalyst was filtered off and evaporated to a smaller volume under reduced pressure. To this were added a solution of 2.7 g. of sodium hydroxide in 5 cc. of water and 14.7 g. of anhydrous potassium carbonate. The mixture was kept at 10°C and 15 g. of ethyl chlorocarbonate was added dropwise during 45 minutes with stirring, followed by further stirring for 1 hour at the same temperature. Precipitates were collected and washed well with ether, and the filtrate was thoroughly extracted with ether. The water layer was evaporated under reduced pressure until precipitation began and treated as before. The ethereal solutions were combined and dried over anhydrous potassium carbonate. Evaporation of ether and vacuum distillation gave 11.5 g. (99.1%) of a colorless oil, b. p. 117°C/1 mmHg The oil was fairly soluble in water and did not give a bisulfite addition compound.

Found: N, 7.66. Calcd. for $C_9H_{15}O_3N$: N, 7.56%.

**1-Ethoxycarbonyl-3(or 5)-hydroxymethylene-1-azacycloheptan-4-one (VIIIa or VIIIb).**—A solution of 6 g. of VII and 9.5 g. of ethyl formate in 50 cc. of dry benzene was added with swirling to an ice cold suspension of crushed methanol-free sodium methoxide[9] (from 1.6 g. of sodium) in 50 cc. of dry benzene, and the whole was evacuated and filled with nitrogen. After the mixture had been allowed to stand at room temperature for 3 hours, it was boiled under gentle reflux for 1 hour. After cooling, 10 cc. of water was added and the aqueous layer was separated. The benzene solution was washed twice with 10% sodium hydroxide solution. The combined water layer was washed with ether and adjusted to pH 3.4 by adding hydrochloric acid. A reddish orange oil deposited was extracted three times with benzene. The acidic water layer was evaporated to a smaller volume under reduced pressure and nitrogen atmosphere and extracted with benzene. The benzene extracts were united, washed three times with small portions of saturated sodium chloride solution and dried over anhydrous magnesium sulfate. Evaporation of benzene and vacuum distillation of the residue under nitrogen gave 5 g. of a colorless oil, b.p. 127~130°C/0.7 mmHg in 72.5% yield. It gave a deep purple coloration with ferric chloride solution.

Found: N, 6.80. Calcd. for $C_{10}H_{15}O_4N$: N, 67.5%.

**2, 4-Dinitrophenylhydrazone,** orange prisms, m.p. 172°C (from methanol).

Found: N, 19.24. Calcd. for $C_{15}H_{19}O_6N_5$: N, 19.17%.

**VIII Cyclic Semicarbazone (IXa or IXb).**—A solution of 2.2 g. of VIII in 9 cc. of glacial acetic acid was added to a separately prepared solution of 1.7 g. of semicarbazide hydrochloride and 1.7 g. of anhydrous sodium acetate in as small an amount of water as possible. After the mixture was allowed to stand for a few days with 1 cc. of concentrated sulfuric acid, 50 cc. of water was added to deposit gradually 1.0 g. of cyclic semicarbazone in colorless needles, m. p. 155°C. Recrystallization from ethanol raised the m. p. to 159~159.5°C.

Found: N, 22.16. Calcd. for $C_{11}H_{16}O_3N_4$: N, 22.21%.

**5(or 6)-Ethoxycarbonyl-1, 2, 5(or 1, 2, 6)-triazazulene (Xa or Xb).**—(a) To a solution of 5 g. of VIII in 50 cc. of ether was added dropwise under stirring and ice-water cooling 1.2 g. of hydrazine hydrate (100%), followed by an additional stirring for 1 hour. After decantation of the ethereal solution, a large excess of anhydrous potassium carbonate was added to the viscous water layer in order to remove the water completely. Ether was added, agitated well and decanted repeatedly. The combined ethereal solution was dried over anhydrous potassium carbonate and the ether was removed by distillation. Vacuum distillation of the residue gave 4.3 g. of a colorless viscous oil, b. p. 183~185°C/0.3 mmHg in 87.6% yield.

9) W. S. Johnson and H. Posvic, *J. Am. Chem. Soc.*, 69, 1361 (1947).

Found: N, 20.15. Calcd. for $C_{10}H_{15}N_2O_3$: N, 20.08%.

A **picrate** derived from the above oil showed, after several recrystallizations from ethanol, m. p. 136.5~137.5°C with sintering at about 80°C.

Found: N, 17.53. Calcd. for $C_{10}H_{15}O_2N_3 \cdot C_6H_3O_7N_3 \cdot C_2H_6O$: N, 17.35%.

After drying at 100°C for 1 hour the nitrogen content varied to 19.38%. (Calcd. for $C_{10}H_{15}O_2N_3 \cdot C_6H_3O_7N_3$: N, 19.17%).

The oil also afforded a cream yellow **chloroplatinate,** m. p. 184°C (decomp.) (from aqueous ethanol containing 1 drop of concentrated hydrochloric acid).

Found: N, 10.50. Calcd. for $(C_{10}H_{15}O_2N_3)_2 \cdot H_2PtCl_6$: N, 10.14%.

(b) A mixture of 1.35 g. of IX, 1.7 cc. of concentrated sulfuric acid and 5.1 cc. of water was heated under reflux for 15 minutes. After cooling it was made alkaline by adding aqueous ammonia, extracted with benzene and dried over anhydrous potassium carbonate. Benzene was removed and the residue was distilled in vacuo to give 1.0 g. of colorless viscous oil, b.p. 201°C/0.7 mmHg in 89.3% yield. (Found: N, 19.79%). The **picrate** formed was not depressed on admixture with that described above, m. p. and mixed m. p. 137°C. (Found: N, 17.61%).

**Hexahydro-1, 2, 5 (or 1, 2, 6)-triazazulene (XIa or XIb).**—A solution of 1.5 g. of X in 15 cc. of glacial acetic acid was saturated with dry hydrogen bromide under ice-water cooling. After standing overnight at room temperature, the solution was heated slowly to 90°C and kept for 2 hours at the same temperature, followed by refluxing for 1 hour. The hydrobromide deposited during the refluxing was separated by decantation, washed twice with a small amount of ethanol and recrystallized from methanol and ether to yield 1.4 g. of hygroscopic, colorless long prisms, which softened at above 260°C, and the second crop of the crystal, 0.4 g. was obtained from the filtrate. The total yield was 84%.

Found: N, 13.83. Calcd. for $C_7H_{11}N_3 \cdot 2HBr$: N, 14.05%.

To a solution of 7.5 g. of the hydrobromide in a small amount of water anhydrous potassium carbonate was added to make it sufficiently alkaline and the mixture was evaporated to dryness under reduced pressure. The residual mass was dried in a desiccator and extracted in the Soxhlet apparatus with isopropyl ether for 15 hours to give 3.4 g. of somewhat hygroscopic, hexagonal **free base,** m. p. 155.5~156.5°C in 99% yield. An analytical specimen was recrystallized from benzene and ethanol.

Found: C, 61.40; H, 8.22; N, 30.75. Calcd. for $C_7H_{11}N_3$: C, 61.29; H, 8.08; N, 30.63%.

The free base and a saturated ethanolic solution of picric acid formed a picrate, which was recrystallized from ethanol to yellow rhombo prisms, m. p. 220~221°C (decomp.). These gradually turned brown on standing.

Found: N, 23.04. Calcd. for $C_7H_{11}N_3 \cdot C_6H_3O_7N_3$: N, 22.94%.

**NBS Bromination of Cycloheptanone.**—A mixture of 12.4 g. of cycloheptanone (b. p. 174~181°C), 25 g. of NBS and 1.5 g. of benzoyl peroxide in 600 cc. of carbon tetrachloride was boiled under reflux for 5 hours on a water bath. Initially the mixture was gradually colored, and reaction suddenly started to make it colorless with the evolution of much hydrogen bromide. After cooling in ice-water succinimide was separated, and the filtrate was washed with 50 cc. of 40% potassium carbonate solution and with 10 cc. of water and finally dried over anhydrous potassium carbonate. The solvent was removed and the residue was distilled in vacuo to yield 11 g. of 2-bromocycloheptanone (XIII) as a colorless oil, b. p. 90~130°C/5 mmHg. This was fractionated into three parts, b. p. 90~101°C/5 mmHg, 101~111°C/5 mmHg and 111~128°C/5 mmHg. These, however, gave the same thiazole derivative as described below.

**Condensation of XIII with Thioacetamide.**—A solution of 11 g. of XIII and 6 g. of thioacetamide in 20 cc. of ethanol was refluxed on a water bath for 5 hours. After removing ethanol and heating the residue for 5 hours in an oil bath kept at 160°C, 40 cc. of 4 N hydrochloric acid was added and extracted three times with each 20 cc. portion of ether. The combined ethereal solution was washed with 10 cc. of 4N hydrochloric acid. Acidic solutions were united, made alkaline by adding anhydrous potassium carbonate and 5 cc. of 5N sodium hydroxide solution, and extracted three times with each 20 cc. portion of ether. After drying over anhydrous potassium carbonate, the ether was expelled and the residue was distilled in vacuo to yield 1.4 g. of **4, 5-cyclohepteno-2-methylthiazole (XIV)** as a colorless oil, b. p. 109~111°C/15 mmHg.

Found: N, 8.06. Calcd. for $C_9H_{13}NS$: N, 8.38%.

Ethanolic solution of XIV was boiled with an excessive picric acid to form a **picrate,** which was recrystallized three times from ethanol to yellow crystals, m. p. 129~131°C.

Found: N, 13.84. Calcd. for $C_9H_{13}NS \cdot C_6H_3O_7N_3$: N, 14.15%.

**Ethiodide** of XIV was obtained as an oily substance by refluxing an ethanolic solution of 0.2 g. of XIV with an excessive ethyl iodide for 8 hours, followed by the addition of ether. This, however, gave a crystalline condensation product assumed to be **4, 5-cyclohepteno-2-(*p*-dimethylaminostyryl)-3-ethylthiazolium iodide** by refluxing with *p*-dimethylaminobenzaldehyde for 8 hours in the presence of a small amount of piperidine and adding ether. The condensation product was recrystallized from ethanol to afford 50 mg. of red crystals, m. p. 219~220°C (decomp.).

Found: N, 5.88. Calcd. for $C_{20}H_{27}N_2SI$: N, 6.17%.

The red crystals showed absorption maximum at 480 mμ.

**Dehydrogenation of XIV.**—In a 25 cc. hard ground glass flask jointed with an air condenser, the top of which was connected to a measuring bottle, were placed 1.5 g. of XIV, 1.5 g. of 10% palladium on carbon and 1 g. of roughly crushed boiling stone, and heated in an electric oven. Hydrogen began to evolve when the temperature of the oven indicated about 390°C. About 450 cc. of hydrogen had been collected

after heating for 6 hours at 440~460°C. The reaction mixture was first washed out with hot benzene and then with ether. After drying the combined organic solution over anhydrous magnesium sulfate, the solvent was removed and the residue was distilled in vacuo to yield 0.7 g. of **4, 5-cyclohepta-trieno-2-methylthiazole** (XV) as a colorless liquid, b. p. 104°C/12 mmHg.

Found: C, 65.95; H, 5.66; N, 8.70. Calcd. for $C_9H_9NS$: C, 66. 24; H, 5.56; N, 8.58%.

A **picrate** derived from the liquid was recrystallized three times from ethanol in yellow crystals, m. p. 147~148°C.

Found: N, 14.50. Calcd. for $C_9H_9NS \cdot C_6H_3O_7N_3$: N, 14.27%.

The author wishes to thank Professor A. Yokoo (this laboratory) for his frequent helpful advice and Mr. K. Kurosaki (Research Laboratory of Fuji Photo Film Company) for the infrared measurements and valuable suggestions. Thanks are also due to Mr. A. Kondo (the Department of Organic Chemistry, Tokyo Institute of Technology) for carrying out the carbon and hydrogen micro-analyses.

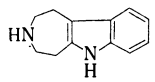
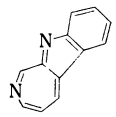
# *Studies on Seven-Membered Heterocyclic Compounds Containing Nitrogen. V. 2, 3, 4, 5-Tetrahydro-1(H)-indolo[2, 3-c]azepine*



By Shiro MOROSAWA

(Received February 6, 1960)



The initial purpose of the present investigation was to prepare 2, 3, 4, 5-tetrahydro-1(H)-indolo[2, 3-c]azepine (Ia) or 1, 2, 4, 5-tetrahydro-3(H)-indolo[3, 2-d]azepine (Ib) which suggests a possibility of dehydrogenation into 2, 3-benzo-1, 7-diazazulene (IIa) or 2, 3-benzo-1, 6-diazazulene (IIb). As similar compounds of this type, 4-ethyl-5, 6, 7, 12-tetrahydro-2-methylindolo[3,2-d] [1]-benzazepine (III)[1], 6,7-dihydro-1-methyl-2, 3-benzindolo[2′ : 3′-4 : 5]-azepine (IV)[2] and 1, 2, 3, 4, 5, 10-hexahydro-7-hydroxy-3-methylazep[4, 5-b]indole (V)[3] have been known. These are, however, compounds of *N*-alkyl or condensed type of phenyl and seven-membered ring, and it may be impossible to bring them into an azulene system by dehydrogenation. After several attempts the author synthesized 2-ethoxycarbonyl-2, 3, 4, 5-tetrahydro-1(H)-indolo[2, 3-c]azepine (XXII), 2-ethoxycarbonyl-7-methoxy-2, 3, 4, 5-tetrahydro-1(H)-indolo[2, 3-c]azepine (XXIII) (as picrate only) and Ia (as picrate only), each of which was assumed to have an angular structure as written from spectral data.

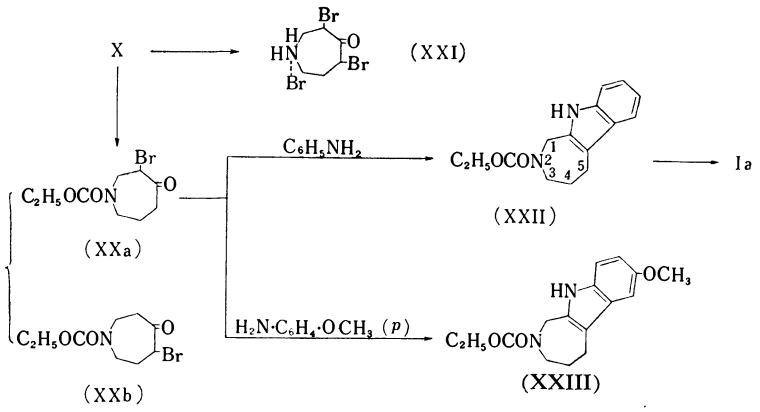
3) J. Harley-Mason and A. H. Jackson, ibid., **1955**, 374.



First of all the author attempted cyclization of phenylhydrazone (VII) and of its hydrochloride of 1-benzyl-1-azacycloheptan-4-one (VI)[4] under the condition of Fischer indole synthesis and under other similar conditions. They have shown a considerable resistance in the cyclizations and were recovered unchanged. In some cases, only a slight indole-like odor and a positive pine-splinter test were observed. Phenylhydrazone (XI) of 1-ethoxycarbonyl-1-azacycloheptan-4-one (X)[5] was also not cyclized with hydrogen chloride in ethanol. An application of the carbazole synthesis to bisulfite compound (IX)[6] of VI resulted in the recovery of VII.

Martynov's method[7], which has obtained 2, 3-pentamethyleneindole in good yield from cyclohexanone via glycidic acid derivative, was applied to 1-ethoxycarbonyl-1-azacyclohexan-4-one (XIV), but the addition reaction of glycidic acid derivative (XV) with aniline failed.

Mühlstädt and Treibs[8] have synthesized 1-keto-2, 3, 4, 5-tetrahydroheptiadole from monophenylhydrazone of cycloheptane-1, 2-dione, and Kent[9] has also obtained 1-keto-1, 2, 3, 4-tetrahydrocarbazole from cyclohexane-1, 2-dione monophenylhydrazone. As a preliminary experiment 1-ethoxycarbonyl-1-azacyclohexane-3, 4-dione monophenylhydrazone (XVIII) derived from XIV was treated under the above conditions, but no expected compound was obtained.

Campbell and McCall[10] have obtained some tetrahydrocarbazoles by heating 2-chlorocyclohexanone with arylamines. In a similar manner, a bromoketone (XXa or XXb)*, which

* Situation of bromine atom is now under investigation by degradative method.

derived from X by NBS bromination, with aniline and *p*-anisidine gave rise to the desired compounds, XXII and XXIII (as picrate) respectively. The elimination of ethoxycarbonyl groupe of XXII gave Ia as a picrate. According to the same procedure of the formation of 3, 5, 7-tribromotropone[11], X was brominated in glacial acetic acid with bromine. But it resulted in elimination of the ethoxycarbonyl group, yielding 3, 5-dibromo-1-azacycloheptan-4-one hydrobromide (XXI). Ultraviolet absorption spectrum of XXII is given in Fig. 1, being compared with that of indole.

In the NBS bromination of X two kinds of bromide, 3-bromo (XXa) and 5-bromo (XXb) derivatives were expected. But only one kind of bromide was obtained. Sprague[12] has reported that NBS bromination of tetrahydro-1, 3-thiapyrone yielded 2-bromo compound exclusively. Similarly one might assume in the 1-azacycloheptan-4-one ring that activated 3-position by neighboring carbonyl, though weak, would be further affected more by the inductive effect of the nitrogen atom than 5-position, making the bromine attack on the position to give 3-bromo compound. Consequently XXII and XXIII may be assumed to be angular structures as shown. This accorded with the spectral data as follows:

The picrate of I indicated four bands near the region due to the hydrogen bending vibration of methylene at 1495, 1486, 1466 and 1430 $cm^{-1}$. The band at 1495 $cm^{-1}$ was due to stretching vibration of the double bond in benzene ring and the other three to 3-, 1-(overlapping with 4-) and 5-methylene in the seven-membered ring as mentioned in the foregoing paper[5]. XXII, on the other hand, gave a broad absorption band in the region owing to overlapping of the above three bands with that arising

from methyl and methylene in the ethoxycarbonyl group. Infrared absorption spectra of these two compounds are given in Fig. 2.

## Experimental

**1-Benzyl-1-azacycloheptan-4-one Phenylhydrazone (VII).**—To a solution of 1 g. of recrystallized phenylhydrazine hydrochloride and 1.6 g. of anhydrous sodium acetate in 10 cc. of water was added 0.8 g. of VI. Ethanol was added to the mixture until a clear solution was obtained and heated on a water bath for 30 minutes. Crystals formed on cooling were recrystallized from diluted ethanol to give 1.1 g. (80%) of **VII hydrochloride** in light greenish yellow needles, m. p. 225°C (decomp.).

Found: N, 12.39. Calcd. for $C_{19}H_{23}N_3 \cdot HCl$: N, 12.74%.

The hydrochloride was mixed with an excessive diluted potassium carbonate solution and evaporated to dryness under reduced pressure. The residual mass was treated with benzene, and benzene was expelled to leave **free phenylhydrazone** as an oil which crystallized on standing. It was recrystallized from diluted ethanol in light yellow needles, m. p. 75°C.

Found: N, 14.98. Calcd. for $C_{19}H_{23}N_3$: N, 14.32%.

**1-Ethoxycarbonyl-1-azacycloheptan-4-one Phenylhydrazone (XI).**—A mixture of 1.6 cc. of phenylhydrazine, 1.6 cc. of glacial acetic acid and 0.8 g. of X was treated as above. Crude product 1.2 g. (100%), m. p. 130°C (decomp.), was recrystallized from diluted ethanol to give 0.9 g. of XI as yellow needles, m. p. 130°C (decomp.).

**1-Ethoxycarbonyl-1-azacyclohexan-4-one (XIV).**—According to the same procedure as that of the formation of X, 15 g. of 1-benzyl-1-azacyclohexan-4-one (XIII)[4] yielded 12.3 g. (90.8%) of XIV, boiling at 93~94°C/1 mmHg as a colorless oil.

Found: N, 8.12. Calcd. for $C_8H_{13}O_3N$: N, 8.18%.

**2, 5-Diethoxycarbonyl-1-oxa-5-azaspiro (5, 2) octane (XV).**—To a mixture of 3.5g. of XIV and 2.4g. of ethyl monochloroacetate was added a solution of 0.74 g. of metallic potassium in 25 cc. of tertiary butanol under stirring and ice-water cooling during 30 minutes in the nitrogen atmosphere. After an additional stirring for 1 hour the butanol was expelled under reduced pressure and the residue was dissolved in 15 cc. of water. The solution was adjusted to pH 2.0 with hydrochloric acid and extracted with ether. The ethereal solution was washed once with water and dried over anhydrous sodium sulfate. The ether was removed and the residue was distilled in vacuo to give 2.5 g. (47.7%) of a colorless viscous oil, b.p. 146~150°C/1.5 mmHg.

Found: N, 5.21. Calcd. for $C_{12}H_{19}O_5N$: N, 5.44%.

**1-Ethoxycarbonyl-3-hydroxymethylene-1-azacyclohexan-4-one (XVII).**—A solution of 12.3 g. of XIV and 10.6 g. of ethyl formate in 150 cc. of dry benzene was added with swirling to an ice cold suspension of crushed methanol-free sodium methoxide[13] (from 3.3 g. of sodium) in 150 cc. of dry benzene. The system was evacuated and filled with nitrogen, and allowed to stand at room temperature overnight. Precipitates were dissolved by adding 60 cc. of water. The benzene layer was separated and washed four times with each 10 cc. of 5% solution of sodium hydroxide. The water layer and the washings were united, washed once with ether and acidified with concentrated hydrochloric acid to deposit an orange oil. The oil was taken up in benzene and the water layer was concentrated under reduced pressure, and extracted further with benzene. Benzene extracts were united, washed five times with a small volume of saturated sodium chloride solution and dried over anhydrous magnesium sulfate. After removal of benzene, the vacuum distillation gave 3.5 g. (24.5%) of a colorless viscous oil, boiling at 130~131°C/2 mmHg.

Found: N, 7.06. Calcd. for $C_9H_{13}O_4N$: N, 7.03%.

The oil gave a **monosemicarbazone**, m. p. 156.5°C (Found: N, 22.09%) and a **cyclic semicarbazone**, m. p. 128.5°C (Found: N, 23.28%).

**1-Ethoxycarbonyl-1-azacyclohexan-3, 4-dione Monophenylhydrazone (XVIII).**—To a mixture of 0.63 g. of redistilled aniline, 0.67 cc. of concentrated sulfuric acid and 5 cc. of water was added dropwise a solution of 0.47 g. of sodium nitrite in 1.8 cc. of water under stirring and ice-water cooling, followed by the addition of a saturated solution of 1.1 g. of anhydrous sodium acetate. Then a solution of 1 g. of XVII in 3 cc. of ether was added dropwise and the resultant mixture was stirred for 15 minutes while cold and for 30 minutes at room temperature. The orange crystals which separated were collected and recrystallized five times from methanol to give 0.6 g. (43.5%) of XVIII, m. p. 116~117°C.

Found: N, 15.07. Calcd. for $C_{14}H_{17}O_3N_3$: N, 15.26%.

**3(or 5)-Bromo-1-ethoxycarbonyl-1-azacycloheptan-4-one (XXa or XXb).**—A mixture of 7.4 g. of X, 0.3 g. of benozyl peroxide and 8 g. of NBS in 400 cc. of carbon tetrachloride was heated on a water bath, protected from moisture. As soon as the boiling took place, the mixture turned red and suddenly the color disappeared. After the boiling was further continued gently for 3 minutes the mixture was cooled under the tap and allowed to stand for 2 hours in a refrigerator. Succinimide was removed and washed with carbon tetrachloride. Carbon tetrachloride solutions were united, washed with 20 cc. of 20% sodium carbonate solution and then with water, and finally dried over anhydrous potassium carbonate. After removal of the solvent, residual oil was distilled in vacuo to yield 5.3 g. (50%) of a slightly colored oil, boiling at 140~145°C/1 mmHg.

Found: N, 5.85. Calcd. for $C_9H_{14}O_3NBr$: N, 5.31%.

A mixture of 0.1 g. of the above oil, 0.1 g. of 2,4-dinitrophenylhydrazine, 3 cc. of ethanol and 0.1 cc. of concentrated hydrochloric acid was boiled on a water bath for 2 minutes and let stand overnight. Crystals formed were recrystallized twice

13) W. S. Johnson and H. Posvic, *J. Am. Chem. Soc.*, 69, 1361 (1947).

from methanol to yield yellow **2, 4-dinitrophenylhydrazone**, m. p. 149~152°C (decomp.).

Found: N, 15.86. Calcd. for $C_{15}H_{18}O_6N_5Br$: N, 15.75%.

**3, 5-Dibromo-1-azacycloheptan-4-one Hydrobromide (XXI).**—A solution of 3 g. of X and 15 g. of bromine dissolved in 5 cc. of glacial acetic acid was allowed to stand overnight. The solution was heated on a water bath for 50 hours and evaporated under reduced preseure. The residue was taken up in ethanol, which was evaporated to leave an oil with some crystals. To this was added a small amount of ethanol to bring the oil into solution and isopropyl ether was added in small portions until precipitation occurred. After standing overnight in a refrigerator, the crystals were collected and charcoaled in 200 cc. of ethanol. Charcoal was separated and the ethanolic solution was concentrated to a smaller volume under reduced pressure. The crystals which were deposited during the evaporation were collected and washed with ethanol to yield 0.8 g. of XXI. Another crop, 0.4 g. was obtained from the filtrate. Crude crystals were recrystallized together from a small amount of water to give 0.7 g. of XXI as slightly colored microneedles, m. p. 186°C (decomp.).

Found: C, 20.33; H, 2.89; N, 3.68. Calcd. for $C_6H_9ONBr_2 \cdot HBr$: C, 20.45; H, 2.84; N, 3.97%.

**2-Ethoxycarbonyl-2, 3, 4, 5-tetrahydro-1(H)-indolo-[2, 3-c]azepine (XXII).**—A mixture of 5.3 g. of XX and 10.6 g. of redistilled aniline was boiled in an oil bath for 3 hours. The reaction mixture was treated with diluted potassium carbonate solution and taken up in ether. Ether was removed and aniline was thoroughly driven off by distillation in an oil bath maintained at 180°C under diminished pressure (0.8 mmHg). The residual tarry oil was dissolved in 70 cc. of benzene and washed once with 5 cc. of 2 N hydrochloric acid, thrice with a small portion of saturated sodium chloride solution and dried over anhydrous potassium carbonate. To the residue left on evaporation of benzene were added ethanol and picric acid, boiled for a while and allowed to stand overnight. Crystals formed were collected, washed with ether and recrystallized from ethanol to yield 1.5 g. (15.3%) of **picrate** as tan needles (indol odor), m. p. 156°C.

Found: N, 14.46. Calcd. for $C_{15}H_{18}O_2N_2 \cdot C_6H_3O_7N_3$: N, 14.37%.

**Free base**, though in poor yield, was obtained by treating the picrate with a saturated sodium bicarbonate solution and extracting with benzene as extremely viscous yellow oil (indole odor), boiling at 216°C/0.4 mmHg. This did not crystallize on standing.

Found: N, 10.75. Calcd. for $C_{15}H_{18}O_2N_2$: N, 10.85%.

The free base again formed a **picrate** which was found to be the same as that mentioned above, giving no m. p. depression.

**2-Ethoxycarbonyl-7-methoxy-2, 3, 4, 5-tetrahydro-1(H)-indolo[2, 3-c]azepine (XXIII) Picrate.**—A mixture of 2.8 g. of XX and 3.3 g. of redistilled *p*-anisidine was treated as before and 0.5 g. (9.1%) of picrate (indole odor) was obtained as deep tan needles, m. p. 164.5°C.

Found: N, 13.66. Calcd. for $C_{16}H_{20}O_3N_2 \cdot C_6H_3O_7N_3$: N, 13.54%.

Free base was distilled in vacuo at 220~228°C/0.5 mmHg with decomposition, and for lack of the distillate it could not be studied further.

**Deethoxycarbonylation of XXII.**—The picrate of XXII, 1 g. was treated with a saturated sodium bicarbonate solution and taken up in benzene. The residual oil which was left on evaporation of benzene was dissolved in 8 cc. of glacial acetic acid and saturated with dry hydrogen bromide under cooling. After standing overnight the solution was boiled under reflux for 2 hours. Acetic acid was removed under reduced pressure and the residue was heated in ethanol with an excessive picric acid. Crystals deposited on standing were recrystallized twice from ethanol to give 0.2 g. of Ia picrate as tan yellow prisms, m. p. 254°C (decomp.).

Found: C, 51.80; H, 4.43; N, 16.65. Calcd. for $C_{12}H_{14}N_2 \cdot C_6H_3O_7N_3$: C, 52.05; H, 4.13; N, 16.86%.

The author wishes to acknowledge the helpful advice of Professor A. Yokoo (this laboratory), and to thank Mr. A. Kondo (the Department of Organic Chemistry, Tokyo Institute of Technology) for carrying out the carbon and hydrogen micro-analyses and Mr. K. Kurosaki (Research Laboratory of Fuji-Photo Film Company) for the infrared measurements and valuable suggestions.

# *Studies on Seven-Membered Heterocyclic Compounds Containing Nitrogen. VI. 7-Methyl-2,3,4,5-tetrahydro-1(H)-thiazolo[5,4-c]azepine*

By Akira YOKOO and Shiro MOROSAWA

(Received February 6, 1960)

The present authors have synthesized 7-methyl-2,3,4,5-tetrahydro-1-(H)-thiazolo[5,4-c]-azepine (III). Spectral studies also supported the structure.

3-Bromo-1-ethoxycarbonyl-1-azacycloheptan-4-one (I)[1] yielded 2-ethoxycarbonyl-7-methyl-2, 3, 4, 5-tetrahydro-1(H)-thiazolo[5,4-c]azepine (II), b. p. 160~164°C/1 mmHg, by condensation with thioacetamide. II gave a chloroaurate of m. p. 180°C (decomp.). On deethoxycarbonylation of II by hydrogen bromide in glacial acetic acid, III was obtained as an oil of b. p. 101~102°C/4 mmHg, which gave a hydrochloride of m. p. 207~212°C (decomp.) and a chloroaurate of m. p. 179°C (decomp.) respectively. Ethiodide (IV) of II condensed with *p*-dimethylaminobenzaldehyde to afford 2-ethoxycarbonyl-7-(*p*-dimethylaminostyryl)-6-ethyl-2, 3, 4, 5-tetrahydro-1(H)-thiazolo[5,4-c]azepinium iodide (V), m. p. 203°C (decomp.). Dehydrogenation of III by heating with 10% palladium on carbon at elevated temperature evolved hydrogen, but led to decomposition of III.

It has already been reported[1] that bromine atom entered the 3-position by NBS bromination of 1-ethoxycarbonyl-1-azacycloheptan-4-one and that the indole compounds derived from the consequent bromoketone by the condensation with some arylamines might have angular structures. As shown in Fig. 1, III gave four bands at 1478, 1468, 1455 and 1430 $cm^{-1}$ near the region due to the hydrogen bending vibration of methylene. These bands were assumed, as stated in the former paper[2], to be ascribed to 3-, 1-, 4- and 5-methylenes respectively. It was considered that the intensity of the band at 1455 $cm^{-1}$ was too strong for the methyl group in the thiazole ring and therefore it

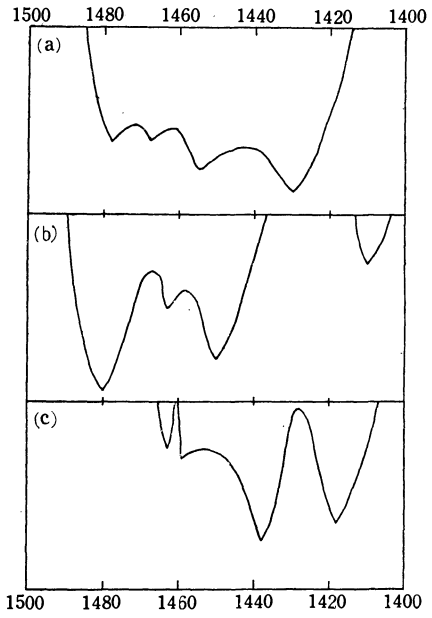

Fig. 1.

(a) III; (b) III hydrochloride; (c) III hydrobromide

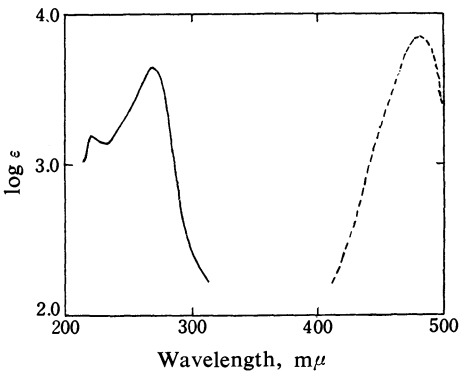

Fig. 2. (in methanol)

—— II, ---- V (concn. unknown)

appeared as an overlapping with 4-methylene. Both hydrochloride and hydrobromide of III gave also four bands, corresponding to the above absorptions. From these facts it may be reasonable to assume that III also had an angular

1) S. Morosawa, This Bulletin, 33, 1113 (1960).
2) S. Morosawa, ibid., 33, 1108 (1960).

form like the compounds reported before[1,2]. Ultraviolet absorption spectra of II and V are also given in Fig. 2.

## Experimental

**2-Ethoxycarbonyl-7-methyl-2, 3, 4, 5-tetrahydro-1 (H)-thiazolo[5, 4-c]azepine (II).**—A solution of 5 g. of I and 2 g. of thioacetamide in 15 cc. of ethanol was boiled under reflux on a water bath for 5 hours. The ethanol was removed and the residue was heated in an oil bath kept at 160~165°C under reduced pressure (water pump) for 5 hours. After cooling, 10 cc. of 4 N hydrochloric acid was added and taken up three times in ether. The ether was washed twice with each 5 cc. portion of 4 N hydrochloric acid. Acidic solutions were united and made alkaline with anhydrous potassium carbonate, followed by adding 5 cc. of 5 N sodium hydroxide solution. The alkaline solution was shaken three times with each 20 cc. portion of ether. After drying over anhydrous potassium carbonate, the ethereal solution was concentrated and the residue was distilled in vacuo to give 1.6 g. of a light yellow viscous oil, b. p. 160~164°C/1 mmHg.

Found: C, 54.53; H, 6.74; N, 11.20. Calcd. for $C_{11}H_{16}O_2N_2S$: C, 54.99; H, 6.71; N, 11.65%.

The nitrogen content showed a slightly low value even after several repetitions, and the inclination was also observed in the following compounds of this series.

Ethanolic solution of the oil was mixed with an excessive chloroauric acid, heated for a while and allowed to cool. The **chloroaurate** formed was recrystallized twice from ethanol to yellow crystals, melting at 180°C with decomposition.

Found: C, 22.20; H, 3.33; Au, 32.50. Calcd. for $C_{11}H_{16}O_2N_2S \cdot HAuCl_4$: C, 22.60; H, 2.94; Au, 33.80%.

The oil and an excessive amount of ethyl iodide were allowed to stand for one day. The mixture was then refluxed for 8 hours to form an **ethiodide IV.** It was filtered and recrystallized from ethanol and ether to colorless crystals, m. p. 155~156.5°C.

Found: C, 39.05; H, 5.32; N, 6.39. Calcd. for $C_{11}H_{16}O_2N_2S \cdot C_2H_5I$: C, 39.40; H, 5.34; N, 7.07%.

**7-Methyl-2,3,4,5-tetrahydro-1(H)-thiazolo[5,4-c]-azepine (III).**—A solution of 0.8 g. of II in 20 cc. of glacial acetic acid was saturated with hydrogen bromide under ice-water cooling. After standing for 2 hours the solution was heated gradually in an oil bath and refluxed for 5 hours. The Hydrobromide which remained as a crystalline residue on evaporation of acetic acid was recrystallized from a mixture of ethanol and methanol to colorless crystals, m. p. 248~252°C (decomp.). These were dissolved in a small amount of water, made alkaline by adding concentrated sodium hydroxide solution and taken up in ether. After drying over anhydrous potassium carbonate, the ether was expelled and the residue was distilled in vacuo to yield 0.4 g. of a colorless, strongly hygroscopic oily substance, b. p. 101~102°C/4 mmHg.

Found: C, 56.60; H, 7.40; N, 16.29. Calcd. for $C_8H_{12}N_2S$: C, 57.14; H, 7.19; N, 16.65%.

The above oil was dissolved in concentrated hydrochloric acid and evaporated to dryness under reduced pressure to afford a **hydrochloride.** This was recrystallized twice from ethanol to extremely hygroscopic colorless plates, m. p. 207~212°C (decomp.).

Found: N, 11.16. Calcd. for $C_8H_{12}N_2S \cdot 2HCl$: N, 11.62%.

The **chloroaurate** which formed by mixing the oil with an excessive amount of chloroauric acid in ethanol containing one drop of concentrated hydrochloric acid was collected and washed with ethanol. This was dissolved in an ethanol-methanol mixed solvent with heating, the methanol was expelled and the solution was allowed to stand with one drop of concentrated hydrochloric acid to yield yellow crystals, which decomposed at about 179°C.

Found: N, 5.06. Calcd. for $C_8H_{12}N_2S \cdot HAuCl_4$: N, 5.50%.

**2-Ethoxycarbonyl-7-(*p*-dimethylaminostyryl)-6-ethyl-2, 3, 4, 5-tetrahydro-1(H)-thiazolo[5, 4-c]azepinium Iodide (V).**—A solution of 0.1 g. of IV and 0.1 g. of *p*-dimethylaminobenzaldehyde in 2 cc. of ethanol containing a small amount of piperidine was boiled under reflux for 10 hours. The ethanol was expelled and water was added to the residue to deposit crystals, which were collected and washed well with ether. The crystals were dissolved in a small volume of ethanol with heating and ether was added until the solution became turbid. The red crystals which formed were treated repeatedly like the above to give 40 mg. of V, m. p. 203°C (decomp.). The nitrogen content showed some deviation from the theoretical value even after several recrystallizations.

Found: N, 7.01. Calcd. for $C_{22}H_{30}O_2N_3SI$: N, 7.97%.

The authors wish to thank Mr. K. Kurosaki (Research Laboratory of Fuji Photo Film Company) for the infrared measurements and Mr. A. Kondo (the Department of Organic Chemistry, Tokyo Institute Technology) for the carbon and hydrogen micro-analyses.

# *The Photolysis of Acetaldehyde in the Presence of Hydrogen Sulfide*

By Naomi IMAI and Osamu TOYAMA

(Received February 17, 1960)

The present authors have recently studied the photolysis of acetone in the presence of hydrogen sulfide in order to obtain information on the hydrogen abstraction from hydrogen sulfide molecules by methyl radicals[1]. The activation energy of the abstraction reaction thus obtained is of such small value that it seems desirable to check it in another way. The present work presents such an attempt on the basis of an investigation on the photolysis of acetaldehyde in the presence of hydrogen sulfide.

We have been interested in this abstraction reaction in conjunction with the mechanism of the thermal decomposition of acetaldehyde in the presence of hydrogen sulfide. The present study is therefore expected to give valuable information also on other elementary reactions involved in common in both kinds of decomposition, photochemical and thermal, in the system consisting of acetaldehyde and hydrogen sulfide.

## Experimental

**Materials.**—Acetaldehyde was prepared by distillation of paraldehyde containing a little quantity of sulfuric acid, and stored in a bulb at 0°C. When the acetaldehyde thus stored was not used at once, it was again purified by distillation befroe use. Hydrogen sulfide was prepared by dropping water on aluminum sulfide in an evacuated vessel, dried by passing through a trap at −78°C and purified by bulb to bulb distillation.

**Apparatus.** — Photolysis was carried out in a cylindrical quartz vessel of about 110 cc. placed in an electric furnace with a thin glass window which cuts off the light of a wavelength region shorter than 2800 Å to prevent absorption by hydrogen sulfide. The reaction vessel was connected to a mercury manometer, to an analytical system, to storage bulbs and to a bulb in which acetaldehyde and hydrogen sulfide were mixed before they were admitted to the reaction vessel. The full light from a medium pressure mercury arc was used in the present study, and its intensity was kept constant for a series of runs by using a voltage stabilizer. For experiments with varied intensity, the distance between the light source and the reaction vessel was changed. The reaction vessel, the manometer, the bulbs for storage and mixing and the analytical system were all attached to a conventional vacuum line.

**Procedure.**—Required quantities of acetaldehyde and hydrogen sulfide were admitted into the mixing bulb at room temperature and left for about 30 minutes to allow them to mix thoroughly. The mixed gases were then introduced into the reaction vessel which had already been irradiated, and the change in the total pressure with time was followed on a manometer.

The analytical technique employed was the same as that described previously[1]. In this work the hydrogen sulfide added initially was found by analysis to remain almost unconsumed even after a prolonged photolysis.

## Results and Discussion

It has been established by many workers[2] that the products of the photolysis of acetaldehyde above 100°C under normal conditions are almost exclusively methane and carbon monoxide. Similarly in this work, i. e., in the presence of hydrogen sulfide, it has been confirmed by analysis that the rate of formation of methane is identical with that of carbon monoxide, and the pressure of either one of these products corresponds to the total pressure increase within the experimental error. Thus, irrespective of the presence of hydrogen sulfide, the total pressure increase is always equal to the decrease in the pressure of acetaldehyde

due to decomposition. Accordingly, the initial rate of decomposition was determined from the initial slope of a total pressure-time curve with the results shown in Figs. 1—4. Fig. 1 shows the dependence of the rate of decomposition on the pressure of acetaldehyde in the experiments with acetaldehyde alone. Figs. 2 and 3 show the dependence of the rate of decomposition in the presence of hydrogen sulfide on its pressure under various experimental conditions. The relative light intensity intensity for the experiments shown in Fig. 2 is four times as great as that in Fig. 3. Fig.

4 shows the dependence of the rate on acetaldehyde pressure in the presence of hydrogen sulfide.

It should be noted that, at a high temperature, in a run with a high concentration of hydrogen sulfide, the rate of decomposition falls off very rapidly, as seen in Fig. 5, compared to the results obtained with low concentrations of hydrogen sulfide. Similar reduction in the rate was observed, as seen in Fig. 2, when the acetaldehyde mixed with a large quantity of hydrogen sulfide was preheated for a few minutes at the experimental temperature prior to irradiation. Although the exact nature of these phenomena has not yet been fully elucidated, it is obvious from these findings that at still higher concentrations of hydrogen sulfide than those given in Fig. 2, determination of the initial rate of decomposition becomes considerably unreliable.

It is generally agreed that the main features of the photochemical decomposition of acetaldehyde can be explained by the following mechanism[3]:

$$CH_3CHO + h\nu = CH_3 + CHO \quad (0)$$

$$CHO = CO + H \quad (1)$$

$$H + CH_3CHO = H_2 + CH_3CO \quad (2)$$

$$CH_3CO = CH_3 + CO \quad (3)$$

$$CH_3 + CH_3CHO = CH_4 + CH_3CO \quad (4)$$

$$CH_3 + CH_3 = C_2H_6 \quad (5)$$

Solution of the steady state equations derived from this scheme yields the rate equation ($I_a$ = the rate of absorption of light quanta)

$$-\mathrm{d}[CH_3CHO]/\mathrm{d}t = k_4 k_5^{-1/2} I_a^{1/2} [CH_3CHO] \quad (I)$$

in general agreement with experimental results obtained by various workers. The existence of a primary reaction other than reaction (0) is well known[4]. This, however, gives no substantial alteration in Eq. I. From the plot given in Fig. 1 it is seen that the rate of decomposition of acetaldehyde alone is proportional to the 3/2 power of its pressure. This simply means that under the present experimental conditions the rate of absorption of light quanta is proportional to the acetaldehyde pressure.

Now in the presence of hydrogen sulfide, the possible additional reactions may be[5]

$$CH_3 + H_2S = CH_4 + HS \quad (6)$$

$$HS + CH_3CHO = H_2S + CH_3CO \quad (7)$$

$$HS + HS = \text{products} \quad (8)$$

If reaction (8) can be neglected and consequently the chain terminates still by reaction (5),

$$-\mathrm{d}[CH_3CHO]/\mathrm{d}t = k_4 k_5^{-1/2} I_a^{1/2} [CH_3CHO] + k_6 k_5^{-1/2} I_a^{1/2} [H_2S] \quad (II)$$

while, if the chain terminates now by reaction (8), the result is

$$-\mathrm{d}[CH_3CHO]/\mathrm{d}t = k_7 k_8^{-1/2} I_a^{1/2} [CH_3CHO] \quad (III)$$

It is readily shown that in the steady state,

$$k_6 [CH_3] [H_2S] = k_7 [HS] [CH_3CHO]$$

or

$$[HS]/[CH_3] = (k_6/k_7)([H_2S]/[CH_3CHO])$$

Therefore, when the value of $(k_6/k_7)([H_2S]/[CH_3CHO])$ is very small, i. e., the concentration of methyl radical is much higher than that of hydrosulfide radical, the rate of decomposition will be represented by Eq. II. On the contrary, when the value of $(k_6/k_7)([H_2S]/[CH_3CHO])$ is very large, Eq. III will hold.

In Figs. 2 and 3 where the rates of decomposition are plotted against pressures of hydrogen sulfide, it is seen that, in the low pressure range of hydrogen sulfide, except for the experiments with preheating, the rate of decomposition increases linearly with the pressure of hydrogen sulfide in agreement with Eq. II. The fact that the intercept on the ordinate is always equal to the rate of decomposition in the absence of hydrogen sulfide also conforms to Eq. II. According to the equation the slope of the linear part divided by the intercept gives the ratio $k_6/k_4$. The values of $k_6/k_4$ thus

TABLE I. VALUES OF $k_6/k_4$

determined are listed in Table I[6]. The fact that neither a two-fold increase in the pressure of acetaldehyde, nor the variation in light intensity by a factor of four, yields any significant change in the values of $k_6/k_4$ may be taken as additional evidence for the validity of Eq. II.

A further check in favor of Eq. II is provided by Fig. 4, where the plot of the rates of decomposition observed at a constant pressure of hydrogen sulfide against acetaldehyde pressures is shown together with the curve predicted from Eq. II as follows: Since the rate of absorption of radiation in the present investigation is proportional to the concentration of acetaldehyde as mentioned above, the values of $k_4k_5^{-1/2}I_a^{1/2}$ and $k_6k_5^{-1/2}I_a^{1/2}$ required for the calculation of the rate of decomposition by means of Eq. II can be obtained from the data given in Figs. 1 and 2. As seen in Fig. 4, the curve representing the rate thus calculated as a function of acetaldehyde pressure is in satisfactory agreement with the experimental plot over a wide range of acetaldehyde pressure.

The Arrhenius plots of the values of $k_6/k_4$ given in the two series in Table I yielded two parallel straight lines lying close to each other from which the values $E_4-E_6=4.0\pm0.3$ kcal./mol. and $A_6/A_4=1.7\pm0.5$ were obtained, where $E$ denotes the activation energy and $A$ the pre-exponential factor. The ratio $A_6/A_4=1.7$ seems to be reasonable since $A$ factors for most hydrogen abstraction reactions by methyl radicals are of the same order of magnitude. The activation energy difference $E_4-E_6=4.0$ kcal./mol., when combined with $E_4=6.8$ kcal./mol. given by Ausloos and Steacie[7], yields 2.8 kcal./mol. for $E_6$ which compares satisfactorily with our previous value of 2.6 kcal./mol. obtained in the photolysis of acetone in the presence of hydrogen sulfide[1]. If, instead, $E_4=7.5\sim8.0$ kcal./mol. reported by Brinton and Volman[8] and Dodd[4d] is accepted, the result is $E_6=3.5\sim4.0$ kcal./mol. which is now clearly higher than the previous value but still lower than 5.6 kcal./mol.[9] estimated for the activation energy of hydrogen abstraction from methane thiol by methyl radical, in agreement with our previous conclusion[1].

It is evident from Figs. 2 and 3 that, for the experiments without preheating, the lower the temperature, the lower is the pressure of hydrogen sulfide at which a plot of the rate of the decomposition against the pressure of hydrogen sulfide shows a departure from a straight line. At a temperature as low as 150°C, the plot (Fig. 2) shows a curvature from the very beginning and, in the range of pressure of hydrogen sulfide higher than about 30 mmHg the rate of decomposition attains an almost constant value in agreement with Eq. III.

Presumably, these fact indicate that the ratio $k_6/k_7$ increases with lowering of temperature, for, with the increase in the ratio $k_6/k_7$, $[CH_3]/[HS]$ and hence the ratio of the rate of reaction (8) to that of reaction (5) increases, provided the ratio $[H_2S]/[CH_3CHO]$ is constant. Such dependence of the ratio $k_6/k_7$ on temperature seems to be reasonable since the activation energy for reaction (6) is very low as estimated above so that it is probably lower than that of reaction (7).

The afore-mentioned observation that, in the presence of a large concentration of hydrogen sulfide, the rate of photolysis suffered considerable reduction not only by preheating the reaction mixture, but also during the photolysis at a high temperature, cannot fully be explained at present. It may, however, be possible that a small quantity of a yet unidentified compound produced in the thermal reaction between acetaldehyde and hydrogen sulfide gives rise to the observed phenomena. Birrell et al.[5c] found that the rate of decomposition of acetaldehyde is reduced appreciably by large quantities of isopropanethiol and tertiary-butanethiol below 300°C, and to almost negligible values by small quantities of tertiary-butanethiol and isopropanethiol above 300°C and 340°C respectively. We have also found[10] that the presence of a little quantity of methanethiol lowers remarkably the rates of photolyses of acetone, acetaldehyde and a mixture of acetaldehyde and hydrogen sulfide. In view of the similarity of the phenomena cited, it seems probable that all of these resulted from similar causes which, however, are to be clarified by further studies of these phenomena in future.

## Summary

Acetaldehyde has been photolyzed in the presence of hydrogen sulfide over the temperature range from 150 to 360°C. The initial rates of decomposition obtained under various experimental conditions are consistent with a mechanism which involves the reactions $CH_3+H_2S=CH_4+HS$ (6) and $HS+CH_3CHO=H_2S+CH_3CO$ (7) in addition to those established already for the photolysis of acetaldehyde alone. Analysis of the data on this basis gives

6) The value of the intercept was actually determined from several repeated runs of the photolysis of 100 mmHg acetaldehyde in the absence of hydrogen sulfide at the same temperature.

7) P. Ausloos and E. W. R. Steacie, *Can. J. Chem.*, **33**, 31 (1955).

a value of 4.0 kcal./mol. for the difference in activation energy $E_4-E_6$, where $E_4$ refers to the reaction $CH_3+CH_3CHO=CH_4+CH_3CO$ (4). This result, when combined with $E_4=6.8$ kcal./mol. found by Ausloos and Steacie, gives $E_6=2.8$ kcal./mol. in excellent agreement with our previous value of 2.6 kcal./mol. obtained in the photolysis of acetone in the presence of hydrogen sulfide. As the temperature is lowered and the ratio $[H_2S]/[CH_3CHO]$ increased, the importance of the combination of methyl radicals to ethane as the chain terminating step decreases, until it is replaced by the combination of hydrosulfide radicals. This is explained in terms of the relationship $E_7>E_6$.

# *Alternating Current Polarization Titration with Two Hanging Mercury Drop Electrodes—Application to Chelatometric Titration of Cadmium*

By Toyokichi KITAGAWA

(Received March 3, 1960)

Both potentiometry at a constant current and amperometry at a small constant applied voltage with two polarized platinum electrodes are widely used for the determination of the equivalent point in a large number of titrations. The relation between the two methods of titration mentioned above has been recently discussed by several authors on the basis of voltammetry[1-4].

On the other hand, conductometric titration using low frequency of 200~1000 c/sec. has been applied to the determination of the equivalent point in titrations involving acid-base neutralization reaction or precipitation reaction. However, alternating current polarization titration, which corresponds to the alternating current analogs of the two direct current method, situated between direct current polarization titration and conductometric titration has not been studied systematically. Recently Franck[5], Laitinen[6] and the present author[7] studied these methods, and applied them to redox, precipitation and complex formation reaction.

The present author studied polarization titration fundamentally, applying to a pair of platinum microelectrodes a square wave or sine wave signal of constant current and measuring the alternating voltage (polarization voltage) in the course of a titration.

This is a suitable method which can be applied in redox reaction, complex formation reaction and neutralization reaction. It is impossible, however, that metal ion concentration is indicated by the platinum electrode, except in the case of some reversible system; for example, ferric-ferrous system. Hence when the chelatometric titration of metal ion is carried out by the polarization titration method, an excess of ethylenediaminetetraacetate (EDTA) solution of a known concentration is added, and the excess of EDTA is back-titrated with standard ferric solution. However, when the stability constant of metal ion titrated is much smaller than that of ferric ion, this titration method can not be used. Accordingly, only a few kinds of metal ion, ferric, indium and nickel, are titrated by this method[8]. For this reason, it seemed desirable and worth while to investigate the chelatometric titration of most metal ions by alternating current polarization titration with two mercury drop electrodes.

In this paper, the experimental results of the application to the cheltometric titration of the cadmium ion are presented, and the factors which affect this titration method are discussed.

## Experimental

**Reagents.** — A standard EDTA solution was obtained by dissolving the pure disodium ethylenediaminetetraacetate dihydrate (Wako Junyaku Co. Ltd.) in distilled water. The concentration was standardized against a standard copper solution by photometric titration using Murexide as indicator. The concentration was 0.100 M. A 0.01 M EDTA solution was prepared by dilution. Standard cadmium solution was prepared by dissolving cadmium nitrate in distilled water. The concentration was determined gravimetrically as cadmium oxinate. Standard mercuric ethylenediaminetetraacetate was prepared by mixing equivalent amounts of mercuric nitrate solution and EDTA solution. The concentration was 0.05 M.

All other chemicals were of analytical reagent grades. Redistilled water was used for the preparation of the solutions.

**Apparatus.**—Alternating current polarization titration apparatus is shown in Fig. 1. Kikusui Type CR oscillator was used for sine wave or square wave generator (20～2000 c/sec.). The circuit of measuring polarization voltage is shown in Fig. 2.

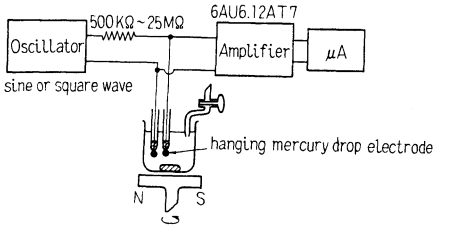

Fig. 1. Alternating current polarization titration apparatus.

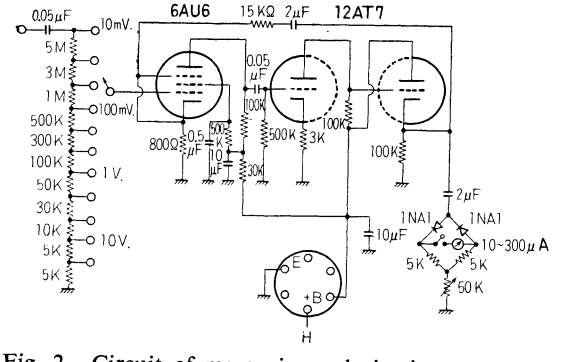

Fig. 2. Circuit of measuring polarization voltage.

The measurement was made at a small current using a large resistor in series with the electrolytic cell and an output voltage (12 volt) from the sine wave or square wave generator. The alternating voltage (polarization voltage) between two electrodes was measured as a function of the volume of reagent added.

The mercury drop electrode was prepared by fixing the mercury drop on the top of amalgamated platinum electrodes. Mercury can be deposited on the platinum electrode out of 1 M mercuric nitrate solution by the impression of an electromotive force of about 2 V. The surface area of the mercury drop was about 0.021 $cm^2$. A calibrated semimicroburet 5 ml. was used for all titrations.

**Procedure.**—About 50 ml. of the solution, which contained definite amounts of cadmium nitrate solution, 50 ml. of 1 M ammoium acetate-acetic acid buffer solution (pH 4.3～5.0), 1 ml. of 0.1% gelatine and 10 ml. of 0.05 M mercury (II) EDTA solution, was titrated with $10^{-1}$ or $10^{-2}$ M standard solution of EDTA. The frequency of square wave or sine wave was 25 c/sec. and the alternating current was 20～25 μA*. The polarization voltage was recorded at every 0.01 ml. of added titrant in the neighborhood of the equivalence point of this titration.

An example of this titration curve is shown in Fig. 3. In the course of this titration, the solution was stirred at a constant speed by a magnetic stirrer.

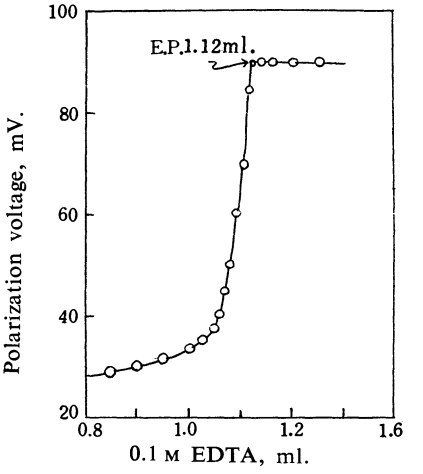

Fig. 3. Titration curve. $Cd^{2+}$ 12.5 mg.

## Results

In the procedure described above, the following factors were specially considered.

*1) Relation between Polarization Voltage and Frequency.*—Polarization voltage was measured at the equivalence point by the procedure described above. As shown in Fig. 4, a plot of polarization voltage against the reciprocal of square root of frequency gives a straight line at frequency 20～200 c/sec. Therefore, the frequency 20 c/sec. was used as a suitable frequency in this titration. In a frequency above 500 c/sec. it was impossible to apply this end point detection method, because the polarization voltage became very small.

*2) Relation between Polarization Voltage and Alternating Current.*—In the potentiometry at a constant direct current, the difference in potential between two identical indicator

* Calculated value $12(V) \div 500(K\Omega) = 24(\mu A)$

electrodes becomes more extended with the increase of the current[2-4]. On the other hand, polarization voltage at alternating current polarization titration is proportional to the alternating current as shown in Fig. 4. Therefore, 25 $\mu$A was used for the suitable alternating current in this titration. If the alternating current becomes very small, it is impossible to use this titration method owing to the decrease of the polarization voltage.

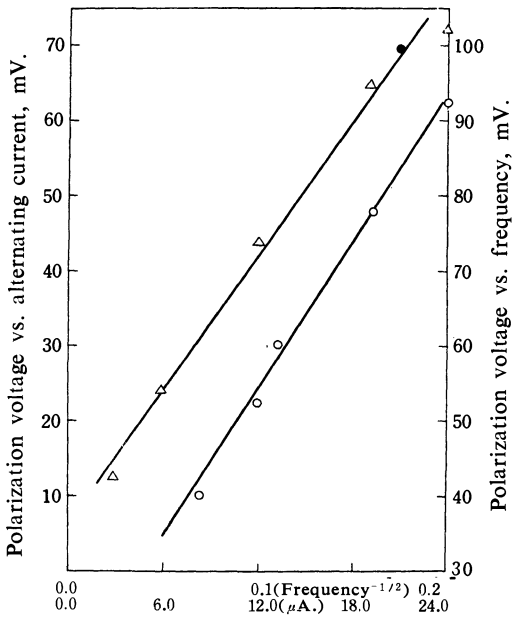

Fig. 4. A) Relation between polarization voltage and frequency (-○-).
B) Relation between polarization voltage and alternating current (-△-).

*3) Effect of Surface Area of Mercury Drop.* —The polarization voltage became smaller with the increase of the surface area of mercury drop as shown in Fig. 5. However, the area of the mercury electrode gave no effect on the experimental result. The pretreatment of the mercury electrode had also little effect on the shape of this titration curve and on the experimental results. Therefore, alternating current polarization titration has advantages in this point over the direct current polarization titration.

*4) Effect of Gelatine.* — In chelatometric titration of cadmium using potentiometry at a constant current and amperometry at a constant potential, the addition of gelatine was necessary[9] in order to suppress the kinetic current due to the dissociation of Cd-EDTA. Experimental results in the presence or the absence

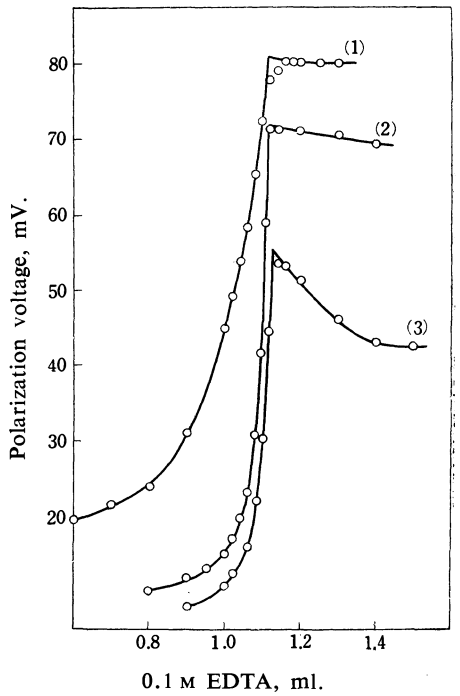

Fig. 5. Effect of surface area of mercury drop.
(1) surface area about 0.02 cm$^2$
(2) 〃 0.03 cm$^2$
(3) 〃 0.05 cm$^2$

of gelatine in this method are shown in Table I. Although experimental results are not reproducible in the absence of gelatine, it is clear that the reproducible and precise results are obtained in the presence of gelatine. Therefore, the addition of 1 ml. of 0.1% gelatine is indispensable in this titration.

TABLE I. EFFECT OF GELATINE ADDED

| Cd taken mg. | 0.1% Gelatine added ml. | Volume of $10^{-1}$M EDTA titrated ml. | Cd found mg. |
|---|---|---|---|
| 6.29 | 0 | $0.55_0$ | 6.18 |
| 6.29 | 0 | $0.53_5$ | 6.01 |
| 6.29 | 0 | $0.55_5$ | 6.18 |
| 6.29 | 0.2 | $0.55_5$ | 6.24 |
| 6.29 | 0.5 | $0.56_0$ | 6.28 |
| 6.29 | 1.0 | $0.56_0$ | 6.28 |
| 6.29 | 2.0 | $0.56_0$ | 6.28 |

*5) Effect of Wave Form.*—The Effect of wave form to this titration (sine wave or square wave) was examined. Although polarization voltage was greater in the case of using sine wave than square wave, it was recognized that the wave form gave little effect on the experimental results.

*6) Effect of Hg-EDTA Added.*—To determine the optimum amount of Hg-EDTA to be added,

9) N. Tanaka et al., *Japan Analyst (Bunseki Kagaku)*, 6, 86 (1957).

various volumes of the Hg-EDTA solution were added to a constant volume of cadmium nitrate solution. In this case, all other conditions were kept constant according to the procedure described above. The results are shown in Table II. It was found that the amount of the reagent did not affect the determination of cadmium provided that it ranged from 5 to 15 ml.

Table II. Effect of Hg-EDTA added

| Cd taken mg. | 0.05 M Hg-EDTA added ml. | Volume of $10^{-1}$ M EDTA titrated ml. | Cd found mg. |

## Discussion

Before the titration is initiated, some of the mercury(II) is displaced from its Hg-EDTA complex by the cadmium ion. The following substitution reaction occurs in the solution[10]

$$HgY^{2-} + Cd \text{ acetate} \rightarrow Hg \text{ acetate} + CdY^{2-}$$

In this case, complete substitution of the Hg-EDTA by the cadmium ion to be titrated is not necessary for successful titration. The end point of chelatometric titration of the cadmium ion in this procedure will be indicated by the change of polarization voltage based on the change of the mercuric ion concentration in the neighborhood of the end point. Accordingly, most metal ions will be titratid by this titration method using suitable solution conditions.

The principle on which alternating current polarization titration is based is the same as that of the direct current method. However, this is a more suitable method than the direct current polarization method in the point that the pretreatment of the mercury drop electrode is not necessary.

## Summary

Cadmium was titrated with the EDTA by the alternating current polarization titration with two hanging mercury electrodes and the factors which affect this titration were examined. As a result, it is clear that the end point is indicated by the change of the mercuric ion con centration in the neighborhood of equivalence point. Pretreatment of the mercury drop electrode is not necessary. By this method, cadmium of $10^{-2}$~$10^{-3}$ M were titrated with a relative error of 0.9%.

The author wishes to express his hearty thanks to Professor M. Ishibashi, Assistant Professor T. Fujinaga, University of Kyoto, and Assistant Professor H. Hayakawa, University of Kobe, for their encouragement throughout this investigation.

# *High Resolution Nuclear Magnetic Resonance Spectra of Ring Protons in Substituted Benzenes*

By Ichiro YAMAGUCHI and Naohiro HAYAKAWA

(Received February 16, 1960)

The electron distribution on the benzene ring has been considered to be a very interesting object by many organic chemists, especially with respect to the correlation with the reactivity of the molecule. An experiment of approach to this problem was carried out by Gutowsky and his coworkers[1]. They measured the fluorine nuclear magnetic resonance in a number of fluorobenzenes and investigated the effect of substituents on the fluorine resonance shift and found the correlations between the values of the Hammett $\sigma$ constant and of the resonance shift. Recently, Bothner-By and Glick[2] and also Corio and Dailey[3] observed the proton resonance spectra of benzene derivatives and discussed the electron densities on the *o*-, *m*- and *p*- protons. The patterns of the proton resonance spectra obtained by them are simple and not adequate for the precise examination of the electron distribution in the benzene derivative molecules. Patterns simpler than the expected ones are mainly due to the fact that the resonance frequency of the experiments was as low as 30 Mc.

Hence, we planned to investigate the proton resonance spectra of the benzene ring protons of a variety of benzene derivatives at 56.4 Mc. This paper reports the results of the analysis of their spectra, and the spectra of disubstituted benzenes are discussed with correlation to the substituents.

## Experimental

The Varian High Resolution NMR Spectrometer was operated at 56.4 Mc. The resolution of the apparatus was higher than $10^{-8}$ when the sample was spun.

The samples measured were of commercial guaranteed grade, and these were used without further purification. The spectra of the liquid samples were taken in pure liquid state. Most of the solid samples were dissolved in acetone to make saturated solutions, and the spectra were taken. The others were dissolved in ethanol or ether.

All of the NMR measurements were carried out at 20°C for the samples sealed in glass tubes with the outer diameter of 5 mm. The spectra were recorded by the Sanborn Recorder and the separations of the resonance peaks were measured on the recorded charts. The magnetic field was swept in both decreasing and increasing directions and the measurements were made by taking the average of the records of both directions of the sweep. The calibration of the sweep rate was made by recording the spectrum of the methylene group of ethanol and by reading the separation of the two highest peaks as 7.0 cps[4]. The sweep rate was about 1 cps/sec.

The chemical shift of the ring proton resonance referred to benzene ring proton was determined for several compounds by adding a small amount of benzene to the sample liquid as an internal standard. This method was found to be inadequate for the precise determination of the shift value, because it was noticed that an additive shift arose by the addition of benzene. Therefore the observed values of the shift referred to benzene, $\delta_B$, include an error of about $\pm 0.05$ p.p.m.

The experimental error over the entire measurements was about 3%. This arose mainly from the instability of the field sweeping of the spectrometer.

## Analysis of the Spectra

The systems of the ring protons of benzene derivatives are represented as in Table I, according to the notation proposed by Bernstein et al.[5]. In these systems, the spectra with simple structure may be analyzed by solving the equations of the Hamiltonian of the nuclear spin system and the assignment of the spectral lines can be made. The ratio $J/\nu_0\delta$, where $J$ and $\nu_0\delta$ are respectively the spin coupling constant and the chemical shift in cps between the two resonating nuclei, ranges from 0.2 to more than 1 in the case of benzene ring protons, and in some cases the chemical shift is very small compared with the values of the spin coupling constant. This should be noted when the analysis is made by any approximate method which neglects higher order perturbation terms or some coupling constants.

For each system of ring protons the appropriate approximation method was adopted to

analyze the spectrum. In the system of *o*-di-X benzene, the result of the analysis of *o*-dichlorobenzene, obtained by solving the secular equation by Pople et al.[6] was adopted. In *m*-di-X benzene the calculation based on the second order perturbation theory could be adopted for molecules where the ratios $J/\nu_0\delta$ in the molecule are comparatively small. In *p*-XY benzene, the secular equation of the system was solved by neglecting the spin couplings between the protons in *m*-position and in *p*-position to each other[7]. In each case of analysis, the coupling constants between protons are assumed to have positive sign.

## Results and Discussion

**Monosubstituted Benzene.** — The spectra of monosubstituted benzenes are generally very complicated ones and none of the spectral lines can be assigned completely by a simple glance of the structure of the spectra. The preliminary analysis of the spectrum of this system shows that the line groups of *o*-, *m*- and *p*-protons have many lines and each of these spreads over a wide range. In most cases, the *m*- and *p*-protons are overlapping each other as the result of the couplings of protons where the chemical shifts are very small. This chemical shift is, in certain cases, much smaller than the coupling constant between the protons concerned. In addition to this, the spreading range of the resonance lines of *p*-protons is generally wide compared to that of *m*-protons. This makes the assignment of the ring proton spectral lines of monosubstituted benzene very difficult

compared with the other symmetrical systems. Though the spectra of the system reported by Corio and Dailey[3] are relatively simple, the simple spectra are due to the low resonance frequency of their experiment. It seems that the values of chemical shift reported by them may have errors as the result of the fact that the spectral patterns are not well resolved. An example of the spectrum of monosubstituted benzene is shown in Fig. 1a. The range of the spreading of the spectral lines is also shown in Table II. The spreading electron-range of the spectrum is wider as the releasing or withdrawing power of the substituent is stronger.

**Disubstituted Benzene.**—*o-Di-X Benzene.*—An example of the spectrum of the system is is shown in Fig. 1b. The spectrum spreads in a rather narrow range showing a symmetrical pattern. The magnitudes of the chemical shift and the spin coupling constants are listed in Table III. Generally, the chemical shift between A and B groups of protons is very small and this shows that the difference of the resultant electronic effects of the substituent on the protons of A and B groups is very small.

The chemical shift of the ring proton resonance referred to the benzene ring proton may be considered to arise from two origins. One is variation in the ring current and the other that in the electronic shielding of the protons affected by the substituent. The ring current variation might cause the shift of the whole spectrum in either direction according to whether the ring current density increases or decreases. On the other hand, electronic effects of the substituent would affect the protons at different positions separately by its inductive and resonance effects and the scectral figure would vary according to the difference in the effect on different protons.

For all *o*-di-X benzenes observed, the spectral lines spread almost in similar magnitude while the variety in $\delta_B$ is rather remarkable. This result would lead to the conclusion that the ring current is considerably affected by the substituent. The same consideration will be held for the other proton systems.

*m-Di-X Benzene.*—The spectrum of this system is characterized by its three-group pattern as illustrated in Fig. 1c. The last column in Table IV shows the arrangement of spectral line groups in increasing field direction. The order of arrangement of these groups in the spectrum is understood mainly in terms of the electron-releasing and withdrawing power of the substituent X. The resonance position of the A proton is greatly influenced by the electronic nature of the substituent because the position of the proton is between two X's,

TABLE III. CHEMICAL SHIFT AND COUPLING CONSTANT IN *o*-di-X BENZENES

while the C proton is not so much influenced.

The analyzed results are tabulated in Table IV. The perturbation treatment of the second order could be applied to two compounds (*m*-dinitrobenzene and *m*-dichlorobenzene) well, but not to the others where the resonance positions of A and B protons are closely located. For these compounds, the analysis of the spectrum should be accomplished with the higher order approximation.

*p-Di-X Benzene.*—The spectra are single line as expected from the symmetry consideration of this system. The chemical shift referred to benzene is shown in Table V.

*p-XY Benzene.*—This system has two different substituents and the different electronic effect is given on the proton neighboring to each of them. In addition to this, the spectrum of this system is comparatively simple and can be analyzed easily Therefore, the investigation of the spectrum of this system is interesting to show the overlapping extent of the effects of both substituents on the ring. An example of the spectrum of this system is shown in Fig. 1d. This consists of two groups A and B, which correspond to the protons A and B in the molecule.

This system has been analyzed for several compounds with appropriate approximation by Richards and Schaefer[7]. The present spectra were analyzed according to their method. The values of the chemical shift and the coupling constant obtained are listed in Table VI, where the $J_{AB}$ is the coupling constant between A and B protons when the $J_{AB'}$ (coupling constant between A and B′ protons which one *p*-position to each other) is neglected.

Qualitatively, the shift between the two groups A and B is large when the electronic effects of the two substituents X and Y upon the ring protons are greatly different and vice versa. For example, $\delta_{AB}$ of *p*-nitroaniline is very large where the electronic nature of $NO_2$ and $NH_2$ group are greatly different to each other as is well known by the evidence of their effect on the substitution reaction of ring protons, whereas the one of bromochloro-benzene is very small as is expected.

*Other Systems.*—The spectral figures of the other systems are generally more complicated than the systems described above. *o*-XY- and *m*-XY-benzenes are of this sort. These systems have no symmetry, therefore their analyses are of course very cumbersome. These systems will not be dealt with further in this paper.

The values of the coupling constant between two protons on the benzene ring are approximately definite with respect to their mutual *o*-, *m*- or *p*-positions. The values deduced from the results of the analyses may be summarized as follows;

$J$ between two protons located at

| | |
|---|---|
| *o*-position mutually | 7∼9 cps |
| *m*-position mutually | 1∼3 cps |
| *p*-position mutually | 0∼1 cps |

The values indicated that the coupling is attenuated in proportion to the exponent of about −5 to the direct bond length between the two protons concerned. The values listed above

coincide well with the description which appeared in the book of Pople et al.[8]

The resonance position of a benzene ring proton is closely related to the relative location of the proton to the substituent on the benzene ring. The same evidence was discussed by Gutowsky et al.[1] with the fluorobenzene derivatives. They showed also that the shift values for the ring fluorine of polysubstituted fluorobenzenes may be calculated from the shift values of monosubstituted fluorobenzenes with the assumption of an additive law of shift. Their calculated results with this law coincide with the experimental values with deviations less than 10%. We applied the law to the samples investigated. The values for the disubstituted benzenes were calculated with the shift values of the monosubstituted benzenes reported by Corio and Dailey[3]. The results of the calculation showed that the shift values do not necessarily coincide well, but showed a close relation with the experimental values. The explanation of the shift values with the additive law may of course be oversimplified by neglecting to take into account all the interactions in the molecule, and further consideration of the results will be postponed until more experimental data with monosubstituted benzenes become available.

The resonance lines for the protons just adjacent to the methyl group on the ring generally show fine structure. This splitting is illustrated in Fig. 1d for the ring proton resonance of *p*-toluidine. Hoffman[9] reported that the ring proton resonance line of mesitylene showed broadening, and he assumed that this broadening arose from the coupling between the ring proton and the methyl protons by hyperconjugation mechanism. Although the observed fine structure reported here may be a similar one to the case of mesitylene, further experimental verification seems necessary for deciding the true origin of the splitting.

The present work is carried out with saturated acetone solutions in almost all cases, however; the solvent effect on the shift between ring protons appears to be noticeable. Thus the shift values may differ from one another among solutions with different concentrations. This intramolecular shift may be assumed to arise from the selective interaction between the proton located at the specific position on the ring and the solvent molecule. The nature of this interaction is at present unexplained.

## Summary

High resolution proton magnetic resonance spectra of a variety of mono- and di-substituted benzenes were observed at 56.4 Mc. The spectra of molecules with higher symmetry were analyzed, and the values of chemical shifts among the ring protons and those referred to benzene were obtained as well as spin coupling constants. The spectra were discussed with correlation to the substituents.

The authors wish to express their thanks to Professor S. Fujiwara for his encouragement and guidance of this work and also to Mr. H. Shimizu for his helpful discussions on this subject.

# *The Effect of Chain Branching and Molecular Weight of Polyethylene on its Glass Transition Temperature*

By Kōji TANAKA

(Received February 16, 1960)

In the previous paper[1] the effects of chain branching, mainly short chain branching, on such properties as the melting point, the crystallizing temperature and the premelting phenomenon were reported and discussed. In this paper the effect of chain branching on the glass transition temperature and the degree of cubic expansion above and below the glass transition temperature are described.

Regarding the glass transition temperature, a sort of second-order transition temperature, of polyethylene, a number of reports have been presented. Hunter and Oakes[2] showed from the measurement of linear expansion that there was a sign of transition occurring at about $-45°C$. Later Danusso et al.[3] reported from the volume expansion measurement that the second-order transition temperature of polyethylene existed arround $-20°C$ regardless of molecular weight, degree of chain branching or degree of crystallinity. According to the paper of Gubler and Kovacs[4] the cubic expansion coefficient changes between $-20$ and $-25°C$ for both a high-pressure and a Ziegler polyethylene. It has also been confirmed by some other methods that a transition occurs at about $-20°C$ or at a still lower temperature[5-10]. By considering the change of mechanical properties of polyethylene at about $-50°C$, reported by Carey et al.[11], and the brittle point of $-68°C$ reported by Boyer and Spencer[12], this second-order transition at arround $-20°C$ seems to be the glass transition, though the existence of another transition at the temperature below $-100°C$ was reported by Schmieder and Wolf[13], Oakes and Robinson[14] and Dannis[15]. As for the effect of the degree of chain branchig on the glass transition temperature, it may be inferred from the results reported hitherto that the degree of chain branching has no effect on the glass transition temperature. Such a conclusion, however, can not be reached so hastily, as only a few kinds of samples were used in each experiment.

The glass transition temperature is generally defined as the point at which the main chain in an amorphous region of a polymer acquires large scale mobility. It is therefore expected that short chain branching and the branch point of long chain branching, which are contained in the amorphous region, disturb the regularity of molecules and keep the molecules from arranging themselves in good order in proportion to the number of them, and consequently the molecular mobility of the amorphous region is affected not a little by them; that is, the more branches the amorphous region contains, the more easily it initiates the large scale molecular motion and as a result the glass transition of polyethylene having the higher degree of chain branching occurs at the lower temperature.

From this point of view, a series of measurements have been taken by using various polyethylenes. From the results obtained it appears that short chain branching has a large effect on the glass transition temperature, independent of the degree of crystallinity. Long chain branching scarcely exists in low-pressure polyethylene, and in high-pressure polyethylene only a few long chain branching are contained in comparison with short one. It is therefore considered that its effect is not noticeable, even if each branch point has some effect on the glass transition temperature.

## Samples

Samples used were Marlex 50-9, Ziegler polyethylene, and eight kinds of high-pressure polyethylenes with the different molecular parameters which were provided by courtesy of Dr. Hammer of E. I. du Pont de Nemours and Company. The molecular parameters are shown in Table I. Marlex 50-9 and Ziegler polyethylene were commercially available polymers made by Phillips Petroleum Company and Dow Chemical Company, respectively. As the molecular parameters for these two samples were not available, the degree of short chain branching was determined by the infra-red method according to Slowinski[16]. It was found to be 0.25 for Marlex 50-9 and 0.4 for Ziegler polyethylene.

TABLE I. THE MOLECULAR PARAMETERS FOR POLYETHYLENE SAMPLES

| Sample | Melt index | $M_n \times 10^{-3}$ | $N_c$* | $N_w$** |
|---|---|---|---|---|
| A*** | 0.2 | 34 | 1.6 | 20 |
| B | 2.1 | 32 | 1.6 | 18 |
| C | 2.1 | 21 | 2.2 | 27 |

## Experimental

Dilatometric measurements were at first taken in the temperature range from −40 to 150°C by using mercury as the confining liquid. However, it seemed to be undesirable to determine the glass transition point merely from the measurements in which mercury was used as the confining liquid, as the temperature range below the glass transition temperature was small. Therefore 99.5% ethanol being used as the confining liquid, measurements were carried out over the temperature range from room temperature to −70°C. In this measurement Bekkedahl's straight type dilatometer[17] was used and the preparation of the most highly crystallized sample was performed by following the way mentioned in the previous paper in the sufficiently evaluated glass tube in order to protect the sample from oxidation before it was enclosed in the dilatometer. A Dewar vessel containing toluene was used as a bath. The details about the experimental procedure were omitted in this paper, as they were described in the previous paper.

The glass transition temperature, $T_g$, was determined by extrapolation of two straight lines connected by a curved section, consisting of the volume-temperature curve of high polymer. As polyethylene is a semi-crystalline polymer and the difference between cubic expansion coefficients above and below $T_g$ is small, an error is apt to be made. In order to eliminate such an error $T_g$ was also determined from the discontinuity of the curve obtained by plotting the volume temperature derivatives, $\Delta V/\Delta t$, as a function of temperature as was done by Hoffmann and Weeks[18].

## Results and Discussion

The specific volume-temperature curves of the most highly crystallized polyethylenes ranging from above to below the glass transition temperature are shown in Fig. 1. The volume temperature derivatives are plotted as a function of temperature in Fig. 2. In these two figures only a few curves were shown to avoid confusion.

The average value of the glass transition temperature obtained for each sample is given in Table II. These values are plotted in Fig. 3 as a function of the degree of short chain branching. As is shown in the figure, the glass transition temperature lowered with the increasing amount of short chain branching

and there seems to be a linear relation between the glass transition temperature and the degree of short chain branching.

The degree of cubic expansion above and below the glass transition temperature, which are presented by the gradients of the straight lines above and below the temperature, are also listed in Table II. These values generally increased as the amount of short chain branching became larger and those above the glass transition point increased in a greater extent than did those below the point, which fact is probably because the large-scale segmental motion in the amorphous region is excited at the temperature above the glass transition point and the more the sample of polyethylene branched, the greater is the scale of the motion. As regards the degree of cubic expansion below the glass transition point there is a view by Price[19] and Danusso et al.[20]

* Degree of expansion below $T_g$.
** Degree of expansion above $T_g$.

that it is considered to be equal for all the polyethylene, but in this experiment the result as above was obtained, that is, the degree of cubic expansion below the glass transition point increased as a whole with the increase of the degree of short chain branching.

Since short chain branching affects the degree of crystallinity of polyethylene as was mentioned in the previous paper, it is expected that the lowering of the transition temperature by the increase of short chain branching shown in Fig. 3 is attributable to the decrease of the degree of crystallinity. However, glass transition temperatures of the quenched samples of these polyethylenes, which showed a low degree of crystallinity about 40% at 25°C, were found at nearly equal temperatures to those of crystallized samples. Therefore the lowering of the glass transition temperature is probably due to the direct effect of short chain branching itself and not to the decrease of the degree of crystallinity. According to the recent result of linear expansion measurements by Saito[21], a transition was found at around −32°C for a low-branched polyethylene and at about −45°C for a highly-branched polyethylene. The difference between these temperatures was almost equal to that found by the author, though each temperature was lower by about 10 degrees than that obtained here.

Considering the results mentioned above, short chain branching of polyethylene appears to affect the glass transition temperature independent of such factors as degree of crystallinity and molecular weight. Moreover, according to Gubler and Kovacs[4] the number of $CH_2$ groups constituting the main chain in amorphous regions of polyethylene thermally

19) F. P. Price, *J. Chem. Phys.*, **19**, 973 (1951).
20) F. Danusso, G. Moraglio and G. Natta, *Ind. Plastiques Mod. (Paris)*, **10**, 40 (1958).
21) S. Saito, private communication.

treated in the same way are almost equal regardless of its kind. Therefore the polyethylene having the higher degree of short chain branching will contain more branches in one amorphous region, provided that short chain branching is distributed equally in all the amorphous regions. It is considered that the shorter the branches which are contained in the amorphous regions equal in size, the smaller is the intermolecular interaction between the segments in those regions in the temperature range below the glass transition temperature, and as a result the Macro-Brownian motion in amorphous regions starts at the lower temperature, that is, the glass transition occurs at the lower temperature.

The relation between the glass transition temperature and degree of short chain branching in high pressure polyethylene shown in Fig. 3 is led to the following expression by using the method of least square,

$$T_g = -4.6N_c - 18.7$$

Marlex 50-9 and Ziegler polyethylene deviate somewhat from this expression. According to Willbourn[22] short chain branches of high-pressure polyethylene are ethyl and butyl branches and those of Marlex and Ziegler polyethylene are methyl, and methyl and ethyl, respectively. Therefore in the amorphous region of Marlex 50-9 and Ziegler polyethylene molecules possess a greater intermolecular interaction than expected from the case of high-pressure polyethylene.

As in short chain branching, so in long chain branching, it is expected that the increasing amount of long chain branching lowers the glass transition temperature. In this experiment, however, no appreciable result was produced. This is probably attributable to the very small amount of long chain branching, that is, the effect of long chain branching on the glass transition temperature is covered by the effect of short chain branching and of molecular weight. For example, as to the samples A, B and E which were equal in degree of short chain branching but different in degree of long chain branching, even the reverse phenomenon was observed that the sample having the larger amount of long chain branching showed a higher glass transition temperature. It is perhaps due to the effect of molecular weight of the sample as is discussed below.

It is generally said that the glass transition temperature is affected by molecular weight. Molecular weights of the samples used cover a wide range, so transition temperaturs are illustrated in Fig. 4 as a function of molecular weight. In the figure the glass transition temperature apparently rises with the increase of molecular weight, but short chain branching considerably affects the glass transition temperature as was stated above. A definite conclusion cannot be deduced without eliminating the effect of short chain branching. In order to remove this effect, the difference between the glass transition temperature obtained from practical measurement and that from the expression already presented is illustrated in Fig. 5 as a function of molecular weight. As is shown in the figure the rise of the glass transition temperature is only less than 2°C as molecular weights increase from 10,000 to 50,000. Therefore it will be evident that molecular weight has a smaller effect on this transition temperature compared with that of short chain branching. According to Fox and Flory[23], however, the glass transition temperature of atactic polystyrene rose by 14°C as the molecular weight increases from 10,000 to 50,000 as is shown in Fig. 5. This difference in polyethylene and polystyrene is probably due to the fact that the former is a crystalline polymer and the latter an amorphous polymer.

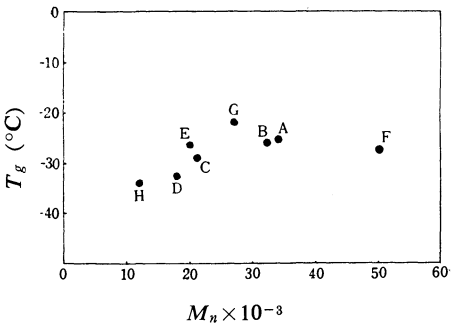

Fig. 4. $T_g$ as a function of molecular weight.

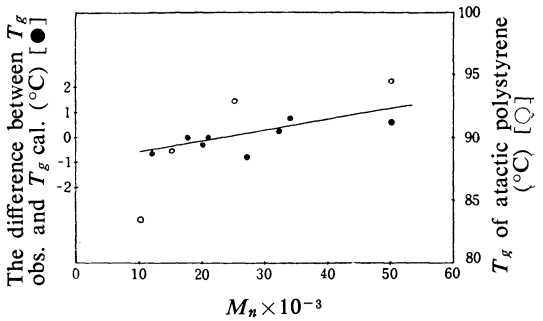

Fig. 5. The difference between $T_g$ from the practical measurement and that from the expression presented in this paper, and $T_g$ of atactic polystyrene are illustrated as a function of molecular weight.

22) A. H. Willbourn, *J. Polymer Sci.*, **34**, 569 (1959).

23) T. G. Fox, Jr. and P. J. Flory, *J. Appl. Phys.*, **21**, 581 (1950).

that is, this contains very large amorphous regions, whose size is greatly affected by molecular weight, while that includes alternately crystalline and amorphous regions. According to Gubler and Kovacs the size of the individual amorphous region in the samples thermally treated in the same way is almost equal regardless of the kind of polyethylene, as was mentioned already. From this point of view, it is considered that the effect of molecular weight on the glass transition temperature is essentially very small in polyethylene.

In addition it is reported by Smith[24] that polyethylene contains double bonds in it and most of them belong to the terminal of the main chain for Marlex and to the side chain for high-pressure polyethylene. But, as the amount of double bonds is very small, the effect on the glass transition temperature and degree of crystallinity will not be worth discussing in this paper.

## Summary

A series of measurements by volume dilatometry were performed in order to know whether short chain and long chain branchings, and molecular weight of polyethylene affected the glass transition temperature or not. The glass transition temperature, $T_g$, was obtained from the intersection of two straight lines of volume-temperature curve and from the discontinuity of the curve obtained by plotting the volume temperature derivatives as a function of temperature. $T_g$ lowered with the increasing amount of short chain branching and there seems to be a linear relationship between $T_g$ and the degree of short chain branching. No appreciable effect of long chain branching on $T_g$ was observed. $T_g$ rose apparently with the increase of molecular weight, but the true rise of $T_g$ was only less than 2°C as molecular weight increased from 10,000 to 50,000. The degree of cubic expansion above and below $T_g$ increased generally as the amount of short chain branching increased.

The author wishes to express his gratitude to Professor Masatami Takeda for his valuable suggestion and discussion, and his thanks to Dr. C. F. Hammer of E. I. du Pont de Nemours and Company for the gift of polyethylene samples. He is also indebted to Miss M. Yoshida for her assistance in experimental work.

# *On the Thermal Dissociation of Organic Compounds*[1]. *XIV. The Effects of the Solvents and of the Substituents on the Thermal Dissociation of Urethans in Amines*

By Teruaki MUKAIYAMA, Toyohiko AKIBA and Tamio ASAHI

(Received February 17, 1960)

In previous papers[2,3] of this series the kinetic studies of the dissociation of *N*-phenyl-alkyl carbamates in basic solvents were described. *N*-phenyl-alkyl carbamates dissociate in the presence of 10 molar excess of an amine at above 120°C; however, *N*-phenyl-phenyl carbamates dissociate instantly under the same condition.

In the case of *N*-phenyl-phenyl carbamates, the addition reaction of isocyanates with phenols to form urethans, which is the reversal of the dissociations, reaction do not proceed under the experimental conditions. Therefore, the dissociation proceeds to essentially 100% completion in the presence of an equimolar amount of an amine.

$$RHNCOOR \rightleftharpoons R\text{-}N{=}C{=}O + HO\text{-}R \quad (1)$$

$$R\text{-}N{=}C{=}O + HNR'R' \rightleftharpoons RHNCONR'R' \quad (2)$$

As described in the previous papers, reaction 1 is the rate-determining step in the above

sequence and the rate constants for the dissociation of urethans can be measured by determining the amount of the remaining amine.

The kinetic order of the dissociation of urethans was studied by the effect of change of initial concentration of both urethan and amine and it was shown that the dissociation is of the first order with respect to urethan and to amine respectively.

In order to study the effects of amines and solvents on the rate of dissociation of urethans, eight amines such as di-*n*-butyl amine and benzyl amine and ten inert solvents such as nitrobenzene and cumene were used. It was observed that the rates of the dissociation increased as the base strength of amines increased and the rates increased also as the dielectric properties of solvents increased.

The rates of dissociation of *N*-phenyl-phenyl carbamates substituted with methyl, methoxyl, chloro and nitro groups in the ortho, meta and para positions were determined to clarify the effects of substituents on the dissociation of urethans in amines. The results show that meta and para substituted *N*-phenyl-tolyl carbamates, N-phenyl-anisyl carbamates and unsubstituted urethans follow the Hammett equation with a positive $\rho$ value, but *N*-phenyl-chlorophenyl carbamates and *N*-phenyl-nitrophenyl carbamates dissociate rapidly and deviate from the linear relationship of the Hammett equation. Except in the case of the methyl derivative, ortho-substituted urethans dissociate faster than the corresponding meta and para substituted urethans; this may be attributed to steric effects.

It can be concluded that, in amine, the dissociation proceeds via the concerted mechanism involving both urethan and amine.

## Experimental

**Procedure.** — The experimental procedure was essentially that used in the earlier investigation[2,3]. The amount of the amine remaining was determined by titrating with 0.025 N hydrochloric acid, using Bromocresol Green as indicator.

**Materials.** — N-phenyl-phenly carbamates were prepared from phenyl isocyanate and the purified corresponding phenols according to the procedure of Leuckart[4]. Amines and solvents were purified by distillation. The boiling points for these substances are listed in Table I and II.

| | | *p*-Xylene | 137.5 |

## Results

The second order rate constant $k_2$ was calculated by Eq. 3

$$k_2 = 1/t \cdot x/a\ (a-x) \qquad (3)$$

where $t$, the time in second; $x$, the amount of reacted amine at time $t$; $a$, the initial concentration of both urethan and amine.

The values of the second order coefficient $k_2$ remained constant until the 60% of the dissociation with a tendency to drift upward in the later stage of the dissociation. It can be considered that the upward drift of $k_2$ might result from weak catalysis of the dissociation by urea or phenol produced. This was confirmed by the demonstration of the catalytic effect of added urea. The results are shown in Table III and Fig. 1. The addition of phenol to the reaction showed no effect on the rate of dissociation.

The kinetic order of the dissociation of urethans in amines were examined further by changing the initial concentration of both the urethan and the amine. The second order rate constants are nearly constant when the initial concentration of the reactants are changed from 1/2 : 1/2 to 2 : 2. When the molar ratio of the initial concentration of urethan to amine are changed from 1 : 1 to 1 : 10, the rates of dissociation increase as the amine concentration increases. When the molar ratio of urethan to amine is less than 2.5, the rate did not conform to the second order kinetics, but a first order plot fits the data well. The $k_2$ values calculated by dividing the $k_1$ value thus obtained by the concentration of the amine are nearly equal as shown in Table IV.

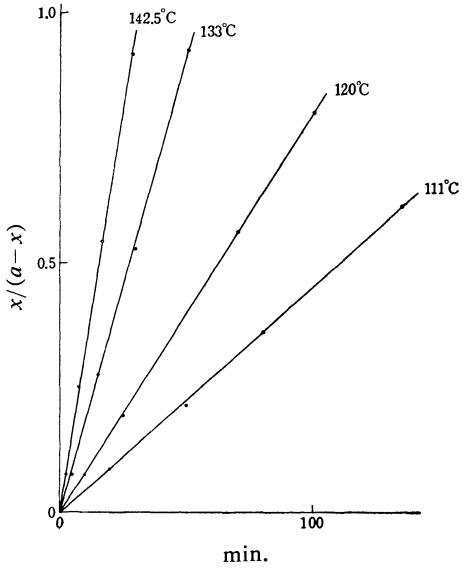

Fig. 2. Second-order plots of the thermal dissociation of N-phenyl-phenyl carbamate in dibenzyl amine and nitrobenzene.

The second order rate constants of various substituted urethans in amines and various inert solvents were obtained. As a typical run, the dissociation of *N*-phenyl-phenyl carbamate in dibenzyl amine and nitrobenzene at temperature betewen 111~142.5°C is shown in Fig. 2. The rate constants of the dissociation of *N*-phenyl-phenyl carbamates in amines were calculated by the method of least squares and are shown in Tables V—VII.

The plot of the logarithm of the rate constants vs. reciprocal absolute temperature gave satisfactory straight lines from which the activation energies and the entropies of activation were calculated by the method of least squares (Tables V—VII).

## Discussion

The rate constants of the dissociation of urethans in various amines increase in the following order,

di-*n*-butyl ≫ lauryl > *n*-hexyl,

cyclohexyl > 2-ethylhexyl,

di-isobutyl > benzyl ≫ dibenzyl.

As noted in the above sequence, urethans dissociate rapidly in di-*n*-butyl amine ($K_b=2.05\times10^3$, at 25°C), moderately in cyclohexyl amine ($K_b=4.39\times10^4$, at 25°C) and slowly in benzyl amine ($K_b=2.4\times10^5$, at 25°C).

The activation energies of the dissociation of urethans in weak bases such as benzyl amine and dibenzyl amine are greater than those in strong bases such as di-*n*-butyl amine.

The results show that, in amines the rates of dissociation increase as the basicities of the amines increase and it can be concluded that the dissociation proceeds via the base catalyzed mechanism in which the process of deprotonation of urethans by a base is a predominant factor.

The rates of dissociation are also affected by the nature of inert solvents. The rate constant of dissociation in a polar solvent such as nitrobenzene is much larger than that in a non-polar solvent such as tetralin and *m*-xylene. As shown in the following sequence, the rates increase as the dielectric properties of solvent increase.

Nitrobenzene ≫ anisole, phenetole >

tetralin, decalin, *o*-xylene, cumene,

triethylbenzene, *m*-xylene, cymene

The results suggest an important solvent interaction in the dissociation process which may stabilize the forming phenoxyl ion and facilitate the cleavage of the carbon-oxygen bond in the activated state.

The results of the rate measurement given in Table VII show that for substitution in the *meta* and *para* position, the greater the electron-attracting power of the substituents, the greater

| | 110 | 7.71 ±0.07 | | |

are the rate constants and the lower the activation energy; the greater the electron-donating power of the substituents, the lower are the rate constants and the greater the activation energy. The logarithm of the $k$ of the dissociation of methyl and methoxy substituted urethans and unsubstituted urethan is a linear function of the substituent constants given by Hammett and the gradient of the plot gave values for the reaction constant, $\rho$, of 1.72 in di-*n*-butyl amine and of 1.90 in benzyl amine, respectively. *N*-phenyl-chlorophenyl carbamate and *N*-phenyl-nitrophenyl carbamate dissociate very rapidly and deviate from the linear relationship of the Hammett equation.

The rates of dissociation of various substituted urethans in di-*n*-butyl amine are greater than those in benzyl amine and the activation energies and the entropies of activation in di-*n*-butyl amine are lower than those in benzyl amine. As mentioned above, the rates of dissociation depend on the basic strength of amine and the results might be attributed to the basicity of the amines which participate in the deprotonation of urethans in the dissociation process.

The higher rates with lower activation energies for the dissociation of urethans with electron-attracting substituents such as chloro and nitro groups may be ascribed to the stability of the phenoxyl ion dissociated. The phenoxyl ion with electron-attracting groups is

more stable than that with electron-donating groups and this ion stabilizing effect may be the chemical driving force in the following dissociation mechanism.

The above one step mechanism involving urethan and amine can be confirmed by the rate dependency on both factors. In the strong bases, such as aliphatic amines, the dissociation proceeds by bimolecular concerted mechanism and not by termolecular mechanism as proposed in the previous reports[2,3].

## Summary

*N*-phenyl-phenyl carbamates dissociate into their component compounds very readily in the presence of a base. Unlike the case of *N*-phenyl-alkyl carbamates, *N*-phenyl-phenyl carbamates dissociate in the presence of an equimolar amount of an amine at lower temperature. The kinetics of the dissociation of *N*-phenyl-phenyl carbamates were of the first order with respect to carbamates and of the first order with respect to base.

The rate constants, the activation energies and the entropies of activation of the dissociation of *N*-phenyl-phenyl carbamates in various amines and solvents were measured throughout temperature interval 0～140°C.

The effects of amines, solvents and substituents on the dissociation of urethans in amines were studied.

The authors wish to express their hearty thanks to Professor Toshio Hoshino for his encouragement throughout the course of this experiment.

# *Rates of Solvolysis of 2-Hydroxycyclohexyl Brosylates*

By Nobuo MORI

(Received February 10, 1960)

In the present paper there will be reported the preparation and the solvolysis rates of *cis*- and *trans*-2-hydroxycyclohexyl brosylates. The *cis* isomer used for solvolysis is a new substance and could not be prepared by the usual method[1]. The *cis* isomer has now been obtained in a good yield by the reaction of *cis*-cyclohexane-1, 2-diol with 2 to 3 equivalent quantities of *p*-bromobenzenesulfonyl chloride in dry pyridine.

The solvolysis rates were measured at 99.8°C in ethanol (98.5% by weight) and also in acetic acid containing a slight excess of acetic anhydride. In all cases, the observed rates, especially in ethanol, were of the first order and the error of the measurements was always lower than 5%. In acetolysis, one free hydroxyl group in each of the isomers will react with acetic acid to form 2-acetoxycyclohexyl brosylate, especially in the presence of *p*-bromobenzenesulfonic acid liberated during the solvolysis. Therefore, a calculated first order rate constant in a run in acetic acid will change continuously and gradually. However, the rates were nearly of the first order. Table I lists the data for a run with *trans*-2-hydroxycyclohexyl brosylate in acetic acid. It is seen that in the run the first order rate constant is almost constant. The slight increase of the rate the during run is probably attributed to the accompanying acetolysis of the corresponding acetoxy cyclohexyl brosylate formed.

TABLE I. ACETOLYSIS OF *trans*-2-HYDROXYCYCLOHEXYL BROSYLATE IN ACETIC ACID AT 99.8°C

| Time (min.) | Brosylate (mol./l.) | $k_1 \times 10^2$ ($min^{-1}$) |
|---|---|---|
| 0.0 | $6.16 \times 10^{-3}$ | |
| 30 | 3.36 | 2.02 |
| 50 | 2.20 | 2.06 |
| 70 | 1.49 | 2.02 |
| 90 | 0.91 | 2.12 |
| 110 | 0.051 | 2.26 |
| 150 | 0.016 | 2.44 |
| | Mean | 2.15 |

The rate constants and the relative rates for the isomeric brosylates are summarized in Table II.

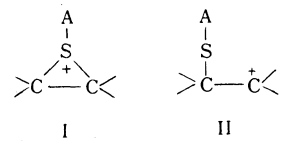

TABLE II. RATE CONSTANTS AND RELATIVE RATES FOR BROSYLATES AT 99.8°C

| 2-Substituent | $k_1 \times 10^2$, $min^{-1}$ EtOH | AcOH | $k_{cis}/k_{trans}$ EtOH | AcOH |

| *trans*-OH | 8.5 | 2.15 | | |
| *cis*-OAc | | 0.0058* | | |
| *trans*-OAc | | 3.1* | | |
| H | | ca. 11** | | |

* From data in Ref. 1

** Calculated from data at lower temperatures in Ref. 1

Generally, in solvolysis of 2-functionally substituted cyclohexyl brosylates and tosylates, the reaction rate of the *trans*-forms is larger than that of the *cis*-form. For example, the relative rates of acetolysis (at 75°C) of 2-acetoxycyclohexyl *p*-brosylates are in the following sequence[1]: unsubstituted(1.0) > *trans* (0.3) ≪ *cis*($1.31 \times 10^{-4}$). In those cases, with the *trans*-group, the reaction proceeds substantially by way of cyclic ion I, and with the *cis*-group, probably carbonium ion II.

I II

However, unlike those compounds, the reactivity of *cis*-2-hydroxycyclohexyl brosylate is slightly greater than that of the *trans*-isomer. Further, the rate constants for the brosylates are in the same order as that for unsubstituted cyclohexyl *p*-brosylate (see Table II). The slightly higher reactivity of the *cis*-isomer and the very small difference in reactivity between the *cis*- and *trans*-isomers can not be explained on the basis of the participation of hydroxyl group alone. The high reactivity of the isomers is probably due to the participation of the hydrogen atom in β-position similar to unsubstituted cyclohexyl brosylate, rather than due to that of hydroxyl group. The fact that the reactivity of the *cis*-isomer is higher than that of the *trans*-isomer is mainly due to steric acceleration based on 1*a*, 3*a*-interaction (or B-strain). Those facts are in good agreement

1) S. Winstein, E. Grundwald and L. L. Ingraham, *J. Am. Chem. Soc.*, **70**, 821 (1948).

with the behavior in solvolysis of 2-*tert*.-butylcyclohexyl *p*-tosylate[2].

## Experimental

**Samples and Solvents. *cis*-2-Hydroxycyclohexyl *p*-Brosylate.**—A solution of 0.5g. of *cis*-cyclohexane-1,2-diol (m. p. 97°C., prepared from cyclohexene in *tert*.-butanol with $OsO_4$[3]) in 2 cc. of dry pyridine was treated with 2.5 g. of *p*-bromobenzenesulfonyl chloride at 5 to 10°C. After 30 to 40 min. the mixture was diluted with cold 6N HCl and the oily product precipitated was triturated with dil. HCl repeatedly to solidify. After recrystallization from benzene and ligroin (b. p. 75~120°C), 0.7 g. of the *cis*-brosylate was obtained as brittle needles, m. p. 110.6°C.

Found: C, 42.93; H, 4.80. Calcd. for $C_{12}H_{15}O_4SBr$: C, 42.99; H, 4.51%.

***trans*-2-Hydroxycyclohexyl *p*-Brosylate** was obtained with a good yield from *trans*-cyclohexane-1,2-diol (m. p. 102~104°C., prepared from cyclohexene and hydrogen peroxide in formic acid[4]) in an analogous way to the *cis*-isomer. After recrystallization from benzene and ligroin, the *trans*-brosylate was obtained as needles, m. p. 108°C (reported 106.9~108.8°C[1]).

**Ethanol** (98.5% by weight).—Commercial reagent grade absolute ethanol was fractionally distilled.

**Acetic Acid.**—Reagent grade glacial acetic acid was crystallized twice by the freezing method, refluxed with 2% by weight of acetic anhydride and 1% by weight of anhydrous sodium acetate for 3 hr., and distilled.

**Procedure for Rate Measurements**[5].—The sample was weighed out and made up to volume in the solvent at 15~20°C. About 6~7 cc. portions were sealed in tubes and immersed in vapor over boiling water (99.8°C). Time was counted from immersion of the tube to its removal and quenching in ice-water. After being cooled the tube was allowed to come to room temperature and then opened, a 5 cc. aliquot was pippetted out and titrated with standard base from a 2 cc. microburet. Concentrations of brosylates (all given at room temperature) were in the range from 0.02 to 0.07 mol./1. and titrations in acetic acid were carried out with a 0.05 N standard solution of AcONa in acetic acid with Bromophenol Blue as indicator, and in ethanol, a 0.05 N standard aquous solution of NaOH was used for titration with phenolphthalein as indicator. Rate constants were calculated from the formula

$$k_1 = 1/t \cdot \ln a/(a-x)$$

in which $a$ was the initial concentration of brosylate and $x$ was the concentration of sulfonic acid at time $t$.

The author expresses his sincere thanks to Professor Y. Tsuzuki for his advice and to Mr. M. Watanabe who prepared the diols used as starting materials.

# SHORT COMMUNICATIONS

## *Reaction of* DL-*Threonine with Recoil Tritium Atoms*

By Yoshishige SATO, Teruhiko MESHI and Tadao TAKAHASHI

(Received April 28, 1960)

Using recoil tritium atoms from the $^{6}Li(n, \alpha)$ $^{3}H$ reaction, the studies on preparation of tritium labeled organic compounds have been carried out by Wolfgang[1], Rowland[2,3] and other investigators. In 1959, Kay, Malson and Rowland[4] investigated recoil tritium reaction with L-alanine having asymmetric carbon atom. They described that the tritium activity which is found on the $\alpha$-carbon is, within error, all in the L(+) form—the substitution reaction proceeds with retention of configuration, and no racemization or inversion occurs. This result is in accord with the essential absence of labeled galactose in irradiated crystalline glucose[5]. We have carried out the same experiments using DL-threonine and found the isomer (allo form) of it. The procedure is as follows.

A mixture of 2 g. DL-threonine and 1 g. lithium carbonate was irradiated with thermal neutron for 17 hr. at flux $2.5 \times 10^{11}$ n/cm$^2$ sec. After irradiation the mixture was somewhat brownish. It was dissolved in water. To the aqueous solution was added basic copper carbonate. After filtering off the unchanged basic copper carbonate, the filtrate was concentrated in vacuo. Alcohol was added and thus crystals of amino acid copper salt were obtained. This amino acid copper salt was dissolved in water and to the solution an aqueous solution of hydrogen sulfide was added until the blue color disappeared. The precipitated cupric sulfide was removed by filtration, and the filtrate was concentrated. By the addition of alcohol to the concentrated solution, white crystals were obtained with yield of 800 mg. (sp. act. 0.113 $\mu$c/mg.).

Paper chromatography of the crystal using *n* - butanol - acetone - concentrated ammonium hydroxide-water (50 : 6.3 : 6.2 : 37.5, upper phase) as developing solvent showed three spots on spraying with ninhydrine. $R_f$ values of three spots were identical with those obtained by pure DL-threonine (0.24), allo-threonine (0.17) and glycine (0.05), respectively. The product (120 $\mu$g.) was employed as sample of paper chromatography, and DL-threonine, allo-threonine and glycine were obtained in the amounts and with activity values as shown in Table I.

TABLE I. SPECIFIC ACTIVITY OF VARIOUS AMINO ACIDS SEPARATED FROM IRRADIATED DL-THREONINE

| | Activity (cpm) | Amount ($\mu$g.)* | Sp. act. $\mu$c/mg. |
|---|---|---|---|
| DL-Threonine | 961 | 65 | 0.082 |
| allo-Threonine | 138 | 7 | 0.108 |
| Glycine | 80 | 40 | 0.011 |

* Paper chromatographic yield from 120 $\mu$g. of the irradiated product.
** Approximate calculation.

In order to determine whether or not the inversion occurs at neutron irradiation, the blank test of the chemical purification described above was carried out, but allo-threonine was not detected. Under the consideration that DL-threonine is heated in the atomic reactor, the mixture of DL-threonine and lithium carbonate was heated at about 70°C for 17 hr. in an electric oven. However, in this experiment, allo-threonine could not be discovered.

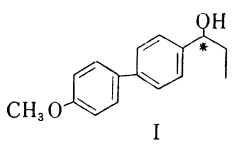
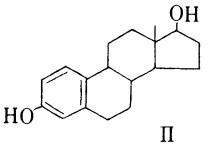
# *Estrogenic Biphenyls. IX*[1]. *Optical Resolution and Estrogenic Activity of 4'-(1-Hydroxypropyl)-4-methoxybiphenyl*

By Takeo SATO, Ken-ichi SASAMORI and Michinori ŌKI*



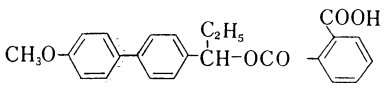
(Received July 5, 1960)

As reported in the preceding paper of this series[1], (4'-1-hydroxypropyl)-4-methoxybiphenyl (I) was moderately estrogenic when injected subcutaneously to ovariectomized mice. Since the location of the hydroxyl group attached to the asymmetric carbon atom in compound I corresponds to that of $C_{17}$-OH of estradiol (II) when the former is regarded as an aromatized BD-ring-lacking model of the latter, it has become of particular interest to examine the estrogenic activity of optically active form of compound I in comparison with the activities of epimeric estradiols, of which 17-$\beta$ isomer represents more active form, being about 40 times more active than 17-$\alpha$ isomer.



* Present address: Department of Chemistry, Faculty of Science, The University of Tokyo, Hongo, Tokyo.

1) Part VIII: T. Sato, This Bulletin, 33, 5 (1960).



(±)-4′-(1-Hydroxypropyl)-4-methoxybiphenyl (I)[1] was treated with phthalic anhydride in pyridine to produce (±)-4′-(1-hydroxypropyl)-4-methoxybiphenyl hydrogen phthalate (III), m. p. 164~165°C (Found: C, 76.64; H, 5.50. Calcd. for $C_{24}H_{21}O_5$: C, 76.58; H, 5.44%). It was converted into strychnine salt, which afforded a well crystallized optically active salt, m. p. 187~188.5°C (Found: N, 3.86. Calcd. for $C_{45}H_{44}N_2O_7$: N, 3.86%) with $[\alpha]_D^{18}$ −69.0° (*C*=2, 95% ethanol) through several recrystallization from ethanol. Combined mother liquors contained an oil which resisted attempts to induce crystallization.

I

II

III

The crystalline strychnine salt was treated with dilute hydrochloric acid to produce (+)-III, m. p. 149~153°C (Found: C, 76.10; H, 5.45. Calcd. for $C_{24}H_{21}O_5$: C, 76.58; H, 5.44%) having $[\alpha]_D^{17}$ +24.9° (*C*=2, 95% ethanol). Levorotatory alcohol (−)-I, m. p. 99~101.5°C (Found: C, 79.42; H, 7.65. Calcd. for $C_{16}H_{18}O_2$: C, 79.31; H, 7.49%) with $[\alpha]_D^{14}$ −23.7° (*C*=2, 95% ethanol) was thus produced by the alkaline hydrolysis of (+)-III.

An attempt to obtain another alcohol with the opposite sign of rotation through cinchonine salt of the hydrogen phthalate III, m. p. 153~155.5°C, obtained by the hydrolysis of the oily strychnine salt mentioned above, failed owing to the unfavorable crystallizability of the salt.

Compound (−)-I, which was found to be active only in 20% of the test animals (ovariectomized mice) at the does of 200 $\gamma$, had weaker estrogenic activity than (±)-I as the latter was active in 80% of the animals at the same level[1]. Although the reason why dextro- and levorotatory 3,4-bis-(*p*-hydroxyphenyl)-hexanes show different estrogenic potencies[2] is still obsure, the present finding which suggests that the levorotatory isomer is the poorer estrogen may be attributed to the absolute configuration about the carbon atom which carries the hydroxyl group.

# *Absorption Spectra of Methylene Blue Adsorbed on Homoionic Bentonites Suspended in Water*

By Choei SATO

(Received June 18, 1960)

The changes of the spectra of dyes added to some colloidal solutions are well-known as metachromasy. When some powdered materials usually used as adsorbents are suspended in water and dye solutions are added to them, color changes of the dye are also frequently observed if the dyes have the possibility ready to be adsorbed by those materials. In order to investigate if any relations exist between the trend of color changes of the dyes adsorbed and the surface structures of powdered materials used, the experiments have been carried out by using some kinds of clay minerals and silica gel, etc.[1] An interesting phenomenon has been observed in montmorillonite-methylene blue system; that is, the spectrum of the dye adsorbed on montmorillonite changes gradually with lapse of time after mixing of them. Furthermore this color change is influenced remarkably according to the kinds of added cation[2]. In order to clarify this phenomenon more thoroughly, the absorption

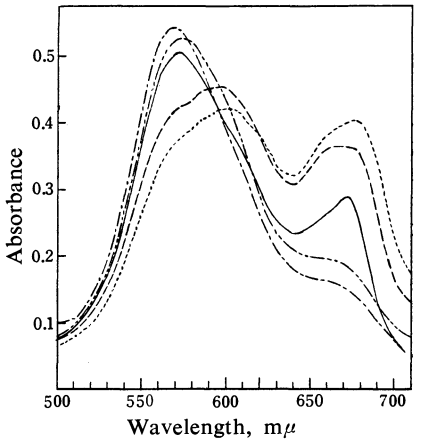

Fig. 1. Absorption spectra of methylene blue adsorbed on homoionic bentonites, after an hour from mixing.

—— Na-; -·-·- Ca-; -··- H-; ---- K-; ------ $NH_4$-bentonite

1) C. Sato, "Advances in Clay Science" Vol. 2, Edited by the Clay Research Group of Japan, Gihodo, Tokyo (1960), p. 69.

2) C. Sato, ibid. Vol., 3, in press; N. E. Vedeneeva, *Chem. Abstr.*, **49**, 4405$^b$ (1955).

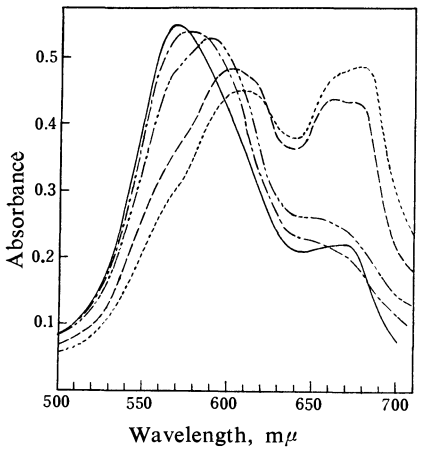

Fig. 2. Absorption spectra of methylene blue adsorbed on homoionic bentonites, after 2 days from mixing.

—— Na-; -·-·- Ca-; -·-· H-; ---- K-; ------ $NH_4$-bentonite

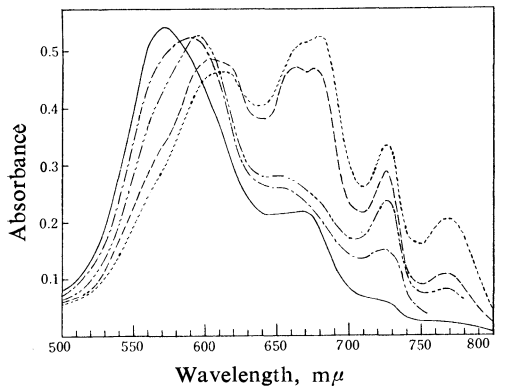

Fig. 3. Absorption spectra of methylene blue adsorbed on homoionic bentonites, after 7 days from mixing.

—— Na-; -·-·- Ca-; -·-· H-; ---- K-; ------ $NH_4$-bentonite

spectra of methylene blue adsorbed on homoionic bentonites suspended in water and having exchangeable cations of hydrogen, sodium, potassium, ammonium and calcium, have been observed.

Homoionic bentonite suspensions were prepared according to the method of Slabaugh, etc.[3] In each run 10 ml. of this suspension (0.13%) was divided into two equivalent parts, to one of which was added 0.5 ml. of the dye solution of a definite concentration, $1.74 \times 10^{-4}$ mol./l., and to the other was added the equivalent amount of distilled water. Then the absorption spectrum of the former was measured with reference to the latter with a spectrophotometer, after about an hour from the addition of dye. Furthermore, the change of spectrum of the above system with longer lapse of time was also examined. The results obtained are indicated in Figs. 1, 2 and 3.

As seen in the figures, in potassium and ammonium bentonites, the band at 570 mμ decreases its intensity remarkably, and the broad bands at 600~620 mμ and 660~680 mμ, especially the latter, increase their absorbance markedly, with lapse of time. The bands at 725 mμ and 770 mμ become also apparent gradually. But in hydrogen and calcium bentonites the above change appears considerably slowly and in sodium one any change is scarcely observed in the spectrum which shows a strong band at 570 mμ and a weak one at 670 mμ. According to the view reported in literature[4] for the interpretation of absorption spectrum of methylene blue dissolved in water, it may be presumed that in ammonium and potassium clays a greater part of dye adsorbed initially in associated form on the outer surface of clay particle migrates easily to the firm binding of the unassociated dye ion on the interlayer surface, but in sodium, calcium and hydrogen clays, especially in sodium type, this migration is impeded. It is also assumed that these differences by the kinds of exchangeable cations may result from the correlation between the arrangement of water molecules adsorbed on interlayer surface and surrounding the hydrated cation, and the size of methylene blue ion. But any quantitative interpretation has not been attempted yet. The interpretation of appearance of the bands at 725 and 770 mμ has also been left unsolved.

## *Synthesen von N-(4-Pyridyl)glycine*

Von Masaki OHTA und Mitsuo MASAKI

(Eingegangen am 6. Juli, 1960)

Bei der Umsetzung von 3-Aminopyridin und 2-Aminopyridin mit Bisulfitverbindungen von Aldehyden und Alkalicyanid wurden die entsprechenden Glycine, *N*-(3-Pyridyl)glycine[1] und *N*-(2-Pyridyl)glycine[2] erhalten.

Weiter durch diesen Methode haben wir aus 4-Aminopyridin *N*-(4-Pyridyl)glycin und seine Derivate erhalten können.

Bei der Einwirkung von Bisulfitverbindung von Formaldehyd und Kaliumcyanid auf 4-Aminopyridin erhält man ein rotes Öl, das 4-Pyridylglycinnitril zu sein schient und beim Kochen mit Salzsäure *N*-(4-Pyridyl)glycin ergibt. Das letztere wird durch Einwirkung von Natriumnitrit in *N*-nitroso-*N*-(4-Pyridyl) glycin umgewandelt. Um 3-(4-Pyridyl)-sydnon darzustellen, versuchten wir Cyclisierung-Reaktion von der Nitrosoverbindung.

Wenn man die Nitrosoverbindung in Essigsäureanhydrid erwarmt, so erhält man farblose Nadeln von Schmp. 144~145°C, die aber nicht Sydnon, $C_7H_5O_2N_3$, sind. Sondern das Produkt zeigt sich durch Elementaranalyse eine Bruttoformel, $C_{10}H_{13}O_2N_3$, dessen Konstitution wir noch jetzt untersuchen.

In ähnlicher Weise reagiert 4-Aminopyridin mit Bisulfitverbindung von Benzaldehyd und Kaliumcyanid, und ergibt ein rotes Öl, woraus *N*-(4-Pyridyl)-phenylglycine durch Kochen mit Salzsäure dargestellt werden kann.

### Beschreibung der Versuche

**Salzsaures *N*-(4-Pyridyl)glycin.** — Man versetzt 4 g von 37 proz. Formalin mit einer Lösung von 5.2 g Natriumbisulfit in 10 ccm Wasser, erhitzt 0.5 Std auf dem Wasserbad und darauf versetzt mit 4.7 g 4-Aminopyridin. Nach 1.5 std. Erhitzen und Umrühren setzt man dazu 3.5 g Kaliumcyanid in wenigem Wasser zu. Das Gemisch wird unter mechanischem Rühren 2 Std auf dem Wasserbad erhitzt, noch 1 Std bei Raumtemperatur umrührt und dann unter vermindertem Druck eingedampft. Der Rückstand wird mit Äthanol ausgezogen, nach dem Abdampfen des Äthanol ergibt die Lösung ein rotes Öl. Man löst das Öl in 30 ccm von 1 : 1 HCl, erhitzt auf dem Wasserbad und nach 3 std. Erhitzen läßt bei Raumtemperatur stehen, bald scheiden sich 2.8 g Nadeln ab. Aus die Mutterlauge erhält man noch 1.6 g Salzsäuresalz. Farblose Nädelchen von Schmp. 255~256°C (aus Wasser).

$C_7H_8O_2N_2 \cdot HCl$

***N*-Nitroso-*N*-(4-pyridyl)glycin.** — Man löst 3.7 g salzsaures *N*-(4-Pyridyl)glycin in 40 ccm Wasser, fügt langsam 1.6 g Natriumnitrit unter Eiskühlung und Umrühren hinzu und läßt im Eisschrank stehen. Nach 30 std. Stehen wird der ausgefallene farblose Niederschlag abfiltriert. Ausb. 3 g. Farblose Nädelchen vom Schmp. 202°C (aus Wasser) zeigen Liebermannsche Reaktion.

$C_7H_7O_3N_3$

Ber. C 46.41 H 3.90 N 23.20
Gef. C 46.56 H 4.14 N 23.22

***N*-(4-Pyridyl)phenylglycin.**—Zur Lösung von 10.4 g Natriumbisulfit in 40 ccm Wasser gibt man 10.6 g Benzaldehyd, erhitzt 1 Std auf dem Wasserbad und dann fügt 9.4 g 4-Aminopyridin hinzu. Nach 2 std. Erhitzen setzt man dazu 7 g Kaliumcyanid gelöst in 20 ccm Wasser zu und rührt 2 Std bei Raumtemperatur und dann 0.5 Std auf siedendem Wasserbad. Das abgeschiedene gelbrote Öl wird mit Chloroform ausgeschüttelt und mit Natriumsulfat getrocknet. Das nach dem Abdampfen des Chloroforms zurückbleibende rote Öl löst man in 70 ccm von 1 : 1 HCl, erhitzt 4 Std auf dem Wasserbad und dann läßt die Lösung bei Raumtemperatur stehen. Nach einer Nacht wird der ausgefallene Niederschlag abfiltriert, im Wasser gelöst und dann mit Natriumbicarbonat neutralisiert. Bald fällt ein farblose Niederschlag aus, der zusammen mit dem durch Neutralisierung von die erste Mutterlauge erhaltenen Niederschlag aus Wasser in Nadeln vom Schmp. 240°C umkristallisiert wird, die zur Analyse 4 Std bei 100°C in Vakuum getrocknet wird.

$C_{13}H_{12}O_2N_2$

# *Oxidation of Terpene Compounds with tert-Butyl Chromate. VI. Oxidation of Terpinolene*

By Tamon MATSUURA, Kozo SAITO and Yasuo SHIMAKAWA

(Received February 4, 1960)

On oxidation of terpene hydrocarbons with *tert*-butyl chromate[1-5] it was recognized that the active methylene group adjacent to a double bond in a molecule was mainly oxidized to $\alpha, \beta$-unsaturated carbonyl. Among diene terpene hydrocarbons, only D-limonene has been researched and the oxidation products were rather more complicated than in the cases of $\alpha$-pinene[1,5], D-carvomenthene[2,5] and D, L-$\alpha$-terpinyl acetate[4]; D-limonene was oxidized to D, L-carvone, D-isopiperitenone, piperitenone and carvacrol. This report is concerned with the oxidation of terpinolene (I) which has an active methylene group at $C_{(3)}$ position situated between two double bonds.

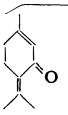
## Results and Discussion

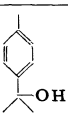
The oxidizing agent was prepared in a manner similar to that in the previous reports[3,4] from chromic anhydride and *tert*-butyl alcohol, glacial acetic acid and acetic anhydride being added.

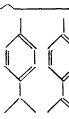
Experiment 1.—The mole ratio of sample to chromic anhydride was 1 to 2. After the reaction was carried out at 10°C during 15 hr., the reaction mixture which resulted was treated with water and oxalic acid under ice-cooling to decompose the excess of the oxidant. Then the mixture was separated into a benzene and an aqueous layer. From the benzene layer was obtained a neutral brown oil which was fractionated and the constituents of which were identified.

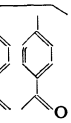
Experiment 2.—The mole ratio of sample to chromic anhydride was 1 to 2, and the reaction was carried out at 10°C during 45 hr. The reaction mixture was treated in the same manner as in Experiment 1.

Experiment 3. — In this experiment glacial acetic acid and acetic anhydride were excluded from the oxidant. This is not the case in Experiments 1 and 2. When the oxidant was added to the sample solution at 0°C during 2 hr., the reaction was stopped and the reaction products were examined.









In the case of each of the above three experiments, piperitenone (II), 8-hydroxy-*p*-cymene (III), *p*-cymene (IV) and $\alpha$,*p*-dimethylstyrene (V) were identified as constituents of the reaction products, and an unidentified carbonyl compound was also recognized.

Experiment 4.—*p*-Cymene was treated with *tert*-butyl chromate under the same condition as in Experiment 1, and small amounts of 8-hydroxy-*p*-cymene and *p*-methylacetophenone were identified as reaction products.

The above results are summarized in Table I.

In the oxidation of terpinolene with *tert*-butyl chromate, the point different from the oxidation of the other cyclic terpene compounds already reported is the aromatization of the hydroaromatic ring by dehydrogenation in addition to the oxidation of the active methylene group adjacent to a double bond. On oxidation of D-limonene and D, L-$\alpha$-terpineol it has been clarified that among two active methylene

5) G. Dupont, R. Dulou and O. Mondou, *Bull. soc. chim. France*, **1953**, 60.

groups adjacent to a double bond in the carbon ring the $C_{(6)}$ active methylene is predominantly oxidized in comparison with the $C_{(3)}$ active methylene. In the case of terpinolene, however, it was found that the oxidation of the $C_{(3)}$ active methylene has proceeded in exclusion of the oxidation of the $C_{(6)}$ active methylene, owing to the existence of a double bond between $C_{(4)}$ and $C_{(8)}$ atoms.

The formation of piperitenone II from terpinolene I by the oxidation of the $C_{(3)}$ active methylene is an analogous reaction to the formation of $\alpha,\beta$-unsaturated ketone from cyclic terpene compounds such as $\alpha$-pinene, limonene, carvomenthene and $\alpha$-terpinyl acetate reported already. However the formation of 8-hydroxy-*p*-cymene III and *p*-cymene IV from terpinolene is due to oxidation of the $C_{(8)}$ position and dehydrogenation, which was found for the first time in the oxidation of terpinolene. An exocyclic double bond between $C_{(4)}$ and $C_{(8)}$ carbons in terpinolene seems to migrate into the carbon ring in the presence of acid to form $\alpha$-terpinene[6]. It has been reported that menthene-4(8) is rearranged into menthene-3 by the action of dilute sulfuric acid solution[7]. Thus it may be considered that an exocyclic double bond of terpinolene molecule migrates into the ring to form a conjugated diene ($\alpha$-terpinene) by acid reagent. Although $\alpha$-terpinene was not found in the reaction products, it has reacted easily with *tert*-butyl chromate to produce a large amount of *p*-cymene*[1]. Therefore *p*-cymene in the reaction products is considered to be produced by dehydrogenation of $\alpha$-terpinene which results from isomerization of terpinolene.

It would seem that 8-hydroxy-*p*-cymene has been formed from *p*-cymene by the oxidation of an active methine group at $C_{(8)}$. But this is not the case, because the result of the oxidation of *p*-cymene with *tert*-butyl chromate in the same conditions as in Experiment 1 (sample, terpinolene) has shown that *p*-cymene is virtually stable against *tert*-butyl chromate, giving only a small amount (1% to the sample) of 8-hydroxy-*p*-cymene and of *p*-methylacetophenone.

Accordingly it can not be considered that 8-hydroxy-*p*-cymene is formed via *p*-cymene.

It has been recognized that on distillation of 8-hydroxy-*p*-cymene in presence of acid (a small amount) $\alpha,p$-dimethylstyrene is produced by dehydration[8], so $\alpha,p$-dimethylstyrene is considered to be a secondary product formed by dehydration during the oxidation reaction or distillation of the reaction products.

On the basis of the above results and discussion the reaction course is summarized as shown in Fig. 1.

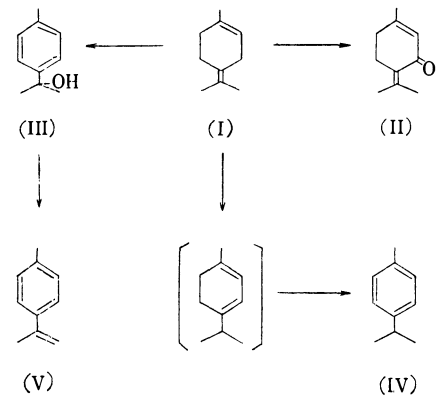

Fig. 1

## Experimental

### 1. Oxidation of Terpinolene

#### 1.1. Preparation of Terpinolene

Terpinolene (b. p.$_{21}$ 78.0°C, $n_D^{25}$ 1.4859, $d_4^{25}$ 0.8577, tetrabromide m. p. 116°C) was prepared, according to Charalton and Day's method[9] by treating $\alpha$-pinene (b. p.$_{28}$ 58~59°C, $n_D^{25}$ 1.4628, $d_4^{25}$ 0.8548, $[\alpha]_D$ +40.62°) with 50% alcoholic solution of sulfuric acid, and by rectifying the crude product.

#### 1.2. Oxidation and Identification of Reaction Products

##### 1.2.1. Experiment 1

*tert*-Butyl chromate was prepared by adding 88 g. of chromic anhydride in small portions to 163 g. of *tert*-butyl alcohol under ice-cooling, diluting the resultant with 650 g. of benzene, and drying the resulting benzene solution on anhydrous sodium sulfate. To the solution were added 10 g. of glacial acetic acid and 10 g. of acetic anhydride just prior to the oxidation. This oxidant was added dropwise with stirring at 10°C to 60 g. of terpinolene in 60 g. of dry benzene during 1 hr., and the mixture was left to stand at 10°C for 15 hr. Then 700 cc. of water and 160 g. of oxalic acid were added under ice-cooling to the viscous reaction mixture and shaken to decompose the excess of the oxidant. The mixture was separated into a benzene layer and an aqueous one, and the latter was extracted with benzene. The combined benzene solution was washed with 10% aqueous solution of sodium carbonate and with water successively, and dried (anhydrous sodium sulfate). After removal of the solvent, 28.1 g. of a neutral brown oil was obtained.

The aqueous solution was neutralized with a sodium carbonate solution and extracted with chloroform. From the extract 7.9 g. of a dark-brown viscous oil was obtained. The sodium carbonate solution was acidified with 10% sulfuric acid solution and

extracted with chloroform, giving 18.9 g. of a dark-brown viscous oil. As neither of the above dark-brown viscous oils could be distilled under reduced pressure and also could not be crystallized, they seemed to be polymer, the further test of which was not undertaken.

The neutral oil was fractionated, giving the physical properties of Fig. 2, and then the constituents of fractions were identified.

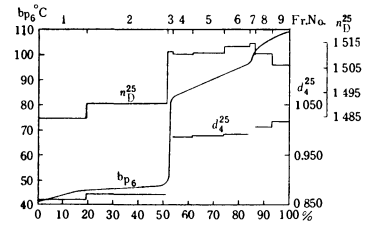

Fig. 2

(i) *p*-Cymene and $\alpha,p$-Dimethylstyrene. Fractions 1 and 2 gave a tetrabromide of m. p. 116°C which was identified as terpinolene tetrabromide by admixture with an authentic sample. On the other hand, the ultraviolet absorption spectra of these two fractions showed the absorption maxima at 247 and 273 m$\mu$ which coincide with those of $\alpha,p$-dimethylstyrene (247 m$\mu$)[10] and *p*-cymene (273 m$\mu$)[11].

Ozone was passed in a solution of 5 g. of the combined fractions 1 and 2 dissolved in 20 cc. of ethyl acetate-glacial acetic acid (6 : 2) under ice-cooling. The ozonized solution, after the solvent having been driven off under reduced pressure and 50 cc. of water being added, was steam-distilled to decompose the ozonide. The distillate was extracted with ether, and the ether extract was washed with 10% aqueous sodium carbonate solution and dried. From the ether extract thus treated, 2.1 g. of an oily product was obtained, after the solvent was driven off. The oily product was eluted through a silica gel column with petroleum benzine and ether successively, and the following two fractions, A and B, were obtained.

| Fraction | Yield (g.) | $\lambda_{max}$ (m$\mu$) (absorptivity $a$*2) |
|---|---|---|
| A | 1.20 | 254(1.42), 260(2.35), 265(2.86), 267(2.95), 273(3.34) |
| B | 0.67 | 252(68.90) |

Fraction A (b. p.$_{15}$ 62~64°C, $n_D^{25}$ 1.4795, $d_4^{25}$ 0.8552) was confirmed to be *p*-cymene from its ultraviolet spectrum. Ultraviolet absorption spectrum of fraction B coincided with that of *p*-methylacetophenone ($\lambda_{max}$; 252 m$\mu$)[12]. 2,4-Dinitrophenylhydrazone m. p. 256.5~257.0°C and semicarbazone m. p. 205~206°C of fraction B were identified to be those of *p*-methylacetophenone by mixing with authentic samples. The formation of *p*-methylacetophenone by ozonolysis of fractions 1 and 2 shows the existence of $\alpha,p$-dimethylstyrene. From the result of ozonolysis the amounts of *p*-cymene and $\alpha,p$-dimethylstyrene in fractions 1 and 2 (unified) were calculated to be 24% and 13% respectively.

(ii) 8-Hydroxy-*p*-cymene. Infrared absorption spectra of fractions 4 and 5 showed a hydroxy band in a region of 3400 cm$^{-1}$, and from these fractions a phenylurethane of m. p. 118~119°C was obtained, which was identified as that of 8-hydroxy-*p*-cymene*3 by the mixed melting point determination.

Three grams of the combined fractions 4 and 5 was heated with 3 g. of powdered potassium hydrogen sulfate at 190~200°C and distilled. The distillate was extracted with petroleum benzine, and the extract was washed with 10% aqueous sodium carbonate solution, dried and eluted through a silica gel column. From the extract thus treated 0.72 g. of an oily product was obtained after the solvent was driven off. Its infrared spectrum showed absorption bands at 1630 cm$^{-1}$ (conjugated double bond), 883 cm$^{-1}$ (end methylene) and 816 cm$^{-1}$ (aromatic *para* substitution), and its ultraviolet spectrum had an absorption maximum at 246 m$\mu$. Thus the dehydration product was confirmed to be $\alpha,p$-dimethylstyrene, and therefore the original alcohol to be 8-hydroxy-*p*-cymene.

(iii) Piperitenone. Ultraviolet absorption spectra of fractions 6 and 7 showed $\lambda_{max}$ 242 m$\mu$ ($\varepsilon$ : 10140) and 276 m$\mu$ ($\varepsilon$ : 7640) which coincide with absorption maxima of piperitenone, 242 m$\mu$ ($\varepsilon$ : 12500) and 278 m$\mu$ ($\varepsilon$ : 7920)[13]. 2,4-Dinitrophenylhydrazone of the above fractions melted at 183.5~184°C. This was identified as that of piperitenone by mixing with a known sample.

Fractions 8 and 9 were unified and eluted through a silica gel—plaster of paris (4 : 1) column with ether-petroleum benzine (3 : 7), and it was verified that 37% of the above unified two fractions was piperitenone.

(iv) Unidentified Carbonyl Compound. By column chromatography of fractions 8 and 9 mentioned above, a carbonyl compound was separated, which gave a 2,4-dinitrophenylhydrazone of m. p. 216.5~217°C and ultraviolet absorption spectrum which had $\lambda_{max}$ 244 m$\mu$ and 257 m$\mu$, but it was not identified.

**1.2.2. Experiment 2**

*tert*-Butyl chromate solution was prepared, in the same way as in Experiment 1, from chromic anhydride (147 g.), *tert*-butyl alcohol (274 g.), benzene (1000 g.), glacial acetic acid (50 g.), and acetic anhydride (50 g.). This oxidant was added dropwise to 100 g. of terpinolene in 100 g. of dry benzene, and the reaction was carried out for 45 hr. at 10°C. Then the reaction mixture was treated as in Experiment 1, and 56.1 g. of a neutral oil was obtained. Piperitenone, 8-hydroxy-*p*-cymene, $\alpha,p$-dimethylstyrene and *p*-cymene were found in the neutral oil*4 (cf. Table I).

*2 The concentration is in g./l. and the cell length in cm.
*3 8-Hydroxy-*p*-cymene was prepared from *p*-bromotoluene and acetone by Grignard reaction (V. N. Ipatieff, H. Pines and R. C. Obberg, *J. Am. Chem. Soc.*, **70**, 2123 (1948)).
13) R. Y. Naves, *Bull. soc. chim. France*, **1951**, 370.
*4 Identification of the constituents in the neutral oils in 1. 2. 2 and 1. 2. 3 was carried out by the similar methods as in 1. 2. 1.

**1.2.3. Experiment 3**

*tert*-Butyl chromate solution was prepared from the same amounts of chromic anhydride, *tert*-butyl alcohol and benzene as in Experiment 1, but glacial acetic acid and acetic anhydride were excluded. Sixty grams of terpinolene in 60 g. of dry benzene was stirred with the above oxidant for 2 hr. at 0°C. Then the reaction mixture was treated as in Experiment 1, and 28.5 g. of a neutral oil was obtained. The same compounds as in Experiment 2 were confirmed to exist in the neutral oil (cf. Table I).

**2. Oxidation of *p*-Cymene (Experiment 4)**

To 60 g. of *p*-cymene (b.p.$_{22}$ 70.5°C, $n_D^{25}$ 1.4860, $d_4^{25}$ 0.8519) dissolved in benzene (60 g.) was added dropwise an oxidant solution consisting of chromic anhydride (89 g.), *tert*-butyl alcohol (166 g.), benzene (650 g.), glacial acetic acid (10 g.) and acetic anhydride (10 g.), and the reaction was carried out for 15 hr. at 25°C. Then the reaction mixture, after being treated as in the preceding experiments, gave 56.4 g. of a neutral oil which was fractionated as follows: fraction 1 (53 g., b.p.$_{25}$ 73～74°C, $n_D^{25}$ 1.4876, $d_4^{25}$ 0.8645), fraction 2 (0.6 g., b.p.$_4$ 46～70°C, $n_D^{25}$ 1.5017) and residue (0.4 g.).

It was confirmed that fraction 1 was unchanged *p*-cymene by its ultraviolet spectrum measurement. Fraction 2 gave 2,4-dinitrophenylhydrazone m.p. 256°C of *p*-methylacetophenone and phenylurethane m. p. 120°C of 8-hydroxy-*p*-cymene, both of which were identified by mixing with authentic samples. An ultraviolet absorption spectrum of fraction 2 have $\lambda_{max}$ 250 m$\mu$ ($a$: 20) which agrees virtually with $\lambda_{max}$ 252 m$\mu$ ($a$: 117) of *p*-methylacetophenone.

## Summary

Oxidation of terpinolene with *tert*-butyl chromate was carried out, and piperitenone, 8-hydroxy-*p*-cymene, *p*-cymene and $\alpha$, *p*-dimethylstyrene were obtained as reaction products. In this oxidation it was found that the active methylene group at $C_{(3)}$ position in terpinolene was oxidized to a carbonyl group, and that the aromatization of carbon ring in terpinolene molecule took place. This could not be recognized in the oxidation of terpene compounds already reported by this oxidant.

This research was aided by a grant from the Ministry of Education.

# *Thermal Decarboxylation of p-Chlorobenzoic Acid*

By S. S. MUHAMMAD

(Received February 13, 1960)

Though Fieser and Fieser[1a] had suggested in 1944 the probability of an electrophilic bimolecular ($S_E2$) mechanism for the decarboxylation of *o*- and *p*-hydroxybenzoic acids, no experimental evidence was available for this till 1948, when Schenkel and Schenkel-Rudin[2] recognized this as likely for the decomposition of anthracene-9-carboxylic acid:

since Schenkel[3] had established the fact that this acid underwent decarboxylation more readily in acidic solvents such as sulfuric or dichloroacetic acid than in basic solvents such as 7:8 benzoquinoline. Schubert[4] tried to establish a relation between the rate of decarboxylation and hydrogen ion concentration of the medium, by studying the decomposition of mesitoic acid in aqueous sulfuric acid of 80 to 100%. Johnson and Heinz[5] obtained evidence for the $S_E2$ mechanism by studying the rates of decarboxylation, under identical conditions, of different substituted cinnamic acids, $PhCR'=CR''COOH$. The order of rates found by them agreed with the electronic effects of the substituents R′ and R″ on the basis of the following bimolecular mechanism:

$$PhCR'=CR''COOH + HA \rightleftharpoons Ph\overset{+}{C}R'CHR''COOH + A'$$

followed by a comparatively fast step:

$$Ph\overset{+}{C}R'CHR''COOH \rightarrow PhCR'=CHR''CO_2 + H^+$$

5) W. S. Johnson and W. E. Heinz, ibid., **71**, 2913 (1949).

Then Brown, Hammick and Scholefield[6] showed that the decarboxylation of salicylic, 2, 4-dihydroxy- and 2, 4, 6-trihydroxybenzoic acids occurs by an $S_E2$ mechanism. These studies were extended by S. S. Muhammad and Mrs. Aziz Mirza on benzoic acid[8], *o*-chloro- and 2, 4-dichlorobenzoic acids[9,10]. The technique employed was primarily to collect the carbon dioxide evolved in a gas burette. But in the present study a slightly different technique has been adopted. The results reported pertain to *p*-chlorobenzoic acid and these will be shortly extended to other acids.

## Experimental and Results

**Materials.** — All the chemicals were of analar grade, and were used without further purification. The solvents, resorcinol, glycerol and aniline were of extra pure quality and when heated alone did not emit carbon dioxide.

**Apparatus.**—The heating device consisted of an oil bath heated electrically, the temperature control being achieved by means of a Sunvic energy regulator and a Sunvic relay. Temperatures were recorded with a 300°C thermometer having an accuracy of ±0.5°C. The bath liquid was a local sweet oil which, on heating for 24 hr. at 300°C, emitted volatile vapours and then behaved as a nonvolatile liquid below this temperature.

The reaction vessel was a modified Walton's[11] apparatus, the mouth of which was made of ground glass joint with stopper to which a glass tube was attached and this served as delivery tube for carbon dioxide liberated. The side tube had also a neck made of glass joint. The stopper for this had a spoon device where a weighed amount of the acid could be kept in a small test tube, which could be dropped by a slight turn of the stopper. Both the stoppers were lubricated with the least quantity of Silicone grease.

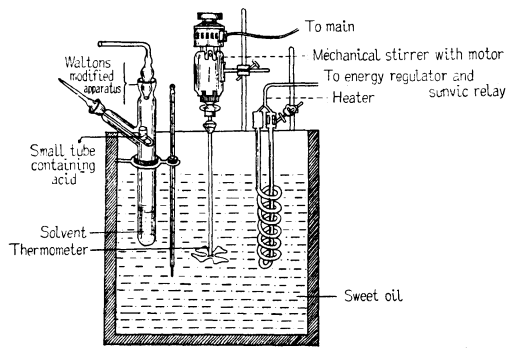

Fig. 1.

The carbon dioxide was absorbed in baryta solution kept in an Erlenmeyer flask.

The oil thermostat with the modified Walton apparatus is shown in Fig. 1.

**Procedure.**—In order to find the order of reaction, different amounts of *p*-chlorobenzoic acid were taken with 20 g. of resorcinol in the Walton tube and heated for a definite interval. The liberated carbon dioxide was absorbed in baryta solution of approximately N/10 strength. Its exact titre value was determined by standardized N/10 oxalic acid before and after the absorption of carbon dioxide. The amount of acid decomposed, $x$, was calculated by the relation: $\Delta v \times 10^{-4}$ g. mol., where $\Delta v$ is the difference in the titre values '$v_0$' initially and '$v$' after absorption. Since the amount of acid initially taken, '$a$', is known, the amount of acid remaining at any interval, '$a-x$', can be found.

In the first series of experiments, the initial amounts '$a$' were converted into relative concentrations, '$c$', and the corresponding amounts '$x$' decomposed in the same interval were converted into relative rates '$r$' (Table I).

The plot of log $c$ against log $r$ yields a slope of 1, indicating the order to be one.

In the second series of experiments, the same initial amount of the acid '$a$', was heated. The carbon dioxide evolved was absorbed in the same volume of the baryta solution of the same concentration. The latter solution was titrated by N/10 oxalic acid after a desired interval. The same operation being repeated for different desired intervals. Table II contains these data.

The plot of log $(a-x)$ against time $t$ gives straight line proving the first order character of the reaction.

The rate constants can be obtained by the equation $k=2.303/t \cdot \log a/a-x$. Thus using the data of Expt. 4, we get $k=2.303/12 \log 29.4/19.6 = 3.378\times10^{-2}\,\mathrm{min}^{-1} = 5.63\times10^{-4}\,\mathrm{sec}^{-1}$. Alternatively the rate constant can be derived by the relation

$$k' = \frac{x}{t} \times \frac{1}{\bar{a}}$$

where $x$ is the amount decomposed in the interval $t$ and $\bar{a}$ is the average concentration during this interval i. e. $\{a+(a-x)\}/2$. Thus the data of Expt. 4, give

$$k' = \frac{9.8\times10^{-4}}{12} \times \frac{1}{(29.4+19.6)\times10^{-4}/2}$$
$$= \frac{9.8\times10^{-4}}{12\times24.5\times10^{-4}} = 3.33\times10^{-2}\,\mathrm{min}^{-1}$$
$$= 5.56\times10^{-4}\,\mathrm{sec}^{-1}$$

In subsequent experiments, the latter method of deriving the rate constant has been used.

In the third series of experiments, different initial amounts of the acid, '$a$', were heated at constant temperature, $T$, and the amounts '$x$', decomposed in 12 minutes were determined in each case. The rate constants were calculated as above. At each temperature, 5 observations were made and the mean of these was taken as the rate constant at that temperature. These results are presented in Table III.

| 0.60 | 29.67 | 5.00 | 5.09 | 0.6990 | 0.7067 |

TABLE II.

A 0.460 g. portion of acid was taken in each experiment (i.e. $a=29.4\times10^{-4}$ g. mol.). The carbon dioxide formed was absorbed in 40 cc. of baryta solution which was titrated with N/10 oxalic acid.

| Expt. No. | Time, $t$ min. | Titre value of N/10 Oxalic acid, $T$ | Amount of acid decomposed, $x$ ($x=T\times10^4$ g. mol.) | $(a-x)\times10^4$ | log$(a-x)$ |
|---|---|---|---|---|---|
| 1 | 0 | 33.4 | — | 29.4 | 1.4683 |
| 2 | 4 | 29.8 | 3.6 | 25.8 | 1.4116 |
| 3 | 8 | 26.4 | 7.0 | 22.4 | 1.3502 |
| 4 | 12 | 23.6 | 9.8 | 19.6 | 1.2923 |
| 5 | 15 | 21.4 | 12.0 | 17.4 | 1.2405 |
| 6 | 20 | 19.0 | 14.4 | 15.0 | 1.1761 |
| 7 | 26 | 16.5 | 16.9 | 12.5 | 1.0969 |
| 8 | 32 | 15.0 | 18.4 | 11.0 | 1.0414 |

In order to examine the above results, it was desirable to derive the activation energy $E$, frequency factor $A$, free energy of activation $\Delta F°$ and entropy of activation $\Delta S°$.

The plot of log $k$ vs. $1/T$ (Fig. 2) gave the activation energy $E$.

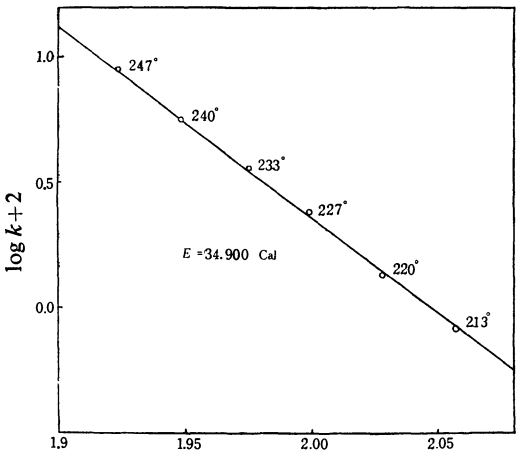

Fig. 2.

The Arrhenius equation $k=Ae^{-E/RT}$ was used to calculate the frequency factor $A$ and the Eyring equations[12]

$$\Delta F°=2.303\ RT\ \log\ (RT/Nhk)$$

$$\Delta S°=(\Delta H°-\Delta F°)/T$$

yielded the free energy and entropy of activation. The term $\Delta H°$ is the enthalpy of activation, taken equal to $E-RT$, where $E$ is the observed activation energy and $T$ the temperature at which entropy and free energy are being calculated. The values of the constants used are[13]: $R=1.987$ cal. and $8.31439\times10^7$ erg, $N=6.02308\times10^{23}$, $h=6.6252\times10^{-27}$ erg, $T°=$ °C+273.15. The results of these calculations are shown in Table IV.

**Effect of Other Solvents.**—The solvent glycerol is also effective in bringing about decarboxylation of *p*-chlorobenzoic acid, but the rate of decarboxylation is less in glycerol than in resorcinol. Thus, while at 233°C in resorcinol 2.5% of the acid decomposed per minute, in glycerol under identical conditions the rate of decarboxylation is 1.9% per minute. Besides, the rate constants for decarboxylation in glycerol calculated from the first and the second order rate equations show large trends.

Addition of a small quantity of aniline to glycerol solution retards the rate of decarboxylation and when enough of aniline is added, the reaction completely stops. When the acid was dissolved in pure aniline, it did not decompose at 247°C, which was the highest temperature employed in the present investigation.

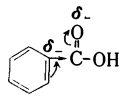
## Discussion

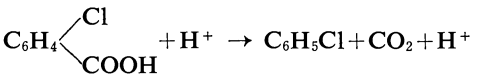
The data presented above show that *p*-chlorobenzoic acid is stable in basic solvents and is unstable in acidic solvents. In this respect, it is analogous with salicylic acid[6] and orthochlorobenzoic acid[9] which undergo decomposition through an electrophilic bimolecular ($S_E2$) mechanism, involving the replacement of the carboxyl:



or $RCH + CO_2 + H^+$

In *p*-chlorobenzoic acid, the inductive effect of chlorine in the para position is likely to cause electron deficiency on the $\alpha$-cabon. The result of this would be that decarboxylation would not occur in acid medium and would be facilitated in neutral and basic media. This would be in harmony with the view of Fairclough[14], according to whom in trichloroacetic and tribromoacetic acids the $\alpha$-carbon is attached to strongly electron attracting chloro and bromo groups which weakens the carbon-carboxy bond and facilitates its unimolecular rupture:

According to Fieser and Fieser[16], the inductive effect estimated from dipole moments accounts well for the activating or deactivating influence of different groups, but does not explain the orientation and it is seen that although the majority of electron attracting groups orient an entering group to the meta position, halogen substituents, like the electron repelling amino and hydroxyl groups are ortho, para directing. This is due to the resonance effect. Thus in chlorobenzene resonance leads to development of electron density at the ortho and para positions (with reference to chlorine atom). In *p*-chlorobenzoic acid, structures in which carboxyl also partakes of the resonance are possible. But according to Schubert[4], in the presence of substituents, the resonance interaction of the carboxyl with the benzene nucleus is inhibited. This leads to the weakening of the bond between the carboxyl and $\alpha$-carbon and to its easy rupture. Another interesting explanation is that of Royals[15], according to whom the presence of meta orienting groups like carboxyl produces an electromeric effect indicated in the accompanying structure, due to which nucleophilic reactivity is developed at the $\alpha$-carbon atom adjacent to meta orienting group. Hence an electrophilic reagent attacks this position and displaces the meta orienting group:



This also accounts satisfactorily the decarboxylation of benzoic acid[8] in the solvent resorcinol.

The bimolecular electrophilic substitution ($S_E2$) mechanism also accounts for the behavior of *p*-chlorobenzoic acid in the solvent glycerol which has been recently used by Clark[16] in decarboxylations. Glycerol being a polyhydric compound may act as a protophilic solvent and facilitate the ionization of *p*-chlorobenzoic acid to a limited extent.

$$\underset{\text{acid}}{HA} + \underset{\text{solvent}}{ROH} \rightleftharpoons (ROH_2)^+ + A^-$$

where $(ROH_2)^+$ is solvated hydrogen ion. The "hydrogen ions" so formed will facilitate the decarboxylation:

The trends in the rate constants during decarboxylation in glycerol may be due to the fact that along with decarboxylation, the ester formation between glycerol and the acid takes place and the ester so formed decomposes decarboxylatively introducing complications in the interpretation of rate data. The retarding effect of aniline on decarboxylation in glycerol is also consistent with the $S_E2$ mechanism proposed, since aniline removes the hydrogen ions present and thus causes retardation in their attack on the carboxylic acid. On the contrary if decarboxylation were to occur via the first order decomposition of the carboxylate anion by the $S_E1$ mechanism, the rate should have increased due to the carboxylate anions being formed in abundance:

$$C_6H_5NH_2 + HA = (C_6H_5NH_3)^+ + A^-$$

## Summary

The decarboxylation of *p*-chlorobenzoic acid has been studied in the solvent resorcinol. The activation energy, frequency factor and free energy and entropy of activation have been calculated. It is shown that the reaction follows the $S_E2$ mechanism.

# *Sur la Dissolution des Minerais Sulfurés en Divers Milieux. III. Facteurs Intervenant à la Dissolution de la Chalcopyrite*

Par Masami ICHIKUNI

(Reçu le 1er Novembre 1959)

On a examiné dans le rapport précédent[1] les influences du pH et de l'oxygène sur la dissolution de la chalcopyrite qui existe indépendamment des autres minéraux. Cependant tous les minerais produits dans la nature sont d'un système complexe de plusieurs minéraux. On ne peut pas supposer que chaque minéral se comporte indépendamment des autres au cours de la dissolution du minerai; il doit y avoir évidemment les actions réciproques entre les minéraux ainsi que celles des ions en solution. Ohashi[2] a déjà traité l'aspect général de ce problème; toutefois, à ce sujet, notre connaissance reste encore peu satisfaisante.

## Expérience

On examine ici les effets de la présence de la pyrite, qui se trouve associée très souvent à la chalcopyrite, et ceux des ions de fer divalent, qui se forment par la désagrégation. Le dispositif destiné à l'expérience est le même que précédemment décrit[1].

**Effets de la Présence de la Pyrite.**—On mélange bien la pyrite et la chalcopyrite, en proportion connue; les deux ont été utilisées dans les expériences du rapport précédent. De ce mélange bien pulvérisé, on met 1 g. dans 200 ml. d'acide chlorhydrique 0,01 N et traite pendant deux heures à la température de 80°C. Le prélèvement de 10 ml. de liqueur s'effectue avec l'interval d'une demi-heure après l'addition du mélange. L'air est introduit dans un ballon contenant de la liqueur et de la poudre des minéraux avec un débit de 1,5 l./min. Quant aux conditions d'expériences, voir le rapport précédent.

**Effets des Ions de Fer Divalent en Solution.**—On dissout une quantité connue de sulfate de fer-(II), $FeSO_4 \cdot 7H_2O$, dans l'acide chlorhydrique 0,01 N, prend 200 ml. de cette solution, y ajoute 1 g. de chalcopyrite pulvérisée, et traite pendant deux heures. Le prélèvement de liqueur s'effectue de la même façon que l'expérience décrite ci-dessus. Dans la liqueur on introduit de l'air ou de l'azote avec un débit de 1,5 l./min., l'introduction de ce dernier ayant pour but de réaliser une condition non-oxydante.

## Résultats et Discussion

**Co-présence de la Pyrite.** — On a préparé quatre mélanges de proportions différentes de ces deux minéraux. La composition des mélanges est donnée dans le Tableau I. Les concentrations de fer divalent, de cuivre et de sulfate, qu'on a calculées en tenant compte de la diminution du volume de liqueur par l'évaporation, sont portées sur le Tableau II.

TABLEAU I. COMPOSITION DES MÉLANGES CONSISTANT EN PYRITE ET EN CHALCOPYRITE

| No. du mélange | Pyrite % | Chalcopyrite % | Cu % | Fe % | $(Cu/Fe)_{min.}$ $\times 10^{-2}$ |
|---|---|---|---|---|---|
| 1 | 95,5 | 4,5 | 1,56 | 45,8 | 3,71 |
| 2 | 84,6 | 15,4 | 5,34 | 44,0 | 12,1 |
| 3 | 62,1 | 37,9 | 13,1 | 40,4 | 32,4 |
| 4 | 51,4 | 48,6 | 16,8 | 38,6 | 43,6 |

Remarque: Les teneurs en cuivre et en fer des mélanges sont calculées d'après les résultats d'analyse des minéraux. La valeur $(Cu/Fe)_{min.}$ représente le rapport de teneur en cuivre sur celle en fer du mélange.

TABLEAU II. VARIATION DE CONCENTRATIONS DE FER DIVALENT, DE CUIVRE ET DE SULFATE AU COURS DE LA DISSOLUTION DE 1 g. DE CHAQUE MÉLANGE

| No. du mélange | Durée du traitement hr. | Cu mg./l. | $Fe^{2+}$ mg./l. | $SO_4^{2-}$ mg./l. |
|---|---|---|---|---|
| 1 | 0,5 | 3,92 | 16,3 | 29 |
| | 1 | 6,05 | 19,2 | 39 |
| | 1,5 | 9,89 | 23,6 | 49 |
| | 2 | 12,0 | 27,1 | 59 |
| 2 | 0,5 | 4,39 | 18,4 | 23 |
| | 1 | 6,89 | 22,5 | 30 |
| | 1,5 | 10,5 | 26,4 | 42 |
| | 2 | 14,4 | 31,0 | 53 |
| 3 | 0,5 | 4,13 | 19,4 | 17 |
| | 1 | 6,06 | 25,8 | 25 |
| | 1,5 | 8,12 | 31,8 | 32 |
| | 2 | 8,85 | 38,1 | 41 |
| 4 | 0,5 | 3,38 | 17,5 | 19,5 |
| | 1 | 4,00 | 23,6 | 24 |
| | 1,5 | 4,95 | 31,0 | 28 |
| | 2 | 5,95 | 37,6 | 36 |

Avec les données du Tableau II, on calcule la vitesse de dissolution à partir de la pente de la droite représentant la concentration de composants en fonction de durée du traitement. Sa vitesse est considérablement grande au

1) M. Ichikuni, Ce Bulletin, 33, 1052 (1960).
2) S. Ohashi, *J. Chem. Soc. Japan, Pure Chem. Sec.* (*Nippon Kagaku Zasshi*), 74, 845 (1953).

Tableau III. Vitesse de dissolution du cuivre, du fer divalent et du sulfate à partir de 1 g. de mélange

| No. du mélange | Cu mg./hr. | $Fe^{2+}$ mg./hr. | $SO_4^{2-}$ mg./hr | $(Cu/Fe)_{soln.}$ $(\times 10^{-2})$ | $\frac{(Cu/Fe)_{soln.}}{(Cu/Fe)_{min.}}$ |
|---|---|---|---|---|---|
| 1 | 1,10 | 1,47 | 4,0 | 74,9 | 20,2 |
| 2 | 1,35 | 1,66 | 4,05 | 81,4 | 6,73 |
| 3 | 0,76 | 2,41 | 3,2 | 31,5 | 0,973 |
| 4 | 0,41 | 2,70 | 2,2 | 15,2 | 0,349 |

début, et après elle prend une valeur constante. Cette irrégularité de dissolution fait supposer la présence des parties facilement solubles du minéral, mais dont l'essentiel reste encore peu clair.

En examinant la vitesse de dissolution des composants sur les quatre échantillons de mélanges, on a trouvé des faits suivants: avec l'augmentation de proportion de chalcopyrite dans les mélanges,

1° la vitesse de dissolution du fer augmente,

2° celle du cuivre va d'abord montant, atteint le maximum, et après, descend graduellement.

3° celle du sulfate ne fait que diminuer.

Cela signifie que la pyrite et la chalcopyrite ne se dissolvent pas indépendamment l'une de l'autre et qu'il existe les influences réciproques sur la dissolution de leur mélange. D'où vient que la vitesse de dissolution des composants à partir du mélange est toujours différente de celle prévue d'après les résultats de la dissolution de chacun des deux minéraux purs.

La vitesse de dissolution des composants est montrée dans le Tableau III, où $(Cu/Fe)_{soln.}$ et $(Cu/Fe)_{min.}$ représentent respectivement le rapport de vitesse de dissolution du cuivre sur celle du fer, et le rapport de teneur en cuivre sur celle en fer du mélange.

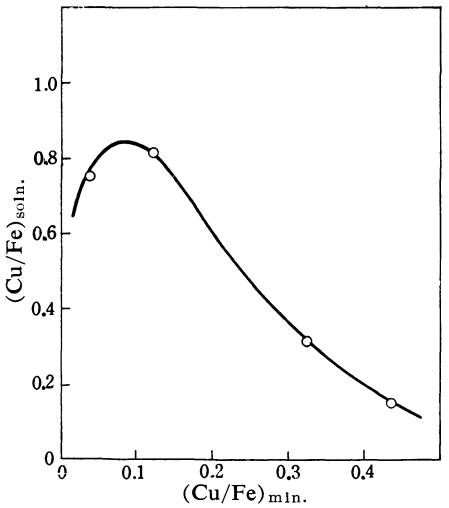

Fig. 1. Relation entre la valeur de $(Cu/Fe)_{min.}$ et la valeur de $(Cu/Fe)_{soln.}$

L'augmentation de teneur en cuivre du mélange, c'est-à-dire celle de valeur de $(Cu/Fe)_{min.}$, diminue la valeur de $(Cu/Fe)_{soln.}$. La Fig. 1 montre cette relation où la valeur de $(Cu/Fe)_{soln.}$ atteint le maximum au moment où la valeur de $(Cu/Fe)_{min.}$ est de 0,1 environ. La diminution de la valeur de $(Cu/Fe)_{min.}$ au-dessous de 0,1 abaisse également la valeur de $(Cu/Fe)_{soln.}$; mais le rapport de $(Cu/Fe)_{soln.}$ sur $(Cu/Fe)_{min.}$ a une signification particulière au point de vue géochimique et pratique.

Ce rapport soit $r$,

$$r=\frac{(Cu/Fe)_{soln.}}{(Cu/Fe)_{min.}}$$

Si $r>1$, le minerai résiduel s'appauvrit en cuivre. Si $r<1$, le minerai résiduel devient riche en cuivre. On a déjà remarqué cette possibilité d'enrichissement du cuivre dans certaines discussions concernant la dissolution de la chalcopyrite. Le point où $r=1$ se trouve à la valeur de $(Cu/Fe)_{min.}$ de 0,32. Supposons que le minerai consiste simplement en pyrite et en chalcopyrite, alors la teneur en cuivre du minerai est de 13%. Comme la plupart des minerais sulfurés cuprifères sont moins riches en cuivre que ce minerai en supposition, l'enrichissement en cuivre du minerai résiduel n'aura pas lieu en réalité au cours de la désagrégation, et l'extraction du cuivre s'effectue efficacement par l'action des eaux.

Le rapport $r$ représente l'efficacité d'extraction du cuivre à partir du minerai, ou le coefficient de concentration du cuivre de la phase solide en phase liquide; la valeur $r$ est d'autant plus grande que la teneur en cuivre du minerai est plus petite (voir le Tableau III). Il est donc avantageux d'extraire du cuivre d'un minerai pauvre en cuivre par l'action des eaux. Ce procédé est exécuté dans certain nombre de mines. A titre d'exemple, on calcule ici la valeur $r$ sur le minerai siliceux (kéi-kô), qui a été utilisé comme échantillon dans le premier rapport relatif à la dissolution des minerais sulfurés[3], où

$$(Cu/Fe)_{min.}=0{,}361\times10^{-2}$$
$$(Cu/Fe)_{soln.}=9{,}83\times10^{-2}$$

3) M. Ichikuni et H. Kamiya, Ce Bulletin, 32, 1368 (1959).

on a donc $r=27,2$, qui est exceptionnellement grand; on notera d'ailleurs que la teneur en cuivre du minerai n'est que de 0,048%.

**Effets des Ions de Fer Divalent en Solution.** —Le Tableau IV donne les concentrations de composants dissous, correspondant à l'heure du prélèvement de liqueur et à la quantité additionnée de fer divalent. La quantité dissoute de fer et de sulfate est très limitée et reste inférieure à l'erreur du dosage de ces composants, lorsque la concentration de fer est plus de 500 mg./l. Notons que le fer est ajouté sous forme du sulfate de fer(II), $FeSO_4 \cdot 7H_2O$. Cela gêne de vérifier l'augmentation de concentration de sulfate.

Le dosage du fer divalent et du sulfate s'est donc effectué, lorsque la concentration initiale de fer était inférieure à 100 mg./l. On montre dans le Tableau V la vitesse de dissolution du fer divalent, du cuivre et du sulfate calculée d'après le Tableau IV.

TABLEAU IV. VARIATION DE CONCENTRATIONS DE CUIVRE, DE FER DIVALENT ET DE SULFATE AU COURS DE LA DISSOLUTION DE 1 g. DE CHALCOPYRITE, EN PRÉSENCE DU FER DIVALENT

| Conc. initiale de $Fe^{2+}$ mg./l. | Durée du traitement hr. | Cu mg./l. | $Fe^{2+}$ mg./l. | $SO_4^{2-}$ mg./l. |

| | 1,5 | <0,10 | — | — |
| | 2 | <0,10 | — | — |

Remarque: Ces expériences ont été effectuées en présence de l'air, à l'exception de la dernière qui a été exécutée en milieu exempt d'oxygène.

TABLEAU V. VITESSE DE DISSOLUTION DU CUIVRE, DU FER DIVALENT ET DU SULFATE À PARTIR DE 1 g. DE CHALCOPYRITE EN PRÉSENCE DU FER DIVALENT

| Conc. initiale de $Fe^{2+}$ mg./l. | Cu mg./hr. | $Fe^{2+}$ mg./hr. | $SO_4^{2-}$ mg./hr. |
|---|---|---|---|
| 30 | <0,05 | 1,05 | 0,15 |
| 55 | <0,05 | 1,28 | 0,80 |
| 100 | 0,11 | 1,33 | 0,90 |
| 500 | 1,55 | — | — |
| 1000 | 2,28 | — | — |
| 1000 | 0 | — | — |

Remarque: Le dernier rang correspond à l'expérience effectuée en milieu exempt d'oxygène.

*Dissolution du Fer.*—A mesure que la concentration de fer divalent augmente, la quantité dissoute de fer à partir de la chalcopyrite augmente. Cette tendance existerait même en présence du fer dont la concentration est plus de 100 mg./l. D'autre part, sous les conditions où la concentration de fer est moins de 100 mg./l., il n'y a presque pas de dissolution du cuivre. On peut donc admettre que la dissolution du fer s'effectue plus facilement que celle du cuivre. L'accélération de dissolution du fer serait attribuable à des ions de fer trivalent. On a donc:

$$(1)\quad CuFeS_2 + 2Fe^{3+} \rightarrow CuS + S + 3Fe^{2+}$$

et on en déduit, en tenant compte de l'augmentation de concentration de sulfate:

$$(2)\quad CuFeS_2 + 8Fe^{3+} + 4H_2O \rightarrow CuS + SO_4^{2-} + 8H^+ + 9Fe^{2+}$$

Toutefois l'augmentation de concentration de sulfate est toujours inférieure à celle de fer,

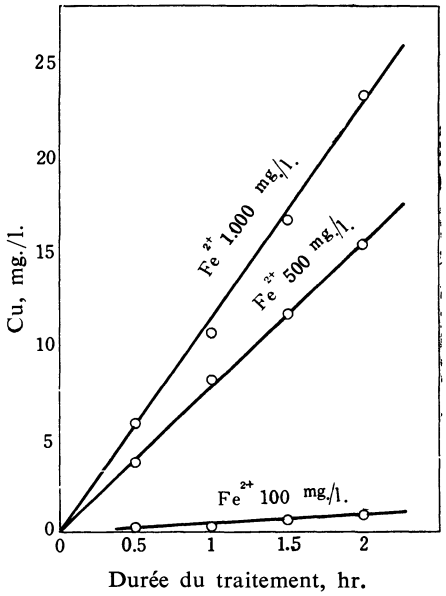

Fig. 2. Dissolution du cuivre à partir de la chalcopyrite en présence du fer divalent et de l'air.

par conséquent la réaction exprimée par l'équation (1) est prédominante dans le cas d'expériences.

*Dissolution du Cuivre.*—Elle n'est presque pas remarquée en présence du fer dont la concentration est inférieure à 100 mg./l. Au delà de 100 mg./l., pourtant, le cuivre se dissout considérablement. La Fig. 2 est dessinée avec les chiffres du Tableau IV. On y voit bien la dissolution du cuivre en présence du fer dont la concentration est supérieure à 100 mg./l. D'après Ohashi[2], la dissolution du cuivre à partir de la chalcopyrite est favorisée par l'action des ions de fer trivalent, ce qui est à comparer avec le résultat décrit ci-dessus. Un mécanisme de dissolution du cuivre, semblable à celui du fer, peut être admis :

$$(3)\quad CuFeS_2 + 4Fe^{3+} \rightarrow Cu^{2+} + 5Fe^{2+} + 2S$$

La quantité de fer trivalent est d'autant plus grande que celle de fer divalent en solution est plus grande, car le fer trivalent est formé par l'oxydation du fer divalent par l'oxygène. Ce phénomène favorise la dissolution de la chalcopyrite dans une mesure considérable.

Ce résultat est soutenu par le fait que la présence d'une quantité importante de fer divalent n'accélère pas la dissolution du cuivre en milieu exempt d'oxygène.

La majeure partie de fer en solution se trouve à l'état divalent, et la quantité de fer trivalent n'est au maximum que de 1% de celle de fer divalent, si la solution est en contact avec un minerai. Cela s'explique bien par le fait que la réaction de l'attaque du fer trivalent sur le minéral s'effectue rapide par rapport à celle de l'oxydation du fer divalent en fer trivalent.

On n'a pas de chiffres en ce qui concerne le soufre, mais il est probable que le fer trivalent intervient à la formation du sulfate. Comme les eaux en contact avec le gisement des minerais sulfurés contiennent généralement une quantité considérable de fer, la dissolution de la chalcopyrite ne peut pas s'expliquer par un mécanisme simple, mais elle est soumise à des influences de plusieurs facteurs, dont dépend la quantité dissoute de cuivre, de fer et de soufre.

## Résumé

La dissolution du cuivre à partir de la chalcopyrite est influencée par le fer en solution qui est en contact avec le minéral, mais plus remarquable est l'effet de la co-présence de la pyrite. L'influence du fer en solution devient considérable, si la concentration de fer dépasse 100 mg./l.

L'auteur exprime ses remerciements profonds à Monsieur le professeur Noguchi qui a bien voulu lire ce rapport et lui donner des conseils utiles, et particulièrement à Monsieur H. Kamiya qui a participé aux expériences et à la discussion sur l'interprétation des résultats.

# *Sur la Dissolution des Minerais Sulfurés en Divers Milieux. IV. Dissolution du Minerai Jaune*

Par Masami ICHIKUNI

(Reçu le 19 Novembre 1959)

La dissolution des minerais sulfurés, notamment celle de la pyrite et de la chalcopyrite, a été systématiquement étudiée, et le résultat des expériences a été réuni dans le 2ème rapport[1] des travaux de la présente série. L'action réciproque des deux minéraux lors de la dissolution de leur mélange était le sujet du rapport précédent[2]. Il serait donc intéressant de vérifier que la dissolution d'un certain minerai peut être expliquée complètement par l'application des résultats obtenus jusqu'ici. Comme les minerais sont d'une association de nombreux minéraux, leur dissolution est influencée à la fois par les facteurs de milieu et par l'action réciproque existant entre les minéraux. Il n'y aurait pas de manière générale d'interpréter le résultat d'expériences concernant la dissolution des minerais. L'état actuel des

1) M. Ichikuni, Ce Bulletin, 33, 1052 (1960).
2) M. Ichikuni, Ce Bulletin, 33, 1159 (1960).

recherches ne permet que d'appliquer les résultats obtenus sur les minéraux ou leur mélange à l'interprétation de la dissolution d'un minerai sulfuré qui a une composition minéralogique simple. On prend donc comme échantillon le minerai jaune, ou *ô-kô*, qui est constitué généralement par le quartz, la pyrite et la chalcopyrite, sans parler des composants mineurs.

## Expérience

On suit la méthode d'expériences qui est déjà mise au point et dont la description détaillée est donnée dans le 2ème rapport.

L'échantillon utilisé dans cette étude est le minerai jaune qui s'est produit à la mine de Kosaka, département d'Akita. Le résultat d'analyse chimique en est montré par le Tableau I. On a décelé par voie spectrographique des traces d'aluminium, d'argent et d'arsenic. Les minéraux arsénifères existent en quantité négligeable. On a soumis ensuite le minerai à l'examen diffractométrique à rayons X, et a décelé le quartz, la pyrite et la chalcopyrite. La présence de la blende est incertaine, car la teneur en zinc est trop petite pour qu'on identifie précisément l'espèce de minéral de zinc. Toutefois il est probable que le zinc se trouve sous forme de blende. En admettant que chaque minéral a une composition correspondant à la formule chimique idéale, on a calculé la composition minéralogique du minerai en question, dont le résultat est porté sur le Tableau II. La présence d'une seule espèce de minéral de cuivre simplifie l'analyse des résultats d'expériences.

Pour chaque expérience, on a utilisé 1 g. de minerai pulvérisé.

Tableau I. Composition chimique du minerai jaune

| Composant | Teneur % |
|---|---|
| Fe | 31,17 |
| Cu | 2,41 |
| Zn | 0,14 |
| S | 35,25 |
| $SiO_2$ | 29,13 |
| Total | 98,10 |

| Chalcopyrite | $CuFeS_2$ | 7,0 |
| Blende | ZnS | 0,2 |
| Quartz | $SiO_2$ | 29,1 |
| Total | | 98,7 |

## Résultats et Discussion

**Expérience de Dissolution Effectuée en Présence de l'Air.**—Le Tableau III rassemble les résultats obtenus. La vitesse de dissolution du fer, de cuivre, du zinc et de soufre a été calculée en traçant la droite de concentration de chaque composant en fonction de la durée du traitement. On envisage ici le soufre qui se dissout sous forme de sulfate. Le résultat du calcul est montré dans le Tableau IV. A mesure que le pH du milieu diminue, la vitesse de dissolution du cuivre et du zinc augmente, tandis que celle du sulfate ne fait que diminuer. La vitesse de dissolution du fer est approximativement constante en milieu à pH inférieur à 3. A partir de ces résultats, on conclut que la dissolution du minerai jaune ressemble à celle de la pyrite que l'on a étudiée sous la même condition. On notera que ce

minéral constitue la plus grande partie (62,4%) du minerai.

*Fer.*—Lors du traitement du minerai avec de l'eau, la dissolution du fer n'a pas lieu, bien que le pH de la liqueur s'abaisse à 3 près. Cependant sous la même condition, une quantité appréciable de fer s'est dissoute à partir de la pyrite. On envisage maintenant le problème du comportement de la pyrite qui se trouve associée à d'autres minéraux. Ce problème pourrait être résolu par l'examen des influences des minéraux co-existants. D'ailleurs il est bien connu que la présence de la blende empêche la dissolution de la pyrite et de la chalcopyrite[3]. Pourtant cette raison n'est pas très convaincante pour la résolution totale du problème.

*Cuivre.*—La dissolution du cuivre est évidemment influencée par le pH du milieu, mais d'une façon différente du cas de dissolution du cuivre à partir de la chalcopyrite qui se trouve indépendamment des autres minéraux. Dans le cas de la chalcopyrite, la vitesse de dissolution du cuivre ainsi que du fer augmente brusquement au moment où l'acidité du milieu atteint 0,1 N, tandis que celle du cuivre à partir du minerai jaune n'augmente que légèrement par l'abaissement du pH de 2 à 1. La dissolution sélective de la chalcopyrite ne se produit pas même à pH 1. La valeur de $(Cu/Fe)_{soln.}$, rapport de vitesse de dissolution du cuivre sur celle du fer, était de 0,38 à pH 1 pour la chalcopyrite. Elle est de 0,71 au même pH pour le minerai, et dépasse le chiffre trouvé pour la chalcopyrite.

On constate ainsi que la dissolution du cuivre à partir de la chalcopyrite est certainement favorisée par la présence de la pyrite, ce qui conforme au résultat du rapport précédent[2]. Les effets de la pyrite sur la dissolution de la chalcopyrite qui ont été trouvés en milieu à pH 2 continuent à exister même à pH 1. Le coefficient de concentration du cuivre par rapport au fer, au cours de la dissolution du minerai, est exprimé par la relation suivante et calculé d'après le résultat d'expériences effectuées en milieu acide 0,01 N. Le coefficient soit $r$, et on a:

$$r=\frac{(Cu/Fe)_{soln.}}{(Cu/Fe)_{min.}}=\frac{51\times10^{-2}}{7{,}75\times10^{-2}}=6{,}6$$

où $(Cu/Fe)_{soln.}$ est le rapport de vitesse de dissolution du cuivre sur celle du fer, et $(Cu/Fe)_{min.}$ est le rapport de teneur en cuivre du minerai sur celle en fer. Ce chiffre n'est pas très éloigné de 10,6, chiffre prévu d'après les expériences effectuées sur le mélange de la pyrite et de la chalcopyrite. Toutefois il n'est pas facile à dire par quelle raison cet écart peut être expliqué. Comme cet écart peut être attribué, d'une part, aux effets des substances co-existantes, telles que la blende, et d'autre part, à l'individualité du minerai, une étude plus approfondie est exigée pour la mise en évidence de la cause de l'écart. Il est probable que les impuretés contenues dans le minerai détermine son individualité, par conséquent on ne peut pas passer des études des composants mineurs.

D'après le Tableau IV, la valeur de $(Cu/Fe)_{soln.}$ est d'autant plus grande que le pH du milieu est plus petit, d'où on désigne comme facteurs intervenant à la dissolution du cuivre à partir de la chalcopyrite située dans la zone d'oxydation les suivants: pH, co-présence de la pyrite et concentration de fer en solution. Comme il a été signalé dans le rapport précédent,[2] l'influence de fer en solution devient remarquable, lorsque sa concentration dépasse 100 mg./l. Il faut qu'on tienne compte de la température, de la pression et de la co-présence des autres substances que la pyrite, mais l'état actuel des recherches ne permet pas de discuter davantage sur ces facteurs de milieu.

*Zinc.*—Le travail effectué par Ohashi a montré que la dissolution de la blende est accélérée par la présence de la pyrite et de la chalcopyrite[3]. Les effets du pH se joignant à ceux de la présence de ces minéraux, le phénomène de la dissolution du zinc a un aspect très compliqué, par conséquent la formation de l'acide par la désagrégation des minerais sulfurés est un facteur non-négligeable, tant qu'on traite la dissolution de ce métal.

**Expérience de Dissolution Effectuée en Milieu Exempt d'Oxygène.** — Le résultat obtenu est porté sur le Tableau V. Comme on a prévu d'après les résultats d'expériences concernant

| | | 4 | 33,6 | 0,2 | 1,6 | 84 |

la dissolution de la pyrite et de la chalcopyrite, la formation du sulfate n'a pas lieu. Au reste, l'indissolution du fer attire notre attention. Il peut y avoir là les influences de la co-présence des minéraux. On remarque encore que sous les conditions acides et non-oxydantes le comportement du cuivre est différent de celui du zinc.

*Cuivre.*—L'échantillon utilisé étant partiellement oxydé par la pulvérisation, une petite quantité de cuivre se dissout au début du traitement, même en milieu exempt d'oxygène. La concentration de cuivre diminue, pourtant, avec la durée du traitement. De ces expériences on ne peut tirer les matières suffisantes pour avoir des idées claires sur le mécanisme de la fixation du cuivre. Il se peut que l'hydrogène sulfuré, formé par l'action de l'acide sur le minerai sulfuré, cause la précipitation ou l'adsorption du cuivre sous forme de sulfure. Ce phénomène se produit même à pH 1, ce qui souligne que la dissolution du cuivre à partir des minerais sulfurés est peu possible dans les conditions acides et non-oxydantes, et que le contact des eaux contenant des ions de cuivre avec un minerai sulfuré conduit à la fixation du cuivre, si le milieu est caractérisé par l'absence de l'oxygène. On reconnaît la fixation de ce métal dans le phénomène de l'enrichissement secondaire du minerai cuprifère. Bien que cette fixation est réalisée par l'expérience, il est difficile d'éclaircir par le moyen de laboratoire les réactions qui prennent part à l'enrichissement secondaire du cuivre.

*Zinc.*—Le comportement du zinc en milieu à pH 1 n'a pas de ressemblance avec celui du cuivre: le zinc n'a pas de tendance à être fixé au cours du traitement. A pH supérieur à 2, la concentration de zinc commence à diminuer avec la durée du traitement. On en déduit la précipitation ou l'adsorption du zinc sous forme de sulfure, analogue à celle du cuivre. Toutefois la vitesse de fixation du zinc est moins grande que celle du cuivre. Ce fait est expliqué par la différence de la propriété chimique des deux métaux.

L'explication des réactions chimiques participant à l'enrichissement secondaire et l'examen des facteurs de milieu intervenant à ce phénomène composeront la suite des études de cette série.

**Résumé**

Les facteurs favorisant la dissolution du cuivre à partir de la chalcopyrite sont les suivants: condition acide et oxydante, co-présence de la pyrite et contact avec l'ion de fer. Ils favoriseraient également la dissolution du zinc à partir de la blende. On peut bien expliquer la dissolution du minerai jaune, en prenant ces facteurs en considération.

L'auteur se permet d'adresser ses remerciements sincères à Monsieur le professeur Noguchi qui a bien voulu lire le manuscrit de ce rapport et aux chercheurs du laboratoire qui lui ont conseillé au cours de l'exécution de ce travail. Il remercie particulièrement Monsieur H. Kamiya pour la collaboration précieuse. Il remercie aussi Monsieur le professeur T. Watanabé et Monsieur le docteur A. Kato, à l'Université de Tokyo, pour l'examen diffractométrique à rayons X de l'échantillon ainsi que les renseignements utiles sur les propriétés des minerais sulfurés.

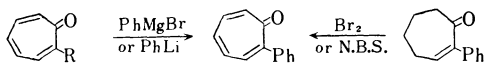
# *Synthesis of 2-Phenyltropone and its Bromo-derivatives from 2-Phenylsuberone*[1]

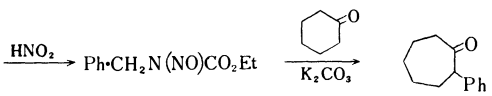


By Tadashi MUROI*

(Received December 22, 1959)

Nozoe, Mukai and their collaborators[2,3] have already reported that 2-phenyltropone (I) is obtained by the reaction of tropolone methyl ether and phenylmagnesium bromide in a good yield. Doering and others[4,5] have also obtained I by the treatment of tropolone and its derivatives with phenylmagnesium bromide or phenyllithium. On the other hand, it is well known that[6-9] various troponoid compounds are derived from cycloheptanons by their direct bromination-dehydrobromination. Nozoe and Ito[10,11] have obtained bromo-derivatives of I by the reaction of bromine and 2-phenylcyclohept-2-enone derived from cycloheptanone. Ginsburg and others[12] have also obtained I by the application of *N*-bromosuccinimide to 2-phenylcycloheptenone.

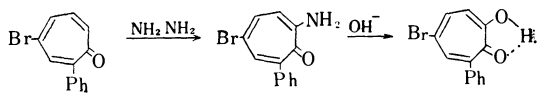
The present author has examined the reaction of 2-phenylsuberone (II) and bromine, and obtained I and its bromo-derivatives in a good yield. This paper describes these results.



2-Phenylsuberone (II) was prepared by the treatment of cyclohexanone with phenyldiazomethane derived from benzylamine according to Gutsche's method[13].

(I)

R=-OH, -OCH$_3$, -O 1/2 Cu or -Cl



(II)

Scheme 1

When three molar equivalents of bromine were added dropwise into a solution of II dissolved in glacial acetic acid, the reaction of bromine proceeded smoothly with the liberation of hydrogen bromide, and yellow needles (III), decomp. p. 185~187°C, were yielded. By the treatment with water, III was decomposed to give yellow needles (IV) m. p. 91~92°C. The yield of IV is about 30% calculated from II. From the mother liquor, a small amount of I was obtained.

Previously, Nozoe and others[10] confirmed the structure of 4-bromo-2-phenyltropone (IV) by deriving from it 5-bromo-3-phenyltropolone (V) through 7-amino-4-bromo-2-phenyltropone (VI). The present author has also obtained V from IV by the same treatment, and the melting point and the ultraviolet spectrum of IV (Fig. 1) are also identical with those of 4-bromo-2-phenyltropone[10]. It is obvious, therefore, that III is a hydrogen bromide adduct of 4-bromo-2-phenyltropone.

(IV) (VI) (V)

Scheme 2

In some cases, especially, when the reaction was carried out at a lower temperature, a small amount of colorless needles (VII), m. p. 155~156°C and colorless needles (VIII), m. p. 128~129°C were obtained besides IV and I. Though the details of the structure of VII and VIII are not clarified yet, each of them has been proved to be a dibromo-derivative of II from their analytical value.

When four molar equivalents of bromine

were applied to II, it was found that the yield of IV increased remarkablly to about 80%. In this case, moreover, yellow needles (IX), m. p. 117~118°C, and yellow acid crystals (X), decomp. p. ca 200°C, were obtained, though in a small amount.

The reaction of five molar equivalents of bromine and II was found to be somewhat complicated. In this case, prolonged heating and stirring were required to complete the reaction, and the yield of IX was increased to about 78%. From the neutral portion of the mother liquor, besides IX and IV, the following compounds were obtained: pale yellow plates (XI) m. p. 79~80°C pale yellow needles (XII) m. p. 112~113°C and colorless needles (XIII) m. p. 149~150°C. From the acidic portion, a fair amount of X was obtained.

Previously, Mukai[14] reported that a dibromo-derivative of I was obtained by the decomposition of 4, 4, 5, 6, 7-pentabromo-2-phenyl-2-cyclohepten-1-one (XIV) which was derived from IV, and that its structure was assumed to be 4, 7-dibromo-2-phenyltropone.

Scheme 3

The author also obtained IX by the bromination of IV as Mukai reported, and moreover found that, when IX was treated with dilute alkali, it easily rearranged itself to give 4-bromo-2-phenylbenzoic acid (XV)[15]. Therefore, IX seems to be 4, 7-dibromo-2-phenyltropone as Mukai assumed.

The crystal (XI) was proved to be identical with the authentic sample of 7-bromo-2-phenyltropone[12] by the mixed melting point.

The crystal (XII) was found to be a tribromo-derivative of I from its analytical value and U. V. spectrum, (Fig. 1) and it was also obtained from XIV by treating with pyridine. When XII was heated for a long period with 75% sulfuric acid, it gave 5, 7-dibromo-4-hydroxy-2-phenyltropone (XVI)[16], whose structure was confirmed by deriving from it 5, 7-dibromo-4-methoxy-2-phenyltropone (XVII)[16]. It was also found that, by heating with dilute alkali, XII was easily rearranged to give colorless needles of m. p. 180~181°C of 4, 5-dibromo-2-phenylbenzoic acid (XVIII). These facts, therefore, indicated that XII was 4, 5, 7-tribromo-2-phenyltropone.

The crystal (XIII) was a tetrabromo-derivative of 2-phenylsuberenone. When XIII was heated to effect dehydrobromination, it gave IX. It is, therefore, found that two of four bromine atoms of XIII, at least, are presented in the C-4 and C-7 position, and XIII is probably one of the intermediate products in the formation of IX from II.

Though the detailed studies on the acidic product (X) will be described in the near future, it will be noted here that X is a mixture of 7-bromo-4-hydroxy-2-phenyltropone-(XIX) and XVI, and that they are isolated from each other with difficulty.

Even when five molar equivalents of bromine were applied to II, the formation of X was very small, if the addition of bromine was carried out at 30~60°C and the duration of heating was shortened. In this case,. the yield of IX was about 30% and that of XIII proved to be increased.

In order to prevent the formation of X completely, II was treated with five moles of bromine in a mixture of acetic acid and acetic anhydride but a considerable amount of X was still found in the acidic portion. In this case, IV was obtained mainly in about 30% yield but IX was in poor yield and, moreover, a trace of yellow needles (XX) m. p. 144~145°C was obtained. This compound XX was proved to be a monobromo-derivative of I from its analytical value and U. V. spectrum (Fig. 1) and gave by the further bromination a dibromo compound XXI as pale yellow needles m. p. 141~142°C.

As it is known that, on the bromination of tropone derivatives, the bromine atom enters at the carbon atoms adjacent to the carbonyl carbon (i. e., C-2 and C-7) preferentially[14,17], at least the one of bromine atoms of XXI was assumed to be in the C-7 position. It was proved, however, that XXI was identical

14) T. Mukai, *Science Repts. Tohoku Univ.*, I, 38, 280 (1954).

with neither 3, 7-[18], 4, 7-, 5, 7-[14] and 6, 7-dibromo-derivative[14] of I. Therefore, the other bromine atom of XXI, i.e., that of XX is assumed not to be in the tropone nucleus but in the phenyl group.

In the above reactions, the yield of I was poor but, as it is known that IV is easily debrominated to give I, this reaction is considered to be a useful synthetic method for the preparation of I. As the mechanism of this reaction is not clarified yet this is considered to be an interesting question in future.

## Experimental[19]

**Action of Bromine on 2-Phenylsuberone (II).**—II was prepared according to the description of "Organic Syntheses"[13], and the fraction of b. p. 110~111°C/0.3~0.4 mmHg; $n_D^{27}$: 1.5390, was used[20].

**a) Application of 3 Molar Equivalents of Bromine.**—i) To a solution of 4.7 g. of II in 7.5 cc. of acetic acid, a mixture of 12 g. of bromine and 2 cc. of acetic acid was added dropwise with stirring for a period of 1 hr. at 30~40°C. After the addition, the reaction mixture was heated on a water bath to about 80°C and kept at the same temperature for 30 min. and then yellow crystals were separated out. Additional heating and stirring were continued until there was no liberation of hydrogen bromide. After cooling, the crystals were collected by filtration and washed with a small amount of acetic acid and benzene, successively. Yellow crystals (III) decomp. p. 185~187°C, 3.7 g. were obtained. On standing overnight, the filtrate gave the second crop of III, 0.28 g. When III was treated with about 50 cc. of water, 2.3 g. of pale yellow crystals were obtained. Recrystallization from alcohol or methanol gave yellow needles (IV) m. p. 91~92°C.

Found: C, 60.06; H, 3.63. Calcd. for $C_{13}H_9OBr$: C, 59.74; H, 3.74%.

The mother liquor was evaporated under reduced pressure and the residue, treated with water, was extracted with chloroform. The extract was washed with 10% sodium carbonate solution. After the removal of the solvent, the residual oil, dissolved in a mixture of benzene and petroleum ether (1 : 1), was chromatographed through a silica-gel column. It was eluted successively with a mixture of benzene and petroleum ether, benzene, chloroform and alcohol. From the chloroform eluent, 0.2 g. of raw crystals of I was obtained but the other eluent gave no crystals.

Acidification of the sodium carbonate solution gave no crystalline products.

ii) As in the above case, 4.7 g. of II in 7.5 cc. of acetic acid was treated with 12 g. of bromine dissolved in 2 cc. of acetic acid. In this case, however, heating was stopped at ones when the separation of III occurred. After cooling, III was collected by filtration and treated with water to give 2.0 g. of IV. The filtrate, after standing for a few days, gave 0.22 g. of pale yellow crystals, m. p. 115~120°C. This was decomposed with water to give colorless crystals m. p. 175~180°C. Recrystallization from alcohol or benzene gave sparingly soluble colorless needles (VII) m. p. 155~156°C and comparatively soluble colorless needles (VIII) m. p. 128~129°C, respectively.

Found for VII: C, 45.41; H, 3.95. Calcd. for $C_{13}H_{14}OBr_2$: C, 45.12; H, 4.08%.

Found for VIII: C, 45.23; H, 3.97. Calcd. for $C_{13}H_{14}OBr_2$: C. 45.12; H, 4.08%.

After being treated as in i), the mother liquor gave 0.5 g. of I.

**b) Application of 4 Molar Equivalents of Bromine.**—To a solution of 4.7 g. of II in 7.5 cc. of acetic acid, 16 g. of bromine dissolved in 2.7 cc. of acetic acid was added dropwise during about 1.5 hr. at 30~60°C. In this case, when treated as in a), it gave three kinds of crystals from the neutral portion as follows: 5.2 g. of IV, 0.28 g. of IX and a small amount of I. Recrystallization of IX from alcohol gave yellow needles, m. p. 117~118°C.

Found: C, 45.68; 2.38. Calcd. for $C_{13}H_9OBr_2$: C, 45.93; H, 2.36%.

The acidic portion gave yellow crystals (X) decomp. p. 185~190°C, 0.02 g.

**c) Application of 5 Molar Equivalents of Bromine.**—i) To a solution of 4.7 g. of II in 7.5 cc. of acetic acid, 20 g. of bromine dissolved in 3.5 cc. of acetic acid was added dropwise over a period of 2.5 hr. at 30~65°C. After the addition, the mixture was heated on a water bath for 4 hr., until there was no liberation of hydrogen bromide. By chilling with ice no crystals were separated out, then the solvent was distilled off under reduced

19) M. p. are uncorrected. The microanalyses and the measurement of U. V. spectra were carried out by Mrs. K. Kodaira of Tohoku University, to whom the author's deep gratitude is hereby expressed.

20) The fractional distillation of II was carried out at Kitahara's Laboratory in the Chemical Research Institute of Non-aqueous Solution, Tohoku University, using the Stedtmann type fractional column (40 plates). The author expresses hereby his deep gratitude to Professor Yoshio Kitahara for his kindness.

pressure. The residue, decomposed with water, was extracted with chloroform. After washing the extract with 10% sodium carbonate solution, the solvent was evaporated off. The residual oil (10 g.), digested with alcohol or ether, gave 0.9 g. of IX m. p. 113~115°C. After being treated as in a) i), the mother liquor was chromatographed through a silica-gel column. The benzene-petroleum ether eluent gave 1.0 g. of XIII, 0.8 g. of XII and 1.0 g. of IX, successively.

Recrystallization of XIII from alcohol gave colorless needles m. p. 149~150°C.

Found: C, 31.49; H, 2.13. Calcd. for $C_{13}H_{10}OBr_4$: C, 31.11; H, 2.00%.

Recrystallization of XII from alcohol gave pale yellow needles m. p. 113~114°C.

Found: C, 37.41; H, 1.19. Calcd. for $C_{13}H_7OBr_3$: C, 37.28; H, 1.99%.

The benzene eluent gave 0.6 g. of IX, 0.7 g. of IV and 0.1 g. of XI, successively. From the chloroform eluent, 0.1 g. of I was obtained, acompanied with a resinous substance. Alcohol eluent did not give any crystals.

In this case, the alkaline washing solution gave no crystals by acidification.

ii) To a solution of 4.7 g. of II in 7.5 cc. of acetic acid, 20 g. of bromine dissolved in 3.5 cc. of acetic acid was added. About 3/4 vols. of bromine solution was added at 40~75°C for a period of 1.5 hrs., then yellow crystals were separated out. These were dissolved again in a dark red solution when the rest of the bromine was added at 85°C. The mixture was further heated for 6 hr. until there was no liberation of hydrogen bromide. After cooling, the yellow crystals (a) thereby separated were collected by filtration. There were digested with benzene and an insoluble portion (b) was filtered off. The filtrate was shaken with 10% sodium carbonate solution and the aqueous layer was combined with (b). This alkaline solution, after being treated with active carbon, was acidified to give 0.27 g. of X, m. p. 200~205°C. The benzene layer, after removal of the solvent, left a crystalline residue which was recrystalized from alcohol or ether to give 4.5 g. of IX.

The mother liquor of (a), treated as in a, i), gave the following crystals: 1.0 g. of IX, 0.44 g. of X, 0.1 g. of XI, 0.2 g. of XII and 0.15 g. of XIII.

iii) To a solution of 4.7 g. of II in 7.5 cc. of acetic acid and 2.5 cc. of acetic anhydride, 20 g. of bromine dissolved in 3.5 cc. of acetic acid was added as in the above case. In this case, no crystals were separated during the reaction. On cooling, 5.3 g. of III was obtained and this was decomposed to 3.1 g. of IV. After being treated as in a, i), 0.2 g. of X was obtained from the 10% sodium carbonate soluble part of the mother liquor. The chromatographic separation of the neutral substance gave successively the following crystals: 0.35 g. of IX, 0.40 g. of IV, 0.15 g. of XX and 0.1 g. of I.

The recrystallization of XX from methanol gave yellow needless of m. p. 144~145°C.

Found: C, 60.29; H, 3.58. Calcd. for $C_{13}H_9OBr$: C, 59.79; H, 3.47%.

**Action of Hydrazine on 4-Bromo-2-phenyltropone (IV).** — A mixture of 0.2 g. of IV, 0.2 cc. of 80% hydrazine hydrate and 2 cc. of alcohol was refluxed on a water bath for 30 min., and the crystals that separated out were collected by filtration. Recrystallization from alcohol gave orange yellow needles of VI, m. p. 210°C.

A mixture of 0.08 g. of VI, 0.3 cc. of 6 N sodium hydroxide solution and 1.6 cc. of alcohol was refluxed for 3 hr. The alcohol was distilled off, the residue was acidified, and the precipitate thereby formed was recrystallized from methanol to give yellow needles of m. p. 135~136°C. This was found to be identical by mixed fusion with the authentic sample of 5-bromo-3-phenyltropolone (V)[10].

**Bromination of 4-Bromo-2-phenyltropone (IV).** — To a solution of 2.6 g. of IV in 40 cc. of acetic acid, 4.8 g. of bromine in 5 cc. of acetic acid was added and this mixture was allowed to stand over night. The crystals that separated out were collected and recrystallized from alcohol and benzene to give colorless prisms of XIV, m. p. 121~122°C (decomp.). Yield, 4.7 g.

Found: C, 27.26; H, 1.68. Calcd. for $C_{13}H_9OBr_5$: C, 26.89; H, 1.56%.

The filtrate was evaporated under reduced pressure and the residue, after being treated with water, was extracted with benzene. After removal of solvent, the extract left a crystalline residue which was recrystallized from alcohol to give yellow crystals of m. p. 110~113°C. This showed no depression of melting point on admixture with IX obtained in the above cases.

**Decomposition of 4,4,5,6,7-Pentabromo-2-phenyl-2-cyclohepten-1-one (XIV).** — i) By heating 0.15 g. of XIV in an oil bath at 120~130°C for 10 min., XIV melted with effervescence and underwent decomposition to an oil. After cooling, this was dissolved in benzene and washed with a diluted sodium hyposulfate solution. The benzene layer, after the removal of solvent, left a crystalline residue that was recrystallized from alcohol to give yellow crystals of m. p. 116~117°C, undepressed on admixture with IX. Yield, 0.05 g.

ii) A mixture of 0.58 g. of XIV, 0.6 cc. of pyridine and 0.3 g. of benzene was heated for 15 min. at 55~60°C. This was diluted with water and extracted with benzene. The extract after evaporation, left yellow crystals. Recrystallization from alcohol gave yellow needles of m. p. 112~113°C, undepressed on admixture with XII obtained above.

**Action of Alkali on 4,7-Dibromo-2-phenyltropone (IX).**—A mixture of 0.06 g. of IX, 1.5 cc. of alcohol and 1 cc. of 2 N sodium hydroxide solution was refluxed on a water bath for 30 min. After the removal of solvent it was acidified and extracted with benzene. The benzene layer gave colorless crystals that were recrystallized from cyclohexane to give XV as colorless needles of m. p. 173~175°C.

Found: C, 56.75; H, 3.47. Calcd. for $C_{13}H_9OBr$: C, 56.34; H, 3.27%.

**Action of Alkali on 4,5,7-Tribromo-2-phenyltropone (XII).**—A mixture of 0.05 g. of XII, 0.7 cc. of alcohol and 0.5 cc. of 2 N sodium hydroxide was refluxed on a water bath for 15 min. This, treated as in the above case, gave colorless needles of XVIII, m. p. 180~181°C.

Found : C, 43.76 ; H, 2.15. Calcd. for $C_{13}H_8O_2Br_2$ : C, 43.76 ; H, 2.26%.

**Action of Sulfuric Acid on 4, 5, 7-Tribromo-2-phenyltropone(XII).**—A solution of 0.25 g. of XII and 2.5 cc. of 75% sulfuric acid was heated for 10 hr. at 170~180°C. This was poured into about 20 cc. of ice water, and thereby precipitated crystals were collected. The crystals, after being dried, were washed with benzene and dissolved in 10% sodium carbonate solution. After being treated with active carbon, the solution was acidified and 0.1 g. of yellow crystals of d. p. ca 190°C were obtained. This was treated with a 2.8% diazomethane-ether solution and the thereby obtained oily product was dissolved in a mixture of benzene and petroleum ether. This was chromatographed on a silica-gel column and gave yellow crystals of m. p. 128~129°C. Recrystallization from methanol gave yellow needles of m. p. 131~132°C, which showed no depression with authentic sample of XVI.

**Thermal Decomposition of 4, 7, *x*, *x*-Tetrabromo-2-phenylsuberenone(XIII).** — By heating 0.12 g. of XIII on an oil bath for 20 min. at 150~160°C, it melted and underwent decomposition. The fused mass, dissolved in benzene, was washed sufficiently with water. The benzene solution was passed through a silica-gel column and yellow needles of m. p. 117~118°C were obtained. These showed no depression on admixture with IX obtained above.

**Bromination of *x*-Bromo-2-phenyltropone(XX).** —To a solution of 0.06 g. of XX in 1 cc. of acetic acid, 0.06 g. of bromine was added and the whole was heated on a water bath for 30 min. Then this was diluted with water and extracted with chloroform. After the removal of solvent, this gave colorless crystals of m. p. 135~140°C, which were recrystallized from benzene or alcohol to give pale yellow needles, m. p. 141~142°C.

Found : C, 45.94 ; H, 2.36. Calcd. for $C_{13}H_8OBr_2$ : C, 45.93 ; H, 2. 36%.

The author takes this opportunity to express his sincere gratitude to professor Tetsuo Nozoe of Tohoku University for his guidance and encouragement throughout the course of this work, to Professor Shuichi Seto, Professor Yoshio Kitahara and Assistant Professor Toshio Mukai for much helpful advice, and to assistant Professor Katsuo Kikuchi of Yamagata University for his kind discussion and helpful advice.

# *Stereoregular Polymers. VI. Copolymerization with the Ziegler Catalysts**

By Shunsuke MURAHASHI, Shun'ichi NOZAKURA and Masao SUMI

(Received January 5, 1960)

Binary copolymerizations of $\alpha$-olefins, which are known individually to form isotactic polymers with the Ziegler catalyst, were investigated to see if stereospecific copolymerization could be seen to yield crystalline copolymers.

Although there are a number of reports by Natta and his collaborators on copolymerization of propylene and ethylene with complex catalysts of the Ziegler type[1], one of the comonomers was always ethylene and this has substantially no concern with the assymmetricity on the polymer. Besides, ethylene has markedly higher activity towards the anionic polymerization as compared to propylene, and their efforts were apparently directed towards the study of amorphous copolymers.

In the present work, the situation was distinctly different from that in the case of Natta. Particular attention was directed to the formation of crystalline copolymers, because it was believed that crystalline copolymers could be produced if the isotactic orientation had been held during copolymerization**.

The monomers chosen here are styrene, allyl- and 3-butenyl-trimethylsilane, which are known by the present authors to yield the corresponding isotactic polymers by themselves and to have the similar reactivity towards the Ziegler catalyst[3,4].

## Results and Discussion

**Polymerization.** — Binary copolymerizations were carried out using these monomers with $AlEt_3$-$TiCl_4$ catalyst at 70°C. The results were summarized in Tables I and II.

VSi, the first member of alkenyltrimethylsilane, was found to enter into copolymerization with great difficulty as anticipated from the case of its homopolymerization with the same catalyst, and hence a further study was omitted from our program.

As is shown in Tables I and II, the compositions of the crude polymers varied with monomer compositions and copolymerization appeared at first to have been realized. The apparent monomer reactivities towards the Ziegler catalyst was found to be in the order of St > BSi > ASi ≫ VSi.

**Fractionation of the Crude Polymers.** — As these copolymers showed some degree of crystallinity on X-ray diffraction patterns, fractionations were carried out with a series of solvents selected from the knowledge of the solubility characteristics of the individual crystalline homopolymers. (Table III).

TABLE III. SOLUBILITY CHARACTERISTICS OF ISOTACTIC POLYMERS OF St, ASi AND BSi

| | *n*-Heptane | Toluene | Decalin |
|---|---|---|---|
| Poly(BSi) | Sol. in hot | Sol. | Sol. |
| Poly(St) | Insol. | Sol. in hot | Sol. |
| Poly(ASi) | Insol. | Insol. | Sol. in hot |

Thus, a St–BSi copolymer was fractionally extracted with a series of solvents: acetone, ether, methylethylketone, *n*-heptane and toluene under reflux in this order. The results are shown in Table IV in which was included, for reference, the results of model fractional extractions of an artificial mixture of two homopolymers, showing practically a complete separation of the crystalline parts into the original components. The acetone-, ether- and methylethylketone-soluble fractions of the copolymer are all found to give almost amorphous X-ray diffraction patterns, while both the *n*-heptane- and the toluene-fraction are found to give crystalline patterns. Analytical data of the last two fractions show that the *n*-heptane-fraction is closely similar to isotactic poly(BSi) with a minor amount of St, while the toluene-fraction is similar to isotactic poly(St) with a minor amount of BSi. The amount of the minor ingredient (St) in the former fraction showed no appreciable change even after repeated purification, that is, extraction with methylethylketone followed by dissolution of the residue into hot *n*-heptane and reprecipitation by cooling the solution. Therefore, it

* The theoretical Si content of BSi and ASi are 21.90 and 24.59%, respectively. The analysis of the fractions was carried out on a microscale.

was concluded that the *n*-heptane-fraction might not be a mixture but a genuine copolymer. It was also found that the same was held to be the case by the latter fraction.

An additional evidence for the copolymeric character of the two crystalline fractions is the change of their compositions with the fed monomer compositions. By increasing the silane content in monomer composition, the silane content of both the *n*-heptane- and the toluene-fraction increased.

Thus, it was confirmed that the crystalline portion of the St–BSi polymer consisted of two kinds of crystalline copolymers of quite different compositions, that is, both a crystalline copolymer with a predominant portion of one component and another crystalline copolymer of another predominant component were produced side by side.

Similar results hold in the copolymerization with the combinations of St–ASi and ASi–BSi (Tables V and VI), though in the latter case the pair selected was of very similar monomers.

From these results, one might postulate that the catalyst surface might possess two kinds of isotactically active sites for each monomer. One kind of the sites is more favorable to polymerize one monomer than other monomers and this is true of other site. More generally, one might say that the catalytic surface possesses several different kinds of active sites suitable for some kinds of monomers. Copolymerization would have taken place on such sites, leading to the crystalline copolymers of different compositions.

An alternative interpretation might also be possible where the nature of an active site may not have been set specifically beforehand at the time when the catalyst is formed, and may become specific after the first attack of a monomer molecule on the catalyst site.

It may not be easy to distinguish which of the two alternative mechanisms is more favorable in our case, but the following experimental results seems to show that the former mechanism might be more favorable. It was demonstrated in one experiment where a small amount of one monomer (about 1millimole) was added preliminarily to the catalyst at 70°C, and after 20 minutes of polymerization a mixture of two monomers St and ASi (20 millimole : 20 millimole) was then added. Two runs that were carried out by the preliminary addition of St in one case and ASi in another case resulted in practically the same distribution of fractions in the extraction experiment.

**X-Ray Examination of the Crystalline Fractions.**—In the case of the copolymerization of St and BSi, for instance, the *n*-heptane- and the toluene-fraction showed some degree of

crystalline patterns on X-ray diagrams. X-Ray powder patterns of these two fractions were compared with those of two homopolymers and of the artificial mixtures of similar compositions. The same comparison was also made in other cases. X-Ray spectra of St–ASi copolymers, St–BSi copolymers, and ASi–BSi copolymers were shown in Figs. 1, 2 and 3, respectively***.

From the close inspection of these results, it was found that in some cases the patterns closely resemble those of artificial mixtures of the similar compositions (Figs. 1a and 1b), some had a new kind of additional reflections over those of artificial mixtures or a superposition of homopolymers (Figs. 2a and 3a), and others showed only very diffuse reflections of one homopolymer (Figs. 2b and 3b). These facts might suggest the possible existence of constitutional varieties in copolymers with the change of monomer species, that is, one copolymer might have a structure of block copolymer and another might have a structure of random copolymer. For instance, the decalin-fraction (Fig. 1a) of St–ASi copolymer has a rather high crystallinity which is comparable to that of poly(ASi) and shows a diffraction pattern that is closely similar to an artificial mixture of the same composition, suggesting a block structure. If it were a random copolymer, incorporation of about 20% of St units, as is the case, would almost destroy the crystallinity of the copolymer.

## Experimental

**Materials.**—A commercial styrene was purified according to the usual method[5].

Vinyl-, allyl, and 3-butenyl-trimethylsilane are prepared and purified just as described in the previous paper[3].

$AlEt_3$ and $TiCl_4$ are the products of Mitsui Chem. Ind. Co. and Osaka Titanium Co., respectively and were used as about 30 and 21% solutions in *n*-heptane.

**Polymerization.**—Polymerization was carried out without agitation in an apparatus described in the previous paper[6]. The solution of $AlEt_3$ was added first to *n*-heptane in the apparatus under nitrogen, and mixed, and then the solution of $TiCl_4$ was dropped slowly along the wall of the vessel. After ten minutes, the mixed monomers were added and polymerization was carried out without agitation.

Polymerization was stopped by the addition of methanol (2 ml.) and concentrated hydrochloric acid (0.3 ml.), and the mixture was poured into a large amount of methanol. After being kept overnight, the polymer was collected, washed with methanol and dried.

**Fractionation of the Crude Copolymers.** — Hot extraction was carried out at the boiling temperature of the solvents, using a modified Soxhlet extraction apparatus. Complete extraction with one solvent generally took about seven to ten hours. After the completion of one extraction, the extraction cup with the residual polymer in it was dried, and was subjected to the next extraction. Each extract was concentrated to about 50 ml. and poured into a large amount of methanol, and the precipitate was collected, washed and dried.

Purification of the crystalline fraction, for example, the *n*-heptane fraction of St–BSi copolymer was carried out as follows: the fraction (Si, 20.08%) was extracted with methyl ethyl ketone, and dissolved in hot *n*-heptane. The hot solution, after being filtered through a glass filter, was poured into a large amount of methanol. The precipitated polymer was collected, washed and dried in vacuum at about 100°C (Si, 19.92%). The toluene fraction (Si, 1.80%) of the polymer was also purified by extraction with *n*-heptane followed by dissolution in toluene and reprecipitation with methanol, giving the silicon content of 1.40 and 1.48%, successively.

**Preparation of Artificial Mixture of Homopolymers.** — Generally, a mechanical mixture of two kinds of polymers was dissolved in a hot solvent common to them and poured quickly into a large amount of methanol and then the precipitate was collected.

**Determination of Copolymer Composition.**—The composition of copolymers was determined by the gravimetric analysis of silicon. Analysis was carried out by wet digestion with fuming sulfuric acid in a platinum crucible. The ignited silica was ascertained by treating it with 60% hydrofluoric acid.

**X-Ray Study.** — All samples were annealed at 150~160°C for 2 hr. The diffraction patterns were taken using nickel filtered Cu$K\alpha$ radiation. The film distance was 4.45 cm.

## Summary

Binary copolymerization of styrene, allyltrimethylsilane and 3-butenyltrimethylsilane was investigated using the Ziegler catalyst at 70°C. It was found to be possible to separate the crystalline part of copolymers by fractional extraction into two kinds of genuine crystalline copolymers, each of which has an extremely different composition from the other.

The nature of the active sites on the catalytic surface was discussed in order to elucidate the above fact.

The constitution of the individual crystalline fractions appeared to vary case by case, i. e., the structure of blockcopolymer might be assigned to some cases and random copolymers to some other cases.

*Nakanoshima, Kita-ku, Osaka*

*** Since the exact copolymer composition was not obvious in the case of ASi-BSi copolymer because of the small difference of silicon content between ASi and BSi units, comparison with artificial mixtures was not indicated in the list.

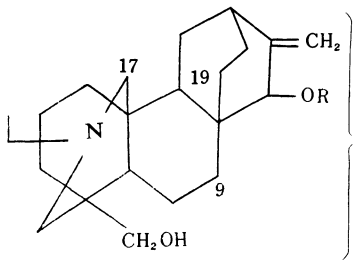
# *The Aconite Alkaloids. XXXIV*[1]*. On Lucidusculine. Part IV*[2]

By Takashi AMIYA

(Received January 6, 1960)

In previous reports[3,4] the partial formula of lucidusculine (I), $C_{24}H_{35}O_4N$, has been summarized as[5],

$C_{16}H_{20}$ { $CH_2OH$, $OCOCH_3$, $>CH(OH)$ (six-membered ring), $>NC_2H_5$, $>C=CH_2$ }



(I)

Moreover, luciculine (II), $C_{22}H_{33}O_3N \cdot H_2O$, which is yielded from compound I by hydrolysis and hence is a sort of trihydric amino alcohol, has been shown to possess an allyl alcohol moiety in its six-membered ring[6].

On the other hand, on dehydrogenation of compound I, phenanthrene and its homologues were obtained by Suginome and Kakimoto[7] in this laboratory.

Under the same conditions as in the case of isomerization of compound II to isoluciculine (III)[6], compound I was found not to isomerize. Instead, a certain compound IV was formed. This compound did not crystallize. It seemed to be a dihydro compound. In the infrared spectrum, compound IV gave no band characteristic of a ketone carbonyl group in a six-membered ring near 5.8 $\mu$ but it did give a band characteristic of an ester carbonyl group. No absorption band near 11 $\mu$, indicative of a terminal methylene group, was observed in the spectrum. On hydrolysis of compound IV by alcoholic potassium hydroxide, an amorphous base V was obtained. In the infrared region, this base showed no band near 5.7~5.8 $\mu$, indicating that carbonyl group, either ester or ketone, was quite absent. The spectrum also showed that no band characteristic of a terminal methylene group near 11 $\mu$ existed. This fact may show that the acetylated hydroxyl group in compound I is the secondary one involved in the allyl alcohol moiety mentioned above. The above hydrogenation seems to proceed similarly to that of Shimoburo base I diacetate[8].

On the basis of these experimental results as well as in view of the structures of other aconite alkaloids, the partial formula of compounds I and II is now represented in Fig. 1.

(I) R=Ac
(II) R=H

Fig. 1.

Lucidusculine has been assumed to have a hexacyclic structure[9]. Considering the structures of hypogenavine[10], kobusine[11], ignavine[12], hetisine[13] and songorine[14], the existence of the C-17—C-19 or C-17—C-9 bond seems to be reasonable. Moreover, to complete the structure of compound I, it is necessary to confirm the position of an indefinite secondary hydroxyl group (see Fig. 1).

## Experimental

**Hydrogenation of Lucidusculine (I) with Pd-C.** —Lucidusculine (0.3 g.) was dissolved in 15 cc. of methanol and hydrogenated with 10% palladium-carbon (0.2 g.) at room temperature for 4.5 hr. After removal of palladium-carbon, the solution was evaporated to dryness. On treatment with methanol, the residue was not crystallized. The infrared absorption spectrum in nujol had no peak attributable to a terminal methylene group but

showed the presence of hydroxyl groups (2.92~2.94 $\mu$) and an acetoxyl group (5.80 and 8.10 $\mu$).

**Hydrolysis of Compound IV.** — A solution of compound IV (0.05 g.) and potassium hydroxide (0.15 g.), dissolved in 2 cc. of ethanol and a drop of water, was heated for 1.5 hr. After removal of the solvents, the residue was washed with water. On treatment with methanol, it was not crystallized. The infrared absorption spectrum in nujol had no peak attributable to a terminal methylene group but showed the presence of hydroxyl groups (2.97 $\mu$).

# *Halogen Substitution in Liquid Sulfur Dioxide. I. Formation of Alkyl Halides from Alcohols and Halogens*

By Niichiro TOKURA, Ritsuro TADA and Ryoichi IGARASHI

(Received December 28, 1959)

The writers clarified the point previously[1] that ketoximes undergo rearrangement by the action of a halogen in liquid sulfur dioxide at room temperature. Scheme 1 was tentatively assigned to the mechanism of the rearrangement. The solvation by the solvent (liq. $SO_2$) may favor the ionization of the bromine molecule.

Sheme 1

$$Br_2 \overset{\text{liq. } SO_2}{\rightleftharpoons} Br^+ + Br^- \quad (1)$$

$$\begin{matrix} R \\ R' \end{matrix}\!\!>\!C{=}N{-}OH \xrightarrow{Br^+} \begin{matrix} R \\ R' \end{matrix}\!\!>\!C{=}N^+ + BrOH \quad (2)$$

$$\begin{matrix} R \\ R' \end{matrix}\!\!>\!C{=}N^+ + Br^- \longrightarrow \begin{matrix} R \\ Br \end{matrix}\!\!>\!C{=}N{-}R' \xrightarrow{H_2O} R{-}\underset{\underset{O}{\|}}{C}{-}NHR' \quad (3)$$

$$BrOH + SO_2 \longrightarrow HBr + SO_3 \quad (3)$$

From the structural similarity between alcohols R–C–OH and oximes R–C=H–OH, it is expected that all alcohols have a similar behavior towards bromine in liquid sulfur dioxide and, consequently, the reaction will proceed to form the corresponding alkyl halides. (Scheme 2).

Scheme 2

$$ROH + Br^+ \longrightarrow R^+ + BrOH \quad (5)$$

$$R^+ + Br^- \longrightarrow RBr \quad (6)$$

$$BrOH + SO_2 \longrightarrow HBr + SO_3 \quad (7)$$

1) N. Tokura, R. Asami and R. Tada, *J. Am. Chem. Soc.*, **76**, 3135 (1957).

The borderline nature[2] of liquid sulfur dioxide as a solvent was first recognized by Ingold[2] and, if the reaction follows the SNl mechanism, Eq. 5 being a slow step, the ease of the reaction of alcohols will be in the order of just tertiary, then, secondary, and finally, primary.[3]

A direct substitution of an alcoholic hydroxyl by a bromine atom has been reported to be the case, though only in tertiary alcohols, but this method[4] is not used because of its low yield. Substitution of the hydroxyl in liquid sulfur dioxide by a halogen has already been carried out[5], but with such halogenating reagents as thionyl halides, phosphorus trihalides and pentahalides, liquid sulfur dioxide being used as a solvent because of its excellence.

In expectation of obtaining alkyl halides by direct application of a halogen in liquid sulfur dioxide at room temperature, the lower members of aliphatic and alicyclic alcohols were submitted to the reaction with bromine with the results summarized in Table I.

The total amount of the products increased in the order of primary, secondary and tertiary alcohols. Only small amounts of alkyl halides were obtained from primary alcohols. Higher boiling halides were produced by further

elimination, dimerization and bromination. In all experimants sulfuric acid separated out on the bottom of the reaction vessel. The highest yield was 38.6% of isopropyl bromide, but it was accompanied by a hexyl bromide with a carbon number twice as large as the original alkyl, and most of the butyl bromides were contaminated with butylene dibromides. (Scheme 3)

* more isomers are possible.

Thus, as might be expected, elimination reaction prevails to a considerable extent in liquid sulfur dioxide. The rather complicated feature of the reaction will be understood if the sulfur trioxide produced by the secondary step is assumed to play an important role in the elimination reaction and the dimerization.

$$RBr \rightleftharpoons R^+ + Br^- \longrightarrow \text{Olefin} + H^+\,Br^- \xrightarrow{+Br_2} \text{dibromide}$$

The equilibrium tends to the formation of the dibromide. It is further supported by the fact that phenethyl chloride and bromine in liquid sulfur dioxide afford styrene, polystyrene and styrene dibromide[6].

As the reaction proceeds, sulfur trioxide, formed according to Eq. 7, will favor the formation of the alkyl cation followed by elimination to olefin and sulfuric acid thus produced separates out owing to its slight solubility in liquid sulfur dioxide. Since this is an irreversible reaction, the reaction reaches a final state when the whole acid is precipitated.

In the case of the Beckmann rearrangement, the formation of a nitrogen cation or its ion-pair is the main reaction and no elimination occurs, the secondarily formed sulfur trioxide bearing a lesser meaning.

In the bromination of alcohols by bromine in liquid sulfur dioxide, the decisive factor is the SNl tendency of both alcohols and the solvent. The larger amounts of reaction products from secondary and tertiary alcohols are well consistent with the above consideration.

The writers have no evidence to rule out the participation of hydrogen bromide afforded by Eq. 7 in the bromine substitution reaction. An exact elucidation of the reaction needs further examination.

TABLE III. ACTION OF CHLORINE AND OF CHLORINE WITH A CATALYTIC AMOUNT OF BROMINE

Alcohol: 0.4 mol., Chlorine: 0.4 mol.
Liq. $SO_2$: 100 ml., Time: 5 hr. at room temperature.

| Alcohol | Reagent | Mole ratio of alcohol to halogen | Alkyl chloride b.p., °C | Alkyl chloride Yield, % |
|---|---|---|---|---|
| *n*-Butyl | $Cl_2$ | 1 : 1 | 77~79 | 11.6 |
| | $Cl_2+Br_2$ | 1 : 1 : 0.02 | 77~79 | 11.6 |
| Isobuyl | $Cl_2$ | 1 : 1 | 60~65 | trace |
| | $Cl_2+Br_2$ | 1 : 1 : 0.02 | 60~65 | 2.4 |
| *sec*-Butyl | $Cl_2$ | 1 : 1 | 67~69 | 6.2 |
| | $Cl_2+Br_2$ | 1 : 1 : 0.02 | 67~69 | 3.5 |
| *tert*-Butyl | $Cl_2$ | 1 : 1 | 49~53 | 18.6 |
| | $Cl_2+Br_2$ | 1 : 1 : 0.02 | 49~53 | 17.2 |
| Cyclohexyl | $Cl_2$ | 1 : 1 | 98~102 | 6.5 |
| | $Cl_2+Br_2$ | 1 : 1 : 0.02 | 98~102 | 9.4 |

A considerable isomerization is also expected in the alkyl cation, but the writers are not yet in a position to discuss the structures of the carbon skeletons of the dimeric alkyl bromides produced.

In the bromine substitution of isopropyl alcohol, besides 38.6% of isopropyl bromide, a hexyl bromide, (probably 2-bromo-4-methylpentane) b. p. 42~43°C (20 mmHg) was formed in a yield of 21.2% of the theoretical. This substance afforded a hexyl acetate of b. p. 135~140°C with potassium acetate in glacial acetic acid. Its hydrolysis gave a hexene, $C_6H_{12}$, b. p. 70~73°C, possessing a comphor-like aroma, and a small amount of a hexyl alcohol, b. p. 125~130°C.

Similar phenomena were observed in the reactions of secondary or tertiary butyl alcohols with bromine, large amounts of octyl bromides being formed besides butyl bromides. Further, formation of dibromobutanes were also observed, which are assumed to have been formed by the addition of bromine to butenes produced from butyl cations.

In the alicyclic alcohols, it was observed that the formation of the cycloalkylene dibromides predominated over the cyclohexyl bromides. Thus, cyclohexyl alcohol afforded dibromocyclohexane in a yield of 64.2% and *d*-borneol afforded 71.2% of 2,10-dibromocamphane, indicating that a path through the Wagner-Meerwein rearrangement was followed.

The relation between the yield of the alkyl bromide vs. the amount of bromine was examined with isopropyl alcohol, the results being listed in Table II.

Only a small yield of the products was obtained with hydrogen bromide formed in the liquid sulfur dioxide[7] according to the formula:

$$Br_2 + 2H_2O + SO_2 \longrightarrow 2HBr + H_2SO_4 \quad (16)$$

In the next place, the action of chlorine on aliphatic alcohols was examined. The results shown in Table III indicate that chlorine is not so reactive as bromine, the yields being depressed. Subsequently, a small amount of bromine was added to chlorine (0.02 mol. of bromine to one mol. of chlorine) in expectation of a better result as in the case of the Beckmann rearrangement by chlorine[1] in liquid sulfur dioxide, but it proved ineffective.

## Experimental

**Materials.**—*1. Liquid Sulfur Dioxide.*—Liquid sulfur dioxide, dehydrated and purified in the plant and filled in an iron cylinder, was used. The water content measured in accordance with the principle of the Karl Fischer method

7) J. Ross, T. H. Percy, R. L. Brandt, A. I. Gebhart, J. E. Mitchell and S. Yolles, *Ind. Eng. Chem.*, 34, 924 (1942).

was 0.05~0.2%. This was further dehydrated with concentrated sulfuric acid and then with phosphorus pentoxide to bring the water content below 0.01%. However, practically no difference was found between these two kinds of liquid sulfur dioxide with respect to the reaction,

*2. Alcohols.* — All the alcohols were commercial products of the purest grade, which were dehydrated by the known method and redistilled.

*3. Bromine.* — Commercial bromine was washed with water and with concentrated sulfuric acid, dehydrated, and distilled once.

*4. Chlorine.*—Commercial chlorine was dehydrated with concentrated sulfuric acid and distilled.

*5. Reaction Vessel.*—A glass pressure bottle of 200 ml. capacity was used.

**Experimental Method.**—The amount of alcohols was 0.4 mol. each and that of bromine 0.4 mol. The solution of bromine in 50 ml. of liquid sulfur dioxide was added gradually to 50 ml. of liquid sulfur dioxide containing the alcohol at room temperature (20°C). The mixture was allowed to stand for a definite time. The reaction of secondary and tertiary alcohols occurred at once, the bromine color disappeared immediately, and the liquid sulfur dioxide solution became turbid. Sulfuric acid separated out as a colorless, translucent liquid on the bottom of the pressure bottle. After a definite time (usually 5 hr.), liquid sulfur dioxide was distilled off and the residual liquid was poured into ice water. The unchanged alcohols, especially butyl alcohols and lower aliphatic alcohols, dissolved out in water. The oily layer, after repeatedly being washed with water and with 1 N sodium carbonate solution and again with water, was dried over calcium chloride, and distilled to examine the amount of the lakyl halide formed.

**Results.**—*(A) Reaction of Alcohols with Bromine.*—1. Ethyl alcohol: From the reaction of 18.4 g. (0.4 mol.) of ethyl alcohol and 64 g. (0.4 mol.) of bromine in 100 ml. of liquid sulfur dioxide for 5 hours, 3.0 g. of a bromide was obtained. B. p. 37~38°C. Yield, 2.0 g. (5.3%). $n_D^{26}=1.425$. The bromide was identified with ethyl bromide by deriving propioanilide from it. Namely, the bromide was changed into a Grignard reagent and the latter was treated with phenyl isocyanate, and propionanilide (m. p. 104°C)[8] was obtained, which showed no depression of the melting point on admixture with an authentic specimen.

2. *n*-Propyl alcohol: A mixture of 24.0 g. (0.4 mol.) of *n*-propyl alcohol, 64 g. of bromine, and 100 ml. of liquid sulfur dioxide was kept at 20°C for 5 hr. and 3.0 g. of a crude halide was obtained. Redistillation afforded 2.5 g. (5.1%) of colorless, translucent liquid, b. p. 68~70°C, $n_D^{26}=1.435$. The bromide was identified with *n*-propyl bromide by deriving butyranilide, m. p. and mixed m. p. 91~92°C.[8]

3. Isopropyl alcohol: A mixture of 24 g. (0.4 mol.) of isopropyl alcohol, 64 g. (0.4 mol.) of bromine, and 100 ml. of liquid sulfur dioxide was kept at 20°C for 5 hr. The bromine color disappeared immediately after the starting of the reaction, the whole liquid became orange-colored and turbid, and ca. 10 ml. of a colorless, translucent liquid was deposited on the bottom. After 5 hr. this liquid was collected and titration gave a value corresponding to 13.2 g. of sulfuric acid. Liquid sulfur dioxide was then evaporated, the residual liquid was poured into ice water, and the oily layer was repeatedly washed with water and with 1 N sodium carbonate as described above. The crude halide thus obtained (30.0 g.) was fractionally distilled into the following fractions:

1) b. p. 59~60°C (760 mmHg), $n_D^{26}=1.425$, 19.0 g. (38.6%).

2) b. p. 42~43°C (20 mmHg), $n_D^{26}=1.525$, 7.0 g. (21.2%).

3) Residue, 0.3 g.

Fraction 1 was isopropyl bromide, forming isobutyranilide,[8] m. p. and mixed m. p. 101~102°C. Fraction 2 was a hexyl bromide (Found: Br, 47.9. Calcd for $C_6H_{13}Br$: Br, 48.41). Five grams of Fraction 2 was refluxed with 30 ml. of glacial acetic acid and 5 g. of potassium acetate, and 3.8 g. of a hexyl acetate, b. p. 135~140°C. (Found: $CH_3CO$, 30.11. Calcd. for $CH_3COOC_6H_{13}$; $CH_3CO$, 29.82), was obtained. Hydrolysis of this hexyl acetate by warming with ethanolic potassium hydroxide for 1 hr. afforded an olefin with camphor-like aroma, a hexene, $C_6H_{12}$, b. p. 70~73°C (Found: C, 85.98, H, 14.02, bromine number, 188.0. Calcd. for $C_6H_{12}$: C, 85.63, H, 14.37%, bromine number, 190.5).

Further, 0.3 g. of an oil, b. p. 125~130°C, assumed to be a hexyl alcohol, was obtained. This hexyl bromide may be assumed to be 2-bromo-4-methylpentane.

4. *n*-Butyl alcohol: A mixture of 30.0 g. (0.4 mol.) of *n*-butyl alcohol, 64 g. (0.4 mol.) of bromine, and 100 ml. of liquid sulfur dioxide was similarly treated and 8.0 g. of the product was fractionated, affording 5 g. (7.2%) of *n*-butyl bromide, b. p. 99~101°C, $n_D^{26}=1.440$ (Found: Br, 57.9. Calcd. for $C_4H_9Br$: Br, 58.33%). Valeranilide[8], m. p. and mixed m. p. 62~63°C. Further distillation of the residual

8) R. L. Shriner and R. C. Fuson, "Sstematic Identification of Organic Compounds", John Wiley & Sons, Inc., New York (1948), p. 255.

liquid afforded about 2.5 g. of an oil which boiled over a wide range of 40~90°C at 10 mmHg.

5. Isobutyl alcohol: Thirty grams of isobutyl alcohol was treated with bromine as above and 17.0 g. of the reaction product was obtained. This liquid was fractionated into three components.

1) b. p. 88~91°C, 1.5 g. (2.7%).
2) b. p. 32~38°C (10 mmHg), 9.0 g. (8.6%).
3) b. p. 90~99°C (10 mmHg), 5.0 g. (5.7%).

Fraction 1, $n_D^{26}=1.438$, was isobutyl bromide, affording isovaleranilide[8], m. p. and mixed m. p. 108~109°C. Fraction 2 was an octyl bromide, (Found: Br, 40.25, Calcd. for $C_8H_{17}Br$: Br, 41.38%). Fraction 3 corresponded to dibromo-isobutane (Found: Br, 72.56. Calcd. for $C_4H_8Br_2$: Br, 73.61%).

6. *sec*-Butyl alcohol: Thirty grams (0.4 mol.) of *sec*-butyl alcohol was similarly treated and 60.0 g. of the reaction product was obtained and fractionated.

1) b. p. 90~92°C, 18.0 g. (32.5%).
2) b. p. 41~44°C (12 mmHg), 25.0 g. (51.8%).
3) b. p. 90~110°C (10 mmHg), 2.0 g. (2.3%).
4) Residue, 3.1 g.

Fraction 1, $n_D^{26}=1.438$, was *sec*-butyl bromide (Found: Br, 57.60. Calcd. for $C_4H_9Br$, 58.3%), forming $\alpha$-methylbutyranilide[8], m. p. and mixed m. p. 107~108°C. Fraction 2 was an octyl bromide (Found: Br, 40.59. Calcd. for $C_8H_{17}Br$; Br, 41.38%), and Fraction 3 was assumed to be a dibromobutane with some impurity (Found: Br, 70.56. Calcd. for $C_4H_8Br_2$: Br, 73.61%).

7. *tert*-Butyl alcohol: Thirty grams (0.4 mol.) of *tert*-butyl alcohol was similarly treated and 69.0 g. of the oil formed was fractions.

1) b. p. 71~73°C, 13.0 g. (23.4%).
2) b. p. 46~51°C (20 mmHg), 31.5 g. (65.1%).
3) b. p. 80~110°C (20 mmHg), 4.0 g. (4.5%).
4) Residue, 7.0 g.

Fraction 1 was *tert*-butyl bromide, $n_D^{26}=1.655$, (Found: Br, 41.96. Calcd. for $C_4H_9Br$: Br, 41.38%). Trimethylacetanilide, m. p. and mixed m. p. 127~128°C. Fraction 2 was an octylbromide, $n_D^{26}=1.655$ (Found: Br, 41.96. Calcd. for $C_8H_{17}Br$: Br, 41.38%). Ten grams of Fraction 2 was refluxed with 10 g. of potassium acetate and 30 g. of glacial acetic acid for 1 hr. and 60 g. of an octyl acetate, with characteristic sweet aroma, was obtained, b. p. 120~126°C, $n_D^{26}=1.644$ (Found: $CH_3CO$, 20.5. Calcd. for $C_{10}H_6O_2$: $CH_3CO$, 21.04%). Hydrolysis of this substance with ethanolic potassium hydroxide afforded 3 g. of a colorless, translucent oil, b. p. 118~121°C, with camphor-like odor (Found: bromine number, 139.0. Calcd. for $C_8H_{16}$ ($F_1$); bromine number, 142.3). Fraction 3 was assumed to be a dibromobutane with some impurity (Found: Br, 71.74. Calcd. for $C_4H_8Br_2$: Br, 73.61%).

The amount of sulfuric acid formed during this reaction was 13.0 g. (titrated as $H_2SO_4$).

8. Isoamyl alcohol: A similar treatment of 35.0 g. (0.4 mol.) of isoamyl alcohol afforded 4.0 g. of a product which was distilled to give 3.0 g. (6.6%) of isoamyl bromide, b. p. 120~121°C, $n_D^{26}=1.443$. Isohexananilide[8], m. p. and mixed m. p. 107~108°C.

9. Cyclohexyl alcohol: Forty grams (0.4 mol.) of cyclohexyl alcohol was treated with 0.4 mol. of bromine in 100 ml. of liquid sulfur dioxide at room temperature for 5 hr. to give 72.2 g. of an oily product, which was fractionated into two fractions:

1) cyclohexyl bromide, b. p. 55~61°C (20 mmHg), 9.2 g. (14.1%), $n_D^{23}=1.496$ (Found: Br, 50.4. Calcd. for $C_6H_{11}Br$; Br, 49.0%).
2) dibromocyclohexane, b. p. 97~108°C (20 mmHg), 62.2 g. (64.2%).

The dibromocyclohexane was redistilled, b. p. 98~101°C (17 mmHg), $n_D^{24}=1.549$ (literature[9]: b. p. 100°C (13 mmHg), $n_D^{25}=1.5506$) (Found: Br, 65.0. Calcd. for $C_6H_{10}Br_2$: Br, 66.0%).

10. *d*-Borneol: *d*-Borneol, m. p. 201~204°C, $[\alpha]_D^{21.5}=+31.88°$, was prepared, according to the procedure of Amagasa et al., by reduction of *d*-camphor with sodium in liquid ammonia followed by rectification and recrystallization. A similar treatment of 15.5 g. (0.1 mol.) of *d*-borneol and 17.6 g. (0.11 mol.) of bromine in 140 ml. of liquid sulfur dioxide at room temperature for 18 hours afforded 26.0 g. of products, from which 11.6 g. of dark crystals were separated and recrystallized from ethyl alcohol in white crystals of m. p. 90~91°C. From the filtrate, 9.7 g. of an oil was distilled at 120~134°C (4.5 mmHg) which after recrystallization showed m.p. 90~91°C, alone and in admixture with the above specimen. Total yield, 71.2%. $[\alpha]_D^{16}=-15.0°$. This was identified with 2, 10-dibromocamphane[11] by a mixed melting point. The small amount of the forerun of the filtrate, b. p. 70~75°C (3 mmHg), 1.8 g. and b. p. 110~122°C (4 mmHg), is yet unidentified. (The optical rotations were measured in 95% ethyl alcohol in a tube of 2 cm. length.)

*(B) The Mole Ratios of Bromine to Alcohols and Yields of Alkyl Bromides.*—Similar treatments were carried out with various mole ratios of bromine to isopropyl and to *tert*-butyl alcohols.

*(C) The Preparation of Alkyl Bromides with 1 mol. of Bromine and 2 mol. of Water in Liquid Sulfur Dioxide.*—The procedures were

similar to those described above but two mol. of water was added to liquid sulfur dioxide to produce hydrogen bromide[7].

*(D) Action of Chlorine with a Small Amount of Bromine on Alcohols in Liquid Sulfur Dioxide.* —In these experiments, chlorine or chlorine with 0.1 mol. of bromine to improve the yield of the chlorides was applied to aliphatic alcohols, the procedures being essentially similar as in the case of bromine.

## Summary

The reaction between aliphatic alcohols and bromine in liquid sulfur dioxide at room temperature was investigated in order to obtain further information concerning the behavior of bromine in liquid sulfur dioxide. The reactivity of the alcohols increased in the order of primary <secondary<tertiary.

In addition to alkyl bromides, higher boiling bromides were also produced. The latter resulted from further elimination, dimerization and bromine addition. The rather complicated feature of the bromination is attributable to the presence of sulfur trioxide secondarily formed in the reaction mixture.

The microanalysis was performed by Miss Yoko Endo. A part of the expenses for the present work was defrayed from the Grant in Aid for Scientific Research from the Ministry of Education. The liquid sulfur dioxide was kindly donated by the Befu Chemical Industries, Ltd. All this help is gratefully acknowledged.

# *On the Oxidation of β-Aminopropionitrile. I*

By Toshihisa TACHIKAWA

(Received January 18, 1960)

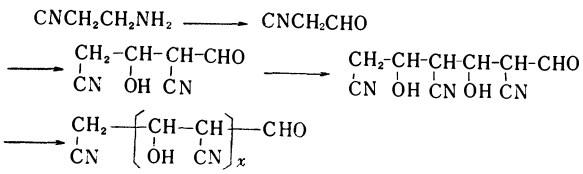
It is known that β-aminopropionitrile which can easily be synthesized from acrylonitrile and ammonia, turns to a viscous liquid and finally to a resinous solid, when it is stored in the air for a prolonged period. However, very little has been investigated on the polymerization of aminonitriles.

Akabori[1] proposed in his interesting theory of protein formation, that the protein-like polyamide would result from the polymerization of α-aminonitrile, $NH_2CH_2CN \rightarrow (-CH_2-CO-NH-)_x$. However he gave no experimental proof on his theory.

Whitmore and Mosher[2] have studied the polymerization of β-aminopropionitrile, and stated that the reaction proceeds according to the following scheme,

$$NH_2CH_2CH_2CN \rightarrow CH_2=CHCN+NH_3$$

$$CH_2=CHCN \rightarrow \left[-CH_2-\underset{CN}{CH}-CH_2-\underset{CN}{CH}-\right]_x$$



where the reaction was initiated by the decomposition of β-aminopropionitrile into acrylonitrile and ammonia, then followed by the polymerization of acrylonitrile. However, it does not seem probable that the polymerization of acrylonitrile will occur in the presence of ammonia, since ammonia is known as a polymerization inhibitor. It is also unlikely that polymerization proceeded through a viscous product because polyacrylonitrile should precipitate from the reaction mixture, as it is not soluble in acrylonitrile, water and ammonia.

As our resinous product obtained from β-aminopropionitrile was found to be easily soluble in methanol, glacial acetic acid and formic acid, this material must be quite different from the polyacrylonitrile obtained by Whitmore and his co-worker.

This paper is to report on the result of our detailed investigation on the reaction products and the mechanism of polymerization reaction of β-aminopropionitrile.

It is well known, that the aliphatic amino group is easily oxidized to aldehyde. So that β-aminopropionitrile could be oxidized in an analogous manner and the resulting aldehyde may polymerize by aldol condensation according to the following reaction scheme;

1) S. Akabori, *Kagaku*, **25**, 54, (1955).
2) F. C. Whitmore and H. S. Mosher, *J. Am. Chem. Soc.*, **66**, 725 (1944).

If this is the case, the resulting polymer may be acetylated and may give rise to the characteristic infrared absorption bands due to -OH and -CN groups. However, it was not successful to acetylate the polymer with various reagents, and no evidence for -OH or -CN was found from the infrared absorption spectrum of this compound as shown in Fig. 1. From these findings, it is believed that the polymerization reaction proceeds in a different way.

The colorless amorphous solid, obtained by treating the resinous polymer with anhydrous acetone to remove water and unreacted β-aminopropionitrile, was found to be very hygroscopic and to decompose at 120°C, resulting in the yellow mass which did not melt even above 250°C. The results of the molecular weight determination and the elementary analysis of this compound indicated the formular of $C_{12}H_{22}N_6O_5$ and the infrared absorption spectrum is shown in Fig. 1. As is clear from the spectrum, some differences were observed between the monomeric aminonitrile and the polymeric product.

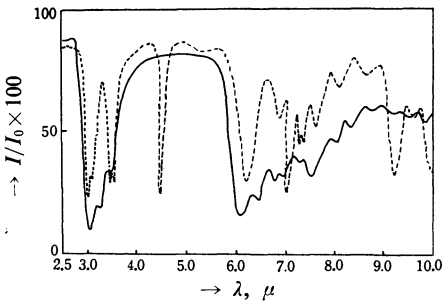


Fig. 1. Infrared absorption spectra.
---- β-Aminopropionitrile
—— Polymerization product

Two bands of N-H stretching vibration at 3.0 and 3.05 μ, splitted into three bands and shifted to 3.1, 3.3 and 3.4 μ. A band due to N-H bending vibration at 6.25 μ shifted to 6.45 μ, and a new band at 6.05 μ due to C=O stretching vibration appeared. These characteristic absorptions resembled very much those of the secondary amide such as *N*-methylacetamide which was investigated by Davis, Evans and Jones[3] as a model compound for polypeptides, and those of 6,6-Nylon. Therefore, it is very likely that this compound has a -CONH- linkage in its structure.

Regarding a new band at 6.70 μ, it is probable, that this band is due to the azoxy group. The reason for this assignment is that the position of this band coincided with that of the band arising from the stretching vibration of the azoxy group which was confirmed by Langley and others[4] in their infrared absorption study on azoxy compounds, such as 2-azoxy-2 : 5-dimethylhexane and ethyl 2-azoxybutylate.

Ultraviolet absorption spectra of these two compounds were also observed by the same authors, and their absorption maxima were reported as having two maxima at 223 and 280 mμ. The ultraviolet absorption spectrum of the polymer is also found to show two maxima at 215 and 275 mμ as shown in Fig. 2, and the locations of maxima are in good agreement with those of azoxy compounds if one considers the hypsochromic shift due to the use of water as a solvent.

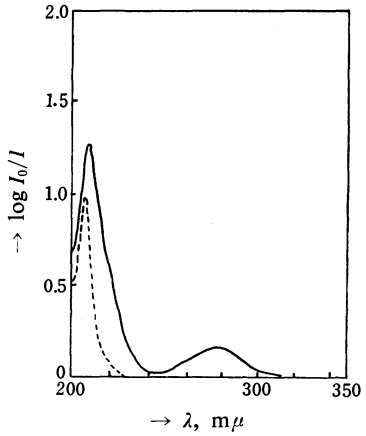

Fig. 2. Ultraviolet absorption spectra.
---- β-Aminopropionitrile
—— Polymerization product

In order to confirm the evidences of the azoxy group and -CONH- linkage in the polymer, the reduction of this compound was carried out, using concentrated hydrochloric acid and tin. The infrared absorption spectrum of the reaction product, which was obtained as colorless crystals, showed five bands at 5.85, 6.30, 6.70, 7.15 and 7.55 μ, as shown in Fig. 3, indicating the presence of amino acid, because these bands are characteristic of the hydrochloride of amino acid. And this supports the evidence of -CONH- linkage in the mother compound.

3) M. Davis, J. C. Evans and R. L. Jones., *Trans. Faraday Soc.*, **51**, 761 (1955).

4) B. W. Langley, B. Lythgoe and N. V. Riggs, *J. Chem. Soc.*, **1951**, 2309.

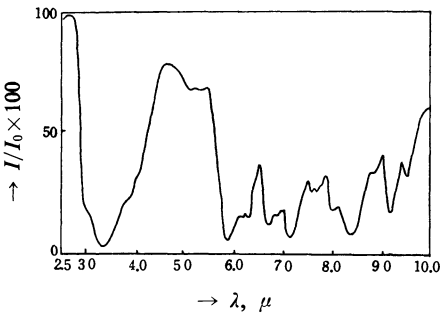

Fig. 3. Infrared absorption spectrum of reduction product of polymerization product.

Further investigation on the reduction product showed that the product was β-alanine and that this was obtained quantitatively by the reduction of the polymer. The presence of $-CONH_2$ group was also proved by the fact that ammonium chloride was found in the reduction products, and it was further confirmed that the nitrile group did not hydrolyze to -COOH group during the reaction, because no metallic salt can be precipitated from the aqueous polymer solution.

The presence of an azoxy group was also confirmed by the rapid evolution of gaseous nitrogen when the aqueous solution of the polymer was decomposed with sulfuric acid at room temperature. The fact that the aqueous solution of polymer was neutral, in contrast to the strong basicity of β-aminopropionitrile, indicated the polymer did not have a free amino group.

After considering above findings, the structure of resinous polymer obtained by standing β-aminopropionitrile in the air, is proposed as below;

$$\begin{array}{l} \bar{O}\text{-}\overset{+}{N}\text{-}CH_2CH_2CONHCH_2CH_2CONH_2 \\ \quad \| \\ \quad N\text{-}CH_2CH_2CONHCH_2CH_2CONH_2 \end{array}$$

And the scheme of decomposition to yield β-alanine during the reduction may be shown as follows;

$$\begin{array}{lll} & \overset{+OH}{\vdots} \; \overset{+H}{\vdots} & \overset{+OH}{\vdots} \; \overset{+H}{\vdots} \\ O\text{-}N\text{-}CH_2CH_2CO & \vdots \; NHCH_2CH_2CO & \vdots \; NH_2 \\ \quad \| \; {}^{+H_2} & \vdots & \vdots \\ \cdots\cdots \| \; \cdots\cdots & \vdots & \vdots \\ \quad \| \; {}^{+H_2} & \vdots & \vdots \\ N\text{-}CH_2CH_2CO & \vdots \; NHCH_2CH_2CO & \vdots \; NH_2 \\ & \underset{+OH}{\vdots} \; \underset{+H}{\vdots} & \underset{+OH}{\vdots} \; \underset{+H}{\vdots} \end{array}$$

The rate of polymerization of β-aminopropionitrile was accelerated by adding small amounts of water and bubbling the air into the reaction mixture. The polymer thus obtained was found to be exactly identical to that obtained by standing the monomer in the air, and since one mole of ammonia and a small amount of hydrogen peroxide were formed from two moles of β-aminopropionitrile, the mechanism of this polymerization can be considered as the oxidation reaction accompanied by the evolution of ammonia in the presence of water as shown in Table I.

Table I. The air oxidation reaction

| Nitrile g. | $H_2O$ g. | Gas used | Gas blown l. | Product g. | $NH_3$ generated g. |
|---|---|---|---|---|---|
| 15 | 0 | Air | 2800 | No change | None |
| 15 | 1.0 | Air | 560 | White solid 15.0 | 1.80 |
| 15 | 3.8 | Air | 560 | White solid 15.8 | 1.91 |
| 15 | 6.0 | Air | 720 | White solid 15.1 | 1.87 |
| 15 | 1.0 | $N_2$ | 2020 | No change | None |

## Experimentals

**1. Raw Material and Sample.**—β-Aminopropionitrile was synthesized from acrylonitrile and aqueous ammonia according to Buc, Ford and Wise[5], and the fraction boiling at 86.3~87.0°C/21 mmHg was collected.

A polymeric sample was prepared by standing β-aminopropionitrile for two months in the air, followed by washing the resulting solid mass with anhydrous acetone to remove unreacted aminonitrile and water. A white amorphous and very hygroscopic solid was thus obtained, and dried in a vacuum. This sample decomposed at 120°C, yielding a product which did not melt above 250°C.

Found: C, 43.27; H, 6.69; N, 25.04%; mol. wt., detd. by freezing point depression using acetic acid. 311.1. Calcd. for $C_{12}H_{22}N_6O_5$: C, 43.63; H, 6.71; N; 24.22%; mol. wt., 330.4.

Ultraviolet absorption spectra were measured for the aqueous solution of 0.0651 g./l. A Shimadzu Model QR 51 spectrophotometer with 1 cm. quart celles was employed. Infrared absorption spectra were recorded with a Perkin Elmer Model 21 spectrophotometer on the sample film which was prepared by evaporating 2—3 drops of 3% methanolic solution on the sodium chloride window.

**2. Reduction of Polymer.**—Twelve grams sample was dissolved into 15 g. of water, and the solution was treated with 19.1 g. of metallic tin and 75 g. of 35% hydrochloric acid at 95~100°C for 10 hr. under stirring until the tin dissolved completely.

The resulting solution was diluted with four volumes of water and stannous ion was precipitated with hydrogen sulfide. The filtrate was concentrated under reduced pressure to get a crystalline product I which was found to be ammonium chloride.

After filtering it, the filtrate was subjected to further evaporation until one could get 16.5 g. of the second crystalline product II. The infrared absorption spectrum was measured on this material II using the potassium bromide pellet method.

The product II was then dissolved in a small amount of water and after neutralizing the solution with 1 N sodium hydroxide solution, it was boiled

5) S. R. Buc, J. H. Ford and E. C. Wise, *J. Am. Chem. Soc.*, 67, 92 (1945).

with an excess amount of freshly prepared cupric hydroxide. The hot filtrate was concentrated and cooled to get dark blue crystals. This was re-dissolved in water, and cupric ion was precipitated with hydrogen sulfide. When the filtrate was evaporated almost to dryness, a crystalline product III was obtained.

Found: C, 40.27; H, 7.86; N, 15.81. Calcd. for $C_3H_7NO_2$: C, 40.44; H, 7.92; N, 15.72%.

**3. Decomposition with Sulfuric Acid.**—According to Curtius procedure, 0.0818 g. of the sample was dissolved in 1.0 ml. of water and 1.5 ml. of 98% sulfuric acid was dropped into this solution with gentle heating. The evolving gas, collected over a 10% potassium hydroxide solution, measured 5.34 ml. As this gas was not absorbed by the alkaline pyrogallol solution, ammoniacal cuprous chloride solution or barium hydroxide solution, it was found to be pure nitrogen. The amount of nitrogen evolved was 8.17% per mole of the sample.

**4. Determination of Neutralization Equivalent.**—A solution of 0.0999 g. sample in 50 ml. of water was titrated with 0.1 N hydrochloric acid using methyl orange as an indicator. Neutralization equivalent was calculated as 951.4 from the titre of 1.05 ml. This value is considerably larger than that of β-aminopropionitrile (69.5), and the sample can be considered as almost neutral material.

**5. Formation of Metallic Salts.**—No precipitation was observed when barium hydroxide, cupric nitrate or silver nitrate solution was added to the aqueous sample solution.

**6. Air Oxidation.**—Decarbonated air or nitrogen was bubbled into β-aminopropionitrile in a 100 ml. reaction flask at the rate of 20 l./hr. The increase of viscosity and the rapid evolution of gas were observed during she introduction of air, which was continued until the content rapidly increased its viscosity, resulting in a resinous material. This product was treated with anhydrous acetone to remove unreacted β-aminopropionitrile and water, then it was dried under reduced pressure. The product was obtained as a very hygroscopic white amorphous mass.

Amount of ammonia evolved during the reaction, was determined by passing the gas into sulfuric acid, and the presence of hydrogen peroxide in the gas was detected by passing it into barium hydroxide solution, followed by the dissolution of the resulting white precipitate into hydrochloric acid, which turned to red with an addition of potassium iodide.

The author wishes to express his sincere thanks to Professor Ryozo Goto of Kyoto University for his kind advice, and also to Mr. Murataro Nakashima, President of Kunoshima Chemical Co., for his permission to publish this paper.

# *The Self-diffusion of Surface Active Agents in Nylon*

By Makoto HAYASHI

(Received January 20, 1960)

Adsorption of surface active agents on various solid surfaces such as metal, carbon, wool, cotton, acetate and polyamide fibers has been studied by many workers[1-5] as the fundamental contributions to the study of the physicochemical properties of detergents or as the first step to study the mechanism of detergency. However, the process of adsorption of detergents by the solid is rather complicated and there are a number of problems to be solved by further investigation.

We have studied[6] the adsorption of the surface active agents such as sodium dodecyl sulfate, sodium tetradecyl sulfate as well as inorganic ions such as sulfate, chloride, phosphate and calcium ions on the surface of nylon plate. The quantities of these substances taken up by nylon are very great and a very long time is required to reach an adsorption equilibrium. From these facts, it seems that the penetration of the adsorbed substances into the solid body plays an important role in the process of sorption and so the measurement of diffusion in solid is considered to be significant in a study of the adsorption of these substances to polymer solid.

In this paper, the self-diffusion rates in nylon

of sodium dodecyl sulfate and sodium tetradecyl sulfate, and also of sulfuric acid and hydrochloric acid were studied, using the nylon plates and the radioactive tracers.

## Experimental Method

The measurement was carried out by the surface radioactivity decrease method, which consists in measuring the decrease in radioactivity of the surface with the time due to the diffusion of the radioactive tracer into nylon. This method has the following advantages: the measurement is accomplished in a short diffusion time when the suitable $\beta$-ray energy such as that of $^{35}S$ is used and it is not necessary to use any particular arrangements.

A nylon plate was 2.5 mm. in thickness, 2.5 cm. $\times$2.5 cm. in size. It was cleaned by washing with ether, acetone and hot water before use.

The surface active agents used in this experiment were sodium dodecyl surfate (SDS) and sodium tetradecyl sulfate (STS). They were prepared from pure dodecyl alcohol and tetradecyl alcohol, respectively, and their purity was confirmed surface-chemically. The radioactive SDS and STS, both tagged with $^{35}S$, were prepared from corresponding alcohols and radioactive sulfuric acid ($H_2{}^{35}SO_4$). Radioactive sulfuric acid ($H_2{}^{35}SO_4$) and hydrochloric acid ($H^{36}Cl$) were used for the measurement of diffusion of the sulfate ion and the chloride ion, respectively. The absorption coefficients of the $\beta$-rays of $^{35}S$ and $^{36}Cl$ in nylon were estimated using the sufficiently swollen nylon film (25$\mu$ in thickness), and the values, 321 $cm^{-1}$ for $^{35}S$ and 12.7 $cm^{-1}$ for $^{36}Cl$ were obtained.

Diffusion experiments were accomplished as follows: the nylon plates are immersed in various concentrations of each non-radioactive solution at 33°C for about two weeks in order that the nylon might sorb the solute by a complete equilibrium amount corresponding to each concentration. (It has been shown that the sorption equilibrium is accomplished completely under these circumstances.) They are taken up from the solution, blotted by filter paper, then immersed instantly in each radioactive solution of the same concentrations as the non-radioactive solution used, for the purpose of making a surface radioactive layer, probably, by surface exchange. They are stirred sufficiently for about 0.5~2 min., then the nylon plates are taken up, washed with a large amount of water for a few seconds, blotted with filter paper and counted instantly under the G-M tube. They are then fitted in a closed glass vessel of saturated humidity which is then kept in a thermostat. When the diffusion has progressed appropriately (about 20 hr. for SDS and STS, 4 hr. for $H_2SO_4$, 48 hr. for HCl at 33°C, respectively), the nylon plates are removed from the vessel and their radioactivity is counted in the same manner as before, and the ratio $A/A_0$ ($A_0$: initial counts of the surface of nylon, $A$: its counts at time $t$) is estimated. $A/A_0$ is given by the following equation[7,8]

$$A/A_0=[1-\mathrm{erf}\{(\mu^2Dt)^{1/2}\}]\exp(\mu^2Dt) \quad (1)$$

where $D$ is the self-diffusion coefficient of the diffusing ion, and $\mu$ is the absorption coefficient of the $\beta$-ray in nylon. $A/A_0$ can be plotted as a function of $\mu^2Dt$ and by using this graph $D$ can be obtained from the measured value of $A/A_0$ since $\mu$ and $t$ are known.

The quantity of each solute sorbed by nylon was measured by the same method as in the previous paper[6] and expressed as millimoles per kilogram of nylon, which was calculated by calibrating the decrease of counts owing to the absorption of radiation by nylon.

Radioactivity measurements carried out by means of a thin mica window G-M tube (1.4 mg./$cm^2$) and the conventional scaler. For the purpose of establishing the counting area and avoiding the edge effect on counting, a brass ring 1 mm. think and 22 mm. in inner diameter was placed on the plate when it was counted.

The change of the efficiency of the counting equipment was always checked by a radioactive standard prepared on a nylon plate. Counting times were made so long that the standard counting error was less than 1%.

## Results

To confirm the compatibility of the above diffusion equation (1) in these measurements the values of $A/A_0$ at various diffusing time were measured at 33°C with SDS and $H_2SO_4$ (Figs. 1 and 2). In these figures, the curves of solid line show the calculated values obtained by the above equation and the value of $D$ at $A/A_0=0.5$. The points are the measured ones. It is seen that this equation can be applied to calculate the diffusion coefficient in these systems.

The sorption isotherms of each substance by nylon plate were measured by the radiotracers to estimate the quantities sorbed in nylon.

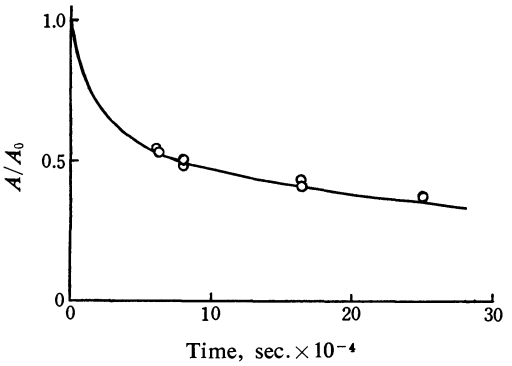

Fig. 1. The check of compatibility of the Eq. 1 by the diffusion of SDS at the concentration of 34 millimol./kg. in nylon at 33°C. The solid line is the calculated values and the points are the measured ones.

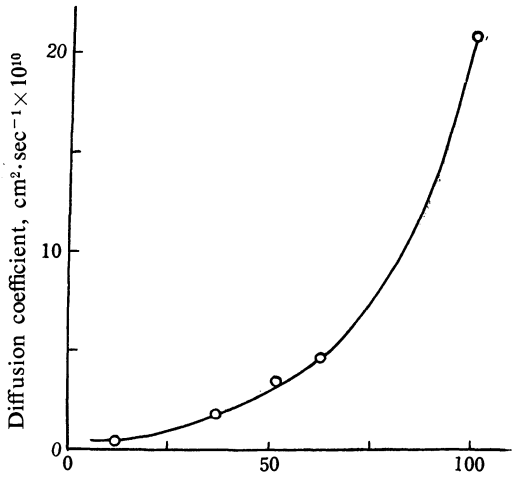

Fig. 6. Diffusion coefficient of $H_2SO_4$ at 33°C.

Table I. Self-diffusion coefficients of HCl at 33°C

| Concentration of HCl* mol./l. | Diffusion coefficient $cm^2 \cdot sec^{-1} \times 10^9$ |
|---|---|
| $10^{-1}$ | 6.46 |
| $10^{-2}$ | 0.120 |
| $10^{-3}$ | 0.176 |

* The concentration of the solution described here is that which is in sorption equilibrium.

The diffusion coefficients of SDS and $H_2SO_4$ at various temperatures were measured to observe the effect of temperature on the diffusion and are shown in Table II. When $\log D$ is plotted against $1/T$, the straight lines are obtained as shown in Fig. 7, from which the

TABLE II. TEMPERATURE DEPENDENCE OF DIFFUSION COEFFICIENTS

| Diffusing substance | Concentration in nylon (millimol./kg) | Diffusion coefficient $cm^2 \cdot sec^{-1} \times 10^{10}$ | | | | | Activation energy, $E$ cal./mol. |
|---|---|---|---|---|---|---|---|
| | | −4°C | 5°C | 10°C | 19°C | 33°C | |
| SDS | 102 | 0.00012 | 0.0053 | 0.0177 | 0.182 | 1.10 | 33400 |
| $H_2SO_4$ | 63 | 0.0209 | 0.102 | 0.241 | 0.927 | 4.69 | 23200 |

activation energy $E$ in the equation $D=D_0 \exp(-E/RT)$ was estimated and shown in the last column of Table II.

If the nylon sample is dried before or after the dipping in radioactive solution, the diffusion is little observed by this method at the room temperature.

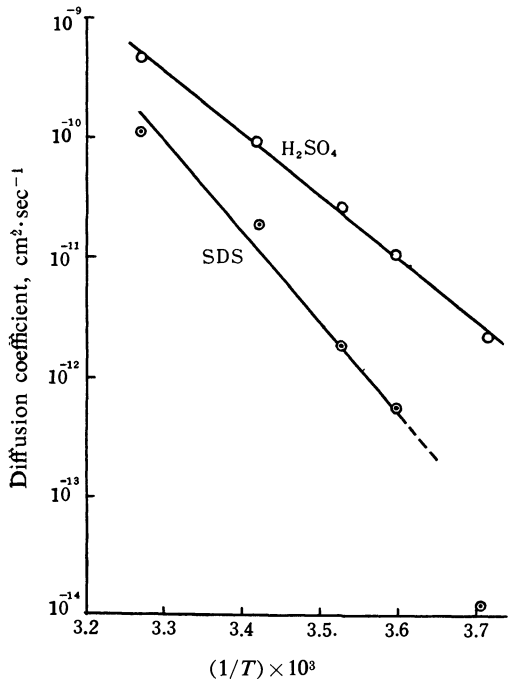

Fig. 7. Temperature dependence of diffusion coefficients of SDS (102 millimol./kg.) and $H_2SO_4$ (63 millimol./kg.).

## Discussion

In this experiment the measurements of the self-diffusion rate were always carried out using sufficiently swollen nylon plates and it has been confirmed by weight that the swelling of each sample under the condition of the present experiment is constant throughout the whole diffusion process. The self-diffusion of the surface active agents or inorganic acids became remarkably slower as a nylon plate was dried and could not be observed at the room temperature in the completely dried state of nylon. It is evident, therefore, that these substances diffuse with the aid of water in nylon.

It is clear from the results of the present experiment that in the sorption of surface active agents and also of inorganic acids from their aqueous solutions by nylon, not only the surface phenomenon but also the diffusion into the solid body is responsible for its process towards equilibrium.

The self-diffusion coefficients of SDS and STS in nylon at 33°C are dependent, though not remarkably, on the concentration of each detergent in nylon as shown in Fig. 5. The values are comparable with those of several dyes reported by some workers[9,10], but they are much smaller than the values[11] in aqueous solutions. We suppose that the internal body of nylon is a gel of extremely close-packed network structures, water being included and forming fine canals among them. The molecules of detergent will penetrate along these canals into the internal structures of nylon, but they are immobilized by the adsorption sites to a large extent and so the rate of diffusion is reduced considerably compared with the free diffusion in aqueous systems. It is considered that the jumping of the adsorbed molecules from site to site occurs just as in the diffusion of ions in their crystals. Indeed the activation energies for diffusion of SDS and sulfuric acid are 33.4 and 23.2 kcal. per mole respectively as shown in Table II. These values are much greater than the values of many substances in aqueous systems, rather resembling these in solid crystals[12].

We suppose that the interaction of ionic detergents and nylon takes place not only by ionic force but also by van der Waals force, since the amount of detergents sorbed by nylon is much larger than that of simple inorganic ions which are considered to be bound to nylon mainly by ionic interaction[6]. This is confirmed by the fact that the amount of detergents taken up is also much larger than the value corresponding to the amine content of nylon[13,14]. The sorption of sulfuric acid

and hydrochloric acid will be caused mainly by the attachment of these substances to the amino groups or to the amide groups in the molecule of nylon. From this point of view, therefore, it is supposed that there is also a difference between detergent and inorganic acid in the mechanism of diffusion. Indeed as shown in Figs. 5 and 6, the diffusion coefficient of the detergent does not change markedly with concentration of the detergent in nylon, while that of the inorganic acid increases remarkably with its concentration. At present, however, it is difficult to give a precise mechanism for the diffusion of the detergent and inorganic acid in nylon. This will be discussed after further investigation has been performed.

## Summary

The self-diffusion rates of sodium dodecyl sulfate, sodium tetradecyl sulfate, sulfuric acid and hydrochloric acid in nylon containing various amounts of each solute and their temperature dependence were measured by the surface radioactivity decrease method using $^{35}S$ and $^{36}Cl$.

From the experimental results, it has become clear that the diffusion of the solute in nylon is important in the process towards the attainment of sorption equilibrium of these substances by nylon, and in this case the presence of water in nylon is necessary for the diffusion to take place appreciably. The diffusion coefficients were much smaller than those in their aqueous solutions.

The diffusion rates of the surface active agents depended little on the concentration in nylon compared with those of the inorganic acids. The diffusion rates of sulfuric acid and hydrochloric acid depended largely on their concentration in nylon. This will be due to a difference of the mechanism of diffusion between the former and the latter.

The activation energies of SDS and sulfuric acid for diffusion were considerably great and approximated to those of many substances in solid.

The author wishes to express his gratitude to Professor R. Matuura of Kyushu University for his kind guidance and for supplying the radioisotopic samples, and also to Toyo Rayon Co. for its supply of nylon samples.

# *Estimation of the Energy of Hydrogen Bonds Formed in Crystals. III. Amides*

By Ariyuki AIHARA

(Received January 20, 1960)

A study of the NH···O bonding bears a particular significance in relation to the basic structure and behavior of proteins, and a fairly large amount of data of the bond have been accumulated up to now. Nevertheless, it cannot be said that the strength of the NH···O bonding has been fully examined so as to allow us to decide definitely whether this type of hydrogen bond is weaker than the OH···O bonding or not, especially in the crystalline state. Thus we find a considerable divergence in the data of the energy of NH···O bondings already published by several investigators. For instance, Coulson cites, in his well-known publication[1], 2~3 kcal./mol. for the energy of the NH···O bond, while the following data are available in the literature: 3.0 kcal./mol. (acetamide, *N*-methylacetamide)[2], (diacetylhydrazine)[3], 3.5 kcal./mol. (urea)[4], 4.2 kcal./mol. (oxamide)[5], 4.7 kcal./mol. (sulfamide)[3], 5.3 kcal./mol. (diketopiperazine)[6], ~6.0 kcal./mol.

(δ-valerolactam and ε-caprolactam)[7], 6.1 kcal./mol. (diformylhydrazine)[4].

In this connection, the author has tried to get more knowledge on the strength of the NH···O bond, and has estimated the energy of the bond with thirteen amides in the crystalline state, following the procedure proposed in previous papers[8]. The obtained values of the energy range from 3.5 to 7.0 kcal./mol., showing that the NH···O bond is not always weaker than the OH···O bond as has hitherto been presumed.

## Experimental

The measurement of the sublimation pressures was done with the same apparatus as that used before[3]. Of the materials dealt with in this investigation, formanilide and *N*-methylbenzamide were prepared in this laboratory following the usual procedure (the former from aniline and formaldehyde, the latter from methylamine and benzoylchloride). δ-Valerolactam and ε-caprolactam were kindly sent by Dr. Tsuboi, the University of Tokyo The result of the measurement of their sublimation pressures was reported before by the author[7], but, for the sake of comparison, it will be included here. 1-Phenyl-3pyrazolidone (phenydone) was sent by Dr. Kurosaki, Fuji Photo Film Co., Ltd., to whom author's thanks are due. Others were all commercial products and were purified by repeated fractional sublimation under high vacuum pressure before use.

## Results and Discussion

**Sublimation Pressures.**—The results of measurements of sublimation pressure of thirteen amides are shown in the following tables (from Table I to Table XIII) together with their

Table I. Sublimation pressure of formanilide

| $T$°K | $P$(mmHg)$\times 10^4$ | $T$°K | $P$(mmHg)$\times 10^4$ |
|---|---|---|---|
| 297.7 | 6.86 | 311.9 | 28.7 |
| 301.6 | 10.3 | 313.6 | 34.2 |
| 308.4 | 20.3 | 314.6 | 37.2 |
| 309.3 | 22.0 | 316.8 | 45.9 |
| 310.7 | 25.9 | 317.8 | 49.4 |

$\log P(\text{mmHg}) = 10.511 - 4071.0/T$: m. p. 48.7°C.

Table II. Sublimation pressure of acetanilide

| $T$°K | $P$(mmHg)$\times 10^4$ | $T$°K | $P$(mmHg)$\times 10^4$ |
|---|---|---|---|
| 317.7 | 8.03 | 327.7 | 21.2 |
| 320.0 | 10.2 | 330.1 | 26.8 |
| 322.7 | 12.9 | 333.2 | 36.2 |
| 325.4 | 16.4 | 335.8 | 48.1 |

$\log P(\text{mmHg}) = 11.166 - 4533.6/T$: m. p. 115.0°C.

Table III. Sublimation pressure of *o*-acetoluidine

| $T$°K | $P$(mmHg)$\times 10^4$ | $T$°K | $P$(mmHg)$\times 10^4$ |
|---|---|---|---|
| 315.2 | 4.20 | 330.8 | 23.6 |
| 318.5 | 6.31 | 334.2 | 35.3 |
| 321.2 | 8.80 | 337.5 | 48.6 |
| 324.2 | 11.8 | 340.0 | 65.6 |
| 327.3 | 16.5 | | |

$\log P(\text{mmHg}) = 12.717 - 5070.8/T$: m. p. 111.5°C.

Table IV. Sublimation pressure of *p*-acetotoluidine

| $T$°K | $P$(mmHg)$\times 10^4$ | $T$°K | $P$(mmHg)$\times 10^4$ |
|---|---|---|---|
| 330.7 | 6.20 | 337.9 | 13.0 |
| 332.1 | 7.23 | 340.6 | 17.5 |

vapor pressure equations obtained by the method of least squares. The linear relation between $\log p$ and $1/T$ is found to be quite satisfactory for all the measurements here mentioned.

In addition to the sublimation pressure of the amides listed above, that of *p*-aminoacetophenone, which should be classified as an amine in the usual sense, is also shown in Table XIV. Since the molecular structure of *p*-aminoacetophenone bears some resemblance to that of acetamide, except that the amino group is separated from the carbonyl group by a phenyl nucleus, it might be expected to form NH···O bonds with neighboring molecules in the crystal.

TABLE XIV. SUBLIMATION PRESSURE OF p-AMINOACETOPHENONE

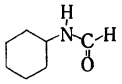
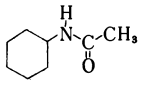
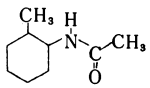
$\log P(\text{mmHg}) = 11.900 - 4832.6/T$: m. p. 106.2°C.

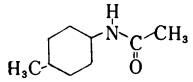
The values of the heat of sublimation ($\Delta H$), the change of free energy at 298.2°K ($\Delta G^{298.2°}$) and of entropy ($\Delta S$) on sublimation are shown in Table XV.

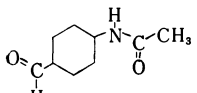
**Energy of Hydrogen Bond.**—Table XV shows the estimated energies ($E$) of hydrogen bonds (NH···O) in the fourth column, together with the hypothetical lattice energies ($\Delta H'$) obtained conventionally, assuming the additivity rule of the lattice energy, without taking into account the formation of hydrogen bonds in the crystalline state[8]. The values of $E$ were obtained by subtracting $\Delta H'$ from $\Delta H$.

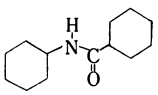


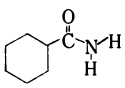


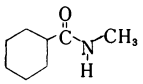


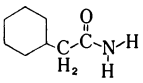


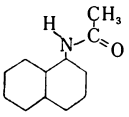


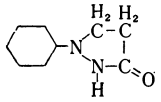


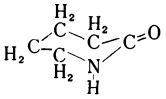


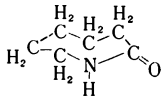


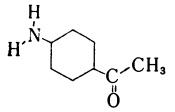












Because the crystal structures of the majority of compounds listed in Table XV are not analyzed as yet except for those of acetanilide[9] and benzamide[10], the formation of the NH···O bond is implicitly assumed for the rest of the compounds. considering the similarity of their molecular structures, this assumption would not be unreasonable.

It is clear, from the values of $E$ in the table, that the compounds dealt with in this investigation can be classified into three categories: the first showing little or no tendency to associate mutually by NH···O bondings (benzanilide, *N*-acetyl-α-naphthylamine and 1-phenyl-3-pyrazolidone); the second forming NH···O bondings of the order of $4\pm1$ kcal./mol. (formanilide, acetanilide, *o*- and *p*-acetotoluidine, *p*-acetaminobenzaldehyde, benzamide, *N*-methylbenzamide and α-phenylacetamide), and the third capable of making hydrogen bondings as strong as 6~7 kcal./mol. (δ-valerolactam and ε-caprolactam).

Let us first examine those which belong to category I. An alternative nomenclature of

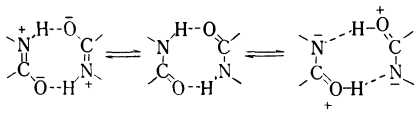
* In these cases, the increment of the lattice energy due to a $CH_2$ group was taken as 1.5 kcal./mol., taking into consideration the volume effect due to ring formation: the value was estimated from the heat of sublimation of cyclohexane, ~8.5 kcal./mol. (the sum of the heats of vaporization and fusion).

benzanilide is *N*-phenylbenzamide and the molecule consists of two large phenyl groups attached to both sides of a peptide linkage. These phenyl groups will inevitablly prevent the molecules from approaching each other closely to make association by the NH···O bonding. The infrared absorption data[11] prove also that the NH···O bond in the crystal of benzanilide is rather weak, if it is formed to any extent: the wavelength of the N-H absorption band in the crystalline state is 2.99 $\mu$ compared with 3.08 $\mu$ in the case of acetanilide, which is known to form NH···O bonds in the crystals[9]. *N*-acetyl-$\alpha$-naphthylamine is also known to show little tendency to form hydrogen bonds with dioxane and cyclohexanone as revealed from the study of ultraviolet absorption of this substance by Baba and Suzuki[12]. The small negative value of $E$ for this compound implies that there would be no hydrogen bond formed in the crystalline state in accordance with the result of ultraviolet absorption. This may be due to the blocking effect of a phenyl nucleus located very close to the N-H group at the $\alpha$-position.

As to 1-phenyl-3-pyrazolidone, Kurosaki[13] has observed the formation of associated dimers in its $CCl_4$ and $CHCl_3$ solutions by the infrared and dielectric technique. But, at the same time, he noticed that its tendency to associate was much decreased in $CHCl_3$ solution due to the high polarity of the solvent which interacts with the solute molecules. Therefore, if an extrapolation is allowed to be made to the extreme case where the solute is surrounded completely by the same substance as a solvent (that is, a pure liquid or solid), we may assume that the molecule should exist as a monomer in the crystalline state without making any association, because the dipole moment of 1-phenyl-3-pyrazolidone 3.5~3.6 D[13] is much greater than that of chloroform 1.05 D[14]. The result obtained by the author shown in Table XV confirms this conclusion.



Those in category II may be regarded as forming "normal" hydrogen bonds of NH···O type, the energy of the bond being about 4 kcal./mol. The small differences between the values of these compounds might have some meaning concerning the strength of the bond formed, but, considering the approximate nature of the method of estimation, a further discussion on the difference of the strength of the bond cannot be made. It is interesting, however, to see that the methyl groups substituted to the phenyl nucleus seem to incsease the strength of the NH···O bond in the case of *o*- and *p*-acetotoluidine, while the formyl group in the para position of *p*-acetaminobenzaldehyde tends to decrease the NH···O bond-forming-power of the molecule: the weakly electron-releasing inductive and hyperconjugative effects of the methyl group might cause an increase of the negative charge on the oxygen atom of the carbonyl group, thereby reinforcing the strength of the hydrogen bond, while the strong electron-withdrawing inductive effect of the formyl group might result in the reverse way. In the case of benzamide and $\alpha$-phenylacetamide, the $E$ values in Table XV were obtained by dividing the difference of $\Delta H$ and $\Delta H'$ by two, because these molecules are connected to each other by two NH···O bonds per molecule in the crystalline state, as is revealed by Penfold and White[10].

The value of $E$ for *p*-aminoacetophenone, 2.8 kcal./mol. (=5.6/2 kcal./mol.), is somewhat smaller than those of the compounds in the second category. This is probably due to the separation of the amino and carbonyl groups by a phenyl nucleus which might prevent the mutual approach of molecules to some extent, although the positive charge on the NH group as well as negative charge on the C=O group are presumably increased to favor the formation of a strong NH···O bond due to the existence of a phenyl nucleus. An alternative way of explaining the smaller value of the energy of hydrogen bond in this compound is that it may behave as an amine forming hydrogen bonds of NH···N type in the crystalline state. This problem must be solved either by infrared absorption measurement or by crystallographic analysis.

The energies of an NH···O bond estimated for $\delta$-valerolactam and $\varepsilon$-caprolactam amount to 6~7 kcal./mol. and can be favorably compared with those observed for carboxylic acids[15] which are known to form dimers in the crystalline state as well as in liquid and in solutions. Here, it would be reasonable to assume that the two lactams exist as dimers in the crystalline state, because their molecular structures are such as to favor the formation of dimers (N-H is located in the *cis* position to C=O), just like those of carboxylic acids, although the crystal structures of the lactams are not analyzed as yet. Thus, the appreciable increase in the strength of NH···O bonds in

these cases, compared with a "normal" NH···O bond, can be understood as due to the conjugation of $\pi$-electrons in the ring system formed by two molecules:

A simple treatment of this problem based on the assumption of a dipole-dipole interaction between hydrogen-bond-forming molecules is mentioned in a previous paper[7]. It should be mentioned that the estimated value of the energy of an NH···O bond for $\delta$-valerolactam, 6.3 kcal./mol., is consistent with Tsuboi's value, 5.2 kcal./mol., obtained by the infrared spectroscopy on the association of the molecules in a $CCl_4$ solution[16].

In relation to the formation of ring dimers by the lactams mentioned above, a comment will be made on the molecular configuration of formanilide which is regarded as forming a "normal" hydrogen bond in this paper. Here it was implicitly assumed that the configurational position of the NH group was *trans* to the C=O group in this molecule, following the experimental result on the molecular structure of acetanilide[9]. Recently, however, Suzuki[17] has observed the existence of a *cis* form of this molecule in a $CCl_4$ solution in the study of its infrared absorptions and dipole moment: *cis* and *trans* forms exist in equilibrium, the energy difference being 600 cal./mol. The problem is whether the two forms should be found even in the crystalline state or not. Considering the "normal" value of the energy of hydrogen bond for formanilide, 4.1 kcal./mol., estimated in this study, the author is inclined to conclude that the molecule exists in the crystalline state as a *trans* form, because, if there is an appreciable amount of *cis* form, forming ring dimers, the energy of the hydrogen bond should be much higher, as can be seen from the values estimated for $\delta$-valero- and $\varepsilon$-caprolactam.

**Comparison of the Energies of Hydrogen Bonds in Crystalline State between the Types NH···O and OH···O.**—In order to get a general view on the strength of NH···O and OH···O bondings in the crystalline state, a comparison was made between the two types of the hydrogen bonds using the energy values of the bonds estimated by the author in series of studies[8], together with those published already by other investigators (recalculated by the author). The result is shown in Fig. 1. In this figure, numbers of the compounds which show particular values of the energy of the hydrogen bond are plotted against the energy values: for the sake of simplicity the values are rounded off to integers approximating to the original values. The following compounds and energy values are picked up mostly from the publications by Seki and his collaborators[18]: $CH_3OH$ 5.9 (6.0), $C_2H_5OH$ 6.5 (5.8), $n$-$C_3H_7OH$ 6.4 (5.6), $n$-$C_4H_9OH$ 6.0 (5.1), $n$-$C_6H_{13}OH$ 6.5 (5.5), cyclohexanol 5.8 (3.5), pentaerythritol 5.4 (4.0), $i$-erythritol 5.4[19] (4.0), phenol 4.5 (5.2), hydroquinone 4.7 (4.2), ice 4.4 (4.7), hydrogen peroxide 4.5 (5.1), diformylhydrazine 6.0[4] (6.6), diacetylhydrazine 3.1[3] (4.8), diketopiperazine 5.3[6] (4.9), urea 3.5[4] (3.4), oxamide 4.2[5] (4.0), sulphamide 4.7[3] kcal./mol., respectively. The figures in parentheses are the energy values estimated by the procedure proposed by the author[2]. Acetamide 3.1, *N*-methylacetamide 3.4[2], acetylglycine-*N*-methylamide 3.2[20] and acetylglycine-anilide 2.5[20] kcal./mol., respectively, are also included in Fig. 1.

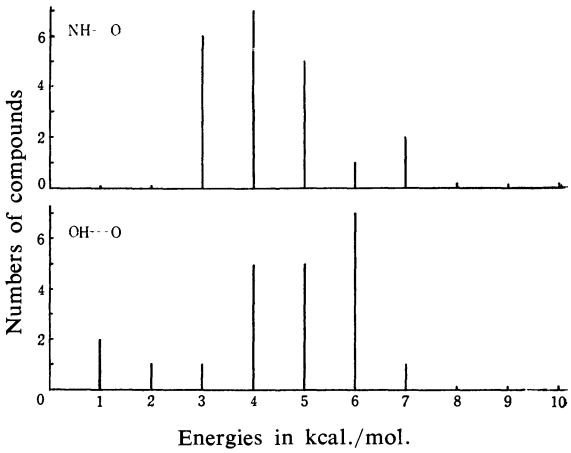

Fig. 1. Comparison of the energy of hydrogen bond between the type NH···O and OH···O.

It may be concluded from the distribution of the energy of hydrogen bonds as is seen in the figure, that the "normal" value of the energy of the NH···O bond can be 4±1 kcal./mol., while that of the OH···O bond amounts to 5±1 kcal./mol., and that a higher value both for NH···O and OH···O bonds can be ascribed to a favorable effect of conjugation in the $\pi$ electron systems as is seen in the formation of ring dimers by lactams and carboxylic acids. The lower values observed in the case of

OH···O bonding are due to the steric hindrance by substituted groups which prevent the mutual approach of hydroxyl groups.

**Summary**

The energies of hydrogen bonds formed in the crystalline state of thirteen amides and one amine have been estimated following the procedure proposed in a previous paper. The values of the energy of an NH···O bond can be estimated at about 4±1 kcal./mol. for the majority of compounds treated in this paper, except two lactams which show energy values as large as 6~7 kcal./mol. A comparison was made between the energy values of NH···O and OH···O bonding using the data obtained by the author and other investigators.

# *Effect of Compacting and Grinding on the Hydrogen Reduction of Nickel Oxide*

By Yoshio IIDA and Kenzo SHIMADA

(Received February 10, 1960)

It has long been known that metal is hardened as a result of plastic deformation when it is pressed or rolled. Recently, it has been reported that the physical or chemical properties of non-metallic substances such as oxide[1], ionic crystal[2] and mineral[3] also vary when they are ground or pressed. Although these phenomena are not explained completely at present, increasing interest is being shown in the plastic deformation of ionic crystal.

In the previous paper[4] dealing with the hydrogen reduction of nickel oxide, it was shown that the rate of reduction was affected by the crystal distortion induced by the dissolution of minor additives. It is thought to be desirable to see how the reduction of nickel oxide is affected by grinding or compacting. In the present paper the isothermal reduction of nickel oxide, in a single crystal form or in powder form, subjected to grinding or compacting has been studied, consideration being given to the surface area of the specimens.

## Experimental

Chemical pure nickel sulfate recrystallized four times was heated at 850°C for 10 hr. to obtain nickel oxide powder. The average unit-particle size of nickel oxide was about 0.5 $\mu$ according to its electron micrograph. Nickel oxide was compacted into tablets at various pressures of 0 to 2000 kg./cm$^2$. A single crystal of nickel oxide was prepared by the method similar to that described by Verneuil[5].

The rate of reduction by hydrogen was determined by a thermobalance with a sensitivity of 0.5 mg. and could be used in hydrogen and in vacuo. Since the rate of reduction of nickel oxide by hydrogen at 200°C was a suitable magnitude for a comparison of the rates of specimens subjected to various treatments, the isothermal reduction was carried out at 200°C in the present study. In all cases of this experiment, nickel oxide of a constant weight of 500 mg. was heated up to 200°C in a vacuum of $10^{-3}$ mmHg and reduced at a constant temperature of 200°C by hydrogen whose flowing velocity was 100 cc./min.

Hydrogen from a commercially available cylinder was used after being purified with concentrated sulfuric acid, hot platinum asbestos, potassium hydroxide and phosphorus pentoxide.

The surface area of nickel oxide powder was determined by the B. E. T. method[6] in which nitrogen was the absorbent.

## Results and Discussion

**Effect of Compacting Pressure.**—The bulk density of nickel oxide pressed at various pressures of 0 to 2000 kg./cm$^2$ was measured from the ratio of weight of dimension. Table I shows that the bulk density increases and the calculated porosity decreases with an increase

TABLE I. BULK DENSITY, POROCITY AND SURFACE AREA OF NICKEL OXIDE PRESSED AT VARIOUS PRESSURES

| Compacting pressure, kg./cm² | 0 | 200 | 500 | 1000 | 2000 |
|---|---|---|---|---|---|
| Bulk density, g./cc. | 1.7 | 2.1 | 2.5 | 3.0 | 3.4 |
| Surface area, m²/g. | 1.60 | — | 1.54 | 1.67 | 1.50 |
| Porosity, % | 75 | 69 | 63 | 56 | 50 |

in the compacting pressure. Although the surface area could be thought to decrease with an increase in the pressure, it does not vary with the pressure as shown in Table I. From these data it is found that a contact point which is formed by an atomic distance between nickel oxide particles and which prevents the adsorption of nitrogen, does not decrease with the pressure in spite of the decreasing porosity. In the previous paper[7] dealing with the oxidation of nickel powders it was shown that a surface area of nickel powders with a ductile property did not vary with the compacting pressure in the range of 0 to 1000 kg./cm². In view of the results concerning nickel powders, the results shown in Table I can be accepted as correct.

The effect of compacting pressure on the isothermal reduction of nickel oxide is shown in Fig. 1. It is seen that the rate of reduction increases with an increase in the compacting pressure below 1000 kg./cm². It should be noted that the amount of reduced nickel oxide in 5 hr. at 200°C is only 50% for an unpressed nickel oxide whereas it is 100% for nickel oxide pressed at 1000 kg./cm². Inasmuch as the surface area does not vary with the compacting pressure as shown in Table I, the accelerated reduction by compacting can be attributed to the crystal distortion which may be induced by compacting. Although the mechanism of hydrogen reduction of nickel oxide compact is very complicated[8] and not yet understood clearly, the porosity of the compact is thought to play an important role in the reduction which is a chemical reaction of solid with gas. The rate is lower at 2000 kg./cm² than at 1000 kg./cm². It is found that the effect of porosity on the reduction exceeds that of compacting when the pressure is relatively high and the porosity is small.

From these data it is expected that the rate becomes higher when nickel oxide compact pressed at a high pressure is ground into fine powders and its porosity becomes larger. Fig. 2 shows that the reduction is promoted further when the compact pressed at 1000 kg./cm² is ground into powders. It is seen that the rate of reduction of nickel oxide powder prepared by compacting and grinding is obviously higher than that of the nickel oxide powder subjected to no mechanical treatment and having the same porosity. This means that the effect of mechanical treatment on the hydrogen reduction is large and the effect of the porosity is small.

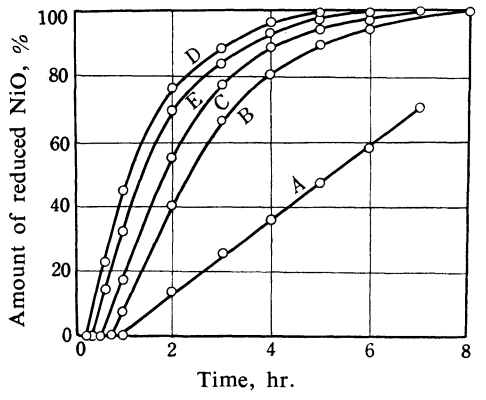

Fig. 1. Isothermal reduction of nickel oxide pressed at various pressures. The reduction temperature is 200°C. A is for nickel oxide unpressed, B, for nickel oxide pressed at 200 kg./cm², C, at 500 kg./cm², D, at 1000 kg./cm², and E, at 2000 kg./cm², respectively.

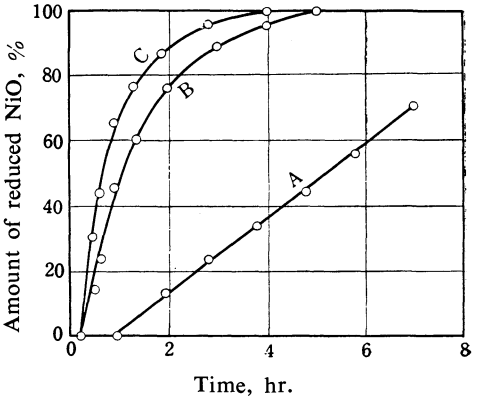

Fig. 2. Effect of compacting and grinding on the hydrogen reduction of nickel oxide at 200°C. A is for nickel oxide without compacting, B, nickel oxide compacted at 1000 kg./cm², and C, nickel oxide ground after compacting at 1000 kg/cm².

**Effect of Grinding.**—Isothermal reductions of a single crystal of nickel oxide and of nickel oxide powders prepared by grinding of the crystal were compared with that of nickel oxide prepared by ignition of nickel sulfate. The results in Fig. 3 show that the rate of

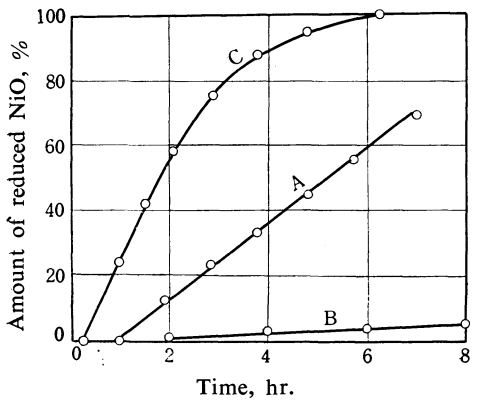

Fig. 3. Effect of grinding of a single crystal on the hydrogen reduction of nickel oxide at 200°C. A is for nickel oxide powders from ignition of nickel sulfate, B, a single crystal of nickel oxide and C, nickel oxide powders from grinding of the single crystal.

reduction of nickel oxide prepared by grinding of the single crystal is larger than those of a single crystal and nickel oxide prepared by ignition of nickel sulfate. It is a natural result from the consideration of the surface area that the rate of reduction of nickel oxide powders prepared by grinding of the single crystal exceeds that of the single crystal. The particles size of nickel oxide prepared by grinding of the single crystal is about 50 $\mu$ by a microphotograph and its surface area is too small to be determined by the B. E. T. method. The particle size of nickel oxide prepared by ignition of nickel sulfate is about 0.5 $\mu$ and is evidently smaller than that of nickel oxide prepared by grinding of the single crystal. The rate of reduction of nickel oxide prepared by ignition, however, is lower than that of nickel oxide prepared by grinding. As the single crystal was prepared from nickel oxide by igniting C. P. nickel sulfate, the purity of both nickel oxides is thought to be essentially the same. From the viewpoint of the surface area of nickel oxides, these facts cannot be understood reasonably.

Recently, it was reported that a change in physical properties of sodium chloride[2], zinc oxide* and kaoline[3] by grinding or compressing might be attributed to the crystal distortion which was caused by the plastic deformation. From these considerations it is concluded that the accelerated reduction of nickel oxide prepared by grinding of the single crystal results from the crystal distortion induced by grinding. On the basis of these data, it seems reasonable to assume that nickel oxide, either in powder form or single crystal form, shows plastic deformation which results in the accelerated hydrogen reduction, when it is compacted or ground.

## Summary

The rate of hydrogen reduction of nickel oxide increases with an increase in the compacting pressure although the bulk density of nickel oxide increases and the surface area does not vary with the pressure. The rate of reduction of nickel oxide which is prepared by the grinding of a single crystal and has a large particle size of 50 $\mu$ is higher than that of nickel oxide which is prepared by ignition of nickel sulfate and has small particle size of 0.5 $\mu$. It seems reasonable to conclude that the accelerated reduction is attributed to the crystal distortion which may result from plastic deformation by grinding or compacting.

The authors wish to express their sincere thanks to Tochigi Kagaku Kogyo Co. for the presentation of the single crystal.

# *A Molecular Orbital Theory of Saturated Compounds. I. Ionization Potential and Bond Dissociation Energy*

By Kenichi FUKUI, Hiroshi KATO and Teijiro YONEZAWA

(Received February 10, 1960)

Recently, several simple quantum-mechanical methods have been proposed to discuss physical properties of saturated compounds. That is to say, the bond energy and the heat of formation have been studied by Brown's bond orbital method[1] and by Dewar's perturbation treatment[2]. The ionization potential and the electron affinity have been investigated by the equivalent orbital method of Lennard-Jones and Hall, Franklin's united atom treatment[4], and Higuchi's UAO method[5].

In the present paper, the aliphatic and alicyclic compounds will essentially be treated by the use of the method previously presented by Yoshizumi[6], in which the skeleton consisting of carbon chain in an aliphatic molecule was exclusively taken into consideration. Thus, the ionization potential, heat of formation and bond energy of various saturated compounds are calculated according to this procedure, and the results obtained are in good agreement with experiments.

## Theoretical

Yoshizumi applied the strategy which was usual for treating the $\pi$-electron system to attacking the $\sigma$ electron system. Namely, in treating aliphatic molecules the $sp^3$-hybridized orbital of a carbon atom appeared in place of the $2p\pi$ atomic orbital in the treatment of conjugated molecules. He neglected the C–H bond of paraffin hydrocarbons for the sake of simplicity. Thus the molecular orbital was represented by a linear combination of $sp^3$ hydridized orbitals of carbon atoms, as follows:

$$\phi_j = \sum_j C_{rj}\phi_r \qquad (1)$$

where $C_{rj}$ is the coefficient of the $r$th atomic $sp^3$ hybridized orbital of carbon, $\phi_r$, in the $j$th molecular orbital, $\phi_j$. All the overlap integrals were neglected as in the simple LCAO MO theory in $\pi$-electron system. The resonance integrals in C–C bond and that between the orbitals attached to the same carbon atom were assumed as

$$\int \phi_i H \phi_{i+1} d\tau = \beta$$

and

$$\int \phi_i H \phi_{i+1} d\tau = m\beta$$

respectively, where $m$ was a small quantity which was determined by Yoshizumi as $m^2 = 0.12$ referring to the value of dipole moment of halogen-substituted hydrocarbons. The resonance integrals between non-neighboring atomic orbitals were neglected. In Fig. 1, it will be seen that when the number of an orbital $i$ is odd, the integral corresponds to that between two adjacent carbon atoms, and when $i$ is even, the resonance integral between two atomic orbitals of one and the same carbon atom.

In Yoshizumi's paper only linear paraffins were treated. In treating the other saturated compounds, it is necessary to introduce some emprical parameters besides.

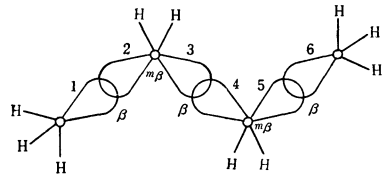

Fig. 1. Carbon $sp^3$ hybridized orbitals in *n*-butane.

## Parameters

For tertiary and quaternary carbon atoms in branched chain hydrocarbons, the Coulomb integral is tentatively taken as $\alpha_C = \alpha - \delta\beta$ in common according to their electronegativity, where $\alpha$ is the Coulomb integral of $sp^3$ hybridized orbital of primary and secondary carbon atoms. The value of $\delta$ is determined as equal to 0.3 considering the value of ionization potential of *i*-butane.

For alkyl halides (R–X), the Coulomb integral, $\alpha_X$, is taken as $\alpha + a\beta$ and the resonance integral, $\beta_{C-X}$ as equal to $b\beta$, where $b$ is determined by the formula $\frac{\beta_{C-X}}{\beta_{C-C}} = \frac{S_{C-X}}{S_{C-C}}$ ($S$ is

obtainable from Mulliken's table[7]*) and $a$ is determined referring to the values of ionization potential of C-X bonding electron of methyl halides assigned by McDowell[8]. The values of $a$ and $b$ used in the present paper are listed in the following table.

| X | $a$ | $b$ |
|---|---|---|
| F | 0.91 | 0.51 |
| Cl | 0.56 | 0.65 |
| Br | 0.54 | 0.58 |
| I | 0.50 | 0.53 |

For alkyl alcohols, the Coulomb integral of alcoholic oxygen, $\alpha_{OH}$, is taken as $\alpha+0.5\beta$ and the resonance integral, $\beta_{C-OH}$, as $0.5\beta$, where $\beta_{C-OH}$ is determined by using the formula stated above (the value of $S_{C-OH}$ is put nearly equal to that of $S_{C-O}$). Since the value of the ionization potential of C-OH bonding electron of methyl alcohol has never been known, the value of $\alpha_{OH}$ is tentatively assumed as above.

## Results and Discussion

**a) Ionization Potential.**—(1) It was pointed out[8,9] that in normal parraffins their first ionization could be attributed to the removal of one electron localized in C-C bonds. This was supported by the difference between observed C-H and C-C bond energies, and also by the result of Hall's calculation[3]. Namely, he elucidated the theory that in the highest occupied orbital of normal paraffins the electron density of C-C bond was larger than that of C-H bond. Therefore, the ionization potential may safely be considered to be equal to the negative of the highest occupied orbital energy obtained by solving the secular determinant. The calculated results are listed in Table I, and the plot of calculated energy values versus observed ionization potentials is shown in Fig. 2. From the linear relation between the calculated and the observed, the values of $\alpha$ and $\beta$ are estimated as $-5.850$ eV. and $-6.364$ eV., respectively. With these values, the recalculated ionization potentials of paraffins are listed in the third column of Table I which are in good agreement with the observed, except in ethane.

TABLE I. CALCULATED ENERGIES OF THE HIGHEST OCCUPIED ORBITAL AND OBSERVED IONIZATION POTENTIALS OF NORMAL PARAFFINS

| Compound | Calcd. energy[a] $\lambda_{ho}$ | $\varepsilon_{ho}$ eV. | Obsd. I. P.[9] eV. |
|---|---|---|---|
| Ethane | 1.0000 | 12.21 | 11.76 |
| Propane | 0.8444 | 11.22 | 11.21 |
| *n*-Butane | 0.7752 | 10.77 | 10.80 |
| *n*-Pentane | 0.7388 | 10.55 | 10.55 |
| *n*-Hexane | 0.7170 | 10.41 | 10.43 |
| *n*-Heptane | 0.7034 | 10.33 | 10.35 |

| *n*-Decane | 0.6820 | 10.19 | 10.19 |

a) $\lambda_{ho}$ is the coefficient in $\varepsilon_{ho}=\alpha+\lambda_{ho}\beta$, where $\varepsilon_{ho}$ is the highest occupied orbital energy.

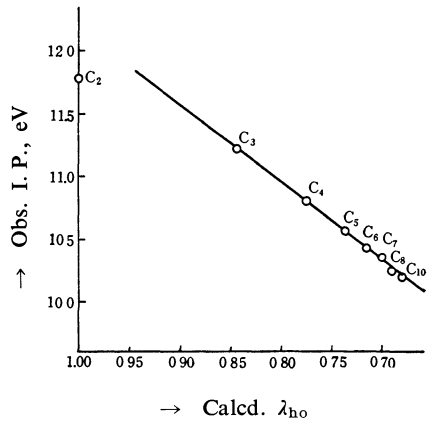

Fig. 2. Ionization potential of normal paraffins vs. $\lambda_{ho}$.

(2) In the calculation of cycloparaffins the steric configuration is left out of consideration, all the C-C-C angles being assumed equal to that of linear molecules. Therefore, no parameter is introduced anew. The results are listed in Table II, together with observed and Franklin's values[4] for the sake of comparison. It is seen that the smaller the deviation of an actual C-C-C angle from the normal one, the better agreement between the observed and the calculated results is found. This suggests that there is some room for improvement in future.

(3) For branched chain paraffins, the calculated values of ionization potentials are listed in the third column of Table III.

(4) It is considered that the first ionization potential of alkyl alcohols is due to removal of one of the lone pair electrons of the oxygen atom. The correlation of calculated values of the highest occupied orbital energies with observed ionization potentials is examined and an apparent linear relation between them is shown in Table IV, and it may result from the following cause. In general, the inductive effect of alkyl group may exert an influence

* The evaluation of the overlap integral, $S_{C-X}$, for bromine using the Slater orbital can not be carried out in the usual way. Therefore, the nearest integral power of $r$ in Slater orbital is adopted in our calculation.

on the electronegativity of oxygen lone pairs[10]. Therefore, the parallelism may be more directly understood by comparing the observed ionization potential with the magnitude of total $\sigma$ electron density the oxygen atom which is also given in the same table.

10) I. Omura, H. Baba and K. Higashi, This Bulletin, **28**, 147 (1955).

**b) Total Electronic Energy and Bond Dissociation Energy.**—The calculated total electronic energies are compared with observed values of heat of formation of several normal paraffins. The results indicate a good parallelism between them. For each increase of one $CH_2$-group the increment in the calculated energy lies between $2\alpha+2.057\beta$ and $2\alpha+2.059\beta$, while the observed difference in energy is in the range $-4.6\sim-5.2$ kcal./mol.[1] as shown in Table V. For cycloparaffins, the calculated total electronic energies are compared with observed heats of combustion and both the values per $CH_2$ are listed in Table VI*. Thus we can conclude that a simple additivity rule may approximately hold in normal paraffins and cycloparaffins.

In order to calculate the bond dissociation energy, we assume that it can be obtained by the following formula**.

$$D(R_1-R_2)=\{E(R_1\cdot)+E(R_2\cdot)\}-E(R_1-R_2) \quad (2)$$

where $D(R_1-R_2)$ denotes the dissociation energy of the bond between $R_1$ and $R_2$ in the compound $R_1-R_2$, $E$ is the total electronic energy, and $R_1$ and $R_2$ are two alkyl groups. For simplicity, the energy of an odd electron in alkyl radical, which is localized on one carbon atom, is assumed equal to $\alpha$. The results are listed in Table VII, where the numbers in parentheses are the observed values of bond energy and the numbers below them are the calculated values of bond energy in units of $(-\beta)$. In lower paraffins, the values obtained by Eq. (2) are shown to be a good measure for bond energy value. In hexane, a slight disagreement is observed. No internuclear repulsion is involved in the present treatment, and hence this discrepancy may, at

* The failure seen in the case of cyclobutane may probably be attributed to the approximation adopted in which steric circumstances are entirely disregarded.
** In the calculation of energy of alkyl radicals, the effect of hyperconjugation of alkyl group is left out of account.

least partly, be ascribed to such a rough approximation adopted. Further improvement should be made on this point.

With regard to ethyl halides, the bond dissociation energies of C-X bond are obtained and compared with experimental values in Table VIII. Compounds are arranged in decreasing order of bond energies. It is seen that the result coincides well with experiments.

## Summary

The ionization potential and the bond dissociation energy of saturated compounds are calculated by Yoshizumi's C-C bond skeleton method. With regard to ionization potentials, the calculated results are parallel to the observed values. In particular, for normal paraffins the parallelism is almost complete. For total electronic energies, the calculated results indicate a simple additivity rule in normal and cycloparaffins, and for bond dissociation energies an approximate agreement is obtained between the calculated and the observed values.

In spite of the rough approximation involved in the present treatment, it may be said that the results obtained are rather satisfactory.

# *A Molecular Orbital Theory of Saturated Compounds. II. Chemical Reactivity in Nucleophilic Substitution*

By Kenichi FUKUI, Hiroshi KATO and Teijiro YONEZAWA

(Received February 26, 1960)

It is well known that a nucleophilic substitution of aliphatic compounds has available two reaction mechanisms, one being the unimolecular ($S_N1$) and the other the bimolecular mechanism ($S_N2$)[1]. The explanation of reactivity in aliphatic substitution has hitherto been carried out only by means of empirical electronic theory. No quantum-mechanical treatment of chemical reactivity in nucleophilic aliphatic substitution has ever been put into practice though some theoretical studies have been made with regard to the Walden inversion by Jaffé[2] and others[3,4].

In Part I[5] of this series of papers the ionization potential and the bond dissociation energy of several aliphatic compounds were calculated by the use of the C–C skeleton method proposed by Yoshizumi[6], resulting in a good agreement with the experiments.

In the present paper, an attempt is made to elucidate the reactivity in nucleophilic substitution of some alkyl halides, following the same quantum-mechanical procedure as used in Part I[5]. Also by the use of the procedure of simple LCAO MO method of conjugated molecules the stability of some aliphatic ions is discussed, in which the hyperconjugative effect is thought to be prevailing.

## $S_N2$ Reaction

The reaction of this type is expressed by the equation[1]

$$A^- + R-X \rightarrow [A\cdots R\cdots X]^- \rightarrow A-R + X^-$$

where $A^-$ is a nucleophilic reagent, R is an alkyl group, X is the group to be expelled, and the compound in brackets, stands for the activated complex.

The structure of activated complex is schematically written in Fig. 1. In this state, R′, R″, R‴ and C-atom lie all in one plane, and also A, C-atom and X lie on one straight line perpendicular to the plane. Four $sp^3$ orbitals of the central carbon atom may change to three $sp^2$ orbitals and one $p$ orbital which binds both A and X to C-atom. However, for the sake of simplicity, we neglect the influence of altered hybridization at the central C-atom and adopt the same values for Coulomb and exchange integrals as $sp^3$ hybridization. The overlap integral between $sp^2$ orbital and $p$ orbital is put equal to zero. The contribution of the reagent A to the energy of the total system is regarded as the same in all the reactions of the same type. We assume that in the transition state two $\sigma$ electrons in the C–X bond to be broken are localized at X-atom*. According to the present model, the difference in the energy between the transition state and the initial state, $\Delta E$, is calculated as

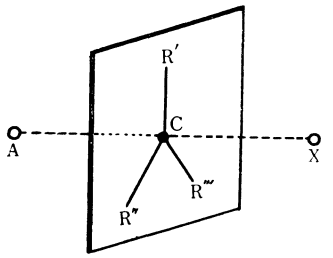

Fig. 1. Transition state in $S_N2$ reaction.

$$\Delta E = \{E[R^+] + E[X^-]\} - E[R-X] \qquad (1)$$

where $E[A]$ is the calculated total energy of the molecule or ion A. This procedure corresponds to the localization method in the theory of aromatic substitution. This energy, $\Delta E$, is considered to be a measure of the activation energy of the reaction.

Calculations are made with respect to some alkyl bromides, chlorides and iodides. The second order reactions of ethoxide anion and

* Two alternative models may be possible. The one is the model in which the two $\sigma$ electrons are localized in the C-X bond, and the other is that in which the two electrons move in A···C and C···X bonds. Whichever of these two models one may adopt, only a constant term will be added to the energy difference obtained in the present treatment and no serious alteration arises with regard to the results.

chloride anion with alkyl bromides are investigated and the calculated results are compared with the ovserved activation energy and reaction rate in Table I. The agreement with this experiment is found satisfactory. In the present calculation, the energetic contribution of the attacking anion is not taken into account, since the anion is regarded as having the same energy in all the reactions of the same type.

In Table I, $\Delta E$ values of several alkyl bromides are listed for two types of nucleophilic reaction. In Table II, the experimental activation energies of alkyl iodides in the Menschutkin type reaction and in the substitution with the chloride anion are compared with the calculated values of $\Delta E$. Table III indicates the results of calculation with regard to the reaction of alkyl chloride with iodide anion. It is observed that the value of $\Delta E$ increases according as the reaction rate decreases.

TABLE I

(1) $RBr+C_2H_5O^- \rightarrow C_2H_5OR+Br^-$ [1]

| RBr | $\Delta E$ calc. $(-\beta)$ | Activation energy obs. (kcal./mol.) | Rate constant obs. $10^8k$ at 55°C ($sec^{-1}mol^{-1}l.$) |
|---|---|---|---|
| C-Br | 0.7420 | 20.0 | 34.4 |
| C-C-Br | 0.8156 | 21.0 | 1.95 |
| C-C-C-Br | 0.8174 | — | 0.55 |
|  | 0.8215 | 22.8 | 0.05 |
|  | 0.9215 | 26.2 | 0.000008 |

(2) $RBr+Cl^- \rightarrow RCl+Br^-$ [1]

| RBr | $\Delta E$ calc. $(-\beta)$ | Activation energy obs. (kcal./mol.) | Relative rate obs. |
|---|---|---|---|
| C-Br | 0.7420 | 15.8 | 100 |
| C-C-Br | 0.8156 | 17.9 | 1.97 |
| C-C-C-Br | 0.8174 | 18.1 | 1.29 |

|  | 0.8911 | 18.7 | 0.040 |
|  | 0.9580 | 21.2 | 0.009 |

The calculated results in these tables indicate that the rate of $S_N2$ reaction decreases in the order methyl>ethyl>higher *n*-alkyl>*i*-propyl >*t*-butyl, in accordance with experience.

The absolute rate of $S_N2$ substitution is strongly affected by an exchange of the group to be displaced. The observed rate of hydrolysis or alcoholysis decreases in the order R–I >R–Br>R–Cl. Calculated values in brackets exhibit a similar tendency as follows:

C–C–I (0.7494($-\beta$))>C–C–Br(0.8156($-\beta$))
>C–C–Cl(0.9288($-\beta$)).
C–C–C–I (0.7524($-\beta$))
>C–C–C–Br(0.8174($-\beta$))
>C–C–C–Cl(0.9305($-\beta$))

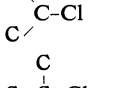
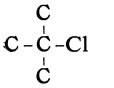
### $S_N1$ Reaction

The rate determining step in this type of reaction is the ionic dissociation represented by the formula $RX \rightarrow R^+ + X^-$. Dewar[7] proposed a model for this transition state which may be written as S···R···X···S, where S stands for a solvent molecule, R is the alkyl group, and X is the group to be expelled. The factors affecting the rate of $S_N1$ reactions are considered to be (1) the rate of ionic dissociation of the molecule R–X, (2) the solvent effect, and so on. Refering to this we adopt as reactivity indexes the electron densities at the central C-atom ($q_C$) and at the X-atom ($q_X$) in the C–X bond. The larger $q_C$ is, the faster is the rate of ionic dissociation of the molecule R–X. Furthermore, the larger $q_X$ is, the stronger is the X···S binding.

TABLE IV





$RBr + OH^- \rightarrow ROH + Br^-$ [1]

| RBr | Calc. total density $q_C$ | Calc. total density $q_{Br}$ | Relative rate obs. |
|---|---|---|---|
| C-Br | 0.5768 | 1.4231 | 1.00 |
| C-C-Br | 0.5979 | 1.4359 | 1.71 |
| C-C-C-Br | 0.6000 | 1.4401 | — |
|  | 0.6005 | 1.4437 | — |
|  | 0.6063 | 1.4511 | 44.7 |
|  | 0.6056 | 1.4667 | $10^8$ |
|  | 0.6091 | 1.4874 | — |

Calculated values of $q_C$ and $q_{Br}$ are listed together with the rate of hydrolysis of alkyl bromide in Table IV in which a parallelism between them is found. Since there exist, however, no sufficient data available for comparison, the heat of reaction, $Q$, i. e. the approximate activation energy in $S_N1$ solvolysis of alkyl halides, computed by Evans[8,9] is used in Table V for this purpose. The magnitudes of $q_C$ and $q_X$ are seen to be parallel with the value of $Q$. Therefore, we conclude that $q_C$ and $q_X$ are useful reactivity indexes in $S_N1$ reaction.

TABLE V

(1) $R-X\ aq \rightarrow R^+\ aq + X^-\ aq$[7]

| R-Cl | Calc. total density $q_C$ | Calc. total density $q_{Cl}$ | Heat of reaction by Evans, $Q$ (kcal./mol.) |

| C-C-Br | 0.5979 | 1.4359 | 56.5 |
|  | 0.6063 | 1.4511 | 34.5 |
|  | 0.6056 | 1.4667 | 23.5 |

TABLE VI

| Ions | Resonance energy calc. $(-\beta_0)$ | Stabilization energy[10] obs. (kcal./mol.) |
|---|---|---|
| $CH_3^+$ | 0 | 0 |
| $C_2H_5^+$ | 0.3350 | 36 |
| $n$-$C_3H_7^+$ | 0.5081 | — |
| $i$-$C_3H_7^+$ | 0.6462 | 66 |
| $t$-$C_4H_9^+$ | 0.9043 | 84 |

Furthermore, it has been shown that the rates of some $S_N1$ reactions can be connected with stabilites of alkyl ions formed by dissociation[10,12]. These stabilities can be represented by the resonance energy. In order to calculate the resonance energy in these saturated molecules, we may apply the simple LCAO MO treatment of conjugated molecules[10]. The following parameters are adopted in this calculation:

Coulomb integrals:

$\alpha_{H_3} = \alpha_0 - 0.3\,\beta_0$, $\alpha_{H_2} = \alpha_0 - 0.5\,\beta_0$,

Resonance integrals:

$\beta_{H_3 \equiv C} = 2.5\beta_0$, $\beta_{H_2 = C} = 2.0\beta_0$,

$\beta_{C-C} = 0.88\beta_0$ (in a C–C bond adjacent to the central C-atom),

$\beta_{C-C} = 0.50\beta_0$ (in other C–C bonds),

where $\alpha_0$ and $\beta_0$ are the Coulomb and resonance integrals in benzene, respectively. The latter two parameters $\beta_{C-C}$ are evaluated by considering the degree of localization in hyperconjugation[11].

The result of calculation with respect to several alkyl ions is indicated in Table VI. In $S_N1$ reaction the rate decreases along the series methyl < ethyl < higher $n$-alkyl < $i$-propyl < $t$-butyl, and the extremely large stability of the

# *Investigation on Mixed Complexes. IV. The Formation of a Mixed Complex by Reaction of Tetracyanoniccolate(II) with Bis-(dithiooxalato)-niccolate(II)*

By Sigeo KIDA

(Received August 31, 1959)

In the preceding paper of this series[1], it was demonstrated that the chlorocyano- and bromocyano- platinum(II) complex could not be formed in solution. However, one can not say that the formation of any mixed cyano complexes must be ruled out. Since it is commonly known that bis-(dithiooxalato)-niccolate(II) and tetracyanoniccolate(II) ions have the planar configuration, one should expect that a reaction between these reactants in solution might produce a complex containing both cyano and dithiooxalato as ligand. The purpose of the present paper is to present spectrophotometric evidence for the formation of a mixed cyano complex of the type, $[Ni(C_2S_2O_2)(CN)_2]^{2-}$, in solution.

Equivalent quantities of potassium bis-(dithiooxalato)-niccolate(II) and potassium tetracyanoniccolate(II) were mixed in solution. At first, the dark red color of the bis-(dithiooxalato)-niccolate(II) ion was predominant in the solution, then the color slowly changed to orange, the reaction being complete in two hours at room temperature (15°C). This change was followed spectrophotometrically, and the results are shown in Fig. 1. The intensity of the absorption band at 501 m$\mu$ of the bis-(dithiooxalato)-niccolate(II) ion decreases remarkably with time, while a new band appears at 380 m$\mu$, the intensity of which increases in nearly reciprocal proporation to that of the band at 541 m$\mu$. This implies that a reaction such as,

$$[Ni(C_2S_2O_2)_2]^{2-} + [Ni(CN)_4]^{2-} \rightleftarrows 2[Ni(C_2S_2O_2)(CN)_2]^{2-},$$

might be taking place in solution. The reasons are: 1) the blue shift of the band from 501 m$\mu$ to 380 m$\mu$ is indicative of the replacement of the dithiooxalate ion by cyanide ions, since the former is placed behind the latter in the spectrochemical series[2], and 2) the frequency of the new band is nearly equal to the mean of frequencies of the bands of the parent complexes, $[Ni(C_2S_2O_2)_2]^{2-}$ and $[Ni(CN)_4]^{2-}$, as shown in Table I. This is the relationship which can always be seen between the mixed complex and its parent complexes[3,4].

Previously[5], polarographic measurements were carried out on a mixed solution of potassium bis-(dithiooxalato)-niccolate(II) by Maki, Kida and Tsuchida, and it was reported that a new compound, perhaps the mixed complex, $[Ni(C_2S_2O_2)(CN)_2]^{2-}$, must be formed in the solution. Thus, the present result is not in consistent with the previous one.

Similar spectrophotometric observations were made also on the bis-dithiooxalato- and the tetracyano- platinum(II) and palladium(II) complexes. Unfortunately, no indication of the expected reactions, such as

$$[Pt(C_2S_2O_2)_2]^{2-} + [Pt(CN)_4]^{2-} \rightleftharpoons 2[Pt(C_2S_2O_2)(CN)_2]^{2-} \text{ and}$$

$$[Pd(C_2S_2O_2)_2]^{2-} + [Pd(CN)_4]^{2-} \rightleftharpoons 2[Pd(C_2S_2O_2)(CN)_2]^{2-},$$

could be detected. At present, however, it is quite uncertain whether this is due to the total inertness of these parent complexes or to the extreme instability of the ligand-mixed complexes.

Therefore, another attempt was made as follows: in order to obtain some information on the possible reaction between the bis-(dithiooxalato)-platinate(II) ion and the cyanide ion, a potassium cyanide solution and a potassium

Table I. Frequencies of absorption bands of the complexes

| $K_2[Ni(C_2S_2O_2)_2]$ | $K_2[Ni(CN)_4]$ | New band | $(\nu_1+\nu_2)/2$ |
|---|---|---|---|
| 59.7 (501 mμ) | 96.9 (310 mμ) | 78.9 (380 mμ) | 78.3 |

$\nu\times10^{13}$: the frequency of the absorption maximum ($sec^{-1}$)

bis-(dithiooxalato)-platinate(II) solution were mixed in the ratio 2 : 1. The intensity of the absorption band due to the bis-(dithiooxalato)-platinate(II) ion at 430 mμ was appreciably reduced, while in a shorter wavelength region, the absorption showed a uniform increase in intensity. No distinct new band was formed, as shown in Fig. 2.

This uniform increase in absorption intensity in the shorter wavelength region may be regarded as being due to the decomposition of the bis-(dithiooxalato)-platinate(II) ion, since it can be demonstrated spectrophotometrically that, in an alkaline solution, this ion is subject to a slow decomposition which results in increased absorption at the shorter wavelength[6]. Accordingly, a mixed complex, such as $[Pt(C_2S_2O_2)(CN)_2]^{2-}$, is unlikely to be present in the solution, though it is better not to draw a decisive conclusion until more experimental data are obtained. On the other hand, there is no doubt that some quantity of the tetracyanoplatinate(II) ion has been produced in this solution, because the characteristic band, of this ion, at 279 mμ, is evidently found in the absorption curve 6 in Fig. 2.

## Experimental

Solutions of the following concentrations were mixed, $(2/3)\times10^{-3}$ F potassium bis-(dithiooxalato)-niccolate(II) and $(2/3)\times10^{-3}$ F potassium tetracyano-niccolate(II), and the mixed solution was placed in the dark at room temperature (15°C). The reaction was almost complete in two hours. It was ascertained by extinction measurements that the decomposition of bis-(dithiooxalato)-niccolate(II) ion was small during the experiment.

6) This was verified by extinction measurements on a weakly alkaline solution of this complex.
The bis-(dithiooxalato)-palladate (II) ion so rapidly decomposed in an alkaline solution that extinction measurements of this complex could not be carried out in a solution containing potassium cyanide.

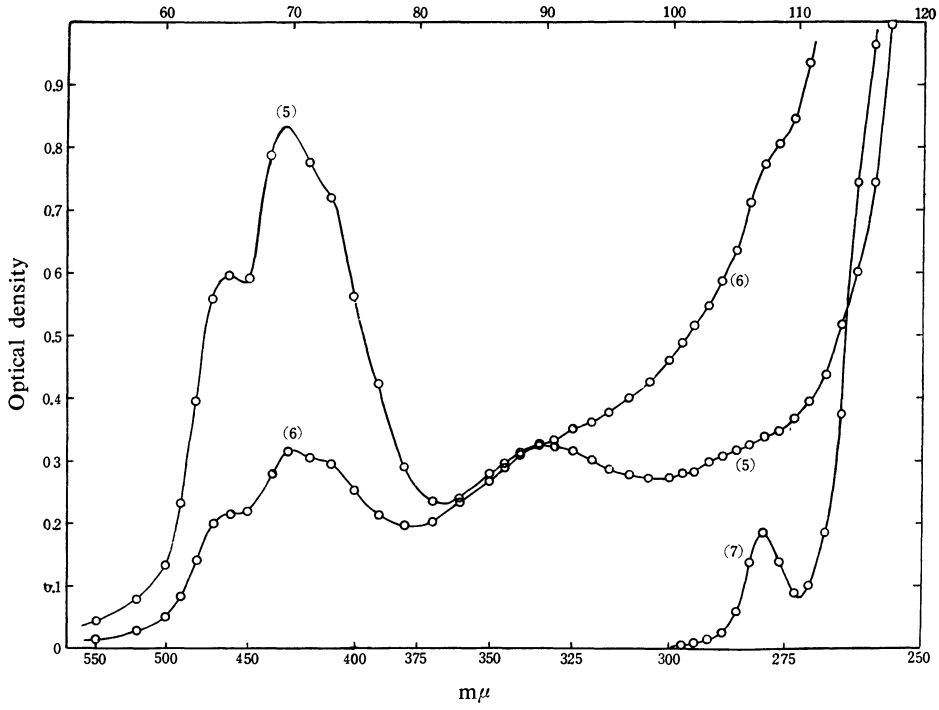

Fig. 2.

(5) $10^{-4}$ F $K_2[Pt(C_2S_2O_2)_2]$ solution
(6) $10^{-4}$ F $K_2[Pt(C_2S_2O_2)_2]$ and $2\times10^{-4}$ KCN solution, (2 days after mixising)
(7) $10^{-4}$ F $K_2[Pt(CN)_4]$

Solutions of potassium cyanide (0.1 F) and of potassium bis-(dithiooxalato)-platinate(II) (0.2 F) were mixed and placed in the dark at room temperature (15°C). For extinction measurements, 5 ml. of the solution was diluted to 500 ml. The extinction measurements were carried out with a Beckman model DU spectrophotometer.

The complexes, $K_2[Ni(C_2S_2O_2)_2]$[7], $K_2Pd(C_2S_2O_2)_2]$[7], $K_2[Pt(C_2S_2O_2)_2]$[7], $K_2[Ni(CN)_4]\cdot H_2O$[8], $K_2[Pd(CN)_4]\cdot 3H_2O$[8], and $K_2[Pt(CN)_4]\cdot 3H_2O$[9], were prepared according to the literature cited.

## Summary

It has been concluded, by the spectrophotometric method, that 1) potassium bis-(dithiooxalato)-niccolate(II) and potassium tetracyanoniccolate(II) react in solution to form a mixed complex, $[Ni(C_2S_2O_2)(CN)_2]^{2-}$, 2) in the case of palladium(II) and platinum(II), bis-(dithiooxalato)- and tetracyano- complexes do not react in solution, unlike the case of nickel(II), and 3) the dithiooxalate ion in the complex, $[Pt(C_2S_2O_2)_2]^{2-}$, is replaced by the cyanide ion in solution, the tetracyanoplatinate(II) ion being formed, but the formation of the mixed complex, such as $[Pt(C_2S_2O_2)(CN)_2]^{2-}$, is not certain.

The author wishes to express his heartfelt thanks to Professor R. Tsuchida for his kind instruction and advice throughout this work.

# *Dichroism of Dyes in the Stretched PVA Sheet. IV.*[1] *Absorption Spectra of Carbocyanines and Note on the Chemical Structures**

By Yoshié TANIZAKI and Hisataké ONO

(Received February 9, 1960)

In the previous paper[1], the dichroic behavior of Pinacyanol in the stretched polyvinylalcohol (PVA) sheet was discussed in detail. It was pointed out that the directions of absorptions, which were judged by an inspection of the dichroic curves observed at a high stretch ratio, are in agreement with those obtained from a quantitative analysis of the relation between the density ratio $R_d$ and the stretch ratio $R_s$[1].

The purpose of this paper is to analyze the dichroism of carbocyanines by this method of inspection, to confirm the fact that the result thus obtained can be explained consistently by the conclusion derived from Pinacyanol[1], and to add some new information about the visible absorption phenomena after the inclusive discussion on the further experimental facts obtained here.

## Experimental

Here were used the following four dyes, which were prepared by the known methods:

1, 1'-Diethyl-2, 2'-cyanine iodide, — m. p. 274°C (277°C in literature[2]). Found: C, 59.92; H, 5.04; N, 6.32. Calcd. for $C_{23}H_{23}N_2I$: C, 60.79; H, 5.07; N, 6.18%.

1, 1'-Diethyl-2, 2'-dicarbocyanine iodide, — m. p. 268~9°C (270°C in literature[4]).

1, 1'-Diethyl-2, 2'-tricarbocyanine iodide, — m. p. 222~3°C (225°C in literature[4]). Found: C, 61.30; H, 5.75; N, 4.80. Calcd. for $C_{29}H_{29}N_2I \cdot 2H_2O$: C, 61.30; H, 5.81; N, 4.93%.

1, 1'-Diethyl-4, 4'-cyanine iodide, — m. p. 282°C (271~3°C in literature[5]). Found: C, 60.96; H, 5.35; N, 6.37. Calcd. for $C_{23}H_{23}N_2I$: C, 60.79; H, 5.07; N, 6.18%.

Let us use the notations, $j=0(2,2')$, $j=2(2,2')$, $j=3(2,2')$ and $j=0(4,4')$, for the respective dyes described above. At the same time, the Pinacyanol used in the previous paper[1] will be denoted by $j=1(2,2')$.

The preparation of the sample sheet, the measurement, etc. followed the manner reported before[1,6]. Here, the dyeing bath of the dye which failed to dissolve in water at the necessary concentration was prepared by adding a calculated amount of water to the hot ethanol solution of the dye concentrated as much as possible.

## Results

Let us number the absorption bands of each dye in the order of wavelength, for the convenience of the following description (see figures and tables).

Figs. 1 and 2 show, the interpretation of the dichroism of $j=0(4,4')$ in the near ultraviolet and in the visible regions, respectively. In Fig. 1, it is seen as a distinctive feature that the $D_{\parallel}$ and $D_{\perp}$ curves cross in the neighborhood of Band VII, that $D_{\perp}$ of Band VIII is apparently higher than $D_{\parallel}$, and that $D_{\theta}$ of Band V does not change much with increasing $\theta$.

Figs. 3 and 4 indicate the dichroism of $j=0$ $(2,2')$ in the ultraviolet and visible regions respectively. Their special feature is that $\lambda_{max}$'s in the region longer than 300 m$\mu$ are

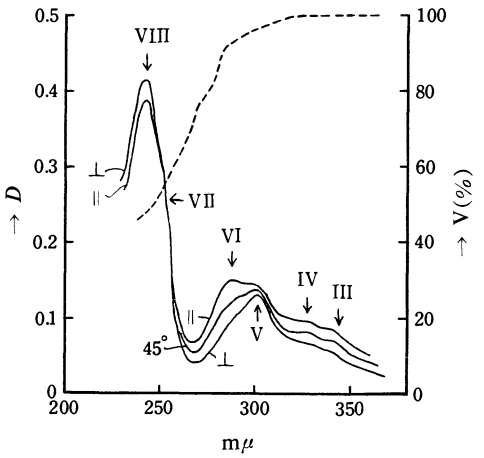

Fig. 1. The dichroism of 1,1'-diethyl-4,4'-cyanine iodide, $j=0(4,4')$, in the stretched PVA sheet. $R_s=5.7$. The broken line indicates the polarization degree curve of the polaroid used, taken from Y. Tanizaki, This Bulletin, **30**, 935 (1957).

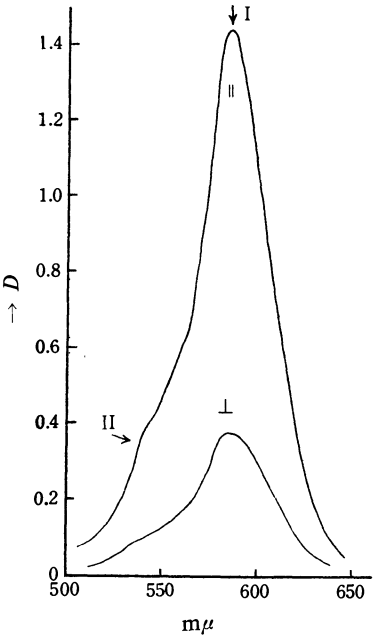

Fig. 2. The dichroism of 1,1'-diethyl-4,4'-cyanine iodide, $j=0(4,4')$, in the stretched PVA sheet. $R_s=10$.

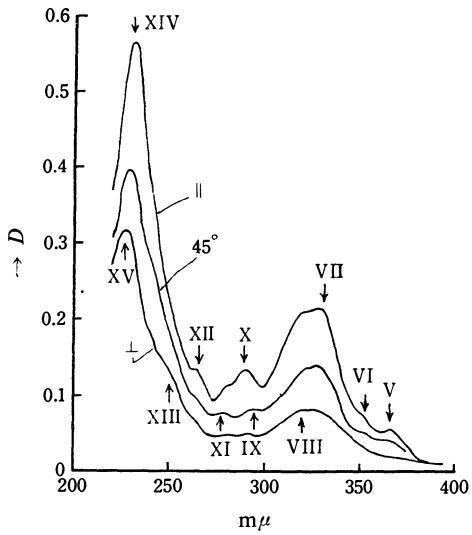

Fig. 3. The dichroism of 1,1'-diethyl-2,2'-cyanine iodide, $j=0(2,2')$, $R_s=9.0$.

almost independent of $\theta$**, while those in the region thereunder show an apparent change. It is also an interesting fact that the shapes of absorption bands in the visible and 300~400 mμ regions resemble each other considerably (see Figs. 3 and 4), though not so closely as in the case of Pinacyanol, $j=1(2,2')$[1].

** A detailed inspection revealed a slight shift of $\lambda_{max}$ with $\theta$ in the visible region. This we will discuss later.

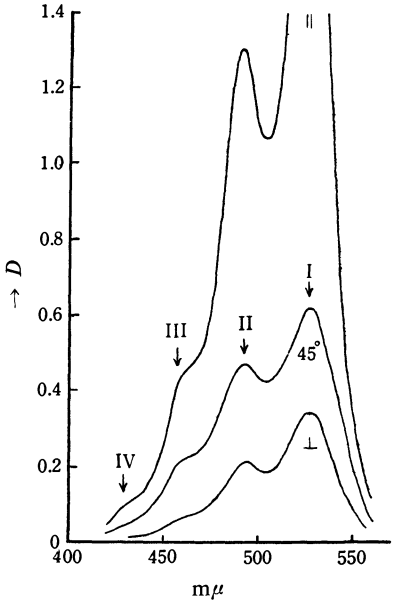

Fig. 4. The dichroism of 1,1'-diethyl-2,2'-cyanine iodide, $j=0(2,2')$, $R_s=9.0$.

Figs. 5 and 6 show the dichroism of $j=2$ $(2,2')$ at 220~500 mμ and 500~850 mμ, respectively. In this case, too, $\lambda_{max}$'s as above 400 mμ show little change with $\theta$**, while those below 400 mμ show a clear change.

Figs. 7 and 8 show the dichroism of $j=3$ $(2,2')$. Here is found the important fact that $\lambda_{max}$'s of $D_\theta$ in Fig. 8, which shows the absorptions supposedly along the long axis of the molecule[1], apparently shift with $\theta$. Similar behavior was also recognized in the case of $j=0$ (Fig. 4) and $j=2$ (Fig. 6), though very slightly. Band II (493 mμ) in Fig. 4, for example, shows a slight shift in $\lambda_{max}$ towards shorter wavelengths with a change from $D_\perp$ to $D_\parallel$ curve. Such a tendency may be due principally to the following fact: small directional differences originally existing between the absorptions along the molecular axis come to be appreciable owing to a sharpening in the

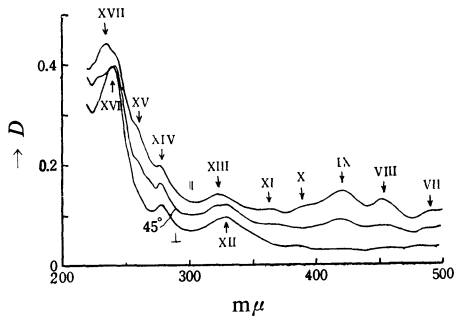

Fig. 5. The dichroism of 1,1'-diethyl-2,2'-dicarbocyanine iodide, $j=2(2,2')$. $R_s=8.1$.

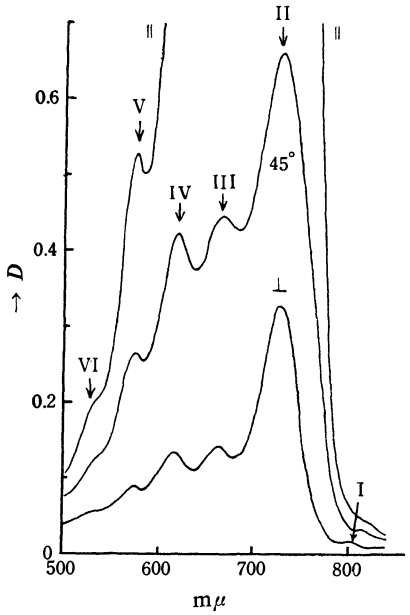

Fig. 6. The dichroism of 1,1'-diethyl-2,2'-dicarbocyanine iodide, $j=2(2,2')$. $R_S=8.1$.

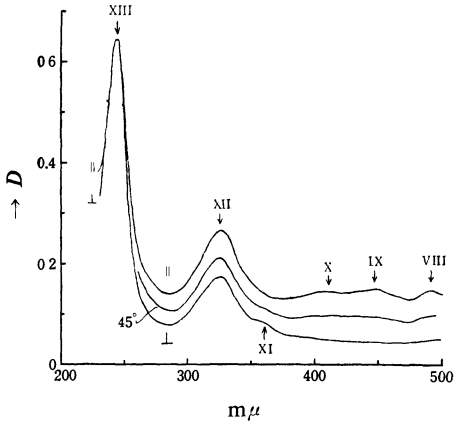

Fig. 7. The dichroism of 1,1'-diethyl-2,2'-tricarbocyanine iodide, $j=3(2,2')$. $R_S=6.1$.

distribution for the direction of the statistic orientation axis attendant on the molecule with the increase of its length. On the other hand, the directional properties of the short wavelength absorptions show a tendency to become indistinct with the increase of $j$. They are most indistinct in the case of $j=3$. It should be noticed that even the absorptions below 350 mμ have no change in $\lambda_{max}$ with $\theta$. Moreover, $D_{\parallel}$ and $D_{\perp}$ of Band XIII coincide with each other (Fig. 7), with the incident light of 50% polarization in this region (cf. Fig. 1).

Tables I—V involve the transition directions, the classification of band-groups, etc., as in the previous paper[1], judged from the data mentioned above. Here, table III shows again the data of Pinacyanol obtained previously[1]. Band-groups in tables have the following meaning: the absorptions in the first and the second group are both due to the transitions along the long axis of the molecule, and the absorption intensities of the second group are considerably

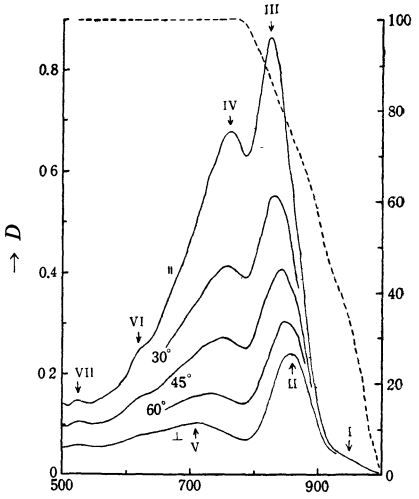

Fig. 8. The dichroism of 1,1'-diethyl-2,2'-tricarbocyanine iodide, $j=3(2,2')$. $R_S=6.9$. The broken line indicates the polarization degree curve of polaroid used, taken from Y. Tanizaki, This Bulletin, **30**, 935 (1957).

Table I. The absorption bands of 1,1'-diethyl-4,4'-cyanine iodide, $j=0(4,4')$, in the stretched PVA sheet

| Band No. | $\lambda$ mμ | $\nu$ cm$^{-1}$ | $\Delta\nu$ cm$^{-1}$ | Direction | Group | $\Delta\tilde{\nu}$ cm$^{-1}$ |
|---|---|---|---|---|---|---|
| I | 585 | 17100 | 1480 | $l$ | 1st | 1480 |
| II | 538 | 18580 | 10640 | $l$ | | |
| III | 342 | 29220 | 1440 | ? | 2nd | 1440 |
| IV | 326 | 30660 | 2540 | ? | | |
| V | 301 | 33200 | 1500 | $\perp(L_{\parallel})$ | 3rd | |
| VI | 288 | 34700 | 4980 | $\parallel(L_{\perp})$ | | |
| VII | 252 | 39680 | 1620 | $\parallel$ ?$(L_{\perp}$?) | 4th | |
| VIII | 242 | 41300 | | $\perp(L_{\parallel})$ | | |

Note: $\Delta\nu$ and $\Delta\tilde{\nu}$ indicate the distance between the adjacent bands and the mean of the band distance among the group, respectively. The notation "$l$" means the longitudinal direction of the molecule, and "$\parallel$" or "$\perp$" means the direction more parallel or more normal to the $l$-direction, respectively, among transitions in the quinoline parts. In this table, $\parallel$ corresponds to $L_{\perp}$, the short axis of the quinoline nucleus, and $\perp$ to $L_{\parallel}$. In the following tables, $\parallel$ corresponds to $L_{\parallel}$ and $\perp$ to $L_{\perp}$.

Note: See the note of Table I.

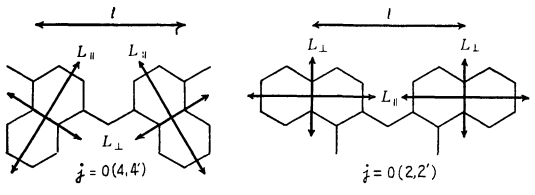
weak compared with those of the first one. There is a clear boundary between these two groups, as seen in their band distances, e.g. the separation of Bands IV and V in Table II is 4040 cm$^{-1}$. Consequently the first and the second groups can be distinguished from each other. The third and the fourth groups consist of the ∥ ⊥ character-absorptions. The third group bands are weak and the fourth strong.

According to the polarization degree curve indicated in Fig. 8, the polarization degree of incident light begins to fall precipitously at about 800 mμ, becomes about 50% at 900 mμ,

Table VI. Average wavenumber of the absorption bands in the first and the second group, difference and ratio



| Dyes | $\tilde{\nu}$ cm$^{-1}$ 1st group | $\tilde{\nu}$ cm$^{-1}$ 2nd group | $\Delta\tilde{\nu}$ cm$^{-1}$ | Ratio (2nd/1st) |
|---|---|---|---|---|
| $j$=0 (4,4′) | 17840 | 29940 | 12100 | 1.68 |
| $j$=0 (2,2′) | 21100 | 29330 | 8230 | 1.39 |
| $j$=1 ( 〃 ) | 16660 | 24300 | 7640 | 1.46 |
| $j$=2 ( 〃 ) | 16260 | 24820 | 8560 | 1.53 |
| $j$=3 ( 〃 ) | 12290 | 19470 | 7180 | 1.58 |

and then vanishes at 1000 m$\mu$. For this reason, it will be expected that when the absorption of 860 m$\mu$ (Band II) in Fig. 8, $j$=3(2, 2′), is measured with the perfect polarized light, the band maximum will be shifted towards the longer wavelength side. Consequently, the distance between Bands I and II in Table V becomes smaller, while the distance between Bands II and III becomes greater. As a result, it will be expected that the two band distances approach the mean value of the first group in Table V.

Table VI includes the mean wave numbers of the absorption bands in the first and the second group, the difference and the ratio between these wavenumbers having been derived from Tables I—V. The ratio is approximately constant at about 1.5, except for the case of $j$=0 (4, 4′) dye.

## Discussion

**Absorptions in the Short Wavelength Region.**— It has already been clarified from a detailed analysis of Pinacyanol that the absorption bands in the third and the fourth group are originated from the electronic transitions, in two directions at right angles, localized in the quinoline nucleus parts[1]. If this is the case with these absorptions, and if both (4, 4′) and (2, 2′) dye of $j$=0 have the planar structures indicated in Figs. 9(a) and (b) as respective possible ones, the dichroism similar to Pinacyanol should be expected for the latter rather than for the former. Nevertheless, according to Figs. 1 and 3, the distinct differences in direction among $l$, $L_{\parallel}$ and $L_{\perp}$ indicated in Fig. 9 are obviously recognized in (4, 4′) but not in (2, 2′) dye. This may be due to the steric hindrance; these molecules ($j$=0), as is well known, can not keep the planar structure. Both quinoline planes are inclined to each other, and this may be contributed mostly by the twisting of the central methine bonds. In Fig. 9(a), therefore, two $L_{\parallel}$ directions through the twisting of the methine bonds approach to being parallel with each other and normal to the $l$-direction. But the relative directions of $L_{\perp}$ are not altered by the twisting just mentioned. On the other hand, in Fig. 9(b), the twisting of methine bonds makes two $L_{\parallel}$'s and two $L_{\perp}$'s oblique to each other, respectively, and it may possibly occur that their oblique angles against $l$-direction become the same in their degree. Owing to this situation, (4, 4′) dye might reveal such dichroic behavior as that shown in for Fig. 1: instance the 288 m$\mu$ band (VI) has the similar tendency as the absorptions parallel with $l$-direction (Fig. 2), and the 301 m$\mu$ (V) and the 242 m$\mu$ band (VIII) have a tendency to be considered almost normal to $l$-direction. As for (2, 2′) dye (Fig. 9(b)), on the other hand, on account of certain resultant inclinations of $L_{\perp}$ and $L_{\parallel}$ against $l$-direction produced by steric hindrance, it has the dichroism indistinctive in $\parallel$ $\perp$ character as shown in Fig. 3. In contrast with this, in case of $j$=1(2, 2′) (Pinacyanol) in which a steric hindrance is considered to be not so great as in $j$=0, the dichroism similar to that in Fig. 1 in appearance was observed with distinct difference in direction among $L_{\parallel}$, $L_{\perp}$ and $l$. This dichroism was already illustrated in the previous paper[1]. Thus, at least concerning $j$=0 dyes, the dichroism is reasonably understood by regarding the third and the fourth group absorptions as being caused by the transition at right angles to one another.

a b

Fig. 9. Molecular skeleton diagrams of (a) 1,1′-diethyl-4,4′-cyanine cation, $j$=0 (4,4′), and (b) 1,1′-diethyl-2,2′-cyanine cation, $j$=0(2,2′).

According to the conventional consideration, the dye molecule becomes more planar with an increase in the number of methine bond, namely $j$. From this point of view, the $\parallel$ and $\perp$ character of absorptions of the third and fourth groups ought to be much more manifest with the increase of $j$. As for the (2, 2′) dyes, however, there is found a tendency to the contrary: the increase of $j$ obscures the $\parallel$ $\perp$ character in dichroism. This character is observed typically in the case of Pinacyanol[1] with small $j$. This fact suggests that the whole strain angle of the molecule in the case of $j>1$ results from the successive summing up of the twisting angle peculiar to one methine bond. That this consideration is correct will

also be supported by the discussion in the following section.

**Absorptions in the Long Wavelength Region.**— It was considered previously that the second group absorptions correspond to an overtone of those of the first group[1]. One of the reasons for such consideration is also found in the dyes used here. That is to say, the second group resembles generally the first group in shape and the former is much weaker in intensity than the latter. Moreover, the ratios of their transition energies lie between 1.4 and 1.7 This fact can be interpreted in quite the same way by *second order absorption* theory on the absorptions with the same direction, proposed by Lewis et al.[7]. For this reason, there seems now no room for doubt that the absorptions of the first group and those of the second group are associated with each other as the first and the second order absorption, respectively.

It is clear from many experimental facts that the absorption phenomena of the first group of Pinacyanol is subject to remarkable change on account of its complex formation[8]. When these absorptions correspond to particular ones of respective complexes, the phenomena could be interpreted by the Davidov splitting. If so, in a case when a band in the first group is split by the formation of a complex, a corresponding absorption band in the second group with the same direction should be split in the same way. The fact that the absorptions of the first and the second group are distributed in respective groups, as shown in the tables, may suggest the very occurrence of the Davidov effect***. According to tables I—V, however, the separation of bands in the first and the second group does not change with the same tendency but with different behaviors with an increase of $j$ (see Fig. 10) : when $j=0$, the band distance in the first group is greater than that in the second, while for $j \geqq 1$ the former becomes smaller and the latter greater with the increase of $j$. These relations are illustrated in Fig. 10. These obvious phenomena do not seem to be explained simply by the consideration of the Davidov effect. One possible interpretation may be given, as below, taking into account the vibrational states whose contribution might be induced by the complex formation.

Interatomic distances, usually, are lengthened by excitation to the upper state unless the ground state is forced to be strained by a particular steric hindrance. In case the molecule is already hindered in the ground state,

*** Davidov splitting of Pinacyanol under a certain condition was found for the electronic transition to the first excited state but not decidedly for the second excited state. In this case the absorption spectrum in acetone was thought to be due to the monomer, though it indicated the $\alpha$ and $\beta$ bands. See, J. W. Weigl, *J. Chem. Phys.*, 24, 364 (1956).

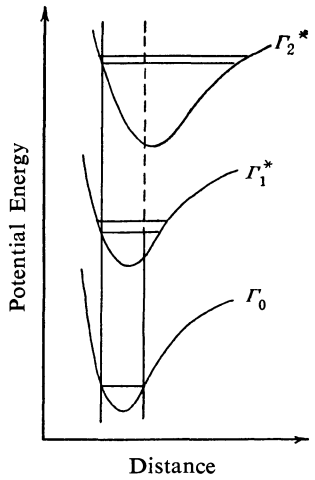

Fig. 12. Schematic potential curves for $j=0$. In this case, the minimum parts of the $\Gamma_0$ and $\Gamma_1^*$ curve do not shift, but only that of the $\Gamma_2^*$ curve deviates to the right side.

it may happen that the interatomic distances are not changed by excitation. Relative configurations of the potential curves in such cases would be represented schematically by Figs. 11 and 12. Fig. 11 corresponds to $j>1$, and Fig. 12 to $j=0$. In the case of Fig. 11, the minimum positions of the ground state ($\Gamma_0$), the first ($\Gamma_1^*$) and the second excited state curve ($\Gamma_2^*$) may shift towards the right hand, usually in this order. Then, if the configurational relations of $\Gamma_1^*$ and $\Gamma_2^*$ to $\Gamma_0$ are such as shown in Fig. 11, the band distances of the first group become smaller than those of the second group, for the higher the vibrational states are along the curve the narrower the space between the two adjacent states becomes. On the other hand, in Fig. 12 the band distances of the first group would become greater than those of the second group, if the correlation of $\Gamma_0$ and $\Gamma_2^*$ curves is like that of $\Gamma_0$ and $\Gamma_1^*$ curves in Fig. 11, because there is no shift between the minimum positions of $\Gamma_0$ and $\Gamma_1^*$ curves as presumed above. Thus, we have one plausible interpretation of the experimental facts, according to the above consideration. At the present stage, however, there is no theoretical base for the diagrams in Figs. 11 and 12. Nevertheless, it has an instructive meaning that the phenomena shown in Fig. 10 can be explained qualitatively only by admitting such a possibility as mentioned above for the potential curves of molecules in a complex formed.

It has already been described that the absorption bands of the first group have the tendency to reveal their directional difference in dichroism with an increase of $j$. This does not seem to agree with conventional consideration that the increase of $j$ makes the molecules approach to planar configurations. The reason is as follows: the better the planarity of the molecule, the better should be the parallelism of any vector in the $l$-direction, regardless of terminated points on both quinoline planes of a transition vector, on account of the symmetry of the molecule as seen from the structure in Fig. 9(b). That is to say, the larger the number $j$, the smaller must become the directional difference in dichroism. This is just opposite to the experimental facts. Thus, applying over again the consideration that the peculiar twisting angle per methine bond is added successively with an increase of $j$ as mentioned in the last section, it stands to reason that the angles against $l$-direction differ in respective absorptions, so far as $j$ is not so large and the terminals of the different transition vectors do not agree with one another; and further taking into account the sharpening of the orientation axis of the molecule, the behavior in dichroism of the first group-bands can be reasonably understood.

## Summary

1. Dichroism of the electronic spectra over 220 m$\mu$ was measured for 1, 1'-diethyl-2, 2'-cyanine, -dicarbocyanine, and -tricarbocyanine iodide, and -4, 4'-cyanine iodide, respectively, in the stretched polyvinylalcohol sheets under the stretch ratio of about 6~10.

2. The correspondence of the transition directions of absorptions and the chemical structures, and the classification of the absorption bands were made into tables.

3. All the dichroic behaviors of the absorption bands could be interpreted by the transitions along the longitudinal axis of the molecule and by those, localized in the quinoline nuclei, of two directions at right angles.

4. It was confirmed that the second group absorptions correspond to the overtone of the first group ones. It was shown by the schematical potential curves that the systematic changes in the band distances in these groups with the variation of the methine bond number may be plausibly explained in connection with the vibrational states.

5. It was pointed out that a reasonable understanding for certain experimental facts in dichroism is given by regarding the molecular structures as follows; 1, 1'-diethyl-2, 2'-cyanine and -4, 4'-cyanine are far from planar because of their particular great steric hindrance, and the other cyanines are strained by the succes-

sive addition of a peculiar twisting angle per methine bond.

The authors wish to express their thanks to Professor N. Ando and Professor I. Tanaka of Tokyo Institute of Technology for their encouragement throughout this work, to Mr. Y. Mori of this Institute for his useful discussion and helpful advice, and also to Mr. Y. Hamada of the Research Laboratory of Fuji Photo Film Co., Ltd. for his help in the preparation of the dyes used.

# *A Molecular Orbital Treatment of Phosphate Bonds of Biochemical Interest. I. Simple LCAO MO Treatment*

By Kenichi FUKUI, Keiji MOROKUMA and Chikayoshi NAGATA

(Received January 18, 1960)

It is well known that adenosine triphosphate (ATP) is used as a catalyst in varions kinds of in vivo chemical processes. Kalckar[1] and Lipman[2] for the first time pointed out that the energy change of hydrolysis of phosphate P–O bond of ATP was much greater than that of ordinary phosphate bonds and that this energy liberated by hydrolysis might promote endergonic reactions. Thus P–O bonds of ATP were named "high energy phosphate bonds" characterized by the sign "P~O". Further, adenosine diphosphate (ADP), phosphoenol pyruvate (PEP) and acetyl phosphate (AcP) are some of the phosphates which were believed to have high energy phosphate bonds[1-4,5]; but they can hardly be used in in vivo reactions. In this they are different from ATP[5].

Recently it has been found in calorimetrical measurements by Podolsky and Morales[6] that the enthalpy change in hydrolysis of ATP is considerably smaller than the value hitherto reported and is parallel with those of simple polyphosphates. This finding has been supported by Benzinger and Kitzinger[7], and by Burton[8]. These results suggested that there might be a revision of our understanding with respect to the role of ATP[6-8].

Kalckar[1] and Lipman[2] studied the high energy phosphate bond on the basis of the mesomeric theory. Lately Ooshika[9] assumed in their quantum-chemical discussions that the phosphate bonds of ATP were of high energy. Grabe[10] calculated the charge density of the system $-\overset{|}{\underset{\|}{C}}-O-\overset{|}{\underset{\|}{P}}-$ (O, O), and discussed at which side of the bridge oxygen the bond dissociation occurred. Gillespie et al.[11] stressed the necessity of studies on this problem from the point of view of reaction kinetics.

In this paper the authors have carried out a systematic computation on the electronic energy changes, the reactivity indexes and charge distributions of four organic phosphates, ATP, ADP, PEP and AcP, with so-called "high energy" bonds and, for comparison's sake, two phosphates lacking such bonds, adenosine monophosphate (AMP) and glycerol 1-phosphate (GLP), by a simple molecular orbital approximation. From these calculated results they have concluded that, so far as the phosphate parts only are considered, the difference, if it might exist, in the energy of

hydrolysis between two kinds of phosphates can not be attributed to the difference of $\pi$ electronic energy change, though their reactivity is somewhat different.

## Method of Calculation

The calculation is carried out in the approximation of the simple LCAO MO (linear-combination-of-atomic-orbitals molecular orbital) treatment neglecting overlap. For AcP and PEP the conjugation is spreading throughout the molecule. For ATP, ADP and AMP, on the other hand, phosphate parts only are taken into account, i.e., the adenine part, which is separated from the phosphate part by the non-conjugating ribose, is assumed not to be interacting with the phosphate part. On this assumption a few essential discussions will be given in the following section. AMP, GLP and other low energy phosphates come to have the same conjugated system in this approximation. Phosphorus atoms in the phosphates have a nearly tetrahedral, $sp^3$-hybridized configuration, with one electron jumping up into one of $3d$ orbitals. Strictly speaking, $2p$ $\pi$ electrons on the neighboring oxygen atoms can interact not only with these $d$ orbitals but also, though presumably only slightly, with the $sp^3$-hybridized orbitals[12,13]. Taking into account all of these interactions, however, complicates the problems extremely and makes it practically impossible to treat large molecules of interest. We conveniently assume, therefore, that only one hybridized $d$ orbital on a phosphorus atom, say e.g. $d^3s$ hybridized orbital which can afford to give a directed valence of tetrahedral symmetry, conjugates with $2p\pi$ orbitals of the neighboring oxygens in this simple treatment. Accordingly ATP, for instance, is regarded as a system consisting of 13 orbitals and 20 electrons.

The Coulomb integral of the atom or group X, that of the carbon atom attached to X and the resonance integral between that carbon atom and X are written as $\alpha+a_X\beta$, $\alpha+a_r\beta$ and $l\beta$, respectively, where $\alpha$ and $\beta$ are the Coulomb and the resonance integrals of a carbon atom and a C-C bond in benzene, respectively. Since the precise value of $a_{-O-}$ seems unsettled, two parallel computations are carried out for two $a_{-O-}$ values. In Table I, together with $a_X$'s of oxygen atoms in the phosphate part, are listed the numerical values of $a_X$, $a_r$ and $l$ adopted by us, which do not differ so much from those which were previously used by the present authors[21,22] and others[15,16]. If some oxygen atoms assigned to different $a_X$'s should be considered to be equivalent, the mean value of their $a_X$'s is employed; for instance, $a_X$ of each oxygen atom in the $-PO_3^{2-}$ group is regarded as 1.0 and that in the $-PO_2^-$ group as 1.25.

Table I. Parameters used in the calculation

1. Phosphate part

| X | $a_X$ |
|---|---|
| =O | 2.0 |
| $-O^-$ | 0.5 |
| -O- | 0.5, 2.0 |

2. Others

| X | $a_X$ | $a_r$ | $l$ |
|---|---|---|---|
| =O | 2.0 | 0.2 | $\sqrt{2}$ |
| -OH | 0.5 | 0 | 0.6 |
| $-CH_3$ | 3.0 | −0.1 | 1 |

The resonance integral between a phosphorus atom and an oxygen atom, $\beta_{P-O}$, is tentatively taken 0.6 $\beta$, regardless of the bonding states of the oxygen atom (-O- type, O=type or $-O^-$ type) from a rather simple theoretical consideration on the overlap integral[13], but the numerical value itself is not essential to our results of calculation, as will be stated below. Furthermore, it is hardly possible to decide semiempirically the Coulomb integral of the phosphorus atom in the valence state in question, $\alpha_P=\alpha+a_P\beta$, because of the lack of sufficient experimental data and knowledge on the $d$ electron phenomena. Therefore in order to avoid the unreliability of the results caused by a rather arbitrary choice of $a_P$, we vary the $a_P$ value as widely as possible, as 0, −0.2, −0.4, −0.6, −1.0, −1.5, −2.0, −3.0 and $-\infty$. It should be stressed concerning this point that by means of this sliding of $a_P$ values we can practically afford to evade not only the ambiguity of the $a_P$ value but also the arbitrariness of the $\beta_{P-O}$ value and moreover, partly, the error due to the above-stated conventional choice of the orbitals on a phosphorus atom, at least for ATP, ADP and AMP where conjugated systems are consisting of only phosphorus and oxygen atoms. In this sense the present treatment has a very general character. Judging from the ionization potential of a $3p$ electron (I=10.98 eV.)[10] and from Pauling's electronegativity scale ($\chi_P=2.1$), −0.6 or smaller would be appropriate for the real $a_P$ value of a hybridized $d$ electron.

The present authors have previously presented the frontier electron theory and have succeeded in interpreting theoretically the experience on

the chemical reactivity of $\pi$ electron system[17-21]. Here we do not repeat the details of the theory but we mention only the fact that the superdelocalizability, $S_r$, has been known as a good intermolecular reactivity index for the substitution and the addition reactions. Also for hydrolysis of phosphates $S_r$ is expected to remain a good measure of reactivity and is used in the present paper for discussing the ease of hydrolysis of phosphates.

## Results and Discussion

**The $\pi$ Electronic Energy Change of Hydrolysis.**—The results of calculation of the $\pi$ electronic energy change of hydrolysis for two $a_{-O-}$ values and various $a_P$ values are listed in Table II. The listed value, $-\Delta E$, is expressed as the difference of $\pi$ electronic energy between the hydrolysis products and the original reactant excepting water. For ATP, for instance, it becomes

$$-\Delta E = E(\mathrm{ADP})^{3-} + E(\mathrm{PO_4}^{3-}) - E(\mathrm{ATP})^{4-}$$

The electronic energy of water is not included in this expression because it is a constant and can not precisely be evaluated. Therefore, not the absolute value of $\Delta E$ but its difference between the two kinds of phosphate or between ATP and other phosphates has practical meaning in further discussions.

As clearly seen in Table II, $\Delta E$ of each compound does not vary so much according to $a_P$ values. Furthermore it should be noticed that its difference between the two kinds of phosphate bonds does not exceed $-0.2\beta$ for any pair of $a_P$ and $a_{-O-}$ values. This maximum value corresponds to ATP when $a_P$ is zero and $a_{-O-}=2.0$. The difference for $a_P=-1.0$, a most probable value of $a_P$, is about $-0.12\ \beta$. Putting $\beta$ as $-20$ kcal./mol., it corresponds to ca. 2.5 kcal./mol. If $\beta_{P-O}$ is taken to be $0.8\ \beta$, it becomes ca. 3 kcal./mol. by changing the energy value of $\beta$. Thus it might be said that in the difference of the free energy change of hydrolysis between the two kinds of phosphate only 2.5 to 3 kcal./mol. at most can be ascribed to the $\pi$ electronic energy.

Consequently it is concluded that, so far as phosphate parts only are taken into account, the peculiarity of ATP in several in vivo reactions cannot be attributed to the electronic energy.

**Superdelocalizability for a Nucleophilic Attack and the Reactivity of Phosphate Bond.**—By this time most contributions to the problem of these organic phosphate bonds of biochemical interest have been carried out from the

energetical point of view. But it seems important and interesting at this juncture for us to discuss the reactivity or the ease of hydrolysis of phosphate bonds. Hydrolysis of phosphates would be initiated by the attack of a hydroxyl anion to the phosphorus atom in vivo or of some nucleophilic group or site of tissue in vivo. So the superdelocalizability, $S_P^{(N)}$, of the phosphorus atom for a nucleophilic attack is expected to represent a theoretical index to the ease of hydrolysis. In Table III are collected the results of the calculation of superdelocalizability for a nucleophilic attack for various $a_P$ values. The larger the $S_P^{(N)}$ is, the more reactive for a nucleophilic attack is the phosphorus atom.

As is seen in Table III, the value of $S_P^{(N)}$ of each compound is reduced markedly with the decrease of $a_P$ values; but it is noticed that comparison of $S_P^{(N)}$ of various compounds at the same $a_P$ value shows us some difference between the two kinds of phosphate bond, which decreases with the decrease of $a_P$, as 0.05 to 0.2 when $a_P=0$, 0.04 to 0.1 when $a_P=-0.4$, 0.02 to 0.04 when $a_P=-1.0$, and less than 0.01 when $a_P=-2$ and $a_P=-3$. Even larger differences of the superdelocalizability, which are realized for larger values of $a_P$ (smaller in the absolute value), would not be sufficient to cause a casual difference of actual ease of hydrolysis. Nor could the conspicuous role of ATP be attributed to this difference, for the difference for ATP is not at all markedly greater than that for other "high energy" phosphates*. So far as phosphate parts only are considered, it would be concluded that, though some distinction can be seen in the reactivity for hydrolysis between the "high energy" bond and the ordinary one, it does not seem great enough to cause a serious difference in the role in biochemical processes.

**Total $\pi$ Electron Density of Oxygen Atoms.** —In some biochemical problems of reactivity of conjugated molecules, effects of subsidiary atoms and bonds in the compounds were often noticed to play an essential part as well as some steric factors. A few examples of this can be seen in the carcinogenic activity of condensed aromatic hydrocarbons[14] and dimethylaminoazobenzene derivatives[22] and also in auxin activity of benzoic acid derivatives[21]. In this sense the total $\pi$ electron density of oxygen atoms ($q_{-O-}$ and $q_{-O^-}$) attached to a phosphorus atom may be expected to prevent electrostatically a nucleophilic reagent from approaching the phosphorus atom, where –O– and $-O^-$ stand for an oxygen atom on the phosphate bond to be broken and an oxygen anion attached to the phosphorus atom on that bond, respectively. The calculation of them has been carried out only when $a_P$ is

* Of the two so-called high energy bonds in an ATP molecule, the inner one seems to be of very low energy (about 4 kcal. lower than the outer) from an energetic point of view, whereas the value of $S_P^{(N)}$ shows that the inner is the more reactive. It would not be possible to decide from this calculation, therefore, which bond is the easier to break.

TABLE IV. TOTAL $\pi$ ELECTRON DENSITY AND SUPERDELOCALIZABILITY OF OXYGEN ATOMS FOR ELECTROPHILIC ATTACK[a]

1) $a_{-O-}=0.5$.

| Class | Compound | $S_{-O-}^{(E)}$ | $q_{-O-}$ | $S_{-O^-}^{(E)}$ | $q_{-O^-}$ |
|---|---|---|---|---|---|
| Low energy | AMP, GLP etc. | 3.055 | 1.868 | 1.797 | 1.914 |
| High energy | ATP (I)[b] | 2.508 | 1.773 | 1.783 | 1.912 |
| | ATP (II)[c] | 2.550 | 1.773 | 1.475 | 1.925 |
| | ADP | 2.546 | 1.783 | 1.818 | 1.963 |

2) $a_{-O-}=2.0$.

| Class | Compound | $S_{-O-}^{(E)}$ | $q_{-O-}$ | $S_{-O^-}^{(E)}$ | $q_{-O^-}$ |
|---|---|---|---|---|---|
| Low energy | AMP, GLP etc. | 0.952 | 1.952 | 1.743 | 1.991 |
| High energy | ATP (I)[b] | 0.900 | 1.906 | 1.742 | 1.990 |
| | ATP (II)[c] | 0.878 | 1.903 | 1.417 | 1.991 |
| | ADP | 0.900 | 1.906 | 1.742 | 1.991 |

[a] $O^-$ stands for the three or the two equivalent oxygens in $-PO_3^{2-}$ or $-PO_2^-$ ; -O- stands for the bridge oxygen in phosphate bonds.
[b] The end "high energy" phosphate bond.
[c] The central "high energy" phosphate bond.

$-1$, since the choice of the value of $a_P$ was proved in the previous paragraph not to affect the results so seriously.

On inspection of the fourth and the sixth columns of Table IV, ATP and ADP would be understood to be to a small extent preferential in hydrolysis, since the interference by the electron density in it must be smaller than in AMP.

**Superdelocalizability of the Oxygen Atom for Electrophilic Attack.**—In this case assuming, as was not done in the preceding paragraphs, that the initial stage of hydrolysis is the attack of proton or an electrophilic group upon the bridge oxygen atom of the phosphate bond, the superdelocalizability of the oxygen atom, $S_O^{(E)}$, for an electrophilic attack was calculated and listed in the third column of Table IV. The order of $S_{-O-}^{(E)}$ cannot explain the singularity of ATP in biochemical reactions. Nor can the order of the superdelocalizability of oxygen, $S_{-O^-}^{(E)}$, do so as clearly seen in the fifth column of Table IV.

In the foregoing discussion we found that the "high energy" phosphate bonds are not of electronically high energy, though to some extent they are more reactive, and that the conspicuous role which ATP exclusively plays in in vivo chemical reactions cannot be explained by these simple models of phosphates.

Two things must be investigated prior to the ascertainment of this conclusion. One of them is that the calculations in the present paper have been performed in the simple LCAO MO approximation: that is to say, no electron interaction has been explicitly taken into account. Interactions to be considered would occur also among $2p\pi$ electrons on a phosphorus atom. As stated in the previous section, however, since the wide sliding of $a_P$ values from zero to minus infinity would considerably diminish the unreliability of this approximation, no serious alteration of results could be expected even in a more precise treatment.

The other is more essential. In the present paper AMP, ADP and ATP have been treated as if they were composed of only polyphosphate parts. No attention has been paid to the other conjugated part of the molecule, the adenine part, which is intervened and separated by the non-conjugated ribose group from the polyphosphate parts. This large conjugated system, however, would have some interaction with the polyphosphate part. Levendahl and James[23] found in their study on the rotatory dispersion of AMP, ADP and ATP that in ATP the last two phosphate groups and the amino group of adenine part were interacting, whereas no such interaction was noticed in the others, and suggested that this stabilized structure would an important significance in the peculiarity of the function of ATP. Szent-Györgyi[24] surmised that, as for ATP, among the 6-amino group and the 7-nitrogen of adenine parts and the two oxygens of the last two phosphate parts, the magnesium cation might intervene, through which the conjugation would spread over the molecule.

From the above calculations and discussions

23) B. H. Levendahl and J. W. James, *Biochim. Biophys. Acta*, **21**, 298 (1956).
24) A. Szent-Gyorgyi, "Biogenetics", Academic Press, New York, 1957.

we might say that the peculiar in vivo behavior of ATP must not be attributed to the polyphosphate part itself, but to the whole system including the polyphosphate part and the adenine part, interacting with each other directly or through a metal cation.

In the latter case the interaction of the polyphosphate part with a metal cation would considerably enhance the reactivity of its phosphorus atoms for a nucleophilic attack. Forming a weak bonding, metal cation will help them to interact. Calculation under the explicit consideration of these interactions is now going to be carried out with respect to several models for different interacting positions, extents of interaction and roles of metal cations. This will be published elsewhere.

# *Studies on the Configuration and Conformation of Polystyrene*

By Masatami TAKEDA, Kazuyoshi IIMURA, Akira YAMADA and Yoshio IMAMURA

(Received February 13, 1960)

This work was undertaken to investigate the relationship between the chemical configuration of vinyl-type polymer determined by the process of polymerization reaction and the conformation of vinyl-type polymer determined by the physical state of a polymer.

Natta[1] showed that the polystyrene prepared by the Ziegler catalyst contains higher isotactic sequences in its chain configuration and that the crystallizability of this polystyrene is due to the helical conformation[2] of the isotactic chain which makes up the crystalline region of crystallized polystyrene.

Williams et al.[3] also found that the polystyrene prepared by the Alfin catalyst has the same tendency of crystallizability but at a lower degree.

These findings led to two different types of problems. One of them is the existence of configurational isomers, and the concept of isotactic or syndiotactic configurations. The concept of tacticity or stereoregularity is developed in this direction. The distribution of configurational isomers in each sample will be determined by the process of polymerization and solvent extraction.

The other is the existence of conformational isomers for each configurational isomer; and the distribution of conformational isomers for each configuration will be determined by the physical state of the sample and its history such as heat treatment. The dominant existence of the helical conformation of the isotactic chain in the crystalline parts of crystallized polystyrene was the only available information about polystyrene in this direction.

In the present work, the infrared spectra have been measured with four different types of polystyrenes which have been prepared by Ziegler, Natta, Alfin and Radical catalysts and by following extraction processes with cold MEK (methyl ethyl ketone). Measurements of spectra were carried out in various physical states such as quenched solid, crystallized solid, molten state and solution. The differences among spectra of the four polystyrenes in each physical state, and the differences among spectra in the physical state of each polystyrene were interpreted in the terms of configuration and conformation. Crystalline contents of samples were determined by infrared and X-ray methods. The quantitative measure of isotactic configuration has been obtained from the analysis of infrared spectra of sample solutions. The relation between the maximum content of crystallization and the measure of isotactic configuration has been studied.

## Experimental

a) **Sample.**—Crystalline polystyrene I (CPS-I) prepared by polymerization with $AlEt_3$-$TiCl_3$ catalyst and crystalline polystyrene II (CPS-II) prepared by polymerization with $AlEt_3$-$TiCl_4$ catalyst and crystalline polystypene III (CPS-III) prepared by polymerization with Alfin Catalyst were used. Each sample of CPS was prepared from the parts insoluble in cold MEK after treating with *n*-heptane. As

the sample of amorphous polystyrene (APS), Styron-666 of Asahi-Dow Company in Japan was used.

Film specimens for the measurement of infrared spectra were prepared by casting from carbon disulfide solution. Solution of polymers were prepared by dissolving the samples in hot carbon disulfide and the undissolved parts of CPS-I and CPS-II were filtered out.

**b) Measurement of Spectra.**—For measurement of the infrared absorption spectra, a Hitachi EPI-2 infrared spectrophotometer equipped with NaCl and KBr prisms was used. Spectra at the molten state of the samples were observed between 240 and 250°C by using the heating cell. Spectra of carbon disulfide solutions were observed at 2~5% concentration contained in a cell with 0.5~1.0 mm. thickness.

**c) Density and X-ray Measurements.**—A flotation method with NaCl solution was used for the measurement of the density at 30°C. X-ray diffraction diagrams were taken by using a Geigerflex made by Rigaku-Denki Co., Ltd.

## Results and Discussion

**1. Comparison of Infrared Spectra in Crystallized Solid, Quenched Solid, Solution and Molten State**[4].—The infrared spectra of the four different samples have been measured in crystallized solid, quenched solid, solution and molten state. The spectra of these samples in various states are shown in Figs. 1 and 2.

In the molten state, the spectra of the four samples are almost the same. However, there

Note. (1) Only the bands which show remarkable change are listed in Table I.
(2) Remarkable change of frequencies of APS is not found with varying state.
(3) w: weak band, b: broad band, s: sharp band.

are definite differences between the band at 555 (symmetrical broad band) of CPS-I and the band at 543 $cm^{-1}$ (asymmetrical broad band) of APS. The band at 546 $cm^{-1}$ (asymmetrical broad band) of CPS-III appeared as the superposition of the above two bands. The rather flat and broad band at 1063 $cm^{-1}$ of CPS-I is different from the sharp band at 1070 $cm^{-1}$ of APS. The spectrum of molten CPS-II is similar to that of molten CPS-I.

The difference of spectra among the samples in quenched solid was very similar to the difference of those in the molten state and became larger in the crystallized solid state.

In the spectra of crystallized CPS-I and CPS-II, a new sharp band appeared at 567 $cm^{-1}$ and the form became an asymmetric one. The broad band at 1063 $cm^{-1}$ of molten CPS-I and CPS-II became a sharp doublet with the maxima at 1085 and 1054 $cm^{-1}$. In the spectrum of crystallized CPS-III, the intensity of the band increased with maximum at 567 $cm^{-1}$. The band around 1070 $cm^{-1}$ of CPS-III has shown a very complicated form and probably it has three maxima at 1080, 1065 and 1053 $cm^{-1}$. It is also recognized that the intensity of the band at 1365, 1314, 1297 and 1185 $cm^{-1}$ increased more in the spectra of crystallized CPS-I, CPS-II and CPS-III than in the spectra of the quenched solids as found by Tadokoro et al.[5] They suggested that these bands may be assigned to CH or $CH_2$ deformation vibrations and are closely related to the intramolecular interactions in the helical chain having the three fold screw axis (alternate sequences of *trans* and *gauche* conformation along the C–C chain). Other new bands with maxima at 984, 923, 901, 620, 587, 499, 465 and 426 $cm^{-1}$ appeared in the crystallized CPS-I and CPS-II, and also the bands with maxima at 982, 921, 620, 587, 499 and 426 $cm^{-1}$ appeared in the crystallized CPS-III. These bands are probably ascribable to the usual crystalline bands. Several heat treatments for crystallization gave no remarkable change in the spectra of APS. This fact suggests that APS does not crystallize appreciably.

The difference of spectrum became very simple in carbon disulfide solution compared to that of the crystallized solid. The bands at 1085, 1054 and 567 $cm^{-1}$ of the crystallized CPS-I, CPS-II and CPS-III still persist in the spectra of the solution, even though slight shifts of absorbance maximum are observed. The bands at 1070 and 543 $cm^{-1}$ of APS remain in the spectra of the solution

5) H. Tadokoro, S. Nozakura, T. Kitazawa, Y. Yasuhara and S. Murahashi, This Bulletin, 32, 313 (1959).

with no change from those of the solid. The bands at 1364, 1314, 1297 and 1185 $cm^{-1}$ of CPS-I and CPS-II also persist in the spectra of the solution, but a slight decrease of their intensity is noted. Other bands ascribable to the crystalline band disappear or are very much weakened in the spectra of the solutions.

According to the above mentioned observation, it is possible to classify the spectra which differ from sample to sample, into three groups, A, B and C as shown in Table I.

The A group bands are characteristic in the crystallized solid and dissappear instantly or are very much weakened when the crystallized solid is dissolved in solution or is melted. These bands, which are not observed in the spectra of APS, may be assigned to the crystalline bands caused by the perturbation due to rather long range intra- and intermolecular interaction in the microcrystals of polystyrene. The assignment of A group bands to the crystalline bands makes it possible to use them for the quantitative estimation of crystalline contents of the crystallized polystyrene. The maximum crystalline content $X_{max}$ in polystyrene might be associated with the contents of isotactic configuration in polystyrene, since only the polystyrene which has isotactic configuration can form crystalline regions with its helical conformation. This problem is studied in the 2nd part of this paper.

The B group bands are stronger in the crystallized polystyrene than in the quenched solid or the molten state, and they persist in the spectra of CPS-I, CPS-II and CPS-III even in their solutions, and are not found in that of APS. Our observations are consistent with the assignment[5] of these bands to the CH or $CH_2$ deformation vibration which are due to the intramolecular interaction in the helical chain conformation having a three-fold screw axis.

The $C_1$ and $C_2$ groups have shown different spectra among four samples in all physical states such as crstallized solid, quenched solid, solution and molten states. The band with maximum at 543 $cm^{-1}$ of APS has been assigned to $\nu_4(B_2)$ vibration mode of mono-substituted benzene by Liang and Krimm[6]. According to this assignment, it can be assumed that the origin of the absorption bands which belong to the C group is the phenyl group vibration which is sensitive to the short range intramolecular interaction along the C–C main chain conformation. It is possible to subclassify the C group bands into $C_1$ and $C_2$ based on the differences of samples as shown in Table I. The $C_1$ group bands then become the characteristic vibrations of the C–C chain, which has the helical conformation or *trans-gauche* alternate conformation along the C–C chain from isotactic configuration. The $C_2$ group bands may be due to the characteristic vibration of the C–C chain which has mainly *trans* confomation along the C–C chain from syndiotactic configuration. Morton and Taylor[7] have used the new IR rating method of isotacticity based on the absorption in the 1070 $cm^{-1}$ region of KBr disk samples. The pattern of their spectra in this region is very similar to the pettern of our spectra in the same region which are observed using the sample of crystallized film and solution.

On the basis of the above empirical classification of the characteristic bands of polystyrenes and a possible interpretation of the origin of these absorption bands, the following conclusions are tentatively drawn.

Based on the behaviors of the C class bands, the conformation of the C–C chain of a few monomer units seems to differ among the samples even in their molten states. The intensity of bands in the $C_1$ group will be related with the content of helical conformation of polystyrene, because its intensity becomes strong in the crystallized state. In the solution, the helical conformation of crystallizable polystyrene is partly preserved, because the persistence of the $C_1$ and B class bands in the spectra of CPS-I, CPS-II and CPS-III is well recognized and their intensities are stronger than these in the quenched solids. It may be suggested that the intensity ratio D560 to D543 (D560/D543) in the spectra of the solution can be used to measure the content of isotactic configuration of the same polystyrene, as well as the band around 1070 $cm^{-1}$. In that case the equilibrium content of helical conformation of polystyrene is determined only by its isotactic content of chain configuration, and not by its previous history like heat treatment in the solid state. The observed values of D560/D543 in solution are shown in Table II.

**2. Behavior of the Crystalline Bands and the Estimation of Crystalline Content.**—Based on the conclusions in part 1, among several crystalline bands of the A group, the intensity of the bands at 984 and 587 $cm^{-1}$ have been used to measure the crystalline content in various polystyrene samples. The possibility of measuring the crystalline content using the intensity of the band at 984 $cm^{-1}$ has also been pointed out by Braun et al.[8] from their investigation on the temperature dependence of the band.

6) C. Y. Liang and S. Krimm, *J. Polymer Sci.*, **27**, 241 (1958).

7) A. A. Morton and L. D. Taylor, ibid., **38**, 7 (1959).

8) D. Braun, W. Betz and W. Kern, *Naturwissenschaften*, **46**, 344 (1959).

For avoiding the difficulty of measurement of film thickness, the band at 1030 $cm^{-1}$ has been used as a reference, since the optical densities of this band had a linear relationship with thickness for each sample and were independent of the crystal content of samples as shown in Fig. 3.

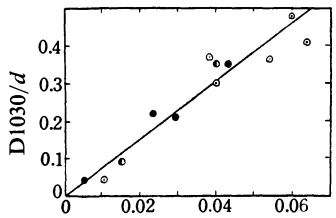

Fig. 3. Linear relation between optical density of 1030 $cm^{-1}$ and thickness.

○ : CPS-I ⊙ : CPS-III
● : CPS-II ◐ : APS

The measured values of D984/D1030 and D587/D1030 are listed in Table II. The linearity between both values suggests that the origin of these bands is the same crystalline band as shown in Fig. 4. The specific volumes of samples were calculated from the measured densities, and are also listed in Table II. From the specific volume, the crystalline content of polystyrene $X_{sv}$ can be calculated by the following equation:

$$X_{sv}=(V_a-V)/(V_a-V_c) \quad (1)$$

where, $V_a$ is the specific volume of the amorphous part and $V_c$ is the specific volume of the crystalline part.

If the intensities of D587 and D984 are proportional to the crystalline content, the following equation can be proved:

TABLE II. NUMERICAL DATA FOR EACH SAMPLE

| Sample | Density (30°C) | Specific volume | D587/D1030 | D984/D1030 | Crystalline content (%) $X_i$ (587) | $X_i$ (984) | $X_{sv}$ | $X_x$ | D560/D543 in $CS_2$ soln. |

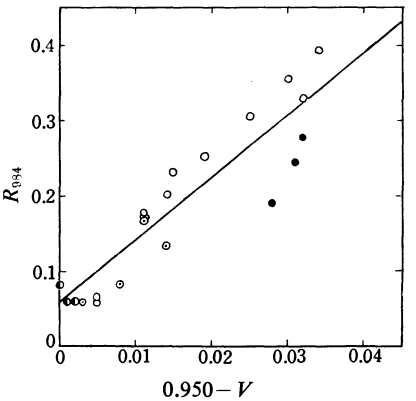

Fig. 6. Relation between $R_{984}$ and $(V_a-V)$.
○ : CPS-I ⊙ : CPS-III
● : CPS-II ◐ : APS

$$R_{587}=\mathrm{D587/D1030}=K_1(V_a-V) \quad (2)$$

$$R_{984}=\mathrm{D984/D1030}=K_2(V_a-V)+A \quad (3)$$

where, $K_1$ and $K_2$ are constant, and $A$ is added because the band at 984 $cm^{-1}$ has some intensity even in the amorphous state. From the linear relation between $R_{587}$ and $V$, and $R_{984}$ and $(V_a-V)$, as shown in Figs. 5 and 6, $K_1$, $K_2$ and $A$ were determined experimentally as follows.

$$K_1=8.729,\ K_2=8.242 \text{ and } A=0.058.$$

The value of $V_a$ is determined, from Fig. 5, as 0.950 from the value of $V$ at $R_{587}=0$. The value of $V_c$ is estimated as 0.888 from the results of Natta's X-ray analysis[9].

Combining the equations (1), (2) and (3), the following relationships are obtained:

$$X_{sv}=16.13(0.950-V) \quad (4)$$

$$X_i(587)=1.85(R_{587}) \quad (5)$$

$$X_i(984)=1.96(R_{984}-0.058) \quad (6)$$

where $X_i(587)$ and $X_i(984)$ are the crystalline content by the infrared method from the 587 $cm^{-1}$ and 984 $cm^{-1}$ bands, respectively. The determined values of crystalline content for each sample are shown in Table II, and the agreement among $X_{sv}$, $X_i(587)$ and $X_i(984)$ is satisfactory considering the difference of methods. Another approximate estimation[10]

● : CPS-II ◐ : APS

of the crystalline content, $X_x$, by X-ray diffraction curve has been tried, and the values are also shown in Table II. The diffraction curve of APS in Fig. 7 has been used as the standard curve of amorphous parts. The estimated curve of amorphous parts was drawn through the point ($2\theta=12.5°$) on the experimental curve of the crystallized polystyrene making it similar to the standard curve in the direction of intensity. The intensity at $2\theta=12.5°$ was little influenced from the scattering of the crystalline parts which had the strong peaks at $2\theta=8.1°$ and $2\theta=16.2°$. The ratio of crystalline region to total area is taken as the agreement between $X_x$ and $X_i(984)$ was satisfactory as shown in Fig. 8. The determined values of $X_x$ for the most crystallized state of the four polystyrenes, CPS-I, CPS-II, CPS-III and APS, are taken as the maximum crystalline content, $X_{max}$, of each polystyrene. A strong correlation was found between $X_{max}$ and the ratio D560/D543 in the solution, as shown in Fig. 9. This will suggest that both the maximum crystalline content, $X_{max}$, and D560/D543 in the solution can be used to measure the content of isotactic configuration of polystyrene from the quantitative point of view. The same treatment of the band at around 1070 $cm^{-1}$ in the solution may be possible for the determination of the isotactic content of polystyrene, but is not considered in this paper.

We are very grateful to Mr. N. Yamazaki of the Tokyo Institute of Technology for his kind donation of the sample of CPS-I, and to Mr. S. Kondo of the Tokyo College of Science for his assistance in making the X-ray measurement.

# *Rate of Desorption from a Heterogeneous Surface*

By Yutaka KUBOKAWA

(Received February 15, 1960)

The previous studies of chemisorption of hydrogen and carbon monoxide on zinc oxide and other catalysts[1], particularly of the rates of desorption at a constant temperature, showed that, although the Elovich equation was approximately obeyed in a limited range of coverage, a slight decrease in the adsorbed amount caused a marked increase in the value of $\mathrm{d}\ln R_{\mathrm{dep}}/\mathrm{d}q$ where $R_{\mathrm{dep}}$ is the rate of desorption and $q$ the adsorbed amount. A typical example is shown in Fig. 1. As was pointed out previously, such a phenomenon cannot be explained in terms of the concept that the decrease in the heat of adsorption is due to interaction between adsorbed species or to the induction effect emphasized by Boudart[2]. The concept of an a priort heterogeneity alone seems therefore to offer a satisfactory explanation of the experimental results.

Rate expressions for adsorption on such a heterogeneous surface were already derived in the previous work[3], whereby the physical meaning of $\mathrm{d}\ln R_{\mathrm{adp}}/dq$ ($R_{\mathrm{adp}}$=rate of adsorption) was also given. This paper presents an attempt to formulate the rate of desorption from a heterogeneous surface in a similar manner, and to explain the variation in $\mathrm{d}\ln R_{\mathrm{dep}}/\mathrm{d}q$ mentioned above on the basis of the surface heterogeneity.

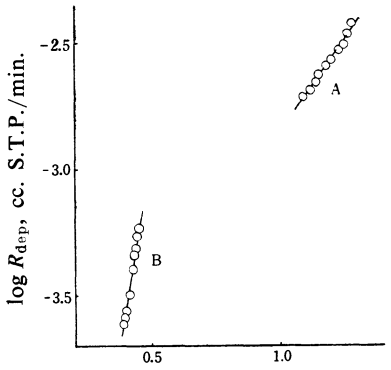

Fig. 1. Rates of desorption of carbon monoxide chemisorbed on zinc oxide. (Reproduced from "Carbon Monoxide Chemisorption on Zinc oxide" by the present author.) Temp., 192°C; The adsorbed amount at saturation is about 10 cc.; the time allowed for adsorption in run A is different from that in run B.

As described previously, the measured rate of desorption is, in most cases, unaffected by the reverse reaction, i.e., the re-adsorption. Consequently, the rate of desorption from any set of sites of the same kind on a heterogeneous surface may be

$$R=N\theta_i k\mathrm{e}^{-kt}=\alpha k\mathrm{e}^{-kt},\quad \alpha=N\theta_i$$

where $\theta_i$ is the coverage at $t=0$ and $N$ is the distribution function of sites, both of which may usually have different values for a different set of sites. At any moment during a desorption experiment, as was found for adsorption, there is always a certain set of sites for which the rate passes through a maximum. The condition for the maximum, can be written as

$$\mathrm{d}R/\mathrm{d}k=\alpha\mathrm{e}^{-kt}(1+\beta-kt)=0,\quad \beta=\mathrm{d}\ln\alpha/\mathrm{d}\ln k$$

or
$$kt=1+\beta \qquad (1)$$

Thus the maximum rate is

$$R_m=\alpha k\mathrm{e}^{-(1+\beta)} \qquad (2)$$

Such a maximum rate may be assumed, as a first approximation, to be proportional to the overall rate on a similar ground to that given previously. Then, from the same argument as that given for the rate of adsorption, the following expression can be derived for the overall rate of desorption $R_{\mathrm{dep}}$ by using Eqs. 1 and 2:

$$\mathrm{d}\ln R_{\mathrm{dep}}/\mathrm{d}q=-(\mathrm{e}^{\beta}/RT\alpha) \qquad (3)$$

In the course of desorption, $k$ and $\alpha$ will vary as the set of sites for which the rate passes through a maximum is replaced by others successively. Hence, the left-hand side of Eq. 3 will generally vary as the desorption proceeds. In a limited range of coverage, however, an approximately constant value of $\mathrm{d}\ln R_{\mathrm{dep}}/\mathrm{d}q$ will be expected. The behavior of desorption such as that shown in Fig. 1 is thus in agreement with what would be expected on a heterogenous surface, although its quantitative discussion is not feasible without complete information on the site distribution function etc.

# *Rate of Adsorption on a Heterogeneous Surface. Determination of the Distribution Function of Sites from Adsorption Rate Curves*

By Yutaka KUBOKAWA

(Received February 24, 1960)

In view of the importance of surface heterogeneity in the chemisorption on oxide catalysts as revealed by desorption experiments[1], the present author has derived in a recent paper[2] the rate of adsorption on a heterogeneous surface for the cases where the distribution function of sites is variable and/or desorption can not be neglected. The rate formula thus obtained has led to an interpretation of the Elovich equation

$$dq/dt = ae^{-bq}$$

where $q$ is the adsorbed amount and $a$ and $b$ are constants. Thus, explicit expressions and hence a physical meaning have been given to the constant $b$ in the Elovich equation on the basis of the surface heterogeneity. The frequently observed variation in the constant $b$ with pressure or temperature has been shown to be explained since the Elovich equation is usually applied only in a limited range of coverage. It is rather customary to use the integrated form of the Elovich equation for its actual application. Nevertheless, as has been pointed out in the previous paper, the constant $b$ obtained from the integrated form of the equation, in most cases, can not be given any such physical meaning as that mentioned above, and consequently can not be related to the surface heterogeneity in a quantitative way. It has therefore been undertaken in the present work to devise a method of obtaining quantitative information on the surface heterogeneity, i. e, the distribution function of sites, directly from the adsorption rate curves.

**Analysis of Adsorption Rate Curves.** — As described in the previous work[2], the rate of adsorption on a heterogeneous surface can be represented by the following equation when desorption is negligibly small during the adsorption rate measurement:

$$v = Kf(p)RTNe^{-\beta} \tag{1}$$

where $K$ and $N$ are the rate constant of adsorption and the distribution function of sites respectively, both referring to the set of sites mainly responsible for adsorption at a given time; the value of $K$ in Eq. 1 varies with time according to

$$Kf(p)t = 1 + \beta \tag{2}$$

where $\beta = d\ln N/d\ln K$. Thus the rate as a function of time becomes

$$v = (RTN/t)(1+\beta)e^{-\beta} \tag{3}$$

Using Eq. 1—3, the constant $b$ of the Elovich equation, $d\ln v/dq$, is given by[3]

$$d\ln v/dq = -(1/RTN)e^{\beta} \tag{4}$$

Transposing Eq. 3,

$$d\ln t/dq = (1/RTN)(1/1+\beta)e^{\beta} \tag{5}$$

Combining Eq. 4 and 5,

$$1+\beta = -(d\ln v/dq)/(d\ln t/dq) \tag{6}$$

The right hand side of Eq. 6 is determined from the adsorption rate curves by graphical differentiation, and consequently the value of $\beta$ at a given adsorbed amount, $q$, is obtained. Substituting $\beta$ thus obtained into Eq. 1 and 4, the values of $N$ and $K$ are determined as a function of the adsorbed amount.

As described previously[3], the chemisorption of hydrogen on chromic oxide gel investigated by Burwell and Taylor[4] belongs to the case where desorption is negligibly small above 457°K. The data at 457°K and 1 atm. have been treated in the manner mentioned above

1) Y. Kubokawa, This Bulletin, 33, 546, 550, 555, 739, 743, 747 (1960).
2) Y. Kubokawa, This Bulletin, 33, 734 (1960).
3) The pressure term in the rate expression, $f(p)$, is assumed to be constant during adsorption.

$q$ is in cc. (S. T. P.), $v$ in cc./min., $N$ in cc./cal., and $K$ in $\mathrm{min}^{-1}$.

with the results listed in Table I[5]. Here, as adsorption proceeds, the value of $\ln N$ increases with decreasing value of $\ln K$. The relationship of $\ln N$ against $\ln K$ is also obtained from a similar treatment for the data at other pressures at 457°K; the plots $\ln N - \ln K$ at different pressures at 457°K thus obtained were found to lie on the same curve, as would be expected.

By assuming that the variation in $\ln K$ arises only from that in activation energy of adsorption $E$, the following expression results:

$$RT \ln K = RT \ln C - E$$

where $C$ is a constant. Plots of $\ln N$ against $\ln K$ at various temperatures combined with the above expression give those of $\ln N$ against

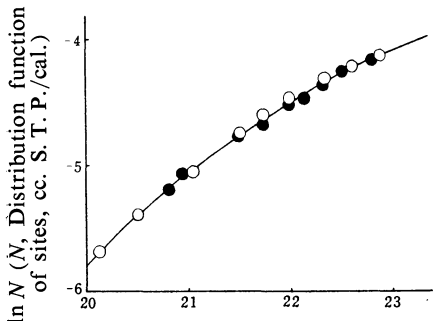

Fig. 1. Hydrogen chemisorption on $Cr_2O_3$ gel (Burwell and Taylor).
-○-, 457°K; -●-, 491°K; $\ln C = 20.1$.

5) $f(p) = p^{0.8}$ ($p$ in atm.) was used, since Burwell and Taylor state that the rate of adsorption is proportional to $p^{0.8}$.

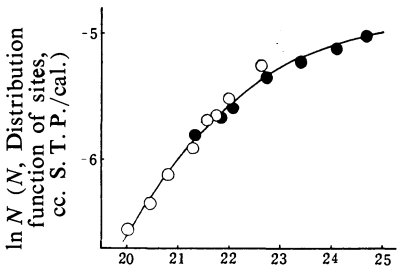

Fig. 2. Hydrogen chemisorption on $ZnO \cdot MoO_3$ (Taylor and Ogden).
-○-, 527°K; -●-, 577°K; $\ln C = 15.5$.

$E$ all of which should lie on the same curve since $N$ has been assumed to be a function of $E$ alone. This requirement is fulfilled by adjusting the parameter $C$ as shown in Fig. 1 where $\ln C = 20.1$. The figure shows that, as adsorption proceeds, the value of $E$ increases with that of $\ln N$ from 20 to 23 kcal./mol. Values of $E$ in this range seem to be reasonable, judging by the temperature dependence of the rate.

Fig. 2 represents the result of a similar treatment of the data of Taylor and Ogden[6] on the chemisorption of hydrogen on $ZnO \cdot MoO_3$, where desorption is negligible as described in the previous paper[1]. It is seen that the sites with a lower value of $E$ are mainly occupied at a lower temperature.

## Summary

A device to obtain the distribution function of sites from adsorption rate curves was worked out for the chemisorption for which desorption is negligible. It was then applied to the rate data of hydrogen chemisorption on chromic oxide gel and on $ZnO \cdot MoO_3$ with reasonable results.

The author wishes to express his sincere thanks to Professor O. Toyama for his guidance and encouragement throughout this work.

# *Oxidation of 5-Methyl-2, 1, 3-benzothiadiazole with Potassium Permanganate**

By Isao SEKIKAWA

(Received February 4, 1960)

As one of the series of studies on the relation between the antitubercular activity and the molecular structure, 2, 1, 3-benzothiadiazole-5-carboxylic acid was synthesized from 5-methyl-2, 1, 3-benzothiadiazole (I) by conversion via the corresponding 5-bromomethyl- into a formyl-derivative, followed by oxidation with silver oxide.[1]

For the purpose of preparing this acid, I was oxidized with potassium permanganate at 60°C but in vain; an acid of different structure (II) was formed.[2] This new acid was finally found to be in its structure a potassium 3-carboxy-1,-2, 5-thiadiazole-4-carboxylate.

I

II R=H, R'=K
III R=R'=$C_2H_5$
V R=R'=H

VI R=H
VII R=$C_2H_5$

X

Product II was an acidic potassium salt, m. p. 278°C decomp., extremely insoluble in organic solvent, with an empirical formula of $C_4HO_4 \cdot N_2SK$ or $C_4H_3O_4N_2SK$ as measured by microanalysis. This salt was recrystallized unchanged from dilute hydrochloric acid and was not hydrogenated over palladium-charcoal at room temperature.

Esterification of product II yielded a colorless diethylester (III), b. p. 140~142°C (10 mmHg). The molecular formula of product III was $C_8H_{10}O_4N_2S$, as measured by microanalysis and molecular weight determination. The diethylester was converted into a diamide (IV), $C_4H_4O_2N_4S$, m. p. 234~235°C decomp., with aqueous ammonia at room temperature. Hydrolysis of the diethylester together with the diamide in boiling aqueous potassium hydroxide, followed by acidification with acetic acid, regenerated product II. From these observations the molecular formula of product II was assumed to be $C_4HO_4N_2SK$. When the diethylester was hydrolyzed with diluted hydrochloric acid, a free diacid (V) was obtained, m. p. 154~155°C, $C_4H_2O_4N_2S \cdot 2H_2O$.

On decarboxylation of diacid V in the presence of quinoline and copper powder, no definite product was obtained, but when heated at 180~190°C in vacuo, the diacid evolved carbon dioxide and was converted into a white mono acid (VI), m. p. 167°C. Acid VI was purified by sublimation, and its molecular formula was formed to be $C_3H_2O_2N_2S$, as measured by microanalysis and molecular weight determination. Mono acid VI formed

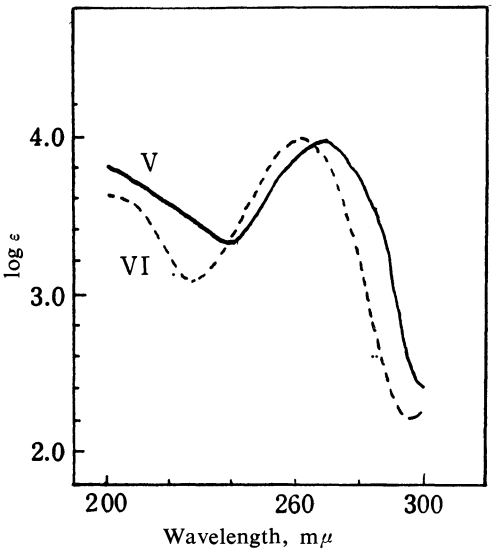

Fig. 1. Ultraviolet spectra of V and VI in water.

an ester (VII), b. p. 72°C (6 mmHg) and an acidhydrazide (VIII), m. p. 150~151°C, $C_3H_4 \cdot ON_4S$. This indicates that the partial structure of mono acid VI may be $C_2HN_2S \cdot COOH$. Mono acid VI was not hydrogenated over palladium-charcoal at room temperature, being stable in boiling concentrated hydrochloric acid.

The ultraviolet spectrum (Fig. 1) of diacid V showed a pattern identical to that of acid VI. The diethylester of diacid V assigned the structure of product III, since the infrared spectra (Fig. 2) of both products VII and III showed a S–N band at 890 $cm^{-1}$ [3].

* A part of this study was presented at the Annual Meeting of the Chemical Society of Japan, Kyoto, April 2, 1959.

1) I. Sekikawa, This Bulletin, **32**, 551 (1959).

2) I. Sekikawa, This Bulletin, **31**, 252 (1958).

3) The seven kinds of 1, 2, 5-thiadiazole compounds, showed a weak absorption band in the region of 900~880 $cm^{-1}$. D. H. Hadzi, *J. Chem. Soc.*, 1957, 847; T. Momose et al., *Chem. Parm. Bull.*, **7**, 734 (1959).

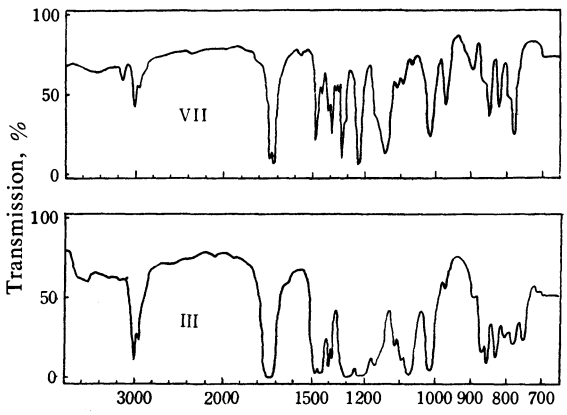

Fig. 2. Infrared spectra of VII and III.

Since the $C_2N_2S$-skeleton exists in sample I, it is almost certain that the white mono acid VI is 1, 2, 5,-thiadiazole-3-carboxylic acid. The presence of the 1, 2, 5-thiadiazole nucleus has been hitherto unknown.

Treatment of diethylester III with excess hydrazine hydrate in alcohol yielded almost quantitatively an orange-yellow dihydrazide (IX), m. p. 245°C decomp. with sintering from 170°C on, $C_4H_6O_2N_4S$. By hydrolysis with boiling dilute hydrochloric acid for 8 hr., one mole hydrazine was split off, from product IX and facile ring closure occurred, giving yellow 4, 5, 6, 7-tetrahydro-4, 7-dioxopyridazino-(4, 5-d)-2, 1, 3-thiadiazole (X), m. p. 333°C decomp., $C_4H_2O_2N_2S \cdot H_2O$. On the contrary, although one mole hydrazine was likewise split off, alkaline hydrolysis of product IX did not lead to product X, but to another product, which contained no sulfur atom and showed an empirical formula of $C_4H_6O_2N_4$, m. p. 331°C decomp. The determination of the structure of this compound is now in progress.

Recently, A. M. Khalexskiĭ et al. reported that acid V was obtained by ozonolysis of 2, 1, 3-benzothiadiazole and that on the contrary alkaline permanganate oxidation gave a 2, 1, 3-thiadiazole-4, 5-dicarboxylic acid *S*, *S*-dioxide.[4] The oxidation of sample I to product II with potassium permanganate was a reaction similar to the oxidation of quinoline to quinolinic acid.[5]

## Experimental[6]

**Oxidation of I with Potassium Permanganate.**—To a suspension of 10 g. of 5-methyl-2, 1, 3-benzothiadiazole in 200 ml. of water, 53 g. of potassium permanganate dissolved in 1300 ml. of water was added during 8 hr. at 60°C with vigorous stirring. After the last addition, the mixture was heated for 30 min. to complete the oxidation and then unchanged 5-methyl-2, 1, 3-benzothiadiazole was removed by steam distillation. The separated manganese dioxide was removed by filtration and washed with 500 ml. of water. The filtrates were combined, acidified with glacial acetic acid and evaporated to dryness. The residue was recrystallized from water to give 8.0 g. of white needles (II), m. p. 276~277°C (decomp.)[7]. The ultraviolet absorption bands at 270 mμ (log ε=3.94).

Found: C, 22.34; H, 0.94; N, 13.05; K, 18.58. C, 22.29; H, 0.99; N, 12.76; K, 18.34. C, 22.32; H, 0.71; N, 13.27.

Calcd. for $C_4HO_4N_2SK$: C, 22.64; H, 0.47; N, 13.20; K, 18.42. $C_4H_3O_4N_2SK$: C, 22.42; H, 1.41; N, 13.08; K, 18.25%.

**III.**—A mixture of 1.3 g. of II, 100 ml. of absolute ethanol and 1 ml. of concentrated sulfuric acid was refluxed for 24 hr. The separated potassium sulfate was filtered off and the filtrate was concentrated in vacuo. The residue was treated with 100 ml. of water and neutralized with sodium hydrogen carbonate. The mixture was extracted with 50 ml. of ether (twice), and the ether extract was dried and evaporated. The pale yellow oil was then distilled in vacuo, and a fraction boiling at 140~142°C (10 mmHg) was collected. The analytical sample distilled at 133°C (8 mmHg).

Found: C, 41.91; H, 4.61; N, 11.55; mol. wt. 235 (Rast mol. wt. determination).

Calcd. for $C_8H_{10}O_4N_2S$ (230.3): C, 41.74; H, 4.38; N, 12.17%.

**IV.**—To a solution of 5 g. of III in 50 ml. of ethanol, 10 ml. of aquous ammonium hydroxide ($d$ =0.8) was added. After about 1 hr. a white precipitate separated. After the solution was kept overnight at room temperature, the white crystalline solid was collected by filtration and washed with cold ethanol; yield; 3 g. Recrystallization from ethanol yielded white needles, m. p. 234~235°C (decomp.).

Found: C, 28.21; H, 2.60; N, 32.38.

Calcd. for $C_4H_4O_2N_4S$: C, 27.90; H, 2.34; N, 32.54%.

**Hydrolysis of III.**—A mixture of 1 g. of III and 25 ml. of 15% hydrochloric acid was heated under reflux for 5 hr. The reaction mixture was filtered to remove a small amount of suspended solid and evaporated under reduced pressure. The residual solid was recrystallized from water to give 0.5 g. of white sandy crystals (V).

It softened at 97°C, melted at 154~155°C with effervescence and was decomposed at 160°C. The ultraviolet absorption bands at 270 mμ (log ε=3.97).

Found: C, 22.71; H, 3.05; $H_2O$, 16.91.

Calcd. for $C_4H_2O_4N_2S \cdot 2H_2O$; C, 22.86; H, 2.88; $H_2O$, 17.14%.

**Pyrolysis of V.**—One gram of V was placed in a sublimation tube and heated for 5 min. at 180~190°C. Under this condition the material rapidly

melted with evolution of carbon dioxide. The tube was then connected to a vacuum-pump and the decarboxylated product was sublimed at 190°C to give 0.5 g. of white crystals (VI), m. p. 164~165°C. The ultraviolet absorption bands at 260 mμ (log ε = 3.98).

Found: C, 27.51; H, 1.42; N, 21.50.

Calcd. for $C_3H_2O_2N_2S$: C, 27.69; H, 1.55; N, 21.53%.

Rast mol. wt. detn. gave value of 135.8, $C_3H_2O_2N_2S$ requires 130.1.

**VII and VIII.**—The esterification was carried out by gently refluxing for 10 hr. a mixtur of 0.9 g. of VI, 10 ml. of absolute ethanol and 0.5 ml. of concentrated sulfuric acid. After removal of the excess of ethanol, the residue was treated with water and neutralized with sodium hydrogen carbonate. The mixture was extracted with ether (twice), and the ether extract was dried, evaporated, and the residual oil was distilled to give 0.6 g. of ester (VII), b. p. 72°C (6 mmHg).

A mixture of 6.2 g. of VII, 0.2 ml. of hydrazine hydrate (80%), and 2 ml. of ethanol was heated on a water bath for 5 hr. After removing the ethanol, the solidified residue was recrystallized from ethanol, affording 0.1 g. of acid hydrazide (VIII) in the form of white needles. It softened at 140°C and melted at 150~151°C.

Found: C, 25.13; H, 3.00; N, 38.53.

Calcd. for $C_3H_4ON_4S$: C, 24.99; H, 2.80; N, 38.87%.

**IX.**—To a solution of 4.2 g. of diethylester III in 20 ml. of ethanol, 3.7 ml. of 80% hydrazine hydrate was added. An orange-red solid immediately separated from the reaction mixture, which was set aside overnight at room temperature and then filtered to give 3.6 g. of product. Recrystallization from water yielded yellow needles.

It softened at 150°C, reddened at 180°C and was decomposed at 248°C.

Found: C, 23.57; H, 3.20; N, 41.33.

Calcd. for $C_4H_6O_2N_6S$: C, 23.76; H, 2.99; N, 41.57%.

**Hydrolysis of IX with Diluted Hydrochloric Acid.**—A mixture of 2 g. of dihydrazide IX, 3 ml. of concentrated hydrochloric acid and 100 ml. of water was heated under reflux for 8 hr. Cooling and filtering yielded 1.3 g. of white crystals, which were recrystallized from water to give light yellow plates. m. p. 333°C (decomp.) (monohydrate). The ultraviolet absorption bands at 265 mμ (log ε = 4.20).

Found: C, 25.63; H, 2.35; N, 29.94; $H_2O$, 9.35.

Calcd. for $C_4H_2O_2N_4S \cdot H_2O$: C, 25.53; H, 2.14; N, 29.78; $H_2O$, 9.57%.

The filtrate from the above reaction mixture was evaporated to dryness. The residue was recrystallized from water to give white needles, m. p. 198°C (decomp.).

This material was identical with a hydrazine hydrochloride..

**Hydrolysis of IV and III with Potassium Hydroxide.**—A mixture of 0.5 g. of diamide IV, 0.3 g. of potassium hydroxide and 20 ml. of water was heated for 2 hr., after which time ammonia evolution had ceased. The reaction mixture was evaporated to dryness under reduced pressure. The residue was dissolved in a small amount of water, acidified with acetic acid and the precipitated solid was collected by filtration. The product was recrystallized from water to give white needles. m. p. 274°C (decomp.).

Hydrolysis of diethylester III with dilute potassium hydroxide for 1 hr., followed by isolation of the product as described above, afforded I in 60% yield.

The products from diamide and diethylester were shown to be identical with I by a microanalysis and by comparison of infrared spectra.

The author wishes to express his gratitude to Professor S. Kakimoto for his kind encouragement and advice.

# *Decay of Free Radicals in γ-Irradiated Polymethyl Methacrylate*

By Jiro HIGUCHI, Shōji SHIDA, Riichiro KUSAKA* and Teruo MIYAMAE

(Received February 16, 1960)

Recently, many investigations have been carried out for polymers by using the electron spin resonance (ESR) technique. Especially the polymethyl methacrylate (PMMA) is one of the most comprehensively investigated ones, and the properties of the radicals produced by γ-irradiation have been clarified fairly well[1,2]. In the present communication, a preliminary work on the decay of radicals in γ-irradiated PMMA above and below the transition point by the ESR spectrometer will be reported, while a similar work by Ohnishi and Nitta was recently carried out independently of ours only below the transition point[3].

The samples used were PMMA plates (a section $0.2\times0.2$ cm$^2$ : columnar-shaped ; Acrylite, Mitsubishi Rayon Co., Ltd.) and the irradiations were carried out $3\times10^6$ r. at room temperature with γ-ray from a $^{60}$Co source (dose rate $2.2\times10^5$ r./hr.). The radicals produced were detected by the ESR spectrometer (JEP-1 E.P.R. Spectroscope; Japan Electron Optics Laboratory Co., Ltd., X-band, bridge-type). The resonance pattern thus obtained is the same as in the case of fine powdered samples sealed in vacuo, and also similar to those by Schneider[1] and by Abraham et al.[2], and no appreciable change by the influence of oxygen was detected in the present experiment, in spite of a considerable change observed in the powdered sample exposed to air. So the experiments were carried out by using plated samples only, to avoid color centers resulting from irradiation in the glass which was used to seal the samples in vacuo.

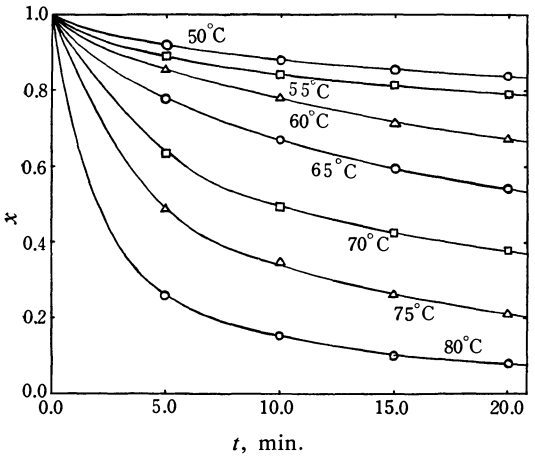

Fig. 1. Relative concentration of free radicals $x$ aginst time $t$.

Decay of the free radicals was investigated at temperatures between 50 and 80°C. In detection, the samples (stored in dry ice after irradiation) kept at the reaction temperature were taken out every five minutes and suddenly cooled to the room temperature by dry ice in order to interrupt the reaction rapidly, because

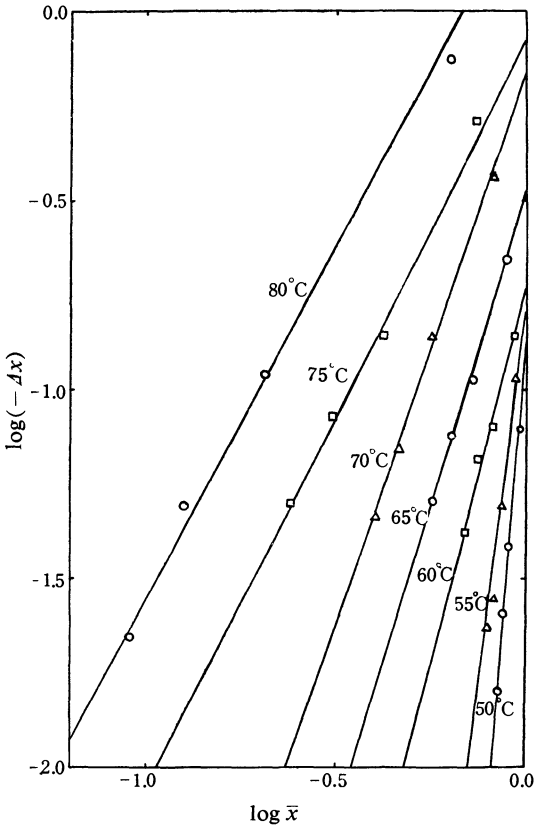

Fig. 2. Logarithm of the change of the relative concentration in five minutes $\log(-\Delta x)$ against logarithm of the mean value of the relative concentration $\log \bar{x}$.

* Present address, Yahata Iron and Steel Co., Ltd., Tokyo Research Institute.

2) R. J. Abraham, H. W. Melville, D. W. Overnall, and D. H. Whiffen, *Trans. Farady Soc.*, **54**, 1133 (1958).
3) S. Ohnishi and I. Nitta, *J. Polymer Sci.*, **38**, 451 (1959). In this paper, our result quoted should be corrected.

the change in the room temperature is very slow. Thus the relative concentrations in these samples were obtained by the ESR spectra at the room temperature comparing with the reference sample which was irradiated under the same condition and stored in dry ice. Under these circumstances, no appreciable change of the resonance pattern was observed.

The variation of the radical concentration so obtained is given in Fig. 1. To determine the order of the reaction, the logarithm of the change of the relative concentration in five minutes $\Delta t$, $\log(-\Delta x)$, was plotted against the logarithm of the mean value of the relative concentration, $\log \bar{x}$, as shown in Fig. 2, since the order $n$ is obtainable from the slope by using the following relation:

$$\log(-\Delta x) = n \log \bar{x} + (\log k + \log \Delta t)$$

From Fig. 2, one can easily find the interesting feature that above 70°C the reaction is of the second order while below 70°C the apparent order is greater than the second and increases with decreasing temperature. Since the PMMA is amorphous and its transition point is considered to be about 70°C, the mechanism of the decay of the radical is considered to be different above and below the transition point taken as the border. That is, above the transition point the motion of the chain segment is rather unrestricted so that the reaction rate is proportional to the concentrations of each radical recombined, because the radicals are considered to be independent for the dose rate used, whereas below the point, the decaying process becomes complicated because of relaxation. This is also consistent with the result by Ohnishi and Nitta[3] in which below the transition point the reaction was the second order except in the beginning range (several hours). The activation energy obtained in the present work is $3 \times 10$ kcal./mol., which is also consistent with their result, although it is rather difficult to obtain accurately because of the aforementioned mechanism.

The present work is preliminary and includes many points requiring improvements as follows: (1) The error due to the fact that the samples were taken out from the reaction temperature and the ESR spectrum was observed at the room temperature. (The decay at the room temperature could not be absolutely negligible. This can be improved by the use of a cavity which can be used at various temperatures in question.) (2) A little influence of oxygen because of the experiment carried out in air. (This can be improved by sealing the sample in vacuo.) (3) The inconsistency of the experimental conditions; i. e. the $\gamma$-irradiation due to the $^{60}$Co irradiation apparatus, and in the change of temperatures.

Although the present experiment encounters the above-mentioned problems, the result gives the following interesting suggestion: investigation of the decay of radicals in the $\gamma$-irradiated polymer gives information concerning the knowledge of the motion of polymers. Although it is not a direct method and the change of the mechanism bordering the transition point has already been observed in the crosslinking of polyethylene and of polyvinyl chloride[4], the present phenomenon is rather simple and favorable to the investigation of the motion of polymers. Though the present PMMA is amorphous, similar investigations can also be carried out for partially crystalline polymers. In this case, it is possible to observe separately the motion of polymers in the crystalline and amorphous regions since the resonance patterns for these regions can not always be the same because of the steric effect of the radical produced. In fact, including the case of PMMA, a more precise investigation is absolutely necessary, especially for the points aforementioned, in order to obtain more conclusive result.

The authors wish to thank Dr. M. Kurata for his helpful advice.

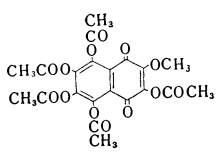
# *Structure of Namakochrome. II**

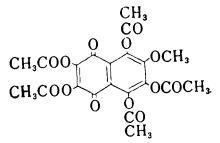
By Toshihiko MUKAI**

(Received February 12, 1960)

Previous paper[1] has reported that namakochrome which is a new pigment isolated from *polycheira rufescens*, should be either 2-hydroxymethyl-3, 6, 7-trihydroxy-naphthazarin (I or II) or 2-methoxy-3, 6, 7-trihydroxy-naphthazarin (III or IV). Thus, for the complete elucidation of the namakochrome structure there remains to be established the form of the functional group in 2-position of the naphthalene nucleus.



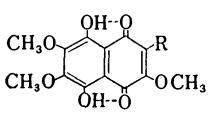
I II



III IV

Although, in the preceding work[1], a qualitative detection of the quinone group in namakochrome by reductive acetylation has been also described, the isolation of crystalline products from the resulting solution was unsuccessful. Namakochrome-trimethyl ether was then acetylated in the presence of zinc dust, and a benzene solution of the reaction products was filtrated through an alumina column, and afforded a leuco-acetyl derivative, $C_{11}H_3O_5\cdot(OCH_3)_3(COCH_3)_4$, as colorless prisms, m. p. 226~227°C.

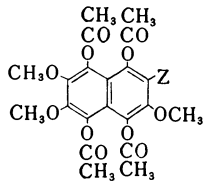
Now, in order to characterize the unascertained oxygen atom in 2-position of namakochrome, the 3, 5-dinitrobenzoate was prepared by the action of 3, 5-dinitrobenzoyl chloride on namakochrome-trimethyl ether. By carrying out this process in the presence of pyridine, there were obtained lemon yellow prisms, melting at 218~220°C. Its analytical composition is in agreement with a formula $C_{11}H_3O_3\cdot(OCH_3)_3[C_6H_3(NO_2)_2(COO)]_2$. The fact that namakochrome-trimethyl ether reacted with two molecular equivalents of 3, 5-dinitrobenzoyl chloride suggests, that the positions for the 3, 5-dinitrobenzoyl groups in the naphthalene nucleus should be at 5 and 8. The functional group at 2-position of the naphthalene nucleus might be a methoxyl group because of its resistance to both of the acetylation[1] and the 3, 5-dinitrobenzoylation. A qualitative detection of the methoxyl group in namakochrome was then made. In the alkoxyl microapparatus of Zeisel, namakochrome was treated with hydriodic acid as usual. The resulting vapor was passed through a bubbler which contained a mixed aqueous solution of sodium thiosulfate and cadmium sulfate, and then swept into a 10% alcoholic solution of dimethylaniline. Thus, it was possible to isolate trimethyl phenyl ammonium iodide, colorless plates, subliming at 216°C. This showed a methoxyl group to be present in namakochrome. The quantitative determination was then carried out by the same method, and namakochrome had shown an average value of 9.26% for the methoxyl group content (calcd. for III or IV: $CH_3O$, 11.6%). Similarly the determination was effected on a few derivatives of namakochrome described in the previous paper[1] and in this paper. A pentaacetyl-derivative[1] was found to show the methoxyl group content of 4.42% (calcd. for V and VI: $CH_3O$, 6.5%).



V

VI

The result for trimethyl ether of namakochrome was 37.38% of the methoxyl group content (calcd. for VII: $4CH_3O$, 40.0%, and for VIII: $3CH_3O$, 30.0%), and then for the leuco-acetyl derivative was found the methoxyl group content of 23.38% (calcd. for IX: $4CH_3O$, 25.81%, and for X: $3CH_3O$, 19.24%).



VII, R=-$OCH_3$,
VIII, R=-$CH_2OH$.

* "Pigments of Marine Animals", X. IX of this series; This Bulletin, 33, 453 (1960).

** Present address, Yoshitomi Pharmaceutical Industries, Ltd. Yoshitomi Factory, Yoshitomi-cho, Chikujo-gun, Fukuoka-ken.

1) This Bulletin, 33, 453 (1960).

IX, Z=-$OCH_3$,

X, Z=-$CH_2OH$.

From these experimental results, it is considered to be very likely that the structure of namakochrome is 2-methoxy-3, 6, 7-trihydroxy-naphthazarin (beta-position in I or II : methoxyl group)***. Although many compounds which contain methoxyl groups have been known as plant components, the author has been unable to find in the literature any reports on the marine-animal pigments, especially on naphthoquinone-derivatives, which contain methoxyl groups. This must be, therefore, the first time, that the pigment containing a methoxyl group is isolated from the marine animal.

## Experimental

**Reductive Acetylation of Namakochrome-trimethyl Ether.**—To a solution of 55 mg. of namakochrome-trimethyl ether in 1 g. of acetic anhydride and 1.5 g. of anhydrous pyridine was added 500 mg. of zinc dust, and shaken at room temperature until the solution becomes colorless. But the colorless solution soon acquired a yellow color and finally an orange yellow color. The colored reaction mixture, after setting overnight and removal of zinc dust, was poured into ice-water and extracted with several portions of benzene. The yellow benzene layer was washed with dilute hydrochloric acid solution and with water. The resulting colorless benzene solution was then dried with sodium sulfate. Removal of all solvent under the diminished pressure left 72 mg. of a pale yellow colored residue. It was purified by recrystallization from ethanol ; colorless prisms, m. p. 226~227°C.

Found : C, 55.26 ; H, 5.22 ; $CH_3O$-, 23.38 ; $CH_3CO$-, 35.27. Calcd. for $C_{22}H_{24}O_{12}$ : C, 55.00 ; H, 5.01 ; $CH_3O$-, 25.81 ; $CH_3CO$-, 35.87%.

**5, 8-Di-(3', 5'-dinitrobenzoyl)-namakochrome-trimethyl Ether.**—40 mg. of namakochrome was dissolved in 10 ml. of hot anhydrous pyridine. To the crimson-colored solution, about 55 mg. of finely pulverized 3, 5-dinitrobenzoyl chloride was added at room temperature, and the reaction mixture was gently shaken. The color changed through yellow to orange red. After an hour, the mixture was poured into ice-water and extracted with benzene. The orange red benzene layer was washed with dilute hydrochloric acid solution, followed by dilute sodium carbonate solution and water. The orange red benzene solution was dried with sodium sulfate, and concentrated to a small volume under reduced pressure. The concentrate was filtered through a calcium carbonate column (3×15 cm.). The orange eluate was evaporated to dryness under reduced pressure, and there was obtained an orange-yellow pasty product which was recrystallized (acetone-ethanol=2 : 1) to afford 66 mg. of the 3, 5-dinitrobenzoate, lemon yellow prisms, m. p. 218~220°C.

Found : C, 48.41 ; H, 3.09 ; N, 7.70. Calcd. for $C_{28}H_{18}O_{18}N_4$ : C, 48.15 ;H, 2.60 ; N, 8.02%.

I am deeply indebted to Professor Dr. Tokuichi Tsumaki for his continuing interest in this work and particularly for his suggestions. The microanalyses were carried out under Mr. Michio Shido and Miss. Sachiko Indo, to whom I extend my thanks. The expenses of the work were partially covered by a scientific Research Grant of the Ministry of Education.

# *The Kinetics of Substitution Reactions Involving Metal Complexes. IV. Reaction between Lead and Zinc-Ethylenediaminetetraacetate Complexes in Aqueous Solutions*

By Nobuyuki TANAKA and Kiyoko KATO*

(Received February 22, 1960)

The substitution reaction of lead ions and zinc-ethylenediaminetetraacetate (EDTA) complexes was investigated by Bril, Bril and Krumholz[1]. The rate of the reaction was followed by measuring the change of the polarographic diffusion current of lead ions with time in acetate buffer solutions using the streaming mercury electrode. The reaction was found to proceed, under the experimental conditions, through three different reaction paths simultaneously, and the rate constants of several reactions were determined.

Although Bril et al.[1] measured the reaction rate in acetate buffer solutions, they did not take consideration of the effect of acetate ions on the reaction rate. Recently, the present authors[2,3] dealt with the substitution reaction of copper ions and lead-EDTA complexes and that of copper ions and zinc-EDTA complexes, and explained the decrease of the reaction rate with increasing concentration of acetate by assuming that the substitution reaction proceeds only through the hydrated metal ions.

In this situation it seems worth while to reinvestigate the substitution reaction of lead ions and zinc-EDTA complexs from the same viewpoint as given in the previous papers[2,3].

## Experimental

The preparation of the solutions of lead nitrate, zinc nitrate and disodium ethylenediaminetetraacetate was described in the previous papers[3,4].

The rate of the reaction between lead ions and zinc-EDTA complexes was followed by measuring the change of the polarographic diffusion current of lead ions with time in acetate buffer solutions. Current-time curves were obtained with a Shimadzu RP-2 pen-recording polarograph and a dropping mercury electrode. The latter was the same as described in the previous papers[2-4] and had an $m$ value of 1.27 mg./sec. and a drop time of 3.69 sec. in an air-free 0.1 M potassium chloride solution at 25°C with open circuit.

Measurements were made at 15 and 25°C in acetate buffers of pH 4.8 to 5.7 which contained 0.1 M of sodium acetate. The ionic strength was adjusted to be 0.2 with potassium nitrate, unless otherwise stated. Gelatin was added as a maximum suppressor by 0.01% in concentration.

## Results and Discussion

In the solution containing acetate ions less than 0.2 M in concentration, lead(II) forms mono- and diacetato complexes, whereas zinc(II) forms only a monoacetato complex[5]. Therefore, the overall substitution reaction of lead ions and zinc-EDTA complexes in acetate buffer solutions is represented with the equations

$$\begin{aligned} Pb^{2+} + 2\,OAc^- &\rightleftharpoons PbOAc^+ + OAc^- \\ &\rightleftharpoons Pb(OAc)_2 \end{aligned} \quad (1)$$

$$Pb^{2+} + ZnY^{2-} \rightleftharpoons PbY^{2-} + Zn^{2+} \quad (2)$$

$$Zn^{2+} + OAc^- \rightleftharpoons ZnOAc^+ \quad (3)$$

where $Y^{4-}$ means a completely dissociated EDTA anion. Under the condition that both zinc ions and zinc-EDTA complexes are present in a large excess over lead ions, the substitution reaction 2 can be treated simply as

$$Pb^{2+} \underset{k^-}{\overset{k^+}{\rightleftharpoons}} PbY^{2-} \quad (4)$$

The rate equation for the reaction 4 is expressed as[2]

$$-\frac{d[Pb^{2+}]_{app}}{dt} = k^+[Pb^{2+}]_{app} - k^-[PbY^{2-}] \quad (5)$$

where $[Pb^{2+}]_{app}$ is the concentration of lead ions that can be determined polarographically, and given by the equation

$$\begin{aligned} [Pb^{2+}]_{app} = {} & [Pb^{2+}] + [PbOAc^+] \\ & + [Pb(OAc)_2] \end{aligned} \quad (6)$$

Integrating Eq. 5,

$$\begin{aligned} \ln\{[Pb^{2+}]_{app} - [Pb^{2+}]_{e,app}\} &= -(k^+ + k^-)t \\ &+ \ln\{[Pb^{2+}]_{0,app} - [Pb^{2+}]_{e,app}\} \end{aligned}$$

is obtained, where subscripts o and e denote

the initial and the equilibrium condition, respectively. At the equilibrium of the reaction, the relation

$$\frac{k^+}{k^-}=\frac{[PbY^{2-}]_e}{[Pb^{2+}]_{e,app}}\doteqdot K^{Pb}_{Zn,app}\frac{[ZnY^{2-}]_0}{[Zn^{2+}]_{0,app}}$$

may be satisfied, where $K^{Pb}_{Zn,app}$ represents the apparent equilibrium constant expressed as

$$K^{Pb}_{Zn,app}=\frac{[Zn^{2+}]_{e,app}[PbY^{2-}]_e}{[Pb^{2+}]_{e,app}[ZnY^{2-}]_e}$$

The values of $K^{Pb}_{Zn,app}$ were determined polarographically to be 9.0 at 15°C and 5.4 at 25°C in acetate buffer solutions which contained 0.1 M of sodium acetate.

The apparent rate constant, $k^+/[ZnY^{2-}]_0$, was obtained at varied pH's at two different concentrations of zinc ions but at the same concentrations of other species. The values obtained were plotted against the hydrogen ion concentration. The plots obtained for 15°C are given in Fig. 1, which clearly indicate linear relations existing between $k^+/[ZnY^{2-}]_0$ and $[H^+]$. Similar relations were also found at 25°C.

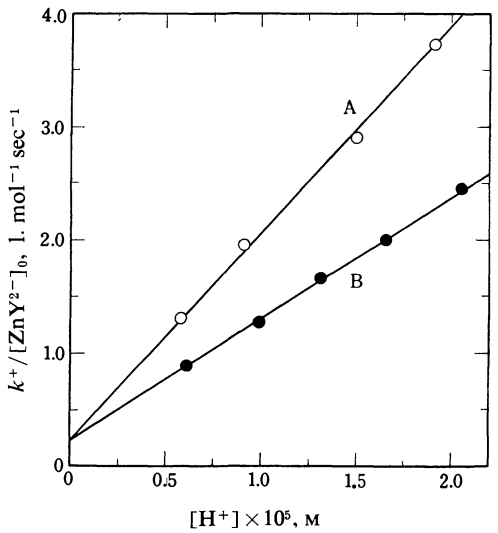

Fig. 1. $k^+/[ZnY^{2-}]_0$ as a function of the hydrogen ion concentration in acetate buffer-potassium nitrate solutions of ionic strength 0.2 at 15°C. Initial concentrations are: $[Pb^{2+}]_{0,app}=1.60\times10^{-4}$ M; $[ZnY^{2-}]_0=5.04\times10^{-3}$ M; $[Zn^{2+}]_{0,app}=5.10\times10^{-3}$ M (curve A) and $1.02\times10^{-2}$ M (curve B). Concentrations of free acetate are: 0.098 M (A) and 0.096 M (B).

According to Bril, Bril and Krumholz[1], the substitution reaction between lead ions and zinc-EDTA complexes is supposed to proceed simultaneously through the following three reaction paths:

$$\text{(i)}\quad Pb^{2+}+ZnY^{2-}\rightleftharpoons PbY^{2-}+Zn^{2+} \quad (7)$$

$$\text{(ii)}\quad ZnY^{2-}+H^+\rightleftharpoons ZnHY^- \quad (8a)$$

$$Pb^{2+}+ZnHY^-\rightleftharpoons PbHY^-+Zn^{2+} \quad (8b)$$

$$PbHY^-\rightleftharpoons PbY^{2-}+H^+ \quad (8c)$$

$$\text{(iii)}\quad ZnY^{2-}+H^+\rightleftharpoons Zn^{2+}+HY^{3-} \quad (9a)$$

$$Pb^{2+}+HY^{3-}\rightleftharpoons PbY^{2-}+H^+ \quad (9b)$$

In the polarographic measurement in acetate media, the concentration of lead ions that is actually measured polarogrphically is not the concentration of hydrated lead ions but the sum of the concentrations of hydrated ions and acetato complexes[2]. Therefore, if it is assumed that the substitution reaction proceeds only through the hydrated ions which are in equilibrium with the acetato complexes, the apparent rate of the forward reaction ($v^+=k^+[Pb^{2+}]_{app}$) determined polarographically is represented by Eq. 10[2,3].

$$v^+=k^+[Pb^{2+}]_{app}=\left\{\frac{k_1^++k_2^+[H^+]+k_3^+[H^+]\dfrac{1+K_{ZnOAc}[OAc^-]}{[Zn^{2+}]_{app}}}{1+\sum_{n=1}^{2}K_{Pb(OAc)_n}[OAc^-]^n}\right\}\times[Pb^{2+}]_{app}[ZnY^{2-}] \quad (10)$$

In Eq. 10

$$\left.\begin{aligned}k_2^+&=k_{II}^+K^H_{ZnHY}\\k_3^+&=k_{III}^+/K_{ZnY}K_{HY}\end{aligned}\right\} \quad (11)$$

where $K^H_{ZnHY}$ represents the equilibrium constant of the reaction 8a, $K_{ZnY}$, the formation constant of $ZnY^{2-}$ and $K_{HY}$, the fourth dissociation constant of ethylenediaminetetraacetic acid. $K_{Pb(OAc)_n}$ and $K_{ZnOAc}$ represent the overall formation constants of acetatolead(II) and acetatozinc(II) complexes, respectively.

From Eq. 10, Eq. 12 is obtained, where the initial concentrations, $[Zn^{2+}]_0$ and $[ZnY^{2-}]_0$, are substituted for $[Zn^{2+}]$ and $[ZnY^{2-}]$,

$$\frac{k^+}{[ZnY^{2-}]_0}=\frac{k_1^++k_2^+[H^+]+k_3^+[H^+]\dfrac{1+K_{ZnOAc}[OAc^-]}{[Zn^{2+}]_{0,app}}}{1+\sum_{n=1}^{2}K_{Pb(OAc)_n}[OAc^-]^n} \quad (12)$$

respectively. Since both $Zn^{2+}$ and $ZnY^{2-}$ are present in the reaction mixture in a large excess over concentration of lead ions, the change of their concentrations during the reaction can be neglected.

The rate constants in Eq. 10 were calculated from the plots of $k^+/[ZnY^{2-}]_0$ against the hydrogen ion concentration, which are tabulated in Table I. The formation constants of acetatolead(II) and acetatozinc(II) complexes which were used in the calculation are those that were determined polarographically at ionic strength 0.2 at 15 and 25°C[5]. The concentration of uncomplexed acetate in the solution was calculated by successive approximation.

The rate constants of both elementary reactions 8b and 9b were calculated from the relations given in Eqs. 11, using the values of $K^{H}_{ZnHY}$, $K_{ZnY}$ and $K_{HY}$ which were obtained with the same procedure as described previously[3,4] and are given in Table II. The rate constants of three elementary reactions 7, 8b and 9b thus calculated are summarized in Table III.

TABLE I. RATE CONSTANTS IN EQ. 10 OBTAINED EXPERIMENTALLY AT IONIC STRENGTH 0.2 AT VARIOUS TEMPERATURES

| Temp., °C | Rate constant, l. mol$^{-1}$ sec$^{-1}$ | | |
|---|---|---|---|
| | $k_1^+$ | $k_2^+$ | $k_3^+$ |
| 15 | 4.6 | $6\times10^5$ | $1.1\times10^4$ |
| 25 | 8.9 | $9\times10^5$ | $2.4\times10^4$ |

TABLE II. EQUILIBRIUM CONSTANTS AT IONIC STRENGTH 0.2 AT VARIUS TEMPERATURES

| Temp., °C | log $K_{ZnY}$ | p$K_{HY}$ | log $K^{H}_{ZnHY}$ |
|---|---|---|---|
| 15 | 16.17 | 10.20 | — |
| 20 | — | — | 2.9 |
| 25 | 15.94 | 10.04 | — |

TABLE III. RATE CONSTANTS FOR REACTIONS 7, 8b AND 9b AT IONIC STRENGTH 0.2 AT VARIOUS TEMPERATURES

| Temp., °C | Rate constant, l. mol$^{-1}$ sec$^{-1}$ | | |
|---|---|---|---|
| | $k_1^+$ | $k_{II}^+$ | $k_{III}^+$ |
| 15 | 4.6 | $8\times10^2$ | $1.0\times10^{10}$ |
| 25 | 8.9 | $1\times10^3$ | $1.9\times10^{10}$ |

From these results, the rate constants expressed in the form of the Arrhenius equation were derived and the heats of activation and entropies of activation were calculated for three elementary reactions 7, 8b and 9b. The results are given in Table IV.

Bril et al. determined the rate constants of this substitution reaction in acetate buffer solutions of ionic strength 1.0 containing 0.1 M acetate at 25°C[1], but they took no account of the effect of acetate ion on the reaction rate. Therefore, the rate constants reported by Bril et al., $R_1$, $R_2$ and $R_3$[6], correspond to those given by the equations,

$$R_1=\frac{k_1^+}{1+\sum_{n=1}^{2}K_{Pb(OAc)_n}[OAc^-]^n}$$

$$R_2=\frac{k_2^+}{f_H\{1+\sum_{n=1}^{2}K_{Pb(OAc)_n}[OAc^-]^n\}} \qquad (13)$$

$$R_3=\frac{k_3^+\{1+K_{ZnOAc}[OAc^-]\}}{f_H\{1+\sum_{n=1}^{2}K_{Pb(OAc)_n}[OAc^-]^n\}}$$

where $f_H$ means the activity coefficient of hydrogen ions. Since the values of $K_{PbOAc}$, $K_{Pb(OAc)_2}$, $K_{ZnOAc}$, $K^{H}_{ZnHY}$, $K_{ZnY}$ and $K_{HY}$ and $f_H$ are all unknown at ionic strength 1.0 at 25°C, it seems impossible to calculate the rate constants $R_1$, $R_2$ and $R_3$ in Eq. 13, using the values of $k_1^+$, $k_2^+$ and $k_3^+$ obtained in this study.

In the measurement of the reaction rate, Bril et al. employed the streaming mercury electrode. They stated that the streaming electrode had an advantage over the conventional dropping mercury electrode when used as an indicator electrode for kinetic measurements. However, the diffusion current obtained with the streaming mercury electrode was considered less accurate and less reproducible than that obtained with the dropping mercury electrode. For comparison, therefore, the measurements were made under the same condition as Bril et al.'s but with the dropping mercury electrode, and the values of $R_1$, $R_2$ and $R_3$ were determined with the same procedure as mentioned above. The results are given in Table V and compared with the values reported by Bril et al. An agreement between both results seems to indicate no significant discrepancy between the two methods[7].

TABLE IV. RATE CONSTANTS, HEATS OF ACTIVATION AND ENTROPIES OF ACTIVATION FOR REACTIONS 7, 8b AND 9b

| Reaction | Rate constant, expressed in l. mol$^{-1}$ sec$^{-1}$ | $\Delta H^{\ddagger}$, kcal. mol$^{-1}$ | $\Delta S^{\ddagger}$, e. u. |
|---|---|---|---|
| $Pb^{2+} + ZnY^{2-} \rightarrow PbY^{2-} + Zn^{2+}$ | $k_1^+ = 1.1\times10^9 \exp(-11,000/RT)$ | 10 | −19 |
| $Pb^{2+} + ZnHY^{-} \rightarrow PbHY^{-} + Zn^{2+}$ | $k_{II}^+ = 9.3\times10^7 \exp(-6,700/RT)$ | 6.1 | −24 |
| $Pb^{2+} + HY^{3-} \rightarrow PbY^{2-} + H^+$ | $k_{III}^+ = 1.2\times10^{18} \exp(-11,000/RT)$ | 10 | 22 |

6) $R_1$, $R_2$ and $R_3$ correspond to $k_0^+$, $k_1^+$ and $k_2^+$, respectively, given in the first paper of Bril, Bril and Krumholz[1].

7) The values of $R_2$ are considerably less accurate than those of $R_1$ and $R_3$[4].

TABLE V. RATE CONSTANTS EXPRESSED IN EQS. 13 OBTAINED EXPERIMENTALLY AT IONIC STRENGTH 1.0 AT 25°C

| | Rate constant, l. $mol^{-1}$ $sec^{-1}$, obtained | |
|---|---|---|
| | by Bril et al. | by the present authors |
| $R_1$ | 0.34 | 0.30 |
| $R_2$ | $2\times10^4$ | $8\times10^4$ |
| $R_3$ | $1.1\times10^3$ | $1.5\times10^3$ |

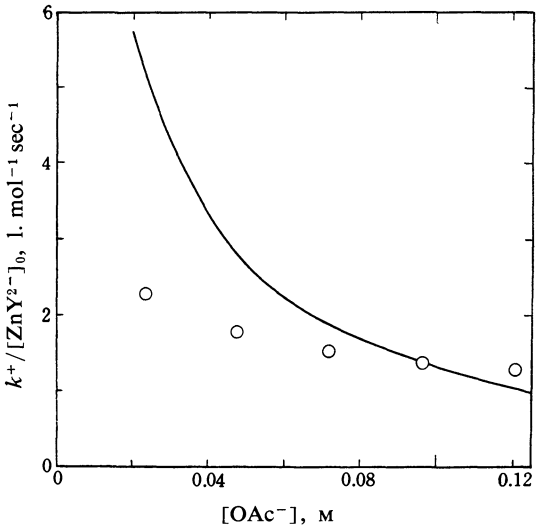

Fig. 2. $k^+/[ZnY^{2-}]_0$ as a function of the acetate concentration in acetate buffer-potassium nitrate solutions of pH 5.09 and ionic strength 0.2 at 15°C. Initial concentrations are: $[Pb^{2+}]_{0,app}=1.65\times10^{-4}$ M; $[ZnY^{2-}]_0=5.00\times10^{-3}$ M; $[Zn^{2+}]_{0,app}=1.00\times10^{-2}$ M. —— indicates the theoretical curve and ○, the experimental value.

From Eq. 10, it is predicted that the reaction rate decreases with increasing concentrations of acetate ions. Using Eq. 12, the values of $k^+/[ZnY^{2-}]_0$ were calculated at various acetate concentrations with the rate constants given in Table I and the formation constants of the acetato complexes. They are plotted against the acetate ion concentration as shown in Fig. 2. The overall rate constants ($k^+/[ZnY^{2-}]_0$) were actually measured at varied acetate concentrations under the conditions in which the theoretical values were calculated. They are also given in Fig. 2. Both the calculated and the experimental values increase with decreasing concentrations of aetate. The discrepancy existing between the calculated and experimental values is considered probably to be due to the contribution of the reaction in which acetato complexes participate.

## Summary

The kinetic study of the substitution reaction of lead ions and zinc-EDTA complexs in acetate buffer solutions has been carried out with the same procedure as that reported previously[2-4]. Under the experimental conditions, the reaction is found to proceed simultaneously through three different reaction paths, and the rate constants for three elementary reactions of those reaction paths are determined at ionic strength 0.2 at 15 and 25°C. The heats of activation and the entropies of activation for the three elementary reactions are calculated.

The authors thank the Ministry of Education for the financial support granted for this research. Part of the experimental work has been carried out with the assistance of Dr. Gen Satô.

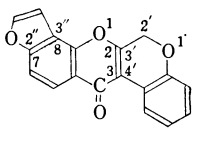
# *Synthetic Studies on the Benzofuran Derivatives. VI. Synthesis of Furano(2'', 3'' : 7, 8)-2'-methoxy-isoflavone Derivatives*

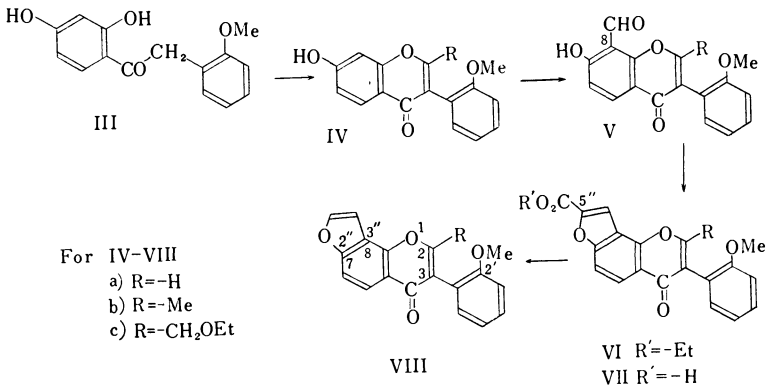


By Yoshiyuki KAWASE, Kiyomi OGAWA, Setsuko MIYOSHI and Kenji FUKUI*

(Received February 15, 1960)

The structure of elliptone, the simplest member of rotenoids, has been established[1] to be a dimethoxy derivative of furano-chromano-chromanone (I), but the synthesis of it and other rotenoids** is not yet achieved. Many efforts have hitherto been made on the synthesis of rotenoids, and recently the total synthesis of dihydrorotenone has been accomplished by Miyano and Matsui[2], who succeeded in the reduction of the chromenochromone system to give the chromanochromanone system. Therefore, it seems desirable for the synthesis of elliptone to prepare the furano-chromenochromone system, from which the furano-chromanochromanone system may be derived by reduction. For the preparation of chromenochromones, two methods are available

I



II

—those are (a) by chromenochromone-ring formation of phenoxyacetic acid-2-(*o*-hydroxy)-acetophenones[3] and (b) by chromen-ring formation of 2-methyl[4] or 2-ethoxymethyl[5] derivatives of 2'-methoxy-isoflavones.

Following the latter method, the authors attempted to synthesize furano(2'', 3'' : 7, 8)-chromeno(3', 4' : 2, 3)chromone (II), and in this paper describe the preparation of three intermediate derivatives (VIIIa, b, c) of furano (2'', 3'' : 7, 8)-2'-methoxy-isoflavone.

Starting from three isoflavones (IVa, b, c), furan-ring was built up on the 7, 8-position of them smoothly by a similar method reported in the previous papers[6] as follows : the isoflavones IVa, b, c were formulated by the hexamine method to give 8-formyl derivatives (Va, b, c), which were converted into $\alpha$-ethoxycarbonyl-furano derivatives (VIa, b, c) by the action of ethyl bromomalonate and potassium carbonate in acetone. Hydrolysis of the esters VIa, b, c under mild alkaline condition (aqueous sodium carbonate in acetone) furnished the corresponding acids VIIa, b, c which were decarboxylated in quinoline with the aid of copper catalyst

to give furano(2'', 3'' : 7, 8)-2'-methoxy-isoflavone*** (VIIIa), furano(2'', 3'' : 7, 8)-2'-methoxy-2-methylisoflavone (VIIIb) and furano-(2'', 3'' : 7, 8)-2'-methoxy-2-ethoxymethylisoflavone (VIIIc) respectively. Attempts to prepare II from VIIIb or VIIIc are now in progress.

## Experimental[7]

**2, 4-Dihydroxyphenyl 2-Methoxybenzyl Ketone (III).**—This ketone was prepared from resorcinol and *o*-methoxyphenylacetonitrile by the Hoesch reaction[4] or more conveniently from resorcinol and *o*-methoxy-phenylacetic acid by means of boron trifluoride[8]. M. p. 158~159°C (reported m. p. 159~160°C[4]).

**7-Hydroxy-2'-methoxy-isoflavone (IVa).**—A mixture of the ketone III (10 g.), ethyl orthoformate (20 ml.), piperidine (4 ml.) and pyridine (80 ml.) was refluxed for 8 hr. in an oil-bath. The resulting solution was cooled and acidified with dilute hydrochloric acid. The crystals formed were recrystallized from ethanol to give IVa, m. p. 226.5~227.5°C (reported m. p. 230~232°C[9]), having negative ferric reaction in ethanol; yield 6.6 g.

**7-Hydroxy-2'-methoxy-8-formyl-isoflavone (Va).**—A mixture of the isoflavone IVa (6 g.), hexamine (32 g.) and acetic acid (100 ml.) was heated in an oil bath (100°C) for 6 hr. The resulting hot solution was treated with hot dilute hydrochloric acid (1 : 1, 100 ml.) and again heated for 10 min., then allowed to stand overnight. The precipitates were collected, washed with water and dissolved in benzene, and the benzene solution was extracted with dilute aqueous sodium hydroxide. The product obtained by acidifying the alkaline solution was recrystallized from ethanol to give Va in faintly yellow colored microcrystals, m. p. 187~189°C, having a red ferric reaction in ethanol; yield 2.1 g.

Found: C, 68.40; H, 4.25. Calcd. for $C_{17}H_{12}O_5$: C, 68.92; H, 4.05%.

**7-Hydroxy-2'-methoxy-8-formyl-2-methylisoflavone (Vb).**—By the similar method as described for Va, 1.3 g. of Vb was obtained from 7-hydroxy-2'-methoxy-2-methylisoflavone[4] (IVb, m. p. 222~223°C, 3 g.), hexamine (16 g.) and acetic acid (50 ml.); m. p. 165.5~166.5°C (from ethanol) faintly yellow colored microcrystals, having a red ferric reaction in ethanol.

Found: C, 69.18; H, 4.67. Calcd. for $C_{18}H_{14}O_5$: C, 69.68; H, 4.52%.

**7-Hydroxy-2'-methoxy-8-formyl-2-ethoxymethyl-isoflavone (Vc).**—By the similar method, 1 g. of Vc was obtained from 7-hydroxy-2'-methoxy-2-ethoxymethylisoflavone[5] (IVc, m. p. 163~164°C, 1.5 g.), hexamine (8 g.) and acetic acid (25 ml.); m. p. 129~130°C (from 80% ethanol) faintly yellow colored microcrystals, having a red ferric reaction in ethanol.

Found: C, 68.04; H, 5.24. Calcd. for $C_{20}H_{18}O_6$: C, 67.79; H, 5.12%.

**5''-Ethoxycarbonyl-furano(2'',3'':7,8)-2'-methoxy-isoflavone (VIa).**—To a solution of the formyl-isoflavone Va (2 g.) and ethyl bromomalonate (2.2 g.) in anhydrous acetone (65 ml.) was added anhydrous potassium carbonate (7.8 g.), and the mixture was refluxed for 8 hr. in a steam bath. The resulting solution was filtered from precipitates and the solvent was distilled off. The residual oily product was recrystallized from ethanol to give VIa, m. p. 164.5°C, having a negative ferric reaction; yield 1.1 g.

Found: C, 69.12; H, 4.50. Calcd. for $C_{21}H_{16}O_6$: C, 69.23; H, 4.40%.

**5''-Ethoxycarbonyl-furano(2'',3'':7,8)-2'-methoxy-2-methylisoflavone (VIb).**—By the similar method as described for VIa, 1.2 g. of VIb was obtained from the formyl-isoflavone Vb (2 g.), ethyl bromomalonate (2.2 g.) and potassium carbonate (7.8 g.); m. p. 161.5~162.5°C (from ethanol), having a negative ferric reaction.

Found: C, 69.97; H, 4.96. Calcd. for $C_{22}H_{18}O_6$: C, 69.84; H, 4.76%.

**5''-Ethoxycarbonyl-furano(2'',3'':7,8)-2'-methoxy-2-ethoxymethylisoflavone (VIc).**—By the similar method, 1 g. of VIc was obtained from the formyl-isoflavone Vc (1.5 g.), ethyl bromomalonate (1.7 g.) and potassium carbonate (6 g.); m. p. 177.5~178.5°C (from ethanol), having a negative ferric reaction.

Found: C, 68.55; H, 5.33. Calcd. for $C_{24}H_{22}O_7$: C, 68.24; H, 5.25%.

**5''-Carboxy-furano(2'', 3'' : 7, 8)-2'-methoxy-isoflavone (VIIa).**—A mixture of the ester VIa (0.8 g.), acetone (40 ml.) and 5% aqueous sodium carbonate (30 ml.) was refluxed for 3 hr. Dilute hydrochloric acid (20 ml.) was added to the resulting mixture, and acetone was distilled off. The precipitates were collected and recrystallized from ethanol; m. p. 273.5~274°C, having a negative ferric reaction; yield 0.6 g.

Found: C, 67.83; H, 3.65. Calcd. for $C_{19}H_{12}O_6$: C, 67.86; H, 3.57%.

**5''-Carboxy-furano(2'', 3'' : 7, 8)-2'-methoxy-2-methylisoflavone (VIIb).**—By the similar method as described for VIIa, 1.1 g. of VIIb was obtained from the ester VIb (1.2 g.), acetone (50 ml.) and 5% aqueous sodium carbonate (50 ml.); m. p. 294°C (from ethanol), having a negative ferric reaction.

Found: C, 68.41; H, 4.02. Calcd. for $C_{20}H_{14}O_6$: C, 68.57; H, 4.00%.

**5''-Carboxy-furano(2'', 3'' : 7, 8)-2'-methoxy-2-ethoxymethylisoflavone (VIIc).**—By the similar method, 0.3 g. of VIIc was obtained from the ester VIc (0.5 g.), acetone (20 ml.) and 5% aqueous sodium carbonate (20 ml.); m. p. 233~234°C (from ethanol), having a negative ferric reaction.

Found: C, 67.21; H, 4.57. Calcd. for $C_{22}H_{18}O_7$: C, 67.00; H, 4.60%.

**Furano(2'',3'' : 7,8)-2'-methoxy-isoflavone (VIIIa).**—A mixture of the acid VIIa (0.5 g.), copper powder (0.3 g.) and quinoline (20 ml.) was heated while stirring in an atmosphere of nitrogen for 20 min.

*** It has recently been reported that munetone is 5''-isopropyl derivative of VIIIa by N. L. Dutta (*J. Indian Chem. Soc.*, 36, 165 (1959)).

7) Melting points are uncorrected, and the products are colorless microcrystals unless otherwise noted.

8) Private communication from H. Fukami of the Agricultural Department of Kyoto University.

at 190~200°C until evolution of carbon dioxide ceased. Quinoline was distilled off by steam-distillation, and the residual product was dissolved in ethyl acetate, filtered from copper, and washed with dilute sulfuric acid and dilute aqueous sodium hydroxide. Evaporation of ethyl acetate gave VIIIa, m. p. 182°C (from ethyl acetate and then from ethanol), having a negative ferric reaction; yield 0.3 g.

Found: C, 74.04; H, 4.20. Calcd. for $C_{18}H_{12}O_4$: C, 73.97; H, 4.11%.

**Furano(2'',3'':7,8)-2'-methoxy-2-methylisoflavone (VIIIb).**—By the similar method as described for VIIIa, 0.6 g. of VIIIb was obtained from the acid VIIb (1 g.), copper powder (0.5 g.) and quinoline (35 ml.); m. p. 168°C (from ethyl acetate and then from ethanol), having a negative ferric reaction.

Found: C, 74.33; H, 4.64. Calcd. for $C_{19}H_{14}O_4$: C, 74.51; H, 4.58%.

**Furano(2'', 3'' : 7, 8)-2'-methoxy-2-ethoxymethylisoflavone (VIIIc).**—By the similar method, 0.5 g. of VIIIc was obtained from the acid VIIc (1 g.), copper powder (0.5 g.) and quinoline (35 ml.); m. p. 119~120°C (from ethyl acetate and then from ethanol), having a negative ferric reaction.

Found: C, 72.18; H, 5.21. Calcd. for $C_{21}H_{18}O_5$: C, 71.99; H, 5.18%.

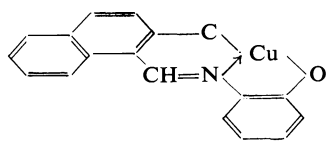
# *Metal Complexes with Terdentate Ligands. II*[1]. *Synthesis and Properties of Tri-coordinated Copper(II) Complexes*[2]

By Yoneichiro MUTO

(Received February 13, 1960)

So-called tri-coordinated copper(II) complexes have been reported by several investigators. For instance, Pfeiffer et al.[3] have prepared salicylaldehyde-2-hydroxyanil copper(II), while Yamaguchi[4], Dikmen et al.[5] and the present author[6] have synthesized salicylaldehyde-2-hydroxybenzylimine copper(II). Although it is presumed that the copper atoms in these chelates have an unusual coordination number, three, it is desirable to study extensively tri-coordinated copper(II) complexes having different types of ligand molecules in order to obtain more definite information about the tri-coordination of the copper atoms. This paper presents the synthesis and properties of some tri-coordinated copper(II) complexes.



**I. Copper(II) Complexes having Schiff Bases of 2-Aminophenol.**—In order to obtain terdentate ligands of similar type to salicylaldehyde-2-hydroxyanil, the present author prepared acetylacetone-mono-(2-hydroxyanil) and benzoylacetone-mono-(2-hydroxyanil) by the condensation of 2-aminophenol with acetylacetone and benzoylacetone, respectively. It is expected that they act as terdentate ligands in their enol forms shown in A′ and B′. That is to say, they have two hydrogen atoms capable of being replaced by metal atoms (i. e., hydrogen

* It is known that primary amines condense with benzoylacetone to form Schiff bases having a general formula $C_6H_5CO\cdot CH_2C(=N-R)\cdot CH_3$. Therefore, benzoylacetone-mono-(2-hydroxyanil) must have the structure shown in B′, althogh it may be presumed that the anil has the structure, $C_6H_5C(=N-C_6H_4OH)\cdot CH_2CO\cdot CH_3$.

of the phenolic and enolic hydroxyl groups) as well as a nitrogen atom capable of being coordinated to a metal atom (i. e., nitrogen of an azomethine group). Therefore, they will react with copper(II) ion to form chelates having a five-membered ring and a six-membered one, which are very common. On being treated with copper(II) acetate, they yielded complexes having the compositions expected for the formulae A and B. Similarly, 2-hydroxynaphthaldehyde-(1)-[*o*-hydroxyanil] yielded a copper(II) complex having the composition shown in C.

These complexes were readily soluble in pyridine, slightly soluble in nitrobenzene, and soluble with difficulty in other common organic solvents. When these complexes were recrystallized from pyridine, the corresponding monopyridinates were formed. The pyridinates liberated pyridine gradually at 70°C and completely at 120°C. The decrease in weight corresponded to one molecule of pyridine per one atom of copper. From these facts, it seems very likely that these pyridine-free complexes have two interlocked chelate rings shown in A, B and C, although their structures might not be so simple as is implied by the ordinary chemical formulae. This conclusion has been suggested further by magnetochemical studies[7,8]. As the present author et al. have already reported in previous papers[7,8], these pyridine-free complexes show magnetic moments considerably smaller than the theoretical value predicted from the presence of one odd electron, and the subnormal moments suggest the presence of dimeric molecules, in which two copper atoms are very close to each other as in copper(II) acetate monohydrate crystals, whereas the pyridinates have the normal moments expected for tetra-coordinated copper(II) complexes (Table I).

It has been presumed by the method of ligand-exchange[9] that these tri-coordinated complexes are more stable than the tetra-coordinated complexes having ligands similar to A′ or B′ from the structural point of view, but that they are less stable than bis-8-oxyquinolin copper(II) or salicylaldehyde-ethylenediimine copper(II) (Table II). For instance, when an alcoholic solution of benzoylacetone-mono-(2-hydroxyanil) was mixed with an alcoholic solution of bis-salicylaldehydeanil copper(II), benzoylacetone-mono-(2-hydroxyanil) copper(II) was formed, whereas the reverse reaction of this exchange did not take place.

**II. Copper(II) Complexes Having Schiff Bases of Anthranilic Acid.** — These complexes were synthesized by essentially the same method as that described in I. Namely, anthranilic acid was subjected to condensation with 5-*X*-salicylaldehyde (*X*-: chloro-, bromo- or nitro-), and the resulting Schiff bases (Formula D′) were treated with copper(II) acetate. In this

way the complexes having the compositions shown in D were obtained. These complexes were soluble with difficulty in common organic solvents such as ethanol or benzene, while their monopyridinates were soluble in ethanol to a certain extent. Pyridine could be removed from the pyridinates by heating at about 150~200°C in air or boiling in ethanol.

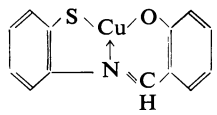
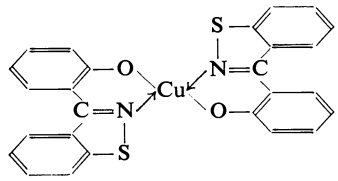
**III. Copper(II) Complexes Having Schiff Bases of 2-Aminothiophenol.**—Unlike the case of 2-aminophenol or anthranilic acid, 2-aminothiophenol condenses with aldehydes to form benzothiazoles. It seems probable from the results of several investigators[10] that the mechanism of the reaction can be represented as follows:

(a) (b) (c) (d)



Although the thiazolines (c) were isolated as intermediates in the formation of the thiazoles (d) from 2-aminothiophenol and aldehydes, neither the aldols (a) nor the anils (b) have been isolated.

Claasz[10] obtained 2-(*o*-hydroxyphenyl)benzothiazol (m. p. 130°C) by the reaction of 2-aminothiophenol with salicylaldehyde. Recently, Charles and Freiser[11] have obtained 2-(*o*-hydroxyphenyl)benzothiazoline (m.p. 136~137°C). However, in the course of this study, the present author has mixed 2-aminothiophenol and salicylaldehyde in ethanol and obtained a product of m. p. 148~148.5°C. This compound was converted into 2-(*o*-hydroxyphenyl)benzothiazol when it was recrystallized from ethanol containing a small amount of hydrogen chloride. On oxidation with hydrogen peroxide, this compound yielded 2-salicylaminophenyldisulfide, $(HO\cdot C_6H_4CH{=}N\cdot C_6H_4S{-})_2$, indicating the presence of a mercapto group. The elementary analysis of this compound agreed with the formula $HO\cdot C_6H_4CH{=}N\cdot C_6H_4SH$. On treating this compound with



10) M. Claasz, *Ber.*, **45**, 1031 (1912); **49**, 1141 (1916); M. T. Bogert and A. Stull, *J. Am. Chem. Soc.*, **47**, 3038 (1925); H. P. Lankelma and P. X. Sharnoff, ibid., **53**, 2654 (1931); M. T. Bogert and B. Naiman, ibid., **57**, 1529 (1935).

11) R. G. Charles and H. Freiser, *J. Org. Chem.*, **18**, 422 (1953).

copper(II) acetate, it yielded a complex having a composition agreeing with the formula E.

E

F

This complex was also prepared by the condensation of bis-salicylaldehyde copper(II) with 2-aminothiophenol. This formula was suggested further by the following observations. First, when this complex was decomposed by dilute sulfuric acid, salicylaldehyde was liberated. If this complex had had a thiazol or thiazoline link, salicylaldehyde would not have been liberated from it. Secondly, when this complex was recrystallized from pyridine, its monopyridinate was formed in the same manner as the tri-coordinated copper(II) complexes described in I and II. This shows that the composition of the complex has the molar ratio 1 : 1 of copper(II) to the ligand molecule.

As an example of metal complexes having the Schiff base of 2-aminothiophenol, only the following zinc complex has been reported. Bogert and Naiman[10] have shown that zinc 2-aminothiophenolate could be condensed directly with aromatic aldehydes to form zinc complexes having a general formula $(R\cdot CH=N\cdot C_6H_4S-)_2Zn$, which yielded 2-R-benzothiazoles when they were boiled in glacial acetic acid. The present author has also found that the corresponding 2-R-benzothiazoline does not form zinc or copper(II) complexes, while 2-(*o*-hydroxyphenyl)benzothiazol forms a copper(II) complex having the molar ratio 1 : 2 of copper(II) to the ligand molecule as shown in F. This result suggests that the thiazolines (c) cannot be converted into anils (b) by the action of metal ions. Therefore, the fact that reaction product of 2-aminothiophenol with salicylaldehyde (m. p. 148~148.5°C) yielded a complex having the composition shown in E gives support to the conclusion that the product must be salicylaldehyde-2-mercaptoanil.

2-Hydroxy-5-methylbenzaldehyde-*o*-mercaptoanil copper(II), 5-bromosalicylaldehyde-*o*-mercaptoanil copper(II) and their monopyridinates could be prepared in an analogous way.

## Experimental

**Preparation of Copper(II) Complexes.**—Appropriate amines were subjected to condensation with suitable ketones or aldehydes in ethanol. The resulting Schiff bases were separated and were treated with copper(II) acetate in the mixture of ethanol and water. The crude products which precipitated were separated, dissolved in pyridine and filtered. When water was added to the filtrates, the monopyridinates of the complexes were formed as crystals. On heating to an appropriate temperature (100~200°C), almost all the pyridine was removed. To ensure the complete removal, the residue were boiled in ethanol on a water bath for about half an hour. After being allowed to cool, the precipitates were filtered and dried at about 90°C. In this way pyridine-free copper(II) complexes were prepared. None of them melted below 300°C.

**(1) Acetylacetone-mono-(2-hydroxyanil) Copper(II).**—This was prepared from copper(II) acetate and acetylacetone-mono-(2-hydroxyanil)[12] (m. p. 187°C, yellow prismatic crystals. Found: N, 7.48. Calcd. for $C_{11}H_{13}O_2N$: N, 7.33%). The copper(II) chelate formed green prismatic crystals, while its pyridinate crystallized as deep green plates.

Found: N, 5.78; Cu, 25.32. Calcd. for $C_{11}H_{11}\cdot O_2NCu$: N, 5.54; Cu, 25.14%. Found: N, 8.69; Cu, 19.34; py., 23.73. Calcd. for $C_{11}H_{11}O_2NCu\cdot C_5H_5N$, N, 8.44; Cu, 19.15; py., 23.84%.

**(2) Benzoylacetone-mono-(2-hydroxyanil) Copper(II).**—Benzoylacetone-mono-(2-hydroxyanil) was prepared by the condensation of benzoylacetone (1.7 g.) with 2-aminophenol (1.1 g.) in ethanol (30 ml.). It was isolated in the form of yellow prismatic crystals; m. p. 169~170°C, yield 2 g.

Found: C, 75.76; H, 6.02; N, 5.81. Calcd. for $C_{16}H_{15}O_2N$: C, 75.87; H, 5.97; N, 5.53%.

The copper(II) chelate formed yellow-green needles, while its pyridinate crystallized as deep green plates.

Found: N, 4.49; Cu, 20.19. Calcd. for $C_{16}H_{13}\cdot O_2NCu$: N, 4.45; Cu, 20.18%. Found: N, 7.01; Cu, 16.23; py., 19.69. Calcd. for $C_{16}H_{13}O_2NCu\cdot C_5H_5N$: N, 7.09; Cu, 16.09; py., 20.03%.

**(3) 2-Hydroxynaphthaldehyde-(1)-[*o*-hydroxyanil] Copper(II).**—This was prepared from copper(II) acetate and 2-hydroxynaphthaldehyde-(1)-[*o*-hydroxyanil][13] (m.p. 248~249°C, brown-red needles, Found: N, 5.41. Calcd. for $C_{17}H_{13}O_2N$: N, 5.32%). The copper(II) chelate was yellow-green, while its pyridinate was brown. Both crystallized as needles.

Found: N, 4.40; Cu, 19.52. Calcd. for $C_{17}H_{11}\cdot O_2NCu$: N, 4.31; Cu, 19.56%. Found: N, 6.99; Cu, 15.71; py., 19.39. Calcd. for $C_{17}H_{11}O_2NCu\cdot C_5H_5N$: N, 6.94; Cu, 15.73; py., 19.59%.

**(4) 5-Chlorosalicylalanthranilic Acid Copper(II).**—5-Chlorosalicylalanthranilic acid was prepared by the condensation of 5-chlorosalicylaldehyde (1.6 g.) with anthranilic acid (1.4 g.) in ethanol (50 ml.). It was isolated in the form of orange prismatic crystals; m. p. 200°C, yield 2 g.

13) A. Senier and R. Clarke, *J. Chem. Soc.*, **99**, 2082 (1911—2).

Found: C, 61.10; H, 3.63; N, 5.39. Calcd. for $C_{14}H_{10}O_3NCl$: C, 60.99; H, 3.66; N, 5.08%.

The copper(II) chelate formed greenish brown needles, while its pyridinate crystallized as bright green plates.

Found: N, 4.29; Cu, 18.63. Calcd. for $C_{14}H_8O_3NClCu$: N, 4.15; Cu, 18.84%. Found: N, 6.83; Cu, 14.98; py., 19.24. Calcd. for $C_{14}H_8O_3NClCu \cdot C_5H_5N$: N, 6.73; Cu, 15.26; py., 19.00%.

(5) **5-Bromosalicylalanthranilic Acid Copper(II).**—5-Bromosalicylalanthranilic acid was prepared by the condensation of 5-bromosalicylaldehyde (2 g.) with anthranilic acid (1.5 g.) in ethanol (50 ml.). It was isolated in the form of orange prismatic crystals; m. p. 202°C, yield 3 g.

Found: C, 52.47; H, 3.12; N, 4.48. Calcd. for $C_{14}H_{10}O_3NBr$: C, 52.52; H, 3.15; N, 4.38%.

The copper(II) chelate formed greenish brown needles, while its pyridinate crystallized as bright green plates.

Found: N, 3.96; Cu, 16.87. Calcd. for $C_{14}H_8O_3NBrCu$: N, 3.71; Cu, 16.82%. Found: N, 6.30; Cu, 13.86; py., 17.36. Calcd. for $C_{14}H_8O_3NBrCu \cdot C_5H_5N$; N, 6.08; Cu, 13.79; py., 17.17%.

(6) **5-Nitrosalicylalanthranilic Acid Copper(II).**—5-Nitrosalicylalanthranilic acid was prepared by the condensation of 5-nitrosalicylaldehyde (1.7 g.) with anthranilic acid (1.4 g.) in ethanol (50 ml.). It was isolated in the form of red prismatic crystals; m. p. 271°C, yield 2.2 g.

Found: C, 58.67; H, 3.48; N, 10.04. Calcd. for $C_{14}H_{10}O_5N_2$: C, 58.74; H, 3.52; N, 9.79%.

The copper(II) chelate was greenish brown, while its pyridinate was bright green. Both formed prismatic crystals.

Found: N, 7.80; Cu, 18.43. Calcd. for $C_{14}H_8O_5N_2Cu$: N, 8.06; Cu, 18.27%. Found: N, 10.12; Cu, 15.15; py., 18.31. Calcd. for $C_{14}H_8O_5N_2Cu \cdot C_5H_5N$: N, 9.85; Cu, 14.89; py., 18.53%.

(7) **Salicylaldehyde-2-mercaptoanil Copper(II).** — *a) Salicylaldehyde-2-mercaptoanil.* — Equimolar amounts (0.01 mol.) of 2-aminothiophenol and salicylaldehyde were dissolved in ethanol (30 ml.). The resulting solution was kept below 30°C by means of a cold water bath for about two hours; meanwhile the crude product precipitated. Recrystallization from ether gave colorless prismatic crystals; m. p. 148~148.5°C, yield 1.5 g.

Found: C, 68.27; H, 5.11; N, 6.08. Calcd. for $C_{13}H_{11}NOS$: C, 68.10; H, 4.84; N, 6.11%.

*b)* The copper(II) chelate was prepared by the reaction of salicylaldehyde-2-mercaptoanil described above with copper(II) acetate. This chelate was also obtained by the condensation of bis-salicylaldehyde copper(II) with 2-aminothiophenol in the same way as that described in (9). The pyridine-free complex was deep green, while the pyridinate was brown. Both crystallized as needles.

Found: C, 53.74; H, 3.41; N, 4.67; Cu, 21.80. Calcd. for $C_{13}H_9NOSCu$: C, 53.69; H, 3.12; N, 4.82; Cu, 21.85%. Found: N, 7.70; Cu, 17.31; py., 21.39. Calcd. for $C_{13}H_9NOSCu \cdot C_5H_5N$: N, 7.57; Cu, 17.18; py., 21.38%.

*c) Oxidation of Salicylaldehyde-2-mercaptoanil.*— Salicylaldehyde-2-mercaptoanil (0.5 g.) was dissolved in a mixture of ethanol (20 ml.) and aqueous hydrogen peroxide (30%, 5 ml.). After being heated gently on a water bath for ten minutes, the solution was allowed to stand overnight in air at room temperature; meanwhile yellow crystals precipitated. Recrystallization from benzene gave yellow needles; m. p. 171°C, yield 0.3 g. When this product was mixed with 2-salicylaminophenyldisulfide, the melting point was unaltered.

Found: N, 6.26. Calcd. for $C_{26}H_{16}O_2N_2S_2$: N, 6.19%.

(8) **5-Bromosalicylaldehyde-*o*-mercaptoanil Copper(II).**—5-Bromosalicylaldehyde-*o*-mercaptoanil was prepared by the condensation of 5-bromosalicylaldehyde (2 g.) with 2-aminothiophenol (1.3 g.) in the same way as that described in (7). It was isolated in the form of colorless prismatic crystals; m. p. 147°C, yield 2 g.

Found: C, 50.90; H, 3.60; N, 4.31. Calcd. for $C_{13}H_{10}NOSBr$: C, 50.66; H, 3.27; N, 4.54%.

The copper(II) chelate was deep green, while its pyridinate was brown-red. Both crystallized as needles.

Found: C, 41.89; H, 2.42; N, 3.84; Cu, 17.25. Calcd. for $C_{13}H_8NOSBrCu$: C, 42.23; H, 2.18; N, 3.79; Cu, 17.19%. Found: N, 6.42; Cu, 14.30; py., 17.66. Calcd. for $C_{13}H_8NOSBrCu \cdot C_5H_5N$: N, 6.24; Cu, 14.16; py., 17.62%.

(9) **2-Hydroxy-5-methylbenzaldehyde-*o*-mercaptoanil Copper(II).**—A solution of 2-aminothiophenol (0.7 g.) in ethanol (10 ml.) was added to a boiling solution of bis-2-hydroxy-5-methylbenzaldehyde copper(II) (1.7 g.) in ethanol (50 ml.). Deep green micro-crystals immediately precipitated. It was purified by recrystallization from pyridine. The copper(II) chelate was deep green, while its pyridinate was brown-red. Both crystallized as needles.

Found: C, 55.10; H, 3.87; N, 4.47; Cu, 20.85. Calcd. for $C_{14}H_{11}NOSCu$: C, 55.16; H, 3.64; N, 4.59; Cu, 20.84%. Found: N, 7.45; Cu, 16.59; py., 20.63. Calcd. for $C_{14}H_{11}NOSCu \cdot C_5H_5N$: N, 7.30; Cu, 16.55; py., 20.60%.

(10) **Bis-2-(*o*-hydroxyphenyl)benzothiazol Copper(II).**—A solution of copper(II) acetate monohydrate (0.5 g.) in water (30 ml.) was added to a boiling solution of 2-(*o*-hydroxyphenyl)benzothiazol (0.6 g.) in ethanol (30 ml.). Dark green microcrystals immediately precipitated. Recrystallization from pyridine gave dark green plates. Yield 0.7 g.

Found: N, 5.40; Cu, 12.38. Calcd. for $C_{26}H_{16}O_2N_2S_2Cu$: N, 5.31; Cu, 12.31%.

Bis-2-(*o*-hydroxy-*m*-bromophenyl)benzothiazol copper(II) could be prepared in a similar manner. It was isolated in the form of dark green plates.

Found: N, 4.21; Cu, 9.52. Calcd. for $C_{26}H_{14}O_2N_2S_2Br_2Cu$: N, 4.16; Cu, 9.43%.

**Decomposition of Complexes (7), (8) and (9).**— The complexes described in (7), (8) and (9) were decomposed by dilute sulfuric acid and then subjected to steam distillation. Salicylaldehyde, 5-bromosalicylaldehyde and 2-hydroxy-5-methylbenzaldehyde in the distillates were identified by their phenylhydrazones which melted at 143°C, 151°C and 149°C respectively.

**Reaction of 2-R-benzothiazolines with Zinc or Copper(II) Acetate.** — The reaction of 2-phenylbenzothiazoline with zinc or copper(II) acetate was

attempted in organic solvents such as ethanol, pyridine or acetic acid, but the product isolated was only 2-phenylbenzothiazol. Similarly, 5-chloro-2-phenylbenzothiazoline did not form zinc or copper-(II) complex.

**Exchange Experiments.**—Calculated amounts of appropriate reagents and suitable complexes were dissolved or suspended in ethanol. The mixtures were heated on a water bath for about five minutes. The resulting complexes were separated, washed with hot ethanol repeatedly and then dried at 80°C. The elementary analysis of the resulting complexes is presented in Table II.

The author is grateful to Mr. Michihiko Kishita of Nagoya University for measurements of magnetic susceptibilities and to Mr. Michio Shido of Kyushu University for elementary analyses.

# *Tropones. V.* Addition Reaction of Tropone and Maleic Anhydride***

By Tetsuo NOZOE, Toshio MUKAI, Tsuneyuki NAGASE and Yasuo TOYOOKA

(Received March 15, 1960)

Troponoid compounds were at first considered to be resistant to the Diels-Alder type addition reactions because of their high aromaticity[1,2] but later, Sebe and others[3] found that hinokitiol underwent an addition reaction with maleic anhydride. Since then, the Diels-Alder reactions of tropolone, its methyl ether[4], 4-methyltropone[4], and 2-phenyltropone[5] have been reported. There still remained many points to be examined regarding the configuration of these adducts.

The present series of works was at first undertaken in order to examine the unsaturation characteristics of tropone and during the course of this work, some observations were gained regarding the configuration of the addition compound, which are described herein.

It has been pointed out[6] that the unsaturation characteristics of a tropone is greater than that of a tropolone and, as anticipated, the heating of tropone with two molar equivalents of maleic anhydride in xylene for a few hours easily effected reaction, affording the adduct I, m. p. 181.5~182.5°C, in a good yield of around 95%.

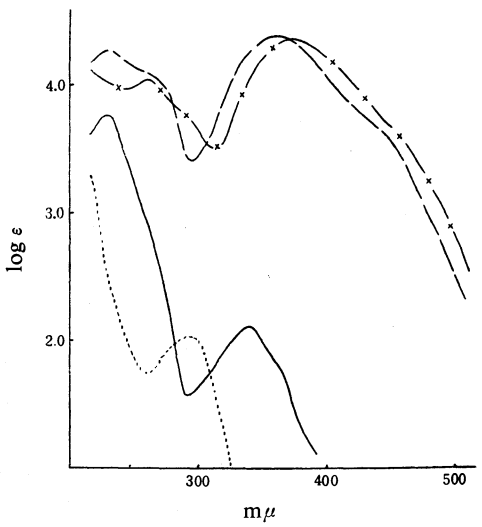

Fig. 1. —— I ----- II
-×- 2.4 DNP of V
—— 2.4 DNP of VI

Catalytic reduction of the adduct I in ethyl acetate or acetone with palladium-carbon as a catalyst, results in absorption of 2 molar equivalents of hydrogen to form a tetrahydro compound II. This shows the presence of two ethylenic linkages in I. The ultraviolet absorption spectra of I and II are shown in Fig. 1 and the spectrum of (I) exhibits a typical absorption of $\alpha\beta$-unsaturated ketone[7].

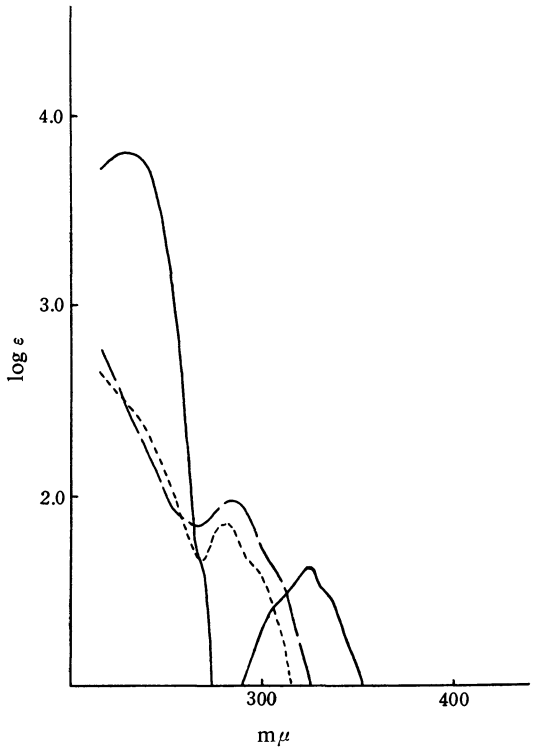

Fig. 2. —— VIII ------ X
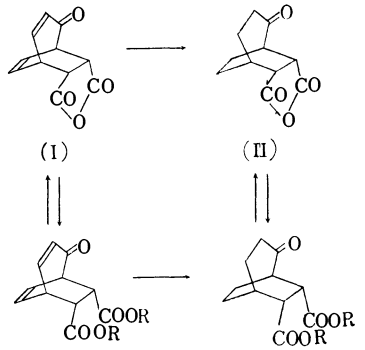
—— XI

The infrared spectra of I and II are shown in Table I. The absorption of a carbonyl in the acid anhydride of a five-membered ring is common to I and II, but while the absorption of an $\alpha\beta$-unsaturated ketone appears at 1665 $cm^{-1}$ in the spectrum of I, absorption of a saturated ketone is present at 1700 $cm^{-1}$ in that of II.



The presence of an $\alpha\beta$-unsaturated ketone in I not only offers an important clue to the structure of I but also proves the addition occurring at C-2 and C-5 positions in the tropone ring.

Treatment of the adduct I with hot water or sodium bicarbonate solution results in facile hydrolysis and a dibasic acid III is formed. The acid III is known to be dibasic from its analytical values and titration, as well as from its infrared spectrum (Table I) which shows the presence of two carbonyls.

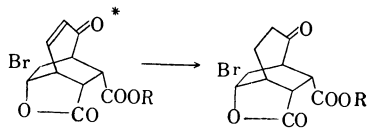
TABLE I.

| | $\nu_{OH}$ $cm^{-1}$ | $\nu_{C=O}$ $cm^{-1}$ | $\nu_{C=C}$ $cm^{-1}$ |
|---|---|---|---|
| I | | 1840, 1780 | 1665, 1625 |
| II | | 1840, 1775, 1700 | |
| III | 3250, 2960 | 1740, 1710 | 1650, 1625 |
| V | | 1730 | 1670, 1633 |
| VIII | 3320 | 1770, 1730 | 1675 |
| XI | | 1780, 1726, 1706 | |

Determination of the melting point of III indicates decomposition at 167.5°C but solidification of the melt and reexamination of the melting point shows it melting at 182.5°C, the same as that of I. This is considered to be due to the facile dehydration of III to form the anhydride.

III, R=H IV, R=H
V, R=$CH_3$ VI, R=$CH_3$

Actually, drying of III at 100°C under a reduced pressure results in the formation of I and such a fact naturally indicates that the two carboxyls are in *cis* configuration.



The tetrahydro compound II is also easily hydrolyzed and forms a dibasic acid (IV) which undergoes facile dehydration as in the case of III. Catalytic reduction of the unsaturated dibasic acid III in acetone, with palladium-carbon as a catalyst, results in absorption of two molar equivalents of hydrogen to form IV. Methylation of these two dibasic acids (III and IV) with diazomethane affords respective dimethyl esters (V and VI). It has been found, however, that reaction of III and excess of diazomethane also affords a compound (VII) of $C_{14}H_{16}O_5N_2$, besides V. In general, it is known that a reaction of $\alpha\beta$-unsaturated ketone and diazomethane results in formation of a pyrazole ring[8] and VII is considered to be this kind of product.

Both the methyl esters (V and VI) easily form crystalline 2, 4-dinitrophenylhydrazones whose ultraviolet absorption spectra are indicated in Fig, 1. The absorption of the 2, 4-dinitrophenylhydrazone of V shows a shift of 13 mμ to the longer wavelength region than that of VI and this fact indicates the presence of $\alpha\beta$-unsaturated ketone in V.[9] Catalytic reduction of V in ethyl acetate over palladium-carbon gives an oily product whose derivation to 2,4-dinitrophenylhydrazone proved that the oily product is VI.

8) H. Gilman, "Org. Chem.", Vol. IV, John Wiley & Sons., Inc., London, (1953), p. 780.
9) E. A. Braude and E. R. H. Jones, *J. Chem. Soc.*, 1945, 498.

Bromination of the adduct I in aqueous solution by the method of Alder-Stein[10] results in addition to the double bond and a bromo-lactone VIII is obtained in a good yield. Titration of VIII shows it to be a monobasic acid and the presence of a carboxyl (3320 and 1730 $cm^{-1}$) and a $\gamma$-lactone (1770 $cm^{-1}$) is also indicated from the infrared spectral values listed in Table I. In addition, there is an absorption of $\alpha\beta$-unsaturated carbonyl at 1675 $cm^{-1}$ in the spectrum of VIII. This fact is also certain from the ultraviolet spectrum of V shown in Fig. 2. These facts indicate that the addition of BrOH occurs at the non-conjugated double bond of the two ethylenic linkages present in I. It is therefore concluded that VIII has the configuration shown in Fig. 2 and that the structure of I to VI is in *endo-cis* form.

The unsaturated bromo-lactone VIII forms a monomethyl ester IX on methylation with diazomethane and IX easily forms a 2, 4-dinitrophenylhydrazone. The ultraviolet spectrum of 2, 4-dinitrophenylhydrazone of IX exhibits absorption maximum at 371 m$\mu$ and

VIII, R=H IX, R=$CH_3$ X, R=H XI, R=$CH_3$

this corresponds to that of 2, 4-dinitrophenylhydrazone of an $\alpha\beta$-unsaturated ketone.

Catalytic reduction of VIII over palladium-carbon in ethyl acetate results in absorption of one mole equivalent of hydrogen and saturated bromo-lactone (X) is produced. The structure of X was confirmed by the derivation of a monomethyl ester (XI) by reaction with diazomethane since it failed to undergo crystallization.

## Experimental

**Diels-Alder Reaction of Tropone and Maleic Anhydride; Formation of Tropone-Maleic Anhydride Adduct (I).**—A mixture of 8.36 g. (0.079 mol.) of tropone and 15.70 g. (0.16 mol.) of maleic anhydride in 60 cc. of dry xylene was refluxed in an oil bath for 2 hr. by which pale yellow crystals began to be deposited on the wall of the vessel. After refluxing for 4.5 hr, the mixture was allowed to stand overnight in a cool place and 16.6 g. (95%) of pale yellow crystals, m. p. 175~179°C, that precipitated out were collected by filtration. Several recrystallizations from acetone afforded I as colorless prismatic crystals, m. p. 181.5~182.5°C.

Found: C, 64.77; H, 4.14%. Cald. for $C_{11}H_8O_4$: C, 64.70; H, 3.95%.

I is easily soluble in acetone, ethyl acetate, ethanol, methanol and chloroform, and sparingly soluble in ether, petroleum ether, carbon tetrachloride and benzene.

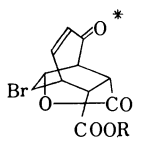
**Catalytic Reduction of I; Formation of the Tetrahydro Compound (II) of the Adduct.**—A solution of 500 mg. of I dissolved in 20 cc. of ethyl acetate, to which 20 mg. of 5% palladium-carbon had been added, was submitted to catalytic reduction at ordinary pressure. After absorption of 2.05 mole equivalent (109 cc.) of hydrogen, the product (500 mg.) was obtained as colorless crystals of m. p. 168~181°C and several recrystallizations from acetone-ether mixture afforded II as colorless leaflets, m. p. 191~192°C.

Found: C, 63.67; H, 5.39%. Calcd. for $C_{11}H_{12}O_4$: C, 63.45; H, 5.81%.

The use of acetone in place of ethyl acetate as a solvent in this reduction also results in absorption of two mole equivalent of hydrogen and the same product is obtained.

**Hydrolysis of I; Formation of the Dicarboxylic Acid (III) of the Adduct.**—*a) Hydrolysis with Water:* A solution of 1 g. of I dissolved in 30 cc. of hot water was allowed to stand overnight and 530 mg. of a colorless prismatic crystals, m. p. 162.5°C (decomp.), was obtained. Concentration of its filtrate on a water bath afforded a second crop of colorless crystals, m. p. 160°C (decomp.). The two kinds of crystals were combined and washed with acetone, affording (III) as colorless crystals, m. p. 167.5°C.

Found: C, 59.34; H, 4.35%. Calcd. for $C_{11}H_{10}O_5$: C, 59.46; H, 4.54%.



*b) Hydrolysis with Sodium Bicarbonate Solution:* To a solution of 420 mg. (0.005 mol.) of sodium bicarbonate dissolved in 4 cc. of water, 500 mg. of I was added and warmed on a water bath to dissolve all the crystals. The reaction mixture was concentrated acidified with hydrochloric acid while cooling with water and 400 mg. of colorless microneedles, m. p. 164~165°C (decomp.). The crystals were collected and washed several times with hot acetone, giving III as colorless microneedles, m. p. 167.5°C.

Ultraviolet spectrum: $\lambda_{max}^{MeOH}$ m$\mu$ (log $\varepsilon$): 228 (3.87), 337 (2.49).

The acid III obtained by both the foregoing methods (a) and (b) showed no depression of the melting point on admixture with I. The melted III, upon solidification, melted at 181.5~182.5°C, same as I.

**Dehydration of III; Formation of I.**—The Acid III obtained from the both methods (a) and (b) as above was each kept in a vacuum (10 mmHg) desiccator over phosphorus pentoxide

10) K. Alder und G. Stein, *Anal. Chem.*, 514, 4 (1934).

In this case there are two possible structures to VIII. Detailed reports on the structure of VIII will be made elsewhere.

11) All m. p. are uncorrected. The microanalyses were carried out by Miss Ayako Iwanaga of this laboratory to whom the authors are indebted.

at 100°C for 2 days. Determination of the melting point of resultant product showed formation of 45 mg. of a product of m. p. 181.5~182.5°C from 50 mg. of III. No depression of the melting point was observed on admixture with I.

Found : C, 64.59 ; H, 4.00%. Calcd. for $C_{11}H_8O_4$ : C, 64.70 ; H, 3.95%.

**Hydrolysis of II; Formation of Dicarboxylic Acid (IV) of the Tetrahydro Derivative of the Adduct.**—A solution of 150 mg. of II dissolved in 3 cc. of hot water was allowed to cool and colorless crystals that separated out were collected to 100 mg. of IV as colorless microneedles, m. p. 173°C (decomp.).

Found : C, 58.33; H, 5.80%. Calcd. for $C_{11}H_{14}O_5$ : C, 58.40 ; H, 6.24%.

The filtrate was concentrated at room temperature under a reduced pressure and a second crop of crystals was obtained as 80 mg. of colorless crystals, m. p. 169~170°C (decomp.).

Ultraviolet spectrum : $\lambda_{max}^{MeOH}$ mμ (log ε) : 285 (1.84).

Admixture of IV and II showed no depression of the melting point. Determination of the melting point after solidification of melted II showed m. p. 191~192°C.

**Dehydration of IV ; Formation of the Tetrahydro Compound (II) of the Adduct.**—Thirty milligrams of IV was kept over phosphorus pentoxide in a vacuum (10 mmHg) desiccator at 100°C for two days and 28 mg. of the resultant product melted at 171~172°C, alone and in admixture with II.

Found : C, 58.43 ; H, 6.30%. Calcd. for $C_{11}H_{12}O_4$ : C, 58.40 ; H, 6.24%.

**Catalytic Reduction of III; Formation of IV.**—A solution of 500 mg. of III dissolved in 70 cc. of acetone, added with 20 mg. of 5% palladium-carbon, was submitted to catalytic reduction at ordinary pressure and 2.08 mole equivalents of hydrogen (105 cc.) was absorbed. The catalyst was removed by filtration and the filtrate was concentrated, affording 460 mg. of colorless crystals, m. p. 154~155.5°C. The crystals were washed several times with warm acetone and (IV) was obtained as colorless crystals of m. p. 173°C (decomp.).

Found : C, 58.30 ; H, 5.93%. Calcd. for $C_{11}H_{14}O_5$ : C, 58.40; H, 6.24%.

The compound (IV) obtained by this means easily lost one mole of water to form II, as was the case with IV obtained by the hydrolysis of II.

**Raction of (III) and Diazomethane.**—*a) Formation of the Dimethyl ester (V) of III*: To a suspension of 220 mg. (ca. 0.001 mol.) of finely pulverized III in 10 cc. of ethyl acetate, 3.6 cc. (0.002 mol.) of ether solution of diazomethane was added dropwise at room temperature by which a vigorous reaction set in and III dissolved almost completely. The solution was evaporated on a water bath, the concentrated solution was cooled in ice, and 20 mg. of colorless crystals VII, m. p. 212°C, separated out.

Concentration of the mother liquor left 200 mg. of yellow oil which solidified gradually upon standing. Recrystallization from a small volume of methanol afforded V as yellow microneedles, m. p. 83~88°C.

Found : C, 62.42 ; H, 5.52%. Calcd. for $C_{13}H_{14}O_5$ : C, 62.39 ; H, 5.64%.

Ultraviolet spectrum : $\lambda_{max}^{MeOH}$ mμ (log ε) : 227 (3.90), 337(2.40).

*b) Formation of VII*: To a suspension of 300 mg. (0.0014 mol.) of III in 20 cc. of ethyl acetate, 9 cc. (0.0042 mol.) of ether solution of diazomethane was added in drops at room temperature by which III dissolved to form a uniform yellow solution. On standing, colorless crystals separated out which were collected and recrystallized from water to 340 mg. of colorless needles (VII), m. p. 212°C (decomp.).

Found : C, 57.19; H, 5.13%. Calcd. for $C_{13}H_{14}O_5 \cdot CH_2N_2$ : C, 57.53 ; H, 5.52%.

Ultraviolet spectrum : $\lambda_{max}^{MeOH}$ mμ (log ε) : 235 (3.36), 307(3.68).

*c) 2,4-Dinitrophenylhydrazone of V*: A solution (conc. sulfuric acid, 1.3 cc., methanol, 6.5 cc.) of 250 mg. (0.0013 mol.) of 2,4-dinitrophenylhydrazine was added to a solution of 250 mg. (0.001 mol.) of V dissolved in 2.5 cc. of methanol by which a fine orange powder precipitated out immediately. The mixture was stirred and allowed to stand overnight at room temperature. The solid was collected and recrystallized several times from acetone-methanol mixture to 230 mg. of VII as lustrous orange powder, m. p. 221.5~222°C.

Found : C, 52.80 ; H, 3.96 ; N, 13.07%. Calcd. for $C_{19}H_{18}O_8N_4$ : C, 53.02 ; H, 4.22 ; N, 13.02.

**Formation of the Dimethyl Ester (VI) of IV.**—(a) The calculated amount (0.004 mol.) of the ether solution of diazomethane was added dropwise at room temperature into a solution of 450 mg. (0.002 mol.) of IV dissolved in 20 cc. of ethyl acetate by which a vigorous effervescence set in. After standing at room temperature for a few hours, the solvent was distilled off and left 480 mg. of pale yellow oil. This oily residue was dissolved in acetone and purified by passage through alumina layer, from which 420 mg. of pale yellow oil (VI) was obtained.

Ultraviolet spectrum : $\lambda_{max}^{MeOH}$ mμ (log ε): 284(1.19).

b) Catalytic reduction of 50 mg. of V dissolved in 10 cc. of ethyl acetate, with 5% palladium-carbon as a catalyst, resulted in absorption of 2 mol. equivalents (5 cc., calcd. 4.5 cc.) and 50 mg. of pale yellow oil (VI) was obtained.

Ultraviolet spectrum : $\lambda_{max}^{MeOH}$ mμ (log ε): 284(1.20).

*c) Formation of 2,4-Dinitrophenylhydrazone of VI:* The hydrazone was prepared as in the case of V and recrystallized from methanol to fine orange needles, m. p. 89°C (decomp.).

Found : C, 52.50 ; H, 4.90 ; N, 12.87%. Calcd. for $C_{19}H_{22}O_8N_4$ : C, 52.53 ; H, 5.10 ; N, 12.90%.

**Formation of Bromolactone-monocarboxylic Acid (VIII).**—To a solution of 500 mg. (0.0025 mol.) of I dissolved in 30 cc. of water, 500 mg. (0.0031 mol.) of bromine was dropped in under ice-cooling and stirring. After some time, pale yellow crystals began to precipitate out. The mixture was stirred under ice-cooling for a further 4 hr., the excess of bromine was removed by addition of sodium bisulfite, and the mixture was filtered, affording 570 mg. of fine colorless crystals, m. p. 185°C

(decomp.). After drying over phosphorus pentoxide in a vacuum desiccator, the crystals were recrystallized from acetone to 500 mg. of colorless plates (VIII), m. p. 219°C (decomp.). VIII dissolved in cold, saturated solution of sodium bicarbonate with effervescence and colors green to the Beilstein test.

Found: C, 43.81; H, 2.99%. Calcd. for $C_{11}H_9O_5Br$: C, 43.87; H, 3.01%.

**Formation of the Methyl Ester (IX) of the Bromo-lactone VIII.**—To a solution of 300 mg. (0.001 mol.) of VIII dissolved in 10 cc. of ethyl acetate, 1.9 cc. (0.001 mol.) of the ether solution of diazomethane was added in drops and the mixture was allowed to stand for a few days from which 150 mg. of colorless scaly crystals of m. p. 213~215°C separated out. These crystals were collected by filtration, the filtrate was concentrated, and a second crop of crystals were obtained as 150 mg. of pale yellow crystals, m. p. 178~195°C. The two crops of crystals were combined and recrystallized from acetone-methanol mixture to IX as colorless scales, m. p. 216~217°C.

Found: C, 45.69; H, 3.25%. Calcd. for $C_{12}H_{11}O_5Br$: C, 45.73; H, 3.52%.

Ultraviolet spectrum: $\lambda_{max}^{MeOH}$ m$\mu$ (log $\varepsilon$): 232 (3.82), 320(2.37).

*2,4-Dinitrophenylhydrazone of IX:* A mixture of 200 mg. of IX dissolved in 20 cc. of methanol and methanolic solution (3.5 cc. of methanol and 0.9 cc. of conc. sulfuric acid) of 150 mg. of 2,4-dinitrophenylhydrazine was refluxed on a water bath for 3.5 hr. Concentration of this solution until only a part of the solvent remained left 220 mg. of dark brown crystals which were collected and recrystallized repeatedly from methanol to dark brown, fine needles, m. p. 146~147°C (decomp.).

Found: C, 43.50; H, 3.00; N, 11.02%. Calcd. for $C_{18}H_{15}O_8N_4Br$; C, 43.65; H, 3.05; N, 11.31%.

Ultraviolet spectrum: $\lambda_{max}^{MeOH}$ m$\mu$ (log $\varepsilon$): 255 (4.13), 371(4.43).

**Catalytic Reduction of VIII; Formation of Dihydro-bromo-lactone (X) and Methyl Ester (XI). of X,**—A solution of 240 mg. of VIII dissolved in 20 cc. of ethyl acetate, to which 20 mg. of palladium-carbon was added, was submitted to reduction at ordinary pressure and 0.95 mole equivalent (24.5 cc.) of hydrogen was absorbed. The product obtained therefrom was 220 mg. of yellowish brown oil (X) which failed to crystallize.

A calculated amount of ether solution of diazomethane was added to a solution of 120 mg. of above oil dissolved in 1 cc. of ethyl acetate and the mixture was allowed to stand overnight, from which 100 mg. of colorless crystals precipitated out. This was recrystallized from methanol-acetone mixture to colorless fine powder (XI), m. p. 167.5°C.

Found: C, 45.46; H, 4.02%. Calcd. for $C_{12}H_{13}O_5Br$: C, 45.44; H, 4.13%.

# *Theory of the Influence of the Dielectric Constant on the Rate of Reaction in Solution with Application to Enzyme Reactions. I. Development of the Theory and its Application to Some Simple Systems**

By Keitaro HIROMI

(Received December 18, 1959)

The rate of the reaction in solution involving ions or dipolar molecules is generally influenced by the dielectric constant of the medium, and this effect, termed the solvent effect, has been quantitatively interpreted by various authors in conformity to the electrostatic theories[1-5]. There is, however, marked inconsistency between the prediction of Amis-Jaffé's theory and that of Laidler-Eyring's for reactions between a negative ion and a dipolar molecule[2]. Recently Laidler and Landskroener developed a more general theory of the solvent effect[6] based on Kirkwood's model for a spherical solute molecule having an arbitrary charge

* Presented in part at the 11th Annual Meeting of Chem. Soc. Japan, Tokyo, April 1958, and at the Symposium on Enzyme Chem., Sapporo, July, 1958.

distribution[7,8], considering the microscopic distribution of charges in the reactants and the activated complexes, which had not been taken into account explicitly in the previous treatments[1-5]. Their theory was applied to the interpretation of the effect of solvent on the rates of the acid and base hydrolyses of esters, amides and anilides, and the results were considered to be successful[6].

The influence of the dielectric constant upon the rates of several enzyme reactions have been treated quantitatively on the basis of simple models[9,10], which seem evidently inadequate to a large complex ion such as protein. The Kirkwood's model may be a suitable one for the treatment of the electrostatic properties of protein molecules[11-13]. Although Laidler-Landskroener's theory is based on this model, it is not applicable to enzyme reactions, because of the approximation made in its derivation, which is not adequate for the large molecules with their charges near the surface of the sphere.

In this paper, a theory of the solvent effect which is applicable to enzyme reactions as well as to reactions involving small ions or molecules is developed, based on the Kirkwood's model. The theory is applied to the interpretation of the effect of solvent on the dissociation constants of carboxylic acids and on the rate constants of unimolecular and bimolecular reactions of simple organic compounds. Application of the theory to enzyme reactions will be treated in the following paper.

## Theoretical

Kirkwood[7] obtained an expression for the work of charging, or the electrostatic free energy, of a spherical solute molecule of radius $b$, having a low dielectric constant $D_i$, within which are situated $M$ discrete point charges $e_1 \cdots e_M$, and which is immersed in a solvent of dielectric constant $D$, as illustrated in Fig. 1. For zero ionic strength, the work of charging, $W_0$, with respect to the energy zero for the completely discharged state, is expressed as follows[7,8,12,14]:

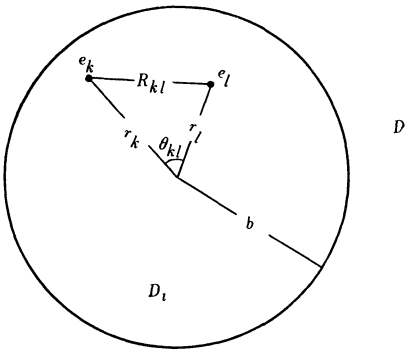

Fig. 1. Kirkwood's model for a spherical solute species having an arbitrary charge distribution.

$$W_0 = \frac{1}{2D_i}\sum_{k=1}^{M}\sum_{l=1}^{M} e_k e_l / R_{kl} + \frac{1}{2}\left(\frac{1}{D} - \frac{1}{D_i}\right)\sum_{n=0}^{\infty} \frac{(n+1)Q_n}{b^{2n+1}[(n+1)+nD_i/D]} \quad (1)$$

$$Q_n = \sum_{k=1}^{M}\sum_{l=1}^{M} e_k e_l r_k{}^n r_l{}^n P_n(\cos\theta_{kl}) \quad (2)$$

where $R_{kl}$ is the distance between the charges $e_k$ and $e_l$, $r_k$ and $r_l$ the distances of charges $e_k$ and $e_l$ from the center of the sphere, $\theta_{kl}$ the angle between $r_k$ and $r_l$, and $P_n(\cos\theta_{kl})$ is the Legendre polynomial. $Q_0$ is simply the square of the total net charge of the ion, and $Q_1$ is equal to the square of the dipole moment of the molecule. The succeeding $Q_n$'s involve the higher multipole moments, and depend not only upon the relative position of the charges, but also upon the distance of the charges from the surface of the sphere.

When the charges are situated not so near to the surface of the sphere, i. e., $r_k/b$ is not so close to unity, the summation in Eq. 1 converges rapidly, and the terms beyond $n=1$ can be dropped without serious error. This is the case in Laidler and Landskroener's treatment[6]. However, this approximation is not a reasonable one, especially when $b$ is large and the charges are situated near the surface, as is the case of a large complex ion such as protein. Now it is necessary to take the sum of the infinite series in Eq. 1. Since $D_i \ll D$ ($D_i$ was taken by Kirkwood to be 2), in a similar manner to Kirkwood's treatment[8], the sum is obtained by expanding the second term of Eq. 1 in increasing powers of $D_i/D$, and dropping all terms

13) C. Tanford, ibid., **79**, 5340 (1957).
14) The first term in Eq. 1 represents the work of charging in an unbounded medium of dielectric constant $D_i$, and is independent of the solvent. It contains self-energy terms (i. e., $k=l$), which are infinite because of the assumption of point charges. But this term does not appear in the final expression for the activity coefficient (Eq. 8 below). The second term represents the mutual electrostatic energy of the molecule and the solvent medium, and is the important term in the present treatment.

higher than the first. Finally we have[15]

$$W_0=\frac{1}{2D_i}\left[\sum_{k=1}^{M}\sum_{l=1}^{M}\frac{e_ke_l}{R_{kl}}-\frac{1}{b}\left(\sum_{k=1}^{M}e_k^2f'_{kk}+\sum_{k=1}^{M}\sum_{l\neq k}e_ke_lg'_{kl}\right)\right]+\frac{1}{2Db}\left[\sum_{k=1}^{M}e_k^2f_{kk}+\sum_{k=1}^{M}\sum_{l\neq k}e_ke_lg_{kl}\right] \quad (3)$$

where

$$\left.\begin{aligned} f_{kk}&=\frac{2}{1-x_{kk}}+\frac{1}{x_{kk}}\ln(1-x_{kk})\\ g_{kl}&=\frac{2}{(1-2\alpha_{kl}x_{kl}+x_{kl}^2)^{1/2}}\\ &+\frac{1}{x_{kl}}\ln\frac{1-\alpha_{kl}}{(1-2\alpha_{kl}x_{kl}+x_{kl}^2)^{1/2}+x_{kl}-\alpha_{kl}}\end{aligned}\right\} \quad (4)$$

$$\left.\begin{aligned} f'_{kk}&=\frac{1}{1-x_{kk}}\\ g'_{kl}&=\frac{1}{(1-2\alpha_{kl}x_{kl}+x_{kl}^2)^{1/2}}\end{aligned}\right\} \quad (5)$$

where

$$x_{kl}=r_kr_l/b^2;\quad x_{kk}=(r_k/b)^2;\quad \alpha_{kl}=\cos\theta_{kl} \quad (6)$$

For zero ionic strength, the activity coefficient $\gamma$ of a solute species in the solvent of dielectric constant $D$ with respect to a standard solvent of dielectric constant $D_0$ ($D_0\gg D_i$) is related to the work of charging $W_0$ and $W_0^0$ in each solvent, respectively, in the following manner

$$\ln\gamma=(W_0-W_0^0)/\boldsymbol{k}T \quad (7)$$

where $\boldsymbol{k}$ is the Boltzmann constant and $T$ the absolute temperature. Insertion of Eq. 3 into Eq. 7 gives rise to

$$\ln\gamma=\frac{\varepsilon^2L}{2b\boldsymbol{k}T}\left(\frac{1}{D}-\frac{1}{D_0}\right) \quad (8)$$

where $\varepsilon$ is the protonic charge and $L$ is a new dimensionless parameter defined as

$$L=\sum_{k=1}^{M}\xi_k^2f_{kk}+\sum_{k=1}^{M}\sum_{l\neq k}\xi_k\xi_lg_{kl} \quad (9)$$

where $\xi_k$ is the valence of the charge $e_k$, i. e., $\xi_k=e_k/\varepsilon$. The value of $L$ is determined by the charge configuration of the species, i. e., $L$ is a function of $\xi$'s, $r$'s, $\theta$'s of the charges and the radius $b$. Thus $L$ will be conveniently termed "charge configuration function". $L/b$ represents the susceptibility of the electrostatic free energy of the solute species to the change in dielectric constant of the medium.

By the use of this new parameter $L$, a relationship between the rate or the equilibrium constant of a chemical change in solution and the dielectric constant of the solvent can readily be obtained. For example, let us consider the reaction

$$A+B\rightleftarrows X_{\neq}\rightarrow \text{Products}$$

where the reactants A, B and the activated complex $X_{\neq}$ may be either ions or molecules with particular charge configuration. Let $k_0$ denote the rate constant in the standard solvent of dielectric constant $D_0$ ($D_0\gg D_i$), then the rate constant $k$ in a solvent of dielectric constant $D$ is[1]

$$k=k_0\gamma_A\gamma_B/\gamma_{\neq} \quad (10)$$

where the $\gamma$'s are the activity coefficients of the corresponding species. Using Eq. 8 we have

$$\ln k=\ln k_0+\frac{\varepsilon^2}{2\boldsymbol{k}T}\left(\frac{1}{D}-\frac{1}{D_0}\right)\left(\frac{L_A}{b_A}+\frac{L_B}{b_B}-\frac{L_{\neq}}{b_{\neq}}\right) \quad (11)$$

where $L$'s and $b$'s are the charge configuration functions and the radii of the species, respectively. This equation indicates that the plot of $\log k$ against $1/D$ gives a straight line and that the slope is

$$\frac{\mathrm{d}\log k}{\mathrm{d}(1/D)}=\frac{\varepsilon^2}{2.303\,(2\boldsymbol{k}T)}\left(\frac{L_A}{b_A}+\frac{L_B}{b_B}-\frac{L_{\neq}}{b_{\neq}}\right) \quad (12)$$

Thus the slope is determined by the charge configuration functions and the radii of the species.

In a similar manner, the relationship between the equilibrium constant $K$ and the dielectric constant of the medium, $D$, can be obtained. For the equilibrium

15) Eq. 2 can be written as

$$Q_n=\sum_{k=1}^{M}e_k^2r_k^{2n}+\sum_{k=1}^{M}\sum_{l\neq k}e_ke_lr_k^nr_l^nP_n(\cos\theta_{kl})$$

When this is inserted into Eq. 1 and the summation is performed, the first term gives the $f$ and $f'$ terms and the second term gives the $g$ and $g'$ terms in Eq. 3.

* When $x$ is zero, the value of $g$ is equal to unity for any value of $\alpha$.

$$A+B \rightleftharpoons C+D$$

the final expression is

$$\frac{d \log K}{d(1/D)}=\frac{\varepsilon^2}{2.303(2kT)}\left[\left(\frac{L_A}{b_A}+\frac{L_B}{b_B}\right)-\left(\frac{L_C}{b_C}+\frac{L_D}{b_D}\right)\right] \quad (13)$$

Assuming that the molecule or ion is a sphere within which each point charge is located at the center of each constituting atom, the value of $L$ of the molecule or ion with known charge configuration can be calculated using Eqs. 4, 6 and 9. For convenience of calculation, the values of $f$ and $g$ for various values of $x$ and $\alpha$ are tabulated in Tables I and II. For $x=0$, $f$ and $g$ are both equal to unity. The value of $g$ for $\alpha=1$ is equal to that of $f$ for the corresponding value of $x$. The value of $L$ is dependent on the position of the center to be chosen. It may be most reasonable to choose the center at the geometrical center of the

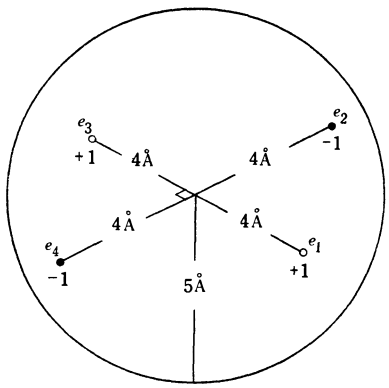

Fig. 2. A hypothetical dipolar ion. Two sets of charges, unit positive charges, $e_1$ anp $e_3$, and unit negative charges $e_2$ and $e_4$, are situated at equal distance 4 Å from the center, on the two diameters which are perpendicular to each other. The radius of the sphere is 5 Å.

molecule or ion concerned. As an example, $L$ of a hypothetical dipolar ion such as that depicted in Fig. 2 is calculated to be 11.8. The procedure of the calculation is illustrated in Appendix I.

For a spherical ion including a charge $Z\varepsilon$ at its center, $L$ is simply $Z^2$ (since $x=0$ and $f$ is unity). Thus for a reaction between such unipolar ions Eq. 12 reduces to the familiar expression of Laidler-Eyring for reactions between ions[1].

For the purpose of comparison, Laidler-Landskroener's equation[6], which corresponds to Eq. 12, is cited below;

$$\frac{\mathrm{d}\log k}{\mathrm{d}(1/D)}=\frac{\varepsilon^2}{2.303(2kT)}\left[\left(\frac{Z_A{}^2}{b_A}+\frac{Z_B{}^2}{b_B}-\frac{(Z_A+Z_B)^2}{b_\ddagger}\right)+\frac{3}{2}\left(\frac{G_A}{b_A{}^3}+\frac{G_B}{b_B{}^3}-\frac{G_\ddagger}{b_\ddagger{}^3}\right)\right] \quad (14)$$

where $b$ and $Z$ represent the radius and the net charge of the species, respectively, and $G$ is a quantity determined by the given charge distribution in the species, which is proportional to the square of the dipole moment.

## Application of the Theory to Some Simple Systems

Before applying the theory to enzyme reactions, it is desirable to test its applicability to some simple systems, for which the structure and the charge distribution in the species concerned can be visualized with considerable certainty. Three examples will be treated here; first, the dissociation equilibria of carboxylic acids; second, the $S_N1$ solvolysis; and third, the acid and base catalyzed hydrolyses of esters, amides and anilides.

**Dissociation of Carboxylic Acids.** — The dissociation constants of some carboxylic acids have been measured by several authors in

a) W: water, E: ethanol, M: methanol, D: dioxane.
b) $b$ (or $d$) indicates the radius (or the depth of the charge on the oxygen atom in $COO^-$) of $A^-$, $AH^-$ or $A^=$ corresponding to the dissociation constant $K$, $K_1$ or $K_2$, respectively. I: Calculated by Method I. II: Calculated by Method II.

various mixed aqueous solvents. The apparent dissociation constant $K_a$ of an acid AH ($K_a = [H^+][A^-]/[AH]$) in various mixed solvents having equal dielectric constants does not give the same value in different media having different water concentrations[16,17]. Yasuda[18] proposed that the dissociation constant $K$ of an acid in aqueous mixed solvents should be given by the following equation:

$$K = [A^-][H_3O^+]/[AH][H_2O]$$

corresponding to the equilibrium

$$AH + H_2O \rightleftharpoons H_3O^+ + A^-$$

He found that the plot of p$K$, instead of p$K_a$, of an acid against $1/D$ becomes a single straight line, irrespective of the sort of mixed solvent used, unless $1/D$ exceeds ca. 0.02[18]. Therefore, it may be reasonable to conclude that the variation in p$K$ is essentially due to the change in the dielectric constant of the medium, at least in the range stated above. The slope $d(pK)/d(1/D)$ is written as follows;

$$-\frac{d(pK)}{d(1/D)} = \frac{\varepsilon^2}{2.303(2kT)}\left(\frac{L_{AH}}{b_{AH}} + \frac{L_{H_2O}}{b_{H_2O}} - \frac{L_{A^-}}{b_{A^-}} - \frac{L_{H_3O^+}}{b_{H_3O^+}}\right) \quad (15)$$

Values of the slopes obtained from Yasuda's results for several carboxylic acids are summarized in Table III, where $K_1$ and $K_2$ are the first and the second dissociation constants of dibasic acids, respectively.

$$K_1 = [AH^-][H_3O^+]/[AH_2][H_2O]$$

$$K_2 = [A^=][H_3O^+]/[AH^-][H_2O]$$

Procedure of testing the theory is as follows; first, for the three species, $H_2O$, $H_3O^+$ and AH (or $AH_2$ for the dibasic acid), $L/b$'s are calculated from the charge configurations and the radii of these species; insertion of these values together with the value of the slope into Eq. 15 leads to an equation for $L_{A^-}/b_{A^-}$; if the magnitudes and the relative positions of the charges in $A^-$ are known, $L_{A^-}$ and $L_{A^-}/b_{A^-}$ are the functions of $b_{A^-}$ only; then the equation can be solved for $b_{A^-}$[19]. If the theory is correct, $b_{A^-}$ thus obtained should be of reasonable magnitude as is expected from the structure of $A^-$. The geometry and the charge distribution of the species which are necessary for the calculation of $L$'s are summarized in Appendix II.

Succinic acid was treated by the following two methods. In Method I, the charge distribution in the COOH group was considered explicitly in the evaluation of $L_{AH_2}$ and $L_{AH^-}$ as in the case of acetic acid and benzoic acid. Since $L_{AH_2}$ was found to be appreciably small,

16) J. C. Speakman, *J. Chem. Soc.*, **1943**, 270.
17) M. L. Dondon. *J chim. phys.*, **54**, 290, 304 (1957).
18) M. Yasuda, This Bulletin, **32**, 429 (1959).
19) Practically $b_{A^-}$ is obtained in the following manner. For several fixed values of $b_{A^-}$ suitably chosen, $L_{A^-}$'s are calculated and $L_{A^-}/b_{A^-}$ is plotted against $b_{A^-}$. By graphical interpolation $b_{A^-}$ to be solved is readily found.

a) W: water, E: ethanol. M: methanol, A: acetone.
b) The depth of the charge on the halogen atom from the surface.
c) $b_{\ddagger}$ calculated by the present author with Laidler-Landskroener's equation (Eq. 14).

in Method II, $L_{AH_2}$ and $L_{AH^-}$ were evaluated assuming that the charge on every atom in the COOH group is zero. This greatly simplifies the calculation, without affecting the results seriously (compare $b$'s for I and II in Table III). Hence, adipic acid and azelaic acid were treated by Method II. For these two acids calculations were made for the all *trans* form and the di-*cis* or tri-*cis* form (see Appendix II).

The results of the calculations are summarized in Table III. In the last two columns are presented the values of $d$, the depth of the charge on the oxygen atom in the $COO^-$ group from the surface of the sphere[20]. It is noted that $d$'s are nearly constant for the acids in spite of the wide variation in $b$'s.

**$S_N1$ Solvolysis.** — The influence of the dielectric constant of the medium upon the rate constant $k_1$ of $S_N1$ solvolysis has been discussed by Shingu and Okamoto[21]. The linear relationship between $\log k_1$ and $1/D$ was interpreted quantitatively on the basis of an ion-pair model for the activated complex. In the present study, the activated complex itself is treated as a sphere, within which positive and negative charges are assumed to be located at the centers of the carbon and halogen atoms, respectively. The equation to be used is as follows;

$$\frac{d \log k_1}{d(1/D)} = \frac{\varepsilon^2}{2.303\,(2kT)}\left(\frac{L_A}{b_A} - \frac{L_{\ddagger}}{b_{\ddagger}}\right) \qquad (16)$$

where $L_A/b_A$ and $L_{\ddagger}/b_{\ddagger}$ are concerned with the reactant molecule and the activated complex, respectively. In the manner similar to that of the preceding example, the radius of the activated complex $b_{\ddagger}$ was determined to fit the experimentally obtained slope.

For *tert*-butyl chloride and *tert*-butyl bromide the charge distributions were calculated from the observed dipole moments[22,23] considering the inductive effect[24], and the $L_A$'s were estimated. Since it was found that they are sufficiently small (see Appendix II), and the final values of $b_{\ddagger}$ are only slightly affected by ignoring them (by 0.01 Å or less), $L_A/b_A$ in Eq. 16 was approximated to zero for the present example. In the activated complexes the carbon-halogen bond lengths were assumed to be increased 50% (Model I) or 10% (Model II) over the normal bond lengths. In calculating $L$, two types of charge distribution were assumed for the activated complexes. Type 1

20) $d$ is equal to $b$ minus $r$ for the oxygen atom.

22) L. E. Sutton, "Determination of Organic Structures by Physical Methods", edited by E. A. Braud and F. C. Nachod, Academic Press, New York (1955), p. 392.
23) C. P. Smyth, "Dielectric Behavior and Structure", McGraw-Hill, New York (1955).
24) R. P. Smith, T. Ree, J. L. Magee and H. Eyring, *J. Am. Chem. Soc.*, **73**, 2263 (1951); R. P. Smith and H. Eyring, ibid., **74**, 229 (1952).

consists of a unit negative charge on the halogen atom, and compensating positive charges distributed on the remaining atoms in the same proportion to those in the normal molecules. In Type 2, simplification was made, so that a unit positive charge is localized solely on the $\alpha$-carbon atom, neglecting the charges on the remaining atoms except for a unit negative charge on the halogen atom. Calculation showed that the solved $b_{\ddagger}$'s are somewhat smaller in Type 2. Since the difference in $b_{\ddagger}$'s is not serious, the other five compounds were treated with the simplified models (Type 2), assuming that the carbon-halogen bond lengths in the activated complexes are increased 50% over the normal ones (Model I).

The results are listed in Table IV, where $b_{\ddagger}$'s calculated with Laidler-Landskroener's equation (Eq. 14) are also included. $d$ indicates the depth of the charge on the halogen atom from the surface of the sphere. It is noticed that $d$'s, in contrast to $b_{\ddagger}$'s, are not affected appreciably by the choice between Models I and II.

**III. Acid and Base Catalyzed Hydrolyses of Esters, Amides and Anilides.**—As an example of bimolecular reactions, and for the purpose of comparing the applicability of the present theory with that of Laidler-Landskroener's, the acid and base hydrolyses of certain esters, amides and anilides are treated along the same line and on exactly the same models for the activated complexes as those they proposed[6]. The relevant equation is

$$\frac{\mathrm{d}\log k}{\mathrm{d}(1/D)} = \frac{\varepsilon^2}{2.303(2kT)}\left(\frac{1}{b_{\mathrm{A}}} - \frac{L_{\ddagger}}{b_{\ddagger}}\right) \qquad (17)$$

where $k$ denotes the bimolecular rate constant, $b_{\mathrm{A}}$ the radius of a hydronium or hydroxyl ion, and $L_{\ddagger}$ and $b_{\ddagger}$ refer to the activated complex. In accordance with Laidler-Landskroener's treatment, it was assumed that the hydronium and the hydroxyl ions are unipolar ions (the charge is located at the center of the ion) with the radii of 1.70 Å[25] and 1.40 Å[26],

respectively. Hence their $L$'s are unity. $L$'s of the substrate molecules were also approximated to zero. By Eq. 17, $b_{\pm}$'s were determined to fit the observed slopes using their models for the activated complexes (see Fig. A-5 in Appendix II). The results are listed in Table V. In the column of $b_{\pm}$, L-L indicates Laidler-Landskroener's values[6], and C or P denotes the results of the present study when the center of the activated complex is taken at the carbonyl carbon atom as in Laidler-Landskroener's calculation, or at the point P depicted in the models, respectively.

## Discussion

In the previous theories of the solvent effect[1-5], an ion or a molecule was treated as a uniformly charged sphere or a dipole, respectively, disregarding the actual distribution of charges within them. It is more reasonable to treat the reactants and the activated complex as those having the particular distribution of charges. In this sense, Laidler-Landskroener's treatment[6] and the present one may be said to be more accurate and general than the previous treatments.

However, as seen from Tables IV and V, the radii of the activated complexes calculated according to Laidler-Landskroener's formula are unreasonably too small for the $S_N1$ solvolysis and the base hydrolysis of esters and amides. These values of radii would lead to an improbable situation where some of the charges are extruded out of the sphere, which is obviously inconsistent with the Kirkwood's model on which the theory is based. On the other hand, the application of the present theory to the above three examples has revealed that the radii of the species concerned are of quite reasonable magnitude as are to be expected from the structures of the species. It is evident from Example III that this discrepancy has come from the approximation made in the derivation of Laidler-Landskroener's equation in which the higher terms were dropped in the sum in Eq. 1, the other circumstances being equal in both treatmnets. The difference between the two theories may be most clearly illustrated in the following example. Suppose a unimolecular reaction in which the reactant is a neutral molecule having no distribution of charge and the activated complex is such as is shown in Fig. 2. Since both the net charge and the dipole moment are zero, the slope $\mathrm{d}\log k/\mathrm{d}(1/D)$ predicted by Laidler-Lands-kroener's equation (Eq. 14) is zero. On the other hand, the slope predicted by the present theory at 25°C is

$$\frac{\mathrm{d}\log k}{\mathrm{d}(1/D)} = -\frac{\varepsilon^2}{2.303(2kT)}\left(\frac{L}{b}\right) = -121.7 \times \frac{11.8}{5}$$

$$= -286 \qquad (18)$$

The value of $L$ depends sensitively upon the depth of the charge, $d$, at which the charge is located within the sphere. It is worthwhile to examine the values of $d$ determined to fit the observed slopes in the above examples, since they serve as a more rigorous check for the validity of the theory than the radii do.

In treating the interaction energies between charges on organic ions, as reflected in p$K$'s of dibasic acids and amino acids, based on the Kirkwood's model, Tanford[27] showed that the interaction energies critically depend upon the depth, $d$, of the charges, and it is necessary that $d$ be assigned a value close to 1.0 Å to account for experimentally observed interaction energies. He also found[13] that in calculating titration curves for simple protein model molecules using the Kirkwood model, merely by placing charges about 1 Å below the surfaces the titration curves can be obtained with a slope whose order of magnitude is in the best agreement with that observed experimentally.

Application of the present theory to the dissociation of carboxylic acids showed, as seen from Table III, that $d$'s of the charge on the oxygen atom in the carboxylate group are of nearly constant value around 1.0 Å within the error of the slope[28]. It is of interest to see that these values of $d$ are in good agreement with Tanford's value obtained from the calculation of interaction energies stated above, although different lines of approach have been made. These values of $d$ are comparable to the van der Waals radius (1.40 Å) or the ionic radius (1.4 Å) of oxygen atom[29]. Considering the simplicity of the Kirkwood model, the agreement may be considered to be satisfactory.

The depths, $d$'s calculated for the $S_N1$ solvolysis are also nearly constant for the series of compounds, but are considerably smaller compared with the van der Waals or ionic radii of the halogen atoms[29]. However, we have good reasons to accept the first example (variation of p$K$ of carboxylic acids with $D$) as the most reliable one, for in the remaining two examples the structures and the charge configurations of the activated complexes are essentially speculative in nature and are not so definitely established. In addition there is

27) C. Tanford, *J. Am. Chem. Soc.*, **79**, 5348 (1957).
28) The error in the slope may amount to ca. 10%, which leads to an uncertainty of 0.2 Å in $b$ or $d$.
29) L. Pauling, "The Nature of the Chemical Bond", Cornell University Press, New York (1940).

some possibility that an influence other than that of the dielectric constant might be included in the experimentally determined slopes. In fact, for the $S_N1$ solvolysis of *tert*-butyl chloride, Okamoto and Shingu[30] have pointed out that the solvent molecules containing one or more hydroxyl groups have some specific effect in accelerating the solvolytic reaction, and this effect is to be distinguished from the dielectric constant effect. Therefore, the observed slopes may be, at least in part, attributed to this specific effect caused by changing the composition of mixed solvents. The true slopes may be less negative, which may lead to larger values of $d$ in the above calculations.

Since the present theory has been developed for zero ionic strength, a comment will be needed about the influence of ionic strength, $\mu$, on the theoretical expressions. According to Kirkwood, the work of charging $W$ of the spherical molecule stated above in the presence of external ions in the solvent is[7]

$$W = W_0 + W_{\text{ion}} \tag{19}$$

where $W_0$ is a work of charging at zero ionic strength which was already expressed in Eq. 1, and $W_{\text{ion}}$ is a term arising from the presence of external ions and is given in the following formula[7,12]

$$W_{\text{ion}} = -\frac{\varepsilon^2}{2a}\sum_{k=1}^{M}\sum_{l=1}^{M}\xi_k\xi_l\, C_{kl} \tag{20}$$

where $a$ is the mean distance of closest approach of ions in the solvent to the solute species and $C_{kl}$ is a complex function of $D$, $D_i$, $a$, $\mu$ and the charge configuration of the species, and is difficult to manage in a simple manner. However, at low ionic strength[31] it is a good approximation to write $C_{kl}$ as

$$C_{kl} \simeq \frac{1}{D}\cdot\frac{\kappa a}{1+\kappa a} \tag{21}$$

where $\kappa$ is the Debye-Hückel parameter

$$\kappa = \sqrt{8\pi N\varepsilon^2\mu/1000DkT} \tag{22}$$

and is also a function of $D$. In a manner similar to that of Eq. 7 through Eq. 13, an expression for $\mathrm{d}\log k/\mathrm{d}(1/D)$ in the presence of ions, corresponding to, e. g., Eq. 12, is obtained as follows;

$$\frac{\mathrm{d}\log k}{\mathrm{d}(1/D)} = \frac{\varepsilon^2}{2.303(2kT)}\left[\left(\frac{L_A}{b_A}+\frac{L_B}{b_B}-\frac{L_\pm}{b_\pm}\right) - \frac{\mathrm{d}}{\mathrm{d}(1/D)}\left(\frac{\Phi_A}{a_A}+\frac{\Phi_B}{a_B}-\frac{\Phi_\pm}{a_\pm}\right)\right] \tag{23}$$

where

$$\Phi = \sum_{k=1}^{M}\sum_{l=1}^{M}\xi_k\xi_l C_{kl} \simeq \frac{Z^2}{D}\cdot\frac{\kappa a}{1+\kappa a} \tag{24}$$

since $\sum_{k=1}^{M}\sum_{l=1}^{M}\xi_k\xi_l$ is equal to the square of the total net charge $Z^2$ of the species. The second term in the right hand side in Eq. 23 represents a contribution of the term dependent on ionic strength to the slope. The contribution at various ionic strengths was estimated for the reaction

$$A + B \rightleftarrows X_\pm \rightarrow \text{Products}$$

for which $a_A = a_B = 5$ Å and $a_\pm = 6$ Å, at 25°C and $D$=78.5. The results are summarized in Table VI, where $\varphi$ designates the contribution of the term dependent on ionic strength to the slope.

$$\varphi \equiv \frac{\varepsilon^2}{2.303(2kT)}\cdot\frac{\mathrm{d}}{\mathrm{d}(1/D)}\left(\frac{\Phi_A}{a_A}+\frac{\Phi_B}{a_B}-\frac{\Phi_\pm}{a_\pm}\right) \tag{25}$$

TABLE VI. THE CONTRIBUTION OF THE TERM DEPENDENT ON IONIC STRENGTH TO THE SLOPE

| | $\varphi$ | | |
|---|---|---|---|
| $\mu$ | $Z_A=+1$ $Z_B=+1$ | $Z_A=+1$ $Z_B=-1$ | $Z_A=\pm1$ $Z_B=0$ |
| 0.01 | − 9.2 | 9.9 | 0.17 |
| 0.04 | −14.7 | 16.7 | 0.49 |
| 0.09 | −18.2 | 21.6 | 0.83 |
| 0.25 | −23.1 | 28.1 | 1.26 |
| 0.49 | −24.9 | 32.2 | 1.83 |
| 1.0 | −26.0 | 37.0 | 2.75 |

$\varphi$ is seen to be positive or negative according as the charges of the reactant ions are of opposite or like sign, and to be small if one of the reactants has no net charge. Although the $\varphi$ is only approximate especially at high ionic strengths, it may serve as a rough estimate of the contribution of the term dependent on ionic strength to the slope.

## Summary

A theory has been developed on the relationship between the equilibrium constant or the rate constant of a reaction and the dielectric constant of the solvent based on the Kirkwood's model. It is applicable to equilibrium states or reaction processes in which ions or molecules having arbitrary charge distributions are involved, including enzyme reactions. The theory predicts that there is a linear relationship between the logarithm of the equilibrium or rate constant and the reciprocal of the dielectric constant of the solvent. The slope is determined by the new parameter $L$, termed the charge

30) K. Okamoto and H. Shingu, reported at the Symposium on Mechanisms of Organic Reactions, Tokyo, 1959.

31) Ionic strength up to $\kappa a$=0.5 with charges near the surface, and to even higher values of $\kappa a$ for charges appreciably below the surface[12].

configuration function, and the radius of each species involved. $L$ of a species is a function of the magnitudes and the relative positions of charges in it and its radius. Tables have been presented in order to facilitate the evaluation of $L$.

The applicability of the theory has been tested for the dissociation of carboxylic acids, the $S_N1$ solvolysis of organic halides, and the acid and base hydrolyses of esters, amides and anilides, and the results are found to be satisfactory.

The influence of ionic strength on the theoretical expressions has also been discussed.

The author is deeply grateful to Professor Sôzaburo Ono for his kind guidance and discussion throughout this work. He is also indebted to Dr. Kunio Okamoto of Kyoto University and to Dr. Ichiro Moritani and Dr. Tsutomu Ishimura of Osaka University for their helpful discussions. He thanks Professor Wasaburo Jôno of Kyoto University for his interest and encouragement.

## Appendix I

**Evaluation of $L$.** — The charge configuration function $L$ of the hypothetical dipolar ion depicted in Fig. 2 is evaluated as follows; $L$ is written as

$$L=\xi_1^2f_{11}+\xi_2^2f_{22}+\xi_3^2f_{33}+\xi_4^2f_{44}+2\xi_1\xi_2g_{12}+2\xi_1\xi_3g_{13}+2\xi_1\xi_4g_{14}+2\xi_2\xi_3g_{23}+2\xi_2\xi_4g_{24}+2\xi_3\xi_4g_{34}$$

where

$$\xi_1=\xi_3=-\xi_2=-\xi_4=1$$

And

$$b=5\text{ Å}$$

$$r_1=r_2=r_3=r_4=4\text{ Å}$$

$$x_{11}=x_{22}=\cdots\cdots=x_{12}=\cdots\cdots=x_{34}=(r/b)^2=0.64$$

$$\alpha_{12}=\alpha_{14}=\alpha_{23}=\alpha_{34}=\cos 90^\circ=0$$

$$\alpha_{13}=\alpha_{24}=\cos 180^\circ=-1$$

The values of $f(x)$ and $g(x,\alpha)$ are given from Tables I and II as follows;

$$f_{11}=f_{22}=f_{33}=f_{44}=3.98$$

$$g_{12}=g_{14}=g_{23}=g_{34}=0.743$$

$$g_{13}=g_{24}=0.447$$

Hence $L$ is evaluated to be

$$L=4\times3.98-2\times4\times0.743+2\times2\times0.447=11.76$$

## Appendix II

The geometry and the charge distribution necessary for the calculation of $L$'s in the above three examples are summarized here. $r$'s and $\theta$'s are readily computed from them with trigonometry. A-B designates the distance between atoms A and B, $\xi_A$ the valence of the charge on A. The positions of the centers of the species are also shown. The procedure of determining $b$ to fit the observed slope is illustrated for the acetate ion.

### Dissociation of Carboxylic Acids.

1) $H_2O$ :— O-H=0.96 Å, ∠HOH=105°[29]. $\xi_0=-0.66$, $\xi_H=0.33$ (calculated from the dipole moment[23]). Center: Oxygen atom. $b=1.40$ Å[32]. $L$ calculated=0.263.

2) $H_3O^+$ :— O-H=1.01 Å, ∠HOH=117°[33] (pyramidal structure with equivalent H). $\xi_H=0.50$, $\xi_0=-0.50$. Center: Oxygen atom. $b=1.70$ Å. $L$ calculated=1.266.

3) Carboxyl group :—The structure of the carboxyl group[23] for acetic acid, benzoic acid and succinic acid (Method I) is shown in Fig. A-1. All the atoms are assumed to lie on the same plane[34]. The charge distribution is shown in the individual articles below.

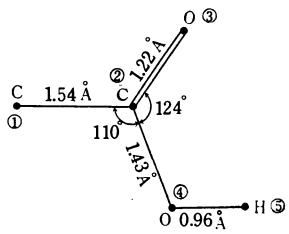

Fig. A-1. The structure of the carboxyl group. The atoms are numbered as indicated.

4) Carboxylate group :—The structure[35] and the charge distribution of the carboxylate group is depicted in Fig. A-2. This was used as the carboxylate model in every acid anion throughout this

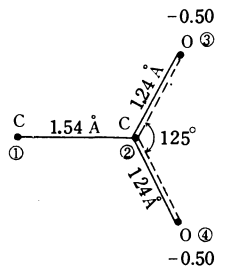

Fig. A-2. The structure of the carboxylate group. The atoms are numbered as indicated. The valences of the charges on the oxygen atoms are also shown.

32) R. W. Gurney, "Ionic Processes in Solution", McGraw-Hill, New York (1953), p. 16.
33) S. Seki et al., "Gendai Kagaku", VIG, Iwanami, Tokyo (1956), p. 51.
34) R. F. Curl, *J. Chem. Phys.*, **30**, 1529 (1959).
35) G. A. Jeffrey and G. S. Parry, *J. Chem. Soc.*, **1952**, 4864.

example. The two oxygen atoms are equivalent[36]. It was assumed that the four atoms are coplanar, and $\xi_1=\xi_2=0$, $\xi_3=\xi_4=-0.50$.

5) Acetic acid (AH):—The charge distribution was calculated from the bond moments[23] and the dipole moment[23] considering the inductive effect[24]. $\xi_1=0.110$, $\xi_2=0.409$, $\xi_3=-0.412$, $\xi_4=-0.435$, $\xi_5=0.325$. Center: Carboxyl C atom. $b=3.00$ Å. $L$ calculated $=0.097$.

6) Acetate ion ($A^-$) : — Center: Point on the $C_1$-$C_2$ line at 0.64 Å apart from $C_2$ atom. $L_{A^-}/b_{A^-}$ calculated for various values of $b_{A^-}$ are as follows;

| $b_{A^-}$(Å) | 2.40 | 2.70 | 3.00 | 3.30 |
|---|---|---|---|---|
| $L_{A^-}/b_{A^-}$(Å$^{-1}$) | 0.689 | 0.529 | 0.437 | 0.376 |

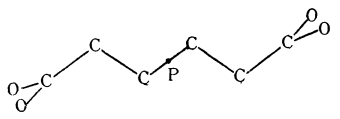
Insertion of the observed slope $d(pK)/d(1/D)$, $L$'s and $b$'s for $H_2O$, $H_3O^+$ and HA into Eq. 15 gives

$$\frac{L_{A^-}}{b_{A^-}}=\frac{118}{121.7}+\frac{0.263}{1.40}+\frac{0.097}{3.00}-\frac{1.266}{1.70}=0.445\ (\text{Å}^{-1}) \qquad \text{(A-1)}$$

$L_{A^-}/b_{A^-}$ is plotted against $b_{A^-}$, and the value of $b_{A^-}$ which fulfils Eq. A-1 can be obtained graphically. $b_{A^-}$ thus obtained is 2.97 Å.

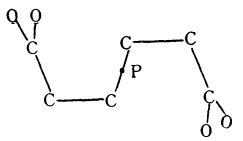
7) Benzoic acid (AH) :—The charge distribution was determined to fit the observed dipole moment[23] assuming that $\xi_3$, $\xi_4$ and $\xi_5$ are the same as those in acetic acid and the remaining charges are shared by the $C_2$ atom and the center of the ring, Q. $\xi_2=0.455$, $\xi_3=-0.412$, $\xi_4=-0.435$, $\xi_5=0.328$, $\xi_Q=0.064$. Center: Point on the $C_2$-Q line at 1.88 Å apart from $C_2$. $b=4.60$ Å. $L$ calculated $=0.102$.

8) Benzoate ion ($A^-$) : — Center: Point on the $C_2$-Q line at 2.32 Å apart from $C_2$ atom.



9) Succinic acid ($AH_2$) (Method I) :—*trans* Form, symmetric with respect to the middle point of the C-C bond in $CH_2$-$CH_2$ group, was assumed. The four carbon atoms lie on the same plane, to which the planes including each carboxyl group are perpendicular. $\xi_1=0$, $\xi_2=0.519$, $\xi_3=-0.412$, $\xi_4=-0.435$, $\xi_5=0.328$. The charge distribution in the two carboxyl groups are the same. Center: Center of symmetry. $b=4.60$ Å. $L$ calculated $=0.210$.

10) Bisuccinate ion ($AH^-$) (Method I) :—*trans* Form similar to $AH_2$ except that one of the carboxyl groups is replaced by carboxylate group. Center: C atom adjacent to the carboxyl C atom. The charge distribution in the carboxyl group is the same as that in $AH_2$.



11) Succinate ion ($A^=$) (Method I) :—Symmetric *trans* form similar to $AH_2$ except that the carboxyl groups are replaced by the carboxylate groups. Center: Center of symmetry.

12) Succinic acid ($AH_2$, $AH^-$, $A^=$)(Method II): —The geometry of each species is the same as that of the corresponding species treated in Method I. The charges on all the atoms in COOH group were assumed to be zero.

13) Adipic acid ($AH_2$, $AH^-$, $A^=$) (Method II) : —The structures assumed are schematically depicted in Fig. A-3. In both forms, all the carbon atoms lie on the same plane, to which the two planes including each carboxyl group are perpendicular.

on the methyl hydrogen atoms were included in $\xi_1$). $b=3.00$ Å. $L$ calculated $=0.048$.

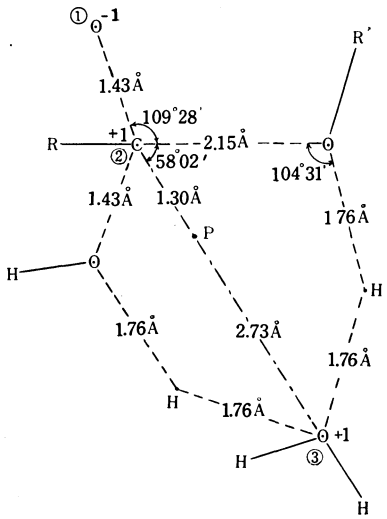
Activated state :— C-X $=2.64$ Å (Model I) ; C-X $=1.94$ Å (Model II). $\xi_1=0.196$, $\xi_2=0.414$, $\xi_3=-1.0$ (Type 1), $\xi_1=0$, $\xi_2=1.0$, $\xi_3=-1.0$ (Type 2).

2) *tert*-Butyl bromide.

Normal state :— C-X $=1.91$ Å, C-C $=1.54$ Å. $\xi_1=0.0403$, $\xi_2=0.085$, $\xi_3=-0.206$. $b=3.00$ Å. $L$ calculated $=0.057$.

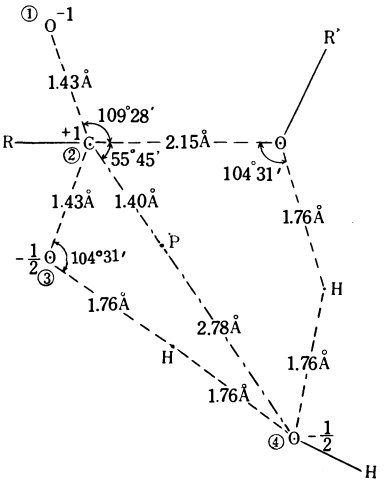
Activated state :— C-X $=2.86$ Å (Model I) ; C-X $=2.10$ Å (Model II). $\xi_1=0.195$, $\xi_2=0.414$, $\xi_3=-1.0$ (Type 1); $\xi_1=0$, $\xi_2=1.0$, $\xi_3=-1.0$ (Type 2).

The following five compounds were treated by the simplified type of charge distribution for the activated complexes (Type 2), $\xi_2=1$, $\xi_3=-1$, ignoring every small charge on the remaining atoms. The C-X bond distance in the activated complex was taken as 2.86 Å for bromide, and 2.64 Å for chloride (Model I).



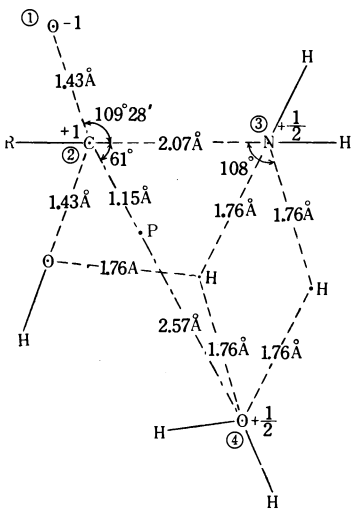
3) Neopentyl bromide :—Center : Middle point between $\alpha$-C and $\beta$-C atoms.

4) Benzhydryl chloride :—Center : Middle point between the two aromatic C atoms to which the $\alpha$-C atom is attached.



5) $\alpha$-Phenethyl chloride :—Center : $C_1$ atom of phenyl group.

6) Pinacolyl-*p*-bromobenzenesulfonate :—Center : Sulfur atom.



7) $\alpha$-Methylallyl chloride:—Center : Middle point between the $\alpha$-C atom and the adjacent double bonded C atom.

**III. Acid and Base Hydrolyses of Esters, Amides and Anilides.**

Laidler-Landskroener's models for the activated complexes are shown in Fig. A-5. It was assumed that the $C_2$ atoms are tetrahedral, and the following four atoms lie on the same plane;

$O_1$, $C_2$, $O_3$ and O(esteric) in Model (1)
$O_1$, $C_2$, $O_4$ and O(esteric) in Model (2)
$O_1$, $C_2$, $N_3$ and $O_4$ in Model (3)
$O_1$, $C_2$, N and $O_4$ in Model (4).

The center was chosen at $C_2$ atom or at point **P** depicted in the models (cf. Table V).

# *Theory of the Influence of the Dielectric Constant on the Rate of Reaction in Solution with Application to Enzyme Reactions. II. Application of the Theory to Enzyme Reactions**

By Keitaro HIROMI

(Received December 18, 1959)

The enzyme molecule in solution has a number of charged groups, some of which play an essential role in the catalytic reactions. Rates of enzyme reactions, therefore, may be expected to be influenced by the dielectric constant of a medium as are generally observed in reactions involving simple ions or dipolar molecules. From this viewpoint, rates of several enzyme reactions have been measured in aqueous mixed solvents, and the results have been discussed in relation to the dielectric constant of the medium[1-8]. In treating catalase and peroxidase reactions, Ogura et al.[1] and Tonomura[3] considered the enzyme or the enzyme-substrate complex as a dipole, to which the expression for the reaction between dipolar molecules[9] was applied. On the other hand, for $\alpha$-chymotrypsin[2] and myosin[4] catalyzed reactions, Laidler and his coworkers applied the coulombic law to the interaction between the charges of the substrate and the essential groups of the enzyme. However, since it is supposed that the reaction may occur in a local region near the surface of a large cavity of low dielectric constant formed by the enzyme molecule in solution, these treatments may be said to be over-simplified, and the validity of the conclusions deduced from them may be subject to criticism.

The Kirkwood's model for a spherical solute molecule having an arbitrary charge distribution, on which a general theory of the solvent effect has been developed in the preceding paper[10], seems to be appropriate as a model for a protein in solution. In this paper, the theory will be extended to include the solvent effect upon enzyme reactions.

## Theoretical

Enzyme reactions in general consist of two stages, formation of an intermediate enzyme-substrate complex, and its breakdown into products and free enzyme.

$$E + S \underset{k_{-1}}{\overset{k_1}{\rightleftharpoons}} ES \overset{k_2}{\rightarrow} E + P$$

The Michaelis constant $K_m$ and the rate constant of breakdown $k_2$ can be obtained in the usual manner[11]. In certain cases in which $k_{-1} \gg k_2$, $K_m$ may be identified with the reciprocal of the equilibrium constant $K$ for the formation of ES complex[12]. In some instances, $k_1$ or $k_{-1}$ can be measured directly[13], or may

be obtained from the analysis of overall reaction rates[14]. These kinetic parameters, $k$'s and $K$, may be influenced by the dielectric constant $D$ of the solvent, and equations similar to Eqs. 12 and 13 in the preceding paper[10] may be available. They involve the charge configuration functions $L$'s of the substrate, enzyme, ES complex and/or $ES_{\neq}$, the activated complex of ES. The $L$'s of the last three species involve the contribution of all the charges of the enzyme molecule, which we cannot evaluate explicitly because of our lack of knowledge about their spatial distribution over the enzyme molecule. However, as will be seen shortly, the following treatment may be allowable. Instead of $L$, the complete charge configuration function involving all the charges in the enzyme, we may use $L^0$, the effective charge configuration function concerned only with the small number of charges of special interest belonging to a limited reaction region, disregarding all the remaining charges in the enzyme which are considered to be kept fixed and not to come into play during the reaction process.

Consider the equilibrium, for example,

$$E + S \underset{k_{-1}}{\overset{k_1}{\rightleftharpoons}} ES$$

The variation of the equilibrium constant $K(=k_1/k_{-1})$ with $D$ can be written as[10]

$$\frac{d \log K}{d(1/D)} = \frac{\varepsilon^2}{2.303(2kT)}\left(\frac{L_S}{b_S} + \frac{L_E}{b_E} - \frac{L_{ES}}{b_{ES}}\right) \tag{1}$$

where $b$'s are the radii of the substrate, enzyme and ES complex, as indicated by the suffixes, $L$'s are the corresponding complete charge configuration functions which contain the contribution of all the charges in E and ES, and the other symbols have the same meaning as those in the preceding paper[10]. For small substrates $b_E$ and $b_{ES}$ may be equated. Let E and ES have in the total $M$ and $M'$ charges, respectively, and let $n$ of them be kept fixed in position and free from any change during the process. Thus

$$\left.\begin{aligned} M &= n+m \\ M' &= n+m' \end{aligned}\right\} \tag{2}$$

where $m$ and $m'$ are the number of charges of special interest which belong to the local reaction region in E and ES, respectively. $L_E$ and $L_{ES}$ are written as follows[10];

$$\begin{aligned} L_E &= \sum_{k=1}^{M} \xi_k^2 f_{kk} + \sum_{k=1}^{M} \sum_{l\neq k} \xi_k \xi_l g_{kl} \\ &= \sum_{i=1}^{m} \xi_i^2 f_{ii} + \sum_{s=1}^{n} \xi_s^2 f_{ss} + \sum_{i=1}^{m} \sum_{s=1}^{n} \xi_i \xi_s g_{is} \\ &\quad + \sum_{i=1}^{m} \sum_{j\neq i} \xi_i \xi_j g_{ij} + \sum_{s=1}^{n} \sum_{t\neq s} \xi_s \xi_t g_{st} \end{aligned} \tag{3}$$

$$\begin{aligned} L_{ES} &= \sum_{k=1}^{M'} \xi_k^2 f_{kk} + \sum_{k=1}^{M'} \sum_{l\neq k} \xi_k \xi_l g_{kl} \\ &= \sum_{i=1}^{m'} \xi_i^2 f_{ii} + \sum_{s=1}^{n} \xi_s^2 f_{ss} + \sum_{i=1}^{m'} \sum_{s=1}^{n} \xi_i \xi_s g_{is} \\ &\quad + \sum_{i=1}^{m'} \sum_{j\neq i} \xi_i \xi_j g_{ij} + \sum_{i=1}^{n} \sum_{t\neq s} \xi_s \xi_t g_{st} \end{aligned} \tag{4}$$

where the suffixes $i$ and $j$ refer to the charge number of the charges belonging to the $m$ or $m'$ group, $s$ and $t$ the $n$ group, and $f$ and $g$ are the functions of the positions of charges as were defined by Eq. 4 in the preceding paper[10].

Hence we have

$$\begin{aligned} L_E - L_{ES} &= \Big(\sum_{i=1}^{m} \xi_i^2 f_{ii} + \sum_{i=1}^{m} \sum_{j\neq i} \xi_i \xi_j g_{ij}\Big)_E \\ &\quad - \Big(\sum_{i=1}^{m'} \xi_i^2 f_{ii} + \sum_{i=1}^{m'} \sum_{j\neq i} \xi_i \xi_j g_{ij}\Big)_{ES} \\ &\quad + \Big(\sum_{i=1}^{m} \sum_{s=1}^{n} \xi_i \xi_s g_{is}\Big)_E - \Big(\sum_{i=1}^{m'} \sum_{s=1}^{n} \xi_i \xi_s g_{is}\Big)_{ES} \end{aligned} \tag{5}$$

The last two terms of the right hand side in Eq. 5 are those from the pair-wise contribution between the $m$ or $m'$ charges of special interest and the $n$ remaining fixed charges in E and ES. If the $n$ charges consist of approximately equal numbers of positive and negative charges, and they are distributed at random over the enzyme molecule, these terms may be appreciably small and may be dropped without serious error. Hence

$$\left.\begin{aligned} L_E - L_{ES} &= L^0{}_E - L^0{}_{ES} \\ L^0{}_E &= \Big(\sum_{i=1}^{m} \xi_i^2 f_{ii} + \sum_{i=1}^{m} \sum_{j\neq i} \xi_i \xi_j g_{ij}\Big)_E \\ L^0{}_{ES} &= \Big(\sum_{i=1}^{m'} \xi_i^2 f_{ii} + \sum_{i=1}^{m'} \sum_{j\neq i} \xi_i \xi_j g_{ij}\Big)_{ES} \end{aligned}\right\} \tag{6}$$

where $L^0{}_E$ and $L^0{}_{ES}$ are the effective charge configuration functions of E and ES, concerned only with the charges of special interest. Eq. 1 becomes, therefore,

$$\frac{d \log K}{d(1/D)} = \frac{\varepsilon^2}{2.303(2kT)} \times \left[\frac{L_S}{b_S} + \frac{1}{b_E}(L^0{}_E - L^0{}_{ES})\right] \tag{7}$$

Similarly for the breakdown process of ES, we have

$$\frac{d \log k_2}{d(1/D)} = \frac{\varepsilon^2}{2.303(2kT)}\left(\frac{L^0{}_{ES}}{b_{ES}} - \frac{L^0{}_{ES\neq}}{b_{ES\neq}}\right) \tag{8}$$

14) H. Gutfreund, *Discussions Faraday Soc.*, **20**, 167 (1955); E. C. Slater, ibid., **20**, 231 (1955).

where $L^0_{ES\neq}$ is the effective charge configuration function of $ES_{\neq}$. Similar equations for $k_1$ or $k_{-1}$ if necessary, may readily be obtained.

### Application to Some Typical Models

In Table I are summarized the data of the solvent effect upon the kinetic parameter $\mathfrak{R}$ which have been obtained for various enzyme reactions[1-8]. $\mathfrak{R}$ represents the rate constant or equilibrium constant specified in each item. The slopes $d \log \mathfrak{R}/d(1/D)$ have been calculated under the assumption that the observed changes in $\mathfrak{R}$ are due entirely to the variation in dielectric constant of the mixed solvent. The radii of the enzymes are computed from the molecular weight and the specific volume[15] assuming the spherical shape of the enzymes. In many cases, the slopes have considerably large negative values of the order of $-200$.

It is worthwhile to see whether the present theory can reasonably account for the slopes of the observed order of magnitude, considering only the electrostatic rearrangement in the local reaction region.

For the present, let us confine our attention to the breakdown process of ES complex in which the bond X–Y of a substrate molecule is to be split. During the activation process a change in charge state may occur in the local reaction region which involves the bound substrate molecule and the catalytic center of the enzyme. We may assume that ES and $ES_{\neq}$ are spheres of equal radii $b_{ES}$, and that the substrate molecule is situated near the surface of the sphere. It is reasonable to suppose that in the activated complex the bond to be split is polarized so that a positive charge and a negative charge will be produced on the atoms X and Y forming the bond, as a preliminary stage of bond splitting[2]. It may lead to a change in $L^0$ by which the slope $d \log k_2/d(1/D)$ will be determined. The increment in $L^0$, and hence the slope, may depend on the magnitude of the charges produced, their position in the sphere (or the depth of the charges from the surface), and the situation of the neighboring charges. Two typical models for $ES_{\neq}$ are shown in Fig. 1. $e_3$ and $e_4$ are the charges produced on the atoms X and Y in $ES_{\neq}$ at a depth $d$ from the surface of the sphere. $e_1$ and $e_2$ are the neighboring charges which represent, for example, the charges of the active site of the enzyme, or the other charges the substrate may bear. In both models, the distance between $e_3$ and $e_4$ is taken as 2 Å, which is nearly equal to 50% stretched bond length of C–O or C–N

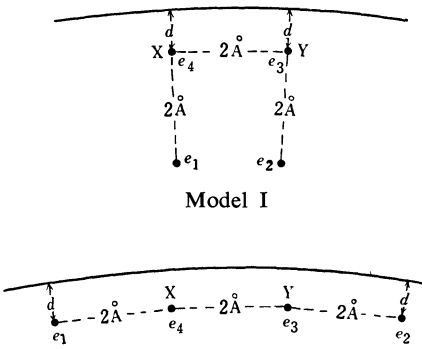

Fig. 1. Models of $ES_{\neq}$.
$e_1$ and $e_2$ represent the neighboring charges, and $e_3$ and $e_4$ the charges produced on the atoms X and Y in the activated state.

bond over their normal ones. In Model I, $e_1$ and $e_2$ are assumed to be situated by 2 Å inside on the lines drawn from the center to the charges $e_4$ and $e_3$, respectively. In Model II, $e_1$ and $e_2$ are situated on both sides of $e_4$ and $e_3$, 2 Å apart from them, respectively, at a depth $d$ from the surface. $\xi$'s denote the valences of the charges. The increment in the effective charge configuration function, $\Delta L^0_{\neq}$ $(=L^0_{ES\neq} - L^0_{ES})$, accompanied with the activation of ES complex, can be calculated from Eq. 6, using Tables I and II in the preceding paper[10], and the slope $d \log k_2/d(1/D)$ from Eq. 8. In the present case, calculations were made under the following conditions; i) the charges $e_3$ and $e_4$ are both zero in ES, ii) $-\xi_3=\xi_4=1$ or 1/2 in $ES_{\neq}$, iii) $e_1$ and $e_2$ are either positive or negative unit charges and are fixed during the activation process, iv) $d$ is taken as 0.5 Å or 1.0 Å, and v) $b_{ES}=b_{ES\neq}=21$ Å and the temperature is 25°C. The results are summarized in Table II. It is seen that the slope is determined primarily by the magnitude of the charges produced and by the depth of the charges below the surface, $d$, and is also dependent upon the situation of the neighboring charges especially in Model II. The slope of the observed order of magnitude is reasonably accounted for, if a pair of charges of opposite sign whose valence is close to unity are produced in the activated complex at the depth of 0.5~1.0 Å below the surface. These values for depth of charges are in reasonable agreement with those determined for the simple systems in the preceding paper[10]. On the other hand, Laidler-Landskroener's equation[16] applied to the above models, yields a slope, at the greatest, of about

$-0.8$, by a factor of $10^2$ less than the observed values.

## Discussion

The present theory which is based on the Kirkwood's model may be more suited for treating the solvent effect upon enzyme reactions than the previous ones[1-4], although some simplifications inevitable in dealing with the complex enzyme molecule have still been made. The application of the theory to the typical models has shown that it successfully accounts for the experimentally obtained slopes, considering only the local rearrangement of charges in the enzyme-substrate complex. An advantage of the present theory over the existing theories is that it can deal with any microscopic change in charge state in any position in the spherical solute. It eliminates the disadvantage of the treatment which regards the enzyme or the enzyme-substrate complex as a dipole[1,3], according to which an extraordinarily large dipole moment had to be assigned to the activated complex in order to account for the slope of the observed order of magnitude[17].

At present we shall have to be content with the successful results of the application of the theory to the typical examples stated above. However, when our knowledge has accumulated about the value of $d$ to be assigned in the individual cases, we may reasonably hope that we can have an insight into the microscopic charge configuration in the activated state from the slope obtained by the study of the solvent effect on the reaction rate, which may serve as a tool for elucidating the mechanism of the reaction.

However, in interpreting the experimental data of solvent effect, attention must be paid to the possibility that the observed effects may involve contributions of various factors other than the purely electrostatic effect of dielectric constant on the rate. The factors that may possibly influence the rate by changing the composition of mixed solvents are enumerated as follows; 1) decrease in water concentration which might result in reduction of rates, if the rate determining step involves participation of the water molecules especially for hydrolytic enzymes, 2) shift of the activity-pH curve which may decrease or increase the rate when the experiments are carried out at constant pH[6], 3) possible inhibition by some component of the mixed solvent, 4) irreversible or reversible denatuation of the enzyme caused by the addition of organic solvents, 5) change in viscosity which may influence the rate if the reaction is diffusion controlled[18-20]. In most cases, the addition of organic solvents may lead to a decrease in rates due to these factors, in addition to a decrease in the dielectric constant of the medium. If this is the case, the observed slopes may possibly have been over-estimated in the negative direction, which would lead to larger values of $d$ in the above calculation.

For non-zero values of ionic strength, the slope may be affected by the inclusion of the term dependent on ionic strength as already discussed in the preceding paper[10]. The contribution of this term may be small except for bimolecular processes in which both of the reactants have non-zero net charges. Of course, the contribution is greater at higher ionic strength. A rough estimate reveals that for ionic strength of 0.02 and the radius of the enzyme taken as 20 Å[21], the contribution to the slope may be less than about $\pm 40$ for a bimolecular process between reactants having univalent net charge. It is desirable that the reaction should be carried out at an ionic strength as low as possible, in order to elucidate the effect of dielectric constant on the rate.

The theory may also be applied to the influence of solvent on binding of substrates or inhibitors to the enzyme, although there are restrictions inherent to the Kirkwood's model.

## Summary

The theory of solvent effect developed in the preceding paper has been extended to include the enzyme reactions. The application to some typical model reactions which resemble the breakdown of enzyme-substrate complex has shown that the order of magnitude of experimentally observed effects can reasonably be accounted for by the theory.

Factors which may possibly influence rates of enzyme reactions by changing the composition of mixed solvents have also been discussed.

The author expresses his hearty thanks to Professor Sôzaburo Ono for his kind guidance

17) For example, if the slope d log $k_2$/d(1/$D$) of the order of $-200$ is interpreted by the equation for dipolar molecules[1,3,9]

$$\frac{\mathrm{d}\log k_2}{\mathrm{d}[(D-1)/(2D+1)]} = \frac{1}{2.303\,kTb_{ES}{}^3}(\mu_{ES^\ddagger}{}^2 - \mu_{ES}{}^2)$$

where $\mu$'s are the dipole moments, it is necessary that $\mu_{ES^\ddagger}{}^2$ be larger than $\mu_{ES}{}^2$ by ca. $2.4\times10^5$ Debye$^2$, for $b_{ES}$ = 21 Å at 25°C. Accepting this large increase in $\mu$, one might be forcibly led to the conclusion that a profound change in shape or charge distribution in the whole body of the enzyme molecule had been brought about during the activation process.

# *Amylose-Iodine Complex. II*[1]. *Effects of Inorganic Salts*

By Takashi KUGE and Sôzaburo ONO

(Received March 21, 1960)

The starch-iodine reaction in solution is markedly affected by some conditions (i. e. temperature, history of amylose solution and concentrations of reactants, etc.) under which the reaction takes place. However, the effect of salts on starch-iodine reaction has scarcely been investigated except in the case of studies[2] made at the beginning of this century at which time starch chemistry had not yet been established. The authors have found that certain salts strongly aid the formation of the amylose-iodine complex in a solution containing small amount of iodide ion. Referring these results to the helical theory[3], the authors intend to elucidate the structure of the amylose-iodine complex in solution.

## Experimental

**Materials.**—Amylose was obtained from potato starch by a selective precipitation method with *n*-butyl alcohol and isoamyl alcohol[4]. This amylose was recrystallized twice from boiling water in the presence of excess butanol. All other reagents were of the purest grade commercially available and used without further purification.

**Procedure.**—Hot water was poured on the recrystallized dry amylose of known amount and the suspension was heated on a water bath, being stirred for one hour in order to complete the dispersion of amylose. After being cooled, the solution was filtered with a glass filter and the filtrate was diluted to a desired volume with water. The above prepared solution, aqueous iodine solution, iodide solution and salt solution were used to make the final solutions which were composed of 0.005~0.015% amylose, $10^{-5}$~$2\times10^{-5}$ M iodine, $10^{-6}$~$10^{-5}$ M potassium iodide and $10^{-5}$~$10^{-1}$ M salt. In these compositions the amount of iodine was less than one third of that sufficient to saturate the amylose, and the ratio of iodide to iodine was unusually small, compared with that in a usual case. After being stood for more than one hour, the final colored solutions were used for spectrophotometric measurements.

A nearly saturated solution of iodine which was used to prepare the final solutions was made by shaking iodine crystals in water at room temperature. The concentrations of iodine and iodide ion in this solution were determined immediately before use by measuring their absorbances at wavelengths 288, 350 and 460 mμ[5], since iodide ion is formed by the hydrolysis of iodine.

The spectrophotometric measurements were carried out at room temperature by a Shimadzu type QB-50 spectrophotometer with 1.00 cm. thick silica cells.

## Results and Discussion

Iodide ion plays an important role in the amylose-iodine reaction but it remains uncertain whether or not amylose can form an iodide-free iodine complex in solution[6]. To solve this question, an aqueous iodine solution, in which iodic acid, perchloric acid or sulfuric acid was contained to repress any iodide ion due to the hydrolysis of iodine, was added to the amylose solution. Absorption at 350 mμ

due to triiodide ion was not observed in 0.2 M iodic acid solution and the blue coloration due to complex formation did not occur with the amylose solution. On the contrary, when the other acid solutions were used, the absorption due to a small amount of triiodide ion was always observed and the coloration took place. Therefore, the blue amylose-iodine complex seems to be formed only when iodide is in solution.

Gilbert and Marriot[7] have suggested that the constitution of the complex is ($3I_2 \cdot 2I^-$) or ($I_8^{2-}$) and this resonating ion is thought to be responsible for the blue color. However, as mentioned in the previous paper[1], the amount of iodide ions necessary for the coloration may be very small compared with that concluded by the above authors. Rundle and French[8] have demonstrated the formation of colored complex by absorption of iodine vapors by helical amylose in solid state[9]. It was, hence, inferred that a large amount of iodide ions is not necessary for the coloration. Recently, Holló and Szejtli[10] have agreed with our opinion concerning the constitution of the complex from amperometric studies. Although there are some evidences[7,11,12] indicating that iodide ions are adsorbed as well as iodine molecules by amylose in solution, it is still in doubt whether they all take part in the resonating polyiodine chains which are responsible for the blue color. The authors are inclined to think that the iodide ions indispensable for the resonating chain are only small fractions of adsorbed iodide ions. The triiodide ion adsorbed on the surface of amylose will be discussed in the following paper[13].

From Fig. 1 it is seen that the amylose-iodine complex has a spectrum having two absorption maxima, each of which is in the visible and ultraviolet region, respectively. The absorption is small in the low concentration of potassium iodide and it increases considerably with increasing iodide concentration until $5\times10^{-3}$ M iodide is reached, after which the blue shift of the spectrum takes place, accompanying the decrease of the visible absorption.

Fig. 2 shows the changes of the spectra with the increase of potassium chloride at constant iodide concentration ($10^{-5}$ M). It is seen that

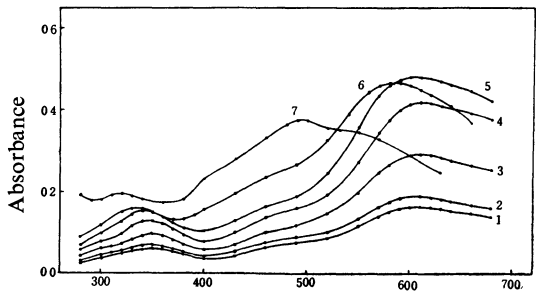

Fig. 1. The absorption spectra of amylose-iodine complexes formed under the various concentrations of potassium iodide: amylose 0.005%, total iodine $1.5\times10^{-5}$ M, potassium iodide (1) $1.3\times10^{-5}$ M, (2) $1.8\times10^{-5}$ M, (3) $6.3\times10^{-5}$ M, (4) $5\times10^{-4}$ M, (5) $5\times10^{-3}$ M, (6) $5\times10^{-2}$ M, (7) $5\times10^{-1}$ M.

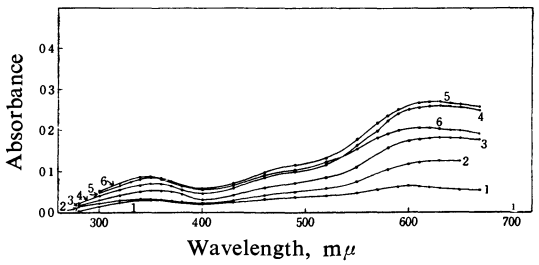

Fig. 2. The absorption spectra of amylose-iodine complexes formed under the various concentrations of potassium chloride: amylose 0.008%, total iodine $1.3\times10^{-5}$ M, potassium iodide $1\times10^{-5}$ M, potassium chloride (1) zero, (2) $5\times10^{-4}$ M, (3) $2.5\times10^{-3}$ M, (4) $1.3\times10^{-2}$ M, (5) $6\times10^{-2}$ M, (6) $1.2\times10^{-1}$ M.

the increase in the concentration of potassium chloride causes the shift of the wavelength of maximum absorption $\lambda_{max}$, to a longer wavelength in the visible region, accompanying the considerable increase of absorption.

Certain other salts[14] also aid the complex formation in a manner similar to that of potassium chloride. These results are collected in Fig. 3. Fig. 3 (a) shows the relationship between $\lambda_{max}$ and the salt concentration and (b) the dependence of absorbance at $\lambda_{max}$ on the salt concentration, in the visible region. The amylose-iodine complexes formed in the solution, which contains 0.005~0.015% amylose, $10^{-5}\sim2\times10^{-5}$ M iodine and $10^{-6}\sim10^{-5}$ M iodide but no any other salt, has $\lambda_{max}$ at 600 mμ, and its absorbance $E_{max}$, is very small. It is seen

that $E_{max}$ shows a maximum value at $5\times10^{-3}$ M iodide. The maximum value seems to be determined by the iodine concentration in the solution, while the maximum values caused by the additions of the other salts seem to be mainly determined by the iodide concentration. The addition of more iodide than $10^{-3}$ M causes the large shift of $\lambda_{max}$ to a shorter wavelength as described in the previous paper[1]. The blue shifts due to additions of an excess of the other salts are small and $\lambda_{max}$ are always more than 600 mμ. Only bromide is exceptionally similar to iodide in respect of the blue shift. This seems to be caused by the formation of the iodine-bromide ion[15] that would enter the polyiodine chain and shorten the resonating length as iodide ions do[1], but it may not be the case with other ions.

As described above, the complex formation seems to be influenced to a great extent by iodide and the other salts. Iodide, however, has a different role in the complex formation from the other salts; that is, iodide is essential for the reaction, while the other salts aid strongly the formation of the complex from amylose, iodine and iodide ion when the concentration of iodide is as low as $10^{-5}$ M. Since the decrease of $E_{max}$ observed with the addition of salts over 0.01 M seems to be partly owing to the precipitation of the complexes, this phenomenon will not be further discussed.

Fig. 4 shows another series of experiments carried out. It can be seen that the investigated salts are divided into three groups according to their valency. The higher the valency which the cation has, the lower becomes the concentration of the salt efficient for the completion of the amylose-iodine reaction. The arrows in Fig. 4 indicate the concentrations at which the precipitant of the complex becomes apparent to the naked eye. This concentration also changes in a regular fashion with the valency of cation. These facts may be connected with the Schulze-Hardy rule. Thus it seems quite natural to correlate the increase in absorbance of the complex by added salts with the increase of the aggregation of amylose through the neutralization of the charge on amylose. It is, hence, plausible that the aggregation of amylose caused by the addition of salts would play an important role in the formation of the stable amylose-iodine complex.

Since amylose has been known to have few ionized groups (about one phosphate group per three thousand glucose residues, calculated from the data obtained by Kerr et al.[16]), adsorbed iodide ions would mainly be the source of the charges that prevent the aggregation of amylose.

Although the nature of the amylose-iodine interaction remains controversial[17], Stein and Rundle[3] have presented a theory for the dipolar attraction between amylose and iodine in solid state on the basis of the helical model of amylose. It should be noted that, according to them, the dipolar field provided from the helical amylose in aqueous solution may be

15) A marked change of the absorption spectrum of aqueous iodine solution was observed by the addition of bromide or chloride, indicating the strong interaction between iodine and bromide or chloride ion. The other salts hardly altered the spectrum.

materially reduced by polarization of water, and no strong interaction between amylose and iodine may occur if the helical amylose is surrounded by water molecules with a higher macroscopic dielectric constant.

It is not unreasonable to thnik that since the complexes consisting of amylose, iodine and iodide ion are negatively charged, they can be kept separated without aggregation owing to their Coulombic repulsive force, if the concentration of cation is largely insufficient to repress the force. The complex thus formed may be supposed to be meta-stable since amylose-iodine interaction may not be strong for the reason described above, and may be called intermediate complex. The intermediate complex may not have well-shaped helical structure because of the charges due to adsorbed iodide ion.

By addition of salts these intermediate complexes may tend to gather to aggregates through which water may be excluded from the interstices among them. Moreover, if the aggregates contain helical amylose molecules in close packing, it may be expected that the dipolar field in a given helix would be enhanced by surrounding amylose chains. Then the amylose-iodine complexes formed in aqueous solution would be stabilized by the formation of the aggregates in which the helical complexes would probably be refined on shape and oriented parallel to one another.

Foster and Paschall[18] found that the disaggregation of amylose aggregates results in a decrease in iodine binding capacity and a decrease in the wavelength of maximum absorption of the complex. They also suggested the significance of crystalline order in the complex formation. This seems to support the authors' opinion concerning the nature of the complex as above described. Mayer and Bernfeld[19] considered that the adsorption of iodine occurs on colloidal micells of amylose molecules. Although their conclusion may not be accepted without modification from the helical theory generally accepted at present, their experimental results also indicate that the state of the aggregate of amylose may be closely related to the formation of the blue complex.

In conclusion, it may be said that the blue complex can hardly be formed in solution where ionic strength is so low that the aggregation of the complex takes place with difficulty. The stable state of the blue amylose-iodine complexes formed in solution may be parallel-oriented aggregates composed of helical complexes.

## Summary

The relations between the light absorptions of the amylose-iodine complex and the concentrations of various added salts have been investigated. The iodide ion appears to be indispensable for the formation of the blue complex. The complex formation can be greatly aided by certain salts when the concentration of iodide is low. This salt effect suggests that the parallel-oriented aggregation of amylose-iodine helical complex is essential for the formation of the stable blue complex.

# *Amylose-Iodine Complex. III. Potentiometric and Spectrophotometric Studies*

By Takashi KUGE and Sôzaburo ONO

(Received March 21, 1960)

Potentiometric titrations and spectrophotometric measurements have been used as methods of studying the starch-iodine reaction by many authors. Most of these investigations, however, were carried out at room temperature. When the temperature of amylose solution is raised, it may be expected that the amylose molecule enormously increases its flexibility and takes a more random configuration[1]. In parallel with this, it becomes difficult to form amylose-iodine complex with increasing temperature. Hence, it seems interesting to investigate the temperature dependence of the amylose-iodine reaction.

In the present paper, the authors describe the enthalpy change of the amylose-iodine reaction obtained by the potentiometric and/or the spectrophotometric method at wider temperature range than previously reported, and some information concerning the nature of the complex which is deduced from the results obtained.

## Experimental

**Potentiometric Titrations with Iodine.**—The amyloses used for potentiometric titrations were those obtained from potato (white potato), corn and sweet potato starch by hot water extraction[2] at 60°, 69° and 72°C, respectively.

The technique of potentiometric titration was essentially similar to that described by Bates et al.[3]: In our procedure about 0.015 g. of amylose was dispersed in 10 ml. of 0.5 M potassium hydroxide. When dispersal was complete, the mixture was made neutral to methyl orange by the addition of hydrochloric acid, added 10 ml. of 0.5 M potassium iodide, and then filled up to 100 ml. The solution thus prepared was titrated with 0.0005 M iodine in 0.05 M potassium iodide solution. A control solution which contains the same components as that described above but no amylose, was also titrated in the same way.

Titration was carried out in a cell immersed in a thermostat.

For the potential measurements, a Yokogawa high precision potentiometer was used in conjunction with a normal calomel electrode and a bright platinum electrode.

**Spectrophotometric Measurements.**—The amylose used was obtained from potato starch by a selective precipitation method with *n*-butyl alcohol and isoamyl alcohol[4].

Spectrophotometric titration was carried out as follows: 100 mg. of amylose was dispersed in 100 ml. of 0.5 M potassium hydroxide and diluted to 500 ml. with distilled water after neutralization with hydrochloric acid. Each 25 ml. of the solution was diluted to 100 ml., a requisite amount of 0.1 M potassium iodide being added to make the final solution 0.01 M in iodide after the addition of 1 to 22 ml. of a solution of 0.0005 M iodine in 0.001 M potassium iodide. Although the absorptions of the sample in which 6.5 ml. or less of 0.0005 M iodine solution was contained, were directly measured, those of the sample in which 8.0 ml. or more of the iodine solution was contained, were measured after twofold dilution with water. The absorptions were measured at 15°C at wavelengths of 288, 350 and 640 m$\mu$, respectively.

The change of the absorption with temperature change was measured in the following way: The solution (0.005% amylose, $2.5\times10^{-5}$ M iodine), in which the amount of iodine was nearly half of the amount to saturated amylose, was prepared in the same way as that for the spectrophotometric titrations. This solution was placed in a 250 ml. colored volumetric flask and kept in a thermostat at each given temperature for 20 min. and then aliquots of the solution were used to measure the absorption at wavelengths of 288, 350 and 640 m$\mu$, respectively.

A Shimadzu type QB-50 spectrophotometer with thermo-regulating device was used with 1 cm. thick silica cell throughout this investigation.

## Results and Discussion

**Potentiometric Titrations.**—Titration curves of potato amylose and control solution (0.05 M in potassium iodide) at various temperatures are shown in Fig. 1. It can be seen that the potential of these systems becomes high with increasing temperature. At a given temperature the potential is determined by the concentration of free iodine which is in equilibrium with amylose-iodine complex, since the concentration of iodide ion is kept practically constant.

Referring to the results of Dube[5] and Gilbert et al.[6], it may be considered that the ratio of

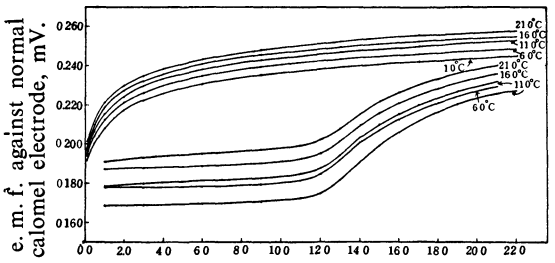

Fig. 1. Potentiometric titration curves: 100 ml. of 0.012% potato amylose solution (the lower five curves), 100 ml. of 0.05 M potassium iodide (the upper five curves).

adsorbed iodide ions to adsorbed iodine molecules on amylose is unity in the present experimental conditions (0.05 M in potassium iodide). Therefore, the amylose-iodine reaction can be expressed as

$$\mathrm{Am} + n\mathrm{I}_2 + n\mathrm{I}^- \rightleftarrows \mathrm{Com} \qquad (1)$$

where Am and Com represent amylose and amylose-iodine complex, respectively.

The equilibrium constant $K$, which is constant for the amylose of a given chain length, is then

$$K = [\mathrm{Com}] / [\mathrm{Am}]\,[\mathrm{I}_2]^n\,[\mathrm{I}^-]^n$$

hence

$$K^{1/n} = [\mathrm{Com}]^{1/n} / [\mathrm{Am}]^{1/n}\,[\mathrm{I}_2]\,[\mathrm{I}^-] \qquad (2)$$

In the amylose-iodine reaction, the activities of the complex and amylose can be regarded as unity, in the manner of a heterogeneous reaction. Eq. 2, therefore, may be written as

$$K^{1/n} = 1/[\mathrm{I}_2]\,[\mathrm{I}^-] \qquad (3)$$

Since the potential of the horizontal part of the titration curve is lower than the lowest potential obtained with the control solution in a given temperature, as can be seen in Fig. 1, direct calculation of free iodine from the potential, which was made by Bates et al.[3], is impossible in the present case. Accordingly, the calculation of $K^{1/n}$ was carried out as follows. The potential difference, $E_d$, between the potential of the sample at the mid-point of the titration (i. e. characteristic potential[7]) and that of the control solution at the corresponding titration point, can be written as

$$E_d = (\boldsymbol{RT}/2\boldsymbol{F}) \ln ([\mathrm{I}_2]_c / [\mathrm{I}_2]_s) \qquad (4)$$

where $[\mathrm{I}_2]_c$ is the concentration of free iodine in the control solution and $[\mathrm{I}_2]_s$ corresponds to that of the sample, and $\boldsymbol{R}$ and $T$ are gas constant and absolute temperature, respectively, and $\boldsymbol{F}$ is Faraday constant. From Eqs. 3 and 4

$$E_d = (\boldsymbol{RT}/2\boldsymbol{F}) \ln [\mathrm{I}_2]_c\,[\mathrm{I}^-]_s\,K^{1/n} \qquad (5)$$

or

$$E_d = (\boldsymbol{RT}/2\boldsymbol{F}) \ln ([\mathrm{I}_3^-]_c\,K^{1/n}/K_1) \qquad (6)$$

where $[\mathrm{I}^-]_s$ is the concentration of iodide ion in the sample, $[\mathrm{I}_3^-]_c$ is the concentration of triiodide ion in the control solution and $K_1$ is the equiliblium constant of the following reaction

$$\mathrm{I}_2 + \mathrm{I}^- = \mathrm{I}_3^-$$

Therefore, $K^{1/n}$ can be calculated from $E_d$, $[\mathrm{I}_3^-]_c$ and $K_1$ which is given in literature[8], using Eq. 6.

In Table I are listed observed $K^{1/n}$, the enthalpy change of the reaction obtained from the temperature dependence of $K^{1/n}$, characteristic potentials, intrinsic viscosities of amylose in 1 M potassium hydroxide by Ostwald viscometer[9] and the temperature of water extraction of amylose. As the temperature of the water extraction is raised, the mean length of the extracted amylose chain may be expected to become longer. This is inferred from their characteristic potentials[7] and intrinsic viscosities, though the contamination of amylopectin may increase. The enthalpy changes of the reaction with amyloses from different sources agree within experimental error in spite of the difference of the size of molecule among these amyloses. Similar values have also been obtained with amyloses partially degraded by bacterial $\alpha$-amylase.

Since the results obtained at temperatures higher than those described above are confused owing to the vaporization of iodine during the procedure, the analysis of the results is not made as those obtained at a lower temperature. However, it seems worth while to mention that the end-point of titration shifted to higher concentration of iodine and became obscure with increasing temperature, from which the occurrence of a complex having a short polyiodine-chain (also suggested in the following spectrophotometric studies) at a higher temperature might be supposed.

**Spectrophotometric Studies.**—Fig. 2 shows the results obtained from spectrophotometric titrations at 15°C. At the beginning of the titration, the curve for 640 m$\mu$ has a small lag and thereafter increases linearly with the amount of iodine added until the vicinity of end-point.

TABLE I. SOME CONSTANTS OBTAINED WITH AMYLOSES FROM DIFFERENT SOURCES

| Amylose | Temp. of water extraction | Equilibrium constant $K^{1/n}$ at 16°C | Enthalpy change kcal./mol. iodine | Charact. potential v.s. N. C. E. at 16°C | Intrinsic viscosity |
|---|---|---|---|---|---|
| Potato | 60°C | $2.2\times10^{9}$ | −15.5 | 0.1890 | 0.80 |
| Corn | 69°C | $2.4\times10^{9}$ | −15.8 | 0.1878 | 1.20 |
| Sweet potato | 72°C | $3.0\times10^{9}$ | −15.3 | 0.1856 | 2.15 |

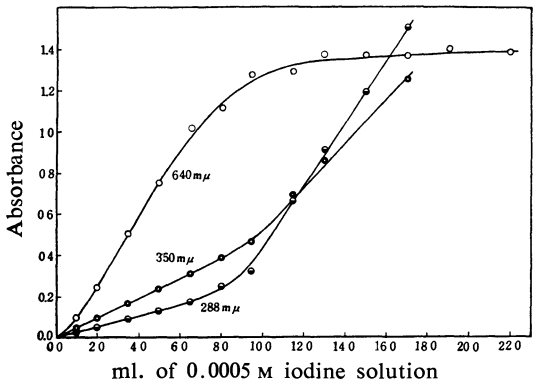

Fig. 2. Spectrophotometric titration curves: 100 ml. of 0.005% potato amylose solution.

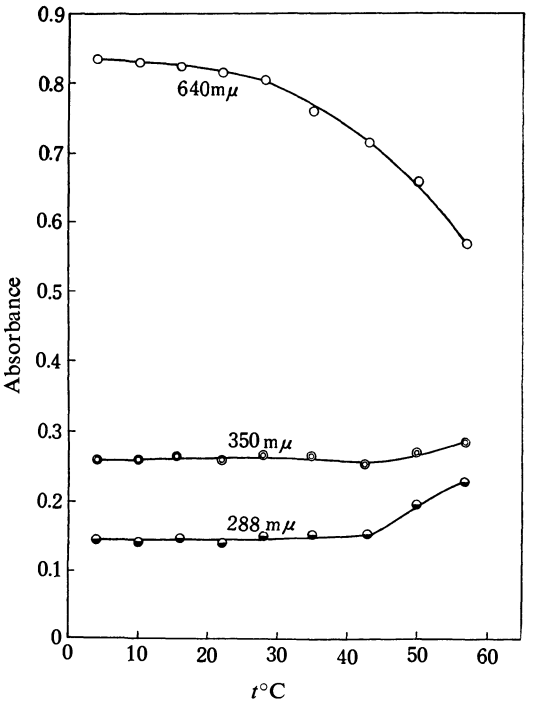

Fig. 3. Temperature dependences of absorptions at wavelengths of 640, 350 and 288 mμ.

The absorptions of ultraviolet region (at 288, 350 mμ) appear to have no such lag and their sharp increases due to free triiodide ion are seen after the end-point. Using the slopes of the initial linear parts of the titration curves, the molecular extinction coefficients of iodine in the complex were estimated to be 36300, 10500 and 5230 at wavelengths of 640, 350 and 288 mμ, respectively. The latter two values are in good agreement with that calculated from Mould's report[10] by the present authors.

The temperature dependences of absorptions are shown in Fig. 3, in which it can be seen that the absorption at 640 mμ decreases in a regular fashion with increasing temperature, while the absorption of the ultraviolet region (at 288 and 350 mμ) remains almost unchanged and has rather a tendency to increase at temperature higher than 40°C.

Free triiodide ion in an aqueous solution exhibits two ultraviolet absorption bands whose maxima are at 288 and 353 mμ[11], respectively. Since the concentration of free iodine molecules which are in equilibrium with the complexes may increase with increasing temperature and consequently the concentration of free triiodide ions may increase, the above described temperature dependence of absorption in the ultraviolet region may be principally ascribed to the increase of the free triiodide ions.

The absorption at 640 mμ may be considered to be due to the complex alone, since free iodine concentration is low enough that its contribution to the absorption can be neglected. Assuming that the absorption of the ultraviolet region is determined by the concentrations of the complex and free triiodide ion, as a first approximation, the following equations can be derived.

$$E_{640}=C_c\varepsilon_{c640} \tag{7}$$

$$E_{288}=C_c\varepsilon_{c288}+C_i\varepsilon_{i288} \tag{8}$$

$$E_{350}=C_c\varepsilon_{c350}+C_i\varepsilon_{i350} \tag{8'}$$

where $E$ represents the absorbance observed, $C_c$ and $C_i$ are the concentrations of the complex and free triiodide ion, respectively, $\varepsilon_c$ and $\varepsilon_i$ are the molecular extinction coefficients of the complex and free triiodide ion, respectively, and the numerical suffixes represent their corresponding wavelengths in mμ. The concentrations of the complex, for the sake of convenience, are expressed as moles of iodine bound.

a) This value was obtained by potentiometric titration.

Assuming that these molecular extinction coefficients are independent of temperature, the concentration of the free triiodide ion at each temperature may be found, using Eqs. 7 and 8 or 8′ [12]. The values obtained are shown in Table II, in which $C_{1288}$ and $C_{1350}$ are the concentrations of free triiodide ion estimated by using the absorbance observed at wavelengths of 288 and 350 mμ, respectively. It can be seen that $C_{1288}$ and $C_{1350}$ do not agree with each other and that the former is smaller than the latter at any temperatures. This seems to suggest that Eq. 8 or 8′ would not be an adequate expression for the observed absorbance. A more favorable equation than Eq. 8 or 8′ is seemed to be written as

$$E=C_c\varepsilon_c+C_i\varepsilon_i+C_u\varepsilon_u+C_a\varepsilon_a \qquad (9)$$

where $C_u$ represents the concentration of the polyiodine of short length and is also expressed as moles of single iodine molecule, $\varepsilon_u$ is the molecular extinction coefficient of iodine in the polyiodine, $C_a$ and $\varepsilon_a$ represent the concentration and molecular extinction coefficient of the triiodide ion loosely adsorbed on the surface of amylose, respectively. It would appear that little attention has been given to the ultraviolet absorption of the amylose-iodine complex and an investigation of the ultraviolet absorption has been inconclusive[10,13]. However, the fact that the titration curve at 640 mμ has a small lag may reasonably suggest the existence of polyiodine of short length which exhibits no appreciable absorption at 640 mμ but ultraviolet absorption similar to that of the complex. It may be assumed that the absorption spectrum of the triiodide ion is unchanged whether in the adsorbed state described above or in an aqueous solution.

The use of Eq. 8 or 8′ instead of Eq. 9 would cause an error $\Delta C_i$ being always positive, in the estimation of the concentration of the free triiodide ion. The error can be expressed as follows.

$$\Delta C_i=C_u\varepsilon_u/\varepsilon_i+C_a\varepsilon_a/\varepsilon_i \qquad (10)$$

Since, $\varepsilon_u$ may be roughly assumed to be not appreciably different from $\varepsilon_c$ and $\varepsilon_a$ may be considered as equal to $\varepsilon_i$, the ratio of $\varepsilon_u$ to $\varepsilon_i$ depends on wavelength while that of $\varepsilon_a$ to $\varepsilon_i$ seems to be unity, independent of wavelength. The smaller the ratio of $\varepsilon_u$ to $\varepsilon_i$, the smaller the error becomes. Therefore, $C_{1288}$ should be smaller than $C_{1350}$, and the experimental results given in Table II satisfy this requirement.

The true concentration of free triiodide ion, $C_{it}$, would be written as

$$C_{it}=C_{1288}-C_u\varepsilon_{u288}/\varepsilon_{i288}-C_a\varepsilon_{a288}/\varepsilon_{i288} \qquad (11)$$

or

$$C_{it}=C_{1350}-C_u\varepsilon_{u350}/\varepsilon_{i350}-C_a\varepsilon_{a350}/\varepsilon_{i350} \qquad (11')$$

Therefore, $C_u$ can be obtained by subtraction of Eq. 11 from Eq. 11′. $C_u$ obtained thus is shown in Table II, and the increase of $C_u$ with increasing temperature is seen. $C_{1c}$ listed in Table II is the corrected concentration of free triiodide ion in respect to $C_u$. It should be noted that $C_{1c}$ is not free from the error due to $C_a$. $C_{1c}$ was used to calculate $K^{1/n}$, and the

12) $\varepsilon_{1288}$ and $\varepsilon_{1350}$ used in the calculation were 40000 and 26000, respectively, which were obtained from our experiments and have no essential difference from the values in reference 11.

13) Y. Tanizaki, T. Kobayashi and N. Andô, *J. Chem. Soc. Japan, Pure Chem. Sec.* (*Nippon Kagaku Zasshi*), **80**, 445 (1959).

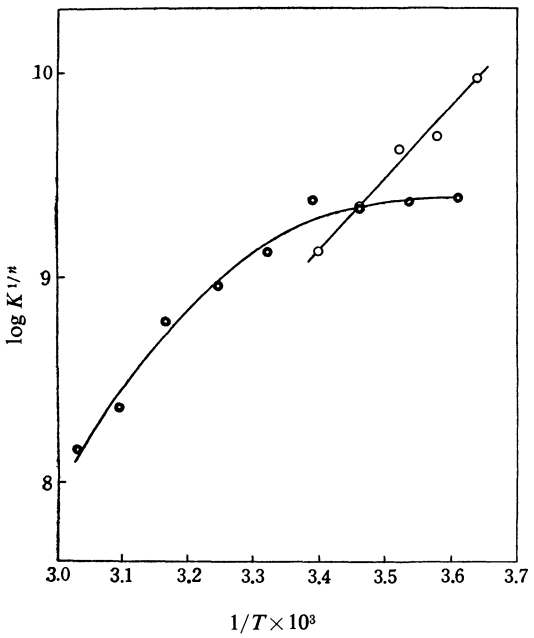

Fig. 4. $\log K^{1/n} \sim 1/T$ plot for potato amylose: —◎—◎—, $\log K_s^{1/n}$, obtained from spectrophotometric method; —○—○—, $\log K^{1/n}$, obtained from potentiometric titration.

value obtained is given in Table II expressed as $K_s^{1/n}$. In Fig. 4, $\log K_s^{1/n}$ is plotted against reciprocal absolute temperature, and it can be seen that the slope of the curve becomes steeper with increasing temperature. Comparing $K_s^{1/n}$ with $K^{1/n}$ obtained by the potentiometric titrations, it can be found that they have similar values at about 16°C, but the slopes as above described, from which the enthalpy change of the reaction would be calculated, are quite different from each other in the neighborhood of the temperature. Such difference may be reasonably explained in terms of the error in the spectrophotometric estimation of free triiodide ion concentration at low temperature region. Considering the data obtained by the potentiometric titrations, it can be seen that free iodine concentration in equilibrium with the complex should decrease with decreasing temperature. However, $C_{ic}$ rather increases with decreasing temperature in the temperature region lower than 22°C. This fact suggests that the amount of the triiodide ion adsorbed on the surface of amylose may be comparable with that of free triiodide ion in the temperature region below 22°C, and a serious error is caused in the estimation of free triiodide ion concentration. It may also be supposed that the lower the temperature, the more the contribution of $C_a$ to $C_{ic}$ becomes. Therefore, it can be inferred that $\log K_s^{1/n} \sim 1/T$ plot should be steeper than that seen in Fig. 4, especially in the lower temperature region. Consequently, the equilibrium constant obtained spectrophotometrically should be larger than that obtained potentiometrically. This result may not be unreasonable, since $K^{1/n}$ is considered as a function of chain length of amylose, being larger with increasing chain length of amylose[9,14], and amylose used in the spectrophotometric study is thought to be longer than that used in potentiometric titration. The selective precipitation method of amylose seems to give amylose with longer chain length than that obtained by the hot water extraction.

For the reason described above, the spectrophotometric method may not be applicable for the estimation of free iodine concentration at room temperature, at which potentiometric titrations are adequate. However, with increasing temperature, when the concentration of free iodine in equilibrium with the amylose-iodine complex increases, the concentration of the free iodine appears to be reasonably estimated by the spectrophotometric method, since, at the higher temperature, $C_a$ can be neglected without a serious error, compared with the free iodine concentration. Even when the vaporization of iodine takes place, free iodine concentration may remain approximately constant as far as amylose-iodine complex exists in solution. Therefore, the present results obtained at a relatively high temperature region may be available for the discussion of the temperature dependence of the amylose-iodine reaction.

From the inspection of the slope of $\log K_s^{1/n} \sim 1/T$ plot in Fig. 4, the enthalpy change of the reaction appears to increase with increasing temperature. The enthalpy change obtained at 50°C is −20.8 kcal. Comparing this value with that obtained potentiometrically at 16°C, −15.5 kcal., it seems certain that the enthalpy change increases as the temperature is raised. This may also be checked with the fact that all the enthalpy changes of the reaction hitherto obtained at different temperatures below 35°C by other authors[5,6,15,16] are −11 to −19 kcal.

At the temperature at which the color of the complex disappears, the free energy change of the reaction should be nearly zero so that the entropy change should have a large value almost corresponding to the enthalpy change at the temperature. This seems to indicate that the amylose, which is free from iodine, would come to take more random configurations

14) Also seen in Table I.

with increasing temperature through the rupture of both inter- and intramolecular hydrogen bonding. This thought is also supported by the results obtained from the studies in viscosity and optical rotatory power[1].

## Summary

The amylose-iodine reaction has been studied in a wider temperature range than hitherto reported by both potentiometric and spectrophotometric methods.

The enthalpy change of the reaction obtained potentiometrically is $-15.5$ kcal. at 16°C, and appears to be independent of the chain length and the kind of parent starch of amylose.

The change of the absorptions of the amylose-iodine complex with temperature has been pursued at wavelengths of 650, 288 and 350 m$\mu$, respectively.

The triiodide ion adsorbed on the surface of amylose causes an error in the spectrophotometric estimation of free iodine concentration. At the higher temperature, however, this error may be neglected, and the results obtained seem to be reliable.

The enthalpy change appears to increase with increasing temperature and $-20.8$ kcal. has been obtained at 50°C.

# *Spectrochemical Study of Microscopic Crystals. XXII.*[1] *The Structure of Cupric Mono-, Di- and Trichloroacetate*[2]

By Shoichiro YAMADA, Hiroaki NISHIKAWA and Ryutaro TSUCHIDA

(Received April 27, 1960)

Previously the present authors[3,4] studied the structure of cupric *n*- and *iso*-alkanoates, anhydrous and hydrated, and showed mostly on the basis of the polarized absorption spectra that these carboxylates, in the crystalline state and in non-coordinating organic solvents, consist of binuclear molecules which are similar to that of cupric acetate and have a sort of copper-to-copper linkage within the molecules. In continuation of the former study, the structure of cupric mono-, di- and trichloroacetate has now been examined, and the effect of replacement by chlorine atoms discussed in relation to the dimer formation of the cupric carboxylates. A brief account of a part of this study was formerly presented as a short communication[5], the details of which are given below.

## Experimental

**Materials.** — All the cupric chloroacetates were prepared according to the method of Bateman et al.[6,7] from cupric carbonate and the corresponding chloroacetic acid or from sodium carboxylate and cupric sulfate. All the compounds were identified by elemental analysis. Crystals of the anhydrous forms of the compounds were obtained by recrystallization using non-aqueous solvents after dehydrating the hydrated crystals. The absence of the water of crystallization was confirmed by infrared spectra and elemental analysis.

Anhydrous and hydrated cupric monochloroacetate were obtained in green crystals. The hydrated monochloroacetate corresponds to the formula, $Cu(ClCH_2COO)_2 \cdot 2.5H_2O$. Calcd.: Cu, 21.5; Cl, 30.6; C, 20.7; H, 2.61. Found: Cu, 21.5; Cl, 30.4; C, 20.4; H, 2.55%. A blue form has also been prepared besides the green form. Thus the blue crystals of the anhydrous monocloroacetate were obtained, when ethanol was added to an aqueous solution of the monochloroacetate.

Anhydrous cupric dichloroacetate was prepared in green crystals. Hydrated crystals, which are colored blue, were also obtained together with the anhydrous crystals, when recrystatallization was made from water. The result with the hydrated crystal is reported elsewhere.

Cupric trichloroacetate was obtained in blue crystals after recrystallization from water. The

elemental analysis by the present authors indicates that the blue crystals correspond to the formula, $Cu(Cl_3C\cdot COO)_2\cdot 3H_2O$, in agreement with the analysis by Bateman et al.[6]

**Measurements.**—Quantitative dichroism measurements in the visible and ultraviolet regions were carried out at room temperature by Tsuchida and Kobayashi's microscopic method[8].

Absorption spectra of the compounds in solution were determined by a Beckman DU spectrophotometer. It was confirmed in all the measurements that Beer's law was obeyed in the presence of the free carboxylic acid.

The notations in the present paper are the same as close used in the former papers of this series. Extinction coefficients, $\varepsilon$, are calculated on the basis of a formula-weight instead of a molecular weight.

## Results and Discussion

**Structure of Cupric Chloroacetates in the Crystalline State.** — Previously the present authors[3-5] reported about the structure of cupric formate, acetate and higher carboxylates on the basis of their polarized absorption spectra. A similar treatment will be made in the present article concerning the structure of cupric chloroacetates. Since some of the results and the discussions in the former papers are used in the present work, it would be appropriate to give a brief account of the conclusions obtained formerly.

Cupric salts of acetic acid and higher fatty acids in the crystalline state and in non-coordinating organic solvents show in the visible and the near-ultraviolet region a band at about $80\times10^{13}\,sec^{-1}$(band II) besides a band at about $43\times10^{13}\,sec^{-1}$(band I), whereas most cupric compounds of an ordinary type show in this wavelength region only one band which may be considered as corresponding to the band at about $43\times10^{13}\,sec^{-1}$ of cupric alkanoates. With the cupric carboxylates consisting of binuclear molecules, the following features characteristic of these compounds were observed in the dichroism. "For the band I, the electric vector is more strongly absorbed along the complex plane than along the *Z*-direction of the binuclear molecule, the *Z*-direction being the direction connecting the two copper ions in the binuclear molecule. For the band II, the electric vector is more strongly absorbed along the *Z*-direction. The polarization for the band II is thus seen to be the reverse of the polarization for the band I". These facts are considered to show that the compounds involve along the *Z*-direction a sort of copper-to-copper linkage characteristic of the binuclear molecules of the cupric alkanoates. On the contrary, cupric formate tetrahydrate[3,4], which is known from examination with X-rays[9] to have no copper-to-copper linkage[10], shows no absorption band at about $80\times10^{13}\,sec^{-1}$. Thus the appearance of the band at about $80\times10^{13}\,sec^{-1}$, combined with the polarization property of the band, may be regarded as showing the existence of the binuclear molecule similar to that of cupric acetate hydrate involving the copper-to-copper linkage.

The results of the present dichroism measurements are shown in Figs. 1 to 4. The components of the cupric compounds in the crystalline state may be under rather weak perturbation owing to the crystalline field, but the polarized absorption spectra as determined on a suitable plane are regarded as representing the main features of the dichroism of the component molecule. The exact arrangement of the molecules in the crystals is unknown for all the cupric compounds reported in the present work. It is easy, however, to find the principal characteristics of the dichroism of the molecules themselves by comparing their polarized absorption spectra with those of cupric acetate monohydrate, whose crystal structure was accurately determined, and also with those of cupric alkanoates, which were extensively studied on the basis of the comparison with cupric acetate.

The present measurement, as seen in Fig. 1, indicates that the green anhydrous cupric monochloroacetate in the crystalline state shows an absorption band at about $80\times10^{13}\,sec^{-1}$, in

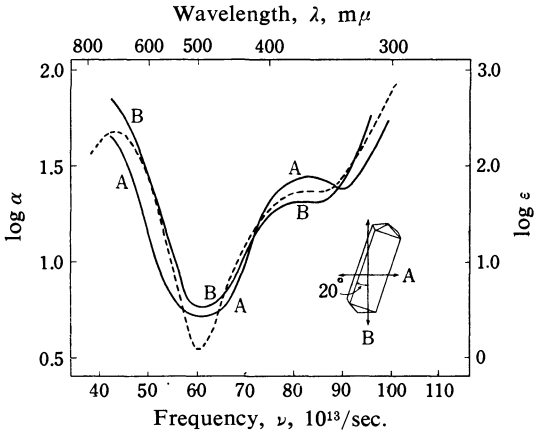

Fig. 1. Absorption spectra of anhydrous $Cu(Cl\cdot CH_2COO)_2$ in the crystalline state (——) and in dioxane (----).

9) R. Kiriyama, H. Ibamoto and K. Matsuo, *Acta Cryst.*, 7, 482 (1954).

10) Cupric formate in dioxan exists mostly as binuclear molecules of the acetate-type, and crystals of the formate consisting of the binuclear molecules were isolated. Cf. R. L. Martin and H. Waterman, *J. Chem. Soc.*, 1959, 1359.

addition to a band at about $40\times10^{13}\,sec^{-1}$. Moreover, it is recognizable that the polarization for the former band is found to be the reverse of the polarization for the latter. This relationship, which closely resembles that encountered in the case of the acetate monohydrate and higher alkanoates[3,4], may suggest that the green anhydrous cupric monochloroacetate in the crystaline state consists of the binuclear molecules of the acetate-type, since the dichroism of the anhydrous monochloroacetate may be readily understandable when it is assumed that A- and B-absorption in Fig. 1 represent the main characteristics of the *Z*- and *X*, *Y*-absorption of the binuclear molecule, respectively.

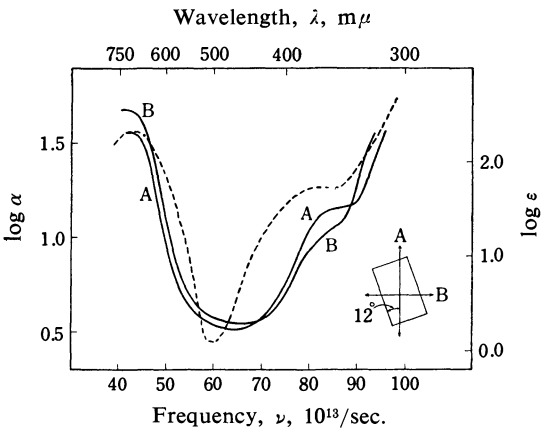

Fig. 2. Absorption spectra of $Cu(Cl\cdot CH_2COO)_2\cdot 2.5H_2O$ in the crystalline state (——) and in dioxane (----).

The present measurement also indicates that cupric monochloroacetate hydrate in the crystalline state shows dichroism with characteristics similar to those of cupric acetate, as is readily seen in Fig. 2. Thus the monochloroacetate hydrate shows an absorption band at about $80\times10^{13}\,sec^{-1}$ in addition to a band at about $40\times10^{13}\,sec^{-1}$. The main characteristics of the dichroism with the component molecule may be recognized, although the dichroism is not very remarkable. It is, therefore, concluded that cupric monochloroacetate hydrate consists of the binuclear molecule of the acetate-type. As comparison of the dichroism of the green anhydrous monochloroacetate with the dichroism of the green monochloroacetate hydrate shows, the presence of the water molecules of crystallization is expected to have a more or less remarkable effect upon the copper-to-copper linkage, but no marked difference was observed in the absorption maxima in the visible and the near-ultraviolet regions between the anhydrous and the hydrated form.

The blue form of anhydrous cupric monochloroacetate is also obtained when ethanol is added to an aqueous solution of the monochloroacetate. The blue crystal is found in the present work to show an absorption band in the near-infrared region, but no absorption band at about $80\times10^{13}\,sec^{-1}$. It is, therefore, concluded that the blue form of the monochloroacetate contains no binuclear molecule.

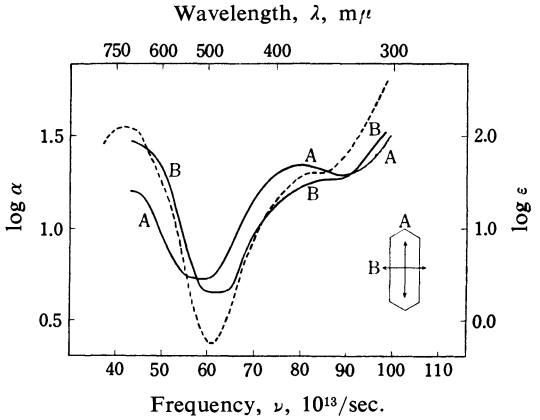

Fig. 3. Absorption spectra of anhydrous $Cu(Cl_2\cdot CHCOO)_2$ in the crystalline state (——) and in dioxane (----).

The present measurement, as seen in Fig. 3, indicates that the green crystal of anhydrous cupric dichloroacetate shows a band at about $80\times10^{13}\,sec^{-1}$ besides a band at about $40\times10^{-13}\,sec^{-1}$, the polarization of the former band being the reverse of the polarization of the latter. This relationship, which is similar to the relationship with cupric acetate hydrate, indicates that anhydorus cupric dichloroacetate in the crystalline state consists of binuclear molecules.

Cupric dichloroacetate is known to exist in a tetrahydrate as well. The dichroism of this form, which is colored blue, is not identical with that of the anhydrous form. The structure of the tetrahydrate will be discussed separately in a later communication.

Cupric trichloroacetate is obtained in the tetrahydrate, when recrystallized from water, ethanol-water, or dioxane-water. The trichloroacetate tetrahydrate shows the dichroism which is quite different from the dichroism of the green form of the mono- or the dichloroacetate. Thus the trichloroacetate tetrahydrate shows only one absorption band at about $40\times10^{13}\,sec^{-1}$, but no absorption band in the neighborhood of the wavelength region around $80\times10^{13}\,sec^{-1}$, as seen in Fig. 4. The absorption spectrum of the trichloroacetate, which is similar to the absorption spectra of ordinary cupric complexes such as cupric sulfate, indicates clearly that cupric trichloroacetate

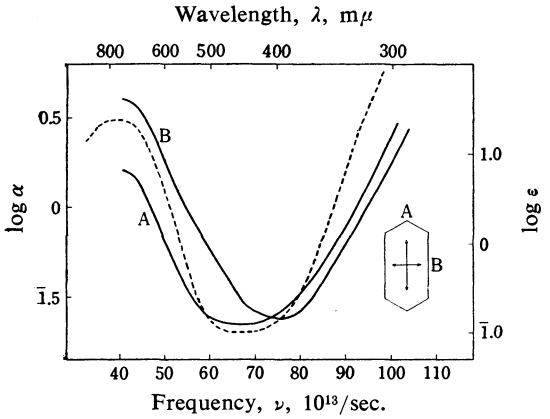

Fig. 4. Absorption spectra of $Cu(Cl_3C\cdot COO)_2\cdot 4H_2O$ in the crystalline state (——) and in dioxane (----).

tetrahydrate contains no binuclear molecule of the acetate-type in the crystalline state.

Anhydrous cupric trichloroacetate, which is obtained in green crystals when recrystallized from ethyl ether after dehydration of the tetrahydrate, may probably consist of the binuclear molecule of the acetate-type, but the dichroism measurement with the crystal has not been performed in the present work. As discussed in a later paragraph of the present article, the ultraviolet spectrum shows that the anhydrous trichloroacetate exists as the binuclear molecules in ethyl ether.

Magnetic susceptibility at room temperature was reported with cupric mono-, di- and trichloroacetates in the solid state[11]. The results seem to be compatible with the conclusions from the present study about the structure of these compounds.

**Structure of Cupric Chloroacetates in Solution.**—The binuclear cupric carboxylates in water are found to undergo dissociation most readily. Even cupric acetate exists in this solvent mostly as the monomer in equilibrium with the binuclear form in a smaller proportion, although the degree of dissociation depends upon the concentration of the solution. All the cupric monocarboxylates so far examined have been found to exist in water as their monomers to a considerable extent if they are soluble in water at all. This may evidently be due to the great tendency of water molecules to be co-ordinated with the cupric ion. On the contrary, dissociation into the monomeric complex-ion has been found to be quite small in non-co-ordinating organic solvents, such as ethanol, dioxane, ethyl ether and chloroform. Needless to say, cupric carboxylates in co-ordinating solvents such as pyridine undergo decomposition to form cupric complexes with the solvent molecules. In the present work, comparison of the absorption spectra is made with the cupric carboxylates in these solvents in almost the same concentration.

It was found in the former investigations that the cupric monocarboxylates having the binuclear molecules of the acetate-type show in non-co-ordinating organic solvents the characteristic absorption spectra with the following features[4].

(1) A band at about $40\times10^{13}\,sec^{-1}$ of the binuclear cupric carboxylate is much stronger than the corresponding band of the mononuclear cupric compounds. (2) Besides the absorption at about $40\times10^{13}\,sec^{-1}$ of the binuclear, cupric carboxylate shows another band at about $80\times10^{13}\,sec^{-1}$, which is about four times less in intensity than the band in the longer wave-length region of the same compound. As reported in the former papers[3,4], these features may be used as criteria in telling whether a cupric carboxylate exists mostly as binuclear molecules of the acetate-type or not.

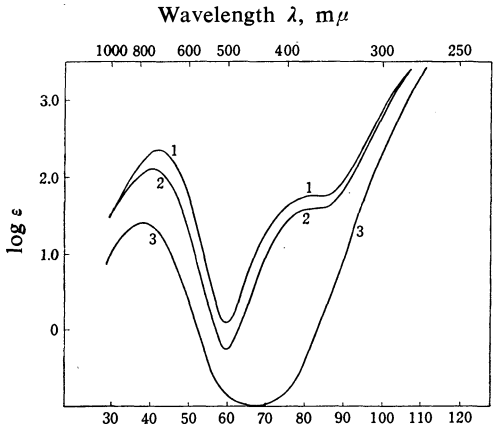

Fig. 5. Absorption spectra of $Cu(Cl_nH_{3-n}C\cdot COO)_2$ in dioxane: 1, $n=1$; 2, $n=2$; 3, $n=3$.

Absorption spectra of cupric chloroacetates in dioxane are shown in Fig. 5. The absorption spectra characteristic of the cupric carboxylates having binuclear structure of the acetate-type are observed with the mono- and the dichloroacetate. Thus the two chloroacetates in dioxan show an absorption band at about $80\times10^{13}\,sec^{-1}$, in addition to a band at about $40\times10^{13}\,sec^{-1}$ which has an extinction coefficient about nine times higher than the corresponding band of an ordinary type of cupric complex such as an aquated ion of copper. This fact indicates, on the basis of the criteria formerly obtained, that the mono- and the

11) M. Kondo and M. Kubo, *J. Phys. Chem.*, 62, 1558 (1958).

dichloroacetate in dioxane exist, at least in most part, as binuclear molecules.

On the contrary, cupric trichloroacetate in dioxane shows an absorption band at about $40\times10^{13}\,sec^{-1}$, but no absorption band at about $80\times10^{13}\,sec^{-1}$. The spectrum shows the main features of the spectrum of ordinary cupric complexes without specific metal-to-metal linkage. It may be concluded, therefore, that cupric trichloroacetate does not contain the binuclear molecule of the acetate-type in dioxan. It is noteworthy that even anhydrous cupric trichloroacetate in dioxane shows no band at about $80\times10^{13}\,sec^{-1}$, having no binuclear molecule in this solvent. It is most probable that two trichloroacetate ions are coordinated as bidentate ligands with a single cupric ion to form a planar complex-ion.

The present work shows that the maximum for the band I of the cupric carboxylate is displaced bathochromically, when the hydrogen atom is replaced by the chlorine atom in the series from the acetate to the trichloroacetate, as seen in Table I. The fact that this order

$\nu$: $10^{13}\,sec^{-1}$.

seems to be parallel with the stability of the binuclear molecule may be readily understandable in terms of the ligand field theory, since the band I corresponds to the electronic transitions between the terms formed by splitting from the cupric ion under the ligand field, which is expected to be stronger, as the cupric carboxylates become more stable.

From the above-mentioned observation with the cupric chloroacetates both in the crystalline state and in dioxane, it may be concluded that the tendency of the cupric carboxylates to form binuclear molecules of the acetate-type seems to decrease in the following order: $CH_3-$ $>Cl\cdot CH_2->Cl_2\cdot CH->Cl_3\cdot C-$ for a series of compounds with an empirical formula of $Cu(R\cdot COO)_2$, R being the afore-mentioned radical. This trend may be understood as due primarily to the accumulation of the inductive effect of the chlorine. Thus, as the hydrogen atom in the $CH_3-$ group is replaced by the chlorine atom, the electron-withdrawing power of group R becomes greater to the effect that the electron density on the oxygen atom of the carboxylate group becomes smaller and consequently the electron on the copper atom would be withdrawn more strongly toward the oxygen atom. If it is assumed that the increase in the electronic density on the copper atom means increase of the electronic charge available for the additional linkage between the two copper atoms, the copper-to-copper linkage might become weaker as the electronic charge on the copper decreases on going from the trichloroacetate to the acetate.

**Dimer Formation of Cupric Chloroacetates in Different Solvents.**—The tendency to the dimer formation of cupric carboxylates in solution is found to depend greatly upon the solvent used. In the present work, water, ethanol, dioxane and ethyl ether as a solvent were compared with one another in respect of the dimer formation of the cupric carboxylates. Examinations were made about the structure of the cupric chloroacetates in these solvents in almost equal concentration. Examinations were also made about the structure of the component molecules in the crystals obtained after recrystallization from these solvents.

Absorption spectra of cupric mono-, di- and trichloroacetates in ethanol are shown in Fig. 6. From the above-mentioned criteria, it may be readily concluded that cupric monochloroacetate in ethanol exists mostly as the binuclear molecules, since the compound shows an absorption band at about $80\times10^{13}\,sec^{-1}$ in addition to a band at about $40\times10^{13}\,sec^{-1}$, the intensity of these bands being characteristic of

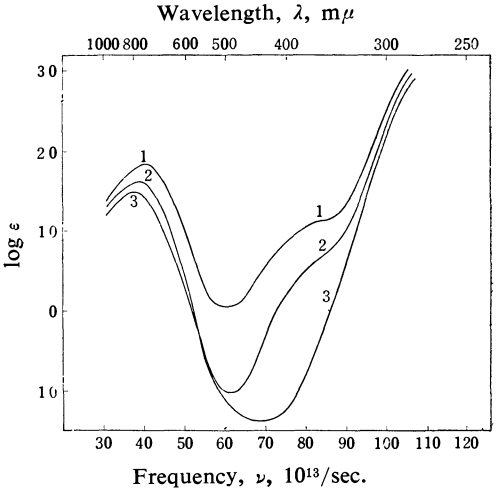

Fig. 6. Absorption spectra of $Cu(Cl_nH_{3-n}C\cdot COO)_2$ in ethanol: 1, $n=1$; 2, $n=2$; 3, $n=3$.

the binuclear cupric carboxylates. On the contrary, the dichloroacetate in ethanol shows only one band at about $40\times10^{13}\,sec^{-1}$ which is much weaker than the corresponding band of cupric monochloroacetate. Moreover, the compound shows no band at about $80\times10^{13}\,sec^{-1}$, although only a very small inflation was observed in this wavelength region. Judging from the criteria mentioned above, the dichloroacetate in ethanol exists mostly in the mononuclear form, although the binuclear molecule might be present in a very minor proportion. The trichloroacetate in ethanol is also seen to show an absorption spectrum, quite similar to the spectrum of the dichloroacetate in ethanol. It is, therefore, concluded that the trichloroacetate exists in the mononuclear form in this solvent. It is to be noted that the band at about $40\times10^{13}\,sec^{-1}$ of the monochloroacetate in ethanol seems to be a little weaker than the corresponding band of the same compound in dioxane, where it exists as binuclear molecules. Therefore, even the monochloroacetate in ethanol contains mononuclear complexes in a very small amount, which is in equilibrium with the binuclear molecules in most part.

In a similar way, the ultraviolet spectra indicate that cupric mono- and dichloroacetate in ethyl ether exist mostly as their binuclear molecules. It is to be noted that anhydrous cupric trichloroacetate shows an absorption spectrum in ethyl ether which is quite different from its spectrum in dioxan, ethanol or water. The spectrum of anhydrous trichloroacetate in ethyl ether was determined in the present work and is shown in Fig. 7. It is seen from the figure that anhydrous cupric trichloroacetate in ethyl ether shows the two absorption bands at about 38 and $80\times10^{13}\,sec^{-1}$, with the

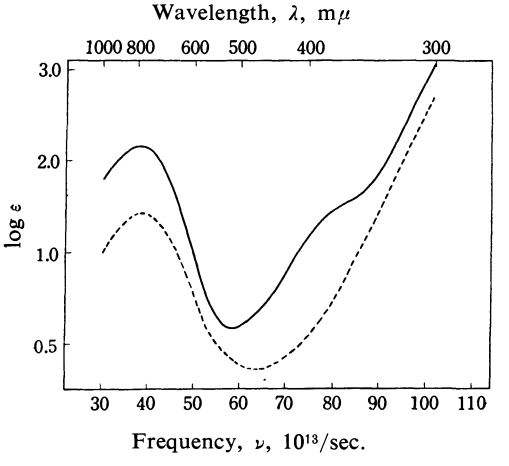

Fig. 7. Absorption spectra of anhydrous $Cu(Cl_3C\cdot COO)_2$ in ethyl ether (——) and in dioxane (----).

principal characteristics of the binuclear cupric carboxylates.

It is seen again that the band I of the cupric chloroacetates is displaced bathochromically, as the hydrogen atom is replaced by the chlorine atom in the series from the acetate to the trichloroacetate. This is in agreement with the relationship, which was derived in the case of dioxane as a solvent, and may be understood in a similar way. It is clearly seen that the cupric chloroacetates exist as binuclear molecules most readily in ethyl ether, of the solvents examined.

Thus the presentd work indicates that cupric trichloroacetate exists as mononuclear complexes in ethanol and in dioxane as well as in water, but that anhydrous cupric trichloroacetate exists in ethyl ether mostly as the binuclear molecules with the metal-to-metal linkage. Similarly it is found that cupric dichloroacetate exists as its binuclear form in dioxane and ether, but as the mononuclear form in ethanol and water. The monochloroacetate is found to exist mostly as binuclear molecules in ethyl ether, dioxane and ethanol, but as mononuclear molecules in water.

The dissociation of the dimer into the monomers takes place most readily in water. Even cupric acetate exists in this solvent mostly as monomeric complexes in equilibrium with the binuclear molecules in a small proportion, although the degree of dissociation depends upon the concentration of the solution. All the cupric monocarboxylates so far examined are found to exist in water as their monomers to a considerable extent if they are soluble in water at all.

Inspection of the data, which are summarized in Table II, reveals that the dimer formation of the cupric carboxylates in different solvents seems to become more difficult in the following order of the solvents: ethyl ether, dioxane, ethanol and water.

The order of the solvents, as presented above, is seen to agree with the increasing order of the electronic charge on the oxygen atom which also represents an increasing order of the co-ordinating capacity of the oxygen to

Table II. Structure of cupric chloroacetates in solution

d: The compound exists mostly as binuclear molecules.
m: The compound exists mostly as mononuclear complexes.

the cupric ion. It is likely that the stronger co-ordination of the solvent molecules at the residual co-ordination position of the copper ion may break the binuclear molecules into the mononuclear complexes more easily. The present examinations also indicate that the mono- and the dichloroacetate give crystals consisting of the binuclear molecules, when recrystallized from water, ethanol or dioxane. On the contrary, the trichloroacetate gives from the same solvents no crystals of the binuclear molecules. The trichloroacetate, however, gives crystals of the binuclear molecules on recrystallization from ethyl ether after careful dehydration of the hydrated crystals. These observations, which are summarized in Table III, seem to be compatible with the above-mentioned order of the solvents concerning the dimer formation of the cupric monocarboxylates.

TABLE III. STRUCTURE OF THE COMPLEXES CONSTITUTING THE CRYSTALS OBTAINED BY RECRYSTALLIZATION OF CUPRIC CHLOROACETATES FROM VARIOUS SOLVENTS

|---|---|---|---|---|
| Acetate | D | D | D | Insoluble |
| Monochloro-〃 | D | D | D | D |
| Dichloro-〃 | D | D | D | D |
| Trichloro-〃 | M | M | M | D |

D : Crystals consisting of dimeric molecules are obtained, aside from the question whether crystals of the monomeric complexes may be obtained or not.

M : Only crystals consisting of the monomeric complexes are obtained.

All these results are found to be in agreement with the conclusion that the trichloroacetate is the cupric chloroacetate which forms the binuclear molecule of the acetate-type with the greatest difficulty, the dichloroacetate being the next. Such a tendency may be understood as due primarily to the accumulation of the inductive effect of the chlorine, which seems to be in parallelism with the decrease in electronic density on the oxygen atom and with the decrease of dissociation constant of the free carboxylic acid. Among cupric carboxylates which are closely related with one another, the dissociation constant of the free carboxylic acid may be regarded as a measure of the formation of the binuclear molecule of the acetate-type.

## Summary

In order to examine the structure of cupric chloroacetates, the dichroism in the visible and the ultraviolet region has been determined at room temperature by the microscopic method with mono-, di- and trichloroacetate. Visible and ultraviolet absorption spectra have also been determined with the above compounds in organic solvents.

The monochloroacetate consists of the binuclear molecules of the acetate-type in the crystalline state and in solution. It has been found that there is another form of the anhydrous monochloroacetate, which is colored blue and contains no binuclear molecule.

The dichloroacetate exists as binuclear molecules in ethyl ether and dioxane, but as mononuclear complexes in ethanol. The anhydrous dichloroacetate in the crystalline state consists of binuclear molecules of the acetate-type.

The trichloroacetate exists as mononuclear complexes in ethanol and in dioxane, and in the crystalline state. The compound exists as binuclear molecules in ethyl ether. Crystals of another form have also been obtained. These possibly consist of binuclear molecules.

The present authors wish to thank the Ministry of Education for a grant-in-aid, and Mr, H. Nakamura for experimental assistance at the earlier stage of this work.

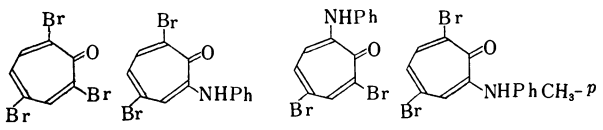
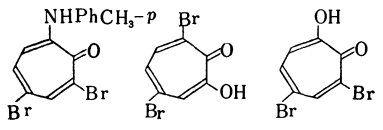
# *The Reaction Products of 2, 4, 7-Tribromotropone and Anilines*

By Tetsuo NOZOE, Kozo DOI* and Shigetaka ENDO**



(Received March 11, 1960)



Nozoe and his co-workers[1] have revealed that the treatment of 2, 4, 7-tribromotropone (I) with aniline or *p*-toluidine affords a mixture of 2-anilino-4, 7-dibromotropone (II) and 7-anilino-2, 4-dibromotropone (III), or 4, 7-dibromo-2-*p*-toluidinotropone (IV) and 2, 4-dibromo-7-*p*-toluidinotropone (V); however, the respective components were not separated.

S. Iseda[2], in 1955, reported that the reaction of tribromotropone and aniline or *p*-toluidine resulted in the selective formation of 2-anilinotropone (II) or 2-*p*-toluidinotropone (IV), hydrolyses of which with ethanolic potassium hydroxide easily gave 3, 6-dibromotropolone (VI).

The present authors have re-examined these reactions in order to prepare the dibromotropolone and have been able to isolate some reaction products besides the ones described above.

Heating of the tribromotropone (I) and aniline in benzene afforded 7-anilino-2, 4-dibromotropone (III) in 21% yield, besides known 2-anilino-4, 7-dibromotropone (II) in 66% yield. Separation of both products was easily effected by the application of the difference in their solubilities in chloroform. The structure of the former (III) was clarified through the formation of known 3, 5-dibromotropolone (VII) on hydrolysis with alcoholic potassium hydroxide.

It had been found that the reaction of the tribromotropone and sodium acetate in acetic acid affords 3, 6- (VI) and 3, 5-dibromotropolones[1] (VII). In a similar manner, the above reaction of the tribromotropone and aniline was proved to give not only a 2-substituted but also a 7-substituted product, unlike that observed by Iseda[2].

The reaction of the tribromotropone and *p*-toluidine appeared to result in the formation of more complicated reaction products. Heating of the two compounds in benzene under the same condition as the above gave the 2-*p*-toluidinotropone (IV) in 55% yield and the 7-*p*-toluidinotropone (V) too in 5% yield, as was expected from the reaction in the case of aniline. The structure of the latter V was proved by the formation of known 3, 5-dibromotropolone (VII) on its hydrolysis with alcoholic potassium hydroxide.

The ultraviolet absorption spectra of the above four kinds of anilinotropone are shown in Figs. 1 and 2. In general, the 7-anilinotropones (III and V) have absorption maxima in the longer wavelength region than the 2-anilinotropones (II and IV); this fact appears

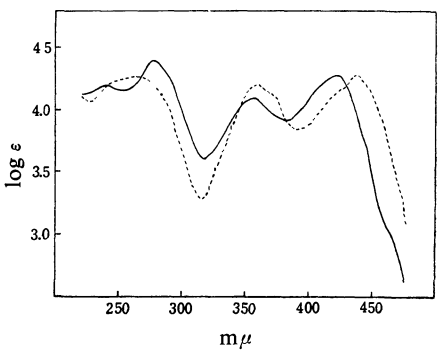


Fig. 1. Ultraviolet absorption spectra.
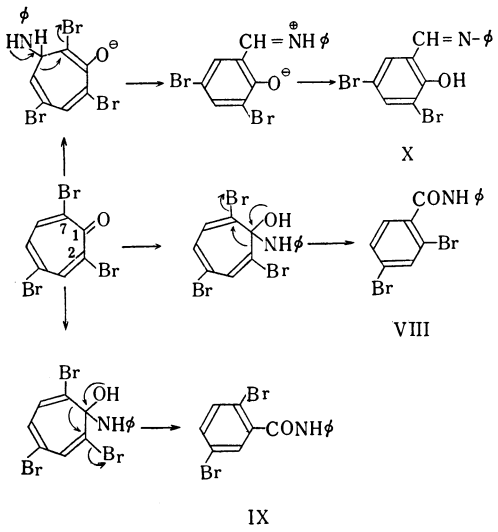
(——): 2-Anilino-4, 7-dibromotropone (II)
(------): 7-Anilino-2, 4-dibromotropone (III)

to be probably due to a stronger resonance effect of the bromine atom in the 4-position of the former (III and V) than that in the same position of the latter (II and IV) on the respective mesomeric interaction between the tropone ring and the benzene ring involving a nitrogen atom.



* Present address: The Chemical Research Institute of Non-Aqueous Solutions, Tohoku University, Katahira-cho, Sendai.

1) T. Nozoe, Y. Kitahara, T. Ando, S. Masamune and H. Abe, *Sci. Repts. Tohoku Univ., Ser. I*, **36**, 166 (1952).
2) S. Iseda, This Bulletin, **28**, 617 (1955).

The reaction mixture, from which the foregoing toluidinotropones (IV and V) were removed, afforded furthermore four kinds of reaction product not isolated to date: 2, 4-dibromobenz-*p*-toluidide (VIII), 2, 5-dibromobenz-*p*-toluidide (IX), 3, 5-dibromosalicylidene-*p*-toluidine (X), and an unidentified substance XI of m. p. 158°C.

The toluidide (VIII and IX) was easily converted into the known dibromobenzoic acid, respectively, on treatment with 75% sulfuric acid. The azomethine compound X was identified with a condensation product of 3, 5-dibromosalicylaldehyde and *p*-toluidine. Another reaction product XI has the composition of $C_{14}H_{12}O_2NBr$, the structure of which will be elucidated in future.

It has been found that the tribromotropone (I) converts into benzoic acid derivatives by the action of bases such as dilute alkali or ammonia[1]. Formations of the dibromobenz-*p*-toluidides (VIII and IX) from the tribromotropone may be taken as the products of the benzilic acid type of rearrangement due to a nucleophilic attack of *p*-toluidine on the 1-position of the molecule. Formation of a Schiff's base X recalls that of 3-bromosalicylaldehyde from 2, 7-dibromotropone by the action of alkali[3,4], and the mechanisms of the above reaction can be illustrated as follows:

## Experimental

The ultraviolet absorption spectra were measured in methanol with a Beckman model DU spectrophotometer.

**Reaction of 2, 4, 7-Tribromotropone (I) and Aniline.**—A mixture of the tribromotropone (I, 70 g.), anhydrous sodium acetate (21 g.), aniline (28 g.) and benzene (1400 ml.) was heated under reflux for 3 hr. The residue obtained by the evaporation of the solvent was washed with water and subsequently extracted with chloroform (100 ml). Crystallization of the part less soluble in chloroform gave 2-anilino-4, 7-dibromotropone (II) as yellow needles from benzene, m. p. 197~198°C (reported[2] m. p. 196~197°C) (47.4 g., 66%). The part more soluble in chloroform, after evaporation of the solvent followed by crystallization from benzene, afforded 7-anilino-2, 4-dibromotropone (III) as yellow needles, m. p. 179.5°C (15 g., 21%).

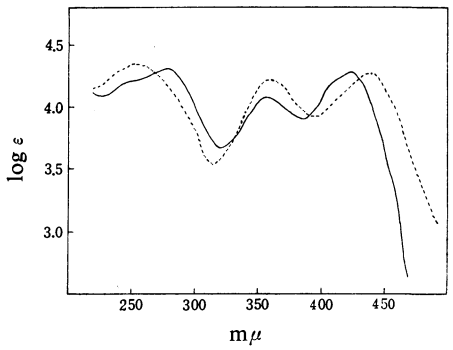

Fig. 2. Ultraviolet absorption spectra.
(——): 4, 7-Dibromo-2-*p*-toluidinotropone (IV)
(------): 2, 4-Dibromo-7-*p*-toluidinotropone (V)

Found: C, 43.52; H, 2.46; N, 4.10. Calcd. for $C_{13}H_9ONBr_2$: C, 43.96; H, 2.56; N, 3.95%. $\lambda_{max}^{MeOH}$ mμ (log ε): 265 (4.25), 361 (4.18), 438 (4.27).

**Hydrolysis of 7-Anilino-2, 4-dibromotropone (III).**—A mixture of III (280 mg.), ethanol (10 ml.), potassium hydroxide (440 mg.) and water (4 ml.) was heated under reflux for 20 min. It was then diluted with water, acidified with concentrated hydrochloric acid to Congo-red and extracted with chloroform. The extract, after evaporation of the solvent followed by crystallization from methanol, gave 3, 5-dibromotropolone (VII), m. p. 154~155°C, undepressed on admixture with an authentic specimen[5].

**Reaction of Tribromotropone (I) and *p*-Toluidine.**—A mixture of the tribromotropone (40 g.), anhydrous sodium acetate (11.6 g.), *p*-toluidine (13 g.) and benzene (700 ml.) was heated under reflux for 3 hr. The residue obtained by evaporation of the solvent was washed with water and extracted with acetone to separate into the less soluble A and the more soluble B portion. The fraction A, 37.3 g., after two recrystallizations from benzene, afforded 4, 7-dibromo-2-*p*-toluidinotropone (IV) as yellow needles, m. p. 194.5°C (reported[2] m. p. 196°C) (24 g., 55%). The benzene mother-liquor, after chromatographic purification (benzene—alumina) followed by two fractional recrystallizations from the same solvent, gave a more soluble product, 2, 4-dibromo-7-*p*-toluidinotropone (V) as yellow needles, m. p. 177°C (2.4 g., 5.6%).

Found: C, 45.68; H, 3.08; N, 3.67. Calcd. for

$C_{14}H_{11}ONBr_2$: C, 45.54; H, 3.01; N, 3.79%. $\lambda_{max}^{MeOH}$ mμ (log ε): 250 (4.35), 361 (4.22), 440 (4.28).

From the same source a less soluble product XI was obtained as yellow plates, m.p. 157.5～158°C (2.3 g).

Found: C, 55.38; H, 4.02; N, 4.58. Calcd. for $C_{14}H_{12}O_2NBr$: C, 54.92; H, 3.95; N, 4.58%. $\lambda_{max}^{MeOH}$ mμ (log ε): 240 (4.17), 283 (4.37), 345 (3.99), 350 (4.01), 400 (4.20).

The fraction B, after evaporation of the solvent, crystallization from ethyl acetate and chromatographic purification (benzene—alumina) followed by several recrystallizations from benzene, yielded the following three products in the order of decreasing of solubilities in the solvent:

2,5-Dibromobenz-*p*-toluidide (IX), colorless needles, m. p. 155～155.5°C (0.25 g.),

Found: C, 45.64; H, 2.85; N, 3.80. Calcd. for $C_{14}H_{11}ONBr_2$: C, 45.54; H, 3.01; N, 3.79%.

2,4-Dibromobenz-*p*-toluidide (VIII), colorless needles, m.p. 174°C (0.2 g.),

Found: C, 45.27; H, 2.70; N, 3.89%.

3,5-Dibromosalicylidene-*p*-toluidine (X), orange needles, m.p. 129.5°C (0.44 g.).

Found: C, 45.58; H, 2.92; N, 4.00%.

**Hydrolysis of 2,4-Dibromo-7-*p*-toluidinotropone (V).**—A mixture of the tropone (V, 90 mg), ethanol (5 ml.), potassium hydroxide (200 mg.), and water (3 ml.) was heated under reflux for 30 min., then acidified with dilute hydrochloric acid to Congo-red, and extracted with chloroform. The extract gave 3,5-dibromotropolone (VII, 40 mg.), m.p. 154～155°C, undepressed on admixture with an authentic sample[5].

**Hydrolysis of 2,4-Dibromobenz-*p*-toluidide (VIII).**—A mixture of the toluidide (VIII, 70 mg.) and 75% sulfuric acid (5 ml.) was heated at 130°C for 30 min. The solid obtained by pouring the reaction mixture onto crushed ice gave 2,4-dibromobenzoic acid, m.p. 166～169°C, undepressed on admixture with an authentic specimen[6].

**Hydrolysis of 2,5-Dibromobenz-*p*-toluidide (IX).**—Hydrolysis of IX under the same condition as the above yielded 2,5-dibromobenzoic acid, m.p. 151～153°C, undepressed on admixture with an authentic sample[7].

**3,5-Dibromosalicylidene-*p*-toluidine (X).**—A mixture of 3,5-dibromosalicylaldehyde[8] (30 mg.), *p*-toluidine (20 mg.) and ethanol (2 ml.) was heated under reflux for one hour. The reaction mixture, when cooled, afforded Schiff's base X as orange needles, m.p. 129～129.5°C, undepressed on admixture with the reaction product X of the tribromotropone and *p*-toluidine.

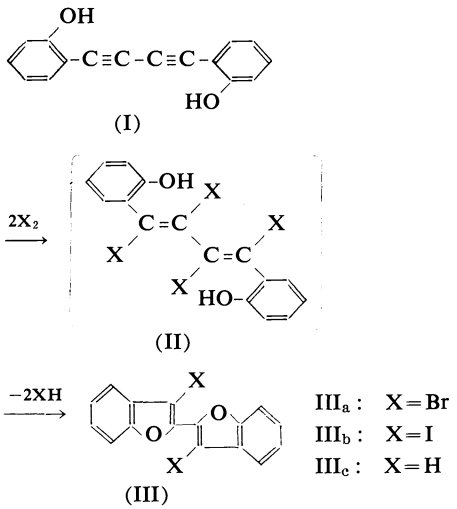
# *Further Studies on the Intramolecular Cyclization of o, o'-Dihydroxydiphenyldiacetylene*

By Fumio TODA and Masazumi NAKAGAWA

(Received February 27, 1960)



In the previous paper, the present authors reported the formation of 2, 2'-dibenzofuranyl ($III_c$) from *o*, *o'*-dihydroxydiphenyldiacetylene (I) in alkaline madia[1]. The present paper deals with the same type of intramolecular cyclization of I and its silver salt IV in a neutral or an acidic medium.

Treatment of I in carbon tetrachloride with bromine yielded colorless needles in a 37% yield with evolution of hydrogen bromide. The structure of $III_a$ was assigned to the substance from the analytical data, ultraviolet and infrared spectroscopic evidences (Figs. 1, 2 and Table I). The cyclization of I to $III_a$ presumably involves the addition of bromine to the triple bands followed by the elimination of hydrogen bromide as indicated in the following scheme. The formation of diindole from *o*, *o'*-dinitrotolan which was reported by Ruggli and his associate seems to involve an essentially similar reaction[2]. In the case of the reaction of iodine with I under the same

1) F. Toda and M. Nakagawa, This Bulletin, **32**, 514 (1959).

2) P. Ruggli, *Ber.*, **50**, 883 (1917); P. Ruggli and O. Schmid, *Helv. Chim. Acta*, **18**, 1215 (1935).

condition, compounds $III_b$ and $III_c$ were isolated in a 10% and a 29% yield respectively.

When the reaction was carried out in the presence of finely powdered calcium carbonate in order to remove the evolved hydrogen iodide, the only product was found to be $III_b$. Treatment of $III_b$ with hydroiodic acid resulted in the formation of $III_c$, therefore, the formation of $III_c$ in the reaction of I with iodine is attributable to the reduction of $III_b$ by

$III_b$: 3,3'-Diiodo-2,2'-dibenzofuranyl
$III_c$: 2,2'-Dibenzofuranyl

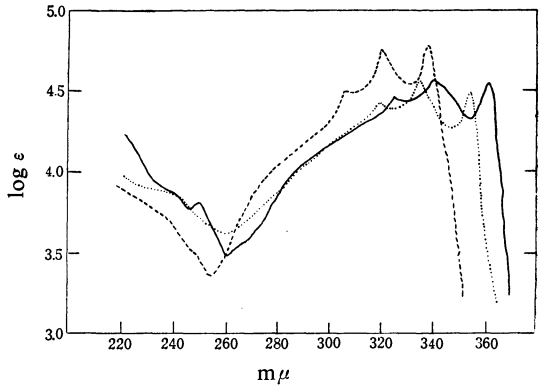

Fig. 2. The ultraviolet spectra of 2,2'-dibenzofuranyl derivatives.
·····: 3,3'-Dibromo-2,2'-dibenzofuranyl ($III_a$)
——: 3,3'-Diiodo-2,2'-dibenzofuranyl ($III_b$)
----: 2,2'-Dibenzofuranyl ($III_c$)

hydrogen iodide. The infrared and ultraviolet spectrum of $III_b$ are shown in Figs. 1, 2 and Table I together with its mother substance and analogues. As illustrated in Fig. 1, the infrared spectra of $III_a$ and $III_b$ lack absorption at 800 and 812 $cm^{-1}$ which exsists in the spectra of $III_c$ and related 2-substituted benzofurans. Therefore, the absorption at ca. 800 $cm^{-1}$ may be ascribed to the out-of-plane deformation of the hydrogen atom at the 3-position of the benzofuran ring.

A quantitative formation of $III_c$ was observed when the silver salt IV was exposed to light for a few days. The reaction of methyl iodide with IV which was kept in a brown desiccator for a day gave 2-(*o*-methoxyphenylethynyl)-benzofuran (VI) together with $III_c$. The structure of VI was inferred from the close resemblance of its ultraviolet and infrared spectrum with those of 2-(*o*-hydroxyphenylethynyl)-benzofuran (VII)[1] as shown in Fig. 3 and Table I.

It is the most interesting result that the silver salt IV was converted into $III_c$ and

its derivatives in good yield by the reaction with various kind of reagents X-Y, such as hydrogen chloride, hydrogen iodide, acetic acid, potassium iodide, ammonium bromide, bromine, iodine and iodine chloride. The results are summarized in Table II.

The photochemical transformation of IV into $III_c$ proceeds probably through a radical mechanism. The photodecomposition of IV may produce a phenoxy radical, and the intramolecular addition of the oxygen radical to the triple bonds would yield an intermediate dibenzofuranyl radical (V) as illustrated in the following scheme. The radical may be stabilized

Table II. Reaction of the silver salt IV with X-Y

| Reagent X | Reagent Y | Medium | Product |
|---|---|---|---|
| H | Cl | Water | 2,2'-Dibenzofuranyl ($III_c$) |
| H | I | 〃 | 〃 |

by the substruction of hydrogen atoms from water or ethanol molecule yielding $III_c$*. Also the formation of VI is quite understandable assuming that the light induced half ring closure of IV is followed or is preceded by the ionic displacement of the silver atom by the methyl group. A same type of photochemical reaction of an acetylenic compound has been reported by Prey[3]. He found that the silver acetylide of *o*-hydroxyphenylacetylene yields benzofuran when irradiated with a quarz lamp. On the other hand, the above mentioned reactions of IV with various kinds of argentphilic reagents presumably proceed through an ionic mechanism. The substruction of silver cation from IV by the attack of the anionic moiety of the reagent $Y^-$ should result in the formation of 2,2'-dibenzofuranyl anion (VIII). The combination of the cationic moiety of the reagent $X^+$ or proton of the

3) V. Prey and G. Pieh, *Monatsh.*, **80**, 790 (1949).
* The silver salt was prepared as a pasty mass by the addition of an aqueous silver nitrate to a solution of I in ammoniacal ethanol.

solvent with VIII gives dibenzofuranyl ($III_c$) or its 3, 3'-disubstituted derivatives.

The bathochromic shifts of the spectrum of $III_a$, $III_b$ and $III_c$ are found to be in the expected sequence of H < Br < I with respect to the substituents at the position of 3 and 3'. On the other hand, the hyperchromic effect of the substituents is in the sequence of H < I < Br. The low $\varepsilon$-values of the K-band of $III_a$ and $III_b$ as compared with that of $III_c$ may be attributable to an increase of twist of the molecule around the 2, 2'-single bond caused by the presence of bulky halogen atoms at 3- and 3'-position. Similar phenomena have already been observed in several instances[4], and were explained in terms of the diminished probability of excitation of the molecule to a coplanar excitation state.

## Experimental*

**Formation of 3, 3'-Dibromo-2,2'-dibenzofuranyl ($III_a$) from *o*,*o*'-Dihydroxydiphenyldiacetylene (I).**—Bromine (3.2 g.) was added to a suspension of finely powdered I (2.4 g.) in dry carbon tetrachloride (40 cc.). An evolution of hydrogen bromide under an exothermic reaction was observed. The mixture was shaken for one hour with occasional cooling with water. The crystals separated were filtered, and the solvent was evaporated. The remaining solid was combined with the crystals, washed with hot ethanol. Recrystallization from benzene yielded $III_a$ as colorless needles, 1.5 g. (37%), m. p. 225°C.

Found: C, 48.58; H, 2.03; Br, 41.02. Calcd. for $C_{16}H_8O_2Br_2$: C, 49.02; H, 2.05; Br, 40.77%.

I. R. max., 1255 (=C-O-), 875(furan ring)$cm^{-1}$.

**Formation of 3, 3'-Diiodo-2, 2'-dibenzofuranyl ($III_b$) and 2, 2'-Dibenzofuranyl ($III_c$) from *o*, *o*'-Dihydroxydiphenyldiacetylene (I).**—A mixture of I (1.2 g.), dry carbon tetrachloride (25 cc.) and iodine (2.6 g.) was allowed to stand for 3 days at room temperature. The solvent was removed by distillation, and the careful fractional recrystallization of the residual solid from ethanol resulted in the separation of two substances. The less soluble substance was found to be $III_b$, 0.25 g. (10%), m. p. 212°C.

Found: C, 39.59; H, 1.59; I, 52.58. Calcd. for $C_{16}H_8O_2I_2$: C, 39.54; H, 1.64; I, 52.22%.

I. R. max., 1252 (=C-O-), 875 (furan ring)$cm^{-1}$.

The more soluble substance, 0.35 g. (29%), m. p. 193~194.5°C was identified as $III_c$ by a mixed melting point determination with an authentic specimen.

A mixture of I (0.95 g.), dry carbon tetrachloride (30 cc.), iodine (2.06 g.) and finely powdered calcium carbonate (1.6 g.) was kept at room temperature for 2 days. The inorganic salt was removed by filtration and extracted with hot benzene. The extract was combined with the filtrate and the solvent was removed under reduced pressure. The residue thus obtained was digested with hot benzene. The crude crystals obtained by the evaporation of the solvent in vacuo was recrystallized from ethanol yielding 0.32 g,. (16%) of $III_b$, m. p. 212°C as colorless needles.

**Reduction of $III_b$ with Hydrogen Iodide.**—Hydroiodic acid (57% aqueous solution, 4 g.) was added to a solution of $III_b$ (50 mg.) in carbon tetrachloride (30 cc.), and the mixture was shaken for 2 days at room temperature. Treatment of the reaction mixture afforded crystalline solid. Fractional recrystallization of the crude solid gave recovered $III_a$, 30 mg., m. p., 211~212°C and a small amount of III, m. p. 190~194°C.

**Preparation of the Silver Salt of *o*, *o*'-Dihydroxydiphenyldiacetylene (IV).**—Silver nitrate (2.8 g.) in water (5.0 cc.) was added to the solution of I (1.8 g.) in a mixture of concentrated ammonia (1.2 cc.) and ethanol (15 cc.). The light yellow precipitate formed was collected by filtration and washed with ethanol, yielding 2.8 g. (ca. 80%) of the silver salt (IV). The attempt to determine the melting point of the saltfailed. A gradual decomposition was observed, when the salt (IV) was heated in a capillary tube, and the substance in the tube fused at 194.5~195.5C showing the melting point of $III_c$.

**Photodecomposition of the Silver Salt (IV).**—Finely powdered IV was exposed to a diffused light in the laboratory for a few days. The resulted greyish powder was digested with benzene. The solvent was removed by distillation, and the residue was recrystallized from benzene or ethanol yielding colorless needles, m. p. 194.5~195.5°C in an almost quantitative yield. This substance was identified as $III_c$ by a mixed melting point determination with an authentic specimen.

**Formation of 2, 2'-Dibenzofuranyl ($III_c$) from the Silver Salt IV.**—A mixture of freshly prepared IV and aqueous hydroiodic acid (57%) was shaken for 5 min. The precipitate formed was collected and washed with water and ethanol, successively. The residue was digested with hot benzene. Concentration of the benzene solution afforded crude crystals. Recrystallization of the crude product from ethanol resulted in colorless needles, m. p. 194.5~195.5°C in good yield. The mixed melting point of this substance with authentic $III_c$ showed no depression. Similar treatment of IV with concentrated hydrochloric acid, acetic acid, aqueous solution of potassium iodide (30%) and aqueous solution of ammonium bromide (30%) also yielded $III_c$ in good yield.

**Formation of 3, 3'-Dibromo-2, 2'-dibenzofuranyl ($III_a$) from the Silver Salt IV.**—To a suspension of a freshly prepared IV in water, bromine was added drop by drop with shaking until the color of bromine persists. The insoluble material was collected by filtration, and washed with water and ethanol successively. The residue was digested with hot benzene and the solvent was evaporated. The crude crystals thus obtained were recrystallized from ethanol yielding colorless needles, m. p. 220~223°C, which showed no depression of the melting point on admixture with previously obtained $III_a$.

* No melting points are corrected.

**Formation of 3,3'-Diiodo-2,2'-dibenzofuranyl ($III_b$) from the Silver Salt IV.** — A mixture of freshly prepared IV, iodine and dry carbon tetrachloride was shaken for 5 min. Silver iodide formed was removed by filtration. The crude crystals obtained by the evaporation of the solvent were recrystallized from ethanol resulting in colorless needles, m. p. 211~212°C. This substance showed no depression of the melting point on admixture with authentic $III_b$.

The reaction of iodine chloride with IV under the same condition also gave $III_b$ in good yield.

**Formation of 2-(*o*-Methoxyphenylethynyl)-benzofuran (VI) from the Silver Salt IV.**—The silver (IV, 2.8 g.) which was kept in a brown desiccator for a day was mixed with methyl iodide (1.5 g.) and dry benzene (5.0 cc.). The mixture was refluxed for 1.5 hr. The precipitate formed was collected by filtration, and extracted with hot benzene (30 cc.). The crude crystals obtained by the evaporation of the solvent was digested with cold ethanol (15 cc.). The insoluble material was recrystallized from benzene resulting in colorless needles, 1.08 g. (78%), m. p. 194.5~195.5°C. The mixed melting point of this substance with 2,2'-dibenzofuranyl ($III_c$) showed no depression. The alcoholic solution was diluted with water, and the crude crystals formed were recrystallized from a diluted ethanol resulting in VI, colorless needles, 100 mg. (6%), m. p. 72°C.

Found: C, 82.33; H, 4.94. Calcd. for $C_{17}H_{12}O_2$: C, 82.24; H, 4.87%.

# *Cyclic Acetylenes. III.* Synthesis of 1, 1'-Dianthryldiacetylene. A Model Substance of a Cyclic Tetraacetylene Containing Anthracene Nuclei*

By Shuzo AKIYAMA and Masazumi NAKAGAWA

(Received March 24, 1960)

In the course of the synthetical studies on the cyclic tetraacetylene containing two anthracene nuclei (I)[1], the authors have studied the synthesis of 1, 1'-dianthryldiacetylene (X) as a model substance of I.

(I)

After several experimentations, the following route to X was developed. 1-Carboxyanthraquinone (III)[2] which was derived from 1, 9-benz-10-anthrone (II) by chromic acid oxidation was converted to 1-carboxyanthracene (IV)[3] by reduction with zinc dust in aqueous ammonia. The acid chloride V[4] which was obtained on treatment of IV with thionyl chloride was caused to react with diethyl ethoxymagnesiomalonate in toluene. The ketomalonate VI thus obtained was treated without further purification with a mixture of propionic acid and sulfuric acid to cause ester exchange and decarboxylation. The over-all yield of 1-acetylanthracene (VII)[5] from II was found to be 52%. The attempt to prepare VII by the reaction of dimethyl cadmium with V was found to be unsatisfactory.

The ketone VII was treated with phosphorus pentachloride in phosphorus oxychloride, and the crude chloride VIII was dehydrochlorinated with sodium amide in liquid ammonia yielding 1-ethynylanthracene (IX) as light yellow cubes. This substance decomposed gradually on standing at room temperature. The presence of a terminal acetylene was confirmed by the formation of yellow cuprous

4) J. W. Cook, *J. Chem. Soc.*, 1931, 566; R. Scholl and J. Donat, *Ber.*, 62, 1297 (1929).

5) VII can be obtained by the fractional recrystallization of a mixture with the 2-isomer which is the product of the direct acetylation of anthracene by the Friedel-Crafts reaction. The authors are grateful to Professor P. H. Gore for private communication suggesting the details of the above mentioned process. cf., P. H. Gore, *J. Org. Chem.*, 22, 135 (1957).

and silver acetylides. Also the infrared spectrum of IX showed an absorption at 3270 $cm^{-1}$ indicating the presence of the ethynyl group as illustrated in Fig. 1.

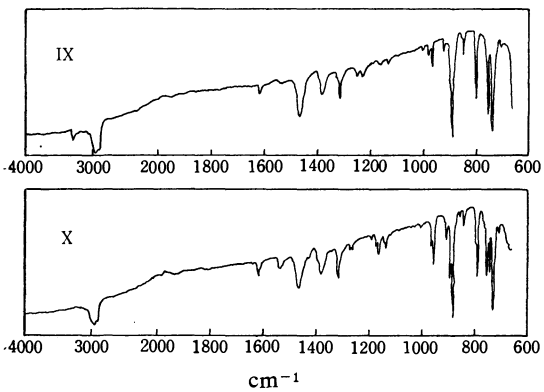

Fig. 1. The infrared spectra of 1-Ethynylanthracene (IX) and 1,1'-dianthryldiacetylene (X). (Nujol mull)

The oxidative coupling of IX according to the procedure of Eglinton[6] afforded fine yellow needles in almost quantitative yield. This was identified as X from its analytical data and the absence of free ethynyl absorption in the infrared spectrum (Fig. 1). X was found to be a stable substance and could be kept unchanged for a long time. X is slightly soluble in benzene and gives a greenish yellow solution with intense blue fluorescence. The diyne X is almost insoluble in common organic solvents such as ethanol and petroleum benzine.

The ultraviolet spectra of IX and X will be discussed in the following paper comparing them with those of the analogous compounds.

## Experimental**

**1-Carboxyanthraquinone (III).**—The acid (III) was prepared by the chromic acid oxidation of 1,9-benz-10-anthrone (II) according to the method of J. W. Cook[2].

**1-Carboxyanthracene (IV).**—III was reduced by means of zinc dust and aqueous ammonia[3], m. p. 245°C, yellow rods (the reported value, m.p. 245°C[3]).

Found: C, 80.83; H, 4.63. Calcd. for $C_{15}H_{10}O_2$: C, 81.06; H, 4.54%.

**1-Acetylanthracene (VII).**—IV was converted to the corresponding acid chloride V by the reaction with thionyl chloride. Diethyl ethoxymagnesiomalonate was prepared from diethyl malonate (48 g., 0.3 mol.), magnesium (7.3 g., 0.3 gram atom) and absolute ethanol (27.6 g., 0.6 mol.) in dry toluene (150 ml.). The excess of ethanol was removed by the azeotropic distillation with toluene. To the refluxed solution of the malonate a solution of crude V (24 g., 0.1 mol.) in dry toluene (400 ml.) was added in 30 min., and the stirring was continued for 3 hr. also under reflux. The reaction mixture was chilled with ice, and decomposed by the addition of 6 N sulfuric acid (100 ml.). The organic layer separated was washed thoroughly with water and dried over anhydrous sodium sulfate. The solvent was removed under reduced pressure. The crude ketomalonate VI was obtained as an orange-yellow oil. The crude product was mixed with propionic acid (80 ml.) and concentrated sulfuric acid (0.5 ml.), and the mixture was refluxed. After 3 hr., 4 N sulfuric acid (50 ml.) was added and the refluxing was further continued for 8 hr. to complete decarboxylation. A small amount of toluene was co-distilled out with water from the reaction mixture. The residue was diluted with water (300 ml.), and the mixture was extracted with benzene (100 ml.×6). The extract was washed with dilute sodium hydroxide and water, successively. The dried benzene solution was concentrated to 200 ml. and filtered through a short column of alumina (20 g.). Light yellow cubes, (15 g., 68%), m. p. 103~106°C were obtained on concentrating the filtrate. Recrystallization of the crude crystals from benzene afforded pure VII as light yellow cubes, m. p. 106~107°C (the reported value, m. p. 105~106°C[5]).

Found: C, 87.52; H, 5.50. Calcd. for $C_{16}H_{12}O$: C, 87.24; H, 5.49%.

I. R. max., 1670 $cm^{-1}$ (C=O).

**1-Ethynylanthracene (IX).**—The acetyl compound VII (10 g., 0.046 mol.) and phosphorus pentachloride (9.8 g., 0.068 mol.) was added to

** All melting points are uncorrected. The infrared spectra were measured by the Nujol mull method.

phosphorus oxychloride (70 ml.) and the mixture was refluxed for 1 hr. The mixture changed to a homogeneous dark red solution with an evolution of hydrogen chloride. Phosphorus oxychloride was removed completely under reduced pressure and the residual dark brown viscous oil was kept for several hours in an evacuated desiccator containing phosphorus pentoxide and potassium hydroxide.

The solution of the crude chloride in dry tetrahydrofuran (20 ml.) was added in 1 hr. to a solution of sodium amide (prepared from 11.5 g. of sodium) in liquid ammonia (500 ml.). After evaporation of ammonia, water (100 ml.) was added to the reaction product and extracted with ligh petroleum (b. p. 60~80°C, 1000 ml.). The extract was washed with water and dried over anhydrous sodium sulfate. The dried solution was filtered through a thin layer of alumina (40 g.). Concentration of the filtrate resulted in IX as light yellow cubes, 5.1 g. (55%), m. p. 88~90°C. This material was recrystallized from light petroleum or sublimed under high vacuum ($0.5\times10^{-4}$ mmHg) to yield pure IX, m. p. 90°C.

Found: C, 95.04; H, 5.10. Calcd. for $C_{16}H_{10}$: C, 95.02; H, 4.98%.

# *Cyclic Acetylenes. IV. Synthesis of a Cyclic Tetraacetylene Containing Anthracene Nuclei**

By Shuzo AKIYAMA, Soichi MISUMI and Masazumi NAKAGAWA

(Received March 24, 1960)

There has already been discussion concerning the fact that a conjugated planar cyclic en-yne system may form a continuous molecular $\pi$-orbital overlapping the *p*-orbitals of the carbon atoms of the unsaturated linkages in the cycle[1]. It is of interest to synthesize such a cyclic acetylene in order to establish experimentally the validity of the theoretical prediction, but the only member of this series known up to now is the completely conjugated planar eighteen membered monocyclic hexaene-triyne which was reported recently by Sondheimer and Wolovsky[2]. They synthesized the hexaene-triyne by a prototropic rearrangement of the corresponding cyclic hexa acetylene which was prepared by the oxidative coupling of 1,5-hexadiyne. Another promising approach to the synthesis of a planar cyclic en-yne system is the oxidative coupling of a diethynyl aromatic compound in which the two ethynyl groups are directly attached to the proper positions of the aromatic nucleus. The rigid geometry of this type of molecule may be favorable to the ring formation by oxidative coupling as pointed out by W. Baker[3]. The

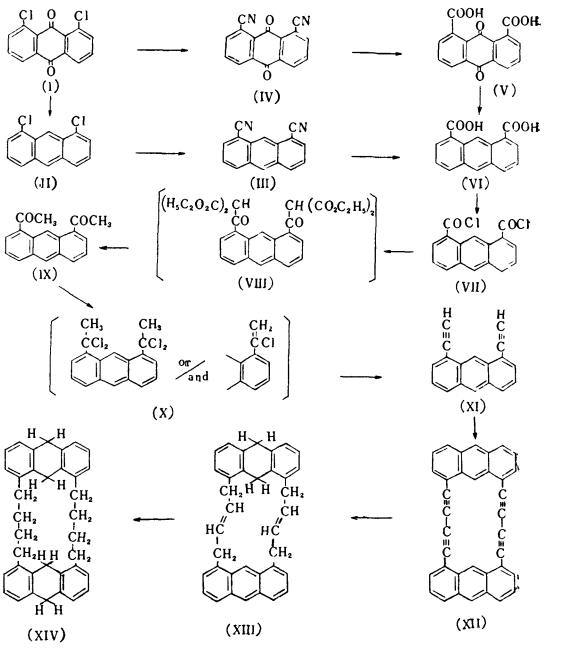
1) T. J. Sworski, *J. Chem. Phys.*, **16**, 550 (1948).



2) F. Sondheimer and R. Wolovsky, *J. Am. Chem. Soc.*, **81**, 1771 (1959).

first attempt according to this principle has been reported by Eglinton and his coworker. They carried out the oxidative coupling of *o*-diethynylbenzene expecting the formation of a fully conjugated strainless cyclic trimer, the tribenzo derivative of cyclo-octadeca-triene-hexayne[4]. But unexpectedly the product was identified to be a highly strained cyclic dimer of *o*-diethynylbenzene[5].

We have synthesized a planar conjugated cyclic tetraacetylene containing two anthracene nuclei (XII) according to the following scheme. The starting material for our work was 1, 8-dichloroanthraquinone (I). The dichloroquinone I was reduced to 1, 8-dichloroanthracene (II)[6], and the reaction of II with cuprous cyanide in quinoline gave 1, 8-dicyanoanthracene (III). The attempt to obtain 1, 8-diacetylanthracene (IX) by the reaction of III with methylmagnesium iodide in anisol failed on account of the poor solubility and inert reactivity of III. Therefore, according to the results of the preliminary experiments[7], the route to the diacetyl compound IX via dicarboxylic acid VI was chosen. 1, 8-Dicarboxyanthracene (VI) was synthesized by the alkaline hydrolysis of the dinitrile III in ethylene glycol. The diacid VI was also prepared according to the procedure of Waldmann[8] by the reduction of 1,8-dicarboxyanthraquinone (V) which was derived from I via IV.

Treatment of VI with thionyl chloride in chlorobenzene afforded the diacid dichloride VII. VII was caused to react with diethyl ethoxymagnesiomalonate in xylene to yield the ketomalonate VIII. The curde VIII was heated without further purification with the mixture of propionic and sulfuric acid. Treatment of the reaction mixture resulted in 1, 8-diacetylanthracene (IX) as light yellow cubes.

The crude chloride X which was obtained by the reaction of the diacetyl compound IX with phosphorus pentachloride in phosphorus oxychloride was dehydrochlorinated with sodium amide in liquid ammonia. 1, 8-Diethynylanthracene (XI) was obtained as yellow cubic crystals which melted at 150~151°C with decomposition. XI was found to be a fairly unstable substance and could not be kept without de-composition for a long time. The in-

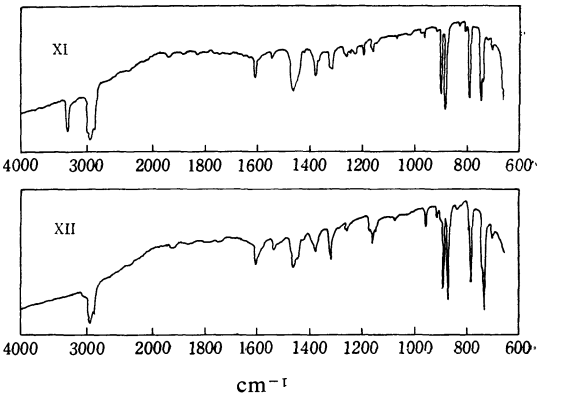


Fig. 1. The infrared spectra of 1,8-diethynylanthracene (XI) and the cyclic tetraacetylene (XII). (Nujol mull)

frared spectrum of XI shows an absorption at 3260 $cm^{-1}$ indicating the presence of terminal acetylene as illustrated in Fig. 1. XI gives also red cuprous and yellow silver acetylides.

The oxidative coupling of the diethynyl compound XI, conducted according to the procedure of Eglinton[9], yielded orange crystals in a high yield. The structure of the cyclic tetraacetylene (XII) was assigned to the substance from the method of preparation and from the following evidences. The cyclic nature of XII was confirmed by the absence of free ethynyl absorption in the infrared spectrum (Fig. 1) and by the negative test against alcoholic silver nitrate solution. Various

methods for determining the molecular weight of XII were tried unsuccessfully as a result of the poor solubility of this substance in organic solvents. Reduction of XII with an excess of sodium in liquid ammonia yielded a substance with a composition $C_{36}H_{30}$ as a main product.

The infrared spectroscopy of this material revealed the presene of a methylene group ($\nu_{as}$: 2860, $\nu_s$: 2920 $cm^{-1}$), unconjugated *trans*-ethylenic bond ($\delta_{CH}$: 952 $cm^{-1}$) and 1,2,4,5-tetrasubstituted benzene ($\delta_{CH}$: 875 $cm^{-1}$) as illustrated in Fig. 1. From these evidences,

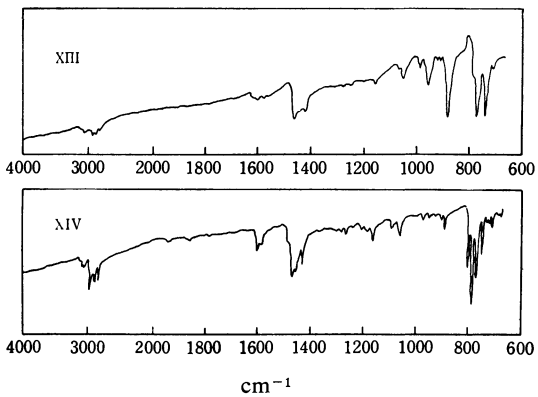

Fig. 2. The infrared spectra of $C_{36}H_{30}$ (XIII) and the hydrogenated product (XIV). (KBr-disk)

the structure of XIII was assigned tentatively to the reduction product. Further hydrogenation of XIII in benzene over palladium on charcoal gave tiny colorless cubes with the empirical formula $(C_9H_9)_n$. The molecular weight of this substance could be determined accurately by Rast's method in camphor. The molecular weight thus determined (450; Calcd. for $C_{36}H_{36}$: 469) provided an unequivocal evidence regarding the dimeric cyclic acetylene for XII. The fully hydrogenated product shows no absorption at 875 $cm^{-1}$ in the infrared spectrum, indicating the absence of the anthracene nucleus in the molecule. The infrared spectrum of this substance was illustrated in Fig. 2 together with that of XIII. The ultraviolet spectrum of the hydrogenated product also indicates the destruction of anthracene chromophor. From these observations structure XIV was given to the reduction product.

The high yield of the oxidative cyclic dimerization of XI to XII seems to reflect the favorable orientation of the ethynyl groups in XI. Examination of the bond angles of the compound XII readily verifies its planar and strainless nature. XII was found to be a very stable compound and can be kept without change for a long time in air and light. In

C: cyclohexane, B: benzene.

solution in dimethylformamide, in which XII is slightly soluble, exhibits an orange yellow color with intense and characteristic green fluorescence.

The ultraviolet spectra of 1-ethynylanthracene (XVI)[7], 1,8-diethynylanthracene (XI), 1,1'-dianthryldiacetylene (XVII)[7] and the cyclic tetraacetylene (XII) are illustrated in Figs. 3 and 4. The bathochromic shifts of the absorption maxima at the longest wavelength and the $\varepsilon$-values of these acetylenes as compared with anthracene are tabulated in Table I. The $\varepsilon$-value of XVII reduced to per acetylene-unit ($0.5\times24,600=12,300$) is approximately the same as that of XVI (11,500), whereas the $\varepsilon$-value of XII reduced per diyne-unit ($0.5\times91,200=45,600$) is much greater than those of XVII (24,600) and XI (17,400). The marked increase in the absorption intensities and the remarkable red-shift of the spectrum of XII indicate that the cyclic tetraacetylene can not be regarded as a simple derivative of anthracene. These ultraviolet spectroscopic properties and, at least to some extent, the unusual stability of XII seem to be attributable to an enhanced interaction of $\pi$-electrons of the acetylenic bonds with those of the aromatic system.

The syntheses of the same type of higher cyclic acetylenes are now being investigated.

## Experimental**

**1,8-Dichloroanthracene (II).**—The reduction of I with zinc dust in aqueous ammonia[6] yielded a product consisting of mainly 1,8-dichloro-9,10-dihydroanthranol[10]. The reduction product was extracted with ethanol. The solvent was removed and the light yellow crystalline residue was recrystallized from carbon tetrachloride to give the pure anthranol, white needles, m.p. 136~136.5°C.

Found: C, 63.52; H, 4.03; Cl, 27.27. Calcd. for $C_{14}H_{10}OCl_2$: C, 63.41; H, 3.78; Cl, 26.80%.

I.R. max., Broad absorption near 3200 (-OH); 1180 $cm^{-1}$ (C-O).

A catalytic amount of concentrated sulfuric acid was added to a solution of the anthranol in hot ethanol. Immediate precipitation of practically pure II, light yellow needles, m.p. 157~158°C, (values in literature, 156°C[6]; 160°C[11]) was observed.

Found: C, 68.04; H, 3.28; Cl, 28.96. Calcd. for $C_{14}H_8Cl_2$: C, 68.05; H, 3.26; Cl, 28.69%.

In practice it was found more convenient to treat the ethanol extract of the reduction product with a small amount of sulfuric acid without the isolation of the anthranol.

**1,8-Dicyanoanthracene (III).**—A mixture of II (50 g., 0.19 mol.), cuprous cyanide (60 g.) and quinoline (500 ml.) was stirred for 24 hr. under reflux. The cooled reaction mixture was filtered and the solid was washed with dilute hydrochloric acid, then treated with dilute aqueous sodium cyanide to dissolve cuprous cyanide, and was washed with water. The dried light brown powder was digested with nitromethane (250 ml.) to remove the resinous material on the powder. Recrystallization of the powder from acetic acid using active charcoal yielded III, long yellow needles, m.p. 299~304°C, 22 g. (48%). Further recrystallization of this material from acetic acid gave pure III, m.p. 304~306°C, (value in literature, m.p. 300.5°C[8]). III is soluble in concentrated sulfuric acid giving a greenish yellow solution.

Found: C, 83.69; H, 3.47; N, 12.13. Calcd. for $C_{16}H_8N_2$: C, 84.19; H, 3.53; N, 12.28%.

I.R. max., 2225 $cm^{-1}$ (-C≡N).

**1,8-Dicarboxyanthracene (VI).**—*a) Hydrolysis of 1,8-Dicyanoanthracene (II).*—A mixture of II (10 g., 0.044 mol.), potassium hydroxide (125 g.) and ethylene glycol (270 ml.) was heated to 150~155°C under stirring until the evolution of ammonia ceased (ca. 70 hr.). The reaction mixture was neutralized with hydrochloric acid resulting in formation of a yellow precipitate. The precipitate was filtered, washed with water and dried, yielding yellow powder, 11 g. (94%), m.p. 341~345°C (decomp.). Recrystallization of this material from 95% ethanol resulted in pure VI, yellow needles, m.p. 347°C (decomp.). (value in literature, 345°C (decomp.)[8]).

Found: C, 71.84; H, 3.77. Calcd. for $C_{16}H_{10}O_4$: C, 72.18; H, 3.79%.

*b) Reduction of 1,8-Dicarboxyanthraquinone (V).*—1,8-Dicyanoanthraquinone (IV) which was obtained by the reaction of I with cuprous cyanide in benzyl cyanide[8a] was hydrolyzed to V by the reaction with sulfuric acid[8]. The reduction of V by means of zinc dust in aqueous ammonia yielded

** All melting points are uncorrected. The infrared spectra were measured by the Nujol mull method otherwise special indication is given.

10) It has been reported that the reduction of anthracene with zinc dust in aqueous ammonia yields anthranol. Cf., H. R. von Perger, *J. prakt. Chem.*, **23**, 137 (1881).

11) E. B. Barnett and M. A. Matthews, *J. Chem. Soc.*, **123**, 2549 (1923).

VI, m. p. 347°C (decomp.). This substance showed no depression of the melting point on admixture with the specimen prepared by route *a*).

**Anthracene-1, 8-dicarboxylic Acid Chloride (VII).**—The acid chloride (VII) was prepared according to the procedure of Waldmann[8b]. Recrystallization of the crude product from toluene gave pure VII, orange needles, m. p. 255~257°C (decomp., in a sealed capillary tube). (value in literature, m. p. lower than 220°C (decomp.)[8b]). VII gives yellow solution in concentrated sulfuric acid.

Found: C, 63.15; H, 2.80; Cl, 23.37. Calcd. for $C_{16}H_8O_2Cl_2$: C, 63.39; H, 2.66; Cl, 23.39%.

**1, 8-Diacetylanthracene (IX).**—1) *Malonation of the Acid Chloride (VII.)*—Diethyl ethoxymagnesiomalonate was prepared from magnesium (11 g., 0.46 gram atom), diethylmalonate (73.5 g., 0.46 mol.) and absolute ethanol (27.6 g., 0.6 mol.) in dry xylene (100 ml.). The excess of ethanol was removed by the azeotropic distillation with xylene. The solution of the malonate was added to the hot solution of VII (17 g., 0.057 mol.) in dry xylene (1.8 l.) in 30 min. under stirring. The mixture was refluxed for 1 hr. and decomposed with the addition of crushed ice (100 g.) and 4 N sulfuric acid (300 ml.). The organic layer was washed with water, and dried over anhydrous sodium sulfate. Evaporation of the solvent under reduced pressure resulted in the crude ketomalonate (VIII) as an orange red oil.

2). *Ester Exchange and Decarboxylation of the Ketomalonate (VIII).*—The crude VIII was mixed with propionic acid (320 ml.) and concentrated sulfuric acid (4 ml.), and the mixture was refluxed for 4 hr. with a vigorous evolution of carbon dioxide. Sulfuric acid (4 N, 250 ml.) was added to the reaction mixture and the reflux was continued until no more evolution of carbon dioxide was observed. The mixture was distilled to remove a small amount of xylene with water, and poured onto ice-water (1 l.). The ice cooled mixture was filtered. The solid thus obtained was washed with water, and dissolved in benzene. The benzene solution was washed with dilute sodium hydroxide solution and water, successively. The dried solution was filtered through a short column of aluminum oxide, and the concentration of the filtrate resulted in IX, light yellow cubes, 7.4 g. (50%.), m. p. 176~179°C (Kofler block). Recrystallization of this substance from benzene resulted in pure IX, light yellow cubic crystals, m. p. 179~180°C. IX gives an orange red solution with concentrated sulfuric acid.

Found: C, 82.49; H, 5.49. Calcd. for $C_{18}H_{14}O_2$: C, 82.43; H, 5.38%.

I. R. max., 1675 $cm^{-1}$ (C=O).

**1, 8-Diethynylanthracene (IX).**—*1) Chlorination of the Diacetylanthracene (IX).*—IX (5.25 g., 0.02 mol.) was mixed with phosphorus pentachloride (12.5 g., 0.06mol.) and phosphorus oxychloride (50 ml.), and the mixture was heated under reflux for 1.5 hr. With an evolution of hydrogen chloride, the mixture changed to a homogeneous dark red solution. The oxychloride was removed completely under reduced pressure. The dark red viscous oil was kept for several hours in a desiccator containing phosphorus pentoxide and potassium hydroxide.

*2). Dehydrochlorination of the Chloride (X).*—The crude chloride (X) in absolute ether (30 ml.) was added in 40 min. to a solution of sodium amide (prepared from sodium, 11.5 g., 0.5 gram atom) in liquid ammonia (500 ml.). The mixture was stirred for 2 hr. at the temperature of dry ice-ethanol bath. After evaporation of ammonia, water (250 ml.) was added cautiously to the reaction mixture and filtered to collect insoluble material. The dark brown solid obtained was digested with light petroleum (b. p. 60~80°C, 1.5 l.). The solution was washed with water and dried over anhydrous sodium sulfate. The solution was passed through a short column of alumina, and the filtrate was evaporated to yield XI, 1.65 g. (37%), m. p. 150~151°C (decomp., Kofler block). XI gave red cuprous, yellow silver and mercuric acetylides.

Found: C, 95.49; H, 4.45. Calcd. for $C_{18}H_{10}$: C, 95.54; H, 4.46%.

I. R. max., 3260 $cm^{-1}$ (-C≡CH).

U. V. max. (in cyclohexane), $\lambda_{max}$ 258 mμ (log ε =5.13), 279 (4.08), 291 (4.08), 312 (2.87)*, 330 (3.22), 345 (3.60), 362 (3.98), 381 (4.22) and 402 (4.24). Asterisk indicates shoulder.

**Oxidative Coupling of 1, 8-Diethynylanthracene (XI).**—To the solution of XI (0.600 g., 0.0027 mol.) in pyridine (100 ml.) and methanol (8 ml.) was added cupric acetate monohydrate (12 g.), and the mixture was vigorously stirred for 4 hr. at 55°C. Stirring was continued for a further 3 hr. period at room temperature. The reaction mixture was filtered and the solid obtained was washed thoroughly with water, a small amount of benzene and ethanol, successively. The cyclic tetrayne XII almost free from inorganic contaminate was obtained as orange powder, 0.562 g. (95%). This substance decomposed over 370°C. A minor amount of XII of poor purity was obtained from the pyridine solution.

The crude XII was recrystallized 3 times from xylene and once from dimethylformamide yielding tiny orange cubes. These crystals decomposed over 370°C in an evacuated capillary tube without any change of the crystal form.

Found: C, 95.72; H, 3.61. Calcd. for $C_{36}H_{16}$: C, 96.40; H, 3.60%.

The unsatisfactory result in the analysis of carbon may be due to explosive decomposition of XII in the combustion tube forming a carbonaceous material difficult to burn.

U. V. max., $\lambda_{max}$ 258 mμ (log ε=5.22) (in *n*-hexane), 307 (4.82), 340 (3.66), 358 (3.79), 376 (3.93), 413 (4.22), 437 (4.67) and 465 (4.96) (in benzene).

**Reduction of the Cyclic Tetraacetylene (XII) with Sodium in Liquid Ammonia.**—The mixture of XII (0.42 g., 0.0009 mol.), sodium (0.9 g., 0.039 gram atom) and liquid ammonia (150 ml.) was stirred for 7 hr. at the temperature of dry ice-ethanol bath. Ammonium nitrate was added to the reaction mixture, and ammonia was evaporated. Water was added to the residue and the light yellow powder formed was collected by filtration. The powder was digested with benzene to remove the insoluble material. The benzene solution was filtered

through a thin layer of alumina (10 g.). Evaporation of the solvent afforded XIII, yellow needles, 0.20 g. (48%), m. p. 365~368°C (decomp., in an evacuated capillary tube, metal block).

Found: C, 93.24; H, 6.67. Calcd. for $C_{36}H_{30}$: C, 93.46; H, 6.54%.

I. R. max. (KBr-disk method), 2920, 2860 ($-CH_2-$), 952 (isolated trans-ethylenic bond), 875 $cm^{-1}$ (tetra-substituted benzene).

U. V. max., $\lambda_{max}$ 257 m$\mu$ ($\log \varepsilon = 4.91$) (in *n*-hexane), 318 (3.71), 332 (3.72), 348 (3.73), 368 (3.84) and 387 (3.89) (in benzene).

**Catalytic Reduction of $C_{36}H_{30}$ (XIII).**—The solution of XII (0.19 g.) in benzene (300 ml.) was shaken in hydrogen with palladium (5%) on charcoal (0.5 g.). The color and the fluorescence of the solution gradually disappeared in the course of the hydrogenation. The catalyst was filtered and washed with benzene. The filtrate was combined with the washing, and the evaporation of the solvent yielded XIV as fine colorless needles in almost quantitative yield. This was recrystallized from benzene to give pure XIV, m. p. 316~318°C, (in an evacuated capillary tube; metal block).

Found: C, 92.10; H, 7.67; Mol. wt. (Rast, camphor), 450. Calcd. for $C_{36}H_{36}$: C, 92.26; H, 7.74%; Mol. wt., 469.

I. R. max. (KBr-disk method), 2935, 2870 ($-CH_2-$), 735 $cm^{-1}$ ($-(CH_2)_4-$).

U. V. max. (in ethanol), $\lambda_{max}$ 256 m$\mu$; $\lambda_{min}$ 248 m$\mu$.

The financial support of this research was granted by the Ministry of Education. The starting material was donated by the Mitsui Chemical Industries Co., Ltd. The elementary analyses were performed by Mr. M. Okumiya and Miss K. Koike. The authors wish to express their sincere thanks for these donation and for the help received.

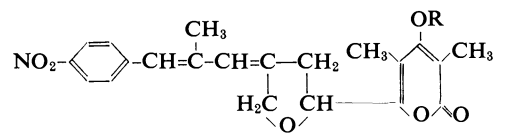
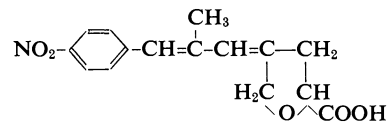
# *The Structure of Aureothin. X*[1]. *Aza Derivatives of Aureothin, Isoaureothin and Desmethylisoaureothin*

By Kiyoyuki YAMADA, Hisao NAKATA and Yoshimasa HIRATA



(Received April 2, 1960)

A recent publication[2] from our laboratory has indicated that the structure of aureothin was shown to be I, on a firm basis of a quantity of chemical and spectroscopic evidence. Aureothin undergoes demethylation with various acids, followed by isomerization, to give desmethylisoaureothin (II, R=H), the methylation of which, in turn leads to isoaureothin (II, $R=CH_3$) as a major product[1].



During the course of the structural investigation, it was found that I, II ($R=CH_3$) and II (R=H) reacted with ammonia and were transformed to aza-aureothin (IV), aza-isoaureothin (V) and aza-desmethylisoaureothin (VI), respectively. In the present paper, the properties of these aza-derivatives are described, being compared with those of other model compounds. Each of these aza-derivatives contains one more nitrogen, besides an original one (nitro group), and is sparingly soluble both in organic solvents and water.

(I)

(II)

(III)

**Aza-aureothin (IV).**—The elemental analysis of IV was incompatible with the molecular formula, expected for γ-pyrone—γ-pyridone

1) For Part IX of this series, see, H. Nakata, This Bulletin, in press.

2) K. Yamada, H. Nakata and Y. Hirata, *J. Chem. Soc. Japan, Pure Chem. Sec.* (*Nippon Kagaku Zasshi*), **81**, 340 (1960).

transformation; there remained no methoxyl group in IV. Thus, somewhat complicated reactions must take place during the formation of IV from I. It is apparent from the ultraviolet spectrum that $\gamma$-pyrone moiety is involved in the reaction, and the conjugated *p*-nitrophenyl system remains intact. Subtraction of the ultraviolet spectrum of aureothinic acid (III) from that of aza-aureothin (IV) gave an absorption spectrum due to the chromophore in question—presumably, a nitrogen-containing ring; the subtraction curves, taken in neutral and acid solutions, were different, as shown in Fig. 1.

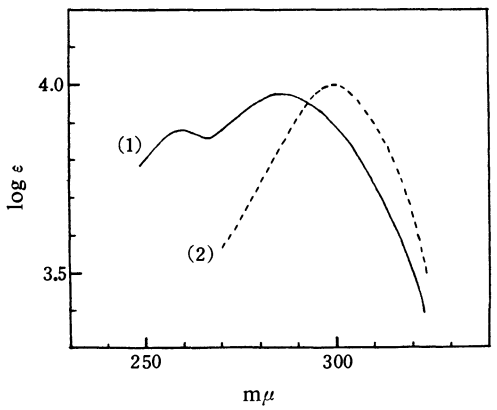

Fig. 1. Substraction curves obtained by aza-aureothin (IV)—aureothinic acid (III) in ethanol.
(1): Neutral and alkaline (0.1 N EtONa) solutions.
(2): Acidic (0.1 N HCl) solution.

The infrared spectrum showed bands at 1666(s), 1643(m), 1583(s), 1529(s), 1509(s) $cm^{-1}$ and at 3385, 3285 and 3175 $cm^{-1}$, the latter group of bands suggesting the presence of N-H and/or O-H. Treatment of IV with acetic anhydride and pyridine yielded an amorphous substance, the infrared spectrum of which showed bands at 1731(s), 1666(s), 1623(s), 1596(s) and 1516(s) $cm^{-1}$ (in chloroform). This must be an ester. The insolubility of IV in various solvents prevented us from attempting further studies on this substance, and the details of the structure are still uncertain.

**Aza-isoaureothin (V).**—Analytical data of V agreed with a molecular formula $C_{21}H_{22}O_5N_2$, identical with that of aza-desmethylisoaureothin (VI), but the chemical behavior, as described below, is quite different from those expected for aza-desmethylisoaureothin (VI). In this case, again, some other reaction might occur concomitantly with the pyrone—pyridone transformation. This compound is not an acidic substance but a neutral one, and an attempted acetylation only resulted in the complete recovery of the starting material. The same procedure used for IV was applied for the measurement of the ultraviolet spectrum; the results obtained by the subtraction method of the ultraviolet curves are shown in Fig. 2. In this case also, the absorption maximum in an acidic medium is situated at somewhat longer wavelength than that in neutral solution.

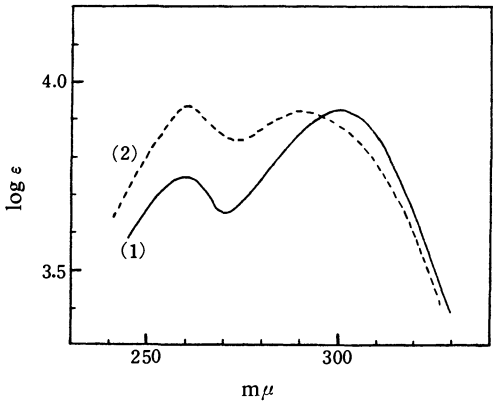

Fig. 2. Subtraction curves obtained by aza-isoaureothin (V) — aureothinic acid (III) in ethanol.
(1): Neutral and alkaline (0.1 N EtONa) solutions.
(2): Acidic (0.1 N HCl) solution.

Remarkable differences were observed in the infrared spectra between isoaureothin (II, R=$CH_3$) and aza-isoaureothin (V), as illustrated in Fig. 3. The following points are worth noticing; the shift of carbonyl band (1716 $cm^{-1}$ for isoaureothin, 1660 $cm^{-1}$ for aza-isoaureothin), and the appearance of a new band at 1554 $cm^{-1}$ and of a series of bands at 3225, 3322, 3434 $cm^{-1}$.

From these spectroscopic data, it is seen that an $\alpha$-pyridone ring is likely to be present in V, but the whole structural aspect of V could not yet be disclosed, owing to the same reason, as that encountered in the case of aza-aureothin (IV).

**Aza-desmethylisoaureothin (VI).** — Aza-desmethylisoaureothin $C_{21}H_{22}O_5N_2$, was prepared via two routes; one is based on a reaction of desmethylisoaureothin (II, R=H) with ammonia, and the other is due to the treatment of aureothin with ammonium acetate in acetic acid. Chemical and spectroscopic behavior of VI, described below, substantiates a simple pyrone-pyridone transformation. VI dissolved in aqueous alkali, although no reaction took place between VI and ethereal diazomethane (under heterogeneous condition). Acetylation of VI with acetic anhydride-pyridine gave aza-desmethylisoaureothin acetate, $C_{23}H_{24}O_6N_2$ (VII), which showed an enol acetate band at 1767 $cm^{-1}$ (KBr).

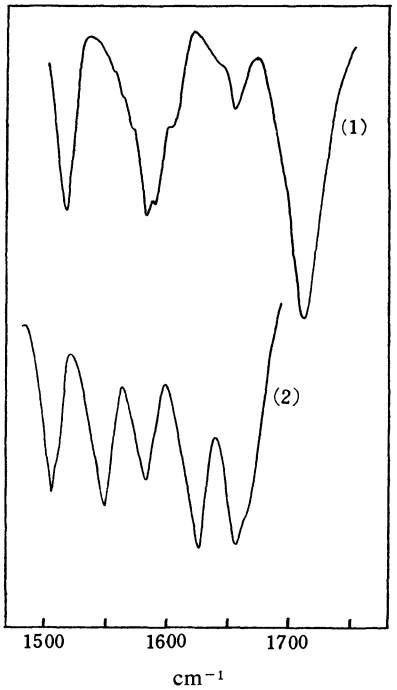

Fig. 3. Infrared spectra (KBr)
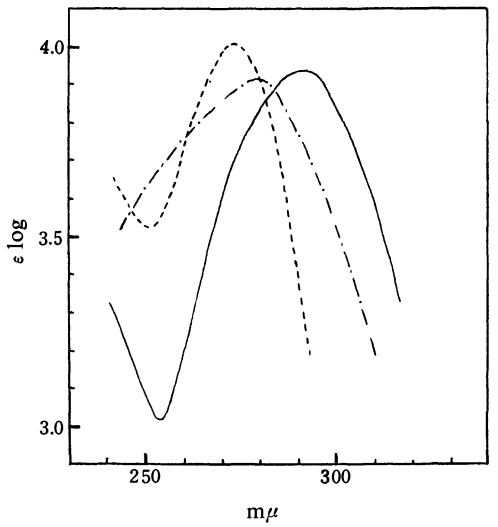
(1): Isoaureothin. (II, R=$CH_3$).
(2): Aza-isoaureothin. (V).



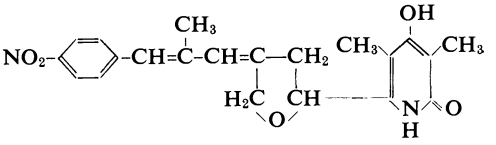


Fig. 4. Subtraction curves obtained by aza-desmethylisoaureothin (VI)—aureothinic acid (III) in ethanol.
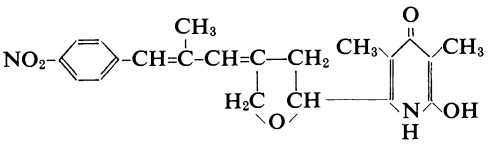
(1): Neutral solution.
(2): Acidic (0.1 N HCl) solution.
(3): Alkaline (0.1 N EtONa) solution.



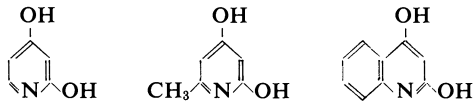
In the infrared spectrum of VI, there appeared bands at 1643(s), 1605(v. s), 1585(v. s), 1564(m) and 1510(s) $cm^{-1}$ in 1800~1500 $cm^{-1}$ region and a broad band ranging from 2500 $cm^{-1}$ to 3000 $cm^{-1}$, which indicates the occurrence of hydrogen bonding. The position of pyridone-carbonyl band unaffected by hydrogen bonding is available from aza-desmethylisoaureothin acetate (VII); i. e., in this case, $\nu_{C=O}$ appeared at 1654 $cm^{-1}$ (KBr).

In the ultraviolet region, the absorption due to the pyridone ring of VI had its maximum at 291 mμ in neutral solution, while acidic and alkaline conditions caused the hypsochromic displacement of the absorption (Fig. 4). The moderate solubility in chloroform made possible the ozonization of VII, which afforded aza-desmethylisoaureonone acetate, $C_{13}H_{15}O_5N$ (VIII). This product VIII, now free from the conjugated *p*-nitrophenyl system, showed an absorption maximum at 304 mμ in the ultraviolet region, and bands at 1762(s), 1658(s), 1640(sh.) and 1577(w) $cm^{-1}$ in the infrared region.

**Structure of Aza-desmethylisoaureothin.** — Both types VIa and VIb would be possible for VI, since enolization can occur in two directions[4].

(VIa)

(VIb)

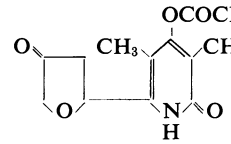


A considerable amount of data[5] concerning the infrared spectra of various α-pyridones is now at hand. The condition of the measurement (solid or solution) has a fairly large influence on the position of carbonyl absorption. The ranges quoted for carbonyl absorption in the solid state are rather wide (1630~1680 $cm^{-1}$)[5], whereas in solution, it has been reported that carbonyl frequencies fell into a somewhat narrow range (1654~1687 $cm^{-1}$)[6].

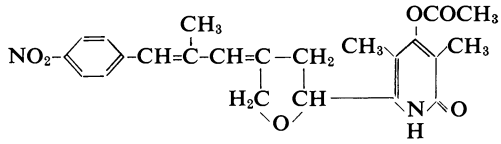
As to γ- pyridones, the data so far are not sufficient to obtain the detailed information about $\nu_{C=O}$; in general, $\nu_{C=O}$ is expected to appear in

4) One more possibilty, the diketo-form, is excluded on the ground of its relation to the ultraviolet spectrum.
5) (a) W. F. Cockburn and L. Marion, *Can. J. Chem.*, **29**, 13 (1951). (b) F. Ramirez and A. P. Paul, *J. Org. Chem.*, **19**, 183 (1954); *J. Am. Chem. Soc.*, **77**, 1035, 3377 (1955). (c) J. A. Gibson, W. Kynaston and A. S. Lindsey, *J. Chem. Soc.*, **1955**, 4340. (d) F. Bohlman, A. Englisch, N. Ottawa, H. Sander and W. Weise, *Chem. Ber.*, **89**, 792 (1956). (e) K. Hoegerle and H. Erlenmeyer, *Helv. Chim. Acta*, **39**, 1203 (1956). (f) R. H. Wiley and S. C. Slaymaker, *J. Am. Chem. Soc.*, **78**, 2393 (1956).
6) S. F. Mason, *J. Chem. Soc.*, **1957**, 4874.

the region 1630~1650 $cm^{-1}$ (solid and solution)[7]. According to Mason, the C=O band of the $\alpha$-pyridones is located at higher frequency than that of $\gamma$-isomers, whilst the reverse relation is observed regarding the N-H band[6]. Further, it was noticed[7d] that in $\alpha$-pyridones, the intensity of $\nu_{C=O}$ is usually stronger than that of $\nu_{C=C}$, whereas in $\gamma$-pyridones carbonyl absorption appears as a relatively weak band.



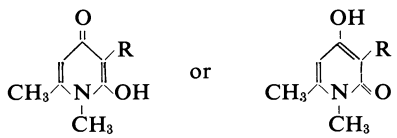
The following compounds may serve as good models of aza-desmethylisoaureothin (VI), in relation to the problem of tautomerism; 2, 4-dihydroxypyridine (IX)[6], 6-methyl-2, 4-dihydroxypyridine (X) and 2, 4-dihydroxyquinoline (XI)[6].



(IX) (X) (XI)

As to dihydroxypyridine (IX) it was believed that an $\alpha$-pyridone form was predominant in aqueous solution[8] on the ground of the ultraviolet evidence, while the possible coexistence of $\alpha, \gamma$-forms was suggested for IX in the solid state[9]. As for 6-methyl-2, 4-dihydroxypyridine (X), it is insufficiently soluble in chloroform to give an infrared spectrum in solution, but in the solid state (KBr), there appeared bands at 1658(s), 1639(s) and 1607(s) $cm^{-1}$ and a broad band near 3000 $cm^{-1}$ indicating a hydrogen bond. With the information about the diagnosis of $\alpha, \gamma$-tautomers at hand, it is concluded that the tautomer of $\alpha$-pyridone form occurs in X. An $\alpha$-pyridone structure was inferred[7d] for XI itself and its acetate, but not established firmly as yet.

With the help of the generalization described above, the structural examination of aza-desmethylisoaureothin (VI) will be made. The structure VIII is assigned to aza-desmethylisoaureonone acetate, the ozonisation product, on the basis of the position (1658 $cm^{-1}$) and the strong intensity of the pyridone carbonyl band. A strong band at 1762 $cm^{-1}$ in VIII is due to two carbonyls of enol acetate and five-membered ketone of tetrahydrofuran ring; two bands at 1640 and 1557 $cm^{-1}$ are ascribed to the unsaturation of the pyridone ring[10]. Establishment of VIII for the ozonisation product leads to structure VII for aza-desmethylisoaureothin acetate.



(VIII)

(VII)

The disagreement in the position of the carbonyl band of aza-desmethylisoaureothin (1643 $cm^{-1}$) with that of the model compound (X, 1658 $cm^{-1}$), taken in conjunction with the weak intensity in the former $\nu_{C=O}$, might be in favor of the $\gamma$-pyridone structure VIb for this derivative of the natural product. However, in aza-desmethylisoaureothin, the intermolecular (or intramolecular) interaction would be more complicated than in a simple molecule, and the overlappings of the bands due to benzene ring with those of the pyridone ring make it difficult to compare exactly the intensities between $\nu_{C=O}$ and $\nu_{C=C}$ in the pyridone ring. Such circumstances give rise to difficulty in making the discrimination between (Va) and Vb, solely on the basis of the infrared spectrum.

The unusual hypsochromic shift of the ultraviolet absorption maximum in alkaline solution was recognized as a characteristic feature of the hydroxypyridones (A), distinguishing the type (A) from other types of hydroxypyridone[11]. As is expected, the model compound IX behaves similarly (see Fig. 4).

(A): R=H or $C_2H_5$

A good paralellism of the ultraviolet spectra between the pyridone part of VI and the model X was observed, in regard to the magnitudes

Soc.*, **1958**, 467; (d) H. Shindo, "Infrared Absorption Spectrum Series No. 3" Nankodo, Tokyo, (1957), p. 186.

8) H. J. den Hertog and D. J. Buurman, *Rec. trav. chim.*, **75**, 257 (1956). Cf. H. M. Woodburn and M. Hellman, ibid.. **70**, 813 (1951).

9) There was recorded in the solid state, a pair of bands, 1661 and 1635 $cm^{-1}$ for IX (1662 and 1628 $cm^{-1}$ for (XI)), upon which the presumption of the coexistence of $\alpha, \gamma$-tautomers was based. Alternative interpretation of the spectrum, however, seems to be more reasonable; both IX and XI exist simply as an $\alpha$-pyridone form on the assumption that bands, 1635 and 1628 $cm^{-1}$ are respectively, associated with the unsaturated bonds of the ring.

10) The positions of bands associated with the unsaturated bonds of the ring are very sensitive to the substituents[5f]; therefore, these bands are not so useful for the identification of the pyridone ring.

(2): Acidic (0.1 N HCl) solution.
(3): Alkaline (0.1 N EtONa) solution.

of the hypsochromic shifts and of the relative intensities. It is inferred that α-pyridone form VIa predominates in aza-desmethylisoaureothin in solution, on the analogy of the preferential α-tautomer in the cases of the models IX and X. Furthermore, the absorption at 292 mμ due to the pyridone part of VI is regarded as a reasonable position of α-pyridone ring[12].

## Experimental

**Aza-aureothin (IV).**—One gram of aureothin was added in a mixture of ethanol (40 ml.) and aqueous ammonia (10 ml.), and the suspension was kept at 90~95°C in a sealed tube for 10~12 hr. Aureothin gradually dissolved with heating, and after several hours a small number of crystals began to appear. The solution on cooling to room temperature deposited yellow crystals, which were filtered and recrystallized from a large amount of ethanol, m. p. 230~231°C. No methoxyl group was detected by Zeisel's method; the ultraviolet spectrum was measured in neutral ethanol, by assuming 380 for its molecular weight: $\lambda_{max}$ 345 mμ (log ε 4.25), 290 mμ (log ε 4.15).

Found: C, 64.75; H, 5.68%.

A suspension of 20 mg. of aza-aureothin was heated in acetic anhydride (5 ml.) and pyridine (1 ml.) at 80~90°C for thirty minutes. Water was added, to give the yellow precipitate, easily soluble in chloroform and ethanol.

**Aza-isoaureothin (V).**—A suspension of 1 g. of isoaureothin in 50 ml. of ethanol-aqueous ammonia (4 : 1) was heated at 90~95°C in a sealed tube for 18 hr. Complete dissolution of isoaureothin was observed within the initial five hours, and then crystallization of V slowly began to take place. As the heating was continued, the solution became dark red. The product was collected and treated with 20 ml. of hot ethanol, in order to remove remaining isoaureothin. Recrystallization from a fairly large amount of dioxane gave 360 mg. of V in yellow prisms, m. p. 228~229°C. The ultraviolet spectrum was measured in neutral ethanol with the assumption of 380 of molecular weight: $\lambda_{max}$ 343 mμ (log ε 4.25), 253 mμ (log ε 4.25).

Found: C, 65.84, 65.62; H, 5.99, 5.97; N, 7.33%.

A mixture, which consisted of 20 mg. of V, 8 ml. of acetic anhydride and 1 ml. of pyridine, was heated at 80~90°C for 1 hr. to give a clear solution. Upon cooling, the yellow needles separated. These were identified as starting material V.

**Aza-desmethylisoaureothin (VI).**—Though aza-desmethylisoaureothin was obtained by a procedure similar to that used for the preparation of IV and V, an efficient method, starting from aureothin, was developed, to give an excellent yield of (VI). A suspension of 1 g. of aureothin in 10 ml. of acetic acid containing 3 g. of ammonium acetate was gently refluxed for 4 hr. To the cooled solution, 200 ml. of water was added, when a brown oily layer at once separated and solidified. The liquid layer was removed by decantation, and the residue turned to a crystalline substance by the addition of 50ml. of hot ethanol. Washed with hot ethanol three times, the product was recrystallized from dimethylformamide and weighed 250 mg., m. p. 238~239°C; ultraviolet spectrum: $\lambda_{max}$ 341 mμ (log ε 4.25), 296 mμ (log ε 4.16), 245 mμ (log ε 4.18) (ethanol as solvent).

Found: C, 65.76, 65.48; H, 5.95, 6.19; N, 7.63. Calcd. for $C_{21}H_{22}O_5N_2$: C, 65.95; H, 5.80; N, 7.33%.

To a solution of 1 ml. of pyridine and 5 ml. of acetic anhydride, 20 mg. of VI was suspended. The mixture became a clear solution when kept at 70~80°C for 30 min. Yellow precipitates were obtained from the cooled solution, by the addition of 20 ml. of water. They were recrystallized from ethanol whereupon yellow needles of VII with m. p. 211~213°C were obtained (15 mg.): ultraviolet spectrum: $\lambda_{max}$ 325 mμ (log ε 4.32), 238 mμ (log ε 4.30); infrared spectrum: 1767(v. s), 1652(s), 1610(m), 1591(s) and 1516(s)cm$^{-1}$ (KBr).

**Aza-desmethylisoaureonone Acetate (VIII).**—A solution of 350 mg. (0.83 m. mol.) of aza-desmethylisoaureothin acetate (VII) in 15 ml. of chloroform was cooled to −5~−10°C and ozone was passed through this solution, until about one equivalent amount (0.95 m. mol.) of ozone was absorbed. On removal of solvent under reduced pressure, a gummy residue was obtained, which was treated with 10 ml. of water in a flask provided by a reflux condenser at 60°C. The aqueous layer in the flask was separated from the solid residue by decantation and the aqueous fraction was distilled under reduced pressure to afford a slightly yellow residue, which on recrystallization from methanol, weighed 10 mg.

12) The ultraviolet technique is not necessarily reliable for the discrimination of α-pyridones from their γ-isomers, in spite of the fact that α-pyridone itself absorbs at a much higher wave length (297 mμ) than γ-isomer (256 mμ); the substitution of the ring often causes an outstanding change in the spectrum.

with m. p. 208~209°C. No volatile carbonyl compound could be detected by distilling the aqueous fraction into a 2, 4-dinitrophenylhydrazine solution. The solid residue, obtained from the decomposition of ozonide, consisted of two components; one was easily soluble in methanol, whereas the other was sparingly soluble. The former was identified as *p*-nitro-$\alpha$-methylcinnamaldehyde by its melting point and infrared spectrum. The latter, sparingly soluble in methanol, was recrystallized from methanol and gave 70 mg. of colorless needles, which turned out to be identical with the crystals obtained from the water soluble fraction, as described before. The total amount was 80 mg., m. p. 209~210°C; ultraviolet spectrum: $\lambda_{max}$ 304 m$\mu$ (log $\varepsilon$ 3.85), 233 m$\mu$ (log $\varepsilon$ 3.81).

Found: C, 58.76, 58.86; H, 5.84, 5.98; N, 5.66, 5.45. Calcd. for $C_{13}H_{15}O_5N$: C, 58.83; H, 5.70; N, 5.28%.

## Summary

Aureothin (I), isoaureothin (II, R=$CH_3$) and desmethylisoaureothin (II, R=H) reacted with ammonia in a somewhat drastic way, and gave aza-derivatives respectively, some properties of which are described. Of these, aza-desmethyl-isoaureothin was shown to be VI containing tautomeric $\alpha, \gamma$-dihydroxypridine, on a basis of chemical and spectroscopic evidence.

The authors are indebted to Dr. Koichi Iwadare, Banyu Pharmaceutical Co. for his generous supply of aureothin used in this research, and to Mr. Takayuki Naito, Banyu Pharmaceutical Co., and Mr. Kunio Okuhara, Government Industrial Research Institute of Nagoya, for their helpful discussion throughout this work. The authors also wish to thank the Ministry of Education for a grant-in-aid.

# *The Structure of Aureothin. XI*[1]. *On the Structure of Some of the Isoaureothin Derivatives*

By Kiyoyuki YAMADA, Takayuki NAITO, Kunio OKUHARA, Hisao NAKATA and Yoshimasa HIRATA

(Received April 2, 1960)

Among many derivatives obtained from isoaureothin (I)[2], there are several, the structures of which has not yet been disclosed. These derivatives, owing to their unexpected behavior, made the investigation of isoaureothin rather complicated. In this paper, the structures of these derivatives are put forward. They are well related to isoaureothin (I) and, of course account for all their properties. Further, the aspect of these reactions is briefly discussed. Of these derivatives, some descriptions were already made as to the nature of the products obtained by complex metal hydride reduction[3].

## On the Structures of Aminol Compounds

*Structure of Aminol H (IIIa).*—The reduction of the nitro group in isoaureothin (I) by ferrous hydroxide afforded a corresponding amino derivative $C_{22}H_{25}O_4N$ (IIa), which in turn was treated with lithium borohydride in tetrahydrofuran to give an acidic compound named "aminol H", $C_{22}H_{27}O_4N$[3]. As regards the acidic nature of aminol H, the infrared evidence (broad band at 2600~2700 $cm^{-1}$ in aminol H: bands at 1795, 1712 $cm^{-1}$ in *N, O*-diacetyl aminol H (IIId)), coupled with the result of the methoxyl analysis[4], showed that it might be due to a carboxyl group. *p*-Bromophenacyl ester of aminol H (m. p. 85~87°C) was obtained. Taking account of the fact that aminol H is optically active and has two more hydrogen atoms than isoaureothamine (IIa), it seems reasonable to deduce the occurrence of the hydrogenolytic cleavage in $\alpha$-pyrone ring,

4) Aminol H (IIIa) contains one methoxyl group, whereas two such groups present in the methylated product, *O*-methyl aminol H (IIIc).

Chart 1. Derivatives of isoaureothin.

Table I. Yield of methyl pyruvate

| Compound | Sample mg. | $CH_3COCOOCH_3$[a] mg. | Equiv. mol. |
|---|---|---|---|
| Isoaureothin (I) | 940 | 130 | 0.19 |
| *N*-Acetyl isoaureothamine (IIb) | 300 | 40 | 0.21 |
| *N*-Benzoyl tetrahydroisoaureothamine (V) | 470 | 32 | 0.15 |
| *N*-Acetyl aminol H (IIIb) | 250 | 38 | 0.22 |
| *N*-Benzoyl tetrahydroaminol H (VI)[b] | 620 | 80 | 0.22 |
| *N*-Acetyl *O*-methyl aminol H (IIIe) | 450 | 311 | 1.05 |

a) Determined as 2,4-dinitrophenylhydrazone.
b) Crude sample (m. p. 78~83°C) was used without recrystallisation.

to produce a carboxyl group[5]. The various properties previously described[3] (infrared and ultraviolet spectra etc.), thus can best be accounted for by assigning the structure IIIa to aminol H. Furthermore, the following experiment supports the correctness of formula IIIa; ozonisation of compounds belonging to the isoaureothin- and aminol-series always afforded methyl pyruvate, the yield of which in each case is listed in Table I. An essentially equal amount of methyl pyruvate (ca., 0.2 equivalent mole) was produced in every case[6], except the largely enhanced amount (1.05 equivalent moles) in the case of *N*-acetyl *O*-methyl aminol H (IIIe). Therefore, in *N*-acetyl *O*-methyl aminol H (IIIe), it becomes evident that there exist in one molecule two such units, from which methyl pyruvate is formed: in addition, one of such units should originate from the newly formed carbomethoxyl group by complex metal hydride reduction and subsequent methylation (cf. methoxyl analysis[4]).

*Structure of N-Acetyl Aminol A (IVa).*—Reduction of *N*-acetyl *O*-methyl aminol H (IIIe) with lithium aluminum hydride gave a neutral product, *N*-acetyl aminol A, $C_{23}H_{28}O_3N$ in poor yield[3]; no other crystalline products than this were isolated. Elemental and methoxyl analysis showed, during the reduction of IIIe, the occurrence of unusual hydrogenolysis of methoxyl group (enol ether), originally present in isoaureothin (I), in addition to the expected transformation of the ester group into alcohol.

*Aspect of Complex Metal Hydride Reduction.*—As described above, plausible structural assignments were made to the reduction products, aminol H (IIIa) and *N*-acetyl aminol A (IVa), on a basis of their chemical and spectroscopic properties. These would, at first sight, be regarded as unusual reduction products.

In the case of aminol H, however, it is expected that $\alpha$-pyrone shows peculiar reactivity far different from that of lactone toward hydride reagents, owing to the high conjugation of $\alpha$-pyrone and a possible effect of substituents of the ring. So far, very little is known about the reduction of $\alpha$- and $\gamma$-pyrones with various complex metal hydrides, except for limited examples of xanthone[7], benzo-$\alpha$-[8] and benzo-$\gamma$-pyrones[9], where not unexpected results were recorded. In contrast to the reduction of such benzopyrones, a situation, however, would be unique in the case of pyrones if no aromatic ring was fused to them. Investigation on the reactivity of pyrones toward complex metal hydrides is desirable.

Of particular interest is a hydrogenolytic cleavage of enol-ether (methoxyl group), during the formation of *N*-acetyl aminol A (IVa). In general, enol ethers are inert to complex metal hydride reduction[10], and so is a $\beta$-alkoxy-$\alpha$, $\beta$-unsaturated ester[11]. An exception[12] was reported; reduction of dihydrocorynantheine (A) with lithium aluminum hydride led to demethoxylated products B and C. Sarett and his coworkers reported a similar exception[13], found in $\beta$-alkoxy-$\alpha$, $\beta$-unsaturated

5) On catalytic hydrogenation, aminol H absorbed quantitatively two moles of hydrogen, with which the double bonds conjugated with aminophenyl group were saturated[3]. From this result, it is tempting to consider the possibility of the existence of an $\alpha$-pyrone ring in aminol H. However, this view is untenable on the ground that a band near 1575 $cm^{-1}$, characteristic of $\alpha$-pyrone, is absent in all of the aminol compounds studied.

6) Ozonisation was carried out repeatedly, in order to ascertain the reproducible yield of methyl pyruvate in each case.

ketone (D), which afforded product E lacking in alkoxyl group. Such an apparent anomaly

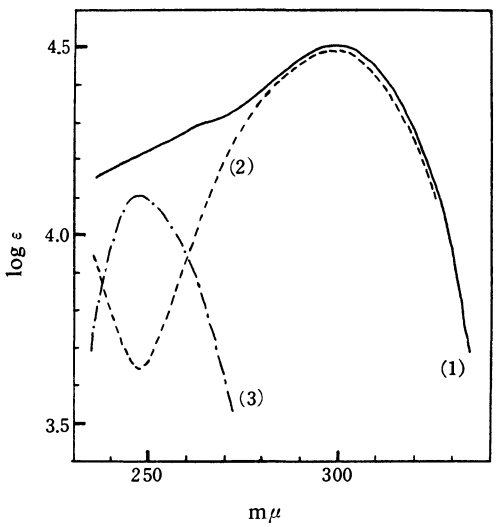
of $\beta$-alkoxyl group in $\alpha$, $\beta$-unsaturated carbonyl system, encountered in the exceptions, can be interpreted in terms of vinylogy in reaction (see F); since $\beta$-carbon is regarded as a vinylogous position of carbonyl carbon, the reactivity of two methoxyl groups would be expected to be comparable.

Therefore, the mode of attack of the hydride reagent would be possible in two directions, as indicated by arrows in F, to give a normal product F1 and/or anomalous product F2. The subtle difference of the reactivity between two such positions would be influenced by structural variations and experimental conditions, neither of which, however, have yet been examined systematically.

## Structure of "Lactol"

*Property of Lactol (VIII).* — *N*-Acetyl isoaureothamine (IIb) was converted to Lactol $C_{24}H_{29}O_6N$ (VIII), by the action of aqueous alkali[14]. The product, Lactol, is soluble in alkali and optically inactive, while the starting material IIb shows remarkable optical activity, $[\alpha]_D^{28°}$ +140°.

The ultraviolet spectrum of Lactol shows the absence of $\alpha$-pyrone chromophore (Fig. 1); the subtraction of ultraviolet spectrum of conjugated *p*-acetylaminophenyl group from that of Lactol gives a curve, which shows its maximum near 248 m$\mu$ and should correspond to that of $\alpha$-pyrone ring ($\lambda_{max}$ 295 m$\mu$) of *N*-acetyl isoaureothamine (IIb). This outstanding hypsochromic shift, observed in the transformation of IIb to Lactol proves the destruction of $\alpha$-pyrone chromophore in the latter[15]. There were observed bands at 1708(sh.), 1675 (s), 1645(s), 1599(s), 1530(s) and 1516(s)cm$^{-1}$ in the 1800~1500cm$^{-1}$ range of the infrared spectrum (KBr). The presence of a hydroxyl



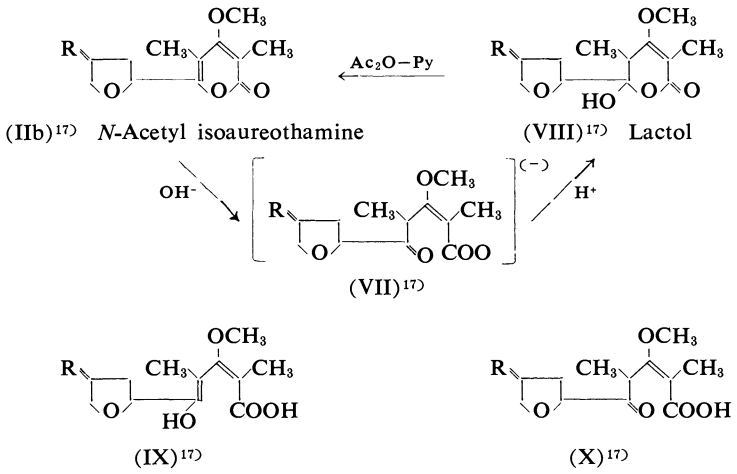


Fig. 1. Ultraviolet spectra (in ethanol)
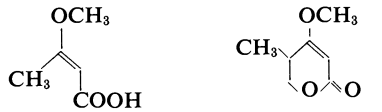
(1): Lactol
(2): $CH_3CONH-C_6H_4-CH=C(CH_3)-CH=CH-CH(CH_3)-OH$
(3): Subtraction curve, (1) — (2)

group in Lactol was detected from a broad band near 3200 cm$^{-1}$ and a band at 1150 cm$^{-1}$. Lactol was neutralized by sodium hydroxide[16], to afford its sodium salt with bands located at 1717, 1672, 1640, 1595(s. and br.), 1530 and 1510 cm$^{-1}$ (KBr). In order to clarify the nature of this hydroxyl group, acetylation with pyridine-acetic anhydride was carried out; an unexpected product, racemic *N*-acetyl isoaureothamine (IIb) was obtained. Methylation

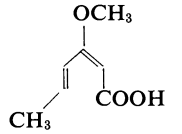
14) In the same treatment of isoaureothin (I) and isoaureothamine (IIa), amorphous products were obtained showing properties similar to that of Lactol.
15) This view was also supported by the lack of the characteristic band of $\alpha$-pyrone at 1575 cm$^{-1}$ in Lactol.
16) The addition of excessive sodium hydroxide did not significantly after the infrared spectrum of the salt.



(IIb)[17] *N*-Acetyl isoaureothamine (VIII)[17] Lactol

(VII)[17]

(IX)[17] (X)[17]



with diazomethane brought out the same result obtained in acetylation. In spite of careful scrutiny of the reaction products, no methylated substance was obtained in crystalline state. Since the formation of sodium salt suggests an acidic nature of Lactol, measurement of acidity constant ($pK_a$) by titration method was undertaken. No consumption of alkali by sample was observed below pH 10.5, implying the absence or masked state of carboxyl group under the conditions studied.

*Structure of Lactol.*—By comparison of the molecular formula between Lactol $C_{24}H_{29}O_6N$ and *N*-acetyl isoaureothamine $C_{24}H_{27}O_5N$, it is at once evident that hydrolysis of $\alpha$-pyrone took place, leading to a product soluble in alkali. Since alcoholic part formed is an enol, it would exist enolate under strongly alkaline condition. Assuming the anion in alkaline solution to be expressed approximately as VII, disappearance of optical activity would naturally result. Examination of the properties of Lactol secures structure VIII for this product and excludes another possibility such as tautomeric $\alpha,\beta$-$\gamma,\delta$-unsaturated carboxylic acid IX and $\alpha,\beta$-unsaturated ketocarboxylic acid X. Thinking of the result on the titration of Lactol, carboxylic acid structures are clearly ruled out and the structure VIII is assigned to Lactol in solution. The use of ultraviolet spectrum is not reliable for the discrimination between lactol structure (VIII) and carboxylic acid structure X[18]; an absorption maximum in question is located near 245 m$\mu$ (Fig. 1), which would be reasonable both for Lactol (VIII) and $\alpha,\beta$-unsaturated carboxylic acid (IX), considering the spectra of models G[19] and H[20].

$\lambda_{max}$ 234 m$\mu$ (G) $\lambda_{max}$ 234 m$\mu$ (H)

From the position and the shape of hydroxyl stretching vibration which appeared in 3000 $cm^{-1}$ region of the infrared spectrum, it becomes highly probable that there is no hydroxyl group of carboxylic nature. There was observed a band at 1708 $cm^{-1}$, the overlapping of which with a strong amide I band (1675 $cm^{-1}$) rendered the former to be a shoulder band of the latter. Utilizing this shoulder band, in conjunction with bands which appeared in sodium salt, it is possible to discriminate a structure VIII from IX and X. First, form IX is taken into account. Considering the infrared spectrum of model J, >C=O vibration of IX is expected to occur near 1660 $cm^{-1}$, which is not an actual case (band observed is at 1708 $cm^{-1}$).

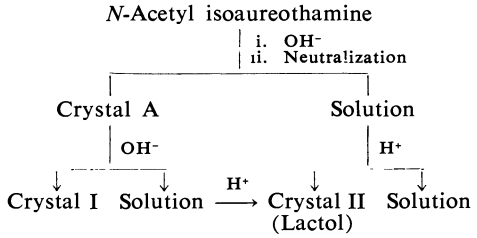
$\nu_{C=O}$: 1665 $cm^{-1}$ (J)

Secondly, if Lactol took form X, it should, in addition to a band due to carboxylic acid, exhibit a band of isolated ketone at 1717 $cm^{-1}$ (observed in sodium salt), which is absent in Lactol itself. Carboxylic acid structures are, in any event, inconsistent with the observation about $\nu_{O-H}$ region as described before.

Structure VIII can, in every respect, be re-

17) R=*p*-acetylamino-$\alpha$-methyl cinnamylidene.
18) The possibility of IX is clearly excluded, since this should show an absorption at much longer wavelengths.
19) K. Bowden, E. A. Braude and E. R. H. Jones, *J. Chem. Soc.*, **1946**, 948.
20) E. R. H. Jones and M. C. Whiting, ibid., **1949**, 1419.

conciled with the infrared spectra of Lactol and of its sodium salt. Looking upon $\alpha,\beta$-unsaturated lactone ($\nu_{C=O}$: 1717~1730 $cm^{-1}$) as the fundamental system, the structure VIII is constructed by attaching hydroxyl and methoxyl group to the fundamental system. These two substituents, in this case, cause opposite effects on the position of carbonyl absorption in the $\alpha,\beta$-unsaturated ester system; i. e., carbonyl frequency tends to be lowered by the mesomeric effect due to the methoxyl group and to be raised by the inductive effect of the hydroxyl group. A slight lowering of carbonyl frequency would be expected as a net result, according to the estimation of two such effects based on the data[21] so far available. Thus, it is reasonable to ascribe a band at 1708 $cm^{-1}$ to the lactonic carbonyl group in structure VIII. Furthermore, the appearance of a band at 1717 $cm^{-1}$ in sodium salt is quite consonant with structure VIII.



Chemical and spectral evidence now substantiates lactol structure VIII and rules out other possibilities, both in solution and solid state.

## Experimental

**Ozonization of Isoaureothin Derivatives.** — In order to estimate the amount of methyl pyruvate produced by ozonization, the following procedure was applied in each run. Through a solution of ca. 500 mg. of sample in 10~15 ml. of chloroform, ozone was passed at −5~−10°C, until the uptake of ozone by sample ceased. On removal of the solvent at reduced pressure, a viscous syrup was obtained which was then treated at 60°C with 10~15 ml. of water in a flask equipped with a condenser. The aqueous fraction was separated, and a solution of 2,4-dinitrophenylhydrazine in 2 N hydrochloric acid was added to it. The crude hydrazone was collected, dried, dissolved in benzene and chromatographed on alumina. 2,4-Dinitrophenylhydrazone of methyl pyruvate, eluted with benzene-ether was collected and weighed, m. p. above 140°C, m. p. 145~147°C after recrystallization from benzene. Formaldehyde was also detected in every sample, except in the cases of *N*-acetyl aminol H (IIIb) and *N*-acetyl *O*-methyl aminol H (IIIe).

**Lactol (VIII).** — To a mixture of 110 ml. of ethanol and 55 ml. of 3 N aqueous sodium hydroxide, 2 g. of *N*-acetyl isoaureothamine was added. The flask was equipped with a reflux condenser and the suspension was warmed on a water bath at about 80°C for ten min., when the mixture became clear and of an orange color. After rapid cooling, the solution was neutralized with dilute hydrochloric acid; the solution turned yellow immediately at the neutralization point (pH 7). The solution was concentrated to 50 ml. under reduced pressure to yield fine crystals ("crystal A"). The yellow filtrate from "crystal A" was acidified gradually with dilute hydrochloric acid and the resultant precipitates (in part oily material) were collected and recrystallized from ethanol to yield almost colorless needles ("crystal II"), named Lactol, m. p. 170~171°C, 500 mg. When "crystal A" was dissolved in aqueous sodium hydroxide solution, a small part was insoluble in alkali. The alkali-insoluble crystals ("crystal I") were collected and recrystallized from ethanol repeatedly, m. p. 223~225°C. 40 mg.

The filtrate from "crystal I" was acidified and the resulting crystals were identified as "crystal II"; yield 250 mg., combined amount of "crystal II", 750 mg. The ultraviolet spectrum of "crystal II" showed $\lambda_{max}$ 299 m$\mu$ (log $\varepsilon$ 4.52) (in ethanol). $[\alpha]_D^{27}$, 0±1.5° (methanol, c=0.75). Titration was carried out in 66% aqueous ethanol solution.

Analysis was carried out on "crystal II" (Lactol):
Found: C, 67.06; H, 7.19; N, 3.63. Calcd. for $C_{24}H_{29}O_6N$: C, 67.43; H, 6.84; N, 3.28%.

**Action of Diazomethane on Lactol.**—Crystalline Lactol was added to ethereal diazomethane, but no reaction took place under the heterogeneous condition and the starting material was recovered. To 20 ml. of ethereal diazomethane was added 100 mg. of Lactol, dissolved in 20 ml. of methanol and the mixture was allowed to stand overnight. After removal of about two-thirds of the volume of solvent at reduced pressure, the precipitated crystals were filtered and recrystallized from ethanol to give colorless needles, m. p. 191~193°C, 25 mg., $[\alpha]_D^{28}$, 0±2° (c=0.8 in a mixture of chloroform and methanol (1:2)). The infrared spectrum taken in solid state (KBr) was identical with that of *N*-acetyl isoaureothamine (m. p. 209~211°C; $[\alpha]_D^{28}$ +140 ±1.5° in a mixture of chloroform and methanol (1:2)), the starting material of Lactol. Mixing two species of *N*-acetyl isoaureothamine (optical active and inactive species), no depression of the melting point was observed; mixted melting point, 193~200°C. Further concentration of filtrate gave a small amount of oily material, the infrared spectrum of which included bands at 1701(sh), 1690(s), 1606(m), 1592(m) and 1512(s) $cm^{-1}$ (in chloroform). The main portion of the product might be an ester.

21) Literatures for the estimation of mesomeric effect of methoxyl group; (a) R. N. Jones and F. Herling, *J. Org. Chem.*, **19**, 1252 (1954); (b) R. S. Rasmussen and R. R. Brattain, *J. Am. Chem. Soc.*, **71**, 1073 (1949); (c) H. Heyman, S. S. Bhatnagar and L. F. Fieser, ibid., **76**, 3689 (1954).
Literatures as to inductive effect of hydroxyl (and alkoxyl) group: (d) R. B. Woodward and E. G. Kovach, *J. Am. Chem. Soc.*, **72**, 1009 (1950); (e) J. F. Grove and G. A. Willis, *J. Chem. Soc.*, **1951**, 877; (f) J. F. Grove ibid., **1952**, 3345; (g) L. A. Duncanson, J. F. Grove and J. Zealley, ibid., **1953**, 1331, 3637.

**Action of Acetic Anhydride on Lactol.**—To a mixture of 1 ml. of pyridine and 5 ml. of acetic anhydride was added 50 mg. of Lactol. It was kept at 70°C for ten minutes and after cooling, water was added to the solution, the resultant crystals were collected, recrystallized from ethanol and identified as the starting material, Lactol. Again, the same procedure was applied with prolonged heating (one hour); the resultant crystals, differing from Lactol, were recrystallized from ethanol and were identified as *N*-acetyl isoaureothamine by the comparison of the infrared spectra, m.p. 193~194°C.

Found: C, 70.59; H, 6.50. Calcd. for $C_{24}H_{27}O_5N$: C, 70.40; H, 6.50%.

All melting points were uncorrected. The ultraviolet spectra were measured with a Hitachi spectrophotometer and the infrared spectra with a Hilger H 800 spectrometer, equipped with rock-salt prisms. The optical rotations were measured with a Rudolf polarimeter.

## Summary

During the course of the investigation of isoaureothin (I), several derivatives were obtained, the structure of which still remains unknown. The structure of these derivatives is presented in this paper on a basis of spectral and chemical evidence. The reduction of isoaureothamine (IIa) with lithium borohydride yielded an unexpected acidic substance, aminol H (IIIa) the formation of which, taken in conjunction with that of *N*-acetyl aminol A (IVa), provides an unusual type of reduction by complex metal hydride. Treatment of *N*-acetyl isoaureothamine (IIb) with alkali yielded an optically inactive substance, Lactol, which was formulated as VIII. The action of acetic anhydride on Lactol resulted in the formation of racemate of *N*-acetyl isoaureothamine (IIb).

## *NMR Spectra of the Metabolites of Monascus. I. NMR Spectra of Several Authentic Pyrones**

By Akira TERAHARA, Mamoru OHASHI, Koji NAKANISHI, Ichiro YAMAGUCHI and Naohiro HAYAKAWA

(Received July 15, 1960)

As with the C–2 and C–5 protons of furans[1] it may be expected that the protons alpha to the pyronoid oxygen will absorb at characteristically low frequencies and thus assist in the identification of the substitution pattern, which is not so facile by other physico-chemical methods. A Varian model V-4300 spectrometer was employedat 56.4 Mc; the band separations were estimated from the toluene peaks and chloroform was used as internal reference. The measurements were carried out in 10~20 percent solutions of 1 : 1 mixtures of chloroform and carbon tetrachloride. The results are summarized in Table I[2]. It can be seen qualitatively that the $\alpha$-protons of both $\alpha$- and $\gamma$-pyrones absorb at lower fields than the chloroform proton, and that they can be clearly differentiated from the other unsaturated protons. The coupling constant of the $\alpha$- and $\beta$-protons, ca. 6 cps, is larger than the 1.3 cps value reported for furans[3]. The C–2 and C–6 methyl groups absorb in the range of 280~300 cps (II, III and VII). One of the nuclear protons of the extended pyronoid compound VII had its peak at an exceptionally low field, and this interesting phenomenon is presumably caused by the strong long range shielding effect of the nearby nitrile group. It is to be noted that this shift is opposite to that encountered in the well-known acetylenic protons[4] and this can be attributed to the directional difference of the triple bond[5]. Citrinin has been chosen

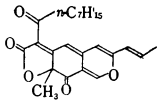
## *NMR Spectra of the Metabolites of Monascus. II. Monascorubrin**



Mamoru OHASHI, Akira TERAHARA and Koji NAKANISHI

(Received July 15, 1960)

Structures I[1] and II[2] have been tentatively proposed for monascorubrin[3], $C_{23}H_{26}O_5$, the orange pigment produced by *Monascus purpureus Wentii*. The NMR spectra of monascorubrin and dihydromonascorubrin have been measured in order to check the gross character of this complicated pigment, and if possible to differentiate between the two structures.

(I)

(II)

The measurements were carried out with a Varian V-4300 High Resolution Spectrometer operating at 40 Mc; chloroform was chosen as the inner reference and the band positions were read by the side-band method. It is seen in Fig. 1 that instead of the doublet "d" and "e" (propenyl methyl) and multiplet around "g", the spectrum of the dihydro-compound (Fig. 2) shows a triplet "j" which corresponds to the $\alpha$-methylene of the propyl chain. Signals "a" and "b" are due to the *n*-alkyl chain and "c" arises from an uncoupled methyl group. Signal "i" corresponds in position to a proton adjacent to the pyronoid oxygen[4] and this is supported by chemical evidence[1]. The other two low-field signals, "g" and "h", undoubtedly arise from the remaining two nuclear protons. The shape and intensity of signal "f" is similar to "j" which has been assigned to a methylene group, and therefore in structure II it could be correlated with the $-CH_2CO-$ protons of the $n$-$C_7H_{15}CO-$ side-chain. On the other hand, in structure I the $-CH_2CO-$protons belong to the ABX type and thus a complicated pattern would be expected. The signal for the bridgehead proton of the ethereal ring in I can not be detected in the expected 100~200 cps region, but this could be due to extensive coupling with adjacent protons. The coupling of signals "h" and "i" (ca. 1.2 cps) presumably correspond to that observed between meta-oriented protons on benzene nuclei[5]. Thus, although no clear-cut differentiation between structures I and II is possible, the present measurements appear to be slightly in favor for the latter; however, chemical and ultraviolet spectroscopic evidence can be accounted for more smoothly

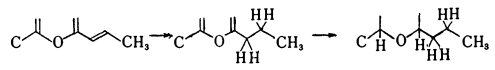
## *NMR Spectra of the Metabolites of Monascus. III. Monascoflavin and Reduction Products**

Mamoru OHASHI, Akira TERAHARA, Koji NAKANISHI, Ichiro YAMAGUCHI and Naohiro HAYAKAWA



(Received July 15, 1960)

The structure of monascoflavin[1], $C_{21}H_{26}O_5$, m. p. 143°C, the yellow metabolite of *Monascus purpureus Wentii* has still not been elucidated. Its chemical properties showed that it was related to γ-pyrones[2], and the close relationship with monascorubrin has also been suggested[3]; structure I was provisionally proposed in 1959 as

(I)

a working hypothesis[4]. The NMR spectra of I, dihydro-I, hexahydro-I, and octahydro-I[5] have been measured with a Varian V-4300 model Spectrometer at 56.4 Mc, in order to correlate the chemical transformations with appropriate changes in the spectra (Figs. 1—4) and thus gain an insight into its structure. Chloroform was employed as an inner reference, and toluene was used for calculating line separation. Unlike monascorubrin[6], the present monascoflavin showed no peak in the −30 cps region corresponding to the α-hydrogen of γ-pyrones[7]. Instead of the "d" doublet ($J$: 6 cps, area for three protons) and the weak "k" multiplet in Fig. 1, the spectrum of II revealed a triplet "1" ($J$: 8 cps); this can be ascribed to the hydrogenation of the propenyl side-chain. The "a" and "b" peaks arise from the methyl and methylene groups, respectively, of the *n*-$C_5H_{11}$ side-chain. The peaks at "c" is due to an uncoupled methyl group, and peaks "i" and "j" (Figs. 1 and 2) suggest that three protons attached to an unsaturated system are present besides the propenyl group. In Fig. 3, only a diffuse absorption "i" is left in this region; instead there appears two ill-defined peaks "m" and "n" which could be assigned to protons attached to α-carbons of an ethereal linkage. The hydrogenation stages can be represented by the following scheme:

(I) (II) (III)

Peaks "g" and "h" seem to originate from the γ-methylene of γ-lactone ring[8]; however, the coupling is not clear. The quadraplet "i" (Figs. 1 and 2) seems to arise from an AB type of coupling ($J$: 10 cps) and is absent in Fig. 3. Although it is apparent that the quadraplet is

due to protons on an unsaturated system, it is questionable that any two protons shown in the partial structure IV should couple so extensively.

(IV)

(V)

Structure V appears to be more appropriate to account for the coupling but this, in turn, can not be reconciled with ultraviolet spectral data[4]. Model compounds are being synthesized in order to check this point further. Peak "e" is presumably due to the $-COCH_2-$ protons but the reason that it is not split into a triplet is not clear. The diffuse "f" signal could arise from the bridgehead proton(s) of the $\beta$-keto-$\gamma$-lactone moiety.

## *On the Unusual Premelting Phenomenon of Potassium Thiocyanate Crystal*

By Takako SHINODA, Hiroshi SUGA and Syûzô SEKI

(Received July 30, 1960)

Recently, Ubbelohde et al.[1] have published a series of papers on the unusual premelting effect of potassium thiocyanate crystal and concluded the rapid homophase increase of lattice defects as the melting point is approached. Quite independently,we have studied the transition phenomenon of this crystal in relation to that found in ammonium thiocyanate[2]. During the course of the differential thermal analysis of potassium thiocyanate we can not detect any such a tendency of premelting found by them, so we have reexamined the existence of the effect by use of the methods of dilatometric and d. c. conductivity measurements.

The sample (special grade, Wakō Pharmaceutical Co.) used were purified three times by fractional recrystallization from aqueous solution and then dried at 150°C under high vacuum ($10^{-5}$ mmHg) for several hours after packing the sample in the glass-made dilatometer. Mercury was employed as a confining liquid, since it was confirmed that the mercury did not react with the sample even above the melting point. The results obtained are shown in Fig. 1 and in Table I in which the data by Ubbelohde and others are also given for comparison. For the d. c. conductivity measurement the specimen purified in the same way

as mentioned above was used in the shape of disk tablet (weight : 100 mg. ; diameter : 13 mm. ; thickness : 1 mm.). The conductivity versus $1/T$ relationships and empirical equations derived are shown in Fig. 2 together with the results by Ubbelohde et al.

From the results of our dilatometric study it is found that the volume changes abruptly at the melting point with almost no hysteresis effect in the cooling direction, standing in remarkable contrast to the case by Ubbelohde et al., and that our data are in good harmony with the thermal expansion determined with the X-ray method by Yamada et al[3]. who kindly measured the temperature dependence of the unit cell dimensions in accordance with our request. The fact that we obtained much larger activation energy ($\sim$35 kcal./mol.) for the d. c. conductivity at lower temperature region seems to indicate that our sample involves less impurities and is also in parallel with the dilatometric data. Detailed descriptions of the experimental procedures and discussion will be published in due course.

## *Isotopic Exchange of Gallium between the Gallium(III) Ion and its Ethylenediamine-N, N, N', N'-tetraacetate and N-2-Hydroxyethylethylenediamine-N, N', N'-triacetate in an Aqueous Solution*

By Kazuo Saito and Michiko Tsuchimoto (née Tamura)

(Received July 11, 1960)

As an extention of the present authors' study of the isotopic exchange of metal chelate compounds having $d^{10}$ structure[1,2], they have examined the kinetics of exchange of gallium between the gallium(III) ion and its ethylenediamine-*N*, *N*, *N'*, *N'*-tetraacetate (EDTA) and *N*-2-hydroxyethylethylenediamine-*N*, *N'*, *N'*-triacetate (EDTA-OH) in water by the use of gallium-67. The radioisotope was produced by the irradiation of zinc with $\alpha$-particles in a cyclotron and the $\gamma$-activity was measured with a scintillation counter having a sodium iodide crystal as scintillator. A gallium nitrate solution of a given pH was mixed with radioactive gallium EDTA or EDTA-OH complex solution of the same pH value and a part of the gallium ion was precipitated with 8-quinolinol at a certain lapse of time. The precipitate was filtered off, with a sintered glass filter plate, washed, dried, weighed and submitted to $\gamma$-ray counting.

The result is quite different from that for the corresponding exchange of indium[2]. The rate is very small in a neutral or an acid solution of pH more than 2, and is very great in a basic medium. In the pH range from 7 to 9, the exchange proceeds at a measurable rate. Since the exchange constant $R$ expressed according to McKay's formula[3] is proportional to the concentration of the chelate $b$ and is independent of that of the gallium ion $a$, the rate constant $k$ is shown as $R/b$. Dependence of $R$ upon various factors is shown in the Table together with other constants of the reaction. It is rather marked that the energy of activation $E_A$ is very great as compared with that for the exchange of indium in an acid solution (10 kcal. per mol.). The present authors tend to suggest that the attack of the hydroxyl ion upon the central gallium in the co-ordination compound might play an important role in determining the exchange rate. Detail of the result and discussion on the reaction mechanism will be published later.

Table. Dependence of $R$ upon various factors and some constants for the exchange in an aqueous solution of pH 7 to 9

| | Ga-EDTA-OH | Ga-EDTA |
|---|---|---|
| $[OH^-]$ | Proportional | Proportional |
| $[a]$ | Independent | Independent |

## *The Polymerization of α-Methylstyrene by Iodine Catalyst*

By Kozo HIROTA, Gisuke MESHITSUKA*, Fukuo TAKEMURA and Tatsuto TANAKA

(Received May 19, 1960)

Although it is well known that iodine is an inhibitor for radical polymerization, its power of polymerizing some vinyl monomers has been reported by several investigators[1-4]. We have also found that iodine plays a role as an initiator for the polymerization of α-methylstyrene (αMS) at room temperature. Since it seems interesting that the reaction proceeds under the presence of lower concentration of iodine (0.1~0.3%) as compared with the case of polymerization of styrene by iodine (10~20%) recently reported[4], preliminary results are reported as follows.

It was found that the reaction proceeded even in the atmosphere but reproducible results were not obtained. The sample, therefore, was dehydrated in vacuo with metallic sodium or calcium hydride and was distilled into a reaction vessel without exposing to the air. The extent of polymerization of the monomer for a week reached maximum when the concentration of iodine added was ca. 0.1~0.3%. When more iodine than 1% was added to the monomer, the temperature of the reactant rose markedly high, as soon as iodine was allowed to contact wiih the monomer. In such cases the reactant became very viscous but the high polymers could not be obtained.

In Fig. 1, the yield of polymer for the reaction at 25°C vs. time are plotted. All the samples were enclosed at the same time and polymerized for different intervals of time, and the polymers were precipitated with excess of methanol. It is shown that the initial rate of polymerization in higher concentration of iodine (0.2%) is larger than that in lower one (0.1%), but in the former case the conversion did not become more than about 25%, while it increased up to more than 50% for an interval of 160 hr. in the latter case.

The color of iodine disappeared in both cases after a long period of reaction. The

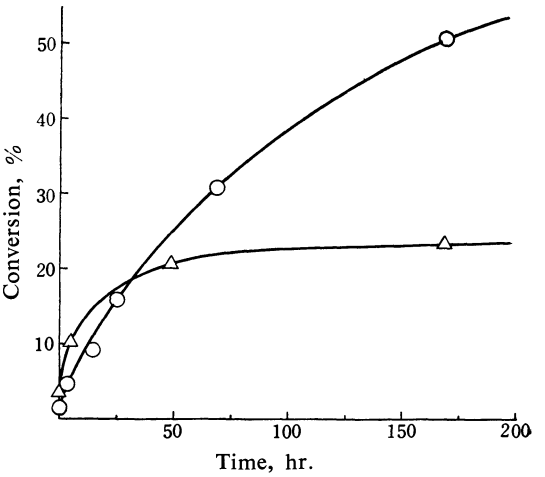

Fig. 1. Conversion of αMS vs. time.
Concn. of iodine: ○ 0.1%; △ 0.2%.

intrinsic viscosity of the polymers was independent of the time of polymerization, i. e., ca. 0.1** dl./g. and slightly larger in the case of lower concentration of iodine.

It is clear from the inhibitory power of iodine for polymerization by free radical mechanisms that this polymerization must be of non-radical and presumably of ionic character. It may be natural to assume that this reaction proceeds by a cationic mechanism as concluded in the polymerization of vinyloctylether[2] and of styrene[4] by iodine in view of the following experimental fact:—The polymer which is obtained from the mixture of αMS and methyl methacrylate (1 : 1 in volume ratio) in the presence of iodine showed essentially the same infrared absorption spectra as that of the polymer obtained from the similar mixture by stannic chloride.

Details of the experiment will be published in *J. Chem. Soc. Japan, Pure Chem. Sec. (Nippon Kagaku Zasshi)*.

## *Crystal Structure and Thermodynamical Investigations of Triethylenediamine, $C_6H_{12}N_2$*

By Tadayoshi WADA*, Etsuko KISHIDA, Yujiro TOMIIE, Hiroshi SUGA, Syûzô SEKI and Isamu NITTA

(Received August 11, 1960)

Triethylenediamine, or 1, 4-diazabicyclo-(2, 2, 2)-octane, is considered to be a typical globular cage molecule with high symmetry. In order to amplify our knowledge on the thermal behavior of molecules in crystals, we have studied the crystal structure and some thermodynamical properties of this material.

The sample used for the present research was kindly offered us by Dr. Oae and by Houdry Process Corporation, Pa., U. S. A.

Small single crystals for the X-ray investigation, obtained from a saturated ethereal solution, were kept in glass capillaries to avoid humidity since the material has strong tendency of forming monohydrate. Useful X-ray data were obtained from Weissenberg photographs around $a$ and $c$ axes respectively taken with Ni-filtered Cu $K_\alpha$ radiation. The crystallographic data are: hexagonal system; $a=6.20 \pm 0.01$, $c=9.58 \pm 0.02$ Å; $Z=2$; $D_X=1.17$, $D_{obs}=1.14$ g. cm$^{-3}$ [1]; space group $C_{6h}^2-P6_3/m$.

After seven and six successive calculations of the $(F_0-F_c)$-syntheses along [001] and [100] respectively, the final atomic parameters (Table I) and temperature factors were obtained. The interatomic distances thus calculated are given in Table II together with their standard deviations. Fig. 1 shows the molecular arrangement in a unit cell projected on (001).

Molecules are approximately closest packed in the hexagonal lattice. The molecule in crystal has nearly $D_{3h}-\bar{6}m2$. The linkage of N-C-C-N shows a cis configuration. The crystal does not show any disordered structure in the room temperature phase.

In connection with the crystal analysis, differential thermal analysis was carried out up to 180°C. (Fig. 2). The sample, recrystallized from ethereal solution and sublimed repeatedly under high vacuum ($10^{-5}$ mmHg), evacuated sufficiently at an elevated temperature prior to the measurement. The curve shows the presence of a phase transition at 79.8°C**, the entropy change of which is larger than that at the m. p. 161.1°C. These temperatures are more or less higher than those reported hitherto[1]. Measurements of vapor pressures have also been carried out below and above the transition point. The data are summarized in Table III.

The relatively small entropy of fusion shows that the high temperature phase of the crystal might belong to the category of the so-called

TABLE III. VAPOR PRESSURE DATA

Low temperature phase (51.3~78.6°C)

$\log p(\text{mmHg}) = -3233.6_3/T + 10.473_2$

$\Delta H = 14.8$ kcal./mol.

$\Delta S = 34.8$ e. u.

$\Delta G = 14.80_6 - 0.0347_6 T$ kcal./mol.

High temperature phase (80.0~96.3°C)

$\log p(\text{mmHg}) = -2722.1_8/T + 9.026_9$

$\Delta H = 12.5$ kcal./mol.

$\Delta S = 28.1$ e. u.

$\Delta G = 12.46_4 - 0.0281_4 T$ kcal./mol.

Transition (79.8°C)

$\Delta H = 2.3_4$ kcal./mol.

$\Delta S = 6.6_2$ e. u.

Fusion (161.1°C)

$\Delta H = 1.4_5$ kcal./mol.*

$\Delta S = 3.3$ e. u.

* This value was estimated from the differential thermal analysis curve.

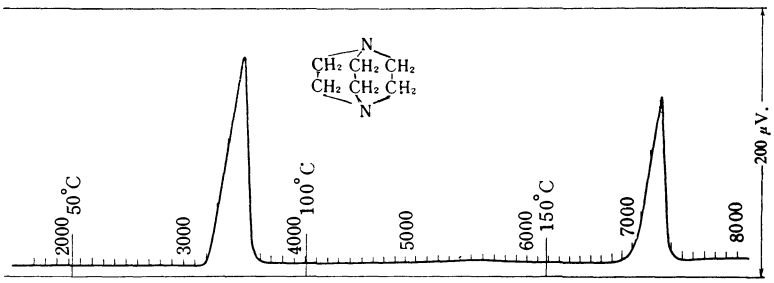

Fig. 2. Automatic recording curve of differential thermal analysis.

" plastic crystals " in the sense as suggested by Timmermans[2]. Accompanied with the large increase of entropy at the transition point, the molecule will gain some orientational, rotational or even translational freedom. Detailed analysis of the crystal structure in the high temperature phase is now going on. The heat capacities near the transition and melting points and the NMR measurement are currently under study in our laboratory. These studies may provide further informations on the mechanism of the phase transition and on the thermal motions in the high temperature phase.

# *Isomerization of Unsaturated Fatty Acids and their Esters with Acetic or Inorganic Acid*

By Yutaka WATANABE

(Received January 18, 1960)

It is generally accepted, that the isomerization of fatty materials includes the following events:

i) Formation of conjugated double bonds in the fatty molecule by heating with alkali; that gives rise to cis → trans isomerization[1].

ii) Shifting of double bonds during catalytic hydrogenation[2].

iii) Elaidinization with selenium or nitrous acid[3].

There are many literatures which describe the reaction of unsaturated fatty materials with concentrated sulfuric acid[4], and a synthesis of hydroxy acids or production of sulfated or sulfonated oils and of "iso-oleic" acid was also given. But no detailed description of analysis of "iso-oleic" acid was shown in previous literatures. Furthermore, it is not possible to find any information which refers to the reaction of unsaturated fatty materials with aqueous sulfuric acid solution at moderate temperatures.

Besides these matters the author[5] found the isomerization of oleate or palmitoleate of the following scheme, followed by oxidative fission with *tert*-butyl chromate (type C)*:

$$CH_3(CH_2)_mCH : CH(CH_2)_7C\overset{O}{\diagdown\!\!\diagup}OCH_3$$

$$\longrightarrow CH_3(CH_2)_nCH : CHC\overset{O}{\diagdown\!\!\diagup}OCH_3$$

$m=7$ or 5; $n=14$ or 12

In this experiment, when methyl oleate in benzene was oxidized with *tert*-butyl chromate (type C) at 40°C for 30 hr., nonanoic, azelaic and palmitic acids were obtained as oxidation products. On the other hand, it was found, that oleate in benzene/acetic acid or benzene/acetic acid/sulfuric acid was isomerized partly into 2-octadecenoate. In the oxidation of palmitoleate under almost the same condition as that of oleate, the author recognized the formation of myristic, lauric, capric, heptanoic and azelaic acid. From these experimental results, he proposed the $\beta$-oxidative action of *tert*-butyl chromate, accompanied by the isomerization shown in the above scheme.

It seems very noticeable that the isomerization of unsaturated fatty materials in acid medium proceeds even at moderate temperature. From this point of view, the action of acetic acid and inorganic acids, including aqueous sulfuric, phosphoric and boric acids, towards sesame oil fatty acid was studied. It was observed that the isomerization (conjugation) of triethylenic fatty acids of sesame oil constituents occurs by the treatment of above reagents except boric acid. The examination of ultraviolet absorption spectra of fatty acid was convenient for this purpose.

## Experimental

**Sample.**—*Methyl Oleate*[6].—Commercial olive oil was saponified with alcoholic potash, and the mixed fatty acids obtained were treated by means of lead salt-alcohol method. The resulted liquid acid had an iodine value of 93.1, and a 10% solution of this acid in acetone was cooled to −20°C and filtered. The cake of oleic acid was collected after maintaining the filtrate at −60°C. This acid (I. V. 90.1) was esterified in the usual manner, and the ester obtained was distilled under reduced pressure. Methyl oleate thus prepared had the following properties: b. p.$_5$ 180°C; $d_4^{25}$ 0.8712; $n_D^{25}$ 1.4469; acid value 0.17; saponification value 183.9; I. V. 86.4.

Ozonization of this oleate in chloroform gave no palmitic acid. This indicates the absence of 2-octadecenoate in the specimen.

*Methyl Palmitoleate.*—Sperm oil fatty acid was fractionated into solid and liquid acid by means of lead salt-alcohol method. The liquid acid obtained was esterified and the ester was distilled in vacuo. Methyl palmitoleate thus obtained had the following properties: b. p.$_4$ 160∼165°C; $d_4^{25}$ 0.8748; $n_D^{25}$ 1.4481; A. V. 3.45; S. V. 201.5; I. V. 86.1. Ozonolysis of this palmitoleate gave a complex mixture

of saturated monocarboxylic acids. Paper chromatographic analysis of the mixed acids, according to the method of Inouye et al.[7] gave the result that the major components of this mixture were nonanoic and heptanoic acids, and the minor were myristic and capric (trace) acids. This means, therefore, that palmitoleate contains a small amount of oleate and a trace of myristate and caprate as contaminants. Ultraviolet and infrared absorption spectra of palmitoleate revealed, that there is neither conjugated diethylenic and more highly conjugated polyethylenic acid esters nor trans type acid esters in the sample.

*Sesame Oil Fatty Acid.* — Saponification of commercial sesame oil ($d_4^{25}$ 0.9097; $n_D^{25}$ 1.4718; A. V. 0.14; S. V. 187.7; I. V. 118.9; unsaponifiable matter 1.11%) with alcoholic potash, gave the mixed fatty acids. This had the following properties: $d_4^{25}$ 0.8983; $n_D^{25}$ 1.4627; A. V. 185.0; I. V. 120.0; content of conjugated diene 0.55%; conjugated triene 0%. Ultraviolet absorption spectrum of this mixed acids is shown in Fig. 1. The content of linoleic and linolenic acids in this sesame oil fatty acid, estimated by the A. O. C. S. standard method[8], was 20.0 and 14.2%, respectively.

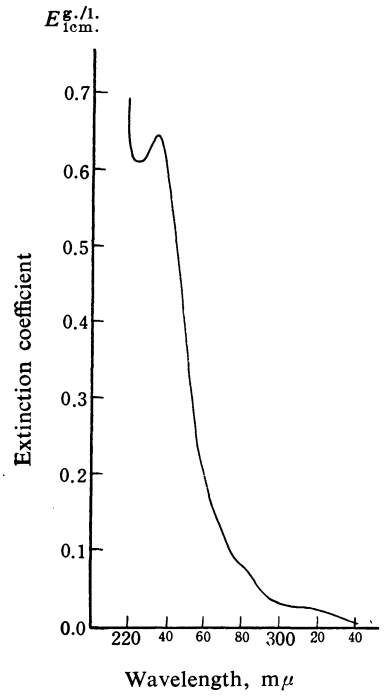

Fig. 1. U. V. absorption spectrum of sesame oil fatty acid.

**Ultraviolet and Infrared Absorption Spectrum.**— All ultraviolet and infrared absorption spectra mentioned in the present paper were measured by using Hilger's UVISPEK and H-800 spectrophotometer, respectively.

Purified ethyl alcohol was used as a solvent for ultraviolet spectroscopy instead of isoöctane.

**Isomerization of Double Bond to α,β-Conjugated Position to Ester Carbonyl Group**[5].—*Methyl Oleate.* — Twenty grams of methyl oleate were added to the mixture of 90 g. of benzene, 36 g. of *tert*-butyl alcohol, 15 g. of acetic acid, and 3.0 g. of acetic anhydride, and the whole was kept at 40°C for 30 hr. with stirring. On the other hand, the mixture of 8 g. of oleate, 26 g. of benzene, 12 g. of acetic acid and 0.1 g. of concentrated sulfuric acid was kept at 70°C for 20 hr. with stirring. After each reaction time mentioned above was over, the reaction mixture was washed with water, 3% aqueous sodium bicarbonate solution, and finally again, water successively dried over anhydrous sodium sulfate, and a mixture of fatty esters was recovered after distilling off the volatile materials.

The fatty esters thus obtained were ozonized at 0°C using chloroform as a solvent. A mixture of monocarboxylic acids was obtained after the oxidative decomposition of the ozonized material, followed by extraction with petroleum ether. Paper chromatographic analyses of samples, derived from different isomerization condition were carried out using the same method as mentioned above. It was recognized that the chromatogram showed the presence of two kinds of fatty acid, namely nonanoic (major) and palmitic (minor) acids. When the mixtures of both of the monocarboxylic acids were fractionally crystallized from methyl alcohol at 0°C, an acid (m. p. 60~63°C) was precipitated in each case. This acid was identified as palmitic acid by the preparation of its *p*-bromophenacyl ester (m. p. 84~84.5°C) and mixed melting point determination with the known specimen.

*Methyl Palmitoleate.* — Eight grams of methyl palmitoleate were added to the mixture of 32 g. of benzene and 5.4 g. of acetic acid, and the whole was kept at 70°C for 30 hr. with stirring. The reaction product was treated in a similar way as in the case of oleate, and the result obtained was as follows. Monocarboxylic acids obtained were heptanoic, nonanoic, capric (trace) and myristic acids. The amount of myristic acid in this case seemed to be larger than that of the sample derived from the starting material (palmitoleate itself); because, the larger and more intense spot of myristic acid on the paper chromatogram was observed in the case of isomerized sample than in the case of the starting material although almost the same quantity of each sample was analyzed by means of paper chromatography mentioned above. However, the conclusive evidence, that the amount of myristic acid increased after isomerization followed by ozonization was not so remarkable.

**Formation of Conjugated Triethylenic Acid in Sesame Oil Fatty Acid.** — *Blank Test.* — Fifteen grams of sesame oil fatty acid and 80 g. of water in a flask provided with a gas-inlet tube, a stirrer, and a reflux condenser, were maintained at 90°C with constant stirring, under nitrogen atmosphere, for 3~30 hr. Contents of conjugated diene and triene in samples calculated from the equation shown in standard method were shown in Table I.

*Aqueous Sulfuric Acid Solution.*—The concentrations of sulfuric acid solutions used for isomerization were 6 N ($d$=1.18), 9 N ($d$=1.26) and 12.4 N ($d$=1.35), respectively. Each time, 30 g. of sesame oil fatty acid and 300 g. of aqueous sulfuric acid solution were treated similarly as in the case of the blank test. These isomerization experiments were carried out at 90°C. After each reaction time (Table II), fatty acid was taken out from the reaction vessel, and washed thoroughly with water and dried, and the ultraviolet absorption spectrum (Fig. 2) was measured, and the contents of diene and triene in it were calculated. The results were shown in Table II.

Table II. Conts. of conjugated diene and triene (treatment with sulfuric acid solution)

When sesame oil fatty acid was treated with 6 N sulfuric acid at room temperature for 30 hr., no remarkable change of the ultraviolet absorption spectrogram was observed.

*Phosphoric Acid.* — Phosphoric acid (300 g.) and sesame oil fatty acid (60 g.) were treated quite similarly as in the case of sulfuric acid solution at 90°C. In this case, remarkable coloration of phosphoric acid was observed during the reaction. After the reaction, the fatty acid was recovered similarly as in the case of sulfuric acid solution. The results obtained were shown in Table III. Ultraviolet absorption spectra of isomerized acids were shown in Fig. 3. Physical properties of recovered fatty acids were shown in Table IV.

*Glacial Acetic Acid.* — Glacial acetic acid (300 g.) and sesame oil fatty acid (30 g.) were mixed and the solution was maintained at 90°C under nitrogen atmosphere, with stirring, for 30 hr. In the course of the reaction, 30 cc. portion of the solution was taken out, poured into water, extracted with ether and the ethereal solution was washed thoroughly with water, and dried over anhydrous sodium sulfate. After evaporation of the solvent, isomerized material was recovered, and its ultraviolet absorption spectrum was measured (Fig. 4). The contents of conjugated diene and triene calculated were shown in Table V.

TABLE V. CONTS. OF CONJUGATED DIENE AND TRIENE (TREATMENT WITH GLACIAL ACETIC ACID)

| Time, hr. | 3 | 10 | 20 | 30 |
|---|---|---|---|---|
| Diene, % | 0.78 | 0.88 | 0.88 | 0.81 |
| Triene, % | 0.0066 | 0.054 | 0.096 | 0.112 |

*Treatment with Boric Acid.* — At 90°C, sesame oil fatty acid (30 g.), boric acid (90 g.) and water (410 g.) were treated similarly as in the case of the blank test. Even after 30 hr., the fatty acid was so stable that the contents of conjugated diene and triene in it were essentially the same as in the case of the blank test.

## Discussion

It will be noticeably demonstrated that the isomerization of unsaturated fatty materials occurs at moderate temperature (30~90°C) in the acid medium mentioned above. In the case of monoethylenic fatty esters, namely methyl oleate and palmitoleate, the double bond migrates to $\alpha,\beta$-conjugated position to ester carbonyl group. Although the isolation of isoöleate or isopalmitoleate was unsuccessful, the formation of $\alpha,\beta$-unsaturated esters was definitely supported by the identification of a shorter-chain saturated fatty acid, which was obtained after ozonolysis of isomerized products. The identification of palmitic and myristic acids has important meaning in this aspect. These facts support the $\beta$-oxidation mechanism of oleate and palmitoleate with *tert*-butyl chromate (type C).

In the case of sesame oil fatty acid, it is sure, that conjugation of triethylenic system in fatty acid molecule proceeds, when it was treated with acetic, phosphoric or aqueous sulfuric acid solution at 90°C. But there was no appreciable formation of a conjugated diethylenic system in such treatment, because the contents of conjugated diene of sesame oil fatty acid were almost constant throughout the whole various conditions. It is certain that the formation of conjugated triethylenic acid proceeds neither in the experiment of the blank test nor with the treatment with boric acid at 90°C. Also, the same result was obtained in the case of the treatment with 6 N sulfuric acid at room temperature. The smallest content found (0.0066%) of conjugated

triene was obtained in the treatment of the fatty acid with acetic acid at 90°C for 3 hr. The highest content observed (0.112%) was obtained in the isomerization with acetic acid at 90°C for 30 hr. This value (0.112%) corresponded to 0.784% for linolenic acid present in sesame oil fatty acid.

According to Privett and Quackenbush[9], no phosphorylation occurred, when ethyl linoleate was treated with a catalytic amount of phosphoric acid (below 1%) in a sealed tube, under vacuum at 100°C for 36 hr. They have refered nothing to the isomerization of linoleate. However, in the case of the treatment of fatty acid with a large amount of phosphoric acid at 90°C described in the present paper, the author recognized the isomerization of fatty acid as above. But the physical properties of the isomerized products shown in Table IV seemed to be virtually constant, the same interpretation as for no phosphorylation can be relied on.

The author wishes to express his gratefulness to Professor T. Matsuura for his suggestions and encouragement, and also to Messrs. H. Tanimoto and A. Ohtawa for their assistance.

# *Studies on Organic Peroxides. VI. Thermal Analysis of the Decomposition of Benzoyl Peroxide by Ferrous Ion**

By Shigeo HASEGAWA, Norio NISHIMURA and Kimpei MIURA

(Received February 11, 1960)

In the previous paper[1], the analytical method was applied to follow the rate of the decomposition of benzoyl peroxide catalyzed by ferrous ion and it was found that the apparent decomposition rate was of the first order with respect to the concentration of benzoyl peroxide and that the activation energy of the decomposition was about 14 kcal./mol. This was much less than that of the spontaneous decomposition. In this report, similar reactions were carried out in methanol, ethanol, *n*-propanol and *n*-butanol and the reaction was followed by means of the method of thermal analysis[2].

## Experimental

**Reagents.**—Benzoyl peroxide and ferrous chloride were prepared by the methods reported earlier[3]. Other chemicals used were of reagent grade and repeatedly distilled.

**Apparatus and Procedure.**—The reaction was carried out in a glass calorimeter shown in Fig. 1. In this figure, A is a Dewar vessel, the capacity of which is about 200 cc., B a glass stirrer sealed by mercury, C a Beckmann thermometer, D a platinum wire heater, E a glass vessel of about 30 cc. and F and F' glass tubes.

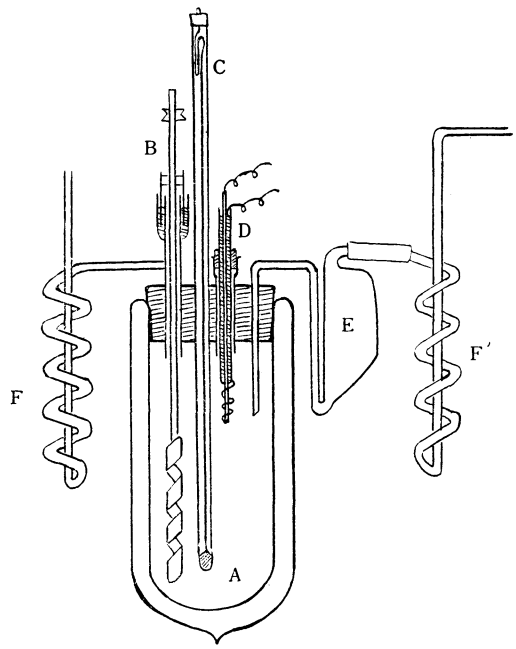

Fig. 1. Reaction vessel.

* Presented in part at the Chugoku-Shikoku and Kinki Local Meeting of the Chemical Society of Japan, Tokushima, August 29 (1958).

1) S. Hasegawa and N. Nishimura, This Bulletin, 33, 775 (1960).

2) S. Horiba and T. Ichikawa, *Rev. Phys. Chem. Japan*, 1, 145 (1927); Ichikawa, *Z. Physik. Chem.*, (B) 10, 299 (1930).

3) S. Hasegawa et al., This Bulletin, 31, 696 (1958).

The atomosphere of the vessel was previously substituted by carbon dioxide. Oxygen-free benzoyl peroxide and ferrous chloride solutions were introduced into A and E, respectively. The calorimeter was held in a thermostat. The temperature in A was adjusted to that of the thermostat by the heater D. After thermal equilibrium was attained, the ferrous chloride solution in E was siphoned into A. As soon as they were mixed, the reaction started and the rise of the temperature was recorded as the time passed.

The initial concentration of benzoyl peroxide was 0.01 mol./l. for all runs.

**The Method of Thermal Analysis.**—The fundamental equation of thermal analysis is given by Eq. 1[2,4],

$$\frac{dT}{dt}+K\Delta T=\frac{Q}{W}\cdot\frac{dx}{dt} \qquad (1)$$

where $dT/dt$ is the velocity of temperature change in solution, and $K\Delta T$ is a correction term for Newtonian cooling due to the temperature difference $\Delta T$ between the system and its surroundings and hence the rise in the temperature of reaction solution, $K$ being the cooling constant. $Q$ and $W$ denote the heat of the reaction and the water equivalent of the reaction vessel, respectively, and $dx/dt$ the rate of the reaction.

The cooling constant $K$ can easily be determined by plotting the temperature difference between the reaction vessel and the thermostat against time.

When a reaction is of the first order, the rate of the reaction may be expressed as:

$$dx/dt=kae^{-kt} \qquad (2)$$

where $k$ is the specific reaction rate and $a$ is the initial concentration of the reactant. From Eqs. 1 and 2, it follows,

$$\log(dT/dt+K\Delta T)=\log\frac{Q}{W}\cdot ka-\frac{kt}{2.303} \qquad (3)$$

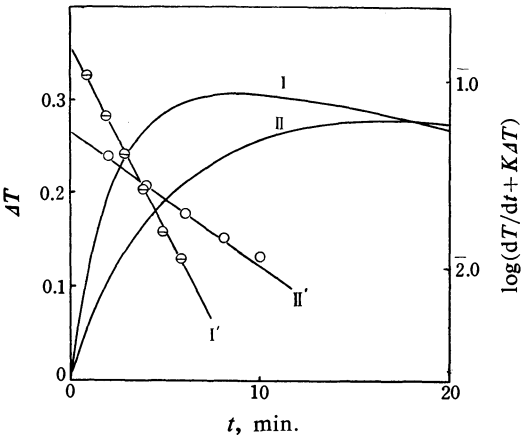

Fig. 2. Curves I and II: $\Delta T$ vs. $t$; curves I′ and II′: $\log(dT/dt+K\Delta T)$ vs. $t$ in ethanol at 15°C; $[FeCl_2]_0$: 0.0038 mol./l. for I and 0.0012 mol./l. for II, respectively; $[BPO]_0$: 0.01 mol./l.

4) E. Suito, *Rev. Phys. Chem. Japan*, **13**, 74 (1939).

Accordingly, the plot of the left hand side of Eq. 3 against time $t$ will give a straight line, the slope of which is $k/2.303$.

## Results

The ferrous ion catalyzed decomposition of benzoyl peroxide is a exothermal reaction and an example is shown in Fig. 2 in which curves I and II show the dependence of $\Delta T$ upon

time $t$ in ethanol at 15°C. The slope $dT/dt$ of the curve at any time $t$ can be obtained from the figure. Curves I′ and II′ which are obtained by plotting the left hand side term in Eq. 3 against time give straight lines, therefore, it may be concluded that this reaction is apparently of the first order. Reactions in methyl, *n*-propyl and *n*-butyl alcohols were also the case, as shown in Fig. 3.

It was also found that the slope of the $\log (dT/dt + K\Delta T)$ vs. $t$ curve was independent of the initial concentration of benzoyl peroxide.

According to Eq. 3, the slope of the line should give $k/2.303$. However, the specific rate constant $k$ thus obtained in this reaction can not be considered as the true rate constants, because the ferrous ion may be considered to take part in the reaction. The discussion will be undertaken shortly.

The initial concentrations of the ferrous ion, alcohols and the values of $k$ at various temperatures are listed in Table I. From the table, it may be concluded that the values of $k$ seem directly proportional to the initial concentration of the ferrous ion. For example, $k$ vs. $[FeCl_2]_0$ was plotted at temperatures between 10 and 30°C in ethanolic solution as shown in Fig. 4. It seems that each of the values falls on a straight line and converges to the origin. If this conclusion is correct, it follows:

$$k = k' [FeCl_2]_0 \qquad (4)$$

where $k'$ is a constant. In the fourth and fifth columns in Table I are listed the values of $k'$ calculated from Eq. 4. The slopes in Fig. 4 represent the average values of $k'$ for each temperature.

It may be seen that the differences in the reaction rates among ethanol, *n*-propanol and

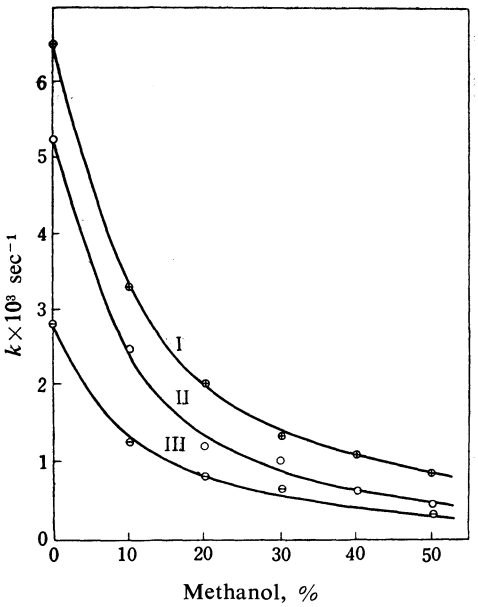

Fig. 5. Values of $k$ for methanol-ethanol mixture : I, 20 ; II, 15 ; III, 10°C ; $[BPO]_0$ : 0.01 mol./l., $[FeCl_2]_0$ : 0.0025 mol./l.

*n*-butanol are not particularly appreciable, but in methanol, the rate is appreciably smaller than in the three other alcohols. In the mixture of methanol and ethanol, $k$ values were rapidly decreased by increasing the proportion of methanol as seen in Fig. 5. Above 50% of methanol, the reaction rates became too small to determine over the experimental temperature range.

## Reaction Mechanism

As suggested in the previous paper[1], the overall reactions in this system will take place as follows:

First of all, reaction between benzoyl peroxide and ferrous ion will occur:

$$Fe^{2+}+P \xrightarrow{k_1} RCOO\cdot+RCOO^-+Fe^{3+} \quad (5)$$

The benzoxy radical thus produced will attack a solvent molecule and abstract a hydrogen atom on $\alpha$-carbon atom.

$$RCOO\cdot+R'CH_2OH \xrightarrow{k_2} RCOOH+R'\dot{C}HOH \quad (6)$$

In addition, the reduction of ferrous to ferric ion is assumed:

$$R'\dot{C}HOH+Fe^{3+} \xrightarrow{k_3} RCHO+Fe^{2+}+H^+ \quad (7)$$

Therefore, the heat evolved in this reaction may be the sum of the contribution from these reactions. Hence, the apparent rate constant $k$ may be considered to include some specific rate constants.

In the previous paper, it was also mentioned that the rate of the decomposition of benzoyl peroxide might well be expressed as

$$-d[P]/dt=k_1[P][Fe^{2+}] \quad (8)$$

In addition, the apparent overall decomposition rate was approximately of the first order, that is

$$-d[P]/dt=k_0[P] \quad (9)$$

where $k_0$ is a constant. Therefore, the ferrous ion concentration should be constant during the reactions, if Eqs. 8 and 9 are not inconsistent with each other. From Eqs. 8 and 9, it follows,

$$k_0=k_1[Fe^{2+}] \quad (10)$$

As was assumed, if the rate of reduction of ferric to ferrous ions are equal or almost equal to that of oxidation, the equilibrium between ferrous and ferric ions would be attained. Then, ferrous ion concentration may be expressed in terms of its initial concentration and the equilibrium constant $K_0$, i. e.,

$$[Fe^{2+}]=\frac{K_0}{1+K_0}[Fe^{2+}]_0 \quad (11)$$

Inserting this value into Eq. 10, it follows,

$$k_0=k_1\cdot\frac{K_0}{1+K_0}\cdot[Fe^{2+}]_0 \quad (12)$$

Thus, as was suggested, in the previous paper, $k_0$ should be a linear function of $[Fe^{2+}]_0$. Eq. 9 shows that $k_0$ can be obtained from the slope of the $\log[P]$ vs. $t$ curve. If Eq. 12 is compared with Eq. 4, the conclusion that the rate constant $k$ obtained from the thermal analysis is a linear function of the initial ferrous ion concentration, agrees formally with the conclusion that the apparent first order rate constant $k_0$ obtained from the analytical data, would be a linear function of the initial ferrous concentration. Each value of $k$ and $k'$ could, therefore, be referred as a measure of $k_0$ and $k_1$, respectively. Thus, it may be concluded that though the data from the thermal analysis in this reaction do not offer true rate constants, they still offer a means for studying the mechanism of this reaction in alcohols.

## Solvent Effect

Since $k'$ corresponds to the true rate constant $k_1$ as mentioned above, it is of interest to calculate the apparent activation energy by plotting $\log k'$ against $1/T$. The Arrhenius plots may be seen in Fig. 6. By applying the least squares method, the activation energies and the frequency factors for each alcohol were calculated and listed in Table II.

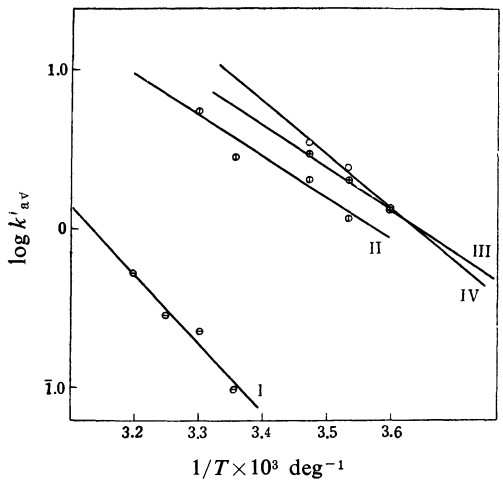

Fig. 6. Plots of $\log k'_{av}$ against $1/T$, solvent, I, methanol; II, ethanol; III, *n*-propanol; IV, *n*-butanol.

TABLE II. ACTIVATION ENERGIES AND FREQUENCY FACTORS

| Solvent | $E$(kcal./mol.) | $A$ | $S^*$(e. u.) 300°K |
|---|---|---|---|
| Methanol | 19.8 | $3.3\times10^{13}$ | 1.3 |
| Ethanol | 12.0 | $2.3\times10^{9}$ | −17.7 |
| *n*-Propanol | 15.0 | $8.7\times10^{11}$ | −5.9 |
| *n*-Butanol | 12.4 | $7.5\times10^{9}$ | −15.3 |
| Methanol (10%)-Ethanol (90%) | 15.2 | $3.2\times10^{11}$ | −7.9 |
| Methanol (20%)-Ethanol (80%) | 16.7 | $2.3\times10^{12}$ | −4.0 |

The influence of the solvent on chemical reaction rate would be partly due to its physical properties such as dielectric constant or molecular size. In reactions between ions and molecules, the solvent will play an important role and the increase in the dielectric constant of the solvent will cause a decrease in the free energy of the system, and hence will result in a decrease in their reaction rates. Since ferrous ions in alcohol are solvated, the reaction rates between ferrous ion and benzoyl peroxide will depend partly on the dielectric constants of the solvents. The dielectric constants of methanol, ethanol, *n*-propanol at 20°C and *n*-butanol at 25°C are 33.7, 25.7, 21.8 and 17.8, respectively[5].

It may be seen from the table that the $k'$ values are increased in the order of methanol, ethanol, *n*-butanol and *n*-propanol, in agreement with the order of decreasing dielectric constants except that the order of *n*-propanol and *n*-butanol is reversed. But the difference in the rates between these alcohols is not so appreciable.

5) International Critical Table, VI, p. 83.

It was pointed out[6] that abstraction of the hydrogen atom from the alcohol molecule took place on the $\alpha$-carbon atom exclusively.

In reaction 6, methylenic hydrogen atoms will exclusively be abstracted in ethanol, *n*-propanol and *n*-butanol, whereas methyl hydrogen atoms will be abstracted in methanol. This will suggest the exceptionally slow reaction rates in methanol.

### Enthalpy-Entropy Relationship

Mention may be made about the relation between activation energy and frequency factor.

There are cases when a linear relationship between $\Delta S^*$ and $E$ can be observed. Especially, it was pointed out that in a series of reactions, $\log A$ was a linear function of $E$ when the Hammett equation held[7].

According to the theory of the absolute reaction rates[8], the specific rate constant $k$ of a reaction is related to the standard free energy of activation $\Delta F^*$ by Eq. 13:

$$k=\kappa\frac{kT}{h}\exp\left(-\frac{\Delta F^*}{RT}\right) \tag{13}$$

The free energy of activation may be a function of the intensity factors such as steric, resonance, or solvent effects. In a series of reactions, all such intensity factors are assumed to remain constant except that there is a change in one of these intensity factors, and $\Delta F^*$ is assumed to be linearly related to it.

Any reaction in the series may be chosen as standard and its specific rate constant may be denoted by $k_0$. If the difference in the intensity factor between any reaction and the standard one is expressed by $\Delta\chi$, then from the assumption mentioned above, the specific rate constant $k$ can be derived from Eq. 13:

$$\ln k/k_0=-\frac{\Delta\Delta F^*}{RT}=-\frac{1}{RT}\left(\frac{\partial\Delta F^*}{\partial\chi}\right)_T\Delta\chi$$
$$=-\frac{1}{RT}\left\{\left(\frac{\partial\Delta H^*}{\partial\chi}\right)_T-T\left(\frac{\partial\Delta S^*}{\partial\chi}\right)_T\right\}\Delta\chi \tag{14}$$

where $\Delta\Delta F^*$ represents the difference in the standard free energy of activation between the reaction and the standard one; $\Delta H^*$ and $\Delta S^*$ denote the standard activation enthalpy and entropy, respectively.

In a case when the intensity factor $\chi$ represents a substituent effect, the reaction constant

7) J. E. Leffler and Shih-Kung Liu, *J. Am. Chem. Soc.*, **78**, 1949 (1956); I. Meloche and K. J. Laidler, ibid., **73**, 1712 (1951); D. A. Brown and R. F. Hudson, *J. Chem. Soc.*, **1953**, 883.

8) S. Glasstone, K. J. Laidler and H. Eyring, "The Theory of Rate Processes", McGraw-Hill, New York (1941), p. 195.

$\rho$ in the Hammett equation[9] may be expressed as

$$-\frac{1}{RT}\left\{\left(\frac{\partial \Delta H^{\ddagger}}{\partial \chi}\right)_T - T\left(\frac{\partial \Delta S^{\ddagger}}{\partial \chi}\right)_T\right\} = \rho \times \text{const} \quad (15)$$

Jaffé[10] has pointed out, quoting many examples, that in a series of reactions where the Hammett equation held, $\rho$ was linearly related to $1/T$. This fact can successfully be explained by Eq. 15 if $(\partial \Delta H^{\ddagger}/\partial \chi)_T$ and $(\partial \Delta S^{\ddagger}/\partial \chi)_T$ are both independent of temperature.

In a series of related reactions, changes in polarity of a substituted group may be associated with the change in the electrostatic field strength at the reaction center.

Hence it may be reasonable to expect that the greater the enthalpy of activation, the greater will become the entropy of activation, because formation of a more rigid activated complex will need fewer entropy and enthalpy changes and vice versa.

In case of solvent changes, the linear relationship between enthalpy and entropy of activation is also observed[11,12]. If reactants are solvated, solvation will cause the decrease in the potential energy and entropy of the system, and hence both the enthalpy and entropy of activation will be increased. Thus, it may be reasonable to assume that the sign of $(\partial \Delta H^{\ddagger}/\partial \chi)_T$ is the same as that of $(\partial \Delta S^{\ddagger}/\partial \chi)_T$ and that neither of them is zero. Then, there must be a temperature, denoted by $\beta$, at which the left hand side of Eq. 14 becomes zero and it must be characteristic in the reaction series. From the discussion mentioned above, it is concluded that at the temperature $\beta$, which has been called "isokinetic temperature"[12], all the reaction rates should become identical.

From Eq. 14, it follows:

$$\left(\frac{\partial \Delta H^{\ddagger}}{\partial \chi}\right)_T \Delta \chi = \beta \left(\frac{\partial \Delta S^{\ddagger}}{\partial \chi}\right)_T \Delta \chi \quad (16)$$

or

$$\Delta \Delta H^{\ddagger} = \beta \Delta \Delta S^{\ddagger} \quad (17)$$

where $\Delta\Delta H^{\ddagger}$ and $\Delta\Delta S^{\ddagger}$ denote the difference in the activation enthalpy and entropy between a reaction and the standard one, respectively. Hence, $\Delta\Delta H^{\ddagger}$ is a linear function of $\Delta\Delta S^{\ddagger}$, in agreement with experimental facts.

In this study, the apparent activation energy

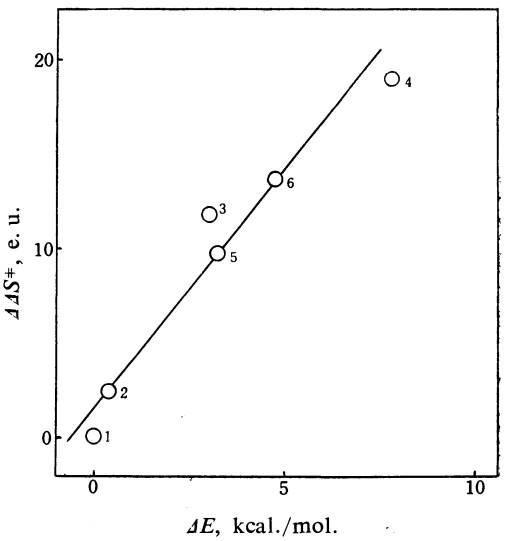

Fig. 7. Relationship between $\Delta E$ and $\Delta\Delta S^{\ddagger}$. 1, ethanol; 2, butanol; 3 propanol; 4, methanol; 5, methanol (10%)-ethanol (90%); 6, methanol (20%)-ethanol (80%).

$E$ was also proportional to the activation entropy. In Fig, 7, the reaction in ethanol was chosen as standard, and the differences in activation energies were plotted against the differences in the activation entropies. A straight line was obtained as shown in the figure. From the slope, the isokinetic temperature was calculated to be 400°K.

## Summary

The thermal analysis method was applied to follow the rate of the decomposition of benzoyl peroxide catalysed by ferrous ion in methanol, ethanol, *n*-propanol and *n*-butanol.

The apparent rates were of the first order and no fundamental difference in the reaction mechanism was observed among these alcohols. However, the reaction rates in methanol were much slower than in three other alcohols. Solvent effects on the reaction rate were discussed.

Linear enthalpy-entropy relationship was deduced, assuming that the free energy of activation is the linear function of an intensity factor in a series of reactions. This was found to be true in our case.

# *Synthesis and Purification of Sexiphenyl for Scintillator*

By Tadashi NOZAKI, Michiko TAMURA, Yuhei HARADA* and Kazuo SAITO

(Received March 21, 1960)

It has been believed that sexiphenyl is an interesting organic semi-conductor and a promising scintillator for charged particles[1]. However its preparation was made only on a small scale[2-4], and an attempt to obtain this compound in sufficient quality and quantity for scintillator met with little success[1]. The present authors have found a favorable condition for the production of 4-nitroterphenyl from *p*-terphenyl (1, 4-diphenylbenzene) and succeeded in obtaining several tens of grams of sexiphenyl in a moderate yield. Although its purification involved a great difficulty, repeated vacuum sublimation and zone refining followed by recrystallization from tetralin afforded this compound in high purity. Its almost colorless single crystal gives an intense violet fluorescence and is satisfactorily used as a scintillator and wavelength shifter for Čerenkov radiation.

**Preparation of Sexiphenyl.**—The process is shown in Table I. Two methods have so far been presented for the synthesis: 1) the Ullmann condensation of 4-iodoterphenyl with the aid of silver powder at 320°C[2]; 2) the same condensation of a mixture of 4-iodobiphenyl and 4, 4'-diiodobiphenyl with copper powder[3]. According to the present authors' re-examination, both gave a very poor yield. Especially the latter provided a product containing as much as 0.7% iodine, after repeated vacuum sublimation and recrystallization from tetralin and dibutylphthalate. Contrary to the description in the literature, the Ullmann condensation of 4-iodoterphenyl with copper gave a good yield (more than 40%), provided that the iodoterphenyl was sufficiently pure and the condensation was carried out on a small scale. It appears as if the exothermic reaction, when carried out on a large scale, raises the temperature so remarkably that both the yield and the purity of the product were lowered.

4-Iodoterphenyl was obtained from 4-aminoterphenyl hydrochloride by diazotization and Sandmeyer's reaction, made free from phenols and the remaining amines by extraction with xylene and further purified by vacuum distillation and recrystallization from isoamyl acetate. Although both the amine and the diazonium salt are sparingly soluble in dilute hydrochloric acid, the diazotization proceeds in a good yield in suspension. This process compares favorably with that in concentrated sulfuric acid[2].

For obtaining pure 4-aminoterphenyl, preparation of pure 4-nitroterphenyl is essential. Nitration of terphenyl usually gives polynitro

TABLE I. SYNTHESIS OF SEXIPHENYL

compounds[5]. Allen et al. obtained 4-nitroterphenyl in 72% yield in glacial acetic acid in the presence of a small excess of nitric acid[6]; they gave, however, no information on the other 28% portion. The present authors have found that at temperatures exceeding 100°C and in glacial acetic acid containing about 10% of acetic anhydride and a trace of sulfuric acid, the rate of mono-nitration of *p*-terphenyl is significantly greater than the decomposition of nitric acid, which is in turn much greater than the rate of nitration of mononitroterphenyls. Higher temperature and greater concentration of acetic anhydride and sulfuric acid increase the solubility of *p*-terphenyl, but facilitates the decomposition of nitric acid, resulting in incomplete nitration of *p*-terphenyl. On the other hand, the amount and the concentration of nitric acid affected the result to a less extent. When the reaction mixture was cooled, fairly pure 4-nitroterphenyl separated as light yellow needles. Column chromatography of the mother liquor gave pure 2-nitro- and 2'-nitroterphenyl.

**Purification of Sexiphenyl.**—Crude sexiphenyl obtained by vacuum sublimation from the condensation product was yellow in color and contained significant amounts of copper and iodine. Most copper was removed by digesting the sublimate in aqueous potassium cyanide solution. Extremely low solubility of sexiphenyl in any organic solvent (e. g. less than 0.1 g. in one litre of boiling tetralin) makes recrystallization and chromatographic purification very laborious or even impracticable. It was further disclosed by neutron activation analysis that vacuum sublimation and recrystallization from various organic solvents were less effective for the removal of iodine-containing compounds. On the other hand, a cycle consisting of zone refining and vacuum sublimation was very useful for this purpose. (Table II) It appears as if the iodine-containing substance suffers thermal decomposition during zone refining to give compounds that are more easily removed through these processes. However, too high a temperature caused considerable decomposition of sexiphenyl itself, especially when the purity was low. Since the thermal decomposition of sexiphenyl becomes marked over 480°C, the zone refining was best effected at a maximum temperature between 440 and 450°C.

After a vacuum sublimation and a recrystallization from tetralin, the crystalline product gave the correct carbon and hydrogen content. Nevertheless the melting point rose with repeated zone refining and vacuum sublimation, until it reached a constant value after four times' repetition of the cycle, a recrystallization from tetralin and a vacuum sublimation. The final product becomes a translucent fluid at 428~429°C; it appears to be present in a liquid crystalline state until the translucent phase becomes transparent sharply at 543°C. Further purification brought about no change in these constants. Formation of a nematic or a smectic state is quite probable for such a long molecule. The melting point seems to be very sensitive toward impurity and the low values (465°C[3] and 475°C[2]) given by former authors appear to be due to insufficient purity.

TABLE II. IODINE CONTENT OF SEXIPHENYL PURIFIED BY ZONE REFINING AND VACUUM SUBLIMATION

| Repetition of the cycle | Location of sample piece (cm. from the bottom) | I content (p.p.m.) |
|---|---|---|
| 2 | 0 | 6.5 |
| | 2 | 3.0 |
| | 4 | 1.6 |
| | 6 | 5.2 |
| | 7.5 (top) | 2.0 |
| | residue on sublimation | 2.5 |
| 4 | 0 | <0.15 |
| | 2 | <0.08 |
| | 4 | <0.3 |
| | 6 | <0.05 |
| | 7 (top) | <0.06 |
| 5 | after recrystaln. and sublimation (final product) | <0.04 |

The quantity decreased to one sixth of that of the crude compound through the purification process, but the purity was so high that no impurity element was detected by chemical and neutron activation analysis. The low iodine content (less than 0.04 p.p.m.) compares with that of silicon for semi-conductor, which is regarded as one of the purest substance available. The final product is evaporated onto the window of a photomultiplier tube in vacuo and used as wavelength shifter. It is also converted into a large single crystal (10×5×2 mm.) and used as scintillator for alpha- and beta-rays. The photomultiplier pulse obtained with this scintillator is higher than that with quaterphenyl or anthracene, which has been regarded the best organic scintillator. The result will be reported elsewhere together with the optical properties of sexiphenyl.

## Experimental

**Preparation of Sexiphenyl.** — *Mono-nitration of p-Terphenyl.*—Chemically pure *p*-terphenyl (I) (m. p.

5) H. France, I. M. Heilbron and D. H. Hey, *J. Chem. Soc.*, **1938**, 1364.
6) C. F. A. Allen and D. M. J. Burness, *J. Org. Chem.*, **14**, 177 (1949).

205~210°C, 500 g.) was dissolved in a boiling mixture of glacial acetic acid (18 l.) and acetic anhydride (2 l.) containing 6 N sulfuric acid (1 ml.). The solution was cooled to 105°C and treated with small portions of nitric acid (*d*, 1.42; total 200 ml.) with good stirring, the temperature being kept below 110°C. When the evolution of brown gas ceased, the solution was heated to boiling and then cooled to give small pale yellow needles of 4-nitroterphenyl (II), which were recrystallized from isoamyl acetate. M. p. 213°C, yield 290 g., corresponding to 60% of I.

Found: C, 78.46; H, 4.71; N, 5.02. Calcd. for $C_{18}H_{13}O_2N$: C, 78.53; H, 4.76; N, 5.01%.

The mother liquor was evaporated to remove most of the acetic acid and acetic anhydride, the orange residue dissolved in a mixture of benzene and petroleum benzine and submitted to column chromatography by the use of activated alumina (10 g.). Only a small amount of dark resinous substance remained on the column and further chromatographic separation of the effluent afforded two sorts of crystalline compound.

1) Colorless small plates melting at 129~130°C gave 4, 2', 4'-trinitroterphenyl and thus was identified as 2'-nitroterphenyl. Yield ca. 20%.

Found: N, 5.03, 5.15. Calcd. for $C_{18}H_{13}O_2N$: N, 5.01%.

2) Clear yellow plates melting at 126~127°C were identified as 2-nitroterphenyl. The corresponding amine, and acetylated amine gave the same melting points with those in the literature. Yield, 15 to 20%.

Found: N, 5.00, 5.12. Calcd. for $C_{18}H_{13}O_2N$: N, 5.01%.

*Reduction of 4-Nitroterphenyl.*—II (250 g.) in hot isoamyl acetate (8 l.) was gradually added to a warm mixture of ethanol (8 l.) and 11 N hydrochloric acid (2 l.) containing stannous chloride (dihydrate, 2 kg.) with a good stirring. The mixture was boiled for 30 min.; the almost colorless 4-aminoterphenyl hydrochloride (III) was filtered off, washed with ethanol, suspended in 0.1 N hydrochloric acid. boiled to remove ethanol and filtered off. The reduction was almost quantitative.

*Diazotization and the Sandmeyer Decomposition.*—To a freshly prepared suspension of III in water (20 l.) containing 11 N hydrochloric acid (250 ml.) and zinc chloride (dihydrate 50 g.), was dripped sodium nitrite (80 g.) in water (1 l.) with good stirring. This was continued for 3 hr. after the addition of nitrite, the temperature being kept at 10°C. No apparent change was observed. The excess of nitrite having been decomposed with urea, the suspension was treated with potassium iodide (200 g.) solution and heated to nearly boiling. When the suspension became colorless and the evolution of nitrogen ceased, the precipitate was filtered off, washed with sodium sulfite solution and dried. Powder of crude 4-iodoterphenyl (IV) was dissolved in hot xylene filtered and shaken first with hot 6 N sodium hydroxide solution and then with hot 6 N sulfuric acid containing stannous chloride and filtered. The filtrate was evaporated to remove most of the xylene and treated with ethanol to give pure IV, which was further distilled in vacuo (240°C, $10^{-2}$ mmHg) and recrystallized from isoamyl acetate. Yield, 40% based on II, m.p. 247~248°C.

Found: C, 60.74, 60.60; H, 3.67, 3.62; I, 35.64, 35.60. Calcd. for $C_{18}H_{13}I$: C, 60.69; H, 3.68; I, 35.63%.

*The Ullmann Condensation.*—In a small test tube, the powder of IV was mixed with copper (1 to 4 by weight), freshly prepared from copper sulfate and zinc dust and dried in vacuo, and placed in a potassium hydrogen sulfate bath at 280°C for 15 min. The reaction mixture was extracted with xylene and the residue sublimed in vacuo (400°C, $10^{-3}$ mmHg) to give crude sexiphenyl (V). The yield of this crude product was 0.25 g. from 1 g. of IV, corresponding to 10% based on I.

**Purification of Sexiphenyl.**—The crude V (12 g.) was boiled in potassium cyanide solution (10%, 500 ml.) for 30 min., sublimed in vacuo and further purified by recrystallization or by zone refining.

*Recrystallization.*—Since V is very sparingly soluble in organic solvents, only those with high boiling points are useful. Tetralin and dibutyl phthalate were passed through a column (diameter, 25 mm.; length, 600 mm.) of activated alumina, distilled in vacuo and used for recrystallization in a nitrogen atmosphere. Sublimed V (0.1 g.) was dissolved in boiling tetralin (1 l.), filtered, and the filtrate gradually cooled to give fluorescent platelets, which were filtered off, washed with ethanol, and dried. The product melted to a translucent fluid at 420°C.

Found: C, 94.04, 93.96; H, 5.75, 5.74. Calcd. for $C_{36}H_{26}$: C, 94.29; H, 5.71%.

*Zone Refining.*—A Bridgemann type furnace (diameter, 35 mm.) was set up to give a narrow region (ca. 2 cm.) of the maximum temperature (450°C) and have a suitable temperature gradient. A Telex tube containing V in vacuo ($10^{-4}$ mmHg) was caused to move downward at a rate of 3 cm. per hr. in the furnace. After this process a pale yellow mass with many dark brown stripes was obtained with a brown segregate on the top. The solid was taken out of the tube, the separable colored part removed and the yellowish mass was sublimed in vacuo. Almost colorless V came out, preceded by a small amount of yellowish substance, and a small amount of dark yellow residue remained. The sublimate consisted of almost pure V.

Since organic iodine compounds quench the fluorescence of organic scintillators to a marked extent[7], the removal of iodine was studied by repeated zone refining and vacuum sublimation. The sublimed V was submitted to zone refining and the iodine content of the solid determined by neutron activation analysis at various locations. The solid was then sublimed in vacuo and a similar cycle repeated. The results are summarized in Table II. It is seen that the difference in iodine content at varying locations in one lot is not marked but there appears to be an overall trend toward a lower iodine content with repetition of the cycle.

**Examination of the Purity of Sexiphenyl.**—The purity of V was examined by the usual chemical analysis and the neutron activation analysis.

*Neutron Activation Analysis.*—This is suitable for the determination of more than 0.005 $\mu$g. of iodine.

7) W. H. Helhuish and W. S. Metcalf, *J. Chem. Soc.*, 1958, 480.

The sample (10 mg.) was sealed in a polyethylene envelope and irradiated with thermal neutrons in a water-boiler type reactor for 1 hr. under a neutron flux $6\times10^{11}$ neutrons per $cm^2$ per sec., together with a standard potassium iodide. The irradiated sample was swiftly taken out of the reactor and the counting rate due to iodine-128 (half life, 25 min.) was determined with a G. M. counter. A known portion of the standard was converted into silver iodide together with a known amount of carrier iodine and the counting rate similarly measured under the same condition. The radioisotope was identified by the measurement of the half life; carbon, hydrogen, oxygen and nitrogen give no appreciable amount of radioisotope.

A similar method was also useful for the determination of copper (more than 0.02 $\mu$g.) by the use of copper acetate as a standard. The irradiated sample was set aside until radioactive iodine decayed and submitted to scintillation spectrometry for the counting rate due to 0.51 MeV annihilation peak of copper-64 (half life, 12.8 hr.) to be measured. No appreciable amount of copper was found in sublimed V.

*Measurement of the Melting Point.*—This involved some experimental difficulty, because V melts at a very high temperature and sublimes to a significant extent at more than 350°C. The sample was sealed in a glass capillary in vacuo and placed in a quartz tube together with an Almel-Chromel thermocouple. The tube was heated from outside with nichrom wire and the temperature was read on a calibrated millivoltmeter. A fused sodium nitrate bath was also useful for the same purpose.

**Summary**

1) Mononitration of *p*-terphenyl is satisfactorily effected at 100 to 110°C in glacial acetic acid containing about 10% acetic anhydride and a trace of sulfuric acid, and 4-nitro- (ca. 60%), 2'-nitro- (20 to 25%) and 2-nitroterphenyl (15 to 20%) are obtained.

2) Sexiphenyl is formed in a fairly good yield (more than 40%) by the Ullmann condensation of 4-iodoterphenyl and copper.

3) Sexiphenyl is satisfactorily purified by repeated zone refining and vacuum sublimation. The final product melts at 428~429°C to form an apparent liquid crystalline state and becomes tranparent at 543°C (475°C in literature). It contains an appreciable amount of neither iodine nor copper and can be converted into a fairly large single crystal to be used as scintillator.

A part of the expenses was defrayed by a grant from the Ministry of Education, to which the authors' thanks are due.

# *On the Reactivity of 4-Hydroxycyclohexyl p-Tosylates*

By Nobuo MORI

(Received March 3, 1960)

The effect of a conformation on the reactivity in cyclohexane systems is very important*, and especially the difference in reactivity between *cis*- and *trans*-cyclohexane compounds serves generally for the study on their configurations.

The present paper describes the unexpected result that *trans*-4-hydroxy or -4-acetoxycyclohexyl *p*-tosylate was solvolyzed more rapidly than the corresponding cis isomer.

## Results and Discussion

The solvolysis rates of 4-hydroxycyclohexyl *p*-tosylates were measured at 99.8°C in ethanol (98.5% by weight), and that of 4-acetoxycyclohexyl *p*-tosylates measured in acetic acid containing a slight excess of acetic anhydride. In all cases, except alkaline ethanolysis, the observed rates were of the first order and the error of the measurements was always lower than 3%. Since the mean rate constants of the acetolysis of the *cis*- and *trans*-4-acetoxylcyclohexyl *p*-tosylates were not substantially affected by addition of a small quantity of anhydrous sodium acetate, the acetolysis is probably of the unimolecular type. On the other hand, a calculated first order rate constant decreased gradually during the solvolysis of the isomeric hydroxycyclohexyl *p*-tosylates in ethanol containing sodium ethoxide in 0.02 mol./l., in agreement with the behavior of 3-methyl

* The importance was first pointed out by D. H. R. Barton (*Experientia*, **6**, 316 (1950)).

cyclohexyl *p*-tosylate described previously[1], and the mean rate constants were about 3 times of that in neutral ethanol. This fact suggests that a part of the alkaline ethanolysis consists of a bimolecular reaction based on the back-side attack of the ethoxide ion. Table I lists the data for a run with *cis*-4-acetoxycyclohexyl *p*-tosylate in acetic acid containing sodium acetate in 0.029 mol./l., while a run with *cis*-4-hydroxycyclohexyl *p*-tosylate in ethanol containing sodium ethoxide in 0.02 mol./l. is given in Table II. It is seen that in the former run a first order rate constant is satisfactorily constant and in the latter run a rate constant decreases gradually during the solvolysis.

| $k_{trans}/k_{cis}$ | 3.3 | 3.5 | 2.6 | 2.5 |

Generally, in solvolysis of rigid cyclohexane systems for example *t*-butylcyclohexyl *p*-tosylate, the compound where the departing group is axial is solvolyzed in ethanol, acetic acid or formic acid at a rate 3~4 times as fast as that of the corresponding isomer where the departing group is equatorial, and also in a mobile substituted cyclohexane system, as that shown in Fig. 1, where that two possible chair conformations are readily interconvertible, for example as 3-methoxycarbonylcyclohexyl *p*-tosylate[3] or 1, 3-di-*p*-toluenesulfoxycyclohexane[1], the solvolysis leads to an essencially similar result.

The possible conformations of 4-substituted cyclohexyl *p*-tosylates are as follows:

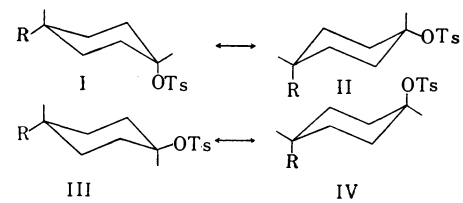

Fig. 1

where R is a substituent and Ts is the tosyl group. The conformation III of the trans form is probably more stable than the conformation IV, while the difference in stability between the conformation I and II of the cis form is probably very small or negligible, when R is not so large a group as *t*-butyl group. Thus, it is expected that the cis form is more reactive than the trans form, as described above.

However, in the present work, the *trans*-4-hydroxycyclohexyl *p*-tosylate was ethanolyzed at a rate 3.5 times as fast as that of the corresponding cis isomer, and also the *trans*-4-acetoxycyclohexyl *p*-tosylate was acetolyzed at a rate 2.5 times as fast as that of the corresponding cis isomer. These facts can not be explained on the basis of the general rule described above.

Further, the configuration of the isomeric cyclohexane-1, 4-diols, which was first established by Bayer[4], is in agreement with the chemical fact that, by direct dehydration of

diol over alumina, the yield of 1, 4-epoxycyclohexane from the *trans*-diol was much higher than that from the *cis*-diol[5], and it is probably right.

A further study concerning this problem will be reported shortly.

## Experimental

**Samples*: *cis*- and *trans*-Cyclohexane-1, 4-diol.**—Quinol (25 g.) in methanol (30 cc.) in an autoclave was hydrogenated at 120°C under 80 initial atm. in the presence of Raney nickel (10 g.) for about 3 hr. until no more hydrogen was absorbed. The filtered solution was evaporated under reduced pressure and the residue was acetylated by refluxing with acetic anhydride (70 cc.) for 3 hr. and the crude diacetate crystallized from hot acetone (30 cc.), to give prisms of the *trans*-diacetate which melted at 100.5 ~102°C after one recrystallization from ligroin (b. p. 75~120°C). The yield was 13.5 g. The acetone filtrate was concentrated, diluted with benzene (5 cc.) and then ligroin, and seeded with the *trans*-diacetate in a refrigerator, to give a small amount of this material. The residual solution was concentrated and placed with occasional stirring in a refrigerator for several days until it crystallized, to give the *cis*-diacetate which melted at 34~35°C after recrystallization from a small volume of ligroin. The yield was 12 g.

A solution of the *trans*-diacetate in absolute methanol (30 cc.) treated with a very small piece of metal sodium was refluxed for 30~60 min., concentrated to a small volume under reduced pressure, dissolved in hot dry ether and cooled to 0°C, to give as prisms the *trans*-diol, m. p. 144°C.

The *cis*-diacetate was similarly treated and the residue obtained by concentration of the reaction mixture was crystallized from hot acetone, to give as needles the *cis*-diol, m. p. 110°C.

The *trans*-diol (4.9 g.) in dry pyridine (25 cc.) was treated under stirring and cooling to 0~5°C with *p*-toluenesulfonyl chloride (7.52 g.) in chloroform (25 cc.). After stirring for 3 hr. at room temperature, the mixture was poured into excess of dilute hydrochloric acid cooled with ice, the resulting chloroform solution was washed with dilute hydrochloric acid, water and then a 10% solution of sodium carbonate, dried over sodium sulfate and evaporated under reduced pressure. The residue was dissolved in hot benzene, treated with hot ligroin and cooled to room temperature, to give the *trans*-monotosylate in needles, m. p. 112.5°C after recrystallization from benzene-ligroin.

When the reaction mixture, treated with *p*-toluenesulfonyl chloride as described above, was further treated with one equivalent quantity of acetyl chloride in chloroform, it gave the *trans*-acetoxy cyclohexyl *p*-tosylate in needles, m. p. 81~81.5°C after crystallization from benzene-ligroin.

When the *cis*-diol was similarly treated and recrystallized, the *cis*-hydroxycyclohexyl tosylate (m.p. 94~95°C) and the *cis*-acetoxycyclohexyl tosylate (m. p. 105°C) were obtained.

**Solvents.**—*Ethanol* (98.5% by weight).—Reagent grade absolute ethanol was fractionally distilled.

*Acetic Acid.* — Reagent grade glacial acetic acid was crystallized twice by the freezing method, refluxed with 2% by weight of acetic anhydride and 1% by weight of anhydrous sodium acetate for 3 hr. and distilled.

**Procedure.**—Rates were measured by the usual ampoule technique[7]. Concentrations are given at room temperature and the reaction was followed by the titration at intervals for the sulfonic acid liberated or the base consumed during the solvolysis. Titrations in acetic acid were carried out with a 0.05 N solution of AcONa or *p*-toluenesulfonic acid in acetic acid with bromophenol blue as indicator, and in ethanol a 0.05 N solution of sodium hydroxide or hydrochloric acid in water was used for titration with phenolphthalein as indicator. Rate constants were calculated from the formula

$$k_1 = 1/t \ln a/(a-x)$$

in which $a$ was the initial concentration of tosylate and $x$ was the concentration of sulfonic acid liberated or base consumed at time $t$.

The author expresses his sincere thanks to Professor Y. Tsuzuki for his advice during the investigation.

# *Ultraviolet Absorption Spectra of Substituted Phenylureas. Part II*[1]. *Solvent Effect and Structure of Carbamide Group*

By Yojiro TSUZUKI, Shinichi MOTOKI and Ritsuko TANESE

(Received April 11, 1960)

In the previous paper dealing with the ultraviolet absorption spectra of substituted phenylureas it was suggested that the carbamide group $-NHCONH_2$ behaves electronically as a peculiar substituent[1].

With disubstituted benzenes in general Doub and Vandenbelt found some semiquantitative relationships[2], which exist between the absorption displacement $\Delta\lambda$ and the electronic properties of the two substituents. Applying these empirical rules to the previous results, it has now been confirmed that the substituent $-NHCONH_2$ behaves as an electron-attracting or releasing group according as the other substituent is electron-releasing or attracting. During the course of an investigation of the unusual property of this group, attention has been drawn to the data given by Schroeder[3] of the spectra of ethyl phenylureas.

As is shown in Table I, *N*-ethyl phenylureas show markedly decreased intensity of absorption, whereas *N'*-ethyl derivatives exhibit strong

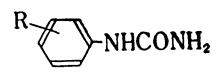
absorption, as is observable in phenylurea itself. Since this effect of the alkyl group is likely to be observed in general when prototropy is set up in the systems[4], the following tautomerism (I, II, and III form) may be possible, and hence aryl ureas may, at least partly, be present in the pseudo form II. This form is impossible for *N*-alkyl phenylureas, which exhibit less intense absorptions.

(I) (II) (III)

The electronically amphoteric property of the carbamide group is thus clearly shown with the following resonance structures of the isomer.

(IV) (V) (VI)



The presence of an acidic, enolizable hydrogen atom in the carbamide group is also supported by the fact that phenylureas are more soluble in aqueous alkalis than in water. From these considerations it becomes a theme of some interest to study the solvent effect on the spectra of these compounds for the purpose of getting further information on the nature of the group. In the present study were used some solvents of different polarity, such as water, ethanol and ethyl ether.

## Results and Discussions

The experimental results are given in Tables II and III. It is clearly seen that the absorption intensity of the compounds increases markedly, as the polarity of the solvent decreases.

Now the remarkable solvent effect seen in Tables II and III should be considered. With common substances the extinction coefficient is, however, only slightly (5~7%) affected by the solvent, whereas the above cases are entirely different, namely $\varepsilon_1$ and $\varepsilon_2$ radically change on the whole according to the solvent. These remarkable solvent effects are occasionally observed by dissolving substances in such solvents as bring about some very mild chemical changes, as complex formation or displacement of tautomeric equilibrium[5]. Thus the data of the absorption spectrum are reasonably interpreted by assuming that in less polar solvents the equilibrium of tautomerism of aryl ureas moves towards the acidic pseudo form II which absorbs more intensely than the normal form I.

Another outstanding feature noticeable in Tables II and III is the blue shift of the absorption bands which shift further as the polarity of the solvent increases, however, with a few exceptions of *p*-nitro-, *m*-methoxy- and *o*-methoxy-phenylureas. This feature is peculiar, for increasing polarity of the solvent usually causes on the contrary a red shift of the absorption band[6].

To see clearly the effect of orientation (*o*, *m* and *p*-RO) on the red shift in ethoxy- and methoxy-phenylureas, the data in Table III were analyzed and the results are shown in Table IV.

|---|---|---|---|
| | | K-band | B-band |
| Ether | $C_2H_5OC_6H_4NHCONH_2$ | $p>o=m$ | $p\gg o>m$ |
| Ether | $CH_3OC_6H_4NHCONH_2$ | $p>o=m$ | $p\gg o>m$ |
| Ethanol | $C_2H_5OC_6H_4NHCONH_2$ | $p>o>m$ | $p\gg o>m$ |
| Ethanol | $CH_3OC_6H_4NHCONH_2$ | $p>o=m$ | $p\gg o>m$ |
| Water | $C_2H_5OC_6H_4NHCONH_2$ | $m>p>o$ | $p>o=m$ |
| Water | $CH_3OC_6H_4NHCONH_2$ | $m>o>p$ | $p>o=m$ |

From Tables III and IV is noticed a third interesting phenomenon, namely, for B-band the absorption maximum of the alkoxy-phenylureas is in the order $p\gg o>m$ in both ethanol and ether, while in aqueous solution the three nuclear isomers absorb nearly the same wave length region; for the K-band, *m*-compounds absorb in aqueous solution the region of the longest wavelength ($m>p=o$), although the former relation $p>o>m$ nearly holds in ethanolic and ethereal solution.

These somewhat peculiar relations may be interpreted, at least partly, by the idea that in aqueous solution the carbamide group mainly takes the urea form, so that it loses the electron-attracting property as the result of the absence of resonance with the alkoxyl group, but in non-aqueous solutions the carbamide group assumes a greater part of the pseudo form, making the resonance possible with the alkoxyl group.

Thus the pseudo form of phenylureas is assumed and may be confirmed from various angles. For this purpose it is desirable to synthesize some of the pseudo derivatives, and to make a special study of the spectrum[7]. The result of this study will be reported in the next paper.

## Experimental

**Preparation of Compounds.**—Substituted phenylureas were prepared from potassium cyanate and the corresponding nuclear substituted anilines by the methods described in "Organic Syntheses"[8], *o*-Methoxyl phenylurea, m. p. 146.5°C, *m*-isomer, m. p. 130°C, *p*-isomer, m. p. 164~5°C. The solvents were purified by distillation. Ethanol was tested to be free from benzene.

**Absorption Spectra.**—The absorption spectra were measured in the region of 200~350 mμ by means of a Beckmann Model DU Quartz spectrophotometer with the solutions of concentration about 1/10,000 M.

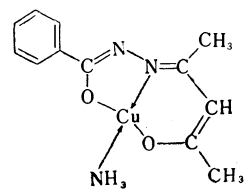
# *Über die Kupfer(II)- und Nickel(II)-komplexsalze der Benzoylhydrazone einiger aliphatischen Carbonylverbindungen**

Von Hiroshi OHTA

(Eingegangen am 18. Februar, 1960)

Als Carbonylreagens bildet das Benzoylhydrazin mit den Aldehyden Benzoylhydrazone. Die Benzoylhydrazone der aromatischen Aldehyde sind in den organischen Lösungsmitteln ziemlich schwer löslich, diejenigen der aliphatischen Reihe sind aber spielend löslich. Im vorliegenden Experiment ist gezeigt worden, daß die ersteren mit zweiwertigem Kupfer- oder Nickel-Ion keine charakterisierbaren Komplexsalze geben, während die letzteren gut gebildete Komplexsalze liefern.

Zuerst sollen die Kupfer(II)- und Nickel-(II)-komplexsalze einiger aliphatischen Monoaldehyde beschrieben werden. Als Aldehydkomponente wurden Acetaldehyd (Äthanal), *n*-Butyraldehyd (*n*-Butanal), *n*-Önanthaldehyd

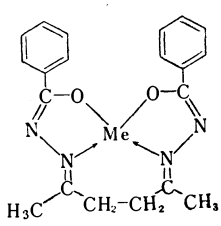


I

Me=Cu oder Ni.
R=1) $CH_3$, 2) $(CH_2)_2CH_3$, 3) $(CH_2)_5CH_3$, 4) $(CH_2)_8CH_3$.

* Organische Metallkomplexsalze IV. III. Mitteilung: H. Ohta, Dieses Bull., 33, 202 (1960).

(*n*-Heptanal) und *n*-Caprinaldehyd (*n*-Dekanal) ausgewählt. Die komplexsalze wurden aus dem Benzoylhydrazin, den Aldehyden und den Metallacetaten in Äthanol leicht dargestellt und in schönen Kristallen erhalten. Die Kupfersalze sind rötlich violett, die Nickelsalze gelbrot. Sie würden mit der Formel I formuliert werden können. Alle diese Komplexsalze, besonders diejenigen des *n*-Heptanal-benzoylhydrazons und des *n*-Dekanal-benzoylhydrozons sind in den meisten organischen Lösungsmitteln leicht löslich und die letzteren zwei zeigen ziemlich niedrige Schmelzpunkte kraft der längeren aliphatischen Ketten[1].



Dann werden die Kupfer(II)- und Nickel-(II)-komplexsalze der Benzoylhydrazone von den aliphatischen 1, 3- und 1, 4-Diketonen, dem Acetylaceton (2, 4-Pentandion) und dem Acetonylaceton (2, 5-Hexandion) beschrieben. Aus Benzoylhydrazin, 2, 4-Pentandion und Kupferacetat in alkoholischem Ammoniak wurde nur 2, 4-Pentandion-monobenzoylhydrazono-monoammin-kupfer(II) (Formel II), nicht 2, 4-Pentandion-dibenzoylhydrazono-kupfer(II) noch 1-Benzoyl-3, 5-dimethyl-pyrazol erhalten. Das entsprechende Nickelkomplexsalz konnte nicht erhalten werden, weil es so sehr leicht löslich war.

II

Die Komplexsalze vom 2, 3-Butandion-dibenzoylhydrazon waren schon von Sacconi[2] berichtet worden. Es ist klar, daß sie beständig sind, weil sie durch den Chelat- und Resonanzeffekt stabilisiert sind.

Um zu entscheiden, welche Komplexsalze das 2, 5-Hexandion-dibenzoylhydrazon gibt, welches zwei mehr Methylen-Gruppen enthält als 2, 3-Butandion-dibenzoylhydrazon, wurde die Synthese seiner Kupfer(II)- und Nickel(II)-komplexsalze versucht. Ein schwärzlich-braunes Kupfersalz und ein rotes Nickelsalz wurden erhalten, die nach den analytischen Daten mit der Formel III formuliert werden können, denn sie sind kristallinisch erhalten und in den organischen Lösungsmitteln leicht löslich.

III

Me=Cu oder Ni

Nach den Farben dieser Komplexsalze (Kupfersalze: rötlich-violett bzw. schwärzlich-braun, Nickelsalze: gelbrot bzw. rot) besitzen sie alle wohl quadratische, ebene Konfiguration. Die Struktur der Nickelkomplexsalze konnte sich aus der magnetischen Suszeptibilität erschließen**. Nach den magnetischen Messungen sind beide Bis-(Äthanal-benzoylhydrazono)-nickel(II) und 2, 5-Hexandion-dibenzoylhydrazono-nickel(II) diamagnetisch, was auf planen Bau hindeutet***.

## Beschreibung der Versuche

Die magnetischen Messungen wurden mit der Gouyschen Waage ausgeführt.

*Bis-(Äthanal-benzoylhydrazono)-kupfer(II).* — Man gibt zur Lösung von 324 mg Äthanal-benzoylhydrazon[3] in 10 ccm Äthanol, 200 mg Kupferacetat (Monohydrat) in 5 ccm Wasser. Die Farbe der Lösung verändert sich zu Dunkelgrün und ein Niederschlag entsteht. Erwärmt man das Gemisch auf dem Wasserbade, so verwandelt sich der Niederschlag nach und nach in hell rötlich-violette Nadeln, die man aus 1, 4-Dioxan umkristallisiert. Hell rötlich-violette Nadeln.

Gef.: C, 56.08; H, 4.72; N, 14.57; Cu, 16.42. Ber. für $C_{18}H_{18}O_2N_4Cu$: C, 56.02; H, 4.70; N, 14.52; Cu, 16.46.

*Bis-(Äthanal-benzoylhydrazono)-nickel(II).* — Man gibt zur Lösung von 342 mg Äthanal-benzoylhydrazon in 10 ccm Äthanol, 250 mg Nickelacetat (Tetrahydrat) gelöst in 5 ccm Wasser. Es entsteht eine klare, dunkelblaue lösung, die sich durch kurzes Erwärmen auf dem Wasserbade in eine bräunlich-grüne verwandelt, aus der sich rötlich-gelbe Nadeln ausscheiden. Man kristallisiert sie aus dem Gemische von 1, 4-Dioxan und Äthylenglykol-monoäthyläther um. Rötlich-gelbe Nadeln.

Gef.: C, 56.70; H, 4.84; N, 14.70; Ni, 15.23. Ber. für $C_{18}H_{18}O_2N_4Ni$: C, 56.73; H, 4.76; N, 14.70; Ni, 15.41.

*Bis-(n-Butanal-benzoylhydrazono)-kupfer(II).* — Man gibt zur Lösung von 272 mg Benzoylhydrazin in 10 ccm Äthanol, 200 mg Kupferacetat (Monohydrat) in 5 ccm Wasser und darauf 144 mg *n*-Butanal. Es

*Bis-(n-Heptanal-benzoylhydrazono)-kupfer(II).* — Man gibt zur Lösung von 272 mg Benzoylhydrazin in 2 ccm Äthanol, 200 mg Kupferacetat (Monohydrat) in 10 ccm Äthanol, und darauf 228 mg *n*-Heptanal. Es entsteht sofort eine schwärzlich-blaue Lösung, die eine kurze Weile auf dem Wasserbade erwärmt wird. Beim Erkalten scheiden sich hell rötlich-violette Kristalle aus (wenn nötig, muß man die Gefäßwand mit dem Glasstab reiben, oder die Lösung etwas konzentrieren), die man aus Äthanol umkristallisiert. Hell rötlich-violette, zarte Nadeln, welche bei 118~119°C (unkorr.) schmelzen. Ziemlich löslich in warmem Äthanol.

Gef.: C, 63.84; H, 7.26; N, 10.71; Cu, 12.44. Ber. für $C_{28}H_{38}O_2N_4Cu$: C, 63.91; H, 7.28; N, 10.65; Cu, 12.07.

*Bis-(n-Heptanal-benzoylhydrazono)-nickel(II).*—Man gibt zur Lösung von 272 mg Benzoylhydrazin in 10 ccm Äthanol, 250 mg Nickelacetat (Tetrahydrat) in 7 ccm Wasser und darauf 228 mg *n*-Heptanal. Es entsteht anfangs eine dunkelblaue, klare Lösung, die sich aber nach einigen Sekunden unter Trübung in eine schmutzig gelbgrüne verwandelt, aus der gelbrote Kristalle auszufallen beginnen. Nach der beinahe vollkommenen Ausscheidung der Kristalle, fügt man noch 3 ccm Wasser hinzu. Die Lösung trübt sich, welche aber durch Umrühren unter Abscheidung von noch einer kleinen Menge Kristalle klar wird. Man kristallisiert das Salz aus Äthylenglykol-monoäthyläther um. Gelbrote Blättchen, die bei 120~121.5°C (unkorr.) schmelzen.

Gef.: C, 64.56; H, 7.48; N, 10.58; Ni, 11.11. Ber. für $C_{28}H_{38}O_2N_4Ni$: C, 64.51; H, 7.35; N, 10.75; Ni, 11.26.

*Bis-(n-Dekanal-benzoylhydrazono)-kupfer(II).*—Man stellt es in derselben Weise wie beim Bis-(*n*-Heptanal-benzoylhydrazono)-kupfer(II) aus 272 mg Benzoylhydrazin in 2 ccm Äthanol, 200 mg Kupferacetat (Monohydrat) in 10 ccm Äthanol und 313 mg *n*-Dekanal dar und kristallisiert aus Äthanol um. Rötlich-violette, zarte Nadeln, die bei 106~107°C (unkorr.) schmelzen. Ziemlich löslich in warmem Äthanol.

Gef.: C, 66.98; H, 8.25; N, 9.24; Cu, 10.35. Ber. für $C_{34}H_{50}O_2N_4Cu$: C, 66.91; H, 8.26; N, 9.18; Cu, 10.41.

*Bis-(n-Dekanal-benzoylhydrazono)-nickel(II).*—Man fügt zur Lösung von 272 mg Benzoylhydrazin in 10 ccm Äthanol, 250 mg Nickelacetat (Tetrahydrat) in 5 ccm Wasser und darauf 313 mg *n*-Dekanal hinzu. Es entsteht sofort eine dunkelblaue, klare Lösung, die sich bald trübt; aus der getrübten Lösung scheiden sich schöne, gelbrote Kristalle aus, welche man aus 1,4-Dioxan umkristallisiert. Rötlich-gelbe Säulchen, die bei 108~109°C (unkorr.) schmelzen.

Gef.: C, 67.33; H, 8.23; N, 9.30; Ni, 9.55. Ber. für $C_{34}H_{50}O_2N_4Ni$: C, 67.44; H, 8.32; N, 9.25; Ni, 9.69.

*2,4-Pentandion-monobenzoylhydrazono-monoammin-kupfer(II).*—Man löst 272 mg Benzoylhydrazin in 200 mg 2,4-Pentandion durch Erwärmen, und darauf fügt man 5 ccm Äthanol zur Lösung zu. Gibt man zu dieser Lösung eine Lösung von 400 mg Kupferacetat (Monohydrat) in 10 ccm wässrigem Ammoniak (ca. 28%), so entsteht sofort eine schwärzlich-grüne, klare Lösung, die man auf dem Wasserbade so lange erwärmt, bis eine kleine Menge Kristalle auf der Oberfläche schwimmt. Beim Erkalten scheiden sich sehr langsam glänzende, schwärzlich-grüne Nadeln aus.

Gef.: C, 48.25; H, 5.19; N, 14.12; Cu, 21.11. Ber. für $C_{12}H_{12}O_2N_2 \cdot NH_3 \cdot Cu$: C, 48.56; H, 5.09; N, 14.16; Cu, 21.41.

*2,5-Hexandion-dibenzoylhydrazono-kupfer(II).* — Man gibt zur Lösung von 272 mg Benzoylhydrazin in 15 ccm Äthanol, 114 mg 2,5-Hxandion und darauf 200 mg Kupferacetat (Monohydrat) in 5 ccm Wasser. Es entsteht sofort eine dunkelgrüne Lösung, aus der sich beim kurzen Erwärmen glänzende, schwärzlich-braune Kristalle ausscheiden. Man kristallisiert sie aus 1,4-Dioxan um. Schwärzlich-braune, glänzende Rauten. Etwas löslich in Dioxan; Lösungsfarbe: dunkelgrün.

Gef.: C, 58.35; H, 4.97; N, 13.67; Cu, 15.41. Ber. für $C_{20}H_{20}O_2N_4Cu$: C, 58.31; H, 4.89; N, 13.60; Cu, 15.42.

*2,5-Hexandion-dibenzoylhydrazono-nickel(II).*—Man gibt zur Lösung von 272 mg Benzoylhydrazin in 20 ccm Äthanol, 114 mg 2,5-Hexandion und darauf 250 mg Nickelacetat (Tetrahydrat) in 5 ccm wässrigem Ammoniak (ca. 28%). Eine hellviolette Lösung entsteht, die sich durch Erwärmen auf dem Wasserbade in eine dunkelgrüne, dann in eine bräunlich-grüne verwandelt. Engt man diese Lösung auf dem Wasserbade stark ein, so scheiden sich rote Kristalle aus, die man aus 1,4-Dioxan umkristallisiert. Rote, glänzende Rauten.

Gef.: C, 59.10; H, 5.07; N, 13.84; Ni, 14.32. Ber. für $C_{20}H_{20}O_2N_4Ni$: C, 59.00; H, 4.95; N, 13.76; Ni, 14.42.

Zum Schluß möchte ich meinem Lehrer, Herrn Prof. Dr. Tokuichi Tsumaki für die Unterstützung und Forderung dieser Arbeit

meinen herzlichen Dank aussprechen. Herrn Professor Dr. Ryohei Matsuura und Herrn Dr. Yasushi Koga (Physikalisch-chemisches Laboratorium) für die magnetischen Messungen danke ich auch herzlichst. Herrn Michio Shido und Frl. Sachiko Indo (Laboratorium der Elementaranalyse, Kyushu Universität) verdanke ich die Durchführung der C-, H- und N-Bestimmungen.

# *Determination of Oxygen in Some Minerals Using Pyrite*

By Iwaji IWASAKI, Takashi KATSURA and Minoru YOSHIDA

(Received February 26, 1960)

A few years ago some experiments on the reactions among various kinds of sulfides, sulfates and oxides which occur in volcanic and hot spring districts were carried out by the present authors to ascertain the relations of their formation and occurrence[1]. The results of the experiments indicated that the amount of oxygen in some minerals can be easily determined with pyrite.

It has been pointed out that pyrite is easily oxidized during the process of grinding in the air and that a remarkable error may be introduced into the result of chemical analysis of pyrite from this oxidation[2]. While no method has yet been found to determine the minute amount of oxygen in pyrite, some reports described oxidation products of pyrite. From those reports, it would be concluded that iron sulfates may be formed by the oxidation[3,4]. In addition to these products, fine powder of pyrite may absorb moisture and oxygen from the air, and it should also be considered that the sample of pyrite may be contaminated with the small amount of oxides or sulfates contained originally in the raw minerals. Thus iron oxides, absorbed oxygen and absorbed water could be the sources of oxygen in pyrite samples, even if the samples, were almost pure under microscopic observation. And it should be pointed out that the oxygen in the samples reacts with the pyrite and is liberated as sulfur dioxide on heating the samples at a high temperature in vacuo. If the liberation of sulfur dioxide is quantitative, the amount of oxygen in the samples can be estimated from that of the sulfur dioxide evolved.

When moisture exists, hydrogen sulfide may also be formed, and the situation may be somewhat complicated because of the equilibrium among hydrogen sulfide, sulfur dioxide and water vapour. The nature of these reactions should be carefully investigated to establish an accurate method for the determination of oxygen in pyrite and other minerals. There are some reports on the reactions between pyrites and iron oxides[5], iron sulfates[6,7] and water[8], but the results are insufficient for the present purpose. In the present paper, the results obtained on these reactions and the method for the determination of a minute amount of oxygen in pyrite and the amount of oxygen in other minerals by using pyrite are given.

## Experimental

**Materials.**—Natural pyrites used in the present study had a chemical composition* nearly equal to the ideal chemical formula, $FeS_2$, and the values obtained for the lattice constant of crystals agreed well with the data described by Parker and Whitehouse[9], and also by Hiemstra[10] (5.416~5.417Å). Iron monosulfide was obtained by thermal decomposition of the pyrites at about 900°C in vacuo. The chemical composition of the artifical

iron monosulfide was somewhat richer in sulfur, and its chemical formula was $FeS_{1.03}$. It was not ferromagnetic and its properties agreed well with those of troilite under microscopic observation. Magnetite was obtained by thermal decomposition of reagent grade $\alpha$-ferric oxide in a quartz tube at about 1200°C and below $1\times10^{-4}$ mmHg of oxygen pressure achieved by pumping it out. The magnetite obtained as above had almost the ideal chemical composition, 49.9% FeO and 50.1% $Fe_2O_3$ in molar ratio. Other chemicals, such as $\alpha$-ferric oxide, ferrous sulfate $FeSO_4\cdot7H_2O$, and ferric sulfate $Fe_2(SO_4)_3\cdot nH_2O$ [78% $Fe_2(SO_4)_3$] employed were all of reagent grade. The reagents were used after removing the water by heating in vacuo.

**Apparatus and Procedure.** — The apparatus employed is shown in Fig. 1. The maximum temperature attained is about 1000°C.

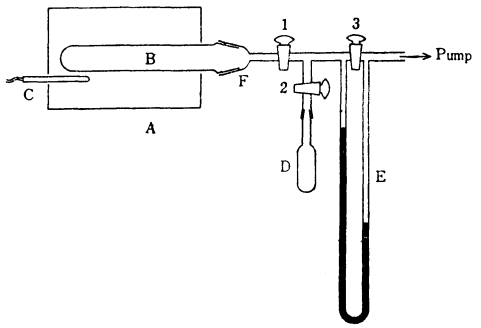

Fig. 1. Apparatus
A. Electric furnace
B. Quartz tube
C. Thermocouple
D. Absorption tube
E. Manometer
1,2,3 Cock

The finely powdered mixture of the sample with the pyrite was packed in a small quartz tube, and then placed at the bottom of a quartz combustion tube B (Fig. 1). Then all of the apparatus was evacuated to a pressure of $10^{-2}\sim10^{-3}$ mmHg. To analyse the gas evolved from the sample, potassium hydroxide was placed in tube D. After evacuation, cocks 2 and 3 were closed, then the temperature was raised at a rate of about 200°C per hr. The pressure of the evolved gas was continuously measured. The correction of the pressure for the temperature change was experimentally determined, and the volume of the evolved gas was calculated in N. T. P. When the reaction came to the end, cock 2 was opened, and the pressure of the unabsorbed gas was determined. This was usually very low in all of the present experiments. Potassium hydroxide which absorbed the acid gas was then dissolved in water and was poured into a suspension of freshly precipitated basic cadmium carbonate. By this procedure hydrogen sulfide is fixed in the precipitate as cadmium sulfide and sulfur dioxide remains in the filtrate as sulfite ions. The amount of hydrogen sulfide from the precipitate and the amount of sulfur dioxide from the filtrate were determined by iodometric titration. As the gas evolved from the reactions of the oxide and the sulfate with the pyrite contained only a negligible amount of hydrogen sulfide, the amount of sulfur dioxide could be determined directly by the manometric method. The nature of the solid products was also examined by chemical, X-ray and microscopic methods.

## Results and Discussion

When the powdered pyrite alone was heated in the apparatus, a dissociated sulfur was deposited inside F the silica tube, and in some cases the evolution of a small amount of a gas which was stable at room temperature was observed. The analysis of the gas showed that it consists mainly of sulfur dioxide, hydrogen sulfide and water vapor, and that its amount is influenced to some extent by the degree of pulverization or other conditions. Therefore, a correction must be made for each kind of pyrite, when the volume of the sulfur dioxide evolved by the reaction between pyrites and iron oxides or iron sulfates is measured. From the repeated blank experiments, the blank values for the pyrite used in the present experiments were obtained as shown in Table I:

TABLE I

| Temp. range | Correction ml. per 1 g. pyrite |
|---|---|
| Below 450°C | Almost negligible |
| 450~550°C | 2.5 |
| 550~650°C | 3.0 |

**(1) The Reaction between Pyrite and Ferric Oxide.**—As will be seen in Fig. 2, the reaction between pyrite and ferric oxide begins at about 500°C and comes to the end at about 600°C. When an excess of pyrite exists, the solid product of the reaction is only troilite, and the reaction may be regarded as follows:

$$7FeS_2+2Fe_2O_3=11FeS+3SO_2 \qquad (1)$$

The amount of sulfur dioxide evolved from

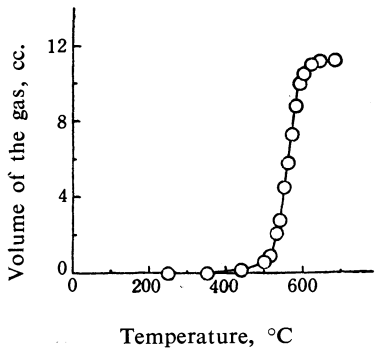

Fig. 2. Reaction between pyrite and $\alpha$-ferric oxide (I).
Pyrite 200 mg.
$Fe_2O_3$ 50 mg.

the mixture of 200 mg. of pyrite and 50 mg. of ferric oxide was 10 ml. (0°C, 1 atm.) in the range 500~600°C, and the value calculated from Eq. 1 is 10.5 ml.

When the amount of pyrite was insufficient to reduce all ferric oxide to troilite, the reaction was likely to proceed through two stages as shown in Fig. 3. The first stage of the reaction would correspond to Eq. 1, and the second to Eq. 2, which shows the reaction between the troilite and the remainder of the ferric oxide.

$$FeS + 10Fe_2O_3 = SO_2 + 7Fe_3O_4 \quad (2)$$

All the results such as the amount of gas evolved through each stage, the range of the reaction temperature, and the properties of the solid products observed by X-ray and microscopic method support the assumption described above. Martin and Fuchs[5] studied the reaction of similar mixtures of pyrite and

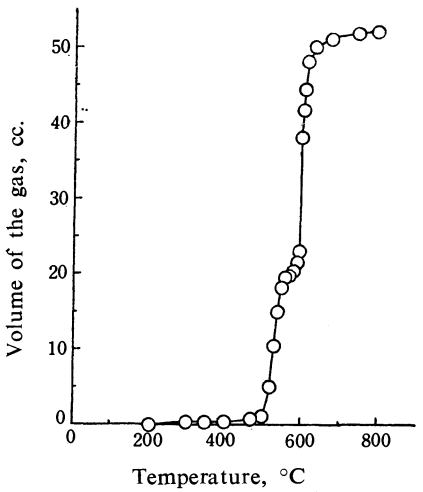

Fig. 3. Reaction between pyrite and α-ferric oxide (II).
Pyrite 250 mg.
$Fe_2O_3$ 2.0 g.

ferric oxide (weight ratio 1 : 2.25 or 1 : 3) and obtained a mixture of troilite and magnetite as solid products. The co-existence of these solid phases can be interpreted by the results obtained by our experiments, but according to theirs, the reaction began at 570°C, came to the end at 870°C, and the range of the reaction temperature was higher than that obtained by the present authors.

As the ferric oxide reacts completely with the pyrite to liberate sulfur dioxide at about 600°C as shown in Fig. 2, the amount of the ferric oxide in the iron sulfides can be determined by measuring the amount of sulfur dioxide evolved from the samples with a sufficient amount of pyrite.

**(2) The Reaction between Pyrite and Magnetite.** — Magnetite ($Fe_3O_4$) also reacts with pyrite to form troilite and sulfur dioxide at a high temperature as shown in Eq. 3.

$$5FeS_2 + Fe_3O_4 = 8FeS + 2SO_2 \quad (3)$$

The amount of the gas evolved was in good agreement with Eq. 3. The reaction began at about 550°C, and came to the end at about 650°C as shown in Fig. 4. The temperature range of the reaction overlapped with that of the reaction between pyrite and ferric oxide. Magnetite did not react practically with troilite below 1000°C.

As magnetite reacts completely with the pyrite to liberate sulfur dioxide at about 650°C as shown in Fig. 4, the amount of the magnetite in the iron sulfides can be determined by measuring the amount of sulfur dioxide evolved from the samples with a sufficient amount of pyrite.

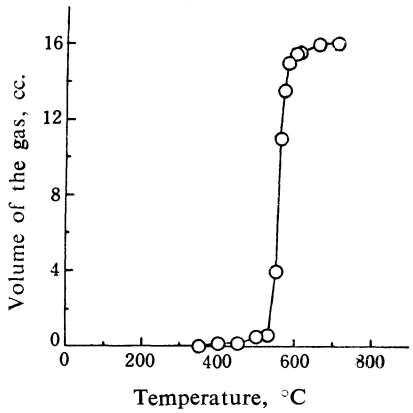

Fig. 4. Reaction between pyrite and magnetite.
Pyrite 200 mg.
$Fe_3O_4$ 100 mg.

**(3) The Reaction between Pyrite and Ferric Sulfate.**—When sufficient amount of pyrite is present, the reaction between pyrite and ferric sulfate began at about 300°C and came to an end at about 650°C proceeding through three stages as shown in Fig. 5. The final product was only troilite, and the equation of the reaction in each stage can be considered as follows:

The first stage (about 300~420°C)

$$FeS_2 + 3Fe_2(SO_4)_3 = 7FeSO_4 + 4SO_2 \quad (4)$$

the second stage (about 450~520°C)

$$FeS_2 + 8FeSO_4 = 3Fe_3O_4 + 10SO_2 \quad (5)$$

the third stage (about 550~650°C)

$$5FeS_2 + Fe_3O_4 = 8FeS + 2SO_2 \quad (3)$$

Example 2 $Fe_2(SO_4)_3 \cdot nH_2O$ 0.2 g., $FeS_2$ 0.4 g.

| | $SO_2$ found, ml. | $SO_2$ calcd., ml. |
|---|---|---|
| First stage | 12 | 11.6 |
| Second stage | 26 | 25.4 |
| Third stage | 20 | 19.4 |

the Eqs. 4, 5 and 3 agreed fairly well with the experimental data for each stage as is seen in Table II. The range of the reaction temperature of the third stage agrees with that of the reaction described in section 2. To ascertain these equations, the reactions were cut off at the end of cach stage by a rapid cooling and the solid products were examined. The product of the first stage was extracted by water, and the ferrous ion in the aqueous solution was titrated by a standard potassium permanganate solution. The value for ferrous sulfate in the solution was 56 mg. which agrees well with the value 54 mg. calculated by Eq. 4. The product of the second stage was strongly ferromagnetic with black color, and its X-ray diagram showed the diffraction lines of magnetite. These results showed that the reaction could be adequately expressed by Eqs. 4, 5 and 3. When the amount of pyrite was reduced, the product was changed as was expected from the Eqs. 3—5.

As ferric sulfate also reacts completely with pyrite to liberate sulfur dioxide around 650°C as shown in Fig. 5, the amount of ferric sulfate in the iron sulfides can be determined by measuring the amount of the sulfur dioxide liberated with a sufficient amount of pyrite.

**(4) The Reaction between Pyrite and Ferrous Sulfate.**—Remembering the three stages of the reaction between pyrite and ferric sulfate described above, the reaction between pyrite and ferrous sulfate would be considered to proceed similarly to the second and the third stage. As will be seen in Fig. 6, the reaction proceeds actually as was expected. Thus, the determination of ferrous sulfate in the mixture of ferrous sulfate and iron sulfides is possible from the amount of sulfur dioxide liberated when they are heated with a sufficient amount of pyrite at about 650°C in vacuo.

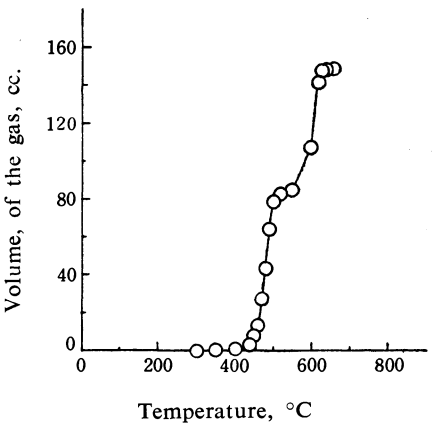

Fig. 6. Reaction between pyrite and ferrous sulfate.

| | |
|---|---|
| Pyrite | 1.0 g. |
| $FeSO_4 \cdot 7H_2O$ | 450 mg. |

When the amount of pyrite was insufficient, hematite was formed as a final product.

$$FeS_2 + 11FeSO_4 = 6Fe_2O_3 + 13SO_2 \qquad (6)$$

When the amount of pyrite was less than that of the stoichiometric ratio of Eq. 6, sulfur trioxide and oxygen were also liberated by the decomposition of the remainder of the ferrous sulfate.

**(5) The Determination of Ferric Sulfate, Ferrous Sulfate and Magnetite in their Mixture.**—When a sufficient amount of pyrite is present, the reaction between ferric sulfate and pyrite proceeds through three stages as stated above. The second stage of the reaction corresponds to the reaction between pyrite and ferrous sulfate, and the third stage to the reaction between pyrite and magnetite. Consequently when a mixture of ferric sulfate, ferrous sulfate and magnetite is heated with a sufficient amount of pyrite, all the gas liberated at the first stage may be attributed to ferric sulfate, and that at the end of the second stage to ferric sulfate and ferrous sulfate, and that at

the end of the third stage to ferric sulfate, ferrous sulfate and magnetite. Therefore, the amount of each substance in the mixture can be determined from the amount of sulfur dioxide liberated at each stage of the reaction. Some results of these determinations of the amount of each substance by this procedure are shown in Table III. As will be seen in Table III, the accuracy of this procedure is sufficient for the present study.

| $FeSO_4 \cdot 7H_2O$ | 50 | 54 | 50 | 48 |
| $Fe_3O_4$ | 30 | 33 | 50 | 54 |

**(6) The Determination of a Very Small Amount of Oxygen in Pyrite.** — The results of the experiments on the reactions between pyrite and iron oxides or sulfates show that the oxygen contained in iron oxides or sulfates are completely liberated as sulfur dioxide, when the samples are heated at 650°C in vacuo with a sufficient amount of pyrite. Therefore, when the powdered pyrite contains a small amount of oxygen-iron compounds such as $Fe_2O_3$ and $FeSO_4$, the total amount of oxygen in the pyrite sample can be determined by the present method. But, as already mentioned above, absorbed oxygen and absorbed water which can not be removed by pumping at a low temperature may be conceivable as another source of oxygen.

The absorbed oxygen will be evolved as sulfur dioxide at 650°C, because the vapor pressure of sulfur in equilibrium with pyrite is fairly high in this condition[11-13] and oxygen is readily converted into sulfur dioxide. Minden[14] reported that the evaporated film of lead sulfide chemisorbs oxygen and evolves it as sulfur dioxide above 200°C. His results may support the view that oxygen absorbed on the surface of pyrite is evolved as sulfur dioxide on heating.

On the reaction between pyrite and water at a high temperature, Grünnert[8] concluded that the reaction proceeds as follows:

$$\text{(I)} \quad 2FeS_2 = 2FeS + S_2$$

$$\text{(II)} \quad 3S_2 + 4H_2O = 4H_2S + 2SO_2$$

$$\text{(III)} \quad FeS + H_2O = FeO + H_2S$$

$$\text{(IV)} \quad 3FeO + H_2O = Fe_3O_4 + H_2$$

These equations may explain the results of his experiments using a large amount of water. However, the amount of water absorbed on the surface of pyrite may be too small to follow the reactions III and IV. Therefore, in our case the reaction between pyrite and water may proceed as the following Eq. 7.

$$3FeS_2 + 2H_2O = 3FeS + 2H_2S + SO_2 \qquad (7)$$

in which water vapor, sulfur dioxide and hydrogen sulfide are equilibrated with pyrite and troilite. From these facts, the amount of oxygen in pyrite can readily be determined by that of sulfur dioxide, hydrogen sulfide and water vapor.

When a small crystal of pyrite was heated without being pulverized, a small amount of gas was liberated and the pyrite was completely decomposed to troilite and sulfur. But, when the same sample was pulverized and heated, a larger amount of gas was liberated as will be seen in Fig. 7. From this fact, it is obvious that as a result of pulverization of pyrite, oxidation occurs or absorption of oxygen or water. The evolved gas was completely absorbed by potassium hydroxide, and about two thirds of the absorbed gas was sulfur dioxide and hydrogen sulfide, and the remainder seems to be water vapor as will be shown in the following experiments. Phosphorus pentoxide was placed in tube D in Fig. 1 and cock 2 was

kept open through the experiment. The amount of gas evolved was fairly small and it consists of only sulfur dioxide.

The results of the experiments for the determination of oxygen content of powder pyrite are shown in Table IV. As will be seen in the analytical results, the precision is sufficient for the present study.

## Summary

In the present paper a method for the determination of a very small amount of oxygen in an almost pure pyrite was proposed. From the results of the fundamental experiments on the reactions between the pyrite and the other minerals containing oxygen, it was ascertained that oxygen is completely liberated as sulfur dioxide and water vapor by heating in vacuo. The reproducibility of this method is fairly satisfactory, but there are no standard samples to examine the accuracy of this method. The results of the experiments indicate that this method could be used as a method for estimating the degree of oxidation of almost pure pyrites, for determining the amount of oxygen in some minerals, and in some cases for calculating the ratio of the oxygen containing compounds in their mixtures. Moreover, it seems possible to use this method for the determination of oxygen in a mixture of sulfides and oxides or sulfates of other metals than iron, and also oxygen in the metals. After the work reported herein had been almost completed, the authors were informed of the work, "The Sulfur Method of Oxygen Determination in Metals", of Babko et al.[15,16] who reported a somewhat similar study on the determination of oxygen in metals by using elementary sulfur instead of pyrite.

The authors are much indebted to Professor T. Watanabe and Mr. A. Sasaki, Department of Geology, The University of Tokyo for kindly supplying the samples of pyrite and for the microscopic study. We also express our hearty thanks to Dr. S. Akimoto, Geophysical Institute, the University of Tokyo, for his great help and valuable advice in X-ray study.

# *Vapor Pressure of Zinc in Tin-Zinc Binary Liquid Alloy*

By Kichizo NIWA, Toshio YOKOKAWA and Harue WADA

(Received April 7, 1960)

For the development of the theory of metallic solution, systematic studies on thermodynamics of multi-component systems are required as well as those on electric and magnetic properties. Vapor pressure measurements directly provide the activity or the partial molar free energy of mixing of vaporizing components, though their temperature coefficients or heat terms are not so reliable as those determined by the calorimetric method. In the present work the applicability of Knudsen's effusion method was examined for the measurement of low vapor pressure of liquid alloy. This method is convenient for a measurement of this kind because small quantities of samples are enough to determine the vapor pressures. Also the concentration change of alloys with measuring time does not bring big error on account of low values of vapor pressure. In Knudsen's method, two conditions must be fulfilled. Firstly, vaporization velocity from alloy surface is so great that the vapor phase in the crucible may be maintained at equilibrium pressure. Secondly, diffusion through bulk phase of the alloy to surface is so rapid as to compensate for the decrease in the concentration of the vaporizing component. In relation to the above conditions, the effect of an oxide film and diffusivity in alloy phase as compared with the vaporization velocity must be taken into consideration. In order to make these points clear the vapor pressure of zinc in tin-zinc

liquid alloy was measured. Further, thermodynamic excess functions of this system were discussed.

## Experimental

**Experimental Method.**—In the effusion method vapor pressure is calculated from effusion velocity by an equation

$$P=\sqrt{\frac{2\pi RT}{M}}\cdot\frac{1}{KA}\cdot\frac{G}{\tau}\left(1+\frac{KA}{\alpha B}\right) \qquad (1)$$

where $A$ is the geometric area of the effusion orifice and $KA$ is the effective area. $K$ is the Clausing factor, a correction for the inevitable thickness of the orifice. $\alpha$ is the accomodation coefficient and $B$ is the effective vaporization area in the crucible. $KA/\alpha B$ is a correction term for deviation of pressure in the crucible from saturation. $G$ is the weight (in grams) of effused molecule within time interval $\tau$ (sec.). $M$ is the molecular weight of the effusing molecule. Other symbols mean ordinary quantities. In the temperature interval of this experiment, vapor pressure of tin may be neglected and besides zinc vapor is taken as monatomic, so $M$ in this case becomes the atomic weight of zinc. As $K$ cannot be precisely determined by experiment, the effective area $KA$ has been determined by combining the effusion velocity of solid zinc and its vapor pressure, presented by Barrow[1]. The correction term $KA/\alpha B$ is negligible compared with unity, provided that $\alpha$ is not very small. As will be shown later, this correction was proved not necessary.

**Apparatus.**—The apparatus, which had been previously used in the authors' laboratory[2], was modified in the reading of thermobalance. The latter is shown in Fig. 1. The beam A is of

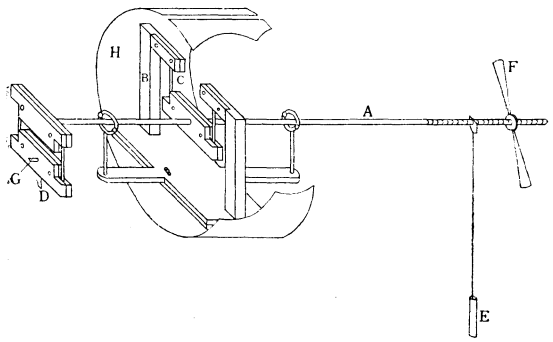

Fig. 1. Schematic diagram of the thermobalance.

aluminum and hung with a phosphorus bronze ribbon C from a frame of brass B, which is held in a brass vessel with a brass ring H. The effusion crucible is hung from D with a platinum wire. E is a dust core of 3 mm. in diameter and 1 cm. in length, and is used to convert the inclination of the balance into a change of electric current by means of a linear differential transformer. F is a counter weight of soft iron which can be shifted at a proper position along the beam by a magnet from the outside of the glass tube. A crucible of pyrex glass is 1 cm. in diameter and 1 cm. in height including its lid. An effusion orifice is bored at the center of the lid which is ground with the crucible. The orifice is ground as thin as possible (0.1 mm.) from both the up and down sides of the lid. The furnace consists of a porcelain tube wound by a nichrome resistance wire. The temperature was manually controlled at a constancy of $\pm 1$°C during each measurement (20 min. to 2 hr.). Temperature was measured by a platinum vs. platinum-rhodium thermocouple, the end of which was nearly in contact with the crucible through a quartz tube. The thermocouple was calibrated at the melting points of zinc, tin, bismuth, lead and antimony.

**Procedure.**—About one gram of metal or alloy sample is placed in the crucible, which is hung from the thermobalance by a platinum wire of 0.2 mm. in diameter, then the counter weight is properly adjusted. Sensitivity of the balance is determined at each run by loading riders of known weight on G in Fig. 1 (about 0.1 mg./$\mu$A). Then a rider of the right weight is again loaded on the same position in order that the balance may be settled through the measuring time within the inclination range where the sensitivity has been measured. After that the system is evacuated to a pressure of $10^{-5}$ mmHg and the furnace is heated up to the desired temperature and the rate of weight loss is measured by way of the current in the transformer circuit.

**Sample.**—Purities of metals used are 99.9% (zinc), chemical pure (tin), 99.9% (bismuth), and 99.999% (indium). Zinc ribbon was used for the measurement in pure solid state. Alloys were prepared in the following way; pure metals of desired amount were sealed in a small pyrex tube in vacuo and kept at about 450°C for ten hr., followed by quenching.

**Experimental Error.**—As the sources of error of this measurement, temperature, area of the orifice, sensitivity of the balance and rate of change of current should be taken into account. Relative errors of these contents are 0.08, 2.7, 1.5 and 1% respectively. Then the fractional average deviation may amount to 3.2%. Next, the error of activity, calculated from the vapor pressure of pure liquid and alloys, amounts to 4%. The decrease in concentration of zinc with vaporization affects the activity coefficient by decreases of 6 and 3% at mole fractions of 0.05 and 0.1, respectively.

**Measurement of Liquid Alloy.**—The applicability of Knudsen's effusion method to alloy of liquid state was examined in the following points.

*(A) Saturation of Vapor Phase.*—In order to make certain that the vapor phase was saturated, vaporization velocity was measured, when the lid of the crucible was removed and the vapor freely escaped from the surface (nearly Langmuir-like). This velocity was about $1\times10^{-2}$ mg./sec., while the ordinary effusion velocity was at most $6\times10^{-4}$ mg./sec. Then, one can assume that zinc vapor is saturated in the crucible even in the case of liquid

1) R. F. Barrow et al., *Trans. Faraday Soc.*, **51**, 1354 (1955).

solution, where a thin film of zinc oxide may cover and disturb vaporization, or may reduce the accommodation coefficient.

*(B) Concentration Difference between the Surface and the Bulk Phase of Liquid Alloy.*—The surface concentration of zinc decreases with its vaporization, while the concentration recovers by diffusion through the bulk phase. The following calculation has been made for the sake of estimation of this concentration gradient in the steady state. Assuming (a) that there exists a linear concentration gradient between the surface and a position, $\Delta L$ cm. distant under the surface, and (b) that there is no convection in the bulk phase, flow of zinc to the surface is given by

$$J(\text{g./sec.}) = -BD\Delta C/\Delta L$$

where $B$ is the surface area and $D$, the diffusion coefficient of zinc in the solution and $C$, the concentration in g. per cc. This flow should be equal to effusion velocity at the steady state. The latter being at most $6\times10^{-7}$ g./sec. at a vapor pressure of $10^{-2}$ mmHg, $\Delta C/\Delta L$ becomes 0.15, if $B$ is 0.42 cm$^2$ and $D$ is $10^{-5}$ cm$^2$/sec. Then $\Delta C$ becomes 0.0045 g./cc., when $\Delta L$ is 0.3 cm., the same length as the depth of the solution. This value of $\Delta C$ corresponds to about 0.01 mol. fraction. At the practical condition the supplement of zinc would be faster, as there may occur convection and the concentration gradient is not linear.

*(C) Concentration Change due to Vaporization.*—In one run 1 to 2 mg. of zinc effuses out. This affects the concentration by 0.003 at 0.05 and 0.0015 at 0.1 respectively in mole fraction. Then this effect is not so severe except in a composition of high dilution, where the effusion time of one run is desirable to be short.

## Results and Discussion

**Vapor Pressure of Pure Zinc.**—For the purpose of determining the effective area of the effusion orifice, effusion velocity was measured with pure solid zinc. An example of the results is shown in Table I. By means of

Table I. Effusion velocity of solid pure zinc

| $T$, °K | $P\times KA$* mmHg×cm$^2$ | $T$, °K | $P\times KA$ mmHg×cm$^2$ |
|---|---|---|---|
| 613 | $4.663\times10^{-6}$ | 646 | $17.15\times10^{-6}$ |
| 621 | 6.678 〃 | 649 | 18.58 〃 |
| 625 | 9.575 〃 | 658 | 25.88 〃 |
| 635 | 11.71 〃 | 661 | 34.46 〃 |
| 636 | 12.27 〃 | | |

* The geometrical area $A$ is $7.566\times10^{-3}$ cm$^2$.

the least square method, these values are expressed as a linear function of $1/T$ by

$$\log P\times(KA) = -6716/T + 5.649 \qquad (2)$$

The vapor pressure of solid zinc has been investigated by many workers. The most reliable value, which Barrow and his coworkers derived[1], is

$$\log P = 9.8253 - 0.1923\log T - 0.2623\times10^{-3}T - 6862.5/T \qquad (3)$$

Comparing Eq. 2 with Eq. 3, the effective area $KA$ of the orifice is calculated as 0.5735 mm$^2$. The geometrical area ($A$) was 0.7566 by microscopic measurement. The ratio of these figures leads to 0.758 as the Clausing factor, which corresponds to 0.099 mm. of thickness of the orifice. Substituting the effective area in Eq. 2, it can be rewritten as

$$\log P = -6716/T + 8.891 \qquad (4)$$

The vapor pressure of liquid zinc can be calculated from Eq. 4 and the free energy change of solidification of zinc[3] as a function of temperature. Thus the vapor pressure at 625°K is $1.603\times10^{-2}$ mmHg, which is used as the reference in derivation of activity of zinc in alloys.

**Vapor Pressure of Zinc in Liquid Alloy.**—At the range of high content of zinc, zinc separates as solid matter over the temperature range where vapor pressure is appropriate in magnitude for the effusion method. The present measurement has covered up to 0.4 of mole fraction of zinc. Measured values are summarized in Table II, and plotted against reciprocal temperature in Fig. 2. The activity of zinc at 625°K, calculated from the above-mentioned values and $1.603\times10^{-2}$ mmHg of

pure liquid zinc, is shown in Fig. 3. On this system Taylor[4] determined activity by e. m. f. method at 400 to 600°C, and Burmeister and Jellinek[5] measured vapor pressure of zinc by the transpiration method at a temperature range of 684 to 785°C. Their results are also shown in Fig. 3.

The thermodynamic property of alloys can be appropriately given in terms of excess function, where solutions are classified as ideal,

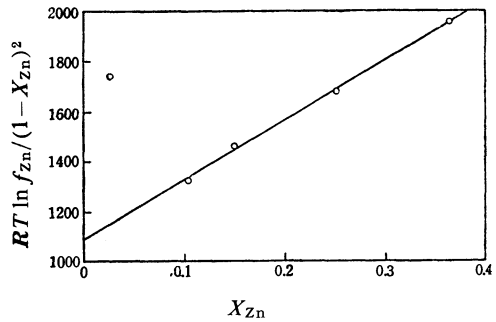

Fig. 4. Relation between $RT\ln f_{Zn}/(1-X_{Zn})^2$ and $X_{Zn}$.

regular or sub-regular ones. Wittig and his coworkers[6] have found that the heat of solution of this system behaves as a sub-regular solution as far as enthalpy is concerned. In Fig. 4 $RT\ln f_{Zn}/(1-X_{Zn})^2$ is plotted against concentration of zinc. All points are on a straight line

$$\frac{RT\ln f_{Zn}}{(1-X_{Zn})^2}=2370\,X_{Zn}+1090 \qquad (5)$$

One point at $X=0.027$ deviates from this line, probably because of the uncertainty of concentration. It would be worth while to find what these figures mean when this system is regarded as a sub-regular solution. By definition[7] excess free energy of solution is related to concentration by

$$\frac{G^e}{X_{Zn}X_{Sn}}=A^0+(X_{Sn}-X_{Zn})A^1 \qquad (6)$$

where $A^0$ and $A^1$ are constants. From this equation one can derive a formula for the excess chemical potential, defined as a difference between partial molar free energy of solution and ideal partial molar free energy of solution,

$$\mu^e{}_{Zn}/X^2{}_{Sn}=RT\ln f_{Zn}\times 1/X^2{}_{Sn}=A^0 +(1-4X_{Zn})A^1 \qquad (7)$$

Comparing Eq. 7 with Eq. 5, values of $A$s are given,

$$A^0=1680 \quad \text{and} \quad A^1=-590$$

Taylor's data at equal range of concentration lead to $A^0=1660$ and $A^1=-430$. Accounting for the temperature dependence of these quantities, two sets of data are in good agreement within experimental error.

This sub-regular behavior has not yet been completely interpreted. In the case of molecular liquid solutions, Hildebrand[8] succeeded in explaining energetic asymmetry by using

4) N. W. Taylor, *J. Am. Chem. Soc.*, **45**, 2865 (1923).
5) E. Burmeister and K. Jellinek, *Z. phys. Chem.*, **A165**. 121 (1933).

8) J. H. Hildebrand and R. L. Scott, "The Solubility of Nonelectrolytes", Reinhold, New York (1952), p. 109.

volume fraction in place of mole fraction. In the present case this correction is not enough. Kleppa[9] and Wittig[6] pointed out the correlation of the energetic asymmetry with valence electron concentration from the experimental data of many alloy systems. Recently some investigators[10] paid attention to the cohesive energy of metals in light of metallic characteristics and considered what happened on mixing. Shimoji[11] discussed the excess energy of binary alloys by using the cellular approximation for metals and explained energetic asymmetry on mixing, not by the simple volume effect, but by the changes of the energy due to the boundary correction, Fermi energy, interelectronic energy, closed shell repulsive energy, polarization energy etc. It is interesting to compare the calculation with the present data. In the moderately dilute range, integral heats of mixing can be expanded in a power series of the mole fraction of the solute,

$$\Delta H^{M} = P_1 x_2 + P_2 x_2^2 + \cdots\cdots \quad (8)$$

According to Shimoji the ratio $-P_2/P_1$ is 0.4 in the zinc dilute portion of tin-zinc system. From Eq. 8 one obtains the relative partial molar enthalpy as

$$\overline{\Delta H}_2 = P_1 + 2P_2 x_2 + \cdots\cdots \quad (9)$$

The corresponding equation can be derived from the present data by the following equation, provided that the partial molar excess entropy is known,

$$\overline{\Delta H}_{Zn} = \mu^e{}_{Zn} + T\overline{\Delta S}^e{}_{Zn} \quad (10)$$

Assuming that the excess entropy is mainly due to volume difference, partial molar excess entropy of solution of zinc can be calculated by free volume model[8]:

$$\overline{\Delta S}^e{}_{Zn} = -R\left[\ln \varphi_{Zn} + \varphi\left(1 - \frac{V_{Zn}}{V_{Sn}}\right) - \ln X_{Zn}\right] \quad (11)$$

where $\varphi$ is the volume fraction and $V$ is the molar volume. Replacing $\varphi$ by the mole fraction and molar volumes, one obtains

$$\overline{\Delta S}^e{}_{Zn} = 1.05 - 1.31\, X_{Zn} + \cdots\cdots \quad (12)$$

where 16.9 and 9.9 is used as molar volumes of tin and zinc. On the other hand, Eq. 5 is rewritten as

$$\mu^e{}_{Zn} = 1090 + 190 X_{Zn} + \cdots\cdots \quad (13)$$

From Eqs. 12 and 13 the partial molar enthalpy of zinc at 625°K is

$$\overline{\Delta H}_{Zn} = 1750 - 630 X_{Zn} + \cdots\cdots \quad (14)$$

giving 1750 and $-315$ cal./mol. for $P_1$ and $P_2$ respectively. Then the present value 0.18 for $-P_2/P_1$ seems to agree with 0.4 (Shimoji's value) in deviation from $P_2/P_1 = -1$ (regular solution). The experimental results about ternary solutions will be reported in the next paper.

## Summary

The vapor pressure of zinc in liquid tin-zinc alloys has been measured by Knudsen's effusion method. Application of this method to liquid alloys has been found to be successful. Observed activity coefficients of zinc are discussed in relation to theoretical calculations. The deviation from the regular solution model has been interpreted in terms of the cellular approximation as well as the volume difference effect.

The authors are indebted to Dr. M. Shimoji for his valuable discussion.

# *Studies on the Decomposition of Ammonia and Hydrazine by High Frequency Discharge*

By Saku TAKAHASHI

(Received February 20, 1960)

The chemical reaction under high frequency discharge has been studied and it has been found that the energy consumed in the reaction is roughly proportional to the frequency of the applied electric current[1]. However, from the standpoint of reaction rate, it is highly questionable whether the rate of reaction under high frequency discharge would be affected by the frequency of the applied electric current or not. In order to obtain information concerning the reactions under high frequency discharge, the selectivities of frequencies to the reactions in the decomposition of both ammonia and hydrazine vapour have been studied.

## Experimental Procedures

The decomposition of ammonia and also of hydrazine under high frequency discharge were carried out in a closed vessel shown in Fig. 1. The volume of the glass vessel, cylindrical in shape, of which the diameter was 7 cm., was approximately 1000 cc. A single electrode was inserted into this vessel at the bottom and high frequency electric current was applied to this electrode. The electric discharge occurred at the top of this electrode.

The frequencies of electric current used in these experiments were 100 and 250 MC. For the purpose of keeping their power applied on these reactions at a definite value, all the electric conditions of a generator were constantly fixed in every case.

The ammonia, hydrazine, nitrogen and hydrogen used in these experiments were purified by ordinary methods. The quantities of ammonia and hydrazine in the reaction vessel were expressed by the partial pressures in the reaction vessel at 25°C. The initial pressure of ammonia was from 50 to 250 mmHg and that of hydrazine was from 3 to 10 mmHg.

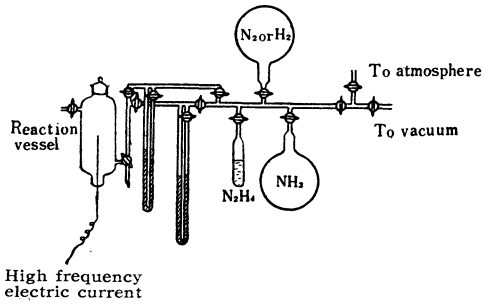

Fig. 1. Apparatus

## Results and Discussion

In these experiments, the amounts of reactant were plotted against the reaction time. Several experiments with additional hydrogen or nitrogen were also carried out. From these results, the rate of the reaction was expressed with the amount of the reactant decomposed in a certain reaction time.

**Decomposition of Ammonia.**—The decomposition products were analysed by gas chromatography. They were nitrogen, hydrogen and hydrazine. The main products were nitrogen and hydrogen. The amount of hydrazine produced was so small that the effect caused by the hydrazine on this reaction may be ignored.

On the decomposition under 100 MC frequency discharge, it is shown in Fig. 2 that the initial stage of the reaction was of the 1st order and that the retardation by both nitrogen and hydrogen was observed. Comparing Fig. 3 with Fig. 4, it is seen that the amount of ammonia decomposed in a definite time decreases according to the quantity of hydrogen added, while the nitrogen added exhibits no effects on the rate of ammonia decomposition. Under 250 MC frequency discharge, it is known from Fig. 5 that the initial reaction is not of the 1st order, but it is an intermediate type between the zero and 1st order reactions, and comparing Fig. 6 with Fig. 7, it may be seen that the overall reaction is retarded by hydrogen.

The molecules in electric discharge are excited by a collision with an impacting electron and change to an excited molecule or a positive ion. It is considered that both a positive ion and an excited molecule are possible agents in the chemical reaction. If excited molecules were responsible, the reaction should be pressure sensitive, for it may be expected that the concentration of excited molecules would decrease with pressure. The outstanding feature of the experiment in electric discharge is that the reaction is directly proportional to the discharge current and it is independent of pressure over a large range of values. Furthermore, it has been observed in the studies[2] with electrons of controlled speed that the reaction hardly occurs below the ionization potential of the gas. These experimental results favor an ionic reaction in electric discharge. Upon neutralization of a positive ion, the entire energy of ionization available may serve as activation energy for chemical processes or else the molecule will return to the normal state after a short average life with the emission of radiation[3]. In a spectroscopic investigation[4], on high frequency discharge, it has been noticed that, in a discharge tube, a molecule with one charge comes to be clearly observed as the frequency of electric current increases. This phenomenon shows one of the specific properties of high frequency discharge and from this fact it is presumed that the life-time and number of positive charge moleculs produced in a discharge tube tend to increase with the frequency of the electric current.

Thus, one accounts for the kinetics of reactions by the following series of reactions:

$$NH_3 \xrightarrow{k_1} NH_3^+ \quad \text{(in electric discharge)}$$

$$NH_3^+ \xrightarrow{k_2} NH_3^*$$

$$NH_3^* \xrightarrow{k_3} \frac{1}{2}N_2 + \frac{3}{2}H_2$$

$$NH_3^+ \xrightarrow{k_4} NH_3 + E$$

$$NH_3^+ + H_2 \xrightarrow{k_5} [NH_3^+ \cdot H_2] \longrightarrow NH_3 + H_2 + E_1$$

$$NH_3^+ + NH_3 \xrightarrow{k_6} [NH_3^+ \cdot NH_3] \longrightarrow NH_3 + NH_3 + E_2$$

In these reactions, it is difficult to understand strictly the behaviour of hydrogen molecules, but from the results obtained in this experiment it is supposed that hydrogen has the greatest probability of deactivation of all ionized molecules. If the life-time of $NH_3^+$ is long, it is known that, as the results of several collisions between hydrogen and the ionized

2) C. H. Kunsman, *Phys. Rev.*, **31**, 307 (1928).

molecule, the ionized molecule loses its excessive energy and becomes a normal molecule, while hydrogen becomes an activated molecule. Applying the steady state assumption, one arrives at expression 1 for the rate of decomposition.

$$\frac{d[NH_3^+]}{dt}=k_1[NH_3]-k_2[NH_3^+]-k_4[NH_3^+]$$
$$-k_5[NH_3^+][H_2]-k_6[NH_3^+][NH_3]=0$$
$$[NH_3^+]=\frac{k_1[NH_3]}{k_2+k_4+k_5[H_2]+k_6[NH_3]}$$
$$\frac{d[NH_3^*]}{dt}=k_2[NH_3^+]-k_3[NH_3^*]=0$$
$$[NH_3^*]=\frac{k_2}{k_3}[NH_3^+]$$
$$V=k_3[NH_3^*]=k_2[NH_3^+]$$
$$=\frac{k_1k_2[NH_3]}{k_2+k_4+k_5[H_2]+k_6[NH_3]} \quad (1)$$

When a hydrogen molecule does not exist in a reaction vessel, the rate of reaction is expressed as follows and this formula expresses the relation between the initial rate $V_0$ and the concentration of ammonia.

$$V_0=k_3[NH_3^*]=k_2[NH_3^+]$$
$$=\frac{k_1k_2[NH_3]}{k_2+k_4+k_6[NH_3]} \quad (2)$$

Using expressions 1 and 2, the following relations are obtained.

$$\frac{V_0-V}{V}=\frac{k_5[H_2]}{k_2+k_4+k_6[NH_3]}=\Theta$$
$$\frac{k_2+k_4}{k_5}+\frac{k_6}{k_5}[NH_3]=\frac{[H_2]}{\Theta} \quad (3)$$

If the life-time of $NH_3^+$ is short, the $k_6$ process may be neglected and the rate of decomposition is approximated as follows:

$$V=\frac{k_1k_2[NH_3]}{k_2+k_4+k_5[H_2]} \quad (4)$$
$$\frac{k_2+k_4}{k_1k_2}+\frac{k_5}{k_1k_2}[H_2]=\frac{[NH_3]}{V} \quad (5)$$

Using the results shown in Figs. 2 and 5, the plots of $NH_3/V$ vs. $H_2$ and $H_2/\Theta$ vs. $NH_3$ are shown in Figs. 12 and 13, respectively. A linear relation between $NH_3/V$ and $H_2$ or $H_2/\Theta$ and $NH_3$ is clearly shown in these figures, being independent of the initial concentration of ammonia, and the agreement between the experiment and the calculation is reasonable.

**Decomposition of Hydrazine.**—The decomposition products of this reaction are nitrogen and hydrogen and ammonia is not produced. In this reaction, comparing Fig. 8 with Fig. 9

it can be shown that the rate of decomposition under high frequency discharge varies with the values of frequencies of the applied electric current. The reaction under the frequency 100 MC is a 1st order reaction, but under the frequency 250 MC the initial rate of decomposition is of zero order. Moreover, as is seen in Figs. 10 and 11, the hydrogen produced in the course of the decomposition does not retard the rate of decomposition

| ●……10.0 | |

under the former condition, but it moderately retards the rate of reaction under the latter condition. From these results, it is possible to explain the reaction processes as follows:

$$N_2H_4 \xrightarrow{k_1} N_2H_4^+ \text{ (in electric discharge)}$$

$$N_2H_4^+ \xrightarrow{k_2} N_2H_4^*$$

$$N_2H_4^* \xrightarrow{k_3} N_2+2H_2$$

$$N_2H_4^+ \xrightarrow{k_4} N_2H_4+E$$

$$N_2H_4^+ + H_2 \xrightarrow{k_5} [N_2H_4^+ \cdot H_2] \longrightarrow N_2H_4+H_2+E_1$$

$$N_2H_4^+ + N_2H_4 \xrightarrow{k_6} [N_2H_4^+ \cdot N_2H_4] \longrightarrow N_2H_4+N_2H_4+E_2$$

Under the frequency 100 MC, if the lifetime of $N_2H_4^+$ is short, it is supposed that $N_2H_4^+$ cannot be deactivated by the collision with $H_2$ or $N_2H_4$. In this case, applying the usual steady state assumption, expression 6 for the rate of decomposition is obtained.

$$\frac{d[N_2H_4^+]}{dt}=k_1[N_2H_4]-k_2[N_2H_4^+]-k_4[N_2H_4^+]=0$$

$$[N_2H_4^+]=\frac{k_1[N_2H_4]}{k_2+k_4}$$

$$\frac{d[N_2H_4^*]}{dt}=k_2[N_2H_4^+]-k_3[N_2H_4^*]=0$$

$$[N_2H_4^*]=\frac{k_2}{k_3}[N_2H_4^+]$$

$$V=k_3[N_2H_4^*]=\frac{k_1k_2}{k_2+k_4}[N_2H_4] \qquad (6)$$

Under the frequency 250 MC, if the lifetime of $N_2H_4^+$ becomes longer with the increase of frequency of electric current, it is supposed that $N_2H_4^+$ comes to be deactivated by each molecule of hydrogen and hydrazine. In this case, the following equations are obtained:

$$\frac{d[N_2H_4^+]}{dt}=k_1[N_2H_4]-k_2[N_2H_4^+]-k_4[N_2H_4^+]-k_5[N_2H_4^+][H_2]-k_6[N_2H_4^+][N_2H_4]=0$$

$$[N_2H_4^+]=\frac{k_1[N_2H_4]}{k_2+k_4+k_5[H_2]+k_6[N_2H_4]}$$

$$\frac{d[N_2H_4^*]}{dt}=k_2[N_2H_4^+]-k_3[N_2H_4^*]=0$$

$$[N_2H_4^*]=\frac{k_2}{k_3}[N_2H_4^+]$$

$$V=k_3[N_2H_4^+]=\frac{k_1k_2[N_2H_4]}{k_2+k_4+k_5[H_2]+k_6[N_2H_4]} \qquad (7)$$

In this decomposition, as the value of hydrogen produced in the course of the decomposition is equal to $2([N_2H_4]_0-[N_2H_4])$ the following equations are derived.

$$V=\frac{k_1k_2[N_2H_4]}{k_2+k_4+2k_5[N_2H_4]_0+(k_6-2k_5)[N_2H_4]}$$

$$\frac{[N_2H_4]}{V}=\frac{1}{k_1k_2}\{(k_2+k_4+2k_5[N_2H_4]_0)+(k_6-2k_5)[N_2H_4]\} \qquad (8)$$

where, $[N_2H_4]_0$ is the initial concentration of hydrazine. Using the results shown in Fig. 9, $N_2H_4/V$ is plotted against $N_2H_4$ as shown in Fig. 14. As is obvious from these figures, the agreement between the experiment and the calculation is satisfactory.

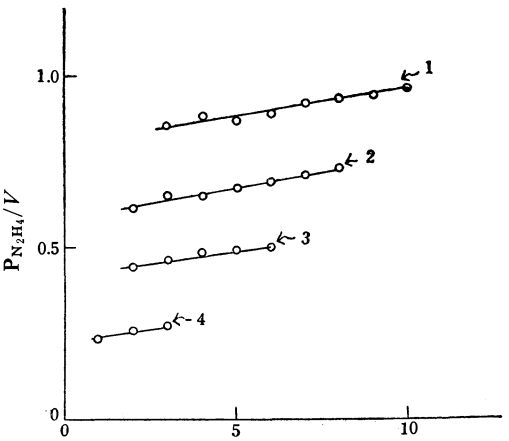

Fig. 14. Plots of $P_{N_2H_4}/V$ vs. $P_{N_2H_4}$.

## Summary

1) The decomposition of both ammonia and hydrazine were carried out under high frequency discharge and the effects of frequency on the chemical reactions were investigated. The frequencies of electric current were 100 and 250 MC.

2) The effects of frequency appeared clearly on the decomposition of hydrazine: under 100 MC frequency discharge the decomposition was a 1st order reaction, while under 250 MC it was approximately zero order reaction, and the overall reaction was retarded moderately by the hydrogen produced in the course of the reaction.

3) As for the decomposition of ammonia, in any case, the reactions were retarded by hydrogen. Under 100 MC frequency discharge the reaction was 1st order, while under 250 MC it was a fractional order reaction.

The author wishes to express her thanks to Professor M. Suzuki for his exceedingly kind direction throughout this work. The author also thanks Professor K. Tamaru of the University of Yokohama for his helpful advice.

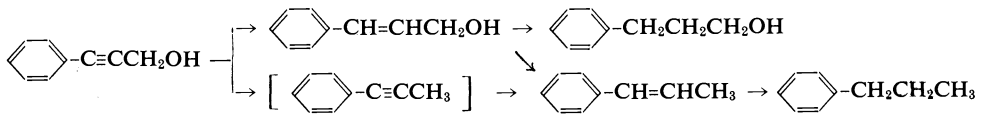
# *Hydrogenation and Hydrogenolysis. IV*[1]*. Catalytic Reductions of Cinnamyl Alcohols and 3-Phenylpropargyl Alcohol**

By Shigeo NISHIMURA, Takeru ONODA and Akiya NAKAMURA

(Received May 9, 1960)



Cinnamyl alcohol may be catalytically reduced either to 3-phenyl-1-propanol, absorbing 1 mole of hydrogen, or to propylbenzene through propenylbenzene, absorbing 2 moles of hydrogen, as far as the hydrogenation is concerned with the side chain:

The reduction with nickel[2,3], cobalt[2] and copper[4] catalysts of Raney type gives phenylpropanol exclusively. Straus and Grindel[5] reduced cinnamyl alcohol with a palladium catalyst prepared by reducing palladium chloride with hydrogen in acetone, and obtained a mixture of propylbenzene (18%) and phenylpropanol (55%) with the absorption 1.38 moles of hydrogen. Baltzly and Buck[6] obtained about equal moles of the two compounds with the use of palladized charcoal in ethanol. Waser[7] obtained cyclohexylpropanol quantitatively by the reduction with a platinum black without using any solvent. Tuley and Adams[8] hydrogenated cinnamyl alcohol to phenylpropanol quantitatively in ethanol in the presence of platinum oxide and a small amount of ferrous chloride.

Different results of previous works on the hydrogenation of cinnamyl alcohol seem to be closely related to solvents and to metals and the methods of preparation of the catalysts. As reported previously[9,10], with platinum oxide as the catalyst, the hydrogenolysis of the C–O linkage with a bouble bond in $\beta,\gamma$- or $\alpha,\beta$-position is much more favored than the hydrogenation of the double bond in acidic media. On the other hand, the double bond can be hydrogenated with little hydrogenolysis or none under neutral or slightly acidic conditions. In the present investigation, the influence of solvents on the hydrogenation and hydrogenolysis of cinnamyl alcohol was re-examined in detail with platinum, palladium, rhodium and rhodium-platinum catalysts.

3-Phenylpropargyl alcohol may be catalytically reduced either to 3-phenyl-1-propanol through *cis*-cinnamyl alcohol, absorbing 2 moles of hydrogen, or to propylbenzene, through *cis*-cinnamyl alcohol or through propynylbenzene, absorbing 3 moles of hydrogen:

In order to know whether the hydrogenolysis would occur or not before the reduction of the triple bond to the double bond, the catalytic reduction of 3-phenylpropargyl alcohol and of the intermediate *cis*-cinnamyl alcohol was investigated with Adams platinum oxide as a catalyst.

## Experimental

**Substrates.**—*Cinnamyl Alcohol* (*trans*). —A commercial preparation was treated with aluminum ethoxide and absolute ethanol followed by hydrolysis with sodium hydroxide solution and extraction with ether[11], and then fractionally distilled twice under reduced pressure. TABLE I. MOLES OF HYDROGEN ABSORBED BY CINNAMYL ALCOHOL AT ORDINARY TEMPERATURE AND PRESSURE[a)]

| Catalyst* | Solvent | | | |
|---|---|---|---|---|
| | EtOH, 20 cc. | AcOH, 20 cc. | EtOH, 20 cc.+ 3N HCl, 0.1 cc. | AcOH, 20 cc.+ 3N HCl, 0.1 cc. |
| Pt oxide | 1.03 | 1.31 | 1.60 | 1.79 |
| Pd oxide | 1.02 | 1.10 | 1.21 | 1.63 |
| Rh-Pt (1 : 1) oxide | | 1.10 | | 1.73** |
| Rh-Pt (2 : 1) oxide | | 1.07 | | 1.71** |
| Rh-Pt (3 : 1) oxide | 0.94 | 1.04 | 1.25 | 1.66** |
| Pd-on-carbon (I) | 0.99 | | 1.22 | |
| Pd-on-carbon (II) | 1.10 | 1.07 | 1.23 | 1.57 |
| Rh-on-carbon (II) | 1.24 | 1.14 | 1.33 | 1.45 |

a) 1.342 g. (0.01 mol.) of cinnamyl alcohol was hydrogenated with 50 mg. of the oxide or 600 mg. of the supported catalysts each time.

* For the notations attached to the catalysts, see the experimental part.

** These are approximate values, because the further hydrogenation of the benzene nucleus made obscure the completion of the reduction of the side chain.

*Cinnamyl Acetate* (*trans*).—Cinnamyl alcohol was refluxed with acetic anhydride and the product was fractionated twice under reduced pressure. B. p. 140~141°C/16 mmHg ; $n_D^{21}$ 1.5439.

*3-Phenylpropargyl Alcohol.*—This compound was prepared by passing mixed nitrogen and formaldehyde gases into an ethereal solution of phenylethynylmagnesium bromide prepared from phenylacetylene and ethylmagnesium bromide[12]. The product was distilled twice under reduced pressure. B. p. 150°C/30 mmHg ; $n_D^{20}$ 1.5845.

*cis-Cinnamyl Alcohol.*—3-Phenylpropargyl alcohol was partially hydrogenated in ethyl acetate with 5% palladium-on-barium sulfate[13] poisoned with a few drops of quinoline. The rate of the hydrogenation became markedly slow after the absorption of 0.97 mole of hydrogen. The product was distilled twice under reduced pressure. B. p. 125°C/14 mmHg (lit.[13] 125.5°C/13 mmHg); $n_D^{16}$ 1.5745 (lit.[13] $n_D^{14}$ 1.573). It was confirmed by the infrared adsorption that the alcohol thus prepared contained, if any, less than 10% of its trans isomer and less than 3% of 3-phenylpropargyl alcohol*.

**Catalysts.** — Platinum oxide was prepared by fusion of ammonium chloroplatinate with sodium nitrate according to the method of Bruce[14].

Palladous oxide was prepared by the fusion of palladium chloride with sodium nitrate according to the method of Shriner and Adams[15].

Rhodium-platinum oxide catalysts were prepared by fusion of the mixtures of rhodium chloride and chloroplatinic acid or ammonium chloroplatinate with sodium nitrate as reported previously[1]. The figures in parentheses in Table I indicate the ratios of rhodium to platinum by the weights of the metals.

Palladium-on-carbon (I) (5% Pd) was prepared by reducing a palladium chloride solution with aqueous formaldehyde and sodium hydroxide[16].

Palladium-on-carbon (II) and rhodium-on-carbon (II) (5% Pd or Rh) were prepared by reducing palladium and rhodium chloride solutions with hydrogen with the addition of sodium acetate[17].

**Solvents.**—*Acetic Acid.* — Glacial acetic acid of Wakō Pure Chemical Industries G. R. grade was used without further purification.

*Ethanol.*—Commercial 95% ethanol was used after distillation.

**Hydrogenation.**—Hydrogenation was carried out at room temperature (20~25°C) and atmospheric pressure. After the catalyst was shaken with hydrogen in 15 cc. of the solvent until no more hydrogen was absorbed, the substance, dissolved in 5 cc. of the solvent, was added. The mixture was shaken with hydrogen at about 350~400 oscillations per minute. In using rhodium-platinum oxide catalysts, hydrochloric acid was added after the oxide was reduced to the metal, since the presence of hydrochloric acid greatly retarded the reduction of the oxide.

## Results and Discussion

**Catalytic Reduction of Cinnamyl Alcohol (trans).**—The effects of solvents on the hydrogenation of cinnamyl alcohol are summarized in Table I in the moles of hydrogen absorbed per mole of cinnamyl alcohol. As expected from previous results, little hydrogenolysis or none occurred in neutral ethanolic solution[18]

18) The hydrogen uptake less than 1 mole with rhodium-platium (3 : 1) oxide in ethanol may be due to dimerization though it has not been investigated further.

TABLE II. EFFECT OF VARYING AMOUNTS OF ADDED HYDROCHLORIC ACID ON THE HYDROGEN UPTAKE BY CINNAMYL ALCOHOL[a]

| Solvent | Hydrogen uptake mol./mol. |
|---|---|
| AcOH, 20 cc.+3N HCl, 0.025 cc. | 1.72 |
| 〃 , 0.05 cc. | 1.78 |
| 〃 , 0.10 cc. | 1.78 |
| 〃 , 0.15 cc. | 1.79 |
| 〃 , 0.20 cc. | 1.79 |

a) 1.342 g. (0.01 mol.) of cinnamyl alcohol was hydrogenated with 50 mg. of platinum oxide each time.

TABLE III. CATALYTIC REDUCTIONS OF CINNAMYL ACETATE AND CINNAMYL ALCOHOL[a]

| Solvent | Hydrogen uptake mol./mol. | |
|---|---|---|
| | Cinnamyl acetate | Cinnamyl alcohol |
| AcOH, 20 cc. | 1.30 | 1.31 |
| EtOH, 20 cc. +3N HCl, 0.1 cc. | 1.50 | 1.60 |
| AcOH, 20 cc. +3N HCl, 0.1 cc. | 1.80 | 1.79 |

a) 0.01 mol. of the substrate was hydrogenated with 50 mg. of platinum oxide each time.

except in hydrogenation with palladium-on-carbon (II) and rhodium-on-carbon (II), which were prepared from acidic media though washed with water many times and dried before use. Generally, the absorption of hydrogen increased in the following order with respect to the solvents; ethanol, acetic acid, ethanol with hydrochloric acid, and acetic acid with hydrochloric acid. This may be interpreted as the order of the abilities of the solvents as proton donors, which may become clearer by considering their conjugate acids, namely, $EtOH < AcOH < EtOH_2^+ < AcOH_2^+$[19], indicating that the hydrogenolysis is acid-catalyzed[20]. With respect to the catalysts, platinum oxide causes the greatest absorption of hydrogen[21], and rhodium added to platinum decreases the hydrogenolysis markedly. For instance, in acetic acid with hydrochloric acid, as much as 79% of cinnamyl alcohol is reduced to propylbenzene with platinum oxide. On the other hand, with rhodium-platinum (3 : 1) oxide only 4% is hydrogenolyzed in acetic acid, compared with 31% with platinum oxide in the same solvent.

Table II shows the effect of varying amounts of added hydrochloric acid on the hydrogen uptake by cinnamyl alcohol in acetic acid with platinum oxide as a catalyst. It is seen that a very small amount of hydrochloric acid is sufficient for the maximum absorption of hydrogen and further addition has little effect. It seems improbable that the greater absorption of hydrogen would result from the intermediate formation of cinnamyl acetate, because cinnamyl acetate absorbed no more hydrogen than cinnamyl alcohol in hydrogenation with platinum oxide as shown in Table III.

With respect to the activities of the three oxide catalysts, it may be said that the order was as follows; rhodium-platinum (3 : 1) oxide > palladous oxide > platinum oxide, though an accurate comparison was not possible because of the different amounts of hydrogen absorbed. For example, with 50 mg. of each catalyst, 1.342 g. (0.01 mol.) of cinnamyl alcohol was reduced in 11 min. with rhodium-platinum (3:1) oxide, in 14 min. with palladous oxide, and in 26 min. with platinum oxide, in 20 cc. of acetic acid at 25°C and under atmospheric pressure.

**Catalytic Reduction of 3-Phenylpropargyl Alcohol and *cis*-Cinnamyl Alcohol.**—Table IV summarizes the results of the hydrogenation of 3-phenylpropargyl alcohol and *cis*-cinnamyl alcohol in various solvents with the use of platinum oxide as a catalyst together with those of the trans isomer. It is seen from the table that 3-phenylpropargyl alcohol absorbs nearly one mole of hydrogen more than *cis*-cinnamyl alcohol in any solvent used. This means that little hydrogenolysis or none occurred before the reduction of the triple bond to the double bond. The result may be explained by the strong affinity of the triple bond for the catalyst surface, which may prevent the C–O linkage from being adsorbed

TABLE IV. CATALYTIC REDUCTIONS OF 3-PHENYLPROPARGYL ALCOHOL AND CINNAMYL ALCOHOL[a]

| Solvent | Hydrogen uptake mol./mol. | | |
|---|---|---|---|
| | 3-Phenylpropargyl alcohol | Cinnamyl alcohol *cis*- | *trans*- |
| EtOH, 20 cc. | 2.01 | 1.04 | 1.03 |
| AcOH, 20 cc. | 2.29 | 1.24 | 1.31 |
| EtOH, 20 cc. +3N HCl, 0.1 cc. | 2.64 | 1.64 | 1.60 |
| AcOH, 20 cc. +3N HCl, 0.1 cc. | 2.79 | 1.77 | 1.79 |

a) 0.01 mol. of the substrate was hydrogenated with 50 mg. of platinum oxide each time.

19) For the superacidic character of hydrochloric acid in acetic acid, see for instance; G. Schwarzenbach and P. Stensby, *Helv. Chim. Acta*, **42**, 2342 (1959).

20) This does not mean that the hydrogenation of the double bond is unaffected by acid, but does mean that the hydrogenolysis is much more promoted by acid than the hydrogenation.

21) This does not mean necessarily that platinum oxide has the highest activity for the hydrogenolysis. The lower values for palladous oxide may probably result from its greater activity for the hydrogenation of the double bond.

on the surface of the catalyst, just as the triple bond is more tightly adsorbed than the double bond. Though the fact that *cis*-cinnamyl alcohol absorbed almost as much hydrogen as its trans isomer seems to suggest isomerization to a large extent in the course of the reduction, it will be difficult to say whether or not this is the case from the data now available[22].

## Summary

1. The hydrogenation and hydrogenolysis of cinnamyl alcohol was studied with platinum, palladium, rhodium, and rhodium-platinum catalysts. The following results were obtained:

(i) The absorption of hydrogen increases with respect to the solvents in the following order; ethanol, acetic acid, ethanol with hydrochloric acid, and acetic acid with hydrochloric acid. The order was interpreted as that of the abilities of the solvents as proton donors.

(ii) With respect to the catalysts, platinum oxide causes the maximum absorption of hydrogen, and rhodium added to platinum decreases the hydrogenolysis markedly.

(iii) With respect to the activities of the three oxide catalysts in acetic acid, the order was; rhodium-platinum (3 : 1) oxide > palladous oxide > platinum oxide.

2. From the comparison of the hydrogen uptakes by 3-phenylpropargyl alcohol and by *cis*-cinnamyl alcohol, it was shown that little hydrogenolysis or none occurs before the reduction of the triple bond of the phenylpropargyl alcohol to the double bond.

The authors wish to express their hearty thanks to Professor Yoshiyuki Urushibara for his valuable suggestions and encouragement. The authors are also indebted to the Ministry of Education for a Grant-in-Aid for Scientific Research.

# *Infrared Spectra and Normal Vibrations of Formamide; $HCONH_2$, $HCOND_2$, $DCONH_2$ and $DCOND_2$*

By Isao SUZUKI

(Received May 7, 1960)

A number of investigations have been made on the molecular structure of formamide. The geometrical structure of the molecule was precisely determined by the studies of the microwave spectrum[1-3], X-ray diffraction[4], and nuclear magnetic resonance[5]. It was indicated that the formamide molecule is planar in the solid state and is nearly planar and of very shallow pyramidal configuration as to the C-$NH_2$ group in the gaseous state. The Raman and infrared spectra of $HCONH_2$ were observed by a number of investigators in the gaseous, liquid, and solid states and in solutions[6-13]. The infrared spectra of *N*-deuterated formamide, $HCOND_2$, were also observed in the liquid state and in solutions[11,13]. A normal coordinate treatment of the molecule as a three-body problem was made by Miyazawa[13]. However, a full analysis of the normal vibrations of the formamide molecule has never been attempted, and the assignments of the observed frequencies are not yet complete.

In order to clarify the nature of the normal vibrations of the formamide molecule, the present writer observed the infrared spectra of *C*-deuterated formamides; $DCONH_2$ and $DCOND_2$. The infrared spectra of undeuterated

formamide ($HCONH_2$) and *N*-deuterated formamide ($HCOND_2$) have been remeasured.

A normal coordinate treatment has been made for all of these four molecules as a six-body problem. Fourteen force constants have been determined so that all the thirty-six observed frequencies are thereby explained. With these force constants, the vibrational mode and the potential energy distribution among the symmetry coordinates have been calculated for each normal vibration.

The purpose of this paper is to give the results of these observations and calculations and to present a complete assignment of the observed frequencies and a detailed discussion on the nature of each normal vibration of the formamide molecule.

## Experimental

**Formamide $HCONH_2$.** — The sample used was obtained from a commercial source, and was purified several times by vacuum distillation; b. p. 86°C (5 mmHg).

***C*-Deuterated Formamide $DCONH_2$.**—This compound was prepared from DCOOD and urea by the following procedures. First, DCOOD was prepared by the thermal decomposition of anhidrous heavy oxalic acid $(COOD)_2$ which was obtained by the exchange reaction of $(COOH)_2$ and $D_2O$[14]. DCOOD was then mixed with urea and heated at about 150°C for 4 hr.[15] Ammonia, carbon dioxide and water produced by the reaction were pumped out in vacuum. From the residual, $DCONH_2$ was distilled out. It was treated with a small amount of aqueous solution of potassium hydroxide to neutralize the remaining free acid and distilled in vacuum again.

Replacement of the amide hydrogen by deuterium was accomplished by adding an excess of $D_2O$, evaporating the heavy water in vacuum, and repeating this procedure three times.

**Infrared Spectra.**—Infrared spectra were measured in the region from 3600 to 525 $cm^{-1}$ with a Perkin-Elmer grating spectrometer model 112G equipped with a KBr foreprism[16], and in the region from 700 to 300 $cm^{-1}$ with a Perkin-Elmer spectrometer model 21, equipped with a CsBr prism. All the measurements were made in the liquid state.

## Infrared Spectra

Infrared spectra of $HCONH_2$ and $DCONH_2$ are shown in Figs. 1 (a)–(c), and those of $HCOND_2$ and $DCOND_2$ in Figs. 2 (a)–(c). As may be expected, the bands at 2882, 1391 and 1056 $cm^{-1}$ of $HCONH_2$ which are assigned respectively to the CH stretching, CH in-plane and out-of-plane deformation vibrations, completely disappear on the *C*-deuteration, and

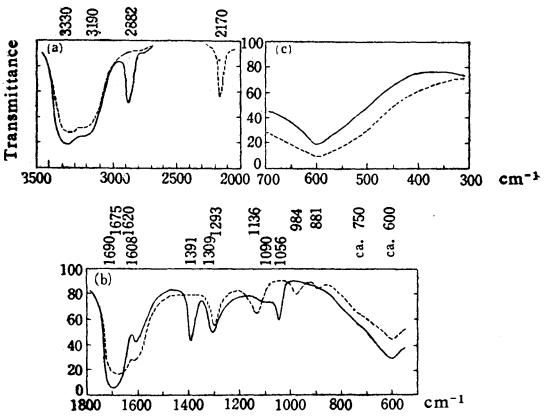

Fig. 1. Infrared spectra of $HCONH_2$ and $DCONH_2$.
(a) 3600~2000 $cm^{-1}$ (b) 1800~525 $cm^{-1}$
(c) 700~300 $cm^{-1}$;
—— $HCONH_2$ and ---- $DCONH_2$.

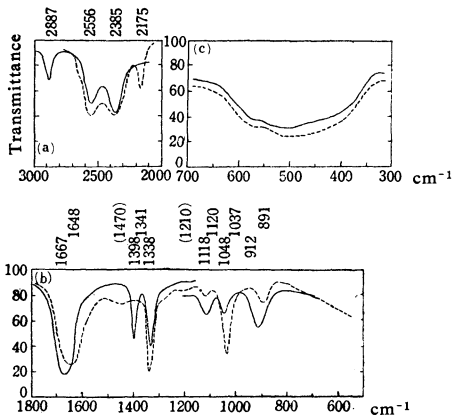

Fig. 2. Infrared spectra of $HCOND_2$ and $DCOND_2$.
(a) 3000~2000 $cm^{-1}$ (b) 1800~525 $cm^{-1}$
(c) 700~300 $cm^{-1}$;
—— $HCOND_2$ and ---- $DCOND_2$.

new bands appear at 2170, 984 and 881 $cm^{-1}$. These are assigned to the CD stretching, CD in-plane and out-of-plane deformation vibrations respectively. Besides these, every band below 1700 $cm^{-1}$ is more or less affected by the *C*-deuteration as well as by the *N*-deuteration. This fact suggests that, in almost every normal mode, the CH, $NH_2$, CD and/or $ND_2$ deformation motions more or less take place.

When $HCOND_2$ or $DCOND_2$ was exposed in the atomopheric air for a while, several weak bands appeared besides the absorption bands illustrated in Figs. 2 (a)–(c). These bands are supposed to be arising from *N*-monosubstituted amides, which were produced by the partial hydrogenation due to the atomospheric water vapour. The positions of these bands were also determined; 3300, 2460, 1470, 1212 and about 700 $cm^{-1}$ for HCONHD (both cis and

TABLE I. THE SYMMETRY COORDINATES

| Symmetry coordinate | | Vibrational mode | Abr. |
|---|---|---|---|
| $S_1$ | $(\Delta r_{NHa}-\Delta r_{NHb})/\sqrt{2}$ | $NH_2$ antisym. stretching | $\nu_a(NH_2)$ |
| $S_2$ | $(\Delta r_{NHa}+\Delta r_{NHb})/\sqrt{2}$ | $NH_2$ symm. stretching | $\nu_s(NH_2)$ |
| $S_3$ | $\Delta r_{CH}$ | CH stretching | $\nu$(CH) |
| $S_4$ | $\Delta r_{CO}$ | CO stretching | $\nu$(CO) |
| $S_5$ | $\Delta r_{CN}$ | CN stretching | $\nu$(CN) |
| $S_6$ | $(2\Delta\alpha_{HNH}-\Delta\alpha_{CNHa}-\Delta\alpha_{CNHb})/\sqrt{6}$ | $NH_2$ bending | $b(NH_2)$ |
| $S_7$ | $(\Delta\alpha_{NCH}-\Delta\alpha_{HCO})/\sqrt{2}$ | CH deformation | $\delta$(CH) |
| $S_8$ | $(\Delta\alpha_{CNHa}-\Delta\alpha_{CNHb})/\sqrt{2}$ | $NH_2$ rocking | $r(NH_2)$ |
| $S_9$ | $(2\Delta\alpha_{OCN}-\Delta\alpha_{NCH}-\Delta\alpha_{HCO})/\sqrt{6}$ | NCO deformation | $\delta$(NCO) |
| $S_{10}$ | $(\Delta\alpha_{CNHa}+\Delta\alpha_{CNHb}+\Delta\alpha_{HNH})/\sqrt{3}$ | redundant | — |
| $S_{11}$ | $(\Delta\alpha_{NCH}+\Delta\alpha_{HCO}+\Delta\alpha_{OCN})/\sqrt{3}$ | redundant | — |

TABLE II. THE FINAL SET OF FORCE CONSTANTS (md/A)

| | | | | | |
|---|---|---|---|---|---|
| $K_{NH}$ | 5.80 | $H_{HNH}$ | 0.40 | $F_{H\cdots H}$ | 0 |
| $K_{CH}$ | 3.74 | $H_{HNC}$ | 0.32 | $F_{H\cdots C}$ | 0.46 |
| $K_{CO}$ | 8.80 | $H_{HCN}$ | 0.18 | $F_{H\cdots N}$ | 0.70 |
| $K_{CN}$ | 6.15 | $H_{HCO}$ | 0.20 | $F_{H\cdots O}$ | 0.92 |
| $F'=-F/10$ | | $H_{NCO}$ | 0.34 | $F_{O\cdots N}$ | 1.50 |

trans forms), and 3300, 2460, 1470, 1290, 1053 and about 700 $cm^{-1}$ for DCONHD.

The values of the observed frequencies are given in the first column of Table III.

## Calculation of Normal Vibrations

The calculation of normal vibrations was made by the method presented by Wilson[17], according to which the secular equation was set in the form $|\boldsymbol{GF}-\lambda\boldsymbol{E}|=0$, where $\boldsymbol{F}$ and $\boldsymbol{G}$ are the potential and reciprocal kinetic energy matrices respectively. It was assumed that the molecule has a planar configuration ($C_s$), the normal vibrations are classified into 9 in-plane (A′) and 3 out-of-plane (A″) vibrations. In the present paper, only the in-plane vibrations were treated. The structural parameters used in this calculation are as follows; the bond lengths of $r$(NH) = 1.04, $r$(CN) = 1.30, $r$(CH) = 1.07 and $r$(C=O) = 1.225 A[4,5], all the bond angles are assumed to be 120°. The symmetry coordinates $\boldsymbol{S}$ obtained from the internal coordinates $\boldsymbol{R}$ by a linear transformation;

$$\boldsymbol{S}=\boldsymbol{UR}$$

are given in Table I.

**Force Constants.** — The potential function employed in the calculation is of the Urey-Bradley type[18];

$$2V=\sum K_i(\Delta r_i)^2+\sum H_{ij}r^0{}_i r^0{}_j(\Delta\alpha_{ij})^2 + \sum F_{ij}(\Delta q_{ij})^2+\text{linear terms}$$

where $r_i$ and $r_j$ are bond lengths with equilibrium values $r^0{}_i$ and $r^0{}_j$; $\alpha_{ij}$ are bond angles and $q_{ij}$ distances betweeen nonbonded atoms. $K$, $H$ and $F$ are stretching, bending and repulsive force constants respectively.

The values of the force constants were first transferred from diformylhydrazine, *N*-methylacetamide[19] and urea[20]. A refinement of the values of the force constants was made by the method developed by Miyazawa[21]. The final set of their values is given in Table II, and the calculated frequencies with these values are shown in the second column of Table III.

The calculated frequencies are in excellent agreement with the observed ones, the maximum deviation being 3.0% and the average deviation 1.3%. Therefore, the values of the force constants obtained in this calculation may be used for the normal vibration calculations of the molecules which are closely related with formamide[22].

***L* Matrix and Potential Energy Distribution.** —In order to clarify the nature of the observed frequencies precisely, it is desirable to calculate the relative amplitude of each symmetry coordinate in a given normal mode of vibration. The symmetry coordinates $\boldsymbol{S}$ are related linearly to the normal coordinates $\boldsymbol{Q}$ through the matrix expression;

$$\boldsymbol{S}=\boldsymbol{LQ}$$

The relative amplitude for each symmetry coordinate in a given normal vibration is given

by the corresponding element of the $L$ matrix. The elements of the $L$ matrix computed for each species of formamide are given in Table IV. (The $L$ matrix is normalized to $G$; $LL' = G$[23])

It has been shown that the ratios of the potential energy distribution (P. E. D.) among the symmetry coordinates ($S_i$) for a given normal coordinate ($Q_s$) can approximately be expressed as $F_{ii}L^2_{is}/\lambda_s$,[24] where $F_{ii}$ is a diagonal element of the $F$ matrix, $\lambda_s$ is $s$th frequency parameter. These are also computed and the results are shown in Table III.

**Numerical Computations.**—All the numerical computations were carried out with a parametron computor PC 1, which was designed and constructed by Professor H. Takahashi and his collaborators in the Department of Physics, Faculty of Science, University of Tokyo. The routines used in the computations have been programmed by Shimanouchi, Takeda and the present writer. The details will be published elsewhere[23].

## The Nature of the Observed Bands

Based on the calculated values of vibrational amplitudes and potential energy distributions

shown in Tables III and IV, the nature of the observed bands will be discussed.

**The Bands above 2000 cm$^{-1}$.**—The 3330, 3190 and 2882 cm$^{-1}$ bands of $HCONH_2$ are undoubtedly assigned respectively to the $NH_2$ antisymmetric, $NH_2$ symmetric stretching and the CH stretching vibrations. As may be seen from Table III, each of the normal vibrations corresponding to these frequencies takes place along one of these symmetry coordinates, and practically no other vibrations are coupled with it. The bands at 3330, 3190 and 2170 cm$^{-1}$ of $DCONH_2$ are likewise shown to be almost pure $NH_2$ antisymmetric, $NH_2$ symmetric stretching and CD stretching vibrations respectively. In a similar way, each of the three high frequencies of $HCOND_2$ and $DCOND_2$ is assigned to almost pure $ND_2$ antisymmetric, $ND_2$ symmetric, CH or CD stretching vibration.

The calculated frequencies of these $NH_2$, $ND_2$, CH and CD stretching vibrations are in agreement with the observed ones with the maximum deviation of 2.5%. In detail, however, there are systematic deviations found between the calculated and observed frequencies. Namely, the frequency difference $\Delta\nu = \nu_{obs} - \nu_{calc}$ is always negative for the $NH_2$ and CH stretching vibrations and always positive for the $ND_2$ and CD stretching vibrations. This may be interpreted as due to the anharmonicity in the internal potential in which the hydrogen or deuterium atoms are placed, which is neglected in the present calculation.

**The Band at 1690 cm$^{-1}$.**—To this band there

are considerable contributions of both the $\nu$(C=O) and $\nu$(CN) vibrations. The energy associated with the $\nu$(C=O) vibration is 50% of the total and that associated with the $\nu$(CN) is 25%, while the amplitude ratio of the $\nu$(CN) to the $\nu$(C=O) is computed to be $-0.73$. Therefore, this band may well be called "N–C=O antisymmetric vibration" rather than "C=O stretching vibration". In addition, the contribution of the $\delta$(CH) motion to this band is not negligible as it is in the case of *N*-methylformamide[22] and diformylhydrazine[19].

This band at 1690 $cm^{-1}$ shifts towards lower frequency both on *N*-deuteration and *C*-deuteration the amount of shift being 23 and 15 $cm^{-1}$ respectively. For $DCOND_2$, it is found at 1648 $cm^{-1}$. On the *C*-deuteration the contribution of the $\delta$(CH) vibration is removed, and on the *N*-deuteration the interaction from the b($NH_2$) vibration is removed. This may be the cause of the shifts of the band in question. The way of coupling of the $\nu$(C=O) and $\nu$(CN) vibrations in this normal mode seems to be unaffected by any deuteration.

**The Band at 1608 $cm^{-1}$.**—The band at 1608 $cm^{-1}$ of $HCONH_2$ corresponds to almost pure b($NH_2$) vibration. This band is not sensitive to the *C*-deuteration and is found at 1620 $cm^{-1}$ in $DCONH_2$. The band corresponding to the b($ND_2$) vibration is found at 1118 $cm^{-1}$ in $HCOND_2$. The position of the band is hardly affected by *C*-deuteration, but its intensity becomes weaker.

**The Band at 1391 $cm^{-1}$.**—The band at 1391 $cm^{-1}$ of $HCONH_2$ can be assigned to the $\delta$(CH) vibration. However, contributions of both the $\nu$(CN) and $\nu$(C=O) vibrations are not negligible. In the normal vibration, the C–N and C=O bonds stretch and contract in phase with an amplitude ratio of $+0.66$. This band is not sensitive to *N*-deuteration and is found at 1398 $cm^{-1}$ in $HCOND_2$. The band at 984 $cm^{-1}$ in $DCONH_2$ corresponds to almost pure $\delta$(CD) vibration. It shifts towards higher frequency on *N*-deuteration by 53 $cm^{-1}$. As is seen from Tables III and IV the shift can be explained as due to the interaction between $\delta$(CD) and r($ND_2$) vibrations.

**The Band at 1309 $cm^{-1}$.**—This band is mainly due to the $\nu$(CN) vibration, although there are energetically small contributions of $\delta$(CH) and r($NH_2$) vibrations. The contribution of the $\nu$(C=O) motion is shown to be quite negligible by the present calculation, in contradiction to some previous authors' expectation[12,13]. On *N*-deuteration the band moves to higher frequency by 29 $cm^{-1}$. The nature of the normal mode corresponding to this band is more complex. Here, the contributions of the $\delta$(CH) and b($ND_2$) vibrations are as important as the $\nu$(CN) vibration.

It is noted that the contribution of the $\nu$(C=O) vibration increases on *C*-deuteration, while that of the $\delta$(CH) becomes negligible. In the corresponding normal vibration at 1341 $cm^{-1}$ of $DCOND_2$ the energy associated with the $\nu$(C=O) vibration is 16% of the total.

**The Bands at 1090 and ca. 600 $cm^{-1}$.**—The band which occurs at about 1090 $cm^{-1}$ in $HCONH_2$ can be assigned to the r($NH_2$) vibration, although there is a small contribution of the $\nu$(C=O) vibration. On *C*-deuteration it shifts towards higher frequency by about 40 $cm^{-1}$. The broad band at about 600 $cm^{-1}$ of $HCONH_2$ corresponds to almost pure $\delta$(NCO) vibration. (It is overlapped with another broad band arising from the $NH_2$ wagging vibration.) The band is insensitive to *C*-deuteration. In *N*-deuterated formamides, an interaction between the r($ND_2$) and $\delta$(NCO) vibrations takes place, and this gives rise to two obserbed bands at 912 and about 570 $cm^{-1}$ in $HCOND_2$ and those at 891 and about 560 $cm^{-1}$ in $DCOND_2$. In addition, there is a small contribution of the $\delta$(CD) vibration to the band at 891 $cm^{-1}$ of $DCOND_2$.

**The Out-of-plane Vibrations**—Of three out-of-plane vibrations, two can easily be identified. They are the CH out-of-plane deformation and $NH_2$ wagging vibrations; $\pi$(CH) and w($NH_2$).

Of $HCONH_2$, the $\pi$(CH) vibration is assigned to a band at 1056 $cm^{-1}$. On *N*-deuteration it is a little shifted, while on *C*-deuteration it disappears as is expected from the assignment. The band at 881 $cm^{-1}$ in $DCONH_2$ can be assigned to the $\pi$(CD) vibration, although its intensity is comparatively weak. In $DCOND_2$ it is probably overlapped by the r($ND_2$) band at 891 $cm^{-1}$ and cannot be distinguished. The above assignment is consistent with the result given by a study on the infrared spectra of $DCONHCH_3$ and $DCONDCH_3$[22]. Both of them show a band at 864 $cm^{-1}$, the intensity of which is as weak as that of the 881 $cm^{-1}$ band of $DCONH_2$.

A broad band found at about 750 $cm^{-1}$ in both $HCONH_2$ and $DCONH_2$ is assigned to the w($NH_2$) vibration. On *N*-deuteration it moves to lower frequency up to about 450 $cm^{-1}$.

Another out-of-plane vibration, the $NH_2$ twisting or torsional vibration, is expected to occur at a lower frequency than 300 $cm^{-1}$. The Raman line found at 200 $cm^{-1}$ of $HCONH_2$[9] may be assigned to this vibration.

Thus, a complete assignment has been made of the infrared absorption bands of the four isotopic species of formamide observed in the 3600~300 $cm^{-1}$ region. The present assignment for $HCONH_2$ and $HCOND_2$ is in comformity

with that proposed by Miyazawa[13] except for a few minor points, but considerably different from others' assignments.

The present writer wishes to express his gratitude to Professor Takehiko Shimanouchi for his kind guidance and encouragement throughout this work and to Professor Hidetoshi Takahashi for allowing to use the PC-1 computor. His thanks are also due to Dr. Michiro Kawano for the infrared measurements in the CsBr region.

# *Investigation on Mixed Complexes. V. A Conductometric Study of Cyano-ethylenediamine Complexes*

By Sigeo KIDA

(Received February 15, 1960)

In the preceding papers of this series[1-3], the present author has dealt with the formation of mixed cyano complexes in solution. It was indicated spectrophotometrically that the octahedral nickel(II) complex ion, such as the hexaquo nickel(II) ion or the bis-(ethylenediamine)-nickel(II) ion, does not react with planar nickel(II) complexes, for example tetracyano niccolate(II) or bis-(dithio-oxalato)-niccolate(II) ion, to form a mixed complex. However, nickel(II) complexes have a tendency to react with each other, when they are of similar configuration, to produce mixed complexes as shown in the following expression:

$$[Ni(C_2S_2O_2)]^{2-} + [Ni(CN)_4]^{2-} \rightleftarrows 2[Ni(C_2S_2O_2)(CN)_2]^{2-}$$

where $C_2S_2O_2$ indicates dithio-oxalate. However, in the case of platinum(II) complex ions such as tetrachloro platinate(II), tetrabromo platinate(II) and tetracyano platinate(II) ions, all of which are of similar configuration, no tendency of forming any mixed cyano-halogeno complex has been observed in solution.

In order to ascertain the exact conditions under which a cyano mixed complex is formed, one needs to carry out further experiments, but unfortunately it is not always easy to find substances which are suitable for the examination by spectrophotometric methods as previously reported. In the present investigation therefore, the conductometric method has been applied to the complexes of platinum(II), palladium(II), zinc(II) and cadmium(II), which are all colorless and hence can not be studied by the spectrophotometric method[4].

## Results and Discussion

It is known that the conductivity of a solution has no linear relationship to the concentration of the dissolved salt in the range of $10^{-2}$ F, used in the present study. A linear relationship, however, is required by the method of continuous variation[5]. However, the data reported in the present work show that, so far as only the detection of a mixed complex formation is desired, the conductometric continuous variation method can be applied satisfactory for this purpose.

Eight solutions were prepared for the respective metals by mixing a solution of the ethylenediamine complex with the potassium cyanide solution in the ratios as shown in Table I. The conductivity was measured at 25°C.

TABLE I. COMPOSITION OF MIXED SOLUTIONS USED IN THE CONDUCTOMETRIC MEASUREMENTS

| | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|
| 0.01 F $[M\,en_n]X_2$ | 20 | 10 | 10 | 10 | 10 | 10 | 5 | 5 | ml. |
| 0.02 F KCN | 10 | 7.5 | 10 | 12.5 | 15 | 20 | 12.5 | 15 | |
| [CN]/[M] | 1 | 1.5 | 2 | 2.5 | 3 | 4 | 5 | 6 | |

X=Cl, $NO_3$, $1/2(SO_4)$

1) Part IV of this series: S. Kida, This Bulletin, 33, 1204 (1960).
2) S. Kida, ibid., 33, 587 (1960).
3) S. Kida, ibid., 32, 981 (1959).
4) The absorption of these complexes in the ultraviolet region are irregular and complicated, probably owing to the presence of association bands resulting from the complex and simple ions in the solution.
5) R. C. Brasted and W. E. Cooley, "Physical Methods in Coordination Chemistry", Ch. 18 in J. C. Bailar and D. H. Busch, ed., "The Chemistry of the Coordination Compounds", Reinhold Pub. Co., New York, (1956), pp. 569-572 and references therein.

The reaction proceeds to decrease the total ionic charge in the solution as follows:

$$[M\,en_n]^{2+} + 4CN^- \rightarrow [M(CN)_4]^{2-} + n\,en \quad (1)$$

or $$[M\,en_n]^{2+} + 2CN^- \rightarrow [M\,en(CN)_2] + (n-1)en \quad (2)$$

(M=Ni, Pd, Pt, Zn and Cd; $n$=2 for Pd and Pt; $n$=3 for Ni, Zn and Cd).

Therefore, if a reaction of type 1 took place in solution the curves in Figs. 1 and 2 should have minimum points at [M]/[CN]=1:4, while that of type 2 should give a minimum point at [M]/[CN]=1:2. In fact, as can be seen in Figs. 1 and 2, minimum points are found at [M]/[CN]=1:4 on curves A and E, and at [M]/[CN]=1:2 on curves B, C and D. This shows that, in the former cases, mixed complexes, such as $[Ni\,en(CN)_2]$ and $[Pt\,en(CN)_2]$, are not formed, but the following reactions take place:

$$[Ni\,en_3]^{2+} + 4CN^- \rightarrow [Ni(CN)_4]^{2-} + 3\,en$$

and

$$[Pt\,en_2]^{2+} + 4CN^- \rightarrow [Pt(CN)_4]^{2-} + 2\,en$$

while in the latter cases the mixed complexes

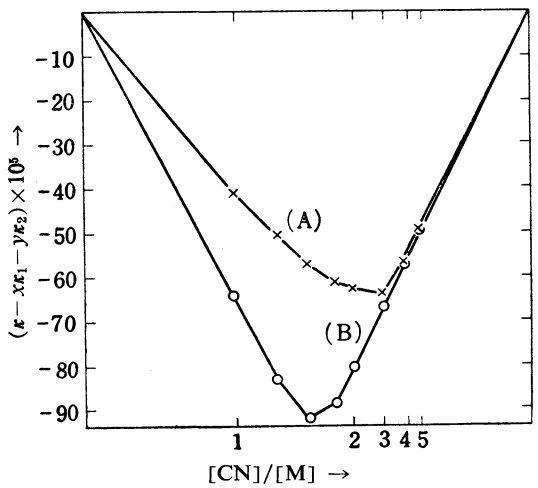

Fig. 1. The curves, (A) and (B), are referred to the complexes of Pd(II) and Pt(II), respectively.
[M]=Concentration of metal in F.
[CN]=Concentration of cyanide ion in F.
$\kappa$=Specific conductivity of a mixed solution ($\Omega^{-1}\times cm^{-1}$).
$\kappa_1$=Specific conductivity of a 0.01 F $[M\,en_n]X_2$ solution ($\Omega^{-1}\times cm^{-1}$).
$\kappa_2$=Specific conductivity of a 0.02 F KCN solution ($\Omega^{-1}\times cm^{-1}$).
$x$=Volume of the complex solution/Volume of the mixed solution.
$y$=Volume of the cyanide solution/Volume of the mixed solution.

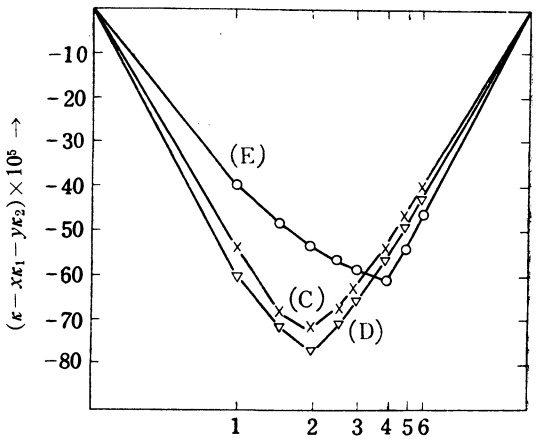

Fig. 2. Curves, (C), (D) and (E), are referred to the complexes of Zn(II), Cd (II) and Ni(II), respectively.

of zinc(II), cadmium(II) and palladium(II) were formed in the solutions through the following reactions:

$$[Zn\,en_3]^{2+} + 2CN^- \rightarrow [Zn\,en(CN)_2] + 2\,en^{6)}$$
$$[Cd\,en_3]^{2+} + 2CN^- \rightarrow [Cd\,en(CN)_2] + 2\,en^{6)}$$
$$[Pd\,en_2]^{2+} + 2CN^- \rightarrow [Pd\,en(CN)_2] + en$$

The result obtained for the nickel complex is in accord with that in the spectrophotometric investigation[3], showing that this conductometric method can be used for the purpose above mentioned. In the cases of zinc, cadmium and palladium complexes, minimum points are found only at [M]/[CN]=1:2 and not at [M]/[CN]=1:4. Neverthless, it should be noted that the formation of tetracyano complexes can not be neglected, since the reaction, $[M\,en(CN)_2] + 2CN^- \rightarrow [M(CN)_4]^{2-} + en$, does not give rise to any decrease in ionic charge in the solution, and accordingly the formation of dicyano complex succeeded by that of tetracyano complex does not always give a minimum point at [M]/[CN]=1:4.

It should also be noted that the curve of the platinum complex is in sharp contrast to that of palladium as a result of their different behavior; the formation of mixed cyano complexes was verified in all the cases of the other metallic ions, but no mixed cyano complex of platinum(II) has ever been observed.

6) It is known that $[Zn\,en_3]^{2+}$ and $[Cd\,en_3]^{2+}$ have octahedral configuration, while $[Zn(CN)_4]^{2-}$ and $[Cd(CN)_4]^{2-}$ are tetrahedral in configuration. However, J. Bjerrum (*Chem. Revs.*, 46, 381 (1950)) has pointed out that tetrammine or bis-ethylenediamine zinc(II) and cadmium(II) complexes tend to be four-co-ordinated and have a tetrahedral configuration as in $[Zn\,en_2]^{2+}$ and $[Cd\,en_2]^{2+}$, but do not tend to have an octahedral one as in $[Zn\,en_2(OH_2)_2]^{2+}$ or $[Cd\,en_2(OH_2)_2]^{2+}$. Therefore, the mixed complexes present in the solution may possibly have tetrahedral configurations of the formulae, $[Cd\,en(CN)_2]$ and $[Zn\,en(CN)_2]$.

The cause of this fact will be the subject of the next investigation.

## Experimental

**Conductometric Measurement.**—The conductivities of the solutions were measured at 25°±0.1°C with Kohlrausch's bridge. The cell constant was determined by using a standard potassium chloride solution of 0.01 F. In the cases of platinum(II) and palladium(II) complexes, the substitution reaction of the cyanide ion for the ethylenediamine molecule was slow, and accordingly the mixed solution was allowed to stand in a thermostat until the conductivity came to show a constant value in each case.

**Materials.** — $[Pt\,en_2]Cl_2$[7], $[Ni\,en_3](NO_3)_2$[8], $[Zn\,en_3]SO_4$[9] and $[Cd\,en_3]Cl_2$[10] were prepared according to the methods described in the references. $[Pd\,en_2]Cl_2$[11] was prepared in a way similar to that for $[Pt\,en_2]Cl_2$. The purity was checked by determining the chloride with silver nitrate.

## Summary

The conductometric method was applied to the determination of the formation of mixed complexes in solution, using the method of continuous variation. It was shown that

1) $[Ni\,en_3]^{2+}$ reacts with $CN^-$ and forms $[Ni(CN)_4]^{2-}$ only, leading to the same conclusion as in the spectrophotometric investigation carried out previously.

2) $[Pt\,en_2]^{2+}$ forms only a tetracyano complex, but no mixed dicyano complex.

3) $[Pd\,en_2]^{2+}$, $[Zn\,en_3]^{2+}$ and $[Cd\,en_3]^{2+}$ form dicyano-ethylenediamine complexes in solution.

The author wishes to express his sincere thanks to Professor R. Tsuchida of Osaka University for his kind advice and encouragement during this work. His appreciation is also expressed to Dr. H. Yoneda for his helpful discussion.

# 2-Carboxymethylthio- and 2-Hydrazino-1, 3-diazaazulenes

By Ichiro MURATA

(Received March 1, 1960)

2-Mercapto-1, 3-diazaazulene[1] (I) easily undergoes condensation with monochloroacetic acid to form 2-carboxymethylthio-1, 3-diazaazulene[2] (II), as has already been reported, and various properties of II, and 2-hydrazino-1, 3-diazaazulene[3] derived from I and II, are described in this paper.

II forms a pale yellow, crystalline powder only sparingly soluble in water and organic solvents, and has a melting point exceeding 300°C. Its esterification by the Fischer method affords methyl ester IV of m. p. 118~118.5°C and the ethyl ester V of m. p. 89°C. V is also obtained upon reaction of ethyl monochloroacetate on the sodium salt of I. These esters easily undergo hydrolysis to regenerate II and are converted into an amide (VI) of m. p. 207~208°C by the action of 40% ammonia water.

It is known, that pyridines[4] and quinolines[5] possessing a carboxymethylthio group in the $\alpha$-position generally form a cyclized product, called meso-ionic compound, on heating with acetic anhydride. On refluxing II in acetic anhydride, it is converted into an extremely sparingly soluble substance* of violet color. The analytical values of this substance suggest an intermolecular dehydrated product but no detailed examination has been made on it.

* A part of this work was presented as a paper at the 10th Annual Meeting of the Chemical Society of Japan, Tokyo, April, 1957.

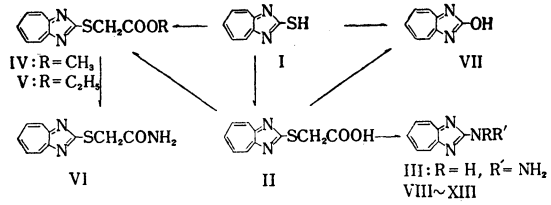
* Duffin and Kendall[4] reported that the use of phosphorus pentoxide or thionyl chloride in place of acetic anhydride as the dehydration agent afforded structurally unkonwn substance as a brown powder.



II

Refluxing of II in concentrated hydrochloric acid results in its conversion to 2-hydroxy-1, 3-diazaazulene (VII) in good yield. Such comparatively facile hydrolysis of II suggests the possibility of I being desulfurized by the action of monochloroacetic acid.

Desulfurization of heterocyclic compounds with a mercapto group by the action of monochloroacetic acid has been reported by numerous workers on thiopyrimidines[6], thioquinoline[7], thiohydantoin[8], thiouracil[9] and thiooxazole and thiothiazole[10]. On heating I in aqueous solution of excess of monochloroacetic acid, II is first formed after 15~20 min. When this mixture is heated for a longer period, such as further 25 hr., without isolation of II, the separated II dissolves gradually and changes almost quantitatively into VII.

Oxidation of the ethyl ester V with hydrogen peroxide in glacial acetic acid, in an attempt to obtain the ethoxycarbonylsulfonyl derivative, invariably gives VII as the product, whether the reaction is carried out at 60~70°C with an excess of the reagent or at room temperature with an equivalent amount of the reagent, and the sulfone is not isolated. Ohta[10] obtained the sulfone by oxidation of carboxymethylthio derivatives of thiazole and thiadiazole under the same conditions but found that the same oxidation of oxadiazole had changed it into the hydroxy derivatives and the sulfone was not obtained. II also undergoes oxidation by hydrogen peroxide to form VII.

IV: R=$CH_3$
V: R=$C_2H_5$

VI II III: R=H, R'=$NH_2$
VIII~XIII

The carboxymethylthio group present in 2-position of pyrimidine is known to be substituted by amino and benzylamino groups[11]. II also reacts comparatively easily with various amines to form derivatives listed in Table I.

In the foregoing reaction, II reacts most readily with hydrazine and III is formed in a good yield only by letting stand their mixture at room temperature.

III has already been obtained by the application of hydrazine to 2-chloro-1, 3-diazaazulene but its properties are almost unknown. As has already been mentioned, III can now be prepared easily from II but it can also be obtained easily from I by refluxing it with hydrazine hydrate in butanol, generating hydrogen sulfide gas.

III easily undergoes condensation with various ketones and aldehydes in alcohol to form the corresponding hydrazones (Table II). The ultraviolet absorption maxima of these hydrazones are indicated in Table III.

In general, six-membered, heterocyclic aromatic compounds of nitrogen possessing a hydrazino group in the $\alpha$-position undergoes cyclization between the ring nitrogen and the hydrazino group by the action of formic acid, ethyl orthoformate, or acetic anhydride and form triazole derivatives. They also undergo

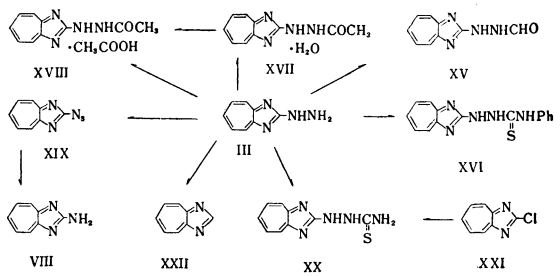
* shoulder



cyclization by the action of nitrous acid to form tetrazole derivatives[13].

III does not cyclize by the reaction of these reagents, even under a rather drastic conditions. The reaction of III with formic acid gives the formate XV of m. p. 249°C (decomp.) and that with phenyl-mustard oil gives the phenylthiosemicarbazide compound XVI. Application of acetic anhydride to III affords two kinds of crystals, m. p. 248°C (decomp.) (XVII) and m. p. 189°C (decomp.) (XVIII). Further application of acetic anhydride to XVII converts it to XVIII. It is therefore known that XVII is an acetylhydrazino compound with one molecule of water of crystallization while XVIII is an acetate of the acetylhydrazino compound.

Application of sodium nitrite in 2 N hydrochloric acid or in acetic acid to III gives extremely labile yellow needles (XIX) of m. p. 135°C (decomp.). The ultraviolet absorption maxima of XIX appear at 228 mμ (log ε 4.03), 262 (4.41), and 337 (4.15), and this makes it impossible to assume any skeletal change in 1,3-diazaazulene molecule. The infrared spectrum of XIX shows distinct absorption of an azide at 2150 $cm^{-1}$ [14] and XIX should therefore be 2-azido-1,3-diazaazulene and not the anticipated tetrazole compound. Actually, reduction of XIX with hydrogen sulfide results in quantitative formation of 2-amino-1,3-diazaazulene[12] and this also endorses above assumption.

Reaction of potassium thiocyanate on III in the presence of hydrochloric acid affords reddish brown prisms XX, m. p. 179.5°C, which is also obtained upon reaction of thiosemicarbazide on 2-chloro-1,3-diazaazulene (XXI), and this shows that XX is 2-thiosemicarbazido-1,3-diazaazulene.

III was decomposed by the Stephens-McFadyen method[15] to 1,3-diazaazulene (XXII).

## Experimental

**2-Carboxymethylthio-1, 3-diazaazulene (II).** — Prepared by the method given in the literature[2].

**2-Methoxycarbonylmethylthio-1, 3-diazaazulene (IV).** — A mixture of II (100 mg.) suspended in methanol (2 ml.) and added with concentrated hydrochloric acid (0.05 ml.) was refluxed on a water bath for 45 min. This mixture was diluted with water and extracted with chloroform. The chloroform extract was washed with water, dried, and the solvent was evaporated. The residue was dissolved in benzene and the solution was purified by passage through an alumina layer. The yellow crystals (100 mg.), m. p. 120~122°C, was recrystallized from benzenepetroleum ether mixture to pale yellow needles (IV), m. p. 121~122°C.

Found: C, 56.71; H, 4.08; N, 12.12. Calcd. for $C_{11}H_{10}O_2N_2S$: C, 56.41; H, 4.30; N, 11.96%. Ultraviolet $\lambda_{max}^{MeOH}$ m$\mu$ (log $\varepsilon$): 238(4.35), 269(4.28), 355(4.19).

**2-Ethoxycarbonylmethylthio-1, 3-diazaazulene (V).**—a) Obtained by a method similar to that for IV, as pale yellow needles, m. p. 89~89.5°C.

b) A solution of the sodium salt (200 mg.) of I dissolved in ethanol (2 ml.) and added with ethyl monochloroacetate (150 mg.) was refluxed on a water bath for 50 min. Sodium chloride formed by the reaction was filtered off, ethanol was evaporated from the filtrate and benzene soluble portion of the residue afforded 230 mg. of V, m. p. 89~89.5°C.

Found: C, 58.11; H, 4.39; N, 11.56. Calcd. for $C_{12}H_{12}O_2N_2S$: C, 58.06; H, 4.87; N, 11.29%. Ultraviolet $\lambda_{max}^{MeOH}$ m$\mu$ (log $\varepsilon$): 238(4.46), 269(4.37), 355(4.29).

**2-Carbamoylmethylthio-1, 3-diazaazulene (VI).**— A mixture of V (70 mg.) and 40% ammonia water (2 ml.) was stirred for 10 hr. at room temperature. After allowing this to stand over night, the crystals (60 mg.) of m. p. 202~205°C (decomp.) were collected and recrystallized from ethanol to pale yellow needles (VI), m. p. 207~208°C (decomp.).

Found: C, 55.15; H, 3.82; N, 19.57. Calcd. for $C_{10}H_9ON_3S$: C, 54.79; H, 4.14; N, 19.17%. Ultraviolet $\lambda_{max}^{MeOH}$ m$\mu$ (log $\varepsilon$): 239(4.49), 270(4.36), 355(4.29).

**Action of Acetic Anhydride on II.**—A suspension of II (40 mg.) in acetic anhydride (1 ml.) was refluxed for 10 min. in an oil bath. The cooled reaction mixture was thoroughly washed with water and ethanol, and brownish violet powder (30 mg.) which turns black from around 220°C, was obtained.

Found: N, 12.83. Calcd. for $C_{20}H_{14}O_3N_4S_2$: N, 12.54%.

**Hydrolysis of II.** — A solution of II (50 mg.) dissolved in concentrated hydrochloric acid (0.5 ml.) was refluxed for 2 hr. in an oil bath, hydrochloric acid was evaporated to dryness, and the residue was neutralized with sodium hydrogen carbonate, and crystals (30 mg.) melting at 225~228°C were obtained. Recrystallization from ethanol after treatment with activated carbon afforded crystals of m. p. 244~245°C, undepressed on admixture with VII.

**Reaction of I and Monochloroacetic Acid.**—a) A suspension of I (100 mg.) in a mixture of monochloroacetic acid (100 mg.) and water (10 ml.) was refluxed for 20 min. in an oil bath, cooled, and the crystals that separated out were collected by filtration to 80 mg. of II, m. p. over 300°C.

b) The reaction was carried out as above but the refluxing was continued for 25 hr. by which the crystals of II dissolved completely. The reaction mixture was evaporated to dryness, ethanol was added to the residue, and this was filtered. The crystals (100 mg.) of m. p. over 300°C so obtained were neutralized with sodium hydrogen carbonate and recrystallized from ethanol to VII, m. p. 244~245°C.

**Oxidation of II with Hydrogen Peroxide.** — To a suspension of II (80 mg.) in glacial acetic acid (0.5 ml.), 30% hydrogen peroxide (0.2 ml.) was added and the mixture was heated with stirring at 75~80°C for 2 hr. The pale yellow solution so obtained was concentrated under a reduced pressure and neutralized with saturated solution of sodium hydrogen carbonate. The crude crystals (40 mg.) of m. p. 229°C were recrystallized from ethanol to VII, m. p. 244~245°C.

**Reaction of II and Ammonia or Amines.**—a) A solution of II (100 mg.) dissolved in 40% ammonia water (1.5 ml.) was sealed in a tube and heated at 100°C for 6 hr. The reaction mixture was allowed to stand over night and the crystals (30 mg.) of m. p. 270°C (decomp.) were collected and recrystallized from water to pale yellow needles (VIII), m. p. 294°C (decomp.). The mother liquor left after separation of VIII afforded the recovered II (55 mg.).

b) A solution of II (150 mg.) dissolved in 40% aqueous solution (2 ml.) of methylamine or dimethylamine was sealed in a tube and heated at 100°C for 20 hr. The reaction mixture was evaporated to dryness over sulfuric acid in a vacuum desiccator and the benzene soluble portion of this residue afforded IX, m. p. 173~174°C, and X, m. p. 133~134°C.

c) A mixture of II (150 mg.) in ethanol (2 ml.) and aniline or benzylamine (1 ml.) was heated in a sealed tube at 165~170°C for 7 hr., cooled over night, and crystals that separated out were collected, afforded 120 mg. of XI, m. p. 239°C, and XII, m. p. 173°C.

**2-Phenylhydrazino-1, 3-diazaazulene (VIII).**—A mixture of II (100 mg.) in ethanol (4 ml.) and added with phenylhydrazine (100 mg.) was heated in a sealed tube at 155~160°C for 6 hr. The crystals that separated out on allowing the reaction mixture to cool were collected (30 mg.) melting with decomposition at 200°C. This was recrystallized from dilute ethanol to orange prisms, XIII, m. p. 222°C (decomp.).

Found: C, 70.64; H, 5.25; N, 23.40. Calcd. for $C_{14}H_{12}N_4$: C, 71.16; H, 5.12; N, 23.72%. Ultraviolet $\lambda_{max}^{MeOH}$ m$\mu$ (log $\varepsilon$): 238(4.18), 260(4.56), 354(4.22).

**2-Hydrazino-1, 3-diazaazulene (III).**—a) II (1 g.) was dissolved in hydrazine hydrate (10 ml.) with warming and the solution was allowed to cool to room temperature by which brown needles, m. p.

187°C (decomp.), separated out. This was recrystallized from ethanol to III (650 mg.), m. p. 188～189°C (decomp.).

b) To a suspension of I (250 mg.) in *n*-butanol (6 ml.), 80% hydrazine hydrate (0.5 ml.) was added and the mixture was refluxed in an oil bath for 4 hr., until there was no longer evolution of hydrogen sulfide. The solvent was evaporated under a reduced pressure, ethanol was added to the residue, and filtration afforded III (220 mg.), m. p. 184～185°C (decomp.).

**Reaction of III and Carbonyl Compounds.**—A mixture of III and a carbonyl compound (1.1 mol. equiv.) in ethanol was heated for 5～10 min., cooled, and the crystals so formed or obtained by evaporation of ethanol was recrystallized from ethanol or a mixed solvent of ethanol and dioxane. The hydrazones listed in Table II were thereby obtained in a quantitative yield.

**Reaction of III and Formic Acid.**—A solution of III (100 mg.) dissolved in 80% formic acid (1 ml.) was heated at 90°C for 4 hr. Formic acid was then evaporated under a reduced pressure, the residue was washed with ethanol, and crystals (85 mg.) of m. p. 245°C (decomp.) were obtained. Recrystallization from ethanol afforded XV, m. p. 249°C (decomp.).

Found: C, 57.36; H, 3.90; N, 30.41. Calcd. for $C_9H_8ON_4$: C, 57.44; H, 4.29; N, 29.77%. Ultraviolet $\lambda_{max}^{MeOH}$ m$\mu$ (log $\varepsilon$): 257(4.42), 347(4.09).

**Reaction of III and Phenyl-mustard Oil.**—Phenyl-mustard oil (90 mg.) was added to the solution of III (100 mg.) dissolved in ethanol (6 ml.) and the mixture was refluxed for 15 min. The crystals that separated out on cooling this reaction mixture were collected by filtration and recrystallized from ethanol to XVI (90 mg.) as reddish violet prisms, which does not indicate any definite melting point, gradually turning black by heating.

Found: C, 59.62; H, 4.00; N, 23.28. Calcd. for $C_{15}H_{13}N_5S$: C, 61.01; H, 4.44; N, 23.72%. Ultraviolet $\lambda_{max}^{MeOH}$ m$\mu$ (log $\varepsilon$): 257(4.61), 347(4.13), 460 (3.50).

**Reaction of III and Acetic Anhydride.**—A mixture of III (50 mg.) and acetic anhydride (0.2 ml.) was allowed to stand at room temperature by which III dissolved once and crystals (30 mg.) of m. p. 210°C separated out. These crystals were recrystallized from ethanol to XVII, m. p. 248°C (decomp.).

Found: C, 54.38; H, 5.34; N, 25.22; $H_2O$, 7.72. Calcd. for $C_{10}H_{10}ON_4 \cdot H_2O$: C, 54.54; H, 5.49; N, 25.44; $H_2O$, 8.18%. Ultraviolet $\lambda_{max}^{MeOH}$ m$\mu$ (log $\varepsilon$): 259(4.48), 350(4.18).

The filtrate left after separation of XVII was concentrated and the crystalline residue was recrystallized from ethanol to XVIII (10 mg.), m. p. 189°C (decomp.).

Found: C, 55.18; H, 5.10; N, 21.34. Calcd. for $C_{10}H_{10}ON_4 \cdot CH_3COOH$: C, 54.95; H, 5.38; N, 21.37%.

**Reaction of III and Nitrous Acid.**—A solution of sodium nitrite (95 mg.) in water (0.3 ml.) was added dropwise into a solution of III (200 mg.) dissolved in 2 N acetic acid (2 ml.) at room temperature. The mixture was then heated for a few minutes at 80°C, diluted with water, and extracted with benzene. The benzene layer was treated with activated carbon and crystals, m. p. 133～134°C (170 mg.), were obtained. This was recrystallized from benzene-petroleum ether mixture to pale yellow prisms XIX, m. p. 134～135°C (decomp.). Ultraviolet $\lambda_{max}^{MeOH}$ m$\mu$ (log $\varepsilon$): 228(4.03), 262(4.41), 337(4.15), 370(shoulder).

Picrate: Yellow needles from ethanol, m. p. 273～274°C (decomp.).

Found: N, 15.68. Calcd. for $C_8H_5N_5 \cdot C_6H_3O_7N_3$: N, 15.79%.

Hydrogen sulfide gas was passed through a solution of XIX (100 mg.) dissolved in water (8 ml.) by which the solution gradually turbid. After thoroughly saturating hydrogen sulfide, the white precipitate so formed was collected by filtration, the portion of the precipitate soluble in hydrochloric acid was combined with the filtrate, and the solution was evaporated. The residue was neutralized with sodium hydrogen carbonate and yellow crystals (60 mg.), m. p. 289°C (decomp.), were obtained. This was recrystallized from water to yellow needles, m. p. 294°C (decomp.), whose ultraviolet and infrared spectra agreed completely with those of 2-amino-1,3-diazaazulene.

**Reaction of III and Potassium Thiocyanate.**—To a solution of III (400 mg.) dissolved in water (2.5 ml.) and added with 4 drops of concentrated hydrochloric acid, aqueous solution of potassium thiocyanate (260 mg.) was added and the mixture was heated on a water bath for 15 min. The crystals formed on coolling this solution were collected (460 mg.) and recrystallized from diluted ethanol to brown prisms, XXI, m. p. 179～179.5°C (decomp.).

Found: C, 49.43; H, 3.92; N, 31.45. Calcd. for $C_9H_9N_5S$: C, 49.31; H, 4.14; N, 31.95%. Ultraviolet $\lambda_{max}^{MeOH}$ m$\mu$ (log $\varepsilon$): 265(4.50), 300(3.75), 367 (4.34).

**Stephens-McFadyen Decomposition of III.**—III (50 mg.) was dissolved in 50% acetic acid (4 ml.), to which 10% copper sulfate solution (1.2 ml.) was added. The mixture was then warmed on a water bath, the solution turned yellowish green and nitrogen gas evolved. After 10 min., the reaction mixture was filtered, and the filtrate was neutralized with a solid sodium hydrogen carbonate, extracted with chloroform. The chloroform extracts were evaporated, and the residue was dissolved in benzene and purified through a short column of alumina. The elute gave yellow needles, m. p. 115～118°C, and no depression with authentic 1,3-diazaazulene on mixed fusion.

The author expresses his deep gratitude to Professor Tetsuo Nozoe of the Faculty of Science of this University for kind and unfailing guidance throughout the course of this work. The elementary analyses were performed by Mr. Shinichi Oyama and Miss Ayako Iwanaga. The author wishs to express his thanks to these helps and donations.

# *Non-stoichiometry of Nickel Oxide*

By Yoshio IIDA, Kenzo SHIMADA and Shunro OZAKI

(Received March 9, 1960)

The physical and chemical properties of nickel oxide have been studied extensively by many investigators[1]. Gray[2] and Iida[3] reported that the electrical properties of nickel oxide varied with the preparation method. Since nickel oxide is a *p*-type semiconductor containing an excess of oxygen, the change in the electrical properties are thought to be attributed to a concentration of an excess of oxygen which produces cation vacancy in nickel oxide. From the electrical neutrality of the crystal, $2x$ $Ni^{3+}$ ions must be formed when there are $x$ vacancies of $Ni^{2+}$ in the crystal.

In the present experiment, the concentrations of $Ni^{3+}$ ion in nickel oxide crystals prepared from various methods have been determined by chemical analysis and a concentration of cation vacancy has been calculated. The concentration of cation vacancy thus obtained has been compared with that obtained by the density and lattice parameter of nickel oxide.

## Experimental

Recrystallized nickel nitrate was prepared by dissolving electro-deposited nickel of 99.9% purity in c. p. nitric acid. Nickel carbonate and nickel hydroxide were precipitated in an aqueous solution of nickel nitrate by ammonium carbonate and ammonium hydroxide. These nickel salts were heated for 3 hr. in air in the temperature range of 400 to 1300°C to obtain nickel oxide.

Electrical resistance was measured in the air from room temperature to 300°C by a method similar to that described by Griffith[4].

The density measurement was the same as that described by Culbertson[5] except that a weighing glass bulb sealed under evacuation was broken off in distilled water containing 0.001% of surface active reagent.

Powder diffraction patterns were recorded by a diffractometer with copper-target radiation. The lattice parameter of nickel oxide was determined by the diffraction peak of (420).

The chemical analysis of $Ni^{3+}$ was made according to the directions of Verwey[6].

The composition ratio of Ni/O was determined by hydrogen reduction of samples at 700°C for 5 hr.

## Results and Discussion

**Non-stoichiometry of Nickel Oxide Prepared from Nickel Nitrate.**—Nickel oxide was prepared by heating nickel nitrate for 3 hr. at temperatures of 400 to 1200°C. Experimental results are shown in Table I. It is seen from electron photographs that particle size increases with an increase in the heating temperature (Fig. 1). At low temperatures of 400 and 500°C, unit particle size can not be determined by an electron photograph because nickel oxide is in the form of very small particles or their aggregates. At 600°C it is about 0.2 $\mu$ and grows to 1 $\mu$ at 1000°C. Inasmuch as the width of diffraction peak (200) at half intensity did not vary with the heating temperature in the range of 400 to 1200°C, the crystallization of nickel oxide heated at 400 and 500°C is thought to be completed.

The composition ratio of O/Ni is larger than 1 below 600°C and is nearly 1 above 600°C. It is seen that nickel oxide prepared by heating the nitrate below 600°C has obviously an excess of oxygen. The lattice parameter of nickel oxide does not vary with the heating temperature within the experimental error. The density of nickel oxide increases with an increase in the heating temperature as shown in Table I. The change in the lattice parameter is more strongly dependent on the oxygen ion which has a larger ion radius than the nickel ion. From the consideration of a constant lattice parameter and the decreasing densities of nickel oxide with an excess of oxygen, it seems to be reasonable to assume that nickel oxide has a cation vacancy as mentioned previously[7].

It has been known[8] that the $Ni^{3+}$ ion is not present in pure and dry nickel oxide. Chemical analysis, however, shows that the $Ni^{3+}$ ion is evidently present in pure and dry nickel

oxide and decreases with the calcining temperature of nickel nitrate. From the reason mentioned above, a concentration of cation vacancy can be calculated as shown in Table I.

From the viewpoint of a semiconducting mechanism, electrical conductivity of nickel oxide should increase with an increase in an excess of oxygen or in a concentration of cation vacancy. The experimental resuls show that the conductivity increases with the cation vacancy. As nickel oxide calcined at low temperatures has a small particle size, the conductivity is thought to increase with an increase in the particle size in view of the contacting resistance of the powder. The conductivity of nickel oxide calcined at low temperatures, however, is high in spite of its small particle size according to the experimental results. Furthermore, Table I shows that the activation energy of the conductivity of nickel oxide decreases with an increase in the cation vacancy. From these facts it is concluded that nickel oxide calcined at low temperatures is obviously a non-stoichiometric compound and has $Ni^{3+}$ ions and cation vacancies, consequently.

Table I shows that the concentration of vacancies calculated from the densities is higher than that from chemical analysis of the

$Ni^{3+}$ ion. As a measurement is liable to give too low density values to small particles because of the incomplete desorption of gases even under the cautious density measurement, the disagreement may be attributed to the lowering of observed density. Further experiment, however, is necessary to determine which method is better to obtain the concentration of vacancy in nickel oxide.

**Effect of Starting Material.** — As nitrogen peroxide which may be responsible for an excess of oxygen in nickel oxide may be formed when nickel nitrate is decomposed, it is of interest to know whether the excess of oxygen in nickel oxide can be formed when nickel carbonate or nickel hydroxide is decomposed. Table II shows that the excess of oxygen is formed in the nickel oxides prepared from nickel carbonate and hydroxide as well as from nitrate. It is seen that the excess of oxygen is higher in nickel oxide from carbonate than in nickel oxides from nitrate and hydroxide. Electrical conductivity measurement shows that the activation energy of electrical conductivity decreases with an increase in the excess of oxygen for all nickel oxides and is the lowest for nickel oxide obtained from carbonate. It is confirmed that the excess of oxygen can be formd in nickel oxide prepared from other salts which are different from the nitrate. No reasonable explanation, however, has yet been found to make clear why the excess of oxygen is the highest in nickel oxide from carbonate, although nickel carbonate, hydroxide and nitrate start to decompose at about 250°C and their purity is essentially the same.

**Isothermal Change in Electrical Conductivity.** —From the above experiments, it has been evident that the nickel oxide obtained by heating nickel salts at low temperatures exhibits a vacant cation structure and its electrical properties vary with the cation vacancy and the concentration of cation vacancy decreases with the increasing heating temperature. It seems to be desirable to determine the isothermal change in electrical conductivity of the nickel oxide. Nickel nitrate was heated at 300°C for 3 hr. to obtain nickel oxide with a high concentration of the vacancy whose ratio of O/Ni

is 1.36. The isothermal change in the electrical conductivity at 300, 400 and 500°C is shown in Fig. 2. It is seen that the behavior of electrical conductivity varies with heating temperature. At 300°C, the electrical conductivity increases with the heating time while it

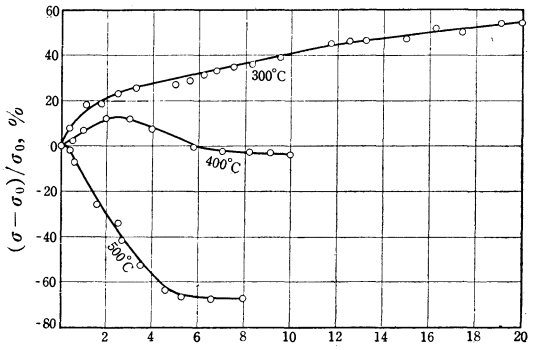

Fig. 2. The isothermal change in electrical conductivity of nickel oxide at various temperatures. Nickel oxide was made by decomposition of nickel nitrate at 300°C for 3 hr.

decreases with the heating time at 500°C. At 400°C, the conductivity increases initially in a heating period of 2 hr. and then decreases with the time. Since the cation deficient structure of nickel oxide is thought to be formed during the decomposition process of nickel nitrate and to be uncompleted in 3 hr. at 300°C, the conductivity increases with the time when it is reheated at 300°C. At 400°C, the uncompleted cation deficient structure is completed in an initial heating period. This may be the result in the initial inrease in the conductivity at 400°C.

The cation deficient structure of nickel oxide is expressed by the following equation according to Hauffe[9]

$$NiO+2\oplus+\square'' \rightleftharpoons \frac{1}{2}O_2$$

where $\square''$ represents the vacancy of nickel site and $\oplus$, a positive hole of the electron. There are equilibrium states at various temperatures between the concentration of the vacancy and oxygen pressure following the above equation. Since nickel oxide calcined at 300°C has a higher concentration of vacancy than the equilibrium state at 400°C, the vacancies greater than the equilibrium value diffuse to the surface of the crystal and disappear. The decreasing conductivity at 400°C in Fig. 2 can be explained by the diffusion of vacancy.

## Summary

Nickel oxide obtained by heating nickel nitrate, carbonate and hydroxide at low temperatures exhibits a non-stoichiometric structure. An excess of oxygen decreases with an increase in the heating temperature of nickel salts. Concentration of $Ni^{3+}$ determined by chemical analysis increases with the excess of oxygen. Densities of nickel oxide or activation energy of electrical conductivity decrease with an increase in the excess of oxygen, whereas lattice parameter does not vary. Isothermal change in electrical conductivity of nickel oxide shows that the decrease in vacancies may be attributed to the diffusion of vacancies to the crystal surface. The concentration of vacancies calculated from the density is higher than that from the concentration of $Ni^{3+}$ ion. The disagreement may be attributed to the density measurement technique.

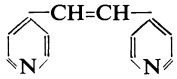
# *Geometrical Isomers of 1,2-Bis-(4-pyridyl)-ethylene*



By Takumi KATSUMOTO

(Received March 11, 1960)

In the preceding paper[1] the author reported the geometrical isomers of 1,2-bis-(2-pyridyl)-ethylene. Regarding 1,2-bis-(4-pyridyl)-ethylene, it is also expected that it will be able to exhibit geometrical isomerism and then to prove its existence in a cis and a trans form. Hitherto, however only one species[2,3] which melts at 151~152°C has been known. The author condensed 4-picoline and 4-pyridylaldehyde into 1,2-bis-(4-pyridyl)-ethylene and then separated two isomers from the ethylene, one corresponding to the known species and the other to the unknown one. The elementary analyses, molecular weight, melting points and ultraviolet and infrared absorptions, all prove that the former is a trans isomer and the latter a cis isomer of 1,2-bis-(4-pyridyl)ethylene.

1,2-Bis-(2-pyridyl)-ethylene

1,2-Bis-(4-pyridyl)-ethylene

## Experimental

**Synthesis of 1,2-Bis-(4-pyridyl)-ethylene.**—The ethylene was synthesized from 4-pyridylaldehyde, 4-picoline and anhydrous zinc chloride according to Thayer and Corson's method[2]. 4-Pyridylaldehyde from the Aldrich Chemicals was distilled under 16 mmHg pressure and the fraction boiling at 85.5°C was used; the phenylhydrazone, m. p. 177.0~178.5°C (lit., 178~179°C[4]). 4-Picoline was separated from the "β-picoline", b. p. 140~148°C, according to the following method[5]. The "β-picoline" contains 3-picoline, 4-picoline and 2,6-lutidine. 2,6-Lutidine was first removed as the urea adduct[6], and then the mixture of the unchanged 3- and 4-picoline was converted into their oxalates[7]. 4-Picoline oxalate was separated by the fractional crystallization from the absolute alcohol solution, as it is less soluble in absolute ethanol than 3-picoline oxalate; 4-picoline oxalate, m. p. 138~139°C. 4-Picoline was recovered by the decomposition of the oxalate with sodium hydroxide and distilled; b. p. 145.0~146.0°C; picrate, m. p. 165.5~166.5C. The infrared absorption spectra of the 4-pyridylaldehyde and the 4-picoline showed the complete absence of the 2- and the 3-isomer, respectively in them. 4-Pyridylaldehyde (0.022 mol.), was heated with the equivaleat moles of 4-picoline and anhydrous zinc chloride in a sealed tube at 200~215°C for 16 hr. The reaction mixture was cooled, dissolved in 40 cc. of 3 N sulfuric acid, and basified with sodium hydroxide. The cooled alkaline solution was extracted twice with 30 cc. portion of ether and four times with 30 cc. portions of chloroform. The chloroform extract was dried over anhydrous potassium carbonate. After the greater part of the solvent was removed, the concentrated chloroform extract was chromatographed on a column (2×40 cm.) of alumina and the column was eluted with chloroform. The chromatograph afforded a satisfactory fractionation. One (**A**), eluted first, formed colorless, long needles, which melted at 151.5~152.5°C after three additional recrystallizations from water and corresponds to the known species of the ethylene. Yield, 17% theoretical. The other (**B**), contained in the next eluate, formed colorless, viscid oil and crystallized by being scratched with a sharp glass rod. The repeated recrystallizations of the crystals from cyclohexane-benzene (1:1) gave colorless, small needles, m. p. 110~111°C. Yield, 17.5% theoretical.

**Measurements.**—Molecular weight was determined by Rast's method. The ultraviolet absorption spectra (in absolute ethanol) were made with a Shimadzu QB-50 quartz spectrophotometer. The wavelengths of the photometer were calibrated with the absorption band at 301 mμ of an aqueous potassium nitrate solution. The infrared absorption spectra were obtained with a Shimadzu IR spectrophotometer equipped with a rock-salt prism. Readings were taken in the range 2000~670 $cm^{-1}$ and calibrated with the absorption bands of polystyrene.

## Results and Discussion

As described above, **A** is colorless, long needles and melts at 151.5~152.5°C, while **B** is colorless, small needles and melts at 110.0~111.0°C. **A** is identified with the known species of 1,2-bis-(4-pyridyl)-ethylene, as the melting point is in good agreement with the published value of the ethylene (lit., 151~152°C[2]) and the result of the elementary analyses is consistent with the calculated value for the ethylene $C_{12}H_{10}N_2$ (Table I). Furthermore, the assignment of the infrared

| Calcd. for $C_{12}H_{10}N_2$ | | 182 |

spectrum makes sure of the above determination, as is described later. The elementary analyses and molecular weight of B are also consistent with the calculated values for the ethylene (Table II); thus **B** is an isomer of **A**. Thayer et al. reported that 1,2-bis-(4-pyridyl)-ethane melted at 110~111°C, which is the same temperature at which **B** melts. Although there is little possibility of producing the ethane in our experimentation, the author has proved that **B** is quite different from the ethane by the mixed examination and the infrared absorption spectra in carbon disulfide as follows; the ethane from the Aldrich Chemicals (m. p. 111~112°C) depresses largely the melting point of **B** in the mixed examination and it shows no absorption in the range 830~670 $cm^{-1}$, while **B** absorbs strongly at 763 $cm^{-1}$.

The infrared absorption spectra of the two isomers, **A** and **B**, are shown in Table II and Fig. 1. They resemble each other very closely except for a few absorptions. **A** and **B** give the following common absorptions; four absorptions in the range 1630~1430 $cm^{-1}$ due to the double bond stretching vibrations of the pyridine ring, three absorptions in the range 1250~950 $cm^{-1}$ due to the C-H in-plane bending vibrations of the 4-substituted pyridine ring and one strong absorption in the range 790~830 $cm^{-1}$ due to the C-H out-of-plane bending vibration of the 4-substituted pyridine ring, respectively[8,9,10]. These absorptions lie always in the range indicated by Shindo[8] and Katritzky[9] for the above vibration modes of the 4-substituted pyridine, as shown in the last column of Table II. A few absorptions that are not common to them arise from the disubstituted ethylene as will be discussed later. No other significant absorptions are found in the spectra. Thus, it is certain that **A** and **B** are the disubstituted ethylenes with 4-pyridyl radicals, i. e. 1,2-bis-(4-pyridyl)-ethylenes and the geometrical isomers with each other.

The geometrical arrangements of **A** and **B** are determined by the infrared and ultraviolet absorption spectra, the melting points, and the solubilities in organic solvents.

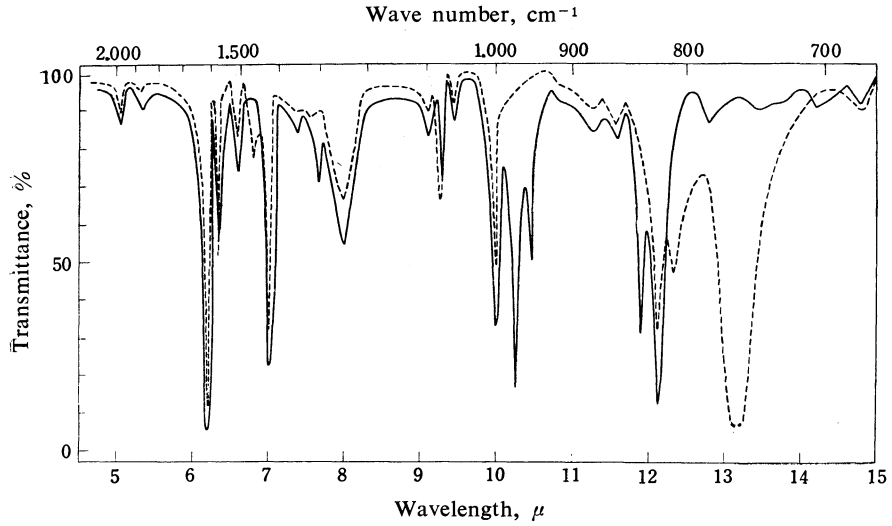

Fig. 1. Infrared absorption spectra of 1,2-bis-(4-pyridyl)-ethylene.
A 5 μ~12.5 μ (chloroform), 12.5~15 μ (acetone).
B 5 μ~12.5 μ (chloroform), 12.5~15 μ (carbon disulfide).
—— A (trans), ------ B (cis)

TABLE III. ULTRAVIOLET ABSORPTION BANDS OF 1,2-BIS-(4-PYRIDYL)-ETHYLENE (in absolute ethanol)

| | E-band | | K-band | |
|---|---|---|---|---|
| | $\lambda_{max}$ | $\varepsilon_{max}$ | $\lambda_{max}$ | $\varepsilon_{max}$ |
| cis Form (**B**) | 212 mμ | 8,390 | 257 mμ | 4,210 |
| trans Form (**A**) | 218 mμ | 11,460 | 288 mμ | 32,490 |
| | 223 | 11,990 | 299 | 33,380 |
| | | | 312 | 19,470 |

The infrared absorptions due to the cis- and the trans form are quite different[11]. trans isomers absorb strongly close to 965 $cm^{-1}$ and weakly in the range 1310~1290 $cm^{-1}$. Rasmussen and Brattain showed that the former absorptions appear only with the trans double bond[12]. This absorption is attributed to the =C-H out-of-plane bending vibration, and the latter to the in-plane bending vibration, of the *trans*-disubstituted ethylene[13]. Cis isomers give no absorptions in this range. **A** gives the two absorptions at 966 $cm^{-1}$ and 1298 $cm^{-1}$, but the absorptions corresponding to them cannot be found in the spectrum of **B**. While, Zechmeister[14] suggested the *cis*-disubstituted ethylenes conjugated with double bonds on both sides give an absorption near 780 $cm^{-1}$. **B** absorbs strongly at 763 $cm^{-1}$ as described above and **A** gives no absorptions in the regions. These absorptions suggest that **A** is a trans isomer and **B** is a cis isomer.

The melting point of **B** is lower by about forty degrees than that of **A**, as shown in

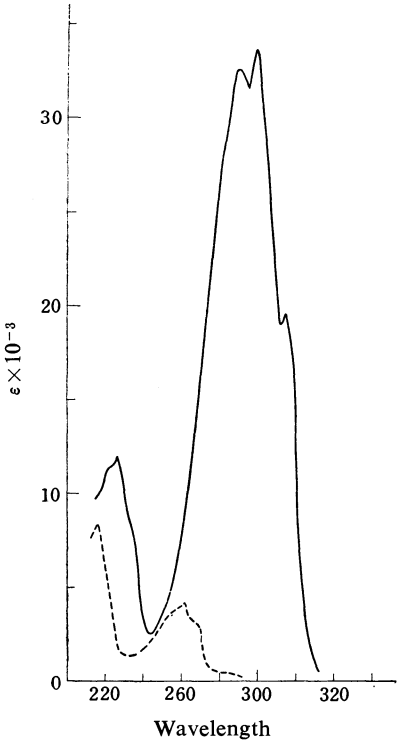

Fig. 2. Ultraviolet absorption spectra of 1,2-bis-(4-pyridyl)-ethylene.
—— **A** (trans), ---- **B** (cis)

11) L. J. Bellamy, "The Infrared Spectra of Complex Molecule", 2nd Ed., Methuen, London (1958), p. 45.
12) R. S. Rasmussen and R. R. Brattain, *J. Chem. Phys.*, 15, 131, 135 (1947).
13) N. Sheppard and G. Sutherland, *Proc. Roy. Soc.* A196, 195 (1949).
14) L. Zechmeister et al., *Acta Chem. Scand.*, 8, 1421 (1954).

Table I. As the cis isomer always melts at a very much lower temperature than trans isomer does, **B** and **A** seem to be a cis and a trans isomer, respectively. The polar substance like a cis isomer is not easily dissolved in the non-polar solvents. **B** is insoluble in cyclohexane, while **A** is readily soluble in it. **B** seems to be a cis isomer.

Regarding the conjugation band of the ultraviolet absorption spectra, a cis isomer gives the spectrum similar to the sum of the spectrum of the component parts of the molecule on the either side of the double bond. The bathochromic displacement and much increase of the absorption intensity of the conjugation band always occur on passing from the cis structure to the trans structure. The ultraviolet absorption spectra of **A** and **B** are shown in Table III and Fig. 2. The conjugation band of 4-picoline has the intensity of some 2,000 at 255 m$\mu$ and that of **B** has about two times as much intensity of 4,210 as the former at 257 m$\mu$. While **A** gives the band at 299 m$\mu$ with intensity 33,380. The ultraviolet absorption spectra of **A** and **B** are typical of the trans and the cis structure.

The conclusion is that the known species of 1, 2-bis-(4-pyridyl)-ethylene (**A**) is the trans isomer and another species (**B**) which was separated by the present author is the cis isomer.

The author wishes to thank Professor S. Kimura of Kyoto University for encouragement, Professor T. Matsu'ura of Hiroshima University for recording infrared spectra and Mr. Yamaguchi of this laboratory for his helpful assistance.

# γ-Hydroxyarginine, a New Guanidino Compound from a Sea-cucumber II. Determination of the Configuration

By Yoshimasa FUJITA

(Received March 21, 1960)

A new guanidino compound was first discovered in a sea-cucumber, *polycheira rufescence*[1], and then isolated purely and identified as γ-hydroxy-L-arginine (I)[2]. The compound contains two asymmetric carbon atoms (α and γ) and should, therefore, exist theoretically in four stereoisomeric forms. In the preceding paper[2] it was concluded that the configuration on the α-carbon is the L$_S$-form[3] in view of the susceptibility to arginase[4] and L-amino acid oxidase[5], whereas that on the γ-carbon was not yet decided. The conclusion was further supported by Makisumi[6] in our laboratory. He observed that I was quantitatively decarboxylated by the action of L-arginine decarboxylase from *E. coli* 7020[7].

In contrast with γ-hydroxyarginine, γ-hydroxyornithine was studied in detail with regard to its stereoisomers by Witkop et al.[8,9]. They proved that *erythro*- and *threo*-γ-hydroxy-L-ornithine were stereochemically equivalent to hydroxy-L-proline and allohydroxy-L-proline, respectively.

In the present study, the configuration on the γ-carbon was established according to the method of Witkop et al.[8] with a slight modification. γ-Hydroxy-L-ornithine (II) produced from I by the action of arginase was treated first with nitrosyl chloride, and then with barium hydroxide. From this reaction mixture, a product which gave a yellow spot with ninhydrin reagent on a paper chromatogram was isolated by fractionation on a column of Amberlite CG-120. The product was identified

as allohydroxy-D-proline (III). The optical purity of III was assured with the aid of column chromatography (Fig. 2).

The fact that a compound having the $L_S$ configuration as to the $\alpha$-carbon atom converts by the action of a certain reagent into a product having the $D_S$ configuration, suggests that it is a result of the Walden inversion. According to the extensive studies by Izumiya et al.[10] on the Walden inversion of $\alpha$-amino acid, it is generally accepted that in an $\alpha$-amino acid possessing a secondary carbon atom at $\beta$-position the inversion does not occur by the halogenation with nitrosyl halide, but takes place on treating the resulting $\alpha$-halogeno acid with basic reagents such as ammonia.

When, as in the case of the present experiment, nitrosyl chloride acts on II, there is a possibility that three chlorinated acids ($\alpha$-chloro-$\delta$-amino-$\gamma$-hydroxyvaleric, $\delta$-chloro-$\alpha$-amino-$\gamma$-hydroxyvaleric, and $\alpha,\delta$-dichloro-$\gamma$-hydroxyvaleric acids) are produced therefrom. Of the three acids, $\alpha$-chloroacid and $\delta$-chloroacid are concerned in the formation of hydroxyproline after cyclization. The composition of the reaction mixture was, therefore, examined by means of determination of the total nitrogen, carbon dioxide liberated with Chloramine T and chloride ions (Table I). The results indicated that the amount of $\alpha$-chloroacid was much grater than that of $\delta$-chloroacid, showing a preferential reactivity of the $\alpha$-amino group of II. It is reasonable, as in the cases of chain compound, that the inversion should also occur in the stage of a base-catalyzed cyclization of $\alpha$-chloro-$\delta$-amino-$\gamma$-hydroxyvaleric acid. Accordingly, the allohydroxy-D-proline obtained by the inversion can be established as originating from *erythro*-$\gamma$-hydroxy-L-ornithine. The latter compound, if the inversion did not occur, would convert into hydroxy-L-proline (IV). Therefore, the whole configuration of I should, as a matter of course, be concluded to be *erythro*-$\gamma$-hydroxy-L-arginine.

## Experimental

**Material.** — The $\gamma$-hydroxy-L-ornithine hydrochloride used in the present study was prepared from $\gamma$-hydroxy-L-arginine hydrochloride by the action of arginase[2]: m. p. 182~183°C (decomp.), $[\alpha]_D^{20}$ +10.6° (*c* 5, in water)[11].

According to Witkop et al.[8], in the conversion of $\gamma$-hydroxyornithine to (allo)hydroxyproline different results are obtained by using either the open acid or the lactone as the starting material. Therefore, whether or not contaminated with lactonized $\gamma$-hydroxyornithine, the material was checked by determining the carbon dioxide evolved with Chloramine T at pH 4.7 and 25°C. On mixing $\gamma$-hydroxyornithine with the reagent, a brisk evolution of the gas was observed. This amounted to 90% after 5 min. and to 100% after 15 min. The observation was in good accordance with that of Witkop on the open acid.

**Conversion of $\gamma$-Hydroxy-L-ornithine to Allohydroxy-D-proline.** — A nitrosyl chloride solution (6 ml.) prepared according to Witkop et al.[8] was added drop by drop to an ice-cold solution of $\gamma$-hydroxy-L-ornithine hydrochloride (185 mg.) dissolved in 9 N hydrochloric acid (10 ml.). The reaction mixture was stirred for 10 min. in the cold and then heated at 55°C for 20 min., followed by evaporation to dryness in vacuo. The residue was dissolved in water (2 ml.), and heated with 0.2 N barium hydroxide solution (10 ml.) in a boiling water bath for 10 min. The solution was freed from barium by neutralizing with sulfuric acid and centrifugation. The supernatant solution was passed through a column of Amberlite CG-120 (H-form, 1×18 cm.). The adsorbed substances were eluted with 0.2 N hydrochloric acid (15 ml./hr.), and collected in 5 ml. fractions. Each fraction was analyzed by paper chromatography and only the fractions (31st to 40th tubes) which gave a single yellow spot with ninhydrin were united. The resulting solution was evaporated up to dryness in

10) N. Izumiya et al., *J. Chem. Soc. Japan, Pure Chem. Sec.* (*Nippon Kagaku Zasshi*), **72**, 26, 149, 445, 550, 1050 (1951); This Bulletin, **25**, 265 (1952); **26**, 53 (1953).

11) The author wishes to correct the erroneous figure for the specific rotation described in Ref. 2.

vacuo. The crystalline residue was dissolved in a small volume of water and the solution was passed through a column of Amberlite IR-4B (OH-form). The effluent freed from chloride by this treatment was again concentrated in vacuo and the crystalline residue was triturated with methanol (2 ml.), filtration and washing with methanol and ether being followed. The product was recrystallized from water-ethanol. Yield 31 mg.; m. p. 237~239°C (decomp.); $[\alpha]_D^{15}$ +57.0° (*c* 1, in water).

Found: C, 45.87; H, 6.78; N, 10.86. Calcd. for $C_5H_9NO_3$: C, 45.80; H, 6.92; N, 10.68%.

The above product (1 mg.) dissolved in citrate buffer pH 3.20 (1 ml.) was passed through a column of Dowex 50-X8 (0.9×50 cm.)[12,13] maintained at 37°C, and eluted (4 ml./hr.) with the same buffer. The effluent was collected in 1 ml. fractions and each fraction was analyzed by ninhydrin colorimetry[14]. The elution pattern of the product had a single peak which corresponded to allohydroxyproline and no other peak was observed, while the authentic mixture of hydroxyproline and allohydroxyproline[15] was completely resolved into two peaks under the same condition (Fig. 2).

15) The author is indebted to Dr. S. M. Birnbaum and Dr. M. Winitz for a generous supply of the sample of hydroxy-L-proline and allohydroxy-D-proline, respectively.

**Composition of the Reaction Mixture with Nitrosyl Chloride.** — A solution of γ-hydroxy-L-ornithine hydrochloride (100 mg.) was treated with a nitrosyl chloride solution (3 ml.) as described above. The reaction mixture was evaporated up to dryness in vacuo and further dried in a vacuum desiccator on potassium hydroxide until it reached a constant weight. It was analyzed for total nitrogen by the micro Kieldahl method, for the liberation of carbon dioxide with Chloramine T at 25°C in a Warburg manometer and for chloride by the titration with silver nitrate[16]. The following values were obtained: 5.32% total nitrogen, 4.12% $CO_2$ and 13.43% $Cl^-$. The results were summarized in Table I.

TABLE I. COMPOSITION OF THE REACTION MIXTURE WITH NITROSYL CHLORIDE

| Symbol* | Mol. wt. | Theory, % $N_2$ | $CO_2$ | $Cl^-$ | Composition of the reaction mixture, % |
|---|---|---|---|---|---|
| W | 221.09 | 12.7 | 19.9 | 32.1 | 20 |

# *The Dehydration Reactions of Nitroparaffins and Aldoximes*

By Teruaki MUKAIYAMA and Tsujiaki HATA

(Received May 4, 1960)

The preceding paper[1] describes the reaction of primary nitroparaffin with isocyanate which gives *sym*-disubstituted urea, furoxane and carbon dioxide in excellent yields in the presence of a catalytic amount of tertiary amine.

$$4R\text{-}N{=}C{=}O + 2R'CH_2NO_2 \xrightarrow{R_3N} 2RHNCONHR + 2CO_2 + R'C(=N\text{-}O)C(=N\text{-}O)R' \quad (1)$$

This reaction proceeds to the formation of disubstituted urea and furoxane through intermediates or amine and nitrile oxide which are formed by the decomposition of the addition compound of isocyanate and *aci*-nitroparaffin with spontaneous evolution of carbon dioxide. The reaction of the amine with isocyanate yields di-substituted urea and furoxane is formed by the dimerization of nitrile oxide.

Nitrile oxide, one of the two intermediates, was confirmed by the formation of isoxazoline when isocyanate, nitroparaffin and tertiary amine are reacted in the presence of unsaturated compound as shown in the following equation.

$$RCH_2NO_2 + CH_2{=}CH\text{-}OAc + 2R'\text{-}N{=}C{=}O \xrightarrow{R_3N} CO_2 + R'HNCONHR' + CH_2\text{-}CH(\text{-}OAc)\text{-}C(=O)\text{-}N{=}R \quad (2)$$

These two reactions 1 and 2 involve initial formation of nitrile oxide by the dehydration of nitroparaffiin with isocyanate and this suggests an interesting study of the dehydration of nitroparaffin with the other organic reagents. Three organic reagents were used to check the dehydration process of nitroparaffins. Firstly, the reaction of primary nitroparaffin with carbodiimide[2] is studied because of its similar behavior to isocyanate. When di-*p*-tolyl carbodiimide and phenylnitromethane are reacted in the presence of tertiary alkyl amine, *sym*-di-*p*-tolylurea and 3-phenyl-4-*p*-tolyl-5-*p*-tolylimino-oxadiazole are obtained (Eq. 3).

$$2CH_3C_6H_4N{=}C{=}N\text{-}C_6H_4CH_3 + C_6H_5CH_2NO_2 \xrightarrow{R_3N} CH_3C_6H_4NHCONHC_6H_4CH_3 + CH_3C_6H_4N{=}C(\text{-}O\text{-}C_6H_5)\text{-}N{=}C_6H_4CH_3 \quad (3)$$

The reaction is satisfactorily explained by the same consideration described in the case of isocyanate which involves the initial formation of nitronate ion by the interaction of nitroparaffin with tertiary amine. One of the oxygen atoms of the nitro group combines in turn with the positively charged carbon of carbodiimide, forming the addition compound I shown in the next scheme.

$$R''_3N + RCH_2NO_2 \rightleftharpoons R''_3\overset{+}{N}H + \left[R\text{-}C(=N\text{-}O^-)\text{-}H \longleftrightarrow R\text{-}C(=N\text{-}O)\text{-}H\right] \xrightarrow{R'N=C=N-R'} R'\text{-}N(H)\text{-}C(=N\text{-}R')\text{-}O\text{-}N{=}C(H)\text{-}R \quad (I)$$

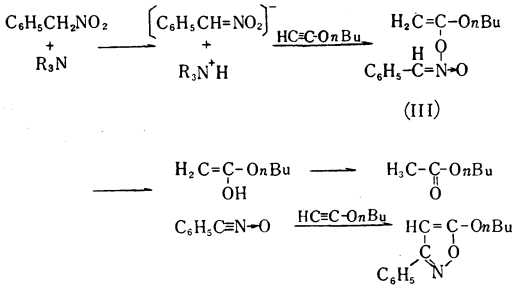
By transferring the hydrogen atom attached to the carbon as a proton, the adduct I decomposes to nitrile oxide and isourea. The latter readily isomerizes to urea and the nitrile oxide adds to carbodiimide, forming oxadiazolone-anil.

$$(I) \rightarrow \begin{cases} CH_3C_6H_4\text{-}N(H)\text{-}C(=N\text{-}C_6H_4\text{-}CH_3)\text{-}OH \longrightarrow CH_3\text{-}C_6H_4N(H)\text{-}C(=O)\text{-}N(H)\text{-}C_6H_4CH_3 \\ C_6H_5C{\equiv}N{\rightarrow}O \xrightarrow{CH_3C_6H_4N=C=NC_6H_4CH_3} CH_3C_6H_4\text{-}N(\text{-}C(=O)\text{-}C_6H_5)\text{-}C(=N\text{-}C_6H_4CH_3)\text{-}O\text{-}N \end{cases}$$

1) T. Mukaiyama and T. Hoshino, *J. Am. Chem. Soc.*, in press.

2) H. G. Khorana, *Chem. Revs.*, 53, 145 (1953).

From the above result it appears interesting to extend the dehydration reaction to aldoxime which has a structure similar to that of *aci*-nitroparaffin. When aldoximes and carbodiimide react with each other, *sym*-disubstituted urea and corresponding nitriles result in high yields either in the absence or the presence of tertiary amine according to the Eq. 4.



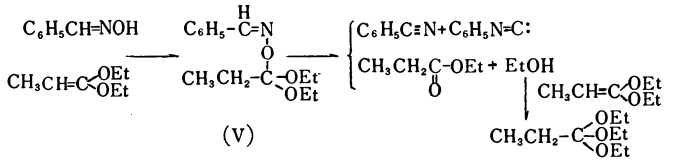
$$\begin{aligned} &R\text{-}CH{=}NOH + R'\text{-}N{=}C{=}N\text{-}R' \\ &\longrightarrow R'HNC(=NR')\text{-}ON{=}HC\text{-}R \quad (II) \\ &\longrightarrow R\text{-}C{\equiv}N + R'HNCONHR' \end{aligned} \tag{4}$$

Unlike the case of nitroparaffin, the dehydration of aldoxime is carried out even in the absence of catalyst. This would be rationalized if the intermediate II is considered to be formed by the addition of aldoxime, which contains a reactive hydroxyl group in itself, to carbodiimide.

Secondly, the reactions of nitroparaffin and aldoxime with acetylenic ether which is known as a strong dehydrating agent were tested, and the similar results were obtained[3,4]. When *n*-butyl acetylenic ether and phenylnitromethane are reacted in the presence of tertiary alkyl amine, *n*-butyl acetate and 3-phenyl-5-*n*-butoxyisoxazole are obtained along with by-product, i. e. 3, 4, 5-triphenylisoxazole, formed by the self-condensation of phenylnitromethane[5].

$$\begin{aligned} &HC{\equiv}C\text{-}O\text{-}n\text{-}Bu + C_6H_5CH_2NO_2 \\ &\longrightarrow CH_3COO\text{-}n\text{-}Bu + HC(C_6H_5)(O)=C\text{-}O\text{-}n\text{-}Bu \\ &+ C_6H_5C(C_6H_5)(O)=C\text{-}C_6H_5 \end{aligned} \tag{5}$$

The reaction can be understood by considering the addition compound III formed by the addition of the nitronate ion of nitroparaffin to acetylenic ether. By transferring a hydrogen atom, this decomposes to nitrile oxide and enolic derivative of ester. The latter readily isomerizes to ester, and the nitrile oxide adds to acetylenic ether to form isoxazole.



(III)

Aldoxime reacts with acetylenic ether to give ester and nitrile in high yields at room temperature in the absence of tertiary amine probably through intermediate IV.

$$\begin{aligned} &HC{\equiv}C\text{-}OR + R'CH{=}NOH \\ &\longrightarrow H_2C{=}C(ON{=}CHR')\text{-}OR \longrightarrow CH_3COOR + R'C{\equiv}N \end{aligned} \tag{6}$$

(IV)

Thirdly, further study on the dehydration of aldoxime with ketene acetal[6] which reacts with water to form ester and alcohol was tested. In the presence of a catalytic amount of boron trifluoride and yellow mercuric oxide, the reaction of benzaldoxime and methyl ketene diethyl acetal gives two dehydrated products, benzonitrile and benzoisonitrile, in nearly the same amount, along with ethyl propionate and ethyl orthopropionate. The unexpected formation of benzoisonitrile is of much interesting and this rearrangement found in this reaction is considered to be the simplest model of the Beckmann rearrangement.

(V)

Although the addition compound V can not be isolated when benzaldoxime and the ketene acetal are reacted in the presence of the said catalysts, it can be produced in good yield by reacting them either in the presence of triethylamine or in the absence of a catalyst. When the addition compound thus obtained is decomposed in the presence of boron trifluoride and mercuric oxide, both benzoisonitrile and benzonitrile are obtained. But when the adduct is decomposed in the presence of boron trifluoride alone, benzoisonitrile is not obtained

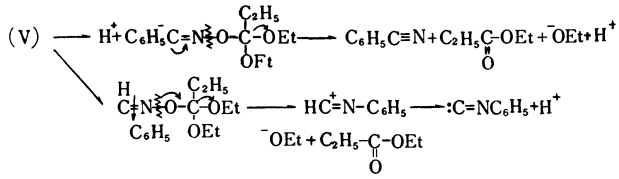
4) T. L. Jacobs, R. Cramer and J. E. Hanson, *J. Am. Chem. Soc.*, **64**, 223 (1942).
5) W. R. Dunstan and T. S. Dymond, *J. Chem. Soc.*, **59**, 410 (1891); S. B. Lippincott, *J. Am. Chem. Soc.*, **62**, 2604 (1940).
6) S. M. McElvain, *Chem. Revs.*, **45**, 453 (1949).



and benzonitrile is exclusively obtained. And no reaction is observed when only mercuric oxide is used. This gives the conclusion that the coexistence of boron trifluoride and mercuric oxide is a necessary condition for the formation of isonitrile.

$$V \xrightarrow{BF_3} C_6H_5C{\equiv}N + CH_3CH_2COOC_2H_5$$

$$V \xrightarrow{HgO} \text{no reaction}$$

Since it has been confirmed that the reaction of aliphatic aldoxime or *n*-heptanaldoxime and ketene acetal gives only nitrile under the same condition, the above-mentioned rearrangement is surely one of the characteristics of aromatic aldoximes.

The course of the rearrangement can be shown by the following scheme.

The addition compound V containing three oxygen atoms attached to one carbon atom has two pathways of decomposition, namely the decomposition with oxygen-carbon bond fission and that with nitrogen-carbon bond fission. The analogous reaction is already known in the decomposition of orthoester[4] to form ester and ether. In the compound V, the decomposition with oxygen-carbon bond fission to form alkyl cation is considered to be more difficult than that with nitrogen-carbon bond to form nitrile or isonitrile cations shown in the above scheme. By direct deprotonation from V, nitrile and orthoester anions are formed. On the other hand, with the migration of phenyl group, the isonitrile cation is formed along with simultaneous formation of the orthoester anion. The former deprotonates to form isonitrile and the orthoester anion loses the alkoxyl anion by the shift of an electron pair and forms ethyl propionate. Further work on this rearrangement of aldoximes and ketoximes is now in progress and will be reported in a later paper.

It is worth while reconsider the above-discussed dehydration reactions carried out with carbodiimide, acetylenic ether and ketene acetal. It is known that these compounds react readily with water to form urea, ester, and ester and alcohol according to the Eqs. 7, 8 and 9, respectively.

$$R\text{-}N{=}C{=}N\text{-}R + H_2O \longrightarrow R\text{-}NHC(OH){=}N\text{-}R \longrightarrow RHNCONHR \quad (7)$$

$$HC{\equiv}C\text{-}OR + H_2O \longrightarrow CH_2{=}C(OH)\text{-}OR \longrightarrow CH_3COOR \quad (8)$$

$$CH_2{=}C(OR)_2 + H_2O \longrightarrow CH_3C(OH)(OR)_2 \longrightarrow CH_3COOR + R\text{-}OH \quad (9)$$

Finding a compound reactive with water would accordingly provide a method of looking for a dehydrating agent. If compounds with carbon-carbon or carbon-nitrogen bond are considered, allene with a twinned double bond and nitrile with a triple bond may also be used as an effective dehydrating agent.

$$R\text{-}CH{=}C{=}CH\text{-}R + H_2O \longrightarrow RCH_2C(OH){=}CH\text{-}R \longrightarrow RCH_2COCH_2R \quad (10)$$

$$R\text{-}C{\equiv}N + H_2O \longrightarrow R\text{-}C(OH){=}NH \longrightarrow RCONH_2 \quad (11)$$

The hydration reactions of Eqs. 10 and 11 have already been studied[7,8]. These compounds may be added to the agents of the intramolecular dehydration reactions of the here-discussed type.

## Experimental

**Reaction of Phenylnitromethane with Di-*p*-tolylcarbodiimide.**—To a solution of phenylnitromethane (6.1 g., 0.045 mol.) and di-*p*-tolylcarbodiimide (10 g., 0.045 mol.) in 25 ml. dry benzene were added 10 drops of triethylamine. Then the mixture was heated under reflux for 2.5 hr. and *sym*-di-*p*-tolylurea precipitated. It was filtered and washed with benzene and weighed 5.2 g., (48% of theoretical), m. p. 257~9°C. 3-Phenyl-4-*p*-tolyl-5-*p*-tolylimino-oxadiazole was separated as a white crystal on standing the filtrate overnight at room temperature. It was recrystallized from 95% ethanol, 1.5 g., (10% of theoretical), m. p. 171~2°C.

Found: C, 77.42; H, 5.57; N, 12.30. Calcd. for $C_{22}H_{19}ON_3$: C, 77.75; H, 5.56; N, 12.24%.

**Reactions of Aldoximes with Di-*p*-tolylcarbodiimide.**—A solution of α-benzaldoxime (4.4 g., 0.036 mol.) and di-*p*-tolylcarbodiimide (8 g., 0.036 mol.) in 35 ml. dry ether was heated under reflux for 11 hr. and *sym*-di-*p*-tolylurea precipitated. It was filtered and washed with ether and weighed 5.5 g., (63% of theoretical), m. p. 258~259°C. The filtrate was evaporated and distilled. Benzonitrile, b. p. 70~2°C (21 mmHg), 2.4 g., (65% of theoretical) was obtained. The same result was obtained when α-benzaldoxime and di-*p*-tolylcarbodiimide were reacted in the presence of tertiary alkyl amine.

When *n*-heptanaldoxime (4.7 g., 0.036 mol.) in place of α-benzaldoxime in the above experiment was used, di-*p*-tolylurea, 7.3 g., (67% of theoretical) and *n*-heptanneitrile, 2.3 g., (57% of theoretical) were obtained.

**Reactions of Aldoximes with Dicyclohexylcarbodiimide.**—To a solution of dicyclohexylcarbodiimide (10 g., 0.049 mol.) in 50 ml. dry benzene was added α-benzaldoxime (5.9 g., 0.049 mol.). Then the reaction started soon with the liberation of heat and *sym*-dicyclohexylurea began to precipitate. After the mixture was refluxed for 7 hr., it was cooled and filtered. The precipitate of *sym*-dicyclohexylurea was weighed 11 g., (92% of theoretical), m. p. 226~228°C. The filtrate was worked up in the usual manner, benzonitrile 5.1 g., (77% of theoretical), b. p. 83~84°C (21 mmHg), was obtained.

With *n*-heptanaldoxime (6.3 g., 0.049 mol.) in place of α-benzaldoxime in the above experiment, dicyclohexylurea 8.9 g., (81% of theoretical) and *n*-heptaennitrile 3.3 g., (62% of theoretical) were obtained.

**Reaction of Phenylnitromethane with *n*-Butyl Acetylenic Ether.** — To a solution of phenylnitromethane (2.8 g., 0.02 mol.) and *n*-butyl acetylenic ether (4.0 g., 0.04 mol.) in 10 ml. dry benzene were added 20 drops of triethylamine and the mixture was refluxed for 10 hr. After removing benzene and triethylamine in vacuo, *n*-butyl acetate 1.5 g., (32% of theoretical), b.p. 123~126°C and 3-phenyl-5-*n*-butoxyisoxazole 0.8 g., (18% of theoretical), b. p. 120~125°C (0.1 mmHg) were obtained. The latter solidified on cooling and melted at 59~61°C (recrystallized from ethanol-water).

Found: C, 71.8; H, 6.94; N, 6.63. Calcd. for $C_{13}H_{15}NO_2$: C, 71.8; H, 6.93; N, 6.46%.

The residual oil crystallized by the addition of 95% ethanol and melted at 209~210°C (recrystallized from 95% ethanol), (0.2 g.). It was 3,4,5-triphenylisoxazole.

**Reaction of Benzaldoxime with Methyl Acetylenic Ether.** — To a solution of α-benzaldoxime (6.1 g., 0.05 mol.) and methyl acetylenic ether (2.8 g., 0.05 mol.) in 10 ml. dry ether were added 20 drops of triethylamine and the mixture was allowed to stand for 43 hr. at room temperature. Then it was worked up in the usual manner, methyl acetate 1.5 g., (41% of theoretical), b. p. 57°C and benzonitrile 3.6 g., (69% of theoretical), b. p. 187~189°C, were obtained.

**Reaction of α-Benzaldoxime with Methyl Ketene Diethyl Acetal in the Presence of Boron Trifluoride and Mercuric Oxide.** — To a solution of methyl ketene diethyl acetal (3 g., 0.023 mol.) and α-benzaldoxime (2.8 g., 0.023 mol.) in 10 ml. dry ether were added 2 drops of boron trifluoride (40% ether solution) and 0.1 g. of mercuric oxide. After the mixture was refluxed for 6 hr., ether was removed and distilled. Ethyl propionate 0.8 g., (68% of theoretical), b. p. 45°C (108 mmHg), benzonitrile 0.9 g., (38% of theoretical), b.p. 57~59°C(4 mmHg), benzoisonitrile 0.5 g., (21% of theoretical), b. p. 38~42°C (3 mmHg), and ethyl orthopropionate 0.6 g., (30% of theoretical), b. p. 89°C (75 mmHg) were obtained.

**Reaction of α-Benzaldoxime with Methyl Ketene Diethyl Acetal in the Presence of Triethylamine.** —To a solution of methyl ketene diethyl acetal (3 g., 0.023 mol.) and α-benzaldoxime (2.8 g., 0.023 mol.) in 10 ml. dry ether was added 2 drops of triethylamine. After refluxing the mixture for 7 hr., it was worked up in the usual manner, the addition compound of α-benzaldoxime and methyl ketene diethyl acetal 4.8 g., (83% of theoretical), b. p. 157~158°C (18 mmHg), was obtained.

Found: C, 66.75; H, 8.25; N, 5.57. Calcd. for $C_{14}H_{21}NO_3$: C, 66.90; H, 8.42; N, 5.57%.

The same result was observed when α-benzaldoxime and methyl ketene diethyl acetal were reacted in the absence of catalyst.

**Decomposition of the Addition Compound in the Presence of Boron Trifluoride and Mercuric Oxide.**—To a solution of the above addition compound (2.5 g., 0.01 mol.) in 5 ml. dry ether were added 2 drops of boron trifluoride (40% ether solution) and 0.1 g. of mercuric oxide. After refluxing the mixture for 6 hr., it was treated in the usual manner and ethanol 0.1 g. (22% of theoretical), ethyl propionate 0.6 g. (59% of theoretical), b.p. 38°C (120 mmHg), benzonitrile 0.5 g. (40% of theoretical), b. p. 52°C (2 mmHg), and benzoisonitrile 0.6 g. (50%. of theoretical), b. p. 54°C (12 mmHg) were obtained.

**Decomposition of the Addition Compound in the Presence of Boron Trifluoride.**—With 2 drops of boron trifluoride (40% ether solution) in place of the said two catalysts in the above experiment, ethanol 0.1 g. (22% of theoretical), ethyl propionate 0.5 g. (49% of theoretical), b. p. 42°C (96 mmHg) and benzonitrile 0.5 g. (41% of theoretical), b. p. 68.5°C (10 mmHg) were obtained.

Decomposition reaction of the addition compound in the presence of mercuric oxide could not be observed and the starting material was recovered.

**Reaction of *n*-Heptanaldoxime with Methyl Ketene Diethyl Acetal in the Presence of Boron Trifluoride and Mercuric Oxide.**—To a solution of *n*-heptanaldoxime (2.8 g., 0.022 mol.) and methyl ketene diethyl acetal (2.8 g., 0.022 mol.) in 10 ml. dry ether were added 2 drops of boron trifluoride (40% ether solution) and 0.1 g. of mercuric oxide. After the mixture was refluxed for 7 hr., it was treated in the usual manner and ethanol 0.7 g. (78% of theoretical), ethyl propionate 0.2 g. (10% of theoretical), b. p. 44~47°C (89 mmHg) and *n*-heptanitrile 1.3 g. (54% of theoretical), b. p. 67~67.5°C (13 mmHg) were obtained.

The authors wish to express their hearty thanks to Professor Toshio Hoshino for his encouragement and to Mr. Norio Shibata

for his help throughout the course of this experiment. Thanks are also due to Mr. Asaji Kondo for the microanalyses.

# *On Solvolysis of α-Phosphorus(V) Oxide*

By Masako SHIMA, Kazue HAMAMOTO* and Seiichiro UTSUMI

(Received April 11, 1960)

It has been well-known[1-3] since 1940 that phosphorus(V) oxide exists in three crystalline modifications ($\alpha$, $\beta$, $\gamma$)[4] and that the crystal of the $\alpha$-modification is composed of $P_4O_{10}$ molecules in which four phosphorus atoms are at the apices of a tetrahedron and are bonded to one another with six P-O-P linkages[1,2,5], as is shown in Fig. 1. Water reacts violently

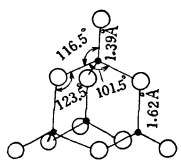

Fig. 1. The structure of the molecule $P_4O_{10}$.
○ Oxygen atoms • Phosphorus atoms

with it, and organic solvents such as alcohols and acetone[6] also indicate some chemical action. As regards the reaction process of $\alpha$-phosphorus(V) oxide with water and the resulting products thereof, much information is available[7-11], but little is known about the reactions with organic solvents.

The present authors attempted to clarify the general reaction mechaniem of $\alpha$-phosphorus (V) oxide to which special attention was given to the solvolytic opening of the P-O-P linkages in this molecule and the accompanying condensation processes of phosphate radicals. Experiments were conducted along three lines: (a) direct hydrolysis with a large quantity of pure water, (b) solvolysis with organic solvents (e.g. ethanol and acetone) which are miscible with water and have some reaction with the oxide and (c) hydrolysis of the oxide dispersed in organic solvents which are non-reactive and able to hold a limited amount of water.

equipment proved to be unsuitable because of the extraordinarily strong absorptive power of the sublimate against traces of moisture remaining in dried vessels. However, as this material was confirmed to be very pure by X-ray examination (as shown in Fig. 2) it was used without further purification.

**Organic Solvents.** — Diethyl ether and benzene were dried with sodium metal, acetone with anhydrous sodium sulfate and ethanol with calcium oxide. The diethyl ether, benzene and acetone were of reagent grade and ethanol was of guaranteed grade. They were distilled at least twice and used dry or after a definite weight or volume of water had been added.

**Reaction Procedure.**—Each solvent was weighed in a beaker or in a large weighing bottle[12], kept at 0°C and agitated vigorously with a magnetic stirrer. Then 0.5 g. of α-phosphorus(V) oxide was added to the solvent in small portions using a special vessel equipped with a closely fitting lid worked by a spring so as to cause complete dispersion[13].

When water or any solvent miscible with water, for example, acetone or ethanol with or without added water, was used, stirring was continued until the added oxide thoroughly dissolved, the resulting solution was still kept at 0°C and neutralized with 1 N sodium hydroxide[14] (indicator; litmus test paper). In the case of pure water 10 ml. was used each time. Since α-phosphorus(V) oxide went almost completely into solution[15], no treatment was necessary before spotting 0.01 ml. or 0.02 ml. of the sample with a micropipette on a chromatographic paper along a starting line. Different species of the condensed phosphates in this solution were successfully separated. At the same time, a 2 ml. aliquot of the sample solution was taken in order to determine the total phosphorus-(V) concentration by colorimetric analysis. In the case of acetone or ethanol with or without added water (20 ml. in total volume), α-phosphorus(V) oxide dissolved only to a limited extent, and the remaining precipitate had to be separated from the solution with decantation and dissolved in 20 ml. of pure water. After the volume had been adjusted, the contents of the various condensed phosphates, and the total phosphate concentration were determined for these two solutions. On the other hand, in the case of diethyl ether (13 ml.) or benzene (10 ml.), α-phosphorus(V) oxide was dispersed in it as perfectly as possible, and, the mixture being kept in vigorous agitation with a magnetic stirrer, 10 ml. of water was added, and the resulting solution was neutralized with 1 N sodium hydroxide, and then transferred to a separating funnel. The organic phase was removed from the aqueous phase and washed with 2 ml. of water; it was discarded, for no trace of phosphorus(V) was found in it. The aqueous phase was added to the above wash water, and was subjected to analysis for the various condensed phosphates and the total phosphate concentration.

**The Separation of Various Species of Condensed Phosphates by Filter Paper Chromatography.**— Various condensed phosphates differing in degree and mode of polymerization were separated by ascending chromatography on filter paper. The method has been studied by many workers[9,16-21]. In the present work, eleven kinds of acidic solvent and six kinds of basic solvent already reported were tested with Toyo Roshi No. 5B for quantitative analysis[22], and the two following solvents were chosen for their most effective separating ability. Acidic solvent: a mixture of propan-2-ol (70 ml.), water (30 ml.), trichloroacetic acid (5 g.) and concentrated aqueous ammonia (0.3 ml.). Basic solvent: a mixture of isobutanol (30 ml.), ethanol (30 ml.), water (39 ml.) and concentrated aqueous ammonia (1 ml.). $R_f$ values are given in Table I. For further work, experimental conditions were made as follows; length of the filter paper, 40 cm.; width, 2.5 cm.; time of chromatographic development, about 20 hr.; temperature, 10~20°C (room temperature). Lower ends of filter papers were narrowed after the method of Thilo et al.[19a]. The chromatographic separation seemed to improved by this cutting. Each condensed phosphate distributed in bands on a chromatogram was identified by Crowther's method[17c].

**Colorimetric Estimation of Each Condensed Phosphate.** — The condensed phosphates separated in bands on each chromatogram were determined by Crowther's method[17c] by the following procedure. Bands were cut out, soaked with 10 ml. of 1 N aqueous ammonia and eluted by warming on a

12) When dry or volatile solvent was used, reaction was performed in a large weighing bottle with a fitted stopper to prevent moist air from entering or the solvent from evaporating.

13) α-Phosphorus(V) oxide must be kept moisture-tight during the operation. The above-mentioned vessel, originally designed as a receptacle of "Ajinomoto powder", was obtained from the Ajinomoto Co., and was found to be very suitable for this purpose.

14) In the case of solvolysis with a large amount of water, the resulting solution was almost clear. This solution was subjected to moderate neutralization with Amberlite IRC-50, Na-form resin, or with sodium carbonate, so that the hydrolysis that might otherwise proceed during this procedure could be prevented. But these three neutralizing procedures with respective agents did not show any difference in results, as is shown in Table II.

15) A slight turbidity may appear in the solution, but it can be dispersed uniformly in a colloidal form and made to disappear when the solution is stirred sufficiently.

21) G. G. Berg, *Anal. Chem.*, **30**, 213 (1958).

22) Filter papers often contain phosphorus(V) which can be detected by a qualitative method or with colorimetric analysis of eluted solution. Toyo Roshi No. 52 for chromatography contains substances which reduce ammonium molybdate during the procedure of phosphorus(V) detection. In Toyo Roshi No. 53 or No. 54 for chromatography, this was not noticed, but by the use of No. 54 paper, separation of various species of condensed phosphates was notably poor. In this work, No. 53 paper was also used.

TABLE I. SEPARATION OF VARIOUS CONDENSED PHOSPHATES BY ASCENDING CHROMATOGRAPHY WITH THE USE OF TWO KINDS OF SOLVENT

Filter paper; TOYO ROSHI No. 5B for quantitative analysis.

| Solvents | pH | Distances from base to front cm. | Time of development hr. | $R_f$ | | | | | | Reference |
|---|---|---|---|---|---|---|---|---|---|---|
| | | | | Ortho- | Pyro- | Tripoly- | Trimeta- | Tetra-meta- | Highpoly- | |
| Acidic | 1.65 | 20.6 | 9.67 | 0.75 | 0.52 | 0.38 | 0.26 | 0.12 | 0 | 18b, 20 |
| Basic | 11.35 | 19.2 | 8.5 | 0.37 | 0.28 | 0.25 | 0.59 | 0.47 | 0 | 18b |

* All phosphates were used in the form of sodium salts. Standard substances were sodium salts. Test samples were neutralized with sodium hydroxide, sodium carbonate or sodium-form resin. But as the hydrogen ion concentration of chromatographic solvents was adjusted with aqueous ammonia, sodium may have been replaced by ammonium during the development process. In our experiments, the appearance of a spot of another phosphate species was very often noticed, especially in a basic solvent. This additional spot was confirmed to correspond to amomnium salt, for when the sodium in the phosphate had been replaced by ammonium through ion exchange resin column of Amberlite IR-120 ammonium-form, this spot alone was observed.

** The composition of the solvents are described in the text.

TABLE II. DISTRIBUTION OF PHOSPHORUS AMONG THE SOLVOLYSIS PRODUCT OF PHOSPHORUS(V) OXIDE BY A LARGE AMOUNT OF ICE WATER

** Figures in this Table are the values of percentage distribution of phosphorus among respective phosphates.

*** During separation by filter paper chromatography, hydrolysis of the condensed phosphates seemed to advance more by the use of basic solvent than by the use of the acidic solvent. Accordingly, use of the basic solvent was avoided except in the experiment with a large amount of water.

water bath for 1 hr. The eluted sample solutions were treated with the molybdenum reagent in the ordinary way. The absorbance due to molybdenum blue was measured by a Hitachi EPU-2A type spectrophotometer at 830 m$\mu$ in glass cells with a 1 cm. light path using distilled water as the reference.

## Results

**Solvolysis (or Direct Hydrolysis) by a Large Quantity of Water.**—The main product in this case was tetrametaphosphoric acid mounting up to ca. 60% of phosphorus in agreement with the results of Bell et al.[7], Thilo et al.[8] and Westman et al.[9]. The detailed numerical records of contents of each condensed phosphate produced by this direct action are given in Table II.

**Solvolysis by Acetone.**—The ratio of acetone to water was varied as follows: 10 : 0, 9.5 : 0.5, 9.0 : 1.0, 5.0 : 5.0, 0 : 10 by volume. The solvolysis by pure acetone gave 28.5% of tetrametaphosphoric acid and 42% of highpolyphosphoric acid as the major product. The percentage of tetrametaphosphoric acid increased with the water content of the solvent. The results are illustrated in Fig. 3.

**Solvolysis by Ethanol.**—The ratio of ethanol to water was varied in the same way as for acetone and water. $\alpha$-Phosphorus(V) oxide reacted with anhydrous ethanol and most of phosphorus(V) changed into pyrophosphoric acid, less than 5% of it becoming highpolyphosphoric acid and none turning into tetrametaphosphoric acid. Up to 50% of water

content, the yield of tetrameta- and highpoly-phosphoric acid is linerly related to the water content, the yield of pyrophosphoric acid being rapidly decreased with increase in water content. The entire result is shown in Fig. 4.

**Hydrolysis with Diethyl Ether and Benzene as Dispersing Agents.**—It was considered that when these solvents were used in a completely anhydrous state, results might differ essentially from what would be the case when they contained initially a minute amount of water. However, results did not show the expected tendency distinctly, as may be seen in Table III.

## Discussion

The molecular structure of α-phosphorus(V) oxide can be conveniently represented by a square formula I in Fig. 5, in which four P=O bonds are at the four corners and six P-O-P linkages are shown by four sides and two diagonals.

The P=O bonds are very stable as indicated by the short distances shown in Fig. 1, and they remain unaffected throughout the reactions dealt with in this study. Only the P-O-P linkages are attacked by reactive solvent molecules. Reaction of α-phosphorus(V) oxide

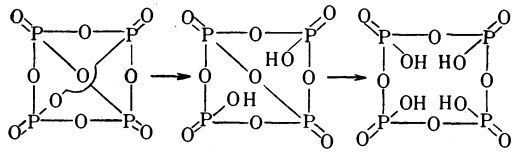

Fig. 5. Formulation of the process of tetrametaphosphoric acid formation.

with a large quantity of water, yielding tetrametaphosphoric acid as a principal product, can be formulated as shown in Fig. 5. The first water molecule approaching the oxide molecule opens any one of the six P-O-P linkages and produces an intermediate hydrolyzate (II), which is attacked by the second water molecule in succession. The fact that the main product is III can be explained by assuming that the weakest P-O-P linkage in II is the one situated diagonally opposite. This is quite easy to understand because only this P-O-P linkage is left to be strained owing to the bond angles of phosphorus atoms. Moreover, as the molecule of tetrametaphosphoric acid (III) has a fairly symmetrical structure, it is sufficiently stable and resists further attack of water molecules; it can be detected practically intact after the hydrolysis experiment. When the oxide reacts with alcohol, reaction proceeds I-IV-V-VI as shown in Fig. 6, yielding pyrophosphoric acid by the hydrolysis of the rather unstable ester formed. The reason why V receives further attack is attributable to its asymmetrical structure.

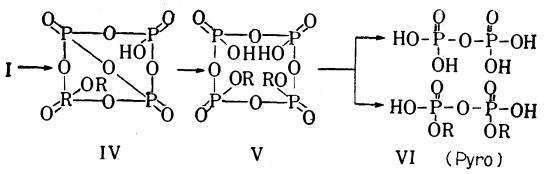

Fig. 6. Formulation of the process of pyrophosphoric acid formation.

A small quantity of trimeta- and tripolyphosphoric acids together with a still smaller quantity of orthophosphoric acid appearing in this case is explained as owing to the simultaneous reaction occurring along the schemes shown in Fig. 7. The reason why this branch reaction is possible in the case of alcoholic solvolysis must lie in the fact that the weak linkages in the intermediate IV are not restricted to the one diagonally opposite, because the ethyl radical is very large as compared with hydrogen atom and does not become ionized while hydrogen does. Other P-O-P linkages

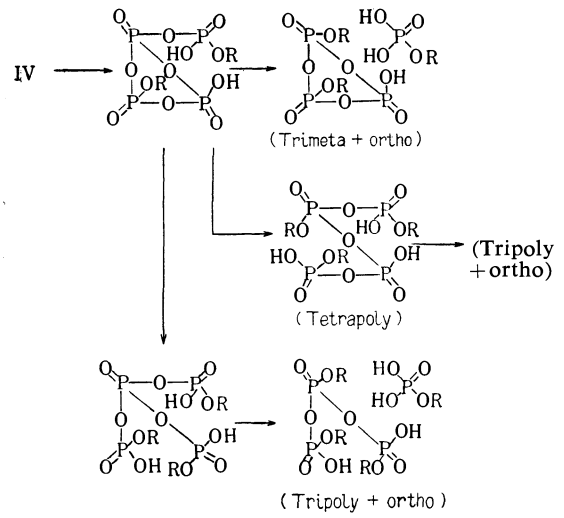

Fig. 7. Formulation of the process of tripoly-, tetrapoly- and orthophosphoric acid formation.

represented by sides of the square in IV may rupture though to a less extent. The phosphorus atom quota found in trimeta- and tripolyphosphoric acids and that found in orthophosphoric acid are in the ratio of three to one, which is quite consistent with the above-mentioned postulation.

When alcohol mixed with a small quantity of water is the reacting solvent against the oxide, tripoly- and trimetaphosphoric acids appear in a conspicuous amount in place of pyrophosphoric acid. As the water content further increases, these tri- species are very rapidly replaced by tetrametaphosphoric acid. It must, however, be noted that the above-mentioned transient increase in tripoly- and trimetaphosphoric acid is not accompanied by the production of a corresponding amount of orthophosphoric acid.

The branch reaction mentioned above does not explain the missing of orthophosphoric acid in this case, and for that same reason, it can explain the increase neither in tripoly- nor in trimetaphosphoric acid. These tri-species can not originate from highpolyphosphoric acid as precursor, because the production of the latter increases only gradually and without a maximum with the increase of water content in the solvent.

Involvement of condensation mechanism of phosphate radicals is the only conceivable explanation for the above. Condensation of phosphate radicals is an endothermic reaction, and does not occur under usual conditions in solution. It is here postulated that it does occur when a solvolytic opening of the P-O-P

linkages gives rise to the excitation of phosphate radicals and when they are close to one another. The same argument will explain the ever increasing formation of highpolyphosphoric acid in hydrolysis. The maximum yield of tripoly- and trimetaphosphoric acid with 90% ethanol may be attributable to the condensation between a pyrophosphoric acid radical and free orthophosphate radical.

Vigorous reaction between the oxide and water evolves much heat, and even under a cooling condition, some local heating can not be avoided. This must undoubtedly promote the condensation process.

Thorough dispersion of the oxide in dry ether or benzene was attempted to ensure synchronized contact with a large amount of water. Similar experiments, using ether and benzene containing trace quantities of water were carried out as well. In the former case, one would expect complete transformation to 100% tetrametaphosphoric acid, whereas in the latter case, one would expect 100% highpolyphosphoric acid. Difficulty in pulverizing the oxide crystals and the reacted mass prevented us from obtaining clear-cut results, but the expected tendency was observed.

Acetone may behave as a solvent having -OH radicals, as is explicable by its enol form, forming $-P-O-C\diagdown\begin{matrix}CH_3\\CH_2\end{matrix}$ on solvolytic opening of a P-O-P linkage. This must be an intermediate very liable to undergo subsequent decomposition giving rise to a fairly large amount of highpolyphosphoric acid as the final hydrolysis product. Tetrametaphosphoric acid can be detected right from the beginning of the reaction, as well as tripoly- and trimetaphosphoric acid. In this case too, almost no orthophosphoric acid is produced.

Orthophosphoric acid is the most easily detectable species among various phosphates; it is inconceivable for us to have missed it in the analysis.

## Summary

1. α-Phosphorus(V) oxide was allowed to react with water, with ethanol or acetone, both dry or mixed with water by adding the powder crystal directly into these liquids. The oxide was also brought in contact with water after being dispersed in diethyl ether or benzene mechanically.

2. The main final hydrolysis products formed in the following cases were tetrametaphosphoric acid by direct action of a large quantity of water, pyrophosphoric acid by anhydrous ethanol, tripolyphosphoric acid by ethanol with a low water content, and highpolyphosphoric acid by anhydrous acetone. Quick contact with water after the oxide has been dispersed in ether or benzene leads to the formation of a larger amount of tetrametaphosphoric acid when these solvents were dry, while the formation of an increased amount of highpolyphosphoric acid was the result when they contained trace quantities of water initially.

3. Separation, identification and estimation of various condensed phosphate species were executed by paper chromatography and colorimetric analysis.

4. Reaction mechanisms were postulated to explain these results. Special attention was given to the solvolytic opening of P-O-P linkages and the accompanying condensation process of phosphate radicals.

# *Untersuchungen über Meso-ionischen Verbindungen. XI. Versuche zur Darstellung von 3-(2'-Pyridyl)sydnon*

Von Masaki OHTA und Mitsuo MASAKI

(Eingegangen am 11. März, 1960)

In der X. Mitteilung[1] dieser Reihe wurde gezeigt, daß bei der Einwirkung von Bisulfitverbindungen der Aldehyde und Alkalicyanid auf 3-Aminopyridin $\alpha$-substituierte 3-Pyridylglycinnitrile bzw. 3-Pyridylglycinnitril selbst entstehen, und daß diese Nitrile sich durch Hydrolyse in die entsprechenden Glycine umsetzen, die weiter bei der Einwirkung von Natriumnitrit in *N*-Nitrosokörper umgewandelt werden und aus den letzteren 4-substituierte 3-(3'-Pyridyl) sydnone durch Cyclisierung-Reaktion mit Essigsäureanhydrid dargestellt werden können.

Nach dieser Methode haben wir eine Reihe von Untersuchungen ausgeführt, die das Ziel hatten, 2-Pyridylglycin, 3-(2'-Pyridyl)sydnon und dessen derivate darzustellen.

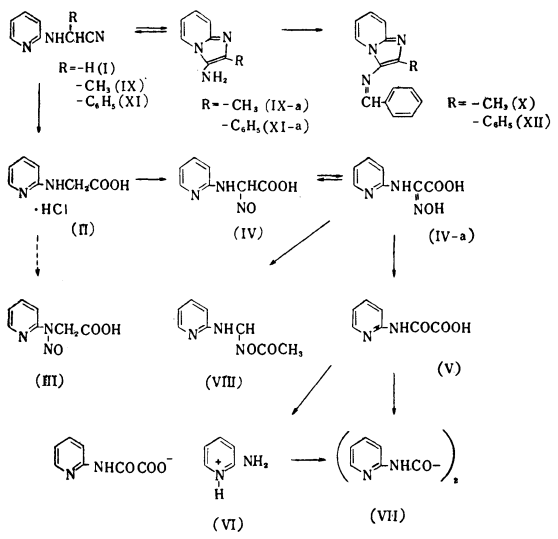
Schon ist von Bristow u. a.[2] die Darstellung von 2-Pyridylglycinnitril nach der oben erwähnten Methode berichtet worden. Andererseits wurde von Reynaud u. a.[3] beschrieben, daß sie nach dieser Methode nur ein dunkelfarbiges Produkt und kein Nitril erharten konnten. Sie erhielten dabei das Nitril durch einen anderen Weg, nähmlich bei der Einwirkung von Bromdiäthylacetal auf 2-Aminopyridin in der Gegenwart von Natriumamid erhielten sie Pyridylaminodiäthylacetal, das durch Hydrolyse in das entsprechende Aldehyd umgewandelt wurde, dessen Oxim beim Versetzen mit Essigsäureanhydrid den *N*-Acetylkör per des Nitrils lieferte.

Durch die Einwirkung von Bisulfitverbindung des Formaldehyds und Natriumcyanid auf 2-Aminopyridin erhalten wir das Nitril (I), das durch Kochen mit Salzsäure salzsaures *N*-(2-Pyridyl)glycin[3](II) ergibt.

Bei der Einwirkung von Natriumnitrit auf II in Kälte, entsteht eine kristalline Substanz von Schmp. 119°C, die nicht *N*-Nitroso-*N*-(2-pyridyl)glycin (III), sondern $\alpha$-Nitroso-*N*-(2-pyridyl)glycin (IV) ist, dessen Konstitution durch Elementaranalyse und durch Reaction mit Essigsäureanhydrid festgestellt wurde.

Wenn man die Nitrosoverbindung in Essigsäureanhydrid löst und bei Raumtemperatur stehen läßt, so fällt langsam der farblose Niederschlag vom Schmp. 196~8°C aus, dessen Molekularformel, $C_7H_6O_3N_2$, durch Elementaranalyse festgestellt wurde. Unsere Vermutung, daß dieses Produkt *N*-(2-Pyridyl)-oxamidsäure (V) sei, wurde durch IR-Absorptionen bei 1300, 1540 und 1655 $cm^{-1}$ als dem sekundären Amid typische Banden und durch die Bildung von *N*, *N'*-Di-(2-pyridyl)oxamid (VII) bei der Pyrolyse bestätigt.

Beim Erhitzen auf 200~220°C ergibt V in guter Ausbeute VII, das durch die Mischprobe mit dem authentischen[4] Präparat bestätigt wurde. Laurent u. a.[5] beobachteten beim Erhitzen von Oxanilsäure auf höheren Temperaturen die Bildung von Oxanilid. Man kann sich die Bildung von VII aus V so denken, daß zunächst aus V durch Pyrolyse 2-Aminopyridin entsteht, und das letztere durch weitere Einwirkung von V in VII umgewandelt wird. In der Tat kann man Aminopyridiniumsalz vom V als Zwischenverbinding erhalten.



Wenn man IV mit Essigsäureanhydrid erhitzt, so erhält man *N*-(2-Pyridyl)acetylformamidoxim (VIII), dessen Bildung man sich so vorstellen kann, daß zunächst in der tautomeren Form (IV-a) des IV Acetylierung erfolgt, darauf dieses sich unter Decarboxylierung in VIII überführen läßt.

Wie oben erwähnt, ist die bei Nitrosierung auf 2-Pyridylglycin erhaltene Verbindung nicht *N*-Nitroso- (III), sondern $\alpha$-Nitroso-körper (IV), so versuchten wir die substituierten 2-Pyridylglycine, die $CH_3$- oder $C_6H_5$- Gruppe am $\alpha$-Kohlenstoffatom tragen, darzustellen, um *N*-Nitroso-(2-pyridyl)glycin zu erhalten, das durch Cyclisierung 3-(2'-Pyridyl)sydnon ergeben sollte.

Im Wasser reagiert 2-Aminopyridin mit Bisulfitverbindung des Acetaldehyds oder des Benzaldehyds und Natrium cyanid, wobei $\alpha$-(2-Pyridylamino)propionitril (IX) oder $\alpha$-(2-Pyridylamino)phenylacetnitril (XI) entsteht.

Unter verschiedenen Bedingungen versuchten wir die Hydrolyse des XI, doch konnten wir kein entsprechendes Glycin erhalten, z. B. beim Erhitzen von XI mit Mineralsäuren entsteht

nur sein stabiles Salz. Diese Tatsache scheint zu zeigen, daß bei XI Ringschluß eintritt[2] und ein Imidazol-Kern sich bildet, nähmlich, XI befindet sich in der tautomeren Form (XI-a). In der Tat läßt sich XI mit Benzaldehyd in nah-quantitativer Ausbeute in Benzal-Derivat (XII) überführen.

Es gelang uns auch nicht aus IX das entsprechende Glycin darzustellen. In ähnlicher Weise ergibt IX bei Einwirkung von Benzaldehyd Benzal-Derivat (X) in guter Ausbeute.

## Beschreibung der Versuche

**2-Pyridylaminoacetnitril (I).**—Man versetzt 4.1 g von 37 proz. Formalin mit einer Lösung von 5.4 g Natriumbisulfit in 8 ccm Wasser, erhitzt 0.5 Std und versetzt daraufhin mit 4.7 g 2-Aminopyridin. Nach ein stdg. Erhitzen und Umrühren setzt man 5 g Natriumcyanid in wenigem Wasser zu. Das Gemisch wird unter mechanischem Rühren noch 4 Std auf dem siedendem Wasserbad erwärmt, und der ausgefallene Niederschlag abfiltriert. Das Filtrat schüttelt man 5 mal mit je 30~50 ccm Chloroform aus. Das vereinigte Chloroformextract wird mit Natriumsulfat getrocknet und im Vakuum eingedampft. Es hinterbleibt schwarzes Öl, wozu 30~40 ccm Äther hinzugefügt wird und läßt es stehen. Dabei fallen braune Prismen aus. Ausbeute 2~3 g (30~45%). Schmp. 126~7°C (aus Benzol).

**Salzsaures 2-Pyridylglycin (II).**—Man löst 2.1 g I in 20 proz. Salzsäure, erhitzt 3~4 Std auf dem Wasserbad und dampft das Reaktionsgemisch im Vakuum ein. Der Rückstand wird mit Äthanol ausgezogen, die Lösung mit Aceton versetzt und bei Raumtemperatur stehen gelassen. Dabei fallen farblose Kristalle aus. Ausbeute 2.7 g (70%). Schmp. 206°C (aus Äthanol).

Gef.: N 14.71. Ber. für $C_7H_9O_2N_2Cl$: N 14.85.

*Pikrat.* Gelbliche Nadeln vom Schmp. 199°C (aus Methanol)

Gef.: N 18.59. Ber. für $C_{13}H_{11}O_9N_5$: N 18.37.

**α-Nitroso-(2-pyridyl)glycin (IV).**—Man löst 1.9 g II in 20 ccm Wasser und fügt 0.7 g Natriumnitrit unter Eiskühlung hinzu, wobei sich langsam ein farbloser Niederschlag abscheidet. Nach 3~4 std. Stehen unter Eiskühlung wird er abfiltriert. Ausbeute 1.5 g. Gelbliche Nadeln vom Schmp. 119°C (aus Wasser).

Gef.: C 46.61; H 3.90; N 23.20. Ber. für $C_7H_7O_3N_3$: C 46.31; H 4.02; N 23.32.

Diese Subtanz zeigt Liebermannsche Reaktion.

***N*-(2-Pyridyl)oxamidsäure (V).**—Man löst 1 g IV in 35 ccm Essigsäureanhydrid auf, wobei fast augenblicklich Farbumschlag von grün nach gelb erfolgt, und läßt dies bei Raumtemperatur stehen. Bald fing sich ein farbloser amorpher Niederschlag auszuscheiden an. Nach eintägigem Stehen wird der Niederschlag abfiltriert, und das Filtrat läßt sich bei Raumtemperatur untergehalten. Nach noch zwei Tagen filtriert man den aufs neue abgeschiedenen Niederschlag ab, der zusammen mit dem oben erhaltenen Produkt umkristallisiert wird. Farblose Naldeln vom Schmp. 196~8°C (aus Äthanol oder Essigsäure). Ausbeute 0.8 g (87%).

Gef.: C 50.71; H 4.13; N 16.95. Ber. für $C_7H_6O_3N_2$: C 50.60; H 3.61; N 16.87.

IR-Spektrum in KBr: 1300, 1540 und 1655 $cm^{-1}$ (-NHCO-).

***N*,*N'*-Di-(2-pyridyl)oxamid (VII).**—Beim Erhitzen auf 200~220°C in Ölbad schmilzt V unter heftiger Zersetzung, und nach 2~3 min. Erhitzen wird das erhaltene, ölige Produkt abgekühlt, das bald kristallinish erstarrt Aus äthanol umkristallisiert, farblose Nadeln oder Prismen zeigen den Schmp. 161°C.

Gef.: C 59.30; H 4.19; N 23.19. Ber. für $C_{12}H_{10}N_4O_2$: C 59.50; H 4.16; N 23.13.

Mischprobe mit dem authentischen[4] Präparat zeigt keine Depresion.

***N*-(2-Pyridyl)oxamidsäure-Aminopyridiniumsalz (VI).**—Man erhitzt V in einem Kolben im Ölbad vorsichtig auf 200~210°C, und wenn V unter der Zersetzung kaum anfängt zu schmelzen, da kühlt man den Kolben ab. Bald erstarrt die erhaltene, ölige Substanz kristallinisch. Aus Äthanol umkristallisiert, erzeugen sich grünliche Blättchen vom Schmp. 206°C.

Gef.: C 55.08; H 4.98; N 21.40. Ber. für $C_{12}H_{12}O_3N_4$: C 55.39; H 4.62; N 21.54.

Die Substanz läßt sich durch nochmaliges Erhitzen unter Wasserabspaltung in VII umwandeln.

***N*-(2-Pyridyl)acetylfomamidoxim (VIII).**—Man löst 2 g IV in 25 ccm Essigsäureanhydrid und erhitzt auf siedendem Wasserbad. Nach einer Stunde wird die schwarze Lösung in $N_2$ unter vermindertem Druck eingedampft. Es hinterbleibt ein braunrotes Öl, das mit Äther ausgeschüttelt wird. Die ätherische Lösung wird mit Natriumsulfat getrocknet und eingeengt, wobei ein roter Rückstand erhalten wird, der aus Benzol umkristallisiert wird. Ausbeute 0.2 g. Bräunliche Nadeln vom Schmp. 192~5°C.

Gef.: C 53.87; H 5.15; N 23.50. Ber. für $C_8H_9O_2N_3$: C 53.62; H 5.06; N 23.45.

**α-(2-Pyridylamino)phenylacetnitril (XI).**—Man versetzt 10.6 g Benzaldehyd mit einer Lösung von 10.4 g Natriumbisulfit in 25 ccm Wasser, erhitzt 1

Std und dann versetzt man es mit 9.4 g 2-Aminopyridin. Nach 3 stdg. Erhitzen setzt man dazu 6.5 g Kaliumcyanid in wenigem Wasser zu, rührt 2～3 Std bei Raumtemperatur um und filtriert den gebildeten gelben Niederschlag ab. Gelbe Nadeln vom Schmp. 210～211°C (aus Äthanol). Ausbeute 8.5 g (40%).

Gef.: N 20.15. Ber. für $C_{13}H_{11}N_3$: N 20.08.

**4-Phenyl-5-benzylidenaminopyrimidazol (II).**—Eine Lösung von 2 g XI und 1 g Benzaldehyd in 10 ccm Äthanol wird 2 Std am Rückfluß erhizt und dann eingeengt. Es hinterbleibt ein gelbes Fett, das aus Ligroin umkristallisiert wird. Gelbe Nadeln vom Schmp. 137°C. Ausbeute nah-quantitativ.

Gef.: C 80.86; H 5.37; N 13.94. Ber. für $C_{20}H_{15}N_3$: C 80.80; H 5.05; N 14.14.

**α-(2-Pyridylamino)propionitril** (IX).—Man versetzt eine Lösung von 10.5 g Natriumbisulfit in 20 ccm Wasser mit 10 g. von 44 proz. Acetaldehyd, erhitzt 1 Std auf dem Wasserbad und dann fügt man 9.4 g 2-Aminopyridin hinzu. Nach 2 stdg. Erhitzen setzt man 7 g Natliumcyanid, in 10 ccm von heissem Wasser gelöst zu, und erhitzt es unter mechanischem Rühren 2 Std auf dem Wasserbad. Das abgeschiedene Öl kristallisiert beim Abkühlen bis Raumtemperatur. Ausbeute 8 g. Gelbliche Nadeln vom Schmp. 133～135°C (aus Benzol).

Gef.: N 28.33. Ber. für $C_8H_9N_3$: N 28.57.

**4-Methyl-5-benzylidenaminopyrimidazol (X).**—Eine Lösung von 1 g IX und 1 g Benzaldehyd in 10 ccm Äthanol wird 2 Std am Rückfluß erhitzt und das Gemisch wird wie vorstehend aufgearbeitet, wobei 1.5 g X erhalten wird. Gelbe Schuppen vom Schmp. 52～56°C (aus Ligroin).

Gef.: N 17.59. Ber. für $C_{15}H_{13}H_3$: N 17.86.

Herrn Asaji Kondo für die Ausführung der Mikroanalysen und Dr. Tadashi Sato (Waseda Universität) für die Aufnahme der IR-Spektren danken wir bestens.

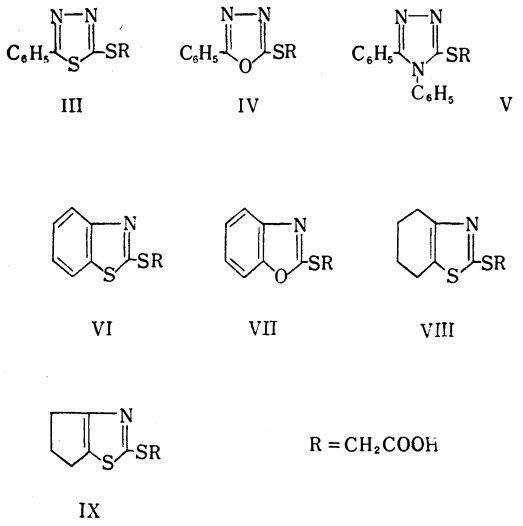
# *Studies on Meso-ionic Compounds. XII*[1]*. Reaction between Acetic Anhydride and Azoles having Carboxymethylmercapto-group**

By Mutsuko HASHIMOTO and Masaki OHTA

(Received April 14, 1960)

Duffin et al.[2,3] already reported that when a heterocyclic compound of the type I was subjected to the action of acetic anhydride, water was eliminated and a ring closure followed to give a meso-ionic compound of the type II.



I II

Y=Remainder of heterocyclic nucleus.

Fig. 1

The heterocyclic nuclei used by them were pyridine, quinoline, imidazole and benzimidazole.

In the present paper, this reaction is extended further to several kinds of azoles containing oxygen or sulfur (III–IX), and their behavior to acetic anhydride is investigated in detail.

III IV V

VI VII VIII

IX

R = $CH_2COOH$

Fig. 2

**Action of Acetic Anhydride on the Azoles.**— 5-Phenyl-1, 3, 4-thiadiazolyl-2-thioglycollic acid (III) is sparingly soluble in acetic anhydride at room temperature, while being heated on a

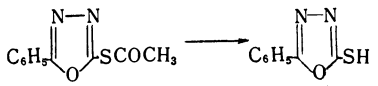
* Presented at the 12th Annual Meeting of the Chemical Society of Japan, Kyoto, April 2, 1959.

2) G. F. Duffin and J. D. Kendall, *J. Chem. Soc.*, **1951**, 734.

3) G. F. Duffin and J. D. Kendall. ibid., **1956**, 361.

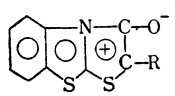


water bath, it dissolves in acetic anhydride and the solution quickly turns from yellow to dark red, and after 5 min. yellow crystals separate, which can be recrystallized unchanged from acetic anhydride. Elemental analysis indicates the compound to be an anhydro-compound of the structure X**, which is also supported by infrared analysis described below. When refluxed gently with 50% aqueous sulfuric acid or pyridine, the anhydro-compound X gives bis-5-phenyl-1, 3, 4-thiadiazolyl-2-thioacetone (XI).

X XI

Fig. 3

When 5-phenyl-1, 3, 4-oxadiazolyl-2-thioglycollic acid (IV) is boiled in acetic anhydride, no intense color develops, but 5-phenyl-1, 3, 4-oxadiazolyl-2-thioacetate (XII) is obtained. The product XII is hydrolyzed to 2-mercapto-5-phenyl-1, 3, 4-oxadiazole (XIII) with 10% aqueous sodium hydroxide.

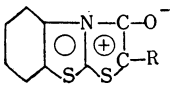


XII XIII

Fig. 4

Under similar conditions, 1, 5-diphenyl-1, 3, 4-triazolyl-2-thioglycollic acid (V) gives no pure reaction product.

When benzothiazolyl-2-thioglycollic acid (VI) is dissolved in acetic anhydride and the solution is warmed, it rapidly becomes dark red, and lustrous red-purple crystals separate. The compound is sparingly soluble in organic solvents and so difficult to burn that its elemental analysis corresponds to $C_{11}H_7O_2NS_2$ for the acetyl derivative of an anhydro-compound (XIVa ; R=$COCH_3$) with a difference of 1% or so in the carbon content. However, the same colored crystals are obtained by the action of propionic anhydride instead of acetic anhydride on the acid VI, and consequently the assignment of the structure XIVa for the colored compound would not be correct.



XIV

Fig. 5

On being treated with acetic anhydride, benzoxazolyl-2-thioglycollic acid (VII) gives only a yellow gummy material.

When cyclohexenothiazolyl-2-thioglycollic acid (VIII) is warmed in acetic anhydride, an orange color quickly develops which gradually changes to intense blue-violet, and black-violet crystals separate. The compound is as sparingly soluble in organic solvents and as difficult to burn as that obtained from the acid VI. Elemental analysis of the compound corresponds to $C_{11}H_{11}O_2NS_2$ with a difference of 1% or so in the carbon content. Although the formula $C_{11}H_{11}O_2NS_2$ suggests the structure of the acetyl derivateve of an anhydro-compound derived from the acid VIII (XVa ; R=$COCH_3$), this structure should be excluded by the fact that the same compound is also obtained on treating with propionic anhydride.

XV

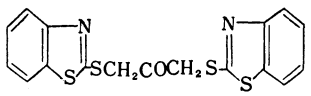
Fig. 6

The infrared spectra of the compounds $C_{11}H_7O_2NS_2$ and $C_{11}H_{11}O_2NS_2$ are similar to each other and show that there is great resemblance between structures of both compounds, and these structures are under investigation.

**Action of Acetic Anhydride and Pyridine or Triethylamine on the Azoles.**—When 5-phenyl-1, 3, 4-thiadiazolyl-2-thioglycollic acid (III) is added to a mixture of acetic anhydride and dry pyridine (volume ratio of 1 : 2), a yellow color immediately develops and the color changes to orange as the acid III dissolves. After several minutes yellow crystals separate, which are identical with the anhydro-compound X described above.

Under similar conditions, 5-phenyl-1, 3, 4-oxadiazolyl-2-thioglycollic acid (IV) affords 5-phenyl-1, 3, 4-oxadiazolyl-2-thioacetate (XII) which is obtained from IV by treating with acetic anhydride only, while 1, 5-diphenyl-1, 3, 4-triazolyl-2-thioglycollic acid (V) is recovered unchanged.

When benzothiazolyl-2-thioglycollic acid (VI) is added to acetic anhydride and dry pyridine (volume ratio of 1 : 2), the mixture immediately turns yellow as the acid VI dissolves, and the color finally becomes dark green. After a few minutes blue-green crystals separate, from which yellow needles are obtained by extraction with benzene. Elemental analysis shows



** The formulation adopted is that put forward by Baker and Ollis. W. Baker and W. D. Ollis, *Quart. Rev.*, **11**, 15 (1957); W. Baker, *Proc. Chem. Soc.*, **1959**, 75.

the compound to be an anhydro-compound of the structure (XIVb; R=H), which is also supported by infrared analysis described below.

Besides the anhydro-compound XIVb, the lustrous red-purple crystals are obtained from the benzene-insoluble portion in a considerable yield.

When the acid VI is dissolved in a mixture of acetic anhydride and triethylamine (volume ratio of 1 : 2), a yellow color develops and yellowish-brown crystals separate, which are recrystallized from benzene to yield the anhydro-compound XIVb.

On refluxing gently with pyridine the anhydro-compound XIVb affords bisbenzothiazolyl-2-thioacetone (XVI), which is identical with a specimen prepared from sym-dichloroacetone and 2-mercaptobenzothiazole. With hot 50% aqueous sulfuric acid the compound XIVb affords the compound XVI and the parent acid VI.

XVI

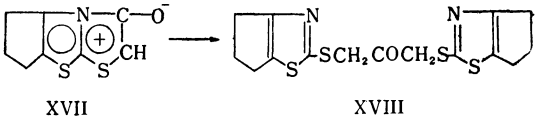


Fig. 7

When benzoxazolyl-2-thioglycollic acid (VII) is treated with acetic anhydride in pyridine or triethylamine, no anhydro-compound can be obtained but the starting material is recovered.

When cyclohexenothiazolyl-2-thioglycollic acid (VIII) is dissolved in a mixture of acetic anhydride and dry pyridine (volume ratio of 1 : 2), a deep yellow color quickly develops which gradually changes to blue-green, and light blue crystals separate. Extraction of the crystals with benzene gives benzene-soluble light green needles and the benzene-insoluble black-violet crystals. The former compound is also obtained exclusively on treating the acid VIII with acetic anhydride and triethylamine. Elemental analysis of the compound indicates that it is not an anhydro-compound of the structure (XVb; R=H), but a compound of the formula $C_{10}H_9ONS_2$.

With hot 50% aqueous sulfuric acid the compound $C_{10}H_9ONS_2$ is hydrated to the parent acid VIII, and with boiling pyridine it affords a compound of the formula $C_8H_{11}ONS_2$. The structures of both compounds $C_{10}H_9ONS_2$ and $C_8H_{11}ONS_2$ await further investigation.

When cyclopentenothiazolyl-2-thioglycollic acid (IX) is dissolved in a mixture of acetic anhydride and triethylamine (volume ratio of 1 : 2), deep yellow crystals immediately separate, which are shown to be an anhydro-compound of the structure XVII by elemental and infrared analyses. The compound XVII is hydrated to the parent acid IX with hot 50% aqueous sulfuric acid, and with boiling pyridine it affords monohydrate of biscyclopentenothiazolyl-2-thioacetone (XVIII).

XVII XVIII

Fig. 8

It seems very interesting that the behavior of the acid VIII to acetic anhydride and triethylamine differs greatly from that of the acid IX; nevertheless, the structures of two acids nearly the same. However, the question what factor of the acids can give rise to such a significant difference remains obscure.

The results presented in this paper speak for themselves. Several points deserve further comment, however.

In the first place, it is clear that the azoles free from sulfur in their nuclei; IV, V and VII give no intensely colored compounds like the compounds $C_{11}H_{11}O_2NS_2$ and $C_{11}H_9O_2NS_2$ on treating with acetic anhydride. Duffin et al., on the other hand, did not report that such a colored compound was obtained. Consequently, it is considered that the reaction center in formation of the colored compounds might be at the ring-sulfur of heterocycle.

It is also clear that the azoles containing sulfur in their nuclei; III, VI and IX can be subjected to two different types of reactions to give the colored compound and the anhydro-compound like X, XIVb and XVII, respectively.

The mechanism of formation of the anhydro-compounds is obscure, but in this case the reaction center seems to be at the ring-nitrogen of heterocycle.

**Infrared Analyses of the Anhydro-compounds X, XIVb and XVII.**—The infrared spectra of the anhydro-compounds, their parent acids and decomposition products were taken.

When the spectra of the anhydro-compounds are compared with those of their parent acids, three remarkable changes can be observed. Firstly, the disappearance of the band at 1720～1708 $cm^{-1}$ due to the C=O vibration of carboxylic group and the appearance of a band at 1645 $cm^{-1}$, which is probably due to the amide I band of tertiary amide. Secondly, the appearance of a new strong band near 1600 $cm^{-1}$, which disappears again in the spectrum of the decomposition product. Consequently, this band seems to be produced by formation of a meso-ionic ring, but the assignment of the band is still unknown. Lastly, the red

shift of 35 $cm^{-1}$ or so of the band at 1180± 10 $cm^{-1}$.

The three remarkable changes mentioned above can be also observed in the spectra of the anhydro-compound derived from (2-pyridylthio)acetic acid, whose structure has been confirmed synthetically.[2]

## Experimental

**5-Phenyl-1, 3, 4-thiadiazolyl-2-thioglycollic Acid (III).**—This acid was prepared by Sato's method[4].

**Anhydro-compound X from III.** — (a) A solution of the acid III (5.0 g.) in acetic anhydride (100 ml.) was heated on a boiling water bath for 5 min., quickly turning from yellow to red. Yellow crystals which separated were filtered off and recrystallized from acetic anhydride to give the anhydro-compound as small yellow needles (1.9 g.), m. p. 231°C (decomp.).

Found: C, 51.54; H, 2.80; N, 11.71. Calcd. for $C_{10}H_6ON_2S_2$: C, 51·29; H, 2.58; N, 11.96%.

(b) III (1.0 g.) was dissolved with stirring at room temperature in a mixture of acetic anhydride (3 ml.) and dry pyridine (6 ml.). A yellow color immediately developed and the color changed to orange. After several minutes yellow crystals separated, which were filtered off after 0.5 hr., washed with water, and dried to give deep yellow crystals (0.6 g.), m. p. 229~230°C (decomp.). Recrystallization from acetic anhydride gave small yellow needles, m. p. 231°C (decomp.).

Found: N, 11.70. Calcd. for $C_{10}H_6ON_2S_2$: N, 11.96%.

**Action of Aqueous Sulfuric Acid on the Anhydro-compound X.**—X (1.0 g.) was refluxed gently with 50% aqueous sulfuric acid (10 ml.) for 10 min. The cooled solution was diluted with water (50 ml.) to give a crystalline precipitate which was filtered off and recrystallized from ethanol, affording small colorless needles of bis-5-phenyl-1, 3, 4-thiadiazolyl-2-thioacetone (XI) (0.69 g.), m. p. 148°C.

Found: C, 51.36; H, 3.42; N, 12.75; S, 29.06; mol. wt. (Rast), 455. Calcd. for $C_{19}H_{14}ON_4S_4$: C, 51.58; H, 3.17; N, 12.67; S, 28.96%; mol. wt., 442.

**Action of Pyridine on X.**—X (0.3 g.) was refluxed gently with pyridine (10 ml.) for 5 min. After cooling, the solution was diluted with water (50 ml.) to give a crystalline precipitate (0.24 g.), m. p. 146 ~147°C. Recrystallization from ethanol yielded small colorless needles, m. p. 148°C, undepressed by admixture with XI.

**5-Phenyl-1, 3, 4-oxadiazolyl-2-thioglycollic Acid (IV).**—A solution of chloroacetic acid (2.0 g.) and sodium carbonate (1.1 g.) in water (20 ml.) was added to a solution of crude 2-mercapto-5-phenyl-1, 3, 4-oxadiazole (3.0 g.) and potassium hydroxide (1.0 g.) in water (30 ml.). The solution was kept to stand at room temperature overnight, neutralized with dilute hydrochloric acid. The resulting precipitate was filtered off, dissolved in aqueous sodium bicarbonate to remove insoluble impurities and neutralized with dilute hydrochloric acid. After filtration and drying 5-phenyl-1, 3, 4-oxadiazolyl-2-thioglycollic acid was obtained (5.0 g.), m. p. 157~ 162°C. Recrystallization from hot water gave white needles, m. p. 168~169°C.

Found: N, 12.15. Calcd. for $C_{10}H_8O_3N_2S$: N, 12.86%.

**Action of Acetic Anhydride on IV.** — The acid IV (1.0 g.) and acetic anhydride (10 ml.) were boiled under reflux for 0.5 hr. The anhydride was evaporated under reduced pressure and the residue was recrystallized from ethanol to give 5-phenyl-1, 3, 4-oxadiazolyl-2-thioacetate (XII) as colorless needles (0.22 g.), m. p. 152.5~153°C.

Found: C, 54.33; H, 3.63; N, 12.74. Calcd. for $C_{10}H_8O_2N_2S$: C, 54.54; H, 3.64; N, 12.73%.

XII was dissolved in 10% aqueous sodium hydroxide and then neutralized with 10% aqueous sulfuric acid to give colorless needles, m. p. 217°C, undepressed by admixture with authentic 2-mercapto-5-phenyl-1, 3, 4-oxadiazole.

**1, 5-Diphenyl-1, 3, 4-triazolyl-2-thioglycollic Acid (V).**—This acid was prepared by Ueda's method[5].

**Action of Acetic Anhydride on V.**—The acid V (0.5 g.) and acetic anhydride (10 ml.) were boiled under reflux for 0.5 hr., affording a yellow solution. On addition of water (100 ml.) the solution yielded a pale brown gummy material from which no pure compound could be isolated.

**Benzothiazolyl-2-thioglycollic Acid (VI).**—This acid was prepared by Ohta's method[6].

**Action of Acetic Anhydride on VI.**—The acid VI (1.0 g.) was added to acetic anhydride (20 ml.) and warmed on a water bath. The solution rapidly became dark red and at the same time crystals separated, which were filtered off and washed with hot ethanol, giving lustrous red-purple crystals (0.57 g.), m. p. 297°C.

The anhydride filtrate was diluted with water (100 ml.) and washed with hot ethanol to give lustrous red-purple crystals (0.35 g.), m. p. 297°C. Total yield, 0.92 g.

Found: C, 51.80; H, 3.00; N, 5.85. Calcd. for $C_{11}H_7O_2NS_2$: C, 53.01; H, 2.81; N, 5.62%.

The above experiment was repeated but with propionic anhydride instead of acetic anhydride, the same product being obtained.

**Benzoxazolyl-2-thioglycollic Acid (VII).**—A solution of chloroacetic acid (1.9 g.) and sodium carbonate (1.06 g.) in water (20 ml.) was added to a solution of 2-mercaptobenzoxazole (3.0 g.) and sodium hydroxide (0.8 g.) in water (20 ml.). The solution was warmed on a water bath for 0.5 hr. and kept standing at room temperature overnight. After neutralization with dilute hydrochloric acid, the resulting precipitate was filtered off, washed with water and recrystallized from dilute ethanol to give colorless plates of VII (3.85 g.), m. p. 160~ 161°C.

Found: N, 6.27. Calcd. for $C_9H_7O_3NS \cdot H_2O$; N, 6.17%.

**Action of Acetic Anhydride on VII.**—The acid VII (1.0 g.) was refluxed gently with acetic anhydride (10 ml.) for 0.5 hr., affording a deep yellow

solution. The anhydride was evaporated under reduced pressure, the residue of violet gum extracted with ether and the extract evaporated to dryness to give yellowish gummy material which could not be purified.

**Cyclohexenothiazolyl-2-thioglycollic Acid (VIII).**—This acid was prepared by the same process as used for benzothiazolyl-2-thioglycollic acid (VI)[6]. Colorless lancets, m. p. 124~125°C. Yield, 80.4%.

**Action of Acetic Anhydride on VIII.**—The acid VIII (1.0 g.) was added to acetic anhydride (2 ml.) and warmed on a water bath. An orange color quickly developed which gradually changed to intense blue-violet, and black-violet crystals separated. The crystals were filtered off and washed with hot ethanol to give black-violet crystals (0.7 g.), m. p. 254.5~255°C (decomp.).

The anhydride filtrate was diluted with water (200 ml.), and the resulting precipitate was filtered off and washed with hot ethanol to give black-violet crystals (0.02 g.), m. p. 254.5~255°C (decomp.). Total yield, 0.76 g.

Found: C, 50.84; H, 4.35; N, 5.72. Calcd. for $C_{11}H_{11}O_2NS_2$: C, 52.17; H, 4.35; N, 5.53%.

The above experiment was repeated but with propionic anhydride instead of acetic anhydride, the same product being obtained.

**Action of Acetic Anhydride and Pyridine on IV.**—The acid IV (1.0 g.) was refluxed in a mixture of acetic anhydride (5 ml.) and dry pyridine (5 ml.) for 0.5 hr. and the solvent was removed in vacuo to give a black oil, which was solidified by addition of a small amount of ethanol. Recrystallization from ethanol gave XII as colorless needles (0.12 g.), m. p. 149~150°C, undepressed by admixture with authentic sample.

**Action of Acetic Anhydride and Pyridine on V.**—The acid V (0.5 g.) was refluxed in a mixture of acetic anhydride (3 ml.) and dry pyridine (6 ml.) for 5 min., the solvent removed in vacuo and the residue recrystallized from ethanol to give colorless needles, m. p. 238°C, undepressed by admixture with the acid V.

Found: N, 13.65. Calcd. for $C_{16}H_{13}O_2N_3S$: N, 13.50%.

**Anhydro-compound XIVb from VI.**—(a) The acid VI (1.0 g.) was dissolved with stirring at room temperature in a mixture of acetic anhydride (3 ml.) and dry pyridine (6 ml.). The solution immediately turned yellow and the color finally became dark green. After a few minutes crystals separated, which were filtered off, washed thoroughly with water, dried and then extracted with hot benzene. The extract was evaporated to dryness giving yellow crystals (0.3 g.), m. p. 209~212°C (decomp.). Recrystallization from benzene yielded the anhydro-compound as bright yellow leaflets, m. p. 215~216°C (decomp.).

Found: C, 51.94; H, 2.58; N, 6.89. Calcd. for $C_9H_5ONS_2$: C, 52.18; H, 2.43; N, 6.76%.

From the benzene-insoluble portion, the lustrous red-purple crystals were obtained (0.33 g.).

(b) VI (1.0 g.) was dissolved with stirring at room temperature in a mixture of acetic anhydride (3 ml.) and triethylamine (6 ml.), a yellow color quickly developing. After a few minutes yellowish brown crystals separated, which were filtered off, washed thoroughly with water, dried and extracted with hot benzene. The extract was evaporated to dryness to give yellow crystals (0.47 g.), m. p. 210~212°C (decomp.). Recrystallization from benzene yielded the anhydro-compound as bright yellow leaflets, m. p. 216~216.5°C (decomp.).

Found: N, 6.55. Calcd. for $C_9H_5ONS_2$: N, 6.76%.

**Action of Pyridine on the Anhydro-compound XIVb.**—XIVb (0.3 g.) was refluxed gently with pyridine (10 ml.) for 5 min. After cooling, the solution was diluted which water (50 ml.) to give a crystalline precipitate with was filtered off and recrystallized from ethanol, affording bisbenzothiazolyl-2-thioacetone (XVI) as colorless needles (0.18 g.), m. p. 127°C, undepressed by admixture with authentic sample.

Found: N, 7.36. Calcd. for $C_{17}H_{12}ON_2S_4$: N, 7.21%.

**Bisbenzothiazolyl-2-thioacetone.**—To a solution of 2-mercaptobenzothiazole (5.5 g.) in absolute ethanol (50 ml.) containing metallic sodium (0.8 g.) was added *sym*-dichloroacetone (2.0 g.). After 5 min. crystals separated at a time. The crystals were filtered off, washed with water and recrystallized twice from ethanol to give colorless needles (8.0 g.), m. p. 127°C.

Found: C, 52.83; H, 3.37; N, 7.18. Calcd. for $C_{17}H_{12}ON_2S_4$: C, 52.56; H, 3.09; N, 7.21%.

**Action of Aqueous Sulfuric Acid on XIVb.**—XIVb (0.3 g.) was refluxed gently with 50% aqueous sulfuric acid (10 ml.) for 10 min. and the cooled solution was diluted with water (50 ml.) to give a crystalline precipitate which was filtered off and recrystallized from ethanol, affording colorless needles (0.05 g.), m. p. 124°C, undepressed by admixture with authentic sample of XVI. Addition of water to the mother-liquor precipitated pale yellow prisms (0.06 g.), m. p. 157~158°C, undepressed by admixture with the acid VI.

**Action of Acetic Anhydride and Pyridine on VII.**—The acid VII (1.0 g.), acetic anhydride (1 ml.) and dry pyridine (3 ml.) were heated on a boiling water bath for 0.5 hr. and after cooling, the solution was concentrated under reduced pressure to give colorless leaflets (0.9 g.), m. p. 160~162°C, undepressed by admixture with the acid VII.

**Action of Acetic Anhydride and Triethylamine on VII.**—The acid VII (1.0 g.) was dissolved in a mixture of acetic anhydride (1 ml.) and triethylamine (3 ml.) and the solution kept to stand at room temperature for 3 hr. The solution was concentrated under reduced pressure to give an orange oily material, which rapidly solidified by addition of water. Colorless leaflets (0.91 g.), m. p. 163°C, undepressed by admixture with the acid VII.

**Action of Acetic Anhydride and Pyridine on VIII.**—The acid VIII (1.0 g.) was dissolved with stirring at room temperature in a mixture of acetic anhydride (3 ml.) and dry pyridine (6 ml.). A deep yellow color quickly developed which gradually changed to blue-green and light blue crystals separated. After 0.5 hr., the crystals were filtered off, washed thoroughly with water, dried and then

extracted with hot benzene and the extract was evaporated to dryness to give light green needles (0.52 g.), m. p. 198~199°C (decomp.). Recrystallization from benzene gave m. p. 198~199°C (decomp.).

Found: C, 53.51; H, 4.60; N, 6.08. Calcd. for $C_{10}H_9ONS_2$: C, 53.81; H, 4.06; N, 6.28%.

From the benzene-insoluble portion, the black-violet crystals were obtained (0.17 g.).

**Action of Acetic Anhydride and Triethylamine on VIII.**—The acid VIII (1.0 g.) was dissolved with stirring at room temperature in a mixture of acetic anhydride (3 ml.) and triethylamine (6 ml.). Light brown crystals rapidly separated, which were filtered off, washed thoroughly with water, dried and extracted with hot benzene. The extract was evaporated to dryness to give light yellow crystals (0.68 g.), m. p. 197~199°C (decomp.). Recrystallization from benzene yielded light yellow needles, m. p. 198°C (decomp.).

Found: N, 6.26. Calcd. for $C_{10}H_9ONS_2$: N, 6.28%.

**Action of Aqueous Sulfuric Acid on the Compound $C_{10}H_9ONS_2$.**—The compound (0.5 g.) was refluxed gently with 50% aqueous sulfuric acid (12 ml.) for 0.5 hr. The cooled solution was diluted with water (50 ml.) and extracted with ether. The ether extract was evaporated and the residue recrystallized from ethanol to give colorless prisms, m. p. 125~126°C, undepressed with the acid VIII.

Found: N, 5.94. Calcd. for $C_9H_{11}O_2NS_2$: N, 6.11%.

**Action of Pyridine on the Compound $C_{10}H_9ONS_2$.**—The compound (1.0 g.) was refluxed gently with pyridine (20 ml.) for 20 min. After cooling, the solution was diluted with water (150 ml.) and colorless needles which separated were filtered off and dried. M. p. 94.5°C, 1.0 g. Recrystallization from dilute pyridine gave colorless silky needles, m p. 98.5~99.5°C.

Found: C, 47.60; H, 5.35; N, 6.86; S, 31.1. Calcd. for $C_8H_{11}ONS_2$: C, 47.76; H, 5.47; N, 6.97; S, 31.84%.

**Cyclopentenothiazolyl-2-thioglycollic Acid (IX).**—This acid was prepared by the same process as used for benzothiazolyl-2-thioglycollic acid (VI)[6]. Colorless needles, m. p. 126°C, yield, 45.6%.

**Anhydro-compound XVII from IX.**—The acid IX (1.0 g.) was dissolved with stirring at room temperature in a mixture of acetic anhydride (3 ml.) and triethylamine (6 ml.). After one minute crystals separated, which were filtered off, washed thoroughly with water and dried. M. p. 198~201°C, 0.67 g. Recrystallization from benzene gave the anhydro-compound as deep yellow crystals, m. p. 213.5~214°C (decomp.).

Found: C, 48.65; H, 3.97; N, 7.20. Calcd. for $C_8H_7ONS_2$: C, 48.74; H, 3.58; N, 7.11%.

**Action of Aqueous Sulfuric Acid on the Anhydro-compound XVII.**—XVII (0.5 g.) was dissolved in 50% aqueous sulfurid acid (12 ml.) and the resultant yellow solution refluxed gently for 10 min., the yellow color disappearing. The solution was diluted with water (150 ml.), neutralized with sodium carbonate, extracted with ether and the extract evaporated to give colorless needles (0.38 g.), m. p. 117°C. Recrystallization from dilute ethanol gave colorless needles, m. p. 124~126°C, undepressed by admixture with the acid IX.

Found: N, 6.41. Calcd. for $C_9H_9O_2NS_2$: N, 6.51%.

**Action of Pyridine on XVII.**—XVII (0.3 g.) was refluxed gently with pyridine (10 ml.) for 5 min. The solution was diluted with water (50 ml.) and a crystalline precipitate filtered off, washed with water and dried. M. p. 81.5°C, 0.27 g. Recrystallization from dilute ethanol afforded colorless silky needles, m. p. 81~82°C.

Found: C, 46.39; H, 4.83; N, 7.53. Calcd. for $C_{15}H_{16}ON_2S_4 \cdot H_2O$: C, 46.63; H, 4.66; N, 7.25%.

The authors are indebted to Mr. Asaji Kondo for performing the microanalyses and to Dr. Tadashi Sato for assistance in the infrared determinations.

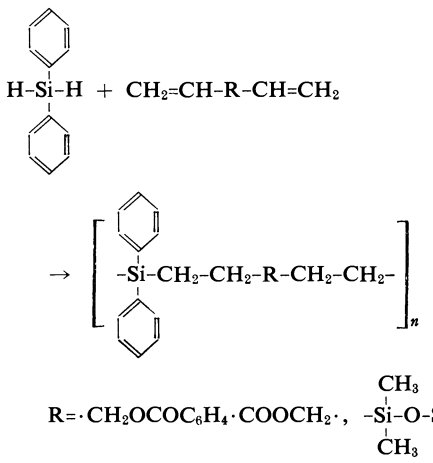
# *Polyaddition Reaction of Diphenylsilane to Difunctional Unsaturated Compounds. II*

By Kuniharu KOJIMA

(Received March 22, 1960)



Several literatures have been published on the addition reaction of silicon hydrides to a number of olefines using peroxide, ultraviolet light, $\gamma$-rays or platinum catalysts.

In 1947, L. H Sommer reported that *n*-octyltrichlorosilane was prepared by the addition reaction of 1-octene with trichlorosilane in the presence of a small amount of diacetyl peroxide catalysts at 50~63°C[1,2]. This addition reaction was also carried out using $\gamma$-rays from a 30 kilocurie $Co^{60}$ source at room temperature in an almost quantitative yield[3].

The addition reaction of trichlorosilane to styrene was first carried out by C. A. Burkhard in the presence of peroxide catalysts, resulting in the formation of only non-volatile telomeric products[4]. W. S. Wagner and coworkers succeeded in the preparation of $\beta$-phenylethyltrichlorosilane by the above mentioned addition reaction using platinized charcoal as the catalyst at 200°C[5]. S. Nozakura reported the formation of $\alpha$- and $\beta$-trichlorosilylethylbenzene by the same reaction using tetrapyridine nickel chloride as the catalyst at 160°C[6]. The platinum catalyzed addition reaction of methyldichlorosilane with methyl methacrylate was carried out by L. H. Sommer and coworkers in the preparation of $\alpha$-methyl-$\beta$-methyldichlorosilyl propionate[7].

The addition reaction of methyldichlorosilane with vinyl acetate was studied by J. L. Speier and coworkers in the preparation of 2-methyldichlorosilylethyl acetate[8]. L. Goodman reported similar reactions of various silanes (phenylsilane, methyldiethoxysilane, trichlorosilane or methyldichlorosilane to allyl acetate[9]. J. W. Curry and coworkers have recently described the polymerization of certain silanes having an unsaturated organic group and a hydrogen on the same silicon atom[10,11].

In the previous paper, we have reported the result of the polyaddition reaction of diphenylsilane with diallyl phthalate or methyldisiloxane in the presence of a small amount of platinum black[12].

By these reactions carried out in sealed glass tubes, new polymers containing silicon were obtained in good yield. As a continuation of the experiment, the present paper deals with a new synthetic method of polymers which can be generally applied to the polyaddition reaction of diphenylsilane with various difunctional unsaturated compound (diallyl adipate, divinyl adipate, tetramethylene dimethacrylate, divinylbenzene and hexadiene).

Our first work was to examine the polyaddition reaction of diphenylsilane with diallyl phthalate using platinum black as the catalyst. As the extension of this work, the effect of various catalysts (i. e. platinum black, chloroplatinic acid, benzoyl peroxide, *tert*-butyl hydroperoxide, and azobisisobyturonitrile) has been studied. The results are shown in Table I.

Platinum catalysts were more effective than other catalysts. The effect of the irradiation of $\gamma$-ray or ultraviolet light in this reaction was hardly recognized at room temperature.

Similarly, by the polyaddition reaction of diphenylsilane with diallyl adipate was also prepared a linear polyaddition product in a

TABLE I. POLYADDITION OF DIPHENYLSILANE WITH DIALLYL PHTHALATE

| Catalyst (mol.) | React. time (hr.) | Temp. (°C) | Yield (%) | Mol. wt. |
|---|---|---|---|---|
| Pt-black, $2 \cdot 10^{-4}$ | 50 | 110~20 | 76 | 2390 |
| Chloroplatinic acid, $2 \cdot 10^{-6}$ | 〃 | 〃 | 73 | 2060 |
| Benzoyl peroxide, $2 \cdot 10^{-4}$ | 〃 | 〃 | 60 | 955 |
| *tert*-Butyl hydroperoxide, $2 \cdot 10^{-4}$ | 〃 | 〃 | 67 | 765 |
| Azobisisobutyronitrile, $2 \cdot 10^{-4}$ | 〃 | 〃 | 69 | 775 |

In these experiments, 0.02 mol. of diphenylsilane and 0.02 mol. of diallyl phthalate were used.

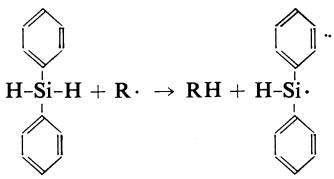
76% yield. The molecular weight of this polyadduct was 1400.

In the polyaddition reaction of diphenylsilane with divinyl adipate using platinum black as catalyst, however, the linear polyaddition product was obtained in 34% yield and the other polyadduct was a highly branched (or a cross-linked) polymer. The molecular weight of the linear polymer was 1660. The combination ratio of divinyl adipate and diphenylsilane of the branched polymer was 4 : 1.

The reaction of diphenylsilane with tetramethylene dimethacrylate did not produce a linear high polymer, but gave a low molecular weight adduct (mol. wt. 460) in 37% yield and a branched polymer (combination ratio, tetramethylene dimethacrylate 2 moles : diphenylsilane 1 mole).

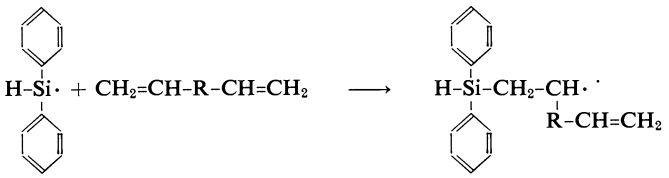
When diphenylsilane and divinylbenzene were heated at 120°C in the presence of Pt-black, the highly branched polymer and low molecular weight adducts were obtained. The molecular weight of this low-adduct was 440. The combination ratio of branched polymer was diphenylsilane 1 mol. : divinylbenzene 18 mol.

In the addition reaction of diphenylsilane with hexadiene using platinum black catalyst, the low molecular weight adduct (mol. wt. 685) was only obtained in a 43% yield.



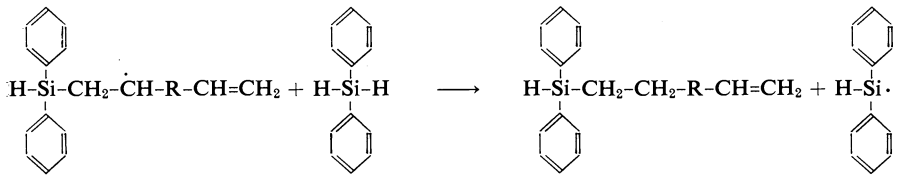
The mechanism of the addition reaction of silicon hydride to olefinic compounds catalyzed by platinum is not clear yet. But it has been asserted, that the addition reaction of silicon hydride to alkene using peroxide catalyst is a free radical chain reaction[1]. The proposed mechanism for the reaction is

$$R\cdot + HSi\equiv \rightarrow RH + \equiv Si\cdot$$

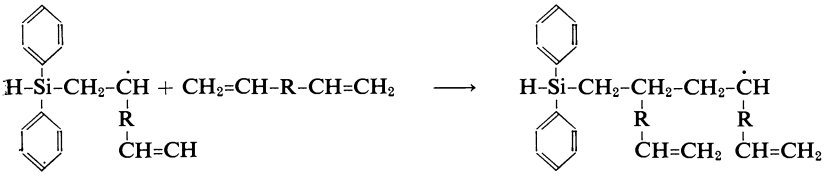


$$RCH{=}CH_2 + \equiv Si\cdot \rightarrow R\dot{C}H{-}CH_2Si\equiv$$

$$R\dot{C}HCH_2Si\equiv + HSi\equiv \rightarrow RCH_2CH_2Si\equiv + \equiv Si\cdot$$



In this paper, the reaction of diphenylsilane with difunctional unsaturated compound to form the linear high molecular weight polymer was predominant.



(1)

(2)

(3)

(4)

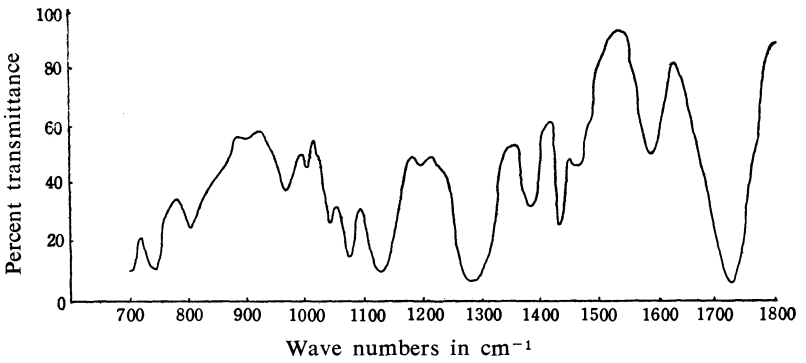


Fig. 1. Infrared spectrum of adduct of diphenylsilane with diallyl phthalate.

But in some cases, it was found that the second reaction shown in Eq. 4 also took place.

This reaction is responsible for the formation of branched polymer and a strong competitor for the normal addition reaction 3. In case of diallyl phthalate, diallyl adipate and hexadiene, only the reaction 3 can proceed. Theerfore it gave linear products only. But, in the case of divinyl adipate, tetramethylene dimethacrylate and divinylbenzene, branched polymers were obtained together with linear polymers.

The addition reaction of silicon hydrides to some unsaturated compounds has been shown to yield two isomers by other investigators[9,13,14]. The addition compound of trichlorosilane to acrylonitrile could be either $NCCH_2CH_2SiCl_3$ ($\alpha$-adduct) or $NCCH(CH_3)SiCl_3$ ($\beta$-adduct).

But, in the case of platinum catalyzed reaction, the addition reactions of silicon hydrides to vinyl acetate and to methyl methacrylate have been shown to yield $\beta$-adducts, and the addition to allyl acetate has been shown to yield $\gamma$-adducts.

By analogy, the addition compounds of diphenylsilane with each of divinyl adipate, and tetramethylene dimethacylate are presumed to be mainly $\beta$-adducts, and the adduct of diallyl phthalate are $\gamma$-adduct. But, it was shown, that the infrared absorption spectra of the addition compounds obtained in this work were identical in all important respects with that of the mixture of them.

In the isolation of the polymer, it was found, thats ome volatile by-products are also obtained from the reaction mixture. In the case of tetramethylene dimethacrylate, the volatile product was obtained in considerable quantities, and the yielded gas was identified as propylene and propane by gas-chromatography. But the mechanism of the production of propylene and propane is indistinct.

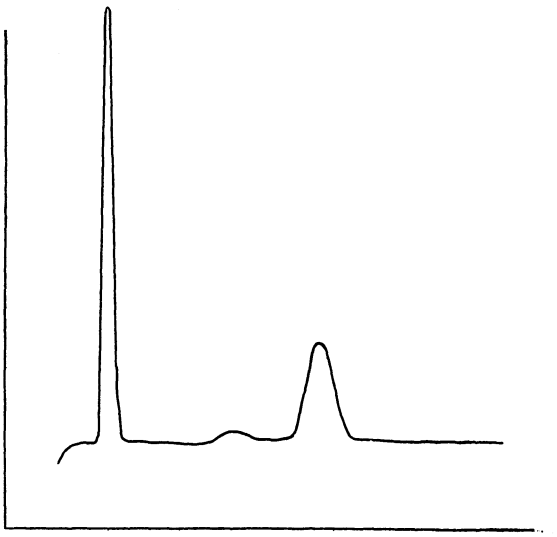

Fig. 2. Gas-chromatograph of the reaction by-products of diphenylsilane with tetramethylene dimethacrylate. Carrier gas, hydrogen; column dimethyl formamid-active charcoal.

## Experimental

**Materials.**—Diallyl adipate[15] and divinyl adipate[16] were prepared by the published methods. Tetramethylene dimethacrylate was prepared by the ester interchange reaction of methyl methacrylate with 1,4-butanediol in the presence of sulfuric acid and hydroquinone[17]. Diallyl phthalate and divinylbenzene were commercial products. Hexadiene was prepared by the reaction of allyl bromide with metallic magnesium in ether[18]. Diphenylsilane was prepared from diphenyldichlorosilane by lithium

aluminum hydride by ordinary method[19]. Diphenyldichlorosilane was supplied by Shin-etu Chem. Co. and redistilled before being used.

**Polyaddition of Diphenylsilane with Diallyl Phthalate.**—*Method 1—Pt Black Initiation.*—Diallyl phthalate (4.92 g., 0.02 mol.), diphenylsilane (3.68 g., 0.02 mol.) and platinum black (0.03 g.) as catalyst were placed in a glass tube and the tube was sealed in nitrogen stream, and then heated at 110~120°C in an air oven for 50 hr. The reaction product was dissolved in 100 ml. benzene and reprecipitated by 200 ml. methanol. The precipitated material was separated and dried in a vacuum desiccator at 50°C for 7 days. Yield, 76%.

Found: Si, 5.34. Calcd. for $C_{26}H_{26}O_4Si$: Si, 5.83% mol. wt., 2390.

*Method 2—Chloroplatinic Acid Initiation.*—Under similar condition as described for Pt black initiation, chloroplatinic acid ($2\cdot10^{-5}$ mol.) in methanol solution, diphenylsilane (3.65 g.) and dially phthalate (4.92 g.) were heated and the product was reprecipitated. The average molecular weight of this polymer was found to be 2060. Yield 73%.

*Method 3—Benzoyl Peroxide Initiation.*—The mixture of diphenylsilane (3.68 g.), diallyl phthalate (4.92 g.) and benzoyl peroxide (0.005 g.) were heated in an air oven for 50 hr. at 110~20°C. The reaction gave a linear polymer of mol. wt. 954. Yield 60%.

*Method 4—tert-Butyl Hydroperoxide Initiation.*—Under similar condition as described above, 0.002 g. of *tert*-butyl hydroperoxide was used as the catalyst. The reaction gave a linear polymer of mol. wt. 765. Yield 67%.

*Method 5—Azobisisobutyronitrile Initiation.*—Under similar condition as employed in the preceding experiment, diphenylsilane (3.68 g.), diallyl phthalate (4.92 g.), and azobisisobutyronitril (0.003 g.) were traced to produce 5.81 g. of the linear polymer with 69% of theoretical yield. mol. wt. 774.

*Method 6—*$^{60}$Co *Initiation.*—Diphenylsilane (3.68 g.) and diallyl phthalate (4.92 g.) were charged in a glass tube. The tube was sealed in dry nitrogen atmosphere, and then exposed to $^{60}$Co irradiation at room temperature for 150 hr. at a rate of $2.1\cdot10^{-5}$ r.e.p./hr. The molecular weight of this product was 600. Yield 9.8%.

*Method 7—Ultraviolet Light Initiation.*—The same mixture employed in the preceding experiment was exposed to ultraviolet light irradiation at room temperature for 150 hr. at 10170 c. d. by merucric lamp but the unreacted diphenylsilane and diallyl phthalate were recovered.

**Polyaddition of Diphenylsilane with Diallyl Adipate.**—A mixture of diphenylsilane (3.68 g.) and diallyl adipate (4.52 g., 0.02 mole) with 0.03 g. platinum black were heated for 50 hrs. at 120°C in a sealed glass tube. The product was dissolved in benzene and reprecipitated by methanol. The average molecular weight of this polymer was found to be 1400. Yield 68%.

Found: Si, 6.69. Calcd for $C_{24}H_{28}OSi$: Si, 6.84%.

**Polyaddition of Diphenylsilane with Divinyl Adipate.**—Divinyl adipate (3.96 g., 0.02 mole), diphenylsilane (3.68 g., 0.02 mole) and 0.03 g. platinum black as the catalyst were heated at 120°C for 50 hr. in a sealed glass tube. The product was dissolved in benzene and reprecipitated in methanol. The molecular weight of benzene-soluble polymer was 1660.

Found: Si, 7.12. Calcd. for $C_{22}H_{24}O_4Si$: Si, 7.38%. Yield 39%.

The benzene-insoluble polymer was found to be an adduct of diphenylsilane and divinyl adipate at the mole ratio of 1 : 4.

Found: Si, 3.32. Calcd. for 1 : 4 adduct: Si, 3.59%.

**Polyaddition of Diphenylsilane with Tetramethylene Dimethacrylate.**—Tetramethylene dimethacrylate (4.52 g., 0.02 mol.), diphenylsilane (3.68 g., 0.02 mol.) and 0.03 g. platinum black were heated for 50 hr. at 120°C in a sealed glass tube. The product was dissolved in benzene and reprecipitated by methanol. The low molecular weight addition product (benzene-soluble part) was obtained in a 37% yield. The average molecular weight of this polymer was found to be 460. A branched (or cross-linked) polymer was also formed and it has been cleared by Si analysis, that it was the addition product of diphenylsilane and tetramethylene dimethacrylate at the mole ratio of 1 : 2.

Found: Si, 4.18, Calcd. for 1 : 2 adduct: Si, 4.18%.

**Polyaddition of Diphenylsilane with Divinylbenzene.**—Divinylbenzene (2.60 g., 0.02 mol.), diphenylsilane (3.68 g., 0.02 mol.) and platinum black (0.03 g.) were charged in a glass tube. The tube was sealed under the atmosphere of nitrogen and heated in an air oven for 50 hr. at 125~130°C. The product was dissolved in benzene. The average molecular weight of the soluble product was 440. Yield 65%. The insoluble product was an addition product of diphenylsilane 1 mol. and divinylbenzene 18 mol.

Found: Si, 1.11. Calcd. for 1 : 18 adduct: Si, 1.10%.

**Polyaddition of Diphenylsilane with Hexadiene.** Hexadiene (1.64 g., 0.02 mol.), diphenylsilane (3.68 g. 0.02 mol.) and platinum black (0.03 g.) were charged in a glass tube, and the tube was sealed under the nitrogen atmosphere and heated in an air oven for 50 hr. at 110~120°C. Only the low molecular weight product (mol. wt. 685) was obtained in a 43% yield.

Found: Si, 9.87. Calcd for $C_{18}H_{22}Si$: Si, 10.78%.

The author is much indebted to Prof. Yoshio Iwakura for his many useful suggestions and to Mr. Niro Tarumi for his help in the experiments. Appreciation is also due to Shin-etu Chem. Co. for their kindness in supplying the diphenyldichlorosilane.

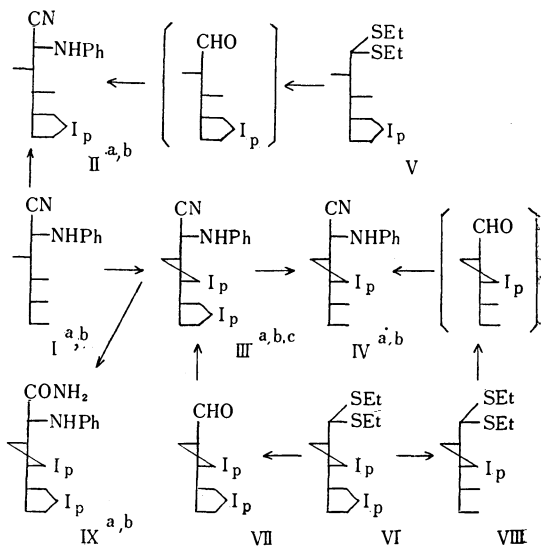
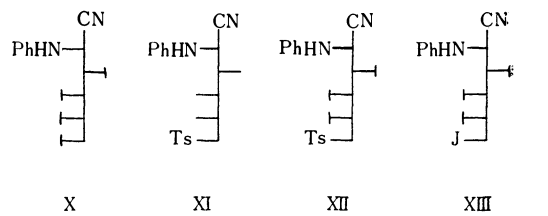
# *Studies on D-Glucosamine Derivatives. V. Some Derivatives of N-Phenyl-D- and L-glucosaminonitrile*

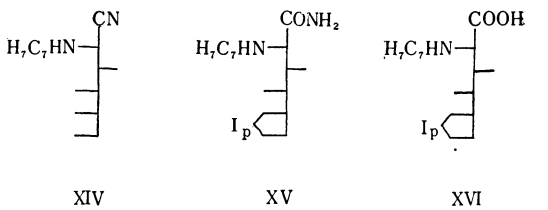
By Juji YOSHIMURA



(Received April 22, 1960)



In the preceding paper of this series[1], syntheses of isopropylidene and some other derivatives of D-glucosamine diethylmercaptals were described. In the present paper, the corresponding derivatives of *N*-phenyl-D- and L-glucosaminonitrile were synthesized, and the structure of isopropylidene derivatives were unambiguously confirmed by different derivations.



Warming of *N*-phenyl-D- ($I^a$) or L-glucosaminonitril ($I^b$), prepared from anhydrous hydrogen cyanide, aniline and D- or L-arabinose by Kuhn's method[2], with anhydrous cupric sulfate in acetone afford the corresponding 5, 6-*O*-isopropylidene derivatives ($II^a$ or $II^b$) respectively, whilst these are converted into the corresponding 3, 4 ; 5, 6-di-*O*-isopropylidene derivatives ($III^a$ or $III^b$) by treating with acetone in the presence of concentrated sulfuric acid. $III^a$ and $III^b$ are partially hydrolyzed to the corresponding 3, 4-*O*-isopropylidene derivatives ($IV^a$ and $IV^b$) under an acidic condition.

All these derivations of isopropylidene derivatives are very similar to that of D-glucosamine diethylmercaptals described in Part IV. To determine the position of isopropylidene groups, these were synthesized from isopropylidene *aldehydo*-arabinose, aniline and anhydrous hydrogen cyanide in ethanol. Thus, 2,3 ; 4,5-di-*O*-isopropylidene-*aldehyde*-D-arabinose (VII)[3] was converted in good yield into a mixture of $III^a$ and its epimer ; 3, 4 ; 5, 6-di-*O*-isopropylidene-*N*-phenyl-D-mannosaminonitrile ($III^c$). Meanwhile, the unpurified 5, 6- and 2, 3-*O*-isopropylidene-D-arabinose obtained from the corresponding diethylmercaptal (V)[3] and (VIII) which is the partial hydrolyzed product of 2, 3 ; 4, 5-di-*O*-isopropylidene-D-arabinose diethylmercaptal (VI)[3] were converted into $II^a$ and $IV^a$ in poor yield.

Aldonic acidamides known as an intermediate of Weerman's degradation for shortening the carbon chain of sugars are generally synthesized from aldonic acids or lactones and alcoholic[4] or liquid[5] ammonia. Partial

TABLE I. RESULTS OF PERIODATE OXIDATION EXPERIMENTS

| Compounds | Mol. of periodate consumed/mol. of compds. | | | | Mol. of formaldehyde liberated |
|---|---|---|---|---|---|
| | 1 hr. | 2 hr. | 3 hr. | 9 hr. | |
| $I^a$ | 3.50 | 3.53 | 3.69 | 3.80 | 1.07 |
| $II^a$ | 1.70 | 1.70 | 1.92 | 2.20 | 0.02 |
| $III^b$ | 0.00 | 0.00 | 0.00 | 0.00 | — |
| $IV^b$ | 0.85 | 0·89 | 0.93 | 1.09 | 1.02 |
| IX | 0.00 | 0.00 | 0.00 | 0.26 | — |
| X | 0.00 | 0.00 | 0.00 | 0.00 | — |
| XV | 1.82 | 1.85 | 1.90 | 2.13 | 0.03 |
| XVI | 1.93 | 1.97 | 2.15 | 2.35 | — |

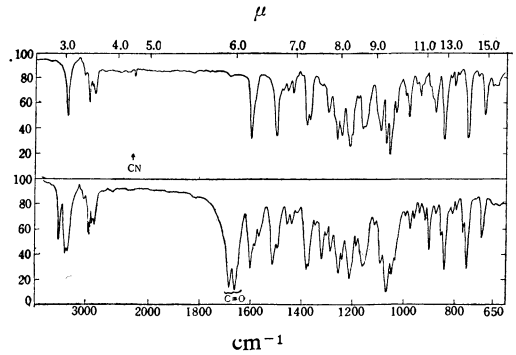

Fig. 1. The infrared specta of $III^a$ and $IX^b$.

hydrolysis of organic nitriles[6] to acidamides in alkalline hydrogen peroxide was applied to the above isopropylidene glucosaminonitriles. $III^a$ and $III^b$ are successfuly hydrolyzed to the corresponding glucosaminic acidamide ($IX^a$ and $IX^b$) in good yield, though $II^a$ or $IV^a$ does not afford a crystalline product. The infrared spectra (Fig. 1) show the absorption peak of nitrile (4.5 $\mu$) in $III^a$ but not in $IX^b$, while as for the carbonyl peaks (5.94, 6.01 $\mu$) the condition is vice versa.

Different from the corresponding *N*-methyl[7] and *N*-benzyl[2] derivatives, acetylation of $I^b$ with acetic anhydride in pyridine affords the corresponding tetra-*O*-acetate (X) in which the hydrogen atom attached to nitrogen is not being replaced by an acetyl group. Tosylation of $I^b$ in pyridine led to the crystalline 6-*O*-*p*-toluenesulfonyl derivative (XI), which is acetylated to the corresponding 3, 4, 5-tri-*O*-acetyl derivative (XII), and the position of *p*-toluenesulfonyl group was confirmed by conversion to the 6-iodo derivative (XIII).

Periodate oxidation of these derivatives (Table I) shows that a nitrile group does not consume the periodate as a mercaptal group[1,8] does, and nitriles having the unprotected hydroxyl group at carbon 3 (adjacent to amino group) are over-oxidized similarly to that of mercaptals[1].

There are a few examples[2,9] in which the reactivity of glucosaminonitrils are different with *N*-substituted groups. Thus, the reaction of *N*-benzyl-L-glucosaminonitrile (XIV) with acetone in the presence of concentrated sulfuric acid does not lead to the corresponding isopropylidine derivative, but crystalline 5, 6-*O*-isopropylidene-*N*-bynzyl-L-glucosaminic acid amide (XV) and 5, 6-*O*-isopropylidene-*N*-benzyl-L-glucosaminic acid, (XVI) in which the position of these isopropylidene groups was deduced from the results of periodate oxidation in Table I, were separated by chromatography of the reaction product on a magnesol-celite column. These aspects are now under investigation.

## Experimental

**5, 6-*O*-Isopropylidene-*N*-phenyl-D-glucosaminonitrile ($II^a$).**—(i) A mixture of 1 g. of *N*-phenyl-D-glucosaminonitrile ($I^a$), 30 ml. of anhydrous acetone and 4 g. of anhydrous cupric sulfate was stirred at 37~40°C for 6 hr., and the acetone solution separated from solids was concentrated in vacuo. The residual sirup crystallized on scratching with a little amount of ether was recrystallized twice from ethanol-petrolum ether; m. p. 124~5°C. Yield, 0.8 g. $[\alpha]_D^{26}+141°$ (*c* 0.82, methanol).

Found: C, 61.55; H, 7.02; N, 9.54. Calcd. for $C_{15}H_{20}O_4N_2$ (292.3): C, 61.63; H, 6.90; N, 9.58%.

(ii) To a mixture of 9.0 g. of 5,6-*O*-isopropylidene-D-arabinose diethylmercaptal (V) in 50 ml. of acetone and 70 g. of moist cadmium carbonate was added a solution of 30 g. of mercuric chloride in 40 ml. of acetone and the mixture was vigorously stirred for 4 hr. at room temperature. 20 g. of moist cadmium carbonate was again added, and then heated at 50°C for 1 hr. The reaction mixture was cooled, diluted with acetone, filtered and the solid was washed with the same solvent. After complete removal of acetone from the combined filtrate and washings at room temperature in the presence of cadmium carbonate, the mixture was extracted with chloroform and the extract dried with sodium

sulfate. A pale yellow sirup (2.5 g.) remained by evaporation of the solvent was dissolved in 4 ml. of ethanol, and 1 ml. of aniline and 1.5 ml. of ethanol, and 1 ml. of aniline and 1.5 ml. of hydrogen cyanide was added. After being kept in the refrigerator for 3 hr., the mixture was concentrated to dryness in vacuo, and the residual syrup was dissolved in ethanol-petroleum ether. The solution was seeded with II[a] and stored in the refrigerator overnight and 0.8 g. of crystals, m. p. 123~5°C, was yielded. These showed no depression on admixture with II[a].

**5, 6-*O*-Isopropylidene-*N*-phenyl-L-glucosaminonitrile (II[b]).**—0.8 g. of *N*-phenyl-L-glucosaminonitrile (I[b]) was treated in exactly the same manner as in the case of II[a], and 0.6 g. of colorless needles was obtained, m. p. 124~5°C. $[\alpha]_D^{25}-138°$ (*c* 0.70, methanol).

Found: C, 61.66; H, 7.05; N, 9.60. Calcd. for $C_{15}H_{20}O_4N_2$ (292.3); C, 61.63; H, 6.90; N, 9.58%.

**3, 4; 5, 6-Di-*O*-isopropylidene-*N*-phenyl-D-glucosaminonitrile (III[a]).**—To a mixture of 3 g. of I[a] and 60 ml. of anhydrous acetone, 1.6 ml. of concentrated sulfuric acid was added dropwise. After standing at room temperature for 4 hr., the slightly colored clear solution was poured into an excess amount of saturated aqueous solution of sodium carbonate in cooling, and filtered. The filtrate was extracted with chloroform used for washing the filtered sodium sulfate, and the extract was washed with water and dried with anhydrous sodium sulfate. The colorless crystals obtained by evaporation of the chloroform extract were recrystallized twice from ethanol: m. p. 106~8°C, Yield 2.5 g., $[\alpha]_D^{26}$ +140° (*c* 0.37, methanol.)

Found: C, 64.74; H, 7.27; N, 8.50. Calcd. for $C_{18}H_{24}O_4N_2$ (332.4): C, 65.04; H, 7.28; N, 8.43%.

**Reaction of 2, 3; 4, 5-Di-*O*-isopropylidene-aldehydo-D-arabinose (VII), Aniline and Hydrogen Cyanide.**—To a solution of 15 ml. of absolute ethanol and 9 g. of VII (b. p. 182~3°C/0.35 mmHg) were added 5 ml. of aniline and 10 ml. of anhydrous hydrogen cyanide. After being kept overnight in the refrigerator, the solution was concentrated in vacuo to a sirup, which was crystallized on scratching with a small amount of petroleum ether, and recrystallized from ethanol; yield 9 g., m. p. 106~8°C. $[\alpha]_D^{25}$+138° (*c* 2.0, methanol). These showed no depression on admixture with III[a]. 3,4; 5,6-Di-*O*-isopropylidene-*N*-phenyl-D-mannosaminonitrile obtained from the above mother liquor by concentration was recrystallized twice from ether-petrolum ether; yield 3 g., m. p. 93~5°C. $[\alpha]_D^{26}$ +12.8° (*c* 0.35, methanol).

Found: C, 64.97; H, 7.50; N, 8.36. Calcd. for $C_{18}H_{24}O_4N_2$ (332.4): C, 65.04; H, 7.28; N, 8.43%.

**3, 4-*O*-Isopropylidene-*N*-phenyl-D-glucosaminonitrile (IV[a]).**—(i) A mixture of 2 g. of III[a] in acetone (65%, 50 ml.) and aqueous sulfuric acid (6 N, 10 ml.) was warmed at 45~55°C for 40 min., and then poured into an excess amount of saturated sodium bicarbonate solution under cooling; it was then filtered. The residue was washed with chloroform, and the filtrate was extracted with the washings. The chloroform extract was washed with water and dried with anhydrous sodium sulfate, and evaporated in vacuo. The residual syrup was crystallized from ether-petroleum ether; m. p. 97~9°C. Yield 1.2 g. $[\alpha]_D^{24}$+75.6° (*c* 0.79, methanol).

Found: C, 61.46; H, 7.38; N, 9.52. Calcd. for $C_{15}H_{20}O_4N_2$ (292.3): C, 61.63; H, 6.90; N, 9.58%.

(ii) Freshly precipitated moist cadmium carbonate, 90 g. was heated rapidly to 50°C in a solution of 10.5 g. of 2,3-*O*-isopropylidene-D-arabinose diethylmercaptal in 55 ml. of acetone with vigorous stirring in nitrogen atmosphere. As soon as 50°C was reached 40 g. of mercuric chloride in 50 ml. of acetone was added over a period of 10 min. and stirring continued at 50°C for further 5 min. The mixiure was immediately cooled, diluted with acetone, centrifuged and washed on the centrifuge with the same solvent. After complete removal of acetone from the combined filtrate and washings at room temperature in the presence of fresh cadmium carbonate, the mixture was extracted with chloroform and the extract dried with sodium sulfate. Evaporation of the solvents gave 2 g. of pale yellow sirup. This syrup was dissolved in 5 ml. of ethanol with 1 g. of aniline and 1 ml. of anhydrous hydrogen cyanide, and left to stand for 3 hr. at room temperature. The mixture was concentrated in vacuo to a sirup, again dissolved in 5 ml. of ethanol, and water was added just before clouding took place at 40°C. A little amount of syrup separated was decanted at room temperature and the clear solution was stored in the refrigerator overnight. The crystals separated were collected and recrystallized from ethanol-water, m. p. 97~9°C. Yield 0.6 g. These showed no depression on admixture with IV[a].

**3, 4-*O*-Isopropylidene-*N*-phenyl-L-glucosaminonitrile (IV[b]).**—In exactly the same manner in the case of IV[a], 1.3 g. of crystals was obtained from 2 g. of III[b]. It was recrystallized from aqueous ethanol, m. p. 97~9°C, $[\alpha]_D^{26}-78.3°$ (*c* 0.97, methanol).

Found: C, 61.34; H, 7.28; N, 9.54. Calcd. for $C_{15}H_{20}O_4N_2$ (292.3): C, 61.63; H, 6.90; N. 9.58%.

**2, 3-*O*-Isopropylidene-D-arabinose Diethylmercaptal (VIII).**—A mixture of 16 g. of 2, 3; 4, 5-di-*O*-isopropylidene-D-arabinose diethylmercaptal in acetone (90 ml.) and aqueous sulfuric acid (6 N, 18 ml.) was heated at 45~50°C for 20 min. The solution was poured into an excess amount of cold saturated sodium bicarbonate solution and filtered. The residue was washed with chloroform, and the filtrate was extracted with washings. The chloroform extract was washed, dried and concentrated in the usual manner. By fractional distillation of the residue was obtained 10.4 g. of colorless syrup; b. p. 140°C/0.07 mmHg, 150~1°C/0.3 mmHg. $[\alpha]_D^{26}$ +86.2° (*c* 0.44, methanol).

Found: C, 48.94; H, 8.39; S, 21.23. Calcd. for $C_{12}H_{24}O_4S_2$ (296.4): C, 48.62; H, 8.16; S. 21.63%.

**2, 3; 4, 5-Di-*O*-isopropylidene-*N*-phenyl-D-glucosaminic Acidamide (IX[a]).**—A mixture of 2 g. of III[a], 35 ml. of acetone, hydrogen peroxide (30%, 7 ml.), sodium carbonate (10%, 3 ml.) and 18 ml. of water was refluxed 80 min. on a steam bath, and acetone was then removed in vacuo. The remained mixture of crystalline substances and water was extracted with chloroform in the usual

manner. The crystals obtained by evaporation of solvents in vacuo were recrystallized from ethanol; yield, 1.4 g., m. p. 147~8°C. $[\alpha]_D^{25}$ −5.1° (*c* 0.33, methanol).

Found: C, 61.40; H, 7.56; N, 8.00. Calcd. for $C_{18}H_{26}O_5N_2$ (350.4): C, 61.70; H, 7.48; N, 8.00%.

**2, 3, 4, 5-Di-*O*-isopropylidene-*N*-phenyl-L-glucosaminic Acidamide (IX[b]).**—In exactly the same manner in the case of IX[a], 3.5 g. of crystals was obtained from 5 g. of III[b]. It was recrystallized from ethanol-petroleum ether, m. p. 146~8C. $[\alpha]_D^{26}$ −4.5° (*c* 1.81, methanol).

Found: C, 61.80; H, 7.66; N, 7.17. Calcd. for $C_{18}H_{26}O_5N_2$ (350.4): C, 61.70; H, 7.48; N, 8.00%.

**3, 4, 5, 6-Tetra-*O*-acetyl-*N*-phenyl-L-glucosaminonitrile (X).**—To a solution of 3 g. of I[b] in 16 ml. of dry pyridine, 15 ml. of acetic anhydride was added under cooling, and the mixed solution was left to stand for 24 hr. at room temperature. The reaction mixture was then poured into ice-water and extracted with chloroform in the usual manner. The extract was evaporated to dryness, and the residue was crystallized from ethanol. Yield 3.2 g., m. p. 127~8°C. $[\alpha]_D^{25}$ −83.5° (*c* 0.55, methanol).

Found: C, 56.59; H, 5.99; N, 6.82. Calcd. for $C_{20}H_{24}O_8N_2$ (420.6): C, 57.13; H, 5.75; N, 6.66%.

**6-*O*-(*p*-Toluenesulfonyl)-*N*-phenyl-L-glucosaminonitrile (XI).**—To a solution of 2 g. of I[b] in 10 ml. of dry pyridine, a solution of 1 g. of *p*-toluenesulfonylchloride in 5 ml. of dry pyridine was added under cooling. After standing overnight at room temperature, the reaction mixture was poured into ice-water and extracted with chloroform. In the course of washing the extracts with 1 N sulfuric acid crystalls precipitated, and these were collected and recrystallized from ethanol. Yield, 1.5 g., m. p. 131~4°C, $[\alpha]_D^{25}$ −96.5° (*c* 0.96, methanol).

Found: C, 56.48; H, 5.71, N, 6.87; S, 7.55. Calcd. for $C_{19}H_{22}O_6N_2S$ (406.5): C, 56.15; H, 5.46; N, 6.89; S, 7.89%.

**3, 4, 5-Tri-*O*-acetyl-6-*O*-(*p*-toluenesulfonyl)-*N*-phenyl-L-glucosaminonitrile (XII).**—A mixture of 3 g. of XI, 20 ml. of acetic anhydride and 20 ml. of dry pyridine was left to stand overnight at room temperature and then poured into ice-water. The solution was extracted with chloroform in the usual manner. The crystals obtained by evaporation of the solvent was recrystallized from ethanol; yield. 2.9 g., m. p. 132~4°C., $[\alpha]_D^{25}$ −62.5° (*c* 0.28, methanol).

Found: C, 56.54; H, 5.50; N, 5.26; S, 5.85. Calcd. for $C_{25}H_{28}O_9N_2S$ (532.6): C, 56.38; H, 5.30; N, 5.26; S, 6.02%.

**3, 4, 5-Tri-*O*-acetyl-6-iodo-*N*-phenyl-L-glucosaminonitrile (XIII).**—In a glass tube 2 g. of XII. 0.56 g. of sodium iodide and 40 ml. of dry acetone were sealed and heated in a steam bath for 1 hr. Sodium *p*-toluenesulfonate separated (0.69 g., 95% of the theoretical amount) was filtered off. The filtrate was evaporated to dryness in vacuo, and the residue was extracted with chloroform in the usual manner. Evaporation of the extracts afford 1.6 g. of pale yellow syrup, which could not crystallize or distill for purification. $[\alpha]_D^{25}$ −51.5° (*c* 0.55, methanol).

Found: C, 44.73; H, 4.68; N, 6.06; I, 25.18. Calcd. for $C_{18}H_{21}O_6N_2I$ (488.3): C, 44.27; H, 4.33; N, 5.74; J, 25.99%.

**Reaction of *N*-benzyl-L-glucosaminonitrile (XV) and Acetone in the Presence of Concentrated Sulfuric Acid.**—A mixture of 10 g. of XV, 200 ml. of anhydrous acetone and 5 ml. of conc. sulfuric acid was stirred at room temperature for 4 hr. The brown reaction mixture was treated similarly to that the case of III[a]. The crude syrup (9 g.) was fractionated on a magesol-celite column (25 g. of 1 : 5 mixture) with every 100 ml. of the solvent; (1) benzene-petroleum ether (1 : 1), (2) benzene-petroleum ether (2 : 1), (3) benzene, (4) benzene-ethanol (2 : 1), (5) benzene-ethanol (1 : 2) as mobile phase.

Fraction 3 gave needles of 5,6-*O*-isopropylidene-*N*-benzyl-L-glucosaminic acid (0.5 g.) which were recrystallized from ethanol, m. p. 192~3°C decomp., $[\alpha]_D^{25}$ −165° (*c* 0.2, methanol).

Found: C, 59.10; H, 7.36; N, 4.35. Calcd. for $C_{16}H_{23}O_6N$ (325.3): C, 59.06; H, 7.13; N, 4.31%.

Fraction 4 gave crystals of 5,6-*O*-isopropylidene-*N*-benzyl-L-glucosaminic acidamide (2.0 g.) which were recrystallized from ethanol-ether, m. p. 163~4°C, $[\alpha]_D^{24}$ −42.5° (*c* 0.65, methanol).

Found: C, 58.89; H, 7.35; N, 8.70. Calcd. for $C_{16}H_{24}O_5N_2$ (324.4): C, 59.24; H, 7.46; N, 8.64%.

**Periodate Oxidation Experiments.**—In each case, a mixture of 0.2 M-sodium periodate (5 ml.) and the compound (25~30 mg. accurately weighed) and 4 ml. of ethanol was made up to 25 ml. with water and stored in a refrigerator. A blank containing none of the compound was worked concurrently. At intervals, the periodate uptake was estimated by transferring sample (2 ml.) from the oxidation mixture and the blank into mixtures of phosphate buffer (pH 6.98; 25 ml.) and 20% potassium iodate solution (1 ml.), and the liberated iodine titrated with 0.01 N sodium thiosulfate solution, starch being used as indicator[10]. Formaldehyde was determined colorimetrically with chromotropic acid according to O'Dea and Gibbon's method[11], D-glucose being used as standard.

The author wishes to express his hearty thanks to Professor T. Sato, Tokyo Institute of Technology, for his encouragement throughout this work.

# *The Thermal Decomposition of Acetaldehyde in the Presence of Methanethiol*

By Naomi IMAI and Osamu TOYAMA

(Receiced April 16, 1960)

It is well known that reactions between thiols and free redicals, and between organic compounds and thiol radicals occur easily compared to other radical-molecule reactions. But only a few kinetic studies about these reactions are found in the literature[1,2]. The present authors have recently studied the photochemical[3] as well as the thermal[4] decomposition of acetaldehyde in the presence of hydrogen sulfide. These studies have shown that the chain decomposition of acetaldehyde is catalyzed by hydrogen sulfide, and this catalytic effect has been attributed to a chain mechanism involving reactions between methyl radical and hydrogen sulfide and between hydrosulfide radical and acetaldehyde. In a mixture of acetaldehyde and a thiol, a similar catalysis may be expected to take place. In this work a kinetic study of the thermal decomposition of acetaldehyde in the presence of methanethiol has been carried out to obtain information on elementary reactions involving methanethiol or its radical.

## Experimental

**Materials.**—Acetaldehyde was prepared by distillation of paraldehyde containing a small quantity of sulfuric acid and purified by bulb-to-bulb distillation. Methanthiol was obtained[5] by adding a sodium hydroxide solution to *S*-methyl isothiourea sulfate, which was prepared by the reaction between dimethyl sulfate and thiourea. It was then passed through a trap containing concentrated sulfuric acid and through a tower containing dry calcium chloride, and finally purified by bulb-to-bulb distillation.

**Apparatus.**—The thermal decomposition was carried out in a cylindrical glass vessel of 137 cc. placed in an electric furnace. The reaction vessel was connected to a mercury manometer, to an analytical system, to storage bulbs and to a bulb in which acetaldehyde and methanethiol were mixed before they were admitted to the reaction vessel. The reaction vessel, the manometer, the bulbs for storage and mixing and the analytical system were all attached to a conventional vacuum line.

**Procedure.**—Required quantities of acetaldehyde and methanethiol were admitted into the mixing bulb at room temperature and left for about 30 minutes to allow them to mix thoroughly. The mixed reactant gases were then introduced into the reaction vessel, which had already been kept at the experimental temperature, and the change in the total pressure with time was followed on a manometer. The products of decomposition in several runs were analyzed quantitatively in the same way as described previously[6].

## Results

It has been established by many workers that the products of the thermal decomposition of acetaldehyde are almost exclusively equal quantities of methane and carbon monoxide[7]. Similarly in this work, i. e., in the presence of methanethiol, it has been confirmed by analysis that the rate of formation of methane is identical with that of carbon monoxide, and the pressure of either one of these products corresponds to the total pressure increase within the experimental error. Thus, irrespective of the presence of methanethiol, the total pressure increase is always equal to the decrease in the pressure of acetaldehyde due to decomposition. Accordingly, the initial rate of decomposition was determined from the initial slope of a total pressure-time curve with the results shown in Figs. 1 and 3 and Table I. Fig. 1 shows the dependence of the rate of decomposition on the pressure of acetaldehyde in the experiments with acetaldehyde alone. Table I and Fig. 3 show the dependence of the rate of decomposition in the presence of methanethiol on the pressures of methanethiol and of acetaldehyde, respectively.

## Discussion

It is generally agreed that the main feature of thermal decomposition of acetaldehyde can

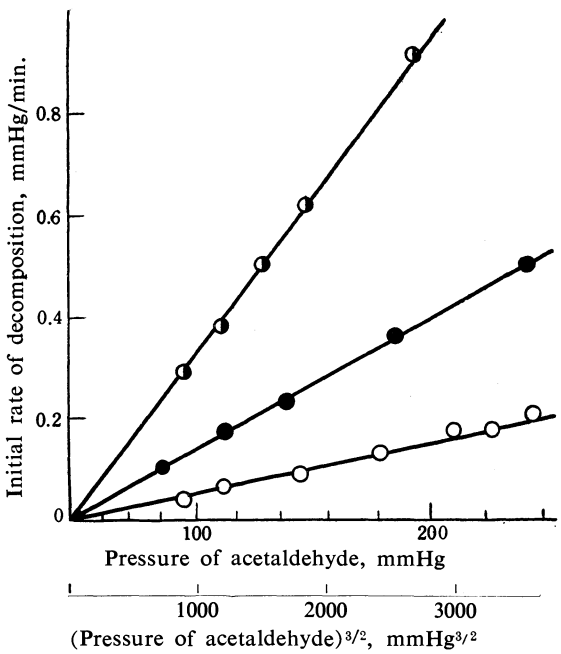

Fig. 1. Rate of decomposition of acetaldehyde alone. ○, 400; ●, 420; ◑, 440°C.

be explained by the following mechanism[8]

$$CH_3CHO = CH_3 + CHO \quad (1)$$

$$CHO = CO + H \quad (2)$$

$$H + CH_3CHO = H_2 + CH_3CO \quad (3)$$

$$CH_3CO = CH_3 + CO \quad (4)$$

$$CH_3 + CH_3CHO = CH_4 + CH_3CO \quad (5)$$

$$CH_3 + CH_3 = C_2H_6 \quad (6)$$

The steady state equations derived from this scheme yield the rate equation

$$-d[CH_3CHO]/dt = k_1^{1/2}k_5\ k_6^{-1/2}[CH_3CHO]^{3/2} \quad (I)$$

in general agreement with experimental results obtained by various workers. Also in this work, the rate of decomposition was found to be proportional to the 3/2 power of the pressure of acetaldehyde as seen in Fig. 1. From the slopes of the straight lines in the figure, the value of $k_1^{1/2}k_5\ k_6^{-1/2}$ at each temperature was obtained and listed in Table II.

TABLE II. VALUES OF $k_1^{1/2}k_5k_6^{-1/2}$, $k_1k_{11}^2k_{12}^{-1}$ AND $k_7k_{11}^2k_{12}^{-1}$

| Temp. (°C) | $k_1^{1/2}k_5k_6^{-1/2}$ ($mol^{-1/2}$ $cc^{1/2}$ $sec^{-1/2}$) | $k_1k_{11}^2k_{12}^{-1}$ ($mol^{-1}$ cc $sec^{-1}$) | $k_7k_{11}^2k_{12}^{-1}$ ($mol^{-1}$ cc $sec^{-1}$) |
|---|---|---|---|
| 400 | 0.045 | 0.245 | 7.4 |
| 420 | 0.116 | 1.40 | 33 |
| 440 | 0.28 | 7.4 | 141 |

Now in the presence of methanethiol, the additional possibilities may be[9]

$$CH_3SH = CH_3 + SH \quad (7)$$

$$SH + CH_3SH = H_2S + CH_3S \quad (8)$$

9) Reactions similar to 10, 11 and 12 have been proposed by the following workers: E. F. P. Harris and W. A. Waters, *Nature*, **170**, 212 (1952); K. E. J. Banett and W. A. Waters, *Discussions Faraday Soc.*, **14**, 221 (1953); Ref. 1.

$$SH + CH_3CHO = H_2S + CH_3CO \quad (9)$$

$$CH_3 + CH_3SH = CH_3S + CH_4 \quad (10)$$

$$CH_3S + CH_3CHO = CH_3SH + CH_3CO \quad (11)$$

$$CH_3S + CH_3S = \text{Product} \quad (12)$$

Sehon and Darwent[10] suggest that in the thermal decomposition of methanethiol the split of C–S bond, and not that of S–H, takes place, in view of the fact that major products found by using toluene as a carrier are methane, hydrogen sulfide and dibenzyl. Their suggestion seems reasonable judging from the dissociation energies of C–S and S–H bonds of methanethiol which have been estimated as 74.2 and 88.8 kcal./mol., respectively[11]. Skerrett and Thompson[12] have shown that the product of reaction 12 is mainly methyl disulfide $(CH_3)_2S_2$ by analysis of the products obtained in the photolysis of methanethiol, where the primary reaction is the split of S–H bond of the methanethiol molecule that absorbed light.

When reactions 10 and 11 are much faster than reaction 5, acetaldehyde decomposes mostly by a chain mechanism consisting of reactions 10, 11 and 4. If, in addition, reaction 10 is faster than reaction 11, the concentration of methylthio radicals will be greater than that of methyl radicals and reaction 12. These assumptions lead to the following rate equation.

$$-d[CH_3CHO]/dt = k_{11}k_{12}^{-1/2}(k_1[CH_3CHO] + k_7[CH_3SH])1/2[CH_3CHO] \quad (II)$$

or

$$(-d[CH_3CHO]/dt)^2 = k_{11}^2k_{12}^{-1}(k_1[CH_3CHO]^3 + k_7[CH_3CHO]^2[CH_3SH]) \quad (III)$$

As seen in Fig. 2, except in a low pressure range of methanethiol, the square of the rate of decomposition increases linearly with the pressure of methanethiol in agreement with equation III. At lower pressures of methanethiol, the relative concentration of methylthio radicals to that of methyl radicals falls off and consequently the importance of the recombination of methyl radicals becomes greater. This explains the deviation from equation III at

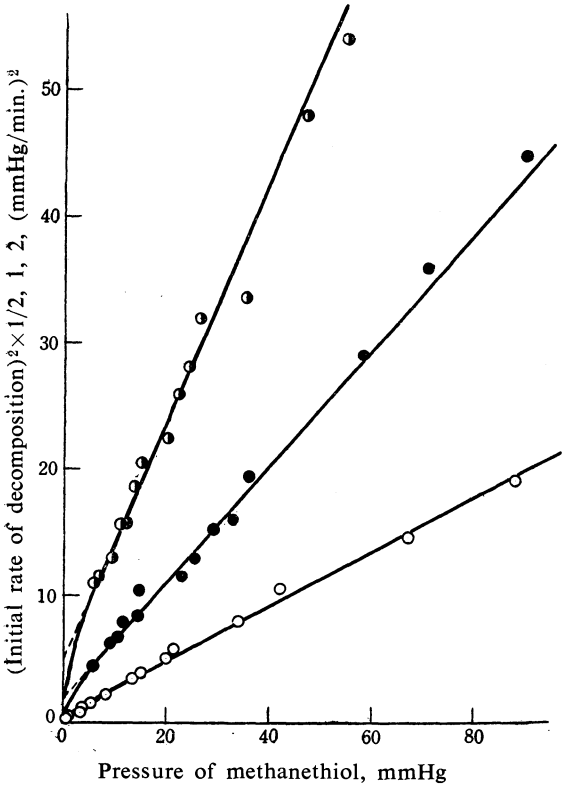

Fig. 2. Dependence of the rate of decomposition in the presence of methanethiol on its pressure. $CH_3CHO$ : 100 mmHg. ○, (Rate)²×2, 400°C; ●, (Rate)²×1, 420°C; ◑, (Rate)²×1/2, 440°C.

11) J. L. Franklin and H. E. Lumpkin, ibid., 74, 1023 (1952).
12) N. D. Skerrett and N. W. Thompson. *Trans. Faraday Soc.*, 37, 81 (1941).

low pressures of methanethiol. From the intercepts and slopes of the straight lines in Fig. 2 values of $k_1k_{11}^2k_{12}^{-1}$ and $k_7k_{11}^2k_{12}^{-1}$ are obtained, which are listed in Table II together with values of $k_1^{1/2}k_5k_6^{-1/2}$ already mentioned above.

Fig. 3 shows the plots of the rate of decomposition observed at a constant pressure of methanethiol against the pressure of acetaldehyde, together with the curves representing the rate calculated as a function of acetaldehyde pressure by equation II using the values of $k_1k_{11}^2k_{12}^{-1}$ and $k_7k_{11}^2k_{12}^{-1}$ given in Table II. The fact that the calculated curves are in satisfactory agreement with the experimental plots over a wide range of acetaldehyde pressure may be taken as an additional evidence for the validity of equation II.

The values given in Table II lead to the following Arrhenius expressions:

$$k_1^{1/2}k_5k_6^{-1/2}=10^{12.8}\exp(-43{,}500/\boldsymbol{RT})$$
$$(\mathrm{mol}^{-1/2}\ \mathrm{cc}^{1.2}\ \mathrm{sec}^{-1/2})$$
$$k_1k_{11}^2k_{12}^{-1}=10^{25.8}\exp(-81{,}300/\boldsymbol{RT})$$
$$(\mathrm{mol}^{-1}\ \mathrm{cc.}\ \mathrm{sec}^{-1})$$
$$k_7k_{11}^2k_{12}^{-1}=10^{23.7}\exp(-70{,}200/\boldsymbol{RT})$$
$$(\mathrm{mol}^{-1}\ \mathrm{cc.}\ \mathrm{sec}^{-1})$$

The expression for $k_1^{1/2}k_5k_6^{-1/2}$ agrees with those reported previously by various workers. Combining the expression for $k_1^{1/2}k_5k_6^{-1/2}$ with that for $k_1k_{11}^2k_{12}^{-1}$, we obtain

$$(k_5/k_{11})\,(k_{12}/k_6)^{1/2}=0.8\exp(-2{,}800/\boldsymbol{RT})$$

If we assume that $k_{12}$ has zero activation energy and a pre-exponential factor of the same value as that of $k_6$, the left-hand side of the equation becomes equal to $k_5/k_{11}$. The difference in activation energies $E_5-E_{11}=2.8$ kcal./mol. thus obtained compares with 1.6 kcal./mol. obtained by Birrel et al.[1] in the photolysis of mixtures of acetaldehyde and methanethiol. The value of the ratio $A_5/A_{11}=0.8$ also seems reasonable, as pre-exponential factors of these two reactions are expected to be of the same order of magnitude.

From the expressions for $k_1k_{11}^2k_{12}^{-1}$ and $k_7k_{11}^2k_{12}^{-1}$ given above, it follows that

$$k_1/k_7=130\exp(-11{,}100/\boldsymbol{RT})$$

The difference in activation energies $E_1-E_7=11$ kcal./mol., when combined with $E_1=75$ kcal./mol., yields a value of 64 kcal./mol. for $E_7$. Franklin and Lumpkin[11] estimated the dissociation energy of C-S bond in methanethiol to be 74.2 kcal./mol. by an electron impact method. Sehon and Darwent[10] obtained a lower dissociation energy of 67 kcal./mol. from the rates of decomposition of methanethiol in the presence of toluene as a carrier, assuming a pre-exponential factor of $3\times10^{13}$ $\mathrm{sec}^{-1}$. The value of 64 kcal./mol. obtained above in the present work is still lower than that of Sehon and Darwent. As can be seen in Fig. 2, the straight lines representing the square of the rate of decomposition as a function of acetaldehyde pressure cut the ordinate axis very close to the origin. Hence the values of the intercept and consequently the expression for $k_1/k_7$ given above must be accepted with some reserve. In fact, a value of the ratio $A_1/A_7$ amounting to $1.3\times10^2$ may be too large. If this ratio has really a smaller value, $E_7$ is greater than the value estimated above; if $A_1/A_7$ is put equal to unity, $E_7$ becomes as large as 70 kcal./mol.

As has been shown above, the results obtained in the present work comform to equation II based upon a mechanism in which the reaction chain terminates by the combination of methylthio radicals, while, in the photochemical[3] and thermal[3] decomposition of acetaldehyde in the presence of hydrogen sulfide, the experimental results indicate that the chain terminates by the combination of methyl radicals and not of hydrosulfide radicals. In these decomposition reactions, factors determining the chain-ending step may be the concentration ratio $[RS]/[CH_3]$, where R represents $CH_3$ or H, and the relative abilities of radicals to recombine. The former quantity in the steady state is given by $k_A[RSH]/k_B[CH_3CHO]$ where $k_A$ and $k_B$ are respectively the specific rates of the following reactions:

$$CH_3 + RSH = CH_4 + RS \qquad (A)$$
$$RS + CH_3CHO = RSH + CH_3CO \qquad (B)$$

Although our experimental results indicate that the activation energy of reaction A, $E_A$, is lower than $E_B$ for hydrogen sulfide, and that $k_A=10^{11.4}\exp(-2{,}600/\boldsymbol{RT})$ $\mathrm{mol}^{-1}$[6] cc. $\mathrm{sec}^{-1}$ for hydrogen sulfide and $E_B$ is around 4 kcal./mol. methanethiol, we are yet given no complete expressions for all the $k_A$'s and $k_B$'s at present and accordingly cannot compare the value of the ratio $[RS]/[CH_3]$ for methanethiol with that for hydrogen sulfide. If, however, these values were of comparable magnitudes in these experiments, the difference between the chain-ending steps in the experiments with methanethiol and with hydrogen sulfide would mean the lower ability of hydrosulfide radicals to recombine, compared to that of methylthio radicals.

It has been found in the present work that the rate of decomposition falls off during a run faster than can be expected from the rate equation. The higher are the pressure of methanethiol and the temperature, the greater is the extent of this reduction in the rate. Similar

phenomena have been observed in the photolysis of acetaldehyde in the presence of hydrogen sulfide[3]. The exact nature of these phenomena are not clear at present.

## Summary

Acetaldehyde has been decomposed thermally in the presence of methanethiol over the temperature range from 400° to 440°C. The presence of methanethiol markedly enhances the rate of decomposition. Analysis of the initial rates of decomposition obtained under various experimental conditions suggests: a) one of the chain-carrying steps $CH_3+CH_3CHO=CH_4+CH_3CO$ (5) in the decomposition of acetaldehyde alone is replaced by $CH_3+CH_3SH=CH_4+CH_3S$ (10) and $CH_3S+CH_3CHO=CH_3SH+CH_3CO$ (11) in the presence of methanethiol; b) the reaction $CH_3SH=CH_3+SH$ (7), in addition to $CH_3CHO=CH_3+CHO$ (1), contributes to the chain initiation; c) the chain terminates by the combination of methylthio radicals in contrast to the decomposition in the presence of hydrogen sulfide where the chain-ending step is the combination of methyl radicals under similar experimental conditions; d) $k_5/k_{11}=0.8\exp(-2{,}800/\boldsymbol{RT})$ and $k_1/k_7=130\exp(-11{,}000/\boldsymbol{RT})$, the latter expression being less certain.

The present study was partly supported by the finantial aid of the Ministry of Education, to which the authors' thanks are due.

# *The Formation Constants of Metal Acetate Complexes. III. Polarographic Determination of the Formation Constants of Acetatocadmium(II) and Acetatocobalt(II) Complexes*

By Nobuyuki TANAKA, MINORU KAMADA, Hisao OSAWA and Gen SATÔ

(Received May 18, 1960)

In the previous papers[1,2], the formation constants of acetato complexes of nickel(II), copper(II), lead(II) and zinc(II) were reported. They were determined by the newly devised methods, which are based on the polarographic measurement of the sum of the equilibrium concentrations of hydrated metal ions and metal acetate complexes. In the case of acetatocopper(II), acetatolead(II) and acetatozinc(II) complexes, the substitution reaction of the type,

$$M^{m+} + M'Y^{(m'-4)+} \rightleftarrows MY^{(m-4)+} + M'^{m'+} \quad (1)$$

where $Y^{4-}$ means a completely dissociated ethylenediaminetetraacetate(EDTA) anion, was used for the determination of the formation constants. This was based on the fact that, in acetate buffers, the substitution reaction (Eq. 1) was considered to be

$$\left\{\begin{matrix} M^{m+} \\ \uparrow\downarrow \\ M(OAc)_n^{(m-n)+} \end{matrix}\right\} + \left\{\begin{matrix} M'Y^{(m'-4)+} \\ \uparrow\downarrow \\ M'HY^{(m'-3)+} \end{matrix}\right\} \rightleftarrows \left\{\begin{matrix} MY^{(m-4)+} \\ \uparrow\downarrow \\ MHY^{(m-3)+} \end{matrix}\right\} + \left\{\begin{matrix} M'^{m'+} \\ \uparrow\downarrow \\ M'(OAc)_{n'}^{(m'-n')+} \end{matrix}\right\} \quad (2)$$

In this paper are presented the formation constants of acetatocadmium(II) and acetatocobalt(II) complexes which have been determined by the same procedure as used for the acetato complexes of copper(II), lead(II) and zinc(II).

## Experimental

**Reagent.**—Standard solutions of copper(II) nitrate and cadmium(II) nitrate were prepared by dissolving known amounts of pure copper and pure cadmium metals (Merck Co. Ltd.), respectively, in reagent-grade nitric acid. In the case of cadmium metal, the oxide layer on the metal surface was removed with hydrochloric acid. This cadmium metal was found by the a. c. polarographic method to contain 0.08% of lead as impurity. The careful examination, however, showed that this minute quantity of lead would give no appreciable effect on the equilibrium determination, and therefore no further purification was carried out. The solution of disodium ethylenediaminetetraacetate (EDTA) was standardized against the standard solution of copper(II) nitrate by amperometric titration with the dropping mercury electrode[3]. A standard solution of cobalt(II) nitrate was prepared by dissolving an appropriate

2) N. Tanaka and K. Kato, ibid., **33**, 417 (1960).
3) N. Tanaka, M. Kodama, M. Sasaki and M. Sugino, *Japan Analyst (Bunseki Kagaku)*, **6**, 86 (1957).

amount of cobalt metal in reagent-grade nitric acid. Its concentration was determined with the standardized EDTA solution volumetrically using murexide as an indicator[4] and also amperometrically using the dropping mercury electrode as an indicator electrode[3]. The polarographic analysis showed that the cobalt metal contained 0.2% of nickel as impurity. Therefore, the equilibrium study of the reaction involving cobalt(II) ions or cobalt(II)-EDTA complexes was carried out, taking into consideration the substitution reaction involving nickel(II)-EDTA complexes (see below).

Sodium acetate-acetic acid buffers were prepared by mixing the solutions of sodium carbonate and acetic acid. Sodium carbonate, acetic acid and other reagents used for the supporting electrolyte were of guaranteed reagent grade and used without further purification.

**Apparatus and procedure.** — A Shimadzu RP-2 pen-recording polarograph and a manual apparatus similar to that of Kolthoff and Lingane[5] were used for the measurement of current-voltage curves. Two dropping mercury electrodes were used. One had an $m$ value of 2.57 mg./sec. and a drop time $\tau$ of 3.52 sec. in an air-free acetate buffer of pH 4.7 containing 0.1 M acetate, 0.1 M potassium nitrate and 0.01% gelatin at 25°C with open circuit. The other had an $m$ value of 2.93 mg./sec. and a drop time $\tau$ of 3.16 sec. in an air-free 0.1 M potassium nitrate solution at 25°C with open circuit. A saturated calomel electrode with a large area was used as the anode, which was connected to the electrolytic solution by a Hume and Harris-type agar bridge[6]. A Hitachi Model EHP-1 pH meter was used for the pH measurement. Dissolved oxygen in the solution was removed by bubbling pure tank nitrogen through the solution.

The measurements of the diffusion current of copper(II) in acetate buffer solutions were carried out with the following two reaction mixtures:

(a) copper(II)—cadmium(II)—EDTA

(b) copper(II)—cobalt(II)—EDTA.

The measurements were made at 15, 25 and 35°C in acetate buffers of pH 4.75 (for cadmium(II)) and pH 4.70 (for cobalt(II)) of which the acetate concentrations were varied from 0.02 M to 0.10 M (for cobalt(II)) or to 0.15 M (for cadmium(II)). The ionic strength was adjusted to be 0.2 with potassium nitrate. Gelatin was added as a maximum suppressor by 0.01% in concentration.

In the preliminary experiments, it was found that the substitution reactions between copper(II) ions and cadmium(II)-EDTA complexes and those between copper(II) ions and cobalt(II)-EDTA complexes proceeded at considerable reaction rates. The reaction mixtures of the copper(II)-cadmium-(II)-EDTA system were kept standing at the given temperature for ten to twenty hours after the preparation and were subjected to the measurement, though they were found to reach nearly the equilibrium within 60 minutes. In the case of the copper(II)-cobalt(II)-EDTA system, the diffusion currents of the copper(II) in the reaction mixtures were measured 45 min. after the preparation at 15°C, 30 min. at 25°C and 25 min. at 35°C. This was decided from the consideration of the effect of the reaction between copper(II) and nickel(II)-EDTA complexes on the equilibrium under consideration, because the cobalt(II) solution used in this experiment contained a small amount of nickel as impurity. It was found in the preliminary experiments that the reaction between copper(II) and nickel(II)-EDTA complexes affect more or less the equilibrium concentration of copper(II) in the substitution reaction between copper(II) and cobalt-(II)-EDTA complexes after the above-mentioned period, though the former reaction proceeds at much slower rate than the latter[7].

## Results

The apparent diffusion current constants[2] of copper(II) were determined by measuring the diffusion current at various acetate concentrations. The values of $[Cu^{2+}]_{app}$ which is given by[2]

$$[Cu^{2+}]_{app} = [Cu^{2+}] + \sum_{1}^{n} [Cu(OAc)_n^{(2-n)+}] \tag{3}$$

were determined with the aid of those apparent diffusion current constants from the diffusion currents obtained with the reaction mixtures of systems a and b. Then, the apparent equilibrium constants ($K^{M}_{M',app}$) for Eq. 2, expressed as[2]

$$K^{M}_{M',\,app} = \frac{[M'^{m'+}]_{app}\{[MY^{(m-4)+}] + [MHY^{(m-3)+}]\}}{[M^{m+}]_{app}\{[M'Y^{(m'-4)+}] + [M'HY^{(m'-3)+}]\}} \tag{4}$$

were culculated. The $F_n$ functions expressed as[2]

$$F_0 \equiv K^{M}_{M',\,app}\left\{1 + \sum_{1}^{n} K_{M(OAc)}[OAc^-]^n\right\} = K^{M}_{M'}\frac{\beta}{\beta'}\left\{1 + \sum_{1}^{n'} K_{M'(OAc)_{n'}}[OAc^-]^{n'}\right\} \tag{5}$$

$$F_1 = \frac{F_0 - \frac{\beta}{\beta'}K^{M}_{M'}}{\frac{\beta}{\beta'}K^{M}_{M'}[OAc^-]} = K_{M'OAc} + K_{M'(OAc)_2}[OAc^-] + \cdots\cdots \tag{6}$$

$$F_2 \equiv \frac{F_1 - K_{M'OAc}}{[OAc^-]} = K_{M'(OAc)_2} + K_{M'(OAc)_3}[OAc^-] + \cdots\cdots \tag{7}$$

7) unpublished work.

$$F_{n'} \equiv \frac{F_{n'-1} - K_{M'(OAc)_{n'-1}}}{[OAc^-]} = K_{M'(OAc)n'} \qquad (8)$$

were successively obtained, where $K^{M}_{M'}$ means the true equilibrium constant given by

$$K^{M}_{M'} = \frac{[M'^{m'+}]\,[MY^{(m-4)+}]}{[M^{m+}]\,[M'Y^{(m'-4)+}]} \qquad (9)$$

and $\beta$ and $\beta'$ are

$$\beta = 1 + K^{H}_{MHY}[H^+]$$

$$\beta' = 1 + K^{H}_{M'HY}[H^+]$$

The results obtained for systems a and b are given below. The values of $\beta/\beta'$ were calculated to be approximately unity for both a and b systems at the pH's in the present experiments, using the equilibrium constants $K^{H}_{MHY}$ and $K^{H}_{M'HY}$ given by Schwarzenbach, Gut and Anderegg[8].

**(a) Copper(II)-Cadmium(II)-EDTA System.** —The formation constants of acetatocadmium (II) complexes were determined by the measurement of $K^{Cu}_{Cd,app}$ at various acetate concentrations with the aid of the formation constants of $CuOAc^+$ and $Cu(OAc)_2$ obtained in the previous paper[2], where, under the experimental condition, $K^{Cu}_{Cd,app}$ is given by the equation

$$K^{Cu}_{Cd,app} = \frac{[Cd^{2+}]_{app}\{[CuY^{2-}] + [CuHY^-]\}}{[Cu^{2+}]_{app}\{[CdY^{2-}] + [CdHY^-]\}}$$

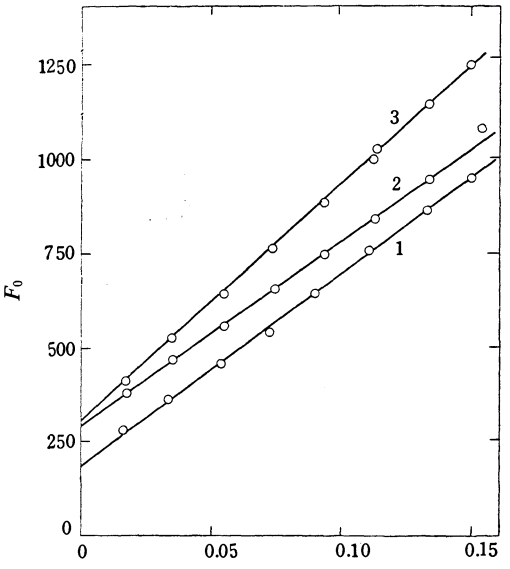

Fig. 1. $F_0$ (Eq. 5) as a function of the acetate ion concentration in copper(II)-cadmium(II)-EDTA system: 1, at 15°C; 2, at 25°C; 3, at 35°C.

8) G. Schwarzenbach, R. Gut and G. Anderegg, *Helv. Chim. Acta*, **37**, 937 (1954).

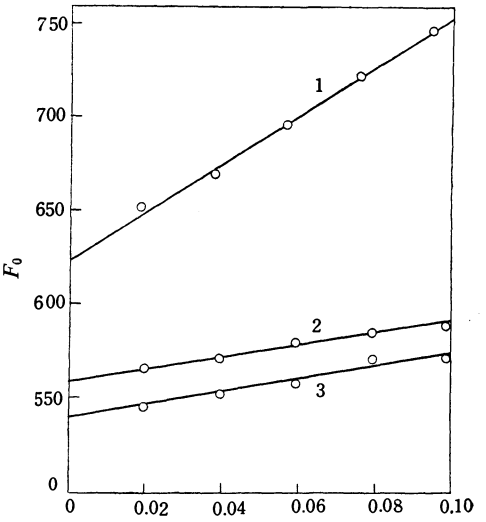

Fig. 2. $F_0$ (Eq. 5) as a function of the acetate ion concentration in copper(II)-cobalt(II)-EDTA system: 1, at 15°C; 2, at 25°C; 3, at 35°C.

The values of $F_0$ given by Eq. 5 were calculated and plotted against the acetate ion concentration. These plots for 15, 25 and 35°C are shown in Fig. 1, in which all $F_0$ plots give straight lines indicating that at acetate concentrations up to 0.15 M $CdOAc^+$ is only species of acetatocadmium(II) complex which exists in the solution at an appreciable concentration. The formation constants of $CdOAc^+$ are listed in Table I.

**(b) Copper(II)-Cobalt(II)-EDTA System.** —The formation constants of acetatocobalt(II) complexes were determined with the same procedure as for the acetatocadmium(II) complexes. $K^{Cu}_{Co,app}$ which is given by the equation

$$K^{Cu}_{Co,apq} = \frac{[Co^{2+}]_{app}\{[CuY^{2-}] + [CuHY^-]\}}{[Cu^{2+}]_{app}\{[CoY^{2-}] + [CoHY^-]\}}$$

was determined at various acetate concentrations. In this case also, the $F_0$ plots gave straight lines as shown in Fig. 2. From these plots the formation constants of $CoOAc^+$ were determined, which are given in Table I.

TABLE I. FORMATION CONSTANTS OF ACETATOCADMIUM(II) AND ACETATOCOBALT(II) COMPLEXES AT VARIOUS TEMPERATURES

| Metal ions | Temp., °C | $K_{MOAc}$ ($\mu$=0.2) |
|---|---|---|

* Those values are the formation constants which were calculated by the present authors with the values reported in the literature referred to. In the calculation, the activity coefficients of cadmium(II), cobalt(II) and acetate ions were estimated to be 0.30, 0.33 and 0.73, respectively, and the activity coefficient of monoacetato complexes was assumed to be equal to that of acetate ions[2,15].

## Discussion

The formatiom constants of the acetato complexes of cadmium(II) and cobalt(II) have been reported by several researchers. In Table II some of them are given, which are compared with the formation constants listed in Table I.

Recently, Yasuda and Yamasaki[16] determined the formation constants of acetato complexes of some bivalent metal ions and found that the stabilities of those complexes decreased in the order of Pb > Cu > Cd > Zn > Ni. The formation constants of $K_{MOAc}$ obtained in the previous[1,2] and present investigations agree with the above order.

The equilibria of the substitution reaction represented by Eq. 1 have been studied with the same procedure as that reported previously[2]. The equilibrium constants, $K_{Cd}^{Cu}$ and $K_{Co}^{Cu}$, are given in Table III. Schwarzenbach and his co-workers[8] studied the substitution reaction of copper(II) ions and cadmium(II)-EDTA complexes at 20°C in the solution of ionic strength 0.1 with $8\times10^{-3}$ M sodium acetate. The equilibrium constant which was reported by those researchers was corrected for the acetato complex formation using the formation constants $K_{CuOAc}$, $K_{Cu(OAc)_2}$ and $K_{CdOAc}$. The resulting constant is also given in Table III. On the other hand, no investigation had been reported on the substitution reaction between copper(II) ions and cobalt(II)-EDTA complexes. Therefore, the equilibrium constant of the reaction was calculated with the formation constants of copper(II)-EDTA and cobalt(II)-EDTA complexes[8]. This is also shown in Table III. It is seen that the $K_{M'}^{M}$ values obtained in this study are in satisfactory agreement with those calculated from the equilibrium or the formation constants reported by Schwarzenbach et al.

## Summary

The formation constants of acetatocadmium-(II) and acetatocobalt(II) complexes were determined at ionic strength of 0.2 at 15, 25 and 35°C with the procedure that is based on the polarographic measurement of the sum of the equilibrium concentrations of the hydrated metal ions and the metal acetate complexes in the substitution reaction involving EDTA complexes. The resulting formation constants $K_{CdOAc}$ and $K_{CoOAc}$ are 27 and 2.1 at 15°C, 16 and 0.6 at 25°C and 20 and 0.6 at 35°C, respectively.

# *Infrared Spectrum of Some Deuterated Crystalline Polystyrenes. I. Isotactic Poly-$\alpha d_1$-styrene*

By Masamichi KOBAYASHI

(Received April 14, 1960)

During these a few years many studies have been made on the molecular structure of the stereospecific vinyl polymer, and it has been found that most of isotactic polymers have the helical structure in their crystalline regions mainly because of steric hindrances of side groups.

To makë clear the helical structure of the polymer molecule, infrared spectroscopy is one of the most powerful methods as well as X-ray analysis.

Recently, Tadokoro et al[1]. reported the studies on the infrared spectra of isotactic polystyrene and its $\alpha, \beta, \beta$-tri-deuterated derivative and detected that in the spectrum of the polystyrene the absorption bands appearing in region of 1400~1180 $cm^{-1}$, such as the bands at 1364, 1314, 1297 and 1185 $cm^{-1}$, are characteristic of the three-fold helical structure of the polystyrene molecule and assumed to be associated with the vibrations of $CH_2$, CH and the carbon skeletal chain.

To make the assignments of these bands more clearly it is desirable to study the spectra of several other deuterated derivatives. For this purpose, isotactic poly-$\alpha d_1$-styrene was prepared and its infrared spectrum was studied.

## Experimental

**1. Preparation of $\alpha d_1$-Styrene.**—$\alpha d_1$-Styrene was prepared by hydrolysis with deuterium oxide of the Grignard reagent of $\alpha$-bromostyrene. From the massspectroscopic data, it was proved that the monomer prepared contained 99.5% of $d_1$-styrene. The infrared spectrum of this monomer is shown in Fig. 1 (solid line) in comparison with that of styrene (dotted line). It is justifiable to regard the sample as $\alpha d_1$-styrene from a few spectroscopic evidences ; the appearance of the band at 2230 $cm^{-1}$ corresponding to the stretching vibration of CD group, the shift of the band corresponding to the C=C stretching from 1628 to 1614 $cm^{-1}$ on deuteration and appearances of the bands corresponding to the bending vibration (at near 1400 $cm^{-1}$) and the rocking vibration (at near 1160 $cm^{-1}$) of $CH_2$ group in the spectra of both monomers.

To determine more precisely the position of the

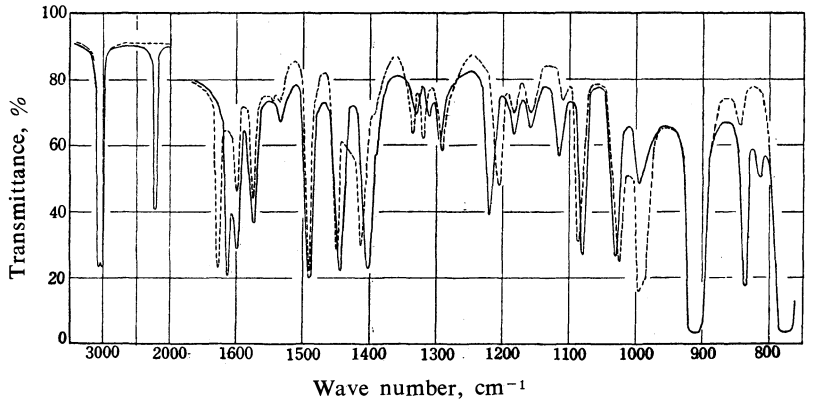

Fig. 1. Infrared spectra of $\alpha d_1$-styrene (——) and styrene (——).

deuterium atom in this monomer, the proton magnetic resonance spectrum of this monomer was compared with that of styrene. The spectra were measured using a Nihon Denshi Kogaku N. M. R. spectrometer.

Proton signals of the spectrum of styrene, from lower to higher field, are assigned[2] to $H_1$, $H_2$, $H_4$ and $H_3$ respectively as shown in Fig. 2. While the signals due to $H_3$ and $H_4$ of styrene both split into quartets by spin coupling with $H_2$ and with each other, the spectrum of the ethylenic protons of the deuterated styrene is doublet with some closely spaced fine structure. If a small coupling constant between $H_3$ and $H_4$ is taken into account, this deuterated styrene can be identified as $\alpha d_1$-styrene.

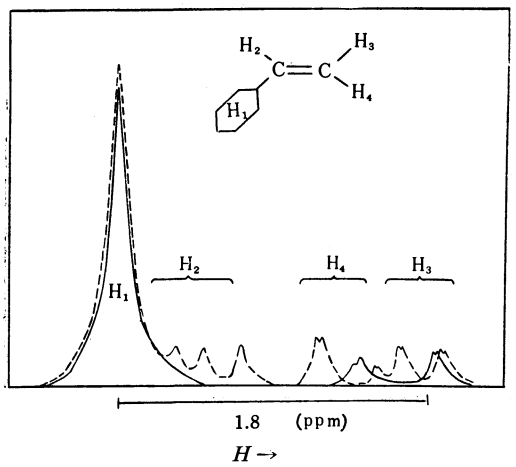

Fig. 2. Proton magnetic resonance spectra of $\alpha d_1$-styrene (——) and styrene (----) at 40 Mc/sec.

**2. Polymerization and Preparation of the Samples for I. R. Measurements.**—The monomer was polymerized with Ziegler catalyst ($AlEt_3+TiCl_4$) in *n*-heptane and the polymer prepared was purified by the usual method. The films cast from the toluene solution were oriented by drawing them to about five times their original lengths in boiling water and were crystallized by heating at 60°C for 10 minutes in glycerol.

The I. R. spectra were measured in the region of 3500~400 $cm^{-1}$ using a Hilger H800 I. R. spectrometer and the polarized spectra were measured in the region of 3500~650 $cm^{-1}$ using a selenium polarizer.

## Experimental Results

In Fig. 3a and 3b are shown the polarized spectra of isotactic poly-$\alpha d_1$-styrene in the region of 3500~2000 $cm^{-1}$ and 1600~650 $cm^{-1}$ respectively. The wave numbers, the dichroisms and the relative intensities of the absorption bands are given in Table I in comparison with those of isotactic polystyrene.

* Assignments of the normal mode of monosubstituted benzene according to Whiffen's notation.
** This band is assumed to overlap the band at 1183 $cm^{-1}$.

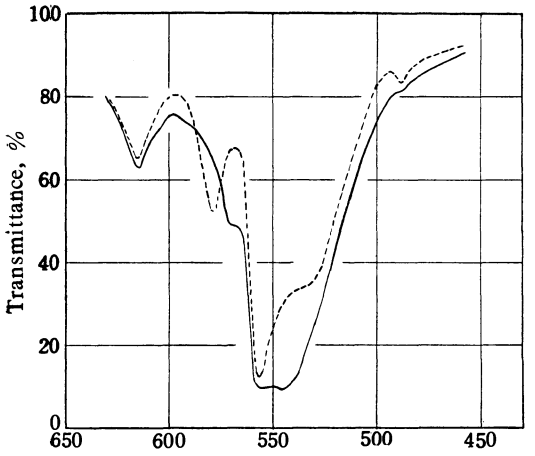

Fig. 3c. Infrared spectra of isotactic poly-$\alpha d_1$-styrene (——) and isotactic polystyrene (----).

## Discussions

**1. General Discussions.**—In the crystalline region, the molecule of isotactic polymer consists of a sequence of repeating units with a regular spatial arrangement. Strictly speaking, therefore, the molecular vibrations of the whole polymer molecule should be considered for the analysis of the absorption bands. Nevertheless, the normal modes of the phenyl group and the skeletal chain may be analyzed separately for the sake of simplicity. Comparing the spectrum of the isotactic polystyrene with that of the atactic one, most of the absorption bands associated with the phenyl group differ from each other by a small amount and, hence, this approximation seems reasonable for our case.

Since the molecular vibrations of the phenyl groups of polystyrene and its deuterated derivatives in which the deuterium is substituted in the skeletal chain may be regarded as those of monosubstituted benzene having a point symmetry $C_{2v}$[3], the assignments of some bands of these polymers immediately can be made from the well-known results on the molecular vibrations of monosubstituted benzene. In our case, the assignments are made according to Whiffen's notaion[4]. The results are given in the last column of Table I. These bands are common to polystrene and the deutero-derivatives in wave number and dichroism. The bands assignable to the modes belonging to $A_1$ species, e. g., 1600, 1495, 1031 $cm^{-1}$ bands, and $B_1$ species, e. g., 1580, 1462 $cm^{-1}$ bands have $\sigma$ nature, and, on the other hand, $B_2$ species, e. g., 765 $cm^{-1}$ band, have $\pi$ nature. These polarization properties may be interpreted by the molecular structure determined by Natta and Corradini[5].

The $\sigma$ band which is crystallization-sensitive appears at the same wave number, 985 $cm^{-1}$, as those of polystyrene and poly-$\alpha, \beta, \beta$ $d_3$-styrene. This may be due to interactions between the phenyl groups of the neighboring molecules in the crystalline lattice.

In Fig. 3c are shown the spectra of isotactic poly-$\alpha d_1$-styrene (solid line) and isotactic polystyrene (dotted line) in the region of 650~450 $cm^{-1}$. The band at 557 $cm^{-1}$ which has been detected[6] as characteristic of the isotactic configuration of the polystyrene molecule also appears in isotactic poly-$\alpha d_1$-styrene. This band might be assigned to the v-mode coupling with the skeletal vibration.

The molecular vibrations of the skeletal chain (consisting of CH (or CD) and $CH_2$ groups) of isotactic polystyrene or isotactic poly-$\alpha d_1$-styrene may be considered as those of a one-dimensional three-fold helical chain having a point symmetry C $(2\pi/3)$[7]. From the factor group analysis it is concluded that the normal vibrations of this chain are divided into two symmetry species; A (non-degenerate) and E (doubly degenerate), and the fundamentals of the former should have $\pi$ nature and those of the latter $\sigma$ nature. In physical meanings, the symmetry species correspond to the phase differences between the vibrations of the neighboring monomer units. Therefore, the normal modes of the helix can be considered as ones composed of the basic modes of the monomer units.

As for the stretching vibrations of $CH_2$ and CH (or CD) groups and the $CH_2$ bending vibration, the normal modes under the symmetry species A have almost the same frequencies as those under E species. The observed absorption band due to each of such modes, therefore, may be considered as that consisting of two overlapping bands, one being assigned to the mode under A and another to that under E.

The polarization properties of these bands depend on the chain conformation of the polymer molecule. In the spectrum of poly-$\alpha d_1$-styrene, the band at 2923 $cm^{-1}$ (antisymmetric $CH_2$ stretching) has $\sigma$ nature and the band at 2849 $cm^{-1}$ (symmetric $CH_2$ stretching)

shows almost no dichroism. These results coincide whih Tadokoro et al.'s results on isotactic polystyrene and its several derivatives[8]. The band at 2134 $cm^{-1}$ (CD stretching) has $\sigma$ nature, and the band at 1440 $cm^{-1}$ ($CH_2$ bending) shows almost no dichroism. Dichroic ratio is expressed for a uniaxial orientation as

$$(A_{\parallel}/A_{\perp}) = 2 \cot^2 \psi$$

where $\psi$ is the angle between the transition moment accompanied with the vibration and the fiber axis.

The dichroic ratios calculated on the basis of the predicted molecular conformation are as follows; zero for $\nu_{asym}(CH_2)$, 0.78 for $\nu_{sym}(CH_2)$ and $\delta(CH_2)$, and 0.27 for $\nu$(CD). The results well fit the polarization properties of these bands.

As for the deformation vibrations of $CH_2$ and CH (or CD) groups except $\delta(CH_2)$, the frequencies of the normal modes under A species, in general, differ from those under E. Since the relative intensity of each fundamental of these modes depends on the chain conformation of the polymer molecule, the assignments of some bands, therefore, may be made from the polarization properties and the relative intensities of the bands. Further, the changes in spectrum on deuteration give us some additional information for this purpose. On the basis of the molecular structure of isotactic polystyrene, it seems reasonable that relatively large intensities are expected for the banbs assignable to the deformation of CH (or CD) under E, $\delta$(CH)E ($\delta$(CD)E), the wagging of CH (or CD) under A, w(CH)A (w(CD)A), the rocking of $CH_2$ under E, r($CH_2$)E, the wagging of $CH_2$ under A, w($CH_2$)A, and the stretching of the skeletal carbon atoms under A, $\nu$(CC)A.

**2. Bands in the Region of 1400~1180 $cm^{-1}$.** —In this region appear the bands which have been considered by Tadokoro et al. as characteristic to the helical structure of polystrene.

The $\sigma$ band at 1364 $cm^{-1}$ of isotactic polystyrene disappears on deuteration, and the corresponding $\sigma$ band of similar intensity appears at 1334 $cm^{-1}$ in poly-$\alpha d_1$-styrene. This fact may support the assumption that the band at 1364 $cm^{-1}$ is mainly due to $\delta$(CH)E. Whether the 1334 $cm^{-1}$ band may be assigned to $\delta$(CD)E is still in question, for there is a possibility of the appearance of the band associated with the phenyl group at this position.

The 1297 $cm^{-1}$ band of isotactic polystyrene appears also in isotactic poly-$\alpha d_1$-styrene, but not in the trideutero-derivative. Therefore, this band may be assigned to w($CH_2$)A.

In the spectrum of isotactic polystyrene, there are three bands, i. e., 1195 ($\pi$), 1185 ($\pi$) and 1180 $cm^{-1}$ ( ? ) bands in the vicinity of 1180 $cm^{-1}$. The two $\pi$ bands disappear in isotactic poly-$\alpha d_1$-styrene. Since the CC stretching band and the CH wagging band are expected to be observed in this region, it seems reasonable to presume that one of them is due to $\nu$(CC)A and another is to w(CH)A. The following facts may be cited to support the assignments of $\nu$(CC)A to the 1185 $cm^{-1}$ band and w(CH)A to the 1195 $cm^{-1}$ band. (1) The 1195 $cm^{-1}$ band appears in isotactic poly-$\beta d_1$-styrene.[9] (2) The 1183 $cm^{-1}$ band of poly-$\alpha d_1$-styrene shows a remarkable $\pi$ nature. Although a band assignable to the a-mode ($A_1$) of the phenyl group is expected to appear in the vicinity of 1180 $cm^{-1}$, the 1183 $cm^{-1}$ band could not be assigned to this mode because of its polarization property. Therefore, this may be due to the overlapping of the CC stretching mode and the a-mode.

The weak $\pi$ band appears at 1275 $cm^{-1}$ on deuteration. This may be due to the CD deformation. The weak $\pi$ band at 960 $cm^{-1}$ which appears on deuteration may be assigned to w(CD)A.

**3. Other Bands.** — Remarkable changes in the spectrum on deuteration are observed in the regions of 1085~1040 $cm^{-1}$ and 920~810 $cm^{-1}$. While the atactic polystyrene band at 1070 $cm^{-1}$ splits into two $\sigma$ bands at 1080 and 1048 $cm^{-1}$, the corresponding bands of isotactic poly-$\alpha d_1$-styrene appear at 1084 $cm^{-1}$ and 1072 $cm^{-1}$. It seems reasonable to assume these bands as associated rather with the characteristics of the helical polymer chain themselves than with the interaction between the neighboring molecules in the crystalline lattice, for these bands do not disappear even at molten state. From the fact that the bands corresponding to them do not appear in some ring-substituted derivatives, e. g., poly-*p*-deutero-styrene[8] or poly-*p*-halogeno-styrenes[10], these may be due to the coupling of a vibrational mode of the phenyl group and that of $CH_2$ or CH (or CD).

Corresponding to the bands of isotactic polystyrene at 920 ($\sigma$), 910 (no dichroism) and 898 ($\pi$) $cm^{-1}$ which are very sensitive to the crystallization degree of the sample, the $\pi$ band and the band showing almost no dichroism appear at 891 $cm^{-1}$ and 910 $cm^{-1}$

respectively in isotactic poly-$\alpha d_1$-styrene. The band at near 910 $cm^{-1}$ of both polymers may be assigned to an out-of-plane deformation of CH of the phenyl group (probably i-mode) since the corresponding band appears also in poly-$\alpha$, $\beta$, $\beta d_3$-styrene. The assignments of the other two bands are left uncertain for the present.

## Summary

In Table I are given the results of discussions described above on the assignments of the absorption bands.

The bands characteristic to the isotactic polymers, i. e. the bands appearing in the region of 1400~1180 $cm^{-1}$ or in the vicinity of 1070 and 900 $cm^{-1}$, are proved as associated with the $CH_2$ and CH groups.

To make assignments of the bands more precisely, the studies are in progress on the infrared spectra of the other several deuterated derivatives, such as poly-$\beta d_1$-, poly-$\alpha$, $\beta d_2$ and poly-$\beta$, $\beta$ $d_2$-styrenes.

# *On the Infrared Spectra of Crystalline Poly-p-fluorostyrene*

By Masamichi KOBAYASHI, Kazuo NAGAI and Eiichi NAGAI*

(Received April 30, 1960)

During the last few years, many isotactic vinyl polymers have been obtained from various ring-substituted styrene monomers with Ziegler type catalysts[1]. Most of them crystallize with helical molecular conformation similar to that of isotactic polystyrene, but the pitches of the helixes are different from each other depending on the size, the site and the number of substituents. For instances, while poly-*o*-fluorostyrene crystallizes in three-fold helix with the identity period of 6.65 Å, but poly-*p*-fluorostyrene in four-fold helix with the period of approximately 8.3 Å[1]. Further, it has been noticed by Murahashi et al.[2] that the polymers of *p*-methyl, *m*-methyl and *p*-trimethylsilyl styrene prepared with Ziegler catalyst have larger fiber periods of 12.9, 57 and 60.4 Å, respectively.

Recently, from the infrared spectroscopic studies on several isotactic polymers, Tadokoro et al.[3] found that the characteristics of helical structure of the polymers would be indicated in common by the infrared dichroisms of the several absorption bands, especially of the stretching vibrations of the $CH_2$ groups. Keeping in mind their findings, we measured the infrared spectra of crystalline poly-*p*-fluorostyrene with an aim to find in what respects they would reflect the characteristics of the helical structure of its own.

As a result, it was found that the dichroic ratios of the bands, especially those assigned to the stretching vibrations of $CH_2$ groups differed from those of polystyrene.

To obtain a theoretical ground for this fact, we calculated the dichroic ratios of the bands associated with $CH_2$ and CH groups, assuming the polymer chain to have a four-fold helical structure allowed for the observed fiber period.

On the other hand, we analyzed the infrared spectrum of the polymer under the assumption that they, in an approximation, may be divided into two parts, one being associated with the side group and another with the skeletal chain. The molecular vibrations of the former were analyzed in terms of $D_{2h}$ symmetry and those of the latter in terms of $C(\pi/2)$ symmetry.

## Experimental

*p*-Fluorostyrene (4 g.) prepared by an usual method was polymerized in *n*-heptane at 70°C for 10 hr. using triethyl aluminum (0.53 g.)+titanium tetrachloride (0.18 g.) as a catalyst in a sealed tube. The solid product was washed with hot methanol and then boiled in water to change the organometallic compounds contaminated in the polymer into insoluble oxides. The white polymeric substance was dissolved in boiling xylene and the

solution was filtered. The gelatinous precipitate separated from the filterate kept at room temperature was dried after centrifugation.

To gain a high degree of crystallinity, the polymer film cast from the toluene solution was subjected to heat-treatment at 160°C for 1 hr. in glycerol. It had the density of 1.23 and melting point of 240°C. The oriented film for measurements of the polarized spectrum was made by drawing it to five times the length of the original in boiling water.

The infrared measurements were made in the region of 3500~400 $cm^{-1}$ using Hilger H 800 and Perkin Elmer Model 21 I. R. spectrometers; the former was equipped with the polarizer consisting of a set of six selenium films, each approximetely 5 $\mu$. thick. The amorphous polymer for comparison was prepared with benzoyl peroxide as a catalyst.

## Experimental Results

**X-ray Diagram.** — In Fig. 1 is illustrated the X-ray fiber diagram of the stretched film of crystalline poly-*p*-fluorostyrene (abbreviated to PFS). The measured identity period along the fiber axis was 8.31 Å being similar value reported by Natta et al.[1] This value assumes that the polymer chain is of isotactic configuration and takes four-fold helix in the crystalline regions. The calculated angles

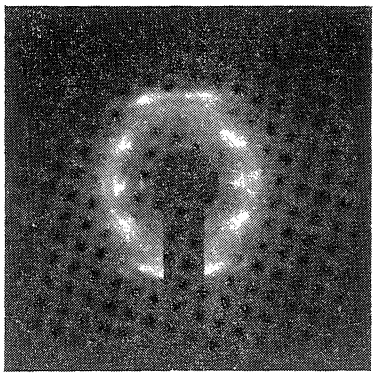

Fig. 1.

of internal rotation of the chain about the C–C bonds with which the helix is formed will be presented later.

**Infrared Spectra.**—In Fig. 2 are shown the spectra infrared in the region of 3500~400 $cm^{-1}$ of atactic and isotactic PFS together with that of the latter measured at molten state.

In Fig. 3 are shown the polarized spectra of isotactic PFS in the region of 3500~650 $cm^{-1}$.

The wave numbers, the dichroisms and the relative intensities of the absorption bands are given in Table I.

## Discussions

In this paper the molecular vibractions of the polymer molecule with four-fold helical structure are analyzed following the same way as described in the previous paper[4] on isotactic poly-$\alpha d_1$-styrene; the vibrations of the side group and the skeletal chain are considered separately.

**Vibrational Modes of the Side Group.** — The molecular vibrations of the side group of PFS correspond to those of *p*-disubstituted benzene. The data useful for our study have

4) M. Kobayashi, to be published in this Bulletin.

already been published. Freguson et al.[5] and Tobin[6] have made assignments of the absorption bands of *p*-fluorotoluene and *p*-dichlorobenzene respectively. In applying their results to our aim, it is assumed that the analysis using a point group of $D_{2h}$ woluld be preferable, if it is taken into account that fluorine atom and CH group attached to the para position of benzene nucleus are similar in mass.

Symmetry species, irreducible representations, numbers of normal modes and selection rules for the point group $D_{2h}$ are given in Table II. The selection rules can not be applied rigorously in our case, since the two substituents at the para positions will not suffer the same transition moment. As a result, the fundamentals under all species would become Raman active and those except $A_u$ and $B_{1g}$ infrared active. Referring to the assignments of the bands of *p*-fluorotoluene given by Freguson, we selected out from the spectrum of PFS the bands which might be assigned to the vibrational modes of the side group. They are given in Table III.

It is, of course, anticipated that they will be more or less under the influences of the crystalline field. In fact, considerable differences are observed in some of the bands before and after crystallization or on melting. For example, the band at 1056 $cm^{-1}$ assigned to CH in-plane deformation ($B_{3u}$) becomes sharper and the intensity of the band at 932 $cm^{-1}$ assigned to CH out-of-plane deformation ($B_{3g}$) increases on crystallization.

**Vibrations of the Skeletal Chain.** — Since the molecule of isotactic PFS has four-fold helical structure in the crystalline region, the molecular vibrations of the skeletal chain may be accounted for by using the factor group $C(\pi/2)$[7]. From the result of the factor group analysis, the normal modes are divided into three symmetry species; A (non-degenerate), B (non-degenerate) and E (doubly degenerate) species. Symmetry species, irreducible representations, selection rules and numbers of the normal modes are given in Table IV. In the calculation of the numbers of the normal modes, the side group attached to the skeletal chain is taken as a mass point. The modes under A and E are infrared active and ones under B are inactive. The fundamentals under

* The 1300 $cm^{-1}$ band observed may be due mainly to $w$ ($CH_2$).

A and E should exhibit parallel ($\pi$) and perpendicular ($\sigma$) dichroisms respectively. Physically, the symmetry species A, E and B mean that the neighboring monomer units constituting the helix vibrate with a definite phase difference of 0, $\pm\pi/2$ and $\pi$, respectively.

**Infrared Dichroism.** — Bearing in mind the fact noted in the introduction that infrared dichroisms of several bands, especially of those due to the $CH_2$ stretching vibrations, have been detected as reflecting helical structures of the isotactic polymers, the infrared dichroisms of the stretched film of isotactic PFS were measured (see Fig. 3). It was demonstrated that the 2849 $cm^{-1}$ band assigned to the $CH_2$ symmetric stretching exhibited a considerable $\pi$ nature and the 2924 $cm^{-1}$ band assignable to the $CH_2$ antisymmetric stretching showed a slight $\sigma$ nature. These facts do not coincide with Tadokoro et al.'s results on isotactic polystyrene and others; the former band shows almost no dichroism and the latter a considerable $\sigma$ nature.

This discrepancy may be attributed to the reason that the plane of the methylene group in the helix of PFS is inclined to the fiber axis in a different way from that of isotactic polystyrene. In other words, this is attributed to the difference in conformation of the skeletal carbon chain between them.

To gain a concrete ground for this, we calculated the theoretical dichroic ratios ($A_{\parallel}/A_{\perp}$) of the absorption bands. In doing this, however, precise knowledge about the conformation of the molecule of PFS is needed. For this purpose, the data available at present is the observed fiber period of the polymer. A helical structure of an isotactic polymer which gives a definite identity period is determined by the angles of internal rotation of the chain elements about the C–C bonds, provided that the length of C–C bond and the bond angle are kept at constant.

From the mathematical calculations presented in the appendix, we can search for the angles of internal rotation which will fulfill the conditions that the helix of PFS has the observed identity period of 8.31 Å and contains four monomer units in one pitch. In Table V is given the relation between the angles of internal rotation ($\theta_1$ and $\theta_2$) and the calculated identity period, $R$. In this table $\nu_x$, $\nu_y$ and $\nu_z$ are the components of the unit vector of the fiber axis in an internal Cartesian coordinate. Using them, calculation of the dichroic ratio may be made.

$\theta_1$ (or $\theta_2$) is the angle with which a given bond is rotated from the trans position with the clockwise direction taken as plus when seen from the lower indexed carbon atom (see Fig. 4). If $\theta_1=0°$ and $\theta_2=120°$, $R$ will give an identity period 6.65 Å of the three-fold helix (isotactic polystyrene).

The most reasonable values of $\theta_1$ and $\theta_2$ for PFS will be present between $-10°$ and $-12°$ and between 94° and 95° respectively, provided

* Assuming C-C bond length of 1.54 Å and C-C-C bond angle of 116°.
** The observed fiber period of PFS is 8.31 Å.

that the C-C-C bond angle takes the same value as that of polystyrene, 116°.

Dichroic ratio is expressed for a uniaxial orientation as follows;

$$A_{\parallel}/A_{\perp}=2\cot^2\varphi$$

where $\varphi$ is the angle between the transition moment and the fiber axis. If a unit vector $\boldsymbol{m}$ of a transition moment accompanied with a vibrational mode of the $CH_2$ group is defined by the components $m_x$, $m_y$ and $m_z$ in the Cartesian system ($x_i$, $y_i$, $z_i$), it follows that

$$\cos\varphi=\boldsymbol{\nu}^{\top}\cdot\boldsymbol{m}=\nu_x m_x+\nu_y m_y+\nu_z m_z$$

On the other hand, if a unit vector $\boldsymbol{m}'$ of a transition moment accompanied with a vibrational mode of the CH or the phenyl group is defined by the components $m'_x$, $m'_y$ and $m'_z$ in the Cartesian coordinate ($x_{i+1}$, $y_{i+1}$, $z_{i+1}$), the corresponding expression is

$$\begin{aligned}\cos\varphi&=\boldsymbol{\nu}^{\top}\cdot\boldsymbol{A}_1\boldsymbol{m}'\\&=\nu_x(m'_x\cos\omega+m'_y\sin\omega)\\&+\nu_y(m'_x\sin\omega\cos\theta_1\\&-m'_y\cos\omega\cos\theta_1+m'_z\sin\theta_1)\\&+\nu_z(m'_x\sin\omega\sin\theta_1\\&-m'_y\cos\omega\sin\theta_1+m'_z\cos\theta_1)\end{aligned}$$

where $\boldsymbol{A}_1$ is the matrix of the orthogonal transformation defined in the appendix.

Using the values of $\nu_x$, $\nu_y$ and $\nu_z$, the dichroic ratios of the absorption bands due to the vibrational modes of the $CH_2$ and CH groups were calculated. The results are given in Table VI.

It is shown as expected that they depend on the angles of internal rotation, $\theta_1$ and $\theta_2$. The changes in dichroic ratio of the bands due to the $CH_2$ stretching vibrations are of importance by reason of that described above. The dichroic ratios of the $\nu_{sym}$ ($CH_2$) band and the $\nu_{asym}$ ($CH_2$) band increase with $\theta_2$.

TABLE VI. THE CALCULATED DICHROIC RATIOS FOR FOUR-FOLD HELICAL POLYMER

| Vibrational mode | $\theta_1=0°$ | $\theta_1=-10°$ | $\theta_1=-12°$ |

| $\nu_{asym}$ ($CH_2$), $r$ ($CH_2$) | 0 | 0.013 | 0.019 |
| $w$ ($CH_2$) | 5.122 | 3.626 | 3.422 |
| $\delta$ (CH) | 0 | 0.013 | 0.019 |
| $w$ (CH) | 5.122 | 3.626 | 3.422 |

Since when $\theta_1=0$, the calculated values do not depend on the number of monomer unit in one pitch provided that the bond angle is kept at constant ($\theta_2=120°$ for three-fold helix, $\theta_2=90°$ for four-fold helix), the values for $\theta_1=0°$ may be regarded as those of isotactic polystyrene. Therefore, the results well explain the differences between PFS and polystyrene in polarization property of the bands due to the $CH_2$ stretching vibrations.

Although the coincidence between the observed property and the predicted value of dichroism of the $\nu_{asym}$ ($CH_2$) is yet qualitative, it would be accepted as correct if we take into account of the contribution from the chain segments randomly oriented in the amorphous regions.

**Absorption Bands Characteristic to the Helical Structure of PFS.** —As in the cases of polystyrene and its several derivatives, the bands characteristic of the helical structure (alternate sequence of trans and gauche conformations) of the polymer molecule are observed in the spectrum of isotactic PFS. They do not disappear even at molten state and are assumed to be associated mainly with the deformational vibrations of the $CH_2$ or CH group or the skeletal modes.

The band at near 1450 $cm^{-1}$ may be ascribed to the $CH_2$ bending ($\delta(CH_2)$). Using the differential method it was made clear that this band consisted of two bands at 1454 and 1448 $cm^{-1}$, having $\sigma$ and $\pi$ nature respectively, and the former might be assigned to $\delta(CH_2)E$ and the latter to $\delta(CH_2)A$.

The five bands at 1361 ($\sigma$), 1336 ($\pi$), 1309 ($\sigma$), 1300 ($\pi$) and 1191 ($\pi$)$cm^{-1}$ of isotactic PFS may correspond to the bands which have been detected by Tadokoro et al. as characteristic of the helical structure of isotactic polystyrene and others. Measurements of the dependence of the spectrum on temperature showed that with increasing temperature the band at 1336 $cm^{-1}$ decreased its relative intensity and disappeared at molten state, on the other hand, the other four bands were hardly affected by temperature change. Then, the four bands may be considered as indicating rather the characteristics of the polymer molecule itself than the interactions of neighboring molecules in the crystalline lattice.

On the basis of the results on the assignments of the bands characteristic of isotactic polystyrene[4], the assignments of these bands may be made as follows; the 1361 $cm^{-1}$ band is assigned to the CH deformation under the E species ($\delta$ (CH)E), the 1300 $cm^{-1}$ band to the $CH_2$ wagging under the A species (w

$(CH_2)A$), the 1191 $cm^{-1}$ band to the CC stretching under the A species ($\nu$ (CC)A). The 1309 $cm^{-1}$ band is still unassigned.

The difference between isotactic PFS and atactic one in spectrum are observed also in the region of 690~750 $cm^{-1}$. The band at 738 $cm^{-1}$ of isotactic PFS has smaller intensity than the corresponding band at 748 $cm^{-1}$ of atactic one. This fact remains even at molten state. The $\sigma$ band at 708 $cm^{-1}$ of isotactic PFS decreases its intensity with increasing temperature, on the other hand, the band at 694 $cm^{-1}$ shows the reverse change. Although the $CH_2$ rocking mode is anticipated to be ovserved in this region and, from polarization property, the 708 $cm^{-1}$ bond is assumed to be assigned to it, the precise assignment to date is open to question.

The results of the discussions on the assignments of the absorption bands are given in the last column of Table I.

## Appendix

**The Geometrical Structures of Polymers with Helical Structure.** — Spatial configuration of a vinyl polymer is determined primarily by angles of internal rotation of C-C bonds. If the spatial position of each monomer unit in the helix is equivalent, the conformation of the polymer chain is defined by two angles of internal rotation as described below. The internal Cartesian coordinates are defined as shown in Fig. 4. The matrix which transforms the coordinate from $(x_{i+1}, y_{i+1}, z_{i+1})$ to $(x_i, y_i, z_i)$ system, or from $(x_{i+2}, y_{i+2}, z_{i+2})$ to $(x_{i+1}, y_{i+1}, z_{i+1})$ system is represented by $\boldsymbol{A}_1$ (or $\boldsymbol{A}_2$);

$$\boldsymbol{A}=\begin{pmatrix}\cos\omega & \sin\omega & 0\\ \sin\omega\cos\theta & -\cos\omega\cos\theta & \sin\theta\\ \sin\omega\sin\theta & -\cos\omega\sin\theta & -\cos\theta\end{pmatrix}$$

where $\theta=\theta_1(\boldsymbol{A}_1)$ or $\theta=\theta_2(\boldsymbol{A}_2)$, and $\omega$ is the supplement angle of C-C-C and angle.

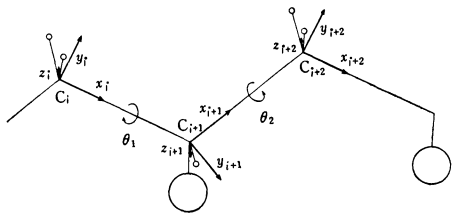

Fig. 4. Internal coordinates for vinyl polymer.

If the unit vector of the fiber axis in $(x_i, y_i, z_i)$ system is defined by $\boldsymbol{\nu}$ $(\nu_x, \nu_y, \nu_z)^\top$, the following relation is introduced;

$$\boldsymbol{\nu} = \boldsymbol{A}_1\boldsymbol{A}_2\boldsymbol{\nu}$$

Since $\boldsymbol{A}$'s are matrixes of orthogonal transformation,

$$(\boldsymbol{A}_1{}^\top-\boldsymbol{A}_2)\boldsymbol{\nu} = \boldsymbol{0}$$

Then, it follows that

$$(\cos\theta_1-1)\nu_y+(\sin\theta_1)\nu_z = 0 \quad (1)$$

$$\sin\omega(1-\cos\theta_2)\nu_x+\cos\omega(\cos\theta_2-\cos\theta_1)\nu_y - (\cos\omega\sin\theta_1+\sin\theta_2)\nu_z = 0 \quad (2)$$

$$-(\sin\omega\sin\theta_2)\nu_x+(\sin\theta_1+\cos\omega\sin\theta_2)\nu_y + (\cos\theta_2-\cos\theta_1)\nu_z = 0 \quad (3)$$

As $\boldsymbol{\nu}$ is unit vector

$$\nu_x{}^2+\nu_y{}^2+\nu_z{}^2 = 1 \quad (4)$$

If the fiber period of $n$-fold helix is $R$,

$$R/n = \boldsymbol{\nu}^\top\cdot(\boldsymbol{b}+\boldsymbol{A}_1\boldsymbol{b})$$

where

$$\boldsymbol{b} = (b, 0, 0)^\top$$

$b$ is the CC bond length. Therefore,

$$R/n = b\{(1+\cos\omega)\nu_x+(\sin\omega\cos\theta_1)\nu_y + (\sin\omega\sin\theta_1)\nu_z\} \quad (5)$$

To construct $n$-fold helix, the following condition must be satisfied; the angle between the projection of $\overline{C_iC_{i+1}}$ to the plane perpendicular to the fiber axis and the one of $\overline{C_{i+2}C_{i+3}}$ to the same plane must be $2\pi/n$. Then,

$$(\boldsymbol{A}_1\boldsymbol{A}_2\boldsymbol{1}\times\boldsymbol{\nu})\cdot(\boldsymbol{1}\times\boldsymbol{\nu}) = \cos(\pi-2\pi/n)$$

Then,

$$\cos^2\omega+\sin^2\omega\cos\theta_2 -\{\nu_x{}^2+\nu_x\nu_y\sin\omega\sin\theta_1\sin\theta_2 -\nu_x\nu_z(1+\cos\theta_1)\sin\omega\sin\theta_2\} = \cos(n-2)\pi/n \quad (6)$$

Provided that fiber period, C-C-C bond angle, C-C bond length and number of monomer units in one pitch of the helix are known, it is possible to calculate the angles of internal rotation, $\theta_1$ and $\theta_2$, using the Eqs. 1—6.

In Table V are given the results of the calculation for four-fold helix. In this calculation, the C-C bond length of 1.54 Å and the C-C-C bond angle of 116° are assumed.

# *Neutron Activation Analysis of Halogens in High-Purity Silicon*

By Tadashi NOZAKI, Toshi KAWASHIMA, Hideo BABA and Hidemaro ARAKI

(Received May 6, 1960)

Extreme purification is of vital importance when silicon is used as a semiconductor material, and many papers treating many kinds of trace impurity in high-purity silicon have been published. However, neither the method of the determination nor the behavior of halogens in a given material has been studied enough. Previously, we reported[1] on the neutron activation analysis of iodine in silicon. In this paper, a method for simultaneous determination of chlorine, bromine and iodine in one sample is presented with some results.

Fusion of the neutron-irradiated silicon with potassium hydroxide containing potassium iodide as carrier was proved suitable for decomposing the sample in the determination of iodine. A similar fusion with alkali chloride, bromide and iodide as carrier should serve satisfactorily for their simultaneous determination. On such fusion under a reducing atmosphere, both chlorine and bromine in the sample will be converted into chloride and bromide respectively. Even if they were present in other forms than halide ions, they would be converted into chloride and bromide, when the basic cake is dissolved in an aqueous sulfuric acid in the presence of a large excess of iodide. Although perchlorate is not readily reduced to chloride on such a treatment, the formation of perchlorate under the given condition is least probable. Thus the carriers should work satisfactorily.

When a sulfuric acid solution containing the three halides was distilled in the presence of chromium(VI) oxide, the following three fractions of the distillate were successively obtained: (1) light brown solution containing bromine, (2) almost colorless solution containing only a small amount of halogen, (3) faintly yellow solution containing chlorine and hydrogen chloride. Addition of a sufficient quantity of oxalic acid and some water into the residual solution resulted in the reduction of the iodate to iodine. This was easily distilled, purified and converted into silver iodide for $\beta$-ray counting.

The bromine must be carefully purified. This is because after neutron irradiation of natural bromine, three radioactive nuclides of bromine are present as shown in Table I. The radiochemical purity of the bromine sample, however, can be checked precisely neither from its decay curve nor from the $\gamma$-ray spectrum. The first fraction, containing some chlorine and perhaps a trace of iodine too, was submitted, before being converted into silver bromide for counting, to a further purification, whose usefulness was checked by a tracer technique using $^{36}Cl$ and $^{131}I$. On the

TABLE I. RADIOACTIVE NUCLIDES OF THE HALOGENS FORMED BY THE NEUTRON IRRADIATION

| Nuclide | Half-life | $\beta$-Ray energy (MeV.) | $\gamma$-Ray energy (MeV.) | *Activity formed (dpm) |
|---|---|---|---|---|

* Just after 1 hr's irradiation of 1 g. of a natural halogen under a thermal neutron flux of $6\times10^{11}$ $n/cm^2$ sec.

1) T. Nozaki et al., This Bulletin, 33, 320 (1960).

other hand, chlorine in the third fraction was converted into silver chloride for counting without further purification, for it involves some difficulty and is time-consuming, and there is no possible nuclide that enters the silver chloride and decays with a similar half-life emitting an energetic $\gamma$-ray. The silver chloride was proved to be radiochemically pure, as far as the distillation was carried out with care to prevent contamination with radioactive silica.

When the sample contains by far the least amount of iodine amidst the three halogens, there is another preferable process, which consists of the distillation of iodine after the treatment of the fused cake as reported previously and the separation of bromine and chlorine by the method indicated above. The two complete processes require nearly equal time, with a good yield and radiochemical purity.

Unfortunately, fluorine can not be determined by a similar technique because of the lack of a suitable radioactive nuclide formed by neutron irradiation.

## Experimental

*Sample.*—All of the silicon samples were of transistor grade, purified by the chloride process (in U. S. A.), by the iodide process (in the Electrical Communication Laboratory) or by an unknown method (in Europe). Many other impurities in them were determined by emission spectroscopy or by neutron activation analysis with an irradiation under a higher flux and for a longer period, the results indicating their high purity. In most cases, two portions of the same sample were analyzed, each being 0.5 to 1 g.

*Irradiation.*—The samples enveloped in thick polyethylene sheets were irradiated in a water boiler type reactor, (Japan Research Reactor 1) for an hour under a neutron flux of about $6\times10^{11}$ $n/cm^2$ sec., placed side by side with the radioactivation standard of ammonium chloride, ammonium bromide and potassium iodide, and taken out swiftly through a neumatic tube.

*Chemical Separation.*—The irradiated samples were etched with a mixture of hydrofluoric and nitric acid, to avoid possible surface contamination pulverized, weighed and fused with potassium hydroxide (10 to 15 g.) kept just above its melting point and containing a known ammount of sodium chloride, potassium bromide and potassium iodide (each 5 to 10 mg.) as carriers. The fused cake was dissolved in sulfuric acid (2 : 3, 100 ml.) containing a small quantity of sodium sulfite (about 0.01g.). The solution was transferred into a crooked neck distillation flask (in order to protect the distillate from contamination by the radioactive silicon) and distilled after the addition of chromium(VI) oxide (10 g.).

The bromine distilled out in the first few minutes. The colored distillate was caught in an aqueous sodium sulfite (25 ml. of 10 g./l. solution) containing sodium chloride and potassium iodide (each a few mg.), oxidized by adding concentrated phosphoric acid (10 ml.) and potassium permanganate (20 ml. of 10 g./l. solution), and the bromine was extracted with carbon tetrachloride (20 ml.), back-extracted with hydroxylamine (0.1 g.) in nitric acid (1 : 100, 20 ml.) and converted into silver bromide.

A tracer study to prove the usefulness of this purification was carried out preliminarily by the use of $^{36}Cl$ and $^{131}I$. On oxidation with permanganate, no detectable $^{36}Cl$ (less than 1/5,000) entered the organic phase, but a trace of iodine did when the treatment was performed with less care. However, the iodine was removed completely (to less than 1/5,000) by back-extraction, for a solution of hydroxylamine in dilute nitric acid reduces molecular bromine to bromide and oxidizes iodide to iodine.

The distillation was continued, and after several minutes from the disappearence of the bromine color when a faint color of chlorine became recognizable by a careful observation, the distillate was introduced into an aqueous sodium sulfite (10 g./l. 25 ml.). When the color of chlorine in the distillate disappeared, the chloride was converted into silver chloride without further purification. It was somewhat preferable to carry out the distillation of bromine with a smaller amount (1 g.) of chromium(VI) oxide and to add a larger amount (10 g.) before the distillation of chlorine.

When the determination of iodine was necessary, it was attained by adding a sufficient quantity (more than 30 g.) of oxalic acid and some water (30 ml.) into the residual solution, distilling the liberated iodine and converting it into silver iodide after the purification as mentioned previously[1].

Each silver halide was filtered off with a glass filter (No. 3), washed with nitric acid (1 : 100, 50 ml.), water, ethanol and ether, and submitted to counting and weighing. The time required for the chemical process was less than an hour for bromine, about one hour for chlorine and 1.2 hr. for iodine, with a yield exceeding 50%.

*Radioactivation Standard.*—Each of the irradiated bromide and iodide was dissolved in water containing a known amount of the same halide as carrier, and converted into silver bromide and iodide after being purified by the oxidation, extraction and back-extraction. On the other hand, silver chloride was precipitated without purification.

*Counting.*—A simple G-M counter of an end window type was used in all cases. For chlorine, a scintillation counter with a large sodium iodide crystal ($4''\times4''$) and a single channel analyzer was also used (the region between 1.8 MeV. and 3.5 MeV.). More precise determination could be done by the latter, but the efficiency of the former was somewhat higher. The decay curve of the chlorine measured by a G-M counter agreed well with that of the standard sample and the theoretical curve. The agreement of the decay curve of the bromine and iodine with that of the corresponding standard was complete. For lowering the detection limit, use of a $2\pi$ counter was also examined, and its efficiency was found to be about five times higher

than that of the G-M counter with the sample kept as near as possible.

## Results and Discussion

Some of the results are shown in Tables II and III. It is natural that a silicon purified by the chloride method contains a trace of chlorine and that purified by the iodide method contains iodine. On the other hand, it should be an interesting fact that most of the high-purity silicons contain two other halogens too, indicating a tendency that the less the concentration of a halogen becomes, the greater the persistency with which it remains in the silicon. Silicon powder obtained by the thermal decomposition of silicon tetraiodide usually contained several ppm of iodine. The iodine content could be lowered down to about 0.3 ppm by a simple technique (i. e. fusion under an argon flow or segregation). Table III indicates the segregation of iodine in a single crystal of silicon about 7 cm. long prepared by pulling it from the melt at a rate of 1 cm. per min. Here, it is also shown tha the iodine content decreased fairly rapidly down to 0.3 to 0.2 ppm. However, a high-purity silicon prepared by the iodide process and purified by 30 times' zone refining still contained nearly the same amount of iodine. On the other hand, a determination showed that heating in a hydrogen atmosphere seems to be effective to reduce the iodine as low as several hundredths ppm.

TABLE II. HALOGEN CONTENT OF HIGH-PURITY SILICONS

| Method of purification | Halogen content (ppm) | | |
|---|---|---|---|
| | Cl | Br | I |
| Chloride method | 2.2 | 0.18 | 0.15 |
| Iodide method | 0.2 | 0.05 | 0.38 |
| (Unknown) | <0.15 | <0.02 | 0.17 |

TABLE III. SEGREGATION OF IODINE

| Location (centimeter from the tail) | 0.3 | 1.6 | 2.9 | 4.8 | 6.2 |
|---|---|---|---|---|---|
| Iodine content (ppm) | 1.5 | 0.94 | 0.83 | 0.32 | 0.22 |

As the result, a trace of any of the three halogens remains in a high-purity silicon quite persistently after many physical purifications, and the persistency increases with the decrease of its concentration. The authors are wishing to elucidate this reason.

When it is assumed that an activity of 150 cpm at the initiation of counting is essential for precise identification of the nuclide, the detection limit is $1.5\times10^{-7}$ g., $1.5\times10^{-8}$ g. and $3.0\times10^{-8}$ g. for chlorine, bromine and iodine respectively by the use of a G-M counter and under the conditions described above. Use of a $2\pi$ counter could lower the limit down to one-fifth of the above values.

## Summary

A trace quantity of chlorine, bromine and iodine was determined simultaneously by neutron activation analysis. By careful distillation of a solution containing the alkali-fused silicon, chromium(VI) oxide and sulfuric acid, bromine and chlorine were distilled out separately, leaving iodine in the residual solution, which was then distilled out after adding oxalic acid.

Most kinds of high-purity silicon contained more than 0.1 ppm of a halogen, which was used in the course of its purification process, and also two other halogens, though of a smaller quantity.

# *Long-chain Phosphates. I. Reactions of Solid Potassium Kurrol Salt with Solutions of Various Metal Salts*

By Shigeru OHASHI and Kazuo YAMAGISHI

(Received May 12, 1960)

Long-chain potassium metaphosphate, $(KPO_3)_n$, which is called potassium Kurrol salt, can be readily prepared by dehydrating potassium dihydrogen orthophosphate. It is a well-known fact[1] that potassium Kurrol salt is not easily soluble in pure water, but dissolution takes place in dilute solutions of salts of alkali metals other than potassium to give a highly viscous solution which is characteristic of a linear polymer of a high molecular weight. Thilo et al.[2,3], investigated the reactions between solutions of potassium Kurrol salt and those of various metal ions. It is the purpose of this paper to present some information on the behavior of potassium Kurrol salt in a solid state toward solutions of various metal ions. Solid potassium Kurrol salt reacts with solutions of certain multivalent cations to give gummy substances. The authors investigated particularly in details a reaction of potassium Kurrol salt with nickel ion, since the colored substance produced allowed easy observation upon the process of the reaction. The results indicated that the potassium ion in solid potassium Kurrol salt can be replaced by the nickel ion in a solution through a cation-exchange process. In the course of this investigation Weiss and Michel[4] found that reactions of solid potassium Kurrol salt with solutions of various alkylammonium ions can be regarded as a cation-exchange process.

## Experimental

**Preparation of Potassium Kurrol Salt.**—Potassium Kurrol salt is usually prepared by dehydrating potassium dihydrogen orthophosphate. Pfanstiel and Iler[5] investigated the effect of minute variations in the original K/P ratio on the viscosity of the solution of potassium Kurrol salt and indicated that when there is a deficiency of potassium in a starting material, cross-linking occurs between phosphate polymer chains in the resulting potassium Kurrol salt crystal. An excess of potassium in a starting material forms potassium tripolyphosphate as a separate phase. Pfanstiel and Iler[5] gave the relationship between pH of a 0.1 M solution of potassium dihydrogen orthophosphate and its K/P ratio. A 0.1M solution of potassium dihydrogen orthophosphate of Wako special grade (lot 1335) was prepared in carbon dioxide-free distilled water. The pH of the solution was 4.50. According to Pfanstiel and Iler's data the K/P ratio of the potassium dihydrogen orthophosphate was calculated to be $0.9998 \pm 0.0008$. This value means that no further adjustment of the K/P ratio is necessary for the present purpose.

In a platinum dish 156.4 g. of the potassium dihydrogen orthophosphate was dehydrated at a lower temperature than the melting point, 807°C, of potassium Kurrol salt. Then it was melted in an electric furnace at 870°C. After being kept at this temperature for 30 min., it was gradually cooled to 775°C in 3 hr. After being kept at 775°C for 25 hr., the sample was removed from the furnace and chilled by holding the lower part of the dish in water. A transparent crystalline product was prepared. According to Malmgren and Lamm's study[6,7] the molecular weight of the potassium Kurrol salt prepared in this work was presumed to be about $10^6$.

**X-ray Diffractometry.**—X-ray patterns of the potassium Kurrol salt as well as hydrated metaphosphate containing potassium and nickel and its dehydrated products were taken with Copper $K_\alpha$ radiation and a nickel filter by means of an automatic recording X-ray diffractometer, "Geigerflex", of Rigaku Denki Co., Ltd. For the potassium Kurrol salt a rotating mount was used to avoid the preferred Crientation.

**Paper Chromatography.**—Two-dimensional paper chromatography was carried out according to Karl-Kroupa's procedure[8]. Acid solvent was made by mixing 735 ml. of isopropyl alcohol, a solution of 50 g. of trichloroacetic acid in 265 ml. of water, and 2.5 ml. of concentrated aqueous ammonia. Basic solvent was made by mixing 387 ml. of isopropyl alcohol, 200 ml. of isobutyl alcohol, 408 ml. of water, and 5 ml. of concentrated aqueous ammonia. Filter papers used in this work were Toyo No. 53.

**Analytical Methods for the Determination of Phosphate, Potassium, Nickel and Other Metal Ions.**—For the determenation of phosphate, potassium, and nickel ions in a solid and an aqueous

phase obtained by the reaction of the potassium Kurrol salt with an aqueous solution of nickel sulfate, the following method was used. An aliquot of the solution was charged into an ion-exchange column of Dowex 1-X4 of chloride form and the column was washed with water. From the solution which passed through the column, the nickel ion was precipitated with dimethylglyoxime and aqueous ammonia and determined gravimetrically. After the separation of nickel the filtrate containing the potassium ion was evaporated to dryness in a platinum dish and the residue was heated at a temperature 300~320°C. Ammonium chloride and the excess of dimethylglyoxime were sublimed and the potassium was determined gravimetrically as potassium chloride. The phosphate absorbed on the column was eluted with 3N hydrochloric acid, hydrolyzed to orthophosphate by boiling, precipitated with a magnesia mixture, and determined gravimetrically as magnesium pyrophosphate. The solid phase was dissolved in 1N hydrochloric acid, evaporated to dryness, dissolved in water, and neutralized with a dilute solution of sodium hydroxide. The solution thus obtained was treated using the same procedure as in the case of the aqueous phase.

In the process of the reaction with the potassium Kurrol salt, variation of nickel ion concentration was followed by a direct colorimetric method for the nickel ion with a filter of 390 mμ. Various metal ions in aqueous phases were determined as follows: the cobalt(II) ion was determined by the tricarbonato cobalt(III) method[9], the calcium, the magnesium, and the zinc ion were by the chelatometric titration with ethylenediaminetetraacetate, the iron(II) ion was by the permanganometric titration, and copper ion by the iodometric titration. The manganese(II) ion was oxidized with silver nitrate and ammonium persulfate to permanganate, a solution of ammonium iron(II) sulfate, of a known concentration was added, and the excess of iron-(II) was titrated with a standard solution of permanganate. The iron(III) ion was reduced with zinc amalgam to iron(II) and determined by the permanganometric titration. A minute amount of condensed phosphate dissolved in the aqueous solution was determined by the colorimetry[10], after being hydolyzed to orthophosphate.

## Results and Discussion

**1. X-ray Diffraction Data of the Potassium Kurrol Salt.**—Klement and Schmid[11] took the X-ray powder diffraction photographs of potassium Kurrol salt used in his study. Both results in Klement and Schmid's and the present work indicated a good coincidence as shown in Table I. The X-ray pattern of potassium Kurrol salt was not changed by any of the following treatments: Drying at 100° to 110°C for 1 hr., washing with ethanol and ether, and drying in air after being immersed in water for 50 hr.

**2. Non-existence of Tripolyphosphate in the Potassium Kurrol Salt.**—About 0.9 g. of the pulverized potassium Kurrol salt was further ground in 100 ml. of ice-water and the suspension was filtered. By this treatment potassium tripolyphosphate, if present, can be washed out of the sample and at the same time the hydrolysis of condensed phosphate may be reduced to a negligible extent. After the filtrate was dried by the use of a freeze-drying machine, the residue was brought into a solution with 0.5 ml. of water. In a two-dimensional paper chromatogram of this solution, there was only a non-moving spot at the original point. This means that the potassium Kurrol salt did not contain any tripolyphosphate or any other shorter chain or ring phosphates and that a minute amount of the potassium Kurrol salt was brought into the solution without intense hydrolysis.

**3. Solubility of the Potassium Kurrol Salt.**—About 1 g. of the potassium Kurrol salt was

put into 1 l. of water and stirred at room temperature (20~23°C). After 1, 2, 3, and 25 hr. the phosphorus content of the phosphate in the solution were determined to be 19, 17, 20, and 23 $\gamma$ P per ml., respectively. From these values the solubility was calculated to be 0.007 ~0.009 per cent.

**4. Qualitative Observation on the Behavior of the Potassium Kurrol Salt toward Aqueous Solutions of Various Metal Ions.**—As mentioned previously, potassium Kurrol salt is dissolved in aqueous solutions of sodium salts. To 0.1 g. of the potassium Kurrol salt 10 ml. of a 0.1 M solution of each of the following sodium salts was added; acetate, bromide, carbonate, chloride, cyanate, dihydrogen orthophosphate, monohydrogen carbonate, monohydrogen orthophosphate, nitrate, orthophosphate (normal), oxalate, pyrophosphate, sulfate, and tripolyphosphate. In every case a greater part of the potassium Kurrol salt was dissolved. However, it appeared that the potassium Kurrol salt was more rapidly dissolved in the solutions of ortho-, pyro- and tripolyphosphate in comparison with the other salts.

To 0.1 g. of the potassium Kurrol salt, 10 ml. of 1, 0.5, 0.1, or 0.01 M solution of sodium chloride was added, respectively, where the ratio Na/K was 10, 5, 1, or 0.1. When the ratio was 5, the sample was most easily dissolved. When the ratio was 10, a part of the sample was converted into a gelatinous substance. Probably it was due to salting-out effect.

The results of the qualitative observation on the behavior of the potassium Kurrol salt toward solutions of various metal ions are summarized in Table II. These results were obtained when 0.1 g. of the potassium Kurrol salt was added to 10 ml. of a 0.1 M solution of the metal ion.

Table II. Reactions of potassium Kurrol salt with solutions of metal ions

| Metal ion | Reaction |
|---|---|
| $Na^+$, $NH_4^+$ | Potassium Kurrol salt is gradually dissolved. |
| $Ca^{2+}$, $Cr^{3+}$, $Ag^+$ | Potassium Kurrol salt forms a lump which has not plasticity. |
| $Mg^{2+}$, $Mn^{2+}$, $Fe^{2+}$, $Co^{2+}$, $Ni^{2+}$, $Cu^{2+}$, $Sn^{2+}$ | Potassium Kurrol salt forms a gummy substance. |
| $Al^{3+}$, $Fe^{3+}$, $Ce^{3+}$, $Hg^{2+}$, $Bi^{3+}$, $Pb^{2+}$ | Potassium Kurol salt reacts with them very slowly. |

**5. Reaction between the Potassium Kurrol Salt and Solutions of Nickel Sulfate.**—When the potassium Kurrol salt was added to a solution of nickel sulfate, the white crystalline potassium Kurrol salt was gradually converted into a green gummy substance. The absorption of nickel ion was investigated as follows. At a bottom of an Erlenmeyer flask of 300 ml., 1 g. of the ground potassium Kurrol salt was flatly placed and 200 ml. of a 0.0984 M solution of nickel sulfate was added to it. The mixture was kept at 20°C without agitation. The variation of the amounts of the nickel ion absorbed with time was determined by measuring the decrease of the nickel ion concentration in the solution. As shown by the curve A in Fig. 1,

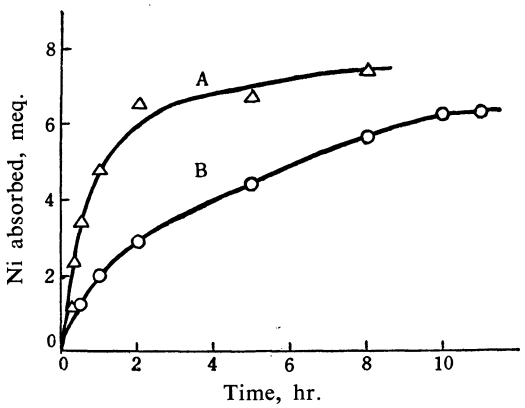

Fig. 1. The variation of the amounts of ion absorbed with time. The initial concentrations of nickel sulfate are 0.0984 M in Curve A and 0.0366 M in Curve B.

after about 8 hr. the reaction reached the equilibrium. When a 0.0366 M solution of nickel sulfate was used, the curve B in Fig. 1 was obtained by a similar experiment. In this case the reaction reached the equilibrium after about 11 hr. After the reaction was equilibrated, the solid phase was removed from the solution, washed quickly with water, and analyzed for potassium, nickel and phosphorus. The amounts of sulfate ion absorbed by the solid phase were negligibly small. The phosphorus contents in the solid phases were 8.50 mg. atom in both cases in comparison with 8.47 mg. atom which was the calculated value of phosphorus content in the initial potassium Kurrol salt. Therefore, all of the phosphorus in the initial sample were assumed to remain in the solid phase in the process of the reaction. As shown in Table III the quantity of the potassium ion which came out of the solid phase was equivalent to the quantity of the nickel ion which went into the solid phase. It was concluded that the reaction mentioned above is a kind of cation-exchange reaction. In the systems of 1 g. of the potassium Kurrol salt and 200 ml. of the 0.0984 M and 0.0366 M solution of nickel sulfate 91 and 74 per cent of potassium ion was exchanged with nickel

TABLE IV. PROPERTIES OF THE NICKEL-SUBSTITUTED PRODUCTS HEATED AT VARIOUS TEMPERATURES

| Product | Heated at, °C | Appearance | For X-rays | Two-dimensional paper chromatographic information |
|---|---|---|---|---|
| A | 100~110 | green, transparent | amorphous | — |
| B | 300 | dark brown, powder | amorphous slightly crystalline | — |
| C | 600 | light yellow, powder | crystalline | non-moving spot indicating long-chain phosphate |
| D | 1000 | yellowish green, powder | crystalline | chain series containing ortho-, pyro-, tripolyphosphate, etc., ring series containing trimeta-, tetrameta,, pentametaphosphate, etc. and non-moving spot |
| E | 1200 | dark yellow, powder | crystalline | chain series containing ortho-, pyro-, tripolyphosphate, etc. and non-moving spot |

ions in 8 and 11 hr., respectively.

In order to confirm the reversibility of the cation-exchange reaction, a green product obtained by the reaction between 1 g. of the potassium Kurrol salt and 200 ml. of a 0.1052 M solution of nickel sulfate for 8 hr. at 20°C was subjected to react with 50 ml. of a 0.2 M solution of potassium chloride for 40 hr. at 20°C. Before and after the reverse reaction, the solid phase was analyzed for potassium, nickel and phosphorus. Phosphate was not dissolved in the process of this reaction. The quantity of the potassium ion which went into the solid phase was 1.48 meq. and the quantity of the nickel ion which came out of the solid phase was 1.47 meq. This fact indicates that the reaction is reversible. The rate of the reverse reaction was slower than that of the ordinary reaction, since the surface area of the primary product was smaller than that of the initial potassium Kurrol salt. The equilibration of the reverse reactoin was attained after about 40 hr.

**6. Properties of the Nickel-substituted Product.**—The nickel-substituted product in which about 90 per cent of the initial amount of the potassium ion is replaced by the nickel ion is green-colored and gummy. It is quite similar to chewed chewing-gum. The green product is gradually dissolved into a large amount of water. A similar product can be made in a short time by dissolving potassium Kurrol salt in a dilute solution of sodium chloride or sodium tripolyphosphate and adding a concentrated solution of nickel sulfate. This fact may be due to salting-out effect.

The variation in the properties of the green product by heating was investigated and the results are summarized in Tablle IV. The green primary product and the product A were completely amorphous for X-rays. The product B was practically amorphous for X-rays, but it contained a small amount of crystalline substance. The products C, D and E were all crystalline for X-rays and their X-ray patterns were different from one another. The products A and B were soluble in mineral acids, but the products C, D, and E were soluble in mineral acids only with difficulty. The product E was not dissolved even by heating it with 6 N hydrochloric acid, 6 N nitric acid, aqua regia, or 3 N sodium hydroxide. Each 0.1 g. of the products C, D and E was well mixed with 1 g. of Amberlite IR-120 resin in sodium form (100~200 mesh) in 8 ml. of water. After centrifugation the supernatant was concentrated

TABLE V. CATION-EXCHANGE REACTION BETWEEN POTASSIUM KURROL SALT AND SOLUTIONS OF VARIOUS METAL IONS

| Metal salt | Concn. | pH, initial | Quantity of metal ion exchanged | Exchange capacity at the end of the reaction | % exchange |
|---|---|---|---|---|---|
| | M | | meq. | meq. | |
| $MgCl_2$ | 0.0946 | 5.6 | 7.08 | 8.45 | 83.8 |
| $CaCl_2$ | 0.0981 | 3.9 | 6.95 | 8.43 | 82.4 |
| $MnCl_2$ | 0.1300 | 3.0 | 7.84 | 8.32 | 94.2 |
| $FeSO_4$ | 0.0928 | 1.3 | 7.59 | 8.39 | 90.5 |
| $Fe_2(SO_4)_3$ | 0.1568 | 0.8 | 3.80 | 7.35 | 51.7 |
| $CoCl_2$ | 0.0987 | 4.7 | 7.39 | 8.46 | 87.3 |
| $NiSO_4$ | 0.0984 | 5.6 | 7.68 | 8.47 | 90.8 |
| $CuSO_4$ | 0.1006 | 4.3 | 5.03 | 5.77 | 87.2 |
| $ZnCl_2$ | 0.0910 | 2.1 | 7.92 | 8.46 | 93.7 |

at room temperature. Two-dimensional paper chromatography for the solution was carried out. The results are shown in Table IV. Although only minute parts of the products C, D and E were brought into the solutions, the paper chromatographic data suggested the difference of the chemical compositions of these products.

**7. Exchange-reactions of Various Metal Ions.** —In conformity to the procedure used for the nickel ion, 1 g. of the potassium Kurrol salt was subjected to react with 200 ml. of about 0.09~0.16 M solution of each of the following metal ions for 8 hr. at 20°C: magnesium, calcium, manganese(II), iron(II), iron(III), cobalt(II), copper(II) and zinc. After the exchange reactions, the amounts of phosphate dissolved in the solution and the decreases in the metal ion concentrations were measured. With the aid of these measurements, percentages of exchange based on millieqivalent of cations were calculated as shown in Table V. Only in the case of copper(II) sulfate a large amount of the initial potassium Kurrol salt was dissolved in the course of the reaction. Except for iron(III), percentages of exchange for all cations investigated in the present work were in the range 82 to 94.

## Summary

Pure crystalline potassium Kurrol salt was prepared and its X-ray pattern was compared with that obtained by Klement et al. The solubility of the potassium Kurrol salt in water was 0.007~0.009 per cent at room temperature. Qualitative observation was made for the reactions of the potassium Kurrol salt with various metal ions. Therefore was an optimum concentration of sodium chloride to dissolve the potassium Kurrol salt. The investigation of reactions of the potassium Kurrol salt in a solid state with solutions of nickel sulfate indicated that the reaction is a cation-exchange reaction between potassium and nickel ions. It was also found that the reaction is reverssible. The nickel-substituted product is green-colored and gummy. Some properties of the substances obtained by heating the above green product were studied. Exchange reactions of potassium Kurrol salt with various metal ions were investigated. Percentages of exchange for magnesium, calcium, manganese(II), iron(II), cobalt(II), nickel(II), copper(II) and zinc were all in the range 82 to 94 under the conditions used in the present work.

The authors are indebted to Professor T. Kiba for his continued encouragement.

# *Distribution of Unpaired π-Electron in Some Semiquinone Ions*

By Yoshio MATSUNAGA

(Received May 2, 1960)

The hyperfine structure (hfs) of the electron spin resonance (ESR) spectra of free radicals in the dissolved state arises from the interaction between the magnetic moment of the unpaired π-electron and the magnetic moments of the protons and some other magnetic nuclei in the molecule. Based on the spectra of *o*- and *p*-benzosemiquinone ions McConnell has suggested that the magnitude of ring proton splitting constant $a_j$ is approximately proportional to the density of unpaired π-electron $\rho_j$ on the adjacent aromatic carbon atom $j$ given by a simple MO treatment, and proposed the relation $a_j=34\rho_j$[1]. Later he has developed a theoretical study in terms of configurational interaction and concluded that the above-mentioned empirical relation can be used for practical calculation[2]. This approximation has been applied successfully to the interpretation of hfs of ESR spectra of a number of alternant aromatic hydrocarbon monopositive and mononegative ions[3,4].

McConnell has used a set of parameters $\alpha_O=\alpha+\beta$ and $\beta_{CO}=\beta$ in his simple MO treatment of benzosemiquinone ions[1]. These values have been originally proposed for the oxygen atoms and the carbon-oxygen bonds in neutral quinone molecule[5], and the effect of negative charge on the magnitude of these parameters has not been taken into consideration in the treatment of semiquinone ions. Therefore, it seemed to be desirable to find a correct set of parameters for the extension of theoretical work to the semiquinone ions with more complicated molecular structure. The MO treatment with such a set of parameters might be very helpful to the analysis of hfs of ESR spectra of semiquinone ions. In the previous paper the author has attempted to estimate the required parameters based on the frequencies of the C-O stretching vibration in alkali salts of *p*-benzo- and *p*-biphenosemiquinones and obtained a set of $\alpha_O=\alpha+(1/3\sim1/2)\beta$ and $\beta_{CO}=\beta$[6]. Here we wish to present the results of simple MO treatment with the suggested parameters and compare with the experimental results for several semiquinone ions.

## Method of Calculation

The calculations in the present paper were carried out by the simple LCAO MO method. The density of unpaired π-electron at each carbon atom was approximated by the square of the coefficient of its $2p$ function in the singly occupied MO. The coulomb integrals for carbon atoms were assumed to be $\alpha$, and the exchange integrals were taken as $\beta$ including that for C-O bonds. The coulomb integral for the oxygen atoms was assumed to be $\alpha+(1/2)\beta$ or $\alpha+(2/3)\beta$. The former value was taken from the previous paper[6] and the latter was estimated by the following method. Naphthosemiquinone ion gives a spectrum of three quintets, therefore the density of unpaired π-electron on the aromatic carbon atoms 5 and 5′ is practically equal to that on the carbon atoms 6 and 6′ (see structural formula). The singly occupied MO of this semiquinone ion is antisymmetric. Accordingly, if we assume $\beta_{CO}=\beta$, the magnitude of the coulomb integral for the oxygen atoms $\alpha_O=\alpha+\delta\beta$ can be determined by the system of equations for the coefficient $c_j$ of $2p$ function at carbon atom $j$;

$$
\begin{aligned}
&(y+\delta)c_1+c_3=0\\
&(y-1)c_2+c_3=0\\
&c_1+c_2+yc_3+c_4=0\\
&c_3+(y-1)c_4+c_5=0\\
&c_4+yc_5+c_6=0\\
&c_5+(y-1)c_6=0,
\end{aligned}
$$

where $y=(\alpha-E)/\beta$, and the normalizing condition $\sum c_j^2=1$. If the coefficients of $2p$ function at the carbon atoms 5 and 6 are supposed to be exactly equal to each other, we obtain $\alpha_O=\alpha+(2/3)\beta$. We used $a_j=32\rho_j$ throughout this paper instead of $a_j=34\rho_j$ proposed by McConnell for semiquinone ions simply by the reason that the former seems to fit better with the experimental results. The structural formula and the numbering of oxygen and carbon atoms chosen for convenience are summarized in Fig. 1.

## Results and Discussion

***p*-Benzosemiquinone Ion (I).**—This free radical ion has four equivalent protons and gives a predicted quintet with intensity ratios 1 : 4 : 6 : 4 : 1. The splitting constant has been reported as 2.37±0.01 oersteds by Adams, Blois, and Sands[7]. The densities of unpaired π-electron given by a simple MO treatment and the predicted splitting constant are presented in Table I for various values of $\delta=(\alpha_O-\alpha)/\beta$. Since the magnitude of splitting constant depends only slightly on the value of $\delta$, it is hard to tell which value of $\delta$ gives the best result.

Table I. Unpaired electron densities ($\rho_j$) and splitting constant ($a_3$ in oersted) for *p*-benzosemiquinone ion

| $\delta$ | $\rho_1$ | $\rho_2$ | $\rho_3$ | $a_3$ |
|---|---|---|---|---|
| 0 | 0.332 | 0.032 | 0.068 | 2.18 |
| 1/2 | 0.286 | 0.071 | 0.071 | 2.27 |
| 2/3 | 0.264 | 0.088 | 0.074 | 2.37 |
| 1 | 0.221 | 0.123 | 0.078 | 2.50 |

**Naphthosemiquinone Ion (II).**—The splitting constants have been reported as 3.22±0.03 oersteds for the ring protons attached to the positions 2 and 2′ and 0.57±0.03 oersteds for those 5, 5′, 6 and 6′. The results of calculation are given in Table II. With a difference of 0.1 oersted it is difficult to distinguish experimentally the splittings due to $a_5$ and $a_6$, therefore both of the results obtained assuming $\delta=1/2$ and 2/3 may be considered to be in good agreement with the observed values.

It has been shown that the hf splitting constant for a methyl proton is related to the unpaired π-electron density on the carbon atom, to which the methyl group is attached, by a formula of the same type as for a ring proton[8,9]. Besides the proportional constants for these two kinds of protons seem to be nearly the same. As the unpaired electron density in a methyl group is only in the order of 0.01, we may expect the distribution of unpaired π-electron is not much modified by methyl substitution. Therefore, the magnitude of a methyl proton splitting may be close to that of the ring proton attached to the corresponding carbon atom in the unsubstituted free radical ion. The following splitting constants could be assigned for monomethylnaphthosemiquinone ion; 3.2 oersteds for the methyl group attached to the position 2, 2.6 oersteds for the ring proton attached to the position 2′, and 0.6 oersteds for the remaining four ring protons. The spectrum consists of twenty-four lines as shown in Fig. 2. For dimethyl-derivative 2.3 oersteds for the six protons in the methyl groups attached to the positions 2 and 2′ and 0.57 oersteds for the ring protons have been assigned by Vivo[10]. Contrary to Vivo's result, an expected quintet with a spacing of

0.6 oersteds was found in the case of dichloronaphthosemiquinone ion. We may conclude that the ring protons at 5 and 6 are nearly equivalent in all of the examined derivatives.

The semiquinone ion formed on reduction of hydroxynaphthoquinone in alkaline medium has an ionized oxygen atom attached to the position 2. The effect of this substituent is so strong that the distribution of unpaired $\pi$-electron in naphthosemiquinone ion is completely changed. The spectrum consists of partially resolved two doublets (1.6 and 1.8 oersteds) instead of two quintets. By comparison with the well-resolved two doublets with 1.5 and 1.9 oersteds given by the semiquinone ion from hydroxychloronaphthoquinone, in which the chlorine atom can be considered inactive to hf splitting, it appears that the observed hfs is entirely due to the interaction between unpaired electron and two protons among four attached to the positions 5, 5′, 6 and 6′ (see Fig. 3).

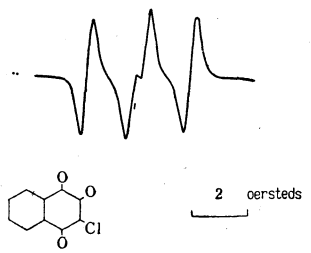

Fig. 3. Electron spin resonance spectrum of the semiquinone ion from hydroxychloronaphthoquinone.

**Anthrasemiquinone Ion (III).**—This semiquinone ion gives a spectrum of thirteen lines resulting from one set of four equivalent protons and another of four. The splitting constant for one set must be 1.0 oersted and for the other 0.5 oersteds. However, without further information we cannot determine which of the two possible assignments is responsible. The results by simple MO treatment with the proposed parameters suggest that the proton at 5 and its three equivalents give the larger splitting.

TABLE III. UNPAIRED ELECTRON DENSITIES ($\rho_j$) AND SPLITTING CONSTANTS ($a_j$ IN OERSTED) FOR ANTHRASEMIQUINONE ION

| $\delta$ | $\rho_1$ | $\rho_2$ | $\rho_3$ | $\rho_4$ | $\rho_5$ | $a_4$ | $a_5$ |
|---|---|---|---|---|---|---|---|
| 0 | 0.277 | 0.050 | 0.046 | 0.010 | 0.030 | 0.32 | 0.96 |
| 1/2 | 0.214 | 0.098 | 0.042 | 0.021 | 0.031 | 0.67 | 0.99 |
| 2/3 | 0.191 | 0.115 | 0.040 | 0.026 | 0.031 | 0.83 | 0.99 |
| 1 | 0.143 | 0.143 | 0.036 | 0.036 | 0.036 | 1.15 | 1.15 |

**Biphenosemiquinone Ion (IV).**—As shown in Table IV, the splitting due to the proton at 3 is expected to be twice or a little more larger than that due to the proton at 4. Unfortunately this free radical ion was found too unstable to be examined by our spectrometer. Tetramethylbiphenosemiquinone ion has four methyl groups attached to the position 3 and its equivalents and gives a spectrum of twenty-one lines with a spacing of 0.78 oersteds[11]. This pattern could be explained using the splitting constants 2.34 oersteds for the ring protons and 0.78 oersteds for the methyl protons as well as using 0.78 oersteds for the ring protons and 1.56 oersteds for the methyl protons. The theoretical results given in Table IV are definitely favorable to the latter assignment.

TABLE IV. UNPAIRED ELECTRON DENSITIES ($\rho_j$) AND SPLITTING CONSTANTS ($a_j$ IN OERSTED) FOR BIPHENOSEMIQUINONE ION

| $\delta$ | $\rho_1$ | $\rho_2$ | $\rho_3$ | $\rho_4$ | $\rho_5$ | $a_3$ | $a_4$ |
|---|---|---|---|---|---|---|---|
| 0 | 0.278 | 0.005 | 0.067 | 0.011 | 0.060 | 2.14 | 0.35 |

| 1 | 0.152 | 0.072 | 0.056 | 0.038 | 0.088 | 1.79 | 1.22 |

***o*-Benzosemiquinone Ion (V).** — The three triplets observed in the ESR spectrum of this radical ion have been analyzed by Hoskins[12]. The major splitting has been attributed to the protons attached positions 4 and 4′ and the minor one to those at 3 and 3′. The values have been estimated as $3.65\pm0.04$ and $0.95\pm0.04$ oersteds by Adams et al.[7] Both of the splitting constants calculated using $\delta=1/2$ and 2/3 were found in serious disagreement with the experimetnal ones. Since our parameters seemed not applicable to *o*-semiquinone ions, we attempted to estimate a new one which gives a ratio of $c_4^2/c_3^2=4$ in the present case. Although the value thus estimated as high as 1.611 might suggest that a more refined model is required for the MO treatment of *o*-semiquinone ion, it must be noted that the calculated splitting constants are in good agreement with the observed ones. The unpaired $\pi$-electron distribution cited in the last line of Table V is taken from Kuboyama's work on *o*-quinones[13]. As we may expect for the reasons discussed above, his results obtained with the following parameters for neutral quinone molecule predict the splitting constants not far from the experimental ones; $\alpha_O=\alpha+1.3\beta$, $\alpha_2=\alpha+0.2\beta$, $\beta_{22'}=0.8\beta$, $\beta_{23}=\beta_{44'}=0.9\beta$, $\alpha_3=\alpha_4=\alpha$ and $\beta_{12}=\beta_{34}=\beta$.

**Semiquinone Ion from Ninhydrin (VI).** — Adams et al. have observed that ninhydrin on reduction gives a spectrum of three triplets due to the two pairs of equivalent protons on the aromatic ring, and estimated the splitting constants to be 1.95±0.04 and 1.59±0.04 oersteds[7]. The conjugated system of this radical ion was considered to be similar to that of *o*-divinylbenzene and examined by the simple MO method changing the magnitude of $\delta$. The results suggest that the larger splitting is attributed to the protons attached to the positions 5 and 5', and the value of $\delta$ close to 1.6 is again required for quantitative agreement with the experimental results.

Table VI. Unpaired electron densities ($\rho_j$) and splitting constants ($a_j$ in oersted) for the semiquinone ion from ninhydrin

**Semiquinone Ion from Dihydroxy-*p*-benzoquinone (VII).** — It has been found that the ring proton splitting changes from 1.83 oersteds in dimethyl-*p*-benzosemiquinone ion to 0.30 oersteds in dimethoxy-derivative[11]. This considerable decrease suggests the localization of unpaired π-electron on the oxygen atoms in the methoxyl groups. We extended here our measurements to the highly symmetric semiquinone ion formed on reduction of dihydroxy-*p*-benzoquinone. Although we do not know the correct value of $\delta$ for this triply charged semiquinone ion, the value must be in the range from −1 for negatively charged oxygen to +1 for the oxygen atom in carbonyl group[14]. The singly occupied level predicted by a simple MO treatment for this semiquinone ion is antisymmetric with respect to the *x*-plane. Therefore, no unpaired π-electron density is found on the carbon atoms to which the ring protons are attached and we may expect no hfs in the ESR spectrum of the present radical ion. The small splitting due to the ring protons observed in the case of dimethoxy-*p*-benzosemiquinone ion may be correlated with the difference between the electronegativities for two kinds of oxygen atoms.

Contrary to the expectation, on reduction with sodium dithionate dihydroxy-*p*-benzoquinone dissolved in a mixture of pyridine, ethylene glycol, and 2 N pottasium hydroxide (1 : 2 : 1 by volume) shows a triplet with a spacing of 0.78 oersteds. If we substitute the two ring protons with chlorine or bromine atoms, the semiquinone ion gives an expected single line spectrum. Apparently there is the ring proton splitting in the ESR spectrum of the radical ion formed by reduction of dihydroxy-*p*-benzoquinone. The unpaired π-electron density on the adjacent carbon atoms must be as high as 0.02. Therefore, we may conclude that a single configuration MO treatment does give neither the correct symmetyr of energy level nor the correct distribution of unpaired π-electron for the present radical. A similalr disagreement as to the symmetry of energy level has been reported by de Boer and Weissman in the case of pyrene negative ion[3].

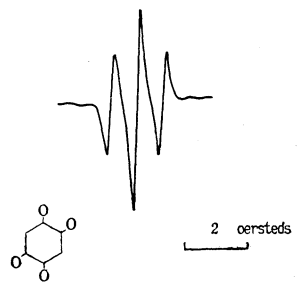

Fig. 4. Electron spin resonance spectrum of the semiquinone ion from dihydroxy-*p*-benzoquinone.

## Summary

The distribution of unpaired π-electron was calculated by the simple MO method using the proposed parameters $\alpha_O = \alpha + (1/2)\beta$ and $\alpha + (2/3)\beta$ for six semiquinone ions. The calculated splitting constants for the ring protons in *p*-benzo- and naphtho-semiquinone ions were found in good agreement with the experimental ones and the MO treatment with the proposed parameters seemed to be very helpful to the analysis of the hfs of ESR spectra of anthra- and bipheno-semiquinone ions. In the case of *o*-semiquinone ion, a much higher value of $\alpha_O$ was required to obtain quantitative agreement. The assignment of splitting constants was

14) H. H. Jaffe, *J. Am. Chem. Soc.*, 77, 4448 (1955).

attempted for the semiquinone ion from ninhydrin. It was found that the simple MO method fails to predict the symmetry of the singly occupied MO in the semiquinone ion formed on reduction of dihydroxy-*p*-benzoquinone. In addition the ESR spectra of the semiquinone ions from methyl- and hydroxynaphthoquinones etc. were described.

The spectra quoted in this paper were obtained at the University of British Columbia during the tenure of a National Research Council of Canada Postdoctorate Fellowship. The author wishes to express his sincere thanks to Professor C. A. McDowell for his generous keep and hospitality.

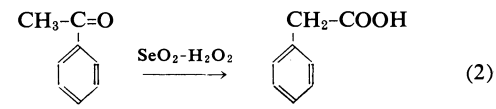
# *Hydrogen Peroxide Oxidation. IV. A New Rearrangement Reaction of Phenyl Alkyl Ketones by Selenium Dioxide Catalyst*[1]

By Noboru SONODA and Shigeru TSUTSUMI

(Received May 10, 1960)

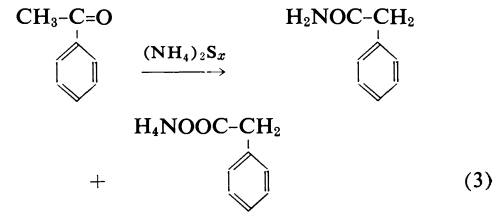
In the previous papers[2,3] we reported the rearrangement reactions of dialkyl ketones by selenium dioxide catalyzed oxidation with hydrogen peroxide, and now the present paper deals with a similar study using several phenyl alkyl ketones.

The rearrangement reaction mode of a dialkyl ketone is shown generally as below;



(1)

$R_1, R_2$=H or alkyl, $R_3$=alkyl

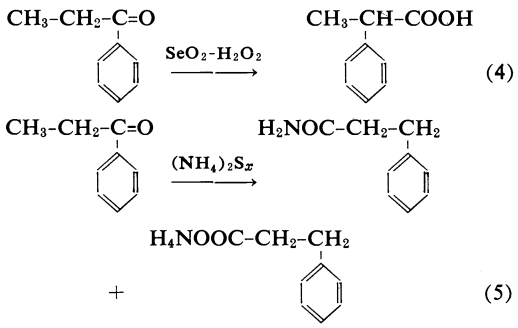


where either of the two alkyl groups $R_1R_2CH$- and $R_3$, can migrate onto the $\alpha$-carbon atom of the other alkyl group so that the two isomeric acids containing the same number of carbon atoms as original ketone are produced when unsymmetrical ketone is used. In the case of phenyl alkyl ketone, only the rearrangement of the phenyl group is possible, because the phenyl group does not possess an $\alpha$-hydrogen atom which may be substituted by the migrating alkyl group. Thus, the $\alpha$-phenyl carboxylic acids are synthesized from phenyl alkyl ketones by the oxidation with selenium dioxide-hydrogen peroxide reagent.

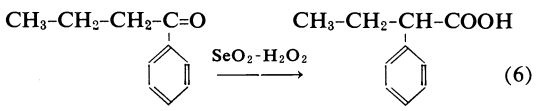
For example, when acetophenone was treated with hydrogen peroxide in *tert*-butyl alcohol in the presence of a small amount of selenium dioxide as catalyst at about 80~82°C, phenyl acetic acid was isolated from the reaction products as well as some cleavaged products.

(2)

Synthesis of phenyl acetic acid derivatives from acetophenone had also been undertaken by Willgerodt[4] showing that phenyl acetamide and ammonium phenyl acetate were obtained by the oxidation of acetophenone with ammonium polysulfide. But in the Willgerodt reaction[5] no change of carbon skeleton was observed because of the reduction of the carbonyl group to the methylene group and the oxidation of the methyl group to carbonamide or salt of carboxylic acid.



(3)



On the other hand the production of phenyl acetic acid from acetophenone by selenium

5) For a review of the Willgerodt reaction, see (a) M. Carmack, "Organic Reactions", Vol. III, John Wiley & Sons, Inc., New York, N. Y. (1946), pp. 83-107; (b) R. Wegler, E. Kühle and W. Schäfer, *Angew. Chem.*, **70**, 351 (1958).

dioxide catalyzed hydrogen peroxide oxidation is clearly based on the migration of the phenyl group to the methyl carbon atom. An evidence of the rearrangement was shown by the fact that $\alpha$-phenyl propionic acid was produced by the phenyl migration when phenyl ethyl ketone was treated under the reaction condition similar to that of acetophenone, whereas $\beta$-phenyl propionic acid derivatives were formed from phenyl ethyl ketone under the Willgerodt reaction condition[4].

In a similar manner, phenyl *n*-propyl ketone was oxidized with selenium dioxide-hydrogen peroxide reagent to give $\alpha$-phenyl butyric acid.

These facts suggest that similar treatment may be generally applicable to the other aryl alkyl ketones.

The reactivity of phenyl alkyl ketones was apparently lower than that of dialkyl ketones[2,3]. The yield of the rearrangement products was only about 10 per cent based on the treated ketones in spite of using an excess amount of hydrogen peroxide, and fairly good recovery of starting ketones was observed in all the cases.

On the other hand, oxidative cleavage was also observed. Benzoic acid was isolated as a main cleavage product in a comparable yield to the rearrangement product and phenol was identified as its tribromide in all cases. Aliphatic acids derived from the aliphatic fragments of the ketones or oxidative decomposition product[6] of *tert*-butyl alcohol used as solvent were also detected by gaschromatography. These products are listed in Table I.

We have proposed the probable mechanism[2] of these rearrangement reactions, which comprise the enol formation of the ketones

Table I. Cleavage products from oxidative reaction of phenyl alkyl ketones

b) This propionic acid was supplied from the solvent.

followed by the attack of peroxyselenious acid as the most possible active species. Since peroxyselenious acid is a kind of peracid, it is reasonable to believe that the Baeyer-Villiger oxidation[7] may be accompanied in this reaction system. Formation of phenol and aliphatic acid from the corresponding ketone may be interpreted as results of hydrolysis of the phenyl ester produced by the Baeyer-Villiger reaction. In addition, the other cleavage path is assumed to be present, because alkyl benzoate will not be formed from phenyl alkyl ketone[7] under the Baeyer-Villiger reaction condition so that benzoic acid may not be the reaction product via the Baeyer-Villiger oxidation.

## Experimental[8]

**Oxidative Reagent.**—Selenium dioxide-hydrogen peroxide reagent was prepared in the same manner as previously described[2]. This reagent includes 2.0 g. of selenium dioxide and 1.0 mol. of hydrogen peroxide in about 500 ml. of *tert*-butyl alcohol solution.

**Oxidation of Acetophenone.**—To a 100 ml. of the selenium dioxide-hydrogen peroxide reagent (0.4 g. of selenium dioxide and 0.2 mol. of hydrogen peroxide) was added 12.0 g. (0.1 mol.) of acetophenone, and the resulting mixture was heated to 80~82°C for 17 hr. The reaction mixture turned red during the oxidation. The mixture was distilled to remove the solvent and the small amount of metallic selenium deposited was filtered off. The filtrate was poured into 200 ml. of ether, and the ethereal solution was extracted first with saturated sodium bicarbonate solusion (A) and then with 8% sodium hydroxide solution (B). After the ethereal solution was dried over anhydrous sodium sulfate,

6) Propionic acid was partly produced from acetone which was formed by the decomposition of *tert*-butyl hydroperoxide or di-*tert*-butyl peroxide being furnished by the oxidation of *tert*-butyl alcohol used as solvent. This reaction path was already confirmed (see Ref. 2).

7) C. H. Hassall, "Organic Reactions", Vol. IX, John Wiley & Sons, Inc., New York, N. Y. (1957), p. 73-106.

8) The boiling and melting points are uncorrected.

the ether was removed and the residue was distilled under reduced pressure; 6.6 g. of neutral substance, consisting mainly of unreacted acetophenone, was obtained, b. p. 62~65°C (4 mmHg), 2,4-dinitrophenyl-hydrazone of this fraction melted at 245~246°C (lit.[9] m. p. 247~248°C) and mixed melting point with an authentic sample (m. p. 245~246°C) showed no depression.

The sodium bicarbonate solution A was acidified with 3 N hydrochloric acid and was extracted with ether. After the ethereal solution was dried over anhydrous sodium sulfate, the ether was removed by distillation and the residue was distilled under reduced pressure. Acetic acid and propionic acid were identified in the low boiling products by gaschromatography: column, tricresylphosphate; column temperature, 140°C; carrier gas, $H_2$; flow rate of $H_2$, 40 ml./min. The fraction boiling between 112~122°C (4 mmHg), which solidified at once, was collected. This gave 2.8 g. of a mixture of acids. A small portion of the mixture was recrystallized from hot water, and a mixture of two kinds of crystalline solids was obtained. One of them was white plate, phenyl acetic acid, which was separated as floats over the surface of water by shaking. After further recrystallization from petroleum ether, a sample (m. p. 75.5~76°C) was obtained (lit.[10] m. p. 76°C), mixed melting point with an authentic sample was not depressed. The yield of phenyl acetic acid was 9.6% based on the used ketone calculated from ultraviolet spectrum of the mixture of acids.

Found: C, 70.65; H, 6.02. Calcd. for $C_8H_8O_2$: C, 70.57; H, 5.92%.

Benzoic acid, white needle crystals from hot water, was obtained as residue after removal of phenyl acetic acid; the melting point and mixed melting point with an authentic sample was 121°C (lit.[10] m. p. 121°C); the yield was 12.3% calculated from the ultraviolet spectrum.

The sodium hydroxide solution B was acidified and extracted with ether. After the ethereal solution was dried over anhydrous sodium sulfate, the ether was removed by distillation. On distillation of the residual brown oil under reduced pressure, 0.15 g. of phenol was isolated; the tribromide was prepared which melted at 94°C (lit.[10] m. p. 95°C), mixed melting point with an authentic sample showed no depression.

**Oxidation of Phenyl Ethyl Ketone.**—To a 100 ml. of the selenium dioxide-hydrogen peroxide reagent (0.4 g. of selenium dioxide and 0.2 mol. of hydrogen peroxide) was added 13.4 g. (0.1 mol.) of phenyl ethyl ketone, and the reaction was carried out at 80~82°C for 20 hr. The reaction products were separated in the same manner as described for the oxidation of acetophenone.

Uureacted phenyl ethyl ketone (9.1 g.) was recovered from the neutral part; b. p. 70~73°C (5 mmHg); 2.4-dinitrophenylhydrazone of this fraction melted at 191~192°C (lit.[10] 191°C), mixed melting point with an authentic sample showed no depression.

Acetic acid and propionic acid were identified in the acidic part by the gaschromatography. A mixture of acids, 2.2 g. of oily product of b. p. 115~120°C (3 mmHg), was obtained. After a portion of this product was cooled to 0°C, a crystalline solid deposited was collected on a filter and was purified by recrystallization from petroleum ether to give benzoic acid. The melting point and mixed melting point with an authentic sample was 120~121°C (4.1% yield calculated from ultraviolet spectrum of the mixture of acids). The filtrate was an oily product, which was proved to be $\alpha$-phenyl propionic acid (11.3% yield). The amide was prepared according to the usual procedure[10] and was recrystallized from benzene, melting at 92.5~93°C (lit.[11] 93°C).

Found: C, 72.34; H, 7.58; N, 9.57. Calcd. for $C_9H_{11}NO$: C, 72.45; H, 7.43; N, 9.39%.

The presence of phenol was identified in the phenolic part by the ferric chloride test.

**Oxidation of Phenyl *n*-Propyl Ketone.**—To a 100 ml. of the selenium dioxide-hydrogen peroxide reagent (0.4 g. of selenium dioxide and 0.2 mol. of hydrogen peroxide) was added 14.8 g. (0.1 mol.) of phenyl *n*-propyl ketone, and the reaction was carried out at 80~82°C for 24 hr. The reaction products were separated in the same manner as described for the oxidation of acetophenone.

The unreacted phenyl *n*-propyl ketone (10.2 g.) was recovered from the neutral part; b. p. 104~108°C (14 mmHg); 2,4-dinitrophenylhydrazone melted at 190~191°C (lit.[9] 191~192°C), mixed melting point with an authentic sample was not depressed.

Propionic acid and butyric acid were identified by the gaschromatography. On distillation, 1.5 g. of a mixture of acids, b. p. 105~110°C (1 mmHg), was obtained. After the mixture was allowed to stand at room temperature for several hours, the crystalline product deposited was filtered and recrystallized from hot water to give 0.6 g. (4.9% yield) of benzoic acid, m. p. 121°C. The filtrate, 0.7 g. (4.3% yield) of $\alpha$-phenyl butyric acid, froze to a crystalline solid, which melted slightly above room temperature (lit.[12] m. p. 43°C). A redistilled sampe showed neutral equivalent 162; calculated for $C_{10}H_{12}O_2$: 164.2. The amide was prepared according to the usual procedure[10] and was recrystallized from benzene-ligroin, melting at 83~84°C (lit.[13] 84°C). The phenol was isolated from the phenolic part, 0.2 g.; the tribromide melted at 94°C (lit.[10] 95°C), mixed melting point with an authentic sample showed no depression.

## Summary

1) Selenium dioxide catalyzed oxidation of phenyl alkyl ketone with hydrogen peroxide in *tert*-butyl alcohol gave $\alpha$-phenyl carboxylic acid which was produced by the rearrangement of the phenyl group to the $\alpha$-carbon atom as shown by Eqs. 2, 4 and 6.

9) G. D. Johnson, *J. Am. Chem. Soc.*, **75**, 2720 (1953).

11) J. A. King and F. H. H. McMillan, *J. Am. Chem. Soc.*, **68**, 635 (1946).

12) M. M. Rising and T. W. Zee, *J. Am. Chem. Soc.*, **50**, 1211 (1928).

13) *Beilstein*, **9** II, p. 356, Springer-Verlag, Berlin (1946).

Therefore, the reaction mode is quite different from the Willgerodt reaction. The fact described above suggests that similar treatment may be generally applicable to the other aryl alkyl ketones.

2) The reactivity of phenyl alkyl ketone was lower than that of dialkyl ketone, and cleavage reaction was also observed. It is assumed that the cleavage products may be produced partly from the Baeyer-Villiger oxidation product because an active species in this reaction system is considered to be peroxyselenious acid, a kind of peracid.

# *Inorganic Extraction Studies on the System of Tri-n-butyl Phosphate—Nitric Acid*

By Tomitaro ISHIMORI and Kenju WATANABE

(Received May 17, 1960)

Tri-*n*-butyl phosphate*, an excellent extracting agent for inorganic salts, has been widely used for the reprocessing of reactor fuel, the separation of some actinide elements from fission products and the analysis of uranium.

Results on the distribution of inorganic salts between TBP and nitric acid solution have been published by a number of investigators. Peppard et al. studied the behavior of scandium[1], yttrium[2], zirconium[1], lanthanide elements[2,3,4,5] and some actinide elements[1,3,5-7] in the extraction from nitric acid solution. McKay et al. also studied in detail the extraction of nitrates of yttrium[8], zirconium[9], lanthanide elements[8,10] and some actinide elements[11-16] with both diluted and undiluted TBP.

Distribution of uranyl[13-31] and thorium nitrate[1,7,11,15,16,20,23-25,32-39] between TBP and nitric acid solution has been studied at various concentrations of TBP, and nitric acid and/or nitrate using aluminum nitrate[18,23,25,26,33],

* Tri-*n*-butyl phosphate is abbreviated as TBP in the present paper.

sodium nitrate[15,18] or calcium nitrate[7,17] as the salting-out agent. In some cases sulfate[27,37], phosphate[27,37] or fluoride[27,33] was added in order to observe the influence of these anions on the partition of the objectives.

Distribution data for protactinium[40], neptunium[13,16,24,64] and plutonium[12,13,15,16,24,28,41,42] were also presented in the extraction with diluted TBP. According to Yakovlev and Kosyakov[43] extractabilities of americium and curium increase with the concentration of nitrate as salting-out agent in the aqueous solution. Behavior of lanthanide elements[20,23,34,35,44-49] has been often studied in the presence of uranium and/or thorium. The extraction of tetravalent cerium[48,50] from nitric acid solution with TBP was very easy in comparison with other trivalent lanthanide elements. Diluted TBP was used in order to separate zirconium from hafnium[51-53]. The extraction of fission products[23,41,42,48,54] with TBP has been evaluated for the decontamination of fissionable materials. Krieger et al.[48], who presented the extraction data of major long-lived fission products (Cs, Sr, Ru, Zr-Nb and lanthanide elements), observed that cesium was not extracted at all while strontium was extracted very slightly from a solution containing aluminum nitrate. They also mentioned that ruthenium and niobium could be extracted in a yield more than 99% into undiluted TBP. According to Bruce[54], molecular iodine was easily extracted with many diluents for TBP, but iodine extraction may have been minimized by maintaining iodine in the reduced valence state. The extractability of zirconium and niobium, given by Scadden et al.[55], from nitric acid solution containing oxalic acid into undiluted TBP was lower than that from nitric acid alone[1]. Morrison and Beaumont[20] showed that distribution ratio of molybdenum between 30% TBP-kerosene and 1 M nitric acid was 0.060 to 0.088. Diamond's observation[56] shows that molybdenum(VI) is not extracted with TBP from nitric acid. It was reported that the distribution of vanadium was very low between 25% TBP and 5 N nitric acid[57]. The distribution coefficients of ferric, cupric, nickel and chromic nitrate between TBP and nitric acid solution were given by Bartlett[18]. McKay et al[14,58,59] and Tuck[60] studied the system of TBP-diluent-nitric acid.

In this paper are presented the comprehensive and systematic studies on the distribution of ions between undiluted TBP and nitric acid of various concentration.

## Experimental

The general techniques used were described in the previous paper[61]. TBP was purified in the usual way[1-3,8-13], and was used without any dilution. Nitric acid solutions were prepared by diluting concentrated chemically pure nitric acid. The acidity was determined volumetrically whenever necessary. Tracers of sodium and potassium were prepared by irradiation of the nitrates while those of manganese, nickel, germanium and tellurium were prepared from irradiated metals. A nickel tracer was separated from radiochemical impurities by an anion-exchange technique[62]. Germanium and tellurium tracers were used immediately after the separation from their daughters, respectively arsenic and iodine, by solvent extraction[63]. The imported tracers, Rb-86, Sb-124, and Os-191 were used as received. The sources of radioactive tracers other than mentioned above were the same as those shown in the previous paper[61].

The specific counting rate of these radiochemical tracers was higher than $10^4$ count per min. per 100 $\mu$g. Although in some cases the oxidation state and the chemical form of the tracer could not clearly be defined, the most familiar chemical forms were chosen as far as possible. Distribution

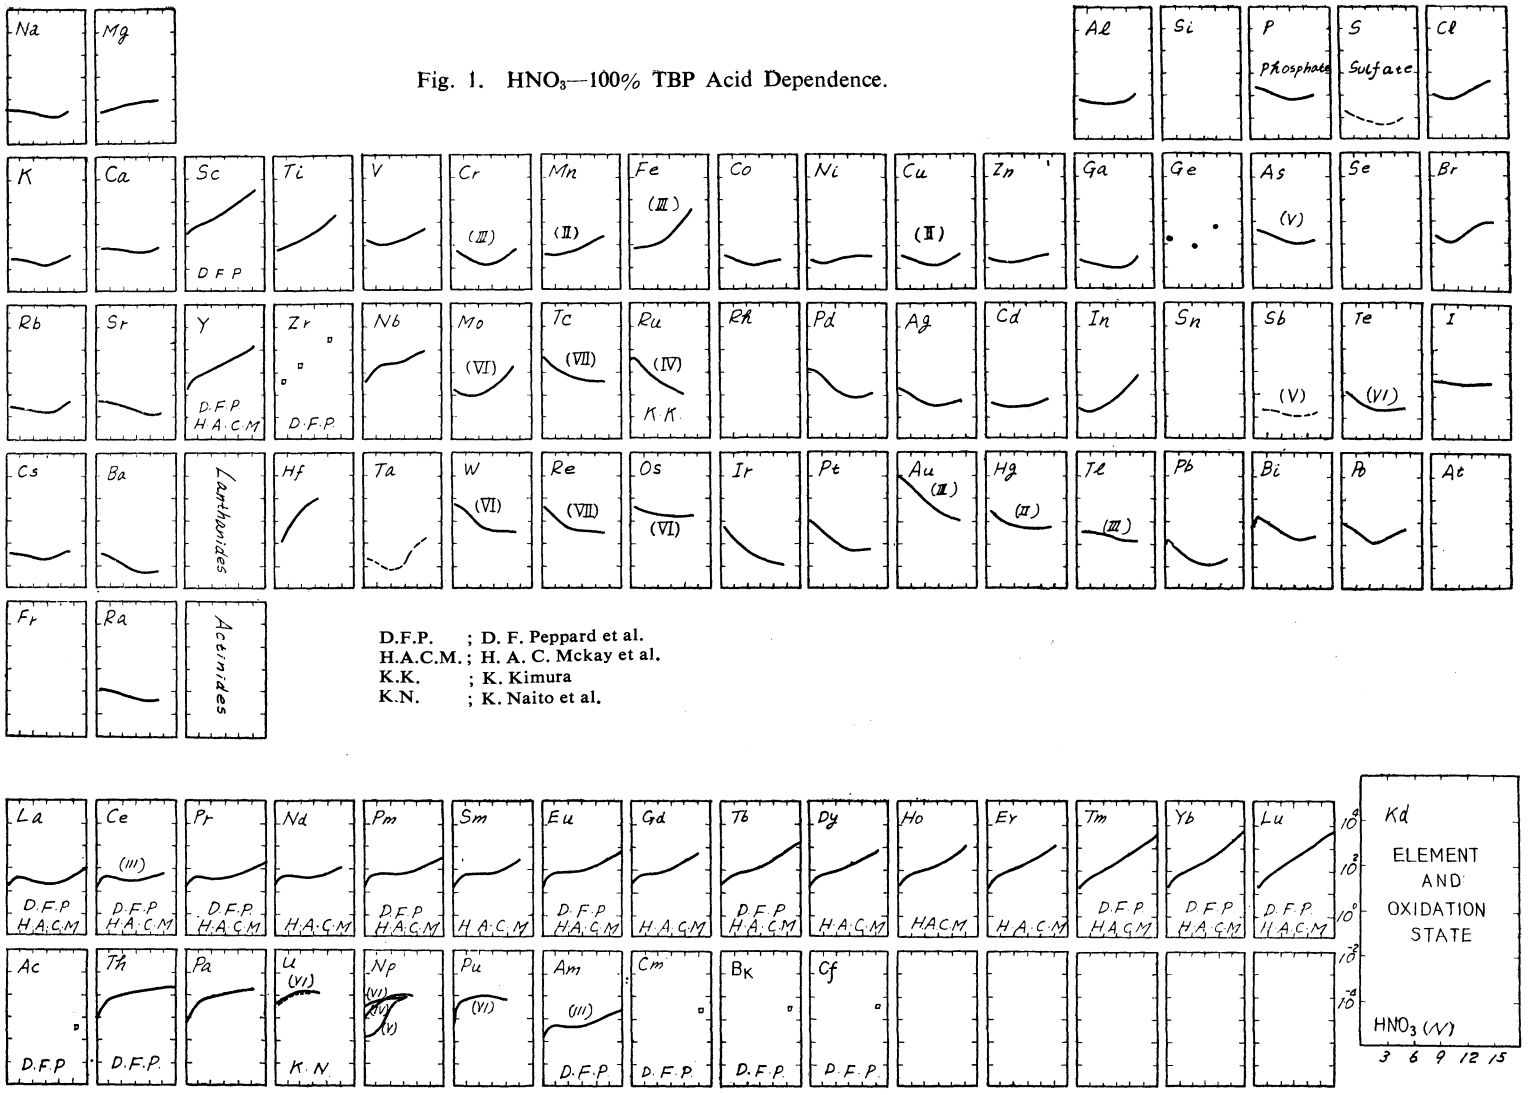

Fig. 1. $HNO_3$—100% TBP Acid Dependence.

ratios were determined radiometrically in the ordinary way[1,3,61,64].

## Results and Discussion

The results are summarized in Fig. 1 as a series of graphs of $\log K_d$ vs. $N$, where $K_d$ is the distribution ratio and $N$ the acidity of nitric acid in normality. Some of the graphs in Fig. 1 were compiled from some published and unpublished results. Data for scandium[1], zirconium[1], thorium[1], americium[3] and some other actinide elements[5] are taken from the work of Peppard and his coworkers. Curves for yttrium[2,8] and lanthanide elements[2,3,8,10] are quoted from the reports of Peppard et al. and McKay et al. Data for ruthenium[65] and uranium(VI)[66] are cited from the observations of Kimura and Naito, respectively. A dotted line for uranium(VI) is based on the result by Bartlett[18]. The curves for hafnium, protactinum and neptunium are taken from the paper[64] of Nakamura et al. The data for plutonium(VI), lead and bismuth were obtained by one of the present authors (T. I.) during his stay in the Argonne National Laboratory, U. S. A.

The $K_d$ values for sulfate and antimony could not be determined exactly, because the activities extracted into the organic phase were very low.

As Fig. 1 shows, four alkali elements behave in a similar way, showing always very low $K_d$ values. There are some similarities in the shape of the acid-dependence curves for chloride and bromide; ruthenium, palladium and platinum. The $K_d$ values of scandium, yttrium and lanthanum increase with the decreasing atomic number, $Z$. Calcium, strontium and barium also show a similar relationship between $K_d$ vs. $Z$ in a high acidity range. As far as these fifteen elements, namely, alkali metals, chloride, bromide, ruthenium, palladium, platinum, calcium, strontium, barium, scandium, yttrium and lanthanum, are concerned, there is a remarkable difference in the shape of $\log K_d$ vs. $N$ curve between TBP-nitric and TBP-hydrochloric acid system. On the other hand, the group of alkali metals, chloride and bromide, ruthenium, palladium and platinum, calcium, strontium and barium, and scandium, yttrium and lanthanum shows a similar $K_d$ vs. $Z$ relationship between TBP-nitric and TBP-hydrochloric system. Among zirconium, hafnium and thorium, thorium gives the highest extractability into TBP from a nitric acid solution while it shows the lowest into TBP from a hydrochloric acid solution.

Concerning the group of zinc, cadmium and mercury, there is a marked similarity both in the shape of acid dependence curve and in values of $K_d$ in the hydrochloric acid system[61]. In the nitric acid system, howerver, the $K_d$ values of these three elements increase with atomic number, showing a noticeable difference between the shape of the acid-dependence curve for mercury and that for two other elements.

The $K_d$ values for 12 N nitric acid were

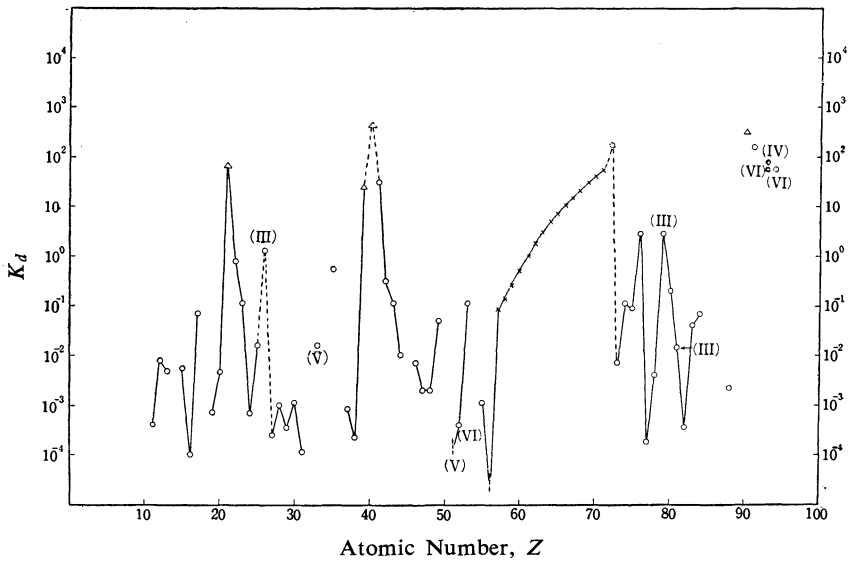

Fig. 2. Relationship between atomic number and $K_d$ values at 12 N $HNO_3$.

64) T. Ishimori and E. Nakamura, This Bulletin, 32, 713 (1959).

65) K. Kimura, unpublished.

66) K. Naito et al., unpublished.

plotted against the atomic number $Z$, in Fig. 2. The values for lanthanides are quoted from the paper of McKay et al.[10] The values for scandium, yttrium, ruthenium and thorium are taken from both published and unpublished works[1-3,65]. There were no data for zirconium, hafnium and neptunium in 12 N nitric acid in the original papers. Accordingly the present authors indicate the values with dotted marks which are estimated from the original data. A regularity in the variation of $K_d$ values seen in Fig. 2 is analogous to that in the TBP-hydrochloric acid system[61]. In $\log K_d$ vs. $Z$ relationship, however, one peak for one long period of the periodic table is seen in the nitric acid system, whereas two peaks are found in the hydrochloric acid system.

Niobium and ferric nitrate give relatively high $K_d$ values in the extraction with TBP from a concentrated nitric acid, while technetium, ruthenium, tungsten, rhenium, osmium and gold are extractable from nitric acid in low concentrations. Protactinum, uranium, neptunium(IV) and -(VI) and plutonium are extracted easily from a nitric acid solution of more than about 3 N.

Fig. 3 gives $K_d$ values for 100% TBP-nitric acid system. This will be convenient for checking the possibility and the efficiency of a mutual separation of a couple of elements chosen arbitrarily. For example, technetium-99 will be separated with TBP from a irradiated molybdenum in 1 N nitric acid solution, because the $K_d$ value for technetium is 18.7 in 1 N nitric acid, while that for molybdenum is 0.02.

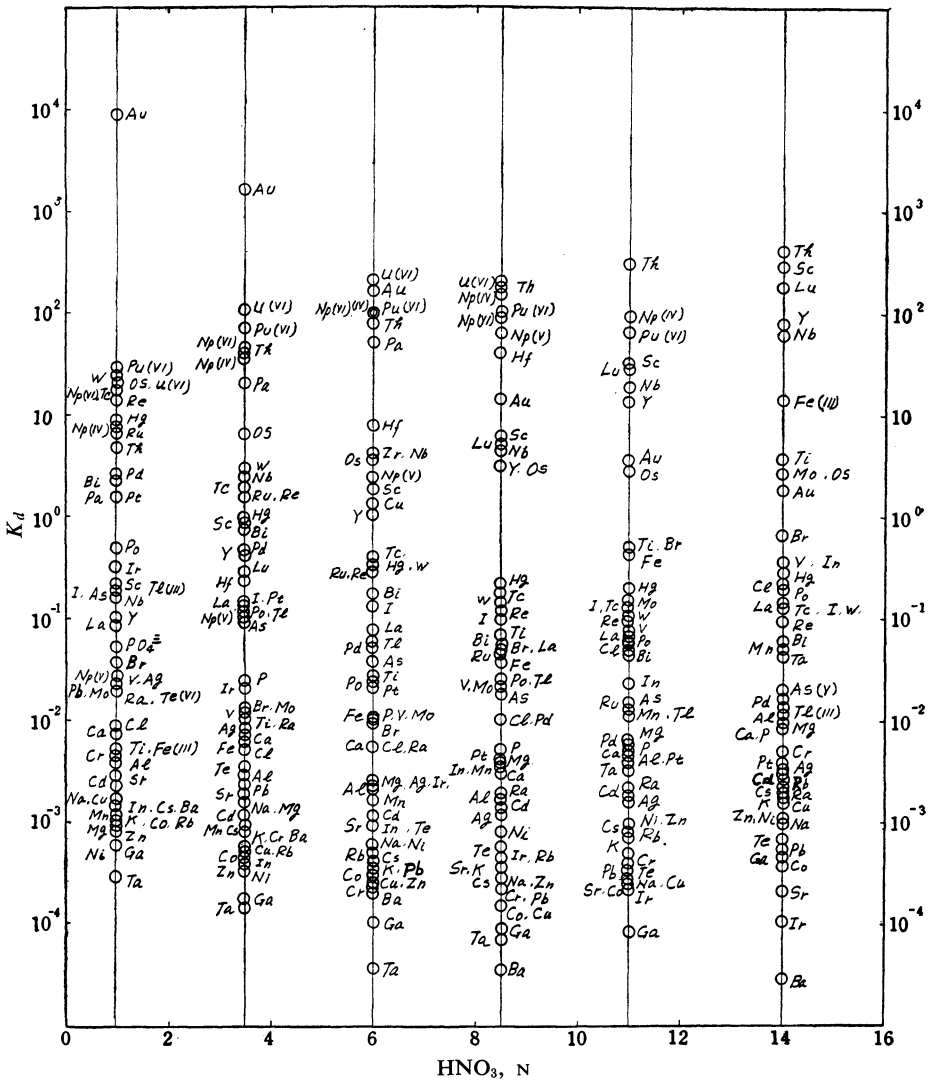

Fig. 3. $K_d$ values in 100% TBP—$HNO_3$ System.

As the $K_d$ values were obtained with a tracer in the present work, the optimum conditions of separation found in Fig. 3 will well fit a chemical separation on a tracer scale. However, some cautions must be paid in macro-scale separations.

Generally most elements give lower $K_d$ values in the TBP-nitric acid system than in the hydrochloric acid system. In other words, it would be easy to find out a favorable condition, where many kinds of element remain in the aqueous phase after TBP extraction from nitric acid solution, while a few kinds of element are extracted into the organic phase. Accordingly, the extraction from nitric media could be applied to a chemical or a radiochemical separation not so widely as that from hydrochloric acid media could be. However, this means that a small number of elements could be isolated selectively. Isolation and group separation of scandium, yttrium, zirconium, hafnium, some actinide and lanthanide elements are promising, according to the TBP extraction data from nitric acid solution of a high acidity. Similarly, extraction from dilute nitric acid well be favorable for the isolation and group separation of technetium and ruthenium.

# *4- and 6-Isopropyl-2-mercaptotropones*

By Kazuo MATSUI*

(Received April 22, 1960)

Detailed studies have been made by Nozoe and his co-workers on mercaptotropones[1-4] and mercapto derivatives of 2-phenyltropone has recently been studied by Muroi[5,6]. These studies still leave room for examination of the structure of the parent compound, 2-mercaptotropone, itself with reference to its tautomerism. As a preliminary study to this problem, homologous 4- and 6-isopropyl-2-mercaptotropones were synthesized and some reactions were carried out, which are described herein.

2-Hydrazino-4-isopropyltropone (I) and 2-hydrazino-6-isopropyltropone[7] (VII), obtained from hinokitiol (β-thujaplicin or 4-isopropyltropolone), were converted to 2-chloro-4-isopropyltropone (II) and 2-chloro-6-isopropyltropone[7] (VIII), respectively, and mercapto derivatives were prepared from them.

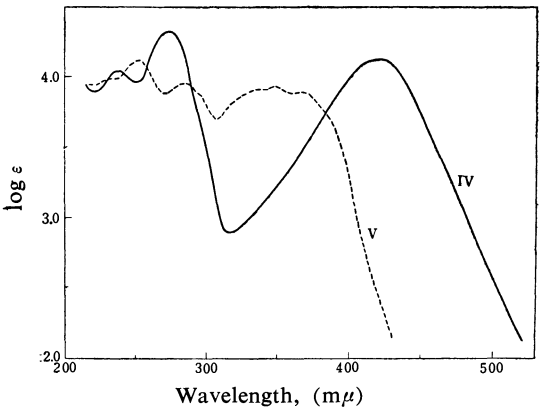
II easily reacted with potassium salt of *p*-thiocresol when heated in ethanol and formed 4-isopropyl-2-*p*-tolylthiotropone (III) as pale yellow plates, m. p. 110.5~112°C. Heating of II in methanol with four mol. of potassium hydrogensulfide produced 4-isopropyl-2-mercaptotropone (IV) as orange crystals, m. p. 63~65°C, in 80% yield. IV was stable in the air and the benzene layer colored dark red with ferric chloride. Methylation of IV with diazomethane in ether afforded 4-isopropyl-2-methylthiotropone (V) as a yellow oil. The identity of this compound was established by agreement of its ultraviolet spectrum with that of the product obtained by the reaction of II and potassium salt of methanethiol and admixture of their respective 2, 4-dinitrophenylhydrazone, purple needles, m. p. 183°C. Reaction of V with excess of hydrazine by refluxing in methanol for 5 hr. produced I which was identified by admixture of its benzylidene compound, yellow needles, m. p. 203°C, with that of the authentic sample.



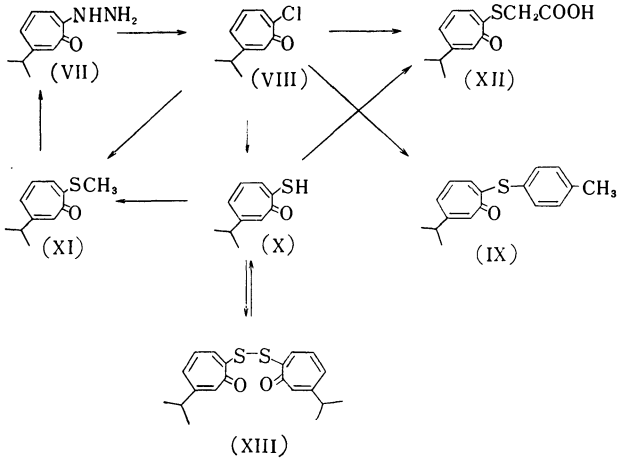


Fig. 1. Ultraviolet absorption spectra[8] of IV and V in methanol.

Application of 0.5 mol. of bromine to ethanolic solution of IV resulted in dehydrogenation from 2 mol. of IV to form 4, 4'-diisopropyl-2, 2'-ditroponyl disulfide (VI) as pale yellow cubic crystals, m. p. 155~156°C.

Heating of VIII with potassium salt of *p*-thiocresol in ethanol afforded 6-isopropyl-2-*p*-tolylthiotropone (IX) as pale yellow plates, m. p. 129~130.5°C. Similarly, application of 4 mol. of potassium hydrogensulfide gave 6-isopropyl-2-mercaptotropone (X) as dark red oil, b. $p._2$ 125~130°C. X was stable in the air like IV and solely formed 6-isopropyl-2-methylthiotropone (XI) as yellow oil by the action of diazomethane. The identity of this compound was established by comparison of its ultraviolet spectrum with that of the product obtained by the reaction of VIII and potassium salt of methanethiol in ethanol and by admixture of respective 2, 4-dinitrophenylhydrazone, purple needles, m. p. 193~195°C.

Heating of XI with excess of hydrazine in methanol for 9 hr. produced VII, which was confirmed by admixture of the benzylidene compound of yellow prisms, m. p. 167°C. The formation of I from V and of VII from XI prove that in substitution reaction of halotropones with thiols, abnormal reaction seen in the case of substitution reaction with amines[9,10] does not take place.

Scheme 2

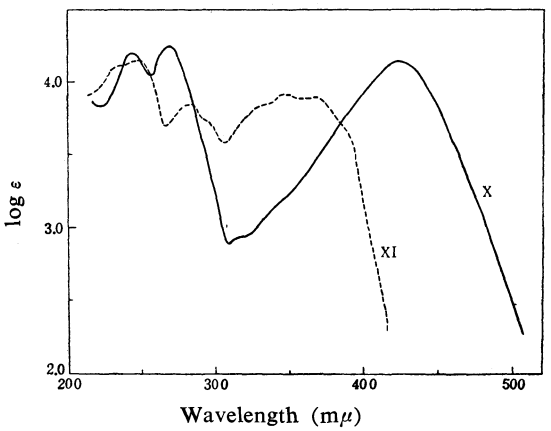
10) T. Sato, *J. Chem. Soc. Japan, Pure Chem. Sec.* (*Nippon Kagaku Zasshi*), **80**, 1056 (1959).

The reaction of the sodium salt of X and sodium monochloroacetate produced 6-isopropyl-2-carboxymethylthiotropone (XII) as pale yellow prisms, m. p. 158~160°C. This compound agreed with the product obtained from the reaction of VIII and potassium thioglycolate through admixture.



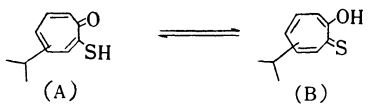


Fig. 2. Ultraviolet absorption spectra of X and XI in methanol.

Bromination of X in ethanol afforded 6, 6'-diisopropyl-2, 2-ditroponyldisulfide (XIII) as pale yellow leaflets, m. p. 210~211°C. XIII is also obtained by tosylation of X in pyridine, while heating of XIII with alkaline aqueous solution of sodium sulfide results in its reduction to form X.

(A) (B)

There are two possible tautomeric structures, A and B, for both IV and X but this problem will be discussed in a separate report, together with that of the parent 2-mercaptotropone.

## Experimental[11]

**4-Isopropyl-2-*p*-tolylthiotropone (III).**—A solution of 80 mg. of *p*-thiocresol, 0.5 ml. of ethanol, and 0.1 ml. of 50% potassium hydroxide was added to a solution of 0.1 g. of 2-chloro-4-isopropyltropone (II) dissolved in 0.3 ml. of ethanol and the mixture was heated on a water bath for a short time. The mixture was diluted with water and the oil that separated out was taken up in benzene. The solid obtained therefrom was recrystallized from cyclohexane to 80 mg. of III as pale yellow plates, m. p. 110.5~112°C.

Found: C, 75.22; H, 6.46. Calcd. for $C_{17}H_{18}OS$: C, 75.51; H, 6.71%[12].

11) All melting points are not corrected.

2, 4-Dinitrophenylhydrazone: Dark red prisms (from ethanol-benzene mixture), m. p. 206~207°C.

Found: C, 60.98; H, 4.73; N, 12.72. Calcd. for $C_{23}H_{22}O_4N_4S$: C, 61.32; H, 4.92; N, 12.44%.

**4-Isopropyl-2-mercaptotropone (IV).**—To a solution of 0.1 g. of II dissolved in 2 ml. of methanol, a solution of potassium hydrogensulfide, prepared by saturation of hydrogen sulfide in a solution of 0.26 ml. of 50% potassium hydroxide in 2 ml. of methanol, was added and the mixture was heated on a water bath for a short time. Methanol was evaporated under a reduced pressure, water was added to the residue, and the solution was treated with activated carbon. The filtrate thereby obtained was acidified with 6N sulfuric acid and the crystals that separated out were collected by filtration. Sublimation of this product under 5 mmHg pressure afforded IV as orange-red crystals m. p. 63~65°C. Yield, 80 mg.

Found: C, 66.39; H, 6.94. Calcd. for $C_{10}H_{12}OS$: C, 66.63; H, 6.71%.

Picryl derivative: Prepared from the potassium salt of IV and picryl chloride, and recrystallized from ethanol to yellow needles, m. p. 174°C.

Found: C, 49.24; H, 3.26; N, 10.88. Calcd. for $C_{16}H_{13}O_7N_3S$: C, 49.10; H, 3.35; N, 10.74%.

**4-Isopropyl-2-methylthiotropone (V).**—i) To a solution of 0.2 g. of II dissolved in 1 ml. of ethanol, 0.2 ml. of 50% potassium hydroxide saturated with methanethiol was added by which exothermic reaction took place. The mixture was diluted with water, extracted with benzene, and the extract was submitted to low pressure distillation, from which 0.2 g. of V was obtained as a yellow oil.

2, 4-Dinitrophenylhydrazone: Purple needles (from ethanol-benzene mixture), m. p. 183°C.

Found: C, 54.21; H, 4.62; N, 14.79. Calcd. for $C_{17}H_{18}O_4N_4S$: C, 54.53; H, 4.85: N, 14.97%.

ii) IV was methylated with diazomethane in ether by the usual process. The product thereby obtained showed good agreement with V obtained above, in ultraviolet absorption spectrum and 2, 4-dinitrophenylhydrazone.

**Reaction of V and Hydrazine.**—A mixture of 30 mg. of V, 0.5 ml. of methanol, and 1 drop of 80% hydrazine hydrate was refluxed for 5 hr., methanol was evaporated under a reduced pressure, and the residue was heated after addition of 2 drops of methanol and 3 drops of benzaldehyde. The crystals that separated out were collected and recrystallized from ethanol to give yellow needles, m. p. 202°C, identical with the bezylidene compound, m. p. 202°C, of 2-hydrazino-4-isopropyltropone (I).

**4, 4'-Diisopropyl-2, 2'-ditroponyl Disulfide (VI).**—A solution of 50 mg. of bromine in 0.5 ml. of ethanol was added to 0.1 g. of IV dissolved in 2 ml. of ethanol, by which crystals began to separate out gradually. After about 30 min. the crystals were collected and recrystallized from ethanol to give 50 mg. of VI as pale yellow, cubic crystals, m. p. 155~156°C.

Found: C, 66.96; H, 5.89. Calcd. for $C_{20}H_{22}O_2S_2$: C, 67.00; H, 6.18%.

12) The microanalyses were carried out by Miss A. Iwanaga and Mr. S. Azumi to whom the author expresses his gratitude.

**6-Isopropyl-2-*p*-tolylthiotropone (IX).**—A solution of 80 mg. of *p*-thiocresol, 0.1 ml. of 50% potassium hydroxide, and 0.5 ml. of ethanol was added to 0.1 g. of 2-chloro-6-isopropyltropone (VIII) in 0.3 ml. of ethanol and the mixture was heated on a water bath for a short time. This was diluted with water, crystals that separated out were collected, and recrystallized from cyclohexane to give 90 mg. of (IX) as pale yellow plates, m. p. 129～130.5°C.

Found: C, 75.19; H, 6.41. Calcd. for $C_{17}H_{18}OS$: C, 75.51; H, 6.71%.

2, 4-dinitrophenylhydrazone: Purple prisms (from ethanol-benzene mixture), m. p. 227～228°C.

Found: C, 61.03; H, 4.76; N, 12.64. Calcd. for $C_{23}H_{22}O_4N_4S$: C, 61.32; H, 4.92; N, 12.44%.

**6-Isopropyl-2-mercaptotropone (X).**—A solution of potassium hydrogensulfide, prepared by saturating hydrogen sulfide in a mixture of 0.46 ml. of 50% potassium hydroxide and 1.5 ml. of methanol was added to the solution of 0.18 g. of VIII dissolved in 0.5 ml. of methanol and the mixture was heated on a water bath for a short time. Methanol was evaporated under a reduced pressure, the residue was dissolved in water, and acidified with 6N sulfuric acid. The oil that separated out was taken up in chloroform and the residue from the chloroform extract was distilled under a reduced pressure, affording 0.13 g. of X as a dark red oil, b. $p._2$ 125～130°C.

Found: C, 66.68; H, 6.48. Calcd. for $C_{10}H_{12}OS$: C, 66.63; H, 6.71%.

2, 4-dinitrophenyl derivative: Prepared from the potassium salt of X and 2, 4-dinitro-chlorobenzene and recrystallized from ethanol to give yellow prisms, m. p. 156～158°C.

Found: C, 55.17; H, 3.85; N, 8.46. Calcd. for $C_{16}H_{14}O_5N_2S$: C, 55.48; H, 4.07; 8.09%.

Picryl derivative: Prepared from the potassium salt of X and picryl chloride, and recrystallized from ethanol to give yellow needles, m. p. 145～147°C.

Found: C, 49.07; H, 3.29; N, 10.96. Calcd. for $C_{16}H_{13}O_7N_3S$: C, 49.10; H, 3.35; N, 10.74%.

**6-Isopropyl-2-methylthiotropone (XI).**—i) To a solution of 0.2 g. of VIII dissolved in 0.5 ml. of ethanol, 0.2 ml. of 50% potassium hydroxide saturated with methanethiol was added, by which an exothermic reaction occurred. The mixture was diluted with water, separated oil was extracted with benzene, and residue from the benzene extract was distilled under a reduced pressure, affording 0.17 g. of XI as a yellow oil.

2, 4-Dinitrophenylhydrazone: Purple needles (from ethanol), m. p. 193～195°C.

Found: C, 54.23; H, 4.48; N, 15.19. Calcd. for $C_{17}H_{18}O_4N_4S$: C, 54.53; H, 4.85; N, 14.97%.

ii) Methylation of X with diazomethane by the usual process afforded a product which was identical with the product obtained in (i) in ultraviolet absorption spectrum and 2, 4-dinitrophenylhydrazone.

**Reaction of XI and Hydrazine.**—A mixture of 0.1 g. of XI, 1 ml. of methanol, and 2 drops of 80% hydrazine hydrate was refluxed for 9 hr. Methanol and excess of hydrazine were removed by low pressure distillation and the residue was heated after addition of 0.5 ml. of ethanol and 5 drops of benzaldehyde. The crystals that separated out were recrystallized from ethanol to give 50 mg. of yellow prisms, m. p. 165～167°C, undepressed on admixture with the benzylidene compound, m. p. 167°C, of 2-hydrazino-6-isopropyltropone (VII).

**2-Carboxymethylthio-6-isopropyltropone (XII).**—(i) A solution of 60 mg. of monochloroacetic acid in 0.5 ml. of 2 N sodium hydroxide and 1 ml. of water was added to the mixture of 0.1 g. of X, 0.3 ml. of 2 N sodium hydroxide, and 1 ml. of water, and the mixture was heated on a water bath for 10 min. by which the solution changed its color from red to yellow. After treatment with activated carbon, the filtrate was acidified with 6N sulfuric acid and the crystals that separated out were collected by filtration. Recrystallization from hydrous ethanol afforded 50 mg. of XII as pale yellow prisms, m. p. 158～160°C.

Found: C, 60.88; H, 5.91. Calcd. for $C_{12}H_{14}O_3S$: C, 60.48; H, 5.92%.

ii) A solution of 50 mg. of thioglycolic acid, 0.3 ml. of 20% potassium hydroxide, and 3 ml. of ethanol was added to the solution of 90 mg. of VIII dissolved in 1 ml. of ethanol, and the mixture was heated on a water bath for 30 min. After evaporation of ethanol under a reduced pressure, water was added to the residue and the solution was treated with activated carbon. The filtrate was acidified with 6 N sulfuric acid and the crystals that precipitated out were recrystallized from hydrous ethanol to give 50 mg. of XII, m. p. 158～159°C, undepressed on admixture with the product obtained in (i).

**6, 6'-Diisopropyl-2, 2'-ditroponyl Disulfide (XIII).**—i) A solution of 50 mg. of bromine in 0.5 ml. of ethanol was added to the solution of 0.1g. of X dissolved in 1 ml. of ethanol, with stirring and ice-cooling. After an hour, the crystals that separated out were collected and recrystallized from benzene-ethanol mixture to give 60 mg. of XIII, as pale yellow leaflets, m. p. 210～211°C.

Found: C, 66.71; H, 6.05. Calcd. for $C_{20}H_{22}O_2S_2$: C, 67.00; 6.18%.

ii) A solution of 50 mg. of X dissolved in 0.3 ml. of pyridine was cooled with ice and 60 mg. of tosyl chloride was added to it, by which the reaction occurred with evolution of heat. The mixture was acidified with 2N hydrochloric acid and the crystals that separated out were recrystallized from a large amount of ethanol affording 30 mg. of XIII, m. p. 210～210.5°C , undepressed on admixture with the product obtained in (i).

Found: C, 67.25; H, 6.03%.

**Reduction of (XIII).**—A mixture of 50 mg. of XIII, 2 ml. of 2N sodium hydroxide, and 50 mg. of sodium sulfide was heated on a water bath for 10 min. by which XIII dissolved completely to form a red solution. After treatment with activated carbon, the filtrate was acidified with 6 N sulfuric acid and the oil that separated was extracted with chloroform. The residue from the chloroform extract was distilled under a reduced pressure to yield 30 mg. of X as a dark red oil, which was identified by ultraviolet absorption spectrum and the picryl derivative.

The present work was carried out while the author was a resident research chemist in the Nozoe Laboratory, Faculty of Science, Tohoku University. The author expresses his deep gratitude to Professor Tetsuo Nozoe for his kind and unfailing guidance throughout this period and to the authorities of Tanabe Seiyaku Co., Ltd. for giving him the chance to study at the above place.
