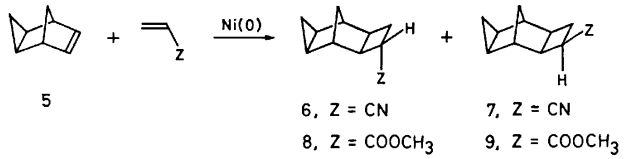
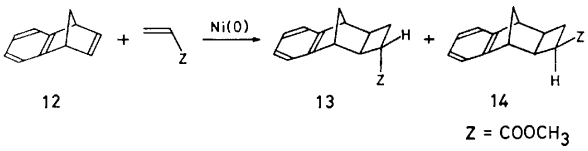
Nickel(0) Catalyzed [$_{\pi}2+_{\pi}2$] *Cross-addition.* When a solution of the cyclopropanated hydrocarbon **5** in acrylonitrile was kept at 70 °C for 120 h in the presence of a catalytic amount of bis(acrylonitrile)-nickel(0) [Ni(an)$_2$], the [2+2] cycloadducts **6** and **7** were obtained in 55% yield in a ratio of 63:37. Neither other cycloadducts nor dimeric products were obtained. Neither were rearrangement products of the starting hydrocarbon **5** detected. Similarly, the reaction of **5** with methyl acrylate (45 °C, 48 h) in the presence of bis(1,5-cyclooctadiene)nickel(0) [Ni-(cod)$_2$] gave a 78:22 mixture of **8** and **9** in 72% yield. Reaction of **5** with 1,2-disubstituted olefins proceeds more sluggishly. Dimethyl maleate and **5** in toluene



5 6, Z = CN 7, Z = CN 8, Z = $COOCH_3$ 9, Z = $COOCH_3$

10 11 Z = $COOCH_3$

in the presence of Ni(cod)$_2$ (35 °C, 72 h) afforded **10** and **11** (97:3) in 10% yield. Since dimethyl fumarate did not give any adducts under similar conditions, the origin of the production of **11** as a stereo impurity is presently unknown.[8)] The reaction of the benzo derivative **12** and methyl acrylate in the presence of Ni(cod)$_2$ afforded an 87:13 mixture of the stereoisomeric cycloadducts **13** and **14** in 34% yield. On the other hand, the endo cyclopropane isomer of **5** (**15**), bicyclo[2.2.1]heptene (**16**), and 5-methylene-bicyclo[2.2.1]heptene (**17**) gave no or very little cycloadducts with electron-deficient olefins.



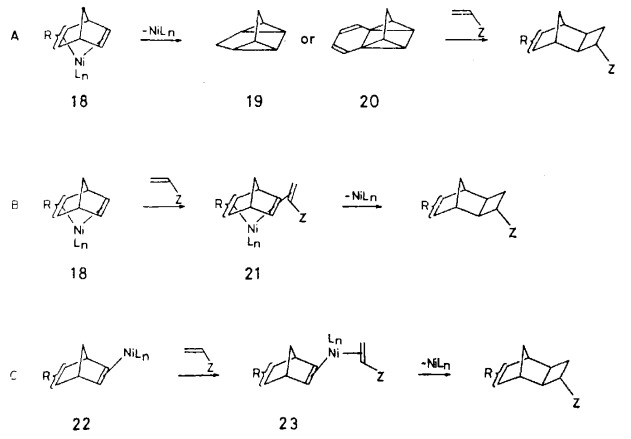
12 13 14 Z = $COOCH_3$

15 16 17

Thus the hydrocarbons **5** and **12** react with olefins in the presence of Ni(0) catalysts under mild reaction conditions to give formal [$_{\pi}2+_{\pi}2$] cycloadducts as the sole products. Characteristic features of these Ni(0)-catalyzed reactions include: (a) The reactions provide new examples of completely selective [2+2] cross-additions promoted by transition metal complexes. (b) The reactions afford only exo adducts, in contrast with the reaction of **1** with methylenecyclopropane

which produced endo adducts as the major products.[6] (c) The cycloaddition proceeds with a high degree of stereospecificity concerning the electron-deficient olefinic substrates. (d) The reactivities of the bicyclo-[2.2.1]heptenes are highly sensitive to the structural change at the site remote from the reacting double bond.

Possible Reaction Paths. Three paths, A, B, and C, may be conceivable "*a priori*" as possible mechanisms which are consistent with the characteristics of the reactions (Scheme 1). The first two, A and



Scheme 1.

B, involve the coordination complex **18** where the strained hydrocarbon is acting as an endo bidentate ligand.[9,10] Thus path A assumes initial metal catalyzed skeletal change of **18** to **19**[11] or **20** and subsequent uncatalyzed, symmetry-allowed [$\sigma 2+\sigma 2+\pi 2$] cycloaddition,[12,13] whereas path B involves the donor-acceptor complex **21** in which the electron-deficient olefin is interacting with the bicycloheptene double bond from the side opposite the coordinated metal atom.[14] Reaction *via* path C goes through the metal complexes **22** and **23** in which the strained olefin binds to the Ni(0) atom as an exo unidentate ligand.

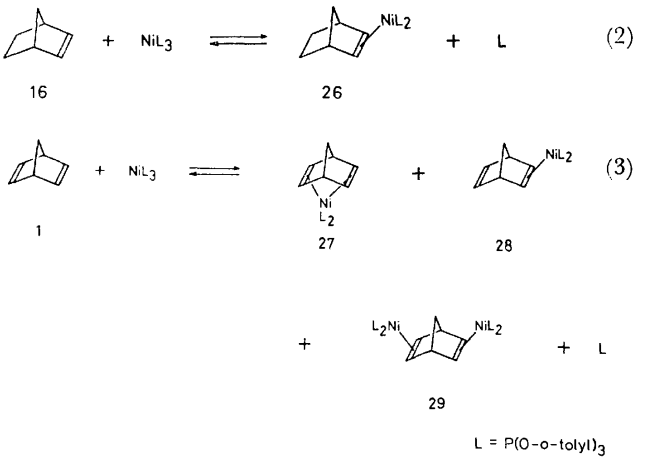
Operation of the path A could be readily dismissed on the basis of the following experiments. Gas chromatographic analysis of the reaction mixture of **5** with methyl acrylate did not indicate the presence of **19**. Moreover, when separately prepared **19**[11] was exposed to the Ni(0) catalyst in methyl acrylate, no traces of cycloadducts **8** and **9** were formed; the compound **19** was recovered unchanged.

Elucidation of the Mode in the Coordination of the Strained Olefins to Nickel(0) Complex. In order to differentiate the remaining two possibilities, B and C, the mode of coordination of the initial strained olefins to the Ni(0) atom was examined by Tolman's method. An olefinic substrate and a Ni(0) complex are known to exist in equilibrium as depicted in Eq. 1.[15]

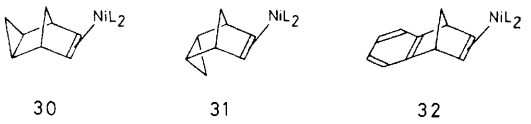
$$\underset{\mathbf{24}}{\text{Olefin}} + \text{NiL}_3 \rightleftharpoons \underset{\mathbf{25}}{\text{(olefin)NiL}_2} + \text{L} \qquad (1)$$

$$\text{L}=\text{P(O-}o\text{-tolyl)}_3$$

A monoolefin of an appropriate concentration reacts with Ni[P(O-*o*-tolyl)$_3$]$_3$ to give a single 1:1 complex **25**. whose electronic spectrum exhibits an absorption maximum around 350 nm and a shoulder near 400 nm irrespective of the structure of the olefins. Thus two isosbestic points are to be observed when the spectra are taken at various concentration of olefins. The compound **16** presents a typical example (Eq. 2 and Fig. 1). On the other hand, the diene **1** exhibited the complex spectra shown in Fig. 2, where no absorption maxima were observed over the range 300—550 nm. This is ascribed to the fact that **1** acts as both an endo bidentate and an exo unidentate ligand to give a mixture of **27**—**29** (Eq. 3).[15] The



hydrocarbons **5**, **12**, and **15** displayed spectroscopic behavior quite similar to that observed for the monoolefin **16** (Figs. 3, 4, and 5), which indicates that these strained hydrocarbons coordinate to Ni(0) atom as exo unidentate ligands to give complexes **30**—**32**. Although the structure and properties of the complex **24** are different from those of the catalysts employed



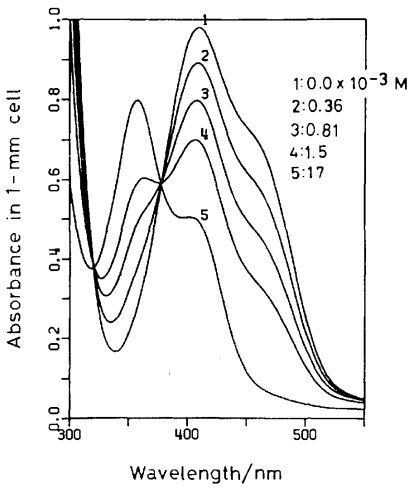


Fig. 1. Electronic spectra of benzene solution containing 1.94×10^{-3} M (1 M = 1 mol dm^{-3}) of Ni[P(O-*o*-tolyl)$_3$]$_3$ and increasing concentration of **16** at 24 °C.

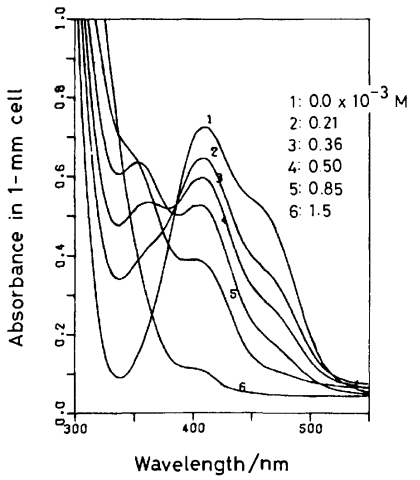

Fig. 2. Electronic spectra of benzene solution containing 1.32×10^{-3} M of Ni[P(O-*o*-tolyl)$_3$]$_3$ and increasing concentration of **1** at 24 °C.

in the actual catalytic reactions, these results strongly suggest that complexes of a similar type play an important role in the present catalytic reactions. Thus path C is thought to be most probable.

Determination of the Equilibrium Constant of the Complex Formation. Based on the electronic spectra (Figs. 1—5) of the mixtures of the complex **24** and the strained olefins, the equilibrium constants of the complex formation at 24 °C were calculated following Tolman's procedure.[15] The results are summarized in Table 1.

Reactivity of the Strained Olefins. The rate of the reaction of the strained olefins with methyl acrylate catalyzed by Ni(cod)$_2$ was measured at 40 °C. The results are listed in Table 1. The relative reactivities decrease in the order **5**>**12**>**15**. The competition experiments using **5** and **15** at 40 °C showed that the presence of varying amounts of **15** does not affect the reactivity of **5**.

Homoconjugation in the Olefinic Substrates. The existence of homoconjugation in **1**,[2] **5**,[2b] and **12**[2c] has been well-established mainly on the basis of photoelectron and charge-transfer spectra. The influence

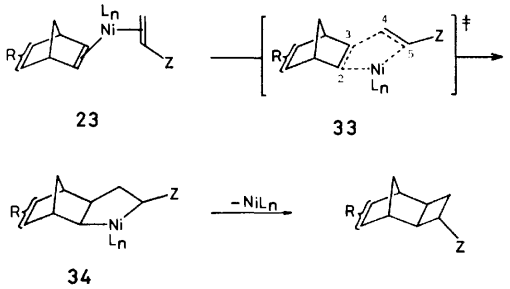
a) $K=[(\text{olefin})NiL_2][L]/[\text{olefin}][NiL_3]$. b) Very large.

of stereoelectronic factors on the degree of these through-space interactions are considerable. In exo derivative **5**, there is substantial homoconjugation which arises from the direct overlap between the π-orbital of the double bond and the Walsh-orbital of the cyclopropane ring. On the other hand, the cyclopropane ring of the endo isomer **15** does not participate

in the cyclic homoconjugation with the double bond.[2b] The extent of the homoconjugative interaction decreases in the order **1**>**12**>**5**≫**15**.

Discussion. It should be emphasized that in these catalytic reactions the benzene ring or cyclopropane rings which are located remote from the reacting carbon–carbon double bond exert definitive influences on the reactivities of the strained hydrocarbons. In certain cases the reactivities of the strained olefinic hydrocarbons can be gauged from the strain energies of these hydrocarbons.[16] There is no appreciable difference in strain energies between these hydrocarbons, because the carbocyclic frameworks are quite similar to each other. Further, as can be seen from the values of equilibrium constants and the results of competitive experiments, there no good correlation seems to exist between the reactivity and the coordination ability of the strained olefins with the Ni(0) atom. For instance, the compound **12** has a large equilibrium constant, but is less reactive than **5**. The exo cyclopropane derivative **5** has an equilibrium constant only three times larger than that of the endo isomer **15**, but only the former compound reacts with methyl acrylate.

The present catalytic reactions can be considered to proceed in a stepwise manner with the initial formation of a transitory five-membered metallacycle **34** as outlined in Scheme 2.[17,18] The observed structure-reactivity relationship leads us to consider that the cyclic homoconjugation between the double bond and cyclopropane or the benzene ring exerts a great influence on lowering the energy of the transition state **33** which gives rise to the metallacyclopentane intermediate **34**. MO considerations are consistent with this assumption; the cyclic homoconjugation in bicyclo[2.2.1]heptene system reduces the bond order of the C=C bond and consequently increases the free valency of C_2 and C_3. This effect facilitates the bonding interaction between C_2 and Ni, and C_3 and C_4, which results in lowering the transition state energy. If the formation of **34** *via* **33** is the rate-determining step, such effects are conceived to determine the reactivity of the strained olefins in the present catalysis.[19]



Scheme 2.

Experimental

General. The nuclear magnetic resonance (NMR) spectra were recorded either on a Varian HA-100D (100 MHz) or a JEOL JNM-FX 100 (100 MHz, FT-NMR) spectrometer. Chemical shifts were indicated as parts per million down field from tetramethylsilane as an internal standard. Singlet, doublet, triplet, and multiplet are abbreviated to s, d, t, and m. Infrared (IR) spectra were taken on a JASCO Model DS-402G spectrophotometer in carbon tetrachloride. Analytical gas chromatography (GLC) was done on Hitachi Model 063 instrument equipped with a flame ionization detector using nitrogen as the carrier gas. Preparative gas chromatography was performed on a Varian Model 1700 instrument using helium as the carrier gas. The columns used follow: A, 3 mm×2 m 10% Silicone DCQF-1 on 100—120 mesh Chromosorb W AW; B, 10 mm× 3 m 10% Silicone DCQF-1 on 100—120 mesh Neosorb; C, 3 mm×2 m 10% Silicone DCQF-1 on 100—120 mesh Neopak 1A; D, 1/8 inch×4 m 10% Silicone DCQF-1 on 80—100 mesh Chromosorb W AW; E, 3 mm×2 m 5% poly(ethylene glycol) 20M on 80—100 mesh Chromosorb G NAW. The visible spectra were recorded on a Hitachi Model 323 spectrometer using a 1-mm cell equipped with a serum cap. Low-resolution mass spectra were obtained at 70 eV on Hitachi Model RMU-6C instrument. High resolution mass spectra were taken on a JEOL JMS-D300 spectrometer equipped with JMA-2000 mass data analysis system. Analytical thin layer chromatography (TLC) was done on E. Merck Kieselgel PF_{254} precoated plates (0.25-mm layers). Preparative TLC separation was performed using 20 cm×20 cm glass plates coated with a 1.0-mm thick layer of E. Merck Kieselgel PF_{254}. The positions of spots were visualized by exposure to iodine vapor or a spray of a solution of Cerium(IV) sulfate in 1 mol dm^{-3} H_2SO_4 followed by heating on a hot plate.

Materials. Guaranteed grade 1-hexene and benzene for spectrometry, and reagent grade methyl acrylate, acrylonitrile, acetonitrile, diethyl ether, and hexane for handling air-sensitive metal complexes were distilled under argon over powdered calcium hydride and stored in Schlenk tubes under argon. E. Merck norbornadiene and norbornene were distilled over calcium hydride and stored in the presence of a small amount of hydroquinone. Other reagent grade solvents and reagents were distilled before use.

Ni(an)$_2$-catalyzed Reaction of **5** *and Acrylonitrile.* $Ni(an)_2$ was prepared in a glass ampoule from $Ni(CO)_4$ (34.0 mg, 0.20 mmol) and acrylonitrile (2.5 ml) by the literature procedure[20] and to this was added a solution of **5**[21] (240 mg, 2.26 mmol) in acrylonitrile (1.5 g, 28 mmol). The tube was sealed under argon and the mixture was kept at 70 °C for 120 h. After addition of dichloromethane (20 ml) to the reaction mixture, the nickel complex was decomposed by air. The resulting precipitates were removed by filtration through Celite 545 and the filtrate was evaporated to give a colorless oil. Fractional distillation by Kugelrohr afforded a mixture of *anti*-3-cyano-*exo*,*exo*-tetracyclo[4.3.1.-$0^{2,5}.0^{7,9}$]decane (**6**) and its syn isomer **7** (210 mg, 55% combined yield), bp 90—100 °C (3 mmHg††). No other products were detected by TLC analysis (R_f 3.9, **6**, and **7** unseparable, hexane–ether 10:1). GLC analysis (column A, 150 °C) indicated that **6** (t_R 25.6 min) and **7** (t_R 28.8 min) produced in a ratio of 63:37. Analytical samples of **6** and **7** were obtained by preparative GLC (column B, 180 °C). Spectral and analytical data of the products follow: **6**: IR 2235 cm^{-1} (CN); NMR δ 0.00 (dt, $J_{8a,8s}=J_{8a,7}=J_{8a,9}=7.0$ Hz, H_{8a}), 0.38 (dt, $J_{8s,7}=J_{8s,9}=3.0$ Hz, H_{8s}), 0.59 (dd, H_7, H_9), 0.97 (A part of ABq, $J_{10s,10a}=12.0$ Hz, H_{10s}), 1.12 (B part of ABq, H_{10a}), 1.6—2.0 (m, H_5), 2.13 (broad s, H_6), 2.26 (broad s, H_1), 2.3—2.7 (m, H_2, H_3, $2H_4$). Mass spectrum *m/e* 158 (M^+-1). Found: C, 82.76; H, 8.13; N, 8.58%. Calcd for $C_{11}H_{13}N$: C, 82.97; H, 8.23; N, 8.80%. **7**: IR 2230

†† 1 mmHg≈133.322 Pa.

cm^{-1} (CN); NMR δ −0.03 (dt, $J_{8a,8s}$=8.0 Hz, $J_{8a,7}$=$J_{8a,9}$=6.5 Hz, H_{8a}), 0.44 (dt, $J_{8s,7}$=$J_{8s,9}$=3.0 Hz, H_{8s}), 0.55 (dd, H_7, H_9), 1.09 (A part of ABq, $J_{10s,10a}$=13.0 Hz, H_{10s}), 1.62 (B part of ABq, H_{10a}), 1.6—1.9 (m, H_5), 2.12 (broad s, H_1), 2.2—2.6 (m, H_2, $2H_4$, H_6), 3.0—3.4 (m, H_{3n}). Mass spectrum *m/e* 158 (M^+-1). Found: C, 83.14; H, 8.25; N, 8.61%. Calcd for $C_{11}H_{13}N$: C, 82.97; H, 8.23; N, 8.80%.

Preparation of the Authentic Samples of **6** *and* **7**. *anti*- and *syn*-3-cyano-*exo*-tricyclo[4.2.1.$0^{2,5}$]oct-7-ene (**35**) and (**36**) were prepared by the application of the reported procedure.[12] In a 20-ml reaction ampoule were placed quadricyclane (500 mg, 5.43 mmol), acrylonitrile (3.0 ml), and hydroquinone (3 mg) and the tube was sealed under argon. The mixture was kept at 95 °C for 72 h. Distillation of the reaction mixture *in vacuo* afforded a mixture of **35** and **36** (700 mg, 92%). GLC analysis (column C, 140 °C) indicated that **35** (t_R 14.0 min) and **36** (t_R 12.0 min) were produced in 33:67. Pure samples of the adducts were obtained by GLC purification (column D, 130 °C). Spectral properties of **35** and **36** follow: **35**: NMR ($CDCl_3$) δ 1.40 (d, $J_{9a,9s}$=10.0 Hz, H_{9a}), 1.59 (d, H_{9s}), 2.71 (broad s, H_6), 2.80 (broad s, H_1), 5.99 (m, H_7, H_8), 1.2—2.6 (m, other protons). High resolution mass spectrum. Found: *m/e* 145.087. Calcd for $C_{10}H_{11}N$: *m/e* 145.089. **36**: NMR ($CDCl_3$) δ 1.49 (d, $J_{9s,9a}$=10.0 Hz, H_{9s}), 2.02 (d, H_{9a}), 2.73 (broad s, H_6), 2.98 (broad s, H_1), 3.0—3.4 (m, H_{3n}), 6.01 (broad s, H_7, H_8), 1.5—2.7 (m, other protons). High resolution mass spectrum. Found: *m/e* 145.090. Calcd for $C_{10}H_{11}N$: *m/e* 145.089. Conversion of **35** to **6** was performed by the cyclopropanation by gaseous diazomethane catalyzed by bis[*N*-(1-phenylethyl)salicylideneaminato]copper(II).[22] Purification by GLC (column B, 180 °C) gave pure sample of **6**. Compound **7** was obtained from **36** by the similar procedure. NMR and mass spectra of the authentic samples were superimposable on those of **6** and **7** obtained by metal catalysis.

$Ni(cod)_2$-catalyzed Reaction of **5** *and Methyl Acrylate*. In a 30-ml glass ampoule equipped with a serum cap was placed $Ni(cod)_2$[23] (1.50 g, 5.51 mmol) under argon and to this was added **5** (1.06 g, 10.0 mmol) and methyl acrylate (10.0 ml) with a syringe. The reaction tube was sealed under argon and kept at 45 °C for 72 h. After opening the tube dichloromethane (20 ml) was added to the mixture and air was bubbled gently for 2 h to decompose the nickel complex. The resulting black precipitates were filtered off by passage through a short column packed with Celite 545. The filtrate was concentrated and the residue was analyzed by GLC (column A, 150 °C) indicating that essentially two products *anti*-3-methoxycarbonyl-*exo*,*exo*-tetracyclo[4.3.1.$0^{2,5}$.$0^{7,9}$]decane (**8**) (t_R 15.3 min) and its syn isomer **9** (t_R 14.2 min) were produced in a ratio of 78:22. Distillation by Kugelrohr (1 mm, 150 °C) gave a mixture of **8** and **9** (1.46 g, 72% yield). Analytical samples of **8** and **9** were obtained by preparative GLC separation (column B, 180 °C). The structures of **8** and **9** were determined by the comparison of their spectral data with those of authentic samples prepared as follows. A mixture of **35** and **36** (20 g, 0.138 mol) and KOH (15 g, 0.21 mol) in 80% aqueous ethylene glycol was kept at 140 °C for 12 h. The reaction mixture was acidified by HCl and the resulting carboxylic acid was taken up into ether. Esterification by adding a solution of diazomethane in ether to the acid afforded a mixture of *anti*- and *syn*-3-methoxycarbonyl-*exo*-tricyclo[4.2.1.$0^{2,5}$]oct-7-enes (16.4 g, 67%). The ester (5.6 g, 31.5 mmol) was cyclopropanated by the reported procedure[22] to give a mixture of **8** and **9** (4.0 g, 66%). Separation by preparative GLC (column B, 180 °C) gave pure samples of **8** and **9**. The stereochemistry of the ester groups was determined on the basis of the NMR spectra taken in the presence of $Eu(fod)_3$. Physical properties of **8**: IR 1735 cm^{-1} (C=O); NMR δ −0.06 (dt, $J_{8a,8s}$=$J_{8a,7}$=$J_{8a,9}$=7.0 Hz, H_{8a}), 0.36 (dt, $J_{8s,7}$=$J_{8s,9}$=3.0 Hz, H_{8s}), 0.56 (dd, H_7, H_9), 0.93 (A part of ABq, $J_{10s,10a}$=12.0 Hz, H_{10s}), 1.22 (B part of ABq, H_{10a}), 1.5—1.8 (m, H_5), 2.09 (broad s, H_6), 2.18 (broad s, H_1), 2.2—2.6 (m, H_2, H_3, $2H_4$), 3.61 (s, OCH_3). When the $Eu(fod)_3$-induced shifts were plotted against the relative molar ratios of the shift reagent and the substrate, a linear relationship was observed. The gradients, ppm/mol of $Eu(fod)_3$ per mole of substrate, of these lines were 26.6 (OCH_3), 25.0 (H_3), 20.5 (H_{4n}), 20.0 (H_2), 10.0 (H_5), 7.8 (H_{4x}), 6.1 (H_1), 6.1 (H_{10a}), 3.8 (H_6), 3.3 (H_{10s}). Values for cyclopropane protons could not be determined. Mass spectrum *m/e* 192 (M^+). Found: C, 75.04; H, 8.32%. Calcd for $C_{12}H_{16}O_2$: C, 74.97, H, 8.39%. Physical properties of **9**: IR 1738 cm^{-1} (C=O); NMR δ −0.11 (dt, $J_{8a,8s}$=$J_{8a,7}$=$J_{8a,9}$=7.0 Hz, H_{8a}), 0.31 (dt, $J_{8s,7}$=$J_{8s,9}$=3.0 Hz, H_{8s}), 0.50 (dd, H_7, H_9), 0.78 (A part of ABq, $J_{10s,10a}$=12.0 Hz, H_{10s}), 1.22 (B part of ABq, H_{10a}), 2.07 (broad s, H_6), 1.8—2.6 (m, H_2, $2H_4$, H_5), 3.0—3.4 (m, H_{3n}), 3.60 (s, OCH_3). The gradients of the lines derived from the $Eu(fod)_3$-induced spectra were 19.5 (OCH_3), 20.2 (H_{10a}), 14.6 (H_1), 12.3 (H_{4x}), 9.9 (H_2), 7.8 (H_{4n}), 6.0 (H_{10s}), 5.1 (H_5), 5.0 (H_{3n}), 3.8 (H_6). Values for cyclopropane protons could not be determined. Mass spectrum *m/e* 192 (M^+). Found: C, 75.06; H, 8.33%. Calcd for $C_{12}H_{16}O_2$: C, 74.97; H, 8.39%.

$Ni(cod)_2$-catalyzed Reaction of **5** *and Dimethyl Maleate*. In a 10-ml reaction ampoule was placed $Ni(cod)_2$ (50 mg, 0.18 mmol) under argon and to this was added at −60 °C, a mixture of **5** (110 mg, 1.04 mmol), dimethyl maleate (710 mg, 4.87 mmol), and toluene (1.8 ml). The reaction tube was sealed and dipped in a water-bath kept at 30 °C for 72 h. The colorless oil obtained after the usual work-up was analyzed by GLC (column C, 175 °C) indicating that the adducts *anti*,*anti*-3,4-bis(methoxycarbonyl)-*exo*,*exo*-tetracyclo[4.3.1.$0^{2,5}$.$0^{7,9}$]decane (**10**) (t_R 21.0 min) and its *anti*,*syn*-isomer **11** (t_R 14.0 min) were produced in 10 and 0.3% yields respectively. The GLC analysis also revealed that the recovered diester consisted of dimethyl maleate (30%) and dimethyl fumarate (70%). Pure samples of **10** and **11** (mp 81.0—81.5 °C) were isolated by preparative GLC (column B, 200 °C). Spectral properties of **10**: IR 1740 cm^{-1} (C=O); NMR (benzene as a lock signal): δ −0.02 (dt, $J_{8a,8s}$=$J_{8a,7}$=$J_{8a,9}$=7 Hz, H_{8a}), 0.36 (dt, $J_{8s,7}$=$J_{8s,9}$=3 Hz, H_{8s}), 0.60 (dd, H_7, H_9), 0.93 (A part of ABq, $J_{10s,10a}$=12 Hz, H_{10s}), 0.99 (B part of ABq, H_{10a}), 2.16 (broad s, H_1, H_6), 2.64 (broad s, H_2, H_5), 2.5—2.8 (m, H_3, H_4), 3.57 (s, $2OCH_3$); mass spectrum *m/e* 250 (M^+). Found: C, 67.17; H, 7.35%. Calcd for $C_{14}H_{18}O_4$: C, 67.18; H, 7.23%. Spectral properties of **11**: IR 1734 cm^{-1} (C=O); NMR (benzene as a lock signal): δ −0.07 (dt, $J_{8a,8s}$=$J_{8a,7}$=$J_{8a,9}$=7 Hz, H_{8a}), 0.34 (dt, $J_{8s,7}$=$J_{8s,9}$=3 Hz, H_{8s}), 0.53 (dd, H_7, H_9), 0.70 (A part of ABq, $J_{10s,10a}$=13 Hz, H_{10s}), 1.11 (B part of ABq, H_{10a}), 2.24 (broad s, H_6), 2.32 (broad s, H_1), 2.1—2.6 (m, H_2, H_3, H_5), 2.95 (dd, J=4 Hz, J'=7 Hz, H_4), 3.58 (s, OCH_3), 3.60 (s, OCH_3); mass spectrum *m/e* 250 (M^+). Found: C, 66.93; H, 7.27%. Calcd for $C_{14}H_{18}O_4$: C, 67.18; H, 7.23%. The authentic samples of **10** and **11** were prepared by the cyclopropanation[22] of *anti*,*anti*- and *anti*,*syn*-3,4-bis(methoxycarbonyl)-*exo*-tricyclo[4.2.1.$0^{2,5}$]oct-7-ene,[12] respectively. NMR and IR spectra as well as GLC behavior of **10** and **11** were identical with those of authentic samples.

Attempted $Ni(cod)_2$-catalyzed Reaction of **5** *with Dimethyl Fumarate*. To $Ni(cod)_2$ (46 mg, 0.17 mmol) placed in

a 10-ml reaction ampoule was added a mixture of **5** (117 mg, 1.10 mmol), dimethyl fumarate (287 mg, 1.99 mmol), and toluene (3.0 ml) at −60 °C under argon. The reaction tube was sealed and kept at 30 °C for 72 h with occasional shaking. The reaction mixture was worked up as usual and analyzed by GLC (column C, 175 °C), indicating that no 1:1 adducts were formed.

*Ni(cod)$_2$-catalyzed Reaction of Benzonorbornadiene (**12**) and Methyl Acrylate.* In a 10-ml reaction ampoule equipped with a serum cap was placed Ni(cod)$_2$ (270 mg, 0.99 mmol) and the system was flushed with argon. To this was added a mixture of degassed **12**[24] (250 mg, 1.76 mmol) and methyl acrylate (3.0 ml) with a hypodermic syringe. The reaction tube was sealed and the mixture was kept at 40 °C for 5 d. After opening the tube, the remaining nickel complex was decomposed by introduction of a gentle stream of air. The solid substance was removed by filtration and evaporation of methyl acrylate under reduced pressure gave 460 mg of a colorless oil. Distillation *in vacuo* (160 °C (0.1 mm)) afforded a mixture of *anti*-3-methoxycarbonyl-7,8-benzo-*exo*-tricyclo[4.2.1.0^{2,5}]non-7-ene (**13**) and its syn isomer **14** (130 mg, 32%). GLC analysis (column A, 200 °C) indicated that **13** (t_R 5.4 min) and **14** (t_R 4.9 min) were produced in 80:20 ratio. No distinct coupling between H_1 and H_3, and H_5 and H_6 were observed in NMR spectra of **13** and **14**, which support the exo fusion of cyclobutane rings in these products. The stereochemistries of the ester groups were determined on the basis of the Eu(fod)$_3$-aided NMR spectra. Spectral properties of **13**: IR 1734 cm^{-1} (C=O); NMR δ 1.78 (A part of ABq, $J_{9s,9a}$=10.0 Hz, H_{9s}), 1.6—2.7 (m, H_2, H_3, $2H_4$, H_5), 2.12 (B part of ABq, H_{9a}), 3.13 (broad s, H_6), 3.22 (broad s, H_1), 3.62 (s, OCH_3), 6.8—7.2 (m, aromatic protons). The gradients of the lines derived from the Eu(fod)$_3$-induced spectra were 11.8 (OCH_3), 12.7 (H_3), 11.0 (H_{4n}), 9.7 (H_2), 5.1 (H_{4x}), 3.6 (H_5), 3.0 (H_1), 3.0 (H_{9a}), 1.6 (H_{9s}), 1.5 (H_6). Mass spectrum *m/e* 228 (M^+). Found: C, 79.01; H, 7.02%. Calcd for $C_{15}H_{16}O_2$: C, 78.92; H, 7.06%. Spectral properties of **14**: IR 1737 cm^{-1} (C=O); NMR δ 1.62 (A part of ABq, $J_{9s,9a}$=11.0 Hz, H_{9s}), 1.9—2.6 (m, H_2, $2H_4$, H_5, H_{9a}), 3.0—3.5 (m, H_3), 3.12 (broad s, H_6), 3.32 (broad s, H_1), 3.69 (s, OCH_3), 6.8—7.2 (m, aromatic protons). High resolution mass spectrum. Found: *m/e* 228.1146. Calcd for $C_{15}H_{16}O_2$: *m/e* 228.1150.

*Attempted Ni(cod)$_2$-catalyzed Reaction of **15** and Methyl Acrylate.* Ni(cod)$_2$ (380 mg, 1.38 mmol) was placed in a 20-ml reaction ampoule under argon and the tube was cooled to −70 °C in a Dry Ice–methanol bath. To this was added a solution of **15** (0.56 g, 5.28 mmol) in methyl acrylate (5.0 ml). The sealed reaction tube was kept at 45 °C for 48 h. After decomposition and removal of the resulting precipitates the reaction mixture was analyzed by GLC (column A, 140 °C) indicating that no 1:1 adducts were formed.

*Attempted Ni(cod)$_2$-catalyzed Reaction of **16** with Methyl Acrylate.* In a 10-ml glass ampoule was placed Ni(cod)$_2$ (60 mg, 0.22 mmol) under argon. Then a solution of **16** (100 mg, 1.06 mmol) in methyl acrylate (2.0 ml) was added to this and the tube was sealed. The mixture was kept at 45 °C for 48 h. After opening the tube and addition of dichloromethane (2.0 ml) the catalyst was decomposed by the introduction of a gentle stream of air. Black precipitates were filtered off through a pad of Celite 545 and the filtrate was analyzed by GLC (column A, 140 °C), which revealed that no 1:1 addition compounds were produced.

*Attempted Ni(cod)$_2$-catalyzed Reaction of **17**.* A solution of **17**[25] (56 mg, 0.53 mmol) in methyl acrylate (2.0 ml) was added to Ni(cod)$_2$ (100 mg, 0.37 mmol) placed in a 10-ml reaction ampoule under argon. The yellow solution was kept at room temperature for 20 h and then at 50 °C for 12 h. After the usual work-up, the reaction mixture was analyzed by GLC (column A, 140 °C). No products were detected.

*Comparison of the Reactivities of **5** and **12**.* A competition experiment was done by keeping a mixture of **5** (117 mg, 1.11 mmol), **12** (153 mg, 1.08 mmol), and Ni(cod)$_2$ (100 mg, 0.37 mmol) in methyl acrylate (3.0 ml) at 45 °C under argon. Aliquots of the reaction mixture were taken out with hypodermic syringes after appropriate time intervals and analyzed by GLC (column A, 200 °C). The ratio (**8**+**9**)/(**13**+**14**) varied from 1.6 to 2.4.

*Ni(cod)$_2$-catalyzed Reaction of **5** and Methyl Acrylate with or without Added **15**.* Solutions of Ni(cod)$_2$ (0.37 mmol) and eicosane (0.13 mmol, an internal standard for GLC analysis) in methyl acrylate (2 ml) containing varying amounts of **5** (0.13—0.64 mmol) and **15** (0.56—0 mmol) were kept at 40 °C for 22 h under argon. After the usual work-up, the reaction mixtures were analyzed by GLC (column E, 180 °C). The initial rates of reactions of **5** were calculated based on the above experiments. The results indicated that the presence of varying amounts of **15** caused little change in the reactivity of **5** (only by a factor of 1.0—1.1).

*Spectrophotometric Determination of the Modes and Equilibrium Constants of the Coordination of the Olefins **5**, **12**, and **15** on Nickel Atom.* Special precautions were necessary to get rid of oxygen for handling air-sensitive dilute solutions of the nickel(0) complexes. The olefinic compounds **1**, **5**, **12**, **15**, and **16** were distilled over CaH_2 under argon before use. The complex [P(O-*o*-tolyl)$_3$]$_3$Ni(0) (**24**)[26] was obtained by the procedure described by Tolman. All liquid materials were transferred with gas-tight syringes. The 5 mM (1 M= 1 mol dm^{-3}) benzene solution of **24** (2.0 ml) was freshly prepared just before use and was placed in a 5-ml flask equipped with a Teflon stopcock. To this was added an appropriate amount of the olefinic substrate in benzene. Finally the volume of the solution was adjusted strictly to 5 ml by adding benzene. Thus, 0.8 M solution of **24** in benzene containing variable concentrations (10^{-1} to 10^{-4} M) of strained olefins were prepared. For measurements of visible spectra these solutions were transferred into quartz cells of 1-mm path capped with rubber septa under argon by the use of a gas-tight syringe. The following procedure for determination of the equilibrium constants of the reaction of **5** and **24** is representative for all the other olefins. Visible spectra of a solution of **24** with variable concentration of **5** are shown in Fig. 3. The values of [(olefin)NiL$_2$] where L is P(O-*o*-tolyl)$_3$ were obtained from the loss of absorbance at 450 nm due to the complex **24**, and K was calculated according to the Eq. 4. To minimize the error, which becomes large when the K value is much greater than unity, appropriate amounts of the phosphite ligand were added so that the apparent K values become close to unity. Addition of phosphite ligand, however, causes the formation of NiL$_4$ species as shown in Eq. 5. Thus, the concentration of the each species in Eq. 4 was obtained at first assuming that K is zero, and then the concentration of NiL$_4$ was calculated using the reported formation constant.[15] Finally from the corrected concentration of the each species in

$$K = \frac{[(\text{olefin})\text{NiL}_2][\text{L}]}{[\text{olefin}][\text{NiL}_3]}, \quad (4)$$

$$\text{NiL}_3 + \text{L} \overset{k}{\rightleftharpoons} \text{NiL}_4, \quad (5)$$

Eq. 4, equilibrium constants were obtained (Table 1). Visible

spectra of the solution of **24** and other olefins are shown in Figs. 1, 2, 4, and 5.

14) Such a path is not well-established, but formation of a similar type of complex has been reported for ferrocene and TCNE or tetrafluoroethylene: M. Herberhold, "Metal π-Complex," Elsevier, Amsterdam (1972), p. 309; D. R. Fahey, *Organomet. Chem. Rev.*, **7**, 245 (1972).

15) C. A. Tolman, *J. Am. Chem. Soc.*, **96**, 2780 (1974).

16) It has been pointed out that there exists some relationship between the reactivities of olefinic bonds and their strain energies in metal catalyzed reactions. See Refs. 4b and 6.

17) For the metallacyclopentane formation from transition metal complexes and two moles of olefins, see: A. R. Fraser, P. H. Bird, S. A. Bezman, J. R. Shapley, R. White, and J. A. Osborn, *J. Am. Chem. Soc.*, **95**, 597 (1973); R. H. Grubbs and A. Miyashita, *J. Organomet. Chem.*, **161**, 371 (1978); S. J. McLain, C. D. Wood, and R. R. Schrock, *J. Am. Chem. Soc.*, **101**, 4558 (1979); S. J. McLain, J. Sancho, and R. R. Schrock, *ibid.*, **101**, 5451 (1979). A number of catalytic olefin cyclooligomerization reactions are thought to involve metallacycle intermediates: G. Wilke, *Pure Appl. Chem.*, **50**, 677 (1978).

18) A concerted mechanism has been proposed for metal catalyzed olefin cyclizations, although the mechanistic implication of the concertedness is losing its importance: W. Merk and R. Pettit, *J. Am. Chem. Soc.*, **89**, 4787 (1967); R. Pettit, H. Sugahara, J. Wristers, and W. Merk, *Discuss. Faraday Soc.*, **1969**, 71; F. D. Mango and J. H. Schachtschneider, *J. Am. Chem. Soc.*, **89**, 2484 (1967); G. N. Schrauzer, "Transition Metals in Homogeneous Catalysis," Marcel Dekker, New York, N.Y. (1971), p. 223; W. Slegeir, R. Case, J. S. McKennis, and R. Pettit, *J. Am. Chem. Soc.*, **96**, 287 (1974).

19) Thus, the reactivity of the strained olefins in the present catalytic reactions can be best explained in terms of homoconjugation. The extent of the homoconjugation of **12** is larger than that of **5**,[2b,c] while the former is less reactive than the latter, the reason of this is not clear at present. We need more informations on the energies of the transition states for such quantitative discussion.

A Novel Synthesis of 3-Aryl-1,2,4-benzotriazines *via* *N*-Phenylsulfonyl-*N*″-arylbenzamidrazones

Suketaka Ito,* Yumo Tanaka, and Akikazu Kakehi

Department of Industrial Chemistry, Faculty of Engineering, Shinshu University, Wakasato, Nagano 380

(Received June 10, 1981)

3-Aryl-1,2,4-benzotriazines were obtained in good yields by the mercury(II) oxide-oxidation of *N*-phenylsulfonyl-*N*″-arylbenzamidrazones prepared from *N*-(phenylsulfonyl)benzohydrazonoyl chlorides and anilines. From the synthetic viewpoint for benzotriazines, this method may be of high utility on account of the availability of starting materials and higher yields.

The oxidation of 2-substituted (arylsulfonyl)hydrazines leads to the formation of diazonium intermediates with the elimination of arylsulfonyl group as an arenesulfinate anion.[1] An analogous type of reaction is involved in the formation of 2,5-disubstituted tetrazoles from N^2-substituted N^4-(phenylsulfonyl)benzohydrazide hydrazones, in which the cyclization of intermediate formazan, the oxidation product of hydrazide hydrazone, has been postulated to proceed with the elimination of benzenesulfinato moiety.[2]

Such an azo or diazo group formation by the oxidation of (arylsulfonyl)hydrazine derivatives and the subsequent cyclization with the elimination of arenesulfinato moiety may be an attractive method for the synthesis of aza-heterocycles. The present paper deals with the synthesis of 3-aryl-1,2,4-benzotriazines (**1**) by the mercury(II) oxide-oxidation of *N*-phenylsulfonyl-*N*″-arylbenzamidrazones (**2**).

Results and Discussion

N-Phenylsulfonyl-N″-arylbenzamidrazones (2).[3] Amidrazones (**2**)[4] were obtained in good yields by the reaction of *N*-(phenylsulfonyl)benzohydrazonoyl chlorides (**4**)[2a] with anilines (**3**) (Scheme 1, Table 1).

The amidrazones are capable of existing in tautomeric forms, **2**(I)⇄**2**(II), as shown in Scheme 1. Furthermore, the *syn-anti* isomerism can be expected for each tautomer. For each of compounds **2**, plural, wide-spread, definitely unassignable bands due to the NH stretching were noted in the 3400—2950 cm^{-1} region in the IR spectra ($CHCl_3$),[5] and two medium peaks to be assigned to the asymmetric SO_2 stretching vibration at approximately 1380 and 1325 cm^{-1} were also found along with a strong peak due to the symmetric SO_2 stretching vibration near 1160 cm^{-1} (Table 1).

N-Methylbenzanilide phenylsulfonylhydrazone (**5**), prepared as a reference compound from *N*-methylaniline and **4** (X=H), exhibits two broad bands at 3260 and 3030 cm^{-1} (ν_{NH}), a band with a minor side peak (1601 cm^{-1}) at 1590 cm^{-1} ($\nu_{C=N}$), and three peaks at 1377, 1326 (asym. ν_{SO_2}), and 1169 cm^{-1} (sym. ν_{SO_2}, with a shoulder at 1177 cm^{-1}) ($CHCl_3$). Since this type of amidrazone cannot tautomerize, compound **5** would be expected to exhibit one band due to each of the NH, asymmetric SO_2, and symmetric SO_2 stretching vibrations; thus, the origin of the duality of absorption peaks for compound **5** should be related to the *syn-anti* isomerism and/or differences in the type of hydrogen bonding. The IR spectral pattern of each of **2** has a close resemblance to that of **5**; compounds **2**, therefore, may exist in the amide hydrazone form, **2**(I). The characteristics of IR spectra of **2** may reflect also strong hydrogen bonding in these compounds. Several geometrical forms involving intra- or intermolecular hydrogen bonding are conceivable for **2**, and the possibility of hydrazide imide structure, **2**(II), for **2** still remains.

In the ^{1}H-NMR spectra of **2**, broad *N*-H proton signals are concealed by those of aromatic protons appeared at approximately δ 6.5—8.9 ppm.

The amidrazones dissolve both in dilute mineral acids and aqueous alkali solutions. On treatment with

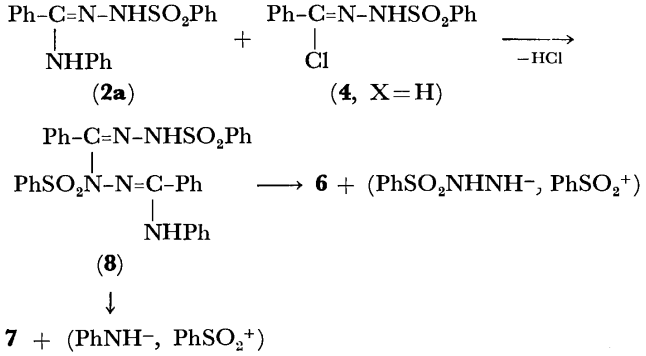
a) Solvent for recrystallization. A: Acetone, B: benzene, E: diethyl ether, H: hexane. b) Abbreviations are as follows: m, medium; s, strong; sh, shoulder; d, doublet with the counterpart peak. c) The symmetric ν_{SO_2}-peak ($\approx$1165 cm^{-1}) of each compound is accompanied with a shoulder near 1175 cm^{-1}.

hydrogen chloride in an organic solvent, **2a**, for example, gave the corresponding hydrochloride, from which the free amidrazone was recovered by neutralization.

In the amidrazone preparation, in the case of **2a** for example, small amounts of 3,4,5-triphenyl-4*H*-1,2,4-triazole (**6**) and 3,5-diphenyl-4-phenylsulfonylamino-4*H*-1,2,4-triazole (**7**) were formed as by-products. The formation of these by-products can be explained in terms of the intramolecular nucleophilic process with



the elimination of anilino or (phenylsulfonyl)hydrazino group *via* *N*-phenylsulfonyl-*N*-[*N*-(phenylsulfonyl)benzohydrazonoyl]-*N''*-phenylbenzamidrazone (**8**) which would be formed from **2a** and **4** (X=H).[6] Amidrazones are a sort of amidines: the formation of 1,2,4-triazoles by the reaction of the hydrazonoyl chloride (**4**, X=H) with amidines has been previously discussed.[7]

Oxidation of Amidrazones (2) with Mercury(II) Oxide. When amidrazone **2a** was stirred with potassium carbonate in dioxane at room temperature for 8 d, 3-phenyl-1,2,4-benzotriazine (**1a**) was obtained in a 33% yield together with benzanilide (**9a**) and small amounts of diphenyl disulfide (**10**) and *S*-phenyl benzenethiosulfonate (**11**). However, on treatment with mercury(II) oxide in the presence of potassium carbonate, the reaction proceeded smoothly to give **1a** in a 55% yield after stirring for 18 h (along with **9a**, **10**, and **11**). The similar treatment of **2b—p** afforded the corresponding 3-aryl-1,2,4-benzotriazines (**1b—p**) in widely changing yields from 11 to 82%, along with benzanilides (**9b—p**), **10**, and **11**. The results are summarized in Tables 2 and 3.

Table 2. Oxidation of amidrazones (**2**) with HgO

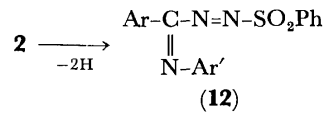
The triazines obtained were identified by their analytical and spectral data, and the confirmation of known compounds was made by direct comparison with authentic specimens prepared according to other synthetic methods.[8] The spectral data of the products are listed in Table 4. In the IR spectra, all the triazines exhibit a similar absorption pattern, exclusive of absorptions due to the substituent at the 7-position (Y) and to that in the 3-aryl group (X). Because of the presence of 3-aryl group, the absorption peaks in the region of aromatic skeletal vibrations cannot be assigned with respect to the benzotriazine skeleton. However, two strong peaks near 1320 and near 1010 cm^{-1} were observed in common with the benzotriazines; these characteristic bands may be assigned to the benzotriazine ring.[9] The maximum absorption in the range of 350—400 nm in the UV spectra should be due to the $n\rightarrow\pi^*$ transition, which also characterizes benzotriazines. The ^{1}H-NMR spectra are consistent with the benzotriazine structures.

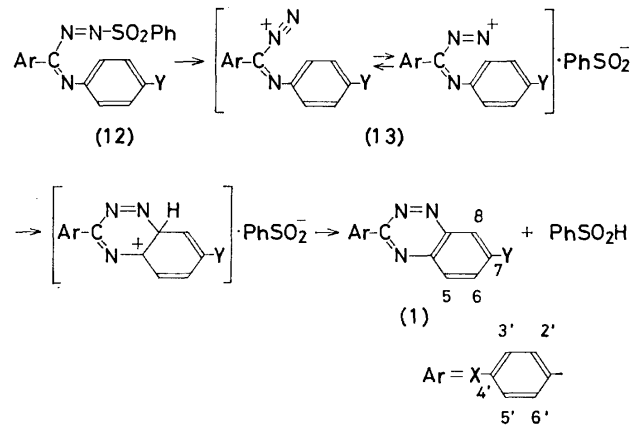
Mechanistic Consideration for the Benzotriazine Formation. The oxidation of amidrazone with mercury(II) oxide has been reported to give an imidoylazo compound;[10] thus, by analogy,[11] the primary product in the present reaction can be considered to be an imidoylazo sulfone (**12**), by the intermediacy of which the triazine formation may be reasonably interpreted.



2 $\xrightarrow[-2H]{}$ Ar–C(=N–N–SO_2Ph)–N–Ar′ (**12**)

In the case of reaction without mercury(II) oxide, the same intermediate may be formed by the oxidation with air in the presence of a base. The air oxidation of hydrazine derivatives to azo compounds has been reported for hydrazidines[2a,12] but not for amidrazones.

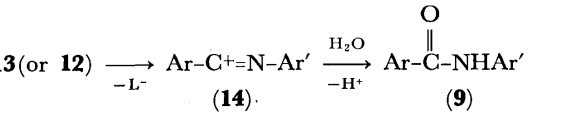
In view of the fact that the precursor of the disulfide (**10**) and *S*-phenyl benzenethiosulfonate (**11**) is benzenesulfinic acid,[13] the following route involving a diazonium intermediate can be given as the most probable mechanism for the formation of **1** from **12** (Scheme 2).



Scheme 2.

The dissociation of azo sulfones to diazonium arenesulfinates is well known,[1,3c,14] and the cyclization process might be an intramolecular diazo-coupling. From the fact that diazonium *p*-toluenesulfinate generated from α-(*p*-tolylsulfonylazo)stilbene does not cyclize to 3-phenylbenzopyridazine,[14a] the imino nitrogen of **13** may play a significant role for the cyclization as an electron-donor. The sequence of reaction shown in Scheme 2 is similar to the mechanism suggested for the acid-catalyzed benzotriazine formation from 1,3,5-triphenylformazan[15] from the viewpoint of electronic structure.

The formation of benzanilides (**9**) can be well interpreted in terms of the hydrolysis of imino-carbonium ion (**14**) which is generated from the diazonium ion (**13**) by releasing molecular nitrogen or directly from **12**.



13(or **12**) $\xrightarrow[-L^-]{}$ Ar–C$^+$=N–Ar′ (**14**) $\xrightarrow[-H^+]{H_2O}$ Ar–C(=O)–NHAr′ (**9**)

L = N_2^+(or $PhSO_2N_2$)

The formation of **1** should be competitive with that of **9**. As seen in Table 2, the anilide formation is dominant in such a case that the para-substituent of *C*-phenyl group of **12** is electron-donating (X=Me or MeO), which may be explained in terms of the labilization of the C–N linkage holding phenylazo or diazo group and the increased stability of the imino-

Table 3. Physical and analytical data for 3-aryl-1,2,4-benzotriazines (**1**)

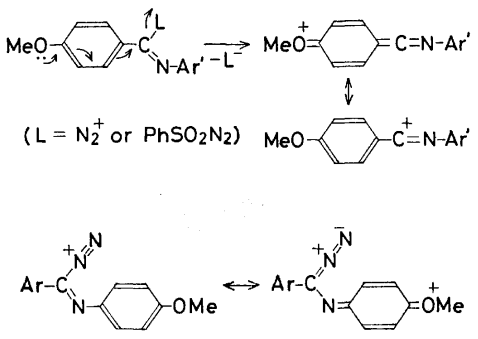
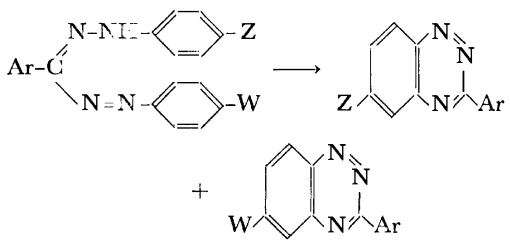
Soc.*, **1957**, 3186. e) Lit, mp 151—152 °C: R. F. Robbins and K. Schofield, *J. Chem. Soc.*, **1957**, 3186.



Scheme 3.

carbonium ion (Scheme 3). On the other hand, the para-substitution of *N*-phenyl group with an electron-donor (Y=Me or MeO) seems to be favorable to some extent for the formation of **1**, which may be ascribed to an increase in the stability of diazonium ion (Scheme 3).

It is known that the Bamberger synthesis of 3-aryl-1,2,4-benzotriazines from substituted formazans is widely applicable.[8] In general, however, this method gives two benzotriazines from a mixed formazan in which



the 1- and the 5-phenyl groups are substituted unsymmetrically,[15] and formazans are not always obtained in high yields depending upon the nature of substituents.[16] On the other hand, the present method gives only one triazine. Furthermore, the starting materials are readily obtainable, and the yield of product is high in general, except the case in which the *C*-phenyl group of **2** is substituted with an electron-donating group. In conclusion, this method possesses a higher synthetic utility for 3-aryl-1,2,4-benzotriazines.

Experimental

The melting points were determined with a Yanagimoto MP-S3 micromelting point apparatus, and are uncorrected.

Table 4. Spectral data of 3-aryl-1,2,4-benzotriazines (**1**)

a) Compound **1k** (**1l**) is almost insoluble in $CDCl_3$. b) The signal (dd) of 6-H is partially concealed by those of 8,3',5'-H.

The microanalysis was performed on a Perkin-Elmer 240 elemental analyzer. The UV, IR, and NMR spectra were recorded with a Hitachi 220, a Hitachi 260-10, and a Varian EM-360A spectrometer, respectively. *N*-(Phenylsulfonyl)benzohydrazonoyl chlorides (**4**) were prepared by the method previously reported.[2a]

Preparation of Amidrazones (2). General Procedure: A solution of **3** (21 mmol) in THF (10 ml) was added to a solution of **4** (10 mmol) in THF (30 ml) with stirring at room temperature. After being stirred for 18—20 h, the reaction mixture was poured into cold water. The resulting precipitates were filtered, washed with water, and dried. The crude product was chromatographed on a silica-gel column (100—200 mesh, 2.0 cm × 12 cm) to afford the corresponding amidrazone, which was recrystallized from an appropriate solvent. The results are summarized in Table 1.

N-*Phenylsulfonyl*-N''-*phenylbenzamidrazone (2a). (A Typical Example)*: Compound **2a** (2.71 g) generated from aniline (**3**, Y=H, 1.96 g) and **4** (X=H, 2.95 g) was eluted from a silica-gel column with benzene–ether (50:1, v/v); elution with benzene–ethanol (50:1, v/v; then the proportion of ethanol was increased gradually) gave **6**[7] (100 mg, mp 292—293 °C) and **7**[2b] (150 mg, mp 312—315 °C).

N-*Phenylsulfonyl*-N''-*phenylbenzamidrazone Hydrochloride*. Dry hydrogen chloride was introduced into a solution of

2a (100 mg) in ethanol. Removal of the solvent from the mixture under reduced pressure gave a solid (110 mg), which was crystallized from chloroform–ethanol to afford the hydrochloride as colorless prisms, mp 187—189 °C; IR (KBr): 2960—2650 (ν_{N^+H}), 1625 ($\nu_{C=H}$), 1320, 1155 cm^{-1} (ν_{SO_2}); Found: C, 58.70; H, 4.74; N, 10.65%. Calcd for $C_{19}H_{18}N_3O_2SCl$: C, 58.83; H, 4.68; N, 10.83%. Neutralization with aqueous ammonia or sodium hydrogencarbonate gave the free amidrazone, **2a**.

Oxidation of **2** *with Mercury(II) Oxide. General Procedure*: A mixture of **2** (2 mmol), HgO (yellow, 650 mg, 3 mmol), K_2CO_3 (830 mg, 6 mmol), and $CaSO_4$ (820 mg, 6 mmol) was stirred in dry dioxane (30 ml) for 18—20 h at room temperature. The reaction mixture was filtered to remove insoluble inorganic substances, which were washed with dioxane (20 ml). The filtrate combined with washings was concentrated under reduced pressure to afford a semi-solid residue. By using a hexane–benzene–ether system (4:1:0–1:1:0–0:50:1, v/v) as the eluent, the residue was chromatographed on a silica-gel column (2.0 cm × 10 cm) to give diphenyl disulfide (**10**), *S*-phenyl benzenethiosulfonate (**11**, mp 43—44 °C, lit,[17] mp 45 °C), benzotriazine (**1**), and the corresponding benzanilide (**9**). The results are summarized in Tables 2 and 3. The IR spectra of **10** and **11** were identical with those of authentic samples, respectively.

Furan Derivatives. IV. On the Effects of Substituents in the Syntheses of 4,5-Dihydro-3*H*-naphtho[1,8-*bc*]furans

Sakaaki Horaguchi*, Mamoru Hara, and Tsuneo Suzuki†

Department of Chemistry, Faculty of Science, Niigata University, Ikarashi, Niigata 950-21

†*Nippon Dental University, Niigata, 1-8, Hamaura-cho, Niigata 950*

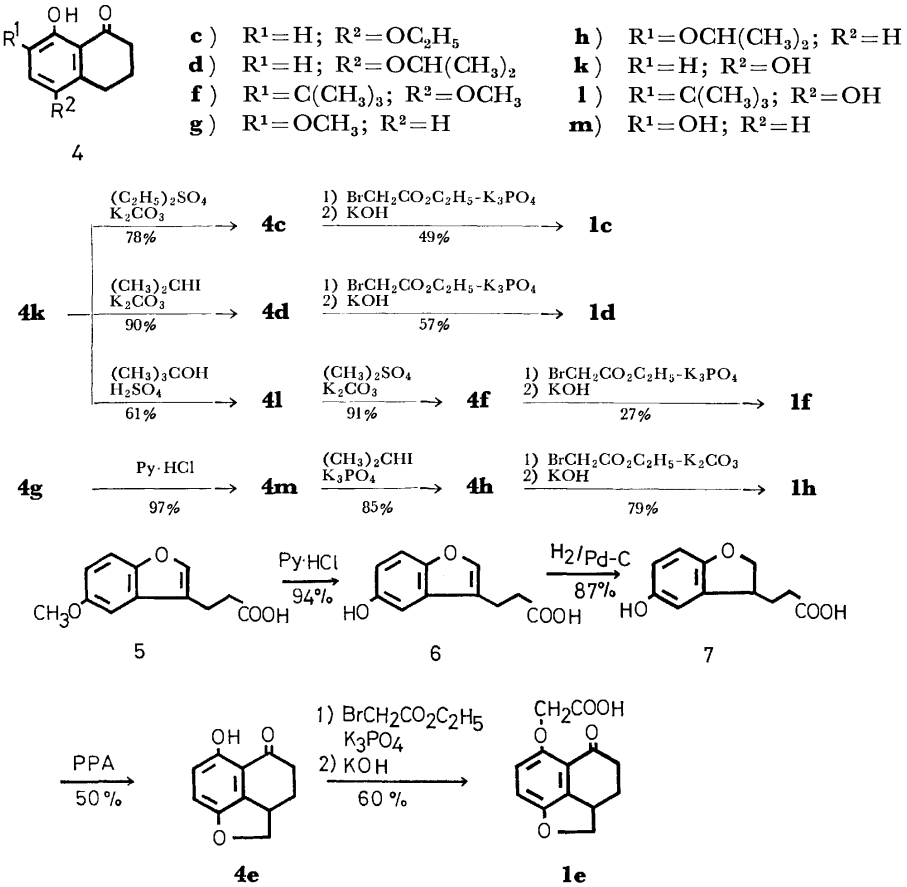
(Received June 13, 1981)

The reaction of (8-oxo-5,6,7,8-tetrahydro-1-naphthyloxy)acetic acids with acetic anhydride and sodium acetate give a mixture of 4,5-dihydro-3*H*-naphtho[1,8-*bc*]furans and lactones. The relative yields of 4,5-dihydro-3*H*-naphtho[1,8-*bc*]furans and lactones varied according to kinds of substituents on the benzene ring of (8-oxo-5,6,7,8-tetrahydro-1-naphthyloxy)acetic acids. Substituents which make the methylene group approach closer to the carbony carbon atom of (8-oxo-5,6,7,8-tetrahydro-1-naphthyloxy)acetic acids by a steric effect seem to favor the production of 4,5-dihydro-3*H*-naphtho[1,8-*bc*]furans. On the other hand, substituents which make the methylene group separate from the carbonyl carbon atom seem to favor the production of lactones. An electron-withdrawing chlorine atom on the benzene ring of (8-oxo-5,6,7,8-tetrahydro-1-naphthyloxy)acetic acids also favors the production of 4,5-dihydro-3*H*-naphtho[1,8-*bc*]furans.

4,5-Dihydro-3*H*-naphtho[1,8-*bc*]furans (**2**) are important intermediates for the syntheses of phenanthro[4,5-*bcd*]furan derivatives.[1] 4,5-Dihydro-3*H*-naphtho[1,8-*bc*]furans (**2**)[2] have been synthesized by heating (8-oxo-5,6,7,8-tetrahydro-1-naphthyloxy)acetic acids (**1**) with acetic anhydride and sodium acetate. However, the yields of 4,5-dihydro-3*H*-naphtho[1,8-*bc*]furans (**2**) were not good because lactones (**3**) were obtained as by-products. Formation of a considerable amount of lactones (**3**) may be due to the long distance between the methylene group adjacent to the carboxyl group and the carbonyl carbon atom of **1**, since the peri-positions in a naphthalene skeleton are too far apart for the formation of the five-membered furan ring.[3] The relative yields of 4,5-dihydro-3*H*-naphtho[1,8-*bc*]furans (**2**) and lactones (**3**) varied according to kinds of substituents (R^1 and R^2). In the present investigation we examined the factors which influenced relative yields of 4,5-dihydro-3*H*-naphtho[1,8-*bc*]furans (**2**) and lactones (**3**); the steric influence of R^1 and R^2 was examined in detail.

Results and Discussion

Some (8-oxo-5,6,7,8-tetrahydro-1-naphthyloxy)acetic acid (**1a—j**) were prepared to investigate the in-

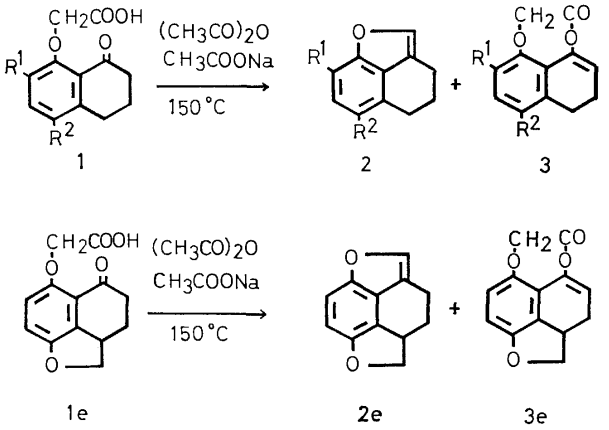


Scheme 1. The synthetic pathways of (8-oxo-5,6,7,8-tetrahydro-1-naphthyloxy)acetic acids (**1c**, **1d**, **1e**, **1f**, and **1h**).

fluence of substituents (R^1 and R^2) in the syntheses of 4,5-dihydro-3*H*-naphtho[1,8-*bc*]furans (**2a—j**) and lactones (**3a—j**). The syntheses of **1a**, **1b**, **1g**, **1i**, and **1j** were carried out according to the methods reported.[2] The synthetic methods of **1c**, **1d**, **1e**, **1f**, and **1h** are summarized in Scheme 1.

When (8-oxo-5,6,7,8-tetrahydro-1-naphthyloxy)acetic acids (**1a—j**) were heated at 150 °C with acetic anhydride and sodium acetate for 1 h, 4,5-dihydro-3*H*-naphtho[1,8-*bc*]furans (**2a—d** and **2f—j**) and lactones (**3a—j**) were obtained. The relative yields and isolated yields of 4,5-dihydro-3*H*-naphtho[1,8-*bc*]furans (**2a—j**) and lactones (**3a—j**) are summarized in Table 1.

Table 1. The reaction of (8-oxo-5,6,7,8-tetrahydro-1-naphthyloxy)acetic acids (**1a—j**) with acetic anhydride and sodium acetate



a) R^1=H; R^2=H, **b**) R^1=H; R^2=OCH_3, **c**) R^1=H; R^2=OC_2H_5, **d**) R^1=H; R^2=$OCH(CH_3)_2$, **f**) R^1=$C(CH_3)_3$; R^2=OCH_3, **g**) R^1=OCH_3; R^2=H, **h**) R^1=$OCH(CH_3)_2$; R^2=H, **i**) R^1=OCH_3; R^2=CH_3, **j**) R^1=OCH_3; R^2=Cl.

1j	**2j**	87	72
	3j	13	11

a) 4,5-Dihydro-3*H*-naphtho[1,8-*bc*]furans (**2**) are stable under the reaction conditions. b) The lactone was hydrolyzed to the starting material during isolation. c) The yield is low because of the easy hydrolysis of the lactone during isolation.

The results of Table 1 suggest the following conclusions. The reaction of **1a** (R^1=H; R^2=H) with acetic anhydride and sodium acetate gave an almost equal amount of 4,5-dihydro-3*H*-naphtho[1,8-*bc*]furan (**2a**) and a lactone (**3a**) in relative yields of 48 and 52%. Similarly, in the case of **1b—d** (R^1=H; R^2=OCH_3, OC_2H_5, or $OCH(CH_3)_2$), the relative yields of 4,5-dihydro-3*H*-naphtho[1,8-*bc*]furans (**2b—d**) and lactones (**3b—d**) were almost the same in spite of the various kinds of substituents R^2. This suggests that the steric or electronic effect of substituents R^2 have no influence on the relative yields of 4,5-dihydro-3*H*-naphtho[1,8-*bc*]furans (**2a—d**) and lactones (**3a—d**). On the other hand, compound **1e**, in which the electronic effect of a substituent will be similar to that of **1b—d**, gave only a lactone (**3e**) and no 2,2a,3,4-tetrahydronaphtho[1,8-*bc*:4,5-*b'c'*]difuran (**2e**) was obtained. In the case of **1e**, the distance between the methylene group and the carbonyl carbon atom will be longer than that in **1a—d** because the five-membered furan ring of **1e** separates opposite peripositions in the partially saturated naphthalene skeleton.[3] Therefore, the production of **2e** will be difficult because of the strain in the five-membered furan ring. However, the production of **3e** is not so affected by strain owing to formation of the seven-membered lactone ring. The reaction of **1f** (R^1=$C(CH_3)_3$; R^2=OCH_3) with acetic anhydride and sodium acetate gave 4,5-dihydro-3*H*-naphtho[1,8-*bc*]furan (**2f**) and a lactone (**3f**) in the relative yields of 92 and 8% respectively. The large steric effect of the *t*-butyl group in **1f** will make the methylene group approach[4] closer to the carbonyl carbon atom and will favor formation of the five-membered 4,5-dihydro-3*H*-naphtho[1,8-*bc*]-furan (**2f**). The steric repulsion between the *t*-butyl group and the methylene group is observed in the difficult etherification of **4f** with ethyl bromoacetate. The electronic effect of the *t*-butyl group will be negligible.

The reaction of **1g—h** (R^1=OCH_3 or $OCH(CH_3)_2$; R^2=H) with acetic anhydride and sodium acetate gave mainly 4,5-dihydro-3*H*-naphtho[1,8-*bc*]furans (**2g—h**) in the relative yields of 65 and 60% respectively; the yields of lactones (**3g—h**) were 35% and 40% respectively. The steric effect of the methoxyl or isopropoxyl group seems to favor the production of 4,5-dihydro-3*H*-naphtho[1,8-*bc*]furans (**2g—h**), though the substituents are not so bulky as is the *t*-butyl group.

The reaction of **1i** (R^1=OCH_3; R^2=CH_3) with acetic anhydride and sodium acetate gave 4,5-dihydro-3*H*-naphtho[1,8-*bc*]furan (**2i**) and a lactone (**3i**) in the relative yields of 67 and 33% respectively. These yields are similar to those of **2g—h** and **3g—h** and so the effect of the methyl group of **2i** is small. On the other hand, **1j** (R^1=OCH_3; R^2=Cl) with acetic anhydride and sodium acetate gave mostly 4,5-dihydro-3*H*-naphtho[1,8-*bc*]furan (**2j**; 87%) and the yield of a lactone (**3j**) was very low (13%). The electronegative chlorine atom will pull electrons from the benzene ring of **1j** and make the carbonyl carbon

atom more reactive. Therefore, formation of the 4,5-dihydro-3*H*-naphtho[1,8-*bc*]furan (**2j**) will be more favorable than that of the lactone (**3j**).

Experimental

All the melting points are uncorrected. The column chromatography was performed on silica gel (Wakogel C-200). Unless otherwise stated, anhydrous sodium sulfate was employed as the drying agent. The infrared absorption spectra were determined with a Hitachi Model EPI-G grating infrared spectrophotometer. The ultraviolet absorption spectra were determined with a Shimadzu UV-200 spectrophotometer. The nuclear magnetic resonance spectra (^{1}H NMR) were determined at 90 MHz with a JEOL Model JNM-FX 90Q FT NMR spectrometer, using tetrametylsilane as the internal standard.

*A General Procedure for the Reactions of (8-Oxo-5,6,7,8-tetrahydro-1-naphthyloxy)acetic Acids (**1**) with Acetic Anhydride and Sodium Acetate.* A mixture of **1** (1.0 g), acetic anhydride (15 ml), and sodium acetate (4.6 g) was refluxed at 150 °C for 1 h. The mixture was poured into ice–water, stirred for 5 min to decompose excess acetic anhydride, and extracted with ether. The ethereal solution was washed with a 10% potassium carbonate solution and then with water, dried, and evaporated. The resulting oil was chromatographed and eluted with benzene. The first fraction gave 4,5-dihydro-3*H*-naphtho[1,8-*bc*]furans (**2**). The second fraction afforded lactones (**3**).

*6-Ethoxy-4,5-dihydro-3*H*-naphtho[1,8-*bc*]furan (**2c**).* Colorless oil (37% yield); bp 171 °C at 20 Torr (1 Torr≈133.322 Pa). ^{1}H NMR ($CDCl_3$): δ 1.38 (3H, t, J=7 Hz, CH_3), 1.83—2.10 (2H, m, $-CH_2-$), 2.67—2.89 (4H, m, $-CH_2-+-CH_2-$), 4.03 (2H, q, J=7 Hz, $-CH_2-$), 6.78 (1H, d, J=9 Hz, Ar–H), 7.12 (1H, dd, J=1 and 9 Hz, Ar–H), 7.24 (1H, d, J=1 Hz, furan H). UV(EtOH): λ_{max} (ε) 214 (23100), 253 (9200), 291 (2600), 302 nm (2000). Found: C, 77.02; H, 6.83%. Calcd for $C_{13}H_{14}O_2$: C, 77.20; H, 6.98%.

*Lactone (**3c**).* Colorless needles from benzene–hexane (41% yield); mp 87—88 °C. IR (KBr): ν_{max} 1650 (C=C), 1765 cm^{-1} (–COO–). ^{1}H NMR (CD_3COCD_3): δ 1.36 (3H, t, J=7 Hz, CH_3), 2.15—2.41 (2H, m, $-CH_2-$), 2.76 (2H, t, J=8 Hz, $-CH_2-$), 4.03 (2H, q, J=7 Hz, $-CH_2-$), 4.71 (2H, s, $-OCH_2-$), 5.87 (1H, t, J=5 Hz, –OC=CH–), 6.78 (1H, d, J=9 Hz, Ar–H), 6.92 (1H, d, J=9 Hz, Ar–H). Found: C, 68.01; H, 5.49%. Calcd for $C_{14}H_{14}O_4$: C, 68.28; H, 5.73%.

*6-Isopropoxy-4,5-dihydro-3*H*-naphtho[1,8-*bc*]furan (**2d**).* Colorless plates from methanol (38% yield); mp 68—69 °C. ^{1}H NMR ($CDCl_3$): δ 1.31 (6H, d, J=6 Hz, $C(CH_3)_2$), 1.96 (2H, dt, J=7 and 7 Hz, $-CH_2-$), 2.75 (2H, t, J=7 Hz, $-CH_2-$), 2.82 (2H, t, J=7 Hz, $-CH_2-$), 4.37 (1H, m, =CH–), 6.82 (1H, d, J=8 Hz, Ar–H), 7.12 (1H, d, J=8 Hz, Ar–H), 7.24 (1H, s, furan H). UV (EtOH): λ_{max} (ε) 214 (24200), 253 (9400), 292 (2100), 305 nm (1100). Found: C, 77.53; H, 7.29%. Calcd for $C_{14}H_{16}O_2$: C, 77.75; H, 7.46%.

*Lactone (**3d**).* Colorless needles from benzene–hexane (40% yield); mp 90—91 °C. IR (KBr): ν_{max} 1665 (C=C), 1780 cm^{-1} (–COO–). ^{1}H NMR (CD_3COCD_3): δ 1.29 (6H, d, J=6 Hz, $C(CH_3)_2$), 2.17—2.40 (2H, m, $-CH_2-$), 2.57—2.97 (2H, m, $-CH_2-$), 4.49 (1H, m, =CH–), 4.72 (2H, s, $-OCH_2-$), 5.87 (1H, t, J=5 Hz, –OC=CH–), 6.78 (1H, d, J=9 Hz, Ar–H), 6.95 (1H, d, J=9 Hz, Ar–H). Found: C, 68.98; H, 6.09%. Calcd for $C_{15}H_{16}O_4$: C, 69.21; H, 6.20%.

*Lactone (**3e**).* Colorless needles from benzene–hexane (48% yield); mp 104—105 °C. IR (KBr): ν_{max} 1660 (C=C), 1760 cm^{-1} (–COO–). ^{1}H NMR (CD_3COCD_3): δ 2.12—2.86 (4H, m, $-CH_2-+-CH_2-$), 3.46—3.93 (1H, m, =CH–), 4.20 (1H, dd, J=9 and 12 Hz, –OCH=), 4.54—4.95 (3H, m, $-CH_2-+-$OCH=), 5.70 (1H, dd, J=3 and 7 Hz, –OCH=), 6.60 (1H, d, J=8 Hz, Ar–H), 6.72 (1H, dd, J=1 and 8 Hz, Ar–H). Found: C, 67.56; H, 4.41%. Calcd for $C_{13}H_{10}O_4$: C, 67.82; H, 4.38%.

*6-Methoxy-8-t-butyl-4,5-dihydro-3*H*-naphtho[1,8-*bc*]furan (**2f**).* Colorless needles (72% yield); mp 45—46 °C. ^{1}H NMR ($CDCl_3$): δ 1.48 (9H, s, $C(CH_3)_3$), 1.95 (2H, dt, J=6 and 6 Hz, $-CH_2-$), 2.73 (2H, t, J=6 Hz, $-CH_2-$), 2.80 (2H, t, J=6 Hz, $-CH_2-$), 3.85 (3H, s, CH_3), 6.75 (1H, s, Ar–H), 7.26 (1H, s, furan H). UV (EtOH): λ_{max} (ε) 216 (25700), 252 (9800), 292 (3100), 302 nm (2600). Found: C, 78.61; H, 8.21%. Calcd for $C_{16}H_{20}O_2$: C, 78.65; H, 8.25%.

*Lactone (**3f**).* Colorless plates (7% yield); mp 105—106 °C. IR (KBr): ν_{max} 1650 (C=C), 1770 cm^{-1} (–COO–). ^{1}H NMR (CD_3COCD_3): δ 1.37 (9H, s, $C(CH_3)_3$), 2.22—2.38 (2H, m, $-CH_2-$), 2.63—2.79 (2H, m, $-CH_2-$), 3.83 (3H, s, OCH_3), 4.77 (2H, s, $-OCH_2-$), 5.87 (1H, t, J=5 Hz, –OC=CH–), 6.93 (1H, s, Ar–H). Found: C, 70.65; H, 6.83%. Calcd for $C_{17}H_{20}O_4$: C, 70.81; H, 6.99%.

*8-Isopropoxy-4,5-dihydro-3*H*-naphtho[1,8-*bc*]furan (**2h**).* Colorless oil (50% yield); bp 178 °C at 20 Torr. ^{1}H NMR ($CDCl_3$): δ 1.37 (6H, d, J=6 Hz, $C(CH_3)_2$), 1.97 (2H, dt, J=6 and 6 Hz, $-CH_2-$), 2.74 (2H, t, J=6 Hz, $-CH_2-$), 2.81 (2H, t, J=6 Hz, $-CH_2-$), 4.83 (1H, m, =CH–), 6.70 (1H, d, J=8 Hz, Ar–H), 6.84 (1H, d, J=8 Hz, Ar–H), 7.25 (1H, s, furan H). UV (EtOH): λ_{max} (ε) 217 (29200), 249 (10300), 255 (9600), 281 (1600), 291 nm (1100). Found: C, 77.84; H, 7.46%. Calcd for $C_{14}H_{16}O_2$: C, 77.75; H, 7.46%.

*Lactone (**3h**).* Colorless oil (33% yield); bp>200 °C at 2 Torr. IR (neat): ν_{max} 1650 (C=C), 1780 cm^{-1} (–COO–). ^{1}H NMR (CD_3COCD_3): δ 1.27 (6H, d, J=6 Hz, $C(CH_3)_3$), 2.17—2.41 (2H, m, $-CH_2-$), 2.62—2.80 (2H, m, $-CH_2-$), 4.46 (1H, m, =CH–), 4.78 (2H, s, $-OCH_2-$), 5.87 (1H, t, J=5 Hz, –OC=CH–), 6.86 (2H, s, Ar–H). Found: C. 69.04; H, 6.12%. Calcd for $C_{15}H_{16}O_4$: C, 69.21; H, 6.20%.

*8-Methoxy-6-methyl-4,5-dihydro-3*H*-naphtho[1,8-*bc*]furan (**2i**).* Colorless prisms from hexane (60% yield); mp 42—43 °C. ^{1}H NMR (CCl_4): δ 1.82—2.07 (2H, m, $-CH_2-$), 2.22 (3H, s, Ar–CH_3), 2.59—2.76 (4H, m, $-CH_2-+-CH_2-$), 3.95 (3H, s, Ar–OCH_3), 6.41 (1H, s, Ar–H), 7.17 (1H, s, furan H). UV (EtOH): λ_{max} (ε) 217 (3200), 248 (9900), 255 (9400), 284 (2000), 295 nm (1800). Found: C, 77.10; H, 7.06%. Calcd for $C_{13}H_{14}O_2$: C, 77.20; H, 6.98%. The physical properties of **2a**, **2b**, **2g**, **2j**, **3b**, **3g**, and **3j** are described in Ref. 2.

*5-Ethoxy-8-hydroxy-1,2,3,4-tetrahydro-1-naphthalenone (**4c**).* A mixture of **4k** (10 g), diethyl sulfate (11 g), potassium carbonate (17 g), and acetone (100 ml) was refluxed for 6 h. The acetone was distilled off and water was added to the mixture. The mixture was refluxed for 0.5 h to decompose the excess diethyl sulfate and extracted with ether. The ethereal solution was washed with water, dried, and evaporated. The residue was chromatographed and eluted with benzene to give 11.2 g (96%) of **4c**. Recrystallization from methanol gave yellow plates; mp 61.5—62.5 °C. IR (KBr): ν_{max} 1645 cm^{-1} (C=O). ^{1}H NMR ($CDCl_3$): δ 1.38 (3H, t, J=7 Hz, CH_3), 2.05 (2H, dt, J=6 and 6 Hz, $-CH_2-$), 2.65 (2H, t, J=6 Hz, $-CH_2-$), 2.89 (2H, t, J=6 Hz, $-CH_2-$), 3.98 (2H, q, J=7 Hz, $-CH_2-$), 6.72 (1H, d, J=9 Hz, Ar–H), 7.05 (1H, d, J=9 Hz, Ar–H), 11.90 (1H, broad s, Ar–OH). Found: C, 69.75; H, 7.12%. Calcd for $C_{12}H_{14}O_3$:

C, 69.88; H, 6.84%.

*8-Hydroxy-5-isopropoxy-1,2,3,4-tetrahydro-1-naphthalenone (**4d**).* A mixture of **4k** (5.0 g), isopropyl iodide (10 g), potassium carbonate (10 g), and acetone (70 ml) was refluxed.[5] After 1 h, isopropyl iodide (5 g) and potassium carbonate (5 g) were added and the mixture was refluxed for additional 9 h. After removal of the acetone, the residue was extracted with ether. The ethereal solution was washed with water, dried, and evaporated. The resulting oil was chromatographed and eluted with benzene to give 5.6 g (90%) of **4d**. Recrystallization from methanol gave yellow plates; mp 55—56 °C. IR (KBr): ν_{max} 1645 cm^{-1} (C=O). ^1H NMR ($CDCl_3$): δ 1.30 (6H, d, J=7 Hz, $C(CH_3)_2$), 1.97 (2H, dt, J=6 and 6 Hz, $-CH_2-$), 2.64 (2H, t, J=6 Hz, $-CH_2-$), 2.88 (2H, t, J=6 Hz, $-CH_2-$), 4.20—4.47 (1H, m, =CH–), 6.72 (1H, d, J=9 Hz, Ar–H), 7.07 (1H, d, J=9 Hz, Ar–H), 12.00 (1H, s, Ar–OH). Found: C, 70.95; H, 7.30%. Calcd for $C_{13}H_{16}O_3$: C. 70.89; H, 7.32%.

*5,8-Dihydroxy-7-t-butyl-1,2,3,4-tetrahydro-1-naphthalenone (**4l**).* To a *t*-butyl alcohol solution (20 ml) of **4k** (2.0 g) concentrated sulfuric acid (20 g) was gradually added with stirring under cooling with ice–water.[6] The mixture was stirred for 0.5 h, decomposed with ice–water, and extracted with ether. The ethereal solution was washed with water, dried, and evaporated. A high boiling oil was removed by reduced distillation (*ca.* 140 °C at 30 Torr). The residue was chromatographed and eluted with benzene(9)–ether(1) to give 1.6 g (61%) of **4l**. Recrystallization from benzene–hexane gave yellow plates; mp 154—155 °C. IR (KBr): ν_{max} 1615 (C=O), 3360 cm^{-1} (Ar–OH). ^1H NMR ($CDCl_3$): δ 1.38 (9H, s, $C(CH_3)_3$), 1.92—2.20 (2H, m, $-CH_2-$), 2.67 (2H, t, J=7 Hz, $-CH_2-$), 2.83 (2H, t, J=6 Hz, $-CH_2-$), 4.69 (1H, broad s, Ar–OH), 6.02 (1H, s, Ar–H), 12.83 (1H, s, Ar–OH). Found: C, 71.75; H, 7.69%. Calcd for $C_{14}H_{18}O_3$: C, 71.77; H, 7.74%.

*8-Hydroxy-5-methoxy-7-t-butyl-1,2,3,4-tetrahydro-1-naphthalenone (**4f**).* The compound **4f** was prepared from **4l** by a method similar to the synthesis of **4c** from **4k**. Yellow needles from methanol (91% yield); mp 57—58 °C. IR (KBr): ν_{max} 1635 cm^{-1} (C=O). ^1H NMR ($CDCl_3$): δ 1.42 (9H, s, $C(CH_3)_3$), 2.03 (2H, dt, J=6 and 6 Hz, $-CH_2-$), 2.65 (2H, t, J=6 Hz, $-CH_2-$), 2.86 (2H, t, J=6 Hz, $-CH_2-$), 3.79 (3H, s, OCH_3), 7.13 (1H, s, Ar–H), 12.81 (1H, s, Ar–OH). Found: C, 72.70; H, 8.35%. Calcd for $C_{15}H_{20}O_3$: C, 72.55; H, 8.12%.

*(4-Ethoxy-8-oxo-5,6,7,8-tetrahydro-1-naphthyloxy)acetic Acid (**1c**).* A mixture of **4c** (1.0 g), ethyl bromoacetate (4.0 g), potassium phosphate (4.0 g), and dioxane (20 ml) was refluxed for 5 h.[2] After removal of potassium phosphate by filtration the dioxane was evaporated under reduced pressure. The residue was dissolved in ethanol (10 ml) and hydrolyzed with a 20% potassium hydroxide solution (50 ml). The alkaline solution was acidified with 6 M (1 M=1 mol dm^{-3}) hydrochloric acid and the resulting precipitates were extracted with ether. The ethereal solution was washed with water, dried, and evaporated. Trituration of the residue with benzene gave 0.63 g (49%) of **1c**. Recrystallization from methanol gave colorless plates; mp 140—141 °C. IR (KBr): ν_{max} 1655 (C=O), 1765, 1780 cm^{-1} (COOH). ^1H NMR (CD_3COCD_3): δ 1.40 (3H, t, J=7 Hz, CH_3), 1.92—2.20 (2H, m, $-CH_2-$), 2.65 (2H, t, J=6 Hz, $-CH_2-$), 2.92 (2H, t, J=6 Hz, $-CH_2-$), 4.08 (2H, q, J=7 Hz, $-CH_2-$), 4.70 (2H, s, $-CH_2-$), 7.01 (1H, d, J=9 Hz, Ar–H), 7.21 (1H, d, J=9 Hz, Ar–H). Found: C, 63.41; H, 6.19%. Calcd for $C_{14}H_{16}O_5$: C, 63.62; H, 6.10%.

*(4-Isopropoxy-8-oxo-5,6,7,8-tetrahydro-1-naphthyloxy)acetic Acid (**1d**).* The compound **1d** was prepared from **4d** by a method similar to the synthesis of **1c** from **4c**. Colorless plates from methanol (57% yield); mp 130—131 °C. IR (KBr): ν_{max} 1660 (C=O), 1765, 1785 cm^{-1} (COOH). ^1H NMR (CD_3COCD_3): δ 1.32 (6H, d, J=6 Hz, $C(CH_3)_2$), 1.92—2.19 (2H, m, $-CH_2-$), 2.65 (2H, t, J=5 Hz, $-CH_2-$), 2.90 (2H, t, J=6 Hz, $-CH_2-$), 4.58 (1H, m, =CH–), 4.71 (2H, s, $-CH_2-$), 7.00 (1H, d, J=9 Hz, Ar–H), 7.25 (1H, d, J=9 Hz, Ar–H). Found: C, 64.74; H, 6.43%. Calcd for $C_{15}H_{18}O_5$: C, 64.73; H, 6.52%.

*(4-Methoxy-8-oxo-2-t-butyl-5,6,7,8-tetrahydro-1-naphthyloxy)-acetic Acid (**1f**).* The compound **1f** was prepared from **4f** by a method similar to the synthesis of **1c** from **4c**. Colorless plates from ether–hexane (27% yield); mp 139—140 °C. IR (KBr): ν_{max} 1665 (C=O), 1770, 1785 cm^{-1} (COOH). ^1H NMR (CD_3COCD_3): δ 1.43 (9H, s, $C(CH_3)_3$), 1.97—2.17 (2H, m, $-CH_2-$), 2.59 (2H, t, J=7 Hz, $-CH_2-$), 2.84 (2H, t, J=6 Hz, $-CH_2-$), 3.88 (3H, s, OCH_3), 4.41 (2H, s, $-OCH_2-$), 7.20 (1H, s, Ar–H). Found: C, 66.41; H, 7.00%. Calcd for $C_{17}H_{22}O_5$: C, 66.65; H, 7.24%.

*7,8-Dihydroxy-1,2,3,4-tetrahydro-1-naphthalenone (**4m**).* A mixture of **4g** (1.0 g) and pyridinium chloride (10 g) was heated at 200 °C for 1 h.[7] The mixture was poured into ice–water and extracted with ether. The ethereal solution was washed with water, dried, and evaporated to give 0.90 g (97%) of **4m**. Recrystallization from benzene–hexane gave yellow plates; mp 92—93 °C. IR (KBr): ν_{max} 1640 (C=O), 3530 cm^{-1} (Ar–OH). ^1H NMR (CD_3COCD_3): 2.04 (2H, dt, J=6 and 6 Hz, $-CH_2-$), 2.65 (2H, t, J=6 Hz, $-CH_2-$), 2.85 (2H, t, J=6 Hz, $-CH_2-$), 6.62 (1H, d, J=8 Hz, Ar–H), 7.00 (1H, d, J=8 Hz, Ar–H), 7.49 (1H, s, Ar–OH), 12.51 (1H, s, Ar–OH). Found: C, 67.43; H, 5.91%. Calcd for $C_{10}H_{10}O_3$: C, 67.40; H, 5.66%.

*8-Hydroxy-7-isopropoxy-1,2,3,4-tetrahydro-1-naphthalenone (**4h**).* The compound **4h** was prepared from **4m** by a method similar to the synthesis of **4d** from **4k**. Yellow plates from hexane (85% yield); mp 74—75 °C. IR (KBr): ν_{max} 1640 cm^{-1} (C=O). ^1H NMR ($CDCl_3$): δ 1.34 (6H, d, J=6 Hz, $C(CH_3)_2$), 2.06 (2H, dt, J=6 and 6 Hz, $-CH_2-$), 2.65 (2H, t, J=6 Hz, $-CH_2-$), 2.86 (2H, t, J=6 Hz, $-CH_2-$), 4.50 (1H, m, =CH–), 6.59 (1H, d, J=8 Hz, Ar–H), 7.02 (1H, d, J=6 Hz, Ar–H), 12.62 (1H, s, Ar–OH). Found: C. 71.16; H, 7.39%. Calcd for $C_{13}H_{16}O_3$: C, 70.89; H, 7.32%.

*(2-Isopropoxy-8-oxo-5,6,7,8-tetrahydro-1-naphthyloxy)acetic Acid (**1h**).* The compound **1h** was prepared from **4h** by a method similar to the synthesis of **1c** from **4c**. Colorless needles from benzene–hexane (79% yield); mp 89—90 °C. IR (KBr): ν_{max} 1670, 1685 (C=O), 1760, 1775 cm^{-1} (COOH). ^1H NMR (CD_3COCD_3): δ 1.37 (6H, d, J=6 Hz, $C(CH_3)_2$), 1.91—2.18 (2H, m, $-CH_2-$), 2.67 (2H, t, J=6 Hz, $-CH_2-$), 2.94 (2H, t, J=6 Hz, $-CH_2-$), 4.46—4.80 (1H, m, =CHO–), 4.73 (2H, s, $-OCH_2-$), 7.06 (1H, d, J=8 Hz, Ar–H), 7.33 (1H, d, J=8 Hz, Ar–H). Found: C, 64.56; H, 6.68%. Calcd for $C_{15}H_{18}O_5$: C, 64.73; H, 6.52%.

*3-(5-Hydroxybenzofuran-3-yl)propionic Acid (**6**).* A mixture of **5** (15 g) and pyridinium chloride (100 g) was heated for 1 h at 200 °C,[7] poured into ice–water, and extracted with ether. The ethereal solution was washed with 1 M hydrochloric acid and then with water, dried, and evaporated to give 17.4 g (93%) of **6**. Recrystallization from acetone–benzene gave colorless needles; mp 170—171 °C. IR (KBr): ν_{max} 1720 (COOH), 3270 cm^{-1} (Ar–OH). ^1H NMR (CD_3COCD_3): δ 2.59—3.06 (4H, m, $-CH_2-+-CH_2-$), 6.83 (1H, dd, J=2 and 9 Hz, Ar–H), 7.02 (1H, d, J=2 Hz, Ar–H), 7.27 (1H, d, J=2 Hz, Ar–H), 7.27 (1H, d, J=9 Hz, Ar–H), 7.55 (1H, s, furan H). Found: C, 64.19;

H, 4.98%. Calcd for $C_{11}H_{10}O_4$: C, 64.07; H, 4.89%.

*3-(5-Hydroxy-2,3-dihydrobenzofuran-3-yl)propionic Acid (**7**).* An ethanolic solution (50 ml) of **6** (12 g) was hydrogenated for 16 h in the presence of 7% palladium on charcoal (2.4 g) as a catalyst under 7 atm at 65 °C.[8] After removal of the catalyst by filtration the partially produced ester was hydrolyzed with a 30% potassium hydroxide solution. The alkaline solution was acidified with 6 M hydrochloric acid and extracted with ether. The ethereal solution was washed with water, dried, and evaporated to give 10.6 g (87%) of **7**. Recrystallization from acetone–benzene gave colorless needles; mp 117—118 °C. IR (KBr): ν_{max} 1750 (COOH), 3310 cm^{-1} (Ar–OH). ^1H NMR (CD_3COCD_3): δ 1.61—2.16 (2H, m, $-CH_2-$), 2.30—2.49 (2H, m, $-CH_2-$), 3.26—3.57 (1H, m, =CH–), 4.17 (1H, dd, J=6 and 9 Hz, –OCH=), 4.56 (1H, t, J=9 Hz, –OCH=), 6.56—6.76 (3H, m, Ar–H). Found: C, 63.65; H, 5.85%. Calcd for $C_{11}H_{12}O_4$: C, 63.45; H, 5.81%.

*6-Hydroxy-2a,3,4,5-tetrahydro-2H-naphtho[1,8-bc]furan-5-one (**4e**).* A mixture of **7** (20 g) and polyphosphoric acid (300 g) was heated at 80 °C for 5 h under stirring.[8] The mixture was poured into ice–water and extracted with ether. The ethereal solution was washed with a 10% potassium carbonate solution and then with water, dried, and evaporated to give 9.1 g (50%) of **4e**. Recrystallization from benzene–hexane gave yellow needles; mp 123—124 °C. IR (KBr): ν_{max} 1650 (C=O), 3220 cm^{-1} (Ar–OH). ^1H NMR ($CDCl_3$): δ 1.65—2.75 (4H, m, $-CH_2-+-CH_2-$), 3.45—3.85 (1H, m, =CH–), 4.10 (1H, dd, J=9 and 11 Hz, –OCH=), 4.85 (1H, dd, J=8 and 8 Hz, –OCH=), 6.64 (1H, dd, J=1 and 9 Hz, Ar–H), 6.91 (1H, d, J=9 Hz, Ar–H), 9.86 (1H, s, Ar–H). Found: C, 69.62; H, 5.48%. Calcd for $C_{11}H_{10}O_3$: C, 69.46; H, 5.30%.

*(5-Oxo-2a,3,4,5-tetrahydro-2H-naphtho[1,8-bc]furan-6-yloxy)acetic Acid (**1e**).* The compound **1e** was prepared from **4e** by a method similar to the synthesis of **1c** from **4c**. Colorless plates from acetone–benzene (60% yield); mp 155—156 °C. IR (KBr): ν_{max} 1670 (C=O), 1760 (COOH), 3120 cm^{-1} (COOH). ^1H NMR (CD_3COCD_3): δ 1.86—2.52 (2H, m, $-CH_2-$), 2.63—2.78 (2H, m, $-CH_2-$), 3.57—3.99 (1H, m, =CH–), 4.14 (1H, dd, J=8 and 11 Hz, –OCH=), 4.68 (2H, s, $-OCH_2-$), 4.90 (1H, dd, J=8 and 8 Hz, $-CH_2-$), 6.94 (2H, s, Ar–H). Found: C, 62.83; H, 4.69%. Calcd for $C_{13}H_{12}O_5$: C, 62.90; H, 4.87%.

The authors wish to thank Mr. Yoshiaki Takahashi for the elemental analyses.

Reactions of Aldonitrones with Phenylphosphonothioic Dichloride and Related Compounds. Formation of 2-Arylbenzothiazoles from α,*N*-Diarylnitrones

Masaaki Yoshifuji, Rihei Nagase, Takayuki Kawashima, and Naoki Inamoto*

Department of Chemistry, Faculty of Science, The University of Tokyo, Hongo, Bunkyo-ku Tokyo 113

(Received June, 19, 1981)

Reactions of α-aryl-*N*-methylnitrones with phenylphosphonothioic dichloride (**1**), diphenylphosphinothioic chloride (**6**), or thiophosphoryl trichloride (**7**) gave *N*-methylbenzamide and *N*-methylthiobenzamide derivatives, and the latter became major in the presence of tertiary amine. α,*N*-Diarylnitrones (**4**) reacted with **1** to give 2-arylbenzothiazoles (**5**) at room temperature in moderate yields. Reaction of **4** with **6** (at room temperature) or **7** (in refluxing THF) gave **5** in a low yield, whereas a similar reaction of **4** with **7** at 0 °C afforded *N*-benzylidene-2-chloroaniline in a high yield. A mechanism for the formation of **5** has been discussed briefly.

During the course of investigations on phosphinothioylidenes (R–P̈=S),[1] we tried reaction of *N*-methyl-α-phenylnitrone with phenylphosphonothioic dichloride (**1**) in the presence of magnesium in an attempt to prepare phosphorus-containing heterocycles such as 1,3,5,2-oxathiazaphospholidine, but the products were *N*-methylbenzamide (**2**) and *N*-methylthiobenzamide (**3**).

$$\underset{\mathbf{1}}{PhP(S)Cl_2} + PhCH{=}N(O)Me \longrightarrow PhCONHMe + PhCSNHMe$$
$$\mathbf{2} \qquad \mathbf{3}$$

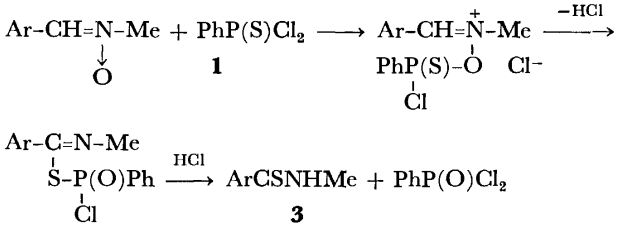
Even without magnesium, however, a similar result was obtained. Therefore, reactions of nitrones with **1** and related compounds were investigated and it was found that α,*N*-diarylnitrones gave 6-substituted 2-arylbenzothiazoles.[2] This paper describes these results.

Reactions of N-*Methylaldonitrones.* Reaction of *N*-methyl-α-phenylnitrone with **1** gave **2** (43%) and **3** (41%), together with the nitrone hydrochloride (17%). A similar reaction with diphenylphosphinothioic chloride gave also **2** (61%) and **3** (6%), and that with thiophosphoryl trichloride gave only **3** (60%). However, *N*-methyl-α-phenylnitrone did not react with triphenylphosphine sulfide even at 140 °C.

In order to remove hydrogen chloride evolved during the reaction, a base such as triethylamine and pyridine was added. As shown in Table 1, in the presence of base, formation of **3** was remarkably suppressed.

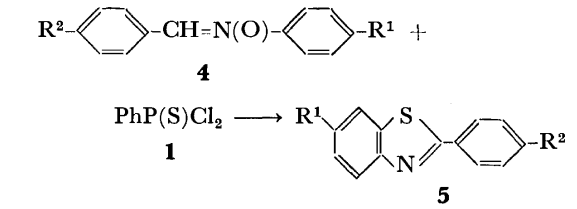
Similarly, reaction of α-(*p*-methoxyphenyl)-*N*-methylnitrone with **1** gave the corresponding amide (8%) and thioamide (28%), along with the nitrone hydrochloride (17%).

It has been reported that the nitrones rearrange to give the corresponding amide by acid chlorides and anhydrides such as phosphoryl trichloride, phosphorus trichloride, thionyl chloride, benzoyl chloride, benzenesulfonyl chloride, and acetic anhydride.[3] Analogously to these rearrangements,[3e,3f] the formation of thioamide (**3**) is explained as follows:



Phenylphosphonic dichloride produced during the reaction can similarly react with the nitrones to give amide (**2**). Therefore, in the presence of a base, hydrogen chloride eliminated during the reaction is trapped by the base, and decomposition of the second intermediate by hydrogen chloride is prevented before work-up. Thus the formation of amide (**2**) is strongly retarded.

Reactions of α,N-*Diarylnitrones.* α,*N*-Diarylnitrones (**4**) reacted with an equimolar amount of **1** in tetrahydrofuran (THF) at room temperature to give 6-substituted 2-arylbenzothiazoles (**5**) unexpectedly, along with the nitrone hydrochloride. The results are summarized in Table 2.



a: $R^1=R^2=H$; **b**: $R^1=H$, $R^2=OMe$; **c**: $R^1=H$, $R^2=Cl$; **d**: $R^1=Me$, $R^2=H$; **e**: $R^1=Me$, $R^2=OMe$; **f**: $R^1=Me$, $R^2=Cl$; **g**: $R^1=H$, $R^2=Me$; **h**: $R^1=H$, $R^2=NMe_2$

The nitrones **4g** and **4h** did not give **5g** and **5h**, respectively. The reason is obscure.

In order to suppress the formation of nitrone hydrochloride, a scavenger of hydrogen chloride such as pyridine and methyloxirane was added. Reaction of **4a** in the presence of pyridine gave thiobenzanilide

Table 1. Effect of base on formation of **2** and **3**

Base	**2** (%)	**3** (%)
None	43	41[a]
Et_3N	9	35[a]
Et_3N	0	60[b]
C_5H_5N	20	41[b]

a) A solution of **1** was added dropwise. b) A solution of nitrone was added dropwise.

Table 2. Yield of 2-arylbenzothiazole (5) from 4

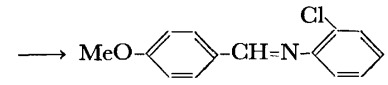
4			
	R^1	R^2	5(%)
4a	H	H	32
4b	H	OMe	54
4c	H	Cl	39
4d	Me	H	33
4e	Me	OMe	34
4f	Me	Cl	39

(36%) instead of **5a**, but that of **4b** in the presence of methyloxirane gave **5b** (57%), indicating no improvement of the yields.

Next, diphenylphosphinothioic chloride (**6**) analogous to **1** was used in order to examine the effect on the yield of **5**. Reaction of **4b** with **6** in the absence or the presence of methyloxirane gave *N*-(4-methoxybenzylidene)-2-chloroaniline (**8**) instead of **5b** in 4 or 18% yield, respectively.

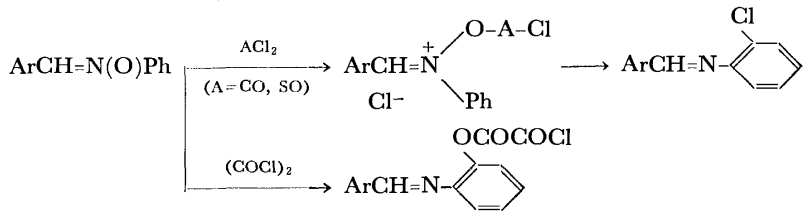
Furthermore, reaction of **4b** with thiophosphoryl trichloride (**7**) also gave **5b** in refluxing THF, but the yield was low (22%). On the other hand, reaction of **4b** with **7** at 0 °C gave **8** in 78% yield, which gave *o*-chloroaniline after hydrolysis. No *p*-chloro derivative was detected.

4b **7**

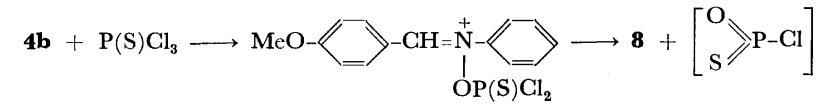


8

It has been reported that α-aryl-*N*-phenylnitrones gave *N*-benzylidene-2-chloroanilines in the reactions with thionyl or carbonyl chloride and gave *N*-benzylidene-2-(chlorooxalyloxy)anilines in the reactions with oxalyl chloride.[4]

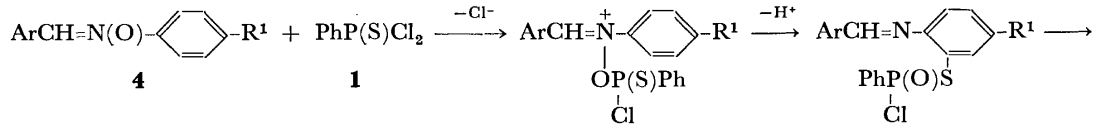


Therefore, the formation of **8** is analogously explained as follows:

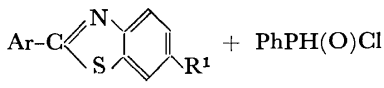


Analogously to reactions of *N*-methylaldonitrones with **1**, it is possible that thiobenzanilide is first formed by reaction of **4** with **1** and then thiobenzanilide may cyclize to **5**. However, thiobenzanilide did not give 2-phenylbenzothiazole with **1** under similar conditions.

Thus, a mechanism for formation of **5** is considered as follows, in connection with the formation of **8**.



4 **1** **9** **10**



5

An intermediate (**9**) formed by a nucleophilic attack of **4** towards **1** rearranges to second intermediate (**10**) through [3,3] sigmatropic rearrangement containing P=S bond, and then **10** is converted into benzothiazole (**5**).

This new reactions might be used as a preparation method of 2-arylbenzothiazoles under mild conditions.

Experimental

All the melting points are uncorrected. The IR spectra were taken with a Hitachi EPI-G2 spectrophotometer, and the NMR spectra were measured with a Hitachi R-24 or R-20B spectrometer using TMS as an internal standard.

Materials. The following compounds were prepared by reported methods; phenylphosphonothioic dichloride (**1**),[5] diphenylphosphinothioic chloride (**6**),[6] and *N*-methyl-α-phenyl-,[7] *N*-methyl-α-(4-methoxyphenyl)-,[8] α,*N*-diphenyl- (**4a**),[7] α-(4-methoxyphenyl)-*N*-phenyl- (**4b**),[7] α-(4-chlorophenyl)-*N*-phenyl- (**4c**),[9] α-phenyl-*N*-(*p*-tolyl)- (**4d**),[10] α-(4-methoxyphenyl)-*N*-(*p*-tolyl)- (**4e**),[10] α-(*p*-chlorophenyl)-*N*-(*p*-tolyl)- (**4f**),[11] *N*-phenyl-α-(*p*-tolyl)- (**4g**),[3e] and α-(*p*-dimethylaminophenyl)-*N*-phenyl-nitrones (**4h**).[12]

Reaction of N-*Methyl-α-phenylnitrone with* **1**. *Reaction in the Absence of Base*: To a THF solution (25 ml) of the nitrone (1.29 g, 9.6 mmol) was added **1** (2.0 g, 9.5 mmol) with stirring under nitrogen. After the mixture was slightly heated, an exothermic reaction took place and white precipitates were formed. After the reaction mixture was allowed to stand overnight, the precipitates (278 mg) were collected and washed with THF. The filtrate and the washings were evaporated to give a red residue. Since the precipitates contained halogen (by Beilstein test), a mixture of the precipitates and triethylamine in benzene

was stirred overnight at room temperature to give the starting nitrone. Thus, the precipitates were identified with the nitrone hydrochloride (17% yield). The red residue was subjected to dry column chromatography (DCC; SiO_2, CH_2Cl_2) to give recovered **1** (48 mg, 2.3%), **3** (497 mg, 41%), mp 79.5—81 °C (from CCl_4) (lit,[13] mp 79 °C); IR (KBr): 1520, 1340, and 1240 cm^{-1}, and **2** (459 mg, 43%), mp 78—81 °C (from EtOH) (lit,[14] mp 78—80 °C); IR (KBr): 1630, 1540, 1400, and 1300 cm^{-1}. The yields of the amides are based on the nitrone consumed.

Reaction in the Presence of Base: Only typical procedure is described.

To a THF solution (5 ml) of **1** (928 mg, 4.42 mmol) and triethylamine (1.5 ml) was added a THF solution (15 ml) of the nitrone (506 mg, 3.75 mmol) dropwise and the mixture was stirred at room temperature for 1 h. After addition of water, the mixture was extracted with ether, the ethereal extract was dried ($MgSO_4$), and evaporated. The residue was subjected to DCC (SiO_2, CH_2Cl_2) to give **3** (317 mg, 60%) (by IR). The other results were shown in Table 1.

Reaction of N-*Methyl-α-phenylnitrone with Other Phosphorus Chlorides*. Reaction with diphenylphosphinothioyl chloride is described as a typical procedure.

A THF solution (25 ml) of the nitrone (1.30 g, 9.6 mmol) and the phosphinothioyl chloride (2.47 g, 9.8 mmol) was stirred at room temperature overnight. After usual work-up, the recovered chloride (1.70 g, 69%), and **3** (90 mg, 6%), and **2** (786 mg, 61%) were isolated by DCC (SiO_2, CH_2Cl_2).

*Reaction of α-(*p-*Methoxyphenyl)*-N-*methylnitrone with* ***1***. A THF solution (25 ml) of the nitrone (1.41 g, 8.52 mmol) and **1** (1.82 g, 8.64 mmol) was stirred at room temperature overnight. After precipitates (296 mg, 17%) (the nitrone hydrochloride) were removed by filtration, the residue from the filtrate was subjected to DCC (SiO_2, CH_2Cl_2) to give *N*-methyl-*p*-methoxythiobenzamide (365 mg, 28%), mp 118—119 °C (from C_6H_6–hexane (1:1)) (lit,[15] 110—111 °C) and *N*-methyl-*p*-methoxybenzamide (89 mg, 8%), mp 122.5—124 °C (from C_6H_6) (lit,[16] 119.5—120.5 °C).

Reactions of α,N-*Diarylnitrones with* ***1***. Reaction of α-(*p*-methoxyphenyl)-*N*-phenylnitrone (**4b**) is described as a typical procedure.

A mixture of **4b** (2.12 g, 9.33 mmol) and **1** (1.96 g, 9.27 mmol) in THF (25 ml) was stirred at room temperature overnight under nitrogen and precipitates thus obtained were filtered off. The precipitates were the nitrone hydrochloride (340 mg, 14%). The residue (3.27 g) from the filtrate was subjected to DCC (SiO_2, $CHCl_3$) to give **5b** (1.04 g, 54%), mp 123—125 °C (from EtOH) (lit,[17] 121.5—122 °C).

Reactions of other nitrones were carried out similarly. **4a** gave the nitrone hydrochloride (4%) and **5a** (32%), mp 108—113 °C (from EtOH) (lit,[18] 112—114 °C) by DCC (SiO_2, C_6H_6). **4c** gave **5c** (39%), mp 119—120 °C (from EtOH) (lit,[17] 120—121 °C) by DCC (SiO_2, CH_2Cl_2–CCl_4 (1:1)). **4d** gave **5d** (33%), mp 125.5—127 °C (from EtOH) (lit,[19] 125—125.5 °C) by DCC (SiO_2, CH_2Cl_2–CCl_4 (1:2)). **4e** gave **5e** (34%), mp 176—177 °C (from EtOH) (lit,[19] 174 °C) by DCC (SiO_2, CH_2Cl_2). **4f** gave **5f** (39%), mp 160—161 °C (from EtOH) (lit,[20] 160 °C) by DCC (SiO_2, CH_2Cl_2–CCl_4 (1:1)).

Reaction of ***4a*** *with* ***1*** *in the Presence of Pyridine*. To a mixture of **1** (1.14 g, 5.43 mmol) and pyridine (1 ml) in THF (5 ml) was added a solution of **4a** (990 mg, 5.03 mmol) in THF (15 ml) and then the mixture was stirred at room temperature overnight. After addition of water, the reaction mixture was extracted with ether, the ethereal extract was dried with $MgSO_4$, and evaporated. The residue was subjected to DCC (SiO_2, CH_2Cl_2–CCl_4 (1:1)) to give thiobenzanilide (387 mg, 36%), mp 100—101 °C (lit,[13] 97 °C).

Reaction of ***4b*** *with at 0 °C*. A mixture of **4b** (351 mg, 1.5 mmol) and **7** (275 mg, 1.63 mmol) in THF (10 ml) was stirred at 0 °C under nitrogen overnight. After addition of hexane (50 ml), the precipitates thus produced were collected by filtration and washed twice with hexane. The precipitates were suspended in benzene (10 ml) and stirred in the presence of triethylamine (0.3 ml). After precipitates were filtered off, the filtrate was evaporated to give **8** (282 mg, 78%); NMR ($CDCl_3$): δ 3.9 (s, 3H), 6.95—7.6 (m, 6H), 7.86 (d, J=10, 2H), and 8.3 (s, 1H). The NMR spectrum was the same as that of an authentic sample prepared from *p*-methoxybenzaldehyde and *o*-chloroaniline.

Reactions of α,*N*-Diarylnitrones with *O*-Methyl Diphenylphosphinothioate and Oxidations of *N*-Alkylidene-2-hydroxyanilines with Silver Oxide. Preparation of Benzoxazoles

Masaaki Yoshifuji, Rihei Nagase, and Naoki Inamoto*

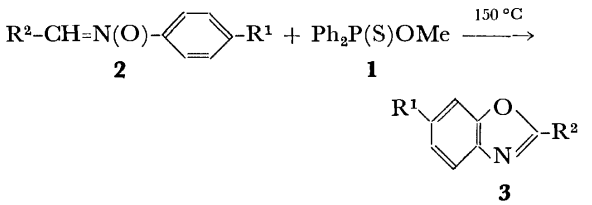
Department of Chemistry, Faculty of Science, The University of Tokyo, Hongo, Bunkyo-ku, Tokyo 113

(Received June 19, 1981)

Reactions of α,*N*-diarylnitrones in the presence of *O*-methyl diphenylphosphinothioate at 150 °C gave 2-arylbenzoxazoles (**3**) in fairly good yields. Oxidation of *N*-alkylidene-2-hydroxyanilines with silver oxide afforded 2-alkenyl-, 2-alkyl-, or 2-arylbenzoxazoles (**7** and **3**) in good yields under mild reaction conditions (at room temperature). A plausible mechanism for formation of **3** and **7** has been discussed briefly.

In the previous paper,[1] we reported that reactions of α,*N*-diarylnitrones with phenylphosphonothioic dichloride gave 2-arylbenzothiazoles at room temperature in moderate yields. When *O*-methyl diphenylphosphinothioate (**1**) was used instead of phenylphosphonothioic dichloride, reactions with α,*N*-diarylnitrones (**2**) at 150 °C gave unexpectedly 2-arylbenzoxazoles (**3**).[2] Furthermore, in order to prepare **3** under mild conditions, we investigated oxidations of *N*-alkylidene-2-hydroxyanilines (**4**).[3] This paper describes these detailed results.

Reactions of α,N-*Diarylnitrones (2) with* O-*Methyl Diphenylphosphinothioate (1).* Reactions of **2** with an equimolar amount of **1** did not occur at room temperature, but gave 2-arylbenzoxazoles (**3**) at 150 °C in *o*-dichlorobenzene in fairly good yields. The results are summarized in Table 1.



As shown in Table 1, in the case of α,*N*-diphenylnitrone (**2a**), 2-phenylbenzoxazole (**3a**) was not obtained but an intractable mixture was obtained. The reason is obscure.

These reactions in the absence of **1** gave only a trace amount of **3** under similar conditions. For example, in the case of **2g**, the yield of **3g** was only 1%.

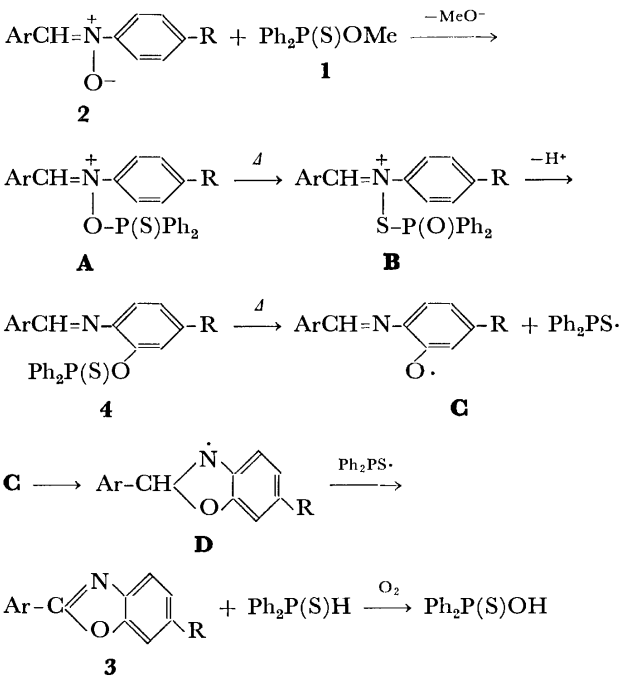
Moreover, after the reactions in the presence of **1**, about a half amount of **1** was recovered (see Table 1). The fact suggests that **1** works catalytically. In fact, in the case of **2b**, a similar reaction with a 0.1 molar amount of **1** gave **3b** in 53% yield, and the yield was nearly the same as that with an equimolar amount of **1** (61%).

Table 1. Yields of **3** from **2** and **1**

2	R^1	R^2	Time/d	**3** (%)	Recovery of **1**/%
2a	H	C_6H_5	1	**3a** 0	a)
2b	H	*p*-$MeOC_6H_4$	2	**3b** 61	a)
2c	H	*p*-ClC_6H_4	7	**3c** 50	32
2d	Me	C_6H_5	2	**3d** 69	52
2e	Me	*p*-$MeOC_6H_4$	1	**3e** 56	33
2f	Me	*p*-ClC_6H_4	1	**3f** 47	63
2g	H	*p*-MeC_6H_4	1.75	**3g** 40	53

a) Not determined.

A plausible mechanism for formation of **3** might be as follows:



The anionic oxygen atom in the nitrone (**2**) nucleophilically attacks on the phosphorus atom in **1** to afford an intermediate (**A**) which thermally rearranges to a more stable intermediate (**B**) because P=O bond is stronger than P=S bond. Then the intermediate (**B**) is converted into *N*-benzylidene-*o*-(diphenylphosphinothioyloxy)aniline (**4**) by attack of the oxygen atom of the P=O group on the electron-deficient benzene ring. Next, **4** undergoes a homolytic cleavage to produce phenoxyl (**C**) and diphenylphosphinothioyl radicals. The radical (**C**) intramolecularly cyclizes to give a radical (**D**), and diphenylphosphinothioyl radical abstracts hydrogen atom from the radical (**D**) to afford 2-arylbenzoxazole (**3**) and diphenylphosphine sulfide. The latter compound may be oxidized to diphenylphosphinothioic acid under the reaction conditions. Since diphenylphosphinothioic acid can react with **2** to produce **A** analogously to **1**, it is considered that **1** can work catalytically even in a trace amount.

In fact, **2e** gave **3e** in the presence of 0.11 molar

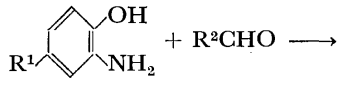
amount of diphenylphosphinothioic acid under similar conditions in 44% yield. On the other hand, **3e** was obtained in a lower yield (23%) in a similar reaction of **2e** with a 0.1 molar amount of **1** under argon atmosphere. A similar reaction of **2e** in the presence of diphenylphosphine sulfide under argon atmosphere afforded **3e** only in 7% yield. These results support the above mechanism.

It was shown in a separate experiment that **4** (Ar= *p*-$MeOC_6H_4$), prepared from diphenylphosphinothioic chloride and *N*-(4-methoxybenzylidene)-2-hydroxyaniline, gave **3b** in 52% yield (based on the Schiff's base) under similar conditions, also supporting the above mechanism.

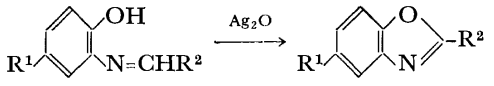
Oxidations of N-Alkylidene-2-hydroxyanilines (5) with Silver Oxide. If phenoxyl radicals (**C**) can be generated under mild conditions in a high efficiency, it is expected from the above mechanism that 2-substituted benzoxazoles (**3** and **7**) would be produced in high yields under mild conditions.

It has been reported that **5** are oxidized with lead(IV) tetraacetate,[4] lead(IV) tetraphosphate,[5] or nickel peroxide[6] to give **3** or **7** in fairly good yields and the intermediate is phenoxyl radical (**C**),[4] supporting the above mechanism.

In this connection, other oxidizing agents were examined. *N*-(4-Methoxybenzylidene)-2-hydroxyaniline (**5b**) was oxidized with iodine and potassium iodide[7] at room temperature, but the yield of **3b** was only 11%. On the contrary, oxidation of **5b** with silver oxide[8] gave **3b** at room temperature in 92% yield. Therefore, we used silver oxide as oxidizing agent for **5**. It is considered that silver oxide can generate phenoxyl radical from **5**.



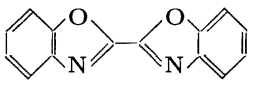
6



5 **3** or **7**

The Schiff's bases (**5**) are easily prepared from the corresponding aldehydes and *o*-aminophenols (**6**). Since Shiff's bases (**5k**—**m**) could not be purified, these were used in the oxidation reactions without further purification. The results of oxidation reactions of **5** with silver oxide are summarized in Table 2.

2-Alkyl- (**7f** and **7g**) and 2-alkenylbenzoxazoles (**7d**, **7h'**, and **7i**), which have not been prepared by oxidation with lead(IV) tetraacetate, were also obtained by the present method. 2,2'-Bis(benzoxazolyl) (**7j**) was prepared using glyoxal.



7j

However, in the case of butanal, the product was not 2-propylbenzoxazole, but 2-(1-ethyl-1-pentenyl)-benzoxazole (**7h**) was obtained unexpectedly, showing that an aldol-type condensation occurred at first during the preparation of the corresponding Schiff's base. **7h** was also prepared from the corresponding Schiff's base which was prepared from *o*-aminophenol and 2-ethyl-2-hexenal. 2-(1-Methyl-1-butenyl)benzoxazole (**7i**) was prepared by a similar method.

An aldol-type condensation during the preparation of the Schiff's base is supported by the fact that *N*-butylideneaniline gives *N*-(2-ethyl-2-hexenylidene)aniline through the dimerization followed by elimination of aniline.[9] Thus, we did not further apply this method to aldehydes which can undergo the corresponding reaction easily.

The benzoxazoles are usually prepared by heating *o*-aminophenols with acid anhydrides or acid halides.[10] To the best of our knowledge, yields in the present method were better and the reaction conditions employed were milder than any other methods for preparation of oxazoles. The present method is generally applicable to the 2-substituted benzoxazoles (**3** and **7**).

N-Benzylidene-2-hydroxyethylamine and -*o*-phenylenediamine did not produce the expected 4,5-dihydro-2-phenyl-1,3-oxazole and 2-phenylbenzimidazole, respectively, under similar conditions.

Table 2. Yields of benzoxazoles (**3** and **7**) from Schiff's bases (**5**)

5		R^2	**3** or **7** R^1	Yield/%
5a	**3a**	C_6H_5	H	76
5b	**3b**	*p*-$MeOC_6H_4$	H	92
5c	**3c**	*p*-ClC_6H_4	H	81
5d	**7a**	*p*-$NO_2C_6H_4$	H	80

5m	**7j**		H	25[a]

a) Yield based on *o*-aminophenol used. b) This compound was obtained in the reaction of *o*-aminophenol with butanal followed by silver oxide oxidation (see text).

Experimental

All the melting points are uncorrected. The ^1H NMR spectra were measured with a Hitachi R-24 or R-20B spectrometer using TMS as an internal standard, the IR spectra were taken with a Hitachi EPI-G2 spectrophotometer, and the mass spectra were determined with a Hitachi RMU-6L spectrometer.

Materials. *O*-Methyl diphenylphosphinothioate (**1**) was prepared by reported method.[11] α,*N*-Diarylnitrones (**2a**—**f**) were prepared by the methods described in the previous paper.[1]

Reactions of 2 with 1. A typical procedure is described

on the reaction of **2b**.

Using an Equimolar Amount of ***1***: A solution of **2b** (252 mg, 1.11 mmol) and **1** (288 mg, 1.16 mmol) in *o*-$C_6H_4Cl_2$ (15 ml) was heated at 150 °C for 2 d. After removal of *o*-$C_6H_4Cl_2$ *in vacuo*, the residue was subjected to dry column chromatography (DCC)(SiO_2, CH_2Cl_2) to give **3b** (152 mg) in 61% yield, mp 100—101 °C (from EtOH) (lit,[12] mp 101 °C).

Using a Catalytic Amount of ***1***: A solution of **2b** (458 mg, 2.02 mmol) and **1** (50 mg, 0.2 mmol) in *o*-$C_6H_4Cl_2$ (15 ml) was heated at 150 °C for 24 h. Usual work-up gave **3b** (239 mg, 53%) and unchanged **1** (28 mg, 56%).

These results in reaction of other nitrones (**2**) were summarized in Table 1. Isolation method and mp (lit, mp) of **3** are shown below.

3c: DCC (SiO_2, CH_2Cl_2–CCl_4 (1:1)); mp 151.5—153 °C (from EtOH) (lit,[12] 150 °C). **3d**: DCC (SiO_2, CH_2Cl_2–CCl_4 (1:2)); mp 93—94 °C (from aq EtOH) (lit,[13] 92.5—93.0 °C). **3e**: DCC (SiO_2, CH_2Cl_2); mp 87—90 °C (from EtOH) (lit,[14] 91 °C). **3f**: DCC (SiO_2, CH_2Cl_2–CCl_4 (1:1)); mp 154—155 °C (from EtOH) (lit,[13] 151.5—152.0 °C). **3g**: DCC (SiO_2, CH_2Cl_2–CCl_4 (2:1)); mp 114.5—116.0 °C (from EtOH) (lit,[12] 116—117 °C).

Reaction of ***2e*** *with Diphenylphosphinothioic Acid.* A solution of **2e** (239 mg, 0.99 mmol) and diphenylphosphinothioic acid (27 mg, 0.11 mmol) in *o*-$C_6H_4Cl_2$ (7 ml) was heated at 150 °C for 24 h. After twice DCC (Al_2O_3, CCl_4 and then SiO_2, C_6H_6), **3e** was obtained in 44% yield (105 mg).

Formation of ***3b*** *from* ***4*** *(Ar=*p*-MeOC$_6$H$_4$)*. To a solution of *N*-(4-methoxybenzylidene)-2-hydroxyaniline[15] (1.142 g, 5.03 mmol) in *o*-$C_6H_4Cl_2$ (10 ml) were added triethylamine (0.7 ml, 5.0 mmol) and then diphenylphosphinothioic chloride (1.2 ml, 5.2 mmol) at 0 °C. After stirring at 0 °C for 30 min and then at 20 °C for 3 h, the resulting precipitates (1.65 g) were filtered off and a yellow oil (3.008 g) was obtained as the residue after removal of the solvent from the filtrate *in vacuo*; ^{1}H NMR ($CDCl_3$): δ 3.87 (s, 3H) and 6.5—8.5 (m, 19H); MS (FD): *m/e* 443 (M^+). A solution of the yellow oil (0.271 g) in *o*-$C_6H_4Cl_2$ (10 ml) was heated at 150 °C for 4 d. After removal of the solvent *in vacuo*, the residue was subjected to DCC (Al_2O_3, CCl_4 and then SiO_2, $CHCl_3$) to give **3b** (53.3 mg), yield 52% based on the starting Schiff's base, mp 102—103 °C (from EtOH).

Oxidations of ***5*** *with Silver Oxide.* The following Schiff's bases were prepared by reported methods: **5a**,[15] **5b**,[15] **5c**,[4] **5d**,[6] **5e**,[16] **5f**,[17] and **5g**.[4]

General procedure of oxidation is as follows. A mixture of **5** (1 mmol) and Ag_2O (1.1—1.3 mmol) in CH_2Cl_2 (20—40 ml) was stirred at room temperature for 2—5 h and an insoluble material was filtered off. The filtrate was evaporated and the residue was purified by recrystallization (recryst) or DCC to give pure **7**. The results were shown in Table 2.

Isolation method and mp (lit, mp) of **3** and **7** are shown below.

3a: DCC (SiO_2, CH_2Cl_2); mp 103—105 °C (from EtOH) (lit,[4] 102 °C). **3b**: DCC (SiO_2, CH_2Cl_2); mp 101—102 °C (from aq EtOH) (lit,[12] 101 °C). **3c**: DCC (SiO_2, CH_2Cl_2–CCl_4 (1:1)); mp 151—152 °C (from aq EtOH) (lit,[4] 151—152 °C). **7a**: recryst from xylene; mp 266.5—268.0 °C (lit,[4] 268 °C). **7b**: DCC (SiO_2, CCl_4); mp 109—111 °C (from EtOH) (lit,[18] 98—100 °C). **7c**: DCC (Al_2O_3, CH_2Cl_2–CCl_4 (1:1)); mp 155—156 °C (from EtOH) (lit,[17] 153—154 °C). **7d**: DCC (Al_2O_3, CCl_4); mp 83—85 °C (from aq EtOH) (lit,[4] 83 °C).

Preparation of ***7e*** *from Furfural.* A mixture of *o*-aminophenol (294 mg, 2.7 mmol), furfural (0.2 ml, 2.2 mmol), and anhydrous sodium sulfate (2 g) in benzene (20 ml) was stirred for 20 h at room temperature and filtered. The residual oil (325 mg) (^{1}H NMR ($CDCl_3$): δ 6.45 (q, J=2 Hz, 1H), 6.83—7.3 (m, 6H), 7.52 (d, J=2 Hz, 1H), and 8.4 (s, 1H)) from the filtrate was stirred with Ag_2O (461 mg, 2 mmol) in CH_2Cl_2 (20 ml) overnight and the reaction mixture was subjected to DCC (Al_2O_3, CCl_4) to give **7e** (225 mg, 45%), mp 88—89 °C (from aq EtOH) (lit,[6] 86.0—86.5 °C).

Preparation of ***7f*** *from 2-Methylpropanal.* A mixture of *o*-aminophenol (272 mg, 2.49 mmol), 2-methylpropanal (0.3 ml, 3.31 mmol), and anhydrous sodium sulfate (2 g) in benzene (30 ml) was stirred for 30 min at 0 °C and then for 3 h at room temperature and filtered. The residue (376 mg) from the filtrate was stirred with Ag_2O (769 mg, 3.31 mmol) in CH_2Cl_2 (20 ml) at 0—10 °C overnight and the reaction mixture was subjected to DCC (Al_2O_3, CCl_4) to give oily **7f** (217 mg, 54%) (lit,[19] bp 109—111 °C/10 mmHg, 1 mmHg=133.322 Pa); ^{1}H NMR ($CDCl_3$): δ 1.42 (d, J=7 Hz, 6H), 3.2 (m, 1H), and 7.1—7.85 (m, 4H); MS: *m/e* 161 (M^+, 34%) and 146 (100).

Preparation of ***7g*** *from 2,2-Dimethylpropanal.* A mixture of *o*-aminophenol (253 mg, 2.32 mmol), 2,2-dimethylpropanal (0.3 ml, 2.8 mmol) in benzene (20 ml) was refluxed using Dean-Stark apparatus for 3.5 h, the reaction mixture was concentrated to remove unchange *o*-aminophenol (36 mg), and then evaporated. The residue (360 mg) was stirred with Ag_2O (568 mg, 2.45 mmol) in CH_2Cl_2 (20 ml) at room temperature overnight, and the reaction mixture was subjected to DCC (Al_2O_3, CCl_4) to give oily **7g** (231 mg, 57%) (lit,[20] bp 124 °C/17 mmHg); ^{1}H NMR ($CDCl_3$): δ 1.5 (s, 9H) and 7.15—7.8 (m, 4H); MS: *m/e* 175 (M^+, 32%), 160 (100), and 133 (43).

Preparation of ***7h***. *From Butanal*: A mixture of *o*-aminophenol (259 mg, 2.37 mmol), butanal (0.5 ml, 5.67 mmol), and anhydrous sodium sulfate (2 g) in toluene (15 ml) was stirred at 0 °C for 6 h and filtered. The residue (558 mg) from the filtrate was stirred with Ag_2O (600 mg, 2.58 mmol) in CH_2Cl_2 (20 ml) at 0 °C overnight and the reaction mixture was subjected to DCC (Al_2O_3, CCl_4) to give oily **7h** (191 mg, 37%); ^{1}H NMR ($CDCl_3$): δ 1.0 (t, J=7 Hz, 3H), 1.2 (t, J=7 Hz, 3H), 1.3—1.8 (m, 2H), 2.3 (q, J=7 Hz, 2H), 2.7 (q, J=7 Hz, 2H), 6.71 (t, J=7 Hz, 1H), and 7.1—7.8 (m, 4H); MS: *m/e* 215 (M^+, 41%), 200 (100), 186 (40), 133 (47), and 120 (38).

Found: C, 77.90; H, 8.06; N, 6.75%. Calcd for $C_{14}H_{17}NO$: C, 78.14; H, 7.91; N, 6.51%.

From 2-Ethyl-2-hexenal: A mixture of *o*-aminophenol (275 mg, 2.52 mmol), 2-ethyl-2-hexenal[21] (500 μl), and anhydrous sodium sulfate (2 g) in benzene (50 ml) was refluxed overnight and filtered. The residue from the filtrate (527 mg) was stirred with Ag_2O (570 mg, 2.46 mmol) in CH_2Cl_2 (20 ml) at 0 °C overnight and the reaction mixture was subjected to DCC (Al_2O_3, CCl_4) to give **7h′** (=**7h**) (401 mg, 74%).

Preparation of ***7i*** *from 2-Methyl-2-pentenal.* A mixture of *o*-aminophenol (275 mg, 2.52 mmol) and 2-methyl-2-pentenal (452 mg, 4.61 mmol) in benzene (20 ml) was refluxed for 6 h using Dean-Stark apparatus and evaporated to give a residue (498 mg); ^{1}H NMR ($CDCl_3$): δ 1.1 (t, J=6 Hz, 3H), 2.0 (s, 3H), 2.4 (m, 2H), 6.2 (t, J=7 Hz, 1H), 6.8—7.3 (m, 4H), and 8.2 (s, 3H).

The residue was stirred with Ag_2O (781 mg, 3.37 mmol) in CH_2Cl_2 (20 ml) at room temperature overnight and the reaction mixture was subjected to DCC (Al_2O_3, CCl_4) to give oily **7i** (191 mg, 41%); ^{1}H NMR ($CDCl_3$): δ 1.1 (t,

J=7 Hz, 3H), 2.1 (s, 3H), 2.0—2.5 (m, 2H), 6.8 (t, J= 7 Hz, 1H), 7.3 (m, 3H), and 7.65 (m, 2H).

Found: C, 77.15; H, 7.06; N, 7.57%. Calcd for $C_{12}H_{13}NO$: C, 76.98; H, 7.00; N, 7.48%.

Preparation of ***7j*** *from Glyoxal.* A mixture of *o*-aminophenol (1.50 g, 13.8 mmol), 40% aq glyoxal (1.0 g, 6.9 mmol), and anhydrous sodium sulfate (10 g) in benzene (40 ml) was stirred at room temperature overnight and filtered. The solvent was removed, $CHCl_3$ (50 ml) was added and an insoluble part was filtered off. After removal of $CHCl_3$, the residue (849 mg) was stirred with Ag_2O (1.677 g, 7.23 mmol) in CH_2Cl_2 (50 ml) at room temperature overnight, and the reaction mixture was filtered through Celite. After evaporation of the filtrate, the residue was subjected to DCC (Al_2O_3, $CHCl_3$) to give **7j** (404 mg, 1.71 mmol, 25%), mp 262—263 °C (from EtOH) (lit,[22] 255—257 °C); MS: *m/e* 236 (M^+, 100%).

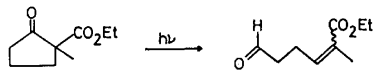
Photochemical Reaction of Ethyl 3-Oxo-2,4-diphenylbutanoate

Michikazu Yoshioka,* Haruhiko Osawa, and Shinji Fukuzawa
Department of Chemistry, Saitama University, Shimo-okubo, Urawa, Saitama 338
(Received July 6, 1981)

Irradiation of ethyl 3-oxo-2,4-diphenylbutanoate in hexane gave the products formed by recombination of the radicals (Ph–$\dot{C}H_2$ and/or Ph–$\dot{C}H$–CO_2Et) resulting from decarbonylation, together with small amounts of 1,2-diphenylethanol and ethyl α-hydroxyphenylacetate, whereas in benzene no 1,2-diphenylethanol was found. Under oxygen an increased amount of ethyl α-hydroxyphenylacetate and no radical recombination products were observed.

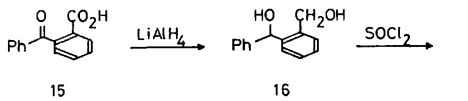
Although the influence of UV-irradiation on the keto-enol equilibrium ratio of β-keto esters has been studied,[1] few reports about the photochemistry of β-keto esters to yield isolatable products have been found.[2,3] Moritur reported[2] that irradiation of the β-keto ester (**1**) gave aldehydes (**2**) resulting from α-cleavage. It is expected that β-keto esters with phenyl group at α-position to both carbonyl groups are easily subject to α-cleavage upon irradiation, and the resulting radicals may couple to yield products. In this paper we wish to report a photolysis of ethyl 3-oxo-2,4-diphenylbutanoate (**3**) which is expected to yield coupling products of radicals resulting from initial α-cleavage of the excited molecule.



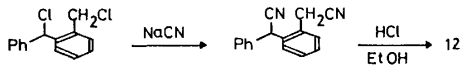
1 2 (E + Z)

Results and Discussion

Irradiation of **3** in hexane with Pyrex filtered light led to the formation of eleven products; bibenzyl (**4**, 13%), ethyl phenylacetate (**5**, 5%), ethyl α-hydroxyphenylacetate (**6**, 5%), 1,2-diphenylethanol (**7**, 2%), ethyl 2,3-diphenylpropionate[4] (**8**, 32%), ethyl *o*-benzylphenylacetate[5] (**9**, 4%), diethyl *meso*-α,α′-diphenylsuccinate[6] (**10**, 7%), diethyl *dl*-α,α′-diphenylsuccinate[6] (**11**, 7%), ethyl *o*-(α-ethoxycarbonylbenzyl)-phenylacetate (**12**, 3%), $PhCH_2C_6H_{13}$ compound (**13**, 4%), and $PhCH(C_6H_{13})CO_2Et$ compound (**14**, 4%). The products **4**, **5**, **6**, and **7** were identified by comparison of their spectroscopic data with those of commercially available authentic samples. The structures of **8**, **9**, **10**, and **11** were established by comparison with the specimens independently synthesized according to published methods.[4–6] The product **12** was confirmed by comparison with an independently synthesized one from *o*-benzoylbenzoic acid by the sequence **15**→**16**→**17**→**18**→**12** (overall yield, 16%).



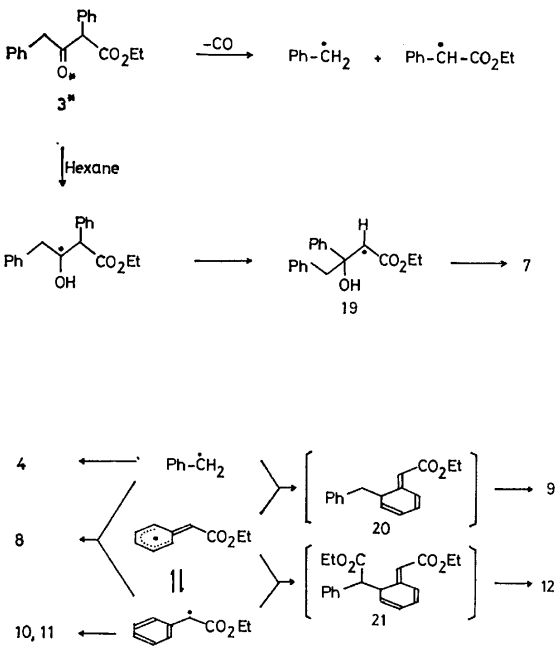
15 16



17 18

The products **13** and **14** were characterized by their spectroscopic data (see Experimental), although the structures of the $-C_6H_{13}$ residues of both **13** and **14** were not clear. ^1H NMR spectrum of **13** shows thirteen hydrogen atoms between δ=0.7 and 1.8 ($-C_6H_{13}$), two hydrogen atoms between δ=2.1 and 2.7 ($-CH_2-$ adjacent to the phenyl group) and five hydrogen atoms between δ=7.0 and 7.3 (phenyl), while that of **14** shows a triplet at δ=1.17 and a quartet at δ=4.07 ascribed to the ethoxycarbonyl group.

The formation of **4**—**6** and **8**—**14** may be explained in terms of cleavage of both the C_2–C_3 and the C_3–C_4 bonds of excited **3** to produce a benzyl radical and an α-ethoxycarbonylbenzyl radical. Homogeneous combination of the benzyl radicals and α-ethoxycarbonylbenzyl radicals yields bibenzyl **4** and two diastereomeric diesters **10** and **11**, respectively. Mixed combination of benzyl radical with α-ethoxycarbonylbenzyl radical yields **8**. Attack of the benzyl radical on a phenyl ring of α-ethoxycarbonylbenzyl radical yields **9** through an intermediate **20**. Similarly, coupling of α-ethoxycarbonylbenzyl radicals yields **12** through an intermediate **21**. Reaction of the α-ethoxycarbonylbenzyl radical with the solvent yields either **5** or **14**. Reaction of benzyl radical with the solvent yields **13**. Ethyl α-hydroxyphenylacetate **6** probably arises *via* the reaction of the α-ethoxycarbonylbenzyl radical with oxygen dissolved in the solvent. In fact, irradiation of **3** under oxygen afforded **6** with an increased yield. The formation of 1,2-diphenylethanol **7** may



be explained in terms of phenyl migration from C-2 to C-3 of the starting β-keto ester. Since irradiation of **3** in benzene, which is inert toward hydrogen abstraction, affords no **7**, the phenyl migration is considered to follow the hydrogen abstraction by excited **3** from the solvent. Therefore, **7** may arise *via* radical **19**. In conclusion, the present work elucidated that photolysis of a β-keto ester having a phenyl group at the C-2 position proceeded predominantly by an α-cleavage and slightly by hydrogen abstraction from the solvent followed by phenyl migration.

Experimental

^{1}H NMR spectra were recorded on a Varian A-60D apparatus in carbon tetrachloride with tetramethylsilane as the internal standard. IR spectra were recorded on a JASCO IRA-2 spectrometer in carbon tetrachloride. Gas liquid chromatography (GLC) was carried out on a Hitachi K-53 (FID) or a Gasukuro Kogyo KOR-70 (TCD) instrument, using a 2 m×3 mm stainless steel (for K-53) or a 5 m×6 mm aluminium column (for KOR-70), both of which were packed with 10% SE-30 on 60—80 mesh Diasolid L. Irradiations were conducted through a Pyrex filter using an Ushio UM-452 high pressure mercury lamp (450 W). Thin layer chromatography (TLC) was carried out on Merck Silica Gel 60 TLC Plates Art. 5737. Column chromatography was carried out on Merck Silica Gel 60 Art. 7734. Ethyl 3-oxo-2,4-diphenylbutanoate (**3**) was prepared by the published method.[7]

Photolysis. a): A solution of 2.64 g of **3** in 1100 cm^3 of hexane (8.5 mmol/dm^3 solution) was irradiated, and the reaction was monitored by TLC. Irradiation was continued until almost all the starting ester was consumed (*ca.* 8 h). The solvent was removed under reduced pressure, and the residue was analyzed by GLC to reveal the following product distribution: **4** (13%), **5** (5%), **6** (5%), **7** (2%), **8** (32%), **9** (4%), **10** (7%), **11** (7%), **12** (3%), **13** (4%), and **14** (4%). These photo-products were separated from the irradiation mixture by a combination of column chromatography using benzene as eluent and preparative GLC. The products **4**—**12** were identical with authentic samples.

b): A solution of 960 mg of **3** in 400 cm^3 of hexane was irradiated under oxygen for 3 h. The solvent was removed under reduced pressure. Column chromatography of the residue gave only **6** with 37% yield.

c): A solution of 10.1 mg of **3** in 1 cm^3 of benzene was placed in a Pyrex tube and irradiated for 1 h. GLC-analysis indicated that the irradiation mixture contained **4** (18%), **5** (2%), **8** (50%), **9** (4%), **10** (10%), **11** (10%), **12** (3%), and no **7**.

$PhCH_2C_6H_{13}$ Compound ***13***. IR 2950, 2900, 695 cm^{-1}. ^{1}H NMR: δ=0.7—1.8 (m, 13H), 2.1—2.7 (m, 2H) and 7.0—7.3 (m, 5H). Found: C, 88.02; H, 11.22%. Calcd for $C_{13}H_{20}$: C, 88.56; H, 11.44%.

$PhCH(C_6H_{13})CO_2Et$ Compound ***14***. IR: 2950, 2920, 1730, 1160, 1030, 700 cm^{-1}. ^{1}H NMR: δ=1.17 (t, J=7.5 Hz, 3H), 0.6—2.4 (m, 13H), 3.0—3.5 (m, 1H), 4.07 (q, J=7.5 Hz, 2H), and 7.1—7.5 (m, 5H). Found: C, 77.64; H, 9.70%. Calcd for $C_{16}H_{24}O_2$: C, 77.37; H, 9.74%.

Synthesis of ***12***. To a suspension of $LiAlH_4$ (2.0 g) in absolute ether (30 cm^3) under reflux was added slowly a solution of *o*-benzoylbenzoic acid (**15**, 5.0 g) in absolute ether (50 cm^3). After the addition was completed, the mixture was heated under reflux for an additional 2 h. After the remaining $LiAlH_4$ had been destroyed by addition of saturated NH_4Cl solution (40 cm^3), the ether layer was separated. The ethereal solution was washed with water, dried over $MgSO_4$, and evaporated. The residue was submitted to chromatography using hexane-ethyl acetate 1:1 as eluent to give 4.1 g (87%) of diol **16**; bp (bath temp) 190 °C/93 Pa. IR: 3300, 700 cm^{-1}. ^{1}H NMR: δ=3.3—3.8 (broad, 1H), 4.1—4.6 (broad, 1H), 4.45 (AB q, J=14.5 and 12.5 Hz, 2H), 5.95 (s, 1H), and 7.15—7.45 (m, 9H). To a solution of **16** (3.0 g) and pyridine (2.3 g) was added slowly $SOCl_2$ (3.4 g) with stirring under cooling with ice. After the addition was completed, the mixture was stirred for 1 h at room temperature and extracted with ether. The ethereal solution was worked up in the usual way. Column chromatography using benzene as eluent gave 1.75 g (50%) of dichloride **17**; bp (bath temp) 155 °C/53 Pa. IR: 3100, 3050, 1500, 1450, 1265, 695 cm^{-1}. ^{1}H NMR: δ=4.68 (AB q, J=18.5 and 12.0 Hz, 2H), 6.68 (s, 1H) and 7.20—7.70 (m, 9H). Dichloride **17** (382 mg) was added at room temperature to the stirred partially soluble NaCN (210 mg) in dimethyl sulfoxide (2 cm^3). The mixture was stirred at room temperature for 90 min, diluted with water (4.5 cm^3), and extracted with ether. The ethereal solution was worked up. Column chromatography eluted with benzene gave 305 mg (86%) of dicyanide **18**; IR: 2260, 1500, 1460, 700 cm^{-1}. ^{1}H NMR: δ=3.63 (s, 2H), 5.35 (s, 1H), and 7.25—7.90 (m, 9H). Dry hydrogen chloride was bubbled through a solution of **18** (252 mg) in ethanol (5 cm^3). The solution was heated under reflux for 50 h. The reaction mixture was cooled with ice, and the precipitated NH_4Cl was filtered off. The filtrate was concentrated. The residue was extracted with ether, and the ether extract was washed with saturated $NaHCO_3$ and water, dried over $MgSO_4$, and evaporated. The residue was submitted to chromatography using benzene as eluent to yield 153 mg (43%) of diester **12**; IR: 1730, 1150, 1030, 690 cm^{-1}. ^{1}H NMR: δ=1.15 (t, J=7.5 Hz, 3H), 1.19 (t, J=7.5 Hz, 3H), 3.56 (s, 2H), 4.03 (q, J=7.5 Hz, 2H), 4.15 (q, J=7.5 Hz, 2H), 5.32 (s, 1H), and 7.1—7.4 (m, 9H). Found: C, 73.83; H, 6.78%. Calcd for $C_{20}H_{22}O_4$: C, 73.59; H, 6.79%.

Synthetic Approach toward Antibiotic Tunicamycins. II.

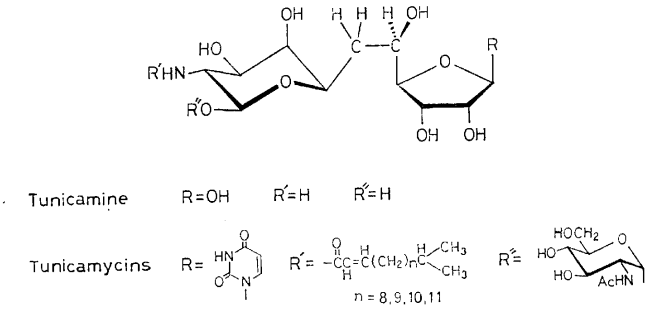
Yoshimasa FUKUDA, Hiderou KITASATO, Hiroaki SASAI, and Tetsuo SUAMI*

Department of Applied Chemistry, Faculty of Engineering, Keio University, Hiyoshi, Kohoku-ku, Yokohama 223

(Received July 16, 1981)

Some higher-carbon carbohydrates, dodecose derivatives, have been synthesized by means of the base-catalyzed addition of nitro sugar to sugar aldehyde. The addition reaction of 6,7-dideoxy-1,2:3,4-di-*O*-isopropylidene-7-nitro-α-D-*galacto*-heptopyranose to 2,3:4,5-di-*O*-isopropylidene-D-arabinose yielded three isomeric dodecose derivatives, and their configurations have been studied. The nitro dodecose derivatives were converted into the corresponding hydroxy and acetoxy derivatives.

The higher-carbon carbohydrates, such as the undecose, decose, and octose derivatives, have been found in nucleoside antibiotics, such as tunicamycins,[1,2] anthelmycin[3,4] (hikizimycin), sinefungin,[5] ezomycin,[6] and mildiomycin.[7] The tunicamycins are produced by a strain of *Streptomyces* and exhibit broad-spectrum antitumor activities. They have a unique common structure consisting of uracil, fatty acid, and an undecose derivative named tunicamine, together with *N*-acetyl-D-glucosamine[2] (Scheme 1).



Scheme 1.

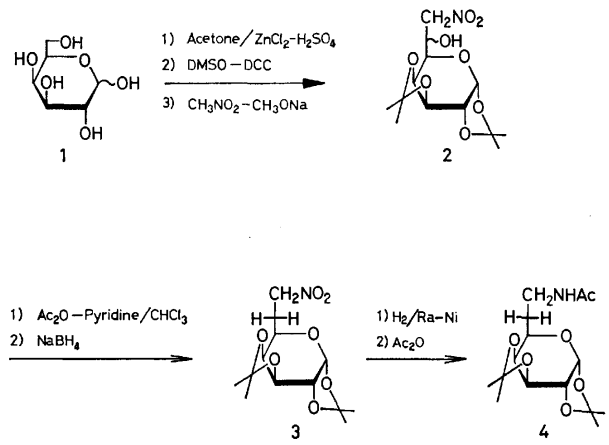
The occurrence of the higher-carbon carbohydrates in nature stimulated us to attempt to synthesize higher-carbon carbohydrates. In recent years the development of new methods of chain extension has been described in the literature.[8–14] In a previous paper of this series, we ourselves described the synthesis of 3,5-*O*-benzylidene-6,7-dideoxy-1,2:9,10:11,12-tri-*O*-isopropylidene-7-nitro-α-D-dodecofuranoses by the addition of the 7-nitro-α-D-glucofuranose derivative to 2,3:4,5-di-*O*-isopropylidene-D-arabinose (**5**).[15] Now we wish to report, as a part of a synthetic study toward tunicamycins, the addition reaction of 6,7-dideoxy-1,2:3,4-di-*O*-isopropylidene-7-nitro-α-D-*galacto*-heptopyranose (**3**) to **5**, in which three diastereoisomeric dodecose derivatives have been afforded. The conversion of the nitro group in these derivatives into an oxo or a hydroxyl group has been performed successfully.

This reaction can be used as a general procedure for the conversion of a hindered nitro group of a sugar into an oxo or a hydroxyl group.

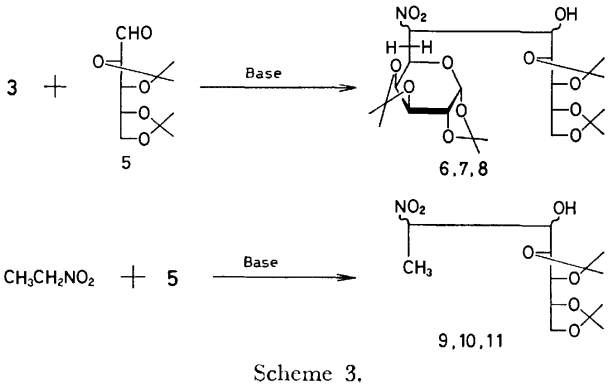
Results and Discussion

The oxidation of 1,2:3,4-di-*O*-isopropylidene-α-D-galactopyranose,[16] obtained from D-galactopyranose (**1**), by the method of Pfitzner-Moffatt oxidation[17,18] yielded the aldehyde derivative. A reaction of the intact aldehyde with nitromethane in methanol in the presence of sodium methoxide gave 7-deoxy-1,2:3,4-di-*O*-isopropylidene-7-nitro-DL-*glycero*-D-*galacto*-heptopyranose (**2**). The acetylation of **2** with acetic anhydride in chloroform–pyridine, followed by treatment with sodium borohydride, afforded 6,7-dideoxy-1,2:3,4-di-*O*-isopropylidene-7-nitro-α-D-*galacto*-heptopyranose (**3**) in a 21% yield from **1**. The catalytic hydrogenation of **3** in methanol with Raney nickel and the subsequent acetylation of the reduction product with acetic anhydride in pyridine gave 7-acetamido-6,7-dideoxy-1,2:3,4-di-*O*-isopropylidene-α-D-*galacto*-heptopyranose (**4**) in a 56% yield.

When **3** was reacted with the arabinose derivative, **5**,[19] in the presence of a base catalyst, a mixture of three diastereomers of dodecose derivatives was obtained in a 65—67% yield after chromatography. These three isomeric dodecose derivatives, **6**, **7**, and **8**, were successfully isolated after repeated chromatographic fractionations. Their structures were establish-



Scheme 2.



Scheme 3.

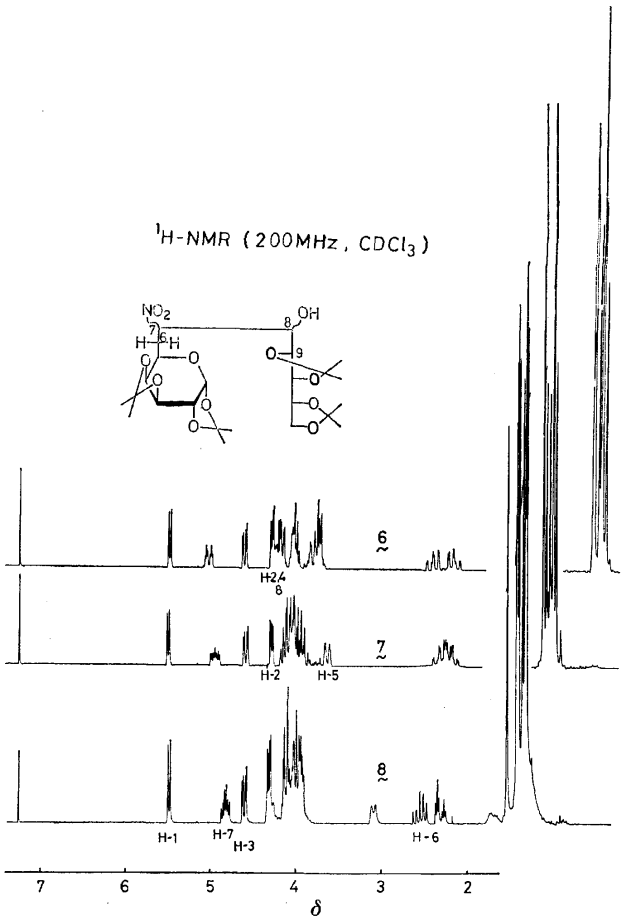


Fig. 1.

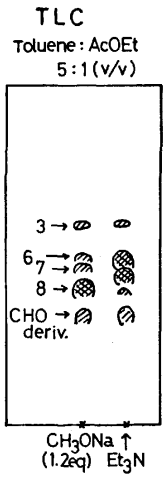
ed by means of the ^{1}H NMR, ^{13}C NMR, and IR spectra as 6,7-dideoxy-7-nitro-1,2:3,4:9,10:11,12-tetra-*O*-isopropylidene-α-D-dodecopyranoses.

Concerning the stereochemistry of the two newly introduced chiral centers on the C-7 and C-8 positions of compounds **6**, **7**, and **8**, four diastereomers (**A**)—(**D**) are theoretically possible, as is shown in Scheme 5. Their relative configurations among the C-7, C-8, and C-9 positions of **A**—**D** are *erythro-threo*, *threo-erythro*, *erythro-erythro*, and *threo-threo* respectively. In this reaction, three isomers have been obtained, but the fourth one was scarcely produced at all. As **D**, *threo-threo*, seems to be most unstable; compared to the other three diastereomers, scarcely no **D** is produced. These configurations were determined primarily on the basis of the course of the nucleophilic addition of nitronate anion to the sugar aldehyde, and secondarily on the basis of the course of the protonation of the nitronate anion, according to thermodynamic and kinetic controls.[20,21] Also **C**, *erythro-erythro*, is thermodynamically the most stable among them.

In this reaction, the ratio of the formation of three isomeric dodecose derivatives, **6**, **7**, and **8**, was markedly influenced by the amounts and kinds of catalysts used, as is shown in Table 1, but was little affected by the reaction time. That is, in the presence of a 1.2 equiv. of sodium methoxide as a base catalyst, **8** became the major product. On the other hand, in the presence of triethylamine or a 0.2 equiv.

Table 1. Isomeric ratios of nitrododecoses obtained by condensation of **3** and **5** under various base catalysts

Base	Nitrododecoses 6	7	8
$(CH_3CH_2)_3N$	7—10	: 7—11	: 1
CH_3ONa (0.1 equiv.)	4—7	: 4—8	: 1
CH_3ONa (1.2 equiv.)	0.3—0.6	: 0.3	: 1
CH_3OLi (1.2 equiv.)	0.6—0.8	: 0.7—1	: 1
CH_3OK (1.2 equiv.)	1	: 2	: 1



The reaction mixture was developed on TLC (solvent system: toluene-ethyl acetate 3:1 (v/v)) and was charred with 10% sulfuric acid. Then the ratio of dodecose isomers was estimated by by chromatoscan methods (Shimadzu CS-910).

Table 2. ^{13}C-NMR chemical shifts[a] of **6**, **7**, **8**, and **3**

C-No.	6	7	8	3
1	96.4	96.3	96.4	96.2
2	70.6	70.5	70.4	70.4
3	71.2	71.0	70.9	70.9
4	73.1	72.8	72.6	72.5
5	63.9	63.9	64.8	64.1
6	27.0	31.5	30.8	28.0
7	85.6	88.0	86.2	71.8
8	73.7	70.8	69.6	
9	80.3	77.3	77.2	
10	81.6	77.1	77.0	
11	76.1	79.8	79.0	
12	67.9	68.0	67.7	

a) Ppm downfield from internal TMS in $CDCl_3$.

of sodium methoxide, **6** and **7** were formed more readily than **8**.

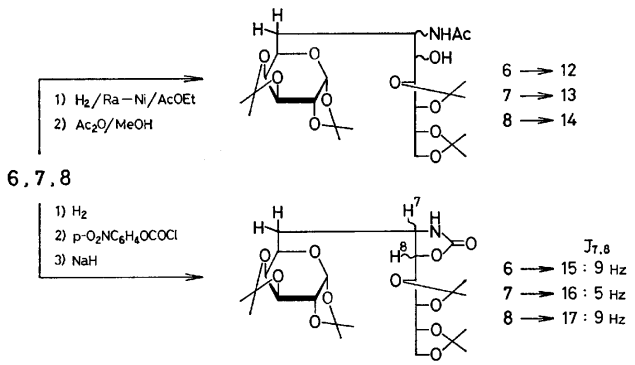
The epimerization of **7** and **8** in the presence of triethylamine occurred very slowly until the ratio of **7** and **8** reached to *ca.* 7:1, but under the same conditions the epimerization of **6** to another isomer was not observed. These results showed that the configurations of C-8 in **7** and **8** were the same but those of C-7 were different. Compounds **7** and **8** are assigned to be **B** or **C**, while **6** is designated as **A**, since scarcely no **D** is produced because of the instability.

In the ^{13}C NMR spectrum, the chemical shifts of 4 carbon signals, C-9, 10, 11, and 12, of **7** were similar to those of **8**, but they were different from those of **6** as is shown in Table 2. That is, the configurations on the C-8 of **7** and **8** seem to be same.

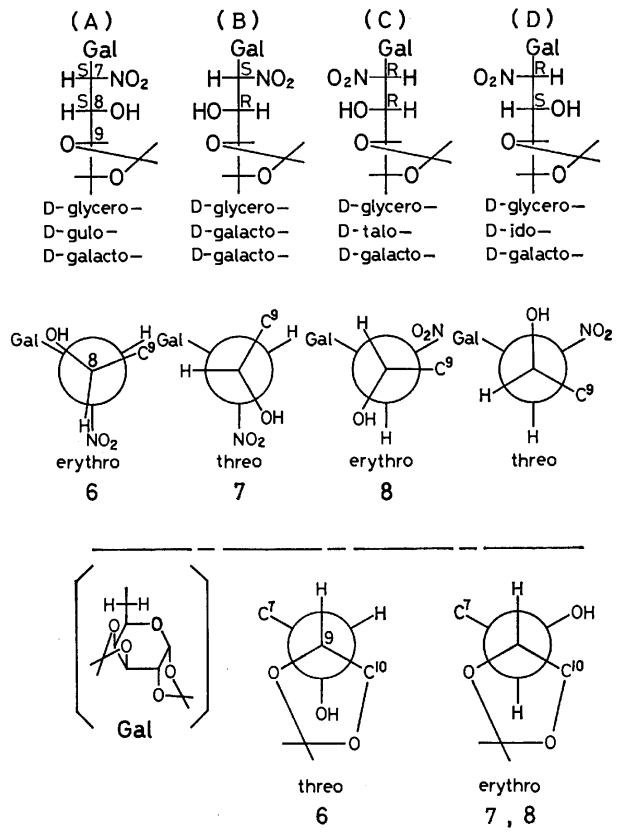
Then the configurations of the nitro dodecose derivatives were established by the conversion of the nitro groups to amino groups. The catalytic hydrogenation of each one of the nitro dodecose derivatives

in ethyl acetate in the presence of Raney nickel, followed by *N*-acetylation, afforded a corresponding acetamidodideoxy-dodecose, **12** from **6**, **13** from **7**, and **14** from **8**.

The catalytic hydrogenation of the nitro-dodecose isomers, followed by *N*-benzyloxycarbonylation and cyclic *N,O*-carbonylation, gave the corresponding 7,8-*N,O*-carbonyl derivatives; **15** from **6**, **16** from **7**, and **17** from **8**. The structures of **15**, **16**, and **17** were determined by means of ^{1}H NMR and IR spectroscopy as 7-amino-7,8-*N,O*-carbonyl-6,7-dideoxy-1,2:3,4:9,10:11,12-tetra-*O*-isopropylidene-α-D-dodecopyranoses. The ^{1}H NMR spectra showed that the coupling constants of H-7 and H-8 of **15** and **17** were 9 Hz, while that of **16** was 5 Hz. These results suggested that the oxazolidinones of **15** and **17** had *vicinal cis* protons and that the 5 Hz coupling of **16** was due to the *trans* protons.[22,23]



Scheme 4.



Scheme 5.

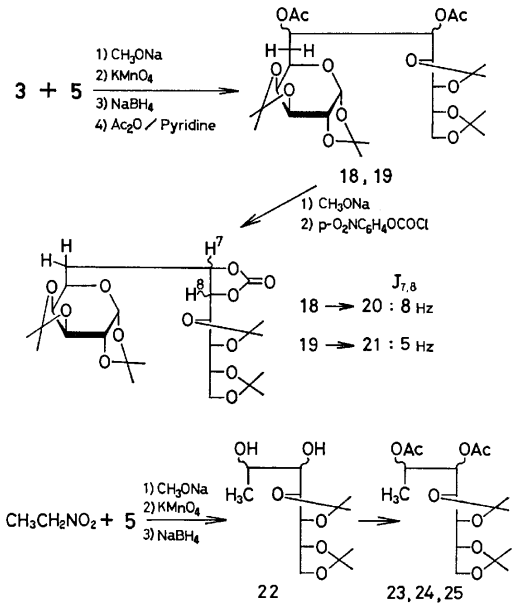
Considering the above-mentioned results, the configurations of **6**, **7**, and **8** were tentatively assigned as D-*glycero*-D-*gulo*-D-*galacto*-, **A**, D-*glycero*-D-*galacto*-D-*galacto*-, **B**, and D-*glycero*-D-*talo*-D-*galacto*-dodecose, **C**, respectively (Scheme 5).

The analogous addition reaction between the aldehyde **5** and nitroethane, instead of the D-galactose derivative, **3**, has been carried out as a simple model reaction. The reaction yielded a mixture of all theoretically predictable diastereomers in a 74% yield from **5**. Three of the four diastereomers (**9**, **10**, and **11**) have been isolated by column chromatography. Their structures have been identified as 1,2-dideoxy-4,5:6,7-di-*O*-isopropylidene-2-nitro-D-heptitols by means of ^{1}H NMR and IR spectroscopy. The ratio among the four isomers was not affected by the kind or amount of the catalyst in this model reaction.

The most notable difference between the two above-mentioned addition reactions between **5** and **3** and between **5** and nitroethane was the absence of one of the four diastereomers in the former reaction; this may be due to the existence of the bulky D-galactosyl group.

Then, the conversion of the nitro groups of **6**, **7**, and **8** into hydroxyl groups was attempted under mild conditions where the cleavage of a protective group does not occur. Since the Nef reaction[24,25] and the titanium trichloride method[26,27] are rather drastic, though these reactions have been used widely to convert a nitro group to an oxo group, an oxidative denitration with permanganate[28-31] has been employed in the present experiment.

The oxidation of the intact mixture of the nitro-dodecoses, **6**, **7**, and **8**, with potassium permanganate in water, followed by reduction with sodium borohydride and acetylation with acetic anhydride, afforded a mixture of three 7,8-di-*O*-acetyl derivatives, from which two diastereomers, **18** and **19**, were isolated by column chromatography. The ^{1}H NMR of **18** and **19** showed two acetyl metyl signals each at δ 2.07



Scheme 6.

and 2.11 for **18**, and at δ 2.04 and 2.16 for **19**.

The deacetylation of **18** and **19** in methanolic sodium methoxide, followed by the cyclic carbonylation of the *vicinal* hydroxyl groups on C-7 and C-8, gave the corresponding 7,8-*O*-carbonyl derivatives, **20** and **21** respectively. In the ^{1}H NMR spectra of **20** and **21**, H-7 was observed as a doublet at δ 4.82 with $J_{7,8}$= 8 Hz on **20** and as a double-doublet at δ 4.49 with $J_{7,8}$=5 Hz on **21**.

The analogous reaction processes were carried out with an addition compound between the aldehyde, **5**, and nitroethane. The reactions gave three of the four theoretically predictable diastereomers after column chromatography. Their structures were established by ^{1}H NMR as 1-deoxy-2,3-di-*O*-acetyl-4,5:6,7-di-*O*-isopropylidene-D-heptitols, **23**, **24**, and **25**.

It has been demonstrated by the present study that a higher-carbon carbohydrate, dodecose, is prepared by the base-catalyzed addition of a nitro sugar to a sugar aldehyde, and that a hindered nitro sugar is converted to the corresponding keto or hydroxy derivative.

Experimental

General Methods. The melting points were taken in capillary tubes in a liquid bath and are uncorrected. The solutions were concentrated under reduced pressure below 50 °C. The IR spectra were measured with a Hitachi 225 spectrophotometer and are expressed in reciprocal centimeters. The ^{1}H NMR spectra were obtained on a Varian EM-390 (90 MHz) and a JEOL FX-200 (200 MHz) spectrometer. The chemical shifts are reported as δ values in parts per million, relative to tetramethylsilane as the internal standard. The TLC was performed on precoated silica gel 60 F-254 plaques (Merck, Darmstadt; Art. 5715, 0.25 mm thickness). The silica-gel column used for chromatography utilized Wako gel C-200 (Wako Pure Chemical Industries, Ltd.).

*7-Deoxy-1,2:3,4-di-O-isopropylidene-7-nitro-*DL*-glycero-*D*-galacto-heptopyranose (**2**) and 6,7-Dideoxy-7-nitro-1,2:3,4-di-O-isopropylidene-α-*D*-galacto-heptopyranose (**3**).* Nitromethane (228 ml) and 1 M† methanolic sodium methoxide (232 ml) were added to a solution of crude 1,2:3,4-di-*O*-isopropylidene-α-D-*galacto*-dialdopyranose-(1,5)[16] in methanol (400 ml), obtained from D-galactose (**1**) (50.0 g), under ice cooling with agitation. After 1 h at the ambient temperature, the solution was neutralized with Amberlite IR-120B(H$^+$) resin, and the resin was filtered off. The filtrate was concentrated to give an oily residue which contained **2** as the main product. A part (1/20) of the residue was purified on a silica-gel column using 7:1 (v/v) toluene–ethyl acetate to give 1.52 g (34%) of a homogeneous oily product of **2**: $[\alpha]_D^{20}$ −51.4° (*c* 0.3, methanol); IR (neat): 3450 (OH), 1550, 1390, 1380 cm^{-1} (NO_2); ^{1}H NMR ($CDCl_3$) δ 5.53 (1H, d, J=5 Hz, H-1), 1.37—1.53 (12H, isopropylidene CH_3). Found: C, 48.60; H, 6.59; N, 4.12%. Calcd for $C_{13}H_{21}NO_8$: C, 48.90; H, 6.63; N, 4.39%.

To a solution of the crude **2** in chloroform (500 ml), was added acetic anhydride (102 ml) and pyridine (68 ml) under ice cooling. After 6 h at the ambient temperature, the solution was washed with water, a saturated sodium hydrogencarbonate solution, and water, and concentrated under reduced pressure at 30 °C. To a solution of the residue in ethanol (600 ml), was added sodium borohydride (24 g) under ice cooling. After 1 h, the solution was neutralized with Amberlite IR-120B(H$^+$) resin, and the resin was filtered off. The filtrate was concentrated, and the residue was purified on a silica-gel column, using 30:1 (v/v) toluene–ethyl acetate, to give 17.0 g (21% yield from **1**) of **3** as a syrup: $[\alpha]_D^{18}$ −35.6° (*c* 3.4, chloroform); IR (neat) 1560, 1380 cm^{-1} (NO_2); ^{1}H NMR ($CDCl_3$) δ 5.35 (1H, d, $J_{1,2}$= 5 Hz, H-1), 1.25—1.75 (12H, isopropylidene CH_3). Found: C, 51.66; H, 6.87; N, 4.54%. Calcd for $C_{13}H_{21}NO_7$: C, 51.48; H, 6.98; N, 4.62%.

*7-Acetamido-6,7-dideoxy-1,2:3,4-di-*O*-isopropylidene-α-*D*-galacto-heptopyranose (**4**).* A solution of **3** (368 mg) in methanol (5 ml) was hydrogenated in the presence of Raney nickel in a hydrogen atmosphere (2.7 kg/cm^2) for 19 h. After the catalyst had then been filtered off, acetic anhydride (0.5 ml) was added to the filtrate. After 3 h, the product was purified on a silica-gel column, using 1:1 (v/v) chloroform–ethyl acetate as the eluent. Fractions corresponding to R_f 0.16 on the TLC in the same solvent were collected and concentrated. The residue was recrystallized from cyclohexane to give 214 mg (56%) of **4**: mp 98—99 °C; $[\alpha]_D^{23}$ −40° (*c* 1.5, methanol); ^{1}H NMR ($CDCl_3$) δ 5.50 (1H, d, $J_{1,2}$=5 Hz, H-1), 4.53 (1H, dd, $J_{2,3}$=2 Hz, $J_{3,4}$=7.5 Hz, H-3), 4.26 (1H, dd, $J_{1,2}$=5 Hz, $J_{2,3}$=2 Hz, H-2), 4.07 (1H, dd, $J_{3,4}$=7.5 Hz, $J_{4,5}$=1.5 Hz, H-4), 3.80 (1H, dt, $J_{4,5}$=1.5 Hz, $J_{5,6}$=6 Hz, H-5), 3.37 (2H, q, J=6 Hz, H-7), 2.93 (3H, s, NHAc), 1.80 (2H, q, J=6 Hz, H-6), 1.50, 1.76, 1.66 (3H×2 and 6H, s×3, isopropylidene CH_3). Found: C, 56.84; H, 7.81; N, 4.36%. Calcd for $C_{15}H_{25}NO_6$: C, 57.13; H, 7.99; N, 4.44%.

*6,7-Dideoxy-7-nitro-1,2:3,4:9,10:11,12-tetra-*O*-isopropylidene-α-*D*-dodecopyranoses (**6**, **7**, and **8**).* *a)*: 1 M Methanolic sodium methoxide (9 ml) was added to a solution of **3** (1.76 g) and **5** (2.01 g) in methanol (17 ml) at the ambient temperature. After 18 h, the solution was neutralized with Amberlite IR-120B(H$^+$) resin under ice cooling, and the resin was filtered off. The filtrate was concentrated, and the residue was chromatographed on a silica-gel column two times. (C-200, 90 g, 10:1 (v/v) toluene–ethyl acetate, wet column), (1:1 (wt/wt) C-200:C-300, 50 g, 6:1 (v/v) toluene–ethyl acetate, dry column). The fractions were combined and concentrated to give 183 mg (6%) of only **6**, 625 mg (20%) of a mixture of **6** and **7**, 443 mg (14%) of **7**, 500 mg (16%) of **7** and **8**, and 329 mg (11%) of only **8** (total yield 2.08 g (67%)); **6**; R_f=0.49 (3:1 (v/v) toluene–ethyl acetate); mp 161—162 °C; $[\alpha]_D^{23}$ −32° (*c* 0.5, methanol); IR ($CHCl_3$ solution) 3540, 3440 (OH), 1550, 1390, 1380 cm^{-1} (NO_2); ^{1}H NMR ($CDCl_3$) δ 5.48 (1H, d, $J_{1,2}$=5 Hz, H-1), 4.29 (1H, dd, $J_{2,3}$=2.5 Hz, H-2), 4.61 (1H, dd, $J_{3,4}$=8 Hz, H-3), 2.40 (1H, m, $J_{5,6}$=2 Hz, $J_{6,6}$=15 Hz, $J_{6,7}$=11.5 Hz, H-6), 2.16 (1H, m, $J_{5,6}$=11 Hz, $J_{6,6}$=15 Hz, $J_{6,7}$=2 Hz, H-6), 5.03 (1H, m, $J_{7,8}$= 3 Hz, H-7). Found: C, 54.27; H, 7.22; N, 2.43%. Calcd for $C_{24}H_{39}NO_{12}$: C, 54.03; H, 7.37; N, 2.63%.

7; R_f=0.45 (3:1 (v/v) toluene–ethyl acetate); mp 121—122 °C; $[\alpha]_D^{23}$ −30° (*c* 0.8, methanol); IR ($CHCl_3$ solution) 3510 (OH), 1555, 1390, 1380 cm^{-1} (NO_2); ^{1}H NMR ($CDCl_3$) δ 5.49 (1H, d, $J_{1,2}$=5 Hz, H-1), 4.28 (1H, dd, $J_{2,3}$=2.5 Hz, H-2), 4.58 (1H, dd, $J_{3,4}$=8 Hz, H-3), 2.24 (2H, m, H-6), 4.95 (1H, m, $J_{7,8}$=7 Hz, H-7). Found: C, 54.22; H, 7.26; N, 2.81%.

8; R_f=0.37 (3:1 (v/v) toluene–ethyl acetate); mp 125—127 °C; $[\alpha]_D^{23}$ −27° (*c* 1.0, methanol); IR ($CHCl_3$ solution) 3410 (OH), 1550, 1390, 1380 cm^{-1} (NO_2); ^{1}H NMR ($CDCl_3$) δ 5.48 (1H, d, $J_{1,2}$=5 Hz, H-1), 4.31 (1H, dd,

† 1 M=1 mol dm^{-3}.

$J_{2,3}$=2.5 Hz, H-2), 4.60 (1H, dd, $J_{3,4}$=8 Hz, H-3), 2.55 (1H, m, $J_{5,6}$=7 Hz, $J_{6,6}$=15 Hz, $J_{6,7}$=7.5 Hz, H-6), 2.30 (1H, m, $J_{5,6}$=4 Hz, $J_{6,6}$=15 Hz, $J_{6,7}$=4 Hz, H-6), 4.82 (1H, m, $J_{7,8}$=7 Hz, H-7). Found: C, 50.85; H, 7.37; N, 4.70%.

b): Triethylamine (0.75 ml) was added to a solution of **3** (426 mg) and **5** (393 mg) in methanol (7 ml) at the ambient temperature. After 4 days, the solution was concentrated at 30 °C under reduced pressure. The residue was chromatographed on a silica-gel column two times, (C-200, 50 g, 10:1 (v/v) toluene–ethyl acetate), (C-200, 20 g, 5:1 (v/v) toluene–ethyl acetate), to give 164 mg (22%) of only **6**, 62 mg (8%) of a mixture of **6** and **7**, 198 mg (26%) of **7**, 49 mg (7%) of **7** and **8**, and 17 mg (2%) of **8** (total yield, 490 mg (65%).

*1,2-Dideoxy-2-nitro-4,5:6,7-di-*O*-isopropylidene-*D*-heptitols (**9**, **10**, and **11**).* Triethylamine (0.67 ml) was added to a solution of **5** (895 mg) and nitroethane (1.68 ml) in methanol (9 ml). After 2 days, the reaction mixture was concentrated to dryness under reduced pressure at 30 °C. The oily residue was purified on a silica-gel column, using 10:1 (v/v) toluene–ethyl acetate (C-200, 33 g, C-300 10 g), to give a mixture of four isomers (800.3 mg, 69% from **5**) as crystals. The chromatography of the mixture was repeated several times to give homogeneous compounds of the three isomers, **9**, **10**, and **11**: **9**; R_f=0.42 (5:1 (v/v) toluene–ethyl acetate); mp 111—113 °C; $[\alpha]_D^{23}$ +8.55° (*c* 1.0, methanol); IR (CCl_4 solution) 3420 (OH), 1560, 1390, 1380 cm^{-1} (NO_2); ^1H NMR ($CDCl_3$) δ 1.78 (3H, d, $J_{1,2}$=6.5 Hz, CH_3), 1.34—1.44 (12H, isopropylidene CH_3). Found: C, 51.36; H, 7.41; N, 4.65%. Calcd for $C_{11}H_{17}NO_7$: C, 51.13; H, 7.59; N, 4.59%.

10; R_f=0.36 (5:1 (v/v) toluene–ethyl acetate); mp 96—98 °C; $[\alpha]_D^{23}$ +31.0° (*c* 1.4, methanol); IR (CCl_4 solution) 3420 (OH), 1560, 1390, 1380 cm^{-1} (NO_2); ^1H NMR ($CDCl_3$) δ 1.64 (3H, d, $J_{1,2}$=6.5 Hz, CH_3), 1.33—1.44 (12H, isopropylidene CH_3). Found: C, 51.36; H, 7.52; N, 4.64%.

11; R_f=0.31 (5:1 (v/v) toluene–ethyl acetate); mp 95—96 °C; $[\alpha]_D^{32}$ +12.7° (*c* 0.9, methanol); IR (CCl_4 solution) 3550 (OH), 1560, 1390, 1380 cm^{-1} (NO_2); ^1H NMR ($CDCl_3$) δ 1.60 (3H, d, $J_{1,2}$=6.5 Hz, CH_3), 1.33—1.44 (12H, isopropylidene CH_3). Found: C, 50.85; H, 7.37; N, 4.70%.

*7-Acetamido-6,7-dideoxy-1,2:3,4:9,10:11,12-tetra-*O*-isopropylidene-α-D-dodecopyranoses (**12**, **13**, and **14**).* One of three compounds, **10**, **11** and **12** (50 mg), was hydrogenated in ethyl acetate (6 ml) with a Raney nickel catalyst in a hydrogen atmosphere (2.7 kg/cm²) for 18 h. The catalyst was then filtered off, and the filtrate was concentrated. The residue was acetylated with acetic anhydride (0.5 ml) in methanol (4 ml) for 4 h. The reaction mixture was then concentrated, and the residue was purified on a silica-gel column, using 1:3 (v/v) toluene–ethyl acetate, to give a 7-acetamido-dodecose derivative: **12**; 68% yield from **6**; R_f=0.12 (1:2 (v/v) toluene–ethyl acetate); mp 178—179 °C; $[\alpha]_D^{28}$ −13.5° (*c* 0.4, methanol); ^1H NMR ($CDCl_3$) δ 5.46 (1H, d, J=5 Hz, H-1), 1.93 (3H, s, NHAc). Found: C, 56.98; H, 7.77; N, 2.52%. Calcd for $C_{26}H_{43}NO_{11}$: C, 57.23; H, 7.94; N, 2.57%.

13; 61% yield from **7**; R_f=0.25 (1:2 (v/v) toluene–ethyl acetate); mp 162—163 °C; $[\alpha]_D^{23}$ −25° (*c* 0.35, methanol); ^1H NMR ($CDCl_3$) δ 5.50 (1H, d, J=5 Hz, H-1), 1.97 (3H, s, NHAc). Found: C, 57.22; H, 7.78; N, 2.56%.

14; 56% yield from **8**; R_f=0.15 (1:2 (v/v) toluene–ethyl acetate); mp 62—63.5 °C (amorphous solid); $[\alpha]_D^{23}$ −30° (*c* 0.7, methanol); ^1H NMR ($CDCl_3$) δ 5.43 (1H, d, J=5 Hz, H-1), 1.97 (3H, s, NHAc). Found: C, 57.31; H, 7.81; N, 2.41%.

*7-Amino-7,8-*N,O*-carbonyl-6,7-dideoxy-1,2:3,4:9,10:11,12-tetra-*O*-isopropylidene-α-D-dodecopyranoses (**15**, **16**, and **17**).* A solution of a 7-nitro-dodecose, **6**, **7**, or **8** (40 mg), in ethyl acetate (5 ml) was hydrogenated analogously to the preparation of **12**, **13**, and **14**, and subsequently reacted with *p*-nitrophenoxycarbonyl chloride (56 mg) in pyridine (2 ml) for 1 d. The reaction mixture, diluted with ethyl acetate (20 ml), was then washed with water, saturated $NaHCO_3$, and water. The ethyl acetate solution was co-evaporated with toluene to give an oily residue, which was subsequently allowed to react with sodium hydride 60% in oil (5 mg) in dioxane (10 ml) to afford a carbamate derivative, **15**, **16**, or **17**, after short silica-gel column chromatography.

15; 59% yield from **7**; R_f=0.35 (1:1 (v/v) toluene–ethyl acetate); mp 48—49.5 °C (amorphous solid); IR ($CHCl_3$ solution) 3400 (NH), 1760 cm^{-1} (C=O); ^1H NMR ($CDCl_3$) δ 5.52 (1H, d, $J_{1,2}$=5 Hz, H-1), 4.59 (1H, dd, $J_{2,3}$=2 Hz, $J_{3,4}$=6 Hz, H-3), 4.53 (1H, dd, $J_{7,8}$=9 Hz, $J_{8,9}$=7.5 Hz H-8), 4.31 (1H, dd, $J_{1,2}$=5 Hz, $J_{2,3}$=2 Hz, H-2). Found: C, 56.55; H, 7.37; N, 2.49%. Calcd for $C_{25}H_{38}NO_{11}$: C, 56.81; H, 7.25; N, 2.65%.

16; 41% yield from **8**; R_f=0.37 (1:1 (v/v) toluene–ethyl acetate); mp 67—69° (amorphous solid); IR ($CHCl_3$ solution) 3460 (NH), 1760 cm^{-1} (C=O); ^1H NMR ($CDCl_3$) δ 5.46 (1H, d, $J_{1,2}$=5 Hz, H-1), 4.57 (1H, dd, $J_{2,3}$=2 Hz, $J_{3,4}$=5.5 Hz, H-3), 4.34 (1H, d, $J_{7,8}$=5 Hz, H-8), 4.28 (1H, dd, $J_{1,2}$=5 Hz, $J_{2,3}$=2 Hz, H-2). Found: C, 57.04; H, 7.39; N, 2.67%.

17; 37% yield from **9**; R_f=0.33 (1:1 (v/v) toluene–ethyl acetate); mp 196—197 °C (crystallized from ethyl acetate–hexane); IR (KBr) 3380 (NH), 1755 cm^{-1} (C=O); ^1H NMR ($CDCl_3$) δ 5.50 (1H, d, $J_{1,2}$=5 Hz, H-1), 4.72 (1H, d, $J_{7,8}$= 9 Hz, H-8), 4.60 (1H, dd, $J_{2,3}$=2 Hz, $J_{3,4}$=7.5 Hz, H-3), 4.32 (1H, dd, $J_{1,2}$=5 Hz, $J_{2,3}$=2 Hz, H-2). Found: C, 56.50; H, 7.28; N, 2.59%.

*7,8-Di-*O*-acetyl-6-deoxy-1,2:3,4:9,10:11,12-tetra-*O*-isopropylidene-α-D-dodecopyranoses (**18** and **19**).* To a solution of **3** (842 mg) and **5** (2.09 g) in methanol (30 ml) was added 1 M methanolic sodium methoxide (3 ml). After 18 h at the ambient temperature, the reaction mixture was poured into ice cold water (250 ml). To the solution was then added a solution of magnesium sulfate (722 mg) in water (18 ml); subsequently, a solution of potassium permanganate (553 mg) in water (430 ml) was stirred, drop by drop, into the mixture under ice cooling. After 1 h at the ambient temperature, acetic acid (1 ml) and chloroform (100 ml) were added to the reaction mixture and the inorganic precipitate was removed by filtration. The chloroform layer was separated, and the aqueous layer was extracted with chloroform (100 ml × 3). The organic layers were combined and concentrated. The residue was dissolved in ethanol (100 ml), and sodium borohydride (150 mg) was added to the solution under ice cooling. After 1 h, the mixture was concentrated under reduced pressure. The residue was dissolved in ethyl acetate (120 ml). The solution was washed with brine and water, and concentrated. The oily residue was purified on a silica-gel column, using 3:1 (v/v) toluene–ethyl acetate (C-200 50 g), and acetylated with pyridine (20 ml) and acetic anhydride (8 ml) for 2 d. The reaction mixture was then concentrated to dryness. The residue was purified on a silica-gel column, using 6:1 (v/v) toluene–ethyl acetate (C-200, 40 g), to give a mixture of isomers of diacetyl-dodecoses (492.4 mg, 30% from **3**). The mixture was chromatographed several times as has been described above to separate **18** and **19** as homogeneous compounds. However, another one, corresponding to R_f 0.51 on TLC using 3:1 (v/v) toluene–ethyl acetate, could not

be isolated.

18; R_f=0.52 (3:1 (v/v) toluene–ethyl acetate); mp 48—50 °C; $[\alpha]_D^{20}$ −24.0° (*c* 2.1, methanol); ^{1}H NMR ($CDCl_3$) δ 5.49 (1H, d, $J_{1,2}$=5 Hz, H-1), 4.27 (1H, dd, $J_{2,3}$=2 Hz, H-2), 4.57 (1H, dd, $J_{2,3}$=8 Hz, H-3), 5.26 (1H, dd, $J_{7,8}$=3.5 Hz, $J_{8,9}$=7 Hz, H-8), 2.11 (3H×2, s×2, Ac). Found: C, 57.30; H, 7.51%. Calcd for $C_{28}H_{44}O_{13}$; C, 57.13; H, 7.53%.

19; R_f=0.46 (3:1 (v/v) toluene–ethyl acetate); mp 98—99 °C; $[\alpha]_D^{20}$ −10.5° (*c* 0.8, methanol); ^{1}H NMR ($CDCl_3$) δ 5.51 (1H, d, $J_{1,2}$=5 Hz, H-1), 4.28 (1H, dd, $J_{2,3}$=2 Hz, H-2), 4.57 (1H, dd, $J_{3,4}$=8 Hz, H-3), 5.25 (1H, dd, $J_{7,8}$=4.5 Hz, $J_{8,9}$=2 Hz, H-8), 2.04, 2.16 (3H×2, s×2, Ac). Found: C, 56.90; H, 7.32%.

*7,8-O-Carbonyl-6-deoxy-1,2:3,4:9,10:11,12-O-isopropylidene-α-D-dodecopyranoses (**20** and **21**).* 1 M methanolic sodium methoxide (1 ml) was added to a solution of an acetyl derivative, **18** or **19** (40 mg), in methanol (5 ml). After 3 h at the ambient temperature the solution was neutralized with Amberlite IR-120B (H^+) resin; the resin was then filtrated off, and the filtrate was concentrated. The residue was reacted with *p*-nitrophenoxycarbonyl chloride (50 mg) in pyridine (3 ml) for 20 h at the ambient temperature. The reaction mixture, diluted with ethyl acetate (20 ml), was washed with water, brine, and water. The solution was then concentrated to give an oily residue, which was purified on a short silica-gel column to give **20** or **21** as a crystal, **20**; 63% from **18**; R_f=0.42 (3:1 (v/v) toluene–ethyl acetate); mp 136—137 °C; IR ($CHCl_3$ solution) 1800 cm^{-1} (C=O); ^{1}H NMR ($CDCl_3$) δ 5.51 (1H, d, $J_{1,2}$=5 Hz, H-1), 4.33 (1H, dd, $J_{2,3}$=2 Hz, H-2), 4.64 (1H, dd, $J_{3,4}$=8 Hz, H-3), 4.94 (1H, m, $J_{7,8}$=8 Hz, H-7), 4.82 (1H, d, $J_{7,8}$=8 Hz, H-8). Found: C, 56.50; H, 7.05%. Calcd for $C_{25}H_{38}O_{12}$: C, 56.60; H, 7.22%.

21; 70% from **19**; R_f=0.44 (3:1 (v/v) toluene–ethyl acetate); mp 159.5—161 °C; IR ($CHCl_3$ solution) 1795 cm^{-1} (C=O); ^{1}H NMR ($CDCl_3$) δ 5.47 (1H, d, $J_{1,2}$=5 Hz, H-1), 4.30 (1H, dd, $J_{2,3}$=2 Hz, H-2), 4.62 (1H, dd, $J_{3,4}$=8 Hz, H-3), 4.88 (1H, m, $J_{7,8}$=5 Hz, H-7), 4.49 (1H, dd, $J_{7,8}$=5 Hz, H-8). Found: C, 56.43; H, 7.03%.

*1-Deoxy-4,5:6,7-di-O-isopropylidene-D-heptitol (**22**) and 2,3-Di-O-acetyl-1-deoxy-4,5:6,7-di-O-isopropylidene-D-heptitols (**23**, **24**, and **25**).* To a solution of **5** (3.30 g) and nitroethane (2.30 ml) in methanol (23 ml), was added 1 M methanolic sodium methoxide (14 ml) under ice cooling. After 3 h at the ambient temperature, the mixture was poured into ice cold water (400 ml) containing sodium hydroxide (6.4 g), and then we added to the solution a solution of magnesium sulfate (3.4 g) in water (70 ml). The mixture was subsequently cooled in an ice–water bath, and potassium permanganate (4.5 g) in water (250 ml) was slowly stirred in. After 2 h, acetic acid (4 ml) and chloroform (100 ml) were added to the mixture, and the inorganic precipitate was removed by filtration. The chloroform layer was separated, and the aqueous layer was extracted with chloroform (250 ml×2). The organic phases were combined and concentrated. To a solution of the residue dissolved in ethanol (150 ml) was added sodium borohydride (1.04 g) under ice cooling. After 2 h, the mixture was evaporated. The residue was dissolved in chloroform (200 ml), and the solution was washed with brine and water, and concentrated. The oily residue was purified on a silica-gel column, using 7:1 (v/v) toluene–ethyl acetate (C-200, 100 g), to give a single isomer, **22**, R_f=0.2 (3:1 (v/v) toluene–ethyl acetate), of a diol derivative (476 mg) and a mixture of two other isomers (827 mg) which could not be separated. (Total yield, 1.3 g, 33.5% from **5**) **22**; recrystallization from cyclohexane–hexane; mp 91—92 °C; $[\alpha]_D^{25}$ +23.5° (*c* 1.0, chloroform); ^{1}H NMR ($CDCl_3$) δ 1.20 (3H, d, $J_{1,2}$=6 Hz, CH_3), 1.40, 1.50 (9H and 3H, s×2, isopropylidene CH_3). Found: C, 56.86; H, 8.30%. Calcd for $C_{13}H_{22}O_6$: C, 56.92; H, 8.09%.

22 (123 mg) was acetylated with acetic anhydride (0.23 ml) and pyridine (0.77 ml) for 18 h. The reaction mixture, diluted with chloroform (30 ml), was then washed with water, a saturated sodium hydrogencarbonate solution, and water, and concentrated to give a syrupy residue. The residue was purified on a silica-gel column, using 7:1 (v/v) toluene–ethyl acetate (C-200, 4 g and C-300, 1 g), to give a homogeneous oily product, **23** (96 mg, 60%); R_f=0.34 (5:1 (v/v) toluene–ethyl acetate); $[\alpha]_D^{20}$ +11.0° (*c* 1.3, methanol); ^{1}H NMR ($CDCl_3$) δ 1.25 (3H, d, $J_{1,2}$=6 Hz, CH_3), 1.35—1.42 (12H, isopropylidene CH_3), 2.04, 2.16 (3H×2, s×2, Ac). Found: C, 56.54; H, 7.77%. Calcd for $C_{17}H_{28}O_8$: C, 56.65; H, 7.83%.

The mixture of the two isomers was acetylated analogously to the method described above to a mixture of the two isomers of **24** and **25** (872 mg, 80.5%). The mixture was chromatographed several times to give two homogeneous products, **24** and **25**; **24**; R_f=0.35 (5:1 (v/v) toluene–ethyl acetate); $[\alpha]_D^{25}$ +29.1° (*c* 0.6, methanol); ^{1}H NMR ($CDCl_3$); δ 1.30 (3H, d, $J_{1,2}$=6.5 Hz, CH_3), 2.00, 2.10 (3H×2, s×2, Ac). Found: C, 56.37; H, 7.64%. Calcd for $C_{17}H_{28}O_8$: C, 56.65; H, 7.83%.

25; R_f=0.31 (5:1 (v/v) toluene–ethyl acetate); $[\alpha]_D^{20}$ +27.5° (*c* 0.2, methanol); ^{1}H NMR ($CDCl_3$); δ 1.30 (3H, d, $J_{1,2}$=6.5 Hz, CH_3), 2.05, 2.10 (3H×2, s×2, Ac). Found: C, 57.06; H, 7.86%.

The authors wish to thank Professor Gakuzo Tamura, Tokyo University, for his helpful suggestions. They also wish to express their appreciation to Shiseido, Ltd., and the Pharmaceutical Development Laboratories, Meiji Seika Kaisha, Ltd., for the NMR spectral data; to Mr. Saburo Nakada for the elemental analyses, and to Mr. Masazumi Kameda for the IR spectral data.

Functionalization of *trans*-Decalin. V. A Synthesis of (±)-Nootkatone and (±)-Valencene from 4β,4aβ-Dimethyl-$\Delta^{6,7}$-octalin-1-one Ethylene Acetal

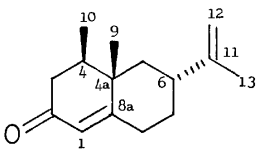
Sigeru Torii,* Tsutomu Inokuchi, and Ko Handa

Department of Industrial Chemistry, School of Engineering, Okayama University, Okayama 700

(Received July 17, 1981)

A synthesis of (±)-nootkatone (**1**) and (±)-valencene (**18**) starting from 4β,4aβ-dimethyl-$\Delta^{6,7}$-octalin-1-one ethylene acetal (**2**) is described. Epoxidation of the double bond of **2** followed by regiospecific reduction of the oxirane ring at the C-6 position gave the corresponding C-7 alcohol **4**. Oxidation of **4** and subsequent methoxycarbonylation at the C-6 position afforded methyl 1,1-ethylenedioxy-4β,4aβ-dimethyl-7-oxodecalin-6-carboxylate (**6**) in good yield. The keto ester **6** was converted to methyl 1,1-ethylenedioxy-4β,4aβ-dimethyldecalin-6α-carboxylate (**10b**) by the reduction with $NaBH_4$ followed by dehydration and subsequent hydrogenation over PtO_2 and epimerization of the 6β-methoxycarbonyl group with MeONa in MeOH. Deacetalization of **10b** followed by reduction and dehydration afforded methyl 4β,4aβ-dimethyl-$\Delta^{1(8a)}$-octalin-6α-carboxylate (**15**). The conversion of **15** into (±)-**18** was carried out directly by the reaction with salt-free methylenetriphenylphosphorane in refluxing tetrahydrofuran (76%) or by hydrolysis of **15** followed by methylation with MeLi, and subsequent Wittig reaction (60%). The allylic oxidation of (±)-**18** with $CrO_3 \cdot (pyridine)_2$ complex gave the desired (±)-**1**, smoothly.

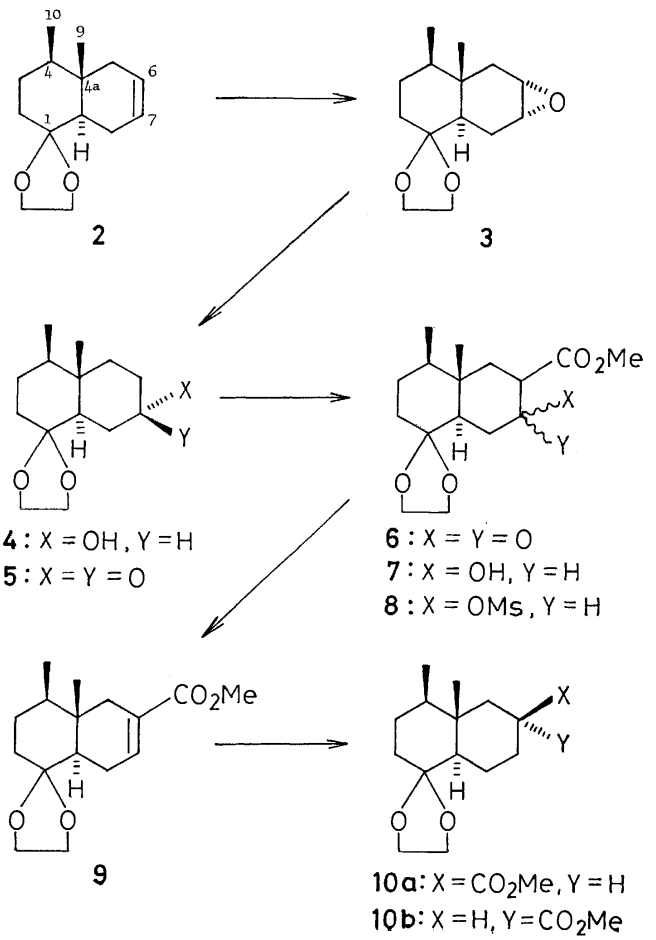
The stereoselective introduction of 4β,4aβ-dimethyl groups of valencene (**18**) is an essential strategy for the nootkatone synthesis.[1] Most of Robinson-type annelation procedures[1f-h,j] for the preparation of (±)-nootkatone (**1**) except for cyclopentenone annulation by Nazarov-type reaction[1k] lack the stereoselectivity on introducing the 4β,4aβ-dimethyl groups in the $\Delta^{1(8a)}$-octalin skeleton. However, an exquisite procedure for the stereoselective synthesis of **1** has been devised by employing a Diels-Alder type reaction.[11] In connection with preparative investigations of eremophilane-type sesquiterpenes,[2] we have also developed the stereo-controlled construction of *trans*-4β,4aβ-dimethyl-$\Delta^{6,7}$-octalin-1-one ethylene acetal (**2**) by Diels-Alder reaction of 4-methyl-3-methoxycarbonyl-2-cyclohexen-1-one with butadiene.[2b] The present work is concerned with the stereoselective synthesis of the flavoring sesquiterpenes **1** and **18**[3] from the adduct **2**.



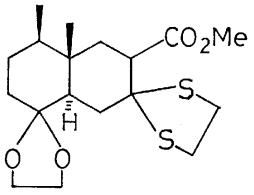
1

The strategy of leading **2** to the targets **1** and **18** involves the introduction of a methoxycarbonyl group at the C-6 carbon of **2**. Epoxidation of **2** with *m*-chloroperbenzoic acid at −60—10 °C gave the corresponding 6α,7α-epoxide **3** in 97% yield. The following reduction of the epoxy ring at the C-6 position of **3** based on the axial ring opening rule[4] with lithium in liquid ammonia afforded the 7α-alcohol **4** in 96% yield. Oxidation of **2** with pyridinium chlorochromate (PCC)[5] gave the ketone **5**, and subsequent methoxycarbonylation at the C-6 position of **5** with sodium hydride in refluxing dimethyl carbonate gave the keto ester **6** in 81% yield (from **4**).[6] The completely enolized form of **6** was characterized by two singlet signals at δ 95.7 and δ 171.5 due to the C-6 and C-7 carbons in homogeneous sixteen peaks in the ^{13}C NMR spectra.[7]

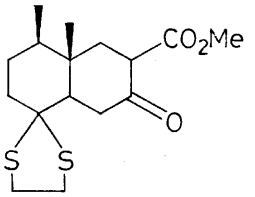
The hydrogenolysis of the ethylene dithioacetal[8] and the lithium metal reduction of methoxymethyl ether in liquid ammonia[9] were explored for the reduction of the β-keto esters. However, we have encountered some difficulties in obtaining the ethylene dithioacetal **11** on treatment of **6** with 1,2-ethanedithiol–boron trifluoride etherate, since the acetal-thioacetal



exchange occurred at the C-1 position of **6**, giving **12** exclusively. The lithium metal reduction of **6** was not feasible due to the reduction of the ester moiety to a hydroxymethyl group.



11



12

Because of the above results, stepwise transformation of **6** to **10** by ways of the dehydration of **7** and subsequent catalytic hydrogenation of **9** seemed to be promising for the present purpose. Reduction of **6** with sodium borohydride gave the epimeric alcohols **7** in 82% yield, and subsequent dehydration of the corresponding mesylates **8** with 1,8-diazabicyclo[5.4.0]-undec-7-ene (DBU) in refluxing benzene afforded α,β-unsaturated ester **9** in 64% yield (from **7**).[10] Catalytic hydrogenation of **9** over platinum oxide gave **10a** bearing the desired 6β-methoxycarbonyl group in 98% yield, as the result of preferential attack of hydrogen to the α side of the $\Delta^{6,7}$-double bond. The ^{13}C NMR spectra of **10a** showed homogeneous peaks, and the assigned configuration was also confirmed by the conversion of **10a** into the thermodynamically favorable 6α-isomer, **10b** on treatment with sodium methoxide at 85—90 °C in methanol (93% yield). The assigned stereochemistry at the C-6 position of **10b** can be rationally interpreted on the basis of downfield shift of ^1H NMR signals due to the angular C-4a methyl protons (δ 0.87) in comparison with that of **10a** (δ 0.72). This is due to the absence of shielding effects of the carbonyl group for a pair of axial and equatorial ester groups.[11]

Hydrolysis of the ethylene acetal of **10b** with perchloric acid and subsequent reduction of **13** with sodium borohydride provided the 1β-alcohol **14** in 95% yield (from **10b**). Dehydration of the hydroxyl group of **14** *via* the corresponding mesylate afforded **15** in 73% yield, the key precursor for the valencene synthesis.

The previous methods reported in the literature for the conversion of an ester into an isopropenyl group comprise the following two methods: one involves hydrolysis of the ester with an aqueous base, and treatment of the produced acid with methyllithium, giving the corresponding methyl ketone, and its subsequent treatment with methylenetriphenylphosphorane, giving the desired product.[1f,k] The other deals with the novel reaction of the ester with an excess of methylenetriphenylphosphorane, giving directly isopropenyl derivatives.[12] The reaction of **15** with an excess of salt-free methylenetriphenylphosphorane in tetrahydrofuran under reflux afforded the desired **18** in 76% yield. Meanwhile, the reaction of the acid **16** prepared by hydrolysis of **15** gave with methyllithium the ketone **17**, and subsequent olefination of **17** by Wittig reaction with methylenetriphenylphosphorane provided **18** (60% yield from **15**). The allylic oxidation of **18** with a slurry of the anhydrous chromium trioxide complex[13] furnished (±)-nootkatone (**1**) in 80% yield.[14]

Experimental

Melting points are uncorrected and boiling points are indicated without correction by the air bath temperature. IR spectra were determined on a JASCO IRA-1 grating spectrometer. ^1H NMR (60 MHz) spectra were obtained on a Hitachi R-24 spectrometer and ^{13}C NMR (25.05 MHz) spectra on a JEOL FX-100 spectrometer. Samples were dissolved in $CDCl_3$ and the chemical shift values (δ) are expressed in parts per million downfield from the internal standard Me_4Si. Elemental analyses were performed in our laboratory.

6α,7α-Epoxy-1,1-ethylenedioxy-4β,4aβ-dimethyl-trans-*decalin (**3**).* To a solution of *m*-CPBA (324 mg, 1.88 mmol) in CH_2Cl_2 (10 ml) was added a solution of **2** (320 mg, 1.44 mmol) in CH_2Cl_2 (10 ml) at −60 °C. After 1 h, the mixture was allowed to be warmed to 10 °C during 5 h, at which temperature it was stirred for 2 h. The mixture was filtered and the filtrate was washed with aqueous 20% KOH and aqueous $NaHCO_3$, dried (Na_2SO_4), and concentrated to give 332 mg (97%) of **3** after chromatography (SiO_2, hexane–AcOEt 5:1): bp 119—121 °C/2 Torr;† IR (neat) 1297, 1277, 1197, 1162, 1150, 1085, 1041 cm^{-1}; ^1H NMR δ 0.75 (s, 3, CH_3), 0.79 (d, J=6 Hz, 3, CH_3), 1.05—2.22 (m, 10, CH_2, CH), 2.80—3.11 (m, 2, CH–O), 3.51—3.96 (m, 4, CH_2O); ^{13}C NMR δ 13.2 (q, C-9), 15.1 (q, C-10), 20.2 (t, C-8), 28.0 (t, C-3), 34.9 (s, C-4a), 35.5 (t, C-2), 39.7 (t, C-5), 42.6 (d, C-4), 42.9 (d, C-8a), 50.3 (d, C-7), 52.7 (d, C-6), 64.0, 65.3 (t, CH_2O), 110.0 (s, C-1). Found: C, 70.65; H, 9.47%. Calcd for $C_{14}H_{22}O_3$: C, 70.56; H, 9.30%.

1,1-Ethylenedioxy-4β,4aβ-dimethyl-trans-*decalin-7α-ol (**4**).* To a blue solution of Li (55 mg, 7.93 mmol) in liquid NH_3 (45 ml) was added a solution of **3** (350 mg, 1.47 mmol) in THF (5 ml) at −70 °C. After being stirred for 3 h at −70 °C and for 1.5 h at −33 °C, the mixture was quenched with NH_4Cl (500 mg), allowed to stand at room temperature until the liquid NH_3 was removed, and worked up in the usual manner to give 340 mg (96%) of **4** after chromatography (SiO_2, hexane–AcOEt 3:1): bp 157—159 °C/0.035 Torr; IR (neat) 3400 (OH) cm^{-1}; ^1H NMR δ 0.80 (m, 3, CH_3), 0.82 (s, 3, CH_3), 1.00—2.10 (m, 12, CH_2, CH), 3.17

† 1 Torr ≈ 133.322 Pa.

(br, 1, OH), 3.54—4.00 (m, 4, CH_2O), 4.11 (complex t, J=2.5, 1 Hz, 1, CH–O); ^{13}C NMR δ 11.5 (q, C-9), 14.8 (q, C-10), 27.1 (t), 28.2 (t), 28.4 (t,) 33.7 (t, C-5), 35.8 (t, C-2), 37.7 (s, C-4a), 42.5 (d, C-4), 44.7 (d, C-8a), 64.0, 65.2 (t, CH_2O), 66.0 (d, C-7), 110.5 (s, C-1). Found: C, 69.87; H, 10.17%. Calcd for $C_{14}H_{24}O_3$: C, 69.96; H, 10.07%.

1,1-Ethylenedioxy-4β,4aβ-dimethyl-trans-*declain-7-one (5).* To a suspension of $Py \cdot CrO_3 \cdot HCl$ (1.06 g, 3.96 mmol) and AcONa (550 mg, 6.70 mmol) in CH_2Cl_2 (15 ml) was added a solution of **4** (320 mg, 1.33 mmol) in CH_2Cl_2 (5 ml). After being stirred for 3 h at 5 °C and for 3 h at room temperature, the mixture was diluted with ether (20 ml) and filtered. The concentrated filtrate was chromatographed (SiO_2, hexane–AcOEt 3:1) to give 294 mg (93%) of **5**: mp 59—61 °C; IR (Nujol) 1705 cm^{-1} (C=O); ^1H NMR δ 0.91 (m, 3, CH_3), 1.04 (s, 3, CH_3), 1.12—2.14 (m, 8, CH_2, CH), 2.15—2.57 (m, 4, CH_2CO), 3.57—4.10 (m, 4, CH_2O); ^{13}C NMR δ 11.7 (q, C-9), 15.3 (q, C-10), 28.3 (t, C-3), 35.6 (t, C-2), 36.4 (t), 37.1 (s, C-4a), 37.7 (t), 39.1 (t, C-5), 42.1 (d, C-4), 50.9 (d, C-8a), 64.1, 65.4 (t, CH_2O), 109.3 (s, C-1), 211.8 (s, C-7). Found: C, 70.63; H, 9.11%. Calcd for $C_{14}H_{22}O_3$: C, 70.56; H, 9.30%.

Methyl 1,1-Ethylenedioxy-4β,4aβ-dimethyl-7-oxo-trans-*decalin-6-carboxylate (6).* A mixture of **5** (340 mg, 1.43 mmol) and NaH (65 mg, 2.71 mmol) in dimethyl carbonate (1.7 ml) was heated under reflux for 3 h and quenched with cold aqueous $NaHCO_3$. The mixture was extracted with benzene–AcOEt (1:1) and the extract was worked up in the usual manner to give 369 mg (87%) of **6** after chromatography (SiO_2, hexane–AcOEt 2:1): mp 99—102 °C; IR (Nujol) 1655 (COO), 1621 cm^{-1} (C=C); ^1H NMR δ 0.78 (s, 3, CH_3), 0.89 (m, 3, CH_3), 1.05—2.00 (m, 6, CH_2, CH), 2.04—2.48 (m, 4, CH_2), 3.72 (s, 3, OCH_3), 3.80—4.12 (m, 4, CH_2O), 12.11 (s, 1, OH); ^{13}C NMR δ 11.8 (q, C-9), 15.3 (q, C-10), 25.4 (t, C-8), 28.1 (t, C-3), 35.5 (t, C-2), 36.4 (s, C-4a), 38.2 (t, C-5), 42.4 (d, C-4), 47.0 (d, C-8a), 51.3 (q, OCH_3), 64.1, 65.5 (t, CH_2O), 95.7 (s, C-6), 109.4 (s, C-1), 171.5 (s, C-7), 173.1 (s, COO). Found: C, 64.93; H, 8.31%. Calcd for $C_{16}H_{24}O_5$: C, 64.84; H, 8.16%.

Methyl 1,1-Ethylenedioxy-7-hydroxy-4β,4aβ-dimethyl-trans-*decalin-6-carboxylate (7).* To a solution of **6** (462 mg, 1.58 mmol) in MeOH (25 ml) was added a solution of $NaBH_4$ (59 mg, 1.56 mmol) in H_2O (1 ml) at 0 °C. The mixture was stirred for 12 h at room temperature, poured into aqueous $NaHCO_3$, and extracted with AcOEt–benzene (1:1). The extract was worked up in the usual manner to give 381 mg (82%) of **7** after chromatography (SiO_2, hexane–AcOEt 1:1): bp 143—145 °C/0.025 Torr; IR (neat) 3500 (OH), 1740 (COO), 1710 cm^{-1} (COO); ^1H NMR δ 0.71, 0.90 (s, 3, CH_3), 0.81 (m, 3, CH_3), 1.05—2.60 (m, 11, CH_2, CH), 2.90 (br, 1, OH), 3.46—4.40 (m, 5, CH_2O, CH–O), 3.66 (s, 3, OCH_3). Found: C, 64.69; H, 8.79%. Calcd for $C_{16}H_{26}O_5$: C, 64.41; H, 8.78%.

Methyl 1,1-Ethylenedioxy-7-methylsulfonyloxy-4β,4aβ-dimethyl-trans-*decalin-6-carboxylate (8).* To a solution of **7** (438 mg, 1.47 mmol) and Et_3N (1.04 g, 2.94 mmol) in ether (10 ml) was added $MeSO_2Cl$ (337 mg, 2.94 mmol) at 0 °C. The mixture was stirred for 2 h at 0 °C and for 1 h at room temperature, poured into cold aqueous $NaHCO_3$, and taken up in AcOEt–benzene (1:1). The extract was worked up in the usual manner to give 480 mg (87%) of **8**: mp 123—126 °C; IR (Nujol) 1718 cm^{-1} (COO); ^1H NMR δ 0.85 (m, 3, CH_3), 0.91 (s, 3, CH_3), 1.00—2.85 (m, 11, CH_2, CH), 2.99 (s, 3, SO_2CH_3), 3.50—4.15 (m, 4, CH_2O), 3.70 (s, 3, OCH_3), 4.50—5.00 (m, 1, CH–O). Found: C, 54.07; H, 7.52%. Calcd for $C_{17}H_{28}SO_7$: C, 54.25; H, 7.50%.

Methyl 1,1-Ethylenedioxy-4β,4aβ-dimethyl-$\Delta^{6,7}$-trans-*octalin-6-carboxylate (9).* A mixture of **8** (460 mg, 1.22 mmol) and DBU (1.36 g, 8.93 mmol) in benzene (20 ml) was heated at reflux for 12 h, poured into aqueous $NaHCO_3$, worked up in the usual manner to give 255 mg (74%) of **9** after chromatography (SiO_2, hexane–AcOEt 5:1): mp 79—81 °C; IR (Nujol) 1718 (COO), 1650 cm^{-1} (C=C); ^1H NMR δ 0.76 (s, 3, CH_3), 0.93 (m, 3, CH_3), 1.10—2.55 (m, 10, CH_2, CH), 3.70 (s, 3, OCH_3), 3.90 (m, 4, CH_2O), 6.95 (m, 1, HC=C); ^{13}C NMR δ 11.8 (q, C-9), 15.2 (q, C-10), 22.4 (t, C-8), 28.3 (t, C-3), 35.5 (t, C-2), 36.1 (s, C-4a), 40.0 (t, C-5), 42.6 (d, C-4), 46.9 (d, C-8a), 51.4 (q, OCH_3), 64.0, 65.5 (t, CH_2O), 109.7 (s, C-1), 128.2 (s, C-6), 138.7 (d, C-7), 167.9 (s, COO). Found: C, 68.50; H, 8.89%. Calcd for $C_{16}H_{24}O_4$: C, 68.55; H, 8.63%.

Methyl 1,1-Ethylenedioxy-4β,4aβ-dimethyl-trans-*decalin-6β-carboxylate (10a).* A mixture of **9** (123 mg, 0.44 mmol) and PtO_2 (40 mg) in AcOEt (7 ml) was treated with excess H_2 for 4 d at room temperature, filtered, and concentrated to give 122 mg (98%) of **10a**: bp 110—111 °C/0.017 Torr; IR (neat) 1730 cm^{-1} (COO); ^1H NMR δ 0.72 (s, 3, CH_3), 0.82 (m, 3, CH_3), 1.00—2.70 (m, 13, CH_2, CH), 3.67 (s, 3, OCH_3), 3.86 (m, 4, CH_2O); ^{13}C NMR δ 12.5 (q, C-9), 14.9 (q, C-10), 16.8 (t, C-8), 26.3 (t, C-7), 28.2 (t, C-3), 35.9 (t, C-2), 37.4 (d, C-4), 38.1 (s, C-4a), 41.2 (t, C-5), 43.0 (d, C-8a), 51.4 (q, OCH_3), 52.7 (d, C-6), 64.3, 65.4 (t, CH_2O), 109.9 (s, C-1), 176.4 (s, COO). Found: C, 70.52; H, 9.46%. Calcd for $C_{16}H_{26}O_4$: C, 70.56; H, 9.30%.

Epimerization of ***10a*** *to* ***10b.*** **10a** (110 mg, 0.39 mmol) was heated in MeOH (6 ml) containing MeONa (540 mg, 10 mmol) at 85—90 °C for 12 h. The mixture was poured into aqueous 5% tartaric acid and extracted with AcOEt–benzene (1:1). The crude product obtained after the usual workup was treated with excess CH_2N_2, giving 102 mg (93%) of **10b**: bp 121—123 °C/0.015 Torr; IR (neat) 1730 cm^{-1} (COO); ^1H NMR δ 0.86 (m, 3, CH_3), 0.87 (s, 3, CH_3), 1.10—2.75 (m, 13, CH_2, CH), 3.64 (s, 3, OCH_3), 4.87 (m, 4, CH_2O); ^{13}C NMR δ 12.7 (q, C-9), 14.8 (q, C-10), 19.0 (t, C-8), 28.4 (t), 28.9 (t), 35.8 (t, C-2), 37.7 (s, C-4a), 38.9 (d, C-4), 42.5 (t, C-5), 42.6 (d, C-8a), 51.4 (q, OCH_3), 51.9 (d, C-6), 64.2, 65.3 (t, CH_2O), 110.0 (s, C-1), 176.7 (s, COO). Found: C, 70.65; H, 9.51%. Calcd for $C_{16}H_{26}O_4$: C, 70.56; H, 9.30%.

Methyl 4β,4aβ-Dimethyl-1-oxo-trans-*decalin-6α-carboxylate (13).* To a solution of **10b** (122 mg, 0.43 mmol) in THF (6 ml) and H_2O (3 ml) was added 70% $HClO_4$ (0.2 ml). The mixture was stirred for 12 h at room temperature and worked up in the usual manner to give 101 mg (98%) of **13**: mp 68—69 °C; IR (Nujol) 1725 (COO), 1705 cm^{-1} (C=O); ^1H NMR δ 0.66 (s, 3, CH_3), 0.90 (d, J=6 Hz, 3, CH_3), 1.10—2.80 (m, 13, CH_2, CH), 3.65 (s, 3, OCH_3); ^{13}C NMR δ 11.7 (q, C-9), 14.5 (q, C-10), 19.8 (t, C-8), 27.8 (t), 31.3 (t), 38.6 (d, C-4), 40.8 (t), 41.2 (t), 41.4 (s, C-4a), 42.5 (d, C-8a), 51.7 (q, OCH_3), 57.2 (d, C-6), 176.3 (s, COO), 212.0 (s, C-1). Found: C, 70.52; H, 9.46%. Calcd for $C_{14}H_{22}O_3$: C, 70.56; H, 9.30%.

Methyl 1β-Hydroxy-4β,4aβ-dimethyl-trans-*decalin-6α-carboxylate (14).* To a solution of **13** (217 mg, 0.91 mmol) in MeOH (10 ml) was added a solution of $NaBH_4$ (35 mg, 0.92 mmol) in H_2O (0.5 ml) at 0 °C. The mixture was stirred for 3 h at room temperature, quenched with aqueous 10% AcOH, and taken up in AcOEt–benzene (1:1). The extract was worked up in the usual manner to give 213 mg (97%) of **14** after chromatography (SiO_2, hexane–AcOEt 3:1): bp 93—94 °C/0.005 Torr; IR (neat) 3480, 3400 (OH), 1730 (COO), 1715 cm^{-1} (COO); ^1H NMR δ 0.81 (m, 3, CH_3), 0.94 (s, 3, CH_3), 1.00—2.85 (m, 13, CH_2, CH), 1.68

(brs, 1, OH), 3.63 (s, 3, OCH_3), 3.67 (m, 1, CH–O); ^{13}C NMR δ 14.3 (q, C-10), 15.1 (q, C-9), 25.2 (t), 25.7 (t), 29.3 (t), 34.1 (t), 36.5 (s, C-4a), 39.2 (d, C-4), 42.7 (t, C-5), 43.1 (d, C-8a), 48.6 (d, C-6), 51.5 (q, OCH_3), 71.9 (d, C-1), 176.9 (s, COO). Found: C, 69.91; H, 10.08%. Calcd for $C_{14}H_{24}O_3$: C, 69.96; H, 10.07%.

Methyl 4β,4aβ-Dimethyl-$\Delta^{1(8a)}$-octalin-6α-carboxylate (15). To a solution of **14** (213 mg, 0.89 mmol) and Et_3N (629 mg, 6.22 mmol) in ether (10 ml) was added $MeSO_2Cl$ (203 mg, 1.77 mmol) at 0 °C. The mixture was stirred for 12 h at room temperature, quenched with aqueous $NaHCO_3$, and worked up in the usual manner. Without purification, the crude product was treated with benzene containing DBU (946 mg, 6.21 mmol) for 12 h under reflux. The usual workup and the subsequent chromatography (SiO_2, hexane–AcOEt 5:1) gave 144 mg (73%) of **15**: bp 74—76 °C/0.025 Torr; IR (neat) 1725 cm^{-1} (COO); ^1H NMR δ 0.85 (m, 3, CH_3), 0.93 (s, 3, CH_3), 1.10—2.60 (m, 12, CH_2, CH), 3.64 (s, 3, OCH_3), 5.35 (m, 1, HC=C); ^{13}C NMR δ 15.5 (q, C-10), 18.0 (q, C-9), 25.8 (t), 27.2 (t), 30.4 (t), 31.7 (t), 37.5 (s, C-4a), 39.7 (d), 40.8 (d), 41.9 (t, C-5), 51.4 (q, OCH_3), 121.0 (d, C-1), 141.6 (s, C-8a), 176.4 (s, COO). Found: C, 75.57; H, 9.97%. Calcd for $C_{14}H_{22}O_2$: C, 75.63; H, 9.97%.

4β,4aβ-Dimethyl-$\Delta^{1(8a)}$-octalin-6α-carboxylic Acid (16). Hydrolysis of **15** (58 mg, 0.26 mmol) in the MeOH (5 ml)–KOH (170 mg, 4.35 mmol)–H_2O (1 ml) system was carried out at room temperature for 24 h, acidified with aqueous 5% HCl, and extracted with AcOEt–benzene (1:1). The usual workup gave 49 mg (91%) of **16**; IR (neat) 3400—2600 (COOH), 1700 cm^{-1} (COO); ^1H NMR δ 0.87 (m, 3, CH_3), 0.93 (s, 3, CH_3), 1.10—2.90 (m, 12, CH_2, CH), 5.35 (m, 1, HC=C), 9.10 (br, 1, OH). Found: C, 75.24; H, 9.87%. Calcd for $C_{13}H_{20}O_2$: C, 74.96; H, 9.68%.

6α-Acetyl-4β,4aβ-dimethyl-$\Delta^{1(8a)}$-octalin (17). To a solution of **16** (54 mg, 0.26 mmol) in ether (5 ml) was added an ethereal solution of 1.05 M MeLi (0.74 ml, 0.78 mmol) at 0 °C. The mixture was stirred for 1 h at 0 °C, quenched with aqueous NH_4Cl, and extracted with AcOEt–benzene (1:1). The extract was worked up in the usual manner to give 43 mg (80%) of **17**: bp 109—112 °C/0.04 Torr (lit,[1h] 100—105 °C/0.02 Torr); IR (neat) 1710 (C=O), 1660 cm^{-1} (C=C); ^1H NMR δ 0.90 (m, 3, CH_3), 0.94 (s, 3, CH_3), 1.00—2.80 (m, 12, CH_2, CH), 2.14 (s, $COCH_3$), 5.32 (m, 1, HC=C).

(±)-Valencene (18) from 15. To a solution of **15** (110 mg, 0.50 mmol) in THF (5 ml) was added a salt-free solution of methylenetriphenylphosphorane prepared from methyltriphenylphosphonium bromide (715 mg, 2.0 mmol) and $NaNH_2$ (200 mg, 5.13 mmol) in THF (4 ml). The mixture was heated for 12 h under reflux and worked up in the usual manner to give 78 mg (76%) of **18**: bp 116—118 °C/14 Torr (lit,[1h] 73—75 °C/0.03 Torr); ^{13}C NMR δ 15.7 (q, C-10), 18.4 (q, C-9), 20.8 (q, C-13), 25.9 (t), 27.2 (t), 32.8 (t), 33.2 (t), 37.9 (s, C-8a), 41.0 (d), 41.1 (d), 45.0 (t, C-5), 108.3 (t, C-12), 120.1 (d, C-1), 143.1 (s, C-8a), 150.6 (s, C-11). IR and ^1H NMR spectra of **18** were identical with those of the reported ones.[3a,15]

Preparation of 18 from 17. To a solution of **17** (62 mg, 0.3 mmol) in benzene (5 ml) was added a benzene solution of 0.5 M methylenetriphenylphosphorane (1.2 ml, 0.6 mmol). The mixture was stirred at room temperature for 5 h, quenched with water, and worked up in the usual manner to give 51 mg (83%) of **18** after chromatography (SiO_2, hexane).

(±)-Nootkatone (1). To a solution of **18** (42 mg, 0.21 mmol) in CH_2Cl_2 (5 ml) was added a slurry of CrO_3·(pyridine)$_2$ complex (553 mg, 3.09 mmol) in CH_2Cl_2 (5 ml). The mixture was stirred for 12 h at room temperature, quenched with aqueous 5% tartaric acid, and worked up in the usual manner to give 36 mg (80%) of **1** after chromatography (SiO_2, hexane–AcOEt 3:1); mp 42—43 °C, crystallized from petroleum ether (boiling range 30—70 °C) at −70 °C (lit,[1f] 44—45 °C); ^{13}C NMR δ 14.9 (q, C-10), 16.8 (q, C-9), 20.8 (q, C-13), 31.7 (t), 33.1 (t), 39.3 (s, C-4a), 40.4 (d), 40.5 (d), 42.1 (t), 43.9 (t), 109.2 (t, C-12), 124.7 (d, C-1), 149.0 (s, C-11), 170.4 (s, C-8a), 199.5 (s, C-2). Except for the optical rotation, the physical data (IR, ^1H and ^{13}C NMR, and TLC analyses) of the product **1** were identical in all respects with those of the authentic sample.[14]

(Received July 24, 1981)

Fusion of 6-hydroxy-5βH-abieta-6,8,11,13-tetraen-18-oic acid 18,6-lactone (**2**) with potassium hydrogensulfate at 220 °C afforded bis[3-(2,3-dihydro-7-isopropyl-3,4-dimethyl-2-oxonaphtho[2,3-*b*]furan-3-yl)propyl] ether (**12**) in 37% yield, together with two minor products in 12% yield: 2,3-dihydro-7-isopropyl-3,4-dimethyl-3-propylnaphtho[2,3-*b*]furan-2-one and 3-allyl-2,3-dihydro-7-isopropyl-3,4-dimethylnaphtho[2,3-*b*]furan-2-one. Treatment of **12** with *p*-toluenesulfonic acid at 160 °C gave 2,3-dihydro-7-isopropyl-3,4-dimethyl-3-(3-tosyloxypropyl)naphtho[2,3-*b*]furan-2-one, which was converted into 2,3-dihydro-3-(3-hydroxypropyl)-7-isopropyl-3,4-dimethylnaphtho[2,3-*b*]furan-2-one (**16**). The alcohol **16** was further characterized as its acetate (**17**). After several attempts, the above C(1)–C(10) bond cleavage and B ring aromatization reaction were improved by use of concentrated sulfuric acid in refluxing acetic acid. Under these conditions, **2** gave **17** in 47% yield. Hydrolysis of **17** with hydrochloric acid afforded **16**. Subsequently, 12-hydroxy-, 12-methoxy-, 12-acetoxy-, and 12-nitro-6-hydroxy-5βH-abieta-6,8,11,13-tetraen-18-oic acid 18,6-lactones were each refluxed with concentrated sulfuric acid in acetic acid to give 6-hydroxy-, 6-methoxy-, 6-acetoxy-, and 6-nitro-3-(3-acetoxypropyl)-2,3-dihydro-7-isopropyl-3,4-dimethylnaphtho[2,3-*b*]furan-2-ones, respectively. From the present study, the 12-acetoxy derivative seems to be a suitable intermediate for the synthesis of coleon A.

Coleon A has been isolated from the leaves of *Coleus igniarius* Schweinf. (Labiatae) by Eugster *et al.*[1] On the basis of chemical and spectroscopic studies, they deduced the structure of coleon A to be **1**.[2,3] This is a very unique structure possessing a highly oxygenated 1,10-secoabietane skeleton. During the course of our synthetic studies on natural diterpenes we found[4] that, when 6-hydroxy-5βH-abieta-6,8,11,13-tetraen-18-oic acid 18,6-lactone (**2**) was treated with potassium hydrogensulfate or concentrated sulfuric acid, the C(1)–C(10) bond cleavage and B ring aromatization occurred. This paper[5] describes a novel synthesis of the coleon A skeleton.

Oxidation[7] of methyl abieta-6,8,11,13-tetraen-18-oate (**3**)[6] in chloroform with perbenzoic acid at room temperature afforded a mixture of the B ring oxygenated products, which was immediately treated with *p*-toluenesulfonic acid monohydrate in refluxing toluene to afford **2**. The IR spectrum of **2** showed bands at 1800 and 1692 cm^{-1} corresponding to a γ-lactone and a double bond, and its ^1H NMR spectrum showed signals at δ 2.65 (d, J=2.5 Hz) and 5.96 (d, J=2.5 Hz) due to the C-5 and C-7 protons. The stereochemistry of the C-5 position in **2** was established as follows. Catalytic hydrogenation of **2** in acetic acid over PtO_2, followed by esterification with diazomethane yielded the known methyl 5βH-abieta-8,11,13-trien-18-oate (**4**)[8] (IR: 1725 cm^{-1}), together with 6α-hydroxy-5βH-abieta-8,11,13-trien-18-oic acid 18,6α-lactone (**5**) (IR: 1758 cm^{-1}) and a small amount of its 18,6β-lactone epimer (**6**) (IR: 1760 cm^{-1}); their structures were supported by the following ^1H NMR spectra. The spectrum of **5** showed two singlet signals at δ 1.18 and 1.29 due to the C-10 and C-4 methyls, and signals for the C-5, C-6, and C-7 protons at δ 2.21 (1H, d, J=8.5 Hz), 4.88 (1H, dt, J=8.5 and 4 Hz), and 3.06 (2H, d, J=4 Hz). These spectral data suggested that **5** exists in a steroidal conformation (**5a**) in which the C(6)–O bond is axial to the twist-boat B ring and the A ring is a chair, as has been reported for 6α-hydroxy-5βH-podocarpa-8,11,13-trien-18-oic acid 18,6α-lactone (**7**).[9] While the spectrum of **6** showed the C-4 and C-10 methyl signals at δ 1.41 (6H), and signals for the C-5, C-6, and C-7 protons at δ 1.77 (1H, d, J=11 Hz), 4.38 (1H, dt, J=11 and 5 Hz), and 2.88 (1H, dd, J=15

9 5α H

and 11 Hz) and 3.18 (1H, dd, J=15 and 5 Hz). These coupling patterns of the protons in the B ring and the chemical shifts of the C-10 methyl which is deshielded by the aromatic C ring, suggested that **6** exists in the nonsteroidal conformation (**6a**).[10] Methanolysis of **2** with concentrated hydrochloric acid in refluxing methanol afforded an A/B *cis* keto ester, methyl 6-oxo-5β*H*-abieta-8,11,13-trien-18-oate (**8**). On the other hand, the corresponding A/B *trans* keto ester, methyl 6-oxoabieta-8,11,13-trien-18-oate (**9**)[11] which was obtained from the above oxidation mixture of **3** with perbenzoic acid, was never epimerized to **8** with concentrated hydrochloric acid in refluxing methanol.

Fusion of **2** with potassium hydrogensulfate at 220 °C for 12 h afforded three naphthalene derivatives (**10**, **11**, and **12**), which were separated by a careful column chromatography on silica gel. The compound **10** was obtained as a minor product (6%) and showed the presence of a naphthalene chromophore in the UV spectrum,[12] an enol γ-lactone moiety in the IR spectrum (1798 cm^{-1}), and a molecular weight 296 in the mass spectrum. The ^1H NMR spectrum of **10** showed signals due to an isopropyl at δ 1.32 (6H, d, J=7 Hz), two methyls at δ 1.59 and 2.61 (each 3H and s), a propyl at δ 0.7—1.25 (5H, m) and 2.05 (2H, m), and four aromatic protons at δ 7.20 (1H, s), 7.26 (1H, dd, J=8.5 and 2 Hz), 7.50 (1H, d, J=2 Hz), and 7.82 (1H, d, J=8.5 Hz). These spectral data clarified the structure of **10** to be (*R*)-2,3-dihydro-7-isopropyl-3,4-dimethyl-3-propylnaphtho[2,3-*b*]furan-2-one. This structure was further confirmed by the conversion of **10** with dimethyl sulfate in the presence of potassium hydroxide in refluxing acetone to the corresponding methoxy ester (**13**) [IR: 1725 cm^{-1}; ^1H NMR: δ 3.53 (3H, s, $-CO_2CH_3$) and 3.78 (3H, s, $-OCH_3$)].

The compound **11** was also obtained as another minor product (6%), whose IR and ^1H NMR spectra were very similar to those of **10**, except for the presence of an allyl group [IR: 1633, 987, 910 cm^{-1}; ^1H NMR: δ 2.79 (2H, d, J=6.5 Hz) and 4.75—5.60 (3H, m)] instead of the propyl group in **10**. Catalytic hydrogenation of **11** in methanol over Pd–C gave **10**. Thus, the structure of **11** was assigned as (*R*)-3-allyl-2,3-dihydro-7-isopropyl-3,4-dimethylnaphtho-[2,3-*b*]furan-2-one.

The compound **12** was obtained as a major product (37%); its IR and ^1H NMR spectra were also very similar to those of **10**; a molecular weight of 606 was found from the mass spectrum. A triplet signal at δ 3.07 (2H, J=6 Hz) in the ^1H NMR spectrum suggested the structure of **12** to be a dimer possessing an ether linkage at both the ω-positions of propyl groups in two monomers (**10**). The ether dimer **12** was heated at 160 °C with *p*-toluenesulfonic acid in 1,1,2,2-tetrachloroethane to give (*R*)-2,3-dihydro-7-isopropyl-3,4-dimethyl-3-(3-tosyloxypropyl)-naphtho[2,3-*b*]furan-2-one (**14**) (IR: 1795, 1637, 1360, 1172 cm^{-1}), which was converted into the corresponding iodide (**15**) by refluxing with potassium iodide in acetone. Treatment of **15** with potassium *t*-butoxide in dimethyl sulfoxide at room temperature afforded (*R*)-2,3-dihydro-3-(3-hydroxypropyl)-7-isopropyl-3,4-dimethylnaphtho[2,3-*b*]furan-2-one (**16**), together with a small amount of **11**. The alcohol **16** was further characterized as its acetate (**17**) (IR: 1797, 1730, 1640 cm^{-1}). The structures of **14**, **15**, **16**, and **17** were also supported by their ^1H NMR spectra.[12]

Subsequently, we examined the reaction of **2** with concentrated sulfuric acid to find more effective conditions. Treatment of **2** with concentrated sulfuric acid in refluxing toluene for 2 h gave the tosylate **14** in 17% yield. However, when **2** in acetic acid was refluxed for 3 h with concentrated sulfuric acid, the acetate **17** was obtained in 47% yield. Hydrolysis of **17** with hydrochloric acid in refluxing methanol yielded the alcohol **16**, which was converted into the tosylate **14** by treatment with *p*-toluenesulfonyl chloride in pyridine and into a chloride (**18**)

by refluxing with triphenylphosphine in carbon tetrachloride.

To obtain further information on the C(1)–C(10) bond cleavage and B ring aromatization leading to a suitable intermediate for the synthesis of coleon A, some C(12)-substituted derivatives of **2** were synthesized. Oxidation of methyl 12-acetoxyabieta-8,11,13-trien-18-oate (**19**)[13,14] with chromium trioxide in aqueous acetic acid afforded methyl 12-acetoxy-7-oxoabieta-8,11,13-trien-18-oate (**20**)[15] which, without purification, was converted into methyl 12-hydroxyabieta-6,8,11,13-tetraen-18-oate (**21**) by reduction with sodium borohydride in methanol, followed by refluxing with *p*-toluenesulfonic acid monohydrate in benzene. The crude hydroxy compound **21** was acetylated with acetic anhydride in pyridine to give methyl 12-acetoxyabieta-6,8,11,13-tetraen-18-oate (**22**), and methylated with methyl iodide in the presence of potassium *t*-butoxide in refluxing *t*-butyl alcohol to give methyl 12-methoxyabieta-6,8,11,13-tetraen-18-oate (**23**). Oxidation of **22** and **23** with perbenzoic acid in chloroform, followed by treatment with *p*-toluenesulfonic acid monohydrate in refluxing toluene, afforded respectively 6,12-dihydroxy-5βH-abieta-6,8,11,13-tetraen-18-oic acid 18,6-lactone (**24**) and 6-hydroxy-12-methoxy-5βH-abieta-6,8,11,13-tetraen-18-oic acid 18,6-lactone (**25**). Acetylation of **24** with acetic anhydride in pyridine yielded 12-acetoxy-6-hydroxy-5βH-abieta-6,8,11,13-tetraen-18-oic acid 18,6-lactone (**26**). The methoxy lactone **25** was also obtained from **24** by methylation with dimethyl sulfate in the presence of anhydrous potassium carbonate in refluxing acetone. Nitration of **2** in acetic anhydride with fuming nitric acid gave 6-hydroxy-12-nitro-5βH-abieta-6,8,11,13-tetraen-18-oic acid 18,6-lactone (**27**), whose ^{1}H NMR spectrum showed two singlet signals at δ 7.08 and 7.69 due to the two aromatic protons, suggesting that the nitration occurred at the C-12 position in **2**. The ^{1}H NMR spectra[12] of **24**, **25**, **26**, and **27** also suggested that the stereochemistry of the C-5 position in these γ-lactones was identical with that of **2**.

Subsequently, the γ-lactones were subjected to the C(1)–C(10) bond cleavage and B ring aromatization. The reaction conditions and yields are summarized in Table 1. The hydroxy γ-lactone **24** in acetic acid was refluxed for 1 h with concentrated sulfuric acid to give (*R*)-3-(3-acetoxypropyl)-2,3-dihydro-6-hydroxy-7-isopropyl-3,4-dimethylnaphtho[2,3-*b*]furan-2-one (**28**) and a small amount of (*R*)-6-acetoxy-3-(3-acetoxypropyl)-2,3-dihydro-7-isopropyl-3,4-dimethylnaphtho-[2,3-*b*]furan-2-one (**29**). Acetylation of **28** with acetic anhydride in pyridine afforded **29**. Similar treatment of **25**, **26**, and **27** also yielded the corresponding 2,3-dihydronaphtho[2,3-*b*]furan-2-one derivatives, **30**, **29**, and **31**, respectively. From the present study, the 12-acetoxy lactone **26** seems to be a useful intermediate for the synthesis of coleon A.

One possible mechanism of the reaction of the 5βH-γ-lactones (**2**, **24**, **25**, **26**, and **27**) with concentrated sulfuric acid in refluxing acetic acid would be the following. These lactones should exist in a non-steroidal conformation (**32**), because no steroidal conformation could be constructed with molecular models. The reaction would be initiated by oxidative elimination of an allylic C-5β hydrogen atom with concentrated sulfuric acid.[16] Then the C(1)–C(10) bond antiperiplaner to the C(5)–H one is cleaved with a back attack of an acetate anion at the C-1 position. This would stabilize the molecule by the B ring aromatization and by the disappearance of any 1,3-diaxial interaction between the C-4 and C-10 methyl groups.

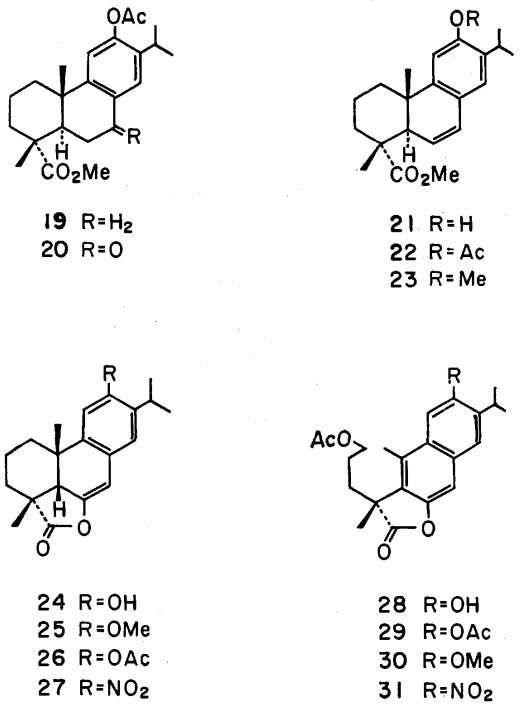

Table 1. The C(1)–C(10) bond cleavage and B ring aromatization of γ-lactones

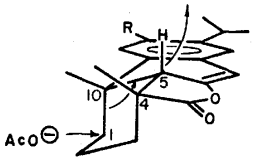
γ-Lactone	Refluxing time/h	Product	Yield/%
2	3	**17**	47
24	1	**28**+**29**	27
25	1	**30**	32
26	1.5	**29**	42
27	2	**31**	16[a]

a) 64% of **27** was recovered.



32

Experimental

All melting points are uncorrected. The IR and optical rotations were measured in chloroform, and the ^{1}H NMR spectra in carbon tetrachloride at 90 MHz, with tetramethylsilane as an internal standard, unless otherwise stated. The

chemical shifts are presented in terms of δ values; s: singlet, bs: broad singlet, d: doublet, bd: broad doublet, dd: double doublet, t: triplet, dt: double triplet, m: multiplet. The low-resolution mass spectra were obtained by direct inlet (ion-source temperature 200 °C and ionizing voltage 70 eV). The column chromatography was performed using Merck silica gel (0.063 mm).

6-Hydroxy-5βH-abieta-6,8,11,13-tetraen-18-oic Acid 18,6-Lactone (2). A solution of perbenzoic acid[17] (38.5 mmol) in chloroform (110 ml) was added to a solution of methyl abieta-6,8,11,13-tetraen-18-oate (**3**)[6] (10.8 g, 34.6 mmol) in chloroform (80 ml) at room temperature. After standing at room temperature for 24 h, the solution was diluted with ether (500 ml), and washed successively with aqueous potassium iodide, aqueous sodium thiosulfate, aqueous sodium hydrogencarbonate, and brine. The organic solution was dried over sodium sulfate and evaporated *in vacuo* to give yellowish brown oil (13.2 g).

This oil (13.2 g) was immediately refluxed with *p*-toluenesulfonic acid monohydrate (5.6 g) in toluene (260 ml) for 3 h, cooled, and diluted with ether (250 ml). The solution was washed successively with aqueous sodium hydrogencarbonate and brine, dried over sodium sulfate, and evaporated *in vacuo*. The residual brown oil (10.5 g) was crystallized from hexane to afford **2** (6.4 g) as colorless needles, mp 106—107 °C. The mother liquor of crystallization was evaporated and the residue was chromatographed on silica gel (410 g), using hexane–benzene (1:1) as the eluent, to give some additional **2**, which was crystallized from hexane to give colorless crystals (0.9 g), mp 105—106 °C. The total yield was 70%. Further crystallization gave an analytical sample; mp 106.5—107 °C; $[\alpha]_D$ −116° (*c* 1.54); IR: 1800, 1692 cm^{-1}; ^1H NMR: 1.22 (6H, d, J=7 Hz, $-CH(C\underline{H}_3)_2$), 1.46 and 1.52 (each 3H and s, C_4-CH_3 and $C_{10}-CH_3$), 2.65 (1H, d, J=2.5 Hz, $C_{5\beta}-H$), 2.80 (1H, m, $-C\underline{H}(CH_3)_2$), 5.96 (1H, d, J=2.5 Hz, C_7-H), 6.78 (1H, d, J=2 Hz, $C_{14}-H$), 6.89 (1H, dd, J=8 and 2 Hz, $C_{12}-H$), 7.08 (1H, d, J=8 Hz, $C_{11}-H$); UV: λ_{max}^{EtOH} 271 nm (log ε 4.07), 277 (4.07). Found: C, 80.89; H, 8.19%. Calcd for $C_{20}H_{24}O_2$: C, 81.04; H, 8.16%.

Catalytic Hydrogenation of 2. A mixture of **2** (5.93 g) and PtO_2 (600 mg) in acetic acid (180 ml) was submitted to catalytic hydrogenation with 1 atm hydrogen pressure at room temperature for *ca.* 100 min. After the usual work-up, the crude product was treated with an ethereal diazomethane solution at room temperature for several hours. The solvent was evaporated *in vacuo* and the residue was chromatographed on silica gel (300 g), using hexane–benzene (1:1) at the eluent, to give methyl 5β*H*-abieta-8,11,13-trien-18-oate (**4**)[8] (3.10 g: 49%); $[\alpha]_D$ −79° (*c* 7.35); IR: 1725 cm^{-1}; ^1H NMR: 1.21 (6H, d, J=7 Hz, $-CH(C\underline{H}_3)_2$), 1.31 (6H, s, C_4-CH_3 and $C_{10}-CH_3$), 3.24 (3H, s, $-CO_2CH_3$), 6.76 (1H, bs, $C_{14}-H$), 6.89 (1H, dd, J=8 and 2 Hz, $C_{12}-H$), 7.08 (1H, d, J=8 Hz, $C_{11}-H$); ^1H NMR in $CDCl_3$: 1.22 (6H, d, J=7 Hz, $-CH(C\underline{H}_3)_2$), 1.38 (6H, s, C_4-CH_3 and $C_{10}-CH_3$), 3.42 (3H, s, $-CO_2CH_3$). Found: C, 80.50; H, 9.78%. Calcd for $C_{21}H_{30}O_2$: C, 80.21; H, 9.62%.

Subsequent elution with ether–benzene (1:99) afforded 6β-hydroxy-5β*H*-abieta-8,11,13-trien-18-oic acid 18,6β-lactone (**6**), which was recrystallized from hexane to give colorless crystals (29 mg: 0.5%); mp 133—134 °C; $[\alpha]_D$ −90° (*c* 0.335); IR: 1760 cm^{-1}; ^1H NMR: 1.22 (6H, d, J=7 Hz, $-CH(C\underline{H}_3)_2$), 1.41 (6H, s, C_4-CH_3 and $C_{10}-CH_3$), 1.77 (1H, d, J=11 Hz, $C_{5\beta}-H$), 2.80 (1H, m, $-C\underline{H}(CH_3)_2$), 2.88 (1H, dd, J=15 and 11 Hz, $C_{7\beta}-H$), 3.18 (1H, dd, J=15 and 5 Hz, $C_{7\alpha}-H$), 4.38 (1H, dt, J=11 and 5 Hz, $C_{6\alpha}-H$), 6.87 (1H, bs, $C_{14}-H$), 6.97 (1H, dd, J=8 and 2 Hz, $C_{12}-H$), 7.07 (1H, d, J=8 Hz, $C_{11}-H$). Found: C, 80.76; H, 8.87%. Calcd for $C_{20}H_{26}O_2$: C, 80.49; H, 8.78%.

Further elution with the same solvent afforded 6α-hydroxy-5β*H*-abieta-8,11,13-trien-18-oic acid 18,6α-lactone (**5**), which was recrystallized from hexane to give colorless crystals (1.80 g: 30%); mp 109—109.5 °C; $[\alpha]_D$ −45° (*c* 1.21); IR: 1758 cm^{-1}; ^1H NMR: 1.18 and 1.29 (each 3H and s, $C_{10}-CH_3$ and C_4-CH_3), 1.24 (6H, d, J=7 Hz, $-CH(C\underline{H}_3)_2$), 2.21 (1H, d, J=8.5 Hz, $C_{5\beta}-H$), 2.83 (1H, m, $-C\underline{H}(CH_3)_2$), 3.06 (2H, d, J=4 Hz, C_7-H_2), 4.88 (1H, dt, J=8.5 and 4 Hz, $C_{6\beta}-H$), 6.9—7.1 (3H, m, $C_{11}-H$, $C_{12}-H$, and $C_{14}-H$). Found: C, 80.45; H, 8.88%. Calcd for $C_{20}H_{26}O_2$: C, 80.49; H, 8.78%.

Methanolysis of 2. A mixture of **2** (297 mg) and concentrated hydrochloric acid (0.15 ml) in methanol (15 ml) was refluxed for 1 h, and evaporated *in vacuo*. The residue was dissolved in ether and the ether solution was successively washed with sodium hydrogencarbonate and brine. After drying over sodium sulfate, the solvent was evaporated *in vacuo* and the residue was chromatographed on silica gel (33 g), using benzene as the eluent, to give the starting **2** (15 mg: 5%). Further elution with ether–benzene (1:99) gave methyl 6-oxo-5β*H*-abieta-8,11,13-trien-18-oate (**8**) (265 mg: 81%), which was recrystallized from hexane; mp 126—127 °C; $[\alpha]_D$ +36° (*c* 2.59); IR: 1723, 1700 cm^{-1}; ^1H NMR: 1.09 and 1.18 (each 3H and s, $C_{10}-CH_3$ and C_4-CH_3), 1.23 (6H, d, J=7 Hz, $-CH(C\underline{H}_3)_2$), 2.04 (1H, s, $C_{5\beta}-H$), 2.82 (1H, m, $-C\underline{H}(CH_3)_2$), 2.90 (3H, s, $-CO_2CH_3$), 3.44 (2H, s, C_7-H_2), 6.84 (1H, bs, $C_{14}-H$), 6.99 (1H, dd, J=8 and 2 Hz, $C_{12}-H$), 7.12 (1H, d, J=8 Hz, $C_{11}-H$). Found: C, 76.50; H, 8.56%. Calcd for $C_{21}H_{28}O_3$: C, 76.79; H, 8.59%.

Methyl 6-Oxoabieta-8,11,13-trien-18-oate (9). Chromatographic purification of the crude oxidation product of **3** with perbenzoic acid afforded **9** in *ca.* 30% yield; $[\alpha]_D$ +156° (*c* 1.93); IR: 1720, 1705 cm^{-1}; ^1H NMR: 1.18 (3H, s, $C_{10}-CH_3$), 1.24 (6H, d, J=7 Hz, $-CH(C\underline{H}_3)_2$), 1.44 (3H, s, C_4-CH_3), 2.87 (1H, m, $-C\underline{H}(CH_3)_2$), 3.15 (1H, s, $C_{5\alpha}-H$), 3.52 (2H, s, C_7-H_2), 3.58 (3H, s, $-CO_2CH_3$), 6.90 (1H, bs, $C_{14}-H$), 7.01 (1H, bd, J=8 Hz, $C_{12}-H$), 7.17 (1H, d, J=8 Hz, $C_{11}-H$). Found: C, 76.80; H, 8.38%. Calcd for $C_{21}H_{28}O_3$: C, 76.79; H, 8.59%.

A mixture of **9** (300 mg) and concentrated hydrochloric acid (0.15 ml) in methanol (15 ml) was refluxed for 1 h. The same work-up as described for the methanolysis of **2** gave an oil (270 mg), whose IR and ^1H NMR spectra showed that it was almost the recovered **9** and did not contain the 5β*H*-epimer (**8**).

Fusion of 2 with Potassium Hydrogensulfate. A mixture of **2** (13.31 g) and potassium hydrogensulfate (91.58 g) was heated at 220 °C for 12 h with stirring under a stream of nitrogen. The mixture was cooled, diluted with water, and extracted with ether. The ether extract was washed successively with aqueous sodium hydrogencarbonate and brine, dried over sodium sulfate, and evaporated *in vacuo* The residue was chromatographed on silica gel (800 g), using hexane–benzene (3:2) as the eluent, to give a mixture of naphtho[2,3-*b*]furan-2-one derivatives (3.13 g), whose purification is described later. Subsequent elution with the same solvent recovered the **2** (3.66 g: 27%).

Further elution with ether–benzene (3:97) afforded bis-[3-(2,3-dihydro-7-isopropyl-3,4-dimethyl-2-oxonaphtho[2,3-*b*]furan-3-yl)propyl] ether (**12**) (5.08 g: 37%) as an oil; $[\alpha]_D$ +45° (*c* 1.59); IR: 1780, 1635 cm^{-1}; ^1H NMR: *ca.* 1.1 (4H, m, $2\text{-}CH_2C\underline{H}_2CH_2O-$), 1.31 (12H, d, J=7 Hz, $2\text{-}CH(C\underline{H}_3)_2$), 1.58 (6H, s, $2C_3-CH_3$), *ca.* 2.1 (4H, m, $2\text{-}C\underline{H}_2CH_2CH_2O-$), 2.59 (6H, s, $2C_4-CH_3$), 3.00 (2H, m, 2-

C<u>H</u>$(CH_3)_2$), 3.07 (4H, t, J=6 Hz, 2-$CH_2CH_2C\underline{H}_2O$–), 7.13 (2H, s, $2C_9$–H), 7.26 (2H, dd, J=9 and 2 Hz, $2C_6$–H), 7.47 (2H, d, J=2 Hz, $2C_8$–H), 7.83 (2H, d, J=9 Hz, $2C_5$–H); MS (*m/e*): 606 (M^+); UV: λ_{max}^{EtOH} 235 nm (log ε 5.14), 271sh (4.05), 281.5 (4.08), 292sh (3.93), 312 (3.29), 326.5 (3.36). Found: C, 79.24; H, 7.81%. Calcd for $C_{40}H_{46}O_5$: C, 79.17; H, 7.64%.

The above mixture of naphtho[2,3-*b*]furan-2-one derivatives (3.13 g) was further purified by repeated column chromatography on silica gel.

The less polar fraction gave (*R*)-2,3-dihydro-7-isopropyl-3,4-dimethyl-3-propylnaphtho[2,3-*b*]furan-2-one (**10**) (0.80 g: 6%), which was recrystallized from hexane; mp 130—130.5 °C, $[\alpha]_D$ +81° (*c* 1.52); IR: 1798, 1642, 1595, 1508 cm^{-1}; UV: λ_{max}^{EtOH} 235.5 nm (log ε 4.80), 281.5 (3.76), 293sh (3.63), 312 (3.07), 320sh (2.90), 327 (3.08): ^1H NMR: 0.7—1.25 (5H, m, $-CH_2C\underline{H}_2C\underline{H}_3$), 1.32 (6H, d, J=7 Hz, $-CH(C\underline{H}_3)_2$), 1.59 (3H, s, C_3–CH_3), *ca.* 2.05 (2H, m, $-C\underline{H}_2CH_2CH_3$), 2.61 (3H, s, C_4–CH_3), 7.20 (1H, s, C_9–H), 7.26 (1H, dd, J=8.5 and 2 Hz, C_6–H), 7.50 (1H, d, J=2 Hz, C_8–H), 7.82 (1H, d, J=8.5 Hz, C_5–H; 18% NOE enhancement was observed on irradiation of the signal at δ 2.61); MS (*m/e*): 296 (M^+). Found: C, 81.21; H, 8.18%. Calcd for $C_{20}H_{24}O_2$: C, 81.04; H, 8.16%.

The more polar fraction gave (*R*)-3-allyl-2,3-dihydro-7-isopropyl-3,4-dimethylnaphtho[2,3-*b*]furan-2-one (**11**) (0.83 g: 6%), which was recrystallized from hexane; mp 118—119 °C; $[\alpha]_D$ +130° (*c* 1.25); IR: 1792, 1633, 987, 910 cm^{-1}; ^1H NMR: 1.35 (6H, d, J=6.5 Hz, $-CH(C\underline{H}_3)_2$), 1.64 (3H, s, C_3–CH_3), 2.67 (3H, s, C_4–CH_3), 2.79 (2H, d, J=6.5 Hz, $-C\underline{H}_2CH{=}CH_2$), 3.04 (1H, m, $-C\underline{H}(CH_3)_2$), 4.75—5.60 (3H, m, $-CH_2C\underline{H}{=}C\underline{H}_2$), 7.22 (1H, s, C_9–H), 7.29 (1H, dd, J=9 and 2 Hz, C_6–H), 7.52 (1H, d, J=2 Hz, C_8–H), 7.86 (1H, d, J=9 Hz, C_5–H; 18% NOE enhancement was observed on irradiation of the signal at δ 2.67). Found: C, 81.64; H, 7.61%. Calcd for $C_{20}H_{22}O_2$: C, 81.60; H, 7.53%.

Catalytic Hydrogenation of ***11***. A mixture of **11** (122 mg) and 5% Pd–C (25 mg) in methanol (6.0 ml) was subjected to catalytic hydrogenation at room temperature. After the usual work-up, the crude product was recrystallized from hexane to give a dihydro derivative (95 mg: 77%), mp 129—130 °C, whose IR and ^1H NMR spectra were identical with those of **10**.

*(R)-7-Isopropyl-2-methoxy-3-(1-methoxycarbonyl-1-methylbutyl)-4-methylnaphthalene (**13**).* Dimethyl sulfate (7.5 ml) and 50% aqueous potassium hydroxide (15.5 ml) were added to a stirred solution of **10** (119 mg) in refluxing acetone (15 ml) over a period of 63 min. After addition of acetone (6.0 ml), the mixture was further refluxed for 90 min, diluted with water, neutralized with dilute hydrochloric acid, and then extracted with ether. The ether extract was washed with water, dried over sodium sulfate, and evaporated *in vacuo*. The residue was chromatographed on silica gel (20 g), using benzene as the eluent, to give **13** (68 mg: 50%) as an oil; $[\alpha]_D$ −31° (*c* 1.44); IR: 1725, 1627, 1605 cm^{-1}; ^1H NMR: 0.88 (3H, t, J=6.5 Hz, $-CH_2CH_2C\underline{H}_3$), *ca.* 1.25 (2H, m, $-CH_2C\underline{H}_2CH_3$), 1.30 (6H, d, J=7 Hz, $-CH(C\underline{H}_3)_2$), 1.67 (3H, s, C_3–$\underset{|}{\overset{|}{C}}CH_3$), *ca.* 2.05 (2H, m, C_3–$\underset{|}{\overset{|}{C}}C\underline{H}_2$–), 2.63 (3H, s, C_4–CH_3), 2.98 (1H, m, $-C\underline{H}(CH_3)_2$), 3.53 (3H, s, $-CO_2CH_3$), 3.78 (3H, s, $-OCH_3$), 6.86 (1H, s, C_1–H; 28% NOE enhancement was observed on irradiation of the signal at δ 3.78), 7.14 (1H, dd, J=9 and 2 Hz, C_6–H), 7.37 (1H, d, J=2 Hz, C_8–H), 7.83 (1H, d, J=9 Hz, C_5–H; 22% NOE enhancement was observed on irradiation of the signal at δ 2.63). Found: C, 76.97; H, 8.81%. Calcd for $C_{22}H_{30}O_3$: C, 77.15; H, 8.83%.

*(R)-2,3-Dihydro-7-isopropyl-3,4-dimethyl-3-(3-tosyloxypropyl)-naphtho[2,3-b]furan-2-one (**14**).* A solution of **12** (330 mg) in 1,1,2,2-tetrachloroethane (5.0 ml) was added to *p*-toluenesulfonic acid which was prepared from the monohydrate (270 mg) and 1,1,2,2-tetrachloroethane (5.0 ml) by azeotropic distillation. The mixture was stirred at 160 °C for 12 h under a stream of nitrogen, cooled, and diluted with ether. The ether solution was washed with aqueous sodium hydrogencarbonate and brine, dried over sodium sulfate, and evaporated *in vacuo*. The residue was purified by column chromatography on silica gel (55 g), using benzene as the eluent, to give **14** (232 mg: 45%); $[\alpha]_D$ +69° (*c* 2.13); IR: 1795, 1637, 1360, 1172 cm^{-1}; ^1H NMR: *ca.* 1.2 (2H, m, $-CH_2C\underline{H}_2CH_2OTs$), 1.31 (6H, d, J=7 Hz, $-CH(C\underline{H}_3)_2$), 1.54 (3H, s, C_3–CH_3), *ca.* 2.05 (2H, m, $-C\underline{H}_2CH_2CH_2OTs$), 2.33 (3H, s, $-C_6H_4C\underline{H}_3$), 2.57 (3H, s, C_4–CH_3), 3.01 (1H, m, $-C\underline{H}(CH_3)_2$), 3.77 (2H, t, J=6 Hz, $-CH_2CH_2C\underline{H}_2OTs$), 7.14 (2H, d, J=8 Hz, aromatic protons of *p*-tosyl group), 7.16 (1H, s, C_9–H), 7.28 (1H, dd, J=8.5 and 2 Hz, C_6–H), 7.50 (1H, d, J=2 Hz, C_8–H), 7.58 (2H, d, J=8 Hz, aromatic protons of *p*-tosyl group), 7.84 (1H, d, J=8.5 Hz, C_5–H); UV: λ_{max}^{EtOH} 234 nm (log ε 4.86), 269.5 (3.80), 273.5 (3.81), 281 (3.80), 293sh (3.65), 312.5 (3.07), 318sh (2.92), 326 (3.10). Found: C, 69.66; H, 6.61%. Calcd for $C_{27}H_{30}O_5S$: C, 69.51; H, 6.48%.

Further elution with ether–benzene (3:97) gave the recovered **12** (117 mg: 34%).

*(R)-2,3-Dihydro-3-(3-iodopropyl)-7-isopropyl-3,4-dimethylnaphtho[2,3-b]furan-2-one (**15**).* A mixture of **14** (362 mg), potassium iodide (791 mg), and acetone (13 ml) was refluxed for 5 h in a dark place. After the solvent had been evaporated *in vacuo*, the residue was mixed with water, and extracted with ether. The ether extract was washed with water, dried over sodium sulfate, and evaporated *in vacuo*. The residual oil was chromatographed on silica gel (35 g), using hexane–benzene (2:1) as the eluent, to give **15** (291 mg: 89%) as an oil; $[\alpha]_D$ +19° (*c* 2.91); IR: 1790, 1632 cm^{-1}; ^1H NMR: 1.33 (6H, d, J=7 Hz, $-CH(C\underline{H}_3)_2$), *ca.* 1.4 (2H, m, $-CH_2C\underline{H}_2CH_2I$), 1.64 (3H, s, C_3–CH_3), *ca.* 2.2 (2H, m, $-C\underline{H}_2CH_2CH_2I$), 2.69 (3H, s, C_4–CH_3), 3.03 (2H, t, J=6 Hz, $-CH_2CH_2C\underline{H}_2I$), 3.03 (1H, m, $-C\underline{H}(CH_3)_2$), 7.18 (1H, s, C_9–H), 7.27 (1H, dd, J=8 and 2 Hz, C_6–H), 7.49 (1H, d, J=2 Hz, C_8–H), 7.82 (1H, d, J=8 Hz, C_5–H).

Reaction of ***15*** *with Potassium* t*-Butoxide in Dimethyl Sulfoxide.* A solution of potassium *t*-butoxide (560 mg) in dimethyl sulfoxide (5.0 ml) was added to a stirred solution of **15** (200 mg) in dry benzene (3.0 ml). After being stirred overnight at room temperature under a stream of nitrogen, the mixture was diluted with water, acidified with dilute hydrochloric acid, and extracted with ether. The ether extract was washed with water, dried over sodium sulfate, and evaporated *in vacuo*. The residue was chromatographed on silica gel (20 g), using hexane–benzene (1:2) as the eluent, to give a solid (9 mg: 6%) whose IR and ^1H NMR spectra were identical with those of **11**.

Subsequent elution with ether–benzene (1:3) yielded (*R*)-2,3-dihydro-3-(3-hydroxypropyl)-7-isopropyl-3,4-dimethylnaphtho[2,3-*b*]furan-2-one (**16**) (37 mg: 25%); $[\alpha]_D$ +50° (*c* 0.875); IR: 3620, 3450br, 1795, 1637 cm^{-1}; ^1H NMR: *ca.* 1.1 (2H, m, $-CH_2C\underline{H}_2CH_2OH$), 1.32 (6H, d, J=7 Hz, $-CH(C\underline{H}_3)_2$), 1.59 (3H, s, C_3–CH_3), 1.82 (1H, bs, –OH; disappeared with D_2O), *ca.* 2.1 (2H, m, $-C\underline{H}_2CH_2CH_2OH$), 2.61 (3H, s, C_4–CH_3), 3.02 (1H, m, $-C\underline{H}(CH_3)_2$), 3.33 (2H, t, J=6 Hz, $-CH_2CH_2C\underline{H}_2OH$), 7.21 (1H, s, C_9–H), 7.27 (1H, dd, J=9 and 2 Hz, C_6–H), 7.51 (1H, d, J=2 Hz,

C_8–H), 7.84 (1H, d, J=9 Hz, C_5–H). Found: C, 77.17; H, 7.93%, Calcd for $C_{20}H_{24}O_3$: C, 76.89; H, 7.74%.

*(R)-3-(3-Acetoxypropyl)-2,3-dihydro-7-isopropyl-3,4-dimethylnaphtho[2,3-b]furan-2-one (**17**).* A mixture of **16** (67 mg), acetic anhydride (0.13 ml), and pyridine (0.34 ml) was allowed to stand overnight at room temperature. After the usual work-up, the crude product was purified by column chromatography on silica gel (7.0 g), using benzene as the eluent, to give **17** (70 mg: 92%) as an oil; $[\alpha]_D$ +11° (c 3.75); IR: 1797, 1730, 1640 cm^{-1}; ^1H NMR: *ca.* 1.2 (2H, m, $-CH_2C\underline{H}_2CH_2OAc$), 1.33 (6H, d, J=7 Hz, $-CH(C\underline{H}_3)_2$), 1.62 (3H, s, C_3–CH_3), 1.91 (3H, s, $-OCOCH_3$), *ca.* 2.1 (2H, m, $-C\underline{H}_2CH_2CH_2OAc$), 2.62 (3H, s, C_4–CH_3), 3.01 (1H, m, $-C\underline{H}(CH_3)_2$), 3.83 (2H, t, J=6 Hz, $-CH_2CH_2C\underline{H}_2OAc$), 7.20 (1H, s, C_9–H), 7.26 (1H, dd, J=8 and 2 Hz, C_6–H), 7.49 (1H, d, J=2 Hz, C_8–H), 7.81 (1H, d, J=8 Hz, C_5–H); UV: λ_{max}^{EtOH} 235.5 nm (log ε 4.83), 281.5 (3.78), 293sh (3.62), 313 (2.95), 327 (3.03). Found: C, 74.51; H, 7.46%. Calcd for $C_{22}H_{26}O_4$: C, 74.55; H, 7.39%.

*Reaction of **2** with Concentrated Sulfuric Acid in Toluene.* A stirred mixture of **2** (297 mg), concentrated sulfuric acid (0.33 ml), and toluene (6.0 ml) was refluxed for 2 h. The mixture was cooled, diluted with water, and extracted with ether, The ether extract was washed successively with brine, aqueous sodium hydrogencarbonate, and brine. After drying over sodium sulfate, the solvent was evaporated *in vacuo* and the residue was purified by column chromatography on silica gel (31 g), using benzene as the eluent, to give an oil (78 mg: 17%) whose IR and ^1H NMR spectra were identical with those of **14**.

*Reaction of **2** with Concentrated Sulfuric Acid in Acetic Acid.* A stirred mixture of **2** (148 mg) and concentrated sulfuric acid (0.75 ml) in acetic acid (7.5 ml) was refluxed for 3 h. The reaction mixture was cooled, diluted with water, and extracted with ether. The ether extract was washed successively with water, aqueous sodium hydrogencarbonate, and brine. After drying over sodium sulfate, the solvent was evaporated *in vacuo*. The residue was chromatographed on silica gel (16 g), using benzene as the eluent, to give an oil (83 mg: 47%) whose IR and ^1H NMR spectra were identical with those of **17**.

*Hydrolysis of **17**.* A mixture of **17** (354 mg) and concentrated hydrochloric acid (0.5 ml) in methanol (14 ml) was refluxed for 1 h. After the solvent had been evaporated *in vacuo*, the residue was diluted with water and extracted with ether. The ether extract was washed successively with aqueous sodium hydrogencarbonate and brine, dried over sodium sulfate, and evaporated *in vacuo* to give an oil (306 mg) whose IR and ^1H NMR spectra were identical with those of **16**.

*Reaction of **16** with p-Toluenesulfonyl Chloride.* A mixture of **16** (320 mg) and *p*-toluenesulfonyl chloride (229 mg) in pyridine (1.6 ml) was allowed to stand overnight at room temperature. After the usual work-up, the crude product was chromatographed on silica gel (32 g), using hexane–benzene (1:1) as the eluent, to give (*R*)-3-(3-chloropropyl)-2,3-dihydro-7-isopropyl-3,4-dimethylnaphtho[2,3-*b*]furan-2-one (**18**) (44 mg: 13%), which was recrystallized from hexane; mp 63—65.5 °C; $[\alpha]_D$ +10° (c 0.965); ^1H NMR: *ca.* 1.4 (2H, m, $-CH_2C\underline{H}_2CH_2Cl$), 1.33 (6H, d, J=7 Hz, $-CH(C\underline{H}_3)_2$), 1.63 (3H, s, C_3–CH_3), *ca.* 2.25 (2H, m, $-C\underline{H}_2CH_2CH_2Cl$), 2.64 (3H, s, C_4–CH_3), 3.02 (1H, m, $-C\underline{H}(CH_3)_2$), 3.35 (2H, t, J=6 Hz, $-CH_2CH_2C\underline{H}_2Cl$), 7.20 (1H, s, C_9–H), 7.26 (1H, dd, J=9 and 2 Hz, C_6–H), 7.48 (1H, d, J=2 Hz, C_8–H), 7.82 (1H, d, J=9 Hz, C_5–H); MS (*m/e*): 332 (M^++2), 330 (M^+). Found: C, 72.84; H, 7.30%. Calcd for $C_{20}H_{23}O_2Cl$: C, 72.61; H, 7.01%.

Subsequent elution with benzene afforded a tosylate (228 mg: 49%) whose IR and ^1H NMR spectra were identical with those of **14**.

Further elution with ether–benzene (15:85) recovered some of the **16** (32 mg: 10%).

*(R)-3-(3-Chloropropyl)-2,3-dihydro-7-isopropyl-3,4-dimethylnaphtho[2,3-b]furan-2-one (**18**).* A mixture of **16** (312 mg) and triphenylphosphine (290 mg) in carbon tetrachloride (2.0 ml) was refluxed for 4 h. The solvent was removed *in vacuo* and the residue was purified by column chromatography on silica gel (55 g), using hexane–benzene (1:1) as the eluent, to give a solid (275 mg: 83%) whose IR and ^1H NMR spectra were identical with those of **18**.

*Methyl 12-Acetoxyabieta-6,8,11,13-tetraen-18-oate (**22**).* A solution of chromium trioxide (30 g) in 80% aqueous acetic acid (150 ml) was added dropwise to a stirred solution of methyl 12-acetoxyabieta-8,11,13-trien-18-oate (**19**)[13,14] (37.2 g) in acetic acid (560 ml) at 20—25 °C over a period of 1 h. The mixture was stirred at this temperature for 18 more h, poured into water, and extracted with chloroform. The chloroform extract was washed successively with aqueous sodium hydrogencarbonate and brine, dried over sodium sulfate, and evaporated *in vacuo* to give methyl 12-acetoxy-7-oxoabieta-8,11,13-trien-18-oate (**20**);[15] IR: 1755, 1725, 1678, 1612 cm^{-1}; ^1H NMR: 6.90 (1H, s, C_{11}–H), 7.87 (1H, s, C_{14}–H).

The above crude 7-oxo compound (**20**) (40 g), without purification, was allowed to reduce overnight with sodium borohydride (5.7 g) in methanol (400 ml) at room temperature. After removal of the solvent *in vacuo*, the residue was diluted with water (1.5 l) and acidified with dilute hydrochloric acid. The precipitates were collected, washed with water, and dried at 80—90 °C to yield a mixture of epimeric 7-hydroxy compounds as a solid which, without purification, was used in the next reaction.

This dried solid (36.5 g) in benzene (1.5 l) was refluxed with *p*-toluenesulfonic acid monohydrate (1.8 g) for 2 h. The mixture was concentrated *in vacuo* to a half volume, cooled, and diluted with ether (750 ml). The ether solution was washed successively with aqueous sodium hydrogencarbonate and water, dried over sodium sulfate, and evaporated *in vacuo* to give the crude methyl 12-hydroxyabieta-6,8,11,13-tetraen-18-oate (**21**); IR: 3600, 3330br, 1722 cm^{-1}; ^1H NMR: 2.76 (1H, t, J=2.5 Hz, $C_{5\alpha}$–H), 5.47 and 6.34 (each 1H and dd, J=10 and 2.5 Hz, C_6–H and C_7–H), 6.47 and 6.72 (each 1H and s, C_{11}–H and C_{14}–H).

The crude 12-hydroxy compound (**21**) (32 g) was acetylated with acetic anhydride (32 ml) in pyridine (96 ml) at room temperature for 1 h. After the usual work-up, the crude product was purified by column chromatography on silica gel (350 g), using benzene as the eluent, to give **22** (26.9 g: 73% from **19**) as an oil; $[\alpha]_D$ −19° (c 1.89); IR: 1748, 1715 cm^{-1}; ^1H NMR: 1.08 (3H, s, C_{10}–CH_3), 1.34 (3H, s, C_4–CH_3), 2.22 (3H, s, $-OCOCH_3$), 2.84 (1H, t, J=2.5 Hz, $C_{5\alpha}$–H), 3.60 (3H, s, $-CO_2CH_3$), 5.66 and 6.43 (each 1H and dd, J=10 and 2.5 Hz, C_6–H and C_7–H), 6.68 and 6.89 (each 1H and s, C_{11}–H and C_{14}–H). Found: C, 74.50; H, 8.10%. Calcd for $C_{23}H_{30}O_4$: C, 74.56; H, 8.16%.

*Methyl 12-Methoxyabieta-6,8,11,13-tetraen-18-oate (**23**).* A mixture of the above crude **21** (3.3 g) and potassium *t*-butoxide (1.35 g) in *t*-butyl alcohol (44 ml) was stirred at room temperature for 10 min and methyl iodide (2.82 g) was added dropwise over a 5 min period. The mixture was refluxed for 2 h and evaporated *in vacuo*. The residue was diluted with water, acidified with dilute hydrochloric acid, and extracted with ether. The ether extract was

washed with water, dried over sodium sulfate, and evaporated *in vacuo*. The crude product was chromatographed on silica gel (200 g), using benzene as the eluent, to give **23** (2.4 g: 63% from **19**), which was recrystallized from methanol; mp 73.5—74.5 °C; $[\alpha]_D$ −9.6° (*c* 2.08); IR: 1722 cm^{-1}; ^1H NMR: 1.04 (3H, s, C_{10}–CH_3), 1.15 and 1.18 (each 3H and d, J=7 Hz, $-CH(C\underline{H}_3)_2$), 1.35 (3H, s, C_4–CH_3), 2.79 (1H, t, J=3 Hz, $C_{5\alpha}$–H), 3.21 (1H, m, $-C\underline{H}(CH_3)_2$), 3.60 (3H, s, $-CO_2CH_3$), 3.80 (3H, s, $-OCH_3$), 5.52 and 6.38 (each 1H and dd, J=10 and 3 Hz, C_6–H and C_7–H), 6.57 and 6.78 (each 1H and s, C_{11}–H and C_{14}–H). Found: C, 77.45; H, 9.08%. Calcd for $C_{22}H_{30}O_3$: C, 77.15; H, 8.83%.

*6,12-Dihydroxy-5βH-abieta-6,8,11,13-tetraen-18-oic Acid 18,6-Lactone (**24**).* Oxidation of **22** (45.7 g) in chloroform (340 ml) with a chloroform solution (270 ml) of perbenzoic acid (1.2 mol equivalent) was carried out, followed by refluxing with *p*-toluenesulfonic acid monohydrate (23.4 g) in toluene (1140 ml). This procedure, described for the preparation of **2**, yielded an unstable lactone (**24**) (40.0 g) as a solid. Aliquots of this were recrystallized from benzene; mp 163—165 °C; $[\alpha]_D$ −212° (*c* 0.660); IR: 3600, 3370br, 1794, 1690 cm^{-1}; ^1H NMR: 1.22 (6H, bd, J=7 Hz, $-CH(C\underline{H}_3)_2$), 1.47 (6H, s, C_4–CH_3 and C_{10}–CH_3), 2.62 (1H, d, J=3 Hz, $C_{5\beta}$–H), 3.10 (1H, m, $-C\underline{H}(CH_3)_2$), 5.22 (1H, bs, –OH; disappeared with D_2O), 5.93 (1H, d, J=3 Hz, C_7–H), 6.57 (1H, s, C_{11}–H), 6.71 (1H, s, C_{14}–H); UV: λ_{max}^{EtOH} 286.5 nm (log ε 4.22). Found: C, 77.00; H, 7.68%. Calcd for $C_{20}H_{24}O_3$: C, 76.89; H, 7.74%.

*6-Hydroxy-12-methoxy-5βH-abieta-6,8,11,13-tetraen-18-oic Acid 18,6-Lactone (**25**). a)*: Oxidation of **23** (2.05 g) in chloroform with perbenzoic acid (1.1 mol equivalent), followed by treatment with *p*-toluenesulfonic acid monohydrate (1.14 g) in refluxing toluene, was carried out as described for the preparation of **2**. The crude product was purified by column chromatography on silica gel (70 g), using hexane–benzene (1:1) as the eluent, to afford **25** (1.12 g: 57%) as an oil; $[\alpha]_D$ −101° (*c* 3.40); IR: 1800, 1695 cm^{-1}; ^1H NMR: 1.18 (6H, bd, J=7 Hz, $-CH(C\underline{H}_3)_2$), 1.47 and 1.54 (each 3H and s, C_4–CH_3 and C_{10}–CH_3), 2.65 (1H, d, J=3 Hz, $C_{5\beta}$–H), 3.18 (1H, m, $-C\underline{H}(CH_3)_2$), 3.79 (3H, s, $-OCH_3$), 5.94 (1H, d, J=3 Hz, C_7–H), 6.66 (1H, s, C_{11}–H), 6.74 (1H, s, C_{14}–H). Found: C, 76.97; H, 8.06%. Calcd for $C_{21}H_{26}O_3$: C, 77.27; H, 8.03%.

b): A stirred mixture of the crude **24** (2.44 g), dimethyl sulfate (1.05 ml), anhydrous potassium carbonate (10.8 g), and dry acetone (98 ml) was refluxed for 6 h. After the usual work-up, the crude product was chromatographed on silica gel (350 g), using hexane–benzene (2:3) as the eluent, to give an oil (0.48 g: 19% from **22**) whose IR and ^1H NMR spectra were identical with those of **25**. The compound **25** was so unstable that it converted into a complex mixture during the column chromatography.

*12-Acetoxy-6-hydroxy-5βH-abieta-6,8,11,13-tetraen-18-oic Acid 18,6-Lactone (**26**).* The above crude **24** (20.0 g) was acetylated with acetic anhydride (20 ml) in pyridine (60 ml). After the usual work-up, the product was chromatographed on silica gel (400 g), using benzene as the eluent, to give **26** (15.1 g: 69% from **22**) as an oil; $[\alpha]_D$ −70° (*c* 2.44); IR: 1800, 1758, 1694 cm^{-1}; ^1H NMR: 1.18 (6H, bd, J=7 Hz, $-CH(C\underline{H}_3)_2$), 1.45 and 1.50 (each 3H and s, C_4–CH_3 and C_{10}–CH_3), 2.22 (3H, s, $-OCOCH_3$), 2.67 (1H, d, J=3 Hz, $C_{5\beta}$–H), 2.89 (1H, m, $-C\underline{H}(CH_3)_2$), 5.98 (1H, d, J=3 Hz, C_7–H), 6.76 (1H, s, C_{11}–H), 6.84 (1H, s, C_{14}–H).

*6-Hydroxy-12-nitro-5βH-abieta-6,8,11,13-tetraen-18-oic Acid 18,6-Lactone (**27**).* A mixture of fuming nitric acid (d=1.50: 1.8 ml) and acetic anhydride (3.6 ml) was added dropwise to a stirred solution of **2** (6.0 g) in acetic anhydride (60 ml) at 0—5 °C over a period of 15 min. The mixture was stirred at room temperature for 1 h and then poured into ice–water. The aqueous mixture was stirred for another 30 min and then extracted with ether. The ether extract was washed successively with brine, aqueous sodium hydrogencarbonate, and brine. After being dried over sodium sulfate, the solvent was removed *in vacuo*. The residue was chromatographed on silica gel (350 g), using hexane–benzene (1:1) as the eluent, to give **27** (0.46 g: 7%), which was recrystallized from ethanol; mp 156.5—158 °C; $[\alpha]_D$ −29° (*c* 2.67); IR: 1808, 1690, 1515, 1345 cm^{-1}; ^1H NMR ($CDCl_3$): 1.27 and 1.29 (each 3H and d, J=7 Hz, $-CH(C\underline{H}_3)_2$), 1.55 and 1.62 (each 3H and s, C_4–CH_3 and C_{10}–CH_3), 2.81 (1H, d, J=3 Hz, $C_{5\beta}$–H), 3.48 (1H, m, $-C\underline{H}(CH_3)_2$), 6.15 (1H, d, J=3 Hz, C_7–H), 7.08 (1H, s, C_{14}–H), 7.69 (1H, s, C_{11}–H). Found: C, 70.20; H, 7.08; N, 4.07%. Calcd for $C_{20}H_{23}O_4N$: C, 70.36; H, 6.79; N, 4.10%.

*Reaction of **24** with Concentrated Sulfuric Acid in Acetic Acid.* A mixture of **24** (117 mg), concentrated sulfuric acid (0.61 ml), and acetic acid (5.85 ml) was refluxed for 1 h. After the same work-up as described for the preparation of **17**, the crude product was chromatographed on silica gel (12 g), using ether–benzene (5:95) as the eluent, to give an oil (6 mg: 4%) whose IR and ^1H NMR spectra were identical with those of (*R*)-6-acetoxy-3-(3-acetoxypropyl)-2,3-dihydro-7-isopropyl-3,4-dimethylnaphtho[2,3-*b*]furan-2-one (**29**).

Further elution gave (*R*)-3-(3-acetoxypropyl)-2,3-dihydro-6-hydroxy-7-isopropyl-3,4-dimethylnaphtho[2,3-*b*]furan-2-one (**28**) (32 mg: 23%) as an oil; $[\alpha]_D$ +25° (*c* 2.05); IR: 3600, 3320br, 1793, 1730 cm^{-1}; ^1H NMR: *ca.* 1.2 (2H, m, $-CH_2C\underline{H}_2CH_2OAc$), 1.30 (6H, d, J=7 Hz, $-CH(C\underline{H}_3)_2$), 1.57 (3H, s, C_3–CH_3), *ca.* 2.1 (2H, m, $-C\underline{H}_2CH_2CH_2OAc$), 1.94 (3H, s, $-OCOCH_3$), 2.48 (3H, s, C_4–CH_3), 3.32 (1H, m, $-C\underline{H}(CH_3)_2$), 3.86 (2H, t, J=6.5 Hz, $-CH_2CH_2C\underline{H}_2OAc$), 7.12 (2H, s, C_5–H and C_9–H; 11% NOE enhancement was observed on irradiation of the signal at δ 2.48), 7.43 (1H, s, C_8–H); UV: λ_{max}^{EtOH} 238.5 nm (log ε 4.72), 268.5 (4.00), 279.5 (3.89), 290sh (3.61), 334.5 (3.49), 346.5 (3.57). Found: C, 71.04; H, 7.22%. Calcd for $C_{22}H_{26}O_5$: C, 71.33; H, 7.08%.

The compound **28** (25 mg) was acetylated with acetic anhydride (0.03 ml) in pyridine (0.05 ml) at room temperature for 1 h. After the usual work-up, the crude product was purified by column chromatography on silica gel to give **29** (21 mg); $[\alpha]_D$ +12° (*c* 2.09); IR: 1797, 1753, 1735 cm^{-1}; ^1H NMR: *ca.* 1.2 (2H, m, $-CH_2C\underline{H}_2CH_2OAc$), 1.29 (6H, d, J=7 Hz, $-CH(C\underline{H}_3)_2$), 1.60 (3H, s, C_3–CH_3), 1.91 (3H, s, $-OCOCH_3$), *ca.* 2.1 (2H, m, $-C\underline{H}_2CH_2CH_2OAc$), 2.32 (3H, s, $-OCOCH_3$), 3.05 (1H, m, $-C\underline{H}(CH_3)_2$), 3.83 (2H, t, J=6.5 Hz, $-CH_2CH_2C\underline{H}_2OAc$), 7.20 (1H, s, C_9–H), 7.49 (1H, s, C_5–H), 7.58 (1H, s, C_8–H). Found: C, 70.05; H, 6.98%. Calcd for $C_{24}H_{28}O_6$: C, 69.88; H, 6.84%.

*Reaction of **25** with Concentrated Sulfuric Acid in Acetic Acid.* A mixture of **25** (326 mg), concentrated sulfuric acid (1.48 ml), and acetic acid (16.5 ml) was refluxed for 1 h. After the same work-up as described for the preparation of **17**, the crude product was chromatographed on silica gel (30 g), using ether–benzene (1:99) as the eluent, to give (*R*)-3-(3-acetoxypropyl)-2,3-dihydro-7-isopropyl-6-methoxy-3,4-dimethylnaphtho[2,3-*b*]furan-2-one (**30**) as an oil (123 mg: 32%); $[\alpha]_D$ +25° (*c* 1.93); IR: 1800, 1740 cm^{-1}; ^1H NMR: *ca.* 1.2 (2H, m, $-CH_2C\underline{H}_2CH_2OAc$), 1.29 (6H, d, J=7 Hz, $-CH(C\underline{H}_3)_2$), 1.61 (3H, s, C_3–CH_3), 1.92 (3H, s, $-OCOCH_3$), *ca.* 2.1 (2H, m, $-C\underline{H}_2CH_2CH_2OAc$), 2.59 (3H,

s, C_4–CH_3), 3.38 (1H, m, –C<u>H</u>$(CH_3)_2$), 3.84 (2H, t, J=6.5 Hz, –$CH_2CH_2C\underline{H}_2OAc$), 3.95 (3H, s, –$OCH_3$), 7.07 (1H, s, C_5–H; 20% and 17% NOE enhancements were observed on irradiation of the signal at δ 2.59 and at δ 3.95 respectively), 7.18 (1H, s, C_9–H), 7.49 (1H, s, C_8–H). Found: C, 71.61; H, 7.35%. Calcd for $C_{23}H_{28}O_5$: C, 71.85; H, 7.34%.

Reaction of ***26*** *with Concentrated Sulfuric Acid in Acetic Acid.* A mixture of **26** (1.50 g), concentrated sulfuric acid (6.80 ml), and acetic acid (110 ml) was refluxed for 1.5 h. After the same work-up as described for the preparation of **17**, the crude product was immediately acetylated with acetic anhydride (1.5 ml) in pyridine (4.0 ml) at room temperature for 1 h. The crude acetate, after the usual work-up, was purified by column chromatography on silica gel (75 g), using ether–benzene (5:95) as the eluent, to afford an oil (0.73 g: 42%) whose IR and ^{1}H NMR spectra were identical with those of **29**.

Reaction of ***27*** *with Concentrated Sulfuric Acid in Acetic Acid.* A mixture of **27** (132 mg), concentrated sulfuric acid (0.58 ml), and acetic acid (6.60 ml) was refluxed for 2 h. After the same work-up as described for the preparation of **17**, the crude product was chromatographed on silica gel (12 g), using hexane–benzene (2:3) as the eluent, to give the recovered **27** (85 mg: 64%).

Further elution with ether–benzene (3:97) afforded (*R*)-3-(3-acetoxypropyl)-2,3-dihydro-7-isopropyl-3,4-dimethyl-6-nitronaphtho[2,3-*b*]furan-2-one (**31**) (25 mg: 16%) as an oil; $[\alpha]_D$ +34° (*c* 0.955); IR: 1808, 1740, 1643, 1533, 1355 cm^{-1}; ^{1}H NMR: *ca.* 1.25 (2H, m, –$CH_2C\underline{H}_2CH_2OAc$), 1.37 (6H, d, J=7 Hz, –$CH(C\underline{H}_3)_2$), 1.65 (3H, s, C_3–CH_3), 1.94 (3H, s, –$OCOCH_3$), *ca.* 2.15 (2H, m, –$C\underline{H}_2CH_2CH_2OAc$), 2.71 (3H, s, C_4–CH_3), 3.55 (1H, m, –C<u>H</u>$(CH_3)_2$), 3.87 (2H, t, J=6.5 Hz, –$CH_2CH_2C\underline{H}_2OAc$), 7.32 (1H, s, C_9–H), 7.74 (1H, s, C_8–H), 8.36 (1H, s, C_5–H; 20% NOE enhancement was observed on irradiation of the signal at δ 2.71); UV: λ_{max}^{EtOH} 227 nm (log ε 4.68), 261 (4.36), 278sh (4.18), 361 (3.96), 410sh (3.51), 430sh (3.40). Found: C, 66.03; H, 6.49; N, 3.40%. Calcd for $C_{22}H_{25}O_6N$: C, 66.15; H, 6.31; N, 3.51%.

Synthesis and Stereochemistry of Hypusine, a New Amino Acid in Bovine Brain.[1]

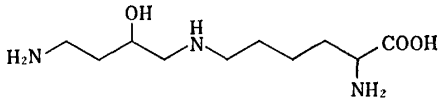
Tetsuo SHIBA,* Hitoshi AKIYAMA, Isao UMEDA, Satoshi OKADA, and Tateaki WAKAMIYA

Department of Chemistry, Faculty of Science, Osaka University, Toyonaka, Osaka 560

(Received July 25, 1981)

Hypusine, a new basic amino acid occurring in the homogenate of bovine brain tissue, was synthesized to determine the absolute structure. N^{α}-Benzyloxycarbonyl-L-lysine benzyl ester was coupled with (*S*)- or (*R*)-4-benzyloxycarbonylamino-1-bromo-2-butanol derived from L- or D-malic acid, respectively. The products were deprotected by catalytic hydrogenation. One of the synthetic compounds, *i.e.*, (2*S*,9*R*)-2,11-diamino-9-hydroxy-7-azaundecanoic acid, was completely identical with natural hypusine in all respects.

Hypusine (**1**) had been isolated from bovine brain and its unique structure was determined chemically and spectrometrically to be 2,11-diamino-9-hydroxy-7-azaundecanoic acid.[2] The term of hypusine came from hydroxyputrescine and lysine as composite moieties which joined together by an elimination of ammonia as shown in Fig. 1. Of the two asymmetric carbon atoms in hypusine molecule, the configuration of *C*-2 corresponding to α-carbon atom of lysine had been decided to be of L(*S*) form. This conclusion was given by the fact that periodic acid–permanganate oxidation of hypusine afforded L-lysine.[2] On the other hand, the configuration of *C*-9 in hydroxyputrescine moiety could not be ascertained yet. To clarify the stereochemistry of this carbon atom, we attempted to synthesize two possible isomers, namely (2*S*,9*S*)- and (2*S*,9*R*)-2,11-diamino-9-hydroxy-7-azaundecanoic acid.

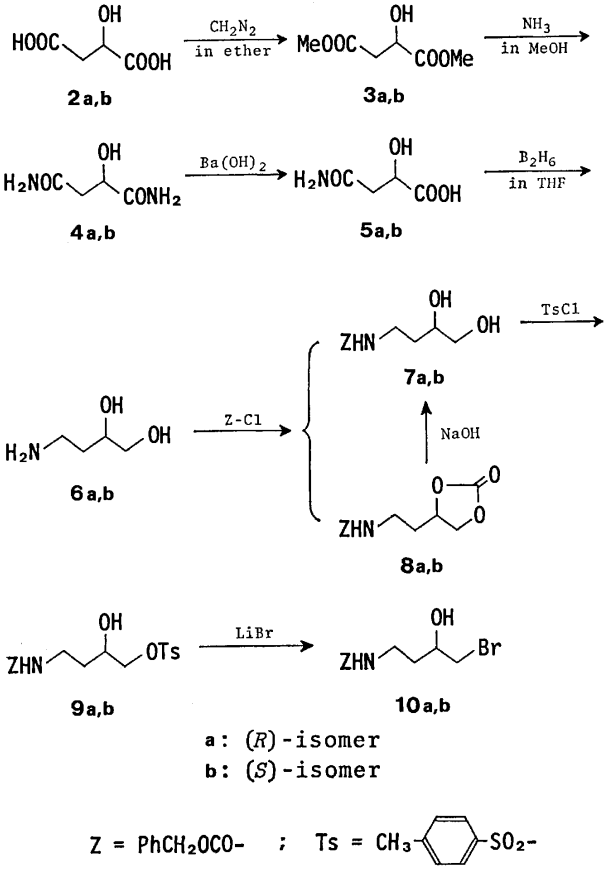


Hypusine (**1**)

Fig. 1. The structure of hypusine.

A principle of the synthesis of this new amino acid is based on the coupling of L-lysine and 4-amino-1-bromo-2-butanol as shown in Scheme 4. Both enantiomers of the latter component can be obtained from L- and D-malic acid, respectively. While L-malic acid was commercially available, D-isomer had to be prepared by optical resolution of the racemic compound with *S*(−)-1-phenylethylamine.

Malic acid (**2**) of either configuration was esterified with diazomethane to give dimethyl ester **3**, which was converted to β-malamic acid (**5**) according to Freudenberg's procedure.[3] Hydrogenation of β-malamic acid (**5**) to 4-amino-1,2-butanediol (**6**) with $LiAlH_4$ failed because of a poor solubility of the acid **5** in ether or THF. However, reduction with diborane could be employed satisfactorily for this purpose. Thus, the suspension of β-malamic acid in THF was heated under reflux with diborane.[4] The product was purified by ion-exchange column chromatography of Dowex 50 W×2 (NH_4^+ form) to isolate the desirable amino alcohol **6**. The amino group of the compound **6** was then protected with benzyloxycarbonyl group to give 4-benzyloxycarbonylamino-1,2-butanediol (**7**).



Scheme 1.

Although, a small amount of cyclic carbonate derivative **8** was formed in this reaction as a by-product, the carbonate was quantitatively saponified to **7** giving the total yield of *N*-benzyloxycarbonylation of around 90%. Presumably, benzyloxycarbonylation to primary hydroxyl group occurred in a minor degree and a cyclization through an elimination of benzyl alcohol gave the carbonate **8**.

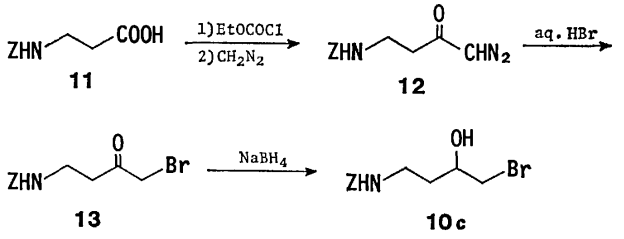
O-Tosylation of **7** in dichloromethane using pyridine as a base afforded predominantly the primary *O*-tosylate **9** along with formation of the ditosylate as a minor product. *O*-Tosylate **9** was finally converted into 4-benzyloxycarbonylamino-1-bromo-2-butanol (**10**) with LiBr. Thus, we could prepare successfully the carbon unit to construct hydroxyputrescine moiety.

According to this method, two optically active isomers were obtained starting from D- and L-malic acid, respectively.

Parallel to the preparation of optically active **10**, a racemic compound was also synthesized for the preliminary experiment to find out the optimum coupling conditions with lysine residue. The racemic compound **10c** was prepared rather easily from *N*-benzyloxycarbonyl-β-alanine as shown in Scheme 2. Mixed carbonic carboxylic anhydride of *N*-benzyloxycarbonyl-β-alanine (**11**) was allowed to react with diazomethane to give the diazo ketone derivative **12**.[5] The diazo ketone in ether was treated with an equivalent of hydrobromic acid to afford the bromo ketone **13**. Sodium borohydride reduction of **13** gave the racemic bromo alcohol **10c**.

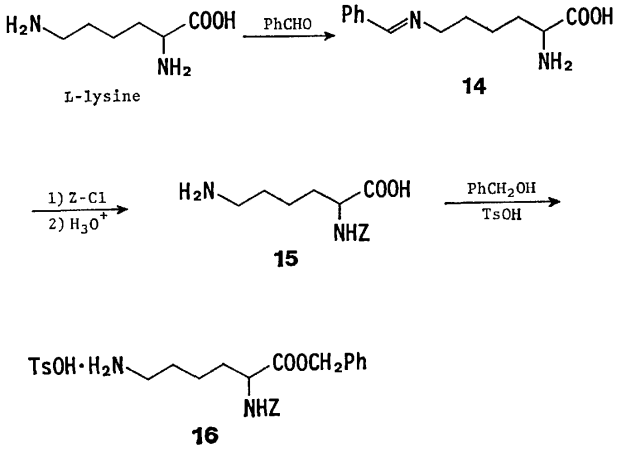
For modification of the lysine moiety to a suitable form for the coupling, L-lysine was first converted to N^{α}-benzyloxycarbonyl-L-lysine (**15**) *via* N^{ε}-benzylidene derivative **14**.[6] Since monoacylated lysine was scarcely soluble in both organic solvents and water, the compound **15** was changed to benzyl ester **16** in the usual way using benzyl alcohol and *p*-toluenesulfonic acid as a catalyst in benzene[7] (Scheme 3).

Coupling reaction of racemic 4-benzyloxycarbonylamino-1-bromo-2-butanol (**10c**) with N^{α}-benzyloxycarbonyl-L-lysine benzyl ester (**16**) was carried out in several organic solvents. The yield of hypusine was estimated by amino acid analysis after hydrogenation of the coupling product without any purification procedure. From the results of this preliminary experiment as shown in Table 1, methanol, ethanol, and *t*-butyl alcohol seemed to be preferable solvents. However, we realized later on that the use of methanol and ethanol caused undesirable ester exchange reaction. This disadvantage could be effectively overcome by employment of *t*-butyl alcohol as a reaction solvent.



11 12 13 10c

Scheme 2.



Scheme 3.

Based on the above results, optically active bromo alcohol **10** was condensed with N^{α}-benzyloxycarbonyl-L-lysine benzyl ester *p*-toluenesulfonate (**16**) in *t*-butyl alcohol in the presence of two equivalents of triethylamine.[8] Protecting groups of the coupling product were then removed by catalytic hydrogenation in 50% *t*-butyl alcohol (Scheme 4). Crude hypusine thus obtained was purified by column chromatography of Dowex 50 W×2 (NH_4^+ form) with dilute NH_4OH eluent.

According to the above procedure, both (2*S*,9*S*)- and (2*S*,9*R*)-hypusine were obtained as crystalline dihydrochloride. Several comparisons of synthetic compounds with natural hypusine were achieved physicochemically, chromatographically, and spectrometrically. However, both isomers did not show significant differences in most respects. For example, NMR spectra (Fig. 2) and retention times in amino acid analyses of both synthetic products were virtually identical with those of natural one. Only melting point and

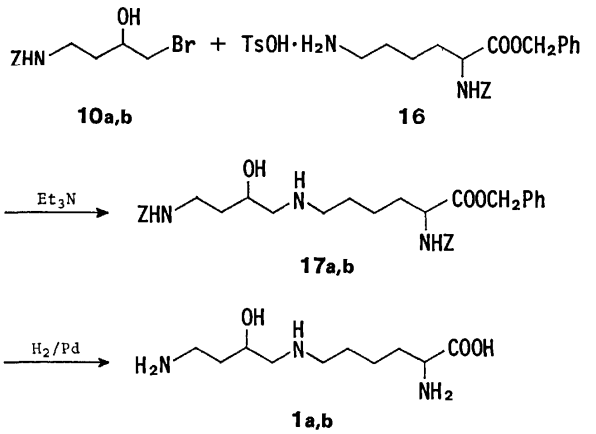

Scheme 4.

specific rotation indicated that the natural compound should be (2*S*,9*R*)-isomer rather than (2*S*,9*S*)-one, though still ambiguously. Fortunately, IR spectra of synthetic compounds showed much difference each other and the spectrum of (2*S*,9*R*)-isomer was completely identical with that of natural hypusine (Fig. 3). Judging from these results thus obtained, we could now determine the absolute structure of hypusine to be (2*S*,9*R*)-2,11-diamino-9-hydroxy-7-azaundecanoic acid.

The total synthesis of hypusine established in this investigation may contribute also to supply an enough amount of the sample of this unique brain amino acid for biological tests.

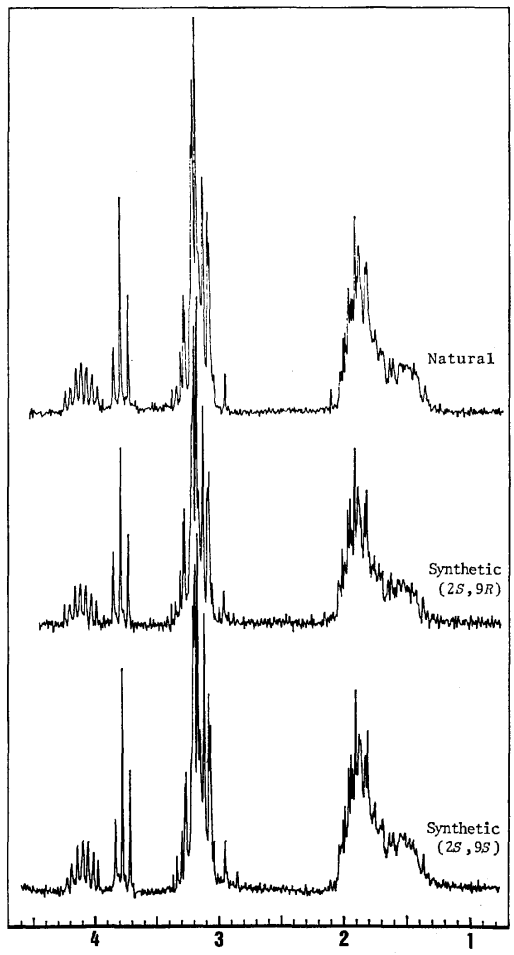

Fig. 2. NMR spectra of natural hypusine and synthetic compounds in D_2O.

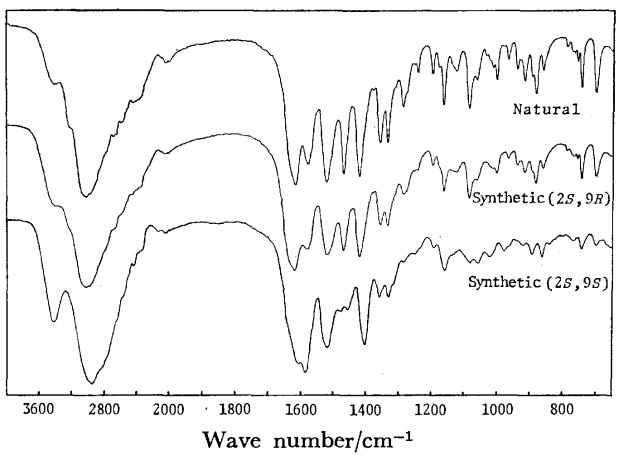

Fig. 3. IR spectra of natural hypusine and synthetic compounds (KBr disk).

Experimental

All melting points are uncorrected. The specific rotations were measured with a Perkin-Elmer 141 polarimeter. NMR spectra were obtained with a Varian XL-100-15 spectrometer and the chemical shifts were given in δ values (ppm) from sodium 2,2-dimethyl-2-silapentane-5-sulfonate (DSS). IR spectra were taken in KBr disk with a Hitachi EPI-G21 spectrophotometer. Amino acid analyses were carried out on a 15 cm column at 55 °C with a Hitachi KLA-3 amino acid analyzer. A buffer solution of 0.7 M (1 M=1 mol dm^{-3}) sodium citrate, pH 5.28, containing 3% NaCl was used for the analysis.

Preparation of D-*Malic Acid by Optical Resolution.* To a solution of DL-malic acid (131 g, 0.98 mol) in 650 ml of water was added *R*(+)-1-phenylethylamine (118 g, 0.98 mol). The mixture was allowed to stand for 2 d and *R*(+)-amine salt of L-malic acid precipitated was filtered off. The filtrate was concentrated *in vacuo* until a small amount of crystals appeared. After allowing to stand overnight, the second precipitate was filtered again. This procedure was repeated three times and the precipitates combined were recrystallized from water.

The filtrate after taking off fourth precipitate and the mother liquor of recrystallization were combined and concentrated *in vacuo*. To the residue was added 310 ml of 4 M NaOH, and then *R*(+)-amine freed was extracted with benzene three times. Aqueous layer was neutralized with 4 M HCl and concentrated *in vacuo*. Solid residue was triturated with acetone several times to extract malic acid and acetone extract was concentrated *in vacuo*. The residue (56 g) was dissolved in 280 ml of water and *S*(−)-1-phenylethylamine (67 g, 0.54 mol) was added. The precipitate of *S*(−)-amine salt of D-malic acid was obtained by the same procedure as mentioned above and crude salt was recrystallized from water. The pure salt (58 g) was dissolved in 120 ml of 4 M NaOH and *S*(−)-amine was extracted with benzene. Aqueous layer was neutralized with 4 M HCl and concentrated *in vacuo*. D-Malic acid was extracted with acetone by the same treatment as mentioned above and recrystallized from anhydrous ether, yield 17 g (13%), mp 97—99 °C,[9] $[\alpha]_D^{14}$ +6.4° (*c* 1.9, acetone).[9] When *S*(−)-1-phenylethylamine was first used for the resolution, actually, optically active D-malic acid in a satisfactorily pure state was not obtained.

*β-Malamic Acid (**5**).* Optically active malic acid dimethyl ester, was converted to β-malamic acid according to Freudenberg's method.[3]

*(R)-4-Amino-1,2-butanediol (**6a**).* Powdered D-β-malamic acid (**5a**) (9.0 g, 0.068 mol) was suspended in 600 ml of anhydrous tetrahydrofuran (THF). To this suspension was introduced diborane, which was generated from boron trifluoride etherate (60 g, 0.42 mol) in diglyme by addition of small portions of sodium borohydride (12.5 g, 0.33 mol) with a gentle stream of nitrogen under cooling in an ice bath. The suspension was then heated under reflux for 3 d and the clear solution obtained was cooled in an ice bath. To the reaction mixture was added water

carefully until no gas generation occurred. The solution was acidified to pH 4 with hydrochloric acid and concentrated *in vacuo*. The residue was dissolved in cold water and insoluble material was filtered off. The filtrate was concentrated *in vacuo* again and the residue was chromatographed on Dowex 50W×2 (200—400 mesh, NH_4^+ form) column, which was first washed with 1 l of water. Elution with 2.8% NH_4OH gave a fraction of positive ninhydrin reaction, which was then concentrated *in vacuo*. (*R*)-4-Amino-1,2-butanediol was obtained as highly hygroscopic oil, yield 4.3 g (61%).

*(S)-4-Amino-1,2-butanediol (**6b**).* L-β-Malamic acid (**5b**) gave (*S*)-amino alcohol **6b** with the same procedure as in the preparation of **6a** in a yield of 56%. A part of (*S*)-amino alcohol was distilled to obtain an analytical sample, bp 172—175 °C/0.10—0.15 mmHg,† $[\alpha]_D^{25}$ −23.0° (*c* 1.87, CH_3OH). Found: C, 41.53; H, 10.40; N, 11.85%. Calcd for $C_4H_{11}NO_2 \cdot 3/5H_2O$: C, 41.43; H, 10.61; N, 12.08%.

*(R)-4-Benzyloxycarbonylamino-1,2-butanediol (**7a**).* To a solution of (*R*)-4-amino-1,2-butanediol (**6a**) (4.20 g, 40.0 mmol) in 20 ml of water and 30 ml of ether were added benzyloxycarbonyl chloride (7.50 g, 44.0 mmol) and 11 ml of 4 M NaOH dropwise with vigorous stirring at 0 °C. After addition of reagents, the reaction mixture was stirred at room temperature overnight and neutralized with 2 M HCl. The product was extracted with ether several times. The extract was dried over magnesium sulfate and concentrated *in vacuo*. Oily residue obtained was purified by silica-gel column chromatography. Elution was carried out with chloroform and methanol (95:5 v/v) to separate (*R*)-4-benzyloxycarbonylamino-1,2-butanediol (**7a**) and its carbonate **8a**. The main product **7a** was recrystallized from chloroform and petroleum ether, yield 7.30 g (76%), mp 67—68 °C, $[\alpha]_D^{22}$ +5.8° (*c* 1.9, $CHCl_3$), and IR 3300 cm^{-1}. Found: C, 60.09; H, 7.15; N, 5.90%. Calcd for $C_{12}H_{17}NO_4$: C, 60.24; H, 7.16; N, 5.85%.

By-product **8a** was recrystallized from ethyl acetate and hexane, yield 1.38 g (13%), mp 36—38 °C, $[\alpha]_D^{22}$ +27.6° (*c* 1.20, AcOEt), and IR 1790 cm^{-1}. Found: C, 59.07; H, 5.73; N, 5.25%. Calcd for $C_{13}H_{15}NO_5$: C, 58.86; H, 5.70; N, 5.28%.

The carbonate **8a** was quantitatively saponified to **7a** in methanol with two equivalents of 2 M NaOH.

*(S)-4-Benzyloxycarbonylamino-1,2-butanediol (**7b**).* The same procedure as in the preparation of **7a** was applied to get (*S*)-isomer (**7b**). Carbonate **8b** was also obtained in 10% yield, mp 37—39 °C, $[\alpha]_D^{25}$ −27.4° (*c* 1.10, AcOEt). Found: C, 58.99; H, 5.72; N, 5.48%. It was quantitatively saponified to **7b** and the total yield of diol **7b** was 80%, mp 66—67 °C, $[\alpha]_D^{25}$ −6.0° (*c* 2.2, $CHCl_3$). Found: C, 59.87; H, 7.13; N, 5.94%.

*(R)-4-Benzyloxycarbonylamino-1-p-tolylsulfonyloxy-2-butanol (**9a**).* (*R*)-4-Benzyloxycarbonylamino-1,2-butanediol (**7a**) (2.00 g, 8.36 mmol) was dissolved in 25 ml of dichloromethane and pyridine (1:1 v/v). To the solution was added *p*-toluenesulfonyl chloride (1.75 g, 9.18 mmol) by portions in 15 min at 5 °C. The reaction mixture was stirred for 21 h at the same temperature. The product was extracted with chloroform several times after an addition of water. The extract was washed with water three times, dried over magnesium sulfate, and concentrated *in vacuo*. Oily residue was chromatographed on silica-gel column. Elution was carried out with benzene–ethyl acetate (9:1 v/v) to separate ditosylate (0.55 g, 12%) and monotosylate **9a** which was recrystallized from ethyl acetate and hexane, yield 2.22 g (68%), mp 68—69 °C, $[\alpha]_D^{22}$ +3.1° (*c* 1.1, AcOEt). Found: C, 57.93; H, 5.97; N, 3.63; S, 8.00%. Calcd for $C_{19}H_{23}NO_6S$: C, 58.00; H, 5.89; N, 3.56; S, 8.15%.

*(S)-4-Benzyloxycarbonylamino-1-p-tolylsulfonyloxy-2-butanol (**9b**).* (*S*)-Monotosylate (**9b**) was prepared similarly to (*R*)-isomer in a yield of 65%, mp 67—69 °C, $[\alpha]_D^{22}$ −3.0° (*c* 1.1, AcOEt). Found: C, 57.69; H, 5.89; N, 3.55; S, 8.14%.

*(R)-4-Benzyloxycarbonylamino-1-bromo-2-butanol (**10a**).* The mixture of (*R*)-monotosylate **9a** (300 mg, 0.76 mmol) and $LiBr \cdot H_2O$ (250 mg, 2.40 mmol) was heated under reflux in 8 ml of acetone for 5 h. Solvent was evaporated *in vacuo* and the residue was dissolved in ethyl acetate. Insoluble material was once filtered off and the filtrate was washed with water several times. Organic layer was dried over magnesium sulfate and concentrated *in vacuo*. Oily residue was chromatographed on silica-gel column using an eluent of benzene–ethyl acetate (4:1 v/v). Bromo alcohol **10a** was obtained in a yield of 95% (220 mg), $[\alpha]_D^{18}$ +15° (*c* 1.6, AcOEt). Found: C, 47.22; H, 5.36; N, 4.62; Br, 26.14%. Calcd for $C_{12}H_{16}NO_3Br$: C, 47.69; H, 5.34; N, 4.64; Br, 26.45%.

*(S)-4-Benzyloxycarbonylamino-1-bromo-2-butanol (**10b**).* (*S*)-Bromo compound **10b** was prepared similarly in a yield of 97%, $[\alpha]_D^{25}$ −15° (*c* 1.7, AcOEt). Found: C, 47.53; H, 5.43; N, 4.56; Br, 26.30%.

*4-Benzyloxycarbonylamino-1-bromo-2-butanone (**13**).* To a solution of *N*-benzyloxycarbonyl-β-alanine (9.4 g, 0.042 mol) in 300 ml of chloroform were added triethylamine (5.8 ml, 0.042 mol) and ethyloxycarbonyl chloride (4.0 ml, 0.042 mol) under cooling in an ice bath. The reaction mixture was stirred for 1 h at 0 °C and then a large amount of anhydrous ether was added to precipitate triethylamine hydrochloride. The precipitate was quickly filtered off and the filtrate was added to an excess of diazomethane in ether which was precooled in an ice bath. The reaction was continued for 1 h at 0 °C. Since a small amount of triethylamine hydrochloride was precipitated again during the reaction, the reaction mixture was once filtered. The filtrate was then warmed at 30 °C to remove unreacted diazomethane and concentrated *in vacuo*. The crude product was purified by silica-gel column chromatography using chloroform as an eluent to give the diazo ketone **12** (5.7 g, 60%).

To a solution of the diazo ketone (1.1 g, 4.5 mmol) in 30 ml of ether was added 0.78 ml of 48% hydrobromic acid (4.5 mmol) dropwise in 1 h under vigorous stirring in an ice bath. After stirring for more 1 h, the reaction mixture was neutralized with aqueous sodium hydrogencarbonate and extracted with ethyl acetate. The extract was dried over magnesium sulfate and concentrated *in vacuo* to obtain 4-benzyloxycarbonylamino-1-bromo-2-butanone (**13**), yield 1.3 g (95%). The crude product was recrystallized from ethanol and petroleum ether, yield 1.0 g (73%), mp 42—43 °C. Found: C, 48.36; H, 4.80; N, 4.84; Br, 26.92%. Calcd for $C_{12}H_{14}NO_3Br$: C, 48.02; H, 4.70; N, 4.67; Br, 26.62%.

*(±)-4-Benzyloxycarbonylamino-1-bromo-2-butanol (**10c**).* 4-Benzyloxycarbonylamino-1-bromo-2-butanone (**13**) (900 mg, 3.0 mmol) was dissolved in methanol and sodium borohydride (38 mg, 1.1 mmol) was added to the solution under cooling in an ice bath. After stirring for 2 h, the reaction mixture was neutralized to pH 7 by an addition of 5% acetic acid and concentrated *in vacuo*. Ethyl acetate was added to the residue and an insoluble material was filtered off. The solution was washed with water, dried over magnesium sulfate, and concentrated *in vacuo*. Oily residue was pu-

† 1 mmHg≈133.322 Pa.

rified by silica-gel column chromatography and racemic 4-benzyloxycarbonylamino-1-bromo-2-butanol (**10c**) was eluted with benzene–ethyl acetate (4:1 v/v) in a quantitative yield (900 mg) as colorless oil. Found: C, 47.55; H, 5.30; N, 4.50; Br, 26.15%. Calcd for $C_{12}H_{16}NO_3Br$: C, 47.69; H, 5.34; N, 4.64; Br, 26.45%.

Coupling Reaction of ***10c*** *and* ***16***. A solution of (±)-4-benzyloxycarbonylamino-1-bromo-2-butanol (**10c**) (30 mg, 0.10 mmol), N^{α}-benzyloxycarbonyl-L-lysine benzyl ester *p*-toluenesulfonate (**16**) (54 mg, 0.10 mmol), and triethylamine (21 mg, 0.20 mmol) in 10 ml of benzene was refluxed for 5 d. The reaction mixture was concentrated *in vacuo*. A solution of the residue in 50% *t*-butyl alcohol, added with 2 M hydrochloric acid, was hydrogenated with Pd catalyst. After the completion of hydrogenation, catalyst was filtered off. The filtrate was concentrated *in vacuo* and the residue was dissolved in water. The solution was applied to an amino acid analysis.

*(2S,9R)-2,11-Diamino-9-hydroxy-7-azaundecanoic Acid (Hypusine) (**1a**) Dihydrochloride*. A solution of (*R*)-4-benzyloxycarbonylamino-1-bromo-2-butanol (**10a**) (0.82 g, 2.7 mmol), N^{α}-benzyloxycarbonyl-L-lysine benzyl ester *p*-toluenesulfonate (1.5 g, 2.8 mmol), and triethylamine (0.76 ml, 5.5 mmol) in *t*-butyl alcohol was refluxed for 5 d. The reaction mixture was concentrated *in vacuo* and the residue was dissolved in 10 ml of 50% *t*-butyl alcohol. It was hydrogenated to remove the protecting groups in the presence of Pd black under a gentle stream of hydrogen. The solution was kept acidic by an addition of 1 M hydrochloric acid through the hydrogenation reaction. After the completion of reduction, catalyst was filtered off and the filtrate was concentrated *in vacuo*. The crude product was purified by column chromatography on Amberlite IRC-50 (CG-Type 1, 1×68 cm, NH_4^+ form) using 0.28% NH_4OH as an eluent. Fractions containing hypusine were collected and concentrated *in vacuo*. The residue was dissolved in water and pH of the solution was adjusted to 5.2 with dilute hydrochloric acid. It was concentrated *in vacuo* to obtain hypusine (**1a**) dihydrochloride, which was recrystallized from 90% methanol, yield 172 mg (21%),[8] mp 234—236 °C (decomp),[10] $[\alpha]_D^{17}$ +6.8° (*c* 0.12, 6 M HCl).[10] Found: C, 38.10; H, 8.24; N, 13.27; Cl, 22.79%. Calcd for $C_{10}H_{25}N_3O_3Cl_2 \cdot 1/2\ H_2O$: C, 38.10; H, 8.31; N, 13.33; Cl, 22.49%.

*(2S,9S)-2,11-Diamino-9-hydroxy-7-azaundecanoic Acid (**1b**) Dihydrochloride*. This was prepared by the same procedure as described above. The hydrochloride was recrystallized from 90% methanol and ethanol in a yield of 21%, mp 238—240 °C (decomp),[10] $[\alpha]_D^{23}$ +16° (*c* 0.10, 6 M HCl).[10] Found: C, 39.14; H, 8.28; N, 13.44; Cl, 23.02%, Calcd for $C_{10}H_{25}N_3O_3Cl_2$: C, 39.22; H, 8.23; N, 13.72; Cl, 23.16%.

The authors wish to express their thanks to Professor Yasuo Kakimoto of Ehime University Medical School and Dr. Teruo Nakajima of Osaka University Medical School for supply of natural hypusine. The present work was partially supported by Grant-in-Aid for Scientific Research No. 921107 from the Ministry of Education, Science and Culture.

Solvent Effects in the Conversion of Phenyldiazomethane into Stilbene and Spirooxetane in the Reaction with Chloranil

Takumi Oshima, Ryoji Nishioka, and Toshikazu Nagai*

Institute of Chemistry, College of General Education, Osaka University, Toyonaka, Osaka 560

(Received July 29, 1981)

A stereochemical study was made of the reaction of phenyldiazomethane(**1**) with chloranil(**2**) at 20 °C in 28 aprotic solvents. The products were *trans*-spirooxetane(**4**) and *cis-trans* mixtures of stilbene(**3**) (*ca.* 2—5 times *cis*-rich). The molar ratios of *cis*-**3** to the sum of the *trans*-**3** and **4** tended to increase, whereas the **4** to *trans*-**3** ratios decrease with the increase in the solvent basicity and polarity. These effects of solvents on the product distributions were interpreted in terms of the effects of the solvent basicity and polarity on the stereoselective formation of the diazonium betaine intermediate and on the conformational isomerism. Moderately successful linear-free-energy(LFE) relationships were established for these product ratios with the aid of the combination of the empirical solvent basicity parameter, D_n, and the Kirkwood function, $f(\varepsilon)$, or E_T values as the solvent polarity parameters.

Our recent studies have shown that the decomposition of phenyldiazomethane (**1**) and its substituted homologs with chloranil(**2**) gives *trans*-spirooxetanes and stilbenes.[1] The stereochemistry of these products was 100% *trans* for spirooxetanes and *cis*-isomer-rich for stilbenes: the *cis*:*trans* ratios of the stilbenes increased with the electron withdrawal of the substituents. The preliminary solvent effects showed that THF brings about higher *cis*:*trans* ratios of stilbenes and lower relative yields of spirooxetanes than 1,2-dichloroethane. We have now extended the work to various aprotic solvents. Thus, the present paper is aimed to make a more penetrating interpretation of the effects of solvents on the stereochemical phenomena and on the product distributions. For this purpose, the use of the linear correlations with solvent basicity and the polarity parameters was examined.

Results and Discussion

As was described in a previous paper,[1] the formation of stilbene (**3**) and *trans*-spirooxetane(**4**) can be well explained by postulating two diazonium betaine intermediates, I and II (Scheme 1). II may be produced by a nucleophilic attack of **1** on I. II is degradated to **3** *via* the elimination of N_2 and **2** (Path a) or to **4** *via* the intramolecular cyclization (Path b). The reaction of **1** with **2** also gave several by-products resulting from the nucleophilic attack of residual water on I.[1]

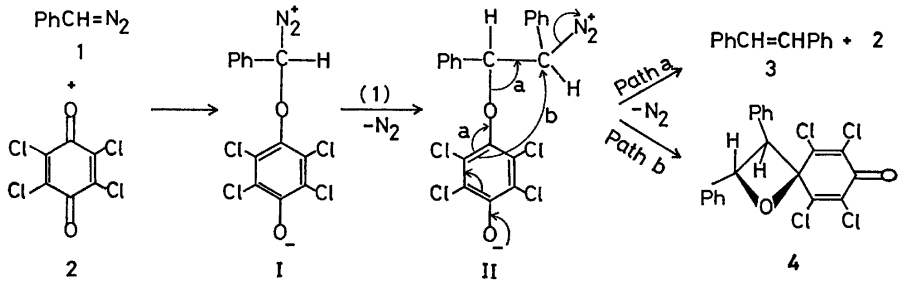
Our attention in the present study was restricted to the solvent effects in the stereochemical pathway leading to **3** and **4**; thus, the only efforts to determine the distribution of *cis*-, *trans*-**3** and **4** were made by the use of high-performance liquid chromatography. The results in a wide variety of aprotic solvents are tabulated in Table 1.

It is noteworthy that the thermodynamically less stable *cis*-**3** was preferentially formed, *ca.* 2 to 5 times more than *trans*-**3**. The isomer ratios of **3** were high in acyclic ethers, such as diethyl ether and dipropyl ether, but considerably decreased in nitro compounds and nitriles. However, **4** was found to be a stable *trans*-isomer in any solvent, and its relative yields increased in the nonpolar solvents, such as benzene and carbon tetrachloride.

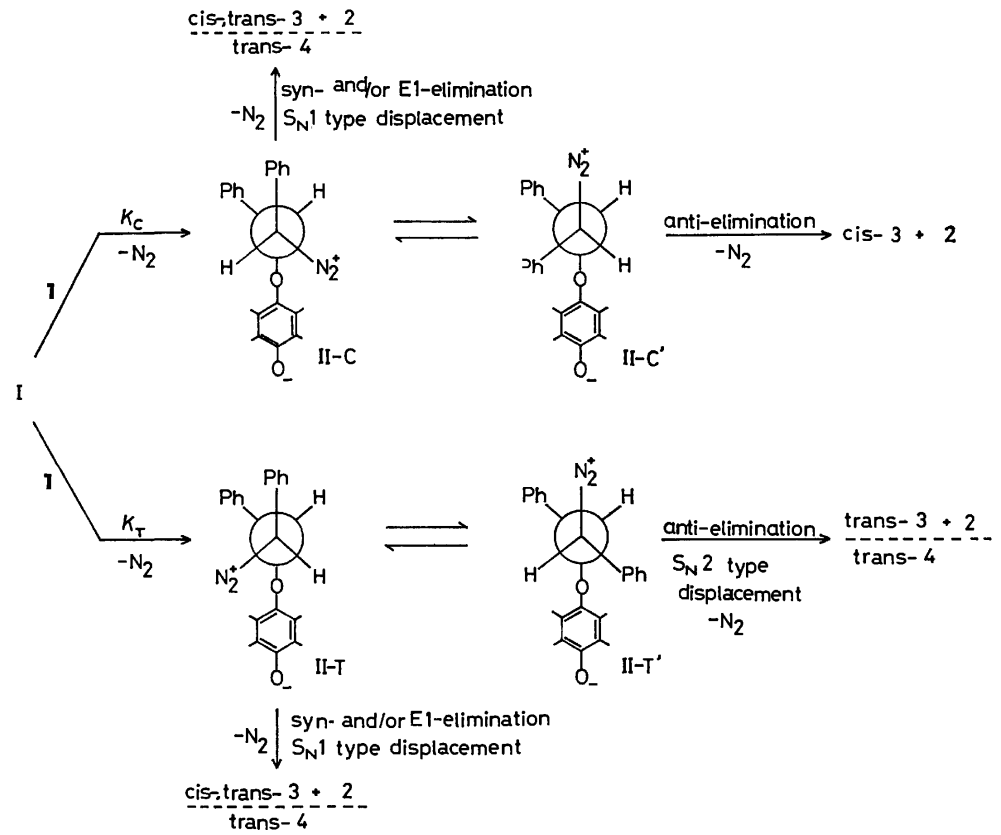
Table 1, Product distributions on the reaction of phenyldiazomethane(**1**) with chloranil(**2**) in various aprotic solvents

	Solvent	Relative yields[a]	
		3(*cis*/*trans*)	**4**
1	Diethyl ether	67.7(5.01)	32.3
2	Dibutyl ether	65.3(4.89)	34.7
3	Dipropyl ether	66.7(4.75)	33.3
4	Carbon tetrachloride	57.7(4.55)	42.3
5	Dimethoxymethane	69.6(4.46)	30.4
6	Tetrahydropyran	78.4(4.32)	21.6
7	Cyclohexanone	86.2(4.03)	13.8
8	Butyl acetate	83.2(3.97)	16.8
9	1,4-Dioxane	70.9(3.94)	29.1
10	1,2-Dimethoxyethane	81.9(3.89)	18.1
11	Tetrahydrofuran	78.9(3.77)[b]	21.1
12	Benzene	60.3(3.70)	39.7
13	Chloroform	59.4(3.65)	40.6
14	Methyl acetate	81.1(3.53)	18.9
15	Isopropyl acetate	79.4(3.45)	20.6
16	Ethyl methyl ketone	87.1(3.40)	12.9
17	1,1-Dichloroethane	63.9(3.39)	36.1
18	1,2-Dichloroethane	61.6(3.34)[b]	38.4
19	Propyl acetate	77.8(3.16)	22.2
20	Nitrobenzene	78.7(3.08)	21.3
21	Butyronitrile	82.3(2.97)	17.7
22	Propionitrile	77.7(2.96)	22.3
23	Acetone	82.9(2.89)	17.1
24	Dichloromethane	59.4(2.88)	40.6
25	Ethyl acetate	81.3(2.71)	18.7
26	Benzonitrile	71.1(2.31)	28.9
27	Acetonitrile	78.2(2.23)	21.8
28	Nitromethane	72.6(1.92)	27.4

a) The total yields of **3** and **4** exceeded 50% in most cases. b) The present values, determined by high-performance liquid chromatographic analyses, are somewhat different from the data obtained by a usual column chromatographic separation method and NMR measurements, probably because of the degradation of **4** into *trans*-**3** and **2** in the previous column-chromatographic treatment.



Scheme 1.



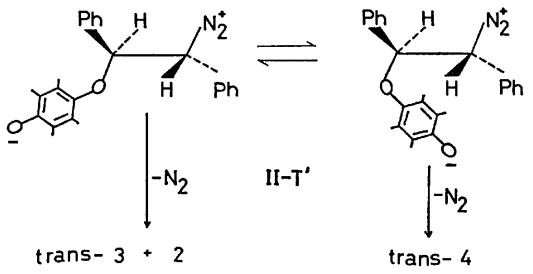
Scheme 2.

Conformational Analysis. As was shown in our previous paper,[1] two conformers, II-C and II-T, may be depicted as the most stable ones for the resulting threo and erythro stereoisomers of II respectively, as may be seen in Scheme 2. From the sterical point of view, II-C is slightly more stable than II-T; *i.e.*, the formation of II-C is a lower-energy process than that of II-T($k_C > k_T$). These conformers, II-C and II-T, can be in equilibrium with each other with the respective conformational isomers, II-C′ and II-T′. On grounds of both the steric and electronic factors, the populations of these threo and erythro rotamers are thought to be in the order of II-C>II-C′, and II-T>II-T′, II-C′ being the most unstable rotamer. The more populous II-C and II-T will afford *cis-trans* mixtures of **3** *via* the syn- and/or *E*1-type elimination, and *trans*-**4** *via* the intramolecular S_N1-type displacement. On the other hand, the less populous II-C′ will prefer to give *cis*-**3** *via* the anti-elimination. II-T′ will prefer to give *trans*-**3** *via* the anti-elimination and *trans*-**4** *via* the intramolecular S_N2-type displacement (Scheme 2).

It should also be noted here that the S_N2-type displacement giving *trans*-**4** is only possible when the bent-ether linkage of these rotamers can be aligned so as to build up a four-membered ring with the central C–C bond, as is represented in the conformational equilibrium of II-T′ (Scheme 3). However, II-C′ will not be transformed into such a crowded structure because of the unfavorable phenyl-phenyl *cis* repulsion. This steric repulsion is the reason why *cis*-**4** was not formed in the present reaction.

Most of the solvents provide a higher yield of *cis*-**3** than the sum of *trans*-**3** and **4**. This apparently means that the reactions from II-C′ and II-T′ proceed more rapidly than those from II-C and II-T.

Solvent Effects on the cis- *to* trans-*Products Ratios.* In the nucleophilic attack of **1**, basic and polar sol-



Scheme 3.

vents tend to stabilize the cation center of I, and thereby appear to suppress its reactivity. As a guiding principle of chemical behavior, the reactivity-selectivity principle(RSP)[2] suggests that the less reactive the diazonium betaine, I, the more stereoselective will be the attack of **1**. Assuming that most of the **3** and **4** arise from the II-C′ and II-T′ conformers, as has been mentioned above, the molar ratios of *cis*-**3** to the sum of *trans*-**3** and **4** may be said to be approximately parallel to the rate ratio(k_C/k_T).

Keeping these considerations in mind, we preliminarily attempted to correlate the logarithms of the molar ratios of *cis*-**3** to the sum of *trans*-**3** and **4** with such empirical solvent-basicity parameters as D_π,[3] Kagiya's $\Delta\nu_D$,[4] Gutmann's *DN*,[5] and Kamlet-Taft's β.[6]

When correlated with these conventional parameters, the regression equations are as follows: log *cis*-**3**/(*trans*-**3**+**4**) $= 0.142+0.149D_\pi$($r=0.782$, $n=24$), $=-0.00512+0.0027\Delta\nu_D$($r=0.731$, $n=22$), $=-0.0337+0.0115DN$ ($r=0.808$, $n=14$), and $=-0.142+0.698\beta$ ($r=0.727$, $n=13$), where r and n are the correlation coefficients and the number of data points respectively. However, the correlations with the solvent-polarity parameters, *i.e.*, the Kirkwood function[7] of dielectric constants ε, $f(\varepsilon)=(\varepsilon-1)/(2\varepsilon+1)$ and Dimroth and Reichart's E_T values,[8] provided worse results for $f(\varepsilon)$, ($r=0.156$, $n=23$) and for E_T, ($r=0.102$, $n=20$). Thus, the specific role of the solvent basicity is much more important than its polarity effects. These statistical results are substantially in accordance with the above assumption that the further stereoselective formation of II-C is achieved by the nucleophilic solvation of the cation of I. The better correlation with D_π than with $\Delta\nu_D$ or β is suggestive of a soft acidity of the cation center(N_2^+) of I, because the indicator compounds employed for the determination of D_π and $\Delta\nu_D$ or β are typical soft-acid TCNE and hard-acid methanol or phenol respectively.[9] Though D_π is a slightly less successful parameter than *DN*, the ten more available values for D_π force us to adopt this parameter in the present discussion.

The more basic and the more polar the solvents are, the easier the conformational rotation into II-C′ and II-T′ will be. Thus, II-C′ and II-T′ play a much more significant role in the product distributions, ultimately increasing the net amount of *cis*-**3**. Therefore, we attempted to improve the above unsatisfactory correlation by the use of two parameters, D_π and the polarity parameter, $f(\varepsilon)$ or E_T. Equations 1 and 2

$$\log\frac{cis\text{-}3}{trans\text{-}3+4} = -0.105 + 0.169D_\pi + 0.632f(\varepsilon) \quad (r=0.863,\ s=0.0684,\ n=23) \quad (1)$$

$$\log\frac{cis\text{-}3}{trans\text{-}3+4} = -0.0957 + 0.155D_\pi + 0.00589E_T \quad (r=0.801,\ s=0.0801,\ n=20) \quad (2)$$

were obtained for the D_π-$f(\varepsilon)$ and D_π-E_T systems respectively. The positive coefficients of both D_π and $f(\varepsilon)$ or E_T are in harmony with the hypothesis that the solvent with a more basic and polar nature induces a more stereoselective formation of II-C than II-T and promotes the conformational transformation into II-C′ and II-T′. A plot of log *cis*-**3**/(*trans*-**3**+**4**) (obsd) *versus* log *cis*-**3**/(*trans*-**3**+**4**)(calcd) according to Eq. 1 is shown in Fig. 1. It is noticeable that nonpolar solvents, such as benzene and carbon tetrachloride, afforded exceptionally lower *cis*-**3** values with respect to the *trans*-products; *i.e.*, the logarithmic ratios were below null. These phenomena may be attributed to the more significant participation of the minor syn- and/or *E*1-type elimination and S_N1-type displacement, most probably from II-C. The reason for this may be that the conformational rotation into II-C′ is energetically more costly compared to the corresponding transformation of II-T into II-T′.

*Solvent Effects on the Spirooxetane(**4**) to* trans-*Stilbene (**3**) Ratios.* It is also interesting to examine the solvent effects on the competitive S_N2-type and anti-elimination processes, giving **4** and *trans*-**3**, from II-T′, because the solvent-dependent equilibrium situation between the extended and the crowded structures, as represented in Scheme 3, plays a significant role in these product ratios. The more basic and more polar solvents are liable to separate the opposite charges of II-T′, so that the amount of **4** decreases as a result of the reduced contribution of the crowded structure. On the other hand, in the less basic and

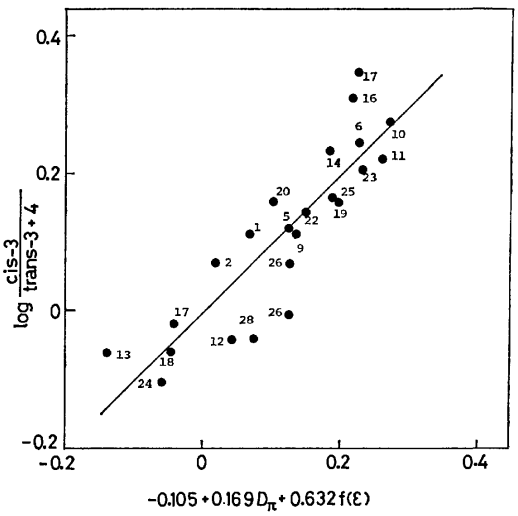


Fig. 1. Plot of $\log\frac{cis\text{-}3}{trans\text{-}3+4}$ (obsd) *versus* $\log\frac{cis\text{-}3}{trans\text{-}3+4}$ (calcd) according to Eq. 1; for point numbers, see Table 1.

less polar solvents the opposed charges should come close together; thus, the growing participation of the crowded structure increases the formation of **4**. A similar type of solvent contribution to product distributions can be expected for the minor S_N1- and/or $E1$-type elimination processes. In consideration of this, we attempted to correlate the logarithms of the molar ratios of **4** to *trans*-**3** with the linear combination of two parameters, D_π and $f(\varepsilon)$ or E_T. Equations 3 and 4 were thus obtained:

$$\log\frac{\mathbf{4}}{\textit{trans}\text{-}\mathbf{3}} = 1.07 - 0.232D_\pi - 2.37f(\varepsilon)$$
$$(r=0.921,\ s=0.0937,\ n=23), \quad (3)$$

$$\log\frac{\mathbf{4}}{\textit{trans}\text{-}\mathbf{3}} = 2.16 - 0.259D_\pi - 0.0514E_T$$
$$(r=0.930,\ s=0.0883,\ n=20). \quad (4)$$

The negative coefficients in both the basicity and the polarity parameters are consistent with the solvation environment expected above.

A comparison of the coefficients in Eqs. 1 and 2 with those in Eqs. 3 and 4 shows that the effects of the solvent basicity are more enhanced in log *cis*-**3**/(*trans*-**3**+**4**) than in log **4**/*trans*-**3**. The reverse is necessarily true for the contribution of the solvent polarity. A plot of log **4**/*trans*-**3**(obsd) *versus* log **4**/*trans*-**3**(calcd) according to Eq. 4 is shown in Fig. 2.

This figure consists of two solvent groups except for 1,4-dioxane. One group on the high side contains aliphatic chlorinated solvents (very low D_π and moderate high E_T) and acyclic ethers and benzene (moderate high D_π and very low E_T). Therefore, the high **4**:*trans*-**3** ratios can be ascribed to the low D_π or E_T values; that is, these solvents can not well stabilize the cation or anion center of II, increasing the population of the crowded structures. On the other hand, the other group on the low side is characterized by such solvent properties as a relatively strong nucleophilicity(high D_π) and/or electrophilicity

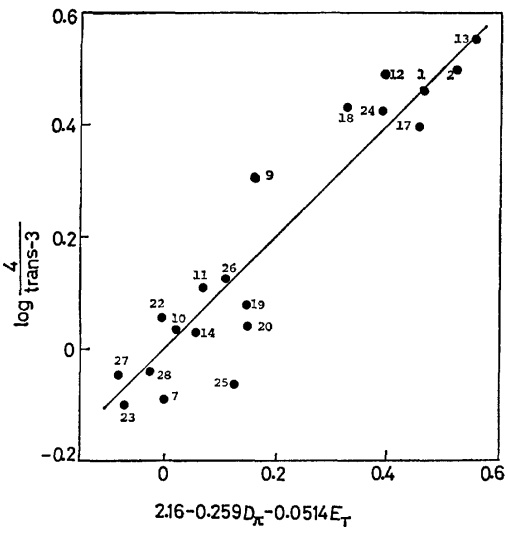

Fig. 2. Plot of $\log\frac{\mathbf{4}}{\textit{trans}\text{-}\mathbf{3}}$ (obsd) *versus* $\log\frac{\mathbf{4}}{\textit{trans}\text{-}\mathbf{3}}$ (calcd) according to Eq. 4; for point numbers, see Table 1.

(high E_T). Thus, the ketones, such as acetone and cyclohexanone, reduce the **4**: *trans*-**3** ratios much more because of both the effective nucleophilic and electrophilic solvations of the respective cation N_2^+ and anion chloranil moieties of II, consequently decreasing the population of the crowded structures. Though the esters have D_π values very close to those of ketones, the **4**:*trans*-**3** ratios appreciably increased on account of the slight decrease in E_T values. Similarly, though the E_T values for nitro compounds and nitriles are higher than those for ketones, the less basic properties (lower D_π) of these solvents induce more formation of **4**.

Experimental

The *cis*:*trans* ratio of **3** and the overall yields of **3** and **4** were determined by means of JASCO tri-rotor high-performance liquid chromatography (HPLC), using naphthalene as the internal standard. The HPLC analysis was carried out at room temperature using a 250 mm×4.6 mm column packed ODS (octadecyl silane on silica gel; methanol–water(4:1 by volume); flow rate, 1—1.5 ml/min. The UV detector was calibrated at 280 nm with standard mixtures of known concentrations of *cis*- and *trans*-**3** and **4**. The average error in the *cis*:*trans* ratio was *ca.* 3% or better. The relative retention times were as follows: naphthalene (1.0), *cis*-**3**(1.8), *trans*-**3**(2.3), and **4**(4.5).

Materials. The phenyldiazomethane(**1**) was prepared according to the procedure described by Closs and Moss[10] and was used without further purification. The chloranil (**2**) was of commercial origin and was recrystallized from benzene. All the solvents used were purified by the usual method.[11]

General Procedure. To a solution or suspension of **2** (0.50 g, 2.03 mmol) in a solvent (30 ml) was added, drop by drop, a solution of **1** (0.50 g, 4.24 mmol) in the same solvent(10 ml) for 10 min at 20 °C. The deep-red color of the mixture rapidly disappeared with a violent evolution of N_2. After 1-h stirring, the solvents (except for benzene) boiling below 100 °C were evaporated, and the pasty residue was redissolved in benzene (40 ml). In the case of the higher-boiling solvents, the reaction solutions were submitted to the following treatment without any work-up. In these reaction solutions, naphthalene(100 mg) was dissolved as an internal standard and two-milliliter aliquots were diluted with benzene until the total volume of solution rose to 25 ml. The sample solutions thus prepared were analyzed by HPLC.

(Received July 30, 1981)

Dialkyl arylphosphonates are prepared by the palladium-catalyzed reaction of aryl bromides with dialkyl phosphite in the presence of triethylamine. The similar treatment of vinyl bromides gives dialkyl vinylphosphonates stereoselectively.

Arbuzov and Michaelis-Becker reactions provide facile procedures for the formation of carbon-phosphorus bonds.[1] These methods, however, are not applicable to the formation of sp^2 hybridized carbon-phosphorus bonds. Only few methods have been reported for the syntheses of arylphosphonates[1,2] and vinylphosphonates.[1,3] For example, the photoinitiated reaction of iodobenzene with trialkyl phosphite[2f,g] or dialkyl phosphite ion[2e] affords dialkyl phenylphosphonate. Direct reaction of aryl[2i] or vinyl halides[3g] with trialkyl phosphite in the presence of nickel halide requires severe reaction conditions, and the stereochemistry of vinylphosphonates has not been clarified. In our preceding reports, we found new and versatile syntheses of dialkyl arylphosphonates[4] and vinylphosphonates[5] using palladium catalyst. The stereoselective synthesis of dialkyl vinylphosphonates has been accomplished by this method. Herein, we wish to report further details of the palladium-catalyzed carbon-phosphorus bond formation.

Results and Discussion

Preparation of Dialkyl Arylphosphonates. Dialkyl arylphosphonates (**1**) were prepared in good yields by the reaction of aryl bromides or iodide with *O,O*-dialkyl phosphonate in the presence of triethylamine and a catalytic amount of tetrakis(triphenylphosphine)-palladium. The results are summarized in Table 1.

$$\underset{\text{X=Br, I}}{\text{ArX}} + \text{HP(O)(OR)}_2 \xrightarrow[\text{Et}_3\text{N}]{\text{catal Pd(PPh}_3)_4} \underset{\mathbf{1}}{\text{ArP(O)(OR)}_2} + \text{Et}_3\text{N}\cdot\text{HX}$$

Use of palladium acetate instead of tetrakis(triphenylphosphine)palladium resulted a moderate yield of **1a**. But palladium chloride was less effective. Triethylamine was superior to tri-*n*-butylamine and pyridine as base. Although bromobenzene readily underwent phosphonation with *O,O*-diethyl phosphonate, chlorobenzene did not react under the same reaction conditions. On treatment of *p*-bromochlorobenzene with *O,O*-diethyl phosphonate, diethyl *p*-chlorophenylphosphonate was obtained in 85% yield as a sole product. *O,O*-Diisopropyl and *O,O*-dibutyl phosphonates were also allowed to react with bromobenzene to give the corresponding phosphonates. Diethyl arylphosphonates, bearing a variety of electron-withdrawing and electron-donating substituents, such as *p*-NO_2, *p*-CN, *p*-MeCO, *o*-COOMe, *p*-MeCONH, *p*-MeO, *p*-Me, *o*-Me, were prepared in high yields. *o*-Bromobenzoic acid was subjected to esterification with diethyl phosphite as well as phosphonation to give diethyl *o*-ethoxycarbonylphenylphosphonate in 24% yield. Attempts to prepare *p*-hydroxy- and *p*-aminophenylphosphonates were unsuccessful. These observations are consistent with the results reported by Heck[6] that aryl bromides with strongly electron-donating substituents do not undergo the palladium-catalyzed vinylic substitution reaction in acceptable yields. The palladium-catalyzed phosphonation of 1-bromonaphthalene and 3-bromopyridine gave the corresponding phosphonates in good yields.

It should be noted that *o*-dibromobenzene reacted with 2 equiv. of *O,O*-diethyl phosphonate to yield *o*-bromophenylphosphonate (34%) and phenylphosphonate (6%), whereas substitution of both bromine atoms of *p*-dibromobenzene was observed. Though the mechanism for the formation of diethyl phenylphosphonate from *o*-dibromobenzene has not been clarified, it is conceivable that diethyl phosphite plays an important role in the present reduction reaction. Previously, we reported a facile reduction of *gem*-dibromo derivatives with diethyl phosphite and triethylamine.[7] In this connection, the dark reactions of *o*-fluoroiodobenzene and *o*-chloroiodobenzene with $(EtO)_2PO^-$ in liquid ammonia were reported to give fluorobenzene and chlorobenzene, respectively, and such a reduction reaction has not been observed for *m*- and *p*-iodohalobenzenes.[8] *o*-Bromobenzyl alcohol was also subjected to reduction of hydroxyl group to produce diethyl *o*-tolylphosphonate in 18% yield.

The formation path of dialkyl arylphosphonates is outlined in Scheme 1. Palladium(0) species undergoes oxidative addition with aryl bromide to give the arylpalladium complex, which may be considered to be a key intermediate. The attack of dialkyl phosphite to the arylpalladium complex leads to dialkyl arylphosphonate. Triethylamine regenerates palladium(0) species with the deposition of $Et_3N\cdot HBr$. Thus obtained palladium(0) species is available to another reaction cycle. In the nickel-catalyzed Arbuzov reaction, arylnickel complexes have also been suggested.[9]

Diethyl sodiophosphonate was able to be employed in the palladium-catalyzed reaction. For prevention of the photoinitiated phosphonation,[2e] the reaction

$$\text{ArBr} + \text{Pd}^0 \longrightarrow \text{ArPd}^{II}\text{Br} \xrightarrow{\text{HP(O)(OR)}_2} \text{ArP(O)(OR)}_2 + \text{HPd}^{II}\text{Br}$$

$$\text{HPd}^{II}\text{Br} + \text{Et}_3\text{N} \longrightarrow \text{Pd}^0 + \text{Et}_3\text{N}\cdot\text{HBr}$$

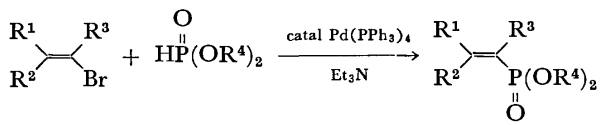
Preparation of Dialkyl Alkenylphosphonates. The palladium-catalyzed phosphonation was successfully applied to stereoselective syntheses of dialkyl vinylphosphonates (**2**) from vinyl bromides. The results are summarized in Table 2.



2

Stereoselectivity is illustrated as follows. Treatment of (*E*)- and (*Z*)-β-bromostyrenes with diethyl phosphite in the presence of palladium catalyst gave diethyl (*E*)- and (*Z*)-styrylphosphonates, respectively, without any contamination of the isomer. Phosphonomycin, (−)-(1*R*,2*S*)-1,2-epoxypropylphosphonic acid, is a new antibiotic.[10] Diisopropyl (*Z*)-1-propenylphosphonate, its important synthetic intermediate, was obtained in a high yield by this phosphonation.

1-Monobromodiene was easily prepared by the reaction of *gem*-dibromodiene with *O,O*-diethyl phosphonate and triethylamine according to our method.[8] 1-Bromo-4-phenylbutadiene was converted to diethyl 4-phenylbutadienylphosphonate (**3**) by the palladium-catalyzed phosphonation. One-step synthesis of the dienylphosphonate **3** was attempted by the reaction of 1,1-dibromo-4-phenylbutadiene with *O,O*-diethyl phosphonate in the presence of triethylamine and a

$$PhCH{=}CH{-}CH{=}CBr_2 \xrightarrow[Et_3N]{HP(O)(OEt)_2} PhCH{=}CH{-}CH{=}CHBr$$

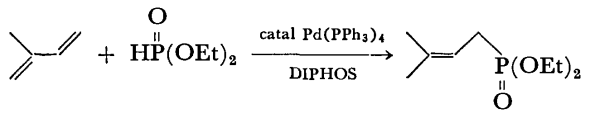
78% **3**

catalytic amount of tetrakis(triphenylphosphine)palladium, but only 1-bromo-4-phenylbutadiene was obtained. The substitution with diethyl phosphite was not observed.

Vinylpalladium complexes seem to be involved as key intermediates,[11] and the same mechanism as given for dialkyl arylphosphonates may be operative.

It is well known that the reaction of diene with nucleophiles is catalyzed by palladium complex.[12] But the reaction of dienes with dialkyl phosphite has not been studied. Isoprene was treated with *O,O*-diethyl phosphonate in the presence of a catalytic amount of tetrakis(triphenylphosphine)palladium and 1,2-bis(diphenylphosphino)ethane (DIPHOS) to give diethyl 3-methyl-2-butenylphosphonate (**4**) in 10% yield selectively. Although there are two possible routes of nucleophilic attack of *O,O*-diethyl phosphonate to isoprene, formation of diethyl 1-methyl-2-butenylphosphonate was not observed in the ^1H NMR spectrum.



4

The results described here thus show the palladium-catalyzed phosphonation to be a useful method for organophosphorus syntheses, especially in the synthesis of dialkyl aryl- and vinylphosphonates.

Experimental

^1H NMR spectra were obtained on a JEOL JNM-PMX-60 with tetramethylsilane as an internal standard. IR spectra were recorded with a JASCO IRA-1 spectrometer. The mass spectra were taken with a Hitachi RMU-6E spectrometer.

Materials. (*Z*)-*β*-bromostyrene,[13] bromocyclohexene,[13] (*Z*)-1-bromo-1-propene,[14] and 1-bromo-4-phenylbutadiene[8] were prepared by the reported methods. Tetrakis(triphenylphosphine)palladium was easily prepared from palladium chloride.[15] Other reagents and solvents are commercial ones and were purified by distillation under nitrogen atmosphere or recrystallization.

Dialkyl Arylphosphonate (1). General Procedure: To a stirred mixture of *O,O*-dialkyl phosphonate (4.4 mmol), triethylamine (0.61 ml, 4.4 mmol), and tetrakis(triphenylphosphine)palladium (0.23 g, 0.2 mmol), aryl bromide (4.0 mmol) was added under nitrogen atmosphere, and the resultant mixture was stirred at 90 °C for 2—64 h. When aryl bromide is solid, toluene (1 ml) was added as a solvent. After the addition of ether (50 ml), triethylamine hydrobromide was removed by filtration. The residue obtained upon evaporation was purified by Kugelrohr distillation or column chromatography on silica gel to give dialkyl arylphosphonate (Table 1). Dialkyl arylphosphonates (**1a**,[2i] **1b**,[2i] **1c**,[1b] **1d**,[2i] **1e**,[2i] **1f**,[2i] **1g**,[2i] **1h**,[16] **1i**,[2i] **1j**,[2j] **1k**,[17] **1l**,[2i] **1m**,[2i] **1n**,[2i] **1o**,[2i] **1q**,[1b] and **1r**[18]) were identified by comparison of their IR and ^1H NMR spectra with those of authentic samples. **1p**: IR (neat) 1245, 1050—1020, and 965 cm^{-1}; ^1H NMR ($CDCl_3$) δ 1.37 (t, 6H, J=7.0 Hz), 4.20 (dq, 4H, J=7.0 and 7.0 Hz), 7.30—8.30 (m, 4H); MS *m/e* 293 (M^+); Found: C, 40.96; H, 5.05; Br, 27.48; P, 10.32%. Calcd for $C_{10}H_{14}BrO_3P$: C, 40.98; H, 4.81; Br, 27.26; P, 10.57%.

Palladium-catalyzed Reaction of Aryl Bromide with Diethyl Sodiophosphonate. To a stirred mixture of bromobenzene (0.63 g, 4.0 mmol) and tetrakis(triphenylphosphine)palladium (0.23 g, 0.2 mmol) in toluene (3 ml), diethyl sodiophosphonate (4.4 mmol) in toluene (4 ml) was added. The resultant mixture was stirred at 90 °C for 30 h under nitrogen atmosphere. After the addition of ether (20 ml), sodium bromide was removed by filtration. The residue obtained upon evaporation was distilled by Kugelrohr to give diethyl phenylphosphonate (**1a**, 0.46 g, 54%). Diethyl *p*-tolylphosphonate (**1d**) was prepared in 36% yield similarly (reaction time, 24 h).

Dialkyl Vinylphosphonate (2). General Procedure: The vinylphosphonate **2** was prepared in the similar manner as that of **1** (Table 2). In the case of (*Z*)-1-bromo-1-propene as a starting bromide, reactions were carried out by mixing (*Z*)-1-bromo-1-propene (0.58 g, 4.8 mmol), *O,O*-dialkyl phosphonate (4.0 mmol), triethylamine (0.55 ml, 4.0 mmol), and tetrakis(triphenylphosphine)palladium (0.23 g, 0.2 mmol) in toluene (1 ml) at 90 °C. Yields of **2g** and **2h** were based on the starting *O,O*-dialkyl phosphonate. Dialkyl vinylphosphonates (**2a**,[3g] **2e**,[3g] **2f**,[1b] **2g**,[3f] and **2h**[10a]) were identified by comparison of their IR and ^1H NMR spectra with those of authentic samples. **2b**: IR (neat) 1600, 1235, 1050—1020, and 955 cm^{-1}; ^1H NMR ($CDCl_3$) δ 1.12 (t, 6H, J=7.0 Hz), 3.98 (dq, 4H, J=7.0 and 7.0 Hz), 5.78 (dd, 1H, J=14.0 and 14.9 Hz), 6.70—7.90 (m, 5+1H); MS *m/e* 240 (M^+). **2c**: IR (neat) 1605, 1240, and 1030—960 cm^{-1}; ^1H NMR ($CDCl_3$) δ 1.15 (d, 6H, J=6.5 Hz), 1.25 (d, 6H, J=6.5 Hz), 4.25—5.08 (m, 2H), 5.69 (dd, 1H, J=14.0 and 14.5 Hz), 6.53—7.83 (m, 5+1H); MS *m/e* 268 (M^+). **2d**: IR (neat) 1605, 1245, and 1080—950 cm^{-1}; ^1H NMR ($CDCl_3$) δ 0.62—1.75 (m, 14H), 3.19 (dt, 4H, J=6.5 and 6.5 Hz), 5.70 (dd, 1H, J=14.0 and 15.0 Hz), 6.69—7.83 (m, 5+1H); MS *m/e* 296 (M^+).

Diethyl 4-Phenylbutadienylphosphonate (3). The butadienylphosphonate **3** was similarly prepared by the palladium-catalyzed reaction of 1-bromo-4-phenylbutadiene with *O,O*-diethyl phosphonate in the presence of triethylamine. The *E*:*Z* ratio could not be determined.[19]

Diethyl 3-Methyl-2-butenylphosphonate (4). The mixture of isoprene (1.70 g, 25 mmol), *O,O*-diethyl phosphonate (3.45 g, 25 mmol), 1,2-bis(diphenylphosphino)ethane (0.10 g, 0.25 mmol), and tetrakis(triphenylphosphine)palladium (0.29 g, 0.25 mmol) in a sealed tube was heated at 150 °C for 20 h. After evaporation of unreacted isoprene, **4** was isolated in 10% yield by preparative GLC. The structure of **4** was confirmed by the ^1H NMR spectrum.[20]

An X-Ray Crystallographic Study on *cis-trans* Configurational Assignment to "*cis*-" and "*trans*-1,8-Terpins"[1] and a Proposal of New Designation for Discriminating between the Configurational Isomers

Takayuki Suga,* Toshifumi Hirata, and Tadashi Aoki
Department of Chemistry, Faculty of Science, Hiroshima University, Higashisenda-machi, Naka-ku, Hiroshima 730

(Received August 5, 1981)

The crystal structures of "*cis*-terpin" (terpin hydrate) and "*trans*-terpin" were elucidated by X-ray crystallography. This crystal structure elucidation showed that the hydroxyl group at C-1 and the 1-hydroxy-1-methylethyl group at C-4 are in *cis* and *trans* relationships in the "*cis*-" and "*trans*-1,8-terpin" molecules, respectively, similarly to the structures in solutions. A new designation for discriminating between the configurational isomers is proposed on the ground of the IUPAC Rule for Nomenclature.

It has been documented[2-5] that "*cis*-1,8-terpin" and "*trans*-1,8-terpin" are configurational isomers represented by structures (**1**) and (**2**), respectively and that the spatial arrangement of the hydroxyl group at C-1 and the 1-hydroxy-1-methylethyl group at C-4 of **1** was deduced to be *cis* on the basis of the preferential formation of 1,8-cineol (**3**) from **1** on reaction with aqueous sulfuric acid. The stereochemistry of these 1,8-terpins had been deduced by the ease of ring closure to the cineol. However, a controversy as to the stereochemical structure of these terpins was raised on the ground of observation that 1,8-cineol (**3**) had also been produced from "*trans*-1,8-terpin" (**2**) under the same acidic conditions.[6] Reexamination of the *cis-trans* configurational assignment of these terpins by the ^{1}H NMR method[6,7] dispelled the ambiguity, bearing out the earlier assigned structures. All the studies hitherto done have dealt with the configuration of 1,8-terpins in solutions. In order to clarify unambiguously the configurational isomer of "*cis*-" and "*trans*-1,8-terpins," the determination of the molecular structures of the "1,8-terpins" was made by X-ray crystallographic analyses. On the other hand, there have been various designations and no consistency among the nomenclatures[3,8,9] of the "1,8-terpins." A new designation for discriminating between these 1,8-terpins is, therefore, required to standardize their nomenclature.

In this paper, we will deal with the configurational assignment of "*cis*-" and "*trans*-1,8-terpins" in the crystals and propose a new designation for discriminating between the configurational isomers of the "1,8-terpins."

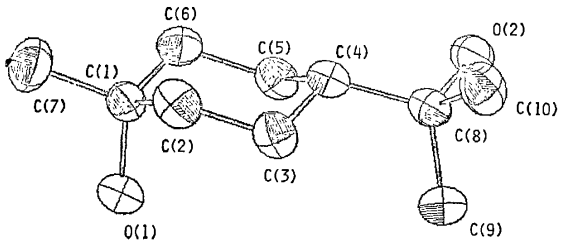

Fig. 1. ORTEP drawing of the molecular structure of "*cis*-1,8-terpin" (**1**).

using MULTAN.[10] Final atomic coordinates, bond lengths, and bond angles are given in Tables 1 and 2 for **1**, and Tables 3 and 4 for **2**. The perspective view (Fig. 1) of the "*cis*-terpin" molecule showed that the hydroxyl group at C-1 is *cis* to the 1-hydroxy-1-methylethyl group at C-4. This corroborates the previously assigned configurational isomer[3-9] of "*cis*-1,8-terpin." Furthermore, it was found that the hydroxyl group at C-1 and the 1-hydroxy-1-methylethyl group at C-4 are axial and equatorial, respectively and also the C-8 hydroxyl group is gauche to the hydrogen atom at C-4. Each hydroxyl group at C-1 and C-8 is linked by intermolecular hydrogen bonding to water of crystallization, as shown in Fig. 2. On the other hand, H(2) is linked to O(1)′ by intermolecular hydrogen bonding. The molecules of the "1,8-terpin" are packed along the a axis and the crystal structure is stabilized by the network of hydrogen bondings (Fig. 2).

On the other hand, the perspective view (Fig. 3) of a molecule of "*trans*-terpin" indicated that the hydroxyl group at C-1 is *trans* to the 1-hydroxy-1-methylethyl group at C-4. Both the hydroxyl group at C-1 and the 1-hydroxyl-1-methylethyl group at C-4 are equatorially oriented, and the C-8 hydroxyl group is gauche to the C-4 hydrogen atom similarly to the

case of **1**. As shown in Fig. 4, the "*trans*-1,8-terpin" molecules form an infinite chain along the a axis by intermolecular hydrogen bonding. The chain is coupled with the next chain by other intermolecular hydrogen bonding to form pairs of the chain. These pairs build up the layered structure by the van der Waals force among the hydrophobic groups.

A Proposal of New Designation for Discriminating between "cis-" *and* "trans-*1,8-Terpins.*" 1,8-Terpins have two different substituents, such as the methyl and the hydroxyl groups, at the 1-position. For designating the steric relationship of these terpins, an arbitrary selection of these two substituents as the reference substituent has thrown the nomenclature of the terpins in confusion. The IUPAC Rule for Nomenclature (E. 2.3.4.)[11] has recommended that,

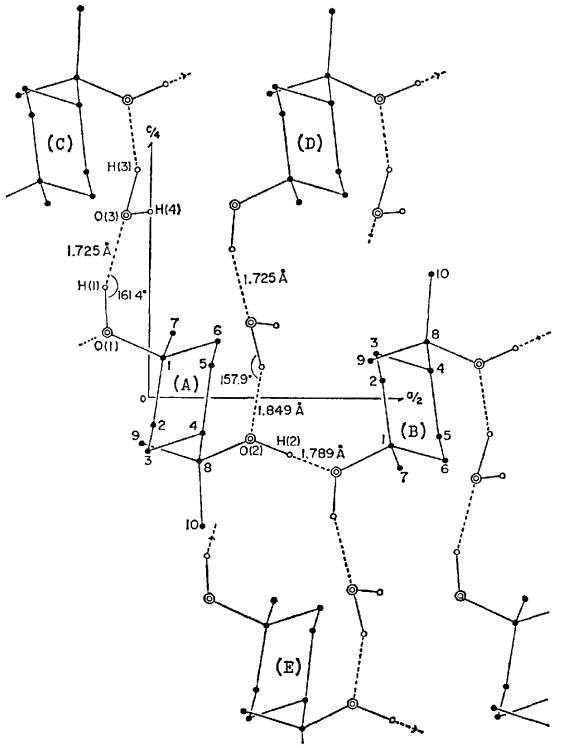

Fig. 2. Projection of **1** viewed along the b axis. The atoms indicated with ●, ◎, and ○ denote carbon, oxygen, and hydrogen atoms, respectively. The transformations of the atomic coordinates are (A) x, y, z; (B) $1/2+x$, $1/2-y$, $-z$; (C) $-1/4+x$, $-1/4+y$, $1/4-z$; (D) $1/4+x$, $1/4+y$, $1/4-z$; (E) $1/4+x$, $3/4-y$, $-1/4+z$.

when two different substituents locate at the same position of a monocycle, a characteristic group or a predominant substituent in the sequence rule is

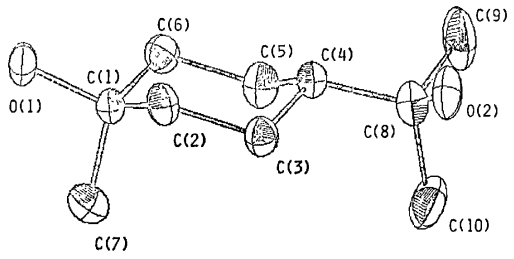

Fig. 3. ORTEP drawing of the molecular structure of "*trans*-1,8-terpin" (**2**).

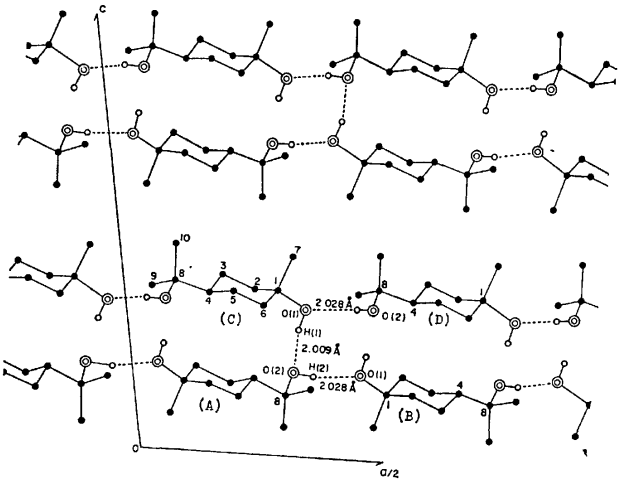

Fig. 4. Projection of **2** viewed along the b axis. The atoms indicated with ●, ◎, and ○ denote carbon, oxygen, and hydrogen atoms, respectively. The transformations of the atomic coordinates are (A) x, y, z; (B) $1/2+x$, $-1/2+y$, z; (C) $1/2-x$, $1/2+y$, $1/2-z$; (D) $1-x$, $1+y$, $1/2-y$.

expressed by adding *r* as the reference substituent and a substituent being in the *cis* or *trans* relationship to this reference substituent is expressed by *c* or *t*, instead of *cis* or *trans*, respectively. According to the IUPAC Rule, therefore, "*cis*-terpin" (**1**) should be represented as *c*-4-(1-hydroxy-1-methylethyl)-1-methyl-*r*-1-cyclohexanol and "*trans*-terpin" (**2**) as *t*-4-(1-hydroxy-1-methylethyl)-1-methyl-*r*-1-cyclohexanol. In the case of using *p*-menthane as a conventional name, **1** and **2** are called *c*-4-*p*-menthane-*r*-1,8-diol and *t*-4-*p*-menthane-*r*-1,8-diol, respectively. However, it is hard to exclude the designation of "terpin" for the reason that this designation has been most widely used for a long time among chemists in the field of terpenoids. For the nomenclature of compounds **1** and **2** by using the appellation of "terpin," we will propose that "*cis*-1,8-terpin" (**1**) is expressed as *c*-1,8-terpin and "*trans*-1,8-terpin" (**2**) as *t*-1,8-terpin, hereafter.

Experimental

Material. "*cis*-1,8-Terpin" (**1**), mp 105—106 °C (lit,[6] 104—105 °C), used for X-ray analysis was obtained by repeated recrystallization of the commercial terpin hydrate (Yoneyama Kogyo Yakuhin Co. Ltd.). "*trans*-1,8-Terpin" (**2**), mp 157—158 °C (lit,[12] 158—159 °C), was prepared from 1,8-cineol (**3**) according to the literature method[12]

and purified by repeated recrystallization. A single crystal of **1** and **2** for X-ray studies was prepared by crystallization from hot water. Spectroscopic data (IR and ^{1}H NMR) of each compound were identical with the data[6,7] reported for the corresponding terpins.

Crystallographic Measurements. The crystallographic analyses were performed on a Syntex R3 diffractometer using graphite-monochromated Mo $K\alpha$ radiation. Cell dimensions were derived by the least-squares method from setting angles of 18 well-centered diffraction peaks for **1** and 15 peaks for **2**. Intensity data were collected by ω-scan ($\theta_{max}=58.0°$), and $I_0>1.96\sigma(I_0)$ were used as observed reflections; 1091 reflections for **1** and 1261 reflections for **2**.

Crystal Data of ***1***. $C_{10}H_{20}O_2\cdot H_2O$, $M=190.28$. Crystal dimensions 0.20 mm×0.25 mm×0.23 mm. Orthorhombic, $a=10.930(2)$, $b=18.425(5)$, $c=22.791(6)$ Å, $U=4589.8$ Å^3, $D_c=1.03$ g cm^{-3}, $Z=16$, $D_m=1.08$ g cm^{-3}, μ(Mo $K\alpha$)=0.8 cm^{-1}. Space group Fdd2.

Crystal Data of ***2***. $C_{10}H_{20}O_2$, $M=172.26$. Crystal dimensions 0.47 mm×0.50 mm×0.30 mm. Monoclinic, $a=17.167(2)$, $b=6.233(2)$, $c=19.325(6)$ Å, $\beta=98.910(2)°$, $U=2043.1$ Å^3, $D_c=1.12$ g cm^{-3}, $Z=8$, $D_m=1.16$ g cm^{-3}, μ(Mo $K\alpha$)=0.8 cm^{-1}. Space group C2/c.

Structure Analyses and Refinements. The phases of 106 reflections with $|E|>1.65$ for **1** and 172 reflections with $|E|>1.80$ for **2** were determined by MULTAN.[10] An E map for the best solution yielded positions for all atoms except hydrogens. These atomic parameters were anisotropically refined, followed by a difference map to find the positions of all hydrogen atoms. Anisotropic refinement for carbon and oxygen atoms and isotropic refinement for hydrogen atom by full-matrix least-squares calculation reduced the R index finally to 0.044 for **1** and 0.049 for **2**.

The complete F_o-F_c data and the tables of anisotropic thermal parameters for **1** and **2** are deposited as Document No. 8208 at the Office of the Editor of the Bulletin of the Chemical Society of Japan.

Preparation of Homologs of L-2-Amino-5-(*p*-methoxyphenyl)pentanoic Acid

Nobuo Kosui,* Michinori Waki, Tetsuo Kato, and Nobuo Izumiya

Laboratory of Biochemistry, Faculty of Science, Kyushu University 33, Higashi-ku, Fukuoka 812

(Received August 15, 1981)

Lower and higher homologs, L-2-amino-4-(*p*-methoxyphenyl)butanoic acid (L-Amb) and L-2-amino-6-(*p*-methoxyphenyl)hexanoic acid (L-Amh), of L-2-amino-5-(*p*-methoxyphenyl)pentanoic acid were prepared by optical resolution of *N*-acetyl-DL-Amb and of *N*-acetyl-DL-Amh with *Aspergillus* acylase. *N*-Acetyl-DL-Amb or *N*-acetyl-DL-Amh was synthesized from [2-(*p*-methoxyphenyl)ethyl or butyl](acetamido)malonic acid by heating with *p*-xylene.

AM-Toxin I is a host specific phytotoxin, its structure being determined as *cyclo*(-L-Amp[1]-ΔAla[2]-L-Ala[3]-L-Hmb[4]-).[1] Shimohigashi *et al.* synthesized AM-toxin I[2] and its analog, [L-Tyr(Me)[1]]-AM-toxin,[3] and observed that [L-Tyr(Me)[1]]-AM-toxin showed extremely weak necrotic activity toward apple leaves. This finding implies that the methylene length of side chain in L-Amp affects the necrotic activity. Therefore, it is interesting to synthesize L-Amb or L-Amh, which is a lower or higher homolog of L-Amp (Fig. 1), in an attempt to prepare an AM-toxin analog containing an aromatic amino acid residue with a different methylene chain.

Only DL-Amb has been synthesized by Strecker's method,[4] but none of L-Amb, DL- and L-Amh have been prepared so far. This paper deals with the preparation of *N*-acetyl-DL-Amb (Ac-DL-**1a**) and *N*-acetyl-DL-Amh (Ac-DL-**1b**) and their optical resolution by acylase (Fig. 2). The procedure used for resolution is similar to that used for the preparation of L-Amp.[5] In the synthesis of diethyl [2-(*p*-methoxyphenyl)ethyl](acetamido)malonate (**3a**) from arylalkyl bromide (**2a**) and diethyl acetamidomalonate (**5**), we suffered from relatively low yield (27%). In contrast, diethyl [4-(*p*-methoxyphenyl)butyl](acetamido)-malonate (**3b**) in the present study and diethyl [3-(*p*-methoxyphenyl)propyl](acetamido)malonate reported in the previous paper[5] were synthesized in moderate yields of 66% and 64% from the corresponding bromide and the malonate (**5**), respectively. We found that the reaction mixture of the bromide (**2a**) and the malonate (**5**) contained a decarboxylated product (DL-**6**) besides the desired **3a**. The malonic acid derivative (**4a** or **4b**) was obtained in good yield from the diester derivative (**3a** or **3b**) by complete saponification with excess sodium hydroxide. The important intermediate Ac-DL-**1a** or Ac-DL-**1b** was prepared in good yield from **4a** or **4b** by heating in *p*-xylene.

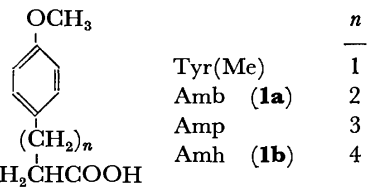

Fig. 1. Structure of homologs of Amp.

Prior to the preparative resolution of Ac-DL-**1a** and Ac-DL-**1b** by *Aspergillus* acylase, the rates of hydrolysis of two substrates were determined using Ac-DL-Tyr(Me) and Ac-DL-Amp as reference substrates, the results being shown in Table 1. It is observed that the rates of hydrolysis are decreased with the increase of the methylene length of side chain in aromatic amino acids. Although Ac-L-**1b** was less susceptible than Ac-L-Tyr(Me), the results indicate that optical resolution of Ac-DL-**1b** is achieved with an increased amount of the acylase. Ac-DL-**1a** or Ac-DL-**1b** was subjected to the action of the acylase, the desired L-amino acid (L-**1a** or L-**1b**) being obtained in a yield of 82% or 81% (Fig. 2). *N*-Acetyl-D-amino acid (Ac-D-**1a** or Ac-D-**1b**) was isolated from the mother liquor, and subsequently D-amino acid (D-**1a** or D-**1b**), which

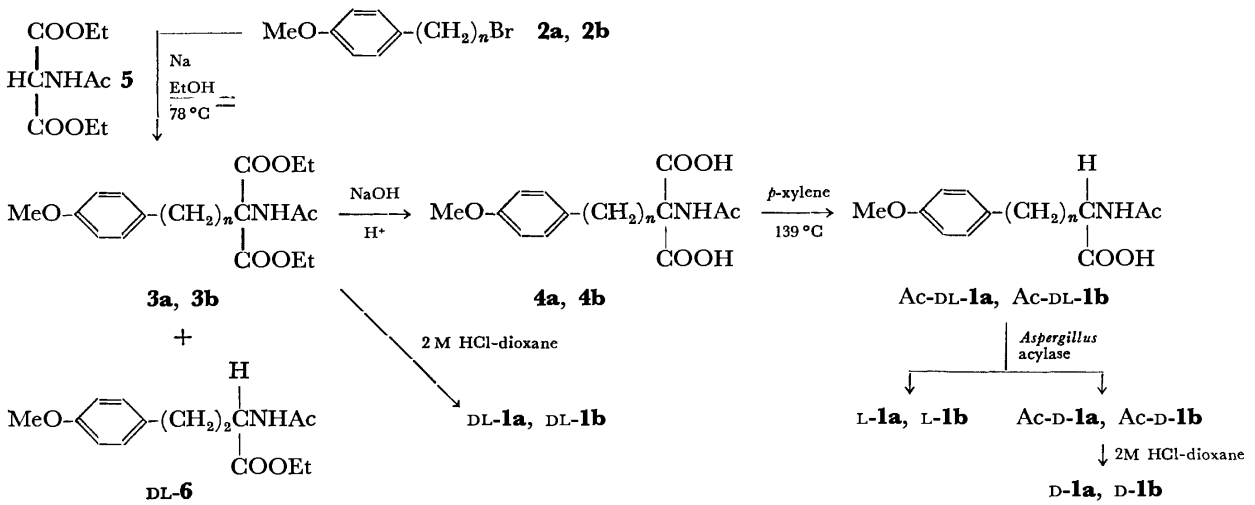

Fig. 2. Synthesis and resolution of *N*-acetyl-DL-amino acids (Ac-DL-**1a**, Ac-DL-**1b**). **a**: $n=2$, **b**: $n=4$.

Table 1. Proteolytic coefficients (C_0) of acetylamino acids by *Aspergillus* acylase

Substrate	C_0[a] at 0.01 M[b]
Ac-DL-Tyr(Me)	28 (100)[c]
Ac-DL-**1a**	24 (86)
Ac-DL-Amp	14 (50)
Ac-DL-**1b**	12 (43)

a) $C_0=K_0/E$ where $K_0=\%$ hydrolysis$\times$min^{-1} of $E=$mg protein $N\times$ml^{-1}; pH 7.3, temp 38 °C. b) Concentration of L-form of substrate. c) The values in the parentheses indicate the relative hydrolytic rate.

is also useful compound for synthesis of AM-toxin analogs, was prepared from Ac-D-**1a** or Ac-D-**1b** by heating in 6 M HCl.

Experimental

All the melting and boiling points are uncorrected. TLC was carried out on silica gel (Merck) with the following solvent systems: R_f^1, benzenea–cetone (1:1); R_f^2, 1-butanol–AcOH–pyridine–H_2O (4:1:1:2). Paper chromatography was carried out on Toyo Roshi No. 52 paper with the following solvent systems: R_f^3, the same solvent as used for R_f^2; R_f^4, 1-butanol–AcOH–pyridine–H_2O (15:3:10:12). The ratio in parenthesis is given in terms of volume. Powder of *Aspergillus* acylase was obtained from Kyowa Hakko Co., Ltd.

*2-(p-Methoxyphenyl)ethyl Bromide (**2a**).* 2-(*p*-Methoxyphenyl)ethanol (**7**) was synthesized following the literature;[6] yield, 76%; bp 121—125 °C/7 mmHg.† Compound **2a** was synthesized from **7** (0.69 mol) and PBr_3 (0.345 mol) by a slight modification of the literature;[7] yield, 77%; bp 122 °C/9 mmHg. In the literature,[7] PBr_5 had been used.

*4-(p-Methoxyphenyl)-1-butanol (**8**).* 4-Oxo-4-(*p*-methoxyphenyl)butanoic acid (**9**) was synthesized from anisole and succinic anhydride by a slight modification of the literature,[8] yield, 89%; mp 142—143 °C. 1-Nitropropane had been used as a solvent in the literature,[8] but anisole was used as a reagent and also as a solvent for the present synthesis of **9**. 4-(*p*-Methoxyphenyl)butanoic acid (**10**) was synthesized from **9** with amalgamated Zn following the literature;[9] yield, 88%; mp 60—61 °C. Compound **8** was synthesized from **10** following the literature.[10] However, the procedure will be described here because the description in the literature was not enough to carry out the experimental work. To a suspension of $LiAlH_4$ (4.75 g, 0.125 mol) in anhydrous ether (180 ml) was added portionwise **10** (19.4 g, 0.1 mol) in ether (450 ml) at 0 °C under stirring within 1 h. The mixture was stirred at 0 °C for another 4 h. Water (300 ml) was added to decompose an excess $LiAlH_4$. To the mixture was added 10% H_2SO_4 (150 ml) and insoluble material was filtered off. The ethereal layer was separated, and the aqueous layer was extracted with ether. The combined ethereal solution was washed with 2 M NaOH, water, and dried (Na_2SO_4). After removal of the solvent, distillation under reduced pressure gave **8**; yield, 13.2 g (73%); bp 135—140 °C/4 mmHg; mp 4 °C. Literature, mp 3—4 °C.[10]

*4-(p-Methoxyphenyl)butyl Bromide (**2b**).* To a solution of **8** (48.3 g, 0.268 mol) in CCl_4 (54 ml) was added dropwise PBr_3 (30.6 g, 0.113 mol) in CCl_4 (27 ml) at 50—55 °C under stirring within 4 h. The mixture was stirred at 40—50 °C for another 2 h and CCl_4 was evaporated. The residue was dissolved in ether, and the solution was washed with water, dried (Na_2SO_4), and evaporated. Then distillation under reduced pressure gave **2b**; yield, 56.3 g (86%); bp 125—130 °C/3 mmHg.

Found: C, 54.13; H, 6.34%. Calcd for $C_{11}H_{15}OBr$: C, 54.34; H, 6.22%.

*Diethyl [2-(p-Methoxyphenyl)ethyl](acetamido)malonate (**3a**).* To a solution of Na (14.4 g, 0.626 mol) in absolute EtOH (840 ml) was added diethyl acetamidomalonate (**5**) (114 g, 0.523 mol) under stirring. A solution of **2a** (113 g, 0.523 mol) in absolute EtOH (260 ml) was added to the previous solution within 1 h. The reaction mixture was stirred under reflux for 8 h, and the precipitate was filtered off and washed with EtOH. The combined filtrates were evaporated *in vacuo* to give an oil which was crystallized by the addition of water and petroleum ether. The product was recrystallized from EtOH–water; yield, 49.4 g (27%); mp 81—84 °C; R_f^1 0.72.

Found: C, 61.39; H, 7.12; N, 3.98%. Calcd for $C_{18}H_{25}O_6N$: C, 61.52; H, 7.17; N, 3.99%.

Ethyl DL-*2-Acetamido-4-(p-methoxyphenyl)butanoate (*DL-*6*).* This was obtained from **2a** (3.9 g, 18 mmol) and **5** (3.9 g, 18 mmol) as described for **3a** except that the reaction mixture was refluxed for 4 d; yield, 1.1 g (22%); mp 94—96 °C; R_f^1 0.66.

Found: C, 63.99; H, 7.49; N, 4.90%. Calcd for $C_{15}H_{21}O_4N$: C, 64.49; H, 7.58; N, 5.01%.

*Diethyl [4-(p-Methoxyphenyl)butyl](acetamido)malonate (**3b**).* This was prepared from **2b** (40.2 g, 0.165 mol) and **5** (35.8 g, 0.165 mol) as described for **3a**. The product was recrystallized from EtOH–water; yield, 41.0 g (66%); mp 37—40 °C; R_f^1 0.83.

Found: C, 63.01; H, 7.72; N, 3.70%. Calcd for $C_{20}H_{29}O_6N$: C, 63.30; H, 7.70; N, 3.69%.

*[2-(p-Methoxyphenyl)ethyl](acetamido)malonic Acid (**4a**).* A solution of **3a** (16.0 g, 46 mmol) and 2 M NaOH (230 ml) in EtOH (500 ml) was allowed to stand at 38 °C for 3 d until none of **3a** and the intermediate 2-acetamido-2-ethoxycarbonyl-4-(*p*-methoxyphenyl)butanoic acid (R_f^2 0.65) were detected in the reaction mixture. The solution was evaporated and acidified with 6 M HCl (138 ml). The liberated oil was extracted with EtOAc and the extract was washed with water, dried (Na_2SO_4), and evaporated. The residue was crystallized by the addition of ether and petroleum ether; yield, 10.5 g (78%); mp 124—126 °C; R_f^2 0.53. Compound **4a** was unstable; on being left to stand at room temperature for 10 d, purified crystals of **4a** gave a small amount of decarboxylated material (Ac-DL-**1a**). The values of elemental analysis of crystalline **4a** deviated from the calculated ones as **4a**.

*[4-(p-Methoxyphenyl)butyl](acetamido)malonic Acid (**4b**).* This was prepared from **3b** (8.1 g, 21.3 mmol) as described for **4a**; yield, 6.1 g (88%); mp 102—103 °C; R_f^2 0.66. Compound **4b** was unstable and its property was similar to **4a**.

DL-*2-Acetamido-4-(p-methoxyphenyl)butanoic Acid (Ac-*DL-*1a).* Compound **4a** (3.0 g, 10.2 mmol) suspended in *p*-xylene (100 ml) was refluxed for 2 h. After being cooled to room temperature, crystals were collected and washed with petroleum ether; yield, 1.96 g (77%); mp 144—145 °C; R_f^2 0.73.

Found: C, 62.03; H, 6.86; N, 5.52%. Calcd for $C_{13}H_{17}O_4N$: C, 62.14; H, 6.82; N, 5.57%.

DL-*2-Acetamido-6-(p-methoxyphenyl)hexanoic Acid (Ac-*DL-*1b).* This was prepared from **4b** (5.87 g, 18.2 mmol) as described for Ac-DL-**1a**; yield, 4.02 g (79%); mp 93—94 °C; R_f^2 0.83.

Found: C, 64.49; H, 7.57; N, 4.96%. Calcd for $C_{15}H_{21}O_4N$: C, 64.49; H, 7.58; N, 5.01%.

† 1 mmHg≈133.322 Pa.

*DL-2-Amino-4-(p-methoxyphenyl)butanoic Acid (DL-**1a**).* A suspension of Ac-DL-**1a** (100 mg, 0.4 mmol) in a mixture of 2 M HCl (20 ml) and dioxane (20 ml) was refluxed on an oil bath at 110 °C for 15 h. The solution was evaporated *in vacuo* several times by the addition of water. The residual solid was recrystallized from 1 M HCl–1 M aqueous Et_3N; yield, 70.3 mg (84%); mp 244—245 °C (dec); R_f^3 0.82, R_f^4 0.76. Literature, mp 245—246 °C.[4]

*DL-2-Amino-6-(p-methoxyphenyl)hexanoic Acid (DL-**1b**).* This was prepared from Ac-DL-**1b** (279 mg, 1 mmol) as described for DL-**1a**; yield, 205 mg (87%); mp 253—254 °C (dec); R_f^3 0.93, R_f^4 0.88.

Found: C, 65.69; H, 8.21; N, 5.82%. Calcd for $C_{13}H_{19}O_3N$: C, 65.80; H, 8.07; N, 5.90%.

Determination of Proteolytic Coefficient (C_0) by Acylase. In a 2-ml flask, an *N*-acetyl-DL-amino acid (0.04 mmol) and 0.2 M NaOH (0.2 ml) were added. Further, 1/7 M Na barbital buffer (1 ml) of pH 7.5, 1/40 M $CoCl_2$ (0.1 ml), and an aqueous enzyme solution (0.2 ml) containing the acylase (0.2 mg) were added. The solution was made up to 2.0 ml with the buffer. The reaction mixture was incubated at 38 °C, aliquots being withdrawn at selected intervals. The rate of appearance of free amino acid was followed by a Hitachi amino acid analyzer KLA-5: column, 0.6 cm × 10 cm; buffer, standard 0.2 M Na citrate at pH 5.28. The hydrolysis of substrates follows zero-order kinetics within experimental error, the results being shown in Table 1.

*Resolution of Ac-DL-**1a**.* L-**1a**: Ac-DL-**1a** (2.51 g, 10 mmol) was dissolved in 0.0125 M aqueous Et_3N (800 ml), the pH being adjusted to 7.5 with AcOH. To the solution were added the acylase (50 mg), 1/80 M $CoCl_2$ (100 ml), and water (100 ml). The solution was left to stand at 38 °C for 5 d, the pH being adjusted occasionally to 7.5. The precipitate formed was collected by filtration (later, the precipitate was subjected to recrystallization). The pH of the combined filtrates was adjusted to 5 with 1 M HCl. A small amount of Norit was added, and the mixture was maintained at 50—60 °C for 10 min. The filtrate was concentrated to a small volume, and its pH was adjusted to 3 with 1 M HCl. The oil separated was extracted with EtOAc and the extract was washed with water (the extract was used for the preparation of Ac-D-**1a**). The aqueous layers were applied to a column of Dowex 50 (H^+ form), and the column was washed with water and eluted with 2 M NH_4OH. The eluate was evaporated, and the residue was combined with the above precipitate. Then, the product was recrystallized from dilute HCl–Et_3N–acetone; yield, 0.86 g (82%); mp 268—271 °C (dec); $[\alpha]_D^{20}$ +42.2 (*c* 0.2, 5 M HCl); R_f^3 0.82, R_f^4 0.76.

Found: C, 62.81; H, 7.44; N, 6.76%. Calcd for $C_{11}H_{15}O_3N$: C, 63.14; H, 7.23; N, 6.69%.

*Ac-D-**1a***: The extract with EtOAc obtained above was dried (Na_2SO_4) and evaporated. The residual solid was recrystallized from EtOH–water; yield, 1.07 g (85%); mp 172—173 °C; $[\alpha]_D^{20}$ −22.5 (*c* 1, EtOH); R_f^2 0.73.

Found: C, 62.05; H, 6.95; N, 5.32%. Calcd for $C_{13}H_{17}O_4N$: C, 62.14; H, 6.82; N, 5.57%.

D-***1a***: This was prepared from Ac-D-**1a** (0.50 g, 2 mmol) as described for DL-**1a**; yield, 0.34 g (81%); mp 268—270 °C (dec); $[\alpha]_D^{20}$ −41.8 (*c* 0.2, 5 M HCl); R_f^3 0.82, R_f^4 0.76.

Found: C, 63.21; H, 7.26; N, 6.42%. Calcd for $C_{11}H_{15}O_3N$: C, 63.14; H, 7.23; N, 6.69%.

*Resolution of Ac-DL-**1b**.* L-***1b***: Ac-DL-**1b** (2.79 g, 10 mmol) was treated with the acylase as mentioned above. Amino acid L-**1b** was obtained from the reaction mixture; yield, 0.96 g (81%); mp 230—233 °C (dec); $[\alpha]_D^{20}$ +31.1 (*c* 0.1, 5 M HCl); R_f^3 0.93, R_f^4 0.88.

Alkaline Hydrolysis of Propella-δ- and ε-lactones

Kiyomi Kakiuchi,* Yoshito Tobe, and Yoshinobu Odaira

Department of Petroleum Chemistry, Faculty of Engineering, Osaka University, Suita, Osaka 565

(Received September 4, 1981)

Second-order rate constants for the alkaline hydrolysis of a series of propella-δ- and ε-lactones at 32.3 °C have been determined. The conclusion to be drawn from the kinetic data is as follows. In the case of propella-δ-lactones, the steric effect of the third ring on the hydrolysis plays an important role, whereas the hydrolysis of propella-ε-lactones is mainly governed by the steric effect attributable to the flexibility of the ε-lactone ring, and, on the contrary, the steric effect of the third ring is of no great consequence.

In a continuation of the studies on the transformation of readily available [*n*.3.2]propellanes into other important polycarbocyclic ring systems,[1] we previously reported on the novel cyclobutyl-cyclopropylcarbinyl rearrangement of propella-δ-lactones (**1**)—(**4**), composed of a cyclobutane ring, a δ-lactone ring, and one of five to eight membered rings as the third ring, to the corresponding dispiro-γ-lactones (**9**)—(**12**) under acidic conditions as well as thermal conditions.[2] In these reactions, the remarkable ring size effect of the third rings on the rearrangement was observed, and it was inferred that the steric effect of the third rings reinforced the puckered geometry of the cyclobutane ring in δ-lactones which was favorable for the rearrangement to the γ-lactones. Of all the propella-δ-lactones, in particular, this was the case for **2** because of the steric requirement of the cyclohexane ring fused to bridgehead positions to adopt the chair conformation. Furthermore, this reasoning could be applicable to the results of the rearrangement of propella-ε-lactones (**5**) and (**6**), being higher homologues of δ-lactones (**1**) and (**2**).[3]

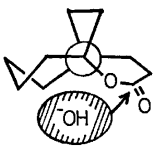
On the other hand, it is well-known that the transition state of alkaline hydrolysis of lactones is the formation of the tetrahedral intermediate and that the hydroxide anion attacks perpendicularly to the plane of the carbonyl group.[4] Also, it becomes apparent that the substituent effect which affects the rate of the hydrolysis is primarily due to the steric factor in the transition state.[4c,5]

In this connection, it is very interesting to see if the steric effect of the third ring influences the rate of alkaline hydrolysis of propellalactones. Therefore, we have studied the rate constants for the alkaline hydrolysis of a series of propella-δ- and ε-lactones.

Results and Discussion

The kinetic data for the alkaline hydrolysis of various lactones studied are summarized in Tables 1 and 2.

Firstly, the effect of alicyclic rings or two methyl groups substituted at the 4- and 5-positions of δ-valerolactone on the alkaline hydrolysis was taken up. As shown in Table 1, the rate constants of a series of δ-lactones obviously decreased with going on from δ-valerolactone to tricyclic propella-δ-lactones through bicyclic ones. The striking aspect of the present data is that the rate constant of bicyclic δ-lactone (**7**) compared with that of δ-valerolactone decreased by a factor of about one-twentieth by the fusion of such a small cyclobutane ring. Moreover, the further deceleration was naturally observed in the cases of propella-δ-lactones (**1**)—(**4**), or bicyclic δ-lactone (**8**), being substituted by two methyl groups at the both angular bridgehead positions of **7**. For example, the rate constant of **4** is less than that of **7** by a factor of about twenty-eighth by the additional fusion of a eight membered ring to the bicyclo[4.2.0] ring system. The effect of the third ring on the present alkaline hydrolysis may be regarded as the steric hindrance toward the attack of the hydroxide anion to the carbonyl group which is situated in position β to a bridgehead carbon atom, and, accordingly, it would be expected that the degree of the deceleration of the rate might be consistent with that of enlargement of the third ring size. In fact, however, the rate constants was in the order of **2**>**1**>**3**≈**4**, and that of **2**, having a cyclohexane ring, was twice of that of **1**, having a cyclopentane ring, and was even one and half times larger than that of **8**.



These results are of very significance in connection with those of the rearrangement of **1**—**4** to the corresponding dispiro-γ-lactones (**9**)—(**12**) described in the introduction. The two reactions exhibited very similar feature of the ring size effect of the third ring. As borne out by the inspection of molecular model as well as by the reasoning for the previous rearrangement, this unique feature of **2** in reactivity may be attributed to the puckered geometry of the cyclobutane ring reinforced by the chair conformation of

the cyclohexane ring. Namely, **2** is packed closely like a compact hemisphere, in other words, **2** has a widespreading room to the direction of endo in comparison with the others, such as **1** and **8**. Therefore, the attack of the hydroxide anion upon the carbonyl carbon atom of **2** may take place more smoothly.

In the case of ε-lactone series, on the other hand, the steric effect of two alicyclic rings fused to ε-caprolactone on the alkaline hydrolysis was much less than in the case of δ-lactone series. Namely, the rate constants of two propella-ε-lactones (**5**) and (**6**), which were the same, were only one-fourth as small as that of ε-caprolactone as shown in Table 2. This marked difference in reactivity between two propellalactone series can be attributed to the difference in flexibility or rigidity between δ- and ε-lactone rings. Inspection of molecular models of two lactone rings clearly indicates that the ε-lactone ring is more flexibile than the δ-lactone one. It may be reasonable that the rate of more flexible ε-lactone for the hydrolysis is much slower than that of more rigid δ-lactone.[6] This consideration implies that the flexibility of the ε-lactone makes it possible to depress the hydrolytic rate by the steric effect of adjacent methylene groups to the carbonyl one in the lactone ring itself. In addition, it is deduced from the kinetic data that the steric effect based on the flexibility of the ε-lactone ring plays more important role than that of the third ring.

In conclusion, from the kinetic study of the alkaline hydrolysis of a series of propella-δ- and ε-lactones, the steric effect of the third ring toward the attack of the hydroxide anion has been elucidated. In particular, in the case of propella-δ-lactones, this effect played as important role as in the case of cyclobutylcyclopropylcarbinyl rearrangement of them. In the case of propella-ε-lactones, on the other hand, the alkaline hydrolysis was dominantly governed by the steric effect attributable to the flexibility of the ε-lactone ring, and, that of the third ring was of no great consequence.

Experimental

δ-Valero- and ε-caprolactones are commercial samples (Wako Pure Chemical Ind. or Tokyo Kasei) and were purified by distillation before use. Bicyclic δ-lactones (**7**) and (**8**) and propellalactones (**1**)—(**6**) were prepared as our previous reports[2b,3] and were purified by silica-gel column chromatography or distillation. Water was prepared by distillation of deionized water under nitrogen atmosphere and was used throughout. Commercially available ethanol (Wako, super special grade) was used without further purification. Hitachi-Horiba pH meter H-7 SD and Horiba combination electrode #6326 were used for pH measure-

ment.

Kinetic Measurement. The rates of the hydrolysis of the lactones were determined by the pH method of Hall *et al.*[4b,d] Water containing 25% ethanol was used as the solvent to form a homogeneous solution.[8] The second-order rate constants were calculated from the pseudo first-order rate constants and were the avarage of at the least three runs of the same lactone concentration. The rate measurements were made at three different temperatures in the range of 25.0—41.5 °C[9] and the activation parameters were evaluated from the slope of the least-square Arrhenius plots.

6) This fact may be also explained on the basis of the differences of I-strain between seven and six membered rings as mentioned by Blackburn and Dodds.[7]

7) G. M. Blackburn and H. L. H. Dodds, *J. Chem. Soc., Perkin Trans. 2*, **1974**, 377.

8) In the case of **4**, the satisfactory data were not obtained at 25.0 and 41.5 °C because the solubility was limited at 25.0 °C and ethanol evaporated at 41.5 °C during the long reaction time. Also, the rate constant of **3** at 25 °C did not give reliable data.

9) Since **6** was more reactive and rearranged easily to **13** at 32.3 and 41.5 °C, we could not measure the rate under the above conditions.

The Configurations of Benzylmethyl(*o*- or *p*-tolyl)silylmethylamine and the Stereochemistry of the Reactions of Benzylmethyl-methoxyphenylsilane with Some Organometallic Agents

Daiyo TERUNUMA,* Kazuhisa SENDA, Masato SANAZAWA, and Hiroyuki NOHIRA
Department of Applied Chemistry, Faculty of Engineering, Saitama University, Urawa, Saitama 338
(Received September 9, 1981)

Optically active α-amino organosilanes such as benzylmethyl(*o*- or *p*-tolyl)silylmethylamine were converted into benzylmethylphenyl(*o*- or *p*-tolyl)silane, of which the configurations had been known. From these observations, it was found that (+)- and (−)-benzylmethyl(*o*- or *p*-tolyl)silylmethylamine has *S* and *R* configuration respectively. Furthermore, the stereochemistry of the reaction of benzylmethyl(methoxy)phenylsilane with some organometallic agents was investigated.

Previously, we reported on the successful optical resolutions of the α-amino organosilanes, *i.e.*, benzylmethylphenylsilylmethylamine(**1**), benzylmethyl(*o*-(**2**), *m*-(**3**), and *p*-tolyl(**4**))silylmethylamine, and on the determination of the configuration of **1**.[1] In this paper, we wish to report on the determination of the configurations of **2** and **4**, and on the stereochemistry of the nucleophilic substitutions of benzylmethylmethoxy(phenyl(**23**) and *p*-tolyl(**6**))silane by some organometallic agents.

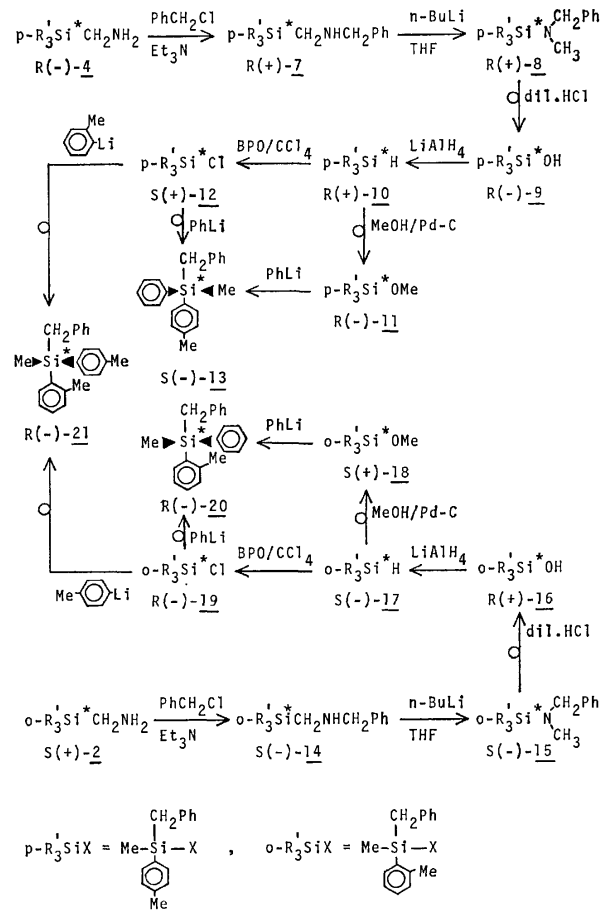
Results and Discussion

Chemical Conversions of 2 and 4. In order to determine the configuration of **4**, the chemical conversion of **4** into benzylmethylphenyl-*p*-tolylsilane, of which the absolute configuration was known, was undertaken, following the route described in our prior paper[1] (Scheme 1). Thus, (−)-**4**, which was obtained from the less soluble salt of **4** with (+)-tartaric acid by the fractional crystallization, was converted into (+)-benzylmethyl-*p*-tolylsilane(**10**). The treatment of **10** with methanol in the presence of Pd–C at 0 °C, and with a catalytic amount of BPO in CCl_4 at 80 °C gave (−)-benzylmethylmethoxy-*p*-tolylsilane (**11**) and (+)-benzyl(chloro)methyl-*p*-tolylsilane(**12**) respectively. Both reactions of (−)-**11** and (+)-**12** with phenyllithium in ether gave *S*(−)-benzylmethylphenyl-*p*-tolylsilane(**13**). In these chemical conversions, it is already known that the three of them, *i.e.*, the hydrolysis of **8**, the replacement of hydrogen by methoxyl radical, and the reaction of **12** with phenyllithium, proceed with inversion of the configurations, and the others proceed with retention of the configurations.[2]

On the other hand, *R*(−)-benzylmethylphenyl-*o*-tolylsilane(**20**) was obtained from (+)-**2** in the manner similar to that described above.

From these observations, it was noted that (−)-**4** and (+)-**2** had *R* and *S* configurations respectively. These configurations were furthermore confirmed by treating *S*(+)-**12** with *o*-tolyllithium, and *R*(−)-**19** with *p*-tolyllithium to give the product of the same sign of the optical rotation, *i.e.*, *R*(−)-benzylmethyl-*o*-tolyl-*p*-tolylsilane(**21**).

Reaction of the Methoxysilanes with Organometallic Agents. It is generally known that the stereochemistry of nucleophilic substitution at silicon is mainly controlled by the nature of leaving groups on silicon, and the

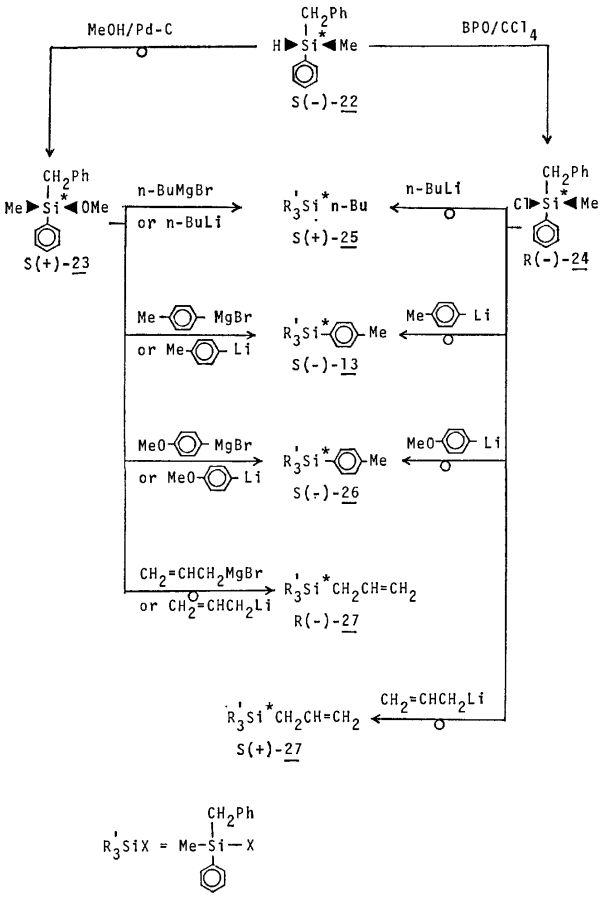


Scheme 1.

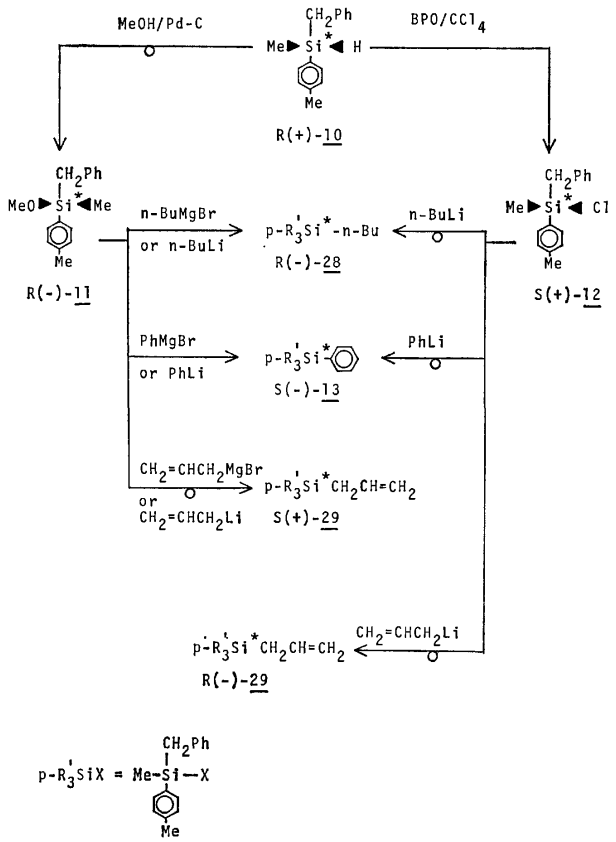
electronic character of the nucleophiles.

However, the stereochemistry of the reaction of methoxysilane with organometallic agents seems to be complex. There have been conflicting reports in the literature concerning the stereochemistry of the reaction of methoxysilanes: an inversion reaction of the configuration of benzylphenylmethylmethoxysilane with the aryl Grignard reagents such as mesityl-, and 1-naphthylmagnesium bromide,[3] and a retention reaction of the configuration of methylmethoxy(1-naphthyl)phenylsilane with allyllithium.[4]

On the other hand, we indicated previously that the stereochemical courses of the reaction of *S*(+)-**23** with the organolithium agents such as butyl-, *p*-methoxyphenyl-, and allyllithium, were in agreement with those for methylmethoxy(1-naphthyl)phenylsilane.[1]



Scheme 2.



Scheme 3.

Thus, the investigation of the reaction courses of *S*(+)-benzylphenylmethylmethoxysilane(**23**) with the Grignard reagents were carried out (Scheme 2).

The stereochemical courses of the reaction of *S*(+)-**23** with the Grignard reagents were also in accordance with those of organolithium agents, *i.e.*, the reaction of *S*(+)-**23** with the alkyl-, and arylmagnesium bromide proceed with a retention of the configuration, whereas that of *S*(+)-**23** with allylmagnesium bromide proceeds with an inversion of configuration.

Furthermore, the reactions of *R*(−)-**11** and S(+)-**12** with some organometallic agents were investigated (Scheme 3). It was noted that these results were in fair agreement with those of the benzylmethylphenylsilyl system.

Experimental

The boiling points are uncorrected. The IR spectra were determined with a JASCO IR-A2 spectrometer. The NMR spectra were determined at 60 MHz with a Varian A-60D spectrometer in CCl_4, using TMS as an internal standard. The optical rotations were measured with a JASCO DIP-181 polarimeter. All the reactions of the chlorosilanes and methoxysilanes with organometallic agents were carried out under a dry nitrogen atmosphere. Optically active (+)-**2**, (−)-**4**, and (−)-**22** were obtained in manners described in our report.[1)]

(+)-N-Benzylbenzylmethyl-p-tolylsilylmethylamine (7). A solution of (−)-**4** (18.1 g, 0.071 mol) $[\alpha]_D$ −6.6° (c=3, Et_2O), benzyl chloride (9.0 g, 0.071 mol), and Et_3N (21.6 g, 0.213 mol) was stirred for 4 h at 110 °C. Water (30 ml) and hexane (100 ml) were added to the reaction mixture. The organic layer was separated, washed three times with 10% NaOH, and then dried (Na_2SO_4). Subsequent evaporation and distillation gave (+)-**7**. Bp 159—162 °C/0.1 Torr.** Yield 15.0 g (61%). $[\alpha]_D$ 0° (c=2, Et_2O). NMR δ 0.20 (s, 3, Si–CH_3), 1.0 (s, 1, NH), 2.22 (s, 2, $SiCH_2N$), 2.38 (s, 5, $SiCH_2Ph$, C–CH_3), 3.70 (s, 2, N–CH_2Ph), 6.8—7.5 (m, 14, aromatic protons). Found: N, 3.90%. Calcd for $C_{23}H_{27}NSi$: 4.05%.

(+)-N-Benzyl-N-methylbenzylmethyl-p-tolylsilylamine (8). To a solution of (+)-**7** (14.8 g, 0.043 mol) in THF (150 ml), was added *n*-BuLi (5 ml of 10% w/v hexane solution) by means of a syringe under nitrogen atmosphere. After stirring the solution for 10 h at room temperature, water was added to the solution at 0 °C. The organic layer was separated, washed with water, and then dried (K_2CO_3). Subsequent evaporation and distillation gave (+)-**8**. Bp 163—165 °C/0.16 Torr. Yield 14.4 g (97%). $[\alpha]_D$ +3.6° (c=2, Et_2O). NMR δ 0.29 (s, 3, Si–CH_3), 2.38 (s, 6, N–CH_3, C–CH_3), 2.47 (broad s, 2, Si–CH_2Ph), 3.85 (s, 2, N–CH_2Ph), 6.8—7.5 (m, 14, aromatic protons).

(−)-Benzylmethyl-p-tolylsilanol (9). A solution of (+)-**8** (14.3 g, 0.041 mol) $[\alpha]_D$ +3.6° (c=2, Et_2O), in ether (100 ml) was treated with 0.2 M HCl (150 ml)*** in a separating funnel at 0 °C. The organic layer was separated, washed two times with cold water, and then dried (K_2CO_3). Evaporation of the solvent gave (−)-**9**. It was used in the next reaction without further purification. $[\alpha]_D$ −9.7° (c=1, pentane). NMR δ 0.28 (s, 3, Si–CH_3), 2.1 (s, 1, OH), 2.30 (s, 2, $SiCH_2Ph$), 2.35 (s, 3, C–CH_3), 6.8—7.5 (m, 9, aromatic protons).

** 1 Torr ≈ 133.322 Pa.

*** 1 M = 1 mol dm^{-3}.

*(+)-Benzylmethyl-*p*-tolylsilane (**10**).* A solution of (−)-**9** (8.7 g) in dibutyl ether (100 ml) was added to a suspension of $LiAlH_4$ (4.7 g, 0.125 mol) in ether (110 ml). The mixture had been kept at 90 °C for 30 min, and then the ether was removed. The mixture was stirred for additional 3 h at 140—145 °C. The usual workup of the mixture gave (+)-**10**. Bp 106—107 °C/1.0 Torr. Yield 6.0 g (74%). $[\alpha]_D$ +11.1° (c=2, pentane). NMR δ 0.25 (d, J=3.5 Hz, 3, Si–CH_3), 2.33 (s, 5, $SiCH_2$–, CCH_3), 4.45 (q, J=3.5 Hz, 1, Si–H), 6.8—7.5 (m, 9, aromatic protons).

*(−)-Benzylmethylmethoxy-*p*-tolylsilane (**11**).* Methanol (1.6 g, 0.048 mol) was added slowly to the mixture of (+)-**10** (5.8 g, 0.025 mol) $[\alpha]_D$ +11.1° (c=2, pentane), and 5% Pd/C (0.47 g) in pentane at 0 °C. After evolution of hydrogen ceased, the catalyst was removed off by filtration. Subsequent evaporation and distillation gave (−)-**11**. Bp 123 °C/1.0 Torr. Yield 5.8 g (90%). $[\alpha]_D$ −2.6° (c=2, pentane). NMR δ 0.23 (s, 3, Si–CH_3), 2.31 (s, 5, Si–CH_2Ph, C–CH_3), 6.8—7.5 (m, 9, aromatic protons).

*(+)-Benzyl(chloro)methyl-*p*-tolylsilane (**12**).* A solution of (+)-**10** (1.0 g, 4.4 mmol) and BPO (78 mg, 0.23 mmol) in CCl_4 (4 ml) was sealed in a sample tube under nitrogen atmosphere. The tube was then maintained for 11 h at 80 °C. The subsequent evaporation gave (+)-**12**. The chlorosilane (+)-**12** was extreamly moisture-sensitive, and extensive racemization of (+)-**12** was observed in the presence of a trace of H_2O. The product was used without further purification. $[\alpha]_D$ +5.2° (c=1.3, CCl_4). NMR δ 0.55 (s, 3, Si–CH_3), 2.36 (s, 3, C–CH_3), 2.54 (s, 2, $SiCH_2$Ph), 6.8—7.5 (m, 9, aromatic protons).

*Preparation of the Series of the Benzylmethyl-*o*-tolylsilyl Systems, (−)-**14**—(−)-**19**.* In manners similar to that described above, the series of benzylmethyl-*o*-tolylsilyl systems *i.e.*, (−)-**14**, (−)-**15**, (+)-**16**, (−)-**17**, (+)-**18**, and (−)-**19** were obtained from (+)-**2** (22.8 g, 0.089 mol) $[\alpha]_D$ +5.1° (c=2, Et_2O).

*(−)-**14***: Yield 22.8 g (74%). Bp 175—180 °C/0.3 Torr. $[\alpha]_D$ −7.9° (c=2, Et_2O). NMR δ 0.29 (s, 3, Si–CH_3), 0.9 (s, 1, NH), 2.28 (s, 2, $SiCH_2N$), 2.34 (s, 3, C–CH_3), 2.38 (s, 2, $SiCH_2$Ph), 3.68 (s, 2, NCH_2Ph), 6.5—7.5 (m, 14, aromatic protons). Found: N, 4.10%. Calcd for $C_{23}H_{27}NSi$: N, 4.05%.

*(−)-**15***: $[\alpha]_D$ −9.4° (c=2, Et_2O). NMR δ 0.32 (s, 3, Si–CH_3), 2.36 (s, 6, N–CH_3, C–CH_3), 3.90 (s, 2, $SiCH_2$Ph), 6.7—7.5 (m, 14, aromatic protons).

*(+)-**16***: $[\alpha]_D$ +8.2° (c=1.2, pentane). NMR δ 0.33 (s, 3, Si–CH_3), 1.7 (broad s, 1, OH), 2.38 (s, 2, $SiCH_2$Ph), 2.43 (s, 3, C–CH_3), 6.6—7.5 (m, 9, aromatic protons).

*(−)-**17***: Yield 8.5 g (57% from (−)-**14** employed). Bp 114 °C/1.5 Torr. $[\alpha]_D$ −16.8° (c=2.2, pentane). NMR δ 0.29 (d, J=3.5 Hz, 3, Si–CH_3), 2.35 (s, 5, $SiCH_2$–, C–CH_3), 4.55 (q, J=3.5 Hz, 1, SiH), 6.8—7.5 (m, 9, aromatic protons).

*(+)-**18***: Bp 130 °C/1.5 Torr. $[\alpha]_D$ +5.3° (c=2, pentane). NMR δ 0.30 (s, 3, Si–CH_3), 2.39 (s, 5, $SiCH_2$Ph, C–CH_3), 3.40 (s, 3, O–CH_3), 6.8—7.6 (m, 9, aromatic protons).

*(−)-**19***: $[\alpha]_D$ −14.5° (c=1.3, CCl_4). NMR δ 0.65 (s, 3, Si–CH_3), 2.25 (s, 3, C–CH_3), 2.60 (s, 2, $SiCH_2$Ph), 6.8—7.5 (m, 9, aromatic protons).

*(−)-Benzylmethylphenyl-*p*-tolylsilane (**13**).*[1] To a solution of PhLi (*ca.* 12 mmol) in ether (10 ml) was added a solution of (−)-**11** (1.0 g, 3.9 mmol) $[\alpha]_D$ −2.6° (c=2, pentane), in THF (10 ml) at 0 °C by means of a syringe. The mixture was refluxed for 2 h with stirring. The usual workup of the reaction mixture gave (−)-**13** in a 36% (0.43 g) yield. Bp 160 °C/0.2 Torr. $[\alpha]_D$ −1.9° (c=8.7, CH_2Cl_2).

In a manner similar to that described above, the reaction of (−)-**11**, $[\alpha]_D$ −2.6° (c=2, pentane) with PhMgBr gave (−)-**13** in 20% yield. $[\alpha]_D$ −1.7° (c=4.6, CH_2Cl_2). The reaction of (+)-**12**, $[\alpha]_D$ +5.2° (c=1.3, CCl_4) with PhLi gave (−)-**13** in 80% (0.91 g) yield. $[\alpha]_D$ −2.6° (c=8.7, CH_2Cl_2).

*(−)-Benzylmethylphenyl-*o*-tolylsilane (**20**).*[1] In manners similar to that described above, reaction of (+)-**18** with PhLi and PhMgBr, and of (−)-**19** with PhLi was carried out. The reaction of (+)-**18**, $[\alpha]_D$ +5.3° (c=2, pentane) with PhLi gave (−)-**20** in a 52% yield. $[\alpha]_D$ −7.0° (c=2, CH_2Cl_2). The reaction of (+)-**18** $[\alpha]_D$ +5.3° (c=2, pentane) with PhMgBr gave (−)-**20** in a 30% yield. $[\alpha]_D$ −5.2° (c=2, CH_2Cl_2). The reaction of (−)-**19**, prepared from (−)-**17** $[\alpha]_D$ −16.8° (c=2.2, pentane), with PhLi gave (−)-**20** in a 60% yield. $[\alpha]_D$ −12.1° (c=7, CH_2Cl_2).

*(−)-Benzylmethyl-*o*-tolyl-*p*-tolylsilane (**21**).* To a solution of (−)-**19**, prepared from (−)-**17** (1 g, 4.4 mmol) $[\alpha]_D$ −16.8° (c=2, pentane) in Et_2O (10 ml), was added a solution of two fold excess of *p*-tolyllithium by means of a syringe at 0 °C. The mixture was stirred for 1 h at room temperature, and then refluxed for additional 1 h with stirring. The usual workup of the mixture gave (−)-**21** in a 60% (0.84 g) yield. $[\alpha]_D$ −14.5° (c=5.5, CH_2Cl_2). NMR δ 0.41 (s, 3, Si–CH_3), 2.19 (s, 3, *o*-CH_3), 2.32 (s, 3, *p*-CH_3), 2.63 (s, 2, $SiCH_2$Ph), 6.6—7.5 (m, 13, aromatic protons).

In a manner silmilar to that described above, (−)-**21** was obtained from (+)-**10** $[\alpha]_D$ +11.1° (c=2, pentane) in a 51% yield. $[\alpha]_D$ −5.5° (c=3, CH_2Cl_2).

*(+)-Benzylbutylmethylphenylsilane (**25**).*[1] (+)-**23** (1 g, 4.1 mmol) $[\alpha]_D$ +3.5° (c=2, pentane) in Et_2O (10 ml) was added to a large excess amount of *n*-BuMgBr in Et_2O. The mixture was refluxed for 90 h with stirring. The usual workup of the mixture gave (+)-**25** in an 83% (0.92 g) yield. $[\alpha]_D$ +3.5° (c=10, CH_2Cl_2).

*(−)-Benzyl(*p*-methoxyphenyl)methylphenylsilane (**26**).*[1] To a solution of (+)-**23** (1 g, 4.1 mmol) $[\alpha]_D$ +3.5° (c=2, pentane) in Et_2O (10 ml) was added a large excess amount of *p*-methoxyphenylmagnesium bromide in Et_2O. The mixture was refluxed for 80 h with strring. The usual workup of the mixture gave (−)-**26** in a 31% (0.41 g) yield. $[\alpha]_D$ −6.6° (c=4, CH_2Cl_2).

*(−)-Allylbenzylmethylphenylsilane (**27**).*[1] To a solution of (+)-**23** (1 g, 4.1 mmol) $[\alpha]_D$ +3.5° (c=2, pentane) in Et_2O (10 ml), was added a solution of allylmagnesium bromide (*ca.* 6.9 mmol) in Et_2O. The mixture was refluxed for 50 h with stirring. The usual workup of the mixture gave (−)-**27** in a 71% (0.74 g) yield. $[\alpha]_D$ −0.42° (c=12.3, CH_2Cl_2).

*(−)-Benzylbutylmethyl-*p*-tolylsilane (**28**).* To a solution of (−)-**11** (1 g, 3.9 mmol) $[\alpha]_D$ −2.6° (c=2, pentane) in Et_2O (20 ml) was added 4 ml of a 10% w/v solution of *n*-BuLi by means of a syringe at 0 °C. After stirring for 1 h at 0 °C, the mixture was hydrolyzed. The usual workup of the mixture gave (−)-**28**. Yield 59% (0.65 g). $[\alpha]_D$ −3.3° (c=11, CH_2Cl_2). NMR δ 0.19 (s, 3, $SiCH_3$), 0.5—1.5 (m, 9, *n*-Bu), 2.28 (s, 2, $SiCH_2$Ph), 2.34 (s, 3, CCH_3), 6.7—7.4 (m, 9, aromatic protons).

In a manner similar to that described above, the treatment of (−)-**11** with butylmagnesium bromide gave (−)-**28** $[\alpha]_D$ −0.96° (c=14, CH_2Cl_2) in a 73% yield. The reaction of (+)-**12** $[\alpha]_D$ +3.2° (c=1.3, CCl_4), prepared from (+)-**10** (1.0 g, 4.4 mmol) $[\alpha]_D$ +6.8° (c=2, pentane) with *n*-BuLi gave (−)-**28** $[\alpha]_D$ −0.72 (c=10, CH_2Cl_2) in a 56% (0.69 g) yield.

*(+)-, and (−)-Allylbenzylmethyl-*p*-tolylsilane (**29**).* To a solution of allyllithium (*ca.* 8 mmol) in Et_2O (70 ml) was added (−)-**11** (1.0 g, 3.9 mmol) $[\alpha]_D$ −2.6° (c=2, pentane)

in ether (10 ml) with stirring at 0 °C. After the mixture had been stirred for 2 h at 0 °C, the usual workup of the mixture gave (+)-**29** $[\alpha]_D$ +1.6° (c=3, CH_2Cl_2) in a 24% (0.25 g) yield. Bp 140 °C/0.2 Torr. NMR δ 0.20 (s, 3, Si–CH_3), 1.72 (d, J=8 Hz, 2, Si–CH_2–C), 2.29 (s, 2, $SiCH_2Ph$), 2.34 (s, 3, CCH_3), 4.6—5.0 (m, 2, =CH_2), 5.3—6.1 (m, 1, CH=C), 6.7—7.4 (m, 9, aromatic protons).

In a manner similar to that described above, the reaction of (−)-**11** (1.0 g, 3.9 mmol) with Allylmagnesium bromide gave (+)-**29** $[\alpha]_D$ +1.6° (c=6, CH_2Cl_2) in a 76% (0.79 g) yield. The reaction of (+)-**12**, prepared from (+)-**10** (1.0 g, 4.4 mmol) $[\alpha]_D$ +6.8° (c=2, pentane) with allyllithium in Et_2O (70 ml), gave (−)-**29** $[\alpha]_D$ −0.63° (c=4.7, CH_2Cl_2) in a 39% (0.28 g) yield.

The authors wish to thank the Shin-etsu Chemical Industry Co. for the gift of dichlorodimethylsilane.

(Received September 16, 1981)

At room temperature in aqueous solution, isoalloxazines and 5-deazaisoalloxazines with 10- dodecyl substituent gave a well-resolved, three-banded Sl peak which has been believed to appear only in nonpolar solvents or in enzymic hydrophobic pockets where isoalloxazines and 5-deazaisoalloxazines become free of hydrogen-bonding effects. On the other hand, 3-methyl-10-ethylisoalloxazine and 5-deazaisoalloxazines with 10- ethyl or 10- octyl group did not give such a fine-structured Sl peak. We have found that (i) the fine structure disappears on the addition of organic solvents (ethanol>40 vol% or pyridine>20 vol%), (ii) the fine structure also disappears on the addition of surfactants (CTAB, Brij-35, and SDS) above the critical micelle concentrations, (iii) 10-dodecylisoalloxazine with hydrophilic 3-(thiazolinio)propyl group at 3-position has not the fine structure, and (iv) the fluorescent intensity of 3-methyl-10-dodecyl-5-deazaisoalloxazine is much weaker than that of 3-methyl-10-ethyl-5-deazaisoalloxazine in aqueous solution but these intensities become comparable above 40 vol% ethanol. These findings are consistently rationalized in terms of an aggregation-deaggregation equilibrium of amphiphilic flavin analogues, supporting that the fine structure in aqueous solution is due to the "stacking" association of (5-deaza)isoalloxazine nuclei, like that of dye molecules. The aggregation-deaggregation phenomenon is sensitively reflected by the reactivity: the reaction of 3-methyl-10-ethyl-5-deazaisoalloxazine and cyanide ion gave $k_2=1.27\ M^{-1}\ s^{-1}$ in aqueous solution at 30 °C, whereas aggregated 3-methyl-10-dodecyl-5-deazaisoalloxazine did not react with cyanide ion. These findings have significant implications on the chemistry of flavoproteins, because the absorption spectra of enzyme-bound flavins and 5-deazaflavins have frequently been cited to discuss the flavin reactivities.

The light absorption spectra of a flavin (vitamin B_2) family have characteristic dependence upon the medium polarity and have been used as a useful probe in enzymic and membrane biology. Flavins usually have two characteristic absorption maxima at the ultraviolet region (around 330 nm: peak S2) and the visible region (440 nm: peak S1). The absorption spectra can be classified into three categories on the basis of solvent effects on the S1 peak: a simple gaussian-type peak in aqueous solution (type A), two-to-three shoulders in dipolar solvents (DMF, acetonitrile, tetrahydrofuran, *etc.*) (type B), and a three-banded fine structure in nonpolar solvents (benzene, 3-methylpentane, *etc.*) (type C).[1-5] It is also known that the absorption maximum of S2 shifts to shorter wavelengths in nonpolar solvents.[1,2] Thus, the S2 band is frequently used as an indicator of solvent polarity.

We previously found that the S1 peak of 3-methyl-10-dodecylisoalloxazine (amphiphilic flavin analogue) gives a well-resolved, three-banded fine structure even in aqueous solution at room temperature.[6] Since the fine structure of S1 has been believed to appear only in nonpolar solvents or in enzymic hydrophobic pockets where isoalloxazine becomes free of hydrogen-bonding effects,[1-5,7,8] the novel finding in the nonenzymatic aqueous solution helps understanding the origin of the fine structure in enzymatic systems. Based on the spectral examination, we proposed that the fine structure is attributable to "stacking" association of the isoalloxazine nuclei which is induced by hydrophobic aggregation of 10-dodecyl groups.[6,9]

As an extention of the study, we examined the spectral characteristics of following isoalloxazines (**1**) and 5-deazaisoalloxazines (**2**) (see Table 1 for their 3- and 10- substituents) in aqueous solution. The results support again the importance of the aggregation in the absorption and the fluorescent spectrum.

TABLE 1. ABBREVIATIONS OF ISOALLOXAZINES AND 5-DEAZAISOALLOXAZINES

Abbreviation	R_3	R_{10}
1MeEt	CH_3-	CH_3CH_2-
1MeDod	CH_3-	$CH_3(CH_2)_{11}$-
1HDod	H-	$CH_3(CH_2)_{11}$-
1ThDod		$CH_3(CH_2)_{11}$-
2MeEt	CH_3-	CH_3CH_2-
2MeOct	CH_3-	$CH_3(CH_2)_7$-
2MeDod	CH_3-	$CH_3(CH_2)_{11}$-

Experimental

Preparations of isoalloxazine derivatives (**1**MeEt, **1**MeDod, **1**HDod, and **1**ThDod) were described previously.[9-11] The preparation method of **2**MeEt was also reported.[12] Preparations of **2**MeOct and **2**MeDod will be described soon in a separate paper.

The absorption spectra of isoalloxazines and 5-deazaisoalloxazines were taken at 30±0.1 °C on a Hitachi 200 spectrophotometer equipped with a thermostated cell-holder. The concentration was usually 5.00×10^{-5} M.†† The fluorescent spectra were taken at 30±0.1 °C on a Hitachi 650-10S spectrophotometer equipped with a thermostated cell-holder. The concentration was usually 5.00×10^{-7} M. The excitation wavelengths for isoalloxazines and 5-deazaisoalloxazines were 380 and 330 nm, respectively, and the slit widths of excitation and emission were 3 and

†† 1 M=1 mol dm^{-3}.

15 nm, respectively.

The reaction of cyanide ion and 5-deazaisoalloxazines was monitored spectrophotometrically at 30±0.1 °C by following the disappearance of 5-deazaisoalloxazines at their λ_{max}. The typical conditions were: $[CN^-]=1.00\times10^{-3}$ M and [5-deazaisoalloxazine]$=5.00\times10^{-5}$ M in aqueous 2 vol% DMF solution. The first-order behavior was observed for at least up to three half-lives. The pseudo-first-order rate constants thus obtained were proportional to the cyanide ion concentration. Hence, the reaction is first-order in cyanide ion and 5-deazaisoalloxazine.

Results and Discussion

Absorption Spectra in Various Solvents. The typical absorption maxima of isoalloxazines and 5-deazaisoalloxazines are summarized in Tables 2 and 3, respectively. Table 2 shows that **1**MeEt is subject to typical solvent effects:[1-5] S1 is a gaussian-type peak in aqueous solution (type A), has shoulders in polar solvents (type B), and has a three-banded fine structure in nonpolar solvents (type C). The λ_{max} of S2 shifted to shorter wavelengths with lowering the solvent polarity, as reported by Koziol and others.[1-5] On the other hand, S1 of **1**MeDod and **1**HDod was a well-resolved fine structure even in aqueous solution (*i.e.*, type C: Fig. 1). The shape of the S1 peak was almost unaffected at the concentration range $(0.10—2.40)\times10^{-4}$ M. Although these fine-structured peaks in aqueous solution are similar to that of **1**MeEt in benzene, the blue shift of S2 was not observed for aqueous **1**MeDod and **1**HDod (*e.g.*, 340 and 343 nm, respectively; compare with the blue shift of **1**MeEt, 341 (water)→328(benzene)). The result suggests that the fine structure observed in the aqueous system cannot be rationalized in terms of the simple solvent effect.

Table 2. Absorption maxima(nm) of isoalloxazines in various media (30 °C)[a]

Medium	1MeEt S2	1MeEt S1	1MeDod S2	1MeDod S1	1HDod S2	1HDod S1	1ThDod S2	1ThDod S1

Benzene	318(S),	405(S) 427			318(S),	405(S) 428

a) (S) indicates that the peak has shoulders. Two-to-three values given for S1 indicate each absorption maximum for the fine structure split.

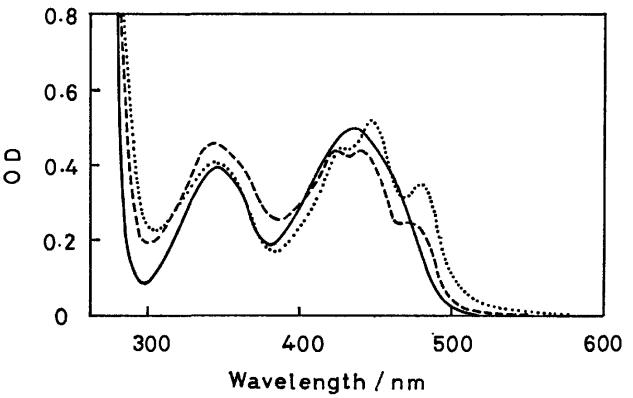

Fig. 1. Absorption spectra of **1**HDod(- - -), **1**MeDod (·····), and **1**ThDod(——) in water. [isoalloxazine]$=5.00\times10^{-5}$ M.

Interestingly, the fine structure of **1**MeDod and **1**HDod has disappeared completely in aqueous solutions containing surfactants above the critical micelle concentrations(cmc), and the spectra were classified as type B (Table 2). Similarly, the fine structure disappeared on the addition of organic solvents (*vide infra*). The fine structure also disappeared by introducing a hydrophilic 3-(thiazolinio)propyl group at 3-position of 10-dodecylisoalloxazine (Fig. 1). These results, together with our previous findings,[6,9] strongly suggest that the fine structure of aqueous **1**MeDod and **1**HDod stems from the association of the isoalloxazine nuclei which is induced by hydrophobic interaction between 10- dodecyl groups. The disappearance of the fine structure in the micellar system is accounted for by the loss of the interaction between the isoalloxazine nuclei in the micellar phase (*i.e.*, dilution effect). The phenomenon is similar to that of the absorption spectrum of dye molecules: "stacking" association of dye molecules induces the split of the absorption bands in aqueous solution, but it disappears in micellar solutions.[13-16] The disappearance of the fine structure by adding organic solvents is accounted for by deaggregation due to the enhanced solubility.

It occurred to us that if the fine structure is induced by the aggregation, the S1 peak of **1**ThDod may split above its cmc. The cmc of cationic C_{12}-surfactants is about 10 mM,[17] so that we measured the spectrum of **1**ThDod at 0.05—30 mM by using 1 cm—0.1 mm width cuvettes. As shown in Fig. 2, the shape of the S1 peak was almost identical below 10 mM while clear shoulders were observed above 20 mM. Probably, the cmc of **1**ThDod is at this concentration. The result supports that the split of the S1 peak is significantly associated with the aggregation phenomenon.

The solvent effect on the absorption spectrum of 5-deazaisoalloxazine has not been examined systematically. Table 3 and Fig. 3 show that in general, the solvent effects on S1 of **2**MeEt are quite similar

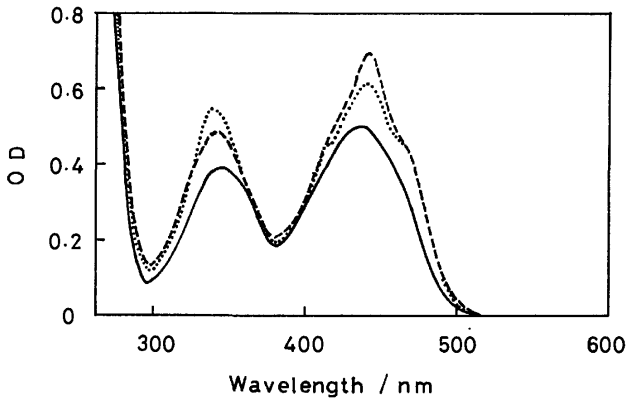

Fig. 2. Absorption spectra of **1**ThDod in water at different concentrations.
——: 10 mM, - - -: 20 mM, ·····: 30 mM. The Y-axis is normalized to 5×10^{-5} M in 1 cm cell.

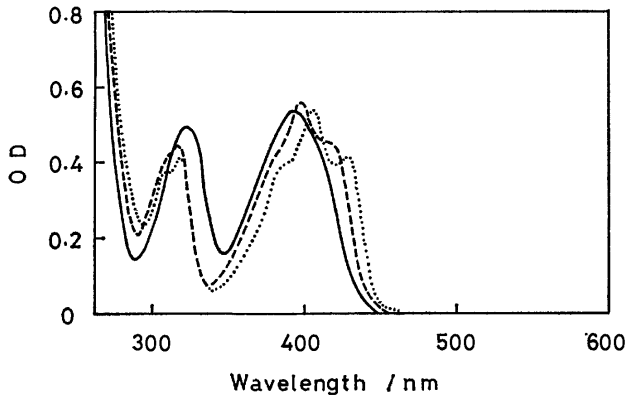

Fig. 3. Absorption spectra of **2**MeEt in water (——), acetonitrile (- - -), and benzene (·····).
[**2**MeEt]$=5.00\times10^{-5}$ M.

to those on **1**MeEt. The following points are noticeable differences: (i) the blue shift of S2 in nonpolar solvents is smaller than that of S2 of isoalloxazines (*e.g.*, 323 nm in water→318 nm in benzene) and (ii) the S2 peak in benzene and *o*-dichlorobenzene(*o*-DCB) has a shoulder at 310 nm (Fig. 3). A similar shoulder on S2 has been observed for tetra-*O*-butyrylriboflavin in carbon tetrachloride.[4] As expected, **2**MeDod (amphiphilic 5-deazaisoalloxazine) gave a three-banded S1 peak. Being different from that of amphiphilic isoalloxazines, the ε_{max} of S2 (12300) is greater than any of S1 (9000, 10400, and 6040). Since the fine structure disappeared in surfactant micellar solutions, the association of 5-deazaisoalloxazine nuclei is responsible for the appearance of the fine structure.

Another amphiphilic 5-deazaisoalloxazine, **2**MeOct in water did not give a three-banded S1 peak but a broad absorption band spreading to 500—600 nm, and the ε_{max} of S1 was smaller than that of S2 (Fig. 4). The longer-wavelength absorption band disappeared in 20 vol% ethanol. One may thus presume that **2**MeOct forms some aggregate in aqueous solution though it is not stable enough to induce a fine structure split. Attempting to stabilize the aggregate, we measured the spectrum of **2**MeOct (5.00×10^{-5} M) in KCl (0.25—2 mM) containing aqueous solutions and at high

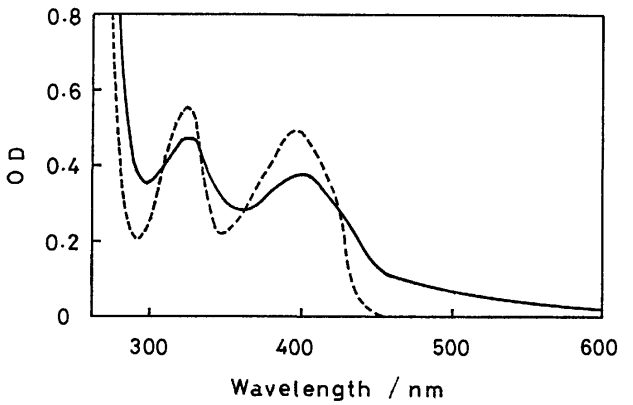

Fig. 4. Absorption spectra of **2**MeOct in water (——) and 20 vol% aqueous ethanol (- - -).
[**2**MeOct]$=5.00\times10^{-5}$ M.

2MeOct concentrations ($\approx2.40\times10^{-4}$ M). However, the spectra were apparently identical under these measurement conditions.

Absorption Spectra in Water–Ethanol and Water–Pyridine Mixed Solvents. Since the fine structure of amphiphilic isoalloxazines and 5-deazaisoalloxazines stems from the association of the nuclei, addition of organic solvents which causes the deaggregation of these amphiphiles would change the shape of the S1 speak. The spectral results are summarized in Tables 4 and 5. Addition of ethanol or pyridine changed the spectral shape of S1 of **2**MeEt from type A to type B (ethanol) or to type C(pyridine). More peculiar spectral changes were observed for **2**MeDod: a new, broad absorption band appeared at 500—600 nm region below 40 vol% ethanol and 20 vol% pyridine, and both the fine structure and the longer-wavelength absorption band disappeared above these solvent compositions (Fig. 5). We previously reported that a similar longer-wavelength absorption band is observed for **1**MeDod in ethanol (<45 vol%) and pyridine (<20 vol%) solutions.[6,9] In particular, the absorption band in aqueous pyridine was so strong (*e.g.*, ε_{550} 4420 in

[**2**MeDod]$=5.00\times10^{-5}$ M.

18 vol% pyridine) that we ascribed the new absorption band to a specific charge transfer interaction between pyridine and isoalloxazine. A similar band was observable in aqueous solutions containing 4-(dimethylamino)pyridine, 3-indoleacetic acid, and *o*-aminobenzoic acid. Since the longer-wavelength absorption band of **2**MeDod in aqueous pyridine was not so strong and was rather comparable with that in aqueous ethanol, this band may not be ascribed to a simple charge transfer interaction. Probably, the electron-acceptability of **2**MeDod may be weaker than that of **1**MeDod.

In Fig. 6, OD_{500} as a measure of the strength of the longer-wavelength absorption band is plotted as a function of solvent compositions. The OD_{500} became largest at 33 vol% ethanol and 13 vol% pyridine and decreased sharply at higher solvent compositions.

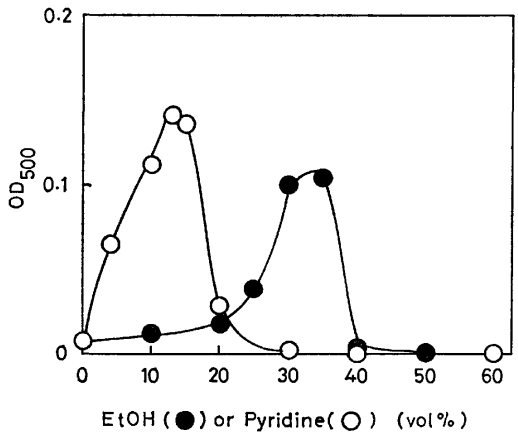

Fig. 6. OD_{500} *vs.* solvent concentration.
[**2**MeDod]$=5.00\times10^{-5}$ M.

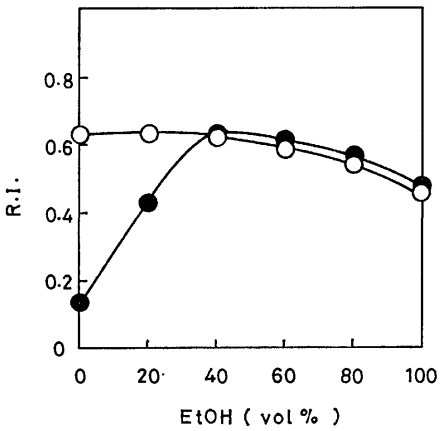

Fig. 7. Relative intensity(R.I.) of emission maxima *vs.* ethanol concentration.
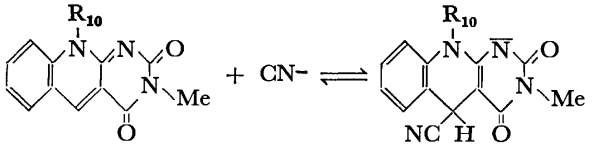
○: **2**MeEt(5.00×10^{-7} M), ●: **2**MeDod(5.00×10^{-7}).

These results indicate that there is a critical transition from the aggregated form to the monomeric form at 40 vol% ethanol or 20 vol% pyridine. In **1**MeDod and **2**MeDod as amphiphiles, (5-deaza)isoalloxazines are hydrophilic head groups. The "stacking" association between the head groups induces the fine structure split of S1. On the other hand, addition of organic solvents, more or less, would disturb the orientation of the aggregation form, and probably, the disturbed orientation would be responsible for the longer-wavelength absorption band. At the transition points, both the fine structure and the longer-wavelength absorption disappear because of the deaggregation to the monomeric forms.

Fluorescent Spectra. Figure 7 shows the influence of added ethanol on the relative intensity (R.I.) of fluorescent maxima (about 460 nm) of **2**MeEt and **2**MeDod in aqueous solution. The R.I. value of **2**MeEt was affected to a smaller extent by added ethanol, slightly decreasing with increasing ethanol concentration. On the other hand, the R.I. of **2**MeDod in water was very small, increasing rapidly with increasing ethanol concentration. The value at 40 vol% was almost equal to that of **2**MeEt. The results indicate that the fluorescent spectra of **2**MeDod

are also explicable on the basis of the aggregation-deaggregation phenomenon: the weak R.I. of **2**MeDod in water is ascribed to concentration quenching due to the association of 5-deazaisoalloxazine nuclei, and solvent-induced deaggregation leads to the increase in R.I. more than expected from the simple solvent effect. The 40 vol% ethanol composition where the abnormality of **2**MeDod disappears is exactly equal to the transition estimated from the absorption spectra.

Nucleophilic Reactivity of Cyanide Ion. It is interesting to assess whether the aggregation-deaggregation equilibrium of **2**MeDod is reflected by its reactivity. To test the possibility, we determined the rate constants for the nucleophilic reaction of cyanide ion toward 5-deazaisoalloxazines[18,19] in water–ethanol mixed solvents.



(1)

The reaction was first-order in cyanide ion and 5-deazaisoalloxazine. In Fig. 8, the second-order rate constants (k_2) are plotted as a function of the ethanol concentration. In aqueous solution, the k_2 values for **2**MeEt and **2**MeOct were 1.27 and 0.86 $M^{-1} s^{-1}$, respectively, whereas that for **2**MeDod was not detected at all under the present experimental conditions ($k_2 < 0.001\ M^{-1} s^{-1}$). The k_2 for **2**MeEt increased with increasing ethanol concentration. The reaction rate of **2**MeDod in 20 vol% ethanol was still very slow ($k_2 = 0.003\ M^{-1} s^{-1}$) but suddenly became fast in 30 vol% ethanol ($k_2 = 1.48\ M^{-1} s^{-1}$). **2**MeOct in most cases gave the medium rate constants. The rate constants for three 5-deazaisoalloxazines were almost identical above 40 vol% ethanol. The plots in Fig. 8 are well correlative to those in Figs. 6 and 7, indicating that the reactivity of 5-deazaisoalloxazines is significantly related to the aggregation-deaggregation equilibrium.

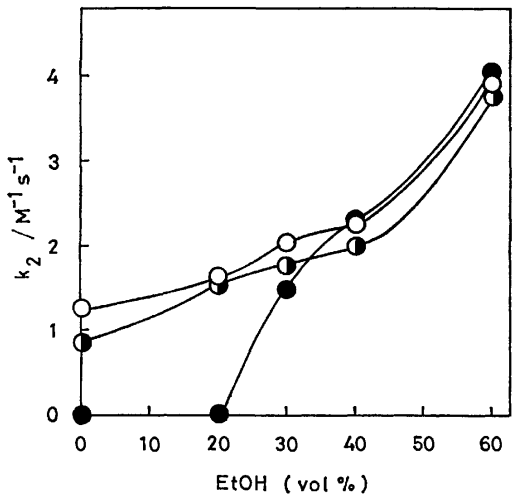


Fig. 8. Second-order rate constants for the reaction of cyanide ion (1.00×10^{-3} M) and 5-deazaisoalloxazines (5.00×10^{-5} M). ○: **2**MeEt, ◑: **2**MeOct, ●: **2**MeDod.

Branched-chain Sugars. XXVIII. Synthesis of 2-*C*-Methyl-L-glyceraldehyde, 2-*C*-Methyl-D-erythrose, and 3-*C*-Methyl-L-erythrose Derivatives[1]

Juji YOSHIMURA,* Kazutoshi HARA, Masanori YAMAURA, Kazutoshi MIKAMI, and Hironobu HASHIMOTO

Laboratory of Chemistry for Natural Products, Faculty of Science, Tokyo Institute of Technology, Nagatsuta, Midori-ku, Yokohama 227

(Received August 19, 1981)

As synthons for the synthesis of bicyclomycin, the title compounds were derived from 1,2:5,6-di-*O*-isopropylidene-3-*C*-methyl-α-D-allofuranose by the descendent method.

Recent advances in the chiral synthesis established the general recognition that monosaccharides are valuable sources of chiral synthons for optically active, non-sugar natural products.[2-4] However, it seems likely that the strategy for the derivation of a desired synthon from a proper monosaccharide is still under development. As a part of the synthetic studies on branched-chain sugars, this paper describes the preparation of 2-*C*-methyl-L-glyceraldehyde, 2-*C*-methyl-D-erythrose, and 3-*C*-methyl-L-erythrose derivatives as synthons for the chiral synthesis of bicyclomycin[5] (**1**) which contains a (1*S*,2*S*)-1,2,3-trihydroxy-2-methylpropyl group attached to a bicyclic 2,5-piperazinedione ring. After a few attemps, the aimed compounds were derived from 1,2-*O*-isopropylidene-3-*O*-benzyl-3-*C*-methyl-α-D-allofuranose,[6] obtained from D-glucose *via* four-step conversions, by the descendent method.

Results and Discussion

In general, two approaches, *i.e.* i) introduction of a methyl-branching into an appropriate tetrose or triose derivative and ii) decrement of carbon number from a higher carbon branched-chain sugar, are considered for the present synthesis.

Firstly, periodate oxidation of 2,5-di-*C*-methyl-L-iditol protected at 1,2,5,6-positions was considered to be the ideal method for the preparation of 2-*C*-methyl-L-glyceraldehyde derivatives, as the preparation of 2,3-*O*-isopropylidene-D-glyceraldehyde from 1,2:5,6-di-*O*-isopropylidene-D-mannitol has been well-known.[7] For the protection of 1,6-positions of 3,4-*O*-isopropylidene-D-mannitol,[8] the usual tritylation with triphenylmethyl chloride in pyridine gave the corresponding di-*O*-trityl derivative (**2**) in 74% yield. However, benzoylation with benzoyl chloride under similar conditions gave a mixture of di- (**4**), tri- (**5**), and tetrabenzoate (**6**) in the ratio of 2:2:1, together with a small amount of monobenzoate and the unchanged starting material. When the benzoylation was conducted in chloroform at 0 °C in the presence of pyridine, the desired **4** was selectively obtained in 80% yield. The structure of **2** and **4** was confirmed by the derivation into the corresponding 2,5-diacetates (**3** and **7**).

Oxidation of **4** with dimethyl sulfoxide (DMSO)–acetic anhydride gave only 5-*O*-acetyl-1,6-di-*O*-benzoyl-3,4-*O*-isopropylidene-D-fructose (**8**) in 90% yield, but did not give the corresponding diketone. The structure of **8** was ascertained by the comparison of its NMR spectrum with that of the corresponding 5-*O*-benzoyl derivative (**9**) obtained by the similar oxidation of **5**. These compounds showed a characteristic larger geminal coupling constant (17.5 Hz) of H-1 and H-1′ protons. Attemped oxidation of **4** with DMSO–phosphorus pentaoxide[9] gave a complex product from which the corresponding monoketone (**10**) was separated. All other oxidations with ruthenium tetraoxide, pyridimium chlorochromate,[10] and potassium permanganate gave unsuccessful results. Moreover, NMR spectra of the reaction products obtained by the reactions of these monoketones with methylmagnesium iodide showed the presence of epimeric *C*-methyl (δ 1.25—1.15) derivatives in the ratios from 1:4 to 1:1. Therefore, this approach was given up.

Secondly, *C*-methylation of known 2,4-*O*-ethylidene-D-erythritol[11] was considered. Partial benzoylation of the substrate with benzoyl chloride gave 1-*O*-benzoyl-2,4-*O*-ethylidene-D-erythritol (**11**) in 80% yield. However, oxidation of **11** with DMSO–trifluoroacetic an-

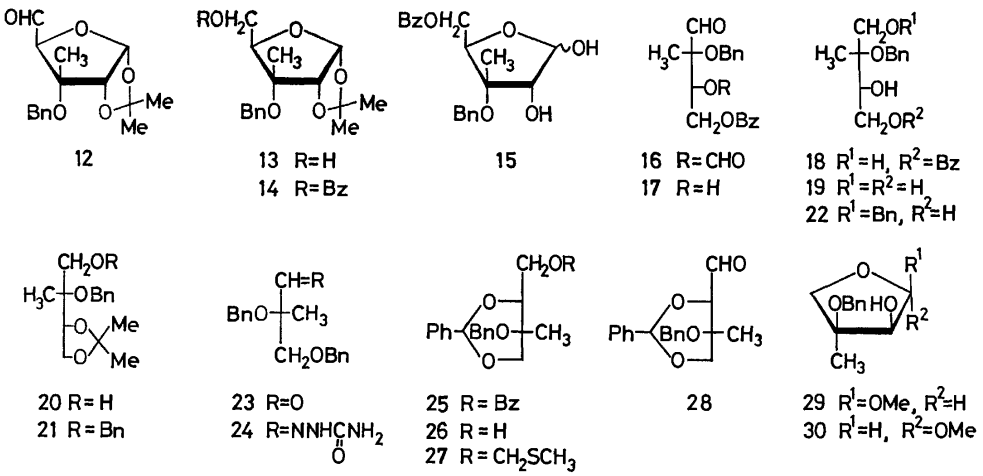
11



hydride[12] was unsuccessful, probably due to the accompanying β-elimination and also oxidation of the ethylidene group.[13]

From the aforementioned failed results, the descendent method from 1,2-*O*-isopropylidene-3-*O*-benzyl-3-*C*-methyl-α-D-allofuranose,[6] which seems to be the most certain, was thirdly adopted.

Periodate oxidation of the starting α-D-allofuranose gave 3-*O*-benzyl-1,2-*O*-isopropylidene-3-*C*-methyl-α-D-*ribo*-pentodialdofuranose (**12**) quantitatively. Reduction of **12** with sodium borohydride gave the corresponding α-D-ribofuranose (**13**) in 94% yield. The usual benzoylation of **13** gave the corresponding benzoate (**14**) in 95% yield. Partial hydrolysis of **14** with 70% acetic acid gave de-*O*-isopropylidenated product (**15**) in 96% yield. Periodate oxidation of **15** and successive reduction with sodium borohydride gave 4-*O*-benzoyl-2-*O*-benzyl-2-*C*-methyl-D-erythritol (**18**) in 92% yield. The intermediary 4-*O*-benzoyl-2-*O*-benzyl-3-*O*-formyl-D-erythrose (**16**) could not be purified, but characterized by its NMR spectrum, and 4-*O*-benzoyl-2-*O*-benzyl-2-*C*-methyl-D-erythrose (**17**) could be incidentally obtained as crystals from an incomplete reduction products. Treatment of **18** in methanol with a catalytic amount of sodium methoxide gave de-*O*-benzoylated product (**19**) in a good yield.

For the conversion of **19** into branched-chain sugars of L-series, periodate oxidation of **19** was tried. However, the product showed eight kinds of *C*-methyl signals in the NMR spectrum, indicating 2-*O*-benzyl-2-*C*-methyl-L-glyceraldehyde exists in polymeric states. Therefore, **19** was treated with acetone containing sulfuric acid catalyst to give the corresponding 3,4-*O*-isopropylidene derivative (**20**) in 70% yield. Successive benzylation of **20** with sodium hydride and benzyl chloride gave the 1-*O*-benzyl derivative (**21**) in 68% yield, which was partially hydrolyze into the corresponding de-*O*-isopropylidenate product (**22**) in 84% yield. Periodate oxidation of **22** gave the desired 2,3-di-*O*-benzyl-2-*C*-methyl-L-glyceraldehyde (**23**) quantitatively. Because **23** is stable at room temperature only for a few h, it was instantly characterized as the crystalline semicarbazone (**24**).

On the other hand, benzylidenation of **18** with dimethoxytoluene gave the corresponding benzylidene derivative (**25**) which was then converted into the de-*O*-benzoyl derivative (**26**) in a good yield, by treatment with sodium methoxide. Oxidation of **26** with DMSO–dicyclohexylcarbodiimide gave 3-*O*-benzyl-2,4-*O*-benzylidene-3-*C*-methyl-L-erythrose (**28**) and the corresponding methylthiomethyl ether (**27**) in 27 and 25% yield, respectively. The L-erythose derivative **28** was further characterized by the conversion into methyl 3-*O*-benzyl-3-*C*-methyl-α- and β-L-erythrofuranosides (**29** and **30**) by treatment with methanolic hydrogen chloride.

Thus, it was shown that the descendent method of a branched-chain hexose having a proper configuration provides certain pathways to various lower carbon branched-chain sugars of D- and L-series, by the combination of the protection of hydroxyl groups with an aldehyde or a ketone and periodate cleavage of carbon-chain.

Experimental

General Methods. Melting points were determined with a Mel-Temp melting point apparatus and not corrected. Evaporations were conducted under diminished pressure. Optical rotations were measured in a 0.5 dm tube with Carl Zeiss LEP-Al or JASCO DIP-4 polarimeter, using chloroform as a solvent unless otherwise stated. IR spectra were recorded with a Hitachi EPI-G2 grating spectrometer. NMR spectra were recorded with a JEOL JNM PS-100 spectrometer for solutions in chloroform-*d* containing tetramethylsilane as the internal reference. Chemical shifts and coupling constants were recorded in δ and Hz units, respectively, and IR frequencies in cm^{-1}.

3,4-O-Isopropylidene-1,6-di-O-triphenylmethyl-D-mannitol (2) and Its 2,5-Diacetate (3). To a solution of 3,4-*O*-isopropylidene-D-mannitol[8] (10 g, 45 mmol) in pyridine (30 ml) was added triphenylmethyl chloride (27 g, 96.9 mmol) portionwise, and the resulting solution was kept at room temperature for 2 d, poured into ice–water, and extracted with dichloromethane. The extract was washed successively with water, 0.1 M sulfuric acid, saturated aqueous sodium hydrogencarbonate, and water, and then evaporated. The residual syrup was crystallized from ethanol to give **2** as prisms in 74% (23.5 g) yield. Mp 174—175 °C; $[\alpha]_D^{24}$ +10.5° (*c* 1.0, MeOH).

Found: C, 79.25; H, 6.33%. Calcd for $C_{47}H_{46}O_6$: C, 79.86; H, 6.56%.

The usual acetylation of **2** (1.4 g, 2 mmol) in pyridine (2 ml) with acetic anhydride (4 ml) gave **3** as needles in 83% (1.3 g) yield. Mp 154—155 °C (ethanol); $[\alpha]_D^{22}$ −5.5° (*c* 1.0, MeOH); NMR: 7.5—7.1 (m, 30H, 6 Ph), 5.18 (dd, 2H, $J_{2,3}=J_{4,5}=4.5$, H-2 and 5), 3.98 (d, 2H, H-3 and 4), 3.30 (d, 4H, $J_{1,2}=J_{5,6}=4.7$, H-1,1′,6, and 6′), 2.09 (s, 6H, 2Ac), 1.15 (s, 6H, Ip).

Found: C, 76.82; H, 6.32%. Calcd for $C_{51}H_{50}O_5$: C, 77.45; H, 6.37%.

*Benzoylation of 3,4-*O*-Isopropylidene-*D*-mannitol.* To an ice-cooled solution of 3,4-*O*-isopropylidene-D-mannitol (22.2 g, 0.1 mol) in pyridine (100 ml) was added with stirring benzoyl chloride (29.5 g, 0.21 mol) dropwise. The mixture was kept at room temperature overnight, poured into ice-water, and extracted with dichloromethane. The usual processing of the extract and fractionation of the products on a column of silica gel with 50:1 benzene–acetone gave in turn tetra- (**6**), tri- (**5**), and dibenzoate (**4**) in 12% (7.65 g), 24% (12.8 g), and 24% (10.3 g) yield, respectively.

6: mp 120—122 °C; $[\alpha]_D^{24}$ −0.59° (*c* 0.8, MeOH); NMR: 8.0—7.8 and 7.6—7.2 (m, 20H, 4Ph), 5.61 (m, 2H, H-2 and 5), 4.75 (dd, 2H, $J_{1,2}=J_{5,6}=3.2$, $J_{1,1'}=J_{6,6'}=12.2$, H-1 and 6), 4.59 (d, 2H, $J_{2,3}=J_{4,5}=6.0$, H-3 and 4), 4.56 (dd, 2H, $J_{1',2}=J_{5,6'}=6.0$, H-1′ and 6′), 1.49 (s, 6H, Ip).

Found: C, 69.52; H, 5.32%. Calcd for $C_{37}H_{30}O_{10}$: C, 69.58; H, 5.37%.

5: mp 115—118 °C (prisms from EtOH); $[\alpha]_D^{24}$ +5.5° (*c* 0.7, MeOH). NMR and IR patterns were very similar to those of **4**.

Found: C, 67.25; H, 5.42%. Calcd for $C_{30}H_{30}O_9$: C, 67.40; H, 5.66%.

4: mp 96—97 °C; $[\alpha]_D^{20}$ +29.2° (*c* 0.4, MeOH); IR: 3400 (OH), 1720 and 1690 (C=O); NMR; 8.1—7.9 and 7.6—7.2 (m, 10H, 2Ph), 4.63 (bd, 2H, $J_{2,3}=J_{3,4}=11.0$, H-1 and 6), 4.5—4.3 (m, 2H, H-1′ and 6′), 3.97 (bs, 6H, H-2,3,4,5 and OH), 1.40 (s, 6H, Ip).

Found: C, 64.67; H, 6.09%. Calcd for $C_{23}H_{26}O_8$: C, 64.17; H, 6.09%.

The usual acetylation of **4** (200 mg, 0.59 mmol) in pyridine (10 ml) with acetic anhydride (10 ml) gave the corresponding diacetate (**7**) in 83% (198 mg) yield. Mp 75—76 °C (ethanol); $[\alpha]_D^{20}$ +21.1° (*c* 1.0, MeOH); IR: 1760—1720 (C=O); NMR: 8.1—7.9 and 7.6—7.3 (m, 10H, 2Ph), 5.33 (m, 2H, H-2 and 5), 4.68 (dd, 2H, $J_{1,2}=J_{5,6}=3.1$, $J_{gem}=12.0$, H-1 and 6), 4.43 (dd, 2H, $J_{1',2}=J_{5,6'}=6.7$, H-1′ and 6′), 4.24 (d, 2H, $J_{2,3}=J_{4,5}=4.6$, H-3 and 4), 2.07 (s, 6H, 2 OAc), 1.46 (s, 6H, Ip).

Found: C, 62.87; H, 5.84%. Calcd for $C_{27}H_{30}O_{10}$: C, 63.03; H, 5.88%.

When the benzoylation of 3,4-*O*-isopropylidene-D-mannitol (5 g, 22.5 mmol) with benzoyl chloride (6.6 g, 47 mmol) was performed in chloroform (50 ml) at 0 °C in the presence of pyridine (3.3 g, 78 mmol), **4** was selectively obtained in 80% (7.75 g) yield.

*5-*O*-Acetyl-1,6-di-*O*-benzoyl-3,4-*O*-isopropylidene-*D*-fructose (**8**).* A solution of **4** (1.5 g, 3.5 mmol) in dimethyl sulfoxide (DMSO, 35 ml) and acetic anhydride (25 ml) was kept at room temperature overnight, and then evaporated. The residual syrup was extracted with dichloromethane. The usual processing of the extract and purification of the product on a column of silica gel with 50:8 petroleum ether–benzene gave syrupy **8** (1.47 g, 89.7%) which was crystallized from hexane. Mp 54—56 °C; $[\alpha]_D^{22}$ +0.67° (*c* 1.13, acetone); IR: 1760—1720 (C=O); NMR: 8.1—7.9 and 7.6—7.3 (m, 10H, 2 Ph), 5.46 (m, 1H, H-5), 5.28 and 5.08 (ABq, 2H, $J=17.5$, H-1 and 1′), 4.8—4.2 (m, 4H, H-3,4,6, and 6′), 2.08 (s, 3H, OAc), 1.46 (s, 6H, Ip).

Found: C, 63.50; H, 5.72%. Calcd for $C_{25}H_{26}O_9$: C, 63.82; H, 5.72%.

*1,5,6-Tri-*O*-benzoyl-3,4-*O*-isopropylidene-*D*-fructose (**9**).* Compound **5** (4.3 g, 8 mmol) was oxidized with DMSO (75 ml) and acetic anhydride (50 ml) as above. Purification of the product gave syrupy **9** (4.2 g) quantitatively, which was crystallized from ethyl acetate–ligroine. Mp 129—130 °C; $[\alpha]_D^{23}$ +15.5° (*c* 1.4, acetone); IR: 1740—1710 (C=O); NMR: 8.1—7.9 and 7.6—7.2 (m, 15H, 3 Ph), 5.69 (m, 1H, H-5), 5.31 and 5.10 (ABq, 2H, $J=17.5$, H-1 and 1′), 4.73 (dd, 1H, $J_{5,6}=4.0$, $J_{6,6'}=12.5$, H-6), 4.72 (d, 1H, $J_{2,3}=4.2$, H-3), 4.69 (t, 1H, H-4), 4.54 (q, 1H, $J_{5,6'}=6.3$, H-6′), 1.45 (s, 6H, Ip).

Found: C, 67.24; H, 5.32%. Calcd for $C_{30}H_{28}O_9$: C, 67.66; H, 5.30%.

*1,6-Di-*O*-benzoyl-3,4-*O*-isopropylidene-*D*-fructose (**10**).* To an ice-cooled mixture of phosphorus pentaoxide (5 g) and DMSO (50 ml) was added with stirring a solution of **4** (6 g, 14 mmol) in DMSO (40 ml), and the resulting solution was kept at room temperature overnight, poured into excess aqueous sodium hydrogencarbonate, and extracted with dichloromethane. The usual processing of the extract gave a syrup (4.8 g) which showed four spots on TLC, excepting a small amount of the starting material. Separation of the syrup on a column of silica gel with 8:1 benzene–acetone gave **10** as the second polar fraction in 19% (1.15 g) yield. NMR spectrum of the most nonpolar fraction indicated that it is a monobenzoyl derivative. Mp 90—91 °C; NMR: 8.2—8.0 and 7.7—7.3 (m, 10H, 2Ph), 5.31 and 5.21 (ABq, 2H, $J=17.5$, H-1 and 1′), 4.75—4.3 (m, 4H, H-3,4,6, and 6′), 4.14 (m, 1H, H-5), 3.0 (bs, 1H, OH), 1.50 and 1.46 (each s, 6H, Ip).

Found: C, 66.18; H, 5.25%. Calcd for $C_{25}H_{24}O_8$: C, 66.36; H, 5.35%.

*1-*O*-Benzoyl-2,4-*O*-ethylidene-*D*-erythritol (**11**).* The usual benzoylation of 2,4-*O*-ethylidene-D-erythritol[11] (3.16 g, 20 mmol) in pyridine (20 ml) with benzoyl chloride (3.08 g, 22 mmol) at 0 °C gave **11** as crystals in 80% (4.58 g) yield. Mp 103—105 °C; $[\alpha]_D^{26}$ +13.4° (*c* 1.0); NMR: 8.2—8.0 and 7.7—7.3 (m, 5H, Ph), 4.77 (dd, 1H, $J_{1,2}=3.0$, $J_{1,1'}=12.0$, H-1), 4.50 (q, 1H, $J=5.0$, CHMe), 4.44 (dd, $J_{1',2}=2.0$, H-1′), 4.15 (dd, $J_{3,4e}=2.6$, $J_{4e,4a}=10.0$, H-4e), 3.75—3.55 (m, 2H, H-2 and 3), 3.48 (t, 1H, H-4a), 3.02 (s, 1H, OH), 1.36 (d, 3H, CMe).

Found: C, 58.02; H, 6.10%. Calcd for $C_{13}H_{16}O_5$: C, 58.20; H, 6.01%.

*3-*O*-Benzyl-1,2-*O*-isopropylidene-3-*C*-methyl-α-*D*-ribo-pentodialdofuranose (**12**).* A solution of 3-*O*-benzyl-1,2-*O*-isopropylidene-3-*C*-methyl-α-D-allofuranose[6] (10 g, 30.8 mmol) and sodium periodate (7.0 g, 32.7 mmol) in aqueous acetic acid (1:1, 60 ml) was stirred for 30 min at room temperature, diluted with water (60 ml), and then extracted with chloroform. The usual processing of the extract gave **12**, quantitatively. Mp 74—76 °C (ether–petroleum ether); $[\alpha]_D^{23}$ +55.5° (*c* 1.1); IR: 1745 (CHO); NMR: 9.67 (s, 1H, CHO), 7.3 (m, 5H, Ph), 5.85 (d, 1H, $J_{1,2}=4.0$, H-1), 4.64 (s, 3H, H-4 and CH_2Ph), 4.38 (d, 1H, H-2), 1.60 (s, 3H, CMe), 1.40 and 1.29 (each s, 6H, Ip).

Found: C, 65.47; H, 7.01%. Calcd for $C_{16}H_{20}O_5$; C, 65.74; H, 6.90%.

*3-*O*-Benzyl-1,2-*O*-isopropylidene-3-*C*-methyl-α-*D*-ribofuranose (**13**).* To an ice-cooled solution of **12** (8.87 g, 30.3 mmol) in aqueous methanol (1:1, 160 ml) was added sodium borohydride (1.15 g, 30.4 mmol) portionwise, and the mixture

was stirred for 3 h, neutralized with 0.1 M hydrochloric acid, evaporated, and the residue was extracted with chloroform. The usual processing of the extract and crystallization and recrystallization of the product from ether–petroleum ether and ethanol–hexane gave **13** (8.58 g, 94%) as needles. Mp 65—66 °C; $[\alpha]_D^{22}$ +46.3° (*c* 0.99); NMR: 7.3 (m, 5H, Ph), 5.72 (d, 1H, $J_{1,2}$=3.6, H-1), 4.51 (s, 2H, CH_2Ph), 4.22 (d, 1H, H-2), 4.15 (dd, 1H, H-4), 3.74 (dd, 1H, $J_{4,5}$=4.0, $J_{5,5'}$=12.5, H-5), 3.60 (dd, 1H, $J_{4,5'}$=7.0, H-5'), 2.81 (bs, 1H, OH), 1.56 (s, 3H, CMe), 1.31 and 1.14 (each s, 6H, Ip).

Found: C, 65.34; H, 7.47%. Calcd for $C_{16}H_{22}O_5$: C, 65.29; H, 7.53%.

*5-O-Benzoyl-3-O-benzyl-1,2-O-isopropylidene-3-C-methyl-α-D-ribofuranose (**14**).* To an ice-cooled solution of **13** (10g, 34 mmol) in pyridine (100 ml) was added dropwise benzoyl chloride (5.25 g, 37.3 mmol) with stirring, and the mixture was kept for 1 h at room temperature, poured into ice–water, and then extracted with chloroform. The usual processing of the extract and recrystallization of the product from ether–petroleum ether gave **14** as needles (12.7 g, 95%). Mp 84—85 °C; $[\alpha]_D^{22}$ +12.5° (*c* 1.55); IR: 1720 (ester); NMR: 8.1—7.9 and 7.6—7.4 (m, 10H, 2Ph), 5.70 (d, 1H, $J_{1,2}$= 4.0, H-1), 4.55 (s, 2H, CH_2Ph), 4.3—4.5 (m, 3H, H-4, 5, and 5'), 4.23 (d, 1H, H-2), 1.60 (s, 3H, CMe), 1.33 and 1.21 (each s, 6H, Ip).

Found: C, 69.04; H, 6.50%. Calcd for $C_{23}H_{26}O_6$: C, 69.33; H, 6.58%.

*5-O-Benzoyl-3-O-benzyl-3-C-methyl-D-ribofuranose (**15**).* A solution of **14** (5.28 g, 13.3 mmol) in acetic acid (70%, 60 ml) was refluxed for 2 h, diluted with water, and extracted with chloroform. The usual processing of the extract and purification of the product on a column of silica gel with 8:1 benzene–acetone gave pure **15** as a syrup in 96% (4.56 g) yield. $[\alpha]_D^{22}$ +36.3° (*c* 1.67).

Found: C, 66.70; H, 6.35%. Calcd for $C_{20}H_{22}O_6$: C, 67.03; H, 6.19%.

*4-O-Benzoyl-2-O-benzyl-2-C-methyl-D-erythritol (**18**).* To a solution of **15** (1.11 g, 3.1 mmol) in methanol (5 ml) was added a solution of sodium periodate (0.8 g, 3.7 mmol) in water (5 ml), and the resulting suspension was stirred for 30 min at room temperature, neutralized with sodium hydrogencarbonate and then extracted with chloroform. The usual processing of the extract gave 4-*O*-benzoyl-2-*O*-benzyl-3-*O*-formyl-2-*C*-methyl-D-erythrose (**16**, 0.84 g, 83%) as a syrup, but it could not be purified on a column of silica gel. However, the crude product gave reasonable NMR spectrum as follows. NMR: 9.63 (s, 1H, CHO), 8.10 (s, 1H, OCHO), 8.0—7.9 and 7.6—7.2 (m, 10H, 2Ph), 5.74 (dd, 1H, H-3), 4.62 (dd, 1H, $J_{3,4}$=4.0, $J_{4,4'}$=12.0, H-4), 4.60 and 4.52 (ABq, 2H, J=12.5, CH_2Ph), 4.51 (q, 1H, $J_{3,4'}$=7.4, H-4'), 1.49 (s, 3H, CMe).

To an ice-cooled solution of syrupy **16** (0.84 g, 2.56 mmol) in methanol (5 ml) and water (10 ml) was added sodium borohydride (110 mg, 2.9 mmol) with stirring. After stirring at room temperature for 3 h, the reaction mixture was neutralized with 0.1 M hydrochloric acid, and filtered. The filtrate was evaporated, and the residue was extracted with chloroform. The usual processing of the extract and purification of the product on a column of silica gel with 3:1 benzene–acetone gave pure **18** in 92% (0.78 g) yield. $[\alpha]_D^{22}$ +9.1° (*c* 1.03); NMR: 8.1—7.9 and 7.6—7.4 (m, 10H, 2 Ph), 4.66 (dd, 1H, H-4'), 4.57 (s, 2H, CH_2Ph), 4.43 (dd, 1H, $J_{4,4'}$=11.6, H-4), 4.17 (dd, 1H, $J_{3,4'}$=2.6, $J_{3,4}$=7.6, H-3), 3.77 (s, 2H, H-1 and 1'), 1.32 (s, 3H, CMe).

Found: C, 68.62; H, 6.95%. Calcd for $C_{19}H_{22}O_5$: C, 69.07; H, 6.71%.

In one instance, fractionation of the incomplete reduction product on a column of silica gel with 3:1 hexane–ethyl acetate gave 4-*O*-benzoyl-2-*O*-benzyl-2-*C*-methyl-D-erythrose (**17**) as crystals. Mp 97—98 °C (ether–ligroine); $[\alpha]_D^{22}$ +26.8° (*c* 0.98); IR: 3500 (OH), 1740 and 1700 (C–O); NMR: 9.71 (s, 1H, CHO), 8.1—7.9 and 7.6—7.1 (m, 10H, 2 Ph), 4.7—4.4 (m, 4H, H-4,4' and CH_2Ph), 4.24 (dd, 1H, $J_{3,4}$=5.6, $J_{3,4'}$=9.2, H-3), 2.98 (bs, 1H, OH), 1.50 (s, 3H, CMe).

Found: C, 69.47; H, 6.04%. Calcd for $C_{19}H_{20}O_5$: C, 69.50; H, 6.14%.

*2-O-Benzyl-2-C-methyl-D-erythritol (**19**).* A solution of **18** (12 g, 36.3 mmol) in methanol (100 ml) containing a catalytic amount of sodium methoxide was stirred for 3 h at room temperature, neutralized with 0.1 M hydrochloric acid, and then evaporated. The residual syrup was purified on a column of silica gel with 2:1 benzene–acetone to give pure **19** as a syrup (6.1 g, 74%). $[\alpha]_D^{23}$ +8.7° (*c* 1.89); IR: 3600—3100 (OH); NMR: 7.3 (m, 5H, Ph), 4.42 (s, 2H, CH_2Ph), 3.80 (dd, 1H, H-3), 3.78 (dd, 1H, $J_{3,4}$=2.6, H-4), 3.64 (bs, 3H, 3 OH), 3.57 (s, 2H, H-1 and 1'), 3.50 (dd, 1H, $J_{3,4'}$=8.0, $J_{4,4'}$=11.6, H-4'), 1.08 (s, 3H, CMe).

Found: C, 64.00; H, 8.12%. Calcd for $C_{12}H_{18}O_4$: C, 63.70; H, 8.02%.

*2-O-Benzyl-3,4-O-isopropylidene-2-C-methyl-D-erythritol (**20**).* A solution of **19** (5.5 g, 24.3 mmol) in dry acetone (60 ml) containing concd sulfuric acid (1 ml) was stirred for 2 d at room temperature, poured into aqueous sodium hydrogencarbonate, and extracted with ether. The usual processing of the extract and purification of the product on a column of silica gel with 8:1 benzene–acetone gave **20** as crystals in 70% (4.5 g) yield. Mp 42—43 °C (methanol–hexane); $[\alpha]_D^{22}$ +13.2° (*c* 1.02); NMR: 7.3 (m, 5H, Ph), 4.56 and 4.62 (ABq, 2H, J=11.0, CH_2Ph), 4.26 (dd, 1H, $J_{3,4}$=6.0, $J_{4,4'}$=7.6, H-4), 4.1—3.9 (m, 2H, H-3 and 4'), 3.65 (s, 2H, H-1 and 1'), 2.21 (bs, 1H, OH), 1.45 (s, 3H, CMe), 1.24 and 1.35 (each s, 6H, Ip).

Found: C, 67.86; H, 8.44%. Calcd for $C_{15}H_{22}O_4$: C, 67.64; H, 8.33%.

*1,2-Di-O-benzyl-3,4-O-isopropylidene-2-C-methyl-D-erythritol (**21**).* To a solution of **20** (4.5 g, 16.9 mmol) in *N*,*N*-dimethylformamide (20 ml) was added sodium hydride (0.9 g) with stirring portionwise, and the mixture was kept at room temperature for 1 h. Benzyl chloride (3.2 g, 25.3 mmol) was further added dropwise to the above mixture with stirring, and the reaction mixture was stirred for 12 h, poured into water (50 ml), and then extracted with ether. The usual processing of the extract and purification of the product on a column of silica gel with 10:1:20 benzene–ethyl acetate–hexane gave **21** as a syrup in 68% (4.1 g) yield. $[\alpha]_D^{23}$ +2.8° (*c* 2.88); NMR: 7.3 (m, 10H, 2Ph), 4.53 and 4.57 (each s, 4H, $2CH_2Ph$), 4.30 (dd, 1H, $J_{3,4}$= 6.0, $J_{4,4'}$=8.0, H-4), 4.1—3.9 (m, 2H, H-3 and 4'), 3.49 and 3.56 (ABq, 2H, J=10.0, H-1 and 1'), 1.43 (s, 3H, CMe), 1.25 and 1.34 (each s, 6H, Ip).

Found: C, 74.18; H, 7.80%. Calcd for $C_{22}H_{27}O_4$: C, 74.13; H, 7.92%.

*1,2-Di-O-benzyl-2-C-methyl-D-erythritol (**22**).* A solution of **21** (3.65 g, 10.2 mmol) in acetic acid (70%, 30 ml) was stirred at room temperature for 72 h, diluted with water and then extracted with chloroform. The usual processing of the extract and purification of the product on a column of silica gel with 8:1 benzene–acetone gave **22** as a syrup in 84% (2.71 g) yield. $[\alpha]_D^{22}$ −7.5° (*c* 1.72); NMR: 7.3 (m, 10H, 2Ph), 4.52 (s, 4H, $2CH_2Ph$), 3.7—3.9 (m, 3H, H-3,4, and 4'), 3.55 and 3.60 (ABq, 2H, J=11.0, H-1 and 1'), 3.02 and 2.64 (each bs, 2H, 2OH), 1.30 (s, 3H, CMe).

Found: C, 71.60; H, 7.47%. Calcd for $C_{19}H_{24}O_4$: C, 72.12; H, 7.65%.

*2,3-Di-O-benzyl-2-C-methyl-L-glyceraldehyde (**23**).* To a solution of **22** (388 mg, 1.23 mmol) in methanol (5 ml) was added a solution of sodium periodate (299 mg, 1.39 mmol) in water (5 ml), and the mixture was stirred at room temperature for 40 min, neutralized with sodium hydrogencarbonate, and then filtered. Methanol in the filtrate was evaporated and the water layer was extracted with ether. The usual processing of the extract gave **23** as a syrup in 95% (332 mg) yield. IR: 1730 (CHO); NMR: 9.69 (s, 1H, CHO), 7.3 (m, 10H, 2Ph), 4.50 and 4.55 (ABq, 2H, J=10.8, CH_2Ph), 4.51 (s, 2H, CH_2Ph), 3.61 and 3.67 (ABq, 2H, J=9.6, H-3 and 3'), 1.34 (s, 3H, CMe).

*2,3-Di-O-benzyl-2-C-methyl-L-glyceraldehyde Semicarbazone (**24**).* To a solution of **23** (200 mg, 0.7 mmol) in methanol (0.5 ml) was added semicarbazide hydrochloride (78.1 mg, 0.7 mmol), and the mixture was scrached with glass rod to produce crystals (193 mg, 80%) which were recrystallized from benzene. Mp 108—109 °C; $[\alpha]_D^{23}$ +13.2° (*c* 0.68); IR: 1690 (amide); NMR: 10.04 (s, 1H, NH), 7.3 (m, 10H, 2Ph), 7.16 (s, 1H, CH=N), 5.99 (s, 2H, NH_2), 4.50 and 4.39 (each s, 4H, $2CH_2Ph$), 3.54 (s, 2H, H-3), 1.41 (s, 3H, CMe).

Found: C, 66.29; H, 6.22; N, 12.54%. Calcd for $C_{19}H_{23}O_3N_3$: C, 66.84; H, 6.79; N, 12.31%.

*1-O-Benzoyl-3-O-benzyl-2,4-O-benzylidene-3-C-methyl-L-erythritol (**25**).* A solution of **18** (3.1 g, 9.4 mmol), dimethoxytoluene (1.71 g, 11.3 mmol), and catalytic amount of *p*-toluenesulfonic acid (170 mg, 0.89 mmol) in *N,N*-dimethylformamide (5 ml) was stirred at room temperature for 3 h, and then methanol produced was removed for 3 h under diminished pressure. The reaction mixture was neutralized with aqueous sodium hydrogencarbonate, evaporated, and the residual syrup was extracted with ether. The usual processing of the extract gave crystals which were recrystallized from methanol. Yield, 1.8 g (52%); mp 110—111 °C; $[\alpha]_D^{23}$ +58.4° (*c* 1.88); NMR: 8.1—7.9 and 7.6—7.2 (m, 15h, 3Ph), 5.57 (s, 1H, CHPh), 4.73 (dd, 1H, $J_{1,2}$=2.0, $J_{1,1'}$=11.6, H-1), *ca.* 4.52 and 4.57 (ABq, 2H, CH_2Ph), 4.42 (dd, 1H, $J_{1',2}$=8.4, H-1'), 4.41 and 3.87 (ABq, 2H, J=11.0, H-4 and 4'), 4.34 (dd, 1H, H-2), 1.60 (s, 3H, CMe).

Found: C, 74.92; H, 6.35%. Calcd for $C_{26}H_{26}O_5$: C, 74.62; H, 6.26%.

*3-O-Benzyl-2,4-O-benzylidene-3-C-methyl-L-erythritol (**26**).* A solution of **25** (1.3 g, 3.1 mmol) in methanol containing a catalytic amount of sodium methoxide was stirred at room temperature for 2 h, neutralized with 0.1 M hydrochloric acid, evaporated, and the resulting sirup was extracted with chloroform. The usual processing of the extract and purification of the product on a column of silica gel with 1:3 ethyl acetate–hexane gave pure **26** as a syrup in 93% (862 mg) yield. $[\alpha]_D^{23}$ +12.9° (*c* 1.46); NMR: 7.4 (m, 10H, 2Ph), 5.51 (s, 1H, CHPh), 4.44 and 4.56 (ABq, 2H, J=10.4, CH_2Ph), 3.6—4.3 (m, 5H, H-1,1',3,4, and 4'), 2.18 (bs, 1H, OH), 1.53 (s, 3H, CMe).

Found: C, 72.43; H, 7.07%. Calcd for $C_{19}H_{22}O_4$: C, 72.59; H, 7.05%.

*3-O-Benzyl-2,4-O-benzylidene-3-C-methyl-L-erythrose (**28**).* To a solution of **26** (335 mg, 1.12 mmol) in DMSO (3 ml) containing catalytic amount of pyridine and phosphoric acid was added dicyclohexylcarbodiimide (500 mg), and the mixture was stirred at room temperature for 24 h, poured into ice–water, and extracted with ether. The usual processing of the extract and fractionation of the products on a flash column with 1:7 ethyl acetate–hexane gave **28** (91 mg, 27%), together with 3-*O*-benzyl-2,4-*O*-benzylidene-3-*C*-methyl-1-*O*-methylthiomethyl-L-erythritol (**27**: 100 mg, 25%) and the starting material (67 mg, 20%).

28: mp 81—82 °C; $[\alpha]_D^{22}$ +73.7° (*c* 0.93); IR: 1735 (CHO); NMR: 9.78 (s, 1H, CHO), 7.3 (m, 10H, 2Ph), 5.50 (s, 1H, CHPh), 4.88 and 4.64 (ABq, 2H, J=11.4, CH_2Ph), 4.33 (s, 1H, H-2), 3.86 and 4.12 (ABq, 2H, J=10.2, H-4 and 4'), 1.60 (s, 3H, CMe).

Found: C, 73.09; H, 6.41%. Calcd for $C_{19}H_{20}O_4$: C, 73.06; H, 6.45%.

27: syrup; $[\alpha]_D^{23}$ +53.7° (*c* 0.3); NMR: 7.29 (m, 10H, 2Ph), 5.51 (s, 1H, CHPh), 4.67 (s, 2H, OCH_2S), 4.58 and 4.46 (ABq, 2H, J=12, CH_2Ph), 4.07 (t, 1H, $J_{1,2}=J_{1,1'}$=10.0, H-1), 3.84 (dd, 1H, $J_{1',2}$=8.0, H-2), 4.00 and 3.82 (ABq, 2H, J=11.5, H-4 and 4'), 3.65 (dd, 1H, H-1'), 2.11 (s, 3H, SMe), 1.51 (s, 3H, CMe).

Found: C, 67.02; H, 6.95; S, 8.28%. Calcd for $C_{21}H_{26}O_4S$: C, 67.35; H, 7.00; S, 8.56%.

*Methyl 3-O-Benzyl-3-C-methyl-α-L-erythrofuranoside (**29**) and Its β-Anomer (**30**).* A solution of **28** (110 mg, 0.35 mmol) in methanolic hydrogen chloride (1%, 3 ml) was refluxed for 3 h, neutralized with sodium hydrogencarbonate, evaporated, and the residue was extracted with chloroform. The usual processing of the extract and fractionation of the product on a preparative TLC with 1:5 ethyl acetate–hexane gave the corresponding α-(**29**: 4.1 mg, 4.9%, R_f 0.29) and β-glycosides (**30**: 34.7 mg, 41%, R_f 0.39) as syrups.

29: $[\alpha]_D^{23}$ −82.9° (*c* 1.03); NMR: 7.3 (m, 5H, Ph), 4.89 (d, 1H, J=4.8, H-1), 4.63 and 4.52 (ABq, 2H, J=11.0, CH_2Ph), 4.12 and 3.66 (ABq, 2H, J=9.8, H-4 and 4'), 3.84 (dd, 1H, $J_{2,OH}$=10.4, H-2), 3.48 (s, 3H, OMe), 3.00 (d, 1H, OH), 1.48 (s, 3H, CMe).

30: $[\alpha]_D^{23}$ +99.5° (*c* 1.74); NMR: 7.3 (m, 5H, Ph), 4.86 (d, 1H, J=2.4, H-1), 4.52 (s, 2H, CH_2Ph), 4.12 and 3.77 (ABq, 2H, J=10.1, H-4 and 4'), 3.79 (dd, 1H, $J_{2,OH}$=7.8, H-2), 3.42 (s, 3H, OMe), 3.07 (d, 1H, OH), 1.50 (s, 3H, CMe).

Found for **30**: C, 65.32; H, 7.59, and for **31**: C, 65.20; H, 7.69%. Calcd for $C_{13}H_{18}O_4$: C, 65.53; H, 7.61%.

Branched-chain Sugars. XXIX. Synthesis of Moenuronic Acid (4-*C*-Methyl-D-glucuronic Acid)[1]

Ken-ichi SATO, Kazusuke KUBO, Namgi HONG, Hisashi KODAMA, and Juji YOSHIMURA*

Laboratory of Chemistry for Natural Products, Faculty of Science, Tokyo Institute of Technology, Nagatsuta, Midori-ku, Yokohama 227

(Received September 18, 1981)

Moenuronic acid (4-*C*-methyl-D-glucuronic acid), a branched-chain sugar component of moenomycin A, was synthesized by the introduction of an axial *C*-methyl group into methyl 2,3-di-*O*-benzyl-6-*O*-trityl-α-D-*xylo*-hexopyranosid-4-ulose by the reaction with methyllithium, followed by deprotection and platinum-catalyzed oxidation of the *C*-6 position. Stereoselectivities in a few reactions for the introduction of *C*-methyl group were examined.

Moenomycin A[2] is a phosphoglycolipid antibiotic, which inhibits strongly the formation of linear polysaccharide-chain of murein from disaccharide intermediates[3] in the cell-wall biosynthesis. A new brancehd-chain uronic acid called moenuronic acid (**1**; 4-*C*-methyl-D-glucuronic acid) was found as a component.[4] By the ethanolysis of moenomycin A, the moiety was isolated as the corresponding ethyl β-D-glucofurano-sidurono-6,3-lactone(**2**), and the structure was determined by the IR, NMR, CD, and mass spectroscopic data of **2** and its diacetate (**3**).[5] This paper describes the first syn thesis of **3**.

Results and Discussion

The introduction of an axial *C*-methyl group to the *C*-4 position of a D-*xylo*-hexopyranosid-4-ulose and the following oxidation of *C*-6 position of the product are necessary for the synthesis of **1**.

For the former problem, a few pathways from benzyl[6] and methyl 2,3-di-*O*-benzyl-6-*O*-trityl-α-D-*xylo*-hexopyranosid-4-uloses (**4** and **5**) and 4-*C*-methylene derivative (**6**) of **5** were examined. Compound **5** was synthesized by the oxidation of methyl 2,3-di-*O*-benzyl-6-*O*-trityl-α-D-glucopyranoside[7] with dimethyl sulfoxide–trifluoroacetic anhydride in quantitative yield. Compound **6** was obtained in 63% yield by the usual Wittig reaction of **5**.

It is known that the reaction of α-D-*xylo*-hexopyranosid-4-uloses[8] or a α-L-*threo*-pentopyranosid-4-ulose[9] with methyllithium at a low temperature gives axial *C*-methyl derivatives, whereas that with methylmagnesium iodide affords equatorial *C*-methyl derivatives predominantly. Therefore, these reactions of **4** and **5** were examined at first. As shown in Table 1, reaction of **4** with methyllithium at −78 °C in ether gave exclusively the axial attack product (**7**), while that with methylmagnesium iodide in ether at −78 °C gave only the equatorial attack product (**8**). The Grignard reaction in ether–tetrahydrofuran (1:1) under reflux gave **7** and **8** in the ratio of 1 to 1. A similar tendency was also observed in the reaction of **5**, and the corresponding *C*-methyl derivatives (**9** and **10**) were obtained. Configuration of **7**—**10** was determined from the chemical shifts of axially (**7**: δ 15.79 ppm, **9**: δ 14.92 ppm) and equatorially (**8**: δ 22.03 ppm, **10**: δ 22.02 ppm) oriented *C*-methyl carbons in ^{13}C-NMR spectra.[8–10]

On the other hand, diazomethane reaction[11] of **4** and **5** gave one epimer of the corresponding spiro epoxides (**11** and **12**) in 20 and 15% yields, respectively, together with larger amount of ring-expanded products (**13** and **14**). The structures of **13** and **14** were throughly proved by the ^{1}H-NMR spectra (see Experimental). While, epoxidation[12] of **6** with *m*-chloroperbenzoic acid gave a 1:1 mixture of the corresponding spiro epoxides (**12** and **15**) in 80% yield. Reduction of **11**, **12**, and **15** with lithium aluminium hydride gave **7**, **9**, and **10** in fairly good yields, respectively. From these facts, configurations of **11**, **12**,

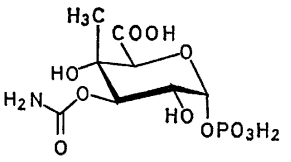
a) The rotational values of **2** and **20** were measured in ethanol and methanol, respectively. b) ^{1}H-NMR spectrum of **20** was taken in methanol-*d*. The spectrum of **2** showed signal of hydroxyl protons at δ 2.90 bs.

and **15** were established. Peroxy acid oxidation of methylene derivative such as **6** usually proceeds unselectively,[12] and the selectivities in the reaction of 4-uloses with methyllithium or diazomethane will be discussed in detail in the following papers.

For the oxidation of *C*-6 position, **7**—**9** were partially hydrolyzed with 70% acetic acid to give the corresponding de-*O*-tritylated products (**16**—**18**), respectively. However, attempted oxidation of **16** and **17** with chromium trioxide,[13] potassium permanganate,[14] and oxygen–platinum[15] gave commonly complex results, accompanying with the oxidation of the benzyl groups.[6,16] Therefore, *O*-benzyl groups of **18** were previously removed by hydrogenolysis to give methyl 4-*C*-methyl-α-D-glucopyranoside (**19**) in quantitative yield. Oxidation of **19** in slightly alkaline aqueous solution with oxygen in the presence of platinum–carbon gave the corresponding glucuronic acid (**20**) in 86% yield. Treatment of **20** with 0.1 M ethanolic hydrogen chloride for 16 h under reflux, and then base-catalyzed acetylation of the products gave **3** and methyl 2,3-di-*O*-acetyl-4-*C*-methyl-α-D-glucopyranosiduronic acid ethyl ester (**21**) in 28 and 55% yields, respectively. The formation of **21** implies the incomplete ethanolysis of the glycoside linkage of **20**. A similar ethanolysis of **21** for 3 d gave **2** in quantitative yield. Physical constants of 4-*C*-methyl-D-glucuronic acid derivatives were summarized in Table 2, together with those of 3-*O*-carbamoyl-1-phosphate derivative (**22**) of **1**, obtained by hydrolysis of moenomycin A with trifluoroacetic acid and 2-propanol.[4]



(22)

Although the rotational value and the magnetical non-equivalency of methylene protons in 1-ethoxyl group were not shown in the literature,[5] physical properties of **3** prove that **3** synthesized here is identical with that obtained from Moenomycin A. The non-equivalency of methylene protons will be attributed to the restricted rotation of 1-*O*-CH_2 bond, due to the steric hindrance between 1-ethoxyl and 5-acetoxyl groups oriented into the inside area of *cis*-fused five-membered ring. Data of **2** also support this deduction, though $\Delta\nu$ value of methylene protons is rather smaller. While, the coupling constants ($J_{1,2}$ and $J_{2,3}$) of **20**—**22** indicate their $^4C_1$ (D) conforma-

tions.

Thus, it was conclusively shown that synthesis of methyl glycoside (**20**) of **1** can be accomplished by the pathway of **5**→**9**→**18**→**19**→**20** in 73% overall yield.

Experimental

General Methods. Melting points were determined with a Mel-Temp hot-plate and are uncorrected. The solutions were evaporated under diminished pressure at a bath temperature not exceeding 50 °C. Specific rotations were measured with Carl Zeiss LEP-A1 or JASCO DIP-4 polarimeter, using chloroform as a solvent unless otherwise stated. IR spectra were recorded with Hitachi Model EPL-G2 spectrometer. ^{1}H-NMR spectra were taken with JEOL PS-100 spectrometer in chloroform-*d* unless otherwise stated, using tetramethylsilane as the internal standard. ^{13}C-NMR data were recorded with JEOL FX-100 spectrometer at 25.16 MHz for the solutions in chloroform-*d*, using 8K data points, with proton-noise decoupling. Chemical shifts and coupling constants were recorded in δ (ppm) and Hz units, and IR frequencies in cm^{-1}. Column chromatography was performed on silica gel (Wakogel C-200) and preparative TLC on silica gel (Merck type 60).

*Methyl 2,3-Di-*O*-benzyl-6-*O*-triphenylmethyl-α-*D*-xylo-hexopyranosid-4-ulose (**5**).* A solution of methyl 2,3-di-*O*-benzyl-6-*O*-trityl-α-D-glucopyranoside[7] (3 g, 4.86 mmol) in acetic anhydride (25 ml) and dimethyl sulfoxide (50 ml) was kept overnight at room temperature, poured into ice–water, and then extracted with ether. The usual processing of the extract and purification of the product on a column of silica gel with 15:1 hexane–ethyl acetate gave **5** as a syrup in 72% (2.15 g) yield. $[\alpha]_D^{22}$ +47.1° (*c* 1.2); IR: 1735 (C=O); NMR: 7.55—7.15 (m, 25 H, 5×Ph), 4.82 (d, 1 H, $J_{1,2}$=3.2, H-1), 4.52—4.98 (m, 4 H, 2×CH_2Ph), 4.36 (d, 1 H, $J_{2,3}$=10.0, H-3), 4.20 (dd, 1 H, H-5), 3.78 (dd, 1 H, H-2), 3.56 (dd, 1 H, $J_{6,6'}$=11.0, H-6), 3.53 (s, 3 H, OMe), 3.35 (dd, 1 H, $J_{5,6'}$=7.0, $J_{5,6'}$=10.0, H-6'). Found: C, 78.53; H, 6.31%. Calcd for $C_{40}H_{38}O_6$: C, 78.15; H, 6.23%.

*Methyl 2,3-Di-*O*-benzyl-4-deoxy-4-*C*-methylene-6-*O*-triphenylmethyl-α-*D*-xylo-hexopyranoside (**6**).* To an ice-cooled suspension of methyltriphenylphosphonium bromide (0.6 g, 1.68 mmol) in tetrahydrofuran (THF, 2 ml) was added butyllithium (10%, 8.7 ml, 1.36 mmol) in hexane with stirring, and to the resulting orange-coloured solution, a solution of **5** (1.02 g, 1.6 mmol) in THF (9 ml) was further added. After stirring the mixture for 30 min, the excess reagent was quenched with acetone, diluted with ether (20 ml), and then filtered. The filtrate was evaporated, and the residual syrup was purified on a column of silica gel with benzene to give **6** as a syrup in 63% (640 mg) yield. $[\alpha]_D^{23}$ +40.3° (*c* 0.9); IR: 1660 (C=C); NMR: 7.70—7.10 (m, 25 H, 5×Ph), 5.20—5.40 (bs, 2 H, methylene), 4.60—5.00 (m, 5 H, 2×CH_2Ph and H-1), 4.5—4.2 (m, 2 H, H-3 and 5), 3.53 (s, 3 H, OMe), 3.30—3.50 (m, 3 H, H-6,6', and 2). Found: C, 80.52; H, 6.71%. Calcd for $C_{41}H_{40}O_5$: C, 80.36; H, 6.58%.

Reaction of 4-Uloses with Methyllithium. To a solution of **4** (120 mg, 0.174 mmol) in ether (2 ml) cooled with Dry Ice and acetone was added an excess amount of methyllithium (1.2 M, 1 ml) in ether with stirring, and then the mixture was kept at room temperature for 2 h, poured into saturated ammonium chloride solution. The usual processing of the ether layer and purification of the product on a column of silica gel with 3:1 hexane–ethyl acetate gave pure benzyl 2,3-di-*O*-benzyl-4-*C*-methyl-6-*O*-triphenylmethyl-α-D-glucopyranoside (**7**) as a syrup in 58% (71 mg) yield. $[\alpha]_D^{23}$ +26.8° (*c* 1.1); ^{13}C NMR: CMe, 15.79 ppm; ^{1}H NMR: 7.54—7.12 (m, 30 H, 6×Ph), 5.01—4.40 (m, 6 H, 3×CH_2Ph), 4.80 (d, 1 H, $J_{1,2}$=4.0, H-1), 4.00 (t, $J_{5,6'}$=5.8, H-5), 3.84 (d, 1H, $J_{2,3}$=10.6, H-3), 3.36 (dd, 1H, $J_{5,6}$=5.8, H-6), 3.36 (dd, 1H, H-2), 3.25 (dd, 1H, $J_{6,6'}$=11.6, H-6'), 2.32 (s, 1H, OH), 0.98 (s, 3H, CMe). Found: C, 79.42; H, 6.65%. Calcd for $C_{47}H_{46}O_6$: C, 79.86; H, 6.56%.

A similar reaction of **5** with methyllithium gave methyl 2,3-di-*O*-benzyl-4-*C*-methyl-6-*O*-triphenylmethyl-α-D-glucopyranoside (**9**) in 95% yield. $[\alpha]_D^{23}$ +7.8° (*c* 1.5); ^{13}C NMR: CMe, 14.92 ppm; ^{1}H NMR: 7.60—7.14 (m, 25H, 5×Ph), 5.03—4.52 (m, 4H, 2×CH_2Ph), 4.59 (d, 1H, $J_{1,2}$=3.8, H-1), 3.88 (dd, 1H, $J_{2,3}$=10.0, H-2), 3.87 (t, 1H, $J_{5,6}$=6.0, H-5), 3.51 (d, 1H, H-3), 3.48 (s, 3H, OMe), 3.39 (d, 2H, H-6 and 6'), 2.37 (s, 1H, OH), 1.00 (s, 3H, CMe). Found: C, 78.29; H, 6.78%. Calcd for $C_{41}H_{42}O_6$: C, 78.07; H, 6.71%.

Reaction of 4-Uloses with Methylmagnesium Iodide. To a solution of methylmagnesium iodide, prepared from magnesium turnings (124 mg, 5.17 mmol) and methyl iodide (1 ml, 7 mmol), in ether (5 ml) chilled with Dry Ice and acetone was added dropwise a solution of **4** (187 mg, 2.72 mmol) in ether (2 ml) with stirring, and after 2 h, the reaction mixture was poured into saturated aqueous ammonium chloride solution. The usual processing of the ether layer and purification of the product on a column of silica gel with 3:1 hexane–ethyl acetate gave benzyl 2,3-di-*O*-benzyl-4-*C*-methyl-6-*O*-triphenylmethyl-α-D-galactopyranoside (**8**) as a syrup in 84% (160 mg) yield. $[\alpha]_D^{23}$ +54.9° (*c* 0.8); NMR: 7.64—7.14 (m, 30H, 6×Ph), 5.10—4.25 (m, 6H, 3×CH_2Ph), 4.98 (d, 1H, $J_{1,2}$=3.5, H-1), 3.90 (dd, 1H, $J_{2,3}$=9.5, H-2), 3.79 (t, 1H, $J_{5,6}$=5.0, H-5), 3.59 (d, 1H, H-3), 3.42 (d, 2H, H-6 and 6'), 2.60 (s, 1H, OH), 1.00 (s, 3H, CMe). Found: C, 79.74; H, 6.62%. Calcd for $C_{47}H_{46}O_6$; C, 79.86; H, 6.56%.

The reaction of **4** (16.6 g, 24 mmol) with methylmagnesium iodide in ether–THF (1:1) at refluxing temperature and separation of the products on a flash column of silica gel with 6:1 hexane–ethyl acetate gave **7** and **8** in 35.2% (5.98 g) and 36.3% (6.15 g) yields, respectively.

A similar reaction of **5** (1.02 g, 1.6 mmol) with methylmagnesium iodide in ether at −78 °C and purification of the products on a flash column of silica gel with 6:1 hexane–ethyl acetate gave methyl 2,3-di-*O*-benzyl-4-*C*-methyl-6-*O*-triphenylmethyl-α-D-galactopyranoside (**10**) as a syrup in 84% (850 mg) yield. $[\alpha]_D^{27}$ +18.2° (*c* 1.0); NMR: 7.68—7.16 (m, 25H, 5×Ph), 5.06—4.56 (m, 5H, H-1 and 2×CH_2Ph), 3.90 (dd, 1H, $J_{1,2}$=3.0, H-2), 3.70 (t, 1H, $J_{5,6}$=4.0, H-5), 3.54 (d, 1H, $J_{2,3}$=9.5, H-3), 3.52 (s, 3H, OMe), 3.41 (d, 2H, H-6 and 6'), 0.98 (s, 3H, CMe). Found: C, 77.82; H, 6.83%. Calcd for $C_{41}H_{42}O_6$: C, 78.07; H, 6.71%.

When the reaction of **5** with methylmagnesium iodide in ether is carried out at room temperature, separation of the products on a flash column of silica gel with 6:1 hexane–ethyl acetate gave **9** and **10** in 29 and 64% yields, respectively.

Reaction of 4-Uloses and Diazomethane. To a solution of **4** (138 mg, 2.0 mmol) in ethanol (50 ml) was added dropwise a solution of diazomethane (4.0 mmol) in ether (20 ml) at 0 °C. After keeping the mixture at room temperature for 12 h, the solution was evaporated to give a syrup. Separation of the syrup on a preparative TLC gave a ring-expanded product, benzyl 2,3-di-*O*-benzyl-5-deoxy-7-*O*-triphenylmethyl-α-D-*xylo*-heptaseptanosid-4-ulose (**13**) and corresponding spiro epoxide, benzyl 4,4'-anhydro-2,3-di-*O*-benzyl-4-*C*-hydroxymethyl-6-*O*-triphenylmethyl-α-D-gluco-

pyranoside (**11**) in 60 and 20% yields, respectively.

11: syrup, $[\alpha]_D^{23}$ +56.4° (*c* 2.8); NMR: 7.6—7.1 (m, 30H, 6×Ph), 5.0—4.40 (3×ABq, 6H, J=11.0 and 12.0, 3×CH_2Ph), 4.97 (d, 1H, $J_{1,2}$=3.6, H-1), 4.64 (t, 1H, $J_{5,6}$=4.0, H-5), 4.20 (d, 1H, $J_{2,3}$=10.0, H-3), 3.55 (dd, 1H, H-2), 3.04 (d, 2H, H-6 and 6′), 3.06 and 2.43 (ABq, 2H, J=5.0, epoxy CH_2). Found: C, 80.38; H, 6.33%. Calcd for $C_{47}H_{44}O_6$: C, 80.09; H, 6.29%.

Compound **13** could not be completely purified, but the NMR and IR spectra could be analyzed. IR: 1720 (C=O); NMR: 7.50—7.10 (m, 30H, 6×Ph), 5.03 (d, 1H, $J_{1,2}$=1.8, H-1), 4.95—4.43 (m, 7H, 3×CH_2Ph and H-6), 4.18 (d, 1H, $J_{2,3}$=8.0, H-3), 3.74 (dd, 1H, H-2), 3.35—3.00 (m, 2H, H-7 and 7′) 2.78 and 2.50 (dABq, 2H, $J_{A,B}$=14.0, $J_{5,6}$=11.0, $J_{5',6}$=4.0, H-5 and 5′).

A similar reaction of **5** and diazomethane and the separation of the products on prepative TLC gave a ring-expanded product, methyl 2,3-di-*O*-benzyl-5-deoxy-7-*O*-triphenylmethyl-α-D-*xylo*-heptaseptanosid-4-ulose (**14**), and the corresponding spiro epoxide, methyl 4,4′-anhydro-2,3-di-*O*-benzyl-4-*C*-hydroxymethyl-6-*O*-triphenylmethyl-α-D-glucopyranoside (**12**) 60 and 15% yields, respectively.

12: syrup; $[\alpha]_D^{23}$ +17.8° (*c* 0.8); NMR: 7.56—7.14 (m, 25H, 5×Ph), 4.91—4.59 (m, 4H, 2×CH_2Ph), 4.69 (d, 1H, $J_{1,2}$=3.2, H-1), 4.36 (t, 1H, $J_{5,6}$=4.2, H-5), 4.18 (d, 1H, $J_{2,3}$=10.0, H-3), 3.64 (s, 3H, OMe), 3.58 (dd, 1H, H-2), 3.07 (d, 2H, H-6 and 6′), 3.02 and 2.42 (ABq, 2H, J=5.0, epoxy CH_2). Found: C, 78.01; H, 6.58%. Calcd for $C_{41}H_{40}O_6$: C, 78.32; H, 6.41%.

14: syrup, $[\alpha]_D^{23}$ +19.5° (*c* 0.9); IR: 1720 (C=O); NMR: 7.50—7.15 (m, 25H, 5×Ph), 4.81 (d, 1H, $J_{1,2}$=2.0, H-1), 4.82—4.03 (2×ABq, 4H, 2×CH_2Ph), 4.05—4.35 (m, 2H, $J_{2,3}$=9.0, H-3 and 6), 3.71 (dd, 1H, H-2), 3.42 (s, 3H, OMe), 3.40—2.98 (m, 2H, H-7 and 7′), 2.79 and 2.55 (dABq, 2H, $J_{A,B}$=14,0, $J_{5,6}$=10.0, $J_{5',6}$=2.0, H-5 and 5′). Found: C, 78.30; H, 6.38%. Calcd for $C_{41}H_{40}O_6$: C, 78.32; H, 6.41%.

Reduction of Spiro Epoxides with Lithium Aluminium Hydride. To a solution of **11** (200 mg, 0.28 mmol) in THF (20 ml) was added lithium aluminium hydride (LAH, 50 mg, 1.3 mmol) and then the mixture was refluxed for 2 h. The excess hydride was decomposed with water, and then filterd. The water layer was extracted with chloroform. The combined extract was washed with water, dried, and evaporated to give a syrupy **7** in quantitative yield, which was identical with that obtained by the reaction of **4** and methyllithium at −78 °C.

A similar reduction of **12** (200 mg) in THF (20 ml) as above gave **9** in quantitative yield, which was identical with that obtained by the reaction of **5** and methyllithium at −78 °C.

Reduction of **15** (200 mg) in THF (20 ml) as above gave **10** in quantitative yield, which was identical with that obtained by the reaction of **5** and methylmagnesium iodide at −78 °C.

m-Chloroperoxybenzoic Acid Oxidation of ***6***. A solution of crude **6** (500 mg, 0.82 mmol) and *m*-chloroperoxybenzoic acid (630 mg, 3.65 mmol) in dichloroethane (50 ml) was stirred overnight at room temperature, and then washed successively with aqueous sodium hydroxide (0.1 M), water, saturated sodium chloride, and water, and then dried and evaporated. The residual syrup was separated on a column of silica gel with 5:1 hexane–ethyl acetate to give methyl 4,4′-anhydro-2,3-di-*O*-benzyl-4-*C*-hydroxymethyl-6-*O*-triphenylmethyl-α-D-glucopyranoside (**12**) and -α-D-galactopyranoside (**15**) as syrups each in 21.3% (110 mg) yield. Physical constants of **12** were indentical with the authentic sample that was derived from the reaction of **5** and diazomethane.

15: $[\alpha]_D^{32}$ +4.4° (*c* 0.8): NMR: 7.60—7.10 (m, 25H, 5×Ph), 4.66 (d, 1H, $J_{1,2}$=3.4 H-1), 4.53—4.98 (m, 4H, 2×CH_2Ph), 4.14 (d, 1H, H-3), 4.12 (t, 1H, H-5), 3.73 (dd, 1H, $J_{2,3}$=10.0, H-2), 3.41 (s, 3H, OMe), 3.26 (dd, 1H, $J_{5,6'}$=5.2, H-6′), 2.99 (dd, 1H, $J_{5,6}$=6.2, $J_{6,6'}$=10.0, H-6), 2.89 and 2.74 (ABq, 2H, J=5.0, epoxy CH_2). Found: C, 78.51; H, 6.62%. Calcd for $C_{41}H_{40}O_6$: C, 78.32; H, 6.41%.

*De-O-tritylation of 4-C-Methyl Derivatives (****7****—****9****).* A solution of **7** (1.47 g, 2.05 mmol) in acetic acid (70%, 30 ml) was heated at 100 °C for 5 h, filtered at room temperature, and then evaporated. The resulting syrup was purified on a column of silica gel with 3:1 hexane–ethyl acetate gave pure benzyl 2,3-di-*O*-benzyl-4-*C*-methyl-α-D-glucopyranoside (**16**) as a syrup in 98% (1.1 g) yield. $[\alpha]_D^{23}$ +88.7° (*c* 1.1); NMR: 7.6—6.8 (m, 15H, 3×Ph), 5.02—4.36 (m, 6H, 3×CH_2Ph), 4.81 (dd, 1H, $J_{5,6}$=3.5, H-6), 4.78 (d, 1H, $J_{1,2}$=4.0, H-1), 4.74 (t, 1H, $J_{5,6'}$=3.5, H-5), 4.59 (dd, 1H, $J_{6,6'}$=7.0, H-6′), 3.71 (d, 1H, H-3), 3.38 (dd, 1H, $J_{2,3}$=10.0, H-2), 2.92 (bs, 1H, OH), 1.14 (s, 3H, CMe). Found: C, 72.11; H, 7.07%. Calcd for $C_{28}H_{32}O_6$: C, 72.39; H, 6.94%.

In a similar manner, de-*O*-tritylation of **8** (1.29 g, 1.8 mmol) and purification of the product on a column of silica gel with 3:1 hexane–ethyl acetate gave benzyl 2,3-di-*O*-benzyl-4-*C*-methyl-α-D-galactopyranoside (**17**) as a syrup in 96% (0.96 g) yield. $[\alpha]_D^{23}$ +101° (*c* 1.1), NMR: 7.6—7.1 (m, 15H, 3×Ph), 5.1—4.4 (m, 6H, 3×CH_2Ph), 4.88 (d, 1H, $J_{1,2}$=4.0, H-1), 3.94—3.54 (m, 4H, H-3,5 and 6), 3.42 (dd, 1H, $J_{2,3}$=10.0, H-2), 2.26 (s, 1H, OH), 1.18 (s, 3H, CMe). Found: C, 72.23; H, 7.15%. Calcd for $C_{28}H_{32}O_6$: C, 72.39; H, 6.94%.

In a similar manner, de-*O*-tritylation of **9** (6.3 g, 10 mmol) and purification of the products gave methyl 2,3-di-*O*-benzyl-4-*C*-methyl-α-D-glucopyranoside (**18**) in 90% (3.5 g) yield, together with a small amount of its 6-acetate as syrups.

18: $[\alpha]_D^{23}$ +31.4° (*c* 0.9); NMR: 7.6—7.1 and 5.10—4.52 (m, 14H, 2×CH_2Ph), 4.61 (d, 1H, $J_{1,2}$=4.0, H-1), 4.0—3.5 (m, 5H, H-2,3,4 and 6), 3.40 (s, 3H, OMe), 3.36 (bs, 1H, OH), 1.18 (s, 3H, CMe). Found: C, 67.77; H, 7.10%. Calcd for $C_{22}H_{28}O_6$: C, 68.02; H, 7.27%.

6-Acetate showed the following ^{1}H-NMR deta: 7.6—7.1 and 5.16—4.52 (m, 14H, 2×CH_2Ph), 4.59 (d, 1H, $J_{1,2}$=4.0, H-1), 4.38 (dd, 1H, $J_{5,6}$=2.0, $J_{6,6'}$=12.0, H-6), 4.11 (dd, 1H, $J_{5,6'}$=6.0, H-6′), 3.75 (d, 1H, $J_{2,3}$=9.5, H-3), 3.49 (dd, 1H, H-2), 3.40 (s, 3H, OMe), 2.16 (bs, 1H, OH), 2.05 (s, 3H, Ac), 1.17 (s, 3H, CMe).

*Methyl 4-C-Methyl-α-D-glucopyranoside (****19****).* The usual hydrogenation of **18** (3.9 g, 10 mmol) in ethanol in the presence of palladium-charcoal (10%) gave **19** as a syrup in quantitative (2.08 g) yield. $[\alpha]_D^{23}$ +100° (*c* 0.8, MeOH); NMR (CD_3OD): 4.67 (d, 1H, $J_{1,2}$=4.0, H-1), 3.96—3.10 (m, 5H, H-2,3,5, and 6), 3.43 (s, 3H, OMe), 1.07 (s, 3H, CMe). Found: C, 46.50; H, 7.68%. Calcd for $C_8H_{16}O_6$: C, 46.15; H, 7.75%.

*Methyl 4-C-Methyl-α-D-glucuronic Acid (****20****).* Gaseous oxygen was bubbled into a solution of **19** (1.0 g, 4.8 mmol) in water at 90 °C for 40 h in the presence of platinum-carbon (10%, 0.3 g), and pH of the reaction mixture was maintained about 8.0 with sodium hydrogencarbonate. After **19** has disappeared on TLC, the mixture was filtered, and treated with Amberlite (IR-120) and the filtrate was evaporated to give 20 as a syrup in 86% (917 mg) yield. Physical data of **20** were shown in Table 2. Found: C, 42.97; H, 6.01%. Calcd for $C_8H_{14}O_7$: C, 43.24; H, 6.35%.

Ethyl 2,5-Di-O-acetyl-4-C-methyl-β-D-glucofuranosidurono-6,3-

lactone (3) and Methyl 2,3-Di-O-acetyl-4-C-methyl-α-D-glucopyranosiduronic Acid Ethyl Ester (21). A solution of **20** (500 mg, 2.25 mmol) in ethanolic hydrogen chloride (0.1 M) was refluxed for 16 h, and then evaporated to give a syrup. Acetic anhydride (2 ml) was added to a solution of the syrup in pyridine (2 ml). After keeping overnight at room temperature, the mixture was evaporated together with ethanol to give a syrup. Separation of the syrup on a preparative TLC (benzene–acetone 8:1) gave **21** {mp 99—101 °C (from ether–hexane); Found: C, 50.27; H, 6.61%. Calcd for $C_{14}H_{22}O_9$: C, 50.29; H, 6.63%} and **3** (syrup; Found: C, 51.84; H, 6.26%. Calcd for $C_{13}H_{18}O_8$: C, 51.65; H, 6.00%) in 55% (414 mg) and 28% (190 mg) yields, respectively. Physical constants of **3** and **21** were shown in Table 2.

Ethyl 4-C-Methyl-β-D-glucofuranosidurono-6,3-lactone (2). A similar ethanolysis of **21** (334 mg, 1.0 mmol) as above for 3 d gave syrupy **2** (Found: C, 49.47; H, 6.50%. Calcd for $C_9H_{14}O_6$: C, 49.54; H, 6.47%.) in quantitative (218 mg) yield. Physical data of **2** were shown in Table 2.

The authors thank Mr. Y. Nakamura for measurements of ^{13}C-NMR spectra.

The Crystal Structure of *o*-Phenylenediamine Dihydroiodide

Kozo Kozawa* and Tokiko Uchida

Department of Industrial Chemistry, Faculty of Science and Technology, Science University of Tokyo, Noda, Chiba 278

(Received May 6, 1981)

Synopsis. Crystals of *o*-phenylenediamine dihydroiodide are orthorhombic; $a=7.828(1)$, $b=13.158(1)$, $c=5.043(1)$ Å, $Z=2$, and space group Pmnm. The structure was solved by the heavy-atom method and refined with 1359 diffractometer data points to the final $R=0.052$. It is isostructural with *o*-phenylenediamine dihydrobromide. Protonated amino groups link to iodide ions by hydrogen bonds.

Recently, studies of polyiodides have often been presented in relation to one-dimensional conductors.[1] *o*-Phenylenediamine(OPD)[2] forms many complexes with iodine at various mole ratios and with different crystal systems. In a series of structural studies of OPD–iodine system, we have taken up the crystal structure of OPD dihydroiodide (OPD·2HI). Some OPD–hydrohalides[3] have been studied, but not this one.

Experimental

Colorless a-elongated needle crystals were obtained by mixing an ethanol solution of OPD with an aqueous solution of HI in a nitrogen atmosphere. A crystal with dimensions $0.3\times0.3\times0.25$ mm^3 was sealed in a glass capillary in a nitrogen atmosphere. It was mounted with the a-axis parallel to the ϕ axis of a Rigaku four-circle diffractometer. Intensities and cell parameters were obtained with graphite-monochromatized Mo $K\alpha$ radiation ($\lambda=0.7107$ Å) at room temperature. Intensities of 1620 independent reflections were collected by the 2θ-ω scan method with a scan speed of 4° min^{-1} in 2θ in the range $2\theta\leq75°$, and 1359 intensities ($F_o\geq3\sigma(F)$) were used in the analysis. No absorption correction was applied.

Crystal Data. $C_6H_8N_2\cdot2HI$, $F.W.=364.0$; Orthorhombic, Space group Pmnm, $a=7.828(1)$, $b=13.158(1)$, $c=5.043(1)$ Å, $V=519.4(1)$ Å^3, $D_m=2.27$, $D_x=2.31$ g cm^{-3}, $Z=2$, μ(Mo $K\alpha$)$=59.2$ cm^{-1}, Systematic absences $h0l$ with $h+l=2n+1$.

Structure Determination and Discussion

The structure was solved by the heavy-atom method and refined by full-matrix least-squares with anisotropic thermal parameters for non-hydrogen atoms, and with anomalous dispersion factors for the iodide ion. The hydrogen atoms bonded to carbon atoms were located in the difference synthesis. These hydrogens were introduced and fixed at those positions with temperature factors B of 4.5 Å^2. The discrepancy index, R, was finally reduced to 0.052.

The atomic scattering factors and anomalous dispersion factors were taken from "International Tables for X-Ray Crystallography."[4] The quantity minimized in the refinement was $\Sigma w(|F_o|-k|F_c|)^2$; $w=1.0$ for all the F's. All the computations were performed at the Computer Centre of the University of Tokyo, using the UNICS program system.[5] The final atomic parameters are shown in Table 1. The tables of F_o-F_c data and anisotropic thermal parameters are kept as Document No. 8210 at the Office of the Chemical Society of Japan.

The crystal consists of OPD$^+$ cations and iodide ions, and is essentially isostructural with OPD·2HBr.[3d] Figure 1 shows the molecular arrangement in a cell and the numbering of atoms. OPD molecule is completely planar with an mm symmetry and parallel to the ab plane, except for the amino hydrogens. Partial intercalation of iodide ions permits relatively wide spacing between OPD$^+$ molecular planes, 5.04 Å ($=c$); this suggests the absence of interaction between cations. The distances and angles of OPD skeleton,

Table 1. Atomic coordinates and their standard deviations

Atom	x	y	z

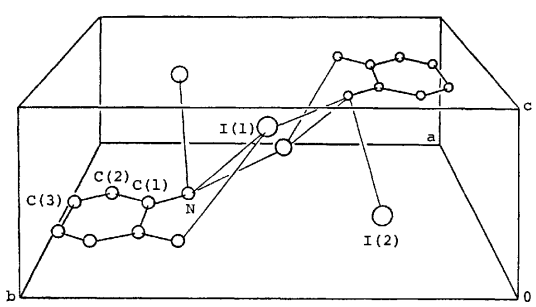

Fig. 1. Perspective view of the non-hydrogen atoms in a cell.

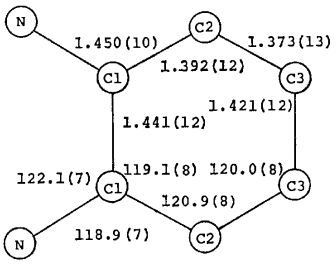

Fig. 2. Bond lengths (Å) and bond angles (°) of OPD^+ skeleton.

shown in Fig. 2, are normal. The C–N length, 1.450 Å, agrees with the C–NH_3^+ bond length, found in the related compounds (1.450—1.501 Å).[3a,3b,3d,6] Domenicano *et al.*[7] proposed that the 'standard' length of the aromatic C–NH_3^+ bond was 1.464 Å, which they calculated as the weighted mean value of 6 ring-substituted anilinium cations. On the other hand, the lengths of reported non-protonated C–NH_2 bond are significantly shorter than those of C–NH_3^+, namely, 1.351—1.391 Å.[3a,6,8] Judging from the C–N bond length, the amino groups in OPD·2HI are protonated. The nitrogen atom is surrounded by 5 iodide ions. Both of the two crystallographically non-equivalent iodide ions, I(1) and I(2), are on the mm symmetry points and surrounded by 4 OPD^+ cations. The I(1) ion has 2 types of I···N distances: 4 equivalent N's to a distance of 3.517 Å and the other 2 equivalent N's at 3.639 Å. The I(2) ion has the only 1 type of 4 I···N distances, 3.608 Å. The reported N···I hydrogen bonding distances are distributed from 3.46 to 4.06 Å.[9]

The authors express their hearty thanks to Professor Yoshio Sasada and Dr. Yuji Ōhashi of Tokyo Institute of Technology for the use of the diffractometer. The authors are also indebted to Mr. Naoya Tanabe and Mr. Hirotaka Hashimoto for their help as undergraduate students.

Synopsis. The crystal structure of *trans*-2,5-dimethylpiperazine has been determined by means of the X-ray method. The molecule is centrosymmetric, the piperazine ring having a *chair* form. The methyl groups are in the equatorial position. The molecules are linked together by N–H···N hydrogen bonds (N···N=3.305(3) Å) to form infinite ribbons along [011].

As a part of conformation studies of piperazine derivatives, we wish hence to report our structure analysis of *trans*-2,5-dimethylpiperazine(mp 119 °C). The structure thus far determined by means of the X-ray method are *cis*- and *trans*-1,4-dibenzoyl-2,5-dimethylpiperazine(DDP).[1,2]

Experimental and Structure Determination

Colorless prisms elongated along the b axis were obtained by the slow evaporation of a petroleum–benzene solution of the title compound. A prismatic crystal was ground to a cylinder 0.3 mm in diameter and 0.5 mm in length. As the substance was hygroscopic, the sample was sealed in a glass capillary tube 0.3 mm in diameter. The crystal data are as follows: $C_6H_{14}N_2$, F.W.=114.0, space group $P2_1/c$, a=8.582(2), b=5.231(1), c=8.953(2) Å, β=118.09(2)°, V=354.7(3) Å^3, Z=2, D_m=1.06 g cm^{-3} (flotation method), D_c=1.067 g cm^{-3}, μ=0.711 cm^{-1} for Mo $K\alpha$ radiation. The intensity data were obtained for 1097 independent reflections with $|F_o| \geqq 3\sigma(F_o)$ by measuring all the reflections within $2\theta \leqq 60.0°$. Correction for Lorentz-polarization factor was made as usual.

The structure was solved by an interpretation of the three-dimensional Patterson map. Refinement was made with a block-diagonal least-squares program, HBLS V[3]. The calculations were carried out on two computers, the CDC-6600 in the Century Research Center Co., Ltd., and the NEAC-2200/575 in the National Defense Academy. The final R value was 0.059. The atomic parameters are given in Table 1.***

Discussion

The numbering scheme and the thermal ellipsoids are illustrated in Fig. 1, while the bond distances and angles are given in Table 2. The molecule is centrosymmetric, showing that the piperazine ring has

Table 3. Torsion angles (ϕ/°)

The torsion angle $A(i)$-$A(j)$-$A(k)$-$A(l)$ is viewed down $A(j)$-$A(k)$, with the clockwise rotation of $A(i)$ to $A(l)$ taken to be positive. The e.s.d.'s are 0.5—0.9°.

C(3)-C(2)-N(1)-C(6)	60.8	C(2)-N(1)-C(6)-C(7)	178.5
C(2)-N(1)-C(6)-C(5)	−59.7	C(7)-C(6)-C(5)-N(4)	180.0
N(1)-C(6)-C(5)-N(4)	59.0	C(3)-C(2)-N(1)-H(9)	−179.6
		C(5)-C(6)-N(1)-H(9)	−179.9
		C(7)-C(6)-N(1)-H(9)	−58.8

a *chair* form. The mean N–C bond length, 1.464 Å, is in good agreement with that of *trans*-DDP(1.476 Å),[2] that of *cis*-DDP(1.472 Å),[1] and that of piperazine (1.467 Å).[4] The C–C bond distance is comparable to those found in *N,N'*-dimethylpiperazine(1.521 Å),[5] cyclohexane(1.536 Å),[6] *cis*-DDP(1.535 Å), and *trans*-DDP(1.517 Å). The C(2)–N(1)–C(6) bond angle is comparable to the 109.0° of piperazine or the 112.6° of piperidine.[7] The C(2)–N(1)–H(9) and C(6)–N(1)–H(9) bond angles agree with that of 109° for C–N–H in dimethylamine.[8]

The torsion angles are given in Table 3. The values of the ring torsion angles correspond to the typical chair form. The exocyclic torsion angles show that C(7) is in the equatorial position. This result supports Sudmeier's suggestion.[9] The H(9) atom is in the equatorial position.

The molecular packing with intermolecular distances less than 4.000 Å is shown in Fig. 2. The shortest contact of 3.305 Å is seen between N(1) and the equivalent atom related by a two-fold screw axis. The value of the N–H···N' angle (168°) suggests the presence of a weak hydrogen bond. These hydrogen bonds form infinite ribbons of molecules along the [011] direction. The ribbons of molecules are held together by the van der Waals interactions.

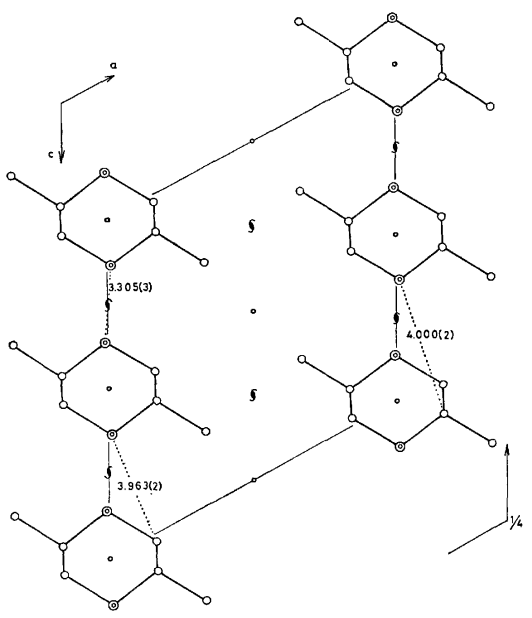

Fig. 2. The molecular packing viewed down the b axis, showing all intermolecular distances less than 4.000 Å.

The authors would like to thank Mr. Kazumasa Maruyama for his kind aid in the computation.

Liquid Crystals as Reaction Media. I. Photochemical Dimerization of Acenaphthylene in Cholesteric Liquid Crystal

Tomoko NAKANO* and Hirotaka HIRATA

Niigata College of Pharmacy, 5829 Kamishin'ei-cho, Niigata 950-21

(Received April 13, 1981)

Synopsis. The photodimerization of acenaphthylene in liquid crystalline media exhibiting cholesteric or nematic phase was studied from the view point of the stereoselectivity of the products. In the cholesteric phase *trans*-isomer formation increased remarkably and the ratio of the *trans*-isomer to *cis*-isomer depended significantly upon the acenaphthylene concentration. These results suggest a steric effect of the cholesteric phase structure on stereoselectivity on photodimerization compared with the predominant *cis*-isomer formation in the nematic phase.

The photodimerization of acenaphthylene is known to yield both *trans*- and *cis*-stereoisomer.[1-2] Figure 1 and Table 1 show the results of the photodimerization in cholesteric, nematic liquid crystalline media and in an organic solvent. As reported recently by R. G. Weiss *et al.*[3] the quantum yield of photodimerization considerably increased in cholesteric phase media in comparison with that in nematic phase media or in benzene. The irradiation time required to attain the same degree of conversion was much shortened in the cholesteric phase media than in the nematic media or in benzene (Table 1). *cis*-Isomer formation was dominant in nematic media and in benzene, whereas in cholesteric media the *trans*-isomer formation increased significantly.

In cholesteric or nematic phase systems doped with acenaphthylene, the mesophase appears over a rather narrow concentration range of acenaphthylene, less than about 5%. More acenaphthylene destroys the mesophase structure and generates isotropic phase.

In Fig. 1-(a) it is shown that the dominant *trans*-isomer formation in the cholesteric phase media is restricted to a low concentration range of acenaphthylene. The ratio of *trans*-isomer (**1**) to *cis*-isomer (**2**) is remarkably depended upon the acenaphthylene concentration, increasing with decreasing acenaphthylene. In nematic phase media the ratio of **1** to **2** was rather constant over a wider concentration range, irrespective

a) Irradiation was carried out in a Petri dish at 40 °C for 4 h. b) In a Petri dish at 40 °C for 24 h. c) In a Pyrex tube at room temperature for 6 h. d) For 4 h. e) For 24 h.

of the phase change of the medium.

The effect of a triplet quencher (ferrocene) on the photodimerization in cholesteric phase media was examined. In the presence of 1 w/w% ferrocene, the *trans*-isomer was scarcely detected at acenaphthylene concentrations ranging from 1 to 10 w/w %. The amount of the *cis*-isomer formed was, however, nearly the same as in the absence of ferrocene (*cis*-Isomer was formed to the extent of more than 98%.). These results indicate that the preferable *trans*-isomer formation in the cholesteric phase is to be attributed to the increase of dimerization *via* the triplet state compared to *via* the singlet state.[1] The preferable formation of the *trans*-isomer with high quantum yield in the cholesteric phase implies that photodimerization *via* the triplet state is more enhanced in the cholesteric phase than that *via* the singlet state.

Generally photodimerization *via* the triplet state is more probable in dilute and highly viscous media, such as liquid crystalline media, owing to the difference of the life times of the triplet and singlet states.[3,4] In nematic phase media as highly viscous as cholesteric, dependence of the ratio of **1** to **2** upon the acenaphthylene concentration was scarcely observed, *cis*-isomer formation being dominant and the enhancement of the quantum yield not being observed. Accordingly the preferance for *trans*-isomer formation and the dependence of the ratio of **1** to **2** upon acenaphthylene concentration in the cholesteric phase might scarcely be attributed to the high viscosity of the solvent media, but these results might be characteristic of photodimerization in cholesteric phase media.

The effect of tetralin, which disturbs solvent order but does not interfere electronically with the photodimerization, is shown in Table 2. The ratio of **1** to **2** diminished with increasing tetralin concentration. This effect suggests that the ordered structure of the cholesteric phase definitely affects the *trans*-isomer formation advantageously.

Table 2. The effect of tetralin addition on stereoisomeric product distribution (**1**)/(**2**) in the photodimerization of acenaphthylene in cholesteric phase media

Acenaphthylene (%) in solvent media	Tetralin (%)[a]			
	No addition	5%	10%	20%
1% in cholesteryl myristate (70 °C)	5.40	3.55	2.70	3.02
1% in cholesteryl oleate (40 °C)	3.74	3.01	2.85	2.78

a) Tetralin (%) stands for percentage to the weight of solvent media. The mesophase appears at 5% concentration, whereas it raises the isotropic phase above 10% concentration of tetralin.

In cholesteryl myristate a remarkable change in the ratio of **1** to **2** was recognized between cholesteric phase regions ($T>70$ °C) and the solid phase region (60 °C) (Fig. 1-(b)). The influence of the ordered structure of the cholesteric phase on stereoselectivity is also supported by this result.

Experimental

Materials. Commercially available acenaphthylene was recrystallized several times from methanol. The *trans*-isomer and the *cis*-isomer were isolated from the reaction mixture obtained by irradiation of acenaphthylene in benzene, by silica-gel column chromatography using cyclohexane as eluent. The mp, NMR, and UV spectra of these compounds were identical with those reported by R. Livingston.[1] The mesomorphous reaction media were recrystallized before use.

Photochemical Reaction Procedures. Irradiation was carried out using a 1000 W-high pressure mercury arc lamp (TOSHIBA H 1000 L) filtered through a Toshiba cut-off glass filter UV-34. The sample solutions were irradiated in Pyrex tubes or Petri dishes without de-aeration and the reaction temperature was controlled in a thermostated oil bath with an accuracy of ±2 °C.

LC Measurement. After removal of the reaction media, high performance liquid chromatography(LC) was carried out using a WATERS ASSOCIATES ALC/GPC 204 using a 3.9 mm×30 cm column packed with μ-Bondapack C_{18}. The mobile phase solvent was acetonitrile–water (85:15) at a flow rate of 1.0 ml/min. The detector wavelength was 254 nm. Retention times were 3.86 min for acenaphthylene, 4.90 min for the *cis*-isomer, and 7.24 min for the *trans*-isomer respectively. The ratio of **1** to **2** was determined from the ratio of the peak areas by an external standard method.

DSC Measurements. The transition temperatures for liquid crystals doped with acenaphthylene were measured by differential scanning calorimetry (Rigaku Denki DSC) and polarization microscope observation. It was confirmed that the properties of liquid crystalline reaction media underwent no change under these irradiation conditions.

The authors wish to express their thanks to Dr. Yoshiaki Ohgo and Dr. Yoshihiko Hatano of Niigata College of Pharmacy for their helpful discussions.

Infrared Study of 12-Molybdophosphoric Acid Reduced by Organic Compounds

Tian-hsi Tsai, Ken-ichi Maruya,* Mamoru Ai, and Atsumu Ozaki

Research Laboratory of Resources Utilization, Tokyo Institute of Technology, 4259 Nagatsuta, Midori-ku, Yokohama 227

(Received July 24, 1981)

Synopsis. Reaction of 12-molybdophosphoric acid with ethyl methyl ketone, crotonaldehyde, methacrylaldehyde, 1-butene, or 1,3-butadiene is enhanced by the presence of water, and leads to preferential decrease in ν(P–O) at 1060 cm^{-1} with preference over that in ν(Mo–O–Mo) at 880 cm^{-1}, while the reaction with methanol is not dependent on the presence of water and results in rapid disappearance of ν(Mo–O–Mo) and retention of ν(P–O).

The IR spectrum of 12-molybdophosphoric acid (HPA) shows four absorption bands at 1060, 960, 880, and 790 cm^{-1} for the stretching vibrations of the anion structure, which are assigned to ν(P–O), ν(Mo=O), and two ν(Mo–O–Mo), respectively.[1] Tsuneki *et al.*[2] examined H_2 reduction of trisilver 12-molybdophosphate, followed by reoxidation with $^{18}O_2$, by means of IR spectroscopy, and suggested that the oxygen removed by the reduction is not from P–O but from Mo–O–Mo, because the isotope shift associated with the reoxidation by $^{18}O_2$ was observed only for ν(Mo=O) and two ν(Mo–O–Mo)'s. In this paper, we report different behaviors of IR spectral changes in reduction of HPA with various organic compounds.

Experimental

HPA was purchased from Kanto Chemical Co. and used without further purification. Organic compounds were dried on anhydrous $CaSO_4$ or molecular sieve 5A and degassed by distillation *in vacuo*. The film of HPA was prepared as described previously.[3] The film was placed in an IR cell connected with a closed circulating system and evacuated at room temperature for 5 min or at 130 °C for 2 h, after which the vapor of an organic compound with or without water was introduced into the cell. Since the volume of the cell was about 280 cm^3, the amounts of the compound and water were in a large excess over that of HPA (2—5 mg/cm^2).

Results and Discussion

Figure 1 shows IR spectra of HPA treated with ethyl methyl ketone. ν(P–O), $\nu(Mo–O–Mo)_H$ (880 cm^{-1}), and $\nu(Mo–O–Mo)_L$ (790 cm^{-1}) decrease with increase in reaction temperature. The decrease for the HPA preevacuated at lower temperatures is obviously much more eminent, indicating that the reduction of HPA is enhanced by the hydrated water.

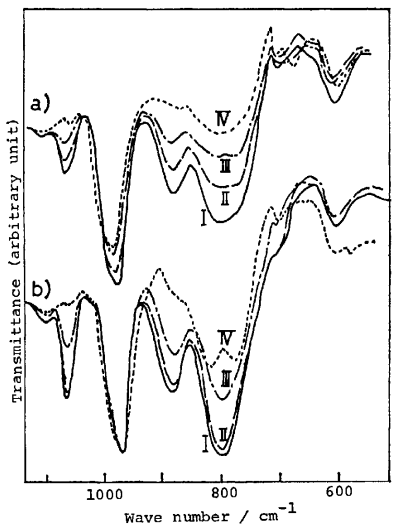

Fig. 1. IR spectra of HPA treated with ethyl methyl ketone (7 mmHg)† for 30 min. a) Preevacuated at 130 °C for 2 h and treated at I: room temp, II: 130 °C, III: 178 °C, and IV: 240 °C. b) Preevacuated at room temp for 5 min and treated at I: room temp, II: 50 °C, III: 90 °C, and IV: 125 °C.

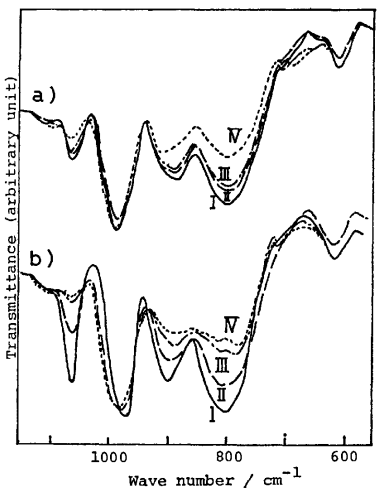

Fig. 2. IR spectra of HPA treated with 1-butene (7 mmHg) for 30 min. a) Preevacuated at 130 °C for 2 h and treated at I: room temp, II: 122 °C, III: 185 °C, and IV: 225 °C. b) Preevacuated at room temp for 5 min, after which water (4 mmHg) was added and treated at I: room temp, II: 124 °C, III: 175 °C, and IV: 220 °C.

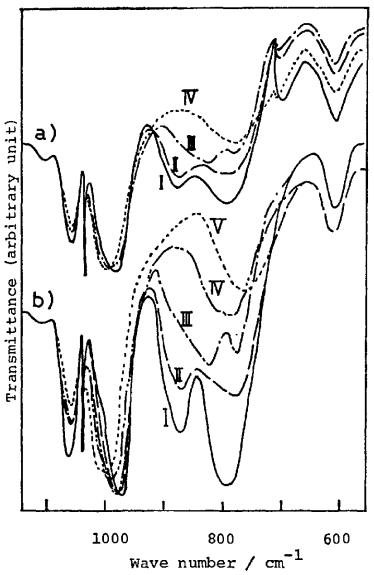

Fig. 3. IR spectra of HPA treated with methanol (4 mmHg) for 30 min. a) Preevacuated at 130 °C for 2 h and treated at I: room temp, II: 125 °C, III: 180 °C, and IV: 225 °C. b) Preevacuated at room temp for 5 min, after which water (4 mmHg) was added, and treated at I: room temp, II: 123 °C, III: 173 °C, IV: 210 °C, and V: 257 °C.

The decreases in ν(P–O) and $\nu(\text{Mo–O–Mo})_H$ are nearly parallel to each other.

The same dependence on the coexistence of water vapor is found in the reaction with 1-butene, as shown in Fig. 2. The spectra shown in Fig. 2b display quicker decrease of ν(P–O) than that of $\nu(\text{Mo–O–M})_H$. On the other hand, the reaction with methanol results both in almost complete retention of the absorption of ν(P–O) and in disappearance of $\nu(\text{Mo–O–Mo})_H$, as shown in Fig. 3.

The change in both the bands obtained with the above three compounds is plainly plotted together with those obtained with crotonaldehyde, 1,3-butadiene, and methacrylaldehyde in Fig. 4, where it is assumed that either the preevacuation or the reaction conditions have no effect on ν(Mo=O) since the absorption seems to be always superposed as seen in Figs. 1, 2, and 3. Each spectrum is, therefore, normalized on the basis of the intensity of ν(Mo=O), and each change in absorption is represented as the ratio of intensity at a reaction temperature to that at room temperature. With 1-butene and 1,3-butadiene, the intensities of ν(P–O) decrease steeply with increase in reaction temperature, while the lowering of $\nu(\text{Mo–O–Mo})_H$ is very dull, the ratio remaining still more than 0.8 even at 170 °C. With ethyl methyl ketone and crotonaldehyde, too, the decrease in ν(P–O) always precedes that of $\nu(\text{Mo–O–Mo})_H$, although they seem to be nearly parallel. The behavior of the decrease in the two bands with methacrylaldehyde is similar to that with 1-butene in the absence of water and to that with ethyl methyl ketone in its presence. It was reported in our previous paper[3] that absorbed methacrylaldehyde could hardly reduce HPA with or without water at 180 °C, which should be revised. It is, therefore, obvious that the reaction of HPA with all the above five compounds, except methanol, is enhanced by the presence of water and gives rise to the preferential decrease in ν(P–O). The catalytic oxidation of the compounds by HPA is known to depend on the amount of water,[4,5] in conformity with the reduction of HPA. Thus, the lowering of ν(P–O) may be characteristic of reactions in which water participates.

On the other hand, the reaction with methanol results in the striking decrease in $\nu(\text{Mo–O–Mo})_H$ and the almost complete retention of ν(P–O), which seems to be much less affected by water as shown in Figs. 3 and 4f. The catalytic reaction by HPA to produce formaldehyde is not enhanced by water.[5] The decrease in $\nu(\text{Mo–O–Mo})_H$, therefore, may be attributed to the loss of oxygen in Mo–O–Mo.

The results of Fig. 4 show that there would be no appreciable interaction between ν(P–O) and $\nu(\text{Mo–O–Mo})_H$, indicating no fast oxygen exchange between them. In addition, the oxygen mixing between $\nu(\text{Mo–O–Mo})_H$ and $\nu(\text{Mo–O–Mo})_L$ appears to be very slow even at 257 °C, because the latter band remains while the former disappears, as shown in Figs. 2 and 3. In the reduced state, the latter band often splits into two bands at 825 and 780 cm^{-1}, and the splitting was observed both in the disappearance (Figs. 1 and 2) and in the retention (Fig. 3) of ν(P–O), indicating a very complicated behavior. At present, the relation between $\nu(\text{Mo–O–Mo})_L$ and the reduction of HPA is obscure. Katamura *et al.*[6] investigated the mechanism of the H_2 reduction of HPA and the interaction of water with it by means of TPD and IR measurements, suggesting that lower symmetry of the anion structure caused by the reduction may explain the change in IR spectra in the P–O region. It might, however, be suggested from no interaction between the bands that the decrease in ν(P–O) relates to loss of the bridged oxygen showing $\nu(\text{Mo–O–Mo})_L$ but not $\nu(\text{Mo–O–Mo})_H$, if Tsuneki's[2] and Katamura's[6] suggestions would be taken. Another interpretation might be loss of the oxygen in P–O, though there seems to be no change in the band at 610 cm^{-1} which is assigned to δ(O–P–O)[2] as shown in Figs. 1, 2, and 3.

The Effect of Pressure on the Mutual Solubility of a Nonionic Surfactant–Water System

Shoji KANESHINA,* Osamu SHIBATA, and Makoto NAKAMURA

College of General Education, Kyushu University-01, Ropponmatsu, Chuo-ku, Fukuoka 810

(Received July 27, 1981)

Synopsis. The cloud-point temperature (T) of an aqueous hexa(oxyethylene) dodecyl ether solution was determined as a function of the pressure (P) and the composition (x_2). The volume (ΔV) and entropy (ΔS) changes for the separation of the surfactant phase from the water phase were estimated from the T-P-x_2 relation. Both ΔV and ΔS were positive.

An aqueous solution of nonionic surfactants suddenly becomes turbid on being heated to a critical temperature, known as the cloud point, and the solution separates into two phases. This peculiar dissolution phenomenon has been explained especially by an acceptable model based on the thermodynamic properties of a nonionic surfactant–water system,[1,2] since accurate thermodynamic data have been determined for pure nonionics in water. Although the pressure is necessarily an important thermodynamic variable, as well as the temperature and the concentration, defining the state of solution, few studies have been made on the effect of pressure on the solution behavior of nonionic surfactants in water.[3–5] In this paper, the cloud-point temperature of an aqueous hexa(oxyethylene) dodecyl ether solution has been determined as a function of both the pressure and the composition. From the relation of the cloud-point-temperature-pressure-composition, the thermodynamic quantities (volume ΔV and entropy ΔS) accompanied by the separation of the surfactant phase from the water phase were estimated.

Experimental

Homogeneous hexa(oxyethylene) dodecyl ether ($C_{12}E_6$) was obtained from Nikko Chemicals. Its purity was checked by gas chromatography, and it was found to show a single peak. The cloud-point temperature of a 1.0% (w/w) solution was 48.8 °C. The cloud points under a high pressure were determined by a method described previously.[4]

Results and Discussion

The cloud-point temperatures of aqueous $C_{12}E_6$ solutions were determined in the pressure range of 0.1—150 MPa and the composition range of 0.1—10% (w/w). The cloud-point temperatures for all the surfactant solutions increase monotonously with an increase in the pressure up to 150 MPa (Fig. 1). Since the cloud point of a surfactant solution is generally taken to be the temperature where the separation of the liquid-surfactant phase containing dissolved water is caused by the dehydration of ether oxygens of the poly(oxyethylene) group,[1] a pressure of up to 150 MPa seems to favorable for the dissolution of surfactant molecules in water. An increase in the pressure enhances the formation of hydrogen bonds between water and ether oxygens of the poly(oxyethylene) group.[6]

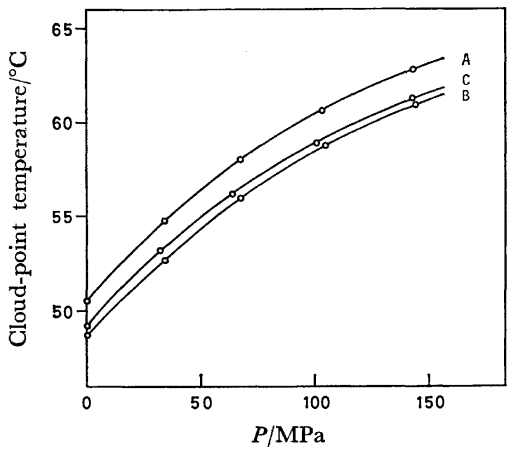

Fig. 1. Cloud-point temperature *vs.* pressure curves for some aqueous hexa(oxyethylene) dodecyl ether solutions. Concentration; A: 0.124, B: 2.06, and C: 5.02 %(w/w).

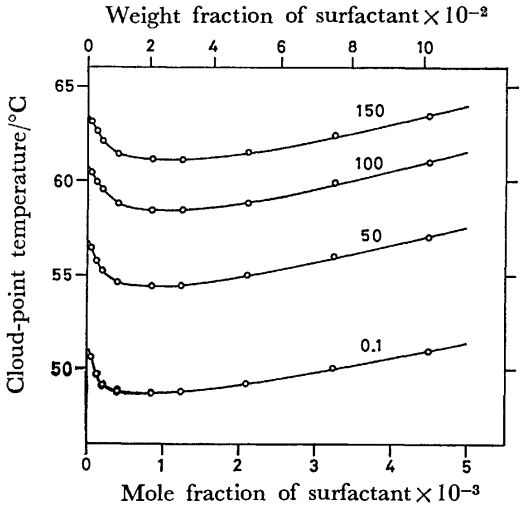

Fig. 2. Cloud-point temperature of aqueous hexa(oxyethylene) dodecyl ether solutions as a function of surfactant concentration at various pressures. Numerical values refer to the pressure in MPa.

In Fig. 2, the cloud points are shown as a function of the concentration of $C_{12}E_6$ at various pressures. Note that each curve in Fig. 2 is a part of the phase diagram representing the liquid-liquid mutual solubility, which has a lower critical solution temperature (LCST). As may be seen from Fig. 2, the LCST can be elevated by increasing the pressure.

At the cloud point, the two phases (an aqueous phase containing a small amount of a singly dispersed surfactant and a liquid surfactant phase containing dissolved water) are in equilibrium.[1,2] In the two-component, two-phase system, the curves of the co-

existence of pairs of phases are described by these equations:[7]

$$\left(\frac{\partial T}{\partial x_2}\right)_P = g_{22}\left(\frac{RT}{y_1\Delta\bar{s}_1+y_2\Delta\bar{s}_2}\right)\left(\frac{x_2-y_2}{x_1x_2}\right), \quad (1)$$

$$\left(\frac{\partial P}{\partial x_2}\right)_T = -g_{22}\left(\frac{RT}{y_1\Delta\bar{v}_1+y_2\Delta\bar{v}_2}\right)\left(\frac{x_2-y_2}{x_1x_2}\right), \quad (2)$$

and:

$$\left(\frac{\partial T}{\partial P}\right)_{x_2} = \frac{y_1\Delta\bar{v}_1+y_2\Delta\bar{v}_2}{y_1\Delta\bar{s}_1+y_2\Delta\bar{s}_2}, \quad (3)$$

where x and y refer to the mole fraction in an aqueous phase and a surfactant phase respectively. $\Delta\bar{s}_1$ and $\Delta\bar{s}_2$ are the partial molal entropy changes in the water and surfactant respectively transferred from the aqueous into the surfactant phase, and $\Delta\bar{v}_1$ and $\Delta\bar{v}_2$ are the partial molal volume changes in the water and surfactant respectively transferred from the aqueous into the surfactant phase. The expression for g_{22} can be written:

$$g_{22} = \left(\frac{\partial \ln a_2}{\partial \ln x_2}\right)_{T,P}. \quad (4)$$

In a dilute solution, the activity is usually proportional to the concentration, and Eq. 4 becomes $g_{22}=1$.

The entropy change on the phase separation of a surfactant solution, ΔS ($\equiv y_1\Delta\bar{s}_1+y_2\Delta\bar{s}_2$), can be estimated by applying Eq. 1 to Fig. 2 (T-x_2 diagram). The volume change on the phase separation of a surfactant solution, ΔV ($\equiv y_1\Delta\bar{v}_1+y_2\Delta\bar{v}_2$), can be estimated by using Eq. 3, the value of ΔS, and the slope of Fig. 1 (T-P diagram).

The values of ΔV and ΔS, which were calculated at the surfactant concentration of $x_2=5.0\times10^{-5}$, are listed in Table 1. Both ΔV and ΔS are positive. These positive changes in volume and entropy are attributable partly to the dehydration of the poly(oxyethylene) chain and partly to the hydrophobic bonding of alkyl chain. The value of ΔV, 2.1 cm^3 is in good agreement with the volume change of 2.2 cm^3, which was determined from the density measurements above and below the cloud point.[8]

The volume change for the transfer of the poly(oxyethylene) chain from the aqueous solution into the pure liquid state amounts to about 2.0 cm^3 per oxyethylene unit.[6] Therefore, the volume change of 12 cm^3 may be expected for the complete dehydration of the hexa(oxyethylene) group. On the other hand, the volume change for the transfer of the hydrocarbon part from the aqueous to the nonpolar environment amounts to 1.2—1.5 cm^3 per methylene group.[9-11] Despite the large volume change to be expected for both the dehydration and the hydrophobic bonding, the volume change calculated thermodynamically or measured directly is appreciably small. Since the liquid-surfactant phase contains a considerable amount of water, the partial dehydration of the poly(oxyethylene) chain and the incomplete transfer of the alkyl chain are considered to be responsible for the small volume change on the separation of the liquid-surfactant phase from the aqueous phase.

Table 1. Thermodynamic parameters on the cloud point of an aqueous hexa(oxyethylene) dodecyl ether solution at the concentration of $x_2=5.0\times10^{-5}$

P / MPa	T / K	ΔS / J K^{-1} mol^{-1}	ΔV / cm^3 mol^{-1}
0.1	323.6	16	2.1
50	329.4	20	1.9
100	333.4	26	1.7
150	336.1	31	1.4

As is shown in Table 1, the value of ΔV decreases with the increase in the pressure, while the value of ΔS increases with the pressure. The large compressibility of the dehydrated system compared with the hydrogen-bonded system is considered to be responsible for the decrease in the ΔV with the pressure. The increased in ΔS with the pressure may be ascribed to the increased numbers of the hydrogen bonds between the poly(oxyethylene) chain and water molecules. In other words, the hydrogen-bonded water, which should be released at the cloud point, is likely to be increased by applying pressure. The hydrophobic bonding may also be responsible for the increase in ΔS with the pressure; the value of ΔS for the hydrophobic bonding (*i.e.*, micelle formation) increases initially with an increase in the pressure and then decreases with the pressure *via* the maximum at about 100 MPa.[11]

Solvent Effects on the Isomerization of 1-Pentene Catalyzed by Cationic Platinum Complexes

Hiroyoshi KANAI* and Osamu HIRAKO†

Department of Hydrocarbon Chemistry, Faculty of Engineering, Kyoto University, Sakyo-ku, Kyoto 606

(Received September 7, 1981)

Synopsis. The isomerization of 1-pentene with $[PtH(PPh_3)_3]X$ ($X=SO_4H$, ClO_4) occurred only in ethers. The decrease in the concentrations of 1-pentene and the platinum complexes leads to high *cis*-selectivity.

Wells *et al.* deduced that stereoselectivity in the isomerization of 1-alkenes was determined by the degree of molecular congestion at a catalyst site:[1,2] the preferential *cis*-alkene formation occurred when the site of catalytic activity was highly congested.[1-3] A wide range of metal-phosphine complexes catalyze 1-pentene isomerization to 2-pentenes *via* the formation of secondary pentyl intermediates with preferential formation of *cis*-2-pentene.[2-5] The selectivity was explained in terms of the restriction of the normal rotations in the secondary pentyl intermediate by phosphine ligands as low the conformation of molecular volume predominates as possible.[1,2] We observed selective *cis*-isomerization of 1-pentene catalyzed by $NiX(PPh_3)_3$–$SnCl_2$ (X=halogen) systems which was attributed to the bulkiness and *trans*-effect of $SnCl_2X^-$ ligands.[4]

$[PtH(PPh_3)_3]X$ ($X=SO_4H$, ClO_4) isomerized 1-pentene slowly at 50 °C to give 2-pentene having an initial *cis*/*trans* ratio of more than 3 only in ethers (Table 1). No isomerization occurred with $[PtH(PPh_3)_3]SO_4H$ in homogeneous solutions of ethyl methyl ketone, methanol, *N*,*N*-dimethylformamide, acetonitrile, and nitromethane, or in a heterogeneous solution of benzene. However, in homogeneous solutions of benzene and dichloromethane, or in heterogeneous solutions of dioxane, THF, and 1,2-dimethoxyethane (glyme) the isomerization of 1-butene[6] or 1-pentene[7] with $PtH(PPh_3)_2ClO_4$ proceeded readily in preferential formation of the *trans*-isomers. The initial *trans*/*cis* ratio in glyme (Table 1) is in excess of the equilibrium value as is only known in cases of the isomerization of 1-pentene catalyzed by Pt(II)–$SnCl_2$ complex,[8] $RuH_4(PPh_3)_3$, and $RuH_2(N_2)(PPh_3)_3$.[9] $[PtH(PPh_3)_3]ClO_4$ (tris-complex) is lower in reactivity and higher in *cis*-selectivity than $PtH(PPh_3)_2ClO_4$ (bis-complex). Although relative rates are not determined exactly owing to the heterogeneity, isomerization proceeds favorably in glyme among ethers investigated. First-order dependency and constant *cis*/*trans* ratios were observed in ethers listed in Table 1. When excess of PPh_3 was added to the bis-complex, there appeared reaction features characteristic of the tris-complex: the *cis*/*trans* ratios increased gradually from 0.55 to 0.99, 2.00 and 2.70 in accordance with excess PPh_3/bis-complex=0.85, 0.90, 0.95, and 0.97, respectively.

The isomerization catalyzed by the tris-complex occurs *via* a metal-hydride addition-elimination mechanism: (1) Pt–H bond was detected in the IR spectrum after isolation of the catalyst from the reaction mixture of $[PtD(PPh_3)_3]ClO_4$ and 1-pentene in glyme; (2) intermolecular hydrogen transfer between C_2D_4 and C_2H_4 occurred.

The lower the concentrations of 1-pentene and of the platinum complex become, the higher *cis*-selectivity rises (Fig. 1). The increase of 1-pentene results in the dissociation of the tris-complex to give

† Present address: Mitsubishi Motors Corporation, Kyoto Works, Ukyo-ku, Kyoto 615.

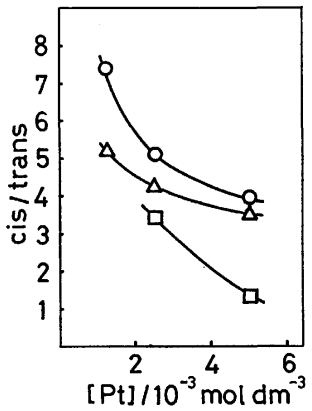

Fig. 1. Plots of *cis*-selectivity *vs.* the concentration of $[PtH(PPh_3)_3]ClO_4$. The ratios of 1-pentene to the Pt complex: 10 (○); 20 (△); 100 (□).

the bis-complex which is high in catalytic activity and low in *cis*-selectivity. Conversions of 1-pentene after 4 h at 10, 20, and 100 of 1-pentene/Pt ratios were 8.6, 10.0, and 11.9%, respectively in 5×10^{-3} mol dm^{-3} of $[PtH(PPh_3)_3]ClO_4$. The opposite tendency in regard to the effect of the concentration of catalysts would be attributed to a gradual increase in the degree of dissociation of the catalyst by losing PPh_3 ligands.[3] The rise in the *cis/trans* ratio with decreasing catalyst concentration in Fig. 1 would be due to the lack of dissociation of the tris-complex in ethers.

The presence of compounds having an ether linkage is essential for catalytic activity of the tris-complex. Diallyl ether and allyl phenyl ether were isomerized by the tris-complex in neat liquid or a non-ether solvent such as ethyl methyl ketone. No isomerization of allylbenzene occurred in neat liquid but it was isomerized to propenylbenzene in glyme.

Experimental

1-Pentene was obtained from Tokyo Kasei Kogyo Co. and distilled prior to use. Tetrahydrofuran, dioxane, and glyme were refluxed over sodium, distilled and stored in a nitrogen atmosphere. Other chemicals were commercial materials and used without further purification.

$[PtH(PPh_3)_3]X$ ($X=SO_4H$, ClO_4)[10] and $PtH(PPh_3)_2ClO_4$[11] were prepared according to the methods given in the literature.

Procedure. A two-necked 100 ml flask was charged in a nitrogen atmosphere with $(2.5—10)\times10^{-4}$ mol of a platinum complex, (10—20) ml of dry, degassed solvent, and a micro stirring bar. The flask was cooled in liquid nitrogen and evacuated, and $(5—10)\times10^{-3}$ mol of 1-pentene was added. The flask was immersed in a bath maintained at 50 °C or r.t. Samples of the solution, *ca.* 0.1 ml, were withdrawn through the side arm at intervals with a syringe and the distillates obtained from thaw-to-thaw distillation were analyzed by a Shimadzu GC gas chromatograph on the 2,4-dimethylsulfolane (30%)/C-22 column operated at ambient temperature.

Syntheses of Six-membered Cyclopalladated Complexes of 2-Benzoylpyridine

Yoshio FUCHITA, Katsuma HIRAKI,* and Yasunori KAGE

Department of Industrial Chemistry, Faculty of Engineering, Nagasaki University, Bunkyo-machi, Nagasaki 852

(Received July 23, 1981)

Synopsis. 2-Benzoylpyridine reacts with $Pd(OAc)_2$ to give a new six-membered cyclopalladated complex, $[\{Pd(pcph)(OAc)\}_2]\cdot 0.25CH_2Cl_2$ [pcph=2-(2-pyridylcarbonyl)phenyl-C^1,N] (**1**). A chloro-bridged analogue, $[\{Pd(pcph)Cl\}_2]$, prepared by the metathetical reaction of **1** with LiCl, undergoes bridge-splitting reactions with 3,5-lutidine and Tl(acac) to yield the corresponding mononuclear cyclopalladated complexes.

Many studies have been reported on the five-membered cyclopalladated complexes of aryl-substituted nitrogen bases.[1,2] However, as concerns six-membered cyclopalladated complexes having nitrogen donor atoms, only two reports have appeared on *N,N'*-diarylamidines[3] and *N,N*-diethyl-3-phenylthiomethoxy-4-methoxyphenethylamine.[4] Recently, it was found in our laboratory that 2-benzylpyridine readily produces a six-membered cyclopalladated complex by the reaction with palladium(II) acetate.[5] In continuation of our studies about the six-membered cyclopalladated complexes, we wish to report on the cyclopalladation of 2-benzoylpyridine (bzopy) by palladium(II) acetate resulting in the formation of $[\{Pd(pcph)(OAc)\}_2]$ (**1**) [pcph=2-(2-pyridylcarbonyl)phenyl-C^1,N].

Experimental

All the new complexes synthesized in this study were characterized in the same way as described in an earlier paper.[6] Molecular weights were determined in benzene with a Corona Model 114 molecular weight apparatus at 41.7° C.

Preparation of $[\{Pd(pcph)(OAc)\}_2]\cdot 0.25CH_2Cl_2$ (**1**). An acetic acid suspension (20 ml) containing palladium(II) acetate (3.1 mmol) and bzopy (3.7 mmol) was refluxed for 1.5 h, and then filtered, to give a yellow cake and a yellow solution. The yellow cake was successively washed well with water and a small amount of methanol, and recrystallized from dichloromethane/hexane to give 0.56 g of **1** as yellow crystals. An additional amount (0.28 g) of **1** was obtained as yellow precipitates from the yellow solution after extraction of it with dichloromethane, concentration of the extract, and dilution with hexane. Yield 76%; mp 240—243 °C (dec); MW 705.4 (Calcd 716.6).

Preparation of $[\{Pd(pcph)Cl\}_2]$ (**2**). A THF–water (120 ml/10 ml) suspension containing **1** (1.2 mmol) and LiCl (7.5 mmol) was stirred for 12 h. The precipitated yellow solid was filtered, and washed with a methanol/water (20 ml/20 ml) mixture to give **2**. Yield 95%; mp>300 °C.

Reaction of **2** *with 3,5-Lutidine.* A dichloromethane solution (10 ml) containing **2** (0.23 mmol) and 3,5-lutidine (lut) (0.51 mmol) was stirred at room temperature for 5 h. Addition of hexane to the resulting mixture gave $[Pd(pcph)Cl(lut)]\cdot 0.1CH_2Cl_2$ (**3**) as pale yellow crystals. Yield 79%; mp>300 °C.

Reaction of **2** *with Tl(acac).* A dichloromethane suspension (15 ml) of **2** (0.46 mmol) and thallium(I) acetylacetonate (0.95 mmol) was stirred at room temperature for 1 d. After centrifuging the resulting milky suspension, the supernatant solution was passed through a silica-gel column (200 mesh, $20\phi\times 140$ mm) with dichloromethane as an eluent. A pale yellow fraction was collected and concentrated. Addition of hexane gave [Pd(pcph)(acac)] (**4**) as yellow crystals. Yield 39%; mp 229—230 °C (dec).

Results and Discussion

2-Benzoylpyridine reacted with palladium(II) chloride in refluxing ethanol to afford only an addition complex, bis(2-benzoylpyridine)dichloropalladium(II), giving no cyclopalladated complex. However, bzopy reacted readily with palladium(II) acetate in refluxing acetic acid to produce a new six-membered cyclopalladated complex **1** in a high yield. It is noteworthy that bzopy, which contains an electron-attracting carbonyl group, undergoes easily cyclopalladation reaction with palladium(II) acetate, in contrast with the results of the earlier studies concerning the electronic effect on the cyclopalladation reaction of substituted azobenzenes.[7,8] Complex **1** was treated with LiCl to give **2**, which reacted with lut and Tl(acac) to afford the corresponding mononuclear cyclopalladated complexes, **3** and **4**, respectively (Scheme 1). All the new complexes prepared in this study show considerably high thermal stability. The IR spectra of **1**—**4** showed bands at *ca.* 1670 cm^{-1} due to a ν(C=O) vibration in pcph moiety. This band did not shift virtually in comparison with that in free bzopy (1670 cm^{-1}).

The IR spectrum of **1** showed two characteristic bridging acetato bands[9] at 1585 and 1430 cm^{-1}. This

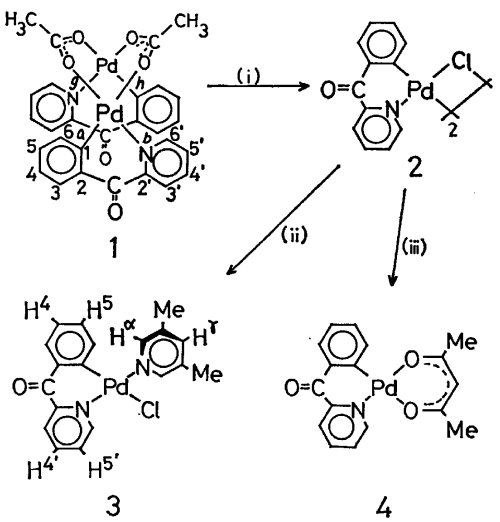
complex did not show temperature-dependent ^{1}H NMR spectra in the range of 57——50 °C, indicating that the six-membered pcph-palladium ring is virtually planar; if this ring were nonplanar and had a boat conformation, temperature-dependent ^{1}H NMR spectra attributable to an inversion of the ring would be observed as was seen in the palladated 2-(2-picolyl)-phenyl-C^1,N ring.[5] The ^{1}H NMR spectrum of **1** exhibited one sharp singlet due to the μ-acetato-methyl protons at δ 2.05, indicating that **1** has only one (*a*-C^1,*b*-N)(*g*-N,*h*-C^1) typed isomer[10] (Scheme 1).

In the ^{13}C{^{1}H} NMR spectrum of **1** in $CDCl_3$, three aromatic quaternary carbon signals at δ 132.6, 143.2, and 150.5 were ascribed to 2-C, 1-C, and 2'-C, respectively, by comparison with the data of acetophenone (1-C, δ 137.1),[11] a cyclopalladated complex (1-C, δ 143.3),[5] and 2-acetylpyridine (2-C, δ 154.1).[12] These data confirm strongly a cyclopalladated structure of the pcph moiety in **1**. Other eight aromatic tertiary carbon signals appeared as singlets at δ 124.6, 125.4, 126.6, 128.5, 130.4, 134.0, 138.6, and 151.6. Only the last signal (δ 151.6) was assigned to 6'-C (6-C of 2-acetylpyridine, δ 149.5).[12] Two lower field singlets at δ 181.3 and 190.3 were ascribed to μ-acetato-carboxylato carbon [Mo_2(μ-O_2CMe)(Ph)$_3$(PMe_3)$_3$, δ 182.7][13] and carbonyl one, respectively. The μ-acetato-methyl carbon signal also appeared as a singlet at δ 24.5.

Complex **2** was assigned to a chloro-bridged binuclear complex on the basis of the elemental analysis and the characterization of the derivatives from **2** as stated below.

In the ^{1}H NMR spectrum of **3**, eight aromatic protons of the pcph moiety appeared as two sets of well-separated ABCD pattern (Fig. 1). In consideration of the magnetic anisotropy due to the lutidine ring[5,6] and the original chemical shifts of free bzopy,[14] four double doublets at δ 6.69, 7.75, 8.14, and 9.52 were assigned to H^6, H$^{3'}$, H^3, and H$^{6'}$, respectively, and four double triplets at δ 6.98, 7.12, 7.49, and 7.95 were ascribed to H^5, H^4, H$^{5'}$, and H$^{4'}$, respectively. The coupling constants were $^3J_{HH}$=7 Hz and



Scheme 1. (i) LiCl. (ii) 3,5-Lutidine. (iii) Tl(acac).

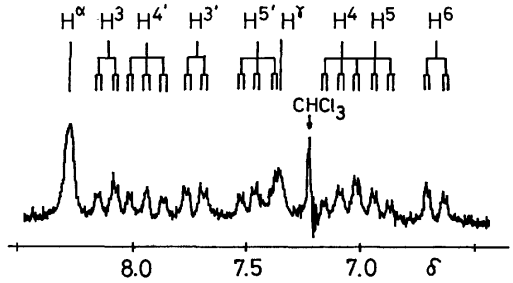


Fig. 1. Low field region of the ^{1}H NMR spectrum of **3**.

$^4J_{HH}$=2 Hz.

The IR spectrum of **4** exhibited two strong bands at 1590 and 1515 cm^{-1}, characteristic of the *O*,*O'*-chelating acetylacetonato ligand. This complex also showed two sets of relatively clear ABCD pattern, which consisted of two doublets at δ 7.72 and 7.78, two double doublets at δ 8.82 and 9.08 (H$^{6'}$) [$^3J_{HH}$=*ca.* 7 Hz, $^4J_{HH}$=*ca.* 2 Hz], two triplets at δ 7.13 and 7.27, and two double triplets at δ 7.51 and 7.98. The mass spectrum exhibited the parent ion peak at *m*/*e* 387, together with the fragment ion peak at *m*/*e* 288 [(P—acac)$^+$].

Styrene reacted with **2** in the presence of tripropylamine in refluxing *m*-xylene for 30 h to give a brownish black oil. After column chromatographic treatment on alumina, this oil was proved to contain both bzopy and *trans*-2-(2-pyridylcarbonyl)stilbene (**5**) in about 68 and 25% yields, respectively. The formation of **5** was confirmed by the ^{1}H NMR spectrum of the oil in CCl_4 [δ 6.82 d ($^3J_{HH}$=16 Hz, 1H, olefinic proton)] and its mass spectrum [*m*/*e* 285 (P$^+$)], supporting the cyclopalladated structure in **2**. However, the separation of these two compounds has not been achieved even after repeated column chromatographic treatments.

The Nafion-H-catalyzed Acylation of Thiophene with Acid Anhydrides

Hisatoshi KONISHI,* Kazuhiro SUETSUGU, Tamon OKANO, and Jitsuo KIJI

Department of Environmental Chemistry and Technology, Faculty of Engineering, Tottori University, Koyama, Tottori 680

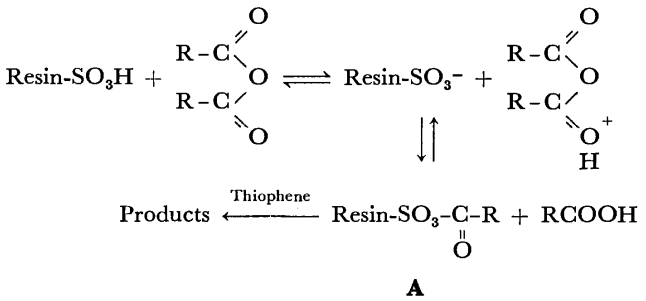
(Received May 22, 1981)

Synopsis. The reaction of thiophene with acyclic acid anhydrides in the presence of Nafion-H (fluorocarbon resin sulfonic acid) afforded the corresponding 2-acylthiophenes in moderate yields. Acylation with cyclic acid anhydrides gave only low yields, however. The Nafion-H catalyst could be reused for the acylation with a little loss of activity.

Ion-exchange resins have widely been used as renewable catalysts for organic synthesis. The resin catalysts are insoluble in organic solvents and can be recovered by filtration, with a retention of the catalytic activity. Considerable attention has been focused on the use of fluorocarbon resin (Nafion-H) containing strongly acidic groups, $-CF_2CF_2SO_3H$, in recent years. The catalytic activity and the stability of Nafion-H are superior to those of Amberlyst 15 (polystyrenesulfonic acid).[1] It has previously been shown that Nafion-H is a good catalyst for a variety of reactions, *e.g.*, alkylation,[2] hydration,[3] acylation,[4] and aldol condensation.[5] We have now examined the applicability of the Nafion-H-catalyzed reaction to thiophene chemistry. This paper is concerned with the Nafion-H-catalyzed acylation of thiophene with acid anhydrides and with a comparative study of the catalytic activity of Nafion-H and Amberlyst 15.

Results and Discussion

The results are summarized in Table 1. The reaction of thiophene with aliphatic acid anhydrides (**1a**—**c**) in dichloromethane under refluxing gave the corresponding ketones in sufficient yields. An increase in the chain-length of the acyl group results in a gradual increase in the yield of the ketones. This finding is consistent with the competitive acylation. The acylation rates of propionic anhydride, **1b**, and butyric anhydride, **1c**, relative to acetic anhydride, **1a**, at 38 °C in dichloromethane are as follows: **1a**, 1.00; **1b**, 1.56; **1c**, 1.88. The reactivity of the acid anhydrides increased with an increase in the +I effect of the alkyl group. The electron-releasing groups diminish the reactivity of electrophiles. In these acylations, therefore, the relative reactivity of the acid anhydrides appears to be anomalous. The acylations probably involve the mixed anhydrides intermediate, **A**, as is shown in Scheme 1. The mixed anhydride has been proposed as an intermediate in the acylation.[4]



A

Scheme 1.

It has been reported that an equimolar mixture of acetic anhydride and acetic acid was efficient in the Nafion-H-catalyzed acylation of reactive alkylbenzenes, and that acetic anhydride alone was not an effective acylating agent under the reaction conditions.[4] In our reaction conditions, however, the addition of acetic acid decreased the yield of 2-acetylthiophene.

Thiophene reacted with benzoic anhydride in the 1,2-dichloroethane solvent to give 2-benzoylthiophene in a good yield. Acylation with cyclic anhydrides (**2e**—**h**) gave only low yields under similar conditions.

The catalytic activity of Nafion-H was compared with that of Amberlyst 15. Under the same reac-

tion conditions (Runs 5 and 7), the acylation with **1c** and **1d** catalyzed by Amberlyst 15 gave **3c** and **3d** in 75 and 74% yields respectively. Judging from the yield, the Nafion-H catalyst is superior to the Amberlyst 15 catalyst. We also investigated the stability of Nafion-H under the present reaction conditions. Repeating the reaction of thiophene with propionic anhydride with the recovered catalyst gave the ketone in a somewhat lower yield than that using the original one. (Table 2). The recovered catalyst was black, and its weight increased. The loss of the catalytic activity seems to be ascribable to the adsorption of polymeric materials on the catalyst.

The present procedure offers a convenient method for the preparation of 2-acylthiophenes with an easy work-up. After the removal of the catalyst, the products were obtained by the fractional distillation of the reaction mixture. The yield of **1a** was comparable to that with the standard method.[6)]

Experimental

Catalysts. Nafion-511 resin, as the potassium salt of the fluorocarbon resin sulfonic acid, was obtained from the Mitsui Fluorochemicals Co., Ltd. Nafion-H, the acid form of the resin sulfonic acid, was generated by the treatment of the resin with 15% hydrochloric acid at room temperature for 12 h, followed by washing with deionized water. After the acid-treatment had been repeated four times, the resin was dried under evacuation at 80 °C for 4 h. The dried resin contained 0.80 mequiv. of SO_3H groups per gram of resin. Amberlyst 15 (Rohm & Haas Co.) was dried under a vacuum at 80 °C for 6 h. The ion-exchange capacity of the resin was 2.88 mequiv./g.

Acylation of Thiophene. A mixture of thiophene (20 mmol), acid anhydride (20 mmol), Nafion-H (0.2 g), or Amberlyst 15 (0.06 g), and a solvent (10 ml) was stirred under refluxing for 16 h. The catalyst was then filtered off and washed with dichloromethane. The filtrate was analyzed by gas chromatography. Naphthalene or *p*-di-*t*-butylbenzene was used as the internal standard. The products were identified by means of infrared and ^1H NMR spectroscopies. The recovered catalyst was dried in an air-oven at 105—110 °C for reuse.

Competitive Acylation. A mixture of thiophene (10 mmol), acetic anhydride (10 mmol), propionic anhydride (10 mmol), and Nafion-H (0.1 g) in dichloromethane (5 ml) was stirred at 38 °C for 4 h. The liquid phase was then analyzed by gas chromatography. The relative yield of **3b** to **3a** was 1.56:1. The conversion of propionic anhydride was less than 30% under these conditions.

Competitive acylation with propionic anhydride and butyric anhydride was carried out in a manner similar to that described above. The relative yield of **3c** to **3b** was 1.21:1.

The authors wish to thank the Mitsui Fluorochemicals Co., Ltd., for kindly supplying the Nafion-511 resin.

Thermolysis of 6-Hydroxyimino-1,3,5-tri-*t*-butyl-5-methyl-1,3-cyclohexadiene

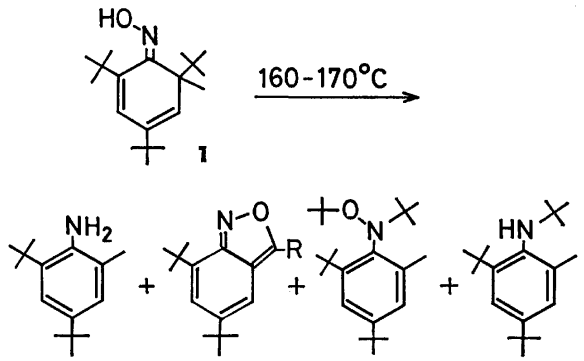
Renji OKAZAKI,* Masako WATANABE, and Naoki INAMOTO
Department of Chemistry, Faculty of Science, The University of Tokyo, Hongo, Bunkyo-ku, Tokyo 113
(Received May 27, 1981)

Synopsis. Mechanism of the thermolysis of the titile compound has been proposed, which begins with a homolytic cleavage leading to *t*-butyl radical and 2,4-di-*t*-butyl-6-methyl-1-nitrosobenzene. The reaction of the nitrosobenzene with *t*-butyl radical generated from photolysis of 2,2′-dimethyl-2,2′-azopropane is also described.

We have previously reported the photoreaction of cyclohexadienone oxime **1** proceeds *via* α-heterolytic cleavage, a new mode of photoreaction of an oxime.[1] In the present paper, we studied the thermal behavior of **1** and found that **1** underwent a decomposition through a homolytic pathway.

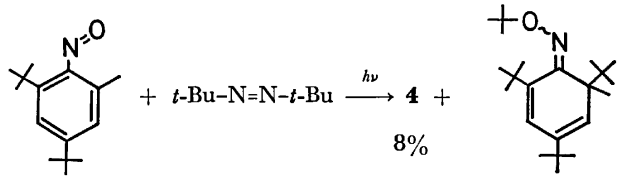
Results and Discussion

Reaction Products. Thermolysis of (*E*)-6-hydroxyimino-1,3,5-tri-*t*-butyl-5-methyl-1,3-cyclohexadiene (**1**) for 30 min at 160—170 °C afforded 2,4-di-*t*-butyl-6-methylaniline (**2**) (39%), 3,5,7-tri-*t*-butyl-2,1-benzisoxazole (**3**) (22%), *N,O*-di-*t*-butyl-*N*-(2,4-di-*t*-butyl-6-methylphenyl)hydroxylamine (**4**) (5%), and *N*-(*t*-butyl)-2,4-di-*t*-butyl-6-methylaniline (**5**) (9%). Identity of the products was established by their spectral and analytical data.



2 **3**: R=*t*-Bu **4** **5**
6: R=H

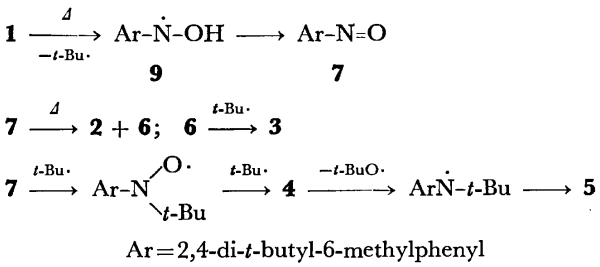
The structure of **4** was also confirmed by the fact that it was one of the products from the following reaction of 1,5-di-*t*-butyl-3-methyl-2-nitrosobenzene (**7**) with *t*-butyl radical generated from photolysis of 2,2′-dimethyl-2,2′-azopropane. Since the reaction of a nitrosobenzene with radicals is known to give a substituted hydroxylamine[2] or a cyclohexadienone oxime derivative[3,4] depending on the relative bulkiness of the reagents, the formation of the hydroxylamine **4** and the cyclohexadienone oximes **8** is reasonable.



7 **8** 29%

Reaction Mechanism. Formation of **2** and **3** suggests that the nitrosobenzene **7** is formed as an intermediate, because thermal disproportionation of **7** has been reported to afford **2** and 5,7-di-*t*-butyl-2,1-benzisoxazole (**6**).[3]

Since the most reasonable mechanism for the formation of **7** is homolytic cleavage of **1** to give **9**, followed by loss of hydrogen atom, a plausible mechanism for the thermolysis of **1** is considered to be as shown in Scheme 1.[5]



Ar=2,4-di-*t*-butyl-6-methylphenyl

Scheme 1.

Attack of the *t*-butyl radical on **6** affords 3-substituted benzisoxazole **3**, because benzisoxazole is known to undergo a substitution reaction with a radical at the position 3.[3]

Radical attack at the nitroso nitrogen atom of **7** and subsequent reaction of the intermediate nitroxide radical with *t*-butyl radical gave **4**.[2-4] Aniline **5** is probably formed from further thermal reactions of **4** (see Scheme).

It is of interest that the thermolysis proceeds *via* homolysis, contrary to the photolysis which proceeds *via* α-heterolytic cleavage.[1]

Experimental

Thermolysis of Oxime 1. Oxime **1** (400 mg, 1.37 mmol)[6] was kept at 160—170 °C for 30 min in a sealed tube. The reaction mixture was subjected to preparative TLC (silica gel, hexane-dichloromethane (5:1)) to give four fractions. The first fraction afforded 21 mg (5%) of **4** as colorless oil, which was identical with the specimen obtained from the reaction of **7** with *t*-butyl radical (*vide infra*). IR (neat) 1200 cm^{-1} (C–O); NMR (CCl_4) δ 1.06 (9H, s), 1.19 (9H, s), 1.27 (9H, s), 1.52 (9H, s), 2.62 (3H, s), and 6.97 (2H, ABq, J=2.6 Hz, $\Delta\delta$=0.45); MS, *m/e* (rel intensity), 305 ($M^+-C_3H_6$, 2), 291 (3), 235 (7), 219 (16), 204 (66), 188 (8), 57 (78), and 41 (100). The second fraction afforded 80 mg (22%) of **3** as colorless crystals, mp 73—74 °C (CH_3OH). Found: C, 79.56; H, 10.10; N, 4.75%. Calcd for $C_{19}H_{29}NO$: C, 79.39; H, 10.10; N,

4.87%. IR (KBr) 1637, 1560, and 1537 cm^{-1};[3] NMR (CCl_4) δ 1.31 (9H, s), 1.50 (9H, s), 1.59 (9H, s), and 7.13 (2H, ABq, J=1.5 Hz, $\Delta\delta$=0.18); UV_{max} (hexane) 260 (ε 2390), 271.5 (3040), 282.5 (3860), and 317 nm (9520);[3] MS, *m/e* (rel intensity), 287 (M^+, 33), 273 (57), 231 (97), 187 (11), 132 (18), and 57 (100). The third fraction afforded 30 mg (9%) of **5** as pale yellow oily material. IR (neat) 3500 cm^{-1}; NMR (CCl_4) δ 1.21 (9H, s), 1.28 (9H, s), 1.44 (9H, s), 2.32 (3H, s), 3.12 (1H, b), and 6.98 (2H, ABq, J=2.6 Hz, $\Delta\delta$=0.23); UV_{max} (hexane) 248 (ε 5620) and 287 nm (sh, 1590); MS, *m/e* (rel intensity), 275 (M^+, 11), 260 (13), 219 (15), 204 (100), 188 (8), and 57 (28). The fourth fraction afforded 122 mg of yellow oil, which was purified with preparative TLC (silica gel, hexane–dichloromethane (2:3)) to give 107 mg (39%) of **2**, which was identified by comparison with an authentic sample (NMR, MS, and TLC).[7]

Reaction of **7** *with* t-*Butyl Radical.* The nitrosobenzene **7** (235 mg, 1.01 mmol) and 2,2′-dimethyl-2,2′-azopropane (1.49 g, 10.5 mmol) were dissolved in benzene (180 ml), and the solution was irradiated for 1 h at 0—5 °C using a 100 W medium pressure mercury arc filtered through aq. $CuSO_4$ solution to cut off the light below about 340 nm and above 550 nm. Under these conditions, only the azopropane absorbed the light. After the solvent was removed under reduced pressure, the residue was subjected to preparative TLC (silica gel, hexane–dichloromethane (5:1)). The first fraction afforded 206 mg of colorless oily material, which was again subjected to preparative TLC (silica gel, hexane) to give three fractions A, B, and C. Fraction A gave 40 mg of **8** ((*Z*)-form) as white crystals. Fraction B gave 78 mg of colorless oily material, which was subjected to preparative TLC (silica gel, hexane) to afford 39 mg of **8** ((*Z*)-form) and 27 mg (8%) of **4** (by NMR and GLC). Thus the total amount of **8** ((*Z*)-form) was 79 mg (23%). Fraction C afforded 57 mg of colorless oil, which was purified by preparative TLC (silica gel) to give 21 mg (6%) of **8** ((*E*)-form). The configuration of **8** was tentatively assigned by analogy with **1**.[6] **8** ((*Z*)-form): mp 89.0—89.7 °C (CH_3OH). Found: C, 79.75; H, 11.72; N, 3.85%. Calcd for $C_{23}H_{41}NO$: C, 79.48; H, 11.89; N, 4.03%. IR (KBr) 978 and 955 cm^{-1} (NO); NMR (CCl_4) δ 0.78 (9H, s), 1.10 (9H, s), 1.31 (18H, s), 1.55 (3H, s), 5.15 (1H, b, J=2.0 Hz), and 6.08 (1H, d, J=2.0 Hz); UV_{max} (hexane) 264 (sh, ε 2650) and 315 (5630) nm. **8** ((*E*)-form): oil; IR (Nujol) 980 and 960 cm^{-1} (NO); NMR (CCl_4) δ 0.92 (9H, s), 1.09 (9H, s), 1.25 (9H, s), 1.33 (12H, s), 5.37 (1H, d, J=1.5 Hz), and 6.03 (1H, d, J=1.5 Hz); UV_{max} (hexane) 254 (ε 2700) and 308 nm (5420). The second fraction afforded 50 mg (21%) of recovered **7**.

The Enantioface-differentiating Methylation of the *N*-Benzylidene-DL-phenylalanine Methyl Ester in the Presence of Chiral Lithium Amides

Tetsushi YAMASHITA,* Hitoshi MITSUI, Hiroyuki WATANABE, and Nobuo NAKAMURA

Department of Chemistry, Faculty of Science, Osaka City University, Sumiyoshi-ku, Sugimoto-cho, Osaka 558

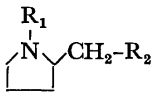
(Received August 3, 1981)

Synopsis. The asymmetric methylation of the *N*-benzylidene-DL-phenylalanine methyl ester was carried out in the presence of lithium salts of secondary amines derived from (*S*)-proline. The lithium amides of poly(imino-1-isobutylethylene) and its corresponding low-molecular-weight model compound, derived from (*S*)-leucine, were similarly used in order to examine the polymer effects with regard to the stereoselectivity.

Several workers[1-3] have recently used Schiff-base derivatives of α-amino acids in order to prepare the higher amino acids by alkylation routes. Yamada *et al.*[2] have furthermore carried out the diastereoface-differentiating alkylation of Schiff bases derived from chiral ketones and achiral α-amino acid esters in the presence of lithium diisopropylamide, thus obtaining optically active α-amino acids. Duhamel *et al.*[4] have also reported that optically active α-amino acid esters were obtained from the corresponding Schiff bases lithiated with chiral lithium amides, followed by protonation with tartaric acid derivatives.

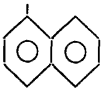
This paper will describe the enantioface-differentiating methylation of Schiff bases lithiated by the use of chiral lithium salts of secondary amines derived from (*S*)-proline and (*S*)-leucine. The Schiff base (*N*-benzylidene-DL-phenylalanine methyl ester) (**A**) was prepared according to the method of Stork.[1]

The chiral lithium amides used in this experiment are as follows:

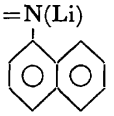


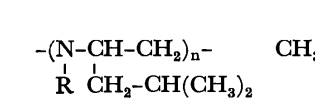
1a R_1=H, R_2=H
1b R_1=Li, R_2=H
2a R_1=H, R_2=N
2c R_1=Li, R_2=N

3a R_1=CH_3, R_2=NHPh
3b R_1=CH_3, R_2=N(Li)Ph
4a R_1=CH_3, R_2=NH

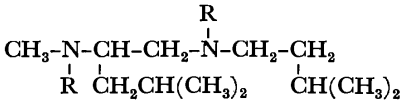


4b R_1=CH_3, R_2=N(Li)



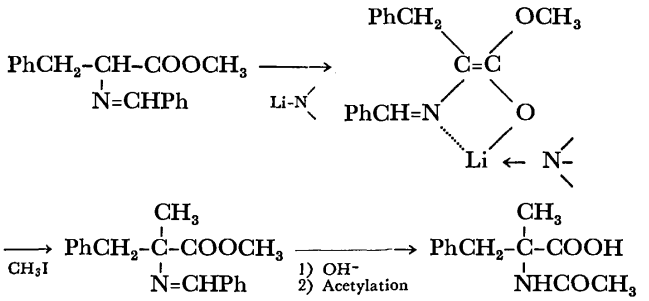


5a R=H **5b** R=Li



6a R=H **6b** R=Li

The methylation of **A** with methyl iodide in the presence of chiral lithium amides at 0 and −78 °C, followed by hydrolysis and successive acetylation, yielded *N*-acetyl-α-methyl-phenylalanine,[2c] whose optical yields (%) and configurations are shown in Table 1.



The product for **3b** showed the highest optical yield (31%) at −78 °C. All the amides except **2c** gave the product of the *S*-configuration. In order to examine the polymer effects with respect to the stereoselectivity, polymeric amide (**5b**) and its corresponding low-molecular-weight model compound (**6b**) were similarly used. At −78 °C, the optical yield of the product for **5b** was, albeit low, about six times as high as that for **6b**.

TABLE 1. THE OPTICAL YIELDS AND CONFIGURATIONS OF *N*-ACETYL-α-METHYLPHENYLALANINE OBTAINED WITH CHIRAL AMIDES

Chiral agents	0 °C	−78 °C
1b	1.0(*S*)	1.8(*S*)
2c	1.0(*R*)	2.1(*R*)
3b	6.2(*S*)	31.0(*S*)
4b	1.3(*S*)	1.9(*S*)
5b	6.0(*S*)	13.5(*S*)
6b	1.5(*S*)	2.2(*S*)

Experimental

The Preparation of Chiral Secondary Amines. (*S*)-2-Methylpyrrolidine (**1a**) was prepared by the method of Kostyanovsky.[5] (*S*)-1-(2-Pyrrolidinylmethyl)pyrrolidine (**2a**) (bp 75—80 °C at 4 mmHg,† $[\alpha]_D^{18}$ +9.6° in C_2H_5OH) was obtained by the reduction (sodium in liquid ammonia) of (*S*)-1-[1-tosyl(2-pyrrolidinyl)methyl]pyrrolidine, which had itself been derived from 1-tosyl(2-pyrrolidinyl)methyl iodide (**2b**) and pyrrolidine; **2b** was made by the reaction of (*N,O*-ditosyl) pyrrolidinylmethanol[5] with sodium iodide. (*S*)-1-Methyl-2-(anilinomethyl)pyrrolidine[6] (**3a**) (bp 123—124 °C at 4 mmHg, $[\alpha]_D^{15}$ −59.3° in C_2H_5OH) was obtained by the reduction (lithium aluminium hydride) of *N*(*N*-benzyloxycarbonylprolyl)aniline, which had itself been prepared from *N*-benzyloxycarbonylproline and aniline by the use of 1-ethoxycarbonyl-2-ethoxy-1,2-dihydroquinoline; (*S*)-1-methyl-2-(1-naphthylaminomethyl)pyrrolidine (**4a**) (bp 180—190 °C at 4 mmHg, $[\alpha]_D^{20}$ −5.6° in $CHCl_3$) was obtained

† 1 mmHg≈133.322 Pa.

using *N*-benzyloxycarbonylproline and 1-naphthylamine as starting materials in a manner similar to that described in **3a**. Poly(imino-1-isobutylethylene) (**5a**) and N^1-isopentyl-N^2-methyl-4-methyl-1,2-pentanediamine (**6a**) were derived from (*S*)-leucine according to the procedure reported earlier.[7,8]

The Asymmetric Methylation of ***A*** *with Chiral Lithium Amides.* The methylation with **3b** will be given as an example. To a solution of **3a** (2 mmol) in dry THF (5 ml), we added butyllithium (2 mmol) in hexane at −78 °C under argon. A solution of **A** (2 mmol) in dry THF (1 ml) was then added to the reaction mixture. The color of the solution gradually changed from red-orange to yellow, showing the formation of a lithium ester enolate.[2,3] After 15 min, methyl iodide (2 mmol) was added to the solution at −78 °C, and the mixture was stirred for 1 h. After the subsequent removal of the solvent, ether and water were added to the residue. The organic layer separated out was washed with water, dried, and evaporated to dryness. The methylated Schiff base thus obtained was subjected to hydrolysis without purification. The hydrolysis was carried out in 15 ml of 1 mol dm^{-3} sodium hydroxide solution under reflux for 2 h. The reaction mixture was washed thoroughly with ether and neutralized with 6 mol dm^{-3} hydrochloric acid. On cooling, α-methylphenylalanine precipitated as a white powder; it was then filtered off. Yield, 50%. In order to determine the optical yield and configuration, the amino acid was acetylated with acetic anhydride in pyridine. The rotation of the acetamide was $[\alpha]_D^{15}$ −25° (*c* 2, CH_3OH) (Lit,[2c] optically pure (*R*)-*N*-acetyl-α-methylphenylalanine, $[\alpha]_D^{19}$ +80.3° in CH_3OH). The other lithium amides were similarly used for the methylation of **A**. The amount of polymeric agent (**5b**) was calculated on the basis of that of the monomer used in the polymerization (*e.g.*, 10 mg of **5a** corresponds to 10 mg of (*S*)-2-isobutylaziridine).

The methylation of the *N*-benzylideneglycine ethyl ester (**B**) was also attempted with the chiral amides used for the methylation of **A**. However, all the reagents except (**2c**) yielded a mixture which consisted of mono- and dimethylated **B** and unreacted **B**. The monomethylated **B** obtained with **2c** was hydrolyzed in 1 mol dm^{-3} hydrochloric acid to give (*S*)-alanine in a 13% (10%) optical yield at −78 °C (0 °C).

In this experiment, a JASCO DIP-4 automatic polarimeter was used for the measurement of the optical rotation.

The Influence of Additives on the Decomposition of an Alkaline Manganate(VII) Solution

Eiichi NARITA,* Tatsuhiko HASHIMOTO, Sakae YOSHIDA, and Taijiro OKABE
Department of Applied Chemistry, Faculty of Engineering, Tohoku University, Aramaki, Sendai 980
(Received July 31, 1981)

Synopsis. The decomposition of manganate(VII) in an alkaline solution was significantly enhanced by the addition of hydrous manganese(IV) oxide or metal ions, such as Ni(II) and Co(II). On the other hand, the inhibitive effect of the tellurate(VI) ion on the decomposition was found even in the presence of the additives described above.

The decomposition of manganate(VII) in alkaline solutions, which yields manganate(VI) and oxygen, has been extensively studied and has been shown to be complex. It is well-known that the rate of the decomposition increases with increases in the temperature and alkali concentration.[1,2] In addition, some workers have shown that the decomposition is a function of the surface area of glass[1,3] and the presence of metal oxides, such as MnO_2, SnO_2, and PbO_2.[1,4] Till recently, it has been thought that the decomposition of manganate(VII) in alkaline solutions could be explained by the oxidation of the OH^- ion by manganate(VII) to $OH\cdot$ radicals, which afterwards react to produce oxygen.[1,2,5] However, Vepřek-Šiška and Ettel[6] have recently shown that the kinetic analysis of the earlier workers is invalid because of the presence of traces of Ni(II) and Co(II) ions in the solution, those ions actively assist the decomposition.

Recently some new industrial techniques utilizing a high oxidation potential of manganates have been developed in the field of pollution control. The present authors have also developed the removal of nitrogen oxides from waste gas by using alkaline manganates(VI and VII) solutions.[7] In the course of this development, further information about the decomposition of alkaline manganate(VII) solution was necessary.

This study will deal with the stimulative effect of various kinds of hydrous manganese(IV) oxides (abbreviated as hydrous MnO_2) and of nickel and cobalt ions, and the inhibitive effect by the tellurate(VI) ion on the decomposition of manganate(VII) in an alkaline solution.

Experimental

A 0.5-dm^3 four-necked flask equipped with a reflux condenser, a thermometer, and a stirrer was used as the reaction vessel. Potassium hydroxide was dissolved in distilled water. Then, the concentrated solution of potassium manganate(VII) was added to the alkali solution and the total volume of the reaction solution was immediately adjusted to 200 cm^3 with distilled water. The additives, such as hydrous MnO_2 and metal sulfates, were added, together with distilled water, at the end. At all times the solution was vigorously stirred. The basic conditions were: $KMnO_4$; 0.05 mol dm^{-3}, KOH; 6 mol dm^{-3}, temperature; 80 °C. All the reagents used were commercial, extra pure reagents, and they were used without further purification. The decomposition of manganate(VII) was determined by pipetting 5 cm^3 of the reaction solution from the flask at regular time intervals, filtering out the insoluble matter, and chemically analyzing the manganates(VI and VII) in the filtrate.[8] The analysis of the chemical composition of the insoluble matter was done in the manner previously reported.[9] The amount of the tellurate(VI) ion adsorbed by the hydrous MnO_2 was calculated from the tellurate(VI) ion concentrations in the solution before and after the adsorption was affected. The tellurate(VI) ion was analyzed according to the method of Kishioka *et al.*[10]

Results and Discussion

Stimulative Effect of Hydrous MnO_2 and Ni(II), Co(II) Ions. The decomposition of manganate(VII) in alkaline solutions is well-known to be accelerated by the presence of manganese(IV) oxide, but there remains a lack of understanding of the relationship between this effect and the chemical composition of the manganese(IV) oxide. In this study, several kinds of hydrous MnO_2 (shown in Table 1) were prepared, and their stimulative effects on the decomposition (Eq. 1) were investigated by the addition of 0.05—

$$4MnO_4^- + 4OH^- = 4MnO_4^{2-} + O_2 + H_2O \quad (1)$$

0.06 g (5×10^{-4} mol Mn) of the hydrous MnO_2 to the alkaline manganate(VII) solution. The hydrous MnO_2 substances are amorphous, and their surface areas range from 140 to 160 $m^2\,g^{-1}$. The results given in Fig. 1 show that the stimulative effect of the hydrous MnO_2 increased with an increase in the content of MnO_2. That is, the hydrous MnO_2 with many manganese atoms on its surface became effective in stimulative action. The significant stimulative effect of the hydrous MnO_2 could be similarly explained by the electron-transfer mechanism proposed by Vepřek-Šiška and Ettel,[6] which was previously used to explain the stimulative effect of transition metal ions.

Figure 2 shows the stimulative effect of Ni(II) and Co(II) ions in concentrations of 2.5×10^{-3} mol dm^{-3}

on the decomposition. It was found that the decomposition was markedly accelarated by the addition of these ions; this agreed well with the result obtained by Vepřek-Šiška and Ettel.[6] Therefore, the resulting precipitates obtained after the decomposition was analyzed here. The results indicate these precipitates were peroxides with a higher oxidation state than trivalent, having potassium and chemically bonded water (*e.g.*, $0.17K_2O \cdot NiO_{1.98} \cdot 2.30H_2O$; $0.04K_2O \cdot CoO_{1.71} \cdot 1.45H_2O$).

Inhibitive Effect of the Tellurate(VI) Ion. According to Issa *et al.*,[11] the inhibitive effect of the tellurate(VI) ion could be explained by the mechanism that the manganese(IV) ion formed by the decomposition of manganate(VII) forms a complex with the tellurate(VI) ion prior to precipitation as MnO_2 and before the stimulation action becomes effective. On the other hand, another mechanism, in which the inhibitive effect is caused by the adsorption of the tellurate(VI) ion on the surface of the metal oxide originating from the impurities in the reagent and on the reaction vessel wall, was also observed in this preliminary experiment.

Figure 1 shows the inhibitive effect of the tellurate(VI) ion on the decomposition in the presence of the hydrous MnO_2 (1 and 3). It was found that the tellurate(VI) ion exhibited a remarkable inhibitive effect on the hydrous MnO_2(1), but not on the hydrous MnO_2(3). The adsorption data of the tellurate(VI) ion on the hydrous MnO_2 obtained under the same conditions as that of the decomposition except that no manganate(VII) ion was present were as follows: hydrous MnO_2(1)—3.85×10^{-4}, (3)—1.96×10^{-4} mol Te(VI) adsorbed/g. The results show that the hydrous MnO_2(1), with a large amount of potassium, adsorbed more of the tellurate(VI) ion than did the hydrous MnO_2(3).[12] This tendency was correlated to the results of the decomposition experiments. These results indicate that the tellurate(VI) ion becomes effectively inhibiting by its adsorption on the surface of the hydrous MnO_2.

Figure 2 shows the similar inhibitive effect of the tellurate(VI) ion on the decomposition in the presence of Ni(II) and Co(II) ions. On changing the addition order of the reagents, namely, by adding the manganate(VII) after a sufficient contact of Ni(II) and Co(II) hydroxides with the tellurate(VI) solution, the inhibitive effect remarkably increased. The inhibitive effect of the tellurate(VI) ion in the presence of the cobalt precipitate was smaller than that in the presence of the nickel precipitate. It was thought to depend upon the small content of potassium in the cobalt precipitate, which caused the less adsorption of the tellurate(VI) ion on it.

Hydrothermally Activated Silica-Alumina. II. Variations in Catalytic Activities for 1-Butene Isomerization and Polymerization, and in the Amount of Acid with Pretreatment Temperature

Shozo FURUYAMA,* Osamu MURASHITA,** Kotomasa ICHISAKA,*** and Tetsuo MORIMOTO

Department of Chemistry, Faculty of Science, Okayama University, Tsushima, Okayama 700

(Received February 27, 1981)

The technique of hydrothermal activation was used to prepare well-mixed and fully hydroxylated silica-alumina catalysts, SA-*n*MHT ($n=13$, 25, or 50 denotes the alumina content (wt%)). Their catalytic activities and *cis*/*trans* selectivities for the 1-butene isomerization (k_i and c/t), the catalytic activities for the 1-butne polymerization (k_p), the amount of acid (A), and the number of the surface hydroxyl group (N_{OH}) were measured as a function of the degassing temperature (T_d) over the 25—700 °C range; the following results were obtained: (1) k_i changed prominently with T_d and reached its maximum around 300 °C. (2) c/t was about 0.9 below 500 °C, but exceeded 1.2 at 700 °C. (3) k_p increased till 300 °C and became constant above that temperature. (4) A was almost independent of T_d above 100 °C. (5) N_{OH} decreased from 11—15 (at 100 °C) to 0.5 group nm^{-2} (at 700 °C). An analysis of these data led to the conclusion that the SA-*n*MHT sample underwent the surface structural changes three times during the thermal dehydroxylation between 25 and 700 °C. The sequence of the structural change was sketched, and the different dependencies upon T_d of k_i, k_p, and A were explained.

Silica–alumina is a strong solid acid and is widely used as a catalyst for various reactions. From the similarities to zeolite in composition, acidic nature, and other aspects, it has been established that the acid center (*i.e.*, the catalytic active site) of silica–alumina originates from the isomorphic replacement of a silicon atom by an aluminium atom in the tetrahedral silicate network.[1-3] To obtain a catalyst with a high acidity and catalytic activity, one must devise a method to complete the isomorphic substitution.

In the previous studies, we developed the technique of hydrothermal activation to prepare a well-mixed and fully hydroxylated silica–alumina catalyst.[4] The relationships between the catalytic activity for the 1-butene isomerization, the amount of acid, and the amount and distribution of the aluminium atom were then investigated on the catalyst.[4]

In the present study, the dependencies upon the degassing temperature of the catalytic activities for the 1-butene isomerization and polymerization, the amount of acid, and the number of the surface hydroxyl group were measured on a hydrothermally activated silica–alumina catalyst. The sequence of the surface structural changes with the dehydroxylation is depicted to explain those dependencies.

Experimental

Materials. Three kinds of silica–alumina SA-*n*M ($n=$ 13, 25, or 50 denotes the alumina content (wt%)) samples were synthesized from purified tetraethyl silicate and aluminium isoproxide as has been described elsewhere.[4] Three kinds of hydrothermally activated silica–alumina SA-*n*MHT samples were prepared by heating the corresponding SA-*n*Ms in hot water in Pyrex ampoules at 110 °C for 14 d.[4] A commercial catalyst, SA-C (FCC high alumina (25 wt%) supplied by the Shokubai Kasei Co., Ltd.) was also used for comparison. The BET (N_2) surface areas of those samples were almost independent of the degassing temperature, T_d, till 700 °C. They were 340, 280, and 310 m^2 g^{-1} for the 13, 25, and 50 MHT samples; 550, 500, and 430 m^2 g^{-1} for the 13, 25, and 50 M samples, and 280 m^2 g^{-1} for the SA-C sample, respectively. Dicinnamylideneacetone was used without further purification. The Hammet (H_0) value of the acid center determined by this indicator is equal to or lower than -3.0; *i.e.* the acid strength of the acid center is equivalent to, or higher than, that of 48 wt% of sulfuric acid.[5]

Apparatus and Procedure. The apparatus and procedures used to measure the catalytic activity for the isomerization and the amount of acid were conventional ones which have been described elsewhere.[4,6,7] To measure the catalytic activity for the polymerization, the catalyst (0.15 g) was placed in an adsorption cell (240 cm^3) and degassed at 25—700 °C for 4 h. Butene gas (16×10^3 Pa$=$120 Torr) was then introduced into the cell maintained at 0 °C, and the drop in pressure of the reacting gas was followed to determine the amount of the butene adsorbed and polymerized. After a certain period, the reacting gas was withdrawn from the adsorption cell into a trap (kept at 77 K). The amount of butene gas which could not be recovered from the catalyst surface was defined as the amount of the butene polymer. The number of the surface hydroxyl group was determined by the successive-ignition loss method.[8]

Results

Isomerization. The apparent rate constant for the conversion of 1-butene to 2-butenes, k_i/min^{-1}(g-catalyst)$^{-1}$, was determined at 0 °C by applying the usual equation for the first-order reaction.[4] The k_i *vs.* T_d curve, plotted in Fig. 1, shows that the maximum activity k_i(max) was obtained around 300 °C in the cases of the 13MHT, 25MHT, and C samples, while it appeared around 320—350 °C in the cases of 50MHT and three kinds of M samples. The appearance of the maximum activity around 300—350 °C accords well with the results obtained by other laboratories.[9-11] The value of k_i(max) of the MHT sample was about 3—4 times as large as that of the corresponding M samples. The position and magnitude of the k_i(max) of the SA-C were almost the same as those of the 25MHT, but its k_i *vs.* T_d curve obviously differed from that of the

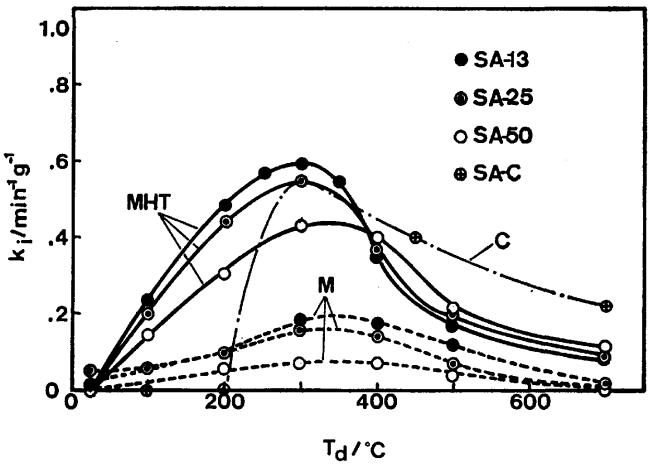

Fig. 1. Variation of apparent rate constant for 1-butene isomerization (k_i) at 0 °C with degassing temperature (T_d).

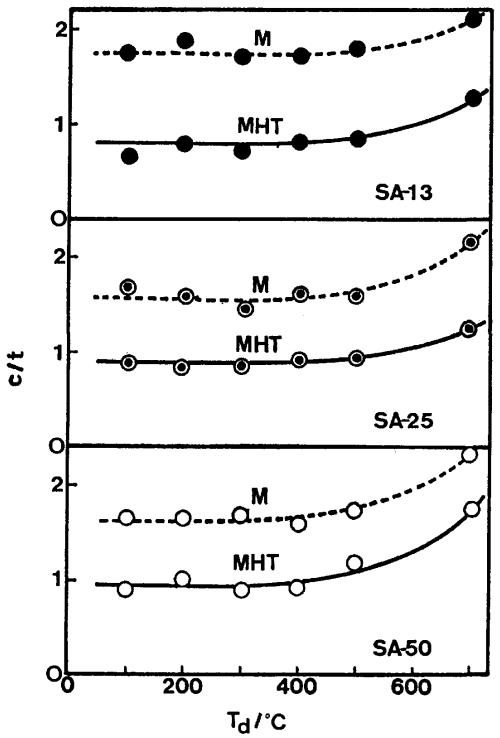

Fig. 2. Variation of c/t ratio for 1-butene isomerization at 0 °C with degassing temperature (T_d).

25MHT.

The value of the selectivity to form *cis*-2-butene against *trans*-2-butene, c/t, was measured at a 10% conversion point; it is plotted against T_d in Fig. 2. The values of the MHT samples fell in a range of 0.8—1.0, while those of the M samples ranged from 1.6 to 1.8 when degassed below 500 °C. The c/t ratio started to increase when degassed at 500 °C and reached about 1.5 and 2.0 at 700 °C in the cases of the MHT and M samples respectively. The increase in the c/t with the increase in T_d above 500 °C was also observed by Gerberich and Hall.[10]

The appearance of the k_i(max) around 300 °C and the increase in the c/t ratio from 500 °C suggest that the

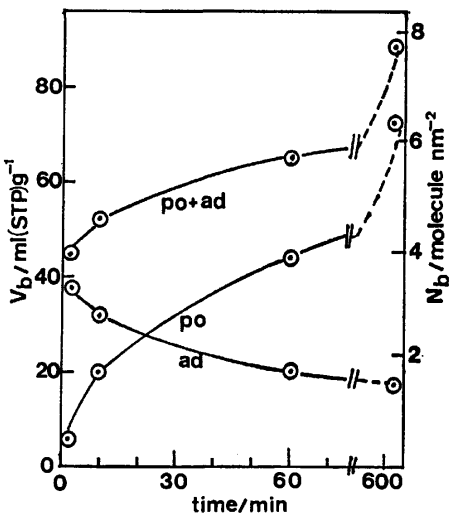

Fig. 3. Variation of amount of butene gas (V_b or N_b) adsorbed (ad) and/or polymerized (po) at 0 °C with contact time. Sample: SA-C degassed at 300 °C.

structure of the catalytic active site of the silica–alumina changed around these temperatures. This will be discussed later.

The dependency upon T_d of the c/t ratio of the SA-C was almost the same as that of the SA-25MHT.

Polymerization. The amounts of butene gas adsorbed and polymerized were measured at 0 °C as a function of the contact period. An example (measured on the SA-C sample degassed at 300 °C) is shown in Fig. 3. It can be seen in Fig. 3 that the adsorption was completed almost instantaneously, while the polymerization proceeded gradually, much slower than the isomeri-

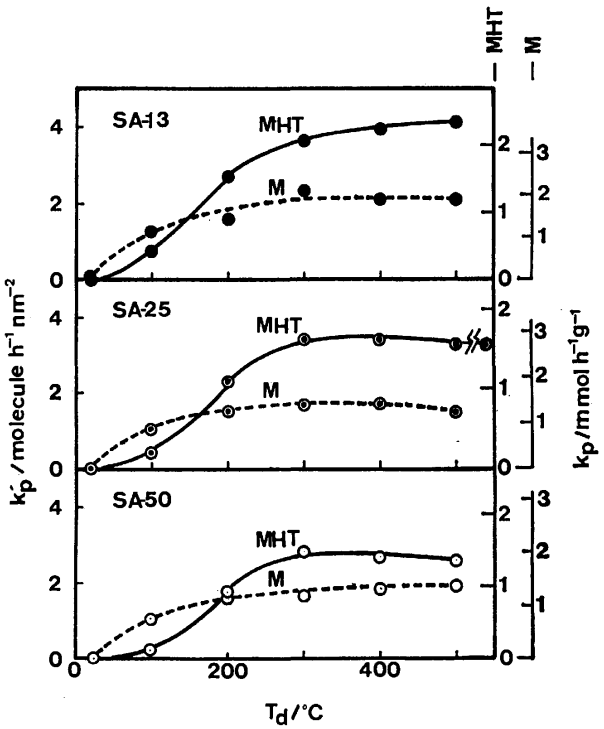

Fig. 4. Variation of amount of butene gas polymerized at 0 °C for 1 h (k_p or k_p') with degassing temperature (T_d).

zation. The amount of gas instantaneously adsorbed was almost 4 molecule nm^{-2}, irrespective of the sample and the degassing temperature. It was concluded that the rapid adsorption was probably a kind of physisorption and had no relation with the isomerization.

The amount of the butene polymer was quite small at first, but reached 4 and 7 molecule nm^{-2} at 1 and 10 h after the reaction started. The amount of butene polymerized in the first 1 h was designated as k_p/mmol h^{-1} g^{-1} or k_p'/molecule h^{-1} nm^{-2}; it is plotted against T_d in Fig. 4. The k_p value increased with the increase in T_d till 300 °C in the cases of the MHT samples and till 200 °C in the cases of M samples, and became almost constant above these temperatures. The k_p value of the MHT sample was smaller than that of the corresponding M samples at lower temperatures, but their values became almost comparable with each other at higher temperatures. These trends clearly differed from the trends observed in the k_i value.

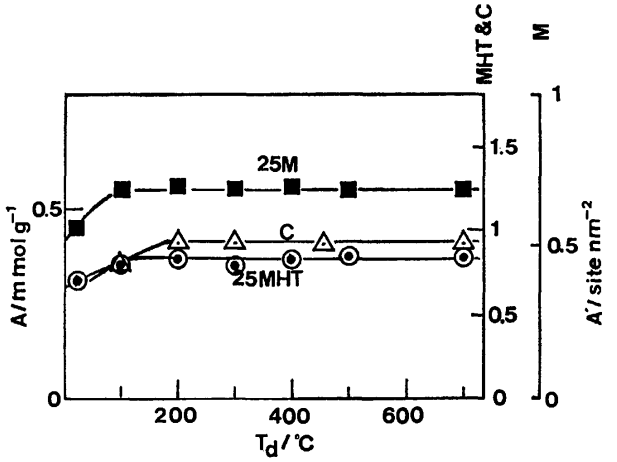

Fig. 5. Variation of acid amount (A or A') with degassing temperature (T_d).

Amount of Acid. The amount of acid, A/mmol^{-1} g^{-1} (or the number of the acid center designated as A'/site nm^{-2}), was measured as a function of T_d, as is shown in Fig. 5. Figure 5 shows that the A value became almost independent of T_d when degassed above 100 °C. Even the value obtained at 25 °C did not differ much from the saturation value. The shape of A *vs.* T_d curve clearly differed not only from the shape of the k_i *vs.* T_d curve, but also from the shape of the k_i *vs.* T_d curve.

The preceding study revealed that the number of the acid center corresponded to the number of the Al atom exposed on the catalyst surface.[4] The value shown in Fig. 5 indicates that almost 0.7—1 molecule nm^{-2} of the Al atom is exposed on the surface of silica-alumina containing 25 wt% of alumina.

Surface Hydroxyl Group. The number of the surface hydroxyl group, N_{OH}, was measured as a function of T_d; it is plotted in Fig. 6. Figure 6 shows that the N_{OH} values of the MHT and C samples were larger than 11 group nm^{-2}, while those of the M samples ranged from 4 to 6 group nm^{-2}, before the heat treatment. It is clear that the surfaces of the MHT and C samples were fully hydroxylated, while those of the M

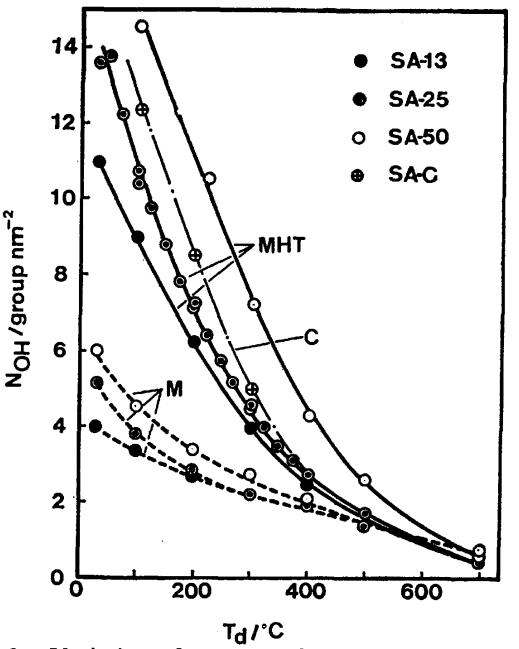

Fig. 6. Variation of number of hydroxyl group (N_{OH}) with degassing temperature (T_d).

samples were only partially hydroxylated. The N_{OH} value decreased with the increase in T_d and became 1/2—1/3, as small as the initial value, when degassed at 300 °C and nearly 1 group nm^{-2} at 600 °C. These values are very suggestive and will later be used to elucidate the sequence of the surface structural change.

Discussion

It was revealed by the present study that the k_i (including c/t ratio), k_i, and A values of the hydrothermally activated silica-alumina are different functions of T_d (and therefore, of N_{OH}), as is shown in Fig. 7. The k_i value varies with T_d very prominently, while the k_p value changes less prominently. The A is almost independent of T_d. These different dependencies upon T_d are very interesting; the causes must be elucidated in the present discussion. A complete set of data for k_i, c/t, k_p, A, and N_{OH} were obtained for the SA-25MHT

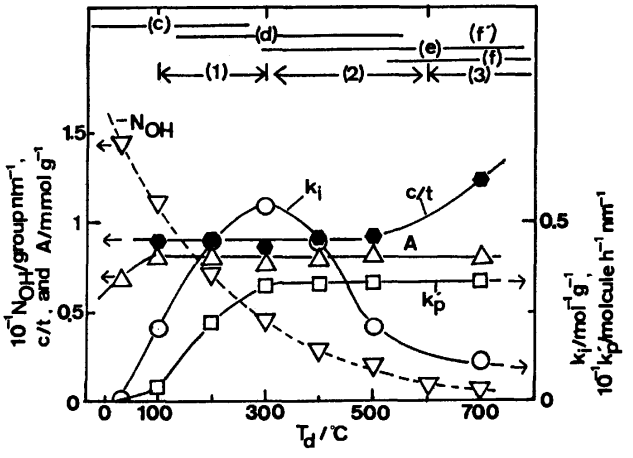

Fig. 7. Dependencies upon T_d of k_i, c/t, k_p', A, and N_{OH} of SA-25MHT sample.

sample. They are used for the explanation. Let us start with the simplest function, A.

The k_i *vs.* T_d curve, when combined with the c/t *vs.* T_d curve, suggests that the surface structure of the SA-25MHT changes three times during the dehydroxylation between 100 and 700 °C. These structural changes are characterized, respectively, by: (1) an increasing k_i value with a constant c/t ratio ≈ 1 between 100 and 300 °C, (2) a decreasing k_i value with a constant c/t ratio ≈ 1 between 300 and 600 °C, and (3) a decreasing k_i value with an increasing c/t ratio >1 above 600 °C. The N_{OH} values of SA-25MHT degassed at 100, 300, 600, and 700 °C are 10.5, 4.5, 1, and 0.5 group nm^{-2} respectively. Therefore, we designate the surface degassed at those temperatures as a highly hydroxylated surface (c), a partially dehydroxylated surface (d), a highly dehydroxylated surface (e), and an extremely dehydroxylated surface (f'), respectively (see Fig. 7).

The accumulated data show that the value of the monolayer capacity of the surface hydroxyl group of various metal oxides falls around 4—8 group nm^{-2}.[12] This implies that the (c) contains the hydronium cation, H_3O^+, as the main acid source. On the other hand, since the A value of the SA-25MHT is 0.8 site nm^{-2}, about 40% of the acid center on the (f') must be of the Lewis-type (*i.e.*, an acid center having no proton, but a vacant orbital). The acid centers on the (d) and (e), therefore, are of the Bronsted-type (*i.e.*, an acid center having either a free proton or an acidic silanol (>SiOH Al<)).

The finding that the A value is almost independent of T_d above 100 °C, simply indicates that the acid strength of all the four structures including the (c) is equivalent to, or higher than, that of 48 wt% sulfuric acid. This conclusion is not surprising, because there must be no free proton, but a hydrated proton, in 48 wt% sulfuric acid.

We will explain the k_p *vs.* T_d curve next. Figure 7 shows that the temperature range of the increasing k_p accords to the temperature range of the surface structural change (c)→(d). This implies that only the (c) is inactive for the polymerization. This can be explained as follows. The butene polymerization may proceed through the cationic polymerization mechanism. Therefore, it is the acid strength which determines the magnitude of the k_p value. Since the acid source of the (c) is the hydronium cation, its acid strength must be much lower than those of (d), (e), and (f') (although they are all equivalent to, or higher than, that of 48 wt% sulfuric acid). This results in the increasing k_p value between 100 and 300 °C. On the other hand, the (d), (e), and (f') possess either a free proton, an acidic silanol, or a vacant orbital; their acid strengths are thus all strong enough to catalyze the polymerization equally. Therefore, the k_p value becomes almost constant above 300 °C. To elucidate how much the acid strength of the (c) differs from those of other structures, anthraquinone ($pK_a = -8.0$) and 4-nitro-toluene ($pK_a = -10.5$) were used.[13] No clear conclusion was obtained, however.

Figure 7 also shows that the k_i values of the (c), (e), and (f') are all much smaller than that of the (d). The reason for the smaller k_i values of the (c) and (f') compared to that of the (d) can easily be explained.

A number of mechanisms have hitherto been proposed for the 1-butene isomerization catalyzed by silica–alumina. Now it is widely accepted that the isomerization proceeds through the intermolecular hydrogen-exchange (IHE) mechanism (*s*-butyl cation intermediate mechanism) on a silica–alumina catalyst.[9-11,14-16] However, a part of the isomerization proceeds through the intramolecular mechanism on the extremely dehydroxylated silica–alumina.[10] According to the IHE mechanism, the transfer of a proton from the acid center to the α-carbon of 1-butene to form the *s*-butyl cation (*i.e.*, proton donation) occurs first. Then a different proton is transferred from the β-carbon of the *s*-butyl cation to the acid center to produce 2-butene (*i.e.*, proton acception). The reason why the c/t ratio becomes nearly unity with the IHE mechanism, but exceeds unity with the intramolecular mechanism, has already been elucidated.[10] From the knowledge about the two mechanisms, we can explain the variations in the k_i and c/t ratio with T_d between 100 and 300 °C, and above 600 °C, as follows.

The acid source of the (c) is the hydronium cation, while that of the (d) is either the free proton or acidic silanol. The acid strength, *i.e.*, the ability of proton donation, of the (d) is much larger than that of the (c). Therefore, the intermolecular hydrogen-exchange reaction proceeds much faster on the (d) than on the (c), resulting in an increase in the k_i value with the constant $c/t \approx 1$ between 100 and 300 °C.

Since the (f') contains a Lewis-type acid center (about 40%), a part of the isomerization proceeds through the intramolecular mechanism. The decrease in the k_i value with the increase in the c/t ratio above 600 °C originates from the slow intramolecular hydrogen shift.

The reason for the decrease in the k_i value with the constant c/t ratio ≈ 1 between 300 and 600 °C is not easily explanable, because both (d) and (e) possess the same number of the Brønsted-type acid centers. To elucidate the reason, we will examine the structural difference between the (d) and (e) in more detail.

Silica glass displays a diffused X-ray diffraction pattern which provides bond parameters close to those obtained from cristobalite.[17] Silica gel and silica–alumina also show a very diffused diffraction peak around $2\theta(\text{Cu } K\alpha) = 22°$, where β-cristobalite shows the most intense peak.[18,19] From these facts, it is widely accepted that the structures of amorphous silica and silica–alumina may be similar to that of β-cristobalite.[3] A crystallographic examination shows that the (100), (110), and (111) planes of β-cristobalite contain about 4, 7, and 4.7 Si atoms per one nm^2 respectively.[20] It is a well-established theory that the plane containing the least number of atoms develops most (Bravais's law[21]). Therefore, it may be reasonable to approximate the surface of SA-25MHT to the (100) plane of β-cristobalite, which is shown in Fig. 8. As can be seen in Fig. 8, the Si (and Al) atom is disposed in an array of "OSiO··· OSiO" linear lines, the spacing of which is about 0.5 nm. Since this spacing is wide enough to prevent interaction between the different lines, we can depict the two-dimensional surface one-dimensionally as in Fig. 9.

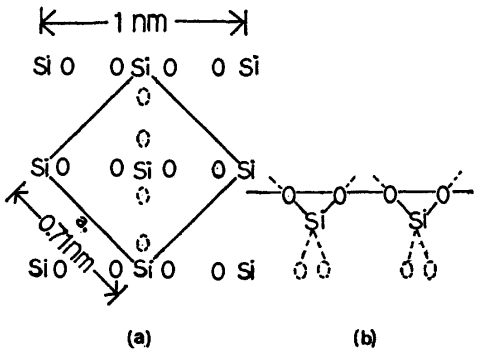

Fig. 8. A schematic representation of surface structure of silica–alumina assumed as the same as surface structure of (100) plane of β-cristobalite. (a): Perpendicular view, (b): horizontal view.

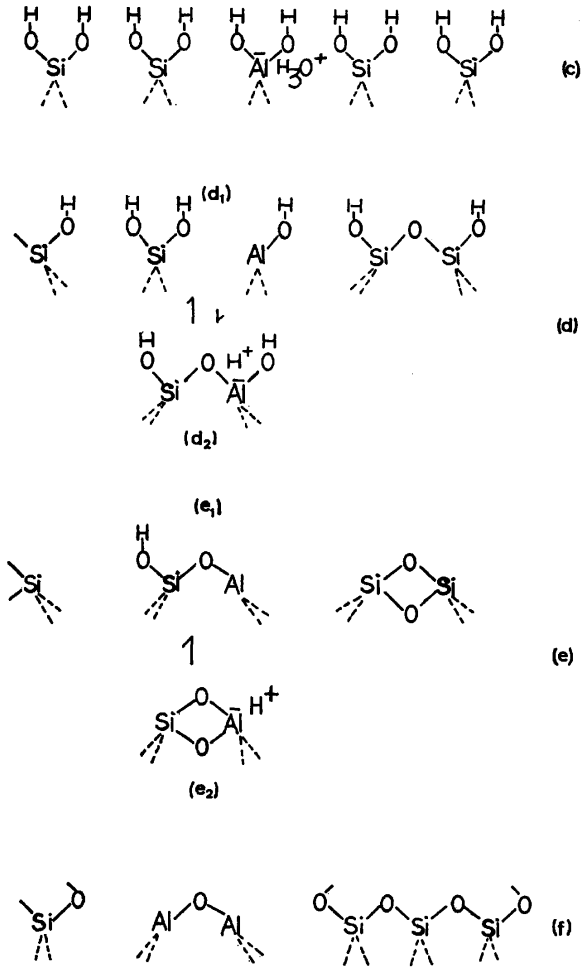

Fig. 9. One-dimensional schematic display of silica–alumina surface at different hydroxylation level. (c): Full hydroxylation (around 100 °C), (d): partial dehydroxylation (around 300 °C), (e): high dehydroxylation (around 600 °C), and (f): complete dehydroxylation (above 600 °C).

Since the acid amount of SA-25MHT is about 0.8 site nm^{-2}, we will set the Al/Si ratio as 1/4 in Fig. 9.

Figure 9 shows that the surfaces of full hydroxylation (c), partially dehydroxylation (d), and high dehydroxylation (e) contain 10.4, 4.8, and 0.8 OH group per one nm^2 respectively. These values coincide with the values of the N_{OH}/group nm^{-2} of 10.5, 4.5, and 1 obtained at 100, 300, and 600 °C. It can thus be concluded that the SA-25MHT takes surface structures like (c), (d), and (e) when degassed at 100, 300, and 600 °C respectively. To eliminate the last proton from the surface, two Al atoms must be paired. To bring about this situation, the surface network must be rearranged greatly. Only a temperature beyond 600 °C can give rise to this rearrangement, resulting in the (f). It must be noticed that the (c), (d), and (e) designations above corespond exactly to the earlier designations, while the (f) does not correspond to the (f'). The (f') consists of 40% of the (f) and 60% of the (e).

When we examine Fig. 9 carefully, we notice that the two M (M=Si or Al) atoms must approach each other to give rise to the structural change (c)→(d). This, in turn, limits the occurrence of the successive dehydroxylation to only the dehydroxylation between the paired M atoms, resulting in the structure of (e) being more strained than that of (d). In general, the surface strain increases with the increase in T_d.[22] This increasing strain may be responsible for the lower k_i value of the structure (e) than that of (d). The following is one possible explanation.

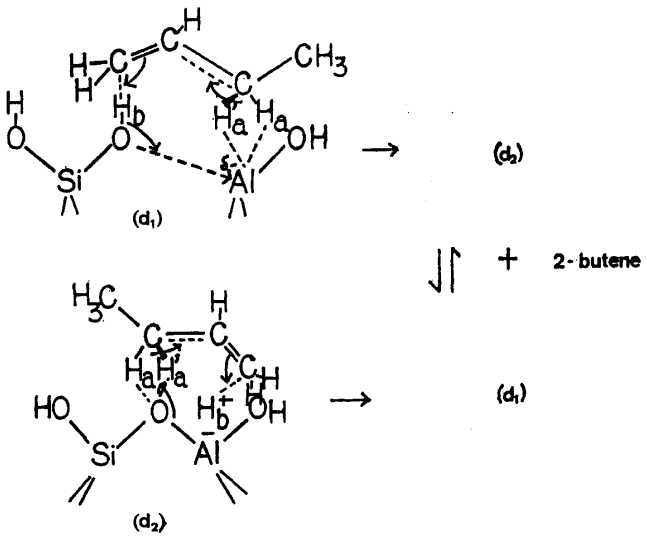

Fig. 10. A schematic representation of intermolecular hydrogen exchange between acid center and butene on the (d_1) and (d_2).

When we compare the structures of (e_1) and (e_2) (the two modifications of the (e)) with each other, we notice that the (e_2) is much more strained and, therefore, thermodynamically much more unstable than the (e_1). Therefore, the mutual transformation between (e_1) and (e_2) is extremely difficult, while the mutual transformation (d_1)⇄(d_2) is easy. As can be seen in Fig. 10, the intermolecular hydrogen exchange can proceed very smoothly (but not necessarily concertedly) on the (d) by using the (d_1)⇄(d_2) transformation. On the other hand, because of the extreme difficulty of the (e_1) ⇄(e_2) transformation, the intermolecular hydrogen exchange does not occur smoothly on the (e). This results in k_i value of the (e) being smaller than that of the (d).

Here we can understand that the k_i value is determined by two factors. One is the acid strength (*i.e.*, the ability of proton donation), and the other is the special configuration (*i.e.*, the ability of proton acception) of the acid center. On the other hand, the k_p is determined by the acid strength alone.

Other Samples. The data for other samples are incomplete. However, the similar dependencies upon T_d of the k_i, c/t, and N_{OH} values show that the surface structures of the 13MHT and 50MHT are both close to that of the 25MHT. The slower appearance (about 20 °C) of the k_i(max) of the 50MHT may arise from its dehydroxylation, slower than that of the 25MHT (see Fig. 6).

Although the curves of c/t, A, and N_{OH} against T_d and the position of k_i(max) are similar to each other, there is a clear difference in the shape of the k_i *vs.* T_d curve between the 25MHT and the C sample (Fig. 1). The surface structures corresponding to the (e) may also be different.

Finally, we should mention the different surface characters between the M and MHT samples. The variations with the T_d of the k_i, k_p, and N_{OH} values of the M sample are not so prominent as those of the corresponding MHT sample. The starting N_{OH} value of the M is much lower than that of the MHT. Moreover, the c/t ratio of the M is much larger than that of the MHT. These facts indicate that the M sample originally contains large fractions of the (e) and (f). The presence of the less active (e) and (f) for the butene isomerization on the 25M sample results in its lower k_i value, with a higher c/t ratio, than those of the 25MHT, although the total acid amount of the 25M is larger than that of the 25MHT (Fig. 5).

Conclusion. The values of k_i, k_p, and A of the hydrothermally activated silica–alumina are different functions of T_d. An analysis of the N_{OH} *vs.* T_d curve shows that the surface structure of the catalyst changes in this fashion: (c)→(d)→(e)→(f) with the increase in T_d. By this, the different dependencies upon T_d of k_i and k_p are consistently explained.

The dependencies upon T_d of k_i, c/t, and k_p of the M sample differ from those of the corresponding MHT sample. This arises from the presence of the (e) and (f) in the original M sample. In other words, the role of the hydrothermal activation exists in the modification of the less active structures, (e) and (f), into the highly active structure (d).

22) Peri's model is also based on the (100) plane of β-cristobalite and limits the condensation of the hydroxyl group to a narrow region by considering the surface strain. However, his model is made for silica–alumina produced by depositing $AlCl_3$ vapor on a silica-gel surface. Therefore, the surface structure of his catalyst differs considerably from that of the present catalyst.

The Crystal Structure of Bis(methyl 3-benzylidenedithiocarbazato)nickel(II)

Tetsuo Uechi* and Takayuki Oniki†

College of General Education, Kyushu University 01, Ropponmatsu, Fukuoka 810
†Pre-dental Course, Kyushu Dental College, Manazuru, Kokurakita-ku, Kitakyushu 803

(Received March 30, 1981)

The title compound crystallizes in the monoclinic space group $P2_1/a$ with two molecules in a unit cell of dimensions; $a=21.479(5)$, $b=4.2092(6)$, $c=14.257(3)$ Å, and $\beta=129.53(2)°$. The structure was refined by block-diagonal least-squares procedures to give a final R value of 0.032 for 1693 reflections with $I>3\sigma(I)$ collected on a four-circle X-ray diffractometer. The complex consists of two methyl 3-benzylidenethiocarbazate groups, each bound to the central Ni atom through the thiol S atom and the hydrazine N atom, to yield a five-membered chelate ring. The NiN_2S_2 moiety is *trans* square-planar, with Ni–S and Ni–N bond distances of 2.1767(9) and 1.927(3) Å respectively. An examination of the bond distances and the planarity of the molecule revealed a delocalization of the π electrons over the chelate ring. The intra-molecular contact of S···H is 2.35(4) Å, which indicates a definite C–H···S interaction or hydrogen bonding.

In the course of our ESR study of $^{63}Cu(II)$ doped in the title compound (abbreviated as $Ni(bdc)_2$), an extra hyperfine structure (hfs) due to azomethine protons was observed.[1,2] The proton hfs was large, though the proton is attached to a carbon atom which is not included in the chelate ring. This proton hfs can be expected to be enhanced through the π electron in a C=N bond, and so the A^H value is sensitive to the geometry around the C=N bond. Therefore, it is interesting to investigate the structure around the C=N bond. The coordination geometry around the nickel atom in $Ni(bdc)_2$ is *trans*, while those in related 1-(2-naphthyl)ethylidene-, 1-(*p*-tolyl)ethylidene-, 1-phenylethylidene-, 1-(*m*-nitrophenyl)ethylidene-, and 1-(*p*-nitrophenyl)ethylidene-dithiocarbazatonickel(II) complexes were found from ESR measurements to be *cis*.[1] This paper will describe the crystal structure of $Ni(bdc)_2$ determined by the single-crystal X-ray-diffraction method.

Experimental

Preparation of Methyl 3-Benzylidenedithiocarbazate. A methanol solution of *S*-methyl dithiocarbazate (10 g), prepared as previously described,[3] was added to a methanol solution of benzaldehyde (11 g). The mixture was heated on a steam bath for 10 min. The deposited crystals were filtered off, washed with methanol, and recrystallized from methanol to give pale yellow crystals of the Schiff base.

Preparation of $Ni(bdc)_2$. A hot methanol solution of the nickel acetate (0.001 mol) was added to a hot methanol solution of the Schiff base (0.002 mol), the solution was heated on the steam bath for 10 min; on cooling, crystals of the $Ni(dbc)_2$ were deposited. Single crystals were obtained by the slow evaporation of the chloroform–methanol solution. Found: C, 44.99, H, 3.71, N, 11.68%. Calcd for $Ni(dbc)_2$: C, 45.29, H, 3.80, N, 11.74%.

X-Ray Diffraction. Preliminary X-ray photographs showed the space group to be $P2_1/a$. The unit cell parameters and intensity data were measured on a Syntex $P\bar{1}$ automated four-circle X-ray diffractometer with monochromated Mo $K\alpha$ radiation ($\lambda=0.71073$ Å). The unit-cell parameters were determined by a least-squares procedure, using 30 reflections within the range of $30<2\theta<43°$. The crystal used for X-ray work was ground to a sphere 0.32 mm in diameter. The density was measured by flotation in an aqueous KI solution. The crystal data are given in Table 1.

Table 1. Crystal data[a]

Molecular formula	$NiS_4N_4C_{18}H_{18}$
Molecular weight	477.31
Space group	$P2_1/a$
$a=21.479(5)$ Å	$Z=2$
$b=4.2092(6)$ Å	$D_m=1.593$ g cm^{-2}
$c=14.257(3)$ Å	$D_x=1.594$ g cm^{-2}
$\beta=129.53(2)°$	$\mu=1.39$ mm^{-1}
$V=994.17(45)$ Å^3	(for Mo $K\alpha$ radiation)

a) Numbers in parentheses here and elsewhere in this paper are the e.s.d.'s in the last significant digits.

The intensity data of 2202 independent reflections within a range of $2\theta<56°$ were collected by the θ-2θ scan technique, with a variable scan rate from 4.0 to 24.0° min^{-1}. Of these, the intensities of 505 reflections were less than $3\sigma(I)$; these reflections were not used in the least-squares refinement. The intensity data were corrected for Lorentz and polarization effects, but not for absorption and extinction.

Structure Determination and Refinement

The Ni atoms must lie on a set of twofold special positions, since there are only two molecules in a unit cell; therefore, the molecule is required to have a center of symmetry. The positions of all the non-hydrogen atoms were deduced from a Patterson synthesis and a subsequent Fourier synthesis. Refinement was carried out by the block-diagonal least-squares method. The function minimized was $\sum\omega(|F_o|-|F_c|)^2$, in which ω was chosen according to Cruickshank's weighting schemes.[4] All the H atoms were located by means of a difference Fourier synthesis. After several further cycles of refinement including all the H atoms, four reflections with $|F_o|-|F_c|>10.0$ were eliminated from the F_o-data set because of the strong imbalances of the background intensities on both sides of each Bragg peak. Refinement was terminated when all the shift/e.s.d. ratios for the non-hydrogen atoms became less than 0.2. The final conventional R index was 0.032 for the 1693 measurable reflections. The final difference Fourier synthesis showed no significant features except for two implausible peaks

a) The B's of the non-hydrogen atoms are the equivalent ones of the anisotropic thermal parameters.[15)] The H atoms are labelled in terms of the C atom to which they are attached.

of *ca.* 0.5 eÅ^{-3} in the vicinities of the Ni atom and the center of the chelate ring. The atomic scattering factors for Ni^{2+}, S, N, and C_{cov}, with correction factors for anomalous dispersion for the first two, were taken from International Tables for X-Ray Crystallography.[5)] Those for H atom were adopted from the table of Stewart *et al.*[6)] All the calculations were carried out on a FACOM M-200 computer in the Computer Center of Kyushu University, mainly by the use of the UNICS-II program system.[7)] The drawings were made by the use of the *ORTEP* program.[8)] The final atomic parameters are listed in Table 2, along with their estimated standard deviations. Lists of the structure factors and anisotropic thermal parameters have been deposited with the office of the Chemical Society of Japan as Document No. 8206.

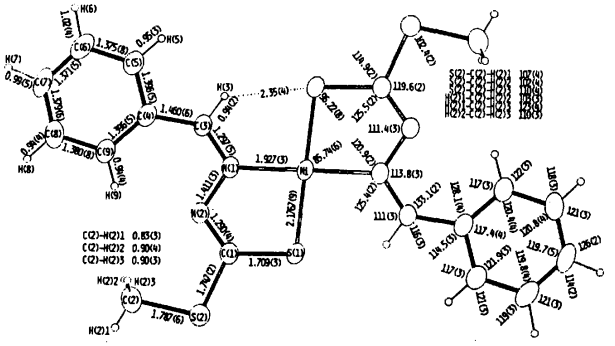

Fig. 1. Bond distances (l/Å) and angles (θ/°) of the molecule. The H atoms are shown as open circles of arbitrary size, and the shapes of the other atoms represent the thermal-motion ellipsoids scaled to enclose 50% probability.

Results and Discussion

The molecular structure is shown in Fig. 1, together with the bond distances(l), bond angles(θ), and atomic nomenclature scheme. The complex consists of two methyl 3-benzylidenedithiocarbazate groups, each bound to the central Ni atom through the thiol S atom and the hydrazine N atom, to yield a five-membered chelate ring. The NiN_2S_2 moiety is *trans* square planar (coordination plane). This coordination geometry is compatible with the results of the ESR measurement of Cu^{2+} doped in $Ni(bdc)_2$.[1,2)]

The Ni–S bond distance of 2.1767(9) Å is in the range of 2.1—2.3 Å found in the four-coordinated Ni(II) complexes, as has been pointed out by Lopez-Castro and Truter.[9)] The Ni–N bond distance of 1.927(3) Å is comparable with the value of 1.896(7) Å found in bis(ethyldithiocarbazate)nickel(II), in which the environment about the Ni atom is similar to that in $Ni(bdc)_2$.[10)] The bond distances of S–C(1.709 Å), C–N(1.290 Å), and N–N(1.411 Å) in the chelate ring are intermediate between the usual values for single and double bonds. The chelate ring is nearly planar, with the maximum deviation of 0.041 Å, as shown in Table 3. The bond distances and the planarity are indicative of an extensive delocalization of π electrons over the chelate ring. Such a large delocalization of π electrons can be expected to give rise to a large proton hfs. The thiomethyl group has the normal S–C(sp^3) bond distance of 1.787(6) Å and is attached to the ring carbon with the C–S–C bond angle of 102.4(2)° and at

TABLE 3. LEAST-SQUARES PLANES AND TORSION ANGLES

(a) Coefficient of least-squares plane equations.

Equations are of the form $lu+mv+nw=d$, where u, v, and w are in Å units referred to the a, b, and c* axes respectively.

	Plane	l	m	n	d/Å
I	Coordination	−0.2870	0.8560	−0.4300	0.0
II	Chelate ring	−0.2722	0.8408	−0.4680	−0.0307
III	Benzene ring	−0.2341	0.8364	−0.4957	−0.3623

(b) Deviations (l/Å) from least-squares planes.

Atoms with an asterisk are not included in the calculation of the plane.

I		II		III	
Ni	0	Ni	0.031	C(3)*	0.064
S(1)	0	S(1)	−0.024	C(4)	0.007
N(1)	0	N(1)	−0.041	C(5)	−0.007
N(2)*	0.120	N(2)	0.025	C(6)	0.002
C(1)*	0.099	C(1)	0.010	C(7)	0.003
C(3)*	−0.092	S(2)*	0.005	C(8)	−0.002
		C(2)*	−0.007	C(9)	−0.003
		C(3)*	−0.138		

(c) Selected torsion angles (θ/°).

S(1)–C(1)–S(2)–C(2)	−178.3(2)	Ni–N(1)–C(3)–C(4)	−175.7(3)
N(1)–N(2)–C(1)–S(2)	−177.1(2)	N(1)–C(3)–C(4)–C(5)	173.5(4)
N(2)–C(1)–S(2)–C(2)	1.0(3)	N(1)–C(3)–C(4)–C(9)	−4.9(7)

the normal S–C(sp^2) distance (1.747(2) Å). These bond distances and angle suggest that the delocalization of π electrons is not extended to this part, although the thiomethylic S–C is almost coplanar with the chelate ring. The coordinated N atom is also bonded to the benzylidene group; the N(1)–C(3) distance (1.297(5) Å) falls within the range of 1.29—1.34 Å established for the coordinated N=C bond;[11] it is longer than the generally accepted value for N(sp^2)–C(sp^2) of 1.24 Å.[12] Judging from the planarity and lengthening of the bonds about N(1), the π electrons seem to be delocalized over C(3). An inspection of the bond angle at C(3) reveals that there is a steric repulsion between the chelate ring and the phenyl group. The benzene ring is planar, with a maximum deviation of 0.007 Å. This ring rotates slightly about the C(3)–C(4) bond; the torsion angles about this bond are 173.5(4) and −4.9(7)°. The intramolecular contact of S(1)···H(3) is 2.35(4) Å, where the C···S distance and the C–H···S angle are 3.053(4) Å and 130.4° respectively. The S···H distance is far shorter than the sum of the van der Waals radii of these atoms (3.05 Å);[13] it indicates a definite C–H···S interaction or hydrogen bonding. The large proton hfs of the ESR spectra of Cu^{2+} doped in Ni(bdc)$_2$ is expected to occur also through this H···S short contact. Such a short contact has also been observed in nickel(II) bis(dipropyldithiocarbamate).[14]

Fig. 2. An edge-on view of the molecule. The H atoms have been omitted for clarity.

An edge-on view of the molecule, as shown in Fig. 2, shows that the molecule is, as a whole, roughly planar. The normal to the coordination plane makes an angle of 31.1° with the b axis; also, the directions of the Ni–N(1) and Ni–S(1) bonds make angles of 85.3 and 59.0° with the b axis respectively. These angles correspond to the angles between the b axis and the g_z, g_x, and g_y directions (30.7, 87.1, and 59.3° respectively) determined from the single-crystal ESR measurement of Cu^{2+} doped in Ni(bdc)$_2$.[1]

The molecular packing projected on the ac plane is

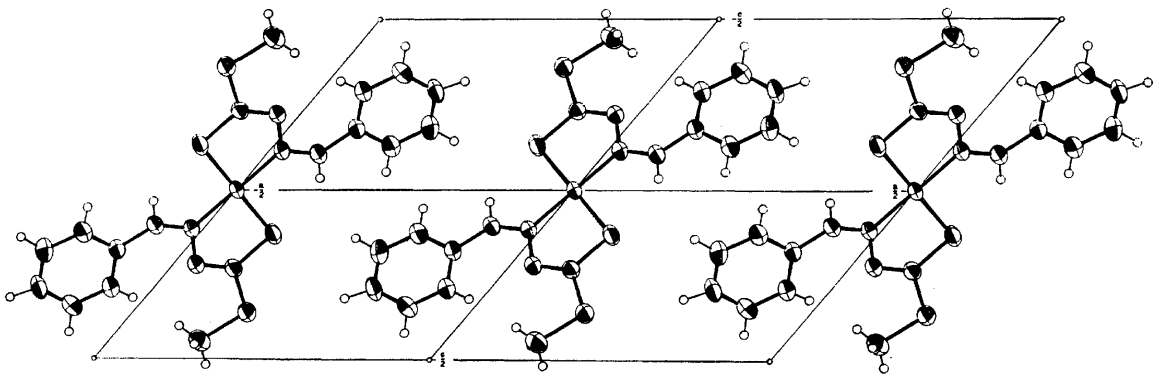

Fig. 3. Projection of the crystal structure on the ac plane.

shown in Fig. 3. There are no unusually close intermolecular contacts; thus, the crystal can be said to be held together primarily by van der Waals forces.

The authors are grateful to Professor Toshio Kawasaki at the Faculty of Pharmaceutical Sciences of Kyushu University for allowing them to use the automated diffractometer, and to Asst. Professor Shigeaki Kawano at the College of General Education of this University for his advice on the computation process.

Polymerization of Silicic Acid Adsorbed on Aluminium Hydroxide

Takushi YOKOYAMA,* Osamu NAKAMURA,** and Toshikazu TARUTANI

Department of Chemistry, Faculty of Science, Kyushu University 33, Hakozaki, Higashi-ku, Fukuoka 812

(Received June 19, 1981)

Factors controlling the absorption of silicic acid on aluminium hydroxide from aqueous solution and the polymerization of adsorbed silicic acid were studied. Measurements included the amount of silicic acid adsorbed on aluminium hydroxide, the amount and size distribution of the polysilicic acid formed, and the differential thermal analysis curve of aluminium hydroxide which had adsorbed silicic acid. The adsorption and the polymerization of silicic acid are affected by pH, the relative amounts of silicic acid and aluminium hydroxide, the reaction time between monosilicic acid and aluminium hydroxide, and the formation of amorphous aluminosilicate. The amount of adsorbed silicic acid and the rate of its polymerization are maximum at pH 9.0—9.5. A part of adsorbed monosilicic acid reacts with aluminium hydroxide to form an aluminosilicate. In an early stage of the polymerization of the adsorbed silicic acid, the polymerization mainly proceeds by the reactions between monosilicic acids and between monosilicic and polysilicic acids; the particle sizes of polysilicic acids gradually increase with time. When the polymer particles grow large enough to touch neighboring polymers, the growth rate of polymer particles becomes faster due to the polymer-polymer reactions.

Siliceous deposits from hot springs generally contain Al_2O_3 and Fe_2O_3; some deposits contain several percent of Al_2O_3.[1-3] Aluminium thus plays an important role in the formation of siliceous deposits. Adsorption characteristics of monosilicic acid on aluminium hydroxide have been studied,[4-6] but only a few reports were published with respect to the polymerization of silicic acid adsorbed on or coprecipitated with aluminium hydroxide.

Hingston and Raupach[7] suggested that a multilayer of silicic acid was formed by polymerization of silicic acid on an aluminium hydroxide surface. Jepson *et al.*[8] reported that, under given conditions, the adsorption of monosilicic acid on gibbsite exceeded the monolayer coverage. Yokoyama and Tarutani[9] reported that, when aluminium hydroxide was placed in a flask and then monosilicic acid solution (150 ppm SiO_2, pH 8) was made to flow continuously through the flask, the monosilicic acid adsorbed on aluminium hydroxide gradually polymerized to form silica particles of larger sizes than 0.1 μm after about 20 d.

In this work, factors controlling the amount of silicic acid adsorbed on aluminium hydroxide and the polymerization of adsorbed silicic acid were studied. The mechanism for the growth of particles of polysilicic acid is proposed.

Experimental

Samples and Reagents. All the reagents used were of analytical reagent grade. A stock solution of monosilicic acid was prepared by dissolving silica gel (Mallinckrodt Chemical Works) in sodium hydroxide solution. A monosilicic acid solution of the desired concentration was prepared by diluting a stock solution before use. Aluminium hydroxide was precipitated by adding sodium hydroxide solution to aluminium chloride solution; the hydroxide was then washed with distilled water. This was prepared immediately before each experiment.

Procedure. The pH of monosilicic acid solution (500 cm^3) of an appropriate concentration was adjusted to a desired pH value with hydrochloric acid or sodium hydroxide solution. A known amount of aluminium hydroxide was then introduced to the solution and the pH of the solution was readjusted. The suspension was stirred vigorously with a magnetic stirrer. The variation of pH of the suspension was maintained within ± 0.1 pH by adding hydrochloric acid or sodium hydroxide solution. Adsorption experiments were carried out in a thermostated bath at 25 °C. After 5 h or at appropriate intervals, an aliquot of suspension was pipetted and filtered through a membrane filter having pore size of 0.1 μm. The concentration of monosilicic acid in the filtrate was determined by colorimetry. The aluminium hydroxide on the membrane filter was dissolved with 1 mol dm^{-3} hydrochloric acid. The resulting solution was filtered and diluted to 100 cm^3 with distilled water (solution A). The amount of monosilicic acid in the solution A was determined by colorimetry and the total silicic acid was determined after decomposing polysilicic acid with alkali. Silica particles larger than 0.1 μm remaining on the filter were determined by colorimetry after the filter had been ashed and the silica was fused with sodium carbonate. Aluminium ion concentration in the solution A was determined by EDTA titration.

The following symbols will be used: Si(M): the amount of monosilicic acid in the solution A; Si($<$0.1): the total amount of silicic acid (particles smaller than 0.1 μm) in the solution A; Si($>$0.1): the amount of silica (particles larger than 0.1 μm) remaining on the filter; Si(T): the sum of Si($<$0.1) and Si($>$0.1); Al(A): the amount of aluminium ion in the solution A; Si/Al(MR): the mole ratio of monosilicic acid to aluminium hydroxide in the initial solution; Si(T)/Al(A): the mole ratio of total silicic acid adsorbed to aluminium hydroxide; Si(M)/Si(T): the mole ratio of monosilicic acid to total silicic acid adsorbed on aluminium hydroxide. Since the difference between Si(M) and Si(T) can be regarded as the amount of polysilicic acid formed on the aluminium hydroxide, this ratio is an indicator of the amount of polysilicic acid formed.

Gel Chromatography. The size distribution of polysilicic acids formed on aluminium hydroxide was measured by gel chromatography. The pH of the solution A was adjusted to 2 and silicic acid was chromatographed on 1 cm × 60 cm column of Sephadex G-75 (Pharmacia Fine Chemicals) according to the procedure of Shimada and Tarutani.[10] After the effluent had been collected with a fraction collector, the amounts of silicic acid in the fractions were measured by colorimetry after decomposition of the polysilicic acid with alkali.

** Present address: Department of Commerce and Industry, Fukuoka Prefectual Office, Hakata-ku, Fukuoka 812.

Differential Thermal Analysis. Aluminium hydroxide which had adsorbed silicic acid was filtered, and then was dried at 25 °C for 10 d. Differential thermal analysis (DTA) was performed using a Rigaku Denki Thermaflex 8002 H/D thermoanalyzer.

Results

Effect of pH. The kinetic data for adsorption of silicic acid on aluminium hydroxide in 300 ppm (SiO_2) monosilicic acid solution of pH 9 showed that a rapid decrease in monosilicic acid concentration occurred in 1 h and then the rate of adsorption of silicic acid became relatively slow. Since, in 300 ppm monosilicic acid solution, monosilicic acid did not polymerize within 5 h, only monosilicic acid was adsorbed by aluminium hydroxide.

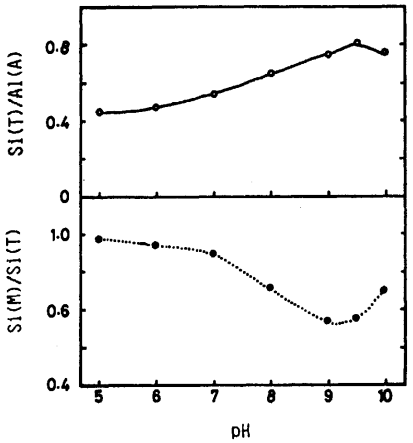

Fig. 1. The effect of pH on Si(T)/Al(A) and Si(M)/Si(T) ratios after 5 h.
Initial monosilicic acid concentration : 300 ppm. Si/Al-(MR)=2.1.

Adsorption of silicic acid by aluminium hydroxide and polymerization of adsorbed silicic acid were examined in the pH range 5—10. The results are shown in Fig. 1. The Si(T)/Al(A) ratio increased with increase in pH range 5.0—9.5, showing a maximum adsorption at pH 9.5. The Si(M)/Si(T) ratio decreased with increasing pH up to 9.0—9.5, increasing with further increase in pH. This indicates that the formation rate of polysilicic acid from silicic acid adsorbed on aluminium hydroxide is most rapid at pH 9.0—9.5. Silicic acid adsorbed on aluminium hydroxide at various pH's was chromatographed on a Sephadex G-75 column. Elution curves obtained are shown in Fig. 2. The dotted line is the elution curve for monosilicic acid, the position V_0 being the elution volume of Blue Dextran 2000, which is not diffusible in the gel phase. Polysilicic acid is eluted between the position V_0 and the elution position of monosilicic acid; the elution volume of monosilicic acid; the elution volume of polymer decreases with increasing particle size. The tailing from the peak for monosilicic acid indicates the presence of polysilicic acid in various sizes. Polymers larger in size than those in the particles separation range available with the gel are eluted together at V_0. As seen from the

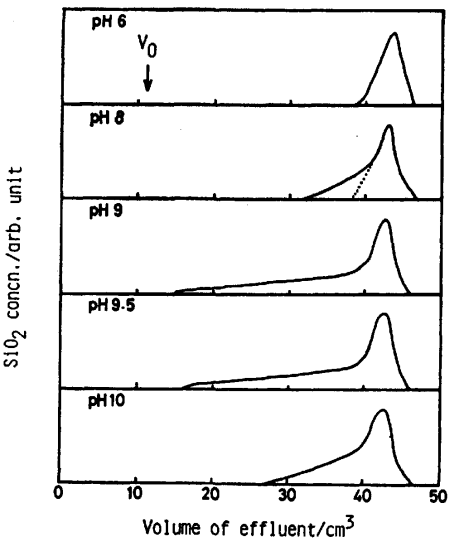

Fig. 2. Gel chromatograms for silicic acid adsorbed on aluminium hydroxide at various pH's after 5 h.
Initial monosilicic acid concentration : 300 ppm. Si/Al-(MR)=2.1. Gel : Sephadex G-75. Column: 1 cm×60 cm.

elution curves shown in Fig. 2, polysilicic acids formed at pH 9.0 and 9.5 have larger particle sizes than those formed at other pH's. This indicates that the rate of growth of polymer particles formed on aluminium hydroxide is most rapid at pH 9.0—9.5.

Effect of Initial Concentration of Monosilicic Acid. The variations of Si(T)/Al(A) and of Si(M)/Si(T) ratios with the initial concentration of monosilicic acid are shown in Fig. 3. The Si(T)/Al(A) ratio increased with increasing initial concentration of monosilicic acid, whereas the Si(M)/Si(T) ratio decreased. The amount of adsorbed silicic acid and the degree of polymerization are strongly affected by the initial monosilicic acid concentration.

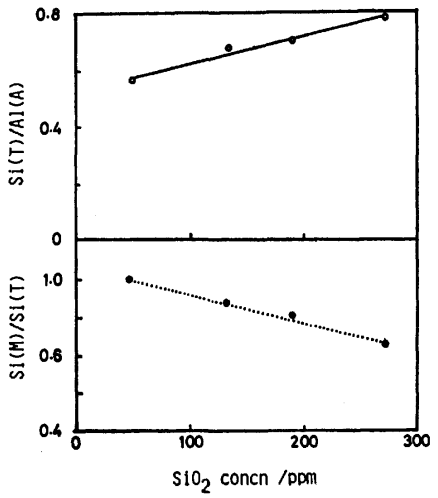

Fig. 3. Variation of Si(T)/Al(A) and Si(M)/Si(T) ratios as a function of initial monosilicic acid concentration.
Si/Al(MR)=0.96. pH : 9. Reaction time : 5 h.

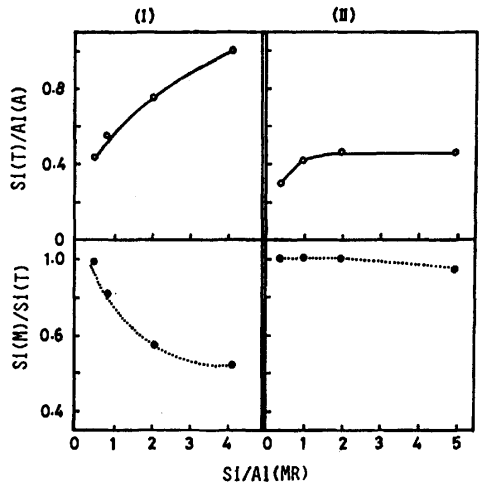

Fig. 4. Variation of Si(T)/Al(A) and Si(M)/Si(T) ratios as a function of Si/Al(MR) ratio.
Initial monosilicic acid concentration : (I) 300 ppm, (II) 100 ppm. pH : 9. Reaction time : 5 h.

Effect of the Relative Amount of Silicic Acid to Aluminium Hydroxide. Figure 4 shows the variations of Si(T)/Al(A) and of Si(M)/Si(T) ratios as a function of Si/Al(MR) ratio. The Si(T)/Al(A) ratio increased with an increase in the Si/Al(MR) ratio in 300 ppm monosilicic acid solution and the Si(M)/Si(T) ratio decreased. In 100 ppm monosilicic acid solution, above the Si/Al(MR) ratio of 2, the Si(T)/Al(A) ratio reached a limiting plateau region. The Si(M)/Si(T) ratio was unity in the Si/Al(MR) range of 0.3—2.0 and was slightly less than unity at the Si/Al(MR) ratio of 5.

Effect of Standing Time. The variations of Si(T)/Al(A), Si(M)/Si(T), and Si(>0.1)/Al(A) ratios with time in 300 ppm monosilicic acid solution are shown in Fig. 5. The Si(T)/Al(A) ratio increased with time, whereas the Si(M)/Si(T) ratio decreased. After 25 h, both ratios became almost constant. On the other hand, silica of particle size above 0.1 μm formed after 35 h; its amount (Si(>0.1)/Al(A)) increased with time.

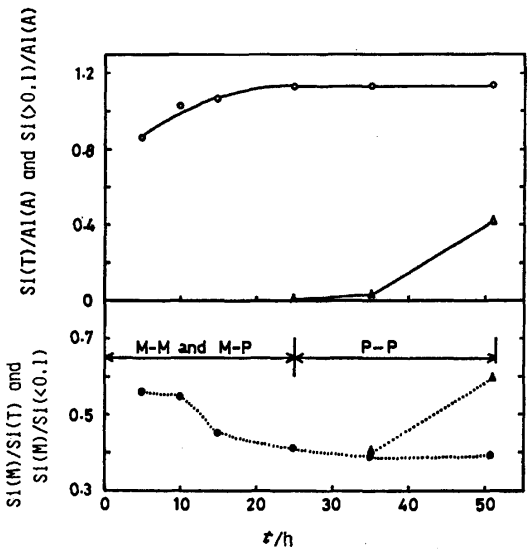

Fig. 5. Polymerization of silicic acid adsorbed on aluminium hydroxide.
Initial monosilicic acid concentration: : 300 ppm. Si/Al(MR)=2.1. pH : 9.3.

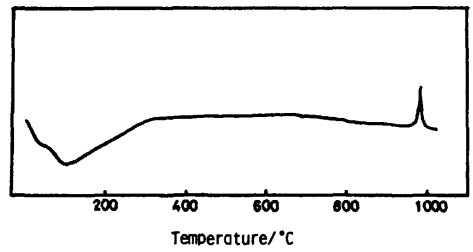

Fig. 6. DTA pattern of sample prepared at pH 8.

Differential Thermal Analysis. Figure 6 shows the DTA curve of aluminium hydroxide which had adsorbed silicic acid, prepared at pH 8. This curve has an endothermic peak at *ca.* 100—300 °C and an exothermic peak at around 1000 °C; it is very similar in basic features to the thermal curve of allophane, that is, amorphous aluminosilicate.[11] Appearance of the exothermic peak at around 1000 °C indicates that aluminosilicate is formed by the reaction of the adsorbed monosilicic acid and aluminium hydroxide. The exothermic peak was observed in all aluminium hydroxide which had adsorbed silicic acid.

Discussion

In 300 ppm (SiO_2) monosilicic acid solution, monosilicic acid did not polymerize within 5 h, whereas the monosilicic acid adsorbed on aluminium hydroxide did polymerize.

The amount of silicic acid adsorbed on aluminium hydroxide, the rate of polymerization of adsorbed silicic acid, and the formation of silica were affected by many factors, such as pH (Figs. 1 and 2), initial monosilicic acid concentration (Fig. 3), Si/Al(MR) ratio (Fig. 4), and standing time (Fig. 5). Amorphous aluminosilicate is formed by the reaction of adsorbed monosilicic acid and aluminium hydroxide (Fig. 6). The process of polymerization of adsorbed silicic acid is discussed on the basis of the data obtained at pH 9.3 (Fig. 5).

According to the preceding report,[12] the polymerization reaction of silicic acid in an aqueous solution is divided into three steps: (1) the reaction between monosilicic acids (M-M reaction), (2) the reaction between monosilicic and polysilicic acids (M-P reaction), and (3) the reaction between polysilicic acids (P-P reaction). Silicic acid adsorbed on aluminium hydroxide may also polymerize through similar reactions. An M-M reaction consists of two reactions, the reaction of the monosilicic acid adsorbed, and the reaction between the adsorbed monosilicic acid and that in the solution. The M-P reaction consists of the reaction between the adsorbed monosilicic acid and the polysilicic acid formed on the surface of solid, and the reaction between monosilicic acid in the solution and the polysilicic acid

formed. The P-P reaction occurs between polysilicic acids formed on the surface of the solid, because polysilicic acid does not exist in the solution.

In Fig. 5, the Si(T)/Al(A) ratio reached nearly a constant value after 25 h. Similarly, the Si(M)/Si(T) ratio showed a constant value after 25 h. However, the Si(>0.1)/Al(A) and Si(M)/Si(<0.1) ratios increased even after 35 h. Since the Si(T)/Al(A) and Si(M)/Al(A) ratios were nearly constant after 25 h, the increase in the Si(M)/Si(<0.1) ratio after 35 h suggests a decrease in the amounts of polymers smaller than 0.1 μm in size (Si(<0.1)) according to P-P reactions.

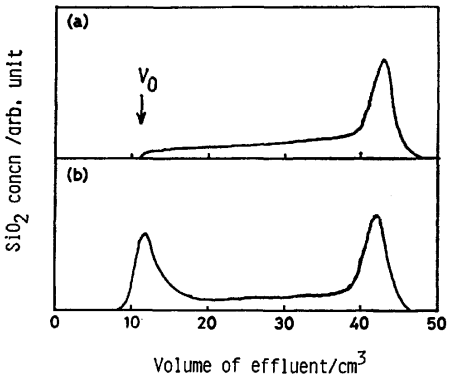

Fig. 7. Gel chromatograms for silicic acid adsorbed on aluminium hydroxide after (a) 20 h and (b) 30 h. Initial monosilicic acid concentration: 300 ppm. Si/Al(MR)=2.1. pH: 9.3. Gel: Sephadex G-75. Column: 1 cm×60 cm.

In order to confirm that a P-P reaction occurred, silicic acid absorbed on aluminium hydroxide after 20 and 30 h was chromatographed on a Sephadex G-75 column. Elution curves for silicic acid are shown in Fig. 7. Figure 7(a) shows no peak at the position V_0, while Fig. 7(b) shows a large peak. Polysilicic acids having larger sizes than the possible separation range of the gel are eluted together at the position V_0. These results suggest that the gradual increase in particle size of polymers occurred for the first 20 h (Fig. 7(a)) and then the further increase between 20 and 30 h occurred by P-P reaction (Fig. 7(b)). If a P-P reaction occurs from the beginning of the polymerization along with M-M and M-P reactions, the elution curve shown in Fig. 7(a) should show a peak at the position V_0, though the peak may be small. As shown in Fig. 5, the Si(T)/Al(A) ratio increased with time until 25 h and the Si(M)/Si(<0.1) (=Si(M)/Si(T)) ratio decreased. From the evidence of gel chromatography, it is concluded that the polymerization of silicic acid mainly proceeds by M-M and M-P reactions in the reaction time up to 25 h.

The process of polymerization of silicic acid adsorbed on aluminium hydroxide can be explained as follows. Monosilicic acid is at first adsorbed on aluminium hydroxide and a part of monosilicic acid adsorbed forms amorphous aluminosilicate (Fig. 6). In an early stage of polymerization of adsorbed silicic acid, the polymerization mainly proceeds by M-M and M-P reactions and the particle sizes of polymers gradually increase with time. When the particles of the polymers grow large enough to touch neighboring polymers, the growth rate of polymers becomes faster due to P-P reaction.

Molecular Structures of [2](2,5)(7,7,8,8-Tetracyanoquinodimethano)[2]-paracyclophane and 14,17-Dimethoxy[2](2,5)(7,7,8,8-tetracyanoquinodimethano)[2]paracyclophane†

Takashi Mizuma,†† Hideaki Matsuura,††† Yasushi Kai, Noritake Yasuoka,†††† and Nobutami Kasai*

Department of Applied Chemistry, Faculty of Engineering, Osaka University, Yamadaoka, Suita, Osaka 565

(Received June 24, 1981)

The molecular structures of two [2.2]paracyclophanes containing a 7,7,8,8-tetracyanoquinodimethan (TCNQ) moiety as an electron acceptor have been determined by means of X-ray diffraction. The electron-donating moieties in these cyclopahnes are benzene (TCNQ-X) and *p*-dimethoxybenzene (TCNQ-X$(OMe)_2$) rings. TCNQ-X crystallizes in a triclinic space group $P\bar{1}$ with two molecules per unit cell; $a=9.772(2)$, $b=18.477(4)$, $c=6.569(1)$ Å, $\alpha=90.38(2)$, $\beta=107.92(2)$, $\gamma=100.32(2)°$. The crystals of TCNQ-X$(OMe)_2$ belong to the orthorhombic system; space group *Fdd2*; $a=25.618(3)$, $b=31.895(5)$, $c=9.808(1)$ Å, $Z=16$. Both structures were solved by the direct method and refined by the block-diagonal least-squares procedure to $R=0.088$ (TCNQ-X) and 0.109 (TCNQ-X$(OMe)_2$) for 3141 and 1695 non-zero rehections. In the two structures determined, the [2.2] paracyclophane skeleton has the usual structure; the benzene ring and six-membered ring of the TCNQ moiety have a boat form, and two $C(CN)_2$ portions in the TCNQ moiety are bent down from the mean plane defined by the C(12), C(13), C(15), and C(16) atoms.

As part of a series of structural studies of layered cyclophanes, the X-ray structure determination of [2,2]paracyclophanes containing a 7,7,8,8-tetracyanoquinodimethan (TCNQ) moiety as an electron acceptor has been carried out. This paper will deal with the molecular structures of **1**, [2](2,5)(7,7,8,8-tetracyanoquinodimethano)[2]paracyclophane (abbreviated as TCNQ-X, hereafter) and **2**, 14,17-dimethoxy[2](2,5)-(7,7,8,8-tetracyanoquinodimethano)[2]paracyclophane (TCNQ-X$(OMe)_2$).

2, R=OCH_3

Experimental

For the X-ray experiment, a Rigaku automated four-circle diffractometer was used.

TCNQ-X. Graphite-monochromatized Mo $K\alpha$ radiation was used. A reddish violet crystal with approximate dimensions of 0.30 mm×0.25 mm×0.17 mm was mounted on a goniometer of the diffractometer. By searching for the locations of strong diffractions, the setting parameters of the crystal with a primitive lattice were first determined. Based on these parameters, a set of 206 diffraction intensities were measured by the θ-2θ scan technique up to $2\theta=14.3°$ as a preliminary work. By statistically treating these data, the point group symmetry of the crystal was determined as $\bar{1}$, and then the space group as $P\bar{1}$. The *SPAGD* program[1] was used. At this stage, the tentative unit-cell was transformed into the reduced cell, the parameters of which were then refined by the least-squares fit.

Crystal Data. $C_{22}H_{14}N_4\cdot C_6H_6$, *F.W.* 412.5, triclinic, space group $P\bar{1}$, $a=9.772(2)$, $b=18.477(4)$, $c=6.569(1)$ Å, $\alpha=90.38(2)$, $\beta=107.92(2)$, $\gamma=100.32(2)°$, $V=1107.8(4)$ Å^3, $D_m=1.240$ (by flotation), $D_c=1.236$ g cm^{-3} for $Z=2$.

The integrated intensities were measured by the θ-2θ scan method at a rate of 4° min^{-1}. The backgrounds were counted for 7.5 s before and after the scan of each peak. A total of 4412 (3141 non-zero) reflections was collected up to $\sin\theta/\lambda=0.62$ Å^{-1}. The usual Lp corrections were made, but absorption corrections were ignored [μ(Mo $K\alpha$)=0.81 cm^{-1}].

TCNQ-X(OMe)$_2$. The space group was determined by means of photographic work. The unit-cell parameters were determined by the least-squares fit of 2θ values of higher-order reflections determined on the Rigaku diffractometer.

Crystal Data. $C_{24}H_{18}N_4O_2$, *F.W.* 394.4, orthorhombic, space group *Fdd2*, $a=25.618(3)$, $b=31.895(5)$, $c=9.808(4)$ Å, $V=8014(3)$ Å^3, $D_m=1.30$, $D_c=1.307$ g cm^{-3} for $Z=16$.

The intensity data were collected on the diffractometer with Zr-filtered Mo $K\alpha$ radiation. The θ-2θ scan technique was employed at a rate of 4° min^{-1}. A bluish violet crystal with approximate dimensions of 0.15 mm×0.18 mm×0.30 mm was used. A total of 2336 reflections was collected up to $2\theta=54°$, of which 1695 $|F|$'s larger than $3\sigma(F)$ were classed as observed. The usual Lp corrections were made, but no absorption correction was applied [μ(Mo $K\alpha$)=0.92 cm^{-1}].

Structure Solution and Refinement

TCNQ-X. The structure was solved by the direct method (*MULTAN* 74)[2] and refined by the block-diagonal least-squares procedure (*HBLS* V).[3] Of the two crystalline benzene molecules centered on (0,0,0) and (1/2,0,1/2), the latter was supposed to be disordered by the feature of peaks on the Fourier map, but the isotropic refinement in which the disorder (two locations with a 3:2 occupancy ratio) was considered was unsuccessful ($R=0.102$). Isotropic refinement was, therefore, again carried out from the beginning, the

atoms of the benzene molecules being not included. Six carbon atoms of the benzene molecules were located on the difference Fourier map. The possibility of disorder of the benzene molecule at (1/2,0,1/2) was ignored in the subsequent refinement. All the hydrogen atoms except those belonging to the benzene centered on (1/2,0,1/2) could be located on the difference Fourier map computed during the course of anisotropic refinement; they were included in the subsequent cycles with isotropic temperature factors. The final R was 0.088 for non-zero reflections (R_w=0.124). The weighting schemes used at this stage were $w=\{\sigma^2(F)+0.0204|F_o|+0.0015|F_o|^2\}^{-1}$ for $|F_o|>0$ and $w=0.6236$ for $|F_o|=0$. The final atomic parameters are given in Table 1.**

TCNQ-X(OMe)$_2$. The structure was solved by using the *MULTAN* 74 program.[2] On the E map, 25 atoms of the 30 non-hydrogen atoms could be located. The successive Fourier synthesis revealed the remaining 5 atoms.

The structure was refined, isotropically with the unit weight at the earlier stage and anisotropically at the later stage, by means of the *HBLS* V program.[3] The hydrogen atoms were located on the difference Fourier map and then included in the refinement with isotropic temperature factors. R converged to a rather large value of 0.109 for 1615 observed reflections (R_w=0.113). The weighting schemes used were $w=\{\sigma^2(F)+0.0483|F_o|-0.0002|F_o|^2\}^{-1}$ and $w=0$ for $|F_o|=0$ at the final cycle of the refinement. The final atomic parameters are listed in Table 2.** In the analyses of the two compounds, the atomic scattering factors for C, N, and O were taken from "International Tables for X-Ray Crystallography," Vol. IV,[4] and those for H, from Stewart, Davidson, and Simpson.[5]

Results and Discussion

Molecular Structure. TCNQ-X: A perspective view of the molecule (*ORTEP* II)[6] is shown in Fig. 1, while selected bond distances and bond angles are given in Fig. 2. The most remarkable feature of the structure is that the [2.2]paracyclophane skeleton has the usual structure. The upper benzene ring takes a boat form, as is observed in [2.2]paracyclophane;[7,8] the planes defined by the C(3), C(4), and C(8) atoms and by the C(5), C(6), and C(7) atoms form angles of 12.1(5) and 9.7(5)° respectively with the mean plane made by the C(4), C(5), C(7), and C(8) atoms. The C(3)–C(2) and C(6)–C(9) bonds are further bent down by 12.8(5) and 11.9(5)° from the planes formed by the C(3), C(4), and C(8) atoms and by the C(5), C(6), and C(7) atoms respectively. The TCNQ moiety has a twisted structure. The six-membered ring is in a twisted boat form, the planes formed by the C(13), C(14), and C(15) atoms and by the C(11), C(12), and C(16) atoms are bent up from the mean plane made by the C(12), C(13), C(15), and C(16) atoms by 15.2(4) and 15.7(4)° respectively. On the other hand, both of the two $C(CN)_2$ portions are bent down from the mean plane. The two vectors,

Non-hydrogen atoms are drawn as thermal ellipsoids at 50% probability level.

C(13)–C(17) and C(16)–C(20), make angles of 11.9(3) and 12.8(3)° respectively, with the plane defined by the C(12), C(13), C(15), and C(16) atoms. The dihedral angles between two $-C(CN)_2$ planes and the plane made by the C(12), C(13), C(15), and C(16) atoms are 15.0(3) and 15.9(3)°. The C(10)–C(11)–C(16), C(11)–

** Tables of observed and calculated structure factors and anisotropic thermal parameters are kept at the Chemical Society of Japan; Document No. 8207.

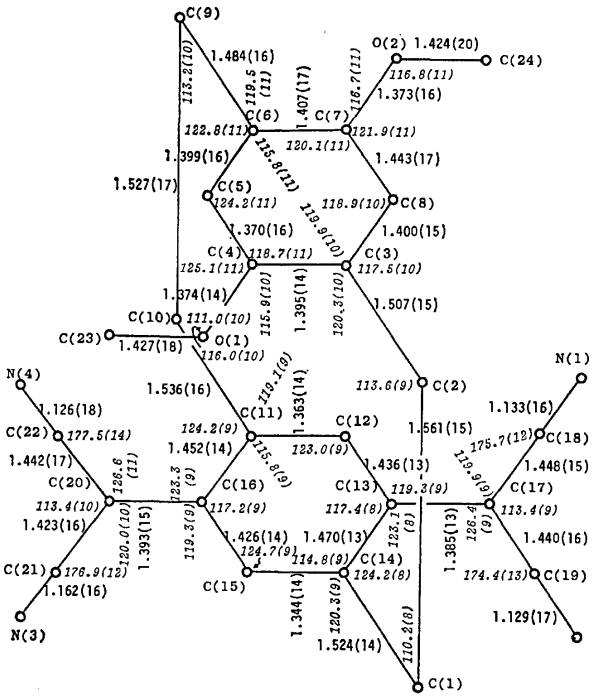

Fig. 4. Bond distances and bond angles in the TCNQ-X-$(OMe)_2$ molecule (Estimated standard deviations in parentheses).

C(16)–C(20), C(16)–C(20)–C(22), C(1)–C(14)–C(13), C(14)–C(13)–C(17), and C(13)–C(17)–C(19) angles ((av. 124.6°) are larger than 120°; they are considered to be due to the repulsions between two pairs of C–C≡N portions and $-(CH_2)_2-$ bridges in the molecule. The C(14)–C(1) and C(11)–C(10) bonds bent up by 7.7(4) and 11.3(4)° from the lower ring. In the $-(CH_2)_2-$ bridges, the torsion angles around the C(1)–C(2) and C(9)–C(10) bonds are −21.0(6) and 5.1(5)° respectively.

TCNQ-X(OMe)$_2$: The molecular structure (*ORTEP* II)[6] is shown in Fig. 3, while the distances and bond angles are given in Fig. 4. The present molecule has a structure similar to that of TCNQ-X except for the OMe portions. As is observed in TCNQ-X, both the upper and lower six-membered rings take boat forms. In the upper ring, the planes formed by the C(3), C(4), and C(8) atoms and by the C(5), C(6), and C(7) atoms are bent down by 8.2(12) and 12.4(12)° respectively from the plane formed by the C(4), C(5), C(7), and C(8) atoms. The OMe groups lie within 0.08 Å on the

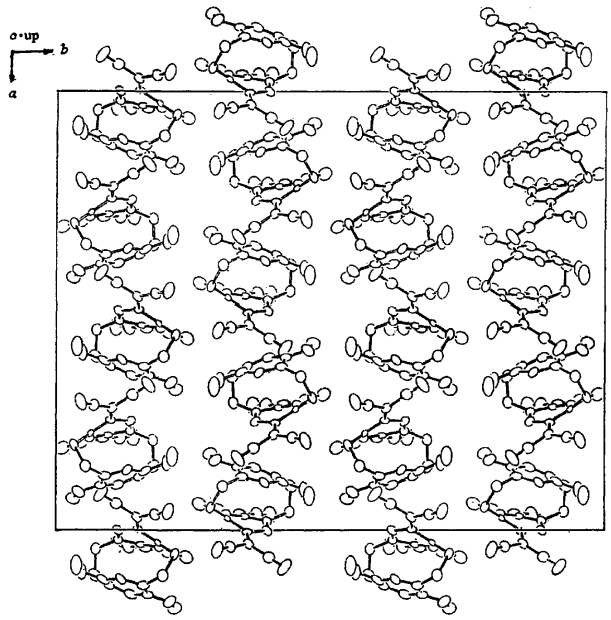

Fig. 6. Crystal structure of TCNQ-X$(OMe)_2$ projected along the c axis.

plane made by the C(4), C(5), C(7), and C(8) atoms. The C(3)–C(2) bond is further bent down by 15.3(12)° from the plane made by the C(3), C(4), and C(8) atoms, and the C(6)–C(9) bond, by 13.0(13)° from the C(5), C(6), and C(7) plane. The TCNQ moiety has a structure similar to that in TCNQ-X. The six-membered ring is also in a boat form; the plane defined by the

C(13), C(14), and C(15) atoms and the plane defined by the C(11), C(12), and C(16) atoms form angles of 16.9(10) and 16.4(10)° respectively with the mean plane formed by the C(12), C(13), C(15), and C(16) atoms. On the other hand, both of the $C(CN)_2$ portions are bent down from the mean plane, and the C(10)–C(11)–C(16), C(11)–C(16)–C(20), C(16)–C(20)–C(22), C(1)–C(14)–C(13), C(14)–C(13)–C(17), and C(13)–C(17)–C(19) angles (av. 124.6°) are slightly distorted from 120°. The torsion angles around the C(1)–C(2) and C(9)–C(10) bonds in the [2.2] bridges are 23.8(12) and −4.0(12)° respectively.

Crystal Structure. *TCNQ*: Figure 5 shows the crystal structure. The crystalline benzene molecule centered on (1/2,0,1/2) does not give any good shape. Short intermolecular atomic distances less than 3.5 Å are listed in Table 3, the shortest distance being 3.240(7) Å (C(22)(x,y,z)···N(2)($-1+x, y, -1+z$)).

TCNQ-X(OMe)$_2$. The molecular packing in the TCNQ-$X(OMe)_2$ crystal is drawn in Fig. 6. The closest intermolecular atomic contact is 3.293(15) Å (N(3)(x,y,z)···C(1)($-x$, $0.5-y$, $-0.5+z$)), which is listed in Table 3 along with other close contacts.

The calculations were done on an ACOS 700S computer at the Crystallographic Reserach Center, Institute for Protein Research, Osaka University.

The authors wish to express their deep thanks to Professor Soichi Misumi and his co-workers, Institute of Scientific and Industrial Research, Osaka University, for the supply of crystals and for their helpful discussions.

(Received July 15, 1981)

The conformational changes of poly(L-lysine) (PLL) were observed in alkyl sulfate solutions by a circular dichroic method. PLL forms a β-structure in sodium dodecyl sulfate solution with an apparent first-order rate constant of 3.0×10^{-2} s^{-1} (20 °C). In sodium octyl sulfate (SOS) solution, PLL assumes the α-helix within a certain concentration range of the surfactant, above which the β-structure is favored. The rate of coil to β-structure transition slows down with increase in hydrophobic interaction between surfactants and PLL. The presence of sodium ions decreases the rate of coil to α-helix transition by about two orders of magnitude (2.0×10^{-1} s^{-1} salt free to 3.0×10^{-3} s^{-1} in the presence of 2.0×10^{-2} mol/dm^3 NaCl at 20 °C). These phenomena are explained in terms of a rearrangement process of bound surfactants adjusting for a free energy minimum; a stronger binding force brings about a slower rearrangement rate.

Extensive circular dichroism (CD) studies have been made on the conformational changes of polypeptides in surfactant solutions. Poly(L-lysine) (PLL) has been an interesting material, since it can take on three kinds of conformations depending on experimental conditions.[1-8] For example, the PLL conformation is changed to β-structure in the presence of sodium dodecyl sulfate (SDS) at neutral pH.[1,3,6] However, few kinetic aspects of the conformational changes of PLL in surfactant solutions have been studied. We have applied a CD stopped-flow method to the study of the conformational changes of the PLL in sodium octyl sulfate (SOS) solution.[9] We reported the SOS concentration dependences of both the PLL conformations and the rate constants of the conformational changes; our results are briefly summarized as follows.[9] PLL adopts an α-helix only in a certain concentration range of SOS, taking a disordered structure below the SOS concentration range and β-structure above it. The rate constant of coil to β-structure transition sharply increases with SOS concentration, while that of coil to α-helix transition is almost independent of SOS concentration.

This work examined the above mentioned dependences in the presence of NaCl and also in solutions of an alkyl sulfate with different chain lengths. The main purpose of this paper is to discuss the effects of the chain length of alkyl sulfate and the added NaCl on the conformational changes.

Experimental

The sources of PLL and SOS have been described elsewhere.[9] The SDS is the same sample as before.[10]

The measurements of CD were carried out with a JASCO J-500A spectropolarimeter equipped with a JASCO DP-501 data processor, using a 1.0 mm path length cell with water-circulating jacket. The path length of a cell used in a stopped-flow measurement was also 1.0 mm.[9] Details of the CD and the stopped-flow measurements have been stated previously.[9]

Results

The addition of SDS causes a conformational change of PLL from coil to β-structure, as seen in Fig. 1; this

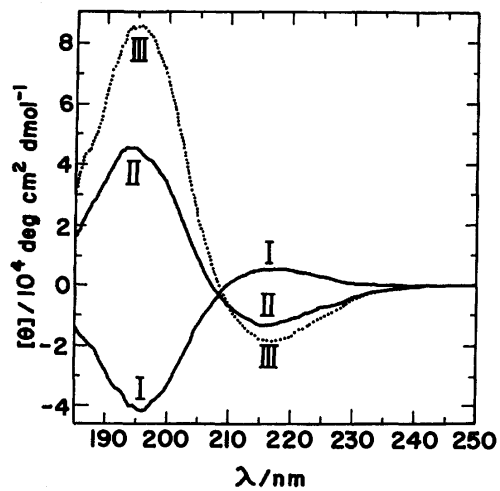

Fig. 1. Typical CD spectra of PLL solutions in the absence (curve I) and the presence (curve II) of 10 mM SDS and the difference CD spectrum between them (curve III) at 20 °C. The concentration of PLL was 2.8×10^{-4} M (residue). The time constant and the scanning speed of the spectropolarimeter were 1.0 s and 20 nm/min, respectively. These spectra are averaged over 8 repetitions and the difference CD spectrum was directly obtained using the data processor.

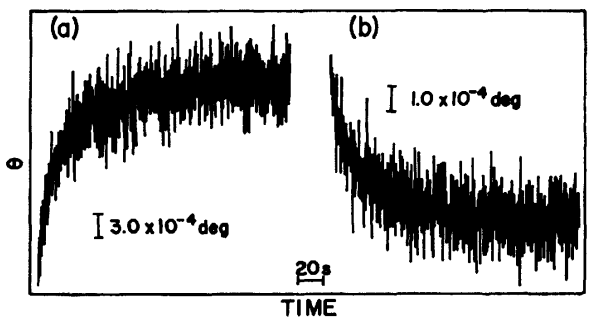

Fig. 2. Typical time courses of ellipticity changes at 195 (a) and 217 nm (b) at 20 °C. The traces (a) and (b) are averages of 8 and 2 repetitions, respectively. The final concentrations of PLL and SDS were 2.8×10^{-4} M (residue) and 10 mM, respectively.

result was previously reported by other investigators.[1,3,6] The CD stopped-flow measurements on the conformational change were made by tracing ellipticities at 195 and 217 nm, where positive and negative peaks appeared in the difference CD spectrum (III in Fig. 1). Typical time courses of the ellipticity changes at both wavelengths are seen in Fig. 2. The direction of the ellipticity change at each wavelength is in accord with the results in Fig. 1, suggesting that the observed process is due to the conformational change from coil to β-structure. The conformational change obeyed first-order kinetics in the ordinary treatment.[9] The rate constant was 3.0×10^{-2} s^{-1} (20 °C), and was independent of the SDS concentration (not shown here).

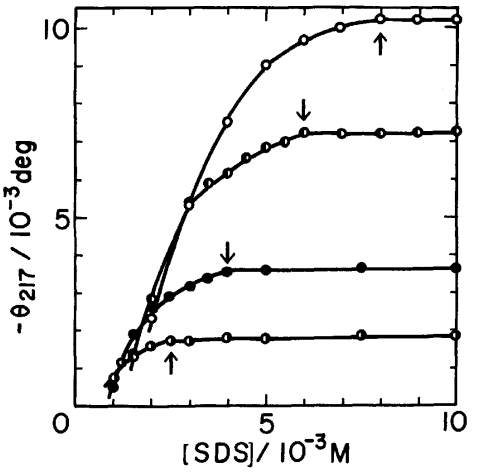

Fig. 3. Effect of PLL concentration on ellipticity, θ_{217} at various SDS concentrations. Residual PLL concentrations are 1.4 (◑), 2.8 (●), 5.6 (◐), and 7.9×10^{-4} M (○). These data were obtained from the measurements under the same experimental conditions as in Fig. 1 except for PLL concentration.

Figure 3 shows the plots of the ellipticities at 217 nm, θ_{217} *vs.* SDS concentration at several PLL concentrations. The conformation of PLL grows with the SDS concentration after a sudden increase in ellipticity. The increase in PLL concentration shifts the range of the SDS concentration where the sudden conformational change of PLL occurs and eventually the conformational change is completed, as seen in Fig. 3.

Figure 4 shows that the CD spectrum of α-helical PLL in the SOS solution is not appreciably affected at a low NaCl concentration; the double negative maximum gradually fades out with increase of NaCl concentration. Since the NaCl added beyond 25 mM (the concentration unit: 1 M=1 mol/dm^3 is used) decreased the ellipticities over the entire wavelength range, the effects of the added salt were examined in the concentration range below 20 mM. The addition of NaCl does not change the characteristic concentration ranges of the surfactants where the conformation of PLL changes, although the critical micelle concentration sharply changes on addition of such an electrolyte. The added NaCl has some effect on the rate constants of the conformational changes in SOS solution and their SOS concentration dependences, as depicted in Figs. 5 and 6. Figure 5 shows the increase of the rate constant with SOS concentration in the presence of NaCl. This exhibits marked contrast with the insensitiveness to SOS concentration in such a concentration range without NaCl.[9] The combination of the 4 figures in Fig. 5 also indicates that the rate constant, k, decreases with increase in the added NaCl concentration at each SOS concentration. As seen in Fig. 6, the presence of NaCl markedly decreases the rate constant of the conformational change at 4.0 mM SOS, which is the lowest concentration where a coil to α-helix transition appears.[9] The rate constant rapidly decreased up to 10 mM NaCl and then gradually leveled off. On the

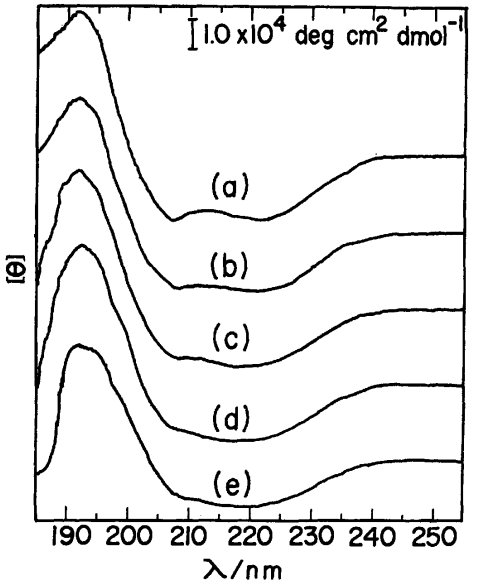

Fig. 4. Changes of CD spectrum of PLL in 5.0 mM SOS solution by addition of NaCl at 20 °C. NaCl concentrations: (a); 0, (b); 5.0, (c); 10.0, (d); 15, and (e); 20 mM.

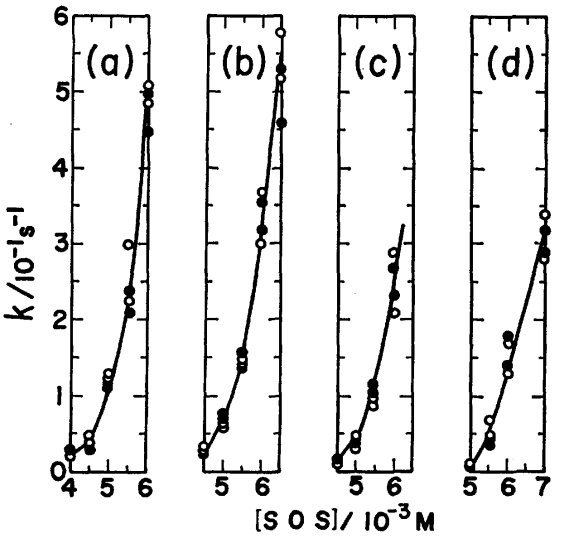

Fig. 5. SOS concentration dependences of rate constant, k, in the presence of NaCl at 20 °C. NaCl concentrations: (a); 5.0, (b); 10.0, (c); 15, and (d); 20 mM. The rate constants were obtained from ellipticity changes at 192 (○) and 221 nm (●) with time. PLL concentration was 2.8×10^{-4} M (residue).

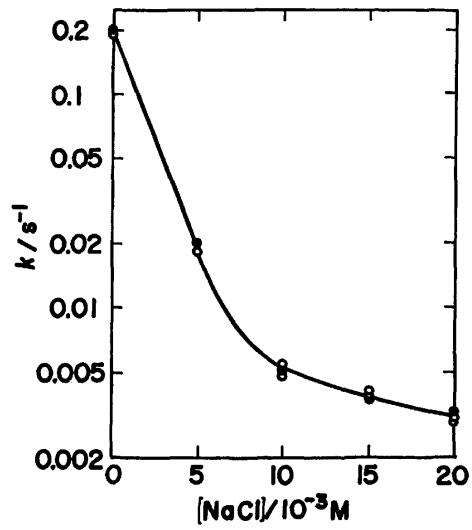

Fig. 6. Effect of NaCl on rate constant of coil to α-helix transition in 4.0 mM SOS solution at 20 °C. The solid and open circles respectively denote the same meanings as in Fig. 5. PLL concentration was 2.8×10^{-4} M (residue).

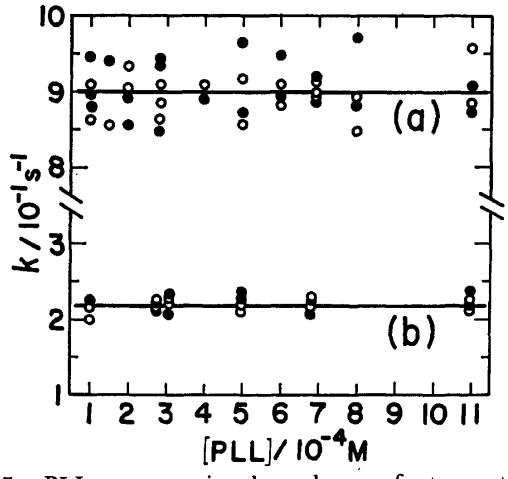

Fig. 7. PLL concentration dependences of rate constants of conformational changes of PLL in 5.0 mM (a) and 8.0 mM (b) SOS solutions at 20 °C. The solid and open circles denote the same meanings as in Fig. 5.

other hand, the presence of NaCl does not affect the rate constant of coil to β-structure transition in SDS solution.

The PLL concentration dependences of two kinds of rate constants, one for the coil to α-helix transition and the other for the coil to β-structure one, were examined in SOS solution, as shown in Fig. 7. The rate constant is almost constant (irrespective of the PLL concentration) in each case. In the same PLL concentration range, the rate constant of coil to β-structure transition induced by SDS is not affected by changing PLL concentration (not shown here).

Discussion

Effect of Chain Length of Alkyl Sulfate on the Conformational Change. As previously reported,[9] PLL adopts an α-helical state in a certain concentration range of SOS. In the PLL residual concentrations between $1.4—7.9\times 10^{-4}$ M, the characteristic SOS concentration range remains almost unchanged. The SOS concentration dependences of residual ellipticities at 192 and 221 nm, $[\theta]_{192}$ and $[\theta]_{221}$ do not differ from those in Fig. 2 of the previous paper.[9] On the contrary, the PLL adopts a β-structure in a solution of SDS whose concentration range is similar to that of SOS. The SDS concentration range where the coil to β-structure transition is observed is clearly dependent on PLL concentration, as seen in Fig. 3; this indicates that about 10 SDS molecules are required for 1 residue of PLL when the conversion to β-structure completes. It is expected that the binding ratio of surfactant to polypeptide determines the conformation of the surfactant-polypeptide complex. The fact that the effect of the PLL concentration on the range of the characteristic surfactant concentration is quite different for these two surfactants may indicate that the β-structured PLL binds a large number of surfactant molecules, while the α-helical PLL does not require so many bound surfactants. It is also expected that the ratio of bound surfactants to free ones is smaller in the case of SOS than in the other because of the difference in binding forces to the polypeptide. Therefore, the SOS concentration range where the coil to α-helix transition is induced is apparently independent of the PLL concentration. This is in line with the results by Satake and Yang[8] that PLL and poly(L-ornithine) (PLO) adopt β-structure and α-helix, respectively, in sodium decyl sulfate solution, and that such a difference is also reflected in the binding isotherm, which is much steeper for the β-structured polypeptide than the α-helical one. Alkyl sulfates may be probably oriented in the same direction on the β-structured polypeptide, while they may be oriented radially on the α-helical one. So, alkyl sulfates would be in contact with each other more efficiently on the β-structure than on the other, leading to a stronger binding. Such a difference in the mode of binding would reflect the difference in the amounts of surfactants bound to PLL.

The conformational change of PLL induced by SDS was followed as the ellipticity changes at 195 and 217 nm with time. The observed process must be the change from random coil to β-structure, on the basis of the comparison of the time courses in Fig. 2 with the changes of CD spectra in Fig. 1. The first-order rate constant of the conformational change of PLL induced by SDS is *ca.* 3.0×10^{-2} s^{-1} (20 °C); it is independent of SDS concentration. This rate constant is slower than that of the SOS-induced coil to β-structure transition ($6—10\times 10^{-1}$ s^{-1}). The clear distinction in the transition rates must be attributed to the differences in the chain length of alkyl sulfates, since binding energies are different for these surfactants. It should be noted that the rate constants of the conformational changes are quite independent of PLL concentrations in SOS solution, as seen in Fig. 7. These facts would suggest that the binding process between the surfactants and the polypeptide is not a rate-determining step in the conformational changes. Alkyl sulfates bound to

polypeptides can be in contact with each other through their alkyl chains, and the conformational changes of the polypeptide must be made together with many surfactant molecules bound on it. In the course of a conformational change of polypeptide, some of the bound surfactants may be forced to move from the initial binding sites to some other sites to achieve a more thermodynamically favorable conformation. Through this process, the bulky hydrophobic groups of surfactants should find maximal contacts between the hydrophobic groups of bound surfactants and the hydrophobic parts of the polypeptide, reconciling with the structure formation to reach minimal free energy. In the initial binding stage before the conformational change, the interaction with SDS is stronger than that with SOS. So, the coil to β-structure transition in SDS solution seems to require a much longer time in the rearrangement process than that in SOS solution.

The rate constant for the coil to β-structure transition sharply depends on SOS concentration, as seen in Fig. 5 of Ref. 9, although it is independent of SDS concentration. The SOS concentration dependence of the rate constant may be due to the transitional concentration range of SOS where the coil to α-helix transition shifts to the coil to β-structure one. Subsequently, it might be expected that the rate of the coil to β-structure transition is independent of surfactant concentration except for a very narrow range of surfactant concentrarion where the cooperative conformational change begins to occur. This indicates that the transitional concentration range of SOS is wider than that of SDS because the cooperativity of conformational change is expected to be greater for SDS than for SOS.

Sarkar and Doty[1] and Li and Spector[3] suggest that the intramolecular β-structure of PLL is formed in SDS solution, but Satake throws some doubt on this.[11] If the intermolecular β-structure is formed, the rate of the coil to β-structure transition should be dependent on PLL concentration. However, the opposite is the case, as stated above, suggesting the probability of the intramolecular structure formation in both α-helix and β-structure. In addition, the coil to β-structure transition obeys first-order kinetics, as in the case of the coil to α-helix one.[9] If the intermolecular β-structure is formed, the kinetics of the coil to β-structure transition will not be of first-order but of mixed order, as previously discussed by Snell and Fasman.[12] All these results would be indicative of the intramolecular β-structure formation in the surfactant solution. Whether the β-structure formation is intramolecular or intermolecular is considered to be essentially responsible for the degree of polymerization of the PLL used.[3,6,13] The intramolecular β-structure seems to be predominant in the present PLL with polymerization degree of 140.[9]

Effect of Added NaCl on the Conformational Change. Addition of NaCl as much as 10 mM seems to cause very slight changes in the α-helical conformation of PLL in SOS solution, as judged from the CD spectra in Fig. 4. The effect of added NaCl is so weak that the α-helical conformation itself does not change to some other conformation, in marked contrast with the effect of added 1-octanol which causes another transition from α-helix to β-structure.[9] The addition of the salt does not alter the surfactant concentration range where the conformation changes, probably because the amount of bound surfactant molecules is not affected by the presence of the salt.

As seen in Figs. 5 and 6, however, the addition of NaCl causes a considerable effect on the rate constant of the coil to α-helix transition in the SOS solution, while that of the coil to β-structure transition in the SDS solution is not affected by the addition of NaCl. As discussed above, the surfactant molecules are considered to be implanted radially on an α-helical polypeptide and the amount of bound surfactants seems to be much smaller on the α-helical polypeptide than on the β-structured one. This indicates that, although the surfactant molecules bound to the polypeptide would be in contact with each other, they are less compact when bound on α-helical polypeptide than on the other one. Sodium ions, as counter ions, must condense around the surfactant-α-helical polypeptide complex and weaken the repulsive force between the surfactants, just as in the case of ordinary micelle formation. Thus, the presence of NaCl can be considered to cause stronger interactions between the surfactants and the α-helical polypeptide. It is expected in such situations that the more strongly bound surfactants have a slower rearrangement process on the α-helical PLL. This phenomenon would markedly appear as the drastic decrease of the rate constant at 4.0 mM SOS, which is the lowest concentration at which the coil to α-helix transition is induced, as seen in Fig. 6. On the contrary, many surfactant molecules can bind onto the β-structured polypeptide with their hydrocarbon chains oriented in the same direction with strong contacts. The interaction between the surfactants is so strong that the added NaCl can hardly change the rate of the rearrangement of surfactant molecules.

In conclusion, the random coiled conformation of PLL changes to β-structure in the presence of SDS. This is because SDS gives a more hydrophobic atmosphere to host polypeptide than SOS which induces the coil to α-helix transition within the limited concentration range. The intramolecular β-structure is considered to be formed in the PLL with the polymerization degree of 140. The rate of coil to β-structure transition has a tendency to become slower with increase in the hydrophobic interactions of surfactants. The rate of the conformational change is affected very little by the added NaCl, probably because of the strong interactions between the surfactant molecules bound to the β-structured polypeptide. On the other hand, the added NaCl appreciably decreases the rate of coil to α-helix. This would be due to the fact that the surfactants bound to the α-helical PLL are less compact, and so the α-helical-surfactant complex is much more influenced by the addition of sodium ions.

This work was partly supported by a Grant-in-Aid for Scientific Research to K. T. from the Ministry of Education, Science and Culture (No. 56540270).

Properties of Magnesium Oxides Prepared from Various Salts and Their Catalytic Activity in 1-Butene Isomerization

Tsuneo MATSUDA,* Jun TANABE, Nobuatsu HAYASHI, Yoh SASAKI, Hiroshi MIURA, and Kazuo SUGIYAMA

Department of Applied Chemistry, Faculty of Engineering, Saitama University, Saitama 338

(Received August 10, 1981)

The basicity, one-electron donor property, and surface area were examined on the magnesium oxide catalysts prepared from six different kinds of magnesium salts. Magnesium oxide prepared from magnesium nitrate, oxalate, and acetate exhibited strong basicity and relatively large surface area and, on the other hand, MgO prepared from magnesium chloride, carbonate and sulfate had relatively weak basicity and small surface area. Number of one-electron donor centers hardly changed in the variety of magnesium oxides, except the one prepared from magnesium chloride. Magnesium oxide prepared from chloride showed both the lowest basicity with less strength than $H_-=15.0$ and surface area in the six kinds of catalysts. In order to examine the influence of remaining anions in MgO a variety of catalysts were prepared by the addition of ammonium chloride, sulfate, and carbonate, respectively in MgO prepared from the nitrate. Ammonium chloride brought the greatest influence on the basicity, one-electron donor property, and surface area. Thus the remaining chloride ion greatly affected such properties as cited above. Sodium nitrite which decomposes at higher temperature than 320 °C was added to the magnesium oxides for the examination of the effect of the sodium cation. The amount of the basicity with a moderate strength ($H_-=15.0$—22.3) increased by the addition of $NaNO_2$. This was ascribed to the formation of the moderate strength of basicity by the interaction of Na_2O, one of the decomposed products of $NaNO_2$ and MgO. Isomerization of 1-butene was carried out on the six kinds of catalysts at 30 °C. The magnesium oxides prepared from nitrate, oxalate, and acetate salts (group A) exhibited isomerization activity and the ones from chloride, sulfate, and carbonate (group B) did not entirely. The isomerization activity could be correlated with the stronger basicity than $H_-=22.3$. Temperature pregrammed desorption curves of acetic acid adsorbed on the catalysts indicated two peaks at around 350 and 420 °C in group A catalysts and only one at 350 °C in group B. The desorbed peak at around 420 °C was assigned to the adsorbed acetic acid on the stronger basic sites than $H_-=22.3$.

It is well known that magnesium oxide is characterized by extremely strong basicity[1-3] and one-electron donor property.[4] Kijenski and Malinowski[5,6] reported that magnesium oxide prepared from magnesium nitrate exhibited such strong basicity as $H_-=33.0$ and that magnesium oxide doped with sodium vapor had further stronger basicity than $H_-=35.0$. Accordingly we examined at first the basicity of magnesium oxide prepared from basic magnesium carbonate, on which sodium vapor was doped as a trace experiment of Kijenski and Malinowski. The results, however, did not entirely show stronger basicity than $H_-=35.0$. Kijenski[7] suggested to us that a trace of remaining carbonate ion in MgO, when it was prepared by from basic magnesium carbonate, would hinder the formation of the stronger basic sites. Consequently, it was considered that the remaining anions, when MgO was prepared from the different magnesium salts, would greatly affect the strength of basicity. On the basis of the consideration basicity, one-electron donor property and surface area of magnesium salts were undertaken to examine in this study. On the six kinds of MgO catalysts isomerization of 1-butene was carried out and their activity was connected with such physico-chemical properties of the catalysts as basicity, one-electron dnor and safaoe area. Temperature progammed desorption (TPD) method of acetic acid adsorbed on the catalysts was also undertaken forthe examination of basicity distribution, as anothermethod from a titration method.

Experimental

Materials. Magnesium oxides were prepared from six different magnesium salts as shown in Table 1. In each of the saturated aqueous solutions of magnesium nitrate, chloride, and sulfate, two times as dilute aqueous ammonia as the concentrated one was gradually added to precipitate magnesium hydroxide. The precipitates were washed well with distilled water; 5 times in the case of nitrate, 11 times in chloride, and 8 times in sulfate, respectively. Thus even by

Table 1. Basicity, number of one-electron donor centers, and specific surface area of MgO prepared from six different magnesium salts

Magnesium salts	Basicity H_-/mmol g^{-1}						Number of one-electron donor centers	Surface area
	9.3—15.0	15.0—17.2	17.2—22.3	22.3—27.0	27.0—33.0	Total	spins g^{-1} × 10^{18}	m^2 g^{-1}
$Mg(NO_3)_2$	0.08	0.01	0.04	0.05	0.03	0.21	1.8	85.7
$MgSO_4$	0.18	0.01	0.01	—	—	0.20	2.1	86.3
$MgCl_2$	0.04	trace	—	—	—	0.04	0.047	19.0
$MgCO_3$-$Mg(OH)_2$	0.02	0.11	—	—	—	0.13	1.8	59.4
MgC_2O_4	0.03	0.12	0.03	0.04	0.03	0.25	1.2	140
$Mg(CH_3COO)_2$	0.04	0.03	0.03	0.03	0.02	0.15	2.1	117

washing with water so well every trace of anion could not be eliminated in every case. Magnesium acetate was dissolved in 6 mol dm^{-3} acetic acid solution, in which the aqueous ammonia of the same concentration as that indicated above was added to precipitate magnesium hydroxide. The precipitate was also washed 5 times with the distilled water All precipitates described above were dried at 120 °C for 12 h and then calcined at 550 °C for 20 h in air. Both magnesium oxalate and basic magnesium carbonate were decomposed to MgO at 550 °C for 20 h in air. Thus prepared samples were analyzed by X-ray diffraction (Rigaku Denki DS type, target Cu $K\alpha$) and could be confirmed to be MgO, and designated as MgO–N (MgO prepared from magnesium nitrate), MgO–Cl (from chloride), MgO–S (from sulfate), MgO–C (from basic carbonate), MgO–O (from oxalate), and MgO–A (from acetate), respectively. Additional compounds of anions and $NaNO_2$ in MgO were prepared as folows; $Mg(OH)_2$ prepared from magnesium nitrate according to the method described above was impregnated in the solutions of ammonium chloride, sulfate, and carbonate, respectively and then evaporated to dryness on the water bath. Thus prepared $Mg(OH)_2$ containing anions was also decomposed at 550 °C for 20 h in air. Sodium nitrite was mixed with MgO and then their mixture was calcined at 400 °C for 2 h under evacuation.

Measurement of Basicity and One-electron Donor Centers. Before the measurements, MgO catalysts were treated at 400 °C for 2 h in a vacuum. The basicity of the catalysts was determined by the titration method with the solution of benzoic acid in benzene (0.05 mol dm^{-3}) in the presence of appropriate Hammett indicatores. The following was applied as basicity indicators;[3,4] phenolphalein ($H_-=9.3$), 2,4-dinitroaniline ($H_-=15.0$), 4-chloro-2-nitroaniline ($H_-=17.2$), aniline ($H_-=27.0$), and triphenylmethane ($H_-=33.0$). By the way the basicity of MgO treated at 500 °C for 2 h in a vacuum showed nearly the same values as the one treated at 400 °C. This agreed with the results of the report of Kijenski that the basicity hardly changed by heat-treatment at the temperature of less than 500 °C.[7] The number of one-electron donor centers was determined by the mesurement of concentration of the anion radical formed by tetracyanoethylene adsorption (in benzene solution) on MgO surface. ESR spectrometer in X-band (Varian E-Line Modulation 100 KHz) was used to record the signal of the resulting radical at room temperature. Spin concentrations were determined by comparison of the area obtained by double integration of the first derivative curves for the sample and for a standard of 2,2-diphenyl-1-picrylhydrazyl benzene solution.

All the reagents used in this study were special grade from Wako Junyaku Co. and used without further purification except benzene and benzoic acid. Benzene and benzoic acid were purified by rectification after reflux in the presence of molecular sieve and recrystallization from water, respectively.

1-Butene Isomerization. 1-Butene isomerization was carried out at 30 °C in a closed system with a volume of 181 cm^3 which was directly connected to a gas chromatograph. The catalysts were evacuated at 500 °C for 2 h before the reaction. Reaction products were analyzed by gas chromatograph equipped with a thermal conductivity detector at 0 °C. The column consisted of 4 m long stainless steel tube (2 mm i.d.) packed with VZ-7. The reaction products released from the system were detected time dependently. The amount of 1-butene fed in the reactor was usually 2.97 mmol and catalysts used was 0.1 g.

TPD of Adsorbed Acetic Acid. TPD of adsorbed acetic acid on MgO consisted of a step-wise heating procedure (5 °C min^{-1}) under flowing N_2 (30 cm^3 min^{-1}). The catalyst (0.2 g) was heated at 550 °C for 2 h under vacuum before adsorption of acetic acid at 35 °C for 30 min. Desorbed compounds were detected by gas chromatograph equipped with the column packed with SiO_2 sand.

Results

Basicity and One-electron Donor Centers of Six Kinds of MgO. The basicity, number of one-electron donor centers and specific surface area of magnesium oxides were summarized in Table 1. The MgO–N, MgO–O, and MgO–A (group A) showed stronger basicity than $H_-=22.3$, but MgO–Cl, MgO–S, and MgO–C (group B) showed a weaker one than that value. However, one could not find stronger basicity than $H_-=35$ in the former catalysts. The MgO–O exhibited both the highest basicity and surface area, and in group B, basicity and surface area of MgO–Cl were the lowest. In the catalysts of group B a trace of anion can be considered to be left. Thus a trace of remaining anions, especially chloride ion, greatly affects basicity and surface area towards the decrease of their values. Number of one-electron donor centers was not almost concerned with the remaining ions except chlorine and was nearly constant.

Additional Effects of Anions and $NaNO_2$. The influences of anions were further examined by the addition of ammonium chloride, sulfate, and carbonate in MgO–N as a standard, since this had a broad distribution of basicity. As shown in Table 2 a large influence

a) Added amount of $NaNO_2$ is 0.9 mmol/g-MgO.

of chloride ion could also be detected in this case. By addition of only 0.12 mmol as chloride ion per gram of MgO the stronger basic sites than $H_-=17.2$ rapidly diminished. The influences of other ions as sulfate and carbonate were not so remarkable as those of the chloride ion, but stronger basic sites decreased to a large extent in all ions. On the contrary total basicity increased by addition of ammonium salts. Surface area increased by addition of $(NH_4)_2SO_4$ and decreased by NH_4Cl and hardly changed by $(NH_4)_2CO_3$. The extent of the influence of anions on the surface area was in the order; $Cl^- > SO_4^{2-} > CO_3^{2-}$. It could be also confirmed that the number of one-electron donor centers was hardly changed by the addition of anions.

Instead of anions, cation was added to magnesium oxides to examine its influence on physicochemical properties. The results were summarized in Tables 3 and 4. With increase of the added amount of $NaNO_2$ basicity with a moderate strength ($H_-=15.0$—17.2) increased and total basicity attained a maximum of 0.9 mmol/g MgO of $NaNO_2$ (see Table 3). By addition of $NaNO_2$ into the group B catalysts, strong basic sites which did not exist before addition appeared. Total basicity hardly changed except MgO–N. It was confirmed by titration method that $NaNO_2$ did not exhibit any basicity. When $NaNO_2$ was decomposed in air or under vacuum, a fused solid was obtained. The solid was very hard and deliquesced during grinding in air. Therefore, measurement of the basicity of the decomposed solid did not suceed.

1-Butene Isomerization. Isomerization of 1-butene was carried out on the six kinds of MgO catalysts at 30 °C. The group A catalysts alone exhibited isomerization activity and group B did not entirely. Time dependency of 1-butene conversion was shown in Fig. 1. The slope between 2 and 7 or 8 min in a plot of conversion *vs.* reaction time was taken as an initial rate. The good correlation between the rate and the basicity

stronger than $H_-=22.3$ or 27 per each unit surface area was obtained as shown in Fig. 2.

TPD Measurement. With the aim of examining the basicity distribution by another method except the titration method, and of comparing the results of both methods TPD was carried out. The typical results are shown in Figs. 3(a) and (b). Group A catalysts exhibited two desorbed peaks at near 350 and 420 °C, repectively (Fig. 3(a)). Group B which was inactive for the isomerization exhibited only a peak at 350 °C (Fig. 3(b)). The TPD curve of the catalyst prepared by addition of NH_4Cl in MgO–N was entirely similar to that of Fig. 3(b). It could be demonstrated that the desorbed peak at higher temperature was diminished by the chloride ion left in MgO. By the TPD method a detailed basicity distribution could not be obtained, but a broad one.

Discussion

Basicity nad One-electron Donor Centers of Six Kinds of MgO, Additional Effects of Anions and $NaNO_2$. It is obvious from the results in Tables 1 and 2 that the remaining anions during the preparation of MgO remarkably affect the basicity, one-electron donor centers (only in the case of Cl^-) and surface area. The added ammonium salts decompose evolving gases[8] by heating at 550 °C. In the decomposition of ammonium chloride both NH_3 and HCl are evolved. The strong acid, HCl will interact with MgO to shrink MgO, reducing its basicity and surface area. Chloride ion in HCl probably sinters MgO particles to reduce surface area, as it is known that Cl^- sinters UO_2 particle.[9] The effect of NH_3 would be much smaller than Cl^- in this case. Ammonium sulfate and carbonate decompose as follows:[8]

$$(NH_4)_2CO_3 \longrightarrow 2NH_3 + CO_2 + H_2O,$$

$$(NH_4)_2SO_4 \longrightarrow NH_3 + (NH_4)HSO_4.$$

As the effect of NH_3 seems to be stronger than that of CO_2 or $(NH_4)HSO_4$, more basic sites are produced than acidic sites. The increase of surface area by addition of ammonium sulfate is not due to NH_3, but to sulfate ion, because it was not found in the case of ammonium carbonate.

The basic center is considered mainly to consist of surface O^{2-}.[10,11] Chloride ion added will reduce the electron density of surface O^{2-} by its large electron negativity, leading to the decrease in basicity of MgO. One-electron donor centers consist of anion vacancies in MgO, in which free electron enters.[11,14] Cordischi *et al.*,[15] however, proposed a model of the electron donor surface site consisting of dual site (O^{2-}_{cus}, OH^-), where O^{2-}_{cus}, indicates O^{2-}_{cus} ions in a coordinatively unsaturated site. Thus the accurate structure of one-electron donor centers is still obscure. In either case chloride ions existing in MgO will also attract electron by strong electron affinity, reducing the number of one-electron donor centers. The effect of both sulfate and carbonate ions with weak electron affinity hardly affect the electron donor property. This also agrees with the results in the literature.[15] Both sulfate and carbonate ions do not affect one-electron donor property, as already described, but certainly do the strong basicity, (see Tables 1 and 2) *i.e.*, both affect only the strong basic site to reduce the strength. The strong basic sites ($>H_-=17.2$ or 22.3) will be high in charge density, onto which electrons will easily transfer. Therefore the sites might be affected even by weaker ions such sulfate and carbonate, or one could consider that both ions occlude the strong basic sites. That MgO–S, MgO–C, and MgO added with $(NH_4)_2SO_4$ or $(NH_4)_2CO_3$ had larger surface area than MgO–Cl might be associated with less sintering effect of both ions than Cl^-. Rather larger surface areas of MgO–O and MgO–A might be due to the evolving gases in the decomposition of organic radicals in magnesium salts. Thus, this study provides usuful indications of suitable methods for preparing magnesium oxide having the most favorable catalytic and surface properties.

Sodium nitride decomposes according to the following reaction at more than 320 °C.[16]

$$2NaNO_2 \longrightarrow Na_2O + N_2O_3(=NO+NO_2)$$

and a mechanical mixture or interacted products between them will be formed. By addition of $NaNO_2$ the concentration of the moderate basicity increased, but further addition caused a decrease of the strong basicity, as shown in Table 3. These indicate that Na_2O interacts with the strong basic sites in MgO to reduce the basicity, resulting in the increase of the moderate strength by the increment of Na_2O. Additional details of the interaction of $NaNO_2$ cannot be provided at present, but will be further studied in the future.

1-Butene Isomerization and TPD. As shown in Fig. 2 a good correlation of the initial rate with the stronger basicity than $H_-=22.3$ or 27 indicates that 1-butene isomerization proceeds on such strong basic sites. Therefore the isomerization is inactive on the group B catalysts existing only on weak basic sites. This fact agrees with the results of isomerization of 1-pentene on MgO doped with metalic sodium,[6] requiring stronger basic sites than $H_-=35$. By the reactivity of 1-butene and pentene the isomerization of the former would occur on the weaker basic sites than those in the case of the latter. The reaction mechanism of 1-butene isomerization will be started with proton abstration from the alkene molecule by the stronger

basic site than $H_-=22.3$. Therefore a mechanism similar to that proposed by Pines and Schaap[17] can also hold in this case. As a result an allyl-type carbanion as an intermediate would be formed:

$$CH_2=CH-CH_2-CH_3 + O^{2-} \longrightarrow \underset{\ominus}{CH_2-CH-CH-CH_3} + OH^-,$$

where O^{2-} indicates the basic site. With back donation of one proton from OH^- the intermediate would transform into 2-butene.

$$\underset{\ominus}{CH_2-CH-CH-CH_3} + OH^- \longrightarrow CH_2-CH=CH-CH_3 + O^{2-},$$

It was concluded by Kijenski and Malinowski that the one-electron donor center was independent from the basic site.[6] Cordischi and Indovina reported that there existed a parallelism between basic and one-electron donor properties.[18] In either case the catalytic activity of alkene isomerization and cumene dehydrogenation was unambiguously associated with the one-electron donor center.[6] The center will similarly attract a proton from 1-butene to proceed the reaction, probably in the same way as indicated by Kijenski and Malinowski.[6] As suggested by this study, however, isomerization mainly proceeds on the strong basic sites already described.

The ratio of *cis* to *trans* isomers was rather low in comparison with such a value of 18, as indicated by Tanabe *et al.*[2] This difference might be either due to the concecutive reaction from *cis* to *trans*, as the conversion of 1-butene was so high, or to the thermodynamical stability of *trans* isomer.

TPD curve of the group A catalysts is characterized by two desorption peaks of 350 and 420 °C as shown in Fig. 3(a). The desorption peak at high temperature corresponds to the stronger basicity than $H_-=22.3$ or 27 in comparison with the results of 1-butene isomerization. It should be noted that TPD of adsorbed acetic acid can provide a suitable method to detect the existence of the basicity stronger than $H_-=22.3$. By the way the TPD of adsorbed CO_2 and gaseous HCl did not succeed, because no desorption peak appeared upto 550 °C, but that of magnesium acetate exhibited similar behavior as in Fig. 3(b). Consequently magnesium acetate by adsorption of acetic acid was not formed, which was also confirmed by X-ray analysis. Detailed basicity distribution may be obtained by the TPD method of other acidic compounds adsorbed.

Phase Transitions in Tetramethylammonium Hexachloroplatinate(IV), -tellurate(IV), and -stannate(IV) as Studied by ^{35}Cl NQR and Powder X-Ray Diffraction

Yoshihiro FURUKAWA,* Laxman S. PRABHUMIRASHI,† Ryuichi IKEDA, and Daiyu NAKAMURA

Department of Chemistry, Faculty of Science, Nagoya University, Chikusa-ku, Nagoya 464

(Received August 15, 1981)

The ^{35}Cl NQR spectra of $[(CH_3)_4N]_2PtCl_6$, $[(CH_3)_4N]_2TeCl_6$, and $[(CH_3)_4N]_2SnCl_6$ were recorded in a temperature range between 77 and *ca.* 350 K. Below room temperature, the temperature dependence measurements of NQR frequencies for all of these complexes confirmed the presence of structural phase transitions reported very recently. From the experiments of DTA carried out above room temperature, structural phase transitions were located at 385, 351, and 365 K in the same order of the above complexes. The X-ray powder patterns taken in the highest-temperature phase of these complexes (at *ca.* 390 K) were well interpreted as arising from the K_2PtCl_6-type cubic structure with the lattice constant $a_0 = 12.82_8$, 13.05_3, and 12.97_5 Å for the Pt, Te, and Sn complexes, respectively. In this phase of each complex, however, no NQR spectra were observed. The mechanism of the phase transitions detected is discussed in connection with the structure of these complexes.

Recently, tetramethylammonium hexahalometallates(IV), $(tetMA)_2MX_6$, have been extensively studied because of their interesting phase transitions observed at low temperatures.[1-5] In our previous paper,[6] we reported the accurate transition temperatures of $(tetMA)_2PtCl_6$, $(tetMA)_2TeCl_6$, and $(tetMA)_2SnCl_6$ determined from the experiments of differential thermal analysis (DTA) and of proton spin-lattice relaxation time (T_1) carried out below room temperature. However, the nature of these phase transitions is still unclear.

Berg and Søtofte[7] reinvestigated the room-temperature structure of $(tetMA)_2PtCl_6$ by using a single crystal X-ray diffraction method, and found that the structure could be approximately described in the cubic system belonging to the space group Fm3m. In a subsequent paper,[8] Berg and Nielsen also studied the room-temperature structure of $(tetMA)_2TeBr_6$ and found that the complex forms cubic crystals in the space group Fd3c. Based on this new result, they indicated in their paper that the room-temperature structure of $(tetMA)_2PtCl_6$ might be the same because some weak Fm3m-forbidden reflections had been detected in the previous X-ray study. In fact, Mackenzie *et al.*[9] found, very recently, from the neutron powder diffraction study of $[N(CD_3)_4]_2PtCl_6$ that the compound also forms Fd3c crystals. The three hexachlorometallates(IV) described above are known to have the room-temperature crystal structure being isomorphous with each other.[10,11] For these complexes, therefore, a phase transition from the Fd3c structure to the simple Fm3m one may be expected to take place at a higher temperature. The present investigation of ^{35}Cl NQR in these hexachlorometallates(IV) has been undertaken to clarify the nature of the phase transitions already located at lower temperatures, and also to detect another phase transition possibly existing at higher temperature.

† Present address: Chemistry Department, Poona University, Pune 411007, India.

Experimental

The NQR spectra of ^{35}Cl were observed by means of a modified Dean-type super-regenerative spectrometer already described.[12] A chromel-alumel thermocouple was used for the determination of temperature. Observed temperatures were estimated to be accurate within ±1 K. The measurements of DTA were carried out by use of a home-made apparatus.[13] X-Ray powder patterns were taken by means of a Model D-3F diffractometer from Rigaku Denki Co. equipped with a copper anode. A goniometer was calibrated with the standard sample of silicon.

All the sample employed in the present investigation were the same as those prepared in the previous NMR and DTA experiments.[6]

Results and Discussion

Temperature Dependence of ^{35}Cl NQR Frequencies. Figure 1 shows the temperature dependence of ^{35}Cl NQR frequencies in $(tetMA)_2PtCl_6$, $(tetMA)_2TeCl_6$, and $(tetMA)_2SnCl_6$. The resonance frequencies of these complexes determined at various temperatures are listed in Table 1.

At room temperature, a single ^{35}Cl NQR frequency was observed for $(tetMA)_2PtCl_6$ indicating that all the chlorine atoms are crystallographically equivalent in

TABLE 1. ^{35}Cl NQR FREQUENCIES IN $(tetMA)_2PtCl_6$, $(tetMA)_2TeCl_6$, AND $(tetMA)_2SnCl_6$

			17.51±0.05

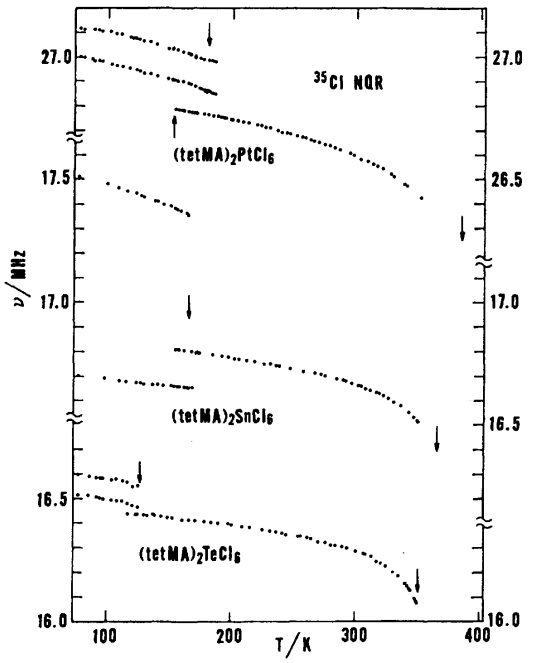

Fig. 1. Temperature dependence of ^{35}Cl NQR frequencies observed for $(tetMA)_2PtCl_6$, $(tetMA)_2TeCl_6$, and $(tetMA)_2SnCl_6$. Arrows indicate T_{tr} determined by the experiments of DTA.[6]

the crystal. With decreasing temperature, it was noticed that the resonance line became suddenly weak at 181 K. On further cooling, two very broad signals appeared at 178 K on the high-frequency side of the weak line labelled as **a**. These experimental facts indicate that $(tetMA)_2PtCl_6$ undergoes a structural phase transition at 181 K in good agreement with the previous DTA experiments.[6] In the temperature range between 181 and 178 K, only the weakened **a** line could be detected. This is presumably because the two new lines appearing at 178 K are too broad to be detected immediately below the transition temperature, T_{tr}. The two broad lines, the lower-frequency one (denoted as **b**) of which was about twice stronger than the higher-frequency one (**c**), could be observed continuously down to 77 K. However, the **a** line gradually weakened with decreasing temperature and disappeared in the noise level at 153 K, which agreed well with the second T_{tr} determined from the measurements of DTA.[6] The fact that three and two NQR lines were observed above and below the lower T_{tr}, respectively, indicates that the phase transition at 153 K is also a structural one. As in the previous paper,[6] we call the three phases determined below room temperature as α, β, and γ in the order of decreasing temperature. The above NQR results indicate that there exist at least three and two nonequivalent chlorine atoms in the β and γ phases, respectively. It is interesting to note that no discontinuity can be seen in the temperature dependence of the **a** line and also of the **b** and **c** lines at $T_{tr}(\alpha\rightarrow\beta)$ and $T_{tr}(\beta\rightarrow\gamma)$, respectively.

When the sample of $(tetMA)_2PtCl_6$ was warmed from 77 K, the **b** and **c** lines followed exactly the same temperature dependence curves obtained on the cooling run. Although both lines became weak above *ca.* 180 K, they could be recorded up to *ca.* 190 K which is higher by *ca.* 10 K than $T_{tr}(\alpha\rightarrow\beta)$. On the other hand, the **a** line did not appear at $T_{tr}(\beta\rightarrow\gamma)$ but it became detectable again at 181 K which agreed well with $T_{tr}(\alpha\rightarrow\beta)$. These experimental facts indicate that, when the sample was heated from 77 K, no phase transition takes place at $T_{tr}(\beta\rightarrow\gamma)$ and both phases α and β may coexist in a narrow range of temperature above 181 K.

It is known from the previous DTA experiments[6] that, on heating $(tetMA)_2PtCl_6$ from a temperature below 107 K, heat anomaly corresponding to the phase transition $\beta\rightarrow\gamma$ disappears, but it reversibly appears unless the sample is once cooled down below 107 K. In the present NQR experiments, the same behavior in the temperature dependence of the NQR frequencies was observed, *i.e.*, the **a** line appeared at 153 K $[T_{tr}(\beta\rightarrow\gamma)]$ on heating the sample which was once cooled down to a temperature not lower than 107 K. This suggests that the phase obtained by cooling the sample to 77 K is different from that existing between 153 and 107 K when the sample was cooled and warmed to and from, respectively, a temperature above 107 K.

Although no heat anomaly could be detected below $T_{tr}(\beta\rightarrow\gamma)$ on both cooling and warming runs, we call the phase obtained by cooling $(tetMA)_2PtCl_6$ to 77 K as δ as was defined in the previous paper.[6] The reason why no heat anomaly corresponding to the phase transitions $\gamma\rightleftarrows\delta$ was observed is considered as that the transition $\gamma\rightarrow\delta$ may take place very gradually as already suggested by Berg,[5] and δ transforms directly into β or α at 181 K. The latter statement means that δ is the stable phase at lower temperatures than 181 K. In the T_1 experiments,[6] two phases γ and δ are clearly distinguishable from one another. However, they are almost indistinguishable in the present NQR experiments. Accordingly, it is thought that the change of the orientation of $tetMA^+$ cations in the crystal or the change of the orientation of methyl groups in a cation may be responsible for the transition $\gamma\rightarrow\delta$. Both changes of the orientations of the cations in the crystal of $(tetMA)_2PtCl_6$ are considered to give only minor influence on the electric field gradient of resonant chlorine nuclei (possibly a change in the NQR linewidth) because $tetMA^+$ is highly symmetric.

With increasing temperature above $T_{tr}(\delta\rightarrow\alpha)$, the frequency of the **a** line decreased quite normally and faded out in the noise level at *ca.* 350 K, indicating the absence of phase transition up to this temperature.

At room temperature, $(tetMA)_2TeCl_6$ yielded a single ^{35}Cl NQR line.[11] With decreasing temperature, the line became gradually weak from *ca.* 150 K and finally disappeared at 117 K. On cooling further, no resonance was observed until two broad signals appeared at 106 K. The two signals became gradually strong with decreasing temperature and could be detected down to 77 K. When $(tetMA)_2TeCl_6$ was heated from 77 K, on the other hand, the doublet lines could be observed up to 128 K, above which temperature a single line was observed at the same frequency as that detected on the cooling run. These experimental facts indicate that $(tetMA)_2TeCl_6$ undergoes a first-order structural phase

transition at 128 K in agreement with the previous DTA and NMR results,[6] and that all chlorine atoms are equivalent in the crystal of the high-temperature phase whereas two nonequivalent chlorine atoms exist in the low-temperature phase crystal.

With increasing the temperature above room temperature, the frequency of the single line of $(tetMA)_2TeCl_6$ decreased unusually before it weakened and disappeared at *ca.* 350 K. This observation suggested the occurrence of another phase transition at a temperature immediately above 350 K.

For $(tetMA)_2SnCl_6$, a structural phase transition showing a thermal hysteresis was located at 168 K from the measurements of the temperature dependence of ^{35}Cl NQR frequencies. The results agree with those of the previous DTA experiments.[6] In the low-temperature phase, two largely separated very broad signals, the lower-frequency one of which was stronger, were observed suggesting that the crystalline lattice of $(tetMA)_2SnCl_6$ undergoes a tetragonal distortion below T_{tr}. With increasing temperature, the frequency of the high-temperature line decreased rather rapidly and the line disappeared at *ca.* 350 K.

DTA above Room Temperature. To locate another high-temperature phase transition expected for the present complexes from the temperature dependence measurements of ^{35}Cl NQR frequencies, we carried out DTA experiments above room temperature. The results were that thermal anomalies indicating the presence of phase transitions were found at 385, 351, and 365 K for the Pt, Te, and Sn complexes, respectively. Hereafter, the highest-temperature phase of these complexes is denoted as α'. It is worthwhile to note here that no ^{35}Cl NQR spectra were observed in the α' phase of these complexes although signals were searched carefully above T_{tr}.

Powder X-Ray Diffraction. The present study has revealed the presence of the high-temperature phase for the three hexachloro complexes. Therefore, we took X-ray powder patterns at various temperatures in order to obtain detailed information on the structure of the complexes in their high-temperature phase as well as on their room-temperature structure.

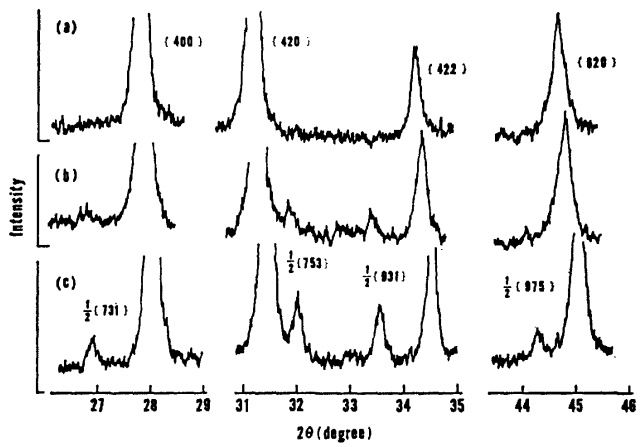

Fig. 2. X-Ray powder patterns of $(tetMA)_2PtCl_6$ taken at (a) *ca.* 400 K, (b) *ca.* 370 K, and (c) *ca.* 300 K. Indices are referred to the Fm3m unit cell.

The diffraction patterns (below $2\theta=60°$) of $(tetMA)_2PtCl_6$ recorded at room temperature could be attributed to the Fm3m cubic lattice with $a_0=12.73_1$ Å, in agreement with the results of Berg and Søtofte.[7] However, there remained four unassignable weak diffraction lines, the *d*-spacing values of which were 3.32_0, 2.79_5, 2.67_1, and 2.04_4 Å (see Fig. 2). These four reflections cannot be indexed by any Fm3m-allowed sets of integers along with $a_0=12.73_1$ Å. If we take a large cubic unit cell consisting of eight Fm3m units, however, the four reflections can be indexed by the following Miller indices, {731}, {753}, {931}, and {975} in the order of the above *d*-spacing values.

Berg and Nielsen reported that $(tetMA)_2TeBr_6$ has approximately the Fm3m structure but exactly it forms cubic crystals belonging to the space group Fd3c with $a_0=26.563$ Å and $Z=32$. The large unit cell is formed by doubling each edge of the Fm3m unit and, therefore, includes eight Fm3m units. Even in this structure, all the bromine atoms are crystallographically equivalent in agreement with the earlier NQR results.[14] Moreover, it is of interest to note that the Fm3m-forbidden reflections observed for $(tetMA)_2PtCl_6$ are allowed for the Fd3c system and are interpreted well. Accordingly, it can be concluded that, at room temperature, $(tetMA)_2PtCl_6$ forms cubic crystals belonging to the space group Fd3c with $a_0=25.46_2$ Å and $Z=32$. Very recently, Mackenzie *et al.* showed that $[N(CD_3)_4]_2PtCl_6$ also forms Fd3c cubic crystals at room temperature.[9] The diffraction patterns of $(tetMA)_2TeCl_6$ and $(tetMA)_2SnCl_6$ could be well described in the Fd3c cubic system with a_0 being 25.86_8 and 25.73_6 Å, respectively.

The diffraction patterns of the complexes studied were recorded at various temperatures above room temperature as shown in Fig. 2 for $(tetMA)_2PtCl_6$. When the temperature was raised, the Fm3m-forbidden reflections became weak and finally disappeared from the patterns taken in the α' phase of the complex. Therefore, the patterns of α'-$(tetMA)_2PtCl_6$ are completely interpreted in terms of the Fm3m lattice with a_0 being 12.82_8 Å at *ca.* 388 K. Similarly, the Fm3m lattice constant a_0 of α'-$(tetMA)_2TeCl_6$ and α'-$(tetMA)_2SnCl_6$ were determined as 13.05_3 Å at *ca.* 394 K and 12.97_5 at *ca.* 389 K, respectively. The lattice constants determined in the present study are estimated to be accurate to 0.010 Å.

This work was supported in part by a Grant-in-Aid for Scientific Research No. 543006 from the Japanese Ministry of Education, Science and Culture. One of the authors (L. S. P.) wishes to express his sincere thanks to the Japanese Ministry of Education, Science and Culture for the award of a research fellowship 1979—1980. He is also grateful to the Poona University authorities for granting him study leave to take up the present research work.

Vibrational Spectra and Normal Coordinate Calculations for Trimethylstannane

Yoshika IMAI* and Koyo AIDA

Department of Engineering Science, Faculty of Engineering, Tohoku University, Sendai 980

(Received October 14, 1981)

The infrared and Raman spectra of trimethylstannane and its deuterated analogues were obtained. Assignments for all the fundamentals except internal torsions were made and normal coordinate calculations were carried out to confirm the proposed assignments.

Our previous studies[1,2] have concerned with the reexamination of the vibrational spectra for $(CH_3)_3MH$ (M=Si, Ge). This work extends the studies to trimethylstannane. The vibrational spectra of trimethylstannane have been reported by previous authors,[3,4] but there are some discrepancies in the vibrational assignments. For example, Dillard and May[3] have assigned an infrared band at *ca.* 670 cm^{-1} for $(CH_3)_3SnH$ to the SnH bending vibration, while Kriegsmann and Pischtschan[4] have assigned a band at *ca.* 540 cm^{-1} to this vibration.

Kriegsmann and Pischtschan have calculated the force constants, assuming the methyl groups as a point mass. Our previous studies revealed that for trimethylsilane and trimethylgermane the methyl rocking, the MH bending, and the degenerate MC_3 stretching vibrations are fairly strongly coupled with one another. Since a similar vibrational coupling will be encountered in the case of the present compound, it seems inadequate to make the calculation by assuming that the methyl groups is a point mass.

In this paper we will report the vibrational spectra of trimethylstannane including its three deuterated analogues and the results on normal coordinate calculations without assuming the methyl groups as a point mass.

Experimental

Trimethylstannane and its deuterated analogues were prepared by reacting $(CH_3)_3SnCl$ or $(CD_3)_3SnCl$ with $LiAlH_4$ or $LiAlD_4$ in dibutyl ether. The crude compounds were purified by trap-to-trap fractionations by using a conventional vacuum line. The purity of the compounds was checked by their gas-phase infrared spectra. $(CH_3)_3SnCl$ and $(CD_3)_3SnCl$ were prepared by the reaction of $SnCl_4$ with $(CH_3)_4Sn$ and $(CD_3)_4Sn$, respectively. $(CH_3)_4Sn$ and $(CD_3)_4Sn$ were prepared by reacting $SnCl_4$ with $(CH_3)_2Zn$ and $(CD_3)_2Zn$, respectively, in sealed glass tubes and purified by trap-to-trap fractionations under vacuum. Dimethylzinc and its deuterated analogue were prepared by a method described in the literature.[5]

The infrared spectra were recorded on a Hitachi 345 spectrophotometer (4000—300 cm^{-1}) and on a Hitachi FIS-III spectrophotometer (400—30 cm^{-1}) in the gas phase and in the solid state at liquid nitrogen temperature.

Raman spectra were recorded on a JEOL-JRS-Sl Raman spectrophotometer equipped with a 50 mW NEC GLG 5800 He-Ne laser in the liquid state. Qualitative polarizations were also obtained.

Results and Vibrational Assignments

Since each methyl group of trimethylstannane is staggered with respect to the Sn–H bond,[6] the molecule has a C_{3v} molecular symmetry. Under this symmetry, its normal vibrations distribute as $8A_1+4A_2+12E$, where the A_1 and E modes are infrared and Raman active while the A_2 mode is inactive in both. Symmetry coordinates have been classified, according to the description of the modes, as given in Table 1, where the numbering of the symmetry coordinates is the same as those for the corresponding coordinates for trimethylsilane[1] and trimethylgermane.[2] Infrared spectra of trimethylstannane and its deuterated analogues in the gas phase are shown in Fig. 1. The Raman spectra

in the liquid are shown in Fig. 2. Observed fundamental frequencies are listed in Tables 2—4.

The asymmetric and symmetric CH_3 stretches were observed at *ca.* 2980 and *ca.* 2900 cm^{-1}, respectively, for $(CH_3)_3SnH$ and $(CH_3)_3SnD$. For $(CD_3)_3SnH$ and $(CD_3)_3SnD$, these modes were observed at *ca.* 2240 and *ca.* 2120 cm^{-1}.

Polarized Raman bands at *ca.* 1850 cm^{-1} for $(CH_3)_3SnH$ and $(CD_3)_3SnH$ are assigned to the SnH stretching vibration. Upon deuteration of the SnH group, these bands shift to *ca.* 1300 cm^{-1} for $(CH_3)_3SnD$ and $(CD_3)_3SnD$. The corresponding infrared band of each compound in the gas phase has a definite PQR band contour.

Weak infrared bands at *ca.* 1400 cm^{-1} for $(CH_3)_3SnH$ and $(CH_3)_3SnD$ are assigned to the asymmetric methyl deformation. The corresponding Raman bands are

SnH and $(CD_3)_3SnD$ upon deuteration of the methyl groups.

Three methyl rocking, two SnC_3 stretching and one SnH or SnD bending vibrations are expected to appear in the region 900—300 cm^{-1}. Raman bands at *ca.* 510 cm^{-1} for $(CH_3)_3SnH$ and $(CH_3)_3SnD$ are strong and polarized. Upon deuteration of the methyl groups these bands shift to *ca.* 480 cm^{-1} for $(CD_3)_3SnH$ and $(CD_3)_3SnD$. Therefore, they are evidently assigned to the A_1 SnC_3 stretching mode. The infrared band due to this mode is weak and could not be observed in the gas phase owing to the obscuration of strong neighbouring bands. However, in the solid state this is clearly observed as a sharp band for each isotopic analogue except for $(CH_3)_3SnH$. For $(CH_3)_3SnH$ three bands were observed at 547, 521, and 512 cm^{-1} in the solid infrared spectrum. The 512 cm^{-1} band is very strong while the 547 cm^{-1} and the 521 cm^{-1} bands are weak and the 521 cm^{-1} band is observed as a shoulder of the 512 cm^{-1} band. Considering its frequency and intensity, we assigned the shoulder to the A_1 SnC_3 stretching mode. Of the 547 cm^{-1} and the 512 cm^{-1} bands, one band should be due to the SnH bending mode and another due to the E SnC_3 stretching mode. Dillard and May have assigned an infrared band at *ca.* 670 cm^{-1} for $(CH_3)_3SnH$ to the SnH bedning mode. We also observed the very weak band at the same position. However, since its intensity was decreased by repeating purification of the compound, it was concluded that this band is due to some other species than trimethylstannane. For $(CH_3)_3SnD$ two bands at *ca.* 530 and *ca.* 390 cm^{-1} were assigned to the E SnC_3 stretching and the SnD bending vibrations, respectively. The 530 cm^{-1} band shifts to *ca.* 490 cm^{-1} for $(CD_3)_3SnH$ and $(CD_3)_3SnD$ upon deuteration of the methyl groups. A strong infrared band at *ca.* 650 cm^{-1} for $(CD_3)_3SnH$ was assigned to the SnH bending, since no corresponding band was observed in the same region for $(CD_3)_3SnD$.

Since the A_1 methyl rocking frequencies are approximately identical with each other for $(CH_3)_3MH$ and $(CH_3)_3MD$ and for $(CD_3)_3MH$ and $(CD_3)_3MD$ (M=Si, Ge),[1,2] we assigned infrared bands at *ca.* 770 cm^{-1} for $(CH_3)_3SnH$ and $(CH_3)_3SnD$, and at *ca.* 480 cm^{-1} for $(CD_3)_3SnH$ and $(CD_3)_3SnD$ to the A_1 methyl rock. For trimethylsilane and trimethylgermane the band due to this mode coincides with that due to one of the E modes. Therefore, it may be considered that the same accidental degeneracy is encountered in trimethylstannane. Assignments of the remaining E modes which appear in the range 900—300 cm^{-1} is impossible without the aid of normal coordinate calculations.

The two skeletal deformation modes should be expected in the region below 300 cm^{-1}. However, only one band is observed in the Raman spectrum for each isotopic compound below 300 cm^{-1}. Since the corresponding infrared band is observed as two closely bands in the solid state and the same modes coincide with each other for $(CH_3)_3SnCF_3$ and $(CD_3)_3SnCF_3$,[7] we assigned bands at *ca.* 150 cm^{-1} for $(CH_3)_3SnH$ and $(CH_3)_3SnD$ and at *ca.* 130 cm^{-1} for $(CD_3)_3SnH$ and $(CD_3)_3SnD$ to the A_1 and E skeletal deformations.

One methyl torsional mode should be expected. However, no band ascribable to this mode was observed in both the infrared and Raman spectra for each isotopic compound.

Normal Coordinate Calculations and Discussion

Normal coordinate calculations were carried out on an ACOS 77/900 computer at the Computer Center,

a) The stretching force constants are given in 10^2 N m^{-1}, the defor mation force constants in 10^{-18} N m rad^{-2}, and the stretching-deformation interaction constants in 10^{-8} N rad^{-1}. The subscript number i in F_i corresponds with that in S_i in Table 1.

Table 7. Comparison of force constants ($10\ N^2\ m^{-1}$)

	f(Sn–C)	f(Sn–H)
$(CH_3)_4Sn$	2.19[10]	
$(CH_3)_3SnH$	2.18[a]	1.99[a]
$(CH_3)_3SnCl$	2.12[4]	
CH_3SnH_3	2.12[11]	2.23[b]
SnH_4		2.27[b]

a) This work. b) The force constant was calculated from the symmetry force constants reported in the earier papers.[11,12]

Tohoku University, by using the interactive least-squares procedure. G-matrix was calculated by use of the structural parameters from the electron-diffraction study[6] and by assuming a tetrahedral angle around carbon atoms; r(Sn–H)=0.1705 nm, r(Sn–C)=0.2147 nm, r(C–H)=0.1086 nm, ∠C–Sn–C=107.5°. The torsional mode of the methyl groups was neglected in the E class.

The least-squares refinement was carried out in the same manner as with the acetonitrile-borane adducts,[8] trimethylsilane,[1] and trimethylgermane.[2] The calculated frequencies have an average error of 0.42% for A_1 vibrations and 0.76% for E vibrations. The sum for the weighted squares of errors $\sum(\lambda_{obsd}-\lambda_{calcd})^2/\lambda_{obsd}$ was 2.0×10^{-3} for A_1 vibrations and 7.7×10^{-3} for E vibrations. The symmetry force constants from the last cycle in the least-squares refinements are given in Table 6, together with their uncertainties.

Potential energy distributions are also given in Tables 1—4. These show that one of the E methyl rocks, the SnH bend, and the SnC_3 stretch in the E class for $(CH_3)_3SnH$ and $(CD_3)_3SnD$ are strongly coupled with each other.

The Sn–C and Sn–H valence force constants derived from the symmetry force constants are compared with those of the related compounds in Table 7. The Sn–C force constants are almost the same in these compounds. However, the Sn–H force constants seem to decrease slightly with increasing the number of methyl groups attached to a tin atom. This trend is quite similar to that found for the Si–H force constants of methylsilanes.[9]

This work was partly supported by a grant from the Asahi Glass Foundation for Industrial Technology to which our thanks are due. One of the authors (Y. I.) wishes to express his thanks to Prof. Fumio Watari, Iwate University, for the computer programs used in calculations.

Thermodynamic Study of NH_4Br and ND_4Br Crystals under Constant High-pressures†

Kazuo WATANABE,** Masaharu OGUNI, Takasuke MATSUO, Hiroshi SUGA,* and Syûzô SEKI***

Department of Chemistry and Chemical Thermodynamics Laboratory, Faculty of Science, Osaka University, Toyonaka, Osaka 560

(Received October 26, 1981)

Heat capacities and volumes of NH_4Br and ND_4Br crystals were measured in the temperature range from 100 to 260 K at several constant pressures up to 110 MPa with a special attention paid to the behaviors around the point of ND_4Br at 66 MPa and 202 K. The experimental results at an atmospheric pressure were in good agreement with the previously reported ones. The δ-γ and δ-β phase transitions were accompanied with expansion of the volume while the γ-β phase transition with contraction. Detailed phase diagram obtained for ND_4Br disclosed that there was no maximum in any branch of the transition lines. The triple point was represented essentially as the point of intersection of the three straight lines. There was no pressure dependence of the total entropy of transition from the δ to β phase. The entropy values can be explained by the mechanism of the order-disorder change in the orientations of NH_4^+ tetrahedra. The existence of the heat capacity anomaly in the high temperature side of the δ-γ phase transition was discussed as due to the spatial fluctuation of domains of the γ and δ phases. An argument was put forward that the observed δ-γ phase transition was probably superheated. An additional anomalous heat-capacity peak was observed just below the triple point pressure in between the temperatures of the δ-γ and γ-β phase transitions, and explained in terms of the effects of the superheating in the δ-γ phase transition and of the coexistence of the δ and γ phases domains in the crystal.

There have been four phases known to exist in the NH_4Br crystal at the atmospheric pressure.[1] They are named α through δ phases in the order of the high to low temperature in respect of the temperature range of their occurrence. As the pressure increases, the temperature range of the stability of the γ phase becomes small and disappears at the triple point pressure of 160 MPa for NH_4Br and 66 MPa for ND_4Br.[1,2]

These phases are distinguished from one another by the differences in the interrelation of orientations of NH_4^+ ions and in the relative positions of the ions.[3] The α phase has the NaCl structure in which NH_4^+ ions are orientationally disordered. The β phase has the CsCl structure with the NH_4^+ ions in the state of disorder between two different orientations in the octahedral crystal field. The structure of the γ phase is in the tetragonal system; adjacent NH_4^+ ions take a parallel orientation along the c axis and an anti-parallel one within the ab plane, and the Br^- ions accordingly shift themselves slightly along the c-axis with concomitant shortening of the N–H···Br hydrogen bonds. The δ phase has the same cubic structure as the β phase, but with NH_4^+ ions in the parallel ordered state in the orientations.

Two different mechanisms, order-disorder in configurational degrees of freedom and displacement of atoms and ions away from the high symmetry sites, are in general considered as basic atomic processes of phase transitions in ionic crystals. In the transitions among the β, γ, and δ phases there are two competing ordering interactions.[4] A direct octupole-octupole interaction between nearest-neighbor NH_4^+ tetrahedra energetically favors a parallel ordering realized in the δ phase, while an indirect interaction of the tetrahedra through the polarizable Br^- ions stabilizes the anti-parallel ordering accompanied by the displacement of the Br^- ions in the γ phase.

We reported construction of an adiabatic calorimeter working under constant high pressures.[5] In the present paper we report calorimetric and volumetric studies of the phase transitions in NH_4Br and ND_4Br crystals performed with this apparatus with special attention paid to the behavior around the triple point of ND_4Br. In general the behavior of a substance around the triple point involving the gaseous, liquid, crystalline phases is determined only by the difference in the magnitudes of the free energies for these phases. The γ-β and δ-β phase transitions in the present crystals have been well known from various experimental techniques to be of the λ type.[6–9] The behavior around such triple points as associated with phase lines of the λ type was expected to be different from that of the gas-liquid-crystal triple points on account of the continuous interrelation among the crystal structures involved.

Experimental

Materials. Crystalline ammonium bromide NH_4Br (Nakarai Chemical Co. Ltd., special reagent) was purified by sublimation at about 140 °C under vacuum. The powder sample obtained was pressed into pellets of 2 cm in diameter and 0.7 cm in thickness for closer packing in the cell. The mass of the sample used was 37.593 g corresponding to 0.38383 mol.

The sample in the calorimeter cell was pressurized through direct contact with pressure medium, 3-methylpentane, for a uniform hydrostatic pressure. This method is applicable if the sample is insoluble in the liquid. The solubility was checked with a spectroscopic method; NH_4Br was first extracted into water phase from the saturated 3-methylpentane solution, and then the ultraviolet spectra of the aqueous solution was compared with those of the aqueous NH_4Br solutions of known concentration. The amount-of-substance fraction of

† Contribution No. 27 from Chemical Thermodynamics Laboratory.

** Present address: Kanzaki Paper Mtg. Co. Ltd., 1-11, Jōkōji-Motomachi, Amagasaki 660.

NH_4Br in the pressure medium was estimated to be less than 10 ppm, indicating that the above method of pressurization caused no serious problem in the heat capacity measurements.

Ammonium-d_4 bromide (ND_4Br) sample was prepared by recrystallizing the purified NH_4Br crystals from deuterium oxide (Nakarai Chemical Co. Ltd., 99.8%) solution three times. Deuterium exchange ratio of the powder sample was found by high resolution ^1H-NMR method to be 99.5%. The calorimeter cell contained 35.418 g (0.34734 mol) of the sample in pellet form. All the procedures of the preparation and handling were carried out in the atmosphere of dry nitrogen gas.

The densities of NH_4Br and ND_4Br crystals at room temperature were calculated from data of the mass and volume of the pellet. The volume was obtained by measuring the pellet sizes with a micrometer.

Calorimetric Procedures. The calorimeter cell was loaded with the sample at room temperature and screwed up at liquid nitrogen temperature for tight sealing. Setting-up of the cell in the cryostat and introduction of 3-methylpentane into the high-pressure system were carried out in the same manner as described already.[5]

A series of heat capacity measurement at several constant pressures was performed in the intermittent heating mode with the temperature step of 2—3 K. The volume of the sample at each temperature and pressure was calculated by using the compressibility and expansivity data of 3-methylpentane given in the previous paper.[5]

Results and Discussion

Heat Capacities at an Atmospheric Pressure. Heat capacity values of NH_4Br and ND_4Br crystals at an atmospheric pressure are shown in Figs. 1 and 2, respectively, together with the previously reported data obtained by using an ordinary adiabatic calorimeters.[10-12] They are in good agreement within the inaccuracy of 1% except at temperatures just around the phase transition points. In view of the adverse circumstances in determining the heat capacity values with the present calorimeter, this agreement would be satisfactory. Evidently, unfavorable factors incurred by the high pressure were overcome in the present apparatus. It is now possible to measure high-pressure heat capacities with almost the same accuracy as with the ordinary adiabatic calorimeter under the atmospheric pressure.

Agreement between the present and previous data is found also in the entropies of the transition as shown in Table 1.[10-12] The difference (up to 8%) would not be significant because the entropy values depend primarily upon choice of the baseline which one has to assume in the wide temperature range of occurrence of the phase transition.

Heat Capacities under Pressures. Figure 3 shows the results of molar heat capacity and molar volume of NH_4Br at 0.101 and 108.0 MPa. The numerical values are collected in Table 2. Application of the pressure increased the δ-γ phase transition temperature from 108.5 K to 170.9 K and decreased the γ-β one from 234.8 K to 216.4 K. The transition temperatures observed at 108.0 MPa are in good accordance with those on the phase diagram reported before.[13,14] The slope of the transition line, dT_{tr}/dp, is 0.578 K MPa^{-1} for the δ-γ phases and -0.171 K MPa^{-1} for the γ-β phases.

Figure 4 shows the molar heat capacity and molar volume of ND_4Br at 0.101, 50.0, and 111.0 MPa in the temperature range of 130 to 260 K. The numerical values are given in Table 3. The two phase transitions, δ-γ and γ-β, observed at 168.5 and 215.5 K at 0.101 MPa, got close in temperature to each other with the increasing pressure to take place at 194.3 and 206.0 K at 50.0 MPa, and coalesced into one, direct transformation from δ to β phases, around 67 MPa at 201.2 K. The transition temperature was 205.3 K at 111.0 MPa.

The δ-γ phase transition was accompanied with a large expansion in volume, and had a increasingly larger premonitory region on the low temperature side as the pressure was increased. The slope of the transition line, dT_{tr}/dp, was 0.517 K MPa^{-1}. The

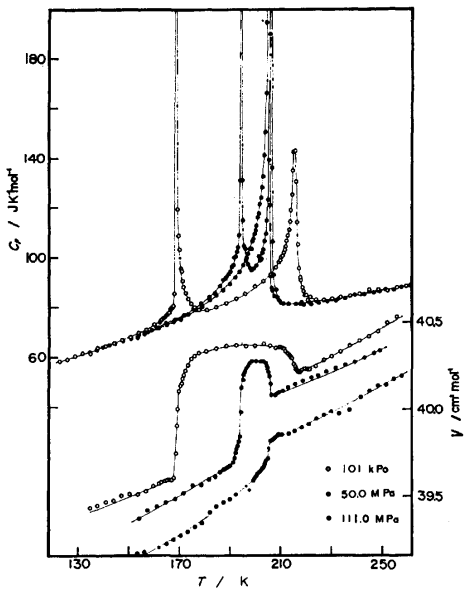

Fig. 4. Molar heat capacity and molar volume of ND_4Br at 0.101 (○), 50.0 (⊕), and 111.0 MPa (●).

γ-β transition, accompanied by the contraction of the volume, got sharper with the increasing pressure. The slope was given as -0.190 K MPa^{-1}. Both slopes of the transition lines changed slightly by deuteration. The deuteration has the same effect on the γ-β transition temperature as Br substitution has in the mixed crystal $NH_4Cl_xBr_{1-x}$.[15] The heat capacities of the β phase above *ca.* 220 K and the δ phase below *ca.* 150 K did not depend on the pressure. This is related to another experimental fact that the volume expansivity is independent of the temperature as required by the thermodynamic relation $(\partial C_P/\partial p)_T = -T(\partial^2 V/\partial T^2)_P$.

Figures 5(a)—(f) shows the temperature dependence of the molar heat capacity and molar volume at the constant pressures (given in the diagram) around the triple point. Those values are tabulated in Table 3. There was another heat capacity anomaly at 57.0 MPa and 62.0 MPa between the temperatures of two phase transitions described above, though the corresponding volume change was too small to be detected. As the pressure increased up to 63.1 MPa to 65.0 MPa, this anomaly overlapped with and merged into the δ-γ phase transition. At 66.0 MPa the heat capacity peak due to the γ-β transition at 202.1 K became quite small, indicating that a very small part of the crystal underwent the transition from the γ to β phases and that most from the δ to β phases. Heat capacity and volume curves at 67.0 MPa were essentially the same as those at 111.0 MPa.

The phase transition temperatures taken as the temperatures of the heat capacity peaks are plotted as a function of pressure as open circles in Fig. 6 where the dashed line stands for the result derived from a dilatometric study by Stevenson.[1] The present result indicates, in contrast to the previous one, that there is no maximum in any one branch of transition lines and the triple point is represented essentially as the point of intersection of the three straight lines. Absence of an exact triplet point in a very close look would be connected with a superheating effect in the δ-γ phase transition and will be discussed later.

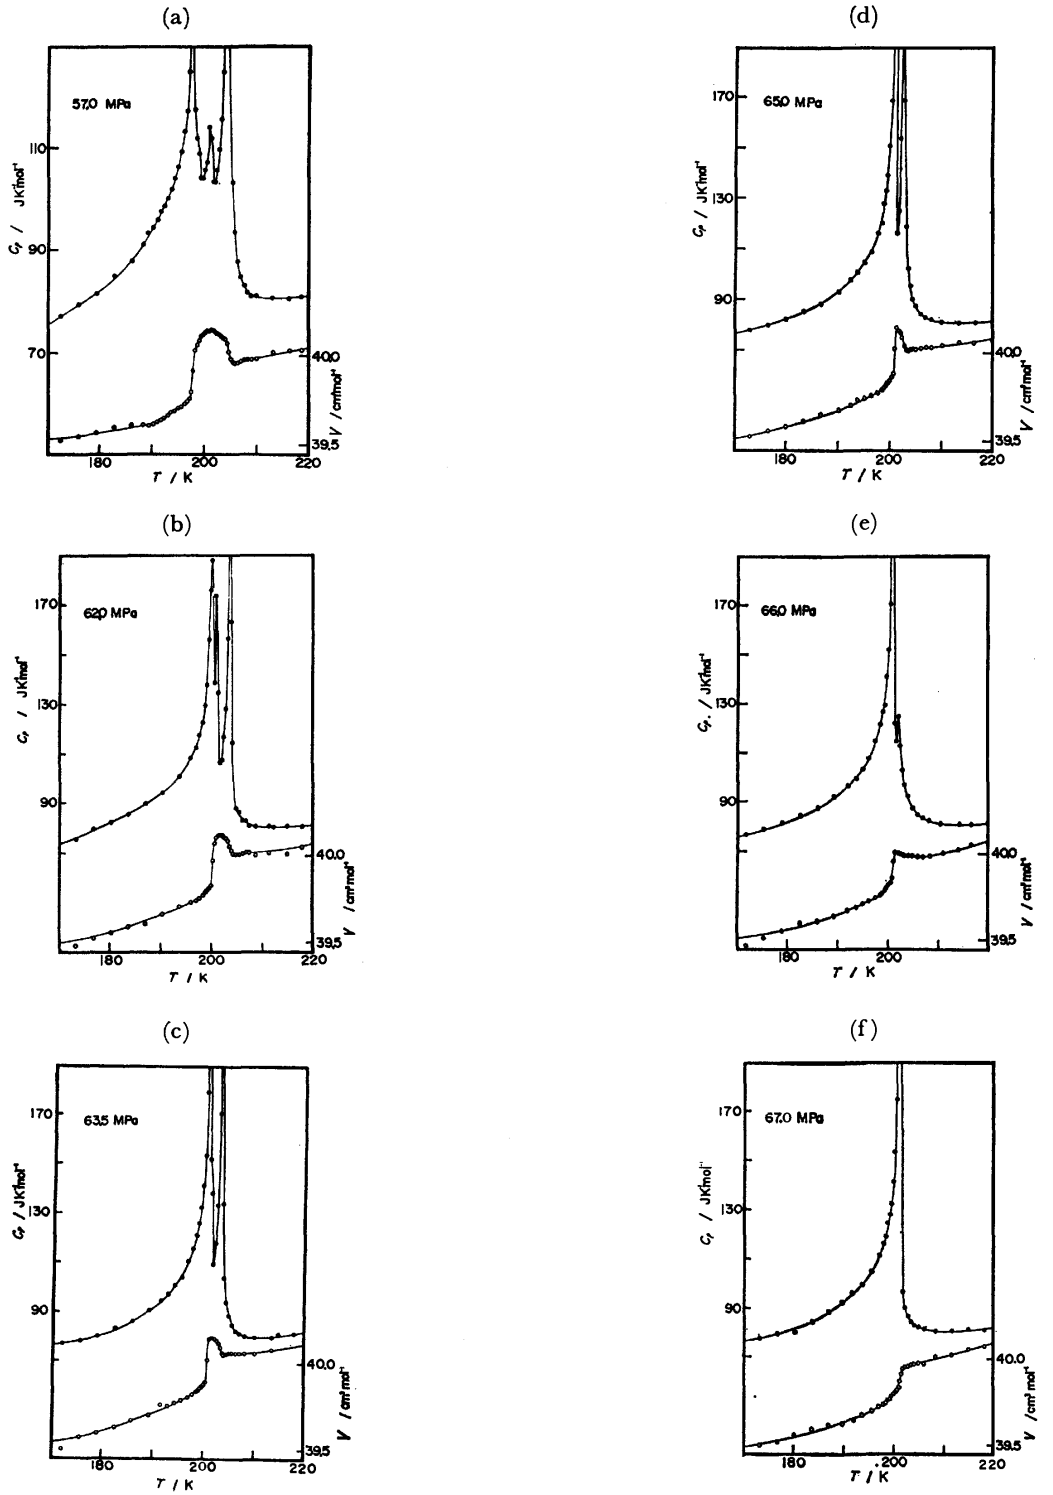

Fig. 5. Temperature dependences of molar heat capacity and molar volume of ND_4Br at the pressures around the triple point.
(a): 57.0 MPa, (b): 62.0 MPa, (c): 63.5 MPa, (d): 65.0 MPa, (e): 66.0 MPa, (f): 67.0 MPa.

Pressure Dependence of the Entropy of the Transition. The excess entropy involved in the successive two transitions for NH_4Br at 0.101 and 108.0 MPa are shown as functions of the temperature in Fig. 7. Here the entropy values were computed by assuming a baseline that joins smoothly the heat capacity curves outside the transition region. The total entropy change associated with the δ-γ-β phase transitions was estimated to be (4.0 ± 0.2) J K^{-1} mol^{-1}.

Figure 8 shows temperature dependence of the entropies of transition in ND_4Br at 0.1, 50.0, and 111.0 MPa and Fig. 9 at six pressures around the triple point. Table 4 lists the total entropy of transition from δ to β phases at all the pressures measured on ND_4Br. There

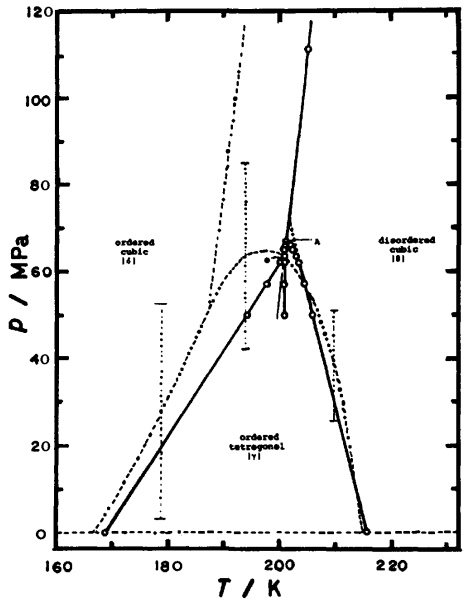

Fig. 6. Phase diagram of ND_4Br crystal as taken from the temperature of heat capacity peak. Previous data by R. Stevenson[1] are represented by dotted lines and error bars.

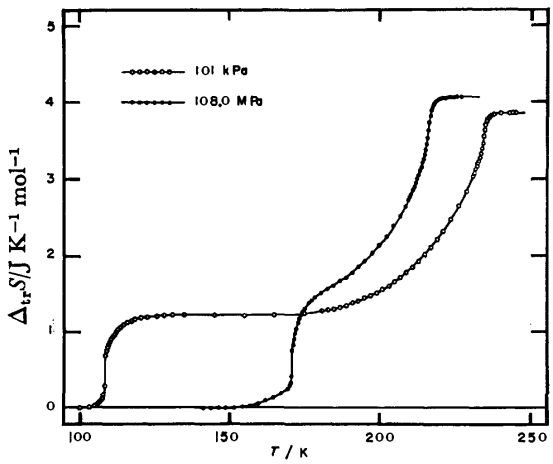

Fig. 7. Temperature dependence of the entropy of δ-γ-β phase transition in NH_4Br.
—○—: 0.101 MPa, —●—: 108.0 MPa.

is no pressure dependence in these values. The values can be explained in terms of the order-disorder mechanism in the orientational degree of freedom of NH_4^+ ions.

Molecular Excitation in the δ Phase. The entropies of transition had a very similar temperature dependence in the δ phase for the five isobaric measurements ranging from 57.0 to 67.0 MPa, as shown in Fig. 15. Correspondingly, the excess heat capacity (ΔC_p) *vs.* temperature curves in the relevant temperature and

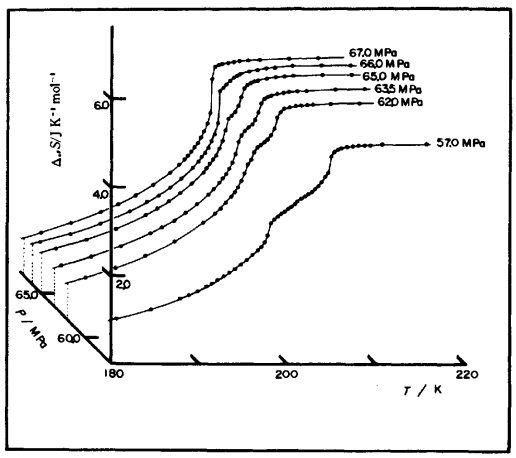

Fig. 9. Temperature dependence of the entropy of δ-γ-β phase transition in ND_4Br at six constant pressures around the triple point.

pressure region were practically independent of pressure as plotted in Fig. 10. It is to be noted here that the crystal transformed from the δ to γ phases below 66.0 MPa and from the δ to β phases at 67.0 MPa. These facts mean that the same process develops in the δ phase irrespective of the phases (γ or β) stable above the transition. This process is considered primarily to be the disordering of the orientation of NH_4^+ tetrahedra in the CsCl lattice, leading to the β phase. The δ-γ phase transition immediately below the triple point pressure therefore takes place between the cubic and tetragonal phases in the stages of low order parameters of the orientational arrangement of NH_4^+ ions.

Discussion on the Coexistence of the γ and δ Phases Domains. The δ-γ phase transition is of the first-order in which the entropy and volume undergo discontinuous change at the transition temperature. This is quite reasonable in view of the fact that the transition occurs between the parallel ordered cubic and the anti-parallel ordered tetragonal phases and that it can not proceed continuously as the homogeneous transition from one phase to the other from the viewpoint of crystal symmetry.

The heat capacity curve at 0.101 MPa in Fig. 1, however, shows a large post-transitional effect. The appearance of such an anomaly in a first-order transition as in the present case can be attributed to the coexistence of the domains of the δ and γ phases around the transition point. Actually the temperature dependence of the molar fraction of the δ phase calculated from the changes in entropy and volume associated with the transition can be explained by the spatial fluctuation of the domains as follows.[16-18]

Let x be the molar fraction of the δ phase, N the number of domains whose size is assumed to be the same throughout the crystal and G_δ and G_γ the free energies of the bulk δ and γ phases, respectively. Then the free energy of the crystal is, disregarding their interfacial energies, expressed by

$$G = [(1-x)G_\gamma + xG_\delta] + NkT[x \ln x + (1-x) \ln (1-x)]. \quad (1)$$

Minimization of the free energy at constant N and T gives the molar fraction

$$x = \frac{\exp\{-(G_\delta - G_\gamma)/NkT\}}{\exp\{-(G_\delta - G_\gamma)/NkT\}+1}. \quad (2)$$

Using the experimental values of 1.22 J K^{-1} mol^{-1} for the total entropy of transition and 108.5 K for the transition temperature in NH_4Br at 0.101 MPa, $(G_\delta - G_\gamma)$ can be approximated by the form 1.22 $(T/K - 108.5)$ J mol^{-1}. If one assumes that a single domain contains 6^3 $(=216)$ NH_4^+ ions, the temperature dependence of the molar fraction x could be calculated as drawn with a broken line in Fig. 11.

Comparison of the calculated and the experimental values shows that the heat capacity anomaly described above is reproduced by this model of spatial fluctuation of δ and γ phases domains. The number of domains in the δ phase actually changes depending on the temperature and the pre-history of the sample, and the interfacial energy should be represented in the expression for the sample free energy. This will be discussed in the subsequent paper.

Superheating of the δ-γ Phase Transition. Superheating is possible in principle in the first-order phase transition, though not found frequently in contrast to supercooling. An evidence for the superheating in the δ-γ phase transition could be given by the consideration of the Gibbs free energies for the δ and γ phases. By way of an example the following discussion is established by the use of the calorimetric data at 50 MPa for ND_4Br. The free energies for the δ and γ phases on the basis of that for the β phase would be written down according to the Landau theory of phase transitions of the second kind as follows;

$$G(\eta^2) = G_\beta + \frac{a}{2}(T-T_0)\eta^2 + \frac{b}{4}\eta^4 + \frac{c}{6}\eta^6, \quad (3)$$

and

$$G(\xi^2) = G_\beta + \frac{a'}{2}(T-T_0')\xi^2 + \frac{b'}{4}\xi^4 + \frac{c'}{6}\xi^6, \quad (4)$$

where η and ξ are the order parameters describing the δ-β and the γ-β phase transitions, respectively, and G_β the free energy for the β phase. With coefficients a, b, c, T_0, a', b', c', and T_0' determined appropriately, the problems of which phase is stable at a given T and where the δ-γ phase transition takes place can be solved by the comparison between $G(\eta^2)$ and $G(\xi^2)$.

The coefficients a, b, c, and T_0 were derived by the extrapolation from those at 111.0 and 67.0 MPa at which the δ phase transformed directly into the β phase. The coefficients at the both pressures, 111.0 and 67.0 MPa, were obtained by use of the two equations;

$$\Delta_{tr}S(T) = S_0 - \frac{a}{2}\eta^2, \quad (5)$$

and

$$a(T-T_0) + b\eta^2 + c\eta^4 = 0, \quad (6)$$

where S_0 is the total entropy of the transition. The relation (5) connected with the experimental data of excess heat capacities yielded the temperature dependence of the order parameter, and the least-squares fit of the relation (6) to the T dependence of η^2 determined the coefficients at the respective pressure values. The coefficient values a', b', c', and T_0' were derived, using relations similar to Eqs. 5 and 6 with the order parameter ξ^2, from the experimental data at 50.0 MPa of the excess heat capacities associated with the γ-β phase transition.

Figure 12 shows the temperature dependence of the order parameters η^2 and ξ^2 with the coefficients thus determined. The δ-γ phase transition at 50.0 MPa took place at 194.3 K on heating in the actual experiment. The Gibbs energy against order parameter curves for both the δ and γ phases at the temperature and the pressure 50.0 MPa are shown in Fig. 13. The minimum free energy for the γ phase is definitely lower than that for the δ, contrary to the thermodynamic relation that the minimum values of free energies for the two phases should be equal to each other at the transition point. This means that the temperature of the heat capacity peak observed at 50.0 MPa is higher than the phase transition point as defined by the equality of the Gibbs energies; in other words, the substance in the δ phase at 194.3 K is in a superheated state.

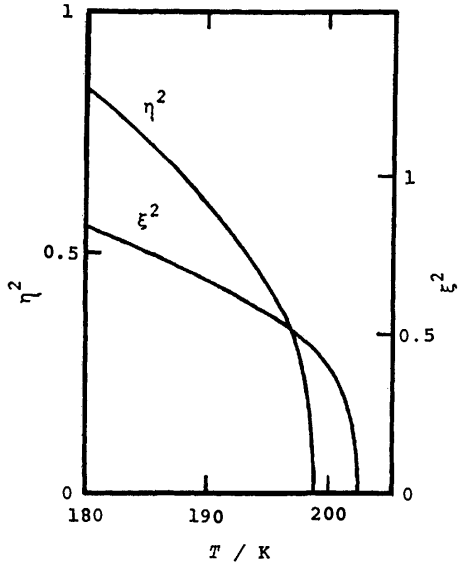

Fig. 12. Temperature dependences of the order parameters for γ and δ phases of ND_4Br at 50 MPa. The order parameter ξ is associated with the γ-β phase transition and η with the δ-β phase transition.

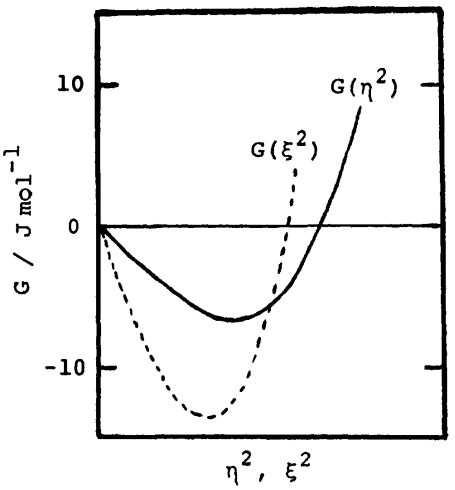

Fig. 13. Gibbs free energy against order parameter curves for the γ and δ phases at 194.3 K and 50 MPa. 194.3 K is the observed δ to γ phase transition point taken as the temperature of heat capacity peak 50.0 MPa.

Interpretation of an Anomalous Heat-capacity Peak. The phase diagram for ND_4Br (Fig. 6) has two peculiarities around the triple point among β, γ, and δ phases; one is the appearance of a new heat-capacity anomaly between the δ-γ and the γ-β phase transitions at pressures just below the triple point pressure, and the other is the apparent presence of two triple-points as shown by A and B. In this section the former phenomenon is discussed as the δ-β phase transition due to the coexistence of the δ and γ domains and of the superheating in the δ to γ phase change, the effects described above.

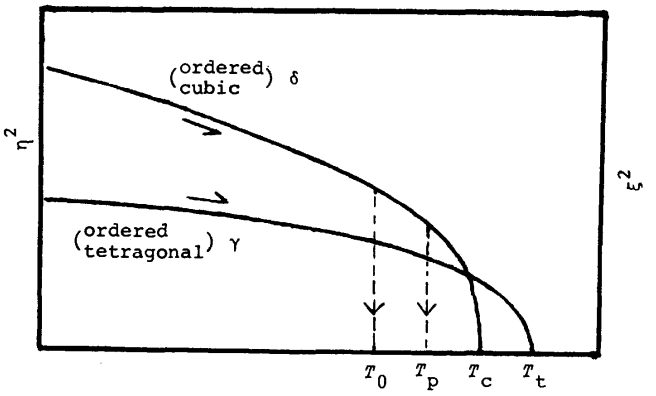

Fig. 14. Schematic temperature dependences of the order parameters for the δ-β and γ-β phase transitions in ND_4Br crystal at a certain constant pressure immediately below the triple point. T_0: the temperature at which $G_\delta = G_\gamma$, T_p: the δ-γ phase transition temperature, T_c: the δ-β phase transition temperature, T_t: the γ-β phase transition temperature.

Figure 14 illustrates diagramatically the path of transformation on heating as curves of order parameter versus temperature, where T_0 is the temperature of equilibrium between the δ and γ phases at which the free energies for the two phases become equal, and T_c and T_t are the temperatures of the δ-β and the γ-β phase changes, respectively. Most of domains of the δ phase transform into the γ phase around T_p with the superheating effect as indicated by an arrows, and subsequently into the β phase at T_t. But some of domains remain in the δ phase until the temperature T_c is reached, at which temperature they transform into the β phase directly. This fluctuational δ-β transition should become important as the pressure approaches

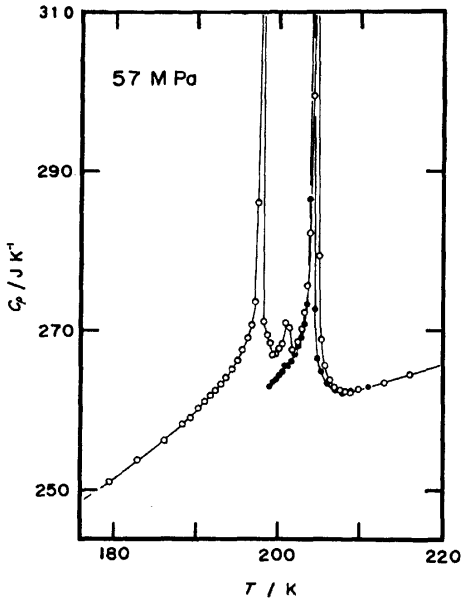

Fig. 15. The effect of thermal hysteresis on the heat capacity curve of ND_4Br crystal at 57.0 MPa. One series of measurement (—○—) was started at 100 K where the crystal was in the δ phase, and the other (—●—) was started at 198 K on the crystal in the γ phase after the treatment of the isothermal pressure increase from 0.101 to 57.0 MPa following the temperature decrease from room temperature to 198 K at 0.101 MPa.

that of the triple point, as the fraction of the substance, namely the number of domains, remaining in the δ phase accordingly increases till T_c.

Figure 15 shows another experimental evidence for the above reasoning with the use of heat capacity curves at 57 MPa as an example, the heat capacity values being the total of contributions from the sample and cell measured in the heating direction. Two sets of data, distinguished by open and solid circles, differed from each other in the prehistories of the sample. The sample in the former case (open circles) was cooled down to liquid nitrogen temperature so as to start the measurement in the δ phase. In the latter, on the other hand, the temperature of the samples was first decreased from 300 K to 198 K at an atmospheric pressure, then the pressure was isothermally increased to 57.0 MPa, and then a set of measurement was started from there in the heating direction. The former sample at 199.5 K, being normally in the γ phase, would consequently still have involved some domains of the δ phase resulting in the anomalous peak at 200.9 K on the subsequent heating while the latter would have been composed of the γ phase and if any the β phase. The results combined with the different thermal-prehistories of the sample therefore indicates the effects of superheating and coexistence as causing the anomalous heat-capacity peak in the decisive way.

It should be pointed out that the extra heat capacity peaks occur practically at the same temperature 200.8—200.9 K even though one would expect the peak temperature to follow the extrapolation of the stable δ-β phase boundary. This cannot be explained by the simplified domain model as discussed above. One would have to incorporate the possibility of distributed internal pressure felt by the less compact γ domains surrounded by the δ or β domains. The situation is, however, not clear at present.

Character of the γ-β Phase Transition around the Triple Point. As already pointed out there appeared two triple points, A and B in Fig. 6, on the phase diagram. The superheating of the δ-γ phase transition explains this unusual behavior of the phase lines (apart from the curvature of the γ-β line) in the close vicinity of the triple point. As we discussed above, the observed δ-γ phase boundary is at higher temperature than the equilibrium phase boundary by several Kelvin. The equilibrium δ-γ phase line which is assumed to be parallel to the observed phase line would then join the point A where the δ-β and γ-β phase boundaries meet thus terminating at a genuine triple point.

The γ-β phase line near the triple point A was found to deviate from a straight line (broken one in Fig. 6). This appears to be an equilibrium properties rather than a hysteretic effect related to the coexistence of the different domains, since the heat capacity measurement performed after approaching the triple point from the lower pressure gave essentially the same γ-β transition temperature. (See Fig. 15) The γ-β phase line is so curved that the β phase region is larger than the linear extrapolation of the γ-β phase line gives. This is explained if one notes that the two ionic interactions stabilizing the γ and δ phases are opposite in nature. The ionic interactions favoring the antiparallel orientation of the NH_4^+ ions within the ab plane stabilizes the γ phase and those favoring the parallel orientation the δ phase. The two interactions have the same strength in the opposite directions at the triple point. They tend to cancel each other resulting in relative stabilization of the disordered β phase, as is experimentally observed. Such fluctuational interaction among different phases does not occur at an ordinary triple point among a solid, liquid, and vapour. It is characteristic of a triple point involving phase transitions of the second kind.[19]

Concluding Remarks

The present results of heat capacity of NH_4Br and ND_4Br crystals evidenced again that the high pressure calorimeter described in the preceding paper has a satisfactory accuracy. The accurate measurements enabled the exact determination of p-T phase diagrams and the detailed examination of phase transitions to be performed under well specified thermodynamic conditions.

The peculiar phenomena observed at high pressures just below a triple point for ND_4Br crystal were reasonably explained in terms of the effects of superheating in the δ-γ phase transition and of coexistence of the δ, γ, and β phases domains (This is quite an instructive point in that the superheating effect causes a new phenomenon in some cases.). The nucleation and growth processes in the δ-γ phase transition is an interesting subject for

further study, as will be described in the subsequent paper. The detailed measurement of the δ-β phase transition line under high pressure (beyond the pressure range of the present apparatus) is desirable for the insight into the competitive interaction between the two different (parallel and anti-parallel) orderings in the disordered β phase.

(Received May 13, 1981)

The rates of dissociation and racemization of the tris(1,10-phenanthroline)iron(II) ion were obtained in aqueous solutions containing fourteen kinds of nucleophile. They ranged from 0.7 to 9.3 and from 0.9 to 3.2 times the rates in pure water, respectively. The results were analyzed by considering simultaneous reactions of free and ion-paired complex ions. The rate constants of the dissociation (ligand release) of the complex existing in ion-pairs increased in the following order of the counter-ions: $I^- < Br^- < Cl^- < (H_2O) < NO_2^- < CH_3COO^- < OCN^- < N_3^- < F^- < OH^- \approx CN^-$; here H_2O is regarded as a nucleophile for the free complex ion. This order is similar to that of proton affinities of nucleophiles. The results show that the dissociation is accelerated by σ donation from the nucleophile, suggesting an ion-pair interchange mechanism. The intramolecular racemization rate constant, given by total recemization rate constant minus dissociation rate constant, increased in the following order of nucleophiles: $OH^- \approx CN^- \approx F^- \approx Cl^- < Br^- \approx NO_2^- < (H_2O) < CH_3COO^- < OCN^- < I^- < N_3^- <$ (thiourea) $\approx SCN^- \approx SeCN^- <$ (pyridine). This suggests that the polarizability of nucleophiles has a greater effect than their basicity. The operation of π interaction between the complex ion and the nucleophile in the transition state is also suggested. The ion-association constants obtained from the rate data were in the range of 1 to 8 (I=1.0, 32.0 °C).

Intramolecular twist mechanisms[1] are among the basic reaction mechanisms of the stereochemical rearrangement of metal chelates. The nature of these mechanisms, however, does not seem to be fully understood.[2] Although such mechanisms are suggested in many systems, firm evidence for the mechanism has been presented for only a few cases.[3] The $[Fe(phen)_3]^{2+}$ (phen=1,10-phenanthroline) ion is one of the few inert complexes which racemize by an intramolecular twist mechanism.[4] Thus, studies of the racemization of this complex are expected to give information concerning the characteristics of the twist mechanism.

A variety of different mechanisms have been proposed for substitution reactions of the iron(II) complex. Margerum *et al.*[5] studied the nucleophilic substitution of $[Fe(phen)_3]^{2+}$ with hydroxide, cyanide, and azide. They proposed a mechanism in which nucleophiles enter into the "pocket" between ligands to form an inner-sphere ion-pair with the complex ion and interact with the metal center. An associative mechanism has been proposed for the nucleophilic ligand substitution of $[Fe(bpy)_3]^{2+}$ and $[Fe(phen)_3]^{2+}$.[6] Gillard[7] proposed a mechanism for hydrolysis involving nucleophilic attack at a chelate-ring carbon adjacent to a nitrogen atom. Recently, Lawrance *et al.*[8] proposed a dissociative interchange mechanism based on the values of activation volume obtained from high-pressure experiments. The conjugate base mechanism proposed for the base hydrolysis of cobalt(III) complexes does not seem to be operative in the present case, where the complex has no readily ionizable protons.

In the present study, the kinetics of dissociation and racemization of $[Fe(phen)_3]^{2+}$ were investigated in the presence of nucleophiles to clarify the dissociation mechanism in which nucleophiles are involved and to gain further understanding of the nature of the twist mechanisms.

Experimental

Materials. All the chemicals used were of guaranteed reagent grade except potassium azide, cyanate, and selenocyanate, and were obtained from Wako Pure Chemical Industries, Ltd. unless otherwise noted.

Complex: (+)-$[Fe(phen)_3](ClO_4)_2 \cdot 2H_2O$ was synthesized and resolved according to the method of Dwyer and Gyarfas.[9] $[\alpha]_{589} = 1380°$.

Nucleophiles: Potassium fluoride, chloride, bromide, iodide, thiocyanate, cyanide, acetate, nitrite (Merck), and azide (Alpha), and thiourea were recrystallized from water. Potassium cyanate (Kanto) was recrystallized twice from water below 40 °C to minimize decomposition. Potassium selenocyanate was recrystallized from aqueous alcohol (1:5.5). Pyridine was fractionally distilled using a Widmer distilling column 30 cm long (bp 116.0—116.1 °C). Potassium hydroxide was used without further purification. The concentrations of the solutions of potassium thiocyanate, cyanide, cyanate, and selenocyanate were determined by argentometry. The concentration of the solution of potassium nitrate was determined by iodometry, that of potassium fluoride by the colorimetric method with a zirconium lake of 4-dimethylaminoazobenzene-4'-arsonic acid,[10] and that of potassium acetate by alkalimetry after passing the solution through a column of H-form cation-exchange resin. The solutions of potassium chloride, bromide, iodide, and azide, as well as those of thiourea, were prepared by weighing well-dried reagents.

Other Reagents: Nickel(II) chloride hexahydrate was recrystallized from water. Nickel(II) perchlorate hexahydrate was synthesized from nickel(II) carbonate and perchloric acid. The concentrations of nickel(II) solutions were determined by chelatometry. Other chemicals were used without further purification.

Kinetic Studies. Dissociation Rates: The dissociation rates were obtained at 32 °C from the changes in the absorbance at 510 nm of the solution containing 5×10^{-5} mol dm^{-3} $[Fe(phen)_3](ClO_4)_2$. Nickel(II) chloride (5.19×10^{-4} mol dm^{-3}) was added as the scavenger of the liberated phenanthroline[11] except in the solutions containing KCN and KOH.

A sodium citrate solution of 1.0×10^{-2} mol dm^{-3} was added to the solutions containing potassium cyanate, potassium acetate, and pyridine to prevent the precipitation of any iron hydroxide which might be produced in the course of the reaction. A 1.0×10^{-3} mol dm^{-3} citric acid solution was added to the solutions containing potassium azide and potassium nitrite, and a 2.0×10^{-3} mol dm^{-3} solution of disodium dihydrogen ethylenediaminetetraacetate (Na_2H_2edta) was added to the solutions containing potassium hydroxide for the same reason. The hydroxide ion concentration of the solution was corrected for the Na_2H_2edta added.[5a] The reactions were followed for four half-lives, and were found to be of the first order in the metal-complex concentration in the time range studied. The data were analyzed by the usual method of the first order reactions. The dissociation rates obtained were reproducible within $\pm1\%$. They were independent of the nickel(II) concentration in the range of $(0.02—1.0)\times10^{-2}$ mol dm^{-3}; the rates obtained in Ni(II)-containing KCl solutions agreed with that obtained in acidic solution. The other added reagents had little effect on the dissociation rate, at least at their concentrations up to 1×10^{-2} mol dm^{-3}; the dependence of the rate on the reagent concentration was checked. For the systems containing KSCN and KSeCN, the dissociation rate could not be obtained because of the precipitation of the complex. Without Ni(II) ions, however, no precipitations nor absorbance changes were observed at least for thirty minutes, and the racemization rate could be obtained.

Racemization Rates: A 1.0 ml portion of a 5×10^{-4} mol dm^{-3} solution of the optically active iron-complex perchlorate, cooled with ice water, was added to a thermostated (32.0 °C) solution containing a nucleophile; the resultant solution was adjusted to a volume of 10.0 ml with water at 32.0 °C, and mixed immediately. After being kept for one minute in a thermostat, the solution was transferred into a thermostated (32.0 °C) quartz cell (5 cm path length) and the change in optical rotation of the solution at 546 nm was followed on a recorder using a Union PM-101 automatic polarimeter. Correction was made for the reproducible instrumental error which occurred when the absorbance of the solution decreased in the course of the kinetic measurement. All the reactions were followed for at least four half-lives. The reactions were first order in the concentration of the optically active metal complex in the time range studied.

The racemization rate constant was defined as $k_r=[\ln(\alpha_0/\alpha_t)]/t$, where α_0 and α_t mean the optical rotations at times zero and t, respectively. The reproducibility of the rate data was estimated to be within $\pm5\%$ from the standard deviation of the multiple measurements under the same experimental conditions.

pH Measurements. After each kinetic run, the pH value of the solution was measured by a Radiometer PHM26 pH-meter. In each case, the pH value was at least 2.0 greater than the pK_a value of the nucleophile contained. More than 99% of the nucleophiles thus existed in the free base form, so that the concentrations of the nucleophilic free bases assumed to be equal to those of the nucleophiles added.

Results and Discussion

Rates of Dissociation. Table 1 gives the rate constants for dissociation (k_d) and racemization (k_r) of the complex in aqueous solutions containing various nucleophiles at different concentrations. In the potassium azide system, the final absorbance value of the solution (A_∞) increased with the increase in citric acid and potassium azide concentrations of the solution. This would be caused by the formation of the mixed complex of nickel or iron with citrate and azide ions. However, linear relationships existed between $\log(A_t-A_\infty)$ and the time for four half-lives (A_t represents the absorbance at time t). The rate was not affected by nickel(II) and citric acid concentrations in the range studied. The rate constants thus obtained are considerably greater than those obtained by Margerum *et al.*,[5b] who reported the slowing-down of the apparent dissociation rate after the first 15% decrease in the absorbance. The rate expression proposed by them (Eq. 10) is also different from that proposed here (Eq. 6).

a) Calculated with Eq. 6 or 9 using the $K^{1P}_{c(X)}$ and $k^{1P}_{d(X)}$ or $k^{1,1P}_{r(X)}$ values given in Table 2. b) The value in parentheses is the number of observations. c) In KCl solutions, the value of k_d was assumed to be independent of the KCl concentration. d) The value changed only within $\pm 1\%$ in 0—1×10^{-2} mol dm^{-3} citric acid. e) Containing 1.0×10^{-2} mol dm^{-3} Na_2H_2-edta.

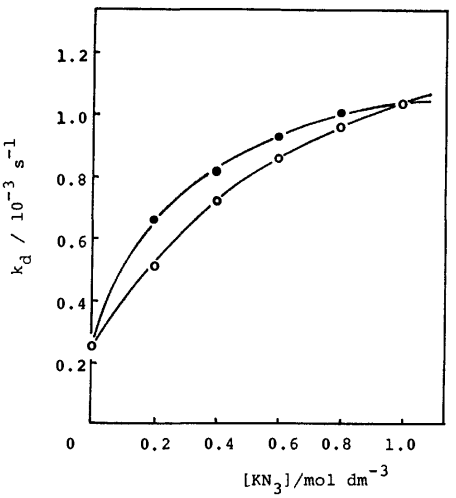

Fig. 1. The dissociation rate constants of $[Fe(phen)_3]^{2+}$ in potassium azide solutions. The solid circles show the rate constants observed in the solutions without ionic-strength adjustment and the open circles are those in the solutions of constant ionic strength (I=1.0, adjusted with KCl).

The effect of nucleophiles on the reaction rate is discussed separately in two groups: anionic and neutral nucleophiles.

Anionic Nucleophiles: An example of the results is shown in Fig. 1. The ion-pair formation mechanism[12] reasonably accounts for the observed dissociation rates. In the systems without added KCl, the proposed mechanism is as follows:

$$[Fe(phen)_3]^{2+} + X^- \overset{K^{IP}_{(X)},\ K^{IP}_{c(X)}}{\rightleftharpoons} [Fe(phen)_3]^{2+}\cdot X^-, \quad (1)$$

$$[Fe(phen)_3]^{2+} \overset{k^0_d}{\longrightarrow} Fe^{2+} + 3\,phen, \quad (2)$$

$$[Fe(phen)_3]^{2+}\cdot X^- \overset{k^{IP}_{d(X)}}{\longrightarrow} Fe^{2+} + 3\,phen + X^-, \quad (3)$$

$$K^{IP}_{(X)} = \frac{[Fe(phen)_3{}^{2+}\cdot X^-]}{[Fe(phen)_3{}^{2+}][X^-]}\frac{f_1}{f_2 f_1} \simeq K^{IP}_{c(X)}\frac{1}{f_2}, \quad (4)$$

where $K^{IP}_{(X)}$ and $K^{IP}_{c(X)}$ represent the thermodynamic and the concentration ion-association constant for reaction (1) and where k^0_d and $k^{IP}_{d(X)}$ are the rate constants for reactions (2) and (3), respectively. The symbol f_z means the activity coefficient of the ion with a charge of $\pm z$; $\log f_z$ can be expressed as:

$$\log f_z = -\frac{z^2 A\sqrt{I}}{1+Ba\sqrt{I}} + bI, \quad (5)$$

where A=0.5181 $mol^{-1/2}\,dm^{3/2}$, B=0.3305$\times 10^8$ cm^{-1} $mol^{-1/2}\,dm^{3/2}$ at 32 °C in water, and the parameters, a and b, are taken to be (7—12)$\times 10^{-8}$ cm and 0.1 z^2, respectively. Then, the observed dissociation rate constant, k_d, is expressed as:

$$k_d = \frac{k^0_d + k^{IP}_{d(X)}K^{IP}_{c(X)}f_2[X^-]}{1+K^{IP}_{(X)}f_2[X^-]}. \quad (6)$$

The $K^{IP}_{(X)}$ and $k^{IP}_{d(X)}$ were obtained by the weighted least-squares fit[13] to Eq. 6 of the kinetic data. The $K^{IP}_{(X)}$ was transformed to the ion-association constant ($K^{IP}_{c(X)}$) at I=1.0 by means of Eqs. 4 and 5.

The following equations were added to Eqs. 1—3 for the systems in which the ionic strength was adjusted to 1.0 with added KCl.

$$[Fe(phen)_3]^{2+} + Cl^- \overset{K^{IP}_{c(Cl)}}{\rightleftharpoons} [Fe(phen)_3]^{2+}\cdot Cl^- \quad (7)$$

$$[Fe(phen)_3]^{2+}\cdot Cl^- \overset{k^{IP}_{d(Cl)}}{\longrightarrow} Fe^{2+} + 3\,phen + Cl^- \quad (8)$$

Then, the observed dissociation rate constant is expressed as:

$$k_d = \frac{k^0_d + k^{IP}_{d(Cl)}K^{IP}_{c(Cl)}[Cl^-] + k^{IP}_{d(X)}K^{IP}_{c(X)}[X^-]}{1+K^{IP}_{c(Cl)}[Cl^-]+K^{IP}_{c(X)}[X^-]}. \quad (9)$$

Since the dissociation rate constants were almost unaffected by the KCl concentration (Table 1), the value of $K^{IP}_{c(Cl)}$ was obtained in the following way.

TABLE 2. THE ION-ASSOCIATION CONSTANTS OF $[Fe(phen)_3]^{2+}$ WITH NUCLEOPHILES ($K^{IP}_{c(X)}$) AND THE DISSOCIATION AND INTRAMOLECULAR RACEMIZATION RATE CONSTANTS ($k^{IP}_{d(X)}$ AND $k^{i.IP}_{d(X)}$) OF THE COMPLEX IN ION-PAIRS AT THE CONSTANT IONIC STRENGTH OF 1.0 (KCl)

a) Rate constants for the total racemization. Other values are for the intramolecular racemization.

Using Eq. 6, an analysis of the kinetic data was made for the systems of various ionic strength containing KI, KN_3, KF, KCH_3COO, and KNO_2 to obtain the values of $k^{IP}_{d(Cl)}$ and $K^{IP}_{e(X)}$. These values were substituted in Eq. 9. The kinetic data for similar systems of the constant ionic strength with added KCl were analyzed with this equation to evaluate $k^{IP}_{d(Cl)}$ and $K^{IP}_{e(X)}$. The latter kinetic data were analyzed again using the resulting $k^{IP}_{d(Cl)}$ and $K^{IP}_{e(X)}$ values to re-evaluate $k^{IP}_{d(X)}$ and $K^{IP}_{e(X)}$. The values thus obtained are in agreement with those derived above from the data for the solutions of variable ionic strength within the experimental error. These $k^{IP}_{d(X)}$ and $K^{IP}_{e(X)}$ values at $I=1.0$ are listed in Table 2.

Margerum[5] reported the rate expression of the type

$$k_d = k_0 + k_1[X] + k_2[X]^2 + k_3[X]^3 \qquad (10)$$

for the azide-, cyanide-, and hydroxide-assisted dissociation of $[Fe(phen)_3]^{2+}$. The square and cubic terms of nucleophile concentration in the rate equation were observed only for hydroxide ions. They were accounted for in terms of the mechanism of the multiple hydroxide attack to the complex, or the multiple hydroxide-association with the complex. However, the rate dependence of the type of Eq. 10 can also be fitted by Eq. 9 for the ion-pair formation mechanism. By substituting C_T(constant) for [Cl]+[X], Eq. 9 is transformed to

$$k_d = \frac{(k^0_d + k^{IP}_{d(Cl)}K^{IP}_{e(Cl)}C_T) + (k^{IP}_{d(X)}K^{IP}_{e(X)} - k^{IP}_{d(Cl)}K^{IP}_{e(Cl)})[X]}{(1+K^{IP}_{e(Cl)}C_T) - (K^{IP}_{e(Cl)} - K^{IP}_{e(X)})[X]}. \qquad (11)$$

On the condition of $\left|\frac{(K^{IP}_{e(Cl)} - K^{IP}_{e(X)})[X]}{(1+K^{IP}_{e(Cl)}C_T)}\right| < 1$, the denominator of Eq. 11 can be expanded to an infinite series and Eq. 11 is then transformed to:

$$\begin{aligned} k_d &= \{(k^0_d + k^{IP}_{d(Cl)}K^{IP}_{e(Cl)}C_T) + (k^{IP}_{d(X)}K^{IP}_{e(X)} - k^{IP}_{d(Cl)}K^{IP}_{e(Cl)})[X]\} \\ &\quad \times \left\{\frac{1}{(1+K^{IP}_{e(Cl)}C_T)} + \frac{(K^{IP}_{e(Cl)} - K^{IP}_{e(X)}}{(1+K_{e(Cl)}C_T)^2}[X] \right. \\ &\quad \left. + \frac{(K^{IP}_{e(Cl)} - K^{IP}_{e(X)})^2}{(1+K^{IP}_{e(Cl)}C_T)^3}[X]^2 + \cdots\right\} \\ &= \frac{(k^0_d + k^{IP}_{d(Cl)}K^{IP}_{e(Cl)}C_T)}{(1+K^{IP}_{e(Cl)}C_T)} + \left\{\frac{(k^0_d + k^{IP}_{d(Cl)}K^{IP}_{e(Cl)}C_T)(K^{IP}_{e(Cl)} - K^{IP}_{e(X)})}{(1+K^{IP}_{e(Cl)}C_T)^2} \right. \\ &\quad \left. + \frac{(k^{IP}_{d(X)}K^{IP}_{e(X)} - k^{IP}_{d(Cl)}K^{IP}_{e(Cl)})}{(1+K^{IP}_{e(Cl)}C_T)}\right\}[X] \\ &\quad + \left\{\frac{(k^0_d + k^{IP}_{d(Cl)}K^{IP}_{e(Cl)}C_T)(K^{IP}_{e(Cl)} - K^{IP}_{e(X)})^2}{(1+K^{IP}_{e(Cl)}C_T)} \right. \\ &\quad \left. + \frac{(K^{IP}_{e(Cl)} - K^{IP}_{e(X)})(k^{IP}_{d(X)}K^{IP}_{e(X)} - k^{IP}_{d(Cl)}K^{IP}_{e(Cl)})}{(1+K^{IP}_{e(Cl)}C_T)}\right\}[X]^2 + \cdots \\ &= k_0 + k_1[X] + k_2[X]^2 + \cdots. \end{aligned} \qquad (12)$$

For KF, KNO_2, KCH_3COO, KCN, and KOH, the observed dissociation rate constants were nicely expressed by Eq. 9 with the parameter values listed in Table 2, although the rate constants could also be expressed by Eq. 10. In fact, the kinetic data for hydroxide-assisted dissociation obtained by Margerum[5a] can also be reproduced by Eq. 9 with a $K^{IP}_{e(X)}$ value of 1.0 ± 0.7, consistent with the value of 3.2 ± 1.8 obtained here. Thus, in our opinion, Eq. 10 may be regarded as an approximation to Eq. 9.

As shown in Table 2, the $k^{IP}_{d(X)}$ values increase in the order:

$$I^- < Br^- < Cl^- < (H_2O) < NO_2^- < CH_3COO^- < OCN^- < N_3^- < F^- < OH^- \approx CN^-,$$

where H_2O means free complex ions not forming ion-pairs. A good correlation is observed between the logarithm of $k^{IP}_{d(X)}$ and the pK_a value of the conjugate acid of the nucleophile, as shown in Fig. 2. Considering that pK_a is a measure of the σ-donating ability of a nucleophile, the dissociation is likely to proceed by an ion-pair interchange mechanism where the nucleophile in an ion-pair would interact directly with the central metal of the complex. The dissociation rate constant of the free complex cation follows the trend observed in Fig. 2, where a water molecule is regarded as a nucleophilic reagent for the free cation. Thus, the free cation would also dissociate by a similar interchange mechanism, *e.g. via* a 7-coordinate transition state with an H_2O ligand, as suggested by Burgess.[14]

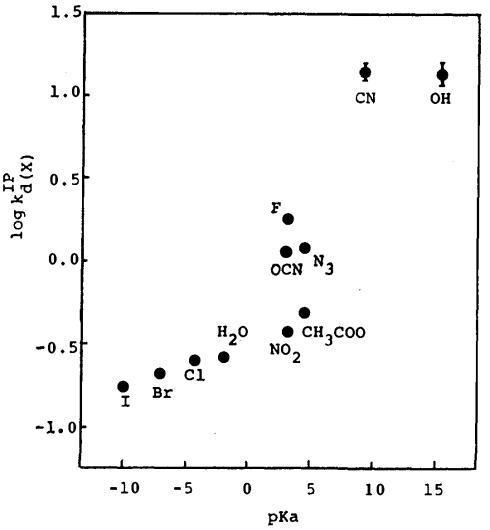

Fig. 2. The plot of the logarithm of $k^{IP}_{d(X)}$ *vs.* the pK_a value of nucleophile.

Alternative mechanisms which may account for the observed dissociation rates are: (i) dissociative mechanism, (ii) associative mechanism, and (iii) Gillard's mechanism. If dissociation of the complex proceeds dissociatively, the rate constant would be independent of the kind of nucleophile. As different rates were observed in the presence of different nucleophiles (Table 2), the dissociative mechanism can be excluded. Maestri *et al.*[15] proposed an associative mechanism for the base hydrolysis of $[Cr(bpy)_3]^{3+}$ to account for the rate expression, $k^{obsd} = [OH^-]/(B + A[OH^-])$, a special case of Eq. 6 with $k^0_d = 0$. The mechanism assumes that, as soon as the heptacoordinate complex is formed by the coordination of a water molecule, it undergoes an acid-base equilibrium, and that the conjugate-base form of the heptacoordinate complex (hydroxide associated species) tends to dissociate; the step of water coordination is considered to be rate-determining. A similar but slightly different mechanism may be considered to account for a rate expression of the type like Eq. 6; the mechanism assumes that a water molecule

associated with the complex is subjected to nucleophilic proton subtraction to form a hydroxide-associated species which undergoes dissociation. In this mechanism, the rate constant for the proton subtraction would be proportional to the probability of the nucleophile approaching the complex (or, in a sense, the ion-association constant) and to the ease of the proton subtraction. As the former does not change very much, the latter may be correlated with the strength of the nucleophile as a base. Although the order in which the nucleophiles increase the dissociation rate of the complex is in general consistent with the trend of increasing basicity of the nucleophiles, the deceleration effect shown by halide ions cannot be explained by this mechanism. Gillard's mechanism supposes the direct nucleophilic attack to a carbon atom of the phenanthroline molecule. The order of nucleophilic reactivity obtained in this study is very different from that obtained from the rate of nucleophilic displacement of the iodide ion from methyl iodide.[16] Thus, Gillard's mechanism is not adequate to interpret the experimental results. Therefore, the ion-pair interchange mechanism proposed in this paper very probably takes place.

Pyridine and Thiourea: In the systems containing pyridine and thiourea, the kinetic data could not be reproduced by Eq. 6 nor by Eq. 9 (see Table 1). The coordination of pyridine molecules to the second coordination sphere of the complex may be important for the system containing pyridine. In the system containing thiourea, a steep decrease in the rate was observed at 0—0.1 and 0.8—0.9 mol dm^{-3} thiourea concentrations. This may reflect the change in water activity or in the solution structure around these thiourea concentrations, if a water molecule is coordinated to the complex ion in the transition state.

Rates of Racemization. The observed racemization rate constants (k_r) are listed in Table 1, along with the dissociation rate constants (k_d) obtained under the same experimental conditions. Since the complex racemizes intramolecularly and dissociatively, the intramolecular racemization rate is given by total racemization rate minus dissociation rate. The total racemization rates increased considerably with added nucleophiles, except in the systems containing KCl and KBr. On the other hand, the intramolecular racemization rates do not appreciably change for the systems containing KF, KCN, and KOH, increase slightly with increasing concentrations of KBr, KNO_2, and KCH_3COO, and increase considerably with the increase in the concentrations of KI, KSCN, KSeCN, KOCN, KN_3, thiourea, and pyridine. The KOH result is in contrast to the intramolecular twist racemization of (ethylenediaminetetraacetato)cobalt(III), for which the racemization was reported to be accelerated by the hydroxide ion.[17] The increase in intramolecular racemization rate of $[Fe(phen)_3]^{2+}$ with increasing nucleophile concentration can resonably be accounted for by considering ion-pair formation, as in the case of dissociation. An analysis similar to that used for the case of dissociation gave the intramolecular racemization rate constants for the ion-paired complex ion ($k_{r(X)}^{I.IP}$) and the ion-association constants ($K_{c(X)}^{I.IP}$); these are listed in Table 2. The variation in the racemization rate constant with different nucleophiles is smaller than that in the dissociation rate constant. The order for $k_{r(X)}^{I.IP}$ is: $OH^- \approx CN^- \approx F^- \approx Cl^- < Br^- < NO_2^- < H_2O < CH_3COO^- < OCN^- < I^- < N_3^- <$ thiourea $\approx SCN^- \approx SeCN^- <$ pyridine. This order of nucleophiles in accelerating the intramolecular racemization rate suggests the importance of the polarizability of nucleophiles rather than their basicity, which was suggested above to be important for nucleophile-assisted dissociation. The order seems to be in rough agreement with that proposed for the reactivity against platinum(II) complexes:[18] $OH^- < H_2O < Cl^-$ < pyridine $< Br^- < NO_2^- < N_3^- \approx SCN^- \approx I^- \approx$ thiourea $< R_3P$. The polarizability of the nucleophile was suggested to be important in determining this order. The absorption spectrum of the complex changed in the presence of KCl, KBr, KI, and KSCN, suggesting a short-range interaction between the complex and the nucleophiles. Red shifts (2—3 nm) of the visible and ultraviolet absorption bands of the complex are observed in the presence of KCl and KBr, while, for KI and KSCN, broadenings of the ultraviolet absorption band (266 nm) toward the longer wave length are observed in addition to the red shift of the visible band. A π interaction between the complex ion (possibly the phen ligand) and a nucleophile would be important for assisting the intramolecular racemization, in contrast to the importance of σ donation of a nucleophile to the central metal of the complex for assisting the dissociation. Thus, it may be said that the central metal of $[Fe(phen)_3]^{2+}$ acts as a hard acid in the dissociation assisted by nucleophilic attack and the ligand phenanthroline acts as a soft acid in the intramolecular racemization assisted by nucleophile. The large accelerating effect of pyridine on the racemization rate may be caused by the solvation-like effect on the complex cation. Remarkable effects of solvents in accelerating the racemization rates were reported for this complex.[19]

The Ion-association Constants. The ion-association constants obtained from the dissociation rates agreed with those obtained from the racemization rates within experimental uncertainties (Table 2). The order of magnitudes of the constants obtained are also in good agreement with the theoretical prediction[20] of $K_{c(X)}^{I.IP} = 1—7$ ($I=1.0$, $a=(3—12)\times10^{-8}$ cm). This can be taken as supporting the ion-pair mechanism for the dissociation and racemization discussed above. The ion-association constant of the complex with an anion increased in the order: $F^- < Cl^- < Br^- < I^-$. The order might seem to be contrary to the theoretical prediction, according to which $K_{c(X)}^{I.IP}$ increases with the increase in the reciprocal of the ionic radius of the nucleophile. However, the reversal of the order can be well understood by considering the hydration of nucleophiles. The hydration number increases with the increase in the reciprocal of the ionic radius. The effective radius of a hydrated ion would increase with the increase in the hydration number. The short-range interactions discussed above may also be a factor affecting the order given above.

(Received June 11, 1981)

Molecular orbital (MO) calculations in the discrete variational Xα (DV-Xα) scheme have been made on linear dicyano complexes, $[Ag(CN)_2]^-$, $[Au(CN)_2]^-$, and $[Hg(CN)_2]$, to clarify their electronic structures. The valence X-ray photoelectron spectra (XPS) for these compounds are also reported. The calculated energy levels are consistent with the XPS results. The relative magnitudes of the bond overlap populations show a good correlation with those of the force constants obtained from infrared data. The calculated MO features show that the mixing of the metal $(n+1)$s orbital is important in stabilizing the linear L–M–L bonds, especially in the partial cancellation of the antibonding character of the σ_g-type highest occupied molecular orbital.

Cyanide complexes have various symmetrical structures belonging to the $D_{\infty h}$, T_d, D_{4h}, and O_h point groups; the simplest of these is a linear two-coordinate complex, NC–M–CN ($D_{\infty h}$), which is formed by heavier ions with d^{10} configuration, such as Ag^+, Au^+, and Hg^{2+}. The study of the linear coordinate bond, L–M–L, is very important for inorganic chemists because it is one of the fundamental structures of coordination compounds. Orgel[1] has attributed the tendency of the d^{10} ions to form linear complexes to the d—s mixing rather than to the special stability of s—p hybrid bonds. Thus, the d_z^2 and s orbitals can be mixed together to give two new orbitals: $(1/\sqrt{2})(d_{z^2}-s)$ and $(1/\sqrt{2})(d_{z^2}+s)$. If the $(1/\sqrt{2})(d_{z^2}-s)$ orbital were occupied and the $(1/\sqrt{2})(d_{z^2}+s)$ orbital left empty, then the ligands in the x-plane would be repelled and a complex ion extending along the z-axis would be stable. However, Orgel's theory does not explain how the metal-ligand bond is formed. Moreover, Mason[2] has carried out absorption and magnetic-circular-dichroism spectral measurements for some linear dicyano complexes and has rejected the argument that metal d orbital predominantly participate in the metal-ligand σ bonding.

We have previously studied the electronic structures of octahedral[3–5] and square-planar[6] cyanide complexes. The studies on the electronic structures of the linear dicyano complexes of Ag^+, Au^+, and Hg^{2+} will complete a series of studies on cyanide complexes. In order to discuss the electronic structures of linear two-coordinate complexes, a systematic investigation of a few representative complexes has been made by means of the molecular orbital (MO) calculations and the measurements of valence X-ray photoelectron spectra (XPS).

Experimental

The complexes studied here are all well-known and were prepared by standard methods. The valence-region X-ray photoelectron spectra were recorded on a JEOL Model JESCA-3A spectrometer. Magnesium $K\alpha_{1,2}$ radiation (1253.6 eV) was used as the X-ray excitation source and the measurements were carried out at a vacuum of 5×10^{-7} Torr (7×10^{-5} Pa) or below.

Computational Method

The computations have been carried out by the discrete-variational Xα (DV-Xα) method, the details of which have been described elsewhere.[7] In the Hartree-Fock-Slater model,[8] the exchange-correlation term is give by

$$V_{xc}(1) = -3\alpha[(3/8\pi)\rho(1)]^{1/3}$$

where $\rho(1)$ is the local charge density and α is the exchange scaling parameter; the value, $\alpha=0.70$, is used for all atoms throughout the present calculations.[9] The DV-Xα self-consistent-charge (SCC) procedure[10] has been performed, where an approximate self-consistent molecular potential is determined from the Mulliken gross orbital populations. The numerical basis functions are obtained with an atom-like potential constructed by spherically averaging the molecular potential around the nucleus for the region inside each atomic sphere.[10] The basis sets include Ag 1s—5p, Au and Hg 1s—6p, and C and N 1s—2p. The molecular geometries for the complexes are assumed as follows:

Ag–C = 2.02 and C–N = 1.13 Å for $[Ag(CN)_2]^-$,

Au–C = 2.12 and C–N = 1.17 Å for $[Au(CN)_2]^-$,

Hg–C = 2.01 and C–N = 1.14 Å for $[Hg(CN)_2]$.

In the present calculations, the complexes are regarded as having the $D_{\infty h}$ symmetry.

Results and Discussion

The MO's of Free CN⁻. The electronic structure of the free cyanide ion is briefly described for convenience of comparison with coordinated cyanide ions. Table 1 shows the orbital energies (with reference to arbitrary zero level) and the Mulliken populations for the free CN^- ion. The contours of the CN^- valence MO's are also shown in Fig. 1. The main features of the CN^- MO's are: (1) the order of the valence MO energies is $3\sigma \ll 4\sigma < 1\pi < 5\sigma$, and (2) the 4σ MO has a higher density on nitrogen, 5σ on carbon, and 1π on nitrogen. The 5σ MO will play the most important role in the coordination of the cyanide ion to a metal ion, and the 4σ, 1π, and 2π MO's also take part in the metal-ligand bond through orbital mixing.

The present result from the DV-Xα calculation and

the previous one from an ab initio MO calculation nearly agree in the wavefunction maps,[4] but disagree significantly in the Mulliken populations.[3] The populations are to some extent an artifact and depend on the basis set used in the calculation.[11] The present result showing a higher population on N (in contrast to the previous one showing a higher population on C) is reasonable, considering the electronegativity of N is greater than that of C.

The Natures of MO's. Figure 2 schematically shows the symmetry-allowed interaction between the $(CN^-)_2$ and metal orbitals in a linear cyanide complex. In the formation of the complex, the σ-type metal s (σ_g), $p\sigma$ (σ_u), and $d\sigma$ (σ_g) orbitals interact with the CN^- 4σ and 5σ orbitals, and the π-type metal $d\pi$ (π_g) and $p\pi$ (π_u) orbitals with the CN^- 1π and 2π orbitals. The metal $d\delta$ orbitals do not interact with ligand orbitals because there is no cyanide valence orbital of δ_g symmetry. Table 2 gives the energies and symmetries of the occupied valence MO's together with their atomic components for $[Ag(CN)_2]^-$, $[Au(CN)_2]^-$, and $[Hg(CN)_2]$. Schematical illustrations of the MO energy levels are given in Fig. 3, which also shows the approximate levels of the metal and ligand orbitals for ready comparison. The metal d orbital level is drawn at the same energy as that of the δ_g MO, which consists almost exclusively of the metal $d\delta$ orbital. The level of the CN^- 1π orbital is drawn at the same energy as that of the $6\pi_u$ MO which consists predominantly of the 1π orbital of CN^-; the contributions of the CN^- 2π and the metal $p\pi$ orbitals to this MO are unimportant, as suggested by the orbital populations. Although such layouts of

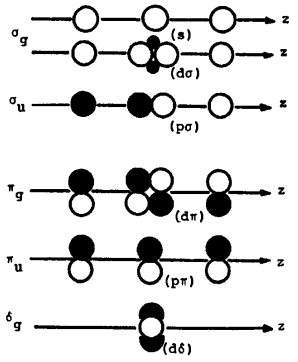

Fig. 2. $D_{\infty h}$ adapted combinations of ligand and metal orbitals.

orbital levels are arbitrary, they show approximate relative positions of the metal and ligand orbital levels in the complexes.

In the case of $[Ag(CN)_2]^-$, selected MO contours are shown in Fig. 4. In the π_g symmetry, the metal $d\pi$ orbital interacts with the 1π and 2π orbitals of CN^-, which lie above the Ag $4d\pi$ orbital. According to the orbital mixing rule,[12] the $2\pi_g$ MO with lower energy

has the dominant contribution from the metal $d\pi$ orbital and consists of the $d\pi+1\pi+2\pi$ combination. (A wavefunction with+sign has positive values in the region between the metal and carbon atoms.) On the other hand, the $3\pi_g$ MO with higher energy is the $1\pi-d\pi-2\pi$ MO (the −sign indicating negative values between M and C), in which the largest component is the 1π orbital. A slight mixing of the 2π orbital with the 1π orbital causes a decrease of the orbital population on nitrogen in the $2\pi_g$ MO and an increase of the same in the $3\pi_g$ MO.

Among σ-type MO's, $6\sigma_u$ and $8\sigma_g$ (not given in Fig. 4) are mainly constructed of the CN^- 3σ orbital. The $7\sigma_u$ and $8\sigma_u$ MO's consist of the $4\sigma+5\sigma+p\sigma$ and $5\sigma-4\sigma-p\sigma$ combinations; the $p\sigma$ orbital of Ag lies far above the 4σ and 5σ orbitals of CN^- and contributes to the MO's only slightly. The calculated orbital populations of these MO's can be explained by assuming an appropriate orbital mixing of the 4σ and 5σ orbitals; thus a mixing of 9: 1 (in the measure of electron-density) gives an estimate of orbital populations (in %) of 49(C2s), 22(C2p), 16(N2s), and 13(N2p) for the $4\sigma+5\sigma$ orbital and 6, 27, 14, and 53 for the $5\sigma-4\sigma$ orbital. These values are very similar to the populations of the $7\sigma_u$ and $8\sigma_u$ orbitals (Table 2). The metal $d\sigma$ ($4d_{z^2}$) and s (5s) orbitals as well as the ligand 4σ and 5σ orbitals belong to the same symmetry, and their energy levels are in the order of $4\sigma<d\sigma<5\sigma<s$. They are mixed together to form the $9\sigma_g$, $10\sigma_g$, and $11\sigma_g$ MO's. The 4σ orbital of CN^- is dominant in the $9\sigma_g$ MO, having

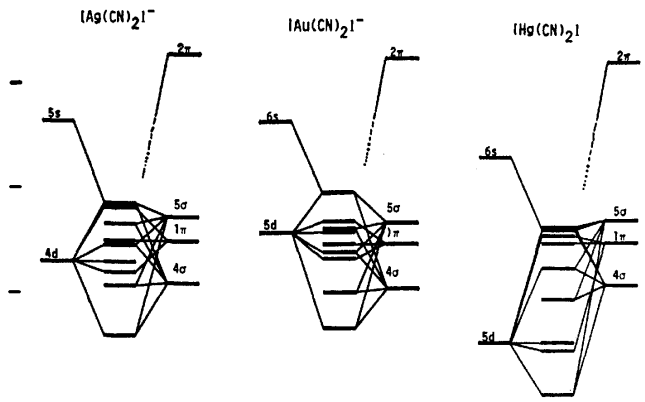

Fig. 3. Schematically illustrated MO energy levels with the levels of metal and cyanide orbitals. The MO level orderings (from the top to the bottom) are: $11\sigma_g$, $3\pi_g$, $8\sigma_u$, $4\pi_u$, $10\sigma_g$, $2\delta_g$, $2\pi_g$, $7\sigma_u$, and $9\sigma_g$ for $[Ag(CN)_2]^-$; $13\sigma_g$, $4\pi_g$, $10\sigma_u$, $3\delta_g$, $6\pi_u$, $12\sigma_g$, $3\pi_g$, $9\sigma_u$, and $11\sigma_g$ for $[Au(CN)_2]^-$; $10\sigma_u$, $13\sigma_g$, $4\pi_g$, $6\pi_u$, $12\sigma_g$, $9\sigma_u$, $3\delta_g$, $3\pi_g$, and $11\sigma_g$ for $[Hg(CN)_2]$.

bonding interactions with the metal orbitals ($4\sigma+5\sigma+d\sigma+s$). Both Table 2 and Fig. 4 show a considerable mixing of the 5σ into the 4σ orbitals (about 4 : 6 in the $9\sigma_g$ MO). They also show that the $10\sigma_g$ MO is nearly nonbonding with regard to the M–C bond and has the highest electron density in the N lone-pair regions; the $10\sigma_g$ wavefunction is expressed as $5\sigma-4\sigma+d\sigma-s$. This minus combination of the 4σ with 5σ orbitals decreases the carbon charge and increases the charge on nitrogen. The HOMO, $11\sigma_g$, is antibonding with respect to the M–C bond and corresponds to a $d\sigma-s$ hybrid orbital with $d\sigma-s-5\sigma(+4\sigma)$ combination (Fig. 5); the antibonding interactions of the $d\sigma$ with the 5σ orbital is relaxed by the mixing of the s orbital of the metal.

In $[Au(CN)_2]^-$, the valence shell MO's are similar to those of the Ag^+ complex. The HOMO is $13\sigma_g$, which corresponds to the $11\sigma_g$ MO of the latter. However, the Au^+ complex gives a slightly different MO level diagram from that for the Ag^+ complex; the relative position of the δ_g MO is higher for the Au^+ complex, indicating that the d level of Au^+ in the complex is higher than that of Ag^+ (Fig. 3). Thus the highest occupied π_g-type orbital, $4\pi_g$, has more the character of the metal $d\pi$ orbital rather than that of the ligand π orbital, while the corresponding orbital of $[Ag(CN)_2]^-$, $3\pi_g$, is characterized as a predominantly ligand orbital.

The atomic d orbital of Hg^{2+} is situated at a lowet energy than those of Ag^+ and Au^+. Thus, in $[Hg(CN)_2]$, the $11\sigma_g$, $3\pi_g$, and $3\delta_g$ MO's are composed predominantly of metal d orbitals, while the HOMO ($10\sigma_u$) is localized mainly on ligands. This feature is very different from those for the Ag^+ and Au^+ complexes. In the σ_g system, the sequence of the orbital energy is $d\sigma<4\sigma<5\sigma<s$. The $11\sigma_g$ MO has the metal $d\sigma$ (d_{z^2}) orbital as the main component, with small contributions of the 4σ, 5σ, and metal s orbitals. This ($d\sigma+4\sigma+5\sigma+s$)-type MO is bonding with respect to the Hg–CN bond. In the $12\sigma_g$ MO, the main component is the 4σ orbital with the combination of $4\sigma-5\sigma-d\sigma+s$, while the 5σ orbital is dominant in the $13\sigma_g$ MO with $5\sigma-4\sigma-d\sigma+s$. The contribution of the metal s orbital in these MO's relaxes the antibonding interaction of the $d\sigma$ with the 4σ or 5σ orbitals, thus strengthening the metal-cyanide bonds.

Main Features of Bonding Structure in NC–M–CN. As can be seen from the MO contours (Fig. 4) and energy-level diagrams (Fig. 3), the σ bond is very strong. This is also suggested by the M–C bond overlap population given in Table 4. The greatest contribution to the stabilization of the complexes is made by the bonding interaction of the metal $d\sigma$ orbital and the ($4\sigma+5\sigma$)-type

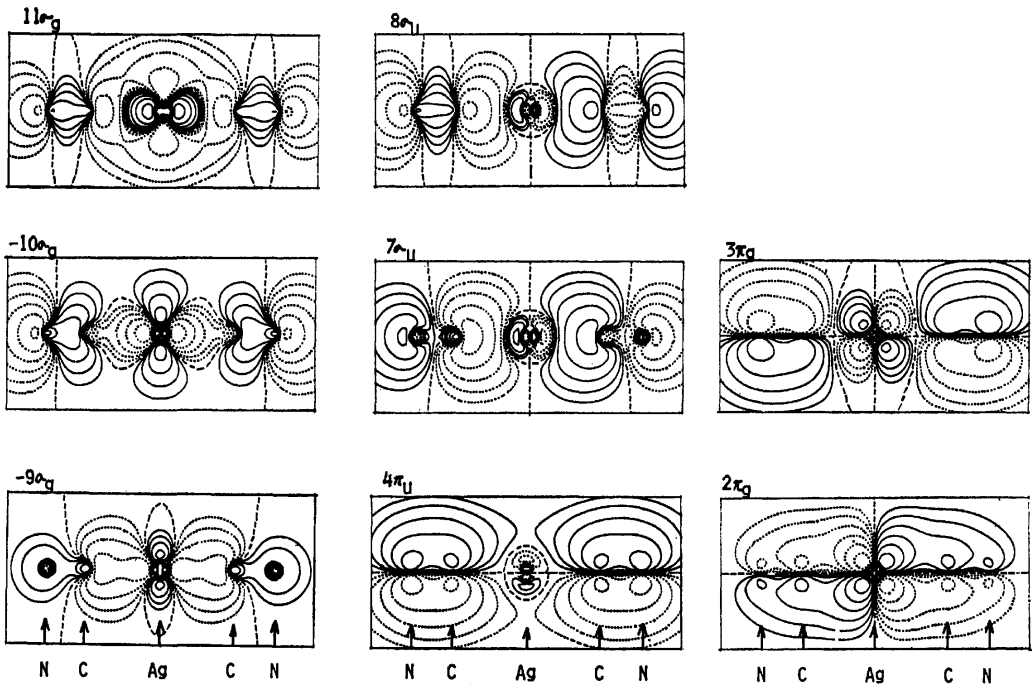

Fig. 4. Selected valence-shell MO contours for $[Ag(CN)_2]^-$.

ligand orbital, resulting in the $9\sigma_g$ (Ag complex) or $11\sigma_g$ (Au and Hg complexes) MO, in which the (dσ+s)-type mixing of the $(n+1)$s with the ndσ orbital also occurs to add a minor contribution to the stabilization of the M–C bond. On the other hand, the (dσ—s)-type metal orbitals interact with the $(5\sigma-4\sigma)$-type ligand orbital to form an antibonding $11\sigma_g$ (Ag complex) or $13\sigma_g$ (Au and Hg complexes) MO, in which the $(n+1)$s orbital is considerably mixed with the ndσ orbital to reduce the antibonding character of the MO. The orbital interactions discussed above are schematically illustrated in Fig. 5.

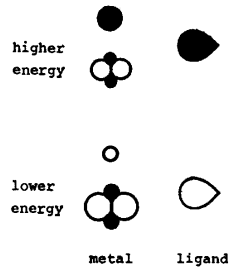

Fig. 5. Orbital interactions of metal dσ and s orbitals and ligand orbitals of σ_g symmetry. (Only one of the ligand orbitals is shown.) The size indicate the magnitudes of orbital components. The positive and negative signs of the orbitals are shown by the white and black area.

The situation mentioned above is in contrast to Orgel's simplified theory,[1] according to which the dσ—s orbital is stabilized while the destabilized dσ+s orbital is empty. However, the bonding structure observed here might be peculiar to the cyanide complexes. In these complexes, the soft cyanide ions strongly interact with the soft noble-metal ion to form bonds of highly covalent character; the cyanide 4σ and 5σ orbitals are mixed with each other to result in the $(4\sigma+5\sigma)$-type orbital, which has an increased electron density at the carbon atoms, and efficiently interact with the metal dσ orbital to form coordinate bonds. Moreover, the small separation of the nd and $(n+1)$s orbital energies (6.7 eV for Ag, 5.7 eV for Au, and 8.8 eV for Hg) results in a large contribution of the metal $(n+1)$s orbital to the valence MO's to relax the antibonding interaction of the dσ and the CN^- σ orbitals, stabilizing a linear complex for Ag^+, Au^+, and Hg^{2+}.

Valence XPS. Figure 6 shows the valence XPS for linear cyanides as well as the calculated energy levels of the MO's with a significant metal d character. The lengths of the lines denote the extents of the metal d contribution, and are roughly proportional to the cross-section of photoionization, because the cross-sections of the d orbitals of heavy atoms are significantly larger than those of cyanide orbitals. For ready comparison, the position of the calculated energy-level of the δ_g orbital with esentially d character is arbitarily adjusted so as to coincide with the largest XPS peak of each spectrum. A reasonably good agreement is observed between the computed d level schemes and the experimental spectra. Thus the main peaks for the silver(I)

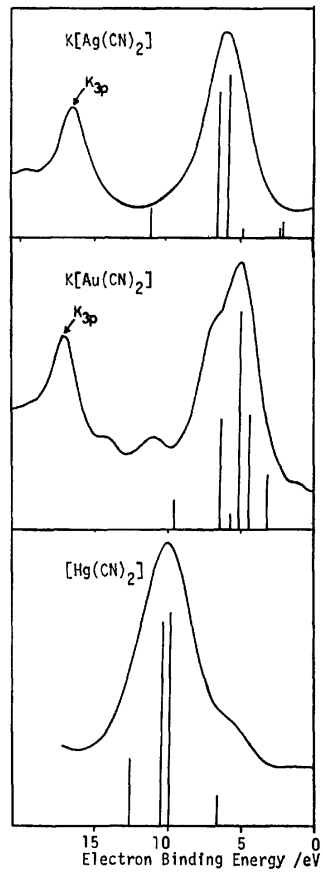

Fig. 6. Valence region of XPS and the orbital energy levels for $K[Ag(CN)_2]$, $K[Au(CN)_2]$, and $[Hg(CN)_2]$. Only the orbitals with large cross-sections are shown.

and gold(I) cyanide complexes appearing near 6.0 and 5.2 eV correspond to the $2\delta_g$ and $3\delta_g$ MO's, respectively. For the mercury(II) cyanide, the main peal at 10 eV is assigned to the $3\delta_g$ and $3\pi_g$ MO's overlapping each other. The complicated structure of the main peak for the Au^+ complex implies a strong interaction between Au and ligands.

Population Analysis. Table 3 gives the results of the Mulliken population analysis for linear dicyano complexes. The deviations of the effective metal charges (+0.42, +0.33, and +1.11) from formal charge for Ag^+, Au^+, and Hg^{2+} are respectively 0.58, 0.67, and 0.89, which show no remarkable difference in the net ligand-to-metal electron donation between uni- and bi-valent metals.

The net negative charge on carbon is largest in the Hg^{2+} complex. This might seem to be in conflict with the conventional argument that the ligand-to-metal electron donation would occur most extensively in the Hg^{2+} complex. However, the consideration of π back-donation will explain the puzzling situation. The variation of carbon charge among these complexes is mainly due to that in the Cpπ population (1.80 for Ag^+, 1.79 for Au^+, and 1.93 for Hg^{2+}). The change in nitrogen charge also results from that in the NPπ population (2.27, 2.27, and 2.07). Since the π back-donation causes a decrease in the carbon population and an increase in nitrogen population, the values of the

Table 3. The Mulliken populations for linear dicyano complexes

		$[Ag(CN)_2]^-$	$[Au(CN)_2]^-$	$[Hg(CN)_2]$

	$2p\pi$	2.27	2.27	2.07
	Charge	−0.50	−0.49	−0.30
Bond overlap populations				
M–C	σ	0.36	0.40	0.41
	π	0.08	0.07	0.05
C–N	σ	0.38	0.41	0 41
	π	0.88	1.05	1.09

$Cp\pi$ and $Np\pi$ populations show that the π back-donation is smallest in the Hg^{2+} complex. On the other hand, the sum of the Cs and $Cp\sigma$ populations is smallest in the Hg^{2+} complex, indicating that the σ donation is largest in this complex. Both the smallest π back-donation and the largest σ donation is consistent with the highest electronegativity of Hg^{2+}.

The bond overlap populations of M–C and C–N increase in the orders of $Ag^+ < Hg^{2+} < Au^+$ and $Ag^+ < Au^+ < Hg^{2+}$, respectively. The infrared results show the orders of $Ag^+ < Hg^{2+} < Au^+$ and $Ag^+ < Au^+ < Hg^{2+}$ for the force constants of the M–C and C–N bonds,[14] respectively. The good agreement between the orders of the bond overlap populations and of the force constants may suggest that both of them are closely related to the bond strength.

The computations reported in this paper have been carried out on the HITAC M-180 computer of the Institute for Molecular Science.

(Received June 30, 1981)

Thermal reactions of the $[Ni(H_2O)_2(AA)_2]X_2 \cdot nH_2O$ complexes in a solid phase were investigated, where AA is *N,N'*-diethylethylenediamine (*NN'*-deen), *N,N*-dimethylethylenediamine (*NN*-dmen), or *N,N'*-dimethylethylenediamine (*NN'*-dmen), and where X^- is Cl^-, Br^-, I^-, NO_3^- or ClO_4^-. By means of thermal analyses and spectral and magnetic measurements in a series of these complexes before and after heating, the following results were obtained. In the case of the *NN'*-deen complexes, only the perchlorate deaquates to change from octahedral to square-planar, but the other salts, such as the chloride, bromide, iodide, and nitrate, undergo deaquation-anation keeping their octahedral configuration. The deaquation-anation was also observed in the chloride, bromide, and nitrate of the *NN*-dmen complexes, but the iodide deaquated, and so was transformed from octahedral to square-planar. In the *NN'*-dmen complexes, only deaquation-anation was detected, irrespective of the anions (Cl^-, Br^-, I^-, and NO_3^-). The effects of *N*-substituents in the diamines and the anions on the above transformation were discussed.

There are three main types of nickel(II) complexes: the first group consists of blue or green, paramagnetic complexes with an octahedral configuration; the second consists of analogously paramagnetic complexes, but with a tetrahedral configuration, and the third consists of red, orange or yellow, diamagnetic complexes with a square-planar configuration.[1] In 1939, Lifschitz *et al.*[2] pointed out that the $[Ni(stien \text{ or } phenen)_2]X_2 \cdot nH_2O$ complexes (stien: 1,2-diphenyl-1,2-ethanediamine; phenen: 1-phenyl-1,2-ethanediamine; X: Cl^-, $ClCH_2COO^-$, $HCOO^-$, and $1/2SO_4^{2-}$; *n*: 0 to 4) easily undergo mutual transformation (yellow diamagnetic ↔blue paramagnetic species), with a slight variation depending upon the kind of X and the hydration states. Since then, such mutual configurational change or equilibration between any two of the three types has often been found in aqueous and some organic solvents.[3,4] Such changes have also been observed in a solid phase in some limited cases. An example of the change from a square-planar to a tetrahedral configuration was reported in nickel(II) complexes with *N*-methylsalicylideneamine and its derivatives in a solid phase.[5,6] One of the examples of the octahedral-to-square-planar change is seen in $[Ni(H_2O)_2(NN\text{-deen})_2]Br_2 \cdot H_2O$, where *NN*-deen is *N,N*-diethylethylenediamine,[7] while the reverse change, square-planar-to-octahedral, is found in the nickel(II) complex with 2-aminobenzimidazole.[8]

In a series of $[Ni(H_2O)_2(NN\text{-deen})_2]X_2 \cdot nH_2O$-type complexes,[7] the chloride undergoes anation by the counter-chloride ion after the liberation of coordinated water, keeping the octahedral configuration, whereas the bromide loses the coordinated water to form a square-planar structure without anation upon heating in a solid phase, as has been described above. For the iodide and perchlorate, the octahedral complexes were not obtained with two coordinated water molecules; only anhydrous square-planar complexes were formed. In addition to the kind of counter ion, the structure of *N*-alkylethylenediamines is expected to affect the feature of the configurational change of nickel(II) complexes.

The present study aimed to investigate what different changes appear when $Ni(AA)_2X_2 \cdot nH_2O$ are heated. As the diamines, AA, *N,N'*-diethylethylenediamine (*NN'*-deen), *N,N*-dimethylethylenediamine (*NN*-dmen), and *N,N'*-dimethylethylenediamine (*NN'*-dmen) were selected; X^- was Cl^-, Br^-, I^-, NO_3^-, or ClO_4^-.

Experimental

Preparation of Complexes. The *NN'*-deen, *NN*-dmen, and *NN'*-dmen were of a commercial-reagent grade and were used without further purification. The $[Ni(H_2O)_2(NN'\text{-deen})_2]X_2$ (X^-=Cl^-, Br^-, I^-, NO_3^-, and ClO_4^-),[9] $[Ni(H_2O)_2(NN\text{-dmen})_2]Cl_2 \cdot 2H_2O$,[10] $[Ni(H_2O)_2(NN\text{-dmen})_2]X_2$ (X^-=Br^-, I^-, and NO_3^-),[10] and $[Ni(H_2O)_2(NN'\text{-dmen})_2]X_2 \cdot 2H_2O$ (X^-=Cl^-, Br^-, I^-, and NO_3^-)[10] complexes were prepared by a method similar to that of the literature, their chemical formulas being identified by means of elemental analyses and spectral measurements. The perchlorates containing *NN*-dmen and *NN'*-dmen were not obtained in a pure form.

Thermal Analyses. The TG, DTA, and DSC measurements were made with a MOM Derivatograph, Typ-OD-102, and a Rigaku Denki Standard TG-DSC apparatus.

Spectral Measurements. The visible and ultraviolet spectra in a solid state were measured by the diffuse reflectance method with a Hitachi EPU-2A spectrophotometer equipped with a standard Hitachi reflection attachment. The IR spectra were obtained with JASCO-IR-E and -IR-F infrared spectrophotometers.

Magnetic Measurements. The effective magnetic moments were evaluated from the magnetic susceptibilities, as measured by the Gouy method at room temperature.

Results and Discussion

$[Ni(H_2O)_2(NN'\text{-deen})_2]X_2$. DSC Measurements: The TG and DSC curves of $[Ni(H_2O)_2(NN'\text{-deen})_2]X_2$ (X^-=Cl^-, Br^-, I^-, NO_3^-, and ClO_4^-) are given in Fig. 1. From the DSC peak temperatures in Fig. 1, the coordinated water molecules are found to be easily evolved in this order: perchlorate (103 °C)<bromide (96 °C)<iodide (93 °C)<nitrate (74 °C)<chloride (66 °C).

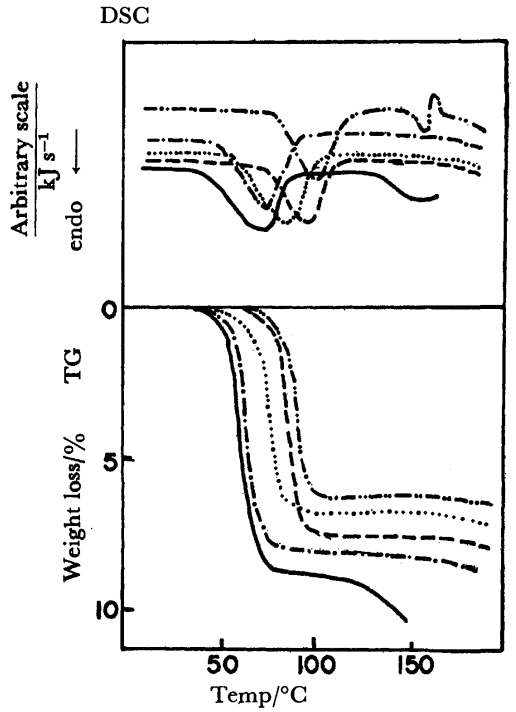

Fig. 1. DSC curves for $[Ni(H_2O)_2(NN'\text{-deen})_2]X_2$, where $X^-=Cl^-$ (——), Br^- (– – –), I^- (------), NO_3^- (-·-·-), and ClO_4^- (-·-·-·-).

A striking difference is, however, seen in the DSC curve for $[Ni(H_2O)_2(NN'\text{-deen})_2](ClO_4)_2$; the successive endo- and exothermic peaks appear at about 160 °C, where no change is observed in the TG curve, which retains a plateau.

Absorption Spectra: The absorption spectra measured by the diffuse-reflectance method for $[Ni(H_2O)_2(NN'\text{-deen})_2]Cl_2$ and $[Ni(H_2O)_2(NN'\text{-deen})_2]Br_2$ before and after heating at 130 °C are shown in Fig. 2.

It can be seen from this figure that both of the aqua complexes give three absorption bands, at 12.5, 17.6, and 27.8×10^3 cm^{-1} at room temperature; these bands can be assigned to the $^3A_{2g}\rightarrow{}^3T_{2g}$, $^3A_{2g}\rightarrow{}^3T_{1g}$ (F), and $^3A_{2g}\rightarrow{}^3T_{1g}$ (P) electron transitions respectively, irrespective of the kind of counter ion, Cl^- or Br^-. The spectra of the anhydrous salts obtained upon heating are almost identical with those of the mother complexes, except for a slight shift of the maximum peaks to the longer-wavelength region (*e.g.*, the third absorption peaks in the chloride and bromide shift to 26.7×10^3 cm^{-1}).

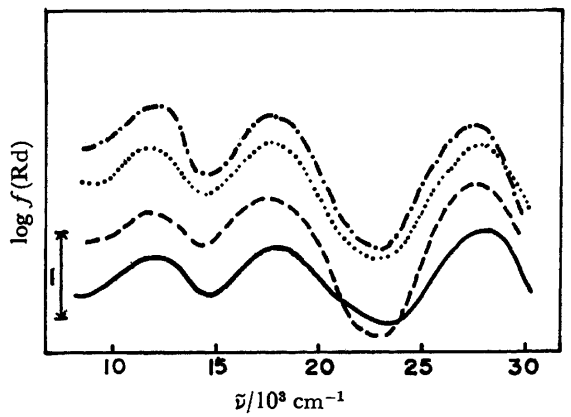

Fig. 2. Absorption spectra for $[Ni(H_2O)_2(NN'\text{-deen})_2]Cl_2$] before (——) and after (– – –) heating, and those for $[Ni(H_2O)_2(NN'\text{-deen})_2]Br_2$ before (------) and after (-·-·-) heating.

Similar patterns were observed in the spectra of the iodide and nitrate (not shown): the third absorption peaks in the iodide and nitrate shift from 28.1 to 26.9×10^3 cm^{-1} and from 28.1 to 27.5×10^3 cm^{-1} respectively. In all these complexes, a color change from violet to blue was observed upon heating, except that the iodide gives a color change from violet to green.

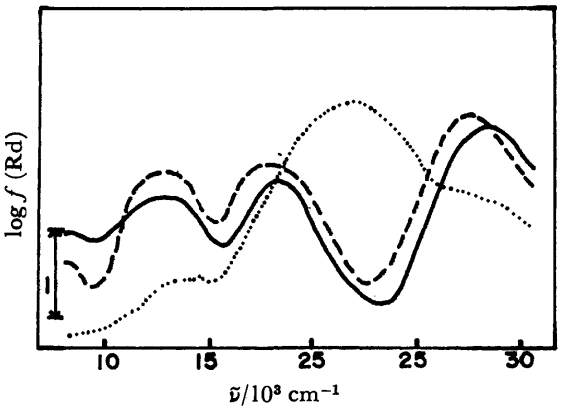

Fig. 3. Absorption spectra for $[Ni(H_2O)_2(NN'\text{-deen})_2](ClO_4)_2$ before (——) and after heating at 130 °C (– – –) and at 160 °C (------).

On the other hand, a color change from violet to orange through gray was observed in the $[Ni(H_2O)_2(NN'\text{-deen})_2](ClO_4)_2$ complex at 160 °C, where a complicated DSC peak appears. The absorption spectra measured at room temperature and those measured at 130 ° and at 165 °C areshown in Fig. 3. As may be seen in the figure, the former two spectra are very similar to each other, indicating three absorption bands characteristic of six-coordinated nickel(II) complexes, although slight shifts are observable in each absorption peak at 130 °C. At 165 °C, however, these three absorption bands disappear, and a strong band at 21.5×10^3 cm^{-1}, characteristic of the square-planar structure and probably assignable to the $^1A_{1g}\rightarrow{}^1A_{2g}$ transition, appears instead.

IR Spectra. The representative infrared absorption spectra before and after heating are given in Fig. 4 for $[Ni(H_2O)_2(NN'\text{-deen})_2](ClO_4)_2$. The figure shows that the considerably weak absorption peak at *ca.* 930 cm^{-1} assignable to the Cl–O stretching vibration grows upon heating at 130 °C as a result of the coordination of ClO_4^- to the metal and is then weakened at 165 °C. This rise and fall of the absorption peak corresponds to the color change of the complex: violet→gray→orange. This suggests that the complex loses the coordinated water to undergo the anation of ClO_4^- at 130 °C, and that ClO_4^- is then liberated from the coordination sphere upon further heating.[11]

Magnetic Susceptibilities. The values of the effec-

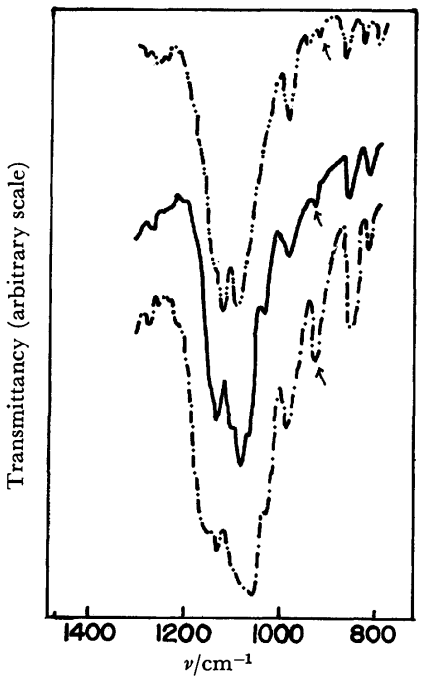

Fig. 4. IR spectra for $[Ni(H_2O)_2(NN'\text{-deen})_2](ClO_4)_2$ at room temperature (——), upon heating at 130 °C (-·-·-) and at 165 °C (-···-···-).

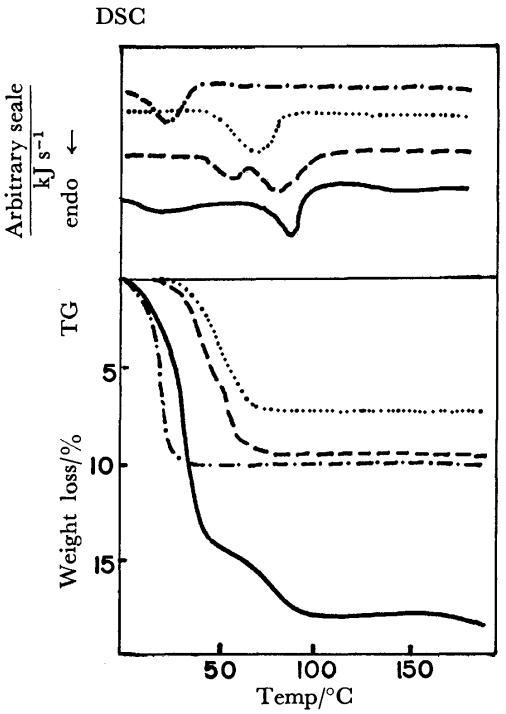

Fig. 5. DSC curves for $[Ni(H_2O)_2(NN\text{-dmen})_2]Cl_2 \cdot 2H_2O$ (——), $[Ni(H_2O)_2(NN\text{-dmen})_2]X_2$, where X= Br^- (----), I^- (·····), and NO_3^- (-·-·-).

tive magnetic moments of the complexes before and after heating are summarized in Table 1. All the $[Ni(H_2O)_2(NN'\text{-deen})_2]X_2$ complexes have paramagnetism corresponding to the two unpaired electrons in octahedral nickel(II) complexes. Upon heating, all except for the perchlorate keep the original paramagnetism. This suggests that the octahedral configuration is still kept as a result of the anation of counter ions in the chloride, bromide, iodide, and nitrate. Only the perchlorate, however, gives a change in the magnetic behavior, paramagnetism→diamagnetism, corresponding to the gray→orange color change. This suggests that ClO_4^- once coordinates to the nickel ion, yielding a six-coordinated complex, and then gets free from the coordination sphere to form a square-planar complex.

$[Ni(H_2O)_2(NN\text{-dmen})_2]X_2 \cdot nH_2O$. DSC Measurements: The TG and DSC curves for $[Ni(H_2O)_2(NN\text{-dmen})_2]Cl_2 \cdot 2H_2O$ and $[Ni(H_2O)_2(NN\text{-dmen})_2]X_2$ (X^-= Br^-, I^-, and NO_3^-) are shown in Fig. 5. The temperature giving DSC peaks becomes lower in this order: chloride (88 °C) >bromide (83 °C) >iodide (70 °C) >nitrate (30 °C).

Absorption Spectra: The absorption spectra of $[Ni(H_2O)_2(NN\text{-dmen})_2]X_2 \cdot nH_2O$ (X^-=Cl^-, Br^-, I^-, and NO_3^-) before and after heating are given in Fig. 6. In the chloride, bromide, and nitrate, the three absorption bands characteristic of the six-coordinated nickel(II) complexes are not quenched, but show a shift to a somewhat longer wavelength region upon heating, the

TABLE 1. EFFECTIVE MAGENTIC MOMENTS OF THE COMPLEXES BEFORE AND AFTER HEATING

$[Ni(H_2O)_2(NN'\text{-deen})_2]Cl_2$	2.96	2.90
$[Ni(H_2O)_2(NN'\text{-deen})_2]Br_2$	3.03	2.95
$[Ni(H_2O)_2(NN'\text{-deen})_2]I_2$	2.96	2.92
$[Ni(H_2O)_2(NN'\text{-deen})_2](NO_3)_2$	2.94	2.94
$[Ni(H_2O)_2(NN'\text{-deen})_2](ClO_4)_2$	2.91	2.94,[a] diamag[b]
$[Ni(H_2O)_2(NN\text{-dmen})_2]Cl_2 \cdot 2H_2O$	3.13	2.90
$[Ni(H_2O)_2(NN\text{-dmen})_2]Br_2$	3.02	2.91
$[Ni(H_2O)_2(NN\text{-dmen})_2]I_2$	3.26	diamag
$[Ni(H_2O)_2(NN\text{-dmen})_2](NO_3)_2$	2.96	3.17
$[Ni(H_2O)_2(NN'\text{-dmen})_2]Cl_2 \cdot 2H_2O$	3.18	3.00
$[Ni(H_2O)_2(NN'\text{-dmen})_2]Br_2 \cdot 2H_2O$	3.08	2.95
$[Ni(H_2O)_2(NN'\text{-dmen})_2]I_2 \cdot 2H_2O$	3.18	2.93
$[Ni(H_2O)_2(NN'\text{-dmen})_2](NO_3)_2 \cdot 2H_2O$	3.16	3.17

a) Upon heating at 130 °C. b) Upon heating at 165 °C.

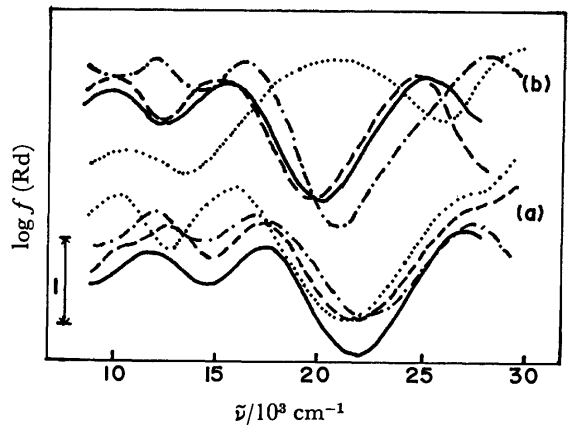

Fig. 6. Absorption spectra for $[Ni(H_2O)_2(NN\text{-dmen})_2]X_2$ before (a) and after (b) heating, where X^-=Cl^- (——), Br^- (——), I^- (·····) and NO_3^- (-·-·-).

color changing from pale blue to greenish blue, to green, and to blue respectively. Only in the iodide does the color change from the original pale blue to orange, and a new strong band due to the formation of a square-planar complex appears after the liberation of the coordinated water.

Magnetic Susceptibilities: As is shown in Table 1, the effective magnetic moments of $[Ni(H_2O)_2(NN\text{-dmen})_2]X_2 \cdot nH_2O$ are all paramagnetic. After heating, the paramagnetism is not lost in the chloride, bromide, and nitrate, indicating that the octahedral configuration is still maintained as a result of the anation of counter ions, whereas only the iodide gives diamagnetism upon heating, suggesting that it undergoes the configurational change to square-planar from octahedral.

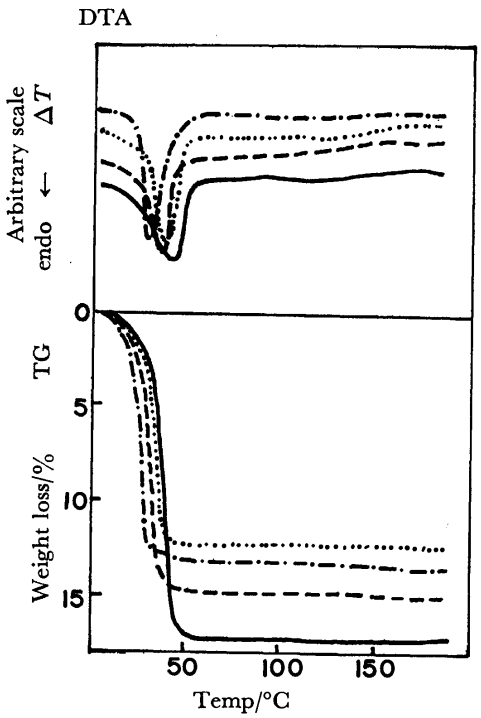

Fig. 7. TG and DTA curves for $[Ni(H_2O)_2(NN'\text{-dmen})_2]X_2 \cdot 2H_2O$, where X^-=Cl^- (——), Br^- (——), I^- (·····), and NO_3^- (-·-·-).

$[Ni(H_2O)_2(NN'\text{-dmen})_2]X_2 \cdot nH_2O$. *DTA Measurements*: The DTA measurements were carried out in this series of compounds because these compounds deaquated even below 50 °C and because our DSC apparatus could not be employed below that temperature. The TG and DTA curves for these compounds are shown in Fig. 7. The temperature giving DTA peaks becomes lower in this order: chloride (52 °C)>iodide (38 °C)>bromide (34 °C)>nitrate (32 °C).

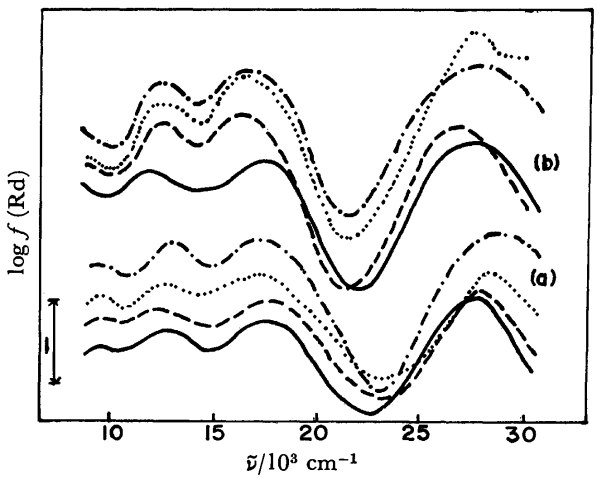

Fig. 8. Absorption spectra for $[Ni(H_2O)_2(NN'\text{-dmen})_2]X_2 \cdot 2H_2O$ before (a) and after (b) heating, where X^-= Cl^- (——), Br^- (----), I^- (·····), and NO_3^- (-·-·-).

Absorption Spectra: The absorption spectra of $[Ni(H_2O)_2(NN'\text{-dmen})_2]X_2 \cdot 2H_2O$ (X=Cl^-, Br^-, I^-, and NO_3^-) before and after heating are given in Fig. 8. In this case, all the complexes are pale blue and give the three absorption bands. After heating, they are still blue, and these absorption bands remain, except for a slight shift to the longer-wavelength region.

Magnetic Susceptibilities: The data in Table 1 show that all the complexes containing *NN'*-dmen, both before and after heating, give paramagnetism, indicating that these complexes undergo the anation of counter ions while keeping their six-coordinated, octahedral configuration.

Effect of N-*Substituents in Ethylenediamine upon Configurational Change*: Table 2 summarizes the configurational changes in $[Ni(H_2O)_2(AA)_2]X_2 \cdot nH_2O$-type complexes.

Table 2. Configurational changes in $[Ni(H_2O)_2(AA)_2]X_2 \cdot nH_2O$-type complexes

AA	X⁻				
	Cl^-	Br^-	I^-	NO_3^-	ClO_4^-
NN'-dmen	A[a]	A	A	A	—
NN'-deen	A	A	A	A	A[b], B[c]
NN-dmen	A	A	B	A	—
NN-deen[d]	A	B[a]	C[a]	C	C

a) A denotes that the complexes undergo deaquation-anation, keeping an octahedral configuration; B, that the complexes deaquate to form square-planar complexes, and C, that square-planar complexes are exclusively obtained. b) At 130 °C. c) At 165 °C. d) Ref. 7.

It shows that the feature of the configurational change is dependent upon the position to which the substituents are attached and upon the kind of substituent, methyl or ethyl. First, in the complexes containing *NN'*-dmen or *NN'*-deen, where two methyl or ethyl groups are combined with different nitrogen atoms, all the complexes undergo anation after liberating coordinated water except for the perchlorate containing *NN'*-deen. On the other hand, in the complexes having *NN*-dmen, where two substituents are combined in the same nitrogen atom, the iodide undergoes the configurational change from octahedral to square-planar after dehydration. In *NN*-deen complexes, on the other hand, the bromide undergoes a similar change to the iodide of the *NN*-dmen complex, while the iodide and perchlorate only give the anhydrous square-planar structure, without any anation. Such differences between the complexes containing *N,N'*- and *N,N*-disubstituted diamines are probably due to the larger steric hindrance of the *N,N*-disubstituent against the anation than that of the *N,N'*-disubstituent. This was because, in the stable form of the *NN'*-dmen and *NN'*-deen complexes, the substituents can all be equatorial, whereas in the *NN*-dmen and *NN*-deen complexes, at least one of the substituents in these diamines is forced to take the axial position.

By inspecting the different behavior in configurational change observed upon heating between octahedral *NN*-dmen and *NN*-deen complexes, the latter has been found more easily to turn or take a square-planar configuration than the former. That is, in the bromide, the *NN*-dmen complex only undergoes anation, while the *NN*-deen complex does not undergo anation, but gives a square-planar configuration, upon heating. In the iodide, where the iodide ion has a larger radius than the bromide ion, the *NN*-dmen complex gives a square-planar configuration after liberating the coordinated water upon heating, but the *NN*-deen complex does not form an octahedral complex with coordinated water, but forms only a square-planar complex. The perchlorate containing *NN*-deen also shows the same behavior as the corresponding iodide. Such differences between *NN*-dmen and *NN*-deen complexes are possibly attributable to the bulkiness of the ethyl group relative to the methyl group. Moreover, the easier formation of square-planar complexes in the iodide than in the bromide is probably also attributable to the larger size of an iodide ion.

The Continuous Determination of Filtered Chemical-oxygen Demand with Potassium Dichromate by Means of Flow-injection Analysis

Takashi KORENAGA

School of Engineering, Okayama University, Tsushima-naka, Okayama 700

(Received August 4, 1981)

A useful method, based on the principle of flow-injection analysis, whose flow system is physically analyzed to operate the apparatus, is proposed for the continuous and rapid determination of chemical-oxygen demand (COD) as a dichromate value in organic-waste-water samples. Potassium dichromate in sulfuric acid (1+2) is pumped as an oxidizing and spectrophotometric reagent stream, and D-glucose is successfully used as a standard substance for COD. A redox reaction between potassium dichromate and organic COD substances is carried out at 100 °C in the poly(tetrafluoroethylene) tubing (0.6 mm i.d. × 50 m) of the system. The peaks, obtained at 445 nm in the recordings, show a good reproducibility over a wide range of COD values. A sampling rate of 10 samples per hour is achieved even when the residence time is 30 min. The precision with this method is 1.3%. Chloride up to 200 mg dm^{-3} does not interfere with the determination even if silver or mercury salts are not added.

Of the water pollution which was recognized in Western countries and in Japan during 1970's, chemical-oxygen demand (COD) due to organic substances was the most common. Hence, in Japan, it was decided that the total loads of COD would be regulated from July, 1981, in Japanese water areas having the characteristics of being semiclosed water bodies around which industries and population have concentrated.[1] In this regulation, it was also decided that only the manual acidic permanganate method (COD_{Mn}),[2] cited as a Japan Industrial Standard (JIS), was to be used officially to measure such organic substances. However, the standard dichromate method (COD_{Cr}),[2,3] based on the reduction of a potassium dichromate solution under specific conditions, is ordinarily used to measure such organic substances as the COD value in Western countries. This method is, though, very time-consuming, poisonous, and dangerous because of its complicated manual procedure (*i.e.*, refluxing for 2 h, the use of mercury sulfate, and the use of a concentrated and hot sulfuric acid solutions).

Previously, the present author proposed an idea for the COD measuring apparatus with potassium permanganate using the flow-injection analysis (FIA),[4] a method which was developed by Růžička and Hansen[5] and reviewed by Betteridge.[6] Since then, this apparatus has been utilized in the field of practical analysis of COD values;[7] the apparatus and its derivatives have, for instance, been used for the continuous determination of the COD values ($COD_{FIA\text{-}Mn}$) of various waste-water samples.[8–11] However, the redox reaction with permanganate was essentially incomplete and was variable for the COD determination. Therefore, the FIA method was fairly troublesome for a continuous operation of the apparatus because of a precipitate formation (*i.e.*, manganese(IV) oxide), Hence, to obtain good continuously operating conditions, potassium dichromate should be used as an oxidizing and spectrophotometric reagent for the COD determination by the FIA method, since the redox reaction with dichromate was much more complete and constant than that with permanganate.

This paper will, therefore, describe a version of a newer FIA method with potassium dichromate for the continuous determination of $COD_{FIA\text{-}Cr}$ values in organic, waste-water samples; an improvement of the previous FIA method with permanganate,[4,7–11] reported in this laboratory, by utilizing potassium dichromate in sulfuric acid (1+2) and by analyzing the flow system of the FIA apparatus, and an evaluation of the present FIA method by comparing it with the manual COD_{Cr} method,[2,3] already optimized as a standard.

Experimental

Reagent. About 3 mol m^{-3} potassium dichromate in a sulfuric acid (1+2) solution was used as an oxidizing and spectrophotometric reagent for a carrier stream. D-Glucose, of an analytical reagent grade, was used as a standard substance for COD.[12,13] Various concentrations of aqueous solutions, the COD_{Cr} values of which had beforehand been measured by the standard manual method,[2,3] were used to determine the operating conditions of the present FIA apparatus with potassium dichromate.

Apparatus and Procedure. A flow diagram of the apparatus for measuring $COD_{FIA\ Cr}$ using potassium dichromate developed here is shown in Fig. 1. The apparatus is simply constructed of commercially available parts for high-performance liquid chromatography and poly(tetrafluoroethylene) (PTFE) tubings to give the highest performance.

The potassium dichromate in a sulfuric acid (1+2) solution (A in Fig. 1), which is filtered with a PTFE membrane filter (B) and degassed with a glass degassor (C), is pumped up to the FIA system with a Kyowaseimitsu Model KHU-52, single-reciprocating micro-pump (D) at a pumping rate of 0.6 cm^3 min^{-1}. The two tubes, (a) and (b), are made of 2-mm inner diameter (i.d.) × 0.5-m length and 0.5-mm i.d. × 0.5-m length PTFE tubings respectively. A small volume (*e.g.*, 20 mm^3) of a properly diluted sample solution is introduced just after a line filter (E) through a sample injector with a septum rubber (F) by means of manual injection using a glass syringe. The sample merged with the carrier solution (A) in a reaction tube (c), made of 0.6-mm i.d. and 50-m length, is heated at 100 °C with a Toyoseisakusyo Model VC-250, thermostatted bath using corn oil (G). The resulting solution is transported to a quartz tubular flow cell (I; 10 mm light path and 8 mm^3 inner volume), placed in a Hitachi Model 200-10 spectrophotometer (H), for the absorbance measurements at 445 nm. The absorbances are continuously recorded with time by using a Hitachi Model 056 multirange recorder (J). A 0.25-mm i.d. and 1-m length PTFE tube is placed just after the flow

cell (I) as a waste line (d) in order to prevent bubbling in the reaction tube (c). The calibration curve is made between the peak areas in the recordings and the manual COD_{Cr} values of aqueous glucose solutions.

Results and Discussion

Choice of a Standard. Considering various organic-waste-water samples, many oxidation reactions have to be examined with regard to many organic substances in the sample solutions. However, D-glucose,[12,13] which has been available as the standard substance for COD, was used to determine the optimum operating conditions of the present FIA apparatus using potassium dichromate.

In the previous FIA method with potassium permanganate,[4,7-11] manganese(VII) was reduced by organic substances (*e.g.*, glucose as the standard) to Mn(II), Mn(III), Mn(IV), *etc.* ions in a sulfuric acid solution. For instance, a black precipitate of manganese-(IV) oxide, which had been produced by the redox reaction between permanganate and organic substances, often blocked the PTFE reaction tube of that apparatus. In the present FIA method with dichromate, however, chromium(VI) is quantitatively reduced to Cr(III) by such organic substances, and therefore forms no precipitate in the tube. Hence, the FIA apparatus could be composed of a longer PTFE tubing as the reaction tube, and its continuous operation could easily be achieved for a long time. Moreover, no contamination by organic substances occurred in the tubes of this FIA system because the acidic dichromate solution as a strong oxidant constantly flowed into them.

Design of the Apparatus. With D-glucose as a standard substance for COD, to design the FIA apparatus using potassium dichromate, the effects of such experimental variables as the sulfuric acid concentration, the reaction temperature, the reaction tube (inner diameter and length of PTFE tubing), and the flow rate were examined.

Although a 41.7 mol m^{-3} potassium dichromate in sulfuric acid (1+1) is used as an oxidizing reagent in the standard dichromate method (COD_{Cr}),[2,3] an about 3 mol m^{-3} potassium dichromate in sulfuric acid (1+2) was found suitable as an oxidizing and spectrophotometric reagent for the present FIA method of continuous COD determination because of the high viscosity of sulfuric acid (1+1).

The effect of the temperature on the redox reaction was examined between acidic dichromate and glucose over a long time span (residence time in the reaction tube: almost 30 min). The experiment, controlled with a thermostatted bath using corn oil at 100 °C, was found proper in the case of heating a long-looped PTFE reaction tube. Though the digestion in the COD_{Cr} method[2,3] was carried out for a longer time at a higher temperature (2 h and about 150 °C respectively; see Table 1), glucose was completely digested at 100 °C within 30 min of residence time in this work. However, if large amounts of less oxidizable organic substances than glucose were present in the sample solutions, glucose was not always the best; a more suitable standard substance for COD should be chosen in order to adjust the operating conditions of the FIA apparatus.

The tubing dimensions form one of the most important parameters to minimize the dispersion of the injected sample zone in a reaction tube over a long time span; PTFE tubings of from 0.5 to 1.0 mm i.d. were found usable for the reaction tube of this system. When 0.6-mm i.d. PTFE tubing was, therefore, used as the most promising reaction tube, the effect of the tubing length was examined at 100 °C by using a glucose solution according to the method described in previous papers.[7-10] With an increase in the tubing length, the dispersion of the sample zone also increases in the carrier stream, and so a shorter length is desirable to prevent dispersion. However, the oxidation of organic substances with dichromate is generally slow, so that the redox reaction of the present FIA system at 100 °C requires a longer tubing length. In this work, a suitable length of the 0.6-mm i.d. PTFE tubing was found to be 50 m, since the dispersion severely affected the peak width in the recordings beyond a tube length of 50 m.

The effect of the flow rate of the carrier solution was also examined by using a 0.6-mm i.d. and 50-m length PTFE reaction tube at 100 °C. It was also found that the flow rate should be chosen carefully in order to minimize dispersion over such a long reaction tube. The pumping rate of about 0.6 cm³ min^{-1} was found the most suitable, and the residence time of the injected sample was about 30 min under these operating conditions.

The degassed carrier solution was pumped up into the FIA apparatus, and then the solution was uniformly heated at 100 °C in the looped PTFE reaction tube. To prevent bubbling of the carrier stream solution, 0.25-mm i.d. and 1-m length PTFE tubing had to be connected as a waste line just after the flow cell in order to obtain back pressure.

The present FIA apparatus using dichromate was, therefore, composed as is shown in Fig. 1. Under these operating conditions, the system was satisfactorily operated at a few atm of back pressure, and no bubble

Table 1. Comparison of operating parameters between the FIA and standard methods for COD determination

Parameter	FIA method	Standard method
Sample volume	10—100 mm^3	<50 cm^3
Reaction medium	H_2SO_4 (1+2)	H_2SO_4 (1+1)
Reaction temperature	100 °C	150 °C (reflux)
Reaction time	30 min	2 h
Detection	Spectrophotometry	Titrimetry (indicator: 1,10-phenanthroline, iron(II) sulfate)
Determination range	50—10000 mg dm^{-3}	10—800 mg dm^{-3}
Masking agent for chloride	None	0.4 g $HgSO_4$+0.33 g Ag_2SO_4
Precision	1.3 %	2.6 %
Sampling rate	10 sample h^{-1}	1 sample $(3\ h)^{-1}$
Standard	D-Glucose	None
Reference	This work	2,3

was observed in the recordings. The residence time of the injected sample was almost 30 min, and the oxidation of glucose with dichromate was found not to proceed even when the sample has been stopped in the reaction tube at 100 °C for a further 30 min (the peak area did not change as compared with the case of not stopping the flow).

For reference, the parameters of this method are compared with those of the already optimized COD_{Cr} method,[2,3] as is shown in Table 1.

Analysis of Flow System. To ensure the operating abilities of the FIA apparatus, the present work provides the following considerations for this useful methodology and this valuable technique.

As the analytical results of fluid viscosity in a laminar flow,[14,15] it has been found experimentally that three distinct stable types of flow, that is, laminar flow without rippling, laminar flow with rippling, and turbulent flow, can be observed in a tube. When the value of the Reynolds number (Re) is less than about 2000, the flow is generally laminar. Therefore, it is customary to define the Reynolds number by $Re=D\bar{u}\rho/\mu$, where $D(=2R)$, $\bar{u}$, ρ, μ are the tubing diameter, the fluid average velocity, the fluid density, and the fluid viscosity respectively. Also, the following equation, called the Hagen-Poiseuille law, has been given,[14,15] since the volume rate of the flow (V) is the product of the area (πR^2) and the average velocity ($\bar{u}$):

$$V = (\pi \Delta p R^4)/(8\mu L). \quad (1)$$

Thus, Eq. 2 is well established for the pressure drop (Δp) in the reaction tube:

$$\Delta p = 32\mu L\bar{u}/D^2. \quad (2)$$

In the FIA system proposed here, the flow being, of course, laminar (the Re value is calculated to be about 20), the opearting conditions are found to be best fixed as follows: $L=ca.$ 5000 cm, $D=ca.$ 0.06 cm, $\bar{u}=V/\pi R^2=ca.$ 3 cm s^{-1}, and $\mu=ca.$ 0.0013 Pa.[16] Consequently, the proposed flow system can physically be allowed to operate satisfactorily because the calculated Δp value is as reasonable as (but little smaller than) the observed one ($\Delta p=ca.$ 3 atm; measured by means of a Kyowaseimitsu Model KPG-50N pressure gauge) in this work.

The present paper describes a unique FIA method for the COD determination, one which requires a very long residence time and a high temperature for the carrier stream because this reaction attains equilibrium slowly. However, the injected sample was not dispersed so widely to be measured, since the glutinous flow of sulfuric acid (1+2) as the carrier solution was just a laminar flow (Re: about 20) in the present FIA apparatus for COD. The back pressure, which was obtained by means of a thin PTFE waste line (0.25 mm i.d. × 1 m), would also allow the apparatus to be operated at 100 °C.

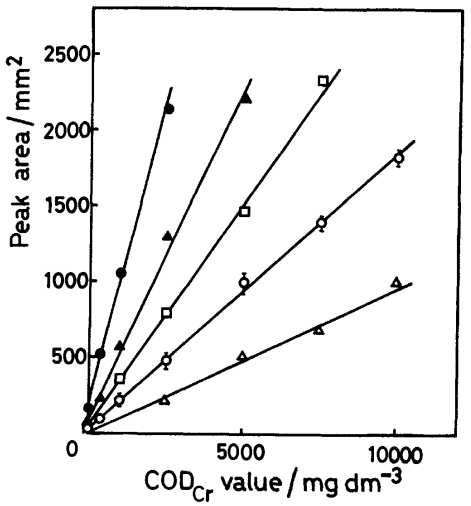

Fig. 2. Calibration curves for glucose.
(△) 10, (○) 20, (□) 30, (▲) 50, and (●) 100 mm^3 of sample solutions are manually injected with a glass syringe.

Calibration Curve and Precision. With the FIA apparatus for COD measurements, peaks at 445 nm in the recordings were obtained with a good reproducibility by using various concentrations of aqueous glucose solutions and by injecting various volumes of the sample solutions. The calibration curves were obtained between the peak areas in the recordings and the COD_{Cr} values of aqueous glucose solutions for several sample volumes (Fig. 2). The curves can be used as the COD_{Cr} value for the range of 50—2500,

100—5000, 150—7500, 200—10000, and 400—10000 mg dm^{-3} when 100, 50, 30, 20, and 10 mm^3 of the aqueous sample solutions are injected respectively. Of course, samples with lower concentrations may be handled whenever a larger volume of the sample can well be introduced into the apparatus. Disappointingly, samples of more than 200 mm^3 were found not to be completely reacted with the carrier solution because of their long sample zones in the reaction tube of this FIA apparatus. The detection limit is, therefore, determined for each sample volume when the increase in the peak area reaches 1.5 times that of the blank peak with distilled water. Accordingly, the detection limits achieved with this method were found to be the COD_{Cr} values of 50, 100, 150, 200, and 400 mg dm^{-3} when 100, 50, 30, 20, and 10 mm^3 of sample solutions were injected respectively. The precision of this method was found to be 1.3% in 16 determinations when 20 mm^3 of a 5000 mg-COD_{Cr} dm^{-3} aqueous glucose solution was injected into the system. A similar precision could also be obtained for other injecting conditions (sample volume and COD concentration) in this work. Moreover, samples with lower concentrations can also be handled, even by using the same sample volume, when a lower concentration of potassium dichromate is used and detected sensitively and stably.

The reproducibility of the total FIA system was also good, and about 10 samples could easily be analyzed in only an hour with the present FIA apparatus. Figure 3 serves as a representative example of this useful method.

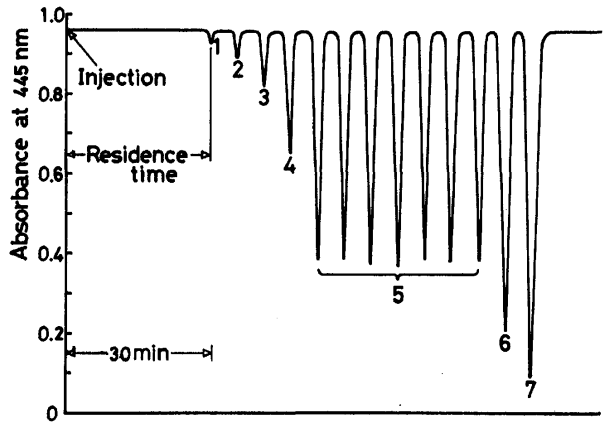

Fig. 3. Typical results of the present FIA for aqueous glucose solutions. 1: 0, 2: 400, 3: 1000, 4: 2500, 5: 5000, 6: 7500, and 7: 10000 mg-COD_{Cr} dm^{-3} of sample solutions of 20-mm^3 volume are manually injected with a glass syringe.

Effect of Chloride. To apply this FIA apparatus to actual organic waste-water samples, the effect of chloride was examined in order to evaluate the interference of co-existing chloride ions in the samples with this COD determination. In this work, it was found that chloride essentially interfered with this method, but its interference could be suppressed by adding suitable amounts of mercury and/or silver salts to the FIA system. However, chloride more than 200 mg dm^{-3} interfered with the determination because of the formation of a silver chloride precipitate, when silver salts (*e.g.*, silver sulfate or nitrate) were added to the carrier reagent solution as a masking agent. As for the results without silver and/or mercury salts, chloride up to 2000 mg dm^{-3} did not interfere with the determination at a COD_{Cr} level of 5000 mg dm^{-3}, whereas more than 200 mg dm^{-3} of chloride interfered with the determination at a COD_{Cr} level of 400 mg dm^{-3} when 20 mm^3 of the sample solution was introduced into the system and the injected sample was properly diluted with the carrier-stream solution by dispersion. Hence, these salts were not used as the masking agent for chloride ions in this work, because the inferference of the co-existing chloride ions was relatively small in comparison with the $COD_{FIA\text{-}Cr}$ values of the organic pollutants, as measured with the present FIA apparatus.

Application to Actual Samples. In order to apply this method to various actual organic-waste-water samples, the following experiments are needed for the pretreatment of the sample solutions. Some of the samples used in this work were highly turbid, so the filtration of the samples was first examined. All the samples were filtered with a 0.45-μm pore-size membrane filter; the filtered samples were then placed in the present FIA apparatus for the continuous determination of the $COD_{FIA\text{-}Cr}$ values.

The samples in glass reservoirs were stored in a refrigerator (about 4 °C) as soon as they were sampled, and then filtered. In this storage, the $COD_{FIA\text{-}Cr}$ values obtained for the filtered samples scarcely changed for at least two weeks.

After the above pretreatment steps, various actual samples such as industrial waste water, civil sewage, human waste, and aqueous waste from the laboratory of a university, could successfully be placed in the proposed FIA apparatus, using potassium dichromate for the determination of organic pollutants as COD values. The results obtained are shown in Table 2. By this continuous determination, about 10 filtered samples could semi-automatically be analyzed in only an hour.

Evaluation of Results. The $COD_{FIA\text{-}Cr}$ values found by this method were evaluated by comparing them with the COD_{Cr} values obtained by the standard dichromate method,[2,3] as is also indicated in Table 2. Both of the methods gave the same results within a permissible error range from −16 to +13%. Of course, samples such as the waste water of the petroleum industry, which contain much less oxidizable susbtances than glucose, probably show lower $COD_{FIA\text{-}Cr}$ values than the COD_{Cr} ones. It was also found that no attention was paid to spectral interferences from organic substances absorbing at 445 nm, since the colored organic substances could generally be changed into colorless ones by an acidic dichromate solution at 100 °C because of their strong oxidizability.

The recovery of $COD_{FIA\text{-}Cr}$ was examined by adding known amounts of glucose to the sample solutions before filtration in order to check the results obtained with this method. As a result, it was found

Table 2. Evaluation of the results obtained with both methods for filtered COD values in actual waste-water samples

Sample		$COD_{FIA\cdot Cr}$ (mg dm^{-3})	COD_{Cr} (mg dm^{-3})	$COD_{FIA\cdot Cr}/COD_{Cr}$
Waste water of chemical industry	1	320	360	0.89
	2	780	820	0.95
	3	1700	1600	1.06
Waste water of textile industry	4	1600	1900	0.84
	5	2300	2200	1.05
Waste water of machinery industry	6	910	1050	0.87
Waste water of food industry	7	550	540	1.02
	8	1700	1800	0.94
	9	3600	4200	0.86
Civil sewage	10	270	280	0.96
	11	450	420	1.07
	12	890	950	0.94
	13	2100	2100	1.00
Human waste	14	600	660	0.91
	15	3400	4000	0.85
	16	5900	5300	1.11
Aqueous waste from laboratory	17	80	95	0.84
	18	700	620	1.13
	19	1000	1020	0.98
	20	2600	2500	1.04
	21	2800	3100	0.90
	22	3400	3700	0.92
	23	3500	4100	0.85
	24	5000	4700	1.06
	25	8600	9300	0.92

that these $COD_{FIA\cdot Cr}$ values could accurately be measured by the present FIA apparatus without loss and gain (the recovery of $COD_{FIA\cdot Cr}$ in the examined range is from 98 to 103%).

Conclusion

The simple apparatus described here succeeded in a continuous determination of the COD in organic-waste-water samples. Although the apparatus is not so good in the determination range for common environmental-water samples, this method will improve COD measurement using dichromate (that is, the FIA method has a much more simple procedure and much less personal error than the standard COD_{Cr} method[2,3]). Furthermore, the present FIA method is more simple, stable, reliable, and less troublesome, though less sensitive, than the previous FIA method using permanganate.[4,7-11] Hence, it possesses the following advantages: (i) the use of potassium dichromate as an oxidant causes a reproducible redox reaction with various organic substances for the $COD_{FIA\cdot Cr}$ values; (ii) no precipitate forms in the PTFE reaction tube of the FIA system; and (iii) an FIA apparatus is simply constructed and easily maintained.

This paper also deals with an analysis of the flow system of the present FIA apparatus. To compose an aqueous system which is operated at 100 °C and has a residence time of almost 30 min, a continuous-flow analysis with air bubbles, which is conventionally available by means of a Technicon Autoanalyzer, will be troublesome. However, this FIA method without air bubbles could succeed in minimizing dispersion by selecting the right tubing dimensions and flow rate of the carrier stream over such a long time span. Although the apparatus presented here may not truly be FIA as a rapid determination method, this application extends FIA to a continuous method of COD analysis based on the acidic dichromate value.

The author is greatly thankful to Professors Kyoji Tôei, Teruo Takahashi, and Tosio Moriwake of Okayama University for their helpful suggestions and encouragement. Proton-transfer Reactions of 5-(*m*- and *p*-Nitrophenylazo)salicylic Acids Coupled with Inclusion Reactions with α- and β-Cyclodextrins†

Noboru Yoshida and Masatoshi Fujimoto*

Department of Chemistry, Faculty of Science, Hokkaido University, Sapporo 060

(Received August 7, 1981)

The title azo compounds, 5-(*m*- and *p*-nitrophenylazo)salicylic acids (*m*- and *p*-NPAS), were found kinetically to be included into a cavity of α- or β-cyclodextrin. The rate constants for the inclusion reactions were found to be in the order of magnitude 10^7 and 10^6 mol^{-1} dm^3 s^{-1} for α-cyclodextrin and β-cyclodextrin systems, respectively. The ^1H and ^{13}C NMR data showed that the hydrophobic nitrobenzene ring moiety of *m*- and *p*-NPAS is situated in the α- and the β-cyclodextrin cavity. The proton-transfer reactions of *m*- and *p*-NPAS were accelerated in the presence of α- and β-cyclodextrins. This indicates the possibility that the inclusion force of cyclodextrins contributes to weakening the intramolecular hydrogen bond of *m*- and *p*-NPAS.

Torus-shaped α- and β-cyclodextrins (α- and β-CD), cyclic α-1, 4-linked D-glucose polymers, have 6 and 7 glucose residues per molecule, respectively, and form a number of stereoselective inclusion complexes with azo and triphenylmethane compounds.[1] The driving force for inclusion has been attributed to hydrogen bonding,[2] van der Waals forces,[3,4] hydrophobic interactions,[5] the relaxation of the conformational strain in the cyclodextrin,[6] and the release of non-hydrogen-bonding water molecules with high energy in the cyclodextrin cavity.[4] Recently, a theoretical approach to the aspect of driving force of inclusion by α-cyclodextrin was carried out.[7]

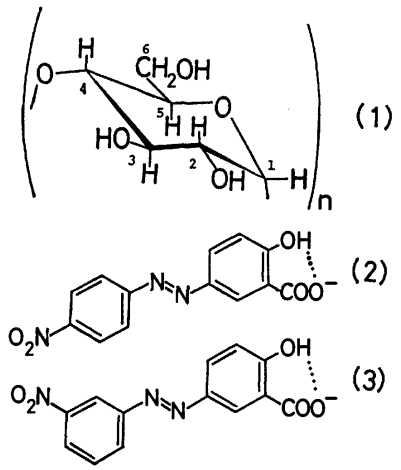

Fig. 1. Structural formulae of α-cyclodextrin ($n=6$; (1)), β-cyclodextrin ($n=7$; (1)); 5-(*p*-nitrophenylazo)salicylate anion (2) and 5-(*m*-nitrophenylazo)salicylate anion (3), HA^-.

5-(*m*- and *p*-Nitrophenylazo)salicylic acids (Fig. 1) were found to form 1 : 1 inclusion compounds with β-CD[8] and α-CD[9] from spectrophotometric and temperature-jump measurements. The ^1H and ^{13}C NMR studies showed that the nitrobenzene ring as hydrophobic portion of *m*- and *p*-NPAS is situated inside the hydrophobic β-CD cavity.[10]

† Presented in part at the 29th Annual Meeting on Coordination Chemistry, Hamamatsu, October 1, 1979, Abstract, p. 300 and 30th Annual Meeting on Coordination Chemistry, Tokyo, October 7, 1980, Abstract, p. 430.

In general the acid dissociation of azo pH indicators is facilitated or retarded by the formation of inclusion compounds with α- and β-CD.[1,8,9,11,13] The enhancement or retardation in acid dissociation has been attributed to Raumalkalität (space alkalinity) in cyclodextrin cavity,[14] topochemische Basizität (topochemical basicity) in cyclodextrin cavity,[15] dipole-ion interaction between dye molecule as nucleophile and cyclodextrin molecule as electrophile,[16] and hydrophobic microenvironment effect of cyclodextrin cavity.[13] On the other hand, it was pointed out qualitatively that the rate constants for the recombination of *m*- and *p*-NPAS with hydroxide ion increase with increasing concentrations of cyclodextrin, irrespective of enhancement or retardation in acid dissociation, namely, the intramolecular hydrogen bond of *m*- and *p*-NPAS is weakened by the formation of inclusion compounds with cyclodextrin molecules.[8,9]

The present paper deals with the detailed quantitative kinetic results on the proton-transfer reactions of *m*- and *p*-NPAS coupled with inclusion reactions with α- and β-cyclodextrins in aqueous solutions.

Experimental

Materials. Water was deionized and distilled. The azo compounds, *m*- and *p*-NPAS, were synthesized by the usual azo coupling method and purified by cellulose column chromatography (Whatman CC 31, 1-butanol : 2 mol dm^{-3} aqueous NH_3 : ethanol=60 : 20 : 20, v/v/v). The monosodium salts of NPAS were acidified with HCl and washed thoroughly with water. The free acids thus obtained were recrystallized from ethanol–water. Found: C, 54.32; H, 3.18; N, 14.41% for *m*-NPAS and C, 54.46; H, 3.23; N, 14.74% for *p*-NPAS. Calcd for $C_{13}H_9N_3O_5$: C, 54.36; H, 3.16; N, 14.63%. Cyclodextrins, α- and β-CD (Tokyo Kasei), were purified by the method of Cramer and Henglein using *p*-cymene, cyclohexane, and fluorobenzene.[17]

A Hitachi-Horiba pH-meter F7-ss was used for the determination of pH values. Acid-dissociation constants were determined spectrophotometrically with a Hitachi recording spectrophotometer Model EPS-3T. The absorption spectra of acid and base forms of *m*- and *p*-NPAS at varying CD concentrations showed isosbestic points at constant pH and ionic strength ($I=0.1$ mol dm^{-3} (KNO_3) at 25 °C). The wavelength of the absorption maximum (λ_{max}) of the absorption spectrum of a solution of NPAS–CD system was dependent on the concentration of CD except for A^{2-} of *m*-NPAS, showing a red shift.[9] Kinetic measurements were carried out with a

Union Giken co-axial-cable temperature-jump apparatus Model RA-105. The reactions were followed on the screen of an oscilloscope Tektronix Type 545 B at a wavelength in the range 350—500 nm.

Deuterium oxide (99.9%) and 40% sodium hydroxide-*d* solution were purchased from E. Merck, Ltd. The NMR spectra of degassed samples (13 mg cm^{-3} *m*-NPAS, 13—180 mg cm^{-3} CD for ^1H NMR and 50 mg cm^{-3} *m*-NPAS, 180 mg cm^{-3} CD for ^{13}C NMR in 0.9 mol dm^{-3} NaOD) were obtained in 5 mm spinning tube at 25±2 °C. The 100 MHz ^1H NMR spectra were taken on a JEOL JNM-FX 100 PFT NMR spectrometer with sodium 2,2-dimethyl-2-silapentane-5-sulfonate as an external reference. The ^{13}C NMR spectra were measured by the PFT NMR spectrometer operating at 25.1 MHz using a deuterium lock. The chemical shifts (measured accuracy approx. ±0.05 ppm) were referred to internal dioxane ($\delta_{TMS} = 67.4 + \delta_{dioxane}$).[18] The assignments of ^{13}C NMR spectra of *m*- and *p*-NPAS were based on proton decoupling, the substituent effects, the additivity rule, and the proton off-resonance irradiation. The theoretical values of chemical shift of *m*- and *p*-NPAS were obtained by the equation δ(substituted benzene)=δ(benzene)+$\sum\Delta\delta$, where $\sum\Delta\delta$ is the sum of the substituent chemical shift.[18] The value of $\Delta\delta$ for azo group of *m*- and *p*-NPAS can be assumed to be approximately equal to that for Ph–N=N– group of azobenzene.[19]

Results and Discussion

Equilibria of the Inclusion Reactions. The formation of 1 : 1 inclusion compounds of *m*- and *p*-NPAS with cyclodextrins in aqueous solutions is confirmed by the presence of isosbestic points in the spectral change. Figure 2 shows the spectral change of *p*-NPAS on addition of α-CD. The equilibria for inclusion reaction in neutral region are expressed as

$$HA^- + \alpha\text{-CD} \underset{K}{\rightleftharpoons} HA\text{-}\alpha CD^-, \quad (1)$$

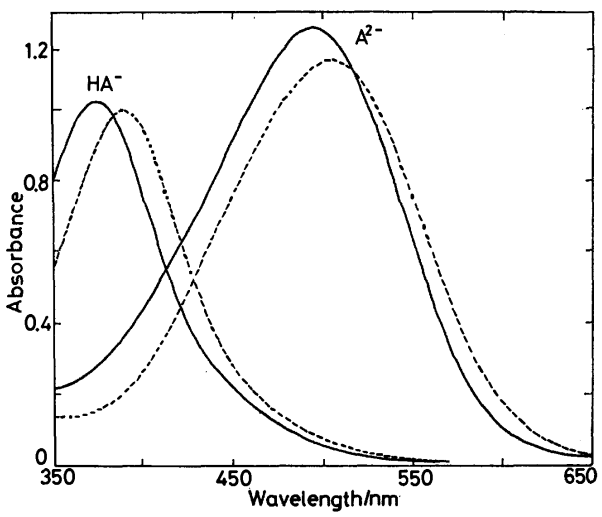

Fig. 2. Absorption spectra of HA^- and A^{2-} forms of *p*-NPAS (full lines) and their inclusion complexes (broken lines).
HA^-: $C_{HA^-}=4.32\times10^{-5}$ mol dm^{-3} and $C_{\alpha\text{-CD}}=(0—6.86)\times10^{-3}$ mol dm^{-3} at pH 7.34. A^{2-}: $C_A=4.32\times10^{-5}$ mol dm^{-3} and $C_{\alpha\text{-CD}}=(0—7.00)\times10^{-3}$ mol dm^{-3} at pH 11.80. At 25 °C and I=0.1 mol dm^{-3} (KNO_3).

and in alkaline region

$$A^{2-} + \alpha\text{-CD} \underset{K'}{\rightleftharpoons} A\text{-}\alpha CD^{2-} \quad (2)$$

where $K=[HA][\alpha\text{-CD}]/[HA\text{-}\alpha CD]$ and $K'=[A][\alpha\text{-CD}]/[A\text{-}\alpha CD]$, and charges are omitted. A plot of $[NPAS]_T[\alpha\text{-CD}]_T/\Delta A$ against $[\alpha\text{-CD}]_T$ gave a straight line (Fig. 3), where ΔA denotes the change in absorbance of a solution of NPAS-αCD system on addition of α-CD and [ ]$_T$ the total concentration.[8,9,13] The values of the dissociation constants of inclusion compounds, K and K', are determined from the slope and the intercept of Fig. 3.[8,9] The *m*- and *p*-NPAS inclusion complexes with α-CD are 2—7 times more stable compared to those with β-CD (Table 3).

^1H NMR and ^{13}C NMR Spectra of Inclusion Compounds. NMR spectroscopy is an effective technique to study the structure in solution of the inclusion complexes.[20] ^1H NMR spectra were obtained for A^{2-} form of *m*-NPAS (Fig. 4). No ^1H NMR data of HA^- form of *m*-NPAS are available owing to the poor solubility of HA^- form in D_2O. Figure 5 shows ^1H chemical shifts of A^{2-} form of *m*-NPAS on addition of β-CD. By the inclusion into β-CD cavity, most of nitrobenzene ring

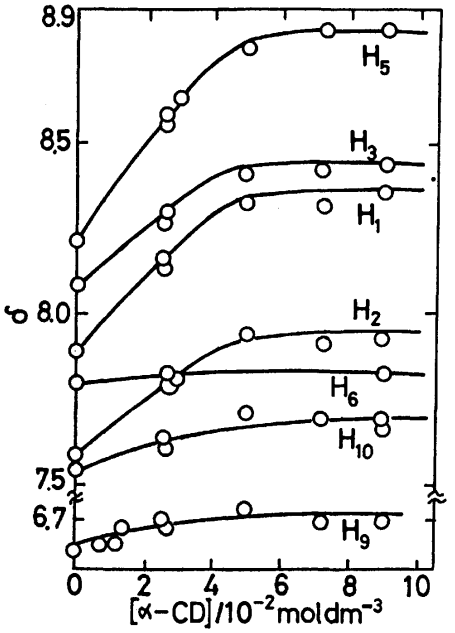

Fig. 6. Chemical shift as a function of α-CD concentration for solutions of the *m*-NPAS–αCD system.

moiety protons showed a downfield shift, while the signals of the hydrophilic moiety protons (H_9, H_{10}, and H_6) changed a little or showed an upfield shift, indicating that the hydrophobic moiety (nitrobenzene ring) of *m*-NPAS is preferentially included into β-CD cavity. Figure 6 shows ^{1}H chemical shifts of A^{2-} form of *m*-NPAS on addition of α-CD.[21] Figure 7 shows ^{13}C spectra of A^{2-} form of *m*-NPAS. The chemical shifts of carbon atoms are shown in Table 1. Nitrobenzene ring moiety carbons show a downfield shift except for C_5, while the hydrophilic moiety carbons an upfield shift. This fact indicates that the nitrobenzene ring moiety of *m*-NPAS preferentially enters the β-CD cavity.[22]

In the case of smaller molecules such as *m*-nitroaniline as compared with *m*-NPAS, the α-CD ring is found by X-ray analysis to include the nitrophenyl group, while the amino group protrudes outside from the secondary hydroxyl group side of α-CD and is hydrogen-bonded to a primary hydroxyl group of α-CD molecules.[23] As for the inclusion compounds in solution of *p*-nitrophenol with α- and β-CD, the similar preferential inclusion of hydrophobic group (nitro group) was confirmed by ^{1}H and ^{13}C NMR methods.[24]

Acid-dissociation Equilibria in the Presence of Cyclodextrins. The acid-dissociation equilibria coupled with the inclusion equilibria can be expressed as follows,

$$\begin{array}{ccc} HA^- + \alpha\text{-CD} & \overset{K_a}{\rightleftharpoons} & A^{2-} + \alpha\text{-CD} + H^+ \\ \Big\Updownarrow K & & \Big\Updownarrow K' \\ HA\text{-}\alpha CD^- & \overset{K'_a}{\rightleftharpoons} & A\text{-}\alpha CD^{2-} + H^+, \end{array} \qquad (3)$$

where $K_a=[A][H]/[HA]$ and $K_a=[A\text{-}\alpha CD][H]/[HA\text{-}\alpha CD]$ are the acid-dissociation constants of HA^- and $HA\text{-}\alpha CD^-$, and $K=[HA][\alpha\text{-CD}]/[HA\text{-}\alpha CD]$ and $K'=[A][\alpha\text{-CD}]/[A\text{-}\alpha CD]$ the dissociation constants for inclusion compounds of HA^- and A^{2-} with α-CD, respectively. The apparent acid-dissociation constants, $\bar{K}_a$, was determined from the pH-dependence of the absorbance of NPAS solution at each α-CD concentration. At each α-CD concentration the isosbestic point was observed in the pH-dependent spectral change. The absorbance, A, for the system expressed by Scheme 3 is given by

$$A = \varepsilon'_{HA}[HA] + \varepsilon'_{A}[A], \quad (4)$$

where $\varepsilon'_{HA}=\varepsilon_{HA}+\varepsilon_{HA\text{-}\alpha CD}[\alpha\text{-CD}]/K$ and $\varepsilon'_{A}=\varepsilon_{A}+\varepsilon_{A\text{-}\alpha CD}[\alpha\text{-CD}]/K'$. The terms, ε_{HA}, ε_{A}, $\varepsilon_{HA\text{-}\alpha CD}$, and $\varepsilon_{A\text{-}\alpha CD}$, are the molar absorption coefficients for corresponding species. Since the sum of [HA] and [A] is a constant at each α-CD concentration, there must be isosbestic points in the pH-dependent spectral change at the wavelength where $\varepsilon'_{HA}=\varepsilon'_{A}$, even though four absorbing species exist.[25] The apparent acid-dissociation constant, $\bar{K}_a$, at each [α-CD] is expressed as follows,[8,11,12]

$$\bar{K}_a = K_a(1+[\alpha\text{-CD}]/K')/(1+[\alpha\text{-CD}]/K), \quad (5)$$

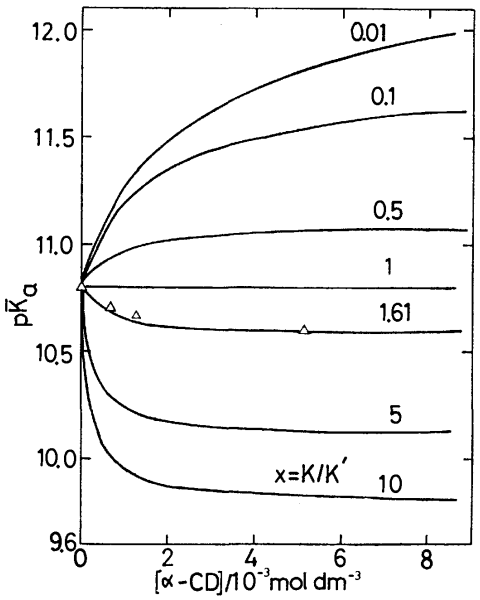

Fig. 8. The dependence of $p\bar{K}_a$ on α-CD concentrations in case of *m*-NPAS–αCD system. $K=4.95\times10^{-4}$ mol dm^{-3} and $\bar{K}_a=1.59\times10^{-11}$ mol dm^{-3}. At $I=0.1$ mol dm^{-3} (KNO_3) and 25 °C. Experimental points are indicated by triangles.

that is, the $\bar{K}_a$ value can be determined by the ratio $x=K/K'$. Figure 8 shows the theoretical curve for the dependence of $p\bar{K}_a$ on α-CD concentrations in case of *m*-NPAS–αCD system. The apparent acid-dissociation constants at each [α-CD] were determined in both *m*-NPAS–αCD and *p*-NPAS–αCD systems (Table 2). The value of $p\bar{K}_a$ decreases with increase in α-CD concentrations, namely, α-CD molecule exerts an enhancement effect on the acid dissociation of *m*- and *p*-NPAS. The quantity $\Delta pK_a=pK'_a-pK_a$ in *p*-NPAS–αCD system is more negative and larger than that in *m*-NPAS–αCD system. The change in $\bar{K}_a$ with increase of α-CD concentrations is larger as compared with the corresponding change for β-CD system.

Kinetics of the Inclusion Reactions. Kinetic study of inclusion reaction of azo compounds with α-CD was investigated for the first time by Cramer *et al.*[26] They indicated that the dissociation constant of inclusion complex (K and K') are almost in the same orders of magnitude, while the rate constants (k_+, k'_+, k_-, and k') varies considerably over the range of 1—8 orders of magnitude. Very recently Ise *et al.* determined the rate constants $\vec{k}$ and $\overleftarrow{k}$ of the inclusion reactions of phenolphthalein to be 1.45×10^5 mol^{-1} dm^3 s^{-1} and 1.30×10^3 s^{-1}, 3.66×10^7 mol^{-1} dm^3 s^{-1} and 1.18×10^3 s^{-1}, and 2.95×10^7 mol^{-1} dm^3 s^{-1} and 1.19×10^3 s^{-1} for α-CD, β-CD, and poly-βCD systems, respectively.[27] Eyring

$$HA^- + CD \underset{\overleftarrow{k}}{\overset{\vec{k}}{\rightleftharpoons}} H_2A\text{–}CD \quad (6)$$

et al. measured the rate constants of inclusion reactions of some inorganic anions with β-CD using ultrasonic relaxation technique.[28]

The kinetic data were obtained under pseudo-first-order conditions using a large excess of α-CD and β-CD. The rate of inclusion reaction was followed at λ_{max} of the inclusion species. The inclusion reaction of α-CD system in neutral region is

$$HA^- + \alpha\text{-CD} \underset{k_-}{\overset{k_+}{\rightleftharpoons}} HA\text{-}\alpha CD^-, \quad (7)$$

and in alkaline region,

$$A^{2-} + \alpha\text{-CD} \underset{k'_-}{\overset{k'_+}{\rightleftharpoons}} A\text{-}\alpha CD^{2-}. \quad (8)$$

The observed relaxation time, τ, for Reactions 7 and 8 can be expressed as

$$\tau^{-1} = k_+[\alpha\text{-CD}] + k_- \quad (9)$$

and

$$\tau^{-1} = k'_+[\alpha\text{-CD}] + k'_-, \quad (10)$$

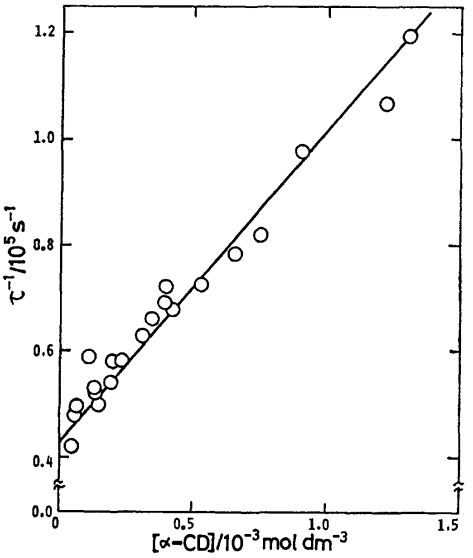

Fig. 9. A plot of Eq. 9 for the inclusion reaction of HA$^-$ form of *p*-NPAS with α-CD.

respectively. The plot of Eq. 9 gave a straight line with a slope k_+ and an intercept k_- (Fig. 9). The values of rate constants, k_+, k_-, k'_+, and k'_- for α-CD and β-CD systems are summarized in Table 3.

In the inclusion processes of *m*- and *p*-NPAS with α-CD, one can expect that the rate constant, k_+ (k'_+), decreases owing to the smaller α-CD cavity.[29] However, the higher stability of inclusion complex with α-CD may be attributed to the increase in k_+ (k'_+).[30] Actually in our investigations, the rate constant k_+ (or k'_+) of α-CD system was considerably larger than that of β-CD system, showing that α-CD exerts the inclusion force more strongly than β-CD does. The value of k_+ in α-CD system was found to depend on the position of the nitro group on *m*- and *p*-NPAS, *i.e.*, the values of k_+ of *m*- and *p*-NPAS was fairly different from each other compared to the case of the β-CD system. Larger steric hindrance of the nitro group in *m*-NPAS contributes to decreasing the rate constants k_+ (or k'_+). This indicates that the inclusion process takes place at the hydrophobic site (nitrobenzene moiety).

The value of k^+ is reported to be almost 2—3 orders of magnitude larger than that of k'_+ when a hydrophilic group such as hydroxyl group is included into α-CD cavity.[26,31] In the present kinetic study, however, the value of k_+ and k'_+ were found to be in the same order of magnitude ($\simeq10^6$ mol^{-1} dm^3 s^{-1} for *m*-NPAS and 10^7 mol^{-1} dm^3 s^{-1} for *p*-NPAS).[32] This fact kinetically supports the inclusion of hydrophobic site of *m*- and *p*-NPAS as a guest molecule into α-CD cavity.

Kinetics of Proton-transfer Reactions Coupled with the Inclusion Reactions. Kinetic data on the proton-transfer reaction coupled with the inclusion reaction with α-CD interpreted in terms of the following scheme,

$$\begin{array}{ccc} HA^- + \alpha\text{-CD} + OH^- & \underset{k_r}{\overset{k_f}{\rightleftharpoons}} & A^{2-} + \alpha\text{-CD} + H_2O \\ k_+ \downarrow\uparrow k_- & & k'_+ \downarrow\uparrow k'_- \\ HA\text{-}\alpha CD^- + OH^- & \underset{k'_r}{\overset{k'_f}{\rightleftharpoons}} & A\text{-}\alpha CD^{2-} + H_2O. \end{array} \quad (11)$$

As mentioned above, it was concluded that the inclusion process takes place at the hydrophobic site (nitrobenzene ring moiety). The apparent rate constants, $\bar{k}_f$ and $\bar{k}_r$, at each α-CD concentration were obtained under pseudo-first-order conditions using a large excess of hydroxide ion. The observed relaxation time, τ, for the proton-transfer reaction can be expressed as

$$\tau^{-1} = \bar{k}_f[\overline{OH}] + \bar{k}'_r, \quad (12)$$

where $[\overline{OH}]$ denotes the equilibrium concentration of hydroxide ion determined from pH-meter readings. The plot of τ^{-1} against $[\overline{OH}]$ gave a straight line at each α-CD concentration. The values of $\bar{k}_f$ and $\bar{k}_r$ at each α-CD concentration are summarized in Table 4. Because of the strong intramolecular hydrogen bond[33] of *m*- and *p*-NPAS, the k_f value (10^7 mol^{-1} dm^3 s^{-1}) is three orders of magnitude smaller as compared with that of diffusion-controlled proton-transfer reactions (10^{10} mol^{-1} dm^3 s^{-1}). Since the interior of α-CD cavity contains a ring of C–H groups, a ring of glycosidic oxygen, and another ring of C–H groups, the interior of α-CD cavity is relatively hydrophobic and apolar as compared with bulk solvent water.[1] Then, the recombination rate constant with OH^- ion, $\bar{k}_f$, should decrease provided the reaction site (–COO$^-$···HO–) of the proton-transfer reaction is included into hydrophobic α-CD cavity,[33] where the dielectric constant is probably small compared with that of the bulk solvent water. As shown in Table 4, $\bar{k}_f$ value increased with increase in α-CD concentrations, which suggests that the reaction site (–COO$^-$···HO–) in the proton-transfer reaction is situated outside the hydrophobic α-CD cavity, and the inclusion force exerts a weakening effect to

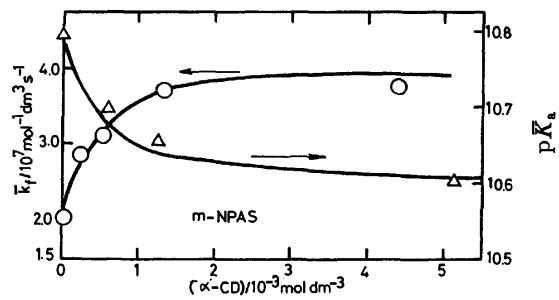

Fig. 10. The dependence of $p\bar{K}_a$ and $\bar{k}_f$ on α-CD concentrations in case of *m*-NPAS–αCD system at I=0.1 mol dm^{-3} (KNO_3) and 25 °C.

the intramolecular hydrogen bond.

The rate constant, $\bar{k}_f$, and $p\bar{K}_a$ of *m*-NPAS thus obtained in the present experiment were plotted against α-CD concentrations in Fig. 10. A definite correlation was observed between the [α-CD]-dependence of $\bar{k}_f$ and $p\bar{K}_a$, that is, with an increase of α-CD concentrations the $p\bar{K}_a$ value decreases and the $\bar{k}_f$ value increases particularly in the α-CD concentration range (0—2)$\times 10^{-3}$ mol dm^{-3}; about 91% of HA^- form of *m*-NPAS is included by α-CD at [α-CD]$=2\times10^{-3}$ mol dm^{-3}. By forming an inclusion compound with *m*-NPAS, α-CD is capable of altering the reactivity of the recombination site in the proton-transfer reaction. Similar observations were made for the proton-transfer reactions of *p*-NPAS in the presence of α-CD and β-CD (Table 4).

21) The observed chemical shift (δ_{obsd}) associated with Reaction 2 will be given by

$$\delta_{obsd} = \frac{[A]}{[A]_T}\delta_A + \frac{[A\text{-}\alpha CD]}{[A]_T}\delta_{A\text{-}\alpha CD}$$
$$= \frac{1}{[A]_T}\{[A]_T\delta_A + (\delta_{A\text{-}\alpha CD}-\delta_A)[A\text{-}\alpha CD])\},$$

with

$$[A\text{-}\alpha CD] = [Q-\sqrt{Q^2-4[A]_T[\alpha\text{-}CD]_T)}]/2,$$

and

$$Q = [A]_T + [\alpha\text{-}CD]_T + K',$$

where δ_A, $\delta_{A\text{-}\alpha CD}$, $[\alpha\text{-}CD]_T$, and $[A]_T$ are the chemical shifts of A and A-αCD species and the total concentrations of α-CD and *m*-NPAS anion. The theoretical curves are obtained by plotting δ_{obsd} against $[\alpha\text{-}CD]_T$.

22) Assignments of α-CD and β-CD ^{13}C spectra by Kuge *et al.* were applied to these systems. See, K. Takeo, K. Hirose, and T. Kuge, *Chem. Lett.*, **1973**, 1233. Upon binding to CD of NPAS, CD carbons showed an upfield shift. The order of upfield shifts was $C_4>C_2\gtrsim C_1>C_3\gtrsim C_5\gg C_6$ in *m*-NPAS–βCD system, $C_1\gtrsim C_2>C_3\gtrsim C_4>C_5\gg C_6$ in *p*-NPAS–βCD system, $C_6\gtrsim C_2\gtrsim C_4>C_5>C_1\gg C_3$ in *m*-NPAS–αCD system,

and $C_1 \gtrsim C_2 > C_4 > C_5 > C_3 > C_6$ in *p*-NPAS–αCD system, indicating that the inclusion into CD cavity takes place from the secondary hydroxyl group side.

23) K. Harata, *Bull. Chem. Soc. Jpn.*, **53**, 2782 (1980).

Studies on Characteristics of Electron Capture Responses. VI.[1] A Consideration on the Response Mechanism of the Electron Capture Detector

Masahiro TAKEUCHI

Tokyo Metropolitan Research Laboratory of Public Health, Hyakunincho, Shinjuku-ku, Tokyo 160

(Received August 10, 1981)

In order to improve the understanding of the electron capture detector (ECD), a study on the response mechanism has been carried out by using the pulse sampling technique. The ECD currents in the presence and the absence of electron capturing molecules were measured under various pulse conditions. The responses of the ECD probably arise from the current drop based on the slower electron drift velocity in the presence of electron capturing molecules than that in the absence of them.

The electron capture detector (ECD) has been widely used as the most suitable gas chromatographic detector for trace amounts of halogen-containing compounds on account of its high sensitivity and selectivity. Therefore, the ECD is necessary in laboratories concerned with the analysis of environmental contaminations such as organochloro pesticides and polychlorinated biphenyls. However, the response mechanism of the ECD has not completely establised yet, that is, the details of the events which occur within the ECD are not known so well. Several views have been proposed about the ECD.

Wentworth *et al.*[2] have described the behavior of electrons within a pulse-sampled ECD on the basis of the following assumptions:[3] (1) The current measured is due to electrons which are drawn to the positive electrode during the application of pulses. (2) The relatively immobile ions contribute little to the current. (3) The ECD cell is cleared of electrons during each pulse. (4) Positive ions will be in very large excess of electrons because the electrons diffuse quickly to cell boundaries. (5) The charge associated with negative ions formed by electron capture is quickly lost because of the much faster recombination between positive ions and negative ions than that between positive ions and electrons.

Siegel and McKeown,[4] however, criticised assumptions (3), (4), and (5), and insisted that both electrons and positive ions become characterized by a single (ambipolar) diffusion coefficient. According to this view, the current measured from the ECD should be considered to reflect the motion of electrons and positive ions within one Debye length from the positive electrode surface. Though undeniable for the present, this view has not been commonly accepted.

Grimsrud *et al.*[3] have proposed based on the positive space-charge field created by positive ions, and recalled the Wentworth assumption (3). Their modification has the merit that it does not depart so drastically from the Wentworth view, which has become the conventional one because of being strongly supported in many experiments.[2,5-7]

Under the circumstances described above, the author has measured the ECD currents under various pulse conditions in order to understand the behavior of electrons within the ECD and to reveal its response mechanism.

Experimental

A Shimadzu gas chromatograph Model 5A equipped with a Shimadzu ECD Model EDC-5 was used. The ECD has coaxial geometry and contains a 10 mCi ^{63}Ni or a 300 mCi ^{3}H radioactive source. The radius of the electrode is 2.0 mm, and the distance from the center of the electrode to the surface of the radioactive source is 5.0 mm. The carrier gas used (Nihon Sanso, A grade pure gas) was nitrogen of a purity over 99.9995%. Before being introduced into the gas chromatograph, the gas was passed through a Molecular Sieve 13 X column and an oxygen scrubber (Alltech, Oxy-Trap). For the gas chromatographic column, a 1 m×3 mm i.d. glass column packed with 2% Silicone OV-17 on Chromosorb W (AW-DMCS), 60—80 mesh was used at temperatures up to 200 °C. The other conditions were set up as follows: flow-rate, 60 ml/min; ECD temperature, 220 °C.

Results and Discussion

Effect of Pulse Conditions on ECD Current. As shown in Fig. 1, the ECD current measured increased with increasing the pulse width (t_w), and finally attained a plateau for each different pulse period (t_p).

According to Wentworth *et al.*[1] the current is due to electrons which are drawn to the positive electrode during the application of pulses. The appearance of the plateau indicates that the number of electrons collected by the positive electrode increases with increasing t_w, and all electrons formed between pulses are collected when t_w becomes sufficiently large. This is because slower electrons can drift to the positive electrode with increasing t_w, without recombination with positive ions.

Electron Drift Velocity. The value of $t_w^{1/2}$, which is denoted by an arrow in Fig. 2 and represents the time required for half the electrons drifting to the positive electrode, is the mean time of the electrons drifting to the electrode. Hence, the reciprocal of $t_w^{1/2}$ is proportional to the electron drift velocity, ω:

$$\omega \propto (t_w^{1/2})^{-1}. \quad (1)$$

As shown in Fig. 2, the value of $(t_w^{1/2})^{-1}$ decreases with decreasing the pulse amplitude (V_a), and finally approaches zero at approximately 2 V in any t_p. These results suggest that the positive ion cloud created within the cell reduces the applied field by about 2 V, *i.e.*, about 2 V of the electrical potential is induced by positive ions.

According to Grimsrud *et al.*,[3] the electrical potential, V, expressed in the form of Eq. 2 is induced by positive

ions at any point within the cell, if one assumes that the positive ions are uniformly distributed throughout the cell:

$$V=\frac{\rho_o}{4\varepsilon_o}\left\{(b^2-a^2)\frac{\ln(r/b)}{\ln(b/a)}+(b^2-r^2)\right\}. \quad (2)$$

Here ρ_o is the density of the positive ions, ε_o is the permittivity of free space, a is the radious of the electrode, b is the distance from the center of the electrode to the surface of radioactive source, and r is the distance from the center of the electrode to any point within the cell.

The potential calculated from Eq. 2 for the ^{63}Ni ECD used in the present study becomes a maximum value of approximately 10 V at r=2.73 mm. If this value is reasonable, the electrons within the cell will distribute most densely near the middle of the radioactive source and the positive electrode under the field-free, *i.e.*, pulse-free conditions, and then they will drift to the positive electrode against the electrical potential under pulse-sampled conditions. Therefore, the field strength will become lower than that applied to the positive electrode by the maximum value of the induced potential. Consequently, the value of $(t_W^{1/2})^{-1}$ should become zero at approximately 10 V. In practice, however, the value becomes zero at approximately 2 V in any t_P as shown in Fig. 3. This discordance of the theoretical and the observed values suggests the deficiency of Grimsrud's view: The center of the ionization was hitherto considered 1—2 mm for ^{3}H and 6—8 mm for ^{63}Ni, judging from commonly used ECD dimensions.[8,9] Recently, however, Aue *et al.*[9] have reported that the center of ionization is much closer to the radioactive foil than commonly assumed, *i.e.*, at approximately 0.2 mm for ^{3}H and approximately 1 mm for ^{63}Ni in nitrogen at ambient conditions. These experimental facts tend to contradict Grimsrud's view, in which it is assumed that positive ions are uniformly distributed throughout the cell.

The electron drift velocity, ω, in a gas under electric field is expressed in the form of Eq. 3:[10]

$$\omega=\frac{e}{m}\cdot\frac{\lambda}{u}\cdot\frac{E}{p}, \quad (3)$$

where e is the charge, m is the mass, λ is the mean free path, u is the agitation velocity, E is the field strength, and p is the pressure of a gas.

In the ECD used as a gas chromatographic detector, e, m, and p are constant. Hence,

$$\omega \propto \lambda \cdot \frac{E}{u}. \quad (4)$$

On the other hand, electrons which are at thermal equilibrium state under the field-free conditions obtain some kinetic energy proportional to the field strength:

$$\frac{1}{2} \cdot m \cdot u^2 \propto E. \quad (5)$$

Equations 4 and 5 give Eq. 6:

$$\omega \propto \lambda \cdot E^{1/2}. \quad (6)$$

Figure 3 is the ln-ln plots of the curves shown in Fig. 2, where the abscissa is converted into $E=V_a-2.0$. In any t_P, the plot gives a straight line whose slope is approximately 0.5. This result indicates that ω is proportional to $E^{1/2}$.

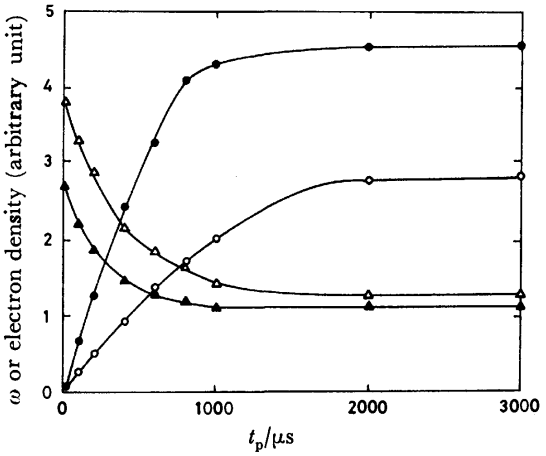

Fig. 4. Variations of ω and electron density with t_p. △: ω (^{63}Ni), ▲: ω (^{3}H), ○: Ion density (^{63}Ni), ●: Ion density (^{3}H). E: 30 V.

Figure 4 shows the variations of ω and the electron density with t_P. The value of ω decreases, and oppositely the electron density increases with increasing t_P for constant E. These results suggest that ω is inversely proportional to the electron density. Since the interaction between electrons and positive ions increases with increasing the electron density, the value of λ should be inversely proportional to the electron density, and consequently ω may be proportional to λ, as in Eq. 5. Therefore, as discussed above, the curves of Fig. 2 are expressed in the form of Eq. 6.

Response Mechanisms. Figure 5 shows the ECD current versus t_w curves in various t_P at 30 °C(a), and 200 °C(b) of column temperatures. In any t_P, the values of $t_w^{1/2}$ increases, *i.e.*, the electron drift velocity decreases, with increasing the column temperature. According to Aue *et al.*,[9] the ECD can simply be considered a non-linear impedance device, whose impedance increases with the introduction of electron capturing molecules. The higher the column temperature is, the more electron capturing molecules which bleed from the column. Consequently, the impedance of the ECD cell increases with the rise of column temperature. The increase of the impedance rusults in the decrease of the electron drift velocity. The curves c, which are the plots for (a−b), correspond to the current drop based on the increase of the impedance. If the drop arises from the increase of the impedance, the curves c should gradually approach zero with increasing t_w. The reason is that even slower electrons can drift to the positive electrode with increasing t_w, and curve b consequently approaches to the corresponding curve a. However, the curves do not practically become zero, but constant in each t_P. These results lead to the probability that the current drop occurs by some other factor rather than the increase of the cell impedance. In the absence of electron capturing molecules, electrons within the ECD attain a thermal equilibrium state through numerous collisions with the carrier gas molecules. In the presence of electron capturing molecules, the thermally equilibrated electrons collide with electron capturing molecules and finally attach to them to form negative ions.[11] Consequently, the value of λ should become smaller than that in the absence of electron capturing molecules. Considered from this view, the curves c correspond to the current drop arising from the decrease of the electron drift velocity, which results from the decrease of λ.

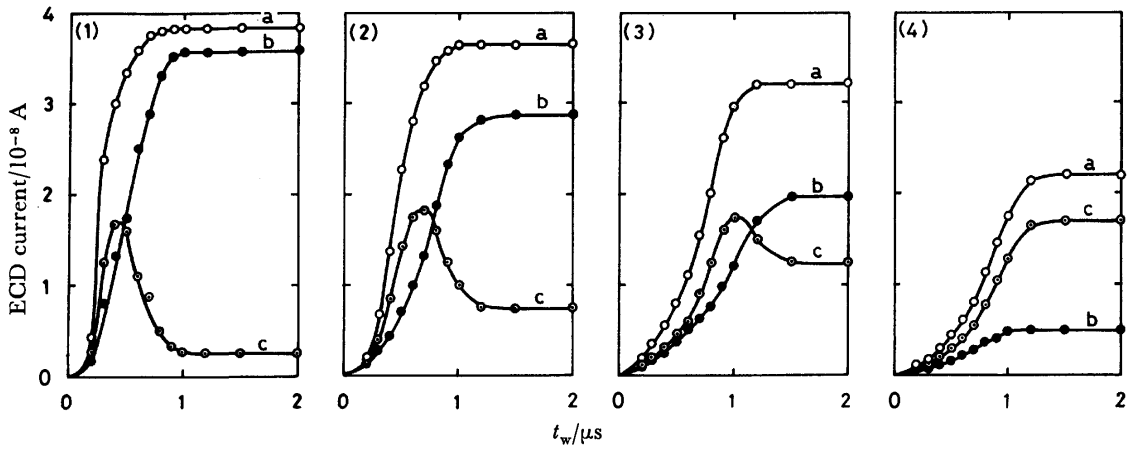

Fig. 5. Effect of t_w on ECD current at column tempertures of 30 °C (a) and 200 °C (b). $t_p/\mu s$: (1); 100, (2); 500, (3); 1000, (4); 2000. V_a: 30 V. ECD: ^{63}Ni. Curves c are the plots of (a−b).

The view described above can explain why the curve c does not become zero, but constant, with increasing t_w. So long as the value of λ is not zero, all electrons within the cell can drift to the electrode by applying a sufficiently large t_w of pulses, *i.e.*, the current drop decreases and finally becomes zero with increasing t_w. However, if the value of λ is zero, the electrons can not drift to the electrode even if sufficiently large t_w of pulses are applied, *i.e.*, the current drop approaches a constant value which is proportional to the number of electrons attached to electron capturing molecules. By applying the above discussion for the region where the current drop remains constant, the proposed view recalls the classical mechanism of electron capture detection by Wentworth *et al.*, *i.e.*, attachment to electron capturing molecules, followed by positive ion-negative ion neutralization.

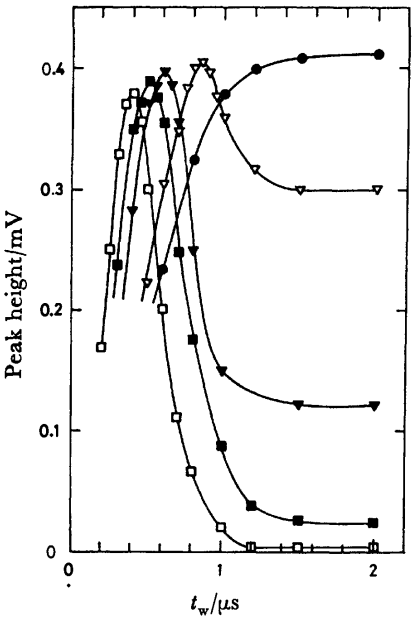

Fig. 6. Effect of t_w on the peak height of γ-BHC.
t_p/μs: □; 10, ■; 100, ▽; 500, ▼; 1000, ●; 2000.
V_a: 30 V. ECD: ^{63}Ni.

Figure 6 shows the variation of the peak height for γ-BHC with t_w. The profile of the peak height, which represents the sensitivity of the ECD, is in accord with the curves c in Fig. 5. Such a profile is not specific for γ-BHC, but general for the other several samples examined, *e.g.*, α-BhC, β-BHC, δ-BHC, *p,p'*-DDE, aldrin, dieldrin, 2,4,5-trichlorobiphenyl, and 2,2',4,4',6,6'-hexachlorobiphenyl.[12] These results lead to the conclusion that the response of the ECD arises from the current drop due to the decrease of the electron drift velocity resulting from the decrease of λ, and the removal of the electrons whose values of λ become zero as the result of attachment to electron capturing molecules.

The author wishes to express his thanks to Emeritus Professor Shun Araki and Professor Shigetaka Suzuki, Tokyo Metropolitan University, for their encouragement and advice.

Multidentate Ligand Kinetics. III. The Ligand-substitution Reaction between the Ethylenediaminetetraacetatocuprate(II) Ion and the Tetraethylenepentaminezinc(II) Ion

Tetsuo KATSUYAMA* and Toshihiko KUMAI

Department of Basic Technology, Faculty of Engineering, Yamagata University, Yonezawa, Yamagata 992

(Received August 24, 1981)

The kinetics and mechanism of the ligand-substitution reaction between the ethylenediaminetraacetatocuprate(II) ion (Cu(II)-edta) and the tetraethylenepentaminezinc(II) ion (Zn(II)-tetren) were studied spectrophotometrically over the pH range from 7.0 to 9.0 at I=0.2 M (1 M= mol dm^{-3}) and 25.0 °C. The substitution reaction was shown to proceed by means of a chain-reaction mechanism where the chainpropagating steps are the reaction of Cu(II)-edta with tetren and the reaction of Zn(II)-tetren with edta. Each chain-propagating step was investigated. The ligand-substitution reaction of Zn(II)-tetren with edta was studied by the use of the chain reaction. The rate law is expressed as

$$-\frac{d[\text{Zn(II)-tetren}]}{dt}=k_L[\text{Zn(tetren)}^{2+}][\text{edta}^{4-}]+k_{HL}[\text{Zn(tetren)}^{2+}][\text{Hedta}^{3-}]+k'_{HL}[\text{Zn(Htetren)}^{3+}][\text{Hedta}^{3-}].$$

The rate constants, k_L,k_{HL}, and k'_{HL} were determined at 25.0 °C and I=0.2 M as: $k_L \approx 3\times10^2$ M^{-1} s^{-1}, $k_{HL}=(4.1\pm0.7)\times10^2$ M^{-1} s^{-1}, and $k'_{HL}=(1.7\pm0.2)\times10^5$ M^{-1} s^{-1}.

Ligand-substitution reactions between two multidentate ligand complexes often proceed by means of a coordination chain-reaction mechanism, in which two free multidentate ligands are the chain-reaction centers and the chain-propagating steps are the reactions of the metal complexes with the free ligands.[1-7]

In a previous paper,[8] the ligand-substitution reactions of the triethylenetetraminecadmium(II) ion and the tetraethylenepentaminecadmium(II) ion with the ethylenediaminetetraacetatocuprate(II) ion (Cu(II)-edta) were reported. The reactions were found to proceed by means of a coordination chain-reaction mechanism. In the present study, the ligand-substitution reaction between the Cu(II)-edta and tetraethylenepentaminezinc(II) ions (Zn(II)-tetren) was undertaken in order to obtain further understanding of the ligand-substitution reaction between two multidentate ligand complexes:

$$\text{Cu(II)-edta} + \text{Zn(II)-tetren} \longrightarrow \text{Cu(II)-tetren} + \text{Zn(II)-edta}. \quad \text{(R1)}$$

The coordination chain reaction of the present system provides a useful method for the study of the ligand substitution of Zn(II)-tetren with edta.

Experimental

Reagents. Reagent-grade zinc(II) and copper perchlorates, and guaranteed reagent-grade sodium perchlorate were recrystallized from their aqueous solutions. GR-grade tetren was purified by distillation under reduced pressure. A standard copper nitrate solution was prepared from copper plate and was subsequently used to standardize the tetren and edta solutions.

Solutions of Cu(II)-edta and Zn(II)-tetren were prepared by the following procedure: a slight excess of the metal perchlorate was added to a solution containing a known quantity of the ligand; the excess metal in the solutions of Cu(II)-edta and Zn(II)-tetren was then precipitated as hydroxide at about pH 9.3 and 9.5 respectively.

Measurements. The reactions were run in the presence of a large excess of Cu(II)-edta and small amounts of edta. The initial Zn(II)-tetren concentration was 1.8×10^{-3} M and the ionic strength was adjusted to 0.2 M with sodium perchlorate. The reaction temperature was controlled at 25.0±0.1 °C. A mannitol–boric acid–sodium borate buffer system was used to control the pH of the solution. The pH values were measured with a Toa Electronics Model HM-15A digital pH-meter. The reaction was followed spectrophotometrically at 575 nm by means of a stopped-flow technique using a Hitachi Model RSP-2 rapidscan spectrophotometer.

Results and Discussion

Rate Equation. The plots of log $(A_\infty-A_t)$ *vs.* t, where A_t and A_∞ denote the absorbances at time t and infinity respectively, were linear over 85% of the reaction. Thus, the reaction was considered to be first-order in Zn(II)-tetren. The conditional first-order rate constant was independent of the concentration of Cu(II)-edta. From these results, it seems that the rate law is given by

$$-\frac{d[\text{Zn(II)-tetren}]}{dt}=k'_o[\text{Zn(II)-tetren}]. \quad (1)$$

In addition, the values of the conditional rate constant, k'_o, at a constant pH are linearly related to the added free edta concentration in the region above the threshold value of b. Thus, the conditional rate constant, k'_o, is given by

$$k'_o = k_o([\text{edta}]_a - b). \quad (2)$$

The values of k_o are plotted against the pH in Fig. 2.

Steady-state Treatment. On the basis of the above results, the ligand-substitution reaction between Cu(II)-edta and Zn(II)-tetren was considered to proceed by means of a chain-reaction mechanism:

$$\text{Cu(II)-edta} + \text{tetren} \underset{k_{-2}}{\overset{k_2}{\rightleftharpoons}} \text{Cu(II)-tetren} + \text{edta}, \quad \text{(R2)}$$

$$\text{Zn(II)-tetren} + \text{edta} \underset{k_{-3}}{\overset{k_3}{\rightleftharpoons}} \text{Zn(II)-edta} + \text{tetren}. \quad \text{(R3)}$$

The conditional equilibrium constants[8] of Reactions R2 and R3 will be useful in the following discussion. The constants were thus calculated from the stability

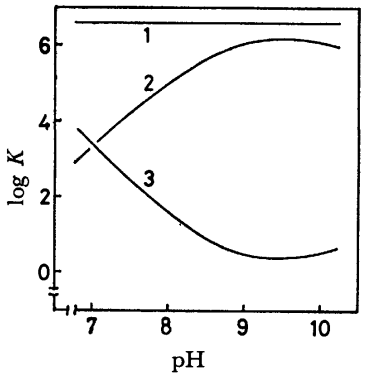

Fig. 1. Dependence of conditional equilibrium constants of reactions R1, R2, and R3 on pH at 25.0 °C and I=0.2 M.
1: R1, 2: R2, 3: R3.

constants of the related complexes and the protonation constants of the related ligands.[9] The calculated values are plotted against the pH in Fig. 1.

According to the proposed mechanism, the following rate law (general equation) is derived from a steady-state treatment reported previously:[8]

$$-\frac{d[\text{Zn(II)-tetren}]}{dt} = \frac{(k_2k_3[\text{Cu(II)-edta}][\text{Zn(II)-tetren}] - k_{-2}k_{-3}[\text{Zn(II)-edta}][\text{Cu(II)-tetren}])[\text{L}]}{k_2[\text{Cu(II)-edta}] + k_{-2}[\text{Cu(II)-tetren}] + k_3[\text{Zn(II)-tetren}] + k_{-3}[\text{Zn(II)-edta}]}, \quad (3)$$

where [L] is the total concentration of free ligands, edta and tetren. Since the R2 equilibrium is highly favored to proceed to the right, the $k_2 \gg k_{-2}$ inequality holds. Therefore, Eq. 3 may be simplified to

$$-\frac{d[\text{Zn(II)-tetren}]}{dt} = \frac{k_2k_3[\text{Cu(II)-edta}][\text{Zn(II)-tetren}][\text{L}]}{k_2[\text{Cu(II)-edta}] + k_3[\text{Zn(II)-tetren}] + k_{-3}[\text{Zn(II)-edta}]}. \quad (4)$$

The conditional rate constant, k_2, was calculated from the rate constants of the reaction of Cu(II)-edta with tetren.[10] The values of k_2 are plotted against the pH in Fig. 2.

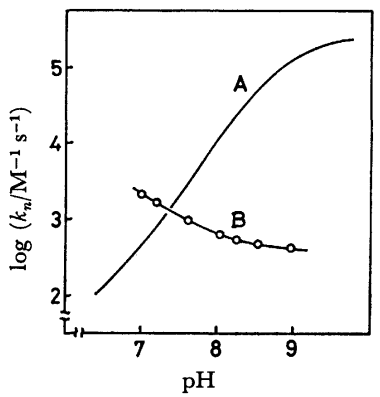

Fig. 2. Dependence of the conditional rate constants of reactions R2 and R3 on pH at 25.0 °C and I=0.2 M ($NaClO_4$).
A: k_2, B: $k_3(=k_0)$. The line A is the curve calculated with the aid of the individual rate constants.[14]

The following approximation seems reasonable from Figs. 1 and 2. In the denominator of Eq. 4, the k_2[Cu(II)-edta] term is predominant, while the other terms may be neglected under the present conditions. Thus, Eq. 4 may be simplified to

$$\frac{d[\text{Zn(II)-tetren}]}{dt} = k_3[\text{Zn(II)-tetren}][\text{L}]. \quad (5)$$

Since Eq. 5 agrees with the rate equation derived experimentally, k_3 corresponds to the k_0 of Eq. 2. The value of k_3 thus determined is plotted against the pH in Fig. 2.

Ligand-substitution Reaction of Zn(II)-tetren with edta. Acid Complex of Zn(II)-tetren: When the successive formation constants of the ammine copper(II) complex, K_n, are compared with those of the ammine zinc(II) complex, K'_n, the constants, K_n and K'_n, differ at n= 1,2,3; however, they are equal at n=4 ($K^{NH_3}_{Cu(NH_3)_4}$= $10^{2.1}$, $K^{NH_3}_{Zn(NH_3)_4}=10^{2.1}$), and the constants over n=4 are extremely small in both complexes.

The successive formation constant, K_1, of the dien (diethylenetriamine : tridentate ligand) copper(II) complex and that of the dien zinc(II) complex differ from one another ($K_{Cudien}=10^{16.0}$, $K_{Zndien}=10^{8.9}$); however, the successive formation constant, K_2, of the copper(II) complex is approximately equal to that of the zinc(II) complex ($K^{dien}_{Cu(dien)_2}=10^{5.3}$, $K^{dien}_{Zn(dien)_2}=10^{5.5}$).

Therefore, in hexadentate polyamine complexes of copper(II) and zinc(II), it may be said that the fifth and sixth nitrogen atoms (which dissociate secondarily and firstly respectively in the dissociation reaction) are weakly bonded to the central metal, and that the intensities of the fifth and sixth Cu–N bonds in the copper(II) complex are approxinately equal to those of the fifth and sixth Zn–N bonds respectively in the zinc(II) complex. Consequently, the protonation constant of the hexadentate polyamine copper(II) complex is expected to be close to that of the zinc(II) complex; in practice, the protonation constant of the penten (tetrakis(2-aminoethyl)ethylenediamine : hexadentate ligand) copper(II) complex is equal to that of the penten zinc(II) complex ($K^H_{CuHpenten}=10^{8.16}$, $K^H_{ZnHpenten}=10^{8.16}$).

If the above considerations can be applied to the pentadentate polyamine complex, it can be assumed that the protonation constant of Cu(II)-tetren ([Cu-(H_2O)tetren]$^{2+}$) is approximatly equal to that of Zn(II)-tetren ([Zn(H_2O)tetren]$^{2+}$). Thus, the protonation constant of Zn(II)-tetren may be estimated as follows: $K^H_{ZnHtetren}=K^H_{CuHtetren}=10^{5.18}$. The protonation constant of Zn(II)-tetren has been reported[11] as $K^H_{ZnHtetren}K^H_{ZnH_2tetren}=10^{9.4}$($K^H_{ZnH_2tetren}$=[Zn($H_2$tetren)$^{4+}$]/[Zn(Htetren)$^{3+}$][H$^+$]). Then, $K^H_{ZnH_2tetren}$ can be calculated to be $10^{4.2}$.

Resolution of the Conditional Rate Constant, k_3: B in Fig. 2 shows the pH dependence of the conditional rate constant for the ligand-substitution reaction of Zn(II)-tetren with edta. The pH dependence of the conditional rate constant was analyzed in the pH range of 7.5—9.0. In this pH range, the dominant species of edta are Hedta^{3-} and edta^{4-}, while the dominant species of acid complex of Zn(II)-tetren is [Zn(Htetren)]$^{3+}$.[12]

Thus, the rate equation for the ligand substitution

of Zn(II)-tetren with edta is given by

$$-\frac{d[\text{Zn(II)-tetren}]}{dt} = k_3[\text{Zn(II)-tetren}][\text{edta}]$$
$$= k_L[\text{Zn(tetren)}^{2+}][\text{edta}^{4-}] + k_{HL}[\text{Zn(tetren)}^{2+}]$$
$$[\text{Hedta}^{3-}] + k'_{HL}[\text{Zn(Htetren)}^{3+}][\text{Hedta}^{3-}], \quad (6)$$

where k_L, k_{HL}, and k'_{HL} are defined as follows:[13]

$$\text{Zn(tetren)}^{2+} + \begin{matrix} \text{edta}^{4-} & \xrightarrow{k_L} & \\ \text{Hedta}^{3-} & \xrightarrow[k_{HL}]{} & \text{Zn(edta)}^{2-}. \\ \text{Zn(Htetren)}^{3+} + \text{Hedta}^{3-} & \xrightarrow{k'_{HL}} & \end{matrix} \quad (7)$$

Hence, the following relationship is derived from Eq. 6:

$$k_3(1+K_1[H^+])(1+K^H_{ZnHtetren}[H^+])$$
$$= k_L + [H^+]K_1k_{HL} + [H^+]^2K_1K^H_{ZnHtetren}k'_{HL}, \quad (8)$$

where K_1 is the formation constant of $Hedta^{3-}$. The rate constant, k_3, was resolved into individual rate constants, k_L, k_{HL}, and k'_{HL}, to fit Eq. 8. The calculation of the resolved rate constants was performed with the aid of an electronic computer. The resolved rate constants are shown in Table 1.

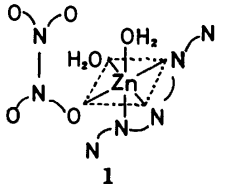
TABLE 1. RATE CONSTANTS FOR THE LIGAND-SUBSTITUTION REACTION OF Zn(II)-tetren WITH edta AT 25.0 °C AND I=0.2 M ($NaClO_4$)

k_L / $M^{-1}s^{-1}$	k_{HL} / $M^{-1}s^{-1}$	k'_{HL} / $M^{-1}s^{-1}$
$\approx 3\times10^2$	$(4.1\pm0.7)\times10^2$	$(1.7\pm0.2)\times10^5$

Mechanism of the Substitution Reaction of Zn(tetren)$^{2+}$ with edta: The reaction scheme can be described as

$$\begin{array}{ccc} \text{ZnL-(edta)}^{2-} & \overset{K_w}{\rightleftharpoons} & \text{ZnL(edta)}^{2-} \\ \Big\uparrow\Big\downarrow K_{os} & & \Big\downarrow k \\ \text{ZnL}^{2+} \overset{K_d}{\rightleftharpoons} \text{ZnL}_d^{2+} & & \text{Zn(edta)}^{2-}, \\ \Big\uparrow\Big\downarrow K'_{os} & & \Big\uparrow k' \\ \text{ZnL-(Hedta)}^{-1} & \overset{K'_w}{\rightleftharpoons} & \text{ZnL(Hedta)}^{-1} \end{array} \quad (9)$$

where K_d is the dissociation constant of ZnL^{2+} to the partially dissociated complex ZnL_d^{2+}, K_{os} is the formation constant of the outer-sphere conplex ZnL-(edta)$^{2-}$, K_w is the equilibrium constant between [ZnL-(edta)]$^{2-}$ and the mixed-ligand intermediate ZnL(edta)$^{2-}$, and L refers to the ligand tetren. Since the structure for the mixed-ligand intermidiate is considered to be the same as that of the nickel system,[14] the structure for the mixed-ligand intermediate (for edta^{4-}) seems to be as follows:



1

where edta^{4-} and tetren are symbolized as  and N–N–N–N–N respectively and where the charges are omitted; the rate-determining step for the formation of [Zn(edta)]$^{4-}$ is considered to be the loss of a water molecule from the intermediate **1**, as in the nickel system.

According to the proposed mechanism, the following equation is obtained:

$$k[\text{ZnL(edta)}^{2-}] + k'[\text{ZnL(Hedta)}^{-1}]$$
$$= K_dK_{os}K_wk[\text{edta}^{4-}][\text{ZnL}^{2+}]$$
$$+ K_dK'_{os}K'_wk'[\text{Hedta}^{3-}][\text{ZnL}^{2+}]$$
$$= k_L[\text{edta}^{4-}][\text{ZnL}^{2+}] + k_{HL}[\text{Hedta}^{3-}][\text{ZnL}^{2+}]. \quad (10)$$

from Eq. 10, the k_L/k_{HL} ratio is given by

$$\frac{k_L}{k_{HL}} = \frac{K_{os}K_wk}{K'_{os}K'_wk'} \quad (11)$$

Since k_L is approximately equal to k_{HL} (Table 1), Eq. 11 becomes

$$\frac{K_{os}K_wk}{K'_{os}K'_wk'} \approx 1. \quad (12)$$

The release of a water molecule from the outer-sphere complex is the rate-determining step in the formation of the inner-sphere complex,[15] and the loss of a water molecule from the mixed-ligand intermediate seems to be the rate-determining step in the formation of [Zn(edta)]$^{2-}$. Therefore, it appears reasonable to assume that $K_w \approx K'_w$ and that $k \approx k'$. Thus, K_{os} is nearly equal to K'_{os}.

In the formation of a metal complex, a charged group removed from the eventual coordination site is relatively unimportant.[16] The negative charge removed from the coordination site in edta thus seems unimportant in the formation of the above mixed-ligand intermediate. Consequently, K_{os} can be expected to be equal to K'_{so}.

Mechanism of the Substitution Reaction of Zn(II)-tetren with Hedta^{3-}: The following reaction mechanism was proposed:

$$\begin{array}{ccccc} \text{ZnL}_d^{2+} & \overset{K_{os}}{\rightleftharpoons} & \text{ZnL-(Hedta)}^{-1} & \overset{K_w}{\rightleftharpoons} & \text{ZnL(Hedta)}^{-1} \\ \Big\uparrow\Big\downarrow K_d & & & & \Big\downarrow k \\ \text{ZnL}^{2+} & & & & \\ \Big\uparrow\Big\downarrow & & & & \text{Zn(edta)}^{2-}. \\ \text{ZnHL}^{3+} & & & & \Big\uparrow k' \\ \Big\uparrow\Big\downarrow K'_d & & & & \\ \text{ZnHL}_d^{3+} & \overset{K'_{os}}{\rightleftharpoons} & \text{ZnHL-(Hedta)} & \overset{K'_w}{\rightleftharpoons} & \text{ZnHL(Hedta)} \end{array} \quad (13)$$

On the basis of the reaction mechanism, the following equation is derived:

$$k[\text{ZnL(Hedta)}^{-1}] + k'[\text{ZnHL(Hedta)}]$$
$$= K_dK_{os}K_wk[\text{Hedta}^{3-}][\text{ZnL}^{2+}]$$
$$+ K'_dK'_{os}K'_wk'[\text{Hedta}^{3-}][\text{ZnHL}^{3+}]$$
$$= k_{HL}[\text{Hedta}^{3-}][\text{ZnL}^{2+}] + k'_{HL}[\text{Hedta}^{3-}][\text{ZnHL}^{3+}]. \quad (14)$$

From Eq. 14, the k_{HL}/k'_{HL} ratio is given by

$$\frac{k_{HL}}{k'_{HL}}=\frac{K_d K_{os} K_w k}{K'_d K'_{os} K'_w k'}. \quad (15)$$

Since it appears reasonable to assume that $K_{os}\approx K'_{os}$, $K_w\approx K'_w$, and that $k\approx k'$, Eq. 15 can be simplified to

$$\frac{k_{HL}}{k'_{HL}}\approx\frac{k_d}{k'_d}. \quad (16)$$

The difference between k_{HL} and k'_{HL} is mostly determined by the difference between K_d and K'_d. Since the k'_{HL}/k_{HL} ratio is about 400 : 1, the partial dissociation rate of the $Zn(Htetren)^{3+}$ complex is 400 times faster than that of the $Zn(tetren)^{2+}$ complex; the proton bonded to the tetren facilitates the partial dissociation.

Solubility Measurements of Benzene and the Alkylbenzenes in Water by Making Use of Solute Vapor

Isao SANEMASA,* Masatake ARAKI, Toshio DEGUCHI, and Hideo NAGAI
Department of Chemistry, Faculty of Science, Kumamoto University, Kurokami 2-39-1, Kumamoto 860
(Received September 7, 1981)

Aqueous solubilities of benzene and of alkylbenzenes, toluene, ethylbenzene, propyl- and isopropylbenzene, (*o*-, *m*-, and *p*-) xylene, and (1,2,3-, 1,2,4-, and 1,3,5-) trimethylbenzene, have been measured. An apparatus is described which provides a convenient means of obtaining aqueous solutions saturated with solute vapor. The method involves introducing solute vapor, which is in equilibrium with a liquid solute, into water and circulating it in a closed system. This method has three principal advantages: (1) The solubility equilibrium can be attained within 3 min, (2) it can be determined whether the solubility obeys Henry's law, and (3) based on Henry's law, solutions of any desired concentrations of solute at a given temperature of water can be easily prepared.

The solubilities of slightly soluble organic compounds in water have been studied by many reseachers. The solubility measurement generally consists of two steps; the first is a preparation of aqueous solution saturated with solute and the second is a measurement of solute concentration in the solution. The latter step has been markedly improved in sensitivity and selectivity by advances in instruments such as spectrophotometer and gas-liquid chromatography, whereas the former step seems to have remained unchanged for a long time. The former step is still the more important, since it often influences the precission and accuracy of the results. At the present time, it is true to say that the reproducibility of the solubility data mainly depends on this step.

Most of the earlier investigators prepared the saturated solutions by adding an excess quantity of a solute to a water and shaking the mixture mechanically for at least 24 h. The solutions thus prepared were usually allowed to stand for at least another 24 h or centrifuged to ensure removal of any organic droplets entrained in suspension, and then the solute concentrations were determined. Particular attention should be paid to the possible inclusion of a suspended micro-emulsion which may arise when liquid solute has been dispersed by vigorous shaking, and also to the extreme volatility and the strong adsorption on the container walls which are both characteristic of organic solutes in water. Instead of this conventional method, some attempts have recently been made to attain the solubility equilibrium. Sutton and Calder estimated solubilities of alkylbenzenes by equilibrating water with solute vapor in a closed vessel where water and liquid solute were separately placed.[1] Brown and Wasik used an apparatus which made it possible to measure the equilibrium distribution of a hydrocarbon between a gas phase and a liquid phase.[2] Mackay *et al.* estimated Henry's law constants for some liquid and solid hydrocarbons by measuring solute concentrations in aqueous solution while being stripped from solution at a known gas flow rate.[3]

This paper will describe a simple and useful technique that allows a rapid preparation of aqueous solutions of desired solute concentrations at a given temperature of water by making use of solute vapor.

Experimental

Materials. Materials used as solute were analytical reagent grade (Wako Pure Chemical Industries Ltd.) except 1,2,3- and 1,2,4-trimethylbenzene. The stated minimum purities (mass %) were: benzene; 99.5, toluene; 99.0, ethylbenzene, (*o*-, *m*-, and *p*-)xylene, and isopropylbenzene; 98.0, 1,3,5-trimethylbenzene; 97.0, 1,2,4-trimethylbenzene; 95.0, propylbenzene; no description. All these solutes were used without further purification. Redistilled water was used as solvent. Analytical reagent grade chloroform (minimum purity 99.8%) was used for solvent extraction and preparation of standard solution of solute.

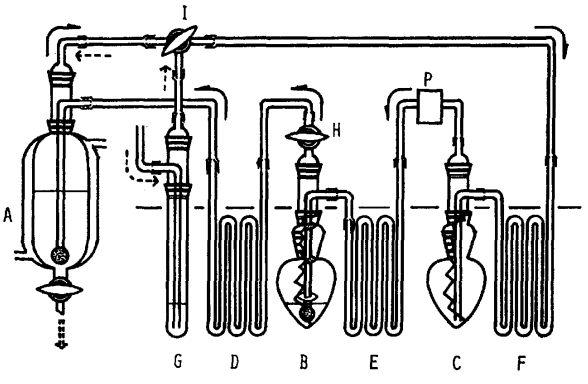

Fig. 1. Solubility apparatus.
The solid and the dotted arrows indicate, respectively, the direction of circulation and the sampling system.

Apparatus and Procedures. The apparatus used is shown in Fig. 1, which is essentially similar to that previously reported,[4] but with some modifications. It is composed of a separatory funnel (300 cm^3), A, two pear-shaped flasks (each 50 cm^3) B, and C, three triplicated-U-shape glass pipes (ϕ 8 mm, each 20 cm^3), D, E, and F, a glass test tube (30 cm^3), G, and a Viton diaphragm pump (Iwaki Type AP-32 Z), P. We will hereafter call A and B by the name "solubility flask" and "solute reservoir," respectively. Gas inlet-type adapters were mounted in A, B, C, and G. Teflon tubes (ϕ 8 mm), a stopcock, H, and a three-way cock, I, were used for connection. The U-shape glass pipes and the flask C serve as traps of water or liquid solute. The test tube, in which was placed some 5 cm^3 of the same liquid solute as the one being measured, was included in the system to facilitate withdrawing sample solution from the solubility flask. In order to prevent liquid solute from being carried over from the solute reservoir by

bubbling air, three sheets of Teflon disks, each of which was bored in the center to fit the glass pipe, were attached to the gas inlet-type adapter inserted in the solute reservoir. Of these three disks, two were made with about 20 pinholes and they were tightly fitted to the lower parts of the ground glass joints and the other was set just above liquid solute phase. The temperature of the solubility flask was held constant by circulating water through a surrounding jacket from a thermostat, and the temperature of the solute reservoir was maintained constant by immersing in another thermostat, in which the other glass wares were also immersed as shown in Fig. 1. These thermostats were controlled within 0.01 °C (in some cases 0.1 °C). The assembled apparatus was placed in a draft chamber, the temperature of which was always kept higher than that of the solute reservoir.

A redistilled water of 100 to 200 cm^3 and a liquid solute of 10 to 20 cm^3 were placed in the solubility flask and in the solute reservoir, respectively. When the conditions of temperature were attained, the pump was started, and the solute vapor, which was generated by bubbling air through the liquid solute *via* a sintered glass ball, was introduced into the water *via* another sintered ball, and circulated as indicated in Fig. 1. The circulation rate, which can be changed by means of a Variac and had been calibrated in advance by a flow meter, was set at 2 dm^3/min in most instances. After the solubility equilibrium was attained, the stopcock (H) was closed and the three-way cock (I) was turned left through 90° so as to connect the system with the test tube (G) as indicated in Fig. 1. Then, by opening a stopcock attached to the bottom of the solubility flask, about 30 cm^3 was first discarded and 10 cm^3 portions were transferred successively into five cylindrical separatory funnels of 50 cm^3 capacity, to which each 10 cm^3 volume of chloroform had previously placed. Each separatory funnel had been calibrated in advance and the volume of aqueous solution poured into it was read off. The mixtures in the separatory funnels were hand shaken and allowed to stand for 30 min, then after dehydrating the chloroform phase with anhydrous sodium sulfate, UV-absorptions were measured using a Hitachi Model 100-50 spectrophotometer against the blank extract as a reference. In the case of benzene, the extracts were further diluted with chloroform. Wavelengths used for the measurements and the molar absorptivities were: benzene; 260.8 nm (126 $dm^3\ mol^{-1}\ cm^{-1}$), toluene; 262.0 (275), ethylbenzene; 261.2 (257), *o*-xylene; 263.0 (324), *m*-xylene; 265.0 (302), *p*-xylene; 268.0 (562), propylbenzene; 261.4 (257), isopropylbenzene; 260.2 (234), 1,2,3-trimethylbenzene; 262.4 (234), 1,2,4-trimethylbenzene; 267.7 (537), 1,3,5-trimethylbenzene; 265.8 (229). Standard solutions were prepared by weighing out suitable quantities of the liquid solutes, followed by dilution with chloroform in volumetric flasks. Calibration curves were made as follows: into separatory funnels aliquots of less than 10 cm^3 of the standard solution were pipetted in succession, diluted with chloroform to 10 cm^3, and then 10 cm^3 portions of redistilled water were added, and the chloroform extracts were measured in the same way as the sample solution. The molar absorptivities described above were thus determined. Values of equilibrium solubilities were the average of at least five determinations.

When the apparatus was used in an open method, the system was modified to remove I, G, P, C, and F from the apparatus. A round-bottom flask of 300 cm^3 capacity was used as the solute reservoir instead of B and the liquid solute of 100 cm^3 was placed in it. Nitrogen gas was allowed to flow continuously through the solute reservoir and to escape through the solubility flask to the atmosphere.

Results

Factors Affecting the Solubility Measurement. When the circulation rate was set at 2 dm^3/min, the solubility equilibrium can be attained after 3 min for each solute. The typical results are shown in Fig. 2. With decreasing the circulation rate, the curve of solubility plotted against time appeared to level off after a somewhat prolonged time, but the solubilities were not affected. In the present method, it is essential to carry out under such experimental conditions that temperature of

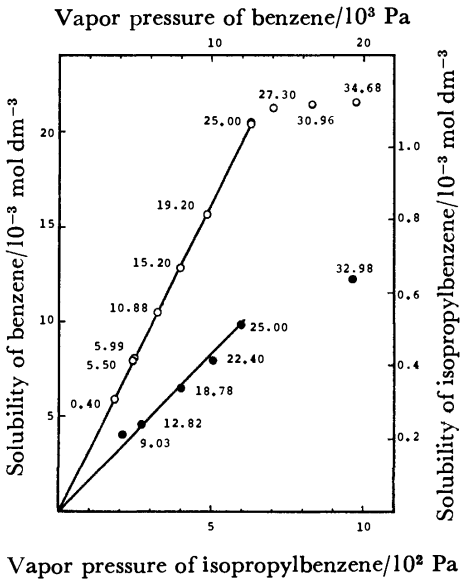

Fig. 4. The effect of temperature of solute reservoir at constant temperature of solubility flask on the solubilities of benzene and isopropylbenzene.
Benzene (○), isopropylbenzene (●). Temperature of solubility flask: 25.00 °C. The figure near each circle indicates the temperature of solute reservoir.

water≥temperature of liquid solute<room temperature. In fact, when the temperature of room was lower than that of the solute reservior, the measured solubilities were lowered correlatively depending on the former temperature. The results are shown in Fig. 3. On the other hand, when the temperature of the solute reservoir was higher than that of the solubility flask, the solute vapor condensed and separated in the solubility flask to form two immiscible phases. Under such conditions, solubilities were found to be considerably higher than those at the same temperature of water and solute. The results are shown in Fig. 4.

Solubility and Vapor Pressure. Solubility runs were made under conditions such that the temperature of the solute reservoir was made to vary while that of the solubility flask was maintained at a constant temperature. The experimental results for all the solutes used here are listed in Table 1. Vapor pressures for pure luquid solutes have been estimated by reference to published tabulations.[5] In this paper, the vapor pressure of liquid solute was taken to be that of pure solute, neglecting the effects of water dissolution in the solute phase and of solute-solvent interaction in the water phase. It can be seen from Table 1 that the concentrations of each solute in aqueous solutions increase linearly with the solute vapor pressure at a constant temperature of water. That is, solubilities obey Henry's law

$$P = K_H X_2, \quad (1)$$

where P is the partial pressure of solute vapor in Pa, X_2 is the mole fraction of the dissolved solute, and K_H is Henry's law constant. Henry's law constants thus determined are given in Table 2. We estimated the solubilities when the temperature of solute was the same as that of water from K_H and P using Eq. 1, since the experimental values under such conditions were somewhat poor in precision. The results are listed in Table 2. To compare the present results with the literature, the reported values, most of which are available only at 25 °C, are summarized in Table 3. In Table 4 are also given some available data of Henry's law constant. Our results are in accord with the literature values except for benzene and propylbenzene. With respect to the latter, the literature value would be overestimated when considered the relationship between the number of methyl group and the solubility.

a) In the course of this study, the thermostats were replaced by new ones, temperature of which could be controlled within 0.01 °C. b) Correlation coefficient of the equation, $X=P/K_H$ (the symbols are described in the text). c) Estimated under the conditions where the temperatures of water and liquid solute were the same.

Solubility in an Open Method. An alterative method may be applicable to attain the solubility equilibrium between the water phase and the saturated solute vapor phase. Thus, solubility runs were undertaken in an open method as described in the experimental section. In the open method, it seems to be natural that the flow rate of nitrogen gas should affect the solubility results to a large extent. The results are shown in Fig. 5. Contrary to our expectation, the nitrogen gas flow rate up to 1.2 dm^3/min had no effect on the solubility and the steady solubility was reached within a relatively short time. The solute vapor generated by bubbling through the liquid solute phase is considered to be sufficient to saturate the nitrogen gas in the wide range of its flow rate. Solubilities of benzene and toluene plotted against vapor pressures are shown in Figs. 6

Table 3. Solubilities of benzene and the alkylbenzenes at 25 °C reported in the literature

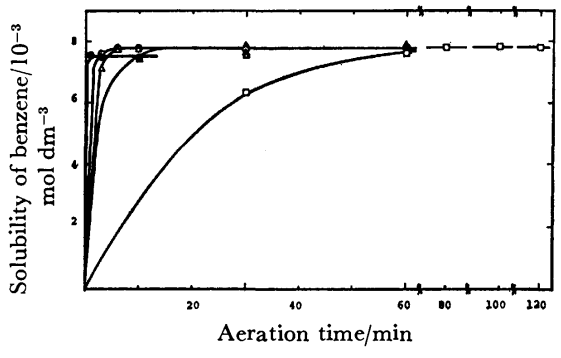

Fig. 5. The effect of nitrogen gas flow rate on the solubility of benzene in the open method.
Temperature of solubility flask; 35.00 °C. Temperature of solute reservoir; 15.00 °C. Flow rate: 3.0 (●), 1.2 (○), 0.5 (△), 0.2 (▲), 0.02 dm³/min (□).

and 7, respectively, where those obtained in the closed method are also given for the sake of comparison. Similarly Henry's law was applied in the open method

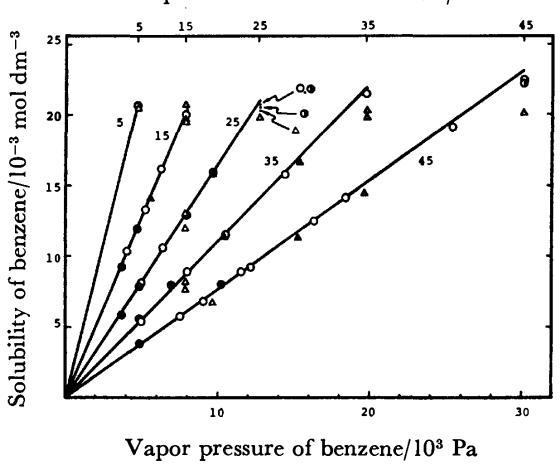

Fig. 6. The solubility of benzene plotted against vapor pressure.
The closed method: circulation rate; 2 dm³/min, time; 5 min, measured on Oct. 26—28 (1980) (●) Dec. 14—16 (1980) (◑) July 25—30 (1981) (○). The open method: nitrogen gas flow rate; 0.2 dm³/min, time; 60 min, measured on May 6—28 (1981) (△) Aug. 3—10 (1981) (▲). The figure near each solid line indicates the temperature of solubility flask in °C.

to these solutes, but the reproducibility was somewhat poor. However, the open method has an advantage that the liquid solute phase is free from contamination with water vapor.

Discussion

The Evaluation of the Present Method. The present method is essentially the same as that previously employed in determining the solubility of metallic mercury in water.[6] In writing this paper, we have searched the literature for the one most similar to the present method and found a paper published by Joris and Taylor.[7] They made use of a similar closed circulatory system

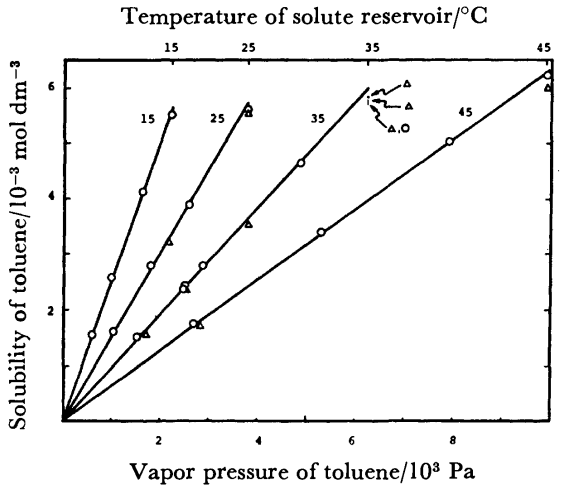

Fig. 7. The solubility of toluene plotted against vapor pressure.
The closed method (○), circulation rate; 2 dm³/min, time; 5 min. The open method (△), nitrogen gas flow rate; 0.2 dm³/min, time; 60 min. The figure near each solid line indicates the temperature of solubility flask in °C.

in determining the solubility of water in organic solvent, which is just the opposite situation to the present study. In their method, temperatures of solvent and solute are nearly equal to each other, while the whole circulatory system is kept at a higher temperature than either.

It is a thermodynamic requirement that the solubility measurement should be done under the same temperature of solvent and solute. From this standpoint, two basic questions arise concerning the validity of the present method; the first is that the temperature of the solute reservoir differs from that of the solubility flask and the second is that the partial pressure of the solute vapor may be affected by the temperature change in a different part of the closed system. The temperature of the solute vapor just before entering the solubility flask certainly differs from that in the solubility flask; the former is higher than that of the solute reservoir owing to the room temperature. However, the solubilities were found to be independent of the room temperature so far as being kept above the temperature of the solute reservoir (Fig. 3). We have assumed that when the solute vapor is bubbled into the water phase through the sintered ball and bubbles come into contact with the water, the temperature of the interface of each bubble can be equated to that of bulk water almost immediately. The temperature change in the bulk water was examined in the preliminary experiment by introducing solute vapor at 2 dm³/min into the solubility flask in which a thermometer was inserted. A slight decrease in the temperature of the bulk water was observed, probably due to the vaporization of water. We have concluded that such temperature change is negligibly small in the solubility measurement.

On the other hand, the second question is more substantial, since the total pressure undoubtedly relates to the temperature of system. In the closed system, however, it seems likely that the different temperature inside the apparatus (solute, solvent, and room) dose not cause the pressure change, but contributes to the flow rate of the gas phase in the corresponding parts of the system. That is, the flow rate of the circulating gas is faster in places of higher temperature. Thus, the total pressure remains constant at atomospheric pressure over the temperature range investigated. This situation may be more easily understood by referring to the open method, where the nitrogen gas carrying the solute vapor is always open to the atmosphere after having been introduced into the water phase. We suppose from the following observation that the total pressure in the closed system is also kept under atmospheric pressure: when the three-way cock was turned prior to sampling so as to connect the system to the test tube as indicated in Fig. 1, only a small change was observed in the liquid solute level inside the glass pipe in the test tube.

Concerning the evaluation of the present method, we have taken account of the serious disagreement of benzene with the literature; some 10% lower than most literature values. After presenting our short communication,[4] we have continued the solubility measurements by the modified apparatus employed here. However, the results always indicated the lower values. The reason is not explicable at present, but it is felt that the present method may give lower saturated solution for such solute exhibiting high vapor pressure as benzene. It can be seen from Figs. 6 and 7 that the solubilities of benzene obtained by the open method are a little lower than those by the closed method, especially at higher temperature of water, and that the agreements between the open and the closed methods are better for toluene than for benzene. It seems likely that an escape of solute vapor from aqueous solution occurs in preference to a dissolution into it in the open system. This escaping tendency may have likewise taken place even under the closed system owing to the extreme volatility of benzene in water. The solubility measured by the present method might be called "steady state solubility," that is, the solubility determined under such condition that the rate of escape of solute vapor from the aqueous phase is equal to the rate of dissolution of solute vapor into it. The balance for benzene may be changed in favor of escape.

Interpretation of the Solubility Results. As suggested by Amidon and Anik,[8] the solution process of liquid hydrocarbon can be divided into two steps; pure liquid to gas and gas to aqueous solution. The present study is concerned with the latter step, that is, the solvation process. The thermodynamic parameters estimated from the temperature dependence of Henry's law constant are tabulated in Table 5, in which are given the solvation enthalpies reported by the two groups. They estimated these values indirectly by subtracting the heat of vaporization to form ideal gas from the energy of solution. Our results are in fair agreement with them. It should be noticed, however, that the present results have been derived on the assumption of ΔH being temperature independent. Thermodynamic features of the solution process of benzene and the alkylbenzenes will be reported and discussed elsewhere.

It can be seen from Table 2 that the number of the methyl groups is predominant in determining the

a) Thermodynamic parameters determined in this work were derived based on the assumption of ΔH being temperature independent. b) S. J. Gill, N. F. Nichols, and I. Wadsö, *J. Chem. Thermodyn.*, **8**, 445 (1976). c) R. D. Wauchope and R. Haque, *Can. J. Chem.*, **50**, 133 (1972).

solubility; the solubility decreases to *ca.* 1/3.6 with an increase of one methyl group. Moreover, as pointed out by Sutton and Calder,[1)] the positions of the substituents on the benzene ring are of secondary importance. The expression in terms of Henry's law constant seems to indicate more pronounced differences among the substituted isomers rather than the solubility proper. Henry's law constant might be predictable from the scaled particle theory,[9)] which requires many parameters for a single solute such as molecular diameter, energy parameter, polarizability, and dipole moment. Of these parameters, the last one appears to play an important role in the solubility characteristic of isomers; Henry's law constant decreases with increasing dipole moment of the solute. On the basis of the scaled particle theory, we have tried briefly to correlate Henry's law constants of a series of benzene and the alkylbenzenes with their molecular parameters. The results, however, were not satisfactory.

Applicability of the Present Method. The present method has three principal advantages. Firstly, the solubility equilibria can be attained in quite a short time such as 3 min, and they are easily reproducible. Secondly, it can be easily confirmed whether the solubility obeys Henry's law. Henry's law constant and its temperature dependence should help to clarify the solution process in more detail than the solubility itself. Finally, the apparatus is best suited for preparing aqueous solutions of any desired concentrations of solute, which are equal or below the saturation, at a given temperature of water.

Of these, the last one is the most remarkable feature of the present method and attractive from the practical point of view. For instance, certain specific interaction of a third component such as an electrolyte or another organic compound with organic liquid solutes can be substantiated experimentally by measuring the solubility change in the presence of the third component.

Recent workers have taken it as an advantage that their methods of solubility measurement do not necessarily require the preparation of truly saturated solutions.[2,3,10)] Nevertheless, it is still important and indispensable in some cases to prepare the truly saturated solutions.

Structural Study of Optical Resolution. XI. The Crystal Structures of $(+)_{589}$-Tris(biguanide)cobalt(III) Chloride *d*-Tartrate Trihydrate and Racemic Tris(biguanide)cobalt(III) Trichloride

Toshiji TADA, Yoshihiko KUSHI, and Hayami YONEDA*

Department of Chemistry, Faculty of Science, Hiroshima University, Higashi-senda-machi, Naka-ku, Hiroshima 730

(Received September 9, 1981)

The crystal structures of the more-soluble diastereomeric salt, $(+)_{589}$-$[Co(Hbg)_3]Cl(d\text{-tart})\cdot 3H_2O$ (**1**), and the racemic chloride salt, $[Co(Hbg)_3]Cl_3$ (**2**), have been determined by X-ray analysis ($R=0.033$, 2788 reflections for **1** and $R=0.056$, 2785 reflections for **2**), where $Hbg=C_2H_7N_5$, *d*-tart$=C_4H_4O_6^{2-}$. The more-soluble salt **1** is orthorhombic, with the space group $P2_12_12_1$, $Z=4$, $a=15.654(2)$, $b=13.758(2)$, and $c=11.010(1)$ Å. The racemic salt **2** is monoclinic, with the space group C2/c, $Z=8$, $a=19.441(9)$, $b=14.901(7)$, $c=15.911(6)$ Å, and $\beta=127.63(2)°$. In **1**, the complex cations and the Cl^- ions are arranged alternately to form an infinite spiral chain, $\{\Delta\text{-}[Co(Hbg)_3]Cl\}_\infty$. Each *d*-tartrate is hydrogen-bonded to a twofold-screw-axis-related neighbor (-OH··· OOC- 2.792 Å) to form an infinite chain, $(d\text{-tart})_\infty$. In **2** two kinds of similar infinite spiral chains, $\{\Delta\text{-}[Co(Hbg)_3]Cl\}_\infty$ and $\{\Lambda\text{-}[Co(Hbg)_3]Cl\}_\infty$, which are mirror images of each other are found. The structures of these two salts **1** and **2** are compared with those of the less-soluble diastereomeric chloride *d*-tartrate and the optically active chloride in both of which a similar infinite chain has been found, and the mechanism of chiral discrimination *via* the diastereomer formation is discussed.

In a previous paper, we reported the crystal structure of the less-soluble diastereomeric salt, $(-)_{589}$-$[Co(Hbg)_3]Cl(d\text{-tart})\cdot 5H_2O$ **3** (Hbg stands for biguanide, and *d*-tart stands for the *d*-tartrate ion).[1] Two characteristic features were noted to be important in connection with the mechanism of optical resolution *via* the less-soluble diastereomeric salt: 1) The chiral complex and Cl^- ions are arranged alternately to form an infinite spiral chain which is cationic and left-handed as a whole, and 2) two *d*-tart anions exist closely to each other and form a dimeric unit with 4 negative charges, similar in structure to the antimony *d*-tartrate ion. Such a dimeric unit of *d*-tart anions has never been found in the crystal structures determined so far. A similar infinite spiral chain was found in the optically active chloride salt, $(+)_{589}$-$[Co(Hbg)_3]Cl_3\cdot H_2O$.[2] In this case, the spiral chain consists of Δ complexes and is right-handed as a whole. With these findings in mind, we have attempted here to determine the crystal structures of the more-soluble diastereomeric salt, $(+)_{589}$-$[Co(Hbg)_3]Cl(d\text{-tart})\cdot 3H_2O$ **1**, as well as the racemic chloride salt, $[Co(Hbg)_3]Cl_3$ **2**, in order to see whether the infinite spiral chain of the complex ions exists in common and to see how the *d*-tart anions are packed in the more-soluble salt **1**. Through these crystal structure analyses, we have tried to find out a clue to the mechanism of optical resolution of the biguanide complex.

Experimental

Preparation of Compound. Biguanide sulfate was prepared by the method given in the literature.[3] The racemic chloride salt, $[Co(Hbg)_3]Cl_3$ **2**, was prepared by the method of Ray and Dutt.[4] The crystals are brownish yellow parallelepiped. Found: C, 15.60; H, 4.56; N, 45.10%. Calcd for $CoC_6H_{21}N_{15}Cl_3$: C, 15.38; H, 4.52; N, 44.83%. The more-soluble diastereomeric salt, $(+)_{589}$-$[Co(Hbg)_3]Cl(d\text{-tart})\cdot 3H_2O$ **1**, was prepared by the method of Ray and Dutt.[5] After removal of the crystals of the less-soluble diastereomeric salt **3**, the filtrate was allowed to stand at room temperature for several days. Large and thick plate-like crystals of the more-soluble salt were easily separated mechanically from the fine thin plates of the remaining less-soluble salt. The optical purity of the crystals was checked by the CD measurement ($\Delta\varepsilon_{510}=+3.52$ and $\Delta\varepsilon_{452}=-4.76$).[6] Found: C, 19.37; H, 4.96; N, 35.90%. Calcd for $CoC_{10}H_{25}N_{15}O_6Cl\cdot 3H_2O$ ($2H_2O$): C, 20.02 (20.64); H, 5.21 (5.02); N, 35.03 (36.11)%.

Data Collection. The size of crystal used for the X-ray measurement was 0.53 mm × 0.32 mm × 0.15 mm for the more-soluble salt **1** and 0.25 mm × 0.13 mm × 0.08 mm for the racemic salt **2**. For **1**, the systematic absences for *h*00 ($h=2n+1$), 0*k*0 ($k=2n+1$), and 00*l* ($l=2n+1$) indicated the space group $P2_12_12_1$. For **2**, the systematic absences for *hkl* ($h+k=2n+1$) and *h*0*l* ($h=2n+1$ and $l=2n+1$) suggested the following possible space groups: Cc and C2/c. The three-dimensional Patterson map indicated the space group C2/c and the success of the structure determination confirmed the wisdom of this selection. The determination of cell dimensions and the collection of intensity data were carried out on a Rigaku AFC-5 automated four-circle diffractometer with Mo $K\alpha$ radiation ($\lambda=0.71069$ Å) monochromated by a graphite plate. Both unit-cell dimensions were refined by a least-squares method with 23 high angle reflections ($2\theta>26°$). The crystal data are summarized in Table 1. Densities of the

a) $B_{eq}=8\pi^2(U_{11}+U_{22}+U_{33})/3$.

crystals were measured by the flotation method in a mixture of chloroform and bromoform. The intensity data were collected in the ω-2θ scan mode up to $2\theta=55°$ with scan rates of 6°/min for **1** and of 16°/min for **2** (50 kV, 170 mA). The ω scan range was $(1.0+0.5 \tan\theta)°$. Of the 2949 and 3322 unique observed reflections, 2788 and 2785 reflections with $|Fo| \geq 3\sigma(F)$ were used for the structure determination in **1** and **2** respectively. Corrections for the absorption effect were neglected (μ(Mo $K\alpha$)=8.96 cm^{-1} for **1** and 14.42 cm^{-1} for **2**).

Determination and Refinement of Crystal Structures

The More-soluble Diastereomeric Salt, $(+)_{589}$-[Co(Hbg)$_3$]Cl(d-tart). 3H$_2$O (1). The structure was determined by the heavy-atom method and refined by the block-diagonal least-squares method. Three kinds of water molecules were found on a difference Fourier map after the other non-hydrogen atoms were located by an application of the Fourier method. The refinement using anisotropic thermal parameters for non-hydrogen atoms reduced the R value (defined as $\sum||F_o|-|F_c||/\sum|F_o|$) to 0.061. At this stage, all the hydrogen atoms were located from a difference Fourier map. The final refinement including the contribution of these H atoms with isotropic temperature factors converged the R value to 0.033. The final difference map showed no peaks higher than 0.4 electron/Å^3. The absolute configuration of $(+)_{589}$-[Co(Hbg)$_3$]$^{3+}$ was assigned as Δ on the basis of the configuration (2R, 3R) of the d-tart anion as an internal reference.[7]

The Racemic Chloride Salt, [Co(Hbg)$_3$]Cl$_3$ (2). The determination and the refinement of the structure were made in a way similar to that used for **1**. The final refinement converged the R value to 0.058. The final difference map showed no peaks higher than 0.4 electron/Å^3.

In the refinement, the quantity minimized was $\sum w(|F_o|-k|F_c|)^2$. The weighting scheme used was $w=(\sigma_{cs}^2+a|F_o|+(b|F_o|)^2)^{-1}$, where σ_{cs} is the standard deviation obtained from the counting statistics for each reflection; the values of a and b were 0.2 and 0.03 respectively. All the atomic scattering factors, with the effect of the anomalous dispersion of Co and Cl atoms were taken from the International Tables for X-Ray Crystallography, Vol. IV.[8]

All the computations were carried out by a HITAC M-180 computer at the Hiroshima University Information Processing Center. The computer programs used were FOUR-MMM, FOUR-2/M,[9] and HBLS-IV with a slight modification.[10] An ORTEP drawing was carried out by a computer system, XTL, in a Syntex R3 automated four-circle diffractometer.[11] The final atomic parameters are listed in Table 2 for the more-soluble salt **1** and in Table 3 for the racemic salt **2**, respectively. The anisotropic thermal parameters and complete lists of the $|F_o|$ and $|F_c|$ values have been preserved by the Chemical Society of Japan (Document No. 8220).

Results and Discussion

The projections of the crystal structure for the more-soluble diastereomeric salt **1**, $(+)_{589}$-[Co(Hbg)$_3$]Cl(d-tart)·3H$_2$O, along the a- and c-axes are shown in Figs. 1 and 2. The projections of the crystal structure for the racemic chloride salt **2**, [Co(Hbg)$_3$]Cl$_3$, to the (110) plane and along the b-axis are shown in Figs. 3 and 4. In Figs. 1 and 3, the part of the components in the unit

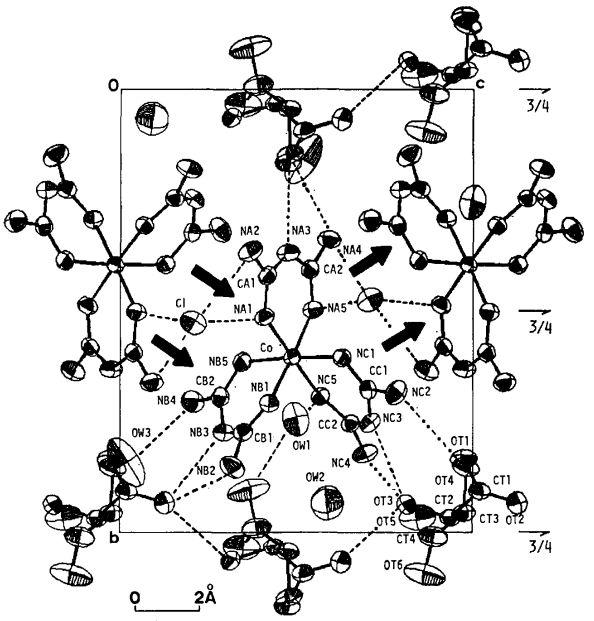

Fig. 1. An ORTEP drawing of the part of the components in the unit cell viewed down the a-axis with the numbering scheme for $(+)_{589}$-[Co(Hbg)$_3$]Cl(d-tart)·3H$_2$O. All atoms are drawn with 50% probability ellipsoids. Possible hydrogen bonds are indicated by broken lines. Hydrogen atoms are omitted for clarity.

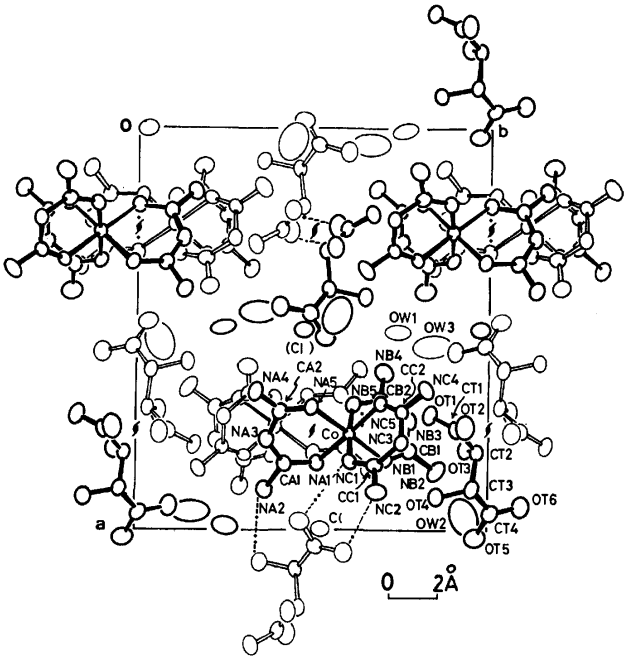

Fig. 2. An ORTEP drawing of the crystal structure viewed down the c-axis for $(+)_{589}$-[Co(Hbg)$_3$]Cl(d-tart)·3H$_2$O.

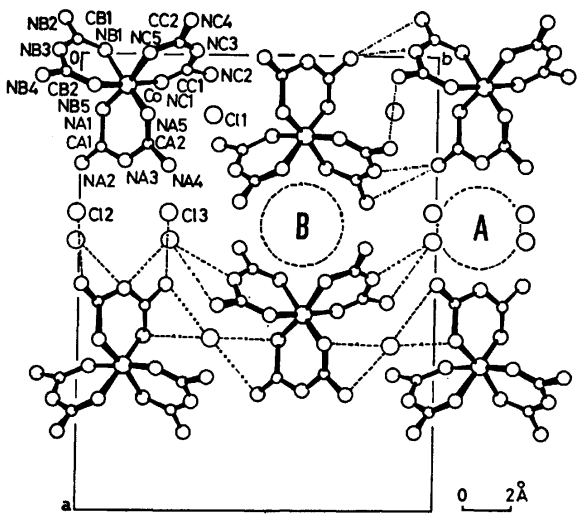

Fig. 3. A drawing of the part of the components in the unit cell projected on the (110) plane with the numbering scheme for $[Co(Hbg)_3]Cl_3$. Possible hydrogen bonds are indicated by broken lines. Hydrogen atoms are omitted for clarity. A and B indicate positions of void A and void B respectively.

cell are omitted in order to show the crystal features more clearly.

Geometry of Complex Cation. The bond distances and angles for the complex cation of both salts **1** and **2** are listed in Tables 4 and 5 respectively. They are in good agreement with those found in the two crystal structures, the less-soluble diastereomeric salt **3**, $(-)_{589}$-$[Co(Hbg)_3]Cl(d\text{-tart})\cdot 5H_2O$,[1] and the optically active chloride salt **4**, $(+)_{589}$-$[Co(Hbg)_3]Cl_3\cdot H_2O$:[2] averaged bond distances all differ by less than 0.012 Å and all averaged bond angles differ by less than 1.9°.

However, there is a small but significant difference in the geometry of complex cations among the four salts, **1**, **2**, **3**, and **4**. While the planarity of a biguanide ligand itself is bearly preserved in all these crystals, the planarity of a chelate ring as a whole (including the Co atom) is lost in some cases. The values of the dihedral angle between the plane of the Hbg ligand and the plane formed by Co and two donor N atoms are summarized in Table 6. The chelate ring A is approximately planar in all these crystals. In these crystals, two Cl^- ions approach the chelate ring A from both sides. Deviation from the planarity is found for the chelate rings B and C in the diastereomeric salts **1** and **3**. In **1** and **3**, both chelate rings B and C are bent inside toward each other. This is clearly reflected by the shorter distances between the central imino-nitrogen atoms of the two chelate rings B and C (Table 6). It is not reasonable to assume the attraction between these two N atoms. The bending of the chelate ring plane being observed only in the crystals containing the *d*-tart anion, such a bending can be attributed to the electrostatic attraction by the *d*-tart anion.

Geometry of d-*Tart.* The bond distances and angles for the *d*-tart anion of the more-soluble salt **1** are listed in Table 4. These values are in accordance with those reported previously.[1,7,12] Five non-hydrogen atoms of each α-hydroxy carboxylate moiety lie approximately on a plane. The dihedral angle between the planes of the two moieties in the more-soluble salt **1** is 62.1°. This value is larger than the corresponding value of 50.8° in the less-soluble salt **3**. Such a relation in the dihedral angle has been found also in the crystal structures of two diastereomeric salt pairs containing the *d*-tartH anion $(C_4H_5O_6^-)$.[13-15]

Crystal Packing. *The More-soluble Salt* ***1***: The intermolecular distances and angles are summarized in Table 7. The complex cation and the Cl^- ion are arranged alternately to form an infinite spiral chain, $\{\Delta\text{-}[Co(Hbg)_3]Cl\}_\infty$, along the twofold screw axis which is parallel to the c-axis through the position $(x=3/4, y=1/2)$ (Figs. 1 and 2). Hydrogen bonds are formed between the N atoms of Hbg A and the Cl^- ion.

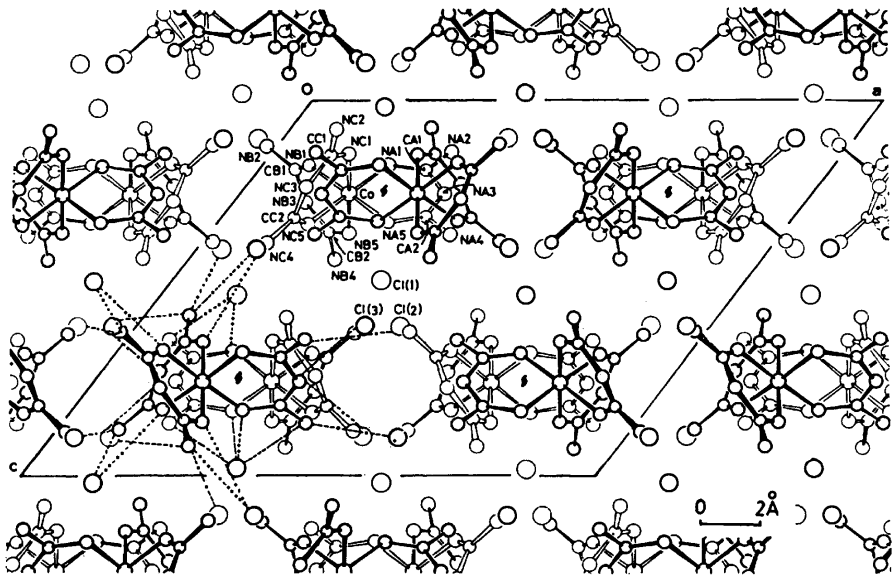

Fig. 4. A drawing of the crystal structure viewed down the b-axis for $[Co(Hbg)_3]Cl_3$. Possible hydrogen bonds are indicated by broken lines.

1: More-soluble salt. 2: Racemic salt. 3: Less-soluble salt. 4: Optically active salt.

If we assume a spiral chain which connects the complex and the Cl ions alternately along the hydrogen bonds as shown by broken lines in Fig. 1, the spiral arrangement is left-handed. However, the same spiral arrangement is considered to be right-handed, if we imagine a spiral chain which connects the central Co and Cl ions alternately as shown by arrows in Fig. 1. In this paper we take the latter definition. Such a spiral arrangement has been found in the crystal structures of **3** and **4**, too.[1] It is worth noting that the spiral configuration, $\{\Delta$-$[Co(Hbg)_3]Cl\}_\infty$, in **4** is right-handed, while that, $\{\Lambda$-$[Co(Hbg)_3]Cl\}_\infty$, in **3** is left-handed.

The *d*-tart anions are arranged along the c-axis to

N(C5)–H(NC5)···Cl(1)^{vii}	3.482(6)	2.72(10)	151(9)

Roman numerals as superscripts refer to the following equivalent positions relative to the reference molecule at x, y, z:

i ($1/2-x, -1/2+y, 1/2-z$),
ii ($x, -y, -1/2+z$),
iii ($1-x, -y, 1-z$),
iv ($x, 1-y, -1/2+z$),
v ($1-x, 1-y, 1-z$),
vi ($-1/2+x, 1/2-y, -1/2+z$),
vii($1/2-x, 1/2-y, 1-z$),
viii($x, -1+y, z$),
ix ($1/2-x, 1/2+y, 1/2-z$),
x ($1-x, y, 3/2-z$)

D, hydrogen donor; A, hydrogen acceptor.

make an infinite chain, $(d\text{-tart})_\infty$, in which two adjacent anions are related by the twofold screw axis (Figs. 1 and 2). A hydrogen bond is formed between the O atoms of hydroxyl and carboxylato groups of adjacent *d*-tart anions, OT3–H(OT3)···OT2^{vi} 2.792 Å. The pitch of the chain is equal to the length of the c-axis, 11.010 Å. A similar infinite chain related by the twofold screw axis has been found in several crystals containing the *d*-tart anions.[16–20] In these crystals the pitch of the chain shows a wide variation from 6.128 Å in $(NH_4)_2\cdot d\text{-tart}$[18] to 10.989 Å in $[Pt(en)_2]d\text{-tart}$.[20] The pitch in the present case (11.010 Å) is the longest one ever observed. The framework of the crystal structure is built up of two kinds of chains, $\{\Delta\text{-}[Co(Hbg)_3]Cl\}_\infty$ and $(d\text{-tart})_\infty$, along the c-axis. These chains are closely packed with each other (Fig. 2).

As shown in Table 1, the V/Z value, 592.8 Å^3, of **1** is 103.7 Å^3 smaller than that, 696.5 Å^3, of **3**. When the volume (2×20.6 Å^3)[21] corresponding to two water molecules (the difference in the number of water of crystallization between **1** and **3**) is subtracted from the V/Z value of **3**, a large positive value, 62.5 Å^3, still remains. Thus, it can be concluded that the packing density in the more-soluble salt **1** is larger than that in the less-soluble salt **3**. This makes a marked contrast to the cases of two diastereomeric salt pairs containing *d*-tartH, in which the packing density is larger in the less-soluble salt than in the more-soluble salt.[13–15]

The Racemic Chloride Salt **2**: The intermolecular distances and angles are summarized in Table 8. The complex cation of the same chirality and a kind of Cl^- ions (Cl(1)) are arranged alternately along the twofold screw axis to form an infinite spiral chain, $\{[Co(Hbg)_3]Cl\}_\infty$, which is similar to that found in the crystal structures, **1**, **3**, and **4**, (Figs. 3 and 4). Moreover, the spiral chain made up of the *Λ* complex is left-handed and that made up of the *Δ* complex is right-handed. Short contacts between some N atoms of adjacent complexes are 3.21(1)—3.43(1) Å (Fig. 3). The distances between H and N atoms are H(NB22)···N(A4)

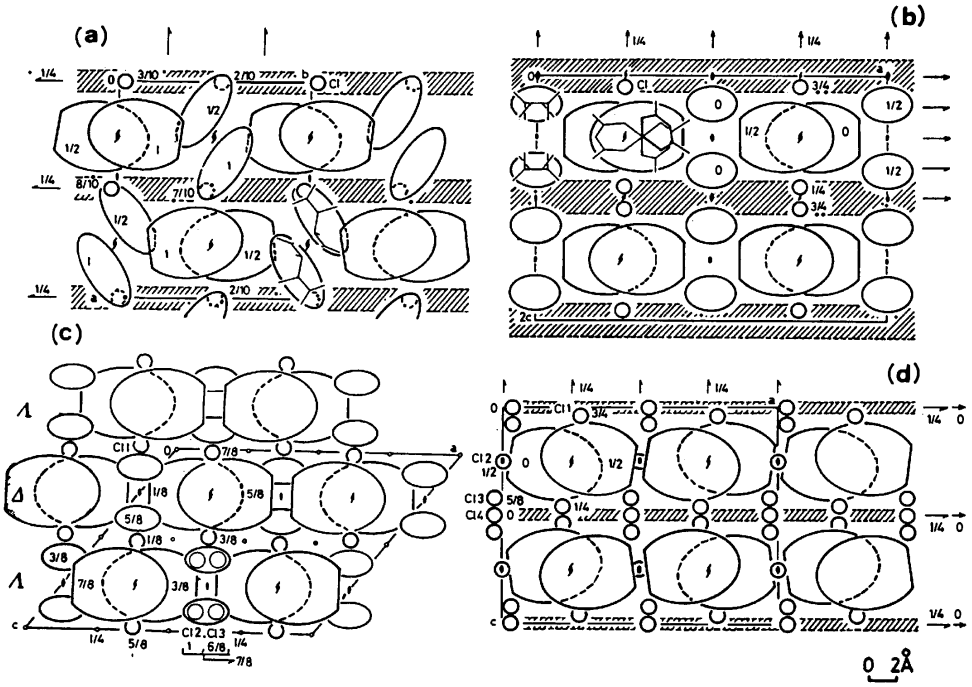

Fig. 5. A schematic drawing of the crystal structures of the four salts, (a) the more-soluble salt $(+)_{589}$-$[Co(Hbg)_3]Cl(d\text{-tart})\cdot 3H_2O$ **1**, (b) the less-soluble salt $(-)_{589}$-$[Co(Hbg)_3]Cl(d\text{-tart})\cdot 5H_2O$ **3**, (c) the racemic salt $[Co(Hbg)_3]Cl_3$ **2**, and (d) the optically active salt $(+)_{589}$-$[Co(Hbg)_3]Cl_3\cdot H_2O$ **4**, along the c-axis for **1** and the b-axis for **2**, **3**, and **4**. Shaded parts indicate positions of water molecules.

2.85(11), H(NB3)···N(A4) 2.63(12), H(NB42)···N(C2) 2.83(11), and H(NC3)···N(A2) 2.65(10) Å. These values are close to the sum, 2.75 Å, of van der Waals radii of H, 1.20 Å, and N, 1.55 Å, atoms.[22] Therefore, the complex cations tend to pack together as closely as their geometry allows in the formation of the spiral chains.

*Comparison of the Packing Modes of the Four Salts, **1**, **2**, **3**, and **4**.* The most characteristic point common to all these four crystal structures is that they contain the infinite spiral chain, $\{[Co(Hbg)_3]Cl\}_\infty$. The four crystal structures projected along the infinite spiral chain are shown schematically in Fig. 5. In these crystals, the spiral chains are packed in parallel with each other.

In the racemic salt **2** and the optically active salt **4**, the spiral chains are arranged almost in contact with each other, and the remaining two Cl^- ions are placed in a void formed by the arrangement of the spiral chains. Here, if we regard the spiral chain as a cylinder, the packing mode in **2** and **4** can be regarded as somewhat irregular, hexagonal and tetragonal packings of parallel cylinders respectively. These two modes, hexagonal and tetragonal, are known as two types of the simplest packings of parallel cylinders. Moreover, the density of the hexagonal packing is larger than that of the tetragonal packing.[23] Indeed, the density of **2** is larger than that of **4** (Table 1).

In the racemic salt **2**, the spiral chains of the same chirality are related along the a-axis by the twofold operation to form a chiral layer on the ab plane as shown in Figs. 4 and 5(c). Also in the less-soluble salt **3** and the optically active salt **4**, the spiral chains are related along the a-axis by the same twofold operation (Figs. 5(b) and 5(d)). Therefore, in these crystals, the voids formed between the adjacent spiral chains on the ab plane can be divided roughly into two groups; one is between two Hbg A (void A) and the other is between Hbg B and C (void B) (see Fig. 3). In **2**, two kinds of Cl^- ions (Cl(2) and Cl(3)) are concentrated in void A to form (4^-)-charged conglomerate. The distances between these Cl^- ions are Cl(2)···Cl(2)^x 3.907(4), Cl(3)···Cl(3)^x 3.908(4), and Cl(2)···Cl(3) 4.106(4) Å. These distances seem to be fairly short, considering the radius of the Cl^- ion of 1.81 Å.[24] In **3**, it has been found that two *d*-tart anions are concentrated in voild A to form a dimeric unit, $(d\text{-tart})_2^{4-}$ (Fig. 5(b)). Therefore, the packing mode in the layer for **2** bears a striking resemblance to that in the layer for **3**. In **4**, three kinds of Cl^- ions (Cl(2), Cl(3), and Cl(4)) are not concentrated in a particular void but scattered in the whole crystal (Fig. 5(d)).

On the other hand, in the more-soluble salt **1**, the spiral chains are related along the b-axis by a unit translation and the relation of the adjacent spiral chains in **1** is different from that in the other three crystals, **2**, **3**, and **4** (Fig. 5(a)). Therefore, in **1**, Hbg A always faces with Hbg B and C in the adjacent spiral chains along the b-axis. The *d*-tart anions are evenly distributed in the void formed by the arrangement of the spiral chains. As a result, the *d*-tart anions themselves form an infinite chain, $(d\text{-tart})_\infty$, through hydrogen bonds (–OH···OOC–). Thus, the packing mode of **1** resembles that of **4** in terms of a dispersive distribution

of the counter anions. Therefore, it might be assumed that the localization of negative charges plays a dominant role in the stabilization of the crystal structure for the less-soluble salt **3** and the racemic salt **2**.

Chiral Discrimination Mode. Since the complex ions, Δ and Λ, in these four crystals are linked together *via* Cl^- ions to form the infinite spiral chains, $\{\Delta\text{-}[Co(Hbg)_3]Cl\}_\infty$ and $\{\Lambda\text{-}[Co(Hbg)_3]Cl\}_\infty$, we can safely conclude that the chiral discrimination by the *d*-tart anion is effected not on the individual complex ion but on these infinite chains in the diastereomer formation. Namely, the crystal-packing mode as a whole is responsible for the chiral discrimination. Here, the question is how the *d*-tart anions collect the spiral chains of the same chirality to form a crystal.

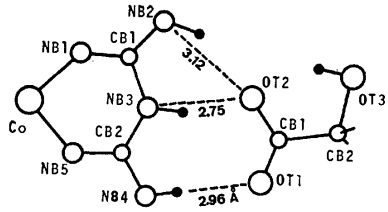

Fig. 6. Disposition of the Hbg ligand and the α-hydroxy carboxylate moiety of the *d*-tart anion for the less-soluble salt **3**. The broken lines indicate hydrogen bonds.

In relation to this point, in the less-soluble salt **3**, a specific close contact between Hbg B (Hbg C is equivalent to Hbg B in crystallography) and *d*-tart has been found along the twofold axis of complex. This specific close contact between the guanidino moiety of Hbg and carboxylato group of *d*-tart is illustrated in Fig. 6. The atoms in Hbg and α-hydroxy carboxylate moiety of *d*-tart lie on nearly the same plane. In the previous paper,[1] it was presumed that this specific close contact (specific interaction) plays a dominant role in collecting left-handed spiral chains. This specific close contact mode is expected to be more stable than any other modes of interaction between the guanidino moiety and the carboxylato group.[25] In other words, it is concluded that this specific close contact mode is most reasonable mode of access for the *d*-tart anion to combine the left-handed spiral chains. It is worth noting that a similar specific interaction has been found between the guanidyl group of arginine and the γ-carboxylato group of glutamate in the crystal structure of L-arginine L-glutamate.[26]

Such a specific close contact mode is not found in the more-soluble salt **1**. A complex cation is surrounded by six *d*-tart anions through hydrogen bonds in different modes of close contact, among which the mode of access to the complex nearly along the threefold axis seems to be important in relation to chiral discrimination as shown in Figs. 2 and 7. One α-hydroxy carboxylate moiety of *d*-tart are hydrogen-bonded to the adjacent *d*-tart anions related by the twofold screw axis to form an infinite chain, $(d\text{-tart})_\infty$, as shown by a broken line A in Fig. 7. On both sides of this infinite chain, are running parallel two infinite spiral chains, $\{\Delta\text{-}[Co(Hbg)_3]Cl\}_\infty$. The other α-hydroxy carboxylate moiety

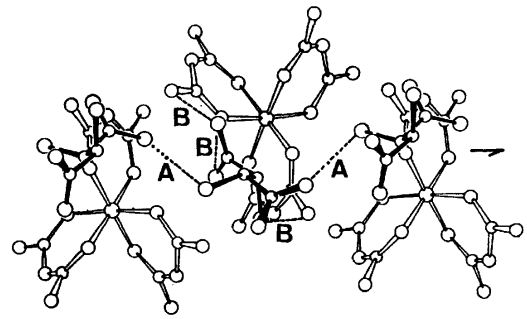

Fig. 7. Disposition of the *d*-tart anions in $(d\text{-tart})^\infty$ and the complex cations in $\{\Delta\text{-}[Co(Hbg)_3]Cl\}_\infty$ for the more-soluble salt **1**. Broken lines A and B indicate OH···O and NH···O hydrogen bonds respectively.

of each *d*-tart is hydrogen-bonded to Hbg A and C of each complex in these two infinite chains, $\{\Delta\text{-}[Co(Hbg)_3]Cl\}_\infty$, as shown by a broken line B in Fig. 7. Through such hydrogen bonds, the right-handed, spiral chains are collected by the infinite chain, $(d\text{-tart})_\infty$. This is supported by the pitch of the two infinite chains (11.010 Å). Namely, in the spiral chain $\{[Co(Hbg)_3]Cl\}_\infty$, the pitch is considerably short when it is compared with pitches of other spiral chains, 12.970, 14.086, and 14.901 Å in **3**, **4**, and **2** respectively (Table 1), and in the chain, $(d\text{-tart})_\infty$, the pitch is long when it is compared with pitches of other chains, $(d\text{-tart})_\infty$, found so far.[16–20]

Therefore, it is clear that the more-soluble salt **1** is quite different from the less-soluble salt **3** in the close contact mode between the complex and *d*-tart ions. Here, the question is why the salt **3** is less-soluble than the salt **1**. Previously, in the crystal structures of two diastereomeric salt pairs containing *d*-tartH, it has been found that the density of the less-soluble salt is larger than that of the more-soluble salt, and the cation and the anion in the less-soluble salt fit with each other more compactly than those in the more-soluble salt (compact fitting model).[13–15] Contrary to the *d*-tartH systems, in the present case the density of the less-soluble salt **3** is smaller than that of the more-soluble salt **1**. In the present diastereomeric salt pair, no significant difference is found in the number of the hydrogen bonds and in the distances between the cation and the anion. Thus, the compact fitting model can not be applied successfully to the present diastereomeric salts. This seems to be due to quite different arrangements of *d*-tart: the infinite chain, $(d\text{-tart})_\infty$, for **1** and the dimeric unit, $(d\text{-tart})_2^{4-}$, for **3**. From the comparison of the crystal structures of the four salts, **1**, **2**, **3**, and **4**, it should be considered that the difference in the arrangement of the *d*-tart anions is important for the solubility difference in the present case. It can be concluded that the localization of the negative charge, which results from the formation of the dimeric unit $(d\text{-tart})_2^{4-}$ containing the specific interaction between Hbg and *d*-tart, plays a dominant role in the stabilization of the crystal structure for the less-soluble diastereomeric salt **3**.

Studies of the Separation Mechanism in Ion-exchange Chromatography. III. Elution Order of *cis*-Bis(ethylenediamine)cobalt(III) and *cis*-α-Triethylenetetraminecobalt(III) Complexes on SP-Sephadex C-25 and IEX 510 Resins

Hayami YONEDA,* Shin-Ichi WAKIDA, Hiroshi NAKAZAWA, and Ushio SAKAGUCHI

(Received September 26, 1981)

Chromatographic separation of *cis*-dianionobis(ethylenediamine)cobalt(III) and *cis*-α-dianionotriethylenetetraminecobalt(III) complexes has been investigated by using SP-Sephadex C-25 and IEX 510 cation-exchange resins. The elution order of the complex cations on both resins are rather similar to each other and the adjusted retention volumes of these complexes correlate very closely with the crystallographic volumes (the unit cell volumes divided by the number of molecules in a unit cell) of $[Co(X)(NH_3)_5]Cl_2$, where $X=CN^-$, Cl^-, NO_2^-, N_3^-, and NCS^-. This has been taken to indicate that the affinity of the complex cation to the functional group of the resins increases as the size of the cation, and hence the character of water-structure breaker of the cation, increases. Thus, the elution order obtained seems to be determined primarily by the difference in the affinities of the complex cations to the resins, rather than by the difference in the association constants for the ion-pairs formed between the complex cation and the eluent anion.

Ion-exchange chromatography has been used widely to separate metal complexes.[1] The mechanism of chromatographic separation of octahedral complexes with different charges or polarities on ion-exchange resins has been explained[2] mainly be electrostatic interactions between the complex ion and the functional group of the resin in the stationary phase and/or by those between the complex ion and the eluent ion in the moving phase. Our recent studies[3,4] were concerned with the inversion of the elution order of differently charged complexes and of geometrically isomeric complexes (*cis*/*trans*). The results pointed clearly to the importance of two processes in chromatographic separation; adsorption on the complex ion to the resin and elution by eluent ions. For example, the separation of the $[Co(N)_6]^{3+}$ type of complexes has been explained[5] by the difference in the strengths of the hydrogen bonding formed between the N–H hydrogen(s) of the complex cation and the eluent anions in the moving phase. Thus, the system can be considered to be a case of elution-governing.

Very few works[6] have, however, been made which discussed the mechanism of the separation of complexes with the same charge and geometric configuration, *e.g.*, the separation of a series of *cis*-$[Co(X)_2(en)_2]^+$ with various substituents X, where en stands for ethylenediamine. For univalent complex cations *cis*-$[Co(X)(Y)(en)_2]^+$ or *cis*-α-$[Co(X)(Y)(trien)]^+$ (trien=triethylenetetramine), if the eluent concentration is not so high, it may be expected that the interaction between the complex cation and the eluent anion is weak and therefore the separation is dominated by the difference in the affinities of the complex cations to the resin; the systems are adsorption-governed. Thus, a detailed mechanism of the adsorption to the resin might be clarified. With this idea in mind, we have measured the retention volumes of substitution-inert complexes, *cis*-$[Co(X)(Y)(en)_2]^+$ and *cis*-α-$[Co(X)_2(trien)]^+$, where X and Y stand for CN^-, NO_2^-, NCS^-, N_3^-, and Cl^-. The resins used were strongly acidic cation-exchangers, SP-Sephadex C-25 and IEX 510, both of which have the sulfonate group as the functional group.

Experimental

Materials. All the complexes used in this work were prepared by the literature methods and identified by UV/VIS absorption spectra, proton magnetic resonance spectra, and chemical analyses. The geometrically isomeric purity was checked by ion-exchange chromatography. All the complexes were confirmed to be stable against hydrolysis and isomerization during the chromatographic experiments.

The resins used were IEX 510 (Toyo soda Manufacturing Co., Ltd., Japan) and SP-Sephadex C-25 (Pharmacia Fine Chemicals, Sweden), which are strongly acidic ($-SO_3^-Na^+$) cation-exchangers based on silica gel and cross-linked dextran, respectively.

Apparatus. All the chromatographic experiments were carried out on a laboratory-built chromatographic apparatus. The sample solution and Blue Dextran 2000, which was used as a marker for the void volume measurement, was injected by a syringe. The detector, Shimadzu UV-140 double beam spectrophotometer, was operated at the first absorption band of each complex. The adjusted retention volume was obtained from the elution curve.

Results and Discussion

Tables 1 and 2 show the adjusted retention volumes of *cis*-$[Co(X)(Y)(en)_2]^+$ and *cis*-α-$[Co(X)_2(trien)]^+$ on IEX 510 and SP-Sephadex C-25, respectively, when eluted by 0.1 M (1 M=1 mol dm^{-3}) aqueous solution of sodium chloride. When IEX 510 was used, the difference in the adjusted retention volumes of these complexes is rather large and the degree of separation is high. With SP-Sephadex C-25, though the degree of separation is not so high as with IEX 510, almost the same elution order was obtained. The elution order of *cis*-$[Co(X)_2(en)_2]^+$ and *cis*-α-$[Co(X)_2(trien)]^+$, expressed in terms of the substituent X, is as follows.

$$CN > Cl > NO_2 > N_3 > NCS$$

It can be seen in Table 1 that the adjusted retention volume of *cis*-$[Co(X)(Y)(en)_2]^+$ with $X \neq Y$ falls midway between the retention volumes of *cis*-$[Co(X)_2(en)_2]^+$ and *cis*-$[Co(Y)_2(en)_2]^+$. This appears to be true also on SP-Sephadex C-25. Further, it will also be apparent

TABLE 1. THE ADJUSTED RETENTION VOLUMES (ml) OF $[Co(X)(Y)(N)_4]^+$ ON IEX 510 WHEN ELUTED BY 0.1 M AQUEOUS SOLUTIONS OF SODIUM CHLORIDE

The column size was 4×300 mm, flow rate 0.30 ml min^{-1}, and void volume 1.38 ml.

$(CN)_2$	8.07	8.01
$(Cl)_2$	10.78	11.21
$(Cl)(NO_2)$	12.31	
$(NO_2)_2$	12.80	12.60
$(N_3)(NO_2)$	13.41	
$(N_3)_2$	14.98	14.75
(Cl)(NCS)	16.29	
(NO_2)(NCS)	18.17	
$(NCS)_2$	32.00	30.09

TABLE 2. THE ADJUSTED RETENTION VOLUMES (ml) OF $[Co(X)(Y)(N)_4]^+$ ON SP-SEPHADEX C-25 WHEN ELUTED BY 0.1 M AQUEOUS SOLUTION OF SODIUM CHLORIDE

The column size was 6.5×52.5 mm, flow rate 0.69 ml min^{-1}, and void volume 0.72 ml.

(X)(Y)	*cis*-$(en)_2$	*cis*-α-trien
$(CN)_2$	6.93	6.52
$(Cl)_2$	8.20	8.26
$(Cl)(NO_2)$	8.71	
$(NO_2)_2$	8.75	8.44
$(N_3)_2$	8.77	8.79
$(N_3)(NO_2)$	8.81	
(Cl)(NCS)	9.09	
(NO_2)(NCS)	9.16	
$(NCS)_2$	9.70	9.40

TABLE 3. THE ADJUSTED RETENTION VOLUMES (ml) OF *cis*-$[Co(X)_2(en)_2]^+$ ON IEX 510 WHEN ELUTED BY 0.1 M AQUEOUS SOLUTIONS OF VARIOUS SALTS

The conditions are the same as in Table 1.

$(X)_2$	NaCl	$phSO_3Na$	$NaClO_4$	KCl
$(CN)_2$	8.07	8.05	7.94	6.06
$(Cl)_2$	10.78	10.91	10.90	8.83
$(NO_2)_2$	12.80	12.31	12.26	10.22
$(N_3)_2$	14.98	13.13	13.06	10.26
$(NCS)_2$	32.00	30.25	28.54	21.64

from these tables that the *cis*-α-$[Co(X)_2(trien)]^+$ ions show adjusted retention volumes similar in magnitude to those of *cis*-$[Co(X)_2(en)_2]^+$ on both resins (correlation coefficient 0.9995 on IEX 510 and 0.981 on SP-Sephadex C-25). These results imply that two series of complexes are separated on both resins by a similar mechanism and we may discuss collectively the results of two series of complexes on both resins.

We may first confirm that the retention volumes listed in Tables 1 and 2 are obtained under the adsorption-governed conditions. If the system is adsorption-governed, the complex cations will be eluted primarily according to the difference in the affinities of the complex cation and the eluent cation to the resin. Therefore, the adjusted retention volume will be influenced more strongly by the kind of the eluent cation than by the eluent anion which may associate with the complex cation in the moving phase. Thus, the adjusted retention volumes have been measured on IEX 510 by using several eluents. The results for *cis*-bis(ethylenediamine)cobalt(III) complexes are given in Table 3. The adjusted retention volumes obtained by various eluents are highly correlated (correlation coefficients>0.995) and more importantly the change in the adjusted retention volume brought about by changing the eluent cation is much larger than the change caused by changing the eluent anion. Thus, the eluent cation has a dominant effect upon the adjusted retention volumes, which supports the view that the degree of adsorption to the resin is mainly affecting the retention volumes obtained on both resins.

If we look at Table 3 more closely, it can be seen that the adjusted retention volumes decrease, though slightly, as the eluent anion is changed from chloride through benzenesulfonate to perchlorate. This result indicates that the association between the complex cation and the eluent anion in the moving phase does have a contribution, though small, to the retention volumes. That the association between the complex cation and the eluent anion is important in ion-exchange chromatography will be most clearly appreciated by considering the optical resolution of metal complexes. For example, let us consider the case where a racemic complex cation is loaded on a resin and eluted by an aqueous solution containing some optically active anion, *e.g.*, *d*-tartrate or *d*-tartratoantimonate(III). Since in such a case the affinities of the *Λ*- and *Δ*-complex cations are exactly the same, we have to attribute the achievement of optical resolution by such a technique to the difference in the association constants of the *Λ*- and *Δ*-complex cations with the optically active anion.[7] There are many reported examples[8] of chromatographic optical resolution of metal complexes and it is apparent that retention volumes are more or less influenced by the association between the complex cation and the eluent anion in the moving phase. Note here, however, that the degree of optical resolution is always smaller than the degree of separation of different kinds of complexes, which suggests that the effect of elution is smaller than that of adsorption. This is also consistent with the view that our systems are adsorption-governed.

The data of Table 3 also indicate that the degree of ion association increases in the order Cl^-<benzenesulfonate<perchlorate. If we note that this order parallels the order of increasing character of water-structure breaker,[9] it follows that the univalent complexes examined in this work bear the character of water-structure breaker, because a water-structure breaker associates more favorably with water-structure breakers rather than with water-structure makers.[9] This inference gains some support from the works of Oh[10] and Pethybridge and Spiers.[11] Oh showed that for several ethylenediamine complexes of nickel(II), copper(II), and cobalt(III) with an overall charge of +1 or +2 the association of the complex cation with the iodide anion is favored over that with the chloride anion; the iodide ion is a well-known water-structure breaker while the chloride ion is a water-structure

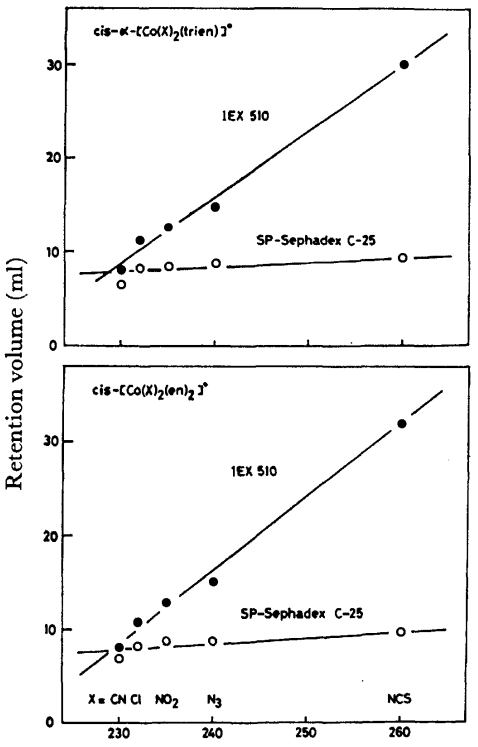

Fig. 1. The correlation between the adjusted retention volumes and the crystallographic volumes of $[Co(X)(NH_3)_5]Cl_2$.

maker.[12] Pethybridge and Spiers showed from conductance measurements that the association constants of $[Co(ox)(en)_2]X$ and *trans*-$[Co(NO_2)_2(en)_2]X$ in water increase in the order $X=Cl^-<Br^-<I^-<ClO_4^-$, where ox stands for the oxalate ion. Though they gave no explanation to these results, their results are most reasonably understood if we consider that univalent and bivalent complex cations bear the character of water-structure breaker.

Since the character of water-structure breaker is expected to get prominent as the volume of the complex cation increases,[9] we have plotted the adjusted retention volumes of *cis*-$[Co(X)_2(en)_2]^+$ and *cis*-α-$[Co(X_2)(trien)]^+$ on both resins against the crystallographic volumes of corresponding anionopentaamminecobalt(III) chlorides, $[Co(X)(NH_3)_5]Cl_2$, all of which are anhydrous and were analysed previously by X-ray diffraction.[13] The abscissa of Fig. 1 is thus the crystallographic volume of $[Co(X)(NH_3)_5]Cl_2$, namely, the unit cell volume divided by the number of molecules in a unit cell. As seen from Fig. 1, the correlation between the two quantities is very good; the correlation coefficients are 0.996 and 0.878 for *cis*-$[Co(X)_2(en)_2]^+$ on IEX 510 and SP-Sephadex C-25, respectively, and 0.995 and 0.754 for *cis*-α-$[Co(X)_2(trien)]^+$ on IEX 510 and SP-Sephadex C-25, respectively. This correlation, in conjunction with the system being adsorption governed, indicates that the complex cation is more tightly bound to the resin function as the crystallographic volume of the cation increases. The correlation in Fig. 1 seems to be quite reasonable in view of the previously reported trend in the association constants of various metal salts. For example, Pethybridge and Spiers[14] reported that the association constants of most 1 : 1 salts in water, including those forming outer-sphere complexes, are primarily determined by the combined size of the two ions; the association constants gets larger as the sum of the crystallographic radii of the two ions increases. It is very interesting to note that the quantity which is correlated with the association constants or the retention volumes is the crystallographic volume of the complex cation, not the hydrodynamic volume of the cation as estimated from, *e.g.*, conductance measurements. In fact, we could find no correlation between the retention volumes and the effective ionic radii of *cis*-$[Co(X)_2(en)_2]^+$, which we have estimated from conductance measurements in water.[15]

Finally, it will be pertinent to point out that the dipole moments of the complex cations do not contribute significantly to the observed retention volumes. This statement follows from the observation that the *trans*-$[Co(X)_2(en)_2]^+$ ions exhibited the same elution order as the corresponding *cis* complexes and the retention volume of *trans*-$[Co(X)(Y)(en)_2]^+$ $(X\neq Y)$ fell midway between the retention volumes of *trans*-$[Co(X)_2(en)_2]^+$ and *trans*-$[Co(Y)_2(en)_2]^+$.[15] Clearly the *trans*-$[Co(X)(Y)(en)_2]^+$ ion can have a dipole moment but the parent complexes can not. Therefore, we conclude that the univalent cations, *cis*-$[Co(X)(Y)(en)_2]^+$ and *cis*-α-$[Co(X)_2(trien)]^+$, assume more and more the character of water-structure breaker and hence get adsorbed to the resins more strongly as the crystallographic volume of the complex cation increases.

The authors thank Mr. S. Yamazaki, Toyo Soda Manufacturing Co., Ltd., for supplying the IEX 510 resin.

(Received September 24, 1981)

A cobalt(III) complex with the sexidentate ligand, *N*,*N*′-ethylenebis(*S*-methyl-L-cysteine), was newly synthesized and chromatographically isolated. Of two possible geometrical isomers, trans(O) and trans(N), one isomer was formed selectively. The dark-red crystals are orthorhombic, space group $P2_12_12_1$, $a=9.055(2)$, $b=22.123(7)$, $c=17.111(4)$ Å, and $Z=8$. The structure was solved by the direct method and refined to $R=0.066$ for 2380 non-zero reflections. The complex is trans(O) isomer and the crystal consists of two kinds of complex cations with respect to the absolute configurations of the coordinated asymmetric sulfur atom. One takes an *S*(S),*S*(S) configuration and the other an *R*(S),*S*(S) one. The changes in configuration between the asymmetric sulfur atoms in the crystal and those in aqueous solution are discussed on the basis of NMR (^{13}C and ^1H) spectral studies.

Cobalt(III) complexes with sulfur-containing amino carboxylates have been extensively investigated during the past several years.[1-12] However, the properties of the thioether type sulfur atom which takes *R* or *S* configuration by coordination have been little known yet. Recently, Jackson and Sargeson suggested that a sulfur inversion in the *S*-bonded thioether–cobalt(III) complexes occurs in aqueous solution.[5] The sexidentate ligand in this work, *N*,*N*′-ethylenebis(*S*-methyl-L-cysteine), has two chiral centers, *R*(C) and *R*(C).[13] As seen in Fig. 1, the possible geometrical isomers for the

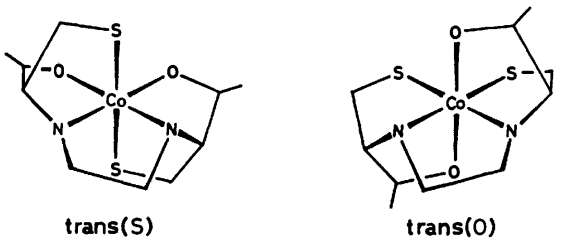

Fig. 1. Two geometrical isomers of [Co(*R*,*R*-ebsmc)]$^+$.

[Co(*R*,*R*-ebsmc)]$^+$ complex are limited to two, *trans*(*O*)-*R*(N),*R*(N) and *trans*(*S*)-*S*(N),*S*(N), where the abbreviation, *R*,*R*-ebsmc, is used for the present sexidentate ligand. For each of the two isomers, three other isomers, *S*(S),*S*(S), *R*(S),*S*(S), and *R*(S),*R*(S), due to the asymmetric sulfur atoms of the coordinated *R*,*R*-ebsmc are possible.

In the present study, the *R*,*R*-H_2ebsmc ligand has been prepared from *S*-methyl-L-cysteine and 1,2-dibromoethane. The [Co(*R*,*R*-ebsmc)]$^+$ complex has been prepared and it has been chromatographically confirmed that only one geometrical isomer is formed. The crystal structure and absolute configuration of the isomer are established by X-ray diffraction studies. The chiral behavior of the sulfur atoms in solution is discussed on the basis of the ^1H and ^{13}C NMR spectra of the isomer, by comparison with the asymmetric sulfur atoms in the crystal. A preliminary report has been presented.[14]

Experimental

Preparation of R,R-H_2*ebsmc.* The *R*,*R*-H_2ebsmc ligand was prepared by a procedure modified from that used in the preparation of ethylenediaminedisuccinic acid.[15] *S*-Methyl-L-cysteine (16.9 g) was dissolved in 30 cm^3 of an aqueous solution containing sodium hydroxide (5.0 g). The solution was poured into a 100 cm^3 round bottom flask fitted with a condenser, and refluxed. To the solution were slowly added 1,2-dibromoethane (11.8 g) and sodium carbonate (6.6 g) over a period of 30 min. The mixture was continuously stirred under reflux for 3 h. The resulting reddish-brown mixture was cooled to room temperature and filtered to remove insoluble materials. When the pH of the filtrate was adjusted to 6 with concentrated hydrochloric acid, white crystals appeared (5.2 g). The crude product obtained was washed well with 80 cm^3 of warm water (*ca.* 60 °C). The product was recrystallized from a dilute aqueous solution of sodium hydroxide by adding concentrated hydrochloric acid. The crystals were collected, washed with water and then with acetone, and dried in a vacuum desiccator over $CaCl_2$. Yield 4.5 g. Found: C, 40.39; H, 6.67; N, 9.36; S, 21.41%. Calcd for $C_{10}H_{20}N_2O_4S_2$: C, 40.52; H, 6.80; N, 9.45; S, 21.63%.

Preparation of trans(O)-[*Co*(R,R-*ebsmc*)]ClO_4. To a suspension of *R*,*R*-H_2ebsmc (0.7 g) in 50 cm^3 of hot water (70 °C) were added $CoCl_2\cdot 6H_2O$ (0.55 g) and lead dioxide (1.5 g). The mixture was stirred at about 70 °C for 20 min, whereupon the solution became orange-red. The reaction mixture was cooled to room temperature and filtered to remove the excess of lead dioxide. The orange-red filtrate was poured onto an ion-exchange column (5 × 15 cm) containing SP-Sephadex C-25 resin (Na^+ form). After sweeping the column with water, the adsorbed band was eluted with 0.2 mol dm^{-3} aqueous solution of $NaClO_4$. Only one orange-red band was eluted and fractionated. It was found, from the absorption and CD spectra of the fractionated eluates, that the eluate contained only *trans*(*O*)-[Co(*R*,*R*-ebsmc)]$^+$. The eluate was concentrated to 20 cm^3 using a rotary evaporator below 30 °C, and then kept in a refrigerator. The dark-red crystals obtained were collected, washed with ethanol and then with ether, and dried in air. Yield 0.06 g. Found: C, 26.49; H, 4.18; N, 6.27%. Calcd for $CoC_{10}H_{18}N_2O_8S_2Cl$: C, 26.53; H, 4.01; N, 6.19%.

The halide (Cl^-, Br^-, or I^-) salt of this complex cation was also obtained by the elution with an aqueous solution of NaCl,

NH_4Br, or NaI instead of that of $NaClO_4$.

Measurements. The electronic absorption spectrum was recorded with a JASCO UVIDEC-1 spectrophotometer,and the CD spectrum with a JASCO J-20 spectropolarimeter. All measurements were carried out in aqueous solution at room temperature.

The ^1H and ^{13}C NMR spectra were recorded in deuterium oxide on a JEOL JNM-FX-100 NMR spectrometer at the probe temperature. For ^1H NMR spectrum, sodium 2,2-dimethyl-2-silapentane-5-sulfonate was used as an internal reference. The ^{13}C chemical shifts were measured relative to external benzene and converted into the chemical shifts from TMS using the relation $\delta_{TMS}=\delta_{benzene}-128.50$ ppm.

The symmetry and approximate cell dimensions of the crystal were determined from Weisenberg and precession photographs. The more accurate cell dimensions were obtained by a least-squares analysis of 2θ measured on a Philips PW 1100 automated four circle diffractometer. The crystal data are summarized in Table 1.

Table 1. Crystal data

Molecular formula	$CoC_{10}H_{18}N_2O_8S_2Cl$
Molecular weight	452.77
Space group	$P2_12_12_1$
Cell constants	$a=9.055(2)$ Å
	$b=22.123(7)$ Å
	$c=17.111(4)$ Å
Density obsd	1.77 g/cm^3
calcd	1.76 g/cm^3
	(for $Z=8$)

A crystal with dimensions of 0.4 mm × 0.2 mm × 0.1 mm was used for data collection. Intensity data were collected on the Philips PW 1100 automated four circle diffractometer with Mo $K\alpha$ radiation monochromatized by graphite. The ω-2θ scan technique was employed and reflections for $2\theta<70°$ were recorded. A total of 2380 independent non-zero reflections were used for the structure determination. The intensities were corrected for the Lorentz and polarization factors, but no absorption correction was applied.

Structure Determination

The structure was solved by the use of MULTAN.[16] Four sets of phases were calculated using the 180 $|E|$'s greater than 1.58. The set of phases with the highest confined figures of merit was used to calculate an E map which yielded the positions of the cobalt, sulfur, oxygen, nitrogen, and chlorine atoms. Fourier and difference-Fourier maps based on these atoms revealed the rest of the structure. The structure was refined by a full-matrix least-squares refinement of the positional and anisotropic thermal parameters (program ORFLS by W. R. Busing, K. O. Martin, and H. A. Levy was used). The final R value ($\sum||F_o|-|F_c||/\sum|F_o|$) was 0.066 for all the non-hydrogen atoms. The atomic scattering factors were taken from "International Tables for X-Ray Crystallography."[17] The calculations were carried out on an ACOS 800II computer at The University of Tsukuba. The final atomic parameters and their standard deviations are given in Table 2. A list of the anisotropic thermal parameters and a table of the observed and calculated structure factors are kept at the Chemical Society of Japan (Document No. 8215).

Results and Discussion

Description of the Structure. Perspective drawings of the complex cations obtained are given in Fig. 2 and their packing mode is illustrated in Fig. 3. The bond lengths and angles with their estimated standard deviations in the complex ions are given in Tables 3 and 4, respectively. There are two crystallographically independent complex cations in an asymmetric unit. In both complex cations, the *R*,*R*-ebsmc ligand is sexidentate and the coordination around cobalt atoms is approximately octahedral. The cobalt atoms are surrounded by two *cis* sulfur, two *cis* nitrogen, and two trans oxygen atoms. Both cations can be designated as trans(O) configuration. The preferred *cis* configiration of the two coordinated sulfur atoms was also recognized in the case of the cobalt(III) complexes with the sulfur-containing amino carboxylates.[10,11] The absolute configuration of the complex cations in the crystal can be confirmed on the basis of the asymmetric carbon atoms, *R*(C),*R*(C), in the coordinated sexidentate ligand. As a result, the absolute configurations of the two nitrogen atoms in each of the two complex cations are determined to be *R*(N),*R*(N), as expected. Each of the two sulfur atoms in these cations becomes chiral by coordination. This means, as seen in Fig. 2, that the two sulfur atoms take the *S*(S),*S*(S) configuration in complex (a), whereas the sulfur atoms are in the *R*(S),*S*(S) one in complex (b). The *S*(S),*S*(S) complex has a pseudo-twofold axis through the Co(1) which bisects the S(1)–S(2) edge of the octahedron, whereas the *R*(S),*S*(S) complex takes a C_1 symmetry (Fig. 2).

The cobalt-ligand bond lengths are all similar to those for the cobalt(III) complexes with the sulfur-containing amino carboxylates.[7-12] The bond angles at the cobalt atoms of both complex cations are slightly distorted from their idealized values, that is, *cis* angles are in the range of 82.6—98.5° and *trans* angles 171.8—177.4° (Table 4). The interatomic distances and bond angles in the two crystallographically independent complex cations corre-

spond well with each other. Only the S–Co–S angles are significantly different. The angles S(1)-Co(1)-S(2) and S(3)-Co(2)-S(4) are 98.5° and 96.6°, respectively. The values are significantly larger than the normal ones; these deviations may be attributed to the repulsion between methyl groups on the sulfur atoms.

Several hydrogen bonds are recognized between the two complex ions, and between the complex ions and the perchlorates: *e.g.*, N(1)-O(6), N(3)-O(2), N(2)-O(15), and N(4)-O(9) (Fig. 3). The bond lengths of the Co(1)-O(1) and Co(2)-O(5) are apparently longer than those of the Co(1)-O(3) and Co(2)-O(7), respec-

a) sh: Shoulder.

tively (Table 3). These differences may be reflected by the stronger hydrogen bondings caused by the O(2) and O(6) atoms.

In order to examine the conformations of chelate rings, the displacements of relevant atoms from the chelate ring plane, which is defined by the central cobalt atom and the two coordinated atoms in the chelate ring, were calculated. The results are given in Table 5. The diamine chelate rings in both cations have asymmetric gauche form with λ conformation. This is in line with the case of diamines such as ethylenediamine and its derivatives.[18]

Electronic Absorption and CD Spectra. The electronic absorption and CD spectra of the *trans*(*O*)-[Co(*R*,*R*-ebsmc)]$^+$ are shown in Fig. 4 and their data are summarized in Table 6. The electronic absorption spectrum of the trans(O) complex shows an explicit shoulder on the lower energy side of the major peak in the first absorption band region. The splitting behavior is in line with the results from the semi-empirical calculation on the basis of the ligand field strength order N>S>O.[2,3,6] The sulfur-to-metal charge transfer band of the complex is observed at 34010 cm^{-1}.

The CD spectrum shows (+), (−), and (+) bands, listing from the lower energy side in the first absorption band region. A similar splitting pattern was observed in those of the $(-)_{576}$-[Co(*S*,*S*-edds)]$^-$ [15] and $(-)_{589}$-[Co(*S*,*S*-ebm)]$^+$ [1] which have a similar framework to that of the present trans(O) complex, where *S*,*S*-edds and *S*,*S*-ebm denote the *S*,*S*-ethylenediaminedisuccinate and ethylenebis(*S*-methioninate), respectively.

NMR Spectra. The ^{13}C and ^{1}H NMR spectra of the *trans*(*O*)-[Co(*R*,*R*-ebsmc)]$^+$ complex were measured in D_2O solution. The results are shown in Figs. 5 and 6. Taking the absolute configurations of the coordinated sulfur atoms into consideration, the ^{13}C NMR spectrum of the *S*(S),*S*(S) or *R*(S),*R*(S) isomer having a twofold axis is expected to show a single peak for each of the *S*-methyl, methylene, and methine

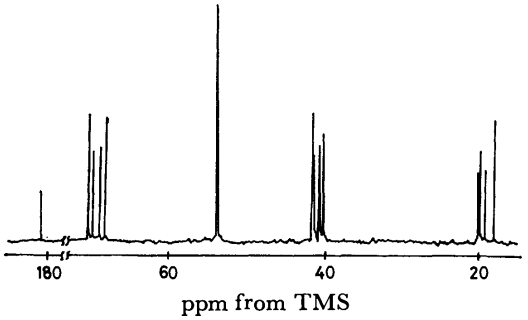

Fig. 5. ^{13}C NMR spectrum of *trans*(*O*)-[Co(*R*,*R*-ebsmc)]$^+$ in D_2O.

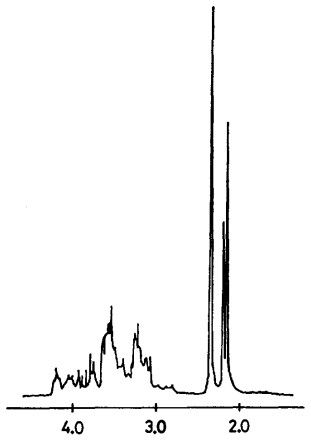

Fig. 6. ^1H NMR spectrum of *trans*(*O*)-[Co(*R*,*R*-ebsmc)]$^+$ in D_2O.

carbons. On the other hand, the *R*(S),*S*(S) isomer is expected to show two peaks for each of them because of a C_1 symmetry of the complex. If the configurations, *S*(S),*S*(S) and *R*(S),*S*(S), in crystal are retained in solution, the ^{13}C NMR spectrum will show the three peaks for each of the *S*-methyl, methylene, and methine carbons. As seen in Fig. 5, the spectrum exhibits the four peaks for each of the *S*-methyl (18.3—20.3 ppm from TMS), methylene (40.3—41.8 ppm), and methine (68.1—70.3 ppm) carbons, respectively. This fact suggests that the sulfur atoms of the *trans*(*O*)-*R*,*R*-ebsmc complex in solution take a different configuration from those in the crystal, that is, the present spectrum indicates a mixture of the *S*(S),*S*(S), *R*(S),*S*(S), and *R*(S),*R*(S) configurations. A similar trend was also observed for the ^1H NMR spectrum.

The ^1H NMR spectrum of *trans*(*O*)-*R*,*R*-ebsmc complex shows three peaks, at 2.19, 2.23, and 2.38 ppm (in the ratio 1.5 : 1.0 : 2.4) from DSS in the *S*-methyl proton region, soon after its dissolution (Fig. 6). It may be considered that the peak at 2.38 ppm is caused by partial overlap of the two peaks due to the two isomers. The peaks did not change significantly in the range from 5 °C to 60 °C. These facts are in agreement with the suggestion from the ^{13}C NMR study and suggest that the rate of the sulfur inversion in the present complex cations is slow on the NMR time scale. The complex chromatographed, however, gave only one adsorbed band and all of its fractionated eluates showed the same CD spectra. The attempt to precipitate fractionally as ClO_4^-, Cl^-, Br^-, and I^- salts from water yielded homogeneous crystals, which exhibited identical CD and NMR spectra. These results suggest that in aqueous solution a sulfur inversion similar to that for the *S*-bonded thioether-cobalt(III) complexes[5] occurs also in the present complex at room temperature, *i.e.*, *S*(S),*S*(S)$\rightleftarrows$*R*(S),*S*(S)$\rightleftarrows$*R*(S),*R*(S).

The authors thank to Prof. Y. Iitaka, The University of Tokyo, for his help in the collection of X-ray data.

Stereochemistry of Bis[*N*-(2,6-diisopropylphenyl)salicylideneaminato]-copper(II) and nickel(II) Complexes

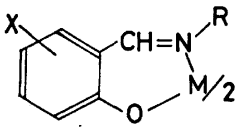
Shoichiro YAMADA* and Kuniko YAMANOUCHI

Institute of Chemistry, College of General Education, Osaka University, Toyonaka, Osaka 560

(Received October 3, 1981)

Bis[*N*-(2,6-diisopropylphenyl)salicylideneaminato]copper(II) and nickel(II) complexes have been synthesized. Their configurations in the solid state, in chloroform, and in pyridine have been examined and discussed in comparison with those of the related complexes.

The stereochemistry of copper(II) and nickel(II) complexes with bidentate *N*-arylsalicylideneaminates (I,



abbreviated as M(X-sal-R)$_2$) has been extensively studied.[1,2] For the most part, the copper(II) complexes of this series are planar, while the nickel(II) complexes are planar or multinuclear.[3] Bis[*N*-(2,6-dialkylphenyl)-salicylideneaminato]copper(II) and nickel(II) complexes, the alkyl being methyl or ethyl, were examined previously, with the view of investigating the effects of the substituents at the 2- and 6-positions of the salicylidene moiety on the structure of the metal complexes.[2-5] According to previous data on crystal structure analyses, the phenyl group is expected to be essentially perpendicular to the salicylideneaminate plane.[1] It also seems to be significant to examine the corresponding complexes with 2,6-diisopropylphenyl, the isopropyl being evidently more bulky than methyl and ethyl. Examination of bis[*N*-(2,6-diisopropylphenyl)-salicylideneaminato]cobalt(II) complexes, abbreviated as Co(X-sal-dpp)$_2$, revealed that the planar structure was neither precluded nor destabilized, but some of the cobalt(II) complexes (X=5-Br and 5-Cl) were forced into the planar structure in the solid state.[5] A similar study has now been extended to the copper(II) and nickel(II) complexes with the same ligands. The present paper describes the accounts of the study.

Experimental

Materials. 2,6-Diisopropylaniline was obtained commercially. Bis[*N*-(2,6-diisopropylphenyl)salicylideneaminato]-copper(II) and nickel(II) and analogous species, which are abbreviated as M(X-sal-dpp)$_2$, were synthesized in the same way as reported previously.[3] They are readily soluble in chloroform, benzene, and acetone, but sparingly soluble in ethanol. The nickel(II) complexes are olive-green, while the copper(II) complexes are brown-olive. Monopyridine adducts of the copper(II) complexes were obtained in dark green crystals by the addition of water or hexane to the pyridine solutions of the parent complexes. Analytical data of these complexes are given in Table 1.

Measurements. Electronic absorption spectra of the complexes in solution and in Nujol were recorded on a Shimadzu MPS-500 spectrophotometer. Magnetic measurements at room temperature were carried out by the Gouy method using CoHg(SCN)$_4$ as a calibrant.

Results and Discussion

Copper(II) Complexes. Bis(*N*-arylsalicylideneaminato)copper(II) complexes (I, R=Ph, Y-C$_6$H$_4$) normally prefer the planar geometry.[1-3] Electronic absorption spectra of Cu(X-sal-dpp)$_2$ (X=H, 5-Br, 5-NO$_2$, and 3-CH$_3$O) in chloroform and in Nujol (Fig. 1) are remarkably similar to each other and bear a close resemblance to the spectra of the copper(II)

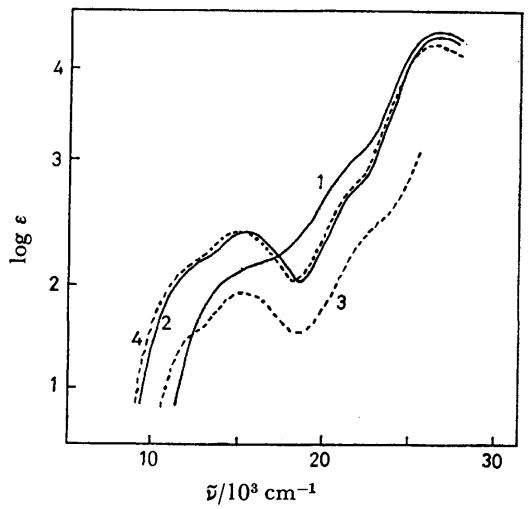

Fig. 1. Electronic absorption spectra of copper(II) complexes: 1, Cu(H-sal-dpp)$_2$ in $CHCl_3$; 2, Cu(H-sal-dpp)$_2$ in pyridine; 3, Cu(H-sal-dpp)$_2$–py in Nujol; 4, Cu(H-sal-2,6-Et_2-C_6H_3)$_2$ in pyridine.

complexes (I, R=Ph, 2,6-Me_2–C_6H_3, and 2,6-Et_2–C_6H_3), which were previously concluded to be planar.[2,3] Some of the representative spectra are shown in Fig. 1. It is thus presumed that the complexes Cu(X-sal-dpp)$_2$ are planar in the solid state and in chloroform.

The spectra of Cu(X-sal-dpp)$_2$ in pyridine have a d-d band maximum at 15.3×10^3 cm^{-1} with a shoulder on the lower frequency side. They are strikingly similar to each other, irrespective of the substituent X, showing that all these copper(II) complexes have essentially the same geometry. The spectra obey Beer's law in pyridine as well as in chloroform and are also remarkably similar to those of the complexes (I, R=Ph, 2,6-Et_2–C_6H_3), as shown in Fig. 1.[3] It is thus presumed that all these copper(II) complexes in pyridine exist exclusively as penta-coordinate monopyridine adducts. The monopyridine addusts can also be isolated in crystals from the pyridine solutions of the parent complexes. Electronic spectra of the monopyridine adducts in Nujol are similar to those of the parent complexes in pyridine (Fig. 1).

Nickel(II) Complexes. The complexes Ni(X-sal-dpp)$_2$ (X=H, 5-Cl, 5-Br, 5-NO_2, and 3-CH_3O) are all diamagnetic and consist of tetra-coordinate planar complexes in the solid state. Their spectra in chloroform and in Nujol are typical of the spin-paired, planar nickel(II) complexes with a d-d band at about $16—17 \times 10^3$ cm^{-1}. Representative spectra are shown in Fig. 2 and the maxima of the d-d bands are set out in Table 2. It is thus found that the steric condition in these complexes does not exclude the planar geometry. In this connection, it is interesting to remark that the complexes Co(X-sal-dpp)$_2$ (X=5-Br and 5-Cl) in the solid state prefer the planar geometry to the tetrahedral one, which is normally adopted by the tetra-coordinate

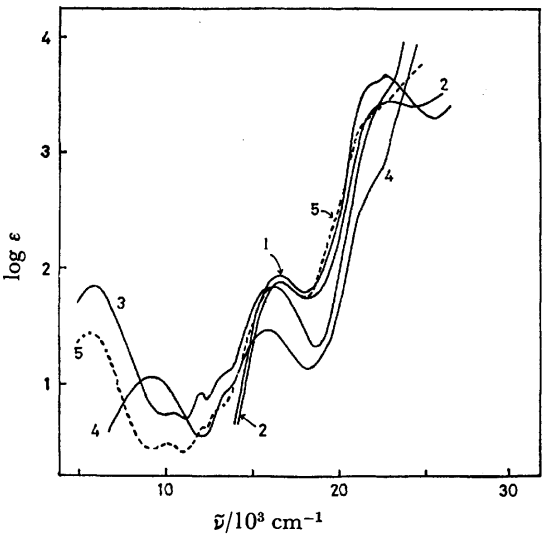

Fig. 2. Electronic absorption spectra nickel(II) complexes: 1, Ni(H-sal-dpp)$_2$ in $CHCl_3$; 2, Ni(H-sal-dpp)$_2$ in pyridine; 3, Ni(5-NO_2-sal-dpp)$_2$ in pyridine; 4, Ni-(3-CH_3O-sal-dpp)$_2$ in pyridine; 5, Ni(5-Cl-sal-dpp)$_2$ in pyridine.

Table 2. Absorption maxima of d-d bands of bis[*N*-(2,6-diisopropylphenyl)-salicylideneaminato]nickel(II), Ni(X-sal-dpp)$_2$

Compound	Medium	$\tilde{\nu}/10^3$ cm^{-1} (log ε)
Ni(H-sal-dpp)$_2$	$CHCl_3$	16.6(1.92)
	Nujol	16.6
	Pyridine	16.5(1.87)
Ni(5-Cl-sal-dpp)$_2$	$CHCl_3$	16.5(2.02)

cobalt(II) complexes.[5]

The d-d band maxima ($\tilde{\nu}$) of the planar nickel(II) complexes Ni(X-sal-dpp)$_2$ decrease in the following order as to the substituent X: 5-NO_2>H>5-Cl≈5-Br>3-CH_3O (series 1).

The present study indicates that it depends upon X whether or not and to what extent the complexes Ni(X-sal-dpp)$_2$ bind additional pyridine molecules, when dissolved in pyridine. The complex Ni(H-sal-dpp)$_2$ in pyridine exists mostly as the planar species, the penta-coordinate or hexa-coordinate pyridine adducts hardly being detected. The spectrum of the pyridine solution differs very little from that of the chloroform solution (Fig. 2).

On the contrary, Ni(3-CH_3O-sal-dpp)$_2$ in pyridine exists exclusively as hexa-coordinate species. The spectra have d-d bands at 9.4 and 15.9×10^3 cm^{-1} (Table 2), no absorption being observed at about $5—6\times10^3$ cm^{-1} (expected for the penta-coordinated species) or at about $16—17\times10^3$ cm^{-1} (for the tetra-coordinate species).

The complex Ni(5-NO_2-sal-dpp)$_2$ in pyridine exists entirely as penta-coordinate species. The spectrum is strikingly similar to that of the penta-coordinate nickel-(II) complex.[4] Beer's law is found to hold, so that the assumption of equilibria involving various species with different structures is not required.

Table 3. Structures of bis[*N*-(2,6-dialkylphenyl)-salicylideneaminato]nickel(II) complexes Ni(X-sal-R)$_2$ in pyridine[a]

X	R		
	2,6-Me_2-C_6H_3[b]	2,6-Et_2-C_6H_3[b]	2,6-(*i*-Pr)$_2$-C_6H_3
5-NO_2	6	6	5
H	4(65)+5(35)	4(80)+5(20)	4(95)+5(5)
5-Cl	4(20)+5(80)	4(40)+5(60)	4(70)+5(30)
5-Br	4(20)+5(80)	4(50)+5(50)	4(70)+5(30)
3-CH_3O	6	6	6

a) These nickel(II) complexes are tetra-coordinate-planar in non-donor solvents and in the solid state. The numbers in the parentheses are approximate proportions in percentage of the species in the solutions. The numbers of one figure in the table denote the coordination numbers. See also the text. b) The data are taken from Refs. 3 and 4 in the text.

The complexes Ni(5-Br-sal-dpp)$_2$ and Ni(5-Cl-sal-dpp)$_2$ in pyridine exist as equilibrium mixtures of the tetra-coordinate planar and penta-coordinate species. The spectra have a d-d band characteristic of the planar species at about 16.5×10^3 cm^{-1} and another d-d band characteristic of the penta-coordinate species at about 5.5×10^3 cm^{-1}, no absorption being observed at about $9—10\times10^3$ cm^{-1}, where the hexa-coordinate species is expected to absorb. McKenzie and coworkers made some approximate but useful estimates of the relative amounts of the species present in the solutions of the nickel(II) complexes (I, R=2,6-Me_2-C_6H_3 and 2,6-Et_2-C_6H_3) on the basis of the intensities of the various d-d bands in the spectra of these nickel(II) complexes.[4] Similar estimates have been made for the present nickel(II) complexes, following the method of McKenzie. The results of the estimates are shown in Table 3, the relevant data on the related complexes being included for comparison.[3,4] Numbers of one figure in the table represent the coordination numbers at the nickel(II) ion. The number 4 denotes "planar tetra-coordination."

Inspection of Table 3 indicates that the order as to the ability of Ni(X-sal-dpp)$_2$ to bind additional ligands is found to be lower than that of the corresponding dimethylphenyl and diethylphenyl complexes, showing that the steric effect of 2,6-diisopropylphenyl is larger than that of the 2,6-dimethyl- or 2,6-diethylphenyl. For instance, the difference in this respect is apparently noticed in the complexes with X=5-NO_2. Attempts to isolate penta-coordinate pyridine adducts Ni(X-sal-dpp)$_2$·py have not been successful so far, whereas the penta- and hexa-coordinate pyridine adducts of the 2,6-dimethylphenyl and 2,6-diethylphenyl complexes were isolated in crystals.[4]

Inspection of Table 3 also indicates that higher coordination numbers are favored in the following order as to X: 3-CH_3O>5-NO_2>5-Br≈5-Cl>H. The order, which is not in agreement with the series (1), results from the total effects of such factors as bulk steric effects, the electron-withdrawing power of the ring substituent, and the ligand-field strength of the salicyl-ideneaminates. At the moment, however, there seems to be no unambiguous explanation for the order.

Binuclear Metal Complexes. XLIV.[1] Crystal Structures and Magnetic Properties of Alkoxo-oxygen Bridged Binuclear Copper(II) Complexes with 2-[2-(Dialkylamino)ethylthio]ethanol

Masahiro MIKURIYA, Hisashi ŌKAWA, and Sigeo KIDA*

Department of Chemistry, Faculty of Science, Kyushu University 33, Hakozaki, Higashi-ku, Fukuoka 812

(Received October 22, 1981)

Six binuclear copper(II) complexes with 2-[2-(dialkylamino)ethylthio]ethanol, $Cu_2\{R_2N(CH_2)_2S(CH_2)_2O\}_2X_2$ (abbreviated as Cu(R-nso)X, where R=CH_3, C_2H_5, n-C_3H_7, n-C_4H_9; X=Cl, Br), were characterized by magnetic susceptibility (80—300 K). The temperature dependence of the magnetic susceptibilities of Cu(C_2H_5-nso)Cl and Cu(n-C_4H_9-nso)Cl can be interpreted by the Bleaney-Bowers equation based on a binuclear structure, while the magnetic data of the other complexes do not obey the Bleaney-Bowers equation. X-Ray structure analyses have revealed that the structures of all the complexes consist of discrete alkoxo-bridged binuclear units, and the coordination geometry of each copper atom is a distorted square pyramid with two oxygen, one sulfur and one chlorine or bromine atoms in the basal plane and a nitrogen atom in the apical position. The major structural difference corresponding to the different magnetic behaviors was attributed to the conformations of the chelate ring Cu–O–C(1)–C(2)–S.

In the preceding paper, we reported the synthesis, structure, spectra and magnetic properties of binuclear copper(II) complexes with 2-[2-(dialkylamino)ethylthio]ethanol, $Cu_2\{R_2N(CH_2)_2S(CH_2)_2O\}_2X_2$ (abbreviated as Cu(R-nso)X, where R=CH_3, C_2H_5, n-C_3H_7, n-C_4H_9; X=Cl, Br).[2] The X-ray structure analysis of Cu(CH_3-nso)Br showed that the crystal consists of discrete binuclear units. However, the temperature dependence of the magnetic susceptibility of Cu(CH_3-nso)Br does not obey the Bleaney-Bowers equation[3] based on a binuclear structure. Similar behaviors were also observed for other Cu(R-nso)X complexes so far prepared except for Cu(n-C_4H_9-nso)Cl. In order to clarify the origin of their unusual magnetic property, it is desirable to compare the detailed structures for a series of this type of complexes in relation to their magnetic behaviors. Hence, in this study, we have undertaken single-crystal X-ray structure analyses for Cu(CH_3-nso)Cl, Cu(C_2H_5-nso)Cl, Cu(n-C_3H_7-nso)Cl, Cu(n-C_4H_9-nso)Cl, Cu(n-C_3H_7-nso)Br and Cu(n-C_4H_9-nso)Br.

Experimental

Crystals of Cu(R-nso)Cl (R=CH_3, C_2H_5, n-C_3H_7, n-C_4H_9) and Cu(R-nso)Br (R=n-C_3H_7, n-C_4H_9) were prepared by the method previously reported.[2] The diffraction data were measured on a Rigaku AFC-5 automated four-circle diffractometer with graphite-monochromated Mo $K\alpha$ radiation (λ=0.71069 Å) at 20±0.5 °C. The unit-cell parameters of each crystal were determined by the least-squares refinement based on 20 high-angle reflections. The crystal data are shown in Table 1. The intensity data were collected by the 2θ-ω scan technique with a scan rate of 8° min^{-1}. For weak reflections the peak scan was repeated up to four times depending on their intensities. Three standard reflections were monitored every 100 reflections, and their intensities showed a good stability. The intensity data were corrected for the Lorentz and the polarization effects, but not for absorption.

The structures were solved by the heavy-atom method. The positions of the copper atoms were obtained from three-dimensional Patterson syntheses. Successive Fourier syntheses revealed all the nonhydrogen atoms. Refinement was

carried out by the block-diagonal least-squares method. All the hydrogen atoms were located from the subsequent difference Fourier maps. The final R values were $R_1=\sum||F_o|-|F_c||/\sum|F_o|=0.033$, $R_2=[\sum w(|F_o|-|F_c|)^2/\sum w|F_o|^2]^{1/2}=0.048$ for Cu(CH_3-nso)Cl, $R_1=0.049$, $R_2=0.065$ for Cu(C_2H_5-nso)Cl, $R_1=0.043$, $R_2=0.063$ for Cu(n-C_3H_7-nso)Cl, $R_1=0.036$, $R_2=0.054$ for Cu(n-C_4H_9-nso)Cl, $R_1=0.056$, $R_2=0.074$ for Cu(n-C_3H_7-nso)Br and $R_1=0.045$, $R_2=0.070$ for Cu(n-C_4H_9-nso)Br. In the least-squares refinement, the function minimized was $\sum w(|F_o|-k|F_c|)^2$, and the weighting schemes[4] were $w=(2.0+|F_o|+0.018\ |F_o|^2)^{-1}$ for Cu(CH_3-nso)Cl, $(4.0+|F_o|+0.016\ |F_o|^2)^{-1}$ for Cu(C_2H_5-nso)Cl, $(8.0+|F_o|+0.012\ |F_o|^2)^{-1}$ for Cu(n-C_3H_7-nso)Cl, $(6.0+|F_o|+0.010\ |F_o|^2)^{-1}$ for Cu(n-C_4H_9-nso)Cl, $(10.0+|F_o|+0.010\ |F_o|^2)^{-1}$ for Cu(n-C_3H_7-nso)Br and $(10.0+|F_o|+0.009\ |F_o|^2)^{-1}$ for Cu(n-C_4H_9-nso)Br. Final difference Fourier syntheses were featureless.

The atomic scattering factors for Br, Cu, Cl, S, O, N, and C_{val} and the anomalous dispersion corrections, $\Delta f'$ and $\Delta f''$ for Br, Cu, Cl, and S, were taken from the International Tables for X-Ray Crystallography.[5] For the hydrogen atom, the scattering factors were adopted from the Tables of Stewart *et al.*[6] All the calculations were carried out on the FACOM

M-200 computer in the Computer Center of Kyushu University by the use of a local version[7] of the UNICS-II[8] and the ORTEP[9] programs. The final positional and thermal parameters with their estimated standard deviations are given in Table 2. The coordinates and isotropic temperature factors of the hydrogen atoms, the anisotropic thermal parameters of the nonhydrogen atoms, and the F_o-F_c tables have been deposited as a Document No. 8213 at the Office of the Editor of Bull. Chem. Soc. Jpn.

Magnetic susceptibilities were measured by the Faraday method in the temperature range from liquid nitrogen temperature to room temperature. The apparatus was calibrated by the use of $[Ni(en)_2]S_2O_3$.[10] All the susceptibilities were corrected for the diamagnetism of the constituting atoms by the use of Pascal's constants.[11]

Description of the Structures and Discussion

The molecular structures of Cu(*n*-C_4H_9-nso)Cl and Cu(*n*-C_4H_9-nso)Br are shown in Figs 1 and 2, respectively. Selected bond lengths and bond angles are listed in Table 3.

The structures of all the complexes studied here are similar to that of Cu(CH_3-nso)Br[2] and consist of alkoxo-bridged binuclear units each of which has a center of symmetry. The coordination around each copper atom is essentially a distorted square pyramid with two alkoxo oxygen, a thioether sulfur and a chlorine or a bromine atoms in the basal plane and an amino nitrogen atom in the apical position. As can be seen in Table 3, the Cu–O and the Cu–O^i bond lengths fall in the range of 1.925—1.957 Å and 1.930—1.945 Å, respectively, and there was no definite relationship between these bond distances and the alkyl substituents, R, or the anions, X. The Cu–X distances (X=Cl or Br) are not much affected by the alkyl substituents and fall in the ranges, 2.229—2.236 Å for Cu(R-nso)Cl and 2.381—2.391 Å for Cu(R-nso)Br. These distances are comparable to the values found in chloro- or bromo[2-(dialkylamino)ethanolato]copper(II) (2.220—2.240 Å for the chloro complexes[12] and 2.333—2.395 Å for the bromo complexes[13]). The Cu–S distances fall in the ranges, 2.330—2.3446 Å for Cu(R-nso)Cl and 2.314—2.316 Å for Cu(R-nso)Br. It is to be noted that the Cu–S distances of Cu(R-nso)Cl are longer than those of Cu(R-nso)Br by 0.02 Å on the average. Since the Cu–S distance of Cu(CH_3-nso)NCS is 2.361(3) Å,[14] the Cu–S bond length decreases in the order Cu(R-nso)NCS>Cu(R-nso)Cl>Cu(R-nso)Br. The observed trend seems to accord with the

a) Superscript (i) refers to the equivalent position ($-x$, $-y$, $-z$). b) X denotes Cl or Br atom.

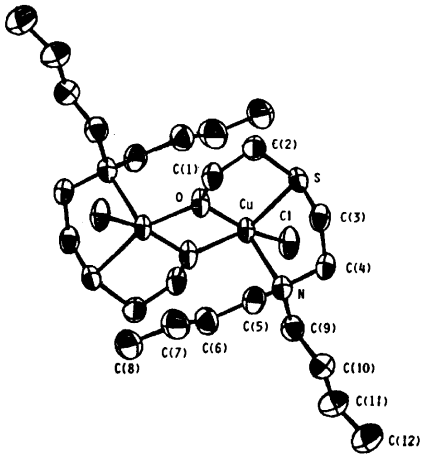

Fig. 1. Molecular Structure of Cu(n-C_4H_9-nso)Cl. Thermal ellipsoids are drawn at 50% probability level.

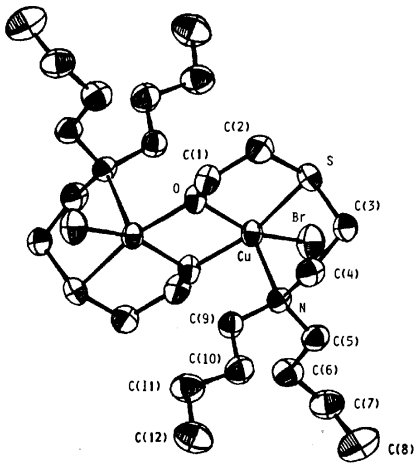

Fig. 2. Molecular Structure of Cu(n-C_4H_9-nso)Br. Thermal ellipsoids are drawn at 50% probability level.

softness of the anion X. It is known that Cu(I)–S bond length is shorter than Cu(II)–S bond length when S is a thioether sulfur.[15] Therefore, our results may be interpreted in the following way: when a donor atom is replaced with softer one, the softness of the copper ion would increase and, consequently, the Cu–S bond would become to be more covalent and shortened. The axial Cu–N bond distances increases in the order Cu(CH_3-nso)X < Cu(C_2H_5-nso)X < Cu(n-C_4H_9-nso)X < Cu(n-C_3H_7-nso)X.

The five-membered chelate ring, Cu–O–C(1)–C(2)–S, assumes two types of conformation. One is the gauche conformation as is usually observed for saturated five-membered chelate rings, *i.e.*, C(1) and C(2) are located below and above the plane defined by Cu, S, and O, respectively. The other is the envelope conformation *i.e.*, both carbon atoms, C(1) and C(2) are placed in the same side of the Cu–S–O plane (Table 4).[16] The chelate ring of Cu(n-C_4H_9-nso)Cl assumes the former conformation and the latter is observed for Cu(CH_3-nso)Cl, Cu(n-C_3H_7-nso)Cl, Cu(CH_3-nso)Br, Cu(n-C_3H_7-nso)Br and Cu(n-C_4H_9-nso)Br. As for Cu(C_2H_5-nso)Cl, the chelate ring is intermediate between the envelope and the gauche conformations. The other chelate ring, Cu–S–C(3)–C(4)–N, is of the gauche conformation for all the Cu(R-nso)X complexes.

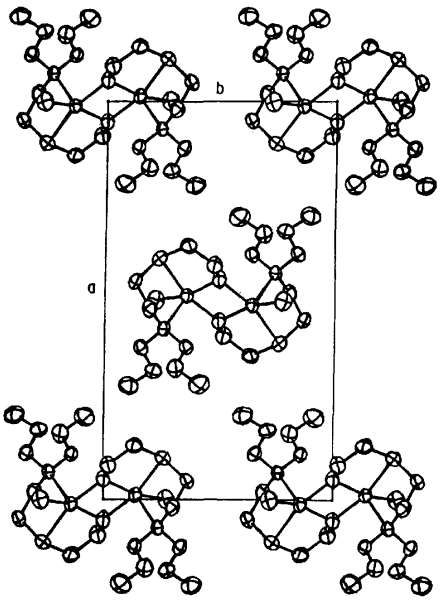

Fig. 3. Projection of the unit cell of Cu(n-C_3H_7-nso)Cl on the ab plane.

The packing diagram is exemplified by the projection of the unit cell of Cu(n-C_3H_7-nso)Cl in Fig. 3. As is evident from the shortest separations between the nonhydrogen atoms of the binuclear units (S···S ($1-x$, $-y$, $-z$ of 3.538(1) Å in Cu(CH_3-nso)Cl, Cl···C(4) (x, y, $z-1$) of 3.534(5) Å in Cu(C_2H_5-nso)Cl, Cl···C(4) (x, y, $z-1$) of 3.669(6) Å in Cu(n-C_3H_7-nso)Cl, Cl···C(4) ($-x$, $1-y$, $-z$) of 3.480(3) Å in Cu(n-C_4H_9-nso)Cl, Br···C(4) (x, y, $z-1$) of 3.772(8) Å in Cu(n-C_3H_7-nso)Br and C(2)···C(12) ($1/2-x$, $1/2+y$, $1-z$) of 3.78(1) Å in Cu(n-C_4H_9-nso)Br), all the crystals consist of discrete binuclear units. Therefore, their magnetic properties were expected to be interpreted by the Bleaney-Bowers equation based on the Heisenberg model on the assumption of a binuclear structure,[3]

$$\chi_A = \frac{Ng^2\beta^2}{3kT}\left[1+\frac{1}{3}\exp(-2J/kT)\right]^{-1} + N\alpha, \qquad (1)$$

where χ_A is susceptibility per copper atom and N, g, J, β, and $N\alpha$ have the usual meanings. However, the temperature dependence of the magnetic susceptibilities of the majority of the Cu(R-nso)X complexes can not be explained by the above equation. This result might be due to the fact that there are polymorphism and by chance the crystal structures of the samples used for magnetic measurements and X-ray analyses are different. In order to check this possibility, magnetic susceptibilities have been measured over the temperature range 80—300 K for crystals taken from the same crop as those used in the X-ray work. Similarly to the previous result, the data for Cu(n-C_4H_9-nso)Cl obey the Bleaney-Bowers equation using $g=2.10$, $-2J=745$ cm^{-1} and $N\alpha=34\times10^{-6}$ cgs emu with very slight deviations from the previous ones ($g=2.10$, $-2J=735$ cm^{-1}, $N\alpha=60\times10^{-6}$ cgs emu)[2] and the experimental χ_A-T curves for the other complexes except for Cu(C_2H_5-nso)Cl

a) The equation of the plane is expressed as $lX+mY+nZ=d$, where X, Y, Z are in Å units referred to the crystallographic axes. b) Superscript (i) refers to the equivalent position $(-X, -Y, -Z)$.

largely deviate from the Bleaney-Bowers equation. However, in the case of Cu(C_2H_5-nso)Cl, contrary to the previous result, the present data can almost be fitted to the curve calculated by the Bleaney-Bowers equation with $g=2.10$, $-2J=425\ cm^{-1}$ and $N\alpha=60\times10^{-6}$ cgs emu although the fitness between the calculated and observed curves is slightly poor in the range near room temperature. Thus, we have found that the major structural difference corresponding to these magnetic behaviors lies in the conformation of the five-membered chelate ring. Among the complexes presently studied Cu(n-C_4H_9-nso)Cl and Cu(C_2H_5-nso)-Cl are the only complexes which obey the Bleaney-Bowers equation and are also the only complexes whose chelate ring Cu–O–C(1)–C(2)–S assumes a gauche or an intermediate conformation. As for the other complexes the magnetic behaviors can not be interpreted by any theoretical equations and the Cu–O–C(1)–C(2)–S rings all assume envelope conformations. In the envelope conformation, the strain of the chelate ring may be larger than that for the gauche conformation, although the energy difference between them seems to be little. Therefore, it is likely that an interconversion between the two conformations takes place with change of temperature. Assuming that the envelope conformation changes to a stable gauche conformation with lowering of temperature, this change may cause a slight structural change of the coordination sphere and the geometry

The straight line represents the linear relationship observed for the hydroxo-bridged copper(II) complexes.[18]

around the bridging oxygen atom. This may lead to a temperature dependence of the J value, since it is known that a slight change in bond angle may bring about a considerable change in J value.[17,18] In the case of Cu(C_2H_5-nso)Cl, the small deviation from the binuclear model in the magnetic susceptibilities may arise from the intermediate conformation of the chelate ring at room temperature.

In Fig. 4, the exchange parameters, $2J$, for Cu(R-nso)X are plotted against the Cu–O–Cu angles together with the data available in the literature for hydroxo- and alkoxo-bridged binuclear copper(II) complexes. For the complexes which show the unusual magnetic behavior, the values are estimated from Eq. 2[19] by the use of the magnetic moments, μ_{eff}, at room temperature. Hatfield and co-workers found a linear relationship between the spin singlet-triplet separation, $2J$, and the Cu–O–Cu angle for hydroxo-bridged binuclear copper(II) complexes.[18] As shown in Fig. 4, no such clear relationship is found for alkoxo-bridged complexes including Cu(R-nso)X. This may be due to the variation of planarity of the equatorial coordination plane and the effects of axial coordination.

$$-2J = 0.695\,T\ln[3[4.41/\mu_{eff}^2-1)] \quad (2)$$

(Received March 6, 1981)

Titanium tetrachloride rapidly anomerizes methyl 2,3,4,6-tetra-*O*-benzyl-β-D-glucopyranoside in dichloromethane at 25 °C. Evidence for the proposal that the benzyloxymethyl group on C-5 and the ring oxygen of the glucoside cooperate to prompt the reaction is described. The reagent anomerizes the interglycosidic linkage of several disaccharide derivatives.

The anomerization of per-*O*-acetyl-β-D-glucopyranosides,[1] as well as of per-*O*-benzoyl ones,[2] with titanium tetrachloride (**1**) is useful for preparing the corresponding α-D-glucopyranosides[3] and has been well studied.[4] In spite of this, no report about such a reaction of per-*O*-benzyl-β-D-glucopyranosides has appeared. As has been communicated, however, methyl 2,3,4,6-tetra-*O*-benzyl-β-D-glucopyranoside (**2b**) was anomerized with an extraordinary rapidity into the α-anomer (**2a**) in the presence of **1** in dichloromethane at 25 °C.[5] This paper will present evidence for the mechanism previously proposed[5] in which the benzyloxymethyl group and the ring oxygen of **2b** play an important role in accelerating the reaction. The reagent was applied to the anomerization of the interglycosidic linkage of several disaccharide derivatives.

Results and Discussion

Table 1 shows the dependence of the anomerization reaction of **2b** on the molar ratio of **1** to **2b** and the time course of the reaction. The molar ratio should be greater than 0.5 to keep the efficiency of the reaction high. The equimolar amount of **1** completed the reaction within 10 s.

Table 1. Anomerization of methyl per-*O*-benzyl-β-D-glucopyranoside (**2b**) with titanium tetrachloride in dichloromethane

Mole ratio of $TiCl_4$ to the glucoside	Time/s	Content of the α-anomer/%[a]	Recovery of the glucosides/%[b]
0.2	300	42	96
0.2	3600	76	92
0.5	300	89	93
1.0	4	90	78
1.0	10	96	78
1.0	300	96	77

a) Mol% of α-glucoside to the sum of unchanged β-glucoside and anomerized α-one. b) Sum of yield of α-glucoside and recovery of unchanged β-one.

Interestingly, Table 2 shows that **2b** was anomerized much faster than was methyl 2,3,4,6-tetra-*O*-acetyl-β-D-glucopyranoside (**3b**). The replacement of the acetyl group at C-6 of **3b** with a benzyl one (Compound **4b**) had remarkable accelerating effects on the reaction. However, the replacement of acetyl groups at C-2, -3, and -4 with a benzyl one (Compound **26b**) did not accelerate the reaction appreciably. Compounds **19b**, **21b**, and **25b**, all of them with a benzyloxyl group at C-6, showed fast anomerization rates.

Table 2. Effect of substituents on the anomerization[a]

Compd	R^1	R^2	R^3	R^4	Time/s	Content of the α-anomer/%[b]	Recovery of the glucosides/%[b]
2b	Bn	Bn	Bn	Bn	4	90	78

13b	Me	OMe	H
14a	H	H	OMe
14b	H	OMe	H

Furthermore, the methoxyl group at C-6 considerably accelerates the reaction; the effect was even greater than that by a benzyloxyl group. This indicates that an ether group at C-6 is essential for the rapid anomerization. The slight retardation shown by **4b** and **28b** at 4 s seems to be due to electron-withdrawing acetoxyl groups, which might depress the affinity of O-5 to **1**

Table 3. Retarding effect of additives on the anomerization[a)]

Additives	Mole ratio to the glucoside, **2b**	Content of the α-anomer/%[b)]	Recovery of the glucosides/%[b)]
5	2.0	34	86
6	1.0	57	84
7	2.0	85	87
8	1.0	7	87
9	1.0	8	86
10	1.0	2	89
11	1.0	21	84

a) The mole ratio of $TiCl_4$ to the glucoside was 1.0; reactions were conducted for 4 s. b) They are defined in Table 1.

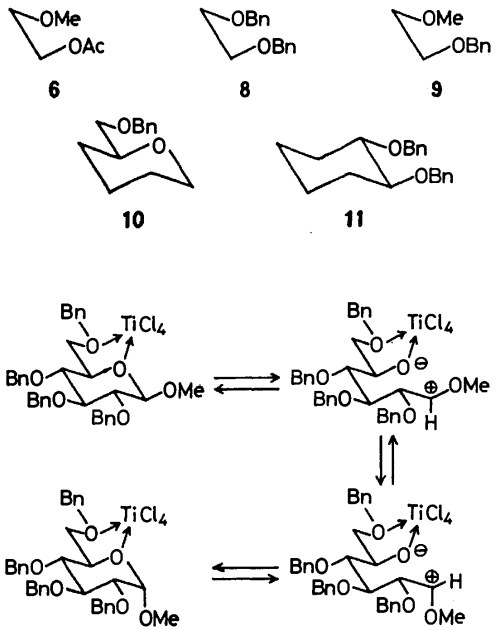

Fig. 1. A mechanism for the rapid anomerization reaction of methyl per-*O*-benzyl-β-D-glucopyranoside.

and/or the ability of C-1 to dissociate the bond between O-5 (Fig. 1).[6)]

These facts caused us to wonder if the benzyloxymethyl group in **2b** or **4b** has a special promoting function, possibly by assisting the interaction between the ring oxygen and **1**.[4a)] Additives which structurally resemble the $C_6H_5CH_2$–O–CH_2–C(5)–O(5)–moiety of **2b** are thought to compete with **2b** in capturing **1**, thus retarding the reaction. Table 3 shows how additives with benzyloxyl and/or acetoxyl group(s) in their structure retard the reaction of **2b**. Additives, such as ethyl acetate(**5**), 2-methoxyethyl acetate(**6**), and benzyl ethyl ether (**7**), did not clearly retard the anomerization of **2b**. This indicates that neither of these additives can be a ligand possessing more affinity to **1** than can **2b** Especially, the fact that **7** did not impede the reaction, while **4b** was anomerized rapidly, suggests that the benzyloxymethyl group of **4b**, and consequently of **2b**, is not fully responsible for the rapidity of the anomerization of **4b** and, hence, of **2b**. However, 1,2-bis(benzyloxy)ethane (**8**) and 1-benzyloxy-2-methoxyethane (**9**), as expected, inhibit the reaction clearly. 2-(Benzyloxymethyl)tetrahydropyran (**10**), whose structure is closely related to the pyranose ring system, hindered the reaction almost completely. This indicates that the $C_6H_5CH_2$–O–CH_2CH_2–O– moiety can effectively compete with **2b** in capturing **1**. It should also be noted that Compound **11**, in which the benzyloxyl groups are linked to the cyclohexane ring, showed a weaker inhibitory effect; this is apparently because benzyloxymethylene groups have lesser flexibility than the benzyloxymethyl one when they complex with **1**. From the things described so far there emerges the conclusion that the difunctional $C_6H_5CH_2$–O–CH_2–C(5)–O(5)– moiety of **2b** is the part which preferentially coordinates with **1**, in competition with other benzyloxyl groups, in the reaction where **1** assists the cleavage of the C(1)–O(5) bond[7,8b)] (Fig. 1). The fact that the 6-*O*-methyl glucoside derivative (**12b**) is rapidly anomerized, while the 6-deoxy one (**13b**) is not, is consistent with the above conclusion (Table 2). In this connection, it is remarkable that methyl 2,3,4-tri-*O*-benzyl-β-D-xylopyranoside (**14b**) was anomerized slower than **2b**, whereas methyl 2,3,4-tri-*O*-acetyl-β-D-xylopyranoside was anomerized faster than **3b**.[8b)]

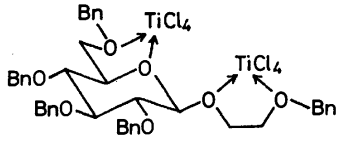
Table 4. Effect of aglycon on the anomerization

Compd	Aglycon	Time/s	Content of the α-anomer/%[a)]	Recovery of the glucosides/%[b)]
29b	Cyclohexylmethyl	4	100	80
30b	Cyclohexyl	2	100	87
31b	Benzyl	4	100	78
32b	2-Benzyloxyethyl	4	93	54
33b	3-Benzyloxypropyl	4	99	80
34b	6-Benzyloxyhexyl	4	100	76

a) The mole ratio of $TiCl_4$ to the glucoside was 1.0. b) They are defined in Table 1.

As for aglycon, **1** was even more effective for such alkyl groups as cyclohexylmethyl, cyclohexyl, and benzyl (Table 4). In some cases, no trace of β-glucoside was found in the reaction mixture.

The positional effect of the benzyloxyl group in aglycon was then studied in order to ascertain the scope of the reaction.[8a)] Table 4 shows that, when the benzyloxyl group is present at the carbon vicinal to the one which links with the glucosyloxyl residue, the efficiency of the reaction decreases and the recovery of the anomeric glucosides is seriously diminished. In this case, 2,3,4,6-tetra-*O*-benzyl-α-D-glucopyranose was isolated in a fair yield after the chromatography of the reaction mixture. This seems to be produced *via* the hydrolysis of the complex (**15**). Therefore, the reaction is not suitable for anomerizing the interglycosidic linkage of per-*O*-benzylated disaccharides.



15

Nevertheless, the findings described so far stimulated us to try to anomerize the per-*O*-benzyl derivative of disaccharides.[3a,b] The gentiobiose derivative (**16b**) was rapidly transformed into the isomaltose one (**16a**) with **1** at room temperature. The per-*O*-benzyl derivative (**17b**) of methyl 3-*O*-(β-D-glucopyranosyl)-α-D-xylopyranoside, the aglycon monosaccharide of which has no benzyloxymethyl group, inverted the configuration of its interglycosidic linkage, though the recovery was not so high. To our knowledge, the latter is the first case of the anomerization of the interglycosidic β-linkage of a secondary hydroxyl group of disaccharide.[3a]

Experimental

The melting points were determined on an MP-1 melting point apparatus (Yanagimoto) and are uncorrected. The optical rotations were measured with a DIP-180 automatic polarimeter (Japan Spectroscopic) in a jacketed 1-dm cell at 20 °C. The ^1H NMR spectra were recorded with a Varian S-60T spectrometer, and the ^{13}C NMR spectra, with a JEOL-PS-100, using TMS as the internal standard. The refractive indexes were determined with an Abbe refractometer, Model 3 (Atago), at 20 °C. Column chromatography was carried out on silica gel (Kanto Kagaku), using an appropriate solvent system of Solvent A (benzene–2-butanone), B (hexane–ethyl acetate), or C (chloroform–methanol); each fraction was examined by means of TLC on silica gel (Merck, 7731). The dichloromethane (Wako) was distilled and stored over a molecular sieve (Linde 3A). The catalyst **1** (Wako) was distilled before use. The ethyl acetate (**5**, Wako), 2-methoxyethyl acetate (**6**, Tokyo Kasei), benzyl ethyl ether (**7**, Wako), and 1,2-bis(benzyloxy)ethane (**8**, Tokyo Kasei) were used without any pre-treatment.

General Procedure for Anomerization. The β-glucoside (0.1 mmol) was dissolved in dichloromethane (1.0 ml) in a stoppered vial, into which **1** was then injected under stirring at room temperature. The reaction was quenched by the addition of a mixture of aq sodium hydrogencarbonate (5%, 1.0 ml) and ice (≈5 g). In the case of the reaction within 4 s, an open vessel was used: dichloromethane was injected into a stoppered vial containing the β-glucoside, and then, just after the removal of the stopper, **1** was shot into the solution under efficient stirring, with care taken to avoid any bubbling. The mixture was extracted with benzene (15 ml), and the organic layer was washed with water (5 ml) and evaporated to give the product mixture, which was then chromatographed.

The additive, when necessary, was injected into the vessel before the addition of **1**.

Preparation of β-Glucosides and Isolation of α-Glucosides Formed by Anomerization. Methyl 2,3,4,6-Tetra-O-benzyl-α-D-glucopyranoside (2a): The treatment of **2b**[9] with **1**, followed by processing and chromatography (Solvent A, 30 : 1), gave **2a** as a syrup, identified with an authentic sample.[10]

Methyl 2,3,4-Tri-O-acetyl-6-O-benzyl-β-D-glucopyranoside (4b): A mixture of methyl β-D-glucopyranoside (1.0 g, 5.2 mmol), sodium hydride (≈50% dispersion, 0.39 g, ≈8.1 mmol), and benzyl chloride (Tokyo Kasei, 30 ml) was stirred for 1.5 h at 100 °C and then evaporated on a boiling water bath to give an oily product mixture. Column chromatography (Solvent C, gradient) and subsequent crystallization from diisopropyl ether containing ethanol gave methyl 6-*O*-benzyl-β-D-glucopyranoside (**18**, 0.28 g, 19%): mp 97—98 °C, $[\alpha]_D$ −36° (*c* 1.0, $CHCl_3$), NMR ($(CD_3)_2CO$) δ=3.51 (s, 3, CH_3O), 4.61 (s, 2, $PhCH_2$), and 7.36 (s, 5, C_6H_5). Found: C, 58.91; H, 7.08%. Calcd for $C_{14}H_{20}O_6$: C, 59.14; H, 7.09%.

The acetylation of **18** with acetic anhydride in pyridine and subsequent crystallization from diisopropyl ether gave **4b**: mp 104—105 °C, $[\alpha]_D$ −1° (*c* 0.7, $CHCl_3$): NMR (CCl_4) δ=1.84 (s, 3, CH_3CO), 1.94 (s, 3, CH_3CO), 1.98 (s, 3, CH_3CO), 3.45 (s, 3, CH_3O), 4.33 (d, 1, *J*=7.8 Hz, H-1), 4.48 (s, 2, $PhCH_2$), and 7.27 (s, 5, C_6H_5). Found: C, 58.24; H, 6.37%. Calcd for $C_{20}H_{26}O_9$: C, 58.53; H, 6.39%.

Methyl 2,3,4-Tri-O-acetyl-6-O-benzyl-α-D-glucopyranoside (4a): The treatment of **4b** with **1**, followed by the aforementioned work-up and chromatographic separation (Solvent B, 6 : 1), gave **4a** as a syrup: $[\alpha]_D$ +131° (*c* 2.0, $CHCl_3$); NMR(CCl_4) δ=1.85 (s, 3, CH_3CO), 1.93 (s, 3, CH_3CO), 2.01 (s, 3, CH_3CO), 3.39 (s, 3, CH_3O), 3.86 (m, 1, H-5), 4.46 (s, 2, $PhCH_2$), 4.72 (dd, 1, *J*=3.5 and 9.0 Hz, H-2), 4.85 (d, 1, *J*=3.5 Hz, H-1), 4.92 (t, 1, *J*=9.0 Hz, H-4), 5.31 (t, 1, *J*=9.0 Hz, H-3), and 7.25 (s, 5, C_6H_5). Found: C, 58.48; H, 6.28%. Calcd for $C_{20}H_{26}O_9$: C, 58.53; H, 6.39%.

Methyl 2-O-Acetyl-3,4,6-tri-O-benzyl-β-D-glucopyranoside (19b): A mixture of 3,4,6-tri-*O*-benzyl-1,2-*O*-(1-ethoxyethylidene)-α-D-glucopyranose[11] (0.88 g), methanol (68 μl), mercury(II) bromide (18 mg), and nitromethane (10 ml) was stirred for 1 h at 100 °C[12] and then evaporated after a few drops of pyridine had been added. The residue was chromatographed (Solvent B, 10 : 1), and the fractions (R_f=0.45, Solvent B, 5 : 1) were collected and crystallized from diisopropyl ether to give **19b** (0.24 g, 28%): mp 51.5—52 °C; $[\alpha]_D$ +4° (*c* 1.0, $CHCl_3$); NMR(CCl_4) δ=1.96 (s, 3, CH_3CO), 3.47 (s, 3, CH_3O), 4.32 (d, 1, *J*=8.0 Hz, H-1), 7.22—7.33 (15, $3C_6H_5$). Found: C, 70.90; H, 6.70%. Calcd for $C_{30}H_{34}O_7$: C, 71.13; H, 6.77%.

Methyl 2-O-Acetyl-3,4,6-tri-O-benzyl-α-D-glucopyranoside (19a): The treatment of **19b** with **1** and subsequent chromatographic separation (Solvent A, 30 : 1) gave **19a** as a syrup: $[\alpha]_D$ +83° (*c* 0.8, $CHCl_3$); NMR(CCl_4) δ=1.90 (s, 3, CH_3CO), 3.30 (s, 3, CH_3O), and 7.13—7.21 (15, $3C_6H_5$). Found: C, 70.70; H, 6.83%. Calcd for $C_{30}H_{34}O_7$: C, 71.13; H, 6.77%.

Methyl 3-O-Acetyl-2,4,6-tri-O-benzyl-β-D-glucopyranoside (21b): A mixture of methyl β-D-glucopyranoside hemihydrate (Tokyo Kasei, 1.02 g, 5 mmol), sodium hydride (≈60% dispersion, 0.80 g, ≈20 mmol), and benzyl chloride (10 ml) was heated under efficient stirring for 3 h at 100 °C. The mixture was processed and chromatographed (Solvent A, gradient) to afford **2b** (0.33 g, 12%, R_f=0.75, Solvent A, 10 : 1) and then methyl 2,4,6-tri-*O*-benzyl-β-D-glucopyranoside (**20**, 0.56 g, 24%, R_f=0.45): $[\alpha]_D$ +19° (*c* 1.0, $CHCl_3$). Found: C,

72.23; H, 7.09%. Calcd for $C_{28}H_{32}O_6$: C, 72.39; H, 6.94%.

The acetylation of **20** with acetic anhydride in pyridine and subsequent crystallization from hexane gave **21b**: mp 109.5—110 °C, $[\alpha]_D$ +18° (*c* 1.0, $CHCl_3$); NMR ($CDCl_3$) δ=1.83 (s, 3, CH_3CO), 3.56 (s, 3, CH_3O), 4.34 (d, 1, J=8.0 Hz, H-1), and 7.22—7.31 (15, $3C_6H_5$). Found: C, 71.29, H, 6.78%. Calcd for $C_{30}H_{34}O_7$: C, 71.13; H, 6.77%.

Methyl 3-O-Acetyl-2,4,6-tri-O-benzyl-α-D-glucopyranoside (21a): The treatment of **21b** with **1** and subsequent chromatographic separation (Solvent A, 30 : 1) gave **21a**, whose ^1H NMR spectrum was identical with that of an authentic sample.[13]

Methyl 4-O-Acetyl-2,3,6-tri-O-benzyl-β-D-glucopyranoside (25b) and Methyl 6-O-Acetyl-2,3,4-tri-O-benzyl-β-D-glucopyranoside (26b): Methyl 2,3-di-*O*-benzyl-β-D-glucopyranoside[14] (**22**, 1.4 g, 3.74 mmol) was heated in benzyl chloride (14 ml) containing sodium hydride (≈50% dispersion, 0.22 g, ≈4.6 mmol) under stirring for 75 min at 75°C. The mixture was then processed and chromatographed (Solvent A, gradient) to afford **2b** (0.28 g, 13%), methyl 2,3,6-tri-*O*-benzyl-β-D-glucopyranoside (**23**, 1.12 g, 60%, R_f=0.40, Solvent A, 10 : 1), and methyl 2,3,4-tri-*O*-benzyl-β-D-glucopyranoside[15] (**24**, 0.34 g, 18%, R_f=0.25).

The acetylation of **23** with acetic anhydride in pyridine furnished **25b**: $[\alpha]_D$ −7° (*c* 2.0, $CHCl_3$); NMR($CDCl_3$) δ=1.73 (s, 3, CH_3CO), 3.51 (s, 3, CH_3O), 4.22 (d, 1, J=7.2 Hz, H-1), and 7.18—7.25 (15, $3C_6H_5$). Found: C, 70.41; H, 6.66%. Calcd for $C_{30}H_{34}O_7$: C, 71.13; H, 6.77%.

The acetylation of **24** gave **26b**: mp 70—70.5 °C (from hexane); $[\alpha]_D$ +19° (*c* 1.0, $CHCl_3$) [lit,[16] mp 61—63 °C; $[\alpha]_D$ +26° ($CHCl_3$)]. Found: C, 70.91; H, 6.68%. Calcd for $C_{30}H_{34}O_7$: C, 71.13; H, 6.77%.

Methyl 4-O-Acetyl-2,3,6-tri-O-benzyl-α-D-glucopyranoside (25a): The treatment of **25b** with **1** and subsequent chromatographic purification (Solvent A, 30 : 1) afforded 25a as a syrup: $[\alpha]_D$ +14° (*c* 2.0, $CHCl_3$); NMR(CCl_4) δ=1.74 (s, 3, CH_3CO), 3.36 (s, 3, CH_3O), and 7.21—7.26 (15, $3C_6H_5$). Found: C, 70.27; H, 6.40%. Calcd for $C_{30}H_{34}O_7$: C, 71.13; H, 6.77%.

Methyl 6-O-Acetyl-2,3,4-tri-O-benzyl-α-D-glucopyranoside (26a): The treatment of **26b** with **1** and subsequent chromatographic separation (Solvent A, 20 : 1) gave **26a** as a syrup: $[\alpha]_D$ +28° (*c* 1.0, $CHCl_3$); NMR CCl_4) δ=1.96 (s, 3, CH_3CO), 3.34 (s, 3, CH_3O), and 7.23—7.27 (15, $3C_6H_5$). Found: C, 70.80; H, 6.79%. Calcd for $C_{30}H_{34}O_7$: C, 71.13; H, 6.77%.

Methyl 2,3,4-Tri-O-benzyl-6-O-methyl-β-D-glucopyranoside (12b): A mixture of **24** (0.41 g), methyl iodide (2.7 ml), and silver oxide (1.0 g) was vigorously stirred for 40 h at room temperature. Chromatography (Solvent A, 30 : 1) and subsequent crystallization from hexane afforded **12b** (0.31 g, 74%): mp 64—65.5 °C; $[\alpha]_D$ +5° (*c* 1.0, $CHCl_3$); NMR(CCl_4) δ=3.31 (s, 3, CH_3O), 3.48 (s, 3, CH_3O), 4.15 (d, 1, J=7.4 Hz, H-1), and 7.15—7.18 (15, $3C_6H_5$). Found: C, 72.69; H, 7.07%. Calcd for $C_{29}H_{34}O_6$: C, 72.78; H, 7.16%.

Methyl 2,3,4-Tri-O-benzyl-6-O-methyl-α-D-glucopyranoside (12a): The treatment of **12b** with **1** and subsequent chromatographic separation (Solvent A, 30 :1) gave **12a** as a syrup: $[\alpha]_D$ +12° (*c* 2.0, $CHCl_3$) [lit,[17] $[\alpha]_D$ +8° (*c* 0.71, $CHCl_3$)]. Found: C, 72.48; H, 7.05%. Calcd for $C_{29}H_{34}O_6$: C, 72.78; H, 7.16%.

Methyl 2,3,4-Tri-O-acetyl-6-O-methyl-β-D-glucopyranoside (28b): The hydrogenolysis of **12b** in acetic acid and methanol in the presence of palladium black at 340 kPa and subsequent acetylation with acetic anhydride and pyridine, followed by crystallization from diisopropyl ether, furnished **28b**: mp 113—113.5 °C; $[\alpha]_D$ −14° (*c* 0.4, $CHCl_3$); NMR ($CDCl_3$) δ=2.03 (s, 3, CH_3CO), 2.06 (s, 6, $2CH_3CO$), 3.40 (s, 3, CH_3O), 3.53 (s, 3, CH_3O), and 4.44 (d, 1, J=8.0 Hz, H-1). Found: C, 50.39; H, 6.75%. Calcd for $C_{14}H_{22}O_9$: C, 50.29; H, 6.63%.

Methyl 2,3,4-Tri-O-acetyl-6-O-methyl-α-D-glucopyranoside (28a): The treatment of **28b** with **1** and subsequent chromatography (Solvent B, 6 : 1) gave **28a**: mp 77.5—78.5 °C; $[\alpha]_D$ +137° (*c* 2.0, $CHCl_3$); +150° (*c* 1.0, MeOH) [lit,[18] mp 73.5—74 °C, $[\alpha]_D$ +145° (*c* 0.99, MeOH)], NMR($CDCl_3$) δ=2.00 (s, 3, CH_3CO), 2.03 (s, 3, CH_3CO), 2.07 (s, 3, CH_3CO), 3.36 (s, 3, CH_3O), and 3.42 (s, 3, CH_3O). Found: C, 50.02; H, 6.71%. Calcd for $C_{14}H_{22}O_9$: C, 50.29; H, 6.63%.

Methyl 2,3,4-Tri-O-benzyl-6-deoxy-β-D-glucopyranoside (13b): Methyl 2,3,4-tri-*O*-acetyl-6-deoxy-β-D-glucopyranoside[19] was benzylated with hot benzyl chloride containing powdered potassium hydroxide to afford **13b**: mp 106.5—107 °C (from hexane); $[\alpha]_D$ +8° (*c* 0.5, $CHCl_3$) [lit,[20] mp 98 °C; $[\alpha]_D$ +6.8° (*c* 0.7, $CHCl_3$)]. Found: C, 74.87; H, 7.14%. Calcd for $C_{28}H_{32}O_5$: C, 74.97; H 7.19%.

Methyl 2,3,4-Tri-O-benzyl-6-deoxy-α-D-glucopyranoside (13a): The treatment of **13b** with **1** and subsequent chromatography (Solvent A, 50 : 1) gave **13a** as a syrup: $[\alpha]_D$ +21° (*c* 0.6, $CHCl_3$) [lit,[20] $[\alpha]_D$ +20.8° (*c* 0.7, $CHCl_3$)]. Found: C, 74.01; H, 6.91%. Calcd for $C_{28}H_{32}O_5$: C, 74.97; H, 7.19%.

Methyl 2,3,4-Tri-O-benzyl-α-D-xylopyranoside (14a): The treatment of **14b**[21] with **1** and subsequent chromatography (Solvent A, 40 : 1), followed by crystallization from hexane, gave **14a**: mp 68—69 °C, $[\alpha]_D$ +16° (*c* 0.7, $CHCl_3$), +50° (*c* 0.7, CH_2Cl_2) [lit,[21] mp 61 °C; $[\alpha]_D$ +50.5° (*c* 5.22, CH_2Cl_2)]. Found: C, 74.41; H, 6.86%. Calcd for $C_{27}H_{30}O_5$: C, 74.63; H, 6.96%.

Cyclohexylmethyl 2,3,4,6-Tetra-O-benzyl-α-D-glucopyranoside (29a): The treatment of **29b**[22] with **1** and subsequent chromatography (Solvent B, 15 : 1) gave **29a** as a syrup, identified with an authentic sample.[22]

Cyclohexyl 2,3,4,6-Tetra-O-benzyl-α-D-glucopyranoside (30a): The treatment of **30b**[10] with **1** and subsequent chromatography (Solvent B, 15 : 1) gave **30a** as a syrup, identified with an authentic sample.[10]

Benzyl 2,3,4,6-Tetra-O-benzyl-α-D-glucopyranoside (31b): The treatment of **31b**[23] with **1** and subsequent chromatography (Solvent B, 15 : 1) furnished **31a**: mp 94.5—95 °C (from hexane); $[\alpha]_D$ +53° (*c* 1.0, $CHCl_3$) [lit,[23] mp 93.5—94.5 °C; $[\alpha]_D^{28}$ +55.8° (*c* 1.63, $CHCl_3$)]. Found: C, 78.02; H, 6.70%. Calcd for $C_{41}H_{42}O_6$. C, 78.07; H, 6.71%.

2-Benzyloxyethyl, 3-Benzyloxypropyl, and 6-Benzyloxyhexyl 2,3,4,6-Tetra-O-benzyl-β-D-glucopyranosides (32b, 33b, and 34b): A mixture of 2,3,4,6-tetra-*O*-acetyl-α-D-glucopyranosyl bromide[24] (1.0 g, 2.4 mmol), 1,2-ethanediol (Wako, 0.27 ml), 4.8 mmol), silver oxide (1.1 g, 4.8 mmol), and benzene (10 ml) was agitated for 20 h at room temperature. The mixture was filtered, evaporated, and then chromatographed (Solvent A, 5 : 1) to afford 2-hydroxyethyl 2,3,4,6-tetra-*O*-acetyl-β-D-glucopyranoside[25] (0.80 g, 84%). This (0.26 g) was treated with hot benzyl chloride (5 ml) containing powdered potassium hydroxide (0.93 g) for 4 h at 100 °C. Usual work-up and chromatography (Solvent A, 30 : 1), followed by crystallization from hexane, gave **32b** (0.36 g, 81%); mp 67.5—68.5 °C; $[\alpha]_D$ +5° (*c* 1.0, $CHCl_3$). Found: C, 76.49; H, 6.88%. Calcd for $C_{43}H_{46}O_7$. C, 76.53; H, 6.87%.

The condensation of the bromide with 1,3-propanediol (Tokyo Kasei) and 1,6-hexanediol (Tokyo Kasei) afforded 3-hydroxypropyl 2,3,4,6-tetra-*O*-acetyl-β-D-glucopyranoside[26] (80%) and 6-hydroxyhexyl 2,3,4,6-tetra-*O*-acetyl-β-D-glucopyranoside[27] (46%) respectively. The yields were substantially improved. The subsequent benzylation of them furnished **33b** and **34b** respectively. **33b**: $[\alpha]_D$ +8° (*c* 2.8, $CHCl_3$). Found: C, 76.33; H, 6.96%. Calcd for $C_{44}H_{48}O_7$: C, 76.71; H, 7.02%. **34b**: $[\alpha]_D$ +4° (*c* 2.6, $CHCl_3$) Found: C, 76.79; H, 7.47%. Calcd for $C_{47}H_{54}O_7$: C, 77.23; H, 7.45%.

2-Benzyloxyethyl, 3-Benzyloxypropyl, and 6-Benzyloxyhexyl 2,3,-4,6-Tetra-O-benzyl-α-D-glucopyranosides (32a, 33a, and 34a): The treatment of **32b**, **33b**, and **34b** with **1**, and subsequent chromatographic separation (Solvent B, 10 : 1) gave **32a**, **33a**, and **34a** respectively. **32a**: $[\alpha]_D$ +37° (*c* 0.3, $CHCl_3$). Found: C, 75.50; H, 6.61%. Calcd for $C_{43}H_{46}O_7$: C, 76.53; H, 6.87%. **33a**: $[\alpha]_D$ +42° (*c* 0.4, $CHCl_3$). Found: C, 75.85; H, 6.97%. Calcd for $C_{44}H_{48}O_7$: C, 76.71; H, 7.02%. **34a**: $[\alpha]_D$ +33° (*c* 1.0, $CHCl_3$). Found: C, 76.25; H, 7.21%. Calcd for $C_{47}H_{54}O_7$: C, 77.23; H, 7.45%.

In the case of the reaction of **32b**, 2,3,4,6-tetra-*O*-benzyl-α-D-glucopyranose (22%), whose IR and NMR spectra were superimposable with those of an authentic specimen,[28] was isolated on chromatography.

Preparation of Additives. 1-Benzyloxy-2-methoxyethane (9): 2-Benzyloxyethanol (Tokyo Kasei) was methylated with methyl iodide in the presence of silver oxide to form **9**: bp 161—163 °C/123 mmHg,† n_D 1.4967 NMR(CCl_4) δ=3.33 (s, 3, CH_3O), 3.55 (s, 4, $(CH_2)_2$), 4.53 (s, 2, $PhCH_2$), and 7.25 (s, 5, C_6H_5). Found: C, 72.22; H, 8.30%. Calcd for $C_{10}H_{14}O_2$: C, 72.26; H, 8.49%.

2-(Benzyloxymethyl)tetrahydropyran (10): The benzylation of 2-(hydroxymethyl)tetrahydropyran[29] with hot benzyl chloride containing powdered potassium hydroxide afforded **10**: bp 169—172 °C/23—25 mmHg; n_D 1.5132; NMR($CDCl_3$) δ=23.2, 26.0, 28.3, 68.5, 73.4, 73.8, 76.8, 127.5, 127.7 (2C), 128.3 (2C), and 138.3. Found: C, 75.46; H, 8.82%. Calcd for $C_{13}H_{18}O_2$: C, 75.69; H, 8.79%.

trans-*1,2-Bis(benzyloxy)cyclohexane (11)*: The benzylation of *trans*-1,2-cyclohexanediol (Aldrich) with hot benzyl chloride and potassium hydroxide furnished **11**: bp 202—204 °C/2.5 mmHg; n_D 1.5470 [lit,[30] bp 182—183 °C/2 mmHg, n_D^{20}1.5468]; NMR(CCl_4) δ=0.93—2.23 (m, 8, $(CH_2)_4$), 3.31 (m, 2, H-1 and H-2), 4.56 (s, 4, $2PhCH_2$), and 7.21 (s, 10, $2C_6H_5$). Found: C, 81.09; H, 8.20% Calcd for $C_{20}H_{24}O_2$: C, 81.04; H, 8.16%.

Anomerization of Disaccharides. Anomerization of Methyl 6-O-(2,3,4,6-Tetra-O-benzyl-β-D-glucopyranosyl)-2,3,4-tri-O-benzyl-α-D-glucopyranoside (16b) into the α-Disaccharide (16a): A solution of **16b**[31] (36.4 mg, 0.037 mmol) in dichloromethane (0.37 ml) was treated with **1** (4.1 μl 0.037 mmol). After 30 s, the reaction was quenched and the mixture was processed as usual. Subsequent chromatographic separation (Solvent A, 30 : 1) gave **16a** (16.6 mg, 46%): mp 105—106 °C; $[\alpha]_D$ +59° (*c* 1.0, $CHCl_3$) [lit,[32] mp 101.5 °C; $[\alpha]_D^{20}$ +59.3° (*c* 1.78, $CHCl_3$)]. Found: C, 75.38; H, 6.71%. Calcd for $C_{62}H_{66}O_{11}$. C, 75.43; H, 6.74%.

The slower-moving, unchanged **16b** (4.9 mg, 14%) was recovered.

Anomerization of Methyl 3-O-(2,3,4,6-Tetra-O-benzyl-β-D-glucopyranosyl)-2,4-di-O-benzyl-α-D-xylopyranoside (17b) into the α-Disaccharide (17a): A solution of **17b**[33] (297 mg, 0.34 mmol) in dichloromethane (3.4 ml) was treated with **1** (38 μl, 0.34 mmol). After 60 s, the reaction was quenched. The mixture was then processed and chromatographed (Solvent B, 4 : 1) to furnish **17a** (40 mg, 14%), which was identified with a sample prepared alternatively:[33] $[\alpha]_D$ +58° (*c* 1.0, $CHCl_3$); NMR($CDCl_3$) δ=96.7 (C_{glc}-1) and 97.7 (C_{xyl}-1). Found: C, 74.04; H, 6.93%. Calcd for $C_{54}H_{58}O_{10}$: C, 74.81; H, 6.94%.

The faster-moving, unchanged **17b** (42 mg, 14%) was recovered.

Phosphatosulfates. Metal-ion Effects on the Acid-catalyzed Hydrolysis of Phenyl Phosphatosulfate in an Acetonitrile-Water Mixed Solvent

Toshio EIKI, Yoshio ASAI, and Waichiro TAGAKI*,†

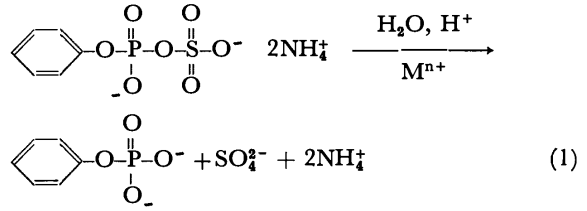
(Received March 17, 1981)

The rates of the acid-catalyzed hydrolysis of phenyl phosphatosulfate (PPS) have been found to be highly dependent on the water content in the mixed solvent of acetonitrile–water. A remarkable rate acceleration was observed with a rate maximum near the 1 : 1 ratio of PPS and metal ion, and with a solvent with a low water content. Under such conditions, the site of the cleavage of the P–O–S linkage was observed to be predominantly the S–O bond.

Active sulfates[1] are the key starting intermediates in the sulfur metabolism in biological systems.[2,3] They contain the P–O–S phosphatosulfate linkage, and a number of biological transformations, such as the phosphate- or sulfate-group transfer to various nucleophilic acceptors or the reduction of sulfate groups, are all initiated by the cleavage of the P–O–S linkage. However, the mechanisms of the corresponding enzymatic catalyses have largely been left unclarified. The biomimetic chemistry of the phosphatosulfate linkage has also been relatively unexplored compared to that of the related P–O–P phosphate linkage.

An interesting feature of the chemistry of the P–O–S linkage is the role of metal ions—how they affect the rate and selectivity in the cleavage of the P–O *vs.* S–O bond. Previously we reported that the Mg^{2+} ion enhanced the rate of the acid-catalyzed hydrolysis of PPS, a simple model of active sulfates, in mixed solvents of acetonitrile–water when their water content was low.[4,5] The details will now be described in this paper, along with additional data for some other metal ions (Eq. 1). The substrate PPS was used in the form of diammonium salt.



diammonium salt of PPS

(1)

Results and Discussion

Kinetics. The reactions were generally carried out in an acetonitrile–water mixed solvent containing appropriate amounts of PPS ($1.8—2.0\times10^{-3}$ M), a metal ion ($0—4\times10^{-2}$ M) and buffer reagents of $HClO_4$ ($0.3—3.0\times10^{-3}$ M)-*n*-$Bu_4N^+ClO_4^-$ (2×10^{-2} M), at 25 °C (1 M=1 mol dm^{-3}). For some experiments with solvents of a low water content, the water was partially replaced by methanol (see Fig. 2b and Table 3). Under these conditions the hydrolysis of acetonitrile was not detected.

The rates were determined by measuring the formation of phenyl phosphate.[4-6] Most reaction mixtures were homogeneous during the reaction. Occasionally, ammonium sulfate was precipitated out at the end of reaction in the solvents with a low water content (3 M). Nevertheless, good pseudo-first-order rate constants were obtained up to more than 90% completion of the reaction.

Effect of Water Concentration. The rates of acid-catalyzed hydrolysis were found to be highly dependent on the water content of the medium, in both the absence and presence of a metal ion.

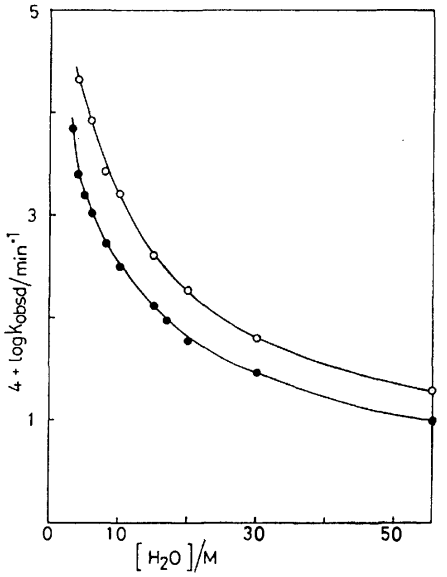


Fig. 1. Effect of water concentration on the rates of hydrolysis of PPS (1.8×10^{-3} M) in the presence of $HClO_4$(●; 2×10^{-3} M, ○ ; 4×10^{-3} M) and $(n\text{-Bu})_4NClO_4$ (2×10^{-2} M) at 25 °C.

In the absence of a metal ion, Fig. 1 shows that the rates in pure water (55.5 M) are enhanced by some 10^3 times in an acetonitrile–water mixed solvent when the water content is reduced to 3 M. A similarly large rate enhancement has also been reported for other acid-catalyzed sulfate hydrolysis in solvents of low polarity (ether or moist dioxane).[7,8] A suggestion has been made that the hydrolysis of aryl hydrogensulfate based on an Al mechanism (Eq. 2) is due to a specific solvation of the zwitter ionic-transition state of sulfur trioxide by ether.[9] Since an Al mechanism to give sulfur trioxide has been suggested for the acid-catalyzed hydrolysis of PPS in pure water,[6,10,11] the specific solvation of sulfur

trioxide by acetonitrile may also be possible as an explanation in such a medium with a low water content. However, the effect of water seems to be too complex to allow a simple interpretation, as will be described below.

Effects of Metal Ions. The metal-ion effect in water was examined by Benkovic and Hevey.[10] They observed rates faster by 1.26—3.16 times in the hydrolysis of PPS by Mg^{2+}, Ca^{2+}, or Al^{3+} ions at pH 3.1 and 55 °C. They also observed that the rates were 1.2—2.05 times slower in the cases of Mn^{2+}, Co^{2+}, or Zn^{2+} ions. Thus, the effect of these metal ions is not large in pure water. Meanwhile, we have found remarkable metal-ion effects in the medium of acetonitrile–water mixed solvents.[4]

As is shown in Fig. 2a and Table 1, the rate acceleration by the Mg^{2+} ion is not observable when the water content of the medium exceeds 8 M; rather, the addition of the Mg^{2+} ion tends to inhibit the acid catalysis (see the k_{obsd} values in the absence of a metal ion). On the other hand, a large rate acceleration takes place in a medium with a low water content, showing a maximum in each plot of k_{obsd} *vs.* $[Mg(ClO_4)_2]$ where the concentration of the Mg^{2+} ion is very close to the initial concentration of the substrate ($[PPS]=1.8\times10^{-3}$ M). For example, in the solvent of $H_2O=3$ M, the k_{obsd} at

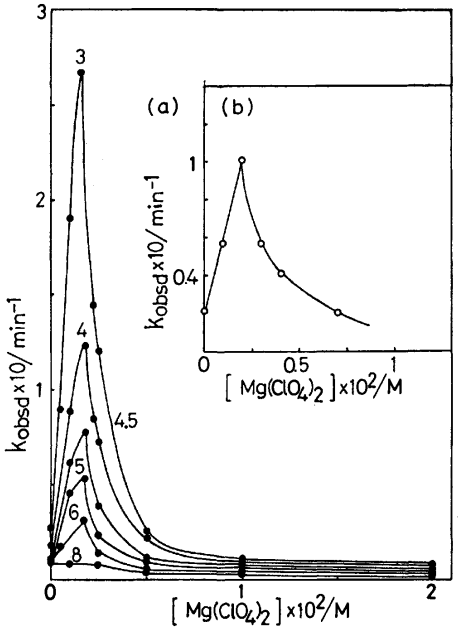

Fig. 2. Mg^{2+} ion effect on the (a) hydrolysis and (b) methanolysis of PPS at 25 °C.
(a): $[PPS]=1.8\times10^{-3}$ M, $[HClO_4]=1.0\times10^{-3}$ M $[n\text{-}Bu_4NClO_4]=0.02$ M. The numbers in the plots are the molar concentrations of water in acetonitrile–water mixed solvent. (b): In acetonitrile containing methanol (1 M), water (3 M), PPS (2.0×10^{-3} M), $HClO_4$ (1×10^{-3} M), and n-Bu_4NClO_4 (0.03 M), 25 °C. The k_{obsd} values are for the formation of phenyl phosphate.

3.00	2.52	$12.3\times10^{-1}(7.80\times10^{-1})$	$4.28\times10^{-1}(3.63\times10^{-1})$	$3.42\times10^{-1}(1.86\times10^{-1})$

a) $[PPS]=1.8\times10^{-3}$ M; $k_o([Mg(ClO_4)_2]=0$ M), k_{max} ($[Mg(ClO_4)_2]=1.8\times10^{-3}$ M) $[(n\text{-}Bu)_4NClO_4^-]=2.0\times10^{-2}$ M, 25 °C.

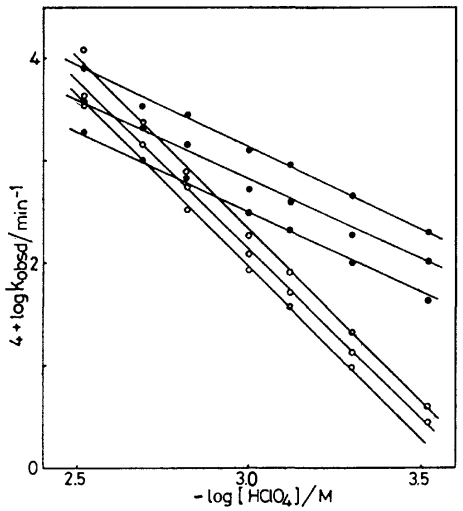

Fig. 3. Effect of acid and water concentration on the rates of hydrolysis of PPS in the absence (○) and presence of Mg^{2+} ion (●) in the mixed solvents of water–acetonitrile. Water concentrations are from the bottom 4,5, and 6 M, respectively (see Table 2).

the maximum ($k_{max}=2.67\times10^{-1}$ min^{-1}) is ten times larger than the k_{obsd} in the absence of the Mg^{2+} ion ($k_0=2.66\times10^{-2}$ min^{-1}). These k_{max} and k_0 values are dependent on both the water and acid concentrations as shown in Fig. 3 and Table 2.

As has previously been reported,[4,10,11] the acid hydrolysis of PPS in water gives a linear pH-log k_{obsd} plot with a slope of −1. In Fig. 3, the corresponding slopes of the plots of $-\log[HClO_4]$ *vs.* $\log k_0$ and $\log k_{max}$ are −3.2 and −1.6 respectively in the ranges of $[HClO_4]=0.3$—3.0×10^{-3} M and $[H_2O]=4$—6 M. Thus, the apparent number of protons involved in the rate-limiting step changes from one in pure water to more than three in the medium with a low water content and in the absence of a metal ion, while the number changes from −3.2 in the absence of the Mg^{2+} ion to −1.6 in its presence. Whatever the cause, these dependencies of k_{max} and k_0 on both the water and acid concentrations lead to the conclusion that the ratio of k_{max}/k_0 (*i.e.*, the metal-ion effect) increases linearly with a decrease in the water concentration (see Table 1) and exponentially with a decrease in the acid concentration (see Fig. 3 and Table 2), at least in the ranges of $[H_2O]=3$—8 M and $[HClO_4]=0.3$—3×10^{-3} M. Conversely, such metal-ion effects become unimportant at higher acid concentrations and in pure water.

The Mg^{2+} ion is most frequently encountered as a cofactor in the reactions of phosphates including active sulfates in biological systems.[2,3,12] The above findings may offer important suggestions regarding the role of the Mg^{2+} ion in such a biological reaction. In order to obtain further knowledge, the effects of some other metal ions have also been examined, as will be described below.

As is shown in Figs. 4 and 5, the effects of Ca^{2+}, Zn^{2+}, Al^{3+}, and Th^{4+} on the rates were found to be similar to those of Mg^{2+} in Fig. 2. For example, the [PPS]/[metal ion]=1 ratio at the k_{max} is the same for both

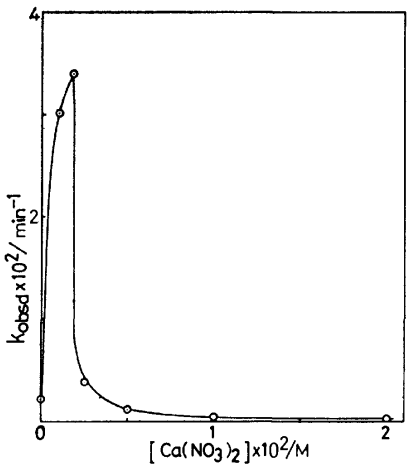

Fig. 4. Effect of Ca^{2+} ion on the rates of hydrolysis of PPS, 25 °C in 4 M water–acetonitrile.
$[PPS]=1.8\times10^{-3}$ M; $[HClO_4]=5.0\times10^{-4}$ M; $[(n\text{-}Bu)_4NClO_4]=0.02$ M.

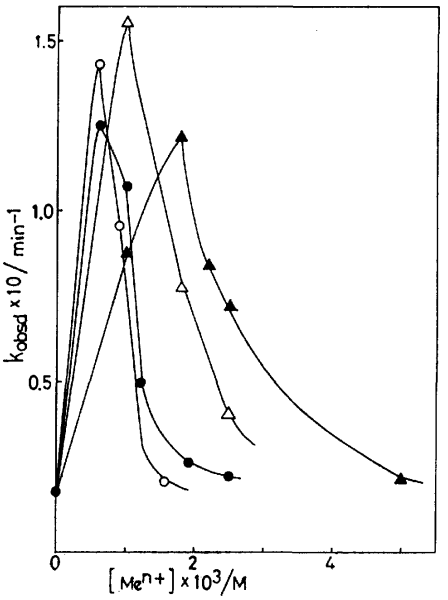

Fig. 5. Effect of metal ions on the rates of hydrolysis of PPS. 25 °C in 4 M water–acetonitrile.
$[PPS]=1.8\times10^{-3}$ M; $[HClO_4]=1.0\times10^{-3}$ M; $[(n\text{-}Bu)_4ClO_4]=0.02$ M; Me^{n+} are Zn^{2+} (△), Al^{3+} (●), Th^{4+} (○), and Mg^{2+} (▲).

Ca^{2+} and Mg^{2+}, and they give comparable k_{max}/k_0 values of 16 and 23 respectively under the same conditions ($[H_2O]=4$ M, $[HClO_4]=5\times10^{-4}$ M). However, the details are different; the metal-ion concentrations which give the rate maximum with $[PPS]=1.8\times10^{-3}$ M are $[Th^{4+}]=0.6\times10^{-3}$ M, $[Al^{3+}]=0.6\times10^{-3}$ M, $[Zn^{2+}]=1.0\times10^{-3}$ M, $[Ca^{2+}]=1.8\times10^{-3}$ M, and $[Mg^{2+}]=1.8\times10^{-3}$ M; all the curves in Figs. 2, 4, and 5 are unusually sharp, but those of Th^{4+} and Al^{3+} are much sharper than for those of Ca^{2+} and Mg^{2+}. Apparently, complicated equilibria are taking place between PPS and a metal ion, which are both highly dependent on both the water and acid concentrations. The fact that [PPS]/[metal ion]=1—3 at the rate maximum suggests

that the 1 : 1, 1 : 2, or 1 : 3 complex of a metal ion and PPS is catalytically active depending on the nature of metal ion, but that a further increase in the metal-ion coordination stabilizes the complex toward the hydrolysis.

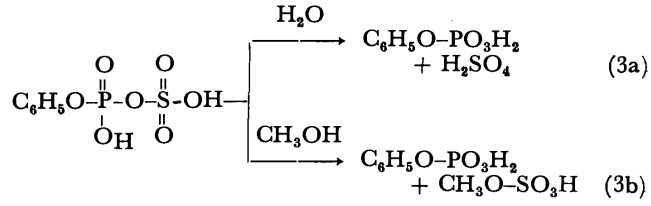
Selective S–O Bond Cleavage. It has already been shown by an ^{18}O-tracer study that the S–O bond of PPS was selectively cleaved in the acid-catalyzed hydrolysis in water.[4,10] Similarly, methyl hydrogensulfate was obtained in a reaction in aqueous methanol.[10] However, the metal-ion effect was found to be small in water, as has been mentioned above, and so it was not examined in the latter aqueous methanol.

Table 3. Mg^{2+} ion effect on the rate of hydrolysis of PPS in mixed solvents of methanol (1.0 M)–water (3.0 M)–acetonitrile at 25 °C[a]

$[Mg(ClO_4)_2]$/M	k_{obsd}/min^{-1}
0	2.06×10^{-2}
1.0×10^{-3}	5.69×10^{-2}
2.0×10^{-3}	1.04×10^{-1}
3.0×10^{-3}	5.72×10^{-2}
4.0×10^{-3}	4.15×10^{-2}
7.0×10^{-3}	2.00×10^{-2}

a) $[PPS]=2.0\times10^{-3}$ M; $[HClO_4]=1.0\times10^{-3}$ M; $[(n\text{-Bu})_4NClO_4]=3.0\times10^{-2}$ M.

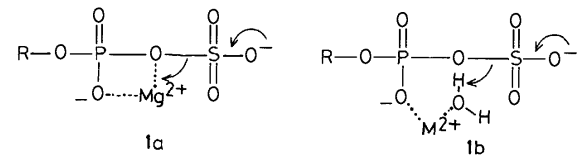
As is shown in Table 3 and Fig. 2b, a partial substitution of 4 M water by methanol in acetonitrile did not change the essential features of the Mg^{2+}-ion effect; a rate maximum was also observed at [PPS] : [metal ion]=1 : 1. From the reaction mixture at the rate maximum, methyl hydrogensulfate was then detected in a 60% yield by NMR analysis. The alternative formation of methyl phenyl phosphate by the P–O bond cleavage was not detected in spite of the fact that it is stable under the present reaction conditions (Eq. 3a) and should be easily detected by means of the NMR doublet of the CH_3 signal. Thus, the methanolysis of

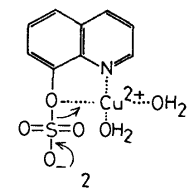


PPS occurs by means of the predominant S–O bond cleavage (Eq. 3b). Here, it should be noted that this S–O cleavage is the subject of Mg^{2+}-ion catalysis.

Mechanism of Metal-ion Catalysis. In the related phosphate hydrolysis, the metal-ion effects have been extensively studied, but the catalysis observed is generally not large.[12] Rate acceleration has been observed only in the hydrolysis of esters which have a neighboring functional group for chelation with a metal ion.[13] In other well-designed models for ATP hydrolysis, neighboring polyamine ligands showed essentially no effect on the metal-ion catalysis.[12] An exception was the observation that the hydrolysis or phosphate group-transfer reaction of ATP was accelerated in the presence of the Mg^{2+} ion when the reactions were conducted in dimethyl sulfoxide with a low water content.[14]

For an efficient catalysis to occur, a metal ion and phosphate (or sulfate) must form a complex. This process would, however, not be favored in water because of the favored hydration of the metal ion and the ester, whereas in an enzymatic reaction the medium at the active site is not necessarily water, but rather would be hydrophobic or dipolar aprotic in favor of metal ion-substrate binding. This idea may be supported by the findings shown above in Figs. 2, 4, and 5. However, even if this is true, the question still remains of how such complexation can activate the selective S–O bond cleavage. One may consider the present metal-ion effect to be electrophilic catalysis, as is illustrated in **1a**.





This type of catalysis was proposed in the Cu^{2+}-ion catalyzed hydrolysis of 8-quinolyl sulfate, as is shown in **2**.[13f] However, the present metal-ion effect is highly acid-dependent; under neutral conditions, no such metal-ion-assisted S–O cleavage was detected with divalent metal ions.[15] Therefore, the results may be tentatively accounted for by a mechanism of metal-ion-assisted proton-transfer catalysis, as is illustrated in **1b**, where the leaving group to capture the proton is the phosphoryl group. This type of catalysis is essentially the same as that considered in the hydrolysis of aryl hydrogensulfates, where a neighboring carboxyl or imidazolium group acts as the proton-transfer catalyst to the leaving phenoxyl group.[16,17] In **1b**, the proton transfer seems to be smooth when the metal ion coordinates only to the phosphate group, leaving the sulfate group free. Thus, any further coordination of the metal ion to the sulfate group would stabilize the complex and inhibit the reaction.

Experimental

Materials. The diammonium phenyl phosphatosulfate (PPS) was prepared by the previously reported method.[6] The tetrabutylammonium perchlorate was prepared by the literature method.[18] Deionized water was treated with $KMnO_4$ and distilled twice before use. The metal ions were used in the forms of perchlorate (Mg^{2+}) and nitrate (Zn^{2+}, Ca^{2+}, Al^{2+}, Th^{4+}) of an analytical grade.

Product Analyses. The hydrolysis products were found to be solely phenyl phosphate and inorganic sulfate, regardless of the presence or absence of metal ions. No phenol or other possible organic products were detected. In the reactions shown in Fig. 2b, methyl hydrogensulfate, phenyl phosphate,

and inorganic sulfate were the sole products, and methyl phenyl phosphate was not detected.

Phenyl phosphate was analyzed by UV absorption and paper chromatography.[6] Inorganic sulfate was analyzed colorimetrically by the barium chloranilate method.[19] Methyl hydrogensulfate was analyzed by NMR in the following way: the evaporation of acetonitrile gave $(n\text{-Bu})_4NClO_4$ precipitates, which were then removed by filtration. The filtrate was adjusted to pH 11 with aqueous sodium hydroxide to give insoluble magnesium hydroxide, which was subsequently removed by centrifugation. The supernatant was then neutralized with hydrochloric acid, and the solution was lyophilized. The residue was dissolved in D_2O and analyzed by NMR for phenyl and methyl (3H, δ 3.81, singlet) protons. The yield of methyl hydrogensulfate thus analyzed was 60% for the reaction mixture at the rate maximum shown in Fig. 2b.

Kinetics. The rate of the reaction was followed spectrophotometrically by quenching the reaction mixture with aqueous sodium hydroxide according to the previously reported method, except for the centrifugation of the quenched solutions to remove magnesium hydroxide.[4,11] Good pseudo-first-order rate constants were obtained up to a 90% completion of the reaction in the range of $[HClO_4]=0.3-3.0\times10^{-3}$ M, both in the presence and in the absence of $Mg(ClO_4)_2$ (see Fig. 3), although significant deviation from the first-order kinetics due to autocatalytic rate acceleration was observed below $[HClO_4]=0.3\times10^{-3}$ M. The pseudo-first-order rate constants were computed as usual by using $k_{obsd}=\frac{1}{t}\ln\frac{OD_\infty-OD_0}{OD_\infty-OD_t}$. The rate of reaction shown in Fig. 2b was determined by the same method.

(Received August 3, 1981)

The effects of Mg^{2+} ion and imidazole were examined on the hydrolysis of phenyl and *p*-decylphenyl phosphatosulfate (PPS and DPPS) in the presence of micelle of sodium dodecyl sulfate (SDS). It was observed that Mg^{2+} ion and imidazole increased the rates of hydrolysis cooperatively and the rate enhancement was much larger in the case of DPPS than in the case of PPS. The difference in the reactivities of two esters was discussed in terms of micellar effects.

Active sulfates[1] containing the phosphatosulfate linkage (P–O–S) are the key intermediates in the biological sulfur metabolism.[2] Yet a little has been understood for the mechanism of enzymic catalyses involving P–O–S linkage. In the model reactions, the P–O–S linkage is now known to be susceptible to the hydronium ion catalysis to give a selective S–O bond cleavage.[3,4] Such an acid catalysis can be enhanced by Mg^{2+} ion when the water content of the medium is low.[5,6] However, under the neutral conditions, the effect of Mg^{2+} ion alone is small even in the medium of low water content. Related fact is the requirement of bivalent metal ions as the cofactors in some hydrolytic enzymes of active sulfates which are active under the neutral conditions.[2e] Thus it is interesting to know a mechanism of activation of P–O–S linkage by Mg^{2+} ion under the neutral conditions. In this paper, we describe our observation that Mg^{2+} ion activates the P–O–S linkage toward the attack of imidazole nucleophile and the activation is enhanced under the micellar conditions.

Results and Discussion

Products. The substrates used were phenyl phosphatosulfate (PPS) and *p*-decylphenyl phosphatosulfate (DPPS). Their aminolysis was reported previously.[6,7] In the absence of Mg^{2+} ion and in the neutral or basic media, amines were observed to attack phosphorus to give phosphoramidates and inorganic sufate with a selectivity of 70—85% P–O cleavage. In the presence of Mg^{2+} ion, the selectivity of P–O cleavage increased further up to almost 100%.

In the case of imidazole, the corresponding phosphoramidates were not detected, but presumed to undergo rapid hydrolysis (Eq. 1). This presumption appears to be supported by the formation of methyl phenyl phosphate from PPS when the reaction was conducted in aqueous methanol (Eq. 1), while methyl hydrogensulfate was not detected which would be formed if the alternative cleavage of S–O bond occurred to give imidazole-*N*-sulfonic acid.

Kinetics. *Effect of SDS*: The kinetics of hydrolysis of PPS and DPPS were generally conducted in the micellar solution of SDS (6×10^{-2} M, 1 M=1 mol dm^{-3}), although the latter DPPS and its hydrolysis product diammonium *p*-decylphenyl phosphate (DPP)

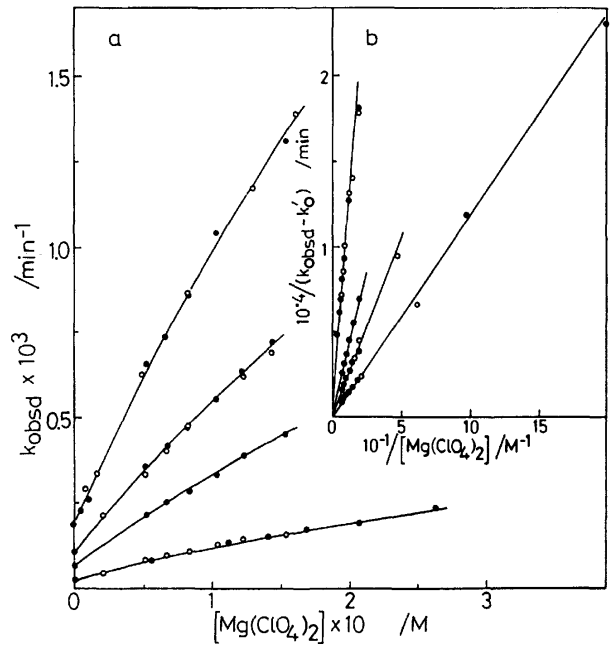

Fig. 1. a) Mg^{2+} ion effects on the imidazole catalyzed hydrolysis of PPS (2×10^{-2} M) in *N*-ethylmorpholine buffer (0.02 M, pH 7.90) at 55.0 °C: ●, in the presence of SDS (6×10^{-2} M); ○, in the presence of NaCl (6×10^{-2} M). Initial total concentrations of imidazole are from the bottom, 0.0, 1.0×10^{-2}, 2.0×10^{-2}, and 4.0×10^{-2} M, respectively. Solid lines are theoretical curves calculated from the values in Table 1 and Eq. 3; b) the reciprocal plots.

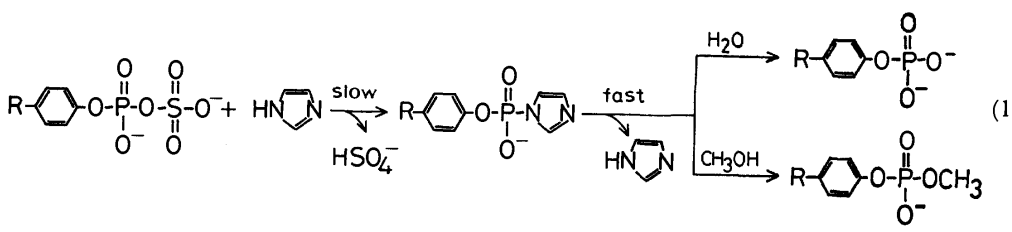

(1)

both form micelles above their CMC.[7] The reason of using SDS was the following. In the absence of SDS, an initially homogeneous reaction mixture of DPPS and Mg^{2+} ion became cloudy as the reaction proceeded due to the formation of an insoluble DPP–Mg^{2+} ion complex which could be solubilized by SDS micelle. The presence of SDS micelle, however, did not cause any detectable effect on the rates (k_{obsd}) of hydrolysis of DPPS.[8] The effect of SDS was also negligible on the hydrolysis of PPS as shown in Fig. 2. Thus in each case of PPS and DPPS, the effect of SDS on the rates was not apparent except for solubilization of the insoluble product. Nevertheless, a higher reactivity of DPPS than PPS appears to be due to a micellar effect as discussed later.

Hydrolysis of PPS: *N*-Ethylmorpholine used as the buffer reagent was confirmed to be unreactive toward the P–O–S linkage.[6,7] The effects of imidazole and Mg^{2+} ion concentration on the rates were then examined as shown in Fig. 1. The figure indicates that there was no difference in the rates between the medium of non-micellar NaCl (0.06 M) and micellar SDS (0.06 M). The figure also indicates that the rates tend to be saturated with increasing Mg^{2+} ion concentration at each fixed concentration of imidazole (0—4×10^{-2} M). On the other hand, the rates were linear with the increase in imidazole concentration at a fixed concentration of Mg^{2+} ion. These observations appear to be accounted for by assuming a reaction scheme involving preequilibrium formation of 1 : 1 complex (M.S) of substrate (S) and Mg^{2+} ion (M), where $[M.S]\ll[M]_T$, according to Eq. 2. From Eq. 2, the pseudo-first-order

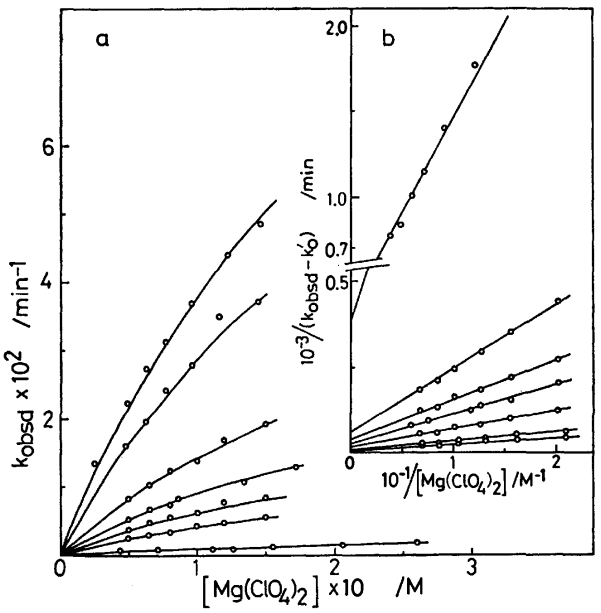

Fig. 2. a) Mg^{2+} ion effects on the imidazole catalyzed hydrolysis of DPPS (2×10^{-2} M) in the presence of SDS (6×10^{-2} M) in *N*-ethylmorpholine buffer (0.2 M, pH 7.90) at 55.0 °C. Initial total concentration of imidazole are from the bottom, 0.0, 2.4×10^{-3}, 4.0×10^{-3}, 6.0×10^{-3}, 1.0×10^{-2}, 2.1×10^{-2}, and 2.8×10^{-2} M, respectively. Solid lines are theoretical curves calculated from the values in Table 1 and Eq. 3; b) the reciprocal plots.

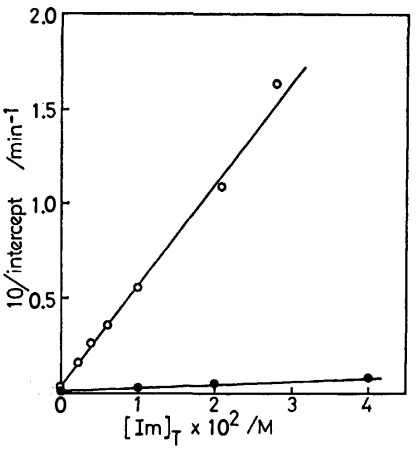

Fig. 3. Plots of 1/intercept *vs.* initial total concentration of imidazole ($[Im]_T$) for DPPS (○) and PPS (●), see text.

rate constant, k_{obsd} is given by Eq. 3, where $[Im]_T$ and $[M]_T$ are the initial stoichiometric concentration of imidazole and Mg^{2+} ion, respectively; k_o, k_o^{Im}, k_m^{Im}, and K_m (association constant) are defined in Eq. 2. Equation 3 gives Eq. 4 (Fig. 1b).

$$M + S \underset{}{\overset{K_m}{\rightleftharpoons}} M.S \xrightarrow{k'_m} \text{products} \qquad (2)$$

$$k'_o$$

$$k'_m = k_m + k_m^{Im}[Im]_T;\ k'_o = k_o + k_o^{Im}[Im]_T$$

$$k_{obsd} = \frac{k'_o + k'_m K_m [M]_T}{1 + K_m[M]_T} \qquad (3)$$

$$\frac{1}{(k_{obsd}-k'_o)} = \frac{1}{(k'_m-k'_o)} + \frac{1}{(k'_m-k'_o)K_m}\cdot\frac{1}{[M]_T} \qquad (4)$$

$$\frac{1}{(\text{intercept})} = (k_m-k_o) + (k_m^{Im}-k_o^{Im})[Im]_T \qquad (5)$$

The intercepts of Eq. 4 (Fig. 1b) should be linearly related to the imidazole concentration (Eq. 5) as verified in Fig. 3. Thus the k_{obsd} values could be analyzed based on these equations to give the kinetic parameters for PPS as listed in Table 1.

Hydrolysis of DPPS: The kinetic procedures and the analysis were essentially the same as in the above hydrolysis of PPS. The results are shown in Figs. 2 and 3, and in Table 1.

Table 1. Rate parameters for the hydrolysis of PPS and DPPS[a]

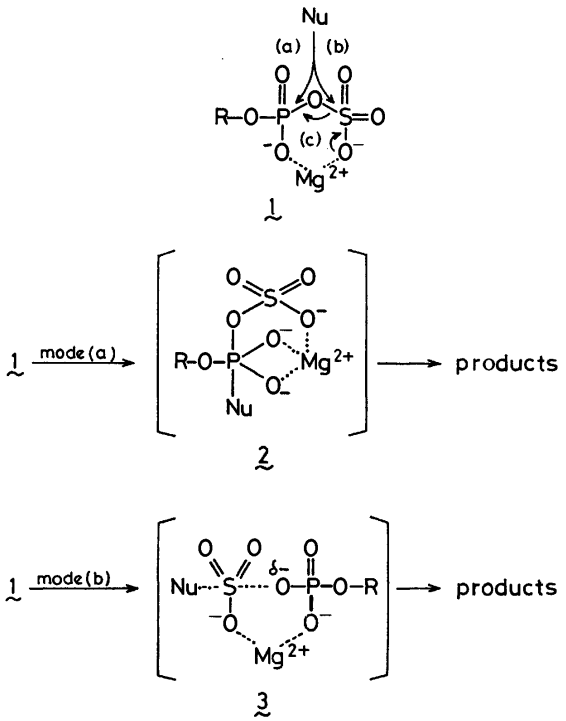
Constant	PPS	DPPS	k_{DPPS}/k_{PPS}
k_o/min^{-1}	2.57×10^{-5}	2.31×10^{-5}	0.898
k_m/min^{-1}	8.98×10^{-4}	37.6×10^{-4}	4.18
k_o^{Im}/M^{-1} min^{-1}	4.14×10^{-3}	13.3×10^{-3}	3.21
k_m^{Im}/M^{-1} min^{-1}	0.171	5.29	30.9
K_m/M^{-1}	1.19	3.39	

a) pH 7.90, 55 °C, in the presence of 6×10^{-2} M SDS; other conditions, see Figs. 2 and 3.

Comparison of PPS and DPPS Reactivities. The k_o values in Table 1 indicates that the reactivities of two esters toward water are nearly the same at pH 7.9 and

55 °C and in the absence of Mg^{2+} ion and imidazole. These water rates are enhanced by 35 and 163 fold (k_m/k_0 ratio) for PPS and DPPS respectively, when the ester are complexed with Mg^{2+} ion. Similarly the nucleophilic reactivities of imidazole (k_0^{Im}) in the absence of Mg^{2+} ion are enhanced by 41 and 400 fold (k_m^{Im}/k_0^{Im} ratio) for PPS and DPPS respectively by the complexation. Thus these rate enhancements are much larger for DPPS than PPS. Such comparison can also be made by relative rates, k_{DPPS}/k_{PPS} shown in Table 1.

Since DPPS is a surfactant,[7] it is reasonable to assume that DPPS forms a co-micelle with SDS.[9] On the other hand, it is known to be difficult to incorporate such a hydrophilic anion as PPS into an anionic micelle like SDS.[9] Therefore, it can be considered that the reaction of DPPS occurs in the micellar phase, while that of PPS in the bulk water phase. It is known that the binding of a counter ion on an ionic micelle is stronger in general than in the corresponding ion pair formation in the bulk water phase.[9] As expected, the K_m value of DPPS is larger than that of PPS. A plausible structure for the M.S complex (Eq. 3) is a cyclic one as illustrated in **1**, in which the bonding of $P\text{-}O^-\cdots Mg^{2+}$ is presumably stronger than that of $S\text{-}O^-\cdots Mg^{2+}$.



Three modes (a—c) may be conceivable for the cleavage of P–O–S linkage of such a complex **1**. The modes (a) and (b) are the biomolecular nucleophilic attack of imidazole on phosphorus and sulfur, respectively, to give either the P–O or the S–O bond cleavage. The mode (c) is the unimolecular cleavage of the S–O bond. In each case, Mg^{2+} ion is assumed to act as an electrophilic catalyst to polarize the reacting bonds or to neutralize the developing negative charge of the intermediate or the transition state. As mentioned already, what actually observed is the mode (a). Presumably, the formation of pentacovalent intermediate or transition state (**2**) through the mode (a) (Eq. 6) is energetically more favored than to make a S_N2 transition state (**3**) by mode (b) (Eq. 7). The stabilization by charge neutralization by Mg^{2+} ion seems to be more effective in **2** than in **3**, because the developement of negative charge must be more pronounced in **2** than in **3**. Such electrostatic interaction must be stronger in the micellar phase than in the bulk water phase, because of the hydrophobic nature of the micellar phase.[10]

As for the micellar effects on the metal ion catalysis, a positive micellar effect, although small, was reported by Melhado and Gutsche for the catalysis of cationic micellar chelates of 4-alkyl-3,6-diazaoctane-1,8-diamine in the decomposition of acetyl phosphate.[11] Very recently, we also reported a larger micellar effect on the catalytic activity of a lipophilic metal ion chelate in the hydrolysis of carboxylic acid esters in a cationic micelle.[12] In these reactions, the reacting bond undergoing nucleophilic attack is the ester carbonyl group. The present results indicate that a large micellar effect is also possible in the metal ion assisted nucleophilic attack on phosphorus. For enzyme catalysis, the present results suggest that if an enzyme require a bivalent metal ion as the cofactor in the hydrolysis of active sulfates, the medium of the active site is somewhat like a micellar phase and the site of cleavage of the P–O–S linkage is the P–O bond, as suggested by Roy.[2e] The results also suggest the importance of the histidyl residue at the active site of enzymes as the nucleophilic catalyst toward the phosphate substrates.

Experimental

Material. The ammonium salts of DPPS and PPS were prepared by our previous method.[4,7] Inorganic salts, EDTA and SDS were of commercial analytical grade and were used without further purification. Mg^{2+} ion was the perchlorate. All liquid reagents were purified by distillation. Imidazole was recrystallized from benzene. Demineralized water was treated with $KMnO_4$ and distilled twice before use.

Kinetics. A Hitachi-Horiba F-7DE pH meter and a Shimadzu UV-200 spectrophotometer were used for the kinetics. Kinetic procedures were the same as previously described.[7]

Methanolysis. The substrate PPS (144 mg) or DPPS (214 mg) was dissolved in 80% aqueous methanol (25 cm^3) containing imidazole (340 mg) and $Mg(ClO_4)_2$ (1.11 g). This reaction mixture was kept at 55 °C for 24 h and concentrated to dryness. The residue was dissolved in an alkaline solution (pH 11) and centrifuged to remove magnesium hydroxide. The supernatant was concentrated to dryness. The residue dried on P_2O_5 was washed with ether and again dried. The final residue was dissolved in D_2O and analyzed by NMR[6] for methyl phenyl phosphate: $\delta CH_3=3.74$ (3H, doublet). The yield of inorganic sulfate was quantitative as determined by Ba-chloranilate method.[7]

(Received May 12, 1981)

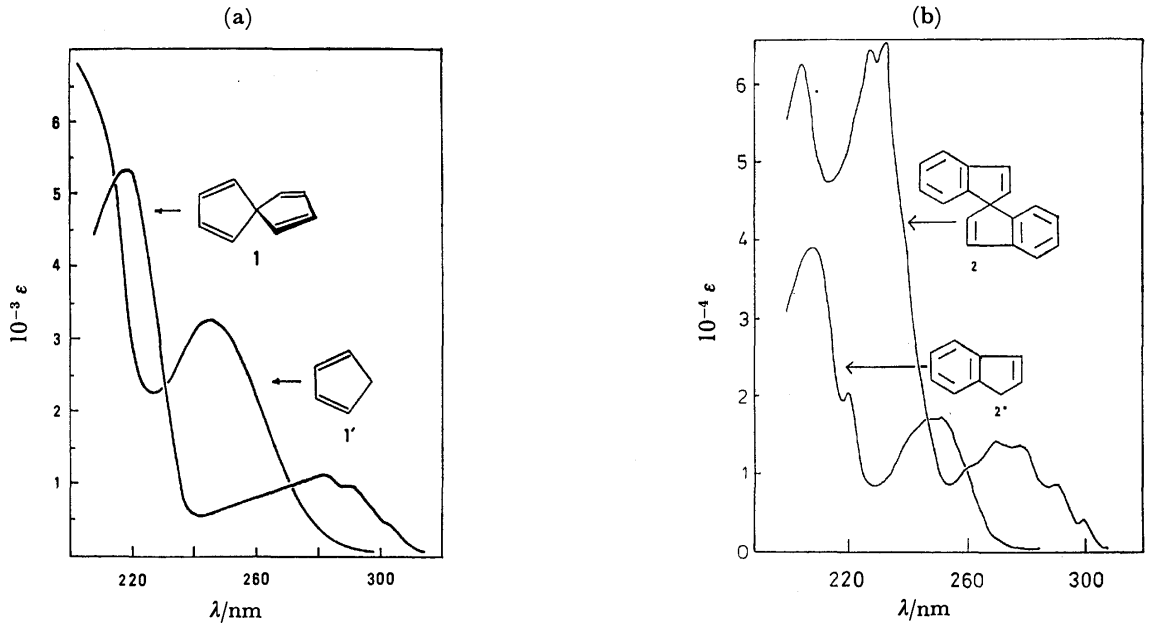
UV and ^{13}C NMR spectra of spirocyclic orthocarbonates, a spirobi(benzodithiepin) and a spirobi(naphthopyran) have been measured and compared with those of the "half compounds" to see the spiroconjugation effect. Whereas batho- and hyperchromic shifts are usually brought about by spiroconjugation, hypso- and hypochromic effects have been observed for 2,2′-spirobi[1,3-benzodioxole]. Through-bond interaction similar to the mechanism for the anomeric effect is considered to be operative in attenuating the electron release from the orthocarbonate moiety to the benzene chromophore. The downfield shifts of 20—25 and *ca.* 40 ppm were noted for the spirocarbons of the conformationally flexible and rigid orthocarbonates, respectively, as compared to the corresponding methylene carbons of the half compounds. The largest paramagnetic shift of 66.3 ppm is observed for the orthothiocarbonate and attributed to the presence of the low-lying d-orbitals due to through-space interaction of the four sulfur atoms.

Stimulated by the concept of spiroconjugation put forward by Simmons and Fukunaga,[2] and by Hoffmann *et al.*,[3] a number of theoretical[4] and experimental works[5] have since been carried out to delineate the extent and the mechanism of such conjugative effects. UV absorption and photoelectron spectroscopy have proved to be most instrumental in studying spiroconjugation. In the well-known case of spiro[4.4]nona-1,3,6,8-tetraene (**1**), the effect of spiroconjugation can be shown by comparing the UV spectra of the spiran and its half moiety, cyclopentadiene (**1′**). A large bathochromic shift (35 nm) of the long-wavelength band of the spiran is observed.[5b] The He(I) photoelectron spectra of spirocompounds have revealed that the splitting pattern in the low-energy region provides a measure of splitting of occupied MO's due to spiroconjugation. The spiro-splitting amounts to 1.23, 0.57, and 0.3 eV for **1**, 3,3′-spirobi[3*H*-indene] (**2**) and 9,9′-spirobi[9*H*-fluorene] (**3**), respectively,[6] showing that spiroconjugation is weakened by increasing benzoannelation which enhances the number of mesomeric structures of the "half compound."

In the present work, we would like to report the UV and ^{13}C NMR spectral data for spirocyclic orthocarbonates **4**—**6**, a spirobibenzodithiepin **7**, spirobinaphthopyran **8**, related spiran **9**, and their half compounds **4′**—**9′** to see the effect of spiroconjugation. Because of high electronegativity and consequent contraction of the 2p orbitals of the oxygen atoms, we expect a rather low through-space oxygen lone pair interaction. In such a case other mechanisms can be important. Conformational flexibility and/or rigidity may also affect the conjugation.

Results and Discussion

UV Spectra. Typical absorption spectra are given in Fig. 1. The data for the absorption maxima



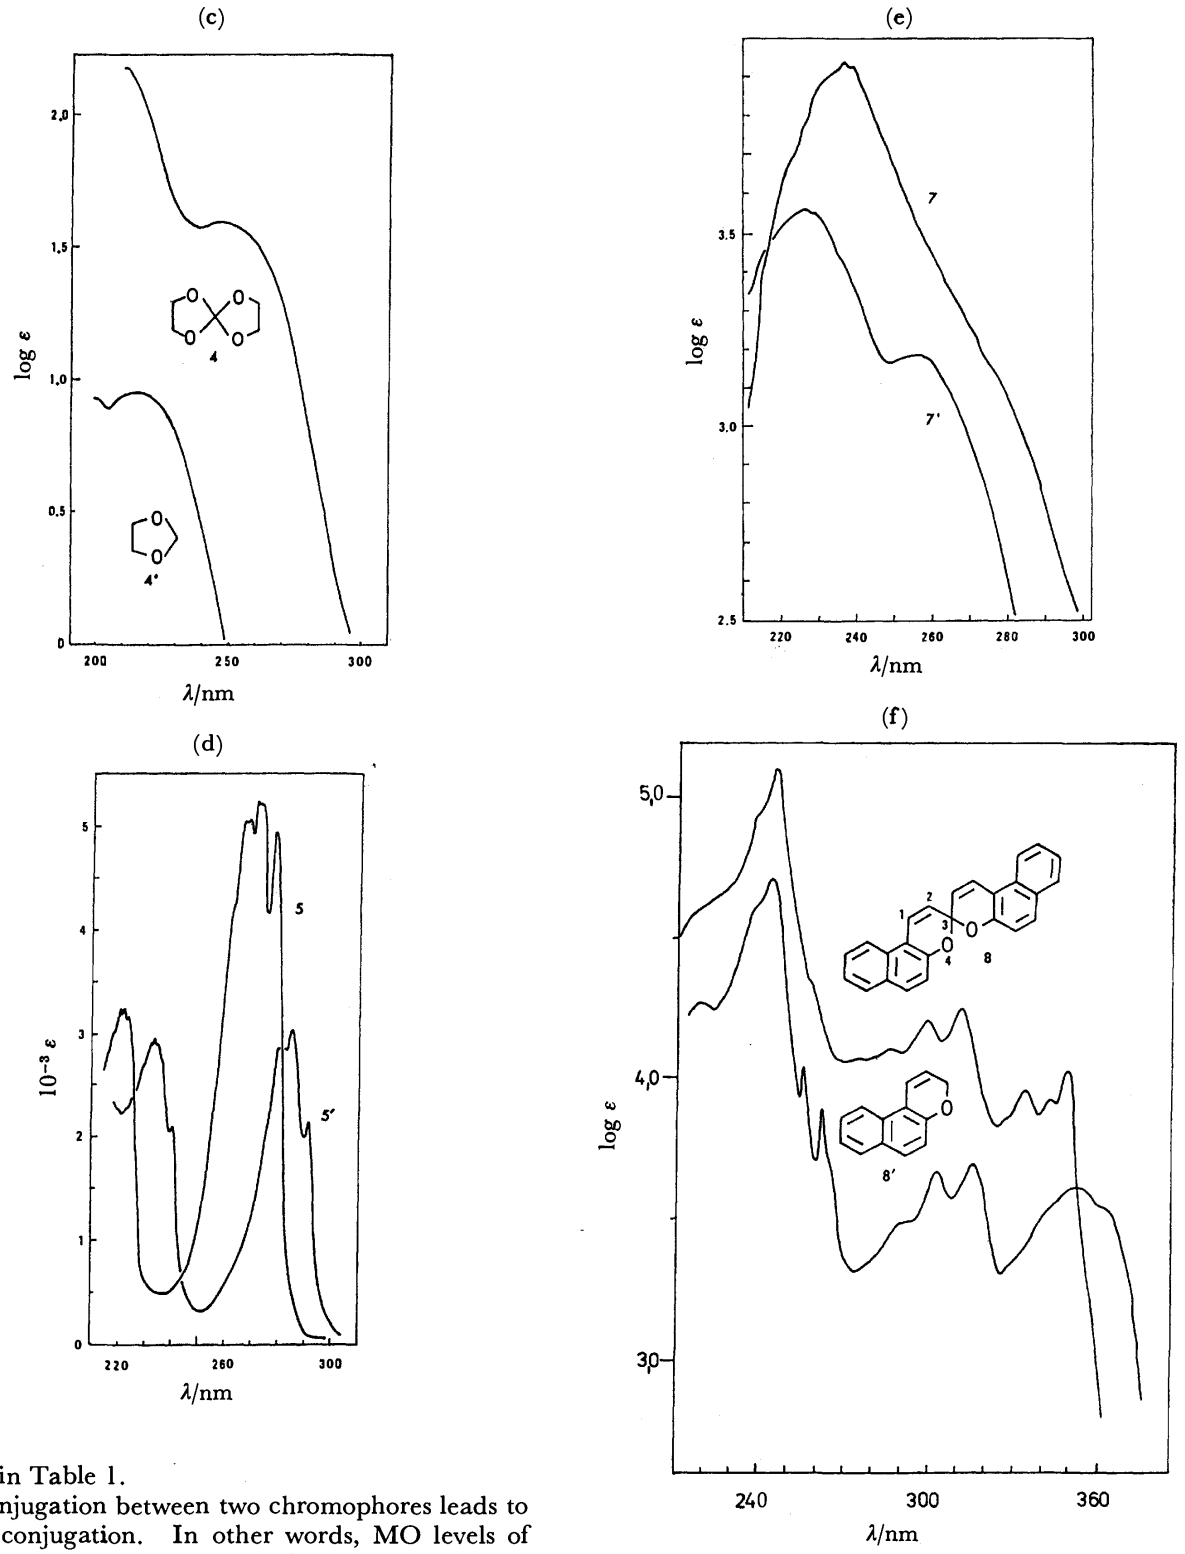


Fig. 1. UV absorption spectra of heteraspirans and their half compounds.

are listed in Table 1.

Spiroconjugation between two chromophores leads to extended conjugation. In other words, MO levels of each chromophore interact to split in energy and to make excitation of electrons more feasible. As a result, bathochromic shift of the UV absorption takes place. This is illustrated by the absorptions of **1** and **2**. There appears to be no exception to this rule for spiroconjugation through carbon $2p\pi$ orbitals. Whereas **4** and **4'** are not the π-system and it is not clearly defined whether the excited state pertinent to the UV absorption should be $n\rightarrow\sigma^*$ or the Rydberg state,[7] they show the spectral pattern similar to those of **1** and **1'** with the exception that the long-wavelength band in **4** has greater intensity than the corresponding band in **4'**. The difference in absorption maxima ($\Delta\lambda=32$ nm$\approx$0.75 eV) approximates the spiro-splitting of 0.55 eV obtained by PE spectroscopy.[8]

2,2'-Spirobi[1,3-benzodioxole] (**5**) provides an excep-

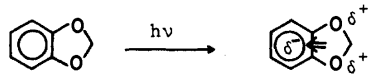
tion. We have encountered for the first time an example in which hypso- and hypochromic effects are observed in the spiroconjugative system relative to the half moiety. The phenomenon is most reasonably explained in terms of inhibition by spiroconjugation of the local charge-transfer absorption from the oxygen lone pair to the benzene ring.



The $^1B_{2u}\leftarrow{}^1A_{1g}$ transition in benzene is forbidden and is observed only because of vibrational interaction. In the case of substituted compounds, the corresponding band is no longer strictly forbidden. When two oxygen atoms are introduced to the ring, the inductive effect affects the ground and excited states about equally and in the same direction. However, the lone pair of electrons on the two oxygen atoms interact with the π-electrons of the benzene ring to give a total of ten electrons on the eight center system. As a consequence of this delocalization, the energy of the highest occupied orbitals rich in the lone pair character is raised and the lowest unoccupied orbitals are affected only to a minor extent. The low-intensity band at 260 nm as well as the 203 nm high-intensity band is shifted to the red. The red shift is greater for the substituent in which the lone pair participation is enhanced by some electron release effect. This is exactly what is observed as we go from anisole (λ_{max}=217 (log ε 3.81) and 269 nm (log ε 3.17) in methanol) to 1,3-benzodioxole (**5′**) (see Table 1). On the other hand, the larger the electronegativity which is directly related to the ionization potential, the more difficult it is to remove an electron. The migration of charge distorts the symmetry responsible for the forbiddenness of the $^1B_{2u}\leftarrow{}^1A_{1g}$ transition of benzene and removes some of the forbiddenness. The absorption intensifies. The greater the migration of charge, the greater the intensification.

With the above generalization of the benzenoid absorption in mind, the observed hypo- and hypsochromic effects for **5** are concluded to be due to the diminution of the ease of electron release from the moiety as compared to . The interpretation is supported by the observed PE spectral data for **5** and **5′**.[9] We note that the HOMO of **5** which is rich in the lone pair orbitals is stabilized relative to that of **5′** by 0.27 eV. There are at least two *a priori* mechanisms possible for the spiroconjugative interaction in orthocarbonates. One is through-space interaction which usually leads to repulsion of the non-bonding orbitals or reduction of ionization potential of the oxygen lone pair,[10] the trend which is not compatible with our observation (see Fig. 2). Second is through-bond interaction in which polar C–O bonds take part.[9] Since a pair of the C–O bonds in one half of the molecule are in the plane perpendicular to the other half in **5**, the skeleton with D_{2d} symmetry is quite adequate for the through-bond interaction. If the lone pair orbitals interact with the high-lying C–O bonding orbital, destabilization of the former would take place. The effect is similar to the through-space lone pair-lone pair interaction. It is the interaction of the lone pair orbitals

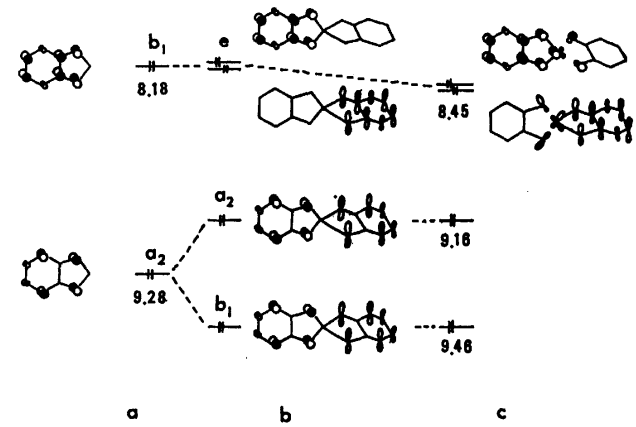


Fig. 2. Schematic correlation diagram for the higher occupied orbitals of **5** and **5′**. Stage (a): b_1 and a_2 orbitals of **5′** with C_{2v} symmetry obtained by mixing of the symmetric and antisymmetric combinations of the lone pair orbitals of 1,3-dioxolane with the HOMO's of benzene. Stage (b): the MO with a_2 symmetry of **5′** (and not the b_1 MO) splits into a_2 and b_1 orbitals as a result of through-space interaction in **5** (D_{2d} symmetry). Stage (c): throug.-bond interaction with the C–O σ^* orbitals of the other half of the 1,3-benzodioxole moiety stabilizes the e orbital (no such effect for a_2 and b_1 orbitals). The numbers are from ionization potential values in the literature.

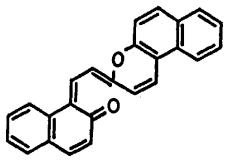
with the low-lying C–O anti-bonding orbitals which should be responsible for the stabilization of the HOMO of **5** with e symmetry relative to the b_1 orbital of **5'**, and for the observed hypo- and hypsochromic effects in the UV absorptions of **5** and **5'**.

The interaction of the lone pair of electrons with the anti-bonding orbital of the neighboring polar bonds is exactly what is currently adopted for the origin of the anomeric effect in carbohydrate chemistry.[11] The interpretation is also supported by a rather short C_{spiro}–O bond length of 1.38 Å in **5** as compared to the normal value of 1.43 Å.[12]

A pair of 3,3'-spirobi[3*H*-naphtho[2,1-*b*]pyran] (**8**) and 3*H*-naphtho[2,1-*b*]pyran (**8'**) provide an intermediate case where hypsochromic shift is observed only for the long-wavelength band. Through-bond interaction between the carbon 2pπ orbitals and the C–O anti-bonding orbitals would make the C–O single bond weaker and vulnerable to cleavage on heating.[13] As a result, compound **8** shows characteristic thermochromism attributable to reversible formation of **10**.



(10)

The spectrum of **7** somewhat resembles that of 1,5,7,11-tetrathiaspiro[5.5]undecane[14] in both bathochromic shift and hyperchromic effect as compared to the half compound. The transition giving rise to the absorption at 274 and 292 nm is considered to arise from an excitation of a non-bonding electron of a sulfur atom to a molecular orbital formed by overlap of d-orbitals on the four sulfur atoms. Let us take the d_{z^2} atomic orbitals, for example, as forming such a molecular orbital. These combine to give a pair of bonding and anti-bonding levels. The former splits further into two levels b_2 and a_1 after spiroconjugative interaction of one ring with another (see Fig. 3). Thus the bathochromic shift can be taken as a measure of the splitting due to spiroconjugation. The splitting amounts to 0.28 eV for **7** and 0.37 eV for the tetrathiaspiroundecane.[14]

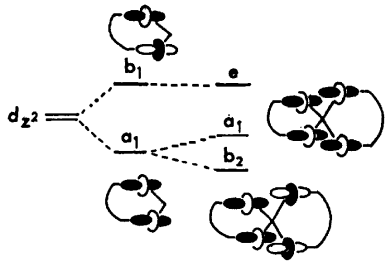


Fig. 3. Splitting of the vacant MO's due to through-space interaction of the d_{z^2} atomic orbitals of four sulfur atoms in orthothiocarbonates. Note that, in contrast to p orbitals where less stable a_2 orbitals are split by spiroconjugation, splitting of more stable a_1 orbitals in the C_{2v} moiety takes place for a combination of d_{z^2} orbitals.

^{13}C NMR Spectra. The proton-noise-decoupled ^{13}C NMR spectra were obtained at 20.1 and/or 25.0 MHz and the data are collected in Table 2. The signal due to the spirocarbons is among the most difficult to measure by the pulsed FT technique owing to their slow spin-lattice relaxation. Spin-lattice relaxation of ^{13}C nuclei in typical organic molecules is practically dominated by dipolar interaction with the near-by proton spins within the molecule. The spirocarbon of **5** which is four bonds apart from the nearest hydrogens thus resisted our effort to detect the signal under the standard pulsed FT measurement conditions of the pulse repetition time as long as 15 s. The difficulty was not overcome by addition of a few mg of a typical relaxation reagent such as $Cr(acac)_2$. The signal was finally obtained by adding a trace of cupper nitrate trihydrate in an acetone solution.[15] In Table 2 are also given differences in chemical shifts on going from the half compounds to the corresponding spiro compounds. The minus sign indicates the upfield shift of the latter signals relative to the former.

Examination of the data in Table 2 shows several trends. First of all, downfield shift of the spirocarbons is most conspicuous. The size of this shifts is 20—40 ppm for orthocarbonates **4**—**6** and ethyl orthocarbonate (**11**), 6—53 ppm for the spirocarbons attached to four carbon atoms, and 66 ppm for orthothiocarbonate **7**. Secondly, the spirocarbon chemical shifts for the orthocarbonates fall in two regions: 20—25 ppm for the conformationally flexible compounds and *ca.* 40 ppm for the rigid tetraoxaspiro[4.4] systems. For a third, upfield shifts up to 5 ppm are observed for the non-spirocarbons attached to oxygens on going from the reference to spiro compounds.

Chemical shifts of ^{13}C nuclei have been shown to be governed by local paramagnetic screening which arises from contributions of higher electronic states to the description of the ground state in the magnetic field. The screening increases as the mean inverse cube of the radius of the 2p orbitals on the carbon atom increases or effective excitation energy of the electron at the carbon decreases.[16] The observed downfield shifts of the central carbons as we go from the acetal (bonded to two oxygens) to the orthocarbonate (bonded to four oxygens) are ascribed to contraction of the radius of the carbon 2p orbitals by bonding to the increased number of the electronegative oxygen atoms. The larger paramagnetic shift in rigid **4** and **5** may be interpreted in terms of two effects; the synergic σ-bond polarization towards oxygen and the steric γ-effect. As described in the discussion of the UV spectra, the lone pair of electrons are donated to the adjacent σ^* orbitals of the C–O bonds. Synergic to this flow of electrons from oxygen to carbon, the C–O bonding orbital, *i.e.*, σ-bonds will tend to polarize more towards oxygen atoms. As a result, contraction of the radius of the spirocarbon 2p orbitals may take place to effect stronger paramagnetic screening of the central spirocarbons. The effect is more pronounced in conformationally rigid **4** and **5** where the lone pair orbitals of the oxygens on one ring and the σ^* orbitals of the C–O bonds on the other ring are

better aligned. Secondly and perhaps less importantly, there is an additional γ-carbon atom gauche to the spirocarbons introduced as we go from **6′** to **6**. As a result, the stereospecific γ-effect will operate to move the signal due to the spirocarbon somewhat upfield.[17] The same effect may also be operative in the conformationally flexible **11**.

One of the largest downfield shifts ever observed for the spirocarbon is 66.3 ppm in 1,1′,5,5′-tetrahydro-3,3′-spirobi[2,4-benzodithiepin] (**7**). As discussed in the section of its UV absorption, the low-lying d-orbitals are presumably contributing to the low-energy excited states for the 2p electrons of the spirocarbon to be mixed with the ground state.

Dowinfield shift of 53.3 ppm on going from fluorene to **3** may be compared with the shift difference of 23.3 ppm between diphenylmethane and tetraphenylmethane. Here again diminution of effective excitation energy of the carbon 2p electrons is considered to be responsible for the larger paramagnetic screening.

In conclusion, spiroconjugation in heteraspirans is reflected in their characteristic UV and ^{13}C NMR spectra. The spectral changes due to the spiroconjugation in these compounds are often different from those of spirohydrocarbons and are interpreted mainly in terms of the through-bond $n \rightarrow \sigma^*$ interaction.

Experimental

Materials. The previously described procedures were employed to prepare 2,2′-spirobi[1,3-dioxolane](**4**),[18] 2,2′-spirobi[1,3-benzodioxole](**5**),[19] 2,2′-spirobi[1,3-dioxane] (**6**),[20] (**6**),[20] 1,1′,5,5′-tetrahydro-3,3′-spirobi[2,4-benzodithiepin] (**7**),[21] 1,5-dihydro-2,4-benzodithiepin (**7′**),[22] 3,3′-spirobi[3*H*-naphtho[2,1-*b*]pyran] (**8**),[23] 3*H*-naphtho[2,1-*b*]pyran (**8′**),[24] and 5,5′-spirobi[1,3-dioxane] (**9**).[25] Purity of the samples for spectral studies was confirmed by their ^1H NMR spectra and VPC.

Spectra. The UV absorption spectra were taken from hexane solutions, unless otherwise stated, at 25 °C with a UNICAM SP-1800 and a Cary 17 spectrophotometer. Compounds **7** and **7′** were measured in dioxane and their absorption maxima were obtained by resolving the observed curve by using the program BANDF run on a Cyber 72 computer.

^{13}C NMR spectra were recorded on a JEOL FX-100 spectrometer operating at 25 MHz in the pulsed FT mode. A radiofrequency pulse of width 6 μs (45°) was generally employed with the repetition time of *ca.* 10 s. For Fourier transformation, 8 K spectral data points were available for spectral width 4000 Hz. Samples were *ca.* 10% solutions in $CDCl_3$ unless otherwise stated. Only a few mg samples of **7** and **8** were soluble in $CDCl_3$. The chemical shift due to the spirocarbon of **5** was obtained for the solution of 10 mg of **5** and 1 mg of $Cu(NO_3)_2 \cdot 3\,H_2O$ in 0.35 ml of acetone-d_6 with TMS as an internal standard.

We are grateful to Professor Tadashi Suehiro of Gakushuin University for his kindness in furnishing us with a sample of tetraphenylmethane.

Photoinduced Intramolecular Substitution. II.[1,2] Absence of *meta*-Favoring Effect in Nucleophilic Photosubstitution of Nitroveratrole Derivatives

Kiyoshi MUTAI,* Kenji YOKOYAMA,† Sei-ichiro KANNO, and Keiji KOBAYASHI

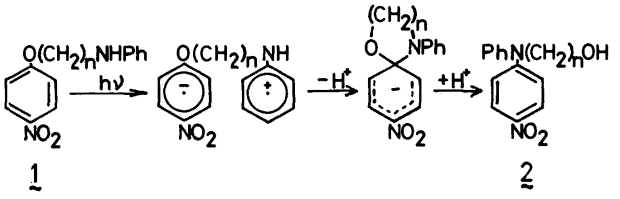
Department of Chemistry, College of General Education, The University of Tokyo, Komaba, Meguro-ku, Tokyo 153

†*The Institute of Physical and Chemical Research, Wako, Saitama 351*

(Received June 2, 1981)

Possible occurrence of the photo-Smiles rearrangement accompanying *meta*-favoring nucleophilic aromatic substitution was examined in a homologous series of 1-(2-methoxy-4-nitrophenoxy)-ω-anilinoalkanes. The structure of reaction products, the reaction kinetics, and absorption spectra of intermediates showed no appreciable alteration of reaction pathway by the introduction of 2-methoxyl group. The photoreaction was exclusively a *para*-directing nucleophilic substitution.

In the previous papers[1,3] we have reported the photo-Smiles rearrangement (intramolecular nucleophilic aromatic substitution) of **1**, along with the reaction mechanism involving a radical ion pair and a *spiro*-type Meisenheimer complex, both ascertained by laser flash photolysis (Scheme 1).

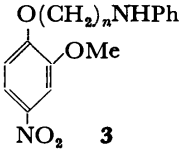


Scheme 1.

The product **2** is also obtained by a catalytic action of strong base such as sodium hydride or sodium ethoxide in DMF. Thus, both the photoinduced and thermal reactions (the Smiles rearrangement) of **1** afford the same product.

On the other hand, intermolecular photoreaction of nitroanisoles and nitroveratrole (3,4-dimethoxynitrobenzene) with nucleophiles shows preference of *meta*- to *para*-substitution.[4,5]

It is worthy of note that the *meta*-orientation observed in the intermolecular photoreactions is not exclusive in contrast with the thermal nucleophilic reactions. Therefore, the coincidence of the product of the photorearrangement with that of the Smiles rearrangement may not be the result of the exclusive photoreaction, but merely due to the lack of an appropriate substituent at the position to undergo the replacement. In other words, the photoreaction of **1** may have several pathways available, the relative importance of which changes according to conditions provided. In this regard, it is interesting to see whether the *meta*-substitution takes place when a methoxyl group is introduced to the *meta* position of the nitro group. Methoxyl is known as a good leaving group in nucleophilic substitution reactions. The present paper is concerned with the photoreaction of the homologs of **3**.

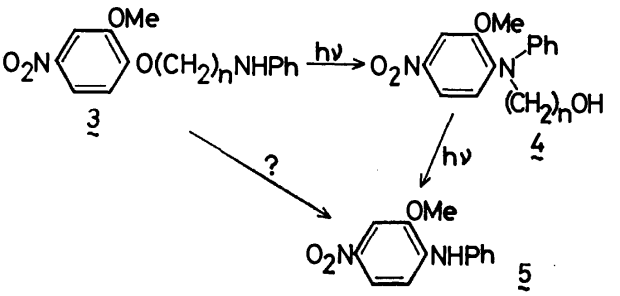


Results and Discussion

Irradiation of **3**. Irradiation of **3** was performed under the same conditions that were applied to **1**.[1] Nitroveratrole type chromophore has UV spectral peaks at *ca.* 300 and 340 nm, and irradiation with any one of 313-, 334-, and 366-nm lines of a high-pressure Hg lamp is plausibly effective for the reaction. However, filter isolation of the longer wavelength lines is accompanied by fairly strong reduction in their intensity, and these lines are also effective for further degradation of photoproducts. For these reasons, only the 313 nm line, isolated through an aqueous solution of $NiSO_4$ (1 cm in path-length), was adopted for the light source.

The photoreaction proceeded with development of yellow color in the solution. The coloration corresponded to the increase in the intensity at *ca.* 410 nm, accompanied by a concomitant decrease in the maxima in the 300—340 nm region in the UV-VIS spectrum. Structures of the products were assigned to **4** on the basis of elemental analysis as well as of the following spectral characteristics: their ^1H NMR spectra showed neither loss of methoxyl group nor remarkable change in the signal patterns of aromatic and polymethylene protons from those of **3**. Appearance of OH group was detected by NMR and IR spectroscopies. Additional evidence was the absorption peak around 410 nm, attributable to *p*-nitroaniline type chromophore.

The $n=2$ and $=3$ homologs dissolved in purified acetonitrile decomposed only to polymeric substances on irradiation, but addition of triethylamine accelerated the photorearrangement to give **4** in high yields. Addition of the amine was unnecessary for the reaction of the $n=4$ homolog. In this case, another nitroaniline derivative (**5**) was obtained as a by-product in a low



yield. The structure of **5** was confirmed by its ^1H NMR spectrum which showed loss of $(CH_2)_4OH$ group and appearance of a broad singlet at δ 6.75. The UV spectrum (λ_{max} at 401 nm in acetonitrile) and mass spectrum also supported the assignment. Since **5** was also obtained on irradiation of the rearranged product **4**, this compound is probably a secondary photolysis product, though direct formation from **3** cannot completely be eliminated.

Photorearrangement rates were obtained in acetonitrile in the absence and presence of triethylamine by the determination of time dependence of the absorption of **4**, and are summarized in Table 1.

Table 1. Relative initial rate constants (k_{rel}) of the photorearrangement of **3** in acetonitrile

	$\frac{Et_3N}{mol\ dm^{-3}}$	$n=2$	$n=3$	$n=4$
k^0_{rel}	0	*ca.* 0[a)]	*ca.* 0[a)]	4.0
k^{TEA}_{rel}	2.84×10^{-2}	4.4	0.9	1.0[b)]

a) A slight but steady increase in absorbance at 410 nm suggested occurrence of the rearrangement, but accompanying decomposition to unidentified polymeric subustances made it difficult to determine unambiguous values. b) k^{TEA}_{rel} ($n=4$) = 1.0.

From Table 1, it is evident that the reaction is catalyzed by base, especially in the lower homologs ($n=2$ and 3). Furthermore, these homologs scarcely showed reactivity in the absence of base, and only the

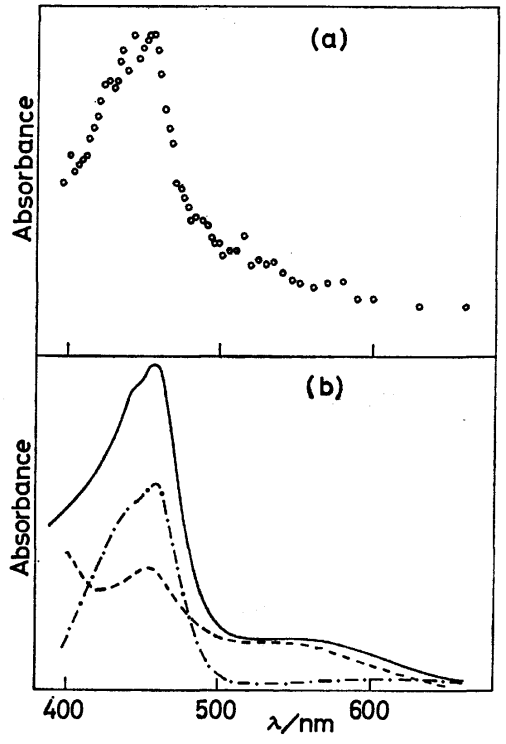


Fig. 1. (a) Transient absorption spectrum of **3** ($n=2$) in CH_3CN (10 ns after excitation). (b) Superposed spectrum (——) of nitroveratrole radical anion (------) and *N*-ethylaniline radical cation (-·-·-).

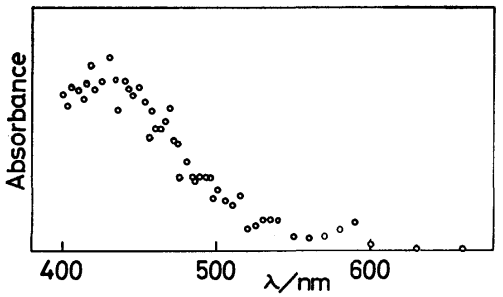

Fig. 2. Transient absorption spectrum of **3** ($n=2$) in CH_3CN–Et_3N (3 μs after excitation).

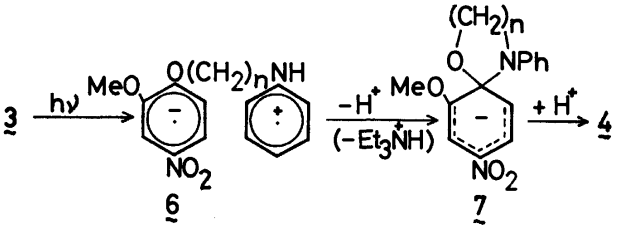
$n=4$ homolog gave a significant value. These characteristics are similar to those observed in **1**, implying a similar reaction mechanism in the present case.

Intermediates in the Photoreaction. In order to obtain evidence for this mechanism, transient spectra of the solution irradiated with an N_2 laser were observed. The spectra of the $n=2$ homolog observed in the presence of triethylamine at 10 ns and 3 μs after irradiation are reproduced in Figs. 1a and 2, respectively.

The transient species which gave the absorption curve shown in Fig. 1a has a lifetime of *ca.* 75 ns in acetonitrile and 35 ns in the same solvent containing triethylamine, though the spectra in both cases are comparable in shape and peak intensity. The species which gave the spectrum shown in Fig. 2 has a lifetime exceeding 200 μs with no remarkable peak, and its intensity is very low in the absence of triethylamine. These facts seem to suggest that a short-lifetime species formed immediately after the irradiation is converted into a long-lifetime one through a process facilitated by the base.

In all respects these characteristics coincide with the mechanism proposed for the photorearrangement of **1** (Scheme 1). If the same mechanism really works for **3**, the transient species with the shorter lifetime should be a radical ion pair produced by electron transfer from aniline to nitroveratrole moieties, and its spectrum should be a superposition of those of *N*-alkylaniline radical cation and nitroveratrole radical anion.[6] The supposed spectrum is shown in Fig. 1b. Though the peak position is somewhat different, probably due to the difference in the conditions adopted for measurement such as solvent and temperature, other spectral features are almost the same. Therefore, the short-lifetime intermediate is probably the radical ion pair **6**. The long-lived species then should be a *spiro*-type Meisenheimer complex depicted as **7**, but unfortunately any appropriate model anion to be compared has not been known. It may be argued that the spectrum in Fig. 2 is due to the absorption of the triplet state of



Scheme 2.

nitroveratrole chromophore. This T-T transition, however, was observed at 490 nm with a lifetime of *ca.* 250 ns in acetonitrile, which was reduced to 36 ns in an oxygen saturated solution. Thus the Meinsenheimer complex is a more plausible assignment. A supporting evidence for this is the increase in the intensity due to this species in the presence of triethylamine, since the formation of **7** is greatly facilitated by base (Scheme 2).

In conclusion, it can safely be said that the introduction of a methoxyl group to the *meta*-position of the nitro group has little effect on the reaction pathway of Scheme 1. Consequently the mechanism of the photoreaction of **3** could be written as in Scheme 2.

Experimental

^{1}H NMR spectra were recorded on JEOL-60HL (60 MHz) and MH-100 (100 MHz) spectrometers. The chemical shifts are in ppm with TMS as the internal standard. Electronic spectra were recorded on Hitachi EPS-3T and 100-50 spectrophotometers.

Kinetics of the Photoreaction. The rate constants were determined as described in the previous paper.[1] Acetonitrile (Wako, G. R. grade) used for the solvent was distilled from a mixture with phosphorus pentaoxide.

Transient Spectra Measurement. The absorption spectra of the transient species were determined as described previously.[3]

Materials. 2-Methoxy-4-nitrophenol was prepared by the procedure of Drake *et al.*[7]

1-(2-Methoxy-4-nitrophenoxy)-2-bromoethane: To a mixture of 8.40 g (50 mmol) of 2-methoxy-4-nitrophenol, 11.75 g (62.5 mmol) of dibromoethane, and 50 cm^3 of water, stirred and refluxed, was added 1.95 g (48.8 mmol) of sodium hydroxide in 10 cm^3 of water during 1.5 h, and reflux was further continued for 24 h. After cooling the reaction mixture, the organic layer was extracted with three portions of 20 cm^3 dichloromethane. The solvent was removed from the combined extracts, and a remaining solid mass was charged on a column packed with active alumina. Elution with benzene yielded 5.60 g (40%) of pale yellow crystals of mp 82—83 °C: NMR ($CDCl_3$) δ=3.77 (2H, t, J=6 Hz, CH_2Br), 4.03 (3H, s, OCH_3), 4.53 (2H, t, J=6 Hz, OCH_2), 7.13 (1H, d, J=9 Hz), 7.9 and 8.00 (2H, dd, J=9 and 3 Hz). Found: C, 39.31; H, 3.69; N, 5.21%. Calcd for $C_9H_{10}NO_4Br$: C, 39.15; H, 3.65; N, 5.07%.

1-(2-Methoxy-4-nitrophenoxy)-3-chloropropane: This compound was prepared from 2-methoxy-4-nitrophenol and 1,3-dichloropropane in the same method as was applied for the ethane derivative in 52% yield: mp 79—81 °C; NMR ($CDCl_3$) δ= 2.38 (2H, m, C-CH_2-C), 3.86 (2H, t, J=6 Hz, CH_2Cl), 4.01 (3H, s, OCH_3), 4.35 (2H, t, J=6 Hz, OCH_2), 7.10 (1H, d, J=9 Hz), 7.90 (1H, d, J=3 Hz), and 8.02 (1H, dd, J=9 and 3 Hz). Found: C, 49.02; H, 4.89; N, 5.76%. Calcd for $C_{10}H_{12}NO_4Cl$: C, 48.90; H, 4.92; N, 5.70%.

1-(2-Methoxy-4-nitrophenoxy)-4-bromobutane: This compound was prepared from 2-methoxy-4-nitrophenol and 1,4-dibromobutane in 38% yield: mp 51—52 °C; NMR ($CDCl_3$) δ= 2.01 (4H, m, C-CH_2CH_2-C), 3.71 (2H, t, J=6 Hz, CH_2Br), 4.01 (3H, s, OCH_3), 4.18 (2H, t, J=6 Hz, OCH_2), 7.09 (1H, d, J=9 Hz), 7.9 and 8.02 (2H, dd, J=9 and 3 Hz). Found: C, 43.59; H, 4.67; N, 4.63%. Calcd for $C_{11}H_{14}NO_4Br$: C, 43.44; H, 4.64; N, 4.61%.

Preparation of 1-(2-Methoxy-4-nitrophenoxy)-ω-anilinoalkanes (3): A mixture of the halide (30—50 mmol) and aniline (5 cm^3) was heated at 110 °C for 2 h. After cooling, the reaction mixture was neutralized with 10% aqueous sodium carbonate solution, and unreacted aniline removed by steam distillation. From the remaining liquid was isolated the desired aniline derivative by column chromatography (active alumina, with benzene as an eluent).

1-(2-Methoxy-4-nitrophenoxy)-2-anilinoethane (3, n=2): This compound was obtained in 64% yield as yellow crystals: mp 133—135 °C; UV_{max} (CH_3CN) 297 (ε 8100)and 340 nm (ε 8700); NMR (DMSO-d_6) δ=3.42 (1H, br s, NH), 3.58 (2H, t, J=5 Hz, CH_2N), 3.93 (3H, s, OCH_3), 4.33 (2H, t, J=5 Hz, OCH_2), and 6.7—8.2 (8H, m). Found: C, 62.75; H, 5.52; N, 9.61%. Calcd for $C_{15}H_{16}N_2O_4$: C, 62.49; H, 5.59; N, 9.72%.

1-(2-Methoxy-4-nitrophenoxy)-3-anilinopropane (3, n=3): This compound was obtained in 69% yield as yellow crystals: mp 99—100 °C; UV_{max} (CH_3CN) 298 (ε 8300) and 341 nm (ε 8900); NMR ($CDCl_3$) δ=2.20 (2H, m, C-CH_2-C), 3.43 (2H, t, J=6 Hz, CH_2N), *ca.* 4.0 (1H, br s, NH), 4.00 (3H, s, OCH_3), 4.29 (2H, t, J=6 Hz, OCH_2), 6.6—7.5 (6H, m), 7.87 (1H, d, J=3 Hz), and 8.00 (1H, dd, J=9 and 3 Hz). Found: C, 63.73; H, 6.21; N, 9.28%. Calcd for $C_{16}H_{18}N_2O_4$: C, 63.57; H, 6.00; N, 9.26%.

1-(2-Methoxy-4-nitrophenoxy)-4-anilinobutane (3, n=4): This compound was obtained in 40% yield as yellow crystals: mp 94—95 °C; UV_{max} (CH_3CN) 297 (ε 8600) and 341 nm (ε 9200); NMR ($CDCl_3$) δ=*ca.* 1.9 (4H, m, C-CH_2CH_2-C), 3.28 (2H, t, J=6 Hz, CH_2N), 3.83 (1H, br s, NH), 3.98 (3H, s, OCH_3), 4.20 (2H, t, J=6 Hz, OCH_2), 6.7—7.5 (5H, m), 7.89 (1H, d, J=3 Hz), and 8.03 (1H, dd, J=9 and 3 Hz). Found: C, 64.79; H, 6.67; N, 8.90%. Calcd for $C_{17}H_{20}N_2O_4$: C, 64.54; H, 6.37; N, 8.85%.

N-*(2-Methoxy-4-nitrophenyl)-2-anilinoethanol (4, n=2)*: A solution of 12 mg (0.042 mmol) of **3** (n=2) in 200 cm^3 of acetonitrile containing 1 cm^3 of triethylamine was irradiated with a 100-W high-pressure Hg lamp through an aqueous $NiSO_4$ filter under N_2 for 1.5 h. The process was repeated five times. After removing the solvent and amine from the combined solution, the residue was charged on a slica-gel column, and **4** (n=2) was separated by chromatography using benzene–dichlromethane mixture. The alcohol was obtained in 83% (50 mg) as a viscous dark red liquid: UV_{max} (CH_3CN) 256 (ε 11100) and 411 nm (ε 9000); NMR ($CDCl_3$) δ=2.4 (1H, br s, OH), *ca.* 3.95 (4H, m, NCH_2CH_2O), 3.90 (3H, s, OCH_3), 6.8—7.55 (6H, m), and 7.9—8.15 (2H, m). Found: C, 62.71; H, 5.65; N, 9.57%. Calcd for $C_{15}H_{16}N_2O_4$: C, 62.49; H, 5.59; N, 9.72%.

N-*(2-Methoxy-4-nitrophenyl)-3-anilino-1-propanol (4, n=3)*: This compound was obtained by the same procedure as has been described for the n=2 homolog in 86% isolated yield as a viscous dark red liquid: UV_{max} (CH_3CN) 256 (ε 11100) and 413 nm (ε 9500); NMR ($CDCl_3$) δ=1.86 (2H, m, C-CH_2-C), 2.77 (1H, br s, OH), 3.73 (2H, t, J=6 Hz, CH_2N), 3.80 (3H, s, OCH_3), 3.84 (2H, t, J=6 Hz, OCH_2), 6.7—7.4 (6H, m), and 7.7—7.9 (2H, m). Found: C, 63.81; H, 6.16; N, 9.12%. Calcd for $C_{16}H_{18}N_2O_4$: C, 63.57; H, 6.00; N, 9.26%.

N-*(2-Methoxy-4-nitrophenyl)-4-anilino-1-butanol (4, n=4)*: A solution of 500 mg (1.58 mmol) of **3** (n=4) in 800 cm^3 of acetonitrile was irradiated with a 100-W high-pressure Hg lamp through an aqueous $NiSO_4$ filter under N_2 for 7.5 h. After removing the solvent, the remaining mass was charged on silica gel and eluted with benzene and benzene–dichloromethane mixture. The alcohol (460 mg, 92%) was obtained as a viscous dark red liquid: UV_{max} (CH_3CN) 255 (ε 11200) and 414 nm (ε 9600); NMR ($CDCl_3$) δ=*ca.* 1.65 (5H, m, C-CH_2CH_2-C+OH), 3.5—4.0 (4H, m, CH_2N+OCH_2), 3.79 (3H, s, OCH_3), 6.8—7.4 (6H, m), and 7.7—8.0 (2H, m).

Found: C, 64.66; H, 6.45; N, 8.78%. Calcd for $C_{17}H_{20}N_2O_4$: C, 64.54; H, 6.37; N, 8.85%.

2-Methoxy-4-nitro-N-*phenylaniline* (**5**): This compound was obtained as a first eluate by the chromatograph for the separation of **4** (n=4) described above in 7% yield: yellow crystals, mp 77—78 °C; UV_{max} (95% EtOH) 251 (ε 9900) and 403 nm (ε 17600); NMR ($CDCl_3$) δ=4.01 (3H, s, OCH_3), 6.75 (1H, br s, NH), and 6.9—8.0 (8H, m); MS (70 eV), m/e, 244 (M^+), 229 (M^+-15), 198 (M^+-NO_2), 154, and 148. Found: C, 63.84; H, 4.98; N, 11.63%. Calcd for $C_{13}H_{12}N_2O_3$: C, 63.92; H, 4.95; N, 11.47%.

Photolysis of **4** (n=4) *for the Preparation of* **5**: A solution of 23 mg (0.073 mmol) of the alcohol **4** (n=4) in 240 cm^3 of acetonitrile was irradiated with a 100-W Hg lamp through a Pyrex filter for 6 h. After removing the solvent *in vacuo*, the residue was extracted with three 2-cm^3 portions of chloroform. From the combined extracts, the solvent was distilled off, and the remaining mass was charged on a silica-gel column, eluted with benzene–dichloromethane (1 : 1) mixture. The product **5** was obtained (4.5 mg, 23% yield) as a first eluate, followed by 13 mg of the unreacted starting material.

The authors are grateful to Professor Tadamasa Shida, Kyoto University for providing them with the spectra of the radical ions, and to Professor Saburo Nagakura, Institute for Molecular Science, for his interest and encouragement.

The Transition Metal-catalyzed *N*-Alkylation and *N*-Heterocyclization. A Reductive Transformation of Nitroarenes into (Dialkylamino)-arenes and 2,3-Dialkyl-substituted Quinolines Using Aliphatic Aldehydes under Carbon Monoxide

Yoshihisa WATANABE,* Naoki SUZUKI, Yasushi TSUJI, Sang Chul SHIM, and Take-aki MITSUDO
Department of Hydrocarbon Chemistry, Kyoto University, Sakyo-ku, Kyoto 606

(Received June 5, 1981)

The catalytic *N*-alkylation and *N*-heterocyclization of nitroarenes occur at 180 °C under a carbon monoxide pressure of 70 atm and in the presence of aldehyde and such transitionmetal complexes as rhodium and palladium complexes, thus giving 2,3-dialkyl-substituted quinolines and (dialkylamino)arenes in good yields. The product selectivity depends greatly on the catalysts: a binary catalyst, $RhCl(PPh_3)_3$ and $PdCl_2$, is effective for the *N*-heterocyclization, while $[Rh_2Cl_2(cod)_2]$ is effective for the *N*-alkylation.

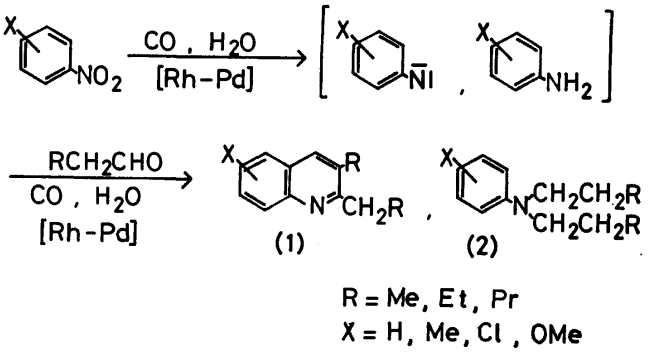
The reduction of nitroarenes by carbon monoxide using rhodium, palladium, and selenium compounds as catalysts has been of much interest recently.[1] Nitroarenes can be converted into a wide variety of useful *N*-containing compounds, such as aminoarenes,[1a] diarylureas,[1b] aryl isocyanates,[1c] alkyl carbanilates,[1d] and *N*-arylbenzamides.[1e]

On the other hand, during the course of our study of the rhodium-catalyzed *N*-alkylation of amines by means of a carbon monoxide–water system,[2] we found that a rhodium complex is an efficient catalyst for the *N*-heterocyclization, the preparation of quinolines from aminoarenes and aliphatic aldehydes under non-acidic conditions.[3]

Ortho-substituted nitroarenes such as *o*-nitrocinnamaldehyde can also be converted into quinolines by means of an intramolecular cyclization using tetracarbonylferrate(0).[4]

More recently, we also found that nitrobenzene was selectively transformed into substituted quinolines and *N,N*-dialkylanilines by the rhodium- and/or palladium-catalyzed reduction with carbon monoxide in the presence of an aldehyde.[5]

In this paper a detailed study of the reductive transformation of nitroarenes catalyzed by transition-metal complexes to quinolines and aminoarenes will be described.



Scheme 1.

Results and Discussion

Effects of Rhodium Complexes as Catalysts. Nitrobenzene combined with butanal in this procedure gave 3-ethyl-2-propylquinoline (**1**) or *N,N*-dibutylaniline (**2**). This combination for the preparation of **1** and **2** was examined in some detail in order to determine the optimum conditions for *N*-heterocyclization and *N*-alkylation.

A variety of rhodium complexes was examined as catalysts; the results are shown in Table 1.

TABLE 1. EFFECTS OF RHODIUM COMPLEXES AS CATALYSTS[a]

Run No.	Rh complexes[b]	Conversion[c] %	Product yield %[c,d] 1	2
1	$RhCl(PPh_3)_3$	51	11	0
2	$RhH(CO)(PPh_3)_3$	50	11	0
3	$RhCl(CO)(PPh_3)_2$	44	10	0

a) A mixture of nitrobenzene (40 mmol), butanal (90 mmol), water (2 ml), rhodium complex (0.09 mmol), and ethanol (20 ml) was treated at 180 °C under pressures of carbon monoxide (70 atm) for 4 h. b) [Rh] =0.09 mmol c) Based on the amount of nitrobenzene used. Determined by GLC. d) **1**: 3-Ethyl-2-propylquinoline, **2**: *N,N*-dibutylaniline. e) The reaction time, 8 h.

The products depended greatly on the catalysts. Chlorotris(triphenylphosphine)rhodium(I), (carbonyl)(hydrido)tris(triphenylphosphine)rhodium(I), and (carbonyl)chlorobis (triphenylphosphine)rhodium(I) gave **1** exclusively, while di-μ-chloro-bis[(cyclooctadiene)rhodium(I)], $[Rh_2Cl_2(cod)_2]$, di-μ-chloro-bis[(norbornadiene)rhodium(I)], $[Rh_2Cl_2(nbd)_2]$, dodeca(carbonyl) tetrarhodium(0), and tetra(carbonyl)dichlorodirhodium(I) favored the formation of **2**. Rhodium(III) chloride and hexadeca(carbonyl)hexarhodium(0) gave a mixture of **1** and **2**. The yields of **2** were improved by prolonging the reaction time to 8 h, while the yields of **1** were not. Only trace amounts *N*-butylaniline and aniline were detected as by-products. The reac-

tion by the use of $RhCl(PPh_3)_3$ gave a poor yield and selectivity of **1**. We can suggest two reasons for this. One is that butanal might be reduced to alcohol or suffer condensation to give the unreactive high-molecular-weight species by self-condensation or reaction with nitrobenzene. The other is that nitrobenzene might be reduced and transformed into urea or carbamate.[1] This situation is not yet clear.

Effects of Phosphine and Phosphite Ligands. The product selectivity of the rhodium catalysts appears to be highly affected by the triphenylphosphine coordination. The rhodium complexes with triphenylphosphine as a ligand are favorable for **1**, while $[Rh_2Cl_2(cod)_2]$ is favorable for **2**. Therefore, a combination of several phosphines and phosphite with $[Rh_2Cl_2(cod)_2]$ was tested in the reaction. The results are summarized in Table 2.

When 3 molar equivalents of triphenylphosphine, bis(diphenylphosphino)methane, 1,2-bis(diphenylphosphino)ethane, and 1,3-bis(diphenylphosphino)propane were added to $[Rh_2Cl_2(cod)_2]$, the product selectivity was dramatically changed to **1** from **2**. However, in the case of triphenyl phosphite, trimethyl phosphite, and triethyl phosphite, the product selectivity was not changed. Tributylphosphine combined with $[Rh_2Cl_2(cod)_2]$ showed a unique reactivity. The conversion of nitrobenzene was very high, and *N*-(2-ethylhexylidene)aniline (**3**) was isolated in a 36% yield.

Table 2. Effects of phosphine and phosphite ligands[a]

Run No.	Ligands	Conversion[b] %	Product yield/%[b,c] 1	2

a) A mixture of nitrobenzene (40 mmol), butanal (90 mmol), water (2 ml), $[Rh_2Cl_2(cod)_2]$ (0.09 mmol), phosphine or phosphite (P/Rh=3), and ethanol (20 ml) was treated at 180 °C under pressures of carbon monoxide (70 atm) for 4 h. b) Based on the amount of nitrobenzene used. Determined by GLC. c) **1**: 3-Ethyl-2-propylquinoline, **2**: *N,N*-dibutylaniline. d) *N*-(2-Ethylhexylidene)aniline (**3**) was isolated in a 36% yield.

Effects of a Binary Catalyst. A binary catalyst, $RhCl(PPh_3)_3$ and palladium(II) chloride, $PdCl_2$, was examined for the preparation of **1**. Several reports have demonstrated that palladium complexes are effective for the reduction of nitrobenzene.[6] Some typical results are listed in Table 3.

The catalytic activity and product selectivity were highly improved by using the binary catalyst. The combination of 0.17 mmol of $RhCl(PPh_3)_3$ and 0.26 mmol of $PdCl_2$ gave an excellent conversion and a fairly good yield of quinolines **1**. The selectivity of **1** amounted to more than 70% (Run 23). $PdCl_2(PhCN)_2$ can also be used for this reaction. On the other hand, the combination of $[Rh_2Cl_2(cod)_2]$ and $PdCl_2$ improved conversion to 100%, but gave a mixture of **1** and **2** with a poorer selectivity.

A palladium species is liable to form an ortho-metallated complex.[7] Therefore, in this study the palladium catalyst may work in activation of the ortho carbon–hydrogen bond.

The Application to a Variety of Nitroarenes and Aldehydes. This produce using butanal can be applied to a variety of nitroarenes for the preparation of 2,3-dialkyl-substituted quinolines and (dialkylamino)arenes. A binary catalyst, $RhCl(PPh_3)_3$ (0.17 mmol) and $PdCl_2$ (0.26 mmol), is effective for the formation of **1** derivatives, while $[Rh_2Cl_2(cod)_2]$ (0.17 mmol) is effective for the formation of **2** derivatives. The results of *o*- and *p*-substituted nitrobenzenes including methyl, methoxyl, and chloro groups are summarized in Tables 4 and 5.

p-Methyl- and *p*-chloronitrobenzene reacted with butanal to give the corresponding 2,3,6-trisubstituted quinolines or *N,N*-dibutylaniline derivatives in fairly good isolated yields. *p*-Nitroanisole, however, gave the products in poor yields, indicating that the methoxyl group located at the para position has an inhibitory

Table 3. The reaction by a binary catalyst[a]

Run No.	Catalyst	Conversion[b] %	Product yield/%[b,c] 1	2

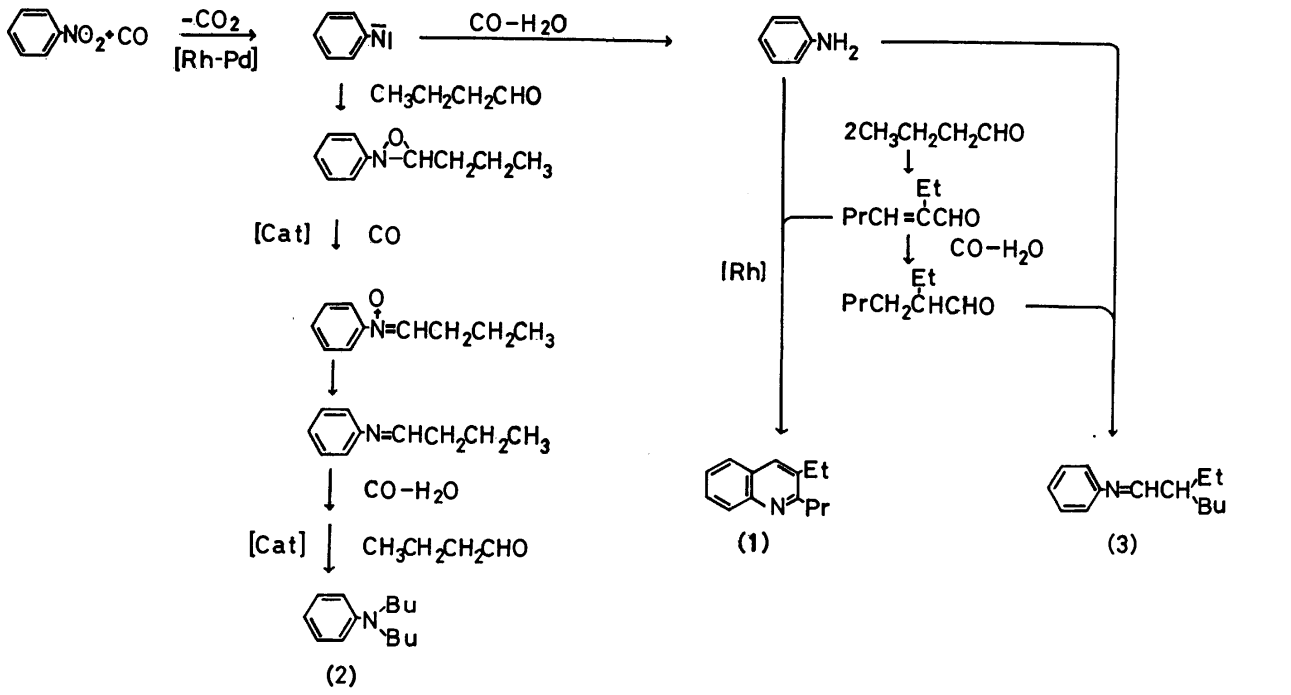
a) A mixture of nitroarene (40 mmol), aldehyde (90 mmol), water (2 ml), $[Rh_2Cl_2(cod)_2]$ (0.17 mmol), and ethanol (20 ml) was treated at 180 °C under pressures of carbon monoxide (70 atm) for 4 h. b) Isolated yield based on the amount of nitroarene used.

effect on the reaction. With *p*-nitroanisole, the *N*-(2-ethylhexylidene)aniline derivative was also given as a product. *o*-Methylnitrobenzene had a moderate reactivity to give the corresponding products. *o*-Chloronitrobenzene gave the corresponding 2,3,6-trisubstituted quinoline in moderate yields, but it gave *N*-butyl-2-chloroaniline in good yields. The reaction appeared to stop in the step of *N*-monoalkylation, so *N*,*N*-dibutyl-2-chloroaniline was not formed at all. The combination of *o*-nitroanisole with butanal almost failed to give the corresponding products.

This procedure is also applicable to a variety of aldehydes with two α-hydrogens. The combination of nitrobenzene with propanal gave 2-ethyl-3-methylquinoline and *N*,*N*-dipropylaniline in fairly good yields. Pentanal also gave 2-butyl-3-propylquinoline and *N*,*N*-dipentylaniline. In contrast to propanal, butanal, and pentanal, such aldehydes as isobutyraldehyde and benzaldehyde failed to give *N*-heterocyclization products, but did give *N*,*N*-dialkylaniline in poor yields.

Mechanism for the Reactions. The mechanism of the rhodium-catalyzed synthesis of quinolines[3] and (dialkylamino)arenes is not yet clear. An attempt to prepare **2** directly from aniline and butanal was unsuccessful. The rhodium-, even $[Rh_2Cl_2(cod)_2]$, catalyzed reaction between aniline and butanal gives **1** in excellent yields.[3] Thus, the formation pathways are probably different between **1** and **2**. For the formation of **1**, nitrobenzene would be reduced to aniline by the carbon monoxide–water system.[8] The addition of aniline to the aldol condensate, α,β-unsaturated aldehyde, might occur, followed by ring closure with dehydration to form 1,2-dihydroquinoline, which would then be oxidized by nitrobenzene to form **1**. If the aldol condensates, α,β-unsaturated aldehydes, were reduced to saturated aldehyde before the Michael addition, the product **3** would be formed from aniline and the aldehyde. The fact that aldehyde with two α-hydrogens shows a great tendency toward aldol condensation under the conditions used, 200 °C in the presence of a base,[9] suggests that α,β-unsaturated aldehyde is also one of the key intermediates in this reaction, as the case of the Doebner-von-Miller reaction.[10] With the formation of **2**, we believe that the first step involves a catalytic deoxygenation of nitrobenzene to a nitrene, whose subsequent addition to aldehyde would give an oxaziridine and, correspondingly, an isomeric nitrone. A nitrene intermediate has been proposed for the reduction of nitrobenzene with carbon monoxide.[1] Then, the nitrone would be reduced by carbon monoxide to a Schiff base. These steps have been proposed for the synthesis of the Schiff base from nitrobenzene.[11] This Schiff base is



Scheme 2.

easily reduced to the secondary amine, which then reacts with one more aldehyde to form an iminium ion and finally gives **2**.

Experimental

The melting points and boiling points were uncorrected. The melting points were taken on a Yanagimoto capillary melting-point apparatus. The IR spectra were measured on a Hitachi model 215 grating spectrophotometer. The ^{1}H NMR spectra were obtained at 60 MHz with a JEOL JNM-60 or at 220 MHz with a Varian model HR-220 NMR spectrometer. The ^{13}C NMR spectra were determined at 25.05 MHz with a JEOL pulsed Fourier Transform spectrometer, model FX-100. Samples were dissolved in $CDCl_3$, and the chemical-shift values were expressed in δ relative to Me_4Si as the internal standard. Elemental analysis was performed at the Microanalytical Center of Kyoto University. The mass spectra were recorded on a JMS OlSG mass spectrometer.

The aldehydes, nitroarenes, and other compounds employed in this study were commercial products. The aldehydes and nitroarenes were distilled before use. Carbon monoxide was used without further purification. The ethanol was dried by the usual methods.

An autoclave with a capacity of 100 ml, made of stainless= steel and equipped with a magnetic stirrer, was used in the reaction. A typical reaction with butanal and nitrobenzene will be described here to exemplify the general procedure adopted. A mixture of nitrobenzene (4.92 g, 40 mmol), butanal (6.49 g, 90 mmol), water (2 ml), chlorotris(triphenylphosphine)rhodium(I) (0.17 mmol), palladium(II) chloride (0.26 mmol), and anhydrous ethanol (20 ml) was stirred at 180 °C under carbon monoxide (initial pressure, 70 atm).

The autoclave was heated for 20 min to 180 °C and held at this temperature for 4 h. After cooling, the autoclave was discharged and the ethanol was evaporated from the reaction mixture under a vacuum. The GLC analysis of the reaction product was made using bibenzyl as the internal standard with 10% Varsamide on Neopack 60—80 mesh (0.3 cmϕ × 3 m) The reaction products were then subjected to fractional distillation. The identity of the compound was confirmed by IR, ^{1}H NMR, ^{13}C NMR, mass spectra, and elemental analysis.

The analytical data of the quinoline derivatives gave satisfactory results.[3] The (alkylamino)- and (dialkylamino)-arenes and Schiff bases obtained here are described below. Although the products could not be isolated in an analytically pure form, they were identified on the basis of their spectral data.

3-Ethyl-2-propylquinoline (Run 23):[3] Yellow oil, bp 89—91 °C/0.24 Torr.†

N,N-*Dibutylaniline (Run 36)*: Yellow oil, bp 82—84 °C/0.23 Torr. ^{1}H NMR (220 MHz) ($CDCl_3$): δ=0.89 (t, 6H, $2CH_3$), 1.28 (sex, 4H, $2CH_2$), 1.50 (quin, 4H, $2CH_2$), 3.18 (t, 4H, $2CH_2$), 6.57—7.11 (m, 5H, Ar). Found: C, 82.03; H, 11.59; N, 6.87%. Calcd for $C_{14}H_{23}N$: C, 81.89; H, 11.29; N, 6.82%.

N-*(2-Ethylhexylidene)aniline (Run 19)*: Yellow oil, bp 78—82 °C/0.23 Torr. IR (neat) 1650, 1710, 1730 cm^{-1}. ^{1}H NMR (220 MHz) ($CDCl_3$): δ=0.86 (t, 3H, CH_3), 0.91 (t, 3H, CH_3), 1.26—1.39 (m, 4H, $2CH_2$), 1.45—1.61 (m, 4H, $2CH_2$), 2.30 (m, 1H, CH), 6.96—7.28 (m, 5H, Ar), 7.54 (d, 1H, N-CH-). ^{13}C NMR (25.05 MHz) ($CDCl_3$): δ=11.68 (q, CH_3), 14.03 (q, CH_3), 22.84 (t, CH_2), 25.36 (t, CH_2), 29.41 (t, CH_2), 31.82 (t, CH_2), 47.20 (d, CH), 120.53 (ortho), 125.22 (para), 128.86 (meta), 152.41 (arom, C-1), 170.26 (d, CH). Found: C, 80.63; H, 10.15; N, 7.02%. Calcd for $C_{14}H_{15}N$: C, 82.70; H, 10.41; N, 6.89%.

3-Ethyl-6-methyl-2-propylquinoline (Run 23):[3] Yellow oil, bp 110—114 °C/0.35 Torr.

N,N-*Dibutyl-4-methylaniline (Run 37)*: Yellow oil, bp 89—90 °C/0.28 Torr. ^{1}H NMR (220 MHz) ($CDCl_3$): δ=0.94 (t, 6H, $2CH_3$), 1.35 (sex, 4H, $2CH_2$), 1.54 (quin, 4H, $2CH_2$), 2.24 (s, 3H, CH_3), 3.23 (t, 4H, $2CH_2$), 6.56—7.24 (m, 4H, Ar).

† 1 Torr≈133.322 Pa.

6-Chloro-3-ethyl-2-propylquinoline (Run 29):[3] Yellow oil, bp 108—110 °C/0.28 Torr.

N,N-*Dibutyl-4-chloroaniline (Run 38)*: Yellow oil, bp 107—112 °C/0.28 Torr. ^{1}H NMR (220 MHz) ($CDCl_3$): δ=0.92 (t, 6H, $2CH_3$), 1.31 (sex, 4H, $2CH_2$), 1.51 (quin, 4H, $2CH_2$), 3.19 (t, 4H, $2CH_2$), 6.49—7.10 (m, 4H, Ar).

3-Ethyl-6-methoxy-2-propylquinoline (Run 30):[3] Yellow oil, bp 118—120 °C/0.28 Torr.

N,N-*Dibutyl-4-methoxyaniline (Run 39)*: Yellow oil, bp 111—114 °C/0.35 Torr. ^{1}H NMR (220 MHz) ($CDCl_3$): δ= 0.73 (t, 6H, $2CH_3$), 1.14 (sex, 4H, $2CH_2$), 1.34 (quin, 4H, Ar).

N-*(2-Ethylhexylidene)-4-methoxyaniline (Run 39)*: Yellow oil, bp 120—122 °C/0.35 Torr. IR (neat) 1650, 1700, 1730 cm^{-1}. ^{1}H NMR (220 MHz) ($CDCl_3$): δ=0.89 (t, 3H, CH_3), 0.93 (t, 3H, CH_3), 1.27—1.39 (m, 4H, $2CH_2$), 1.48—1.64 (m, 4H, $2CH_2$), 2.32 (m, 1H, CH), 3.73 (s, 3H, $-OCH_3$), 6.84—7.07 (m, 4H, Ar), 7.63 (d, 1H, N=CH–).

3-Ethyl-8-methyl-2-propylquinoline (Run 31):[3] Yellow oil, bp 105—113 °C/0.32 Torr.

N,N-*Dibutyl-2-methylaniline (Run 40)*: Yellow oil, bp 74—78 °C/0.23 Torr. ^{1}H NMR (220 MHz) ($CDCl_3$): δ=0.84 (t, 6H, $2CH_3$), 1.30 (sex, 4H, $2CH_2$), 1.41 (quin, 4H, $2CH_2$), 2.30 (s, 3H, CH_3), 2.92 (t, 4H, $2CH_2$), 6.98—7.26 (m, 4H, Ar).

8-Chloro-3-ethyl-2-propylquinoline (Run 32):[3] Yellow oil, bp 113—118 °C/0.03 Torr.

N-*Butyl-2-chloroaniline (Run 41)*: Yellow oil, bp 76—82 °C/0.50 Torr. IR (neat) 3450 cm^{-1}. ^{1}H NMR (220 MHz) ($CDCl_3$): δ=0.92 (t, 3H, CH_3), 1.41 (sex, 2H, CH_2), 1.60 (quin, 2H, CH_2), 3.09 (t, 2H, CH_2), 4.17 (s, 1H, NH), 6.61—7.27 (m, 4H, Ar).

3-Ethyl-8-methoxy-2-propylquinoline (Run 33):[3] Yellow oil, bp 116—120 °C/0.12 Torr.

2-Ethyl-3-methylquinoline (Run 34):[3] Yellow oil, bp 73—83 °C/0.57 Torr.

N,N-*Dipropylaniline (Run 43)*: Yellow oil, bp 62—66 °C/0.23 Torr. ^{1}H NMR (60 MHz) ($CDCl_3$): δ=0.88 (t, 6H, $2CH_3$), 1.57 (sex, 4H, $2CH_2$), 3.17 (t, 4H, $2CH_2$), 6.48—7.25 (m, 5H, Ar). Found: C, 81.36; H, 10.68; N, 8.00%. Calcd for $C_{12}H_{19}N$: C, 81.30; H, 10.80; N, 7.90%.

The Replacement of Electronegative Substituents by an Electron-transfer Mechanism. The Factors Governing the Reaction of Carbonyl and Imino Compounds with Organomagnesium Reagents

Masao Ōkubo* and Yumiko Uematsu

Department of Chemistry, Faculty of Science and Engineering, Saga University, Honjō-machi, Saga 840

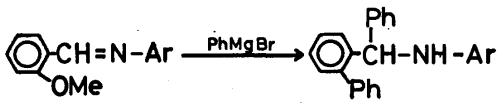
(Received June 19, 1981)

For the purpose of studying the electron-transfer initiated replacement of *ortho*-methoxy and *ortho*-halogeno substituents of diaryl ketone anils by the aryl group of ArMgBr, eight anils were prepared. The expected *o*-methoxy replacement by the phenyl group of PhMgBr, however, was extremely slow, and no *o*-chloro replacement took place. In contrast, anils of 1-substituted (MeO, Br, Cl) fluorenones gave the replacement products: The distribution of by-products formed *via* radical pathway in the cases of halogeno-anils was clearly different from that in the case of the methoxy-anil. In the reaction with $ArN(MgBr)_2$, 1-halogenofluorenones afforded the normal condensation products, while 1-methoxyfluorenone gave the "condensation-replacement" product. On the basis of the characteristic product-distributions obtained in the two organomagnesium reactions, the mechanism of methoxy replacement was distinguished from that of halogen replacement. Factors governing the two reactions were proposed and discussed: The structures of the substrates favorable to spin-delocalization, the electron-accepting ability of the substrates, the electron-donating ability of the reagents, the leaving ability of substituents, and their leaving manner.

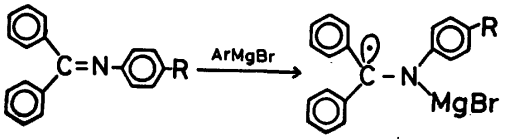
During the past decade, the electron-transfer mechanism in the Grignard addition to carbonyl compounds has been studied extensively, and it was finally established very recently.[1] However, the electron-transfer-initiated replacement of electronegative substituents, such as the methoxy,[2,3] cyano,[2] and halogeno[4] groups of carbonyl and imino compounds, has been reported independently, and a systematic investigation is needed. In this paper, the authors wish to report the results of their study of the replacement of methoxy, bromo, and chloro substituents on the 1-position of 9-fluorenylidene compounds in the reaction with organomagnesium reagents: the reaction of aryliminodimagnesium ($ArN(MgBr)_2$, aryl-IDMg)[5] reagent with fluorenones and that of the Grignard (ArMgBr) reagent with fluorenone anils. The product-distributions found in the reactions with methoxy-substituted substrates are clearly different from those in the reactions with halogeno-substituted ones. On the basis of these results, factors governing the replacement reaction will be discussed.

On the basis of the previous observation[3] that the imino compound, **1**, reacts with PhMgBr (Eq. 1) much more moderately than with carbonyl compounds and that ESR evidence for electron-transfer is obtained in the Grignard reaction with diaryl ketone anils (Eq. 2), a replacement reaction initiated by electron-transfer can be expected to proceed moderately in the Grignard reaction (Eq. 3) with anils of *o*-methoxy- and *o*-chlorobenzophenones, **2**.

In the following, the results of the study to find the best route for preparing anils, **2**, will first be described.



1 (1)



(2)

(3)

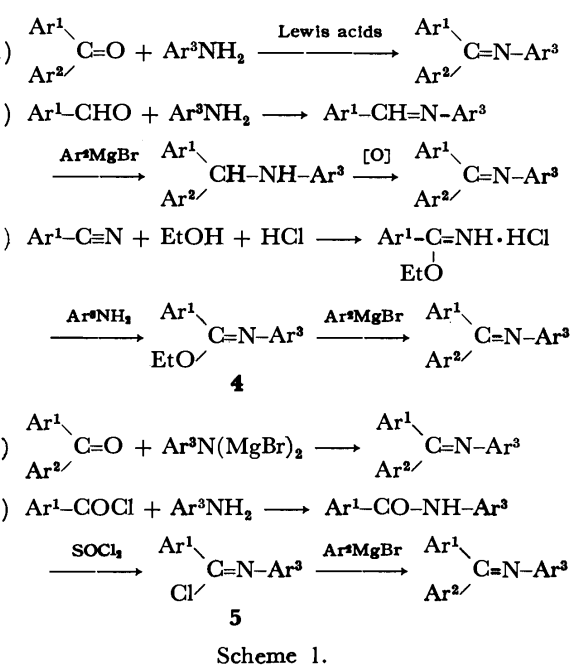
2 X = OMe, Cl

The reaction of Eq. 3, however, is too sluggish, and so the study was extended to the reaction of anils with a planar fluorenylidene system (Schemes 4 and 5).

Results and Discussion

Preparation of Anils of o-*Methoxy- and* o-*Chlorobenzophenone.* In order to prepare anils of *ortho*-substituted benzophenones effectively, five possible methods (A—E, Scheme 1) were examined.

Method A is the conventional one, but it cannot be



Scheme 1.

used for *o*- and *p*-methoxy-substituted ketones and anilines.[5] Method B proved to be ineffective because the *o*-methoxy group on Ar^1 was replaced by the Ar^2 group of the Grignard reagent (*cf.* Eq. 1).[3]

Method C, which consists of an ethoxy-relacement reaction can be expected to be applicable for synthesizing the anils, since the well-known "*N*-(ethoxymethylene)aniline (**3**) procedure[6] for aldehyde synthesis" involves a quite similar reaction (Eq. 4). After

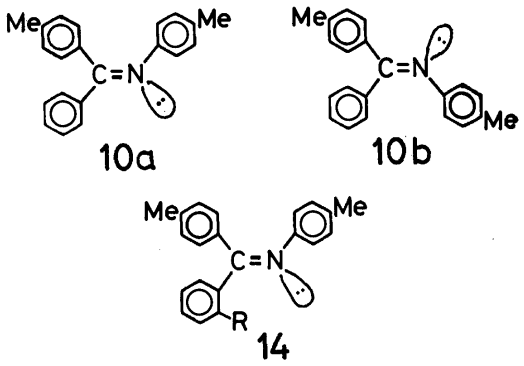
$$\underset{\mathbf{3}}{EtO\text{-}CH{=}N\text{-}Ph} \xrightarrow{ArMgBr} Ar\text{-}CH{=}N\text{-}Ph \xrightarrow{HCl} ArCHO + PhNH_2 \quad (4)$$

treatment with excess PhMgBr at 55 °C for 5 h, however, *N*-(α-ethoxybenzylidene)-*p*-methylaniline **4** ($Ar^1=C_6H_5$, $Ar^2=p\text{-}MeC_6H_4$) was recovered unchanged: this result will be discussed in the final section.

Method D, using the aryl-IDMg reagent, reported recently, is effective for preparing anils with strongly electron-releasing substituents.[5] However, the reaction of *o*-methoxybenzophenone with phenyl-IDMg gave only a 25% yield of the expected anil, even when excess molar amounts of the reagent were used.[7] The addition of excess metallic magnesium, which acts as a more efficient electron-donor than PhMgBr,[7] caused the methoxy group to be replaced by the Ar^3NH-group, the yield of the replacement product being less than 20%.

Method E proved to be the best one: It was reported earlier,[8] but was not extensively studied. When *N*-(α-chlorobenzylidene)aniline, **5**, obtained almost quantitatively by treating the corresponding benzanilides with $SOCl_2$,[8] was added at 0 °C into a THF solution of equimolar *o*-$MeOC_6H_4MgBr$, a strong exothermic reaction took place. After heating at 55 °C for 2 h and quenching with aqueous NH_4Cl, followed by usual work-up, good yields of the **6**—**13** anils were obtained (Table 1). The *o*-chloro-derivative, **9**, was prepared by the treatment of *N*-(α,*o*-dichlorobenzylidene)aniline, which had been obtained from the corresponding benzanilide, with *p*-MeC_6H_4MgBr. The *p*-chloro-derivative, **12**, was prepared similarly utilizing *o*-MeC_6H_4MgBr.

Twisted Molecular Structure and Sluggish o-*Methoxy Replacement of a Benzophenone Anil in a Grignard Reaction.* Among the anils listed in the table, the *ortho*-unsubstituted anil, **10**, shows unusual physical data. Its wide range of melting temperatures and its split pattern of CH_3-proton signals of NMR (3 : 1.5 : 1.5) indicate that the product is an equimolar mixture of *syn* and *anti* isomers, **10a** and **10b**. Taking the fact and the steric hindrance effect of *ortho*-substituents into account, the data of the other anils are assignable to the sterically preferred configuration, **14** (R=Me, MeO, and Cl).



A characteristic purple coloration indicative of radical formation is observed on the treatment of the **8**, **9**, and **10** anils with PhMgBr (*cf.* Eq. 2[3]). The relative concentration of the radicals, as estimated by ESR measurement, is *o*-Cl>H>*o*-MeO.

The expected methoxy replacement of the **8** anil (Scheme 2, Path a) takes place, but the reaction is too sluggish: treatment with five molar equivalents of PhMgBr at 55 °C for 5 h afforded only a 13% yield of the replacement product, which was identified by comparison with an authentic sample prepared by an independent procedure (Path b). The addition of excess metallic magnesium[7] does not improve the yield of the

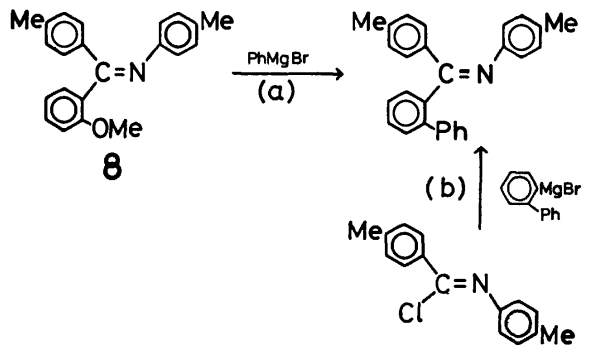
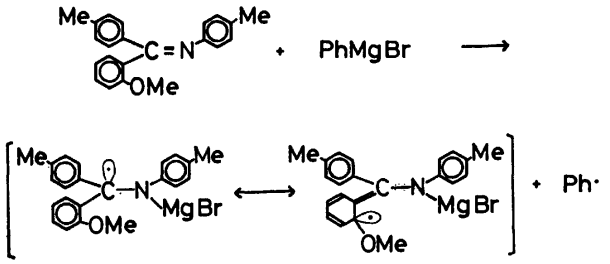
a) Group Ar^2 was introduced as Ar^2MgBr.



Scheme 2.

replacement product. The *o*-chloro-substituted anil, **9**, was recovered unchanged after being treated under the same reaction conditions.

On the basis of the previous observation that the free spin of the ketyl radicals of hindered benzophenones is delocalized mainly on their unhindered phenyl group,[2] the low replacement reactivity of **8** and **9** is ascribable to restricted spin-delocalization onto their *ortho*-substituted phenyl groups due to their twisting out of the plane of the >C=N- group (*cf.* Scheme 3). This suggestion is verified by the results obtained in the reaction with anils of 1-substituted fluorenones. The ESR spectrum of the radical derived from the non-substituted fluorenone anil show that the free spin is delocalized solely on its fluorenylidene moiety.[3]



Scheme 3.

Facile Replacement Reaction of 1-Substituted Fluorenones and their Anils with Aryliminodimagnesium and Grignard Reagents. Facile methoxy replacement takes place simultaneously in the condensation of 1-methoxyfluorenone, $\mathbf{15}_{MeO}$, with the *p*-methylphenyl-IDMg reagent, the reaction being carried out in preparing the

a) N and R designate "normal" and "reverse" additions respectively. b) Yields obtained after heating the reaction mixture at 55 °C for 2 h.

anil[5] (Scheme 4 and Table 2; *cf.* Scheme 1D): The normal condensation product, $\mathbf{16}_{MeO}$, and condensation-replacement product, **17**, were obtained. In contrast, 1-halogenofluorenones, $\mathbf{15}_{Br}$ and $\mathbf{15}_{Cl}$, afforded only "normal" condensation products, $\mathbf{16}_{Br}$ and $\mathbf{16}_{Cl}$, accompanied by small amounts of the azo compound, the formation of the latter being ascribable to the oxidative coupling of the reagent molecules initiated by electron-transfer due to the higher electron-accepting ability of the halogeno-fluorenones.

Isolated "normal" anils, $\mathbf{16}_{MeO}$, $\mathbf{16}_{Br}$, and $\mathbf{16}_{Cl}$, were submitted to the study of the reaction with *p*-MeC_6H_4MgBr (Scheme 5 and Table 3). The main reaction was the expected replacement affording **18**, the formation of by-products, **19** and **20**, being clearly explainable by the radical pathways given in Scheme 6.

The monomeric reduction product, **19a**, found only in the case of $\mathbf{16}_{MeO}$, originates from the hydrogen-abstraction of the THF molecule (Step 2) by the radical, I, resulting from the initial electron-transfer (Step 1). The dimeric reduction product, **19b**, found in the cases of $\mathbf{16}_{Br}$ and $\mathbf{16}_{Cl}$, originates from the radical, II, produced after the release of the halide anions (Step 3); the structure of the radical II is given tentatively and a detailed mechanism for the formation of **19b** is still equivocal. The dehalogenated anil, **20**, found in the reaction of $\mathbf{16}_{Br}$ and $\mathbf{16}_{Cl}$, originates from the hydrogen-abstraction of the solvent molecule (Step 4) by the radical II. Biaryl, observed in the cases of the halogeno-anils, is formed by the dimerization (Step 7) of the aryl radical generated *via* Step 1: no biaryl was detected in a control experiment carried out without the addition of a substrate. Unexpectedly, in the case of $\mathbf{16}_{MeO}$, a 1-methoxyfluorenone, $\mathbf{15}_{MeO}$, was isolated; its formation is ascribable to the attack of the water molecule upon the I radical because $\mathbf{16}_{MeO}$ itself is not

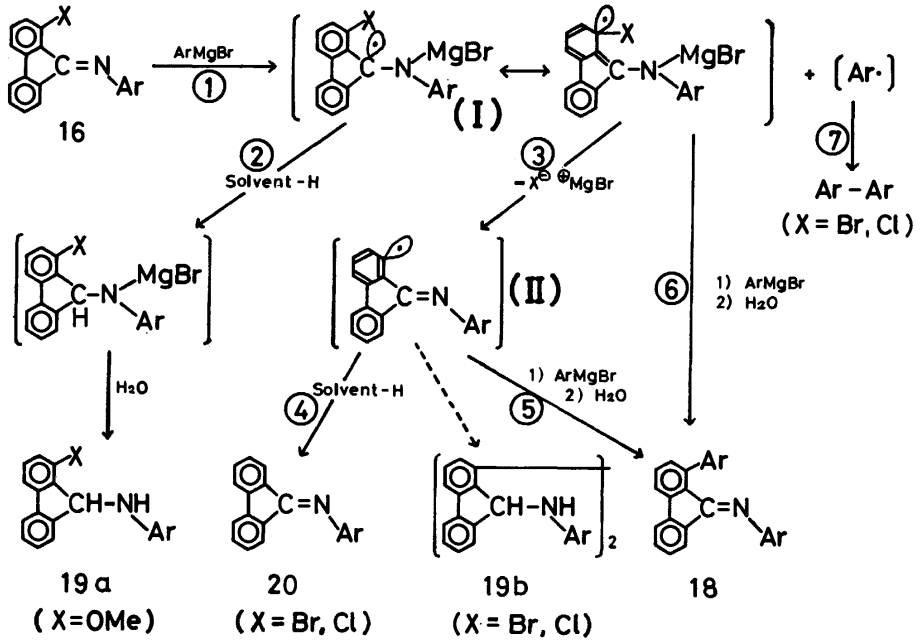


Scheme 6.

hydrolyzed during treatment with aqueous NH_4Cl.

Factors Governing the Replacement Initiated by Electron-transfer. The two clearly different patterns of distribution of the main by-products observed in the Grignard reaction of Scheme 5 should be noted: $\mathbf{16}_{Br}$ and $\mathbf{16}_{Cl}$ give two dehalogenated by-products, **19b** and **20**, while $\mathbf{16}_{MeO}$ affords the methoxy-retaining **19a**. This result is indicative that, according to Scheme 6, the replacement reaction of $\mathbf{16}_{MeO}$ proceeds *via* the methoxy-retaining radical I (Step 6), while the reactions of $\mathbf{16}_{Br}$ and $\mathbf{16}_{Cl}$ proceed *via* the dehalogenated radical II (Step 5). These features are symbolically represented: an S_N1-like mechanism operates for halogen replacement, whereas an S_N2-like one operates for methoxy replacement.

The mechanistic difference is interpretable on the basis of five governing factors: i) The structure of the substrates favorable to spin-delocalization, ii) the electron-accepting (*i.e.*, oxidizing) ability of the substrates, iii) the electron-donating (*i.e.*, reducing) ability of the reagents, iv) the leaving ability of the substituents, and v) their leaving manner. The term "low (or high) reduction potential" can be substituted for "high (or low) electron-accepting ability," and the term "low (or high) oxidation potential" can be substituted for "high (or low) electron-donating ability." The lower electrophilicity of imino compounds in comparison with carbonyl compounds was reported previously;[3] however, the term "electron-accepting ability" should be substituted for "electrophilicity," since the latter term is used for explaining the reactivity in ordinary ionic reactions.

The effect of the first factor, the structure of substrates, is demonstrated by the results given above: the planar fluorenylidene structure is evidently more favorable to replacement than the twisted diarylmethylene structure. The second factor, the electron-accepting ability of the substrates (Cl>Br>MeO),

affects the initial electron-transfer from the reagent.[9] The higher electron-accepting $\mathbf{16}_{Cl}$ and $\mathbf{16}_{Br}$ cause a higher radical concentration which, in comparison with that in the case of the lower electron-accepting $\mathbf{16}_{MeO}$, is responsible for the formation of two dehalogenated products, **19b** and **20**. The formation of biaryl in the Grignard reaction of $\mathbf{16}_{Br}$ and $\mathbf{16}_{Cl}$, like that of azoarene in the IDMg reaction of $\mathbf{15}_{Br}$ and $\mathbf{15}_{Cl}$, is also ascribable to the high electron-accepting ability of the halogeno substrates.

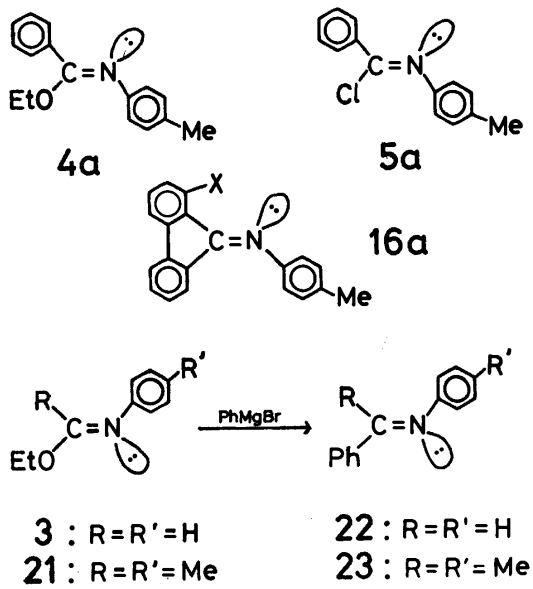
The third factor, the electron-donating ability of the reagents, also affects the intial electron-transfer process. Since the thermographic study of the Grignard reaction[1b] correlates the extent of heat evolution with that of initial electron-transfer, the very slight heat evolution detected in the reaction of $ArN(MgBr)_2$ with benzophenones[5] is indicative that the reagent is moderately electron-donating in comparison with ArMgBr. The absence of the condensation-replacement product, **17**, in the IDMg reaction with highly electron-accepting $\mathbf{15}_{Cl}$ and $\mathbf{15}_{Br}$ is ascribable to the moderate electron-donating ability of the reagent. Even *p*-methoxyphenyl-IDMg, which is more electron-donating than the *p*-methylphenyl reagent, does not afford **17** in the reaction with $\mathbf{15}_{Br}$: an improved yield of the normal anil $\mathbf{16}_{Br}$ (Ar=*p*-$MeOC_6H_4$, 78%), *ca.* a 1% yield of the debrominated anil **20** (Ar=*p*-$MeOC_6H_4$), and a trace amount of the corresponding azoarene were obtained. The effect of the electron-donating ability will be discussed again below in connection with the replacement manner of the methoxy substituent.

The fourth factor, the leaving ability of the substituents (Br>Cl>MeO), is responsible for the considerable recovery of $\mathbf{16}_{Cl}$ in comparison with the absence of any recovery of $\mathbf{16}_{Br}$, even in the reaction with highly electron-donating ArMgBr. This result is compatible with the leaving ability of groups found in ordinary S_N reactions.[10]

The fifth factor, the leaving manner of the substituents, is important for understanding the characteristic behavior of the methoxy substituent in the reactions of Schemes 4 and 5. It should be noted that the group is easily replaced by the use of the "normal addition" procedure, but the replacement is noticeably suppressed by use of the "reverse addition" procedure (Table 2). At the initial stage of the former procedure, an extremely high molar ratio of the moderately electron-donating IDMg reagent to the substrate is realized, the condition being favorable to an S_N2-like replacement of the substituent. In the reaction with the highly electron-donating Grignard reagent, even the least electron-accepting $\mathbf{16}_{MeO}$ affords a sufficiently high concentration of the radical I responsible for the formation of **19a**, which retains the methoxy substituent. The formation of **18** in this case is thus ascribable to its S_N2-like replacement manner.

The behavior of halogeno substituents in the two reactions should be discussed again in terms of their S_N1-like leaving manner. Even by the "normal addition" of the highly electron-accepting halogeno fluorenones, the moderately electron-donating IDMg reagent gives no sufficiently high radical concentration responsible for an S_N1-like halogen release, leading to the formation of **17**. In the reaction with the highly electron-donating Grignard reagent, halogeno-anils give radical concentrations sufficiently high for an S_N1-like halogen release, leading to the formation of **19b** and **20**.

Also explainable in terms of the proposed factors is the apparent contradiction found in the Grignard reactions carried out for preparing benzophenone anils (Scheme 1); Method E owes its success to the high reactivity of chloro-imine **5** whereas Method C fails because of the inertness of ethoxy-imine **4**, despite of their quite similar preferred configurations, **4a**, and **5a**. However, ethoxy-imines, **3** and **21** (Eq. 5), are converted into an aldimine, **22**,[6] and an anil, **23**, respectively, though the latter formation is slower than the former. The sterically preferred configurations and observed reactivities of the three ethoxy-imines suggest that S_N2-like alkoxy replacement requires a "syn-located" lone pair of nitrogen. Regardless of the seemingly unfavorable configuration, **5a**, its high electron-accepting ability and the S_N1-like leaving manner of chlorine supports the success of Method E.



(5)

3 : R=R'=H **22** : R=R'=H
21 : R=R'=Me **23** : R=R'=Me

Taking the additional factor, the configuration of the imines, into account, it is clear that the preferred configuration, **16a**, of the fluorenone anils is responsible not only for the S_N1-like halogen replacement, but also for the S_N2-like methoxy replacement with the Grignard reagent. Properly selected combinations of substrates with reagents, *i.e.*, the combination of highly oxidizing fluorenones with moderately reducing $ArN(MgBr)_2$ as well as that of moderately oxidizing anils with highly reducing ArMgBr, provides useful results for clarifying the factors which depend on each other and which govern the replacement reaction.

Experimental

The melting and boiling points are uncorrected.

Materials. *N*-(α-Ethoxybenzylidene)-*p*-methylaniline, **4**, was obtained by treating a slurry of α-ethoxybenzylideneamine hydrochloride[11] in dry benzene with equimolar *p*-

methylaniline at 60 °C for 5 h:[12] bp 125—128 °C/0.5 mmHg; NMR (CCl_4): δ=6.44—7.38 (9H, m), 4.36 (2H, q), 2.24 (3H, s), 1.40 (3H, t). The similar treatment of α-ethoxybenzylideneamine hydrochloride[11] with *p*-methyl aniline afforded *N*-(α-ethoxyethylidene)-*p*-methylaniline, **21**: bp 63 °C/0.5 mmHg; NMR (CCl_4): δ=6.94 (2H, d), 6.50 (2H, d), 4.14 (2H, q), 2.12 (3H, s), 1.72 (3H, s), 1.26 (3H, t). An authentic sample of *N*-(α-methylbenzylidene)-*p*-methylaniline, **22**, was prepared according to the reported method using $ZnCl_2(p\text{-}MeC_6H_4NH_2)_2$:[13] bp 138—143 °C/0.5 mmHg; NMR (CCl_4): δ=6.60—8.12 (9H, m), 2.45 (3H, s), 2.18 (3H, s).

N-(α-Chlorobenzylidene)-aniline and -*p*-methylaniline, as well as their nuclear-substituted derivatives, **5**, were obtained in good yields by the treatment of the corresponding benzanilides with excess $SOCl_2$.[8] An authentic sample of the *o*-phenylated anil (Scheme 2) was prepared according to Method E using the Grignard reagent derived from 2-bromobiphenyl: mp 106—107 °C; NMR ($CDCl_3$); δ=5.94—7.80 (17H, m), 2.36 (3H, s), 2.16 (3H, s).

1-Methoxyfluorenone, $\mathbf{15}_{Meo}$, was obtained by the methylation of 1-hydroxyfluorenone with Me_2SO_4 and NaOH,[14] the 1-hydroxy derivative being prepared by the diazotation of 1-aminofluorenone, followed by heating at 75—80 °C.[14] 1-Halogenofluorenones, $\mathbf{15}_{Br}$[15] and $\mathbf{15}_{Cl}$.[16] were prepared by the Sandmeyer reaction of 1-aminofluorenone. 1-Aminofluorenone was prepared starting from fluoranthene: oxidation with CrO_3 to 9-oxo-1-fluorenecarboxylic acid[17] and conversion to the amide,[15] followed by a Hofmann reaction using NaOCl.[16] For the purification of 1-substituted fluorenones, **15**, sublimation under reduced pressure was applied more conveniently than column chromatography.[14]

Procedures. All the Grignard reactions of Scheme 5 were carried out using 4.0 mmol of substrates in THF (50 ml) under N_2. The IDMg reactions were done according to the previously reported method[5] using 2.2—2.5 mmol of substrates and THF (40 ml). The Grignard reaction in the presence of metallic Mg was carried out using a reagent solution prepared from bromobenzene and a calculated excess of Mg. The yield of *o*-phenylated product of Scheme 2 was estimated by means of high-pressure liquid chromatography, using the calibration line of an authentic sample: MeOH–H_2O (65 : 35) was used as the eluent.

The ESR measurement was carried out according to the previously reported manner.[18]

Products. For the isolation and purification of the product formed in reactions of Schemes 4 and 5, column chromatography was used.

The melting point and NMR spectrum of **20** were compared with those of an authentic sample.[19] The by-product, **19a** (X=MeO), was identified by converting it into **16** (X=MeO) by dehydrogenation with freshly prepared MnO_2 in refluxing dry benzene.[20] Anils of 1-bromo- and 1-chlorofluorenone, **16**, gave the same by-product, **19b**: its dimeric structure was confirmed by molecular-weight measurement.

The melting points, NMR data, and results of elemental analyses of *N*-fluorenylideneaniline obtained in the reactions of Schemes 4 and 5 are given below: $\mathbf{16}_{Meo}$: mp 143—145 °C; NMR (CCl_4): δ=6.50—7.66 (11H, m), 4.00 (3H, s), 2.40 (3H, s). Found: C, 84.31, H, 5.65, N, 4.69%. Calcd for $C_{21}H_{17}NO$: C, 84.28, H, 5.69, N, 4.68%. $\mathbf{16}_{Br}$: mp 113—115 °C; NMR (CCl_4): δ=6.64—7.88 (11H, m), 2.42 (3H, s). Found: C, 69.01, H, 4.10, N, 3.99%. Calcd for $C_{20}H_{14}BrN$: C, 68.97, H, 4.02, N, 4.02%. $\mathbf{16}_{Cl}$: mp 139—141 °C; NMR (CCl_4): δ=6.58—7.62 (11H, m), 2.42 (3H, s). Found: C, 78.99, H, 4.57, N, 4.65%. Calcd for $C_{20}H_{14}ClN$: C, 79.08, H, 4.61, N, 4.61%. **17**: mp 118—120 °C; NMR (CCl_4): δ=9.92 (1H, s), 6.64—7.64 (15H, m), 2.44 (3H, s), 2.32 (3H, s). Found: C, 86.59, H, 5.82, N, 7.59%. Calcd for $C_{27}H_{22}N_2$: C, 86.63, H, 5.88, N, 7.49%. **18**: mp 171—173 °C; NMR (CCl_4): δ=6.54—7.68 (15H, m), 2.36 (6H, broad s). Found: C, 90.71, H, 5.81, N, 3.48%. Calcd for $C_{27}H_{31}N$: C, 90.25, H, 5.85, N, 3.90%. $\mathbf{16}_{Br}$ (Ar=*p*-$MeOC_6H_4$): mp 144—146 °C; NMR ($CDCl_3$): δ=6.72 (11H, m), 3.88 (3H, s). Found: C, 65.84, H, 3.79, N, 3.87%. Calcd for $C_{20}H_{14}BrNO$: C, 65.93, H, 3.84, N, 3.84%.

Photocycloadditions of Benzophenone with 6-Methylenetricyclo[3.2.1.$0^{2,7}$]-oct-3-en-8-one and Its Related Compounds. Di-π-methane Photorearrangement of the Primary Photocycloadducts[1]

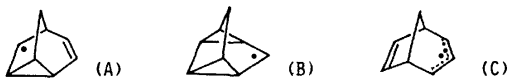
Makoto NITTA* and Hiroshi SUGIYAMA

Department of Chemistry, School of Science and Engineering, Waseda University, Shinjuku-ku, Tokyo 160

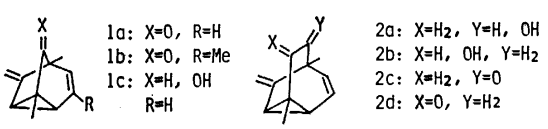
(Received July 3, 1981)

The photocycloadditions of benzophenone with constrained divinylcyclopropanes such as 1,5-dimethyl- and 1,3,5-trimethyl-6-methylenetricyclo[3.2.1.$0^{2,7}$]oct-3-en-8-ones, 5,8-dimethyl-9-methylenetricyclo[3.3.1.$0^{2,8}$]non-3-en-6-one, 5,8-dimethyl-9-methylenetricyclo[3.3.1.$0^{2,8}$]non-3-en-7-one, and their corresponding alcohols were investigated. In no cases, was oxetane formation observed but the formal [2+6] cycloaddition which originates from the cleavage of a cyclopropane ring was observed. In the case of the compounds which have a carbonyl function, benzophenone sensitized di-π-methane or oxadi-π-methane rearrangement of the primary photocycloadducts was observed. The mechanism of the formation of photoproducts is discussed with emphasis on (i) the nature of the intermediates having tricyclo[3.2.1.$0^{2,7}$]oct-3-en-6-yl and tricyclo[3.3.1.$0^{2,8}$]non-3-en-9-yl radicals, (ii) the regioselectivity of the di-π-methane or oxadi-π-methane rearrangement of the primary photocycloadducts.

Rearrangement of free radicals has been observed in reactions with low activation energies.[2] Photocycloaddition of benzophenone with olefins has afforded oxetanes,[3] while with cyclopropylethylenes, oxetanes and tetrahydrooxepins originating from the cleavage of a cyclopropane ring are obtained.[4] An example of this class of cycloaddition reaction involving the constrained divinylcyclopropane moiety was the cycloaddition of benzophenone with barbaralone investigated by Mukai and Kuribayashi.[5] Recently, we have reported that the cycloaddition of benzophenone with 1,5-dimethyl- and 1,3,5-trimethyl-6-methylenetricyclo[3.2.1.$0^{2,7}$]oct-3-en-8-ones (**1a** and **1b**) and 1,5-dimethyl-6-methylenetricyclo[3.2.1.$0^{2,7}$]oct-3-en-8-*endo*-ol (**1c**) afforded formal [2+6] cycloadducts originated from cleavage of the cyclopropane ring.[6] It was recently concluded[7] from product analysis and ESR spectroscopy that of radicals containing the bicyclo[3.2.1]octane skeleton

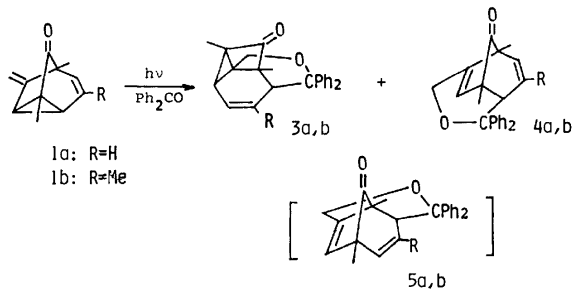


(**A**), (**B**), and (**C**), the allyl radical (**C**) was the most stable. The radical (**A**) or (**B**) rearranges rapidly to radical (**C**). Because of the interest in clarifying the ring size effect and substituent effect[8] of the radical rearrangement and the detailed photochemical behavior of the primary photocycloadduct, we have also investigated the photocycloaddition of benzophenone with the one-carbon ring enlarged compounds such as 5,8-dimethyl-9-methylenetricyclo[3.3.1.$0^{2,8}$]non-3-en-6-*endo*-ol (**2a**), 5,8-dimethyl-9-methylenetricyclo[3.3.1.$0^{2,8}$]-non-3-en-7-ol (**2b**), 5,8-dimethyl-9-methylenetricyclo-[3.3.1.$0^{2,8}$]non-3-en-6-one (**2c**), and 5,8-dimethyl-9-methylenetricyclo[3.3.1.$0^{2,8}$]non-3-en-7-one (**2d**). Through these studies, it was proven that the adduct **3a** is a rearrangement product of a primary photocycloadduct and **4a** has a different regiochemistry from that assigned in an ealier communication.[6] We would like to report the full details of the results.



Results and Discussion

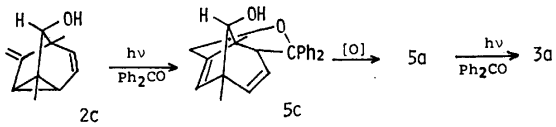
Photocycloaddition of Benzophenone with ***1a***, ***1b***, *and* ***1c***. The photocycloaddition of benzophenone with **1a**[9] was performed in anhydrous benzene with RPR-350 nm lamps in a nitrogen atmosphere.[6] The major product was a cycloadduct **3a** (mp 166—167 °C, 47%) and a minor cycloadduct was **4a** (mp 270—271 °C, 15%). The photoreaction of benzophenone with **1b**[9] afforded a similar cycloadducts **3b** and **4b** in 28% and 8% yields respectively. The adduct **3a** exhibited a parent ion peak at 342 in the mass spectrum, and a strong IR absorption



band at 1763 cm^{-1} due to the cyclobutanone ring. The NMR spectrum of **3a** exhibited a proton of the cyclopropane ring at δ 2.10 (d, J=4.0 Hz), and three protons of an allylic moiety at δ 3.50 (d, J=7.8 Hz), δ 5.60 (dxd, J=8.2, 7.8 Hz), and δ 6.02 (dxd, J=8.2, 4.0 Hz), in addition to the protons of two methyl groups at δ 0.92, δ 1.56, two methylene protons at δ 4.34 (d, J=10.0 Hz), δ 4.90 (d, J=10.0 Hz), and ten protons of the phenyl groups. These chemical shifts and the coupling patterns are in good agreement with the proposed structure **3a**. Similarly the structure of **3b** was assessed by the comparison of the spectral data with those of **3a** (see Experimental). The compound **4a** exhibited a parent ion peak at 342, and a strong IR absorption band at 1752 cm^{-1} which is suggestive of a skeleton **4a**. The NMR spectrum of **4a** exhibited a

singlet vinyl proton at δ 4.90 and three protons of an allylic moiety at δ 3.78 (m), δ 5.10 (dxd, J=10.0, 4.0 Hz), δ 5.68 (dxd, J=10.0, 2.0 Hz), in addition to the two methyl signals at δ 0.68, δ 1.57, two methylene protons at δ 4.05 (d, J=13.0 Hz), δ 4.53 (d, J=13.0 Hz), and ten protons of the phenyl groups. These chemical shifts and the coupling patterns suggest the structure **4a**. In our ealier communication, we assigned the structure **5a** for these spectral data, and the structure **4a** was discarded because of the ring strain of the tetrahydrooxepin which contains a *trans* double bond.[10] The following reaction sequences, however, elucidate the correctness of the structure **4a** and **4b**.

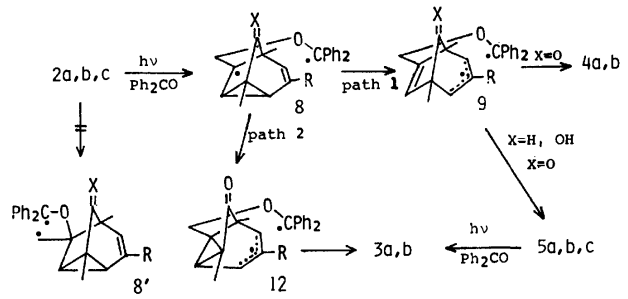
The photocycloaddition of benzophenone with **1c**[11] was carried out in a similar manner, and **5c** (mp 74—75 °C) was obtained in 76% yield. The adduct **5c** exhibited a parent ion peak at 344 in the mass spectrum. The NMR spectrum of **5c** exhibited a vinyl proton at δ 6.15 and three protons of allylic moiety at δ 3.17 (m), δ 5.15 (dxd, J=9.5, 3.8 Hz), δ 5.74 (broad d, J=9.5 Hz), in addition to two methyl groups at δ 0.97, δ 1.09, two methylene protons at δ 4.90 (d, J=11.2 Hz), δ 4.38 (d, J=11.2 Hz), a methine proton at δ 3.49 (broad s), hydroxyl proton at δ 1.72 and ten protons of the phenyl groups. Therefore the structure **5c** was deduced as depicted in the scheme. On oxidation with pyridinium chlorochromate[12] in dichloromethane, the adduct **5c** was converted to **5a** (mp 152—153 °C) in 23% yield. The compound **5a** exhibited a parent ion peak at 342



in the mass spectrum, and a strong IR absorption band at 1750 cm^{-1} due to a cyclopentenone moiety. The NMR spectrum exhibited a singlet vinyl proton at δ 6.50, three protons of allylic moiety at δ 3.66 (m), δ 4.98 (dxd, J=9.0, 4.0 Hz), δ 6.00 (dxd, J=9.0, 2.0 Hz), in addition to two methyl signals at δ 1.00, δ 1.17, two methylene protons at δ 4.23 (d, J=10.0 Hz), δ 4.47 (d, J=10.0 Hz), and ten protons of the phenyl groups. Where the vinyl and the allylic moieties are concerned, the coupling patterns of the NMR spectra of **4a**, **b**, and **5a** are very similar to each other. Since the methyl group in **4b** occupies a position corresponding to a proton in an allylic moiety of **4a** (see Experimental), the coupling patterns of **4b** are simplified. However, the relatively high chemical shift of the vinyl proton at δ 4.90 of **4a** or at δ 4.95 of **4b** as compared to δ 6.50 of **5a** or δ 6.15 of **5c** should be ascribed to the anisotropy effect of the phenyl groups, which located very close to the singlet vinyl proton in the case of **4a**, **b**. Therefore the structure of **4a** and **4b** could be reasonably assessed to have a *trans*-tetrahydrooxepin ring.

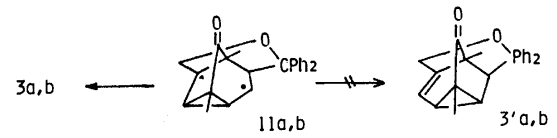
As reported previously,[6] independent irradiation of **4a**, in the presence or absence of benzophenone, did not cause rearrangement affording **3a**. The benzophenone sensitized photoreaction of **5a**, on the other hand, afforded the di-π-methane rearrangement product **3a** (70% yield), which was identical with an authentic specimen. Therefore **5a** and then **5b** should be the supportive intermediates affording **3a**, **b** in the photocycloaddition of benzophenone with **1a**, **b**.

We proposed a mechanistic scheme for the formation of the photocycloadducts (Scheme 1). The diradical **8** has been considered to be the intermediate[3,4] and it may be produced either because it is more stable than **8'**, or from an initially formed complex of a prefered orientation.[13] Recently kinetic data [E_a 5.9 kcal/mol; log (A/s^{-1}) 12.48] for the cyclopropylcarbinyl→allylcarbinyl radical rearrangement have been obtained from ESR spectroscopy in the temperature range of −120 °C to −140 °C.[14] However, the type (**A**) radical [which has the same skeleton as **8**] has not been detected at −140 °C, and only the rearranged radical species has been detected.[7] These facts may suggest that the rearrangement of the constrained radical species such as **8** may be faster than that of a simple cyclopropylcarbinyl radical itself. Furthermore the combination in **8** affording oxetane should have some degree of F-strain. Therefore the tricyclic radical species **8** rearranges rapidly to the allyl radical species **9** (path 1),

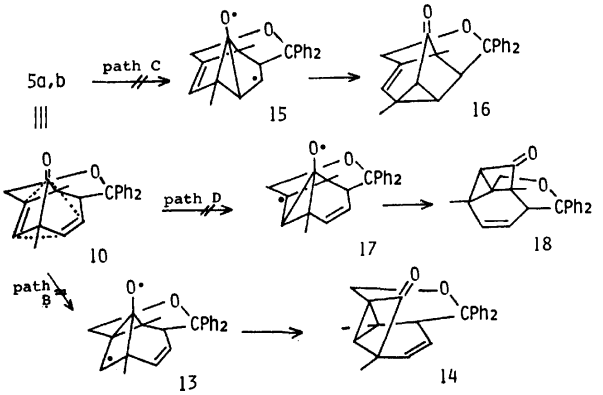


Scheme 1.

and the latter combines to give **4a**, **b**. The cycloadducts **4a**, **b** contains a *trans*-tetrahydrooxepin ring, which seems to be very constained. Therefore the pathway affording **4a**, **b** should be a relatively high-energy process. Another major pathway from **9** to the photocycloadducts should afford **5a**, **5b**, and **5c**, all of which have no *trans*-tetrahydrooxepin ring. However, we have no explanation for the formation of **4a**, **b** in the case of **1a**, **b** as compared to the case of **1c**. It may be impossible for the cycloadduct **5c** to absorb light in the present conditions. Furthermore a benzophenone sensitized di-π-methane rearrangement may be impossible because of its high triplet-state energy. This assumption is reminiscent of the acetone or acetophenone sensitized rearrangement of bicyclo[3.2.1]octadiene.[15] On the other hand, the energy transfer from benzophenone is possible in the case of the corresponding ketones, **5a**, **b** and results in the di-π-methane rearrangement giving **3a**, **b**. The carbonyl group seems to be indespensable for this rearrangement. In an earlier communication, the direct formation of **3a**, **b** from **8** *via* **12** (path 2) was considered.[6] However, the selective formation of **4a**, **b** seems unreasonable because of the high strain energy. In addition, the photochemical behavior of the independently prepared **5a** can contradict the path 2. This explanation is also supported by the experimental results of the similar reaction of the one-carbon ring



enlarged compounds **2** (*vide infra*). Other di-π-methane rearrangement such as **3'a, b** were not obtained *via* **11**. The examples of the directionality for migration of the vinyl group in the di-π-methane rearrangements are reported.[16] The less substituted or less conjugated double bond can migrate because the high electron density is needed for migration. However, the present selectivity affording **3a, b** might be controlled by the steric factor originated from the $-CH_2-O-CPh_2-$ bridge: In compounds **3'a, b**, an end of $-CH_2-O-CPh_2-$ moiety is attached to a double bond, therefore **3'a, b** are more constained as compared to **3a, b**.

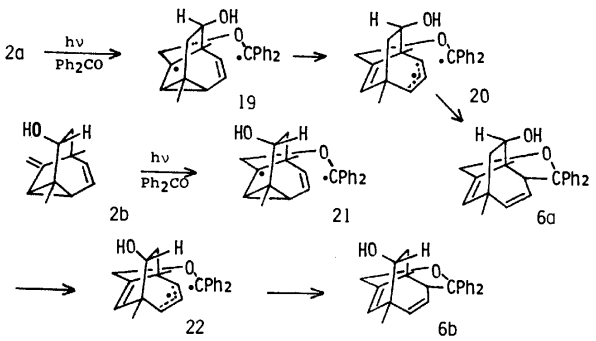


It is noticeable that the oxadi-π-methane rearrangement affording **14, 16,** and **18** were not observed on photoreaction. We think this fact should imply the fully homoconjugated interaction of the carbonyl group with the two basal double bonds, as indicated in the structural formula **10**, and that the full interaction leads to the di-π-methane rearrangement.

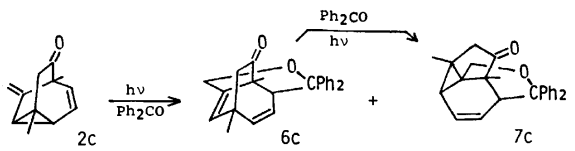
Photocycloaddition of One-carbon Ring Enlarged Compounds ***2a—d.*** In order to clarify the ring size effect on the radical rearrangement of **8** or **9** as well as on the photochemical behavior of the primary photocycloadducts such as **5**, photocycloadditions of benzophenone with **2a—d** were also investigated.

The irradiation of a benzene solution of benzophenone and **2a**[17] or **2b**[18] afforded an cycloadduct **6a** or **6b** in 78% or 73% yield, respectively. The chemical shifts and the coupling patterns of the NMR spectra of **6a, b** are very similar to those of **5a, c** (see Experimental). Especially the chemical shifts of the singlet vinyl protons at δ 6.55 of **6a** and at δ 6.17 of **6b** are similar to those of **5a** (δ 6.55) or **5c** (δ 6.50), therefore the structures **6a, b** were deduced. The adduct **6a** or **6b** could arise from the diradical species **20** or **22**, which originate from the rearrangement of the initially formed cyclopropylcarbinyl radical species **19** or **21**, respectively, as in the case of the reaction of benzophenone with **1**.

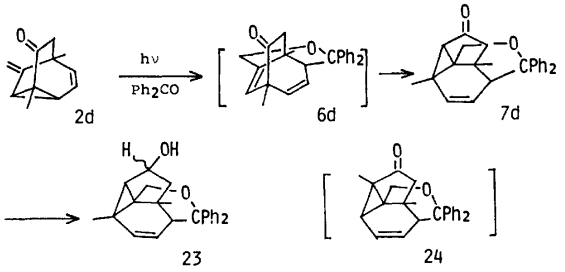
Irradiation of a benzene solution of **2c**[19] with benzophenone, on the other hand, afforded two photoproducts **6c** and **7c** in 13% and 40% yields, respectively. The mass spectral data and the analytical data of **6c** and **7c** were satisfactory for the 1 to 1 adducts of **2c** and benzophenone. The adduct **6c** exhibited a very similar NMR spectrum to those of **6a** or **6b**, and a strong absorption band at 1715 cm^{-1} in the IR spectrum; therefore the structure was attributed it. The formation of **6c** is explained by the similar reaction sequences to the case of **1** or **2a, b**. The IR spectrum of **7c** exhibited a strong absorption at 1735 cm^{-1} due to the cyclopentanone moiety. The NMR spectrum of **7c** was in full accord with the proposed structure (see Experimental). The double peak at δ 1.34 (J=4.0 Hz) was assigned to a proton on the cyclopropane ring by the help of a decoupling technique. Independent irradiation of a benzene solution of **6c** in the presence of benzophenone afforded **7c** in 80% yield. This fact indicates that **7c** originates from the benzophenone sensitized di-π-methane rearrangement of primary photocycloadduct **6c**.



On the other hand, the irradiation of a benzene solution of **2d**[19] and benzophenone in 1/5 molar ratio gave an adduct **7d** (mp 182—183 °C) in 69% yield. The adduct **7d** exhibited a parent ion peak at 356 in the mass spectrum, and a strong absorption band at 1705 cm^{-1} due to a cyclopropyl ketone. The NMR spectrum of **7d** exhibited a cyclopropane proton at δ 2.45 (1H, s) and three protons of an allylic moiety at δ 3.43 (1H, d, J=6.8 Hz), δ 5.50 (1H, dxd, J=8.0, 6.8 Hz) and δ 5.70 (1H, d, J=8.0 Hz), in addition to the protons of two methylene groups, two methyl groups, and two phenyl groups. On LAH reduction, **7a** was converted to the alcohol **23** (mp 158—160 °C)

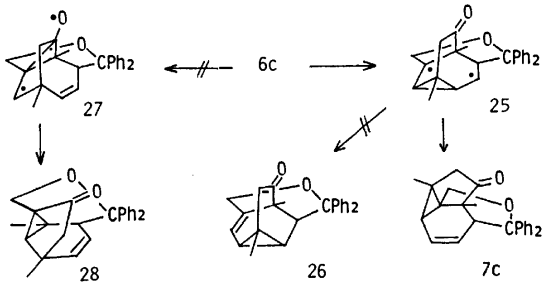


in 65% yield. The stereochemistry of the hydroxyl group of **23** was not determined, however, the NMR spectrum of **23** exhibited a doublet peak at δ 2.06 (J=4.5 Hz), which was assigned to the proton of the cyclopropane ring by the help of a decoupling technique: decoupling of the proton at δ 4.50—4.75 shows change a doublet peak at δ 2.06 to a singlet. This fact and the other spectral data (see Experimental) supported the structures **23** and **7d**, and could eliminate the other possible structure such as **24**, which is expected from the di-π-methane rearrangement on the two basal



double bonds of the postulated primary photocycloadduct **6d**.

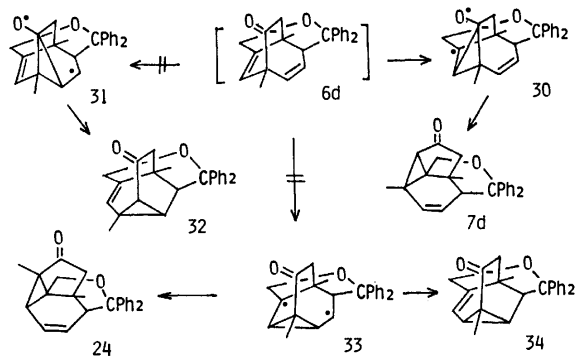
Several remarkable points are noticed here. Tricyclo-[3.2.1.$0^{2,8}$]non-3-en-9-yl radical species, which are derived from the addition of triplet benzophenone to **2a—d**, underwent cyclopropylcarbinyl-allylcarbinyl radical type rearrangement as in the case of type **A** radical or **8**. The rearrangement was independent of the presence of the carbonyl group. The reaction site of the benzophenone sensitized rearrangement of the primary photocycloadducts seemed to be dependent on the position of the carbonyl group in the similar skeleton. The cycloadduct **6c** underwent di-π-methane rearrangement on the two basal double bonds to afford **7c** *via* 1,4-diradical species **25**. This feature is similar to the



Scheme 2.

rearrangement of **5a** (*vide supra*). The carbonyl group of **6c** can also interact with two basal double bonds in a fully homoconjugated manner as in the case of **5c**. Another isomer **26** should be constrained as mentioned in the case of **3'a**, **b**, therefore the pathway affording **26** should be a higher energy process than that of **7c**. The compound **26** which is a one-carbon ring enlarged derivative of **3'a** seems to be more constrained even than **3'a** judging from a molecular model. The other oxadi-π-methane rearrangement product **28**, which has a very constrained molecular geometry, could not be obtained.

On the other hand, in the postulated primary photocycloadduct **6d**, the carbonyl group and two double bonds build up a special cross homoconjugated system, unlike the case of **5a** or **6c**. The adduct **7d** was considered to be derived from **6d** by the oxadi-π-methane rearrangement *via* **30**. Another oxadi-π-methane rearrangement product **32** was expected to be derived from the interaction of the carbonyl group with another vinyl group *via* **31**, however, it was not obtained. The compound **32** has a similar skeleton to **26** and it is supposed to be constrained, therefore the pathway to **32** should be a high-energy process and **31** possibly goes back to **6d**. Other isomers such as **24** and **34** may be



Schelme 3.

derived formally from a di-π-methane rearrangement of the two basal double bonds *via* **33**. Concerning the ring constraint, **34** has a similar skeleton to **26** or **32**, therefore this ring system is suggested to be unfavorable. The compound **24** has a similar skeleton to **7d**, on the other hand, it was not obtained. These observations seem to suggest that excited-state energy is localized on the homoconjugated system of the carbonyl group and a vinyl group.

In conclusion, it was clarified that tricyclo[3.2.1.$0^{2,7}$]-oct-3-en-6-yl or tricyclo[3.3.1.$0^{2,8}$]non-9-yl radical species, which were generated by an initial attack of a triplet benzophenone on **1** or **2**, could not afford oxetanes and rearranged to the less strained bicyclic allyl radical species affording formal [2+6] cycloadducts. The electron-withdrawing carbonyl group which is located to conjugate with the cyclopropane ring in **1** or **2d** could not reflect the electronic property on the radical rearrangement[8] in the present case. The regioselectivity of the subsequent benzophenone sensitized rearrangement of the primary photocycloadducts, however, was much affected by the position of the carbonyl group.

The investigation of photochemical reactions of β,γ-unsaturated carbonyl compounds has been accumulated.[20] Among these investigations, bicyclic ketones such as bicyclo[2.2.2]octenone derivatives undergo acetone sensitized 1,2-acyl migration (oxadi-π-methane rearrangement), 1,3-acyl migration and a bridge elimination.[20,21] The bicyclo[2.2.2]octa-2,5-dien-7-one derivatives are also known to eliminate ketene to afford benzene derivatives. The other noticeable example has been reported by Mukai and Kurabayashi: The triplet photorearrangement of bicyclo[4.2.1]non-2,4,7-trien-9-one, which containes a carbonyl group, a vinyl group and a butadiene moiety in a bicyclic skeleton, afford barbaralone.[23] The presented di-π-methane and oxadi-π-methane rearrangement are good examples reflecting the interactions of the carbonyl group with the two other vinyl groups in the homoconjugated manner. The explanation of the selectivity of the rearrangements is rather qualitative and the ring constraint is proposed as the reason for supressing the possible products such as **14**, **28** or **16**, and **26** and **32**. For profound confirmation of the selectivity for the rearrangement involving the interaction of the carbonyl group with the two other vinyl groups, the study of the compounds containing no $-CH_2-O-CPh_2-$ moiety in **5**, **6c**, and **6d** might be helpfull.

Experimental

IR spectra were measured on a Shimadzu IR-100 spectrometer. NMR spectra were recorded on a JEOL PS-100 high resolution NMR spectrometer. Chemical shifts were determined in carbon tetrachloride or in deuteriochloroform. The abbreviations given in the NMR data are s=singlet, d=doublet, dxd=doublets of doublet, t=triplet, and m=multiplet. VPC analysis was carried out either on Shimadzu GC-6A or on a Varian model-920 gas chromatograph using columns packed with either 5% SE-30 or 5% FFAP on Chromosorb W. The mass spectral studies were conducted using a Hitachi RMU-60 spectrometer. All melting points are uncorrected.

General Procedure of Irradiation. All photoreactions were carried out in a deoxygenated (nitrogen bubbled) benzene solution of a mixture of substrate and benzophenone. Irradiation was made with a RPR-100 photoreactor, which was fitted with RPR-350 nm lamps.

Photoreaction of Benzophenone with **1a**. A benzene (40 cm^3) solution of 3.64 g (20 mmol) of benzophenone and 640 mg (4 mmol) of **1a** was irradiated in a Pyrex cell at room temperature for 7 h. VPC analysis indicated that almost all of **1a** was consumed. Solvent was removed under reduced pressure. The residue was chromatographed on alumina (130 g). Elution with hexane–benzene mixture (19/1) gave a colorless solid. Recrystallization of this solid from chloroform–ethanol mixture gave colorless crystals (647 mg, 47% based on **1a** used), which were characterized as **3a**: mp 166—167 °C; IR (KBr): 3050, 1763, 1630, 1597, 1498, 1447, 1025 cm^{-1}; NMR ($CDCl_3$): δ 0.92 (3H, s), 1.56 (3H, s), 2.10 (1H, d, J=4.0 Hz), 3.50 (1H, d, J=7.8 Hz), 4.34 (1H, d, J=10.0 Hz), 4.90 (1H, d, J=10.0 Hz), 5.60 (1H, dxd, J=8.2, 7.8 Hz), 6.02 (1H, dxd, J=8.2, 4.0 Hz), 7.2—8.2 (1H, m); MS, *m/e* (rel intensity): 342 (M^+, 9), 132 (100). Found: C, 84.04; H, 6.49%. Calcd for $C_{24}H_{22}O_2$: C, 84.17; H, 6.47%. Further elution of the column with hexane–benzene mixture (1/1) gave a colorless solid. Recrystallization of this solid from chloroform–ethanol mixture gave colorless crystals (199 mg, 15% based on **1a** used), which were characeterized as **4a**: mp 270—272 °C; IR (KBr): 1752, 1595, 1025 cm^{-1}; NMR ($CDCl_3$): δ 0.68 (3H, s), 1.57 (3H, s), 3.87 (1H, m), 4.05 (1H, d, J=13.0 Hz), 4.53 (1H, d, J=13.0 Hz), 4.90 (1H, s), 5.10 (1H, dxd, J=10.0, 4.0 Hz), 5.68 (1H, dxd, J=10.0, 2.0 Hz), 7.2—7.8 (1H, m); MS, *m/e* (rel intensity): 342 (M^+, 18), 132 (100). Found: C, 84.53; H, 6.23%. Calcd for $C_{24}H_{22}O_2$: C, 84.17; H, 6.47%.

Photoreaction of Benzophenone with **1b**. A benzene solution (40 cm^3) of 3.64 g (20 mmol) of benzophenone and 696 mg (4 mmol) of **1b** was irradiated in a Pyrex vessel at room temperature for 12 h. VPC analysis indicated that almost all of **1b** was consumed. After solvent removal in vacuo, the resulting residue was chromatographed on alumina (60 g). Elution with hexane–benzene mixture (9/1) gave 430 mg of a colorless solid and 130 mg of the second colorless solid. Recrystallization of the first solid from chloroform–ethanol mixture gave colorless crystals (402 mg, 28% based on **1b** used), which were identified as **3b**: mp 144—145 °C; IR (KBr): 1750, 1598, 1025 cm^{-1}; NMR ($CDCl_3$): δ 0.75 (3H, s), 0.84 (3H, s), 1.54 (3H, s), 2.02 (1H, m), 2.90 (1H, s), 4.12 (1H, d, J=10.0 Hz), 4.64 (1H, d, J=10.0 Hz), 5.57 (1H, m), 7.0—7.7 (1H, m); MS, *m/e* (rel intensity): 356 (M^+, 5), 146 ((100). Found: C 84.02; H, 6.72%. Calcd for $C_{25}H_{24}O_2$: C, 84.24; H. 6.79%. Recrystallization of the second solid from chloroform–ethanol mixture gave colorless crystals (110 mg, 8% based on **1b** used), which were characterized as **4b** by the following physical data: mp 290—291 °C; IR (KBr): 1748, 1600, 1035, 1023 cm^{-1}; NMR ($CDCl_3$): δ 0.50 (3H, s), 0.82 (3H, s), 1.54 (3H, broad s), 3.51 (1H, s), 3.88 (1H, d, J=10.0 Hz), 4.36 (1H, d, J=10.0 Hz), 4.95 (1H, s), 5.43 (1H, broad s), 7.2—7.8 (10H, m); MS, *m/e* (rel intensity): 356 (M^+, 24), 146 (100). Found: C, 83.95; H, 6.45%. Calcd for $C_{25}H_{24}O_2$: C, 84.24; H, 6.79%.

Photoreaction of Benzophenone with **1c**. A benzene solution (10 cm^3) of 182 mg (1 mmol) of benzophenone and 324 mg (2 mmol) of **1c** was irradiated at room temperature for 4 h. After solvent removal *in vacuo*, the residue was chromatographed on alumina (20 g). Elution with benzene–benzene–hexane (1/1) and benzene gave 260 mg (76% based on benzophenone used) of **5c** which was recrystallized from hexane as colorless crystals: mp 74—76 °C; IR (KBr): 3400, 1155, 1125 cm^{-1}; NMR (CCl_4): δ 0.97 (3H, s), 1.09 (3H, s), 1.72 (1H, s), 3.17 (1H, m), 3.49 (1H, broad s), 4.09 (1H, d, J=11.2 Hz), 4.38 (1H, d, J=11.2 Hz), 5.15 (1H, dxd, J=9.5, 3.8 Hz), 5.74 (1H, broad d, J=9.5 Hz), 6.15 (1H, s), 7.1—7.8 (10H, m).

Oxidation of **5c**. To a stirred solution of 204 mg (0.95 mmol) of pyridinium chlorochromate and 164 mg of anhydrous sodium acetate in 5 cm^3 of dichloromethane was added 218 mg (0.63 mmol) of **5c** in a nitrogen stream. Upon completion of the addition, the mixture was stirred at room temperature for 2.5 h. After addition of water, the mixture was extracted with ether (4×20 cm^3). The combined organic portion was dried over sodium sulfate, followed by solvent evaporation. The crude product was purified by TLC on silica gel using benzenes as the eluent to give 50 mg of **5a** (23%) as a colorless crystalline solid, which was recrystallized from ethanol: mp 152—153 °C; IR (KBr): 1750, 1600, 1040, 1007 cm^{-1}; NMR ($CDCl_3$): δ 1.00 (3H, s), 1.17 (3H, s), 3.66 (1H, m), 4.23 (1H, d, J=10.0 Hz), 4.47 (1H, d, J=10.0 Hz), 4.98 (1H, dxd, J=9.0, 4.0 Hz), 6.00 (1H, dxd, J=9.0, 2.0 Hz), 6.50 (1H, s), 7.1—7.6 (10H, m); MS, *m/e* (rel intensity): 342 (M^+, 1), 132 (100). Found: C, 84.01; H, 6.27%. Calcd for $C_{24}H_{22}O_2$: C, 84.17; H, 6.47%.

Irradiation of **4a** *in the Presence or Absence of Benzophenone.* Two Pyrex vessels, which containes **4a** (20 mg, 0.06 mmol) in, (a) benzene (2 cm^3), and (b) benzene (10 cm^3) containing benzophenone (22 mg, 0.12 mmol) were irradiated for 5 h. After removal of the solvent, each of the residues was purified by TLC on silica gel using benzene–dichloromethane (1/1) as the eluent to give **5a**, 90% (a), **5a**, 90% and 17 mg of benzophenone (b).

Benzophenone-sensitized Irradiation of **5a**. A solution containing 22 mg (0.12 mmol) of benzophenone and 20 mg (0.06 mmol) of **5a** in 2 cm^3 of benzene was irradiated in a Pyrex vessel for 3 h. After solvent removal *in vacuo* the resulting residue was separated by TLC on silica gel using benzene–dichloromethane (1/1) as the eluent. The first band isolated from the TLC plates contained 18 mg of benzophenone. The second band from the TLC plates contained 14 mg (70%) of **3a**, which was identical with the authentic specimen.

Photoreaction of Benzophenone with **2a**. A solution of 69 mg (0.38 mmol) of benzophenone and 134 mg (0.76 mmol) of **2a** in 8 cm^3 of benzene was irradiated at room temperature for 2 h. After evaporation of the solvent under reduced pressure, the residue was separated by TLC on alumina using chloroform as the eluent to give 61 mg of **2a** (R_f=0.43, 46%), and 106 mg of **6a** (R_f=0.69, 78% based on benzophenone used). The cycloadduct **6a** gave the following physical data: IR (film): 3450, 1600, 1040 cm^{-1}; NMR (CCl_4): δ 1.06 (3H, s), 1.16 (3H, s), 1.76 (1H, d, J=13.0 Hz), 2.15 (1H, dxd, J=13.0, 8.8 Hz), 3.55 (1H, dxd, J=5.0, 2.0 Hz), 3.84 (1H,

broad d, J=8.8 Hz), 4.10 (1H, d, J=10.0 Hz), 5.62 (1H, d, J=10.0 Hz), 5.70 (1H, dxd, J=11.0, 5.0 Hz), 5.75 (1H, dxd, J=11.0, 2.0 Hz), 6.55 (1H, s), 7.1—8.0 (10H, m). Found: C, 83.37; H, 7.07%. Calcd for $C_{25}H_{26}O_2$: C, 83.76; H, 7.31%.

Photoreactions of Benzophenone with **2b**. A solution of 75 mg (0.41 mmol) of benzophenone and 146 mg (0.83 mmol) of **2b** in 8 cm³ of benzene was irradiated at room temperature for 3 h. After solvent remolval *in vacuo*, the resulting residue was separated by TLC on alumina using hexane–ethyl acetate (3/1) to give 62 mg (R_f=0.40, 42%) of **2b** and 108 mg (R_f=0.23, 73% based on benzophenone used) of **6b**. The cycloadduct **6b** gave the following physical data: IR (film): 3420, 1600, 1045 cm⁻¹; NMR (CCl_4): δ 0.94 (3H, s), 1.22 (3H, s), 1.63 (1H, d, J=15.0 Hz), 2.30 (1H, dxd, J=15.0, 9.0 Hz), 3.06 (1H, dxd, J=4.8, 2.0 Hz), 3.68 (1H, broad d, J=9.0 Hz), 4.05 (1H, d, J=11.0, 4.8 Hz), 4.57 (1H, d, J=10.0 Hz), 4.58 (1H, dxd, J=11.0, 4.8 Hz), 5.52 (1H, dxd, J=11.0, 2.0 Hz), 6.17 (1H, s), 7.7—7.8 (10H, m). Found: C, 84.28; H, 7.12%. Calcd for $C_{25}H_{26}O_2$: C, 83.76; H, 7.31%.

Photoreaction of Benzophenone with **2c**. A solution of 150 mg (0.83 mmol) of benzophenone and 144 mg (0.83 mmol) of **2c** in 9 cm³ of benzene was irradiated at room temperature for 3.5 h. After solvent removal *in vacuo*, the resulting residue was separated by TLC on silica gel using hexane–ethyl acetate (4/1) as the eluent to give 25 mg (R_f=0.85, 17%) of **2c**, 35 mg (R_f=0.45, 13%) of **6c**, and 119 mg (R_f=0.30, 40%) of **7c**. Recrystallization of **6c** gave colorless crystals: mp 205—206 °C: IR (KBr): 1718, 1595, 1045 cm⁻¹; NMR ($CDCl_3$): δ 1.04 (3H, s), 1.26 (3H, s), 2.50 (2H, s), 3.40 (1H, dxd, J=4.0, 2.0 Hz), 4.14 (1H, d, J=10.0 Hz), 4.53 (1H, d, J=10.0 Hz), 4.67 (1H, dxd, J=12.0, 4.0 Hz), 5.75 (1H, dxd, J=12.0, 2.0 Hz), 6.60 (1H, s), 7.00—7.70 (10H, m); MS, *m/e* (rel intensity); 356 (M^+, 1), 132 (100). Found: C, 84.49; H, 6.56%. Calcd for $C_{25}H_{24}O_2$: C, 84.24; H, 6.79%.

The cycloadduct **7c** was crystallized from ethanol to give colorless crystals: mp 139—140 °C; IR (KBr): 1733, 1595, 1040 cm⁻¹; NMR ($CDCl_3$): δ 0.76 (3H, s), 1.40 (3H, s), 1.34 (1H, d, J=4.0 Hz), 2.30 (1H, d, J=18.8 Hz), 2.47 (1H, d, J=18.8 Hz), 3.73 (1H, d, J=6.8 Hz), 3.88 (1H, d, J=11.0 Hz), 4.59 (1H, d, J=11.0 Hz), 5.50 (1H, dxd, J=9.0, 6.8 Hz), 5.72 (1H, dxd, J=9.0, 4.0 Hz), 7.05—7.83 (10H, m); MS, *m/e* (rel intensity): 356 (M^+, 1), 132 (100). Found: C, 84.00; H, 6.90%. Calcd for $C_{25}H_{24}O_2$: C, 84.24; H, 6.79%.

Photoreaction of Benzophenone with **2d**. A solution of 91 mg (0.5 mmol) of benzophenone and 87 mg (0.5 mmol) of **2d** in 5 cm³ of benzene was irradiated at room pemperature for 8 h. After solvent removal *in vacuo*, the resulting residue was separated by TLC on silica gel using ether–hexane (1/1) as the eluent to give 10 mg (R_f=0.90, 10%) of **2d** and 95 mg (R_f=0.50, 69%) of **7d**. Recrystallization of **7d** from ethanol gave colorless crystals: mp 182—183 °C: IR (KBr): 1705, 1595, 1035 cm⁻¹; NMR ($CDCl_3$): δ 0.95 (3H, s), 1.47 (3H, s), 1.86 (1H, d, J=18.8 Hz), 2.34 (1H, d, J=18.8 Hz), 2.45 (1H, s), 3.43 (1H, d, J=6.8 Hz), 4.06 (1H, d, J=11.0 Hz), 4.62 (1H, d, J=11.0 Hz), 5.50 (1H, dxd, J=8.0, 6.8 Hz), 5.79 (1H, d, J=8.0 Hz), 7.05—7.77 (10H, m); MS, *m/e* (rel intensity): 356 (M^+, 1), 132 (100). Found: C, 84.72; H, 6.78%. Calcd for $C_{25}H_{24}O_2$: C, 84.24; H, 6.79%.

Reduction of **7d**. To a suspension containing 19 mg (0.5 mmol) of lithium aluminium hydride in 2 cm³ of anhydrous tetrahydrofuran was added 89 mg (0.25 mmol) of **7d**. After the addition was completed, the reaction mixture was stirred at room temperature for 1 h. The reaction mixture was then treated with water (3 cm³) followed by aqueous ammonium chloride, and extracted with ether (10 cm³×4). The combined organic portion was dried over sodium sulfate. The solvent was removed under reduced pressure and the resulting residue was chromatographed on alumina column using benzene as the eluent to give a colorless crystalline solid, which was recrystallized from carbon tetrachloride to give 58 mg (65%) of **7e**: mp 158—159 °C; IR (KBr): 3450, 1600, 1075, 1010 cm⁻¹; NMR ($CDCl_3$): δ 0.87 (3H, s), 1.35 (3H, s), 1.72 (1H, dxd, J=14.0, 9.6 Hz), 1.96 (1H, dxd, J=14.0, 9.6 Hz), 2.06 (1H, d, J=4.6 Hz), 3.37 (1H, d, J=6.2 Hz), 3.96 (1H, d, J=10.8 Hz), 4.53 (1H, d, J=10.8 Hz), 4.50—4.75 (1H, m), 5.26 (1H, dxd, J=9.0, 6.2 Hz), 5.94 (1H, d, J=9.0 Hz), 7.0—7.75 (1H, m). Found: C, 84.48; H, 7.38%. Calcd for $C_{25}H_{26}O_2$: C, 84.70; H, 7.39%.

Photochemical Electrocyclic Reaction Mechanism of Methyleneamine *N*-Oxide to Form Oxaziridine. MINDO/3 CI Study

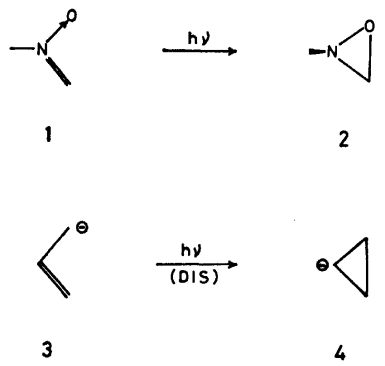
Osamu KIKUCHI,* Kenji MORIHASHI, and Keizo SUZUKI

Department of Chemistry, The University of Tsukuba, Sakura-mura, Ibaraki 305

(Received July 9, 1981)

The photochemical electrocyclic reaction mechanism of methyleneamine *N*-oxide to form oxaziridine was explored on the basis of the potential energy surfaces obtained by the MINDO/3 CI calculation. The strong interaction between the ground state and the doubly-excited state, which appears in the disrotatory cyclization process of the corresponding hydrocarbon system, was not observed. Instead, a deep potential well, which can be a leakage channel from the excited state to the ground state, was found in the S_1 surface. The predicted reaction path is characteristic of hetero-atom conjugated systems, and an important participation of the oxygen σ lone-pair electrons is expected in this reaction path.

Photochemical isomerization reactions of methyleneamine *N*-oxide, **1**, are quite common;[1-3] they undergo *cis-trans* isomerization reaction and electrocyclic reaction to form oxaziridines, **2**. Although the thermal (ground state) *cis-trans* isomerization reaction of **1**[4] and the photo-isomerization of **2** into amides[5] have been studied theoretically, little attention has been paid to the electron behavior and reaction paths for the photochemical electrocyclic **1**→**2** reaction. From the orbital



symmetry arguments,[6,7] the allyl anion is expected to cyclize photochemically by disrotatory rotation of the methylene groups. The formal electrocyclic **1**→**2** reaction may be considered to proceed by means of a mechanism similar to that of the **3**→**4** reaction.[2] However, there are two essential differences between the **1**→**2** and **3**→**4** reactions. The first is the mode of rotation of the methylene groups. In the conjugated hydrocarbon system, **3**→**4**, the disrotatory and conrotatory modes give potential curves of very different shapes, while there is no distinction between these two rotation modes in the **1**→**2** reaction, since only one methylene group is involved in methyleneamine *N*-oxide. The second difference is the existence of the lone-pair electrons of the terminal oxygen atom of methyleneamine *N*-oxide. Since the lone-pair electrons distribute on the σ framework where the new σ bond is being formed, the lone-pair electrons should participate in the electrocyclic reaction mechanism of the **1**→**2** reaction, even if the photochemical reaction proceeds from the $\pi\rightarrow\pi^*$ excited state. Because of these essential differences, the mechanism of the **1**→**2** reaction cannot be understood sufficiently well by analogy with the **3**→**4** reaction; therefore it is worthwhile to investigate the reaction process of the **1**→**2** reaction and to compare the reaction mechanism with that of the all-hydrocarbon conjugated system, **3**→**4**. In the present study, the reaction paths of the **1**→**2** reaction will be explored on the basis of the potential energy surfaces obtained by means of the semi-empirical MINDO/3[9] CI calculation.

Method and Results

The structures of the compounds **1** and **2** were optimized by the SCF MINDO/3 (without CI) calculation. They are shown in Fig. 1. The potential energy

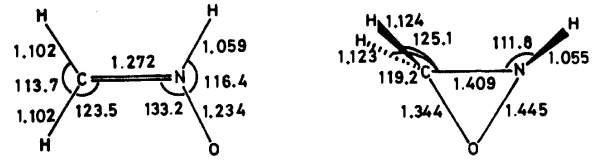


Fig. 1. Molecular structures of methyleneamine *N*-oxide and the oxaziridine optimized by the MINDO/3 method. Bond lengths are in Å and bond angles are in degrees.

surfaces for the **1**→**2** reaction are a function of many geometrical variables. In the present study, the potential energy surfaces were calculated with respect to two independent variables. One of these is the rotation angle, θ, of the methylene group. All the other geometrical variables were allowed to vary simultaneously from their initial to final values. This variation is expressed by the second parameter, d, which varies from 0.0 (initial) to 1.0 (final). In the CI calculation, 40 and 39 configuration functions were selected from the singly- and doubly-excited configurations for the singlet and triplet states respectively. The potential energy surfaces of four lower singlet states are shown in Fig. 2. The symbols W and H correspond to local minimum and maximum points on the potential surfaces respectively. The broken line in Fig. 2-a indicates the concerted path in which all the geometrical variables vary simultaneously. The potential energy curves along this concerted path are shown in Fig. 3. The S_1 and S_2 states of methyleneamine *N*-oxide consist of the $n_o\rightarrow\pi^*$ and $\pi\rightarrow\sigma^*$ excited configurations. The $\pi\rightarrow\pi^*$ configuration is involved in the S_3 and S_5 excited states. The T_1 state is the $\pi\rightarrow\pi^*$ triplet state and the T_3 state is the $n_o\rightarrow\pi^*$ triplet state.

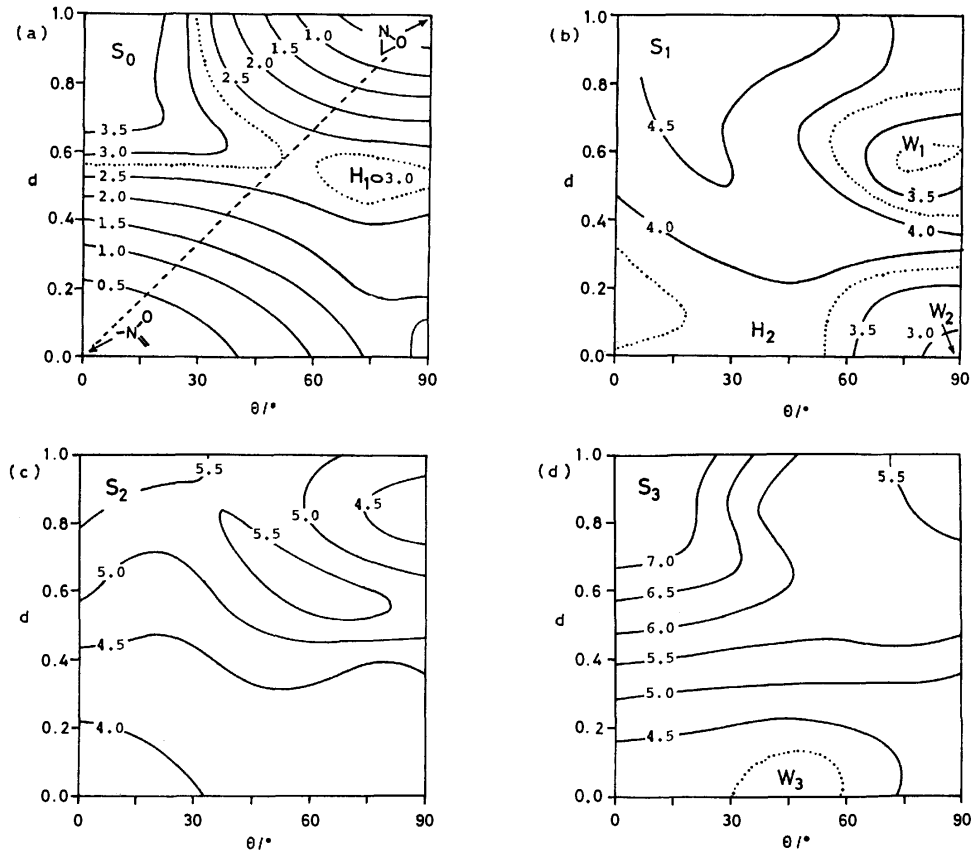

Fig. 2. Two-dimensional potential energy surfaces of (a) S_0, (b) S_1, (c) S_2, and (d) S_3 states of the methyleneamine *N*-oxide–oxaziridine system. The energies (eV) are relative values with respect to the ground state of methylenimine *N*-oxide.

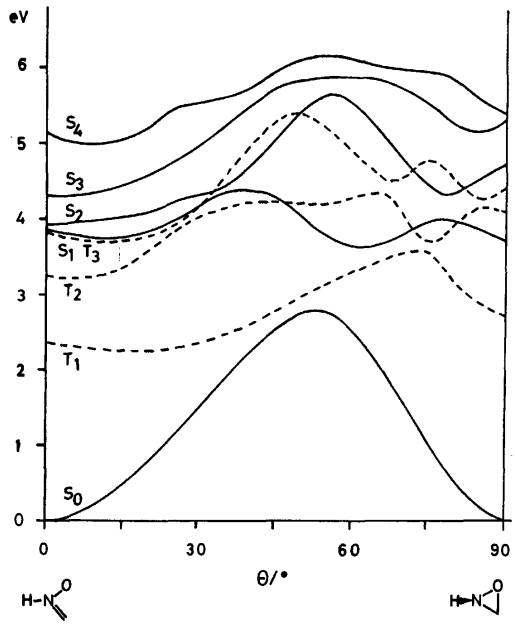

Fig. 3. Potential energy curves for the methyleneamine *N*-oxide–oxaziridine system along the concerted path. All the geometrical variables are varied simultaneously between the optimized structures of methyleneamine *N*-oxide and the oxaziridine.

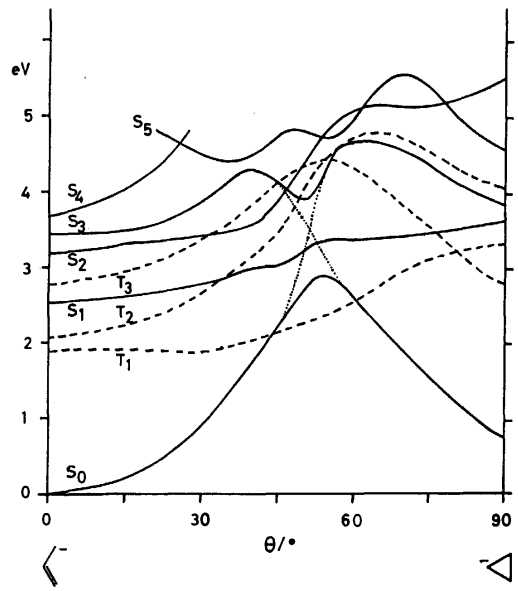

Fig. 4. Potential energy curves along the disrotatory mode of cyclization of the allyl anion into the cyclopropyl anion. All the geometrical variables are varied simultaneously between the two species.

The potential curves for the disrotatory cyclization of the allyl anion along the concerted path are shown in Fig. 4. The S_1 and S_2 states are the $\pi\rightarrow\sigma^*$ singlet states. The S_4 state is the $\pi\rightarrow\pi^*$ singlet state. The $\pi\rightarrow\pi^*$ doubly-excited configuration is involved in the S_5 state. The T_1 state is the $\pi\rightarrow\pi^*$ triplet state. The π_2 and π_3 MO's of the allyl anion cross during the cyclization; avoided crossing at the middle stage of the cyclization involves the ground state and $\pi_2\rightarrow\pi_3$ doubly-excited configurations. The true crossing which involves the $\pi\rightarrow\pi^*$ singly-excited state and its doubly-excited counterpart occurs between the S_4 and S_5 curves at the begining of cyclization. This crossing point lies higher (1 eV) than the S_4 state of the allyl anion; it is expected that the photochemical cyclization of the allyl anion from its $\pi\rightarrow\pi^*$ singlet state is inefficient.

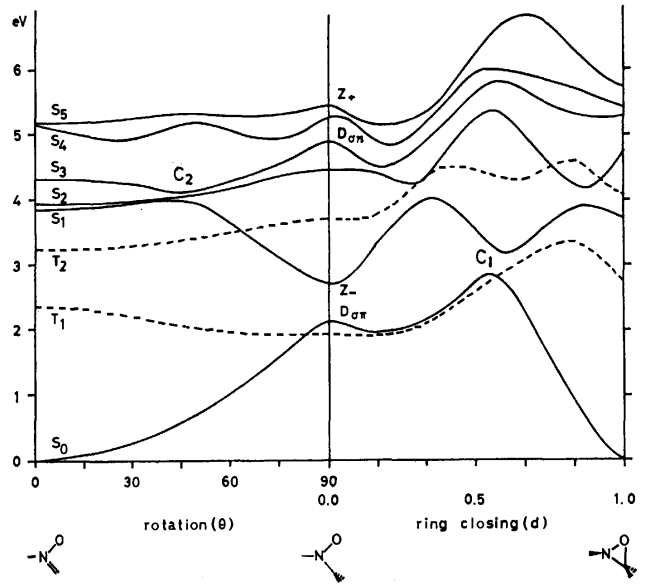

Fig. 5. Potential energy curves for the step-by-step path of the methyleneamine *N*-oxide–oxaziridine system. θ is the rotation angle (degree) of the terminal methylene and d represents the simultaneous change of all the geometrical variables other than θ.

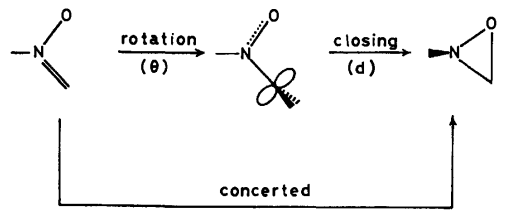
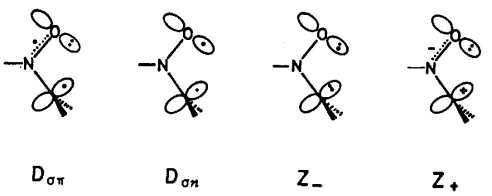
It has been pointed out that the step-by-step path in which the methylene rotation is followed by ring closure may exist in the photochemical electrocyclic reaction of hetero-atom conjugated systems.[8,10] The potential curves along this path are shown in Fig. 5. The vertical



line at the center of Fig. 5 corresponds to the twisted structure of methyleneamine *N*-oxide. The D and Z states of the twisted structure have the following electron configurations. In the twisted structure, the $D_{\sigma\pi}$ diradical state has a symmetry property different from



that of the Z–, $D_{\sigma n}$, and Z+ states. The C_1 avoided crossing is caused by pyramidalization of the nitrogen atom during the ring closing.

Discussion

During the photochemical electrocyclic reaction of the allyl anion, the symmetry-allowed crossing occurs between the highest occupied π_2 orbital and the unoccupied π_3 orbital. In this crossing region, strong coupling exists between the ground and the $\pi_2\rightarrow\pi_3$ doubly-excited configurations, and it gives the avoided crossing between the S_0 and S_2 potential energy curves shown in Fig. 4; this is the "C" type of avoided crossing in Salem's classification.[11] In the case of the cyclization of methyleneamine *N*-oxide, the strong coupling between the ground and the doubly-excited configurations does not exist due to the non-symmetric property of the system with respect to the vertical plane; no crossing occurs between π_2 and π_3 orbitals of methyleneamine *N*-oxide. The interaction between the S_0 and S_1 states observed in Fig. 3 is a different kind of avoided crossing. As may be seen from Figs. 2-a and 2-b, the S_0-S_1 interaction observed in Fig. 3 originates from the S_0-S_1 interaction at the W_1 region in the two-dimensional surfaces. Since the θ value at this region is large (80°), this crossing can be understood from the state correlation diagram between the 90°-twisted structure and its cyclization product (Fig. 6). The ground $D_{\sigma\pi}$ state correlates

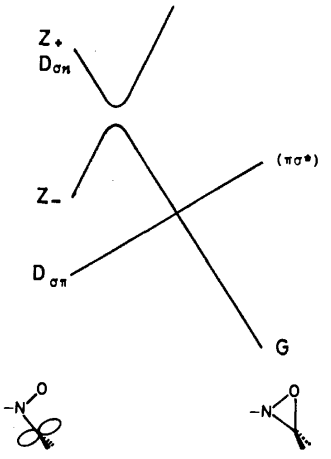


Fig. 6. State correlation diagram between the twisted structure of methyleneamine *N*-oxide and its cyclic structure.

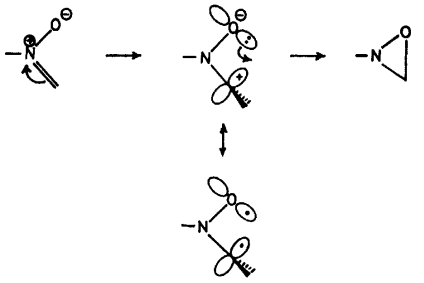
with the $\pi\sigma^*$ excited state of the cyclic product, while the Z+ (or $D_{\sigma n}$) excited state correlates with the ground state of the cyclic product. If the symmetry property with respect to the CN(H)O molecular framework is preserved during the cyclization, the $D_{\sigma\pi}$-Z+ crossing

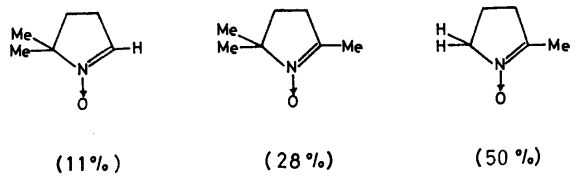
is allowed symmetrically as shown in the correlation diagram. In reality, however, the N–H hydrogen atom moves out of the plane during the cyclization, and the two states mix. The avoided crossing appeared in Figs. 2-a and 2-b is caused by this geometrical change; this is the "A" type of avoided crossing in Salem's classification.[11]

The clear difference between the potential energy curves of the **1**→**2** and **3**→**4** reactions indicates that the photochemical electrocyclic reaction of **1** proceeds by means of a mechanism different from that of its corresponding all-hydrocarbon system, **3**. The W_1 well in the S_1 surface can be a leakage channel from the excited state to the ground state, and the photochemical formation of the oxaziridine is expected to proceed through the non-adiabatic transition from the W_1 well to the S_0 surface; the reaction mechanism can be expressed by the following scheme.



In this mechanism, the oxygen lone-pair electrons on the CNO plane play a key role. The important role of the lone-pair electrons on the terminal hetero atom in the photochemical electrocyclic reaction of hetero-atom conjugated systems has been pointed out in our previous studies on the acrylaldehyde–oxetene system.[8,10]

The calculated potential surfaces (Fig. 2) indicate a strong interaction between the S_3 and S_1 surfaces at the W_3 region. The $\pi\rightarrow\pi^*$ excited state (S_3) of methyleneamine *N*-oxide will have high chance to access the W_1 well and to form the oxaziridine through the $W_3\rightarrow H_2$ transition. On the other hand, the formation of the twisted Z– state (W_2 well in Fig. 2) from the $\pi\rightarrow\pi^*$ excited state results in reproduction of methyleneamine *N*-oxide; this is the *cis-trans* isomerization process. As may be seen from Fig. 2-b, the formation of oxaziridine (the $H_2\rightarrow W_1$ path) competes with the *cis-trans* isomerization (the $H_2\rightarrow W_2$ path). It is expected that the methyleneamine *N*-oxides having a lower W_1 well and a higher W_2 well undergo cyclization to form oxaziridines preferably than the *cis-trans* isomerization. Since the electronic structure at W_1 involves the Z_+ character and that at W_2 is of the Z– type, the electron-donating substituents at the carbon atom increases the formation of the oxaziridine, while the electron-donating substituents at the nitrogen atom decreases it. The oxaziridine formation (%) from the above three compounds[12,13] is parallel to this prediction.



(11%) (28%) (50%)

Since only one methylene group is involved in methyleneamine *N*-oxide, there is no distinction between the conrotatory and disrotatory modes of methylene rotation. However, it may be interesting to illustrate the change in the orbital shape on the oxygen atom, which is induced by the rotation of the terminal methylene group. When the terminal methylene group is rotated, the π_1 orbital fragment on the oxygen atom rotates in the conratatory manner, while other π orbitals remain unchanged.

A Dimethyl Sulfoxide-mediated Oxidation of Arylalkyl and Alkyl Alcohols to Corresponding Aldehydes and Ketones *via* Tropolonyl Ethers

Hitoshi TAKESHITA,* Hiroaki MAMETSUKA, and Norihide MATSUO†

Research Institute of Industrial Science, 86, Kyushu University, Hakozaki, Higashi-ku, Fukuoka 812

†*Graduate School of Engineering Sciences, 39, Kyushu University, Hakozaki, Higashi-ku, Fukuoka 812*

(Received July 9, 1981)

The arylmethyl and diarylmethyl ethers of tropolones were oxidized to the corresponding carbonyl derivatives by heating in dimethyl sulfoxide. The free alcohols were oxidized at a much slower rate, suggesting that some sort of DMSO-linked intermediates are responsible for the oxidation. Inertness of free alcohols was proven by means of the cross-over experiments, including deuterium-labelling. This oxidation was applicable to alkyl ethers, but not to alkenyl ethers, which are known to cause the Claisen-rearrangement.

Recently, dimethyl sulfoxide (DMSO)-oxidation of alcohols or organic halides has been shown to be useful in organic synthesis.[1] We have found that several tropolonyl ethers, of which the preparations are tabulated in Table 1, are also capable of forming carbonyl compounds in a manner to be described in this paper. The investigations of non-benzenoid aromatic compounds have been hitherto focussed on the peculiarity of their chemical properties, and there seems to have been no attempt to utilize them as a reagent or catalyst.

When a mixture of 2-benzyloxytropone (**1a**)[2] and DMSO in a sealed tube was heated at 180 °C for 2 h, a clean reaction occurred to give tropolone (**2**), dimethyl sulfide, and benzaldehyde (**3a**) in good yields. Although their isolated yields were in the range of 60 to 85%, the NMR spectrometry of **3a** in the reaction mixture proved a nearly quantitative formation. Some other (arylmethoxy)tropones also gave aroyl derivatives, including 2-(diphenylmethoxy)tropone (**1g**) and 2-(1-naphthylmethoxy)tropone (**1h**) to benzophenone (**3g**) and 1-naphthaldehyde (**3h**).

However, the reaction was not applicable to the alkanals, *i.e.*, the yield of hexanal (**4a**) obtained from 2-(hexyloxy)tropone (**5a**) was less than 3% when heated in DMSO. This was at least partly due to the secondary reaction of the aldehyde with regenerated **2**.[3] This was also the case when 2-[4-(methoxycarbonyl)-butoxy]tropone (**5b**) gave ethyl 4-oxobutyrate (**4b**), in a trace amount. Alkanones, inert to tropones under these conditions, were prepared in a moderately good yield; 2-isopropoxytropone (**5c**) gave acetone (**4c**) in a 55% yield.

Table 1. Preparations and characterizations of tropolonyl ethers

	Ethers	Yield/%	Mp θ_m/°C	Found(%)[a] C	Found(%)[a] H	Calcd(%) C	Calcd(%) H (Compositions)	Ref.

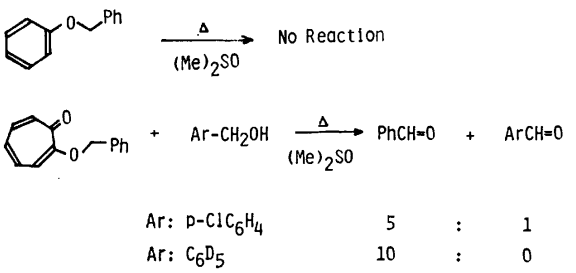
a) Me_2S was undetectable.

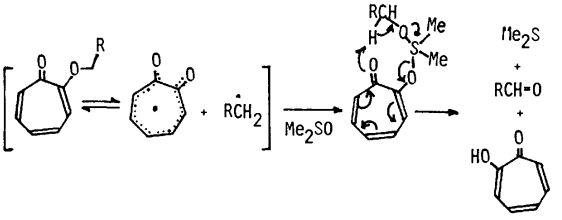
To determine the responsibility of the troponyl ethers, the reaction was checked by phenyl benzyl ether (**A**); but it was completely recovered unchanged. In addition, a 1 : 1-mixture of **1a** and *p*-chlorobenzyl alcohol (**6b**) gave aromatic aldehydes which consisted of **3a** : **3b** in a ratio of 5 : 1. Furthermore, **1a** and benzyl-2,3,4,5,6-d_5 alcohol (**6a**-d_5), prepared from benzoic-d_5 acid (**B**-d_5),[4] resulted in the overwhelming formation of the deuterium-free aldehyde (**3a**): In the NMR spectrum of the reaction mixture in DMSO-d_6, the intergral ratio for the signals ascribable to aldehydic protons and to 2,6-protons of **3a** was exactly 1 : 2. Even more convincingly, the mass-spectral analysis of the resultant **3a** showed less than 3% of **3a**-d.[5] Thus, within experimental error, hydrolyzed alcohols, if any, are not primarily responsible for the aldehyde formation. Therefore, the present oxidation can be termed a novel DMSO-mediated reaction of tropolonyl ethers.

As in the recently-found radical rearrangement: 2-(arylmethoxy)tropones to 3- and 5-(arylmethyl)-tropolones,[2] the present radical-induced oxidation also revealed a sensitization effect when analyzed kinetically;



Scheme 2.

throughout the oxidation up to 70% conversion of **1a** in DMSO-d_6, the rate enhancement by addition of the radical sensitizer, benzoyl peroxide (BP, 0.5 mol equiv.), k_{BP}/k_o, was *ca.* 2.7 at 180 °C ($k_o=2.3\times10^{-2}$, $k_{BP}=6.1\times10^{-2}$/min mol). In addition to this, the rate was also increased by addition of 2,4,6-tri-*t*-butylphenol (TB, 0.5 mol equiv.), *i.e.*, $k_{TB}/k_o=1.7$ at 140 °C ($k_{TB}=3.1\times10^{-3}$, $k_o=1.8\times10^{-3}$/min mol). The observed rate increase by introduction of TB, generally regarded as a radical scavenger, may indicate an intermediate formation of some condensate which can be homolyzed to regenerate the benzyl radical. However, these thermodynamic parameters might not be accurate enough to calculate $\Delta S^{\neq}$. But 2-(2-alkenyloxy)tropones, feasible for concerted intramolecular 3,3-sigmatropy, must not yield the oxidation products. Indeed, 2-allyloxytropone (**7a**) and some other analogs (**7b** and **7c**)[6] gave only the Claisen rearrangement products (**8a**—**c**).[7] But 2-(3-methyl-2-butenyloxy)-tropone (**7d**), the Claisen rearrangement product of which should suffer serious steric hindrance, failed to give either oxidation product or Claisen rearrangement product. The identified compounds were regenerated **2** together with isoprene.[8]



Scheme 3.

As an alternative of **2**, 3,5,7-trimethyltropolone (**9**)[9] can be used; 2-benzyloxy-3,5,7-trimethyltropone (**10a**) gave **3a** in 64% yield after silica-gel chromatographic work up. However, again 2-allyloxy-3,5,7-trimethyltropone (**11a**) gave only a Claisen rearrangement product: 3-allyl-3,5,7-trimethyl-4,6-cycloheptadiene-1,2-dione (**12a**),[10] and no oxidation occurred. On the other hand, the oxidation of 2-alkoxy-3,5,7-trimethyltropones (**13**) proceeded, after an induction period, to give the corresponding aldehydes in good yields; *i.e.*, from 2-hexyloxy-3,5,7-trimethyltropone (**13a**), **4a** was obtained in a 55% yield. This might be a result of blocking of the *o*- and *p*-position with methyl groups to prevent electrophilic attack of the resultant aldehydes. Similar features were observed in several derivatives, as shown in Table 2, and the reaction thus became applicable for the preparation of saturated aldehydes in general.

Related studies are in progress, and will be reported in future.

Experimental

Preparation of Tropolonyl Ethers (General Method). A hexamethylphosphoric triamide (HMPA) solution of tropolones and sodium hydride (1.2 mol equiv.) was treated with alkyl, allyl, or arylmethyl halides until the starting troponoids disappeared. In the cases of alkyl and arylmethyl derivatives, the mixture had to be heated as high as 120 °C,

but allyl and other thermally-sensitive derivatives gave good results when the mixture was kept at room temperature. After dilution with water, the mixture was extracted with ether, dried on $MgSO_4$, and chromatographed on a silica-gel column, if necessary. Yields varied depending on the steric circumstances of the halides, as compiled in Table 1; these are not optimized results.

Reaction of ***1a*** *with DMSO.* A DMSO solution (2 cm³) of **1a** (50 mg) was heated in a sealed tube for 6 h at 180 °C (refluxing *o*-dichlorobenzene bath). After dilution with water, the mixture was extracted with diethyl ether and chromatographed on a silica-gel column to give a colorless oil, **3a**, which was directly identified to be benzaldehyde. The isolated yield was 65%, but the latter fractions of chromatography contained colorless needles, which was identified to be benzoic acid (**B**).

Attempted Reaction of Phenyl Benzyl Ether (A) in DMSO-d_6. A DMSO-d_6 solution (0.5 cm³) of **A** (50 mg) was heated in a sealed tube at 180 °C for 15 h. The NMR spectroscopy revealed that the reaction did not proceeded at all.

The NMR Analysis of the Reaction of ***1a*** *with DMSO-*d_6 *in a Presence of p-Chlorobenzyl Alcohol (****6b****).* A DMSO-d_6 solution (0.5 cm³) of **1a** (25 mg) and **6b** (12 mg) was heated in a sealed tube (in refluxing *o*-dichlorobenzene bath) for 3 h. The mixture was then directly analyzed by an FT-NMR spectrometer: the result was **3a** : **3b**=5 : 1. If we judge only from the NMR spectrum, the reaction was very clean; there are no signals other than those of **1a**, **3a**, **3b**, regenerated **2**, and **6b**.

Reaction of ***1a*** *with DMSO in a Presence of Benzyl-*d_5 *Alcohol (****6a****-*d_5). A DMSO solution (2 cm³) of **1a** (90 mg) and **6a**-d_5 (50 mg)[4] was heated in a sealed tube at 180 °C for 2 h. The product isolated by the usual manner was a colorless oil, **3a**, from which autoxidized benzoic acid (**B**), colorless needles, mp 122—123 °C, were obtained in a pure form, 10 mg (20%). Its mass-spectrum [Found: *m/e*, 122 : 123 : 124 : 125 : 126 : 127=100.0 : 8.1 : 0.7 : 0.2 : 0.6 : 1.3] confirmed that there was only a negligible incorporation of deuterium atoms.[5]

Kinetic Analysis of the Reaction of ***1a*** *in DMSO-*d_6 *in a Presence of BP or TB.* Each DMSO-d_6 solution (0.4 cm³) of **1a** (each 30 mg) with various amounts of BP or TB (0 to 50 mg) was heated in a sealed tube at a constant temperature (140—160 °C), and the rates of formation of **3a** were measured.

Attempted Reaction of 2-(Alkenyloxy)tropones with DMSO. a): A DMSO solution (0.5 cm³) of 2-allyloxy tropone (**7a**, 25 mg) was heated in a sealed tube at 180 °C for 30 min. The product isolated after preparative silica-gel column chromatography was a pale yellow oil, 21 mg (84%), **8a**.[6]

b): A DMSO solution (0.3 cm³) of 2-(2-methyl-2-propenyloxy)tropone (**7b**, 30 mg) was heated in refluxing *o*-dichlorobenzene for 1.5 h. The mixture was then extracted by ether and water, and the organic extract was chromatographed on a silica-gel column to give a colorless oil, which was identified to be the Claisen product (**8b**), 21 mg (70%) [Found: *m/e*, 176.0824 (M^+). Calcd for $C_{11}H_{12}O_2$: 176.0837. δ: 1.33 (3H, d, J=7 Hz), 4.31 (1H, dqt, J=7, 5, 1.5 Hz), 5.13 (1H, dt, J=10, 1.5 Hz), 5.15 (1H, dt, J=17, 1.5 Hz), 5.99 (1H, ddd, J=17, 10, 4 Hz), 6.97 (1H, ddd, J=10, 7, 4 Hz), 7.27 (2H, m), 7.41 (1H, dt, J=10, 1 Hz), and 8.8—9.6 (1H, OH)].

c): A DMSO solution (0.3 cm³) of **7c** (50 mg) was heated in a sealed tube at 180 °C for 1 h. Silica-gel column chromatography of the mixture afforded a colorless oil (**8c**), 48 mg (96%), which was identical with the authentic sample.[6]

d): A DMSO solution (0.3 cm³) of **7d** (50 mg) was heated in a sealed tube at 180 °C for 30 min. Silica-gel column chromatography of the mixture gave only **2**, 31 mg (97%), together with isoprene, which was identified by NMR spectroscopy.

Reaction of 2-(Benzyloxy)-3,5,7-trimethyltropone with DMSO. A DMSO solution (0.3 cm³) of **10a** (50 mg) was heated in a sealed tube in a refluxing decalin bath. Preparative thin-layer chromatography of the mixture yielded benzaldehyde (**3a**), 13 mg (64%).

*Attempted Oxidation of 2-(Allyloxy)-3,5,7-trimethyltropone (****11a****)*[10] *with DMSO.* A DMSO solution of **11a** (50 mg) was heated in a secaled tube at 180 °C for 20 min. After dilution with water, the mixture was extracted with ether to give a colorless oil, 29 mg (58%), whose NMR spectrum was identical with the Claisen rearrangement product (**12a**) described previously:[10] δ: 1.28 (3H, s), 1.91 (3H, d, J=2 Hz), 1.99 (3H, d, J=2 Hz), 2.50 (2H, m), 4.99 (1H, m), 5.12 (1H, m), 5.60 (1H, m), 5.65 (1H, *q*, J=2 Hz), and 6.58 (1H, q, J=2 Hz). No other product was identified.

*Reaction of 2-Alkoxy-3,5,7-trimethyltropones (****13****). a)*: A DMSO solution (2 cm³) of 2-(hexyloxy)-3,5,7-trimethyltropone (**13a**, 50 mg) was heated in a sealed tube at 180 °C for 8 h. The product isolated after silica-gel column chromatography was hexanal (**4a**) [δ: 0.89 (3H, tm, J=7 Hz), 1.2—1.7 (6H, m), 2.38 (2H, td, J=7, 2 Hz) and 9.66 (1H, t, J=2 Hz). δ (C): 14.0, 22.5, 23.3, 31.5, 43.8, and 201.1], 11 mg (55%).

b): A DMSO solution (0.4 cm³) of 2-(decyloxy)-3,5,7-trimethyltropone (**13b**, 50 mg) was similarly heated in a sealed tube at 180 °C for 5 h. Eight mg of decanal (**14b**) was obtained (31%) [δ: 0.87 (3H, tm, J=7 Hz), 1.26 (12H, m), 1.60 (2H, m), 2.38 (2H, td, J=7, 2 Hz), and 9.67 (1H, t, J=2 Hz). δ (C): 14.1, 22.2, 22.8, 29.4 (2C), 29.7 (2C), 32.0, 43.9, and 201.6].

(Received July 13, 1981)

Substituent effects and directional selectivity in iodine-induced cycloisomerization reaction of [2.2]metacyclophane were tested using several derivatives of the latter. The reaction was found to be highly selective, and electron-donating groups gave a hexahydropyrene preserving a substituted aryl ring. On the other hand, an alkyl group *ortho* to the bridge gave a hexahydropyrene with a hydrogenated substituted ring.

Transannular reactions of mesocyclic compounds constitute an important synthetic strategy for constructing bridged systems.[1] We have found a highly efficient cycloisomerization reaction of [2.2]metacyclophane (**1**) to give 1,2,3,3a,4,5-hexahydropyrene (**2**) by treatment with a catalytic amount of iodine.[2] This remarkable transformation has been shown to be widely applicable for the synthesis, in high yields, of hitherto unaccessible alkyl-substituted hexahydropyrenes,[3] starting from alkyl derivatives of **1**.[2,4]

Instead of iodine, aluminium chloride,[2,5,6] bromine,[2] sulfuric acid[2,5] and silver salts[2] have also been used as the catalyst, but these were less selective and also less efficient than iodine. This paper will describe the substituent effects and directional control of the iodine-induced reaction using substituted [2.2]metacyclophanes, **3a**, **3b**, **6a**, **6b**, **9**, **13a**, **13c**, and **13d**, in which two benzene rings are differently substituted.

Results. [2.2]Metacyclophanes prepared according to the method described before[7] were treated with 0.14 equiv. of iodine in benzene at 60 °C for 15—20 h. The reaction mixture was then analyzed by vapor-phase and column chromatography. The yields shown in Table 1 are for a diastereomeric mixture. The analytical data are shown in Table 2.

TABLE 1. IODINE-INDUCED CYCLOISOMERIZATION REACTION[a]

Compound	Hexahydropyrene(%)	Tetrahydropyrene(%)	Starting material recovery/%
3a	**4a**, 80		20
3b	**4b**, 100		
6a	**7a**, 88	**8a**, 6	6
6b	**7b**, 89	**8b**, 10	1
9	**10**, 98	**12**, 2	
13a	**15**, 100		
13c			100
13d			100

a) The relative yields were determined by gas chromatography after treating the substrate with 0.14 equiv. of iodine in benzene at 60 °C (for **9**, 45 °C) for 15—20 h.

TABLE 2. 1,2,3,3a,4,5-HEXAHYDROPYRENES

Compound	Mp θ_m/°C	Formula	Found (%) C	Found (%) H	Calcd (%) C	Calcd (%) H
4a	97—98	$C_{17}H_{18}$	91.97	8.17	91.84	8.16
4b	116—118	$C_{20}H_{24}$	90.60	9.18	90 85	9.15
7a	101[a]	$C_{19}H_{22}$	91.92	8.23	91.14	8 86
7b	108[a]	$C_{22}H_{28}$	90.45	9.41	90.35	9.65

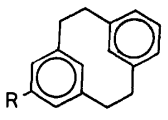
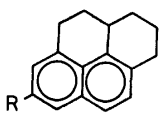
15	140—141	$C_{18}H_{20}$	85.65	8.05	85.67	7.99

a) Half crystalline.

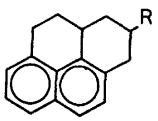
5-Methyl derivative **3a** gave a 80% yield of **4a**, with 20% of the recovered material. That the product was not isomeric **5a** was proved by the appearance of a ^{1}H NMR resonance at δ 2.46 as a singlet. A methyl proton



3



4



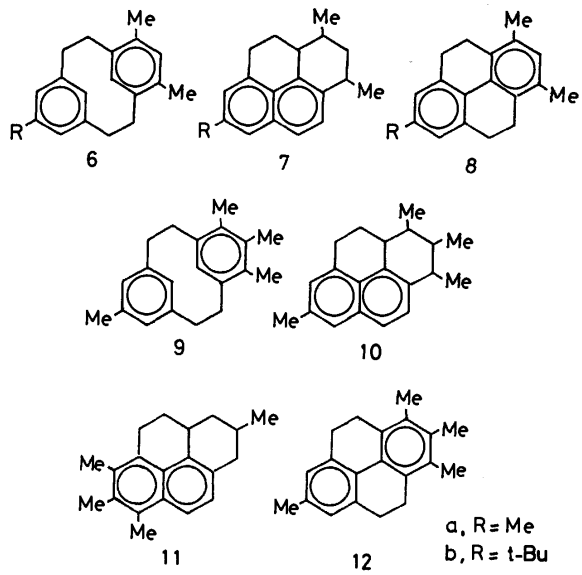
5

a, R=Me
b, R=t-Bu

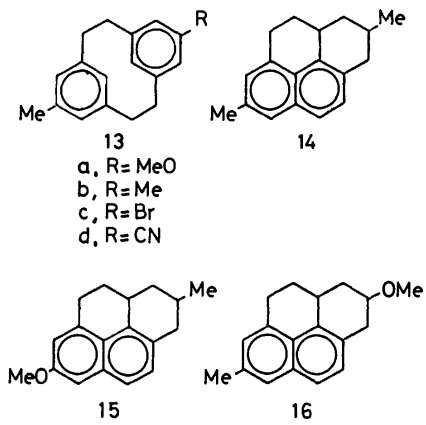
resonance in **5a** would require a doublet at around δ 1.10, as is observed in the 2,7-dimethyl derivative **14** prepared from **13b**.[2] The substitution pattern in a naphthalene ring was consistent with **4a**, as was proved by the UV and NMR spectra (see below). Similarly, the *t*-butyl derivative **3b** gave a quantitative yield of **4b**.

The directional selectivity was then studied using trialkyl and tetraalkyl derivatives, **6** and **9**. Compound **6a** gave 88% of **7a**. Similarly, **6b** and **9** gave 89 and 98% respectively of **7b** and **10**. In addition, these gave dehydrogenation products, 4,5,9,10-tetrahydropyrenes, **8a** (6%), **8b** (14%), and **12** (2%) as by-products. In any case, no isomeric hexahydropyrene in which a multi-substituted aryl ring was preserved as in **11** was isolated, as was evidenced by a careful examination of the reaction mixture by means of UV and NMR.

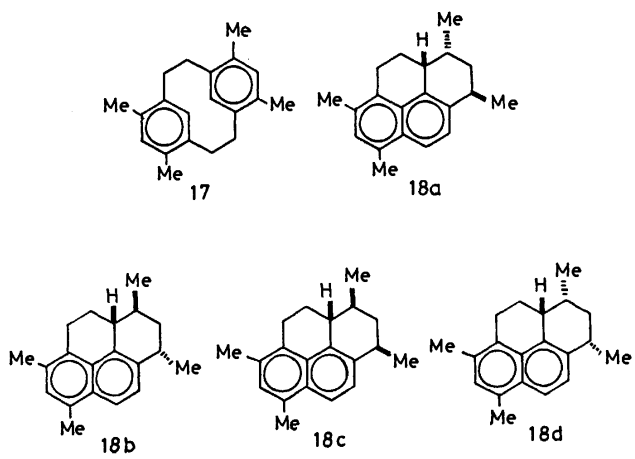
Competition between a methyl group and several functional groups were then studied using compounds **13a**, **13c**, and **13d**. Dimethyl derivative **13b** has been shown to give **14** in a quantitative yield.[2] 5-Methoxy-13-methyl derivative **13a** gave **15** exclusively. A methoxy methyl proton resonance at δ 3.90 suggests



the formation of an aromatic ether **15** but not the isomeric **16**. On the other hand, two bromo and cyano derivatives, **13c** and **13d**, gave no isomerization reaction product and were recovered unchanged under the present reaction conditions.



Structural Evidence. When an alkyl-substituted aryl ring becomes hydrogenated, the reaction mixture has been shown to be a diastereomeric mixture.[2] These isomers were separated partially by passing through alumina containing silver nitrate. The mixture could be completely analyzed by means of NMR spectroscopy with the aid of the ASIS and NOE methods and also shift reagents.[2] For example, the tetramethyl derivative **17** has been shown to give three isomeric tetramethylhexahydropyrenes, **18a**, **18b**, and **18c**, each as in a *dl* pair. The possible fourth isomer involving 1,3-diaxial methyl interaction, **18d**, could not be detected.[2]



In view of the lack of stereospecificity in this transformation, no attempt was made in the present studies to separate and characterize diastereomers. Structural evidence for the suggested structure is illustrated by the case of **10**, formed from **9**. The assignment of the five aromatic protons in **2**, H_a—H_e, has already been reported.[2] The aryl proton resonances in **10** are in agreement with the suggested substitution pattern. The compound showed a three-proton singlet corresponding to an aromatic methyl resonance at δ 2.38. The methyl groups on saturated carbon showed complex resonances at δ 0.5—1.5, suggesting a diastereomeric mixture.

The substitution pattern in the naphthalene nucleus can conveniently be learned from a UV spectral comparison. Alkyl substitution at an α position causes both bathochromic and hyperchromic shifts of the ^1L_a bands, whereas β substitution results in a red shift and intensity increase in the ^1L_b bands.[8] Figure 1 shows the UV spectra for **10**, **14**, and **18**. The examination of both the ^1L_a and ^1L_b bands suggests that the substitution pattern in the naphthalene ring for **10** is similar to that of **14**.[2] An alternative structure, **11**, would require a further shift of these bands beyond **18**.

Mass-spectral measurements also served as structural

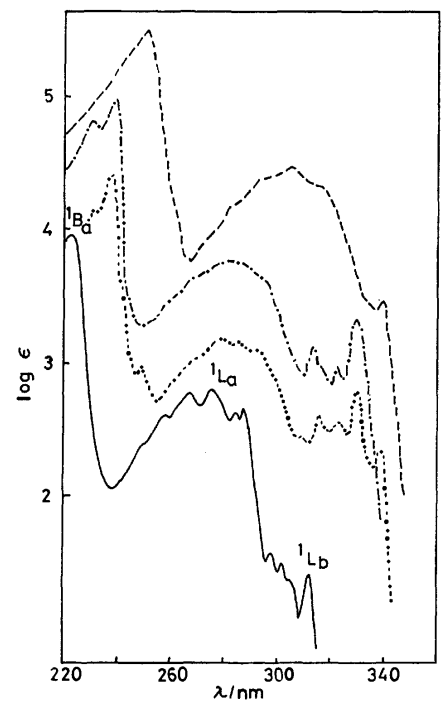


Fig. 1. The UV spectra for —— naphthalene, ------ 1,2,3,7-tetramethyl- (**10**), ····· 2,7-dimethyl- (**14**), and —— 1,3,6,8-tetramethyl-1,2,3,3a,4,5-hexahydropyrenes (**18a**, **18b**, and **18c**) determined in cyclohexane. Absorption, log ε, is for compound **10**.

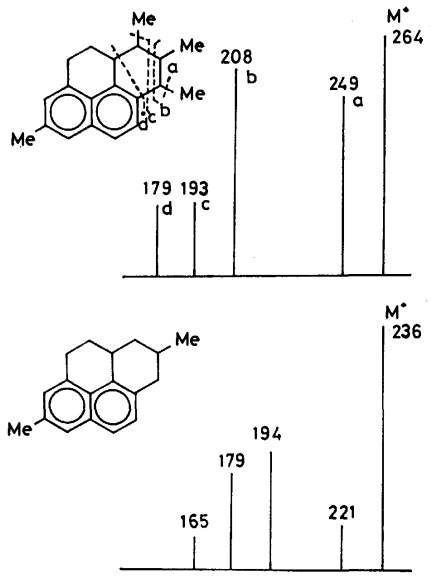

Fig. 2. The mass-spectral fragmentation for 2,7-dimethyl (**14**) and 1,2,3,7-tetramethyl-1,2,3,3a,4,5-hexahydropyrenes (**10**) determined at 70 eV.

proof. Figure 2 shows a comparison of the fragmentation pattern for **10** and **14**. The appearance of assigned peaks for **10** excludes the alternative structure, **11**, which possesses a hydroaromatic partial structure similar to that of **14**.

Compound **7a** gave poor analytical data, probably because of difficulty in purification. Its formation was supported by GC-MS carried out on an OV-1 column, which separated the diastereomeric mixture into two fractions. Both fractions gave essentially the same fragmentation pattern, with *m/e* at 208 ($-C_3H_6$: *cf.* Fig. 2, fragmentation b), 235 ($-CH_3$), and 250 (parent peak). In going into **7a** from **6a**, the NMR signals at δ 2.26, 4.08, and 4.20 in **6a** disapeared and methyl signals appeared at δ 2.40 ($ArCH_3$) and at around 1.3 (aliphatic CH_3).

Conclusion. The results obtained so far can be summarized as follows: 1) The iodine-induced cycloisomerization of substituted [2.2]metacyclophanes proceeds with a high directional selectivity. 2) An electron-donating group at the 5- (or 13-) position directs the transformation toward hexahydropyrene formation, preserving the substituted aryl ring (*cf.* compounds **3a**, **3b**, and **13a**). 3) An electron-withdrawing substituent gives no cycloisomerization reaction products under the present reaction conditions.[9] 4) When an alkyl group is present at the *ortho* position of the bridge (4,6,12,14-positions), the hydrogenation occurs on the alkyl-bearing aromatic ring. 5) An alkyl group ortho to the bridge not only enhance the rate of cycloisomerization, but gives a dehydrogenation product (*cf.* **6**→**8**, **9**→**12**).

With regard to 4) and 5), we have observed[4] that the cycloisomerization reaction of the tetramethyl derivative, **17**, and a hexamethyl derivative[4] are quite rapid compared with that of **1** and also with those of less highly substituted derivatives. The enhanced reactivity for these has been attributed to an additional strain imposed on the bridging methylene group by the vicinal methyl group. The driving force of the cycloisomerization reaction is assumed to be the internal strain of a ten-membered ring, the proximity of two reacting aryl positions, and the π-basicity of the benzene ring(s) for complexation with iodine.[2,4] With **6** and **9**, the additional strain term outweighs the normal substituent effects operating in **3** and directs the reaction toward the formation of **7** and **10**, but not **11** or the isomeric **7**, with a different naphthalene ring disposition.

Experimental

[2.2]Metacyclophane Derivatives. Compounds **3a**,[10] **3b**,[11] **6a**,[10] **6b**,[10] **13a**,[7] **13b**,[2] **13c**,[7] and **13d**[7] were prepared as has been described in the literature.

2,11-Dithia-5,6,7,15-tetramethyl[3.3]metacyclophane. 4,5,6-Trimethyl-α,α'-dichloro-*m*-xylene was treated with thiourea in ethanol and then with a potassium hydroxide solution to give 4,5,6-trimethyl-*m*-xylene-α,α'-dithiol. Benzene solutions (200 cm^3) of the dithiol (5.1 g, 24 mmol) and α,α'-dibromomesitylene (6.7 g, 24 mmol) were dropped, slowly and simultaneously, into a solution of 1.9 g (48 mmol) of sodium hydroxide in benzene (200 cm^3)–ethanol (1000 cm^3) during 24 h under reflux. The solvent was then evaporated, and washed dichloromethane extracts were passed through a silica-gel column. The bis(sulfide) was thus obtained in a 55% yield: mp 123—124 °C: NMR ($CDCl_3$) δ 2,12 (3H, s, Me), 2.16 (9H, s, Me), 3.62 (4H, s, CH_2), 3.68 (4H, s, CH_2), and 6.92 (4H, m, ArH).

Found: C, 72.86; H, 7.27%. Calcd for $C_{20}H_{24}S_2$: C, 73.11; H, 7.36%.

4,5,6,13-Tetramethyl[2.2]metacyclophane (9). The above bis(sulfide) was converted to bis(sulfone), 2,11-dithia-5,6,7,15-tetramethyl[3.3]metacyclophane 2,2,11,11-tetraoxide by oxidation with 30% hydrogen peroxide in benzene–acetic acid at room temperature. The pyrolysis of bis(sulfone) at 550 °C gave **9** (mp 113.5—114.5 °C) after chromatography on silica gel: NMR ($CDCl_3$) δ 2.29 (9H, s, Me), 2.36 (3H, s, Me), 1.9 and 3.2 (8H, m, CH_2), 4.13 (1H, t, C-16H), 4.30 (1H, s, C-8H), and 6.89 (2H, ArH).

Found: C, 90.71; H, 1.13%. Calcd for $C_{20}H_{24}$: C, 90.85; H, 9.15%.

Cycloisomerization of 9 to Give 10. A solution of (820 mg, 3.1 mmol) and iodine (110 mg, 0.43 mmol) in 9.6 cm^3 of benzene was warmed at 45 °C for 14 h. Column chromatography on alumina eluted with hexane gave **10** as an oily diastereomeric mixture in a 98% yield. Further elution gave a 2% yield of tetrahydropyrene **12**:[10] mp 117—121 °C. The cycloisomerization was nearly complete within 20 min at 51 °C, as has been observed in a preliminary experiment carried out in a NMR tube in C_6D_6: NMR ($CDCl_3$) δ 0.5—1.5 (9H, m, Me), 2.38 (3H, m, MeAr), 7.01 (1H, s, a-ArH), 7.33 (1H, s, c-ArH), 7.42 (2H, dd, d,e-ArH) (for the designation of naphthalene proton, see Formula **2**).

Synthesis of 1,1′-, 2,2′-, 1,2′-, and 2,6′-Biazulenes and Their Derivatives by Ullmann Reaction[1]

Tadayoshi MORITA* and Kahei TAKASE

Department of Chemistry, Faculty of Science, Tohoku University, Aoba Aramaki, Sendai 980

(Received July 20, 1981)

Four kinds of biazulenes, 1,1′- (**1a**), 2,2′- (**2a**), 1,2′- (**3a**), and 2,6′-biazulenes (**4a**), and their derivatives were synthesized by utilizing Ullmann-type coupling of haloazulene derivatives. Ullmann reaction of ethyl 3-iodo- (**5a**) and 2-iodoazulene-1-carboxylates (**6b**) gave diethyl 1,1′-biazulene-3,3′-dicarboxylate (**1b**) and diethyl 2,2′-biazulene-1,1′-dicarboxylate (**2b**), respectively, in excellent yields. The reaction of 2-iodoazulene gave **2a** directly. Diethyl 2-chloroazulene-1,3-dicarboxylate (**7a**) and its 5-alkyl derivatives also reacted to give tetraethyl 2,2′-biazulene-1,1′,3,3′-tetracarboxylate (**2d**) and its 5,5′-dialkyl derivatives, respectively. A mixed Ullmann reaction of **5a** and **6b** afforded a mixture of **1b**, **2b**, and diethyl 1,2′-biazulene-1′,3-dicarboxylate (**3b**). Similarly, a mixed Ullmann reaction of **7a** and diethyl 6-iodoazulene-1,3-dicarboxylate gave a mixture of **2d** and tetraethyl 2,6′-biazulene-1,1′,3,3′-tetracarboxylate (**4b**). The parent hydrocarbons of biazulenes, **1a**, **2a**, **3a**, and **4a**, could be derived from the corresponding ethoxycarbonyl derivatives, **1b**, **2b**, **2d**, **3b**, and **4b**, respectively, by decarboxylation. The planarity of biazulenes and their ester derivatives is also discussed on the basis of the spectral data.

Although benzenoid biaryls, such as biphenyls and binaphthalenes, have been known for a long time and studied extensively from the chemical and physical points of view, no biazulene, one of the non-benzenoid biaryls, had been known until Hagen *et al.*[2] reported the photochemical synthesis of 2,2′- and 3,3′-biguaiazulenes. A number of positional isomers are possible for biazulenes. Recently, 4,4′-,[3] 5,5′-,[4] and 6,6′-biazulenes[5] have been synthesized. The Ullmann-type biaryl coupling of aryl halides using copper at elevated temperature has been utilized for the synthesis of benzenoid biaryls. This reaction was applied on some haloazulene derivatives for synthesis of 1,1′- (**1a**), 2,2′- (**2a**), 1,2′- (**3a**), and 2,6′-biazulenes (**4a**), and their derivatives.

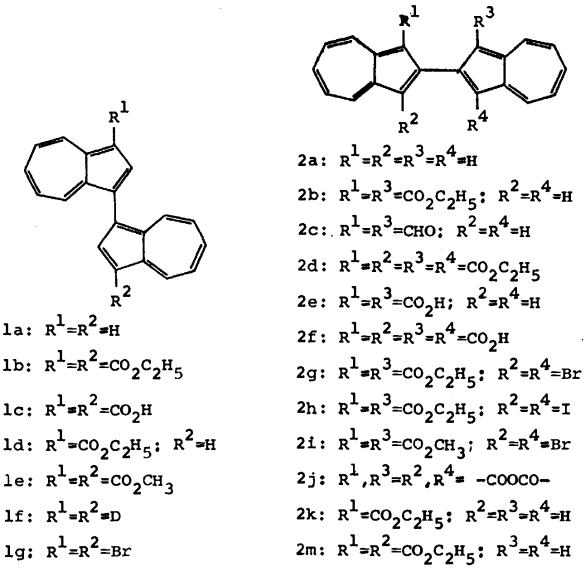

Chart 1.

Results and Discussion

A mixture of haloazulene and activated copper[6] was heated at about 200—220 °C in an evacuated sealed tube and then the products were isolated. The results are listed in Table 1.

1,1′-Biazulene. Ethyl 3-chloro- and 3-bromoazulene-1-carboxylates[7a] did not react at 220 °C, but changed into an unidentified black resinous substance at 250 °C. On the other hand, ethyl 3-iodoazulene-1-carboxylate (**5a**)[7a] easily reacted at 220 °C to give diethyl 1,1′-biazulene-3,3′-dicarboxylate (**1b**), accompanied by a small amount of dehalogenated[8] ethyl azulene-1-carboxylate (**5b**).[9]

The complete hydrolysis of **1b** with alkali, and the subsequent decarboxylation of the resulting dicarboxylic acid (**1c**) upon heating gave the parent hydrocarbon, **1a**, in 55% yield. The mass spectrum of **1a** shows a molecular ion peak at *m/e* 254. A partial hydrolysis of **1b** with alkali, followed by decarboxylation afforded ethyl 1,1′-biazulene-3-carboxylate (**1d**) as a major product. Methylation of **1c** with diazomethane yielded a dimethyl ester (**1e**). Deuteration[10] of **1a** with D_3PO_4 gave 1,1′-biazulene-3,3′-d_2 (**1f**) and bromination of **1a** with NBS gave an expected 3,3′-dibromo derivative (**1g**).

2, 2′-Biazulene. 2-Iodoazulene (**6a**)[7c] and ethyl 2-iodoazulene-1-carboxylate (**6b**)[7b] when heated with activated copper, reacted to give 2,2′-biazulene (**2a**) and diethyl 2,2′-biazulene-1,1′-dicarboxylate (**2b**), accompanied by small amounts of azulene and **5b**, respectively. 2-Iodoazulene-1-carboxaldehyde (**6c**), derived from **6a**, also reacted to give 2,2′-biazulene-1,1′-dicarboxaldehyde (**2c**). 2-Chloroazulene and ethyl 2-chloroazulene-1-carboxylate[7c] did not react at 220—240 °C. However, diethyl 2-chloroazulene-1,3-dicarboxylate (**7a**),[7b,7c] in which two electron-withdrawing ethoxycarbonyl substituents will activate the halogen, easily reacted to give tetraethyl 2,2′-biazulene-1,1′,3,3′-tetracarboxylate (**2d**) in an excellent yield, accompanied by a small amount of dehalogenated diethyl azulene-1,3-dicarboxylate (**7d**).[9] Similarly, 5-methyl (**7b**)[7b] and 5-isopropyl derivatives (**7c**)[7b] also yielded tetraethyl 5,5′-dimethyl- (**8a**) and 5,5′-diisopropyl-2,2′-biazulene-1,1′,3,3′-tetracarboxylate (**8b**), respectively, along with the dehalogenated azulenes (**7e** and **7f**), although some of the starting haloazulenes were recovered unchanged. Besides the direct formation from **6a**, the parant hydrocarbon, **2a**, was derived from **2b** and **2d** by deethoxy-

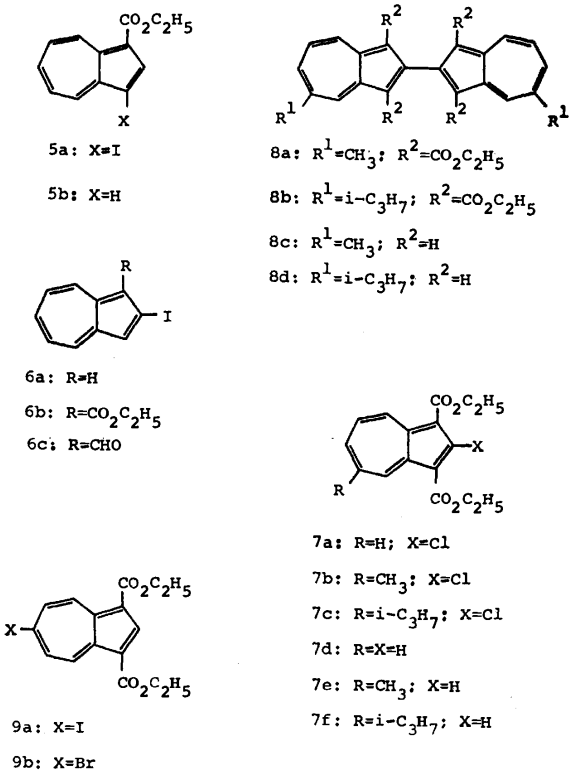

Chart 2.

TABLE 1. THE ULLMANN-TYPE COUPLING OF HALOAZULENES INTO BIAZULENES

Haloazulene	Temp °C	Time h	Products (yield/%) Biazulenes	Others
5a	200	5	**1b** (83)	**5b** (8)
6a	180	6	**2a** (54)	Azulene (trace)
6b	220	6.5	**2b** (82)	**5b** (trace)
6c	220	4.5	**2c** (40)	
7a	220	9	**2d** (83)	**7d** (6)
7b	220	6.5	**8a** (53)	**7e** (7)
7c	235	6	**8b** (11)	**7f** (trace)
5a+**6b**	200	5.5	**1b** (28), **2b** (27), **3b** (22)	**5b** (18)
7a+**9a**	245	6	**2d** (21), **4b** (7)	**7d** (28)

carbonylation. Thus, alkaline hydrolysis of **2b** and **2d** and the subsequent decarboxylation of the resulting di- (**2e**) and tetracarboxylic acids (**2f**) upon heating gave **2a**. Conveniently, **2a** could be obtained directly from **2b** and **2d** by deethoxycarbonylation upon heating with 100% phosphoric acid[7a,7b,11] in excellent yields. Similar treatment of **8a** and **8b** gave 5,5'-dimethyl (**8c**) and 5,5'-diisopropyl-2,2'-biazulenes (**8d**), respectively. The mass spectrum of **2a** shows a molecular ion peak at *m/e* 254.

Vilsmeier reaction of **2a** gave a diformyl derivative which is identical with **2c**. Halogenation of the diester, **2b**, with **NBS** or **NIS** gave diethyl 3,3'-dibromo- (**2g**) or 3,3'-diiodo-2,2'-biazulene-1,1'-dicarboxylates (**2h**). Dimethyl 3,3'-dibromo-2,2'-biazulene-1,1'-dicarboxylate (**2i**) was derived from **2g** by alkaline hydrolysis, followed by methylation. When treated with acetic anhydride, the tetracarboxylic acid, **2f**, yielded a dianhydride (**2j**), whose ethanolysis with sodium ethoxide followed by decarboxylation upon heating afforded a mixture of **2a**, **2b**, ethyl 2,2'-biazulene-1-carboxylate (**2k**), and diethyl 2,2'-biazulene-1,3-dicarboxylate (**2m**).

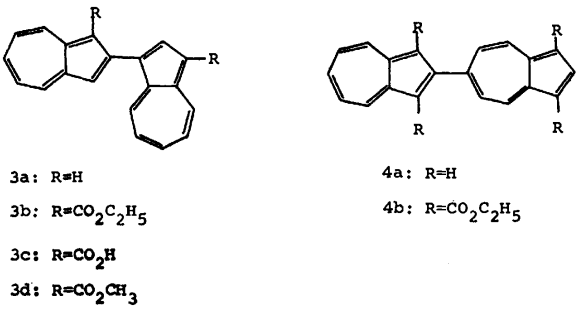

Chart 3.

1,2'-Biazulene. A mixed Ullmann reaction of **5a** and **6b** afforded a mixture of **1b**, **2b**, and diethyl 1,2'-biazulene-1',3-dicarboxylate (**3b**). The parent hydrocarbon, **3a**, was obtained from **3b** upon alkaline hydrolysis followed by decarboxylation of the resulting dicarboxylic acid (**3c**). Its mass spectrum shows a molecular ion peak at *m/e* 254. Dimethyl 1,2'-biazulene-1',3-dicarboxylate (**3d**) was derived from **3c** by methylation.

2,6'-Biazulene. A mixed Ullmann reaction of **7a** and diethyl 6-iodoazulene-1,3-dicarboxylate (**9a**) prepared from 6-bromo compound (**9b**)[12] gave a mixture of **2d** and tetraethyl 2,6'-biazulene-1,1',3,3'-tetracarboxylate (**4b**). The expected 6,6'-biazulene could not be obtained. The parent hydrocarbon, **4a**, was obtained by deethoxycarbonylation of **4b** upon heating with 100% phosphoric acid.

The structures of biazulenes and their derivatives obtained here were confirmed on the basis of the spectral data described below, as well as the above-mentioned chemical evidence.

Infrared Spectra of Biazulenes. The C=O stretching vibrations in the ester derivatives of biazulenes are listed in Table 2. Even for the sterically crowded biazulene derivatives, **2b**, **2d**, **4b**, **8a**, and **8b**, these bands appear in the region comparable to those of the

conjugated esters in azulene derivatives. This suggests that, in these compounds, the ester groups are favorably in the same plane with the azulene ring and, consequently, the two azulene rings in **2b**, **2d**, **4b**, **8a**, and **8b** are not coplanar.

Electronic Spectra of Biazulenes. Biazulenes show four main electronic absorption bands (A, B, C, and D) in analogy with azulene (shown in Tables 3 and 4). As shown in Figs. 1 and 2, in the spectra of the parent biazulenes, **1a**, **2a**, **3a**, and **4a**, the bands (B, C, and D) in the ultraviolet region show large red shifts with increasing intensities compared with those of azulene, while the visible absorptions (A) exhibit increases in intensities accompanied by loss of the fine structures that appeared in the spectrum of azulene. It is known[13] that the substitution of alkoxycarbonyl groups at C-1 and/or C-3 of azulenes results in blue shift of the band (A) and in red shift of the bands (B and C). The substitution of ethoxycarbonyl groups at C-3 (and C-3′) of 1,1′-biazulene causes blue shifts while decreasing the intensity of band (A), but no apprecible effect on band (B). The substitution of ethoxycarbonyl groups at C-1′, 3 of 1,2′-biazulene results in blue shifts of the bands (A and B).

In the case of 2,2′-biazulene, the substitution of ethoxycarbonyl groups at C-1, 1′ (and C-3, 3′) results in blue shifts of the bands (A and B). Especially the spectra of tetraesters, **2d**, **8a**, and **8b**, are similar to those of diethyl azulene-1,3-dicarboxylates, **7d**, **7e**, and

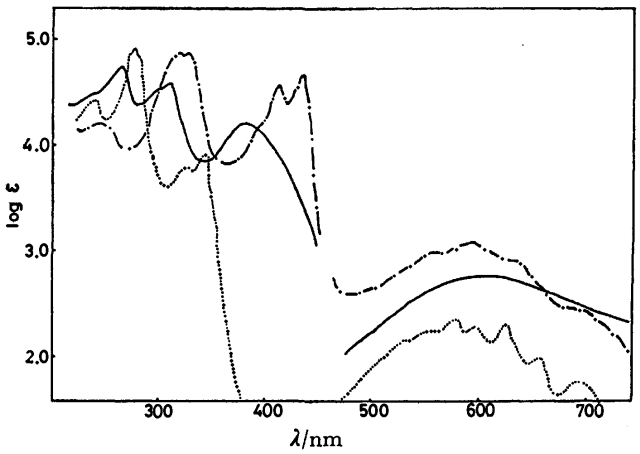

Fig. 1. Electronic Spevtra of **1a** (—— in methanol for UV, isooctane for visible region), **2a** (—·— in chloroform), and azulene (····· in cyclohexane).

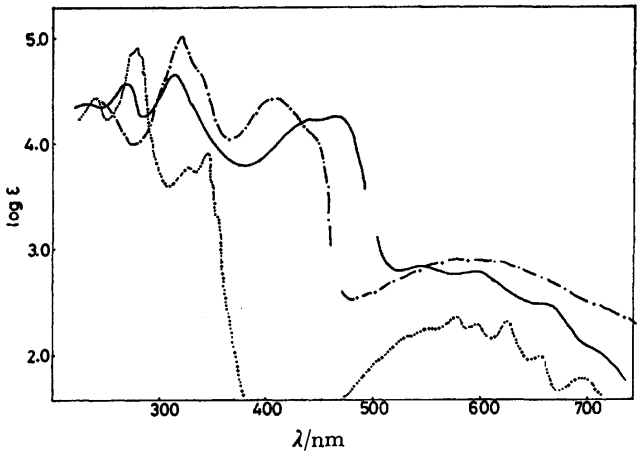

Fig. 2. Electronic Spectra of **3a** (—— in methanol for UV, isooctane for visible region), **4a** (—·— in chloroform), and azulene (····· in cyclohexane).

7f, but the molar absorption coefficients being approximately doubled. This observation suggests that the two azulene rings in **2d**, **8a**, and **8b** are twisted around the 2,2′-bond.

The NMR Spectra of Biazulenes. The NMR spectra data of biazulenes and chemical shift differences ($\Delta\delta$) between biazulenes and the reference compounds are listed in Tables 5 and 6. A study using a Dreiding model of 1,1′-biazulene shows that the steric interactions for H-2···H-8′, H-2′···H-8, and H-8···H-8′ are significant and sugests that the two azulene ring are not coplanar with each other. In fact, in the NMR spectral data of 1,1′-biazulenes, **1a**, **1b**, and **1d**, it is observed that there is no large chemical shift deference ($\Delta\delta$) between the ring protons in **1a** and those in azulene, and between the ethyl protons in esters, **1b** and **1d**, and

a) In symmetrical biazulenes (**1a**, **1b**, **2a**, **2b**, and **8a**—**d**), the chemical shift differences for two identical protons are listed on upper line. b) In asymmetrical biazulenes (**3a**, **b** and **4a**, **b**), the chemical shift difference for the protons numbered with prime are listed on lower line.

those in **5b**. So, it seems that the two azulene rings in 1,1′-biazulenes, **1a**, **1b**, and **1d**, are not coplanar. In contrast with this, in the NMR spectra of 2,2′-biazulenes, **2a**, **8c**, and **8d**, it is shown that the ring protons (H-1, 1′, 3, and 3′) at the 1 and 3-positions of azulene rings are shifted markedly downfield by 0.35—0.43 ppm and the other ring protons slightly upfield. The downfield shifts of H-1, 1′, 3, and 3′ in 2,2′-biazulenes suggest that these protons are located in the peripheral zone of another azulene ring and consequently, 2,2′-biazulenes, **2a**, **8c**, and **8d**, exist in such a conformation that the two azulene rings are coplanar or nearly coplanar. This result is consistent with the conclusion from the ESR study on 2,2′-biazulene anion radical in which the two azulene rings were found to be coplanar.[14] The NMR spectrum of 2,6′-biazulene, **4a**, also shows downfield shifts of H-1, 3 and H-5′, 7′ by δ 0.39 and 0.78 ppm, respectively, compared with the corresponding protons of azulene. This fact suggests that **4a** also exists in a coplanar conformation.

On the other hand, in the NMR spectra of sterically crowded ester derivatives of 2,2′-biazulenes, **2b**, **2d**, **8a**, and **8b**, the ethyl proton signals of the ethoxycarbonyl groups appear at higher field than of **5b** and **7b**. Such a large upfield shift of ethyl proton signals presumably arises from long-range shielding by another azulene ring. This fact suggests that ethoxyl groups are located above the plane of another azulene ring and consequently, that the two azulene rings in ester derivatives, **2b**, **2d**, **8a**, and **8b**, are twisted to avoid the large steric interactions between the ethoxycarbonyl groups at C-1, 3 and C-1′, 3′.

Experimental

All mp's were uncorrected. Electronic spectra were measured on a Hitachi EPS-3 Spectrometer and IR Spectra on a Shimadzu IR-27 infracord. NMR spectra were obtained by a Varian A-60 D Spectrometer and in some cases on a JNM-100 instrument in Fourier transform mode. Mass spectra were recorded on a Hitachi RMU-6 mass spectrometer at 25 eV.

General Procedure for Ullmann Reaction of Haloazulenes. A mixture of haloazulenes and activated copper[6] was heated in an evacuated, sealed glass tube (see Table 1). After cooling, the reaction mixture was extracted with chloroform. The solvent was evaporated *in vacuo* and the resulting residue was chromatographed.

Reaction of **5a**. A mixture of **5a**[7a] (500 mg) and copper (500 mg) was treated according to the general procedure. A green residue from the extract was chromatographed on a silica-gel column with benzene as an eluent to give two fractions. The first fraction gave 23 mg of **5b**.[9] The second fraction gave 254 mg of **1b** as bluish green needles (from cyclohexane–benzene): mp 211—212 °C; IR (KBr) 1684, 1449, 1414, 1285, 1205, 1044, 781, and 741 cm^{-1}. Found: C, 78.62; H, 5.84%. Calcd for $C_{26}H_{22}O_4$: C, 78.37; H, 5.57%.

Reaction of **6a**. A mixture of **6a**[7c] (300 mg) and copper (600 mg) was treated according to the general procedure. The products were chromatographed on an alumina column with benzene. The first fraction gave a small amount of azulene. The second fraction gave 81 mg of **2a** as green scales (from chloroform): mp 320 °C.

Reaction of **6b**. A mixture of **6b**[7b] (100 mg) and copper (200 mg) was treated in the usual way. The products were chromatographed on an alumina column with benzene to give three fractions. The first fraction gave a small amount of a mixture of **5b** and **6b**. The second fraction gave 50 mg of **2b** as bluish needles (from ethanol); mp 151.5—152 °C. Found: C, 78.63; H, 5.53%. Calcd for $C_{24}H_{18}O_4$: C, 78.37; H, 5.57%. The third fraction eluted with chloroform gave 4 mg of brown needles[15] (from benzene); mp 245—246 °C. [MS, *m/e*: 352 (M^+, 100%); calcd for $C_{24}H_{16}O_3$, 352 (M)].

Reaction of **6c**. A mixture of **6c** (363 mg) and copper

(700 mg) was treated according to the general procedure. The products were chromatographed on an alumina column with chloroform to give 160 mg of **2c** as dark violet scales (from chloroform); mp 284—285 °C (dec); IR (KBr) 1635 cm^{-1}; NMR ($CDCl_3$) δ=7.45 (2H, s, H-3,3'), 7.6—8.1 (6H, m, H-5,5',-6,6' and -7,7'), 8.55 (dm, J=10 Hz, H-4,4'), 9.90 (2H, dm, J=10 Hz, H-8,8'), and 10.37 (s, 2 CHO). Found: C, 85.10; H, 4.34%. Calcd for $C_{22}H_{14}O_2$: C, 85.14; H, 4.55%.

Reaction of 7a. A mixture of **7a**[7c] (100 mg) and copper (200 mg) was treated in the usual way. The products were chromatographed on a silica-gel column with benzene to give three fractions. The first fraction gave 5 mg of **7d**.[9] The second fraction gave 8 mg of **7a**. The third fraction eluted with chloroform gave 73 mg of **2d** as red prisms (from ethanol); mp 181—182 °C. Found: C, 71.01; H, 5.72%. Calcd for $C_{32}H_{30}O_8$: C, 70.83; H, 5.57%.

Reaction of Diethyl 2-Chloro-5-methylazulene-1,3-dicarboxylate (7b). A mixture of **7b**[7b] (1.09 g) and copper (2.18 g) was treated in the usual way. Chromatography of the products on a silica-gel column with benzene gave two fractions. The first fraction gave 140 mg of a mixture of **7b** and diethyl 5-methylazulene-1,3-dicarboxylate (**7e**)[16] (1 : 1 ratio by NMR). The second fraction gave 515 mg of **8a** as red prisms (from benzene–cyclohexane); mp 179—180 °C. Found: C, 71.69; H, 6.25%. Calcd for $C_{34}H_{34}O_8$: C, 71.56; H, 6.01%.

Reaction of Diethyl 2-Chloro-5-isopropylazulene-1,3-dicarboxylate (7c). A mixture of **7c**[7b] (500 mg) and copper (1.0 g) was treated in the manner described above. The chromatography of the products on a silica-gel column with benzene gave two fractions. The first fraction gave a small amount of a mixture of **7c** and diethyl 5-isopropylazulene-1,3-dicarboxylate (**7f**).[17] The second fraction gave 50 mg of **8b** as red prisms (from ethanol); mp 174—175 °C. Found: C, 72.93; H, 6.90%. Calcd for $C_{38}H_{42}O_8$: C, 72.82; H, 6.76%.

Reaction of a mixture of 5a and 6b. A mixture of **5a** (200 mg), **6b** (200 mg), and copper (400 mg) was treated in the usual way. The chromatography of the product on a silica-gel column with benzene gave fractions, a, b, c, and d. The fraction a, b, and d gave **5b** (45 mg), **1b** (68 mg), and **2b** (65 mg), respectively. The yellow fraction c gave 53 mg of **3b** as dark green needles (from cyclohexane); mp 119—120 °C. Found: C, 78.12; H, 5.74%. Calcd for $C_{26}H_{22}O_4$: C, 78.37; H, 5.57%. TNB-complex: brown needles (from ethanol); mp 130—131 °C. Found: C, 63.04; H, 4.42; N, 6.73%. Calcd for $C_{32}H_{25}O_{10}N_3$: C, 62.80; H, 4.12; N, 6.87%.

Reaction of a Mixture of 7a and 9a. A mixture of diethyl 6-bromoazulene-1,3-dicarboxylate (**9b**)[12] (900 mg), potassium iodide (17 g), water (10 cm^3), and acetic acid (80 cm^3) was treated under reflux for 50 h. The reaction mixture was diluted with water and the resulting precipitate was collected by filtration and dried *in vacuo*. Chromatography on a silica-gel column with benzene gave a mixture of diethyl 6-iodoazulene-1,3-dicarboxylate (**9a**) and **9b** (1 : 5 ratio by NMR), which could not be separated by thin layer chromatography. NMR of **9a**: δ=1.45 (t, J=7.0 Hz, 2 $OCH_2C\underline{H}_3$), 4.45 (q, J=7.0 Hz, 2 $OC\underline{H}_2CH_3$), 7.81 (d, J=11.5 Hz, H-5,7), 8.80 (s, H-2), 9.61 (d, J=11.5 Hz, H-4,8). This mixture of 6-haloazulenes (680 mg) was mixed with **7a** (1.0 g) and copper (2.0 g) and the mixture was treated in the manner described above. The chromatography of the crude products on a silica-gel column with benzene gave six bands. The fifth band afforded 61 mg of **4b** as red needles (from ethanol); mp 257—258 °C. Found: C, 70.50; H, 5.31%. Calcd for $C_{32}H_{30}O_4$: C, 70.83; H, 5.51%. From the sixth band 276 mg of **2d** was obtained.

1,1'-Biazulene-3,3'-dicarboxylic Acid (1c). A solution of **1b** (256 mg) dissolved in a solution of potassium hydroxide (100 mg) in ethanol (25 cm^3) containing water (0.5 cm^3) was heated under reflux for 5 h. After cooling the solution was diluted with water (30 cm^3) and acidified with 2 mol dm^{-3} HCl. Greenish crystals separated out were collected by filtration and washed repeated with water, to afforded 224 mg (98%) of **1c** as microcrystals, mp 290—293 °C (dec). IR (KBr): 3000—2570, 1647, 1456, 1287, 1236, 1029, 755, and 732 cm^{-1}. Found: C, 77.02; H, 4.24%. Calcd for $C_{22}H_{14}O_4$: C, 77.18 ; H, 4.12%.

1,1'-Biazulene (1a): Heating of **1c** (280 mg) at 250 °C/15 Torr† in a sublimation apparatus afforded 120 mg of blue crystals which were chromatographed on an alumina column (benzene) to give a single bluish green fraction, yielding 115 mg (55%) of **1a** as bluish green scales (from hexane): mp 104—105 °C; MS, *m/e*, 255 (M^+ +1, 21.4%), 254 (M^+, 100), 253 (M^+ −1, 18.5), 252 (41.4), and 251 (22.8); IR (KBr) 2990 (w), 1567 (s), 1488 (m), 1453 (m), 1406 (w), 1389 (vs), 1304 (m), 1290 (m), 1269 (w), 1212 (m), 1142 (w), 1130 (w), 1043 (w), 967 (w), 961 (w), 943 (m), 900 (m), 877 (w), 855 (w), 827 (m), 787 (vs), 747 (m), 735 (m), and 727 (s) cm^{-1}. Found: C, 94.35; H, 5.83%. Calcd for $C_{20}H_{14}$: C, 94.45; H, 5.55%.

TNB Complex of 1a: Dark blue neeldes (from ethanol): mp 200—201 °C. Found: C, 56.23; H, 3.17; N, 12.06%. Calcd for $C_{32}H_{20}O_{12}N_6$: C, 56.52; H, 2.96; N, 12.13%. IR (KBr) 2990, 1972, 1569, 1488, 1453, 1389, 1304, 1290, 1269, 1212, 1147, 1130, 1043, 967, 961, 943, 936, 900, 877, 855, 827, 787, 747, 735, and ,727 cm^{-1}.

Ethyl 1,1'-Biazulene-3-carboxylate (1d). To a warmed ethanol solution (25 cm^3) of **1b** (76 mg, 0.19 mmol) was added 1 cm^3 of aqueous KOH (11 mg, 0.19 mmol) . The solution was heated under reflux for 15 min and then diluted with water (50 cm^3). The precipitated **1b** (3 mg) was colloected by filtration. The filtrate was acidified with diluted HCl to give a mixture of di- and monocarboxylic acids which was collected by filtration and dried. The mixture, without further purification, was heated at 270—280 °C/10 Torr in a sublimation apparatus to give a mixture of the decarboxylated products, which was chromatographed on an alumina column with benzene. The first elution with benzene afforded 4 mg of **1a**. The second elution with benzene yielded 18 mg of **1d**, blue needles (from ethanol), mp 137—138 °C. Found: C, 84.89; H, 5.72%. Calcd for $C_{23}H_{18}O_2$: C, 84.64; H, 5.56%.

Dimethyl 1,1'-Biazulene-3,3'-dicarboxylate (1e). Treatment of **1c** (51 mg) with ethereal diazomethane gave 39 mg of **1e** as bluish green needles (from benzene–cyclohexane): mp 232—233 °C; UV_{max} (MeOH), nm (log ε), 240 (4.64), 279 (4.83), 304 (4.71), and 405 (4.14), [575 (2.30) in isooctane]; IR (KBr) 1701, 1200, 1029 cm^{-1}. Found: C, 77.76; H, 4.66%. Calcd for $C_{24}H_{18}O_4$: C, 77.82; H, 4.90%.

1,1'-Biazulene-3,3'-d_2 (1f). This compound was prepared by a modification of the method reported.[10] To a solution of **1a** (50 mg) in cyclohexane (5 cm^3) was added 85% D_3PO_4 (3 cm^3) under a nitrogen atmosphere. The solution was shaken until **1a** in the organic layer had transferred completely into the D_3PO_4 phase and then the upper layer was removed by using a small pipette. To the brown phosphoric acid layer obtained was added 3 cm^3 of deuterium oxide. The resulting solution was extracted with cyclohexane. The organic layer was passed through anhydrous sodium sulfate and evaporated under a reduced pressure. The crude product was recrystallized from pentane to give 39 mg of **1f** as bluish green scales: mp 103—104 °C; MS, *m/e*, 256 (M^+,

† 1 Torr≈133.322 Pa.

100%); NMR ($CDCl_3$) δ=6.97 (t, J=9.5 Hz, H-7,7'), 7.05 (t, J=9.5 Hz, H-5,5'), 7.50 (t, J=9.5 Hz, H-6,6'), 8.04 (s, H-2,2'), 8.25 (d, J=9.5 Hz, H-4,4' or H-8,8'), and 8.29 (d, J=9.5 Hz, H-8,8' or H-4,4').

*3,3'-Dibromo-1,1'-biazulene (**1g**).* To a solution of **1a** (50.8 mg) in benzene (2 cm^3) was added NBS (72 mg) with stirring at room temp. After stirring for a day, the reaction mixture was chromatographed on an alumina column with benzene to give 52.8 mg of **1g** as blue needles (from cyclohexane–benzene 9 : 1 mixture): mp 173—175 °C; IR (KBr) 1579, 1381, 862, and 737 cm^{-1}; NMR ($CDCl_3$) δ= 7.20 (t, J=10 Hz, H-5,5' and H-7,7'), 7.78 (t, J=10 Hz, H-6,6'), 7.96 (s, H-2,2'), and 8.20 and 8.35 (d, J=9.5 Hz, H-4,4' and H-8,8'). Found: C, 58.00; H, 3.07%. Calcd for $C_{20}H_{12}Br_2$: C, 58.29; H, 2.94%.

*2,2'-Biazulene-1,1'-dicarboxylic Acid (**2e**).* A solution of **2b** (180 mg) and potassium hydroxide (60 mg) in 0.5 cm^3 of water and 5 cm^3 of ethanol was heated under reflux for 3 h, and diluted water (10 cm^3). After cooling, the solution was acidified by 1 mol dm^{-3} HCl to give 150 mg (97%) of **2e** as red crystals (from ethanol): mp 160—165 °C (dec); IR (KBr) 3030, 1650, 1395, 1239, 950, and 814 cm^{-1}. Found: C, 77.08; H, 4.30%. Calcd for $C_{22}H_{14}O_4$: C, 77.18; H, 4.12%.

Dimethyl 2,2'-Biazulene-1,1'-dicarboxylate was obtained by treatment of **2e** with ethereal diazomethane as blue-violet needles (from methanol): mp 183—184 °C; IR (KBr) 1689 cm^{-1}; NMR ($CDCl_3$) δ=3.63 (s, 2 CO_2CH_3), 7.40 (s, H-3,3'), 7.3—7.9 (m, H-5—7 and H-5'—7'), 8.38 (d, J=9 Hz, H-4,4'), and 9.56 (d, J=9 Hz, H-8,8'). Found: C, 77.73; H, 4.81%. Calcd for $C_{24}H_{18}O_4$: C, 77.82; H, 4.90%.

*2,2'-Biazulene-1,1',3,3'-tetracarboxylic Acid (**2f**).* A solution of **2d** (300 mg) and potassium hydroxide (320 mg) in 0.5 cm^3 of water and 8 cm^3 of ethanol was refluxed for 10 h. The solution was diluted with 20 cm^3 of water and filtreted through a glass-filter to remove an insoluble material. The filtrate was acidified with 2 mol dm^{-3} HCl and then red crystals separated out were collected by filtration and repeatedly washed with water to give 231 mg of **2f** as red crystalline powder, mp 210—215 °C, which is sparingly soluble in organic solvents. IR (KBr) 3030, 1701 sh, 1658, 1449, and 1229 cm^{-1}. Found: C, 67.03; H, 3.41%. Calcd for $C_{24}H_{14}O_8$: C, 66.98; H, 3.28%.

Treatment of **2f** with diazomethane afforded the tetramethyl ether as red prisms (from chloroform): mp—320 °C; NMR ($CDCl_3$) δ=3.45 (s, OCH_3), 7.5—8.0 (m, H-5—7 and H-5'—7'), 9.75 (br d, J=9 Hz, H-4,4' and H-8,8'); IR (KBr) 1695, 1451, 1391, 1193, and 1151 cm^{-1}. Found: C, 68.81; H, 4.54%. Calcd for $C_{28}H_{22}O_8$: C, 69.13; H, 4.56%.

*2,2'-Biazulene (**2a**).* *Decarboxylation of **2e**:* Heating of **2e** (100 mg) at 250 °C/0.5 Torr in a sublimation apparatus afforded green solid which was dissolved in chloroform and the solution was passed through an alumina column. The solvent of the eluent was removed *in vacuo*. The residue was recrystallized from chloroform to give 43 mg of **2a** as green scales with metallic luster: mp>320 °C; IR (KBr) 3030 (w), 1567 (m), 1534 (m), 1451 (m), 1408 (s), 1389 (m), 1359 (m), 1299 (w), 1248 (w), (1096 w), 1012 (w), 989 (w), 971 (w), 899 (w), and 720 (s) cm^{-1}; NMR (DMSO-d_6, at 150 °C) δ= 7.15 (br t, J=9 Hz, H-5,5',7,7'), 7.40 (br t, J=9 Hz, H-6,6'), 7.85 (s, H-1,1', 3,3'), 8.31 (br d, J=9 Hz, H-4,4',8,8'); MS, *m/e*, 255 (M^+ +1, 20.6%), 254 (M^+, 100), and 252 (27.4). Found: C, 94.47; H, 5.41%. Calcd for $C_{20}H_{14}$: C, 94.45; H, 5.55%.

*Decarboxylation of **2f**:* The treatment of **2f** in a manner similar to that described above gave 23 mg of **2a**.

*Deethoxycarbonylation of **2b** with 100% Phosphoric Acid:* A mixture of **2b** (300 mg) and 100% phosphoric acid (3 cm^3) was heated at 95 °C for 1 h. The reaction mixture was diluted with ice–water (10 g). Green crystals were collected by filtration, washed repeatedly with water and dried, yielding 19 mg (99%) of **2a**.

*Deethoxycarbonylation of **2d** with 100% Phosphoric Acid:* A mixture of **2d** (50 mg) and 100% phosphoric acid (3 cm^3) was heated at 95 °C for 2 h. The reaction mixture was treated in a manner to the above, yielding 20 mg (95%) of **2a**.

*5,5'-Dimethyl-2,2'-biazulene (**8c**).* A mixture of **8a** (55 mg) and 100% phosphoric acid (3 cm^3) was treated in a manner similar to the above, yielding 28 mg (99%) of **8c** as green needles (from chloroform): mp 244—245 °C; MS, *m/e*, 282 (M^+, 100%), 265 (14), 141 (M^{2+}, 11); IR (KBr) 2985 (w), 2890 (w), 1572 (m), 1522 (m), 1464 (m), 1418 (m), 1391 (s), 1376 (m), 1302 (w), 1250 (w), 1218 (m), 1157 (w), 1057 (w), 979 (m), 936 (m), 910 (m), 837 (m), 804 (s), 794 (m), 763 (w), and 733 (m) cm^{-1}; NMR (DMSO-d_6) δ=2.58 (s, 2 CH_3), 7.05 (t, J=10 Hz, H-7,7'), 7.47 (d, J=10 Hz, H-6,6'), 7.72 (s, H-1,1',3,3'), 8.18 (d, J=10 Hz, H-8,8'), and 8.27 (br s, H-4,4'). Found: C, 93.13; H, 6.48%. Calcd for $C_{22}H_{18}$: C, 93.57; H, 6.43%.

*5,5'-Diisopropyl-2,2'-biazulene (**8d**).* *Deethoxycarbonylation of **8b** with 100% Phosphoric Acid:* A mixture of **8b** (40 mg) and 100% phosphoric acid (3 cm^3) was treated in a manner similar to the above, afforded 20 mg of **8d** (from pentane): mp 150—151 °C; MS, *m/e*, (M^+ +2, 40%), 339 (M^+ +1, 30), 338 (M^+, 100), 323 (M^+ −15, 40), 308 (M^+ −30, 6), 265 (12), and 169 (M^{2+}, 9); IR (KBr) 2985 (m), 2959 (m), 1572 (m), 1520 (m), 1460 (m), 1445 (m), 1403 (vs), 1381 sh (m), 1333 (w), 1299 (w), 1250 (w), 1220 (w), 1182 (w), 1136 (w), 1101 (w), 1012 (w), 941 (w), 928 (m), 882 (w), 815 (vs), and 770 (m) cm^{-1}. Found: C, 91.86; H, 7.63%. Calcd for $C_{26}H_{26}$: C, 92.26; H, 7.74%.

With Alkaline Hydrolysis: A solution of **8b** (100 mg) and potassium hydroxide (80 mg) in a mixture of water (0.3 cm^3) and ethanol (5 cm^3) was heated under reflux for 3 h. After cooling, the solution was diluted with water (10 cm^3) and acidified with 1 mol dm^{-3} HCl to give 72 mg of a tetracarboxylic acid. Decarboxylation of the acid (60 mg) by heating at 260 °C/0.5 Torr in sublimation apparatus afforded 37 mg of **8d** as green needles, mp 150—151 °C (from pentane).

*2-Iodoazulene-1-carboxaldehyde (**6c**).* To a solution of **6a**[7c] (100 mg) in DMF (0.5 cm^3) was added phosphoryl chloride (0.1 cm^3) at room temp with stirring. After being stirred for another 1 h, the reaction mixture was poured into sat. aq $NaHCO_3$ and extracted with ether. The organic extract was washed with water, dried over Na_2SO_4, and evaporated. The residue was chromatographed on an alumina column with benzene to give 110 mg (99%) of **6c** as red prisms (from ethanol); mp 140—141 °C; IR (KBr) 1639 cm^{-1}; NMR ($CDCl_3$) δ=7.43 (s, H-3), 7.3—8.0 (m, H-5—7), 8.33 (d, J=10 Hz, H-4), 9.70 (d, J=10 Hz, H-8), and 10.12 (s, CHO). Found: C, 47.18; H, 2.70%. Calcd for $C_{11}H_7OI$: C, 46.85; H, 2.52%.

*Formylation of **2a**.* To a suspension of **2a** (20 mg) in DMF (3 cm^3) was added $POCl_3$ at room temp with stirring. The mixture was heated at 60 °C for 1 h and then quenched with water to give green crystals, which were collected by filtration, dried over $CaCl_2$, in a desiccator. The chromatography of the crude products on an alumina column with chloroform gave 24 mg (98%) of **2c**, dark violet scales, mp 284—285 °C (dec).

*Diethyl 3,3'-Dibromo-2,2'-biazulene-1,1'-dicarboxylate (**2g**).* To a solution of **2b** (580 mg) in dry benzene (50 cm^3) was added NBS (636 mg). The mixture was stirred overnight at room temp. The color of the solution turned bluish violet

from reddish violet. The solvent was evaporated and the residue was chromatographed on a silica-gel column with benzene to give 569 mg of **2g** as blue needles (from ethanol): mp 178—179 °C. λ_{max} (MeOH), nm (log ε), 239 (4.37), 315 (4.78), 364 sh, and 380 (3.93) [560 (3.00), 598 (2.97), 656 (2.62) in benzene]; IR (KBr) 1686 cm^{-1}; NMR ($CDCl_3$) δ=0.65 (t, J=7.0 Hz, 2 $OCH_2C\underline{H}_3$), 4.00 (q, J=7.0 Hz, 2 $OC\underline{H}_2CH_3$), 7.35—8.10 (m, H-5—7 and H-5'—7'), 8.58 (d, J=9 Hz, H-4,4'), and 9.73 (br d, J=9 Hz, H-8,8'). Found: C, 56.30; H, 3.72%. Calcd for $C_{26}H_{20}O_4Br_2$: C, 56.16; H, 3.63%.

Diethyl 3,3'-Diiodo-2,2'-biazulene-1,1'-dicarboxylate (2h). To a solution of **2b** (292 mg, 0.73 mmol) in CH_2Cl_2 (3 cm^3) was added *N*-iodosuccinimide (352 mg) with stirring at room temp. After stirring for 1.5 h, the reaction mixture was chromatographed on an alumina column with benzene to give violet crystals (496 mg) of 2 h. Recrystallization from EtOH–CH_2Cl_2 (9 : 1) afforded blue prisms: mp 207—208 °C; IR (KBr) 1675, 1195, and 1031 cm^{-1}; NMR ($CDCl_3$) δ= 0.60 (t, J=7.0 Hz, 2 $OCH_2C\underline{H}_3$), 3.90 (q, J=7.0 Hz, 2 $OC\underline{H}_2CH_3$), 7.36—7.96 (m, H-5—7 and 5'—7'), 8.65 (br d, J=9.5 Hz, H-4,4'), and 9.75 (br d, J=9.5 Hz, H-8,8'). Found: C, 48.26; H, 3.13%. Calcd for $C_{26}H_{20}O_4I_2$: C, 48.04; H, 3.10%.

Dimethyl 3,3'-Dibromo-2,2'-biazulene-1,1'-dicarboxylate (2i). A solution of **2g** (988 mg) and potassium hydroxide (1.5 g) in a mixture of water (5 cm^3) and ethanol (10 cm^3) was heated under reflux for 15 h. The solution was diluted with water and acidified with dilute HCl. The precipitates were collected by filtration, washed with water, dried over $CaCl_2$, and recrystallized from ethanol to give a dicarboxylic acid as black prisms; mp near 300 °C (dec); IR (KBr) 2940 and 1630 cm^{-1}. Found: C, 53.17; H, 2.73%. Calcd for $C_{22}H_{12}O_4Br_2$: C, 52.84; H, 2.24%. This acid was treated with ethereal diazomethane to give **2i** as violet needles (from ethanol): mp 285—286 °C; IR (KBr) 1684 cm^{-1}; NMR ($CDCl_3$) δ= 3.55 (OCH_3). Found: 54.28; H, 3.20%. Calcd for $C_{24}H_{16}O_4Br_2$: C, 54.27; H, 3.04%.

2,2'-Biazulene-1,1' : 3,3'-tetracarboxylic Dianhydride (2j). A mixture of **2f** (1.89 g) in acetic anhydride (15 cm^3) was heated under gentle boiling for 2 h to give 1.6 g of **2j** as red crystals: mp$>$300 °C; IR (KBr) 1706, 1133, 1016, and 762 cm^{-1}. Found: C, 72.81; H, 2.65%. Calcd for $C_{24}H_{10}O_6$: C, 73.10; H, 2.56%.

Ethanolysis of 2j. To an ethanol solution of sodium ethoxide, prepared from 207 mg of sodium, was added 1.3 g of **2j** and the mixture was heated for 1 h. After cooling, the solution was diluted with water (50 cm^3) and acidified with dilute HCl to give precipitates which were collected by filtration, washed with water and dried over $CaCl_2$ in a desiccator. Decarboxylation of the mixture of carboxylic acids by heating at 260—280 °C/10 Torr gave a brown violet substance. Chromatography over a silica-gel column using benzene as an eluent gave four fractions, a, b, c, and d. The fraction a gave 7 mg of **2a**. The fraction b gave 183 mg (15%) of ethyl 2,2'-biazulene-1-carboxylate (**2k**) as blue sacles (from cyclohexane): mp 145—146 °C; IR (KBr) 1682 cm^{-1}; NMR ($CDCl_3$) δ=1.26 (t, J=7.0 Hz, $OCH_2C\underline{H}_3$), 4.41 (q, J=7.0 Hz, $OC\underline{H}_2CH_3$), 6.78—7.83 (9H, m, H-1',3,3', H-5—7, and H-5'—7'). 8.26 (3H, br d, J=9.5 Hz, H-4,4',8'), and 9.28 (br d, J=9.5 Hz, H-8). Found: C, 84.35; H, 5.70%. Calcd for $C_{23}H_{18}O_2$: C, 84.64; H, 5.56%. The fraction c gave 323 mg (22.4%) of diethyl 2,2'-biazulene-1,3-dicarboxylate (**2m**) as blue scales (from ethanol): mp 151—152 °C; IR (KBr) 1677 cm^{-1}; NMR ($CDCl_3$) δ=0.80 (t, J=7.0 Hz, 2 $OCH_2C\underline{H}_3$), 4.08 (q, J=7.0 Hz, 2 $OC\underline{H}_2CH_3$), 7.46 (s, H-1',3'), 7.0—8.0 (m, H-5—7 and H-5'—7'), 8.30 (br d, J=9.5 Hz, H-4',8'), and 9.58 (br d, J=9.5 Hz, H-4,8). Found: C, 78.64; H, 5.79%. Calcd for $C_{26}H_{22}O_4$: C, 78.37; H, 5.57%. The fraction d afforded 528 mg (36.6%) of **2b**.

1,2'-Biazulene-1,3-dicarboxylic Acid (3c). A mixture of **3b** (123 mg) and potassium hydroxide (166 mg) in a mixture of water (0.5 cm^3) and ethanol (3 cm^3) was heated under reflux for 5 h. The solution was diluted with water (10 cm^3) and acidified with 2 mol dm^{-3} HCl. The brown precipitates separated out were collected by filtration, repeatedly washed with water and dried over $CaCl_2$ in a desiccator to give 97 mg of **3c** as brown crystals (from ethanol): mp 240—243 °C (dec); IR (KBr) 2915, 1650, and 1645 cm^{-1}. Found: C, 77.31; H, 4.20%. Calcd for $C_{22}H_{14}O_4$: C, 77.18; H, 4.12%.

Dimethyl 1,2'-Biazulene-1',3-dicarboxylate (3d). Treatment of **3c** with diazomethane gave **3d** as dark brown-blue needles (from ethanol): mp 124—125 °C; IR (KBr) 1686 and 1684 cm^{-1}; UV_{max} (MeOH), nm (log ε), 237 (4.58), 288 (4.71), 306 (4.70), 344 sh (4.45), and 426 (4.14). Found: C, 77.76; H, 4.66%. Calcd for $C_{24}H_{18}O_4$: C, 77.83; H, 4.86%.

1,2'-Biazulene (3a). Heating of **3c** (64 mg) at 215—220 °C/15 Torr afforded 43 mg of crude crystals which were chromatographed on an alumina column with benzene as an eluent to give 34 mg of **3a** as green scales with metallic luster (from pentane): mp 144—145 °C; MS, *m/e*, 255 (M^+ +1, 20.7%), 254 (M^+, 100), 253 (M^+ −1, 65.1), 252 (M^+ −2, 81.7), 226 (12), 148 (33), 127 (M^{2+}, 15), and 126 (37); IR (KBr) 3030 (w), 1590 (w), 1565 (s), 1513 (vs), 1468 (w), 1412 (s), 1391 (vs), 1337 (m), 1297 (m), 1261 (w), 1215 (w), 1193 (w), 1110 (w), 1017 (w), 988 (w), 971 (w), 965 (w), 943 (m), 908 (w), 898 (m), 885 (w), 852 (w), 827 (m), 810 (s), 780 (s), and 722 (s) cm^{-1}. Found: C, 94.29; H, 5.55%. Calcd for $C_{20}H_{14}$: C, 94.45; H, 5.55%.

TNB-complex: Brown scales (ethanol); mp 189—190 °C. Found: C, 67.20; H, 3.51; N, 8.74%. Calcd for $C_{26}H_{17}O_6N_3$: C, 66.81; H, 3.67; N, 8.99%.

2,6'-Biazulene (4a). A mixture of **4b** (13 cm^3) in 5 cm^3 of 100% phosphoric acid was heated at 95 °C for 2 h. The reaction mixture was treated similarly to the cases of **2a** from **2b**, giving 5 mg (90%) of **4a** as green scales (from chloroform): mp 300 °C; MS, *m/e*, 255 (M^+ +1, 21.0%), 254 (M^+, 100), and 252 (35.2); IR (KBr) 3070 (w), 1570 (w), 1445 (w), 1399 (m), 1370 (m), 1227 (w), 1196 (w), 1186 (w), 1110 (w), 1014 (w), 990 (w), 971 (w), 909 (w), 899 (w), 876 (m), 810 (vs), 885 (w), and 727 (m) cm^{-1}. Found: C, 94.70; H, 5.52%. Calcd for $C_{20}H_{14}$: C, 94.45; H, 5.55%.

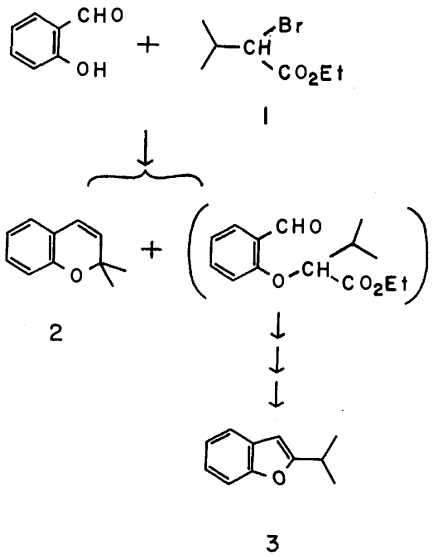
A New Preparative Method of 2,2-Dimethyl-2*H*-chromenes

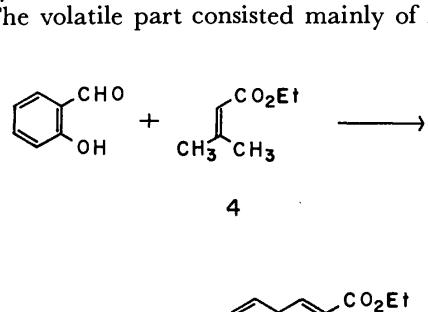
Yoshiyuki KAWASE,* Seiji YAMAGUCHI, Hisanori HORITA,
Junko TAKENO, and Hideaki KAMEYAMA
Department of Chemistry, Faculty of Science, Toyama University, Gofuku 3190, Toyama 930
(Received July 24, 1981)

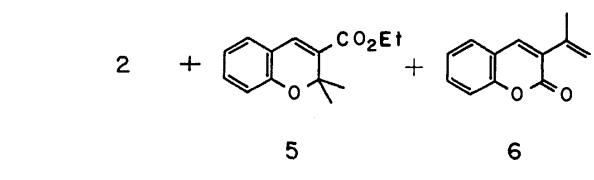
2,2-Dimethyl-2*H*-chromene was prepared from salicylaldehyde and ethyl 3-methyl-2-butenoate (or ethyl α-bromoisobutyrate) in one step. This new method of preparing 2,2-dimethyl-2*H*-chromene was studied and applied to some 2,2-dimethyl-2*H*-chromene derivatives.

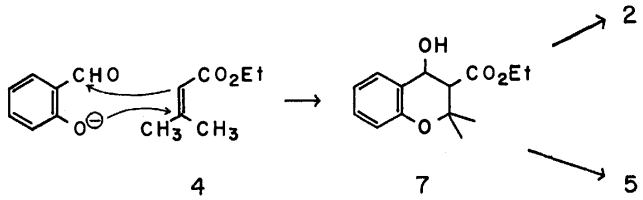
Many methods to prepare 2,2-dimethyl-2*H*-chromenes have been reported,[1] but they have involved many reaction steps and low yields. In our preparative study of 2-isopropylbenzofuran, we found a new method to prepare 2,2-dimethyl-2*H*-chromenes. In this paper, we will report this new method.



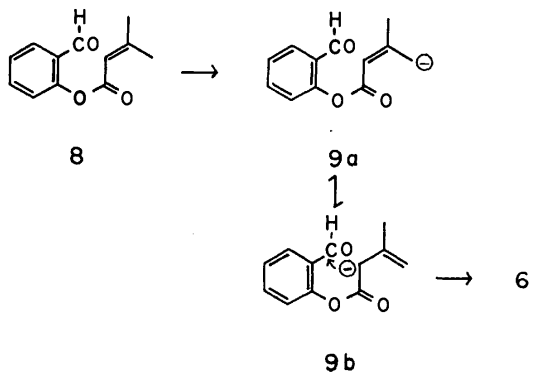
In general, 2-alkylbenzofurans are prepared from salicylaldehyde and ethyl α-bromocarboxylate.[2] In our preparative study of 2-isopropylbenzofuran (**3**) by this method, a solution of salicylaldehyde and ethyl α-bromoisobutyrate (**1**) in DMF was heated at 130 °C in the presence of potassium carbonate, and the products were distilled under reduced pressure. Moreover, the non-volatile part gave the expected 2-isopropylbenzofuran (**3**) after treatment with a 30% aqueous potassium hydroxide solution and sodium acetate-acetic anhydride. The volatile part consisted mainly of 2,2-dimethyl-2*H*-chromene (**2**). It was of great interest that 2,2-dimethyl-2*H*-chromene (**2**) was obtained in a one-step reaction. Next, the reaction of salicylaldehyde and ethyl α-bromoisobutyrate (**1**) was examined under several conditions. The results are given in Table 1. The reactions in DMF or in DMSO gave 2,2-dimethyl-2*H*-chromene (**2**), but those in THF or in pyridine did not. Also, satisfactory yields were obtained after 8 h both in DMF and in DMSO.







This reaction is thought to proceed as follows. Ethyl α-bromoisobutyrate (**1**) is converted to ethyl 3-methyl-2-butenoate (**4**) by dehydrobromination. Then, the phenolate ion attacks the C=C double bond in ethyl 3-methyl-2-butenoate (**4**), and the resulting carbanion attacks the C=O double bond in salicylaldehyde. These two nucleophilic attacks form ethyl 4-hydroxy-2,2-dimethylchroman-3-carboxylate (**7**) as an intermediate, which then readily loses ethanol and carbon dioxide to give 2,2-dimethyl-2*H*-chromene (**2**).



Next, the reaction of salicylaldehyde and ethyl 3-methyl-2-butenoate (**4**) was also examined under similar conditions; the results are given in Table 2. The yield of 2,2-dimethyl-2*H*-chromene (**2**) was the best at 8 h in this reaction. In several cases, 3-isopropenylcoumarin (**6**) was obtained. This new coumarin is thought to be formed as follows: The phenolate ion

attacks the C=O double bond in ethyl 3-methyl-2-butenoate (**4**) to give *o*-formylphenyl 3-methyl-2-butenoate (**8**), which loses the γ proton in 3-methyl-2-butenoate (**8**) to give the mesomery of the γ carbanion (**9a**) and the α carbanion (**9b**). Then, the α carbanion attacks the C=O double bond in the aldehyde to form 3-isopropenylcoumarin (**6**). Ethyl 2,2-dimethyl-2*H*-chromene-3-carboxylate (**5**) was also obtained. This ester is thought to be formed by the dehydration of ethyl 2,2-dimethyl-4-hydroxychroman-3-carboxylate (**7**).

This new method was applied to various salicylaldehydes, and some of them gave the corresponding 2,2-dimethyl-2*H*-chromene derivatives. All the reactions were carried out in DMF at 130 °C, for 8 h or 15 h. The results are given in Table 3. Methoxy-, methyl-, chloro-, bromo-, and phenyl-substituted salicylaldehydes gave the corresponding chromenes in good yields, but the others produced poor yields or nothing at all. This showed that this reaction was useful only for the preparation of 2,2-dimethyl-2*H*-chromenes with electrodonating or less electroaccepting substituents. Also, it was strange that 4-hydroxysalicylaldehyde and 2,4-dihydroxybenzaldehyde gave no corresponding chromene.

In two cases, the isopropenylcoumarins were also obtained. These two methyl substituted isopropenylcoumarins showed spectra similar to those of 3-isopropenylcoumarin (**6**) (Table 4). Their structures were confirmed by the partial catalytic hydrogenation of 3-isopropenyl-5-methylcoumarin to 3-isopropyl-5-methylcoumarin, which showed a doublet signal (J=7 Hz) at 1.3 ppm in its ^{1}H-NMR spectrum (Table 4).

Experimental

The boiling points and melting points have not been corrected; the IR spectra were measured on a Hitachi EPI-S2 spectrophotometer, and the ^{1}H-NMR spectra, on a JEOL JNM-MH-60 spectrometer in a carbon tetrachloride solution.

The Reaction of Salicyladehyde and Ethyl α-Bromoisobutyrate (1). A mixture of salicyladehyde (0.1 mol), ethyl 3-bromoisobutyrate (0.1 mol), potassium carbonate (40 g), and the solvent (shown in Table 1) (150 ml) was heated at 130 °C for the time shown in Table 1. After the removal of the solvent and ethyl 3-methyl-2-butenoate (**4**) *in vacuo*, the dark reaction mixture was diluted with water and extracted with ether. The ether solution was washed with 10% hydrochloric acid and a 5% aqueous sodium hydroxide solution, and then dried over anhydrous sodium sulfate. After the removal of the ether, the resulting liquid was distilled. 2,2-Dimethyl-2*H*-chromene (**2**) was thus obtained as a 106—108 °C/29 mmHg† fraction; the yield are summarized in Table 1. The residue was mixed with a 30% aqueous potassium hydroxide solution and refluxed for 3 h with stirring. After cooling, the mixture was treated with water and washed with ether. The aqueous layer was acidified with 10% hydrochloric acid and extracted with ether. The ether solution was washed with water and dried over anhydrous sodium sulfate. After the removal of the ether, the resulting liquid was mixed with a mixture of anhydrous sodium acetate (12 g) and acetic anhydride (18 g). The mixture was then refluxed for 3 h. Still hot, the reaction mixture was poured onto 70 g of ice and extracted with ether. The ether solution was washed with saturated sodium hydrogencarbonate solution and dried over anhydrous sodium sulfate. After the removal of the ether, the resulting liquid was distilled. 2-Isopropylbenzofuran (**3**) was thus obtained as a 111—113 °C/20 mmHg fraction; yield: 7% (8 h).

The Reaction of Salicylaldehyde and Ethyl 3-Methyl-2-butenoate (4). A mixture of salicylaldehyde (0.1 mol), ethyl 3-methyl-2-butenoate (**4**) (0.1 mol), anhydrous potassium carbonate (40 g), and DMF (80 ml) was heated at 130 °C for the time shown in Table 2. After the removal of the solvent and the recovered ethyl 3-methyl-2-butenoate (**4**) *in vacuo*, the dark reaction mixture was diluted with water and extracted with ether. The ether solution was washed with 10% hydrochloric acid and a 5% aqueous sodium hydroxide solution, and then dried over anhydrous sodium sulfate. After the removal of the ether, the resulting liquid was distilled. A fraction of 2,2-dimethyl-2*H*-chromene (**2**), boiling at 106—108 °C/29 mmHg, was then collected. The residue was chromatographed by the use of a silica-gel column with benzene–hexane (1 : 4) to afford ethyl 2,2-dimethyl-2*H*-chromene-3-carboxylate (**5**); bp 185—200 °C/18 mmHg; mp 43—45 °C; IR: 1710 cm^{-1}; ^{1}H-NMR: 1.3 (3H, t, J=7 Hz), 1.6 (6H, s), 4.2 (2H, q, J=7 Hz), 6.5—7.3 (4H, m), 7.2 ppm (1H, s); and 3-isopropenylcoumarin (**6**); mp 96.5—97.5 °C (recrystallized from hexane). The yields are summarized in Table 2, while the spectral data of **6** are sumarized in Table 4.

The General Procedure for the Preparation of Chromenes. A mixture of salicylaldehyde (0.1 mol), ethyl 3-methyl-2-butenoate (**4**) (0.1 mol), anhydrous potassium carbonate (40 g), and DMF (80 ml) was heated at 130 °C for 8 or 15 h. After treatment similar to that described above, the corresponding chromenes were obtained. Their data are summarized in Table 3. Two methyl isopropenylcoumarins were also obtained as white crystals (recrystallized from hexane); their data are summarized in Table 4.

Partial Hydrogenation of 3-Isopropenyl-5-methylcoumarin. 3-Isopropenyl-5-methylcoumarin (151 mg) was dissolved in 50 ml of ethanol, and then mixture was hydrogenated by means of a Raney Ni catalysts (prepared from 1 g of 50% Al–Ni alloy). After 30 m, about 23 ml of hydrogen absorbed. The catalyst was filtered off, and the filtrate was concentrated under reduced pressure and extracted with ether. The ether solution was dried over anhydrous sodium sulfate. After the removal of the ether, 3-isopropyl-5-methylcoumarin (114 mg; 75%) was obtained as white crystals; mp 87—91 °C (recrystallized from hexane).

† 1 mmHg≈133.322 Pa.

The Total Synthesis of Antibiotic Fortimicin B

Yutaka HONDA and Tetsuo SUAMI*

Department of Applied Chemistry, Faculty of Science and Technology, Keio University, Hiyoshi, Kohoku-ku, Yokohama 223

(Received August 1, 1981)

The total synthesis of antibiotic fortimicin B (**1b**) is described. The sugar component of **1b**: 6-*epi*-purpurosamine B was converted to the sugar chloride: 2,6-bis(2,4-dinitrophenylamino)-2,3,4,6,7-pentadeoxy-β-L-*lyxo*-heptopyranosyl chloride (**5**). The aminocyclitol component of **1b**: fortamine B was also converted to the partially protected aglycone (**9**). The condensation of aglycone **9** with the sugar chloride **5** gave the desired condensation product in 37% yield. The analogous condensation of the DL-form of the aglycone with **5** afforded the same condensation product in 19% yield, it was then converted to **1b** by step-by-step hydrolysis.

Fortimicin A (**1a**), B (**1b**),[1,2] and C,[3,4] SF-1854,[5] SF-2052,[6,7] sporaricin A, B,[8-10] KA-6606 III, and KA-6606 IV[11] are members of a family of structually similar aminocyclitol antibiotics which are found in fermentation broths of various strains of *Actinomycetes*. The general feature of the structures of the antibiotics is a pseudodisaccharide consisting of 6-*epi*-purpurosamine B and a novel aminocyclitol named fortamine. The structural diversity of the antibiotics is due to the configurational difference in the amino group on the 1-position, the existence or the absence of the hydroxyl group on the 2-position, and the variety of aminoacyl groups attached to the methylamino group on the 4-position.

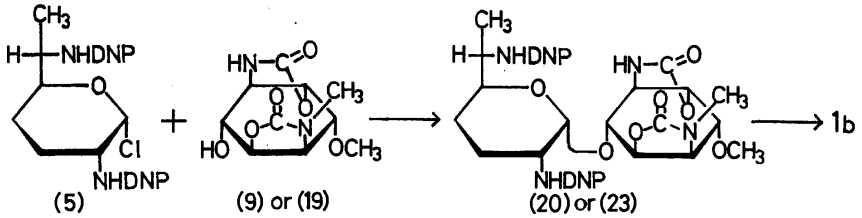
In preceding papers,[12-14] Suami and his coworkers have reported the synthesis of 6-*epi*-D-purpurosamine B and, in a communication letter,[15] a synthesis of the antibiotic fortimicin B in which natural fortamine B has been used as one of the starting materials. The synthesis of DL-fortamine B from *muco*-inosadiamine-3,6 has been described by a Kyowa Hakko research group.[16] We wish to report here the details of the total synthesis of fortimicin B, together with the synthesis of a DL-fortamine B derivative from 1,4-diazido-1,4-dideoxy-*muco*-inositol.

Fortimicin A, **1a**, the first members of this family to be discovered, exhibits high antimicrobial activities against Gram-positive and Gram-negative bacteria. The structures of **1a** and **1b** have been established by Egan and his coworkers.[17] The important biological activities and unique structures of these antibiotics make then attractive subjects of synthetic studies.

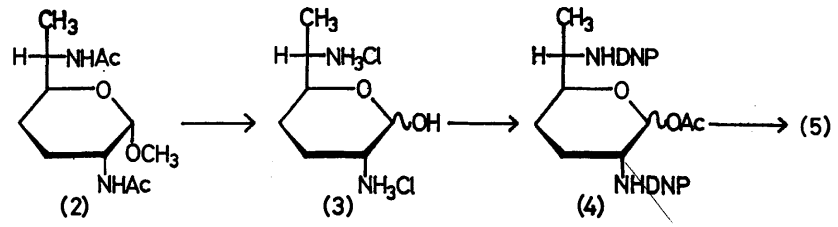
1a differs from **1b** in the existence of a glycyl group on the 1-methylamino group, and the former is converted into the latter by the loss of the glycyl group in an alkaline solution,[17] while it has been described in the literature that **1a** has been reconstructed from **1b** by a selective *N*-acylation.[18] Therefore, we have attempted to synthesize **1b** by condensing a glycosyl halide with a partially protected fortamine B derivative. Scheme 1 represents the reaction sequence leading to the total synthesis of **1b**.

The glycosyl chloride has been prepared by the reaction shown in Scheme 2. The acid hydrolysis of methyl 2,6-di-*N*-acetyl-2,6-diamino-2,3,4,6,7-pentadeoxy-β-L-*lyxo*-heptopyranoside (methyl 2,6-di-*N*-acetyl-6-*epi*-α-purpurosaminide B) (**2**)[13] in hydrochloric acid afforded the dihydrochloride (**3**). On treatment with acetic anhydride in the presence of diethyl ether-boron trifluoride, **3** gave the 1-*O*-acetyl derivative, which was then converted into the bis(*N*-2,4-dinitrophenyl) derivative (**4**) in 52% yield by reaction with 2,4-dinitrofluorobenzene in methanol containing triethylamine. The conversion of **4** into the crystalline glycosyl chloride (**5**) was accomplished in 82% yield by reaction with hydrogen chloride in the presence of acetyl chloride in dry diethyl ether.

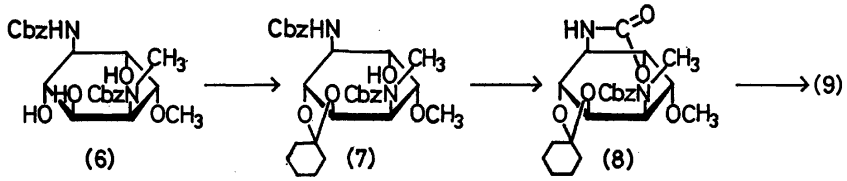
The aglycone was synthesized as follows. For the



Scheme 1.



Scheme 2.



Scheme 3.

conversion of optically active L-1,4-bis(*N*-benzyloxycarbonyl)-4-amino-1,4-dideoxy-6-*O*-methyl-1-methylamino-*chiro*-inositol (**6**)[19] into the partially protected aglycone (**9**), it was necessary to protect selectively the two amino groups on the 1- and 4-positions and the two hydroxyl groups on the 2- and 5-positions with an appropriate protective group, prior to the condensation with the glycosyl chloride **5**. This has been accomplished by the reaction route shown in Scheme 3.

The protection of the two vicinal *trans* hydroxyl groups on the 2- and 3-positions of **6** was achieved by treating **6** with 1,1-dimethoxycyclohexane in *N,N*-dimethylformamide (DMF) in the presence of an acid catalyst. The yield of the 2,3-*O*-cyclohexylidene derivative (**7**) from **6** was 67%. The protection of the 5-hydroxyl group of **7** was accomplished by the reaction of **7** with sodium hydride in DMF, forming a cyclic 4,5-*N,O*-carbamate (**8**) in 91% yield. The transformation of **8** into 1,2:4,5-di-*N,O*-carbonyl-fortamine B (**9**) was performed by the mild hydrolysis of **8** in aqueous acetic acid, followed by cyclic 1,2-*N,O*-carbonylation with sodium hydride in DMF; 83% yield.

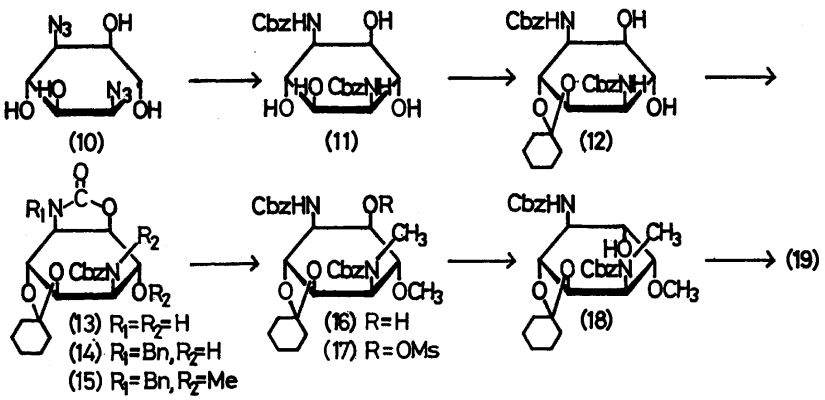
The reaction sequence shown in Scheme 4 represents a synthesis of the DL-form of the aglycone. As a starting material, 1,4-diazido-1,4-dideoxy-*muco*-inositol (**10**) was used; it was readily converted to *muco*-inosadiamine-1,4 by catalytic hydrogenation.[20] The stereochemistry of *muco*-inosadiamine-1,4 is similar to that of fortimicin B, except for the 5-hydroxyl group.

The catalytic hydrogenation of **10**, followed by benzyloxycarbonylation with benzyloxycarbonyl chloride in aqueous methanol containing sodium hydrogencarbonate, afforded 1,4-bis(*N*-benzyloxycarbonyl)-*muco*-inosadiamine-1,4 (**11**). The protection of one of the two sets of vicinal *trans* diols of **11** with 1,1-dimethoxycyclohexane in DMF furnished the 2,3-*O*-cyclohexylidene derivative (**12**) in 79% yield.

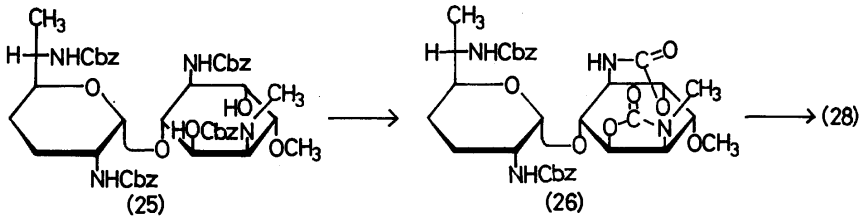
On treatment with sodium carbonate in aqueous dioxane, **12** was converted into the 4,5-*N,O*-carbamate (**13**) in 82% yield, since the formation of the cyclic carbamate occurs more readily between vicinal *cis*-arranged amino and hydroxyl groups than between those which are *trans*-related.

The *N*-benzylation of **13** in DMF with benzyl bromide and silver oxide afforded a mono-*N*-benzyl derivative (**14**) in 56% yield. The position of the benzyl group, shown in Scheme 4, has been deduced from the ^{1}H NMR spectroscopy and successive reaction products. The methylation of the 1-acylamino and the 6-hydroxyl groups of **14** with methyl iodide and silver oxide in DMF gave the 1-*N*-methyl-6-*O*-methyl derivative (**15**) in 82% yield.

The catalytic hydrogenolysis of **15** in the presence of palladium charcoal, followed by hydrolysis in a barium hydroxide solution, the catalytic hydrogenolysis of *N*-benzyl group in the presence of palladium black, and



Scheme 4.



Scheme 5.

N-acylation with benzyloxycarbonyl chloride afforded the 1,4-bis(*N*-benzyloxycarbonyl) derivative (**16**).

The mesylation of the 5-hydroxyl group of **16** with methanesulfonyl chloride in pyridine afforded the 5-*O*-sulfonate derivative (**17**) in 71% yield; this was, in turn, converted to the epimer by reaction with sodium acetate in DMF. The reaction mixture was hydrolyzed in a barium hydroxide solution, followed by *N*-acylation to give 1,4-bis(*N*-benzyloxycarbonyl)-2,3-*O*-cyclohexylidene-DL-fortamine B (**18**).

On treatment with sodium hydride, followed by hydrolysis and again treatment with sodium hydride, **18** was converted into the DL-form of aglycone (**19**) in 72% yield.

The attempted condensation of the optically active aglycone **9** with the glycosyl chloride **5** in dioxane in the presence of silver trifluoromethanesulfonate afforded two condensation products (**20** and **21**) in 37% and 9% yields respectively. The ^{1}H NMR spectrum of the main product **20** revealed a signal at δ 5.53 with a small coupling constant (3.3 Hz) which was due to the anomeric proton of the α-D-glycoside, while the spectrum of **21** showed a signal at δ 5.13 with a large coupling constant (8.1 Hz) which was attributed to the anomeric proton of the β-D-glycoside.

The analogous condensation of the DL-aglycone **19** with the glycosyl chloride **5** gave three component which were subsequently separated by column chromatography to give **22**, **23**, and **24** in 20, 19, and 23% yields respectively. The structural assigments of the condensation products were made by means of ^{1}H NMR spectroscopy. Compound **23** was identical with **20** in all respects, while **22** was identified as its diastereomer containing D-fortamine B. Compound **24** was a mixture of two products possessing β-D-glycosidic linkages. Compounds **20** and **23** were also identical with an authentic sample (**28**) prepared from natural fortimicin B by the reaction sequence shown in Scheme 5.

The removal of the protective groups of **23** by Amberlite IRA-400 (OH^-) resin, followed by hydrolysis in a barium hydroxide solution, afforded **1b** in 98% yield; it was then converted into tetra-*N*-acetylfortimicin B[17] (**25**). Compound **25** was identical with an authentic sample (**29**) prepared from natural fortimicin B by *N*-acetylation.

Experimental

General Procedures. The melting points were determined in capillary-tubes and are uncollected. The solutions were concentrated under reduced pressure below 40 °C. The optical rotations were meassured on a Japan Spectroscopic DIP-SL polarimeter. The infrared spectra were taken on a Hitachi HPL-225 spectrophotometer. ^{1}H NMR spectra were recorded on Varian EM-360A and 390 spectrometers at 60 and 90 MHz respectively. Deutriochloroform was used as a solvent, with tetramethylsilane as the internal standard. The peak position are given in δ values. TLC was preformed on Wakogel B-10 plates (Wako Pure Chemical Co., Ltd.), and silica-gel (Wakogel C-300) was employed for column chromatography.

*2,6-Diamino-2,3,4,6,7-pentadeoxy-*L*-lyxo-heptopyranose Dihydrochloride (6-*epi*-*D*-Purpurosamine B Dihydrochloride) (**3**).* A 1.0 g portion of methyl 2,6-diacetamido-2,3,4,6,7-pentadeoxy-β-L-*lyxo*-heptopyranoside (**2**)[13] was heated in 2 M (1 M=1 mol dm^{-3}) HCl (60 ml) under reflux. After 15 h, the solution was concentrated to give 0.89 g (99%) of crude **2** as a syrupy residue; it was recrystallized from ethanol to give 0.47 g (52%) of **3**; mp 183—184 °C (dec); $[\alpha]_D^{23}$ −15→−9.8° (*c* 1, methanol) $[\alpha]_D^{23}$ −5.4→+23.5° (*c* 1, water). Lit,[19] mp 186—191 °C (dec), $[\alpha]_D^{24}$ +6→+23° (*c* 0.6, water).

Found: C, 36.03; H, 7.50; N, 12.02; Cl, 30.20%. Calcd for $C_7H_{16}N_2O_2 \cdot 2HCl$: C, 36.06; H, 7.78; N, 12.02; Cl, 30.41%.

*1-O-Acetyl-2,6-bis(2,4-dinitrophenylamino)-2,3,4,6,7-pentadeoxy-*L*-lyxo-heptopyranose (**4**).* To a suspention of crude **3** (2.0 g) in acetic anhydride (20 ml), diethyl ether–boron trifluoride (3.3 ml) was added under ice cooling with agitation. After 12 h, the solution was concentrated. To a solution of the residue in 80% aq methanol, 2,4-dinitrofluorobenzene (4.0 g) was added, and a solution of triethylamine (4.8 ml) in methanol (20 ml) was dropped in over 1 h under ice cooling. After 16 h, the solution was diluted with chloroform, it washed with dil HCl and water, dried over Na_2SO_4 and concentrated. The residue was purified by column chromatography using 1 : 15 (v/v) ethanol–toluene. The fractions corresponding to R_f 0.49 on TLC in 1 : 10 (v/v) ethanol–toluene were combined and concentrated to give 2.4 g (52%) of **4**: mp 120—122 °C; ^{1}H NMR ($CDCl_3$) δ 1.48 (2d, 3, J=7.2 Hz, J=6.3 Hz, H-7), 1.97·2.23 (2s, 3, intensity ratio 2 : 1, OAc), 5.65 (d, 2/3, $J_{1,2}$=8.7 Hz), 6.35 (d, 1/3, $J_{1,2}$=3.3 Hz).

*2,6-Bis(2,4-dinitrophenylamino)-2,3,4,6,7-pentadeoxy-β-*L*-lyxo-heptopyranosyl Chloride (**5**).* A suspension of **4** (1.0 g) in dry diethyl ether (200 ml) was staturated with dry HCl, and then, to the mixture, acetyl chloride (4 ml) was added. After 18 h, the crystals which was appeared were collected by filtration and washed with diethyl ether to give 0.78 g (82%) of **5**: mp 130—132 °C; $[\alpha]_D^{20}$ +130° (*c* 0.49, acetone); ^{1}H NMR (acetone-d_6) δ 1.45 (d, 3, $J_{6,7}$=6.6 Hz, H-7), 6.72 (d, 1, $J_{1,2}$=3.0 Hz, H-1), 8.69 (d, 1, J=9.0 Hz, NH), 8.80 (d, 1, J=9.9 Hz, NH); IR (KBr) 1610·1580 (Ar), 1510·1325 cm^{-1} (NO_2).

Found: C, 44.38; H, 3.81; N, 16.17; Cl, 7.18%. Calcd for $C_{19}H_{19}N_6ClO_9$: C, 44.67; H 3.75; N, 16.45; Cl, 6.94%.

*1,4-Bis(N-benzyloxycarbonyl)-5,6-O-cyclohexylidenefortamine B (1L,4-Amino-1,4-bis(N-benzyloxycarbonyl)-2,3-O-cyclohexylidene-1,4-dideoxy-6-O-methyl-1-methylamino-*chiro*-inositol) (**7**).* A

mixture of 1,4-bis(*N*-benzyloxycarbonyl)-fortamine B[19] (**6**, 2.0 g) and 1,1-dimethoxycyclohexane (15 ml) in DMF (60 ml) was heated at 70 °C under reduced pressure (30 mmHg)† in the presence of a catalytic amount of *p*-toluenesulfonic acid. After 3 h, triethylamine (1 ml) was added to the solution, and the mixture was concentrated. The residue was purified by column chromatography using 15 : 1 (v/v) benzene–ethanol. Fractions corresponding to R_f 0.52 on TLC in 10 : 1 (v/v) benzene–ethanol were collected and concentrated. The residue was recrystallized from ether–petroleum ether to give 1.46 g (63%) of **7**: mp 94—96 °C; $[\alpha]_D^{24}$ +25.1° (*c* 0.97, methanol) IR (KBr) 1700 (NC=O), 1615 cm^{-1} (NH); ^1H NMR ($CDCl_3$) δ 1.5 (m, 10, C_6H_{10}), 3.07 (s, 3, NCH_3), 3.39 (s, 3, OCH_3), 4.52 (dd, 1, J=3.6 Hz, J=6.1 Hz, H-4), 5.10 (s, 2, CH_2 of benzyl), 5.24 (d, 1, J=7.5 Hz, NH-1), 7.37 (s, 10, $2\times C_6H_5$).

4-N-Benzyloxycarbonyl-1,2-N,O-carbonyl-5,6-O-cyclohexylidene-fortamine B (8). To a stirred solution of **7** (0.50 g) in DMF (10 ml), 50% sodium hydride (0.13 g) was added under ice cooling in a N_2 atmosphere. After 2 h, the solution was neutralized with acetic acid, diluted with water, and extracted with chloroform. The organic layer was concentrated, and the residue was purified by column chromatography, using 15:1 (v/v) benzene–ethanol. Fractions corresponding to R_f 0.67 on TLC in 10 : 1 (v/v) benzene–ethanol were collected and concentrated to give 0.34 g (84%) of crude **8** as an amorphous solid: mp 71 °C. It was recrystallized from chloroform–petroleum ether to give 0.23 g (57%) of **8**: mp 87—90 °C; $[\alpha]_D^{24}$ −9.1° (*c* 0.99, methanol); IR (KBr) 1780 (*trans* cyclic carbamate), 1695 cm^{-1} (NC=O); ^1H NMR ($CDCl_3$) δ 1.62 (m, 10, C_6H_{10}), 3.14 (s, 3, NCH_3), 3.43 (s, 3, OCH_3), 4.75 (m, 1, H-2), 5.17 (s, 2, CH_2 of benzyl), 5.52 (s, 1, NH-1), 7.39 (s, 5, C_6H_5).

Found: C, 62.10; H, 6.91; N, 6.17%. Calcd for $C_{23}H_{30}N_2O_7$: C, 61.87; H, 6.77; N, 6.28%.

1,2:4,5-Di-N,O-carbonylfortamine B (9). To a solution of crude **8** (0.35 g) in methanol (3 ml), 50% aq acetic acid (12 ml) was added, after which the mixture was warmed at 60 °C. After 2 h, the solution was concentrated. To a solution of the residue in DMF (10 ml), 50% sodium hydride (63 mg) was added. After 1 h at 0 °C in a N_2 atmosphere, the solution was neutralized with acetic acid and concentrated. The residue was purified by column chromatography, using 10 : 1 (v/v) benzene–ethanol. Fractions corresponding to R_f 0.42 on TLC in 5 : 1 (v/v) benzene–ethanol were collected and concentrated. The recrystallization of the residue from chloroform gave 168 mg (83%) of **9**: mp 225—228 °C; $[\alpha]_D^{20}$ −84.3° (*c* 1.06, methanol); IR (KBr) 1772 (*trans* cyclic carbamate), 1725 cm^{-1} (*cis* cyclic carbamate); ^1H NMR (CD_3OD) δ 3.01 (s, 3, NCH_3), 3.73 (s, 3, OCH_3), 4.63 (dd, 1, J=6.3 Hz, J=7.9 Hz, H-5).

DL-*1,4-Diamino-1,4-bis(*N-*benzyloxycalbonyl)-2,3*-O-*cyclohexylidene-1,4-dideoxy-1*-N-*methyl-6*-O-*methyl*-chiro-*insoitol* (**18**). To a stirred solution of **16** (0.27 g) in pyridine (10 ml), methanesulfonyl chloride (2.7 ml) was added. After 27 h, the solution was concentrated and the residue was dissolved in chloroform. The solution was washed with water, dried over Na_2SO_4 and concentrated. The residue was purified by column chromatography, using 1 : 7 (v/v) acetone–toluene. Fractions corresponding to R_f 0.36 on TLC in the same solvent were collected and concentrated to give 0.22 g of the 5-*O*-mesyl derivative (**17**) as a residue. The residue (0.69 g) was dissolved in 90% aq DMF (60 ml) containing sodium acetate (4.4 g), after which the solution was heated under reflux. After 22 h, the solution was concentrated and the residue was dissolved in 50% aq dioxane (30 ml) containing barium hydroxide (1.2 g); the solution was then heated under reflux. After 5 h, the solution was neutralized with CO_2 gas and the resulting precipitate was removed by filtration. The filtrate was concentrated, and the residue was dissolved in aq methanol (40 ml). To the solution, sodium hydrogencarbonate (0.36 g) and a 30% solution of benzyloxycarbonyl chloride in toluene (1.85 ml) were added under ice cooling. After 4 h, the solution was concentrated and the residue was purified by column chromatography, using 1 : 5 (v/v) acetone–toluene. Fractions corresponding to R_f 0.40 on TLC in the same solvent were collected and concentrated to give 0.23 g (38%) of **18** as a syrup: ^1H NMR ($CDCl_3$) δ 1.5 (m, 10, C_6H_{10}), 3.08 (s, 3, NCH_3), 3.40 (s, 3, OCH_3), 4.51 (dd, 1, J=3.6 Hz, J=6.1 Hz, H-1), 5.09 (s, 2, CH_2 of benzyl), 5.13 (s, 2, CH_2 of benzyl), 5.20 (d, 1, J=7.5 Hz, NH-4), 7.37 (s, 10, 2×C_6H_5).

DL-*1,4-Diamino-1,2 : 4,5-di*-N,O-*carbonyl-1,4-dideoxy-1*-N-*methyl-6*-O-*methyl*-chiro-*inositol* (**19**). To a solution of **18** (192 mg) in DMF (10 ml), 50% sodium hydride (42 mg) was added under ice cooling. After 3 h, the solution was diluted with water and neutralized with acetic acid. The solution was extracted with chloroform, and the organic layer was concentrated. The residue was hydrolyzed in 50% aq acetic acid (10 ml) at 60 °C for 2 h and then concentrated. To a solution of the residue in DMF (10 ml), 50% sodium hydride (28 mg) was added, after which the mixture was worked up as has been described above. The residual product was purified on a silica-gel column, using 1 : 10 (v/v) methanol–toluene. Fractions corresponding to R_f 0.07 in the same solvent were collected and concentrated. The residue was recrystallized from chloroform to give 64 mg (72%) of **19**: mp 224—228 °C; IR (KBr) 1775 (*trans* cyclic carbamate), 1725 cm^{-1} (*cis* cyclic carbamate); ^1H NMR (CD_3OD) δ 3.02 (s, 3, NCH_3), 3.74 (s, 3, OCH_3), 4.64 (dd, 1, J=6.4 Hz, J=7.7 Hz, H-5).

Found: C, 46.24; H, 5.35; N, 10.57%. Calcd for $C_{10}H_{14}N_2O_6$; C, 46.51; H, 5.46; N, 10.85%.

Condensation of **9** *(*L*-Form) with* **5**. Compound **9** (0.10 g) was dissolved in freshly distilled dioxane (4 ml) at 100 °C. After the solution had cooled to the ambient temperature, **5** (0.58 g) and silver trifluoromethanesulfonate (0.29 g) were added, portion by portion to the solution (under N_2) with agitation in the dark. After 27 h, acetone was added to the reaction mixture, and it was filtered. The filtrate was concentrated, and the residue was purified by column chromatography, using 1 : 3 (v/v) acetone–toluene. Fractions corresponding to R_f 0.26 on TLC in the same solvent were collected and concentrated to give 0.11 g (37%) of **20**: mp 226—228 °C; $[\alpha]_D^{20}$ +43.2° (*c* 1.01, acetone); ^1H NMR (acetone-d_6) δ 1.44 (d, 3, $J_{6',7'}$=6.3 Hz, H-7'), 2.85 (s, 3, NCH_3), 3.61 (s, 3, OCH_3), 4.67 (dd, 1, J=6.0 Hz, J=7.5 Hz, H-5), 5.53 (d, 1, $J_{1',2'}$=3.3 Hz, H-1'), 7.20 (s, 1, NH-1), 7.3 (d, 1, J=9.0 Hz), 7.4 (d, 1, J=9.0 Hz), 8.24 (dd, 2, J=2.4 Hz, J=9.0 Hz), 8.92 (d, 1, J=2.4 Hz), 8.94 (d, 1, J=2.4 Hz) (total 6H, DNP), 8.82 (d, 2, J=8.1 Hz, NH-2',6').

Found: C, 47.50; H, 4.47; N, 14.99%. Calcd for $C_{29}H_{32}N_8O_{15}$: C, 47.54; H, 4.40; N, 15.30%.

Fractions corresponding to R_f 0.23 on TLC were collected to give 25 mg (9%) of the corresponding β-anomer **21**: mp 180—182 °C; $[\alpha]_D^{20}$ −12.5° (*c* 1.00, acetone); ^1H NMR (acetone-d_6) δ 1.47 (d, 3, $J_{6',7'}$=6.3 Hz, H-7'), 2.82 (s, 3, NCH_3), 3.44 (s, OCH_3), 4.48 (dd, 1, J=6.0 Hz, J=7.5 Hz), 5.13 (d, 1, $J_{1',2'}$=8.1 Hz), 6.33 (s, 1, NH-1), 7.33 (d, 1, J=9.3 Hz), 7.49 (d, 1, J=9.3 Hz), 8.29 (dd, 2, J=3.0 Hz, J=9.3 Hz), 8.94 (d, 1, J=3.0 Hz), 8.96 (d, 1, J=3.0 Hz) (total 6H, DNP), 8.64 (d, 1, J=8.4 Hz), 8.9 (d, 1, NH).

Found: C, 47.25; H, 4.45; N, 14.98%. Calcd for $C_{29}H_{32}N_8O_{15}$: C, 47.54; H, 4.40; N, 15.30%.

Condensation of **19** *(*DL*-Form) with* **5**. Compound **19** (49 mg) was dissolved in dioxane (5 ml). To the solution, **5** (288 mg) and silver trifluoromethanesulfonate (145 mg) were added, after which the reaction mixture was worked up as was described in the case of the previous condensation of **9** with **5**. Fractions corresponding to R_f 0.34 on TLC in 1 : 3 (v/v) acetone–toluene were collected and concentrated to give 28 mg (20%) of **22**: mp 306—307 °C; $[\alpha]_D^{20}$ +100.7° (*c* 1.12, acetone); ^1H NMR (DMSO-d_6) δ 1.36 (d, 3, $J_{6',7'}$= 5.1 Hz, H-7'), 2.80 (s, 3, NCH_3), 3.48 (s, OCH_3), 4.60 (dd, 1, J=6.0 Hz, J=7.5 Hz, H-5), 5.20 (d, 1, $J_{1',2'}$=3.0 Hz, H-1'), 8.16 (s, 1, NH-1), 7.23 (d, 2, J=10.8 Hz), 8.23 (m, 2), 8.65 (m, 2) (total 6H, DNP), 8.65 (d, 1, J=9 Hz, NH-2',6').

Found: C, 47.30; H, 4.37; N, 15.10%. Calcd for $C_{29}H_{32}N_8O_{15}$: C, 47.54; H, 4.40; N, 15.30%.

Fractions (R_f 0.26) were collected and concentrated to give 26 mg (19%) of **23**: mp 226—228 °C; $[\alpha]_D^{20}$ +41.9° (*c* 0.48, acetone); ^1H NMR (acetone-d_6) δ 1.44 (d, 3, $J_{6',7'}$= 6.3 Hz, H-7'), 2.87 (s, 3, NCH_3), 3.58 (s, 3, OCH_3), 4.66 (dd, 1, J=6.0 Hz, J=7.5 Hz, H-5), 5.54 (d, 1, J=3.3 Hz), 7.23

(s, 1, NH-1), 7.36 (d, 1, J=9.0 Hz), 7.46 (d, 1, J=9.0 Hz), 8.34 (dd, 2, J=2.4 Hz, J=9.0 Hz), 9.00 (d, 1, J=2.4 Hz), 9.02 (d, 1 J=2.4 Hz) (total 6H, DNP), 8.88 (d, 2, J=8.1 Hz, NH-2',6').

Fractions (R_f 0.23) were collected and concentrated to give 31 mg (23%) of a mixture of β-anomer **24**: ^{1}H NMR (acetone-d_6) δ 1.46 (d, 3, $J_{6',7'}$=6.3 Hz, H-7'), 2.77·2.99 (2s, 3, NCH_3), 3.37·3.40 (2s, 3, OCH_3), 4.91·5.05 (2d, 1, $J_{1',2'}$=8.1 Hz, H-1'), 6.30·6.33 (2s, 1, NH-1), 7.2—7.6 (m, 2), 8.2 (dd, 2, J=3.0 Hz, J=9.0 Hz), 8.86·8.89 (2d, 2, J=3.0 Hz) (total 6H, DNP), 8.56 (d, 1, J=8.1 Hz, NH), 8.8 (d, 1, NH).

*Fortimicin B (**1b**).* To a solution **23** (28 mg) in a mixture of acetone (2 ml) and methanol (6 ml), Amberlite IRA 400 (OH^-) resin (0.23 ml) and water (2 ml) were added. After 15 h at the ambient temperature with agitation, the resin was filtered off and the filtrate was concentrated to give 17 mg of a residue. The residue was dissolved in ethanol (4 ml), and to the solution, a 0.1 M barium hydroxide solution (10 ml) was added. The mixture was then heated at 85 °C overnight and neutralized with CO_2. The precipitate was filtered off, and the filtrate was concentrated. The residue was purified on a column of Amberlite CG-50 (NH_4^+) by the use of 1 M ammonia. Fractions showing ninhydrin-positive and R_f 0.38 on TLC in 1 : 1 : 4 (v/v) chloroform–concd ammonia–isopropyl alcohol were combined and concentrated to give 13 mg (98%) of **1b** as an amorphous residue, $[\alpha]_D^{16}$ +25.3° (c 0.65, water). Lit,[17] $[\alpha]_D^{25}$ +22.2° (c 0.1, water); ^{1}H NMR (D_2O) δ 1.07 (d, 3, $J_{6',7'}$=6.6 Hz, H-7'), 2.40 (s, 3, NCH_3), 3.46 (s, 3, OCH_3), 3.98 (dd, 1, J=4.5 Hz, J=9.2 Hz, H-5), 5.03 (d, 1, $J_{1',2'}$=3.0 Hz).

*Tetra-N-acetylfortimicin B (**25**).* To a solution of **1b** (13 mg) in methanol (4 ml), acetic anhydride (0.5 ml) was added. After 3 h, the solution was concentrated to give 18 mg (96%) of **25** as a monohydrate: mp 161—163 °C; $[\alpha]_D^{20}$ +91.6° (c 0.61, methanol). Lit,[22] $[\alpha]_D$ +92.72° (c 1.0, methanol). ^{1}H NMR (D_2O) δ 1.15 (d, 3, $J_{6',7'}$=6.0 Hz, H-7'), 2.00 (s, 3, NAc), 2.02 (s, 3, NAc), 2.05 (s, 3, NAc), 2.18 (s, 3, NAc), 3.10 (d, 3, J=10.2 Hz, NCH_3), 3.44 (s, 3, OCH_3).

*2',6'-Bis(N-benzyloxycarbonyl)-1,2:4,5-di-N,O-carbonylfortimicin B (**27**).* To a solution of 1,2',4,6'-tetrakis-*N*-(benzyloxycarbonyl)foltimicin B[19] (**26**, 0.50 g) in DMF (6 ml), 50% sodium hydride (70 mg) was added under ice cooling with agitation. After 6 h at the ambient temperature, the pH of the solution was adjusted to 4 by adding acetic acid. The solution was then diluted with cold water, and the precipitates were collected by filtration. Recrystallization of the product from chloroform–ether gave 0.31 g (81%) of **27**: mp 121—128 °C; $[\alpha]_D^{20}$ −1.6° (c, 1.3, methanol); ^{1}H NMR ($CDCl_3$) δ 1.16 (s, 3, $J_{6',7'}$=6.3 Hz, H-7'), 2.83 (s, 3, NCH_3), 3.49 (s, 3, OCH_3), 6.75 (s, 1, NH-1), 7.36 (s, 10, $2\times C_6H_5$).

Found: C, 59.42; H, 6.12; N, 8.16%. Calcd for $C_{33}H_{40}N_4O_{11}$: C, 59.27; H, 6.03; N, 8.38%.

*1,2:4,5-Di-N,O-carbonyl-2',6'-bis(N-2,4-dinitrophenyl)fortimicin B (**28**).* Compound **27** (150 mg) was hydrogenated in methanol (10 ml) in the presence of 10% Pd on charcoal (30 mg) under a hydrogen atmosphere (3.4 kg/cm^2). After 16h, the catalyst was filtered off and the filtrate was concentrated. To a solution of the residue in 67% aq ethanol (25 ml) containing sodium hydrogencarbonate (57 mg), 2,4-dinitrofluorobenzene (104 mg) was added under ice cooling. After 18 h, the solution was diluted with water and repeatedly extracted with chloroform. The combined organic layers were concentrated, and the residue was recrystallized from acetone–chloroform to give 139 mg (85%) of **28**: mp 226—228 °C; $[\alpha]_D^{20}$ +40.7° (c 0.87, acetone); IR (KBr) 1770 (cyclic carbamate), 1624·1594 (nitrophenyl), 1525·1535 cm^{-1} (NO_2); ^{1}H NMR (acetone-d_6) δ 1.45 (d, 3, $J_{6',7'}$=6.3 Hz, H-7'), 2.86 (s, 3, NCH_3), 3.61 (s, 3, OCH_3), 4.66 (dd, 1, J=6.0 Hz, J=7.5 Hz, H-5), 5.53 (d, 1 $J_{1',2'}$=3.3 Hz, H-1'), 7.20 (s, 1, NH-1), 7.32·7.42 (2d, 2, J=9.0 Hz), 8.26 (dd, 2, J=2.4 Hz, J=9.0 Hz), 8.94·8.96 (2d, 2, J=2.4 Hz), 8.83 (d, 2, NH-2' and NH-6').

Found: C, 47.23; H, 4.47; N, 14.91%. Calcd for $C_{29}H_{32}N_8O_{15}$: C, 47.54; H, 4.40; N, 15.30%.

*Tetra-N-acetylfortimicin B (**29**).* To a solution of natural fortimicin B (58.8 mg) in methanol (10 ml), acetic anhydride (4 ml) was added. After 3 h, the solution was concentrated to give 82.2 mg (94%) of **29** as a monohydrate: mp 161—163 °C; $[\alpha]_D^{20}$ +92.5° (c 0.72, methanol); ^{1}H NMR (D_2O) δ 1.17 (d, 1, $J_{6',7'}$=7.2 Hz, H-7'), 2.00 (s, 3, NAc), 2.02 (s, 3, NAc), 2.05 (s, 3, NAc), 2.18 (s, 3, NAc), 3.09 (d, 3, J=10.6 Hz, NCH_3), 3.43 (s, 3, OCH_3).

The authors wish to express their appreciation to Dr. Kunikatsu Shirahata, Kyowa Hakko Kogyo Co., Ltd., for supplying fortimicin A and B; to Mr. Itsuki Sakamoto for his helpful technical assistance, and to Mr. Saburo Nakada for his elemental analysis.

New Building Blocks for Heterocyclic Syntheses. Silylated Methyl Isothiocyanates

Toshikazu HIRAO, Atsushi YAMADA, Ken-ichiro HAYASHI, Yoshiki OHSHIRO,* and Toshio AGAWA

Department of Petroleum Chemistry, Faculty of Engineering, Osaka University, 2-1 Yamada-oka, Suita, Osaka 565

(Received August 3, 1981)

Trimethylsilylmethyl isothiocyanate, bis(trimethylsilyl)methyl isothiocyanate, and tris(trimethylsilyl)methyl isothiocyanate were prepared. The fluoride-catalyzed reaction of trimethylsilylmethyl isothiocyanate with aldehydes or ketones afforded oxazolidine-2-thione derivatives, which involves the isothiocyanato carbanion as an intermediate. Imidazolidine-2-thiones were similarly prepared from imines. The reaction of bis(trimethylsilyl)methyl isothiocyanate with benzaldehyde in the presence of a catalytic amount of *n*-Bu_4NF gave styryl isothiocyanate and 5-phenyl-4-trimethylsilyloxazolidine-2-thione. On the similar treatment of tris(trimethylsilyl)methyl isothiocyanate, 4-benzyl-5-phenyl-4-oxazoline-2-thione, and α-(trimethylsilyl)styryl isothiocyanate were obtained.

The chemistry of functionalized heterocumulene has been recently developed in the field of heterocyclic synthesis.[1] From this point of view, we have previously reported the synthesis of methyl(phenylthio)ketene,[2] methyl(phenylseleno)ketene,[3] α-alkylthio(or arylthio)-vinyl isocyanate,[4] and *N*-[2-(diethoxyphosphoryl)-1-propenylidene]ethylamine,[5] and (2-aryl-2-halovinylidene)arylamine[6] and their cycloaddition reactions.

It is thought to enhance the synthetic utility of isothiocyanates that carbanion center can be generated in the α-position relative to nitrogen. The metalation of activated isothiocyanates was reported by Hoppe,[7] but this method is not applicable to methyl isothiocyanate. We addressed ourselves to this problem by preparing trimethylsilylmethyl isothiocyanate because fluoride ion has been reported to cause bond cleavage between carbon and silicon.[8] In our previous paper, trimethylsilylmethyl isothiocyanate was proved to be an equivalent of isothiocyanatomethanide.[9] Herein, we wish to report further details of the investigation on silylated methyl isothiocyanates as new building blocks for heterocyclic syntheses.

Results and Discussion

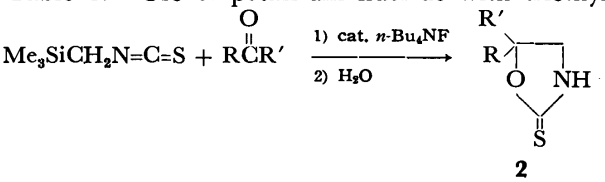
Trimethylsilylmethyl Isothiocyanate. Trimethylsilylmethyl isothiocyanate (**1**) was prepared by the addition of sulfur to trimethylsilylmethyl isocyanide in 76% yield. The isothiocyanate **1** is a stable liquid at room temperature, and can be stored under nitrogen atmosphere.

$$Me_3SiCH_2N{\equiv}C + S_x \xrightarrow[\text{reflux}]{\text{PhH}} Me_3SiCH_2N{=}C{=}S$$

1

The cleavage of a carbon-silicon bond by fluoride ion was confirmed by treatment of the isothiocyanate **1** with D_2O in the presence of a catalytic amount of tetrabutylammonium fluoride to give methyl-d_1 isothiocyanate in 76% yield.

The isothiocyanate **1** was subjected to the *n*-Bu_4NF-catalyzed reaction with aldehydes or ketones to produce the oxazolidine-2-thiones **2**. The results are summarized in Table 1. Use of potassium fluoride with triethylbenzylammonium chloride (TEBA·Cl) or 18-crown-6 instead of tetrabutylammonium fluoride also gave the oxazolidine-2-thione **2a** in a good yield.



2

A possible reaction path is shown in Scheme 1. The isothiocyanato carbanion **3**, which is generated from the fluoride-catalyzed reaction of **1**, may be involved as a key intermediate. The carbanion **3** reacts with carbonyl compound to give the 1 : 1 adduct, which undergoes intramolecular cyclization resulting in **4**. The following mechanism may be operative to achieve a reaction cycle. The fluoride ion appears to be regenerated by the reaction of trimethylsilyl fluoride with **4**. It is also

Table 1. Preparation of oxazolidine-2-thiones (**2**)

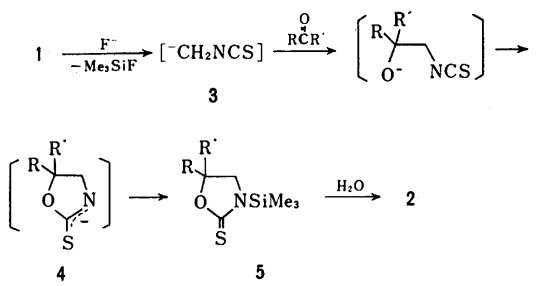
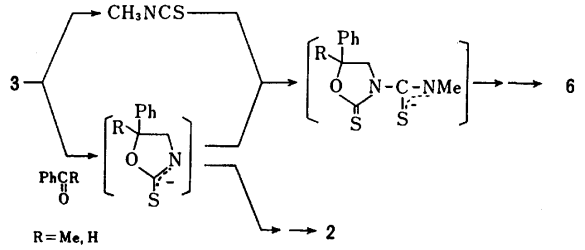
a) 5-Methyl-3-[methyl(thiocarbamoyl)]-5-phenyloxazolidine-2-thione (**6a**) was obtained in 17% yield.



Scheme 1.

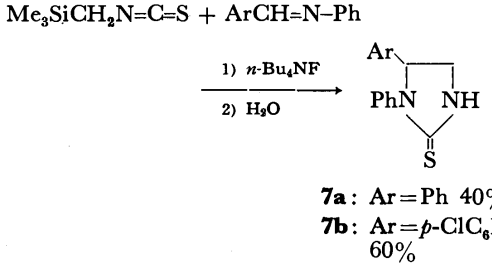
conceivable that the attack of **4** to **1** gives the isothiocyanato carbanion **3** and the 3-trimethylsilyloxazolidine-2-thione **5**. It has not been clarified which path is preferred. Thus formed **5** is easily hydrolyzed to **2**.

When the phase-transfer reaction of the isothiocyanate **1** with benzaldehyde was carried out in the presence of potassium fluoride and TEBA·Cl in benzene–water, 3-[methyl(thiocarbamoyl)]-5-phenyloxazolidine-2-thione (**6b**, 30%) was produced together with 5-phenyloxazolidine-2-thione (**2a**, 31%). The formation of the 3-[methyl(thiocarbamoyl)] derivative **6a** (17%) was also observed in the *n*-Bu_4NF-catalyzed reaction of **1** with acetophenone in dry THF, but only a trace amount of the corresponding 3-[methyl(thiocarbamoyl)]oxazolidine-2-thione was given from aldehyde. These 3-[methyl(thiocarbamoyl)] derivatives are considered to be produced by the reaction of **4** with methyl isothiocyanate, which is derived from proton abstraction of **3** from H_2O (phase-transfer reaction) or acetophenone[8a] (Scheme 2). The possibility of desilylation of 3-(*N*-trimethylsilylmethylthiocarbamoyl)oxazolidine-2-thiones, however, could not necessarily be excluded.



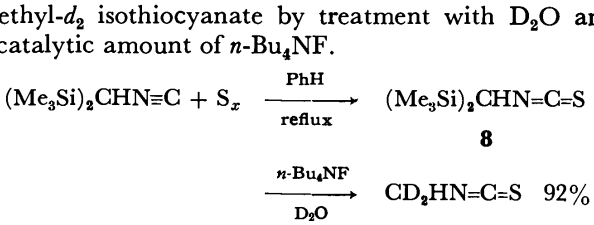
Scheme 2.

Imines were also allowed to react with **1** in the presence of a catalytic amount of *n*-Bu_4NF to produce the imidazolidine-2-thione derivatives **7**.

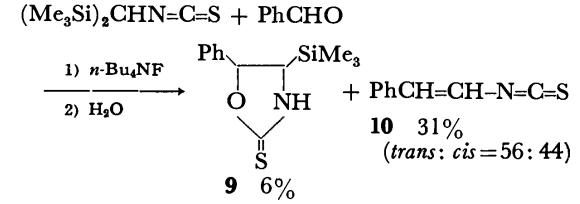


7a: Ar=Ph 40%
7b: Ar=*p*-ClC_6H_4 60%

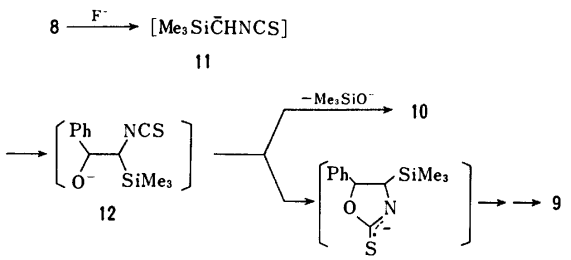
Bis(trimethylsilyl)methyl Isothiocyanate. Bis(trimethylsilyl)methyl isothiocyanate (**8**) was analogously prepared from the corresponding isocyanide and sulfur in 80% yield. The isothiocyanate **8** was desilylated to methyl-d_2 isothiocyanate by treatment with D_2O and a catalytic amount of *n*-Bu_4NF.



The methodology mentioned above was able to be applied to the reaction of **8** with benzaldehyde, but 5-phenyl-4-trimethylsilyloxazolidine-2-thione (**9**) was produced in only 6% yield. It is of interest that styryl isothiocyanate (**10**) was obtained as a main product in this case.

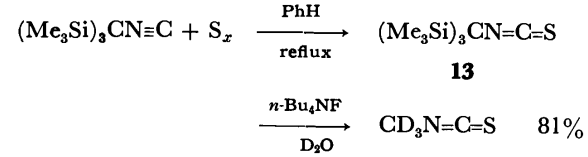


The formation path for styryl isothiocyanate is outlined in Scheme 3. The β-trimethylsilylalkoxide intermediate **12** undergoes elimination of Me_3SiO^- to give styryl isothiocyanate. Both silyl groups of **8** participate in the synthesis of **10**, generation of carbanion by fluoride ion and Peterson-olefination.[14] Ring closure of a rotamer of **12** leads to **9**.

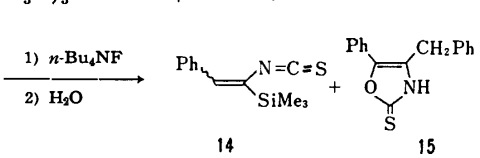


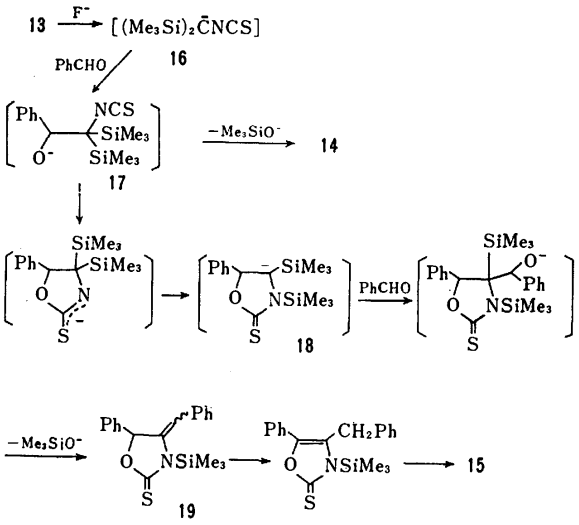
Scheme 3.

Tris(trimethylsilyl)methyl Isothiocyanate. Tris(trimethylsilyl)methyl isothiocyanate (**13**) was prepared by the addition of sulfur to tris(trimethylsilyl)methyl isocyanide in 76% yield. The isothiocyanate **13** was converted to methyl-d_3 isothiocyanate on treatment with D_2O in the presence of a catalytic amount of *n*-Bu_4NF.



The isothiocyanate **13** reacted with benzaldehyde in the presence of a catalytic amount of *n*-Bu_4NF to afford α-(trimethylsilyl)styryl isothiocyanate (**14**) and 4-benzyl-5-phenyl-4-oxazoline-2-thione (**15**) in 26% and 7% yields, respectively.





Scheme 4.

The probable reaction path for these products is outlined in Scheme 4. The isothiocyanate **14** was formed by the elimination of Me_3SiO^- from **17**. A rotamer of **17** is subjected to ring closure, followed by transposition of trimethylsilyl group to generate the carbanion **18**. The carbanion **18** reacts with another benzaldehyde to give the benzylideneoxazolidine-2-thione **19**, which may be rearranged and hydrolyzed to **15**.

The fluoride-catalyzed reactions of silylated methyl isothiocyanates provide a facile and mild generation of isothiocyanato carbanions (**3**, **11**, and **16**).

Experimental

Melting points were measured by a Yanagimoto micro melting point apparatus and uncorrected. ^1H NMR spectra were obtained on a JEOL JNN-PMX-60 with tetramethylsilane as an internal standard. IR spectra were recorded with a JASCO IRA-1 spectrometer. The mass spectra were taken with a Hitachi RMU-6E spectrometer.

Materials. Trimethylsilylmethyl isocyanide, bis(trimethylsilyl)methyl isocyanide, and tris(trimethylsilyl)methyl isocyanide were prepared by the reported method.[10] Tetrabutylammonium fluoride was prepared by the literature method[8a] and dried before use. Imines were obtained by the reaction of aldehydes with aniline,[11] and recrystallized prior to use. Carbonyl compounds were purified by distillation or recrystallization.

*Preparation of Trimethylsilylmethyl Isothiocyanate (**1**).* Trimethylsilylmethyl isothiocyanate was prepared by the addition of sulfur to the isocyanide in the same manner as mentioned in the reported method.[12] A mixture of trimethylsilylmethyl isocyanide (12.3 g, 109 mmol) and sulfur (4.2 g, 130 mmol) in benzene (20 ml) was refluxed for 26 h. Hexane (20 ml) was added to the cooled solution. After excess of sulfur was removed by filtration, the solution was distilled *in vacuo* to give **1** (12.0 g, 76%): bp 46 °C/3 mmHg;† IR (neat) 2180 and 2080 cm^{-1}; ^1H NMR ($CDCl_3$) δ 0.18 (s, 9H), 3.00 (s, 2H); MS *m/e* 145 (M^+); Found: C, 41.16; H, 7.98; N, 9.72; S, 22.32%. Calcd for $C_5H_{11}NSSi$: C, 41.33; H, 7.63; N, 9.64; S, 22.07%.

† 1 mmHg≈133.322 Pa.

*Treatment of **1** with D_2O in the Presence of* n-Bu_4NF. To a solution of *n*-Bu_4NF (78 mg, 0.3 mmol) and D_2O (66 mg, 3.3 mmol) in THF (3 ml), the isothiocyanate **1** (0.44 g, 3.0 mmol) in THF (2 ml) was added dropwise at room temperature. The mixture was stirred for 4 h under nitrogen atmosphere. Water (60 ml) was added to the resultant mixture, which was extracted with chloroform (3×30 ml). The combined organic layer was washed with water (10 ml) and dried on anhydrous sodium sulfate. After evaporation, methyl-d_1 isothiocyanate was isolated in 76% yield by preparative GLC (conditions: PS-410 column, 100 °C). IR (neat) 2230 and 2120 cm^{-1}; ^1H NMR ($CDCl_3$) δ 3.27 (t, 2H, J=2.0 Hz); MS *m/e* 74 (M^+).

n-*Bu_4NF-Catalyzed Reaction of **1** with Benzaldehyde.* To a solution of benzaldehyde (0.64 g, 6.0 mmol) and *n*-Bu_4NF (78 mg, 0.3 mmol) in THF (3 ml), the isothiocyanate **1** (0.44 g, 3.0 mmol) in THF (2 ml) was added dropwise at room temperature. The resultant solution was stirred for 8 h under nitrogen atmosphere. Water (60 ml) was added to the resultant mixture, which was extracted with chloroform (3×30 ml). The combined organic layer was washed with water (10 ml) and dried on anhydrous sodium sulfate. After evaporation, the residue was chromatographed on a silica gel column eluting with chloroform to give 0.40 g (74%) of 5-phenyloxazolidine-2-thione (**2a**): mp 130—131 °C; IR (Nujol) 3160 and 1520 cm^{-1}; ^1H NMR ($CDCl_3$) δ 3.68 (dd, 1H, J=8.4 and 10.0 Hz), 4.13 (dd, 1H, J=9.2 and 10.0 Hz), 5.87 (dd, 1H, J=8.4 and 9.2 Hz), 7.35 (s, 5H), 8.20 (br, 1H); MS *m/e* 179 (M^+). Found: C, 60.35; H, 4.89; N, 7.66; S, 17.67%. Calcd for C_9H_9ONS: C, 60.31; H, 5.06; N, 7.81; S, 17.89%.

In a similar manner, 5-ethyloxazolidine-2-thione (**2b**), 5-isopropyloxazolidine-2-thione (**2c**), 5,5-diphenyloxazolidine-2-thione (**2d**), and 5-methyl-5-phenyloxazolidine-2-thione (**2e**) were prepared in 63%, 67%, 25%, and 35% yields, respectively. Reaction time was shown in Table 1. In the preparation of **2e**, 5-methyl-3-[methyl(thiocarbamoyl)]-5-phenyloxazolidine-2-thione (**6a**) was obtained in 17% yield as a by-product.

2b: mp 87—89 °C; IR (Nujol) 3200 and 1520 cm^{-1}; ^1H NMR ($CDCl_3$) δ 1.04 (t, 3H, J=7.0 Hz), 1.87 (dq, 2H, J=6.4 and 7.0 Hz), 3.47 (dd, 1H, J=8.4 and 9.6 Hz), 3.93 (dd, 1H, J=8.8 and 9.6 Hz), 4.97 (ddt, 1H, J=6.4, 8.4, and 8.8 Hz), 8.55 (br, 1H); MS *m/e* 131 (M^+); Found: C, 45.60; H, 6.89; N, 10.70; S, 24.29%. Calcd for C_5H_9ONS: C, 45.78; H, 6.91; N, 10.68; S, 24.44%.

2c: mp 101—101.5 °C; IR (Nujol) 3220 and 1535 cm^{-1}; ^1H NMR ($CDCl_3$) δ 0.97 (d, 3H, J=6.4 Hz), 1.03 (d, 3H, J=6.4 Hz), 2.00 (m, 1H), 3.53 (dd, 1H, J=8.4 and 8.8 Hz), 3.87 (dd, 1H, J=8.8 and 8.8 Hz), 4.76 (ddd, 1H, J=6.4, 8.8, and 8.8 Hz), 8.53 (br, 1H); MS *m/e* 145 (M^+); Found: C, 49.45; H, 7.61; N, 9.68; S, 22.06%. Calcd for $C_6H_{11}ONS$: C, 49.63; H, 7.63; N, 9.65; S, 22.08%.

2d: mp 186—188 °C; IR (Nujol) 3180 and 1530 cm^{-1}; ^1H NMR ($CDCl_3$) δ 4.30 (s, 2H), 7.30 (s, 10H), 8.30 (br, 1H); MS *m/e* 255 (M^+); Found: C, 70.66; H, 5.05; N, 5.47; S, 12.71%. Calcd for $C_{15}H_{13}ONS$: C, 70.56; H, 5.13; N, 5.49; S, 12.56%. **2e**: mp 201—203 °C; IR (Nujol) 3210 and 1510 cm^{-1}; ^1H NMR ($CDCl_3$) δ 1.83 (s, 3H), 3.83 (s, 2H), 7.33 (s, 5H), 8.20 (br, 1H); MS *m/e* 193 (M^+); Found: C, 62.09; H, 5.72; N, 7.29; S, 16.31%. Calcd for $C_{10}H_{11}ONS$: C, 62.15; H, 5.74; N, 7.25; S, 16.59%.

6a: IR (Nujol) 3150 and 1560 cm^{-1}; ^1H NMR (CCl_4) δ 1.85 (s, 3H), 3.15 (d, 3H, J=5.0 Hz), 4.77 (s, 2H), 7.20—7.60 (m, 5H), 11.80 (br, 1H); MS *m/e* 266 (M^+).

*KF-Catalyzed Reaction of **1** with Benzaldehyde in the Presence of TEBA·Cl or 18-Crown-6 in Acetonitrile.* To a mixture of

benzaldehyde (0.64 g, 6.0 mmol), anhydrous KF (0.17 g, 3.0 mmol), and TEBA·Cl (68 mg, 0.3 mmol) or 18-crown-6 (72 mg, 0.3 mmol) in acetonitrile (3 ml), the isothiocyanate **1** (0.44 g, 3.0 mmol) in acetonitrile (2 ml) was added dropwise at room temperature. The resultant mixture was stirred under nitrogen atmosphere for 2 or 5 h, respectively. Work up was carried out in the same procedure as mentioned above. The yields of 5-phenyloxazolidine-2-thione (**2a**) were shown in Table 1.

*KF-Catalyzed Reaction of **1** with Benzaldehyde in the Presence of TEBA·Cl in Benzene–Water.* To 1.5 ml of aqueous solution of TEBA·Cl (68 mg, 0.3 mmol) and KF (1.00 g, 17.2 mmol), benzaldehyde (0.64 g, 6.0 mmol) and the isothiocyanate **1** (0.44 g, 3.0 mmol) in benzene (1 ml) were added at room temperature. The mixture was stirred for 4 h, and then chloroform (10 ml) was added. The organic layer was dried on anhydrous sodium sulfate. After evaporation, the residue was chromatographed on a silica-gel column to give 5-phenyloxazolidine-2-thione (**2a**, 0.17 g, 31%) and 3-[methyl-(thiocarbamoyl)]-5-phenyloxazolidine-2-thione (**6b**, 0.22 g, 30%). **6b**: mp 85—86 °C; IR (Nujol) 3130 and 1545 cm^{-1}; ^1H NMR ($CDCl_3$) δ 3.22 (d, 3H, J=5.0 Hz), 4.62 (dd, 1H, J=8.4 and 11.6 Hz), 5.12 (dd, 1H, J=8.4 and 11.6 Hz), 5.72 (dd, 1H, J=8.4 and 8.4 Hz), 7.40 (br, 5H), 11.80 (br, 1H); MS *m/e* 252 (M^+); Found: C, 52.47; H, 4.79; N, 11.12; S, 25.26%. Calcd for $C_{11}H_{12}ON_2S_2$: C, 52.36; H, 4.79; N, 11.10; S, 25.41%.

*Preparation of 1,5-Diphenylimidazolidine-2-thione (**7a**).* To a solution of *N*-benzylideneaniline (1.09 g, 6.0 mmol) and *n*-Bu_4NF (0.16 g, 0.6 mmol) in THF (3 ml), the isothiocyanate **1** (0.44 g, 3.00 mmol) in THF (2 ml) was added dropwise at room temperature. The resultant solution was stirred for 13 h under nitrogen atmosphere, and worked up in the same procedure as given for **2a**. The imidazolidine-2-thione **7a** was isolated by column chromatography on silica gel eluting with chloroform in 40% yield (0.31 g). **7a**: mp 188—190 °C; IR (KBr) 3200, 1620, 1590, and 1575 cm^{-1}; ^1H NMR ($CDCl_3$) δ 3.63 (dd, 1H, J=7.6 and 9.8 Hz), 4.13 (dd, 1H, J=8.8 and 9.8 Hz), 5.40 (dd, 1H, J=7.6 and 8.8 Hz), 7.00—7.50 (m, 10H); MS *m/e* 254 (M^+); Found: C, 70.56; H, 5.53; N, 11.02; S, 12.38%. Calcd for $C_{15}H_{14}N_2S$: C, 70.83; H, 5.55; N, 11.01; S, 12.61%.

Similarly, 5-(*p*-chlorophenyl)-1-phenylimidazolidine-2-thione (**7b**) was prepared in 60% yield. **7b**: mp 212 °C; IR (KBr) 3200, 1620, 1580, and 1570 cm^{-1}; ^1H NMR ($CDCl_3$) δ 3.55 (dd, 1H, J=7.6 and 10.4 Hz), 4.12 (dd, 1H, J=9.2 and 10.4 Hz), 5.35 (dd, 1H, J=7.6 and 9.2 Hz), 7.05—7.50 (m, 10H); MS *m/e* 288 (M^+); Found: C, 61.96; H, 4.42; Cl, 12.46; N, 9.56; S, 11.13%. Calcd for $C_{15}H_{13}ClN_2S$: C, 62.38; H, 4.54; Cl, 12.28; N, 9.70; S, 11.10%.

*Preparation of Bis(trimethylsilyl)methyl Isothiocyanate (**8**).* The isothiocyanate **8** was prepared in 80% yield by the reaction of bis(trimethylsilyl)methyl isocyanide and sulfur in benzene at 80 °C for 26 h in the same manner as given for **1**. **8**: bp 48—50 °C/0.5 mmHg, mp 45—47 °C; IR (neat) 2140 and 2060 cm^{-1}; ^1H NMR ($CDCl_3$) δ 0.17 (s, 18H), 2.56 (s, 1H); MS *m/e* 217 (M^+); Found: C, 44.35; H, 9.09; N, 6.53; S, 14.37%. Calcd for $C_8H_{19}NSSi_2$: C, 44.18; H, 8.76; N, 6.44; S, 14.74%.

*Treatment of **8** with D_2O in the Presence of* n-*Bu_4NF.* The reaction of **8** (3.0 mmol) with D_2O (6.6 mmol) in the presence of *n*-Bu_4NF (0.3 mmol) was carried out in the same manner as given for **1** to produce methyl-d_2 isothiocyanate in 92% yield. IR (neat) 2220, 2180, and 2100 cm^{-1}; ^1H NMR (CCl_4) δ 3.30 (quintet, 1H, J=2.0 Hz); MS *m/e* 75 (M^+).

*n-Bu_4NF-Catalyzed Reaction of **8** with Benzaldehyde.* In the same manner as described in the preparation of **2a**, *n*-Bu_4NF-catalyzed reaction of **8** with benzaldehyde gave styryl isothiocyanate (**10**)[13] and 5-phenyl-4-trimethylsilyloxazolidine-2-thione (**9**) in 31% and 6% yields, respectively. The *trans-cis* ratio (56 : 44) of **10** was determined by the ^1H NMR spectrum.

9: mp 178 °C (dec); IR (Nujol) 3180 and 1500 cm^{-1}; ^1H NMR ($CDCl_3$) δ −0.18 (s, 9H), 3.89 (d, 1H, J=9.4 Hz), 6.06 (d, 1H, J=9.4 Hz), 7.26—7.47 (m, 5H), 8.20 (br, 1H); MS *m/e* 251 (M^+); Found: C, 57.21; H, 6.88; N, 5.55; S, 13.13%. Calcd for $C_{12}H_{17}ONSSi$: C, 57.33; H, 6.81; N, 5.57; S, 12.75%.

10: IR (neat) 2100, 2040, and 1620 cm^{-1}; ^1H NMR ($CDCl_3$) δ 6.10 (2d, 0.88H, J=8.6 Hz, cis CH=CH), 6.60 (2d, 1.12H, J=12.2 Hz, *trans* CH=CH), 7.20—7.90 (m, 5H); MS *m/e* 161 (M^+).

*Preparation of Tris(trimethylsilyl)methyl Isothiocyanate (**13**).* Tris(trimethylsilyl)methyl isothiocyanate was prepared in 76% yield by the reaction of tris(trimethylsilyl)methyl isocyanide and sulfur in benzene at 80 °C for 29 h in the same manner as given for **1**. The isothiocyanate **13** was purified by column chromatography on silica gel eluting with hexane. **13**: mp>300 °C; IR (KBr) 2140 cm^{-1}; ^1H NMR ($CDCl_3$) δ 0.20 (s, 27H); MS *m/e* 289 (M^+); Found: C, 45.93; H, 9.62; N, 4.60; S, 11.08%. Calcd for $C_{11}H_{27}NSSi_3$: C, 45.61; H, 9.40; N, 4.34; S, 11.07%.

*Treatment of **13** with D_2O in the Presence of* n-*Bu_4NF.* The reaction of **13** (3.0 mmol) with D_2O (9.9 mmol) in the presence of *n*-Bu_4NF (0.3 mmol) was carried out in the same manner as given for **1** to produce methyl-d_3 isothiocyanate in 81% yield. IR (neat) 2260, 2200, and 2120 cm^{-1}; MS *m/e* 76 (M^+).

*n-Bu_4NF-Catalyzed Reaction of **13** with Benzaldehyde.* The *n*-Bu_4NF-catalyzed reaction of **13** with benzaldehyde was carried out at room temperature for 24 h in the same manner as mentioned in the preparation of **2a**. After evaporation of the solvent, the residue was chromatographed on a silica-gel column to give α-(trimethylsilyl)styryl isothiocyanate (**14**) and 4-benzyl-5-phenyl-4-oxazoline-2-thione (**15**) in 26% and 7% yields, respectively, with a small amount of styryl isothiocyanate (6%). **14**: IR (neat) 2040 and 1620 cm^{-1}; ^1H NMR (CCl_4) δ 0.28 (s, 9H), 6.23 (s, 1H), 7.00—7.73 (m, 5H); MS *m/e* 233 (M^+). **15**: mp 182—185 °C; IR (KBr) 1480 cm^{-1}; ^1H NMR ($CDCl_3$) δ 4.06 (s, 2H), 7.00—7.77 (m, 10H); MS *m/e* 267 (M^+).

Synthesis of 3β-Hydroxytaxodione and Coleons S and T

Takashi MATSUMOTO,* Hiroyuki KAWASHIMA, and Koji IYO
Department of Chemistry, Faculty of Science, Hiroshima University, Higashisenda-machi, Naka-ku, Hiroshima 730

(Received August 12, 1981)

Hinokiol diacetate was converted into 3β-acetoxyabieta-8,11,13-triene-6β,12-diol *via* 3β,12-diacetoxyabieta-8,11,13-trien-7-one and 3β,12-diacetoxyabieta-6,8,11,13-tetraene. Oxidation of the 6β,12-diol with benzoyl peroxide produced 3β-acetoxy-12-benzoyloxyabieta-8,11,13-triene-6β,11-diol, which was converted into 3β,11,12-triacetoxyabieta-8,11,13-trien-6-one by lithium aluminium hydride reduction, acetylation, and Jones oxidation. Acidic hydrolysis of the triacetoxy ketone, followed by column chromatography on silica gel, afforded 3β-hydroxytaxodione. Oxidation of the 6β,11-diol with *m*-chloroperbenzoic acid afforded 3β-acetoxy-12-benzoyloxy-6β-hydroxyabieta-8,12-diene-11,14-dione. This was further converted into 3β,11,14-triacetoxy-12-benzoyloxyabieta-8,11,13-triene-6,7-dione by a series of reactions: Jones oxidation, reduction with zinc powder and dilute hydrochloric acid, acetylation, and Jones oxidation. Alkaline hydrolysis of the 6,7-dioxo compound afforded coleon T, which was isomerized to coleon S by refluxing with concentrated hydrochloric acid in methanol.

In the previous papers,[1-3] we reported the synthesis of taxodione (**1**), a tumor-inhibitory diterpene quinonemethide isolated from *Taxodium distichum* Rich by Kupchan *et al.*[4] We have now synthesized the analogous quinonemethide compound in order to compare their tumor-inhibiting activity with that of **1**.

Recently, coleon S and coleon T, highly-oxygenated tricyclic diterpenes possessing an abietane skeleton, were isolated from leaf-glands of *Plectranthus caninus* Roth (Labiatae) by Eugster *et al.*[5] On the basis of chemical and spectroscopic studies, they deduced the structures of these coleons, S and T, to be 3β,6,11,12,14-pentahydroxyabieta-5,8,11,13-tetraen-7-one (**2**) and 3β,11,12,-14-tetrahydroxyabieta-8,11,13-triene-6,7-dione (**3**), respectively. As a part of our synthetic studies on the naturally-occurring terpenes, we have attempted the syntheses of these highly-oxygenated tricyclic diterpenes. This paper will describe the syntheses of 3β-hydroxytaxodione (**4**) [3β,11-dihydroxyabieta-7,9(11),13-triene-6,12-dione] and coleons S (**2**) and T (**3**), starting from the optically active hinokiol diacetate (**5**), which has been synthesized[6] from (+)-dehydroabietic acid.

Oxidation of **5** with Jones reagent afforded 3β,12-diacetoxyabieta-8,11,13-trien-7-one (**6**), together with a small amount of 12-acetoxyabieta-8,11,13-triene-3,7-dione (**7**). The diacetoxy ketone **6** was reduced with sodium borohydride in methanol and the resulting mixture of epimeric 7-hydroxy compounds (**8**) was immediately subjected to dehydration with dilute hydrochloric acid in refluxing methanol. Under these conditions, the acetoxyl groups were partially hydrolyzed. Therefore, the crude product was acetylated with acetic anhydride in pyridine and then purified by column chromatography on silica gel to give 3β,12-diacetoxyabieta-6,8,11,13-tetraene (**9**). The 3,7-dioxo compound **7** was also transformed to **9** by a series of reactions: reduction with lithium aluminium hydride in ether, dehydration with dilute hydrochloric acid in refluxing methanol, and acetylation with acetic anhydride in pyridine. The tetraene **9** was subjected to epoxidation at room temperature with *m*-chloroperbenzoic acid in dichloromethane. The resulting epoxide (**10**), without purification, was refluxed with dilute hydrochloric acid in methanol and then acetylated with acetic anhydride in pyridine. Purification of the crude product by column chromatography on silica gel yielded 3β,12-diacetoxyabieta-8,11,13-trien-6-one (**11**) as a major product and 3β,6α,12-triacetoxyabieta-8,11,13-trien-7-one (**12**) as a minor one. The α-configuration of the acetoxyl group at C-6 in **12** was supported by its ^{1}H NMR spectrum, which showed a doublet due to the C-6 proton at δ 5.82 with a coupling constant of 13 Hz, suggesting the presence of a β hydrogen. The minor ketone **12** was easily converted to the major ketone **11** by reduction with lithium aluminium hydride in ether, followed by dehydration with dilute hydrochloric acid in refluxing methanol and acetylation with acetic anhydride. Reduction of **11** with lithium aluminium hydride in refluxing tetrahydrofuran produced abieta-8,11,13-triene-3β,6β,12-triol (**13**), which was partially acetylated at room temperature with acetic anhydride in pyridine to give 3β,12-diacetoxyabieta-8,11,13-trien-6β-ol (**14**) and a small amount of 12-acetoxyabieta-8,11,13-triene-3β,6β-diol (**15**). Similar acetylation of **15** gave **14**. The diacetoxy alcohol **14** was partially hydrolyzed with sodium hydrogencarbonate in refluxing aqueous methanol to yield 3β-acetoxyabieta-

8,11,13-triene-6β,12-diol (**16**). Oxidation of **16** with benzoyl peroxide in chloroform at room temperature afforded a phenol (**17**), along with three dienones (**18**, **19**, and **20**) as minor products. The structures of these products (**17**—**20**) were assigned on the basis of the following evidence. The phenol **17** responded positively to the Gibbs test,[7] which suggested the presence of an aromatic proton para to a phenolic hydroxyl group. Oxidation of **17** with *m*-chloroperbenzoic acid in dichloromethane at room temperature afforded a benzoyloxy-*p*-benzoquinone (**21**). The ^{1}H NMR spectrum of **17** showed a singlet signal at δ 6.60 due to the C-14 proton, while for that of **21** no corresponding signal was observed. Thus, the structure of **17** was assigned to be 3β-acetoxy-12-benzoyloxyabieta-8,11,13-triene-6β,11-diol. The ^{1}H NMR spectrum of **18** showed a signal at δ 1.06 due to the equivalent methyls of the isopropyl group. On the other hand, the spectra of **19** and **20** showed two nonequivalent secondary methyl group signals, at δ 0.96 and 1.15 and at δ 0.88 and 1.13, respectively. From these spectral data and those of the IR spectra (see Experimental section), it is obvious that **18** is a para-substituted dienone,[2,8] while **19** and **20** are ortho-substituted dienones.[2,8] Hydrolysis of **18** with potassium carbonate in refluxing aqueous methanol afforded the corresponding trihydroxy ketone (**22**). In the ^{1}H NMR spectrum of **22**, the downfield shift of the signal (δ 1.64) due to the methyl group at C-10 relative to the corresponding signal (δ 1.43) for **18** suggested a 1,3-diaxial-*cis*-relationship between the methyl group and the hydroxyl group at C-8. Thus, the structure of **18** was assigned to be 3β-acetoxy-8β-benzoyloxy-6β-hydroxyabieta-9(11),13-dien-12-one. In order to determine the stereochemistry at C-13 in the ortho-dienones **19** and **20**, the following thermal rearrangements were carried out. A solution of **19** in toluene was refluxed for 4 h to give **17** (6.7%) together with the starting substance (**19**: 93.0%). However, a similar treatment of **20** gave **17** (63.8%) and **18** (26.0%) along with some recovered **20** (10.0%). From the rearrangement of **20** into **18**, the stereochemistry of the benzoyloxyl group in **20** was assigned to be the β-configuration, and therefore, that in **19** to be the α-configuration. Conversion of **17** into 3β-hydroxytaxodione was successfully carried out as follows. In order to change the benzoyloxyl group in **17** into an acetoxyl group which should be easily hydrolyzed under acidic conditions, **17** was reduced with lithium aluminium hydride in ether. The resulting tetrahydroxy compound (**23**), for the protection of the hydroxyl groups at C-3, C-11, and C-12, was partially acetylated with acetic anhydride in pyridine at room temperature to give 3β,11,12-triacetoxyabieta-8,11,13-trien-6β-ol (**24**). The triacetoxy alcohol **24** was oxidized with Jones reagent at 0 °C to afford 3β,11,12-triacetoxyabieta-8,11,13-trien-6-one (**25**), which was easily converted into 3β,11,12-trihydroxyabieta-8,11,13-trien-6-one (**26**) by refluxing with concentrated hydrochloric acid in ethanol under an atmosphere of nitrogen. Column chromatography of **26** on silica gel afforded a quinonemethide compound; its structure was assigned to be that of the desired 3β-hydroxytaxodione by the IR and ^{1}H NMR spectra.

Our next effort was directed toward the syntheses of coleons S and T. Oxidation of **21** with Jones reagent at 0 °C afforded 3β-acetoxy-12-benzoyloxyabieta-8,12-diene-6,11,14-trione (**27**) which, without purification, was used in the next reaction. For the protection of the unstable C ring, the trione **27** was reduced with a mixture of zinc powder and dilute hydrochloric acid in refluxing benzene. The resulting crude phenol (**28**) was acetylated at 85—90 °C with acetic anhydride in pyridine to give 3β,11,14-triacetoxy-12-benzoyloxyabieta-8,11,13-trien-6-one (**29**). Subsequently, oxidation of the C-7 position in **29** was carried out with Jones reagent at room temperature. The crude 6,7-dioxo compound (**30**) was immediately hydrolyzed with aqueous sodium carbonate in refluxing methanol under an atmosphere of nitrogen to give coleon T (**3**), which was further converted into coleon S pentaacetate (**31**) by treatment with acetic anhydride in pyridine. The

synthetic coleon T was finally isomerized with concentrated hydrochloric acid in refluxing methanol to give coleon S (**2**) which was also converted into the pentaacetate (**31**).

Experimental

All melting points are uncorrected. The IR spectra and optical rotations were measured in chloroform, and the ^{1}H NMR spectra in carbon tetrachloride at 60 MHz, with tetramethylsilane as an internal standard, unless otherwise stated. The chemical shifts are presented in terms of δ values; s: singlet, bs: broad singlet, d: doublet, bd: broad doublet, dd: double doublet, bt: broad triplet, m: multiplet. Column chromatography was performed using Merck silica gel (0.063 mm).

Oxidation of Hinokiol Diacetate (5). Jones reagent (2.5 M (1 M = 1 mol dm^{-3}): 13.6 ml) was added dropwise to a stirred solution of hinokiol diacetate[6] (**5**) (4.289 g) in acetone (80 ml) with cooling in an ice-water bath for 15 min. The mixture was stirred at this temperature for 15 min and at room temperature for 6 h. The mixture was then diluted with water and extracted with ether. The ether extract was washed with brine, dried over sodium sulfate, and evaporated *in vacuo*. The residue was chromatographed on silica gel (150 g), using ether–benzene (3 : 97) as the eluent, to give the recovered **5** (1.051 g: 24.5%). Subsequent elution with ether–benzene (5 : 95) afforded 3β,12-diacetoxyabieta-8,11,13-trien-7-one (**6**) (2.284 g: 51.4%), which was recrystallized from methanol; mp 178—179.5 °C; $[\alpha]_D$ +52.5°; IR: 1755, 1725, 1675, 1610 cm^{-1}; ^{1}H NMR 0.95 and 1.03 (each 3H and s, $-\dot{C}(CH_3)_2$), 1.23 (6H, bd, J=7 Hz, $-CH(C\underline{H}_3)_2$), 1.29 (3H, s, $C_{10}-CH_3$), 2.01 and 2.29 (each 3H and s, $2-OCOCH_3$), 2.63 (2H, d, J=8 Hz, $-CH_2CO-$), 2.99 (1H, m, $-C\underline{H}(CH_3)_2$), 4.51 (1H, bt, $W_{1/2}$=16 Hz, C_3-H), 6.90 (1H, s, $C_{11}-H$), 7.90 (1H, s, $C_{14}-H$). Found: C, 71.87; H, 8.25%. Calcd for $C_{24}H_{32}O_5$: C, 71.97; H, 8.05%.

Further elution with ether–benzene (1 : 9) afforded 12-acetoxyabieta-8,11,13-triene-3,7-dione (**7**) (0.213 g: 5.4%) as an oil; $[\alpha]_D$ +12.4°; IR: 1755, 1705, 1675, 1610 cm^{-1}; ^{1}H NMR: 1.12, 1.20, and 1.47 (each 3H and s, $-\dot{C}(CH_3)_2$ and $C_{10}-CH_3$), 1.25 (6H, d, J=6 Hz, $-CH(C\underline{H}_3)_2$), 2.31 (3H, s, $-OCOCH_3$), 6.95 (1H, s, $C_{11}-H$), 7.91 (1H, s, $C_{14}-H$). Found: C, 74.03; H, 8.10%. Calcd for $C_{22}H_{28}O_4$: C, 74.13; H, 7.92%.

3β,12-Diacetoxyabieta-6,8,11,13-tetraene (9). From 6: Sodium borohydride (125 mg) was added at *ca.* 15 °C to a stirred solution of **6** (871 mg) in methanol (35 ml). The mixture was stirred at room temperature for 1.5 h, acidified with dilute hydrochloric acid (10%: 2.0 ml), and refluxed for 1 h. The methanol was evaporated *in vacuo* and the residue was extracted with ether. The ether extract was washed with water, dried over sodium sulfate, and evaporated. The residual oil was acetylated at 78—80 °C with acetic anhydride (2.0 ml) in pyridine (6.0 ml) for 2 h. After the usual work-up, the crude product was chromatographed on silica gel (15 g), using benzene as the eluent, to give **9** (804 mg: 96.2% from **6**) as an oil; $[\alpha]_D$ −7.1°; IR: 1750, 1725 cm^{-1}; ^{1}H NMR: 0.97 (3H, s) and 1.07 (6H, s) ($-\dot{C}(CH_3)_2$ and $C_{10}-CH_3$), 1.18 and 1.21 (each 3H, d, and J=7 Hz, $-CH(C\underline{H}_3)_2$), 2.01 and 2.24 (each 3H and s, $2-OCOCH_3$), 2.93 (1H, m, $-C\underline{H}(CH_3)_2$), 4.50 (1H, m, C_3-H), 5.90 (1H, dd, J=2.5 and 10 Hz, C_6-H), 6.54 (1H, dd, J=2.5 and 10 Hz, C_7-H), 6.68 and 6.95 (each 1H and s, $C_{11}-H$ and $C_{14}-H$). Found: C, 74.79; H, 8.68%. Calcd for $C_{24}H_{32}O_4$: C, 74.97; H, 8.39%.

From 7: A mixture of **7** (361 mg), lithium aluminium hydride (125 mg), and dry ether (10 ml) was stirred at room temperature for 1 h. The mixture was poured into a mixture of ice and dilute hydrochloric acid, and extracted with ether. The ether extract was washed with water, dried over sodium sulfate, and evaporated *in vacuo* to give a crude triol (333 mg); IR: 3605, 3320 cm^{-1}.

A mixture of the crude triol (333 mg) and 10% hydrochloric acid (1.0 ml) in methanol (10 ml) was refluxed for 1 h, and then evaporated *in vacuo*. The residue was extracted with ether. The ether extract was washed with water, dried over sodium sulfate, and evaporated to give an oil (328 mg).

The above oil (328 mg) was immediately acetylated at 81—84 °C with acetic anhydride (2.0 ml) in pyridine (4.0 ml) for 2 h. After the usual work-up, the crude product was purified by column chromatography on silica gel (20 g), using benzene as the eluent, to give an oil (290 mg: 74.4% from **7**), whose IR and ^{1}H NMR spectra were identical with those of **9**.

Epoxidation of 9. A solution of **9** (2.763 g) and *m*-chloroperbenzoic acid (85%: 2.150 g) in dichloromethane (50 ml) was allowed to stand at room temperature for 9 h. The solution was diluted with ether and then washed successively with aqueous potassium iodide, aqueous sodium thiosulfate, aqueous sodium hydrogencarbonate, and water. After being dried over sodium sulfate, the solution was evaporated *in vacuo* to give a crude epoxide (**10**) (2.783 g); IR: 1750, 1723 cm^{-1}; ^{1}H NMR: 1.99 and 2.23 (each 3H and s, $2-OCOCH_3$), 6.68 and 7.37 (each 1H and s, $C_{11}-H$ and $C_{14}-H$). The crude epoxide was immediately subjected to the next reaction.

3β,12-Diacetoxyabieta-8,11,13-trien-6-one (11). From 10: A solution of the crude epoxide (**10**) (2.783 g) and 10% hydrochloric acid (10 ml) in methanol (60 ml) was refluxed for 1 h. The solution was concentrated *in vacuo* and the residue was extracted with ether. The ether extract was washed with water, dried over sodium sulfate, and evaporated. The oily residue was acetylated with acetic anhydride (5.0 ml) in pyridine (7.0 ml) at 80—82 °C for 1.5 h. After the usual work-up, the crude product was chromatographed on silica gel (100 g), using ether–benzene (3 : 97) as the eluent, to give **11** (2.037 g: 70.8% from **9**), which was recrystallized from acetone–hexane; mp 183—187 °C; $[\alpha]_D$ +107°; IR: 1750, 1720 cm^{-1}; ^{1}H NMR ($CDCl_3$): 1.10, 1.20, and 1.37 (each 3H and s, $-\dot{C}(CH_3)_2$ and $C_{10}-CH_3$), 1.19 (6H, d, J=7

Hz, -CH(C$\underline{H}_3$)$_2$), 2.08 and 2.32 (each 3H and s, 2-OCOC$\underline{H}_3$), 2.53 (1H, s, C_5-H), 3.62 (2H, s, -COC$\underline{H}_2$-), 4.45 (1H, m, C_3-H), 6.91 and 7.00 (each 1H and s, C_{11}-H and C_{14}-H). Found: C, 72.08; H, 8.23%. Calcd for $C_{24}H_{32}O_5$: C, 71.97; H, 8.05%.

Further elution with ether–benzene (1:9) afforded 3β,6α,-12-triacetoxyabieta-8,11,13-trien-7-one (**12**) (300 mg: 9.1% from **9**) as an oil; $[\alpha]_D$ +71.5°; IR: 1750, 1735, 1690, 1613 cm^{-1}; ^{1}H NMR: 1.05, 1.08, and 1.45 (each 3H and s, -C(C$\underline{H}_3$)$_2$ and C_{10}-C$\underline{H}_3$), 1.21 (6H, d, J=7 Hz, -CH(C$\underline{H}_3$)$_2$), 2.01, 2.16, and 2.28 (each 3H and s, 3-OCOC$\underline{H}_3$), 2.29 (1H, d, J=13 Hz, C_5-H), 2.97 (1H, m, -C$\underline{H}$(CH$_3$)$_2$), 4.44 (1H, m, C_3-H), 5.82 (1H, d, J=13 Hz, C_6-H), 6.92 (1H, s, C_{11}-H), 7.90 (1H, s, C_{14}-H).

From ***12***: A mixture of **12** (338 mg), lithium aluminium hydride (150 mg), and dry ether (8.0 ml) was refluxed for 1 h. The mixture was poured into a mixture of ice and dilute hydrochloric acid, and extracted with ether. The ether extract was washed with water, dried over sodium sulfate, and evaporated *in vacuo*.

The oily residue (277 mg) was dissolved in methanol (5.0 ml) containing 10% hydrochloric acid (0.5 ml), and then refiuxed for 1 h. The methanol was evaporated *in vacuo* and the residue was extracted with ether. The ether extract was washed with water, dried over sodium sulfate, and evaporated. The oily residue (250 mg) was acetylated at 80—84 °C with acetic anhydride (2.0 ml) in pyridine (3.0 ml) for 1 h. After the usual work-up, the crude product was purified by column chromatography on silica gel (10 g), using ether–benzene (3 : 97) as the eluent, to give an oil (195 mg; 66.1%), whose IR and ^{1}H NMR spectra were identical with those of **11**.

*3β,12-Diacetoxyabieta-8,11,13-trien-6β-ol (**14**).* A solution of **11** (1.401 g) in dry tetrahydrofuran (45 ml) was added to a stirred suspension of lithium aluminium hydride (700 mg) in dry tetrahydrofuran (150 ml) with cooling in an ice–water bath. The mixture was refluxed for 4 h, cooled, poured into a mixture of ice and dilute hydrochloric acid, and extracted with ether. The ether extract was washed with water, dried over sodium sulfate, and evaporated *in vacuo* to give the crude abieta-8,11,13-triene-3β,6β,12-triol (**13**) as a solid which, without purification, was used in the next reaction.

The above crude **13** was acetylated at 18—19 °C for 4 h with acetic anhydride (8.0 ml) in pyridine (15 ml). After the usual work-up, the crude product was chromatographed on silica gel (50 g), using ether–benzene (3 : 97) as the eluent, to give **14** (1.026 g: 72.8% from **11**), which was recrystallized from acetone–hexane; mp 135.5—136.5 °C; $[\alpha]_D$ +45.4°; IR: 3614, 3500, 1750, 1725 cm^{-1}; ^{1}H NMR ($CDCl_3$): 1.04 and 1.32 (each 3H and s, -C(C$\underline{H}_3$)$_2$), 1.20 (6H, d, J=7 Hz, -CH(C$\underline{H}_3$)$_2$), 1.60 (3H, s, C_{10}-C$\underline{H}_3$), 2.09 and 2.32 (each 3H and s, 2-OCOC$\underline{H}_3$), 4.3—4.8 (2H, m, C_3-H and C_6-H), 6.90 and 6.98 (each 1H and s, C_{11}-H and C_{14}-H). Found: C, 71.32; H, 8.74%. Calcd for $C_{24}H_{34}O_5$: C, 71.61; H, 8.51%.

Further elution with ether–benzene (6 : 94) afforded 12-acetoxyabieta-8,11,13-triene-3β,6β-diol (**15**) (133 mg: 10.6% from **11**), which was recrystallized from acetone–hexane; mp 188—189.5 °C; $[\alpha]_D$ +29.7°; IR: 3618, 3444, 1750 cm^{-1}; ^{1}H NMR ($CDCl_3$): 1.15 and 1.25 (each 3H and s, -C(C$\underline{H}_3$)$_2$), 1.20 (6H, d, J=6 Hz, -CH(C$\underline{H}_3$)$_2$), 1.56 (3H, s, C_{10}-C$\underline{H}_3$), 2.32 (3H, s, -OCOC$\underline{H}_3$), 4.70 (1H, m, $W_{1/2}$=8 Hz, C_6-H), 6.89 and 6.98 (each 1H and s, C_{11}-H and C_{14}-H). Found: C, 73.04; H, 9.06%. Calcd for $C_{22}H_{32}O_4$: C, 73.30; H, 8.95%.

The monoacetate **15** (133 mg) was further acetylated with acetic anhydride (1.5 ml) in pyridine (2.0 ml) at 17—19 °C for 4 h. Chromatographic purification of the crude product yielded **14** (110 mg: 74.3%) and the recovered **15** (27 mg: 20.3%).

*3β-Acetoxyabieta-8,11,13-triene-6β,12-diol (**16**).* A stirred mixture of **14** (993 mg), sodium hydrogencarbonate (420 mg), methanol (25 ml), and water (3.0 ml) was refluxed for 15 min. The mixture was concentrated *in vacuo*, diluted with water, and extracted with ether. The ether extract was washed with brine, dried over sodium sulfate, and evaporated *in vacuo*. The residue was recrystallized from benzene to give **16** (601 mg); mp 220—221.5 °C; $[\alpha]_D$ +31.8°; IR: 3610, 3400, 1725 cm^{-1}; ^{1}H NMR ($CDCl_3$): 1.03 and 1.32 (each 3H and s, -C(C$\underline{H}_3$)$_2$), 1.23 (6H, d, J=7 Hz, -CH(C$\underline{H}_3$)$_2$), 1.56 (3H, s, C_{10}-C$\underline{H}_3$), 2.13 (3H, s, -OCOC$\underline{H}_3$), 6.65 and 6.82 (each 1H and s, C_{11}-H and C_{14}-H). Found: C, 73.41; H, 9.16%. Calcd for $C_{22}H_{32}O_4$: C, 73.30; H, 8.95%. The mother liquor of recrystallization was evaporated *in vacuo* and the residue was chromatographed on silica gel (10 g), using ether–benzene (5 : 95) as the eluent, to give an additional **16** (224 mg). The total yield was 92.7%.

*Oxidation of **16** with Benzoyl Peroxide.* A solution of **16** (863 mg) and benzoyl peroxide (2.939 g) in chloroform (10 ml) was allowed to stand at room temperature for 80 h. The chloroform solution was diluted with ether. This ether solution, after addition of acetic acid (9.0 ml) and aqueous potassium iodide (30%: 30 ml), was stirred at room temperature for 3 h. The mixture was washed successively with water, aqueous sodium thiosulfate, aqueous sodium hydrogencarbonate, and water. After being dried over sodium sulfate, the solvent was evaporated *in vacuo* and the residue was purified by repeated column chromatography on silica gel, using ether–benzene (3 : 97) as the eluent, to give four products (**17**—**20**).

a): 3β-Acetoxy-12-benzoyloxyabieta-8,11,13-triene-6β,11,-diol (**17**) (609 mg: 52.9%), which responded positively to the Gibbs test;[7] mp 224—225.5 °C (from methanol); $[\alpha]_D$ +52.2°; IR: 3575, 3430, 1725 cm^{-1}; ^{1}H NMR ($CDCl_3$): 1.05 and 1.31 (each 3H and s, -C(C$\underline{H}_3$)$_2$), 1.18 (6H, d, J=7 Hz, -CH-(C$\underline{H}_3$)$_2$), 1.72 (3H, s, C_{10}-C$\underline{H}_3$), 1.88 (3H, s, -OCOC$\underline{H}_3$), 4.2—4.7 (2H, m, C_3-H and C_6-H), 6.18 (1H, s, -OH), 6.60 (1H, s, C_{14}-H), 7.3—8.4 (5H, m, -C_6H_5). Found: C, 72.81; H, 7.67%. Calcd for $C_{29}H_{36}O_6$: C, 72.47; H, 7.55%.

b): 3β-Acetoxy-8β-benzoyloxy-6β-hydroxyabieta-9(11),13-dien-12-one (**18**) (22 mg: 1.9%); $[\alpha]_D$ −20.1°; IR: 3605, 1725, 1668, 1640 cm^{-1}; ^{1}H NMR ($CDCl_3$): 1.01 and 1.31 (each 3H and s, -C(C$\underline{H}_3$)$_2$), 1.06 (6H, d, J=6.5 Hz, -CH-(C$\underline{H}_3$)$_2$), 1.43 (3H, s, C_{10}-C$\underline{H}_3$), 2.06 (3H, s, -OCOC$\underline{H}_3$), 4.3—4.7 (2H, m, C_3-H and C_6-H), 6.27 and 6.42 (each 1H and s, C_{11}-H and C_{14}-H), 7.3—8.1 (5H, m, -C_6H_5).

c): 3β-Acetoxy-13α-benzoyloxy-6β-hydroxyabieta-8(14),-9(11)-dien-12-one (**19**) (96 mg: 8.4%), which was recrystallized from benzene; mp 184—185 °C; $[\alpha]_D$ +240°; IR: 3500, 1720, 1660, 1603 cm^{-1}; ^{1}H NMR ($CDCl_3$): 0.96 and 1.15 (each 3H, d, and J=7 Hz, -CH(C$\underline{H}_3$)$_2$), 1.02 and 1.31 (each 3H and s, -C(C$\underline{H}_3$)$_2$), 1.57 (3H, s, C_{10}-C$\underline{H}_3$), 2.10 (3H, s, -OCOC$\underline{H}_3$), 4.3—4.7 (2H, m, C_3-H and C_6-H), 5.95 (1H, s, C_{14}-H), 6.15 (1H, s, C_{11}-H), 7.3—8.2 (5H, m, -C_6H_5). Found: C, 72.73; H, 7.66%. Calcd for $C_{29}H_{36}O_6$: C, 72.47; H, 7.55%.

d): 3β-Acetoxy-13β-benzoyloxy-6β-hydroxyabieta-8(14),-9(11)-dien-12-one (**20**) (70 mg: 6.1%), which was recrystallized from ether–hexane; mp 180—180.5 °C; $[\alpha]_D$ −145°; IR: 3525, 1720, 1665, 1605 cm^{-1}; ^{1}H NMR ($CDCl_3$): 0.88 and 1.13 (each 3H, d, and J=7 Hz, -CH(C$\underline{H}_3$)$_2$), 1.07 and 1.33 (each 3H and s, -C(C$\underline{H}_3$)$_2$), 1.59 (3H, s, C_{10}-C$\underline{H}_3$), 2.10 (3H, s, -OCOC$\underline{H}_3$), 4.3—4.7 (2H, m, C_3-H and C_6-H), 5.95 (1H, s, C_{14}-H), 6.13 (1H, s, C_{11}-H), 7.3—8.2 (5H, m, -C_6H_5). Found: C, 72.73; H, 7.78%. Calcd for $C_{29}H_{36}O_6$: C, 72.47; H, 7.55%.

3β-Acetoxy-12-benzoyloxy-6β-hydroxyabieta-8,12-diene-11,14-

dione (21). A solution of **17** (441 mg) and *m*-chloroperbenzoic acid (85%: 280 mg) in dichloromethane (10 ml) was allowed to stand at room temperature for 36 h, and then diluted with ether. The solution was washed successively with aqueous potassium iodide, aqueous sodium thiosulfate, aqueous sodium hydrogencarbonate, and water. After drying over sodium sulfate, the solvent was evaporated *in vacuo* and the crude product was purified by column chromatography on silica gel (40 g), using ether–benzene (1 : 99) as the eluent, to give **21** (338 mg: 74.4%), which was recrystallized from benzene; mp 260.5—261.5 °C; $[\alpha]_D$ +24.2°; IR: 3610, 3535, 1725, 1660, 1607 cm^{-1}; ^1H NMR ($CDCl_3$): 1.01 and 1.31 (each 3H and s, $-\dot{C}(CH_3)_2$), 1.25 (6H, d, J=7 Hz, $-CH(C\underline{H}_3)_2$), 1.68 (3H, s, C_{10}–CH_3), 2.08 (3H, s, $-OCOCH_3$), 4.3—4.8 (2H, m, C_3–H and C_6–H), 7.45—8.30 (5H, m, $-C_6H_5$). Found: C, 70.70; H, 7.04%. Calcd for $C_{29}H_{34}O_7$: C, 70.42; H, 6.93%.

Further elution with ether–benzene (3 : 97) afforded the recovered **17** (52 mg: 11.7%).

3β,6β,8β-Trihydroxyabieta-9(11), 13-dien-12-one (22). A mixture of **18** (18.0 mg), potassium carbonate (54 mg), methanol (2.0 ml), and water (0.5 ml) was refluxed for 75 min. After the methanol had been evaporated *in vacuo*, the residue was extracted with ether. The ether extract was washed with brine, dried over sodium sulafte, and evaporated *in vacuo*. The crude product was chromatographed on silica gel (5.0 g), using ether–benzene (25 : 75) as the eluent, to give **22** (7.0 mg); IR: 3359, 1661, 1630 cm^{-1}; ^1H NMR ($CDCl_3$, 90 MHz): 1.04 and 1.08 (each 3H, d, and J=7 Hz, $-CH(C\underline{H}_3)_2$), 1.11 and 1.27 (each 3H and s, $-\dot{C}(CH_3)_2$), 1.64 (3H, s, C_{10}–CH_3), 2.44 (2H, dd, J=4 and 14 Hz, $-CH(OH)-C\underline{H}_2-$), 4.55 (1H, m, C_6–H), 6.05 and 6.42 (each 1H and s, C_{11}–H and C_{14}–H).

Thermal Rearrangement of Dienones (19 and 20). *a*): A solution of **19** (125 mg) in dry toluene (9.0 ml) was refluxed for 4 h and the crude product, after evaporation of the solvent, was purified by column chromatography on silica gel (10 g), using ether–benzene (3 : 97) as the eluent, to give **17** (8.4 mg: 6.7%). Further elution with ether–benzene (1 : 9) afforded the recovered **19** (116 mg: 93.0%).

b): A solution of **20** (60.0 mg) in dry toluene (5.0 ml) was refluxed for 4 h. The crude product was chromatographed on silica gel (10 g), using ether–benzene (3 : 97) as the eluent, to give **17** (38.3 mg: 63.8%) and **18** (15.6 mg: 26.0%). Further elution with ether–benzene (1 : 9) afforded the recovered **20** (6.0 mg: 10.0%).

3β,11,12-Triacetoxyabieta-8,11,13-trien-6β-ol (24). Lithium aluminium hydride (372 mg) was added to a stirred solution of **17** (1.180 g) in dry ether (30 ml) with cooling in an ice–water bath. The mixture was refluxed for 2 h, poured into a mixture of ice and dilute hydrochloric acid, and extracted with ether. The ether extract was washed with brine, dried over sodium sulfate, and evaporated *in vacuo* to give the crude tetrol (**23**) which, without purification, was used in the next reaction.

The above crude **23** was acetylated at room temperature for 3.5 h with acetic anhydride (3.2 ml) in pyridine (5.0 ml). After the usual work-up, the crude product was chromatographed on silica gel (30 g), using ether–benzene (6 : 94) as the eluent, to give **24** (832 mg: 73.6% from **17**), which was recrystallized from acetone–hexane; mp 186—187.5 °C; $[\alpha]_D$ 38.1°; IR: 3613, 1762, 1724 cm^{-1}; ^1H NMR: 0.96 and 1.25 (each 3H and s, $-\dot{C}(CH_3)_2$), 1.15 and 1.19 (each 3H, d, and J=7 Hz, $-CH(C\underline{H}_3)_2$), 1.53 (3H, s, C_{10}–CH_3), 1.98 (3H, s) and 2.19 (6H, s) (3-$OCOCH_3$), 4.2—4.65 (2H, m, C_3–H and C_6–H), 6.78 (1H, s, C_{14}–H). Found: C, 67.74; H, 7.97%. Calcd for $C_{26}H_{36}O_7$: C, 67.80; H, 7.88%.

3β,11,12-Triacetoxyabieta-8,11,13-trien-6-one (25). A solution of **24** (842 mg) in acetone (4.0 ml) was oxidized at 0—5 °C for 3 min with Jones reagent (2.5 M: 1.2 ml). The mixture was diluted with water and extracted with ether. The ether extract was washed with brine, dried over sodium sulfate, and evaporated *in vacuo*. The residue was chromatographed on silica gel (25 g), using ether–benzene (3 : 97) as the eluent, to give **25** (703 mg: 83.8%), which was recrystallized from acetone–hexane; mp 121—122.5 °C; $[\alpha]_D$ +113°; IR: 1770, 1719 cm^{-1}; ^1H NMR: 1.02 and 1.21 (each 3H and s, $-\dot{C}(CH_3)_2$), 1.16 and 1.20 (each 3H, d, and J=7 Hz, $-CH(C\underline{H}_3)_2$), 1.35 (3H, s, C_{10}–CH_3), 2.00 (3H, s) and 2.24 (6H, s) (3-$OCOCH_3$), 2.73 (1H, s, C_5–H), 3.58 (2H, bs, $-COCH_2-$), 4.40 (1H, m, C_3–H), 6.82 (1H, s, C_{14}–H). Found: C, 68.00; H, 7.55%. Calcd for $C_{26}H_{34}O_7$: C, 68.10; H, 7.47%.

3β-Hydroxytaxodione (4). A solution of **25** (86.0 mg) in ethanol (5.0 ml) was refluxed for 2 h with concentrated hydrochloric acid (1.5 ml) in a stream of nitrogen. The mixture was concentrated *in vacuo*, diluted with water, and extracted with ether. The ether extract was washed with brine, dried over sodium sulfate, and evaporated *in vacuo* to give the crude 3β,11,12-trihydroxyabieta-8,11,13-trien-6-one (**26**).

The crude **26** was subjected to repeated column chromatography on silica gel (10 g and then 8 g), using ether–benzene (8 : 92) as the eluent, to give **4** (46.4 mg: 74.9% from **25**), which was recrystallized from acetone–petroleum benzine; mp 183.5—184.5 °C; $[\alpha]_D$ +69.0°; IR: 3616, 3340, 1674, 1644, 1628, 1616, 1602 cm^{-1}; ^1H NMR ($CDCl_3$): 1.17 (6H, bd, J=7 Hz, $-CH(C\underline{H}_3)_2$), 1.28 (9H, s, $-\dot{C}(CH_3)_2$ and C_{10}–CH_3), 2.60 (1H, s, C_5–H), 6.22 and 6.90 (each 1H and s, C_7–H and C_{14}–H), 7.61 (1H, s, C_{11}–OH). Found: C, 72.57; H, 8.02%. Calcd for $C_{20}H_{26}O_4$: C, 72.70; H, 7.93%.

3β,11,14-Triacetoxy-12-benzoyloxyabieta-8,11,13-trien-6-one (29). A solution of **21** (590 mg) in acetone (30 ml) was oxidized with Jones reagent (2.5 M: 0.8 ml) at 0—5 °C for 2.5 min. The mixture was diluted with water and extracted with ether. The ether extract was washed with water, dried over sodium sulfate, and evaporated to give the crude 3β-acetoxy-12-benzoyloxyabieta-8,12-diene-6,11,14-trione (**27**) (585 mg); IR: 1720, 1660 cm^{-1}.

A stirred solution of the above crude **27** (585 mg) in benzene (12 ml) was refluxed for 20 min with a mixture of zinc powder (1.2 g) and 10% hydrochloric acid (12 ml). After cooling, the mixture was extracted with ether. The extract was washed with brine, dried over sodium sulfate, and evaporated *in vacuo* to give a crude phenol (**28**); IR: 3575, 3425, 1720 cm^{-1}.

The crude phenol **28** was immediately acetylated at 85—90 °C for 2.5 h with acetic anhydride (4.0 ml) and pyridine (4.0 ml). After the usual work-up, the product was purified by column chromatography on silica gel (30 g), using ether–benzene (5 : 95) as the eluent, to give **29** (480 mg: 69.5% from **21**), which was recrystallized from benzene; mp 284—286 °C; $[\alpha]_D$ +126°; IR: 1765, 1740, 1720 cm^{-1}; ^1H NMR ($CDCl_3$): 1.05, 1.27, and 1.37 (each 3H and s, $-\dot{C}(CH_3)_2$ and C_{10}–CH_3), 1.92, 2.04, and 2.38 (each 3H and s, 3-$OCOCH_3$), 2.80 (1H, s, C_5–H), 3.36 (2H, bs, $-COCH_2-$), 4.45 (1H, m, C_3–H), 7.45—8.35 (5H, m, $-C_6H_5$). Found: C, 68.48; H, 6.71%. Calcd for $C_{33}H_{38}O_9$: C, 68.49; H, 6.62%.

3β,11,14-Triacetoxy-12-benzoyloxyabieta-8,11,13-triene-6,7-dione (30). A solution of **29** (195 mg) in acetone (10 ml) was oxidized with Jones reagent (2.5 M: 1.0 ml) at room temperature for 14 h. The mixture was diluted with water and extracted with ether. The ether extract was washed with brine, dried over sodium sulfate, and evaporated *in vacuo* to give a crude **30** (190 mg); ^1H NMR ($CDCl_3$): 1.97, 2.05,

and 2.47 (each 3H and s, 3-OCOCH$_3$), 3.20 (1H, s, C$_5$–H), 7.45—8.35 (5H, m, –C$_6$H$_5$). The crude **30** was immediately subjected to the next reaction.

Coleon T (3). A stirred mixture of the crude **30** (190 mg) in methanol (15 ml) and aqueous sodium carbonate (10%: 3.0 ml) was refluxed for 7 h in a stream of nitrogen. The methanol was evaporated *in vacuo*. The residue was acidified with dilute hydrochloric acid and extracted with ether. The ether extract was washed with brine, dried over sodium sulfate, and evaporated *in vacuo*. The crude product was purified by column chromatography on silica gel (50 g: Mallinckrodt, Silic AR CC-4), using ether–chloroform (1 : 9) as the eluent, to give **3** (71.2 mg: 58.3% from **29**). Crystallization of **3** from acetone–hexane gave an orange powder; mp 134—137 °C decomp; IR (KBr): 3415, 1725, 1613, 1434, 1381, 1296, 1043, 941 cm^{-1}; ^{1}H NMR (acetone-d_6): 1.14, 1.36, and 1.42 (each 3H and s, –C(CH$_3$)$_2$ and C$_{10}$–CH$_3$), 1.33 (6H, d, J=7 Hz, –CH(CH$_3$)$_2$), 3.15 (1H, s, C$_5$–H), 13.54 (1H, s, C$_{14}$–OH).

Acetylation of 3. A solution of **3** (54.0 mg) and acetic anhydride (1.0 ml) in pyridine (2.0 ml) was heated at 70—75 °C for 6 h. After the usual work-up, the crude product was purified by column chromatography on silica gel (10 g), using ether–benzene (7 : 93) as the eluent, to give 3β,6,11,-12-tetraacetoxy-14-hydroxyabieta-5,8,11,13-tetraen-7-one (**32**) (22.9 mg: 29.0%), which was recrystallized from ether–hexane; mp 160.5—162.5 °C; IR (KBr): 3418, 1777, 1728, 1632, 1615 cm^{-1}; ^{1}H NMR (CDCl$_3$, 90 MHz): 1.31 (6H, d, J=7 Hz, –CH(CH$_3$)$_2$), 1.34 and 1.42 (each 3H and s, –C(CH$_3$)$_2$), 1.74 (3H, s, C$_{10}$–CH$_3$), 2.11 (3H, s), 2.30 (6H, s), and 2.35 (3H, s) (4-OCOCH$_3$), 4.83 (1H, m, C$_3$–H), 13.38 (1H, s, C$_{14}$–OH). Found: C, 63.62; H, 6.61%. Calcd for C$_{28}$H$_{34}$O$_{10}$: C, 63.38; H, 6.46%.

Further elution with ether–benzene (15 : 85) afforded 3β,6,-11,12,14-pentaacetoxyabieta-5,8,11,13-tetraen-7-one (colen S pentaacetate) (**31**) (49.6 mg: 58.1%), which was recrystallized from acetone–hexane; mp 215.5—217.5 °C; [α]$_D$ +79.3°; IR (KBr): 1778, 1764, 1722, 1667, 1632, 1602 cm^{-1}; ^{1}H NMR (CDCl$_3$): 1.24 (6H, d, J=7 Hz, –CH(CH$_3$)$_2$), 1.34 and 1.41 (each 3H and s, –C(CH$_3$)$_2$), 1.75 (3H, s, C$_{10}$–CH$_3$), 2.12 (3H, s), 2.35 (9H, s), and 2.41 (3H, s) (5-OCOCH$_3$), 4.83 (1H, m, C$_3$–H). Found: C, 62.96; H, 6.44%. Calcd for C$_{30}$H$_{36}$O$_{11}$: C, 62.92; H, 6.34%. The synthetic **31** was shown to be identical with authentic coleon S pentaacetate by mixed melting point determination and by IR and ^{1}H NMR spectral comparisons.

Coleon S (2). A solution of **3** (51.0 mg) in methanol (6.0 ml) was refluxed for 30 min with concentrated hydrochloric acid (0.5 ml). The mixture was evaporated *in vacuo*, diluted with water, and extracted with ether. The ether extract was washed with brine, dried over sodium sulfate, and evaporated *in vacuo*. The residue was chromatographed on silica gel (10 g: Mallinckrodt, Silic AR CC-4), using ether–chloroform (5 : 95) as the eluent, to give **2** (24.9 mg: 48.8%); IR (KBr): 3383, 1616, 1594, 1561, 1446, 1297, 1259, 1173, 1112, 1061, 1045, 1017, 972, 940, 900, 810, 777 cm^{-1}; ^{1}H NMR (acetone-d_6, 90 MHz): 1.34 (6H, d, J=7 Hz, –CH(CH$_3$)$_2$), 1.40 and 1.55 (each 3H and s, –C(CH$_3$)$_2$), 1.75 (3H, s, C$_{10}$–CH$_3$), 7.55 (1H, s, C$_6$–OH), 13.08 (1H, s, C$_{14}$–OH).

The synthetic **2** was refluxed for 4 h with acetic anhydride in pyridine to give **31**, mp 212.5—214.5 °C (from acetone–hexane), which was shown to be identical with authentic coleon S pentaacetate by mixed melting point determination and by IR and ^{1}H NMR spectral comparisons.

The authors are grateful to the Arakawa Chemical Co. Ltd. for a generous gift of rosin. Thanks are also due to Professor C. H. Eugster for kindly supplying the natural samples. This work was partially supported by a Grant-in-Aid for Scientific Research No. 56540324 from the Ministry of Education, Science and Culture.

The Preparation of Cyclic Dithia and Thiaza Compounds by the Reaction of Potassium Carbonate with Heterocumulenes and Alkylene Dibromides or Carbonate Catalyzed by Organostannyl Compounds

Tatsuo FUJINAMI,* Shinichi SATO, Norimasa UCHIDA, and Shizuyoshi SAKAI

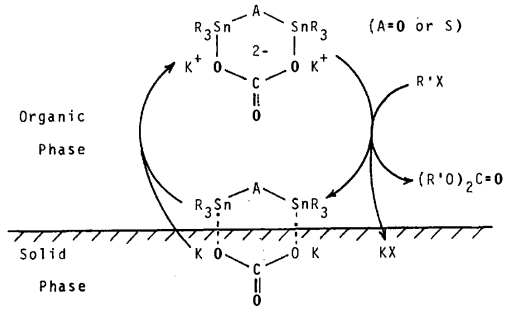
Department of Industrial Chemistry, Faculty of Engineering, Shizuoka University, Hamamatsu 432

(Received August 17, 1981)

Cyclic 1,3-dithia- and 1,3-thiaza-2-ylidene compounds were obtained by the heterogeneous reaction of solid potassium carbonate, a sulfur-containing heterocumulene, such as aryl isothiocyanate, carbon disulfide, or carbonyl sulfide, and alkylene dibromides or ethylene carbonate in the presence of bis(tributylstannyl) compounds. The effect of an organostannyl catalyst on these reactions is discussed.

Alkali carbonates are usually insoluble in aprotic organic solvents and are generally used as weak bases in organic reactions. It was recently reported that potassium and sodium carbonates acted as strong bases for the generation of ylide[1] and carbanions[2] by means of a two-phase procedure catalyzed by a crown ether or quarternary salt. From the viewpoint of the further utilization of alkali carbonates other than a base, the fixation of carbonate ion into organic compounds is attractive, but all attempts to do so have been unsuccessful till lately; Soga[3] has reported that the polycarbonate was obtained by the reaction of potassium carbonate with α,α'-dibromo-*p*-xylene in the presence of a crown ether.

In a previous report,[4] we found that bis(tributylstannyl) compounds were effective two-phase catalysts for the heterogeneous nucleophilic reaction of solid potassium carbonate with alkyl bromides in polar aprotic solvents, affording dialkyl carbonates in good yields (Scheme 1).



Scheme 1. Preparation of dialkyl carbonates.

Exchange reactions between the CO_2 group in the dimetallocarbamate and heterocumulenes have been observed in organostannyl compounds (Eq. 1).[5]

$$Bu_3SnOSnBu_3 \xrightarrow{+\ O{=}C{=}NR} Bu_3Sn{-}\underset{\displaystyle R}{\overset{\displaystyle |}{N}}{-}\overset{\displaystyle O}{\overset{\displaystyle ||}{C}}{-}O{-}SnBu_3$$

$$\xrightarrow[-CO_2]{+\ R'N{=}C{=}Z} Bu_3Sn{-}\underset{\displaystyle R}{\overset{\displaystyle |}{N}}{-}\overset{\displaystyle NR'}{\overset{\displaystyle ||}{C}}{-}Z{-}SnBu_3 \qquad (1)$$

$Z = O$ or S

It is supposed that, analogously to Eq. 1, the stannate complex proposed for the soluble intermediate in Scheme 1 takes part in the exchange reactions of the CO_2 group in the ate-complex with various heterocumulenes. Also the stannate complexes resulting from the exchange reaction can be expected to give the corresponding heterocyclic compounds by cyclization with bifunctional alkylene compounds. On the basis of this working hypothesis, we wish to report here the use of organostannyl compounds in the activation of potassium carbonate in the preparation of cyclic 1,3-thiaza- and 1,3-dithia-2-ylidene compounds from sulfur-containing heterocumulenes and alkylene dibromides or ethylene carbonate. This procedure is carried out under mild conditions using an insoluble weak base, potassium carbonate, and does not require poisonous or awkward reagents.

Results and Discussion

Reaction of Potassium Carbonate with Aryl Isothiocyanates or Carbon Disulfide and Alkylene Dibromide. Anhydrous potassium carbonate, alkylene dibromide, two equivalents of aryl isothiocyanate, and hexabutyldistannathiane (5 mol%) were stirred for 8 h in refluxing acetonitrile under dry nitrogen to form 1,3-thiaza and 1,3-dithia compounds, **1**—**3**, accompanied by the elimination of carbon dioxide, carbonyl sulfide, and aryl isocyanate (Eq. 2). The carbonyl sulfide was trapped and confirmed by means of its IR spectrum.

$$\underset{\mathbf{1a\text{-}c}}{\text{(1-Ar-2-imino-1,3-thiaza)}} + \underset{\mathbf{2a\text{-}c}}{\text{(1-Ar-2-thioxo-1,3-thiaza)}} + \underset{\mathbf{3a\text{-}c}}{\text{(2-Ar-imino-1,3-dithia)}} \qquad (2)$$

a: Ar=Ph, n=2, b: Ar=p-Tol, n=2, c: Ar=Ph, n=3

From the reaction products, triaryl isocyanurate was isolated; it supported the elimination of aryl isocyanate in the reaction. The cyclic 3-aryl-2-arylimino-1,3-thiaza compound (**1**), 2-thioxo-1,3-thiaza compound (**2**), and 2-arylimino-1,3-dithia compound (**3**) were isolated and identified by their melting points and IR, NMR, and mass spectra. The results are summarized in Table 1.

From the results shown in Table 1, hexaalkyldistannoxane and -distannathiane can be seen to promote Reaction 2 distinctly. The reaction can scarcely

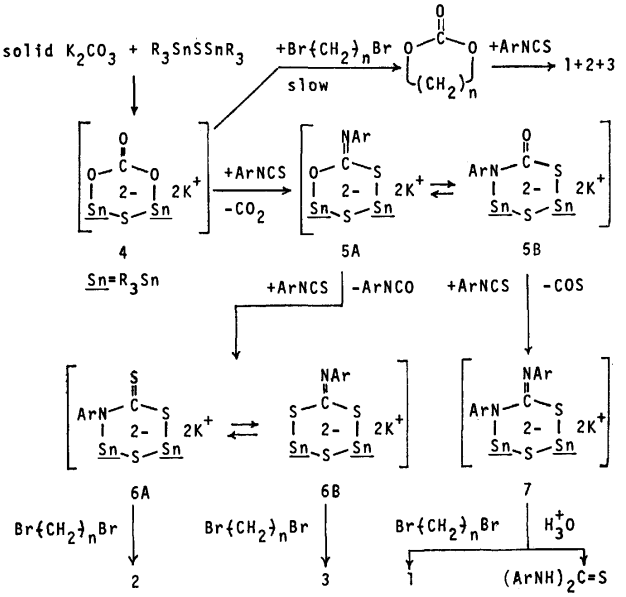
a) Reaction conditions: potassium carbonate (10 mmol), aryl isothiocyanate (20 mmol), alkylene dibromide (10 mmol), acetonitrile (10 ml), at the refluxing temperature. b) Based on the alkylene dibromide used.

proceed without the catalyst. However, dibutylstannathiane existing in a cyclic trimer[6] is less effective, and chlorotributylstannane does not accelerate Reaction 2 at all, although it was an excellent catalyst like the bis(tributylstannyl) compounds in the preparation of dialkyl carbonates. In Reaction 2, hexabutyldistannoxane might be converted to the thiane derivative by a rapid reaction with aryl isothiocyanate.[7]

Bis(tributylstannyl) compounds may act as two-phase catalysts, as is shown in Scheme 1. The bis(tributylstannyl) compounds interact with solid potassium carbonate to form an ate-complex **4**. Since potassium carbonate and 1,2-dibromoethane gave only a low yield (<5%) of ethylene carbonate (**8**) even in the presence of a bis(tributylstannyl) catalyst, under the same conditions, the products, **1**—**3**, cannot be considered to be formed *via* **8**. Therefore, the ate-complex **4** may react with aryl isothiocyanate in the first step to form the ate-complex **5** which further reacts with another molecule of isothiocyanate to form sulfur- and nitrogen-containing ate-complexes, **6A**, **6B**, and **7** (Scheme 2).

Although these ate-complexes have not been established, the mild hydrolysis of the reaction mixture of potassium carbonate with phenyl isothiocyanate in the presence of hexabutyldistannathiane gave *N,N'*-diphenylthiourea which suggests the formation of **7**.



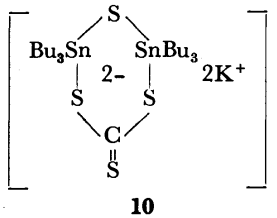
Scheme 2. Preparation of cyclic 1,3-thiaza and 1,3-dithia compounds.

The reaction *via* the ate-complexes **4**—**7** will be the same type of reaction as in the case of a heterocumulene exchange reaction (1) using neutral bis(tributylstannyl) compounds.

The ate-intermediates **6A** and **7** have reactive Sn–N sites and react with alkylene dibromide to afford **1** or **2**. On the other hand, **6B** has no Sn–N site but a less reactive Sn–S site, and the yield of **3**, which may be expected to be a major product from the dithiocarbamate dianion because of the large nucleophilicity of its S⁻ site,[8] is lower than that of **2**.

Hexabutyldistannathiane is inert in many reactions of organostannyl compounds, such as Reaction 1,[5] but in Reaction 2 this compound is highly active. This activity of hexabutyldistannathiane may be ascribed to the formation of ate-complexes.

Contrary to the reaction of aryl isothiocyanate, the reaction of carbon disulfide with potassium carbonate and 1,2-dibromoethane in acetonitrile for 12 h at reflux gave 1,3-dithiolane-2-thione (**9**) in a 90% yield, even in the absence of an organostannyl compound. Potassium trithiocarbonate from carbon disulfide and potassium carbonate is conceived of as the reactive intermediate because of its strong nucleophilicity. Futhermore, the tin atom in organostannyl compounds shows a strong affinity to the sulfur atom serving to stabilize the trithiocarbonate anion by the formation of the ate-complex **10**. This may explain the lowering of the yield of **9** down to 68% by the presence of hexabutyldistannathiane.



10

Reaction of Potassium Carbonate with Heterocumulenes and Ethylene Carbonate. When ethylene carbonate (**8**) is used instead of dibromoethane in the above reactions, the displacement of the CO_2 group in **8** by other hetero-

TABLE 2. REACTIONS OF ETHYLENE CARBONATE WITH VARIOUS HETEROCUMULENES CATALYZED BY HEXABUTYLDISTANNATHIANE AND/OR POTASSIUM CARBONATE[a)]

a) Ethylene carbonate (10 mmol), heterocumulene (20 mmol or more), and catalysts were heated in the solvent at reflux. b) Based on ethylene carbonate used. c) Accompanied by the formation of **1a** (11%) and **2a** (34%). d) In an autoclave at 80 °C.

cumulenes can be expected.

These heterocyclic compounds, **1a, 2a,** and **3a**, were obtained in the reaction of **8** with phenyl isothiocyanate in refluxing acetonitrile using 5 mol% of potassium carbonate and hexabutyldistannathiane (Eq. 3). Contrary to Reaction 1, the main product was **3a** (not **1a**).[9)]

$$K_2CO_3 + 2PhNCS + Bu_3SnSSnBu_3 \longrightarrow \mathbf{6A} + \mathbf{6B} + \mathbf{7} \longrightarrow \mathbf{1a} + \mathbf{2a} + \mathbf{3a} \quad (8),\ -K_2CO_3,\ -Bu_3SnSSnBu_3 \qquad (3)$$

Potassium carbonate is reproduced in Reaction 3 so that the carbonate can act as a catalyst. Therefore, the activity of the organostannyl compound as a two-phase catalyst for solid potassium carbonate is less in the catalytic reaction (3) than that in the stoichio reaction (2) of the carbonate.

In a less polar solvent such as benzene, a mixed catalyst system of the distannathiane and 18-Crown-6 was found to be more effective in Reaction 3 as well as in the reaction for the preparation of dialkyl carbonates.[4)]

The analogous reaction of **8** with carbon disulfide or carbonyl sulfide, catalyzed by potassium carbonate in an autoclave at 80 °C, gave **9** and 1,3-dithiolane-2-one (**11**) respectively (Eq. 4).

$$2\ S{=}C{=}Z + \underset{\mathbf{8}}{\text{cyclic carbonate}} \xrightarrow[-CO_2,\ -COS]{K_2CO_3} \underset{\mathbf{9}(Z=S),\ \mathbf{11}(Z=O)}{\text{cyclic trithiocarbonate}} \qquad (4)$$

Z=O or S

The organostannyl catalyst was not effective either in the reaction with carbon disulfide or in that with carbonyl sulfide (Table 2). This can be also explained similarly by the strong Sn–S interaction in the proposed ate-complexes consisting of CS_3^{2-} and COS_2^{2-} as was described about that for **10**.

The attempted analogous reactions using phenyl isocyanate or di-*o*-tolylcarbodiimide, which contains no sulfur atom, gave no corresponding heterocyclic compounds.

Experimental

All the melting points were determined on a micro hot stage and were not corrected. The IR spectra were taken on a JASCO IR A-1 or A-3 spectrometer. The NMR spectra were recorded on a Hitachi R-24 spectrometer. The mass spectra were measured on a Hitachi RMU-7M spectrometer. Commercial potassium carbonate was dried at about 300 °C before use. The other reagents and solvents were dried by the usual methods. All the procedures were carried under a dry nitrogen atmosphere.

Reactions of Potassium Carbonate, Aryl Isothiocyanate, and Alkylene Dibromide. Potassium carbonate (10 mmol), phenyl isothiocyanate (10 mmol), and hexabutyldistannathiane (0.5 mmol) were stirred in refluxing acetonitrile (10 ml) for 8 h. Carbonyl sulfide thus evolved was trapped at −78 °C and identified by means of its IR spectrum (ν_{COS} 2038 cm^{-1}). After the reaction mixture had been filtered to remove the inorganic salts and acetonitrile had been evaporated *in vacuo*, hot diethyl ether was added to precipitate triphenyl isocyanurate: mp 283—287 °C (lit,[10)] 285—286 °C); IR (KBr) 1700 cm^{-1} (C=O). The ether solution was cooled to precipitate 3-phenyl-2-phenylimino-1,3-thiazolidine (**1a**, 48%), contaminated with a small amount of triphenyl isocyanurate, which was removed by recrystallization from diethyl ether. The solvent was evaporated from the ether solution, and then 3-phenyl-1,3-thiazolidine-2-thione (**2a**, 17%) and 2-phenylimino-1,3-dithiolane (**3a**, 15%) were isolated by column chromatography on silica gel (chloroform). **1a**: mp 135—137 °C (lit,[11)] 136—137 °C); IR ($CHCl_3$) 1628 cm^{-1} (C=N); NMR ($CDCl_3$) δ 3.15 (2H, t, J=6.6 Hz, SCH_2), 4.04 (2H, t, J=6.6 Hz, NCH_2), and 6.8—7.6 (10H, m, arom.); MS *m/e* 254 (M^+). **2a**: mp 132—134 °C (lit,[12)] 133—134 °C); IR ($CHCl_3$) 1260 cm^{-1} (C=S); NMR ($CDCl_3$) δ 3.40 (2H, t, J=7.6 Hz, SCH_2), 4.42 (2H, t, J=7.6 Hz, NCH_2), and 7.35 (5H, s, arom.); MS *m/e* 195 (M^+). **3a**: mp 42—44 °C (lit,[13)] 47—48 °C); IR ($CHCl_3$) 1592 cm^{-1} (C=N), NMR ($CDCl_3$) δ 3.36 (4H, s, SCH_2CH_2S) and 6.7—7.4 (5H, m, arom.);

MS *m/e* 195 (M^+).

Similarly, other heterocyclic compounds were obtained. Their yields, melting points, and spectral data were as follows: 3-*p*-Tolyl-2-*p*-tolylimino-1,3-thiazolidine (**1b**): 35%; 107—109 °C (lit,[11] 110 °C); IR ($CHCl_3$) 1629 cm^{-1} (C=N); NMR ($CDCl_3$) δ 2.29 (6H, s, CH_3), 3.16 (2H, t, J=6.6 Hz, SCH_2), 4.02 (2H, t, J=6.6 Hz, NCH_2), and 6.7—7.5 (8H, m, arom.); MS *m/e* 310 (M^+). 3-*p*-Tolyl-1,3-thiazolidine-2-thione (**2b**): 18%, 123—125 °C (lit,[12] 126 °C); IR ($CHCl_3$) 1263 cm^{-1} (C=S); NMR ($CDCl_3$) δ 2.36 (3H, s, CH_3), 3.42 (2H, t, J=7.7 Hz, SCH_2), 4.44 (2H, t, 7.7 Hz, NCH_2), and 7.28 (4H, s, arom.); MS *m/e* 209 (M^+). 2-*p*-Tolylimino-1,3-dithiolane (**3b**): 12%; oil (lit,[13] oil); IR ($CHCl_3$) 1580 cm^{-1} (C=N); NMR ($CDCl_3$) δ 2.32 (3H, s, CH_3), 3.51 (4H, s, SCH_2CH_2S), and 6.8—7.3 (4H, m, arom.); MS *m/e* 209 (M^+). 3-Phenyl-2-(phenylimino)perhydro-1,3-thiazine (**1c**): 24%; 139—141 °C (lit,[10] 139 °C); IR ($CHCl_3$) 1623 cm^{-1} (C=N); NMR ($CDCl_3$) δ 2.24 (2H, m, C-CH_2-C), 3.17 (2H, t, J=6.1 Hz, SCH_2), 3.77 (2H, t, 5.5 Hz, NCH_2), and 6.9—7.5 (10H, m, arom.), MS *m/e* 268 (M^+). 3-Phenylperhydro-1,3-thiazine-2-thione (**2c**): 19%, 105—106 °C; IR ($CHCl_3$) 1232 cm^{-1} (C=S); NMR ($CDCl_3$) δ 2.40 (2H, m, C-CH_2-C), 3.12 (2H, t, J=6.1 Hz, SCH_2), 3.82 (2H, t, J=5.5 Hz, NCH_2), and 7.2—7.5 (5H, m, arom.); MS *m/e* 209 (M^+). 2-Phenylimino-1,3-dithiane (**3c**): 18%; 113—116 °C (lit,[14] 117—118 °C); IR ($CHCl_3$) 1570 cm^{-1} (C=N); NMR ($CDCl_3$) δ 2.17 (2H, m, C-CH_2-C), 3.12 (2H, t, J=6.8 Hz, SCH_2), and 6.7—7.5 (5H, m, arom.); MS *m/e* 209 (M^+).

A reaction mixture from potassium carbonate, phenyl isothiocyanate, and hexabutyldistannathiane (5 mol%), obtained under the conditions described above, was hydrolyzed by the addition of dilute hydrochloric acid after the solvent had been evaporated; the residue was washed with hexane to remove the unreacted phenyl isothiocyanate. A small amount of a water-insoluble precipitate was obtained. By recrystallization from ethanol, *N,N'*-diphenylurea was isolated: mp 149—152 °C (lit,[15] 154 °C); IR (KBr) 1445 cm^{-1}.

Reaction of Ethylene Carbonate (8) with Phenyl Isothiocyanate. Ethylene carbonate (10 mmol), phenyl isothiocyanate (20 mmol), potassium carbonate (0.5 mmol), and hexabutyldistannathiane (0.5 mmol) were stirred in refluxing acetonitrile (10 ml). After the reaction mixture had then been treated as above, **1a** (11%), **2a** (34%), and **3a** (50%) were obtained. By an analogous reaction catalyzed by potassium carbonate (5 mol%), hexabutyldistannathiane (5 mol%), and 18-crown-6 (10 mol%) in refluxing benzene for 24 h, **1a** (16%), **2a** (24%), and **3a** (49%) were obtained.

Reaction of Ethylene Carbonate (8) with Carbon Disulfide or Carbonyl Sulfide. Ethylene carbonate (**8**, 20 mmol), carbon disulfide (40 mmol), potassium carbonate (1 mmol), hexabutyldistannathiane (1 mmol), and 18-crown-6 (2 mmol) were heated in a glass autoclave for 24 h at 80 °C. 1,3-Dithiolane-2-thione (**9**) was then isolated in a 17% yield by means of column chromatography.

By a similar procedure, the reaction of **8** (20 mmol) with carbonyl sulfide (40 mmol), catalyzed by potassium carbonate (1 mmol) and hexabutyldistannathiane (1 mmol) for 48 h at 80 °C, gave 1,3-dithiolane-2-thione (**11**, 42%) and **9** (2%). **11**: mp 31—33 °C (lit, [15] 35 °C); IR ($CHCl_3$) 1716 cm^{-1} (C=O); NMR ($CDCl_3$) δ 3.77 (4H, s, SCH_2CH_2).

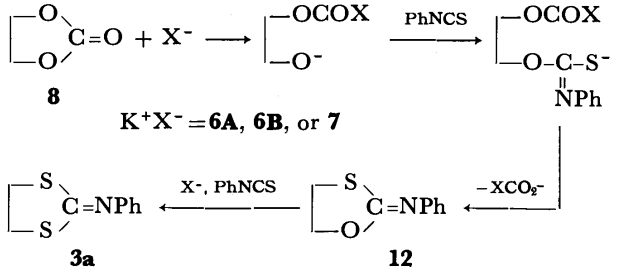
8) We obtained more **3a** (43%) than **2a** (17%) by the reaction of dibromoethane with $PhN(Li)CS_2Li$, which had been prepared *in situ* from aniline, butyllithium, and carbon disulfide; S. Sakai, N. Otani, and T. Fujinami, unpublished.

9) The reason for the formation of **3a** as the main product in Reactions 3 is not yet clear. However, we tentatively consider the reaction scheme to be as follows.



In the first step, the anionic species, X^-(S^- or N^- site in **6A**, **6B**, or **7**) attack the acyl carbon of **8** competitively on the sp^3-carbon. Subsequently, phenyl isothiocyanate adds to the ring-opening product, and a cyclic intermediate is formed by an intramolecular nucleophilic attack of the S^- site. Similar reactions are repeated on **12** to give **3a**.

Syntheses of Lividomycin B Analogues, 5-*O*-[3-*O*-(6-Amino-6-deoxy-β-L-idopyranosyl)-β-D-ribofuranosyl]-3′-deoxyparomamine and 5-*O*-[2-*O*-(6-Amino-6-deoxy-β-L-idopyranosyl)-β-D-ribofuranosyl]-3′-deoxyparomamine

Institute of Bioorganic Chemistry, 1614 Ida, Nakahara-ku, Kawasaki 211

(Received August 28, 1981)

The preparation of lividomycin B analogues, the title pseudotetrasaccharides, is described. Condensation of 6-azido-2,3,4-tri-*O*-benzyl-6-deoxy-L-idopyranosyl chloride with 4′,6′-di-*O*-benzoyl-5-*O*-(5-*O*-benzoyl-β-D-ribofuranosyl)-3,2′-bis(*N*-benzyloxycarbonyl)-1-*N*:6-*O*-carbonyl-3′-deoxyparomamine was followed by deblocking and reduction of the azido groups. Structure determinations and the antibacterial activities of the products are described.

Lividomycin B[1] is an amino glycoside antibiotic which belongs to a pseudotetrasaccharide. Since its pseudotrisaccharide[2] portion (**5**; B-A-C portion of lividomycin B) has almost no antibacterial activity, it is suggested that the fourth sugar (D portion) plays an important role in exhibiting the antibacterial activity of lividomycin B. Until now, however, variation of the D portion has rarely been studied. A lividomycin B analogue,[3] which has 2-amino-2-deoxy-α-D-glucopyranose as the fourth sugar, was reported and found to show much less antibacterial activity than lividomycin B having the 2,6-diamino-2,6-dideoxy-β-L-idopyranose. As the continuation of this work, the present study was performed. Since it appeared that the 6-amino group on the β-L-idopyranose portion of lividomycin B would have an important role in its activity, we undertook to synthesize a lividomycin B analogue having 6-amino-6-deoxy-β-L-idopyranose instead of the diamino sugar. This synthesis was carried out by condensation of a protected idopyranosyl halide (**4**) with a pseudotrisaccharide derivative (**8**), leading to the desired glycoside (**14**) and an isomer (**13**).

6-Azido-3-*O*-benzyl-6-deoxy-1,2-*O*-isopropylidene-L-idofuranose[4] (**1**) was prepared from 1,2:5,6-di-*O*-isopropylidene-D-glucofuranose *via* 5,6-anhydro-3-*O*-benzyl-1,2-*O*-isopropylidene-L-idofuranose[5] through 6 steps. Conversion of the furanose (**1**) to the corresponding pyranose was carried out by treating **1** with 95% formic acid and the crude product was treated with α-bromotoluene in the presence of a base to give benzyl 6-azido-2,3,4-tri-*O*-benzyl-6-deoxy-β-L-idopyranoside (**2**). Acidic hydrolysis of **2** gave the free sugar (**3**). Reaction of **3** with thionyl chloride gave the corresponding glycosyl chloride (**4**), which was used without purification.

The pseudotrisaccharide[2] (**5**) obtained from lividomycin B by cleavage[6] of the 2,6-diamino-2,6-dideoxy-L-idopyranose portion was treated with benzyl chloroformate to give 1,3,2′-tris(*N*-benzyloxycarbonyl) derivative (**6**). Treatment of **6** with sodium hydride in *N*,*N*-dimethylformamide, a procedure producing cyclic carbamate developed by Umezawa, Tsuchiya, and Ikeda,[7] gave 3,2′-bis(*N*-benzyloxycarbonyl)-1,6-carbamate (**7**). Structural proof of the five-membered carbamate was obtained from the presence of an absorption peak at 1770 cm^{-1} [8] in its IR spectrum. Treatment of **7** with phenylboronic acid (1 mol equiv. for **6**), followed by benzoylation and removal of the phenylboronate protecting group[9] gave 4′,6′,5″-tri-*O*-benzoyl derivative (**8**) as the main product with the minor 5″-*O*-benzoyl derivative (**9**). The structure of **8** was confirmed by the result of periodate oxidation, and the structure of **9**, by the formation of its 4′,6′:2″,3″-di-*O*-isopropylidene derivative (**10**). This suggests that the intermediary boronate was mainly formed between 2″- and 3″-hydroxyls, and between 4′- and 6′-hydroxyls in a minor extent.

Condensation of the glycosyl chloride (**4**) with the protected pseudotrisaccharide (**8**) was carried out in benzene in the presence of mercury(II) cyanide to give

a) In ppm downfield from TMS calculated as $\delta^{TMS} = \delta^{dioxane} + 67.4$ ppm. b—l) Figures indicated by the same character may be interconvertible.

2″-*O*- (**11**, 43%) and 3″-*O*-(6-azido-2,3,4-tri-*O*-benzyl-6-deoxy-β-L-idopyranosyl) derivatives (**12**, 19%). Debenzoylation and cleavage[7] of the carbamate groups of the condensation products (**11** and **12**) were carried out with dilute barium hydroxide. Further treatment with sodium metal in liquid ammonia resulted in debenzylation, de(benzyloxycarbonyl)ation and the reduction of the azido into an amino group simultaneously to give the final products (**13** and **14**).

The structures of **13** and **14** were confirmed as follows. The molecular rotations ($[\alpha]_D \times MW/100$) of the final products (**13** : +340; **14** : +310) showed comparative values with that of lividomycin B (+360), but greater than that of **5** (+200), indicating that the contributions of the L-idopyranose moiety of **13** and **14** for their rotations are both positive (*ca.* +120). Since the molecular rotations of α-L- and β-L-idopyranosides are roughly estimated[10] −190 and +100, respectively, it is shown that the L-idopyranoses of **13** and **14** are coupled to the pseudotrisaccharide portion (**5**) with the desired β-L-anomeric configuration. The positions at which the β-L-idopyranose was attached were decided by the ^{13}C-NMR spectra. At first, carbon chemical shifts of lividamine[11] were assigned on the basis of comparison of the data with those of neamine[12] and paromomycin[12] (Table 1); the shifts of pseudotrisaccharide (**5**) were then assigned by comparison of the data with those of lividamine just obtained and paromomycin;[12] finally

a) Agar dilution streak method (nutrient agar, 37 °C, 18 h). b) 48 h.

the shifts of lividomycin B were assigned on the basis of comparison of the data with those of **5** and paromomycin. Shift-assignments of **14** were next made by comparison of the data with that of lividomycin B just obtained. The sole discrepancy in shift-value between **14** and lividomycin B observed was that for C-2‴ at which a hydroxyl group is attached in **14** instead of the amino group in lividomycin B. Downfield shift[13] (6.6 ppm) of C-3″ from the corresponding position of **5** also supported that glycosylation occurred at the 3″-hydroxyl. Compound **14** was, therefore, decided to be 3″-*O*-glycosyl compound. Shift-assignments of **13** were made on the basis of the data of **14**. The chemical shift at 82.9 ppm of **13** can reasonably be assigned to that of C-2″; the shift-difference (7.2 ppm) of the C-2″ between **13** and **5** indicates that **13** is a 2″-*O*-glycosyl isomer.

Antibacterial spectra of **13** and **14** were shown in Table 2 with that of lividomycin B. The results show that **14** has weaker antibacterial activity than that of lividomycin B, and that the position isomer **13** is less active than **14**. This result shows that an important factor with respect to structure-activity relationships in the ring D is the number and location of amino functions, affecting the binding of the antibiotics with bacterial ribosomes. It is noteworthy that the isomer (**13**) does not loss activity against bacteria in spite of the introduction of the D ring at another position of the ribose.

Experimental

^{1}H-NMR spectra were recorded at 90 MHz with a Varian EM-390 spectrometer. ^{13}C-NMR spectra were recorded on a Varian XL-100 spectrometer with Varian 620-L data processing system (25.2 MHz) in deuterium oxide solution containing dioxane as internal reference. Thin-layer chromatography (TLC) was performed on DC-Fertigplatten Kieselgel 60 F_{254} (E. Merck). For column chromatography, silica gel (Wakogel C-200) was used.

*Benzyl 6-Azido-2,3,4-tri-*O*-benzyl-6-deoxy-β-*L*-idopyranoside (**2**).* A solution of **1** (3.00 g) in 95% formic acid (100 ml) was kept at room temperature for 4 h. Evaporation *in vacuo* followed by several coevaporations with toluene gave a residue, which was dissolved in DMF (60 ml). To the solution cooled to 0 °C, α-bromotoluene (5.8 ml. *ca* 3 mol equiv. for **1**), barium oxide (7.26 g) and $Ba(OH)_2 \cdot 8H_2O$ (15 g, powdered) were added and the mixture was stirred overnight at the temperature. Addition of benzene (100 ml) gave precipitates which were removed by centrifugation. Concentration of the solution and the washings (the solid was washed with benzene) combined gave a residue. Column chromatography of the residue with benzene–ethyl acetate (100 : 1) gave a syrup of **2**, 2.90 g (57%), $[\alpha]_D^{24}$ +101° (*c* 1, chloroform).

^{1}H-NMR ($CDCl_3$): δ 3.53 (1H dd, $J_{1,2}$ 2 Hz, $J_{2,3}$ 5 Hz, H-2), and 4.85 (1H d, H-1); IR (KBr): 2100 cm^{-1} (N_3).

Found: C, 72.35; H, 6.31; N, 7.37%. Calcd for $C_{34}H_{35}N_3O_5$: C, 72.19; H, 6.24; N, 7.43%.

*6-Azido-2,3,4-tri-*O*-benzyl-6-deoxy-*L*-idopyranose (**3**).* To a solution of **2** (1.70 g) in acetic acid (93 ml) was added 2 M† sulfuric acid (8.5 ml) and the solution was kept at 80 °C for 3 h. Ice–water (200 g) was introduced and the mixture was extracted with chloroform. The organic solution was washed with sodium hydrogencarbonate solution, water, dried over sodium sulfate and concentrated. The residue was purified by a short column of silica gel with benzene–ethyl acetate (10 : 1) to give a colorless syrup, 1.24 g (86%), $[\alpha]_D^{24}$ +6.5° (*c* 1, chloroform); IR(KBr): 2100 cm^{-1} (N_3).

Found: C, 68.40; H, 6.26; N, 8.88%. Calcd for $C_{27}H_{29}N_3O_5$: C, 68.21; H, 6.11; N, 8.84%.

*6-Azido-2,3,4-tri-*O*-benzyl-6-deoxy-*L*-idopyranosyl Chloride (**4**).* Compound **3** (700 mg) was dissolved in thionyl chloride (7 ml) and the solution was kept at room temperature for 3 h. Evaporation followed by several coevaporations *in vacuo* with dry toluene gave a surup (730 mg).

^{1}H-NMR ($CDCl_3$): δ 5.84 (*ca.* 0.3H d, *J* 3 Hz, α-L-isomer), and 6.16 (*ca.* 0.7 H slightly broadened s, β-L-isomer).

*1,3,2′-Tris(*N*-benzyloxycarbonyl)-3′-deoxy-5-*O*-(β-*D*-ribofuranosyl)paromamine (**6**).* To a cold (−5°C) solution of **5** (4.44 g as the base) in aqueous methanol (1: 1, 50 ml), anhydrous sodium carbonate (4.0 g) and benzyl chloroformate (6.2 g) were added and the solution was kept at 0 °C for 1 h and then at room temperature for 2 h. Concentration followed by addition of water gave a solid, which was thoroughly washed with ether to give a solid, 7.47 g (88%), $[\alpha]_D^{24}$ +27° (*c* 1, methanol).

Found: C, 58.31; H, 6.05; N, 5.13%. Calcd for $C_{41}H_{50}N_3O_{16}$: C, 58.56; H, 5.99; N, 5.00%.

*3,2′-Bis(*N*-benzyloxycarbonyl)-1-*N*:6-*O*-carbonyl-3′-deoxy-5-*O*-(β-*D*-ribofuranosyl)paromamine (**7**).* To a cold (0 °C) solution of **6** (8.0 g) in dry DMF (80 ml), 50% oily sodium hydride (0.6 g as net NaH) was added and the mixture was stirred vigorously for 4 h at the cold. Acetic acid (6.4 ml) was added and the solution was concentrated *in vacuo*. Extraction of the resulting residue with dioxane followed by concentration of the dioxane solution gave a solid, which was chromatographed with chloroform–methanol (8 : 1→ 6 : 1). Starting material (**6**) (1.66 g, 21%) and **7** (4.11 g, 59%) were eluted in this order. **7**: $[\alpha]_D^{24}$ +34° (*c* 1, methanol); R_f 0.24 (TLC with $CHCl_3$–MeOH=6 : 1; **6**: R_f 0.38); IR(KBr): 1770 (cyclic carbamate), and 1710 cm^{-1} (urethane carbonyl).

Found: C, 55.37; H, 6.02; N, 5.43%. Calcd for $C_{34}H_{43}N_3O_{15}$: C, 55.66; H, 5.91; N, 5.73%.

*4′,6′-Di-*O*-benzoyl-5-*O*-(5-*O*-benzoyl-β-*D*-ribofuranosyl)-3,2′-bis(*N*-benzyloxycarbonyl)-1-*N*:6-*O*-carbonyl-3′-deoxyparomamine (**8**).* To a solution of **7** (3.16 g) in dry pyridine (120 ml), phenylboronic acid (527 mg, 1 mol equiv. for **7**) was added and the solution was kept at room temperature for 2 h. To the solution cooled in an ice-bath, benzoyl chloride (7.3 g)

† 1 M=1 mol dm^{-3}.

was added and the solution was kept at room temperature for 2 h. The solution showed a major spot at R_f 0.7 (4′,6′,5″-tri-*O*-benzoyl-2″,3″-boronate derivative), on TLC with chloroform–methanol (10 : 1). After addition of water (2 ml) followed by stirring for 1 h, 1,3-propanediol (1.5 ml) was added and the solution was kept at room temperature overnight. Concentration gave a residue, which was dissolved in chloroform. The solution was washed with 1 M aqueous potassium hydrogensulfate, aqueous sodium hydrogencarbonate, and water, dried over sodium sulfate and concentrated. The residue showed, on TLC with chloroform–methanol (10 : 1), spots of R_f 0.9 (slight, penta-*O*-benzoyl derivative?), 0.43 (slight, another tri-*O*-benzoyl derivative?), 0.38 (major, **8**), 0.22 (minor **9**) and 0.1 (slight, **7**). The residue was chromatographed on a silica-gel column with chloroform–methanol (50: 1→30: 1→15: 1→8: 1→5: 1) as developer to give a solid of **8**, 2.00 g (44%), R_f (0.38 TLC with 10 : 1 chloroform–methanol) and a solid of **9**, 0.84 g (23%), R_f 0.22 (TLC).

8: $[\alpha]_D^{24}$ +48° (*c* 1, chloroform).

Found: C, 63.36; H, 5.35; N, 4.03%. Calcd for $C_{55}H_{55}N_3O_{18}$: C, 63.15; H, 5.26; N, 4.02%.

9: $[\alpha]_D^{24}$ +29° (*c* 1, chloroform).

Found: C, 58.46; H, 5.76; N, 4.77%. Calcd for $C_{41}H_{47}N_3O_{16}$: C, 58.78; H, 5.62; N, 5.02%.

Periodate Oxidation of **8**. To a solution of **8** (10 mg) in ethanol (0.5 ml) was added sodium periodate (5 mg) and the solution was kept at room temperature for 2 h. On checking by TLC with chloroform–methanol (10 : 1), the solution showed a single spot R_f 0.60 (*cf.* **8** : R_f 0.38).

*5-O-(5-O-Benzoyl-2,3-O-isopropylidene-β-*D*-ribofuranosyl)-3,2′-bis(*N*-benzyloxycarobnyl)-1-*N*:6-O-carbonyl-3′-deoxy-4′,6′-O-isopropylideneparomamine* (**10**). A mixture of **9** (50 mg), anhydrous *p*-toluenesulfonic acid (18 mg), and 1,1-dimethoxypropane (1 ml) in DMF (5 ml) was kept at room temperature overnight. Addition of aqueous saturated sodium hydrogencarbonate solution (1 ml) followed by concentration of the mixture gave a residue. Extraction of the residue with chloroform followed by silica gel chromatography of the extracts with benzene–ethyl acetate–triethylamine (1 : 1 : 0.02) gave a solid of **10**, which was reprecipitated from chloroform–hexane, 44 mg (80%), $[\alpha]_D^{25}$ +19° (*c* 1, chloroform): IR(KBr): 1775, and 1725 cm^{-1}; ^{1}H-NMR ($CDCl_3$): δ 1.28, 1.34, 1.42 and 1.46 (each 3H s, Ip).

Found: C, 61.43; H, 5.94; N, 4.61%. Calcd for $C_{47}H_{55}N_3O_{16}$: C, 61.50; H, 6.04; N, 4.58%.

*5-O-[2-O-(6-Azido-2,3,4-tri-O-benzyl-6-deoxy-β-*L*-idopyranosyl)-5-O-benzoyl-β-*D*-ribofuranosyl]-4′,6′-di-O-benzoyl-3,2′-bis(*N*-benzyloxycarbonyl)-1-*N*:6-O-carbonyl-3′-deoxyparomamine* (**11**) *and 5-O-[3-O-(6-azido-2,3,4-tri-O-benzyl-6-deoxy-β-*L*-idopyranosyl)-5-O-benzoyl-β-*D*-ribofuranosyl]-4′,6′-di-O-benzoyl-3,2′-bis(*N*-benzyloxycarbonyl)-1-*N*:6-O-carbonyl-3′-deoxyparomamine* (**12**).

A mixture of **4** (553 mg), **8** (205 mg), mercury (II) cyanide (308 mg, dried at 75 °C under 1 Torr (1 Torr≈133.32 Pa) pressure for 3 h), and Drierite (610 mg, dried at 250 °C for 3 h) in dry benzene (10 ml) was stirred overnight at room temperature. Chloroform (50 ml) was added, filtered, and the organic solution was washed with aqueous saturated sodium hydrogencarbonate and water, dried over sodium sulfate, and concentrated. The residue was chromatographed on a column of silica gel (50 g) with chloroform–methanol (60 : 1) to give a mixture of major products (352 mg). The mixture was separated by preparative TLC (Kieselgel 60 PF_{254}, E. Merck) with chloroform–methanol (30 : 1) to give a solid of **11**, 140 mg (43%, R_f 0.35 on TLC with chloroform–methanol=30 : 1) and **12**, 85 mg (19%, R_f 0.32), with minor products (48 mg, R_f 0.30, a mixture of α-L-isomers?).

11: $[\alpha]_D^{24}$ +51° (*c* 1, chloroform); IR(KBr): 2100 (N_3), 1780, and 1725 cm^{-1}.

Found: C, 65.68; H, 5.48; N, 5.53%. Calcd for $C_{82}H_{82}N_6O_{22}$: C, 65.51; H, 5.46; N, 5.59%.

12: $[\alpha]_D^{24}$ +42° (*c* 1, chloroform); IR (KBr): 2100, 1780, and 1725 cm^{-1}.

Found: C, 65.55; H, 5.44; N, 5.43%.

*5-O-[2-O-(6-Amino-6-deoxy-β-*L*-idopyranosyl)-β-*D*-ribofuranosyl]-3′-deoxyparomamine* (**13**). To a solution of **11** (145 mg) in dioxane (9 ml) was added 0.03 M barium hydroxide solution (2 ml) and the mixture was stirred at 60 °C for 30 min. After introduction of carbon dioxide, the mixture was centrifuged, and the solid was washed thoroughly with dioxane. The solution and the washings combined were concentrated to give a residue. The residue was dissolved in tetrahydrofuran–methanol (1 : 1) and the solution was passed through a column of Sephadex LH-20. The elution was concentrated and the solid was dried thoroughly. A solution of the solid in tetrahydrofuran (3 ml) was adedd to a solution of sodium metal (*ca.* 200 mg) in liquid ammonia (*ca.* 9 ml, −50 °C) and the deep-blue solution was kept at the temperature for 1 h. Addition of water until the solution became colorless, followed by gradual warming to room temperature, and evaporation under diminished pressure, gave a residue. An aqueous solution of the residue was poured onto a column of Dowex 50W×2 (NH_4^+) resin, and the column was washed with water, then eluted with 2 M aqueous ammonia. Ninhydrin-positive fractions were collected and evaporated. The residue was chromatographed on a column of CM-Sephadex C-25 (NH_4^+) with aqueous ammonia (0→0.08 M, gradually changed) to give a solid of **13**, 30 mg (42% as dicarbonate), $[\alpha]_D^{26}$ +47° (*c* 1, water).

^{1}H-NMR (D_2O containing DCl; pD *ca.* 1); δ 1.7—2.7 (4H, H-2,3′), 5.17 (1H d, $J_{1''',2'''} \simeq 1.5$ Hz, H-1‴), 5.43 (1H br s, H-1″), and 5.60 (1H d, $J_{1',2'}$ 3.5 Hz, H-1′).

Found: C, 41.85; H, 6.90; N, 7.69%. Calcd for $C_{23}H_{44}N_4O_{14}\cdot 2H_2CO_3$: C, 41.43; H, 6.68; N, 7.73%.

*5-O-[3-O-(6-Amino-6-deoxy-β-*L*-idopyranosyl)-β-*D*-ribofuranosyl]-3′-deoxyparomamine* (**14**). Compound **12** (145 mg) was treated similarly as described for **13** to give a solid of **14**, 35 mg (50% as dicarbonate), $[\alpha]_D^{26}$ +42° (*c* 0.7, water).

^{1}H-NMR (D_2O containing DCl; pD *ca.* 1): δ 1.7—2.7 (4H, H-2,3′), 5.07 (1H d, $J_{1''',2'''} \simeq 1.5$ Hz, H-1‴), 5.38 (1H br s, H-1″), and 5.62 (1H d, $J_{1',2'}$ 3.5 Hz, H-1′).

Found: C, 41.16; H, 6.96; N, 7.56%. Calcd for $C_{23}H_{44}N_4O_{14}\cdot 2H_2CO_3$: C, 41.43; H, 6.68; N, 7.73%.

The authors wish to express their deep thanks to Prof. Hamao Umezawa of the Institute of Microbial Chemistry for the encouragement.

The Thermal Decomposition of *N,O*-Diacyl-*N*-*t*-butylhydroxylamines. III. Novel Routes to 2-Substituted 1,2-Benzisothiazol-3-(2*H*)-ones[1]

Yuzuru UCHIDA* and Seizi KOZUKA†

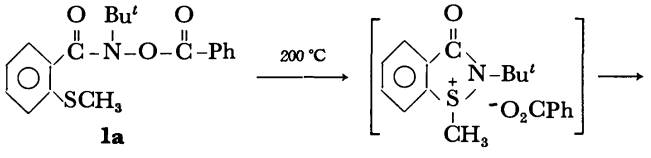
Department of Applied Chemistry, Osaka Institute of Technology, Asahi-ku, Osaka 535
†*Department of Applied Chemistry, Faculty of Engineering, Osaka City University, Sumiyoshi-ku, Osaka 558*

(Received September 1, 1981)

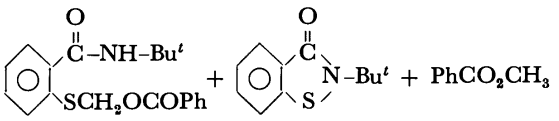
The reactions of *N*-alkyl- and *N*-aryl-2-(methylsulfinyl)benzamides and *N*-[2-(methylthio)benzoyl]-*N*-alkylhydroxylamines with thionyl chloride have been found to give 2-substituted 1,2-benzisothiazol-3(2*H*)-ones in nearly quantitative yields. The reactions of *N*-[2-(methylthio)benzoyl]-*N*-arylhydroxylamines with thionyl chloride gave chlorinated anilides as the major products.

2-Substituted 1,2-benzisothiazol-3(2*H*)-ones (**4**) have received much attention in recent years because of their antibacterial and antifungal properties.[2-5] The 2-substituted 1,2-benzisothiazol-3(2*H*)-ones have been synthesized by the reaction of 2-(chlorothio)benzoyl chloride with appropriate amines,[3] cyclization of 2-carbamoylbenzenesulfenyl halides with amines,[4] reaction of bis(2-carbamoylphenyl) disulfides with thionyl chloride,[5] and catalytic cyclization of *N*-substituted 2-(methoxycarbonyl) benzenesulfenamides by strong base.[6]

On the other hand, we have studied the thermal decompositions of *O*-acyl-*N*-[2-(methylthio)benzoyl]-*N*-*t*-butylhydroxylamines (**1**) and found that 2-*t*-butyl-1,2-benzisothiazol-3(2*H*)-one (**4a**) was formed in moderate yield as one of the products.[7] Acylaminosulfonium salt

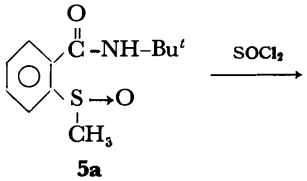


1a **2a**

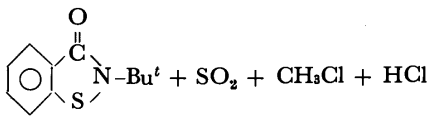


3 **4a**

(**2a**) has been suggested as the intermediate for the thermolysis. In order to prove the intermediacy of **2**, Pummerer reactions of *N*-*t*-butyl-2-(methylsulfinyl)-benzamide (**5a**) with either benzoic anhydride or thionyl chloride were tried; a facile formation of **4a**, by the reaction with thionyl chloride, was found.[7] This reaction would provide a novel and general route to prepare **4**, since a variety of *N*-substituted 2-(methylsulfinyl)benzamides (**5**) can easily be prepared from the corresponding sulfides. Thus, several *N*-alkyl- and *N*-arylbenzamides **5** were prepared and their reactions with thionyl chloride were examined.

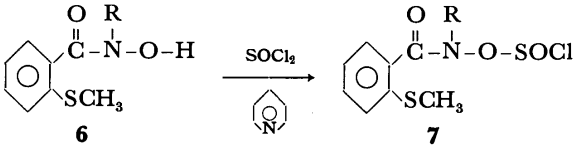


5a



4a

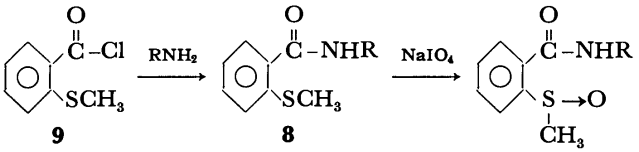
In the thermal decomposition of **1**, the mechanism of the formation of acylaminosulfonium salt (**2**) involves nucleophilic attack of the sulfur atom on the nitrogen atom. A better leaving group would facilitate the formation of **2**. Thus, the reaction of *N*-[2-(methylthio)-benzoyl]-*N*-alkylhydroxylamines (**6**) with thionyl chloride was examined, expecting the formation of the corresponding *N*-chlorosulfinyloxy-2-(methylthio)benzamide (**7**) as the transient product of the reaction. The transient products (**7**) would undergo a subsequent cyclization reaction, since the chlorosulfinate ion would be a better leaving group than the benzoate ion for the nucleophilic attack of the methylthio-sulfur atom on the nitrogen atom.



6 **7**

Results and Discussion

Reactions of N-*Alkyl- and* N-*Aryl-(2-methylsulfinyl)-benzamides with Thionyl Chloride.* Several *N*-substituted 2-(methylthio)benzamides (**8a—j**) were prepared from 2-(methylthio)benzoyl chloride (**9**) with appropriate alkyl- and arylamines. The corresponding sulfoxides (**5a—j**) were obtained by periodate oxidation of the sulfides (**8**) in good yields. The reaction of **5**



9 **8** **5**

with thionyl chloride was carried out in refluxing dichloromethane or chloroform. Evolution of hydrogen chloride and sulfur dioxide was found during the reaction and the reaction was completed within 30 min. 2-Substituted 1,2-benzisothiazol-3(2*H*)-eones were isolated by chromatographic separation with an alumina column in good yields. The results are given in Table 1. The structures of the products were established by elemental and spectral analyses.

TABLE 1. PREPARATION OF 2-SUBSTITUTED 1,2-BENZISOTHIAZOL-3(2*H*)-ONES (**4**) BY THE REACTIONS OF 2-MeS(O)C_6H_4CONHR (**5**) AND 2-MeSC_6H_4CONROH (**6**) WITH $SOCl_2$

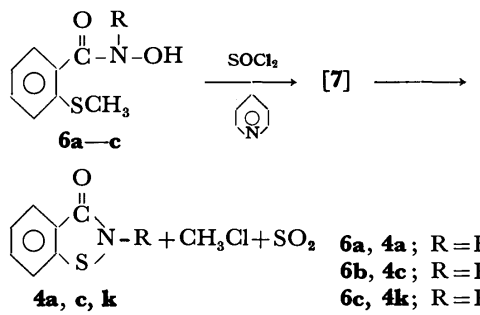
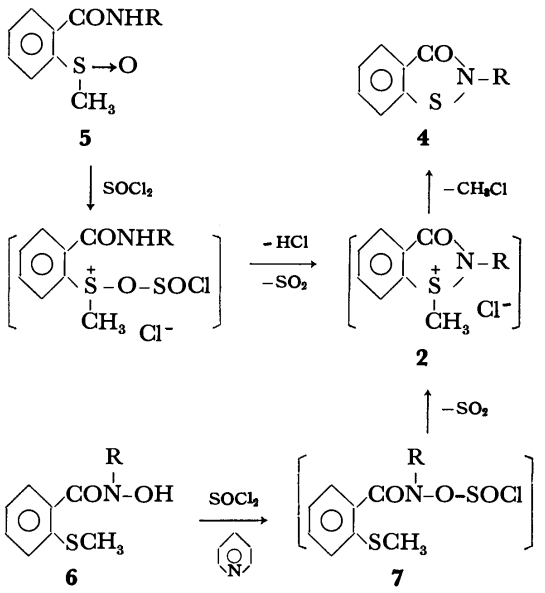
a) Isolated yields following chromatographic separation. b) The yields were estimated by GLC.

Reactions of N-*Alkyl- or* N-*Aryl*-N-[*2-(methylthio)benzoyl*]*hydroxylamines with Thionyl Chloride.* *N*-[2-(Methylthio)benzoyl]-*N*-*t*-butylhydroxylamine (**6a**) was prepared by alkaline hydrolysis of *N*-[2-(methylthio)-benzoyl]-*O*-benzoyl-*N*-*t*-butylhydroxylamine (**1a**).[7] *N*-Isopropyl (**6b**), *N*-propyl (**6c**), *N*-phenyl (**6d**), and *N*-(4-methylphenyl) derivatives (**6e**) were prepared by the reactions of 2-(methylthio)benzoyl chloride with the corresponding *N*-alkyl- and *N*-arylhydroxylamines.

The reaction of **6a** with thionyl chloride was carried out in carbon tetrachloride at 55 °C in the presence of pyridine. The reaction was monitored by following NMR signals of the *t*-butyl protons. After about 3 h, the spectrum showed the signals of **4a** together with chloromethane (δ, 2.99, s).[7] Although the signal due to **7** was not detected during the reactions, **7** would be the intermediate of the reaction. Similarly, **6b** and **6c** gave **4c** and **4k** by the reactions with thionyl chloride in good yields, respectively. The results are summarized in Table 1. The results show that the reactions of *N*-[2-(methylthio)benzoyl]-*N*-alkylhydroxylamines with thionyl chloride are applicable to syntheses of 2-alkyl-1,2-benzisothiazol-3(2*H*)-ones (**4**). The reaction of **6** with thionyl chloride required somewhat longer heating than that of **5**, but proceeded at much lower temperature than that employed for the thermolysis of **1** (200 °C),[7] as expected from the ability of the leaving groups. Accordingly, the present results also support the mechanism involving the nucleophilic attack of the sulfur atom on the nitrogen which has been suggested as the initial step for the thermolysis of **1**.[7]



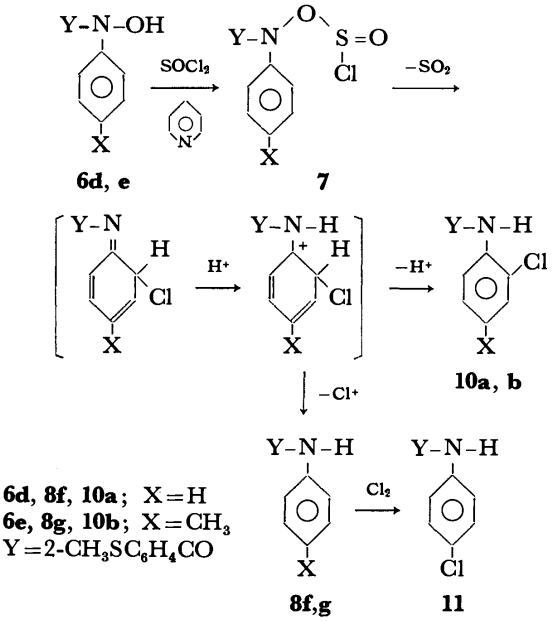


Scheme 1.

Both the reactions examined here appear to be novel and convenient routes to prepare **4**. The probable mechanisms for these reactions are shown in Scheme 1. The acylaminosulfonium salt **2** is involved as the key intermediate of the reactions. The final step of the

reactions would be the nucleophilic attack of the chloride ion on the methyl carbon of the sulfonium ion, since chloromethane was detected as an alternative product.

On the other hand, the reactions of *N*-arylhydroxylamine derivatives (**6d**) and (**6e**) with thionyl chloride gave only trace amounts of **4f** and **4g**, respectively. When the reaction of *N*-[2-(methylthio)benzoyl]-*N*-phenylhydroxylamine (**6d**) with thionyl chloride was carried out in the presence of pyridine, 2'-chloro-2-(methylthio)benzanilide (**10a**), 4'-chloro-2-(methylthio)-benzanilide (**11**), and 2-(methylthio)benzanilide (**8f**) were obtained as the major products. These products were isolated from the reaction products by chromatographic separation and identified by comparison of their physical properties with those of the authentic samples. Similarly, **6e** gave 2'-chloro-4'-methyl-2-(methylthio)-benzanilide (**10b**) and 4'-methyl-2-(methylthio)benzanilide (**8g**). The yields of products were estimated by GLC analysis and the results are summarized in Table 1. A possible mechanism leading to these products involving **7** as the intermediate is shown in Scheme 2.



Scheme 2.

Experimental

All the melting points and the boiling points are uncorrected. The IR spectra were recorded on a Shimadzu IR 430 infrared spectrometer. The NMR spectra were recorded on a Varian EM-360 spectrometer using TMS as the internal standard.

Preparation of N-*Alkyl- and* N-*Aryl-2-(methylthio)benzamides (8).* Typical procedures were as follows: (*a*) A solution of 2-(methylthio)benzoyl chloride (9.3 g, 50 mmol) in benzene (50 cm³) was added to a solution of isopropylamine (6.0 g, 102 mmol) in benzene (100 cm³) with stirring. The mixture was heated at 60 °C for 30 min. The reaction mixture was washed with dil HCl, aqueous Na_2CO_3, and water, then the solvent was evaporated. The residue was recrystallized from benzene–ether to give **8c** (7.1 g, 68%); mp 87.5—88.5 °C. IR (KBr): 3400, 3350 (N-H), and 1625 cm^{-1} (C=O). Found: C, 63.10; H, 7.49; N, 6.44%. Calcd for $C_{11}H_{15}NOS$: C, 63.12; H, 7.22; N, 6.69%.

By the same procedure, amides **8a**, **8b**, and **8d—f** were prepared by the reaction of 2-(methylthio)benzoyl chloride with appropriate amines. Amides **8g**, **8h**, and **8j** were prepared by the reaction of 2-(methylthio)benzoyl chloride and an equivalent of amines in the presence of an equivalent of pyridine in benzene. The yields and the physical properties of the amides were as follows: **8a**, 85%; mp 133—134 °C.[7] **8b**, 62%, mp 90.5—91.5 °C. IR (KBr): 3300 (N-H) and 1630 cm^{-1} (C=O). Found: C, 61.73; H, 6.78; N, 7.06%. Calcd for $C_{10}H_{13}NOS$: C, 61.50; H, 6.71; N, 7.17%. **8d**, 79%; mp 138—139 °C. IR (KBr): 3300 (N-H) and 1630 cm^{-1} (C=O). Found: C, 67.30; H, 7.75; N, 5.57%. Calcd for $C_{14}H_{19}NOS$: C, 67.43; H, 7.68; N, 5.62%. **8e**, 98%; mp 131—132 °C. IR (KBr): 3270 (N-H) and 1640 cm^{-1} (C=O). Found: C, 70.10; H, 5.78; N, 5.15%. Calcd for $C_{15}H_{15}NOS$: C, 70.00; H, 5.88; N, 5.44%. **8f**, 98%; mp 148—149 °C. IR (KBr): 3300 (N-H) and 1645 cm^{-1} (C=O). Found: C, 69.04; H, 5.11; N, 5.53%. Calcd for $C_{14}H_{13}NOS$: C, 69.10; H, 5.39; N, 5.76%. **8g**, 93%; mp 145—146 °C. IR (KBr): 3280 (N-H) and 1645 cm^{-1} (C=O). Found: C, 70.15; H, 5.87; N, 5.28%. Calcd for $C_{15}H_{15}NOS$: C, 70.00; H, 5.88; N, 5.44%. **8h**, 91%; mp 137—138 °C. IR (KBr): 3250 (N-H) and 1650 cm^{-1} (C=O). Found: C, 65.99; H, 5.25; N, 5.13%. Calcd for $C_{15}H_{15}NO_2S$: C, 65.91; H, 5.53; N, 5.12%. **8j**, 96%; mp 130.5—131.5 °C. IR (KBr): 3250 (N-H) and 1640 cm^{-1} (C=O). Found: C, 73.62; H, 4.87; N, 4.52%. Calcd for $C_{18}H_{15}NOS$: C, 73.69; H, 5.15; N, 4.77%.

(*b*) A mixture of 2-(methylthio)benzoyl chloride (9.3 g, 50 mmol), *p*-nitroaniline (8.0 g, 58 mmol), and pyridine (20 cm³) was heated under refluxing for 5 h. The reaction mixture was poured into dil HCl (5%, 500 cm³) with stirring. The precipitate was collected by filtration and washed with hot dil HCl, aqueous $NaHCO_3$, and water, then dried. The crude amide (**8i**) was recrystallized from acetone (11.9 g, 83%); mp 165.5—166.5 °C. IR (KBr): 3300 (N-H) and 1655 cm^{-1} (C=O). Found: C, 58.58; H, 3.97; N, 9.86%. Calcd for $C_{14}H_{12}N_2O_3S$: C, 58.32; H, 4.20; N, 9.72%.

Preparation of N-*Alkyl- and* N-*Aryl-2-(methylsulfinyl)benzamides (5).* A typical run was as follows: A solution of sodium periodate (8.6 g, 40 mmol) in water (50 cm³) was added to a solution of **8f** (9.7 g, 37 mmol) in methnoal (300 cm³) with stirring. The mixture was stirred for 2 h at 50 °C. The solvent was evaporated and the residue was washed with water. The residue was crude **5f**, which was recrystallized from methanol-dichloromethane (9.0 g, 94%); mp 194—195 °C. IR (KBr): 3280 (N-H), 1660 (C=O), and 1010 cm^{-1} (S-O). Found: C, 64.86; H, 4.90; N, 5.22%. Calcd for $C_{14}H_{13}NO_2S$: C, 64.84; H, 5.05; N, 5.40%.

Benzamides (**5a—e**) and (**5g—j**) were prepared by the same procedure. The results were as follows: **5a**: 92%; mp 150—151 °C.[7] **5b**, 81%; mp 157—158 °C. IR (KBr): 1640 (C=O) and 1010 cm^{-1} (S-O). Found: C, 56.60; H, 6.08; N, 6.50%. Calcd for $C_{10}H_{13}NO_2S$: C, 56.85; H, 6.20; N, 6.63%. **5c**, 92%; mp 158—159 °C. IR (KBr): 1635 (C=O) and 1010 cm^{-1} (S-O). Found: C, 58.56; H, 6.79; N, 6.12%. Calcd for $C_{11}H_{15}NO_2S$: C, 58.64; H, 6.71; N, 6.22%. **5d**, 83%; mp 138.5—139.5 °C. IR (KBr): 1640 (C=O) and 1010 cm^{-1} (S-O). Found: C, 63.32; H, 7.21; N, 5.07%. Calcd for $C_{14}H_{19}NO_2S$: C, 63.36; H, 7.22; N, 5.28%. **5e**, 82%; mp 142—143 °C. IR (KBr): 1645 (C=O) and 1030 cm^{-1} (S-O). Found: C, 65.85; H, 5.43; N, 5.01%. Calcd for $C_{15}H_{15}NO_2S$: C, 65.91; H, 5.53; N, 5.12%. **5g**, 94%; mp 180.5—181.5 °C. IR (KBr): 1660 (C=O) and 1010 cm^{-1} (S-O). Found: C, 65.79; H, 5.54; N, 5.14%. Calcd

for $C_{15}H_{15}NO_2S$: C, 65.91; H, 5.53; N, 5.12%. **5h**, 99%; mp 176—177 °C. IR (KBr): 1650 (C=O) and 1010 cm^{-1} (S–O). Found: C, 62.34; H, 5.08; N, 4.73%. Calcd for $C_{18}H_{15}NO_2S$: C, 69.88; H, 4.89; N, 4.53%.

Reactions of N-*Alkyl- and* N-*Aryl-2-(methylsulfinyl)benzamides (***5***) with Thionyl Chloride.* A typical run was as follows: Thionyl chloride (1.50 g, 13 mmol) was added to a stirred suspension of **5f** (2.59 g, 10 mmol) in dry dichloromethane (20 cm^3). The reaction mixture was refluxed for 10 min; then the solvent and the excess of thionyl chloride were removed by distillation under reduced pressure. The residue was chromatographed on alumina with dichloromethane as the eluent to give **4f** (2.34 g, 98%), which was recrystallized from carbon tetrachloride–dichloromethane; mp 140.5—141.5 °C (lit,[5a] 140—141 °C). IR (KBr): 1660 cm^{-1} (C=O). By the same procedure, **4a**—**e** and **4g**—**j** were prepared, and the results are given in Table 1. **4a**; mp 57—58 °C. IR (KBr): 1650 cm^{-1} (C=O).[7] **4b**; bp 132 °C/2.5 Torr.†† IR (neat): 1650 cm^{-1} (C=O). NMR (δ, $CDCl_3$): 1.36 (3H, t, J=7 Hz), 3.93 (2H, q, J=7 Hz), and 7.2—8.2 (4H, m). Found: C, 58.64; H, 4.68; N, 7.29%.[8] Calcd for C_9H_9NOS: C, 60.31; H, 5.06; N, 7.82%. **4c**; bp 128 °C/2 Torr. IR (neat): 1650 cm^{-1} (C=O). Preparation of N-[*2-(Methylthio)benzoyl*]-N-t-*butylhydroxylamine (**6a**).* This compound was prepared by alkaline hydrolysis of *N*-[2-(methylthio)benzoyl]-*O*-benzoyl-*N*-*t*-butylhydroxylamine as described in the previous paper;[7] mp 145—146 °C.

Preparation of N-[*2-(methylthio)benzoyl*]-N-*isopropylhydroxylamine (**6b**).* Aluminium foil (10.5 g) was amalgamated by immersing it in a solution of mercury(II) chloride (3.0 g) in water (200 cm^3). The amalgamated aluminium was washed with water and added to a mixture of ether (500 cm^3) and water (5 cm^3). A solution of 2-nitropropane (18.0 g, 202 mmol) in ether (50 cm^3) was added dropwise into the mixture with stirring under refluxing. After addition of the 2-nitropropane was completed, the reaction mixture was refluxed for 30 min, and then cooled with ice-water. A solution of NaOH (10.0 g) in water (30 cm^3) was added to the mixture with stirring. The ether layer was separated and dried over Na_2SO_4. Into the solution which contained *N*-isopropylhydroxylamine, a solution of 2-(methylthio)benzoyl chloride (9.3 g, 50 mmol) in ether (100 cm^3) was added with stirring. After stirring for 1 h, the reaction mixture was washed with dil HCl and water, and then extracted with aqueous NaOH (5%, 200 cm^3). The extract was acidified with HCl. The crude *N*-[2-(methylthio)benzoyl]-*N*-isopropylhydroxylamine (**6b**) was collected by filtration (6.3 g, 56%), and then recrystallized from dichloromethane–petroleum ether; mp 100.5—101.5 °C. IR (KBr): 3200 (O–H) and 1610 cm^{-1} (C=O). NMR (δ, $CDCl_3$): 1.28 (6H, d, J=7 Hz), 2.47 (3H, s), 3.9 (1H, m), 7.0—7.6 (4H, m), and 8.8 (1H, broad). Found: C, 58.56; H, 6.92; N, 5.69%. Calcd for $C_{11}H_{15}NO_2S$: C, 58.64; H, 6.71; N, 6.22%.

Preparation of N-[*2-(Methylthio)benzoyl*]-N-*propylhydroxylamine (**6c**).* Into an ethereal solution of *N*-propylhydroxylamine which was prepared from 1-nitropropane (18.0 g, 202 mmol) by the procedure described above, pyridine (15.0 g) and a solution of 2-(methylthio)benzoyl chloride (15.0 g, 81 mmol) in ether (100 cm^3) were added with stirring. After the reaction, the mixture was washed with dil HCl and water, and then extracted with aqueous NaOH (5%, 200 cm^3). The extract was acidified with HCl, and the crude *N*-[2-(methylthio)benzoyl]-*N*-propylhydroxylamine (**6c**) was collected by filtration (12.5 g, 69%), and then recrystallized from benzene–petroleum ether; mp 89.5—90.5 °C. IR (KBr): 3100 (O–H) and 1605 cm^{-1} (C=O). NMR (δ, $CDCl_3$) 0.85 (3H, t, J=7 Hz), 1.73 (2H, m, J=7 Hz), 2.50 (3H, s), 3.47 (2H, t, J=7 Hz), 7.0—7.7 (4H, m) and 8.5 (1H, broad s). Found: C, 58.70; H, 6.86; N, 6.04%. Calcd for $C_{11}H_{15}NO_2S$: C, 58.64; H, 6.71; N, 6.22%.

Preparation of N-[*2-(Methylthio)benzoyl*]-N-*arylhydroxylamines (**6d**—**e**).* A solution of 2-(methylthio)benzoyl chloride (5.6 g, 30 mmol) in ether (50 cm^3) was added to a mixture of *N*-phenylhydroxylamine (3.3 g, 30 mmol), pyridine (3.0 g, 38 mmol), and ether (150 cm^3) with stirring. The reaction mixture was refluxed for 30 min, washed with dil HCl, and water, and then extracted with aqueous NaOH (5%, 100 cm^3). The extract was acidified with HCl, and the crude *N*-[2-(methylthio)benzoyl]-*N*-phenylhydroxylamine (**6d**) was collected by filtration (5.6 g, 71%), and then recrystallized from methanol; mp 141.5—142.5 °C. IR (KBr): 3120 (O–H) and 1630 cm^{-1} (C=O). NMR (δ, $CDCl_3$): 2.40 (3H, s), 6.8—7.5 (9H, m), and 9.3 (1H, broad s). Found: C, 64.80; H, 4.83; N, 5.39%. Calcd for $C_{14}H_{13}NO_2S$: C, 64.84; H, 5.05; N, 5.40%.

N-[2-(Methylthio)benzoyl]-*N*-(4-methylphenyl)hydroxylamine (**6e**) was prepared similarly by the reaction of *N*-(4-methylphenyl)hydroxylamine and 2-(methylthio)benzoyl chloride in 80% yield; mp 169—170 °C (decomp). IR (KBr): 3230 (O–H) and 1615 cm^{-1} (C–O). NMR (δ, $CDCl_3$): 2.30 (3H, s), 2.43 (3H, s), 6.8—7.6 (8H, m), and 9.1 (1H, broad). Found: C, 65.86; H, 5.44; N, 4.91%. Calcd for $C_{15}H_{15}NO_2S$: C, 65.91; H, 5.53; N, 5.12%.

Reaction of N-[*2-(Methylthio) benzoyl*]-N-*alkylhydroxylamines (**6a**—**c**) with Thionyl Chloride.* Typical procedure was as follows: Thionyl chloride (1.50 g, 13 mmol) was added to a mixture of **6c** (2.25 g, 10 mmol) and pyridine (1.00 g, 13 mmol) in carbon tetrachloride (100 cm^3). The mixture was stirred for 3 h at 55 °C. The reaction mixture was washed with dil HCl and water, and dried over $CaCl_2$. After evaporation of the solvent, the residue was chromatographed on alumina with dichloromethane as the eluent to give **4k** (1.56 g, 80%), which was distilled under reduced pressure; bp 140 °C/2 Torr (lit,[6] 126—128 °C/0.2 Torr). IR (neat): 1650 cm^{-1} (C=O), NMR (δ, $CDCl_3$): 0.97 (3H, t, J=7 Hz), 1.80 (2H, m), 3.87 (2H, t, J=7 Hz), and 7.2—8.2 (4H, m). By the same procedure, **4a** and **4c** were prepared by the reactions of **6a** and **6b** with thionyl chloride, respectively. The results

†† 1 Torr≈133.322 Pa.

are given in Table 1.

Reactions of N-[*2-(Methylthio)benzoyl*]-N-*arylhydroxylamines (6d and 6e) with Thionyl Chloride.* A solution of thionyl chloride (0.70 g, 6 mmol) in dichloromethane (10 cm^3) was added to a mixture of *N*-[2-(methylthio)benzoyl]-*N*-phenylhydroxylamine (**6d**) (1.176 g, 5 mmol), pyridine (0.80 g, 10 mmol), and dichloromethane (40 cm^3) with stirring. After the reaction for 3 h at room temperature, the reaction mixture was washed with dil HCl, aqueous $NaHCO_3$, and water, then the solvent was removed by distillation under reduced pressure. The residue was subjected to GLC analysis, and the remainder was chromatographed on silica gel to isolate the products. The results are given in Table 1. The reaction of **6e** (1.372 g, 5 mmol) with thionyl chloride (0.70 g) in the presence of pyridine (0.80 g) was carried out in dichloromethane (50 cm^3) by the same procedure. **10a**; mp 93—94 °C. IR (KBr): 3200 (N–H) and 1640 cm^{-1} (C=O). NMR (δ, $CHCl_3$): 2.50 (3H, s), 6.9—8.7 (8H, m), and 8.7 (1H, broad). Found: C, 60.59; H, 4.27; N, 5.00%. Calcd for $C_{14}H_{12}ClNOS$: C, 60.53; H, 4.35; N, 5.04%. **10b**; mp 92.5—93.5 °C. IR (KBr): 3400 (N–H) and 1670 cm^{-1} (C=O). NMR (δ, $CDCl_3$): 2.38 (3H, s), 2.53 (3H, s), 7.0—8.6 (7H, m), and 8.6 (1H, broad). Found: C, 61.54; H, 4.73; N, 4.61%. Calcd for $C_{15}H_{14}ClNOS$: C, 61.74, H, 4.84; N, 4.80%. **11**; mp 137—138 °C. IR (KBr): 3300 (N–H) and 1660 cm^{-1} (C=O). NMR (δ, $CDCl_3$): 2.47 (3H, s), 7.0—7.8 (8H, m), and 8.5 (1H, broad). Found: C, 60.25, H, 4.14; N, 4.97%. Calcd for $C_{14}H_{12}ClNOS$: C, 60.53; H, 4.35; N, 5.04%.

Preferential Crystallization of 2-Amino-2-phenylethanol and Its Application as a Resolving Agent

Kazuhiko SAIGO,* Hisao MIURA, Kozi ISHIZAKI, and Hiroyuki NOHIRA

Department of Applied Chemistry, Faculty of Engineering, Saitama University, Shimo-ohkubo, Urawa 338

(Received September 2, 1981)

(±)-2-Amino-2-phenylethanol (phenylglycinol) prepared from (±)-2-amino-2-phenylacetic acid (DL-phenylglycine) by lithium aluminium hydride reduction was efficiently resolved into a pair of optically active forms by preferential crystallization. The optically active amino alcohol was successfully applied as a basic resolving agent to the resolution of tartaric acid, 2-hydroxy-2-phenylpropionic acid, 2-hydroxy-3-phenylpropionic acid, 2-phenylpropionic acid, and 2-phenyl-2-ureidoacetic acid.

In the fractional crystallization of diastereomers, which is as useful for getting chiral compounds as biological method and asymmetric induction, a natural product or its derivative is widely used as a resolving agent.[1] But, only one of a pair of the enantiomers can be employed as a resolving agent since the other is frequently commercially unavailable. The restriction in utilization of a natural product or its derivative as a resolving agent often becomes to be disadvantageous for fractional crystallization because the desired enantiomer of a chiral compound does not always form the less soluble diastereomer, which is able to be purified by recrystallization, with the resolving agent.[2]

The synthesis of new resolving agents and their optical resolutions by preferential crystallization are tried in our laboratory based on the considerations that preferential crystallization would improve the problem, giving both enantiomers of a resolving agent in preparative quantities and that the desired enantiomer of a chiral compound whould be resolvable as the less soluble diastereomer with either of the enantiomers. The preceding papers presented that 3-*endo*-benzamido-5-norbornene-2-*endo*-carboxylic acid,[3] α-methylbenzylamine,[4] and 1-phenyl-2-(*p*-tolyl)ethylamine[4] were satisfactorily resolved into pairs of enantiomers by preferential crystallization of their achiral amine or carboxylic acid salts. As a part of our further studies along the line concerning the preferential crystallization, the resolution of 2-amino-2-phenylethanol (phenylglycinol) was examined with expectation that it would be useful as a basic resolving agent in the optical resolution of carboxylic acids.

(±)- And (−)-2-amino-2-phenylethanol ((±)-**1** and (−)-**1**) were easily prepared by the lithium aluminium hydride reduction of (±)- and (*R*)-(−)-2-amino-2-phenylacetic acid (DL- and D-phenylglycine), respectively.[5] The optically active **1** has higher melting point and is less soluble in benzene. The physical properties

$C_6H_5CHCH_2OH$
$\quad\quad|$
$\quad\quad NH_2$ **1**

	Mp θ_m/°C	Solubility (g/100 ml C_6H_6 at 20 °C)
(±)-**1**	47—49.5	10.5
(−)-**1**	75—76	1.3

indicate the posibility that crystals of **1** itself are deposited from a supersaturated benzene solution as a conglomerate, which is resolvable by preferential crystallization. Actually, (−)-**1** was obtained from a supersaturated solution of (±)-**1** when (−)-**1** was seeded to the solution and the solution was stood overnight at around 6 °C. Alternate seeding of (+)- and (−)-**1** to the solution supersaturated in a similar magnitude gave (+)- and (−)-**1**, respectively, as shown in Table 1.

TABLE 1. PREFERENTIAL CRYSTALLIZATION OF **1** FROM BENZENE SOLUTION

Run	(±)-**1** (mg)[a]	Seed	Yield mg	$[\alpha]_{435}$/° (*c* 1.00, MeOH)	Optical purity/%[b]
1	—	(−)-**1**	199	−46.8	90
2	375	(+)-**1**	209	+47.3	91
3	254	(−)-**1**	292	−47.7	92
4	232	(+)-**1**	169	+48.2	93

The initial composition of the mother liquor: (±)-**1** (4.00 g) in benzene (100 ml). In all runs, 20—25 mg of seed were added. a) Ammount of (±)-**1** supplied for each run. b) Based on $[\alpha]_{435}^{29.5}$ + and −52.0°(*c* 1.00, MeOH).

The procedure is inapplicable to the optical resolution of (±)-**1** in a preparative scale because only 170—290 mg of optically active **1** is obtainable from 100 ml of benzene solution containing 4.0 g of (±)-**1**. After several examinations on the crystallization conditions such as concentration, cooling temperature, cooling time, and solvent system, it was found that the mixed solvent of benzene and ethanol was more suitable for the preferential crystallization in a preparative scale (see Table 2). Moreover, gentle stirring of the supersaturated solution during crystallization was found to be effective to shorten the cooling time as shown in Table 3. Stirring made the solution uniform and accelerated the crystal growth from seed surface. But, the nucleation of the unseeded antipode crystals of **1** occured when the solution was stirred too vigorously.

Crystals obtained by the preferential crystallization were recrystallized from benzene to yield almost optically pure (+)- and (−)-**1**.

The result that both enantiomers of **1** became obtainable preparatively in high optical purities prompted us to examine the ability of optically active **1** as a basic resolving agent. The resolution of mandelic acid is a unique example, which appears in a patent, for the application of **1** as a resolving agent.[6]

Tartaric acid (**2**), 2-hydroxy-2-phenylpropionic acid (**3**), 2-hydroxy-3-phenylpropionic acid (**4**), 2-phenylpropionic acid (**5**), and 2-phenyl-2-ureidoacetic acid (**6**)

Table 2. Preferential crystallization of **1** from benzene–ethanol mixture on standing

Run	(±)-**1**(mg)[a]	Seed	Cooling time / h	Yield / g	$[\alpha]_{435}$/° (*c* 1.00, MeOH)	Optical purity/%[b]
1	—	(+)-**1**	12	1.71	+47.1	91
2	2.01	(−)-**1**	21	2.47	−45.6	88
3	2.25	(+)-**1**	23	3.32	+47.1	91
4	3.85	(−)-**1**	21	3.24	−47.6	92
5	3.27	(+)-**1**	18	2.61	+48.7	94
6	3.61	(−)-**1**	19	2.94	−43.9	84

The initial composition of the mother liquor: (±)-**1** (38.80 g) and (+)-**1** (0.50 g), which was added to facilitate the preferential crystallization from the first stage, in a mixture of benzene (95 ml) and 99% ethanol (10 ml). In all runs, 0.10 g of seed was added. a) Amount of (±)-**1** supplied for each run. b) Based on $[\alpha]_{435}^{29.5}$ + and −52.0° (*c* 1.00, MeOH).

Table 3. Preferential crystallization of **1** under stirring

Run	(±)-**1**(mg)[a]	Seed	Cooling time / min	Yield / g	$[\alpha]_{435}$/° (*c* 1.00, MeOH)	Optical purity/%[b]
1	—	(+)-**1**	65	2.79	+47.6	92
2	3.00	(−)-**1**	65	3.53	−44.4	85
3	3.50	(+)-**1**	65	3.79	+40.0	77
4	3.60	(−)-**1**	70	2.80	−46.1	89
5	3.30	(+)-**1**	65	2.73	+51.3	99

The initial composition of the mother liquor: (±)-**1** (34.30 g) and (+)-**1** (1.30 g), which was added to facilitate the preferential crystallization from the first stage, in a 9: 1 mixture of benzene and 99% ethanol (84 ml). In all runs, 0.20 g of seed was added. a) Amount of (±)-**1** supplied for each run. b) Based on $[\alpha]_{435}^{29.5}$+ and −52.0° (*c* 1.00, MeOH).

a) Method 1: The salt was decomposed with ion exchange resin, and the product was eluted with water. Method 2: The salt was decomposed with aqueous HCl, and the product was extracted with ether. b) Based on half the amount of (±)-carboxylic acid used.

were chosen as target compounds for optical resolution. The chiral carboxylic acids successfully resolved in high optical purities by fractional crystallization of the diastereomeric salts with the optically active amine **1**. The results are summarized in Tables 4 and 5.

It is especially noteworthy that tartaric acid, which is valuable and widely used as a resolving agent, can be resolved in a high yield and in a high optical purity.

Experimental

The melting points were determined on a Laboratory Devices Mel-Temp apparatus and are uncorrected. The values of specific roration were obtained on JASCO DIP-181 digital polarimeter.

(±)-2-Amino-2-phenylethanol((±)-**1**) was obtained by the reduction of commercially available (±)-2-amino-2-phenylacetic acid (DL-phenylglycine) with lithium aluminium hydride: mp 47—49.5 °C; bp 106—109 °C/133 Pa (lit,[5] mp 47—49 °C; bp 144—147 °C/1866 Pa). Optically active **1**, (−)- and (+)-**1**, used as seeds were prepared in a similar manner from commercially available (*R*)-(−)-2-amino-2-phenylacetic acid (D-phenylglycine), and (*S*)-(+)-2-amino-2-phenylacetic acid obtained by the reciprocal preferential resolution of the salt of (±)-2-amino-2-phenylacetic acid with (±)-10-camphorsulfonic acid,[7] respectively: mp 75—76 °C; $[\alpha]_{589}^{29.5}$ − and +26.7°, $[\alpha]_{435}^{29.5}$ − and +52.0° (*c* 1.00, MeOH) (lit,[8] mp 78—79 °C, 77—78 °C; $[\alpha]_{589}^{17}$ −25.4°, +23.5° in MeOH).

Preferential Crystallization of (±)-2-Amino-2-phenylethanol ((±)-1). A refluxed solution of (±)-**1** (34.30 g) and (+)-**1** (1.30 g), which was added to facilitate the preferential crystallization from the first stage, in a mixture of benzene and 99% ethanol (9 : 1) (84 ml) was cooled at around 13 °C to give a supersaturated solution. The solution was seeded with (+)-**1** (0.20 g) and stirred gently (about 30 min^{-1}) for 65 min at 4—5 °C. The precipitates appeared were collected by filtration, washed with 1 ml of a mixture of benzene and ethanol (9 : 1), and dried over P_2O_5 and solidified paraffin, giving 2.79 g of (+)-**1** ($[\alpha]_{435}^{38}$ +47.6° (*c* 1.00, MeOH)). The optical purity of the product was 92% based on the specific rotation of (−)-**1** prepared from (−)-2-amino-2-phenylacetic acid by the reduction with lithium aluminium hydride ($[\alpha]_{435}^{29.5}$ −52.0° (*c* 1.00, MeOH)). Successively, (±)-**1** (3.00 g) was added to the filtrate and dissolved at an elevated temperature. The solution was similarly cooled, seeded with (−)-**1** (0.20 g), and stirred gently for 65 min at 4—5 °C. Similar treatment of precipitates appeared gave 3.53 g of (−)-**1** ($[\alpha]_{435}^{35.5}$ −44.4° (*c* 1.00, MeOH); 85% optical purity).

After several stages of the preferential crystallization, the crystals having the same sign of optical rotation were combined and recrystallized. Recrystallization of (+)-**1** (7.24 g; 91% optical purity on the average) from benzene (40 ml) gave 6.32 g (87%) of highly pure (+)-**1** ($[\alpha]_{435}^{29.5}$ +51.6°, $[\alpha]_{589}^{29.5}$ +26.3° (*c* 1.00, MeOH); 99% optical purity). In a similar manner, (−)-**1** (8.22 g; 87% optical purity on the average) was recrystallized from benzene (55 ml), giving 7.15 g (87%) of (−)-**1** ($[\alpha]_{435}^{29.5}$ −50.5°, $[\alpha]_{589}^{29.5}$ −25.9° (*c* 1.00, MeOH); 97% optical purity).

Resolution of (±)-Tartaric Acid (2) with (−)-1. To a solution of (±)-**2** (8.00 g, 53 mmol) in methanol (80 ml) was added a solution of (−)-**1** (14.60 g, 107 mmol) in methanol (20 ml), and the mixture was stood overnight at room temperature. White precipitates appeared were filtered off and dried over P_2O_5 to give crude (+)-**2**·(−)-**1** (1 : 2) salt (10.49 g, 93%): $[\alpha]_{435}^{31.5}$ −19.3° (*c* 1.00, H_2O). The suspension of the salt (10.49 g) in methanol (50 ml) was refluxed for 20 min, and insolubilized crystals and precipitates deposited on cooling at room temperature were collected together by filtration, powdered finely, and dried over P_2O_5 to give 9.70 g (86%) of (+)-**2**·(−)-**1** (1 : 2) salt.

The purified (+)-**2**·(−)-**1** (1 : 2) salt (9.70 g) was dissolved in water (65 ml), and the solution was charged on an ion exchange resin column (Amberlite IR 120B, 77 ml) to decompose the salt. Elution with water (450 ml) gave an aqueous solution of (+)-**2**. After evaporation of the water, white precipitates remained were dried over P_2O_5 to yield (+)-**2** (3.08 g, 77% total yield): mp 163—169 °C; $[\alpha]_{589}^{32}$ +16.1° (*c* 1.02, H_2O); 96% optical purity.

Similarly, (−)-**2** was obtained in 63% total yield by the fractional crystallization of the salt of (±)-**2** with (+)-**1**: mp 165—165.5 °C; $[\alpha]_{589}^{22}$ −15.9° (*c* 1.00, H_2O); 95% optical purity.

The ion exchange resin used for the decomposition of the salt was treated with a large excess of 5 M (1 M=1 mol dm^{-3}) aqueous ammonia solution to recover (−)- or (+)-**1**. The eluate was concentrated under reduced pressure, and slightly yellow oil was treated with 10M NaOH solution and extracted with ether. The ethereal solution was dried with Na_2SO_4 and concentrated under reduced pressure to give (−)- or (+)-**1**. Recovery was over 90% and racemization did not take place.

Resolution of (±)-2-Hydroxy-3-phenylpropionic Acid (4) with (−)-1. A clear solution of (±)-**4** (4.98 g, 30 mmol) and (−)-**1** (4.05 g, 30 mmol) in a mixture of ethyl acetate and 2-propanol (7 : 2) (270 ml) at reflux temperature was cooled with ice bath for 4.5 h to give white precipitates. The precipitates were collected by filtration and dried over P_2O_5, giving crude (−)-**4**·(−)-**1** salt (3.91 g, 87%): $[\alpha]_{435}^{28}$ −74.8° (*c* 1.00, MeOH).

Recrystallization of the salt (3.86 g) from a mixture of ethyl acetate and 2-propanol (2 : 1) (95 ml) gave 3.16 g (71%) of (−)-**4**·(−)-**1** salt: mp 145—146 °C; $[\alpha]_{435}^{25}$ −113° (*c* 1.00, MeOH).

To a solution of purified salt (3.12 g) in water (50 ml) was added 1 M HCl solution (20 ml) to decompose the salt. The liberated acid was extracted with ether (3×40 ml), and the ethereal extracts were combined, dried with Na_2SO_4, and concentrated under reduced pressure to yield (−)-**4** (1.62 g, 67% total yield): mp 122—123 °C; $[\alpha]_{589}^{28}$ −17.5° (*c* 1.00, EtOH); 94% optical purity.

The resolving agent was recovered in 93% yield without racemization by treating the aqueous solution with 1M NaOH solution, followed by extraction with ether.

In a similar fashion, 2-hydroxy-2-phenylpropionic acid (**3**), 2-phenylpropionic acid (**5**), and 2-phenyl-2-ureidoacetic acid (**6**) were resolved in high optical purities (see Tables 4 and 5).

Synthesis of Aubergenone, a Sesquiterpenoid Phytoalexin from Diseased Eggplants[1]

Akio Murai, Atsushi Abiko, Mitsunori Ono, and Tadashi Masamune*

Department of Chemistry, Faculty of Science, Hokkaido University, Sapporo 060

(Received September 11, 1981)

The synthesis of aubergenone, a stress metabolite isolated from diseased eggplants, from α-cyperone, which implies revision of the assigned structure to the metabolite, is described.

In 1975 Stoessl and coworkers[2] reported isolation of the title compound (**1**), aubergenone ("enone sesquiterpene"), as a stress metabolite from diseased eggplants (*Solanum melongena*, Solanaceae) and assigned 11-hydroxy-4β,5α-eudesm-1-en-3-one structure (**2**) on the basis of the extensive spectroscopic studies. However, in 1978 Canadian workers[3] and we[4] independently arrived at the same revised structure, 11-hydroxy-4α,5α-eudesm-1-en-3-one (**1**), by synthesis of 4-epiaubergenone (**2**) and anbergenone (**1**) itself, respectively. The sesquiterpene (**1**) is a sole stress compound with a 5α-eudesmane skeleton among the metabolites of the Family and hence stands unique on biogenetic grounds.[4-6] In the present paper we describe details of the synthesis of aubergenone (**1**) and its 4-epimer (**2**), which is divided into three sections as described in the following.

2

Results and Discussion

An Alternative Short-step Transformation of (−)-α-Santonin into (+)-α-Cyperone. A number of synthetic routes of (+)-α-cyperone (**3**) have been reported. Of these routes, most practical ones are those elaborated by Piers,[7] Caine,[8] and coworkers, which start with commercially available (−)-α-santonin (**4**) and (−)-carvone, respectively (overall yields, 20 and 25%). We also started with **4**, which was easily epimerized into epi-α-santonin[7,9] (**5**) in 73% yield. Treatment of **5** with lithium diisopropylamide (LDA, 1.5 equiv.) in tetrahydrofuran (THF) and hexamethylphosphoric triamide (HMPA) at −78 °C followed by addition of methyl iodide afforded 11-methyl-epi-α-santonin (**6**) as a single product, which on hydrogenation in the presence of tris(triphenylphosphine)chlororhodium in degassed dry benzene, formed the 1,2-dihydro derivative (**7**) in 71% yield from **5**. Irradiation of **7** with sunlight by the Ourisson method[10] effected photo-decarboxylation to give 10-epimaalienone,[10] an unstable cyclopropane derivative (**8**), in 68% yield. In accord with the assigned structure, compound **8** exhibited the following spectral data: MS, *m/e* 218 (M^+), 203, 190, and 175; IR, 1665, 1598, 1385, and 1360 cm^{-1}; NMR, δ 0.96, 1.09, 1.23, and 1.77 (each 3H, s). Further treatment of **8** with hydrogen chloride in ethanol gave rise to a known chloride[8] (**9**), mp 86—88 °C, $[\alpha]_D$ +159°, in 82% yield, which was completely identical with the reported data (mp, $[\alpha]_D$, MS, IR, and NMR). The compound (**9**) was converted readily into **3** by a known procedure.[11] This transformation of (−)-α-santonin (**4**) into (+)-α-cyperone (**3**) involved 6 steps and the overall yield amounted to 23.3%.

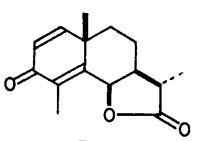
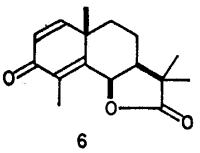
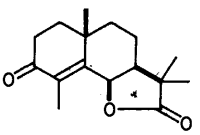
4



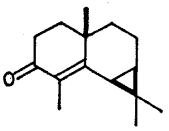
5



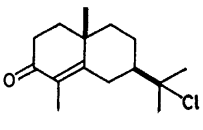
6



7



8



9

Transformation of (+)-α-Cyperone (3) into 4-Epiaubergenone (2). *trans*-Dihydrocarissone[12] (**10**) with the established configuration was first prepared from **3** in two steps (the Birch reduction[13] and oxymercuration-demercuration[14]) in 76% yield. Treatment of **10** with LDA (2.5 equiv.) in THF and then with benzeneselenenyl bromide (2.5 equiv.) in THF at −78 °C afforded its 2α-phenylseleno derivative (**11**) in 75% yield. Oxidation of **11** with sodium periodate (3 equiv.) in 85% aqueous methanol containing sodium hydrogencarbonate (1.5 equiv.) at room temperature[15] led to elimination of benzeneseleninic acid, giving 11-hydroxy-4β,5α-eudesm-1-en-3-one (**2**), mp 105—107 °C, $[\alpha]_D$ −53.5°, in 69% yield, which displayed the following spectra: MS, *m/e* 236 (M^+), 221, 218, 203, 178, and 59; UV_{max}, 228 nm (ε 5700); IR (Nujol), 3500, 1670, and 1655 (sh) cm^{-1}; NMR, δ 1.06 (3H, s, 15-H), 1.13 (3H, d, J=7 Hz, 14-H), 1.22 (6H, s, 12- and 13-H), 2.32 (1H, dq, J=11 and 7 Hz, 4-H), 5.84 and 6.71 (each 1H, ABq, J=10 Hz, 2- and 1-H). While these spectral data were consistent with the formula (**2**), those were different from the reported[2] for aubergenone. Significant difference in the coupling constant $J_{4,5}$ between the synthetic (11 Hz) and natural samples (6 Hz) suggested that the protons at C-4 and C-5 of the latter would probably be oriented *cis* (equatorial-axial).

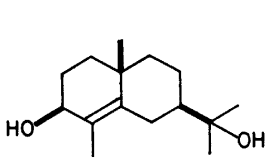
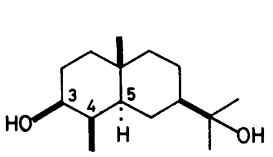
11, 4βH
15, 4αH

Synthesis of Aubergenone (1) from (+)-α-Cyperone (3). The synthesis required *cis*-addition of hydrogen atoms from the rear (α) side to the C-4–C-5 double bond of 4-eudesmene derivatives. Since hydrogenation of carissone, 11-hydroxyeudesm-4-en-3-one, over palladium in acetic acid or in alkaline ethanol gave *trans*-dihydrocarissone (**10**) as a major product, (+)-α-cyperone (**3**) was first transformed into eudesm-4-ene-3β,11-diol[16] (**12**) by a known two-step procedure.[16] Hydrogenation of **12** over platinum in a 40 : 1 mixture of ethyl acetate and acetic acid at room temperature[17] effected the relevant *cis*-hydrogenation to yield 4α,5α-eudesmane-3β,11-diol (**13**) [NMR, δ 3.75 (1H, dt, J=10 and 5.5 Hz, 3-H)], which in turn was oxidized with the Jones reagent, giving 11-hydroxy-4α,5α-eudesman-3-one (**14**) (ORD, a=+2[illegible].0) in 83% yield from **12**. The configurations of C-4 and C-5 of these compounds (**13**) and (**14**) were confirmed by quantitative conversion of **14** into **10** under basic conditions (5% KOH in MeOH, reflux, 6 h). The compound (**14**), when treated with LDA (2.5 equiv.) and then with benzeneselenenyl bromide (2.5 equiv.), afforded the corresponding 2α-phenylseleno derivative (**15**) [NMR, δ 2.61 (1H, qui, J=6 Hz, 4-H) and 4.49 (1H, dd, J=12 and 7 Hz, 2-H)] in 82% yield, which underwent oxidative elimination by treatment with sodium periodate (3 equiv.) in aqueous methanol at room temperature[15] to give α,β-unsaturated ketone, oil, $[\alpha]_D$ −4.0°, in 46% yield. The spectral data (see Experimental) of the ketone were completely identical with those (MS, UV, ORD, IR, ^{1}H and ^{13}C NMR) reported[2] for natural aubergenone. Naturally, aubergenone (**1**) was also converted quantitatively into its 4-epimer (**2**) under the basic conditions. The present result completes the synthesis of aubergenone (**1**) and also establishes the structure.



12



13

Experimental

All the melting points were uncorrected. The homogeneity of each compound was always checked by TLC over silica gel (Wakogel B-5) under various solvent systems, the spots being developed with cerium(IV) sulfate in dilute sulfuric acid and/or iodine. The optical rotations, ORD curves, UV, IR, and NMR (100 MHz) spectra were measured in chloroform, in ethanol, in ethanol, in liquid state, and in chloroform-*d*, respectively, unless otherwise stated.

11-Methyl-epi-α-santonin (6). To a solution of diisopropylamine (0.92 ml, 6 mmol) in dry THF (20 ml) cooled at 0 °C was added dropwise a solution of butyllithium in hexane (3.4 ml, 6 mmol) under nitrogen, and the solution was stirred at 0 °C for 15 min. To the solution cooled at −78 °C was added a solution of epi-α-santonin (**5**) (1 g, 4 mmol) in THF (20 ml) and HMPA (2 ml). The mixture was stirred at −78 °C for 1 h, mixed with a solution of methyl iodide (1 ml, large excess) in THF (2 ml) and HMPA (2 ml), and stirred continuously for 1 h at the same temperature. The reaction mixture was then neutralized with 2 M† hydrochloric acid, concentrated *in vacuo*, diluted with water, and extracted with chloroform. The chloroform solution was washed with water and saturated brine, dried, and evaporated to leave pale yellow oil (4 g), which was purified by chromatography over silica gel. Fractions eluted with benzene–ether (2 : 1) gave **6** (0.83 g), mp 164—165 °C; MS, *m/e* 260 (M$^+$, base), 245, and 217; IR (Nujol), 1762, 1660, and 1625 cm^{-1}; NMR, δ 1.25 [6H, s, 11-$(CH_3)_2$], 1.36 (3H, s, 15-H), 2.04 (3H, s, 14-H), 5.50 (1H, d, J=5 Hz, 6-H), 6.20 and 6.72 (each 1H, d, J=9 Hz, 2- and 1-H). Found: C, 73.52; H, 8.01%. Calcd for $C_{16}H_{20}O_3$: C, 73.85, H, 7.69%.

11-Methyl-1,2-dihydro-epi-α-santonin (7). A solution of **6** (540 mg) in degassed dry benzene (5 ml) was hydrogenated in the presence of tris(triphenylphosphine)chlororhodium (150 mg) for 9 h at room temperature. After the catalyst was removed by filtration through alumina (10 g), the filtrate was evaporated to give crude product (600 mg), which was separated by preparative TLC over silica gel with benzene–ethyl acetate (4 : 1) to give **7** (480 mg), mp 124—125.5 °C (from ether–hexane), $[\alpha]_D$ −113.2°; MS, *m/e* 262 (M$^+$, base), 247, 219; IR (Nujol), 1790, 1695, 1640, and 1400 cm^{-1}; NMR, δ 1.25 [6H, s, 11-$(CH_3)_2$], 1.37 (3H, s, 15-H), 1.72 (3H, s, 14-H), and 5.43 (1H, d, J=5.5 Hz, 6-H). Found: C, 73.44; H, 8.37%. Calcd for $C_{16}H_{22}O_3$: C, 73.28; H, 8.40%.

10-Epimaalienone (8). Compound **7** (135 mg) was exposed under day light (February in Sapporo at about 0 °C) in a Pyrex vessel for 10 d. The reaction mixture was separated by preparative TLC over silica gel with benzene. Fractions (63 mg) with higher R_f value, showing a single spot on TLC, afforded **8**, oil, $[\alpha]_D$ −595°; MS, IR, and NMR, in the text. Found: C, 82.43; H, 10.40%. Calcd for $C_{15}H_{22}O$: C, 82.52; H, 10.16%. The spectral data of **8** were identical with the corresponding reported data.[10] Fractions (32 mg) with lower R_f value, afforded the unchanged starting material (**7**).

11-Chloroeudesm-4-en-3-one (9). A solution of **8** (100 mg) in ethanol saturated with hydrogen chloride (10 ml) was stirred at room temperature for 1 h. The reaction mixture was poured into saturated aqueous sodium hydrogencarbonate and extracted with ether, repeatedly. The ether solution was washed with saturated brine and water, dried, and evaporated to leave crude crystals (111 mg), which were recrystallized from hexane to give **9** (91 mg), mp 86—88 °C, $[\alpha]_D$ +159.4°; MS, *m/e* 254 (M$^+$) and 218; IR (Nujol), 1680, and 1625 cm^{-1}; NMR, δ 1.12 (3H, s, 15-H), 1.59 and 1.61 (each 3H, each s, 12- and 13-H), and 1.73 (3H, s, 14-H). The spectral data of **9** were identical with the corresponding reported data.[8]

trans-*Dihydrocarissone (10).* To liquid ammonia (150 ml) containing lithium (160 mg, 23 mmol) was added dropwise a solution of **3** (500 mg, 2.3 mmol) in ether (25 ml) for 5 min under cooling at −78 °C, and the mixture was stirred at the temperature for 1 h. After addition of ammonium chloride, the mixture was evaporated, mixed with water, and extracted with ether (3 × 50 ml). The ether solution was washed

† 1 M=1 mol dm^{-3}.

with 5% aqueous ammonium chloride and water, dried, and evaporated to leave oily residue (524 mg), which was separated by column chromatography over silica gel (15 g) with hexane. More mobile fractions, showing a single spot on TLC, gave 4β,5α-eudesm-11-en-3-one (340 mg), oil, $[\alpha]_D$ −20.9° (lit,[13] −15.1°); MS, *m/e* 220 (M^+), 205, 177, and 109 (base); IR, 3100, 1720, 1650, 1390, and 890 cm^{-1}; NMR, δ 0.99 (3H, d, J=7.5 Hz, 14-H), 1.10 and 1.74 (each 3H, s, 15- and 13-H), and 4.73 (2H, s, 12-H). Less mobile fractions afforded the unchanged material (**3**) (159 mg).

To a suspended mixture of mercury(II) acetate (611 mg) in THF (2 ml) and water (3 ml) was added the afore-mentioned eudesmene (210 mg, 0.95 mmol) in THF (1 ml), when the mixture became homogeneous and was stirred at 0 °C for 5 min. To the solution was added 3 M aqueous sodium hydroxide (1 ml) and then sodium borohydride (0.5 M) in 3 M aqueous sodium hydroxide (1.6 ml), when mercury precipitated out. After removal of the mercury by filtration over Celite, the filtrate was concentrated, mixed with water (20 ml), saturated with sodium chloride, and extracted with ethyl acetate (4×20 ml). The acetate solution was washed with water, dried, and evaporated to leave crude crystals (280 mg), which on recrystallization from ether–hexane gave **10** (147 mg). The mother liquors obtained on recrystallization was evaporated and purified by chromatography over silica gel (10 g) with benzene–ether (2 : 1) to yield an additional amount (29 mg) of **10**, mp 110—111 °C (from ether–hexane), $[\alpha]_D$ −7.5° (lit,[12] −11.7°), MS, *m/e* 238 (M^+), 223, 220, 205, 180, and 59 (base); ORD (dioxane), $[\phi]^{peak}_{314}$ +2430°, $[\phi]_{278}$ 0°, $[\phi]^{trough}_{272}$ −4180°, a=+66.1; IR ($CHCl_3$), 3480, 1710, and 1390 cm^{-1}; NMR, δ 0.99 (3H, d, J=7 Hz, 14-H), 1.06 (3H, s, 15-H), and 1.20 (6H, s, 12- and 13-H).

*2α-Phenylseleno-11-hydroxy-4β,5α-eudesm-3-one (**11**).* To a solution of LDA in THF, prepared by treatment of diisopropylamine (126 mg, 1.25 mmol) with butyllithium [0.78 M in hexane (0.70 ml)] in THF (5 ml), was added **10** (119 mg, 0.5 mmol) in THF (2 ml) and HMPA (179 mg, 1 mmol) at −78 °C under nitrogen, and the mixture was stirred at the temperature for 1 h. To the mixture was added dropwise benzeneselenenyl bromide (295 mg, 1.25 mmol) in THF (2 ml) at −78 °C, when the mixture became yellow, and was treated with dilute hydrochloric acid and extracted with ether (3× 20 ml). The ether solution was washed with saturated aqueous sodium hydrogencarbonate and saturated brine, dried and evaporated to leave oily residue (300 mg), which was purified by column chromatography over silica gel (10 g) with benzene–ether (1 : 1), giving **11** (141 mg) as needle crystals, mp 154—155 °C (from ethyl acetate–hexane), $[\alpha]_D$ −132.1°; MS, *m/e* 396, 394 (M^+), 392, 378, 376, 374, 218, and 59 (base); IR (Nujol), 3400, 1708, and 1380 cm^{-1}; NMR, δ 1.02 (3H, s, 15-H), 1.06 (3H, d, J=7 Hz, 14-H), 1.19 (6H, s, 12- and 13-H), 2.36 (1H, m, 4-H), and 4.36 (1H, dd, J=13 and 6 Hz, 2-H). Found: C, 63.81; H, 7.71%. Calcd for $C_{21}H_{30}O_2Se$: C, 64.10; H, 7.70%.

*4-Epiaubergenone (**2**)*: A solution of **11** (70 mg, 0.185 mmol) in methanol (5 ml) and water (1 ml) containing sodium hydrogencarbonate (40 mg) and sodium periodate (200 mg, 0.93 mmol) was stirred at room temperature for 3 h, when the solution gradually became heterogeneous. After addition of 10% aqueous sodium thiosulfate, the reaction mixture was concentrated and extracted with ethyl acetate (3×20 ml). The acetate solution was worked up as usual to leave oily residue (57 mg), which was purified by chromatography over silica gel (5 g) with benzene–ether (1 : 1) to yield crude crystals (37 mg). These were recrystallized from ether–hexane to give **2** (30 mg) in pure state, mp 105—107 °C, $[\alpha]_D$ −53.5°; MS, UV, IR, and NMR, in the text; ORD, $[\phi]$ 0°, −50°, −360°, −920°, 0°, +1280°, +510°, +2030°, +510°, and +2850° at 500, 450, 400, 365, 346, 328, 282, 255, 240, and 226 nm. Found: C, 76.43; H, 10.10%. Calcd for $C_{15}H_{24}O_2$: C, 76.22; H, 10.24%.

*4α,5α-Eudesmane-3β,11-diol (**13**).* Eudesm-4-ene-3β,11-diol[16] (**12**) (50 mg) in ethyl acetate (20 ml) and acetic acid (0.5 ml) was hydrogenated over pre-reduced platinum(IV) oxide (20 mg) at room temperature for 2 h, when 4.7 ml of hydrogen (0.9 mol equiv.) had been consumed. After removal of the catalyst, the filtrate was washed with saturated aqueous sodium hydrogencarbonate and saturated brine, dried, and evaporated to leave crystalline substance, which was recrystallized from ethyl acetate–hexane to give **13** (46 mg), mp 166—166.5 °C; $[\alpha]_D$ −2.7°; MS, *m/e* 228 (M^+ −18), 207, 204, 189, and 161 (base); IR ($CHCl_3$), 3360 and 3240 cm^{-1}; NMR, δ 0.86 (3H, d, J=7 Hz, 14-H), 0.89 (3H, s, 15-H), 1.20 (6H, s, 12- and 13-H), and 3.75 (1H, dt, J=10 and 5.5 Hz). Found: C, 74.83; H, 11.71%. Calcd for $C_{15}H_{28}O_2$: C, 74.95; H, 11.74%.

*11-Hydroxy-4α,5α-eudesm-3-one (**14**).* A solution of **13** (111 mg, 0.46 mmol) in acetone (15 ml) was treated with the Jones reagent (*ca.* 0.5 ml, excess) at room temperature for 30 min under stirring. After neutralization by addition of saturated aqueous sodium carbonate, the mixture was filtrated over Celite. The filtrate was concentrated and extracted with ethyl acetate (3×20 ml). The acetate solution was worked up as usual to leave oily residue (110 mg), which was purified by chromatography over silica gel (3 g) with benzene–ether (2 : 1) to give **14** (100 mg), mp 41.5—43 °C (from ether–hexane), $[\alpha]_D$ +2.8°; MS, *m/e* 238 (M^+), 220, 205, 177, and 55 (base); ORD, $[\phi]^{peak}_{314}$ +1100°, $[\phi]_{300}$ 0°, $[\phi]^{trough}_{285}$ −1200°, a=+23; IR, 3500 and 1710 cm^{-1}; NMR, 1.10 (3H, s, 15-H), 1.10 (3H, d, J=7.5 Hz, 14-H), and 1.21 (6H, s, 12- and 13-H). Found: C, 75.27; H, 10.96%. Calcd for $C_{15}H_{26}O_2$: C, 75.58; H, 11.00%.

*2α-Phenylseleno-11-hydroxy-4α,5α-eudesm-3-one (**15**).* To a solution of LDA in THF, prepared by treatment of diisopropylamine (106 mg, 1.05 mmol) with butyllithium [1.7 M in hexane (0.6 ml)] in THF (5 ml), was added dropwise **14** (100 mg, 0.42 mmol) in THF (5 ml) at −78 °C with stirring under nitrogen, and the mixture was stirred at −78 °C for 1 h. To the mixture was added benzeneselenenyl bromide (295 mg, 1.05 mmol) in THF (3 ml) at the temperature, when the mixture became yellow, and was treated with dilute hydrochloric acid and extracted with ether (3×20 ml). The ether solution was worked up as uaual to leave oily residue, which was purified by chromatography over silica gel (10 g) with benzene–ether (2 : 1) to give **15** (130 mg), oil, showing a single spot on TLC, $[\alpha]_D$ −85.5°, MS, *m/e* 396, 394 (M^+), 392, 378, 376, 374, 218, 203, 178, and 59 (base); IR, 3500, 3030, and 1701 cm^{-1}; NMR, δ 1.02 (3H, s, 15-H), 1.14 (3H, d, J= 7.5 Hz, 14-H), 1.18 (6H, s, 12- and 13-H), 2.61 (1H, qui, J= 6 Hz, 4-H), and 4.49 (1H, dd, J=12 and 7 Hz, 2-H). Found: C, 63.83; H, 7.81%. Calcd for $C_{21}H_{30}O_2Se$: C, 64.10; H, 7.70%.

*Aubergenone (**1**).* A solution of **15** (54 mg, 0.14 mmol) in methanol (3 ml) and water (0.5 ml) containing sodium hydrogencarbonate (19 mg) and sodium periodate (94 mg, 0.44 mmol) was stirred at room temperature for 2.5 h, when the solution gradually became heterogeneous. The mixture was treated with 5% aqueous sodium thiosulfate, concentrated, and extracted with ethyl acetate (3×20 ml). The acetate solution was worked up as usual to leave oily residue (48 mg), which was separated by preparative TLC over silica gel with hexane–ethyl acetate (1 : 1). A fraction, showing a single spot, gave **1** (15 mg), oil, $[\alpha]_D$ −4.0°; MS, 236 (M^+), 218, 203, 175, and 59 (base); UV_{max}, 229 nm (ε 5800); ORD,

[ϕ] 0°, 0°, −130°, −520°, −1670°, 0°, +3830°, +4500°, +2800°, and +4500° at 589, 500, 450, 400, 368, 348, 310, 285, 280, and 275 nm; IR, 3400, 1670, 917, 824, and 752 cm^{-1}; ^1H NMR, δ 1.13 (3H, d, J=7.5 Hz, 14-H), 1.16 (3H, s, 15-H), 1.24 (6H, s, 12- and 13-H), 2.44 (1H, dq, J=6 and 8 Hz, 4-H), and 5.87 and 6.78 (each 1H, ABq, J=10 Hz, 2- and 1-H); ^{13}C NMR, δ 13.4, 20.7 (each q), 22.4, 26.0 (each t), 27.1, 27.5 (each q), 36.1 (s), 39.9 (t), 44.3, 45.2, 49.0 (each d), 72.5 (s), 125.8, 160.8 (each d), and 203.8 (s). Found: C, 76.03; H, 10.40%. Calcd for $C_{15}H_{24}O_2$: C, 76.22; H, 10.24%.

Epimerization of ***14*** *to* ***10*** *and* ***1*** *to* ***2***. *a)*: A solution of **14** (20 mg) in methanol (10 ml) containing 5% potassium hydroxide was refluxed for 6 h under nitrogen. The solution was cooled, neutralized with 10% aqueous ammonium chloride, evaporated, and extracted with ethyl acetate (3× 20 ml). The acetate solution was washed with water, dried, and evaporated to leave oil (20 mg), showing a single spot on TLC, which was identified as **10** by comparison of the spectral data (IR and NMR).

b): Compound **1** (10 mg) was treated with 5% potassium hydroxide (10 ml) for 6 h under reflux under nitrogen. The reaction mixture was worked up as mentioned above to give oil (8 mg), showing a single spot on TLC, which was identified as **2** by comparison of the spectral data (IR and NMR).

Synthesis of β- and α-Rotunols. Revision of the Structure of a Stress Metabolite "1-Keto-α-cyperone"[1]

Akio Murai, Mitsunori Ono, Atsushi Abiko, and Tadashi Masamune*
Department of Chemistry, Faculty of Science, Hokkaido University, Sapporo 060
(Received September 11, 1981)

The synthesis of β- and α-rotunols, two sesquiterpene alcohols isolated from nutgrass (*Cyperus rotundus* Linne), is described. This synthetic study also involves revision of the structure of a stress metabolite "1-keto-α-cyperone" isolated from Burley and flue-cured tobaccos (*Nicotiana tabacum* L.).

The title sesquiterpene alcohols, β- and α-rotunols (**1**) and (**2**), were isolated from the crude drug "Ko-bushi," prepared from the dried rhizomes of nutgrass, *Cyperus rotundus* Linne (Cyperaceae) (Japanese name: Hamasuge) by Hikino and co-workers, and the structures were determined in 1969 on the basis of chemical and spectroscopic evidence.[2] In connection with studies on phytoalexins, we preliminarily reported that **1** has been synthesized from α-cyperone (**3**) and has played an important role as a key intermediate for the synthesis of phytuberin, one of the major phytoalexins of the genus *Solanum*.[3] We also found that the structure of a stress compound (**4**), isolated from Burley and flue-cured tobaccos and assigned a formula "1-keto-α-cyperone,"[4] should be represented by structure "2-keto-α-cyperone."[5] In the present paper we describe details of the synthesis of these sesquiterpenes **1**, **2**, and **4**.

Results and Discussion

Revision of the Structure of a Stress Metabolite Named "1-Keto-α-cyperone." The synthesis of β-rotunol (**1**) from α-cyperone (**3**) required oxygenation at C-2 and C-5 as well as removal of the carbonyl group at C-3 of **3**. Thus compound **3** was first transformed into the 4β,5β-epoxy derivative[6] (**5**) in a three-step sequence [(i) reduction ($NaBH_4$ in MeOH), (ii) epoxidation (*t*-BuOOH and $VO(acac)_2$ in benzene), and (iii) oxidation (PCC in dichloromethane)] in 57% overall yield. However, attempted oxygenation reactions at C-2 of **5** under various conditions failed: namely, treatment of **5** with 1,3-propanedithiol di-*p*-toluenesulfonate and base in ethanol[7] gave a complex mixture, no expected dithiane derivative (**6**) being detected. Moreover, the epoxide (**5**), when treated with lithium diisopropylamide (LDA, 1.5 equiv.) in tetrahydrofuran (THF) and then with diphenyl disulfide[8] or benzenesulfenyl chloride, was not converted into the expected 2-phenylthio 3-ketone (**7**) and, instead, produced dienone (**8**) in 62% yield. The structure was assigned easily on the basis of the spectral data (see Experimental). Likewise, treatment of **5** with LDA (1.5 equiv.) in THF at −78 °C followed by addition of molybdenum peroxide $MoO_5 \cdot Py \cdot HMPA$ (MoOPH)[9] (1.5 equiv.) afforded 2-oxo-α-cyperone (**4**) in 75% yield. The structure of **4** was also based on the spectral data: MS, *m/e* 232 (M^+) and 189 (base); NMR, δ 1.28 (3H, s, 15-H), 1.82 (3H, s, 13-H), 1.99 (3H, s, 14-H), 4.84 (2H, s, 12-H), 6.07 (1H, s, 1-H), and 6.53 (1H, s, OH); IR (Nujol), 3400, 3120, 1660(sh), 1635, and 880 cm^{-1}. As expected, compound **8**, when treated with mercury(II) chloride in aqueous acetonitrile[10] under reflux, was converted into **4** in moderate yield (48%).

A plausible pathway for the formation of dienones **8** and **4** is depicted in Scheme 1: unstable 2-phenylthio and 2-oxomolybdenum cyclopropanone derivatives (**10** and **11**) would be formed by initial attack of the C-2 anion to the C-4 oxirane carbon, and subsequent ring cleavage caused by deprotonation at C-1 would produce the dienols (**12** and **13**), which underwent dehydration of the resultant β-hydroxy ketones to yield the dienone derivatives (**8** and **4**). This unexpected result indicated that a hydroxyl group or its equivalent would have to be introduced into C-5 after oxygenation at C-2 of α-cyperone.

Incidentally, the spectral data of the relevant 2-oxo-α-cyperone (**4**) were completely identical with those of a stress compound named "1-keto-α-cyperone," which had been isolated from Burley and flue-cured tobaccos (*Nicotiana tabacum*) by Roberts[4] in 1972 and assigned

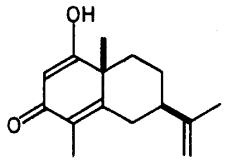
11, R=OMoO$_4$L$_2^-$ 13, R'=OH

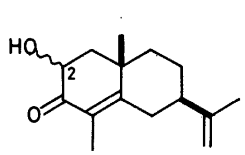
Scheme 1.



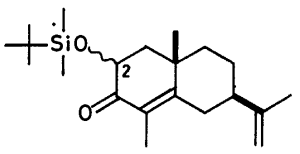
9

formula **9** shown by the name. It follows that this finding implies revision of the assigned structure of the stress metabolite.

Synthesis of β-Rotunol (1). Treatment of α-cyperone (**3**) with LDA (1.5 equiv.) in THF at −78 °C followed by addition of MoOPH effected oxygenation at C-2, giving a *ca.* 2 : 1 inseparable mixture (**14**) of 2β- and 2α-hydroxy-α-cyperones (**14a** and **14b**) in 62% yield, which were converted into the *t*-butyldimethylsilyl ethers (**15a** and **15b**) by treatment with *t*-butyldimethylsilyl chloride and imidazole in *N,N*-dimethylformamide.[11] The β- and α-configurations were assigned to the 2-hydroxyl groups of **14a** and **14b** on the basis of analogy of the contribution ($\Delta\delta$) of the 2-hydroxyl groups to the chemical shift of the 19-methyl protons of Δ^4-3-keto steroids in their NMR spectra:[12] δ_{obsd} 1.34 and 1.22 [total, 3H (2 : 1), each s, 15-H]; δ_{calcd} 1.32 and 1.22 for **14a** and **14b**. This assignment was confirmed by examination of the respective spectra of **14a** and **14b**, which were prepared alternatively as described later: specially, splitting patterns [**14a**, δ 4.21 (1H, dd, J=14 and 6 Hz); **14b**, δ 4.30 (1H, dd, J=12 and 6 Hz)] of the C-2 protons indicated that the A-ring of **14a** and **15a** would take a twist-boat conformation with the relevant functions at C-2 pseudo-equatorial and also with the 3- and 10-carbon atoms at bow-sprit and flag-pole positions, while that of **14b** and **15b** would adopt a half-chair form with the functions at C-2 pseudo-equatorial (Fig. 1). These conformations would probably result from hydrogen bonding between the 2-hydroxyl and 3-oxo groups in **14a** and **14b**, and from large bulkiness of the 2-alkylsilyloxyl group in **15a** and **15b**.



14a, 2α-H
14b, 2β-H



15a, 2α-H
15b, 2β-H

Treatment of the mixture of silyl ethers **15a** and **15b** with lithium tri-*s*-butylborohydride (L-selectride) (1 equiv.) in THF at −78 °C resulted in completely

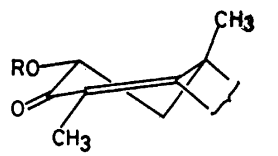
15a, R = t-BuMe$_2$Si



14b, R = H
15b, R = t-BuMe$_2$Si

Fig. 1.

stereoselective reduction of only **15a**, giving 3β-alcohol (**16a**) in 55% yield with 29% yield of the unreacted ketone (**15b**). While reduction of the recovered one (**15b**) with sodium borohydride in methanol afforded a 3 : 1 mixture of 3β- and 3α-alcohols (**16b** and **16c**), treatment with lithium aluminium hydride (LAH) at −78 °C produced 3β-alcohol (**16b**) in 80% yield as a single product. The stereoselective formation of these 3β-alcohols (**16a** and **16b**) with the hydride reagents, specially with L-Selectride, clearly resulted from attack of the reagents to the 3-carbon atom from the less-hindered side. The resultant 3-alcohols were converted into the 3-acetates (**17a**, **17b**, and **17c**), whose NMR spectra [**17a**, δ 3.90 (1H, dt, J=10 and 4.5 Hz, 2-H) and 5.30 (1H, dd, J=4.5 and 2 Hz, 3-H); **17b**, δ 3.90 (1H, m, 2-H, and dd, J=10 and 4.5 Hz, on irradiation at 5.40) and 5.40 (1H, d, J=8 Hz, 3-H); **17c**, 3.90 (1H, dt, J=12 and 4 Hz, 2-H) and 5.28 (1H, d, J= 4 Hz, 3-H)] indicated that **17a** and **17b** would take twist-boat and half-chair conformations, respectively (Fig. 2). The conformation of **17a** was also supported by the long-range coupling (2 Hz) between the hydrogen atoms at C-1 and C-3. Then the 3β-alcohol (**16a**) was oxidized smoothly with activated manganese(IV) oxide[13] in dichloromethane to **15a** in pure state in 93% yield. Moreover, hydrolysis of **15a** and **15b** with acetic acid in aqueous THF[14] gave rise to **14a** and **14b** in pure state quantitatively, respectively.

Introduction of a β-hydroxyl group into C-5 was carried out as follows. Epoxidation of 3β-alcohol **16a** with *t*-butyl hydroperoxide in the presence of bis-(acetylacetonato)oxovanadium(IV) [VO(acac)$_2$][15] in benzene produced 4β,5β-epoxy 3β-alcohol (**18a**), which was converted smoothly into the 3β-mesylate (**19a**) in 84% yield from **16a**: **19a**, δ 3.86 (1H, ddd, J=13, 5,

Fig. 2.

and 4 Hz, 2-H) and 4.85 (1H, dd, J=4, and 2 Hz, 3-H). These splitting patterns again indicated that compounds **18a** and **19a** would possess a twist-boat form with two β-substituents at C-2 and C-3 pseudo-equatorial and pseudo-axial, respectively. Reductive elimination of the epoxy mesylate (**19a**) with sodium in liquid ammonia and dry THF[16] afforded allyl alcohol (**20a**) in 95% yield, which was hydrolyzed in a 1 : 1 : 2 mixture of acetic acid, water, and THF to give Δ^3-2β,5β-glycol (**21a**) in 90% yield. Likewise, 3β-alcohol **16b**, an isomer of **16a**, was transformed into the corresponding Δ^3-2α,5β-glycol (**21b**) *via* the 4β,5β-epoxy 3β-alcohol (**18b**), the 3β-mesylate (**19b**), and the Δ^3-5β-alcohol (**20b**), in 50% yield from **16b**: **19b**, δ 4.01 (1H, ddd, J=10, 9, and 4 Hz, 2-H) and 4.68 (1H, d, J=9 Hz, 3-H). Oxidation of **21a** and **21b** with activated manganese(IV) oxide in dichloromethane produced the same α,β-unsaturated ketone, mp 117—119 °C, $[\alpha]_D$ +41.4° ($CHCl_3$), in 85 and 90% yields. The ketone was identified as β-rotunol (**1**), mp 118—119 °C, $[\alpha]_D$ +44.8° ($CHCl_3$), by comparison of the spectra of synthetic and natural samples. The overall yield amounted to 29.6% from (+)-α-cyperone (**3**). Since β-rotunol has been transformed into dehydrosolavetivone[2] (**22**) and then into solavetivone[17] (**23**), stress metabolites in diseased potatoes, by Hikino,[2] Anderson and co-workers,[17] respectively, the present synthesis of β-rotunol also constitutes, in a formal sence, the synthesis of the metabolites (**22**) and (**23**).

Synthesis of α-Rotunol (2). Treatment of α-cyperone (**3**) under the Shapiro conditions[18] effected reductive deoxygenation to give diene (**24**) in 73% yield, which on oxygenation with triplet oxygen in the presence of tungsten(VI) chloride in the dark at −78 °C[19] followed by treatment of the resulting peroxide (**25**) with alumina afforded α,β-unsaturated ketone, mp 102—104 °C, $[\alpha]_D$ +53°, in 88% yield. The ketone was identified as α-rotunol (**2**), mp 87.5—88.5 °C, by comparison of the spectra of synthetic and natural samples.

25

Experimental

All the melting points were uncorrected. The homogeneity of each compound was always checked by TLC on silica gel (Wakogel B-5) with various solvent systems, the spots being developed with cerium(IV) sulfate in diluted sulfuric acid

and/or iodine. The optical rotations, UV and NMR (100 MHz) spectra were measured in chloroform, ethanol, and chloroform-*d* respectively, unless otherwise stated.

4β,5β-Epoxyeudesm-11-en-3-one (5). *i)*: To a solution of (+)-α-cyperone (100 mg) in methanol (5 ml) cooled at −50 °C was added sodium borohydride (55 mg) with stirring. After stirring for 1.5 h at −45—−50 °C, the reaction was quenched by addition of acetic acid. The product was extracted with chloroform and the extracts were washed with saturated sodium hydrogencarbonate and saturated brine, dried, and evaporated to give eudesma-4,11-dien-3β-ol (95 mg) as a single product, oil; $[\alpha]_D$ +9.7°, (Ref.[6] +10.9°); NMR, δ 4.05 (1H, br, t, W_H=15 Hz, 3α-H). The spectral data were identical with the reported data.[6]

ii): To a stirred solution of eudesma-4,11-dien-3β-ol (220 mg, 1 mmol) and $VO(acac)_2$ (4 mg, 0.014 mmol) in dry benzene (10 ml) was added dropwise *t*-butyl hydroperoxide (0.186 g, 1.5 mmol) under reflux, and the mixture was stirred under reflux for 10 min. The reaction mixture was poured into aqueous sodium hydrogensulfite. The organic layer was separated and the aqueous solution was extracted with ether. The benzene and ether solution were combined, washed with water, dried, and evaporated to leave an oil (300 mg), which was chromatographed over silica gel (9 g) with benzene–ether (5 : 1) to give 4β,5β-epoxyeudesm-11-en-3β-ol (203 mg), oil; $[\alpha]_D$ +57.6°; IR (neat), 3500, 3100, 1625, and 890 cm^{-1}; NMR, δ 1.08 (3H, s, 15-H), 1.40 (3H, s, 14-H), 1.76 (3H, s, 13-H), 3.80 (1H, br, W_H=7 Hz, 3α-H), and 4.74 (2H, s). The spectral data were identical with the corresponding reported data.[6]

iii): To a mixture of pyridinium chlorochromate (PCC, 323 mg, 1.5 mmol) in dry dichloromethane (5 ml) was added a solution of 4β,5β-epoxyeudesm-11-en-3β-ol (234 mg, 1 mmol) in dichloromethane (3 ml). The whole reaction mixture was stirred at room temperature for 2 h, diluted with dry ether (10 ml) and filtered. The filtrate was evaporated to leave an oil (230 mg), which was separated by chromatography over silica gel with benzene–ether (10 : 1). Fractions (180 mg) with high R_f value, showing a single spot on TLC, afforded **5**, oil; IR (neat), 3080, 1710, 1625, and 890 cm^{-1}; NMR, δ 1.20 (3H, s, 15-H), 1.42 (3H, s, 14-H), 1.76 (3H, s, 13-H), and 4.76 (2H, s). The spectral data were identical with the corresponding reported data.[6]

Attempted Phenylsulfenylation of 5. To a solution of diisopropylamine (0.066 ml, 0.48 mmol) in dry THF (1 ml) cooled at 0 °C was added dropwise a solution of butyllithium in hexane (0.272 ml, 0.48 mmol) under nitrogen, and the solution was stirred at 0 °C for 15 min. To the solution cooled at −78 °C was added a solution of **5** (75 mg, 0.32 mmol) in THF (2 ml). The reaction mixture, after being stirred at −78 °C for 50 min, was mixed with a solution of diphenyl disulfide (105 mg, 0.48 mmol) in dry THF (2 ml) at room temperature and stirred for 1 h at room temperature. The whole mixture was poured into ice–water, and extracted with chloroform. The chloroform solution was washed with water and saturated brine, dried, and evaporated to leave an oil (330 mg), which was separated by preparative TLC over silica gel with benzene–ether (5 : 1). Fractions (39 mg) with higher R_f value, showing a single spot on TLC, afforded the dienone derivative (**8**), gum; $[\alpha]_D$ −98.2°; MS, *m/e* 324; IR (neat), 1640, 1625, and 1065 cm^{-1}; NMR, δ 1.76 (3H, s, 13-H), 1.93 (3H, s, 14-H), 6.12 (1H, s, 1-H), and 7.08—7.56 (5H, br m, C_6H_5). Found: C, 77.70; H, 7.37%. Calcd for $C_{21}H_{24}OS$: C, 77.78; H, 7.41%. Fractions (28.5 mg) with lower R_f value afforded the unchanged starting material (**5**).

Attempted hydroxylation of 5. To a solution of LDA (*ca.* 0.64 mmol), prepared by treatment of diisopropylamine (0.0986 ml, 0.64 mmol) with butyllithium in hexane (0.37 ml, 0.64 mmol) in THF (5 ml) at 0 °C for 15 min, was added a solution of **5** (100 mg, 0.427 mmol) in THF (2 ml) at −78 °C under nitrogen. The reaction mixture, after being stirred at −78 °C for 1 h, was mixed with MoOPH (278 mg, 0.64 mmol) and stirred for 1 h at the same temperature and for 30 min at room temperature. After addition of water to quench the reaction, the mixture was concentrated *in vacuo*, and the residue was diluted with water and extracted with ether, repeatedly. The organic layers were washed with saturated sodium hydrogencarbonate, 2 M† hydrochloric acid, and water, dried, and evaporated to leave an oil (190 mg), which was separated by preparative TLC over silica gel with benzene. Fractions (37 mg) with higher R_f value, showing a single spot on TLC, afforded 2-oxo-α-cyperone (**4**), mp 76—77 °C; $[\alpha]_D$ −166°; UV_{max}, 259.5 nm (ε 18000); MS, IR, and NMR, in the text. Found: C, 77.63; H, 8.59%. Calcd for $C_{15}H_{20}O_2$: C, 77.55; H, 8.68%. Fractions (49 mg) with lower R_f value afforded the unreacted starting material (**5**).

Hydrolysis of 8. A mixture of **8** (100 mg, 0.31 mmol) and mercury(II) chloride (251 mg, 0.93 mmol) in water (2 ml) and acetonitrile (8 ml) was stirred under reflux under nitrogen for 1 h. The resulting precipitates were removed by filtration through Celite and the filtrate was concentrated *in vacuo*, diluted with water, and extracted with chloroform, repeatedly. The chloroform solution was worked up as usual to leave an oil (86 mg), which was separated by preparative TLC with benzene. Fractions (32 mg) with higher R_f value afforded the unchanged starting material (**8**). Fractions (33 mg) with lower R_f value, showing a single spot on TLC, afforded 2-oxo-α-cyperone (**4**), mp 74—76 °C, $[\alpha]_D$ −171.0°, which was identical with the sample (**4**) described above in all respects.

*2-Hydroxy-α-cyperones (**14a** and **14b**).* To a solution of LDA (*ca.* 21 mmol), prepared by treatment of diisopropylamine (3.228 ml, 21 mmol) with butyllithium in hexane (11.58 ml, 21 mmol) in THF (30 ml) at 0 °C for 15 min, was added a solution of **3** (3.0 g, 13.8 mmol) in THF (20 ml) at −78 °C under nitrogen. After being stirred at −78 °C for 1 h, the mixture was mixed rapidly with MoOPH (9.12 g, 21 mmol), and stirred at −78 °C for 1.4 h and at room temperature for 30 min. After addition of water, the mixture was concentrated *in vacuo*, and the residue was diluted with water and extracted with ethyl acetate, repeatedly. The organic solutions were worked up as usual to leave an oil (3.2 g), which was chromatographed over silica gel (100 g) with benzene–ether (10 : 1). More mobile fractions (0.5 g) afforded **4**, and less mobile fractions (2.05 g) gave a 2 : 1 inseparable mixture (**14**) of 2β- and 2α-hydroxy-α-cyperones, (**14a** and **14b**), oil; MS, *m/e* 234 (M^+), 216, 190, 147, and 122; IR (neat), 3550, 3100, 1680 (br), 1615, and 890 cm^{-1}; NMR, δ 4.20 (0.67H, dd, *J*=14 and 6 Hz, 2α-H) and 4.28 (0.33H, dd, *J*=12 and 6 Hz, 2β-H).

*2-(t-Butyldimethylsilyloxy)-α-cyperones (**15a** and **15b**).* A mixture of **14** (250 mg, 1 mmol), imidazole (170 mg, 2.5 mmol), and *t*-butyldimethylsilyl chloride (180 mg, 1.2 mmol) in dry dimethylformamide (0.5 ml) was heated at 35—40 °C for 10 h with stirring under nitrogen. The reaction mixture was poured into ice–water and extracted with ether, repeatedly. The organic solutions were washed with water, dried, and evaporated to leave an oil (396 mg), which was chromatographed over silica gel (10 g) with benzene to give **15** (350 mg) as an 2 : 1 inseparable mixture (**15**) of 2β- and 2α-(*t*-butyldimethylsilyloxy)-α-cyperones (**15a** and **15b**), oil; MS, *m/e* 348 (M^+), 333 (base), and 291; IR (neat), 3080, 1695, 1650, 1620, and 895 cm^{-1}; NMR, δ 4.23 (0.67H, dd, *J*=10

† 1 M=1 mol dm^{-3}.

and 7 Hz, 2α-H), 4.35 (0.33H, dd, J=12 and 7 Hz, 2β-H).

*2α-(t-Butyldimethylsilyloxy)eudesma-4,11-dien-3-one (**15b**) and 2β-(t-butyldimethylsilyloxy)eudesma-4,11-dien-3β-ol (**16a**).* To a stirred solution of **15** (430 mg, 1.24 mmol) in THF (10 ml) was added L-Selectride (1 ml, 1.24 mmol) at −78 °C during 1 h under nitrogen. The solution was stirred at −78 °C for 1 h under nitrogen. After dropwise addition of water (1 ml) to decompose the reagent, the reaction mixture was stirred with 10% aqueous potassium hydroxide and 30% aqueous hydrogen peroxide at room temperature for 30 min and then treated with 5% aqueous sodium thiosulfate (10 ml) under cooling to decompose the hydrogen peroxide, and concentrated *in vacuo*. The residue was diluted with water and extracted with chloroform. The chloroform solution was worked up as usual to leave an oil (452 mg), which was chromatographed over silica gel (13 g) with benzene. Fractions (123 mg) with higher higher R_f value, showing a single spot on TLC, afforded **15b**, oil, $[\alpha]_D$ +50.0°; MS, *m/e* 348 (M^+), 333, and 291 (base); IR (neat), 3100, 1690, 1650, 1618, 1145, and 885 cm^{-1}; NMR, δ 0.09 (3H, s), 0.17 (3H, s), 0.92 [9H, s, $(CH_3)_3C$-], 1.31 (3H, s, 15-H), 1.78 (3H, s, 14-H), 1.80 (3H, s, 12-H), 4.34 (1H, dd, J=12 and 7 Hz, 2β-H), and 4.77 (2H, s). Found: C, 71.97; H, 10.33%. Calcd for $C_{21}H_{36}O_2Si$: C, 72.41; H, 10.34%. Fractions (236 mg) with lower R_f value, showing a single spot, afforded **16a**, mp 72—73 °C; $[\alpha]_D$ −79.4°; MS, *m/e* no M^+, 332, 293, 275, and 117; IR (neat), 3560, 3070, 1645, 1080, and 895 cm^{-1}; NMR, δ 0.09 (6H, s), 0.91 [9H, s, $(CH_3)_3C$-], 1.12 (3H, s, 15-H), 1.76 and 1.82 (each 3H, each s, 13- and 14-H), 3.76—3.86 (total 2H, m), and 4.74 (2H, s). Found: C, 71.99; H, 10.30%. Calcd for $C_{21}H_{38}O_2Si$: C, 72.00; H, 10.34%.

*Reduction of **15b** with Sodium Borohydride.* Compound **15b** (530 mg) was treated with sodium borohydride (200 mg) in methanol (10 ml) at −40—−50 °C for 1 h. After being quenched by addition of acetic acid, the reaction mixture was concentrated and extracted with ether. The ether solution was worked up as mentioned above to leave an oil (540 mg), showing two spots on TLC. The oil was separated into two fractions by column chromatography over silica gel (15 g) with benzene–hexane (1 : 1). Fractions (380 mg) with higher R_f value afforded **16b**, oil, $[\alpha]_D$ −9.4°; MS, *m/e* no M^+, 332 ($M^+ - H_2O$), 293 [$M^+ - C(CH_3)_3$], and 117; IR (neat), 3540 (br), 3090, 1645, 1090, and 885 cm^{-1}; NMR, 0.12 (6H, s), 0.92 [9H, s, $(CH_3)_3C$], 1.15 (3H, s, 15-H), 1.74 and 1.76 (each 3H, each s, 13- and 14-H), 3.72—4.04 (2H, m), and 4.74 (2H, s). Found: C, 71.88; H, 9.98%. Calcd for $C_{21}H_{38}O_2Si$: C, 72.00; H, 10.34%. Fractions (104 mg) with lower R_f value gave **16c**, oil; $[\alpha]_D$ +60.8°; MS, *m/e* no M^+, 332, 293, and 117; IR (neat), 3620, 3550 (br), 3110, 1650, 1080, 895, and 885 cm^{-1}; NMR, δ 0.11 (6H, s), 0.92 [9H, s, $C(CH_3)_3$], 1.10 (3H, s, 15-H). 1.76 and 1.82 (each 3H, each s, 13- and 14-H), 3.76—4.04 (2H, m), and 4.74 (2H, s). Found: C, 71.48; H, 10.71%. Calcd for $C_{21}H_{38}O_2Si$: C, 72.00, H, 10.34%.

*Reduction of **15a** with LAH.* To a stirred solution of **15b** (500 mg) in dry THF (30 ml) was added dropwise a suspension (2 ml) of LAH (100 mg) in dry THF (5 ml) at −78 °C during 5 min. The mixture was stirred at the same temperature for 20 min and, after addition of water (0.5 ml) and 1% aqueous potassium hydroxide (0.5 ml), was filtered. The filtrate was dried and evaporated to leave an oil (519 mg), which was chromatographed over silica gel (15 g) with benzene–hexane (2 : 3). Fractions (145 mg) with higher R_f value, showing a single spot on TLC, afforded the unreacted starting material (**15b**). Fractions (280 mg) with lower R_f value, showing a single spot on TLC, gave **16b** in pure state.

Compounds **16a**, **16b**, and **16c** were converted almost quantiatively into the respective monoacetates (**17a**, **17b**, and **17c**) by treatment with acetic anhydride and pyridine at room temperature, which had the following properties: **17a**, oil; $[\alpha]_D$ −135.8°; MS, *m/e* no M^+, 335, 332, and 117 (base); IR (neat), 3100, 1748, 1657, 1240, 1085, and 885 cm^{-1}; NMR, δ 0.08 (6H, s), 0.86 [9H, s, $C(CH_3)_3$], 1.13 (3H, s, 15-H), 1.68 and 1.76 (each 3H, each s, 13- and 14-H), 2.08 (3H, s, $OCOCH_3$), 3.90 (1H, dt, J=10 and 4.5 Hz, 2α-H), 4.74 (2H, s), and 5.30 (1H, dd, J=4.5 and 2 Hz, 3α-H): **17b**, mp 102—104 °C (from ether); $[\alpha]_D$ −45.6°; MS, *m/e* no M^+, 335, 332, and 117 (base); IR (Nujol), 3100, 1743, 1642, 1240, 1080 and 880 cm^{-1}; NMR, δ 0.04 (6H, s), 0.84 [9H, s, $C(CH_3)_3$], 1.12 (3H, s, 15-H), 1.51 and 1.72 (each 3H, each s, 13- and 14-H), 2.06 (3H, s, $OCOCH_3$), 3.76—4.04 (1H, m, and dd, J=10 and 4.5 Hz on irradiation at 5.40, 2β-H), 4.69 (2H, s), and 5.40 (1H, d, J=8 Hz, 3α-H): **17c**, oil; $[\alpha]_D$ +95.2°; MS, *m/e* no M^+, 335, 332, and 117 (base); IR (neat), 3100, 1743, 1657, 1243, 1110, and 890 cm^{-1}; NMR, δ 0.06 (3H, s), 0.10 (3H, s), 0.88 [9H, s, $C(CH_3)_3$], 1.12 (3H, s, 15-H), 1.63 and 1.74 (each 3H, each s, 13- and 14-H), 2.06 (3H, s, $OCOCH_3$), 3.90 (1H, dt, J=12 and 4 Hz, 2β-H), 4.72 (2H, s), and 5.28 (1H, dd, J=4 and 2 Hz, 3β-H).

*Transformation of **15b** and **16a** into **14a** and **14b**.* Compound **15b** (150 mg) was stirred with acetic acid (1 ml) in water (1 ml) and THF (1.5 ml) at room temperature for 16 h under nitrogen. The mixture was worked up as usual to leave an oily residue (159 mg), showing a single spot on TLC, which was purified by preparative TLC over silica gel with benzene–ether (10 : 1) to yield **14b** in pure state (92 mg), oil; $[\alpha]_D$ +99.1°; MS, *m/e* 234 (M^+), 216, 190 (base), 147, and 122; IR (neat), 3550, 3100, 1676, 1658, 1615, and 890 cm^{-1}; NMR, δ 1.33 (3H, s, 15-H), 1.77 and 1.83 (each 3H, each s, 13- and 14-H), 4.30 (1H, dd, J=12 and 6 Hz, 2β-H), and 4.78 (2H, s). Found: C, 76.91; H, 9.38%. Calcd for $C_{15}H_{22}O_2$: C, 76.92; H, 9.40%.

Compound **16a** (110 mg) was stirred with activated manganese(IV) oxide (500 mg) in dry dichloromethane (10 ml) at room temperature for 24 h. The mixture was worked up as usual to leave an oily residue (120 mg), showing a single spot on TLC, which was purified by preparative TLC over silica gel with benzene to give **15a** (102 mg), oil; $[\alpha]_D$ −162.6°; MS, *m/e* 348 (M^+), 333, and 291; IR (neat), 3100, 1695, 1655, 1620, 1170, and 895 cm^{-1}; NMR, δ 0.10 (3H, s), 0.14 (3H, s), 0.91 (9H, s), 1.77 and 1.80 (each 3H, each s, 13- and 14-H), 1.25 (3H, s, 15-H), 4.22 (1H, dd, J=7 and 10 Hz, 2-H), and 4.79 (2H, s). Found: C, 72.77; H, 10.23%. Calcd for $C_{21}H_{36}O_2Si$: C, 72.41; H, 10.34%.

Compound **15a** (50 mg) was stirred with acetic acid (1 ml) in water (1 ml) and THF (1.5 ml) at room temperature for 16 h under nitrogen. The mixture was worked up as usual to leave an oily residue (61 mg), showing a single spot, which was purified by preparative TLC over silica gel to yield **14a** (43 mg), oil; $[\alpha]_D$ −217.8°; MS, *m/e* 234 (M^+), 216, 190, 147, and 122; IR (neat), 3550, 3105, 1690, 1657 (sh), 1622, and 895 cm^{-1}; NMR, δ 1.23 (3H, s, 15-H), 1.75 and 1.83 (each 3H, each s, 13- and 14-H), 4.21 (1H, dd, J=14 and 6 Hz, 2α-H), 4.76 (2H, s). Found: C, 76.85; H, 9.38%. Calcd for $C_{15}H_{22}O_2$: C, 76.92; H, 9.40%.

*2β-(t-Butyldimethylsilyloxy)-4β,5β-epoxyeudesm-11-en-3β-ol (**18a**) and Its 2α-Epimer (**18b**).* *i)*: To a refluxing green-colored solution of **16a** (1.1 g) in dry benzene (30 ml) containing $VO(acac)_2$ (20 mg) was added rapidly *t*-butyl hydroperoxide (72%, 2 ml), when the solution became red-colored. The solution was further refluxed for 10 min and cooled. The resulting yellow mixture was washed with saturated aqueous sodium thiosulfate, 5% aqueous sodium hydrogencarbonate and water, dried, and evaporated to

leave an oil (1.22 g), showing a single spot on TLC, which was purified by column chromatography over neutral alumina (1 g) with benzene to give **18a** (1.0 g), unstable oil; $[\alpha]_D$ −14.3°; MS, *m/e* 366 (M^+), 351, 291, 217, and 131; IR (neat), 3520, 3060, 1640, 1075, and 900 cm^{-1}; NMR, δ 0.09 (3H, s), 0.11 (3H, s), 0.92 [9H, s, $C(CH_3)_3$], 1.12 (3H, s, 15-H), 1.48 (3H, s, 14-H), 1.76 (3H, s, 13-H), 3.52—3.86 (2H, m, 2α- and 3α-H), and 4.72 (2H, s).

ii): A solution of **16b** (360 mg) in benzene (15 ml) was refluxed with *t*-butyl hydroperoxide (0.6 ml) in the presence of $VO(acac)_2$ (6 mg) for 15 min. The reaction mixture was worked up in the same manner as that of **16a** to leave an oil (405 mg), showing a single spot on TLC, which was purified by column chromatography over neutral alumina (500 mg) with benzene to give **18b** (340 mg), unstable oil; $[\alpha]_D$ −14.2°; MS, *m/e* 366 (M^+), 351, 291, 217, and 131; IR (neat), 3510, 3100, 1651, 1100, 1075, and 895 cm^{-1}; NMR, δ 0.09 (3H, s), 0.11 (3H, s), 0.92 [9H, s, $C(CH_3)_3$], 1.11 (3H, s, 15-H), 1.50 (3H, s, 14-H), 1.75 (3H, s, 13-H), 3.52—3.86 (2H, m), 4.74 (2H, s).

2β-(t-Butyldimethylsilyloxy)-4β,5β-epoxyeudesm-11-ene-3β-ol Mesylate (19a) and Its 2α-Epimer (19b). *i)*: To a solution of **18a** (270 mg) in dry pyridine (1.5 ml) was added methanesulfonyl chloride (0.15 ml). The reaction mixture was stirred at room temperature for 2 h, and then poured into ice–water and extracted with chloroform, repeatedly. The chloroform solution was worked up as usual to leave an oil (320 mg), showing a single spot on TLC, which was purified by chromatography over silica gel (4 g) with benzene to give **19a** (292 mg), solid, $[\alpha]_D$ −28.0°; MS, *m/e* no M^+, 387 [$(M^+ - C(CH_3)_3]$, 349, and 313; IR (neat), 3080, 1640, 1180, 1100, and 875 cm^{-1}; NMR, δ 0.12 (6H, s), 0.90 [9H, s, $C(CH_3)_3$], 1.12 (3H, s, 15-H), 1.50 (3H, s, 14-H), 1.72 (3H, s, 13-H), 3.12 (3H, s, OSO_2CH_3), 3.86 (1H, ddd, J=13, 5, and 4 Hz, 2α-H), 4.72 (2H, s), and 4.85 (1H, dd, J=4 and 2 Hz, 3α-H). Found: C, 59.80; H, 9.39%. Calcd for $C_{22}H_{40}O_5SSi$: C, 59.46; H, 9.01%.

ii): A mixture of **18b** (1.1 g) and methanesulfonyl chloride (0.61 ml) in dry pyridine (6.1 ml) was stirred at room temperature for 3 h. The reaction mixture was worked up in the same manner as that of **18a** to leave crude crystals (1.4 g). showing a single spot on TLC, which were purified by simple column chromatography over silica gel (10 g) with benzene to yield **19b** (1.09 g), mp 105—107 °C (from ether–hexane); $[\alpha]_D$ −38.8°; MS, *m/e* no M^+, 387, 349, and 313; IR (Nujol), 3090, 1655, 1090, 1075, and 895 cm^{-1}; NMR, δ 0.09 (6H, s), 0.89 [9H, s, $C(CH_3)_3$], 1.12 (3H, s, 15-H], 1.49 (3H, s, 14-H), 1.73 (3H, s, 13-H), 4.05 (1H, ddd, J=10, 9, and 4 Hz, 2β-H), 4.68 (1H, d, J=9 Hz, 3α-H), and 4.73 (2H, s). Found: C, 59.91; H, 9.19%. Calcd for $C_{22}H_{40}O_5SSi$: C, 59.46; H, 9.01%.

2β-(t-Butyldimethylsilyloxy)eudesma-3,11-dien-5β-ol (20a) and Its 2α-Epimer (20b). *i)*: To a mixture of **19a** (200 mg) in ammonia (10 ml) and dry THF (4 ml) was added sodium (40 mg, 4-fold excess) at −50 °C (bath temp), when the blue color appeared. The reaction mixture was stirred for 5 min, and then ammonium chloride was added until the blue color disappered. After removal of ammonia and THF, the residue was diluted with cold-water and extracted with chloroform. The chloroform solution was worked up as usual to leave an oil (171 mg), showing a single spot on TLC, which was purified by simple column chromatography over silica gel (2 g) with chloroform to give **20a** (140 mg), oil; $[\alpha]_D$ +9.0°; MS, *m/e* 350 (M^+), 332, 293, and 131; IR (neat), 3450, 3060, 1637, 1060, and 880 cm^{-1}; NMR, δ 0.08 (6H, s), 0.90 [9H, s, $C(CH_3)_3$], 1.02, 1.70, and 1.72 (each 3H, each s, 15-, 13-, and 14-H), 4.30 (1H, br m, 2α-H), 4.65 (2H, s), and 5.44 (1H, br, W_H=6 Hz, 3-H). Found: C, 72.33; H, 10.93%. Calcd for $C_{21}H_{38}O_2Si$: C, 72.00; H, 10.86%.

ii): Compound **19b** (72 mg) was reduced under the same Birch conditions (sodium, 15 mg, THF, 3 ml, and ammonia, 8 ml) as described above to give **20b** (45 mg), oil; $[\alpha]_D$ +71.7°; MS, *m/e* 350 (M^+), 332, 293, and 131; IR (neat), 3500, 3095, 1650, 1055, and 890 cm^{-1}; NMR, δ 0.08 (6H, s), 0.91 [9H, s, $C(CH_3)_3$], 1.05, 1.76, and 1.78 (each 3H, each s, 15-, 13-, and 14-H), 4.18 (1H, br, W_H=12 Hz, 2β-H), 4.76 (2H, s), and 5.56 (1H, br, W_H=12 Hz, 3-H). Found: C, 72.29; H, 11.24%. Calcd for $C_{21}H_{38}O_2Si$: C, 72.00; H, 10.86%.

Eudesma-3,11-diene-2β,5β-diol (21a) and Its 2α-Epimer (21b). *i)*: Compound **20a** (150 mg) was stirred with acetic acid (1 ml) in water (1 ml) and THF (2 ml) at room temperature for 16 h. The mixture was worked up as usual to leave crude crystals (120 mg), showing a single spot on TLC, which were purified by preparative TLC over silica gel with etheyl acetate–hexane (3 : 1) to give **21a** (90 mg), mp 170—171 °C (from ether); $[\alpha]_D$ +48.3°; MS, *m/e* 236 (M^+), 218, and 200; IR (Nujol), 3500, 1635, and 885 cm^{-1}; δ 1.24, 1.70, and 1.76 (each 3H, each s, 15-, 13-, and 14-H), 4.18 (1H, br dd, J=10 and 6 Hz, 2α-H), 4.68 (2H, s), and 5.52 (1H, br s, W_H=5 Hz, 3-H). Found: C, 75.93; H, 10.16%. Calcd for $C_{15}H_{24}O_2$: C, 76.27; H, 10.17%.

ii): Compound **29b** (50 mg) was stirred with acetic acid (0.5 ml) in water (0.5 ml) and THF (1 ml) at room temperature for 19 h. The mixture was worked up as uaual to leave a gum (45 mg), showing a single spot on TLC, which was purified by preparative TLC over silica gel with ethyl acetate–hexane (3 : 1) to give **21b** (27 mg), gum, $[\alpha]_D$ +108.4°; MS, *m/e* 236 (M^+), 218, and 200; IR (neat), 3450 (br), 3110, 1650, and 890 cm^{-1}; NMR, δ 1.07, 1.75, and 1.83 (each 3H, each s, 15-, 13-, and 14-H), 4.30 (1H, br, W_H=16 Hz, 2β-H), 4.76 (2H, s), and 5.72 (1H, br, W_H=7.5 Hz, 3-H). Found: C, 75.81; H, 10.21%. Calcd for $C_{15}H_{24}O_2$: C, 76.27; H, 10.17%.

Conversion of 21a and 21b into (+)-β-Rotunol (1). *i)*: Compound **21a** (1 g) was stirred with activated mangnanese-(IV) oxide (4.8 g) in dry dichloromethane (85 ml) at room temperature for 16 h. The reaction mixture was filtered through a Celite column. The filtrate was evaporated to leave crude crystals (1.1 g), showing a single spot on TLC, which were purified by preparative TLC with ethyl acetate–hexane (1 : 2) to give **1** (844 mg), mp 117—119 °C (needles from ether); $[\alpha]_D$ +41.4°; MS, *m/e* 234 (M^+), 216, 173, and 111; IR (Nujol), 3450, 3090, 1625 (sh), and 890 cm^{-1}; NMR, δ 1.15, 1.75, and 2.00 (each 3H, each s, 15-, 13-, and 14-H), 2.08 and 2.72 (each 1H, ABq, J=17 Hz, 1-H), 4.74 (2H, s), and 5.88 (1H, br s, W_H=4 Hz, 3-H).

ii): Compound **21b** (35 mg) was stirred with activated manganese(IV) oxide (300 mg) in dry dichloromethane (5 ml) at room temperature for 16 h. The reaction mixture was worked up in the same manner as that of **21a** to give **1** (29 mg), mp 116—118 °C (needles from ether), whose spectral data ($[\alpha]_D$, MS, IR, NMR) were identical with those obtained from **21a**. These synthetic samples of β-rotunol (**1**) were completely identical with a sample of the natural compound in the spectral data: natural sample, mp 118—119 °C (needles); $[\alpha]_D$ +44.8° ($CHCl_3$); MS, *m/e* 234, 216, 173, and 111; IR (Nujol), 3450, 3100, 1640, and 890 cm^{-1}; NMR, δ 1.15 (3H, s, 15-H), 1.74 (3H, t, J=1 Hz, 13-H), 1.99 (3H, d, J=1 Hz, 14-H), 2.07 and 2.71 (each 1H, ABq, J=17 Hz, 1-H), 4.75 (2H, q, J=1 Hz, 12-H), and 5.89 (1H, q, J=1 Hz, 3-H).

Eudesma-2,4,11-triene (24). A solution of **3** (248 mg, 1 mmol) in THF (5 ml) containing tosylhydrazine (186 mg, 1 mmol) and concd hydrochloric acid (one drop) was heated under reflux for 7 h. After addition of benzene (10 ml), the mixture was evaporated to remove THF, until the boiling

point became 80 °C, and cooled with an ice-bath. To the benzene solution was added methyllithium [0.7 M in ether (3.2 ml), 2.24 mmol], when nitrogen gas was evolved. The reaction was continued by stirring at room temperature for 30 min and ceased by addition of water. The whole mixture was extracted with hexane (3×20 ml), washed with water, dried, and evaporated to leave oily residue (260 mg), which was purified by column chromatography over silica gel with hexane–ethyl acetate (9 : 1) to give **24** (170 mg), oil; $[\alpha]_D$ +170.2°; MS, *m/e* 202 (M^+), 187, and 131 (base); UV_{max}, 266 nm (log ε 3.79) and 208 (3.78); IR (neat), 3100, 3050, 1650, 1590, 890, and 720 cm^{-1}; NMR, δ 0.93 and 1.71 (each 3H, s, 15- and 13-H), 1.76 (3H, t, J=2, 14-H), 4.72 (2H, s, 12-H), and 5.67 (2H, s, 2- and 3-H). Found: C, 88.89; H, 10.88%. Calcd for $C_{15}H_{22}$: C, 89.04; H, 10.96%.

*Transformation of **24** into α-Rotunol (**2**).* To a solution of **24** (50 mg, 0.216 mmol) in dichloromethane (25 ml) cooled at −78 °C was added rapidly tungsten(VI) chloride (17 mg, 0.043 mmol) under nitrogen. Into the mixture was passed oxygen gas under vigorous stirring in the dark for 2 h. The reaction mixture was then kept at room temperature for 10 min, mixed with water, and extracted with ether (3× 20 ml). The ether solution was washed, dried and evaporated to leave oily crude peroxide (**25**), (64 mg), which without further purification was treated with alumina (Merck, activ basisch, Type E, Activitätsstufe I, 1.6 g) in ether at room temperature for 16 h. The mixture was filtered and the insoluble alumina was washed with ether repeatedly. The combined ether solutions were dried and evaporated to give crude **2** (60 mg), which was purified by preparative TLC over silica gel with hexane–ethyl acetate (3 : 1) to afford **2** (51 mg) in pure state, mp 102—104 °C (from ethyl acetate–hexane); $[\alpha]_D$ +53°; UV_{max} 235 nm (log ε 4.20); IR ($CHCl_3$), 3480, 3100, 1660, 1630 (sh), and 890 cm^{-1}; NMR, δ 1.04 and 1.77 (each 3H, each s, 15- and 13-H), 1.96 (3H, d, J=11 Hz, 14-H), 2.72 (1H, d, J=17 Hz, 1-H), 4.77 (2H, s, 12-H), and 5.81 (1H, s, 3-H).

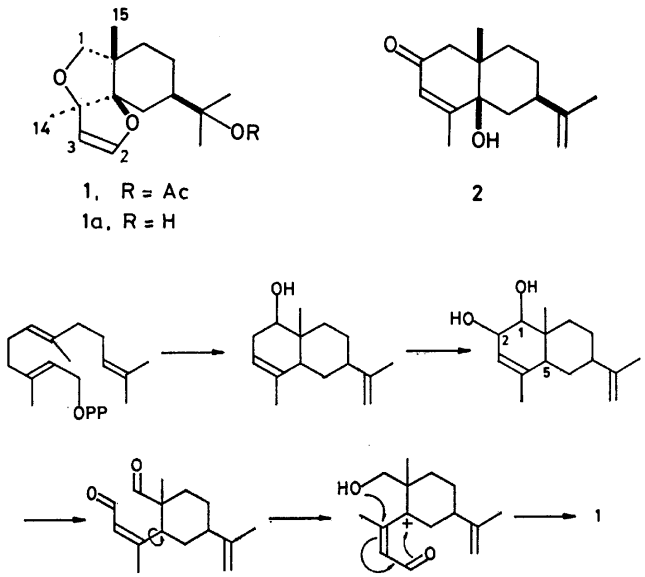
Synthesis of Phytuberin[1]

Akio MURAI, Mitsunori ONO, and Tadashi MASAMUNE*
Department of Chemistry, Faculty of Science, Hokkaido University, Sapporo 060
(Received September 11, 1981)

The first synthesis of phytuberin, which mimics the proposed biogeneses in critical stages, is described. The synthesis also establishes the absolute configuration.

The title compound, phytuberin (**1**), is a potential substance for an effective resistance in diseased potatoes[2] and a representative phytoalexin together with rishitin[3] in the genus *Solanum*. The sesquiterpene was first isolated in 1970 by Varns and Kuć[4] from infected potato tuber tissues (*Solanum tuberosum*), and the structure and relative configuration were determined in 1974 on the basis of the X-ray crystallographic analysis of dihydrophytuberin by Coxon and coworkers.[5] In view of the novel structure characterized by the presence of two hydrofuran rings and the biological importance, **1** is believed to be a subject of intense synthetic investigation. In a preliminary communication[6,7] we reported the synthesis of the compound, which mimics the proposed biogeneses[5,8] (*e.g.*, Scheme 1) in critical stages. The present paper describes details of the transformation of β-rotunol (**2**) into **1**, which, coupled with the synthesis[1] of **2**, completes the synthesis of the title compound.



Scheme 1.

Results and Discussion

The proposed biogeneses[5,8] suggested that phytuberin (**1**) would probably be biosynthesized *via* formation of a C-5 and C-1 and/or C-2 oxygenated eudesmane from farnesyl pyrophosphate and subsequent cleavage of the C-1–C-2 bond followed by recyclization. β-Rotunol (**2**) is an eudesmane with oxo- and hydroxyl groups at C-2 and C-5 and hence a starting material suitable for the relevant cleavage and recyclization. Transformation of **2** into **1** was commenced by oxygenation at C-1; namely, **2** was oxidized under the Vedejs conditions[9] to give 1β,5β-diol (**3**) in 57% yield as a single product. Configuration of the hydroxyl group at C-1 was deduced from the formation of acetonide (**4**) by treatment with acetone in the presence of Amberlyst 15 at room temperature for 1 h. Contrary to the expectation, all attempted oxidative cleavage ($NaIO_4$ in aq THF, $Pb(OAc)_4$ in pyridine, or HIO_4 in aq THF) of the α-ketol (**3**) failed, the isopropenyl group being not left intact. Considering the lability of the isopropenyl group under the conditions, **4** was first converted into the corresponding 11,12-epoxide (**5**) by treatment with *m*-chloroperbenzoic acid in a heterogeneous mixture of 5% aqueous sodium hydrogencarbonate and dichloromethane. Reduction of the epoxy group of **5** with hydride reagents was examined under various conditions. The aimed reduction was achieved by treatment of **5** with lithium aluminium hydride (LAH) in a 5 : 2 mixture of 1,2-dimethoxyethane (DME) and tetrahydrofuran (THF) *in an inverse addition manner*, giving tetrahydroxyeudesmane (**6**) in 56% yield from **3**. Smooth oxidative cleavage of the 1,2-diol system was accomplished by treatment of **6** with lead(IV) acetate in dry pyridine at room temperature. The reaction proceeded as expected to afford the relevant formyl γ-lactone (**7**) in a single step in 80% yield. The structure of **7** was assigned clearly on the basis of the spectral data. The mass spectrum displayed parent and fragmentation peaks at *m/e* 266 and 248 (M^+-H_2O). The IR spectrum (2710, 1755, 1720, and 1630 cm^{-1}) revealed the presence of a five-membered lactone and a formyl group. The NMR spectrum exhibited a six-proton singlet at δ 1.19, two three-proton singlets at δ 1.35 and 2.16, and a one-proton singlet at δ 9.36, which were readily assignable to the protons at 12-, 13-, 15-, 14-, and 1-carbon atoms,[10] respectively. Formation of **7** would involve oxidation of an hemiacetal intermediate (**8**) with excess lead(IV) acetate.

The final and most serious problem for the construction of phytuberin skeleton consisted in stereoselective formation of the A and B rings. Owing to difficulty of regioselective reduction of only the hindered formyl group, it was undertaken to reduce simultaneously both the formyl and lactone carbonyl groups. Treatment of the formyl γ-lactone (**7**) with diisobutylaluminium hydride (DIBAH) (3.5 mol equiv.) in DME followed by usual work-up effected reduction of the two relevant carbonyl groups followed by cyclization to two hydrofuran rings, giving alcohol, oil and $[\alpha]_D$ −40.6°, in a single step in 83% yield. The alcohol was converted smoothly into the acetate, oil and $[\alpha]_D$ −38.8°, in 84% yield by treatment with acetic anhydride and triethylamine in the presence of 4-(dimethylamino)pyridine at

room temperature. The alcohol and acetate were identified as phytuberol (**1a**) and phytuberin (**1**), respectively, by direct comparison of the synthetic and natural samples. The result constitutes the first synthesis of phytuberin, and also establishes the undecided absolute configuration of these sesquiterpenes.

Experimental

All the melting points were uncorrected. The homogeneity of each compound was always checked by TLC over silica gel (Wakogel B-5) with various solvent systems, the spots being developed with cerium(IV) sulfate in diluted sulfuric acid and/or iodine. The optical rotations, UV and NMR (100 MHz) spectra were measured in chloroform, ethanol, and chloroform-*d* respectively, unless otherwise stated.

1β-Hydroxy-β-rotunol (3). To a solution of diisopropylamine (0.24 ml, 1.3 mmol) in dry THF (3 ml) cooled at −78 °C was added dropwise butyllithium in hexane (0.94 ml, 1.3 mmol) under nitrogen, and the solution was stirred at 0 °C for 15 min. To the solution cooled at −78 °C was added a solution of β-rotunol (**2**) (138 mg, 0.52 mmol) in dry THF (3 ml). To the reaction mixture, stirred at −78 °C for 1 h, was added rapidly molybdenum peroxide (MoOPH) (738 mg, 1.3 mmol). The whole mixture was stirred continuously for 1 h at −78 °C and then at room temperature for 30 min. After being treated with water, the reaction mixture was concentrated *in vacuo* to leave oily residue, which was extracted with ethyl acetate, repeatedly. The acetate solution was washed with 2 M† hydrochloric acid, saturated sodium hydrogencarbonate, and water, dried, and evaporated to leave an oil (141 mg), which was separated by chromatography over preparative TLC over silica gel with ethyl acetate–hexane (1 : 2). Fractions (70 mg) with higher R_f value, showing a single spot on TLC, afforded **3** with low mp; $[\alpha]_D$ +27.6°; MS, *m/e* 250 (M^+), 232, and 111; IR (neat), 3400 (br), 3100, 1680, 1630, and 890 cm^{-1}; NMR, δ 1.28 (3H, s, 15-H), 1.80 and 2.04 (each 3H, each s, 13- and 14-H), 3.60 (1H, br s, 1α-H), 4.76 (2H, br s), and 5.88 (1H, s, 3-H). Found: C, 71.77; H, 8.45%. Calcd for $C_{15}H_{22}O_3$: C, 72.00; H, 8.80%. Fractions (24 mg) with lower R_f value, showing a single spot on TLC, afforded the unreacted starting material (**2**). Acetate of **3**, oil; MS, *m/e* 292 (M^+), 274, 234, 214; IR (neat), 1745 cm^{-1}; NMR, δ 2.19 (3H, s, $OCOCH_3$), and 4.96 (1H, s). Acetonide (**4**) of **3**, mp 125—129 °C; IR (Nujol), 1696, 1663, 1645, 1405, 1200, 1155, and 1100 cm^{-1}; NMR, δ 0.79 (3H, s, 15-H), 1.30 and 1.41 [each 3H, s, $(CH_3)_2$], 1.94 (9H, s, 12-, 13-, and 14-H), 3.51 (1H, s, 1α-H), and 5.92 (1H, br s, W_H= 5 Hz, 3-H).

1β-Hydroxy-11,12-epoxy-β-rotunol (5). Compounds **3** (55 mg, 0.22 mmol) was stirred with *m*-chloroperbenzoic acid (45.6 mg) in a heterogeneous mixture of dichloromethane (5 ml) and 5% aqueous sodium hydrogencarbonate (5 ml) at −15 °C for 4 h. The reaction mixture was washed with 5% aqueous sodium thiosulfate and water, dried, and evaporated to leave amorphous residue (**5**)(58 mg), showing a single spot on TLC: MS *m/e* 266 (M^+), and 248; IR (neat), 3380, 1680, 1625, 1020, and 910 cm^{-1}; NMR, δ 1.24, 1.32, and 2.00 (each 3H, 15-, 13-, and 14-H), 2.62 (2H, br s, W_H=9 Hz, 12-H), 3.50 (1H, br s, 1α-H), and 5.84 (1H, s, 3-H). This was used for the next reaction without purification because sample of unstability.

Eudesm-3-ene-1β,2ξ,5β,11-tetrol (6). To a stirred solution of **5** (83 mg) in dry DME (5 ml) at −78 °C was added dropwise a suspension (3 ml) of LAH (100 mg) in dry THF (5 ml) during 15 min. The mixture was stirred at room temperature for 2 h, mixed with water (0.5 ml) and 5% aqueous sodium hydroxide (0.5 ml), and was filtered. The filtrate was dried and evaporated to leave amorphous residue (85 mg), which was purified by column chromatography (3 g) over silica gel with ethyl acetate–hexane (4 : 1) to give **6** (77 mg), gum; MS, *m/e* 270 (M^+), 252, and 234; IR (neat), 3580, 3500, and 1620 cm^{-1}; NMR, δ 1.12 (6H, s, 12- and 13-H), 1.20 and 1.22 (total 3H, each s, 14-H), 3.56 (1H, br s, W_H=5 Hz, 1α-H), 4.14 (1H, br, W_H= 10 Hz, 2-H), 5.35 and 5.56 [total 1H (1 : 3), each br, W_H=5 and 9 Hz, 3-H]. Found: C, 66.88; H, 9.55%. Calcd for $C_{15}H_{26}O_4$: C, 66.67; H, 9.63%.

4,6β-Dimethyl-6α-formyl-9β-(2-hydroxy-2-methyl)ethyl-1-oxaspiro-[4.5]dec-3-en-2-one (7). To a stirred solution of **6** (40 mg) in dry pyridine (3 ml) was added lead(IV) acetate (recrystallized freshly from acetic acid, 295 mg) at room temperature. The reaction mixture was stirred for 30 min and, after addition of oxalic acid (950 mg) and water (2 drops) to decompose excess of the reagent, was submitted to filtration. The filtrate was diluted with water and extracted with ethyl acetate, repeatedly. The acetate solution was washed with 2 M hydrochloric acid, saturated sodium hydrogencarbonate, and water, dried, and evaporated to leave an oil (42 mg), showing a single spot on TLC, which was purified by preparative TLC over silica gel with ethyl acetate–hexane (2 : 1) to yield **7** (32 mg), oil; MS, *m/e* 266 (M^+) and 248; IR (neat), 3480, 2710, 1755, 1720, 1630, and 1380 cm^{-1}; NMR,[10] δ 1.19 (6H, s, 12- and 13-H), 1.35 and 2.16 (each 3H, each s, 15- and 14-H), 5.66 (1H, s, 3-H), and 9.36 (1H, s, 1-H). Found: C, 68.00; H, 8.55%. Calcd for $C_{15}H_{22}O_4$: C, 67.67; H, 8.27%.

Phytuberol (1a). To a stirred solution of **7** (17 mg, 0.064 mmol) in dry DME (5 ml) was added DIBAH in hexane (0.13 ml, 0.224 mmol) at −78 °C under nitrogen. The whole reaction mixture was stirred at −78 °C for 30 min,

† 1 M=1 mol dm^{-3}.

at −20 °C for 30 min, and then at 0 °C for 30 min. The reaction was quenched by addition of water (10 drops), and the mixture was diluted with 2 M hydrochloric acid and extracted with ether, repeatedly. The ether solution was washed with saturated sodium hydrogencarbonate and water, dried, and evaporated to leave colorless oil (21 mg), showing a single spot on TLC [ethyl acetate–hexane (1 : 1)], which was purified by preparative TLC over silica gel with ethyl acetate–hexane (1 : 1) to yield **1a** (13 mg), oil; $[\alpha]_D$ −40.6°; MS, *m/e* 252 (M^+) and 234; IR (neat), 3490, 3090, 1625, 1153, 1088, 1040, 1027, and 735 cm^{-1}; NMR, δ 1.00 and 1.55 each 3H, s, 15- and 14-H), 1.20 (6H, s, 12- and 13-H), 3.24 and 3.39 (each 1H, ABq, J=8 Hz, 1-H), 4.66 and 6.42 (each 1H, d, J=2.8 Hz, 3- and 2-H). Natural sample,[5] oil, $[\alpha]_D$ −36.9°; MS, *m/e* 252.1710; IR (neat), 3440, 3080, 1624, 1153, 1088, 1040, 1027, and 735 cm^{-1}; NMR, δ 0.99 and 1.53 (each 3H, s), 1.18 (6H, s), 3.23 and 3.37 (each 1H, ABq, J=8.5 Hz), 4.64 and 6.41 (each 1H, d, J=2.8 Hz).

Phytuberin (1). A mixture of **1a** (12 mg), acetic anhydride (0.5 ml), and 4-(dimethylamino)pyridine (2 mg) in dry triethylamine (2 ml) was stirred at room temperature for 16 h. The mixture was diluted with water and extracted with ether. The ether solution was worked up as usual to leave colorless oil (14 mg), showing a single spot on TLC, which was purified by preparative TLC over silica gel with ethyl acetate–hexane (1 : 4) to yield **1** (9.8 mg), oil; $[\alpha]_D$ −38.8°; MS, *m/e* 294 (M^+), 249, 234, 219, 205, 189, and 107; IR (neat) 3085, 1730, 1625, 1262, 1154, 1080, and 732 cm^{-1}; NMR, δ 1.02, 1.45, 1.48, and 1.57 (each 3H, s, 15-, 12-, 13-, and 14-H), 1.99 (3H, s, $OCOCH_3$), 3.28 and 3.42 (each 1H, ABq, J=8 Hz, 1-H), 4.68 and 6.44 (each 1H, d, J=3 Hz, 3- and 2-H). Natural sample,[5] oil; $[\alpha]_D$ −35.9°; MS, *m/e* 294.1849; 294, 249, 234, 219, 205, 191, 189, 149, and 107; IR (neat), 3080, 1728, 1620, 1260, 1088, and 735 cm^{-1}; NMR, δ 1.02, 1.44, 1.47, and 1.56 (each 3H, s), 1.99 (3H, s), 3.28 and 3.41 (each 1H, ABq, J=8.5 Hz), 4.68 and 6.44 (each 1H, d, J=2.8 Hz).

Reaction of 1-Lithio-1-arylthio(or alkylthio)methyltrimethylsilane with Acid Derivatives. A Novel Synthesis of Functionalized Vinyl Sulfides

Toshio AGAWA,* Minori ISHIKAWA, Mitsuo KOMATSU, and Yoshiki OHSHIRO

Department of Petroleum Chemistry, Faculty of Engineering, Osaka University, Yamada-oka 2-1, Suita, Osaka 565

(Received September 28, 1981)

Reactions of 1-lithio-1-phenylthiomethyl- (**1a**) and 1-lithio-1-methylthiomethyltrimethylsilane (**1b**) with amides, an ester, acid anhydrides, a urea, and a carbonate are described which provide useful routes to functionalized vinyl sulfides. The reaction of **1** with amides gave β-functionalized vinyl sulfides, 1-dialkylamino-2-phenylthio (or methylthio)ethylenes, in 40—95% yields and the reaction could be extended to the sulfonyl derivatives of **1** to afford 1-dialkylamino-2-phenylsulfonyl(or methylsulfonyl)ethylenes. Although ethyl benzoate and some acid anhydrides were not good substrates for this reaction, tetramethylurea and diethyl carbonate gave α-functionalized vinyl sulfides, 1-amidovinyl- and 1-(ethoxycarbonyl)vinyl sulfides, in moderate yields when treated with **1a** followed by addition of benzaldehyde.

Olefin-forming reaction of α-metallosilanes is known as the Peterson reaction and plays an important role in organic synthesis. For example, 1-lithio-1-arylthio-(or alkylthio)methyltrimethylsilanes **1** react with ketones to give vinyl sulfide derivatives.[1] However, only a few reports mention this type of reactions of the α-metallosilanes **1** with acid derivatives,[2] since they are in general not good substrates for the Peterson olefination.

In our preliminary report we briefly described the reaction of the α-lithiosilanes **1** with several amides which provided a new synthetic method for 2-aminovinyl sulfides.[3] We further investigated the reaction using acid derivatives and found that these reactions can be utilized for preparation of various functionalized vinyl sulfides.

Since vinyl sulfides are very versatile reagents as masked carbonyl compounds,[4] these functionalized vinyl sulfides are expected to have more potential in organic synthesis.[5]

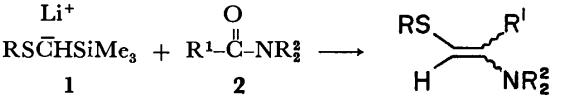
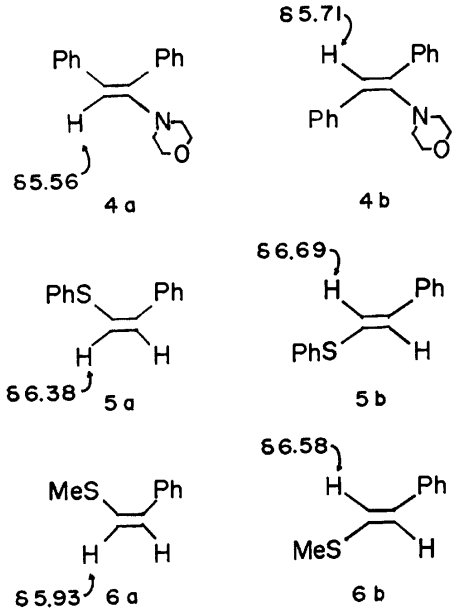
ated by treating phenylthiomethyltrimethylsilane with butyllithium at 0 °C in THF was reacted with *N,N*-dimethylformamide at the same temperature and was allowed to stand overnight. Usual work-up of the reaction mixture gave 64% of (*E*)-1-dimethylamino-2-phenylthioethylene (**3a**). In this reaction only the (*E*)-isomer was obtained and the structure was determined by spectral data and elemental analysis. Similarly several 2-aminovinyl sulfides were obtained from the α-lithiosilanes **1** and amides **2** in good yields under very mild conditions and the results are summarized in Table 1.



1a: R=Ph
1b: R=Me

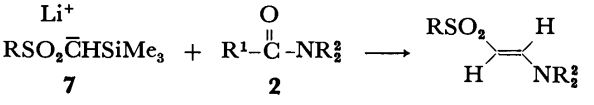
In most cases a mixture of (*E*)- and (*Z*)-isomers was obtained and the ratio was determined by NMR spectroscopy. Estimation of the coupling constant between the phenyl carbon and the vinyl proton ($^3J_{CH}$) by ^{13}C-NMR measurement under selective irradiation of the phenyl protons was tried. However, the values for the compounds **3c** (the major isomer only) and **3e** were ≃7 cps which was not decisive for determination of (*E*)- or (*Z*)-form of olefinic compounds. The assignment of (*E*)- and (*Z*)-isomers of the compounds **3c**—**f** was done by comparison of the chemical shifts of the vinyl protons with those of the known compounds **4**,[6] **5**,[7] and **6**.[8] Thus the isomer which



shows the vinyl proton signal in the higher field is determined to be the (*E*)-isomer of **3** (the vinyl proton is *trans* to the phenyl ring) and the other is the (*Z*)-isomer. For the vinyl sulfide **3b**, the methyl group which appears in the lower field is suggested to be that of the (*Z*)-isomer by comparing chemical shifts of the alkylamino groups of **3c** and **3d**. Hence the major product of the reaction was found to be an (*E*)-isomer except for the case of **3b**.

Although the sterically less favorable (*E*)-isomers were predominant, this result is consistent with the observation that **4a**, sterically less favorable, is thermodynamically more stable than **4b**, which is sterically less crowded.[6] This phenomenon was explained by the continuous overlap between the electron pair on the nitrogen atom and the phenyl group in its polar resonance form[9] and the same reason can be applied to the predominance of the (*E*)-isomers in this reaction. The only exception observed for **3b** may be ascribed to the large steric repulsion caused by the bulky *t*-butyl group which suppressed the formation of the (*E*)-isomer.

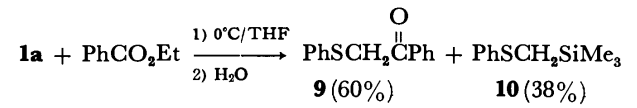
Extension of the reaction to sulfone derivatives was successful. The reaction of 1-lithio-1-phenylsulfonyl(or methylsulfonyl)methyltrimethylsilane **7** with amides **2** gave 2-aminovinyl sulfones **8** and the results are listed



7a: R=Ph
7b: R=Me

in Table 1. Method of lithiation and reaction conditions are different from the preceding reactions (see Experimental). Contrary to the α-phenylthiosilane **1a**, the corresponding phenylsulfonylsilane **7a** gave very poor yields of vinyl sulfones when treated with less reactive amides such as *N,N*-dimethylbenzamide and *N*-benzoylpiperidine. Oxidation of the aminovinyl sulfides to sulfones were also examined, but it was difficult to isolate or to purify the oxidized products. Thus the present reaction is one of the better routes to 2-aminovinyl sulfones.

Reaction with Ester and Acid Anhydride. Reaction of the α-lithiosilane **1a** with ethyl benzoate was carried out in a similar manner to the reaction with amides, and α-phenylthioacetophenone (**9**) was obtained in 60% yield with considerable amount of the starting phenylthiomethylsilane **10**. The anticipated product, 2-ethoxyvinyl sulfide, was not formed at all or the sulfide is quite sensitive to hydrolysis even under basic conditions, since no vinyl proton signals were detected in the NMR spectrum of the reaction mixture immediately after the quenching. Addition of benzaldehyde or

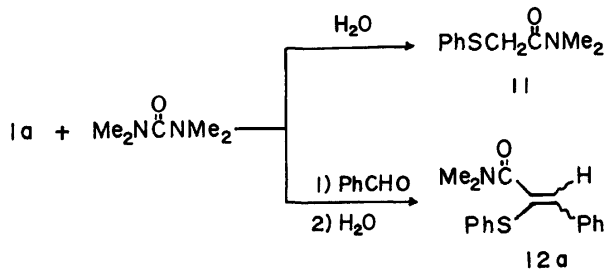


successive addition of lithium diisopropylamide and the aldehyde to the reaction mixture before the quenching was also carried out, but no vinyl sulfide derivatives were detected. Hence, it is not possible that the initial product of the reaction was an acylated phenylthiomethyltrimethylsilane which corresponds to **16** or **18** in Scheme shown later.

Similar reaction of the silane **1a** with benzoic anhydride gave only a small amount of α-phenylthioacetophenone (**9**) and the most part of **1a** was recovered as the starting phenylthiomethylsilane **10**. Some cyclic acid anhydrides such as phthalic anhydride and maleic anhydride were found to be quite unreactive with **1a**.

$$\mathbf{1a} + (PhCO)_2O \xrightarrow[2)\,H_2O]{1)\ rt/THF} \mathbf{9}(18\%) + \mathbf{10}(77\%)$$

Reaction with Urea and Carbonate. The α-lithiosilane **1a** was treated with tetramethylurea at room temperature to give *N,N*-dimethyl-α-phenylthioacetamide (**11**) in 56% yield. As it was likely that the reaction proceeded *via* substitution of the dimethylamino group, benzaldehyde was added to the reaction mixture and was allowed to stand for one day at room temperature. The product was *N,N*-dimethyl-α-phenylthiocinnamamide (**12a**, 41%) and thus one pot synthesis of an 1-amidovinyl sulfide was found. The same treatment of the methylthiomethylsilane **1b** and the urea gave *N,N*-dimethyl-α-methylthiocinnamamide (**12b**, 27%).



Similarly, the silane **1a** reacted with diethyl carbonate to afford ethyl α-phenylthiocinnamate (**13**) after addition of benzaldehyde. The yield was increased by addition of an equimolar amount of lithium diisopropylamide (LDA) because of its higher basicity than that of lithium ethoxide generated by substitution.

$$\mathbf{1a} + EtO\text{-}\overset{O}{\overset{\|}{C}}\text{-}OEt \longrightarrow$$

$$[PhSCH(SiMe_3)CO_2Et + EtOLi] \xrightarrow{LDA}$$

13 (59%)

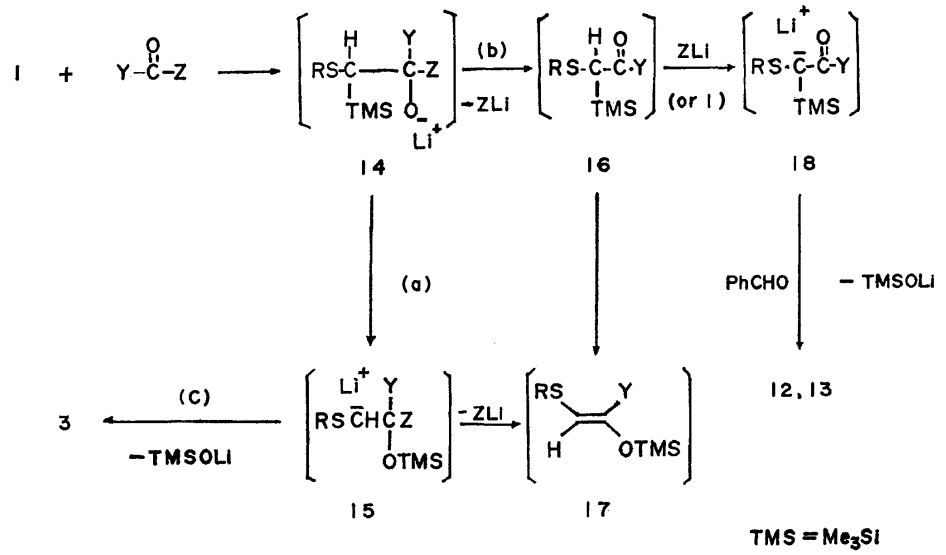
The paths for the whole reactions are assumed to be as shown in Scheme 1. The two paths from the initially formed intermediate **14** is considered to be controlled by the nature of the substituents Y and Z. When Y is not a hetero-atom substituent, rearrangement of the intermediate **14** to **15** occurs to form an olefinic compound **3** or **17**. Thus the reaction with an amide proceeded *via* the paths (a) and (c). On the other hand, the path (b) seems to be predominant when both Y and Z are hetero atoms such as the urea and the carbonate. Formation of 1-acylvinyl sulfides on addition of benzaldehyde implies the intermediacy of **18** and excludes the formation of **11** by hydrolysis of a 1,1-diaminoethylene corresponding to **3**. The path for the reaction with the ester, however, is not clear at the moment. The result that no olefinic product was obtained by addition of lithium diisopropylamide and benzaldehyde suggests less possibility of the formation of **16** or **18**. But we cannot exclude the formation of α-phenylthioacetophenone (**9**) by hydrolysis of a vinyl ether **3** or a silyl ether **17**.

Experimental

Boiling points were uncorrected. A melting point was determined on a Yanagimoto micro melting point apparatus and was uncorrected. ^1H and ^{13}C NMR spectra were obtained with JEOL JNM PMX-60 and JNM FX-90Q FT spectrometers using TMS as an internal standard. IR spectra were taken on a JASCO IRA-1 spectrophotometer. Mass spectrometry was performed on a Hitachi RMU-6E spectrometer at an ionizing voltage of 70 eV.

All experiments were carried out under a dry nitrogen atmosphere.

Materials. Commercially available butyllithium, ethyl benzoate, tetramethylurea, diethyl carbonate, and *N,N*-dimethylformamide were used. The other amides were prepared by the reaction of the corresponding acid chlorides and the amides and purified by distillation except for *N*-benzoylaziridine. Isopropylamine and THF were dried and distilled by the usual method. Phenylthiomethyltrimethylsilane, methylthiomethyltrimethylsilane, phenylsuflonylmethyltrimethylsilane, and methylsulfonylmethyltrimethylsilane



Scheme 1.

were prepared by silylation of methyl phenyl sulfide, dimethyl sulfide, methyl phenyl sulfone, and dimethyl sulfone with triemethylsilyl chloride, respectively, by the known method.[10]

General Procedure for the Reactions of the Silanes **1** *with Acid Derivatives.* To a stirred solution of phenylthio(or methylthio)methyltrimethylsilane (**1**, 5.0 mmol) in THF (5 ml) was added butyllithium (3.8 ml of 15% hexane solution, 6.0 mmol) at 0—5 °C, and the solution was stirred for 2 h at room temperature. An acid derivative (5.0 mmol) in THF (5 ml) was added at 0—5 °C and the stirring was continued for 2 h at the same temperature. The mixture was stood overnight at room temperature, quenched with water after cooling, and extracted (ether). The oragnic layer was dried (Na_2SO_4) and evaporated to give a crude product, which was isolated and purified by distillation and/or chromatography on silica gel. 1-Dialkylamino-2-phenylthio(or methylthio)-ethylenes **3** could be purified only by distillation because of their ready hydrolysis. Hence, some of their elemental analyses were unsatisfactory.

*1-Dimethylamino-2-phenylthioethylene (**3a**)*: Found: C, 66.88; H, 7.43; N, 7.53; S, 18.15%. Calcd for $C_{10}H_{13}NS$: C, 67.02; H, 7.31; N, 7.82; S, 17.86%.

*α-Dimethylamino-β-phenylthiostyrene (**3c**)*: ^{13}C NMR ($CDCl_3$) δ 40.7 (q), 86.8 (d, =CHS–), 158.2 (s, =CPh), and aromatic carbons at δ 123.9, 125.2, 127.6, 127.9, 128.2, 128.8, 136.6 and 141.2. Found: C, 75.17; H, 6.72; N, 5.54; S, 12.38%. Calcd for $C_{16}H_{17}NS$: C, 75.27; H, 6.71; N, 5.49; S, 12.53%.

*β-Phenylthio-α-piperidinostyrene (**3e**)*: ^{13}C NMR ($CDCl_3$) δ 24.5 (t), 25.8 (t), 50.2 (t), 91.2 (d, =CHS–), 158.2 (s, =CPh), and aromatic carbons at δ 124.4, 126.0, 127.8, 128.3, 128.5, 129.3, 137.1, and 140.7. Found: C, 76.81; H, 7.04; N, 4.54; S, 10.90%. Calcd for $C_{19}H_{21}NS$: C, 77.26; H, 7.12; N, 4.74; S, 10.83%.

*α-Phenylthioacetophenone (**9**)*: Bp 120 °C/1.0 mmHg by pot distillation; IR (neat) 1680 cm^{-1} (C=O); ^1H NMR ($CDCl_3$) δ 4.30 (2H, s, CH_2), 7.1—7.5 (8H, m, PhS and a part of PhCO), 7.8—8.0 (2H, m, the rest of PhCO); MS, *m/e* 228 (M^+).

N,N-*Dimethyl-α-phenylthioacetamide (**11**)*: Bp 120 °C/3 mmHg, IR (neat) 1630 cm^{-1} (C=O); ^1H NMR ($CDCl_3$) δ 2.92 (3H, s), 2.98 (3H, s), 3.71 (2H, s), 7.0—7.6 (5H, m).

The Reactions of the Silanes **7** *with Amides.* To a stirred butyllithium (3.8 ml of 15% hexane solution) was added diisopropylamine (0.84 ml, 6.0 mmol) in THF (5 ml) at 0—5 °C. After stirring for 1 h at room temperature, the resulting lithium diisopropylamide (LDA) solution was cooled to −60—−70 °C and phenylsulfonyl(or methylsulfonyl)trimethylsilane (5.0 mmol) was added to the solution. The stirring was continued for 1 h at room temperature followed by addition of an amide (6.0 mmol) in THF (5 ml). Then the mixture was warmed at 50—60 °C for 5 h with stirring. The reaction mixture was quenched with water after cooling, extracted (CH_2Cl_2), dried (Na_2SO_4), and concentrated to give a crude product, which was isolated and purified by crystallization or distillation. Elemental analyses of the products were not satisfactory because of their high sensitivity to hydrolysis.

*1-Dimethylamino-2-phenylsulfonylethylene (**8a**)*: Found: C, 56.69; H, 6.18; N, 6.63; S, 15.10%. Calcd for $C_{10}H_{13}NO_2S$: C, 56.86; H, 6.20; N, 6.63; S, 15.15%.

Formation of the Cinnamamides **12** *and the Cinnamate* **13**. Benzaldehyde (5.0 mmol) in THF (5 ml) was added to a reaction mixture obtained from phenylthiomethyltrimethylsilane (5.0 mmol), butyllithium (6.0 mmol), and tetramethylurea (5.0 mmol) according to the procedure shown above. The mixture was allowed to stand for 1 d at room temperature and was worked up similarly to the previous runs to give 0.58 g (41%) of *N,N*-dimethyl-α-phenylthiocinnamamide (**12a**) as a mixture (57 : 43) of two isomers: bp 130 °C/0.001 mmHg by pot distillation; IR (neat) 1630 cm^{-1} (C=O); ^1H NMR ($CDCl_3$) δ 2.63 (≈1.7H, s), 2.76 (≈1.7H, s), 2.89 (≈1.3H, s), 2.95 (≈1.3H, s), 6.60 (0.57H, s), 6.73 (0.43H, s), 7.1—7.7 (10H, m).

An analytical sample of the major isomer could be isolated by chromatography on silica gel; MS, *m/e* 283 (M^+). Found: C, 71.84; H, 5.01; N, 6.11; S, 11.01%. Calcd for $C_{17}H_{17}NOS$: C, 72.06; H, 4.94; N, 6.05; S, 11.29%.

Similarly 0.30 g (27%) of *N,N*-dimethyl-α-methylthiocinnamamide (**12b**) was obtained from methylthiomethyltrimethylsilane (5.0 mmol), butyllithium (6.0 mmol), the urea (5.0 mmol), and the aldehyde (5.0 mmol) as a mixture (65 : 35) of two isomers: bp 150 °C/5 mmHg; IR (neat) 1620 cm^{-1} (C=O); ^1H NMR ($CDCl_3$) δ 2.24 (1.05H, s), 2.35 (1.95H, s), 2.81 (1.95H, s), 2.98 (≈2H, s), 3.04 (≈1H, s), 3.13 (≈1H, s), 6.48 (0.65H, s), 6.59 (0.35H, s), 7.1—7.6 (5H, m), MS, *m/e* 221 (M^+).

In the case of the reaction starting with phenylthiomethyltrimethylsilane (5.0 mmol), butyllithium (6.0 mmol), and diethyl carbonate (5.0 mmol), THF solution of LDA (5.0 mmol) prepared by the method shown above was added to the reaction mixture at 0 °C. The mixture was stirred for 3 h at the same temperature and overnight at room temperature followed by addition of benzaldehyde (5.0 mmol) in THF (5 ml). The mixture was allowed to stand for 1 d at room temperature and worked up as the previous runs to afford 0.84 g (59%) of ethyl α-phenylthiocinnamate (**13**): bp 150 °C/1 mmHg by pot distillation; IR (neat) 1720 cm^{-1} (C=O); ^1H NMR δ 1.30 (3H, t), 4.07 (2H, q), 7.3—7.9 (10H, m), 8.30 (1H, s, =CH); MS, *m/e* 284 (M^+).

Kinetic Studies on the Amination of Leucoquinizarin

Masashi KIKUCHI, Takamichi YAMAGISHI, and Mitsuhiko HIDA*

Department of Industrial Chemistry, Faculty of Technology, Tokyo Metropolitan University, Fukazawa, Setagaya-ku, Tokyo 158

(Received September 30, 1981)

Leucoquinizarin reacts with amines to give mono- and diaminoanthraquinones. The amination mechanism of leucoquinizarin was investigated on the basis of the kinetics and structures of leuco compounds. The amination reaction of leucoquinizarin was characterized as follows. This amination proceeded in polar solvent but not in nonpolar solvent at all. The reaction rate was not influenced by the addition of a small amount of water (95% ethanol) but enhanced largely in 80% ethanol. This amination reaction has a low activation energy ($\Delta E^*=5.7-9.0$ kcal mol^{-1}) and an extraordinarily small pre-exponential term ($A=10^3-10^5$ l mol^{-1} min^{-1}). Leucoquinizarin was proposed to be aminated by the addition of amine to carbonyl group at its 1,4-position. The oxidation of leuco monoaminohydroxyanthraquinone was also examined.

Leucoquinizarin (**1**) reacts with amines to give mono- and diaminoanthraquinone derivatives, which are among the most important compounds in synthetic dyes. Although many patents[1] and some papers[2] on the amination of **1** have been reported, most of them are nothing but technical reports and no mechanistic investigation has been made. Though some reports concerning the structures of leucoanthraquinones have been published,[3] they have given no convincing data.[4,5] We have recently elucidated the structures of leucoanthraquinones on the basis of ^{13}C-NMR spectra.[6] In this paper we discuss the amination of **1** from the kinetic point of view, and propose that **1** in 1,4-diketo form is the most reactive to amine among the possible tautomeric isomers. The oxidation of leuco monoaminohydroxyanthraquinone was also examined.

Results and Discussion

Kinetics of the Amination of 1 with Butylamine. The reaction of **1** with butylamine in air gave 1-butylamino-4-hydroxyanthraquinone (**2**) and 1,4-bis(butylamino)-anthraquinone (**3**). The reaction under a nitrogen atmosphere gave compounds **2** and **3** in their leuco forms. Since all attempts of quantitative oxidations of these leuco compounds to the anthraquinone derivatives led unsatisfactory results, the amination reaction under a nitrogen atmosphere was followed by taking visible spectra of the amination solution in the presence of citric acid as reducing agent to suppress the oxidations of leuco compounds of **1** and **2**. By using a small amount of butylamine ($C_4H_9NH_2$/**1**=1—5) and by setting the conversion low only leuco compound of **2** was obtained. The reaction was first order on both concentrations of **1** and butylamine and the second order rate constant was independent of these concentrations. The Arrhenius plots showed a good straight line. As shown in Table 1, the reaction proceeded easily in ethanol and DMF, but did not at all in nonpolar solvent such as benzene. These facts show that the polarity of solvent largely enhances the reaction rate and suggest that the reaction intermediate is of ionic character.

If the solvation energy (ΔF_{solv}) of reaction intermediate was approximated by the Born's equation (1), and if the cavity size and the temperature dependency of dielectric constant (D) do not vary with solvent, both values of ΔH^* and ΔS^* will increase with increase in

$$\Delta F_{solv} = C(1-1/D) \quad (1)$$

dielectric constant of the solvent. In accordance with our expectation ΔH^* and ΔS^* have larger values in DMF (D=36.7) than those in ethanol (D=23.2). Since dielectric constant of aqueous ethanol increases in proportion to the amount of water,[7] the reaction rate in aqueous ethanol will increase with increase in water content. But the reaction rate in aqueous ethanol did not increase proportionally to water content and both values of ΔH^* and ΔS^* in 80% ethanol decreased as compared with those in ethanol, though the dielectric constant (D=34) is larger than that of ethanol. Thus the results in aqueous ethanol could not be understood only by the increase in polarity of solvent, but another interaction such as the hydrogen bonding between the reaction intermediate and water should be also assumed.

The amination reaction of **1** was characterized by a low activation energy ($\Delta E^*=5.7$—9.0 kcal mol^{-1}) and extraordinarily small pre-exponential term ($A=10^3$—

Table 1. Solvent effects on the amination of leucoquinizarin

Solvents	$k_{60\,°C}$ / l mol^{-1} min^{-1}	ΔE^* / kcal mol^{-1}	A / l mol^{-1} min^{-1}	ΔH^* / kcal mol^{-1}	ΔS^*[a] / cal deg^{-1} mol^{-1}

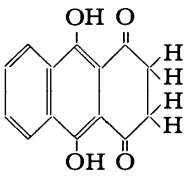
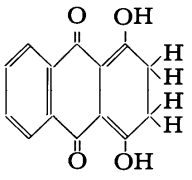
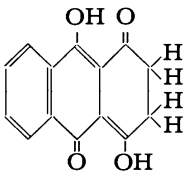
10^5 l mol^{-1} min^{-1}). In many cases the activation energy and pre-exponential term are reported to be 20—30 kcal mol^{-1} and 10^9—10^{11} l mol^{-1} min^{-1}, respectively, while anomalously small activation energy (ΔE^{*}=10—18 kcal mol^{-1}) and pre-exponential term (A=10^5—10^6 l mol^{-1} min^{-1}) are known in the Menschutkin reaction between pyridine or triethylamine and alkyl iodide[8] and in the semicarbazone formation of acetophenones (ΔE^{*}=4—11 kcal mol^{-1}, A=0.27—10^5 l mol^{-1} min^{-1}).[9] These reactions are known to proceed through ionic intermediates.



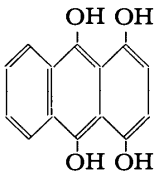
1a



1b



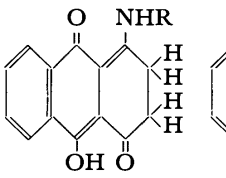
1c



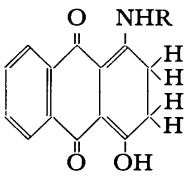
1d

The Structures of 1 and Leuco Compound of 2. The ^{1}H-NMR spectrum of **1** showed methylene protons (4H; singlet, 3.05 ppm), hydroxyl protons (2H; singlet, 13.50 ppm) and aromatic ring protons (4H of A_2B_2 type, 8.42, 7.77 ppm). This result suggests the possibilities of the structures **1a** or **1b**.

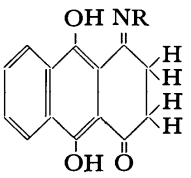
With respect to leuco compound of **2**, the five possible structures (**2a**—**e**; R=C_4H_9) can be written as follows.



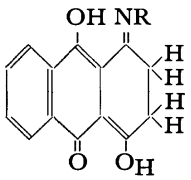
2a



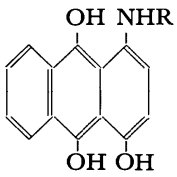
2b



2c



2d



2e

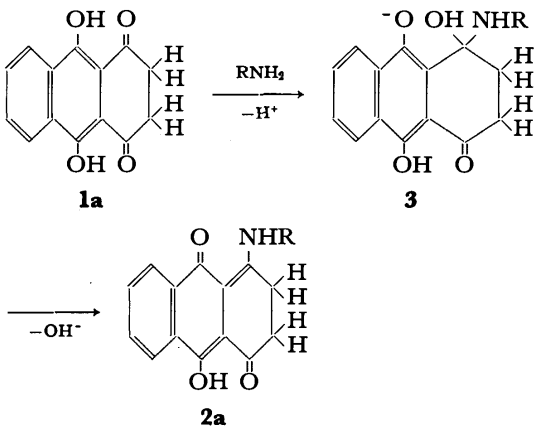
The ^{1}H-NMR spectrum of leuco compound of **2** showed methylene protons (4H; triplet, 2.88 ppm), one hydroxyl proton (1H; singlet, 13.95 ppm), one amino proton (1H; broad, 14.90 ppm) and unsymmetrical ring protons (4H; multiplet, 8.36, 7.62 ppm). This result permits the assignment of leuco compound of **2** to **2a** or **2b**. The presence of the unsymmetrical ring protons seems to demand 4,9-diketo form (**2a**) for leuco compound of **2**.

An examination of ^{13}C-NMR spectra shows that the resonance peaks of carbonyl carbons (C-9, 10) of anthraquinons were characteristically observed at about 180 ppm,[10] but the chemical shifts of carbonyl carbon adjacent to the methylene or methyl carbon are at about 200 ppm.[11] The chemical shift 200.8 ppm of the carbonyl carbon of **1** suggested that **1** may exist in the 1,4-diketo form **1a**. The chemical shifts of the carbonyl carbons of leuco compound of **2** were 199.9 and 172.2 ppm and the latter corresponds to the carbonyl carbon detached from the methylene carbon. These results concluded that the leuco compound of **2** exists predominantly in unsymmetrical 4,9-diketo form **2a** in solution. All ^{1}H-NMR spectra of **1** in $CDCl_3$, DMF-d_7, C_6D_6 and $CDCl_3$–C_2D_5OD (1 : 1) were the same except hydroxyl protons. Also ^{13}C-NMR spectra of **1** in $CDCl_3$, C_6D_6, DMF-d_7 were the same. These spectra showed that **1** retained 1,4-diketo form **1a** predominantly in these solutions. The spectra in C_2D_5OD could not be measured due to low solubility of **1**.

Two possibilities as to the reaction mechanism could be considered as follows.

1. The elementary reaction, which determined the rate of the amination of **1**, has intrinsically a low activation energy and a small pre-exponential term.
2. A very reactive species is one of the tautomers (**1b**—**d**), which exists in a very small amount in the solution.

The compounds of **2a** and 1,4-dimethoxy-9,10-anthracenediol gave no aminated product with butylamine in the same conditions as **1** undergoes amination. This result suggests that **1c** and **1d** are much less reactive than 1,4-diketo form **1a**. Consequently, though the possibility of **1b** to be reactive species cannot be excluded, **1a** could be thought to be the most reactive among tautomeric isomers. The amination of leucoquinizarin seems to proceed by the addition and elimination mechanism as shown in Scheme 1. The addition of amine to carbonyl group of **1a** was led to **2a** *via* an ionic reaction intermediate such as **3**.



Scheme 1.

Base catalysis by amine can be excluded, because the second order rate constant was independent of amine concentration. The possibility of the reaction intermediate having an ion pair also may be excluded, because the polarity effect of solvent was very large, and then the inner solvation cannot be considered.

Dissociation of 1 in Solution. The possibility of the dissociation of **1** in the reaction media was examined since the dissociation may be promoted by the presence

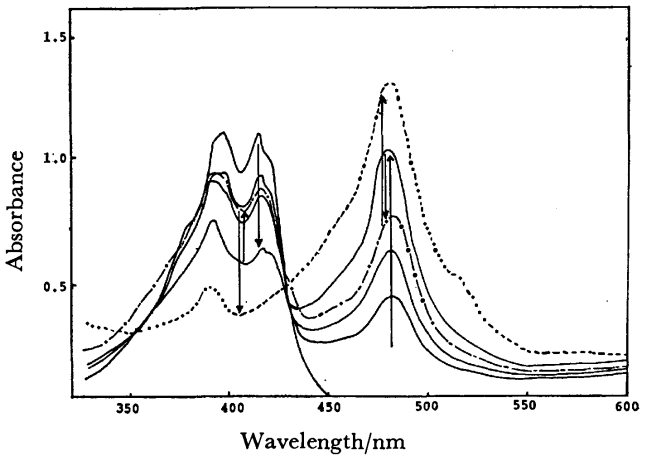


Fig. 1. The visible spectra of leucoquinizarin (**1**) depending on the amount of triethylamine (TEA). [TEA]/mol dm^{-3}: ——; 0—0.358, -·-·-; 0.358—0.574, ------; 0.574—0.717. [**1**]$=8.257\times10^{-5}$ mol dm^{-3}.

of amine. The dissociated **1** may suppress the reactivity of **1** for the nucleophilic attack of amine. Change of the visible spectra of **1** by the presence of triethylamine (inactive for the amination) tells the stepwise dissociation of **1** as shown in Fig. 1. The absorption spectra showed isosbestic points at 353 nm and 429 nm in range of the amine concentration below 0.358 mol dm^{-3}. If a single acid and base equilibrium between **1** and triethylamine can be assumed, the acidity of **1** could be estimated from change of absorbance with the concentration of amine, as shown in Fig. 1, by usual method. But the value of the acid and base equilibrium constant obtained largely depends on wavelength. This means that the single equilibrium cannot be reasonably assumed, but formation of other species, such as radical anion, also should be assumed. Consequently, the amount of dissociated **1** in the amination could not be determined, but it can be considered to be negligible, since the same spectra in the absence and presence of triethylamine were observed in the same conditions as **1** undergoes amination.

The Oxidation of Leuco Compound of **2**. Leuco compounds of aminated product have been oxidized by heating in nitrobenzene,[2a,b] by heating with an excess of amine,[2c] in oleum,[12] or alkaline solution.[1] Currently the heating in nitrobenzene has been reported to be the most plausible method of oxidation of these leuco compounds. As shown in Table 2, the oxidation could not be carried out quantitatively in triethylamine–ethanol solution. The oxidation in nitrobenzene gave **2** in *ca.* 60% at most, accompanied by side reactions such as dealkylation and other reactions. The dealkylated product was confirmed to be 1-amino-4-hydroxyanthraquinone by comparison of its spectra and TLC with those of the authentic sample. The brown product was composed of several compounds and identification of their structures was impossible. It is found that the aminated products are susceptible to dealkylation, while the formation of the brown product is easily formed at lower temperature. Consequently the current method heating in nitrobenzene cannot be approporiate method. The quantitative oxidation method of leuco compounds, which is not accompanied by side reactions, should be investigated.

Table 2. The oxidation of leuco compound of **2**

Solvents	Temp/°C	Time/h	Yield of **2**/%	Conv.
TEA[a]–Ethanol	60	2	72.1	—

Nitrobenzene	180	2	61.5 (14.2)	100
Nitrobenzene	Reflux	0.25	62.5 (27.9)	100

a) Triethylamine. b) Parenthesis shows the yield of 1-amino-4-hydroxyanthraquinone.

Experimental

Materials. The leuco compounds and anthraquinone derivatives were prepared and confirmed as reported previously.[6] Leucoquinizarin (**1**): λ_{max} (ethanol) 398 nm (ε; 12700), 415 nm (ε; 12300).[13] Leuco compound of **2**: λ_{max} (ethanol) 432 nm (ε; 17000), 457 nm (ε; 18570).[13] The butylamine was dried by refluxing on sodium metal and distilled under a nitrogen atmosphere. All the solvents were purified by the usual methods, and stored under a nitrogen atmosphere.

Kinetic Measurements. A typical run is as follows. Leucoquinizarin and ethanol were mixed in a flask. After this solution was brought to the reaction temperature, the reaction was initiated by adding butylamine ethanol solution into the leucoquinizarin solution; the concentrations of leucoquinizarin and butylamine were 5 mmol dm^{-3} and 5—25 mmol dm^{-3}, respectively. All above operations were performed under a dry and oxygen-free nitrogen atmosphere. At regular time interval, 0.3 ml portion of reaction solution was withdrawn and diluted to 25 ml with ethanol containing citric acid (0.603 g/250 ml) to suppress the oxidation of leuco compounds. The yield of leuco aminated product **2a** was determined spectrometrically. Visible spectra were measured with Shimazu UV-210 spectrometer.

^{1}H-NMR and ^{13}C-NMR Measurements. ^{1}H-NMR spectrum of leucoquinizarin in $CDCl_3$ was already reported.[6] ^{1}H-NMR spectra in DMF-d_7, C_6D_6, and C_2D_5OD–$CDCl_3$ (1 : 1) were as follows. The parentheses show the chemical shifts (δ, ppm) of α, β protons of aromatic ring, methylene protons and hydroxyl protons, respectively. DMF-d_7: (8.50, 8.00; 3.10; 14.78), C_6D_6: (8.48, 7.36; 2.28; 14.23), C_2D_5OD–$CDCl_3$(1 : 1) : (8.24, 7.64; 2.97; 4.21). The peaks of carbonyl carbons in ^{13}C-NMR were observed at 200.8 ppm ($CDCl_3$),[6] 200.8 ppm (C_6D_6), and 202.6 ppm (DMF-d_7) showing the existence of the carbonyl carbon adjacent to the methylene carbon. In the case of C_2D_5OD solution, the spectrum could not be measured due to low solubility. ^{1}H-NMR spectra were measured using TMS as an internal standard with a Hitachi R-24 spectrometer. ^{13}C-NMR spectra were measured under a nitrogen atmosphere using TMS as an internal standard with a JEOL FX-60 spectrometer.

The Oxidation of Leuco Compound of **2**. A mixture of leuco compound of **2** (20 mg) and nitrobenzene (0.65 ml) was heated in air. The products were separated by column chromatography on silica gel using benzene as eluent and identified to be **2** and 1-amino-4-hydroxyanthraquinone as the dealkylated product by comparison with authentic samples. The yields of products **2** and 1-amino-4-hydroxyanthraquinone were determined spectrometrically.

Upon DNP-aromatic Rule. Effect of Introducing a Methyl Group to the β-Position upon the CD Spectra of DNP Derivatives of Aromatic α-Amino Acids

Masao KAWAI,* Ukon NAGAI, and Atsuko TANAKA

Mitsubishi-Kasei Institute of Life Sciences, Minamiooya, 11, Machida, Tokyo 194

(Received September 30, 1981)

CD spectra of *N*-DNP-*O*-benzoyl derivatives of L-serine, L-threonine, and L-allothreonine and DNP derivatives of L-phenylalanine and (*βR*)- and (*βS*)-*β*-methyl-L-phenylalanines were studied. The effect of methyl substitution at the *β*-position upon their CD spectra was explained by the change in the population of the rotamer g^- ($\chi^1=-60°$) which was shown to be responsible for the characteristic negative Cotton effect at ≈400 nm. The negative sign of the $[\theta]^{max}_{\approx 400}$ values of the DNP derivatives of aromatic L-α-amino acids described by DNP-aromatic rule was proved to be due to the contribution of the rotamer g^-.

The 2,4-dinitrophenyl (DNP) derivatives of L-α-amino acids having aromatic group on the side chain were found to show a negative Cotton effect around 400 nm. Extensive study upon the chiroptical properties of DNP-α-amino acids and related compounds[1-5] lead us to the proposal of DNP-aromatic rule[3] which predicts a negative $[\theta]_{\approx 400}$ for the compounds DNP·NHCHR$_1$R$_2$ with the absolute configuration corresponding to the aromatic L-α-amino acids, where R$_1$ and R$_2$ are an aromatic and a nonaromatic groups, respectively. The R$_1$ group, which carries an aromatic chromophore, must not contain an additional chiral center, since *N*-DNP-*O*-benzoyl-L-threonine (**1a**) was found to exhibit the positive Cotton effect at 410 nm. The corresponding L-serine derivative (**1b**) showed normal CD spectrum expected as an analog of aromatic L-α-amino acid.[3]

	Ar=OCOPh	Ar=Ph
R=H, R′=CH$_3$	**1a**	**2a**
R=H, R′=H	**1b**	**2b**
R=CH$_3$, R′=H	**1c**	**2c**

For the purpose of investigating the reason why the L-threonine derivative (**1a**), which has one extra methyl group at the *β*-position of the L-serine derivative (**1b**), exhibits an exceptional CD spectrum, *N*-DNP-*O*-benzoyl-L-allothreonine (**1c**) was prepared. The corresponding derivatives (**2a** and **2c**) of DNP-L-phenylalanine (**2b**) were also synthesized. As summarized in Table 1, **1c** exhibited a negative Cotton effect at 405 nm larger than that of **1b**; *i.e.*, the effect of methyl group in **1c** on $[\theta]^{max}_{\approx 400}$ was opposite to that in **1a**. The similar tendency was observed in **2** series, though $[\theta]_{405}$ of **2a** remained negative; *i.e.*, the magnitude of the negative Cotton effects was in the order **2a**<**2b**<**2c**.

Relative orientation of the two chromophores, which is assumed to be the determining factor of the CD spectra, is regulated by the molecular conformation described by the three torsional angles ϕ, χ^1, and χ^2.[6] Restricted rotation around DNP·NH-C$^\alpha$ bond confines the ϕ value to very narrow regions near −160° and near −70°.[7] Assuming that the Cotton effects are due to the exciton coupling between the transition moments of the two chromophores, the rotational strength (RS_1) at the longest wavelength band (400 nm) was calculated using the following equation:[8,9]

$$RS_1 = \frac{2\pi}{ch} \cdot \frac{\lambda_1\lambda_2}{\lambda_1^2-\lambda_2^2} \cdot \left(\frac{(\boldsymbol{\mu}_1\cdot\boldsymbol{\mu}_2)}{R^3} - \frac{3(\boldsymbol{\mu}_1\cdot\boldsymbol{R}_{21})(\boldsymbol{\mu}_2\cdot\boldsymbol{R}_{21})}{R^5}\right) \cdot [\boldsymbol{R}_{21}\cdot(\boldsymbol{\mu}_2\times\boldsymbol{\mu}_1)].$$

The results of the calculation for **2b** with varying χ^1 and χ^2 values were summarized in Fig. 1. As to the side chain conformation, the molecules can be considered to be populated around the three staggered conformations, g^- ($\chi^1=-60°$), g^+ ($\chi^2=+60°$), and t ($\chi^1=180°$), which were expected to exhibit negative, positive, and negligible or slightly negative Cotton effects, respectively. Essentially similar conclusion was obtained by the calculation for **1b**; *i.e.*, in both of **1** and **2** series, the conformer g^- was considered to contribute negative to the observed Cotton effect at ≈400 nm.

Conformational changes induced by the introduction of a methyl group at the *β*-position of **1b** and **2b** were studied by ^{1}H-NMR spectra as summarized in Table 2.[10] As shown in Fig. 2 the *ortho*-proton of the DNP group of **2** was expected to experience an anisotropic shielding effect of the phenyl ring in the conformer g^-, which was considered to be responsible for the negative Cotton

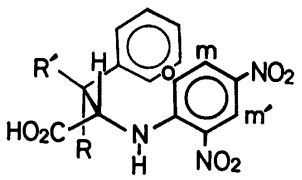

Fig. 2. Conformer g^- of **2a**—**c** in which anisotropic shielding effect of phenyl ring upon the *o*-proton of the DNP group is expected.

effect around 400 nm. The significant difference observed in the chemical shifts of the *ortho*-protons in **2b** and its methyl substituted analogs seem to indicate decrease and increase in the population of the g^- conformer caused by the presence of a methyl group in **2a** and **2c**, respectively, which is consistent with the CD spectral data. In the case of **1b** and its methylated derivatives (**1a** and **1c**), the difference in the chemical shifts of the *ortho*-protons is not prominent, though the same tendency as found in **2** series was observed. The coupling constant between $C^\alpha H$ and $C^\beta H$, however, clearly indicated that the population of g^- conformer is very small for **1a**; *i.e.*, the small coupling constant (2.8 Hz) indicated the two protons to take gauche instead of *trans* positions, to which the g^- conformer corresponds. Thus, the positive $[\theta]_{410}$ value observed for **1a** is explained by significant decrease of the g^- conformer caused by introduction of the methyl group.

In conclusion, the g^- conformer was shown to be responsible for the negative Cotton effect around 400 nm and the effect of methyl substitution at the β-position upon the CD spectra was explained by the change in population of the g^- conformer. Combination of conformational analysis and rotational strength calculation seem to be a useful method for interpreting or predicting chiroptical properties of compounds which show CD spectra due to exciton coupling.

Experimental

Melting points were uncorrected. Compounds **1b** and **2b** were already described in Ref. 3.

N-DNP-O-benzoyl-L-threonine (1a). DNP-L-threonine (713 mg, 2.5 mmol) was benzoylated with Schotten-Baumann method using benzoyl chloride (0.87 cm^3, 7.5 mmol) and NaOH (10 mmol). Crystallization from acetone–benzene afforded **1a** (76 mg) as yellow needles: mp 184—187 °C. Found: C, 52.15; H, 3.85; N, 10.75%. Calcd for $C_{17}H_{15}N_3O_8$: C, 52.45; H, 3.88; N, 10.79%.

N-DNP-O-benzoyl-L-allothreonine (1c). This compound was prepared in the same manner as **1a**, starting from the corresponding L-*allo*threonine derivative: yellow powder; mp 176—177 °C.

As for **2a** and **2c**, the compounds actually synthesized were their enatiomers as described below, starting from the samples supplied by Prof. S. Kuwata of Kōnan University.

(2R,3R)-N-DNP-2-amino-3-phenylbutanoic Acid (Enantiomer of 2a). 2,4-Dinitrophenylation of 38 mg (0.2 mmol) of (2*R*, 3*R*)-2-amino-3-phenylbutanoic acid ($[\alpha]_D^{20}$ +24.2°; *c* 1, H_2O)[11] with the procedure of Sanger[12] afforded the enantiomer of **2a** (45 mg): yellow prisms from ethyl acetate–benzene; mp 169—170 °C. Found: C, 55.59; H, 4.41; N, 12.18%. Calcd for $C_{16}H_{15}N_3O_6$: C, 55.65; H, 4.38; N, 12.17%.

(2R, 3S)-N-DNP-2-amino-3-phenylbutanoic Acid(Enantiomer of 2c). This compound was synthesized from (2*R*, 3*S*)-2-amino-3-phenylbutanoic acid ($[\alpha]_D^{22}$ +6.90°; *c* 1, H_2O)[11] in the same manner as described above. Yellow prisms from ethyl acetate–benzene; mp 159—160 °C. Found: C, 55.58; H, 4.32; N, 12.08%. Calcd for $C_{16}H_{15}N_3O_6$: C, 55.65; H, 4.38, N, 12.17%.

Measurements. CD spectra were recorded on a JASCO spectropolarimeter model J-20 or J-40 at room temperature. PMR spectral data given in Table 2 were measured at 270 MHz on a Bruker WH-270 spectrometer at room temperature.

We wish to thank Prof. Shigeru Kuwata of Kōnan University for his kind gift of the samples of β-methylated phenylalanines. We are also grateful to Dr. Tsutomu Higashijima and Prof. Tatsuo Miyazawa of The University of Tokyo for ^{1}H-NMR measurements and to the members of Analytical Department of System Engineering Laboratory, Mitsubishi-Kasei Industries Ltd., for elemental analyses.

A Convenient Method for Preparation of 2-(Methylthio)alkanoic Acids and Their Related Compounds Using the Carbanions of Substituted Malonic Esters

Katsuyuki OGURA,* Hiroshi ITOH, Toshio MORITA, Kunio SANADA, and Hirotada IIDA
Department of Synthetic Chemistry, Faculty of Engineering, Chiba University, Yayoicho 1-33, Chiba 260
(Received October 1, 1981)

Starting from alkyl- or aryl-substituted malonic esters prepared by various methods, 2-(methylthio)alkanoic acids are synthesized by successive treatment with sodium ethoxide and with S-methyl methanethiosulfonate, followed by alkaline hydrolysis which causes concurrent decarboxylation. Production of 2-(phenylthio)alkanoic acids is also achieved in a similar manner.

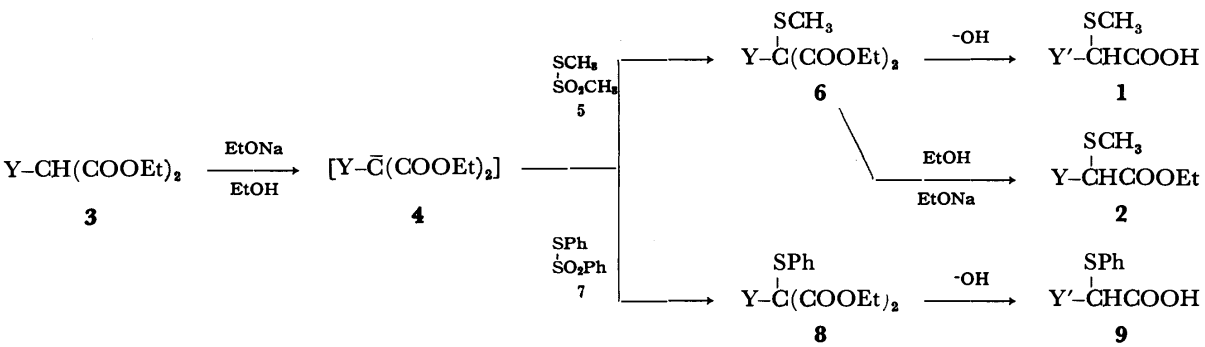
A 2-(methylthio)alkanoic acid (**1**) and its ester (**2**) are well known to be useful intermediates for making a variety of organic compounds such as a 2-alkenoic acid, an aldehyde, a ketone, and an epoxide.[1-6] For preparation of **1** and **2**, there have been explored many kinds of methods including substitution of 2-haloalkanoic ester with methanethiolate anion,[7] methylation of 2-mercaptoalkanoic ester,[7,8] alkylation of (methylthio)-acetic acid,[4] direct sulfenylation of alkanoic acid or its ester,[3,4,9] Michael addition of a carbanion to methyl α-(methylthio)acrylate,[10] and reaction of (ethoxycarbonyl)(methylthio)methyl cation with 1-alkene or arene.[11] Now we wish to describe a convenient route leading to **1**, which comprises the reaction of *S*-methyl methanethiosulfonate (**5**) with the carbanion (**4**) of an alkyl- or aryl-substituted malonic ester (**3**) and subsequent hydrolysis accompanied by simultaneous decarboxylation. This route provides the following distinct features: (i) Inexpensive and handy sodium ethoxide can be employed as a base; (ii) **1** is selectively produced without formation of 2,2-bis(methylthio)alkanoic acid due to masking the hydrogen at 2-position of **1** with ethoxycarbonyl group; (iii) all the reactions take place smoothly in ethanol at room temperature or in refluxing ethanol; and (iv) many methods are available for production of **3** and **4** to make this route widely applicable (*vide post*).

Results and Discussion

For preparation of alkyl- or aryl-substituted malonic esters (**3**), we employed three methods summarized in Scheme 2. When Y of **3** is an alkyl group or a 2-alkenyl group, the corresponding **3** is synthesized by the so-called malonic ester synthesis [Method A].[12] Ethoxycarbonylation of ethyl arylacetate with diethyl carbonate and sodium ethoxide gives the starting material (**3**) having an aryl group as Y [Method B].[13] The Michael reaction of diethyl malonate with ethyl 2-alkenoate can be utilized to afford **3** (Y=-CHR'CH_2COOEt) [Method C].[14]

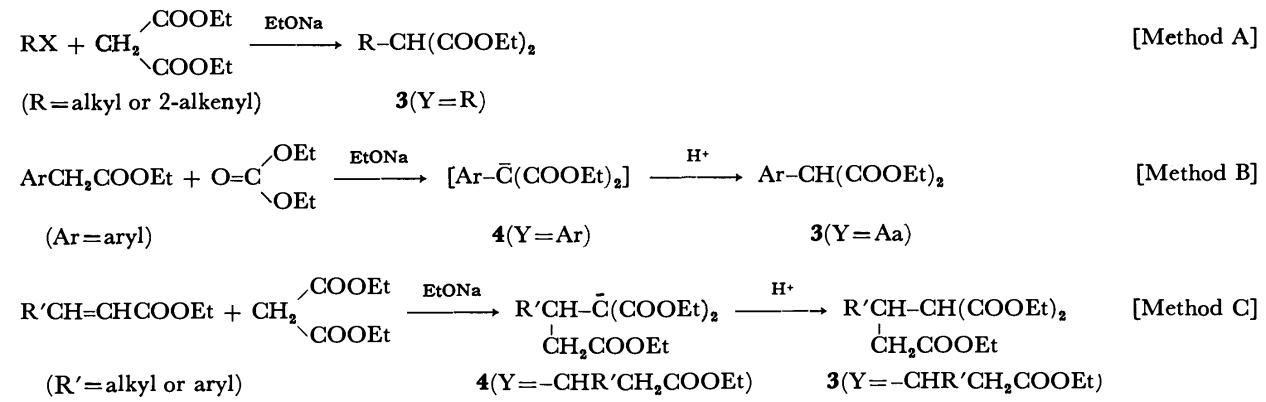
Conversion of the thus-obtained **3** into the corresponding **6** was accomplished by successive treatment with sodium ethoxide and with **5** in ethanol. To 0.47 M ethanolic solution (100 ml) of sodium ethoxide, were added **2a** (9.97 g : 33 mmol) and then **5** (5.30 g : 42 mmol),[15] and the resulting mixture was stirred at room temperature for 4 h. The usual workup followed by distillation afforded **6a** in 90% yield. In analogous manners, various derivatives (**6b—g**) of diethyl (methylthio)malonate were obtained. When *S*-phenyl benzenethiosulfonate (**7**)[15] was utilized instead of **5** in the above reactions, the corresponding phenylthio derivatives (**8a**, **8b**, and **8d**) were also produced in high yields. The results are given in Tables 1 and 2.

As shown in Scheme 2, the carbanion (**4**, Y=Ar) is



a: Y=*n*-$C_{10}H_{21}$-, b: Y=$PhCH_2$-, c: Y=*n*-$C_5H_{11}CH$=$CHCH_2$-, d: Y=Ph,
e: Y=-CH_2CH_2COOEt [Y'=-CH_2CH_2COOH], f: Y=-CHCH$_2$COOEt [Y'=-CHCH$_2$COOH]
g: Y=-CHCH$_2$COOEt [Y'=-CHCH$_2$COOH]
Ph Ph CH$_3$ CH$_3$

Scheme 1.



Scheme 2. Preparation of the starting material (**3**)

intermediately formed in Method B. Hence, we examined whether a "one-pot" reaction is feasible for preparation of **6** (Y=Ar) from ethyl arylacetate. Ethyl phenylacetate (16 mmol) and a large excess of diethyl carbonate (15 ml) were added to an ethanolic solution (15 ml) of sodium ethoxide (1.2 equiv.) and the mixture was heated under slow removal of ethanol and diethyl carbonate to afford an insoluble carbanion (**4d**). Then, tetrahydrofuran (50 ml) and **5** (1.3 mol-equiv.) were added to this reaction system and the resulting mixture was stirred at room temperature for 3 h to give **6d** in 92% yield. Analogously, **8d** was given in 90% yield, starting from ethyl phenylacetate and **7**.

Method C of Scheme 2 also suggests that **6** having $-CHR'CH_2COOEt$ as Y can be produced in one flask from ethyl 2-alkenoate by direct treatment of the carbanion **4** (Y=$-CHR'CH_2COOEt$), which is formed in the reaction of ethyl 2-alkenoate with the carbanion of diethyl malonate, with **5**. After a solution containing ethyl 2-alkenoate, diethyl malonate (1—1.2 equiv.), and sodium ethoxide (1—2.2 equiv.) in ethanol was stirred at room temperature or refluxing temperature, **5** (1—2.7 equiv.) was added and the resulting mixture was further stirred at room temperature. The usual workup gave **6f** and **6g** in 67 and 72% yields, respectively. However, preparation of **6e** using this "one-pot" procedure was found to be less effective because the Michael addition of diethyl malonate to ethyl acrylate was always accompanied with formation of diethyl bis[2-(ethoxycarbonyl)ethyl]malonate to lower the yield of the carbanion **4e**. In this case, it is recommended that **3e** is once isolated by distillation and then subjected to the reaction with **5** in the presence of sodium ethoxide in ethanol as mentioned above from a viewpoint of obtaining **6e** in a pure form.

Transformation of **6** into the desired **1** was easily achieved by alkaline hydrolysis. When **6** was treated with excess potassium hydroxide in refluxing ethanol, hydrolysis of the ethoxycarbonyl groups and decarboxylation took place simultaneously to give **1**. However, it should be noted that **6g** afforded ethyl cinnamate and/or cinnamic acid by cleavage of a C–C bond (the retro-Michael reaction) when the hydrolysis was carried out in refluxing ethanol. This was overcome by performing the hydrolysis at room temperature followed by heating at the final stage to form **1g** in 93% yield. 2-(Phenylthio)alkanoic acid (**9**) was also produced in a good yield by alkaline hydrolysis of **8**. These results are also summarized in Tables 1 and 2.

For preparation of **1d**, benzyl cyanide could be employed as a starting material instead of ethyl phenylacetate. Ethoxycarbonylation of benzyl cyanide with diethyl carbonate in the presence of sodium ethoxide gave sodium salt (**10**) of ethyl α-cyanophenylacetate. After the precipitated **10** was again dissolved by addition of tetrahydrofuran to the reaction system, **5** was added and the resulting mixture was stirred at room temperature for 4 h to afford ethyl α-cyano-α-(methylthio)-

a) In EtOH. b) The (*E*)-isomer was used in this reaction. By an NMR analysis (100 MHz and proton-decoupling), the presence of the corresponding (*Z*)-isomers was not observed in the products **6** and **1**. c) The carbanion (**4**) was obtained by the reaction of ethyl phenylacetate with diethyl carbonate (see Text). This value indicates an overall yield from ethyl phenylacetate.

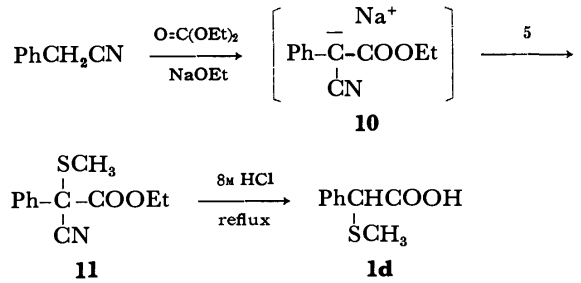
a) In EtOH. b) Contaminated with a small amount of inseparable and unidentified product(s). c) The overall yield from **3**. d) See the footnote (c) of Table 1.

phenylacetate (**11**) in 82% yield. Alkaline hydrolysis of **11** resulted in formation of a complex mixture containing ethyl α-cyanophenylacetate, benzoic acid, and ethyl benzoate. However, transformation of **11** into **1d** was successively accomplished by acidic hydrolysis with 8 M hydrochloric acid to produce the expected **1d** in 76% yield.



Furthermore, direct conversion of **6** into the ethyl ester (**2**) was examined by retro-ethoxycarbonylation. When a mixture of **6** and sodium ethoxide (about 5 equiv.) was stirred in ethanol, the corresponding **2** was produced (**2a** 93%; **2b** 77%; **2c** 76%; **2d** 80%).

Thus, we have established a convenient method for preparation of 2-(methylthio)alkanoic acids, 2-(phenylthio)alkanoic acids, and their esters. Finally, it should be noted that the present method can be suitably applied to selective synthesis of 3-substituted 2-(methylthio)-pentanedioic acids starting from ethyl 2-alkenoates, which is not achieved by the already-mentioned known methods for making **1** and **2**.

Experimental

Synthesis of ***6a****. Typical Procedure*: To a 0.47 M ethanolic solution (100 ml) of sodium ethoxide, were successively added **3a** (9.967 g, 33 mmol) and **5** (5.297 g, 42 mmol), and the resulting mixture was stirred at room temperature for 4 h. After addition of water (100 ml), the mixture was extracted with diethyl ether (50 ml × 3). The organic layer was dried (Na_2SO_4) and evaporated *in vacuo*. Distillation of the residue gave 10.374 g of **6a** as a colorelss oil: bp 145—148 °C/1 mmHg (1 mmHg≈133.322 Pa); NMR ($CDCl_3$): δ 0.75—1.05 (3H, broad t), 1.15—1.40 (24H, broad), 2.10 (3H, s), and 4.24 (4H, q, J=7 Hz); IR (neat): 1730 cm^{-1}.

Found: C, 62.71; H, 10.06; S, 9.25%. Calcd for $C_{18}H_{34}O_4S$: C, 62.39; H, 9.89; S, 9.25%.

In analogous manners using the conditions given in Tables 1 and 2, the following compounds were synthesized.

6b: A colorless oil which was purified by column chromatography on silica gel using hexane–benzene (1 : 1) as an eluent followed by a short-path distilation (bath temperature: 120 °C/3 mmHg); NMR ($CDCl_3$): δ 1.21 (6H, t, J=7 Hz), 2.15 (3H, s), 3.43 (2H, s), 4.21 (4H, q, J=7 Hz), and 7.21 (s, 5H); IR (neat): 1730 cm^{-1}.

Found: C, 60.90; H, 6.72%. Calcd for $C_{15}H_{20}O_4S$: C, 60.79; H, 6.80%.

6c: A colorless oil; bp 103—103.5 °C/4 mmHg; NMR ($CDCl_3$): δ 0.78—0.91 (3H, broad t), 1.13—1.56 (6H, m), 1.28 (6H, t, J=7 Hz), 1.80—2.24 (2H, m), 2.11 (3H, s), 2.74 (2H, d, J=6 Hz), 4.23 (4H, q, J=7 Hz), 5.40 (1H,dt, J=15.5 and 6 Hz), and 5.52 (1H, dt, J=15.5 and 6 Hz); IR (neat): 1730 cm^{-1}.

Found: C, 60.70; H, 8.84%. Calcd for $C_{16}H_{28}O_4S$: C, 60.71; H, 8.94%.

6e: A colorless oil; bp 108—109 °C/1 mmHg; NMR ($CDCl_3$): δ 1.27 (3H, t, J=7 Hz), 1.30 (6H, t, J=7 Hz), 2.07 (3H, s), 2.30 (4H, s), 4.13 (2H, q, J=7 Hz), and 4.25 (4H, q, J=7 Hz); IR (neat): 1725 cm^{-1}.

Found: C, 51.18; H, 7.21%. Calcd for $C_{13}H_{22}O_6S$: C, 50.96; H, 7.23%.

6f: A colorless oil; bp 114.5—117 °C/0.5 mmHg; NMR ($CDCl_3$): δ 1.14 (3H, d, J=6 Hz), 1.25 (3H, t, J=7 Hz), 1.29 (6H, t, J=7 Hz), 2.14 (3H, s), 2.3—3.2 (3H, m), 4.14 (2H, q, J=7 Hz), and 4.26 (4H, q, J=7 Hz); IR (neat): 1725 cm^{-1}.

Found: C, 52.23; H, 7.48%. Calcd for $C_{14}H_{24}O_6S$: C, 52.48; H, 7.54%.

6g: Colorless crystals; mp 62—63 °C (from hexane); NMR (CCl_4): δ 1.02 (3H, t, J=7 Hz), 1.18 (3H, t, J=7 Hz), 1.25 (3H, t, J=7 Hz), 2.14 (3H, s), 2.80—3.25 (2H, m), 3.85—4.40 (7H, m), and 7.0—7.4 (5H, m); IR (KBr): 1725 cm^{-1}.

Found: C, 59.75; H, 6.82%. Calcd for $C_{19}H_{26}O_6S$: C, 59.66; H, 6.85%.

8a: A colorless oil which was purified by column chromatography on silica gel using benzene as an eluent followed by a short-path distillation (bath temperature: 180 °C/1.5 mmHg); NMR ($CDCl_3$): δ 0.65—1.00 (3H, broad t), 1.0—2.1 (24H, broad), 4.16 (4H, q, J=7 Hz), and 7.22—7.60 (5H, broad s).

Found: C, 67.70; H, 9.09%. Calcd for $C_{23}H_{36}O_4S$: C, 67.61; H, 8.88%.

Synthesis of ***9b*** *from* ***3b*** via ***8b***. To a 0.37 M ethanolic solution (20 ml) of sodium ethoxide, were added **3b** (1.656 g, 6.62 mmol) and **7** (2.010 g, 8.04 mmol), and the resulting mixture was stirred at room temperature for 2 h and at 50 °C for 23 h. After addition of water (20 ml) and extraction with diethyl ether (50 ml × 3), the organic layer was dried (Na_2SO_4), evaporated, and subjected to column chromatography on silica gel to give an oil (1.974 g) which was shown by NMR and TLC analyses to consist mainly of **8b**. However, the impurities could not be separated from **8b** by repeated chromatography.

The oil (0.709 g, about 1.98 mmol) was dissolved in ethanol (10 ml) and, after addition of potassium hydroxide (444 mg, 7.92 mmol), the resulting mixture was refluxed for 2 h. After

water (20 ml) was added, the mixture was acidified to pH 2 with 2 M hydrochloric acid and extracted with diethyl ether (50 ml×3). The extract was dried (Na_2SO_4), evaporated, and separated by column chromatography on silica gel using ethyl acetate as an eluent to give **9b** (465 mg) in 76% overall yield from **3b** as a colorless oil, which was further purified by a short-path distillation (bath temperature: 180 °C/1 mmHg); NMR ($CDCl_3$): δ 3.13 (2H, d, J=7 Hz) 3.85 (1H, t, J=7 Hz), 7.12—7.54 (10H, broad), and 11.06 (1H, s); IR (neat): 3300—2500 and 1715 cm^{-1}.

Found: C, 70.11; H, 5.58%. Calcd for $C_{15}H_{14}O_2S$: C, 69.74; H, 5.46%.

Synthesis of 6d from Ethyl Phenylacetate. Typical Procedure: To a 1.27 M ethanolic solution (15 ml) of sodium ethoxide, were added ethyl phenylacetate (2.630 g, 16 mmol) and diethyl carbonate (15 ml), and the resulting mixture was heated under slow removal of ethanol and diethyl carbonate through the top of the Vigreux column equipped on the reaction flask. After diethyl carbonate (9 ml) was removed, the mixture was cooled to an ambient temperature. Then, tetrahydrofuran (50 ml) and **5** (2.620 g, 20.8 mmol) were added and the resulting mixture was stirred at room temperature for 3 h. After addition of water (30 ml) and extraction with diethyl ether (50 ml×3), the extract was dried (Na_2SO_4), evaporated, and distilled *in vacuo* to give **6d** (4.160 g, 92% yield) as a colorless oil: bp 130—132 °C/1 mmHg; NMR ($CDCl_3$): δ 1.24 (6H, t, J=7 Hz), 1.97 (3H, s), 4.28 (4H, q, J=7 Hz), and 7.2—7.8 (5H, broad); IR (neat): 1725 cm^{-1}.

Found: C, 59.64; H, 6.35%. Calcd for $C_{14}H_{18}O_4S$: C, 59.55; H, 6.43%.

In analogous manners, **8d** and **11** were synthesized.

8d: A colorless oil which was purified by column chromatography on silica gel using benzene as an eluent followed by a shortpath distillation (bath temperature: 180 °C/2 mmHg); NMR ($CDCl_3$): δ 1.50 (6H, t, J=7 Hz), (4H, q, J=7 Hz), and 7.0—7.75 (10H, broad); IR (neat): 1750 and 1730 (sh) cm^{-1}.

Found: C, 66.13; H, 5.88%. Calcd for $C_{19}H_{20}O_4S$: C, 66.26; H, 5.85%.

11; A colorless oil; bp 131 °C/3 mmHg; NMR ($CDCl_3$): δ 1.29 (3H, t, J=7 Hz), 2.25 (3H, s), 4.28 (2H, q, J=7 Hz), and 7.3—7.85 (5H, broad); IR (neat): 2250 and 1750 cm^{-1}.

Found: C, 61.33; H, 5.59; N, 5.98%. Calcd for $C_{12}H_{13}NO_2S$: C, 61.25; H, 5.59; N, 5.95%.

Hydrolysis of 6a. Typical Procedure: To a solution of **6a** (2.007 g, 5.80 mmol) in ethanol (20 ml), was added potassium hydroxide (1.208 g, 21.6 mmol), and the resulting mixture was refluxed for 3 h. Then, water (30 ml) was added and the mixture was acidified below pH 2 with 3 M hydrochloric acid. After extraction with diethyl ether (30 ml ×3), the extract was dried (Na_2SO_4), evaporated, and subjected to column chromatography on silica gel using ethyl acetate as an eluent to give **1a** (1.059 g, 74% yield) as a colorless oil which was further purified by a short-path distillation (bath temperature: 145—148 °C/0.1 mmHg); NMR ($CDCl_3$): δ 0.75—1.10 (3H, broad t), 1.10—1.40 (18H, broad), 2.20 (3H, s), 3.19 (1H, t, J=8 Hz), and 10.77 (1H, s); IR (neat): 3300—2500 and 1715 cm^{-1}.

Found: C, 63.54; H, 10.81%. Calcd for $C_{13}H_{26}O_2S$: C, 63.34; H, 10.64%.

In analogous manners using the conditions given in Tables 1 and 2, the following compounds were obtained.

1b: A colorless oil which was purified by column chromatography on silica gel using ethyl acetate as an eluent followed by a short-path distillation (bath temperature: 150 °C/2 mmHg); NMR ($CDCl_3$): δ 2.19 (3H, s), 2.80—3.60 (3H, m), 7.20 (5H, s), and 8.92 (1H, s); IR (neat): 3300—2400 and 1700 cm^{-1}.

Found: C, 61.15; H, 6.32%. Calcd for $C_{10}H_{12}O_2S$: C, 61.20; H, 6.16%.

1c: A colorless oil which was purified by column chromatography on silica gel using benzene-hexane (2 : 1) as an eluent followed by a short-path distillation (bath temperature: 168—170 °C/0.08 mmHg); NMR ($CDCl_3$): δ 0.75—1.06 (3H, broad t), 1.10—1.55 (6H, m), 1.81—2.17 (2H, m), 2.18 (3H, s), 1.94—2.55 (2H, m), 3.20 (1H, t, J=7.5 Hz), 5.40 (1H, dt, J=15.5 and 6 Hz), 5.52 (1H, dt, J=15.5 and 6 Hz), and 10.4 (1H, broad); IR (neat): 3300—2500 and 1715 cm^{-1}.

Found: C, 60.99; H, 9.24%. Calcd for $C_{11}H_{20}O_2S$: C, 61.06; H, 9.34%.

1d: Colorless crystals which were obtained by column chromatography on silica gel using dichloromethane as an eluent; mp 76—77 °C; NMR ($CDCl_3$): δ 2.09 (3H, s), 4.50 (1H, s), 7.2—7.6 (5H, broad), and 10.98 (1H, s); IR (KBr): 3200—2700 and 1690 cm^{-1}.

Found: C, 59.34; H, 5.49%. Calcd for $C_9H_{10}O_2S$: C, 59.32; H, 5.53%.

1e: Colorless crystals; mp 62.5—63 °C (from benzene); NMR (d_6-DMSO): δ 1.83 (2H, m), 2.04 (3H, s), 2.28 (2H, t, J=8 Hz), 3.18 (1H, t, J=8 Hz), and 12.4 (2H, broad); IR (KBr): 3500—2500 and 1695 cm^{-1}.

Found: C, 40.61; H, 5.56%. Calcd for $C_6H_{10}O_4S$: C, 40.44; H, 5.65%.

1f: Colorless crystals; mp 132—134 °C (from dichloromethane–benzene); NMR (d_6-DMSO): δ 1.04 (3H, d, J= 6 Hz), 2.06 (3H, s), 2.24 (3H, m), 3.16 (1H, diffused d, J=7 Hz), and 12.36 (2H, broad); IR (KBr): 3300—2500 and 1700 cm^{-1}.

Found: C, 43.99; H, 6.30%. Calcd for $C_7H_{12}O_4S$: C, 43.73; H, 6.29%.

1g: Colorless crystals; mp 187—188 °C (from dichloromethane); NMR (d_6-DMSO): δ 2.14 (3H, s), 2.9—3.7 (4H, m), 7.28 (5H, s), and 12.2 (2H, broad); IR (KBr): 3300—2500 and 1700 cm^{-1}.

Found: C, 56.41; H, 5.51%. Calcd for $C_{12}H_{14}O_4S$: C, 56.67; H, 5.54%.

9a: A colorless oil which was purified by column chromatography on silica gel using ethyl acetate as an eluent followed by a short-path distillation (bath temperature: 195 °C/1 mmHg); NMR ($CDCl_3$): δ 0.62—1.03 (3H, broad t), 1.03—1.55 (18H, broad), 3.60 (1H, t, J=7 Hz), 7.15—7.58 (5H, broad), and 10.95 (1H, s); IR (neat): 3400—2400 and 1710 cm^{-1}.

Found: C, 70.15; H, 9.35%. Calcd for $C_{18}H_{28}O_2S$: C, 70.09; H, 9.15%.

9d: Colorless crystals which were obtained by column chromatography on silica gel using ethyl acetate as an eluent and subjected to an elemental analysis; mp 100 °C; NMR ($CDCl_3$): δ 4.88 (1H, s), 7.1—7.55 (10H, broad), and 11.08 (1H, s); IR (KBr): 3200—2400 and 1690 cm^{-1}.

Found: C, 68.58; H, 4.97%. Calcd for $C_{14}H_{12}O_2S$: C, 68.83; H, 4.95%.

Hydrolysis of 11. A mixture of **11** (947 mg, 4.0 mmol) and 8 M hydrochloric acid was refluxed for 12 h. After addition of water (50 ml) and extraction with diethyl ether (100 ml×3), the organic layer was dried (Na_2SO_4), evaporated, and subjected to column chromatography on silica gel using dichloromethane as an eluent to afford colorless crystals (558 mg, 76% yield) which were identified with **1d** by their IR and NMR spectra.

Production of 2a from 6a. Typical Procedure: To a 0.66 M ethanolic solution of sodium ethoxide, was added **6a** (432 mg, 1.25 mmol) and the resulting solution was stirred

at room temperature for 88 h and at 50 °C for 5 h. After addition of water (20 ml) and extraction with diethyl ether (50 ml × 3), the extract was dried (Na_2SO_4), evaporated, and subjected to column chromatography on silica gel using benzene–hexane (1 : 1) as an eluent to give **2a** (317 mg, 93% yield) as a colorless oil which was further purified by a short-path distillation (bath temperature: 145 °C/3 mmHg); NMR ($CDCl_3$): δ 0.70—1.10 (3H, broad t), 1.15—1.45 (21H, broad), 2.15 (3H, s), 3.18 (1H, t, J=7 Hz), and 4.22 (2H, q, J=7 Hz); IR (neat): 1725 cm^{-1}.

Found: C, 65.89; H, 10.77%. Calcd for $C_{15}H_{30}O_2S$: C, 65.64; H, 11.02%.

In analogous manners, **6b**, **6c**, and **6d** were converted to **2b**, **2c**, and **2d**, respectively.

2b: A colorless oil; NMR ($CDCl_3$): δ 1.13 (3H, t, J=7 Hz), 2.10 (3H, s), 2.85—3.50 (3H, m), 4.08 (2H, q, J=7 Hz), and 7.20 (5H, s); IR (neat): 1725 cm^{-1}. These data were in complete accordance with those of an authentic specimen prepared by esterification of **1b** (hydrogen chloride/ethanol).

2c: A colorless oil which was purified by column chromatography on silica gel using benzene–hexane (1 : 2) as an eluent followed by short-path distillation (bath temperature: 118—123 °C/0.03 mmHg); NMR ($CDCl_3$): δ 0.69—1.05 (3H, broad t), 1.10—1.59 (6H, m), 1.28 (3H, t, J=7 Hz), 1.74—2.85 (4H, m), 2.14 (3H, s), 3.19 (1H, dd, J=7 and 9 Hz), 4.19 (2H, q, J=7 Hz), 5.40 (1H, dt, J=15.5 and 6 Hz), and 5.52 (1H, dt, J=15.5 and 6 Hz); IR (neat): 1730 cm^{-1}.

Found: C, 63.88; H, 9.72%. Calcd for $C_{13}H_{24}O_2S$: C, 63.88; H, 9.92%.

2d: A colorless oil; NMR ($CDCl_3$): δ 1.20 (3H, t, J=7 Hz), 2.05 (3H, s), 4.15 (2H, q, J=7 Hz), 4.49 (1H, s), and 7.16—7.55 (5H, broad); IR (neat): 1735 cm^{-1}. These data were completely identical with those of an authentic sample prepared by esterification of **1d** (hydrogen chloride/ethanol).

*Preparation of **6f** from Ethyl Crotonate in One-pot Reaction.*
To a 0.63 M ethanolic solution of sodium ethoxide, were added diethyl malonate (1.695 g, 10.0 mmol) and ethyl crotonate (1.223 g, 10.0 mmol), and the resulting solution was refluxed for 2 h. Then, the mixture was cooled to room temperature and **5** (3.363 g, 27 mmol) was added. The mixture was stirred at room temperature for 39 h and refluxed for 1 h. After addition of water (80 ml) and extraction with dichloromethane (70 ml × 3), the extract was dried (Na_2SO_4) and evaporated to give an oil (4.688 g) which was shown by GLC analysis using *trans*-stilbene as an internal standard to contain 2.25 g (67% yield) of **6f**.

*Preparation of **6g** from Ethyl Cinnamate in One-pot Reaction.*
To a 0.91 M ethanolic solution of sodium ethoxide, were added diethyl malonate (7.986 g, 50 mmol) and ethyl cinnamate (8.924 g, 50 mmol), and the resulting mixture was stirred at room temperature for 25 h. Then, **5** (7.153 g, 56 mmol) was added and the mixture was stirred at room temperature for 21 h. After addition of water (100 ml) and extraction with dichloromethane (100 ml × 3), the extract was dried (Na_2SO_4) and evaporated to give a pale yellow oil containing crystals (21.353 g) which was shown by GLC analysis to contain 13.6 g (72% yield) of **6g**. By recrystallization from hexane, 8.628 g of **6g** was isolated in a pure form.

(Received September 3, 1981)

Mass spectral fragmentations of furanoeremophilane derivatives bearing oxygen-function on B ring were investigated. It was found that mass spectra measured by direct inlet system gave characteristic *retro*-Diels-Alder fragmentations, while indirect introduction of the samples afforded intense peaks at *m/e* 159 and *m/e* 145 containing the furan moiety. Fragmentation patterns of other poly-functional derivatives were examined by measurements of accurate masses and metastable ions.

In the course of structure determination of sesquiterpenes in plants of the genera *Farfugium*,[2)] *Ligularia*,[3)] and *Syneilesis*,[4)] mass spectra of furanoeremophilane derivatives have been investigated. We now wish to report their characteristic fragmentations which provide useful information for structural studies of furanoeremophilane derivatives.

The *retro*-Diels-Alder fragmentation induced by electron-impact[5)] is one of the most important processes occurring in many sesquiterpenes of a furanoeremophilane type (Fig. 1). However in the case of furanoeremophilane derivatives possessing oxygen-function(s), such as hydroxyl, acyloxyl, and alkoxyl groups, on ring B, the *retro*-Diels-Alder fragmentation was predominant only when the direct introduction of the sample was employed. The spectra of these compounds measured by use of the indirect inlet system showed intense peaks at either *m/e* 159 or *m/e* 159 and 145 and the *retro*-Diels-Alder fragmentation was scarcely observed. The fragmentations leading to the ions at *m/e* 159 and *m/e* 145 are discussed below.

The mass spectra of ligularol (**1**),[6)] epiligularol (**2**),[6)] furanoeremophilan-9α-ol (**3**),[7)] 6β-methoxyfuranoeremophilane (**4**),[8)] 6β-ethoxyfuranoeremophilane (**5**), ligularol acetate (**6**),[6)] and 6β-senecioyloxyfuranoeremophilane (**7**),[2c)] exhibited characteristic peaks at *m/e* 216 (ion **a**), *m/e* 201 (ion **b**), *m/e* 159 (ion **c**), and *m/e* 145 (ion **d**) when the indirect introduction of the sample was employed. The ion **a** must arise by pyrolysis of these compounds prior to ionization at the surface of the heated inlet system. This is supported by comparison of the mass spectrum of 9-dehydrofuranoeremophilane (**8**), a dehydration product of **1**, **2**, and **3**, with those of **1**, **2**, and **3** (Figs. 2 and 3 and Table 1).

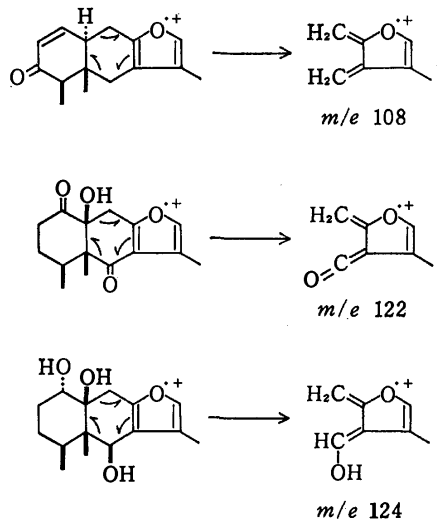

Fig. 1.

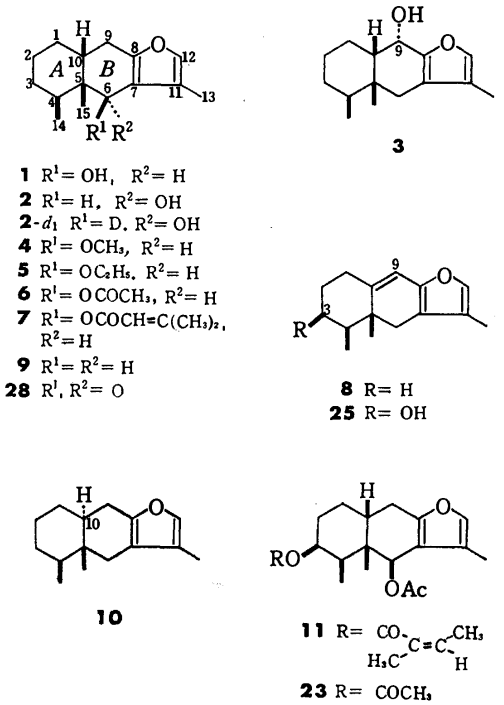

Fig. 2.

Epiligularol (**2**) was treated with *p*-toluenesulfonyl chloride in pyridine under reflux to give 9-dehydrofuranoeremophilane (**8**)[9)] as a major product, formation of which would be explicable by conjugate 1,4-elimination of water followed by [1,5]-hydride shift. The dehydration product (**8**), on hydrogenation over 10% palladium-charcoal, gave an inseparable epimeric mixture, which was revealed to consist of furanoeremophilane (**9**)[10)] and 10-epifuranoeremophilane (**10**)[3a)] in a ratio of 1 : 1 on the basis of comparison of ^{1}H NMR, UV, IR, and mass spectra.

Dehydration of ligularol (**1**) and furanoeremophilan-

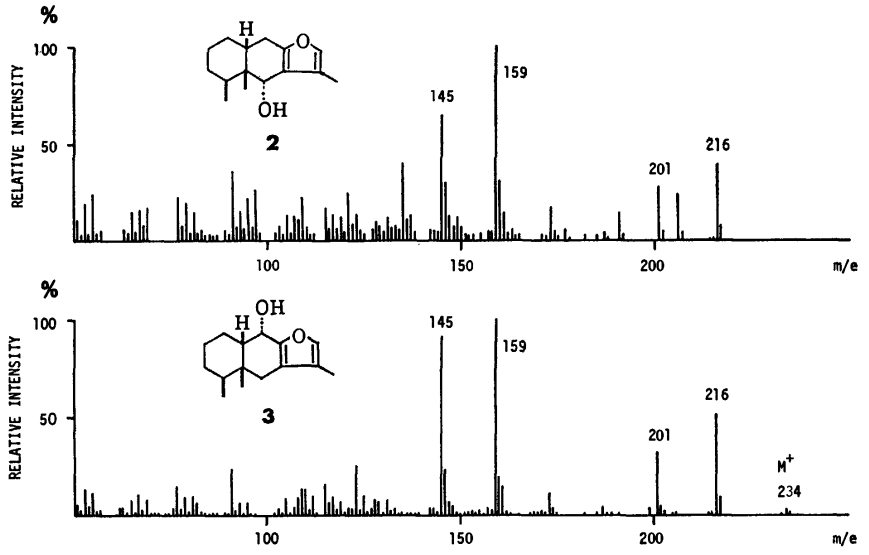

Fig. 3.

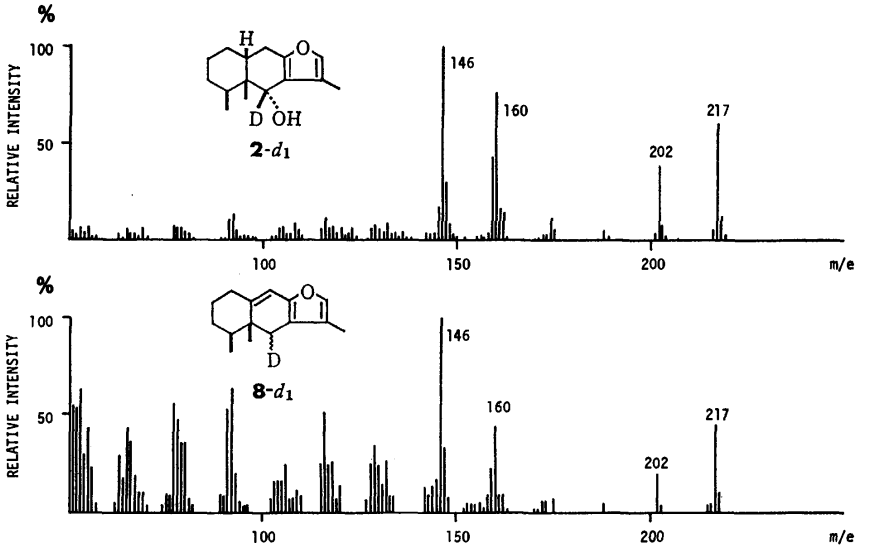

Fig. 4.

9α-ol (**3**) with *p*-toluenesulfonyl chloride in pyridine gave also 9-dehydrofuranoeremophilane (**8**) as a major product. The mass spectrum of **8** measured by direct introduction showed intense peaks at *m/e* 216 (M^+), 201, 159, and 145 and its resemblance to those of **1**, **2**, and **3** is illustrated by the spectra of deuterio compounds, **2**-d_1 and **8**-d_1 (*vide infra*) (Fig. 4 and Table 1).

A plausible mechanism for the fragmentations to afford ion **b**, ion **c**, and ion **d** is depicted in Fig. 5.

The elemental compositions of ion **a** (*m/e* 216.1520; calcd for $C_{15}H_{20}O$: *m/e* 216.1513), ion **b** (*m/e* 201.1297; calcd for $C_{14}H_{17}O$: *m/e* 201.1279), ion **c** (*m/e* 159.0832; calcd for $C_{11}H_{11}O$: *m/e* 159.0810), and ion **d** (*m/e* 145.0652; calcd for $C_{10}H_9O$: *m/e* 145.0655) were determined by the high resolution mass spectrum of epiligularol (**2**). Metastable ions were observed at *m/e* 187.0 (*m/e* 216→*m/e* 201), *m/e* 104.6 (*m/e* 201→*m/e* 145), and *m/e* 117.2 (*m/e* 216→*m/e* 159) in the spectra of epiligularol (**2**), furanoeremophilan-9α-ol (**3**), and ligularol acetate (**6**). These observations indicate that ion **c** arises from ion **a** in one step and ion **d** from ion **a** through ion **b**. The mass spectra of 6β-deuterioepiligularol (**2**-d_1) and its dehydration product (**8**-d_1) showed peaks due to ion **a** at *m/e* 217, ion **b** at *m/e* 202, ion **c** at *m/e* 160 and 159, and ion **d** at *m/e* 146, affording further information for the mechanism of the fragmentations (Table 1). Ion **c** must be derived from ion **a** by the favorable cleavage of $C_{(1)}$–$C_{(2)}$ and $C_{(4)}$–$C_{(5)}$ bonds, both locating β to the Δ^9-double bond. Alternatively, ion **a** loses a methyl radical most probably from the position C-5 to afford ion **b**, the position being allylic to the double bond. The ion **b** may undergo 1,2-hydrogen shift from C-6 to C-5 followed by cleavage of $C_{(1)}$–$C_{(2)}$ and $C_{(4)}$–$C_{(5)}$ bonds to give the fully con-

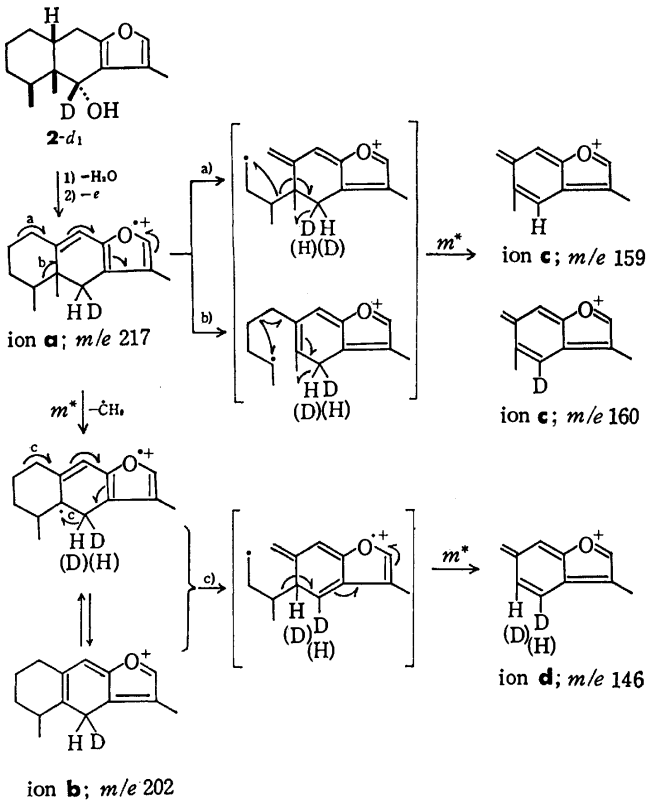

Fig. 5.

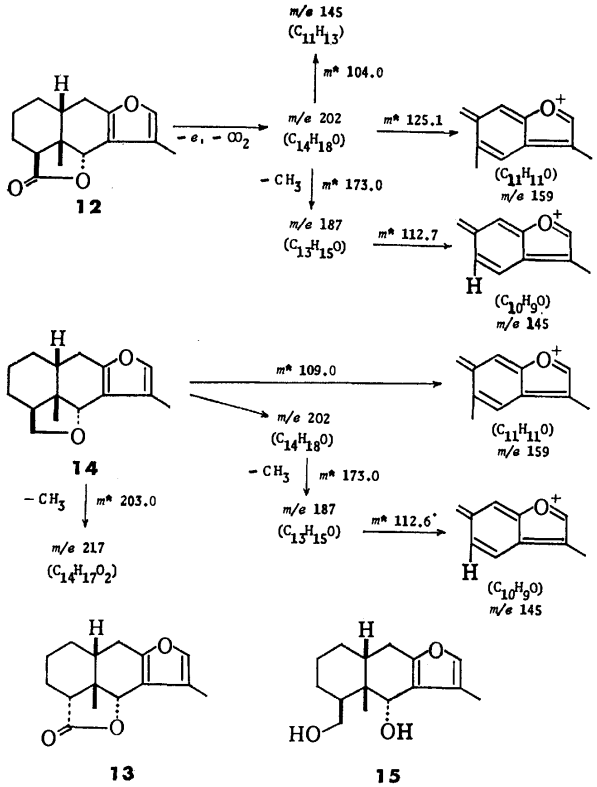

Fig. 6.

jugated ion **d** (Fig. 5).

Now it has been demonstrated that elimination of oxygen-function at C-6 in furanoeremophilane derivatives occurs with ease in mass spectral measurement by the indirect inlet system. A number of natural furanoeremophilanes with different acyloxyl groups at C-3 and C-6 positions have been reported.[11] The electron-impact mass spectral measurement by the indirect inlet method would provide a diagnostic technique for determination of the positions of acyloxyl groups based on the argument developed above.

Mass spectra of 6β-acetoxy-3β-angeloyloxyfuranoeremophilane (**11**)[2b] were then examined by two inlet methods. When mass spectrum of **11** was measured by indirect inlet method, a peak at *m/e* 314 due to elimination of acetic acid by preferential loss of the acetoxyl group at C-6 was observed; a peak at *m/e* 274 due to elimination of angelic acid by loss of the angeloyloxyl group at C-3 was absent. On the other hand, the direct inlet measurement afforded two peaks at *m/e* 314 and *m/e* 274 with an intensity ratio of 9 : 2 (Table 1). This method was successfully applied to determination of the structures of 3β,6β-diacyloxyfuranoeremophilane derivatives obtained from *Syneilesis palmata* (Thunb.) Maxim.[4]

Mass spectra of furanoeremophilan-14,6α-olide (**12**) and its derivatives, **13**, **14**, and **15**,[3b] also exhibited their characteristic ions at *m/e* 159 and *m/e* 145 even when they were measured by the direct inlet method. The fragmentation modes for **12** and **14** are shown in Fig. 6.

Accurate mass measurements for **12** and **14** revealed that the peak at *m/e* 145 splitted into a doublet, a peak at *m/e* 145.0649 (calcd for $C_{10}H_9O$: *m/e* 145.0655) and a peak at *m/e* 145.1001 (calcd for $C_{11}H_{13}$: *m/e* 145.1016). A metastable ion at *m/e* 104.0 for **12** may correspond to the process, $C_{14}H_{18}O^+$ (*m/e* 202)$\rightarrow C_{11}H_{13}^+$ (*m/e* 145). The ion at *m/e* 159 for **12** consists of two species, $C_{11}H_{11}O^+$ (*m/e* 159.0828; calcd: *m/e* 159.0810) and $C_{12}H_{15}^+$ (*m/e* 159.1182; calcd: *m/e* 159.1174). The ion at *m/e* 202 (*m/e* 202.1358; calcd for $C_{14}H_{18}O$: *m/e* 202.1358) for **14** is probably formed from its molecular ion (M^+ at *m/e* 232.1540; calcd: *m/e* 232.1463) by one-step elimination of CH_2O, although the appropriate metastable ion was not observed. In the case of **15**, its dehydration to give **14** dominates over the *retro*-Diels-Alder fragmentation.

Mass spectral fragmentations of the following furanoeremophilane derivatives which have two or three oxygen-functions (Fig. 7) were examined; furanoeremophilane-3β,9β-diol (**16**),[2c] furanopetasine (**17**),[12] furanopetasol (**18**)[12] (Fig. 8), furanoeremophilane-3β,10β-diol (**19**)[2d] (Fig. 8), 3β-angeloyloxy-9β-senecioyloxyfuranoeremophilane (**20**),[2c] furanoeremophilane-6β,10β-diol (**21**)[3c] (Fig. 9), 6β-senecioyloxyfuranoeremophilan-10β-ol (**22**),[2c] 3β,6β-diacetoxyfuranoeremophilane (**23**),[2b] 6β-acetoxy-3β-angeloyloxyfuranoeremophilane (**11**) (*vide supra*), and furanoeremophilane-3β,9β,10β-triol (**24**).[2d] These compounds showed the same fragmentation modes as those of the compounds **1**—**7**; the characteristic fragment ions at *m/e* 159 and *m/e* 145 were observed by the indirect inlet measurement, while the *retro*-Diels-Alder fragmentation was predominant by the direct inlet method (Table 1). Among these compounds, **21**, **22**, and **24** which possess

a) Mass spectra were measured on a Hitachi RMU-6-Tokugata mass spectrometer. Relative intensities are indicated in parentheses and i and d in the second column indicate indirect and direct introduction of samples, respectively. b) RDA fragment represents *retro*-Diels-Alder fragmentation. c) Observed at *m/e* 146. d) Observed at *m/e* 160.

two oxygen-functions at C-10 and either C-6 or C-9 on B ring, showed remarkable intense peak at *m/e* 159 compared with peak at *m/e* 145 by the indirect inlet measurement.

Thermal dehydration of furanoeremophilane-6β,10β-diol (**21**) has been reported to give benzofuran derivatives, farfugins A (**26**) and B (**27**).[2a] The mass spectral investigation showed that farfugin B (**27**) gave a dominant fragmentation due to benzylic cleavage, resulting in the formation of a benzyl (or tropylium) ion at *m/e* 159 (Fig. 9), while the principal peaks in the spectrum of farfugin A (**26**) were a molecular ion at *m/e* 214 and an ion at *m/e* 199 $[M-CH_3]^+$. These results suggest that **21**, **22**, and **24** undergo a facile aromatization into **26** and **27** on the heated surface of the inlet system prior to ionization and give the intense benzyl ion at *m/e* 159, a part of which, however, would be produced through the fragmentation analogous to that shown in Fig. 5. Thus the mass spectral investigation could be applied to the prediction of aptitude for the aromatiza-

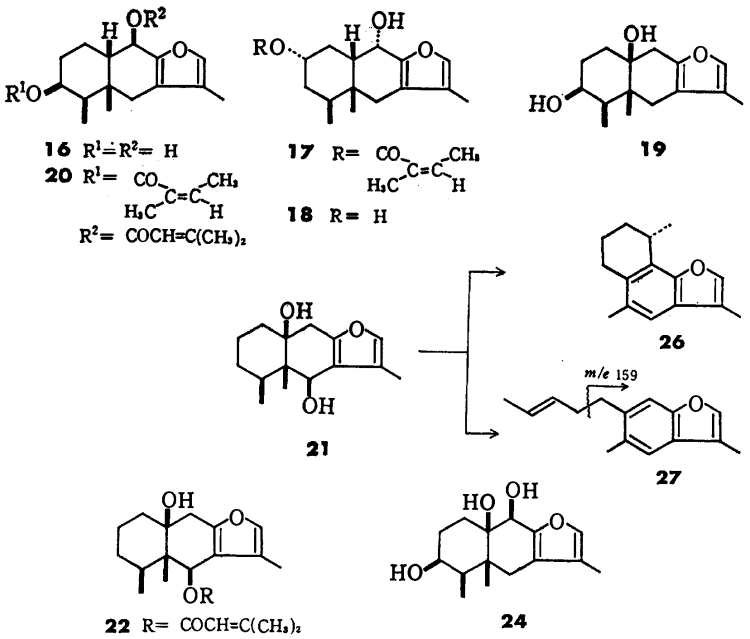

Fig. 7.

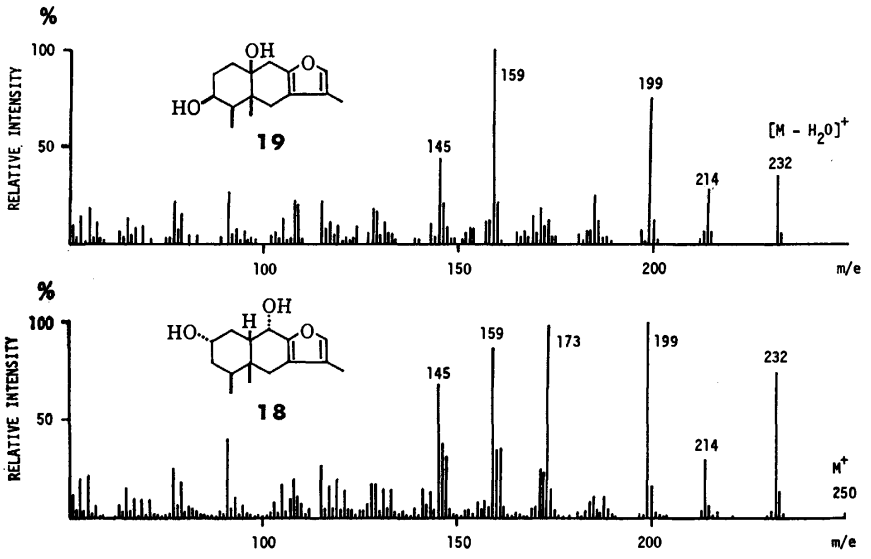

Fig. 8.

tion of furanoeremophilanediol, triol, and their acyl derivatives by elimination of the oxygen-functions to give **27** or its derivatives.[2a,13]

Experimental

Measurement of Mass Spectra. The low-resolution mass spectra were measured on a Hitachi RMU-6-Tokugata mass spectrometer using ionization energy 70 eV with source temperature of 180—230 °C (indirect inlet system) and 120—140 °C (direct inlet system). The high-resolution mass spectra were determined with a CEC 110B type mass spectrometer (indirect inlet system).

Dehydration of Epiligularol (2) with p-Toluenesulfonyl Chloride in Pyridine. *p*-Toluenesulfonyl chloride (100 mg) was added to a solution of **2** (91 mg) in pyridine (8 ml) and the mixture was heated at 120 °C (oil bath temperature) for 2 h under a nitrogen atmosphere. Evaporation of the solvent under reduced pressure gave a residue, which was immediately chromatographed on silical gel (5 g) using light petroleum as an eluent to give an oil (58 mg) containing **8** as the major component. The oil was unstable and therefore further purification was not carried out.

Hydrogenation of 9-Dehydrofuranoeremophilane (8) over Palladium–charcoal. The above product (**8**) prepared from epiligularol (**2**; 67 mg) was hydrogenated over 10% palladium–charcoal (50 mg) in ethanol with stirring for 9.5 h. Filtration of the catalyst and evaporation of the solvent gave a residue (45 mg), which was chromatographed on silica gel using light petroleum as an eluent to afford a mixture of furanoeremophilane (**9**) and 10-epifuranoeremophilane (**10**) in a ratio of 1 : 1. Spectral data of the mixture of **9** and **10** are as

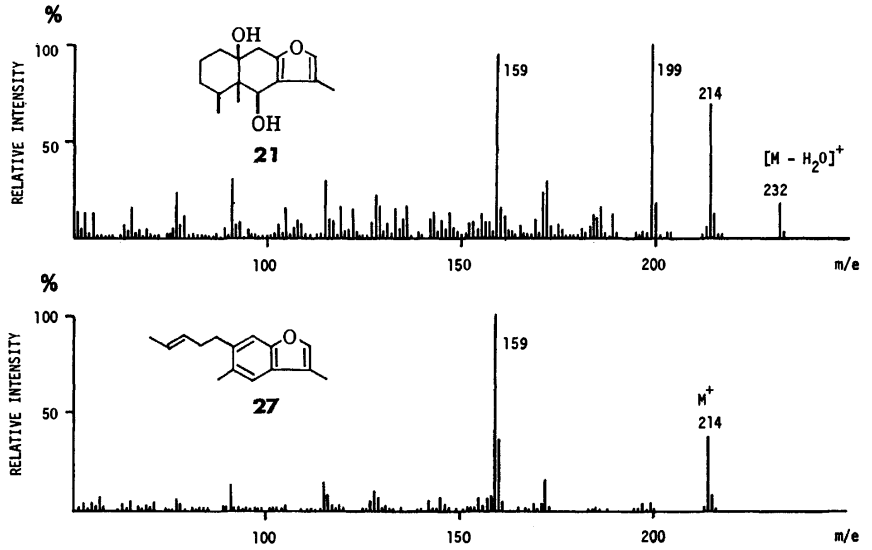

Fig. 9.

follows: UV (EtOH) λ_{max} 220.5 nm (ε 6700); IR (liquid film) 1640, 1560, and 735 cm^{-1}; ^1H NMR (CCl_4) δ 0.69 (s, $C_{(5)}$-CH_3 for **10**), 0.91 (s, $C_{(5)}$-CH_3 for **9**), 1.86 (d, J=*ca.* 1 Hz, $C_{(11)}$-CH_3), and 6.90 (m, $C_{(12)}$-H); ^1H NMR ($CDCl_3$) δ 0.68 (s, $C_{(5)}$-CH_3 for **10**), 0.91 (s, $C_{(5)}$-CH_3 for **9**), 1.89 (d, J=*ca.* 1 Hz, $C_{(11)}$-CH_3), and 7.03 (m, $C_{(12)}$-H); ^1H NMR (C_6D_6) δ 0.61 (s, $C_{(5)}$-CH_3 for **10**), 0.79 (s, $C_{(5)}$-CH_3 for **9**), 1.80 (d, J=*ca.* 1 Hz, $C_{(11)}$-CH_3), and 7.05 (m, $C_{(12)}$-H); the chemical shifts of $C_{(5)}$-CH_3 for furanoeremophilane (**9**) and 10-epifuranoeremophilane (**10**) reported in the literatures[3a,10] are as follows: δ 0.90 ($CDCl_3$) for **9** and δ 0.69 (CCl_4) and 0.61 (C_6D_6) for **10**; MS *m/e* 218 (19%, M^+ ($C_{15}H_{22}O$)) and 108 (100%, *retro*-Diels-Alder fragment).

*6β-Deuterioepiligularol (**2**-d_1).* Ligularone (**28**: 43 mg) in dry ether was stirred with lithium aluminium deuteride (15 mg) for 1 h under a nitrogen atmosphere. The excess of the reagent was decomposed with water, and the reaction product was extracted with ether. The usual work-up gave a crystalline product (34 mg), which was recrystallized from light petroleum to give **2**-d_1. The molecular ion was observed at *m/e* 235.

*6β-Ethoxyfuranoeremophilane (**5**).* A solution of ligularol (**1**; 56 mg) in ethyl iodide (3 ml) was heated under reflux in the presence of silver(I) oxide (113 mg) and *N,N*-dimethylformamide (0.5 ml) for 3 h. After filtration the reaction mixture was evaporated to give an oily residue. The oil was chromatographed on silica gel (3 g) using light petroleum as an eluent to give 6β-ethoxyfuranoeremophilane (**5**; 18 mg).

Extraction of the roots of *Ligularia fischeri* TURCZ. with methanol and ethanol gave 6β-methoxyfuanoeremophilane (**4**) and 6β-ethoxyfuranoeremophilane (**5**), respectively. In the extract of the root of the plant with benzene **4** and **5** were not detected. This indicates that these compounds are artifacts derived from ligularol (**1**) by acid-catalyzed substitution reaction during the extraction procedure. Spectral data of **5**, mp 36—39 °C, are as follows: UV (MeOH) λ_{max} 221 nm (ε 5600); IR (Nujol) 1640 and 1560 cm^{-1}; ^1H NMR ($CDCl_3$) δ 0.77 (d, J=*ca.* 6Hz, $C_{(4)}$-CH_3), 1.03 (s, $C_{(5)}$-CH_3), 1.17 (t, J=7.5 Hz, $-OCH_2\underline{C}H_3$), 2.03 (d, J=*ca.* 1 Hz, $C_{(11)}$-CH_3), 3.67 (q, J=7.5 Hz, $-OC\underline{H}_2CH_3$), 4.22 (br s, $C_{(6)}$-H), and 7.10 (m, $C_{(12)}$-H); Found: C, 77.79; H, 10.59%. Calcd for $C_{17}H_{26}O_2$: C, 77.82; H, 9.99%.

*6ξ-Deuterio-9-dehydrofuranoeremophilane (**8**-d_1).* 6β-Deuterioepiligularol (**2**-d_1) obtained from ligularone (**28**; 50 mg), was treated with *p*-toluenesulfonyl chloride (58 mg) in pyridine (7 ml) under the same conditions as in the case of **2** to afford 6ξ-deuterio-9-dehydrofuranoeremophilane (**8**-d_1).

The authors wish to thank Dr. L. Novotný, Czechoslovak Academy of Science for a gift of furanoeremophilan-9α-ol, furanopetasine, and furanopetasol, and Professor Koji Yamakawa, Science University of Tokyo, for supplying the spectral data of 9-dehydrofuranoeremophilane.

Department of Chemistry, Faculty of Science, The University of Tokyo, Hongo, Bunkyo-ku, Tokyo 113

(Received October 9, 1981)

Structural studies of four new sesquiterpenes, 3β-angeloyloxy-6β-(3-methylbutanoyloxy)- and 3β,6β-bis(angeloyloxy)furanoeremophilan-14-als and 3β-angeloyloxy-6β-(3-methylbutanoyloxy)- and 3β-angeloyloxy-6β-(3-methylpentanoyloxy)furanoeremophilan-14-oic acids, together with 3β,6β-bis(angeloyloxy)furanoeremophilan-14-oic acid from *Syneilesis palmata* (THUNB.) MAXIM. are described.

Investigations on sesquiterpenes in the plants of the genera *Ligularia*,[2] *Eupatorium*,[3] *Farfugium*,[4] and *Cacalia*[5] (Compositae) have been carried out in our laboratory. Furanoeremophilane derivatives have been shown to be main sesquiterpenes for plants of the genera *Ligularia* and *Farfugium*,[6] but benzofuran derivatives[5,7] together with furanoeremophilanes[8] for those of the genus *Cacalia*.[9] In connection with these studies, *Syneilesis palmata* (THUMB.) MAXIM. (Japanese name: Yaburegasa) (Compositae) was now examined. Only a constitutional investigation of *S. palmata* has been reported by Hikichi and Furuya[10] and three alkaloids, syneilesine, acetylsyneilesine, and senecionine have been isolated. While *S. palmata* is classified morphologically into the genus *Syneilesis*, it is also classified taxonomically into the genus *Cacalia* and named *Cacalia Krameri* MAKINO. Therefore, examination on sesquiterpene constituents of this plant is interested from the chemotaxonomical viewpoint.

Chromatographic separation of the ethereal extract of the roots of *S. palmata* afforded two main components **A** and **B**, which were positive to the Ehrlich test.

It was found that the component **A** gave two peaks in high performance liquid chromatographic examination. Since the component **A**, obtained as an oil, crystallized from pentane on standing, separation by fractional crystallization was attempted but was unsuccessful. High performance liquid chromatography (HPLC) was successfully applied to the separation to afford an aldehyde (**1**) and an ether (**2**) in a ratio of 1 : 1. On treatment of the component **A** with sodium borohydride, the ether (**2**) remained unchanged and separated easily from the reaction mixture. The ether (**2**; content: 0.02%), mp 97—98 °C, was found to be a known 3β-angeloyloxy-6α,14-epoxyfuranoeremophilane.[11]

The aldehyde (**1**; content: 0.03%), mp 82—83 °C, was found to be a mixture of two components **1a** and **1b** by appearance of two molecular ions at *m/e* 430.2334 ($C_{25}H_{34}O_6$) and *m/e* 428.2175 ($C_{25}H_{32}O_6$) in the high resolution mass spectrum. HPLC was applied to further separation of **1** into **1a** and **1b** without success, because each retention time was nearly the same due to their structural similarity. Separation by gas-liquid chromatography (GLC) was not available because of thermal unstability of these compounds. Therefore we were obliged to analyze the mixture (**1**) in order to obtain the information for structure determination of **1a** and **1b**.

† Present address: Laboratory of Bioorganic Chemistry, Tokyo University of Agriculture and Technology, Fuchu, Tokyo 183.

†† Present address: Department of Chemistry, Faculty of Science, Ochanomizu University, Otsuka, Bunkyo-ku, Tokyo 112.

The IR and ^1H NMR spectra of the mixture **1** (**1a** and **1b**) showed the presence of a β-methyl-substituted furan with an α-hydrogen, a tertiary methyl, and an

aldehyde group, together with protons on carbon atoms bearing acyloxyl groups [δ 5.47 (br signal, 1H; $C_{(3)}$–H), 6.28 (m, *ca.* 0.7H; $C_{(6)}$–H of **1a**), and 6.36 (m, *ca.* 0.3H; $C_{(6)}$–H of **1b**)]. Reduction of **1** with sodium borohydride afforded a mixture (**3**) of alcohols, **3a** and **3b**, whose ^{1}H NMR spectrum showed the presence of $-C\underline{H}_2OH$. The mixture of alcohols (**3a** and **3b**) was treated with methanesulfonyl chloride to afford a mixture of mesylates (δ 2.86; $-SO_2CH_3$), which, on reduction with lithium aluminium hydride gave two diols, **4** and **5** in 12% and 57% yields, respectively. The diol (**4**) was identified with a known furanofukinol[12] (furanoeremophilane-3β,6β-diol) by direct comparison with an authentic sample.

In the ^{1}H NMR spectrum of **1**, a doublet signal characteristic of a secondary methyl at C-4 of furanoeremophilanes was not observed, suggesting the formyl group must be attached to the C-4. This was supported by a doublet signal (J=5 Hz) due to the aldehydic proton at δ 9.97. Therefore, **1a** and **1b** were deduced to be 3β,6β-bis(acyloxy)furanoeremophilan-14-als.

The diol (**5**), $C_{15}H_{20}O_3$ (*m/e* 248.1482), was determined to be furanoeremophil-3-ene-6β,14-diol, supporting above conclusion. The presence of a secondary hydroxyl group at C-6 was shown by appearance of a multiplet signal at δ 4.77[13] and a *retro*-Diels Alder fragment ion at *m/e* 124.0518 ($C_7H_8O_2$) as a base peak.[14] The partial structure of 3-en-14-ol for **5** was supported by appearance of a broad signal at δ 5.40 ($C_{(3)}$–H) and an AB quartet signal due to a CH_2OH group attached to a carbon atom carrying no hydrogen atom.

The locations and structures of two acyloxyl groups were determined as follows. The component **A** (a mixture of **1** and **2**) was hydrolyzed with alkali. The carboxylic acids derived from the acyloxyl groups were methylated with diazomethane to give a mixture of methyl esters, which was examined by gas chromatography-mass spectrometry (GC-MS) measurement. Methyl angelate and methyl 3-methylbutanoate were detected in a ratio of *ca.* 3 : 1. From these observations together with the high resolution mass spectral data of **1a** and **1b**, a structure of 3β,6β-bis(angeloyloxy)-furanoeremophilan-14-al was suggested for **1b** and either 3β-angeloyloxy-6β-(3-methylbutanoyloxy)- or 6β-angeloyloxy-3β-(3-methylbutanoyloxy)furanoeremophilan-14-al for **1a**.

It is shown that when mass spectrum of 3β-angeloyloxy-6β-acetoxyfuranoeremophilane (**6**) was measured by direct inlet system, peaks at *m/e* 314 and *m/e* 274 due to fragment ions $(M-AcOH)^+$ and $(M-Angelic\ acid)^+$, respectively, were observed in an intensity ratio of 9 : 2, but when measured by indirect inlet system, only the former peak at *m/e* 314 due to $(M-AcOH)^+$ by elimination of the acetoxyl group on C-6 was observed.[15] These observations mean that an acid moiety at C-6 of 6-acyloxyfuranoeremophilane derivatives is easily eliminated to give the corresponding fragment ion by indirect inlet measurement. Table 1 gives the mass spectral data of **3** measured by the two inlet systems. The mass spectrum measured by indirect inlet system of **3** showed a peak at *m/e* 330 due to elimination of carboxylic acids (3-methylbutanoic acid for **3a** and angelic acid for **3b**) derived from the acyloxyl groups at C-6 with a relative intensity 8.7% but no peak at *m/e* 332 due to elimination of angelic acid, suggesting the presence of the angeloyloxyl group on C-3 for both **3a** and **3b**.

Table 1. Mass spectral data for **3**

m/e	Intensity/% Direct	Indirect	Assignment of ion
432	1.7	—	M^+(**3a**)
430	1.0	—	M^+(**3b**)
348	4.5	—	$(M-R^1+H)^+$
347	1.6	—	$(M-R^1)^+$
332	2.5	—	$(M-AngOH)^+$(derived from **3a**)
330	22[a,b]	8.7[a]	[a]$(M-R^1OH)^+$ (derived form **3a** and **3b**) [b]$(M-AngOH)^+$ (derived from **3b**)
248	6.4	—	$(M-R^1OH-Ang+H)^+$
247	7.5	—	$(M-R^1OH-Ang)^+$
230	37	14	$(M-R^1OH-AngOH)^+$
161	—	24	
159	34	21	
124	22	—	
100	—	24	$(AngOH)^+$
99	29	—	$(AngO)^+$
83	100	36	$(Ang)^+$
55	74	100	$(CH_3CH{=}CCH_3)^+$

In conclusion, **1** is shown to consist of 3β-angeloyloxy-6β-(3-methylbutanoyloxy)furanoeremophilan-14-al (**1a**) and 3β,6β-bis(angeloyloxy)furanoeremophilan-14-al (**1b**) in a ratio of *ca.* 7 : 3.

Component **B** (**7**) was obtained in 0.18% yield as a pale yellow oil and positive to the Ehrlich test. The ^{1}H NMR and mass spectral examination revealed that the component **B** consisted of three carboxylic acids, **7a**, **7b**, and **7c** (deuterium-exchangeable broad singlet at δ 10.05 and molecular ions at *m/e* 446, 444, and 460) and the presence of a β-methyl-substituted furan with an α-hydrogen, a tertiary methyl, and protons [δ 6.28 (*ca.* 0.2H), δ 6.37 (*ca.* 0.7H), and δ 6.48 (*ca.* 0.1H); each assigned to $C_{(6)}$–H, and δ 5.37; $C_{(3)}$–H)] on carbon atoms bearing acyloxyl groups, containing an angeloyloxyl group.

On esterification with diazomethane, **7** gave a mixture (**8**) of **8a** (*m/e* 460.2419, $C_{26}H_{36}O_7$), **8b** (*m/e* 458.2296, $C_{26}H_{34}O_7$), and **8c** (*m/e* 474.2818, $C_{27}H_{38}O_7$). Since HPLC separation of neither the mixture (**8**) nor the mixture (**7**) gave satisfactory results, analysis of the mixture (**8a**, **8b**, and **8c**) was carried out by the same procedures as in the case of **1**.

Reduction of **8** with lithium aluminium hydride afforded a triol (**9**), mp 139—140 °C, which was found to be identical with a triol obtained from **1** by treatment with lithium aluminium hydride. The structure of triol (**9**) was determined to be furanoeremophilane-3β,6β,14-triol by ^{1}H NMR and mass spectral measurements together with the fact that **9** was also derived from **1**. The detail of the structure elucidation of **9** was described below. In the ^{1}H NMR spectrum of **7**, a doublet signal characteristic of a secondary methyl at C-4 is absent. The carboxyl group, therefore, must be

located on C-4 and the acyloxyl groups on C-3β and C-6β for **7**.

Alkaline hydrolysis of **7** gave a mixture of carboxylic acids derived from the acyloxyl moieties. The mixture was methylated with diazomethane and examined by GC-MS measurement. Methyl angelate, methyl 3-methylbutanoate, and methyl 3-methylpentanoate were detected in a ratio of *ca.* 6 : 4 : 1. These observations together with high resolution mass spectral data suggest that 3β,6β-bis(angeloyloxy)furanoeremophilan-14-oic acid could be proposed for **7b**, 3β-angeloyloxy-6β-(3-methylpentanoyloxy)- or 6β-angeloyloxy-3β-(3-methylpentanoyloxy)furanoeremophilan-14-oic acid for **7c**, and 3β-angeloyloxy-6β-(3-methylbutanoyloxy)- or 6β-angeloyloxy-3β-(3-methylbutanoyloxy)furanoeremophilan-14-oic acid for **7a**. The alternatives for **7a** and **7c** were determined by mass spectrum of **8** measured by indirect inlet system (Table 2) and this conclusion was confirmed by the formation of 3β-angeloyloxyfuranoeremophilan-14,6α-olide (**10**) (*vide infra*). Based on arguments developed for **1**, appearance of a fragment peak at *m/e* 358 due to elimination of the acid moieties at C-6 suggests the presence of the angeloyloxyl group on C-3 for **8a**, **8b**, and **8c**. Thus the component **B** (**7**) is shown to consist of 3β-angeloyloxy-6β-(3-methylbutanoyloxy)furanoeremophilan-14-oic acid (**7a**), 3β,6β-bis(angeloyloxy)furanoeremophilan-14-oic acid (**7b**),[11,16] and 3β-angeloyloxy-6β-(3-methylpentanoyloxy)furanoeremophilan-14-oic acid (**7c**) in a ratio of *ca.* 7 : 1 : 2.

TABLE 2. MASS SPECTRAL DATA FOR **8**

Bohlmann *et al.*[16] isolated 3β,6β-bis(angeloyloxy)-furanoeremophilan-14-oic acid (**7b**) and related compounds from plants of the genus *Othonna* (Compositae) and these compounds were transformed into the triol (**9**; furanoeremophilane-3β,6β,14-triol) by methylation and reduction with lithium aluminium hydride. The ^{1}H NMR spectrum of our triol (**9**) derived from **8** was kindly measured and compared with that of the specimen (**9**)[11,16] by Professor Bohlmann. However, we were informed that the two compounds are not identical. The physical and ^{1}H NMR spectral data of **9** reported by Bohlmann *et al.*[11,16] were not coincident with those of ours as shown in Experimental. Therefore the structure of triol (**9**) derived from **8** was investigated closely. Treatment of **7** with a mixture of acetic acid and benzene under reflux afforded a lactone (**10**), mp 112—116 °C, IR 1765 cm^{-1}, the purity of which was confirmed by appearance of a single peak on GLC (column: H523, 200 °C, carrier gas: N_2) and a single molecular ion peak at *m/e* 344.1679 ($C_{20}H_{24}O_5$). The mass spectrum of **10** together with ^{1}H NMR spectrum reveals the presence of an angeloyloxyl moiety and the absence of the other two acyloxyl groups, suggesting the angeloyloxyl group remains at C-3β for **10**. The configuration of $C_{(6)}$–H could be established by NOE measurement. It has been reported that the signal due to $C_{(6\beta)}$–H resonated at δ 5.08 shows increase by 28% on irradiation at δ 1.26 assigned to a signal of $C_{(5\beta)}$–Me of furanoeremophilan-14,6α-olide (**11**).[6b] On saturation of a signal due to $C_{(5\beta)}$–Me resonating at δ 1.21, a signal at δ 4.58 due to the $C_{(6)}$–H of **10** resulted in increase by 25%, indicating the structure 3β-angeloyloxyfuranoeremophilan-14,6α-olide for **10**.

Reduction of **10** with lithium aluminium hydride yielded a triol (**12**), mp 170—172 °C [^{1}H NMR ($CDCl_3$) δ 1.21 (s; $C_{(5)}$–Me), 2.06 (d, J=1.5 Hz; $C_{(11)}$–Me], 4.34 [m; $C_{(6)}$–H, and 7.09 (m; $C_{(12)}$–H)], which was *not identical* with the triol (**9**) (*cf.* Experimental). The triol (**12**) is inferred to be furanoeremophilane-3β,6α,14-triol.

On treatment with dilute hydrochloric acid, **9** and **12** gave the same hydroxy ether (**13**), mp 136—138 °C, which was also obtained from the known 3β-angeloyloxy-6α,14-epoxyfuranoeremophilane (**2**)[11] by reduction with lithium aluminium hydride. The presence of a skeletal structure, 6α,14-epoxyfuranoeremophilane (**14**), was confirmed for **2** and **13** by the observed $J_{4,14}$-values (11 and 11.5 Hz, respectively)[6b] and the appearance of the 6β-H signal at δ 4.58 and 4.55 (in $CDCl_3$),[6b] respectively. The $C_{(5\beta)}$–Me of **13** resonates at lower field δ 1.44 (in $CDCl_3$) compared with that (δ 1.16) of **14**[6b] due to deshielding of the 3β(axial)-hydroxyl group. Based on the correlation of **12** with **10** and **13**, the 3β,6α,14-triol structure was shown for the triol (**12**).

From these evidence, the structure of the triol (**9**) derived from **1** and **7**, was unambiguously established to be furanoeremophilane-3β,6β,14-triol. The ^{1}H NMR spectral data[11] of "Bohlmann's triol" are practically identical with those (in $CDCl_3$) of 6α,14-epoxyfuranoeremophilan-3β-ol (**13**) (*cf.* Experimental). This suggests that "the triol" would be **13**, a dehydrated product of the 3β,6β,14-triol (**9**). The epoxy derivative (**13**) can be formed easily from **9** as shown before.

The $C_{(3\alpha)}$–H signal of our triol (**9**) appears as a quintet ($J_{2\beta,3\alpha}$=10, $J_{2\alpha,3\alpha}$=5, and $J_{3\alpha,4\alpha}$=5 Hz; in $CDCl_3$–D_2O) as in the case of 3β-angeloyloxy-6β-acetoxyfuranoeremophilane (**6** and **6a**).[12] This shows that **9** preferentially adopts a non-steroidal-like conformation depicted as in **9a**.

Some compounds (**15**, **16**, and **17**) derived from **13**,

9, and **10**, respectively, are also described.

The fact that benzofuran derivatives are not isolated from *S. palmata* suggests that plants of the genus *Syneilesis* would be chemotaxonomically related to those of the genus *Ligularia* rather than the genus *Cacalia*. Among four new sesquiterpenes (**1a**, **1b**, **7a**, and **7c**), **1a** and **1b** constitute the first examples of natural furanoeremophilanes with a formyl group at C-4.

Experimental

General Procedures. All melting points were measured on a Mel-temp capillary melting point apparatus (Laboratory Devices) and uncorrected. Optical rotations were determined on a JASCO polarimeter DIP-SL. Ultraviolet absorption (UV) spectra and infrared (IR) spectra were measured on a Hitachi EPS-3 and a Hitachi EPI-G2 spectrometer, respectively. Mass (MS) spectra were run on a Hitachi RMU-6 Tokugata mass spectrometer and high resolution mass spectra on a Hitachi RMH-2 or a JEOL JMS-D300 mass spectrometer operating at 70 eV. Gas chromatography-mass spectrometry (GC-MS) was carried out on a Hitachi RM-50 or a Hitachi 063 gas chromatograph connected with a Hitachi RMS-4 mass spectrometer. The relative intensities were expressed in % in parentheses. Proton nuclear magnetic resonance (^{1}H NMR) spectra (60 MHz) were taken using a Hitachi R-20B or a JEOL JNM FX-60 spectrometer. Chemical shifts were expressed in ppm downfield from tetramethylsilane as an internal standard (δ value) and coupling constants in Hz. Gas-liquid chromatography (GLC) was carried out using a Shimadzu GC-4APF or GC-6A equipped with a hydrogen flame ionization detector. Liquid Chromatograph Model ALC/GPC 202/401 (Waters Assoc.) was used for high performance liquid chromatography (HPLC). Thin layer chromatography (TLC) was carried out on Kieselgel 60 PF_{254} or Kieselgel GF_{254} in 0.25 mm- or 0.5 mm-thickness. Wakogel C-200 (Wako) was used for column chromatography.

Plant Material. *Syneilesis palmata* (Thunb.) Maxim. was collected in August 1977 in University Forest at Chichibu, the University of Tokyo.

Extraction and Separation. Extraction of the air-dried roots (7.5 kg) with ether was carried out for 5 d at room temperature. The extract was concentrated to give an oily residue (32 g), which was subjected to separation by silica gel (900 g) column chromatography and eluted (each fraction: 400 ml) with the following solvents: hexane, 100 ml; 5%-ether in hexane, 1000 ml; 10%-, 1500 ml; 20%-, 2500 ml; 25%-, 1000 ml; 50%-, 2000 ml; ether, 1000 ml; and acetone, 500 ml. Fractions 11—14 and fractions 16—18 were subjected to further purification.

Fractions 11—14 (component **A**), containing **1** and **2**, were combined and evaporated to give an oil (4.27 g), which crystallized from pentane. Separation of **1** and **2** was not attained by fractional crystallization, but was successful by HPLC (column; μ-Porasil, solvent: hexane–ether 4 : 1, flow rate: 0.6 ml/min). The mixture afforded **1** (R_t 8.7 min) and **2** (R_t 9.5 min) in a ratio of *ca.* 1 : 1.

Isolation of **2** from the mixture in a large scale was achieved as follows: the mixture (950 mg) in ethanol (100 ml) was treated with sodium borohydride (1.07 g) for 4 h at room temperature and the reaction mixture, after usual work-up, was purified by silica gel column chromatography. Elution with hexane–ether (1 : 1) afforded **2**[11] (387 mg) and **3** (a mixture of **3a** and **3b**; 345 mg).

Fractions 16—18 (component **B**) gave **7** (13.6 g), mp 124—134 °C (decomp.) (from hexane).

*3β-Angeloyloxy-6β-acyloxyfuranoeremophilan-14-als (**1**, a Mixture of **1a** and **1b**).* Mp 82—83 °C (from hexane), one spot on TLC, IR (Nujol) 1725, 1715, 1640, 1565, 1230, and 1160 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ 1.04 (3H, s, $C_{(5)}$–CH_3), 1.83 (3H, d, J=1.5 Hz, $C_{(11)}$–CH_3), 5.47 (1H, br signal, $W_{1/2}$=*ca.* 16 Hz, $C_{(3)}$–H), 6.00 (*ca.* 1.3H, br q, J=7 Hz, $\underline{H}\!>\!C\!=\!C\!<^{CH_3}_{COO-}$), 6.28 (*ca.* 0.7H, m, $C_{(6)}$–H of **1a**), 6.36 (*ca.* 0.3H, m, $C_{(6)}$–H of **1b**), 6.97 (1H, m, $C_{(12)}$–H), and 9.97 (1H, d, J=5 Hz, –CH–CHO); MS *m/e* (%) 430 (M$^+$ of **1a**; 0.9), 428 (M$^+$ of **1b**; 0.5), 346 (8), 345 (1.7), 330 ([**1a** –AngOH]$^+$ [17]; 1.8), 328 ([**1**–R^{1}OH]$^+$ [17] and [**1b**–AngOH]$^+$; 12), 246 (20), 245 (16), 228 (25), 159 (46), 124 (25), 85 (26), 83 (100), 57 (33), and 55 (56); Found for **1a**: *m/e* 430.2334. Calcd for $C_{25}H_{34}O_6$: M 430.2354. Found for **1b**: *m/e* 428.2175. Calcd for $C_{25}H_{32}O_6$: M 428.2197.

*3β-Angeloyloxy-6β-acyloxyfuranoeremophilan-14-oic Acids (**7**, a Mixture of **7a**, **7b**, and **7c**).* An oil (one spot on TLC), IR (liq) 3000, 1730, 1720, 1710, 1645, 1560, 1230, and 1160 cm^{-1}; ^{1}H NMR (CCl_4) δ 1.13 (3H, s, $C_{(5)}$–CH_3), 1.81 (3H, d, J=1.5 Hz, $C_{(11)}$–CH_3), 5.37 (1H, br signal, $W_{1/2}$=*ca.* 15 Hz, $C_{(3)}$–H), 5.59 (*ca.* 1H, br q, J=7 Hz, $\underline{H}\!>\!C\!=\!C\!<^{CH_3}_{COO-}$), 6.28 (*ca.* 0.2H, m, $C_{(6)}$–H of **7c**), 6.37 (*ca.* 0.7H, m, $C_{(6)}$–H of **7a**), 6.48 (*ca.* 0.1H, m, $C_{(6)}$–H of **7b**), 6.97 (1H, q, J=1.5 Hz, $C_{(12)}$–H), and 10.05 (1H, br s, –COOH; disappeared on addition of D_2O); MS *m/e* (%) 460 (M$^+$ of **7c**; 0.05), 446 (M$^+$ of **7a**; 0.17), 444 (M$^+$ of **7b**; 0.07), 362 (0.8), 361 (0.4), 360 ([**7c** –AngOH]$^+$; 0.4), 346 ([**7a**–AngOH]$^+$; 0.2), 344 ([**7** –R^{1}OH]$^+$ and [**7b** –AngOH]$^+$; 2.7), 262 (5.5), 245 (2.3), 244 (3.7), 161 (13), 159 (11), 83 (75), and 55 (100).

*3β-Angeloyloxy-6α,14-epoxyfuranoereomphilane (**2**).* Mp 97—98 °C (from ether), $[\alpha]_D^{22}$ −18° (*c* 1.2, EtOH), IR (Nujol) 1710, 1635, 1560, 1235, and 1155 cm^{-1}; UV (EtOH) 218 nm (ε 28000); ^{1}H NMR ($CDCl_3$) δ 1.40 (3H, s, $C_{(5)}$–CH_3), 2.02 (3H, d, J=1.5 Hz, $C_{(11)}$–CH_3), 3.67 (1H, dd, $J_{4,14\beta}$=11 and $J_{14\alpha,14\beta}$=7.5 Hz, $C_{(14\beta)}$–H), 3.92 (1H, t, $J_{4,14\alpha}$=7.5 and $J_{14\alpha,14\beta}$=7.5 Hz, $C_{(14\alpha)}$–H), 4.58 (1H, m, $C_{(6)}$–H), 5.32 (1H, br s, $W_{1/2}$=*ca.* 7 Hz, $C_{(3)}$–H), 6.07 (1H, q-like, J=7 Hz, $\underline{H}\!>\!C\!=\!C\!<^{CH_3}_{COO-}$), and 7.01 (1H, m, $C_{(12)}$–H); MS *m/e* (%) 330 (M$^+$; 36), 230 (37), 159 (63), 83 (89), and 55 (100). The ^{1}H NMR and mass spectral data are in good agreement with those of **2** reported in lit.[11]

*3β-Angeloyloxy-6β-acyloxyfuranoeremophilan-14-ols (**3**, a Mixture of **3a** and **3b**).* An oil, IR (liq) 3450, 1720, 1710, 1640, 1560, 1230, and 1160 cm^{-1}; ^{1}H NMR (C_6D_6) δ 1.12 (3H, s, $C_{(5)}$–CH_3), 1.90 (3H, d, J=1.5 Hz, $C_{(11)}$–CH_3), 4.36 (1H, br signal, $W_{1/2}$=19 Hz, $C_{(3)}$–H), 4.34 (1H, dd, J=11.5 and J=6 Hz, $C_{(14)}$–H), 4.73 (1H, dd, J=11.5 and J=3 Hz, $C_{(14)}$–H), 5.75 (1H, br q, J=7 Hz, $\underline{H}\!>\!C\!=\!C\!<^{CH_3}_{COO-}$), 6.49 (*ca.* 0.6H, m, $C_{(6)}$–H of **3a**), 6.59 (*ca.* 0.4H, m, $C_{(6)}$–H of **3b**), 6.96 (1H, m, $C_{(12)}$–H); MS are given in Table 1.

*Treatment of **3** with Methanesulfonyl Chloride.* A solution of **3** (135 mg) in pyridine (4 ml) and methanesulfonyl chloride (15 drops) were allowed to stand overnight at room temperature and usual work-up gave a mesylate (crude, 177 mg) as an oil; IR (liq) 1720, 1705, 1635, 1560, 1340, 1230, and 1160 cm^{-1}; ^{1}H NMR (C_6D_6) δ 2.86 (3H, s, $-SO_2CH_3$); MS *m/e* (%) 510 (M$^+$ of a mesylate from **3a**; 0.4), 508 (M$^+$ of a mesylate from **3b**; 0.2), 426 (4.3), 408 (10), 326 (2.7), 325 (3.2), 308 (6.7), 159 (37), 83 (100), and 55 (96).

Reduction of the Mesylates with Lithium Aluminium Hydride.

A mixture of the crude mesylates (177 mg) dissolved in ether (20 ml) and lithium aluminium hydride (200 mg) was stirred at room temperature for 1.5 h and then heated under reflux for 1 h. The reaction mixture was worked up as usual, chromatographed on silica gel, and eluted with ether to give furanoeremophilane-3β,6β-diol (**4**;[12] 9 mg, 12% yield from **3**) and furanoeremophil-3-ene-6β,14-diol (**5**; 44 mg, 57% yield from **3**).

4; Mp 176—179 °C (decomp) (from ether). **5**; An oil, $[\alpha]_D^{27}$ −14° (*c* 0.02, EtOH); IR (liq) 3430, 3250, 1645, and 1565 cm^{-1}; ^{1}H NMR (C_6D_6) δ 1.08 (3H, s, $C_{(5)}$-CH_3), 2.22 (3H, d, J=1.5 Hz, $C_{(11)}$-CH_3), 3.58 (1H, A part of an ABq, J=11 Hz, $C_{(14)}$-H_A), 4.08 (1H, B part of an ABq, J=11 Hz, $C_{(14)}$-H_B), 4.77 (1H, m, $C_{(6)}$-H), 5.40 (1H, br signal, $W_{1/2}$=*ca.* 7.5 Hz, $C_{(3)}$-H), and 7.04 (1H, m, $C_{(12)}$-H); MS *m/e* (%) 248 (M^+; 3.4), 230 (13), 141 (6.1), and 124 (100); Found: *m/e* 248.1482. Calcd for $C_{15}H_{20}O_3$: M 248.1411. Found: *m/e* 124.0518. Calcd for $C_7H_8O_2$: *m/e* 124.0523.

Alkaline Hydrolysis of **1**. A mixture (53 mg) of **1** and **2** was dissolved in methanol (5 ml). Potassium hydroxide (250 mg) in water (1 ml) was added and the reaction mixture was refluxed for 1 h. After addition of water (50 ml), the solution was washed with ether. The aqueous layer was acidified with 2 M** hydrochloric acid to pH 1 and extracted with ether. The ethereal layer was dried (Na_2SO_4) and concentrated carefully. To the concentrated solution, diazomethane in ether was added and the solution was allowed to stand for 1 h. The mixture of methyl esters was analyzed by GC-MS measurement (column: PEG-20M, temperature: heated from 50 °C at a rate of 3 °C/min; carrier gas: He, 0.5 kg/cm^2) and found to be a mixture of methyl angelate (M^+ at *m/e* 114, R_t 15.3 min) and methyl 3-methylbutanoate (M^+ at *m/e* 116, R_t 12.2 min) in a ratio of *ca.* 3 : 1.

Esterification of **7** *with Diazomethane*. 3β-Angeloyloxy-6β-acyloxyfuranoeremophilan-14-oic acids (**7**; 32 mg) was treated with excess diazomethane in ether and the reaction product was purified by silica-gel column chromatography to give methyl 3β-angeloyloxy-6β-acyloxyfuranoeremophilan-14-oates (**8**; 28 mg) as an oil, IR (liq) 1740, 1720, 1640, 1565, 1230, and 1160 cm^{-1}; UV (EtOH) 217 nm (ε 22000); ^{1}H NMR (C_6D_6) δ 1.07 (3H, s, $C_{(5)}$-CH_3), 1.87 (3H, d, J=1.5 Hz, $C_{(11)}$-CH_3), 3.38 (3H, s, -COOCH_3), 5.69 (*ca.* 1H, br q, J=7 Hz, $\underline{H}$>C=C<(COO-, CH_3)), 5.81 (1H, br signal, $W_{1/2}$=13 Hz, $C_{(3)}$-H), 6.50 (*ca.* 0.7H, m, $C_{(6)}$-H of **8a**), 6.60 (*ca.* 0.2H, m, $C_{(6)}$-H of **8c**), 6.63 (*ca*, 0.1H, m, $C_{(6)}$-H of **8b**), and 6.95 (1H, m, $C_{(12)}$-H); MS as given in Table 2; Found for **8a**: *m/e* 460.2419. Calcd for $C_{26}H_{36}O_7$: M 460.2531. Found for **8b**: *m/e* 458.2296. Calcd for $C_{26}H_{34}O_7$: M 458.2442, and Found for **8c**: *m/e* 474.2818. Calcd for $C_{27}H_{38}O_7$: M 474.3021.

Furanoeremophilane-3β,6β,14-triol (**9**). *From* **8**: Methyl 3β-angeloyloxy-6β-acyloxyfuranoeremophilan-14-oates (**8**; 276 mg) in ether (30 ml) was treated with lithium aluminium hydride (530 mg) at reflux temperature for 1.5 h to give **9** (99 mg).

From **1**: A mixture (58 mg) of **1** and **2** was treated with lithium aluminium hydride (100 mg) as above and the reaction mixture was chromatographed on silica gel to yield **9** (16 mg) together with 6α,14-epoxyfuranoeremophilan-3β-ol (**13**).

9; Mp 139—140 °C (from ether; derived from **8**), 137—138 °C (from ether; derived from **1**), mp of the admixture 137—140 °C; lit,[14] 148 °C; lit,[11] 122 °C; $[\alpha]_D^{25}$ −12° (*c* 1.45, EtOH; derived from **8**), $[\alpha]_D^{26}$ −11° (*c* 0.63, EtOH; derived from **1**); lit,[14] $[\alpha]_D^{24}$ −36.9° (*c* 1.48, $CHCl_3$); IR (Nujol) 3250, 1635, and 1560 cm^{-1}; UV (EtOH) 218 nm (ε 8600); ^{1}H NMR [$(CD_3)_2CO$] δ 0.97 (3H, s, $C_{(5)}$-CH_3), 2.03 (3H, d, J=1.5 Hz, $C_{(11)}$-CH_3), 4.46 (1H, m, $C_{(6)}$-H), and 7.02 (1H, br s, $W_{1/2}$=4 Hz, $C_{(12)}$-H); ^{1}H NMR ($CDCl_3$-D_2O, determined by Prof. Bohlmann) δ 1.04 (3H, s, $C_{(5)}$-CH_3), 2.08 (3H, d, J=1.1 Hz, $C_{(11)}$-CH_3), 2.20 (1H, d-like, J=17.5 Hz, $C_{(9\alpha)}$-H), 2.81 (1H, m, $C_{(9\beta)}$-H), 3.89 (1H, dd, J=10.5 and J=3 Hz, $C_{(14)}$-H), 4.14 (1H, t, J=10.5 Hz, $C_{(14)}$-H), 4.45 (1H, quintet, $J_{2\beta,3\alpha}$=10, $J_{2\alpha,3\alpha}$=5, and $J_{3\alpha,4\alpha}$=5 Hz, $C_{(3\alpha)}$-H), 4.89 (1H, br s, $W_{1/2}$=*ca.* 5.5 Hz, $C_{(6)}$-H), and 7.05 (1H, br s, $W_{1/2}$=*ca.* 4 Hz, $C_{(12)}$-H); lit,[14] [$(CD_3)_2CO$] δ 1.48 (3H, s, $C_{(5)}$-CH_3), 2.06 (3H, d, J=1 Hz, $C_{(11)}$-CH_3), 3.95 (2H, d, J=9 Hz, $C_{(14)}$-H_2), 4.29 (1H, ddd, J=2.5, J=2, and J=2 Hz, $C_{(3)}$-H), 4.59 (1H, t, J=1 Hz, $C_{(6)}$-H), and 7.04 (1H, br s, $C_{(12)}$-H); lit,[11] ^{1}H NMR (solvent not registered, probably $CDCl_3$) δ 1.45 (3H, s, $C_{(5)}$-CH_3), 2.03 (3H, d, J=1 Hz, $C_{(11)}$-H), 3.92 (2H, m, $C_{(14)}$-H_2), 4.25 (1H, dd, J=5 and J=2 Hz, $C_{(3)}$-H), 4.57 (1H, t, J=1 Hz, $C_{(6)}$-H), and 7.01 (1H, br s, $C_{(12)}$-H); MS *m/e* (%) 266 (M^+; 4.7), 248 (2.3), 230 (2.5), and 124 (100); Found: C, 67.78; H, 8.63%. Calcd for $C_{15}H_{22}O_4$: C, 67.64; H, 8.33%.

Alkaline Hydrolysis of **7**. A mixture of **7** (158 mg) in methanol (15 ml) and potassium hydroxide (700 mg) in water (3 ml) was heated under reflux for 1.5 h and the reaction product was treated and analyzed by the same procedures as in the case of the alkaline hydrolysis of **1** (*vide supra*) and was found to be a mixture of methyl 3-methylbutanoate (M^+ at *m/e* 116, R_t 12.2 min), methyl angelate (M^+ at *m/e* 114, R_t 15.3 min), and methyl 3-methylpentanoate (M^+ at *m/e* 130, R_t 15.6 min) in a ratio of *ca.* 4 : 6 : 1.

3β-Angeloyloxyfuranoeremophilan-14,6α-olide (**10**). A mixture (207 mg) of **7** in benzene (30 ml) and acetic acid (30 ml) was refluxed under a nitrogen atmosphere for 5 h. After addition of water, the reaction product was extracted with ether and the ethereal layer was washed with sodium hydrogencarbonate solution. The usual work-up gave 111 mg of **10**, mp 112—116 °C (from hexane-ether); $[\alpha]_D^{23}$ +18° (*c* 1.63, EtOH); IR (Nujol) 1765, 1720, 1645, 1635, 1565, 1235, and 1145 cm^{-1}; UV (EtOH) 216 (ε 16000); ^{1}H NMR (C_6D_6) δ 1.21 (3H, s, $C_{(5)}$-CH_3), 1.80 (3H, q, J=*ca.* 2 Hz, CH_3>C=C<(COO-, $\underline{CH_3}$)), 1.93 (3H, d, J=1.5 Hz, $C_{(11)}$-CH_3), 2.01 (3H, dq, J=7 and J=*ca.* 2 Hz, $\underline{CH_3}$>C=C<(COO-, CH_3)), 4.58 (1H, m, $C_{(6)}$-H), 5.43 (1H, br s, $W_{1/2}$=7 Hz, $C_{(3)}$-H), 5.71 (1H, br q, J=7 Hz, $\underline{CH_3}$>C=C<(COO-, CH_3)), and 6.88 (1H, m, $C_{(12)}$-H); MS *m/e* (%) 344 (M^+; 26), 262 (63), 245 (25), 244 (39), 83 (96), and 55 (100); Found: *m/e* 344.1679. Calcd for $C_{20}H_{24}O_5$: M 344.1622.

Furanoeremophilane-3β,6α,14-triol (**12**). 3β-Angeloyloxyfuranoeremophilan-14,6α-olide (**10**; 70 mg) in ether (10 ml) was treated with lithium aluminium hydride (200 mg) at reflux temperature for 1.5 h to give **12** (50 mg), mp 170—172 °C (from acetone); $[\alpha]_D^{17}$ ±0° (*c* 2.37, EtOH); IR (Nujol) 3300, 1645, and 1565 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ 1.21 (3H, s, $C_{(5)}$-CH_3), 2.06 (3H, d, J=1.5 Hz, $C_{(11)}$-CH_3), 4.00 and 4.08 (2H, m, $C_{(14)}$-H_2), 4.34 (1H, m, $C_{(6)}$-H), 4.95 (1H, br signal, $W_{1/2}$=*ca.* 18 Hz, $C_{(3)}$-H), and 7.09 (1H, br s, $W_{1/2}$=*ca.* 3.5 Hz, $C_{(12)}$-H); ^{1}H NMR [$(CD_3)_2CO$] δ 1.18 (3H, s, $C_{(5)}$-CH_3), 2.00 (3H, d, J=1.5 Hz, $C_{(11)}$-CH_3), 3.90 (2H, br signal, $W_{1/2}$=*ca.* 12 Hz, $C_{(14)}$-H_2), 4.26 (1H, m, $C_{(6)}$-H), 4.70 (1H, br signal, $W_{1/2}$=*ca.* 12 Hz, $C_{(3)}$-H), and 7.10 (1H, br s, $W_{1/2}$=*ca.* 4 Hz, $C_{(12)}$-H); MS *m/e* (%) 266 (M^+; 1.7), 248 (2.5), 230 (1.1), 160 (3.4), 159 (2.9), and 124 (100).

6α,14-Epoxyfuranoeremophilan-3β-ol (**13**). *From* **9**: Furanoeremophilane-3β,6β,14-triol (**9**; 30 mg) in methanol

** 1 M=1 mol dm^{-3}.

(a few drop) was stirred with 0.05 M hydrochloric acid (18 ml) at room temperature for 10 min under a nitrogen atmosphere. Extraction with ether and washing with sodium hydrogencarbonate solution afforded **13** (27 mg).

From 12: Furanoeremophilane-3β,6α,14-triol (**12**; 16 mg) in acetone (a few drop) was treated with 0.2 M hydrochloric acid (5 ml) under the same conditions as above to give **13** (9 mg).

From 2: A mixture of 3β-angeloyloxy-6α,14-epoxyfuranoeremophilane (**2**; 72 mg) in ether (10 ml) and lithium aluminium hydride (100 mg) was heated under reflux for 1 h to give **13** (63 mg).

13; Mp 136—138 °C (from ether); $[\alpha]_D^{25}$ −30° (*c* 0.49, EtOH; derived from **9**), $[\alpha]_D^{22}$ −27° (*c* 1.1, EtOH; derived from **12**), $[\alpha]_D^{23}$ −27° (*c* 0.88, EtOH; derived from **2**); IR (Nujol) 3470, 1635, and 1565 cm^{-1}; UV (EtOH) 210 nm (end absorption, ε 8800); ^1H NMR (C_6D_6) δ 1.40 (3H, s, $C_{(5)}$-CH_3), 2.14 (3H, d, J=1.5 Hz, $C_{(11)}$-CH_3), 3.56 (1H, br s, $W_{1/2}$=6 Hz, $C_{(3)}$-H), 3.70 (1H, t, $J_{4,14\alpha}$=7 and $J_{14\alpha,14\beta}$=7 Hz, $C_{(14\alpha)}$-H), 3.87 (1H, dd, $J_{4,14\beta}$=11.5 and $J_{14\alpha,14\beta}$=7 Hz, $C_{(14\beta)}$-H), 4.54 (1H, m, $C_{(6)}$-H), and 6.99 (1H, m, $C_{(12)}$-H); ^1H NMR ($CDCl_3$) δ 1.44 (3H, s, $C_{(5)}$-CH_3), 2.01 (3H, d, J=1.5 Hz, $C_{(11)}$-CH_3), 3.84 and 4.00 (2H, m, $C_{(14)}$-H_2), 4.26 (1H, br s, $W_{1/2}$=6 Hz, $C_{(3)}$-H), 4.55 (1H, m, $C_{(6)}$-H), and 7.02 (1H, br s, $C_{(12)}$-H); MS *m/e* (%) 248 (M^+; 100), 161 (23), 160 (30), 159 (38), and 108 (31); Found: C, 72.40; H, 8.40%. Calcd for $C_{15}H_{20}O_3$: C, 72.55; H, 8.12%.

6α,14-Epoxyfuranoeremophilan-3-one (15). Chromium trioxide (700 mg) was dissolved in a solution of pyridine (1 ml) and dichloromethane (20 ml) and stirred at room temperature for 15 min. 6α,14-Epoxyfuranoeremophilan-3β-ol (**13**; 246 mg) was added to the solution and the whole was stirred for 5 h. The reaction mixture was filtered, and the precipitate was washed with ether. The filtrate and washing were combined and washed with 5% sodium hydroxide solution, 1 M hydrochloric acid, 10% sodium hydrogencarbonate solution, and brine, in turn. The usual work-up gave **15** (103 mg), mp 172—175 °C (from ether); $[\alpha]_D^{24}$ −31° (*c* 1.29, $CHCl_3$); IR (Nujol) 1710, 1630, and 1560 cm^{-1}; ^1H NMR (C_6D_6) δ 0.78 (3H, s, $C_{(5)}$-CH_3), 2.06 (3H, d, J=1.5 Hz, $C_{(11)}$-CH_3), 3.85 (1H, t, $J_{4,14\alpha}$=8 and $J_{14\alpha,14\beta}$=8 Hz, $C_{(14\alpha)}$-H), 4.15 (1H, dd, $J_{4,14\beta}$=11 and $J_{14\alpha,14\beta}$=8 Hz, $C_{(14\beta)}$-H), 4.43 (1H, m, $C_{(6)}$-H), and 6.94 (1H, m, $C_{(12)}$-H); MS *m/e* (%) 246 (M^+; 100), 231 (16), 160 (51), 159 (37), and 145 (43); Found: *m/e* 246.1264. Calcd for $C_{15}H_{18}O_3$: M 246.1255.

3β,6β,14-Triacetoxyfuranoeremophilane (16). Treatment of furanoeremophilane-3β,6β,14-triol (**9**; 28 mg) in pyridine (4 ml) with acetic anhydride (1 ml) at room temperature gave a crude acetate, which was purified by silica-gel column chromatography. Elution with petroleum ether–ether (1 : 1) afforded **16** (33 mg) as an oil, $[\alpha]_D^{30}$ −35° (*c* 1.2, EtOH); IR liq) 1740, 1640, 1560, and 1240 cm^{-1}; UV (EtOH) 217 nm (ε 7700); ^1H NMR (C_6D_6) δ 1.09 (3H, s, $C_{(5)}$-CH_3), 1.68, 1.69, and 1.79 (each 3H, s, -OCOCH_3), 1.88 (3H, d, J=1.5 Hz, $C_{(11)}$-CH_3), 4.33 (2H, m, $C_{(14)}$-H_2), 5.43 (1H, br signal, $W_{1/2}$=*ca.* 16 Hz, $C_{(3)}$-H), 6.49 (1H, m, $C_{(6)}$-H), and 6.94 (1H, m, $C_{(12)}$-H); ^1H NMR [$(CD_3)_2CO$] δ 1.17 (3H, s, $C_{(5)}$-CH_3), 1.87 (3H, d, J=1.5 Hz, $C_{(11)}$-CH_3), 1.99, 2.02, and 2.12 (each 3H, s, -OCOCH_3), 4.29 (2H, d, J=5 Hz, $C_{(14)}$-H_2), 5.28 (1H, dt, J=8 and J=5 Hz, $C_{(3)}$-H), 6.28 (1H, m, $C_{(6)}$-H), and 7.18 (1H, m, $C_{(12)}$-H); MS *m/e* (%) 392 (M^+; 1.8), 350 (7.1), 332 (10), 290 (6.4), 272 (5.8), 230 (15), 212 (20), 166 (10), 159 (30), and 124 (100).

Furanoeremophil-3-en-14,6α-olide (17). Aqueous methanol (80%, 50 ml) and then sodium carbonate (900 mg) in water (10 ml) were added to a solution of 3β-angeloyloxyfuranoeremophilan-14,6α-olide (**10**; 70 mg) in methanol (3 ml), and the mixture was stirred at room temperature for 45 min under nitrogen. The usual work-up afforded **17** (34 mg), mp 103—107 °C (from ether); $[\alpha]_D^{18}$ −68° (*c* 0.96, EtOH); IR (Nujol) 1740, 1670, 1640, and 1560 cm^{-1}; UV (EtOH) 218 nm (ε 28000); ^1H NMR ($CDCl_3$) δ 1.43 (3H, s, $C_{(5)}$-CH_3), 2.05 (3H, d, J=1.5 Hz, $C_{(11)}$-CH_3), 5.25 (1H, m, $C_{(6)}$-H), 6.28 (1H, t-like, J=3 Hz, $C_{(3)}$-H), and 7.03 (1H, m, $C_{(12)}$-H); MS *m/e* (%) 244 (M^+; 59), 187 (48), 185 (27), and 121 (100).

The authors wish to thank Mr. Masaya Sakata and Mr. Noboru Saito, University Forest at Chichibu, the University of Tokyo, for collecting *Syneilesis palmata* (THUNB.) MAXIM. The authors are also grateful to Professor F. Bohlmann, Technical University Berlin, for the discussions and the measurements of the ^1H NMR spectrum (270 MHz) of furanoeremophilane-3β,6β,14-triol.

Synthesis of 3-Aminonocardicinic Acid, the Basic Nucleus of Nocardicins

Minoru HATANAKA,* Noriyoshi NOGUCHI, and Toshiyasu ISHIMARU
The Institute of Scientific and Industrial Research, Osaka University, Suita, Osaka 565
(Received October 27, 1981)

A short and high-yielding synthesis of optically active 3-aminonocardicinic acid (3-ANA) is described. The fourth component condensation reaction of N^2-protected L-2,3-diaminopropanoic acid with *p*-benzyloxybenzaldehyde and butyl isocyanide gave directly the amide derivatives of 3-ANA, as a diastereomeric mixture, which was, after conversion of the amide group into the benzhydryl ester, led in good yield to a single disatereomer with natural chirality *via* epimerization. Deprotection of the 3-ANA derivative gave 3-ANA.

Attension has been given to the synthesis of nocardicins, *e.g.*, **1**, which are unusual monocyclic β-lactam antibiotics isolated from Nocardia species.[1,2] In this paper, we wish to report a short and high-yielding synthesis of optically active 3-aminonocardicinic acid (3-ANA, **2**) which is the key intermediate for the synthesis of nocardicins. It is based on the Ugi reaction using isoncyanides as azetidinone forming reagents.[3] In this reaction, the use of L-2,3-diaminopropanoic acid as a chiral starting material would permit direct formation of the 3-ANA derivatives with the natural chirality at the position 3. On the contrary, one of the most successful approaches to the synthesis of 3-ANA has used D-*p*-hydroxyphenylglycine as a chiral strating material, following asymmetric induction to the position 3 *via* ketene-imine cycloaddition for the azetidinone construction.[2a] The noteworthy feature of our route will be shown by quantitative transformation *via* epimerization of the resulting diastereomeric mixture into a single diastereomer with the natural chirality.

2

Results and Discussion

The starting materials, N^2-protected L-2,3-diaminopropanoic acids (**3a**—**c**), were prepared according to our previous report[4] or the published method.[5] The amino acids **3a**—**c** were allowed to react with *p*-benzyloxybenzaldehyde and butyl isocyanide in methanol at room temperature. In each case, the product was a diasteromeric mixture, in a ratio of approximately 1 to 1, which could be separated by column chromatography on silica gel. The results are summarized in Table 1. The azetidinones **4a** and **5a** were chosen as precursors of 3-ANA because these compounds were obtained in the best yield and the 2,2,2-trichloroethoxycarbonyl *N*-protecting group possessed the advantage of permitting stepwise deprotection of the resulting protected 3-ANA derivative.

b, R = $C_6H_5CH_2OCO$
c, R = Bu^tOCO

TABLE 1. YIELDS AND PHYSICAL PROAERTIES OF THE UGI REACTION PRODUCTS

Substrate	Products 4 Mp θ_m/°C	4 $[\alpha]_D^{b)}$/°	5 Mp θ_m/°C	5 $[\alpha]_D^{b)}$/°	Yield[a)] %
3a	182—184	−119.0 (*c* 1.0)	100—101	+35.2 (*c* 1.0)	68
3b	151—152	−120.5 (*c* 0.99)	175—176	+33.5 (0.94)	31.3
3c	161—162	−104.8 (*c* 1.02)	Oil	—	59

a) Isolated total yield on the basis of **3**. b) In methanol.

Selective cleavage of the exocyclic amide bond was achieved *via* the imidoyl chloride. The azetidinone **4a** was treated with phosphorus pentachloride in dichloromethane in the presence of pyridine, and successively with methanol. The acidic work-up of the reaction mixture gave a 4 : 1 mixture of the methyl esters **6** and **7** in 66% yield together with recovery (16.3%) of a 2 : 1 mixture of **4a** and **5a**, indicating that epimerization at the exocyclic C–H took place to a considerable extent under the reaction conditions. Similarly, the 1 : 1 mixture of **4a** and **5a** gave a 5 : 3 mixture of **6** and **7** in 68% yield.

Hydrolysis of the methyl ester **6** with aqueous sodium hydroxide or lithium iodide–pyridine was also accom-

panied by epimerization to result in a mixture of the acids **8** and **9**. Thus, the epimerization was extremely facile as reported previously.[2b] Therefore, the methyl esters **6** and **7**, in the form of the 5 : 3 mixture, were converted into the benzyl esters **10** and **11** (62% yield as a 4 : 3 mixture) or the benzhydryl esters **12** and **13** (91% yield as a 4 : 3 mixture) by saponification, followed by treatment with benzyl chloride or diphenyldiazomethane. Treatment of **11** with triethylamine in aqueous methanol resulted in an equilibrium mixture of the diastereomers **10** and **11** to provide more **10**. The benzhydryl ester was found to be more convenient in terms of its easy crystallization. The crude product, in the form of the 4 : 3 mixture of **12** and **13**, was directly crystallized from aqueous methanol containing triethylamine to give a single isomer **12** in 85% overall yield from the methyl esters **6** and **7**.

Table 2. ^{1}H-NMR chemical shifts of 4-protons[a]

Compound	4β-Protons	4α-Protons
4a	3.27	3.93

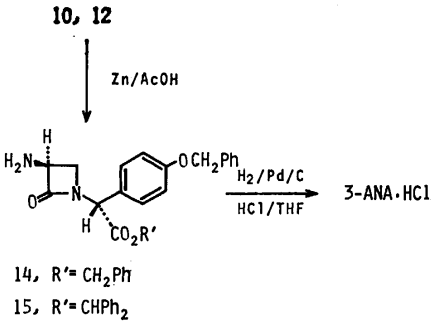
4b	3.25	3.84
5b	3.55	3.40
4c	3.27	3.82
5c	3.53	3.09
6	3.11	3.96
7	3.59	3.45
10	3.09	3.92
11	3.56	3.42
12	3.08	3.92

a) In ppm downfield from internal TMS in $CDCl_3$.

Stereochemistry of the diastereomers was assigned on the basis of the ^{1}H-NMR spectral data. It has been reported that in the NMR spectra of nocardicin series the 4β-protons always appeared in higher field than the 4α-protons.[2a] In agreement with this fact, the 4β-protons of **4a**—**c**, **6**, **10**, and **12** with the natural chirality appeared in higher field by 0.66—0.85 ppm than their 4α-protons, while in the cases of **5a**—**c**, **7**, **11**, and **13** the 4α-protons resonanced in slightly higher field than the 4β-protons (Table 2).

Removal of the 2,2,2-trichloroethoxycarbonyl group



14, R'=CH_2Ph
15, R'=$CHPh_2$

of **10** was carried out with zinc in aqueous acetic acid to yield quantitatively the free amine **14**, the ^{1}H-NMR spectrum of which corresponded well with that of the dibenzyl derivative of 3-ANA previously reported.[2b] Catalytic deprotection of **14** with 10% palladium on carbon as catalyst in the presence of hydrogen chloride produced 3-ANA hydrochloride. Similarly, the benzhydryl ester **12** gave 3-ANA hydrochloride in quantitative yield. Total yield from **3a** was 38%.

Experimental

Melting points (capillary) were uncorrected. IR spectra were recorded on a JASCO IRA-1 spectrometer. NMR spectra were determined with tetramethylsilane as an internal standard on a Hitachi R-600 or a JEOL FX-100 spectrometer, chemical shifts being given in ppm unit. Optical rotations were measured with a Perkin-Elmer 241 polarimeter. Elemental analyses were performed in the material analysis center of this institute. Columns of chromatography were packed with Wakogel C-200.

(3S)-1-(α-Butylcarbamoyl-p-benzyloxybenzyl)-3-(2,2,2-trichloroethoxycarbonylamino)-2-azetidinone (4a, 5a). A mixture of **3a** (2.80 g, 0.01 mol), *p*-benzyloxybenzaldehyde (2.55 g, 0.012 mol) and butyl isocyanide (1.25 g, 0.015 mol) in methanol (80 ml) was stirred at room temperature for 3 d. The methanol was removed *in vacuo*, and the residue was crystallized from ethyl acetate–diisopropyl ether to give **4a** (1.15 g). The filtrate was evaporated *in vacuo*, and the residue was chromatography on silica gel with benzene–ethyl acetate to give **4a** (0.86 g, 36% total yield) and **5a** (1.77 g, 32% yield). The individual properties of **4a** and **5a** follow. **4a**: mp 182—184 °C; $[\alpha]_D$ −119.0° (*c* 1.0, MeOH); IR (Nujol) 1765, 1740, and 1663 cm^{-1}; NMR ($CDCl_3$) δ 0.90 (3H, t, *J*=6, CH_3), 1.41 (4H, m, $(CH_2)_2$), 3.27 (3H, m, NCH_2 and H4β), 3.93 (1H, t, *J*=5, H4α), 4.70 (2H, s, CH_2CCl_3), 4.83 (1H, m, H3), 5.07 (2H, s, OCH_2Ar), 5.23 (1H, s, methine), 5.48 (1H, m, NH), 5.97 (1H, m, NH), and 6.68—7.53 (9H, m, Ar). Found: C, 46.06; H, 4.55; N, 8.85; Cl, 22.95%. Calcd for $C_{25}H_{28}N_3O_5Cl_3$: C, 46.32; H, 4.75; N, 9.00; Cl, 22.78%.

5a: mp 100—101 °C; $[\alpha]_D$ +35.2° (*c* 1.0, MeOH); IR (nujol) 1743, 1733, and 1658 cm^{-1}; NMR ($CDCl_3$) δ 0.93 (3H, t, *J*=6, CH_3), 1.47 (4H, m, $(CH_2)_2$), 3.31 (3H, m, NCH_2 and H4α), 3.57 (1H, dd, *J*=2.7 and 6.6, H4β), 4.46 (1H, m, H3), 4.74 (2H, ABq, *J*=12, CH_2Cl_3), 5.06 (2H, s, OCH_2Ar), 5.44 (1H, s, methine), 5.68 (1H, broad d, *J*=7.5, NH), and 6.92—7.36 (10H, m, Ar and NH).

(3S)-3-(Benzyloxycarbonylamino)-1-(α-butylcarbamoyl-p-benzyloxybenzyl)-2-azetidinone (4b, 5b). By the use of the procedure described above, this compound was obtained in 31.3% yield from **3b** as a solid, in the form of a diastereomeric mixture of **4b** and **5b** in the ratio 10 : 9 (determined by NMR spectra). Repeated column chromatography of the mixture

gave pure **4b** and **5b**, the individual properties of which were as follows. **4b**: mp 151—152 °C; $[\alpha]_D$ −120.5° (*c* 0.99, MeOH); IR ($CHCl_3$) 3420, 3350, 1760, 1728, and 1680 cm^{-1}; NMR ($CDCl_3$) δ 0.89 (3H, t, J=6, CH_3), 1.40 (4H, m, $(CH_2)_2$), 3.25 (3H, m, NCH_2 and H4β), 3.84 (1H, t, J=5.4, 4Hα), 4.80 (1H, m, H3), 5.06 (4H, s, OCH_2Ar), 5.18 (1H, s, methine), 5.37 (1H, m, NH), 6.30 (1H, m, NH), and 6.95—7.50 (14H, m, Ar). Found: C, 69.61; H, 6.41; N, 8.12%. *(3S)-1-(α-Methoxycarbonyl-*p*-benzyloxybenzyl)-3-(2,2,2-trichloroethoxycarbonylamino)-2-azetidinone (**6**, **7**).* Phosphorus pentachloride (313 mg, 1.5 mmol) was added at −20 °C to a suspension of **4a** (557 mg, 1 mmol) and pyridine (237 mg, 3 mmol) in dichloromethane (6 ml). The mixture was stirred at 0 °C for 5 h, and then cooled to −60 °C. After addition of anhydrous methanol (0.6 ml), the mixture was brought gradually to 0 °C, then stirred at 0 °C for 1.5 h, and poured into ice–water (5 ml). The mixture was vigorously stirred at 0 °C for 1 h. The aqueous layer was extracted with dichloromethane. The combined extracts were dried ($MgSO_4$) and evaporated *in vacuo*. The residue was chromatographed on silica gel with benzene–ethyl acetate to give **6** (273 mg, 53%), **7** (68 mg, 13.2%), and a 2 : 1 mixture of **4a** and **5a** (91 mg, 16.3% recovery). The physical properties of **6** follow. Mp 139—140 °C; $[\alpha]_D$ −141.3° (*c* 0.98, MeOH); IR (Nujol) 3240, 1760, and 1735 cm^{-1}; NMR ($CDCl_3$) δ 3.11 (1H, dd, J=2.4 and 5.6, H4β), 3.75 (3H, s, OCH_3), 3.96 (1H, t, J=5.6, H4α), 4.69 (2H, s, CH_2Cl_3), 4.90 (1H, m, H3), 5.07 (2H, s, CH_2Ar), 5.51 (1H, m, NH), 5.57 (1H, s, methine), and 6.94—7.48 (9H, m, Ar). Found: C, 51.27; H, 4.01; N, 5.39, Cl, 20.88%. Calcd for $C_{22}H_{21}N_2O_6Cl_3$: C, 51.23; H, 4.10; N, 5.43; Cl, 20.62%. The physical properties of **7** follow. Oil; $[\alpha]_D$ +65.0° (*c* 3.31, MeOH); IR (neat) 3300 and 1740 cm^{-1}; NMR ($CDCl_3$) δ 3.45 (1H, t, J=5.6, H4α), 3.59 (1H, dd, J=2.4 and 5.6, H4β), 3.76 (3H, s, OCH_3), 4.73 (2H, s, CH_2Cl_3), 4.80 (1H, m, H3), 5.07 (2H, s, OCH_2Ar), 5.55 (1H, s, methine), 5.85 (1H, m, NH), and 6.88—7.50 (9H, m, Ar).

A similar experiment was repeated with the 1 : 1 mixture of **4a** and **5a** on the 0.01 mol scale, yielding a 5 : 3 mixture of **6** and **7** (3.51 g, 68%).

*Benzyl O-Benzyl-N-(2,2,2-trichloroethoxycarbonyl)-3-aminonocardicinate (**10**).* To a solution of the 5:3 mixture of **6** and **7** (346 mg, 0.67 mmol) in 80% aqueous acetone (10 ml), 1 M† aqueous KOH was added dropwise at 0 °C over 1 h. After being stirred at 0 °C for 2 h, the solution was evaporated to dryness *in vacuo*. The residue was suspended in DMF (5 ml), and treated with benzyl chloride (102 mg) and a few drops of *N,N,N′,N′*-tetramethylethylenediamine . The mixture was stirred overnight at room temperature, poured into ice–water (20 ml), and then extracted with ethyl acetate. The extracts were washed with brine, dried ($MgSO_4$), and evaporated *in vacuo*. The residue was separated by preparative TLC in benzene–ethyl acetate to give **10** (135 mg, 34%) as needles and **11** (111 mg, 28%) as an oil. The physical properties of **10** follow. Mp 128—129 °C; $[\alpha]_D$ −104.4° (*c* 0.94, MeOH); IR ($CHCl_3$) 1760 and 1740 cm^{-1}; NMR ($CDCl_3$ δ 3.09 (1H, dd, J=2.4 and 5.6, H4β), 3.92 (1H, t, J=5.6, H4α) 4.68 (2H, s, CH_2Cl_3), 4.87 (1H, m, H3), 5.06 (2H, s, OCH_2Ar), 5.18 (2H, s, OCH_2Ar), 5.47 (1H, m, NH), 5.61 (1H, s, methine), 6.94 (2H, d, J=9, Ar), 7.17 (2H, d, J=9, Ar), 7.30 and 7.39 (10H, each s, Ar). Found: C, 57.88; H, 4.29; N, 4.72%. Calcd for $C_{28}H_{25}N_2O_6Cl_3$: C, 56.82; H, 4.26; N, 4.73%. The physical properties of **11** follow. Oil; $[\alpha]_D$ +42.24° (*c* 0.76, MeOH); IR ($CHCl_3$) 1755 and 1740 cm^{-1}; NMR ($CDCl_3$) δ 3.42 (1H, t, J=5.6, H4α), 3.56 (1H, dd, J=2.4 and 5.6, H4β), 4.70 (2H, s, CH_2CCl_3), 4.83 (1H, m, H3), 5.05 (2H, s, OCH_2Ar), 5.19 (2H, s, OCH_2Ar), 5.59 (1H, s, methine), 5.80 (1H, broad d, J=8, NH), 6.93 (2H, d, J=8.8, Ar), 7.13 (2H, d, J=8.8, Ar), 7.29 and 7.38 (10H, each s, Ar).

The oily isomer **11** (95 mg) was dissolved in aqueous methanol. After addition of a few drops of triethylamine, the solution was allowed to stand at room temperature for 3 days, while the epimerization of **11** was effected to result in a new diastereomeric mixture of **10** and **11** in a ratio of 4 : 3. The solution was seeded with crystals of **10**, and left for an additional day to yield pure **10** (51 mg).

*Benzhydryl O-Benzhyl-N-(2,2,2-trichloroethoxycarbonyl)-3-aminonocardicinate (**12**).* To a solution of the 5 : 3 diastereomeric mixture of **6** and **7** (516 mg, 1 mmol) in 80% aqueous acetone (10 ml), 0.5 M aqueous NaOH (2.2 ml) was added dropwise at 0 °C over 1 h. The solution was stirred at 0 °C for 2 h, and concentrated to 5 ml *in vacuo*. The remaining solution was acidified with hydrochloric acid, and extracted with ethyl acetate. The ethyl acetate solution was dried ($MgSO_4$), and then treated with a small excess of diphenyldiazomethane until the red colour no longer disappeared. The solution was evaporated *in vacuo*, and the residue was purified through a short column of silica gel to yield *ca.* a 4 : 3 mixture of **12** and **13** (610 mg, 91%) as a pale-yellow oil.

The mixture (610 mg) was dissolved in hot aqueous methanol (4 ml) containing one drop of triethylamine. The solution was seeded with crystals of **12** and allowed to stand at room temperature for 3 h. The crystals were colloected by filtration to yield pure **12** (480 mg). Repeated procedure on the filtrate gave an additional crop of **12** (88 mg, 85% total yield).

The physical properties of **12** follow. Mp 135—136 °C; $[\alpha]_D$ −123.2° (*c* 0.44, MeOH); IR (Nujol) 1760 and 1735 cm^{-1}; NMR ($CDCl_3$) δ 3.08 (1H, dd, J=2.4 and 5.6, H4β), 3.92 (1H, t, J=5.6, H4α), 4.68 (2H, s, CH_2CCl_3), 4.86 (1H, m, H_3), 5.07 (2H, s, OCH_2Ar), 5.41 (1H, broad d, J=8, NH), 5.69 (1H, s, methine), 6.91 (2H, d, J=9, Ar), 7.11 (2H, d, J=9, Ar), and 7.00—7.46 (16H, m, $CHPh_2$ and Ar). Found: C, 60.90; H, 4.13; N, 4.29; Cl, 15.56%. Calcd for $C_{34}H_{29}$-

† 1 M=1 mol dm^{-3}.

$N_2O_6Cl_3$: C, 61.14; H, 4.38; N, 4.19; Cl, 15.92%.

Benzyl O-Benzyl-3-aminonocardicinate (14). The compound **10** (150 mg, 0.25 mmol) was dissolved in a mixture of 1 M aqueous KH_2PO_4 (0.25 ml), 90% aqueous acetic acid (2 ml) and THF (3 ml). Zinc powder (165 mg) was added and the mixture was vigorously stirred for 1 h and then filtered. The filtrate was concentrated *in vacuo* below 30 °C. The residue was diluted with water (10 ml), neutralized with $NaHCO_3$, and extracted with ethyl acetate. The extracts were washed with brine, dried ($MgSO_4$), and then evaporated *in vacuo*. The residue was purified by passing through a short column of silica gel with benzene–ethyl acetate to yield **14** (101 mg, 96%) as a colourless oil. The physical properties of **14** were as follows and corresponded well with those previously reported.[2b] $[\alpha]_D$ −128.2° (*c* 0.71, MeOH) [lit,[2b] $[\alpha]_D$ −138° (TFE)]; NMR ($CDCl_3$) δ 2.81 (1H, dd, J=2.2 and 5.4, H4β), 3.86 (1H, t, J=5.4, H4α), 4.22 (1H, dd, J=2.2 and 5.4, H3), 5.06 (2H, s, OCH_2Ar), 5.17 (2H, s, OCH_2Ar), 5.58 (1H, s, methine), 6.93 (2H, d, J=8.8, Ar), 7.16 (2H, d, J=8.8, Ar), 7.29 and 7.39 (10H, each s, Ar).

Benzhydryl O-Benzyl-3-aminonocardicinate (15). By the use of the procedure described above, this compound was obtained from **12** in quantitative yield as an oil, $[\alpha]_D$ −129° (*c* 0.61, THF); NMR ($CDCl_3$) δ 1.67 (2H, broad s, NH_2), 2.80 (1H, dd, J=2 and 5, H4β), 3.85 (1H, t, J=5, H4α), 4.20 (1H, m, H3), 5.07 (2H, s, OCH_2Ar), 5.70 (1H, s, methine), and 6.80—7.60 (20H, m, $CHPh_2$ and Ar).

3-Aminonocardicinic Acid (3-ANA, 2). *From 15*: A mixture of **15** (98 mg, 0.2 mmol) and 10% palladium on carbon (50 mg) as catalyst in anhydrous THF–ethanol (*ca.* 1 : 1, 6 ml) containing hydrogen chloride (0.2 mmol) was placed under a hydrogen atmosphere at atmospheric pressure, and stirred for 6 h at room temperature. The catalyst was removed by filtration and the filtrate was concentrated *in vacuo*. The residue was triturated in ether to give 3-ANA hydrochloride (54 mg, quantitative yield) as a white solid, $[\alpha]_D$ −207° (*c* 0.3, H_2O); NMR (D_2O) δ 3.29 (1H, dd, J=2.2 and 6.5, H4β), 3.93 (1H, t, J=6.5, H4α), 5.57 (1H, s, methine), 6.96 (2H, d, J=8.5, Ar), and 7.30 (2H, d, J=8.5, Ar).

From 14: By the use of the procedure described above the compound **14** (167 mg, 0.4 mmol) was deprotected to give 3-ANA hydrochloride (106 mg), which was identical with that obtained from **15** (NMR, TLC, $[\alpha]_D$ value).

The Enrichment of Tritium in Hydrogen or Deuterium by Thermal Diffusion

Osamu TAKAYASU,* Ikuro MAKINO, Susumu YAMAGAMI, and Toyosaburo TAKEUCHI*
Faculty of Science, Toyama University, Gofuku, Toyama 930
(Received October 3, 1980)

Tritium in H_2 or D_2, 1.7×10^{-2} Ci mol^{-1}, was enriched by means of thermal diffusion at the bottom of a 100-cm glass column with a gas reservoir on top. Four columns with different diameters (8, 20, 30, and 41 mmϕ) were used. The temperature of the wire stretched along the axis of the column was changed over a range from 200 °C to 450 °C. The maximum equilibrium separation factors in hydrogen and in deuterium were 17 and 4.5 respectively. The optimum diameters were estimated by a modification of Waldmann's equation, which can be used for the separation using the flat-type system.

The enrichment of the tritium present in the stable hydrogen isotopes is important in connection with the nuclear-fusion reaction of tritium with deuterium and with the treatment of tritium wastes. This report is concerned with the enrichment of low concentrations of tritium present in hydrogen or deuterium by means of thermal diffusion using a 100-cm glass column with a gas reservoir on top. A short column is desirable because of its ease of handling in a laboratory. The correlation between the column length and the separation factor has been reported elsewhere.[1] In this study, the diameter of the column and the temperature of the wire were changed over wide ranges, and the separation factor was obtained in each case. The possibility of an extended application of Waldmann's equation,[2,3] which can be used for a flat-type system, was examined in the hot-wire type columns, and the optimum diameter was predicted.

Experimental

The main part of the apparatus is shown in Fig. 1, where A is the separation column, constructed of Pyrex glass.

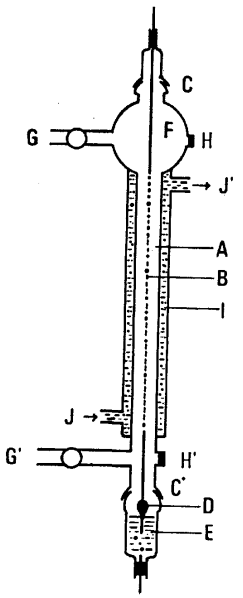

Fig. 1. Thermal diffusion column.
A: Separation column, B: nichrome wire, C and C': greaseless spherical joints, D: weight; E: mercury, F: gas reservoir, G and G': tube, H and H': sampling orifices, I: water jacket, J and J': running water.

Columns of four different diameters, 8, 20, 30, and 41 mmϕ, were used. The nichrome wire, B, stretched in the column was 0.5 mmϕ in diameter and 100 cm in length. The wire could be set along the center of the column by moving the spherical joints, C and C'. In order to stretch the wire, a small lead weight, D, was hung at the end of the wire, and it was immeresed in a mercury reservoir, E, which was connected at the end of the column. The temperature of the wire was changed over the range from 200 °C to 450 °C by means of a direct current. Each temperature was measured by means of the thermal expansion of the wire. Prior to use, the wire was heated in 100 kPa of hydrogen at 500 °C for 5 h; then the evacuation was carried out at a pressure of 10^{-3} Pa for 5 h in order to remove any active oxygen on the surface of the wire. The outside of the column was always kept at 20 °C by the use of running water. The volume of the gas reservoir, F, was 500 cm^3.

Before the study, the effect of the gas reservoir connected to the column was ascertained using the Kr–N_2 system, which had previously been tested in the same type of apparatus by Tanaka *et al.*[4] Their apparatus was devised to circulate readily the gas in the gas reservoir by the aid of a circulation tube, and they concluded that the connection of the gas reservoir with the column is quite effective for the separation. Our results were very similar to those of Tanaka *et al.*

The operating pressure of the gas was 107 kPa. The amount of sampling in each case was 30 mm^3. The concentration of tritium was measured by means of a radio-gas chromatograph.

The carrier-free tritium was diluted with hydrogen or deuterium to a volume of 1.7×10^{-2} Ci mol^{-1}. Prior to use, the gas mixture was put into contact with nickel plates at 100 °C for about 50 h in order to change completely the tritium (T_2) to tritiated hydrogen (HT) or tritiated deuterium (DT), since the following catalytic reaction on nichrome wire took place during the enrichment experiment:

$$T_2 + H_2 = 2HT, \quad T_2 + D_2 = 2DT. \qquad (1)$$

Results

The tritium at the bottom of the column was rapidly concentrated soon after the temperature of the wire had been elevated; the concentrations at both ends of the column became constant within 100 min. The results on H_2–HT in various columns of different diameters are shown in Figs. 2 and 3. The results on D_2–DT are shown in Figs. 4 and 5. The change in the concentration at the bottom occured faster than that at the top, as a result of the large difference in volume between the two ends. The radioactivities of the gas

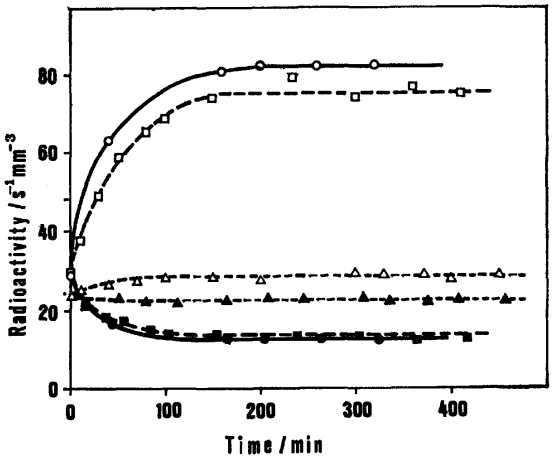

Fig. 2. Enrichment of tritium in the mixture of H_2–HT. Each specimen was taken out of the bottom (white symbols) or of the top (black symbols). The diameters of the column and the wire temperatures were: (○, ●) 20 mmϕ and 300 °C; (□, ■) 20 mmϕ and 200 °C; (△, ▲) 8 mmϕ and 450 °C.

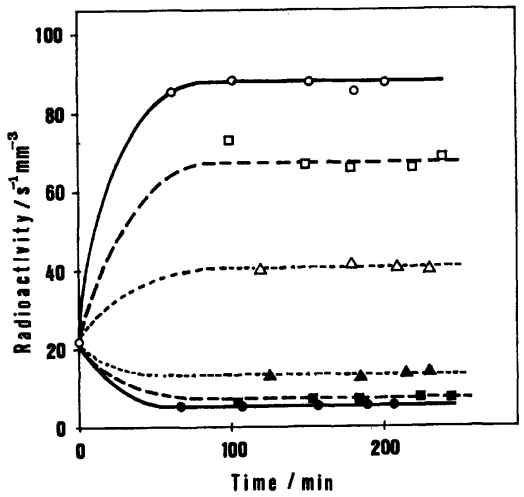

Fig. 3. Enrichment of tritium in the mixture of H_2–HT. Each specimen was taken out of the bottom (white symbols) or of the top (black symbols). The diameters of the column and the wire temperatures were: (○, ●) 30 mmϕ and 450 °C; (□, ■) 30 mmϕ and 300 °C; (△, ▲) 41 mmϕ and 300 °C.

at both ends in the equilibrium state are listed in Table 1, where c and c' are the radioactivities of the bottom and the top respectively. Since the concentration of tritium was extremely low, the equilibrium separation factor, q_e, can be written as:

$$q_e = c/c'. \tag{2}$$

The correlations between the equilibrium-separation factor and the temperature of the wire are shown in Figs. 6 and 7, together with the theoretical values, which will be explained later. In the case of H_2–HT, the separation factors of 8 mmϕ and 20 mmϕ increased initially with the elevation of the wire temperature, and then gradually decreased. However, no decrease was found on the columns of 30 mmϕ and 41 mmϕ up to

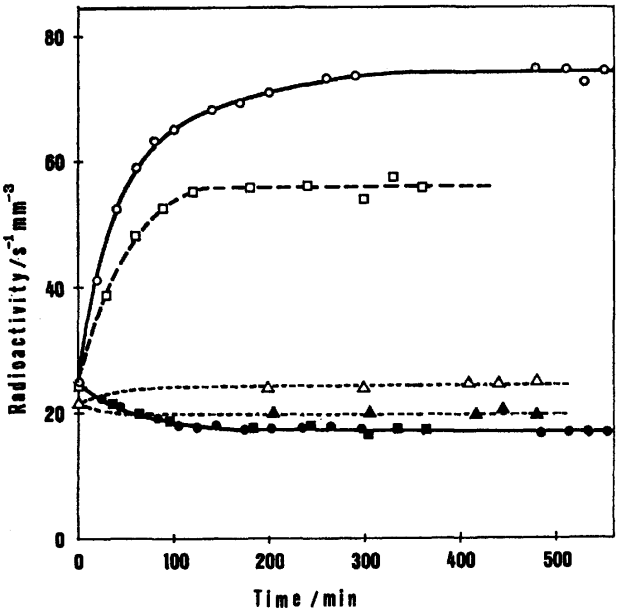

Fig. 4. Enrichment of tritium in the mixture of D_2–DT. Each specimen was taken out of the bottom (white symbols) or of the top (black symbols). The diameters of the column and the wire temperatures were: (○, ●) 20 mmϕ and 450 °C; (□, ■) 20 mmϕ and 200 °C; (△, ▲) 8 mmϕ and 200 °C.

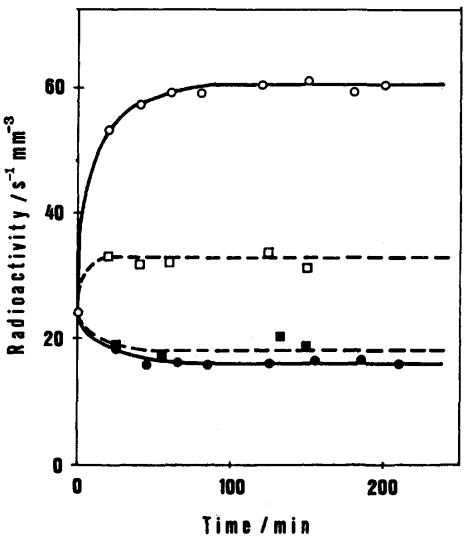

Fig. 5. Enrichment of tritium in the mixture of D_2–DT. Each specimen was taken out of the bottom (white symbols) or of the top (black symbols). The diameters of the column and the wire temperatures were: (○, ●) 30 mmϕ and 450 °C; (□, ■) 30 mmϕ and 200 °C.

450 °C. In the case of D_2–DT, all the separation factors were smaller than those of H_2–HT. It is noticeable that the separation factor of 20 mmϕ in this case became larger than that of 30 mmϕ at all temperature regions investigated.

Discussion

The optimum diameter for the enrichment in a wire-type column may be obtained simply by making

TABLE 1. RADIOACTIVITIES OF TRITIUM AT THE BOTTOM AND THE TOP OF THE COLUMN IN THE EQUILIBRIUM STATE

Mixtures	Column diameter (mmϕ)		Radioactivities/s^{-1} mm^{-3} Temperature of the wire/°C					
			200	250	300	350	400	450

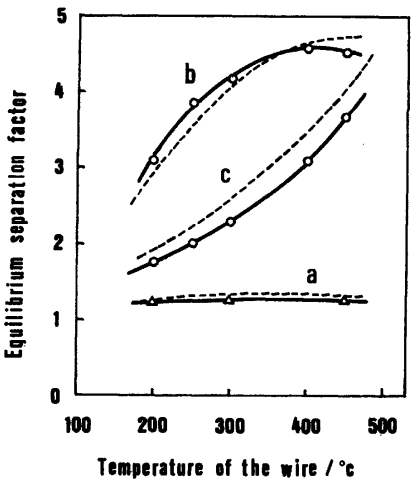

Fig. 7. The temperature dependence of experimental q_e (——) and theoretical q_e (------) in D_2–DT.
(a): 8, (b): 20, (c): 30 mmϕ.

small modifications of Waldmann's method, developed for flat-type systems. Waldmann's equation is written as Eq. 3[4] when the concentration of one component is very low:

$$\ln \Lambda'/\Lambda = -h/H^*, \tag{3}$$

where Λ and Λ' are the concentrations at both ends of the flat-type system and where h is the effective length of the system. H^* is given as follows:

$$H^* = \frac{T_0}{\Delta T} \frac{1+\alpha\left(\frac{d}{d^*}\right)^6}{\beta\left(\frac{d}{d^*}\right)^3} d, \tag{4}$$

where d is the distance between two walls, where T_0 is the average temperature of two walls: $(T_1+T_2)/2$ and

$$\Delta T = T_1 - T_2, \tag{5}$$

where α is the constant which depends on the intermolecular potential of the gas, and where β is the constant which depends not only on the intermolecular potential, but also on the ordinary diffusion coefficient and the thermal-diffusion coefficient. The optimum distance between the two walls, d^*, is given by:

$$d^* = \sqrt[3]{610 \frac{R}{\mu g P} \frac{T_0^2}{\Delta T} D\eta}, \tag{6}$$

where R is the gas constant, g is the gravitational acceleration, P is the pressure of the gas, D is the ordinary diffusion coefficient, η is the viscosity of the gas, and

$$\mu = M_1X_1 + M_2(1-X_1), \tag{7}$$

where M_1 and M_2 are the molecular weights of the two components of the mixture and X_1 is the mole fraction of M_1.

When these equations are applied to wire-type columns, α and β must be modified, and the distance between the two walls, d, is replaced by the radius of the column. The optimum radius of the wire-type column can be simply calculated from d^* by multiplying it by the constant corresponding to α. The constants, α and β, for the column used are evaluated by fitting

the calculated q_e value to the experimental q_e value. The calculated results are shown by dotted lines in Figs. 6 and 7. In the case of H_2–HT, α and β were given as 1.8 and 0.14 respectively, while in the case of D_2–DT, α and β were given as 1.8 and 7.0×10^{-2} respectively. In this calculation, the concentration of tritium was rewritten in terms of radioactivity:

$$\ln c/c' = -h/H^*, \quad (8)$$

and the theoretical separation factor, q_e, was obtained from Eqs. 2 and 8 as follows:

$$q_e = \exp(h/H^*). \quad (9)$$

The viscosity of hydrogen at T_0 was available from the literature.[5] The viscosity of deuterium at T_0 was obtained by postulating that the isotope effect is 1.39[6] at all the temperatures used. The diffusion coefficient of H_2-HT was available from the literature,[7,8] but that of D_2–DT was not. The diffusion coefficient of D_2–DT used was the average of D_2-HT[7] and D_2–T_2.[7] In these cases, the coefficient of each system at T_0 was obtained from the linear relation between $\log D$ and $\log T$. Figs. 6 and 7 show two cases where each calculated q_e value comes closest to the experimental q_e value. Accordingly, it can be said that α and β are independent of the wire temperature. Figures 6 and 7 can be rewritten as Figs. 8 and 9, where the dependence of q_e on d/d^* at various temperatures is shown. These figures indicate that q_e is greatly affected by d/d^* and that the maximum q_e is given at 0.80 on the d/d^* abscissa in both cases, irrespective of the temperature of the wire.

The following results were obtained from this study:

1. The separation factors of tritium in H_2–HT and D_2–DT (1.7×10^{-2} Ci mol^{-1}) systems for thermal-diffusion columns 100 cm in length could be obtained by changing the diameter of the column and the wire temperature.
2. It was found that a modified application of Waldmann's equation to the hot-wire-type column was possible by introducing two parameters. These parameters were independent of the wire temperature.
3. The optimum radius of the column for the enrichment was given as 80% of the optimum distance of a flat-type apparatus.

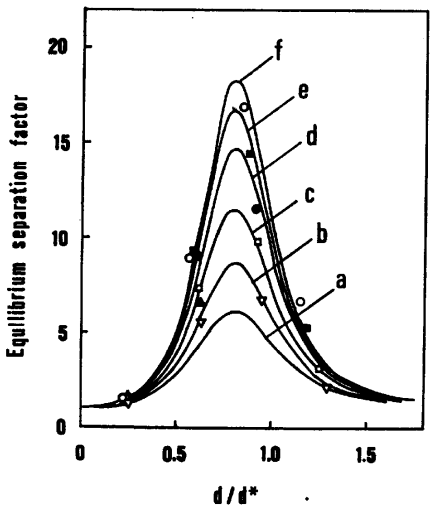

Fig. 8. Dependence of theoretical q_e and experimental q_e on d/d^* in H_2–HT.
The wire temperatures were in the case of theoretical q_e: (a) 200; (b) 250; (c) 300; (d) 350; (e) 400; (f) 450 °C; in the case of experimental q_e: (▽) 200; (▲) 250; (□) 300; (●) 350; (■) 400; (○) 450 °C.

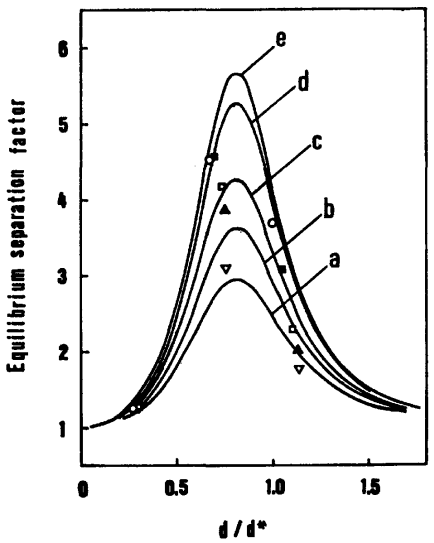

Fig. 9. Dependence of theoretical q_e and experimental q_e on d/d^* in D_2–DT.
The wire temperatures were in the case of theoretical q_e: (a) 200; (b) 250; (c); 300; (d) 400; (e) 450 °C; in the case of experimental q_e: (▽) 200; (▲) 250; (□) 300; (■) 400; (○) 450 °C;.

The authors wish to acknowledge the helpful suggestions and criticisms offered by Professor Emeritus Kozo Hirota (Osaka Univ.) in the course of many fruitful discussions.

Electronic Structure of Transition Metal Complexes. III. A Comparative Study of Bondings in Metal Porphyrins

Eiko KAI and Kichisuke NISHIMOTO*

Department of Chemistry, Faculty of Science, Osaka City University, Sumiyoshi-ku, Osaka 558

(Received March 18, 1981)

In order to elucidate π-type interaction between the metal and the ligand, the electronic structure of various metal porphyrins, [M(Por)], where M=Mn, Fe, Co, Ni, and Cu, has been investigated by the CNDO/2 method. The present calculation shows that the nature of σ-type interaction in M–N bond of porphyrin complex is similar to that of the corresponding ammine complex. The calculated ionization potentials reproduce the experimental data. The electron population of macrocycle π-electron systems in metal porphyrins is about 18 which accords with Hückel's $4n+2$ rule.

In the previous paper,[1] we discussed the mutual influence in ammine complexes of the first transition metals, in which a ligand, NH_3, coordinates to the metal with the lone pair of atom N and has no π-type MO's available. Our next interest is to consider the π-type interaction between the metal and the ligand. Probably, porphyrin is the most interesting ligand for such a purpose. Therefore, in this paper, the electronic structure of various planar metal porphyrins is investigated by the MO theory.

As well known, metal porphyrins are important in the fields of chemistry and biology. For this reason, many experimental and theoretical works have been done.[2] Several *ab initio* and semiempirical MO calculations of metal porphyrins have been carried out in order to elucidate their physicochemical properties.[3] However, most of them have been concerned with heme(Fe-porphyrin) and there are quite a few theoretical works on metal porphyrins in which central metal ions are varied widely. A systematic study of metal porphyrins has been done only with the EHMO method by Zener and Gouterman.[4]

In order to elucidate the nature of metal-ligand bond, particularly, π-type interaction, we have carried out the CNDO/2 calculations of various metal porphyrins systematically using our new bonding parameters.[5] The reason why we use the CNDO/2 method is as follows: The surprising progress in the computer as well as the development of new methods has resulted in the application of the *ab initio* MO method to medium sized molecules. It is, however, not easy to do such calculations on very large molecules, for example, metal porphyrins. In this respect, the semiempirical MO method is still useful for comparative theoretical study of similar and very large molecules.

Calculations

In this paper, metal porphyrins, [M(Por)], where M=Mn, Fe, Co, Ni, and Cu, are considered (see Fig. 1). As the bivalent ions and the porphyrin dianion are taken into consideration, the complex is neutral. Standard values have beenused for CNDO/2 parameters associated with atoms C, N, and H,[6] while a new parameter set which we proposed in the previous paper[5] has been used for those associated with the metals.

Fleischer[7] and Fleischer *et al.*[7] determined molecular dimensions of various metal porphyrins by X-ray analysis. For the sake of simplicity, we assumed the D_{4h} symmetry for the porphyrin molecular framework.[8] The interatomic distances associated with M–N bonds are fixed at 2.0 Å from Mn to Cu. Furthermore, metal porphyrins are supposed to be of planar structure, because they are assumed to be in the low spin state.[9] As we make a comparative study of a series of metal porphyrins, the above-mentioned simplification on the molecular geometry is acceptable.

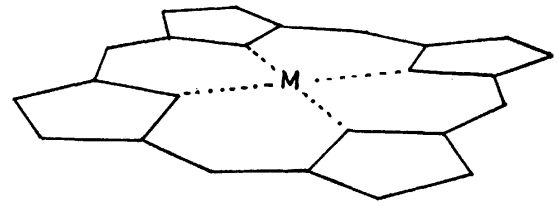

Fig. 1. Planar metal porphyrins, M(Por), where M= Mn, Fe, Co, Ni, and Cu.

Results and Discussion

Binding Energy and Stability. The calculated binding energies of metal porphyrins are shown in Fig. 2. This figure shows that the order of the binding energies is as follows:

$$Mn > Fe > Co > Ni \gtrsim Cu,$$

and that the shape of the binding energy curve is very

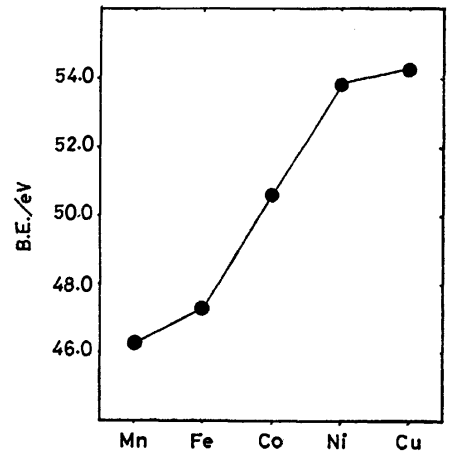

Fig. 2. Calculated binding energies (B.E.) of M(Por)'s.

similar to that of hexaammine or hexaaqua complex.[1] Unfortunately, no experimental data of the binding energies of metal porphyrins are available. However, when calculated binding energies of metal porphyrins are plotted against log (K/mol^{-3} dm^9) (K is stability constant) of the corresponding ethylenediamine complexes determined experimentally,[10] a linear relation is obtained (Fig. 3). Thus, the strength of metal-ligand bonds in metal porphyrins is parallel to that of the corresponding ethylenediamine complexes. This suggests that the strength of metal-ligand bond is determined mainly by the σ-type interaction and that the π-type interaction contributes little to it.

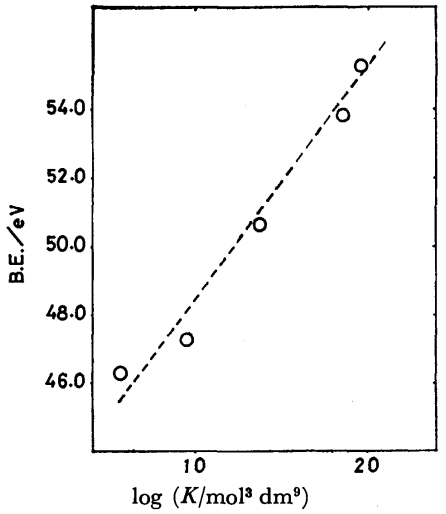

Fig. 3. Binding energy (B.E.) of M(Por) *vs.* log (K/mol^{-3} dm^9), where K is a stability constant of the corresponding ethylenediamine complex.

Bond Order and Bond Strength. As seen from Fig. 2, the calculated binding energy of Cu-porphyrin is nearly equal to that of Ni-porphyrin. This peculiar tendency has been found also with hexaammine and hexaaqua complexes.[1] In order to elucidate this problem, the strength of M–N bond is analyzed from calculated bond orders.

Bond strength is proportional to atomic bond order.[11] However, atomic bond order should not be regarded as a simple sum of bond orders associated with each orbital pair. Therefore, the relative bond strength of M–N bond is considered by comparison of bond orders associated with each orbital pair. The calculated bond orders are shown in Fig. 4. This figure shows that the change of the bond orders associated with 4s-2pσ, 4pσ-2pσ, 3dσ-2s, 3dσ-2pσ, and 3dπ-2pπ is remarkable.

The pattern of the bond-order changes in metal porphyrins is almost the same as those of hexaammine and hexaaqua complexes, as far as σ-type interaction is concerned. The bond orders associated with 3dσ-2s and 3dσ-2pσ decrease abruptly at Cu-porphyrin, as in hexaammine and hexaaqua complexes. This is due to the fact that one of the 3d electrons should enter into the antibonding orbital in the Cu complex. Thus, the decrease in the bond energy contributed from the 3dσ-2s and 3dσ-2pσ pairs cancels out the increase in

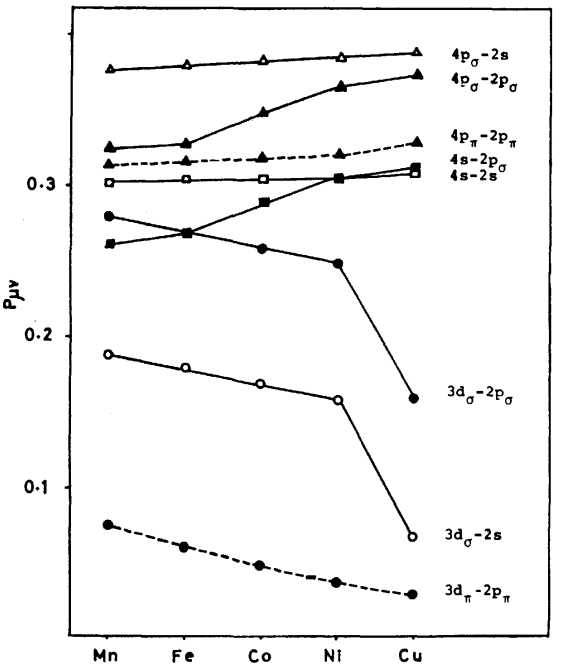

Fig. 4. Calculated bond orders associated with M–N bond in M(Por).

that contributed from the 4s-2pσ and 4pσ-2pσ pairs. Consequently, the shape of binding energy curve shown in Fig. 2 is obtained.

As we expected, the interaction of 3dπ-2pπ is small, because all the complexes are assumed to be in the low spin state in this work. The bond order associated with 3dπ-2pπ decreases according to the increase in atomic number. The reason for this is as follows: Although the ionic radii of the central metal ions decrease according to the increase in atomic number, we fixed the M–N bond distance at 2.0 Å. Therefore, the overlap integral between the metal and ligand will be caused to decrease due to the orbital contraction of the central metal ions.

It can be concluded that the nature of σ-type interaction in the M–N bonds of the porphyrin complexes is similar to that of the corresponding ammine complexes.

Orbital Energy and Ionization Potential. As we assumed these complexes to be in the low spin states, Fe- and Ni-porphyrins are in singlet states, while the others are in doublet states. Figure 5 shows orbital energies of the metal porphyrins. From this figure, some interesting results are derived.

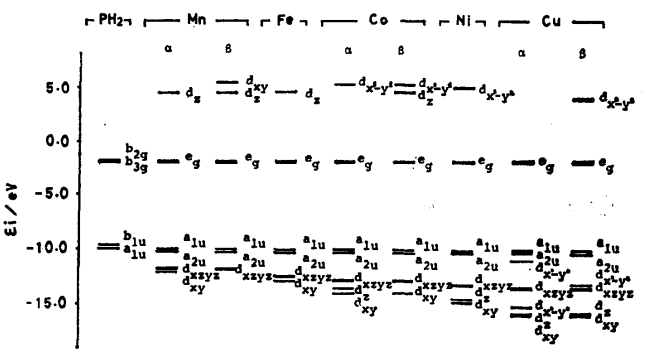

Fig. 5. MO energies (ε_i) of PH_2 and M(Por).

TABLE 1. SPIN DENSITIES OF M(Por)

	Mn	Co	Cu
$3d_{z^2}$	0.0	0.970	0.0
$3d_{x^2-y^2}$	0.0	0.0	0.891
$3d_{xy}$	0.986	0.0	0.0
$3d_{yz}$	0.0	0.0	0.0
$3d_{zx}$	0.0	0.0	0.0

First of all, the change in central metal ions affects MO's which are contributed mainly by the metal itself but barely affects them which are contributed by porphyrin. Although UHF calculations have been done with respect to Mn-, Co-, and Cu-porphyrins which have the open shell structure, the orbital energies of porphyrin parts associated with α- and β-spins resemble each other. In SOMO which has 3d character, the α-spin orbital is different from the β-spin orbital (*e.g.*, d_{xy}-orbital in Mn-porphyrin). This is similar to the result obtained by *ab initio* MO calculations.[12] These results may be due to the following fact that, since most of the MO's are localized on either the ligand or the central metal ion, those belonging to the latter are characterized by the metal itself. The results of calculated spin density given in Table 1 confirm this expectation. It should be noted that in Mn-porphyrin the unpaired spin has π-character, whereas it has σ-character in Co- and Cu-porphyrins. The calculated results accord with the experimental data.[2]

Secondly, although HOMO is b_{1u} (a_{2u} in D_{4h} symmetry) and NHOMO (next HOMO) is a_{1u} in PH_2 (free porphyrin), HOMO is a_{1u} and NHOMO is a_{2u}

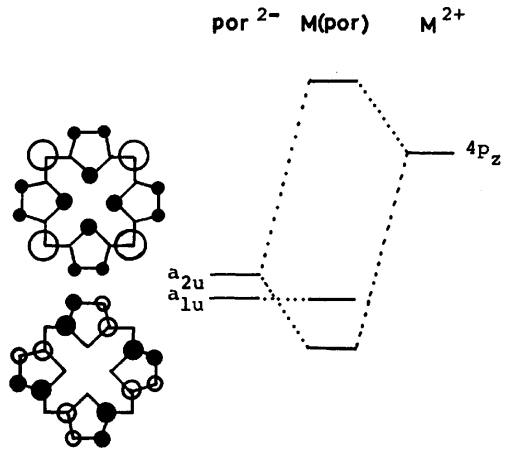

Fig. 6. MO interaction between HOMO and NHOMO of Por^{2-} and 4p-AO of the metal ion.

	a_{2u}	6.39	6.80		6.62

a) Ref. 12. b) Ref. 13.

in all metal porphyrins. The a_{2u} goes down due to $4p\pi$-$2p\pi$ interaction. Figure 6 shows the orbital interaction diagram. This figure indicates that the $4p\pi$-orbital of the metal ion interacts with the a_{2u} of Por^{2-} (porphyrin dianion) but not with the a_{1u} because of its nonbonding character. Therefore, the a_{1u} energy of PH_2 is almost the same as that of metal porphyrin. Table 2 gives calculated ionization potentials which are obtained by using Koopmans' theorem together with experimental data.[13] As shown from this table, the calculated results reproduce the experimental data, that is, the order of the a_{1u} and a_{2u} is reversed when PH_2 coordinates to the metal. Thus, the present results also suggest that the bonding parameter, $\beta_\mu^0(4p)$, is reasonable. Furthermore, the experiment using ESCA shows that the MO energy of PH_2 is almost the same as that of metal porphyrin. The present calculation also explains this fact. Accordingly, it is suggested that Por^{2-} becomes neutral by coordinating to a bivalent metal. This is different from the results calculated by the *ab initio* MO method which are shown in Table 2 for comparison.

Electronic Spectra. The lowest electronic transitions are contributed mainly by the HOMO and LUMO of the complex. In the present study, we obtained the result that the HOMO and LUMO of the complex are localized entirely in the porphyrin part and that their character is very similar among complexes. Therefore, the variation in transition energy is proportional to that in the orbital energy difference between the HOMO and LUMO.

Figure 5 shows that both HOMO and LUMO are almost unchanged by the replacement of metal ions, so that the difference between them is nearly constant. This fact consists with the results obtained through measurement of electronic spectra in which absorption maxima of metal porphyrins are almost the same.[14]

Electronic Population and Net Charge. Let us consider charge densities. Figure 7 shows the calculated

net charge of Co-porphyrin. For comparion, the results obtained by the EHMO and *ab initio* MO methods are also shown. Although the values of calculated net charges depend greatly on the method used, the aspects of polarization resemble each other. The calculated net charge based on the CNDO/2 or EHMO method shows that the central metal ion is almost neutral. This result is different from that calculated by the *ab initio* MO method. For comparison, the calculated charge densities of the central metal ion are shown in Table 3. From this table, it is seen that both the CNDO/2 and EHMO methods calculate the large electron population in the 4s- and 4p-AO's. This is the reason why the central metal ion is neutralized by the coordination. In the EHMO method, the value of q(3d) is also large. Our results coincide with recent X-ray data in which the valence electron distribution is analyzed in detail[15] and also with the results of ionization potential obtained from the photoelectron spectra mentioned above.

In free porphyrin, its macrocycle is highly conjugated and a number of resonance forms can be written. There are nominally 22 π-electrons, but only 18 of them are included in any one delocalization pathway.[2] In metal porphyrin, the very large stability of the porphyrin part may be due to the high aromaticity of the macrocycle part, which is expected to have 18 π-electrons (Hückel's $4n+2$ rule). In order to confirm this, the calculated π-electron density of the macrocycle part is given in Table 4, together with the result calculated by the P-P-P method.[8] This table shows that the number of π-electrons in macrocycle is nearly equal to 18 as expected.

Molecular Mechanical Calculation on Cyclodextrin Inclusion Complexes. I. The Structures of α-Cyclodextrin Complexes Estimated by van der Waals Interaction Energy Calculation

Yoshihisa MATSUI

Department of Agricultural Chemistry, Shimane University, Nishikawazu, Matsue 690

(Received April 23, 1981)

The geometries of inclusion complexes of α-cyclodextrin (α-CD) with krypton, methanol, 1-propanol, and *p*-nitrophenol were estimated on the basis of the calculation of energies (E_{vdw}) due to the van der Waals interactions between the CD and the guest molecules. The E_{vdw} values were computed by the use of Hill's potential equation. A spatial relationship at which the E_{vdw} value became minimal was in good agreement with that observed by X-ray crystallography for such a guest molecule as 1-propanol or *p*-nitrophenol, which is large in size and less polar. On the other hand, a significantly large deviation was found between the observed and the calculated geometries of the inclusion complex in such polar and/or small guest molecules as methanol and krypton.

Cyclodextrin (CD) is a truncated cone-shaped oligosaccharide composed of six (α-CD), seven (β-CD), or more D-glucose residues attached by α-(1,4) linkages. The CD catalyzes a variety of organic reactions in a stereospecific manner *via* the preceding inclusion of guest molecules within its intramolecular cavity.[1,2] For a comprehensive understanding of the stereospecificity in the binding and catalytic processes of CD, it is essential to define the spatial relationships (geometries) within the inclusion complexes. In this regard, the three-dimensional structures of CD and its inclusion complexes have been investigated by means of X-ray crystallography,[2,3] and NMR[4,5] and CD[6,7] spectrometries. However, these methods are too toilsome to be readily applied to any host-guest molecular system. Instead, Corey-Pauling-Koltum (CPK) molecular models have been widely used to predict the geometries of CD inclusion complexes.[1] The CPK models are constructed on the basis of van der Waals radii of atoms and are a convenient tool for the examination of intermolecular spatial relationships in molecular adducts. However, no one can estimate, with the aid of the models, which of the possible geometric isomers of CD–guest inclusion complexes is actually dominant in the complexation process, owing mainly to the lack of information on interaction energies. In order to estimate the geometry of a CD–guest complex more definitively, it is required to evaluate energy differences between the possible geometric isomers. Molecular mechanical calculation (semiempirical force-field calculation)[8,9] is a method available at hand for this purpose. This method involves the calculation of bond stretching, bond angle strain, torsional, and van der Waals interaction energies. Recently, Tabushi *et al.*[10] have successfully applied this method to α-CD systems to elucidate some aspects of the driving force of inclusion.

The present study deals with a structural analysis of some α-CD–guest inclusion complexes on the basis of the calculation of the van der Waals interaction energy (E_{vdw}) alone, as a first step with the intention of relating the structures, stabilities, and reactivities of CD inclusion complexes to energies estimated by molecular mechanical calculation. The van der Waals interaction, together with hydrophobic interaction, is regarded as a dominant binding force contributing to the association of CD with a guest molecule.[10–14] Since the magnitude of the van der Waals interaction is highly dependent on the interatomic distance, the geometry of a CD–guest complex may be largely governed by this interaction. The disregard of other interactions may inevitably result in some discrepancy between observed and calculated geometries. Even so, it is worthwhile to make clear the scope or limitation of this simplified method. For this purpose, the calculation was carried out on several guest molecules, such as krypton, methanol, 1-propanol, and *p*-nitrophenol, which differ in size and in polarity from one another. The molecular structures of α-CD complexes with these guest molecules have already been determined by the X-ray method.[15–18] The E_{vdw} values were computed for each molecular system at a variety of geometric relationships, and the position at which the E_{vdw} value becomes minimum was searched for by the use of the steepest descent method for nonlinear optimization programming.

Method for Calculation

The energy, E_{vdw}, was calculated by the use of Hill's potential equation (Eq. 1),[19] which was first utilized by Tabushi *et al.*[10] for the calculation of CD inclusion.

$$E_{vdw}=a\sum_i\sum_j \varepsilon_{ij}\,(r_{ij}/d_{ij})^6 + b\sum_i\sum_j \varepsilon_{ij}\,\exp(d_{ij}/cr_{ij}) \quad (1)$$

In this equation, the subscripts, i and j, denote interacting atoms belonging to α-CD and a guest molecule respectively, d_{ij}, the interatomic distance, r_{ij} and ε_{ij},

the sum of van der Waals radii (r) and a geometrical mean of energetic parameters (ε) respectively with regard to the interacting atoms of i and j, and a, b, and c, constants equal to -2.25, 8.28×10^5, and -0.0736[19] respectively. The values of r and ε used in the present study are summarized in Table 1. All of the atoms were taken into account in the calculation except hydrogen atoms attached to oxygen atoms of α-CD. Thus, 36 carbon atoms, 30 oxygen atoms, and 42 hydrogen atoms of α-CD were chosen. The structure of a α-CD–guest complex in which E_{vdw} becomes minimum was determined by the steepest descent method with a FACOM M-140F computer at Shimane University.

The Coordinates of Atoms Composing of α-CD. The atomic coordinates of α-CD used in the calculations were determined on the basis of the following three assumptions. (1) Each glucopyranose skeleton of α-CD has the same structure as the "Gl" glucopyranose residue of a α-CD–potassium acetate complex.[20] (2) The α-CD macrocycle retains a regular hexagonal structure with the C_6 element of symmetry, irrespective of the guest molecule. In this connection, the Cartesian coordinates were fixed so that the Z-axis refers to the six-fold axis of rotation, the XY plane to a plane defined by the six O(4) atoms of α-CD, and X-axis to a diagonal through G3O (4) and G6O (4) atoms. (3) The angle of each glucopyranose residue to the Z-axis is determined so as to minimize the conformational energy (E_{conf}) of α-CD. The value of E_{conf} was calculated by the use of semiempirical force-field parameters for the van der Waals and angle bending energies. Since it was assumed that the structure of each glucopyranose residue is unchanged, the conformational energies due to the interactions between atoms belonging to the same residue were excluded from this calculation. The E_{conf} value was minimal at $\phi=12.30°$, where ϕ denotes an angle of a plane defined by C(1), C(3), and C(5) atoms of a glucopyranose residue to the Z-axis. Table 2 shows a part of the atomic coordinates of α-CD obtained, together with a few parameters which represent the aspects of the conformation of the α-CD macrocycle. The ϕ value calculated is slightly larger than that observed.[20] The bond angle (θ) of a glucosidic linkage and the distance (r_d) between a pair of diagonal O(4) atoms for the calculated structure are virtually equal to those for the observed one.

Geometry of an Organic Guest Molecule. The geometry of an organic guest molecule was determined by calculation using bond lengths taken from the literature[21] and with bond angles which were taken as 109.5° for aliphatic carbon and alcoholic oxygen atoms and 120.0° for aromatic carbon atoms. It was also assumed that a straight-chain alkyl group always retains a zigzag *trans* planar conformation.

Results

The atomic coordinates obtained by the E_{vdw} calculation are compared with those observed in Table 3 to 6. Only the z-coordinates of atoms are given in the tables in order to simplify the representation. The observed atomic coordinates were re-calculated from the X-ray crystallographic data.[15–18] In this calculation, the Cartesian coordinates were transformed so that the observed least-squares plane of six O(4) atoms of α-CD accords with the XY plane and the y-coordinates of a pair of diagonal O(4) atoms become equal to zero.

The X-ray study[15] revealed that, in a α-CD–Kr adduct obtained under Kr pressure of 304 kPa, the Kr is statistically disordered over three positions. Each Kr atom is approximately located on the Z-axis. The

a) Parameters representing the conformation of the α-CD macrocycle observed: $\phi=9.7\pm2.3°$, $\theta=118.5\pm0.4°$, and $r_d=0.846\pm0.027$ nm. b) The number of each atom is refered to Fig. 2.

E_{vdw} calculation for this adduct showed two energy minima at $z=-0.158$ and -0.076 nm. The former is close to the z observed for Kr at site A, whereas the latter deviates considerably from those observed. Fairly large deviations were also found between geometries observed and calculated for a α-CD–methanol complex. The methanol molecule observed is two-fold disordered in sites A and B with equal probability. However, both are located far from the position calculated. In contrast to these cases, the geometries calculated are in good agreement with those observed in the cases of α-CD complexes with 1-propanol and p-nitrophenol. The X-ray study[17] showed that the hydroxyl and methyl groups of 1-propanol are two-fold disordered in the α-CD cavity, with site A occupied 80%, site B 20%. The average and standard deviations between the atomic coordinates observed and calculated for 4 atoms of oxygen and carbon of 1-propanol are as follows (standard deviations are in parentheses): x, 0.005 (0.022) and 0.012 (0.048) nm, y,

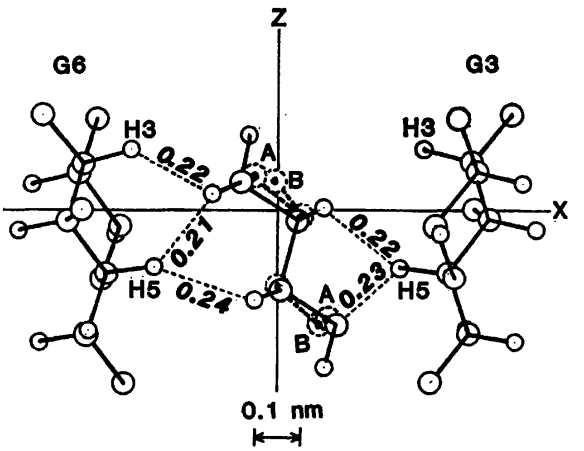

Fig. 1. Geometries calculated (solid lines) and observed (bold dashed lines) for 1-propanol in its α-CD adduct. Letters A and B represent the disordered sites observed for 1-propanol. Interatomic distances are shown in bold italics on fine dashed lines (nm).

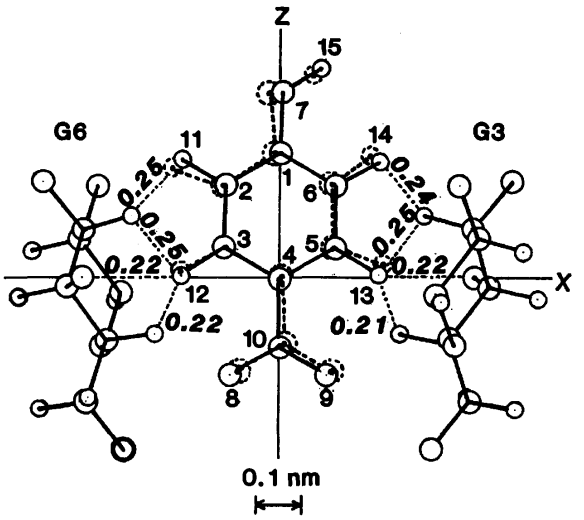

Fig. 2. Geometries calculated (solid lines) and observed (bold dashed lines) for p-nitrophenol in its α-CD adduct. The figures given in roman on the atoms of p-nitrophenol refer to those shown in Table 6. Interatomic distances are shown in bold italics on fine dashed lines (nm).

0.001 (0.032) and −0.004 (0.052) nm, and z, 0.010 (0.005) and 0.005 (0.002) nm for site A and B respectively. On the whole, the coordinates observed for site A are in better agreement than those for site B with the calculated coordinates. Corresponding values for the 15 atoms of p-nitrophenol are −0.004 (0.014) nm for x, 0.028 (0.036) nm for y, and 0.003 (0.010) nm for z. Such deviations, as are shown above, are acceptably small, when taking into account the fact that the atomic coordinates of α-CD and the guest molecules used for the calculation are not exactly the same as those observed. The geometric relationships are illustrated for the adducts of 1-propanol and p-nitrophenol in Figs. 1 and 2 respectively. The calculation of atomic distances between the constituent atoms

of the α-CD complexes revealed that the hydrogen and oxygen atoms of 1-propanol or the hydrogen atoms of *p*-nitrophenol are in van der Waals contact with some of H(3), H(5), and/or O(4) atoms of α-CD as are shown in the figures.

Discussion

Geometric relationships obtained by the E_{vdw} calculation were in good agreement with those observed by the X-ray method in the cases of α-CD complexes with 1-propanol and *p*-nitrophenol. These guest molecules are large enough in size to give significantly large stabilization energies due to the van der Waals interaction ($-E_{vdw}$=57.36 and 52.26 kJ mol^{-1} for 1-propanol and *p*-nitrophenol adducts respectively). On the other hand, deviations between observed and calculated geometries are appreciably large for the krypton and methanol adducts. These molecules are small in size so that the stabilization energies due to the van der Waals interaction are small ($-E_{vdw}$=26.15 or 26.12 kJ mol^{-1} for the krypton adduct and 29.16 kJ mol^{-1} for the methanol adduct). Thus interactions other than the van der Waals one, such as hydrogen bonding and dipole-dipole and hydrophobic interactions, may considerably influence the geometries of these adducts.

The present method of calculation sometimes provides a criterion to judge which of the possible geometric isomers of a α-CD–guest inclusion complex is actually dominant in the complexation process. Harata[18] showed that *p*-nitrophenol is included in such a specific manner that the nitro group is located within the α-CD cavity, whereas the phenolic hydroxyl group protrudes from the O(2), O(3) side. However, it is geometrically possible that *p*-nitrophenol is situated upside down in the cavity. The stabilization energy due to the van der Waals interaction was calculated to be 52.26 kJ mol^{-1} for the former and 41.17 kJ mol^{-1} for the latter. Thus, it is possible to predict the specific orientation of the guest molecule in the α-CD cavity on the basis of the E_{vdw} calculation alone.

A number of problems still remain to be solved. First, it was assumed in the present study that the conformation of α-CD is unchanged during the complexation process. Actually, it has been found that the macrocyclic conformation of α-CD is affected by the inclusion of a guest molecule. The primary hydroxyl groups of α-CD shows both *gauche-gauche* and *gauche-trans* conformations, although only the latter was taken into account in the present study. On the other hand, the E_{vdw} values obtained may serve to elucidate the role of the van der Waals interaction in the stabilization of any α-CD–guest inclusion complexes. In addition, the method can easily be extended so as to include β- and γ-CD systems. These problems will be dealt with in subsequent work.

X-Ray crystallographic studies so far reported showed that each glucopyranose skeleton of α-CD is rigid enough to give virtually similar structure, irrespective of the guest molecule. An advantage of the choice of the α-CD–potassium acetate complex system is that not only the atomic coordinates of the carbon and oxygen atoms but also those of hydrogen atoms attached to the carbon atoms are discussed in the article. The atomic coordinates of the hydrogen atoms attached to the oxygen atoms are not given. However, these atoms are so mobile that the contribution of the atoms to the van der Waals interactions may be regarded as negligible.

Formation of Electronically Excited Fragments (H, CH, NH) by the Electron Impact of Pyrrole and Pyrrolidine

Ikuo Tokue,* Masami Ikarashi, and Yoshio Ito

Department of Chemistry, Faculty of Science, Niigata University, Ikarashi, Niigata 950-21

(Received July 9, 1981)

In the wavelength region of 200—600 nm, photoemissions from electronically excited fragments (H, CH, NH, CN, and C_2) were observed when pyrrole and pyrrolidine were excited by electron impact (0—70 eV). Hydrogen atoms and CH and NH radicals from pyrrole and pyrrolidine are produced *via* a single collision excitation. The appearance potentials for these fragments from pyrrole are 19.4±0.8 eV for the hydrogen Balmer β (H_β), 19.7 ±0.8 eV for the CH($A^2\Delta$-$X^2\Pi$) band, and 20.0±1.0 eV for the NH($A^3\Pi$-$X^3\Sigma$) band. Those from pyrrolidine are 18.7±0.8 eV for H_β, 23.0±0.8 eV for the CH(A-X) band, and 21.8±1.0 eV for the NH(A-X) band. Dissociation processes forming these electronically excited fragments are discussed.

Fragmentation of several cyclic molecules has been studied by electron impact mass spectroscopy.[1,2] Information thus obtained has been restricted to relatively large ionic fragments. Formation of neutral species could be, only indirectly, detected by mass spectroscopy. When atoms and diatomic molecules are produced in their excited states they are easily detected by photoemission spectroscopy. Photoemissions from neutral excited fragments produced by electron impact of aromatic molecules have been investigated extensively.[3—5] However, a few papers[6,7] concerned with large heterocycles have reported emissions from fragments produced by electron impact; very little is known about the formation of neutral fragments from excited parent species.

Appearance potentials of neutral fragments in their excited states produced by electron impact[7] of pyridine and pyrazine are higher than first ionization potentials of parent molecules. In these cases, the formation of ionic fragments can compete with fragmentation to neutral excited species, or ionic fragments seem to be by-products in the formation of neutral fragments. Therefore, we expect that information obtained by mass spectroscopy is also useful for studying the fragmentation mechanism of large heterocycles by electron impact as well as by photoemission spectroscopy.

In the present paper, emission spectra of fragments produced by electron impact of pyrrole and pyrrolidine are identified and appearance potentials for the H_β, CH($A^2\Delta$-$X^2\Pi$), and NH($A^3\Pi$-$X^3\Sigma$) bands are determined. Possible dissociation processes forming H(n=4), CH($A^2\Delta$), and NH($A^3\Pi$) from pyrrole and pyrrolidine are discussed in consideration of thermochemical data.

Experimental

The apparatus and experimental details have been described in the previous paper.[7] The apparatus consists of an electron source, a collision chamber, and an optical detection system. Sample pressures during emission measurements, as measured by an ionization gauge, were 5—40 mPa. Negative potentials from the threshold to 70 eV were applied to a tungsten filament and the maximum beam current measured at Faraday cage was about 0.8 mA for 70 eV. Electron-beam currents of 10 μA at thresholds and 40—50 μA at higher energies were used for the measurement of excitation functions.

In preliminary measurements, the photoemission in the region of 200—600 nm modulated at 225 Hz by a mechanical chopper was detected by a combination of a 30 cm Czerny-Turner monochromator and an HTV R374 photomultiplier connected to a lock-in amplifier. For the measurement of excitation function, an HTV R585 photomultiplier cooled at about −20 °C and an HTV C1230 photon-counter were used with spectral resolution of 0.6 nm ((FWHM).

Pyrrole and pyrrolidine (Nakarai Chemicals, guaranteed grade) were degassed by several freeze-pump-thaw cycles just before use.

Results

Emission Spectra. Figure 1 shows emission spectra produced by electron impact on pyrrole and pyrrolidine in the region of 260—510 nm. The observed spectra were assigned to the hydrogen Balmer series (n= 4—13→2), the NH($A^3\Pi$-$X^3\Sigma$) band around 336 nm, the CN($B^2\Sigma$-$X^2\Sigma$) band around 385 nm, the CH($A^2\Delta$-$X^2\Pi$) band around 431 nm, and the C_2($A^3\Pi$-$X^3\Pi$) band around 470 nm. The NH($c^1\Pi$-$a^1\Delta$) band from neither pyrrole nor pyrrolidine was detected.

The photoemission intensities of the H_β, CH(A-X), and NH(A-X) bands from pyrrole and pyrrolidine were found to be proportional to the electron-beam current up to 0.5 mA and to the sample pressure up to 40 mPa in the collision chamber. The excitation functions for

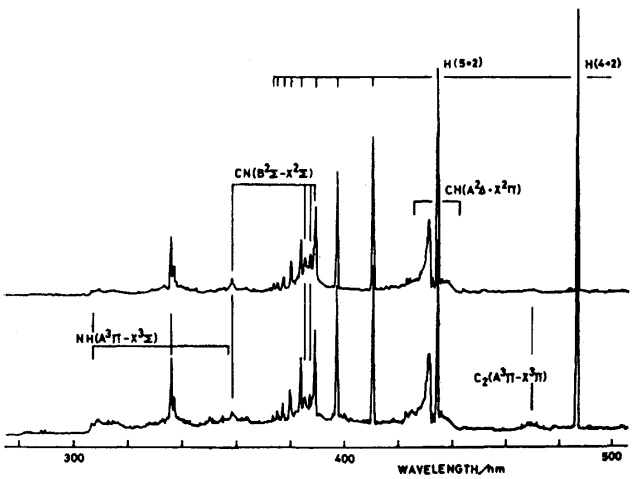

Fig. 1. Emission spectra by electron impact (70 eV, 0.5 mA).
Top view: pyrrolidine at 11 mPa, bottom view: pyrrole at 12 mPa.

these fragment species were observed at sample pressures of 5—11 mPa and the appearance potentials were found to be independent of the sample pressure. Therefore, the excited fragments, H atoms and CH and NH radicals, from pyrrole and pyrrolidine, seem to be formed from fragmentation *via* a single collision excitation by electrons. The two-step collision with another electron seems to be negligible.

Appearance Potentials for Fragment Species. The energy for the impinging electron was calibrated on the basis of both the peak of the excitation function for the (1,0) band of the $N_2(C^3\Pi\text{-}B^3\Pi)$ emission reported by Finn *et al.*[8] and the appearance potential for the (0,0) band of the $N_2^+(B^2\Sigma\text{-}X^2\Sigma)$ emission reported by Borst and Zipf.[9] Nitrogen was mixed with the sample vapor and their emission intensities were measured simultaneously. Slight discrepancies were observed in the steepness of the excitation function for the (1,0) band of the N_2(C-B) emission in the threshold region, probably because of the energy spread of about 2 eV in the present experiment.[7]

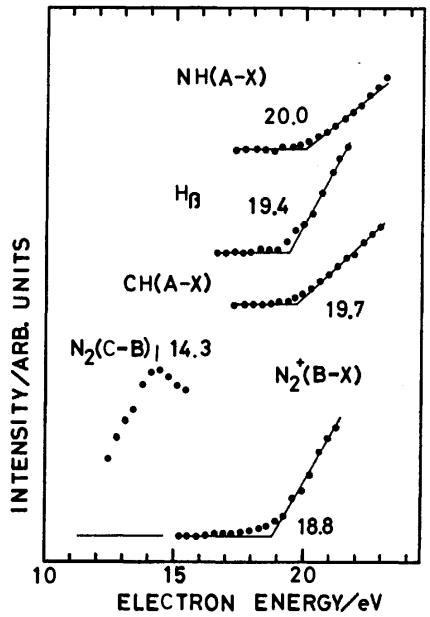

Fig. 2. The excitation functions for the H_β, the CH(A-X) and the NH(A-X) emissions from pyrrole, and those for the N_2(C-B) and N_2^+(B-X) emissions from nitrogen molecule. Typical data are presented and the standard deviation is as large as the diameter of the circles.

The excitation function for the NH(A-X) band could not be measured simultaneously from the gaseous mixture of the sample and nitrogen because the head of the (0,0) band of the N_2(C-B) emission, 337.1 nm,[10] is accidentally overlapped with the head of the (0,0) band of the NH(A-X) emission, 336.0 nm.[11] Therefore, the excitation function for the NH(A-X) band was measured with those for the H_β and CH(A-X) bands from the pure sample vapor, and the appearance potential for NH(A) was calibrated indirectly from those for H(n=4) and CH(A).

Figure 2 shows the excitation functions for the H_β, CH(A-X), and NH(A-X) emissions from pyrrole near their thresholds, together with those for the (1,0) band of the N_2(C-B) emission and the (0,0) band of the N_2^+(A-X) emission measured simultaneously. Figure 3 shows the excitation functions for the same fragments from pyrrolidine. The appearance potentials thus obtained for H(n=4), CH(A), and NH(A) from pyrrole are listed in the third column of Table 1, and those from pyrrolidine are also listed in the third column of Table 2. Dissociation processes which are expected to play an important role in the formation of H(n=4), CH(A), and NH(A) from pyrrole and pyrrolidine are shown in the first column of each table. The threshold energies

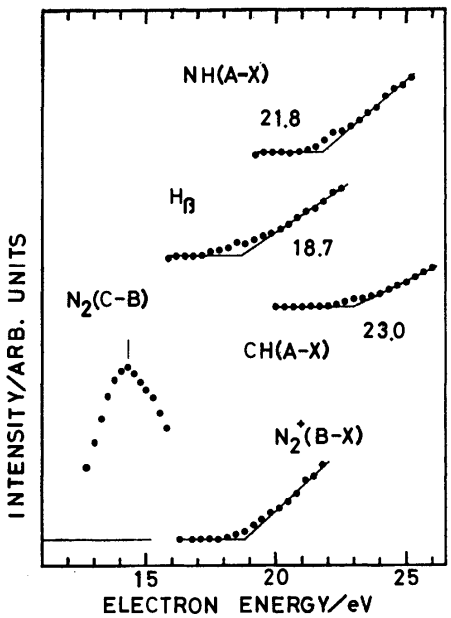

Fig. 3. Same as Fig. 2 from pyrrolidine.

of the dissociation processes leading to the formation of the excited fragments, listed in the second column of Tables 1 and 2, are calculated by using the electronic energies of the excited species and the thermochemical data. The heats of formation used for the calculation of the thresholds are summarized in Table 3.

Discussion

Formation of H(n=4). The onset for the H_β from pyrrole is found at 19.4±0.8 eV. By comparison of the observed threshold energy with the bond dissociation energy of the C–H bond estimated from benzene,[18] 4.86 eV, or the N–H bond,[13] 4.24 eV (estimated), and with the excitation energy of H(n=4), 12.74 eV, the dissociation process for the formation of H(n=4) from pyrrole is considered to be mainly process (1) in Table 1. The onset for the H_β from pyrrolidine is found at 18.7±0.8 eV. A similar consideration on the threshold energy for pyrrolidine leads to process (1) in Table 2. The excess energy of 1.6—2.1 eV for the difference between the observed and calculated threshold in these processes (Tables 1 and 2) is probably dissipated as the kinetic energy of the leaving hydrogen atom. These dissociation processes for the formation of excited H atoms are similar to those with benzene[5,7] and pyridine and pyrazine.[7]

Formation of CH(A) and NH(A). The onsets for the CH(A-X) and NH(A-X) emissions from pyrrole are found at 19.7±0.8 and 20.0±1.0 eV, respectively, and those from pyrrolidine are also found at 23.0±0.8 and 21.8±1.0 eV, respectively. These appearance potentials observed for CH(A) and NH(A) are much higher than the first ionization potentials for pyrrole, 8.97 eV,[19] and for pyrrolidine, 9.0 eV;[2] accordingly, it appears that ionic fragments are possible to be by-products in the formation of CH(A) and NH(A). Dissociation processes leading to the formation of CH(A) and NH(A) from pyrrole and pyrrolidine are still uncertain because available heats of formation of ionic products are insufficient. Nevertheless, if one assumes that the threshold energy consists of the thermochemical values and electron excitation energies of CH(A) and NH(A), main dissociation processes leading to the formation of CH(A) and NH(A) from pyrrolidine seems to include an ionic by-product. Namely, in Table 2, processes (3) and (4) and processes (6) and (7) seem to play an important role in the formation of CH(A) and NH(A) from pyrrolidine, respectively.

Dissociation processes (3) and (5) in Table 1 are expected to play an important role in the formation of CH(A) and NH(A) from pyrrole, respectively. The threshold energies for these processes from pyrrole were calculated from the appearance potential for $C_3H_2^+$ ion from pyrrole reported by Hissel[1] because the heat of formation of $C_3H_2^+$ ion is not known. Furthermore, Gallegos and Kiser[2] have pointed out that the appearance potentials reported by Hissel[1] from tetrahydrofuran and pyrrolidine are in every case lower than the appearance potentials reported by Gallegos and Kiser[2] with the exception of the parent-molecule ions in both molecules. According to these facts, the threshold values for processes (3) and (5) in Table 1 seem to be the lower limits. The threshold energies for dissociation processes from pyrrole including other relatively abundant ions reported by Hissel,[1] $C_3H_3^+$, $C_3H_4^+$, and $C_2H_2N^+$, are higher than the observed values.

Another possibility for the formation of CH(A) and NH(A) from pyrrole and pyrrolidine is that by-products

are formed in their electronically excited states, because the thresholds calculated for the dissociation processes including only neutral by-products in their ground state are much lower the observed thresholds. This possibility will be examined by the photon-photon coincidence technique.[20]

In summary, the appearance potential for H_β from pyrrolidine is slight lower than that from pyrrole, but $H(n=4)$ atoms from both molecules are probably formed *via* a similar mechanism following neither cleavage of skeletal bonds nor new bond formation. The dissociation processes for the formation of CH(A) and NH(A) from pyrrole and pyrrolidine seem to include a fragment ion as a by-product.

(Received July 15, 1981)

The crystal structures of $(NH_3CH_2CH_2CH_3)_6[Mo_7O_{24}]\cdot 3H_2O$ and $(NH_3CH(CH_3)_2)_6[Mo_7O_{24}]\cdot 3H_2O$ have been determined by X-ray analysis. The crystal of the propylammonium salt is triclinic; the space group is $P\bar{1}$; $Z=2$, with $a=14.118(2)$, $b=15.977(2)$, $c=11.368(1)$ Å, $\alpha=90.23(1)$, $\beta=93.00(1)$, $\gamma=111.79(1)°$. That of the isopropylammonium salt is monoclinic; the space group is P2/n; $Z=4$, with $a=23.904(6)$, $b=10.504(1)$, $c=20.652(9)$ Å, and $\beta=115.40(2)°$. The structures were deduced by the direct method and refined by the block-diagonal least-squares technique. The final R values were 0.035 for 8084 observed reflections of the former and 0.060 for 9934 of the latter. The heptamolybdate anion of the two crystals has an approximate 2mm symmetry and its structure is similar to that observed in the crystals of the ammonium, potassium and sodium salts. The propyl- and isopropylammonium cations form some hydrogen bonds to the bridging oxygens of the heptamolybdates. Such hydrogen bonds play an important role in the UV-induced photochromism of these crystals.

Recently it has been reported that various alkylammonium polymolybdates show photochemical and photochromic properties in aqueous solution and in the solid state.[1] On exposure to UV light, they turn blue from colorless in deaerated solutions, whereas they change from colorless to red in the solid state. The photoreduced blue compound of isopropylammonium polymolybdate, $(NH_3CH(CH_3)_2)_4[Mo_{13}O_{40}]_{0.33}[H_4Mo_{12}O_{40}]_{0.67}$, was crystallized and its structure has been reported.[2] The crystal structure of the isopropylammonium salt, $(NH_3CH(CH_3)_2)_6[H_2Mo_8O_{28}]\ 2H_2O$, (IPAM2) has been analyzed by X-rays.[3] It has been proposed from the structure and the ESR measurement of the crystal that the photoreduction from Mo(VI) to Mo(V) in a MoO_6 octahedral site proceeds on irradiation with UV light, accompanying a transfer of a hydrogen-bonding proton from the isopropylammonium nitrogen to a bridging oxygen atom of the octamolybdate.[4]

In order to ascertain the mechanism, crystal structures of the propylammonium and isopropylammonium salts of the polymolybdate with somewhat different compositions have been analyzed. Hereafter the former crystal is abbreviated to PAM and the latter to IPAM.

Experimental and Structure Determination

The preparation of the two crystals was reported in the previous paper,[1] in which their chemical formulae were erroneously given owing to the low accuracy of the elemental analysis.

PAM, $(NH_3CH_2CH_2CH_3)_6[Mo_7O_{24}]\cdot 3H_2O$. Preliminary unit cell dimensions and the space group were obtained from oscillation and Weissenberg photographs. Accurate cell dimensions were determined by a least-squares technique from 19 reflections measured on a Rigaku automated four-circle diffractometer. Crystal adata re summarized in Table 1. Intensity data up to $2\theta\leqq 55°$ were collected on the diffractometer with Mo $K\alpha$ radiation ($\lambda=0.71069$ Å) monochromated by graphite. An ω-2θ scan was employed with a scan rate of 4° (2θ) min^{-1}. A total of 8084 independent reflections, ($|F_o|\geqq 3\sigma(|F_o|)$), were used for the structure determination.

Table 1. Crystal data

	PAM	IPAM
Chemical formula	$(C_3H_{10}N)_6[Mo_7O_{24}]\cdot 3H_2O$	$(C_3H_{10}N)_6[Mo_7O_{24}]\cdot 3H_2O$

μ(Mo $K\alpha$)/cm^{-1}	18.28	18.56

Although the crystal turned red on X-ray exposure, the intensities of the monitor reflections did not change significantly during the data collection. The intensities were corrected for Lorentz and polarization factors but absorption correction was not applied.

The positions of the seven Mo atoms were obtained by the direct method using program MULTAN 78.[5] The C, N, and O atoms and three water molecules appeared on the successive Fourier maps. The structure was refined by the block-diagonal least-squares method with the anisotropic temperature factors. After several cycles of refinement, six atoms of the three propylammonium ions and a water molecule, respectively, were found to be distributed over two positions. The occupancy factors of the disordered atoms were fixed at a value which was estimated from their isotropic temperature factors. All the H atoms bonded to the N atoms and to the O atoms of the ordered water molecules were located on a difference map. Some of the H atoms of the ordered propyl groups obtained from a difference map and the positions of the remaining ones were calculated geometrically. In the final refinement, the disordered atoms and the H atoms except the propyl H atoms were included with the isotropic temperature factors. The final R value became 0.035 for 8084 reflections.

TABLE 2. FINAL ATOMIC PARAMETERS OF PAM, MULTIPLIED BY 10^5 FOR Mo ATOMS, 10^4 FOR C, N, O ATOMS AND 10^3 FOR THE DISORDERED ATOMS WITH *

a) The occupancy factors of O(W1), C(22), C(23), C(62), C(41), C(42), O(W1*), C(22*), C(23*), C(41*), C(42*), and C(62*) are 0.80, 0.80, 0.75, 0.80, 0.65, 0.65, 0.20, 0.20, 0.25, 0.35, 0.35, and 0.20, respectively.

The weighting scheme was $w=(0.00069F_o^2-0.11048|F_o|+5.42077)^{-1}$ for $3.90\leqq|F_o|\leqq156.14$ and $w=0.2$ for $|F_o|<3.90$ and $|F_o|>156.14$. The atomic scattering factors were taken from the International Tables for X-Ray Crystallography.[6] Positional and isotropic or equivalent isotropic temperature factors are given in Table 2.

IPAM, $(NH_3CH(CH_3)_2)_6[Mo_7O_{24}]\cdot 3H_2O$. Experimental details were nearly the same as those in PAM. Refinement of the unit cell dimensions was based on 18 reflections. Crystal data are listed in Table 1. A total of 9936 independent reflections were used for the structure determination.

The positions of the seven Mo atoms were obtained by using program MULTAN 78.[5] The C, N, and O atoms and three water molecules appeared on the successive Fourier maps. The structure was refined by the block-diagonal least-squares method. After several cycles of refinement with anisotropic temperature factors, an isopropylammonium cation (N(6), C(61), C(62), and C(63)), and a water molecule (O(W3)) were found to occupy two disordered positions. The occupancy factors for the two equivalent atoms were assumed to be 0.6 and 0.4, which were estimated from the isotropic temperature factors of the atoms and were not refined in the least-squares calculation. Out of 60 H atoms, 18 were located on the difference map. The H atoms were included in the final refinement with the isotropic temperature factors. Two strong reflections, 010 and 200, were excluded because they seemed to suffer from secondary extinction. The final R value became 0.060 for 9934 reflections. The weighting scheme used in the final stages was $w=[\sigma^2(F_o)+(0.015F_o)^2]^{-1}$. Positional and equivalent isotropic temperature factors are given in Table 3.** The FACOM-HITAC system M-160 and M-170 computers were used in the calculation.

Results

The Structure of Heptamolybdate. The geometries of the heptamolybdate anions in both crystals are quite similar. Seven MoO_6 octahedra are condensed by edge sharing into a structure that has an approximate

** Lists of the positional and isotropic temperature factors of the H atom, lists of the anistropic temperature factors of the Mo, C, N, and O atoms, tables of the bond angles and tables of the observed and calculated structure factors for both crystal structures are kept in the office of the Chemical Society of Japan (Document No. 8214).

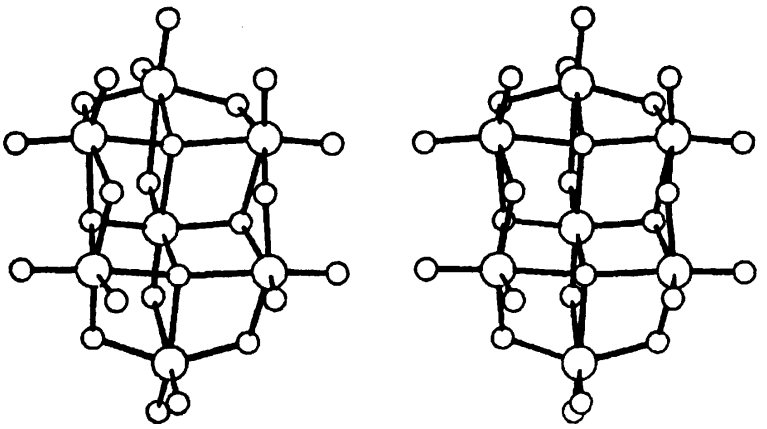

Fig. 1. Stereoscopic drawing of the heptamolybdate anion in PAM.

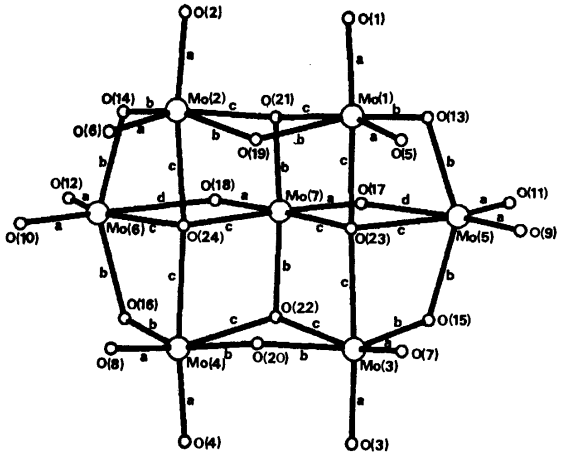

Fig. 2. The numbering of the atoms and the bond types in the heptamolybdate anion.

point symmetry 2mm(C_{2v}). Figure 1 shows the stereoscopic drawing of the heptamolybdate ion in PAM. Such a structure of $[Mo_7O_{24}]^{6-}$ is also found in the crystal of the ammonium,[7] potassium,[7] and sodium[8] salts.

Bond distances of the heptamolybdate ions in PAM and IPAM are listed in Table 4. The corresponding values are in fair agreement, although some distances and angles relevant to O(16), O(21), O(22), and O(24) are significantly different between the two crystals. The discrepancy is probably due to the different hydrogen bonding scheme.

The Mo–O bonds can be classified into four types by their bond distances; *a*(1.69—1.73 Å), *b*(1.90—1.97 Å), *c*(2.16—2.30 Å), and *d*(2.46—2.55 Å). Figure 2 shows the numbering of the atoms and the types of the bonds. The seven MoO_6 octahedra are divided into two classes; five octahedra of Mo(1), Mo(2), Mo(3), Mo(4), and Mo(7) have three types of Mo–O bonds, whereas two octahedra of Mo(5) and Mo(6) have four types of the bonds. The electronic state of Mo(5) and Mo(6) may be different from that of the other Mo atoms. The seven MoO_6 octahedra in the ammonium salt are also divided into two classes.

The Structure of Propylammonium and Isopropylammonium Cations. Bond distances of the propyl- and isopropylammonium ions are listed in Table 5. The rather large deviations from the normal values may be brought

about by the disordered structures of these ions. Table 6 shows the torsion angles of the central C–C bond in the propylammonium ions. The conformation of the ions may be easily changed in the crystal.

Crystal Structure and Hydrogen Bonding Scheme. The crystal structure of PAM viewed along the c axis is shown in Fig. 3. The hydrophobic groups of the propylammonium ions are brought together around the $(1/2,0,z)$ region. All the N–H groups of the propylammonium ions and O–H groups of the water molecules make hydrogen bonds with the heptamolybdate anion or the water molecules. The hydrogen bonds construct a three-dimensional network. The distances of X···O, X–H, and H···O and the angles of X–H···O are listed in Table 7, where X means the N or O atoms. The N(1)–H(N13) and N(2)–H(N32) groups make trifurcate hydrogen bonds with O(1), O(2), and O(W1), and O(8), O(10), and O(W3), respectively. However, the distances of H..O and the angles of N–H···O indicate that N(1)–H(N13)..O(2), N(1)–H(N13)···O(W1), N(3)–H(N32)···O(8), and N(3)–H(N32)···O(10) may

not be those of hydrogen bonds, although the N···O distances of these bonds are rather shorter than those of N(1)–H(N13)···O(1) and N(3)–H(N32)···O(W3).

The crystal structure of IPAM viewed along the b axis is shown in Fig. 4. The isopropylammonium cations occupy the space between the heptamolybdate anions. Interatomic distances of the possible hydrogen bonds are listed in Table 8.

Discussion

It has been proposed from the X-ray analysis[3] and ESR measurement[4] of the IPAM2 crystal that the photoreduction of Mo(VI) to Mo(V) proceeds *via* UV-induced charge transfer in the terminal Mo=O bond of a MoO_6 site, followed by a transfer of a hydrogen-bonding proton from an isopropylammonium nitrogen to a bridging oxygen of the MoO_6 site as follows.

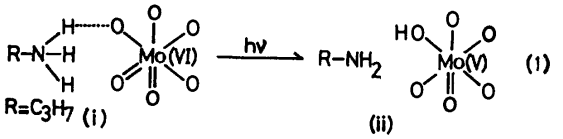

Figure 5 shows the geometry in the environment of the photoreducible MoO_6 site found in the IPAM2 crystal.

In the heptamolybdate anion of the present PAM and IPAM crystals, the photoreducible Mo atom is considered to be Mo(5) or Mo(6), because each of them has a long Mo–O bond, as is observed in the photoreducible site of the IPAM2 crystal. Figure 6(a) and (b) show the geometries of the hydrogen bonding scheme at the Mo(5) and Mo(6), respectively, in the PAM crystal. There are five hydrogen bonds between the N–H groups of the propylammonium cations and the bridging oxygen atoms of the Mo(5) and Mo(6) sites. One of the hydrogen bonds may be responsible for the proton transfer from the cation to the anion. In the crystal of IPAM, only the Mo(5) site has such a hydrogen bonding scheme, which is shown in Fig. 7. One of the two hydrogen bonds may bring about the

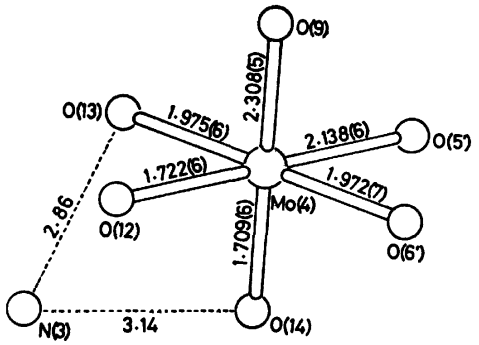

Fig. 5. Bond distances (l/Å) and interatomic distances (l/Å) between the non-bonded atoms in the environment of the photoreducible MoO_6 site in IPAM2. These values are taken from the reference 3. Positions of H atoms are omitted for clarity.

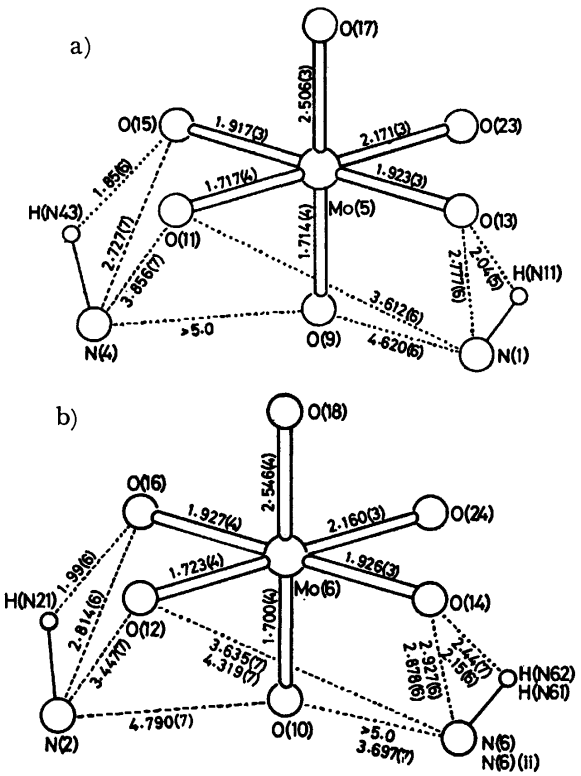

Fig. 6. Bond distances (l/Å) and interatomic distances (l/Å), (less than 5 Å), between non-bonded atoms in the environment of the (a) Mo(5) and (b) Mo(6) sites in PAM. In the Mo(6) site, O(14) makes two hydrogen bonds with N(6)–H(N62) and N(6)–H(N61) in the unit of (ii), $(-x, -y, -z)$. The upper and lower values correspond to the former and latter hydrogen bonds, respectively.

proton transfer.

It should be noted that the crystal of the ammonium heptamolybdate does not exhibit photoreduction on irradiation with UV light,[1] although it has a similar hydrogen bonding scheme.[7] This indicates that some additional factors should be taken into account for the photoreduction. If the positively charged terminal oxygen atom forms a charge transfer complex with the negatively charged alkylamine nitrogen atom in the complex (ii), the Mo(V) species formed by the UV

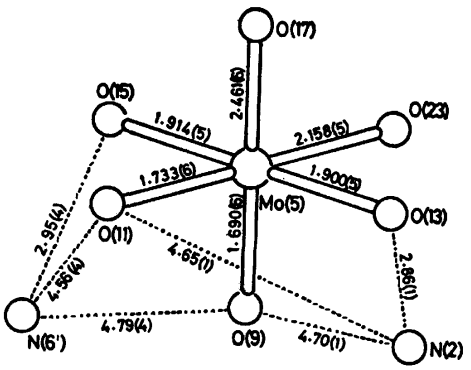

Fig. 7. Bond distances (l/Å) and interatomic distances (l/Å), (less than 5 Å), between the non-bonded atoms in the environment of the Mo(5) site in IPAM. Positions of H atoms are omitted for clarity.

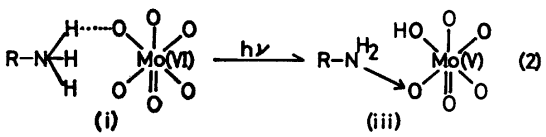
irradiation would be stabilized. Since the propyl- and isopropylammonium cations have considerably loose contacts with the neighboring molecules in the crystal, such a charge transfer complex would be easily formed in the solid state. When the crystal is allowed to stand in the dark after irradiation, the charge transfer complex returns to the initial hydrogen bonding complex (i) and its color is bleached.[1] On the other hand, the ammonium cation has more than four hydrogen bonds with the neighboring heptamolybdates and water molecules. Moreover, it is closely packed in the crystal. The formation of the charge transfer complex may be inhibited and the coloration cannot be observed even if the crystal is exposed to UV light.

It is concluded that the photochromism of alkylammonium isopolymolybdates is brought about by the following reaction process (2) instead of (1) in the



crystal. The mechanism of the change in color when the photoreduced crystal is dissolved in water has been discussed elsewhere.[9]

The Effect of Diluents on the Mechanochemical Change in the Solid State of Amobarbital

Akiko IKEKAWA* and Sohachiro HAYAKAWA†

Faculty of Pharmaceutical Sciences, Showa University, Hatanodai, Shinagawa-ku, Tokyo 142
†*Department of Applied Physics, Faculty of Science, Tokyo Institute of Technology, Oh-okayama, Meguro-ku, Tokyo 152*
(Received July 30, 1981)

The effect of ball-milling with dextran 2000, microcrystalline cellulose, or methylcellulose (MC) on the solid state of amobarbital was investigated. There are three kinds of polymorphs for amobarbital; Crystals I, II, and III. Crystal I is obtained by heating Crystal II recrystallized from a 25 v/v % aqueous ethanol solution at 150 °C. The part of Crystal I decreased remarkably at the first stage of ball-milling, while the amorphous part increased gradually. The heat of fusion decreased remarkably; this was considered to be due to the increase in the amorphous part. The peak of fusion in the DTA thermogram was broadened, and the temperature at which amobarbital began to fuse was lowered. This phenomenon was considered to be due to the increase in the lattice imperfection. The solubility in the KH_2PO_4–Na_2HPO_4 buffer solution with a pH of 6.0 increased; the increase in the amorphous part was considered to contribute to this increase. This phenomenon was the most remarkable in the case of the mixture with MC. The interaction of amobarbital with MC was suggested by the heat of fusion and the DTA thermograms. It was also suggested that the interaction of amobarbital with the diluent was one of the most important reasons for the increase in the solubility upon ball-milling.

It was reported previously that the solubility of amobarbital in the KH_2PO_4–Na_2HPO_4 buffer solution with a pH of 6.0 increased upon ball-milling with such diluents as methylcellulose,[1] though the solubility also increased slightly upon ball-milling in the absence of any diluents at all.[2] In a previous paper, the effect of ball-milling in the absence of diluents on the solid state of amobarbital was investigated.[2] In this paper, the effect of ball-milling with diluents on the solid state of amobarbital was investigated in order to clarify the mechanism of solubilization.

Experimental

The amobarbital (5-ethyl-5-isopentylbarbituric acid), dextran 2000, microcrystalline cellulose (MCC), and methylcellulose (MC) used were described in a previous paper.[1]

A 10-g portion of amobarbital, a mixture of 2 g of amobarbital and 3 g of MC, a mixture of 1 g of amobarbital and 9 g of MCC, a mixture of 3 g of amobarbital and 7 g of MCC, and a mixture of 3 g of amobarbital and 7 g of dextran were ball-milled in the way reported in the previous paper.[1] The following measurements were carried out in the way reported in the previous papers;[1,2] X-ray diffraction diagrams, DTA and DSC thermograms, and the particle-size distribution of amobarbital in the mixture with dextran or MC (dextran and MC are soluble in distilled water). The dissolution of amobarbital from the mixture into a KH_2PO_4–Na_2HPO_4 buffer solution (pH; 6.0, ionic strength; 0.08) at 30 °C was measured by shaking the suspension as has been reported in a previous paper. The concentration of amobarbital in the filtrate of the suspension was obtained from the absorbance at 238 nm.[1]

Results and Discussion

X-Ray Diffraction. Three kinds of polymorphs of amobarbital were obtained in a previous paper. Crystal I was obtained by heating Crystal II (at 150 °C), which had been recrystallized from a 25 v/v % aqueous ethanol solution. Crystal III was obtained by freeze-drying an aqueous solution of amobarbital. The X-ray diffraction intensities at 9.0° and 24.7° of 2θ for Crystal I were higher than those for Crystal III, where 2θ is the angle between the incident X-ray and the scattering X-ray. The intensity at 12.6° of 2θ was lower than the intensity at 16.0° of 2θ, and no line was observed at 14.9° of 2θ in the diagram of Crystal I, while the intensity at 12.6° of 2θ was a little higher than the intensity at 16.0° of 2θ and a line was observed at 14.9° of 2θ in the diagram of Crystal III.[2]

Figure 1 shows the X-ray diffraction patterns of a mixture of amobarbital and MC. No diffraction line was observed in the diagram of MC. The diffraction intensities for amobarbital at 9.0°, 16.0°, and 24.7° of 2θ decreased, while the intensities at 12.6° and 14.9° of 2θ increased, upon ball-milling with diluents; these increases were considered to be due to the transformation of Crystal I into Crystal III. The percentage of Crystal

1: The physical mixture of MC containing 40 w/w % of amobarbital, 2: the powders obtained by ball-milling "1" for 101 h.
a) *I* is the diffraction intensity.

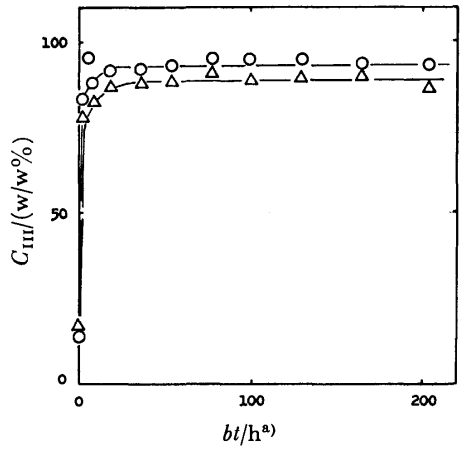

Fig. 2. Increase in C_{III} upon ball-milling with diluents.
The content of amobarbital; 30 w/w%, diluent: △; dextran, ○; MCC.
a) bt is the ball-milling time.

III in the crystal part, C_{III}, was obtained from the ratio of the diffraction intensity at 12.7° of 2θ to the intensity at 16.0° of 2θ. As is shown in Fig. 2, C_{III} increased remarkably at the first stage of ball-milling, while C_{III} was nearly constant after ball-milling with MC for 10 min.

Ruland reported that the crystallinity, x_{cr}, could be obtained by means of Eq. 1, where λ is the wave length of the X-ray, $I_{cr}(s)$ is the intensity of the diffraction line at s, $I(s)$ is the total intensity of the scattering X-ray at s and K is a constant:[3)]

$$x_{cr} = KF_{cr}/\int_{s_o}^{s_p} s^2 I(s)\mathrm{d}s, \qquad (1)$$

$$F_{cr} = \int_{s_o}^{s_p} s^2 I_{cr}(s)\mathrm{d}s, \qquad s = 2\sin\theta/\lambda.$$

The value of $\int_{s_o}^{s_p} s^2\, I(s)\ \mathrm{d}s$ was assumed to be constant in the case of ball-milling with diluents, though the value could not be obtained experimentally. F_{cr} was obtained for the range between 5° and 30° of 2θ, and x_{cr} was obtained from the ratio of F_{cr} for the ball-milled

16.1	0.44	0.43	0.42	0.47	0.34	0.48	0.42	0.47
23.6	0.36	0.40	0.32	0.48			0.28	0.44

a) The content of amobarbital is 100%. b) The content of amobarbital is 30 w/w%. c) bt is the ball-milling time. d) The mean values for the data between the times are tabulated. e) $\Delta H_{1/2}$ is the separation of 2θ where the diffraction intensity is half the maximum intensity at the line.

mixture to the value for the physical mixture of amobarbital ball-milled for 60 h in the absence of any diluents, a mixture whose crystallinity was assumed to be 0.82.[2] The results are shown in Figs. 3, 4, 5, and 6. Some of the values of C_{III} could not be obtained for the mixture with MCC containing 10 w/w% of amobarbital, as diffraction lines were observed in the diagram of MCC at the first stage of ball-milling. However, in all cases, Crystal I decreased remarkably at the first stage of ball-milling, while the amorphous part increased gradually upon ball-milling.

Table 1 suggests that the line-width of amobarbital increases upon ball-milling with diluents; this is probably a result of the increase in the lattice imperfection.

Heat of Fusion. The heat of fusion of amobarbital, ΔH_{obsd}, decreased remarkably upon ball-milling with diluents, as is shown in Fig. 7. In a previous paper, Eq. 2 was applied to the relation between ΔH_{obsd} and x_{cr}:[2]

$$\Delta H_{obsd} = 29.3\, x_{cr} + 5.0\,(1-x_{cr}). \quad (2)$$

The crystallinity which is obtained by Eq. 2 using the data of ΔH_{obsd} is defined as $x_{cr\ heat}$ in this paper. The data of $x_{cr\ heat}$ are shown in Figs, 3, 4, 5, and 6 by the triangles. In the case of the mixture with MC, $x_{cr\ heat}$ was much smaller than x_{cr} even for the physical mixture. This phenomenon is considered to be due to the interaction between amobarbital and MC. However $x_{cr\ heat}$ and x_{cr} were nearly identical for the other mixtures.

Melting Point. As is shown in Fig. 8, the peak of fusion of amobarbital was broadened and caused to branch into two peaks by ball-milling with diluents. In Fig. 8, T_1 is the temperature at which amobarbital begins to fuse, T_2 and T_3 are the melting points for the two peaks, T_3* is the temperature at the beginning of the shoulder, and T_4 is the temperature at which the fusion comes to an end. Table 2 shows the numerical values of these temperatures. T_1 was lowered by ball-milling with diluents. In each case, T_1 was lower when x_{cr} was smaller, as is shown in Fig. 9. These results suggest that the lowering of T_1 by ball-milling is due to the increase in the amorphous part. The relations between T_1 and x_{cr} were influenced by the kind of diluent. The lowering of T_1 was more remarkable for the mixture with MC than for the other mixtures, and T_1 was lowered even by physically mixing amobarbital

The content of amobarbital: 30 w/w%, diluent: ●; dextran, ○; MCC.

with MC. In the case of the mixtures with dextran or MCC, T_4 was not influenced and T_3 was lowered slightly by ball-milling, but T_3 and T_4 were lowered by ball-milling the mixture with MC. A signal was observed in the DTA thermograms of the mixture with dextran or MCC when the sample was heated from room temperature to 200 °C, left alone at room temperature, and then heated again immediately after cooling, and the signal was nearly identical with the signal by heating for the first time. However, in the case of the mixture with MC, no signal was observed upon the same preparation, while only a small signal was observed when the sample was set aside for more than a day at room temperature after heating to 200 °C. This phenomenon was more remarkable for the mixture ball-milled for a long time. It can be considered, on the basis of the above facts, that interaction occurs between amobarbital and the diluents and that the interaction with MC is more remarkable than the interaction with the other diluents. It has also been reported that MC prevented the amorphous noboviocin from crystallization in the aqueous suspension.[4]

Particle Size. Variation in the particle size of amobarbital with ball-milling in the presence of dextran

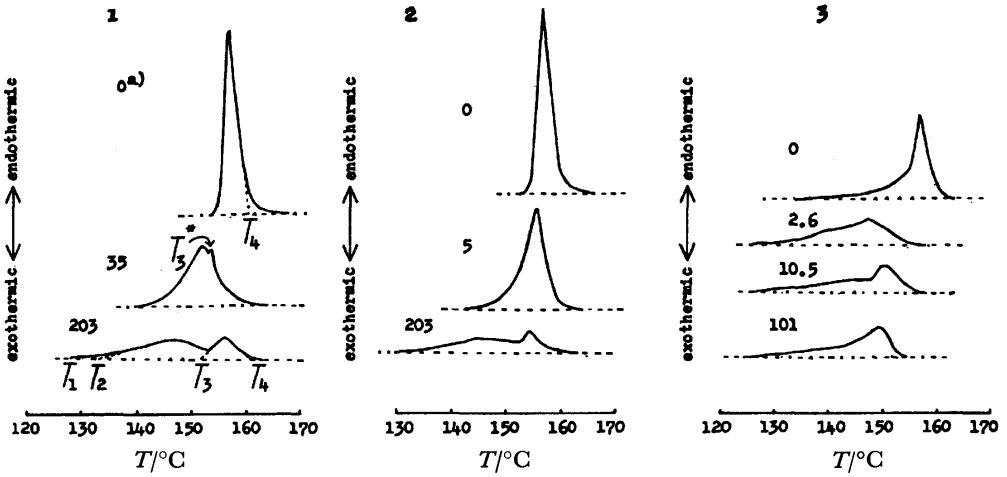

Fig. 8. Influence of ball-milling with diluents on DTA thermograms of amobarbital.
The content of amobarbital in the mixture with MCC is 30 w/w%. Diluent: 1; dextran, 2; MCC, 3; MC. a) The figure on each of the curves is the ball-milling time/h.

or MC was also investigated. In Figs. 10 and 11, D_{50} is the median diameter by weight base, and $W_{0.3}$ is the weight percentage of the particles smaller than 0.3 μm in diamter. In Fig. 10, D_{50} decreased remarkably in the first stage of ball-milling. $W_{0.3}$ increased gradually, and it stayed nearly constant after ball-milling for more than 2 h for the mixture with MC. For the mixture with dextran, D_{50} was at a minimum at a ball-milling time between 17 and 100 h. A similar phenomenon has also been reported for many kinds of inorganic powders.[5] As is shown in Figs, 2, 10, and 11, the change in C_{III} with the ball-milling time was parallel to the decrease in D_{50} at the first stage of ball-milling. It is considered that the transformation of Crystal I into Crystal III is remarkable when the particles are broken at nearly the center. In Figs. 3, 6, 10, and 11, the increase in the amorphous part with ball-milling is parallel to the increase in $W_{0.3}$ at a ball-milling time within 50 h. It is suggested that the amorphous part increases markedly when the particles are broken at the edge. It is also probable that the agglomeration rate is larger than the rate of decrease in the particle size when the amorphous

part increases slightly after ball-milling for more than 100 h in the case of a mixture with dextran.
