Materials. The shift reagents which had not been available commercially were prepared by reacting suitable 1,3-diones with lanthanoid nitrates in aqueous alcoholic solution at suitable pH (adjusted by adding sodium hydroxide).[11–13] Tris (dipivaloylmethanato) complexes of La, Nd, Sm, Gd, Tb, Dy, Ho, Er, and Yb ($Ln(dpm)_3$), tris(6,6,7,7,8,8,8-heptafluoro-2,2-dimethyl-3,5-octanedionato) complexes of La, Nd, Sm, Gd, Tb, Dy, Ho, Er, and Yb ($Ln(fod)_3$), tris(hexafluoroacetylacetonato) complexes of Eu, Pr, and Yb, and tris(1,1,1-trifluoroacetylacetonato) complexes of Eu, Pr, and Yb were prepared by this method. Two transition metal complexes $Co(dpm)_2$ and $Cu(dpm)_2$ were also prepared by the similar procedures. The hexafluoro- and trifluoroacetylacetonato complexes were sparingly soluble in carbon tetrachloride and, therefore, unsuitable for the measurement. These 1,3-diketonato complexes, together with commercially available ones, were purified by sublimation immediately before use. They were sublimed at temperatures about 10 °C lower than their melting points (100—220 °C for $Ln(fod)_3$ and 160—240 °C for $Ln(dpm)_3$). Then, they were dried for 2 d over phosphours pentaoxide at *ca.* 60 °C and used for the measurement. Commercially available spectro grade solvents were used. They were dried over phosphorus pentaoxide and distilled immediately before use.

Measurement of Infrared Spectra. Infrared spectra were recorded with a Hitachi 225 infrared spectrophotometer usually by use of a 2 cm cell. Temperature of the solution under measurement was controlled by circulating water, and other medium if needed, through the cell jacket from a thermostatic bath. The measurement was carried out with a concentration of *ca.* 3×10^{-3} mol l^{-1} for the shift reagent, changing the concentration of aniline from *ca.* 2×10^{-3} to *ca.* 8×10^{-3} mol l^{-1}. The concentration of the free substrate (aniline) [S] was determined by measuring the intensity of the asymmetric stretching band of NH_2 group appearing at 3483 cm^{-1} in carbon tetrachloride solution. As shown by an example of the spectrum in Fig. 1, the absorption band due to the asymmetric stretching mode of NH_2 vibration (located at the higher frequency) does not overlap with those of the complexed species, hence, being suitable for the determination of [S].

Measurement at a far higher concentration is necessary in order to determine the K_2 values for $Ln(dpm)_3$–aniline system. Thus, a variable cell whose length was adjusted to be 0.2 mm was used instead. Since the concentration of aniline can be increased about 100 times larger than that in a 2 cm cell, the equilibrium to form 1:1 adduct lies very far to the product and the second coordination forming 1:2 adduct occurs considerably. In this case, the variable temperature measurement was impossible and the measurement was carried out at 53 °C. Then the K_1's at 53 °C were calculated by assuming the ΔH and ΔS in Table 4. Calculated K_1's and [S]'s from ν_{as} intensities gave K_2 values.

Table 1. The coordination number (n) and the formation constant (K) values for some $Ln(dpm)_3$–aniline complexes in CCl_4

Results

Tris(dipivaloylmethanato)lanthanoid(III)–Aniline Complexes. In our previous report,[14] the composition and the thermodynamic properties of $Eu(dpm)_3$–t-butyl alcohol adduct were investigated by measuring the OH stretching absorption of the alcohol, giving n=0.92 from the Scatchard equation (Eq. 6).[15] The most probable coordination number (n) and the formation constant ($K(=1/K_D)$) were obtained similarly for the $Pr(dpm)_3$–aniline and $Dy(dpm)_3$–aniline complexes by the least squares calculations from the concentration data given in Table 2. The isosbestic points were also observed with the concentration dependent NH_2 absorption intensity data of $Eu(dpm)_3$–aniline in CCl_4.[16]

As expected from the results of the Scatchard plot, the K_1 values obtained by Eq. 1 was nearly constant when the concentrations of the substrate and the shift reagent were changed keeping the temperature constant. Two typical examples are given in Table 2.

Both the Scatchard plot and the constancy of the K_1 values from Eq. 2 show that only the formation of the 1:1 complex (RS) occurs considerably under the experimental conditions in a 2 cm cell. Since the complex formation of a fractional amount of aniline

to the lanthanoid ion is not rationalized from the chemistry involved, the formation of 1:1 complex is supposed to occur actually in the aniline–$Ln(dpm)_3$–CCl_4 ternary system. In this case, the formation constants calculated from Eq. 2 should be better than those from the Scatchard plot (Eq. 6). Therefore, the equilibrum constants (K_1's) were estimated by Eq. 2 at various temperatures ranging from 18 to 47 °C. Results with $Pr(dpm)_3$–aniline complex in carbon tetrachloride solution is given in Table 3(a). The change in the K_1 values at varying temperatures is far larger than the variation among those observed at the same temperature (Table 2(a), standard deviation=6.7), which proves the meaningfulness of the temperature dependence measurement. The log K *vs.* $1/T$ plot (Fig. 2) shows a very good linear relation from which the enthalpy and entropy of the complex formation was estimated to be 58.6 kJ mol^{-1} and 152 J mol^{-1}K^{-1}, respectively. Quite similarly ,the enthalpies and the entropies of formation for a series of $Ln(dpm)_3$–aniline complexes were determined as given in Table 4 from the observed K_1's given in Table 3. In addition to the ΔH and ΔS values, the $\nu_s(NH_2)$ frequency shifts caused by the complex formation ($\Delta\nu_s$),[17] as well as ionic radii of trivalent lanthanoid cations (r)[18] are given in Table 4.

The second equilibrium constants, *i.e.* the formation constants of RS_2 from RS and S, were determined at 53 °C (Table 5). Since the formation of RS_2 proceeds consecutively following the formation of RS, considerably high concentration of the substrate becomes necessary in order to maintain the concentration of RS high enough to produce RS_2 measurably. Thus the measurement was carried out by using a thin cell (optical path length: 0.2 mm) so as to adjust the observed intensity of ν_{NH_2} band measurably. Under the conditions for the K_2 determination, more than 90% of $Ln(dpm)_3$ exists as the complexed species. As the K_2 value could not be determined as a function of temperature, the enthalpy and the entropy of formation of RS_2 from RS were not known. Under the conditions for the measurement with a 2 cm cell at 53 °C, only less than 1% of the shift reagent was estimated to form 1:2 adduct from the K_1 and K_2 values of $Pr(dpm)_3$–aniline system. The extent of the formation of 1:2 adduct becomes less as the atomic number of central lanthanoid ion increases, showing the assumption for K_1 determination is valid.

Tris(6,6,7,7,8,8,8-heptafluoro-2,2-dimethyl-3,5-octanedionato)lanthanoid–Aniline Adducts. The $Ln(fod)_3$ complexes are so hygroscopic that they absorb the moisture even during the infrared spectral measurement in carbon tetrachloride solutions. Free $Ln(fod)_3$'s are especially sensitive to the moisture, sometimes disturbing remarkably the measurement in use of their solu-

tions as references. Thus the measurement on Ln(fod)$_3$-aniline were repeated several times at a temperature, and only statistically meaningful data were used in the subsequent calculation of the enthalpies and the entropies of the adduct formation. Another difficulty arises from the fact that Ln(fod)$_3$ forms a considerable amount of the 1:2 adduct, in addition to the 1:1 adduct, at a low concentration. The K_1 and K_2 values can be estimated, in principle, from the concentration dependence data by use of Eq. 7. However, the $\{[S]^3+(2R_t-S_t)[S]^2\}/(S_t-[S])$ *vs.* $(S_t-[S]-R_t)/(S_t-[S])$ plot deviate remarkably from the regression line calculated statistically, giving only a fair linear relationship.[19] Rough estimation by Eq. 7 of the formation constants gave $K_1=124$ and $K_2=242$ for La(fod)$_3$-aniline (at 30.4 °C), $K_1=124$ and $K_2=56$ for Pr(fod)$_3$-aniline (at 27.5 °C), and $K_1=279$ and $K_2=45$ for Gd(fod)$_3$-aniline (at 30.2 °C).[20] As the formation of the 1:2 adduct is remarkable with the Ln(fod)$_3$ containing lower series of lanthanoid elements, the formation constant calculated by assuming that the 1:1 adduct is solely formed is somewhat less reliable with the complex of lower lanthanoid than with those of higher lanthanoid and also than that of corresponding Ln(dpm)$_3$. The K_1 values for some Ln(fod)$_3$-aniline adducts were given in Table 6. Except the case of the Pr(fod)$_3$ adduct, the effect of the second coordination was estimated to be rather unimportant (containing less than 5% of RS_2) under the conditions for measurement.

β-Diketonato Complexes of Some Transition Metal Ions. In order to compare the coordinational behavior of lanthanoid β-diketonato complexes with those of transition metal ions, some bis(β-diketonato) complexes of cobalt, nickel, and copper were prepared. The measurements similar to those on the lanthanoid shift reagents were carried out again on these complexes, the results being given in Table 7.

Discussion

As a whole, the formation constants of the 1:1 adducts (RS) and their enthalpies of formation (shown in Table 4) gradually decrease as the atomic number of the central lanthanoid ion increases. Evidently the entropic term also decreases accompanying the decrease in the enthalpy according to the general principle of

"enthalpy-entropy compensation." There are some exceptions, however, in the decreasing sequence of the K_1 values. The K_1's for Gd(dpm)$_3$ and Tb(dpm)$_3$ are larger than expected even when the statistical error is taken into account. On the other hand, the enthalpies of formation decreases monotonously with the increase in atomic number, showing no indication of anomalous behavior. Thus the favorable formation of these two 1:1 adducts is due to the contribution of the entropic term, suggesting sterically favored arrangement of pivaloylmethanato ligands and the substrate in these adducts, though the details of their structure could not be clarified.

The atomic numbers of the central lanthanoid ions affect more pronouncely the formation constants of the 1:2 adducts than the case of the 1:1 adducts. For example, the K_2 of Yb(dpm)$_3$–aniline is *ca.* 30 times smaller than that of the similar adduct of Pr, while the difference among K_1's is less than 5 times at the largest. Since the Ln(dpm)$_3$ has a lanthanoid ion surrounded by bulky organic ligands as shown by means of X-ray crystal analyses,[21)] the coordination of the seventh and the eighth ligands, aniline in this case, might be hindered sterically. Important role of the steric effect relative to electronic and other effects has also been pointed out by one of the present authors by determining the coordinating abilities (relative equilibrium constants) towards Eu(dpm)$_3$ of various pyridinoid aza-aromatic compounds.[22)] The ionic radii of trivalent lanthanoid ions decrease with the increasing order of atomic number.[18)] The steric hindrance should become more serious with the lanthanoid complexes of higher atomic numbers because of the contraction of ionic radii. The arrangement of the ligands revealed by the X-ray studies[21)] has only C_2 symmetry, suggesting the remarkable bending of metal-ligand bonds. Therefore the steric effect in the first coordination process might be reduced by the bending of metal-ligand bonds towards the direction for minimizing the strain in the adduct molecule. For this reason, the crowdedness due to the contraction of ionic radii restricts more predominantly the approach of the second aniline molecule than that of the first one, which is in consequence with the fact that the K_2 values are more sensitive to the effect of atomic number. The coordination of the second aniline molecule is restricted more severely in Ln(dpm)$_3$ adducts than in Ln(fod)$_3$ adducts. This fact supports the above interpretation concerning the effect of atomic number.

The formation constants and the enthalpies of formation of bis(trifluoroacetylacetonato) complexes of Co, Ni, and Cu also decrease in the increasing order of atomic number. The decrease can be ascribed to the repulsive interaction between the d-electrons of the transition metal ion and the unshared electrons of aniline, since the ionic radii of these ions do not vary regularly with the change in atomic number (0.79 Å for Co^{2+}, 0.84 Å for Ni^{2+}, and 0.76 Å for Cu^{2+}).[23,24)] The similar effect can occur also in the series of the lanthanoid β-diketonato complexes due to the increasing f-electrons. However, the f-electrons occupy the inner electron shell and might interact considerably lesser extent with the unshared electrons of aniline. At present, we cannot conclude either of the effects plays more important role on the decrease of the formation constants and ΔH in the increasing order of atomic number of lanthanoids.

When compared the Eu(dpm)$_3$ adduct of aniline with that of *t*-butyl alcohol, the formation constant of the *t*-butyl alcohol adduct is somewhat larger than that of aniline adduct in spite of its lower enthalpy of formation even in the 1:1 adduct formation process. Since the alcoholic oxygen atom has two pairs of unshared electrons capable of forming the coordinate bond with the lanthanoid ion, the formation of the alcohol–Ln(dpm)$_3$ adduct should be statistically more favored than the formation of the aniline adduct.

The free shift reagents are supposed to exist as dimeric species under certain conditions.[25)] This possi-

$$2R \rightleftharpoons R_2 \qquad (9)$$

bility could not be excluded completely in our systems though which consisted of much lower concentrations of the shift reagents than the conditions for NMR measurements. However, the infrared spectra in CCl_4 of the shift reagents (in the C=O stretching region) were not dependent on the concentrations, giving no evidence for the equilibrium between monomeric and dimeric species (Eq. 9).

17) The complex formation shifts of the NH_2 stretching bands are evaluated by the frequency shifts of the symmetric stretching mode of vibration, since the asymmetric stretching absorption of the complexed species often overlap with the symmetric stretching absorption of the free species, which prevents the accurate determination of the absorption frequencies without the time-consuming band shape analyses in order to resolve them. The symmetric stretching absorptions of the complexes species did not overlap with any other bands when the measurements were carried out at low concentrations (*ca.* 2×10^{-3}—8×10^{-3} mol l^{-1} both with aniline and with $Ln(dpm)_3$).

(Received February 6, 1981)

A mixture of trimethylsilyl bromide, cobalt(II) bromide, tetrabutylammonium bromide, and a molecular sieve (4A) is effective for the stereoselective, one-stage α-glucosylation of alcohol with 2,3,4,6-tetra-*O*-benzyl-α-D-glucopyranose in dichloromethane. Using this procedure, several disaccharide derivatives as well as *O*-α-D-glucopyranosyl-(1→3)-*O*-[α-D-glucopyranosyl-(1→6)]-D-glucopyranose are synthesized.

A variety of procedure for stereoselective α-glucosylation have recently been reported.[1] However, they all use moisture-sensitive compounds such as glycosyl halides.[1a,b] We are now developing a glycosylation procedure in which the anomeric center of 2,3,4,6-tetra-*O*-benzyl-α-D-gluopyranose (αGOH, **1**) is activated in the presence of an alcohol.[2] The treatment of the mixture of **1** and an alcohol (ROH) in CH_2Cl_2 containing methanesulfonic acid ($MeSO_3H$) and $CoBr_2$ has been found to give an anomeric mixture of the corresponding gucosides.[2c] In this reaction, HBr, generated *in situ* by the reaction of $MeSO_3H$ and $CoBr_2$, cooperates with $CoBr_2$ to convert **1** into the glucosyl bromide (**2**) in the presence of an alcohol, and **2** reacts with alcohol to afford the glucosides (Eq. 1, Q=H).[2c]

$$\alpha\text{GOH} + \text{ROH} \xrightarrow{\text{QBr/CoBr}_2} \alpha\text{GOR} + \beta\text{GOR} \qquad (1)$$

A glucosylation reaction (Eq. 1, $Q=Me_3Si$) was then provisionally set up by replacing the HBr acid with trimethylsilyl bromide (Me_3SiBr).[3a] This paper will report a handy stereoselective α-glucosylation procedure[4] developed by modifying this reaction and its use in the synthesis of several disaccharide derivatives and the first synthesis of *O*-α-D-glucopyranosyl-(1→3)-*O*-[α-D-glucopyranosyl-(1→6)]-D-glucopyranose (**23**), the trisaccharide constituting the branching poing of the dextrans from *Leuconostic mesenteroides*.[5]

Results and Discussion

α-Glucosylation of Simple Alcohols. Table 1 contains the results regarding the glucosylation of cyclohexylmethanol (Runs 1—9) (Eq. 1, $Q=Me_3Si$, R= cyclohexylmethyl). Compared to the previously used method, which uses $MeSO_3H$ and $CoBr_2$,[2c] the efficiency was greatly improved (Runs 2 and 3). The use of the molecular sieve, 4A (MS-4A), was essential (Runs 1 and 3), because it scavenges HBr, which causes an undesirable debenzylation reaction.[2c] The use of the mixture of Me_3SiCl[3b] and $CoBr_2$ also gave good results, but the efficiency was less satisfactory (Run 4).

It was found that the reaction of **1** with Me_3SiBr and $CoBr_2$ efficiently produced the glucosyl bromide **2**.[3c] However, trace amounts of the silylated compounds of **1** and alcohol were isolated from the product mixture of the glucosylation reaction. Hence, the silylation of the starting materials is considered to occur concurrently during the glucosylation reaction. Nevertheless, the experiments using 5α-cholestan-3β-ol as the alcohol confirmed that: (1) the trimethylsilyl compound (**3**) smoothly reacted with the mixture of Me_3SiBr and $CoBr_2$ to generate **2**,[3d] which then underwent the glucosylation of the alcohol in the presence of $CoBr_2$,[2c] and (2) the trimethylsilyl derivative of the alcohol readily reacted with **2** in the presence of $CoBr_2$ to furnish the corresponding glucosides. Therefore, the silylation reactions, if any, seem not to interfere with the glucosylation reaction (Eq. 1, $Q=Me_3Si$).

Because the glucosylation reaction proceeds *via* **2**, tetrabutylammonium bromide (*n*-Bu_4NBr) was then added to the reaction mixture, for the salt was expected to cause bromide ion-catalyzed stereoselective α-glucosylation (Eq. 2).[1b] Table 1 shows that the addition of *n*-Bu_4NBr gave rise to the predominant formation of the α-glucosides, though the reaction was slowed[2c] (Runs 3, 5—7). Slightly excess amounts (30%) of **1** and the reagent mixture in relation to the alcohol achieved a quantative glucosylation (Run 9). Other simple alcohols, such as cyclohexanol and 6-(2,4-dinitroanilino)-1-hexanol, furnished the corresponding α-glucosides in good yields (Runs 10 and 11). Thus, the replacement of HBr with Me_3SiBr and MS-4A makes it possible to carry out a longer glucosylation reaction (Runs 7—12) than before.[2c]

$$\alpha\text{GOH} + \text{ROH} \xrightarrow{\text{Me}_3\text{SiBr/CoBr}_2\text{/}n\text{-Bu}_4\text{NBr}} \alpha\text{GOR}\ (+\beta\text{GOR}) \qquad (2)$$

The Oligosaccharide Synthesis Using the Quarternary Mixture. The α-glucosylation procedure was then used for a systematized oligosaccharide synthesis using the benzyl as the persistent protecting group.[6] Table 1 shows that the reagent mixture was effective for the stereoselective α-glucosylation of the primary hydroxyl group of partially benzylated monosaccharides, such as **9**, **10**, and **11** (Runs 13—15). The reagent mixture performed the α-glucosylation of the secondary hydroxyl group of the xylopyranoside derivatives (**5** and **6**) with acceptable yields (Runs 16 and 17).

The reagent mixture was then applied to the step-by-step synthesis of the branched-chain trisaccharide (**23**) to establish the scope of the applicability of the present procedure, as is summarized in Fig. 1, the symbolism for monosaccharide derivatives exemplified in Table 5 is used. The first glucosylation step for

a) The spectra were recorded by means of a JEOL-PS-100 spectrometer equipped with a JEOL-EC-100 computer and using a 8 mmϕ tube at 37 °C (noise decoupled; pulse width, 13 μs (45°), repetition, 2 s frequency range, 5000 Hz; 8 K data points).

the monosaccharide derivative (**11**) was carried out well (Table 1). After the deacetylation, however, the second glucosylation step for the disaccharide derivative (**17a**) (Run 19) was carried out only with difficulty to furnish the fully benzylated trisaccharide (**22a**). The chemical shift of the anomeric carbons of **22a** (Table 2) closely resembles that of the α(1→3), α(1→6)-trisaccharide derivatives.[7] The hydrogenolysis of **22a** gave **23**. The chemical shift of the anomeric and aglyconic carbons of **23** and its per-*O*-acetate (**24**) corresponds well with those of nigerose (**18**)[8] and isomaltose (**20**)[8] and their acetates (**19** and **21**). It should be noted, however, that the low yield of the glucosylation of the disaccharide derivative (**17a**) with **1** shows the limitations of the present method in a multistep glucosylation.

Experimental

General. The instruments used were identical with those described previously.[2,6] Such compounds as **1**, $CoBr_2$, *n*-Bu_4NBr, and solid glycosyl acceptors were stored *in vacuo* over P_2O_5. Me_3SiBr (PCR) was used without any pretreatments. MS-4A (Linde, 60—80 mesh) was dried at 450 °C in an electric furnace. Column chromatography was performed on silica gel (Kanto Kagaku, 100 mesh), using the gradient eluent system of benzene and 2-butanone (100:1→10:1), unless otherwise stated, each fraction was examined by TLC on silica gel (Merck, 7731).

The fully benzylated oligosaccharides (**14a**, **16a**, and **22a**) was hydrogenated twice over an equal amount of Pd on C (Kawaken, 10%) in AcOH (6 ml) containing H_2O (0.03 ml) at 410 kPa overnight. The oligosaccharides (**18**, **20**, and **23**) were acetylated with Ac_2O and AcONa at 100 °C.

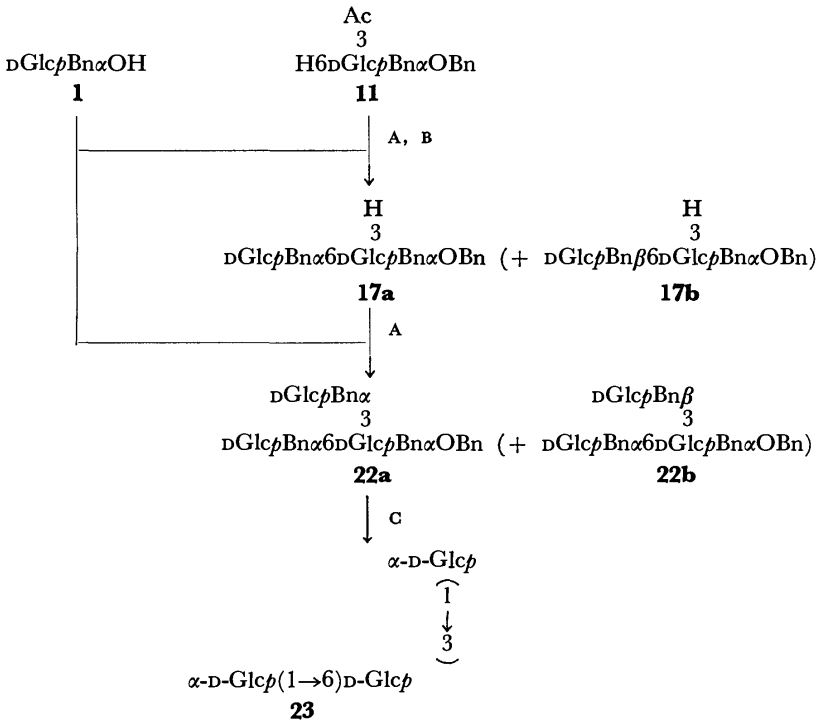
derivatives are listed in Tables 2 and 3, while the physical and analytical data of new compounds are listed in Table 4.

Procedure for the Glucosylation Using the Benzylated Glucose (1). Me_3SiBr (22 μl, 0.17 mmol) was stirred into a mixture of **1** (90 mg, 0.17 mmol), the respective alcohol (0.13 mmol), $CoBr_2$ (37 mg, 0.17 mmol), *n*-Bu_4NBr (54 mg, 0.17 mmol), and MS-4A (180 mg) in CH_2Cl_2 (0.45 ml), and the resulting mixture was agitated at room temperature (22—28 °C). The filtrate of the reaction mixture was then evaporated and chromatographed. The glucosides thus obtained, the yields of which are listed in Table 1, were identified with those prepared before,[2,6)] except for ten compounds, **12a**, **12b**, **13a**, **13b**, **14a**, **14b**, **16a**, **16b**, **22a**, and **22b**.

*Benzyl 2,4,6-Tri-*O*-benzyl-α-D-glucopyranoside (7).* Benzyl α-D-glucopyranoside[6b,c)] (1.0 g, 3.7 mmol) was heated in $PhCH_2Cl$ (Tokyo Kasei, 10 ml) and powdered KOH (Wako, 0.95 g, 17 mmol) at 90—95 °C for 2 h under vigorous stirring. The filtrate of the reaction mixture was then evaporated and chromatographed. Benzyl 2,3,4,6-tetra-*O*-benzyl-α-D-glucopyranoside appeared first, and then the main fraction of **7** was obtained as a syrup (1.3 g). This was purified through acetylation with Ac_2O and pyridine, follow-



A : $Me_3SiBr/CoBr_2/n\text{-}Bu_4NBr/MS\text{-}4A/CH_2Cl_2$,
B : NaOMe/MeOH/1,4-dioxane, C : $H_2/Pd/C/AcOH$.

Fig. 1. Synthetic scheme of the glucotriose, **23**.

ed by chromatography of furnish the acetate (**8**) (1.1 g, 55%), mp 93—95 °C, $[\alpha]_D^{20}$ +81° (*c* 1.0, $CHCl_3$) (lit,[9] mp 76—78 °C, $[\alpha]_D^{20}$ +53.0 (*c* 1, $CHCl_3$)] (Found: C, 74.10, H, 6.63%).

The treatment of **8** with a dil. solution of NaOMe in MeOH gave **7** quantitatively; $[\alpha]_D^{20}$ +88° (*c* 2.3, $CHCl_3$). Found: C, 75.47, H, 6.58%. Calcd for $C_{34}H_{36}O_6$: C, 75.53; H, 6.71%.

Reaction of ***1*** *with* Me_3SiBr *and* $CoBr_2$. Me_3SiBr (11 μl, 0.083 mmol) was stirred into a mixture of **1** (45 mg, 0.083 mmol) and $CoBr_2$ (18.3 mg, 0.083 mmol) in CH_2Cl_2 (0.3 ml). After stirring for 0.5 h at room temperature, the mixture was filtered quickly. The ^1H NMR of the filtrate was essentially identical with that of 2,3,4,6-tetra-*O*-benzyl-α-D-glucopyranosyl bromide (**2**)[10] in CH_2Cl_2 (δ=6.59, J= 4 Hz).[2c]

*Reaction of 2,3,4,6-Tetra-*O*-benzyl-α-*D*-glucopyranosyloxytrimethylsilane (**3**) with* Me_3SiBr *and* $CoBr_2$. Compound **3**[11] (62.7 mg, 0.010 mmol) was treated with Me_3SiBr (13 μl, 0.010 mmol) and $CoBr_2$ (22.4 mg, 0.010 mmol) in CH_2Cl_2 for 15 min at room temperature. The filtrate showed a ^1H NMR spectrum almost identical with that of **2** in CH_2Cl_2.

Reaction of the Bromide **2** *with (5α-Cholestan-3β-yloxy)trimethylsilane in the Presence of* $CoBr_2$. A mixture of **2**[10] (42 mg, 0.07 mmol), and trimethylsilyl compound[12] (32 mg, 0.07 mmol), and $CoBr_2$ (15 mg, 0.07 mmol) in CH_2Cl_2 (0.4 ml) was stirred for 2 h at room temperature. The filtrate of the reaction mixture was then chromatographed[2b] to give **4a** (19 mg, 30%) and **4b** (11 mg, 17%).

Without $CoBr_2$, the glucosylation did not proceed.

Reaction of the Trimethylsilyl Glucose **3** *with 5α-Cholestan-3β-ol,* $CoBr_2$, Me_3SiBr, *and MS-4A.* A mixture of **2a** (55 mg, 0.090 mmol), the alcohol (26.3 mg, 0.068 mmol), $CoBr_2$ (21 mg, 0.095 mmol), MS-4A (72 mg), and Me_3SiBr (12 μl, 0.090 mmol) in CH_2Cl_2 (0.24 ml) was agitated for 6 h at room temperature. The subsequent chromatography of the mixture gave **4a** (15 mg, 24%) and **4b** (24 mg, 38%).

*Benzyl O-(2,3,4,6-Tetra-*O*-benzyl-α- and -β-*D*-glucopyranosyl)-(1→6)-2,4,6-tri-*O*-benzyl-α-*D*-glucopyranosides (**17a** and **17b**).* A mixture of **1** (570 mg, 1.06 mmol), **11** (400 mg, 0.81 mmol), $CoBr_2$ (232 mg, 1.06 mmol), n-Bu_4NBr (340 mg, 1.06 mmol), MS-4A (855 mg), and Me_3SiBr (138 μl, 1.06 mmol) in CH_2Cl_2 (2.45 ml) was stirred for 20 h at room temperature. The filtrate of the reaction mixture was then briefly chromatographed to give a sirupy mixture of the products (602 mg). This was de-*O*-acetylated and then chromatographed in the manner described before[6b] to give **17a** (475 mg, 60%) and **17b** (85 mg, 11%). They were identified with the respective samples synthesized previously.[6b]

*O-α-*D*-Glucopyranosyl-(1→3)-O-[α-*D*-glucopyranosyl-(1→6)]-*D*-glucopyranose (**29**).* Me_3SiBr (78 μl, 0.60 mmol) was stirred into a mixture of **1** (322 mg, 0.60 mmol), the disaccharide **17a** (445 mg, 0.46 mmol), $CoBr_2$ (1313 mg, 0.60 mmol), n-Bu_4NBr (191 mg, 0.60 mmol), and MS-4A (485 mg) in CH_2Cl_2 (1.6 ml), after which the stirring was continued for 40 h at room temperature. The filtrate of the reaction mixture was then evaporated and chromatographed to give a syrupy product mixture (266 mg) with three spots [R_f 0.58 (**22b**), 0.55 (**22a**), and 0.50 (the benzylate of α,α-trehalose[2a]), benzene–2-butanone (20:1)]. This was carefully separated through three chromatographies to give **22a** and **22b** (Table 1).

The hydrogenation of **22a** (90 mg) gave **23** (26 mg) as a foam, $[\alpha]_D^{20}$ +126° (*c* 0.4, H_2O) [lit,[5] $[\alpha]_D^{14}$ +133° (*c* 0.7, H_2O)]. Found: C, 40.37; 6.23%. Calcd for $C_{18}H_{32}O_{16}\cdot 1.5H_2O$: C, 40.67; H, 6.64%.

The reduction of **23** (10 mg, 0.010 mmol) with $NaBH_4$ (Wako, 30 mg) in H_2O (3 ml) for 48 h at room temperature, followed by the usual work-up and acetylation, furnished crystalline *O*-(2,3,4,6-tetra-*O*-acetyl-α-D-glucopyranosyl-(1→3)-*O*-[(2,3,4,6-tetra-*O*-acetyl-α-D-glucopyranosyl-(1→6)]-1,2,4,5-tetra-*O*-acetyl-D-glucitol (**25**) (8.4 mg, 42%).

Deoxygenation of Tertiary Amine Oxides with Carbon Disulfide

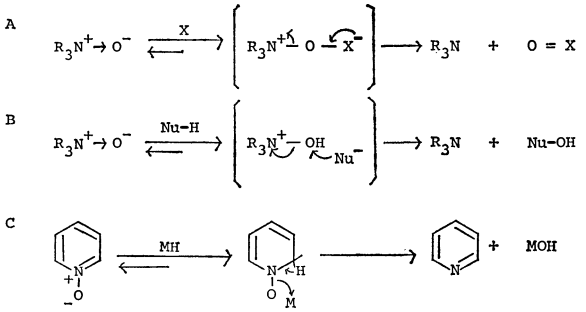
Toshiaki Yoshimura, Kaoru Asada, and Shigeru Oae*

Department of Chemistry, The University of Tsukuba, Niihari-gun, Sakura-mura, Ibaraki 305

(Received March 20, 1982)

Reduction of various tertiary amine oxides with carbon disulfide was examined and kinetic experiments were carried out. Trialkylamine oxides and *N,N*-dialkylarylamine *N*-oxides were readily reduced by CS_2 to give the corresponding tertiary amines in good yields, while heteroaromatic amine *N*-oxides such as picoline *N*-oxide were not affected. The oxygen atom in the *N*-oxide was found to be transferred to CO_2 upon mass spectral analysis of the gas evolved. The kinetic experiments were carried out following the UV spectra of *N,N*-dimethylaniline *N*-oxide in CH_3CN containing much excess of CS_2 and the rate was found to be of 2nd order in the *N*-oxide and CS_2. Activation parameters ($\Delta H^{\ddagger}=55.7$ kJ mol^{-1}, $\Delta S^{\ddagger}=-78.2$ J K^{-1} mol^{-1} at 20 °C) are characteristic of a normal bimolecular reaction. The logarithms of the rate constants for para-substituted *N,N*-dimethylaniline *N*-oxides are nicely correlated with Hammett σ values and a small negative ρ value ($\rho=-0.2$) was obtained. The rate of reaction was faster in polar aprotic solvents than in nonpolar or protic solvents. These observations seem to suggest that the reaction proceeds via an initial nucleophilic attack of the *N*-oxide oxygen at carbon disulfide followed by the rate-determining N–O bond fission to give the tertiary amine.

Tertiary amine oxides can be reduced back to the corresponding amines by various reducing agents such as trivalent phosphorus compounds, sulfur compounds, carbenes, hexachlorodisilane and metal hydride. These deoxygenation can roughly be classified into the following three types mechanistically.



The mechanism A involves initial electrophilic attack of reagent such as trivalent phosphorus compound,[1] carbens,[2] sulfur dioxide[3] followed by back donation of an electron pair from the central atom of the reducing agent to cleave the N–O bond. Meanwhile, the mechanism B involves the initial coordination of electrophile on *N*-oxide oxygen followed by nucleophilic substitution at oxygen atom like in the reduction with thiols.[4] In the reduction of heteroaromatic *N*-oxides with metal hydride, the reaction proceeds *via* an initial addition of metal hydride to α-carbon and oxygen, followed by elimination of metal hydroxide (mechanism C).[5,6]

Tertiary amine oxides are mild nucleophilic oxidants which can oxidize both disulfides and sulfoxides,[7] whereas carbon disulfide is another dicoordinated sulfur compound which could function as a reducing agent.

Indeed, carbon disulfide is known to react with dialkylsulfilimine, which has also a semipolar S–N linkage, eventually affording dialkyl sulfide, the reduction product, and elemental sulfur.[8]

Meanwhile, Hamana *et al.*[9] reported that some tertiary amine oxides reacted with carbon disulfide affording the amines in very poor yields, however, they did not look into the mechanism.

Thus as a part of our systematic studies on the oxidation of organosulfur compounds, it is interesting to investigate the general scope of the reaction and the mechanism of this reduction, since the reaction is presumed to be classified into a modified A type. The reaction was found to be quite general for most aliphatic, aromatic tertiary amine oxides but not heteroaromatic *N*-oxides. This paper describes the scope of the reaction and the kinetic investigation of the reduction of *N,N*-dimethylaniline *N*-oxide (**1**) and substituted derivatives with carbon disulfide and the plausible mechanism based on both kinetic and product analyses.

Results and Discussion

Reaction of Amine Oxides and Carbon Disulfide. The addition of excess carbon disulfide to a stirred solution of a certain amine oxide in chloroform at 0 °C in the presence of anhydrous sodium sulfate[10] afforded the corresponding amine in a good yield. The yield was determined by gas chromatography after confirming by TLC that no amine *N*-oxide remained. As shown in Table 1, picoline *N*-oxide was not reduced at all upon the same treatment with CS_2. All these products were isolated by column chromatography and identified by IR and NMR. A small amount of elemental sulfur (25%) was also obtained when methanol was added to the reaction mixture. The reaction of (**1**) with an equimolar amount of CS_2 under the same conditions for two days also afforded the corresponding amine quantitatively.

When the reaction was carried out under reduced pressure, and gas evolved was analyzed by MS, CO_2 and a trace amount of COS were found. The following mechanism, Scheme, may be conceivable. The reaction is presumed to proceed through the initial nucleophilic attack of the *N*-oxide oxygen to carbon disulfide and subsequent N–O bond cleavage to form the amine and oxathiiranethione (**2**) or dithiiranone (**3**). The intermediate (**2**) is considered to decompose readily to elemental sulfur and COS which would then be hydrolyzed to CO_2 and H_2S. However, in a control experiment, hydrolysis of carbonyl sulfide was found to be very slow in the presence of *N,N*-dimethylaniline and water in acetonitrile. Meanwhile, only trace amounts of carbonyl sulfide and hydrogen sulfide were

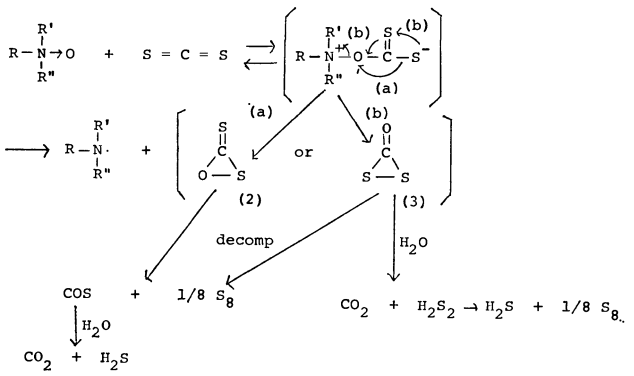
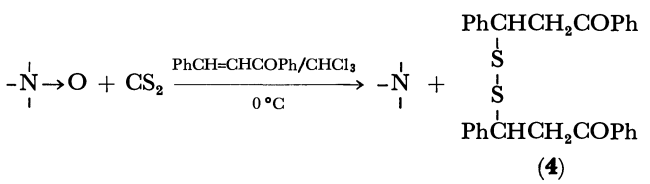
	91		77



Scheme

formed in our system. This would suggest that formation of the intermediate (**2**) is quite unlikely. Meanwhile, the intermediate (**3**) might readily be hydrolyzed to CO_2 and H_2S_2 which is then decomposed to elemental sulfur and H_2S. Thus, a trapping experiment of H_2S_2 was carried out. The reduction of trimethylamine *N*-oxide with carbon disulfide in the presence of benzylidenacetophenone in chloroform at 0 °C afforded the Michael-type adduct of hydrogen disulfide (**4**) in 6% yield together with the usual reduction products. The disulfide (**4**) was identified by com-



(**4**)

paring its mp, IR, NMR, and elemental analyses with those of the authentic sample.[11] In the reaction of **1** under similar conditions the disulfide was not obtained, however, in the presence of triethylamine as a base the same adduct was obtained in 6% yield. This observation alone may not be enough to suggest the reduction to involve the intermediate (**3**), since there are a few other possibilities for the formation of the adduct.

Table 2. Pseudo-first order rate constants of reduction of *N*,*N*-dimethylaniline *N*-oxide in various concentration of carbon disulfide

$[CS_2]$/M	$10^3\ k/s^{-1}$

0.0415	2.67

Hamana *et al.*[9] reported the formation of carbonyl sulfide and elemental sulfur in the reduction of nitrone with carbon disulfide based on their observation of the IR spectra. Meanwhile, the intermediate (**2**) was postulated by Neal *et al.*[12] in the formation of carbonyl sulfide during the oxygenation of carbon disulfide with cytochrome P-450. We have examined the gas evolved from the reaction of *N*-benzylideneaniline *N*-oxide with carbon disulfide. Carbonyl sulfide was found to be formed upon mass spectral analysis in agreement with the result of Hamana *et al.* Therefore, the mechanism for the reduction of *N*-oxide with carbon disulfide should be different from that of the nitrone. In order to clarify the mechanism of the reduction of *N*-oxides, kinetic experiments have been carried out.

Kinetics. Kinetics of the reaction of *N*,*N*-dimethylaniline *N*-oxide (**1**) with a large excess of carbon disulfide was carried out in acetonitrile at 20 °C by following the UV 250 nm absorption of *N*,*N*-dimethylaniline formed in the reaction. The rate of reaction was found to fit with the pseudo first order rate equation. However, it was rather difficult to obtain accurate rate constants in dry acetonitrile since a trace of water affects the rate of reaction. Therefore, acetonitrile containing 2% water was used as the choice solvent. Pseudo-first order rate constants shown in Table 2 were linearly correlated with the concentration of carbon disulfide. From these results, the rate was found to be of first order each with the *N*-oxide and CS_2 suggesting the mechanism to involve the transition state containing one molecule each of *N*-oxide

Table 3. Second order rate constants of the reduction of *p*-substituted *N,N*-dimethylaniline *N*-oxides with carbon disulfide

CH_2Cl_2	0.121
$ClCH_2CH_2Cl$	0.0506
$CHCl_3$	1.687×10^{-3}

and carbon disulfide.

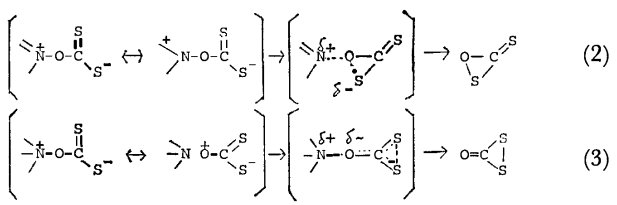
Activation parameters were obtained from Arrhenius plot of the second order rate constants at a temperature range of 15—30 °C as shown in Table 3. Activation parameters ($\Delta H^* = 55.6$ kJ^{-1} mol^{-1}, $\Delta S^* = -78.2$ J K^{-1} mol^{-1} at 20 °C for mol l^{-1} unit) reveal the characteristic feature of the normal bimolecular reaction.

The effect of substituent on the rate of the reactions of para-substituted *N,N*-dimethylaniline *N*-oxides and carbon disulfide was examined. The logarithms of these rate constants were nicely correlated with Hammett σ values and a small negative ρ value ($\rho = -0.2$) was obtained. The electron-releasing substituent accelerates the reaction, indicating the importance of the initial nucleophilic attack of the *N*-oxide oxygen to carbon disulfide. However, the ρ-value ($\rho = -0.2$) seems to be too small for the rate-determining initial attack. Perhaps the effect of polar substituent on the initial equilibrium formation of adduct is partially cancelled by the positive ρ-value on the subsequent rate-determining N–O bond cleavage.

The kinetic experiments in various anhydrous solvents using *N,N*-dimethyl-*p*-nitroaniline *N*-oxide were performed by following UV absorption at 390 nm. The results are shown in Table 4. When the reaction was carried out in methanol, the rate of reaction was too low to be measured. The reaction in dry CH_3CN is about six times faster than that in wet CH_3CN (2% H_2O). These results apparently show that hydrogen-bonding of the solvent such as methanol or chloroform to the *N*-oxide oxygen retards the reaction and the solvents, which have strong affinity for water, such as DMF and acetonitrile, accelerate the reaction. The water which hydrates the *N*-oxide is presumably removed partially from the *N*-oxide in DMF or acetonitrile.

Inspection of these experimental results has led us to postulate the mechanism involving the initial equilibrium attack of the *N*-oxide to carbon disulfide, followed by rate-determining N–O bond cleavage to form the corresponding amine and unstable dithiiranone (**3**) which is readily hydrolyzed to give CO_2 and H_2S_2. However, a question still remains, why the reaction of the nitrone with carbon disulfide did afford carbonyl sulfide instead of carbon dioxide.

The reaction of the nitrone is much slower than that of the *N*-oxide. When one compares the structures of the probable intermediates for both reactions, the leaving ability of a Schiff base from the adduct of nitrone is considered to be much poorer than that of the amine in the *N*-oxide, since the delocalization of positive charge on the nitrogen atom of the nitrone adduct would reduce the leaving ability of the Schiff base as compared to that of amine in the *N*-oxide which bears a full positive charge on the nitrogen atom. Therefore, the N–O bond cleavage in the adduct of the nitrone would require an anchimeric assistance of the neighboring thiocarbonate anion. Thus the direct nucleophilic attack of the neighboring thiolate group preferably occurs on the oxygen atom to form (**2**) rather than (**3**) in the reaction of nitrone with carbon disulfide. Whereas, the N–O bond in the adduct of tertiary amine oxide may be sufficiently polarized to allow the S–S bond formation, giving (**3**). Consequently the reduction of the tertiary amine oxide with carbon disulfide would proceed through a modified mechanism A while the reduction of the nitrone with CS_2 presumably proceeds through a modified mechanism B which involves internal nucleophilic attack as described in the introduction section.



Experimental

Materials. Most of tertiary amine oxides used were prepared by oxidation of tertiary amines and *p*-substituted *N,N*-dimethylanilines[13] with hydrogen peroxide.[14] *N,N*-Dimethyl-*p*-nitroaniline *N*-oxide was prepared by oxidation with *m*-CPBA in $CHCl_3$ at room temperature for 1 week and purified by means of silica-gel column chromatography.

Gas Analysis. Carbon disulfide (1 ml) and acetonitrile (2 ml) were condensed in a 20 ml test tube reactor containing, (**1**) (100 mg) at −195 °C (liq. N_2) in a vaccum line. When the temperature was raised slowly to 0 °C, the reaction started evolving gas which was purified three times and subjected to mass spectroscopic analysis. A peak of CO_2 (m/e=44) was observed mainly and COS peak (m/e=60) was only 1% of that of CO_2.

Reaction of N-*Benzylideneaniline* N-*Oxide with Carbon Disulfide.* Carbon disulfide (1 ml) and acetonitrile (2 ml) were condensed in a 20 ml test tube reactor, connected to a vaccum line, containing *N*-benzylideneaniline *N*-oxide (100 mg) at −195 °C (liq. N_2). Then the temperature was raised to room temperature. The solution was kept standing at room temperature for 24 h. Gas evolved was purified three times and its mass spectrum was taken. m/e=44 (40%), 60 (60%).

Hydrolysis of Carbonyl Sulfide. Carbonyl sulfide (10 ml, 1 atom), prepared from NH_4SCN and H_2SO_4 and purified, was condensed in a 20 ml test tube reactor containing *N,N*-dimethylaniline (100 mg), H_2O (10 ml) in 2 ml of CH_3CN. The reaction was carried out at room temperature for 3 h. Analysis of the gas showed no CO_2 formation.

The Reaction of N-*Oxides and Carbon Disulfide.* To a stirred solution of an amine oxide (1.0—1.5 mmol) in 3 ml of $CHCl_3$ was added dropwise 3 ml of CS_2 over Na_2SO_4 at 0 °C. After 2 h, the solution was filtered and the filtrate was diluted with 3 ml of CH_3OH. Elemental sulfur was deposited. (Sulfur was confirmed by thin layer chromatography, melting point and liquid chromatography. Amines were identified by thin layer chromatography and gas chromatography). Isolation of amines was carried out with silica gel column chromatography.

Trapping Experiments of H_2S_2. *1)*: To a stirred solution of trimethylamine oxide (0.01 mole) and benzylidenacetophenone (0.01 mole) in 15 ml of $CHCl_3$ was added dropwise over Na_2SO_4 at 0 °C 15 ml of CS_2. White crystals were precipitated in 6% yield. The crystals were identified as bis(1,3-diphenyl-3-oxopropyl) disulfide by comparing its mp, IR, NMR, and elemental analyses with those of the authentic sample.[11]

2): To a stirred solution of (**1**) (1.5 g), chalcone (2.0 g) and triethylamine (2 ml) in 15 ml of $CHCl_3$ was added dropwise over *ca.* 1 g of anhydrous Na_2SO_4 at 0 °C in 15 ml of CS_2. After 2 h reaction, the solution was concentrated. The products were separated by silica-gel column chromatography. The disulfide (**4**) was obtained in 6% yield.

Kinetic Experiments. A solution of carbon disulfide (0.166 M) in CH_3CN–H_2O (2%) (2.5 ml) in a UV cell was incubated at a desired temperature for 30 min. To this was added 12 μl solution of (**1**) (8.23×10^{-5} M) in CH_3CN. UV absorption 250 nm (390 nm for *p*-nitro derivative) of *N,N*-dimethylaniline formed was then followed immediately. Pseudo first order rate constants were calculated from the following equation.

$$\ln\frac{A_\infty - A_0}{A_\infty - A_t} = kt \quad A\text{: UV absorption intensity}$$

Solvent Effect. The reaction of *N,N*-dimethyl-*p*-nitroaniline *N*-oxides with CS_2 in DMF, CH_2Cl_2, $ClCH_2CH_2Cl$, $CHCl_3$, and dry CH_3CN were followed with UV at 390 nm. All these solvents used were dried and freshly distilled.

Catalytic Efficiency of Functionalized Vesicles in the Transamination of Pyridoxal-5′-phosphate with a Hydrophobic Amino Acid†

Yukito MURAKAMI,* Akio NAKANO, and Kazunari AKIYOSHI

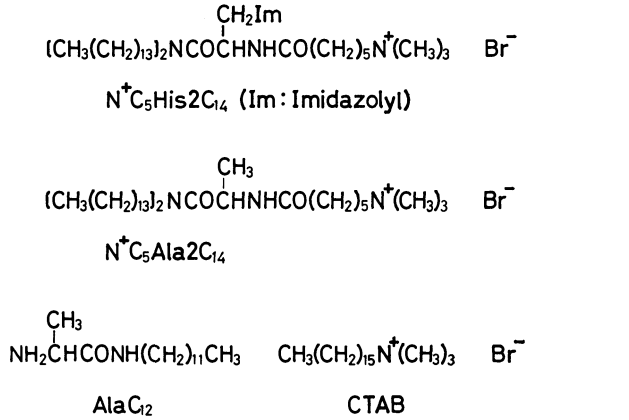
Department of Organic Synthesis, Faculty of Engineering, Kyushu University, Hakozaki, Higashi-ku, Fukuoka 812

(Received April 13, 1982)

The transamination reaction of pyridoxal-5′-phosphate (PLP) with *N*-dodecyl-L-alaninamide ($AlaC_{12}$) was investigated in an aqueous phosphate–borate buffer at pH 7.0, μ 0.10 (KCl), and 30.0±0.1 °C in the presence of single-walled vesicles of *N,N*-ditetradecyl-N^{α}-(6-trimethylammoniohexanoyl)-L-histidinamide bromide ($N^+C_5His2C_{14}$). The electrostatic and hydrophobic interactions between the vesicles and the reactants resulted in incorporation of PLP and $AlaC_{12}$ into polar and hydrophobic domains of the vesicles, respectively, in the Schiff-base formation process. The isomerization of the aldimine Schiff-base to the corresponding ketimine Schiff-base was confirmed to be the rate-determining step in the transamination process. The reaction site in the vesicular system was found to be equivalent in polarity to dioxane–water (7:3 v/v). However, the overall reaction rate in the vesicles was enhanced 230-fold relative to that in dioxane–water (7:3 v/v). A hydrophobic and suitably polar microenvironment constructed at the reaction site is responsible for such a marked rate-enhancement. In addition, each vesicle of $N^+C_5His2C_{14}$ provided functional (imidazolyl) groups in its hydrogen-belt domain to catalyze the intramolecular prototropic shift to yield the ketimine Schiff-base. The microenvironmental effects of molecular assemblies of *N,N*-ditetradecyl-N^{α}-(6-trimethylammoniohexanoyl)-L-alaninamide bromide and CTAB on the overall transamination were also discussed.

Although the apoproteins in vitamin B_6-dependent enzymes play essential roles not only in rate enhancement but also in substrate-recognition and reaction specificity which leads to selective cleavage of the covalent bonds around the α-carbon atom of a substrate,[1] the mechanistic details as regards such functions have not been fully understood up to the present time. These functions may be characterized tentatively as follows: (1) each apoprotein provides a hydrophobic environment in its interior region in which pyridoxal-5′-phosphate is buried; (2) it catalyzes a specific reaction by its various functional groups such as the imidazolyl group of histidine and the ε-amino group of lysine; (3) it constructs a hydrophobic cavity, shape and size of which are specific to its substrate, so that the substrate-selectivity is exercised; (4) such a hydrophobic cavity fixes its specific substrate in space to carry out the desired reaction. On these grounds, micellar surfactants,[2,3] synthetic polymers,[4] and macrocyclic compounds[5,6] have been developed to simulate the functions of vitamin B_6-dependent enzymes.

We have recently reported that amphiphiles involving an amino acid residue interposed between a polar head group and an aliphatic double-chain form stable single-compartment vesicles in aqueous media due to formation of the hydrogen-belt region in the intramembrane region.[7] These amphiphiles were confirmed to construct three characteristic domains in their vesicular aggregates; a polar surface domain composed of charged head groups, semipolar barrier domain composed of amino acid residues (so-called hydrogen belt), and a hydrophobic interior domain composed of aliphatic double-chains. Thus, these various domains may be utilized as reaction site models of the apoenzymes, specific to the nature of reactants. In the present study, the transamination reaction of pyridoxal-5′-phosphate (PLP) with *N*-dodecyl-L-alaninamide ($AlaC_{12}$), a hydrophobic amino acid analogue, in the presence of single-walled vesicles of $N^+C_5His2C_{14}$ and $N^+C_5Ala2C_{14}$ as well as in the presence of CTAB micelles. The microenvironmental effects provided by these cationic amphiphiles on the transamination reaction have been characterized.



Experimental

Spectroscopic data were taken on a JASCO DS-403G grating IR spectrophotometer, a Hitachi Perkin-Elmer R-20 NMR spectrometer, a Union Giken SM-401 high-sensitivity UV-visible spectrophotometer, and a Hitachi 650—60 fluorescence spectrophotometer. pH-Measurements were carried out with a Beckman expandomatic SS-2 pH meter equipped with a Metrohm EA-125 combined electrode after calibration with a combination of appropriate standard aqueous buffers. Melting points were measured with a Yanagimoto MP-S1 apparatus (hot-plate type).

Hexadecyltrimethylammonium bromide (CTAB) of Nakarai Chemicals was recrystallized from ethanol, mp 237—239 °C (decomp). Dodecylamine of Nakarai Chemicals was distilled under reduced pressure, bp 95—98 °C/266 Pa. Pyridoxamine-5′-phosphate (PMP: Calbiochem, U.S.A.; A-grade), pyridoxal hydrochloride (PL: Mann Research Laboratories, U.S.A.), and pyridoxal-5′-phosphate (PLP: Nakarai Chemicals; bio-analytical grade) were used without further purification. *N*-Dodecyl-L-alaninamide ($AlaC_{12}$) was prepar-

ed by condensation of *t*-butoxycarbonyl-L-alanine with dodecylamine in the presence of dicyclohexylcarbodiimide (DCC), followed by elimination of the *t*-butoxycarbonyl group with hydroformic acid. The product was recrystallized from diethyl ether to give a white solid, mp 51—52 °C. Found: C, 69.78; H, 12.38; N, 10.81%. Calcd for $C_{15}H_{32}N_2O$: C, 70.26; H, 12.58; N, 10.92%. *N,N*-Ditetradecyl-N^{α}-(6-trimethylammoniohexanoyl)-L-alaninamide bromide ($N^+C_5Ala2C_{14}$) was synthesized in a manner similar to that reported previously for the preparation of *N,N*-didodecyl-N^{α}-(6-trimethylammoniohexanoyl)-L-alaninamide bromide,[7d] and characterized as reported elsewhere.[7f]

The synthetic procedure for *N,N*-ditetradecyl-N^{α}-(6-trimethylammoniohexanoyl)-L-histidinamide bromide ($N^+C_5His2C_{14}$) is outlined in Scheme 1.

N,N-*Ditetradecyl*-N^{α}-t-*butoxycarbonyl*-N^{im}-*tosyl*-L-*histidinamide* (*1*). To a solution of the dicyclohexylamine adduct of N^{α}-*t*-butoxycarbonyl-N^{im}-tosyl-L-histidine (5.0 g, 8.5 mmol)[8] in dry dichloromethane (40 ml) was added *p*-toluenesulfonic acid (1.7 g, 8.8 mmol) in 5 min with stirring at room temperature. After *N,N*-ditetradecylamine (3.4 g, 8.8 mmol) and dicyclohexylcarbodiimide (1.85 g, 8.9 mmol) were added to the reaction mixture in this order at room temperature and 0 °C, respectively, the mixture was stirred for 3 h at 0 °C and for 12 h at room temperature. The resulting precipitates (*N,N'*-dicyclohexylurea) were removed by filtration, the solvent was evaporated *in vacuo*, and the residual oil was dissolved in ethyl acetate (150 ml). The solution was then washed with 10% aqueous citric acid, saturated aqueous sodium chloride, 4% aqueous sodium hydrogencarbonate, and saturated sodium chloride in this sequence. After being dried over Na_2SO_4, the mixture was evaporated *in vacuo* to afford an oil which was subsequently purified by centrifugal liquid chromatography with a combination of silica gel (Wako gel B-5) and chloroform; a pale yellow oil which was solidified in a refrigerator, yield 5.6 g (83%). IR (neat): 3200 (NH str.), 2840 and 2800 (CH str.), 1705 and 1625 (C=O str.) cm^{-1}. NMR ($CDCl_3$, TMS): δ 0.88 [6H, broad t, $C\underline{H}_3(CH_2)_{13}$–], 1.24 [48H, s, $CH_3(C\underline{H}_2)_{12}CH_2$–], 1.34 [9H, s, $(CH_3)_3COCO$–], 2.40 (3H, s, $-SO_2C_6H_4C\underline{H}_3$), 2.80 [2H, d, $-CH(C\underline{H}_2$Im-Tos)], 3.12 [4H, broad t, $CH_3(CH_2)_{12}C\underline{H}_2N$–], 4.75 (1H, broad q, –CH–), 5.20 (1H, d, NH), 6.98 (1H, s, Im-5H), 7.80 (1H, s, Im-2H), 7.23 (2H, d, tosyl's 3H and 5H), and 7.74 (2H, d, tosyl's 2H and 6H).

N,N-*Ditetradecyl*-N^{α}-*(6-bromohexanoyl)*-L-*histidinamide* (*2*). Trifluoroacetic acid (6 g, 53 mmol) was added to a dichloromethane solution (10 ml) of **1** (1.9 g, 2.4 mmol), and the mixture was stirred for 1.5 h at room temperature. Evaporation of an excess amount of trifluoroacetic acid *in vacuo* below 40 °C gave a pale brown oil (**1a**). Elimination of the *t*-butoxycarbonyl group was confirmed by NMR spectroscopy. The amine (**1a**) was dissolved in dry dichloromethane (5 ml) and the solution was cooled to 0 °C. Triethylamine (3.4 g, 34 mmol) was added dropwise to the solution, and then 6-bromohexanoyl chloride (1.0 g, 4.7 mmol) dissolved in dry dichloromethane (10 ml) was added dropwise to the mixture at 0 °C with stirring. The resulting mixture was stirred for 2.5 h at 0 °C and then washed with 4% aqueous citric acid, saturated aqueous sodium chloride, 4% aqueous sodium hydrogencarbonate, and saturated aqueous sodium chloride in this sequence. After being dried over Na_2SO_4, the solution was evaporated *in vacuo* to give a pale brown oil; yield 1.6 g (93%). A major fraction of the tosyl group was eliminated as confirmed by NMR spectroscopy. The product was used for the subsequent reaction without further purification. NMR ($CDCl_3$, TMS): δ 0.87 [6H, broad t, $C\underline{H}_3(CH_2)_{13}$–], 1.25 [48H, s, $CH_3(C\underline{H}_2)_{12}CH_2$–], ~2.00 [6H, m, $BrCH_2(C\underline{H}_2)_3CH_2CO$–], 2.35 [2H, broad t, $Br(CH_2)_4C\underline{H}_2CO$–], 2.80 (2H, d, $-CHC\underline{H}_2$Im–), 3.35 [2H, t, $BrC\underline{H}_2(CH_2)_4CO$–], 3.00—3.40 [4H, m, $CH_3(CH_2)_{12}C\underline{H}_2N$–], 5.05 (1H, broad q, –CH–), 6.45 (1H, d, NH), 7.15 (1H, s, Im-5H), and 7.94 (1H, s, Im-2H).

N,N-*Ditetradecyl*-N^{α}-*(6-trimethylammoniohexanoyl)*-L-*histidinamide Bromide* ($N^+C_5His2C_{14}$). Dry trimethylamine gas was introduced into a benzene solution (30 ml) of **2** (1.6 g, 2.2 mmol) for 1.5 h to reach the gas saturation level, and the solution was stirred at room temperature for 12 h. The solvent was evaporated off *in vacuo*, and the residual oil was dissolved in benzene–acetone (36 ml, 5:1 v/v). To the solution was added 30% aqueous triethylamine (2 ml) with stirring at room temperature to eliminate the tosyl group completely. After the resulting solution was stirred for 3.5 h, the solvent was evaporated off *in vacuo*. The crude product was purified by gel-filtration chromatography on columns of Sephadex LH-20 and Toyopearl HW-40 in this sequence with methanol as an eluant: a white glassy solid, yield 0.32 g (19%); mp 182 °C, $[\alpha]_D^{20}$ −14.2° (*c* 1.13, ethanol). IR (neat): 3280 (NH, OH str.) and 1630 (C=O str.) cm^{-1}. NMR ($CDCl_3$, TMS): δ 0.85 [6H, broad t, $C\underline{H}_3(CH_2)_{13}$–], 1.22 [48H, s, $CH_3(C\underline{H}_2)_{12}CH_2$–], ~1.90 [6H, m, $N^+CH_2(C\underline{H}_2)_3CH_2CO$–], 2.32 [2H, broad t, $N^+(CH_2)_4C\underline{H}_2CO$–], 2.80—3.62 [8H, m, $CH_3(CH_2)_{12}C\underline{H}_2N$–, $N^+C\underline{H}_2(CH_2)_4CO$–, and $-CHC\underline{H}_2$Im–], 3.35 [9H, s, $(CH_3)_3N^+$–], 5.05 (1H, broad q, NHC<u>H</u>CO–), 6.90 (1H, s, Im-5H), 7.62 (1H, d, NH), and 7.95 (1H, s, Im-2H). Found: C, 63.99; H, 10.58; N, 8.58%. Calcd for $C_{43}H_{84}N_5BrO_2\cdot(3/2)H_2O$: C, 63.75; H, 10.82; N, 8.65%.

Kinetic Measurements. An amount of pyridoxamine-5'-phosphate formed in the transamination reaction was determined by measuring a fluorescence intensity at the emission maximum of PMP excited at 328 nm. Each run was initiated by adding 50 μl of an aqueous solution of PLP (1.02×10^{-3} mol dm^{-3}) and 40 μl of an ethanol solution of *N*-dodecyl-L-alaninamide (1.99×10^{-2} mol dm^{-3}) to 2.00 ml of a reaction medium which was pre-equilibrated at 30.0±0.1 °C in a thermostated cell set in the fluorescence spectrophotometer. The reaction medium was prepared as follows; (1) an appropriate amount of the stock solution of an amphiphile in ethanol was placed in a glass vessel, ethanol was removed *in vacuo*, and 10 ml of the aqueous buffer (6.23 mmol dm^{-3} phosphate–1.88 mmol dm^{-3} borate, pH 7.0) containing 0.1

mol dm^{-3} potassium chloride was added to the residue; (2) the aqueous dispersion of an amphiphile thus prepared was sonicated for 4 min with a probe-type sonicator at 30-W power (W-220F, Heat Systems-Ultrasonics). The resulting vesicle solution was sufficiently clear without noticeable turbidity and gave good kinetic reproducibility. Kinetic measurements in aqueous dioxane were carried out under similar conditions. Light was emitted to an experimental solution only at the instant of each fluorescence intensity measurement.

Electron Microscopy. Both aqueous dispersion (A) and ultrasonicated aqueous solution (B) of $N^+C_5His2C_{14}$ were employed for the measurements. As sample A, 16 mg of $N^+C_5His2C_{14}$ was suspended in 2 ml of deionized and distilled water containing 2%(w/w) uranyl acetate and the dispersion was shaked occasionally and heated until the glassy solid disappeared completely to give slightly turbid dispersion. As sample B, an aqueous dispersion of $N^+C_5His2C_{14}$ (sample A) was sonicated for 4 min with a probe-type sonicator at 30-W power and allowed to stand for 10 min at 5 °C. A clear solution was then obtained. Samples A and B were applied on carbon grids and dried in a vacuum desiccator. A JEOL JEM-200B electron microscope, installed at the Research Laboratory of High Voltage Electron Microscope of our University, was used for the measurements. Electron micrographs for $N^+C_5His2C_{14}$ are shown in Fig. 1, while those for $N^+C_5Ala2C_{14}$ have been reported elsewhere.[7f] Both multiwalled vesicles and lamellae were observed in an electron micrograph of the aqueous dispersion as shown in Fig. 1. On the other hand, the sonicated aqueous solution showed exclusively the formation of single-walled vesicles. Similar patterns of electron micrographs have been observed for respective samples of $N^+C_5Ala2C_{14}$. The present amphiphiles were used in the state of single-walled vesicles for study.

Differential Scanning Calorimetry (DSC). Each 50-μl sample of an aqueous dispersion of the amphiphile [2.0% (w/w)] in an aqueous buffer of 6.23 mmol dm^{-3} phosphate–1.88 mmol dm^{-3} borate, containing 0.1 mol dm^{-3} potassium chloride, was sealed up in a silver sample cell. The measurements were made on a differential scanning calorimeter (Daini Seikosha SSC-560U): heating rate, 0.5 °C/min; sensitivity, 0.025 mcal/s/(full scale); chart speed, 0.5 cm/min. The obtained calorimetric parameters for the amphiphiles are as follows, where T_m represents a temperature at a peak maximum of DSC thermogram.

$N^+C_5Ala2C_{14}$: T_m, 2.0 °C; ΔH, 20.5 kJ mol^{-1}

$N^+C_5His2C_{14}$: T_m, 2.5 °C; ΔH, 19.2 kJ mol^{-1}

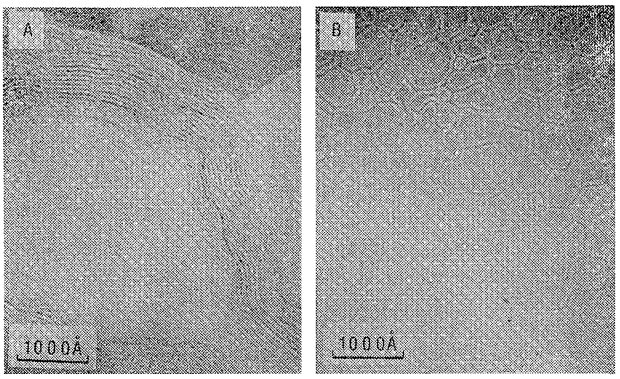

Fig. 1. Electron micrographs for $N^+C_5His2C_{14}$ negatively stained with uranyl acetate: A, 10 mmol dm^{-3} aqueous dispersion (magnification, ×92 000); B, 10 mmol dm^{-3} aqueous solution sonicated for 4 min at 30-W power and subsequently allowed to stand for 10 min at 5 °C (magnification, ×92 000).

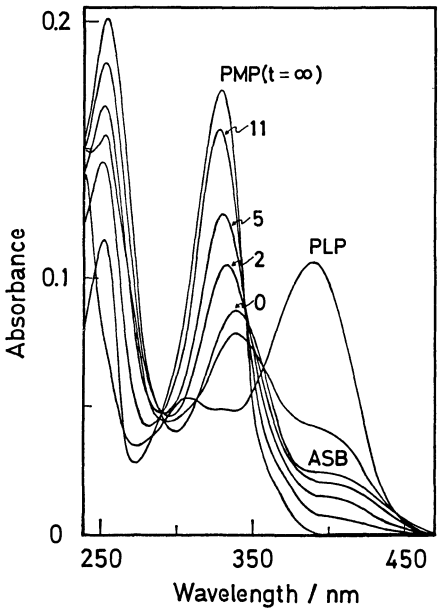

Fig. 2. Spectral change along the progress of reaction of PLP (2.44×10^{-5} mol dm^{-3}) with $AlaC_{12}$ (3.81×10^{-4} mol dm^{-3}) in the presence of $N^+C_5His2C_{14}$ (9.7×10^{-4} mol dm^{-3}) in aqueous phosphate (6.0 mmol dm^{-3}) –borate (1.8 mmol dm^{-3}), containing 1.9%(v/v) ethanol, at pH 7.0, μ 0.1 (KCl), and 30.0±0.1 °C. Numerals refer to reaction times (in h) for the second slow step.

Results and Discussion

The transamination reaction of pyridoxal-5′-phosphate (PLP) with $AlaC_{12}$ in the presence of an amphiphile was followed by electronic spectroscopy in an aqueous phosphate–borate buffer at pH 7.0, μ 0.10 (KCl), and 30.0±0.1 °C. Figure 2 shows the spectral change observed along the progress of transamination in the presence of $N^+C_5His2C_{14}$ vesicles. The spectral change shows that the reaction is consistent with a two-step mechanism. The first step, which reached an equilibrium stage within 4 min, was followed by a comparatively slow step. The isosbestic points associated with the respective steps are as follows: first, 312 and 357 nm; second, 292 and 345 nm. A half-life for the second slow step is several hours. Absorption spectra observed at the final stages of the respective steps showed that the first step is referred to the Schiff-base formation and the second one to the formation of pyridoxamine-5′-phosphate (PMP). The absorption spectrum observed at the final stage of the first step showed maxima at 338 and 415 nm, and is the typical one for a pyridoxylideneamino acid formed with PLP.[9] The absorption spectrum observed at the final stage of the second step, having maxima at 253 and 328 nm, is identical with that of PMP.[10] The absorption spectrum, which can be attributed to the corresponding ketimine Schiff-base (λ_{max} 310—330 nm),[9] was not detected in the course of the second step. A similar spectral behavior

Table 1. Equilibrium constants and spectral parameters for the Schiff-base formation between PLP and $AlaC_{12}$ in various media at 30.0±0.1 °C[a)]

Medium	Dioxane–Water (42:58 v/v)	Dioxane–Water (7:3 v/v)	CTAB	$N^+C_5Ala2C_{14}$	$N^+C_5His2C_{14}$

a) Cationic amphiphile systems: in aqueous phosphate (6.0 mmol dm^{-3})–borate (1.8 mmol dm^{-3}) containing 1.9% (v/v) ethanol at pH 7.0 and μ 0.1 (KCl); CTAB, 2.9×10^{-3} mol dm^{-3}; $N^+C_5Ala2C_{14}$, 9.7×10^{-4} mol dm^{-3}; $N^+C_5His2C_{14}$, 9.7×10^{-4} mol dm^{-3}. Dioxane–water (42:58 v/v): dioxane containing 58%(v/v) aqueous buffer (6.2 mmol dm^{-3} phosphate, 1.8 mmol dm^{-3} borate, and 0.1 mol dm^{-3} potassium chloride) and 1.9%(v/v) ethanol. Dioxane–water (7:3 v/v): dioxane containing 30%(v/v) aqueous buffer (6.2 mmol dm^{-3} phosphate, 1.8 mmol dm^{-3} borate, and 0.1 mol dm^{-3} potassium chloride) and 1.9%(v/v) ethanol. b) Wavelength and molar extinction coefficient of PLP employed for calculation of [ASB] in order to achieve accuracy of spectral analysis, while $\lambda_{max}=370$ nm and $\varepsilon^{PLP}(370\text{ nm})=4.1\times10^3$. c) Cationic amphiphile systems: PLP, 4.93×10^{-5} mol dm^{-3}; $AlaC_{12}$, 4.90×10^{-5} mol dm^{-3}. Dioxane–water (7:3 v/v): PLP, 4.90×10^{-5} mol dm^{-3}; $AlaC_{12}$, 9.80×10^{-5} mol dm^{-3}. Dioxane–water (42:58 v/v): PLP, 4.85×10^{-5} mol dm^{-3}; $AlaC_{12}$, 3.88×10^{-4} mol dm^{-3}.

along the progress of reaction was observed in other amphiphile systems. In the light of these observations, the overall reaction pathway is explicitly given by Eq. 1.

$$\text{PLP} + \text{AlaC}_{12} \underset{\text{fast}}{\overset{K_{SB}}{\rightleftharpoons}} \text{ASB} \underset{\text{slow}}{\overset{k_{AK}}{\rightleftharpoons}} \text{KSB} \xrightarrow[\text{very fast}]{} \text{PMP} + \text{PyC}_{12} \quad (1)$$

Here, ASB, KSB, and PyC_{12} refer to the aldimine Schiff-base, the ketimine Schiff-base, and *N*-dodecylpyruvinamide, respectively. Thus, the rate determining step for the present transamination reaction is the isomerization of the aldimine Schiff-base (ASB) to the corresponding ketimine Schiff-base (KSB). This finding is consistent with the results obtained in PLP-dependent transamination reactions both in an enzyme system[11)] and model systems.[12)] The present two reaction steps were treated separately since the respective rates were much different from each other.

Schiff-base Formation. In order to clarify microenvironmental effects on the aldimine Schiff-base formation, the equilibrium constants (K_{SB}) for the first step were determined in the presence and absence of the cationic amphiphiles. The equilibrium constant, as defined by Eq. 2, for the Schiff-base formation between PLP and $AlaC_{12}$ was evaluated as follows.

$$K_{SB} = \frac{[\text{ASB}]}{[\text{PLP}][\text{AlaC}_{12}]} \quad (2)$$

This is rearranged to give Eq. 3.

$$K_{SB} = \frac{[\text{ASB}]}{(T_P-[\text{ASB}])(T_A-[\text{ASB}])} \quad (3)$$

Here, T_P and T_A refer to total concentrations of PLP and $AlaC_{12}$, respectively. An absorbance (A_λ) at the absorption maximum of PLP (λ, 389 and 380 nm in molecular assemblies of the cationic amphiphiles and aqueous dioxane, respectively) is represented by Eq. 4.

$$A_\lambda = \varepsilon_\lambda^{PLP}(T_P-[\text{ASB}]) + \varepsilon_\lambda^{ASB}[\text{ASB}] \quad (4)$$

Here, $\varepsilon_\lambda^{PLP}$ and $\varepsilon_\lambda^{ASB}$ are molar extinction coefficients of PLP and ASB observed at the absorption maximum

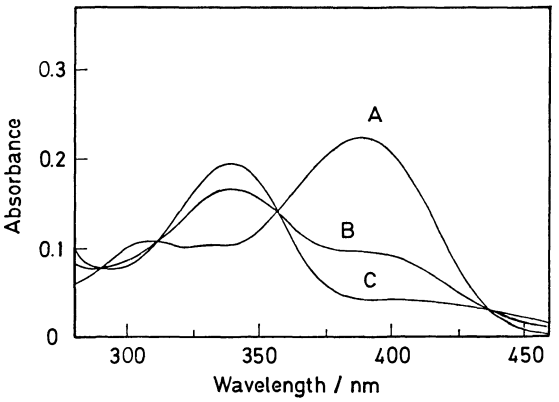

Fig. 3. Absorption spectra for the aldimine Schiff-base system of PLP (4.93×10^{-5} mol dm^{-3}) with varying amounts of $AlaC_{12}$ (A, 0; B, 4.90×10^{-5}; C, 3.86×10^{-4} mol dm^{-3}) in the presence of $N^+C_5His2C_{14}$ (9.7×10^{-4} mol dm^{-3}) in aqueous phosphate (6.0 mmol dm^{-3})–borate (1.8 mmol dm^{-3}), containing 1.9% (v/v) ethanol, at pH 7.0, μ 0.1 (KCl), and 30.0± 0.1 °C.

of PLP, respectively. Then, Eq. 4 is rearranged to Eq. 5. The value of $\varepsilon_\lambda^{ASB}$ was evaluated directly

$$[\text{ASB}] = \frac{\varepsilon_\lambda^{PLP}T_P - A_\lambda}{\varepsilon_\lambda^{PLP} - \varepsilon_\lambda^{ASB}} \quad (5)$$

from the spectrum observed in the presence of a large excess of $AlaC_{12}$; a complete conversion of PLP into the Schiff-base is assured under such conditions. Figure 3 shows the absorption spectra of the PLP–$AlaC_{12}$ system involving varying amounts of $AlaC_{12}$ in the presence of $N^+C_5His2C_{14}$. For a complete conversion of PLP into the aldimine Schiff-base, only a small excess of $AlaC_{12}$ (*ca.* 11 fold) over PLP was needed in the vesicular and micellar systems. On the other hand, over a 90-fold excess of $AlaC_{12}$ was required in aqueous dioxane to complete the conversion. The formation constants thus determined and the relevant spectral parameters in molecular assemblies of the cationic amphiphiles and in aqueous dioxane are listed in Table 1.

Table 2. Equilibrium constants and spectral parameters for two aldimine Schiff-bases (SB_1 and SB_2) in various media at 30.0±0.1 °C[a]

	Dioxane–Water[b]					CTAB	$N^+C_5Ala2C_{14}$	$N^+C_5His2C_{14}$

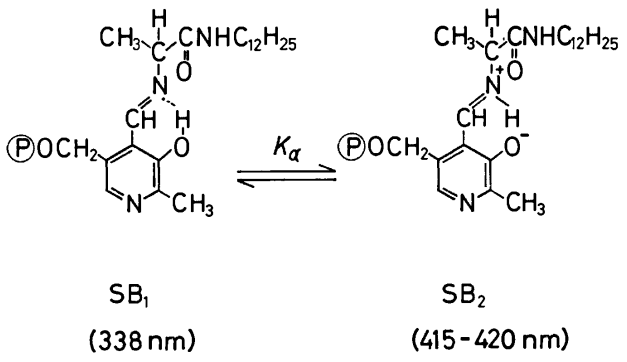
Dioxane–water mixtures: each medium was prepared by mixing dioxane with aqueous buffer (6.2 mmol dm^{-3} phosphate, 1.8 mmol dm^{-3} borate, and 0.1 mol dm^{-3} potassium chloride); PLP, $(4.72—4.83)\times10^{-5}$ mol dm^{-3}; $AlaC_{12}$, $(2.42—4.72)\times10^{-3}$ mol dm^{-3}. b) Numerals refer to the content of aqueous buffer in %(v/v). c) ε_{SB_1}, 4.6×10^3. d) ε_{SB_2}, 9.4×10^3.



Ⓟ: A phosphate group.

Scheme 2.

The microenvironments constructed with the amphiphiles, into which the Schiff-base was incorporated, were characterized in terms of an equilibrium constant (K_α) defined by Eq. 6 on the following basis. An absorption spectrum of the aldimine Schiff-base showed the presence of two species in an equilibrium state (Fig. 3). They differ from each other in the protonation site as shown in Scheme 2. The neutral form (SB_1) with an ordinary amino acid was primarily observed in hydrophobic environments constructed with such components as organic solvents,[9] aqueous micelles,[13] reversed micelles,[3] and alkylamines bearing a long hydrocarbon chain.[14,15] The charged form (SB_2), on the other hand, was found exclusively in aqueous media.[16] These two species of the aldimine Schiff-base are in an equilibrium which is highly dependent on the microenvironmental polarity. The equilibrium constant between SB_1 and SB_2 is, therefore, referred to an efficient polarity parameter for characterization of the microenvironment to which the Schiff-base is bound.

$$K_\alpha = \frac{[SB_1]}{[SB_2]} = \frac{A_{SB_1}/\varepsilon_{SB_1}}{A_{SB_2}/\varepsilon_{SB_2}} \quad (6)$$

Here, A_{SB_1} and A_{SB_2} refer to absorbances observed at the absorption maxima of SB_1 and SB_2 species, respectively; ε_{SB_1} and ε_{SB_2} stand for molar extinction coefficients of SB_1 and SB_2 species at their absorption maxima, respectively. These values were determined according to the reported method employed for evaluation of those values for the Schiff-base of PLP with hexylamine.[15] Equation 7 can be derived on the basis of Scheme 2, where [ASB] refers to a total concentration of SB_1 and SB_2, and is equal to a PLP concentration employed under the conditions that PLP is completely converted into the Schiff-base ([PLP]≪[$AlaC_{12}$]).

$$A_{SB_1}/[ASB] = \varepsilon_{SB_1} - (\varepsilon_{SB_1}/\varepsilon_{SB_2})(A_{SB_2}/[ASB]) \quad (7)$$

The plot of $A_{SB_1}/[ASB]$ *vs.* $A_{SB_2}/[ASB]$ for the Schiff-base of PLP with $AlaC_{12}$ in aqueous dioxane resulted in a good linear relationship ($r>0.993$) as shown in Fig. 4. The data obtained in molecular assemblies of the cationic amphiphiles are also plotted in Fig. 4 and found along the correlation line for the dioxane–water system. The K_α-values thus obtained are summarized in Table 2, together with the relevant spectral parameters. Since the solvent-polarity parameter (Kosower's *Z*-value)[17] can be correlated with the standard Gibbs free energy ($\Delta G^0 = -RT\ln K_\alpha$),[15] we estimated the microenvironmental polarity of the reaction site for the Schiff-base formation in the light of a linear relation shown in Fig. 5. The result indi-

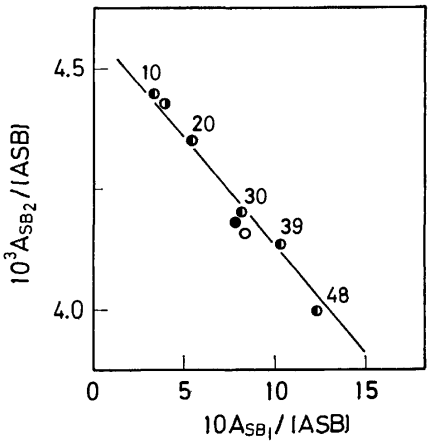


Fig. 4. Plot of $A_{SB_1}/[ASB]$ *vs.* $A_{SB_2}/[ASB]$ for equilibrium of aldimine Schiff-base species of PLP and $AlaC_{12}$ (SB_1 and SB_2) in dioxane–water mixtures (◐) and cationic amphiphile systems: $N^+C_5His2C_{14}$ (○), $N^+C_5Ala2C_{14}$ (●), and CTAB (◑). Numerals refer to the water contents in aqueous dioxane. See Table 2 for experimental conditions.

cates that the reaction sites in the vesicular and micellar systems are equivalent in polarity to dioxane–water (7:3 v/v) and dioxane–water (8:2 v/v), respectively. The reaction sites in the vesicular systems are more polar than that in the micellar system, most likely due to the presence of the hydrogen belt domain in the former. The hydrogen belt region divides the vesicular system into hydrophobic and polar domains,[7c] and PLP of hydrophilic nature is entrapped in the polar domain. The hydrophobic and less polar microenvironment provided by CTAB micelles is in favor of the Schiff-base formation relative to the polar reaction sites by the vesicular systems. The interaction modes of the reactants (PLP and $AlaC_{12}$) with the cationic aggregates were further examined on the basis of the following experimental facts. (1) The absorption maximum of PLP observed in the presence of the cationic aggregates (micelles and vesicles) was identical with that without those if $AlaC_{12}$ was absent. (2) The Schiff-base was not detected spectrophotometrically with a small excess of $AlaC_{12}$ over pyridoxal (PL), which has no phosphate group, in the cationic aggregates. (3) Formation of the Schiff-base of PLP with $AlaC_{12}$ was suppressed at higher ionic strength [μ=1.0 (KCl)]. (4) A large excess of an amino acid (L-alanine) was required to detect formation of the Schiff-base with PLP even in the presence of the cationic aggregates. (5) Without any cationic amphiphile, the content of dioxane in reaction media must exceed 40%(v/v) to investigate the Schiff-base formation between PLP and $AlaC_{12}$ because of the insolubility of $AlaC_{12}$ in water.

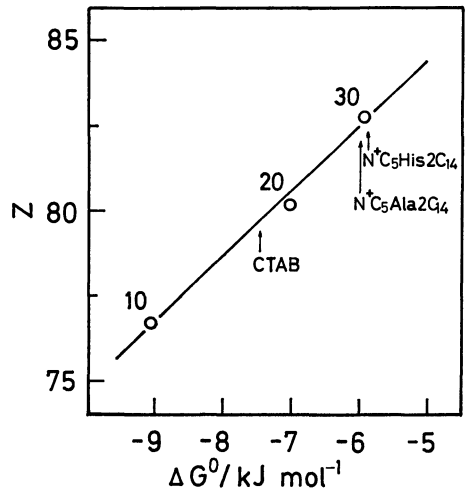

Fig. 5. Correlation of ΔG^0 with solvent polarity parameter (Z). Numerals refer to the water contents in aqueous dioxane. ΔG^0-Values for cationic amphiphile systems are shown by arrows.

These results indicate that PLP is concentrated at the surface area of the cationic aggregates due to the electrostatic interaction between the anionic phosphate group of PLP and the cationic head group of the amphiphile employed, while $AlaC_{12}$ is incorporated into the hydrophobic domain of the aggregates through mutual hydrophobic interaction. Consequently, both electrostatic and hydrophobic interactions play important roles in the Schiff-base formation in the presence of the amphiphile aggregates. The Schiff-base formation step in the present vesicular system is schematically shown in Fig. 6.

Transamination Reaction. The overall transamination reaction of PLP was followed by means of fluorescence spectroscopy at 30.0±0.1 °C in the presence and absence of cationic amphiphiles. The reaction was examined under the conditions of [$AlaC_{12}$]≫[PLP]; PLP was converted completely into the aldimine Schiff-base within 4 min. The reaction, for which the isomerization of the aldimine Schiff-base to the corresponding ketimine Schiff-base becomes rate-determining as mentioned above, was followed after complete formation of the aldimine Schiff-base. The fluorescence intensity at specified wavelengths (cationic aggregates, 393 nm; dioxane–water 405 nm) increased gradually along the progress of the reaction (Fig. 7). When a pseudo-substrate (1-dodecylamine) was used in place of $AlaC_{12}$, the fluorescence intensity remained unchanged. Table 3 summarizes the excitation wavelengths of PLP and PMP and the corresponding relative emission intensities in the presence and absence of the cationic amphiphiles. The fluorescence quantum yield of the Schiff-base was negligibly low compared with that of PMP.[14] The PMP concentration in the reaction system was determined on the basis

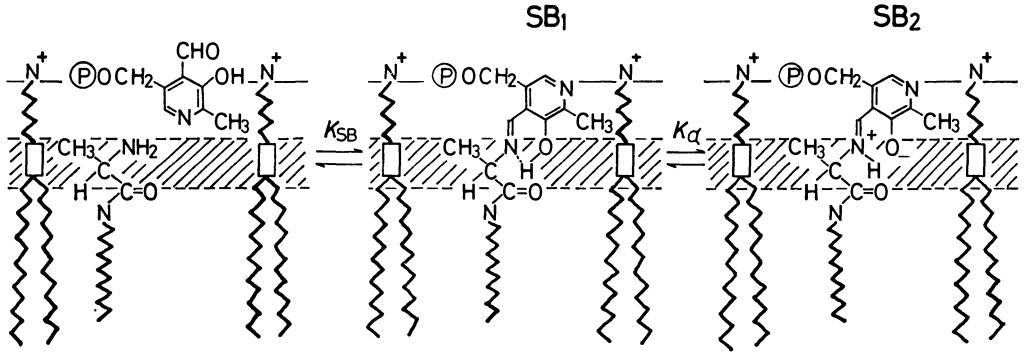

Fig. 6. Schematic representation of the Schiff-base formation step in vesicular phase: a rectangle, an amino acid residue; Ⓟ, a phosphate group. A shaded portion refers to the hydrogen belt region, which has some hydrophobic and polar nature, and to the reaction site for the overall transamination process.

Table 3. Fluorescence maxima (λ_F), relative emission intensities (I_{rel}), and excitation wavelengths (λ_E) for PLP and PMP in various media at 30.0±0.1 °C[a]

Medium	PLP			PMP		
	λ_F/nm	λ_E/nm	I_{rel}[b]	λ_F/nm	λ_E/nm	I_{rel}[b]
Aqueous buffer[c]	500	395	1.0	394	328	1250
Aqueous dioxane[d]	532	390	4.3	405	333	343

$N^+C_5Ala2C_{14}$[e]	504	389	2.0	393	328	687
$N^+C_5His2C_{14}$[e]	480	389	2.0	393	328	673

a) Fluorescence maxima in the absence of $AlaC_{12}$; concentrations of PLP and PMP, 2.44×10^{-5} mol dm^{-3}. b) Relative emission intensity with reference to the intensity for PLP in aqueous buffer. c) Aqueous phosphate (6.2 mmol dm^{-3})-borate (1.8 mmol dm^{-3}), containing 0.1 mol dm^{-3} potassium chloride (pH 7.0). d) Dioxane containing 30%(v/v) aqueous buffer (6.2 mmol dm^{-3} phosphate, 1.8 mmol dm^{-3} borate, and 0.1 mol dm^{-3} potassium chloride). e) In aqueous phosphate (6.1 mmol dm^{-3})-borate (1.8 mmol dm^{-3}) at pH 7.0 and μ 0.1 (KCl); CTAB, 2.9×10^{-3} mol dm^{-3}; $N^+C_5Ala2C_{14}$, 9.8×10^{-4} mol dm^{-3}; $N^+C_5His2C_{14}$, 9.8×10^{-4} mol dm^{-3}.

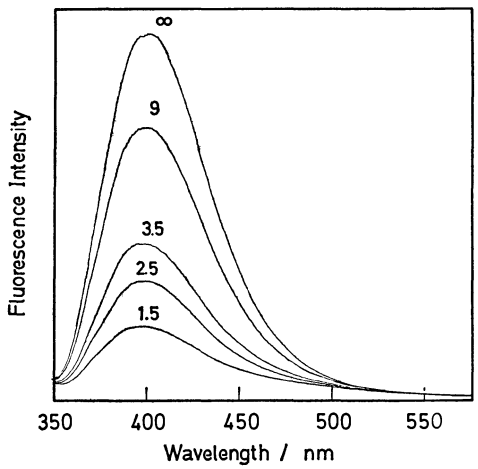

Fig. 7. Fluorescence-spectral change along the progress of reaction of PLP (2.44×10^{-5} mol dm^{-3}) with $AlaC_{12}$ (3.81×10^{-4} mol dm^{-3}) in the presence of $N^+C_5His2C_{14}$ (9.7×10^{-4} mol dm^{-3}) in aqueous phosphate (6.0 mmol dm^{-3})-borate (1.8 mmol dm^{-3}), containing 1.9%(v/v) ethanol, at pH 7.0, μ 0.1 (KCl), and 30.0±0.1 °C. Numerals refer to reaction times (in h) for the second slow step.

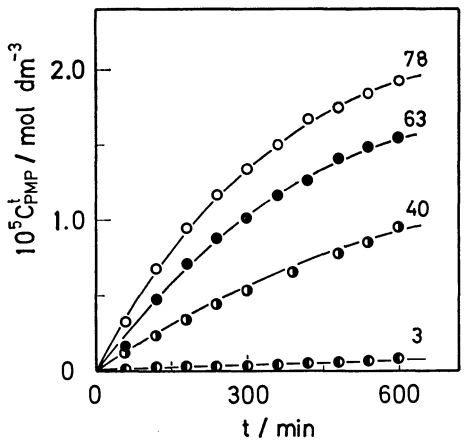

Fig. 8. Time-courses of PMP formation for transamination of PLP with $AlaC_{12}$ in aqueous dioxane (◐) and cationic amphiphile systems: $N^+C_5His2C_{14}$ (○), $N^+C_5Ala2C_{14}$ (●), and CTAB (◑). Numerals represent rates of conversion of PLP into PMP at t=600 min. See Table 4 for experimental conditions.

of Eq. 8 by measuring a fluorescence intensity (I_t) at appropriate time intervals.[18]

$$\frac{I_t}{I_0}=\frac{C^t_{PMP}}{C^0_{PMP}}\times10^{-0.5[(C^t_{PMP}-C^0_{PMP})\varepsilon_{PMP}+\varepsilon_{SB}C^t_{SB}]}. \quad (8)$$

Here, I_0 is a fluorescence intensity of PMP at its known concentration (C^0_{PMP}) in the absence of other reacting species; ε_{PMP} and ε_{SB} are molar extinction coefficients of PMP and the aldimine Schiff-base at a specified excitation wavelength, respectively; C^t_{PMP} and C^t_{SB} refer to concentrations of PMP and the aldimine Schiff-base observed at time t (s) after complete formation of the Schiff-base. C^t_{SB} is related with C^0_{SB} and C^t_{PMP} by Eq. 9, where C^0_{SB} refers to an initial concentration of the aldimine Schiff-base in the isomerization process and is equal to the PLP concentration used here (C^0_{PLP}).

$$C^t_{SB}=C^0_{SB}-C^t_{PMP} \quad (9)$$

The correlations between C^t_{PMP} and time are shown in Fig. 8. The rate equation for PMP formation is given by Eq. 10 in reference to Eq. 1, which is subsequently integrated to give Eq. 11.

$$\frac{dC_{PMP}}{dt}=-k_{AK}C^t_{SB}=-k_{AK}(C^0_{PLP}-C^t_{PMP}) \quad (10)$$

$$\ln\frac{C^0_{PLP}}{(C^0_{PLP}-C^t_{PMP})}=k_{AK}\cdot t \quad (11)$$

In each case, a good linear relationship between the left hand term of Eq. 11 and reaction time t was obtained as shown in Fig. 9 (r>0.998). The reaction was followed for 10 h and the first-order kinetics were found to hold in each kinetic run. The conversion rates of PLP to PMP at the ends of such kinetic runs (after 10 h) were determined as shown in Fig. 8. Under the conditions employed in this work, the reversed reaction from PMP to the aldimine Schiff-base was not detected. The rate constants for the isomerization process are summarized in Table 4, along with the overall second-order rate constants ($K_{SB}\cdot k_{AK}$) and relative effectiveness (k_{rel}) of the reac-

tion media.

The rate-determining step in the transamination reaction investigated here is referred to the isomerization of the aldimine Schiff-base to the ketimine one, since the accumulation of the latter was not detected spectrophotometrically in the course of the reaction. This means that the deprotonation from the α-carbon of the amino acid moiety is essential for the transamination, and such apparent intramolecular proton-transfer to afford the ketimine Schiff-base becomes rate-determining. The reaction was much accelerated in the cationic aggregate systems as compared with that in dioxane–water mixtures. This suggests that the concentration of hydroxide ion becomes efficient on the surface area of the cationic aggregates and is one of the important factors for rate enhancement as often observed in cationic micellar catalysis.[19] Secondly, the increase in a fraction of the active aldimine Schiff-base (SB_2), which is controlled by the microenvironmental property acted on the Schiff-base, is responsible for the rate acceleration. The fractions of the active SB_2 species in the whole aldimine Schiff-base were calculated with reference to K_α-values; 5 and 9% in the micellar and vesicular systems, respectively. Such difference reflects the microenvironmental property of reaction sites. Formation of the polar SB_2 species is favored in a polar microenvironment. Thirdly, the imidazolyl group placed at the

reaction site is in favor of the rate enhancement. The $N^+C_5His2C_{14}$ vesicles enhanced the reaction by more than 1.5 fold relative to the $N^+C_5Ala2C_{14}$ vesicles, even though the former may provide a microenvironment similar to that with the latter as mentioned above. The neutral imidazolyl group may act as a general-base catalyst which promotes the prototropic shift in a manner as observed for the imidazole-catalyzed transamination of α-aminophenylacetic acid.[12b] The overall transamination between PLP and $AlaC_{12}$ in the $N^+C_5His2C_{14}$ vesicles is now plausibly explained by Scheme 3.

In conclusion, a hydrophobic and polar microenvironment accelerates the overall transamination more than a hydrophobic but less polar one, even though the Schiff-base formation is more enhanced in the latter. The bilayer vesicles having an amino acid residue as a molecular component may provide better microenvironments for the transamination than ordinary micelles. This suggests that the hydrogen belt domain constructed in the vesicular assembly may be characterized as a suitable model for reaction sites in enzymes.[20] The vesicles formed with N^+C_5-$His2C_{14}$ provide functional groups in the hydrogen belt domain to catalyze the intramolecular prototropic shift and can be taken as a functionalized apoenzyme model for vitamin B_6-dependent enzymes

Effect of Conformation on Ring Opening of Cis and Trans Dimers of Acenaphthylene in the Triplet State. Direct Detection of Hydrocarbon Biradical, 1,1′-Biacenaphthene-2,2′-diyl[1]

Harumichi Kobashi,* Hiroki Ikawa, Reiko Kondo, and Toshifumi Morita

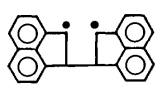
Department of Chemistry, Faculty of Engineering, Gunma University, Kiryu, Gunma 376

(Received October 16, 1981)

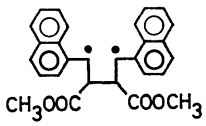
Triplet sensitized photodecomposition of cis and trans dimers of acenaphthylene (c-D and t-D) has been studied in benzene by means of a nanosecond laser flash photolysis. An aromatic hydrocarbon biradical, 1,1′-biacenaphthene-2,2′-diyl (**1**) was found as an intermediate for the decomposition of triplet t-D to acenaphthylene monomers. The rate of bond opening was directly measured to be 8.3×10^6 s^{-1} at 20 °C. The temperature dependence of the rate yields the frequency factor 2.8×10^7 s^{-1} and activation energy 3.1 kJ mol^{-1}. The lifetime of **1** is 330 ns; this is insensitive to temperature changes (6—64 °C). Oxygen quenches **1** with the rate constant of 9×10^9 M^{-1} s^{-1} (1 M=1 mol dm^{-3}). On the other hand, the triplet state of c-D did not show any evidence of the presence of **1** as an intermediate. The difference of ring opening mechanisms between the two isomers is interpreted in terms of different steric hindrances between two acenaphthene rings. The triplet-triplet (T-T) absorption spectra of both dimers resemble each other. No characteristic absorption due to intramolecular triplet excimer of naphthalene was observed even for c-D.

Direct detection of unstable biradicals has been made in the Norrish type II reactions of alkyl phenyl ketones by means of laser photolysis methods.[2,3] Such studies are very important to elucidate reaction mechanisms, *i.e.*, to investigate channels of deactivation of a precursor in the excited state as well as behaviors in the biradical itself.[4]

Takamuku and Schnabel[5] reported the observation of biradical, **2**, produced through ring cleavage in the triplet state of r-1,c-2-bis(methoxycarbonyl)-t-3,t-4-di(1-naphthyl)cyclobutane. The spectrum of **2** drew our attention to the spectrum which had been observed in the triplet photosensitization of trans dimer of acenaphthylene during the course of our study about behavior of the triplet states containing acenaphthene units. We report here direct detection of a pure hydrocarbon biradical, **1**, formed through triplet sensitization of t-D and the influence of cis and trans conformations on the cleavage of a cyclobutane ring of acenaphthylene dimers, as studied by the laser flash photolysis. In addition, we show T-T absorption spectra of both dimers and compare them with the spectrum of acenaphthene.



1



2

Experimental

Materials. The cis and trans dimers of acenaphthylene (c-D and t-D) were synthesized by photodimerization. Acenaphthylene monomer (M) as a starting material was purchased from Wako Pure Chemical Ind. and recrystallized once from ethanol. Procedures of synthesis and purification were essentially the same as the methods described by Nerbonne and Weiss[6] except for a slight modification noted below. A light source was a 450-W Hg-lamp (Ushio, UM-455) with a water-cooled quartz jacket. A few sealed glass tubes containing *ca.* 70 ml of acenaphthylene solution were immersed in a thermostated water bath at 25 °C and irradiated through a side window of the bath. The thick glass window and the tubes cut off the light less than 340 nm. In the preparation of c-D, cyclohexane was used as a solvent in the place of hexane in Ref. 6 and solutions of M were bubbled by oxygen before sealing. Purities of the dimers were checked by UV absorption[7,8a] and emission spectra[9] measured with a spectrophotometer (Hitachi Model 200-10) and a spectrophotofluorimeter (Hitachi Model MPF-2A), respectively.

Acenaphthene (ACN) as a reference to an unit chromophor of the dimers was purified by triple recrystallization from methanol. The zone-refined benzophenone (BP) or the G. R. grade acetophenone (AP) was used as a triplet sensitizer. Methylcyclohexane and isopentane for a mixed glass solvent at 77 K were purified by the usual methods. The spectrograde benzene (Dotite) was used as a solvent in steady illumination and fiash photolysis experiments.

The Nanosecond Flash Photolysis. The solutions of each dimer containing a sensitizer were degassed by several freeze-pump-thaw cycles. The nanosecond flash photolysis was done at 347 nm excitation using a ruby laser described elsewhere.[10] The laser beam excites the sensitizer but does not excite the dimers. Transient absorption spectra in the 340—600 nm range were measured at room temperature. For kinetic measurements, temperature control of a sample was carried out by circulating thermostated water in a quartz Dewar vessel equipped with a thermocouple.

Steady State Illumination. Both solutions of c-D and t-D containing BP were illuminated steadily with 365 nm light for isolation of decomposed products. The 365 nm light was obtained from a 100-W high-pressure Hg-lamp (Toshiba SHL-100UV) using a combination of glass lenses and a filter (Toshiba UV-D1C). After condensation of illuminated solutions with an evaporator, products were separated and identified by the aid of a TLC technique and a UV-VIS absorption measurement.

Results and Discussion

Steady State Illumination. Continuous irradiation with the 365 nm light gave rise to pale-yellow coloration of both dimer solutions. This coloration arises from gradual increase of the characteristic absorption band of M in the visible region. The relative rate of such change, as monitored at the absorption band, was faster for t-D than for c-D. Examination of the R_f

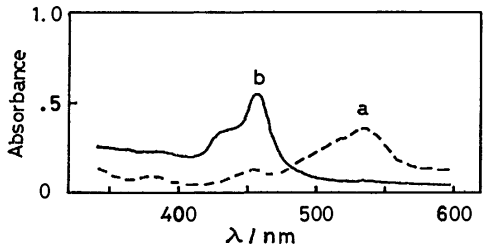


Fig. 1. Transient absorption spectra observed for cis dimer of acenaphthylene (5.0×10^{-3} M) in benzene containing benzophenone (4.0×10^{-3} M) as a sensitizer.
a: 30 and b: 130 ns after the start of laser oscillation.

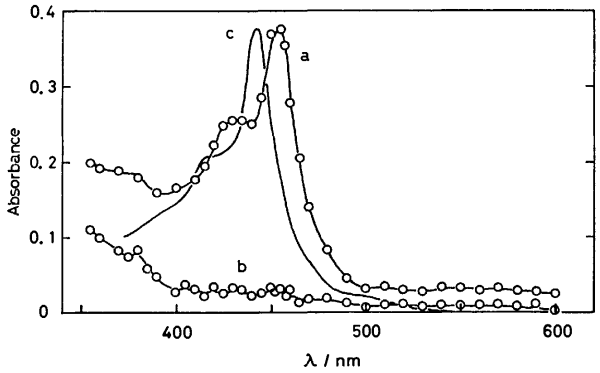

Fig. 2. Transient absorption spectra for cis dimer of acenaphthylene (5.0×10^{-3} M) [a and b] and for acenaphthene (1.0×10^{-2} M) [c] in benzene using acetophenone (1.0×10^{-2} M) as a sensitizer.

value of TLC and the UV absorption spectrum showed recovery of M for each solution. Products other than M, except for the starting materials, were unrecognized on a plate of TLC developed by the mixture of benzene and cyclohexane (1:3 in volume). It was thus confirmed that both of the dimers sensitized to the triplet state cause cycloreversion to acenaphthylene monomers.

Benzophenone (or Acetophenone)——Cis Dimer in Benzene. Figure 1 shows transient absorption spectra in the BP(4.0×10^{-3} M)-c-D (5.0×10^{-3} M) system obtained by the nanosecond flash photolysis. Similar spectra for the AP (1.0×10^{-2} M)-c-D (5.0×10^{-3} M) system is given in Fig. 2 together with the T-T absorption of ACN for the purpose of comparison. The absorption at 530 nm in Fig. 1a is attributable to triplet benzophenone (^{3}BP)[11] formed immediately after excitation. The ^{3}BP decays rapidly with the rate parameter of 1.7×10^7 s^{-1} under the present concentration of c-D. Since c-D has the lowest triplet state energy ($E_T^{(c)}=20.6\times10^3$ cm^{-1}), lower than that of BP ($E_T^{(BP)}=24.25\times10^3$ cm^{-1}),[12] the T-T energy transfer to c-D will dominate deactivation of ^{3}BP. The $E_T^{(c)}$ value was estimated from the 0-0 band of phosphorescence measured in methylcyclohexane–isopentane matrix at 77 K (Fig. 3a). A new band with maximum at 455 nm (Fig. 1b) grows up with a rate identical to the decay rate of ^{3}BP. After reaching its maximum intensity, this band disappears with a life of *ca.* 2 μs and no other specific absorption is observed. Decay time of this band was shortened by air saturation. The absorption spectrum is quite similar to that in Fig. 2a observed by replacing BP with AP ($E_T^{(AP)}=25.75\times10^3$ cm^{-1})[12] as a sensitizer. Namely, this transient is independent of a sensitizer. The band 1b is also similar in position and shape to the T-T absorption of ACN as a reference (Fig. 2c), although the maximum of the former band is slightly red-shifted, from 422 nm of the latter band to 455 nm. These observations allow us to assign both absorptions with the maxima at 455 nm (Figs. 1b and 2a) are to be attributed to the triplet state cis-dimer, ^{3}(c-D).

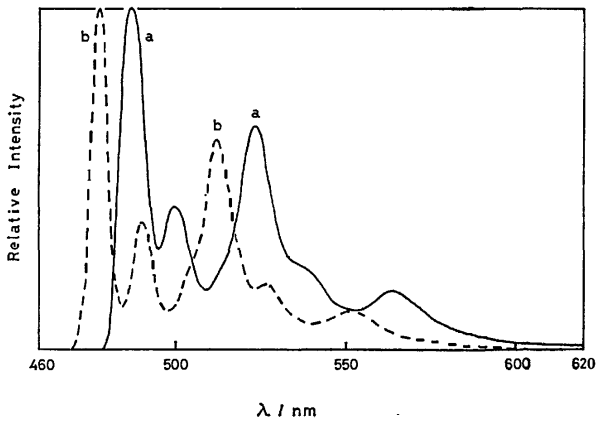

Fig. 3. Phosphorescence spectra measured for c-D [a] and ACN [b] in methylcyclohexane–isopentane matrix at 77 K (uncorrected for spectral response).

Decay rate of the band at 455 nm tends to become faster with each run. The sample solutions were also tinted with yellow by many shots of laser pulses. The UV-VIS absorption measurements confirmed the presence of M in these photolyzed solutions. This corresponds to recovery of M by the steady state illumination mentioned above. Therefore, it is considered that the acceleration of decay rate arises from quenching by M molecules accumulated gradually by each flash photolysis. The T-T energy transfer from ^{3}(c-D) to M by diffusional encounter may be responsible for the quenching, because the triplet energy of M, $E_T^{(M)}$, has been estimated to be 15000—16500 cm^{-1},[13] much lower than that of ^{3}(c-D). The plot of reciprocal lifetimes of ^{3}(c-D) against the number of experimental runs (25 points), in analogy to the Stern-Volmer plot, gave a good linear relation. Then, the intrinsic lifetime of ^{3}(c-D) was estimated, by the least square method, to be 2.2 μs at 20 °C from the extrapolation to the first experiment. An Arrhenius plot for the decay rate determined by this procedure as a function of temperature fits a straight line (Fig. 7c) yielding activation energy, $E_a^{(c)}=(25\pm3)$ kJ mol^{-1}, and the frequency factor, $A^{(c)}=(1.36\pm0.08)\times10^{10}$ s^{-1}, for 6 points between 9 and 58 °C.

Electronic Interaction between Naphthalene Rings of c-D. The electronic interaction between two naphthalene rings of c-D in the triplet state is important, because conformation of naphthalene rings of c-D (dihedral angle between the two rings≈60°)[9] is supposed to

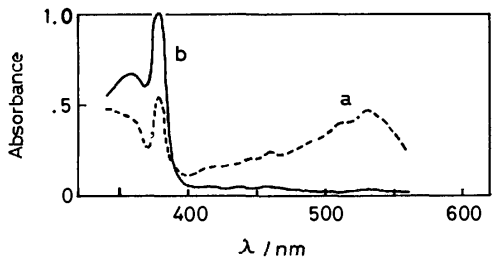

Fig. 4. Transient absorption spectra observed for trans dimer of acenaphthylene ($\approx 2\times10^{-3}$ M) in benzene containing benzophenone (4.0×10^{-3} M) as a sensitizer.
a: 40 and b: 230 ns after the start of laser oscillation.

be similar to that of 1,2-di-(1-naphthyl)ethane (DNE), which exhibits the phosphorescence and absorption of intramolecular triplet excimer of naphthalene.[14]

Let us first compare the phosphorescence spectrum of c-D with that of ACN in a rigid glass at 77 K (Fig. 3). The spectral shape of c-D (3a) is very similar to that of ACN (3b). No broad band characteristic of the triplet excimer[14,15] is observed around 520—500 nm. The 0-0 band of c-D is located at 486 nm, showing a red-shift compared with that of ACN. This red-shift and wavelength position are common to naphthalene dimers stable in the ground state such as an intramolecular sandwich dimer of 1,3-di(1-naphthyl)propane[16] and a dimer in poly(2-vinylnaphthalene).[17] They have the 0-0 bands at 485 nm and 482 nm, respectively. Phosphorescence features noted above indicate that at 77 K, c-D can not take a disposition similar to that of the triplet excimer, although some weak electronic interactions like those in the stable dimers are present between the naphthalene rings of ^{3}(c-D).

Next, we should notice the T-T absorption of c-D. The spectrum of ^{3}(c-D) is composed of the main band around 455 nm and a weak absorption tail in the longer wavelength region (530—600 nm). Since the two naphthalene rings in c-D and in DNE dispose in a similar manner, the transient absorption spectrum of c-D is expected at room temperature to involve a definite absorption band due to triplet excimer at 470 nm, like that observed in DNE.[14] However, the spectrum in Fig. 1b or 2a exhibits no additional absorption band around 470 nm other than the contribution of the red side slope of the main band. Kinetic measurements revealed further that both the main and the weak absorption band decay with approximately identical lifetimes up to 3 μs after excitation. Figures 2a and 2b represent this spectral change with time; the spectrum of ^{3}(c-D) decays monotonously without any spectral change. That is to say, the c-D does not show any distinct absorption around 470 nm due to the triplet excimer of naphthalene, although DNE does show such an absorption. Therefore, we consider that owing to structural rigidity, it is impossible for the two naphthalene rings of c-D, even at room temperature, to take a conformation favorable for exhibiting a distinguished absorption due to triplet excimer.

Benzophenone (or Acetophenone)——Trans Dimer in Benzene. Figure 4 shows time-dependent absorption spectra in the BP (4.0×10^{-3} M)-t-D ($\approx 2\times10^{-3}$ M) system. The spectrum at 40 ns (4a) consists of a band around 530 nm (^{3}BP), a weak band around 450 nm, and a sharp peak at 379 nm. The first and second bands decay rapidly in the initial time domain, but the band at 379 nm grows (4b). The rise time (120 ns) monitored at 379 nm was identical to the decay time observed at 450 nm. After reaching the maximum intensity, the 379 nm band decreases with the lapse of time, obeying the first-order decay kinetics. Its rate was not affected by photolysis numbers, in contrast to the decay of ^{3}(c-D). The decay time is 330 ns. Time dependences for 379 and 450 nm absorptions are illustrated in Fig. 5.

Intermediacy of the triplet t-D, ^{3}(t-D), is ambiguous in Fig. 4, since the expected absorption of ^{3}(t-D) is masked by the absorption of ^{3}BP in the 400—460 nm region. To clarify the spectrum of ^{3}(t-D), we chose AP as a sensitizer, because the extinction coefficient of ^{3}AP is rather low in the wavelength range

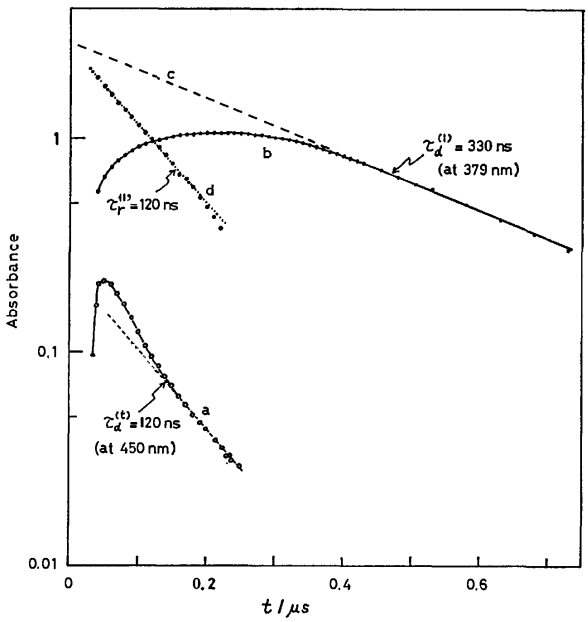

Fig. 5. Rise and decay profiles of transient absorptions monitored at 450 nm [a] and 379 nm [b].
Owing to overlap of ^{3}BP absorption, the linearity of [a] is wrong. [c]: the extrapolation of decay in Curve b. [d]: (Curve c—Curve b) *vs.* *t* plot. This slope derives the rise time of **1**.

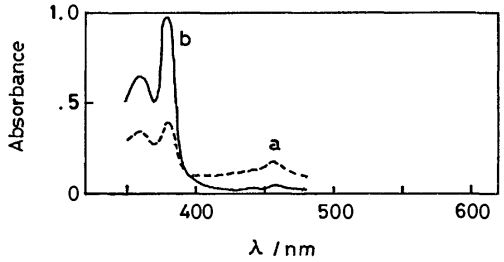

Fig. 6. Transient absorption spectra for the trans dimer (2.0×10^{-3} M) in benzene with acetophenone (1.0×10^{-2} M) as a sensitizer.
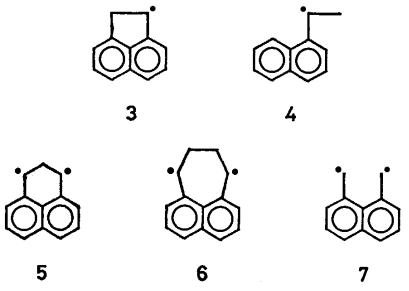
a: 40 and b: 170 ns after the start of laser oscillation.

greater than 400 nm.[18] Figure 6 represents transient spectra measured in such a system. A well-defined absorption band of ^{3}(t-D) is observed with maximum at 455 nm in the early time after excitation. It resembles well the spectra of ^{3}(c-D) in Figs. 1b and 2a, which demonstrates no large difference in the triplet electronic states of both dimers. Decay of this band is accompanied by remarkable growth of the 379 nm band, which is identical to the spectrum of Fig. 4b. It is thus clear that ^{3}(t-D) is a precursor generating the transient with the 379 nm absorption band.

Identification of Biradical **1** *and Its Properties.* We still have to assign the spectrum around 379 nm. The spectrum is quite similar to that of **2**[5] in both shape and position. The decay of this band obeys the first-order kinetics. Its lifetime (330 ns) is close to that of **2** (225 ns in acetonitrile).[5] As mentioned previously, t-D causes cycloreversion to the corresponding monomers, just like r-1,c-2-bis(methoxycarbonyl)-t-3,t-4-di(1-naphthyl)cyclobutane does. Since the biradical **2** is formed through one bond breaking of the cyclobutane ring of the latter, the present transient is supposed to be a transient formed in a similar fashion. Then, the species with 379 nm band is presumed to be biradical **1**. The similarity of the conjugate system of **1** and **2** is a reasonable way to interpret the similarity of their spectra. In fact, acenaphthene radical (**3**) corresponding to a half of **1** has been reported to possess an absorption in the identical wavelength region (320—400 nm)[19] and also 1-ethylnaphthalene-α-yl (**4**) shows an absorption spectrum similar to that of **1** in the near wavelength position.[20] Furthermore, the spectrum observed here differs from spectra of a group of hydrocarbon biradicals such as 2,3-dihydrophenalene-1,3-diyl (**5**) and 7,8,9,10-tetrahydrocyclohepta[*de*]naphthalene-7,10-diyl (**6**) measured by Muller *et al.*[21] and Gisin *et al.*,[22] respectively.



The above statement implys that the present intermediate keeps the acenaphthene structure but not 1,8-diethylnaphthalene-α,α′-diyl (**7**) structure in the bond scission of a cyclobutane ring; namely, the bond scission will occur between 1- and 1′-carbons, but not between 1- and 2-carbons. Hence, the spectrum in question can safely be assigned to be due to biradical **1**.

Dissolved oxygen quenches **1** with a bimolecular rate constant of 0.9×10^{10} M^{-1} s^{-1} in benzene at 19 °C.[23] This value is comparable with 2.1×10^{10} M^{-1} s^{-1} for **2** in acetonitrile[5] and 1.3×10^{10} M^{-1} s^{-1} for **6** in methanol.[22] This profound effect of oxygen has been known as a characteristic behavior for 1,4-biradicals in the triplet spin state produced from

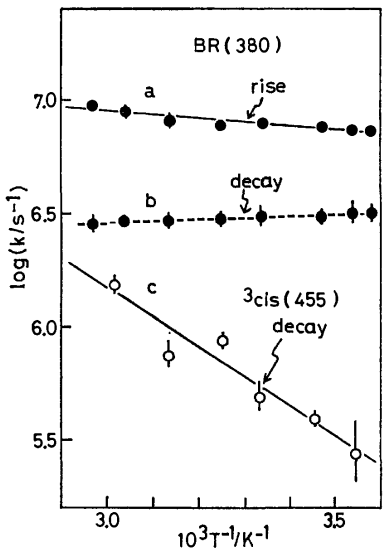


Fig. 7. Arrhenius plots for rise and decay rates of biradical **1** (BR) and for decay rate of triplet cis dimer (^{3}cis). Errors are indicated by bars. The numbers in parentheses denote the absorption wavelengths monitored.

TABLE 1. RISE (τ_r) AND DECAY (τ_d) TIMES OF TRANSIENT MONITORED AT EACH ABSORPTION MAXIMUM (λ_{max}) AT 20 °C

(temperature range: 6—60 °C)

	A/s^{-1}	E_a/kJ mol^{-1}
^{3}cis decay	1.36×10^{10}	25
1 rise	2.8×10^7	3.1
1 decay	1.9×10^6	−1.2

alkyl phenyl ketones by the type II reactions.[2,4] A preliminary result indicates that diethyl mercury, a compound involving a heavy atom, quenches **1** effectively with the rate constant of 3.7×10^7 M^{-1} s^{-1}. This finding would not contradict the assumption that **1** is a triplet biradical. The decay time of **1** was little influenced by temperature changes from 6 to 64 °C.[24] Inverse of the rise time of **1**[25] fits the Arrhenius equation of parameters, $E_a^{(t)}=3.1\pm0.2$ kJ mol^{-1} and $A^{(t)}=(2.8\pm0.4)\times10^7$ s^{-1}.

Arrhenius plots are shown in Fig. 7. Rate constants and Arrhenius parameters are collected in Tables 1 and 2, respectively.

Reaction Scheme. Reaction scheme of the triplet-sensitized ring opening of acenaphthylene dimers can be represented as Fig. 8.

The triplet-sensitized t-D causes a bond scission

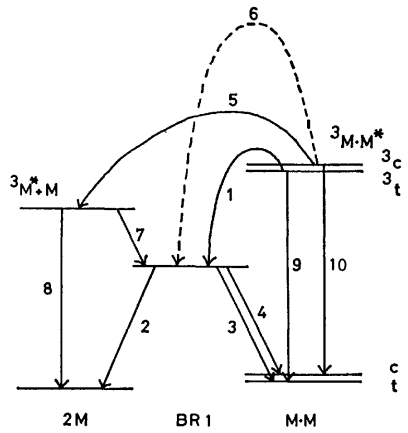

Fig. 8. Reaction scheme of cis and trans dimers of acenaphthylene sensitized to the triplet state.
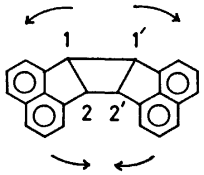
BR **1** refers to biradical **1**, M acenaphthylene monomer, M-M the dimer of acenaphthylene, and c and t indicate the cis and the trans dimer, respectively. The process of direct decomposition from ^{3}c to 2M is omitted. Processes, 1, 5, and 6 are illustrated by curves to emphasize potential barriers.

(Process 1) to generate **1**, which subsequently undergoes the second bond cleavage leading to production of two acenaphthylene monomers, 2M (Process 2). Processes 3 and 4 going back to the ground states of t-D and c-D, respectively, should compete with Process 2, because **1** has been assumed as a common intermediate for the photodimerization of acenaphthylene (Process 7 followed by Processes 3 and 4).[8b,c] The rise time of **1**, $\tau_r^{(1)}$, corresponds to the decay time of ^{3}(t-D), $\tau_d^{(t)}$, which depends on the rates of both Processes 1 and 9. The deactivation to the ground state in ^{3}(t-D), Process 9, would not differ so much from the corresponding one in ^{3}ACN, for the electronic state of ^{3}(t-D) does not differ so much from that of ^{3}ACN. Since the decay time of ^{3}ACN, $\tau_d^{(ACN)}$ (>16 μs),[26] is considerably longer than $\tau_r^{(1)}$ (120 ns), contribution of Process 9 would be negligible to the decay of ^{3}(t-D). Namely, the inverse of $\tau_r^{(1)}$ gives the rate constant of primary bond opening (Process 1). Thus, the Arrhenius parameters, $E_a^{(t)}$ and $A^{(t)}$, obtained from Fig. 7a belong to this process of biradical formation. The small activation energy and moderate frequency factor reflect the ease of the reaction 1. Moreover, it is worth noting that the $E_a^{(t)}$ value (260 cm^{-1}) is very close to the frequency energy (280 cm^{-1}) of vibrational progression in $^1L_a \leftarrow {}^1A$ absorption spectrum and the frequency (269 cm^{-1}) in the Raman spectrum characteristic to t-D.[9] The bond opening of ^{3}(t-D) may be promoted by the thermal excitation of these modes.

On the other hand, the c-D sensitized to the triplet state dissociates to monomers with no production of **1** as an intermediate, *i.e.*, Process 6 was not found. Some possible mechanisms are as follows. Since $E_T^{(M)}$ is 15000—16500 cm^{-1},[13] $E_T^{(c)}$ 20600 cm^{-1}, and the ground state of c-D lies near the state of a pair of monomers (2M),[9] then the energy level of the state, ^{3}M*+M, is lower than that of ^{3}(c-D). Accordingly, two channels for decomposition are energetically possible: one is a pathway generating ^{3}M*+M (Process 5) and another a direct cycloreversion to 2M. According to the spin conservation rule, the spin-allowed Process 5 may be more favorable than the spin-forbidden direct decomposition to 2M. At the present stage of investigation, however, we can not decide clearly which process is dominant. Moreover, Process 10 (deactivation to the ground state) competing with the decomposition process is involved in the total decay of ^{3}(c-D), $\tau_d^{(c)}$. Its contribution to $\tau_d^{(c)}$ is larger than that of Process 9 to $\tau_d^{(t)}$, as judged from their lifetimes: $\tau_d^{(c)}$ 2.2 μs, $\tau_d^{(t)}$ 0.12 μs, and τ_d^{ACN} 16 μs, which is regarded as an approximate value to the reciprocal rates for Processes 9 and 10. Under these circumstances, temperature dependence of $\tau_d^{(c)}$ is swayed by relative contribution of the above competing processes. This suggests that the Arrhenius plot for the decay of ^{3}(c-D) would not become linear. Nevertheless, the present result showed that the plot becomes approximately linear (Fig. 7c). It is probably due to the narrowness of the temperature range. Therefore, the observed values of $E_a^{(c)}$ and $A^{(c)}$ do not directly reflect the temperature change of a certain ring opening reaction process. However, ^{3}(c-D) decays rather slowly compared with ^{3}(t-D); Process 5 proceeds more slowly than Process 1. If frequency factors for these two processes are nearly equal, an activation energy for Process 5 will be higher than $E_a^{(t)}$. This estimation relates to the next discussion.

Reactivity Difference between Cis and Trans Dimers. The striking difference in triplet reactivities between cis and trans dimers can be interpreted in terms of the difference in steric hindrances between two ACN rings, as follows. At least one bond of the cyclobutane ring of c-D or t-D must be stretched prior to bond scission. Stretching of C_1–C_1' bond in the directions



indicated by the arrows moves ACN rings in the directions indicated by arrows and gives rise to changes in the relative disposition of two ACN rings. In the case of c-D, the edges of the two ACN rings on the side of the C_2–C_2' bond are brought close to each other, whereas the other sides of the ACN rings separate. The very high potential barrier resulting from repulsion between two ACN rings should be overcome in order that the bond opening may proceed through such deformation. It seems impossible that c-D can cleave one bond in such a manner as to generate **1** (Process 6 in Fig. 8). It will be rather easy to break two bonds, C_1–C_1' and C_2–C_2', simultaneously, because such a high potential barrier is removed, although a fairly high potential barrier still remains for c-D to open the two bonds. In the case of t-D, the high potential barrier resulting from repulsion between ACN rings is absent and only one bond breaking is necessary to generate **1**. Therefore, it is considered that Process 1 proceeds very smoothly.

The authors wish to thank Prof. Haruo Shizuka for valuable discussion.

(Received February 17, 1982)

Synopsis. The effect of UV radiation in air on the wettability of silicone polymers was studied by measuring the contact angles. From the contact-angle data, the surface energies were also calculated. As the irradiation progressed, the surface energy of the polar component increased, while the surface energy of the dispersive component remained constant, for all the samples. This increase in surface energy is attributable to a surface photooxidation of the silicone polymers. Especially, poly(diphenylsiloxane) showed a remarkable increase in the surface energy of the polar component after the irradiation.

The wettability of surfaces by liquids of known surface tensions has been determined by many investigators.[1,2] In particular, contact-angle measurements have been used to evaluate changes in surface composition.[3] We have ourselves previously reported that the water-contact angles on polystyrene and poly(methyl vinyl ketone) surfaces decreased dramatically as a function of the UV exposure time because of the photooxidation of the surfaces.[4] Generally, it is known that silicone polymers have relatively low surface-energy values. If the surface energy of a silicone polymer could be increased by UV radiation, the adhesion between liquids and the surface of the silicone polymer irradiated would be enhanced by an increase in the work of adhesion.

This report will describe the effect of UV radiation in air on the wettability of silicone polymers.

The silicone polymers used in this study were poly(methyl)3—7%(diphenyl)0.5—1.0%(methyl vinyl) siloxane, poly(diphenyl-siloxane), poly(dimethyl)1—2%-(methyl vinyl)siloxane, and poly(methyl vinyl)siloxane, all supplied by Petrarch System, Inc. (U.S.A.). A film of each polymer was cast from its benzene solution on an aluminum plate. Then, the plate was cured at 100 °C in an oven for 15 min. The plate was exposed in air with a low pressure mercury lamp (55.2 W, 1 W=1 J s^{-1}) supplied by the Oriel Co. (U.S.A.). The distance between the plate and the lamp was 5 cm.

The liquids used for contact-angle measurements were octane and diiodomethane. The contact angles were measured on the irradiated plate by using a goniometer at 20 °C. Three drops of the liquid were measured on both sides of the drops, and the six values were averaged. The overall variation in the contact-angle measurement was about ±3 degrees.

The free energy γ, of any interface can be regarded as the sum of two terms; one, designated γ^d, attributed to dispersion forces, and the other, γ^p, to polar forces. The value of γ_s^p can be calculated from the octane-water contact angle θ_{ows}, by means of Hamilton's[5] equations:

$$\cos\theta_{ows} = \frac{\gamma_w - \gamma_o - \gamma_{sw}}{\gamma_{ow}}$$

and:

$$I_{sw} = 2\sqrt{\gamma_s^p \gamma_w^p},$$

where γ_w and γ_o are the surface tensions of the mutually saturated water phase and octane phase respectively, where γ_{wo} is the interfacial tension of the two phases, where γ_w^p is the polar component of water-surface tension, and where I_{sw} is the term of polar interaction with water.

The value of γ_s^d can also be calculated from the diiodomethane-air contact angle, θ_m, using an equation developed by Fowkes:[6]

$$\gamma_s^d = \gamma_m \frac{(1+\cos\theta_m)^2}{4},$$

where γ_m is the surface tension of diiodomethane. Here, literature values[6,7] are applied in the surface-energy analysis:

$\gamma_w = 72.6$ erg/cm² **, $\gamma_o = 21.8$, $\gamma_{wo} = 50.8$, $\gamma_w^p = 50.8$, and $\gamma_m = 50.8$ at 20 °C.

Five different compositions have been made into plates, irradiated, and measured according to the above procedures. These compositions are:

1. Poly(dimethyl)3—7%(diphenyl)0.5—1.0%-(methyl vinyl)siloxane. This material is referred to as "PS 264".
2. Poly(diphenylsiloxane).
3. Poly(methyl)1—2%(methyl vinyl)siloxane.
4. PS 264+poly(diphenylsiloxane), 1:1 in weight.
5. PS 264+poly(methyl vinyl)siloxane, 5:1 in weight.

Tables 1—5 present the primary data and the derived results for compositions #1—#5. In each table, the last column, headed γ_s, is simply the sum of γ_s^p and γ_s^d. From these tables, it can be seen that the values of γ_s^p are increased as a function of the irradiation time for all the samples, while the values of γ_s^d remain almost constant. Two reasons for the increase in γ_s^p may be considered; a surface cracking due to UV irradiation and a surface photooxidation.

If a surface cracking has occurred during UV irradiation, the contact angle of octane-water might increase, for water can penetrate into such a crack and make the surface more hydrophilic. Also, if the silicone polymer surface is photooxidized during UV irradiation, the contact angle of octane-water is likely to be

** 1 erg=1×10⁻⁷ J.

γ_s^p values after UV irradiation in air is attributed to the surface photooxidation of the silicone polymers. Especially, it is found that Composition #2 is easily photooxidized by UV irradiation.

Accordingly, it can be anticipated from the above results that the adhesion between liquids and irradiated silicone-polymer surfaces is enhanced by the increase in polar-polar interaction which is attributed to the work of adhesion.

Adsorption of Surface Active Agents on Coals

Kunio Esumi,* Kenjiro Meguro, and Hidemasa Honda
Department of Applied Chemistry, Faculty of Science, Science University of Tokyo, Kagurazaka, Shinjuku-ku, Tokyo 162
(Received April 13, 1982)

Synopsis. The interactions between surface active agents and coals with various carbon contents were studied by measuring adsorption isotherms and zeta potentials. A characteristic adsorption behavior was observed for the coals among three different surface active agents, but no correlation was found between the adsorption and the carbon content of the coal.

The surface properties of coal[1,2] have been investigated to understand the mechanisms of coal flotation, coal dust suppression, and coal–oil mixture behavior. Glanville and Wightman[3] studied the wetting rates of powdered coal by alkanol–water solutions; they found that a critical concentration of each alkanol was needed before any wetting occurred and that this critical wetting concentration was lower for alcohols with longer carbon chains. Recently, a coal–water mixture has been found attracting as a fuel source. Although it is important to elucidate the interactions between coal surfaces and surface active agents, there have been few reports on this subject.

In this paper, the interaction between coals of various carbon contents and surface active agents will be reported, using adsorption isotherm and zeta potential measurements.

The coals used in this study were Yallourn, Taiheiyo, Miike, Hon-gay, Tenpoku and Wandoan. They were dry sieved between 60 and 100 mesh screens. The pertinent properties of these coals are given in Table 1.

The surface active agents employed were sodium dodecylbenzenesulfonate (ABS), 1-dodecylpyridinium chloride (DPCl), and polyoxyethylene nonylphenyl ether (NP-7.5) which were supplied by Wako Pure Chemical, Industries, Ltd., Tokyo Kasei, Co. Ltd., and Nikko Chemical, Co., respectively. They were used without purification.

The water used was purified by passing through an ion exchange column followed by filtration from Milli-Q Water Purification System.

The amounts of surface active agents adsorbed on the coals were determined from the difference of the concentration of surface active agents before and after the adsorption by means of UV spectrophotometer (Hitachi ESP-3T). The zeta potentials of the coal surfaces were measured by mean of a Laser Zee Model 500 (Pen Kem Co.). The critical micelle concentration of the surface active agent was determined from the surface tension measurement.

Table 1. Pertinent properties of coals

	C[a] (wt%)	H[a]	H_2O[b]	Ash[b]	Specific surface area[c] $m^2 g^{-1}$
Yallourn	61.5	4.6	12.2	0.9	1.62
Tenpoku	68.1	5.5	14.3	22.9	4.19
Taiheiyo	74.8	6.0	6.6	8.4	0.68
Wandoan	80.2	6.6	9.3	8.0	2.30
Miike	85.2	6.5	1.2	7.8	0.53
Hon-gay	93.0	3.3	1.7	3.4	0.16

a) From JIS M 8813. b) From JIS M 8812, 60-100 mesh. c) From the nitrogen adsorption at 77 K.

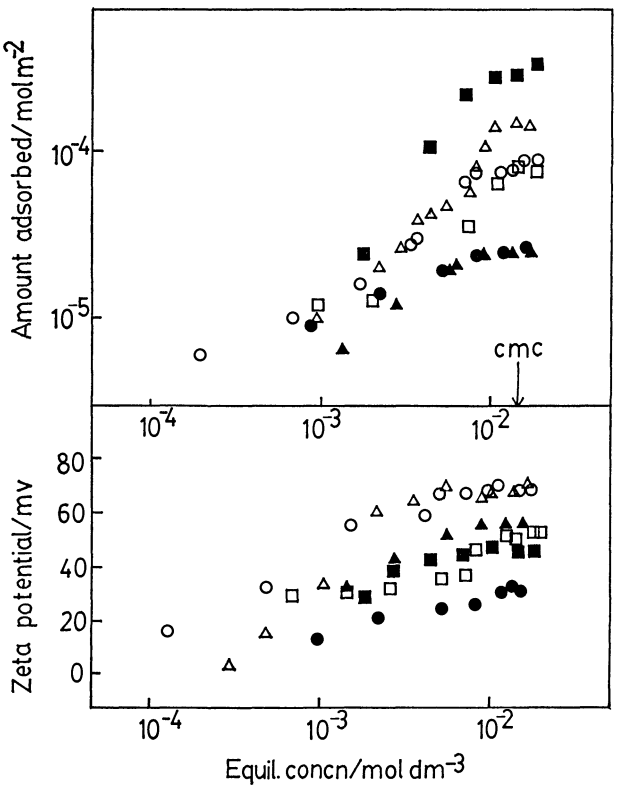

Fig. 1. Adsorption isotherms of DPCl on coals at 25 °C and the corresponding zeta potential result; (○) Yallourn, (●) Tenpoku, (△) Taiheiyo, (▲) Wandoan, (□) Miike, and (■) Hon-gay.

When the coals of various carbon contents shown in Table 1 were dispersed in water, they gave characteristic surface charges. All the coals except Hon-gay coal were found to be negatively charged in electrophoresis, while Hon-gay coal was positively charged. Generally the coal surface is more easily oxidized as the carbon content of the coal decreases. Such an oxidized coal surface would be expected to exhibit a negative charge in water due to dissociation of the carboxyl group. However, in this study, no relation between the carbon content of coal and the surface charge of the coal in water was obtained.

Adsorption isotherms of the surface active agents on coals from water and the corresponding surface charge of the coals are shown in Fig. 1. In Fig. 1, the amount of DPCl adsorbed increased with increasing the concentration of DPCl. Especially, in the case of Yallourn coal, the adsorption isotherm was similar to those which

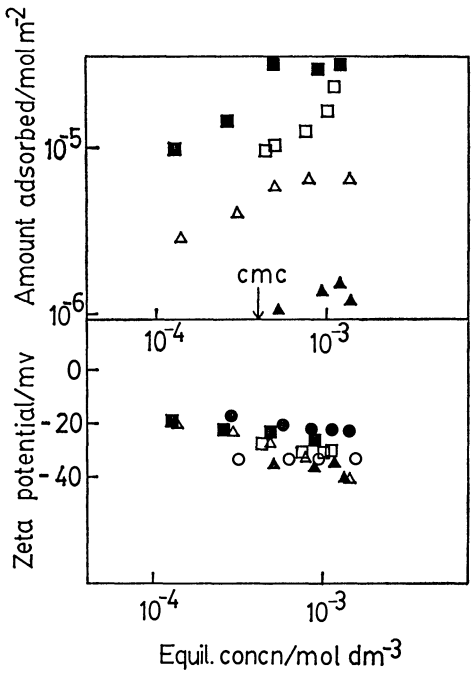

Fig. 2. Adsorption isotherms of ABS on coals at 25 °C and the corresponding zeta potential result; (○) Yallourn, (●) Tenpoku, (△) Taiheiyo, (▲) Wandoan, (□) Miike, and (■) Hon-gay.

Somasundaran and Fuerstenau[4] established in ionic surfactants–alumina system. That is, at low concentration, the adsorption obeyed Henry's law. The adsorption increased rapidly with the concentration of DPCl, but later increased more slowly. Finally, above the cmc, the adsorption reached a plateau. The zeta potential of coal by adsorption of DPCl increased positively on increasing the concentration. Two mechanisms are proposed for the orientation of DPCl on the coals. One is that DPCl molecules are adsorbed on the nonpolar surface of coal with the polar groups outward. The other is that the positively charged group of the DPCl molecule is oriented towards the negatively charged sites on the coal. Further, it is expected that near the cmc, a bimolecular layer of DPCl is formed on polar sites of the coal.

Figure 2 gives the adsorption isotherms of ABS on coals and the corresponding zeta potential measurements. In case of Yallourn and Tenpoku coals, the amount of ABS adsorbed was so small that it could hardly be estimated. The adsorption increased with increasing concentration of ABS and reached plateaus above the cmc for Hon-gay and Taiheiyo coals. On the other hand, the amount of ABS adsorbed on Wandoan and Miike coals increased even above the cmc. The zeta potential of the coals after the adsorption of ABS increased negatively with the concentration. This indicates that ABS molecules are adsorbed on nonpolar surface of coal with their polar groups outward.

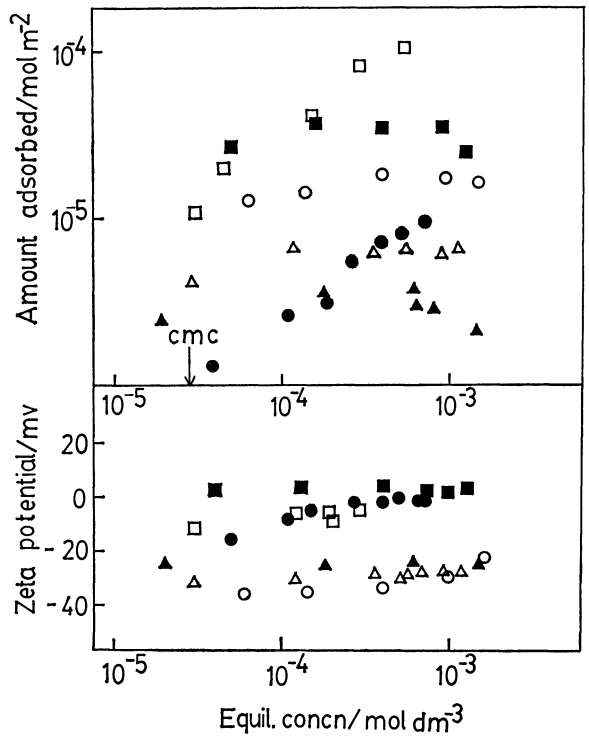

Fig. 3. Adsorption isotherms of NP-7.5 on coals at 25 °C and the corresponding zeta potential result; (○) Yallourn, (●) Tenpoku, (△) Taiheiyo, (▲) Wandoan, (□) Miike, and (■) Hon-gay.

Adsorption isotherms of NP-7.5 on coals and the corresponding zeta potential result are shown in Fig. 3. At above the cmc of NP-7.5, the adsorption increased with the concentration for Tenpoku and Miike coals, whereas for the other coals, the adsorption was almost constant. On the other hand, the zeta potential of the coals was almost constant in spite of different amounts adsorbed, because NP-7.5 is a nonionic surface active agent.

Comparing with the amount adsorbed of surface active agent on coals, the amount of DPCl adsorbed was much larger than that of ABS for all the coals. The amount of NP-7.5 adsorbed was intermediate between those of DPCl and ABS for all the coals. Furthermore, no correlation was observed among the amount of surface active agent adsorbed, the zeta potential of the coal after the adsorption, and the carbon content of the coal.

Preparation and Properties of Octahedral Nickel(II) Complexes with and Schiff Bases Derived from Substituted Salicylaldehydes and Bis(2-aminoethyl) Sulfide

Kiichi Hori* and Kazuko Takahashi

Department of Chemistry, Faculty of Science, Yamagata University, Yamagata 990

(Received December 18, 1981)

Synopsis The octahedral complexes listed in the title have been prepared. The magnetic and spectral properties of these complexes indicate that the non- and 5-substituted complexes have a structure bridged by the phenolic oxygen of the Schiff bases and the 3-substituted complexes probably are mononuclear.

The Schiff bases (H_2(X-saldaes), where X is a substituent on the benzene rings) derived from salicylaldehydes and bis(2-aminoethyl) sulfide form nickel(II) complexes which have electronic spectra characteristic of low spin five-coordinate structures and possess magnetic moments $\approx$1.1 BM in the solid state.[1] Under certain reaction conditions, three types of nickel(II) complexes with H_2(H-saldaes) were prepared: complexes of planar, octahedral, and polynuclear structures.[2] It is therefore of interest to investigate the effect of substituents on the benzene ring of the Schiff bases on the stereochemistry of the resulting complexes. In this paper, we report the syntheses and characterization of octahedral nickel(II) complexes with the substituted Schiff bases.

Experimental

Preparation. *Complexes* ***1*** *and* ***3*****—*****7***: The Schiff base, H_2(X-saldaes), (1 mmol) was dissolved in a minimum quantity of methanol (15—500 cm^3) under reflux. To this hot solution was added a solution of nickel(II) acetate tetrahydrate (1 mmol) in methanol (5 cm^3). The mixture was allowed to stand for 1—2 d at room temperature. For X= 3,5-Cl_2 and 3,5-Br_2, after the mixture had been concentrated to one-third of the volume under reduced pressure, the mixture was allowed to stand. The green crystals which precipitated were collected. The crystals were dissolved in a minimum quantity of methanol and recrystallized by concentrating the solution under reduced pressure.

Complex ***2***: Nickel(II) acetate tetrahydrate (1 mmol) was added to a solution of H_2(5-CH_3-saldaes) (1 mmol) in methanol (10 cm^3). The mixture was stirred, and water (5—10 cm^3) was added in order to facilitate the precipitation. The precipitate, which formed when the solution was cooled, was collected and redissolved in a minimum quantity of methanol. The resulting solution was allowed to stand for a long time (over 30 d) to concentrate very slowly. The green crystals thus precipitated were collected and washed with methanol.

Measurements. The magnetic susceptibilities were measured with a Shimadzu MB-2H magnetic balance over the temperature range of 80—300 K. The effective magnetic moments were calculated from the equation: $\mu_{eff}=2.83\sqrt{(\chi_A-N\alpha)T}$, where the temperature-independent paramagnetism, $N\alpha$, for nickel(II) ion was assumed to be 193×10^{-6} cgs emu.[3] The infrared spectra were measured with a JASCO DS-403 infrared spectrophotometer on Nujol mulls and KBr disks. The electronic spectra were measured with a Hitachi EPS-3T spectrophotometer.

Results and Discussion

The complexes obtained are listed in Table 1 with their analytical, spectral, and magnetic data. The Cl- or Br-substituted complexes were easily prepared, whereas the 5-CH_3-substituted complex was prepared with difficulty. Attempts to prepare the complexes with 3-CH_3 or 3-*i*-C_3H_7 substituents were unsuccessful.

The complexes are soluble only with difficulty in most nonpolar and semipolar solvents. They are soluble in solvents of high donor-ability such as pyridine and DMSO, but they decompose in these solvents. The reflectance spectra of the complexes possess two d-d bands (Table 1), indicating that the geometry around nickel(II) ions is octahedral.[4]

The complexes can be classified into two groups on the basis of the infrared spectral and magnetic data: (A) complexes **1**—**4** and (B) complexes **5**—**7**. The infrared spectra of complexes **1**—**4** show a broad weak band at 3300—3330 cm^{-1}, indicating the presence of a lattice water. The band near 1530 cm^{-1}, which characterizes the coordination mode of the phenolic oxygen in Schiff base complexes, was split into two bands separated by about 15 cm^{-1} (Table 1). This indicates that there are both the terminal and bridged coordination of the phenolic oxygens in complexes **1**—**4**.[5] For complexes **5**—**7** a relatively sharp weak band was observed at 3560—3570 cm^{-1}, which is assigned to the OH stretchings of a coordinated water from the position and shape of the band.

The magnetic moments of complexes **1**—**4** are 2.83—2.88 BM at 295 K and 2.10—2.25 BM at 80 K. The

a) sh = Shoulder.

value at 80 K is greatly less than the spin-only value, 2.83 BM. The temperature dependence of magnetic susceptibility of complex **1** is shown in Fig. 1 as a representative. The magnetic susceptibilities of complexes **1**—**4** obey the Curie-Weiss law over the temperature range of 150—300 K, but deviate in the temperature range of 80—100 K. The Weiss constants show negative large values (Table 1). It is likely that there is a strong antiferromagnetic interaction between nickel(II) ions in the complexes. These facts suggest that in the conformation around the bridging phenolic oxygen in the complexes, the phenolic C–O bond is coplanar with the two bridged nickel(II) ions.[6] The Schiff bases in the complexes seem to function as a quinquedentate ligand, because the analogous quadridentate Schiff bases[7] form nickel(II) complexes with a structure different from that of the present complexes. All the results shown above suggest that complexes **1**—**4** have a binuclear structure bridged by the phenolic oxygen.

On the other hand, complexes **5**—**7** show the magnetic moment value of 3.14—3.15 BM, which falls within the range usually found for octahedral mononuclear nickel(II) complexes. Their magnetic susceptibilities obey the Curie-Weiss law with very small values of the Weiss constant (θ=0—3 K) over the temperature range of 80—300 K. These results indicate that complexes **5**—**7** are magnetically diluted. It is thus probable that complexes **5**—**7** have an octahedral mononuclear structure in which the Schiff bases function as a quinquedentate ligand to form a six-coordination of the nickel(II) ion together with a molecule of water.

Ylide-Metal Complexes. VI.[1] The Preparation and Properties of IVA-group Metal (Ge, Sn, Pb) Complexes of Alkylidenetriphenylphosphoranes

Yoshihisa YAMAMOTO

Faculty of Pharmaceutical Sciences, Higashi Nippon Gakuen University, Ishikari-Tobetsu, Hokkaido 061-02

(Received December 26, 1981)

Synopsis. (Triphenylphosphonium alkylide)triphenylmetal chloride $[(C_6H_5)_3\overset{+}{P}CHR\text{-}M(C_6H_5)_3]Cl^-$ (R: H, Me, *i*-pr; M: Ge, Sn, Pb) and (triphenylphosphonium alkylide)metal chloride $[(C_6H_5)_3\overset{+}{P}CHR]_nMCl_n^-$, (M=Ge, n=4; M=Pb, n=2) have been isolated from a reaction mixture of alkylidenetriphenylphosphoranes and IVA-group metal compounds. The ylide in $[(C_6H_5)_3\overset{+}{P}CH_2\text{-}Pb(C_6H_5)_3]Cl^-$ is bonded to the lead atom through the carbanionic donor atom.

In this series, previous papers have been concerned with IB-group metal (Cu, Ag, Au) complexes[2,3] and IIB-group metal[4] (Zn, Cd, Hg) complexes of alkylidenetriphenylphosphoranes. The complexes of alkylidenetriphenylphosphorane $(C_6H_5)_3P{=}CH\text{-}R$ (R: H, Me, *i*-pr) and IVA-group metal (Ge, Sn, Pb) have, however, been the subject of little research, except for the germanium and tin complexes[5] with methylenetriphenylphosphorane (R=H). The present paper deals with the preparation and properties of IVA-group metal complexes of alkylidenetriphenylphosphoranes. Their properties are compared with those of IB-group metal[2,3] and IIB-group metal[4] complexes of those ylides.

Results and Discussion

(Triphenylphosphonium alkylide)triphenyl IVA-group metal complexes (**1a**, **2a**—**c**, and **3a**—**c**) have been isolated from a reaction mixture of alkylidenetriphenylphosphorane (methylene, **La**; ethylidene, **Lb**; and isobutylidene, **Lc**) and triphenylmetal chloride, $(C_6H_5)_3MCl$ (M: Ge, Sn, and Pb).

$$(C_6H_5)_3P{=}\overset{R}{\underset{|}{C}}H + (C_6H_5)_3MCl \longrightarrow [(C_6H_5)_3\overset{+}{P}\overset{R}{\underset{|}{C}}H\text{-}M(C_6H_5)_3]Cl^-$$

No	La	Lb	Lc
R	H	CH_3	$CH(CH_3)_2$
	Yellow	Orange	Red

No	1a	2a	2b	2c	3a	3b	3c
M	Ge	Sn	Sn	Sn	Pb	Pb	Pb
R	H	H	Me	*i*-pr	H	Me	*i*-pr

The **3a** is stable in dichloromethane, but it is unstable in chloroform.

The ^{1}H-NMR spectrum of the **3a** showed a doublet signal for CH_2P at 2.68 ppm and a multiplet signal for phenyl groups at around 7.5 ppm in a ratio of 2:15 at −60 °C in dichloromethane-d_2. The coupling constant (J_{HCP}) of the **3a** was 13.5 Hz, which was larger than that (7.5 Hz) of the **La**. The chemical shift of **3a** was at a lower field than that (δCH_2P: 0.13 ppm)[6] of **La**. These spectral properties were similar to those of the $[(C_6H_5)_3\overset{+}{P}\overset{R}{\underset{|}{C}}H\text{-}M\text{-}\overset{R}{\underset{|}{C}}H\overset{+}{P}(C_6H_5)_3]Cl_n$ (**4**) (M: IB-group metal,[2,3] IIB-group metal,[4] R: H; n=1, 2), so the ylide is bonded to the lead atom through the carbanionic donor atom.

Other complexes **1a**, **2a**—**c**, and **3b**—**c** are unstable in dichloromethane or chloroform at −60 °C, and ^{1}H NMR spectra of these complexes were not obtained. In both solvents, they are changed to the alkyltriphenylphosphonium chloride, $[(C_6H_5)_3\overset{+}{P}CH_2\text{-}R]Cl^-$ (**5**) (R: H (**5a**), Me (**5b**), *i*-pr (**5c**)). Their melting points or decomposition temperatures are not those of ylides, triphenylmetal chloride or salts **5**. Their color is white and they are thermally stable in the solid state. These properties resemble those of **4** (R: Me, *i*-pr),[2-4] and the ylides seem to be bonded to the metal atom in the solid state. The lability of **3b** and **3c** compared with **3a** complex can be ascribed to the difference in the carbanionic donor character of ylides.

Other types of ylide IVA-group metal chlorides (**6a**—**c** and **7a**—**b**) have been isolated from the reaction mixture of the $GeCl_4$ or $PbCl_2$ with the ylides (**La**—**c**). They are unstable in dichloromethane or chloroform at −60 °C and changed to the corresponding phosphonium salts (**5a**—**c**); therefore, their structures are still uncertain.

$$n(C_6H_5)_3P{=}\overset{R}{\underset{|}{C}}H \xrightarrow{MCl_{4(2)}} [(C_6H_5)_3\overset{+}{P}\overset{R}{\underset{|}{C}}H]_nMCl_{4(2)}$$

The **1a**, **2a**, **6a**, and **7a** complexes are unstable compared with **4** (R=H), *i.e.*, the Cu, Ag, Au, Zn and Cd complexes of **La** are stable at −60 °C. Germanium complexes of **1a** and **6a**—**c** are highly hygroscopic.

Experimental

Measurements. The ^{1}H NMR spectra were measured with an R-40 (Hitachi) spectrometer.

The reaction mole ratio of the ylides and the metal compounds, the melting point, the reaction time and analytical data of complexes are collected in Table 1. The precipitated white complexes are stable in dry THF at r.t. They are soluble in dichloromethane or chloroform and are insoluble in other common organic solvents.

Preparation of Complexes. *(Triphenylphosphonium methylide)triphenyllead Chloride (**3a**)*: Triphenyllead chloride (0.69 g, 1.46 mmol) was added to a dry THF (15 cm^3) solution of triphenylmethylenephosphorane (**La**) (0.46 g, 1.66 mmol) at r.t. under nitrogen. The mixture was stirred for 12 h; then the precipitated white complex was filtered under nitrogen, washed with dry ether and dried under vacuum.

*(Triphenylphosphonium alkylide)triphenylgermanium (**1a**), -tin (**2a**—**c**), and -lead (**3b**, **3c**) Chloride*: These complexes were prepared according to the procedure for **3a**.

*Tetra(triphenylphosphonium methylide)germanium Tetrachloride (**6a**)*: Tetrachlorogermanium (0.066 g, 0.308 mmol) was added to the dry THF (15 cm^3) solution of **La** (0.34 g, 1.23 mmol) at r.t. under nitrogen. The mixture was stirred, and the color of **La** changed from yellow to colorless, after 12 h, the white complex which precipitated was filtered under nitrogen, washed with dry ether, and dried under vaccum.

*Di(triphenylphosphonium ethylide)germanium Tetrachloride (**6b**), Tri(triphenylphosphonium isobutylide)germanium Tetrachloride (**6c**), Di(triphenylphosphonium methylide)lead Dichloride (**7a**), and Di(triphenylphosphonium ethylide)lead Dichloride (**7b**)*: These complexes were prepared according to the procedure for **6a**.

(Received January 26, 1982)

Synopsis. Copper(II) complexes of Schiff bases derived from histamine or 2-(2-aminoethyl)pyridine and 2,3-butanedione or 4-hydroxy-4-methyl-2-pentanone were prepared and characterized by elemental analyses, electronic and ESR spectra, and polarographic half-wave potentials. The relationship between structure of the chelates and the reduction potentials of copper(II) in these complexes was discussed in some detail.

A number of investigations have been carried out for the metal complexes with histidine, histamine, and their related ligands, since the histidine imidazole in metal-containing protein is one of the most important binding sites for metal ions in biological systems.[1] In connection with hemocyanin models, Simmons *et al.*[2] have synthesized copper(I) and copper(II) complexes of Schiff bases derived from 2,6-diacetylpyridine and histamine or 2-(2-aminoethyl)pyridine. We have also prepared four copper(II) complexes (**1**—**4**) of Schiff bases produced from histamine or 2-(2-aminoethyl)-pyridine and 2,3-butanedione or 4-hydroxy-4-methyl-2-pentanone, and studied electronic, ESR and electrochemical properties of these complexes for the purpose of elucidating the relationship between the structure of the chelates and the trends toward the formation of copper(I) species from the parent copper-(II) complexes, **1**—**4**.

Experimental

Preparation of the Complexes. *[Cu(Hist=dia=Hist)](ClO$_4$)$_2$*,** ***1***: A mixture of 0.22 g (2.5 mmol) of 2,3-butanedione and 0.56 g (5.0 mmol) of histamine was dissolved in 40 cm^3 of methanol. The mixture was heated under reflux for 2 h. To this was added 0.96 g (2.5 mmol) of copper(II) perchlorate hexahydrate, and the resulting solution was refluxed again for 1 h. After it had been filtered, the filtrate was cooled to give dark violet crystals. Found: C, 30.29; H, 3.98; N, 14.47%. Calcd for [Cu($C_{14}H_{20}N_6$)]-(ClO_4)$_2$·1.5H_2O: C, 29.93; H, 4.13; N, 14.96%.

[Cu(2-Aep=dia=2-Aep)](ClO$_4$)$_2$,** ***2***: This complex was prepared by the same method as described for **1** using 2-(2-aminoethyl)pyridine instead of histamine. Found: C, 38.78; H, 3.91; N, 10.63%. Calcd for [Cu($C_{18}H_{22}N_4$)]-(ClO_4)$_2$: C, 38.82; H, 3.99; N, 10.06%.

[Cu(Hist=daa-Hist)](ClO$_4$)$_2$,*** ***3***: A mixture of 0.56 g (5.0 mmol) of histamine and 0.14 g (2.5 mmol) of sodium methoxide was dissolved in 50 cm^3 of acetone, being refluxed for 2 h. To this was added 0.96 g (2.5 mmol) of copper(II) perchlorate hexahydrate, and the resulting solution was heated again under reflux for 2 h. After it had been filtered, the filtrate was allowed to evaporate slowly. Dark blue crystalline products were deposited, being washed with acetone. Found: C, 32.19; H, 4.41; N, 14.13%. Calcd for [Cu($C_{16}H_{26}N_6$)](ClO_4)$_2$·1.5H_2O: C, 32.46; H, 4.95; N, 14.20%.

[Cu(2-Aep=daa-2-Aep)](ClO$_4$)$_2$,*** ***4***: This complex was prepared by the similar method as described for **3**. Found: C, 40.50; H, 4.74; N, 9.57%. Calcd for [Cu-($C_{20}H_{28}N_4$)](ClO_4)$_2$·0.5H_2O: C, 40.30; H, 4.91; N, 9.40%.

[Ni(Hist=dia=Hist)](ClO$_4$)$_2$. This was prepared by the same way as described for the corresponding copper(II) complex, **1**. Found: C, 31.08; H, 4.11; N, 15.56%. Calcd for [Ni($C_{14}H_{20}N_6$)](ClO_4)$_2$·0.5H_2O: C, 31.19; H, 3.93; N, 15.59%.

Measurements. IR spectra were recorded with a Hitachi EPI-2 Infrared spectrophotometer by employing the KBr-disk method, visible absorption spectra with a Hitachi 200—10 double beam spectrophotometer. Polarographic measurements were made with a Yanagimoto Polarograph P 8. Water was used as a solvent. Concentration of the copper(II) complexes used was 10^{-3} mol dm^{-3} and the supporting electrolyte used was 0.1 mol dm^{-3} KNO_3. Triton X-100 (0.002%) was employed as a maximum suppressor. The ESR spectra were measured at 77 K on a JEOL-FX-1 X-band ESR spectrometer modulated at 100 kHz. Water containing a small quantity of ethylene glycol was used as a solvent.

** Ligands, Hist=dia=Hist and 2-Aep=dia=2-Aep, represent Schiff bases derived from histamine and 2,3-butanedione, and 2-(2-aminoethyl)pyridine and 2,3-butanedione, respectively.

*** Ligands, Hist=daa-Hist and 2-Aep=daa-2-Aep, represent Schiff bases derived from histamine and 4-hydroxy-4-methyl-2-pentanone, and 2-(2-aminoethyl)pyridine and 4-hydroxy-4-methyl-2-pentanone, respectively.

a) Solvent: H_2O–DMSO (1:1).

Results and Discussion

Copper(II) complex **1** of the Schiff base derived from histamine and 2,3-butanedione had been obtained as greenish oily product by Kovacs and Shepherd.[3] In this work, we isolated the same complex as a dark violet crystal, to which the structural formula **1** was assigned on the basis of elemental analysis and IR spectral data (1620 cm^{-1} (C=N), $\approx$1100 cm^{-1} (ClO_4)). The corresponding complex **2** of the Schiff base containing 2-(2-aminoethyl)pyridine as amino compound and the complexes, **3** and **4** of Schiff bases derived from histamine or 2-(2-aminoethyl)pyridine and 4-hydroxy-4-methyl-2-pentanone were also isolated as blue-violet crystals. The absorption maxima for the d-d transition band, the half-wave potentials for the reduction of copper(II) at the dropping mercury electrode, and ESR parameters of these complexes are listed in Table 1. The ESR data clearly show that the $A_{//}$ values of complexes **1** and **2** are greater than those of complexes **3** and **4**, respectively, and that the $g_{//}$ values for these complexes decrease in the orders 3>1 and 4>2. The $A_{//}$ values for **1** and **2** with 6—5—6 fused ring structure are remarkably large, indicating that the coordination geometry around copper(II) ion is square-planar. On the other hand, complexes **3** and **4** with 6—6—6 fused-chelate-ring display the increasing trend towards the tetrahedral distortion.[4–6] The above conclusion is also supported by some other facts. The nickel(II) complex produced from histamine and 2,3-butanedione was isolated as yellowish brown crystals, whereas the attempts to obtain the nickel(II) complex of the Schiff base from histamine and 4-hydroxy-4-methyl-2-pentanone were unsuccessful. In the latter case the color of the reaction mixture did not even change from light green to yellowish brown which is characteristic of square-planar nickel(II) complexes. As shown in Table 1, the half-wave potential for the reduction of Cu(II) to Cu(I) is more negative in **1** than in **3**. In addition, the d-d absorption band of these complexes was observed at a shorter wavelength in **1** than in **3**. The geometrical difference between complexes **1** and **3** may be reflected by the differences observed in their λ_{max} and $(E_{1/2})_1$ values. The same trend is also observed in the comparison of **2** and **4**. It can be considered that the distortion towards a tetrahedral geometry is necessary for stabilizing the copper(I) state. Further the numerical data in Table 1 indicate that if the carbonyl moiety of the Schiff base is same, the half-wave potentials of the copper(II) complexes are more positive with 2-(2-aminoethyl)pyridine than with histamine. This is consistent with the result obtained through a comparison of $[Cu(pyep)]^{2+}$ and $[Cu(imep)]^{2+}$ as reported by Simmons *et al.*[2,7]

All attempts for preparing the copper(II) complexes of Schiff bases obtained from histamine or 2-(2-aminoethyl)pyridine with 2,5-hexanedione resulted in failure, producing only red-brown powder which could not be characterized as simple compound of definite composition. Further studies of these complexes are now under way.

We thank Mr. K. Hashimoto for technical assistance.

Apparent Extinction Coefficient for a Scanning Photosedimentometer

Junichi TAKAHASHI* and Akinori MUTA
Department of Inorganic Materials, Nagoya Institute of Technology, Gokiso-cho, Showa-ku, Nagoya 466
(Received February 6, 1982)

Synopsis. Particle-size distributions of subdivided samples were analyzed independently with electron microscopy and a scanning photosedimentometer. Apparent extinction coefficient for the optical scanning system was estimated by the comparative examination of the distributions.

In light transmission methods for particle-size distribution analysis, the effect of the extinction coefficient, which is defined as the effective particle cross section divided by its geometric cross section, must be taken into account when a sample under examination contains particles of a size comparable to the wavelength of the incident light. It has been confirmed by Rose[1] that, at any given particle diameter, an increasing solid angle was associated with a decreasing value of extinction coefficient, and for a solid angle of about 10°, deviations from unity in the value of the extinction coefficient were small at particle diameter larger than 3 μm. Therefore it was expected that significant errors as seen in the theoretical treatment of light-scanning properties of fine particles might be eliminated in the determination of particle-size distribution using an apparatus with white light and a large solid angle.

A scanning photosedimentometer has been developed by Muta and co-workers.[2,3] In this optical scanning system, a white light beam can be moved up and down by a specially-designed cam through the sedimentation tank in which steady-state settling conditions have been achieved. The cam has been designed so that the analyst can calculate the particle-size distribution of a sample from the graph of optical density versus square root of depth of the sedimentation tank, which can be easily converted to particle diameter using Stokes equation, in a simple manner. Thus a single quick continuous scan of the concentration gradient set up in the sedimentation tank gives enough information to enable the analyst to establish the particle-size distribution. This apparatus (*PSA*-2) is also characterized by a large solid angle subtended by the photo-sensitive receiver. Few data, however, are available on the examination of particle-size distribution by *PSA*-2 for a sample containing a number of fine particles.[4] Hence an attempt was made in this work to represent that the size distribution estimated using *PSA*-2 for a sample consisting of very small particles could be accepted without any special correction.

For particles with sizes ranging from d_1 to d_2, the energy removed from the forward beam by the particles is related to their cross-sectional area as follows:

$$S_m = \frac{1}{K_m C}(\log I_1 - \log I_2), \quad (1)$$

where S_m is the total cross-sectional area of the particles, I_1 and I_2 is the intensity of transmitted light for each particle of size d_1 and d_2, respectively, C is a constant, and K_m is the extinction coefficient for the particles. Thus the apparent extinction coefficient for *PSA*-2 could be evaluated by comparing the cross-sectional area analyzed independently with both *PSA*-2 and electron microscopy for subdivided samples. The solid material used in this study was Kanto loam JIS 11. Suspensions of the material were prepared by dispersing uniformly a definite amount of the powder in distilled water containing 0.1 wt% sodium *cyclo*-hexaphosphate as a dispersing agent. The original particle-size distribution of Kanto loam JIS 11 was evaluated by electron microscopy. The direct images of deposited particles on electron microscope grids covered with specimen support collodion film were observed with a transmission electrom microscope. The raw data obtained by examining about 3000 particles in electron micrographs were collected in the form of a number distribution and converted to a surface distribution. In Fig. 1 the percentage of particles per micrometer, $d\phi/dD$, is plotted against the projected area diameter which is the diameter of a circle having the same area as the particle. The distribution curve in Fig. 1 indicates that the sample is composed of fine particles smaller than 7 μm with a narrow-ranged size distribution. For the estimation of the apparent extinction coefficient for *PSA*-2, suspensions with the powder concentration of 0.05 vol% were subdivided into several portions, in which particle size ranged as narrow as possible, by a centrifugal withdrawal method described below.

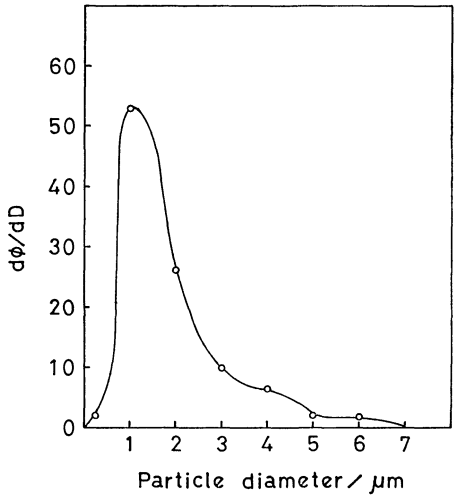

Fig. 1. The relative percentage frequency distribution of the original sample.

For a homogeneous suspension, a particle in a centrifugal field theoretically settles according to the equation,[5]

$$S = R\exp(-kD^2t) \quad k = \frac{\rho_s - \rho_f}{18\eta}\omega^2, \quad (2)$$

where t is the time for a particle of size D and density

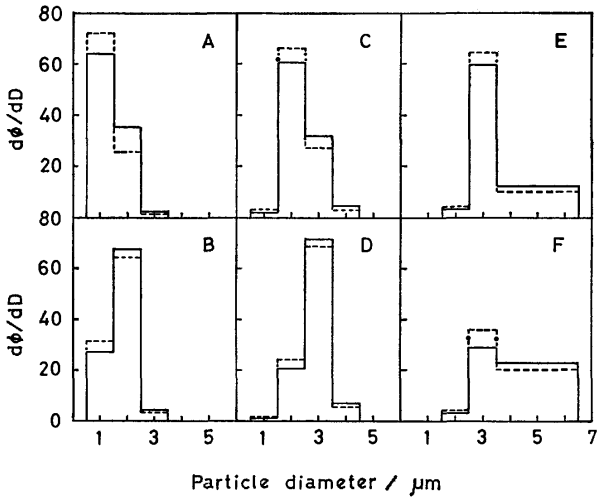

Fig. 2. The particle-size distribution of subdivided samples analyzed independently by *PSA*-2(——) and electron microscopy (----).

ρ_s to settle from the surface of the liquid with density ρ_f and viscosity η at distance S to the bottom of the tube at distance R, both S and R being distances from the axis of the centrifuge rotating at ω in radians per second. After t seconds, all particles greater than D will have settled out to the bottom of the tube with simultaneous partial sedimentation of all particles smaller than D. For each of these smaller sizes, Eq. 2 may be rewritten:

$$x_0 = R\exp(-kD^2t), \tag{3}$$

where x_0 is a starting point beyond which all the smaller particles will have reached R. The volume fraction of the suspension lying between R and x_0 for a cylindrical tube is equal to

$$\frac{R-x_0}{R-S} = \frac{R}{R-S}\{1-\exp(-kD^2t)\}. \tag{4}$$

Firstly, particles smaller than 0.5 μm were removed from the original samples because the presence of these particles yielded experimental errors due to the breakdown in the laws of geometric optics in the submicrometer particle-size range. This was carried out by repeated withdrawals of a definite amount of suspension from a cylindrical tube after centrifugal sedimentation. Electron microscopic observation of the residue after the operation indicated that it contained small amounts of submicron particles, which led to a negligible disturbance in the results obtained in the present study.

Experimental operations necessary for the subdivision of the sample into several portions with different size ranges were determined using Eqs. 2—4. To avoid an agglomeration of particles caused by centrifugal force, suspension of particles which remained at the bottom of the tube after a single withdrawal were placed in the ultrasonic bath prior to a subsequent centrifugal sedimentation. In the series of centrifugal withdrawal experiments, particle-size distribution of withdrawn portions or remaining portions was roughly checked with *PSA*-2, whenever required. Consequently, suspensions with the intended particle-size range, which were required for the estimation of the apparent extinction coefficient for *PSA*-2, were prepared by subdividing the original sample and mixing the subdivided samples up to a fixed particle concentration suitable for size distribution analysis.

Dristributions of the narrowly classified particles were measured using *PSA*-2 for the samples prepared by the procedure mentioned above. Fractional intensities of transmitted light for each sample are plotted against particle diameter in Fig. 2. An independent analysis by electron microscopy of the same sample was made and fractional projected areas of each sample are also included in Fig. 2. Now let the fractional intensity be dI_1, dI_2, dI_3, dI_5, fractional projected area dS_1, dS_2, dS_3, dS_5, and apparent extinction coefficient K_1, K_2, K_3, K_5, where each subscript indicates the corresponding particle diameter. Then from Eq. 1, both measured quantities can be correlated with each other using the apparent extinction coefficient. For instance, from sample A shown in Fig. 2,

$$dI_1 = \frac{K_1dS_1}{K_1dS_1+K_2dS_2+K_3dS_3}$$

$$dI_2 = \frac{K_2dS_2}{K_1dS_1+K_2dS_2+K_3dS_3},$$

and $K_1(dS_1/dI_1)=K_2(dS_2/dI_2)$, hence $K_1/K_2=(dI_1/dI_2\cdot dS_2/dS_1)$. In this way, the relative extinction coefficient of K_1/K_2, K_2/K_3, and K_3/K_5 was calculated from samples A and B, C and D, E and F, respectively, being $K_1/K_2=0.72$, $K_2/K_3=0.80$, and $K_3/K_5=0.75$.

On the basis of the result reported by Rose[1] for the solid angle subtended by the photo-cell of about 10° and that by Muta[2] on the comparative examination of particle-size distribution for several powders, the extinction coefficient for particles ranging from 4 to 6 μm, K_5, was assumed to be 1.3. Therefore the apparent extinction coefficients were evaluated, in turn, as $K_3=1.0$, $K_2=0.8$, and $K_1=0.6$. This result suggests that particle-size distribution of powder with a minimum size of about 1 μm could be accurately analyzed by the scanning photosedimentometer, *PSA*-2, without any substantial error.

Direct Preparation of θ-Zirconium Phosphate

Tsuyoshi KIJIMA

National Institute for Research in Inorganic Materials, Sakura-mura, Niihari-gun, Ibaraki 305

(Received February 17, 1982)

Synopsis The effects of temperature and Zr concentration in solution on the composition and degree of crystallinity of zirconium phosphate have been examined. Pure θ-zirconium phosphate with an interlayer spacing of 10.4 Å has been prepared by direct precipitation.

Cations having a large ionic radius, such as Cs^+, Ba^{2+}, hydrated Mg^{2+} *etc.*, are not, or only slowly, exchanged by α-zirconium phosphate (α-ZrP) $Zr(HPO_4)_2 \cdot H_2O$, owing to the small interlayer spacing (7.6 Å) of this exchanger.[1,2] These cations, however, can be easily exchanged by the highly hydrated form of α-ZrP with an interlayer spacing of 10.4 Å,[3] which was reported as $Zr(HPO_4)_2 \cdot 8H_2O$ and labeled θ-ZrP.[2,4] This ion exchange characteristics of θ-ZrP is noteworthy since it enlarges the practical use of crystalline zirconium phosphate as an ion exchanger. Conventionally, θ-ZrP is obtained by regenerating suitable salt forms of α-ZrP with HCl solution.[3] In this case the phase can be prepared in a pure form only when the starting α-ZrP has a good but not too high degree of crystallinity. A recent paper[5] reported that the methanol intercalate of α-ZrP obtained from the salt form of the exchanger is washed with water to give rise to θ-ZrP. However, both methods are not simple in procedure since they include ion exchange (or intercalation) and regeneration processes.

The composition and degree of crystallinity of solution-grown zirconium phosphate are strongly dependent on the preparation conditions, such as temperature, digestion time, concentrations of solutes, stirring time *etc.* In this study the effects of some of these factors were examined to prepare θ-ZrP directly from solution.

Experimental

Several ZrP samples were prepared as follows. In all runs, the concentration of phosphoric acid solution was held constant at 6 mol dm^{-3} since it was suggested by Clearfield *et al.*[6] that an excess of phosphoric acid as precipitant is available for the growth of ZrP crystals. One volume aliquots of $ZrOCl_2$ aqueous solution at various concentrations were added dropwise to one volume of the phosphate solution at different temperatures with stirring and the reaction mixtures were kept for 48 h at those temperatures while being stirred. The resulting precipitates were filtered and washed with distilled water. X-Ray diffraction patterns were taken on the wet samples obtained.

Results and Discussion

Table 1 shows the composition and degree of crystallinity of the various products obtained under different experimental conditions. The approximate phase composition was estimated by the relative intensity of the peaks at 10.4 and 7.6 Å as in a previous report.[3] When the concentration of the starting $ZrOCl_2$ solution is fixed at 2 mol dm^{-3}, the refluxed product is α-ZrP, while at 94 °C a mixture of the α and θ phases is precipitated. For samples prepared at 94 °C, as the concentration of the $ZrOCl_2$ solution is decreased, the percentage of θ-ZrP increases until at 0.05 mol dm^{-3} 100% of θ-ZrP with high degree of crystallinity is obtained. When 0.05 mol dm^{-3} $ZrOCl_2$ solution is used, the samples obtained at below 94 °C are formed of θ-ZrP, whose degree of crystallinity increases with an increase of the precipitation temperature, while at boiling temperature the θ and α phases are coprecipitated.

From these results the effects of concentration and temperature on the crystallization of θ-ZrP are summarized as follows. (1) The increase in solute concentration makes the θ phase unstable. (2) The crystallization of θ-ZrP is promoted by increasing the precipitation temperature but at near boiling temperature the θ phase is less stabilized. (3) The optimum Zr concentration and temperature for the preparation of pure and highly crystalline θ-ZrP are determined by a combination of these two effects. The Zr concentration of 0.05 mol dm^{-3} and digestion temperature of 94 °C for the use of 6 mol dm^{-3} H_3PO_4 solution and

Table 1. Preparation conditions of ZrP samples and their characterization[a]

0.05	6	60	100	0	L

a) Digestion time, 48 h. b) H, high; M, medium; L, low.

48-h digestion time can be taken to meet this optimum condition satisfactorily. Longer times for digestion will contribute to further increase in the degree of crystallinity of the θ-ZrP.

The preferred formation of θ-ZrP in dilute solution and/or at moderate but not too high temperatures could be explained in terms of the type of hydration in this phase. In the monohydrated phase, α-ZrP, the water molecules are located midway between any two POH sites on the interlayer surface and tightly held by bifurcated hydrogen bonds.[7] Therefore, this type of hydrate bonding is likely to be thermally stable and it also contributes to the increase of only 0.2 Å in the interlayer spacing over that of the anhydrous form of α-ZrP which is called ζ-ZrP.[8] The remaining moles of water in this phase, on the other hand, would be located within the interlayer space and weakly held by hydrogen bonding to free hydrogen atoms of the water molecules covering the layer surface. It is therefore apparent that only in very dilute and/or moderately hot solution θ-ZrP with such unstable interlayer water would be formed in preference to α-ZrP.

The interlayer spacing of θ-ZrP is increased by 2.8 Å over that of α-ZrP. By using a value of 24.3 Å^2 for the occupied area per POH site in α-ZrP[2,9] and about 14 Å^3 for the van der Waals volume of the water molecule,[10] the water content in a mole of θ-ZrP can be evaluated to be 1 plus $24.3 \times 2.8/14$ or 5.9. This value is less than the value of 8 water molecules earlier reported[2,4] but agrees well with a value of 6 ± 1 water molecules observed by Alberti *et al.*[3] It is therefore more reasonable to conclude that θ-ZrP is formed as a hexahydrate $Zr(HPO_4)_2 \cdot 6H_2O$. A similar calculation for another highly hydrated phase which has an interlayer spacing of 11.5 Å and composition $Zr(HPO_4)_2 \cdot 8 \pm 1H_2O$[3] yield a value of 7.8 water molecules, which is in good agreement with the observed value.

The author thanks Dr. M. Goto and Dr. S. Ueno for encouragement during this work.

An Ultrasonic Nebulizer for Microliter Samples in Inductively Coupled Plasma Emission Spectrometry

Hiroshi KAWAGUCHI,* Tomokazu TANAKA, and Atsushi MIZUIKE
Faculty of Engineering, Nagoya University, Furo-cho, Chikusa-ku, Nagoya 464

(Received March 8, 1982)

Synopsis. A batch type ultrasonic nebulizer is constructed for 300-μl samples to produce an aerosol for more than 60 s. Desolvation facilities are not used. The internal standard method is employed to compensate for the instability of nebulization.

The most common method for introducing samples into an inductively coupled plasma (ICP) is the pneumatic nebulization of aqueous or organic solutions. Although ultrasonic nebulizers were extensively used in the early stage of the development of the ICP,[1,2] they were gradually replaced by pneumatic nebulizers mainly due to cumbersome operation procedures in conjunction with desolvation apparatus. Olson *et al.*[3] reported an ultrasonic nebulizer which provided rapid and convenient sample change capability and a long term stability but it is still not widely accepted.

Recently considerable attention has been paid to the microliter sample injection into the ICP by conventional pneumatic nebulization[4,5] or electrothermal vaporization.[6,7] Ultrasonic nebulizers are inherently suited for the nebulization of microliter samples because they can nebulize solutions quite efficiently. Though many types of ultrasonic nebulizers have been reported in the literature,[8–12] none of them were particularly intended to be used for microliter samples. Hoare and Mostyn[8] designed a multicell ultrasonic system in which each sample cell could be rotated in turn to locate in the focussed ultrasonic beam, but they did not mention explicitly the sample size required.

We have constructed a batch type ultrasonic nebulizer with easily exchangeable cells for microliter samples. Simultaneous multielement analysis can be performed with a conventional signal integrator without modification by using 300-μl sample solutions.

Experimental

Apparatus. A Shimadzu 1-m grating spectrometer (GE-100) equipped with a three-channel detector unit (M-4),[5] a three-channel integrator (ES-603) and a 27 MHz ICP generator (ICPS-2H) were used. The entrance and exit slitwidths of the spectrometer were set to 20 and 40 μm, respectively. The ICP was operated at a forward power of 1.2 kW and argon flow-rates of 10, 1.0 and 0.8 l min^{-1} were used for the outer, intermediate and carrier gas, respectively.

Ultrasonic Nebulizer (Fig. 1). An ultrasonic transducer for a household electronic humidifier (Mitsubishi Electric Co.) mounted at the bottom of the cooling water chamber was driven by a 1.72 MHz transistor oscillator. The sample cell was a glass tube (11.5 mm i.d., 25 mm long) with a thin bottom plate (0.15 mm thick microscope cover glass, stuck with an epoxy resin adhesive). Two sample cells were mounted in a sliding cell holder so that they were rapidly exchanged without disturbing the nebulization. A polyethylene buffle made of a sealing cap of a reagent bottle was placed on the top of the cell to prevent large aerosol droplets from reaching the fog chamber. Carrier gas was introduced tangentially at the top of the cell so that the aerosol produced was effectively mixed with the carrier gas. Both the top plate of the sliding cell holder and the cooling water chamber were made of Teflon to make the holder slide smoothly without a leak of cooling water. A 35-ml fog chamber was designed so that the condensed aerosol would not flow into the sample cell and contaminate a new sample. The aerosol was introduced into the ICP without any desolvation facilities.

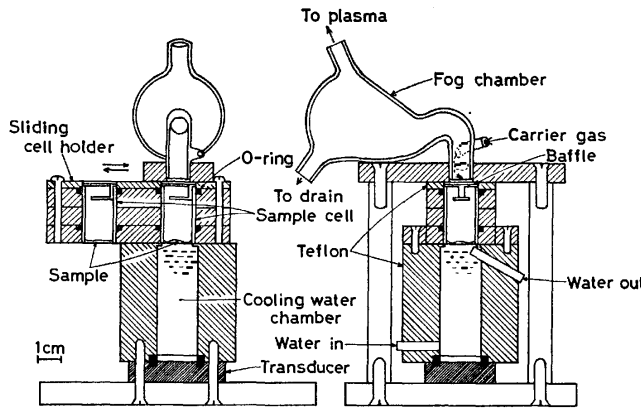

Fig. 1. Schematic diagram of the ultrasonic nebulizer for microliter samples.

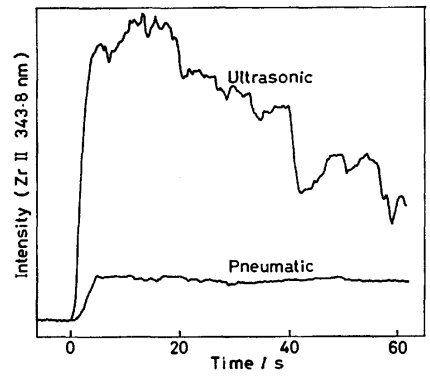

Fig. 2. Intensity-time curves for the Zr II 343.8 nm line.
The same intensity scale for the ultrasonic and pneumatic nebulizers. Zr: 1 μg ml^{-1}.

Solution. Standard solutions were prepared by dissolving reagent-grade salts or pure metals in appropriate mineral acids and diluting with water immediately before use.

Results and Discussion

Sample Volume. As the volume of the sample solutions in the cell was increased from 0 to 500 μl, the emission signals increased at first and then gradually decreased, with the maximum at about 300 μl, where the experiments hereafter were carried out.

Intensity-time Curves. Figure 2 shows intensity-time curves for the Zr II 343.8 nm line (1 μg Zr ml^{-1}) obtained with the present ultrasonic nebulizer and with a conventional pneumatic (concentric glass) nebulizer. In spite of the much smaller consumption of sample,

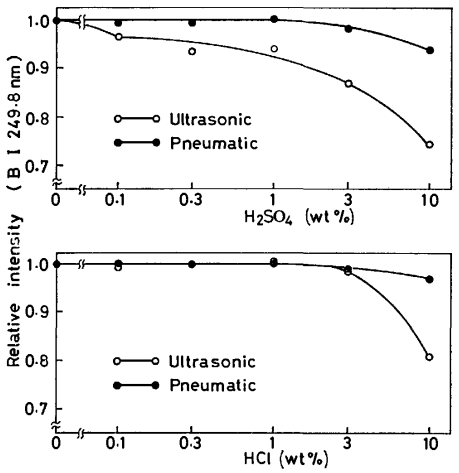

Fig. 3. Effects of acid concentrations on the intensity of the 249.8 nm line.
B: 10 μg ml^{-1}.

the signal intensity with the ultrasonic nebulizer is several times higher than that with the pneumatic nebulizer. The aerosol is produced for more than 60 s, so that a conventional signal integrator can be used without modification. Variation of the signal with time, however, is quite large as compared with that of the pneumatic nebulizer. Although various configurations of the fog chamber and sample cell were tried, the signal stability could not be improved.

Effect of Acid Concentrations. Generally the efficiency of the pneumatic nebulizer is known to be affected by acid concentrations[13] due to the variation of the viscosity of the solutions. The effects of sulfuric and hydrochloric acid concentrations on the emission intensity of the B I 249.8 nm line (10 μg B ml^{-1}) are shown in Fig. 3 for ultrasonic and pneumatic nebulizers. The efficiency of the ultrasonic nebulizer is affected more seriously than that of the pneumatic nebulizer by acid concentration.

Internal Standard Method. The instability of nebulization can be compensated to some extent by adopting the internal standard method. Though this method has not generally been applied in ICP emission spectrometry, it sometimes improves the precision of the analysis.[14] Yttrium was added as internal standard to the sample solutions and intensity-time curves of lines of various elements were compared with those of yttrium lines. The intensity-time curves of all the lines examined strikingly resembled each other irrespective of the excitation characteristics of the lines. Table 1 shows the relative standard deviations of intensities of various elements and those of ratios to the yttrium line intensities. In these experiments, each sample was nebulized for 10 s before the signal integration for 20 s. The determination was repeated 10 times for each sample. The use of the internal standard method reduced the relative standard deviation to less than 2%. The precision, however, is strongly dependent on the concentration level of the material being analyzed since the background fluctuation is not compensated by the internal standard method. Variation of the relative standard deviations with the change of titanium concentrations are shown in Table 2. The relative standard deviation of the intensity ratio increases rapidly below 0.1 μg ml^{-1} of titanium. Thus the detection limits cannot be improved.

Table 1. Relative standard deviations (RSD) of intensities and intensity ratios

Element	Wavelength nm	Concentration μg ml^{-1}	RSD (%) Intensity	RSD (%) Intensity ratio[a]
B I	249.77	5	6.6	1.8

a) Internal standard: 10 μgY ml^{-1}, Y II 371.03 nm for Cu, Ti and Zr, and Y II 224.31 nm for other elements.

Table 2. Relative standard deviation of intensity ratios at different titanium concentrations

Ti (μg ml^{-1})	RSD (%) Intensity[a]	RSD (%) Intensity ratio[b]
0	2.22	14.0
0.01	1.89	13.9
0.1	2.16	6.98
1	9.04	1.59
10	11.8	0.19

a) Line+background. b) Internal standard: 10 μg Y ml^{-1}, Y II 371.03 nm.

Accuracy was tested by analyses of standard reference materials. Titanium (certified values 0.066, 0.098%) and chromium (certified values 0.011, 0.036%) in low alloy steels (Japan Standards of Iron and Steel, JSS 168-2 and 170-2) were determined by preparing solutions containing 10 mg of the sample and 10 μg of yttrium per ml with satisfactory results (0.065 and 0.098%Ti, and 0.012 and 0.038%Cr).

Although the proposed ultrasonic nebulizer is less stable and more susceptible to acid concentrations than the conventional pneumatic nebulizer, it may be quite useful for analyses of samples of limited volumes, *i.e.*, microliter samples.

Oxidizing Action of Complex of *N,N*-Dimethylbenzylamine Oxide with $SbCl_5$

Jiro YAMAMOTO,* Yukio TANIOKA, and Masahiro UMEZU

Department of Industrial Chemistry, Faculty of Engineering, Tottori University, Tottori 680

(Received January 25, 1982)

Synopsis. A 1:1 complex of *N,N*-dimethylbenzylamine oxide–$SbCl_5$ (**1**) was prepared in carbon tetrachloride quantitatively. Complex **1** was found to be a better reagent for oxidation of benzoin, furoin, benzyl alchols and pinacols than the complexes pyridine *N*-oxide–$SbCl_5$ and trimethylamine oxide–$SbCl_5$. The reaction path in oxidation of benzhydrol with **1** is described.

In the previous paper,[1] we reported that 1:1 complexes of pyridine *N*-oxide (**2**) and trimethyamine oxide (**3**) with $SbCl_5$ behave as an oxidizing agent for some compounds. In this paper, we describe the oxidation of benzoin, furoin, benzhydrol and *o*- and *p*-nitrobenzyl alcohols using the complex formed *N,N*-dimethylbenzylamine oxide (**4**) with $SbCl_5$ [$PhCH_2(CH_3)_2N$–$OSbCl_5$, **1**].

Experimental

1:1 Complex of N,N-*Dimethylbenzylamine Oxide with* $SbCl_5$ *(1).* When a solution of **4** (9.50 g, 6.29 mmol) in CCl_4 (90 ml) was added to a solution of $SbCl_5$ (20.9 g, 62.9 mmol) in CCl_4, yellow crystalline complex **1** immediately deposited. The reaction mixture was filtered and washed with CCl_4 and then with petrolium ether. 30.1 g (99.0%), mp 206—208 °C (in a sealed capillary tube). ν_{max}^{KBr}; 1580 cm^{-1}, 1405 cm^{-1}, 1220 cm^{-1}, 1180 cm^{-1}, 1145 cm^{-1}, 975 cm^{-1}, 880 cm^{-1}, $\lambda_{max}^{CHCl_3}$; 268 nm (ε: 7120). Found: Cl, 39.40%. Calcd for $C_9H_{13}NOSbCl_5$: Cl, 40.10%.

Oxidation of Benzoin with **1**. A mixture of benzoin (0.50 g, 2.35 mmol) in nitromethane was kept for 5 h at 60 °C. The reaction mixture was poured into water and filtered. After filtrates were extracted with ether, the ether solution was washed with dil. HCl. The solution was dried, filtered and evaporated, and then benzil (0.48 g, 95%) was separated from the residue by column chromatography (benzene–silica gel). The same procedure was also applied in the oxidation of furoin, except that chloroform was used as a eluent in column chromatography.

Results and Discussion

The oxidation of *o*- and *p*-nitrobenzyl alcohols with **1** gave the corresponding aldehydes in low yield (Table 1). In the equimolar reaction of benzhydrol with **1** in nitromethane at room temperature, bis(diphenylmethyl)ether was obtained in a 58% yield. The yield of benzophenone and bis(biphenylmethyl)ether increased when the reaction was carried out at 40 °C (Table 1). On the other hand, the yield of benzophenone increased at high temperature (Fig. 1). These results indicate that bis(diphenylmethyl)ether changes to benzophenone promptly, but benzophenone does not. After treatment of bis(diphenylmethyl)ether with equimolar **1** in nitromethane, benzhydrol and benzophenone were obtained (Fig. 2). Therefore, it should be concluded that both benzhydrol and bis(diphenylmethyl)ether are in equilibrium in the presence of **1**. The

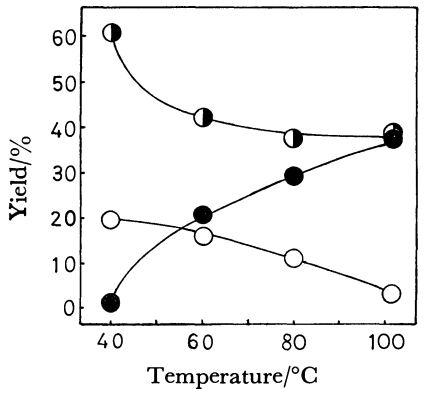

Fig. 1. The dependence of reaction temperature on the oxidation of benzhydrol with *N,N*-dimethylbenzylamine oxide–$SbCl_5$ (1:1) complex.
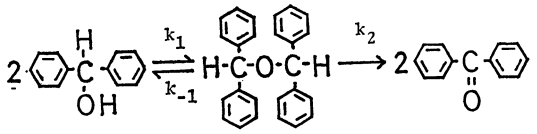
Reaction conditions: benzhydrol; 0.5 g (2.71 mmol), complex; 1.22 g (2.71 mmol), solvent; 10 ml of nitromethane, reaction time; 1 h. ●: Benzophenone, ◑: bis(diphenylmethyl)ether, ○: benbhydrol.

rate constants of each in the following equation depend



upon the reaction temperature, *i.e.* $k_2>k_1>k_{-1}$ near 40 °C, $k_1>k_2>k_{-1}$ from 60 °C to 70 °C and $K_2>k_1>k_{-1}\simeq 0$ near 100 °C (Fig. 1 and Fig. 2). In the first step of the reaction, a proton of benzhydrol is abstracted, as in the reaction of pyridine *N*-oxide with thiophenol.[8] After bis(diphenylmethyl)ether accumulates

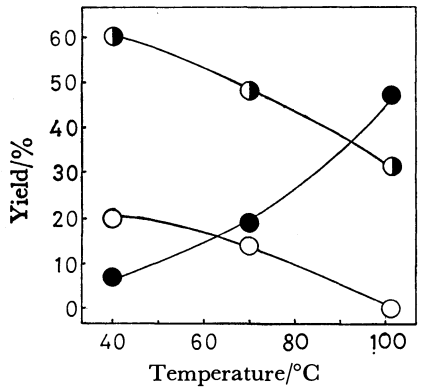


Fig. 2. The treatment of bis(diphenylmethyl)ether with *N,N*-dimethylbenzylamine oxide–$SbCl_5$ (1:1) complex. Reaction conditions: bis(diphenylmethyl)ether; 0.5 g (1.43 mmol), complex; 0.64 g (1.43 mmol), solvent; 10 ml of nitromethane, reaction time: 1 h. ●: Benzophenone, ◑: bis(diphenylmethyl)ether, ○: benzhydrol.

in the reaction system, it changes into both benzhydrol and benzophenone in accordance with the reaction temperature (Fig. 2). Compounds **4** seems to be less reactive than **1** in the reaction with benzhydrol (Table 1).

Although oxidation of benzoin with **1** under mild condition gave benzil in 95% that with **4** gave only 16.4%. A higher yield of benzoin was obtained in comparison with the case of using $SbCl_5$ as done for **2** and **3** reported before.[1] In the oxidation with furoin with **1**, moderate yields of furil were obtained (Table 2). Pinacolones were obtained in good yield in the oxidation of pinacols with **1** may be considered to be an effective catalyst for pinacol–pinacolone rearrangement.

The authors are grateful to Professors M. Tanaka and J. Kiji of Tottori University for their valuable advice.

Solvent Effect on Photooxidation of Triphenylphosphine Selenide Sensitized by Polymer-supported Rose Bengal

Seizo TAMAGAKI* and Ryuji AKATSUKA

Department of Applied Chemistry, Faculty of Engineering, Osaka City University, 3-138, Sugimoto 3-chome, Sumiyoshi-ku, Osaka 558

(Received October 22, 1981)

Synopsis. Solvent effect on the photooxygenation of triphenylphosphine selenide was examined by using crosslinked polystyrene- or silica gel-anchored Rose Bengal as sensitizers. Different types of solvent dependency of the product yields were observed in each case.

Recently, polymer-supported photosensitizers have been extensively utilized for synthetic photochemistry.[1] For instance, Rose Bengal anchored to 1%-crosslinked polystyrene beads have been successfully applied to the photogeneration of singlet oxygen.[2]

As part of our continuing interest in the photosensitized oxidation of thione compounds,[3] we have examined the photosensitized oxidation of triphenylphosphine selenide which has not yet been studied thus far, and shed light on the properties of Rose Bengal bound to different types of supports.

Results and Discussion

First, the efficiency of Rose Bengal itself as a sensitizer was examined in various solvents. Triphenylphosphine selenide was irradiated under oxygen bubbling for 5 h in the presence of Rose Bengal in Me_2C=O, MeCN, MeOH, and $CHCl_3$–MeOH (1:1 V/V) affording the corresponding oxide in 3, 11, 78, and 92% of isolated yields, respectively, but no product was obtained in nonpolar solvents such as benzene, $CHCl_3$, and CS_2, because Rose Bengal is not soluble in these solvents.

$$Ph_3P{=}Se + O_2 \xrightarrow[5\,h,\ \text{Rose Bengal}]{CHCl_3\text{-MeOH},\ h\nu} Ph_3P{=}O + Se$$
(92%) (75%)

Meanwhile, the effect of solvent on product yields for the reaction with styrene–1%-divinylbenzene copolymer-bound Rose Bengal (Ⓟ-RB: **1**) as a sensitizer was compared with that with silica gel-bound Rose Bengal (Ⓢ-RB: **2**).[4] Tables 1 and 2 list the yields for **1** and **2**, respectively. Inspection of these tables reveals that the yield is solvent dependent in both cases.

Ⓟ- -CH_2-RB (**1**) Ⓢ-$(CH_2)_3$-RB (**2**)

Ⓟ=Polystyrene copolymer; RB=Rose Bengal; Ⓢ=silica gel.

When **1** was employed, the yield of the product decreased in the order: CH_2Cl_2–MeOH (1:1)> $CHCl_3$ > CH_2Cl_2>benzene–MeOH (1:1)>CCl_4>benzene>MeCN>MeOH. Apparently, **1** did not act as a sensitizer in MeOH because of the hydrophobicity of the polystyrene copolymer bead. The lifetime of singlet oxygen in single component solvents was reported to decrease in the following order: CCl_4> $CHCl_3$>benzene≥MeCN>MeOH,[5] whereas the degree of swelling of the bead decreases in the order: benzene>$CHCl_3$>CH_2Cl_2>CCl_4>MeCN>MeOH. It is apparent, therefore, that neither the swelling index nor the lifetime of singlet oxygen alone can account for the observed order, but a combination thereof may be a possible explanation for that. The interesting finding is that the photooxidation is more efficient in MeOH-containing solvents such as $CHCl_3$–MeOH and benzene–MeOH than in $CHCl_3$ and benzene, respectively, although MeOH swells the polystyrene bead least and decreases the lifetime of singlet oxygen most of all the solvents examined.[6] This effect of MeOH is best explained if the reaction involves the intermediacy of the zwitterion having a structure like **4** (the peroxyselenide) depicted in Scheme 1 and if MeOH acts as the hydrogen-bonding donor toward **4**, thus promoting the nucleophilic attack on the negative oxygen by the second phosphine selenide. In aprotic solvents the intermediate **4** dissociates readily into the original selenide and ground-state dioxygen.

TABLE 1. SOLVENT EFFECT ON THE PHOTO-SENSITIZED OXYGENATION OF TRIPHENYLPHOSPHINE SELENIDE BY POLYSTYRENE-SUPPORTED ROSE BENGAL (**1**)[a]

Solvent	Ph_3P=O (%)	Ph_3P=Se (recovered) (%)	Swelling index[c]	Lifetime of $O_2{}^1$/μs

Table 2. Solvent effect on the photosensitized oxygenation using silica gel-bound Rose Bengal (**2**)[a]

Sovent	$Ph_3P=O$ (%)	$Ph_3P=Se$ (%)
CCl_4	84	3
CH_2Cl_2	76	16
CH_2Cl_2[b]	28	c
$CHCl_3$	71	10
CH_2Cl_2–MeOH (1:1)	67	20
Benzene	43	43
MeCN	43	39
MeOH	39	34

a) **1**: 200 mg; $Ph_3P=Se$: 0.5 mmol: irradiated for 2 h. b) $Ph_3P=Se$: 0.167 mmol. c) Not determined.

A similar rate-enhancement due to hydrogen-bonding interaction between a zwitterion and MeOH was reported in the singlet oxygenation of sulfide in which the persulfoxide **3** is involved as a reactive intermediate.[7]

$$R_2S + O_2{}^1 \longrightarrow \underset{\mathbf{3}}{R_2\overset{+}{S}\text{-}O\text{-}O^-} \xrightarrow[MeOH]{R_2S} 2R_2S=O$$

Addition of 1,4-diazabicyclo[2.2.2]octane (DABCo), a typical singlet oxygen quencher, significantly inhibits the formation of the phosphine oxide especially in nonpolar solvents, implying that singlet oxygen is the only oxidizing species.[8] Thus, one of the tentative mechanisms of the oxidation may be visualized as follows: The initial pre-equilibrium formation of the peroxyselenide **4**, followed by attack of another selenide on it, yields the oxyselenide **5**, which rearranges and then eliminates selenium, eventually giving the phosphine oxide.

$$Ph_3P=Se + O_2{}^1 \longrightarrow \underset{\mathbf{4}}{Ph_3\overset{+}{P}\text{-}S\text{-}O\text{-}O^-} \xrightarrow{Ph_3P=Se} \underset{\mathbf{5}}{2Ph_3P=Se=O}$$

$$\mathbf{5} \longrightarrow Ph_3P\begin{matrix}\diagup Se \\ | \\ \diagdown O\end{matrix} \xrightarrow{-Se} Ph_3P=O$$

Scheme 1.

On the other hand, when Ⓢ-RB (**2**) was employed,[9] the sequence of the solvent effect on the yield was quite similar to that expected from the lifetime of singlet oxygen (Table 2). In contrast to the case with Ⓟ-RB (**1**) or Rose Bengal itself, no rate-enhancement by MeOH was observed. This is due to the fact that singlet oxygen, photogenerated in a silica particle, does not have sufficient lifetime to diffuse out of the particle with a diameter of 10^{-2} cm, since singlet oxygen has a short mean radius of diffusion of less than 10^{-4} cm during the lifetime.[10] The singlet oxygen would then react with triphenylphosphine selenide predominantly in the solvent channel of the same particle, giving **4**, which is then strongly adsorbed at the silica gel through hydrogen-bonding to react with another selenide. Even in MeOH solvent, **4** may hydrogen-bond effectively to silica rather than to MeOH. Accordingly, the main factor to determine the solvent effect is to be the lifetime or concentration of singlet oxygen in the solvent in question.

In conclusion, with Ⓟ-RB as a sensitizer, the yield of the phosphine oxide is remarkably increased by addition of MeOH, while with Ⓢ-RB, the solvent dependency of the yield just parallels the lifetime or concentration of singlet oxygen and thus the yield is the lowest in MeOH.

Experimental

Materials. Chloromethylated 1%-crosslinked polystyrene beads (0.75 meq CH_2Cl/g resin; 300 mesh) were purchased from Bio Rad Laboratories, Richmond, Cal. and Silica gel (Wakogel C-300) from Wako Pure Chemical Industry, Tokyo. Polystyrene-supported Rose Bengal (**1**: 2 mg of Rose Bengal per g of the polymer) was prepared according to the method of Blossey and Neckers.[2] Silica gel-supported Rose Bengal (**2**) was prepared by heating a DMF solution of Rose Bengal and silica gel modified with (3-chloropropyl)trichlorosilane at 120 °C for 20 h.[4] The resultant reddish silica gel was filtered and washed successively with H_2O, acetone, and $CHCl_3$ and then continuously extracted with $CHCl_3$–MeOH (1:1) until the color due to Rose Bengal did not come out into the eluent. The silica gel thus obtained (**2**: 0.3 mg of Rose Bengal per g of silica gel) was dried in a vacuum oven at 60 °C for 5 h.

Photooxidation of Triphenylphosphine Selenide Using Rose Bengal. Triphenylphosphine selenide (0.5 mmol) and 5 mg of Rose Bengal dissolved in 25 cm^3 of $CHCl_3$–MeOH (1:1) were placed in a Pyrex tube and irradiated with a tungsten-halogen lamp (500 W) under O_2 bubbling for 5 h until the selenide disappeared completely. The filtrate was concentrated to 0.5 cm^3 and the residue was chromatographed on TLC (Kieselgel 60, benzene) giving 92% of triphenylphosphine oxide.

General Procedure for Photooxygenation with Polymer-supported Rose Bengal. The selenide (0.5 mmol) and **1** (100 mg) or **2** (200 mg) in 25 cm^3 of a solvent were placed in a Pyrex tube with a magnetic stir bar and irradiated under O_2 bubbling with the tungsten lamp. After the irradiation, the polymer was filtered off and the filtrate was concentrated to 0.5 cm^3. The residue was subjected to TLC analysis. The results are summarized in Tables 1 and 2.

Friedel-Crafts Reactions of Benzene with 1-Phenylpropanols. Effects of $CuCl_2$, Cu_2Cl_2, and Decalin

Katsuhiko Ichikawa, Keizo Chano, Masashi Inoue, and Toshio Sugita*

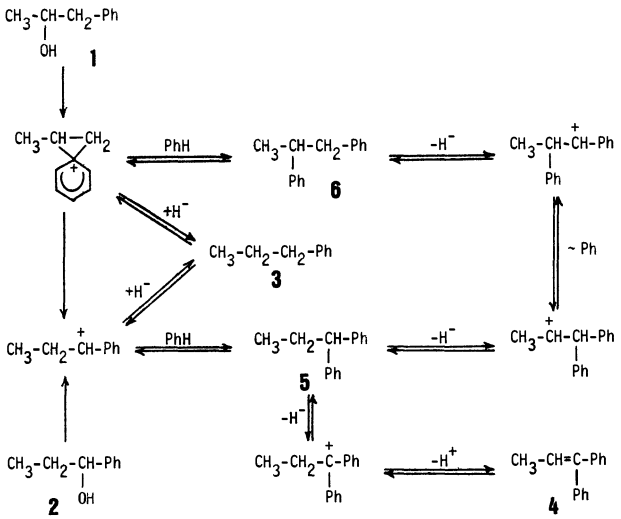
Department of Hydrocarbon Chemistry, Faculty of Engineering, Kyoto University, Sakyo-ku, Kyoto 606

(Received November 16, 1981)

Synopsis. Highly regioselective formation of 1,1-diphenylpropane was observed when copper(I) or (II) chlorides was added to the aluminium chloride-catalyzed reaction of benzene with 1-phenyl-1-propanol. In the reaction with 1-phenyl-2-propanol, the addition of copper salts increased the formation of 1,1-diphenylpropane. The addition of decalin diminished the alkylation reaction to give a reduction product.

In a previous paper, we reported that the Friedel-Crafts reaction of benzene with 2-phenyl-1-propanol, 1-phenyl-2-propanol (**1**), and the related compounds gave a mixture of 1-phenylpropane (**3**), 1,1-diphenylpropene (**4**), 1,1- (**5**) and 1,2-diphenylpropanes (**6**), and we also pointed out that the intermolecular hydride transfer from **5** to an intermediate, 1-methyl-2-phenylethyl or 1-phenylpropyl cation, played an important role in the reaction.[1] Schmerling and Vesely reported that an aromatic hydrocarbon was alkylated with a saturated hydrocarbon when it was treated with copper(II) and aluminium chlorides.[2] They suggested that the alkylation proceeded by an oxidative reaction involving copper(II) chloride. In order to investigate the effects of oxidizing reagents and hydride donors on the reaction, the aluminium chloride-catalyzed reactions of benzene with 1-phenyl-2- (**1**) and 1-propanols (**2**) were studied in the presence of copper(II) and (I) chlorides, and *trans*-decalin.

By the addition of copper(II) chloride as an oxidizing reagent, the yield of 1-phenylpropane (**3**) was diminished as expected, but the yield of 1,1-diphenylpropene (**4**) (an oxidized product) did not increase either in the case of **1** or of **2**. Furthermore, no distinct difference could be observed between the result obtained by the addition of copper(II) chloride and that by copper(I) chloride, in spite of the difference of their oxidizing ability. When the reaction of benzene with **2** was carried out in the presence of the copper salts, the yields of diphenylpropanes remarkably increased and the reaction regioselectively proceeded to afford 1,1-diphenylpropane (**5**). In the reaction with **1**, the addition of the copper salts also increased the yield of diphenylpropanes as well as the ratio of **5** in diphenylpropanes. In the reactions using copper(I) chloride, no distinct difference was observed between the results obtained under the ambient atmosphere and under argon. Nenitzescu and Cantuniari showed that the aluminium chloride-catalyzed hydride transfer reaction took place if the aluminium chloride contained water.[3] In the present case, the reaction mixture should contain water since the substrates were alcohols; thus hydride transfer was expected to occur. The present results, however, indicate that both copper(II) and (I) chlorides prevent the intermolecular hydride transfer reaction. Although the reason why the presence of each chloride gave similar results is still uncertain, it is suggested that the copper salts prevent the rearrangement of 1-phenylpropyl cation to a phenonium-type 1-methyl-2-



Scheme 1.

Table 1. Reaction of benzene with 1-phenylpropanols in the presence of additives

a) Determined by GLPC. b) Determined by NMR.

phenylethyl cation; the rearrangement probably takes place *via* **5** and **6**, accompanied with hydride transfer and phenyl migration.

The addition of *trans*-decalin increased the yield of the reduction product (**3**), and gave a trace of the Friedel-Crafts alkylation products (**5** and **6**). It is thus indicated that the arylpropyl cations abstract a hydride ion from decalin easier than from **5** and other products, *i.e.*, decalin is very reactive as a hydride donor.

Experimental

The ^1H NMR spectra were taken on a JEOL PMX-60 (60 MHz) or a Varian HR-220 (220 MHz) apparatus in $CDCl_3$ with TMS as an internal standard.

Materials. Benzene was washed with conc H_2SO_4, and distilled over CaH_2. Commercial GR grade aluminium chloride was used without further purification. GR grade $CuCl_2$ was used after drying at 120 °C/3 mmHg (1 mmHg $\approx$133.322 Pa) for more than 3 h. White crystalline Cu_2Cl_2 was prepared from $CuCl_2$ and glycerol, washed with ethanol and dried under a reduced pressure.[4] **1**, **2** and *trans*-decalin were commercially available, and used without further purification.

The Reactions of Benzene with 1-Phenyl-1- and 2-propanols. A Typical Procedure: A solution of **2** (12 mmol) in benzene (10 ml) was added to a stirred mixture of $AlCl_3$ (22.5 mmol) and the additive ($CuCl_2$, 22.5 mmol) in benzene (20 ml) at 40 °C. The mixture was stirred at 40 °C for 2 h, and then poured into a mixture of saturated aqueous NH_4Cl solution (100 ml) and 30% aqueous ammonia (20 ml). *p*-Methoxytoluene was added as an internal standard, the organic layer was separated, the aqueous layer was extracted with ether, and the combined extracts were dried over $MgSO_4$. After removal of the solvents, the crude product was submitted to the GLPC analysis (PEG-20M 5% on Chromosorb W, 4 m). The crude product was distilled under a reduced pressure, and the diphenyl fraction (bp 109—111 °C/3 mmHg) was analyzed by means of the integral intensities of terminal methyl signals in its NMR spectrum: 1,1-diphenylpropane (**5**), δ=0.87 (t, J=8, 3H, CH_3), 2.04 (m, 2H, CH_2), 3.71 (t, J=10, 1H, CH), 7.13 (s, 10H, C_6H_5); 1,2-diphenylpropane (**6**), δ=1.20 (d, J=8, 3H, CH_3), 2.86 (m, 3H, $-CH_2-CH\langle$), 7.15 (10H, C_6H_5); 1,1-diphenylpropene (**4**), δ=1.73 (d, J=8, 3H, CH_3), 6.15 (q, 1H, =CH–), 7.19 (s, 10H, C_6H_5).

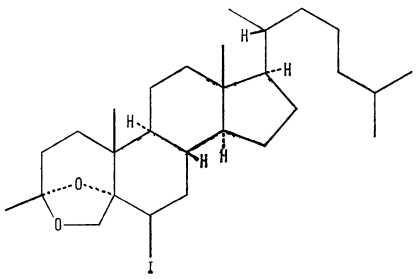
(Received December 5, 1981)

Synopsis. The major product of photo- and thermally-induced radical rearrangements of hypoiodites of 3α- and 3β-methyl-5-cholesten-3-ols in the presence of iodine with mercury(II) or silver(II) oxide has been established as 3α,5-epoxy-6β-iodo-3β-methyl-*A*-homo-4-oxa-5α-cholestane by means of X-ray crystal structure analysis.

The photo- and thermally-induced rearrangements of hypoiodites of several 5-cholesten-3-ols in the presence of mercury(II) oxide and iodine generally lead to the formation of seven-membered oxabicyclics.[2-5] In a previous paper,[3] it was reported that hypoiodites of 3α- and 3β-methyl-5-cholesten-3-ols in benzene containing mercury(II) oxide and iodine gave virtually a single product. The **1** structure was proposed for this product on the basis of the spectroscopic data.[3] There was, however, some ambiguity in assigning the stereochemistry of its oxygen bridge. Therefore, in order to establish **1**, we have now undertaken an X-ray crystal structure analysis.



1

Experimental

A colorless single crystal with dimensions of about 0.2×0.2×0.5 mm³ was used for the X-ray measurement. The crystal data are as follows: $C_{28}H_{47}O_2I$, mol wt 542.6, orthorhombic, space group $P2_12_12_1$, $a=17.44(1)$, $b=21.27(2)$, $c=7.26(1)$ Å, $Z=4$, $D_c=1.338$ g cm^{-3}, μ(Mo $K\alpha$)$=11.9$ cm^{-1}. The cell dimensions and diffraction intensities were measured at about −80 °C on a Hilger & Watts four-circle diffractometer with Zr-filtered Mo $K\alpha$ radiation ($\lambda=0.71069$ Å). The ω-2θ step-scan technique was applied at an ω interval of 0.02°; the counting time at each step was 1 s. The background was measured for 25 s at each end of the scan range. The intensities thus obtained were corrected for the Lorentz and polarization factors, but not for the absorption or the extinction effect. In the range of 2θ values up to 48°, 1786 independent structure-factor amplitudes above the $3\sigma(F)$ level were selected for the structure determination.

Structure Determination

The structure was solved by the Monte Carlo direct method,[6] using the 20 strongest reflections as a starting set. In order to extend the tentative-phase set derived from random numbers, 12 cycles of the tangent procedure were carried out using 489 $|E|$ values above 1.30. Since the first random-phase set gave a low R_K value of 0.142 ($R_K=\Sigma||E_o|-k|E_c||/\Sigma|E_o|$), 6 additional cycles of the tangent procedure were performed by the use of 761 $|E|$ values above 1.10. An *E*-map based on 757 phases afforded all the 31 non-hydrogen atoms. The structure thus obtained was refined by the block-diagonal least-squares method with

Only the torsion angles relevant to atoms which form the same ring are given in the ring.

anisotropic temperature factors. After 29 hydrogen atoms had been located in a difference Fourier map, further least-squares refinements were repeated including the hydrogen atoms with isotropic temperature factors. Since the absolute configuration of the present molecule was known,[3] the anomalous dispersion effects of the iodine atoms were included in these last refinements. The weighting scheme used was as follows:

$$w = 1/\{\sigma(F)^2 \exp(AX^2+BY^2+CXY+DX+EY)\},$$

where $X=|F_o|$ and $Y=\sin\theta/\lambda$. The *A*, *B*, *C*, *D*, and *E* coefficients are constants which were evaluated from the $(\Delta F)^2$ distribution in the (X,Y) space; $A=-0.1136\times10^{-5}$, $B=12.40$, $C=0.04025$, $D=-0.008957$, and $E=-12.24$. The final *R* value was 0.064. The final atomic parameters are listed in Table 1.[7]

The calculations were performed on a HITAC M-200H computer at the Hokkaido University Computing Center, using our own programs. The atomic scattering factors were taken from the International Tables.[8]

Results and Discussion

The molecular framework is shown in Fig. 1. It is concluded that the major product of the rearrangements of hypoiodites of 3α- and 3β-methyl-5-cholesten-3-ols has the **1** structure. The bond distances and torsion angles are given in Figs. 2 and 3, respectively. The A/B ring junction is cis. All the six-membered A-, B-, and C-rings take chair conformations, while the five-membered D- and E-rings adopt half-chair and envelope conformations respectively. The chair conformation of the A-ring is remarkably deformed by the bridging of the C(4)H_2–O(1) group so that the puckering of the C(3)–O(2)–C(5) part is great, whereas that of the C(2)–C(1)–C(10) part is small. Because of the occupation of the 1,3-diaxial positions on the B-ring, the C(19) and I atoms approach each other at a considerably shorter distance (3.49(1) Å) than the sum of their van der Waals radii, 4.15 Å. This severe steric hindrance results in an enlargement of the C(5)–C(10)–C(19) and C(9)–C(10)–C(19) bond angles (116-(1) and 113(1)° respectively) and a closing of the C(5)–C(6)–C(7)–C(8) torsion angle (45°). As Fig. 1 shows, the C(20)–C(22)–C(23)–C(24)–C(25)–C(27) side chain, together with the C(13) and C(17) ring atoms, takes a nearly-planar zigzag conformation.

We thank Professor Jiro Tanaka of Nagoya University for the generous permission to use a four-circle diffractometer.

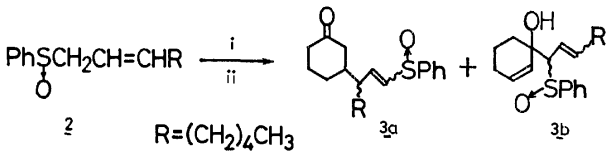
Regioselective Reaction of Allylic Carbanion Derived from 1-Phenylthio-2-octene with Conjugated Cyclopentenone Derivative and Synthesis of Prostaglandin E_1

Junzo NOKAMI,* Toshio ONO, Atsunori IWAO, and Shoji WAKABAYASHI
Okayama University of Science, Ridai, Okayama 700
(Received December 24, 1981)

Synopsis. The reaction of the allylic carbanion derived from 1-phenylthio-2-octene with conjugated cyclopentenone derivatives in the presence of hexamethylphosphoric triamide (HMPA) regioselectively gave the 1,4 adduct at the α carbon of the allylic sulfide. The reaction was employed for the synthesis of prostaglandin E_1.

There are many reports[1] on the regioselective reaction of allyl or allylic carbanions with electrophiles. Recently, Haynes *et al.*[2] reported HMPA-mediated conjugate addition of alkylthio(or phenylthio)allyl anion to cyclopentenone. We have also been interested in the reaction of the carbanion derived from 1-phenylthio(or 1-phenylsulfinyl)-2-octene with conjugated cycloalkenone,[3] because the phenylthio or phenylsulfinyl group shows versatility in functionalization associated with desulfurization.[4] In this report, we describe a synthesis of PG E_1 by using 1-phenylthio-2-octene (**1**) as an ω-side chain equivalent.

We have attempted to build the ω-side chain by the use of the sulfinyl carbanion derived from 1-phenylsulfinyl-2-octene (**2**). However, the reaction resulted in the formation of a mixture of 1,4-γ adduct **3a** (70%) and 1,2-α adduct **3b** (20%), and no additive effect of HMPA was observed.



i) LDA, -78°C, THF; ii) cyclohexenone, -78°C, THF.

Fig. 1.

On the other hand, the reaction of the carbanion derived from **1** in the presence of HMPA gave 1,4 adduct as a sole product.[5] By applying this regioselective 1,4 addition of the carbanion to cyclopentenone derivative **4**, we have attempted the synthesis of PG E_1. The carbanion was prepared by the treatment of **1** with butyllithium at −45 °C. After a few minutes, HMPA and afterwards cyclopentenone derivative **4a** were added at −78 °C, and the mixture was kept for 5 min at that temperature. The reaction mixture was worked up to give the expected 1,4 adduct **5a** in 82% yield. The adduct **5a** was converted to allylic alcohol **7a** by a method similar to that reported.[6] Namely, **5a** was converted to sulfoxide **6a** by the oxidation using *m*-chloroperbenzoic acid at −10 °C in dichloromethane. After concentration, the residue was treated with trimethyl phosphite in methanol at 0 °C for 3 h to afford **7a** (*ca.* 1/1 mixture of 15-α/15-β) in 82% yield based on **5a**. Hydrolysis of **7a** in 1% acetonitrile solution of hydrofluoric acid at 0 °C gave methyl

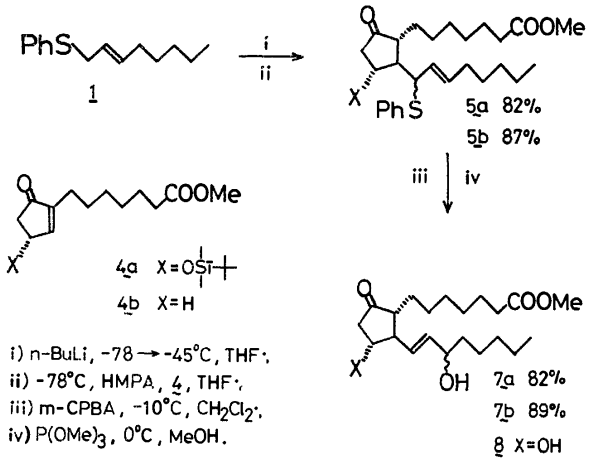


Fig. 2.

prostaglandin E_1 (**8**) (a mixture of 15-α and β) in 78% yield.

Experimental

Boiling points are uncorrected. IR spectra were determined with a Hitachi Model 260-30 spectrophotometer with a grating. ^{1}H NMR spectra were obtained with a Hitachi R-24B and/or a JEOL FX-100 spectrometers. Elemental analyses were carried out in this laboratory.

1-Phenylthio-2-octene (1). A mixture of 1-octene (28 ml, 0.179 mol), *N*-bromosuccinimide (22.7 g, 0.128 mol) and a catalytic amount of benzoyl peroxide was refluxed in carbon tetrachloride for 5 h under nitrogen. The reaction mixture was cooled and insoluble materials were filtered off. The concentrated filtrate was purified by column chromatography on alumina by elution with hexane to give a mixture of 1-bromo-2-octene and 3-bromo-1-octene (3:1) in 98% yield. The mixture of bromooctene (17.8 g, 0.093 mol) was treated with benzenethiol (6.75 ml, 0.066 mol) and sodium carbonate (14 g, 0.132 mol) in acetone with gentle heating. After 5 h, the reaction mixture was cooled and filtered. The filtrate was concentrated and washed with brine. Pure **1** was obtained by distillation in 80% yield, 101 °C/0.25 Torr†; NMR (CCl_4) δ 0.86 (m, 3H), 1.22 (m, 6H), 1.96 (m, 2H), 3.47 (m, 2H), 5.47 (m, 2H), 7.2 (m, 5H). The ratio of *E* and *Z* isomers was not determined.

1-Phenylsulfinyl-2-octene (2). Sulfide **1** was treated with sodium periodate (slight excess) in aqueous methanol at room temperature for 10 h. The reaction mixture was concentrated and extracted with chloroform. The extract was washed with brine, dried, and concentrated. The residue was chromatographed (SiO_2, hexane/ether, 1/1) to give **2** quantitatively; IR (neat) 1045 cm^{-1} (S–O); NMR ($CDCl_3$) δ 0.85 (m, 3H), 1.21 (m, 6H), 3.32 (m, 2H), 5.27 (m, 2H), 7.34 (broad s, 5H).

Reaction of Sulfinyl Carbanion with Cyclohexenone to 3a and 3b. 1-Phenylsulfinyl-2-octene (**2**) (0.1 ml, 0.47 mmol)

† 1 Torr ≈ 133.322 Pa.

was treated with lithium diisopropylamide (prepared from 0.6 mmol of diisopropylamine and 0.4 ml of butyllithium (1.56 mol dm^{-3} in hexane)) in THF at −78 °C for 30 min. 2-Cyclohexenone (0.05 ml, 0.5 mmol) was added to the reaction mixture, which was stirred for 5 min, poured into saturated aqueous ammonium chloride, and extracted with chloroform. After concentration of the extract, the residue was chromatographed on silica gel with hexane/ether (1/4) to give two major products. The less polar product could be assigned to **3b** (31 mg, containing *ca.* 10% non-isolated impurity); IR (neat) 3400 (O–H), 1010 (S–O) cm^{-1}; NMR ($CDCl_3$) δ 3.44 (m, 1H, S–CH–C=C), 4.80—6.20 (m, 4H, 2 CH=CH), 7.5 (m, 5H, phenyl). The polar product was assigned to **3a** (109 mg, 70%); IR (neat) 1705 (C=O), 1040 (S–O) cm^{-1}; NMR ($CDCl_3$) δ 0.84 (m, 3H), 1.0—2.4 (m, 18H), 6.30 (m, 2H, CH=CH–S), 7.51 (m, 5H, phenyl). Found: C, 72.33; H, 8.74%. Calcd for $C_{20}H_{28}O_2S$: C, 72.25; H, 8.49%.

Similar Reaction of the Sulfinyl Carbanion with ***4b*** gave 1,4-γ adduct **9** as the major product (*ca.* 60% yield); IR (neat) 2930, 1730 (C=O), 1040 (S–O), 1020 cm^{-1}; NMR ($CDCl_3$) δ 0.86 (m, 3H), 1.0—2.5 (m, 27H), 3.53 (s, 3H, $COOCH_3$), 6.10 (m, 2H, S–CH=CH), 7.36 (broad s, 5H, phenyl).

Fig. 3.

Reaction of Sulfenyl Carbanion Derived from ***1*** *with* ***4a*** *to* ***5a***. Butyllithium (0.2 ml, 1.56 mol dm^{-3} in hexane) was added to a stirred solution of **1** (67 mg, 0.3 mmol) in THF (2 ml) at −78 °C. The reaction mixture was warmed to −45 °C during 40—50 min, and recooled to −78 °C. Then, HMPA (0.13 ml, 0.76 mmol) and afterward **4a** (90 mg, 0.25 mmol, 0.2 ml of THF solution) were added at −78 °C. After 5-min stirring at that temperature, water was added to the reaction mixture, which was extracted with ether immediately. The extract was washed with brine, dried, and concentrated. The residue was submitted to column chromatography on silica gel (hexane/ether, 1/1) to give a 1:1 diastereomeric mixture of **5a** (120 mg, 82%) as an oil; IR (neat) 2940, 2860, 1735 (C=O), 1460, 1250, 830 cm^{-1}; NMR ($CDCl_3$) δ 0.08 (m, 6H, $Si(CH_3)_2$), 0.84 (m, 3H, CH_3), 0.87 and 0.89 (each s, 9H, $SiC(CH_3)_3$), 1.0—2.7 (m, 24H), 3.65 (s, 3H, $COOCH_3$), 3.90 (m, 1H, S–CH–C=C), 4.40 (m, 1H, O–CH), 5.38 (m, 2H, CH=CH), 7.27 (m, 5H, phenyl). Found: C, 68.72; H, 9.51%. Calcd for $C_{33}H_{54}O_4SSi$: C, 68.94; H, 9.47%.

Similarly, **5b** was obtained from **4b**; IR (neat) 2950, 2870, 1735 (C=O), 1590, 1470, 1180, 1030 cm^{-1}; NMR ($CDCl_3$) δ 0.76 (m, 3H), 0.9—2.6 (m, 26H), 3.54 (s, 3H, $COOCH_3$), 3.56 (m, 1H, S–CH–C=C), 5.20 (m, 2H, CH=CH), 7.18 (m, 5H, phenyl).

Conversion of ***5a*** *to* ***7a***. The adduct **5a** (66 mg, 0.115 mmol) was treated with *m*-chloroperbenzoic acid (80%, 25 mg) in dichloromethane at −10 °C for 2 h. The reaction mixture was concentrated *in vacuo*. The residue was dissolved in methanol (1.5 ml), and treated with trimethyl phosphite (0.03 ml) at 0 °C for 3 h. After removal of the solvent, the residue was submitted to column chromatography on silica gel to yield *ca.* 1:1 of diastereomeric mixture of **7a** (45 mg, 82%); IR (neat) 3500 (O–H), 2860, 1735 (C=O), 1460, 1250, 1110, 830 cm^{-1}; NMR ($CDCl_3$) δ 0.08 (m, 6H, $Si(CH_3)_2$), 0.90 (m, 3H), 0.91 (s, 9H, $SiC(CH_3)_3$), 1.0—2.8 (m, 24H), 3.70 (s, 3H, $COOCH_3$), 4.10 (m, 2H, 2 O–CH), 5.64 (m, 2H, CH=CH). Found: C, 67.35; H, 10.54%. Calcd for $C_{27}H_{50}O_5Si$: C, 67.17; H, 10.44%.

Deprotection of ***7a*** *to* ***8***. To a solution of 28 mg of **7a** (diastereomeric mixture) in 2 ml of acetonitrile was added 0.5 ml of highly diluted hydrofluoric acid (5% acetonitrile solution of commercial HF (45%)) at 0 °C and the reaction mixture was stirred for 2 h to give **8** (78% yield) which was separated by column chromatography on silica gel (cyclohexane/ethyl acetate, 1/2) into two parts. The polar product (8.5 mg) was identified as PG E_1 by TLC comparison with an authentic sample and the less polar product (7 mg) was shown to be 15-epi PG E_1.

We thank Teijin Co. for the gift of an authentic sample. This research was supported by the Hattori Foundation.

A One Step Transformation of the Sodium Salt of α-*aci*-Nitrotoluene into 3,4,5-Triphenylisoxazole

Kimitoshi FUKUNAGA,* Akihiko OKAMOTO,† Keiji FURUMOTO,† and Makoto KIMURA

Faculty of Engineering, Yamaguchi University, Tokiwadai, Ube, Yamaguchi 755

† *Oshima National Mercantile Marine College, Komatsu, Oshima-cho, Yamaguchi 742-21*

(Received January 29, 1982)

Synopsis. 3,4,5-Triphenylisoxazole was produced by the reaction of the sodium salt of α-*aci*-nitrotoluene with the 1-cyano-1-methylethyl radical. The reaction was found to proceed *via* one electron transfer from α-*aci*-nitrotoluene anion to a 1-cyano-1-methylethyl radical.

Although a great number of works have been published on the reactivity of the 1-cyano-1-methylethyl radical,[1] little was known of their one electron transfer reactions.[2] We now report chemical evidence to support that one electron transfer is involved in the reaction of the 1-cyano-1-methylethyl radical generated by decomposition of 2,2'-azobisisobutyronitrile (AIBN) with the sodium salt of α-*aci*-nitrotoluene (**1**).

When a mixture of **1** and AIBN was heated in dimethyl sulfoxide (DMSO) at a bath temperature of 40—80 °C for 2—3 h, a crystalline product was obtained. The structure was confirmed to be 3,4,5-triphenylisoxazole (**2**) by the analysis of the spectra and a mixed melting point determination. From a number of experiments, it was found that the formation of **2** was accelerated with increasing of the reaction temperature (see Table 1). The kinetics of the decomposition of AIBN was studied in various solvents by Kulkarni *et al.*[3] They suggested that AIBN does not decompose to 1-cyano-1-methylethyl radical up to a temperature of 40 °C, that the formation of the radical from AIBN follows first order kinetics and that the rate constant is directly proportional to the reaction temperature. The dependence of the efficiency of this reaction on the reaction temperature correlates well with the dependence of the formation of 1-cyano-1-methylethyl radical on the reaction temperature. These facts imply that this reaction is initiated by thermal evolution of 1-cyano-1-methylethyl radical but not by one electron transfer from **1** to AIBN.

Analogous formation of 3,4,5-triphenyl-2-isoxazoline *N*-oxide (**3**) has been observed in the reaction of **1** with 2-bromo-2-nitropropane in DMSO at room temperature, for which a mechanism involving one electron transfer from **1** to 1-methyl-1-nitroethyl radical has been proposed.[4] In the reaction of **1** with 1-cyano-1-methylethyl radical, a similar mechanism should operate.

The above assumptions were strongly suggested by the fact that the reaction of **1** with 2-bromo-2-nitropropane under conditions similar to those employed for the reaction of **1** with AIBN resulted in the exclusive formation of **2** (see Experimental). It is surprising that relatively mild heating (70 °C, 2 h) of **3** in the reaction mixture afforded **2**, because it has been known that heating of **3** in a boiling ethanolic sodium hydroxide solution or without solvent under a reduced

Table 1. Reactions of sodium salt of α-*aci*-nitrotoluene (**1**) with AIBN[a]

Run	Amount of AIBN/mmol	Temp/°C	Time/h	Yield of **2**[b]/%
1	25	25	6	trace
2	5	40	6	4
3	15	40	3	12
4	25	40	3	16

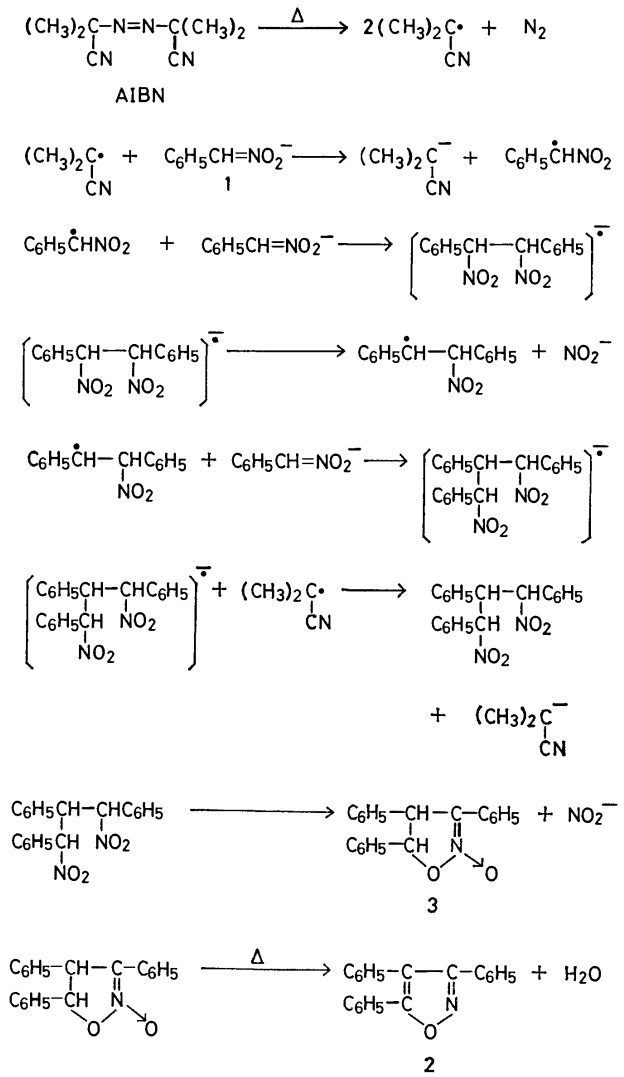
7[c]	25	70	2	25

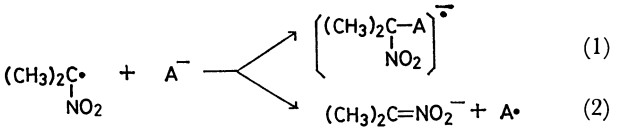
a) All the reactions were carried out using 3.95 g (25 mmol) of **1** in DMSO (25 ml). b) Pure isolated yield on **1**. c) The reaction was carried out under nitrogen.



Scheme 1.

pressure above its melting point give rise to **2**.[5] Thus, reactions of 1-methyl-1-nitroethyl radical and 1-cyano-1-methylethyl radical with **1** give essentially the same product. The process outlined in Scheme 1 may explain the formation of **2**: here an intermolecular cyclization of the resulting 1,3-dinitro-1,2,3-triphenylpropane could lead to **3** which give **2** by thermal dehydration.

It is well known that the scope of the S_{RN} 1 reaction involving the 1-methyl-1-nitroethyl radical is limited by the competition between reaction (1) (leading to substitution) and reaction (2) (leading to the 2-nitropropane dimer) as shown in Scheme **2**.



Scheme 2.

When the anion A^- contains a conjugated phenyl group which can lead to a substituted benzyl radical A, reaction (2) greatly predominates.[6] This may be the reason why 2-bromo-2-nitropropane fails to yield cross-coupling product with **1**.[4]

In order to generalize the preparative route for isoxazoles from nitroalkane, similar reactions of anions of *aci*-nitroalkanes, such as the lithium salt of *aci*-2-nitropropane or *aci*-nitrocyclohexane, with AIBN were studied. However, the reactions under comparable conditions were unsuccessful.

Apparently similar to 1-methyl-1-nitroethyl radical, the 1-cyano-1-methylethyl radical has a sufficiently high electron affinity that electron transfer take preference to the addition reaction. Thus, trapping of the radical A· by the anion A^- is greatly facilitated by the presence of phenyl and nitro groups which will stabilize the resulting radical anion $[A\text{–}A]^{\cdot-}$.

Experimental

General. Melting points were determined in capillary tubes in a liquid bath and are uncorrected. The IR spectra were recorded with a Hitachi 215 grating spectrophotometer. Mass spectra were determined with a Hitachi RMU-6C spectrometer.

Materials. Commercial DMSO was distilled prior to use. Commercial AIBN was recrystallized from methanol. The sodium salt of α-*aci*-nitrotoluene was prepared by addition of methanol solution of phenylnitromethane[7] to an equivalent amount of sodium methoxide in methanol. 2-Bromo-2-nitropropane was prepared as described previously.[4]

General Procedure for Reaction of 1 with AIBN: To a stirred suspension of **1** (3.95 g, 25 mmol) in DMSO (25 ml), AIBN (4.11 g, 25 mmol) was added in portions at 40 °C and the mixture was stirred at 70 °C for 2 h. The mixture was then poured into cold water to give a slightly yellow precipitate, which was collected by filtration, washed with water and dried. To the solid thus obtained methanol (30 ml) was added and the mixture was heated under reflux for 0.5 h, and then cooled to room temperature. The solid was again collected by filtration and recrystallized from ethanol to give **2** as colorless needles in 25% yield; mp 209—210 °C (lit,[8] mp 212 °C); MS 297.4 (M^+); IR (KBr) 1430, 1400, 920 cm^{-1} (C=C), 1210, 1010 cm^{-1} (–O–).

Reaction of 1 with 2-Bromo-2-nitropropane: To a stirred suspension of **1** (3.95 g, 25 mmol) in DMSO (25 ml), 2-bromo-2-nitropropane (2.10 g, 12.5 mmol) was added dropwise at room temperature. The resulting solution was stirred at 70 °C for 2 h, and then poured into cold water. The mixture was extracted with chloroform (100 ml). The extract was washed with water, dried over magnesium sulfate, and concentration gave a solid material. The crude material was twice recrystallized from ethanol to give **2** in 24% yield.

The authors wish to thank Dr. Hachiro Yamaguchi, Hiroshima University, for useful suggestions. The present work was supported by Grant-in-Aid for Scientific Research No. 575546 from the Ministry of Education, Science and Culture.

A New Synthesis of (*Z*)-13-Eicosen-10-one and (*Z*)-12-Nonadecen-9-one, the Pheromones of Peach Fruit Moth

Takashi Yoshida* and Shojiro Saito

Department of Industrial Chemistry, Faculty of Engineering, Meiji University, Tama-ku, Kawasaki 214

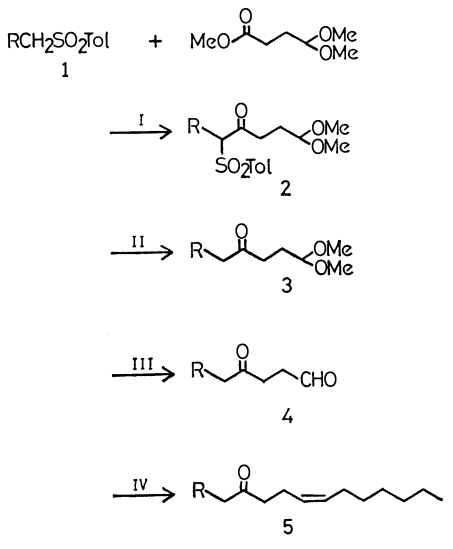
(Received February 4, 1982)

Synopsis. (*Z*)-13-Eicosen-10-one and (*Z*)-12-nonadecen-9-one were easily synthesized from starting 1-(*p*-tolylsulfonyl)nonane and 1-(*p*-tolylsulfonyl)octane *via* 4 steps, respectively.

It is known that (*Z*)-13-eicosen-10-one (**5a**) and (*Z*)-12-nonadecen-9-one (**5b**) are the pheromones of Japanese peach fruit moth (*Carposia niponensis* Walshingham),[1] and that a mixture of **5a** and **5b** in the ratio of 20:1 has the strongest biological activity.[2] Three examples for the preparation of the pheromones have been reported: (i) the addition of 4-undecynal prepared from 3-bromo-1-propanol to nonylmagnesium bromide;[1] (ii) the addition of 3-decynenitrile to nonylmagnesium bromide;[3] (iii) the alkylation of diethyl 3-oxoglutarate.[4]

In previous papers, we reported the synthesis of the jasmonoids and 2,15-hexadecanedione using sulfones, such as *cis*-1-(*p*-tolylsulfonyl)-3-hexene,[5] 1-(*p*-tolylsulfonyl)hexane,[5] 1,1-ethylenedioxy-3-(*p*-tolylsulfonyl)cyclopentane,[6] and 1,6-bis(*p*-tolylsulfonyl)hexane.[7] In this paper, we wish to describe a new and simple synthesis of (*Z*)-13-eicosen-10-one (**5a**) and (*Z*)-12-nonadecen-9-one (**5b**) by the condensation of sulfones with ester,[8] followed by desulfonylation[9] and salt-free Wittig reaction.[10]

The synthesis of the title compounds, **5a** and **5b**, were carried out as follows.



a: R = C_8H_{17}; b: R = C_7H_{15}

I: LDA, -78°C; II: Al(Hg), 10% aq THF; III; H_3O^+; IV: hepthyltriphenylphosphonium bromide

The condensation of the dianion of 1-(*p*-tolylsulfonyl)nonane (**1a**) generated with two equivalents of lithium diisopropylamide (LDA) with methyl 4,4-dimethoxybutanoate gave 1,1-dimethoxy-5-(*p*-tolylsulfonyl)-4-tridecanone (**2a**) in quantitative yield. The treatment of the sulfone **2a** with aluminium amalgam in 10% aqueous THF afforded 1,1-dimethoxy-4-tridecanone (**3a**) in 69% yield. The acetal **3a** was acidified with 5% hydrochloric acid to give 4-oxotridecanal (**4a**) in 81% yield. The salt-free Wittig reagent prepared from heptyltriphenylphosphonium bromide and sodium amide was added to a solution of **4a** in benzene to give (*Z*)-13-eicosen-10-one (**5a**) in 54% yield. (*Z*)-12-Nonadecen-9-one (**5b**) was synthesized from 1-(*p*-tolylsulfonyl)octane (**1b**) in the same procedure. The resulting products, **5a** and **5b**, had no infrared absorption band at 970 cm^{-1} region due to disubstituted trans-alkene. The structure of these products was identified by comparing their IR and NMR spectra with those of the reported data.[3,4] In conclusion, the method described above, compared with other methods, has various advantages: the starting sulfones are readily available, processes are short, simple, and easy, and the reaction proceeds smoothly to form the product in relatively good yield.

Experimental

Melting and boiling points are uncorrected. Melting points were taken on a Yanagimoto micro melting point apparatus. Infrared spectra were measured on a Shimazu IR-27G spectrophotometer. ^{1}H-NMR spectra were recorded on a Varian EM-390 spectrometer at 90 MHz, using TMS (δ=0.00 ppm) as an internal standard.

*1-(*p*-Tolylsulfonyl)nonane (**1a**) and 1-(*p*-Tolylsulfonyl)octane (**1b**).* 1-Bromononane (20 g, 0.097 mol) was added to a stirred solution of sodium *p*-toluenesulfinate tetrahydrate (30 g, 0.12 mol) in methanol (100 ml). The mixture was stirred under reflux for 6 h. After the removal of methanol, the residue was poured onto 300 ml of water. The organic layer was extracted with ethyl acetate. The extract was washed with water, dried over anhydrous sodium sulfate, and concentrated to give **1a** as a solid substance. Recrystallization from methanol–water afforded 26 g (95% yield) of **1a**, mp 51.4—51.5 °C. IR ($CHCl_3$): 2950, 1600, 1470, 1315, 1140 cm^{-1}. NMR (CCl_4): δ 0.75—1.05 (3H, br t, J=5.4 Hz), 1.1—1.5 (12H, br s), 1.5—1.8 (2H, br s), 2.47 (3H, s), 2.8—3.1 (2H, m), 7.38, 7.84 ppm (4H, an A_2B_2 pattern, J=7.5 Hz). Found: C, 68.37; H, 9.23%. Calcd for $C_{16}H_{26}O_2S$: C, 68.04; H, 9.26%. 1-(*p*-Tolylsulfonyl)-octane (**1b**) was obtained from 1-bromooctane (20 g, 0.10 mol) and sodium *p*-toluenesulfinate tetrahydrate (30 g, 0.12 mol) in methanol (100 ml) in the same procedure, mp 34.4—34.5 °C. IR ($CHCl_3$) 2950, 1600, 1470, 1320, 1150 cm^{-1}. NMR (CCl_4) δ 0.7—1.05 (3H, br t, J=5.4 Hz), 1.1—1.8 (12H, br s), 2.43 (3H, s), 2.8—3.1 (2H, m), 7.31, 7.75 ppm (4H, an A_2B_2 pattern, J=7.5 Hz). Found: C, 67.88; H, 8.82%. Calcd for $C_{15}H_{24}O_2S$: C, 67.12; H, 9.00%.

*1,1-Dimethoxy-5-(*p*-tolylsulfonyl)-4-tridecanone (**2a**) and 1,1-Dimethoxy-5-(*p*-tolylsulfonyl)-4-dodecanone (**2b**).* To lithium diisopropylamide (LDA) prepared from *n*-BuLi (15%

hexane solution, 6.0 g, 0.014 mol) and diisopropylamine (1.5 g, 0.015 mol) in dry THF (15 ml) was added a solution of **1a** (2.0 g, 0.007 mol) in dry THF (15 ml) at −78 °C under nitrogen. After the mixture was stirred for 1 h, methyl 4,4-dimethoxybutanoate (1.3 g, 0.008 mol) in dry THF (15 ml) was added. The mixture was stirred for 1 h at −78 °C and for an additional 3 h at room temperature. The mixture was poured onto cold 2% sulfuric acid. The organic layer was extracted with ethyl acetate. The extract was washed with water, dried over anhydrous sodium sulfate, and concentrated to give **2a** as a pale yellow viscous liquid in quantitative yield. The compound **2a** was purified by column chromatography over silica gel (60—80 mesh) with benzene as eluent to give white needles, mp 48.5—49.5 °C. IR (neat): 2900, 1720, 1600, 1470, 1320, 1150, 1080 cm^{-1}. NMR (CCl_4): δ 0.75—1.0 (3H, br t, J=5.4 Hz), 1.0—1.4 (12H, br s), 1.6—2.0 (4H, m), 2.35—3.15 (2H, m), 2.46 (3H, s), 3.35 (6H, s), 3.96 (1H, t, J=6.9 Hz), 4.33 (1H, t, J=6.0 Hz), 7.34, 7.66 ppm (4H, an A_2B_2 pattern, J=8.1 Hz). Found: C, 64.17; H, 8.73%. Calcd for $C_{22}H_{36}O_5S$: C, 64.05; H, 8.79%. 1,1-Dimethoxy-5-(*p*-tolylsulfonyl)-4-dodecanone (**2b**) was obtained from 1-(*p*-tolylsulfonyl)-octane (**1b**) (2.0 g, 0.007 mol) and methyl 4,4-dimethoxybutanoate (1.3 g, 0.008 mol) in quantitative yield, mp 41.5—42.5 °C. IR (neat): 2850, 1710, 1600, 1470, 1300, 1150, 1090 cm^{-1}. NMR (CCl_4): δ 0.75—1.0 (3H, br t, J=5.4 Hz), 1.0—1.4 (10H, br s), 1.6—2.0 (4H, m), 2.35—3.15 (2H, m), 2.45 (3H, s), 3.35 (6H, s), 3.96 (1H, t, J=6.9 Hz), 4.33 (1H, t, J=6.0 Hz), 7.34, 7.66 ppm (4H, an A_2B_2 pattern, J=8.1 Hz). Found: C 63.22; H 8.77%. Calcd for $C_{21}H_{34}O_5S$: C, 63.29; H, 8.60%.

*1,1-Dimethoxy-4-tridecanone (**3a**) and 1,1-Dimethoxy-4-dodecanone (**3b**).* To a stirred solution of **2a** (2.0 g, 4. 8mmol) in 10% aq. THF (60 ml) was added aluminium amalgam (1.5 g, 55.5 mmol). The mixture was stirred for 4 h at room temperature and then filtered. The filtrate was extracted with ethyl acetate. The extract was washed with water, dried over anhydrous sodium sulfate, and concentrated to give **3a** as a pale yellow liquid. The compound **3a** was purified by column chromatography over silica gel (60—80 mesh) with benzene–hexane (7:3) as eluent to give 0.86 g (69% yield) of **3a** as a colorless liquid. IR (neat): 2950, 1720, 1470, 1360, 1190, 1130, 1060 cm^{-1}. NMR (CCl_4): δ 0.8—1.05 (3H, br t, J=5.4 Hz), 1.1—1.9 (16H, m), 2.2—2.5 (4H, m), 3.25 (6H, s), 4.27 ppm (1H, t, J=6.0 Hz). 1,1-Dimethoxy-4-dodecanone (**3b**) was obtained from **2b** (2.0 g, 5.0 mmol) in the same procedure. IR (neat): 2900, 1720, 1460, 1360, 1190, 1120, 1060 cm^{-1}. NMR (CCl_4): δ 0.75—1.1 (3H, br t, J=5.4 Hz), 1.2—1.95 (14H, m), 2.3—2.55 (4H, m), 3.28 (6H, s), 4.33 ppm (1H, t, J=6.0 Hz).

*4-Oxotridecanal (**4a**) and 4-Oxododecanal (**4b**).* The acetal **3a** (0.6 g, 2.3 mmol) was added to 5% hydrochloric acid (5 ml) and the mixture was stirred for 5 h at 50 °C. The organic layer was extracted with ethyl acetate. The extract was washed with water, dried over anhydrous sodium sulfate, and concentrated to give **4a** as a pale yellow liquid. Compound **4a** was purified by column chromatography over silica gel (60—80 mesh) with benzene–hexane (5:5) as eluent to give 0.4 g (81% yield) of pure **4a** as a colorless liquid. IR (neat): 2900, 1730, 1710, 1470, 1410, 1090 cm^{-1}. NMR (CCl_4): δ 0.75—1.1 (3H, br t, J=5.4 Hz), 1.1—1.75 (14H, br s), 2.46 (2H, t, J=6.0 Hz), 2.73 (4H, s) 9.88 ppm (1H, s). 4-Oxododecanal (**4b**) was obtained from **3b** (1.0 g, 4.4 mmol) in the same procedure in 75% yield. IR (neat): 2900, 1730, 1710, 1470, 1400, 1090 cm^{-1}. NMR (CCl_4): δ 0.75—1.0 (3H, br t, J=5.4 Hz), 1.0—1.6 (12H, br s), 2.35 (2H, t, J=6.0 Hz), 3.60 (4H, s), 9.70 ppm (1H, s).

*(Z)-13-Eicosen-10-one (**5a**) and (Z)-12-Nonadecen-9-one (**5b**).* Sodium amide (0.1 g, 2.5 mmol) was added to a stirred solution of heptyltriphenylphosphonium bromide (0.4 g, 1.1 mmol) in dry benzene (50 ml) under nitrogen atmosphere. The temperature of the suspension was then slowly raised to the reflux temperature of benzene. The reaction mixture was stirred for 8 h under reflux. Stirring was discontinued and then the reaction mixture was cooled to room temperature. The upper layer (benzene phosphorane solution, Crystal Violet color) was separated by a syringe. The phosphorane was added to a stirred solution of (**4a**) (0.2 g, 0.87 mmol) in benzene (50 ml) over 0.5 h at room temperature. Stirring was continued for 15 h more at room temperature. Benzene was distilled under reduced pressure and hexane was poured onto the residue. The mixture was filtered and the filtrate was washed with 5% hydrochloric acid, brine, and dried over anhydrous sodium sulfate. Concentration of the hexane gave the crude product. This crude product was chromatographed over silica gel (60—80 mesh) with hexane–benzene (7:3) as eluent to give 0.14 g (54% yield) of **5a** as a pale yellow liquid. IR (neat): 2930, 1710, 1470, 1430, 1370, 1090 cm^{-1}. NMR (CCl_4): δ 0.7—1.0 (6H, br t, J=5.4 Hz), 1.1—1.7 (22H, br s), 1.9—2.15 (2H, m), 2.2—2.45 (6H, m), 5.2—5.45 ppm (2H, m). (*Z*)-12-Nonadecen-9-one (**5b**) was obtained from **4b** (0.2 g, 0.93 mmol) in the same procedure. IR (neat): 2950, 1710, 1460, 1370 cm^{-1}. NMR (CCl_4): δ 0.7—1.0 (6H, br t, J=5.4 Hz), 1.1—1.7 (20H, br s), 1.9—2.15 (2H, m), 2.2—2.45 (6H, m), 5.15—5.4 ppm (2H, m).

We wish to thank Dr. Tetsuo Miyakoshi and Mr. Hiroaki Omichi of Meiji University for their useful discussions and valuable suggestions.

Studies on 2-Aziridinecarboxylic Acid. VI.[1] Synthesis of β-Alkoxy-α-Amino Acids *via* Ring-opening Reaction of Aziridine

Kiichiro NAKAJIMA, Masahiro NEYA, Shinichi YAMADA, and Kenji OKAWA*

Department of Chemistry, Faculty of Science, Kwansei Gakuin University, Nishinomiya 662

(Received February 12, 1982)

Synopsis. The reaction of aziridine derivatives having a urethane-type protecting group with several alcohols in the presence of boron trifluoride etherate afford the corresponding optically pure *O*-alkylserine and *O*-alkylthreonine derivatives *via* a ring-opening reaction of aziridine in good yield.

In 1976, we reported that *N*-aminoacyl 2-aziridinecarboxylic acid derivatives, *e.g.*, Z-Gly-(2*S*)-Azy-Gly-OBzl, were coverted into the corresponding *O*-alkylserine peptide by the reaction of several alcohols in the presence of boron trifluoride etherate.[2] The yields, however, were usually very poor.

In this communication, we describe the results of aziridine derivatives having a urethane-type protecting group, benzyl (2*S*)-1-benzyloxycarbonyl-2-aziridinecarboxylate[(2*S*)-Z-Azy-OBzl(**1**)] and methyl (2*S*,3*S*)-1-benzyloxycarbonyl-3-methyl-2-aziridinecarboxylate [(2*S*,3*S*)-Z-3-MeAzy-OMe(**2**)], with several alcohols. **1** and **2** were synthesized according to our previous report.[3,4]

(2*S*)-Z-Azy-OBzl(**1**) and (2*S*,3*S*)-Z-3-MeAzy-OMe (**2**) were very stable in alcoholic solution at a room temperature, even under heating and no ring-opening reaction of the aziridine residue with alcohols was observed. However, if a catalytic amount of boron trifluoride etherate was added to the alcoholic solution of the aziridine derivatives, the reaction occurred easily to give the corresponding *O*-alkylserine(**3**—**9**) and -threonine(**10**—**16**) derivatives in good yield as shown in Scheme 1 and Table 1.

The synthesized *O*-alkylserine and threonine derivatives were easily transformed into the corresponding L-*O*-alkyl serine(**17**, **18**, **19**) and L-*O*-alkylthreonine (**20**, **21**, **22**, **23**) by catalytic hydrogenolysis or the combination of catalytic hydrogenolysis and hydrolysis as shown in Scheme 1, giving the titled compounds.

This study showed that the ring-opening reaction of aziridine derivatives having the urethane-type protecting groups is an effective method for synthesizing optically active β-alkoxy-α-amino acids.

Experimental

The melting points given are uncorrected. Optical rotations were determined at the D line on a Perkin-Elmer 141 polarimeter. The NMR spectra were obtained with a Hitachi R-20 B high resolution spectrometer using TMS as the internal reference.

(2S)-Z-Azy-OBzl (1). To a solution of (2*S*)-H-Azy-OBzl[3] (1.2 g, 6.7 mmol) and Et_3N (0.76 ml, 5.4 mmol) in $CHCl_3$ was added benzyloxycarbonyl chloride (0.86 ml, 5.4 mmol) at 0 °C with stirring. After being stirred overnight, it was washed with 10% citric acid, 1 M (1 M=1 mol dm^{-3}) $NaHCO_3$, and water, then dried over Na_2SO_4 and concentrated *in vacuo*. The residue was purified by silica gel column chromatography and 1.61 g (96% from Z-Cl[1]) of **1** was obtained, $[\alpha]_D^{23}$ −18.1° (*c* 1.0, MeOH). NMR ($CDCl_3$) δ: 2.37 (1H q, *J*=1.5, 5 Hz), 3.08 (1H q, *J*=3.0, 5.0 Hz), 5.05, 5.07 (4H 2s), 2.54 (1H q, *J*=1.5, 3.0 Hz), 7.26 (10H s).

Found: C, 69.15; H, 5.53; N, 4.42%. Calcd for $C_{18}H_{17}O_4N$: C, 69.44; H, 5.50; N, 4.50%.

(2S,3S)-Z-3-MeAzy-OMe (2). To a solution of (2*S*,3*S*)-H-3-MeAzy-OMe[4] (11.3 g, 78 mmol) and Et_3N (10.9 ml, 78 mmol) in $CHCl_3$ (200 ml) was added 2-benzyloxycarbonyloximino-2-phenylacetonitrile (Z-ON) (19.7 g, 70 mmol) at room temperature with stirring. After the reaction mixture was worked up as described above, 14.8 g (85% from Z-ON) of **2** was isolated as syrup, $[\alpha]_D^{23}$ −66.2° (*c* 1.1, MeOH). NMR ($CDCl_3$) δ: 1.25 (3H d, *J*=6.0 Hz), 2.75 (1H m), 3.20 (1H d, *J*=6.5 Hz), 3.35 (3H s), 5.10 (2H s), 7.28 (5H s).

Found: C, 62.34; H, 6.15; N, 5.48%. Calcd for $C_{13}H_{15}O_4N$: C, 62.64; H, 6.07; N, 5.62%.

L-Z-Ser(OMe)-OBzl (3). General Method via *Ring-opening Reaction of Azy*: **1** (0.3 g, 0.96 mmol) was dissolved in $CHCl_3$ (3 ml) and MeOH (5 ml), then $BF_3 \cdot OEt_2$ (3 drops) was added at room temperature. The reaction mixture was left standing for 12 h, then washed with water, dried over Na_2SO_4, and concentrated *in vacuo*. The residue was subjected to silica gel column chromatography with elution by $CHCl_3$. The effluent was concentrated *in vacuo* and 0.21 g (64%) of **3** was obtained. NMR ($CDCl_3$) δ: 3.26 (3H s), 3.69 (2H m, β-proton), 4.52 (1H, α-proton), 5.74 (1H bd).

Found: C, 66.39; H, 6.21; N, 4.16%. Calcd for $C_{19}H_{21}O_5N$: C, 66.46; H, 6.16; N, 4.08%.

L-Z-Thr(OBu^t)-OMe (13). Via *Ring-opening Reaction of 3-MeAzy*: **2** (0.2 g, 0.8 mmol) was dissolved in $CHCl_3$ (2 ml) and *t*-BuOH (5 ml), then $BF_3 \cdot OEt_2$ (3 drops) was added at room temperature. The reaction mixture was left standing overnight at room temperature and was worked up as described above. 243 mg (94%) of **13** was obtained. NMR ($CDCl_3$) δ: 1.10 (9H s), 1.19 (3H d), 4.15 (1H m, β-proton), 4.25 (1H q, α-proton), 5.50 (1H b).

Found: C, 63.25; H, 7.94; N, 4.21%. Calcd for $C_{17}H_{25}O_5N$: C, 63.14; H, 7.79; N, 4.33%.

Via t-*Butylation with Isobutylene of* L-*Z-Thr-OMe*: To a solution of L-Z-Thr-OMe (2.67 g, 10 mmol) and isobutylene (15 ml) in CH_2Cl_2 (15 ml) was added conc. H_2SO_4 (1 ml). The reaction mixture was left standing at room temperature for 3 d, and then washed with 1 M $NaHCO_3$ and water, dried over Na_2SO_4, and concentrated *in vacuo*. The residue was purified by silica gel column chromatography. 2.42 g (75%) of **13** was obtained, $[\alpha]_D^{24}$ +4.7° (*c* 2.0, DMF).

L-*Z-Ser(OBzl)-OH.* Via *Ring-opening Reaction of Azy*: **1** (0.2 g, 0.64 mmol) was dissolved in $CHCl_3$ (2 ml) and benzyl alcohol (5 ml), then $BF_3 \cdot OEt_2$ (3 drops) was added at room temperarure. The reaction mixture was left standing overnight and then worked up as described above. The obtained **8** (100% yield) was dissolved in MeOH (3 ml) and 2 M NaOH (5 ml) was added with stirring at room temperature for 2 h, then the solution was concentrated *in vacuo*. The residue was dissolved in water and adjusted to pH 2 with 3 M HCl, and the product was extracted with ethyl acetate. The solution was washed with water, dried over Na_2SO_4, and concentrated *in vacuo*. The residue was crystallized from CCl_4, 211 mg (100%), mp 99.5—100 °C, $[\alpha]_D^{24}$ +9.4° (*c* 1.3, MeOH). [mp 99—100 °C, $[\alpha]_D^{24}$ +9.5° (*c* 1.1, MeOH), prepared from Z-Cl and L-H-Ser(OBzl)-OH].

Found: 65.38; H, 5.85; N, 4.32%. Calcd for $C_{18}H_{19}O_5N$: C, 65.64; H, 5.81; N, 4.25%.

*O-Isopropyl-*L-*serine (18)*: H_2 gas was bubbled through a solution of **4** (218 mg, 0.59 mmol) in MeOH (10 ml) containing Pd black (100 mg) for 2 h. The catalyst removed by filtration and the filtrate was concentrated *in vacuo*. The residue was crystallized from water–acetone, and 75.5 mg (87%) of **18** was obtained.

O-*Isopropyl-*L-*threonine (20)*. **11** (224 mg, 0.72 mmol) was hydrolyzed with 1 M NaOH (2.5 ml) in MeOH (3 ml) at room temperature for 1 h. After L-Z-Thr(OPr^i) had been isolated by the usual procedure, the benzyloxycarbonyl group was removed by the catalytic hydrogenation described above. The product was crystallized from water-acetone, and 100 mg (85.7%) of **20** was obtained.

Chemical Studies on the Mistletoe. IV.[1] The Structure of Isoglucodistylin, a New Flavonoid Glycoside Isolated from *Taxillus kaempferi*

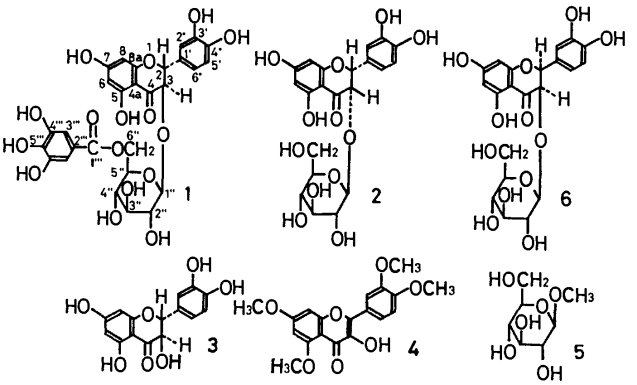
Atsushi SAKURAI,* Kyoji OKADA, and Yasuaki OKUMURA

Department of Chemistry, Faculty of Science, Shizuoka University, Ohya, Shizuoka 422

(Received March 23, 1982)

Synopsis. A new flavonoid glycoside, isoglucodistylin was isolated from *Taxillus kaempferi*, and (2*R*,3*S*)-taxifolin 3-β-D-glucopyranoside was assigned to this substance from studies on the hydrolysis products and on the isomerization products, and from analyses of the carbon-13 NMR spectra.

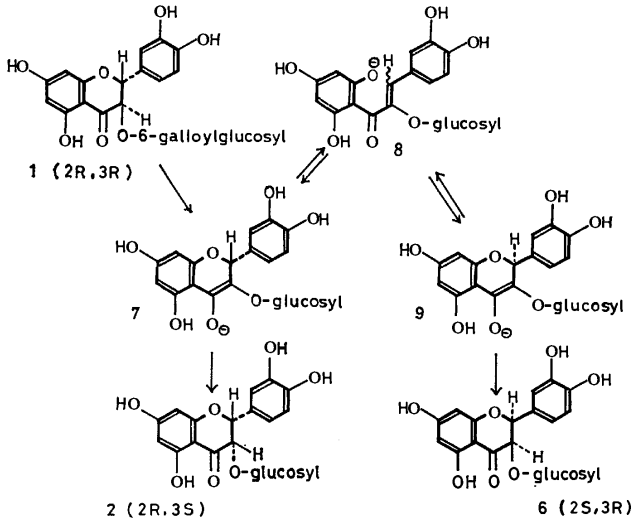
In our studies on the constituents of Japanese mistletoe, we reported the isolation and structure of taxillusin, a new flavonoid glycoside from *Taxillus kaempferi*, which was assigned to be (2*R*,3*R*)-taxifolin 3-β-D-glucopyranoside 6″-gallate (**1**).[2] During the course of the isolation of **1** by Sephadex LH-20 column chromatography, we found a presence of another new flavonoid glycoside and named it isoglucodistylin (**2**).



2 is amorphous white powder, mp 169—171 °C ($[\alpha]_D^{27}$ +25°), and the ultraviolet spectrum of **2** in ethanol shows the absorption maximum at 296 nm. Acid hydrolysis with hydrochloric acid gave (+)-taxifolin (**3**) ($[\alpha]_D^{27}$ +11°)[3] and glucose as the components. Methylation of **2** with dimethyl sulfate and potassium carbonate in acetone followed by acid hydrolysis and by air oxidation gave 3′,4′,5,7-tetra-*O*-methylquercetin (**4**).[4,5] This result indicates that glucose must be linked at the 3-position of taxifolin.

Taxifolin 3-glucoside (glucodistylin) had been isolated from the leaves of *Chamaecyparis obtusa* but this substance shows the ultraviolet absorption maximum at 292 nm in ethanol.[4] Both taxifolin 3-rhamnoside (astilbin) and aromadendrin 3-rhamnoside (engelitin) show their absorption maxima at 292 nm in ethanol and the configuration of the substituents at the 2- and 3-positions of both substances is *trans*.[6] While both the *cis* forms of astilbin and engelitin which have been prepared by isomerization of natural *trans* isomers show their absorption maxima at 296 nm in ethanol.[6] Therefore, glucodistylin must be a substance of *trans* form, and **2** might be 2,3-*cis*-taxifolin 3-glucoside.

The structure of **2** is supported by the carbon-13 NMR spectra of **1**, **2**, **3**, and methyl β-D-glucopyranoside (**5**) in DMSO-d_6 as shown in Table 1. The 3- and 4-carbons of taxifolin in **2** appear at a field



Scheme 1.

higher by 1.1 ppm and a field lower by 0.7 ppm respectively than those of **1**. This fact is the consequence of the difference in the configuration at the 3-position of taxifolin between **1** and **2**.

Acid hydrolysis of **2** gave (+)-taxifolin (**3**) of 2*R* and 3*R* configuration,[7] however, this result might be due to the isomerization at the 3-position from *cis* to *trans* form *via* enol. Therefore, the absolute configuration of **2** should be 2*R* and 3*S*.

The isomerization of **2** with aqueous sodium acetate in ethanol[6] gave a substance **6** but did not give 2,3-*trans*-taxifolin 3-β-glucoside. The ultraviolet spectrum of **6** in ethanol shows the absorption maximum at 295 nm. Acid hydrolysis of **6** with hydrochloric acid gave (−)-taxifolin ($[\alpha]_D^{28}$ −11°).[8] In the carbon-13 NMR spectra, the 1-carbon of glucose and the 2-carbon of taxifolin in **6** appear at fields lower by 1.8 and 0.7 ppm respectively than those of **2** as shown in Table 1. This fact is the consequence of the presence of less steric compression between the C-1 of glucose and the C-2 of taxifolin in **6**. These results indicate **6** to be (2*S*,3*R*)-taxifolin 3-β-D-glucopyranoside.

Hydrolysis of **1** with aqueous sodium carbonate gave **2**, **6**, and gallic acid, but did not give 2,3-*trans*-taxifolin 3-β-glucoside. The isomerization in the hydrolytic conditions was confirmed by high pressure liquid chromatography of recovered **1**. These results indicate that taxifolin glucosides in *cis* form might be more stable than those of *trans* in the conditions described above.

The formation of those **2** and **6** can be rationalized by the mechanistic sequence as shown in Scheme 1. During the base-catalyzed hydrolysis of the galloyl group, **1** is isomerized into **2** with inversion at the 3-position through an enolate **7**. When the C–O bond between the 1- and 2-positions of the enolate

In parts per million downfield from tetramethylsilane. Asterisks indicate that assignments are not unambigous.

7 is cleaved to afford a phenolate **8**, the phenolate oxygen in **8** attacks at the 2-position from the opposite side to afford an enolate **9**, which then converted to **6** with inversion at the 3-position.

These carbon-13 NMR spectroscopic data and all experimental results described above support the structure of isoglucodistylin (**2**) to be (2*R*,3*S*)-taxifolin 3-*β*-D-glucopyranoside.

Experimental

All melting points are uncorrected. The carbon-13 NMR spectra were measured with a JEOL JNM-PFT-60 NMR spectrometer on sampling interval of 2.0 s. Chemical shifts were obtained by δ value (ppm) from TMS as internal standard at 15.04 MHz. The UV spectra were measured with a Hitachi EPS-3 recording spectrophotometer. HPLC apparatus used was JASCO TRI ROTAR high pressure liquid chromatography. Column used was 2.6 mm × 250 mm stainless steal peacked with LiCrosolb RP-8. Elution system was CH_3CN–H_2O (9:1) containing 0.02 M (1 M = 1 mol dm^{-3}) acetic acid.

Isolation of Isoglucodistylin (2). The fresh leaves and twigs of the mistletoe (2 kg) which occurred on *Pinus densiflora* were extracted with ethanol (6 L) and the extract was condensed to a syrup *in vacuo*. The syrup was triturated with water (2 L) and chloroform (2 L), and the undissolved material which accumulated between both layers was collected. The faintly yellowish powder (11.5 g) was subjected to chromatography on a column of Sephadex LH-20 (3.5 × 120 cm) eluting with ethanol. Concentrated to dryness of the fractions containing **2** and recrystallization from ethyl acetate gave **2** as colorless amorphous powder (mp 167—169 °C; yield, 100 mg (0.005% from wet plant); $[\alpha]_D^{27}$ +25° (*c* 0.3, EtOH); UV (EtOH): λ_{max} 296 nm (ε 17100)). Found: C, 51.98; H, 4.46%. Calcd for $C_{21}H_{22}O_{12}\cdot H_2O$: C, 52.07; H, 4.99%.

Acid Catalyzed Hydrolysis of 2. **2** was dissolved into 2 M hydrochloric acid and the mixture was refluxed for 2 h. Extraction with ethyl acetate and recrystallization from water gave **3** as faintly yellowish crystals (mp 240—242 °C; $[\alpha]_D^{27}$ +11° (*c* 1.0, EtOH); UV (EtOH): λ_{max} 291 nm (ε 19400)). Hydrolyzate free from **3** was subjected to TLC for detection of the sugar component. The sugar was proved to be identical with D-glucose.

Methylation of 2. According to Fukui, Nakadome, and Ariyoshi's method,[4] **2** was methylated with dimethyl sulfate and potassium carbonate in acetone followed by acid hydrolysis and then air oxidation. The product was identified with authentic 3′,4′,5,7-tetra-*O*-methylquercetin (**4**) which was prepared by methylation and acid hydrolysis of rutin in the same way.

Isomerization of 2 with Sodium Acetate. **2** was isomerized with ethanolic sodium acetate according to Tominaga and Yoshimura's method.[6] Separation of the isomerized mixture with a column of Sephadex LH-20 in the same way as described above gave **6** as colorless amorphous powder (mp 200—202 °C (decomp); yield, 15%; $[\alpha]_D^{27}$ +150° (*c* 0.1, EtOH); UV (EtOH): λ_{max} 295 nm (ε 18500)). Found: C, 52.16; H, 4.43%. Calcd for $C_{21}H_{22}O_{12}\cdot H_2O$: C, 52.07; H, 4.99%.

Acid Catalyzed Hydrolysis of 6. Acid hydrolysis of **6** with 2 M hydrochloric acid in the same way as described above gave (−)-taxifolin (mp 238—240 °C; $[\alpha]_D^{28}$ −11° (*c* 0.1, EtOH); UV (EtOH): λ_{max} 291 nm (ε 18800)).

Base Catalyzed Hydrolysis of 1. **1** (1.25 g) was dissolved into aqueous 0.5 M sodium carbonate (200 ml) and the mixture was stirred for 18 h at room temperature under nitrogen atmosphere. After having been acidified with hydrochloric acid, the reaction mixture was extracted with ethyl acetate. The extract was subjected to chromatography on a column of Sephadex LH-20 in the same way as described above gave **2** (75 mg), **6** (45 mg), and gallic acid (10 mg).

Ceroalbolinic Acid, a Common Body Pigment of Three *Ceroplastes* Scale Insects in Japan. Confirmation of Structure

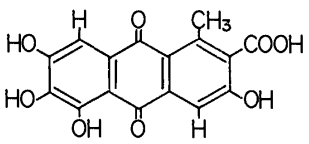
Hajime KOMURA,* Kohsei MIZUKAWA, and Hiroyuki MINAKATA

Suntory Institute for Bioorganic Research, Wakayama-dai, Shimamoto-cho, Mishima-gun, Osaka 618

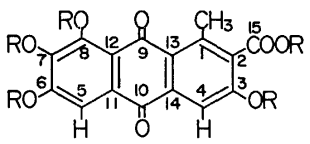
(Received March 26, 1982)

Synopsis. The structure of ceroalbolinic acid, a widely occurring insect pigment, a common body pigment of three Japanese *Ceroplastes* scale insects, has been confirmed as **2** by ^{13}C-NMR long-range selective proton decoupling (LSPD) experiments on its permethylated derivative **3**. Full assignments of skeletal carbons for **3** were also obtained.

The scale insects *Ceroplastes*(Coccidae) are pests which attack persimmon, citrus and other orchard trees and are widely distributed in Japan, Mexico, *etc.* The insect secretion has given rise to numerous new terpenoids[1,2] as well as waxes,[3] whereas one of the body pigments, the red carminic acid,[4] an anthraquinone *C*-glucoside isolated from *Dactylopius coccus*, is popularly used in food coloring and staining.



1



2, R=H; **3**, R=CH$_3$

The three Japanese species of *Ceroplastes*, *C. ceriferus*, *C. floridensis*, and *C. rubens* were treated with chloroform to extract the waxy coating, and then with methanol to extract the orange body pigment. Purification with Sephadex LH-20 and droplet counter-current chromatography(DCCC)[5] gave orange crystals. Yields of the pigment are 0.06, 0.15, and 0.21% respectively from *C. ceriferus*, *C. floridensis*, and *C. rubens* based on their fresh body weights. The ^{1}H-NMR in methanol-d_4 with only three singlets at 7.54, 7.16, and 2.78 ppm in 1:1:3 relative intensities showed the pigment to be identical with ceroalbolinic acid isolated from the Mexican species, *C. albolineatus*.[6-8] Structure **1** was ordiginally proposed,[6] but since a synthetic specimen of structure **1** did not coincide with ceroalbolinic acid, structure **2** was proposed instead without further evidence.[7] Thus, despite the relatively wide occurrence of this pigment, its structure was not settled[9] for long time. Full assignments of ^{13}C-NMR peaks of permethylated derivative **3** by long-range selective proton decoupling(LSPD) led unambiguously to structure **2**.

Permethylation[10] with dimethyl sulfate-potassium carbonate afforded the pentamethyl derivative **3** in quantitative yield. The ^{1}H-NMR peaks of 4-H and 5-H were based on the observation that the 4-H signal was sharpened upon decoupling of the 1-Me singlet. The ^{13}C-gated-^{1}H-decoupled spectrum with NOE show-

Italics denote change in multiplicity. s: Singlet, d: doublet, t: triplet, q: quartet, bs: broad singlet, dq: double quartet.

ed two skeletal carbonyl carbons at 183.0 and 182.6 ppm with broad singlet and triplet(J=4.4 Hz),[11] respectively. Selective irradiation of the 4- and 5-H signals both led to a collapse of the triplet to a doublet, whereas the broad singlet remained unchanged. The 182.6 ppm triplet is thus assigned to C-10 flanked by 4-H and 5-H in structure **3**; if the pentamethyl derivative were represented by the alternative structure, both carbonyls would have been doublets. Relaxation time(T_1) measurement also supported the structure **3**; the T_1 values of the skeletal carbons at lower-half part in the structure **3**, *i.e.* carbons 3,4,5,6, 10,11, and 14, are remarkably shorter compared with those of the upper-half (C-2,7,8,9,12, and 13) because of the presence of two protons in the same side of the ring.

LSPD of 4-H, 5-H, and 1-Me, which were carried out during the course of this study led to assignments of all ^{13}C-NMR peaks, as shown in the table, as well as to a full corroboration of structure **3** for pentamethylated ceroalbolinic acid. The present LSPD method is generally applicable in determining the substitution pattern of polysubstituted aromatic compounds, a problem frequently encountered and difficult to solve otherwise.

Interestingly, similar to the case of carminic acid reported by Eisner *et al.*,[12] ceroalbolinic acid also exhibited antifeedant activity against ants. This ceroalbolinic acid might therefore be working as one of the defense substances together with sticky waxy coating for *Ceroplastes* insects which cannot move anymore once after settled down on a tree, secreting so called honeydews without being attacked by ant or other carnivorous insects.

Experimental

All the melting points are uncorrected. ^{1}H- and ^{13}C-NMR were obtained on a JEOL FX-100 FT instrument at 25 °C, spectral width 2 (^{1}H) and 6 kHz (^{13}C), data points 16 kW, repetition time 5 (^{1}H) and 2.5—3.5 s (^{13}C), pulse width 17 (^{1}H) and 6 μs (^{13}C) (both 45° pulse), power level for LSPD 13 kHz, −50 dB with power attenuator. T_1 experiment was carried out with saturation-recovery method on an undegassed sample. Solvent peak was used as an internal standard for NMR, 7.24 (^{1}H, $CHCl_3$), 3.30 (^{1}H, CHD_2OD), 77.0 (^{13}C, $CDCl_3$), and 49.0 ppm (^{13}C, CD_3OD). EI- and FD-mass spectra were obtained on a JEOL JMS-01SG-2 mass spectrometer.

*Isolation of Ceroalbolinic Acid (**2**).* Crude methanol extracts of each insects were separately treated with almost equal volume of chloroform–water mixture (1:1 v/v) to remove lipophilic part. Aqueous layer of the mixture was then concentrated *in vacuo* to a thick syrup followed by column chromatography on a Sephadex LH-20 with 0.1% acetic acid in methanol to give pigment as a retarded band. After further purification on a DCCC (Tokyo Rika Kikai, Co.) with chloroform–methanol–0.02 mol/dm^3 aqueous hydrochloric acid (7:13:8 v/v) using aqueous layer as a mobile phase in ascending mode, ceroalbolinic acid crystallized out in the test tubes on a fraction collector. Mp>250 °C (lit,[6] 290 °C, decomp). FD-MS, m/z 331 ((M+1)$^+$, 100%), ^{13}C-NMR (methanol-d_4): 190.1 (C-9), 182.7 (C-10), 171.4 (C-15), and 20.4 (1-Me).

Methylation of Ceroalbolinic Acid. Ceroalbolinic acid was methylated for 5 h with excess amount of dimethyl sulfate and anhydrous potassium carbonate in refluxing acetone. The reaction was quenched by adding glacial acetic acid. After regular work-up of the mixture, yellow needles of pentamethyl derivative **3** were obtained in quantitative yield upon concentration and trituration with small amount of methanol. Crystals thus obtained were pure enough without further recrystallization. Mp 200.5—201.5 °C (lit,[6] 201—204 °C). ^{1}H-NMR ($CDCl_3$): 7.64 (4-H, br s, J<1 Hz), 7.57 (5-H, s), 4.05, 4.02, 4.00 4.00 3.92 (OMe ×5, s's), and 2.69 (1-Me, s). FD-MS, m/z 400 (M$^+$, 1005), EI-MS, m/z 400 (M$^+$, 97%), 385 ((M−CH_3)$^+$, 100%), 369 ((M−OMe)$^+$, 23%), and 367 ((M−33)$^+$, 53%).

Radiation-induced Alkylation, Hydroxyalkylation, and Reduction of Pyridinecarboxamides in Acidic Alcoholic Solutions

Akira SUGIMORI,* Masayuki NISHIJIMA, and Hiroshi ITOH

Department of Chemistry, Faculty of Science and Technology, Sophia University, Kioi-cho 7-1, Chiyoda-ku, Tokyo 102

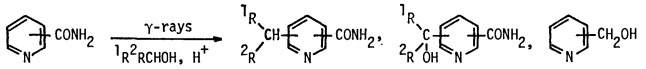
(Received March 27, 1982)

Synopsis. The γ-irradiation of pyridinecarboxamides in acidic methanol or ethanol brings about substitution of the ring hydrogen by alkyl or hydroxyalkyl groups derived from the solvent alcohols in relatively high G-values. In 2-propanol, little alkylation and hydroxyalkylation occur and reduction of $CONH_2$ to CH_2OH occurs in low G-values.

In spite of their biological importance, the radiation-induced reactions of pyridinecarboxamides have not yet been thoroughly studied, at least on the basis of product analyses. Concerning the radiation-induced reactions of model compounds for NAD (nicotinamide dinucleotide), hydroxylation in aqueous solutions[1] and dimer formation[2] have been reported. By means of pulse radiolysis technique, intermediates formed in the radiolysis of pyridinecarboxylic acid derivatives in aqueous alcohol were studied,[3,4] but the reports have not mentioned the structures of products. As an extension of our studies on photo- and radiation-induced reactions of pyridinecarboxylic acid derivatives,[5] we report here the radiation-induced reactions of pyridinecarboxamides, including biologically important 3-pyridinecarboxamide, in acidic alcohols. The radiation-induced reactions may furnish a useful synthetic method, owing to the specific type of reactions, which are different from those induced by a free radical initiator, and their relatively high G-values.

Results and Discussion

Gamma-irradiation of pyridinecarboxamides in acidic alcoholic solutions brings about substitution of the ring hydrogen by alkyl and hydroxyalkyl groups derived from the solvent alcohols and reduction of $CONH_2$ to CH_2OH.



The radiation-induced reactions of pyridinecarboxamides are very similar to those of the corresponding carboxylic esters: 1) In acidic methanolic solutions, 2- and 3-pyridinecarboxamides give methylation products in relatively high G-values. The positions for methylation in carboxamides are similar to those of the corresponding carboxylic esters. 2) In acidic methanol, 4-pyridinecarboxamide undergoes hydroxymethylation rather than methylation. 3) In acidic 2-propanol little isopropylation occurs and, instead, reduction of $CONH_2$ at 2- and 4-positions to CH_2OH occurs.

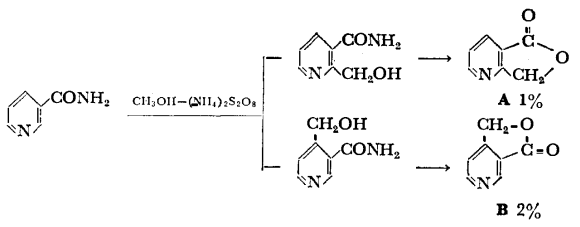
The following differences between the radiation-induced reactions of pyridinecarboxamides and those of carboxylic esters should be noted: 1) Reduction of $CONH_2$ at 2- and 4-positions to CH_2OH is much less efficient than that of the esters. 2) During the irradiation of 3-pyridinecarboxamide in acidic 2-propanol, 6-ethyl-3-pyridinecarboxamide was obtained in higher yield than 6-isopropyl-3-pyridinecarboxamide.

The similarities of the reactions of amides and esters suggest that the mechanism for the radiation-induced reactions of pyridinecarboxamides should be parallel to that of pyridinecarboxylic esters:[5] for alkylation and reduction, hydroxyalkyl radicals and hydrogen atom play important roles. The fact that ethylation occurs more effectively than isopropylation in γ-irradiation of 3-pyridinecarboxamide in 2-propanol suggests that $CH_3\dot{C}HOH$ radical formed by C–C cleavage of 2-propanol is more efficient for alkylation than $(CH_3)_2\dot{C}OH$ radical which is formed predominantly during γ-irradiation of 2-propanol.[6] In the free radical reaction initiated by the thermal decomposition

TABLE 1. RADIATION-INDUCED REACTIONS OF PYRIDINECARBOXAMIDES IN ACIDIC ALCOHOLIC SOLUTIONS
[Pyridinecarboxamide] = 0.03 mol dm^{-3}; [H_2SO_4] = 0.05 mol dm^{-3}; dose rate, 5×10^5 rad h^{-1}; dose, 1.0×10^7 rad.

Substrate	Alcohol	Product (G-value)			
		Substitution product (Position and group introduced)		Reduction product	
2-Pyridinecarboxamide	MeOH	4-Methyl-	(0.55)		
		4-Methyl-6-hydroxymethyl	(0.28)		
	i-PrOH	—		2-Pyridylmethanol	(0.02)
3-Pyridinecarboxamide	MeOH	4-Methyl-	(0.26)		
		6-Methyl-	(0.97)		
	EtOH	6-Ethyl-	(1.04)		
	i-PrOH	6-Isopropyl-	(0.06)		
		6-Ethyl-	(0.14)		
4-Pyridinecarboxamide	MeOH	2-Hydroxymethyl-	(0.22)		
	i-PrOH	—		4-Pyridylmethanol	(0.13)

of ammonium peroxodisulfate,[7] 3-pyridinecarboxamide gives 2- and 4-hydroxymethyl-3-pyridinecarboxylic acid lactones (5,7-dihydrofuro[3,4-*b*]pyridin-5-one (**A**) and 1,3-dihydrofuro[3,4-*c*]pyridin-3-one (**B**)), which are the intramolecular alcoholysis products from 2- and 4-hydroxymethyl-3-pyridinecarboxamides in low yields.



The γ-irradiation of pyridinecarboxamides and esters in methanol (and in the case of 3-pyridinecarboxamide in ethanol) gives methylation (and ethylation) products in rather high *G*-values and methylation by methanol can not be effected by an efficient free radical initiator $S_2O_8^{2-}$. Therefore, this type of radiation-induced alkylation should have synthetic utility for the introduction of alkyl groups to the pyridine nucleus.

Experimental

Materials. Commercial 2-, 3-, and 4-pyridinecarboxamides were used after the purification by recrystallization.

Gamma-irradiation. Solutions containing 0.03 mol dm^{-3} of pyridinecarboxamide and 0.05 mol dm^{-3} of H_2SO_4 were deaerated by bubbling Ar for 30 min. The solutions were irradiated at the ^{60}Co γ-facility of Japan Atomic Energy Research Institute in Takasaki (dose rate, 5×10^5 rad h^{-1}; dose, 1.0×10^7 rad).

$(NH_4)_2S_2O_8$-induced Reaction. A methanolic solution (50 cm^3) containing 3-pyridinecarboxamide (15 mmol), $(NH_4)_2S_2O_8$ (15 mmol), and H_2SO_4 (0.4 cm^3) was refluxed for 30 min.

Separation of Products. The irradiated solutions were concentrated under reduced pressure and neutralized with Na_2CO_3 and $NaHCO_3$. The products were separated by means of TLC (plate, Kieselgel 60 GF_{254} of E. Merck Co.; developing solvents; ethyl acetate, acetone, and their mixture).

Identification of Products. 4-Methyl-2-pyridinecarboxamide: mp 119—120 °C; IR (KBr disk) 3400, 3250, 1680 and 1360 cm^{-1}; ^1H NMR ($CDCl_3$) δ=8.40 (1H, d, J=4.4 Hz, H at 6-position), 8.02 (1H, d, J=1 Hz, H at 3-position), 7.23 (1H, dd, J=4.4 and 1 Hz, H at 5-position), and 2.44 (3H, s, CH_3); Found: C, 61.4; H, 6.2; N, 20.3%; Calcd for $C_7H_8N_2O$: C, 61.8; H, 5.9; N, 20.6%.

6-Ethyl-3-pyridinecarboxamide: mp 161—163 °C; IR (KBr disk) 3220, 1690, 1405, 1395, and 1375 cm^{-1}; ^1H NMR ($CDCl_3$) δ=8.84 (1H, d, J=2.0 Hz, H at 2-position), 8.09 (1H, dd, J=8.0 and 2.0 Hz, H at 4-position), 7.40 (1H, d, J=8.0 Hz, H at 5-position), 2.88 (2H, q, J=7.2 Hz, CH_2), and 1.30 (3H, t, J=7.2 Hz, CH_3); Found: C, 63.7; H, 6.7; N, 18.9%. Calcd for $C_8H_{10}N_2O$: C, 64.0; H, 6.7; N, 18.7%.

2-Hydroxymethyl-4-pyridinecarboxamide: mp 183—184.5 °C; IR (KBr disk) 3360, 3320, 1690, 1420, and 1040 cm^{-1}; ^1H NMR δ=8.56 (1H, d, J=5 Hz, H at 6-position), 7.74 (1H, d, J=1 Hz, H at 3-position), 7.56 (1H, dd, J=5 and 1 Hz, H at 5-position), and 4.80 (2H, s, CH_2); Found: C, 55.0; H, 5.6; N, 19.0%. Calcd for $C_7H_8N_2O_2$: C, 55.3; H, 5.3; N, 18.4%.

6-Isopropyl-3-pyridinecarboxamide (mp 135—136.5 °C) was identified only on the basis of ^1H NMR because of its low yield. ^1H NMR (D_2O) δ=8.80 (s), 8.05 (d, J=8 Hz), 7.35 (d, J=8 Hz), 3.00 (m, J=8 Hz), and 1.23 (d, J=8 Hz).

2-Hydroxymethyl-3-pyridinecarboxylic acid lactone: mp 108—111 °C; IR (KBr disk) 1760 cm^{-1} (γ-lactone C=O); ^1H NMR ($CDCl_3$) δ=8.85 (1H, dd, J=5.2 and 2.0 Hz, H at 6-position), 8.28 (1H, dd, J=7.6 and 2.0 Hz, H at 4-position), 7.45 (1H, dd, J=7.6 and 5.2 Hz, H at 5-position), and 5.33 (2H, s, CH_2); MS (70 eV) *m/e* (relative intensity) 135 (M^+; 58), 106 (100), 78 (38), 77 (22), and 51 (11); Found: *m/e* 135.0323. Calcd for $C_7H_5NO_2$: M, 135.0320.

4-Hydroxymethyl-3-pyridinecarboxylic acid lactone: mp 122—124 °C; IR (KBr disk) 1760 cm^{-1} (γ-lactone C=O); ^1H NMR ($CDCl_3$) δ=9.19 (1H, s, H at 2-position), 8.87 (1H, d, J=5 Hz, H at 6-position), 7.52 (1H, d, J=5 Hz, H at 5-position), and 5.38 (2H, s, CH_2); MS (70 eV) *m/e* (relative intensity) 135 (M^+; 100), 106 (66), 78 (37), and 51 (12); Found: *m/e* 135.0320. Calcd for $C_7H_5NO_2$: M, 135.0320.

4-Methyl-3-pyridinecarboxamide (mp 163.5—164.5 °C; lit, [8] 167—167.5 °C) and 6-methyl-3-pyridinecarboxamide (mp, 199—200 °C; lit,[9] 196—198 °C) were identified by means of melting point measurements and NMR and IR spectral analyses. Pyridylmethanols were identified by the accordance of the gas-chromatographic and spectral properties with the authentic ones.

A Simple Synthesis of 7-*t*-Butyl-4-methyl-2,3-dihydrothiepin

Kagetoshi YAMAMOTO,* Shoko YAMAZAKI, and Ichiro MURATA*

Department of Chemistry, Faculty of Science, Osaka University, Toyonaka, Osaka 560

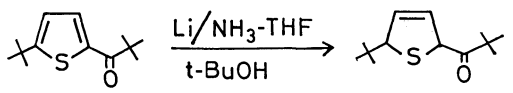
(Received April 16, 1982)

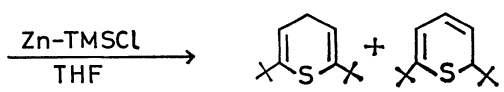
Synopsis The novel ring expansion reaction developed for the synthesis of 2,6-di-*t*-butylthiopyrans has been applied to the short path preparation of a dihydrothiepin derivative. Thus, 4-methyl-6-pivaloyl-3,6-dihydro-2*H*-thiopyran was converted into 7-*t*-butyl-4-methyl-2,3-dihydrothiepin in excellent yield by using chlorotrimethylsilane-zinc reagent in tetrahydrofuran.

Strategies for the synthesis of organic compounds using silicon-based reagents have been developed extensively, and their utility has been well documented.[1] However, one of these, chlorotrimethylsilane-zinc (or zinc amalgam) reagent induces formation of double bonds directly from ketones under mild conditions.[2] It provides some novel synthetic methods,[3] but has received little attention although it appears to occupy a prominent place in organic synthesis. In connection with our efforts directed toward the synthesis of stable monocyclic thiepins[4] we have recently demonstrated the novel and versatile synthesis of 2,6-di-*t*-butylthiopyrans from the corresponding acyldihydrothiophene using this reagent (see Scheme 1). Otherwise this substance is difficult to make.

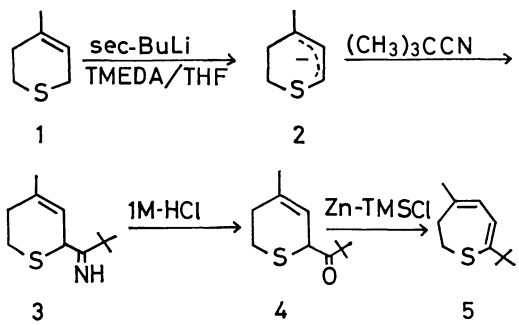
This method appears to have promise as a tool for the synthesis of seven membered rings containing a sulfur atom such as thiepin derivatives directly from appropriate six-membered precursors. In this context, the synthesis of 7-*t*-butyl-4-methyl-2,3-dihydrothiepin (**5**) starting from readily available **1**[5] was examined (Scheme 2).

The desired precursor **4** was prepared starting from **1**; the anion **2**[5,6] generated from **1** with s-butyllithium in THF in the presence of TMEDA at −78 °C was





Scheme 1.



Scheme 2.

treated with pivalonitrile at −20 °C to give exclusively the crude imine **3** in high yield. Hydrolysis of **3** with 1 M (1 M=1 mol dm^{-3}) hydrochloric acid in THF–water formed **4**, whose structure was characterized unequivocally by a combination of elemental analysis and spectral data (^{1}H NMR, IR, and high resolution mass spectrum). It is interesting to note that the ambident anion **2** reacts exclusively at α-carbon of the sulfur atom with pivalonitrile.

The acylthiopyran **4** thus obtained led to the final product, dihydrothiepin (**5**) in excellent yield by treatment with chlorotrimethylsilane and activated zinc powder in THF at 0 °C. It was purified by column chromatography on alumina and elution with hexane. Its structure was confirmed by a full range of spectral data (see experimental section).

The successful conversion of **4** into **5** provides a new methodology for ring expansion reactions of sulfur heterocycles. Numerous applications will undoubtedly follow.

Experimental

^{1}H NMR (100 MHz) spectra were recorded on a Varian XL-100 spectrometer with TMS as the internal standard, IR spectra were recorded on a JASCO A-100 instrument, and mass spectra were obtained on a JEOL JMS-01SG-2 spectrometer.

*4-Methyl-6-pivaloyl-3,6-dihydro-2*H*-thiopyran (4).* To a solution of thiopyran (**1**; 0.31 g, 2.7 mmol) in 6 ml of tetrahydrofuran in the presence of 0.40 ml of TMEDA, was added 5.0 ml of 0.54 M s-butyllithium in hexane at −50 °C. After the solution was allowed to warm to −20 °C for 1 h, 0.28 ml (2.5 mmol) of pivalonitrile was added to the solution cooled to −50 °C with stirring, and the reaction mixture was stirred for an additional 3 h at −20 °C. After addition of water, the product was extracted with ether, and the ether solution dried over anhydrous sodium sulfate. Removal of the solvent gave the crude imine **3**; yield: 0.47 g (88.5%). IR (neat: ν=1620 cm^{-1}. ^{1}H NMR (CCl_4): δ=1.17 (s, 9H); 1.77 (s, 3H); 2.28 (m, 2H); 2.57 (m, 2H), 3.90 (d-like, 1H); 5.17 ppm (m, 1H). To 0.34 g (1.7 mmol) of crude imine **3** in 7 ml of THF was added 2 ml of 1 M hydrochloric acid at room temperature, the reaction mixture was stirred for 3 h. The product was extracted with hexane and the combined extracts dried over anhydrous sodium sulfate. Removal of the solvent gave crude acylthiopyran **4**, which was purified by short column chromatography (alumina) and elution with benzene to give pure **4**; yield: 0.336 g (98%). IR (neat): ν=1695 cm^{-1} (C=O). ^{1}H NMR ($CDCl_3$): δ=1.23 (s, 9H); 1.76 (bs, 3H); 2.22—3.00 (m, 4H); 4.30 (d, 1H, J=6.0 Hz); 5.33 ppm (m, 1H). Found: C, 66.95; H, 9.23; S, 15.72%. Calcd for $C_{11}H_{18}OS$: C, 66.62; H, 9.15; S, 16.17%. High Mass m/e=198.1070 (Calcd for $C_{11}H_{18}OS$; 198.1077).

7-t-Butyl-4-methyl-2,3-dihydrothiepin (5). To a suspension of 1.68 g of activated zinc powder in the solution of **4** (0.30 g, 1.5 mmol) in 15 ml of THF, 3.2 ml (25 mmol) of chlorotrimethylsilane was added dropwise at 0 °C with

stirring over 3 h. To the reaction mixture cooled to −20 °C, 1 ml of 1 M sodium hydroxide solution was added carefully. After removal of the zinc by decantation, the product was extracted with hexane, and the extracts were dried over anhydrous sodium sulfate. Evaporation of the solvent gave **5**, which was distilled at 50 °C/4 Torr. Yield: 270 mg (99%). ^{1}H NMR ($CDCl_3$): δ=1.16 (s, 9H); 1.86 (s, 3H); 2.66 (t-like, 2H); 2.87 (t, 2H, J=5.0 Hz); 5.73 (m, 1H); 5.87 ppm (d, 1H, J=8.0 Hz). Found: C, 72.56; H, 9.95; S, 17.36%. Calcd for $C_{11}H_{18}S$: C, 72.47; H, 9.95; S, 17.58. High Mass m/e=182.1122 (Calcd for $C_{11}H_{18}S$; 182.1127).

Origins and Spin Dependence of Near Infrared Magnetic Circular Dichroism of Iron(III) Hemoproteins

Takao YAMAMOTO,† Tsunenori NOZAWA, Nagao KOBAYASHI,†† and Masahiro HATANO*
Chemical Research Institute of Non-aqueous Solutions, Tohoku University, Sendai 980
(Received October 5, 1981)

Temperature variation experiments on near infrared magnetic circular dichroism spectra (700—2000 nm) have demonstrated that metmyoglobin (iron(III) myoglobin) cyanide and metmyoglobin fluoride derivatives which are typical low and high spin iron(III) heme complexes, respectively, exhibit the Faraday *C* term and the Faraday *C* and *A* terms, respectively. The results are consistent with theoretical predictions based on the assignment that the near infrared bands of the iron(III) heme complexes are attributable to the charge-transfer transitions from the occupied a_1 and a_2 π orbitals to the vacant iron $d\pi$ (d_{xz}, d_{yz}) orbitals in a C_{4v} notation.

The magnetic circular dichroism (MCD) spectra of heme for the ultraviolet and visible bands which consist mainly of porphyrin π to π^* transitions have reflected the electronic states of the heme iron.[1] The origins of the MCD have been explained in several ways.[1-10] Beyond the visible region, hemoproteins show several transitions ascribable to d-d transitions or to charge-transfer transitions associated with the d-electrons in the near infrared region,[11,12] so that these MCD bands should give more direct information of spin, oxidation, and ligand states of hemoproteins.

Cheng *et al.*[13] measured near infrared MCD spectra of methemoglobin (iron(III) hemoglobin) cyanide in the wavelength region from 800 to 2000 nm. Later, Stephens *et al.*[14] extended their studies to methemoglobin derivatives with fluoride, water, and azide. They explained all the MCD spectra as being composed of Faraday *C* terms in the charge-transfer transitions. Near infrared MCD spectra of various derivatives of metmyoglobin and myoglobin (iron(II) myoglobin) have been reported by Nozawa *et al.*[15] Near infrared MCD studies on cytochrome c′,[16] peroxidase,[17] P-450,[18] and cytochrome c[19] have appeared recently.

In this paper, assignment of Faraday parameters has been established experimentally by temperature variation studies on the typical low spin (metmyoglobin cyanide) and high spin (metmyoglobin fluoride) iron(III) hemoproteins. Further, the results are discussed in comparison with theoretical calculations.

Experimental

Horse heart myoglobin used was purchased from Sigma (type III). All chemicals were guaranteed grade reagents and used without further purification. ^2H_2O phosphate buffer (1/15 mol dm^{-3}, pH 6.98) and H_2O phosphate buffer (0.01 mol dm^{-3}, pH 7.0) were used to dissolve metmyoglobin cyanide and metmyoglobin fluoride, respectively. Potassium hexacyanoferrate(III) was used to oxidized myoglobin completely and excess hexacyanoferrate(III) was removed by passage through a column of Sephadex-G25 (medium). Metmyoglobin derivatives were prepared by adding respective solid salts to appropriate concentration (1 mol dm^{-3} KCN, 1.5 mol dm^{-3} NaF). Undissolved fraction was removed by low speed centrifugation (600 g). Amicon ultra filters (CF-25) were used to concentrate metmyoglobin solutions by the centrifugation.

Absorption spectra were recorded on a Hitachi EPS-3T spectrophotometer. MCD spectra from 800 to 1000 nm were obtained by use of a JASCO Model J-20A CD spectrometer with S-20 and S-1 type photomultipliers (Hamamatsu Television). The sensitivity of the J-20A is as high as 1×10^{-3} degree cm^{-1}. MCD spectra beyond 1000 nm were measured on a JASCO Model J-200 CD spectrometer with a CaF_2-photoelastic modulator (Morvue) incorporated. An S-1 type photomultiplier (Hamamatsu Television) and an InSb photovoltaic cell (Judson) were used as detectors for the wavelength regions from 800 to 1100 and beyond 1000 up to 2000 nm, respectively. The J-200 CD instrument has sensitivities of 2×10^{-3} and 5×10^{-3} degree cm^{-1} for the photomultiplier (800—1100 nm) and photovoltaic cell regions (1000—2000 nm), respectively. Electromagnets capable of producing magnetic fields up to 1.48 and 1.14 T were used for MCD measurements. The MCD magnitude is expressed by the molar ellipticity per Tesla ($[\theta]_M/10^4$ degree mol^{-1} dm^3 m^{-1} T^{-1} or 10 degree m^2 mol^{-1} T^{-1}).

Measurements at room temperature were carried out in 1/15 mol dm^{-3} ^2H_2O potassium phosphate buffer (pH 6.98). For low temperature measurements, mixtures of phosphate buffer and ethylene glycol-d_6 (50 : 50 in volume) and of phosphate buffer, potassium glycerophosphate, glycerol, and hydrochloric acid solution (4 : 20 : 10 : 5 in volume) were used in the regions from 1000 to 2000 (for metmyoglobin cyanide) and from 700 to 1000 nm (for metmyoglobin fluoride), respectively, to get transparent glass down to the liquid nitrogen temperature; the temperature was monitored with an alumel-chromel thermocouple inserted in the cell placed in a quartz Dewar vessel, and controlled by a stream of cold gaseous nitrogen evaporated from liquid nitrogen. Each scan was started 30 min after the temperature had reached a constant value. MCD measurements were repeated at least three times, results of a set being in good agreement with one another whithin experimental errors (±5%).

Results

Figure 1 demonstrates the effect of temperature on near infrared MCD and absorption spectra of metmyoglobin cyanide which is a typical low spin derivative. The MCD and absorption spectra at 0 °C show a good agreement with those previously reported by us.[15] The inset in Fig. 1 shows that the $[\theta]_M$ values of the MCD peaks at 6390 cm^{-1} (1560 nm), 7810 cm^{-1} (1280 nm),

In the inset, the $[\theta]_M$ values are plotted against reciprocals of absolute temperatures. Metmyoglobin concentration, 3.83×10^{-3} mol dm^{-3} (on the heme basis), KCN concentration, 1×10^{-3} mol dm^{-3}, 1.48 T. Cell length, 3 mm. Other experimental conditions are described in the text.

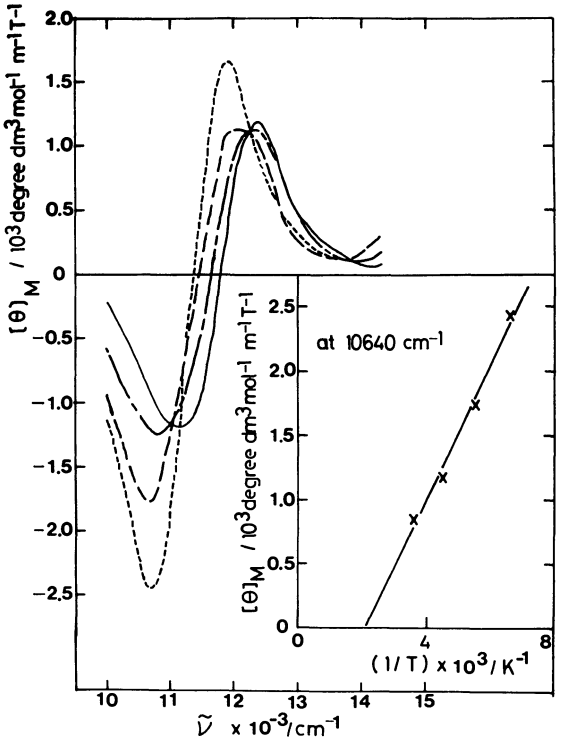

Fig. 2. MCD spectra for metmyoglobin fluoride in the near infrared region at various temperatures (——; 271 K, —·—; 219 K, ----; 179 K, and -----; 150 K). Metmyoglobin concentration, 6.04×10^{-3} mol dm^{-3}, NaF concentration, 1.5 mol dm^{-3}, cell length 2 mm, magnetic field 1.14 T. Other experimental conditions are described in the text.

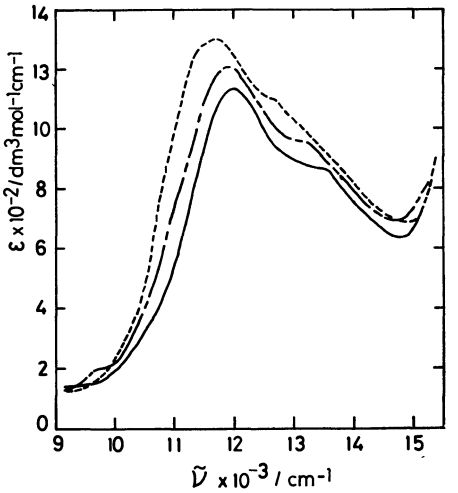

Fig. 3. Absorption spectra for metmyoglobin fluoride in the near infrared region at several temperatures (——; 293 K, —·—; 213 K, -----; 143 K). Other experimental conditions are the same as those for Fig. 2.

and 9430 cm^{-1} (1060 nm) increased in proportion to the reciprocal of absolute temperature ($1/T$). The extraporation of the lines gives zero intercepts at $1/T=0$. The absorption spectra exhibit only small increases in magnitude and band narrowing. These facts clearly indicate that the near infrared MCD spectra of metmyoglobin cyanide are composed of pure Faraday C terms. The intervals of the three peaks are 1420 and 1620 cm^{-1} and the intensity ratio among them is 93 : 35 : 1 at 0 °C.

Figure 2 illustrates the MCD spectra of metmyoglobin fluoride, a typical high spin iron(III) heme complex, at 271, 219, 179, and 150 K. Figure 3 shows the corresponding absorption spectra. The MCD and absorption spectra at 273 K agree with those previously reported by us.[15] The MCD peak around 12100 cm^{-1} (830 nm) exhibited only a small increase in intensity and a red shift by 400 cm^{-1} with temperature change from 271 and 150 K. The trough around 10600 cm^{-1} (940 nm) showed a red shift of 500 cm^{-1} and a 179% intensity increase. The absorption spectra also exhibited a 500 cm^{-1} red shift and an increase in magnitude around 11000 cm^{-1} by 80%. These complicated changes in the absorption and MCD spectra indicate that the near infrared MCD spectra are composed of a few Faraday

terms. The large temperature dependence of the MCD spectra suggests the presence of Faraday C term (around 10600 cm^{-1}). The temperature-independent Faraday A term with the S-shaped dispersion is also presumed to be present around 11500 cm^{-1}. Since the absorption spectra also increased in magnitude and exhibited a red shift, some changes in the MCD spectra should be due to that in the absorption spectra. Therefore it is concluded that the near infrared MCD spectra are composed of the large A term[20] around 11500 cm^{-1} and the C term around 10600 cm^{-1}.

Discussion

Electronic States of Heme. Actual heme chromophore has no C_{4v} symmetry rigorously. However, many studies have shown that it is a good approximation in the first order.[21] In this approximation the 3d iron has five orbitals with four different energies conventionally designated as b_2 (d_{xy} or ζ), e (d_{xz} or η, d_{yz} or ξ), a_1 (d_z^2 or u), and b_1 ($d_{x^2-y^2}$ or v) as shown in Fig. 4. The evidence from experiments and theories showed that the near infrared band in the Fe(III) hemoproteins should be the charge-transfer transition from the porphyrin highest occupied π orbitals (a_1 and a_2) to the iron vacant d-orbitals (e) in a C_{4v} approximation.[11,12]

Iron(III) Low Spin. Since a lower symmetry perturbation lifts the degeneracy in the e orbitals and the spin-orbit interaction mixes the t_{2g} (O_h) orbitals, the ground electronic states of the low spin iron(III) heme can be represented as the following Kramers' doublet:[22-25]

$$\begin{aligned}\phi_k^+ &= -A_k\phi_\xi^+ + iB_k\phi_\eta^+ + C_k\phi_\zeta^-,\\ \phi_k^- &= A_k\phi_\xi^- + iB_k\phi_\eta^- + C_k\phi_\zeta^+,\end{aligned} \quad (1)$$

where

$$\begin{aligned}\phi_\xi^+ &= |a_1\bar{a}_1a_2\bar{a}_2\xi\eta\bar{\eta}\zeta\bar{\zeta}|, \quad \phi_\xi^- = |a_1\bar{a}_1a_2\bar{a}_2\bar{\xi}\eta\bar{\eta}\zeta\bar{\zeta}|,\\ \phi_\eta^+ &= |a_1\bar{a}_1a_2\bar{a}_2\xi\bar{\xi}\eta\zeta\bar{\zeta}|, \quad \phi_\eta^- = |a_1\bar{a}_1a_2\bar{a}_2\xi\bar{\xi}\bar{\eta}\zeta\bar{\zeta}|,\\ \phi_\zeta^+ &= |a_1\bar{a}_1a_2\bar{a}_2\xi\bar{\xi}\eta\bar{\eta}\zeta|, \quad \phi_\zeta^- = |a_1\bar{a}_1a_2\bar{a}_2\xi\bar{\xi}\eta\bar{\eta}\bar{\zeta}|.\end{aligned} \quad (2)$$

In the Slater determinant, bar implies down spin and no bar stands for up spin. Similarly the charge-transfer state from the porphyrin a_1 (π) orbital to metal ξ, η (d_π) can be described as

$$\begin{aligned}\phi_4^+ &= -|a_1a_2\bar{a}_2\xi\bar{\xi}\eta\bar{\eta}\zeta\bar{\zeta}|,\\ \phi_4^- &= -|\bar{a}_1a_2\bar{a}_2\xi\bar{\xi}\eta\bar{\eta}\zeta\bar{\zeta}|.\end{aligned} \quad (3)$$

Electron paramagnetic resonance experiments for metmyoglobin cyanide give three g values as follows:[26]

$$g_x = 0.75,\ g_y = 1.88,\ g_z = 3.41.$$

Since these g values should arise from the Zeeman levels at the lowest Kramers' doublet, the relations expressed by

$$\begin{aligned}g_x &= 2|(B_1-C_1)^2 - A_1^2|,\\ g_y &= 2|(A_1-C_1)^2 - B_1^2|,\\ g_z &= 2|(A_1+B_1)^2 - C_1^2|,\end{aligned} \quad (4)$$

together with a normalization condition ($A_k^2+B_k^2+C_k^2=1$) give the A_k, B_k, and C_k values listed in Table 1, which also contains coefficients and relative energies for the second and third Kramers' doublets derived from a method similar to that of Griffith[23] and Kotani.[24]

Table 1. A set of coefficients and relative energies for respective Kramers' doublet

k	Relative energy	A_k	B_k	C_k
1	0	0.877	0.439	−0.188
2	1.417 λ[a]	0.463	−0.881	0.100
3	3.656 λ[a]	0.122	0.175	0.977

a) λ represents a spin-orbit coupling coefficient.

Iron(III) High Spin. The ground state of the iron(III) high spin heme belongs to the ^6A state described as follows for the state with $M=5/2$:

$$\phi_6 = |a_1\bar{a}_1a_2\bar{a}_2\xi\eta\zeta uv|, \quad (5)$$

and the other five wavefunctions for the ^6A state can be obtained by operating the shift operator $\mathbf{S}_-$ on Eq. 5. In high spin derivatives, the lowest charge-transfer transitions are from a_1, a_2, to b_2, e. These give rise to a

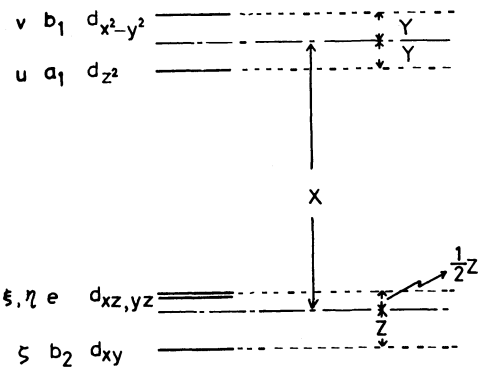

Fig. 4. Nomenclatures of 3d iron orbitals splitted in C_{4v} ligand field symmetry. X reperesents the octahedral (O_h) splitting energy of the 3d orbitals, Y and Z stand for those in the tetragonal field in the e_g and t_{2g} orbitals (O_h), respectively.

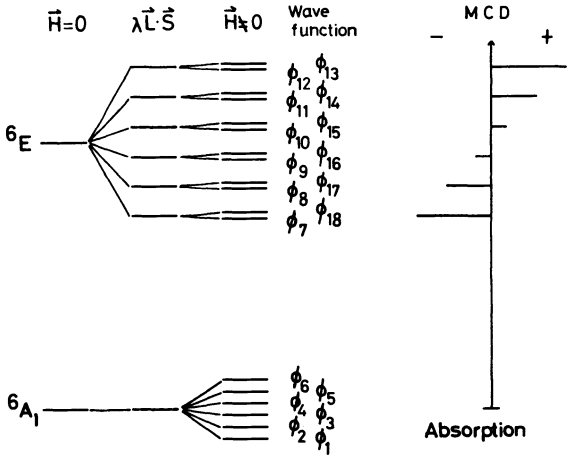

Fig. 5. The splitting pattern for the ground ($^6A_1$) and excited states (^6E) of the charge-transfer band in the high spin iron(III) heme derivatives by the effect of the spin-orbit coupling $\lambda\cdot\vec{L}\cdot\vec{S}$ and the magnetic field (H). The sign and relative magnitudes of Faraday C terms for the respective sublevels are also illustrated in the figure.

variety of states. However, to the first order in spin-orbit coupling only the states to which electric dipole transitions are allowed are the two ^{6}E states arising from e←a_1 and e←a_2, whose wavefunctions diagonalized in μ_z and $\lambda\vec{L}\cdot\vec{S}$ can be expressed for $M=5/2$ as follows:

$$\phi_{18} = -\frac{i}{\sqrt{2}}\left\{\left|\eta\frac{5}{2}\right\rangle + i\left|\xi\frac{5}{2}\right\rangle\right\},$$
$$\phi_{12} = -\frac{i}{\sqrt{2}}\left\{\left|\eta\frac{5}{2}\right\rangle - i\left|\xi\frac{5}{2}\right\rangle\right\}. \quad (6)$$

Similarly, the other diagonalized wavefunctions can be obtained as linear combinations of the two components with $M=-5/2$, $3/2$, $-3/2$, $1/2$, and $-1/2$. A schematic diagram for the iron(III) high spin ground and charge-transfer excited states are shown in Fig. 5 in the absence and presence of applied magnetic field.

Prediction of Faraday Parameters and Comparison with Experimental Results. Now we see how the MCD theory and the electronic states of the heme predict the kind and values of Faraday parameters for the charge-transfer transitions in the Fe(III) low and high spin heme complexes, and will compare calculated results with experimental data.

To calculate the Faraday parameters the following formulas[2-4] are used:

$$[\theta]_M = -24NH_z/\hbar c[f_1A + f_2(B+C/kT)], \quad (7)$$
$$A = (3/d_a)\sum_{a\to j}[\langle j|\mu_z|j\rangle - \langle a|\mu_z|a\rangle]\times \mathrm{Im}\{\langle a|m_x|j\rangle\langle j|m_y|a\rangle\}, \quad (8)$$
$$B = (3/d_a)\sum_{a\to j}\mathrm{Im}\{\sum_{k\neq a}[\langle k|\mu_z|a\rangle/(E_k-E_a)]\cdot[\langle a|m_x|j\rangle\langle j|m_y|k\rangle - \langle a|m_y|j\rangle\langle j|m_x|k\rangle] + \sum_{k\neq j}[\langle j|\mu_z|k\rangle/(E_k-E_j)]\cdot[\langle a|m_x|j\rangle\langle k|m_y|a\rangle - \langle a|m_y|j\rangle\langle k|m_x|a\rangle]\}, \quad (9)$$
$$C = (3/d_a)\sum_{a\to j}\langle a|\mu_z|a\rangle\mathrm{Im}\{\langle a|m_x|j\rangle\langle j|m_y|a\rangle\}, \quad (10)$$
$$f_1 = \frac{\pi^{1/2}\nu(\nu_{ja}-\nu)}{h\Delta_{ja}^3}\exp\left[-\frac{(\nu-\nu_{ja})^2}{\Delta_{ja}^2}\right], \quad (11)$$
$$f_2 = \frac{\pi^{1/2}\nu}{2\Delta_{ja}^2}\exp\left[-\frac{(\nu-\nu_{ja})^2}{\Delta_{ja}^2}\right]. \quad (12)$$

The symbol μ_z represents the z component of the magnetic moment operator and m_x and m_y stand for the x and y components of the electric moment operators. The number of degeneracies in the ground state is expressed by d_a. The summations are taken over all degenerate transitions for j←a.

Iron(III) Low Spin. According to the Boltzmann distribution and the energy separations among the three Kramers' doublets in Table 1, the populations in the lowest Kramers' doublets at 288 K were calculated to be 95 and 79% for the assumed spin-orbit coupling coefficient of 400 and 200 cm^{-1}, respectively. Hence in the following calculations, the contributions from the two higher Kramers' doublets were neglected.

By using the parameters A_1, B_1, and C_1 listed in Table 1 and Eqs. 1—3 and 7—11, one gets the Faraday A, B, and C terms as follows:

$$A = 0.81\langle a_1|m_x|\eta\rangle\langle\xi|m_y|a_1\rangle,$$
$$B = -1.84\times10^{-3}\langle a_1|m_x|\eta\rangle\langle\xi|m_y|a_1\rangle, \quad (13)$$
$$C = -1.96\langle a_1|m_x|\eta\rangle\langle\xi|m_y|a_1\rangle.$$

The extrema in the MCD spectra will be given as follows by assuming a Gaussian line shape:[27]

$$[\theta]_M^{max}(A) = (\pi^{1/2}e^{-1/2}\nu_{ja}/\sqrt{2}h\Delta_{ja}^2)A, \quad (14)$$
$$[\theta]_M^{max}(B+C/kT) = (\pi^{1/2}\nu_{ja}/2\Delta_{ja})(B+C/kT). \quad (15)$$

Here ν_{ja} is the frequency of transition and Δ_{ja} is the band width at $[\theta]_M=(1/e)[\theta]_M^{max}$. The ratios of the maximum values of the Faraday parameters given in Eqs. 14 and 15 can be estimated as follows:

$$[\theta]_M^{max}: \frac{C/kT}{B} = \frac{1}{kT}\cdot\frac{(-1.96)}{(-1.84\times10^{-3})} = 5.19, \quad (16)$$

$$[\theta]_M^{max}: \frac{C/kT}{A} = \frac{\sqrt{e}h\Delta_{ja}(-1.96)}{\sqrt{2}kT\ (0.81)} = -6.88, \quad (17)$$

where we adopted $\Delta_{ja}=500$ cm^{-1} and $kT=205$ cm^{-1}. These results predict that Faraday C terms will dominate in the MCD spectra of the Fe(III) low spin complexes even at 295 K. This agrees with the experimental result that the near infrared MCD spectra of the metmyoglobin cyanide are predominantly composed of Faraday C terms.

Iron(III) High Spin. In this case the spin-orbit interaction makes the excited states split into six sublevels as shown in Fig. 5. Hence Faraday parameters should be calculated for the six transitions to these six excited state sublevels. The calculated Faraday parameters A and C are:

$$A = (3/2)\langle a_1|m_x|\eta\rangle\langle\xi|m_y|a_1\rangle \text{ for all six transitions,}$$
$$C = (-15/2)\langle a_1|m_x|\eta\rangle\langle\xi|m_y|a_1\rangle \text{ for } (\Phi_{12}, \Phi_{13}) \longleftarrow (\Phi_1, \Phi_6),$$
$$(-9/2)\langle a_1|m_x|\eta\rangle\langle\xi|m_y|a_1\rangle \text{ for } (\Phi_{11}\ \Phi_{14}) \longleftarrow (\Phi_2, \Phi_5),$$
$$(-3/2)\langle a_1|m_x|\eta\rangle\langle\xi|m_y|a_1\rangle \text{ for } (\Phi_{10}, \Phi_{15}) \longleftarrow (\Phi_3, \Phi_4)$$
$$(3/2)\langle a_1|m_x|\eta\rangle\langle\xi|m_y|a_1\rangle \text{ for } (\Phi_9, \Phi_{16}) \longleftarrow (\Phi_3, \Phi_4),$$
$$(9/2)\langle a_1|m_x|\eta\rangle\langle\xi|m_y|a_1\rangle \text{ for } (\Phi_8, \Phi_{17}) \longleftarrow (\Phi_2, \Phi_5),$$
$$(15/2)\langle a_1|m_x|\eta\rangle\langle\xi|m_y|a_1\rangle \text{ for } (\Phi_7, \Phi_{18}) \longleftarrow (\Phi_1, \Phi_6). \quad (18)$$

Calculations indicate that so long as the sublevels of the ground and excited states are considered, the Faraday B term makes no contribution to the MCD spectra for this charge-transfer band. Since the signs of the six Faraday A terms are the same, the intensity of the Faraday A terms for the overall ^{6}E←^{6}A will be additive. On the other hand, the Faraday C terms for the transitions from (Φ_1, Φ_6) to (Φ_{12}, Φ_{13}) and (Φ_7, Φ_{18}) are of equal magnitude but of opposite signs, hence they partly cancel with one another. The effects of these addition and cancellations were calculated analytically by taking λ (spin-orbit coupling coefficient) to be equal to 200 cm^{-1} and $\Delta_{ja}=1000$ cm^{-1}. The calculated results indicated that the Faraday A term increased by a factor of about 6, but that the Faraday C term reduced to 1/4 of that of the largest component. Hence the ratio of the maximum intensity of the resultant Faraday terms will be

$$[\theta]_M^{max}: \frac{C/kT}{A} = \frac{f_2(15/2)\times(1/4)}{kTf_1(3/2)\times 6} = 1.24 \quad \text{at } T = 273\text{ K}, \qquad (19)$$
$$= 2.25 \quad \text{at } T = 150\text{ K}.$$

The values suggest that at 273 K the Faraday A term contribution is comparable to that of the Faraday C term, but that at 150 K the contribution from the Faraday C term becomes larger until at very low temperature the Faraday C term predominates in the near infrared MCD spectra. The contribution of the Faraday C terms extracted from the experimental results is rather small as compared with the values estimated above. Magnitudes of the estimated C terms are more sensitive to change in those of the band width (Δ_{ja}) and spin-orbit coupling constant (λ) than that of the A term, because the former is a difference and the latter is an addition of overlapping component bands. The magnitude of the estimated C term becomes smaller as Δ_{ja} increases and λ decreases. Although the set of parameters used in the calculation is one of reasonable sets, the difference between the estimated and experimental values may imply that Δ_{ja} is larger than 1000 cm^{-1} and that λ is smaller than 200 cm^{-1}.

In conclusion, the near infrared MCD bands for the typical low (metmyoglobin cyanide) and high (metmyoglobin fluoride) spin iron(III) heme complexes have experimentally been determined to be composed of Faraday C terms and Faraday C and A terms, respectively. The theoretical calculations of Faraday parameters are consistent with the experimental Faraday parameters.

20) Since heme b in myoglobin has not the true C_{4v} symmetry when all the substituents on the periphery of the porphyrin are taken into consideration, the porphyrin lowest unoccupied e orbitals (C_{4v}) are slightly split into two closely positioned orbitals in the actual symmetry lower than C_{4v}. Hence there can not be expected the true Faraday A term. However, as the calculation indicated (A. Kaito *et al.*, *Chem. Phys. Lett.*, **52**, 154 (1977)), the Faraday B terms predominantly mix among these two split orbitals to give an S-shaped MCD band which is a mimic Faraday A term. In this paper this apparent A term has been treated just like the true Faraday A term.

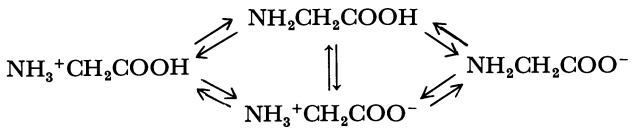
On the Ratio of Zwitterion Form to Uncharged Form of Glycine at Equilibrium in Various Aqueous Media

Goro WADA,* Eiko TAMURA, Mitsuko OKINA, and Mariko NAKAMURA
Department of Chemistry, Nara Women's University, Nara 630

(Received November 19, 1981)

The ratios of the zwitterion form to the uncharged form of glycine, $K_D=[NH_3^+CH_2COO^-]/[NH_2CH_2COOH]$, were determined in mixtures of water with methanol, ethanol, *t*-butyl alcohol, dimethyl sulfoxide, acetonitrile, 1,4-dioxane, *N*,*N*-dimethylformamide, and tetrahydrofuran. The value of ln K_D decreases and, therefore, ΔG°_{298} increases, with the increase in the mole fractions of the organic solvents. The plots of ΔG° *vs.* reciprocal of the dielectric constants of the alcoholic mixtures are simply linear indifferent to the kind of alcohols, indicating that this relation obeys the Scatchard equation and that the free energy change of the process of the intramolecular protonation in glycine is controlled mainly by electrostatic interaction, especially by the entropy change associated with the preferential solvation around the charged amino and carboxyl groups.

In aqueous solution, glycine (aminoacetic acid) exists in various ionized or neutral forms depending upon the hydrogen-ion concentrations of the solution, as shown in the following scheme.[1]



The formulas $NH_3^+CH_2COOH$ and $NH_2CH_2COO^-$ are cationic and anionic forms respectively, whereas NH_2CH_2COOH and $NH_3^+CH_2COO^-$ are both neutral, corresponding to the uncharged and zwitterion forms respectively, and establish a chemical equilibrium between themselves with a constant K_D:

$$K_D = \frac{[NH_3^+CH_2COO^-]}{[NH_2CH_2COOH]}. \quad (1)$$

These neutral forms are also at equilibria with other species with equilibrium constants, defined as follows.

$$K_1 = \frac{[NH_2CH_2COOH][H^+]}{[NH_3^+CH_2COOH]} \quad (2)$$

$$K_2 = \frac{[NH_3^+CH_2COO^-][H^+]}{[NH_3^+CH_2COOH]} \quad (3)$$

$$K_{12} = \frac{[NH_2CH_2COO^-][H^+]}{[NH_2CH_2COOH]} \quad (4)$$

$$K_{21} = \frac{[NH_2CH_2COO^-][H^+]}{[NH_3^+CH_2COO^-]} \quad (5)$$

According to the experimental method due to titration, the uncharged and the zwitterion forms can not be discriminated from each other, but only the sum of the concentrations of both species are determined. Thus, the apparent acidity constant of the acid form $NH_3^+CH_2COOH$ found experimentally, K, has a meaning as expressed by

$$K = \frac{([NH_2CH_2COOH] + [NH_3^+CH_2COO^-])[H^+]}{[NH_3^+CH_2COOH]}. \quad (6)$$

Then, the following relationships are derived from Eqs. 1, 2, 3, and 6.

$$K = K_1 + K_2 \quad (7)$$

$$K_D = \frac{K_2}{K_1} \quad (8)$$

Since $[NH_3^+CH_2COO^-]$ is much larger than $[NH_2CH_2COOH]$ in aqueous solution as will be seen later, K_2 is approximately equal to K, and therefore K_D can be considered to be equal to the ratio of K to K_1.

$$K \fallingdotseq K_2 \quad (7')$$

$$K_D \fallingdotseq \frac{K}{K_1} \quad (8')$$

For the determination of K_1, the ethyl ester of glycine, $NH_2CH_2COOC_2H_5$, was used in place of glycine, in order to mask the acidity of the carboxyl group, on the basis of an assumption that the basicity of amino group in glycine would not be greatly affected by the esterization of the carboxyl group, because the basicities of the methyl ester and ethyl ester of glycine have been known to be approximately identical.[2-4] Therefore,

$$K_1 = \frac{[NH_2CH_2COOC_2H_5][H^+]}{[NH_3^+CH_2COOC_2H_5]}. \quad (2')$$

In the present investigation, the values of K_D were determined in various aqueous solutions mixed with alcohols, such as methanol, ethanol, and *t*-butyl alcohol, and with other organic substances, such as acetonitrile, 1,4-dioxane, *N*,*N*-dimethylformamide (DMF), dimethyl sulfoxide (DMSO), and tetrahydrofuran (THF), at various mole fractions and various temperatures. The K_D values in water can be well compared with the data appearing in the literature.[4] Thus, the thermodynamic functions and the dielectric dependences of the equilibrium, the uncharged form⇄the zwitterion form, will be discussed.

Experimental

Materials. *Glycine*: Commercially obtained glycine of guaranteed reagent grade from Wako Pure Chemical Industries, Ltd. was recrystallized from water.

Glycine Ethyl Ester Hydrochloride: It was prepared by leading hydrogen chloride gas into the glycine suspended in ethanol. The crystals of the ester hydrochloride salt were purified by recrystallization from ethanol and its purity was checked by paper-chromatography.

Various Alcohols and Other Solvents: They were purified by ordinary methods.

Procedure and Calculations. Solutions of glycine which had been added by equimolar amount of hydrochloric acid or solutions of glycine ester hydrochloride were titrated with sodium hydroxide and the pH values of the solutions were

measured simultaneously by a pH-meter in a thermostat at given temperature. The hydrolysis of the ester was not observed appreciably during the course of titration. For the calculations of K and K_1, sets of pH values *vs.* volumes of sodium hydroxide solution at nearly middle points of the neutralization titration were used and averaged.

Results and Discussion

Equilibrium Constants and Related Thermodynamic Quantities. The values of K_1, K_2, and K_D at 25°C in mixtures of water with methanol, ethanol, *t*-butyl alcohol, DMSO, acetonitrile, 1,4-dioxane, DMF, and THF at various mole fractions are listed in Table 1. In the table, it is clearly seen that the zwitterion form is far more predominant than the uncharged one approximately by the order of magnitude 10^5 in water, but its ratio decreases with the increase in mole fraction of organic substances, especially in the case of DMF at $x=0.3$, the ratio being the smallest with the order of magnitude 10^2 among the data ever observed. Another feature is that K_D always decreases with temperature at any x in the all media, although the observed temperature dependences are not shown in Table 1.

In Fig. 1 are shown the variations of the free energies associated with the transformation of the uncharged form to the zwitterion form at various mole fractions of the organic solvents. The standard free energy change is calculated by the equation,

$$\Delta G^\circ = -RT \ln K_D. \quad (9)$$

The value of ΔG°_{298} in pure water is equal to −7.27 kcal mol^{-1} (1 cal=4.2 J), which agrees well with −7.3 kcal mol^{-1} obtained by Edsall and Blanchard.[4] Figure 1 indicates that ΔG°_{298} grows up gradually with the increase of x of alcohols, and is in a sequence at $x=0.3$, DMF> 1,4-dioxane> *t*-butyl alcohol> ethanol> acetonitrile>methanol.

Influence of Dielectric Constants of Media upon ΔG°. When ΔG°'s in various aqueous alcohols at diverse temperatures are plotted against reciprocals of the dielectric constants of the media, they come altogether on a single straight line with a positive slope indifferent to the kind of the alcohols, except for the case of *t*-butyl alcohol at $x=0.3$, as are drawn in Fig. 2. (Points for

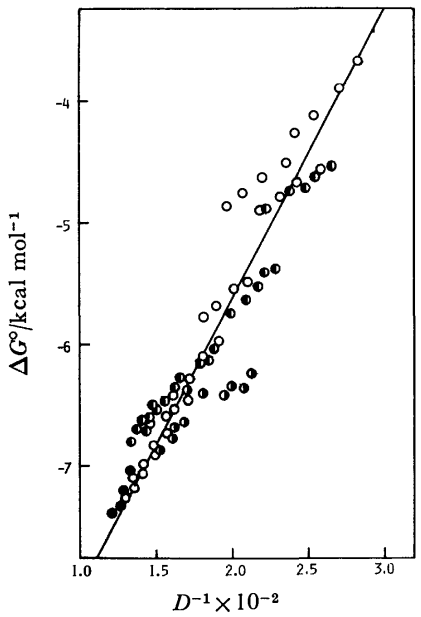

Fig. 2. Dependence of $\Delta G°$ in aqueous alcohols at various temperatures upon reciprocal of dielectric constants D^{-1}.
●: Water, ○: methanol, ◐: ethanol, ◑: *t*-butyl alcohol.

x=0.3 of *t*-butyl alcohol are omitted in the figure, which should appear towards the right out of the figure.) The dielectric constants of the media were calculated by numerical interpolations from the data observed by Åkerlöf.[5]

This linear relationship could be applied to the Scatchard equation,[6,7]

$$\Delta G° = \Delta G°_{\circ} - \frac{z_A z_B e^2 N_A}{rD}, \qquad (10)$$

where $\Delta G°$ originally implies a free energy change related to association of two ions, A and B, bearing electric charges $z_A e$ and $z_B e$ respectively at a distance r in media of various dielectric constants D and $\Delta G°_{\circ}$ and N_A are a constant and the Avogadro's number, respectively. In the present case, the change is not an approach between two separate ions, but an intramolecular prototropy resulting in occurrence of a zwitterion within an uncharged molecule. The zwitterion can be regarded as two ions which are combined with each other by a carbon chain behind. If the Scatchard's relationship could be valid in the zwitterion formation, the value of r may be estimated to be approximately 2 Å from the slope of the straight line in Fig. 2, assuming that the macroscopic value of D is roughly available in the very close vicinity around the polar groups. Since the value of r=2 Å looks like to be shorter than the expected value about 3.3 Å as the probable closest distance between N- and O-atoms ignoring the electric charges on respective atoms, it may be safely said that the positive electricity on the charged group $-NH_3^+$ is partly scattered on the three H-atoms and the centers of the electricities on both $-NH_3^+$ and $-C\overset{O}{\underset{O}{<}}(-)$ are forced to come closer to each other than the initial distance, although r may not be strictly equal to 2 Å, on account of certain theoretical inaccuracies involved in Eq. 10. Recently, these two functional groups were found to interact with each other at a fairly short distance in both gas phase[8] and solutions, from theoretical[9] and dilatometric[10] investigations.

Table 2. THERMODYNAMIC QUANTITIES FOR THE CHEMICAL CHANGE FROM THE UNCHARGED FORM TO THE ZWITTERION FORM, $\Delta G°_{298}$, $\Delta H°$, AND $\Delta S°$, IN AQUEOUS MIXTURES WITH VARIOUS ORGANIC SOLVENTS AT x=0.3
1 cal=4.2 J.

Organic solvent	$\Delta G°_{298}$ kcal mol^{-1}	$\Delta H°$ kcal mol^{-1}	$\Delta S°$ cal K^{-1} mol^{-1}
None(water)	−7.27	−10.3	−10.2
Methanol	−6.27	−10.7	−15.0
Ethanol	−5.60	−10.1	−15.0
t-Butyl alcohol	−5.38	−9.1	−11.5
Acetonitrile	−5.94	−9.1	−10.3
1,4-Dioxane	−4.82	−9.6	−15.8
DMF	−3.74	−11.7	−26.5

In the case of *t*-butyl alcohol, the plot of $\Delta G°$ *vs.* D^{-1} is supposed to deviate gradually from the common linearity in Fig. 2 as the mole fraction becomes larger than 0.1. Thus, the deviation found at x=0.3 might be only recognized by a consideration that the discrepancy between D values at a local spot around the ion and in the bulk of media can be no longer ignored and that the hydrophobicity of *t*-butyl group in the vicinity of the ion alters the structures not only of the zwitterion itself but also of the solvation sheaths surrounding the zwitterion strongly, in addition to the dielectric effect of the medium.

Thermodynamic Quantities, $\Delta G°_{298}$, $\Delta H°$, and $\Delta S°$ in Mixed Media. Table 2 shows the thermodynamic quantities, $\Delta G°_{298}$, $\Delta H°$, and $\Delta S°$, for the transformation of glycine from the uncharged form to the zwitterion form in pure water and in various mixed media at x=0.3. Values of $\Delta H°$ and $\Delta S°$ were obtained from the linear relationship of $\ln K_D$ *vs.* reciprocal of the absolute temperature. On general survey of the table, a trend is seen that the increase in $\Delta G°_{298}$ due to the addition of organic solvents is largely attributed to the decrease in $\Delta S°$, while $\Delta H°$ remains almost unchanged; namely this transformation is rather entropy-controlled.

This fact may indicate that the negative value of $\Delta H°$ is mainly caused by the change in the energy of chemical bondings related to protonation and deprotonation on amino and carboxyl groups respectively, while, on the other hand, the negative value of $\Delta S°$ depends upon the extent of solvation around the charged groups, the circumstances of the preferential solvation being different from solvent to solvent. The fact that $\Delta S°$ is more negative in the mixed solvents than in pure water, may suggest the possibility of the preferential solvation in the mixed solvents which is accompanied by a larger increment in the order than the simple hydration in pure water, in the vicinity of the zwitterions. After all, the gradual depression of K_D as x is increased may be mainly attributed to the growth of the degree of the preferential solvation in the mixed media with alcohols,

as shown in Fig. 1.

When the ionization constant K_a of various aliphatic carboxylic acids R–COOH or protonated amines $R'NH_3^+$ is empirically given by

$$-\log K_a = A_1T^{-1} - A_2 + A_3T, \quad (11)$$

where A_1, A_2, and A_3 are constants characteristic of the substance, ΔH° and ΔS° are expressed by the following equations.[11]

$$\Delta H^\circ = 2.303\,R(A_1 - A_3T^2) \quad (12)$$

$$\Delta S^\circ = 2.303\,R(A_2 - 2A_3T) \quad (13)$$

The transformation of glycine from the uncharged to zwitterion form consists of two processes; the protonation of amino group and the deprotonation of carboxyl group. If these two processes occur on separately different molecules, the total change is roughly expected as the sum of the following respective changes.

$$R'\text{-}NH_2 + H^+ \longrightarrow R'\text{-}NH_3^+ \quad (14)$$

$$R\text{-}COOH \longrightarrow R\text{-}COO^- + H^+ \quad (15)$$

$$R'\text{-}NH_2 + R\text{-}COOH \longrightarrow R'\text{-}NH_3^+ + R\text{-}COO^- \quad (16)$$

By using the values of A_1, A_2, and A_3,[11] the enthalpies and entropies at 25°C for several alkylamines (ammonium type) and aliphatic carboxylic acids can be calculated, and thus the final ΔH° and ΔS° for the Reaction 16 are readily estimated to be approximately -12 ± 2 kcal mol^{-1} and -15 ± 3 cal K^{-1} mol^{-1} respectively. These values are very close to those listed in Table 2, indicating that the thermodynamic quantities associated with a proton transfer in solution is almost unaffected whether it occurs intramolecularly or intermolecularly, although amino and carboxyl groups are located fairly close with each other in α-amino acids, like glycine. The value of ΔG° at $D=1$ (in gas phase) is assumed to be very large from the extrapolation in Eq. 10. This suggests that the value of K_D may be actually equal to zero in vacuum. In fact, it has been studied energetically and geometrically that the zwitterion is not expected to exist in gas-phase during at least an observable life time.[8,12]

Appendix

Examination of K_1 by Hammett-Taft Rule. For the determination of K_1, we have measured the basicity of ethyl ester of glycine in place of glycine, for the purpose of masking the acidic ionization of carboxyl group in glycine. Although the basicity of the ethyl ester has been found not to differ greatly from that of the methyl ester,[2-4] it is necessary to examine how much it differs from that of glycine itself. According to the Hammett–Taft rule for the substitution effect on pK_a, the pK_a of primary alkyl amines can be estimated by the following expression.[13]

$$pK_a = 13.23 - \Sigma\sigma^* \quad (17)$$

Since $\sigma^*(H)$, $\sigma^*(C_2H_5)$, and $\sigma^*(CH_2COOH)$ are $+0.49$, -0.10, and $+1.05$ respectively, $\sigma^*(CH_2COOC_2H_5)$ is supposed to be $+0.98$, taking into account that σ^* is reduced approximately half per every bond as the substitution group goes apart from N-atom. Therefore, the difference of $\log K_1$, $pK_a(NH_2CH_2COOC_2H_5) - pK_a(NH_2CH_2COOH)$ will be 0.22, which could be considered to have so small an effect upon the order of magnitude in K_D. Furthermore, the values of σ^* should be altered in mixed solvents, which are unknown at the present stage, in order to correct the observed data.

Study on the Reaction of Monofunctional Fluorescent Reagents in Organic Solutions by Fluorometry

Akio Okamoto,* Katsumi Uchiyama, and Itaru Mita
Institute of Interdisciplinary Research, Faculty of Engineering, The University of Tokyo, 4-6-1, Komaba, Meguro-ku, Tokyo 153
(Received November 28, 1981)

Rections of some fluorescent reagents with substrates, used widely in biochemistry for quantitative analysis of some functional groups in aqueous media, have been studied in organic solutions with a view that they may be used also in the area of synthetic polymer science. Reactions studied by fluorometry were (i) 5-dimethylamino-1-naphthalensulfonyl chloride with butylamine, (ii) 2-naphthalenesulfonyl chloride with butylamine, and (iii) *N*-(1-naphthyl)maleimide with 1-pentanethiol. In polar solvents all the fluorescent probes studied are too labile and converted spontaneously into fluorescent compounds. In less polar solvents, however, such side reactions do not take place and the reaction of fluorescent reagents with substrates proceeds quantitatively with a simple second-order kinetics. The second-order rate constants for the three reactions are of the order of 10^{-3} to 10^{-1} M^{-1} s^{-1} in the range of about 30 to 50 °C, and they increase with the solvent polarity.

Fluorescent probes have been utilized widely in biochemistry either for analysing quantitatively functional groups in proteins or for probing the environment around the functional groups. In the former case, a component to be analyzed is converted by the reaction with a proper probe into a fluorescent derivative, and its quantity is determined from the emission intensity. In the later case, the details of the spectrum, lifetime, quantum yield, and depolarization provide information about the functional group and its surroundings. Two sorts of fluorescent probes have been used mainly.[1] The one is called fluorescent thiol reagent and comprises certain nonfluorescent *N*-substituted maleimides. They react with thiol compounds in aqueous solution to give fluorescent adducts.[2] The other is called fluorescent amine reagent and comprises nonfluorescent sulfonyl chlorides such as 5-dimethylamino-1-naphthalenesulfonyl chloride,[3] and nonfluorescent "fluorescamine."[4] They react almost quantitatively with primary amines in aqueous solution to give fluorescent products. Since these fluorescent reagents themselves are not soluble in water, it is a common practice to dissolve them first in an organic solvent such as acetone or dioxane then mix the solution with an aqueous solution of substrate.

A useful extension of the fluorescent probes is to make the probes react with substrates in organic solvents which are commonly used in studies on organic reactions or synthetic polymers. If it has become feasible to use the fluorescent probes in organic solutions in a similar manner to in aqueous solution, the fluorescent probes will be utilized more widely in organic chemistry or in polymer science. Only little has been reported, however, on the reaction kinetics of the fluorescent reagents, especially on the reaction in nonaqueous solvent.[5-7]

To advance the utilization of the fluorescent probes more widely, we investigated the reaction of monofunctional fluorescent amine reagents or sulfonyl chlorides with butylamine as well as of monofunctional thiol reagent with 1-pentanethiol in various solvents.

Experimental

Materials. *N*-(1-Naphthyl)maleimide (NMI) was prepared using a modified method of Tsou *et al.*[8] from 1-naphthylamine and maleic anhydride with acetic anhydride as dehydrating agent and sodium acetate and triethylamine as catalysts (51% yield). *N*-Butyl-5-dimethylamino-1-naphthalenesulfonamide (DNSBA) was prepared in a similar manner to the preparation of *N*-ethyl-5-dimethylamino-1-naphthalenesulfonamide.[8] A chloroform solution of 5-dimethylamino-1-naphthalensulfonyl chloride (dansyl chloride; DNSCl) (15 ml; 0.19 mol dm^{-3} (M†)) was mixed with a chloroform solution of butylamine (*n*-$BuNH_2$) (15 ml; 1.86 M) at room temperature. After 6 h the solution was washed with 0.1 M aqueous HCl solution and distilled water, dried over Na_2SO_4 overnight then the solvent was removed. The yellow residue was recrystallized from diethyl ether to give yellow-orange crystals which melted at 95—97 °C (40% yield). The structure was ascertained by NMR and IR. NMR ($CDCl_3$): δ 2.9 (N–C$\underline{H}_3$, –SO_2NH–C$\underline{H}_2$–), δ 5.3 (–SO_2N$\underline{H}$–), *etc.* IR: 3300 cm^{-1} (NH), 1320 and 1150 cm^{-1} (SO_2), *etc.* The purity was confirmed by TLC.

1-Pentanethiol (*n*-AmSH), 2-naphthalenesulfonyl chloride (NDSCl), DNSCl, and *n*-$BuNH_2$, all from Tokyo Kasei, were used without further purification. All the solvents (from Wako Pure Chemical Ind.) were of nonfluorescent "Dotite Luminasol" or "Dotite Spectrosol" grade except pyridine (Reagent grade) and used as received.

Apparatus. The NMR spectra were obtained on a 100-MHz JEOL MH-100 spectrometer. Infrared spectra were measured by using the KBr pellet technique with the aid of a JASCO IR-G spectrometer.

Kinetic studies by fluorometry were performed with a JASCO FP-550 spectrofluorometer using a 1 cm × 1 cm quartz cell with a cap without degassing. Fluorescence was measured using excitation waveloength at 290 nm for NMI, 280 nm for NDSCl, and 340 nm for DNSCl and observed in the range of 325—345 nm for NMI, 330—355 nm for NDSCI, and 480—505 nm for DNSCl, respectively. Fluorescence data are reported without spectral correction, except fluorescence spectra in the wavelength from 400 to 550 nm which were corrected by using the standard solution of quinine sulfate in 0.05 M H_2SO_4.

Results and Discussion

Reaction of 5-Dimethylamino-1-naphthalenesulfonyl Chloride with Butylamine. In the course of investigation of the reaction of 5-dimethylamino-1-naphthalenesulfon-

† 1 M = 1 mol dm^{-3}.

yl chloride (DNSCl) with butylamine (n-$BuNH_2$) in organic solvents, we found that the stability of DNSCl has to be taken into account. DNSCl is unstable at room temperature and even without amines it is converted by an unknown reaction to fluorescent products in polar solvents such as methanol (slow), acetonitrile, pyridine, DMF (rapid), and dimethyl sulfoxide (rapid). No further detailed study of the reaction was carried out in these solvents. One of the probable mechanisms of the solvolysis, however, may be analogous to that proposed for pyridine.[9]

$$RSO_2Cl + C_5H_5N \longrightarrow RSO_2N^+C_5H_5Cl^- \quad (1)$$

The reaction product in Eq. 1 is presumably fluorescent, since DNSCl is nonfluorescent probably because of the intramolecular heavy-atom effect of chlorine.[10]

On the other hand, DNSCl is stable in less polar solvents such as THF, chloroform, and ethyl acetate. So the reaction rate were measured in these solvents. The reaction mechanism is most reasonably formulated as a bimolecular nucleophilic substitution on sulfur, similar to that for the reaction of benzenesulfonyl chloride with aniline.[11]

$$RSO_2Cl + H_2NR' \longrightarrow RSO_2NHR' + HCl \quad (2)$$

In organic solvents, hydrogen chloride formed reacts immediately with amine.[12]

$$HCl + H_2NR' \longrightarrow H_3N^+R'Cl^- \quad (3)$$

Then the overall reaction is expressed as

$$RSO_2Cl + 2H_2NR' \longrightarrow RSO_2NHR' + H_3N^+R'Cl^-. \quad (4)$$

N-Butyl-5-dimethylamino-1-naphthalenesulfonamide (DNSBA), the reaction product of DNSCl with n-$BuNH_2$, was prepared and purified separately to examine its fluorescence prior to kinetic measurement. Figure 1 shows its absorption and fluorescence spectra in ethyl acetate. Although the absorption maxima are invariant with solvent polarity, the fluorescence maxima (λ_{max}) shift gradually to longer wavelength with increasing solvent polarity as is known for dansylamine.[13] The λ_{max} of DNSBA are 467, 487, 497, 499, 502, and 518 nm in cyclohexane, benzene, tetrahydrofuran, ethyl acetate, chloroform, and N,N-dimethylformamide, respectively. The plot of the energy of fluorescence maxima *vs.* solvent polarity parameter

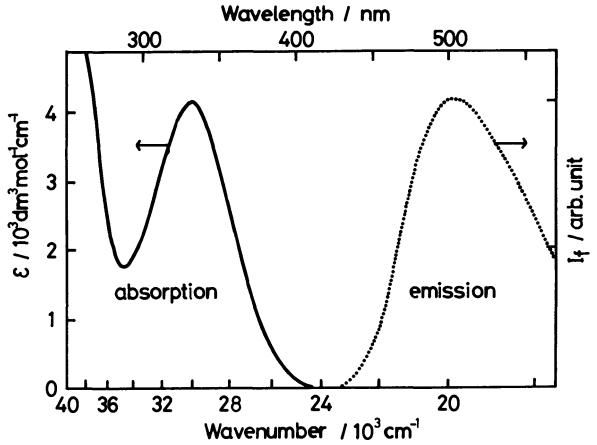

Fig. 1. Absorption and fluorescence spectra of DNSBA in EtAc.

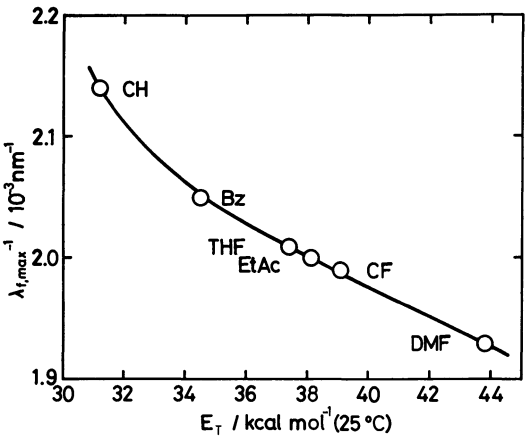

Fig. 2. Relationship between the energy of fluorescence maxima of DNSBA and the solvent-polarity parameter E_T in nonaqueous solents.

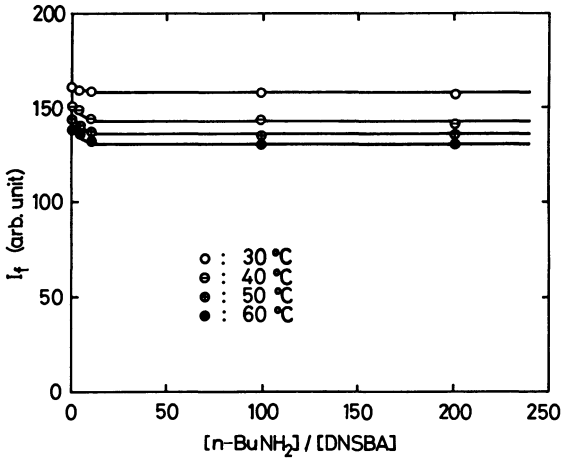

Fig. 3. The effect of addition of n-$BuNH_2$ on I_f of DNSBA in EtAc at several temperatures.

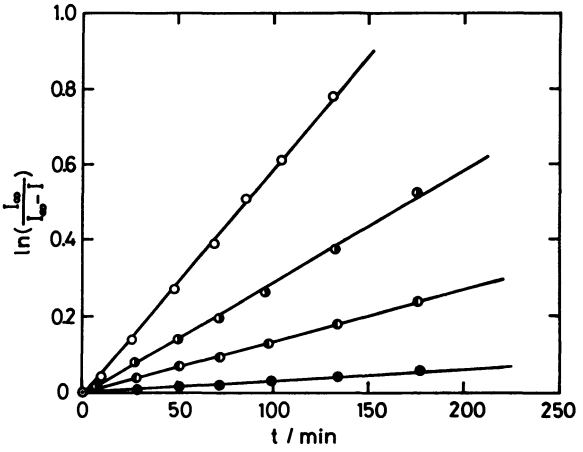

Fig. 4. Pseudo first-order plots of the reaction of DNSCl with n-$BuNH_2$ in THF at 50 °C: [DNSCl]=8.34×10^{-6} M; [n-$BuNH_2$]/[DNSCl]=40 (●), 200 (◐), 400 (◑), and 800 (○).

(Dimroth's E_T) for DNSBA in these solvents shows a satisfactory correlation as for dansylamine[13] (Fig. 2).

The proportionality between I_f and concentration of DNSBA holds for the concentration range [DNSBA]≦

1×10^{-5} mol dm^{-3} in all solvents used. The linearity does not hold at higher concentration of DNSBA. The temperature dependence of fluorescence intensity I_f of DNSBA in ethyl acetate is shown in Fig. 3, together with the effect of addition of n-$BuNH_2$ on I_f of the solution. The fluorescence intensity increases with a decrease in temperature and this may be a result of a decrease in the internal quenching of fluorescence.[14] The fluorescence intensity decreases by a few percent by the addition of n-$BuNH_2$ up to about ten fold excess to DNSBA in molality, but remains constant by further addition of n-$BuNH_2$. In any event, the effect of addition of n-$BuNH_2$ is not large and only a slight correction due to the effect is needed in the following kinetic studies.

Figure 4 shows the pseudo first-order plots of the reaction of DNSCl with excess n-$BuNH_2$ in THF at 50 °C. The second-order rate constants for the reaction in THF at 50 °C, calculated from the observed pseudo first-order rate constants and the concentration of n-$BuNH_2$ used, are entirely constant for widely different n-$BuNH_2$ concentrations as shown in Fig. 5. The second-order rate constants of the reaction in ethyl acetate (EtOAc) are also constant for different n-$BuNH_2$ concentrations. These facts show that the reaction is a simple bimolecular one in these conditions. The final fluorescence intensity of the reaction mixture was in fair agreement with that of the corresponding DNSBA solution as shown in Table 1. This confirms that the reaction proceeds quantitatively in these conditions.

Table 2 lists the second-order rate constants (k_2) of the reaction in various solvents mainly at 60 °C for the concentration of DNSCl ranging from 1×10^{-6} to 1×10^{-5} M. The correlation of k_2 to dielectric constant ε or $(\varepsilon-1)/(2\varepsilon-1)$ in various solvents is quite poor. On the contrary, the second-order rate constants are roughly proportional to the E_T values. This tendency may support the argument that the reaction of DNSCl with n-$BuNH_2$ is S_N2 type, because it is well known that the rate constant of a S_N2 reaction with solvated transition state becomes larger as the solvent becomes more dipolar aprotic in character.[15] The solvent effect of the present reaction may be different from that of the reaction of 2-thiophenesulfonyl chloride with anilines for which a linear correlation is found for the rate constants and the dielectric constants and a S_AN mechanism is proposed, bond-breaking being rate-determining step in aprotic solvents.[16]

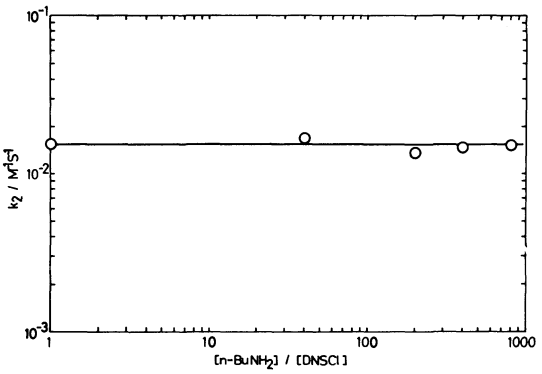

Fig. 5. Constancy of the second-order rate constants k_2 of the reaction of DNSCl with n-$BuNH_2$ in THF at 50 °C at different n-$BuNH_2$ concentration.

Table 1. Final fluorescence intensity of the reaction mixture of DNSCl with n-$BuNH_2$ in EtAc

[DNSCl] / 10^{-5} M	[n-$BuNH_2$] / 10^{-4} M	Temp/°C	I_f	$I_{f,model}$	$I_f/I_{f,model}$

Cyclohexane	2.0	31.2	60	$\ll1\times10^{-3}$

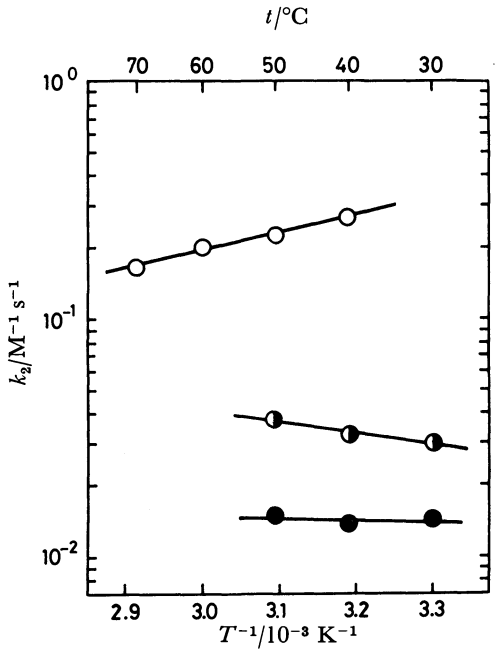

Fig. 6. Arrhenius plots of the second-order rate constants k_2 of the reaction of DNSCl with n-$BuNH_2$ in EtAc (○), chloroform (◑), and THF (●).

Arrhenius plots of the rate constants in ethyl acetate, chloroform, and tetrahydrofuran are shown in Fig. 6. The linear plot for the reaction in chloroform is normal but gives rather small activation energy (ΔE=2.1 kcal/mol). On the contrary, the reaction rate decreases with increasing temperature in ethyl acetate, and almost constant in tetrahydrofuran. In the case of the reaction of 2,4-dinitrobenzenesulfonyl chloride with n-$BuNH_2$ in

benzene, the amine is reported to act as a catalyst and the reaction is not of first-order with respect to amine.[12] In both ethyl acetate and tetrahydrofuran, however, the reaction of DNSCl with *n*-$BuNH_2$ is of first-order with respect to the amine as shown in Fig. 5. The anomalous temperature dependence of the reaction in these solvents may be explained as follows. In some S_N2 reactions, the degree of solvation of the reactants and the transition state are known to vary with solvent nature,[17] and the change in solvation is specified by the corresponding equilibrium constant which depends on the solvent nature as well as temperature. Accordingly, the cause of the anomaly may be ascribed to the temperature dependence of the equilibrium constant for the solvation. In this case, however, the reaction order is not affected and the reaction remains to be a simple bimolecular one.

The fluorescence of the reaction product of DNSCl with *n*-$BuNH_2$ can be excited at 350 nm or longer wavelength. Then DNSCl will be useful for a general fluorescent probe for studies in the field of polymer science and organic chemistry, because even the presence of chromophores such as phenyl groups and indole rings does not interfere the fluorescence measurement. This is the reason why we studied the reaction of DNSCl with *n*-$BuNH_2$ most thoroughly in various organic solvents as shown above. The situation is different for fluorescent probes such as 2-naphthalenesulfonyl chloride and *N*-(1-naphthyl)maleimide which are excited in the range of 270—280 nm. But these reagents are also useful in some cases as fluorescent probes to amino and mercapto groups. So the reaction of 2-naphthalenesulfonyl chloride with *n*-$BuNH_2$ and that of *N*-(1-naphthyl)maleimide with 1-pentanethiol were studied briefly in various organic solvents as shown below.

Reaction of 2-Naphthalenesulfonyl Chloride with Butylamine. 2-Naphthalenesulfonyl chloride (NDSCl) is also unstable at room temperature and converted by an unknown reaction to fluorescent products in such polar solvents as already listed in the preceding chapter. On the other hand, like DNSCl, NDSCl is stable in less polar solvents such as tetrahydrofuran and chloroform. So the reaction rate were measured in tetrahydrofuran (THF) and chloroform. The mechanism for the reaction of NDSCl with *n*-$BuNH_2$ may be similar to that of DNSCl with *n*-$BuNH_2$ as shown in Eq. 2 to 4. The first-order plots of the reaction in such solvents give straight lines, indicating that the reaction is first-order with respect to NDSCl and is a simple bimolecular one in these conditions. Second-order rate constants of the reaction were calculated from the observed pseudo first-order rate constants obtained for the reaction with *n*-$BuNH_2$ in large excess to NDSCl. The second-order rate constants of the reaction thus obtained are 4.6×10^{-2} $M^{-1}s^{-1}$ and 5.3×10^{-1} $M^{-1}s^{-1}$ in THF at 30 °C and in chloroform at 40 °C, respectively.

The emission spectrum of the product of the reaction of NDSCl with *n*-$BuNH_2$ in THF is shown in Fig. 7, together with that of naphthalene in THF. Figure 7 indicates that the emission spectrum is not much affected by the substitution of sulfamide group at β-position of the naphthalene ring.

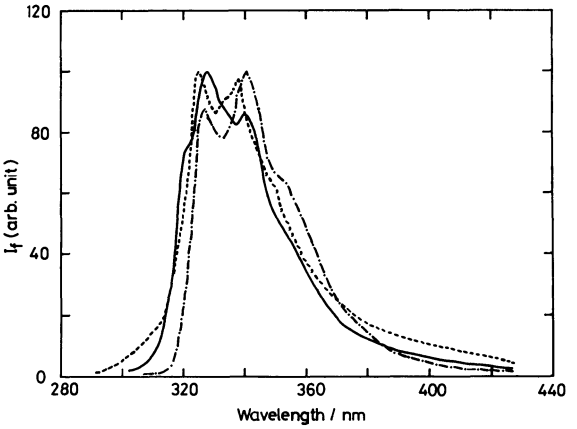

Fig. 7. Fluorescence spectra of naphthalene (——), the reaction product of NSCl with *n*-$BuNH_2$ (-·-·), and that of NMI with *n*-AmSH (------) in THF.

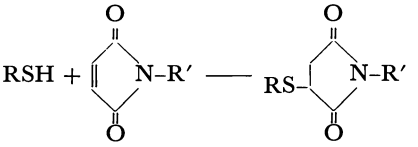
Reaction of N-(1-Naphthyl)maleimide with 1-Pentanethiol. Thiols and thiolate anions are known to add almost quantitatively to some nonfluorescent maleimides to give fluorescent adducts in aqueous solution.[6,18] So



(5)

the reaction is widely used for quantitative analysis for mercapto groups in proteins and amino acids such as cysteine.

In the case of the reaction of *N*-(1-naphthyl)maleimide (NMI) with 1-pentanethiol (*n*-AmSH) in organic solvents, we also found that the stability of NMI has to be taken into account. The maleimide ring is known to be readily hydrolyzed to form the corresponding maleamic acid derivative in alkaline aqueous solution.[19] In addition, highly electrophilic maleimide double bond is easily susceptible to anionic polymerization by appropriate initiators in strongly polar media such as *N*,*N*-dimethylformamide (DMF).[20] In fact, NMI was not stable at room temperature in DMF and fluorescence developed even without thiols. Figure 8 shows the change in fluorescence intensity with time of NMI in

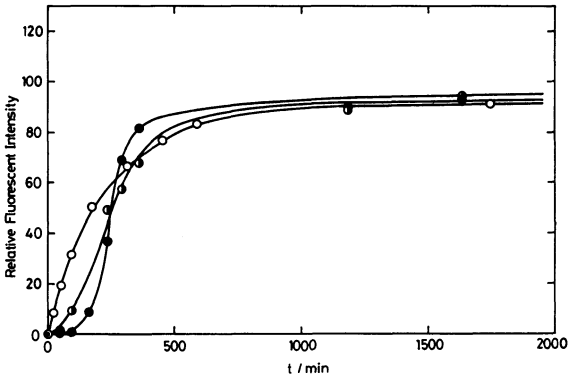


Fig. 8. Variation of the fluorescence intensity of NMI in DMF at 50 °C with time at volume fraction of acetic acid 0% (○), 9% (◑), and 33% (●).

DMF with various concentration of an acetic acid added to supress anionic polymerization. Although acetic acid seems to act as an inhibitor to any side reaction in the begining, its addition induces an autocatalytic reaction at a later stage. On the other hand, the first-order plots of the spontaneous deactivation reaction of NMI in DMF without acetic acid give straight lines. The first-order rate constant of the reaction is 6.5×10^{-5} s^{-1} at 50 °C and the value remains unaltered even when the equimolar amount of *n*-AmSH is added to the NMI solution. Although we did not study the detailed mechanism of the development of fluorescence of NMI in DMF, it is evident that the side reaction of NMI in DMF make impossible the kinetic study of the reaction of NMI with *n*-AmSH. Such a side reaction of maleimide ring is negligible for synthesis from bismaleimide compound and bisthiol in DMF, because the concentration of substrate is sufficiently high (10^{-1} to 10^{-2} M).[20] It should be noted, however, that the side reaction can not be ignored in the reaction of NMI as a fluorescent probe in DMF in which the concentration of substrate is limited (10^{-4} to 10^{-5} M).

NMI is stable in less polar solvents such as ethyl methyl ketone, benzene, and THF, and the fluorescence development of NMI in such less polar solvents is negligible for a few days at 50 °C. The reaction rate of NMI with *n*-AmSH in THF was followed by fluorometry. Since THF is miscible with water in all proportions, the effect of added H_2O is also studied. The pseudo first-order plots of the reaction of NMI with *n*-AmSH in THF at 50 °C with and without a small amount of H_2O give straight lines and the reaction proceeds quantitatively. The second-order rate constants of the reaction are evaluated as 4.3×10^{-2} M^{-1} s^{-1} in pure THF, 8.5×10^{-2} M^{-1} s^{-1} in THF with 0.3% H_2O, and 1.5×10^{-1} M^{-1} s^{-1} in THF with 3% H_2O. So the effect of the presence of H_2O is not very large.

The room temperature emission spectrum of the product of the reaction in THF is also shown in Fig. 7. The emission spectrum is not affected much by the substitution of thiol adduct of maleimide ring at α-position of naphthalene ring similarly to the case of NDSCl.

In conclusion, several reactions of some fluorescent reagents with substrates were confirmed to be simple second-order reactions as well as to proceed quantitatively in less polar solvents. Reaction rate of the fluorescent reagents studied here may be more rapid in polar aprotic solvents as is general for S_N2 type reactions. In polar solvents, however, all the fluorescent probes studied are too labile to study and converted spontaneously into fluorescent compounds. Application of the fluorescent probe to studies on organic reactions or synthetic polymers will be published elsewhere.[21]

Despretz Constants for Individual Ions

Toshiki WAKABAYASHI* and Katsuko TAKAIZUMI
The College of General Education, Tohoku University, Kawauchi, Sendai 980
(Received January 5, 1982)

The shifts (ΔT) in the temperature of maximum density (tmd) of water produced by electrolytes have been revised. It was found that the temperature dependences of S_V and/or b_V coefficients in the Redlich-Meyer equation should be taken into account, to obtain exactly the Despretz constants (K_D) or the standard partial molal expansibility ($\bar{E}°$) from tmd data. The K_D's for 1 : 1 electrolytes were divided into the ionic components ($K_{D,i}$), by applying the value for $\bar{E}_1^\circ$ (H^+, 4 °C). Of the familiar monovalent ions, the $K_{D,i}$ values are negative ($\Delta T>0$) only for H^+ and Li^+ ions and are positive for all the anions examined, including F^- ion. A further attempt was made to extract from $K_{D,i}$'s for organic ions the structural part $K_{st,i}$'s, based on a model. The $K_{st,i}$'s seem to reflect the structure-influencing ability of organic ions, but may not always be the case.

It has been recognized by many authors[1-7] that the shifts (ΔT) in the temperature of maximum density of water (tmd) produced by electrolytes as well as nonelectrolytes reflect the structural effects of ions on the solvent water. The shift produced by any solute at low concentrations is proportional to the solute concentration through the Despretz constant (K_D). Frank and Robinson[1] first noticed that K_D for alkali metal halides with a common anion increases in the order, $Li^+<K^+<Na^+$, in accordance with the effect of the cations on the relative partial molal entropy of water at 25 °C which were discussed in terms of the structural effect of ions. Darnell and Greyson[2] also noticed that with both alkali metal ions and halogenide ions, the ionic contributions to K_D seem to increase with increasing their structure-breaking ability with the exception of Na^+ ion.

With liquid nonelectrolytes as solutes, the observed ΔT's are usually divided into two parts, ΔT_V and ΔT_{st}, and hence K_D is also divided into K_D and K_{st}. The K_V is determined solely by the volumetric properties of the solute in its pure liquid state, while the K_{st}'s have been related qualitatively with the structural influences of the solutes on the solvent water,[8-14] that is, K_{st}'s have been confirmed to be positive for structure breakers ($\Delta T_{st}<0$) and negative for structure makers ($\Delta T_{st}>0$), though somewhat different approaches have been made by some authors.[15-17]

Some question has been recognized, however, with respect to tetraalkylammonium salts (R_4NX); the K_D increases with increasing alkyl-chain length.[2-4] This is contrary to the expectation that the hydrophobic nature of the alkyl radical would elevate the tmd of water similar to nonelectrolytes such as alcohols and some alkylamines.[7,8] Darnell and Greyson[2] inferred that the water structure-promoting characteristics of the species ordinarily found at room temperature would not be manifested in the neighbourhood of the tmd. They attributed the results to ion-size effects which would become important at temperatures approaching the tmd because of the enhanced structure of the solvent.

Estimating the K_{st}'s for R_4NBr, Wada and Miura[3] found that the K_{st} also increases with the alkyl-chain length. They proposed the idea that clathrate-like structures formed in the aqueous solution of $(n\text{-Bu})_4NBr$ contribute to the lowering of the tmd. Recently, Wada *et al.*[6] determined K_D's for twenty complex salts. They divided K_D's into ionic components ($K_{D,i}$) based on the assumption that $K_{D,i}(K^+)=K_{D,i}(Cl^-)$, and attempted further to extract the structural contributions of the complex ions from the $K_{D,i}$'s. They proposed that the hydrophobic ions may be divided into "iceberg" formations which elevate the tmd and "clathrate-like" formations which lower the tmd. In these estimations Wada and his coworkers employed the volumetric properties of the electrolytes in the solid state at 0 °C. As discussed later, the use of the volumetric properties of solutions in solid state seems questionable, particularly when the solutes are electrolytes.

In an earlier publication[7] we evaluated K_D's for some phosphonium halides, $(n\text{-Bu})_{4-n}Ph_nPX$ ($n=0$—4); the K_D for phosphonium chlorides increases with increasing the number of phenyl groups, indicating that in contrast to the conclusion obtained by other authors, the clathrate-like hydration would contribute toward elevating the tmd since the clathrate-like hydration supposed for the $(n\text{-Bu})_4P^+$ ion would successively disappear as the butyl groups are replaced by phenyl group since the K_V would decrease slightly with n.

Thus, the studies about the effects of electrolytes on the tmd may provide useful information about ionic hydration, however, there seems to be two problems; one is the way to divide K_D's for electrolytes into the ionic components; the other is to find a suitable procedure to extract the structural components ($K_{st,i}$) for organic ions from the $K_{D,i}$'s.

In the present work, we revise the procedure to determine the Despretz constants for electrolytes and then attempt to approach these subjects.

Principle

The Despretz Constant of an Electrolyte. The shift in the tmd of water produced by a solute can be derived as follows. The apparent molal volume ϕ_2 of solute is defined by

$$\phi_2 = \frac{1}{m}\left(\frac{1000+mM}{d} - \frac{1000}{d_\circ}\right), \quad (1)$$

where d is the density of solution, $d_\circ$ that of pure water, m the molality, and M the molecular weight of the solute. The molal volume of water, V_1, near the tmd can be expressed as

$$V_1 = V_1^*(1+\alpha_1(T-T_\circ^*)^2), \quad (2)$$

where V_1^* is the molal volume at the tmd ($T_\circ^*$) of pure

water, (namely 3.98 °C), and the value of α_1[8] is 7.8×10^{-6} deg^{-2}. Replacing d_0 in Eq. 1 by M_1/V_1, where M_1 is the molecular weight of water, differentiating with respect to temperature, and rearranging the result, we obtain

$$\Delta T = (T_m - T^*_\circ) = -\frac{d^*_\circ}{2000\,\alpha_1}\frac{\partial\phi_2}{\partial T}m, \qquad (3)$$

where the condition, $\partial d/\partial T=0$, at the tmd is considered; $d^*_\circ$ is the density of water at $T^*_\circ$.

For dilute aqueous solutions of electrolytes, ϕ_2 can be expressed as:

$$\phi_2 = \phi^\circ_2 + S_v m^{1/2} + b_v m, \qquad (4)$$

where ϕ°_2 is the partial molal volume of the electrolyte at infinite dilution and S_V, the Debye-Hückel limiting slope, for which the exact values have been given by Redlich and Meyer,[18] and b_V, the excess volume coefficient which includes all the effects arising from ion-solvent and ion-ion interactions. Insertion of Eq. 3 into Eq. 4 gives

$$\Delta T = -\frac{d^*_\circ}{2000\,\alpha_1}\left(\bar{E}^\circ - \frac{\partial S_v}{\partial T}m^{1/2} + \frac{\partial b_v}{\partial T}m\right)m, \qquad (5)$$

where $\bar{E}^\circ$ is the standard partial molal expansibility of electrolyte. The equation shows that, different from the case of nonelectrolyte solutes, for electrolytes the quantity that is directly proportional to concentration is not ΔT itself but a corrected one, and this is so even at low concentrations. Inserting the numerical values in Eq. 5, we obtain

$$\Delta T + 1.074\,m^{3/2} + 64.1\frac{\partial b_v}{\partial T}m^2 = -64.1\bar{E}^\circ m, \qquad (6)$$

where the value for $\partial S_V/\partial T$ at 3.98 °C was obtained from Eq. 20 in Ref. 19, as 1.675×10^{-2} cm^3 mol$^{-3/2}$ kg$^{1/2}$K.

Thus, it is reasonable to define the Despretz constant by

$$K_D = 64.1\,\bar{E}^\circ, \qquad (7)$$

where the dimensions for K_D and $\bar{E}^\circ$ are mol^{-1} kg K and cm^3 mol^{-1} K^{-1}, respectively. The Despretz constant is obtainable by Eq. 6 from the tmd data or by Eq. 7 from $\bar{E}^\circ$.

It may be a fact worth noting that the contributions from the temperature dependences of S_V and b_V have scarcely been considered, though the equations equivalent to Eqs. 3 and 7 have been treated by many authors. This subject will be discussed in a later section.

Since $\bar{E}^\circ$ can be split into the contributions from cation and anion, $\bar{E}^\circ_+$ and $\bar{E}^\circ_-$, K_D can also be split into the separate contributions, $K_{D,+}$ and $K_{D,-}$. Determination of the ionic Despretz constants is, therefore, a straightforward matter, if a reliable value for $\bar{E}^\circ_{ion}$ for any ion is available. Here the proton is chosen as the reference ion since for this $\bar{E}^\circ_+$ has been given as a function of temperature by Millero,[19]

$$\bar{E}^\circ_+(H^+) = -0.008 - 3.40\times10^{-4}t. \qquad (8)$$

Combining Eq. 7 with Eq. 8, we obtain the value, -0.60 K mol^{-1} kg for $K_D(H^+)$.

Separation of Structural Contribution from $K_{D,I}$ for Organic Ions. It is of interest to separate $K_{D,I}$ for large organic ions into two terms, a volumetric term, $K_{V,I}$, and a structural term, $K_{st,i}$. The latter term is considered to reflect the structural influence of the ion on the solvent water.

For nonelectrolyte solutes that are liquid at temperatures in the region of the tmd, Frank and Watson[9] have derived the following equation and confirmed its validity:

$$\Delta T = -\frac{x\alpha_2 V^\circ_2}{2(1-x)\alpha_1 V^*_1} - \frac{1}{2(1-x)\alpha_1 V^*_1}\frac{\partial\Delta V^M_x}{\partial T}, \qquad (9)$$

where x is the mole fraction of the solute, V°_2 and α_2 are the molar volume and the thermal expansion coefficient of the solute in pure liquid state at the tmd, and ΔV^M_x is the excess volume of mixing referred to a mixture of solute mole fraction x. The first term on the right hand side of the equation, first derived by Wada and Umeda,[8] is determined solely by the volumetric properties of the two pure liquids. This term expresses the shift in the tmd in an ideal mixture for which ΔV^M_x is 0 for all compositions, it is often referred to as the ideal term, and is always negative. The second term, on the other hand, expresses the effect arising from the solute-solvent interactions which induce the system to become nonideal.

Making an approximation, $\Delta V^M_x = bx(1-x)$,[20] and converting the mole fraction into molality, we can write the Despretz constant as:

$$K_D = K_v + K_{st}, \qquad (10)$$

where

$$K_v = d^*_\circ\alpha_2 V^\circ_2/(2000\,\alpha_1), \qquad (11a)$$

and

$$K_{st} = d^*_\circ(\partial b/\partial T)/(2000\alpha_1), \qquad (11b)$$

where in dilute solution $\partial\Delta V^M_x/\partial T$ and hence K_{st} are found to be negative for some organic compounds such as alcohols, alkylamines and tetrahydrofuran; most of these are known as the structure makers for the solvent water.

Equations 9—11 are valid for nonelectrolytes, but not for electrolytes. However, as shown by Wada and his coworkers,[3,6] we may consider that the $K_{D,I}$'s should also consist of two terms similar to the case of nonelectrolytes. The contribution of the volumetric term, $K_{V,i}$, may be significant for organic ions, since they are much larger in size than simple inorganic ions and their intrinsic expansibilities would be relatively large. In an ideal mixture, both the partial molal volume and the expansion coefficient are the same as those in the pure liquid for each component, and hence, the K_V does not contain any contribution from the structural changes of the solvent water induced by the solute. The thermal expansion coefficient of any substance is in general larger in the liquid state than in the solid state; therefore an excessively small value for K_V should be obtained if the solid expansibility is used in place of the liquid one. With electrolytes another factor should be taken into account; this is the electrostatic interactions between the ions in salt crystals. These result in much smaller expansibilities than those of molecular crystals, while in dilute electrolyte solutions the interactions are much weaker. Thus, it is obvious that to use the expansibilities for salt crystals in estimating K_V's would yield excessively

Table 1. The despretz constants, K_D/K mol^{-1} kg, for 1 : 1 electrolytes (Eq. 6)[a),b)]

	H^+	Li^+	Na^+	K^+	Rb^+	Cs^+	NH_4^+
Cl^-	5.9_5	5.1_8	12.4_8	11.0_3	11.0_9	11.5_9	6.5_1

	(11.9_5)	(11.0_0)	(18.8_6)	(17.0_3)	(17.3_2)	(17.5_8)	(12.5_9)

a) Tmd data were, unless otherwise specified, taken from Ref. 21. The last term of the left hand side of Eq. 6 was ignored for all the salts. b) The bracketed values are reproduced from $K_{D,i}$. c) Ref. 3. d) Ref. 2.

small values which in turn would lead to excessively large values for K_{st}'s. This will at least be one of the reasons for finding unexpected values for K_{st}'s for hydrophobic salts.[3)]

Another approach may be possible: Consider a 1 : 1 electrolyte as the solute. Transfer of one ion pair from the solid phase to the solvent water produces two hydrated ions. For each ion we may divide this action into two processes. The first is the transfer of a hypothetical molecule (which is the same in the molecular structure as that of the ion but with no electric charge) from its hypothetical pure liquid to water; the second is the charging process of the molecule in water to yield the ion. The latter process should change the hydration state of the hypothetical molecule, other than possible volume change of the solute molecule itself by electrostriction effect. The changes in the hydration state would be significant for ions of small size while for large sized ions the changes would be comparatively minor due to their low electric fields, *i.e.*, the water structure around the hypothetical molecule will be less affected. In any case, the changes accompanied by the charging process are now all included in the $K_{st,i}$ term except for the volume change due to the electrostriction of the ion itself which should be included in $K_{v,i}$ term.

Thus, we can evaluate the $K_{st,i}$'s for ions by Eq. 11a, and hence, also the $K_{vt,i}$'s, if proper estimation is possible for V_2° and α_2 of hypothetical pure liquids.

Results and Discussion

Table 1 lists the Despretz constants for 1 : 1 electrolytes which were obtained by Eq. 6 from the tmd data found in the literature. For most of the simple electrolytes treated, Eq. 6, neglecting the second correaction term, gave reasonable results, as evidenced by the fact that the standard deviations (σ) between the observed tmd's and those reproduced from the K_D are reduced by one order or more by applying the first correction. As a whole, the contributions to K_D from the correction term amount to about 0.7 K mol^{-1} kg. The second correction term, $(\partial b_V/\partial T)m^2$, seems to be essential for the salts containing so-called hydrophobic ions. For instance, the tmd data for Bu_4NBr[3)] show that the K_D calculated from each tmd at each concentration increases successively with concentration from 782 K (referred to mole fraction scale) at mole fraction 2.3×10^{-4} to 1110 K at 3.42×10^{-3}. The reported value for K_D is 1086 K (σ=0.026 K), which was obtained without any corrections. Equation 6 gives 945 K with $\sigma=6.3\times10^{-3}$ K, where the value for $(\partial b_V/\partial T)$ was taken as 0.209 cm^3 mol^{-2} kg K^{-1}.[22)] On the other hand, $(\partial b_V/\partial T)$'s for Me_4NBr and Et_4NBr are slightly negative[22)] and the two correction terms partially set off each other.

Table 2 lists the ionic Despretz constants which are referred to the standard, $K_{D,+}(H^+)=-0.60$ K mol^{-1} kg. It is of interest to compare $K_{D,-}$'s for Cl^- and Br^- ions in the table with those obtained by extrapolation of the curve obtained by plotting K_D for R_4NX's *vs.* molecular weight of the cation, to zero molecular weight of the cation. Attempts of this kind have been made by other authors to determine the absolute partial molar volumes of halogenide ions[23)] or the absolute ionic molal expansibility for the Cl^- ion.[24)] As in the case of $\bar{E}^\circ$ (R_4NCl, 25 and 35 °C),[24)] the extrapolation was made by using only two lower members for both sets of salts, since the plots were not linear. The $K_{D,-}(Cl^-)$ found from tmd data for R_4NCl[2)] was 7.3 K mol^{-1} kg and $K_{D,-}(Br^-)$, from those for R_4NBr,[3)] 8.4. These are somewhat larger than those in Table 2. Although this may be one possible way to determine $K_{D,-}$, more reliable data are required to do this since disagreement among tmd data for R_4NX's are found (Table 2).

Table 2. The despretz constants for individual ions, $K_{D,i}$/K mol^{-1} kg[a)]

Ion	$K_{D,i}$	Ion	$K_{D,i}$		
H^+	−0.60	NH_4^+	-0.0_4[b)]	-0.1_3[c)]

a) The italicized values are obtained from K_D's which were determined by applying Eq. 6 with the two correction terms, and the others, from K_D's for which only the first correction was applied. The tmd data were taken from; b) Ref. 2, c) Ref. 3, d) Ref. 4, e) Ref. 7, and f) unpublished work.

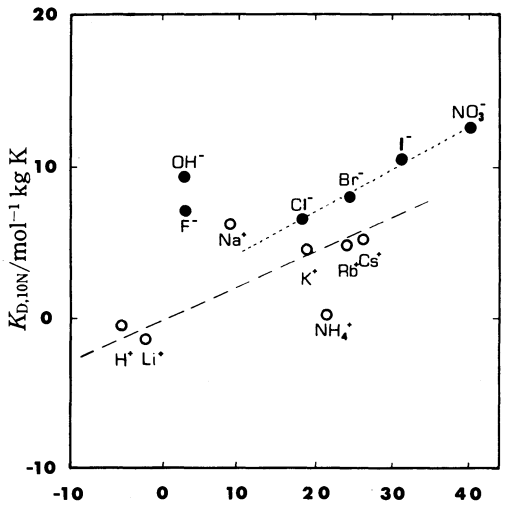

Fig. 1. Ionic Despretz Constants for monovalent ions plotted against the standard partial molal entropy of ion.

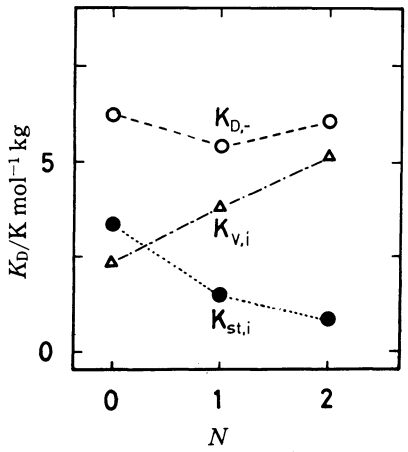

Fig. 2. $K_{D,-}$, $K_{V,i}$, and $K_{st,i}$ for carboxylate ions plotted against the number of carbon atoms (N) in alkyl groups.

The $K_{D,i}$'s for alkali metal ions are in the sequence, $Li^+ < K^+ < Rb^+ < Cs^+ < Na^+$ and those for halogenide ions, $Cl^- < F^- < Br^- < I^-$. These orders are, except for Na^+ and F^- ions, consistent with the sequences in the standard partial molal entropies, $\bar{S}_i^{\ominus}$,[25] for each set of the ions at 25 °C (Fig. 1). The $K_{D,-}$ values are somewhat higher than $K_{D,+}$ values when a comparison is made between cations and anions with the same ionic redius, in accordance with the similar trend found in $\bar{S}_i^{\ominus}$'s. The negative $K_{D,+}$ values for H^+ and Li^+ are notable since these ions are known as typical structure-making ions. The $K_{D,+}(NH_4^+)$ is considerably lower (probably negative) than for alkali metal ions (Table 2), suggesting that the ion would be capable of fitting into the partial water structure through hydrogen bonding. These seem to support an intuitive anticipation that the smaller the ionic Despretz constant, the greater is the structure-making ability of the ion.

However, necessity for reexamining in detail the content of $\bar{E}_{ion}^{\circ}$ and hence that of $K_{D,i}$ for simple ions comes from the disorder for Na^+, OH^-, and F^- ions in the seqiences in $K_{D,i}$. At 25 °C, $\bar{E}_{cation}^{\circ}$ for alkali metal ions[26] are in the sequence, $Na^+ > K^+ > Rb^+ > Cs^+ > Li^+$, which is almost reverse with that at 3.98°, while with anions, $F^- < Cl^- < Br^- < I^- (< NO_3^-)$, which is the same as that at 3.98° except for F^- ion. This fact is thought to reflect the difference in hydration between cation and anion.

The $\bar{E}_{ion}^{\circ}$ for simple ions can be decomposed into components corresponding to the decomposition of $\bar{V}_{ion}^{\circ}$. Applying a semiempirical equation, Millero[19,27] divided $\bar{V}_{ion}^{\circ}$ into three terms, the crystal partial molal volume $\bar{V}_{cryst}^{\circ}$, the electrostriction partial molal volume $\bar{V}_{elect}^{\circ}$, and the disordered or void-space partial molal volume $\bar{V}_{disord}^{\circ}$. Since $\bar{V}_{cryst}^{\circ}$ is hardly affected by temperature change, the corresponding expansibility can be ignored. He showed that $\bar{V}_{elect}^{\circ}$ goes through a minimum at a point near room temperature which depends on the ionic radius while $\bar{V}_{disord}^{\circ}$ increases with increasing temperature. The $\bar{E}_{elect}^{\circ}$, therefore, changes sign from positive to negative with rising temperature while the $\bar{E}_{disord}^{\circ}$ is always positive. The sign of the ionic charge would affect both the temperature at which the $\bar{E}_{elect}^{\circ}$ changes its sign and the magnitude of the $\bar{E}_{disord}^{\circ}$ through the effect of ionic charge on the orientation of water dipoles. This would be responsible for the difference between cation and anion in the ionic-radius dependence of the sequences in $\bar{E}_{ion}^{\circ}$ at the two temperatures.

More satisfactory knowledge is required to explain the irregularity for Na^+, OH^-, and F^- ions found in the magnitudes for $\bar{E}_{ion}^{\circ}$.

Organic Ions. Here, extraction of $K_{st,i}$ from $K_{D,i}$ for some organic ions is examined.

The first example is the carboxylate ion. The nitroalkanes RNO_2, having the same alkyl groups as those of carboxylate ions, may serve as model compounds in estimating $K_{v,i}$'s for the anions, which require expansibilities of the hypothetical liquids composed of hypothetical chargeless molecules, RCOO. The results for three carboxylate ions are shown in Fig. 2, where $K_{D,i}$, $K_{v,i}$, and $K_{st,i}$ are plotted against the number of carbon atoms in the alkyl groups. In the estimation for $K_{v,i}$ for the formate ion, V_2° and α_2 of formic acid were used, since no data are available for liquid HNO_2. This may be allowed as a first approximation, as expected from the following: The molal expansibility E° of nitromethane at 4 °C is 0.064 cm^3 mol^{-1} K^{-1}, comparable to that of super-cooled acetic acid, 0.060, which was estimated by extrapolation. E° of nitroethane, 0.079, is very close to E° of propionic acid, 0.078. These E°'s were calculated from volumetric data compiled by Riddick and Bunger.[28]

Although no regularity is found in $K_{D,i}$ with respect to the alkyl-chain length, a marked tendency is found in the order of $K_{st,i}$ which agrees with our anticipation that since alkyl groups would promote the water structures in their vicinity, the $K_{st,i}$ would decrease with increasing the alkyl-chain length. The results seem to indicate that the charged group, $-COO^-$, contributes positively to $K_{st,i}$ and hence may be regarded as a structure-breaking group.

Some alkanes of the type, R_4C, may permit us to

estimate $E°$'s for the hypothetical liquids corresponding to neutral compounds, R_4N's. The estimated value for $K_V(Me_4C)$ is 13.7 K mol^{-1} kg, with $a_2=1.8\times10^{-3}$ K^{-1} and $V°(4\ °C)=118.6$ cm^3 mol^{-1}.[28] Substitution of this value in Eq. 10 gives a large negative value for $K_{st,i}$, of about -11 K mol^{-1} kg. However, it may be reasonable to regard this value as the lower limit for $K_{st,i}(Me_4N^+)$, since no allowance was made for electrostriction of the ion itself which would lead to a lower $K_{v,i}$ value. Although no data are available for estimating $E°$'s of higher homologs, Pr_4C and $(n\text{-Bu})_4C$, $E°$'s of four *n*-alkanes, C_5, C_9, C_{13}, and C_{17}, are available, that is, 0.175, 0.189,[28] 0.24 and 0.28 cm^3 mol^{-1} K^{-1}, respectively. The last two were estimated by Gunn and Yamada's method,[29] which gives the values 0.169, and 0.195 for the first two members. Employing tentatively, in place of $K_{v,i}$'s, the K_V's calculated from these $E°$'s, 11.2, 12.1, 15.1, and 17.8 K mol^{-1} kg, we obtain large negative values, around -10 K mol^{-1} kg, for $K_{st,i}$ for all R_4N^+ ions.

It is impossible at this stage to judge whether or not the absolute values for "true" $K_{st,i}$ increase with lengthening the alkyl-chain length because any corrections have not been made for the electrostriction effect as already noted and the $K_{v,i}$'s used are tentative. We may at least state that the sign of $K_{st,i}$'s for the higher members of R_4N^+ ions would be negative. The negative sign assigned for lower members, Me_4N^+ and Et_4N^+, seems to be inconsistent with the view that Me_4N^+ ion is a structure breaker and that the Et_4N^+ ion hardly affects the water structure.

Generally it is assumed[25] that there are two contradictory factors that are responsible for the states of cosphere water around R_4N^+ ions, one is a weak electric field exerted by the ions which is important with Me_4N^+ ion and makes the ion a structure-breaker. The other is the structure-making ability of the alkyl groups. As the ion gets larger, from Me_4N^+ through Et_4N^+ and Pr_4N^+, the former effect becomes less important and the two effects balance near the Et_4N^+ ion. There are many criteria[25,30] indicating the Me_4N^+ ion to be a structure breaker, however, other facts have also been found. As revealed by the dielectric relaxation study by Haggis *et al.*,[31] the water relaxation time is lengthened by the presence of Me_4NBr, Me_4NI, and Et_4NCl, while it is shortened by the presence of inorganic salts. Pottel and Lossen[32] showed that the molal change of relaxation time of water in R_4NBr solutions with respect to the relaxation time of pure water is positive for all the R_4NBr examined. However the relative relaxation time change per mole of CH_2 group per kg water increases with the alkyl chain length from Me_4NBr to Et_4NBr and to Pr_4NBr. At this point it reaches a constant value equal to that for aliphatic hydrocarbons with an arbitrary number of CH_2 groups. On the other hand, a negative value was found for NH_4Br. Using the Samoilov equation, Uedaira[33] determined the activation energies of the exchange of the nearest water molecules next to an ion and found them to be positive for four R_4NBr's, from Me_4NBr to Bu_4NBr, *i.e.*, the water molecules close to the non-polar group are less mobile than in pure water. Wen and Hung[34] determined the standard molal free energy of transfer ($\Delta F°_{tr}$) of hydrocarbons (methane, ethane, propane, and butane) from water to 0.1 mol kg^{-1} solutions of R_4NBr at four temperatures. They found that the $\Delta F°_{tr}$ values are all negative except for methane in Me_4NBr solution at 5 °C and with NH_4Br solution they are positive. All these results seem to indicate that the Me_4N^+ ion is different from some simple ions known as structure breakers, such as Cs^+ and I^-. It displays, though weakly and partially, the effect on the water structure inherent to aliphatic hydrocarbons.

Comparison of K_D in D_2O for a given salt with that in H_2O seems to be of interest, since D_2O is known to possess more structure than H_2O and the structure-influencing ability of salt should be stronger in D_2O than in H_2O, while $K_{v,i}$ for any ion should be common to two solvents. The K_D's of R_4NBr's in D_2O were obtained by Conway and Laliberte[4] as well as those in H_2O. In spite of the anticipation that K_D for Me_4NBr would be larger in D_2O than in H_2O and the reverse would be true for Bu_4NBr, all the K_D's in D_2O are smaller by some 2 K mol^{-1} kg, including Me_4NBr, indicating that there would be some factor which is reflected in $K_{st,i}$ but not in other probes.[37] In this respect, Wen's comment[25] about the difference in volumetric property between two structure breakers, Cs^+ and Me_4N^+ ions, seems to be suggestive. The excess heats of mixing ($\Delta_m H^{ex}$) in the systems, Pr_4NBr–CsBr and Pr_4NBr–Me_4NBr, are negative whereas the excess volume of mixing ($\Delta_m V^{ex}$) in the Pr_4NBr–CsBr system is considerably larger than that in Pr_4NBr–KBr system, while $\Delta_m V^{ex}$ in Pr_4NBr–Me_4NBr system is comparable to that in Pr_4NBr–KBr system. He pointed out that $\Delta_m H^{ex}$ is largely a measure of change in the number of hydrogen bonds of water in the solution, whereas $\Delta_m V^{ex}$ is a measure of the change in the geometric arrangement of water and ions. This comment may be valid also in the present case, since K_D is essentially a volumetric property.

From the above, we may conclude that $K_{st,i}$ for the Me_4N^+ ion can be negative in spite of being a net structure breaker. This means that classification of ions into the structure maker and structure breaker based on the sign and magnitude of $K_{st,i}$ is not always consistent with that based on different probes. The situation may be more or less common to all classification criteria because our knowledge about the structures of water and the so-called hydrophobic hydration are far from complete.

For a series of phosphonin salts, $(n\text{-Bu})_{4-n}Ph_nPX$ ($n=0$—4), new values for K_D's are assigned in this work because the preceding values[7] had not been corrected for the temperature dependence of the b_v-coefficients. As seen from Table 2, the present conclusion is essentially the same as the preceding, the $K_{st,i}$ would increase with increase in the number of phenyl groups in agreement with information obtained from other probes[35,36] that the water structures around the cations decrease with *n*.

As a conclusive remark, it can be said that although $K_{D,i}$ for simple inorganic ions and $K_{st,i}$ for organic ions can be regarded as parameters indicating structure-

influencing ability of ions, it may not always be the case. Particularly, $K_{st,i}$'s for R_4N^+ ions are inconclusive, and more elaborate studies are required.

The Behavior of Carbon Black in a Detergent Solution

Yuji YONEYAMA* and Keizo OGINO

Department of Industrial and Engineering Chemistry, Faculty of Science and Technology, Science University of Tokyo, 2641, Yamazaki, Noda, Chiba 278

(Received January 11, 1982)

The behavior of carbon black (CB) in a detergent (sodium dodecyl sulfate (SDS): 20%, zeolite: 20%, sodium silicate: 5%, sodium carbonate: 3%, sodium (carboxylatomethyl)cellulose (CMC): 1%, sodium sulfate: 51%) solution is discussed in terms of the ζ-potential and potential energy of interaction. The ζ-potential of CB in each solution of SDS, various builders, and the detergent was measured by microelectrophoresis. The potential energies between CB and fabrics (nylon and cellulose), between CB and clay, and between CB and zeolite were calculated by the use of the theory of heterocoagulation. The potential energy between one CB particle and another CB particle was calculated by the use of D-L-V-O theory. The ζ-potential was increased by the addition of builders, except sodium sulfate. The high negative ζ-potential of CB in the detergent solution resulted from the effect of builders. From the potential energies, it became evident that 1) CB in the detergent solution deposits with difficulty onto fabrics; 2) The CB coagulates with zeolite only with difficulty; 3) The CB coagulates with clay or CB.

The builder for a detergent should have the following effects: (1) Sequestration for Ca^{2+} and Mg^{2+}; (2) Buffer for a detergent solution at pH 9.0—10.5; (3) Dispersion of soils. Sodium triphosphate has the above effects and had been used as the main builder in detergents. However, in recent years, the sodium triphosphate levels in detergents have been reduced significantly because it accelerates the eutrophication of lakes and rivers. In the many detergents which have no sodium triphosphate, sequestration for Ca^{2+} and Mg^{2+} is performed by zeolite, sodium carbonate, and sodium silicate. On the other hand, the detergent solution is buffered by sodium silicate and sodium carbonate. The question has been raised whether the dispersion of soils in the detergent solution is satisfied or not. In previous work,[1] it was shown that the deposition of the particle soil, clay (Kanto loam), onto fabrics can be depressed by the coagulation of the particle soil with zeolite. Generally, particle soil contains 1.5% carbon black. In this study, carbon black was used as another particle soil. The behavior of carbon black in the detergent solution was discussed in terms of the D-L-V-O theory and the heterocoagulation theory.

Experimental

Materials. Carbon black (DIABLACK-G, Mitsubishi Chemical Indiustries Ltd." were used as a particle soil model. The particle radii of carbon black are 24.5—30 nm.[2] In this study, the radius was assumed to be 27.5 nm. Sodium dodecyl sulfate (SDS) which was extracted with diethyl ether and recrystallized from ethanol was used for a surface active agent in a detergent. The other chemicals used for builders, such as sodium triphosphate, sodium slicate, sodium carbonate, sodium (carboxylatomethyl)cellulose (CMC), and sodium sulfate, were of reagent grade. The detergent composition is shown in Table 1. Doubly-distilled water was used.

TABLE 1. DETERGENT COMPOSITION

Materials	Compositional level wt%
SDS	20
Zeolite	20
Sodium silicate	5
Sodium carbonate	3
CMC	1
Sodium sulfate	51

Measurement of ζ-Potential. The ζ-potential was measured with an electrophoretic mass-transport analyzer in the previous work. The principle of this apparatus utilizes the difference between the density of particles and that of the solution. The surface of carbon black (CB) has many pores and is hydrophobic. The density was measured by a picnometer with hydrocarbon, methanol, or surfactant solution, and is about 1.8 g cm^{-3}.[2] The densities in aqueous solution used in this work seem to be lower than 1.8 g cm^{-3}, and to be changed by the kind of aqueous solution. Therefore, electrophoretic mass-transport analyzer is not well fitted for the measurement of the ζ-potential of CB. In this work, the ζ-potential of CB was measured with an LASER ZEE™ model 500 (PEN KEM Inc.). This apparatus uses microelectrophoresis, and is well fitted for the measurement of the ζ-potential of CB. The measurement was carried out with an applied potential gradient of 10 V cm^{-1} at 25 °C. The 0.0018 wt% suspension for ζ-potential measurement were prepared with an ultrasonic mixer for 10 min and allowed to stand for 12 h. The suspension were dispersed again with an ultrasonic mixer for 5 min before use. In some cases, the pH of the suspension was adjusted to the desired value by using dilute sodium hydroxide solution while stirring. The pH of the suspension was measured by a pH meter (HM-5A, TOA Electronics Ltd.).

Calculation of the Total Potential Energy. The potential energy for interaction between a spherical particle and a flat plate due to an electrical double layer is given by[3]

$$V_{E,S/P} = \frac{aD}{4kT}\left[(\psi_1^2+\psi_2^2)\ln\left\{\frac{\exp(2\kappa H_0)-1}{\exp(2\kappa H_0)}\right\} + 2\psi_1\psi_2 \ln\left\{\frac{\exp(\kappa H_0)+1}{\exp(\kappa H_0)-1}\right\}\right], \quad (1)$$

where a is the radius of the sperical particle, k is Boltzmann's constant, T is the absolute temperature, H_0 is the distance between the surfaces, ψ_1 and ψ_2 are the surface potentials of materials 1 and 2, κ is Debye-Hückel reciprocal length parameter,[4]

$$\kappa = \sqrt{\frac{4\pi e^2(n_+ Z_+^2 + n_- Z_-^2)}{DkT}}. \quad (2)$$

Z_{+or-} is the valence of the ionic species in solution, n_{+or-} is the concentration (ions cm^{-3}) of the same species in solution,

and e is the electronic charge.

The potential energy for interaction between a spherical particle and a flat plate due to van der Waals forces is given by[5,6]

$$V_{A,S/P} = -\frac{A_{12/3}}{6kT}\left[\frac{2a(H_0+a)}{H_0(H_0+2a)} - \ln\frac{H_0+2a}{H_0}\right], \quad (3)$$

$$A_{12/3} = \sqrt{A_{11/3}\cdot A_{22/3}}. \quad (4)$$

$A_{11/3}$ and $A_{22/3}$ are Hamaker's constants for interaction between materials 1, 1 and materials 2, 2 in the separating medium 3.

The total potential energy for interaction between a spherical particle and a flat plate is given by the sum of $V_{E,S/P}$ and $V_{A,S/P}$:

$$V_{T,S/P} = V_{E,S/P} + V_{A,S/P}. \quad (5)$$

The total potential energies for interaction between CB and nylon, between CB and cellulose were calculated from Eqs. 1—5.

It has been shown by Hogg *et al.*[7] that the potential energy for interaction between two spherical particles of radii a_1 and a_2 and surface potentials ψ_1 and ψ_2 is given by

$$V_{E,S/S} = \frac{a_1a_2D}{4(a_1+a_2)kT}\left[(\psi_1^2+\psi_2^2)\ln\left\{\frac{\exp(2\kappa H_0)-1}{\exp(2\kappa H_0)}\right\} + 2\psi_1\psi_2\ln\left\{\frac{\exp(\kappa H_0)+1}{\exp(\kappa H_0)-1}\right\}\right] \quad (6)$$

The potential energy for interaction between two spherical particles due to van der Waals forces is given by Hamaker[8]

$$V_{A,S/S} = -\frac{A_{12/3}}{12kT} \times \left\{\frac{y}{x^2+xy+x} + \frac{y}{x^2+xy+x+y} + 2\ln\frac{x^2+xy+x}{x^2+xy+x+y}\right\}, \quad (7)$$

where $x=H_0/2a_1$ and $y=a_2/a_1$. The total potential energies for interaction between CB and clay, and between CB and zeolite were calculated from Eqs. 6—7.

Verwey and Overbeek[9] have shown that the potential energies of interaction between two spherical particles are given by

$$V_E = \frac{aD\psi^2}{2kT}\ln[1+\exp(-\kappa H_0)], \quad (8)$$

$$V_A = -\frac{A}{6kT}\left(\frac{2}{S^2-4} + \frac{2}{S^2} + \ln\frac{S^2-4}{S^2}\right), \quad (9)$$

where $S=(2a+H_0)/a$. Equations 8 and 9 were used for calculation between one CB particle and another CB particle.

The above equations were expressed in kT units. Since the evaluation of surface potential involves some difficulties, the surface potentials were taken as the ζ-potentials. For the computation, the ζ-potentials of nylon, cellulose, clay, and zeolite in the previous paper were used. The Hamaker's constants for nylon and cellulose in water were estimated to be 5×10^{-14} erg from those for polyethylene and polystyrene.[10] The Hamaker's constants for zeolite and clay in water were estimated to be 4.4×10^{-13} erg from that for kaolinite.[11] The Hamaker's constant for CB in water was estimated to be 5×10^{-13} erg from that for graphite.[10] The radii of clay and zeolite were assumed to be 1×10^{-5} cm. The calculations of potential energies as a function of the distance between the surfaces were performed on an IBM 370 computer.

Results and Discussion

ζ-Potential of CB and the PH-Dependence. The water-soluble builders such as sodium triphosphate, sodium carbonate, and sodium silicate are added to water, and the pH of the solution is shifted to the alkali side. For this reason, the ζ-potentials of CB were measured in solutions of various pH (Fig. 1). The ζ-potential of CB is about −22 mV at pH 7, increased with increase of pH, and reached about −46 mV at pH 11. The structure of carbon black was reported by many investigators. Boehm[12] shows the surface structure model (Fig. 2). Murata and Imagawa[13] reported that the negative ζ-potential of carbon black results from the following mechanisms: (i) Ionization of -COOH and -OH or (ii) Adsorption of OH^- on the surface.

The Effect of Sodium Dodecyl Sulfate (SDS) on the ζ-Potential of CB and the Potential Energy. Figure 3 shows the effect of the concentration of SDS on the ζ-potential of CB. The negative ζ-potential of CB increased with increasing the concentration of SDS. The increase in the negative ζ-potential results from adsorption of dodecyl sulfate anion onto CB with some interactions such as van der Waals forces. Since the surface of CB is hydrophobic, the hydrophobic group of dodecyl sulfate anion are adsorbed directly to the surface of CB.

The ideal concentration of detergent is generally 0.2 wt% in washing process. Assuming the formulation of detergent shown in Table 1, the concentration of SDS in the 0.2 wt% detergent solution is 1.387×10^{-3} mol dm^{-3}. The ζ-potential of CB at this concentration was read from Fig. 3. The ζ-potentials of nylon, cellulose, zeolite, and clay in this concentration were −107,

−3, −53, and −17 mV respectively.[1] The total potential energies, V_T, for interactions between CB and nylon, between CB and cellulose, between CB and zeolite, between CB and clay, and between CB and CB were calculated using the ζ-potentials of nylon, cellulose, zeolite, and clay. The results are shown in Fig. 4. Assuming that the electrolyte added is completely ionized, the Debye-Hückel reciprocal length parameter in the 0.2 wt% detergent solution was calculated to be 7.115×10^6 cm^{-1}. Since the ζ-potential is related to the ionic strength, it is desirable that the ζ-potential be measured in the SDS solution in which κ is controlled to be 7.115×10^6 cm^{-1} by the addition of an electrolyte, for example potassium chloride. However, if κ in the SDS solution is controlled by the addition of an electrolyte, the solution is different from the detergent solution. Therefore, the ζ-potential obtained by such an operation seems not to be assigned a significance purely in terms of the effect of SDS in the detergent solution. For this reason, the addition of an electrolyte to control κ was not carried out. Thus we consider that the total potential energies, V_T, shown in Fig. 4 mean the behavior of CB under only the effect of SDS in the detergent solution.

A maximum total potential energy, $V_{T,max}$, suggests a repulsive force, and is related with the stability of the hydrophobic colloid. It is said that $V_{T,max}$ has to be about 15 kT to ensure a stability sufficient for all practical purposes.[9] If there is no maximum, rapid coagulation takes place. Similarly to the previous work, the coagulation or deposition was judged to take place with difficulty if $V_{T,max}$ is more than 15 kT, to take place easily if $V_{T,max}$ is less than 15 kT, and not to take place if $V_{T,max}$ is more than 100 kT.[14] On the basis of such criteria, it is clear from Fig. 4 that the deposition of CB onto nylon takes place with difficulty, and the deposition of CB onto cellulose and the coagulations between CB and clay, between CB and zeolite, and between CB and CB take place rapidly.

The Effect of Water-soluble Builder on the ζ-Potential of CB and the Potential Energy. The effects of sodium triphosphate, sodium silicate, sodium carbonate, sodium (carboxylatomethyl)cellulose(CMC), and sodium sulfate on the ζ-potential of CB are shown in Figs. 5—7.

As shown in Fig. 5, the negative ζ-potential of CB was increased with addition of sodium triphosphate. However, the negative ζ-potential decreased with increasing concentrations of sodium triphosphate. The ζ-potential of CB in sodium triphosphate solution was higher than the ζ-potential at the pH of suspension, pH 9.4—9.7. The increase of the negative ζ-potential results from the adsorption of triphosphate anion. The ζ-potential is

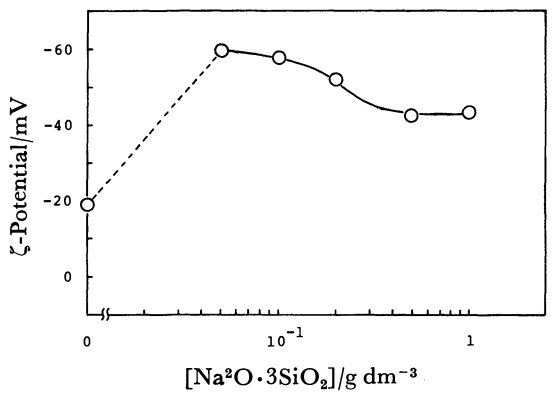

Fig. 6. Effect of the concentration of sodium silicate on ζ-potential of CB at 25 °C.

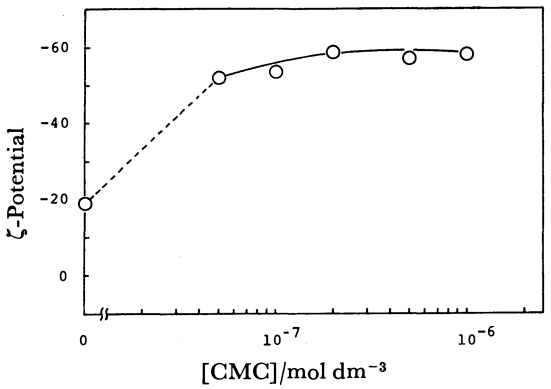

Fig. 7. Effect of the concentration of sodium (carboxylatomethyl)cellulose (CMC) on ζ-potential of CB at 25 °C.

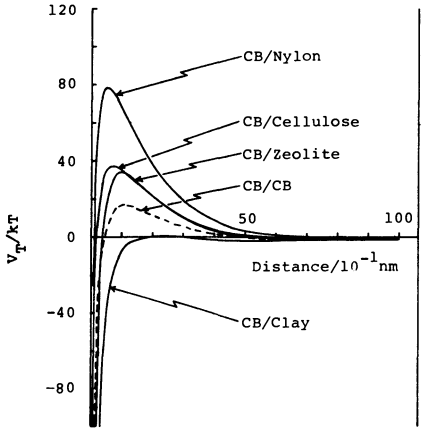

Fig. 8. Total potential energies, V_T, for the interactions between CB/nylon, CB/cellulose, CB/clay, CB/zeolite, and CB/CB in a 1.190×10^{-3} mol dm^{-3} sodium triphosphate solution at 30 °C. The Debye-Hückel reciprocal length parameter is assumed to be 7.115×10^6 cm^{-1}.

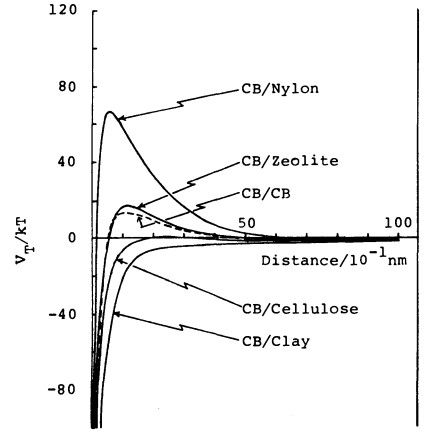

Fig. 9. Total potential energies, V_T, for the interactions between CB/nylon, CB/cellulose, CB/clay, CB/zeolite, and CB/CB in a 0.1 g dm^{-3} sodium silicate solution at 30 °C. The Debye-Hückel reciprocal length parammeter is assumed to be 7.115×10^6 cm^{-1}.

related to the ionic strength. The decrease of negative ζ-potential with increasing concentration of sodium triphosphate seems to result from the increase of the ionic strength.

In the addition of sodium silicate, the negative ζ-potential of CB increased significantly (Fig. 6). The increase was similar to that which occurred in the addition of sodium triphosphate. The ζ-potential was higher than that at the pH of suspension, pH 10.2—11.4. The increase was larger than that of clay.[1] Since the increase results from the adsorption of silicate anions, the adsorption of silicate anion on CB is more than that on clay.

In the addition of sodium carbonate, the negative ζ-potential increased (Fig. 5). The ζ-potential was higher than that at the pH of suspension, pH 10.3—11.4. As described above, the results are attributed to the effect of pH and/or the adsorption of carbonate anion.

The pH of the suspension did not increase due to the addition of CMC and sodium sulfate. Though the concentration of CMC was low, the negative ζ-potential increased significantly (Fig. 7). This suggests that CMC is useful to disperse CB. On the other hand, the increase of ζ-potential in the addition of sodium sulfate was slight (Fig. 5).

As done for SDS, the concentrations of these water-soluble builders in the 0.2 wt% detergent solution were calculated. These ζ-potentials at the concentrations were read from Figs. 5—7. The ζ-potentials of nylon, cellulose, zeolite, and clay and their concentrations are shown in Table 2. The V_T between each pair of materials were calculated with this ζ-potential. The results are shown in Figs. 8—12. The $V_{T,max}$ values in each solution are listed in Table 3. The V_T between CB and nylon in various builders' solutions have maxima: 78.3—14.4 kT. All of these values, except sodium sulfate, were more than the value in SDS solution, and more than 15 kT. CB deposits with difficulty onto nylon fabrics. Though the V_T between CB and cellulose in SDS solution was negative, the V_T in each solution of various builders had maxima. However, the $V_{T,max}$ in the solutions of sodium slicate, sodium carbonate, and sodium sulfate were less than 15 kT. Sodium triphosphate and CMC are useful for prevention of the

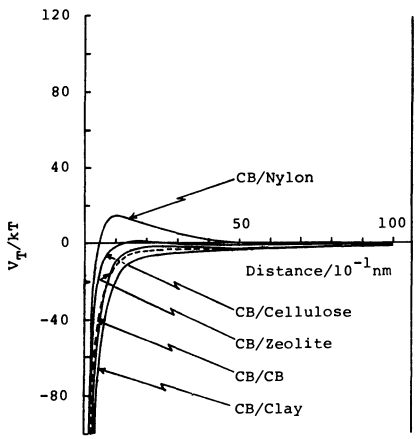

Fig. 12. Total potential energies, V_T, for the interactions between CB/nylon, CB/cellulose, CB/clay, CB/zeolite, and CB/CB in a 7.181×10^{-3} mol dm^{-3} sodium sulfate solution at 30 °C. The Debye-Hückel reciprocal length parameter is assumed to be 7.115×10^6 cm^{-1}.

deposition of CB onto cotton fabrics. The V_T between CB and zeolite in the solutions of various builders, except sodium sulfate, had large maxima of 34.1 − 17.9 kT. The coagulation between CB and zeolite in these builders takes place with difficulty. Though the V_T between CB and CB in the solutions of sodium triphosphate and CMC had maxima of $\geq15\ kT$, the V_T in the solution of the other builders were negative or had small maxima. The V_T values between CB and clay in the solutions of various builders were negative. The coagulation between CB and clay in the various builders' solutions also takes place easily.

The Behavior of CB in the Detergent Solution. The effect of the detergent concentration on the ζ-potential

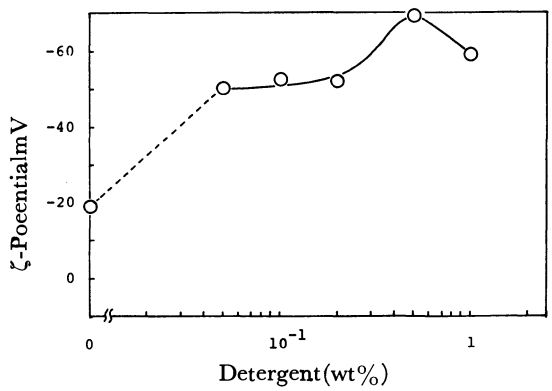

Fig. 13. Effect of the concentration of detergent on ζ-potential of CB at 25 °C.

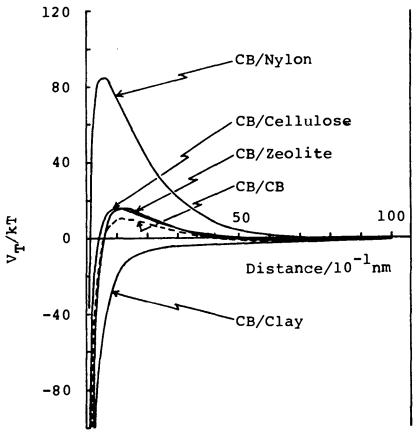

Fig. 14. Total potential energies, V_T, for the interactions between CB/nylon, CB/cellulose, CB/clay, CB/zeolite, and CB/CB in a 0.2 wt% detergent solution at 30 °C. The Debye-Hückel reciprocal length parameter is assumed to be 7.115×10^6 cm^{-1}.

of CB is shown in Fig. 13. The ζ-potential had a maximum at 0.5 wt%. The reason why the maximum existed at this concentration may be interesting; however, since the 0.5 wt% detergent solution is not for practical use, the discussion is excluded from this paper. The ζ-potential of CB at 0.2 wt% was read from Fig. 13. The ζ-potentials of nylon, cellulose, zeolite, and clay in 0.2 wt% detergent solution were −79.9, −28.7, −54.4, and −17.8 mV respectively.[1] The V_T values between each pair of materials in the 0.2 wt% detergent solution were calculated, and are shown in Fig. 14. The $V_{T,max}$ is shown in Table 3. From these results, we can see that CB in the detergent solution deposits with difficulty onto fabrics, coagulates with difficulty with zeolite, and coagulates easily with clay or CB. Consequently, when a detergent which is composed without sodium triphosphate is used, the ζ-potential of CB is increased by the effect of the builders, and the deposition of CB onto fabrics is prevented. Since CB in the detergent solution coagulates easily with clay, the behavior of this coagulated substance in the detergent solution will be discussed in the near future.

Interaction between Hydrophilic Proteins and Nonionic Detergents Studied by Surface Tension Measurements

Nagamune NISHIKIDO,* Tomoyuki TAKAHARA, Hideki KOBAYASHI, and Mitsuru TANAKA
Department of Chemistry, Faculty of Science, Fukuoka University, Nanakuma, Jyōnan-ku, Fukuoka 814-01
(Received January 14, 1982)

The surface tensions of the systems of hexa(oxyethylene) dodecyl ether ($C_{12}E_6$) *vs.* lysozyme (Lyz) or bovine serum albumin (BSA) were measured for constructing the binding isotherms, since the surface tension method is more convenient for the systems of nonionic detergents and proteins than is equilibrium dialysis. The obtained binding isotherms depend on the protein concentration; this effect is much more remarkable for Lyz–$C_{12}E_6$ systems than for BSA–$C_{12}E_6$ ones. The binding isotherms of BSA–$C_{12}E_6$ systems obey the Scatchard equation, and the maximum number and estimated free energy for $C_{12}E_6$ binding to BSA are comparable to those for the system of Triton X-100 and BSA determined by equilibrium dialysis. The agreement suggests that the surface tension method is sound and has advantages over equilibrium dialysis for the estimation of the number of detergent molecules bound to protein. In the systems of Lyz–$C_{12}E_6$, the binding isotherms follow the Freundlich-type equation rather than the Scatchard equation. The remarkable protein concentration dependence of the binding isotherms and this result suggest the occurrence of protein aggregation.

Nonionic detergents such as Triton X-100 (poly-(oxyethylene) (9—10) *p*-(1,1,3,3-tetramethylbuthyl)-phenyl ether) have been widely used to solubilize membranes and to purify membrane proteins.[1,2] That is, they can often extract proteins from membranes without disruption of native conformation or loss of biological activity, in contrast to common synthetic ionic detergents, notably sodium dodecyl sulfate (SDS), which ordinarily solubilize lipid-associated proteins in a denatured and inactive form.

The interaction of proteins with ionic detergents has been a subject of intensive investigation. However, the interaction of nonionic detergents with proteins has not been investigated widely and the information so far gained is as follows.[1,3–5] The lipophilic proteins bind cooperatively large amounts of nonionic detergents at their critical micelle concentrations (cmc's), whereas a number of hydrophilic proteins bind few or no nonionic detergents. It seems that nonionic detergents can bind only to hydrophilic proteins possessing hydrophobic surface patch. For example, ovalbumin does not bind Triton X-100 at all within the concentration range studied (10^{-5}—10^{-4} mol dm^{-3}). Bovine serum albumin (BSA), possessing a hydrophobic surface patch, binds Triton X-100 by the maximum number of four per protein in a Langmuir-type binding, and no gross structural change occurs in BSA by binding of Triton X-100.

The interaction between detergents and proteins may be attributed to the binding of detergents to proteins, *i.e.*, to complex formation, and may be expressed directly and quantitatively by the binding isotherms. The amount of detergents bound to proteins is usually determined by means of equilibrium dialysis. However, nonionic detergents such as Triton X-100 do not penetrate the dialysis membrane fast enough for dialysis experiments.[1,3] On the contrary, the surface tension can be measured more easily and reflects sensitively the changes of dissolved state in bulk.

In this report, we have measured the surface tension of aqueous solutions of hexa (oxyethylene) dodecyl ether ($C_{12}E_6$) *vs.* lysozyme (Lyz) or bovine serum albumin (BSA), and constructed the binding isotherms by applying the surface tension data to the equations derived for determining the number of detergent molecules bound to a protein.

Experimental

Materials. Hen egg-white Lyz was supplied from Miles Biochemicals (six times recrystallized; activity: above 51000 units/mg; homogeneity: above 97%). BSA was also supplied from Miles Biochemicals (monomer standard protein powder; purity: above 99%). $C_{12}E_6$ was supplied from Nikkō Chemicals Co., Ltd. The high purity (above 99.5%) was confirmed by gas chromatography.

Surface Tension Measurements. The aqueous solutions of mixed BSA– or Lyz–$C_{12}E_6$ were free from buffer and salts. The pH's of the solutions were 5.6. The surface tension measurements for the solution were performed at 298.15±0.01 K by the Wilhelmy method with a 24 mm × 24 mm glass plate and a Kyowa CBVP Surface Tension-Meter A-3. Before the measurement the plate was cleaned by heating it in a "chromic acid mixture" for more than six hours and was washed thoroughly with three-times-distilled water.

Results and Discussion

In Figs. 1 and 2 are shown the plots of surface tension *vs.* detergent concentration at constant protein concentration for BAS– and Lyz–$C_{12}E_6$ systems, respectively. Each plot exhibits a sharp break at each cmc and the surface tension remains constant above the cmc. The values of the constant surface tensions for all the systems are identical regardless of the protein concentration. Next, we will derive the equations for determining the amount of nonionic detergents bound to proteins from these surface tension data.

It can be supposed that protein-nonionic detergent complexes are surface inactive, since the hydrophobic areas of protein and detergent are almost hidden by the complex formation. Then the following Langmuir equation may be valid for the adsorption equilibrium of nonionic detergent monomers at the air/water interface from the aqueous solution of protein and detergent, in the same way as in the case of the adsorption of detergent alone:[6–9]

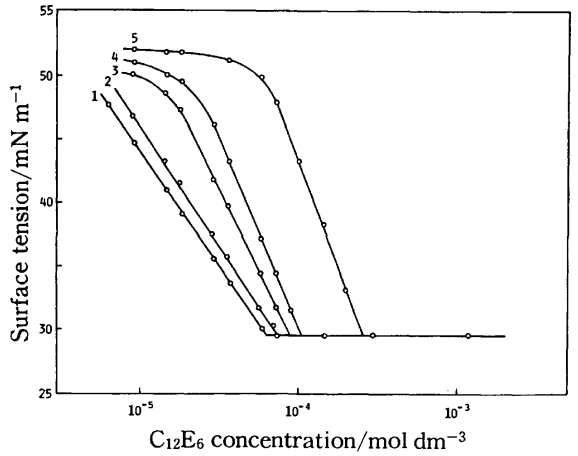

Fig. 1. Plots of surface tension *vs.* logarithm of $C_{12}E_6$ concentration at various BSA concentrations for BSA–$C_{12}E_6$ systems at 298.15 K.
BSA concentration: (1) $C_{12}E_6$ alone, (2) 1×10^{-6}, (3) 5×10^{-6}, (4) 1×10^{-5}, (5) 5×10^{-5} mol dm^{-3}.

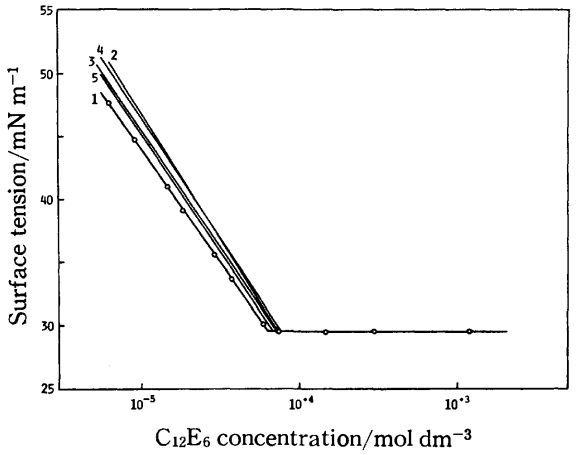

Fig. 2. Plots of surface tension *vs.* logarithm of $C_{12}E_6$ concentration at various Lyz concentrations for Lyz–$C_{12}E_6$ systems at 298.15 K.
Lyz concentration: (1) $C_{12}E_6$ alone, (2) 1×10^{-6}, (3) 2×10^{-6}, (4) 1.25×10^{-5}, (5) 1×10^{-4} mol dm^{-3}.

$$\Gamma_s = \frac{K_s(a-\Gamma_p f)C_s^f}{1+K_sC_s^f}, \tag{1}$$

where Γ_s: the amount of adsorbed detergent at the air/water interface,
Γ_p: the amount of adsorbed protein,
f: the factor for converting Γ_p to Γ_s-basis, defined as the ratio of the maximum adsorption of detergent to that of protein,
a: the maximum adsorption of detergent,
C_s^f: the concentration of detergent monomer,
K_s: the equilibrium constant.

It is also known that the Langmuir equation applies empirically to the adsorption of protein at the low concentration,[10,11] and thus we may write for the protein-component:

$$\Gamma_p f = \frac{K_p(a-\Gamma_s)C_p^f}{1+K_pC_p^f}, \quad \Gamma_p^\circ f = \frac{K_paC_p^\circ}{1+K_pC_p^\circ}, \tag{2a,2b}$$

where the subscript o denotes the quantity for the adsorption in the aqueous solutions of the protein alone, and the subscript p refers to protein. If the protein concentration is low enough so that $K_pC_p^f \approx K_pC_p^\circ \ll 1$ (Henry-type adsorption), we have from Eqs. 2a and 2b:

$$\Gamma_p f = \Gamma_p^\circ f + K_p(\Gamma_s-a)(C_p^\circ-C_p^f) - K_pC_p^\circ\Gamma_s. \tag{3}$$

In the case of the adsorption of nonionic detergent ($C_{12}E_6$) alone, the value of Γ_s is nearly equal to that of a in the concentration range greater than 1×10^{-5} mol dm^{-3}; this is the result of the direct measurement of the adsorption of $C_{12}E_6$ by a radiotracer technique.[12] Then, in the case of the adsorption from protein-detergent mixed solutions, the magnitude of the second term is expected to be much less than those of the others terms in Eq. 3 at the $C_{12}E_6$ concentration studied and we have:

$$\Gamma_p f \simeq \Gamma_p^\circ f - K_pC_p^\circ\Gamma_s = \Gamma_p^\circ f - \frac{\Gamma_p^\circ f}{a}\Gamma_s. \tag{4}$$

Irrespective of the concentration range where Eq. 4 is valid, Eq. 4 may be regarded as a working hypothesis for the mixed adsorption of detergent and protein. That is, Eq. 4 gives a relation between Γ_p and Γ_s, and means that the value of Γ_p decreases linearly with that of Γ_s. By introducing Eq. 4 into Eq. 1, we obtain

$$\Gamma_s = \frac{K_sa(a-\Gamma_p^\circ f)C_s^f}{a+K_s(a-\Gamma_p^\circ f)C_s^f}. \tag{5}$$

Next, we consider the Gibbs adsorption equation under the conditions of constant protein concentration, Eq. 6, since the concentrations of detergent and protein are low in the present case:[13]

$$\left(\frac{\partial\gamma}{\partial\mu_s}\right)_{T,\mu_p} \simeq \left(\frac{\partial\gamma}{\partial\ln C_s^f}\right)_{T,C_p} = -RT\Gamma_s, \tag{6}$$

where γ refers to the surface tension of the aqueous solution containing protein and detergent, and μ is the chemical potential. By integration of Eq. 6 after introduction of Eq. 5, we have

$$\gamma = -aRT\ln[a+K_s(a-\Gamma_p^\circ f)C_s^f] + \gamma_p + aRT\ln a, \tag{7}$$

where γ_p refers to the surface tension of the protein solution. In the case of detergent alone,

$$\gamma_s = -aRT\ln[1+K_sC_s^\circ] + \gamma_{H_2O}, \tag{8}$$

where γ_{H_2O} refers to the surface tension of pure water.

Now we assume: at the concentration (cmc′) where the surface tension γ begins to stay constant, detergent monomers begin to form micelles by themselves and the concentration of monomers is identical with the cmc of detergent alone (cmc°). In addition, as seen from Figs. 1 and 2, we take into account the experimental observation that the surface tensions at the cmc′ and cmc° are identical ($\gamma_{cmc'}=\gamma_{cmc^\circ}\equiv\gamma_{cmc}$). Then, we have by Eqs. 7 and 8:

$$\gamma_{cmc} = -aRT\ln[1+K_s\,cmc^\circ] + \gamma_{H_2O}, \tag{9}$$

$$\Gamma_p^\circ f = \frac{a(1+K_s\,cmc^\circ)\left\{1-\exp\left(-\frac{\gamma_{H_2O}-\gamma_p}{aRT}\right)\right\}}{K_s\,cmc^\circ}. \tag{10}$$

By applying Eqs. 7, 9, and 10 to the surface tension data shown in Figs. 1 and 2, we can obtain the mean number of detergent molecules bound to proteins, $\bar{\nu}$; $\bar{\nu}=$

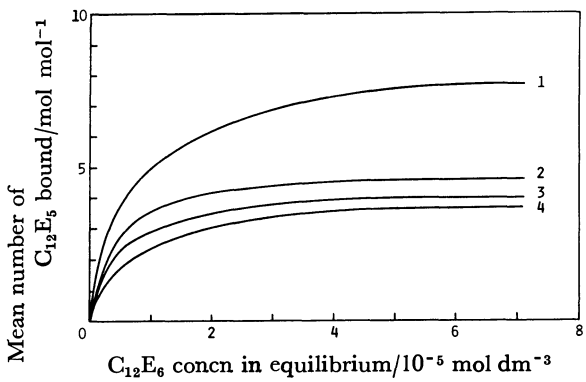

Fig. 3. Binding isotherms at various BSA concentrations for BSA–$C_{12}E_6$ systems at 298.15 K.
BSA concentration: (1) 1×10^{-6}, (2) 5×10^{-6}, (3) 1×10^{-5}, (4) 5×10^{-5} mol dm^{-3}.

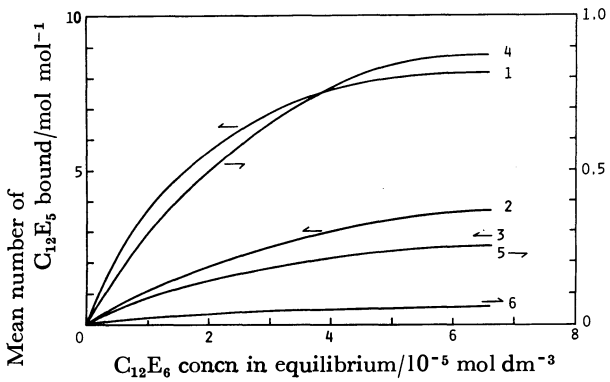

Fig. 4. Binding isotherms at various Lyz concentrations for Lyz–$C_{12}E_6$ systems at 298.15 K.
Lyz concentration: (1) 1×10^{-6}, (2) 2×10^{-6}, (3) 5×10^{-6}, (4) 1.25×10^{-5}, (5) 5×10^{-5}, (6) 1×10^{-4} mol dm^{-3}.

$(C_s-C_s^f)/C_p$, where C_s denotes the total detergent concentration. The process used to obtain the value of $\bar{\nu}$ is as follows. The value of a may be obtained from the slope of the surface tension *vs.* logarithm of concentration plot below the cmc of $C_{12}E_6$ solution (Fig. 1 or 2) by applying the Gibbs adsorption equation. Next, the value of K_s can be calculated by introducing the values of a, cmc° and γ_{H_2O} into Eq. 9 and then that of $\Gamma_p^\circ f$ can be calculated by the use of Eq. 10. Finally, it is possible to calculate the value of C_s^f by introducing the obtained values of K_s and $\Gamma_p^\circ f$ into Eq. 7 and thus we obtain the value of $\bar{\nu}$.

Figures 3 and 4 show the binding isotherms for BSA– and Lyz–$C_{12}E_6$ systems, respectively, at various protein concentrations. The confidence limit of protein concentration for estimating the value of $\bar{\nu}$ primarily depends on the value of cmc of detergent alone (cmc°) since the value of cmc° is the maximum concentration of detergent in unbound state. In this work, the confidence range of protein concentration is estimated to be from 10^{-6} to 10^{-4} mol dm^{-3}. It is realized from Figs. 3 and 4 that the bound number explicitly depends upon the protein concentration and decreases with the increase of concentration. The tendency of the concentration dependence is much more remarkable for Lyz–$C_{12}E_6$ than for BSA–$C_{12}E_6$ systems. In BSA–$C_{12}E_6$ systems, the bound number approaches a constant value with an increase in BSA concentration, in other words, the binding isotherms approximately coincide with one another at higher BSA concentrations. In this case, the maximum number of $C_{12}E_6$ bound is about four moles per mole of BSA, which agrees with that for Triton X-100 and BSA systems determined by equilibrium dialysis.[5] The dependence of the bound numbers on protein concentrations was also found for the systems of SDS *vs.* membrane protein, ferricytochrome *c*,[14] which exhibits a similar behavior to that of hydrophilic protein for the interaction with detergents.[15]

It is known that ionic detergents (at lower concentractions) and nonionic detergents bind to the hydrophobic regions of proteins primarily with hydrophobic bonds.[1,5,16] It may be anticipated that the hydrophobic regions of proteins, which are detergent-binding sites, come into contact and are effectively removed by protein-protein interactions within the protein aggregates; this aggregation effect may be enhanced by the increase in protein concentration.[1] In fact, Lyz is known to aggregate in solution, depending on the pH.[17] In addition, protein aggregation may also be favored sterically by detergent binding by way of the flexible hydrocarbon chain. The concentration dependence of the bound number is considered to be somehow due to the fact that detergent-binding sites become effectively hidden.

Just as the systems of BSA and Triton X-100, which were studied by equilibrium dialysis, the binding isotherms for BSA–$C_{12}E_6$ systems obey the Scatchard equation:[18]

$$\bar{\nu}/C_s^f = k_0 n - k_0\bar{\nu}, \qquad (11)$$

where k_0 denotes the intrinsic binding constant and n the maximum number of binding sites. The estimated values of k_0 and the free energies ΔG for $C_{12}E_6$ binding to BSA are listed in Table 1, with BSA concentrations. The mean value of ΔG, -7.2 ± 0.2 kcal mol^{-1}, can be made comparable to the value for the systems of Triton X-100 and BSA, -5.9 kcal mol^{-1}, by taking into account the difference of hydrophobic chain of $C_{12}E_6$ and of Triton X-100.[19] This agreement and the agreement of the maximum number of detergent molecules bound suggest that the surface tension method is not only sound but very advantageous for the estimation of the number of detergent molecules bound to proteins, since the surface tension measurements are more easily performed than the equilibrium dialysis

Table 1. Intrinsic binding constants k_0 and free energies ΔG for $C_{12}E_6$ binding to BSA

BSA concentration / mol dm^{-3}	k_0 / dm^3 mol^{-1}	ΔG / kcal mol^{-1} a)
1×10^{-5}	1.7×10^5	-7.2 ± 0.2
5×10^{-6}	2.3×10^5	-7.4 ± 0.2
1×10^{-5}	2.2×10^5	-7.3 ± 0.2
5×10^{-5}	1.6×10^5	-7.1 ± 0.2

a) 1 cal=4.184 J.

experiments. To establish the advantage of the surface tension method is one of the objectives of this work. The detergent binding for BSA–$C_{12}E_6$ systems means the statistical binding by hydrophobic bonding. However, the binding isotherms for Lyz–$C_{12}E_6$ systems obey the following Freundlich-type equation rather than the Scatchard equation:

$$\bar{\nu}/n = K(C_s^f)^a, \quad 0 \leq a \leq 1. \tag{12}$$

Equation 12 has been derived by assuming an exponential distribution of binding energies, *i.e.*, the heterogeneity of binding sites. This heterogeneity may be caused by the protein aggregation, which is more remarkable for Lyz. In the present case, the protein aggregate consists of several monomers at the most on the average. They may assume various arrangements, since the aggregating force including steric factors is rather weak compared to that for ordinary micelles of detergents. In addition, it is considered that the hydrophobic areas of protein are not completely hidden by the aggregation and thus the residual areas of the aggregate exhibit different geometries owing to the distribution of arrangements and sizes of aggregate. This may reflect the heterogeneity of binding sites. Thus, binding isotherms must be viewed with some caution, as it is probable that detergent-binding sites are effectively hidden by protein-protein interaction.

The Isomerization of Butenes over KC_8

Susumu Tsuchiya,* Takatoshi Misumi, Noriyuki Ohuye, and Hayao Imamura
Department of Industrial Chemistry, Faculty of Engineering, Yamaguchi University, Tokiwadai, Ube 755
(Received February 15, 1982)

The isomerization of butenes over KC_8 has been investigated. The double-bond-migration and the cis-trans isomerization took place over KC_8, but the skeletal isomerization could not be observed. From the rates of reactions and the selectivity ratios, all six of the relative rate constants and the activation energies of reaction were determined. The reaction paths on the triangular graph calculated from the rates constants show the *cis*-convex-type profile, which suggests one of the catalytic characteristics of KC_8.

It is well known that graphite reacts with alkali metals to form a variety of intercalation compounds with a transition metal-like nature.[1] In these substances, the alkali metal atoms are not merely distributed randomly between the layers of the graphite structure, but have an ordered layer-lattice of their own. The corresponding intercalation compounds exhibit well-defined stoichiometric compounds, *e.g.*, KC_8.

Although the intercalation compounds of graphite have been known for at least fifty years, their catalytic and surface properties have only recently begun to be explored. In the present work, the interest has centered on the catalytic characteristics of KC_8, the isomerization of butenes being employed as a model reaction.

Experimental

Materials. The KC_8 samples used as catalysts were prepared *in vacuo* in the apparatus shown in Fig. 1. The graphite (1.25 g of Union Carbide Spectroscopic-grade powder) in the vessel, G, was first degassed for 3 h at 540 K. The bulb, K, containing potassium metal was then heated by applying a soft flame, so that the metal ran into the preparation vessel, P, the wall of which was covered with potassium film, leaving the dross behind. The weight ratio, potassium/graphite, was set as 0.60. K was then removed at the seal-off. After the stopcock, III, had been closed, this apparatus was removed from the vacuum line and inclined in order to transfer the graphite powder from the vessel, G, to P. After G had been removed from the seal-off, the apparatus was again connected to the vacuum line. P was heated in a electric heater for 24 h at 540 K to form KC_8, and then it was evacuated for 30 min. The excess potassium on KC_8 was separated by the evacuation. The intercalation compound thus formed was kept for another 24 h at the same temperature. The apparatus was then removed from the vacuum line at the seal-off point and inclined so as to transfer the KC_8 powder from P to the reactor, R. A capillary tube sampler connected to the apparatus was used for X-ray analysis *in vacuo* to identify the intercalation compound. The X-ray diffraction data of the KC_8 samples prepared thus agreed quite well with those reported by Rudroff and Schulze.[2] The color of the KC_8 obtained was gold.

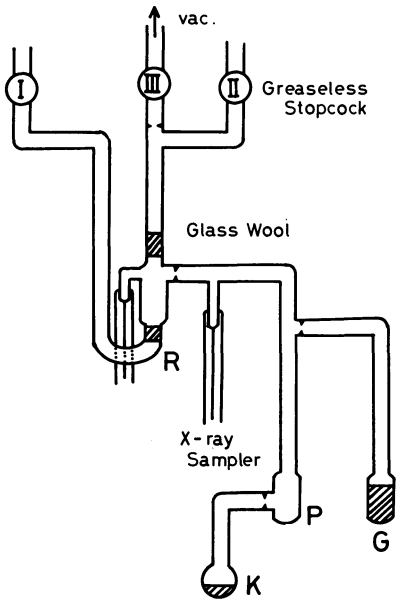

Fig. 1. Apparatus for preparation of KC_8.

The 1-butene, *cis*-2-, and *trans*-2-butene used as the reactants were obtained from the Tokyo Kasei Kogyo Co., Ltd., and were purified by repeated distillation *in vacuo*, the purity was confirmed by gas chromatography to be more than 99%.

Procedure. The apparatus used for the present study was essentially the same as that used previously.[3] A closed circulating system with a U-shaped reactor and with greaseless stopcocks, connected to a conventional vacuum line and a gas chromatograph, was used to follow the reaction. The volume of the reaction system corresponded to about 288 cm^3 at the reaction temperature of 373 K. The reaction mixtures were occasionally analyzed by means of the gas chromatograph with a column of dimethylsulfolane on Celite-545.

Before each run, the catalyst was evacuated for 2 h at 470 K, after which helium was introduced into the reactor. The reactor was then cooled to the reaction temperature and evacuated for a few minutes.

Results and Discussion

The double-bond-migration and the *cis-trans* isomerization of butenes took place over KC_8. The graphite does not show any catalytic activity for a reaction under the same experimental conditions. The skeletal isomerization could not be observed. No gaseous hydrocarbon other than butenes could be detected in the reaction mixtures under the present experimental conditions.

Figure 2 shows how the composition of the butenes changes with the time over KC_8 at 373 K when 1-butene is the reactant; *cis*-2-butene is predominantly formed. The ambient pressure of 1-butene at the initial state was 2.80×10^3 Pa in this reaction. When potassium metal was employed as the catalyst, *trans*-2-butene was predominantly formed as this temperature.[4] The results suggest that the KC_8 used as the catalyst is different in catalytic nature from potassium metal. The active sites of the catalyst are attributed to KC_8, and not to potassium atoms, which might be randomly present

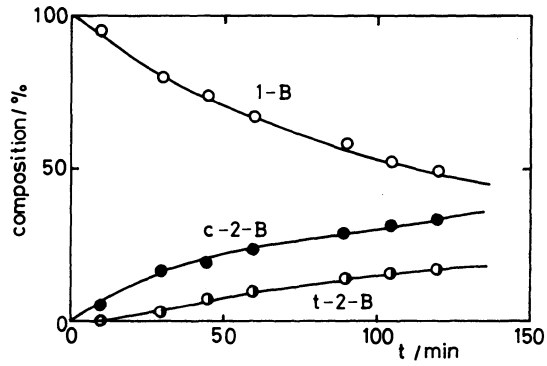

Fig. 2. Isomerization of 1-butene over KC_8 at 373 K.

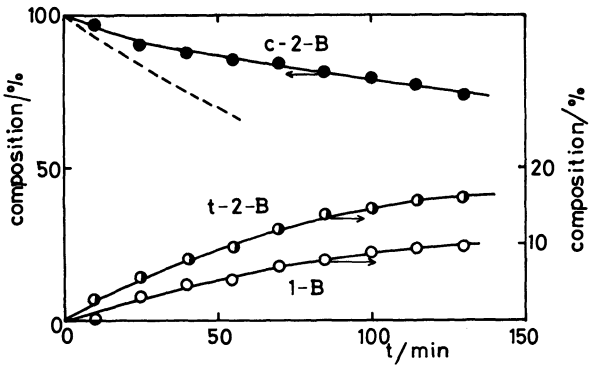

Fig. 3. Isomerization of *cis*-2-butene over KC_8 at 373 K.

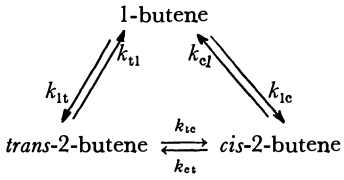
between the layers of the graphite structure.

The equilibrium composition of butenes at 373 K, as calculated from the thermodynamical data,[5] is $x_{1e} : x_{ce} : x_{te} = 0.052 : 0.288 : 0.660$, where x_{1e}, x_{ce}, and x_{te} are the mole fractions of 1-butene, *cis*-2-butene, and *trans*-2-butene respectively at equilibrium. The amount of *cis*-2-butene formed at a later time becomes more than that at the equilibrium.

Figure 3 shows how composition of the butenes changes with the time at 373 K when *cis*-2-butene is the reactant. The ambient pressure of *cis*-2-butene at the initial state was 2.80×10^3 Pa in the reaction. The rate of the isomerization reaction of *cis*-2-butene is lower than that of 1-butene; the dotted line represents the time course of 1-butene shown in Fig. 2. The amount of 1-butene at the later time also exceeds that at equilibrium.

The isomerization reaction of butenes was almost first-order with respect to the pressure of reactants, ranging from 2.0×10^3 to 1.4×10^4 Pa. From the rates of reaction and the selectivity ratios, all six of the relative rate constants expressed by Scheme 1 and the activation energies of reaction were determined. The relative rate constants at 373 K and the activation energies (bracketed) are shown in Fig. 4.



Scheme 1.

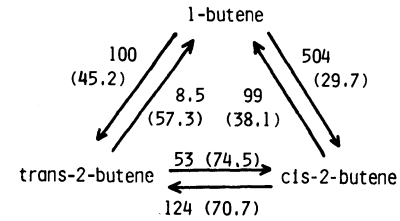


Fig. 4. Relative rate constants at 373 K and activation energies (kJ/mol) bracketed.

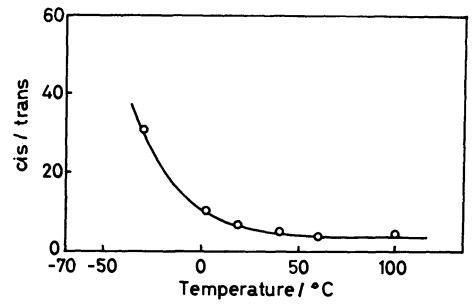

Fig. 5. Temperature dependence of selectivity ratio, *cis*/*trans*, for isomerization of 1-butene.

Figure 5 shows the temperature dependence of the *cis*/*trans* selectivity ratio, 1-butene being the reactant. The ratio became extremely high (more than 30) at a lower temperature.

Since the isomerization of butenes has been the subject of many detailed investigations, three mechanisms have been proposed for different catalytic systems:[6]

(a) A hydride-addition mechanism for metals and organometallic systems;

(b) a carbenium-ion mechanism for acid catalysts, and

(c) an allylic (carbanion) mechanism which is operative over basic catalysts. Each of these mechanisms has certain characteristic features. When the isomerization takes place with the allylic mechanism, the initial *cis*/*trans* ratio is more than unity and the initial 1/*trans* ratio is larger than the 1/*cis* ratio.[6,7]

The relative initial rates of isomerization are also similar to those for the carbanion mechanism; *i.e.*, the rate of the isomerization of 1-butene>that of *cis*-2>that of *trans*-2-butene. The data obtained in the present study are in agreement with an allylic mechanism. A further discussion of the reaction mechanism must await a new result which might be obtained from a rather sophisticated experiment.

Wei and Prater[8] developed an interesting method for evaluating the kinetic parameters of a monomolecular, or pseudomonomolecular, first-order multicomoponent system, triangular diagrams being employed. An extension of the Wei and Prater method was devised by Lombardo and Hall[9] to reduce the required work. Haag and Pines,[10] on the other hand, had proposed a method to estimate the relative values of six rate constants for the interconversion of butenes; they had shown that the reaction path could be calculated from the first-order rate equation by using the relative rate constants. The concentrations of 1- and of *cis*-2-butene were plotted

against that of *trans*-2-butene. Kagawa[11] kinetically analyzed the reaction path in a system consisting of a Langmuir-Hinshelwood-type reaction.

In the Haag and Pines analysis, mixtures of butenes were not used as the reactants; the differential equation employed was applied only for a pure reactant. In the present paper, the isomerization of butenes, is dealt with in a more general way.

Since there is no change in the total number of moles with the extent of reaction:

$$x_l + x_c + x_t = 1, \tag{1}$$

where x_l, x_c, and x_t are the mole fractions of 1-butene, *cis*-2-butene, and *trans*-2-butene respectively. The overall reaction rates can be accordingly expressed by Eq. 2:

$$\frac{dx_l}{dt} = -(k_{lc}+k_{lt})x_l + k_{cl}x_c + k_{tl}x_t \tag{2-l}$$

$$\frac{dx_c}{dt} = k_{lc}x_l - (k_{ct}+k_{cl})x_c + k_{tc}x_t \tag{2-c}$$

$$\frac{dx_t}{dt} = k_{lt}x_l + k_{ct}x_c - (k_{tl}+k_{tc})x_t \tag{2-t}$$

The particular solution of Eq. 2 satisfying the boundary conditions of the initial composition, x_{i0} (i=l, c, t), at $t=0$ and the equilibrium composition, x_{ie}, at $t=\infty$ is:

$$\begin{aligned} x_l = {} & (1/\sqrt{m^2-4n})[(k_{cl}-k_{tl})x_{c0} + k_{tl} \\ & - \{k_{lc}+k_{lt}+k_{tl}-(m+\sqrt{m^2-4n})/2\}x_{l0} \\ & - \{(m+\sqrt{m^2-4n})/2\}x_{le}]\exp[-\{(m-\sqrt{m^2-4n})/2\}t] \\ & - (1/\sqrt{m^2-4n})[(k_{cl}-k_{tl})x_{c0} + k_{tl} \\ & - \{k_{lc}+k_{lt}+k_{tl}-(m-\sqrt{m^2-4n})/2\}x_{l0} \\ & - \{(m-\sqrt{m^2-4n})/2\}x_{le}] \times \\ & \exp[-\{(m+\sqrt{m^2-4n})/2\}t] + x_{le}, \end{aligned} \tag{3-l}$$

$$\begin{aligned} x_c = {} & (1/\sqrt{m^2-4n})[(k_{lc}-k_{tc})x_{l0} + k_{tc} \\ & - \{k_{ct}+k_{cl}+k_{tc}-(m+\sqrt{m^2-4n})/2\}x_{c0} \\ & - \{(m+\sqrt{m^2-4n})/2\}x_{ce}]\exp[-\{(m-\sqrt{m^2-4n})/2\}t] \\ & - (1/\sqrt{m^2-4n})[(k_{lc}-k_{tc})x_{l0} + k_{tc} \\ & - \{k_{ct}+k_{cl}+k_{tc}-(m-\sqrt{m^2-4n})/2\}x_{c0} \\ & - \{(m-\sqrt{m^2-4n})/2\}x_{ce}] \times \\ & \exp[-\{(m+\sqrt{m^2-4n})/2\}t] + x_{ce}, \end{aligned} \tag{3-c}$$

$$\begin{aligned} x_t = {} & (1/\sqrt{m^2-4n})[\{k_{lt}+k_{tl}+k_{tc}-(m+\sqrt{m^2-4n})/2\}x_{l0} \\ & + \{k_{ct}+k_{tl}+k_{tc}-(m+\sqrt{m^2-4n})/2\}x_{c0} \\ & - \{k_{tl}+k_{tc}-(m+\sqrt{m^2-4n})/2+x_{te}(m+\sqrt{m^2-4n})/2\}] \times \\ & \exp[-\{(m-\sqrt{m^2-4n})/2\}t], \\ & - (1/\sqrt{m^2-4n})[\{k_{lt}+k_{tl}+k_{tc}-(m-\sqrt{m^2-4n})/2\}x_{l0} \\ & + \{k_{ct}+k_{tl}+k_{tc}-(m-\sqrt{m^2-4n})/2\}x_{c0} \\ & - \{k_{tl}+k_{tc}-(m-\sqrt{m^2-4n})/2 + x_{te}(m-\sqrt{m^2-4n})/2\}] \times \\ & \exp[-\{(m+\sqrt{m^2-4n})/2\}t] + x_{te}, \end{aligned} \tag{3-t}$$

where $$m = k_{lt} + k_{tc} + k_{cl} + k_{tl} + k_{lc} + k_{ct} \tag{4}$$

$$\begin{aligned} n = {} & k_{tl}k_{cl} + k_{lt}k_{tc} + k_{lt}k_{ct} + k_{tl}k_{lc} + k_{tl}k_{cl} \\ & + k_{tl}k_{ct} + k_{cl}k_{tc} + k_{lc}k_{ct} + k_{cl}k_{tc}. \end{aligned} \tag{5}$$

When the isomerization of butenes proceeds, the composition of butenes in the gas phase varies with the time. The values of x_l, x_c, and x_t corresponding to the reaction time, t, can be calculated from Eqs. 3, k_{ij}, x_{i0}, and x_{ie} being given. Figure 6 shows the reaction paths

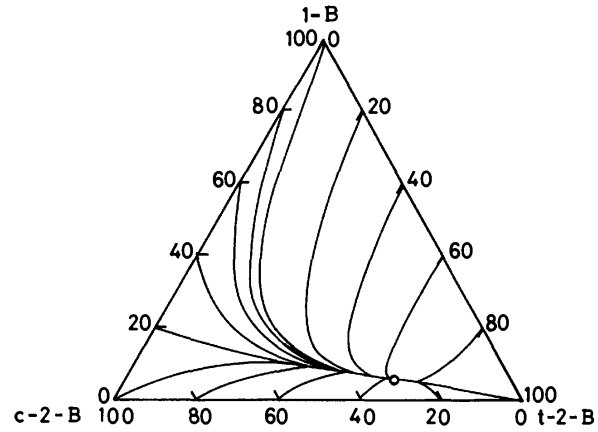

Fig. 6a. Reaction profile of isomerization of butenes over KC_8 at 373 K.

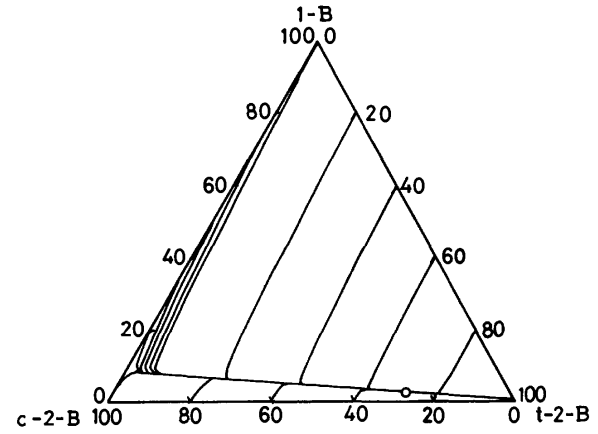

Fig. 6b. Reaction profile of isomerization of butenes over KC_8 at 292 K.

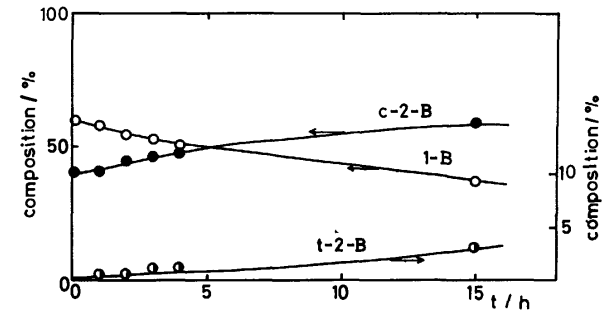

Fig. 7. Composition change with time, when the mixture of 0.6 1-butene/0.4 *cis*-2-butene reacted over KC_8 at 292 K.

calculated at 373 K and at 293 K respectively. These triangular graphs thus represent one of the catalytic characteristics of KC_8 for the isomerization of butenes. The curves, which originate from the left side of the triangle, bend convexly to the left. The profile may be named the *cis*-convex type. The *cis*-convexity became higher at a lower temperature, as is shown in Fig. 6b.

The mole fraction of *cis*-2-butene, x_c, seemingly increases with the time at the earlier period, as is shown in Fig. 6b, when mixtures of 1- and *cis*-2-butene are

employed as the reactants. The tendency is typically shown in Fig. 7; the time course of the 0.6/0.4 mixture is shown. The ambient pressures of 1-butene and of *cis*-2-butene at the initial state were 4.20×10^3 and 2.80×10^3 Pa respectively. The solid lines represent the curves calculated, while the points are the experimental results. The mole fraction of *cis*-2-butene, x_c, increased with the time and exceeded the equilibrium value, x_{ce} (0.288), although that at the initial state, x_{c0} (0.400), was higher than that at equilibrium. The curve of x_c, of course, will show its maximum and go downwards later. These results can be explained kinetically on the basis that k_{lc} (20.31) is much larger than k_{lt} (1.00) and k_{ct} (0.013) at 292 K.

Conclusion

The catalytic selectivity of KC_8 is different from that of potassium metal for the isomerization of butenes. The reaction may proceed by means of an allylic mechanism. One of the catalytic characteristics is thus shown in Fig. 6. The *cis*-convex type profile is due to the fact that the rate constant of the isomerization of 1-butene to *cis*-2-butene is higher than that to *trans*-2-butene and that of *cis*-2-butene to *trans*-2-butene.

The authors are grateful to Professor Tadato Mizota of the Department of Mining and Mineral Engineering of this faculty for his X-ray analysis. This work was supported by a Grant-in-Aid for Scientific Research, No. 56550575, from the Ministry of Education, Science and Culture, for which the authors' thanks are due.

Radiationless Transition between Randomly Fluctuating Levels. S_1-T_2-T_1 Intersystem Crossing in Condensed Phase

Nobuaki KANAMARU

Department of Chemistry, Faculty of Science, Nagoya University, Chikusa-ku, Nagoya 464

(Received February 17, 1982)

Radiationless transitions in aromatic molecules in condensed phase are examined for the case where sparse intermediate levels are involved. Effects of surrounding mediums on radiationless transitions are also discussed in which the random fluctuation of the vibrational manifolds in the solvent cages is shown to be important to meet the resonance conditions in the transitions. The theory is applied to explain the "unusually" fast S_1-T_2-T_1 intersystem crossing in the system such as anthracene derivatives.

The radiationless transitions in aromatic molecules have been studied quite extensively both theoretically and experimentally.[1] However, the quantitative interpretation of the experimental facts are not always in the stage of a good consensus. One of the examples is S_1-T_2-T_1 ISC of aromatic molecules (especially of anthracene derivatives) which may be the case where sparse intermediate levels are involved in the transitions.[2]

In this paper, brief but general discussion of the effect of solvent on the radiationless transitions will be presented. Particularly, the random fluctuations of the vibrational manifolds in the solvent cage is shown to be important to meet the resonance conditions[1b] in the transitions. This is closely related to the earlier discussion by the present author concerning the choice of basis sets in radiationless transitions.[3] Actually, several key features in this paper were already suggested in that paper. So, the present paper is intended to give more quantitative interpretation of S_1-T_2-T_1 ISC of some anthracene derivatives which was not the major subject of the previous paper, by taking the recent experimental data into account.[2,4-6] Thus, the "unusually" fast ISC of these compounds (even without heteroatoms), hardly explained by intramolecular mechanism (*e.g.*, the third triplet state had to be invoked),[2] is now interpreted by taking the effect of solvent cage into account.

Mechanism

Just like the presentation in the previous paper, we'll give kinetical arguments which could be converted into a quantum mechanical picture as a branched sequential decay in a system composed of both aromatic molecules and surrounding medium.[3]

However, before going into mechanism of ISC, we had better to discuss the effect of the medium on the radiationless transition in general which was discussed only implicitly in the previous paper.[3] Most recognized is the vibrational relaxation (VR) between vibrational levels in the same electronic state which allows for rapid communication (as fast as 10^{12} s^{-1}) within the vibrational manifolds generally accepted as a cause for the thermally activated processes of electronic relaxations.[1] In addition, VR works to give uncertainty widths to the initial and the final states of radiationless transitions allowing for transfer from the intermediate case to the statistical limit case as was actually discussed to explain the collisional effect in vapor phase[7] (*vide infra*). Another mechanism is a solvent effect on the location of energy levels (especially energy gap between the ground vibrational levels of the electronic states) which may partially explain the solvent effect on ER's. And thirdly, as was not widely recognized in spite of the earlier suggestions,[3] the location of energy levels are fluctuating with the change of the structure of solvent cages so that the resonance conditions towards the radiationless transition are sometimes met between some levels for every transient conformation of a system composed of a solute molecule plus surrounding solvent molecules. Actually, the interpretation of the collisional effects of S_1-T_1 ISC rates of naphthalene by Fung and Freed[8] and the theory of delayed fluorescences by van der Werf *et al.*[9] as well as that of electronic relaxation (ER) of small molecules in a densed medium by Nitzan and Jortner[10] are just like what to be supplemented by this scheme. The transition through this mechanism may be named as a nonadiabatic transition between randomly fluctuating levels[3] because the initial state and the final state represent different potential curves of the whole system (the solute molecule and the solvent molecules). In this quantum mechanical description, vibrational modes of solvent molecules (phonon modes) may be regarded to be working as accepting modes. However, semiclassical interpretation would be rather suitable to describe the real event, because the initial and final states can not be well defined in solution against the case in gaseous state (or in mixed crystal).[11] Uncertainty broadening of the energy levels due to vibrational relaxation might also give more probability for the resonance conditions to be met in such a way to

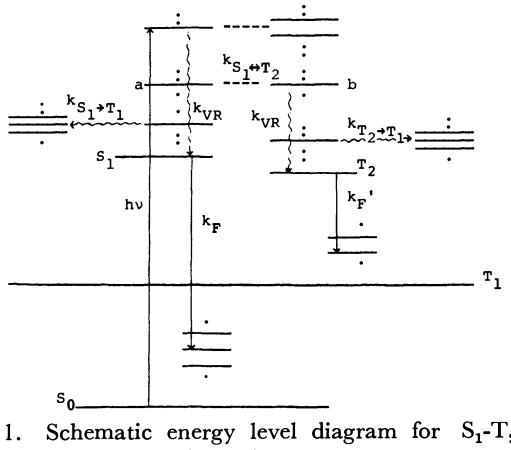

Fig. 1. Schematic energy level diagram for S_1-T_2-T_1 ISC in anthracene derivatives.

bring ER into the statistical limit[7,10] (*vide supra*). However, this VR effect appears to be minor compared to the preceding mechanisms. The most typical evidence to support this conjecture may be found in the "zeroth order" interpretation of the band shapes of radiative electronic transitions by the Franck-Condon intensity distribution of vibronic bands modified by broadening of the bands due to environmental (cage) effects[1,3] (inhomogeneous width), except for those in mixed crystal.[11],* A more quantitative account based on kinetics will be given later.

Now, let us discuss the mechanism of ISC. The energy level scheme suitable for the kinetical interpretation is given in Fig. 1 where only concerned evells and processes are indicated. This may appear to be practically the same as Fig. 2 of the previous paper which is purely intramolecular scheme.[3] However, it has to be noted that these levels are fluctuating under the influence of the medium, thus allowing for the resonance conditions to be met between some vibrational levels of S_1 and T_2. In fact, there always exist the coupled pairs (resonance states) as shown by a-b in the figure which can be populated by thermal activation and fluctuation of the levels. Thence, presentation of the mechanism for S_1-T_2-T_1 ISC would be straightforward:

(1) The first step is of course the optical preparation of an excited level, say, a higher vibrational level of S_1 indicated in the figure.

(2) It is immediately followed by vibrational relaxation ($k_{VR}\approx10^{12}$ s^{-1}) so that thermal equilibrium between vibrational manifolds may be reached unless subsequent processes are extremely fast.

(3) Thenceforth, radiative and radiationless transitions from this manifolds (S_1) to S_0 and T_1 (T_2) would start, if we apply the general picture presented in the previous paper (*e.g.* Fig. 1 therein[3]). However, this is not the case for the present system because of the resonance coupling between some S_1 and T_2 vibronic levels (to be represented by pure spin adiabatic Born-Oppenheimer basis[3]) assisted by the medium. The alternative explanation is based on the assumption of the near (not strictly) thermal equilibrium between S_1 and T_2 manifolds supported by the kinetical argument using the estimated numbers of the rates: *e.g.* for the case of anthracene molecule, $k_F\approx5\times10^7$ s^{-1}, $k_{S_1\to T_1}\lesssim10^5$ s^{-1}, $k_{T_2\to T_1}\approx10^{10}$ s^{-1}, $k_{VR}\approx10^{12}$ s^{-1} and $k_{S_1\leftrightarrow T_2}\lesssim10^{11}$ s^{-1} (H_{SO} matrix element including FC factor suitable for the coupling may be estimated to be $(\lesssim1)\times(\lesssim1)$ *i.e.* $\lesssim1$ cm^{-1}, indicates which the upper limit of the rates due to unknown effective Boltzmann factors[1,2]). In other words, the initial states for the following steps are not always represented by PS ABO basis (At least a-b level is a exactly spin contaminated level.[3]). This may be the reason why triplet-triplet fluorescence quantum yield corresponding to k_F' in the figure estimated from the intensity of T-T absorption (which may be that between PS ABO states) was much larger than the experimentally observed values[2a] (*vide infra*). Actually, possibility of thermal equilibration between S_1 and T_2 is already suggested by Campbell and Liu to account for sensitized chemical reactions from "T_2" states of anthracene derivatives.[12] Recent experimental results by Wilson and Halpern indicating fast T_2-S_1 ISC competing with T_2-T_1 internal conversion also conform to this. Thus, the observed decay rates of S_1 fluorescences should not be taken to be nearly equal to $k_{S_1\to T_1}$ plus $k_{S_1\to T_2\to T_1}$. For, S_1-T_2-T_1 and S_1-T_1 processes interfere with each other. In this respect, no "important" difference[2b] isseen between quantum mechanical and kinetical arguments, where kinetical scheme is represented by $S_1\rightleftarrows T_2\to T_1$ instead of $S_1\to T_2\to T_1$. The more quantum mechanical picture may be given as a behavior of a resonance state which arises from both S_1 and T_2 states with resonance conditions being satisfied and decays to either S_1 or T_2 state with probabilities proportional to the squares of their mixing coefficients.

Similar but different mechanisms were already proposed for slow internal conversions between excited states in strongly coupled systems *i.e.* between singlet excitonic states of multiple molecules and triplet $n\pi^*$ and $\pi\pi^*$ states of 1-indanone in EPA where energy gaps were in the range of 50 to 500 cm^{-1}.[3]

One of the experiments to prove this scheme might be to show the multiple exponential decay of S_1 fluorescence with the fast component corresponding to $k_{S_1\to T_2}$ and slow component corresponding to the weighed average of k_F's, $k_{S_1\to T_1}$, and $k_{T_2\to T_1}$, if a single level a in the figure could be excited by light absorption. This seems to be practically impossible, however, because the molecules are in condensed phase *i.e.* $k_{S_1\to T_2}$ decay process in some molecules would be cancelled out by k_{VR} rise process towards $k_{S_1\to T_2}$ in the other molecules under observation. In case a ground vibrational level of S_1 state is accidentally degenerate with any level in T_2 manifold, solvent fluctuation would rather lower the rate. Difference of collisional effects between vapor phase and condensed phase seems to be taken as one of the evidences (*vide infra*).

Another proof of this mechanism is to explain the observed decay rates of S_1 fluorescences by setting reasonable values of k's and location of a-b levels (Experimentally obtained temperature effect on the rates *i.e.* activation energies might give the rough estimate of the location.). In the case of anthracene where $k_{S_1\to T_2}(\gtrsim10^{11}$ s$^{-1})$ is not fast enough compared to k_{VR}, the upper limit of the decay rate of the fluorescence is approximately $k_{T_2\to T_1}\approx10^{10}$ s^{-1} (by taking account the effective Boltzmann factor suitable for near thermal equilibrium), only one order of magnitude larger than the experimental value,[1a] to be satisfactory. Therefore, the usual interpretation of the decay rate by thermally

---

* To make the contention of this sentence clearer according to referees' suggestions, we can make the following statements:

(1) The locations and the shapes of potential energy surfaces of a solute molecule are regulated by the arrangement (locations and orientations) of solvent molecules and are thermally fluctuating *i.e.* change from time to time.

(2) Therefore, resonance conditions are satisfied within a time scale of solvent relaxation.

These assumptions, though being slightly oversimplified, seem to be fair as long as the "intramolecular" radiationless transition is concerned *i.e.* in case where intermolecular modes are not important due to *e.g.* their lower frequencies compared to intramolecular modes.

activated S_1-T_2-T_1 process would apply for this system although thermal equilibrium between S_1 and T_2 is not well established. For anthracene derivatives such as 9-bromoanthracene,[2,4] however, $k_{S_1 \to T_2}$ would become orders of magnitude larger in spite of the possible reduction of FC factors by the increase of S_1-T_2 energy gaps. So thermal equilibrium between S_1 and T_2 is more reached by the heavey atom effect. Thus, the decay rates of T_2-T_1 fluorescences would not represent the rates ($k_{T_2 \to T_1}$'s) indicated in the figure but rather represent the weighed averages of the decay rates among the S_1 and T_2 levels. This explains "the small TTF quantum yields and apparent internal heavey atom effect"[2,4a] in these systems.

Finally, the kinetical discussion is made to show why the present mechanism is prediminant over the possible alternative based on the statistical limit descriptions in both S_1-T_2 and T_2-S_1 ISC's (*vide supra*) as was implicitly assumed in most of the experimental papers[4-6] though no quantitative verification was given so far. Actually, Gillispie and Lim's papers which showed the need of the third triplet state to explain the rates with a formula given *e.g.* by Nitzan *et al.*[7,10] can be taken to indicate inadequacy of the statistical limit assumption. Somehow, it is almost certain that broadening due to solvent fluctuation (inhomogeneous width) is much larger than the uncertainty broadening (homogeneous width). In actuality, since the rates involved in the observation is $< 10^{11}\ s^{-1}$ (according to the present interpretation), there is enough chance for solvent fluctuation to be involved in the mechanism.** Thus, the present mechanism can be taken as a sublation of the statistical limit picture and the previous mechanism.[2]

Concluding Remarks

Presentation of the mechanism is over. However, to seek other evidences than those presented above and in the previous paper[3] in different kinds of experiments to support this proposal would be desired to clear up some skepticisms. One of the key features in the mechanism is the importance of the resonance coupling. This may be actually evidenced in the recent experiments in isolated molecules.[1] For example, the steep rise of the decay rate of a single rotational level when it is brought into resonance with another by Stark field was suggested for H_2CO.[13] Recent results of Zeeman effect on the quenching rates of gaseous molecules[14] may also be related to this interpretation. Another important key feature is the existence of a possible two-step activation process of ER by a medium *i.e.* thermal activation and thermal fluctuation of energy levels. This may be related to the recent experimental facts of the temperature effect of T_1-S_0 ISC in anthracene and its deuterium substitute reported by Hung and Henry.[15]

Finally, it should be mentioned that this mechanism of ISC is not purely intramolecular, different from those of ordinary ER's in aromatic molecules in condensed phase which have been always assumed to be followed by fast vibrational relaxation.[1,7,10] In this respect, a recent paper by Hirayama on the ISC in cyanoanthracenes[6] is worthwhile subject to discuss. Although these systems do not belong to the case where "sparse" intermediate levels are involved but rather are described by conventional statistical limit picture as is consistent with their not-"unusual" lifetimes, the result indicates the difference of collisional effects in vapor phase from that in condensed phase (in nonpolar solvent). This seems to be an indication of the fact that solvent molecules work not only as vibrational relaxers but also as energy level fluctuators causing enhancement of the rate. As is mentioned before, weakening by solvent fluctuation is also possible, because of dilution of the effect by either more broadening or more rapid thermal equilibration (Thermal equilibration between vibrational levels can not be attained by a few collisions in vapor phase.). This is actually evidenced in Hirayama's data. It should also be noted that this kinds of mechanisms are expected to be playing crucial roles in the more complicated processes such as photoionization in solution[16] or phenomena to be named as solvent induced charge separation.[17] Somehow, the most desired experiments of the anthracene derivatives are high resolution observations in gas phase at collision free condition. Very recently, a preliminary experiment on this line was performed showing longer lifetime in the collision free condition.[18] This seems to conform to the present arguments.

The author is indebted to Prof. A. Nitzan for helpful comments.

** The author has seeked for the formalism which suitably represents the scheme illustrated by the figure but has merely come up with the kinetical interpretation. For, the other formalisms so far the author has tried *e.g.* using a density matrix has become more phenomenological than that of kinetics.

Two-photon Excitation Spectra of 1-Azabicyclo[2.2.2]octane and Trimethylamine

Hitoshi KUNO, Kazuo KASATANI, Masahiro KAWASAKI, and Hiroyasu SATO*
Chemistry Department of Resources, Faculty of Engineering, Mi'e University, Tsu 514
(Received February 24, 1982)

The two-photon fluorescence excitation spectra of 1-azabicyclo[2.2.2]octane (ABCO) and trimethylamine were measured in the excitation wavelength range of 410—520 nm. The effect of the polarization (linear or circular) indicates that the symmetries of the upper states are $\tilde{A}^1A_1$, $\tilde{B}^1A_1$, and $\tilde{C}^1E$ for ABCO while $\tilde{A}^1A_1$ and $\tilde{B}^1E$ for trimethylamine in C_{3v} point group approximation. Rotational envelopes for the sequence structures are calculated forcircularly and linearly polarized light excitation and are in good agreement with experiment.

The ultraviolet absorption bands of amines are considered as Rydberg transitions.[1] The polarization measurements in two-photon absorption have assigned the lowest excited state of the open amines, *e.g.*, trimethylamine as A_1 in C_{3v} point group.[2] In contrast to the open amine the caged one $N(C_2H_4)_3CH$ or ABCO has richly structured UV and multi-photon absorption spectra.[3] All of the observed transitions are considered as two-photon allowed ones to low-lying Rydberg states (3p, 3s←n).[1-3] Because the *ab initio* quantum chemical calculation predicts small core splitting for both trimethylamine and ABCO, the observed bands cannot be further classified as $^1E(3p_{xy})$, $^1A_1(3p_z)$ or the superposition of the two transitions.[4] In this report we have studied two-photon absorption of ABCO by linearly and circularly polarized light in order to assign the symmetries of the low lying Rydberg states and to compare them with those of trimethylamine.

Experimental

The apparatus for the UV fluorescence excitation spectra is similar to that previously reported, except for a dye laser.[2] Briefly, an 1 MW N_2 laser pumped dye laser light was focused into a quartz cell containing gases or solutions of amines with a lens (f=30 mm). The UV fluorescence was viewed through three UV transmitting filters (Toshiba UV-D33S) at 90° to the laser beam, and was detected by a solar blind photomultiplier (HTV-R166UH). The signal was averaged by a gated integrator. Linear polarization of the laser light was achieved by a polarizer which consists of ten quartz plates placed at Brewster's angle. Circularly polarized light was generated by passing the laser light through Fresnel rhombs.

The hydrochloride of ABCO was obtained from Tokyo Kasei Company. ABCO prepared from the hydrochloride solution was purified by sublimation through Molecular Sieves 13X. Trimethylamine was prepared from aq solution (30%, Nakarai Chemicals) with sodium hydroxide.

Results

ABCO. Figure 1 shows the two-photon fluorescence excitation spectra of ABCO in the vapor phase. Both the first and the second absorption bands show extensive progression and sequence structures. The origin of the first band was at 39097 cm^{-1} (511.55 nm). Since that of the second band was weak as has been reported by Parker and Avouris,[3b] the measured value (43940 cm^{-1}) would not be quite accurate. The reported values for the first absorption bands are 39080 cm^{-1} obtained in one-photon absorption by Halpern *et al.*,[3a] 39076 cm^{-1} and 39095 cm^{-1} reported in multi-photon ionization experiment by Halpern *et al.*[3d] and Gonohe *et al.*,[5] respectively.

The two-photon excitation spectrum of the pentane solution (10^{-3}—10^{-2} mol dm^{-3}) was also measured. The spectrum in solution appears blue shifted, compared to the spectrum in the vapor phase. The blue shift is expected for the Rydberg transitions.[1] Since the electronic transitions are Rydberg ones of the lone-pair electron on the nitrogen atom, the repulsion between lone-pair and bonding-pair electrons decreases upon excitation. Because the pyramidal NC_3 skeleton tends to flatten, the cage squashing mode $\nu'_{12}(a_1)$ with frequency 650±10 cm^{-1} is observed up to several quanta, along with many combination bands. These vibrational structures are also observed in one-photon absorption[3a] and multi-photon ionization[3b] spectra. The progression with 625 cm^{-1}/618 cm^{-1} was assigned to this ν_{12} mode in one-photon/multi-photon reports of Halpern *et al.*[3a,d] respectively. At wavelength longer than the 0-0 band, a hot band with frequency 603 cm^{-1} was identified as due to ν''_{12} observed in one-photon absorption (600 cm^{-1}),[3a] multi-photon ionization (602 cm^{-1}),[3d] and infrared spectra (604 cm^{-1}).[6]

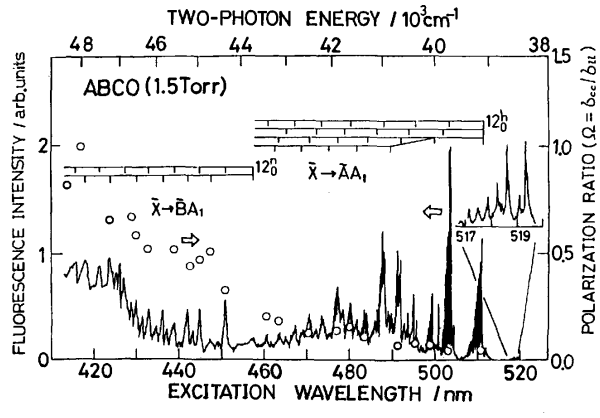

Fig. 1. Two-photon fluorescence excitation spectrum of ABCO in the vapor phase (recorded in linear polarization). The well resolved progressions are ν'_{12} (a_1) cage squashing mode built on the origin and on the ν'_{11} (a_1) and ν_{33}' (e) or ν_9' (a_1) modes after Halpern *et al.* (3a, d). Spectrum is corrected for the laser power. The pressure was a vapor pressure of ABCO at room temperature (1.5 Torr, 1 Torr ≈ 133.322 Pa).

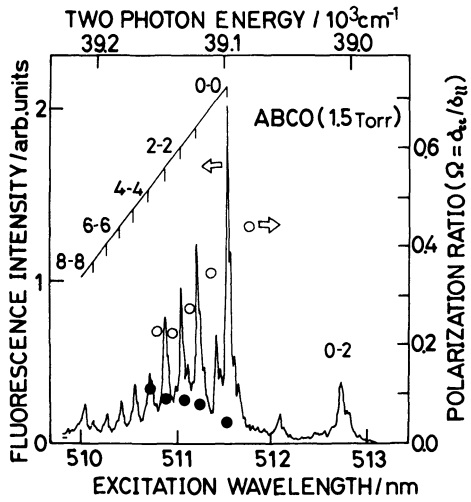

Fig. 2. The sequence structure of torsional motion built on the 0-0 band of ABCO ($\tilde{A}$–$\tilde{X}$) in the vapor phase (recorded in linear polarization) and polarization ratios (δ_{cc}/δ_{ll}) at the peaks (●) and the valleys (○). The origin (0-0) and the hot bands (v′-v″) are indicated in this figure.

The band structures were obtained at higher resolution. The detailed sequence structures of ν_{12} (0-0), (1-0), and (0-1) bands resemble each other (see Fig. 2 for example) while the spectral consequence of combination bands becomes highly conjunct and is different from that of the (0-0) bands. This is probably because of the different rovibronic selection rules *i.e.*, $\Delta K=0$ for A_1-A_1 (the 0-0 band) and $\Delta K=\pm1$, ±2 for E-A_1 transitions (the combination bands).[7]

Figure 2 shows the detailed structures of the first sequence bands. Similar sequence structures are observed in the multiphoton ionization spectrum of 1,4-diazabicyclo[2.2.2]octane.[8] They are assigned as due to the torsional motion about the z axis and the potential energy has a small hump at $\phi=0°$ and a double minimum around $\phi=10°$. Assuming a quartic-quadratic potential for the ground state of ABCO, Gonohe *et al.*[5] have assigned the strongest sequence structures to a cage torsional motion (ν_{19}) with low vibrational frequencies (54 cm^{-1} in the ground state). Actually, our studies show the increase of the hot bands in intensity with temperature from 20 °C to 90 °C.

The polarization ratio was measured to deduce the upper state symmetries (Figs. 1 and 2). According to McClain *et al.*[9] the intensity of two-photon absorption depends upon the polarizations of the two photons and so is different when using circularly and linearly polarized light sources. When the symmetry of the upper state is totally symmetric A_1 in C_{3v} point group, the ratios ($\Omega=\delta_{cc}/\delta_{ll}$) become less than 1.5 for the Q branches, where δ_{cc} is the absorptivity of two identical circularly polarized photons and δ_{ll} that by linearly polarized ones. For other cases, *i.e.*, O/P/R/S branches for A_1 and O/P/Q/R/S branches for E, the ratios are expected to be 1.5. The observed Ω values in Fig. 1 were less than 1.5 for all transitions, indicating two photon allowed A_1 symmetry of the excited states. Figure 2 shows the detailed excitation spectrum measured by the linearly polarized light and the polarization ratios. The Ω value for the peak at 511.55 nm is 0.04 which is in good agreement with $\Omega=0.030$—0.038 reported by Berg *et al.*[3c] The Ω values are larger at the positions between the peaks. This is because of the superposition of the branches other than the Q branches. These Ω values are well reproduced by calculation as will be discussed in the later section. The values at the peaks for the first absorption band were essentially constant while those increase with the excitation energy in the second absorption band (Fig. 1). In the second absorption band the Ω values at the peaks were not different from those for the valleys. The second band has a diffuse absorption structure compared to the first band. This diffuseness increases in the shorter wavelength region. Both the Ω values and the background intensity start increasing at $\lambda\simeq440$ nm. These results indicate the superposition of two state in this region; one is a totally symmetric state and the other one at the shorter wavelength region is a non-totally symmetric one.

Trimethylamine The two-photon excitation spectrum of trimethylamine and the polarization ratios were also measured in the vapor phase and the pentane solution as shown in Fig. 3. The Ω values were obtained in the vapor phase and not in the solution phase. In solution phase solvent induced mixing of electronic states would occur and the measured Ω value is an averaged one of the mixed states.[10] The excitation spectrum was measured in pentane solution in order to suppress the decomposition of trimethylamine at shorter wavelength region. Actually, the increase of the fluorescence quantum yield have been reported by addition of third-body or buffer gases in the vapor phase.[11,12] The shape of the spectrum in solution resembles that of the one-photon absorption spectrum in the ultraviolet region, while the excitation spectrum obtained in the vapor phase is quite different from that in the solution phase. The "structures" observed in the vapor phase are in good agreement with those reported by Halpern *et al.*[3d] The disparities of the excitation spectrum between vapor and solution phases may be due to the photo-decomposition[11,12] and the multiphoton ionization processes,[3d] because both processes quench the fluorescence. Since the Ω values are less than 1.5 for the first absorption band ($\lambda=500$—440 nm), the symmetry of the upper state is assigned to a totally symmetric one.

Although the two-photon fluorescence excitation spectrum in Fig. 3 and the reported one-photon absorption spectra cannot be clearly resolved spectroscopically, the polarization measurement can reveal these overlapped bands. At shorter wavelength ($\lambda<440$ nm) a non-totally symmetric upper state appears, as indicated by increase in the Ω values with decreasing wavelengths. This decomposition of the absorption spectrum into two parts is in good agreement with that reported by Cureton *et al.*[12] According to them, in the fluorescence decay of trimethylamine, one-photon excitation at longer wavelength region produces almost single exponential decay but at $\lambda<230$ nm this becomes dual exponential. This is explained on the basis that there are two strongly overlapping absorption bands, resulting

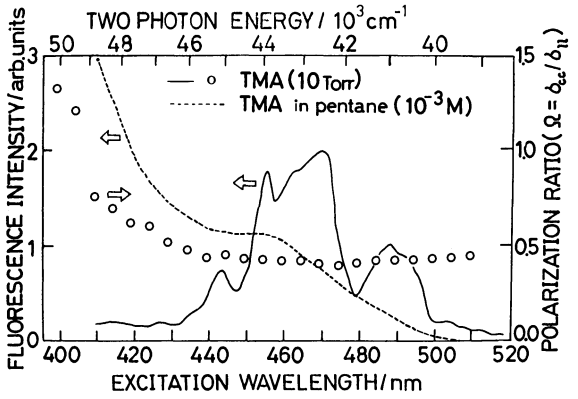

Fig. 3. Fluorescence excitation spectra of trimethylamine in pentane solution (1×10^{-3} mol dm^{-3}, broken line) and in the vapor phase (solid line: 10 Torr) recorded in linear polarization. Polarization ratios (δ_{cc}/δ_{ll}), were measured in the vapor phase (○). Spectrum is corrected for the laser power.

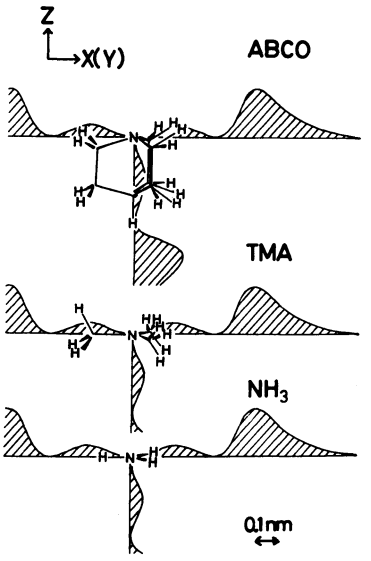

Fig. 4. Schematics for electron density ($r^2\psi(r)^2$) of 3p Rydberg orbitals and molecular structures of ABCO, trimethylamine (TMA), and ammonia.

inevitably in simultaneous excitation of both S_2 and S_1 states. They observed no significant improvement in fitting to three exponentials than was obtained for two, and thus there has been no evidence for multi-exponential fluorescence. This has been the case for other open amines, triethyl- and tripropylamine.

Discussion

Electronic States. Prior to considering the electronic states of ABCO and trimethylamine it is useful to review the states for ammonia. The first few excited states of ammonia result from excitation of an a_1 lone pair electron of the nitrogen atom,[13]

$$\cdots (e)^4(a_1)^2 \qquad \tilde{X}A_1$$
$$\cdots (e)^4(a_1)\,(3sa_1) \qquad \tilde{A}A_1$$
$$\cdots (e)^4(a_1)\,(3p_{xy}e) \qquad \tilde{B}E$$
$$\cdots (e)^4(a_1)\,(3p_za_1) \qquad \tilde{C}A_1.$$

Since alkyl substitution does not change the relative positions in energy of the ($3sa_1$) and ($3p_{xy}e$) orbitals, the first excited state of the open amines has A_1 symmetry, *i.e.* 3s←n. Actually, the Ω values for trimethylamine are less than 1.5 for λ=500—440 nm. Since the Ω values for trimethylamine increased from 0.5 to 1.4 with decreasing excitation wavelengths from 440 to 400 nm, the second absorption band can be assigned as E state.

The first absorption band of ABCO has A_1 symmetry as we saw from the polarization ratios. The observed Ω values in the region $\lambda<460$ nm increase from 0.2 to 1.0 with decreasing the wavelengths. Since the second band consists of two states, *i.e.*, totally and non-totally symmetric states, the second and third excited states have A_1 and E symmetries, respectively. The electronic states observed are $\tilde{A}A_1$, $\tilde{B}A_1$, and $\tilde{C}E$. The relative position of B and C states is reversed compared to ammonia and open amines. This may be explained by the variation of quantum defects caused by interaction between Rydberg orbitals and nuclei. The energy for the Rydberg orbitals is given by,

$$E_n = I_p - R/(n-\delta)^2,$$

where I_p is an ionization potential and R the Rydberg constant. The quantum defect δ will be large if the probability is high that the electron is near the nucleus, while δ will be small where the nuclei are situated on the nodal planes of the orbitals.[1,14] Actually for ammonia where the nuclei are three hydrogen atoms, δ_z for p_z is smaller than δ_{xy} for p_{xy}. The hydrogen atoms strongly interact with $3p_{xy}$ orbital, because ammonia has a planar structure in the excited state. For the $3p_z$ orbital this interaction is expected to be small. Schematics for these interactions are shown in Fig. 4, where radial populations ($r^2\psi(r)^2$) of 3p orbitals are illustrated along with molecular structures of ammonia and the amines. These interactions would be the case for trimethylamine *i.e.*, $\delta_z<\delta_{xy}$. For ABCO the skeletal CH_2 group may interact strongly with $3p_z$ as with $3p_{xy}$ orbitals, then $\delta_z\approx\delta_{xy}$. This difference may change the relative position of A_1 and E electronic states.

The energy difference between $A_1(3p_z)$ and $E(3p_{xy})$ for vertical excitation may be obtained from the threshold wavelength of each states in Fig. 1. It is rather small ($\approx$0.3 eV) as predicted by quantum chemical calculation[4] compared with that for ammonia ($\approx$0.5 eV).

Calculation of Rovibronic Profiles. As previously observed, the rotational profiles in the excitation spectra are strongly dependent upon the polarization of the absorbed photons. The theoretical explanation of this dependence is given by McClain *et al.*[9] and Wunsch *et al.*[15] They computed the polarization dependence of vibronic bands in benzene. In this section we apply this theory to the rovibronic bands in ABCO.

The probability for an identical two-photon absorption is described in detail by Wunsch *et al.*[15] In brief, it is given by two independent contributions, $C_0M_0R_0$ and $C_2M_2R_2$. Geometrical factors C_J, which depend on the polarization of the photons absorbed, are given by $C_0=1/3$, $C_2=2/15$ for linearly polarized photons and by $C_0=0$, $C_2=1/5$ for circularly polarized photons.

The molecular parameters M_J are obtained from the two-photon tensor elements. For the $A_1 \leftarrow A_1$ transition, $M_0=(M_{xx}+M_{yy}+M_{zz})^2/3$ and $M_2=(M_{xx}+M_{yy}-2M_{zz})^2/6$. The rotational factors R_2 are given by the Placzek-Teller factors[16] $b^{JK}_{J'K'}$ and contribute to all branches in the transition of $J \rightarrow J'$ and $K \rightarrow K'$;

for

$$J' = J,\ b^{JK}_{J'K'} = [J(J+1)-3K^2]^2/J(J+1)(2J-1)(2J+3)$$

$$J' = J+1,\ b^{JK}_{J'K'} = 3K^2[(J+1)^2-K^2]^2/J(J+1)(J+2)(2J+1)$$

$$J' = J+2,\ b^{JK}_{J'K'} = 3[(J+1)^2-K^2][(J+2)^2-K^2]/2(J+1)(J+2)(2J+1)(2J+3)$$

and $(2J+1)b^{JK}_{J'K'} = (2J'+1)b^{J'K'}_{JK}$.

Since R_0 is given by $R_0=\delta_{JJ'}\times\delta_{KK'}$ the $C_0M_0R_0$ contributes only to Q branches, where $\delta_{JJ'}$ and $\delta_{KK'}$ are delta functions. The selection rule is $\Delta K=0$ for the $A_1 \leftarrow A_1$ transition. By assuming the symmetric top molecule, rotational energies of ABCO were estimated by the formula,

$$E = BJ(J+1) + (C-B)K^2.$$

To compute a two-photon excitation spectrum, one must assume values for the rotational constants B and C. We took $B'=0.092\ cm^{-1}$, $B''=0.091\ cm^{-1}$, $C'=0.093\ cm^{-1}$, and $C''=0.095\ cm^{-1}$, which correspond to C-N-C angles 111.0° for $\tilde{A}$ and 109.5° for $\tilde{X}$, respectively. The CH_2 group was considered as a mass point in calculation of these constants. The angle 109.5° was taken from the structure of trimethylamine.[17] The shape of the calculated spectrum was very sensitive to these constants. Concerning the vibrational energy levels, the values for the ground state are obtained from Gonohe *et al.*,[5] while those for the excited state are taken from the experimental values in Fig. 2.

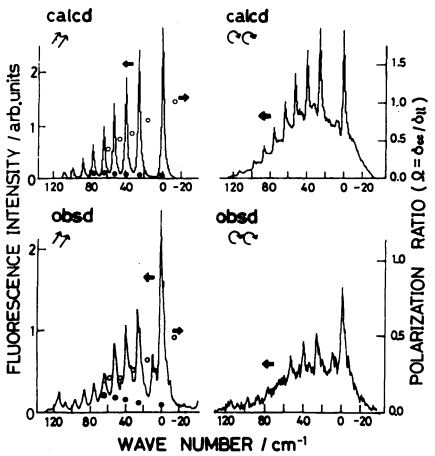

Fig. 5. The calculated and observed rovibronic structures of an A_1, $\Delta v=0$ transition in ABCO. ↑↑ and ↻↻ for linearly and circularly polarized light, respectively. The band in circularly polarized light is enlarged by a factor of 20 (calculation) and 14 (experimental). Circles are polarization ratios (δ_{cc}/δ_{ll}) (See Fig. 2).

Comparison of calculated profiles with experimental band shapes shows good agreement (Fig. 5). To reproduce the observed spectrum for circularly polarized light, the Q branch must include a small contribution from $C_0M_0R_0$ since the polarization of the laser light was not perfect. *Ca.* 1% of the linearly polarized light was included in the calculation. The molecular parameter M_0/M_2 is assumed to be 11.6, that corresponds to $M_{xx}=M_{yy}=0.56\ M_{zz}$. As shown in Fig. 5, this values reproduces experimental Ω values for the peaks and for the valley.

The authors thank Instrument Center, Institute for Molecular Science, Okazaki National Research Institute for the use of the laser.

Viscosities of Aqueous Solutions of Sodium Alkanoates

Koichiro Miyajima,* Masahiro Sawada, and Masayuki Nakagaki
Faculty of Pharmaceutical Sciences, Kyoto University, Yoshida-shimoadachi-cho, Sakyo-ku, Kyoto 606
(Received February 26, 1982)

Viscosities of aqueous solutions of sodium salts of formic acid, acetic acid, propionic acid, and butyric acid were measured in the concentration range 0.01—0.1 mol dm^{-3} at 15, 25, and 35° C. For formate ion, values of B_{st}, the increment of viscosity B-coefficient arising from structural change of water, and of (dB_{ion}/dT), the temperature dependence of ionic B-coefficient, are both nearly zero, indicating that formate ion is neither a structure maker nor a structure breaker. For the alkanoate ions the signs of B_{st} and (dB_{ion}/dT) are positive and negative, respectively. From these facts, alkanoate ions may be concluded to be hydrophobic structure making ions.

It has long been recognized that the water structure around an ion plays an important role with respect to the interionic interactions in water.[1]

In a previous paper[2] concerning the mean activity coefficients ($\gamma_\pm$) of guanidinium salts with hydrophobic carboxylate ions, the order of $\gamma_\pm$ values among these salts was well interpreted by regarding acetate ion as a hydrophobic structure maker, which promotes the water structure by forming an ice-likeness in the vicinity of hydrophobic moiety.

In general, organic ions have more than one functional group besides the ionic residue, such as hydrophobic group and hydrophilic amino or hydroxyl group. These groups also play an important role in interionic interactions in water. In this connection, the simplest example is acetate ion which has the hydrophobic methyl group and the carboxylate ion residue. The structure around the hydrophobic methyl group would be different from that around the carboxylate ion. It has already been known by viscosity[3,4] and NMR measurements[5] that acetate ion is a structure maker. Gurney[3] postulated that the nature of structure promotion by acetate ion was based on the electrostriction of carboxylate ion, on the assumption that the valence electron of oxygen in carboxylate ion is localized. However, this assumption was denied by Spinner on the basis of IR and Raman studies.[6,7] Tamaki reached a similar conclusion from a viscosity study.[4] In the curve of B-coefficient *vs.* alkyl-carbon numbers (C_n) of carboxylate ions, the sign of the intercept at $C_n=0$ was positive. Unfortunately, formate ion was excluded in his study.

In order to elucidate the discrepancy between Gurney's and our views concerning the nature of structure promotion by acetate ion, we measured viscosities of aqueous solutions of some alkanoate ions including formate ion at various temperatures. The results indicate that the alkanoate ions studied are hydrophobic structure makers.

Experimental

Materials. Reagent grade sodium and potassium carboxylates obtained from Wako Chemical Co., Ltd. were used without further purification. Salts were dried *in vacuo* over P_2O_5 at room temperature. These salts were dissolved in redistilled and deionized water.

Methods. Viscosity measurements were made with an Ostwald type viscometer with an efflux time of *ca.* 360 s for water at 25 °C. Efflux time was measured with a Seiko stop watch 89 ST down to 0.01 s. At least five readings of efflux time with variation not exceeding ±0.05 s were taken for each solution. Viscosity η was calculated from average efflux time t and density d according to

$$\eta/d = \alpha t - \beta/t,$$

where α and β are the characteristic constants of the viscometer and are determined from the viscosities and densities of water at 15, 25, and 35 °C. The temperature of the thermostat bath was controlled to ±0.03 °C.

Results

Generally the relative viscosity (η_{rel}) of a dilute electrolyte solution can be expressed by the Jones-Dole equation

$$\eta/\eta_o = \eta_{rel} = 1 + A\sqrt{c} + Bc, \quad (1)$$

where η_o and η are the viscosities of solvent and solution, respectively, and c the molarity of electrolyte. The constant A relates to the interionic interaction of the Debye-Hückel type and is calculated by using molar conductivities of ions. The constant B is a so-called "viscosity B-coefficient" which is closely related to ion-solvent interaction. Equation 1 is valid for concentrations up to about 0.1 mol dm^{-3}. At higher concentrations than 0.1 mol dm^{-3}, an additional term, Dc^2 is required in the right hand side of Eq. 1. In the concentration range studied, the quantity $(\eta_{rel}-1)/\sqrt{c}$ was plotted against $\sqrt{c}$. The constants A and B were obtained from the intercept and slope, respectively. Figure 1 shows $(\eta_{rel}-1)/\sqrt{c}$ *vs.* $\sqrt{c}$ curves for some sodium alkanoates at 25 °C. The A values were found to be very small and agree with those calculated by using molar conductivity data reported by Falkenhagen and Vernon.[8]

The B-coefficient of an electrolyte is expressed by the sum of B-coefficients of each ion

$$B = \sum B_{ion}. \quad (2)$$

For the determination of B_{ion}, Eq. 2 was used by adopting the convention of Gurney[3] and Kaminsky[9] ($B_{K^+}=B_{Cl^-}$). Values of B_{ion} for Na^+ and K^+ at various temperatures were obtained from Kaminsky's data. B-coefficients of acetate ion obtained from aqueous solutions of sodium, potassium, and guanidinium acetate at 25 °C were 0.242, 0.229, and 0.231, respectively. The values of B_{ion} for the alkanoate ions at 25 °C were in fair agreement with those of Tamaki's work.[4] Table 1 shows the B-coefficients of the carboxylate ions at 15, 25, and 35 °C.

a) "Water and Aqueous Solutions," ed by R. A. Horne, Wiley Interscience, New York (1972), p. 575.

B_{ion} is usually expressed by the sum of two contributions: 1) the hydrodynamic obstruction effect based on the size and shape of ion (B_{size}), and 2) the change of water structure induced by the addition of ion (B_{st}):

$$B_{ion} = B_{size} + B_{st}. \quad (3)$$

On the other hand, the viscosity of a dilute suspension of spherical colloid is represented by the Einstein equation

$$\eta_{rel} = 1 + 2.5\,\phi, \quad (4)$$

where ϕ is the volume fraction of colloidal particle. Equation 4 is an expression of the hydrodynamic effect of solute in a viscous flow. On the assumption that Eq. 4 is applicable to a solution of low molecular weight and ϕ is equal to the partial molar ionic volume at infinite dilution ($\bar{V}^\circ_{ion}$), B_{size} and B_{st} are expressed by

$$B_{size} = 0.0025\,\bar{V}^\circ_{ion}, \quad (5)$$

$$B_{st} = B_{ion} - 0.0025\,\bar{V}^\circ_{ion}. \quad (6)$$

As mentioned above, the sign and magnitude of B_{st} are regarded as a measure of ion-solvent interaction. Additional information on this interaction may be obtained from the sign and magnitude of the temperature dependence of B_{ion} (dB_{ion}/dT). Figure 2 shows the temperature dependence of B_{ion} for carboxylate ions. The values of (dB_{ion}/dT) obtained from the slope of B_{ion} *vs.* temperature curve are shown in Table 2 together with the values of B_{st} and $\bar{V}^\circ_{ion}$.

Discussion

The sign and magnitude of B_{st} are considered to reflect the structural change of water by the addition of ion. The ions associated with a large value of B_{st} with positive sign strongly promote the water structure, whereas the ions with a small value of B_{st} with negative sign break the water structure slightly.

As for the temperature dependence of B_{ion}, structure breaking ions should have a positive sign, since the structural water was already broken to a considerable extent by the thermal agitation at a high temperature. Therefore, the absolute value of B_{ion} decreases with temperature increase. From a consideration similar

to that for the case of structure breaking ions, the sign of (dB_{ion}/dT) of structure making ions should be negative. Consequently, the structure making ion has a positive sign of B_{st} and a negative sign of (dB_{ion}/dT), and *vice versa* for the structure breaking ion.

However, some ions of intermediate type between the structure maker and breaker do not obey this rule.[10] Judging from the ambiguity in the estimation of solute volume, the sign of (dB_{ion}/dT) would be more reliable than that of B_{st} for the determination of the structure making or breaking effect of the ion.[11,12]

As shown in Table 2, the values of B_{st} and (dB_{ion}/dT) for formate ion are both close to zero, indicating that formate ion is neither a structure maker nor a structure breaker, that is, formate ion hardly influences the water structure. This result is consistent with the conclusion that the valence electron of the carboxylate group is delocalized on the two oxygen atoms,[6,7] because the delocalization of the electron lowers the surface charge density of the carboxylate group and weakens the ionic hydration by the electrostriction.

The signs of B_{st} of the alkanoate ions are positive and their magnitudes increase with the alkyl-chain length. The signs of (dB_{ion}/dT) for the alkanoate ions are negative and their absolute values increase with the alkyl-chain length. These results indicate that the alkanoate ions are structure making ions. By taking into account the fact that formate ion is neither a structure maker nor a structure breaker, we conclude that the nature of the structure making action for these alkanoate ions originates from the alkyl groups which form the ice-like structure around themselves. In conclusion, alkanoate ions are not ionic or hydrophilic structure makers but hydrophobic structure makers.

Spectroscopic Study of 10-Benzoyl-9-anthrol and Its Anion in Basic Media. An Estimation of Microscopic Polarity of PMMA

Kumao HAMANOUE,* Satoshi HIRAYAMA,† Masayuki AMANO, Kazuo NAKAJIMA, Toshihiro NAKAYAMA, and Hiroshi TERANISHI

Department of Chemistry, Faculty of Technology, Kyoto Institute of Technology, Matsugasaki, Sakyo-ku, Kyoto 606

†*Faculty of Textile Science, Kyoto Institute of Technology, Matsugasaki, Sakyo-ku, Kyoto 606*

(Received March 4, 1982)

The acid-base equilibrium of the title compound (BAOH) was studied in various media containing 4% triethylamine (TEA) by volume as a base. As the polarity of solvents increases, the equilibrium shifts toward the base form (BAO^-) and 100% yield of BAO^- is achieved in solvents with dielectric constant (ε) greater than 20. The equilibrium is also affected by temperature, favoring the base form at lower temperatures. The associated enthalpy change is estimated to be -14.6 kJ mol^{-1}. Of particular interest is the dominant existence of BAO^- in poly(methyl methacrylate) (PMMA), since the acid form (BAOH) dominates in a monomeric solvent (MMA). The microscopic effective dielectric constant of PMMA is estimated to correspond to that of a solvent with $\varepsilon=22$—30 by comparing spectral data in PMMA with those in various solvents. No base form is formed in polystyrene, indicating that not only rigidity but also polar groups in PMMA may be responsible for the anomalously large dielectric constant of PMMA.

In our study on photochemical reaction of nitroanthracenes (9-cyano- and 9-benzoyl-10-nitroanthracene) in various fluid solutions and poly (methyl methacrylate) (PMMA),[1] we have found that the form of the final photoproducts (10-cyano-9-anthrol (CAOH) or its anion (CAO^-) and 10-benzoyl-9-anthrol (BAOH) or its anion (BAO^-)) is very dependent on the basicity, polarity, and rigidity of medium as well as temperature. Of particular interest is the formation of BAO^- in basic PMMA, since in a basic monomeric medium the main photoproduct is BAOH.

According to the results of Kosower,[2] a solvent-environmental effect on a solute molecule is supported by a result of spectral shift which indicates that the molecular energy level is generally sensitive to the matrix. The primary polymer matrix effect is therefore manifested by changes in intermolecular interactions brought about by a decrease in the average separation between solute and solvent molecules and by an alteration of relative orientations of solvent molecules against solute molecule, all of which lead to a change in the coordination number of solvent shells. For this reason the effect of polymer matrix is frequently compared with solvent effects and discussed in the light of tsolven shift theories.[3-10]

Thus, our observation of the medium effect on the form of the final photoproducts of nitroanthracenes leads us to an extensive spectroscopic study on the interchange between BAOH and BAO^- in a wide variety of media. Detailed information on this acid-base equilibrium is not only interesting in itself but also valuable in understanding photochemical processes of the nitroanthracenes.[1]

We will also point out a possibility of utilizing the present acid-base pair of BAOH–BAO^- to estimate the microscopic polarity of polymers which is unaffected by the way of doping probe molecules.

Experimental

Chemicals. BAOH was synthesized from 9-benzoyl-10-nitroanthracene. The details of the methods of preparation of this material have been given in our previous paper.[1] Uvasol diethyl ether was purchased from E. Merck A. G. and used without further purification. Methyl methacrylate monomer (MMA) was of guaranteed grade (Wako Pure Chemical Industries, Ltd.) and was distilled by the method of Collins *et al.*[11] The purified monomer was stored in the dark in a refrigerator.

All the other chemicals used were of guaranteed grade (Wako Pure Chemical Industries, Ltd.) and were used without further purification, unless otherwise stated. In the following, "basic solvent" means a solvent which contains 4 vol% TEA.

To get a basic polymer sample, a solution of BAOH in 5 cm^3 of basic MMA and 0.5 mg of α,α'-azobisisobutyronitrile were poured into a 1 cm rectangular Pyrex cell, and degassed by seven freeze-pump-thaw cycles. After sealing the cell the sample solution was polymerized in bulk at 348 K for 24 h.

Measurements of Absorption Spectra and Z-Values. Using a Hitachi 200-20 spectrophotometer, absorption spectra were taken at room temperature and at low temperatures down to 143 K. To get a given low temperature a cold nitrogen gas, generated by heating liquid nitrogen in a metal Dewar vessel, was introduced into a quartz Dewar vessel in which a 1 cm rectangular sample cell made of Suprasil was mounted. The temperature was measured with a copper-constantan thermocouple which was inserted into a sample cell.

For the estimation of medium polarity, *Z*-values were determined with 1-methyl-4-(methoxycarbonyl)pyridinium iodide, which was recrystallized twice from methanol, yielding the melting point of 175—176 °C. The charge-transfer band of this salt was measured in a 1 cm rectangular quartz cell. (For a polymeric sample, 5 cm^3 of sample solution in MMA was polymerized by the same method as described before.)

Results and Discussion

Acid-base Equilibrium between BAOH and BAO^-. The pK_a value of BAOH has been determined to be 8.8 in water–ethanol mixed solvent by the ordinary spectroscopic method.[12] From this value it is expected that BAOH easily dissociates to BAO^- in slightly basic organic media.

In Fig. 1, we show the absorption spectral change of BAOH in ethanol caused by addition of triethylamine (TEA), which indicates that there exists an acid-base equilibrium between BAOH and BAO^-. The absorption

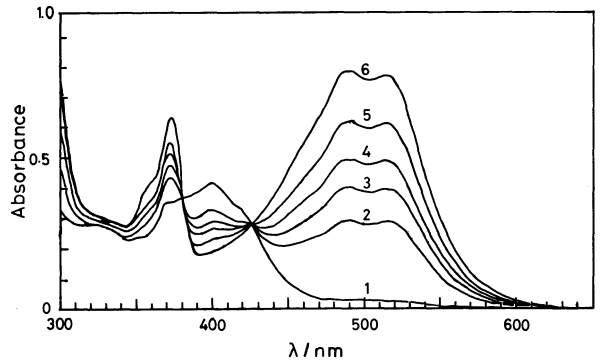

Fig. 1. Absorption spectral change of BAOH in ethanol (initial concentration 1.5×10^{-4} mol dm^{-3}) by the addition of different amount of TEA.
TEA volume ratio: 1; 0%, 2; 0.05%, 3; 0.1%, 4; 0.2%, 5; 0.5%, 6; 4%.

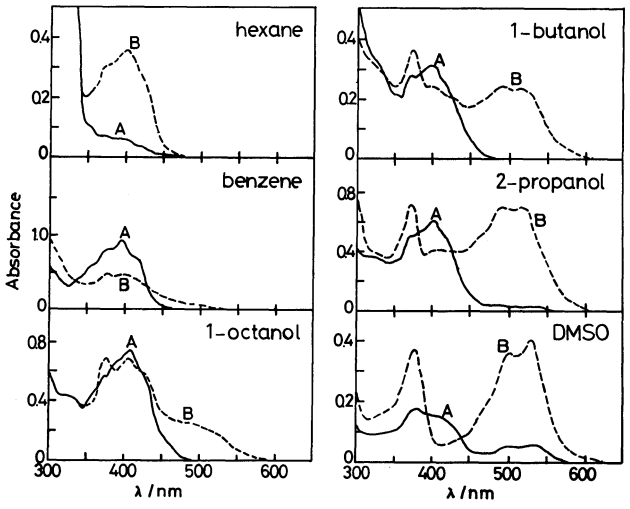

Fig. 2. Absorption spectra of BAOH in various solvents.

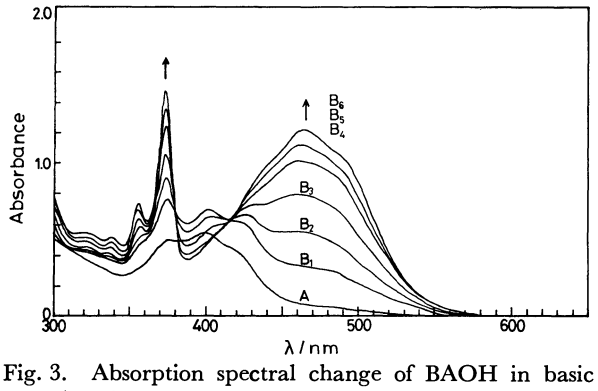

Fig. 3. Absorption spectral change of BAOH in basic EPA at low temperature.
A: At room temperature, B_1: 253 K, B_2: 233 K, B_3: 213 K, B_4: 193 K, B_5: 173 K, B_6: 143 K.

spectrum due to BAO$^-$ lies on the longer wavelength side and has two band maxima around 370 and 500 nm. Although the addition of 4% TEA to the ethanol solution is enough to dissociate BAOH into BAO$^-$ almost completely, which form of BAOH and BAO$^-$ dominates in other solvents depends on the nature of solvents even in the presence of TEA, as shown in Fig. 2. Since the standard free energy change associated with the equilibrium is a function of dielectric constant, it is fully expected that the acid-base equilibrium is affected by the polarity of solvents. However, instead of trying to formulate the general equation to give the standard free energy change, which would be extremely difficult, we measured absorption spectra of the acid-base pair in more than thirty organic solvents, whose dielectric constants range from 1.84 to 46.7, in order to find the threshold of dielectric constant above which BAO$^-$ dominates.

The obtained results indicate that the equilibrium between BAOH and BAO$^-$ is strongly dependent on the dielectric constant ε of solvents, that is, the amount of BAO$^-$ increases as the polarity of solvent increases and nearly 100% yield of BAO$^-$ is obtained in such basic solvents as acetone, ethanol, benzonitrile, methanol, *N*,*N*-dimethylformamide, acetonitrile, and dimethyl sulfoxide, all of which have dielectric constants greater than 20. No pure BAO$^-$ exists in neat TEA or in pure polar solvents even when their dielectric constants exceed 20.

The stability of BAO$^-$ is found to depend not only on the polarity and basicity of solvents but also on the temperature. A typical example is illustrated in Fig. 3. The spectra were taken for BAOH in basic EPA (ether: isopentane : ethanol=5 : 5 : 2 in volume ratio). At room temperature, one can see that the spectrum is mainly due to BAOH, being slightly superposed by that of BAO$^-$. This is because the polarity of EPA is much less than 20. As the temperature decreases, the absorbance of a new spectrum with a band maximum at 466 nm (Spectra B_1—B_6) increases, accompanied by two isosbestic points at 380 and 420 nm. The isosbestic point at 420 nm is not so clear. Spectra B_1—B_6 are similar to that of BAO$^-$ observed in basic ethanol at room temperature, but the former are appreciably blue-shifted compared with the latter. By changing the volume ratio of ethanol in basic EPA, the spectral shift of BAO$^-$ was examined at 196 K. The result shows that the absorption band maximum of BAO$^-$ which lies around 500 nm in basic ethanol shifts to the blue with decrease in the content of ethanol and gradually arrives at Spectrum B_4 in Fig. 3 as the ratio of ethanol approaches to that in EPA, *i.e.*, 5 : 5 : 2. Thus, it is concluded that Spectra B_1—B_6 are not due to new species but to BAO$^-$ (though blue-shifted because of the lower polarity of EPA), and that the spectral change of B_1 to B_6 with lowering temperature is due to a shift in equilibrium between BAOH and BAO$^-$.

Although the proton transfer in *p*-nitrophenol–TEA system has been studied quantitatively by Baba *et al.*,[13] we have roughly estimated the enthalpy change of BAOH into BAO$^-$ from the temperature dependence of the absorbance at 466 nm, by assuming that the absorbance at 143 K is due to BAO$^-$ alone. The estimated value is -14.6 kJ mol^{-1}. Since in basic EPA there is no spectral change in either BAOH or BAO$^-$ at various temperatures and since no change in Kosower's *Z*-value is observed for basic EPA, one can

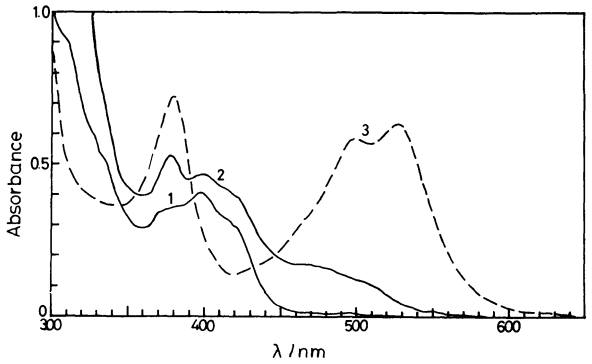

Fig. 4. Absorption spectral change of BAOH.
1: BAOH in MMA, 2: BAOH+BAO⁻ in basic MMA, 3: BAO⁻ in basic PMMA.

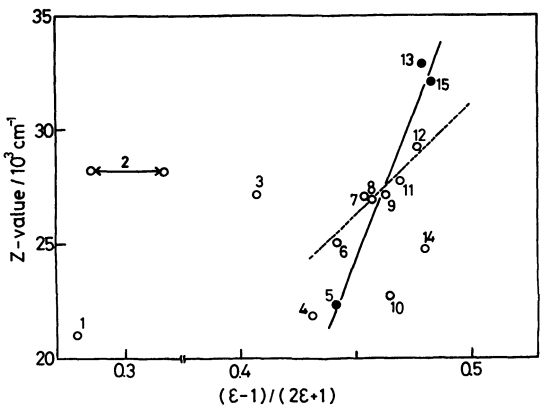

Fig. 5. Plot of Z-value against $(\varepsilon-1)/(2\varepsilon+1)$ for various solvents.
1: MMA, 2: PMMA, 3: tetrahydrofuran, 4: 1,2-dichloroethane, 5: pyridine, 6: 2-methyl-2-propanol, 7: 2-butanol, 8: 1-butanol, 9: 2-propanol, 10: acetone, 11: ethanol, 12: methanol, 13: *N*,*N*-dimethylformamide, 14: acetonitrile, 15: dimethyl sulfoxide.

say that the polarity of EPA is not affected by lowering temperature. Consequently, it can be said that in basic EPA, the observed temperature effect on the equilibrium emerges purely through an enthalpy change ΔH of constant negative value, but not through a change in the dielectric constant of EPA with temperature.

Spectral Shift in PMMA. In our study on the photochemistry of 9-cyano- or 9-benzoyl-10-nitroanthracene in basic PMMA, it was found that absorption spectra of photoproducts (CAO⁻ and BAO⁻) in polymeric media are more red-shifted and become more structured than those in the monomer solution (MMA).[1)]

Figure 4 shows the absorption spectral change of BAOH when the properties of medium (MMA) are modified. Only BAOH exists in MMA and it dissociates only slightly to BAO⁻ by the addition of TEA. After the polymerization of this basic sample solution at 348 K for 24 h, BAO⁻ is obtained in 100% yield. Of particular interest is the appearance of absorption spectra of BAO⁻ in a basic polymeric medium, since in a basic monomeric medium the observed absorption spectrum is dominated by BAOH, being superposed only slightly by that due to BAO⁻. Moreover, the absorption band of BAO⁻ obtained in basic PMMA is red-shifted compared with that in a basic monomeric medium and the spectral shape of the Franck-Condon envelope is rather similar to those in pyridine, 2-propanol, *N*,*N*-dimethylformamide, and dimethyl sulfoxide, each containing TEA.

In relation to this anomalous medium effect of PMMA, it is interesting to know the effect of the rigidity of basic PMMA on the dominant existence of BAO⁻. Upon polymerizing a basic MMA solution of BAOH gradually, a growth of the absorption of BAO⁻ was observed. Initially the almost colorless solutions became red as the medium became viscous and its color deepened upon further polymerization untill such a spectrum as given in Fig. 4 was obtained. This could be interpreted as follows: PMMA may not necessarily be extremely hard to favor the presence of BAO⁻ and even a soft rubber-like PMMA may exhibit a dielectric constant high enough for BAO⁻ to dominate it.

As described above, the equilibrium between BAOH and BAO⁻ is strongly dependent on the dielectric constant of solvents, giving 100% yield of BAO⁻ in basic solvents which have ε greater than 20. The dominant existence of BAO⁻ in basic PMMA can not be interpreted in terms of the formation of small cavities (filled with TEA) created in the polymeric medium in which most of the solute molecules might be located, because BAOH is the main form in both neat TEA and basic MMA.

It is obvious that the solvent molecules immediately around a solute molecule can no longer be described by the same parameters as those used for the bulk solvent. The more polar the solute, the greater would be the divergence between the properties of the solvent molecules near the solute and those of the bulk solvent. Since dielectric constants obtained by the usual macroscopic measurement reflect an average of solvent arrangements over macroscopic distances, they are inappropriate at the microscopic level to represent the solvent properties particularly when highly polar solute molecules are involved. Considering that the values of macroscopic dielectric constants are 2.9 for MMA[14)] and 3.0—3.6 for PMMA,[15)] one may envisage that the microscopic medium polarity in basic PMMA is much greater than that in basic MMA solution.

In order to scale the polarity of PMMA with another solvent-polarity parameter, we have measured the wave number of the longest wavelength charge-transfer absorption band of 1-methyl-4-(methoxycarbonyl)-pyridinium iodide in various solvents. It is obvious that the obtained values, when expressed in energy, should correspond to Kosower's Z-values. Thus we call them simply Z-values for convenience. The obtained Z-values are plotted in Fig. 5 against $(\varepsilon-1)/(2\varepsilon+1)$ for various solvents to see the correlation between Z-value and ε. (For PMMA, ε is the macroscopic dielectric constant, *i.e.*, 3.0—3.6.) As is well known, the points are scattered too much to draw a single correlation line, but two lines can be drawn if the data are restricted to those in akin solvents. The dotted line shows a correlation in basic alcohols and the solid line is drawn for the data in basic pyridine, *N*,*N*-dimethylformamide, and dimethyl sulfoxide. From these different lines, however, one can estimate similar effective dielectric constants 25.4

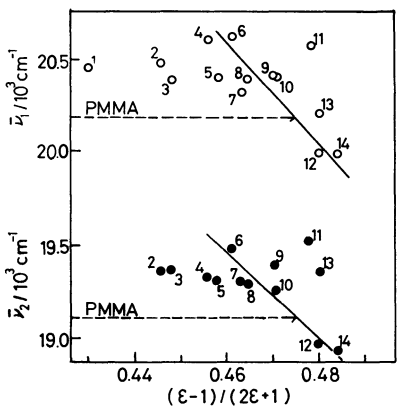

Fig. 6. Plot of two absorption peaks of BAO^- ($\bar{\nu}_1$, $\bar{\nu}_2$) against $(\varepsilon-1)/(2\varepsilon+1)$ for various solvents.
1: 1-Octanol, 2: 1-hexanol, 3: 1-pentanol, 4: 2-butanol, 5: 1-butanol, 6: 2-butanone, 7: 2-propanol, 8: acetone, 9: ethanol, 10: benzonitrile, 11: methanol, 12: *N,N*-dimethylformamide, 13: acetonitrile, 14: dimethyl sulfoxide.

(dotted line) and 21.6 (solid line) for that of PMMA and they are close to that which was estimated before, by comparing the spectral data of the acid-base pair of BAOH–BAO^- in PMMA with those in various solvents.

BAO^- provides a possibility of estimating the polarity of PMMA, since the solvent effect on the spectral shift of BAO^- is significant. Although solvent effects on absorption spectra have been studied for more than a century, it is difficult to understand these effects in terms of only one macroscopic physical solvent parameter. In general, most of the empirical solvent scales constitute a more comprehensive measure of solvent polarity than dielectric constant, and it can be said that only a multiparameter approach which includes terms corresponding to all possible solute-solvent interaction mechanisms is sufficient for the development of a quantitative model for medium effects of all kinds of solvents.[16] Since a large *Z*-value is obtained in PMMA, *i.e.*, 28.2×10^3 cm^{-1} in PMMA and 21.1×10^3 cm^{-1} in MMA, and since BAO^- is dominated in basic PMMA, it is evident that the microscopic medium polarity in PMMA is actually greater than that in MMA. Therefore, we have made a tentative plot of the wave number of two absorption peaks of BAO^- around 500 nm ($\bar{\nu}_1$,$\bar{\nu}_2$) against $(\varepsilon-1)/(2\varepsilon+1)$ for various solvents, and a good correlation is found for aprotic solvents as shown in Fig. 6. From this, one can estimate the effective dielectric constant of the basic PMMA to be 28.9—29.5.

All the values estimated so far for the effective dielectric constant of PMMA are much larger than the macroscopic dielectric constant of PMMA (ε=3.0—3.6) or MMA (ε=2.9), indicating the existence of a very polar microscopic region in PMMA. Thus there will be no doubt that the microscopic effective medium polarity of MMA will increase upon polymerization, resulting in the dominant existence of BAOH in basic MMA but of BAO^- in basic PMMA. Although the reason for this is not clear,[17] it may very well be related not only to the rigidity but also to the methoxycarbonyl group of PMMA, since it was confirmed that BAO^- could not exist in a basic polystyrene medium which was prepared similarly to PMMA. Further study on this problem is now in progress.

Finally, it would be worth mentioning that the present acid-base pair has an advantage as a probe to examine the microscopic dielectric constant of polymeric medium in the sense that it can be photochemically produced without modifying the microscopic environment. When a polar molecule is doped in a medium to probe its microscopic property, it is very likely that the molecules around the probe reorient to minimize the potential energy. This would make it impossible to know the "true face" of the polymer environment. Our "pre-probe" molecule, 9-benzoyl-10-nitroanthracene is, however, expected to behave as an inert molecule when doped in basic PMMA and upon irradiation it would generate BAO^- without modifying the environment; there will be an environment which is different from the polymer environment of BAO^- produced chemically from BAOH. Taking it into account that the two different ways of producing BAO^- yielded the same result, the anomalously high value of ε obtained for PMMA appears to reflect the true microscopic dielectric constant. Consequently, "photochemically producible probes" as described here will open a more reliable way for probing microscopic properties of polymeric media.

The initial part on this study was carried out in association with Messrs. Haruyo Ohya and Toshiharu Hidaka. We wish to express our sincere thanks for their help.

Macromolecular Ion Flotation of Fe^{3+}, Cu^{2+}, and Ni^{2+} Ions by Combined Use of Macromolecular Anions and Cationic Surfactant

Tsunetaka Sasaki,* Takashi Kudō, Ikuko Machida, and Satoshi Ishiwata
Department of Chemistry, Faculty of Science, Tokai University, 1117 Kitakaname, Hiratsuka 259-12
(Received March 8, 1982)

Macromolecular ion flotation of Fe^{3+}, Cu^{2+}, and Ni^{2+} ions was studied using macromolecular ions such as sodium metasilicate, sodium polyacrylate, sodium carboxymethylcellulose, sodium alginate, and sodium cyclo-hexaphosphate (SCHP) together with hexadecyltrimethylammonium chloride (HTAC). Diagrams of floatability *vs.* composition of macromolecular ion and HTAC, and floatability *vs.* pH at fixed composition of macromolecular ions and HTAC were constructed. Regions of optimum composition and pH for the flotation were determined and tabulated. Maximum floatabilities greater than 95%, some attaining nearly 100%, in the alkaline region were obtained for most of the systems, except for the system Fe^{3+}–SCHP–HTAC which showed its maximum floatability, 91.7%, in the acid region. Metallic ions are considered to be combined as hydroxides with macromolecules which are then floated.

In a previous paper,[1] we have reported the flotation of Fe^{3+} and MnO_4^- ions by sodium metasilicate and cationic surfactant and the flotation of MnO_4^- ions by many other macromolecular anions, including macroscopic or colloidal particles possessing ion exchange capacity and organic or inorganic polymer ions together with cationic surfactant.[2] The present paper reports the macormolecular ion flotation of Fe^{3+}, Cu^{2+}, and Ni^{2+} ions by various macromolecular anions, such as sodium polyacrylate (SPA), sodium alginate (SAlg), sodium carboxymethylcellulose (SCMC), sodium metasilicate (SMS), and sodium cyclo-hexaphosphate (SCHP) together with cationic surfactant, hexadecyltrimethylammonium chloride (HTAC).

Experimental

Materials. SPA was commercial pure product of polymerization degree 22000—66000. SAlg was a product of commercial pure grade. Its 0.3% aqueous solution showed relative viscosity to water of 12.5 at 30 °C. SMS, SCHP, and SCMC were commercial products of guaranteed grade. HTAC was a product of commercial pure grade. These reagents were kept in a desiccator and used without further purification. Iron(III) chloride, coppor(II) sulfate, and nickel(II) sulfate of guaranteed grade were used as cations to be floated.

Measurement. For the flotation measurement, 20 cm^3 of a solution containing ions to be floated, macromolecular ions, HTAC and HCl or NH_3 if necessary for controlling pH was introduced in a stoppered test tube of 16 mm in inner diameter and 290 mm in length equipped with a stopcock at the bottom. The test tube was slowly moved upside down for 2 min, then vigorously shaken 20 times by hand. After being kept for 10 min to complete flotation, concentrations of Fe^{3+}, Cu^{2+}, and Ni^{2+} ions in the underlying solution were measured and the floatability percent, F, was calculated by the following equation:

$$F = \frac{C_i - C_f}{C_i} \times 100\%,$$

where C_i and C_f denote concentrations of the ions to be floated in the solution before and after the flotation, respectively.

The concentrations of Fe^{3+}, Cu^{2+}, and Ni^{2+} ions were measured with a Hitachi Atomic Absorption Spectrometer 508 at wave lengths 248.3, 324.7, and 232 nm, respectively.

The measurement of flotation was carried out at room temperature, about 25 °C.

Results and Discussion

Flotation by SPA. Flotation of Fe^{3+} Ions: Figure 1 shows the floatability of Fe^{3+} ions as a function of total concentration of SPA+HTAC and weight fraction of SPA/(SPA+HTAC) at pH about 8.2. The concentra-

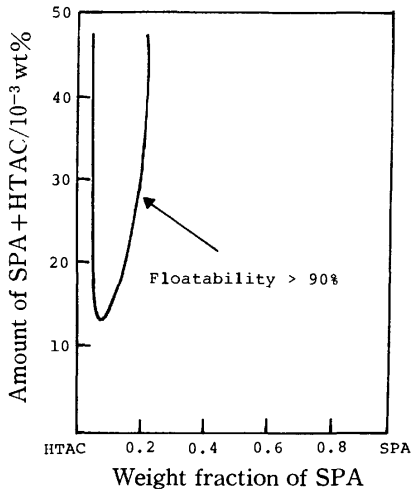

Fig. 1. Diagram of Fe^{3+} ion flotation by SPA and HTAC. F^{3+}: 1.98×10^{-4} mol dm^{-3}, pH: 8.2.

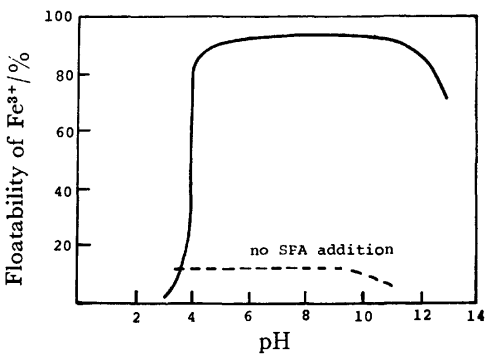

Fig. 2. Floatability of Fe^{3+} ion *vs.* initial pH for SPA+HTAC system.
Fe^{3+}: 1.93×10^{-4} mol dm^{-3}, SPA: 1.5×10^{-3} wt%, HTAC: 3.1×10^{-3} wt%.

tion of Fe^{3+} ions was kept constant at 1.92×10^{-4} mol dm^{-3}. The area inside the curve shows the optimum region of Fe^{3+} ion flotation, more than 90% floatability. Maximum floatability of 93.8% was obtained at 31×10^{-3} wt% SPA and 1.86×10^{-3} wt% HTAC.

Figure 2 shows the pH dependence of floatability of Fe^{3+} ions at the nearly maximum floatability condition of 1.9×10^{-4} mol dm^{-3} Fe^{3+}, 1.5×10^{-3} wt% SPA, and 28.8×10^{-3} wt% HTAC. As shown by the solid line, floatability became perceptible at about pH 3, sharply increased at pH 4, and gave a plateau of nearly 93% in pH range 5 to 11. Beyond pH 12, floatability sharply decreased. The beginning of the floatability increase at pH 3 is near the pH at which $Fe(OH)_3$ precipitation begins to form, as calculated from its solubility product and the concentration of Fe^{3+} ions used. It is confirmed that SPA effectively acts in the macromolecular ion flotation of Fe^{3+}, since the system without SPA exhibited only a slight floatability in this pH range as shown by the broken line in Fig. 2.

Flotation of Cu^{2+} Ions: Figures 3 and 4 show floatability *vs.* composition and floatability *vs.* pH relations for Cu^{2+}–SPA–HTAC system, corresponding to Figs. 1 and 2 for Fe^{3+} flotation, respectively. In Fig. 3, the concentration of Cu^{2+} ions was kept constant at 1.74×10^{-4} mol dm^{-3}, and pH at 9.8. The region of floatability more than 90% is indicated by a curve, the shape of which is different from that of Fig. 1 for Fe^{3+} ions; it forms a narrow vertical area resembling the case of the flotation of Fe^{3+} or MnO_4^- ions by SMS.[1]

The pH dependence of the floatability of Cu^{2+} ions is shown in Fig. 4, where concentrations of Cu^{2+} ions, SPA, and HTAC were 1.79×10^{-4} mol dm^{-3}, 4.1×10^{-3} wt%, and 15.5×10^{-3} wt%, respectively. Floatability sharply rose from about pH 6, showed a flat maximum of nearly 96% in pH range 7 to 9 and decreased to nearly zero beyond pH 10, as shown by the solid line. The sharp rise of floatability at pH 6 is close to the pH of the beginning of $Cu(OH)_2$ precipitate formation as calculated from its solubility product and Cu^{2+} ion concentration. Again, the addition of SPA is found effective for Cu^{2+} ion flotation, as is evident from the comparison of solid line with the floatability curve of the system without the addition of SPA, as shown by the broken line in Fig. 4.

Flotation by SAlg. Flotations of Fe^{3+} and Cu^{2+} Ions: Figures 5 and 6 show the floatability *vs.* composition and floatability *vs.* pH relations for the Fe^{3+}–SAlg–HTAC

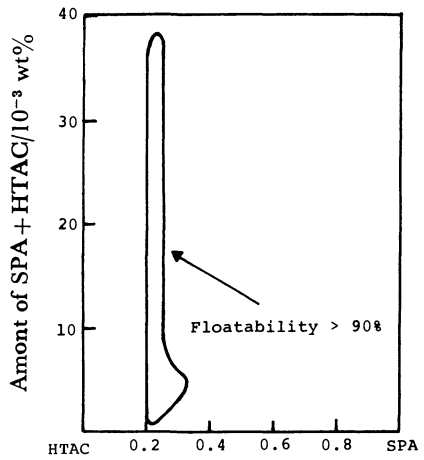

Fig. 3. Diagram of Cu^{2+} ion flotation by SPA and HTAC.

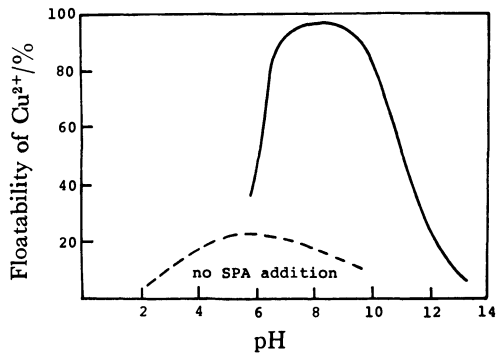

Fig. 4. Floatability of Cu^{2+} ion *vs.* initial pH for SPA+HTAC system.
Cu^{2+}: 1.79×10^{-4} mol dm^{-3}, SPA: 4.1×10^{-3} wt%, HTAC: 15.5×10^{-3} wt%.

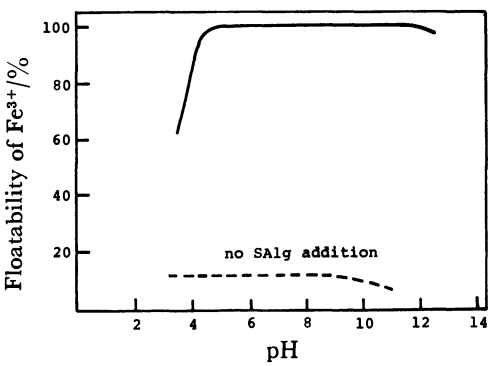

Fig. 6. Floatability of Fe^{3+} ion *vs.* initial pH for SAlg+HTAC system.
Fe^{3+}: 1.79×10^{-4} mol dm^{-3}, SAlg: 8.3×10^{-3} wt%, HTAC: 15.2×10^{-3} wt%.

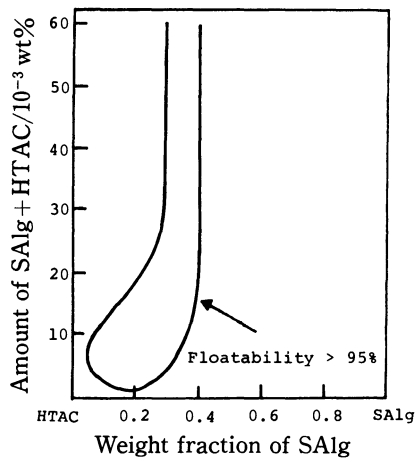

Fig. 7. Diagram of Cu^{2+} ion flotation by SAlg and HTAC.
Cu^{2+}: 1.81×10^{-4} mol dm^{-3}, pH: 9.1.

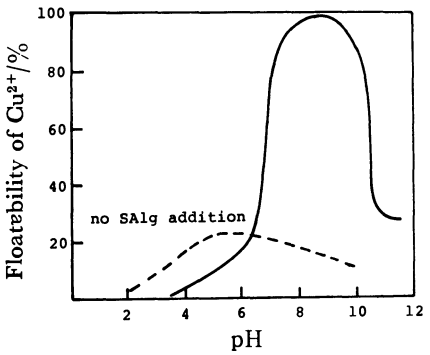

Fig. 8. Floatability of Cu^{2+} ion *vs.* initial pH.
Cu^{2+}: 1.74×10^{-4} mol dm^{-3}, SAlg: 8.2×10^{-3} wt%, HTAC: 15.6×10^{-3} wt%.

system. Figures 7 and 8 show similar relations for the Cu^{2+}–SAlg–HTAC system. Experimental conditions of Figs. 5 through 8 are listed in each figure caption. As shown in Figs. 5 and 7, and Figs. 6 and 8, the floatability behaviors of Fe^{3+} and Cu^{2+} ions for SAlg are similar as a whole to those for SPA. But in the former case, regions of optimum floatability more than 95% are shown in Figs. 5 and 7. The floatability of nearly 100% is seen in the pH region 5 to 12 for the Fe^{3+}–SAlg–HTAC system in Fig. 6. In the case of the Cu^{2+}–SAlg–HTAC system, a flat maximum of nearly 100% floatability is seen in the pH region 8 to 9 in Fig. 8. Figs. 6 and 8 also show the effectiveness of the addition of SAlg for the flotation of Fe^{3+} and Cu^{2+} ions as seen from the comparison of the solid line with the broken line in these figures.

Flotations of Fe^{3+}, Cu^{2+}, and Ni^{2+} Ions by Other Macromolecular Anions. Flotations of Fe^{3+}, Cu^{2+}, and Ni^{2+} were carried out using SMS, SCMC, and SHMP as macromolecular or polymer ions and HTAC as frother. Similar diagrams of floatability *vs.* composition and floatability *vs.* pH were obtained, which are not shown. Instead, the best conditions of flotation for these systems together with those for SPA and SAlg are shown in

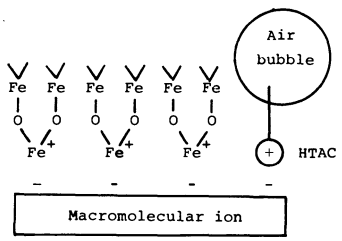

Fig. 9. Sublate structure consisting of macromolecular ion and Fe^{3+} ion.

Table 1. Macromolecular ion flotation of Fe^{3+}, Cu^{2+}, and Ni^{2+}

Ion	Concn of ion / 10^{-4} mol dm^{-3}	Concn of HTAC / wt%	Concn of SMS / wt%[a]	pH	F/%
Fe^{3+}	1.73	0.024	0.075	11.7	97.3
Cu^{2+}	1.82	0.0061	0.078	12.0	96.4
Ni^{2+}	1.72	0.0138	0.173	11.6	97.3
			Concn of SPA / wt%	pH[b]	
Fe^{3+}	1.93	0.0186	0.0031	8.2	93.8
Cu^{2+}	1.74	0.0153	0.0052	9.8	98.0
			Concn of SCMC / wt%	pH[b]	
Fe^{3+}	1.73	0.020	0.0139	9.1	98.4

			Concn of SAlg / wt%	pH[b]	
Fe^{3+}	1.80	0.0182	0.0082	9.0	99.0
Cu^{2+}	1.81	0.0622	0.0005	9.1	98.6
			Concn of SCHP / wt%	pH[c]	
Fe^{3+}	1.77	0.0548	0.0327	1.8	91.7

a) Addition of 0.0008 wt% SPA. b) Addition of NH_3. c) Addition of HCl.

Table 1.

The floatabilities are 97 to 99% for most systems in the alkaline region, except for the Fe^{3+}–SCHP–HTAC system, which gave a maximum floatability of 91% at pH 1.7.

The tentative molecular model of the sublate containing metallic ions, for instance Fe^{3+} ions, is indicated in Fig. 9, except for the Fe^{3+}–SCHP–HTAC system. This model is the generalized reproduction of what has been proposed in the previous paper.[1] In Fig. 9, macromolecular anions take up both HTAC and metallic cations, and HTAC catches bubbles. The metallic ions are presumably in the state of large metallic hydroxide aggregates carrying a few residual positive charges. In the case of the Fe^{3+}–SCHP–HTAC system, simple Fe^{3+} ions are considered to combine with cyclo-hexaphosphate ions. Thus macromolecular ions or polymer ions in general are confirmed to be effective for the flotation of metallic cations such as Fe^{3+}, Cu^{2+}, and Ni^{2+} ions, as well as for the flotation of MnO_4^- ions already reported.[1]

The authors wish to thank the Ministry of Education, Science and culture for the financial support granted for this research.

The Effect of Added NaCl on the Binding of Sodium Perfluorooctanoate to Lysozyme in Aqueous Solutions

Kohsuke FUKUSHIMA,* Gohsuke SUGIHARA, Yoshio MURATA, and Mitsuru TANAKA
Department of Chemistry, Faculty of Science, Fukuoka University, Fukuoka 814-01
(Received March 11, 1982)

The binding isotherms of sodium perfluorooctanoate (SPFO) to lysozyme have been investigated as a function of added NaCl by a potentiometric method utilizing a perfluorooctanoate ion selective electrode. The general feature of the binding of SPFO to lysozyme resembled that of sodium dodecyl sulfate. Although the lysozyme–SPFO system is different in detail from that of lysozyme–sodium dodecyl sulfate system, resulting from the mutual phobicity and the difference in hydrophobicity, the binding mechanism proposed for lysozyme–sodium dodecyl sulfate system can be true also for the binding of SPFO to lysozyme.

The investigations on the interaction of surfactants with proteins have so far been restricted to hydrocarbon surfactants. Fluorocarbon surfactants have been extensively investigated on their physicochemical properties in aqueous solutions,[1–6] and are interesting with respect to the nonideality in mixed micelles with hydrocarbon surfactants.[7–11] The surface activities of fluorocarbon surfactants are stronger than that of the hydrocarbon surfactant with corresponding carbon number. The binding of fluorocarbon surfactants to protein is expected to be the same as that of hydrocarbon surfactants. In the previous paper,[12] the effects of added NaCl on the initial binding ($\bar{\nu}<10$) and the subsequent binding ($\bar{\nu}\geq 10$) of sodium dodecyl sulfate (SDS) to lysozyme were discussed separately. It is interesting to know whether the binding mechanism proposed in the previous paper can be applied to the binding of a fluorocarbon surfactant to lysozyme.

In this work, the binding isotherms of SPFO to lysozyme were determined at different NaCl concentrations. The effect of added NaCl on the binding of SPFO was examined for comparison with that of SDS.

Experimental

Perfluorooctanoic acid (HPFO) was purchased from PCR Research Chemicals, Inc., Lot No. 4764. HPFO was recrystallized four times from distilled carbon tetrachloride. Solutions of the sodium salt (SPFO) were prepared by neutralization with sodium hydroxide. The purity of SPFO was checked by surface-tension measurements below and above the CMC. No minimum was observed. The solutions of hen egg-white lysozyme and other chemicals were the same as mentioned in previous papers.[12,13] The binding isotherms were made by means of potentiometry as described in the previous paper.[12] The carrier used in the SPFO-selective electrode was prepared by mixing equivalent amounts of SPFO and dimethyldioctadecylammonium chloride (Kaō Soap Co., Ltd.) in water. The resulting milky white precipitates (dimethyldioctadecylammonium perfluorooctanoate) were collected by centrifugation (3500 min^{-1} for 45 min) and resuspended in distilled water. Decantation was repeated twice and followed by recrystallization from acetone. The preparation of the poly(vinyl chloride) gel membrane is essentially the same as mentioned in the paper by Shirahama *et al.*[14]

All measurements were carried out at pH 5.8 and 25 °C. NaCl concentrations were 10, 20, 50, and 100×10^{-3} mol dm^{-3}. Every calibration curve of the electromotive force (emf) of SPFO in respective NaCl solutions showed good linearity in the concentration range 2×10^{-4} mol dm^{-3} to its CMC, and gave a slope close to the Nernstian response (56.2 ± 0.7 mV per decade change in perfluorooctanoate ion, PFO^-, at 25 °C).

In order to examine the accuracy of each emf value for the sample solution, emf's for several SPFO solutions of known concentration were also measured after measurments of the three sample solutions.

Results and Discussion

The equilibrium concentration of SPFO in the initial binding region ($\bar{\nu}<10$) increased with increasing NaCl concentration, as is shown in Fig. 1. On the other hand, the equilibrium SPFO concentration in the subsequent binding ($\bar{\nu}\geq 10$) decreased with increasing NaCl concentration. These tendencies were also seen in the binding of SDS in NaCl solutions. The flat region where $\bar{\nu}$ is kept at about 10 in Fig. 1 becomes narrower with increasing NaCl concentration as was seen in the case of SDS. It should be noted that the initial binding begins at a concentration higher than that of lysozyme–

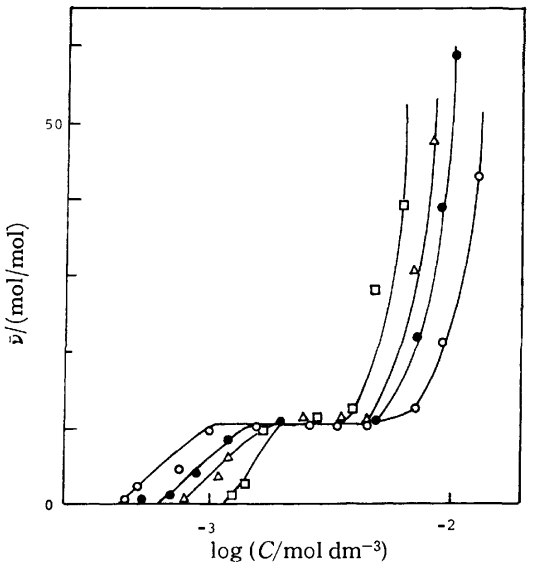

Fig. 1. Binding isotherms of lysozyme–SPFO system at 25 °C and pH 5.8.
$\bar{\nu}$: Binding number, C: equilibrium SPFO concentration, NaCl concentration; ○, 10, ● 20, △ 50, □100 mmol dm^{-3}.

SDS system. Hiramatsu *et al.* reported that the concentration of the initial binding depends on the hydrocarbon chain length of the surfactants for systems of bovine plasma albumin and cationic surfactants; the longer is the chain length, the lower the concentration of the initial binding.[15] Precipitation of lysozyme takes place when the binding begins, and it disappeares with further binding. The general feature of the binding of SPFO to lysozyme resembles that of SDS. So, the analysis of the binding isotherms can be made along a similar line to that discussed in the previous paper.[12]

The free energy difference of PFO^- ion between the states of the initial and final point of the flat region in Fig. 1, where $\bar{\nu}$ could be kept at 10, has been considered to be the free energy accumulation for the subsequent binding. This value (ΔG_{f-i}) is expressed as follows:

$$\Delta G_{f-i} = RT \ln \frac{a_f}{a_i} \simeq RT \ln \frac{C_f}{C_i}, \quad (1)$$

where a_i and a_f are the activities of the PFO^- ions in solution at the initial and final points of the region, respectively, and C_i and C_f are the respective equilibrium SPFO concentrations. The results obtained from Eq. 1 are shown in Fig. 2 together with the results obtained for lysozyme-SDS system. ΔG_{f-i}'s are larger than those of the lysozyme–SDS system in the concentration range of NaCl studied. It may be suggested that both the surface of the complex of lysozyme-PFO^- and singly dispersed PFO^- are less hydrophobic than that of the lysozyme-DS^- complex at a binding number just exceeding 10 and singly dispersed DS^- ion.

The plots of log $C_{\bar{\nu}}$ *vs.* log [Na^+] are given in Fig. 3. $C_{\bar{\nu}}$ and [Na^+] represent the equilibrium SPFO concentration where $\bar{\nu}$ ions of PFO^- are bound to a lysozyme molecule and total Na^+ ion concentration originating from NaCl and SPFO, respectively. The plot of log $C_{0.5}$ *vs.* log [Na^+] gives a straight line with positive slope o 0.3. At present, it is difficult to explain the meaning of the difference between 0.5 for SDS and 0.3 for SPFO. Nevertheless it is certain that the exchange between Cl^- and PFO^- ions and the binding of PFO^- ion to the positively charged sites take place simultaneously as in the case of SDS binding.[12]

According to the discussion in the previous paper,[12] the equilibrium surfactant concentration giving the binding number just exceeding 10 was considered to be the characteristic concentration of protein-ionic surfactant interaction. As is shown in Fig. 1, this concentration (C_{10}) seems to be independent of NaCl concentration. This result agrees with that of the lysozyme-SDS system discussed in the previous paper.[12] C_{10} for the lysozyme-SPFO system (4.8×10^{-3} mol dm^{-3}) is larger than that of the lysozyme–SDS system (2.9×10^{-4} mol dm^{-3}), corresponding to the large CMC in pure water (3.2×10^{-2} mol dm^{-3} at 25 °C) compared with that of SDS (8.2×10^{-3} mol dm^{-3} at 25 °C). Since the driving force for subsequent binding exceeding 10 is mainly hydrophobic interaction as described in the previous paper, C_{10} may be regarded as the concentration where SPFO molecule begins to form hemimicelles on the surface of the lysozyme. Thus there may exist a certain correlation between C_{10} and CMC. The differences between C_{10} and CMC of SPFO and of SDS are about 1 and 1.5 logarithmic units, respectively. The difference is a measure of the binding affinity, *i.e.*, the larger difference means easier binding to the complex compared with self-association (micelle formation) in bulk water. The smaller difference of SPFO means that the affinity between SPFO molecules and the lysozyme-PFO^- complex is smaller than that of the lysozyme-DS^- complex. PFO^- ions on the surface of lysozyme-PFO^- complex at C_{10} are more loosely interacting with each other and with hydrophobic part of lysozyme molecule than DS^- ions on the surface of lysozyme-DS^- complex at C_{10}, because of the shortness of hydrophobic part and mutual phobicity between fluorocarbon and hydrocarbon of lysozyme.[7-11] In other words, less hydrophobicity of lysozyme-PFO^- complex at C_{10} will be responsible for small difference between C_{10} and CMC, and large ΔG_{f-i}.

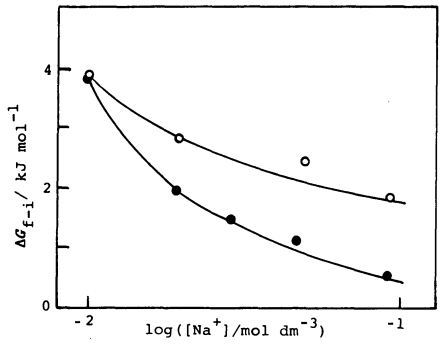

Fig. 2. ΔG_{f-i} *vs.* log [Na^+] plots evaluated from Eq. 1.
○: SPFO, ●: SDS.

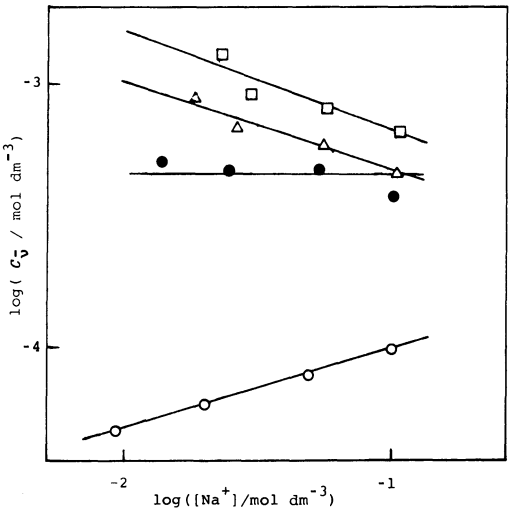

Fig. 3. log $C_{\bar{\nu}}$ *vs.* log [Na^+] plots.
$C_{\bar{\nu}}$: Equilibrium SPFO concentration at binding number $\bar{\nu}$, $\bar{\nu}$: ○0.5, ● 10, △17, □ 40.

Plots of log C_{17} and C_{40} *vs.* log [Na^+] give straight lines with negative slopes, as is shown in Fig. 3. The standard free energy change of the micelle formation from the phase separation model is expessed as

$$\Delta G^\circ/RT = \ln X_{CMC} + \beta \ln X_{Na^+}, \quad (2)$$

where X_{f-i} and X_{Na^+} are the mole fractions of the

surfactant and Na^+ ion in the intermiceller solution at CMC, respectively, and β is the binding number of Na^+ ions per surfactant molecule in micelle.[16] As discussed in the previous paper,[12] the intercept and slope of the straight line in the plot of ln $X_{\bar{\nu}}$ *vs.* ln X_{Na^+} will give $\Delta G^\circ_{\bar{\nu}}$ and β, where $\Delta G^\circ_{\bar{\nu}}$ is the difference between the standard Gibbs free energy of a mole of monomeric hydrated PFO^- ion with β counterion and that of a mole of PFO^- ion with β counterion bound to the complex, and $X_{\bar{\nu}}$ is the mole fraction of DS^- ion in solution at the binding number $\bar{\nu}$. Equation 2 can be applied to the plots of log $C_{\bar{\nu}}$ *vs.* log $[Na^+]$, if the common logarithmic concentration in mol dm^{-3} is converted into the natural logarithmic mole fraction. The results obtained by applying Eq. 2 to the plots in Fig. 3 are listed in Table 1 together with the data for the SPFO micelle itself. The β increases with increasing binding number and seems to approach the value of the micelle. $\Delta G^\circ_{\bar{\nu}}$'s are equal to ΔG° of SPFO micelle formation. These behaviors have also been seen in the lysozyme–SDS system. These suggest that the surface of lysozyme is also covered with PFO^- ions, likewise the lysozyme–DS^- complex, although the lysozyme–SPFO system is different in detail from that of lysozyme–SDS system, resulting from the mutual phobicity and the difference in hydrophobicity. The binding mechanism proposed for lysozyme–SDS system is also concluded to be true for the binding of SPFO to lysozyme.

Table 1. Thermodynamic parameters

$\bar{\nu}$	β	ΔG°/kJ mol^{-1}
17	0.35	−29
40	0.40	−29
Micelle[6]	0.55	−29

Motion of Methylammonium Ions in Solid $CH_3NH_3NO_3$ and CH_3NH_3SCN Studied by ^1H NMR

Hiroyuki Ishida, Ryuichi Ikeda,* and Daiyu Nakamura
Department of Chemistry, Faculty of Science, Nagoya University, Chikusa-ku, Nagoya 464
(Received April 2, 1982)

The proton spin-lattice relaxation time T_1 at 20 MHz and the second moment of ^1H NMR absorptions at 40 MHz were determined at various temperatures between 77 and 300 K for $CH_3NH_3NO_3$ and CH_3NH_3SCN, and their partially deuterated analogs, $CH_3ND_3NO_3$ and CH_3ND_3SCN. A phase transition was located at 242 K for CH_3NH_3SCN. The fully protonated compounds yielded two T_1 minima, the low- and high-temperature one of which could be attributed to the reorientation of the CH_3 and NH_3^+ groups, respectively, of the cation about the C–N bond axis. The activation energy was evaluated for these motional modes.

The motion of methylammonium (MA) ions in crystals has been extensively studied for methylammonium halides[1–7] and hexahalometallates(IV)[8,9] by means of ^1H NMR experiments. From these works, it became evident that the motional modes responsible for the ^1H nuclear spin-lattice relaxation time T_1 observed below room temperature are usually the reorientations of the cation about the C–N bond axis. Two kinds of such reorientations are considered to be possible. The first one is the correlated reorientation of the CH_3 and NH_3^+ groups in the cation, *i.e.*, the reorientation of the cation as a whole about its C_3 axis with keeping its rigid structure. We already observed this kind of motion in the crystals of $(MA)_2MX_6$ (M: Pt, Sn, Te; X: halogens)[8,9] where the interionic potential barrier experienced by the cation for the reorientation is smaller than the intraionic one. Another kind of the motion is the uncorrelated reorientation of the CH_3 and NH_3^+ groups. This was observed, *e.g.*, for (MA)Cl in which crystal the interionic potential barrier is known to exceed the intraionic one.[1–5]

From the size and shape of the anions, methylammonium nitrate and thiocyanate are thought to form crystals, in which the motion of the cations is expected to be hindered from an intermediate interionic potential barrier between those of the chloride and the hexahalometallates(IV). Accordingly, it is interesting to investigate the motion of the cation in these crystals by use of the ^1H NMR methods.

Experimental

Continuous wave ^1H NMR spectra were recorded by means of a JEOL JNM-MW-40S spectrometer operated at 40 MHz. A home-made pulsed NMR spectrometer described elsewhere[10] was employed to determine the T_1 values of ^1H nuclei at 20 MHz. The experiments of differential thermal analysis (DTA) were carried out in order to detect possible phase transition in the crystal of (MA)SCN by use of an apparatus reported previously.[11] Sample temperatures were determined by use of a copper-constantan thermocouple in each of these experiments.

Methylammonium nitrate was prepared by mixing an aqueous solution of methylamine and dilute nitric acid. Methylammonium thiocyanate was synthesized after the method described in the literature.[12] The crystals obtained were purified by repeated recrystallizations from absolute ethanol, twice for the nitrate and three times for the thiocyanate. Partially deuterated compounds, $CH_3ND_3NO_3$ and CH_3ND_3SCN were prepared by dissolving (MA)NO_3 and (MA)SCN, respectively, in heavy water. The extent of deuteration was estimated for both compounds to be more than 95% from the analysis of the infrared spectra. Since all the compounds studied are very hygroscopic, they were handled in a dry bag and placed in glass ampouls. Then, the ampouls filled with helium were sealed off after evacuating for 8 hours to remove a trace of water or solvent involved.

Results and Discussion

The second moment M_2 of ^1H NMR absorptions was determined at various temperatures between 77 and 300 K for (MA)NO_3 and (MA)SCN. The temperature dependences of the observed M_2 values are shown in Fig. 1.

Below 120 K, the almost constant M_2 values of 23 and 26 G^2 were obtained for (MA)NO_3 and (MA)SCN, respectively. With increasing temperature, a new plateau value of *ca.* 8 G^2 was reached for both compounds above 150 K and it continued up to room temperature. The theoretical M_2 values have been calculated for several motional modes of the cation[1,2] and reported to be 30, 19, and 8 G^2 for the rigid cation, for the C_3 reorienting CH_3 groups with rigid NH_3^+ ones, and for both groups reorienting about the C–N bond

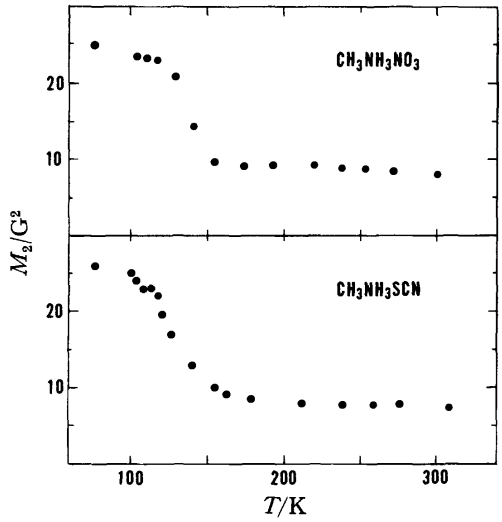

Fig. 1. Temperature dependences of the second moment M_2 of ^1H NMR absorptions for $CH_3NH_3NO_3$ and CH_3NH_3SCN.

axis, respectively. Although the exact interionic M_2 values of these compounds could not be calculated because of the lack of the crystal-structure data, they could be roughly estimated by referring to the data of (MA)Cl.[1] The resultant M_2 values including the interionic ones amount to 38, 23, and 9 G^2 for the three motional states described above in the same order. Comparing the observed and calculated values, the plateau value of M_2 obtained below 120 K for the two compounds can be interpreted in terms of the reorientation of the CH_3 groups alone, and the second plateau obtained above 150 K in terms of the reorientation of both CH_3 and NH_3^+ groups. These results indicate that the CH_3 group of the cation is quite free to reorient in the temperature range, 77—300 K. This is supported from the fact that the partially deuterated analog

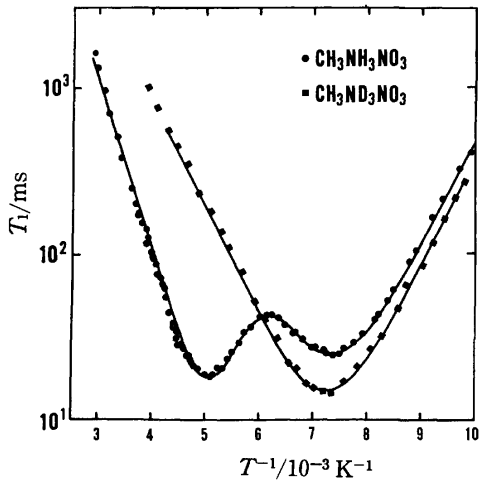

Fig. 2. Temperature dependences of T_1 values determined at 20 MHz for $CH_3NH_3NO_3$ and $CH_3ND_3NO_3$. The full lines are theoretical curves calculated in the manner described in the text.

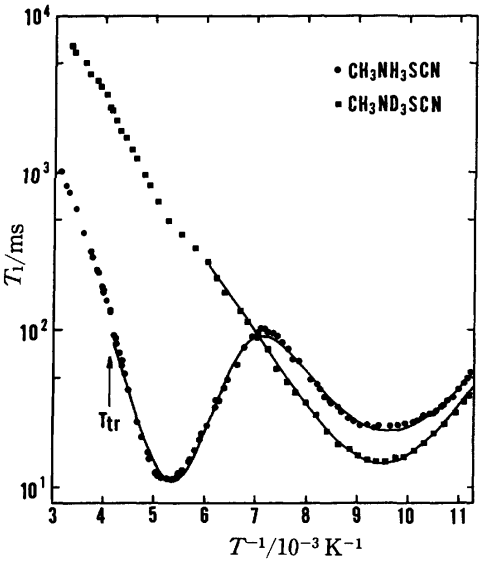

Fig. 3. Temperature dependences of T_1 values observed at 20 MHz for CH_3NH_3SCN and CH_3ND_3SCN. The full lines are theoretical curves calculated in the manner described in the text.

CH_3ND_3SCN yielded the M_2 value of 7.4 G^2 at 77 K. This value is very close to 6.3 G^2 which is calculated for the partially deuterated cation having the reorienting CH_3 group.[5]

The values of T_1 observed at various temperatures for the nitrates and the thiocyanates are shown in Figs. 2 and 3, respectively. The fully protonated nitrate exhibited two considerably well-separated T_1 minima, 24 and 18 ms at *ca.* 135 and 198 K, respectively. Its partially deuterated analog $CH_3ND_3NO_3$, on the other hand, yielded a single minimum of 14 ms at 137 K. Two well-separated T_1 minima, 24 and 11 ms were observed at *ca.* 105 and 192 K, respectively, for CH_3NH_3SCN, while a single minimum of 14.5 ms at *ca.* 105 K was obtained for CH_3ND_3SCN.

The observed T_1 curves can be analyzed by assuming the magnetic dipolar relaxation mechanism formulated by the following BPP equation[13]

$$T_1^{-1} = C[\tau/(1+\omega^2\tau^2) + 4\tau/(1+4\omega^2\tau^2)], \quad (1)$$

where C, τ, and ω denote a constant depending on a motional mode in question, the correlation time of the motion, and an angular resonance frequency, respectively. The correlation time can be related to the activation energy E_a for the motion by assuming the Arrhenius relationship,

$$\tau = \tau_\infty \exp(E_a/RT). \quad (2)$$

Here, τ_∞ and R denote the correlation time at the infinite temperature and the gas constant, respectively.

From the experimental results of T_1 and the foregoing discussion on the ^{1}H NMR second moment, it is evident that the T_1 minimum observed at the lower temperature in each of the fully protonated salts is attributable to the CH_3 reorientation about its C_3 axis, while that at the higher temperature to the NH_3^+ reorientation. The single T_1 minimum observed for the partially deuterated analogs can be naturally attributed to the CH_3 reorientation. For the T_1 curve of CH_3ND_3SCN, a shoulder appeared at *ca.* 200 K. This seems to be another minimum resulting from the incomplete deuteration of the NH_3^+ group in our experiments.

On the high-temperature side of each T_1 minimum, both of $CH_3NH_3NO_3$ and CH_3NH_3SCN showed somewhat nonexponential behavior on the free-induction decay signals plotted against the interval time between the 180° and 90° pulses. This seems to be explainable by the theory of symmetry-restricted spin diffusion by Emid *et al.*[14] When the nonexponential relaxation behavior was observed, the experimental T_1 values were evaluated from the initial linear portion of the recovery of the ^{1}H nuclear magnetization observed after the 90° pulse.

The temperature dependence of T_1 values determined for the thiocyanate showed a small T_1 jump at 242 K. The partially deuterated analog, CH_3ND_3SCN also exhibited a discontinuity in the temperature coefficient of the T_1 curve at 250 K. These experimental facts suggest the existence of a phase transition in these compounds. In fact, the measurements of DTA gave rise to a thermal anomaly for each compound at the same temperature as the T_1 anomaly was observed. Since no thermal hysteresis was observed, these anomalies

TABLE 1. THE ACTIVATION ENERGY E_a AND THE CORRELATION TIME τ_∞ FOR THE CH_3 AND NH_3^+ REORIENTATIONS OF METHYLAMMONIUM NITRATE AND THIOCYANATE

Compound	Reorientational mode	E_a/kJ mol^{-1}	τ_∞/s
$CH_3NH_3NO_3$	CH_3	11.7	1.5×10^{-13}
	NH_3^+	20.0	2.6×10^{-14}
$CH_3ND_3NO_3$	CH_3	12.2	1.2×10^{-13}
CH_3NH_3SCN			
High temp phase	NH_3^+	17.0	—
Low temp phase	CH_3	8.2	3.6×10^{-13}
Low temp phase	NH_3^+	19.9	1.3×10^{-14}
CH_3ND_3SCN			
High temp phase	CH_3	8.3	—
Low temp phase	CH_3	8.9	1.9×10^{-12}

are attributable to a second or higher-order phase transition. Because the transition temperature was observed to be shifted by as much as 8 K on the deuteration of the NH_3^+ group, it is anticipated that the NH_3^+ group plays an important role on the mechanism of the phase transition revealed.

When the reorientation of the CH_3 and NH_3^+ groups about the C–N bond axis is assumed to take place independently of each other, the resultant T_1 value arising from these two relaxation processes can be expressed by

$$T_1^{-1} = \frac{1}{2}[T_1^{-1}(CH_3) + T_1^{-1}(NH_3^+)], \quad (3)$$

where $T_1(CH_3)$ and $T_1(NH_3^+)$ are the relaxation times for the CH_3 and NH_3^+ reorientations, respectively, and are given by Eq. 1. The unknown parameters E_a, τ_∞, and C for the reorientations of these two groups were calculated by a least-squre fitting of Eq. 3 to the observed T_1 curves. The calculation was performed at the computation center of Nagoya University by used of the computer program SALS.[15] The values of E_a and τ_∞ thus calculated for the CH_3 and NH_3^+ reorientations are given in Table 1.

The E_a values obtained for both groups in the nitrate are greater than 8 kJ mol^{-1} which is the E_a value evaluated previously for the internal rotation of the methylammonium cation.[8,9] This means that not only the intraionic potential barrier but also the interionic one is responsible for the present E_a values. For the CH_3 reorientation, the fully and partially protonated thiocyanates yielded the E_a values of 8.2 and 8.9 kJ mol^{-1}, respectively. The fact that these E_a values are very close to that for the internal rotation of the cation, indicates that the barrier hindering the CH_3 reorientation originates almost from the intraionic interaction and the interionic contribution is quite small in this case. For the NH_3^+ reorientation, on the other hand, the thiocyanate gave rise to fairly large E_a values of 19.9 and 17.0 kJ mol^{-1} in the low- and the high-temperature phases, respectively, indicating the existence of interionic interaction, probably, considerably strong hydrogen bonding.

Multiatomic Ion Model for Interdiffusion in the System Na_2O-CaO-SiO_2

Masao NANBA, Yasumichi OISHI,* and Hajimu WAKABAYASHI†
Department of Nuclear Engineering, Kyushu University, Higashi-ku, Fukuoka 812
†*Government Industrial Research Institute, Osaka, Midorigaoka, Ikeda, Osaka 563*
(Received May 4, 1982)

Concentration distributions after interdiffusion at 1200 °C were analysed for the diffusion couple of average composition $16Na_2O \cdot 12CaO \cdot 72SiO_2$ (wt%) in terms of self-diffusion coefficients of constituent elements. Theoretical calculation was conducted using a multiatomic ion model assuming that Si migrates with oxygens as a silicate ion. The composition of the silicate ion was estimated by determining the parameters in the diffusion equation so as to provide the best fit of the theoretical calculations to the experimental concentration profiles.

In spite of its scientific and technological importance,[1,2] the interdiffusion mechanism of liquid silicates has not been thoroughly clarified because of the structural complexity of ionic solutions. Another reason is due to insufficient thermodynamic and self-diffusion data necessary for the analysis of interdiffusion. With respect to the diffusion data, a system CaO-Al_2O_3-SiO_2 is the only multioxide liquid for which tracer diffusion coefficients of all the constituent elements are known.[3] For the present system Na_2O-CaO-SiO_2, tracer diffusion coefficients of sodium,[4] calcium,[5,6] and oxygen[7] are known but that of silicon has not been determined as yet.

In Wakabayashi and Oishi's analysis of liquid-state interdiffusion in the system Na_2O-CaO-SiO_2,[8] simple application of the monoatomic diffusion model did not satisfactorily describe the concentration distribution but the assumption of two different oxygen species with different diffusivities gave theoretically calculated concentration distribution agreeable with the experimental results. They interpreted that the fast and slow oxygen species correspond to the non-bridging and bridging oxygens, respectively. A non-bridging-oxygen controlled mechanism was also discussed for dissolution of solid SiO_2 in liquid $Na_2O \cdot 3SiO_2$ by Barklage-Hilgefort and Frischat.[9] In these two papers, the diffusion coefficient of the fast, not the whole, oxygen is assumed to be equal to that obtained by the tracer technique. In the tracer technique, however, the oxygen diffusion coefficient was calculated on the assumption that all the oxygen atoms are equally capable of undergoing isotope exchange. This contradiction is dissolved in the present work by interpreting the tracer diffusion coefficient as the average of self-diffusion coefficients of the fast and slow oxygen species.[10] This interpretation implies that the constituent element N of compound M_mN_n diffuses not only as monoatomic ion N^{m-}, but also as neutral undissociated molecule M_mN_n or as ion pair $M^{n+}N^{m-}$; tracer diffusion coefficient D_N^* is expressed as the weighted average of the self-diffusion coefficients of those diffusing species, as described by Eq. 1,

$$D_N^* = y_1 D_{N_1} + y_2 D_{MN} + y_3 D_0, \quad (1)$$

where y_1, y_2, and y_3 represent the single-atomic fractions of element N, shared by N^{m-}, $M^{n+}N^{m-}$, and M_mN_n, respectively, and D_{N_1}, D_{MN}, and D_0 the self-diffusion coefficients of diffusing species N^{m-}, $M^{n+}N^{m-}$, and M_mN_n, respectively.

In the analysis[10] of the interdiffusion in liquid system CaO-Al_2O_3-SiO_2, theoretical calculation of the diffusion profiles showed good agreements with the experimental results in the case where the oxygen tracer diffusion coefficient defined as Eq. 1 was employed for a multiatomic ion model, in which the composition of the silicate ion was described in terms of unknown structure parameters. This analytical procedure was used in the present work to examine its applicability to the liquid interdiffusion of the system Na_2O-CaO-SiO_2. Since the Si self-diffusion coefficient in the system Na_2O-CaO-SiO_2 has not been determined, though those of three other elements are known, the self-diffusion coefficients of the fast and slow oxygens can not be determined only from the structure parameters of the silicate ion, as was the case in the system CaO-Al_2O_3-SiO_2. Consequently, the self-diffusion coefficient of the fast oxygen was also described with the aid of a new unknown parameter in the theoretical calculation of the diffusion profiles.

The flux density equation necessary for analysis of the present interdiffusion was derived in terms of self-diffusion coefficients of the constituent ions from Nernst-Haskel's equation modified with the mass flow term as defined by Darken.[11] The system Na_2O-CaO-SiO_2 is understood to be thermodynamically nonideal with respect to oxide components. However, instead of describing the non-ideality in terms of the thermodynamic factor, the present analysis of interdiffusion was conducted on the assumption that a nonideal system with respect to oxide components can be treated as an ideal system with respect to actually diffusing units.[10]

Theoretical

Multicomponent Diffusion Equation for Ionic Systems. The flux density of the ith ion can be described as Eq. 2 for chemical diffusion in a thermodynamically ideal ionic multicomponent system,

$$J_i = -D_i \frac{\partial C_i}{\partial x} + C_i v + D_i C_i Z_i \frac{F}{RT} \varepsilon, \quad (2)$$

where J_i is the diffusion flux density, D_i the self-diffusion coefficient, C_i the concentration, Z_i the valence of the ith diffusing species, x the diffusion distance, v the mass flow velocity, F the Faraday constant, R the gas constant, T the absolute temper-

ature, and ε the strength of the electric field resulted from differing diffusivities of various diffusing ions. The conditions of the volume-fixed frame and no electric current resulted are described by Eqs. 3 and 4, respectively,

$$\sum_{i=1}^{r} V_i J_i = 0 \tag{3}$$

$$\sum_{i=1}^{r} Z_i J_i = 0, \tag{4}$$

where V_i is the molar volume of diffusing species i, and r denotes the number of components. Conditions of the electrical neutrality and a constant molar volume of each component with Eqs. 3 and 4 allow to rewrite Eq. 2 in a general equation as Eq. 5,

$$J_i = -\sum_{i=1}^{r-2} M_{ij} \frac{\partial C_j}{\partial x} \qquad (i = 1,2,\cdots, r-2) \tag{5}$$

where the coefficient M_{ij} is given as Eq. 6 as a function of self-diffusion coefficients, concentrations, valences, and molar volumes of the components,

$$\begin{aligned} M_{ij} = {} & D_i\delta_{ij} - \frac{C_i}{(Z_{r-1}V_r - Z_rV_{r-1})\sum_{k=1}^{r} C_kZ_k^2D_k} \\ & \times \{(Z_{r-1}V_r - Z_rV_{r-1})[Z_iZ_jD_i \\ & + \sum_{k=1}^{r} C_kZ_kD_k(Z_kV_j - Z_jV_k)] \times D_j \\ & + (Z_rV_j - Z_jV_r)[Z_iZ_{r-1}D_i \\ & + \sum_{k=1}^{r} C_kZ_kD_k(Z_kV_{r-1} - Z_{r-1}V_k)] \times D_{r-1} \\ & + (Z_jV_{r-1} - Z_{r-1}V_j)[Z_iZ_rD_i \\ & + \sum_{k=1}^{r} C_kZ_kD_k(Z_kV_r - Z_rV_k)] \times D_r\}, \end{aligned} \tag{6}$$

where δ_{ij} is Kronecker's δ.

Diffusing Units and Their Self-diffusion Coefficients.

The self-diffusion coefficient of sodium[4] is greater than those of calcium[5] and oxygen,[7] in the system Na_2O–CaO–SiO_2, and the activation energy for sodium[4] is half of those for calcium[5] and oxygen.[7] These facts suggest that the diffusing unit of sodium is the single-atomic Na^+ ion. The self-diffusion coefficient of calcium is greater than that of oxygen in this system and similar to that of calcium[12] in the system CaO–Al_2O_3–SiO_2 in which the diffusing unit of calcium is interpreted to be the single-atomic Ca^{2+} ion.[10] Based on these facts, the diffusing unit of calcium in this system is assumed to be the single-atomic Ca^{2+} ion. For a simple demonstration of the present diffusion model, a single multiatomic silicate ion is assumed to be the diffusing unit of silicon as the average of various silicate ions which may actually exist in the liquid silicate.[13–15] Since the composition of the present system is rich in SiO_2, the structure model of the silicate ion is described as discrete ion as proposed by Bockris *et al.*[16] Table 1 summarizes the diffusing units and their self-diffusion coefficients assumed in this study. Here, the structure of the silicate ion is described as n-membered r-fold rings of SiO_4 tetrahedra joined at apices. The oxygens composing this silicate ion are the slower oxygen species and the remainders are the faster species, where the concentrations of the two kind of oxygens are given by Eqs. 7 and 8 from the requirement of the number conservation of the total oxygen atoms.

Table 1. DIFFUSING SPECIES AND THEIR SELF-DIFFUSION COEFFICIENTS

Diffusing species	Self-diffusion coefficient
Na^+	D_{Na}*
Ca^{2+}	D_{Ca}*
$Si_{nr}O_{n(2r+1)}^{2n-}$	D_S
O^{2-}	D_F

$$C_{Si} = C_{Si}\left(2+\frac{1}{r}\right) \tag{7}$$

$$C_F = C_O - C_{Si} \tag{8}$$

where C_{Si} represents the concentration of Si atoms and C_{Si}, C_F, and C_O represent concentrations of the slow, the fast, and the total oxygen atoms, respectively.

In Table 1 star-marked self-diffusion coefficients are those determined by the tracer technique, while the self-diffusion coefficients with no mark are defined as follows: The tracer diffusion coefficient of oxygen, D_O*, is the weighted average of self-diffusion coefficients of the slow and fast oxygen species, as described by Eq. 9,

$$D_O^* = \frac{C_{Si}}{C_O} D_S + \frac{C_F}{C_O} D_F \tag{9}$$

where D_S is the self-diffusion coefficient of the slow oxygen, which is the same as that of the silicate ion, and D_F is that of the fast oxygen.

Determination of Parameters for Diffusing Units.

The diffusion couples in the present work were designed with relatively small concentration differences (10 wt%) so that the self-diffusion coefficients of all the diffusing species may be regarded as composition-independent. Consequently, coefficient M_{ij} in Eq. 6 is also regarded as constant and calculated for the average composition of the diffusion couple where the valences of diffusing species are read from Table 1. The molar volumes are so defined that the volume of the system is determined only by the volume of the oxygen atoms, as described by Eq. 10,

$$\begin{cases} V_{Na^+} = V_{Ca^{2+}} = 0 \\ V(Si_{nr}O_{n(2r+1)})/V_{O^{2-}} = n(2r+1) \end{cases} \tag{10}$$

Self-diffusion coefficients of the constituent elements, D_{Na}*,[4] D_{Ca}*,[5] and D_O*[7] are taken from the literature.

Applying the continuity equation to Eq. 5, the analytical solution can be derived as Eq. 12 for the initial and boundary conditions described by Eqs. 11,

$$\begin{cases} C_i = C_{i,A} & x<0,\ t = 0 \\ C_i = C_{i,B} & x>0,\ t = 0 \\ C_i = C_{i,A} & x = -\infty,\ t>0 \\ C_i = C_{i,B} & x = +\infty,\ t>0 \end{cases} \tag{11}$$

where $C_{i,A}$ and $C_{i,B}$ denote the initial concentrations of diffusing species i in the left and right sides of the diffusion couple, respectively.

$$C_i = C_{i,B} + \frac{1}{2}\sum_{j=1}^{r-2}\sum_{k=1}^{r-2} S_{ik}R_{kj}(C_{j,A} - C_{j,B})\,erfc\left(\frac{x}{2\sqrt{\lambda_k t}}\right), \tag{12}$$

where S_{ij}, R_{ij}, and λ_i are the constants given by Eq. 13,[10]

$$\begin{aligned}
\lambda_1 &= \{(M_{11}+M_{22}) + Q\}/2 \\
\lambda_2 &= \{(M_{11}+M_{22}) - Q\}/2 \\
S_{11} &= (M_{11}-M_{22}) + Q \\
S_{12} &= (M_{11}-M_{22}) - Q \\
S_{21} &= S_{22} = 2M_{21} \\
R_{11} &= 1/2Q \\
R_{12} &= \{-(M_{11}-M_{22})+Q\}/4M_{12}Q \\
R_{21} &= -1/2Q \\
R_{22} &= \{(M_{11}-M_{22})+Q\}/4M_{12}Q \\
Q &= \{(M_{11}-M_{22})^2 + 4M_{12}M_{21}\}^{1/2}.
\end{aligned} \tag{13}$$

Theoretical concentration distributions were repeatedly calculated using Eq. 12 for various magnitudes of the parameters until the best fitting to the experimental distributions are attained. The best fitting was carried out by minimizing the objective function F given by Eq. 14,

$$F = [\sum_{i=1}^{3} \sum_{j=1}^{N_i} \{W_i^e(x_j) - W_i^c(x_j)\}^2/3N_i]^{1/2}, \tag{14}$$

where $W_i^e(x_i)$ and $W_i^c(x_j)$ represent the experimentally determined and calculated concentrations (in wt fraction) of oxide component i at diffusion distance x_j, respectively, and N_i denotes the number of the measurements for oxide component i. The experimental concentration distributions were taken from Wakabayashi and Oishi's paper.[8]

Results and Discussion

Figure 1 shows the theoretical concentration distributions (solid curves) calculated by Eq. 12 for the diffusion couple $16Na_2O \cdot 7CaO \cdot 77SiO_2$–$16Na_2O \cdot 17CaO \cdot 67SiO_2$ (wt%) at 1200 °C for diffusion time 4.00 h so as to best fit to the experimental results determined by Wakabayashi and Oishi[8] (plotted). The theoretical calculation is in good agreement with the experimental results. The experimentally determined "up-hill diffusion" of the component Na_2O which had no initial concentration difference has been satisfactorily described by the theoretical calculation of the present diffusion model. The solid curves for theoretical calculations in Fig. 1 were obtained for the self-diffusion coefficient of fast oxygen species, $D_F = 7.54 \times 10^{-8}$ cm²/s, which determined the self-diffusion coefficient of silicate ion as $D_S = 1.37 \times 10^{-8}$ cm²/s.

The theoretical calculation of the diffusion profiles was carried out also for the second diffusion couple $21Na_2O \cdot 7CaO \cdot 72SiO_2$–$11Na_2O \cdot 17CaO \cdot 72SiO_2$, for which Wakabayashi and Oishi determined the diffusion profiles experimentally at 1200 °C for diffusion time 2.00 h. The second diffusion couple was designed with no initial concentration difference in SiO_2 so as to have the same average composition as and a different compositional direction from the first diffusion couple.

The theoretical calculation for the second diffusion couple gave concentration distributions (solid curves) close to the experimental results (plotted), as shown in Fig. 2. However, with respect to the structure parammeter n, its magnitude could not be successfully optimized within the reasonable magnitude range. This

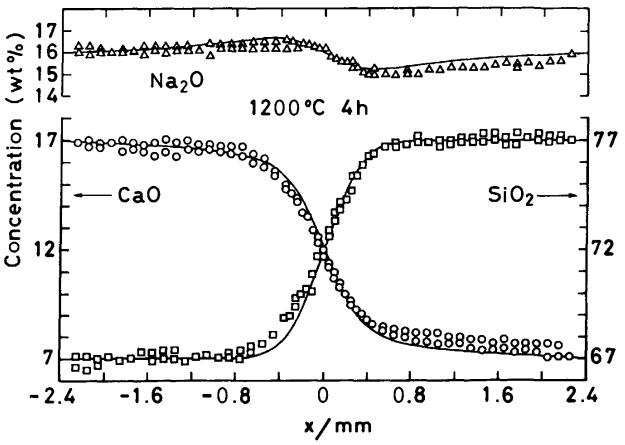

Fig. 1. Theoretical and experimental concentration distributions for the diffusion couple $16Na_2O \cdot 7CaO \cdot 77SiO_2$–$16Na_2O \cdot 17CaO \cdot 67SiO_2$ (wt%).

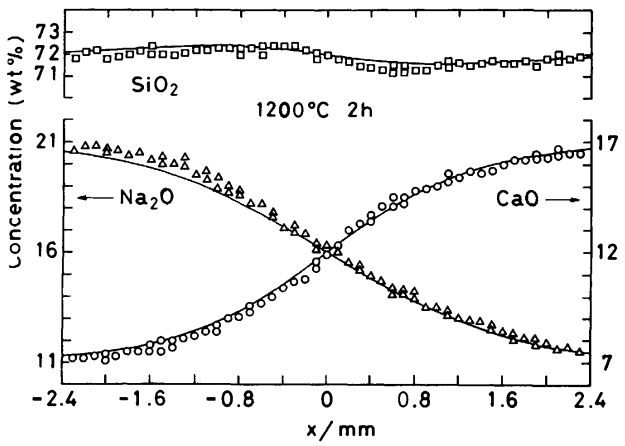

Fig. 2. Theoretical and experimental concentration distributions for the diffusion couple $21Na_2O \cdot 7CaO \cdot 72SiO_2$–$11Na_2O \cdot 17CaO \cdot 72SiO_2$ (wt%).

seems to be due to composition-dependences of the self-diffusion coefficients, the thermodynamical nonideality, or/and the size distribution of the silicate ions, which is suggested by the asymmetrical diffusion profiles.

(Received February 18, 1982)

Amobarbital was ball-milled with methylcellulose (MC), microcrystalline cellulose, or dextran. The analysis of the IR spectra indicated that hydrogen bonds were formed between the C=O groups of amobarbital and the OH groups of the diluents upon ball-milling. It was also shown that formation of the bonds was more predominant with MC than with dextran. After suspensions of various kinds of samples in distilled water had been set aside for a week after the time of preparation, the solid state of the amobarbital remaining undissolved in the suspension was compared with the state before dissolution. There are three kinds of polymorphs for amobarbital: Crystals I, II, and III. Crystal I is given by heating Crystal II (at 150 °C), which has been recrystallized from a 25 v/v% aqueous ethanol solution. Crystal III is given by freeze-drying an aqueous solution. The above comparison suggests that Crystal III and the amorphous part are transformed into Crystal I in the absence of any diluent. It seems that the presence of dextran ball-milled with amobarbital prevents Crystal III from being transformed into Crystal I. The presence of MC ball-milled with amobarbital also seems to prevent both the amorphous part from crystallization and Crystal III from transformation into Crystal I. The solubility of amobarbital in distilled water increased remarkably upon ball-milling with diluents; this was attributed to the stabilization of the amorphous state by the interaction with diluents.

The solubility of amobarbital in distilled water increased upon ball-milling with such diluents as methylcellulose,[1] though the solubility increased only slightly without any diluent.[2] Previously, the effect of ball-milling, both with a diluent and without any diluent, on the solid state of amobarbital was investigated, and the relationship between the solid state and solubility was discussed.[1,2] Consequently, it was suggested that the interaction of amobarbital with diluents was one of the most important reasons for the increase in the solubility.[1] In this paper, the interaction of amobarbital with diluents resulting from ball-milling was investigated, and the influence of the interaction on the solid state was discussed.

Experimental

The materials used were amobarbital (5-ethyl-5-isopentylbarbituric acid), dextran 2000, microcrystalline cellulose (MCC), and methylcellulose (MC), all described in a previous paper.[3]

The following samples were ball-milled in the way described previously;[3] 10 g of commercial powders of amobarbital (AC) dextran or MCC; 5 g of MC; a mixture of 1 g of AC and 9 g of each of the diluents; a mixture of 3 g of AC and 7 g of dextran or MCC; a mixture of 2 g of AC and 3 g of MC. In this paper, the "mixture with dextran" contains 30 w/w% of amobarbital and the "mixture with MC" contains 40 w/w% of amobarbital, when no annotation is given.

Various kinds of samples were prepared as follows.

ACS: A suspension of 1 g of AC in 500 cm^3 of distilled water was stirred for 2 h, allowed to stand at 30 °C for a week, and then filtered. The residue was dried under reduced pressure at 70 °C.

AB: AC was ball-milled for 60 h.

ABS: ABS was prepared from AB in the same way as that used to obtain ACS from AC.

DexAB: A mixture with dextran was ball-milled for 200 h.

DexABS: A suspension of 3 g of DexAB in 500 cm^3 of distilled water was stirred for 2 h, allowed to stand at 30 °C for a week, and then filtered. The residue was washed with an aqueous saturated solution of amobarbital and dried under reduced pressure at 70 °C.

MCAB: A mixture with MC was ball-milled for 100 h.

MCABS: A suspension of 2 g of MCAB in 400 cm^3 of distilled water was stirred for 2 h, allowed to stand at 30 °C for a week, and then centrifuged. The precipitate was washed with an aqueous saturated solution of amobarbital and dried under reduced pressure at 70 °C.

The results of the elemental analysis for ACS, ABS, and DexABS were identical with the results for AC; this fact demonstrated that the amount of dextran contaminating DexABS was negligible. The nitrogen content in MCABS was a little smaller than the content in AC; this finding showed that MC mixed in MCABS because of the low solubility of MC in distilled water. The content of MC in MCABS was presumed to be 7.1 w/w% from the ratio of the content of nitrogen to that of carbon.

The IR spectra and X-ray diffraction diagrams were recorded in the way described previously.[3]

Results and Discussion

IR Spectra. Figures 1, 2, and 3 show the effect of ball-milling on the IR spectra of mixtures of amobarbital, as determined by a KBr method. The absorbances around the 3400, 1300—1450, and 1000—1120 cm^{-1} regions increased upon ball-milling. The bands from 1650—1800 cm^{-1}, corresponding to the stretching vibration of the C=O groups of amobarbital,[4] were also affected by ball-milling. The same trends were also found by a Nujol method. In the IR spectra of cellulose derivatives and dextran, the band around the 3400 cm^{-1} region was assigned to the stretching mode of hydrogen-bonded OH groups,[5] though this band was largely overlapped with the absorption of associated water.[6] Keighley *et al.* reported that the absorbance of the band at 2.92 μm (at 3420 cm^{-1}) was found to be higher by the use of a poly(tetrafluoroethylene) (PTFE) disk method than by the use of a KBr disk method or a nujol method. They suggested that this finding was associated with the formation of hydrogen bonds between the

cellulosic OH groups and the fluorine atoms of PTFE.[7] Marchessault *et al.* pointed out that the difference in a hydrogen-bonding system in various crystal-lattice types affected the intensities and frequencies of the bands in the OH stretching region.[8] The band at 1429 cm^{-1} was assigned to the CH_2 symmetric bending mode. The bands at 1315, 1335, and 1370 cm^{-1} were assigned to the CH_2 wagging mode, the C-O-H in-plane bending mode, and the CH bending mode respectively. The band at 1110 cm^{-1} was assigned to the C-O stretching mode, perhaps coupled to the C-C frequency. These bands were also reported to change with the variation in the crystal modifications or crystallinity; this was probably due to the change in the hydrogen-bonding system.[5,9] The above facts indicate that hydrogen bonds are formed between the C=O groups of amobarbital and the OH groups of the diluents.

The absorbance at each of the wave numbers, ν, was determined, assuming that the transmittance on the straight line passing through 3800 and 2000 cm^{-1}, or 2000 and 900 cm^{-1}, was 100%. Figure 4 represents the variations in $R_{\nu,\nu'}$ with ball-milling for the mixture with MCC containing 10 w/w% of amobarbital, where $R_{\nu,\nu'}$ is the ratio of the absorbance at the wave number of ν to the absorbance at ν'. $R_{1755,1690}$ was little influenced by ball-milling. $R_{1720,1690}$ increased in the first stage, while it stayed nearly constant after ball-milling for 15 h. $R_{1735,1690}$, $R_{1710,1690}$, and $R_{1700,1690}$ increased after ball-milling for 10 h. In the carbonyl absorptions of AB in Fig. 1, the absorption at 1755 cm^{-1} was considered to be due to the mode associated mainly with the C=O group in the 2-position, and the absorptions at 1720 and 1690 cm^{-1} bands, to be the antisymmetric and symmetric vibrations respectively, involving mainly the groups in the 4- and 6-positions.[4] It was previously reported that the 4- and 6-carbonyl groups formed hydrogen bonds with the NH groups, leaving the 2-carbonyl group unaffected in the solid state.[10] It was also noted that these bands showed a drop in frequency upon hydrogen bonding. The results in Fig. 4 support the following interpretations: (1) some part of the band at 1755 cm^{-1} shifts to a lower frequency upon the hydrogen bonding of the free C=O group in the 2-position, probably with the OH groups of MCC; (2) some part of the band at 1690 cm^{-1} shifts to a higher frequency upon the conversion of the bonds of the C=O group in the 4- or 6-position with the NH group of amobarbital to the bonds with the OH groups.

Figure 5 shows the variation in $R_{\nu,1690}$ (ν/cm^{-1} is between 1700 and 1755) with ball-milling for the mixture with MC. All of the $R_{\nu,1690}$ values in Fig. 5 increased in the first stage, while they stayed nearly constant after ball-milling for 10 h. The increase in $R_{1755,1690}$ indicates that the formation of hydrogen bonds of the C=O group in the 2-position with the OH groups of MC is not so predominant as the formation with those of MCC.

Table 1 presents the numerical values of $R_{\nu,1690}$ obtained by the use of a Nujol method. The band at 1640 cm^{-1} is the OH in-plane bending absorption of water adsorbed on diluents.[5,6] $R_{1640,1690}$ decreased upon ball-milling; this was probably a result of the squeezing

out of the adsorbed water caused by the formation of hydrogen bonds between the amobarbital and the diluents. It seemed probable from the change in $R_{1755,1690}$ that the absorbance at 1690 cm^{-1} after ball-milling was approximately 0.9 times as large as that before ball-milling for the mixture containing 30—40 w/w% of amobarbital. In this case, the $R_{3420,1690}$ value after ball-milling was 1.7—2.4 times as large as the value before ball-milling, though $R_{1640,1690}$ decreased upon ball-milling. The $R_{1110,1690}$ and $R_{1050,1690}$ values also doubled upon ball-milling. It is clear from these facts that the absorbances at 3420, 1110, and 1050 cm^{-1} increase upon ball-milling, though the variation in $R_{\nu,1690}$ for ν/cm^{-1} from 1450 to 1300 could not be discussed on the basis of a Nujol method. The band in the 1020—1060 cm^{-1} region has been suggested to be a skeletal vibration characteristic of the barbituric acid ring.[4] The skeletal vibration of amobarbital is probably affected by the change in the hydrogen bonds of the C=O groups. As is shown in Figs. 1, 2, 3, and Table 1, the absorbances of the NH stretching modes at 3200 and 3080 cm^{-1} and those of the NH out-of-plane deformation modes at 855 and 815 cm^{-1} decreased upon ball-milling, though the locations of these bands were not affected. The band of the stretching vibration of free NH has been reported to be observed in the 3300—3400 cm^{-1} region.[4] Probably, the increase in the absorbance at 3400 cm^{-1} is partly attributable to the free NH formed by the hydrogen bonding of the C=O groups with the OH groups of the diluents.

Effect of Dissolution on the Solid State of Amobarbital. A mixture with a water-soluble diluent containing approximately twice as much as the solubility of amobarbital was added to distilled water. After the suspension

a) CA is the content of amobarbital in the mixture. b) bt is the ball-milling time. c) A physical mixture of AB and the ball-milled diluent (Ten g of dextran or MCC was ball-milled for 200 h, and 5 g of MC was ball-milled for 100 h.)

had been allowed to stand for a week, the solid state of the amobarbital remaining undissolved was compared with the state before dissolution. As has been described previously, there are three polymorphs for amobarbital: Crystals I, II, and III. Crystal I was given by heating Crystal II (at 150 °C), which had been recrystallized from a 25 v/v% aqueous ethanol solution. Crystal III was given by freeze-drying an aqueous solution. It was also reported previously that AC and AB particles were composed of Crystal I, Crystal III and an amorphous part. The X-ray diffraction intensity at 12.7° of 2θ was lower than the intensity at 16.0° of 2θ in the diagram of Crystal I, while the opposite was observed in the diagram of Crystal III.[2] Figure 6 shows the X-ray-diffraction patterns of various kinds of amobarbital. Diffraction lines were not observed in the digram of dextran or MC. The crystallinity of amobarbital was determined by Ruland's method.[11] The ratio of the weight content of Crystal III to the content of Crystal I was determined from the ratio of the intensity of the diffraction line at 12.7° of 2θ to the intensity at 16.0° of 2θ.[2] The results of these determinations are shown in Table 2, where the MC content in MCABS was assumed to be 7.1 w/w% and where the contribution of MC to the scattering intensity was assumed to be identical with the contribution of the amorphous part of amobarbital. The contents of Crystal III in DexABS and MCABS were larger than those in ACS and ABS. It was noted previously that the $R_{3085,3020}$ and $R_{850,815}$ values for Crystal III were larger than those for Crystal I.[2] Table 3 presents the numerical values of $R_{\nu,\nu'}$ for various samples. The $R_{3085,3020}$ and $R_{850,815}$ values for DexABS and MCABS were larger than those for the other samples. This fact also shows that the content of Crystal III in DexABS and MCABS is larger than the content in the other samples. By the use of the solubility of amobarbital presented in Table 4, the solid state of the amobarbital remaining undissolved in the suspension was obtained on the basis of the following assumptions; (1) only a part of Crystal III or the amorphous part dissolved, and (2) no transformation occurred between Crystal I, Crystal III, and the amorphous state. A comparison of the results in Tables 2 and 4 demonstrates that Crystal III and the amorphous part are transformed into Crystal I by the dissolution of AB. The presence of dextran ball-milled with amobarbital is shown to prevent Crystal III from being transformed into Crystal I. The presence of MC ball-

milled with amobarbital is also shown to prevent the amorphous part from crystallization, as well as preventing Crystal III from being transformed into Crystal I.

Solubility of Amobarbital and the Stability of Its Amorphous State. Previously, a suspension of various kinds of samples containing amobarbital in a KH_2PO_4–Na_2HPO_4 buffer solution with a pH of 6.0 was shaken at 30 °C immediately after preparation, withdrawn from time to time, and filtered. Then the concentration of amobarbital in the filtrate was determined. In the case of amobarbital ball-milled with MC or without any diluent, the concentration increased with shaking and stayed nearly constant after 2 hs' shaking. The concentration of the mixture with dextran or MCC was at a maximum at the shaking time of 5 min. In Table 5 are summarized the results reported previously, where c_{5min} and c_{2h} are the concentrations after shaking for 5 min and for 2 h respectively, and where c_e is the concentration for the suspension allowed to stand at 30 °C for a week after shaking for 2 h. The concentrations increased more remarkably upon ball-milling with diluents than without any diluent. The c_{5min} values for the mixture with dextran were smaller than the values of c_{5min} or c_{2h} for the other mixtures. In the case of the mixture with MC, c_e was nearly identical with c_{2h}, while c_e was smaller than c_{5min} and approximately equal to the solubility of AC for the other mixtures. It was suggested that the increase in surface energy upon ball-milling was not the main reason for the increase in the solubility. Though the amorphous part seemed to control the solubility of amobarbital, the rate and extent of the increase in the amorphous part upon ball-milling were little influenced by the kind of diluent. After all, it was considered that the interaction of amobarbital with diluents resulting from ball-milling was one of the most important reasons for the increase in the solubility.[1,2]

In the case of the mixture with MCC containing 10 w/w% of amobarbital, c_{5min} was at its maximum around a ball-milling time of 20—25 h.[1] The decrease in c_{5min} after ball-milling for 25 h is probably to be attributed to the adsorption of amobarbital on MCC, as MCC is not soluble in distilled water. In the case of the mixture with MC, the variation in c_e with ball-milling was parallel to the variation in $R_{\nu,1690}$ in Fig. 5.[1] This fact shows that the large value of c_e is attributable to hydrogen bonding between amobarbital and MC. In Figs. 2 and 3, the variation in the carbonyl groups of amobarbital upon ball-milling with dextran was not so remarkable as the variation with MC; this fact shows that the interaction of amobarbital with dextran is weaker than the interaction with MC. The above results show that the solubilization of amobarbital upon ball-milling is attributable to the stabilization of the amorphous state caused by the interaction with diluents.

The authors are grateful to the members of the Analytical Center of Showa University for their measurements of the IR spectra and for the elemental analysis.

Vibration-rotation Spectrum of the Coriolis-interacting Band System ν_6 and ν_3 of Acetonitrile-d_3

Hiroatsu MATSUURA* and Hiromu MURATA

Department of Chemistry, Faculty of Science, Hiroshima University, Higashisenda-machi, Naka-ku, Hiroshima 730

(Received May 6, 1982)

The vibration-rotation infrared spectrum of the Coriolis-interacting band system ν_6 and ν_3 was measured with a resolution of 0.08 cm^{-1}. The analysis of the spectrum gave values, more precise than before, of the parameters for these bands along with the interaction parameters. A close examination of the observed spectrum revealed a weak Fermi resonance between ν_6 and $\nu_4+\nu_8$. The parameters determined, in cm^{-1}, include: $(\nu_0)_6$ 1046.659, α_6^A 0.01550, α_6^B −0.000443, $(\nu_0)_3$ 1110.46, α_3^A −0.0078, and α_3^B 0.00092, where α_6^B and α_3^B do not involve the contribution of the Coriolis interaction between ν_6 and ν_3.

The vibration-rotation infrared spectra of acetonitrile-d_3 or methyl-d_3 cyanide, CD_3CN, have been studied previously by several investigators.[1-4] The resolution of these spectra was, however, not high enough to provide precise values for molecular parameters. In order to improve the spectroscopic data for CD_3CN, Fourier transform infrared spectrum with a higher resolution was measured and analyzed in the present work. We report in this paper the spectral analysis of the ν_6 band (CD_3 degenerate deformation) which is strongly coupled with the ν_3 band (CD_3 symmetrical deformation) through an *xy*-type Coriolis interaction.

Experimental

The sample of acetonitrile-d_3 was a product of CEA, France, with a stated isotope purity of 99.7% and was used for the spectral measurements without further purification. The infrared spectrum was recorded on a JEOL JIR-40X Fourier transform infrared spectrometer. Sample pressures of 7—20 Torr† in a 1-m cell were utilized in the measurements. The effective spectral resolution was 0.08 cm^{-1}. The observed wavenumbers were calibrated by using the IUPAC wavenumber data.[5]

Spectral Analysis

The vibration-rotation spectrum in the whole ν_6 band region and the expanded spectra of the ^RR and ^PP branches are shown in Figs. 1 and 2, respectively. The spectra exhibit a number of P- and R-branch lines together with Q branches, in contrast with the previous spectra[1,3,4] in which only the Q branches were resolved. The assignment of the quantum number K to the Q branches and the associated P and R branches was made straightforwardly by examining the intensity alternation and the starting positions of series of P- and R-branch lines (Fig. 2). The K assignment established in this work agrees with that in the previous analyses.[1,3,4] The ^PP_K-branch lines with K=1—16 and the ^RR_K-branch lines with K=0—15 were finally identified and assigned for the ν_6 band. Vibration-rotation lines assignable definitely to the ν_3 band were not identified because of much weaker intensities than those for the ν_6 band.

Subband Analysis of ν_6. In advance of the analysis of the whole band system, the subbands in ν_6 were analyzed, and the effective rotational constant B'_{eff} was obtained for each subband by using a formula

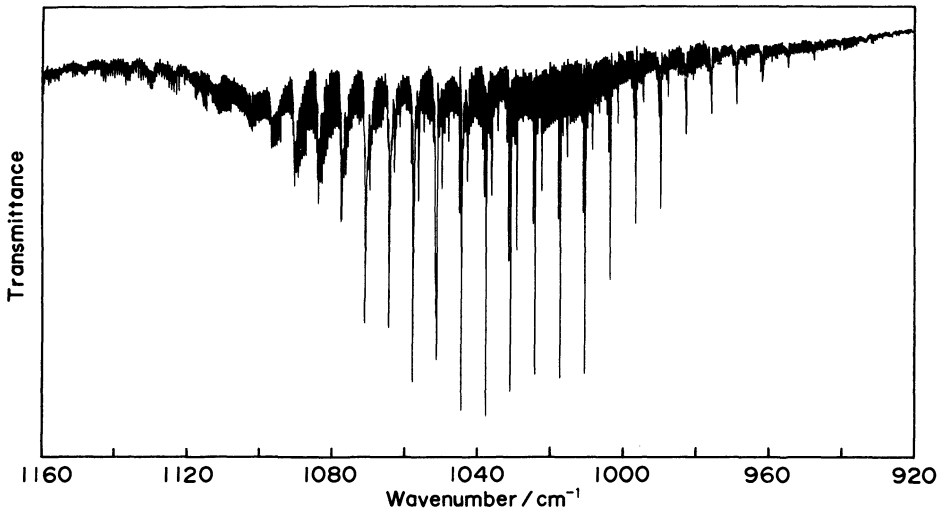

Fig. 1. Infrared spectrum of the ν_6 band region of gaseous CD_3CN.

† 1 Torr=133.322 Pa.

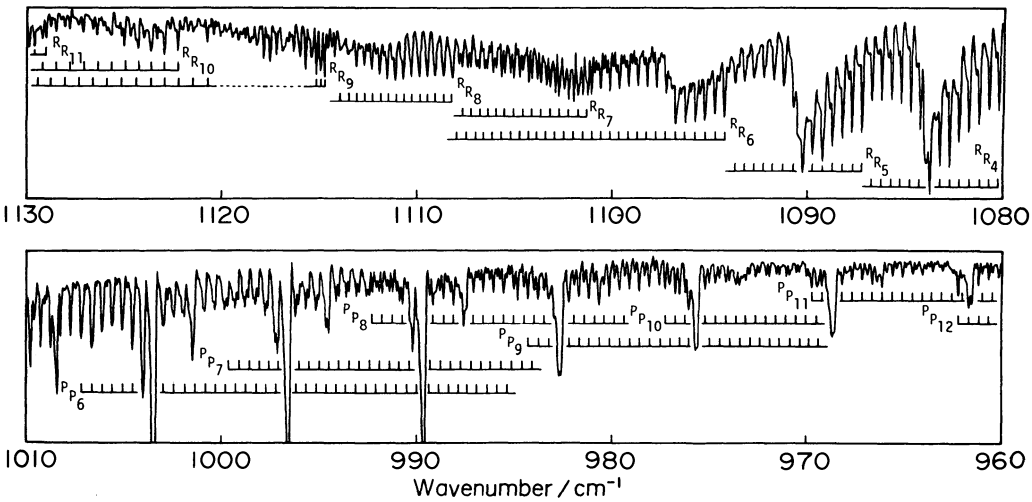

Fig. 2. Infrared spectra and assignments of the ^{R}R and ^{P}P branches of ν_6 of CD_3CN.

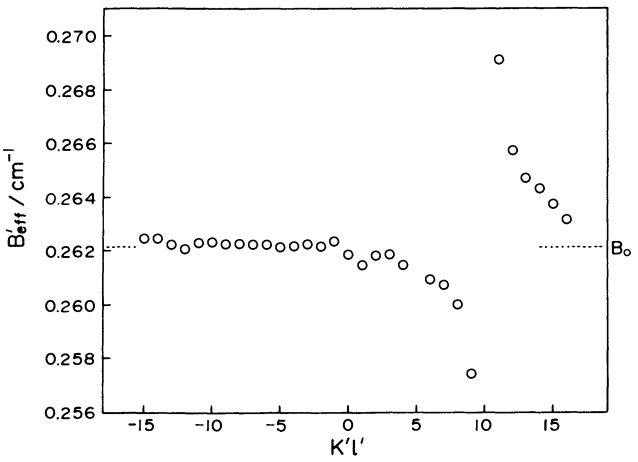

Fig. 3. Effective rotational constant B'_{eff} for ν_6 of CD_3CN. A value of B'_{eff} was not obtained for $K'l'=5$ because of severe overlapping of $^{R}R_4$-branch lines with stronger $^{R}R_3$-branch lines.

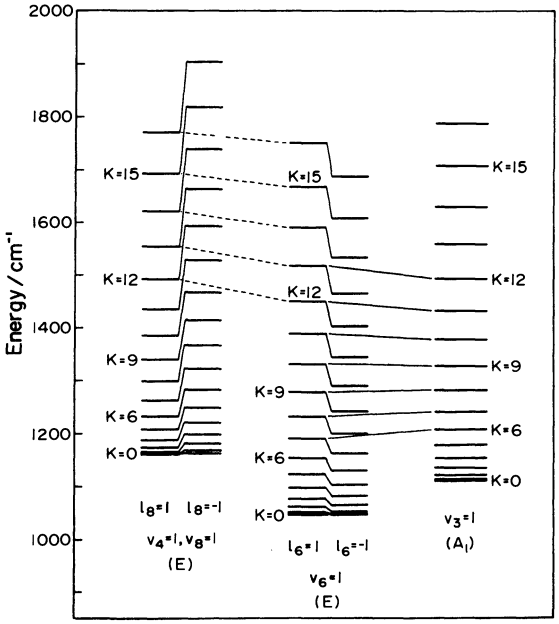

Fig. 4. Vibration-rotation energy levels for the ν_6 (E), ν_3 (A_1), and $\nu_4+\nu_8$ (E) states of CD_3CN and interactions coupling the levels (only significant interactions are shown). ——: Coriolis interaction between ν_6 and ν_3, and ----: Fermi resonance between ν_6 and $\nu_4+\nu_8$.

described previously.[6] The dependence of the B'_{eff} value on the upper-state quantum number $K'l'$ is shown in Fig. 3. If the ν_6 band was not perturbed by any interaction, the B'_{eff} value would be constant for all the subbands, namely for all the $K'l'$ values. Figure 3 shows, however, a striking variation of B'_{eff} between $K'l'=9$ and 11, indicating that an energy-level crossing with another state occurs around $K'l'=10$.

An examination of the energy levels for CD_3CN indicates that the perturbation observed in the ν_6 band is due to the xy-type Coriolis interaction between the $v_6=1$ state (to be denoted by the ν_6 state or simply ν_6) and the $v_3=1$ state (the ν_3 state), which has been noted previously by Masri *et al.*[3] The variation fashion of the B'_{eff} value indicates that the vibration-rotation levels of ν_6 for $K'l'\leq 9$ are lower than the coupling ν_3 levels and, beyond the level crossing, the ν_6 levels are higher than the ν_3 levels. The vibration-rotation energy levels, finally determined in this work, of ν_6 (E), ν_3 (A_1), and $\nu_4+\nu_8$ (E) and the interactions coupling the levels are shown in Fig. 4. The $\nu_4+\nu_8$ state interacts weakly with the ν_6 state through a Fermi resonance, as will be mentioned later.

Analysis of the Band System ν_6 and ν_3. In the band system ν_6 and ν_3, the vibration-rotation energies are strongly perturbed by the Coriolis resonance, so that the treatment of the Coriolis interaction based on the second-order perturbation theory, known as a Van Vleck transformation, which is usually employed in off-resonance systems, is no longer valid. Accordingly, this interaction was explicitly taken into account in the analysis. The non-zero matrix element of the Hamiltonian for the xy-type Coriolis interaction between ν_6 (E) and ν_3 (A_1) is given by[6-8]

$$\langle v_3=1; J,K|H_{Cor}/hc|v_6=1, l_6=\pm 1; J,K\pm 1\rangle = \pm \xi^{(y)}_{3,6} f(J,K\pm 1), \quad (1)$$

where

$$\xi^{(y)}_{3.6} = (1/\sqrt{2})[(\omega_6/\omega_3)^{1/2} + (\omega_3/\omega_6)^{1/2}](B\zeta^{(y)}_{3.6a}) \quad (2)$$

and

$$f(J,K\pm1) = [J(J+1) - K(K\pm1)]^{1/2}. \quad (3)$$

On the other hand, the vibration-rotation Hamiltonian gives the following unperturbed energy[9] with $|k|=K$:

$$\begin{aligned} E^0(v,l;J,k)/hc &= G(v,l) + B_v[J(J+1) - k^2] + A_v k^2 \\ &- \sum_t 2(A\zeta^{(z)}_{ta.tb})_v k l_t - (D_J)_v J^2(J+1)^2 \\ &- (D_{JK})_v J(J+1)k^2 - (D_K)_v k^4 \\ &+ \sum_t (\eta_{tJ})_v J(J+1)kl_t + \sum_t (\eta_{tk})_v k^3 l_t, \end{aligned} \quad (4)$$

where $G(v,l)$ is the vibrational term and the index t refers to the doubly-degenerate modes. The vibrational term $G(v,l)$, and accordingly the band origin $(\nu_0)_v$ to be derived from the spectral analysis, include a term $A(\zeta^{(z)}_{ta.tb})^2$ which originates from the non-vibrational Hamiltonian.

The vibration-rotation transition wavenumbers were calculated by solving the energy matrix with elements given by Eqs. 1 and 4. The ground-state constants B_0, $(D_J)_0$, and $(D_{JK})_0$ were constrained to the well-determined microwave data[10] and the constants A_0 and $(D_K)_0$ were fixed to the estimated values.[3,11] The least-squares calculation gave satisfactory agreement between the observed and calculated wavenumbers with the exception of those for the ${}^{R}R_K(J)$ lines with $K \gtrsim 12$.

The results of this preliminary calculation show that the perturbed ${}^{R}R_K(J)$ lines of ν_6 are shifted down more for larger K values, indicating that the perturbing vibration-rotation levels are higher than, but getting closer at higher levels to, those of the ν_6 levels. Possible interacting vibrational levels are $\nu_4+\nu_8$ and $\nu_7+\nu_8$ with estimated vibrational wavenumbers of about 1165 and 1180 cm^{-1}, respectively. Accordingly, the vibration-rotation energy levels for these combination bands were calculated by using the constants available. The results clarify that the levels of $\nu_4+\nu_8$ approach those of ν_6 within 40 cm^{-1} for $K'l' \geq 13$ but an expected interaction between ν_6 and $\nu_7+\nu_8$ should be much less significant than between ν_6 and $\nu_4+\nu_8$. The minor perturbation observed in ν_6 is thus found to be due to the Fermi resonance between ν_6 (E) and $\nu_4+\nu_8$ (E).

The whole band system was analyzed by taking account of the Coriolis interaction between ν_6 and ν_3 and the Fermi resonance between ν_6 and $\nu_4+\nu_8$, as well as the $q_t^{(+)}$-type l-doubling interaction[9] in the degenerate vibrational state. Thus, in order to obtain perturbed energies, the following 5×5 energy matrix was set up and solved for $K \geq 1$:

$$\begin{pmatrix} E^0(v_6=1,\, l_6=-1;J,\, K-1), & W_{468} & -\xi^{(y)}_{3.6} f(J,\, K-1) & -q_6^{(+)} f(J,\, K+1) f(J,\, K-1)/2 & 0 \\ & E^0(v_4=1,\, v_8=1,\, l_8=-1;J,\, K-1) & 0 & 0 & -q^{(+)}_{4.8} f(J,\, K+1) f(J,K-1)/2 \\ & & E^0(v_3=1;J,\, K) & \xi^{(y)}_{3.6} f(J,\, K+1) & 0 \\ & \text{(Hermitian)} & & E^0(v_6=1,\, l_6=1;J,\, K+1) & W_{468} \\ & & & & E^0(v_4=1, v_8=1,\, l_8=1;\, J,K+1) \end{pmatrix}, \quad (5)$$

where W_{468} is a parameter of the Fermi resonance between ν_6 and $\nu_4+\nu_8$ and is related to Mills' cubic force constant ϕ_{468} by $W_{468}=\phi_{468}/2\sqrt{2}$. For $K=0$, on the other hand, the matrix is reduced to 3×3 and 2×2 matrices; for A- species:††

$$\begin{pmatrix} E^0(v_3=1;J,\, K=0) & \sqrt{2}\,\xi^{(y)}_{3.6}[J(J+1)]^{1/2} & 0 \\ & E^0(v_6=1,\, l_6=1;\, J,\, K=1) + q_6^{(+)}J(J+1)/2 & W_{468} \\ \text{(Herimitian)} & & E^0(v_4=1,\, v_8=1,\, l_8=1;\, J,K=1) + q^{(+)}_{4.8}J(J+1)/2 \end{pmatrix}, \quad (6)$$

and for A+ species:

$$\begin{pmatrix} E^0(v_6=1,\, l_6=1;\, J,K=1) - q_6^{(+)}J(J+1)/2 & W_{468} \\ \text{(Hermitian)} & E^0(v_4=1,\, v_8=1,\, l_8=1;\, J,K=1) - q^{(+)}_{4.8}J(J+1)/2 \end{pmatrix}. \quad (7)$$

The ${}^{R}R_0(J)$ and ${}^{R}P_0(J)$ transitions go to the A- levels, while the ${}^{R}Q_0(J)$ transitions go to the A+ levels.[7,12]

Wavenumbers for the vibration-rotation transitions of CD_3CN were obtained as differences between the perturbed energies in the excited vibrational states and those in the ground vibrational state. These wavenumbers were fitted to the observed wavenumbers by the least-squares adjustment of the spectroscopic parameters. In the calculation, some of the parameters for ν_3 and $\nu_4+\nu_8$ were assumed or set equal to those in the ground state, since pertinent experimental data to fix them were not available in the present work. Approximate values for the band origin of $\nu_4+\nu_8$ and the Fermi resonance parameter W_{468} were predetermined, in advance of the principal calculation, so as to reproduce the observed data most satisfactorily.

The parameters for the ν_6 and ν_3 bands and the interaction parameters were finally determined, as listed in Table 1, from a total of 517 vibration-rotation transition wavenumbers of ${}^{P}P_K(J)$ with $K=1$—16, ${}^{R}R_K(J)$ with $K=0$—15, and ${}^{R}P_0(J)$. The transition lines which were badly overlapped with others were not adopted in the calculation. The parameters in Table 1 reproduce the observed wavenumbers with a root-mean-square error of 0.014 cm^{-1}. A list of the observed transition wavenumbers has been deposited with the Chemical Society of Japan (Document No. 8257).

Results and Discussion

In the present work, the parameters have been

†† In our earlier studies,[6,8] the different notation $A^{\pm}$ has been used; $A^{\pm}=A_{\mp}$.

TABLE 1. PARAMETERS FOR THE ν_6,ν_3, $\nu_4+\nu_8$ AND GROUND VIBRATIONAL STATES OF CD_3CN IN UNITS OF cm^{-1}

Parameter	ν_6	ν_3	$\nu_4+\nu_8$	Ground state
$(\nu_0)_v$	1046.659 (7) [a]	1110.46 (2)	1162 [b]	0

W_{468}	0.91 [b,i]			

a) Standard deviations of the parameters, given in parentheses, apply to the last significant figure. b) Predetermined. c) Ref. 3. d) The value does not involve the contribution of the Coriolis interaction between ν_6 and ν_3. e) Derived from α_4^B and α_8^B (Ref. 16). f) Ref. 10. g) Derived from $\zeta^{(z)}_{8a.8b}$ (Ref. 11). h) Ref. 11. i) This value gives the cubic force constant $\phi_{468}=2\sqrt{2}\,W_{468}=2.6\ cm^{-1}$.

derived for the ν_6 and ν_3 bands along with the parameter of the Coriolis interaction between these vibrational states. The errors in the band origins $(\nu_0)_v$ have been estimated from the uncertainty in the standard wavenumbers[5] used for the calibration, that in the least-squares fitting of the calibration wavenumbers, and that in the least-squares determination of $(\nu_0)_v$.

The values determined in the present analysis for the rotational constants $B_6\equiv B_{v_6=1}$ and $B_3\equiv B_{v_3=1}$ do not involve the contribution of the Coriolis interaction between ν_6 and ν_3, since the perturbed energies for ν_6 and ν_3 were obtained by solving the energy matrix with the off-diagonal terms representing this Coriolis interaction and the diagonal terms representing the unperturbed energies without the contribution of this interaction. The constants α_6^B and α_3^B defined by

$$B_v = B_e - \sum_r \alpha_r^B (v_r + d_r/2), \tag{8}$$

where d_r is the degeneracy of the normal modes, are derived from the values for B_6, B_3, and B_0. The derived values for α_6^B and α_3^B therefore lack the contribution of the above-mentioned Coriolis interaction, and accordingly correspond to the expression for α_r^B in the second-order perturbation theory[13,14]††† with the term containing $\zeta^{(y)}_{3.6a}$ being dropped.

The spectral analysis gave a value for $(A\zeta^{(z)}_{6a.6b})_{v_6=1}$ which shows a vibrational dependence given by[9,15]

$$(A\zeta^{(z)}_{ta.tb})_v = (A\zeta^{(z)}_{ta.tb})_e - \sum_r \alpha_r^{A\zeta_t}(v_r + d_r/2). \tag{9}$$

The constant in the equilibrium state, $(A\zeta^{(z)}_{ta.tb})_e$, is separable into A_e and $\zeta^{(z)}_{ta.tb}$, namely

$$(A\zeta^{(z)}_{ta.tb})_e = A_e\zeta^{(z)}_{ta.tb}. \tag{10}$$

A combination of Eqs. 9 and 10 and an equation for A_v, similar to that for B_v in Eq. 8, gives an explicit relation between the constant $\zeta^{(z)}_{ta.tb}$ and the observable $(A\zeta^{(z)}_{ta.tb})_v$

$$\begin{aligned}\zeta^{(z)}_{ta.tb} &= [(A\zeta^{(z)}_{ta.tb})_v + \sum_r \alpha_r^{A\zeta_t}(v_r+d_r/2)]/A_e \\ &= [(A\zeta^{(z)}_{ta.tb})_v + \sum_r \alpha_r^{A\zeta_t}(v_r+d_r/2)]/ \\ &\quad [A_v + \sum_r \alpha_r^{A}(v_r+d_r/2)].\end{aligned} \tag{11}$$

Since the determination of all of the constants $\alpha_r^{A\zeta_t}$ is practically impossible, a value for the Coriolis constant $\zeta^{(z)}_{ta.tb}$ with physical significance is never derived with a high precision.[9] In order to evaluate an effective value for $\zeta^{(z)}_{ta.tb}$, an approximation

$$(A\zeta^{(z)}_{ta.tb})_v \simeq A_v\zeta^{(z)}_{ta.tb} \tag{12}$$

has been conventionally used.[15] Physical meaning of the value thus derived is ambiguous and the resulting uncertainty in $\zeta^{(z)}_{ta.tb}$ is therefore unestimable. In the present analysis of ν_6 of CD_3CN, an effective value was derived for $\zeta^{(z)}_{6a.6b}$ by using Eq. 12. The value obtained is −0.3827 which may be compared with the value −0.374 calculated from the harmonic force constants.[11] These values agree with each other within 2.3%.

The parameter of the *xy*-type Coriolis interaction between ν_6 and ν_3, $\xi^{(y)}_{3.6}$ given by Eq. 2, involves the Coriolis constant $\zeta^{(y)}_{3.6a}$. This constant is, however, not separable from $\xi^{(y)}_{3.6}$, because the quantity $(B\zeta^{(y)}_{3.6a})$ shows a vibrational dependence as $(A\zeta^{(z)}_{ta.tb})_v$ does (Eq. 9). If an approximation

$$(B\zeta^{(y)}_{3.6a}) \simeq (B_3B_6)^{1/2}\zeta^{(y)}_{3.6a} \tag{13}$$

is made, an effective value for $\zeta^{(y)}_{3.6a}$ may be obtained from the $\xi^{(y)}_{3.6}$ value which was given by the spectral analysis. In doing this, the harmonic vibrational wavenumbers ω_6 and ω_3 are required, which are, in general, not easily derived. If, alternatively, the fundamental wavenumbers, not corrected for the vibrational anharmonicity, $(\nu_0)_6$ and $(\nu_0)_3$ are used for ω_6 and ω_3, possible errors may be involved in the derived value for $\zeta^{(y)}_{3.6a}$. To test the possibility of using the fundamental wavenumbers instead of the harmonic wavenumbers, calculations were made with Eq. 13 in two ways. The use of $(\nu_0)_6$ and $(\nu_0)_3$ determined in this work gave $|\zeta^{(y)}_{3.6a}|=0.505$, while the use of the harmonic wavenumbers,[11] $\omega_6=1061.7$ and $\omega_3=1128.0\ cm^{-1}$, ob-

††† In Ref. 14, there is a typographic error; for 4/3 in the second term of the right side of Eq. 5, read 3/4.

tained by correcting for the anharmonicity by Dennison's rule, gave $|\zeta^{(y)}_{3.6a}|=0.513$. The difference between the two values is 1.5%. These values may be compared with 0.493 calculated from the harmonic force constants.[11] The experimentally derived values (0.505 and 0.513) are larger than the calculated one by 2 and 4%, respectively.

The l-doubling constant $q_6^{(+)}$ determined by the present analysis method does not have, similarly to α_6^B and α_3^B, the contribution of the Coriolis interaction between ν_6 and ν_3. The value obtained is thus explained by the second-order perturbation expression[12,14] for $q_6^{(+)}$ less the term containing $\zeta^{(y)}_{3.6a}$. Strictly speaking, the constant $q_t^{(+)}$ should show a vibrational dependence.[9] However, an estimation of its effect is practically quite difficult.

As seen from Eqs. 6 and 7, the effective rotational constant, not perturbed by the Coriolis and the Fermi interactions, for the $Kl_6=1$ levels of ν_6 is given by

$$B^0_{eff} = B_6 + q_6^{(+)}/2 \text{ for } {}^{R}R_0(J) \text{ and } {}^{R}P_0(J) \text{ transitions} \quad (14a)$$

$$B^0_{eff} = B_6 - q_6^{(+)}/2 \text{ for } {}^{R}Q_0(J) \text{ transitions,} \quad (14b)$$

B^0_{eff} being the coefficient of $J(J+1)$ in the diagonal term of Eqs. 6 and 7 representing the $v_6=1$, $l_6=1$, $J,K=1$ state. The effective rotational constant B'_{eff} for $K'l'=1$, as given in Fig. 3, was derived from the ${}^{R}R_0(J)$ and ${}^{R}P_0(J)$ transitions. The value thus obtained involves the contributions of the l-doubling interaction mentioned above and the Coriolis interaction between ν_6 and ν_3. The smaller value for $K'l'=1$, as compared with those for the neighboring $K'l'$ values, is explained as follows. Although the l-doubling interaction with a positive $q_6^{(+)}$ value shifts up the energy levels associated with the ${}^{R}R_0(J)$ and ${}^{R}P_0(J)$ transitions (Eq. 14a), its effect is overwhelmed by the more dominant Coriolis interaction which shifts down the levels for $K'l'=1$ more largely than those for the neighboring $K'l'$ values (Eqs. 5 and 6). The constant B'_{eff}, if derived from the ${}^{R}Q_0(J)$ transitions, would be larger than that for the neighboring $K'l'$ values, since the levels associated with the ${}^{R}Q_0(J)$ transitions are completely free from the xy-type Coriolis interaction (Eq. 7), although the l-doubling interaction slightly shifts down the energy levels. The spectral observation in Fig. 1 that the contour of the ${}^{R}Q_0$ branch degrades to the higher wavenumber side, unlike the neighboring Q branches with sharper contours, is consistent with the expected B'_{eff} value.

The parameters $(\nu_0)_6 \equiv (\nu_0)_{v_6=1}$, $(\nu_0)_3 \equiv (\nu_0)_{v_3=1}$, α_6^A, α_3^A, α_6^B, α_3^B, $q_6^{(+)}$, $\zeta^{(z)}_{6a.6b}$, and $\zeta^{(y)}_{3.6a}$, determined explicitly or derived on assumptions in the present study are summarized in Table 2 in comparison with those reported previously. It is clearly shown that the precision of the parameters has been largely improved owing to the higher spectral resolution and the more legitimate procedure of the analysis in the present work. It should be noted, however, that the parameters for ν_3 were determined from the ν_6 transition lines through the Coriolis resonance between ν_3 ffnd ν_6. The transition lines associated intrinsically with ν_3 were not definitely identified because of their weak intensities.

The microwave spectra of CD_3CN in the excited vibrational states have been reported by Matsumura *et al.*[16] The observed spectral lines were complicated and they did not make definite assignments of the transitions for the ν_6 and ν_3 states. We therefore refrain from further discussion on their spectroscopic data.

Table 2. Comparison of the parameters for the ν_6 and ν_3 states[a]

Parameter	Present work	Previous works	
		Masri *et al.*[b]	Kondo and Person[c]

(Received November 4, 1981)

An X-ray diffraction study of the title complex has been carried out. The crystal is monoclinic, with the space group $P2_1$; $Z=2$; $a=8.196(4)$, $b=7.275(3)$, $c=7.740(4)$ Å, $\beta=103.73(4)°$. Full-matrix least-squares refinements have led to the final R value of 0.030. The structure consists of one-dimensional polymers bridged by chlorine atoms and a carboxyl group. Four chlorine atoms coordinate to a cadmium atom and form a square plane. The planes extend in the direction of the b axis like an infinite folding screen, sharing opposite edges. From the trough positions in the zigzag structure, the carboxyl oxygen atoms of 4-hydroxy-L-proline coordinate forkedly to two cadmium atoms. The ligand is a zwitter ion in the complex.

Amino acids such as 4-hydroxy-L-proline (Hhpro) and proline are important to biochemists who investigate the constitution and configuration of proteins. The crystal structure of Hhpro has been determined by Donohue and Trueblood[1] and by Koetzele *et al.*[2]

There are few studies, however, about metal complexes with Hhpro. In this work a cadmium complex with Hhpro was prepared. Its crystal and molecular structure was determined in order to investigate how Hhpro coordinates to the metal.

Experimental

Preparation of Dichloro(4-hydroxy-L-proline)cadmium(II); $CdCl_2$-(Hhpro). To an aqueous solution of 2.62 g (0.02 mol) of Hhpro, 4.57 g (0.02 mol) of $CdCl_2 \cdot 2.5H_2O$ was added. Then the solution (pH 3.7) was stirred for several hours on a water bath at 60—70 °C. Clear colorless prisms were obtained by standing at room temperature; they were dried *in vacuo* at 50 °C for several hours.

Found: C, 19.08; H, 2.86; N, 4.49; Cl, 22.40; Cd, 35.9%. Calcd for $CdCl_2(C_5H_9NO_3)$: C, 19.10; H, 2.88; N, 4.45; Cl, 22.55; Cd 35.75%.

X-Ray Measurements. The crystal data are given in Table 1.

The reflections were collected by the θ-2θ scan technique ($2\theta \leqq 70°$) on a Philips PW 1100 automated four-circle diffractometer. The 1990 independent reflections with $|F_o| \geqq 3\sigma(|F_o|)$ were used for the structure refinement. The intensities were corrected for Lorentz and polarization factors, but no correction was made for the absorption because of the low magnitude of $\mu r(=0.42)$. All the calculations were carried out on a HITAC M-200H computer at the Computer Center of the University of Tokyo, using the local versions of UNICS[3] and LINUS.[4] The atomic scattering factors were taken from tables.[5]

Structure Determination. The structure was solved by a heavy-atom method. The positions of the cadmium atom and chlorine atoms were obtained from a three-dimensional Patterson function, while the positions of all the other non-hydrogen atoms were successively located by Fourier syntheses. Since the positions of few hydrogen atoms were obtained by a difference Fourier syntheses, all of the positions were calculated and fixed. Their isotropic temperature factors were all assumed to be 5.0 Å^2. Since the absolute configuration of Hhpro was known, the structure analysis was based on the configuration.

Table 1. CRYSTAL DATA

$CdCl_2(C_5H_9NO_3)$	F.W.=314.44
Monoclinic	Space group $P2_1$
$a=8.196(4)$ Å	
$b=7.275(3)$ Å	$\beta=103.73(4)°$
$c=7.740(4)$ Å	
$Z=2$	$U=448.3(4)$Å^3
$D_m=2.35$ g cm^{-3}	$D_x=2.33$ g cm^{-3}
μ(Mo $K\alpha$)=29.7 cm^{-1}	

The crystal used for data collection showed quite severe extinction, and full-matrix least-squares refinements including an extinction correction were carried out, using LINUS. The weighting scheme was $W=1/[\{\sigma(|F_o|)\}^2+(0.06\times|F_o|)^2]$.

In the last cycle of the refinement with anisotropic temperature factors for all non-hydrogen atoms, all the parameter shifts were less than one-third of the corresponding standard deviations. The final R value ($R=\sum||F_o|-|F_c||/\sum|F_o|$) was 0.030.

IR Measurements. The infrared spectra of the samples were obtained by means of a Hitachi EPI-G2 type infrared spectrophotometer, using Nujol mull and KBr pellets.

Results and Discussion

The final atomic parameters are listed in Table 2,[6] the interatomic distances in Table 3, and the bond angles in Table 4. The perspective drawing of the complex and the numbering scheme of atoms are shown in Fig. 1.

The complex has the structure of a one-dimensional polymer bridged by chlorine atoms and carboxyl oxygen atoms as shown in Fig. 2. Four chlorine atoms coordinate to a cadmium atom and form a square plane within 0.002 Å. The cadmium atom deviates 0.04 Å from the plane. The planes extend zigzag in the direction of the b axis like an infinite folding screen, sharing opposite edges. The dihedral angle between adjacent planes is 142°. From the trough positions in the zigzag folding structure the carboxyl oxygen atoms of Hhpro coordinate forkedly to two cadmium atoms. Therefore the cadmium atom has octahedral coordination.

The bond distances of the coordinating Hhpro are not so different from those of the free molecule. The interatomic distance between N and O(2) is rather short, 2.62 Å. Koetzele *et al.*[2] carried out a neutron diffraction study of Hhpro. Their results also show

TABLE 2. FINAL POSITIONAL PARAMETERS ($\times 10^4$ FOR NON-HYDROGEN ATOMS; $\times 10^3$ FOR HYDROGEN ATOMS) AND EQUIVALENT ISOTROPIC TEMPERATURE FACTORS (B_{eq}/Å^2), WITH THE ESTIMATED STANDARD DEVIATIONS

that the nitrogen atom in the pyrrolidine ring is close to the carboxyl oxygen atom. They have reported that

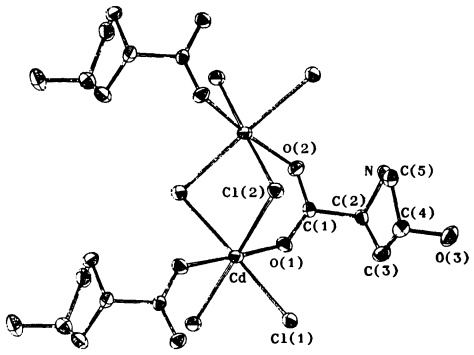

Fig. 1. The perspective drawing of $CdCl_2$(Hhpro) and the numbering scheme of non-hydrogen atoms.

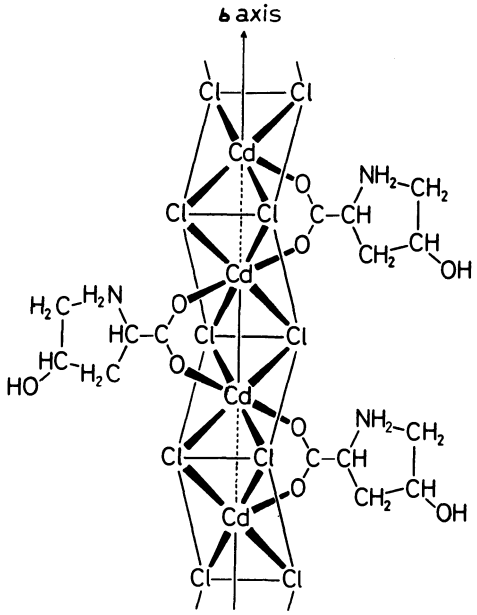

Fig. 2. The sketch of the structure.

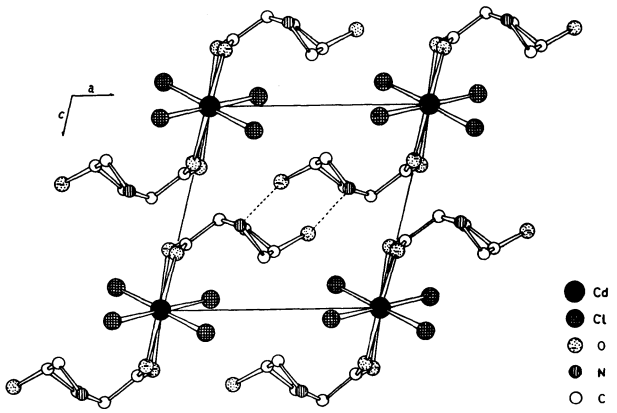

Fig. 3. The projection of the structure along the b axis. ------: Hydrogen bonding.

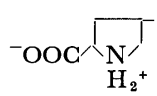
an unusual intramolecular hydrogen bond exists between these atoms: this intramolecular hydrogen bond remains after the coordination to cadmium atoms.

In the free molecule the four atoms of a pyrrolidine ring are nearly coplanar, except for the carbon atom carrying a hydroxyl group. On coordination, however, the pyrrolidine ring is bent on the line from N to C(3)

and C(4) and C(5) atoms deviate from the best-plane of the pyrrolidine ring. Some bond angles, N-C(2)-C(3), N-C(2)-C(1) and C(2)-N-C(5), are smaller than those of the free molecule, and other angles, C(1)-C(2)-C(3) and C(3)-C(4)-C(5), are larger.

The projection along the b axis is given in Fig. 3. The zigzag folding screen is parallel to the b axis with the cadmium atoms lying on the corners and on the middle of the b axis of the unit cell. It is connected with the neighboring one by hydrogen bonds between the nitrogen atom in the pyrrolidine ring and the hydroxyl oxygen atom, as indicated with broken lines in Fig. 3. Thus, a sheet forms parallel to the (101) plane. The whole structure is made up of these sheets, stacked together, only with van der Waals' contacts.

There are a few infinite folding screen structures: $CuCl_2$(1,2,4-triazole),[7] $Cu(benzoato)_2 \cdot 3H_2O$,[8] $CuCl_2$-(*N*-nitrosodimethylamine).[9] Each ligand of these complexes has two adjacent atoms which coordinate to form the structure favorably. In the case of Hhpro there is the nitrogen atom of pyrrolidine ring as a coordinating atom besides the carboxyl oxygen atoms. In general both of them coordinate to a metal, but only carboxyl group coordinates to cadmium atoms in $CdCl_2$(Hhpro). Since the preparation conditions of the complex were at rather low pH, the Hhpro behaves as a zwitter ion,



and the nitrogen atom will not be able to coordinate to a cadmium atom. This suggestion was confirmed by infrared spectra.

The infrared spectra of the free ligand, the deuterated ligand, $CdCl_2$(Hhpro), and the deuterated complex are shown in Fig. 4. The deuterated compounds were obtained by recrystallization from 99.75% D_2O. It has been established that the free ligand molecule is a zwitter ion, and the peaks in the region above 3000 cm^{-1} shift, by deuteration, from 2500 cm^{-1} to 2000 cm^{-1}. These peaks are assigned to an OH stretching vibration and to NH stretching vibrations.[10] The peaks at 1637 cm^{-1} and 1429 cm^{-1} shift to 1133 cm^{-1} and 993 cm^{-1}, respectively. In $CdCl_2$(Hhpro), similarly, the peaks in the region above 3000 cm^{-1} shift from 2500 cm^{-1} to 2250 cm^{-1} (the peak at 3475 cm^{-1} is assigned to an OH stretching vibration, and the others are NH stretching vibrations[11,12]), and the peaks at 1532 cm^{-1} and 1360 cm^{-1} shift to 1145 cm^{-1} and 1000 cm^{-1}, by deuteration respectively. If the ligand in $CdCl_2$(Hhpro) contained NH instead of NH_2^+, only one bending vibration should be observed. Since two corresponding peaks of NH bending vibrations are observed, the ligand can be regarded as a zwitter ion.

The characterization study of some metal complexes with Hhpro has been carried out in our group and will be published soon.

The authors wish to express their thanks to Professor Yoichi Iitaka for the X-ray diffractometer measurements, and to Dr. Shoichi Sato, The University of Tokyo for the helpful discussions. They would also like to thank Dr. F. S. Howell of Sophia University for correcting this manuscript. The present work was partially supported by a Grant-in-Aid for Scientific Research No. 547045 from the Ministry of Education, Science and Culture.

Intercalation Compounds of FeOCl. Systematics of Amine Containing Lewis Base Intercalants

Yonezo MAEDA,* Miyako YAMASHITA, Hiroki OHSHIO,
Naoto TSUTSUMI, and Yoshimasa TAKASHIMA
Department of Chemistry, Faculty of Science, Kyushu University 33, Hakozaki, Higashi-ku, Fukuoka 812
(Received December 7, 1981)

New intercalated compounds of FeOCl and aniline derivatives were synthesized by soaking FeOCl in ethanol solution containing Lewis base intercalants. Only those Lewis base intercalants whose acid-dissociation constant is greater than 5 intercalate into the lattice of FeOCl. The acid-strength of the solvent is important for the formation of an intercalation compound. The intercalates of iron(III) chloride oxide $FeOCl(G)_{1/n}$ have been characterized by elemental analysis, powder pattern of X-ray diffraction, Fe-57 Mössbauer and infrared spectroscopies. The research on expansion of the b-axis of the unit cell and IR data confirm the location of the "guest" molecule within the van der Waals layer or the FeOCl lattice. Effective vibrating mass and lattice temperature derived from the Mössbauer spectra are affected by chemical bonding in the first coordination sphere of the iron atom.

Iron(III) chloride oxide (host matrix) is a layered compound whose crystal structure consists of a stack of double sheets of *cis*-$FeCl_2O_4$ octahedra, linked together with shared edges.[1] The length of the crystallographic b axis (c<a<b) perpendicular to the van der Waals plane (chlorine atom planes) increases along with the progress of intercalation. It has been shown recently that layered FeOCl reacts chemically with ammonia,[2] pyridine,[3,4] pyridine derivatives,[5] and phosphine[6] to give intercalated products.

It is not possible at present to predict whether a particular guest molecule will be able to intercalate or not into the FeOCl lattice. This is due to deficient knowledge of the intercalation of host lattice/guest species and of the influence of kinetics on solid state reactions. Lewis base (guest molecule) aniline does not intercalate into the layered plane of the van der Waals bonding. However, some derivatives of aniline have been found to intercalate into this plane in the present study. Our investigation indicates that a large number of layered compounds form intercalates when treated with Lewis bases of $pK_a>5$ and that the rate of the intercalation depends upon acid-strength of the solvent used.

The present study was also undertaken to examine the interlayer spacing and hence the molecular packing, the hyperfine interactions, lattice dynamics and vibrational spectra of the intercalate system.

Experimental

Sample Preparation. Iron(III) chloride oxide was prepared from Fe_2O_3 and $FeCl_3$ by the usual sealed tube technique discussed in the literature,[7] and was characterized by colorimetric iron determination and X-ray powder patterns. The intercalates listed in Table 1 were obtained by soaking FeOCl in the Lewis base or in the base dissolved in a dehydrated solvent. The experimental conditions for preparation of the compounds and analytical data are summarized in Tables 1 and 2. The stoichiometry was obtained by calculating iron and carbon contents. The progress of the intercalation was followed by X-ray observation of decay in the strongest (010) plane of FeOCl. At the end of the reaction period, the reaction mixture was filtered through sintered glass, the solid product was washed with absolute alcohol, dried *in vacuo*, and stored under nitrogen. The solvents used were dehydrated to avoid the influence of water. The reflection lines due to the (010) and (020) planes of the intercalates were used to calculate the length of the b-axis of the unit cell. The b-axis parameters are listed in Table 1.

Spectroscopy. Mössbauer measurements were carried out with an Austin Science Associates(ASA) spectrometer. The Iron-57 Mössbauer spectra of a powdered thin sample of the compound were recorded between 80 and 300 K using an ASA cryostat. A cobalt-57 source diffused into palladium foil was used. The isomer shift, δ_{Fe} was measured relative to the center of the spectrum of an iron foil enriched with iron-57 at 296 K, which was also used as a standard material for the velocity calibration. Calculation of Mössbauer spectroscopic

data was effected using the least squares method at the Computer Center, Kyushu University. The infrared spectra of the samples in the potassium bromide region (650—4000 cm^{-1}) were obtained using a Hitachi Grating Infrared Spectrophotometer, type 215. X-Ray powder diffraction patterns of the samples were observed using a Rigakudenki Geigerflex Diffractrometer model DF.

Results and Discussion

Lattice Parameter of Intercalated FeOCl. The b-axis parameters of intercalated FeOCl are listed in Table 1 for compounds which attained a reproducible limiting composition. The X-ray powder pattern can be understood on the basis of an expansion of every layer ("stage 1" compound) in the direction of the b-axis of the unit cell. The powder X-ray diffraction patterns of the FeOCl intercalation compounds are usually dominated by (010) and (020) lines. The diffraction lines in a- and c-axis of the unit cell cannot be observed. However, they are assumed not to be significantly different from those in FeOCl pyridine intercalated compounds except that the b-axis parameter has variable values.[3,4] There are several possible orientations which a non-cubic symmetry guest molecule can adopt with respect to the van der Waals planes. In particular, it is interesting to ascertain the orientation of the nitrogen lone pair electrons with respect to the van der Waals plane. The b-axis parameter of 7.91 Å for FeOCl becomes about 13—14 Å for aniline derivatives and for *p*-aminodiphenylamine intercalates whose values are nearly equivalent to 13.27 Å for $FeOCl(pyridine)_{1/3}$. On the other hand, the b-axis parameter for 8-aminoquinoline intercalation is 15.54 Å. The value of 15.54 Å is the maximum in FeOCl intercalated compounds and the interlayer spacing of this compound is calculated to be 7.63 Å. Several structural models are proposed in Fig. 1 to account for the orientation of the Lewis bases, guest molecules in the FeOCl lattice. Substituting the hydrogen in the 4-position of a phenyl ring with a bulky group brings about lower content of the guest molecule with no increase in the b-axis parameter. This phenomena can be understood with model (a) of Fig. 1, which shows the orientation of Lewis bases in the FeOCl lattice.

The powder X-ray diffraction pattern for $FeOCl(p\text{-phenylenediamine})_{1/9}$ suggests that there are two orientations for the guest molecule in this sample, as shown in Fig. 1(b). The superhyperfine pattern could not be observed in the X-ray and electron diffraction patterns. However, it seems reasonable to infer that the presence of the two b-axis parameters is due to the superlattice structure as shown in Fig. 1(b), rather than due to a mixture of the 13.61 Å b-axis parameter sample with the 11.42 Å b-axis parameter sample, although we do not have any evidence for this. The larger b-axis parameter (13.61 Å) is in the same range as that for the FeOCl intercalation compound of aniline derivatives. The interlayer spacing parameter of 3.51 Å is calculated for the part with b-axis parameter of 11.42 Å. In the case of $FeOCl(NH_3)_{3/4}$ an increase of 3.42 Å in the direction of the b-axis of a unit cell has been observed.[2,4] The thickness of the plane of a phenyl ring is assumed to be about 2.0 Å. Accordingly the b-axis expansion of 3.51 Å in this compound would account for an orientation such that the phenyl plane of *p*-phenylenediamine is parallel to the van der Waals plane.

Acid-dissociation Constant and the Rate of Intercalation. All the values of the acid-dissociation constants, pK_a, of the guest molecule listed in Table 1 are larger than 5. The substituted aniline derivatives which could not

intercalate into the FeOCl lattice are *p*-nitroaniline ($pK_a=1.0$), *p*-chloroaniline ($pK_a=4.0$), aniline-4-sulphonic acid ($pK_a=3.2$), and aniline ($pK_a=4.6$). It can be inferred that a neccesary (but not sufficient) condition for forming the FeOCl intercalation of these molecules under the conditions discussed above is that pK_a of guest molecule must be larger than 5. The analogous phenomena have been observed in pyridine intercalation of FeOCl[4] and TaS_2.[8] Table 3 shows the physical properties of various solvents and the relative rate of the intercalation when FeOCl(*p*-methylaniline)$_{1/12}$ is prepared in these solvents. The rate of the intercalation examined in this study depends upon the acid-strength of the solvents, as have been reported by Gerrard and Macklen.[9] The order of acid-strength is ethylene glycol≫methanol>water>ethanol >1-butanol>2-propanol. However, we must take into consideration the dielectric constant of the solvents because there are not such great differences in the pK_a values of the solvents examined; it is reasonable to consider that van der Waals bonding in liquid-solid systems may depend upon the dielectric constant of the solvent. Thus the Lewis base *p*-methylaniline could not intercalate into FeOCl lattice in a solvent of acetone, benzene, chloroform, dichloromethane, isopentyl alcohol, hexane, nitrobenzene, nitromethane, pentane, tetrahydrofuran, toluene, or trichloroethylene.

Mössbauer Spectra and Lattice Dynamics. The X-ray powder pattern can be understood as showing the formation of a "stage 1" compound in which every van der Waals layer includes an array of "guest" molecules. All the Mössbauer spectra were doublets, although the stoichiometry of the intercalation compounds examined in this study shows that not all of the iron atoms in FeOCl(G)$_{1/n}$ are structurally identical. The Mössbauer parameters for the FeOCl intercalates are summarized in Table 4. Full width at half-maximum (0.32—0.40 mm s^{-1}) is somewhat larger than natural line width. The full width at half-maximum of FeOCl(*p*-phenylenediamine)$_{1/9}$ is in the same range as that for other intercalates, which supports the view that all iron atoms of FeOCl(*p*-phenylenediamine)$_{1/9}$ are situated in the same coordination sphere, that is, in the structure of a mixed phase as shown in Fig. 1(b).

Mössbauer spectra for selected samples were measured at various temperatures to calculate the effective vibration mass and "lattice temperature" for the intercalation compounds. Using a Debye model for the solid, and assuming that the appropriate mass of the probe atom corresponds to the free-atom value, leads to a temperature dependence of the recoil-free fraction f, given by[10]

$$\mathrm{d}\ln f/\mathrm{d}T = -6E_R/k_B\theta_M^2 \quad (1)$$

in which E_R is the recoil energy after gamma ray emission and k_B is Boltzmann's constant. At temperatures well above the magnetic ordering temperature, the temperature dependence of the area under the resonance curve can be used to estimate a "lattice temperature," θ_M' based on the thermal motion of the Mössbauer active atom. In the case of ^{57}Fe Mössbauer data, two "lattice temperatures" can be calculated from the temperature dependence of the area under the resonance curve. In Eq. 1 $\mathrm{d}\ln f/\mathrm{d}T$ can be replaced for a thin absorber by the $\mathrm{d}\ln A/\mathrm{d}T$ (the temperature dependence of the area under the resonance curve) to yield the following relationship

$$\theta_M = \frac{E_\gamma}{C}\left[\frac{-3}{M_{eff}k_B\mathrm{d}\ln[A(T)/A(80)]/\mathrm{d}T}\right]^{1/2} = 11.659\left[\frac{-\mathrm{d}\ln(A(T)/A(80))}{\mathrm{d}T}\right]^{-1/2}. \quad (2)$$

A limitation of this approach is that when the Mössbauer active atom is incorporated in the solid by largely covalent bonding forces, the appropriate mass needed to describe its motion may be significantly larger than the atomic mass. The effective vibrating mass can frequently be estimated from the second order Doppler

a) Effective vibrating mass. b) Lattice temperature. c) Modified lattice temperature. d) This value is not calculated because plots of ln $(A(T)/A(80))$ show a linear curve only above 250 K.

shift, as follows:

$$M_{eff} = -4.168 \times 10^{-2}[d(IS)/dT]^{-1}. \quad (3)$$

Using this value for M_{eff} in Eq. 2, a modified "lattice temperature" θ'_M is calculated as follows:

$$\theta'_M = 4.3202 \times 10^2 \left[\frac{d(IS)/dT}{d\ln(A(T)/A(80))/dT}\right]^{1/2}. \quad (4)$$

Figures 2 and 3 show the temperature dependence of the ln $(A(T)/A(80))$ and isomer shift for FeOCl(8-aminoquinoline)$_{1/5}$, respectively. Linear regressions for both parameters were obtained above 150 K. The temperature ranges (T_{range}) for each sample in which a linear regression is maintained are listed in Table 5. The Mössbauer spectra become highly complex below 120 K because the magnetic ordering temperature of the intercalation compounds is about 120 K but is not sharply defined.

FeOCl (*N,N*-dimethylaniline)$_{1/9}$ does not give a linear curve for the temperature dependence of ln A because of the interference of the magnetic hyperfine structure at low temperature (<250 K). It is well known that a solution of *N,N*-dimethylaniline products triphenylmethane dye in the presence of an iron ion. A deep blue color appears in the process of preparing FeOCl-(*N,N*-dimethylaniline)$_{1/9}$ and letting the solution stand overnight brings about decomposition of the intercalation compound. This observation suggests that FeOCl-(*N,N*-dimethylaniline)$_{1/9}$ may not be pure material although no other peaks except those due to the intercalates are observed in X-ray powder pattern.

The fact that $\theta_M/\theta'_M > 1$, as understood from Table 5, leads to the conclusion that M_{eff} is substantially larger than the free-atom value in consonance with covalency of the iron atom bonding in the matrix. However, the concomitant b-axis expansion of the unit cell does not significantly affect the effective mass and "lattice temperature." Therefore, the significance of these data lies in the conclusion that M_{eff} and θ_M are significantly affected by the chemical bonding in the first coordination sphere of iron atoms.

The temperature dependence of the quadrupole splitting parameter for FeOCl (1.0×10^{-4} mm s^{-1} deg^{-1})[4)] is very small as shown in Fig. 4. However, most of the FeOCl intercalates examined in the present study show sigmoidal temperature dependence in the quadrupole hyperfine interaction. The value of the quadrupole hyperfine interaction in the intercalates is larger than that observed for FeOCl at low temperature and decreases at high temperatures, as listed in

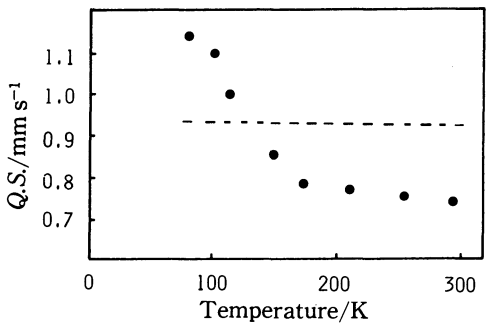

Fig. 4. Temperature dependence of the *Q.S.* parameter for FeOCl(8-aminoquinoline)$_{1/5}$. The dashed line represents the comparison data for unintercalated FeOCl over the same temperature range.

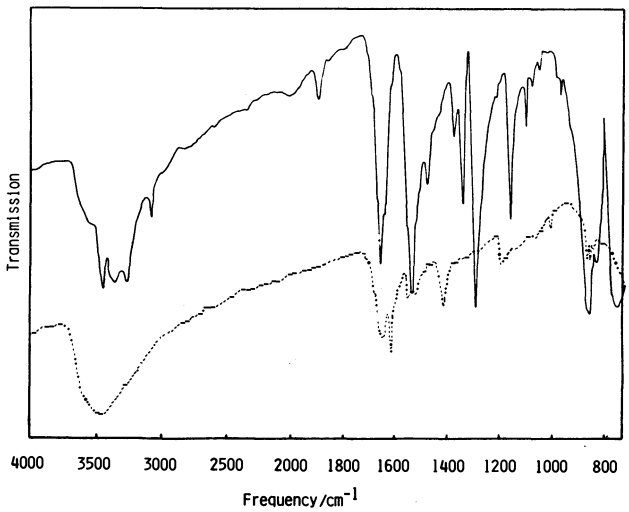

Fig. 5. Infrared spectra of FeOCl(*p*-phenylenediamine)$_{1/9}$ (dotted curve) and *p*-phenylenediamine (full curve).

Table 4.

Infrared Spectra. Some of the IR spectra of the FeOCl intercalates are shown in Figs. 5—8. The FeOCl matrix has absorptions at the bands 1640 (s) and 1400—1500(w) cm^{-1}. Most notable in a comparison between the FeOCl and the intercalation compounds are the facts that the out-of-plane bending modes of phenyl (700—800 cm^{-1}) are clearly noted in the intercalation compounds and that the ring expansion modes between 960—1200 cm^{-1} are strongly suppressed in the intercalate spectra. These observations indicate that the orientation of the aniline derivatives molecule is such that the plane of the aniline ring is perpendicular to the van der Waals layer, except in the case of FeOCl (*p*-phenylenediamine)$_{1/9}$.

In the IR spectrum of FeOCl (*p*-phenylenediamine)$_{1/9}$ the strong C–N stretching band at 1275 cm^{-1} (unintercalate base) is strongly suppressed as shown in Fig. 5. The bands at 1320 and 1352 cm^{-1} of phenyl origin are shifted to 1398 cm^{-1} or suppressed in the intercalation. The band at 1140 cm^{-1} is shifted to 1178 cm^{-1} in the intercalate. The ring expansion bands in plane (960—1200 cm^{-1}) are observed and a new sharp band appears at 1600 cm^{-1} in the intercalate. The IR

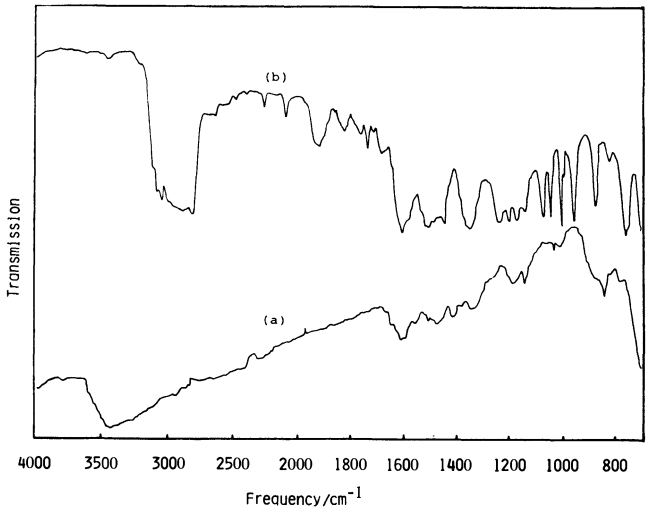

Fig. 6. Infrared spectra of FeOCl(N,N-dimethylaniline)$_{1/9}$ (a) N,N-dimethylaniline (b).

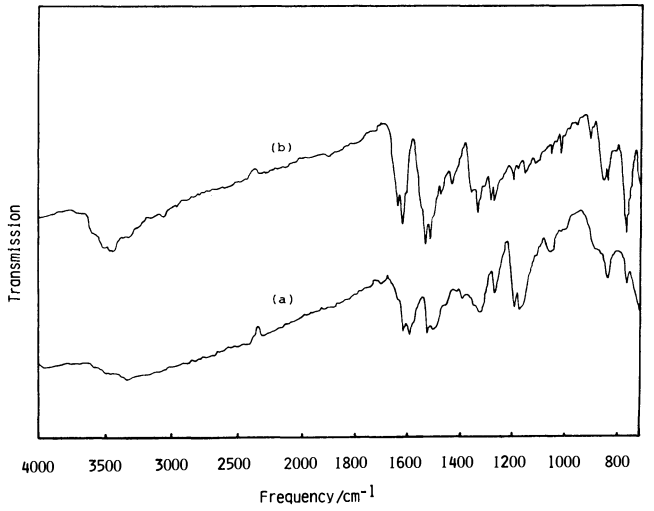

Fig. 7. Infrared spectra of FeOCl(p-aminodiphenylamine)$_{1/15}$ (a) and p-aminodiphenylamine (b).

spectrum of FeOCl (N,N-dimethylaniline)$_{1/9}$ in a KBr matrix is shown in Fig. 6. The symmetric stretching band of C–H in the methyl group at about 2814 cm^{-1} in the unintercalated base, the methyl group asymmetric deformation observed at 1459 cm^{-1} (liquid) and the ring expansion band in the plane between 1200 and 960 cm^{-1} (unintercalate) are not observed in the intercalate. Figure 7 shows the IR spectrum of FeOCl-(p-aminodiphenylamine)$_{1/15}$ in which new bands appear at 1580(s), 1180(s), 1160(s), and 1040(m) cm^{-1} The absorption due to tertiary amine at 1515 cm^{-1} (unintercalate base) is observed at the same position. Most of the bands of the base are observed in the intercalate, although the band at 750 cm^{-1} becomes weak in the intercalate. In the IR spectrum of FeOCl(p-aminophenol)$_{1/4}$ (Fig. 8) the ring expansion bands at 1100, and 983 cm^{-1} and the band at about 900 cm^{-1} (observed in unintercalate base) are not observed, and the phenyl band at 1490 cm^{-1} becomes weak in the intercalate.

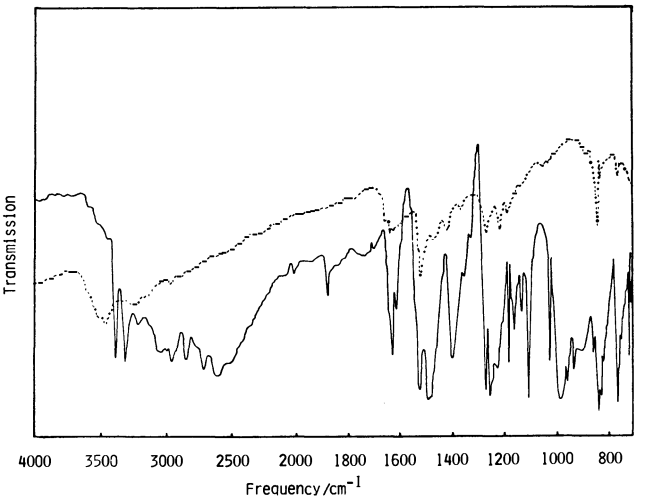

Fig. 8. Infrared spectra of FeOCl(p-aminophenol)$_{1/4}$ (dotted curve) and p-aminophenol (full curve).

It is notable that most of the absorptions observed in unintercalated base are observed in the IR spectrum of FeOCl(p-methoxyaniline)$_{1/6}$, except for the N–H stretching band at about 2900—3000 cm^{-1}. These data reflect a significant non-bonding (Coulomb) interaction between the base and van der Waals chlorine planes. The datum of FeOCl(p-methylaniline)$_{1/12}$ shows that the C–N stretching band of the methyl group is suppressed.

The molecular diameter of an aniline molecule is estimated to be about 4—5.3 Å on the ring plane and the ring thickness to be about 2.0 Å. The observed b-axis expansion of FeOCl intercalation is 5.4—6.5 Å and indicates that the orientation of aniline-derivatives molecule is perpendicular to the van der Waals layer. Within that restriction, two extreme orientations of the intercalant are still possible; an imaginary C_{2v} axis of aniline ring plane is either parallel to or perpendicular to the a direction of the FeOCl lattice. However, no clear-cut distinction between the two orientations can be drawn from the present data alone. The suppression of C–N stretching band supports the view that a lone-pair electron on the nitrogen atom coordinates to the iron atom, *viz.* the coordination structure drawn in Fig. 1.

The Phase Relation of the Titanium-Sulfur System

Masanobu SAEKI* and Mitsuko ONODA
National Institute for Research in Inorganic Materials, 1-1, Namiki, Sakura-mura, Niihari-gun, Ibaraki 305
(Received December 19, 1981)

The phase relation of the titanium–sulfur system was studied in the range from $TiS_{1.38}$ through $TiS_{1.96}$ at 900 °C by the use of the thermobalance method under controlled sulfur pressure. It was found that four phases, (a) Ti_2S_3 (4H) with a short-range ordering of titanium vacancies, (b) the superstructure of Ti_2S_3 (4H) due to the ordering of titanium vacancies, (c) Ti_2S_3 (4H), and (d) TiS_2 (2H), exist in this composition range. The Ti_5S_8 phase of the 12R type reported previously was not detected for any composition.

Several phases have been reported in the TiS–TiS_2 range, namely, TiS (2H), Ti_8S_9 (9R), Ti_4S_5 (10H), Ti_3S_4 (21R), Ti_2S_3 (4H), Ti_5S_8 (12R), and TiS_2 (2H).[1] (The structure designations in the Ramsdell notation are given in the parentheses). The structures are based on close-packed sulfur layers; hexagonal close packing for TiS or TiS_2, and more complex stacking sequences for the intermediate phases. Titanium atoms occupy octahedral holes in the sulfur framework. Polytypism was observed by Tronc and Huber[2] in the composition around $TiS_{1.70}$.

In the composition range near $TiS_{1.5}$, the existence of the 4H-type has been reported by Jeannin[3] from his study of the phase relation in the Ti–S system. The structure of this 4H-type was also studied by Wadsley[4] and by Norrby and Franzen;[5] it was described as follows: the stacking sequences of sulfur layers are represented by chchch.., that is, there is alternating cubic and hexagonal close packing. Titanium atoms occupy the octahedral holes fully and partially in the alternating titanium layers. Recently, the existence of two superstructures related to the 4H-type was found, and the atomic arrangements were determined by means of X-ray diffractometry and high-resolution electron microscopy.[6-8] These superstructure arise from the ordered arrangement of titanium vacancies in partially occupied titanium layers and have been designated as the $(4H)_2$ type and the $(4H)_3$ type respectively.

The phase diagram of the Ti–S system has not been established because of the discrepancies between the experimental data reported by different investigators, as has been pointed out by Kjekshus and Pearson,[9] and Jeannin.[10] The reasons for these discrepancies may be as follows: (1) an equilibrium state is difficult to be attained because of the sluggishness of the transformation rate or the existence of an energy subminimum state, or (2) in the previous investigations, studies were performed for quenched specimens. The high-temperature states might not be held through the quenching processes.

In the present work the phase relation was examined by means of a thermobalance method, that is, an *in situ* observation, under a sulfur partial pressure controlled by H_2S–H_2 mixture gas. The aim is to give the phase relation including the superstructure, which has not yet been reported in any phase diagrams in the Ti–S system. Although the P_{S_2}-composition relation was reported by Abendroth and Schleton,[11] their data were not sufficiently accurate for determining the phase relation.

Experimental

The starting materials, Ti_2S_3 and TiS_2, were prepared by the following procedure. A mixture of titanium metal powder (purity 99.0%) and sulfur (purity 99.9999%) was sealed in an evacuated silica tube and heated in an electric furnace. Reaction was allowed to take place for a few days at 350 °C and subsequently at 900 °C. Quenching was made to water.

The chemical compositions of the starting materials were determined by oxidizing them to TiO_2 at 800 °C in air for several hours. The titanium content was calculated from the weight of TiO_2, while the sulfur content was determined by the weight change in converting sulfide to oxide within a reproducibility of $x=\pm0.004$ in TiS_x.

About 2 g of the starting materials, Ti_2S_3 or TiS_2, were placed in a silica crucible and suspended by means of a silica spring balance in an electric furnace, into the bottom of which H_2S–H_2 mixture gas was introduced at the rate of 5.0 $cm^3\ s^{-1}$. To attain an equilibrium at 900 °C, the sample weight was allowed to change as a result of the absoption or libration of sulfur gas. The equilibrium composition was determined by an *in situ* observation, that is, a measurement of the increase or decrease in the length of the silica spring using a cathetometer. The attainment of an equilibrium state was judged by the following conditions: (1) the sample weight does not change with time, and (2) the compositions determined through a sulfurization process of a sulfur-poor material and through a desulfurization of a sulfur-rich material agree with one another in the same atmosphere.

The oxygen and H_2O in the H_2 and H_2S had to be removed, as titanium sulfide is easily oxidized. The oxygen in the H_2 was allowed to react with hydrogen, while the H_2O was eliminated by passing the mixture gas over P_2O_5. If these procedures had not been performed, the TiO_2 would have occured as an impurity. Once produced, TiO_2 could not be sulfurized easily in the H_2S–H_2 atmosphere at 900 °C. In the present work, the production of titanium oxide could be ignored during the experiment, because an identical P_{S_2}-compoistion relation was obtained in repeated equilibrating experiments.

For identification, the powder samples were prepared by heating weighed quantities of titanium and sulfur at 900 °C in evacuated silica tubes, after which they were quenched. The powder X-ray diffraction patterns were taken by the counter-diffractometer method using Ni-filtered Cu $K\alpha$ ration. Electron-diffraction patterns were taken from the crushed particles by means of the 100 kV electron microscope.

●: Ti atoms, □: Ti vacancies.

$TiS_{1.96}$. The P_{S_2}-composition relation determined as described above is shown in Fig. 1. The P_{S_2} value was calculated from the gas-mixing ratio and the reaction temperature by the use of the thermodynamical data listed in the JANAF thermochemical tables.[12] Figure 1 shows that four ranges exist: (a)—$TiS_{1.475}$, (b) $TiS_{1.483}$—$TiS_{1.535}$, (c) $TiS_{1.550}$—$TiS_{1.730}$, and (d) $TiS_{1.810}$—. The details will be presented below.

(a) Phase up to the $TiS_{1.475}$ Composition: The powder X-ray diffraction pattern of the specimen quenched in the $TiS_{1.38}$—$TiS_{1.475}$ range was that of the Ti_2S_3 (4H) type. However, in the electron-diffraction pattern with an incident beam parallel to the c axis, super spots are observed. In order to assign the integral indices, the hexagonal cell constant, *a*, of the supercell was taken to be $\sqrt{3}$ times that of the 4H type. The diffuse-scattering distribution was observed along the super-spot rows in the pattern with an incident beam perpendicular to the c axis. These results suggest that titanium vacancies are in a long-range order state along the a and b axes and in a short-range order state along the c axis. A detailed analysis of the structure is now in progress.

(b) Phase in the $TiS_{1.483}$—$TiS_{1.535}$ Composition Range: The powder X-ray pattern of the quenched specimen at the composition of $TiS_{1.48}$—$TiS_{1.49}$ or $TiS_{1.51}$—$TiS_{1.53}$ was identical with that of the $(4H)_2$-type superstructure reported previously.[6] The quenched specimen at the composition close to $TiS_{1.50}$ exhibit a powder pattern of the $(4H)_3$ type superstructure whose data were also reported.[6] The superstructures, $(4H)_2$ and $(4H)_3$, arise from ordering of titanium atoms and vacancies in the partially occupied titanium layer and the piling up of the ordered-arrangement layers along the c axis. The titanium arrangements in $(4H)_2$ and $(4H)_3$ are shown in Fig. 2.

The P_{S_2}-composition curve in the (b) range in Fig. 1 does not indicate the boundary of the existence range of the two super-structures, $(4H)_2$ and $(4H)_3$. Either of the following two possibilities can be true; (1) Both the $(4H)_2$ and $(4H)_3$ types may appear at 900 °C within the (b) range; The phase boundary between $(4H)_2$ and $(4H)_3$ is not detected because the experimental procedure is insufficiently precise; or (2) only one of the two structures occurs at 900 °C, and the other appears through the quenching process. As it is difficult to decide which case occurs, the tentative designation "$(4H)_{super}$" is used for the phase in the $TiS_{1.483}$—$TiS_{1.535}$ range.

(c) Phase in $TiS_{1.550}$—$TiS_{1.730}$ Composition Range: Judging the result of X-ray and electron diffractometry, the structure of the quenched sample in this range is the same as that of Ti_2S_3 (4H).

(d) Phase in Compositions Richer in Sulfur than $TiS_{1.810}$: The sample richer in sulfur than $TiS_{1.810}$ gave powder patterns of the TiS_2 (2H) type. Because of the limitations in the sulfur partial pressure controlled by an H_2S–H_2 gas method, most of the P_{S_2} values of the TiS_2 phase shown in Fig. 1 were estimated from the total pressure measurement by means of a quartz Bourdon gauge. The details of the method and results were reported in a previous paper.[13]

Determination of the Phase Boundaries of Ti_2S_3 (4H) and TiS_2. The P_{S_2}-composition curve obtained by the sulfurization of Ti_2S_3 (4H) does not agree with that

obtained by the desulfurization of TiS_2 (2H) in the $TiS_{1.730}$—$TiS_{1.810}$ range, as is shown by the dotted lines in Fig. 1. The horizontal part, representing a two-phase region, does not emerge in this range, because the transformation process was so slow that the equilibrium state was not established. The quenched specimens gave the diffraction patterns of the mixture of TiS_2 (2H) and Ti_2S_3 (4H).

In order to estimate the length of time required to attain equilibrium in this range, powder specimens of Ti_2S_3 (4H) and TiS_2 (2H), put on different sides of an inverted U-type evacuated silica tube, were kept at 900 °C for a week. The quenched specimens on both sides differ from each other in composition and structure. Equilibrium was not established even after a week.

As has been described above, the phase boundary of Ti_2S_3 (4H) and TiS_2 (2H) could not be determined through the equilibration process. After the X-ray diffraction patterns were examined in detail, it was found that TiS_2 (2H) began to be formed at $P_{S_2}=0.023$ atm in the sulfurization process, while in the desulfurization process Ti_2S_3 (4H) began to be formed at the identical P_{S_2} value. This P_{S_2} value corresponds to that of the two-phase region, as is shown by the solid line in Fig. 1.

Discussion

The composition range corresponding to (a), (b), and (c) in Fig. 1 was regarded as a homogeneity range of the Ti_2S_3 (4H) phase by the previous researchers. In the present work, four phases, that is, (a) Ti_2S_3 (4H) with a short range order of titanium vacancies, (b) the superstructure of Ti_2S_3 (4H) due to the ordering of titanium vacancies, (c) Ti_2S_3 (4H), and TiS_2 (2H), were found by an *in situ* observation.

From the P_{S_2}-composition curve shown in Fig. 1, Gibbs free energies for the reactions at 900 °C were calculated:

$$TiS_{1.475}(4H) + ((1.483-1.475)/2)\ S_2(g) = TiS_{1.483}((4H)_{super})$$
$$\Delta G^\circ = (1/2)(1.483-1.475)RT \ln P_{S_2} = -600(J/mol)$$

$$Tis_{1.535}((4H)_{super}) + ((1.550-1.535)/2)\ S_2(g) = TiS_{1.550}(4H)$$
$$\Delta G^\circ = (1/2)(1.550-1.535)RT \ln P_{S_2} = -700(J/mol)$$

$$Tis_{1.730}(4H) + (1/2)(1.810-1.730)S_2(g) = TiS_{1.810}(2H)$$
$$\Delta G^\circ = (1/2)(1.810-1.730)RT \ln P_{S_2} = -1500(J/mol)$$

Although the existence of Ti_5S_8 (12R) has been reported in some papers,[3,14,15] it was not detected in the present experiments.

The authors wish to thank Professor Mitsuoki Nakahira of Okayama College of Science and Drs. Motohiko Ishii, Hiroshi Nozaki, and Isao Kawada of our Institute for their helpful discussions.

The Extraction-spectrophotometric Determination of Lead with Bismuthiol II

Kunihiro WATANABE,* Yoshitaka IMAEDA, and Kyōzō KAWAGAKI
Faculty of Science and Technology, Science University of Tokyo, Yamazaki, Noda, Chiba 278
(Received February 4, 1982)

The solvent extraction-spectrophotometric determination of lead(II) with bismuthiol II was conducted in the presence of 1,10-phenanthroline(phen). Lead(II) was quantitatively extracted as ternary complexes into the chloroform phase over the pH range of 3.0—7.0. The composition of the extracted ternary complexes were confirmed to be Pb: bismuthiol II: phen=1 : 2 : 2 or 1 : 2 : 1, depending on the concentration of bismuthiol II added to the aqueous solution. The absorption maximum of the ternary complex (1 : 2 : 2) in chloroform was found to be at 342 nm, with a molar extinction coefficient of 3.5×10^4 dm^3 mol^{-1} cm^{-1}. Under optimum conditions, the absorbance follows Beer's law up to 300 μg of lead in 10 ml of chloroform. The coefficient of the variation was 1.3% for 30 μg of lead. Many elements interfered with the determination of lead(II). However, the interfering ions, with the exception of the indium and bismuth ions, were masked with a potassium cyanide solution. The proposed method was then applied to the determination of lead in standard zinc metals. A good agreement was observed between the results obtained by the proposed method and the standard values of the samples.

Bismuthiol II (3-phenyl-5-mercapt-1,3,4-thiadiazole-2-thione) has been used for the gravimetric determination of various metal ions, and it is well-known to be chelating reagent which is useful for the sensitive colorimetric determination of selenium[1] and tellurium.[2] The determination of lead(II) with bismuthiol II was made by gravimetry.[3,4] The spectrophotometric determination of lead(II) has not, however, been studied because of the insolubility in water of the complexes formed and because it is impossible to extract them into organic solvents.[5] From experiments employing synergistic extraction, we found that the lead–bismuthiol II chelate was extracted into chloroform to form a ternary complex with 1,10-phenanthroline (phen). In the present study, the fundamental conditions for the extraction of lead(II) as the lead–bismuthiol II–phen in chloroform, the composition of the ternary complex, and its application to the determination of lead(II) are discussed. As a result, a highly selective method for the spectrophotometric determination of small amounts of lead(II) has been established and then applied to the determination of lead(II) in zinc metals.

Experimental

Reagents. *A Lead(II) Standard Stock Solution (1.00 mg/ml)*: 0.2500 g of lead metal (Wako Pure Chemicals, 99.99%) was dissolved in a small amount of dilute nitric acid, and the solution was diluted with water in a 250-ml volumetric flask (nitric acid was added to make the final acidity 0.01 mol dm^{-3}). The solution was then diluted as required.

0.1% Phen Solution: 0.1 g of phen (Wako Pure Chemicals) was dissolved with a small amount of ethanol, after which the mixture was diluted to 100 ml with water.

Buffer Solution: An acetate buffer solution was prepared by mixing 0.5 dm^3 of 2 mol dm^{-3} acetic acid with 0.5 dm^3 of 2 mol dm^{-3} sodium acetate.

The other reagents used were all of an analytical reagent grade.

Standard Procedure. An aliquot of a standard lead(II) solution was transferred to a 100-ml beaker, and then the buffer solution and the phen solution were added. After the solution had been diluted to 50 ml with water, the pH of the solution was adjusted with diluted hydrochloric acid or ammonia and a 0.1% bismuthiol II solution was added. The resulting aqueous solution was then transferred into a separatory funnel. The lead complex thus formed was extracted with 10 ml of chloroform by shaking it vigorously for 2 min. After the separation of the mixture into two phases, the organic phase was transferred into a 10-mm quartz cell and the absorbance of the extract at 342 nm or 370 nm wasmeasured against the reagent blank or chloroform.

Results and Discussion

Absorption Spectra. Bismuthiol II reacts with lead(II) to form a pale yellow complex. The absorption spectra of the Pb–bismuthiol II–phen complex and the Pb–bismuthiol II chelate extracted are shown in Fig. 1. The ternary complex has an apparent absorption maximum at 342 nm, whereas the Pb–bismuthiol II chelate gives hardly any absorbance because it is

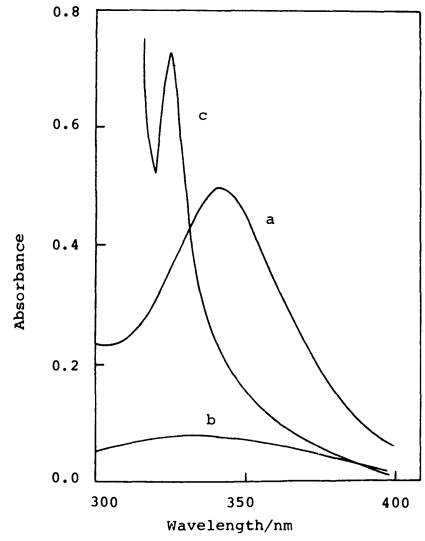

Fig. 1. Absorption spectra.

unextractable into chloroform.

Effect of pH. After the pH of solutions containing 30 μg of lead(II) and 2 ml of a 0.1% phen solution had been controlled to the desired values with aqueous ammonia and hydrochloric acid, 2 ml of a 0.1% bismuthiol II solution was added to the solution and the extraction was carried out by the above procedure. The results are shown in Fig. 2. Since the absorbance of the reagent blank increased remarkably below pH 2.5, the measurement of the absorbance at 342 nm became impossible below pH 2.5; therefore, the absorbance of the organic phase was measured at 370 nm, where the effect of absorption due to the reagent blank was less than at 342 nm. The extraction of the ternary complex starts at pH 0, reaches a maximum at pH 3.0, and thereafter remains constant over the range of pH 3.0—7.0. When a dilute reagent solution (0.2 ml of a 0.1% bismuthiol II solution) and 0.2 ml of 0.1% phen were used to examine the optimum pH over the range of 3.0—7.0, the absorbance of the extract showed a maximum at pH 3.5. All the extraction, however, was carried out at pH 4.0 in consideration of the effect of the reagent blank.

A) Effect of amount of phen: 0.1% bismuthiol II 2 ml, B) effect of amount of bismuthiol II: 0.1% phen 2 ml, Pb: 30 μg, pH: 4.0, wavelength: 342 nm.

Effect of Bismuthiol II and Phen Concentrations. The extraction of lead(II) from aqueous solutions containing bismuthiol II in varying concentrations was examined, the phen concentration (2 ml of a 0.1% solution in 50 ml of an aqueous solution), the amount of lead (30 μg), and other variables being kept constant. The results are shown in Fig. 3. The absorbance of the extract was found to be constant above 2.9×10^{-5} mol dm^{-3} (mole ratio of lead : bismuthiol II = 1 : 10, Curve B). In the same way, the effect of the phen concentration is shown by Curve A, more than three-fold excess of phen over the lead concentration is necessary in order to obtain the maximum absorbance. The absorbance at a mole ratio of zero in Curve A corresponds to that of the binary Pb–bismuthiol II chelate.

Effect of Shaking Time. A 10 ml portion of chloroform was added to a solution containing the ternary complex, and the mixed solution was shaken vigorously. The ternary complex was completely extracted into chloroform by vigorous shaking for 30 s. Shaking for 1 min was found to be satisfactory for complete extraction.

Effect of Standing Time. The absorbance of the ternary complex in a closed quartz cell was measured at 5 min intervals. The absorbance was constant until 30 min, past which it decreased gradually. On the other hand, the absorbance of the ternary complex extracted from an aqueous solution containing 2 ml of 5% ascorbic acid remained unchanged, even after 2 h at room temperature.

Effect of Volume of Aqueous Phase. For the investigation of the effect of the volume of the aqueous solution, the volume of the aqueous phase was changed between 20 and 200 ml, the other factors being kept constant. The absorbance of the extract gradually increased in proportion to the volume of the aqueous phase.

Organic Solvents. Several kinds of organic solvents were tested in order to achieve a quantitative extraction of the lead complex. The ternary complex was extracted only in chloroform, not quantitatively in such solvents as benzene, toluene, xylene, carbon tetrachloride, isobutyl methyl ketone, ethyl acetate, and diisopropyl ether.

Calibration Curve and Molar Extinction Coefficient. A calibration curve for the determination of lead was made under optimum conditions. A good linear relationship was obtained over the concentration range from 3 μg to 300 μg of lead per 10 ml of chloroform. The molar extinction coefficients were 3.52×10^{4} dm^{3} mol^{-1} cm^{-1} (at 342 nm) and 3.72×10^{3} dm^{3} mol^{-1} cm^{-1} (at 400 nm), the sensitivity being 5.9×10^{-3} μg per cm^{2} for an absorbance of 0.001 (at 342 nm). Thirty replicate determinations of a sample solution containing 30 μg of lead(II) gave the coefficient of the variation of 1.3%. The extractability of the lead complex was larger than 99% under optimum conditions.

Composition of the Ternary Complexes. By the use of the equilibrium-shift method, lead: bismuthiol II

was found to be 1 : 2, as is shown in Fig. 4. On the other hand, lead : phen was obtained to be 1 : 1 or 1 : 2, depending on the concentration of bismuthiol II added to the aqueous solution. The 1 : 1 complex was formed in lower concentrations of bismuthiol II (6-fold of the Pb concentration), while the other complex was formed in a higher concentration of the reagent (60-fold) (Fig. 5). A triangular coordinate method extended to the three-component system of the continuous-variation plot was applied to the determination of the ternary complex. The results are shown in Fig. 6. The maximum absorbance is obtained at the mole ratio of lead: bismuthiol II: phen=1 : 2 : 1.

Effects of Diverse Ions and of Masking. The experimental results are summarized in Table 1. Each 10 μg of silver, gold, bismuth, cadmium, cobalt, copper, iron, mercury, indium, nickel, palladium, vanadium, and zinc interferes with the determination of lead. The interference of such ions as silver (up to 10 mg), gold (up to 8 mg), cadmium (up to 1 mg), cobalt (up to 100 μg), copper (up to 10 mg), mercury (up to 1 mg), nickel (up to 10 mg), vanadium (up to 10 mg), iron (up to 20 μg), and zinc (up to 10 mg) can be masked by the use of 20 ml of a 2% potassium cyanide solution. Zinc in the determination of lead in a metal was confirmed to be masked up to 0.5 g with 20 ml of 20%

a) Japanese standard samples (Kagaku Gijutusha Co.).

potassium cyanide. Indium and bismuth were not masked.

Determination of Lead in the Zinc Metal. The proposed method was applied to the analysis of lead in zinc metal. A sample solution was prepared as follows : Take less than 5 g of a sample in a beaker and dissolve the sample with 60 ml of nitric acid (2+1). Then dilute the solution to 100 ml in a volumetric flask.

A 10 ml aliquot (3—300 μg Pb) of this sample solution was taken for analysis, a 20 ml portion of a 20% potassium cyanide solution was used as a masking reagent in a draft chamber, and the pH of the sample solution was adjusted to pH 7. Two ml of a 0.1% phen solution and 2 ml of a 0.1% bismuthiol II solution were used as reagents.

The lead in standard samples of zinc metal was determined by the proposed method. The analytical results are shown in Table 2. Good agreement was observed between results obtained by the proposed method and the standard values of the samples. The present method is rapid and accurate enough for the determination of lead in zinc metal.

Synergistic Effect of Nitrogen Neutral Bases in the Solvent Extraction of Zinc(II) and Cadmium(II) Diphenylcarbazonates

Etsu YAMADA,* Eiichiro NAKAYAMA,† Tooru KUWAMOTO, and Taitiro FUJINAGA

Department of Chemistry, Faculty of Science, Kyoto University, Sakyo-ku, Kyoto 606

†Research Center for Instrumental Analysis, Faculty of Science, Kyoto University, Sakyo-ku, Kyoto 606

(Received February 9, 1982)

The extraction behavior of zinc and cadmium with diphenylcarbazone(DPC) into benzene and chloroform were studied in both the absence and presence of neutral bases(S). In the case of chloroform, all of the neutral bases gave rise to adduct complexes with the formula of $M(DPC)_2S$. On the other hand, in the case of benzene, the adduct complexes can be represented as $M(DPC)_2S$ for all neutral bases except for 1,10-phenanthroline(phen), in which the adduct complexes can be expressed as $M(DPC)_2(phen)_2$. The stability of the adduct complexes is related not only to the basicity of the bases, but also to the steric effect attributable to substitution. Furthermore, the adduct-formation constant increase in the following order against the normalized values of basicity: pyridine bases<2,2′-bipyridyl <1,10-phenanthroline derivatives. This order agrees with the increasing order of the coordinated ability as ligands. The basicity of the bases has a larger effect on the adduct-formation constants for Cd than on those for Zn. This may be attributed to the fact that Zn chelates have greater stability than the Cd chelates, as a result, the "residual Lewis acidity" of Zn is smaller than that of Cd, and therefore zinc chelates form less stable adducts.

In a previous paper by the present authors it has been shown that the cadmium complex of diphenylcarbazone is quantitatively extracted in the presence of 1,10-phenanthroline and that an extract has a higher molar absorptivity than that of diphenylthiocarbazone (dithizone).[1]

Several factors, such as the basicity of the bases and steric considerations, controlling the stability of the adduct complexes, have been investigated by a number of workers in connection with phosphorylated donors or pyridine bases.[2–5] In attempt to establish the relative importance of steric hindrance and other factors in the adduct formation, the present authors decided to study the effects of pyridine bases, and 2,2′-bipyridyl and 1,10-phenanthroline derivatives on the extraction of zinc and cadmium with DPC.

In addition, we investigated the extraction behavior of zinc and cadmium with mixtures of DPC and a neutral base in both solvents, benzene and chloroform, in order to check the solvent effect in this extraction system, which has lately been noted as an interesting problem.[6–8]

Experimental

Apparatus and Reagents. The apparatus and chemicals, such as cadmium, diphenylcarbazone, and 1,10-phenanthroline, used in the extraction have been previously described.[1]

The stock solution of zinc(II) [10^{-2} M (1 M=1 mol dm^{-3})] was prepared by dissolving weighed amounts of zinc chloride in dilute hydrochloric acid and then diluted with distilled water as required. The pyridine was purified by distillation under reduced pressure. All the other neutral bases, such as 2,2-bipyridyl, 2,9-dimethyl-1,10-phenanthroline, 4,7-diphenyl-1,10-phenanthroline, and 4,7-diphenyl-2,9-dimethyl-1,10-phenanthroline, were of an analytical-reagent grade and were used without further purification. All the other chemicals were also of an analytical-reagent grade.

Extraction Procedure. A 20 ml portion of a buffered cadmium or zinc solution (10^{-5} M) and a 20 ml portion of the reagent solution in chloroform or benzene were equilibrated at 25 °C by vigorously shaking for 30 min, a period which was adequate for equilibrium to be attained. The pH value of the aqueous phase after extraction was taken as the equilibrium pH value. After phase separation, the aqueous phase was immediately analyzed with the atomic-absorption spectrophotometer, whereas the organic phase was analyzed after back-extracting into a 0.2 M nitric acid solution.

Isolation of Cd/DPC/Phen Synergistic Complexes. Synergistic complexes were synthesized according to Healy's method.[9] A 250 ml portion of a buffered aqueous solution ($Na_2B_4O_7$–HCl) of 2.5×10^{-3} M cadmium chloride was added to a 250 ml of a chloroform solution of 5×10^{-3} M DPC and 2.5×10^{-3} M 1,10-phenanthroline. The mixture was shaken vigorously for about 20 min, the aqueous phase was removed, and the chloroform solution was dried by the use of anhydrous sodium sulfate and then evaporated with a rotary evaporator. After almost all the chloroform had been evaporated, a red-violet complex was precipitated by the addition of hexane. Further purification was brought about by recrystallization from chloroform. In the case of benzene, a 250 ml portion of a buffered aqueous solution of 2.5×10^{-3} M cadmium chloride was added to a 250 ml portion of a benzene solution of 5×10^{-3} M DPC and 5×10^{-3} M 1,10-phenanthroline. The procedure was also essentially the same as in the case of chloroform. These complexes were dried *in vacuo* at room temperature.

Results and Discussion

Relation of Stability Constants of Base Adducts to the Basicity of Neutral Bases. The equation of the extracted equilibrium of zinc and cadmium with DPC can be represented as follows.

$$M^{2+} + x\mathrm{HDPC}_{(o)} \overset{K_{ex,x}}{\rightleftarrows} M(DPC)_{x(o)} + xH^+, \quad (1)$$

where;

$$K_{ex,x} = \frac{[M(DPC)_x]_0[H^+]^x}{[M^{2+}][HDPC]_0^x} = \frac{D_0[H^+]^x}{[HDPC]_0^x}. \quad (2)$$

When neutral bases(S) are present, the extraction equation can be written as:

$$M^{2+} + x\mathrm{HDPC}_{(o)} + yS_{(o)} \overset{K_{ex,xy}}{\rightleftarrows} M(DPC)_xS_{y(o)} + xH^+. \quad (3)$$

The extraction constant, $K_{ex,xy}$ is given by:

$$K_{ex,xy} = \frac{[M(DPC)_xS_y]_0[H^+]^x}{[M^{2+}][HDPC]_x^0[S]_0^y} = \frac{D[H^+]^x}{[HDPC]_0^x[S]_0^y}. \quad (4)$$

The reaction of primary interest involves adduct formation in the organic phase. By the proper manipulation of the above equilibria, the expression for the adduct formation can be obtained as follows:

$$M(DPC)_{x(o)} + yS_{(o)} \overset{\beta_y}{\rightleftharpoons} M(DPC)_xS_{y(o)}, \quad (5)$$

where β_y is the adduct-formation constant. By introducing Eqs. 2 and 4 into Eq. 6, it can be shown that:

$$\beta_y = \frac{[M(DPC)_xS_y]_0}{[M(DCP)_x]_0[S]_0^y} = K_{ex,xy}/K_{ex,x}. \quad (6)$$

The extraction behavior of zinc and cadmium by DPC into benzene was studied in both the absence and presence of nitrogen neutral bases. The plots of log D *vs.* such variables as the pH of the aqueous phase and the logarithms of the concentrations of DPC and of neutral bases were obtained in order to determine the stoichiometry and equilibrium constants of the extraction.

In the absence of neutral bases, the slopes of log D *vs.* pH are 2; those of log D *vs.* log $[DPC]_0$ are also 2 for Zn and Cd. These results suggest that the extracted species are $Zn(DPC)_2$ and $Cd(DPC)_2$, which is in agreement with Balt's report.[10]

Extraction in the presence of neutral bases was also evaluated by slope analysis. The slopes of log D *vs.* pH are 2; those of log D *vs.* log $[DPC]_0$ are also 2. The plots of log D *vs.* log $[S]_0$ in the presence of pyridine bases, such as pyridine, 2-methylpyridine, 3-methylpyridine and 4-methylpyridine, exhibit a linear range of unit slopes. These results suggest that one pyridine base adducts to $Zn(DPC)_2$ or $Cd(DPC)_2$. In the presence of 1,10-phenanthroline, the plots of log D *vs.* log $[phen]_0$ are as shown in Fig. 1. The slope of log D *vs.* log $[phen]_0$ was 2, so it is suggested that two 1,10-phenanthroline adduct to $Cd(DPC)_2$, while a greater quantity of an additive causes the slope of the line to decrease gradually, become horizontal, and finally turn down in a negative slope, -2. The extraction behavior of zinc with DPC in the presence of 1,10-phenanthroline is similar to that of cadmium. Furthermore, extraction in the presence of 1,10-phenanthroline derivatives, such as 4,7-diphenyl-1,10-phenanthroline, 4,7-diphenyl-2,9-dimethyl-1,10-phenanthroline and 2,9-dimethyl-1,10-phenanthroline, was also examined. The slopes of log D *vs.* log $[S]_0$ are very close to unity. These results suggest that one 1,10-phenanthroline derivative adducts to $Zn(DPC)_2$ or $Cd(DPC)_2$.

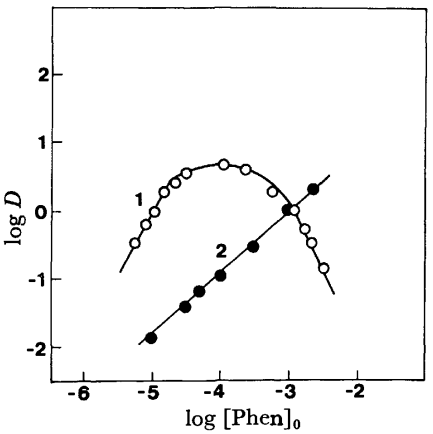

Fig. 1. Extraction of cadmium with mixtures of DPC and 1,10-phenanthroline into benzene and chloroform as a function of the phenanthroline concentration. $[DPC]_0 = 5 \times 10^{-4}$ M, pH 7.1. 1: Benzene, 2: chlofoform.

From these results, the adduct-formation constants were calculated. These values of Cd are listed in Table 1. In the case of pyridine bases, the adduct formation constants increase in the following order: 2-methylpyridine < pyridine < 3-methylpyridine < 4-methylpyridine. The increasing order of the adduct-formation constants corresponds with the increaseing basicity (K_{HB})[11,12] of the bases, except for 2-methylpyridine. The higher stability of 4-methylpyridine as compared with that of pyridine also reflects the increased donor power of the nitrogen atom due to the introduction of a methyl group. The much lower stability of 2-methylpyridine may be attributed to the steric interference of the 2-position methyl group. In the case of 1,10-phenanthroline derivatives, the adduct-formation constants increase in the following order: 2,9-dimethyl-1,10-phenanthroline < 4, 7-diphenyl-2, 9-dimethyl-1, 10-phenanthroline < 4, 7-diphenyl-1, 10-phenanthroline < 1,10-phenanthroline. The increasing order of the adduct-formation constants corresponds with the increasing basicity of the bases, except for 2,9-dimethyl-1,10-phenanthroline and 4,7-diphenyl-2,9-dimethyl-1,10-phenanthroline. The much lower stabilities of 2,9-dimethyl-1,10-phenanthroline and 4,7-diphenyl-2,9-dimethyl-1,10-phenanthroline may also be caused by the steric interference of 2,9-position methyl substituents.

Table 1. The effect of nitrogen bases on the synergistic extraction of cadmium and zinc diphenylcarbazonates into benzene

No.	Base	Cd			Zn			log K_{HB}
		log $K_{ex,x}$	log $K_{ex,xy}$	log β_y	log $K_{ex,x}$	log $K_{ex,xy}$	log β_y	
1	Pyridine	−10.43	−7.12	3.31	−8.36	−4.09	4.27	5.23
2	2-Methylpyridine	−10.43	−7.55	2.88	−8.36	−4.51	3.85	5.97
3	3-Methylpyridine	−10.43	−5.94	4.49	−8.36	—	—	5.68
4	4-Methylpyridne	−10.43	−5.61	4.82	−8.36	−3.56	4.80	6.02
5	2,2′-Bipyridyl	−10.43	−5.45	4.98	−8.36	—	—	4.33
6	1,10-Phenanthroline	−10.43	2.45	12.88	−8.36	1.60	9.96	4.92
7	4,7-Diphenyl-phen	−10.43	−0.58	9.85	−8.36	1.28	9.64	4.30
8	2,9-Dimethyl-phen	−10.43	−2.52	7.91	−8.36	−2.74	5.62	6.15
9	4,7-Diphenyl-2,9-dimethyl-phen	−10.43	−2.09	8.34	—	—	—	—

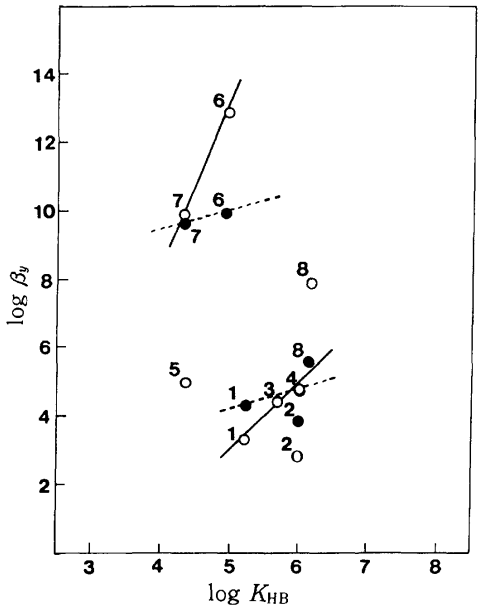

Fig. 2. Relationship of $\log \beta_y$ and $\log K_{HB}$ in the synergistic extraction of cadmium and zinc.
1: Pyridine, 2: 2-methylpyridine, 3: 3-methylpyridine, 4: 4-methylpyridine, 5: 2,2′-bipyridyl, 6: 1,10-phenanthroline, 7: 4,7-diphenyl-1,10-phenanthroline, 8: 2,9-dimethyl-1,10-phenanthroline, ○: cadmium, ●: zinc.

The adduct-formation constants of Zn are also listed in Table 1. The order is related not only to the basicity of the bases, but also to the steric effect due to substitution, in the same manner as in the case of Cd.

The relationship of $\log \beta_y$ and $\log K_{HB}$ in the synergistic extraction of Cd and Zn is shown in Fig. 2. A comparison of the adduct-formation constants of these bases against the normalized values of basicity shows that their values increase in the following order : pyridine bases$<$2,2′-bipyridyl$<$1,10-phenanthroline derivatives. This fact suggests that the stability of the adducts is related not only to the basicity of the bases, but also to the coordinated ability to act as ligands. The basicity of the bases has a larger effect on the adduct-formation constants of Cd than those of Zn. This may be attributed to the fact that zinc chelates have a greater stability than the cadmium chelates: as a result, the "residual Lewis acidity"[3] of Zn is smaller than that of Cd, and therefore zinc chelates form less stable adducts.

Effect of Organic Solvents. The behavior of the extraction of cadmium and zinc chelates into chloroform is similar to that into benzene, except for the case of 1,10-phenanthroline. In the absence of neutral bases, the extracted species are $Cd(DPC)_2$ and $Zn(DPC)_2$; the log D *vs.* pH plots and the log D *vs.* log $[DPC]_0$ plots, give the same slopes as in the case of benzene: the plots of log D *vs.* pH give a slope of 2, and the plots of log D *vs.* log $[DPC]_0$ give a slope 2, for both metals. In the presence of neutral bases, the plots of log D *vs.* pH exhibit a slope of 2, and the plots of log D *vs.* log $[DPC]_0$ exhibit a slope of 2, for both metals. In the case of Cd, the plots of log D *vs.* log $[S]_0$ all exhibit a linear range of unit slopes for pyridine, 2,2′-bipyridyl, and 1,10-phenanthroline. These results suggest that the extracted species are $Cd(DPC)_2S$. In the case of Zn, the plots of log D *vs.* log $[S]_0$ indicate a linear range of unit slopes for pyridine and 1,10-phenanthroline. These results suggest that the extracted species are $Zn(DPC)_2S$.

In the case of benzene, the extracted species of both metals are $M(DPC)_2S$ in all the neutral bases except 1,10-phenanthroline. In the presence of 1,10-phenanthroline, the extracted species of both metals are $M(DPC)_2(phen)_2$, different from those in chloroform. Furthermore, we carried out elementary analyses of the synthesized Cd–DPC–phen chelates and compared the results with those obtained from slope analysis. As is shown in Table 2, the results obtained from elementary analysis fit those obtained from slope analysis. Hence, the extracted species into chloroform can be expressed as $Cd(DPC)_2 \cdot phen$, and that into benzene, as $Cd(DPC)_2(phen)_2$.

Consequently, in the case of chloroform, one neutral base adducts to cadmium chelate and zinc chelate for all neutral bases, so the extraction can be expressed as:

$$M^{2+} + 2HDPC_{(o)} + S_{(o)} \rightleftarrows M(DPC)_2S_{(o)} + 2H^+. \quad (7)$$

On the other hand, in the case of benzene, the extraction can be represented as Eq. 7 for all neutral bases except for 1,10-phenanthroline. In the presence of 1,10-phenanthroline, the extraction stoichiometry can be expressed as:

$$M^{2+} + 2HDPC_{(o)} + 2phen_{(o)} \rightleftarrows M(DPC)_2(phen)_{2(o)} + 2H^+. \quad (8)$$

From these results, it would appear that the adduct stability is enhanced by an increase in the basicity of the adducting base, by an increase in the coordinated ability, and by an increase in the residual Lewis acidity of the metal atom, *i.e.*, after chelation. Furthermore, the composition of the extracted zinc and cadmium chelates with the mixtures of DPC and 1,10-phenanthroline is different depending on the solvent used in extraction.

A Thermodynamic Study of the Synergistic Solvent Extraction of a Series of Zinc(II) and Cadmium(II) Complexes

(Received February 9, 1982)

The extraction of zinc and cadmium using chloroform and benzene solutions constaining diphenylcarbazone (DPC=Hdpc), either alone or combined with pyridine(py) or 1,10-phenanthroline(phen), was studied thermodynamically. The formation constants were measured as functions of the temperature in order to ascertain the free energy, enthalpy, and entropy changes. The thermodynamic parameters support a proposed mechanism for the synergism of zinc in which the coordination number of the zinc ion expands with formation of $Zn(dpc)_2S$, where S is pyridine or 1,10-phenanthroline. On the other hand, the thermodynamic values for the synergistic reaction of cadmium support a mechanism in which pyridine or 1,10-phenanthroline replaces the residual waters of hydration in the first coordination sphere of cadmium.

In recent years, synergistic extractions have been studied by a number of workers. Considerable attention has been given to the mechanism of synergistic solvent extraction. Three possible mechanisms to explain the data of synergistic solvent extraction of metal ions by the combined action of two specific solutes in the organic phase have been proposed:[1]

(i) The neutral additive replaces the residual waters of hydration in the first coordination sphere of the metal ion.

(ii) The neutral additive attaches the metal chelate, by means of a hydrogen bond, to the coordinated waters of the first hydration sphere.

(iii) The coordination number of the non-hydrated chelate expands to accommodate the direct coordination of the adduct to the metal.

Knowledge of the formation constants alone does not allow one to choose between the three mechanisms proposed. However, if the enthalpies and entropies of the extraction reactions are known, it is possible to evaluate the mechanism of synergistic solvent extraction. Accordingly several studies of the thermodynamics of synergistic solvent extraction have been reported.[2-8] Kandil *et al.* have concluded that the mechanisms of adduct formation by tributylphosphate and acetylacetone with tris-thenoyltrifluoroacetone (TTA=Htta) chelates of Eu and Tm involve the expansion of the coordination number of the central metal ions from 6 to 8. These studies have also shown that the third mechanism fits the experimental data best.

Nakayama[9,10] has studied the effect of the temperature on the extraction of several metal chelates of 8-quinolinol. In a previous paper by the present authors it has been shown that the cadmium complex of diphenylcarbazone is quantitatively extracted in the presence of 1,10-phenanthroline and that an extract has a higher molar absorptivity than that for diphenylthiocarbazone (dithizone).[11] In this study, the temperature effects on the distribution equilibraia of zinc and cadmium chelates with DPC alone or when combined with pyridine or 1,10-phenanthroline have been examined in order to explain the extraction mechanism in terms of thermodynamic data.

Experimental

Reagents and Apparatus. The chemicals, such as cadmium, diphenylcarbazone, and 1,10-phenanthroline, used in the extraction have been previously described.[11]

A stock solution of zinc(II)[10^{-2} M(1 M=1 mol dm^{-3})] was prepared by dissolving weighed amounts of zinc chloride in dilute hydrochloric acid and then diluted with distilled water as required. The pyridine was purified by distillation under reduced pressure. All the other chemicals were of an analytical-reagent grade.

Extraction was carried out in a cylindrical tube with a magnetic stirrer in a constant-temperature bath.[9] The temperature was controlled to ± 0.1 °C by means of a thermoregulator. A Komatsu-Yamato Coolnics Dip (CTR-1, CTR-3B) was used for cooling. For the pH measurement, a Hitachi-Horiba M-5 pH meter equipped with a glass-calomel electrode pair for high-temperature work was used. All the other equipment used was the same as has previously been described.

Extraction Procedure. A 30 ml portion of a buffered cadmium or zinc solution was stirred with a 10 ml portion of the reagent solution in a cylindrical tube standing in a constant temperature bath for 30 min, a time period which was found adequate for the attainment of equilibrium. The ionic strength was adjusted by adding sodium sulfate at 0.05. Sodium perchlorate was not used because cadmium and zinc complexes of 1,10-phenanthroline were extracted into the organic phase by forming ion-pair complexes with sodium perchlorate.

After stirring, the pH value of the aqueous phase was measured *in situ*. After phase-separation, the aqueous phase was immediately analyzed with the atomic absorption spectrophotometer, whereas the organic phase was analyzed after back-extracting into an aqueous nitric acid solution.

Results and Discussion

Extraction of Zinc and Cadmium with DPC in the Absence of Phenanthroline and Pyridine. The behavior of the extraction of zinc and cadmium with DPC alone into chloroform and benzene was studied at various temperatures.

For Zn, the plots of log D *vs.* pH when chloroform was used are shown in Fig. 1. The slopes of log D *vs.* pH are 2 at each temperature. The plots of log D *vs.* log $[DPC]_0$ at a constant pH are linear, with a slope of

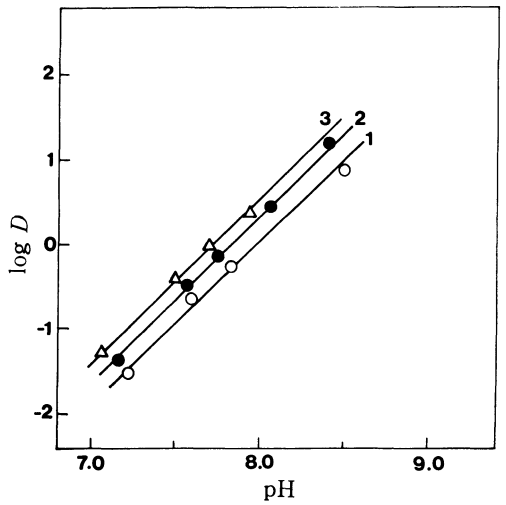

Fig. 1. Effect of pH on the distribution of zinc with DPC between chloroform and water.
$[DPC]_0 = 5 \times 10^{-4}$ M, $[Zn]_T = 10^{-5}$ M. 1: 25 °C, 2: 35 °C, 3: 45 °C.

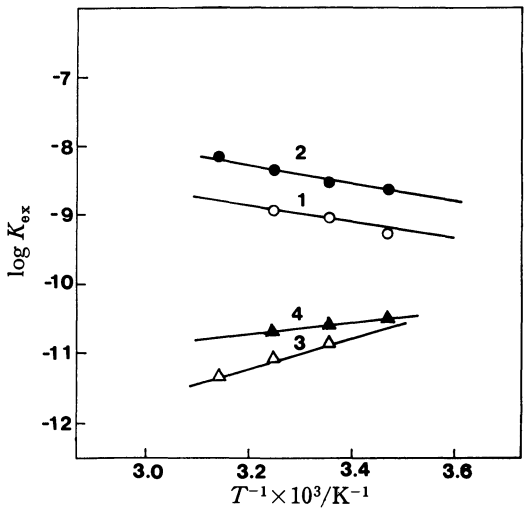

Fig. 2. Temperature effect on the distribution of zinc and cadmium between organic solvents and water.
1: Zinc into chloroform, 2: zinc into benzene, 3: cadmium into chloroform, 4: cadmium into benzene.

2. In the case of benzene, the slopes of log D *vs.* pH are 2 at each temperature, the same as those in chloroform. In this system, the slopes of log D *vs.* log $[DPC]_0$ at various temperatures are also 2. Thus, it can be concluded that only a single species, the simple 1 : 2 chelate, $Zn(dpc)_2$, is present in the organic phase. The overall reaction can be represented by Eq. 1:

$$Zn^{2+} + 2Hdpc_{(o)} \rightleftarrows Zn(dpc)_{2(o)} + 2H^+. \quad (1)$$

The extraction constant, K_{ex}, is a composite of the chelate formation constant, β_2, and its distribution constant, K_{DC}, as well as of the reagent acid-dissociation constant, K_a, and its distribution constant, K_{DR}:

$$K_{ex} = \beta_2 K_{DC} K_a^2 / K_{DR}^2. \quad (2)$$

The product, $\beta_2 K_{DC}$, corresponds to the heterogeneous equilibrium constant of the following reaction:

$$Zn^{2+} + 2dpc^- \overset{\beta_2 K_{DC}}{\rightleftarrows} Zn(dpc)_{2(o)}. \quad (3)$$

In the case of Cd, the plots of log D *vs.* pH in both solvents are linear and exhibit a slope of 2 at each temperature. The analogous log D *vs.* log $[DPC]_0$ plots are also linear, with a slope of 2. These results suggest that the extracted species of cadmium can also be expressed as a simple chelate, $Cd(dpc)_2$. Hence, the extraction constant of cadmium can be represented as:

$$K'_{ex} = \beta'_2 K'_{DC} K_a^2 / K_{DR}^2. \quad (4)$$

The plots of log K_{ex} *vs.* $1/T$ K are shown in Fig. 2. In the case of Zn, the distribution increases with an increase in the temperature. On the other hand, in the case of Cd, the distribution decreases with an increase in the temperature.

From these experimental data, the thermodynamic parameters, ΔG, ΔH, and ΔS, were calculated by using thermodynamic equations. These values are listed in Tables 1—3. The data in Table 1 show an endothermic

reaction for the formation of the Zn-DPC chelate. It has been reported that this behavior is quite characteristic of chelation reactions in which the waters of the inner-coordination sphere of the metal ion are displaced by the chelating reagent.[12] The extraction constants of the two metal chelates can be represented as Eqs. 3 and 4, but K_a and K_{DR} are independent of the metal. Therefore, by using the same solvent, the difference in the extraction constant between the two metal chelates can be related to the difference in the product, $\beta_2 K_{DC}$ $(\beta'_2 K'_{DC})$. Hence, $\Delta(\Delta H)$, which is the difference in enthalpy change calculated from the values of the extraction constant, can be represented as the sum of the difference in the enthalpy change of the chelate formation and of the distribution between the metal chelates. The calculated values of $\Delta(\Delta H)$ and $\Delta(\Delta S)$ are listed in Table 4. The values of $\Delta(\Delta H)$ are largely positive. If the extracted species of Zn had a composition like that of Cd, $\Delta(\Delta H)$ would be predicted to be fairly small, for the difference in enthalpy change of the chelate formation between Zn and Cd is generally small. Hence, it is conceivable that the extracted species of Zn is different from that of Cd. As for lanthanoids, ΔH, which is calculated from the extraction constant, has been reported to be 11.1 kcal/mol (46.4 kJ mol^{-1}) for $Eu(tta)_3$, 9.64 kcal/mol (40.3 kJ mol^{-1}) for $Tb(tta)_3$, and 12.4 kcal/mol (51.9 kJ mol^{-1}) for $Tm(tta)_3$.[3,5] The difference between the ΔH values of these lanthanoids is very small. The positive values of $\Delta(\Delta H)$ and $\Delta(\Delta S)$ would indicate that water molecules would be removed from Zn-DPC chelate in the process of extraction. Since hydrogen-bond energies are usually in the range of 10—25 kJ mol^{-1}, it would be expected to take ΔH values of 20—50 kJ mol^{-1} in order to remove two water molecules. The values of $\Delta(\Delta H)$ are 70.8 kJ mol^{-1} in the case of chloroform and 43.9 kJ mol^{-1} in the case of benzene. Therefore, these values are consistent with the postulate that the Zn-DPC chelate would be extracted as a non-hydrated chelate, $Zn(dpc)_2$, while the Cd-DPC chelate would be extracted as a hydrated species, $Cd(dpc)_2 \cdot 2H_2O$.

Furthermore, it became apparent from these results that the separation of zinc and cadmium may be further enhanced at high temperatures. For the purpose of enhancing the separation of zinc and cadmium, chloroform is better than benzene as the solvent for extraction. However, since chloroform has a low boiling point, for this purpose organic solvents whose boiling points are relatively high, such as 1,1,2,2-tetrachloroethane (TCE), are desirable. It was indicated that the separation of zinc and cadmium is further enhanced at high temperatures when both metals are extracted with 2-methyl-8-quinolinol into TCE.[13] Hence, it is conceivable that

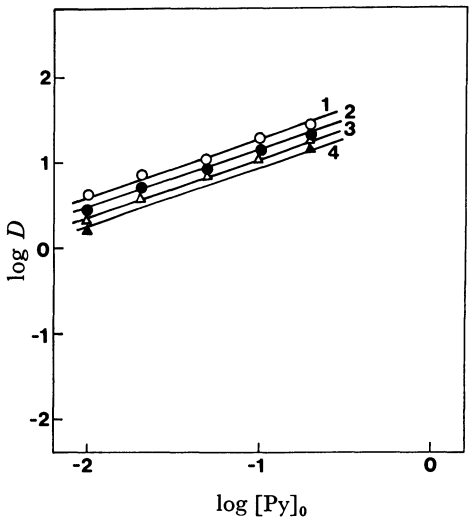

Fig. 3. Distribution of zinc with mixtures of DPC and pyridine into chloroform as a function of the pyridine concentration.
$[DPC]_0=5\times10^{-4}$ M, $[Zn]_T=10^{-5}$ M, pH 7.0. 1: 15 °C, 2: 25 °C, 3: 35 °C, 4: 45 °C.

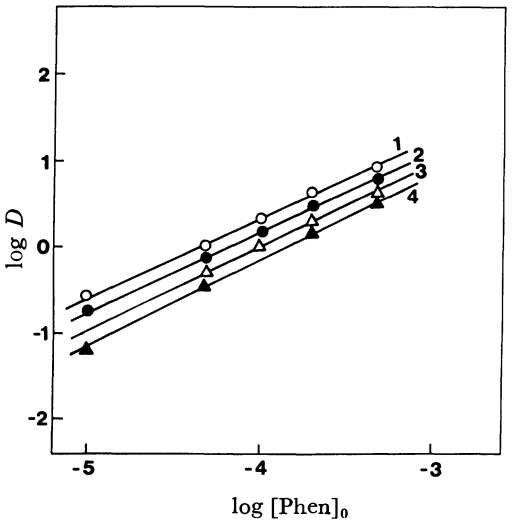

Fig. 4. Distribution of zinc with mixture of DPC and phenanthroline into chloroform as a function of the phenanthroline concentration.
$[DPC]_0=5\times10^{-4}$ M, $[Zn]_T=10^{-5}$ M, pH 6.5. 1: 15 °C, 2: 25 °C, 3: 35 °C, 4: 45 °C.

solvent extraction at high temperatures may be applied to the separation of metals of the same group by using the difference in extraction mechanism between those metals.

Extraction of Zinc with DPC in the Presence of 1,10-*Phenanthroline or Pyridine.* By slope analysis, the extraction of Zn with DPC into chloroform in the presence of 1,10-phenanthroline or pyridine was studied at various temperatures. The log D *vs.* pH plots are linear and exhibit a slope of 2 at each temperature. The plots of log D *vs.* log $[py]_0$ are shown in Fig. 3. The slopes of log D *vs.* log $[py]_0$ are unity, irrespective of the temperature. In Fig. 4, the plots of log D *vs.* log $[phen]_0$ are shown. The slopes of log D *vs.* log

$[phen]_0$ are also unity, irrespective of the temperature. These results indicate that the extracted species are $Zn(dpc)_2 \cdot py$ and $Zn(dpc)_2 \cdot phen$ respectively. These thermodynamic parameters are summarized in Table 1.

In the presence of pyridine, the value of ΔG, which is calculated from the adduct-formation constant, is negative, so it is obvious that the acceptor mother chelate is stabilized by the adduct-chelate formation. The rather large negative experimental enthalpy ($\Delta H = -46.5$ kJ mol^{-1}) clearly eliminates Mechanism (i), because in this system the enthalpy change would be small, since the number of bonds to zinc does not change. Furthermore, in the case of Mechanism (ii), the enthalpy change would be the energy of the hydrogen bond ($\approx$10 to 25 kJ mol^{-1}). Therefore, it may be concluded that the mechanism most likely to explain the experimental results is Mechanism (iii), in which the coordination number of zinc expands from four to five to accommodate the neutral pyridine molecule.

Hence, the synergistic reaction in the organic phase can be expressed as follows:

$$Zn(dpc)_{2(o)} + py_{(o)} \rightleftarrows Zn(dpc)_2 \cdot py_{(o)}. \quad (5)$$

In this case, the entropy change would be largely negative, consisting of the cratic part ($\Delta n = -1$), where Δn is the change in the number of species, and the unitary part of pyridine. The rather large negative experimental entropy change ($\Delta S = -81$ J K^{-1} mol^{-1}) fits Eq. 5. The experimental results for 1,10-phenanthroline are $\Delta H = -56.3$ kJ mol^{-1} and $\Delta S = -58$ J K^{-1} mol^{-1}, which fit only Mechanism (iii).

The synergistic reaction in the organic phase can be represented by Eq. 6:

$$Zn(dpc)_{2(o)} + phen_{(o)} \rightleftarrows Zn(dpc)_2 \cdot phen_{(o)}. \quad (6)$$

Since 1,10-phenanthroline is usually bidentate, in this case the coordination number of zinc increases from four to six. Compared with pyridine, both entropy and enthalpy favor adduct-chelate formation.

Extraction of Cadmium with DPC in the Presence of 1,10-Phenanthroline or Pyridine. The extraction of cadmium with DPC into chloroform and benzene in the presence of 1,10-phenanthroline or pyridine was studied at various temperatures.

In the case of chloroform, the slopes of log D *vs.* pH are 2 at each temperature in the presence of both pyridine and 1,10-phenanthroline, and the distribution ratio decreased with an increase in the temperature. The slopes of log D *vs.* log $[DPC]_0$ are also 2 at each temperature. In the presence of pyridine, the slopes of log D *vs.* log $[py]_0$ are unity. In the presence of 1,10-phenanthroline, the slopes of log D *vs.* log $[phen]_0$ are also unity. These results suggest that the extracted species are $Cd(dpc)_2 \cdot py$ and $Cd(dpc)_2 \cdot phen$. From these results, the thermodynamic parameters, ΔG, ΔH, and ΔS, which were calculated from the thermodynamic equations, are as listed in Table 2. The values of ΔG, which were calculated from the adduct-formation constant, are negative, so it is obvious that the acceptor mother chelates are stabilized by the adduct-chelate formation. In these cases, the ΔH values, which are 7.7 kJ mol^{-1} for pyridine and 0.0 kJ mol^{-1} for 1,10-phenanthroline, are quite small, or even close to zero.

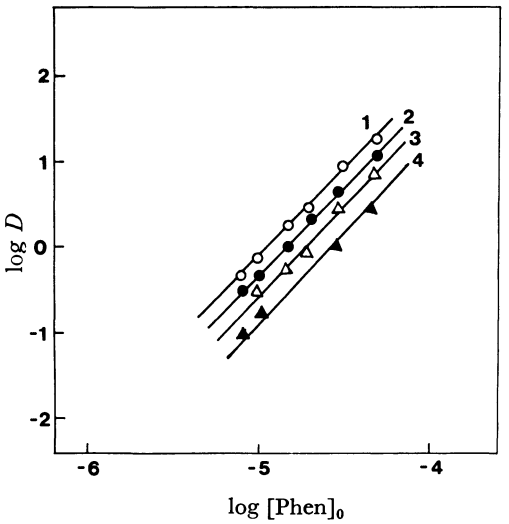

Fig. 5. Distribution of cadmium with mixtures of DPC and phenanthroline into benzene as a function of the phenanthroline concentration.
$[DPC]_0 = 5 \times 10^{-4}$ M, $[Cd]_T = 10^{-6}$ M, pH 7.1. 1: 15 °C, 2: 25 °C, 3: 35 °C, 4: 45 °C.

These relatively small experimental enthalpy changes clearly eliminate Mechanism (iii). These results fit the postulate that, in the absence of pyridine or 1,10-phenanthroline, the Cd-DPC chelate would be extracted as a hydrated species, $Cd(dpc)_2 \cdot 2H_2O$. In the case of Mechanism (ii), the entropy change would be largely negative, since Δn, the change in the number of species, decreases. However, the experimental entropy changes are positive, so these results do no fit Mechanism (ii). Consequently, we may conclude that the mechanism (ii). Consequently, we may conclude that the mechanism most likely to explain the experimental results is Mechanism (i), in which pyridine or 1,10-phenanthroline replaces the residual waters of hydration in the first coordination sphere of the cadmium ion.

Hence, the synergistic reaction in the organic phase can be expressed as follows:

$$Cd(dpc)_2 \cdot 2H_2O_{(o)} + S_{(o)} \rightleftarrows Cd(dpc)_2S_{(o)} + 2H_2O, \quad (7)$$

where S is pyridine or 1,10-phenanthroline.

Next, in the case of benzene, the slopes of log D *vs.* pH are 2 at each temperature in the presence of pyridine or 1,10-phenanthroline, and the distribution ratio decreases with an increase in the temperature. The slopes of log D *vs.* log $[DPC]_0$ are also 2. In the presence of pyridine, the slopes of log D *vs.* log $[py]_0$ are unity. In the presence of 1,10-phenanthroline, the plots of log D *vs.* log $[phen]_0$ are as shown in Fig. 5. The slopes of log D *vs.* log $[phen]_0$ are 2 at each temperature, unlike those with chloroform. These results suggest the idea that the extracted species are $Cd(dpc)_2 \cdot py$ and $Cd(dpc)_2 \cdot 2phen$. The thermodynamic parameters led to from these results are summarized in Table 3. The values of ΔG are largely negative, so the acceptor mother chelates are obviously stabilized by the adduct-chelate formation. In the absence of pyridine or 1,10-phenanthroline, the Cd-DPC chelate would be extracted into benzene as a hydrated species, $Cd(dpc)_2 \cdot 2H_2O$,

like that into chloroform, so it may be concluded that the mechanism most likely to explain the experimental results is Mechanism (i), in which pyridine or 1,10-phenanthroline replaces the residual waters of hydration in the first coordination sphere of the cadmium ion. Compared with the case of pyridine, in the case of 1,10-phenanthroline both entropy and enthalpy changes favor adduct-chelate formation : however, the contribution of the entropy change is larger than that of enthalpy. The difference in ΔS between pyridine and 1,10-phenanthroline in benzene is larger than that in chloroform. A large entropy change of this order reflects the steric hindrance caused by the first 1,10-phenanthroline molecule to the entrance of its second molecule. Furthermore, the steric effect may make it difficult for 1,10-phenanthroline to form a strong bond with the complex.

Thus, the thermodynamic results suggest that the mechanism for the synergism of zinc is different from that of cadmium.

Coordination Structure of Cu^{2+} Ion in Highly Concentrated Aqueous $CuBr_2$ Solution, Determined by X-Ray Diffraction Analysis

Mitsuyoshi Ichihashi, Hisanobu Wakita,* Takeharu Mibuchi,† and Isao Masuda
Department of Chemistry, Faculty of Science, Fukuoka University, Nanakuma, Jonan-ku, Fukuoka 814-01
(Received February 26, 1982)

The solute structure of concentrated aqueous copper(II) bromide solutions was determined by the analysis of the radial distribution curves of X-ray diffraction measured on the solutions with varying concentrations, 4.364—1.016 mol dm^{-3}. The mixed-ligand aquabromocopper(II) complexes were found to be present in these solutions, and to have a distorted octahedral geometry. The Cu^{2+} ion was coordinated with Br^- ions at the equatorial sites whose bond lengths were shorter than the axial sites. The interatomic distances of the equatorial Cu–Br and Cu–OH_2 bonds were, respectively, 2.42—2.46 and 1.96—1.99 Å, and that of the axial Cu–OH_2 bond, 2.37—2.51 Å. The average coordination number of Br^- ions in the nearest neighbor of the Cu^{2+} ion increased from 0.33 to 1.31 as the concentration of $CuBr_2$ increased from 1.016 to 4.364 mol dm^{-3}. Even in the 4.364 mol dm^{-3} solution, which was nearly saturated, the coordination of the Br^- ion at the axial site was not evidenced. In the 1.474 mol dm^{-3} $CuBr_2$ solution dissolved in an aqueous 6.923 mol dm^{-3} HBr solution, the tetrabromocopper(II) complex species was proposed to exist in a flattened tetrahedral form, wherein the Cu–Br distance was 2.41 Å.

The octahedral structure of six-coordinate copper(II) complexes has been characterized by two kinds of coordination bonds, with different bond lengths, *i.e.*, a shorter one toward the equatorial site and a longer one toward the axial site; this has been interpreted as being related to the anisotropic electron-filling on the $d\gamma$ orbitals of Cu^{2+} ion in the octahedral ligand-field. The X-ray investigations have demonstrated that the mixed-ligand complexes $[Cu(en)_2(H_2O)_2]^{2+}$ and $[Cu(NH_3)_4(H_2O)_2]^{2+}$ in the aqueous solution have a structure wherein the two H_2O molecules are coordinated at the elongated axial sites, with a Cu–O bond distance of 2.92 Å in the former and of 2.33 Å in the latter.[1,2] On the other hand, Wertz *et al.* have determined the solute structure and the average coordination number around the Cu^{2+} ion with the concentrated aqueous $CuCl_2$ solutions of 3.18 and 4.35 mol dm^{-3}, and they have concluded that the coordination ability of the Cl^- ligand is $Cl^- \gg H_2O$ toward the axial coordination and $Cl^- > H_2O$ toward the equatorial coordination.[3,4] Judging from the spectrochemical series, Cl^- is expected to exert a weaker ligand-field than H_2O upon Cu^{2+}. The X-ray investigation by Golik *et al.* has shown that in the predominant complex species which are present in the aqueous 2.0 mol dm^{-3} $CuCl_2$ solution, two Cl^- ions are coordinated axially and four H_2O molecules are coordinated equatorially with Cu^{2+}.[5,6] From the UV- and visible-spectral investigations, Libuś has also supported the axial coordination of the Cl^- ligand in the complex $[CuCl(H_2O)_5]^+$ existing in the aqueous $CuCl_2$ solution.[7]

In contrast to the above results, Fontana *et al.* have reported the Raman spectrum of the aqueous 3.4 mol dm^{-3} $CuCl_2$ solution; it shows a pattern similar to that of crystal $(CH_3NH_3)_2CuCl_4$, which is composed of square-planar complex $[CuCl_4]^{2-}$.[8] Moreover, as for the aqueous 0.5 mol dm^{-3} $CuBr_2$ solution, the EXAFS measured by Fontaine *et al.* indicated that in the solution half of both the Cu^{2+} and the Br^- ions are linked each other with an interatomic distance of 2.35 ± 0.05 Å; this distance is rather closer to the equatorial Cu–Br than to the axial Cu–Br bond distances in crystal $CuBr_2$.[9–11] Hence, it is of interest to determine by X-ray investigation whether the coordination of the Br^- ion in the mixed-ligand aquabromocopper(II) complexes occurs at either the axial or the equatorial sites. Previously, we have reported that the X-ray scattering factor of the bromine is larger than that of the chlorine atom. This caused pronounced peak appearance in the X-ray radial distribution curve, which rendered a precise resolution of the solute structure of the aqueous $NiBr_2$ solution.[12] In the present paper, we attempt to elucidate the coordination structure of the mixed-ligand aquabromocopper(II) complexes in the aqueous solution by the X-ray investigation.

Experimental

Sample Solutions. The sample solutions A—D were prepared by dissolving copper(II) bromide obtained by the recrystallization of commercially available material from distilled water. The sample solutions E and F were prepared by dissolving recrystallized copper(II) bromide in an aqueous 47% hydrobromic acid solution, and then by diluting the solutions with distilled water. The copper and bromide ion concentrations of the solutions were determined by EDTA titration and the Volhard method, respectively. The composition of the sample solutions is shown in Table 1.

X-Ray Diffraction Measurements and Data Treatments. After the sample solutions had been left to stand at room temperature for 2—3 d, the diffraction intensities of the solutions were recorded, as previously reported.[12] The scatterd intensities were measured at every 0.1° between $\theta = 0.5°$ and 8°, 0.25° between $\theta = 8°$ and 30°, and 0.5° between $\theta = 30°$ and 65°; 2θ is the scattering angle. The time required for accumulating 40000 counts was recorded for the solutions A, B, C, E, and F; 80000 counts were taken for the solution D.

The measured intensity data were corrected for the air- and multiple-scatterings, and for the polarization and absorption due to the sample solutions, and then normalized to absolute intensities $I(\theta)$ according to the ordinary treatment.[13,14] Reduced intensities $i(\theta)$ were calculated by subtracting incoherent and independent coherent scatterings from $I(\theta)$.

The radial distribution function $D(r)$ employed is given in in Eq. 1:

ρ/g cm^{-3}	1.199	1.374	1.605	1.827	1.606	1.592
μ/cm^{-1}	17.41	33.18	53.20	70.80	60.97	68.56

V, Stoichiometric volume containing one copper atom. This is used for diffraction data normalization; ρ, density; μ, linear absorption coefficient of the solution; *, hydrobromic acid solution.

$$D(r) = 4\pi r^2\rho_0 + \frac{2r}{\pi}\int_0^{15} s\cdot i(s)\cdot M(s)\cdot\sin(r\cdot s)\cdot ds, \quad (1)$$

where ρ_0 is the average scattering density of the sample solution, and is given in the electron units, and s is equal to $4\pi\sin\theta/\lambda$ (λ=0.7107 Å). The modification function $M(s)$ was that employed previously.[12]

As a first approximation to the structure, the theoretical peak shape was drawn by Fourier transformation of the theoretical intensities $i(s)_{calcd}$ given by Eq. 2:

$$i(s)_{calcd} = \sum_i^{i\neq j}\sum_j n_{ij}\cdot f_i(s)\cdot f_j(s)\,\frac{\sin(r_{ij}\cdot s)}{r_{ij}\cdot s}\exp(-b_{ij}\cdot s^2). \quad (2)$$

In Eq. 2, f_i(s) and f_j(s) are the atomic scattering factors of atoms i and j; and n_{ij}, r_{ij}, and b_{ij} are, respectively, the frequency factor, the distance and the temperature factor of the interactions between atom i and j.

In order to attain more precisely the structural parameter values, the above parameter values were refined so as to minimize the difference between $i(s)_{calcd}$ and observed $i(s)$, by means of a least-squares refinement.

Results

The radial distribution curves $D(r)$ and $D(r)-4\pi r^2\rho_0$ are shown in Figs. 1 and 2. For the solutions A—D, four peaks are seen in the $D(r)$ curves at *ca.* 1.0, 2.0, 2.5, and 3.3—3.5 Å; these would be closely concerned with the intra- and inter-molecular atomic interactions of the solute complex and the solvent H_2O molecules. The first broad peak around 1.0 Å is caused by the O–H interaction within the free and complexed H_2O molecules in the solution. The peak ascribable to these O–H interactions has been commonly observed in the $D(r)$ curves measured for the aqueous solution.[12,15]

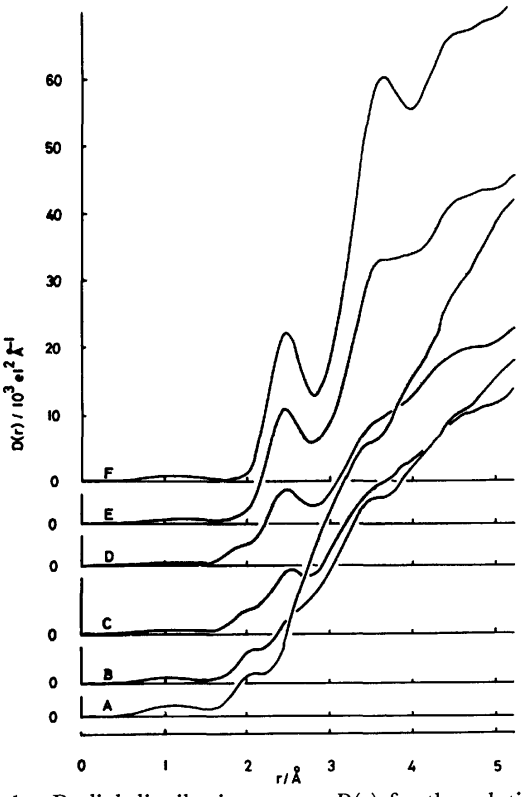

Fig. 1. Radial distribution curves $D(r)$ for the solutions A—F.

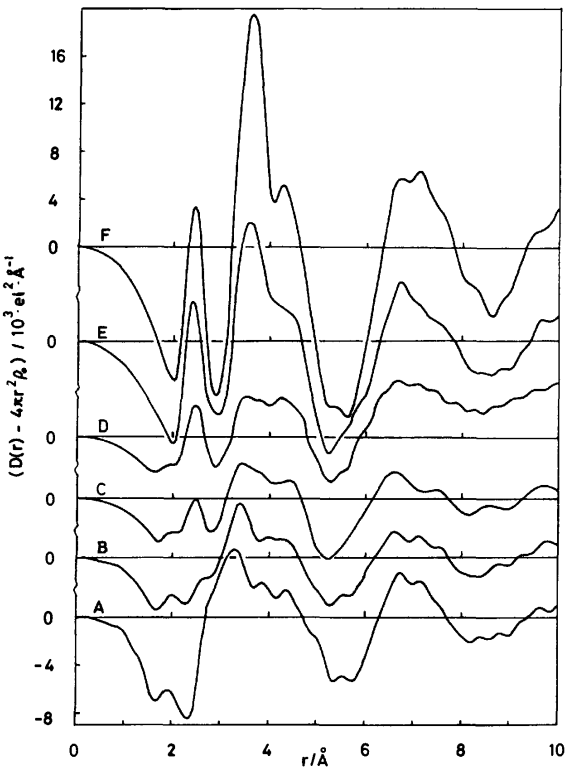

Fig. 2. $D(r)-4\pi r^2\rho_0$ curves for the solutions A—F.

The peak area around 2.0 Å decreases as the concentration of $CuBr_2$ increases, *i.e.*, the area becomes smaller in the order of the solutions, A>B>C>D; for the solution E the corresponding peak becomes very small and obscure; and for the solution F no peak is observed in this region. It has already been established that the hexaaquacopper(II) complex existing in the aqueous 3.550 mol dm^{-3} $Cu(ClO_4)_2$ solution holds a distorted octahedral form wherein the central Cu^{2+} ion binds four H_2O molecules at the equatorial sites with a distance of 1.94 Å and two H_2O molecules at the axial sites with a distance of 2.43 Å.[16] Thus, the above peak around 2.0 Å observed for the present $CuBr_2$ solutions may tentatively be ascribed to the Cu–OH_2 interaction at the equatorial position.

In contrast with the peak around 2.0 Å, the peak around 2.5 Å increases its peak area in the above mentioned order of solutions. The addition of the HBr causes the appearance of a quite distinct peak, as seen for the solutions E and F. In the crystal $CuBr_2$ the equatorial Cu–Br bond distance is 2.40 Å and the axial one, 3.18 Å.[11] Hence, the peak around 2.5 Å could be attributed to the interaction of the equatorial Cu–Br bond.

The broad peak located between 3.3—3.5 Å for the solutions A—D could be interpreted as being composed of the peaks due to the interaction between Br^- and OH_2 (both are free)[17] and those between Br^- and OH_2, and H_2O and OH_2 (these are bound at the *cis*-positions in an octahedral complex). An analogous peak due to these interactions was observed in the $D(r)$ curve of the highly concentrated aqueous $NiBr_2$ solution which contained predominantly $[NiBr(H_2O)_5]^+$ species.[12] In the cases of the solutions E and F that have HBr added, the comparable peak is seen at 3.6 Å, somewhat longer than 3.3—3.5 Å of the solutions A—D; this agrees with the expectation that the increased concentration of the Br^- ion aids the formation of the higher-order bromo-complexes, whereby the Br^-–Br^- interaction at the *cis*-position becomes prominent.

Then, in order to draw the structure of the predominant solute complex, the four possible geometries depicted in Fig. 3 were assumed: these are elongated octahedron (a), square pyramid (b), square plane (c), and tetrahedron (d). And the theoretical intensities $i(s)_{calcd}$ were calculated from Eq. 2, by substituting a set of the parameter values, n, r, and b that were tentatively taken for each of the assumptive models. The parameter n, the frequency factor which represents the number of the interactions between Cu^{2+} and any atom being on the axial position, was fixed at 2.0 with regard to model (a) and at 1.0 to model (b). The further refinements of these parameters were made by a least-squares method so that these gave an $s \cdot i(s)_{calcd}$ curve which was in good agreement with the observed $s \cdot i(s)$ curve in the region above $s>4$.

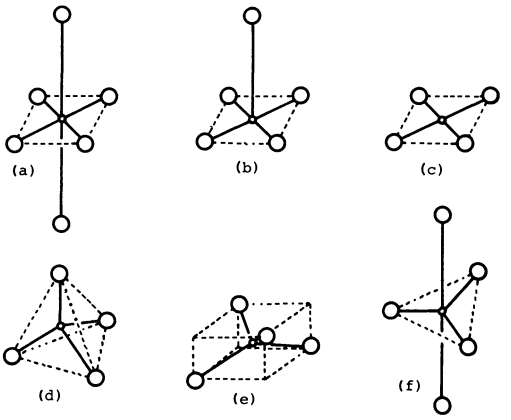

Fig. 3. Assumptive skeletal models.

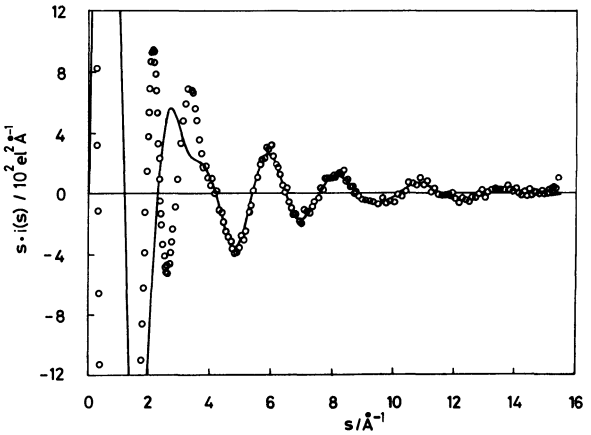

Fig. 4. Observed (○○) and calculated (——) $s \cdot i(s)$ curves for solution D.

Thus, the results indicated that the predominant complex species which existed in the solutions A—D can be most satisfactorily depicted by model (a). The

r, Bond distance, n, frequency factor. a) The parameters obtained when model (a) was used. b) The parameters were evaluated only from the peak of the $D(r)$ curve at 2.4 Å.

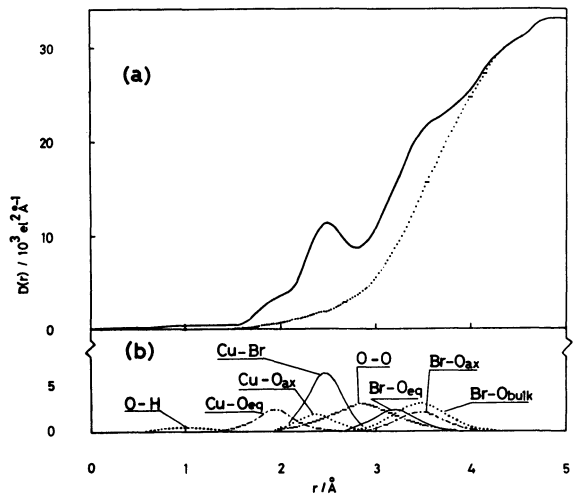

Fig. 5. (a); The $D(r)$ curve (——) and the residual distribution function (·····) for solution D. The residual distribution function is obtained by subtracting the calculated peak shapes shown in (b) from the $D(r)$ curve. (b); The peak shapes calculated by using the parameter values given in Table 2.

parameter values mostly fitted by the refinements are listed in Table 2. And the $s \cdot i(s)_{calcd}$ curve calculated from these data are in good agreement with the observed $s \cdot i(s)$ curve as is exemplified in Fig. 4 for the solution D. In Fig. 5, it is shown that the residual distribution function curve obtained by the subtraction of the $s \cdot i(s)_{calcd}$ curve from the observed $s \cdot i(s)$ curve gives a smooth curve, indicating a good reliability of these parameter values. With regard to the complex in the solution E, the structure model shown in Fig. 3-(d) could be discarded, but any of the three models (a), (b), and (c) could be accepted with the same margin of uncertainty. For the complex in the solution F, none of the above four models was satisfactorily consistent with the resultant data.

Discussion

On increasing $CuBr_2$ concentration in the aqueous solution, if the coordination of the Br^- ion occurred first at the axial and then at the equatorial sites, we think that the peak in the $D(r)$ curve owing to the axial Cu–Br interaction would appear at *ca.* 3.18 Å.[11] However, Figs. 1 and 2 show no appearance of such a peak, indicating no axial coordination of Br^- in the present solute complexes. And Table 2 shows that with increasing $CuBr_2$ concentration the mean frequency factor of the equatorial Cu–Br interaction increases and that of the equatorial Cu–O decreases, while the sum of the respective value is *ca.* 4, being invariable throughout the solutions A—D with different concentrations. These facts concur with the proposed structure-model (a) of the solute complex. The equatorial Cu–Br bond distance, 2.42—2.46 Å, is more close to the equatorial Cu–Br bond distance, 2.40 Å, than to the axial Cu–Br bond distance, 3.18 Å; these are known for the crystal $CuBr_2$.[11] Moreover, the distances of equatorial Cu–O, 1.96—1.99 Å, and of axial Cu–O, 2.37—2.51 Å, of the solute complex are, respectively, comparable to those of 1.943—1.976 and of 2.399—2.448 Å of crystal $CuSO_4 \cdot 3H_2O$.[18]

As has been pointed out, the mixed-ligand complexes $[Cu(NH_3)_4(H_2O)_2]^{2+}$ and $[Cu(en)_2(H_2O)_2]^{2+}$ hold H_2O, which is a weaker ligand than NH_3 or en, at the axial site; this structure of coordination is reasonably interpreted to be more stable than that which holds H_2O at the equatorial site. Thus, only judging from the spectrochemical series, it is predicted that in the mixed-ligand aquabromocopper(II) complexes the coordination of H_2O, which is a stronger ligand than Br^-, would occur at the equatorial site rather than at the axial site. On the contrary, the solute mixed-ligand complex in the aqueous $CuBr_2$ solution seems to have H_2O at the axial site. Though this work offers no kinetic datum of the complex-formation equilibrium, this structure implies a little difference in the apparent coordination abilities of H_2O and Br^- toward Cu^{2+} ion.

No satisfactory result of the data refinements was drawn for the solutions E and F. However, the peak at 2.4 Å on the $D(r)-4\pi r^2\rho_0$ curves might be attributed to the Cu–Br interaction. And in the aqueous solution, the presence of Cu^{2+} ions binding three, five, or six Br^- ions were not evidently indicated from the electronic spectral investigations.[19] By taking these results into consideration, the minimum amounts of Cu^{2+} existing in a tetrabromo complex species in solutions E and F were tentatively calculated from the peak areas in the

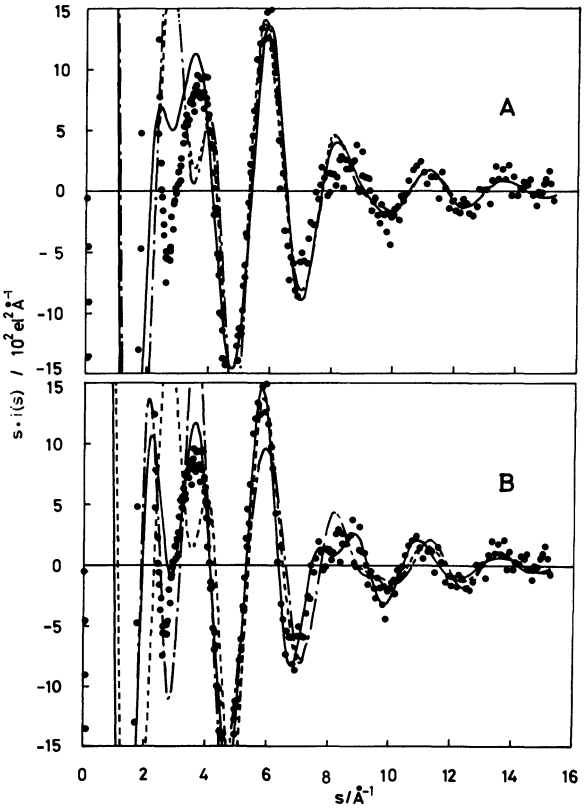

Fig. 6. Observed and calculated $s \cdot i(s)$ curves for solution F. A: Observed (●●); calculated for model (a) (– – –), for model (b) (——), for model (c) (------). B: Observed (●●), calculated for model (d) (– – –), for model (e) (——), for model (f) (------).

$D(r)$ curves: these are 92.5% of the total Cu^{2+} concentration in solution F, and 45.5% of that in solution E.[20] If the tetrabromo complex species had either a square-planar or tetrahedral structure, the Br^-–Br^- interactions within these complex molecules would give rise to the appearence of the peaks on the $D(r)$ and $D(r)-4\pi r^2\rho_0$ curves at around 3.41 and 4.82 Å for the former, or at around 3.94 Å for the latter. However, actually no peak is observed at these positions, but two peaks, a larger one at *ca.* 3.6 and a smaller one at *ca.* 4.35 Å, are observed. These facts led us to propose a flattened tetrahedral structure of the tetrabromo complex species, as shown in Fig. 3-(e). This structure is similar to that of $[CuBr_4]^{2-}$ in the Cs_2CuBr_4 crystal.[21] Then, for solution F, the observed $s\cdot i(s)$ curve is compared with the calculated ones using the refined parameter values which are taken for the assumptive models (a)—(f). In this case, a trigonal bipyramidal model (f) in Fig. 3, is also taken into consideration. As shown in Fig. 6, the curve calculated on model (e) is most like to the observed one.

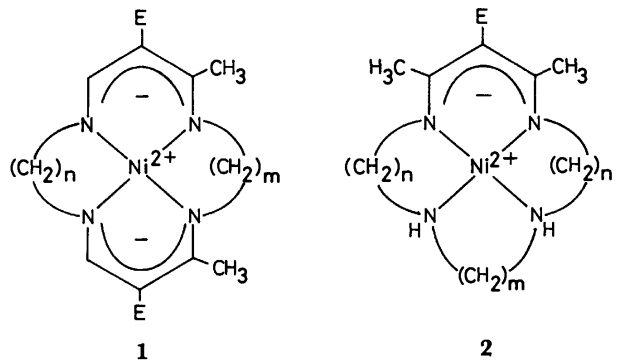
Synthesis and Characterization of Substituted Derivatives of (Tetraazacycloalkadienato)nickel(II) Complexes with Uninegative Ligands, and Crystal Structure of Parent Complex [Ni(Me$_2$[14]dienatoN$_4$)]Br·H$_2$O

Naohide MATSUMOTO,* Kenichiro WAKIZAKA, and Akira OHYOSHI
Department of Industrial Chemistry, Faculty of Engineering, Kumamoto University, Kurokami 2-39-1, Kumamoto 860
(Recieved February 18, 1982)

The (tetraazacycloalkadienato)nickel(II) complexes [Ni(Me$_2$[Z]dienatoN$_4$)]$^+$ (Z=13, 14), which have an unsaturated chelate ring containing nucleophilic center, react with electrophilic reagents such as benzoyl chloride, *p*-methylbenzoyl chloride, and *p*-nitrobenzoyl chloride to give the substituted derivatives [Ni(Me$_2$E[Z]dienatiN$_4$)]-PF$_6$. These complexes have been characterized by elemental analyses, ^{1}H NMR, infrared, and electronic spectra. One of the parent complexes [Ni(Me$_2$[14]dienatoN$_4$)]Br·H$_2$O has been subjected to the single-crystal X-ray diffraction technique and its structural data indicated that the average Ni–N bond distance is longer than that of the corresponding thirteen membered complex.

The γ-position of six-membered diiminato chelate rings[1–6] as well as that of the chelate rings of acetylacetonato complexes[7–9] have been found to be very reactive nucleophilic center. This reactivity has been employed to introduce a large number of substituents into macrocyclic ligands.[1–6] These substituent derivatives have been produced by what have been proposed to be electrophilic attacks on the γ-carbon in a manner similar to substitution in ordinary aromatic rings.

Recently, Busch and coworkers[10,11] reported the synthesis of a broad range of substituted derivatives [Ni(Me$_2$E$_2$[Z]tetraenatoN$_4$)](Z=14, 15, 16, E=acetyl, carbethoxyethyl, α-naphthylcarbamoyl, ethylcarbamoyl, benzoyl, *p*-methylbenzoyl, *p*-nitrobenzoyl, methylsuccinoyl, nitro) (**1**) by electrophilic substitution reaction at the γ-carbons of the parent complexes [Ni(Me$_2$[Z]-tetraenatoN$_4$)], where the parent complex has two nucleophilic centers, and elucidated that both the position of the d-d electronic band maxima and the half-wave potential for the Ni^{2+}/Ni^{3+} couple vary linearly with the Hammett substituent constants. This result indicates that the use of substituents affords a powerful technique for controlling the electronic character of the metal ion without altering the stereochemistry of the coordination sphere.



1 **2**

Fig. 1. Structures of [Ni(Me$_2$E$_2$[Z]tetraenatoN$_4$)] (**1**) and [Ni(Me$_2$E[Z]dienatoN$_4$)]$^+$ (**2**), where E and Z denote the substituent group and ring size, respectively. The abbreviation used in this report are based on Busch's modified scheme.[15,16]

In this study, the complexes [Ni(Me$_2$[Z]dienatoN$_4$)]$^+$ (**2**) firstly synthesized by Cummings and coworkers[12–14] were used as the parent complexes where each parent complex has only one nucleophilic center. The substituted derivatives [Ni(Me$_2$E[Z]dienatoN$_4$)]PF$_6$ have been prepared by electrophilic substitution reaction of the parent complex with *p*-substituted benzoyl chlorides and characterized by elemental analyses, infrared, ^{1}H NMR, and electronic spectra. The effects of the substituents on the properties of the central nickel ion as well as the macrocyclic ring-size effects were examined by the d-d band maxima of the electronic spectra. In addition, the crystal structure of one of the parent complexes [Ni(Me$_2$[14]dienatoN$_4$)]Br·H$_2$O has been determined by the single-crystal X-ray diffraction method in order to investigate the influence of ring-size on the molecular structure.

Experimental

Physical Measurements. Visible and ultraviolet spectra were obtained with a Hitachi recording spectrophotometer 323, while infrared spectra were recorded as KBr disks with a Shimadzu recording spectrophotometer IR-410. The 100 MHz ^{1}H NMR spectra were recorded on a JEOL MH 100 spectrometer. The solvent used was acetone-d_6 and in all cases shift measurements were made relative to tetramethylsilane. Elemental analysis was performed by Mr. S. Miyazaki at the Technical Service Center of Kumamoto University.

Syntheses. *3,7-Diazanonane-1,9-diamine ($H_2N(CH_2)_2NH(CH_2)_3NH(CH_2)_2NH_2$)* was prepared according to the method of Barefield *et al.*[17] The parent complexes [Ni(Me$_2$-[Z]dienatoN$_4$)]X (Z=13, 14 and X=Br, I, PF$_6$) were prepared by the method of Cummings[12] and identified by elemental analyses and infrared spectra.

(12-Benzoyl-11,13-dimethyl-1,4,7,10-tetraaza-10,12-cyclotrideca-dienato)nickel(II) Hexafluorophosphate, [Ni(Me$_2$Byzl[13]dienatoN$_4$)]-PF$_6$, 2(E=C$_6$H$_5$CO–, n=m=2): 0.224 g (1.6 mmol) of benzoyl chloride and 0.126 g (1.6 mmol) of pyridine were added to a solution of 0.357 g (1 mmol) of [Ni(Me$_2$[13]-dienatoN$_4$)]Br·1/2H$_2$O in 100 ml of chloroform. The solution was refluxed for 6 h and then evaporated to dryness under reduced pressure. The resultant orange-red viscous oil was dissolved in 50 ml of ethanol and addition of excess ammonium hexafluorophosphate in ethanol gave red-orange precipitates. This material was collected, recrystallized from ethanol and

dried *in vacuo*.

[12-(p-Methylbenzoyl)-11,13-dimethyl-1,4,7,10-tetraaza-10,12-cyclotridecadienato]nickel(II) Hexafluorophosphate, [Ni(Me$_2$MeBzyl[13]dienatoN$_4$)]PF$_6$, 2(E=p-CH$_3$C$_6$H$_4$CO–, n=m=2): *[12-(p-Nitrobenzoyl)-11,13-dimethyl-1,4,7,10-tetraaza-10,12-cyclotridecadienato]nickel(II) Hexafluorophosphate, [Ni(Me$_2$NitroBzyl[13]dienatoN$_4$)]PF$_6$, 2(E=p-NO$_2$C$_6$H$_4$CO–, n=m=2)*: These complexes were synthesized by a method similar to that for [Ni(Me$_2$Bzyl[13]dienatoN$_4$)]PF$_6$ except for using *p*-methylbenzoyl chloride and *p*-nitrobenzoyl chloride instead of benzoyl chloride, respectively.

(13-Benzoyl-12,14-dimethyl-1,4,8,11-tetraaza-11,13-cyclotetradienato)nickel(II) Hexafluorophosphate, [Ni(Me$_2$Bzyl[14]dienatoN$_4$)]PF$_6$, 2(E=C$_6$H$_5$CO–, n=2, m=3): 0.210 g (1.5 mmol) of benzoyl chloride and 0.151 g (1.5 mmol) of triethylamine were added to a solution of 0.380 g (1 mmol) of [Ni(Me$_2$[14]dienatoN$_4$)]Br·H$_2$O in 100 ml dichloromethane. The solution was refluxed for 6 h and then evaporated to dryness under reduced pressure. The resultant orange-red viscous oil was dissolved in 50 ml of ethanol and small ammount of dichloromethane. The saturated ammonium hexafluorophosphate solution in ethanol was slowly added to the solution to precipitate red-orange material. This material was collected, recrystallized from ethanol and small ammount of chloroform, and dried *in vacuo*.

[13-(p-Methylbenzoyl)-12,14-dimethyl-1,4,8,11-tetraaza-11,13-cyclotetradecadienato]nickel(II) Hexafluorophosphate, [Ni(Me$_2$MeBzyl[14]dienatoN$_4$)]PF$_6$, 2(E=p-CH$_3$C$_6$H$_4$CO–, n=2, m=3): *[13-(p-Nitrobenzoyl)-12,14-dimethyl-1,4,8,11-tetraaza-11,13-cyclotetradecadienato]nickel(II) Hexafluorophosphate, [Ni(Me$_2$NitroBzyl[14]dienatoN$_4$)]PF$_6$, 2(E=p-NO$_2$C$_6$H$_4$CO–, n=2, m=3)*: The above two complexes were synthesized by a method similar to that for [Ni(Me$_2$Bzyl[14]dienatoN$_4$)]PF$_6$ except for using *p*-methylbenzoyl chloride and *p*-nitrobenzoyl chloride, respectively, instead of benzoyl chloride.

X-Ray Diffraction. Red rhombic crystals of the complex [Ni(Me$_2$[14]dienatoN$_4$)]Br·H$_2$O, suitable for X-ray diffraction study, were prepared by slow evaporation from aqueous solution at room temperature. A crystal with dimensions of 0.4×0.3×0.4 mm was examined with a Rigaku AFC-5 four-circle automated diffractometer. The unit cell dimensions and their estimated standard deviations were obtained from a least-squares fit to 15 high angle reflections ($14°<2\theta<38°$) using Mo *Kα* graphite monochromatized radiation ($\lambda=0.71069$ Å) at 24±1 °C. Systematic absences $h0l$, $l=2n+1$ and $0k0$, $k=2n+1$, indicate the space group $P2_1/c$. The crystal data obtained were as follows: $NiC_{12}H_{25}N_4OBr$, F. W.=379.9, monoclinic system, space group=$P2_1/c$, $a=12.637(3)$, $b=11.090(3)$, $c=10.556(1)$ Å, $\beta=91.22(1)°$, $V=1596.1(6)$ Å^3, $Z=4$, $D_x=1.581$ g cm^{-3}.

The intensity data were collected by the 2θ-θ scan technique with a scan rate of 12°min^{-1}. For weak reflections the peak scan was repeated up to four times depending on their intensities. Three standard reflections were monitored every 100 reflections and their intensities showed a good stability. A total of 3130 reflections with $2\theta\leqq52°$ were collected. The ntensity data were corrected for the Lorentz and polarization effects, but not for the absorption, because of the crystal size and low absorption coefficient. Independent 2181 reflections with $|F_o|>3\sigma(|F_o|)$ were considered as "observed" and used for the structure determination.

Solution and Refinement of the Structure. The structure was solved by the conventional heavy-atom method and refined by the block-diagonal least-squares method. In the least-squares calculation, the function minimized was $\sum w(|F_o|-k|F_c|)^2$, where $w=1/\sigma(|F_o|)^2$ was adopted. The neutral atomic scattering factors for H, C_{COV}, N, O, Ni, and Br were taken from International Tables for X-ray Crystallography Vol. IV.[18] Anomalous dispersion corrections $\Delta f'$ and $\Delta f''$ for all the component atoms were also taken from the literature.[18] All the calculations were carried out on a FACOM M-200 computer in the Computer Center of Kyushu University by the use of a local version[19] of the UNICS II Crystallographic Computing System.[20,21]

The coordinates of the bromine and nickel atoms were obtained from a three-dimensional Patterson synthesis. Successive Fourier and difference Fourier syntheses revealed all the nonhydrogen atoms except for the water molecule of crystallization. Refinement with isotropic thermal parameters was carried out and the discrepancy indices $R_1=\sum||F_o|-|F_c||/\sum|F_o|$ and $R_w=[\sum w(|F_o|-|F_c|)^2/\sum w|F_o|^2]^{1/2}$ were 13.6 and 13.4%, respectively. After introducing anisotropic thermal parameters, a difference Fourier synthesis was calculated and revealed the missing water molecule. An occupancy factor of 1.0 was applied for the water, considering the peak height and the adjustment of the elemental analysis. Hydrogen atoms were inserted in their calculated positions and included in the refinement. Further refinement with anisotropic thermal parameters for nonhydrogen atoms and isotropic ones (4.0 Å^2) for hydrogen atoms gave the final values of 5.2 and 5.1% for R_1 and R_w, respectively. The final difference Fourier synthesis showed no significant feature, peaks being less than 0.5 eÅ^{-3}.

Final positional parameters of nonhydrogen atoms with their estimated standard deviations are given in Table 1. List of structure factors, anisotropic thermal parameters and atomic parameters of hydrogen atoms have been deposited at the Chemical Society of Japan as Document No. 8252.

Results and Discussion

Crystal Structure of Parent Complex [Ni(Me$_2$[14]dienatoN$_4$)]Br·H$_2$O. The crystal structure viewed along the b axis is shown in Fig. 2, where possible hydrogen bonds are drawn by dotted lines. A perspective drawing of the cation [Ni(Me$_2$[14]dienatoN$_4$)]$^+$ with the atom numbering scheme is shown in Fig. 3. The

Br···NH2*	2.46(6)	*($1-x,-1/2+y,1/2-z$)	

interatomic bond distances, angles and the intermolecular bond distances with their estimated standard deviations are given in Table 2.

As shown in Fig. 2 and Table 2, the atoms Br and Ow are hydrogen bonded to the secondary amine nitrogen atoms N(2) ($1-x$, $-1/2+y$, $1/2-z$) and N(3), respectively, and the evidence of the hydrogen bonds from this X-ray analysis confirmed the prediction of Cummings[12] based on the infrared and ^{1}H NMR spectra. The hydrogen bonds between the NH-proton and the electronegative anions have been studied for the complexes [Ni(Me_2[Z]dienatoN$_4$)]X (X=Br, I, SCN, BF_4, NO_3, PF_6; Z=13, 14) by the infrared and ^{1}H NMR spectra, in which the NH band shifts to higher energy with the change of the anion $Br^->I^->SCN^->NO_3^->BF_4^->PF_6^-$.[12]

As shown in Fig. 3, the macrocyclic cation exhibits nearly exactly Cs-m symmetry, although not required crystallographically. The pseudomirror plane containing Ni, C(4), and C(9) atoms is perpendicular to the coordination plane NiN_4. This molecular symmetry is also observed in the dicationic analogous compound with the same ring size [Co^{II}(Me_2[14]dieneN$_4$)·H_2O]-

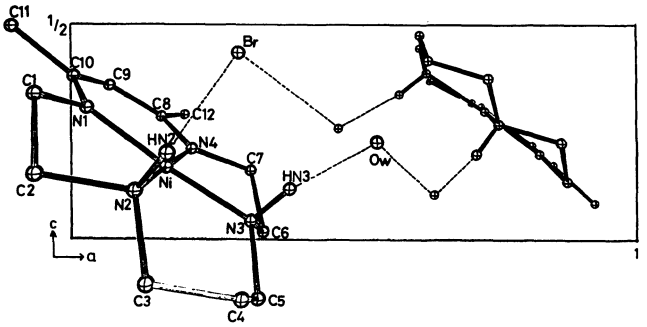

Fig. 2. Projection of the crystal structure [Ni(Me_2[14]-dienatoN$_4$)]Br·H_2O along the b axis.

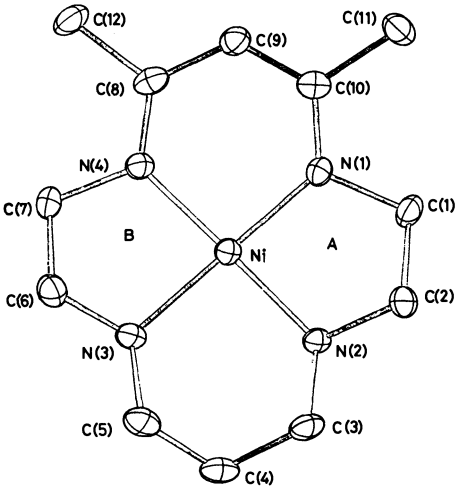

Fig. 3. ORTEP plot of [Ni(Me_2[14]dienatoN$_4$)]$^+$ Hydrogen atoms have been omitted for clarity.

$(PF_6)_2$,[22] while the analogous compound with thirteen ring size [Ni(Me_2[13]dienatoN$_4$)]ClO_4[23] exhibits C_2 symmetry.

The nickel ion has a square planar coordination geometry within the deviations of $\pm$0.03 Å and its four coordination sites are occupied by two iminate and two secondary amine nitrogen atoms. The four Ni–N bond distances fall into two groups, attributing to the difference between iminate and secondary amine nitrogen atoms. The average Ni–N (iminate) bond distance of 1.862(6) Å is shorter than the Ni–N (amine) of 1.937(7) Å. In addition, these two values are longer than the corresponding bond distances of Ni–N (iminate) (1.85(1) Å) and Ni–N (amine) (1.88(1) Å) in the case of [Ni(Me_2[13]dienatoN$_4$)]$^+$, respectively.[23]

For the unsaturated six-membered chelate ring, the planarity is preserved, in which the deviation from the least-squares plane defined by Ni, N(1), N(4), C(8), C(9), and C(10) is in the range from -0.03 to 0.03 Å. The C–C and C–N bond distances of the unsaturated chelate ring are intermediate between the corresponding single and double bond distances, respectively,[24] consistent with the conjugated chelate ring. The saturated six-membered chelate ring takes a chair conformation in which Ni and C(4) atoms displaced at -0.67 and 0.71 Å from the least-squares plane through N(3), N(2), C(3), and C(5), respectively. The

a) Spectra were obtained by KBr method.

saturated five-membered chelate rings (A and B) are all found to occupy gauche conformation with absolute configuration $\lambda\delta$ or $\delta\lambda$ (C(1), 0.09, C(2) −0.52 Å from the plane of Ni, N(1), and N(2): C(6) −0.47, C(7) 0.14 Å from the plane of Ni, N(3), and N(4)), while the absolute configuration of the five-membered chelate rings of $[Ni(Me_2[13]dienatoN_4)]^+$ is $\lambda\lambda$ or $\delta\delta$, either.[23]

As a consequence of the planarity of the conjugated six-membered chelate rings, the combination of the absolute configuration of two five-membered chelate rings ($\lambda\delta$ or $\delta\lambda$) and the chair-conformation of the saturated six-membered chelate ring, the molecular symmetry of the complex should exhibit Cs-m symmetry and the two hydrogen atoms bonded to secondary amine nitrogens are placed on the same side from the coordination plane (NiN_4).

Synthesis and Characterization of the Substituted Derivatives. The parent complex $[Ni(Me_2[Z]dienatoN_4)]^+$ (Z=13, 14) which has an iminato chelate ring containing a nucleophilic center reacts with electrophilies to produce the derivatives that are substituted at the γ-position. The substituted derivatives $[Ni(Me_2E[Z]dienatoN_4)]PF_6$ where E denotes benzoyl, p-methylbenzoyl and p-nitrobenzoyl, and Z=13 and 14, were characterized by elemental analyses, infrared and ^1H NMR spectra. Elemental analyses for the substituted derivatives are given in Table 3. Some selected infrared and ^1H NMR spectral data with their assignments are given in Tables 4 and 5. Infrared spectra of the products differ from the parent complexes, most notably in the appearance of C=O stretch at *ca.* 1640 cm^{-1}. Two vibrations (*ca.* 1740 and 1770 cm^{-1}) due to C=O stretching vibrations of the starting material, benzoyl chlorides, are absent in the products, supporting the introduction of the substituent. These features are also observed in the substituent complexes $[Ni(Me_2E_2[Z]tetraenatoN_4)]$ (**1**) and their parent complexes, supporting the formation of the complex $[Ni(Me_2E[Z]dienatoN_4)]^+$ (**2**). As anticipated, the -CH reasonance at the γ-position has disappeared since the substituted group is introduced at the γ-position.

Electronic Spectra: Visible and ultraviolet spectra of the complexes were obtained on the 10^{-3}—10^{-4} M solution in methanol over the range from 14 to 48$\times 10^3$ cm^{-1} and the band maxima are given in Table 6. This type of complexes showed several band maxima in the ultraviolet region of the spectra with extinction coefficient in the range from 1500 to 10000 M^{-1} cm^{-1} which agree with assignment of the bands as representing charge-transfer transition. The spectra also exhibit a broad band in the visible region with an extinction coefficient in the range 100—200 M^{-1} cm^{-1} which is attributable to the d-d transition band.

As shown in Table 6, the energy of d-d band maxima increase, when the substituent group such as benzoyl group is attached to the γ-carbon of the conjugated six-membered chelate ring. This indicates that the electronic property of the central nickel ion is affected

through the conjugated π-system of the iminato chelate ring by the electronic property of the substituent group. The energy difference of the d-d band maxima of $[Ni(Me_2[Z]dienatoN_4)]^+$ and $[Ni(Me_2Bzyl[Z]dienato N_4)]^+$ (1.2 and $1.0\times10^3\ cm^{-1}$ for Z=13 and 14, respectively) is nearly half of that of $[Ni(Me_2[Z]tetraenatoN_4)]$ and $[Ni(Me_2Bzyl_2[Z]tetraenatoN_4)]$ (2.3, 2.1, and $2.8\times10^3\ cm^{-1}$ for Z=14, 15, and 16, respectively[11]). This result is consistent with the fact that the former (**2**) and latter (**1**) complexes have one and two substituent groups, respectively.

As seen in Table 6, the maximum wavenumber of the d-d transition band of $[Ni(Me_2E[13]dienatoN_4)]PF_6$ is greater than that of $[Ni(Me_2E[14]dienatoN_4)]PF_6$, indicating that the ligand field strength of the thirteen membered complex is greater than that of the fourteen membered complex. This is consistent with that the average Ni–N bond distance of the former complex is shorter than that of the latter, as being evidenced by the crystal structure determinations of $[Ni(Me_2[13]dienato N_4)]ClO_4$[23] and $[Ni(Me_2[14]dienatoN_4)]Br\cdot H_2O$.

The linear correlation between the d-d band maxima and the Hammett substituent constants of the *p*-substituted benzoyl derivatives has not been clearly observed in the present complexes (**2**), while it was observed in the complexes (**1**).[11] This might be the result of that the overall planarity between the conjugated chelate ring and the substituted π-system of benzoyl group is preserved for the complex (**1**), while the charge-delocalized chelate ring can be perpendicular to the benzoyl group for the complex (**2**), owing to the steric hindrance between the neighbouring two methyl groups and the substituent group at the γ-position.

The authors are grateful to Prof. S. Kida at the Faculty of Science, Kyushu University for allowing them to use the diffractometer.

Synthesis, Characterization, and Crystal Structure of Substituted Derivatives of (Tetraazacyclotetradecatetraenato)copper(II) Complexes

Naohide MATSUMOTO,* Masahiko IMAIZUMI, and Akira OHYOSHI
Department of Industrial Chemistry, Faculty of Engineering, Kumamoto University, Kurokami 2-39-1, Kumamoto 860
(Received March 1, 1982)

(Tetraazacyclotetradecatetraenato)copper(II) complexes with the general formula [Cu(Me_2E_2[14]tetraenatoN_4)], where E denotes the substituent group of acetyl, propionyl, isobutyryl, benzoyl, *p*-methylbenzoyl, or *p*-nitrobenzoyl, have been prepared *via* electrophilic substitution of the parent complex [Cu(Me_2[14]tetraenatoN_4)] with acid chlorides, and characterized by elemental analyses and infrared spectra. For the *p*-substituted benzoyl derivatives, both the position of d-d electronic band maxima and reduction potential assignable to $Cu^{2+}+e \rightarrow Cu^+$ vary linearly with the Hammett substituent constants. The crystal structure of one of the complexes [Cu(Me_2Acyl_2[14]tetraenatoN_4)]·H_2O has been determined by the single-crystal X-ray diffraction method. The copper atom assumes a square planar coordination geometry and the overall conformation of the complex assumes a chair-like shape, where the seat and the rests are formed by the coordination plane (CuN_4) and the two conjugated six-membered chelate rings respectively.

Kadish and Morrison[1-3] examined substituent effects in porphyrin complexes by substituting various groups at the para position of the phenyl rings of tetraphenylporphyrin. Busch and co-workers[4,5] reported syntheses of a broad range of substituted derivatives [Ni(Me_2E_2[Z]tetraenatoN_4)] (Z=14, 15, 16) by electrophilic substitution at the γ-carbon of the conjugated chelate rings (Fig. 1), and examined substituent effects on electronic spectral and electrochemical properties of the complexes. These studies elucidated that the use of substituents affords a powerful technique for controlling the electronic character of the metal ion without altering the stereochemistry of the coordination sphere.

In this study, we have prepared the substituted derivatives [Cu(Me_2E_2[14]tetraenatoN_4)] by electrophilic substitution of the parent complex [Cu(Me_2[14]-tetraenatoN_4)] with acid chlorides such as propionyl chloride, isobutyryl chloride, benzoyl chloride, *p*-methylbenzoyl chloride, and *p*-nitrobenzoyl chloride. These complexes were characterized by elemental analyses and infrared spectra. Substituent effects on the properties of the copper ion were examined by electronic spectra and cyclic voltamogram. In addition, the crystal structure of [Cu(Me_2Acyl_2[14]tetraenatoN_4)]·H_2O has been determined by the single-crystal X-ray diffraction method in order to confirm the basic structure for the series of complexes.

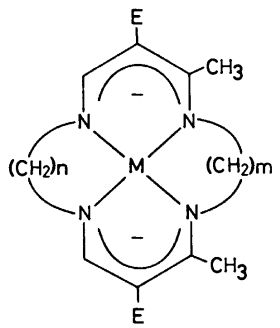

Fig. 1. Structure of [M^{2+}(Me_2E_2[Z]tetraenatoN_4)], where E and Z denote the substituted group and the macrocyclic ring size, respectively. (Z=14($n=m=2$), Z=15($n=2$, $m=3$), Z=16($n=m=3$)) The abbreviations used in this report are based on Busch's modified scheme.[6,7]

Experimental

Physical Measurements. Visible and ultraviolet spectra were recorded with a Hitachi recording spectrophotometer 323, while infrared spectra were recorded as KBr disk or nujol mull with a Shimadzu recording spectrophotometer IR-410. Elemental analyses were performed by Mr. Miyazaki at the Technical Service Center of Kumamoto University. Electrochemical measurements were performed with a Hokuto Denko Potentiostat/Galvanostat HA 101, a Hokuto Denko Function Generator HA 1074A, and a Rikadenki X-Y recorder BW-133. All measurements were made on acetonitrile solution containing 50 mM (1 M=1 mol dm^{-3}) tetrabutylammonium perchlorate as the supporting electrode. The working electrode was platinum disk electrode formed by sealing an 18—20 gauge platinum wire into soft glass. The reference electrode was a silver wire immersed in a 10 mM acetonitrile solution of silver perchlorate. Argon gas was bubbled into the solution for 30 min before measurement.

Syntheses. The acylated complex [Cu(Me_2Acyl_2[14]-tetraenatoN_4)]·H_2O was synthesized by the method of Jäger[8] or Riley and Busch.[9] Found: C, 50.09; H, 6.37; N, 14.59%. Calcd for $C_{16}H_{24}N_4O_3Cu$: C, 50.06, H, 6.30; N, 14.59%. IR (KBr): 1620 (C=O) and 1565 cm^{-1} (iminate ring).

(7,12-Dimethyl-1,4,8,11-tetraazacyclotetradeca-4,6,11,13-tetraenato)copper(II), [Cu(Me_2[14]tetraenatoN_4)]: This complex was first synthesized by Okawa and Busch[10] through a two-step procedure, in which the first step is removal of the acetyl groups along with the central nickel(II) ion and the second is reintroduction of the metal ion. In this work, this compound was synthesized through a one-step procedure by a similar method for the preparation of the corresponding nickel(II) complex.[5] In a 500 ml single-necked flask are combined 19.2 g (0.5 mol) of the complex [Cu(Me_2Acyl_2[14]tetraenatoN_4)]·H_2O, 9.5 g (0.5 mol) of *p*-toluenesulfonic acid monohydrate, and 150 ml of methanol. The mixture is refluxed under nitrogen for 30 min, during which time the solution becomes dark red. The solution is then cooled in a Dry Ice/acetone bath and a solution of 4 g (0.1 mol) of sodium hydroxide in 50 ml of methanol is added under nitrogen, during which time the solution becomes green. The solution is removed from the cold bath and maintained for 30 min at room temperature. The methanol is removed dy evaporation to dryness, and 50 ml of dry benzene is added. The resulting slurry is filtered quickly by a glass filter. The solution is

evaporated to dryness to give a greenish material. Found: C, 50.81; H, 6.50; N, 19.53%. Calcd for $C_{12}H_{18}N_4Cu$: C, 51.14; H, 6.44; N, 19.88%. The complex decomposes gradually even in the solid state under atmosphere, in which the color changes from green to black.

The synthesis of the substituted complexes is exemplified in detail by that of [Cu(Me_2Bzyl$_2$[14]tetraenatoN_4)], because the synthetic procedure is similar to one another.

(6,13-Dibenzoyl-5,14-dimethyl-1,4,8,11-tetraazacyclotetradeca-4,-6,11,13-tetraenato)copper(II), [Cu(Me_2Bzyl$_2$[14]tetraenatoN_4)]: Benzoyl chloride of 0.15 g (10.6 mmol) is added to a solution of 1 g (3.5 mmol) of the deacetylated complex and 1.45 g (14.4 mmol) of triethylamine in 40 ml of dichloromethane and 40 ml of benzene. The mixture is stirred and refluxed under nitrogen for 4 h. The solvent is removed by evaporation and the residue is dissolved in 50 ml of chloroform, and filtered. The volume of the solution is reduced and the solution is chromatographed on a column of Merck 60G ($\phi 2.0 \times 20$ cm^2) with chloroform as the eluent. The eluent of the first band is collected and the solvent is evaporated. Recrystallization is carried out in methanol to give red crystals. Found: C, 63.45; H, 5.27; N, 11.23%. Calcd for $C_{26}H_{26}N_4O_2Cu$: C, 63.72; H, 5.35; N, 11.43%. IR(KBr): 1618 (C=O), 1560 (iminate ring), and 1596 cm^{-1} (benzoyl group).

(6,13-Dipropionyl-5,14-dimethyl-1,4,8,11-tetraazacyclotetradeca-4,6,11,13-tetraenato)copper(II), [Cu(Me_2Propi$_2$[14]tetraenatoN_4)]: Propionyl chloride of 0.99 g (10.67 mmol) was used instead of benzoyl chloride. Found: C, 54.70; H, 6.37; N, 13.87%, Calcd for $C_{18}H_{26}N_4O_2Cu$: C, 54.87; H, 6.65; N, 14.22%. IR(KBr): 1618 (C=O) and 1560 cm^{-1} (iminate ring).

(6,13-Diisobutyryl-5,14-dimethyl-1,4,8,11-tetraazacyclotetradeca-4,6,11,13-tetraenato)copper(II), [Cu(Me_2iso-Butryl$_2$[14]tetraenato-N_4)]: Isobutyryl chloride of 1.14 g (10.67 mmol) was used instead of benzoyl chloride. Found: C, 56.80; H, 7.26; N, 13.19%. Calcd for $C_{20}H_{30}N_4O_2Cu$: C, 56.92; H, 7.16; N, 13.27%. IR(KBr): 1630 (C=O) and 1575 cm^{-1} (iminate ring).

(6,13-Bis(p-methylbenzoyl)-5,14-dimethyl-1,4,8,11-tetraazacyclotetradeca-4,6,11,13-tetraenato)copper(II), [Cu(Me_2p-MeBzyl$_2$-[14]tetraenatoN_4)]: *p*-Methylbenzoyl chloride of 1.65 g (10.67 mmol) was used instead of benzoyl chloride. Found: C, 64.72; H, 5.46; N, 10.34%. Calcd for $C_{28}H_{30}N_4O_2Cu$: C, 64.91; H, 5.83; N, 10.81%. IR(KBr): 1618 (C=O), 1550 (iminate ring), and 1600 cm^{-1} (benzoyl group).

(6,13-Bis(p-nitrobenzoyl)-5,14-dimethyl-1,4,8,11-tetraazacyclotetradeca-4,6,11,13-tetraenato)copper(II) Methanol, [Cu(Me_2p-NitroBzyl$_2$[14]tetraenatoN_4)]·CH_3OH: *p*-Nitrobenzoyl chloride of 1.98 g (10.67 mmol) was used instead of benzoyl chloride. Found: C, 52.76; H, 4.76; N, 14.04%. Calcd for $C_{26}H_{24}N_6O_6Cu\cdot(CH_3OH)$: C, 52.98; H, 4.61; N, 13.73%. IR(KBr): 1620 (C=O), 1560 (iminate ring), and 1595 cm^{-1} (benzoyl group).

X-Ray Diffraction. The crystals of [Cu(Me_2Acyl$_2$[14]-tetraenatoN_4)]·H_2O were grown from a 98% methanolic solution as red prismatic crystals. The cell dimensions were determined by a least-squares method based on the angular settings of 15 reflections measured on a Syntex P$\bar{1}$ automated four-circle diffractometer. Intensity data were also collected with the diffractometer by a θ-2θ scan technique with a variable scan rate from 4.0 to 24.0°min^{-1}. The crystal data obtained are as follows: $C_{16}H_{22}N_4O_2Cu\cdot H_2O$, F.W.=383.9, triclinic system, space group=P$\bar{1}$, a=10.641(5), b=10.649(4), c=7.548(3) Å, α=90.98(3), β=88.95(3), γ=87.59(3)°, V=854.3 Å^3, D_m=1.46 (in KI aqueous solution), D_x=1.48 g cm^{-3} for Z=2, and μ(Mo $K\alpha$)=13.0 cm^{-1}. A total of 1597 independent reflections with $2\theta \leqq 42°$ were collected and these data were corrected for Lorentz and polarization effects, but not for absorption.

Structure Determination. Structure was solved by the conventional heavy-atom method and refined by the block-diagonal least-squares method. The function minimized in the procedure of the least-squares method was $\sum w(|F_o|-k|F_c|)^2$, where w=1 was adopted. The atomic scattering factors for Cu, O, N, C_{cov}, and H were taken from the International Tables for X-ray Crystallography.[11] The anomalous dispersion corrections $\Delta f'$ and $\Delta f''$ for Cu were also taken from the literature.[11] All the calculation was carried out on a FACOM M-190 computer at the Computer Center of Kyushu University by the use of UNICS II program system.[12-14]

The coordinates of the copper atom were determined from a three-dimensional Patterson synthesis. Successive Fourier and difference Fourier syntheses revealed all the nonhydrogen atoms. Refinement was carried out by introducing initially isotropic thermal parameters and then anisotropic ones. At this stage, a difference Fourier synthesis was calculated and revealed all the hydrogen atoms except for those of water molecule. These hydrogen atoms were included in the refinement and gave the final value of 6.45% for $R=\sum||F_o|-|F_c||/\sum|F_o|$. The final difference Fourier synthesis showed four diffuse peaks (0.6 eÅ^{-3}) around the copper atom, but the other peaks are in the range -0.2 to 0.2 eÅ^{-3}. Final positional parameters with their estimated standard deviations are given in Table 1. Lists of structure factors, anisotropic thermal parameters, atomic parameters of hydrogen atoms, and selected least-squares planes have been deposited at the Chemical Society of Japan as Document No. 8245.

Results and Discussion

Crystal Structure of [Cu(Me_2Acyl$_2$[14]tetraenatoN_4)]·H_2O. Perspective drawings with the atom numbering scheme, bond distances, and angles are shown in Fig. 2. The

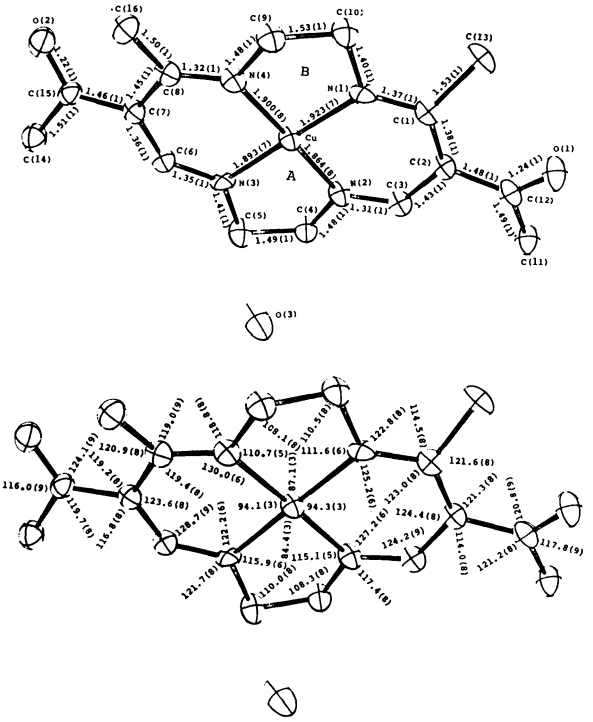

Fig. 2. ORTEP drawing of [Cu(Me$_2$Acyl$_2$[14]tetraenatoN$_4$)]·H$_2$O with the atom numbering scheme, bond distances and angles. The thermal ellipsoids are drawn at 25% probability level. The hydrogen atoms are omitted for clarity.

crystal structure consists of a discrete neutral complex [Cu(Me$_2$Acyl$_2$[14]tetraenatoN$_4$)] and a water molecule as crystal solvent. The copper atom is coordinated by four nitrogen atoms and the deviations of the component atoms from the coordination plane CuN$_4$ are in the range from −0.08 to +0.08 Å, showing a good planarity. The Cu–N bond distances are in the range expected for those of Cu–N(iminate)[15] and considerably shorter than those of the Cu–N (amine).[16]

For the two unsaturated six-membered chelate rings, the planarity for each chelate ring seems to be preserved, in which the deviations of the component atoms from the plane N$_2$C$_3$ are in the range from 0.05 to −0.03 Å. However, the C(13) of the methyl group bonded to C(1) deviates by 0.50 Å from the plane N$_2$C$_3$, due to the steric repulsion between the oxygen atom of the acyl group and itself. The C–C and C–N bond distances of the unsaturated chelate rings are intermediate between the corresponding single and double bond distances,[17] respectively, indicating that the chelate rings are π-electron conjugated systems. The saturated five-membered chelate rings (A and B) are all found to assume the gauche conformation with absolute configuration $\lambda\delta$ or $\delta\lambda$, where C(4) and C(5) deviate by 0.17 and −0.17 Å from the plane of CuN(2)N(3) and C(10) and C(9) deviate by 0.25 and −0.27 Å from the plane of CuN(1)N(4), respectively.

As a consequence of the planarities of the two conjugated chelate rings and the combination of the absolute configurations of the two saturated five-membered chelate rings, the overall conformation of the complex takes a chair-like shape, where the seat and the rests are formed by the coordination plane CuN$_4$ and the two unsaturated six-membered chelate rings, respectively. In other words, the two conjugated chelate rings are folded upward and downward on the CuN$_4$ plane with a gradient of 8°. This molecular conformation is apparently different from the so-called saddle shape conformation, which is observed in the analogous complexes with fifteen[18] and sixteen[19] membered ring sizes and in which the two unsaturated chelate rings are folded upward on the same side of the MN$_4$ plane.

Synthesis and Characterization. The complex [Cu(Me$_2$Acyl$_2$[14]tetraenatoN$_4$)] can be converted into a powerful nucleophile by removal of the acetyl groups. The unsubstituted complex [Cu(Me$_2$[14]tetraenatoN$_4$)] reacts with a variety of electrophiles to produce derivatives that are substituted at the γ and γ' positions. The complexes with substituted groups at the γ and γ' positions were characterized by elemental analyses and infrared spectra. Infrared spectra showed the C=O stretching band in *ca.* 1620 cm^{-1} and the band of the iminate rings in *ca.* 1550—1580 cm^{-1}. Two vibrations (*ca.* 1770 and 1740 cm^{-1}) due to the C=O stretching of the starting material, *i.e.*, acid chlorides, are absent in products, supporting the introduction of the substituent.

Electronic Spectra. Visible and ultraviolet spectra of the complexes were obtained on 10^{-4}—10^{-5} mol dm^{-3} solutions in chloroform over the range (14—48)×10^3 cm^{-1}, and the band maxima are given in Table 2. The complexes show band maxima in the ultraviolet region with extinction coefficients in the range from 20000 to 48000 dm^3 mol^{-1} cm^{-1} which agree with the assignment of the band as representing a charge-transfer transition. The spectrum also exhibits a broad band in the visible region with an extinction coefficient in the range 400—750 dm^3 mol^{-1} cm^{-1} which is attributable to the d-d transition band.

Effect of electronic properties of the substituent groups was observed in the d-d transition band rather than in the charge-transfer band. The energy of the d-d transition increases with an increase in electron-withdrawing strength of the substituent groups, which is consistent with the result of Busch and co-workers[4,5] reported for nickel(II) complexes with a broad range of substituent groups in the same ligand system. For the complexes with *p*-substituted benzoyl groups, the observed d-d band maxima are linearly correlated to the Hammett substituent constants of the *p*-substituted groups, as shown in Fig. 3. This may be a result of the

overall planarity between the charge-delocalized chelate ring and the substituted π-electron system of the benzoyl group. For the complexes with substituent groups CH_3CO-, C_2H_5CO-, and i-C_3H_7CO-, the tendency of their d-d transition band maxima is observed but not so large.

Electrochemistry. Electrochemical measurements were performed on 10^{-3} mol dm^{-3} solutions of the substituted complexes in acetonitrile. For the direct comparison of the values obtained, the conditions were kept as constant as possible with all the complexes. The cyclic voltamograms of these complexes were similar in shape and showed three electrode processes: (1) the irreversible reduction at a negative potential around −1 V, (2) the relatively well-behaved reduction at around 0 V, and (3) the relatively well-behaved oxidation at a positive potential around 1 V, as given in Table 3. Since Yokoi and Addison[20] reported that Cu^{2+}/Cu^{+} reduction potentials of square planar copper(II) complexes with imine or amine nitrogen atoms are in the range from −0.7 to −1.5 V, the reduction around −1 V of these complexes can be assigned to $Cu^{2+}+e\rightarrow Cu^{+}$, although it is irreversible. For the *p*-substituted benzoyl derivatives, only the reduction potential of the three electrode processes is linearly correlated to the Hammett substituent constants of the *p*-substituent groups, and the slope is −0.072, as shown in Fig. 4. For the corresponding nickel(II) complexes,[5] the linear correlation between the Hammett substituent constants and the oxidation potentials due to the Ni^{2+}/Ni^{3+} couple was also observed, the slopes being 0.035, 0.064, and 0.047 for the series of 14-, 15-, and 16-membered complexes, respectively.

Polarographic Behavior of Cobalt-1-Nitroso-2-naphthol Complex in Ammonium Citrate and Tartrate Solutions

Masao SUGAWARA, Toyoaki UCHIDA, and Tomihito KAMBARA*
Department of Chemistry, Faculty of Science, Hokkaido University, Kita-ku, Sapporo 060
(Received March 18, 1982)

The reduction behavior of cobalt(II) in ammonium citrate and tartrate solutions containing 1-nitroso-2-naphthol was investigated by means of d.c., a.c., normal and differential pulse polarography (n. p. p. and d. p. p.). When cobalt(II) is added to the supporting electrolyte of citrate or tartrate in the presence of the nitrosonaphthol, the reduction potential of 1-nitroso-2-naphthol shifts to a more negative value, the well-defined a. c. and d. p. p. peaks appearing. The drop time-potential curve indicated that adsorption of nitrosonaphthol as well as its reduction product at the mercury surface occurs. The analytical potentiality of the use of nitrosonaphthol for the microdetermination of cobalt(II) is also described.

The enhancement of current intensity of metal ions is often observed in solutions containing complex-forming molecules adsorbable at the electrode surface.[1-7] The phenomenon has been used for increasing the sensitivity of determination of metal ions.[2-5,8,9]

The well-known specific reagent for cobalt, 1-nitroso-2-naphthol, is reduced at the mercury electrode in four-electron step to the amine.[10-13] We found that the nitrosonaphthol is adsorbed on the mercury surface in a wide potential region, and by adding cobalt(II), the reduction of nitrosonaphthol shifts to a more negative potential, giving well-defined a.c. and d.p.p. peaks. In the present work, the behavior of cobalt–1-nitroso-2-naphthol complex in ammonium tartrate and citrate solutions is investigated with various methods of polarization of the dropping mercury electrode.

Experimental

Apparatus. D.c. and a.c. polarograms were obtained with a Yanagimoto polarograph model P-8. The dropping mercury electrode used had the characteristics: $m=2.53$ mg s^{-1} in deionized water and $t=3.87$ s in 0.1 M (1 M=1 mol dm^{-3}) ammonium citrate solution of pH 9.1 at open circuit and $h=39$ cm. A saturated calomel electrode was used as the reference electrode. For the a.c. polarography, the reference electrode was connected to a platinum coil counter electrode via a pool condenser of 3300 μF. Normal and differential pulse polarograms were recorded with a Princeton Applied Research model 174A polarographic analyzer, equipped with a Rika Denki X-Y recorder, model RW-11. A PAR 174/70 drop timer was used. The dropping mercury electrode used had the characteristics: $m=3.99$ mg s^{-1} in deionized water and $t=2.41$ s in 0.2 M ammonium tartrate solution of pH 8.7 at open circuit, when $h=71$ cm. A platinum wire served as the counter electrode and SCE as the reference electrode.

Electrolysis solutions were deaerated by bubbling pure nitrogen gas which had been passed through the supporting elcetrolyte of the same pH value. During electrolysis, nitrogen gas was passed over the solution. All polarograms were recorded at 25±0.1 °C. A Hitachi-Horiba glass electrode pH meter, F-5, was used for the pH measurements.

Reagents. Commercially available 1-nitroso-2-naphthol (Wako Chemicals Co.) was purified according to the literature.[14] A 0.01 mol dm^{-3} stock solution of the nitrosonaphthol was prepared by dissolving the purified reagent by weight in 10 cm^3 of 0.1 mol dm^{-3} sodium hydroxide solution and diluting to 50 cm^3 with deionized water. A 1.0×10^{-2} mol dm^{-3} stock solution of cobalt(II) was prepared from chloride and standardized chelatometrically. Other reagents used were all of the G. R. grade. Deionized water was used.

The electrolysis solution was prepared as follows. To a known portion of cobalt(II) solution in a 50-cm^3 volumetric flask are added in sequence 10 cm^3 of 1 mol dm^{-3} ammonium citrate or tartrate solution and 0.1 cm^3 of 0.01 mol dm^{-3} nitrosonaphthol solution, in order to prevent the appearance of precipitate. After standing for 30 min, the pH of solution is adjusted by adding an appropriate amount of 5 mol dm^{-3} ammonia solution and the mixture is diluted to the volume with deionized water. According to the procedure, the citrate or tartrate concentration in the electrolysis solution is always kept at 0.2 mol dm^{-3}.

Results and Discussion

D.c. and a.c. Polarographic Behavior. The cobalt–1-nitroso-2-naphthol complex is sparingly soluble in aqueous solutions and the precipitate once formed does not dissolve in the aqueous solution, but when the amount of cobalt(II) is low, a red-orange solution appears instead of the precipitate. D.c. and a.c. polarograms of cobalt(II) in an ammonium citrate solution of pH 9.1 containing an excess amount of 1-nitroso-2-naphthol are shown in Figs. 1 and 2, respectively. The d.c. first wave corresponds to the reduction of 1-nitroso-

2-naphthol to the amine. When cobalt(II) is added to the solution, the first wave diminishes and an ill-defined second wave at about −0.52 V *vs.* SCE appears. The reduction of 1-nitroso-2-naphthol proceeds in a four-electron step involving four protons,[10,12] and is diffusion-controlled.[10,11] Tomes' method[15] applied to the first wave for evaluating the reversibility gave the difference of $E_{1/2}-E_{3/4}=25$ mV, which is fairly greater than 15 mV, expected from the reversible four-electron process. The d.c. second wave being ill-defined, the further analyses were impossible.

On the a.c. polarogram of cobalt ion, in the presence of an excess amount of 1-nitroso-2-naphthol, two well-developed peaks are observed. The first and second peaks correspond to the d.c. first and second steps, respectively, although the peak potential of the a.c. first peak is more negative by about 70 mV of the half-wave potential of the corresponding d.c. step. Compared with the a.c. polarogram of the supporting electrolyte alone, the depression of base current of the a.c. wave of nitrosonaphthol is observed. A plot of drop time *vs.* potential in the tartrate medium, as shown in Fig. 3, indicates that the nitrosonaphthol and its reduction product are adsorbed on the electrode surface. The similar results were obtained also in the citrate medium. The remarkably enhanced a.c. second peak, as compared with the d.c. second step, is ascribed to the adsorption of complex and its reduction product at the electrode surface, leading to the decrease in faradaic impedance.[1] In the citrate medium the peak height of the cobalt complex depends strongly on the solution pH, as shown in Fig. 4. The plot of peak potential *vs.* pH between 8.6 and 9.3 gave a straight line with a slope of −64 mV for the first and −76 mV for the second peak. The electrode process of nitrosonaphthol and its cobalt complex is seemingly not completely reversible in a.c. sense. The height of a.c. peak of the cobalt complex increases linearly with increasing concentration of cobalt(II) between 0.5 and 5 μmol dm^{-3}. At higher concentration of cobalt(II) above 5 μmol dm^{-3}, the linear relationship does not hold and the value of i_{AC}/C (μS mol^{-1} dm^3) increases with

increasing concentration C of cobalt(II).

Normal Pulse and Differential Pulse Polarographic Behavior. Normal and differential pulse polarograms of cobalt(II) in an ammonium tartrate solution containing an excess amount of nitrosonaphthol are shown in Fig. 5. On the normal pulse polarogram, a maximum, followed by a current suppression, is observed for the both waves at about −0.26 and −0.60 V. The phenomena are ascribed to Barker-Bolzan effect[1] indicating the rather strong adsorption of depolarizer at the electrode surface. On the differential pulse polarogram of the cobalt–nitrosonaphthol system three peaks are observed. The first peak at −0.21 V corresponds to the reduction of nitrosonaphthol and the second at −0.52 V to the reduction of nitrosonaphthol bound to cobalt(II). At a fairly negative potential (−1.20 V), an additional small peak appears, the potential of which coincides well with the potential of Co(II)/Co(Hg) system in the tartrate solution, as the polarograms 2 and 4 in Fig. 5 show. The height of the second peak was almost constant in the pH range from 8.2 to 8.9, and a plot of peak potential *vs.* pH gave a straight line having a slope of −52 mV, as shown in Fig. 4. The slope is in good accordance with the theoretical value of −59 mV for the reversible four-electron process involving four protons. The result indicates that the electrode reaction of cobalt complex is reversible in the d.p.p. sense. The peak height of cobalt complex increases with increasing concentration of cobalt(II) between 0.05 and 0.5 μmol dm^{-3}, but at the concentration of cobalt(II) above 0.6 μmol dm^{-3}, the increase in peak height becomes gradually saturated. The narrow concentration range, in which the calibration graph is linear, is one of the characteristic features indicating the adsorption of depolarizer. The calibration graph does not pass the origin, because a trace amount of cobalt(II) is present in the tartrate buffer solution as an impurity. The concentration of cobalt(II) impurity in the 0.2 mol dm^{-3} ammonium tartrate solution of pH 8.7 was found to be 0.11 μmol dm^{-3}.

The Composition of the Cobalt Complex and Electrode Reaction Mechanism. A plenty of data[10,11,16–20] on the composition of the cobalt-1-nitroso-2-naphthol complex indicate that the number of ligand bound to cobalt ion and the oxidation state of cobalt depend on the media employed. According to Kolthoff and Jacobsen,[11] bis(1-nitroso-2-naphtholato)cobalt(II) is formed in neutral and weakly alkaline solutions, and in an acidic solution, the cobalt(II) complex disproportionates rapidly, forming tris(1-nitroso-2-naphtholato)-cobalt(III). The similar disproportion process is suggested by Collahan *et al.*[18] based on the potentiometric titration in dioxane–water mixture. The formation of bis(1-nitroso-2-naphtholato)cobalt(II) in an ammonium citrate solution of pH 9.8 is also cited in the excellent monograph by Pyatnitskii.[20]

Dependence of a.c. peak height on various concentrations of 1-nitroso-2-naphthol in an ammonium citrate solution of pH 9.1 is shown in Fig. 6. The sharp increase in peak height of the cobalt complex is saturated at 2.3 of the molar ratio of nitrosonaphthol to cobalt(II). Further addition of the nitrosonaphthol decreases the peak height of the complex gradually, while the a.c. first peak of excess ligand appears. It seems that in the citrate solution bis(1-nitroso-2-naphtholato)cobalt(II) is predominantly formed according to

$$Co^{2+} + 2R(NO)OH \rightleftarrows Co[R(NO)O]_2 + 2H^+, \quad (1)$$

where R(NO)OH indicates the 1-nitroso-2-naphthol. The reduction of R(NO)OH at the mercury electrode[11,12] is given by

$$R(NO)OH + 4H^+ + 4e \rightleftarrows R(NH_2)OH + H_2O. \quad (2)$$

The nitrosonaphthol coordinated to cobalt(II) being stabilized, the reduction of the nitrosonaphthol in the complex shifts to a more negative potential. The overall electrode reaction is estimated to be

$$Co[R(NO)O]_2 + 8H^+ + 8e \rightleftarrows Co^{2+} + 2R(NH_2)O^- + 2H_2O. \quad (3)$$

In the ammonium tartrate solution of pH 8.7, the results of titration of 1 μmol dm^{-3} cobalt(II) with R(NO)OH gave the breaking point at around 2.6 of the molar ratio of the nitrosonaphthol to cobalt(II) for both the first and second waves. The results imply that a fraction of bis(1-nitroso-2-naphtholato)cobalt(II) in the tartrate solution differs slightly from that in the citrate medium. It should be noted that the decrease in a.c. and d.p.p. peak heights by adding excess amount of ligand is always observed and is due to the broadening of peaks. At 5 μmol dm^{-3} nitrosonaphthol, the half-width of d.p.p. peak of 1 μmol dm^{-3} cobalt(II) in the tartrate solution is 77 mV, however, it is 94 mV at 80 μmol dm^{-3} nitrosonaphthol. This is probably because the electrode reaction of the cobalt complex is hindered by the stronger adsorption of reduction product of nitrosonaphthol than the adsorption of the complex itself. The appearance of a small d.p.p. peak at −1.20 V in the tartrate solution, as described above, suggests that the cobalt(II) released by reduction is further reduced in the medium.

The adsorption of the cobalt complex at the mercury surface is not clear as judged from the drop time *vs.* potential plot, as shown in Fig. 3. However, the significantly enhanced response in a.c. polarography and also the narrow concentration range, for which the d.p.p. response is linear, imply that the cobalt complex is also adsorbed on the mercury surface.

TABLE 1. EFFECT OF FOREIGN METAL IONS ON THE d.p.p. DETERMINATION OF COBALT(II) IN 50 cm^3 OF 0.2 mol dm^{-3} AMMONIUM TARTRATE-0.05 mol dm^{-3} AMMONIA SOLUTION OF pH 8.7 CONTAINING 10 μmol dm^{-3} 1-NITROSO-2-NAPHTHOL

Metal	Metal added (μg)	Cobalt(II) found (μg)	Reovery %
Ni(II)	0.59	0.53	90
	2.94	0.49	83
Cd(II)	11.24	0.58	98
	22.48	0.31	53
Zn(II)	6.54	0.64	108
	13.08	0.66	112
	13.08	0.59	100 [a]
Fe(III)	5.58	0.62	105
	11.17	0.84	142
Cu(II)	0.64	0.93	158
	3.18	1.69	286

Cobalt(II) taken: 0.59 μg. a) Concentration of the nitrosonaphthol was increased by twice.

Analytical Potentiality. Although the remarkably enhanced a.c. response is obtained, the d.p.p. method is more sensitive, because of the inherent advantage to discriminate faradaic current from nonfaradaic one. In the alkaline solution of ammonium tartrate, cobalt at several ppb levels can be determined by differential pulse polarography. The slightly alkaline tartrate medium is preferable for the analytical purposes, because in this medium the interference by iron(III) is significantly suppressed. Effect of some metal ions on the d.p.p. determination of cobalt(II) is given in Table 1. Serious interference by copper(II) was found, which is due to the overlapping of the reduction peak of the copper(II)–nitrosonaphthol complex with the cobalt(II) peak. Improvement of selectivity of the method may be achieved by selective extraction of the cobalt complex in organic solvents. The extract may be directly subjected to polarographic measurements. Further study is under way.

(Received April 1, 1982)

New complexes of the [Co(O–O)(edpp)$_2$]- and [Co(O–O)(en)(dppe)]- type were prepared from *trans*(Cl, Cl)-[$CoCl_2$(edpp)$_2$]ClO_4 and *trans*-[$CoCl_2$(en)(dppe)]$ClO_4\cdot H_2O$, respectively, where O–O is an acetylacetonate, malonate, oxalate, or carbonate ion, and en, edpp, and dppe denote ethylenediamine, (2-aminoethyl)diphenylphosphine, and 1,2-bis(diphenylphosphino)ethane, respectively. All the complexes of the former type gave two geometrical isomers of trans(P, P) and trans(P, N) configurations, which were assigned on the basis of the ^1H and ^{13}C NMR, and electronic absorption spectra. No trans(N, N) isomers were formed. The yields of the trans(P, N) isomers were always larger than those of the corresponding trans(P, P) isomers. With the decreasing ring members of the O–O chelates, the yield of the trans(P, P) isomer decreases, the trans(P, P)-carbonato complex being formed in trace amounts. The first absorption bands of the trans(P, P) isomers have very strong intensity as compared with those of the corresponding trans(P, N) and the dppe complexes. All the complexes except for [Co(O–O)(en)(dppe)]$^+$ (O–O=malonate and oxalate ions) were resolved by the chemical or SP-Sephadex C-25 column chromatographic method, and the circular dichroism spectra were recorded and compared with those of related complexes.

In previous papers, we have prepared bis(acetylacetonato)-[1] and bis(ethylenediamine)cobalt(III)[2] complexes of (2-aminoethyl)diphenylphosphine (edpp). Since the edpp chelate ligand has two bulky phenyl substituents on the phosphorus atom, inter- or intraligand interactions should be great in octahedral complexes. Stereochemical studies on bulky phosphine metal complexes would be significant in connection with stereoselectivity of transition metal phosphine complex catalysts in asymmetric syntheses. However, few octahedral complexes with bulky phosphine chelate ligands, in particular, those of cobalt(III) are known.[3] Cobalt(III) complexes with chelate phenylphosphine ligands so far known seem to be limited to those with 1,2-bis(diphenylphosphino)ethylene and *trans*-[$Co(CN)_2$(dppe)$_2$]$^+$ (dppe=1,2-bis(diphenylphosphino)ethane).[4] This paper reports the preparation, resolution, and spectroscopic properties of two geometrical isomers, trans(P,P) and trans(P,N), of the [Co(O–O)(edpp)$_2$]-type complexes (O–O=acetylacetonate, malonate, oxalate, or carbonate ion). The corresponding [Co(O–O)(en)(dppe)]-type complexes (en=ethylenediamine) were also prepared, and their properties were compared with those of the edpp complexes.

Experimental

(2-Aminoethyl)diphenylphosphine was prepared according to the literature method[5] and handled under nitrogen atmosphere until it formed cobalt(III) complexes. 1,2-Bis(diphenylphosphino)ethane was purchased from Strem Chemicals Inc. and used without further purification. Absorption, circular dichroism (CD), and ^1H and ^{13}C NMR spectra were recorded on a Hitachi 323 spectrophotometer, a JASCO J-40 spectropolarimeter, and Jeol JNM-PMX 60 and JNM-FX 100 spectrometers, respectively.

trans*(Cl, Cl)*-[$CoCl_2$*(edpp)*$_2$]ClO_4. To a methanol solution (100 cm^3) of $Co(ClO_4)_2\cdot 6H_2O$ (5.10 g, 13.9 mmol) was added edpp (6.36 g, 27.7 mmol) with stirring. A brown solid (probably [Co(edpp)$_2$] $(ClO_4)_2$) was obtained by evaporating the solution under reduced pressure. It was dissolved in dichloromethane, and chlorine gas was bubbled into the solution for 15 min to oxidize the Co(II) ions, giving a green solution. The excess chlorine was removed by bubbling nitrogen, and then the green solution was evaporated to dryness. The green residue was recrystallized by dissolving in hot methanol and by adding excess $NaClO_4$. Yield: *ca.* 50%. The complex is insoluble in water, but soluble in most polar organic solvents.

The perchlorate can be converted to chloride by using Dowex 1×8 (Cl^- form) in methanol. The methanol solution give green crystals by evaporating in a desiccator over P_2O_5. The chloride, *trans*(Cl,Cl)-[$CoCl_2$(edpp)$_2$]$Cl\cdot 2H_2O$ is also insoluble in water, but more soluble in organic solvents than the perchlorate is.

trans-[*$CoCl_2$(en)(dppe)*]$ClO_4\cdot H_2O$. To a solution of dppe (2.00 g, 5.02 mmol) in a mixture of ethanol (20 cm^3) and benzene (40 cm^3) were added ethylenediamine (0.34 g, 5.66 mmol) and $Co(ClO_4)_2\cdot 6H_2O$ (1.90 g, 5.19 mmol) with stirring. The resulting orange brown solution was evaporated to dryness under reduced pressure, and the residue was dissolved in dichloromethane. Chlorine gas was bubbled into the solution for 15 min and then nitrogen gas for 20 min to remove excess chlorine. The green solution obtained was filtered, and the filtrate was evaporated to dryness to give a green product. It was dissolved in methanol by heating at 70 °C for *ca.* 30 min, and the solution was filtered. The filtrate was mixed with excess $NaClO_4$ and allowed to stand at room temperature to yield green crystals. Yield: *ca.* 40%. The complex is insoluble in water, but soluble in most polar organic solvents.

trans*(P, P)*-[*Co(acac)(edpp)*$_2$]$Br_2\cdot 2CH_2Cl_2$ *and* trans*(P,N)*-[*Co(acac)(edpp)*$_2$]$Br_2\cdot 3H_2O$. An ethanol solution (200 cm^3) containing *trans*(Cl,Cl)-[$CoCl_2$(edpp)$_2$]ClO_4 (0.50 g, 0.73 mmol) and lithium acetylacetonate (0.08 g, 0.75 mmol) was stirred at room temperature for 1 h. The resulting red brown solution was diluted with water (1 dm^3) and passed through a column (ϕ 3 cm×50 cm) of SP-Sephadex C-25. The product adsorbed was first eluted with a 0.05 mol/dm^3 NaCl solution to remove a dark red by-product, [Co(acac)$_2$-

† Present address: Department of Chemistry, Faculty of Science, Osaka City University, Sumiyoshi-ku, Osaka 558.

(edpp)]$^{+}$,[1] and then with a 0.4 mol/dm^3 NaCl solution. The orange-red eluate of $[Co(acac)(edpp)_2]^{2+}$ was obtained, diluted twenty times with water, and poured again onto a column (ϕ 3 cm$\times$150 cm) of SP-Sephadex C-25. By elution with a 0.3 mol/dm^3 KBr solution, two orange-red bands (I and II) appeared. The eluate of the first band (I) was concentrated to a small volume under reduced pressure, and the complex was extracted with CH_2Cl_2. On addition of diethyl ether the extract gave red crystals of *trans*(P, P)$[Co(acac)(edpp)_2]Br_2\cdot 2CH_2Cl_2$ (I). Yield: *ca.* 10%. The presence of CH_2Cl_2 was confirmed by the ^{1}H NMR spectrum.

The second orange-red eluate was concentrated to a small volume under reduced pressure and allowed to stand to yield red crystals of *trans*(P, N)-$[Co(acac)(edpp)_2]Br_2\cdot 3H_2O$ (II). Yield: *ca.* 40%.

trans(P,P)-$[Co(O–O)(edpp)_2]^+$ (O–O=Oxalate (ox) and Malonate (mal) Ions), and trans(P,N)-$[Co(O–O)(edpp)_2]^+$ (O–O=CO_3^{2-}, ox, and mal Ions). These complexes were prepared by methods similar to those for the corresponding acetylacetonato complexes. A methanol solution (200 cm^3) containing *trans*(Cl,Cl)-$[CoCl_2(edpp)_2]ClO_4$ (0.50 g, 0.73 mmol), a slight excess of the ammonium salt of O–O (*e.g.*, $(NH_4)_2CO_3$), and a small amount of active charcoal was stirred at 50 °C for 1 h, and then filtered. The red filtrate was diluted with water (1 dm^3) and poured onto a column (ϕ 3 cm$\times$5 cm) of SP-Sephadex C-25. The SP-Sephadex adsorbed the product was placed on the top of the adsorbent layer of an SP-Sephadex column (ϕ 3 cm$\times$120 cm). By elution with a 0.05 mol/dm^3 NaCl or KBr solution, two bands, the first orange and the second red, were eluted. The choice of an eluent was made for better crystallization of the complex. In the case of the carbonato complex, the first orange band was too small in the amount to isolate the complex. Each eluate of the separated bands was concentrated under reduced pressure to a small volume. The concentrate gave crystals of the isomer on addition of NaCl or KBr and standing at a refrigerator. The complexes obtained from the first orange and the second red bands are trans(P, P) and trans(P, N) isomers, respectively. The total yields were *ca.* 30—50% for all the complexes. No formation of the trans(N, N) isomer was observed in all the complexes including the acac complex. The formation ratios, trans(P, N): trans(P, P), for the acac, mal, ox, and CO_3^{2-} complexes were 0.25 : 1, 0.08 : 1, 0.03 : 1, and 0 : 1, respectively.

$[Co(acac)(en)(dppe)]Br_2\cdot 2H_2O$. A methanol solution (250 cm^3) containing *trans*-$[CoCl_2(en)(dppe)]ClO_4\cdot H_2O$ (0.50 g, 0.71 mmol) and lithium acetylacetonate (0.08 g, 0.75 mmol) was stirred for 24 h at room temperature. The resulting red brown solution was diluted with water (2 dm^3) and poured onto a column (ϕ 3 cm$\times$50 cm) of SP-Sephadex C-25. The adsorbed red brown product was eluted with a 0.1 mol/dm^3 NaBr solution, giving first the brown-red band of $[Co(acac)_2(dppe)]^+$ [1] and then the red orange band of $[Co(acac)(en)(dppe)]^{2+}$. The eluate of the latter was concentrated to a small volume, and the complex was extracted with $CHCl_3$. The extract was evaporated to dryness, and the residue was dissolved in a small amount of methanol. On addition of diethyl ether the solution gave crystals of $[Co(acac)(en)(dppe)]Br_2\cdot 2H_2O$. Yield: *ca.* 8%.

$[Co(O–O)(en)(dppe)]^+$ (O–O=CO_3^{2-}, ox, and mal Ions). These complexes were prepared by methods similar to those for the corresponding bis(edpp) complexes, using *trans*-$[CoCl_2(en)(dppe)]ClO_4\cdot H_2O$ (0.50 g) instead of *trans*(Cl, Cl)-$[CoCl_2(edpp)_2]ClO_4$. Each of the resulting orange-red solutions was diluted with a water–methanol mixture (1 : 1, 1 dm^3), and the solution was poured onto a column (ϕ 3 cm$\times$50 cm) of SP-Sephadex C-25. After washing the column thoroughly with water and methanol, the product adsorbed was eluted with a 0.05 mol/dm^3 NaCl or KBr solution. One orange band was eluted. The oxalato complex was isolated as chloride by concentrating the eluate to a small volume and then by storeing in a refrigerator. In a similar manner the malonato complex was obtained as bromide. In the case of the carbonato complex, the eluate obtained with a NaCl solution was concentrated to a small volume, and the concentrate was mixed with $NaClO_4\cdot H_2O$ to give perchlorate of the complex. The yields of all the complexes were *ca.* 40%.

Optical Resolution. *trans(P, P)-* and *trans(P, N)-$[Co(acac)(edpp)_2]^{2+}$.* The racemic trans(P, P) isomer charged on the top of a column (ϕ 3 cm$\times$120 cm) of SP-Sephadex C-25 was eluted with an aqueous 0.1 mol/dm^3 sodium $(+)_{589}$-tartratoantimonate(III) solution, giving two bands of the enantiomers. Each eluate of the bands was concentrated to a small volume under reduced pressure. On addition of excess KBr the concentrate gave white precipitate of potassium $(+)_{589}$-tartratoantimonate(III), which was filtered off. The filtrate was mixed with CH_2Cl_2 to extract the complex. The red extract was evaporated to dryness under reduced pressure, and the residue was dissolved in water. The solution was poured again onto a small column of SP-Sephadex C-25, and the complex adsorbed was eluted with an aqueous 0.1 mol/dm^3 KBr solution. The eluate was concentrated to a small volume under reduced pressure, and the concentrate was stored in a refrigerator to yield dark red crystals of optically active bromide of the trans(P, P) isomer. The $(+)_{589}$-isomer was obtained from the first band.

The trans(P, N) isomer was resolved by the same column chromatographic method as that for the trans(P, P) isomer. The eluate of the complex resolved was poured on a small column of SP-Sephadex, and the complex was eluted with 0.1 mol/dm^3 NaCl. On addition of an aqueous $NaClO_4$ solution the eluate gave pink, crystalline precipitate of the active perchlorate. The $(+)_{589}$-isomer was eluted faster than its antipode.

trans(P, P)-$[Co(O–O)(edpp)_2]^+$ (O–O=ox and mal) and trans(P, N)-$[Co(O–O)(edpp)_2]^+$ (O–O=CO_3^{2+}, ox, and mal). These complexes were resolved by a similar column chromatographic method with an aqueous 0.03 mol/dm^3 NaCl solution. The band-separation of enantiomers was incomplete in all cases, and no better separation was resulted by using an eluent of sodium $(+)_{589}$-tartratoantimonate(III). However, the first several fractions showed an almost constant $\Delta\varepsilon/\varepsilon$ value. These fractions were collected and used for the measurement of CD spectra without isolating the active complex.

$[CoCO_3(en)(dppe)]^+$. The racemic $[CoCO_3(en)(dppe)]ClO_4\cdot 1/2(NaClO_4)\cdot 1.5H_2O$ complex (100 mg) was converted into chloride by stirring with an anion exchanger, Dowex 1$\times$8 in the chloride form in a mixture of methanol (50 cm^3) and water (50 cm^3) at 40 °C for 1 h. The exchanger was filtered off, and the filtrate was mixed with 90 mg of Ag(*d*-bcs)$\cdot H_2O$ (*d*-bcs denotes $(+)_{589}$-(1*R*, 3*S*, 4*S*, 7*R*)-3-bromo-9-camphorsulfonate ion).[6] The mixture was stirred at 40 °C for 20 min, and then white precipitate of AgCl was filtered off. The filtrate was slowly evaporated in a desiccator over silica gel to yield orange crystals of $(+)_{589}$-$[CoCO_3(en)(dppe)](d\text{-bcs})\cdot H_2O$ which were filtered and washed with water. The crystals which are hardly soluble in water were dissolved in methanol. The solution was diluted with about the same volume of water and poured onto a small column of SP-Sephadex C-25. The complex adsorbed was eluted with 0.25 mol/dm^3 NaCl. To the eluate was added an aqueous $NaClO_4$ solution to give orange crystals of $(+)_{589}$-$[CoCO_3(en)(dppe)]ClO_4\cdot 3.5(NaClO_4)\cdot H_2O$ which were filtered and washed with water.

[Co(acac)(en)(dppe)]$^{2+}$. This complex was resolved by SP-Sephadex column chromatography with an eluent of 0.2 mol/dm^3 sodium $(+)_{589}$-tartratoantimonate(III). Although no good separation of the bands of enantiomers was observed, the first several fractions showed an almost constant $\Delta\varepsilon/\varepsilon$ value. These fractions were collected, diluted with water, and poured onto a small column of SP-Sephadex C-25. The complex adsorbed was eluted with 0.5 mol/dm^3 NaCl, and the eluate was used for the measurement of CD spectra. This complex was not resolved by a chemical method with *d*-bcs similar to that for the corresponding carbonato complex.

Attempts to resolve $[Co(O–O)(en)(dppe)]^+$ (O–O=ox and mal) were unsuccessful.

Analytical data of all the new complexes are given in Table 1.

Results and Discussion

trans(Cl,Cl)-[CoCl$_2$(edpp)$_2$]ClO$_4$ and trans-[CoCl$_2$(en)-(dppe)]ClO$_4$·H$_2$O. A *trans*-dichlorobis(diamine)-cobalt(III) complex is known to be a good starting material for preparing various bis(diamine)cobalt(III) complexes. The $[CoCl_2(edpp)_2]ClO_4$ and $[CoCl_2(en)(dppe)]ClO_4\cdot H_2O$ complexes prepared in this study have the green color characteristic of a trans(Cl,Cl) configuration, and these chloride ions are easily replaced by the O–O chelate ligand such as an acetylacetonate or oxalate ion. Both dichloro complexes were prepared in fairly good yield from the corresponding cobalt(II) complexes, $Co(edpp)_2(ClO_4)_2$ and $Co(en)(dppe)(ClO_4)_2$ which had been prepared in methanol, by oxidizing with chlorine in dichloromethane. In the oxidation the presence of methanol lowered remarkably the yield of the cobalt(III) complexes, although the reason for this remains unknown. Attempts to prepare these Co(II)–phosphine complexes in dichloromethane were unsuccessful, because $Co(ClO_4)_2\cdot 6H_2O$ is insoluble in this solvent. The $[CoCl_2(edpp)_2]ClO_4$ complex can also be prepared by oxidizing $Co(edpp)_2(ClO_4)_2$ with air in methanol and by treating with hydrochloric acid, but the yield was very poor.

In Fig. 1 are compared absorption spectra of the two dichlorophosphine complexes with that of *trans*-$[CoCl_2(en)_2]^+$. The phosphine complexes exhibit a medium

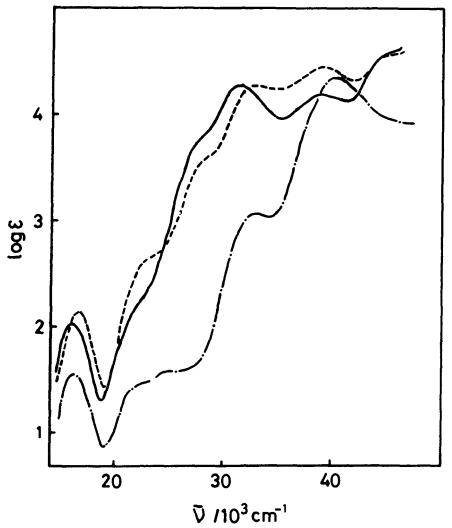

Fig. 1. Absorption spectra of *trans*(Cl,Cl)-$[CoCl_2(edpp)_2]^+$ (——), *trans*-$[CoCl_2(en)(dppe)]^+$ (------), and *trans*-$[CoCl_2(en)_2]^+$ (—·—) in methanol.

intensity band around 16000 cm^{-1} which should correspond to the split component (Ia) of the first absorption band of *trans*-$[CoCl_2(en)_2]^+$ [7] (Table 2). In the Ib and second band region only shoulder absorptions are observed. However, the spectral patterns of three complexes in Fig. 1 are similar to one another in the d-d transition region. Thus both phosphine complexes can be assigned to have the trans(Cl,Cl) configuration.

The *trans*(Cl,Cl)-$[CoCl_2(edpp)_2]^+$ complex has additional isomerism arising from the arrangement of nitrogen and phosphorus donor atoms, trans(P,P) and cis(P,P). In this study, only one isomer was obtained and no formation of the other was observed on column chromatography of Sephadex LH-20. The structure of the isomer obtained was recently determined to be the cis(P,P) configuration by X-ray analysis.[8] The preferential formation of the cis(P,P) isomer, in which steric interactions between the two diphenylphosphino groups should be larger than those in the trans(P,P) isomer, might result from a strong trans effect of the phosphine donor group. The absorption spectrum of *trans*(Cl,Cl),*cis*(P,P)-$[CoCl_2(edpp)_2]^+$ quite resembles that of $[CoCl_2(en)(dppe)]^+$ in which the three kinds of donor atoms are in the same geometrical arrangement. In the ^{13}C NMR spectrum, the edpp complex shows clear triplet signals for all the carbons except for the N-CH_2 and *p*-C of the phenyl group. Appearance of the triplet signals is attributable to the presence of coupling between the two phosphorus atoms in the cis positions (Table 3). Such virtual coupling has been observed for octahedral phosphine complexes of both trans(P,P) and cis(P,P) configurations, although it is observed for almost only a trans(P,P) complex in a four-coordinate, planar type.[1,3]

$[Co(O-O)(edpp)_2]^{n+}$ and $[Co(O-O)(en)(dppe)]^{n+}$ Complexes. The acac and other O-O chelate complexes of edpp were prepared from *trans*(Cl,Cl)-$[CoCl_2(edpp)_2]ClO_4$ and lithium acetylacetonate in ethanol in the absence of active charcoal, and ammonium salts of the O-O anions in methanol in the presence of active charcoal, respectively. The corresponding dppe complexes were prepared by similar methods from *trans*-$[CoCl_2(en)(dppe)]ClO_4 \cdot H_2O$. For the mal, ox, and CO_3^{2-} complexes, the use of the ammonium salts was necessary. No reactions took place with the sodium or potassium salts. All the complexes thus obtained are stable to air in the solid state, and soluble in water, alcohols, CH_2Cl_2, and $CHCl_3$. The complexes in solution, however, decompose gradually on heating above 60—70 °C to give Co(II) species, the acac complexes being the most stable. The CO_3^{2-} complexes regenerate the original *trans*-dichloro complexes by heating with hydrochloric acid.

Attempts to prepare $[Co(acac)(en)(dppe)]^{2+}$ by other methods were all unsuccessful. For example, reactions between $[Co(acac)_2(dppe)]^+$ [1] and en, and $[Co(acac)_2(en)]^+$ and dppe gave $[Co(acac)_2(en)]^+$ and $[Co(acac)(en)_2]^{2+}$, and $[Co(acac)_2(dppe)]^+$, respectively as main products, no desired complex being formed. In general, there is no convenient method for preparing cobalt(III) complexes consisting of three different chelate ligands. A good method for preparing such complexes is to derive from a *trans*-dichloro complex with two different chelate ligands, although preparative methods for which

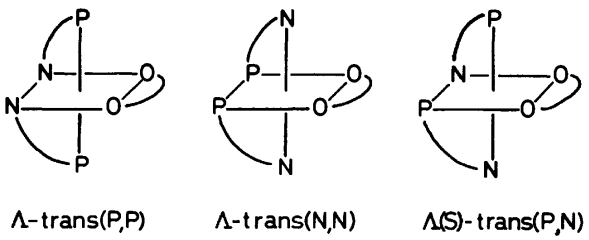

Fig. 2. Geometrical isomers of the $[Co(O–O)(edpp)_2]$-type complex.

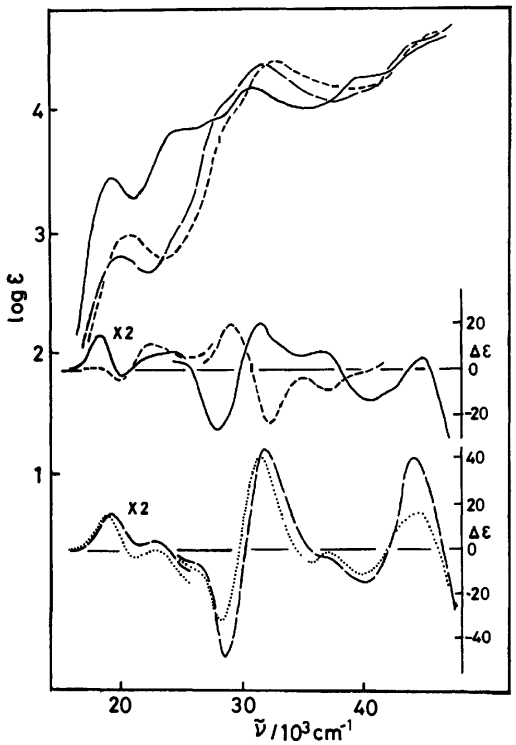

Fig. 3. Absorption and CD spectra of *trans*(P,P)-$[Co(acac)(edpp)_2]^{2+}$ (——), *trans*(P,N)-$[Co(acac)(edpp)_2]^{2+}$ (— —), and $[Co(acac)(en)(dppe)]^{2+}$ (------) in methanol. CD spectrum of *Δ-cis-β*-[Co(acac)(SS-PNNP)]$^{2+}$ (……) in methanol.[12] All of the enantiomers of edpp complexes given in Figs. 3, 6, 7, and 8 are those eluted faster in column chromatography.

are also undeveloped.[9]

The $[Co(O–O)(edpp)_2]$-type complex has three possible geometrical isomers, trans(P,P), trans(P,N), and trans(N,N) (Fig. 2). Except for the CO_3^{2-} complex, all the O–O complexes yielded two isomers. Only one isomer was obtained for the CO_3^{2-} complex, a trace of the other being formed. Isomers of I and II of $[Co(acac)(edpp)_2]^{2+}$ are red and orange-red in color, respectively, and show one and two kinds of the methyl signals for the acac part, respectively in the ^1H NMR spectra (Table 3). Thus I and II can be assigned to either trans(P,P)(C_2) or trans(N,N)(C_2), and trans-(P,N)(C_1) isomers, respectively from symmetry argument. Isomer I as well as isomer II gives the methine proton signal at a higher field than that of the $[Co(acac)(en)_2]^{2+}$ complex.[10] The methine proton signal should shift to the high field when the complex has the trans-

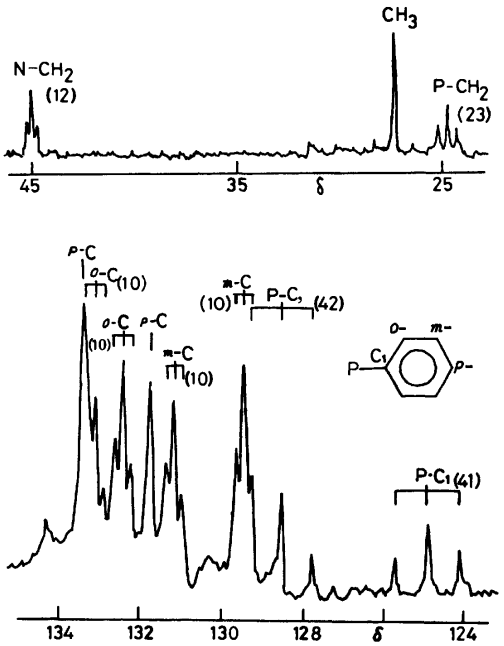

Fig. 4. ^{13}C NMR spectrum of *trans*(P,P)-$[Co(acac)(edpp)_2]^{2+}$. The number in parentheses is a coupling constant in Hz.

(P,P) configuration, since it is shielded by the phenyl group of the phosphine ligand disposed over the acac ring.[1] Thus isomer I can be assigned to the trans(P,P) isomer. The magnitude of the high field shift is fairly small as compared with those of bis(acac) complexes of a phenyl-substituted tertiary phosphine. However, the absorption spectrum confirms the trans(P,P) configuration for isomer I. Figure 3 shows absorption spectra of trans(P,P)(I) and trans(P,N)(II) isomers of $[Co(acac)(edpp)_2]^{2+}$. The former gives the very strong first absorption band and shows the remarkable red shift in the charge transfer bands as compared with the corresponding bands of the latter. Similar spectral differences have been observed between the trans(P,P) and cis(P,P) isomers of $[Co(acac)_2(PMe_2Ph)_2]^+$.[11] The absorption spectrum of the trans(P,N) isomer (II) resembles that of $[Co(acac)(en)(dppe)]^{2+}$ in which the donor atoms are arranged in the same manner, although the whole spectrum of the dppe complex shifts to the high energy side.

The ^{13}C NMR spectrum of the *trans*(P,P)-$[Co(acac)(edpp)_2]^{2+}$ isomer is shown in Fig. 4. Each carbon of the acac and of two methylenes of the edpp ligand is observed as one kind of signal. On the other hand, the signals of the phenyl carbons show two kinds of the phenyl group. The two phenyl groups on each phosphorus atom should be diastereotopic in a complex of chiral symmetry. The spectral assignment was made according to the previous work on bis(acac)cobalt(III) complexes of edpp and related ligands.[1] The chemical shifts and coupling constants are all similar among these complexes except one *m*-carbon of isomer I. Its chemical shift (131.4 ppm) is somewhat apart from those of other complexes (*ca.* 129 ppm). The P–CH_2 and all carbons of the phenyl groups except for the *p*-carbons show triplet signals owing to the couplings with the two

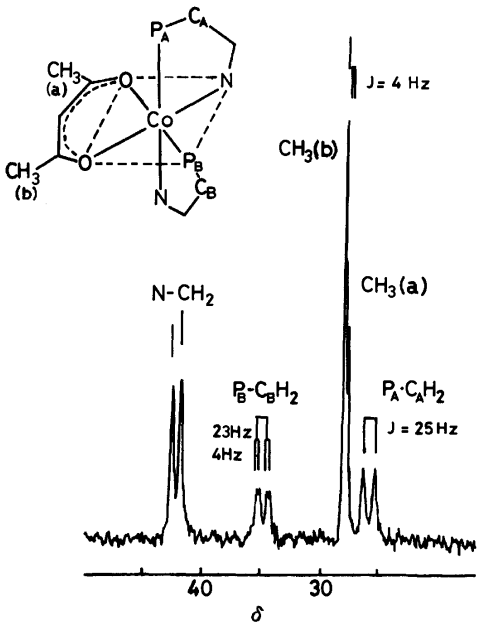

Fig. 5. ^{13}C NMR spectrum of *trans*(P,N)-[Co(acac)-(edpp)$_2$]$^{2+}$.

phosphorus atoms in the trans positions.

Isomer II shows a complicated ^{13}C NMR spectrum, particularly in the phenyl region, because of C_1 symmetry of the complex. The singlet (27.77 ppm) and the doublet (27.56 ppm, $^4J(P_B,C)=4$ Hz) signals of the methyl groups can be assigned to the CH_3(b) and CH_3(a), respectively from a comparison of the spectrum of [Co(acac)$_2$(edpp)]$^+$ [1] (Fig. 5). The doublet (25.56 ppm, $^2J(P_A,C_A)=25$ Hz) and the doublet of doublets

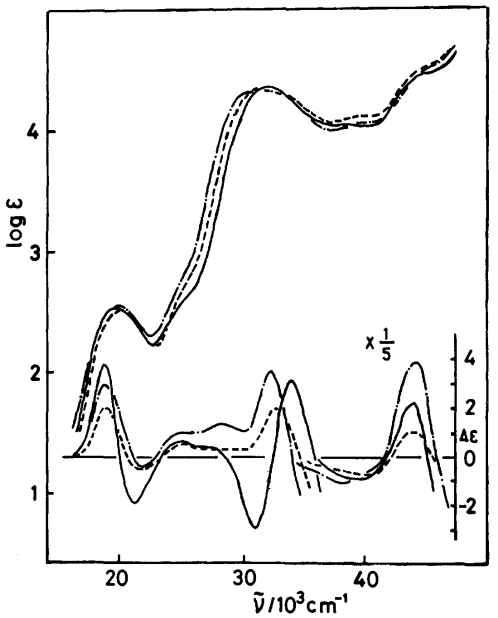

Fig. 7. Absorption and CD spectra of trans(P,N) isomers of [Co(CO_3)(edpp)$_2$]$^+$ (——), [Co(ox)(edpp)$_2$]$^+$ (------), and [Co(mal)(edpp)$_2$]$^+$ (•—•) in methanol.

(34.55 ppm, $^2J(P_B,C_B)=23$ Hz, $^4J(P_A,C_B)=4$ Hz) can be assigned to the C_A and C_B, respectively of the P–CH_2 groups. The coupling constant between the two phosphorus atoms in the cis positions seems to be practically zero. The two N–CH_2 groups show singlet signals with similar chemical shifts (41.59 and 42.24 ppm). The spectrum in the phenyl region is complicated because of the presence of four different phenyl groups, and was not assigned except for one doublet of doublets (122.18 ppm) which can be assigned to the P–C_1 bonded to the phosphorus atom.

The structures of other [Co(O–O)(edpp)$_2$]$^+$ (O–O= mal, ox, and CO_3^{2-}) complexes were also assigned on the basis of the absorption and ^{13}C NMR spectra. Two orange-red isomers of the mal and ox complexes show absorption spectra very similar to each other, and can be assigned to have the same geometrical configuration for the two edpp ligands (Fig. 6). The same conclusions can be given for three red isomers of the mal, ox, and CO_3^{2-} complexes (Fig. 7). The orange-red isomers have strong intensity in the first absorption bands and show a remarkable red shift in the charge transfer bands as compared with the corresponding bands of the red isomers. Such spectral differences between the isomers are the same as those observed for the acac complexes. Thus the orange-red and red isomers can be assigned to trans(P,P) and cis(P,P) (trans(P,N) or trans(N,N)) configurations, respectively. Further, the ^{13}C NMR spectra clearly indicate that the orange-red and red isomers have C_2 and C_1 symmetries, respectively (Table 3). Thus it is concluded that the orange-red and red isomers have trans(P,P) and trans(P,N) configurations, respectively for all the [Co(O–O)(edpp)$_2$]$^+$ complexes.

No trans(N,N) isomers were formed in the [Co(O–O)-(edpp)$_2$]-type complexes. Molecular models indicate

that steric hindrance between the two edpp ligands in the [Co(O–O)(edpp)$_2$]-type complex increases in the order of the trans(P,P)<trans(P,N)<trans(N,N) isomers. In particular, the trans(N,N) isomer involves considerable steric hindrance among the phenyl groups. The reason for this isomer being not formed is attributable to such steric hindrance. However, the yields of the more crowded trans(P,N) isomers are always much larger than those of the less crowded trans(P,P) isomers. The less stability of the trans(P,P) isomers should result from the strong trans effect of phosphine donor groups as seen in the *trans*(Cl,Cl),*cis*(P,P)-[CoCl$_2$(edpp)$_2$]$^+$ complex. The formation ratios of the trans(P,P) to trans(P,N) isomers increase with the increasing size of the O–O chelate ligands; trans(P,P): trans(P,N)=0.25 : 1, 0.08 : 1, 0.03 : 1, and 0 : 1 for the acac, mal, ox, and CO_3^{2-} complexes, respectively. When the O–O chelate ligand becomes larger, the more crowded trans(P,N) isomer will become further crowded to decrease the stability, while the less crowded trans-(P,P) isomer will be less affected. Thus the stability difference between the trans(P,N) and trans(P,P) isomers becomes smaller, and the relative yield of the latter increases. The CO_3^{2-} complex with the smallest O–O ligand forms almost only the trans(P,N) isomer.

Figure 3 shows CD spectra of trans(P,P) and trans-(P,N) isomers of [Co(acac)(edpp)$_2$]$^{2+}$, and [Co(acac)-(en)(dppe)]$^{2+}$, all of which are eluted faster on column chromatography. Both edpp complexes exhibit a similar spectral pattern and give a main CD band with the positive sign in the first absorption band region, suggesting Λ configuration. However, the CD spectrum of [Co(acac)(*SS*-PNNP)]$^{2+}$ (*SS*-PNNP=(*S*,*S*)-(C_6H_5)$_2$PCH$_2$CH(CH$_3$)NHCH$_2$CH$_2$NHCH(CH$_3$)CH$_2$P-(C_6H_5)$_2$), which forms only the Δ-*cis*-β isomer stereoselectively owing to the equatorial preference of the methyl group,[12] is quite similar to that of the trans-(P,N) isomer. In the *cis*-β-PNNP complex, the geometrical arrangement of N, P, and O donor atoms, and the distribution of chelate rings linking these donor atoms are the same as those in the trans(P,N) isomer when the central -NCH$_2$CH$_2$N- chelate ring is ignored. The presence of the central chelate ring would not play an important role in the CD spectrum of the Δ-*cis*-β-(*SS*-PNNP) complex, and the vicinal effect of the asymmetric nitrogen donor atoms would also be small. Thus the trans(P,N) isomer in Fig. 3 is assigned to Δ configuration. The trans(P,P) isomer which gives a CD pattern similar to that of the trans(P,N) isomer should also have the same Δ configuration. In addition to the chiral distribution of chelate rings, the Δ-trans(P,N) isomer as well as the Δ-*cis*-β-(*SS*-PNNP) complex involves another chirality of (*R*) configuration[13] arising from the arrangement of N, P, and O donor atoms. The Δ-trans-(P,P) isomer has no such chirality. However, the similarlity in the CD spectra of both isomers indicates that the optical activity arises mainly from the chiral distribution of chelate rings, the contribution of the chiral arrangement of donor atoms being small.

The CD spectrum of [Co(acac)(en)(dppe)]$^{2+}$ in Fig. 3 gives a pattern differing from those of the Δ-trans(P,N) and -trans(P,P) isomers in the first absorption band region, but nearly the opposite pattern in the higher energy region. The dppe complex has also chirality in the arrangement of the donor atoms, giving Δ(*S*) and Λ(*R*) configurations. The *trans*(P,N)-[Co(acac)-(edpp)$_2$]$^{2+}$ complex forms a different pair of enantiomers from those of the dppe complex, Δ(*R*) and Λ(*S*). Fujinami and Shibata[14] reported CD spectra of cobalt-(III) complexes of a similar type, Λ(*R*)-*cis*-[Co(CN)$_2$-(ox)(en)]$^-$ and Δ(*R*)-*cis*,*cis*,*cis*(C,N,O)-[Co(CN)$_2$(am)$_2$]$^-$ (am=glycinate or β-alaninate ion), and concluded that the CD pattern of the *cis*,*cis*,*cis*(C,N,O)-[CoC$_2$N$_2$O$_2$]-type complex in the first absorption band region depends mainly on the chiral arrangement of the donor atoms. It seems to be difficult to apply this conclusion to the CD spectrum of [Co(acac)(en)(dppe)]$^{2+}$ in Fig. 3, since it differs considerably from that of the *trans*(P,N)-edpp complex in the first absorption band region. However, the whole CD pattern of the dppe complex appears to be opposite to those of both Δ-isomers of the edpp complex. Thus we tentatively assign the dppe complex in Fig. 3 to Λ(*R*) configuration.

The trans(P,N) isomers of the mal, ox, and CO_3^{2-} complexes show CD spectra similar to one another over the whole region (Fig. 7). The spectrum of the CO_3^{2-} complex quite resemble that of Δ(*R*)-*cis*-β-[Co(CO_3)(*SS*-PNNP)]$^+$ prepared as an authentic complex for assigning the absolute configuration.[12] Thus all the isomers in Fig. 7 are assigned to Δ(*R*) configuration, although the CD spectra in the first absorption band region are the pattern characteristic of a Λ-tris(chelate) complex. The trans(P,P) isomers of the mal and ox complexes show CD spectra similar to each other (Fig. 6), and the pattern resembles that of Δ-trans(P,N) isomers. Since both Δ-trans(P,N) and -trans(P,P) isomers of the acac complex exhibit a similar CD spectra, these trans(P,P)

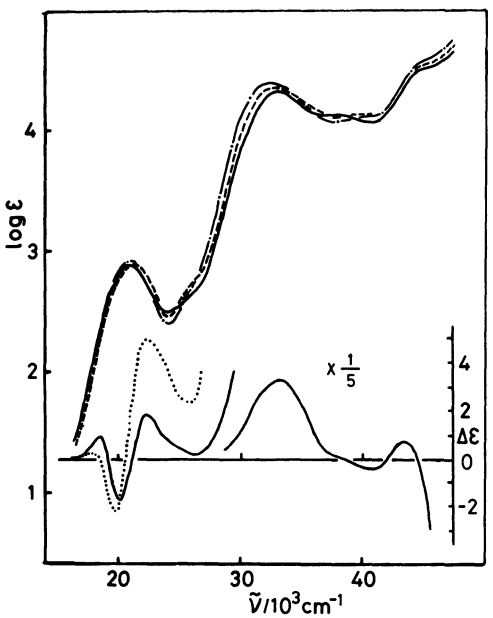

Fig. 8. Absorption spectra of [Co(CO_3)(en)(dppe)]$^+$ (——), [Co(ox)(en)(dppe)]$^+$ (------), and [Co(mal)(en)-(dppe)]$^+$ (—·—) in methanol. CD spectra of (+)$_{589}$-[Co(CO_3)(en)(dppe)]$^+$ and [Co(acac)(en)(dppe)]$^+$ (·····) in methanol.

isomers can be assigned to Δ configuration, although the spectra around 29000 cm^{-1} fairly differ from those of the trans(P,N) isomers. All the trans(P,N) and trans(P,P) isomers given in Figs. 6 and 7 are those eluted faster on column chromatography.

The CD spectrum of $[Co(CO_3)(en)(dppe)]^+$ which was obtained from the less soluble diastereomeric salt with *d*-bcs$^-$ is compared with that of $\Lambda(R)$-$[Co(acac)(en)(dppe)]^{2+}$ in Fig. 8. Both CD spectra are similar in shape in the first absorption band region, although their strength and the spectra in the higher energy region differ remarkably between these complexes. From the similarity in the CD patterns of both isomers in the first absorption band region, we tentatively assign the CO_3^{2-} complex to $\Lambda(R)$ configuration. In order to discuss the optical activity of mixed cobalt(III) complexes containing a phosphine ligand, more CD data will be needed.

Extraction of Titanium(IV)-Pyrocatechol Violet Complex with Tridodecylethylammonium Bromide

Yoshio Shijo,* Tokuo Shimizu, and Kaoru Sakai

Department of Environmental Chemistry, Faculty of Engineering, University of Utsunomiya, Ishii-machi, Utsunomiya 321

(Received April 2, 1982)

The extraction equilibria and the fundamental conditions for extracting the titanium(IV)–Pyrocatechol Volet complex anion in a form of an ionic associate with tridodecylethylammonium bromide into carbon tetrachloride is described. The absorption maxima of the extracted complex occurs at 586 nm, the molar absorptivity and the distribution ratio being 5.17×10^4 dm^3 mol^{-1} cm^{-1} and 2.82×10^2. The optimum pH range for the extraction is 5.1—6.4. The composition of the complex is estimated to be $Ti(PV)_2(R_3R'N)_2$. The extraction constant would be:

$$K_{ex}=\frac{[Ti(PV)_2(R_3R'N)_2]_0}{[Ti(PV)_2{}^{2-}][R_3R'N^+]^2},$$

log K_{ex} obtained is 13.5. The interference of foreign ions is discussed.

The lipophilic quaternary ammonium salts have played a very important role in the extraction of metal complex anions. Trioctylmethylammonium chloride (Aliquat 336 or Capliquat) has been in common use as an extracting reagent in this field. The chloride of several transition metals,[1] of vanadium,[2] of mercury,[3] thiocyanate of cadmium,[4] 2,2′-dihydroxyazobenzene complex of uranium,[5] chromate,[6] tetraboromopalladate,[7] 4,7-bis(*p*-sulfophenyl)-1,10-phenanthroline complex of iron,[8] dithizone complex of palladium,[9] 8-hydroxy-5-quinolinesulfonic acid complex of zinc,[10] and iodide of 18 elements in geochemical samples[11] were extracted with the foregoing reagent.

Tridodecylethylammonium bromide (TDEABr) synthesized in our laboratory which is more lipophilic than trioctylmethylammonium chloride has been used for extraction of the Pyrocatechol Violet (abbreviated to PV) complexes of copper,[12] tin,[13] aluminium,[14] zirconium,[15] niobium,[16] iron,[17] tungsten,[18] and vanadium.[19] The titanium(IV)–PV complex also can be extracted with TDEABr in carbon tetrachloride. The extraction equilibria and the fundamental conditions for extracting the titanium(IV)–PV complex with TDEABr will be discussed in this paper.

Experimental

Reagent. A 2.50×10^{-3} mol dm^{-3} titanium(IV) solution was prepared by following procedure. A definite amount of titanium oxide was fused with potassium disulfate and the melt was dissolved in 2 mol dm^{-3} sulfuric acid. The solution was diluted by 2 mol dm^{-3} sulfuric acid as required. A 5×10^{-4} mol dm^{-3} PV solution was prepared by dissolving the Dotite PV in deionized water without further purification. TDEABr was prepared by the method described in the previous work.[17] A 2×10^{-3} mol dm^{-3} TDEABr solution was prepared by dissolving TDEABr in carbon tetrachloride. A 2 mol dm^{-3} sodium acetate solution was used as a buffer solution. All the other chemicals used were of a guaranteed reagent quality.

Apparatus. A Hitachi 101 spectrophotometer, a Hitachi 200-20 UV-vis. recording spectrophotometer, and a Hitachi Horiba F-7 pH meter were used.

General Procedure. Mix, up to 5 μg of titanium(IV), a definite amount of 1 mol dm^{-3} sulfuric acid, and 2 cm^3 of 5×10^{-4} mol dm^{-3} PV solution in a 100-cm^3 polypropylene beaker. Adjust the pH of the solution to 5.6 by the addition of 2 cm^3 of 2 mol dm^{-3} sodium acetate solution, then dilute to 20 cm^3 with de-ionized water. Transfer the solution into a 35 cm^3 test tube, and extract with 5 cm^3 of 2×10^{-3} mol dm^{-3} TDEABr in carbon tetrachloride for 5 min. Separate the phases and centrifuge the organic phase for 2 min at 3000 min^{-1}. Measure the absorbance of the extract at 586 nm against the reagent blank.

Results and Discussion

Absorption Spectra. The absorption spectra of the titanium(IV)–PV–TDEA complex extracted into carbon tetrachloride and of the titanium(IV)–PV complex anion in an aqueous solution are shown in Fig. 1. The absorption maximum of the complex is slightly shifted toward longer wavelength, and the sensitivity is enhanced a little in an organic phase, as compared with in an aqueous phase.

Effect of pH. The aqueous solution containing titanium(IV) and PV was adjusted to various pH values with the sodium acetate buffer solution, and the extraction was carried out according to the foregoing procedure. As is indicated in Fig. 2, the maximum extraction of the complex is obtained in the pH range 5.1 to 6.4.

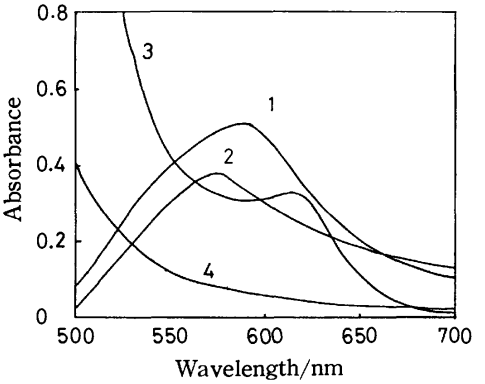

Fig. 1. Absorption spectra of the Ti–PV–TDEA complex in carbon tetrachloride and the Ti–PV complex in aqueous solution.
pH=5.6, $V_{aq}=20$ cm^3, $V_0=5$ cm^3, $[TDEABr]_0=2\times10^{-3}$ mol dm^{-3}. 1: Ti–PV–TDEA $[Ti]=2.5\times10^{-6}$ mol dm^{-3}, 2: Ti–PV $[Ti]=1\times10^{-5}$ mol dm^{-3}, 3: PV–EDEA $[PV]=5\times10^{-5}$ mol dm^{-3}, 4: PV $[PV]=1.25\times10^{-4}$ mol dm^{-3}.

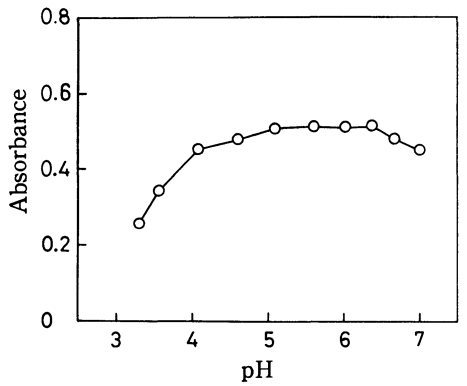

Fig. 2. Effect of pH on the extraction of the Ti-PV-TDEA complex.
[Ti]$=2.5\times10^{-6}$ mol dm^{-3}, [PV]$=5\times10^{-6}$ mol dm^{-3}, [TDEABr]$_0=2\times10^{-3}$ mol dm^{-3}, 586 nm.

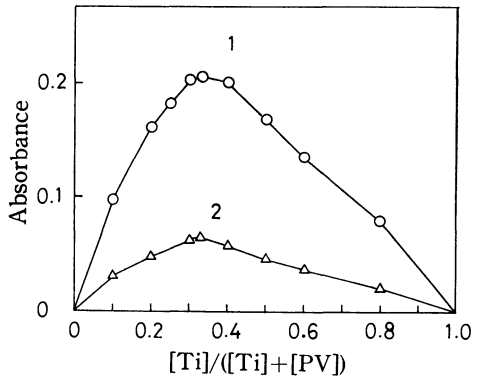

Fig. 3. Continuous variation method applied to the Ti-PV-TDEA and the Ti-PV complexes (Ti: PV).
pH=5.6, [Ti]+[PV]$=2.5\times10^{-5}$ mol dm^{-3}, 1: Ti-PV-TDEA, [TDEABr]$_0=2\times10^{-3}$ mol dm^{-3}, 586 nm, 2: Ti-PV, 572 nm.

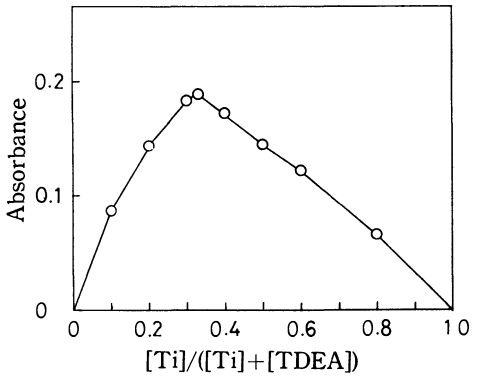

Fig. 4. Continuous variation method applied to the Ti-PV-TDEA complex (Ti: TDEA).
[Ti-PV]+[TDEA]$=5\times10^{-7}$ mol dm^{-3}, pH=5.6, 586 nm.

The absorbance of the extract increase gradually. The PV itself is also readily extracted with TDEABr.

Organic Solvents. Several kinds of organic solvents were tested in order to achieve a quantitative extraction of the complex with TDEABr. The complex is extracted in such solvents as carbon tetrachloride, benzene, toluene, xylene, butyl acetate, isobutyl methyl ketone, and chloroform. There are no serious differences among every solvent on the absorbance of the extract. The stability and the reproducibility of the absorbance, however, are better in the carbon tetrachloride.

Effect of the Reagent Concentration. The extraction of titanium(IV) from the aqueous solutions containing PV in various concentrations was examined. The optimum concentration of PV is in the range 4×10^{-5} mol dm^{-3} to 1×10^{-4} mol dm^{-3}. The concentration of TDEABr in carbon tetrachloride for the quantitative extraction is ranged from 1×10^{-4} mol dm^{-3} to 5×10^{-3} mol dm^{-3}.

Extractability and Molar Absorptivity. An aqueous solution of 20 cm^3 containing 2.40 μg of titanium(IV) and PV was shaken with 5 cm^3 of 5×10^{-3} mol dm^{-3} TDEABr in carbon tetrachloride under the optimum conditions. Extraction was repeated for the remaining aqueous phase after the separation of the extract. The extractability of the titanium(IV) was calculated from the absorbance of the extracts. It was found that 98.6% of the titanium(IV) was extracted by a single extraction. The distribution ratio and the molar absorptivity were 2.82×10^2 and 5.17×10^4 dm^3 mol^{-1} cm^{-1}, respectively. A calibration curve for the determination of the titanium(IV) was made under the optimum conditions. A good linear relationship was obtained over the concentration range from 0.3 μg to 5 μg of titanium(IV) per 5 cm^3 of carbon tetrachloride. The coefficient of the variation in ten measurements was 2.4%.

The Composition of the Complex. The composition of the complex was estimated by the continious-variation method. Figure 3 shows that the mole ratios of titanium(IV) : PV in the titanium(IV)-PV-TDEA complex and in the titanium(IV)-PV complex anion are found either to be 1 : 2. Figure 4 shows the mole ratio of titanium(IV) : TDEA to be 1 : 2. Thus, the composition of the associate complex is estimated to be $Ti(PV)_2(R_3R'N)_2$.

Extraction Constant. When the ionic associate of the titanium(IV)-PV complex anion with TDEA cation is extracted in the organic phase, the equation representing the extraction equilibria will be:

$$Ti(PV)_2^{2-} + 2R_3R'N^+ = Ti(PV)_2(R_3R'N)_{2(o)}. \quad (1)$$

The extraction constant, K_{ex}, is given by:

$$K_{ex} = \frac{[Ti(PV)_2(R_3R'N)_2]_o}{[Ti(PV)_2^{2-}][R_3R'N^+]^2}, \quad (2)$$

Table 1. Extraction constant for $Ti(PV)_2(R_3R'N)_2$ in carbon tetrachloride at 25 °C
pH=5.6 in an acetate buffer solution (2×10^{-2} mol dm^{-3}), [Ti]$=5\times10^{-6}$ mol dm^{-3}, [PV]$=7.5\times10^{-5}$ mol dm^{-3}, [TDEABr]$_0=5\times10^{-3}$ mol dm^{-3}, $V_{aq}=20$ cm^3, $V_0=10$ cm^3

[Br$^-$]/mol dm^{-3}	log K_{ex}
0.2	13.7
0.4	13.5
0.6	13.5
0.8	13.5
1.0	13.4
	av 13.5

All the concentrations in Table 1 indicate the initial concentrations.

where the subscript 0 denotes the organic phase. The extraction constant, K_{ex}, can be determined by the extraction data of the associate complex from various concentration of bromide in aqueous phase and the extraction constant of TDEABr. Table 1 shows the value of log K_{ex}. The average values of log K_{ex} is 13.5.

Effect of Foreign Ions. The masking reagents such as ethylenediaminetetraacetic acid, 1,2-cyclohexanediamine-*N*,*N*,*N*′,*N*′-tetraacetic acid, diethylenetriaminepentaacetic acid suppress thoroughly the extraction of the titanium(IV)-PV-TDEA complex. 3,6-Dioxaoctane-1,8-diamine-*N*,*N*,*N*′,*N*′-tetraacetic acid (GEDTA) is available as masking reagent in this extraction system, however the absorbance of the extract decreases about twenty percent by the addition of GEDTA. Beryllium, chromium(III), iron(III), bismuth, and thorium are masked by GEDTA, however aluminium, vanadium(V), molybdenum(VI), tungsten(VI), and Uranium(VI) interfere seriously. Iodide, thiocyanate, and perchlorate also interfere seriously, and give a negative error.

Effects of *N*-Methylated Diamine on Ion Pair Formation of Bis(2,4-pentanedionato)(diamine) Cobalt(III) Bromides in Nitrobenzene by Conductometry

Kazuaki Ito, Etsuro Iwamoto, and Yuroku Yamamoto*

Department of Chemistry, Faculty of Science, Hiroshima University, Naka-ku, Hiroshima 730

(Received April 2, 1982)

The conductometric study of bis(2,4-pentanedionato)(diamine) cobalt(III) bromides in nitrobenzene at 25 °C indicated that the ion association constant of the chelate salts increases in the order, $[Co(acac)_2(N,N,N',N'\text{-tmen})]Br < Bu_4NBr < [Co(acac)_2(N,N\text{-dmen})]Br < [Co(acac)_2(en)]Br < [Co(acac)_2(N,N'\text{-dmen})]Br$ (acac=2,4-pentanedione anion, diamine: en=ethylenediamine, *N,N*-dmen=*N,N*-dimethylethylenediamine, *N,N'*-dmen=*N,N'*-dimethylethylenediamine, *N,N,N',N'*-tmen=*N,N.N',N'*-tetramethylethylenediamine). The results were discussed from the view points of hydrogen bonds through the N–H protons of the chelate cations to the bromide anion and cation-solvent interactions.

The outer-sphere ion association of $[M(NH_3)_6]^{3+}$ and $[M(en)_3]^{3+}$ (M=Co and Cr) with some anions in aqueous[1-7] and nonaqueous solutions[8,9] has been determined by the conductometric and spectrophotometric methods. The results in aqueous solution indicated that the ion association of $[M(en)_3]^{3+}$ is promoted for the chloride ion,[1,5] but is reduced for the SO_4^{2-} and $C_2O_4^{2-}$ ions,[1-3,6] compared to that of $[M(NH_3)_6]^{3+}$. This result cannot be accounted for by the electrostatic theory of ionic association, suggesting the importance of the following ion-solvent interactions: hydration of the N–H protons of $[M(NH_3)_6]^{3+}$ and $[M(en)_3]^{3+}$, Cl^-, SO_4^{2-}, and $C_2O_4^{2-}$ and the dehydration accompanied by the ion pair formation. On the other hand, ion association of $[Co(en)_3]^{3+}$ salts in nonaqueous solvents such as DMSO is affected by the basicity of the solvents.[8,9]

The present study deals with the conductance of bis(2,4-pentanedionato)(diamine) cobalt(III) bromides([Co(acac)$_2$(diamine)]Br) in nitrobenzene at 25 °C to understand the effects of the replacement of the N–H protons by the CH_3 groups on ion pair formation. Nitrobenzene is dipolar aprotic (dielectric constant=34.82) and poorly basic (Gutmann's donor number=4.4). Thus, the ion pair formation of the chelate salts is affected by the ion-dipole interaction between the chelate cations and nitrobenzene molecules. The title compounds, which were confirmed to be stable in nitrobenzene by both spectrophotometry and conductometry, are 1 : 1 electrolytes and advantageous to elucidate the ligand and solvent effects on ion pair formation from conductance data.

Experimental

Four bis(2,4-pentanedionato)(diamine)cobalt(III) perchlorates were prepared by mixing $Na[Co(acac)_2(NO_2)_2]$ with equimolar amounts of the corresponding diamine, followed by addition of an aqueous solution of $NaClO_4$.[10] After triple recrystallizations, these samples were converted into the bromide salts by anion exchange resin in the Br^- form, and purified by recrystallizing twice from acetone (or ethanol)–ether. The purity of samples was checked by chemical analysis of C, H, and N, potentiometric titration of the bromide ion with silver nitrate, and the coulometric determination of water content by a Hiranuma AQ-3 aquacounter. Nitrobenzene was purified by shaking with sodium hydroxide, sulfuric acid, and distilled water, successively, and then by distillation under reduced pressure after drying over calcium chloride.

Conductances were measured at 1592 Hz by a LCR 10 type bridge (Ando Electric Co. Ltd.) which was calibrated with a standard resistance box(Shimadzu Seisakusho Co.). The cell was of the Kraus-Erlenmeyer type which was calibrated by fitting the conductance of KCl solutions (0.001—0.01 mol dm^{-3}) to the equation due to Lind, Zwolenik, and Fuoss.[11] The density and viscosity (0.01847 P) were measured with a digital density meter (Anton Paar Model DMA 02D) and Ubbelohde viscometer modified for use in a closed, dry atmosphere, respectively. All measurements were carried out in a water bath thermostated to 25±0.005 °C.

Results and Discussion

a) From Ref. 15.

corresponding electrolyte concentrations in mol dm^{-3} are given in Table 1 for nitrobenzene solutions of [Co(acac)$_2$(diamine)]Br. The data were analyzed by using the Fuoss-Hsia equation[12a)] with Fernández-Prini coefficients[12b)] and $E=E_1\Lambda_0-2E_2$,[12c)]

$$\Lambda = \gamma[\Lambda_o - SC^{1/2}\gamma^{1/2} + EC\gamma\log C\gamma + J_1(\mathrm{d})C\gamma + J_2(\mathrm{d})C^{3/2}\gamma^{3/2}], \quad (1)$$

where the symbols have their usual meaning:[13)] S, E, J_1, and J_2 contain contributions from both the electrophoretic and the relaxation effects, and each depends on Λ_0, and γ is the fraction of free ions. The association constant K_a can be expressed as

$$K_a = (1-\gamma)/\gamma^2 C f_\pm^2, \quad (2)$$

The mean ionic activity coefficient $f_\pm$ is given by the extended Debye-Hückel equation

$$-\log f_\pm = A(C\gamma)^{1/2}/[1+Bd(C\gamma)^{1/2}]. \quad (3)$$

The method of fitting in terms of Λ_0, K_a and the ion-size parameter d is based on that of Hanna *et al.*[14)] The values of the standard deviation is defined as

$$\sigma_\Lambda = [\sum(\Lambda_{\mathrm{calcd}}-\Lambda_{\mathrm{obsd}})^2/(n-3)]^{1/2}, \quad (4)$$

where n is the number of experimental points. The results are given in Table 2.

The association constants of the chelate electrolytes show two features: (a) the chelate electrolytes associate more strongly than tetrabutylammonium bromide (Bu_4NBr) ($K_a=74$)[15)] except for [Co(acac)$_2$(*N*,*N*,*N*′,*N*′-tmen)]Br, and (b) the K_a value of [Co(acac)$_2$(*N*,*N*′-dmen)]Br is much larger than those of [Co(acac)$_2$(en)]Br and [Co(acac)$_2$(*N*,*N*-dmen)]Br.

Since the chelate electrolytes have approximately the same hydrodynamic size as Bu_4NBr, the electrostatic theory of ionic association predicts that they should have a similar association constant. However, en, *N*,*N*-dmen, and *N*,*N*′-dmen complexes have much larger association constants compared with that of Bu_4NBr. This increase in K_a should be attributed to the hydrogen bond between the N–H protons of the chelate cations and the bromide anion. This explains well that K_a of the *N*,*N*-dmen complex is smaller than that of the en complex due to the decrease in the number of the N–H protons by the introduction of the *N*-methyl groups. Furthermore, this effect was confirmed from the fact that the K_a value of the *N*,*N*,*N*′,*N*′-tmen complex without the N–H protons is much smaller than those of en, *N*,*N*-dmen, and *N*,*N*′-dmen complexes, and is further smaller than that of symmetrical Bu_4NBr in spite of the enhanced effect of the unsymmetrical charge distribution in the chelate cation on K_a. This suggests that when there is no hydrogen bonding, the pseudo aromaticity of the acac ligand reduces the ion pair formation, probably due to the repulsion between Br^- and the π electrons or solvation of the acac ligand by nitrobenzene through π-π interaction.

As to observation (b), it has been shown by the studies of the rate of H–D exchange[16)] and the acid ionization constant[17)] in aqueous solution that the alkyl substitution (CH_3NH– and $-CH_2NH_2$) in the coordinated amine results in stronger acidity of the residual N–H protons. Therefore, the result (b) suggests that the *N*-methyl groups of the *N*,*N*′-dmen complex activate the residual N–H protons to associate more strongly with the bromide anion.

As is clear from Table 2, the limiting ionic conductance (λ_o^+) of the chelate cations which was estimated using $\lambda_o^-(Br^-)=21.6$ in nitrobenzene[18)] is increased in spite of the increasing size with the introduction of CH_3 groups. Particularly, it is noteworthy that the mobility of the [Co(acac)$_2$(*N*,*N*,*N*′,*N*′-tmen)]$^+$ ion is much larger than that of the [Co(acac)$_2$(en)]$^+$ ion. This result conflicts with hydrodynamic theory, suggesting specific ion-solvent interactions. Since nitrobenzene is a dipolar aprotic and poorly basic solvent, the chelate cations are considered to be solvated mainly by cation-solvent dipole interaction. In this case, the N–H protons of the [Co(acac)$_2$(en)]$^+$ ion would be solvated and the introduction of the CH_3 groups promotes the desolvation, leading to the increase in mobility due to the decrease in its effective size. For the [Co(acac)$_2$(*N*,*N*′-dmen)]$^+$ ion, the methyl substitution (CH_3NH–) prevents the solvation of the residual N–H protons because of the steric hindrance by the nearest neighboring CH_3 groups, which corresponds to the activation of the N–H protons. This leads to the larger association of [Co(acac)$_2$(*N*,*N*′-dmen)]Br compared to [Co(acac)$_2$(en)]Br and [Co(acac)$_2$(*N*,*N*-dmen)]Br in which the methyl groups are too far from the residual N–H protons.

The above discussion explains well the data of [M(NH$_3$)$_6$]$^{3+}$ and [M(en)$_3$]$^{3+}$ salts: the larger K_a value of [M(en)$_3$]Cl^{2+} compared to that of [M(NH$_3$)$_6$]Cl^{2+}[1,5)] in spite of the increasing cation size is attributed to the stronger acidity of the N–H protons of [M(en)$_3$]$^{3+}$, which is considered as the result of the dehydration of the N–H protons by the hydrophobicity of the C_2H_4 groups. On the other hand, for SO_4^{2-} and $C_2O_4^{2-}$ salts,[1-3,6)] the hydrogen bonding of the N–H protons with SO_4^{2-} and $C_2O_4^{2-}$ is prevented by the strong hydration of divalent anions. This leads to the smaller

ionic association of SO_4^{2-} and $C_2O_4^{2-}$ with $[Co(en)_3]^{3+}$ than that with $[Co(NH_3)_6]^{3+}$.

A further study in other solvents is under way to ascertain the above concept.

This work was supported in part by a Grant-in-Aid for Scientific Research Nos. 443013 and 454183 from the Ministry of Education, Science and Culture.

Reaction Process of Titanium Tetrachloride with Ammonia in the Vapor Phase and Properties of the Titanium Nitride Formed

Yuzo Saeki,* Ryoko Matsuzaki, Akimasa Yajima, and Masayo Akiyama

Research Laboratory of Resources Utilization, Tokyo Institute of Technology, 4259, Nagatsuta-cho, Midori-ku, Yokohama 227

(Received March 13, 1982)

The reaction products of gaseous $TiCl_4$ with ammonia were $TiCl_4 \cdot 5NH_3$ at 200 °C, $TiCl_4 \cdot 5NH_3$, TiClN, and NH_4Cl at 250—400 °C, $TiCl_4 \cdot 5NH_3$, TiClN, TiN_x, and NH_4Cl at 450—650 °C, TiN_x and NH_4Cl at 700—1000 °C, and TiN_x, NH_4Cl, and HCl at 1100—1400 °C. The N/Ti atomic ratio, x, of the TiN_x formed was 1.21 at 700 °C, 1.16 at 800 °C, 1.13 at 900 °C, and 1.10 above 1000 °C. The lattice constants of the TiN_x formed are shown. The reaction process can be represented as follows: The reaction of gaseous $TiCl_4$ with ammonia occurs first to form $TiCl_4 \cdot 5NH_3$. Above *ca.* 220 °C, the $TiCl_4 \cdot 5NH_3$ decomposes to TiClN. Above *ca.* 430 °C, the TiClN reacts with ammonia to form TiN_x. Above *ca.* 1100 °C, in addition to these reactions, the reaction of $TiCl_2$, formed by the reduction of $TiCl_4$ with hydrogen resulting from the thermal dissociation of ammonia, with ammonia occurs to form TiN_x. On heating the TiN_x, formed by the vapor-phase reaction, at temperatures higher than 500 °C in an argon atmosphere, the value of x decreased and became close to that of the stoichiometric nitride, being 1.02 at 900—1100 °C.

The vapor-phase reaction of transition metal chlorides with ammonia has recently become important for the preparation of fine powders of transition metal nitrides; these are acquiring importance as new industrial materials. Concerning the formation of titanium nitride from titanium tetrachloride ($TiCl_4$) by a vapor-phase reaction, Kato *et al.*[1] have studied the preparation of fine titanium nitride powders by a vapor-phase reaction of the $TiCl_4$–NH_3–H_2–N_2 system at 700—1500 °C with emphasis on the effects of reaction conditions on the particle size and chemical composition. However, no information is at present available on the reaction process of $TiCl_4$ with ammonia in the vapor phase.

In this paper, the reaction products of gaseous $TiCl_4$ with ammonia at 200—1400 °C were examined in detail. The possible reactions which were considered to occur on the basis of the above experiments were examined. The N/Ti atomic ratios, lattice constants, and thermal stability of the titanium nitrides formed at various temperatures were examined. The titanium nitrides formed were also examined by electron microscopy.

Experimental

Materials. The $TiCl_4$ was prepared by the reaction of titanium sponge (Ti 99.7%) with chlorine at 500 °C and purified by fractional distillation. The chemical analysis gave Ti, 25.2; Cl, 74.7% (calcd for $TiCl_4$: Ti, 25.24; Cl, 74.76%). The ammonia was dried by passing it over sodium hydroxide granules.

Experimental Procedures. A transparent quartz or alumina reaction tube (1000 mm length) was used for examining the reaction products of gaseous $TiCl_4$ with ammonia. Gaseous $TiCl_4$ was formed by heating liquid $TiCl_4$ (17 g) at 105 °C and was carried by a stream of argon (50 cm³/min) into the reaction zone (28 mm i.d., 250 mm length) held at specified temperature. The $TiCl_4$ inlet tube consisted of two concentric tubes. Gaseous $TiCl_4$ carried by arogn was introduced through the inner tube and the outer tube was utilized for introducing argon (50 cm³/min) as a sheath gas to prevent formation of titanium nitride deposits at the chloride inlet tube. Ammonia was simultaneously introduced at a flow-rate of 100 cm³/min into the reaction zone through a separate tube. The mean flow-rate of gaseous $TiCl_4$ was 6.0 cm³/min. A quartz or alumina tube was inserted inside the reaction tube to make the removal of the reaction product easier. The reaction was allowed to proceed for 2 h.

The by-product NH_4Cl which deposited outside the reaction zone together with the titanium nitride formed was separated by heating the mixture in an argon stream at 400 °C (the sublimation point of NH_4Cl: 339 °C)[2] for 10—15 h.

Analytical. The chemical analysis of the reaction products was performed as follows: The titanium content was gravimetrically determined as TiO_2 using cupferron as a precipitating agent, after dissolving the sample in 3 M-nitric acid. The chlorine content was gravimetrically determined as AgCl from the filtrate. The ammonia content was determined by the Kjeldahl method from the nitric acid solution.

X-Ray analysis of the solid product was performed with an X-ray powder diffractometer equipped with a proporitonal counter using Ni filtered Cu radiation. The sample chamber of the diffractometer was maintained under a dry nitrogen atmosphere, if necessary, to prevent contamination of the sample by atmospheric moisture during the irradiation.

The sensitivity of the quartz helix used for thermogravimetry (TG) was approximately 94 mm/g. The sample (0.2 g) was heated at a rate of 2.5 °C/min and the flow-rate of ammonia was maintained at 50 cm³/min.

The N/Ti atomic ratio of the titanium nitride formed was evaluated as follows: The sample titanium nitride was oxidized to TiO_2 by heating in an oxygen atmosphere to 700 °C, using a Shimazu high-sensitive thermal balance Model TGA31. The titanium content of the sample was calculated from the amount of TiO_2 formed. The amount of nitrogen was determined as the difference between the amount of the initial sample and that of the titanium. The value of the N/Ti atomic ratio was evaluated with an accuracy within ± 0.01.

The lattice constant of the titanium nitride was calculated based on the X-ray diffraction data obtained by using silicon powders as an internal standard and under the scanning speed of 1/2—1/4°/min.

Throughout this work, the $TiCl_4$ and the reaction products were handled in an argon atmosphere to prevent contamination by atmospheric moisture.

Results and Discussion

Reaction Products of Gaseous Titanium Tetrachloride with Ammonia. The products formed by heating gaseous

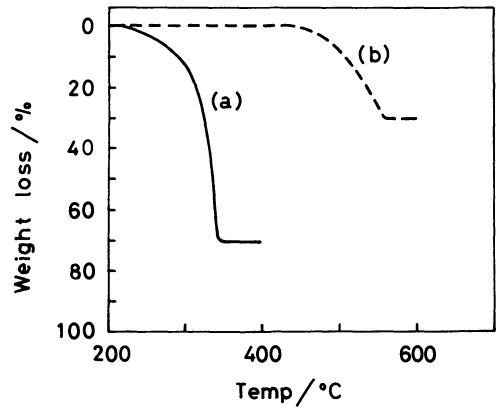

Fig. 1. TG curves of $TiCl_4 \cdot 5NH_3$ and TiClN in an ammonia stream.
(a): $TiCl_4 \cdot 5NH_3$, (b): TiClN.

$TiCl_4$ in an ammonia stream at various temperatures above 200 °C were examined both by X-ray analysis[3-5] and chemical analysis. The product formed at 200 °C showed a hitherto unknown X-ray diffraction pattern which was clearly different from those of known titanium compounds. The chemical analysis of the product gave Ti, 17.4; Cl, 51.6; NH_3, 30.8%. The ratio of Ti : Cl : NH_3 was calculated to be 1 : 4.00 : 4.98. This was considered to indicate that the product formed at 200 °C had a composition of $TiCl_4 \cdot 5NH_3$ (calcd for $TiCl_4 \cdot 5NH_3$: Ti, 17.42; Cl, 51.60; NH_3, 30.98%). The reaction products at various temperatures are shown in Table 1. Unreacted $TiCl_4$ was not observed throughout the temperature range of this work.

Reaction Process of Gaseous Titanium Tetrachloride with Ammonia. To elucidate the reaction process of gaseous $TiCl_4$ with ammonia, the behavior of the $TiCl_4 \cdot 5NH_3$ and the TiClN, which had been formed during the reaction process, on heating in an ammonia stream were examined. The thermal dissociation of ammonia[6] and the thermal decomposition of NH_4Cl[7] under the experimental conditions in this work were also examined.

Behavior of $TiCl_4 \cdot 5NH_3$ and TiClN on Heating in an Ammonia Stream: The TG curve of $TiCl_4 \cdot 5NH_3$ in an ammonia stream is shown in Fig. 1(a).

$TiCl_4 \cdot 5NH_3$ lost weight above 220 °C. The weight loss was accompanied by the vaporization of NH_4Cl and a small amount of $TiCl_4 \cdot 5NH_3$. The sample after heating to 400 °C was found to be TiClN by X-ray analysis.

In order to obtain more detailed information on the behavior of $TiCl_4 \cdot 5NH_3$ on heating in an ammonia stream, $TiCl_4 \cdot 5NH_3$ (1.0 g) in a quartz boat (70 mm length, 15 mm width, 7 mm depth) was placed in a straight reaction tube (28 mm i.d., 1000 mm length). Ammonia was introduced into the reaction tube at a flow-rate of 100 cm^3/min. The sample part was then placed in the centre of an electric furnace (300 mm heating length) maintained at a specified temperature for 1 h. The products obtained inside and outside the boat were examined by X-ray analysis and chemical analysis. The results are shown in Table 2.

From the results, it was found that $TiCl_4 \cdot 5NH_3$ decomposed to TiClN above about 220 °C and a part of $TiCl_4 \cdot 5NH_3$ vaporized above about 300 °C in an ammonia stream.

The TG curve of TiClN in an ammonia stream is shown in Fig. 1(b). The TiClN used was prepared by the reaction of gaseous $TiCl_4$ with ammonia at 400 °C. The chemical analysis gave Ti, 49.1; Cl, 36.4% (calcd for TiClN: Ti, 49.19; Cl, 36.42%). TiClN lost weight above 430 °C. The weight loss was accompanied by the vaporization of NH_4Cl alone. The sample after heating to 600 °C was found to be TiN_x. From these results, it was found that TiClN reacted with ammonia above about 430 °C to form TiN_x.

Table 2. Experimental results for $TiCl_4 \cdot 5NH_3$ on heating in an ammonia stream

Heating temp/°C	Products		Unreacted $TiCl_4 \cdot 5NH_3$ (%)
	In the boat	Outside the boat	
250	TiClN(4)	NH_4Cl	96
300	TiClN(41)	$TiCl_4 \cdot 5NH_3$(15), NH_4Cl	44
350	TiClN(71)	$TiCl_4 \cdot 5NH_3$(29), NH_4Cl	—

Note: the value in( ) is mole percentage of $TiCl_4 \cdot 5NH_3$ converted to the product.

Thermal Dissociation of Ammonia and Thermal Decomposition of NH_4Cl: Ammonia alone was introduced at a flow-rate of 100 cm^3/min into the reaction zone held at a specified temperature and the total volume of nitrogen and hydrogen, formed by the dissociation of ammonia, was measured. From the results, the percentage of the dissociated ammonia was found to be <1% at 800 °C, 1% at 900 °C, 2% at 1000 °C, 6% at 1100 °C, 23% at 1200 °C, 88% at 1300 °C, and 98% at 1400 °C.

Gaseous NH_4Cl was formed by heating solid NH_4Cl and was carried by a stream of argon at a flow-rate of 100 cm^3/min into the reaction zone held at a specified temperature for 2 h. The amount of NH_4Cl introduced, 6.5 g, was the same as that formed during the reaction of gaseous $TiCl_4$ with ammonia for 2 h at 700—1000 °C (Table 1). The percentages of the decomposed NH_4Cl at various temperatures were evaluated from the amount of HCl formed by the decomposition. From the results, the percentage of the decomposed NH_4Cl was found to be <1% at 1100 °C, 8% at 1200 °C, 29% at 1300 °C, and 65% at 1400 °C.

Based on the above experimental results, the reaction process of gaseous $TiCl_4$ with ammonia was discussed. As shown in Table 1, $TiCl_4 \cdot 5NH_3$ alone was formed at 200 °C. This fact indicates that the reaction of gaseous $TiCl_4$ with ammonia to form $TiCl_4 \cdot 5NH_3$ occurs first. The TiClN formed at 250—650 °C (Table 1) is considered to be due to the decomposition of $TiCl_4 \cdot 5NH_3$, because the $TiCl_4 \cdot 5NH_3$ decomposes above about 220 °C to TiClN, as described above. The TiN_x formed above 450 °C is considered to be due to the reaction of TiClN with ammonia, because the TiClN reacts with ammonia above about 430 °C to form TiN_x.

Above 1100 °C, HCl was formed in addition to TiN_x and NH_4Cl (Table 1). The percentage of HCl formed to the total amount of chlorine introduced as $TiCl_4$ was 36% at 1100 °C, 75% at 1200 °C, 92% at 1300 °C, and 93% at 1400 °C. This amount of HCl is considerably larger than the amount of HCl formed by the thermal decomposition of NH_4Cl at each temperature, as described above. Also, it has been reported that gaseous $TiCl_4$ reacts with hydrogen above about 800 °C to form gaseous titanium dichloride ($TiCl_2$) and HCl.[8] From these facts, it was considered that the reduction of gaseous $TiCl_4$ with hydrogen, formed by the thermal dissociation of ammonia, to $TiCl_2$ also occurred above 1100 °C and that the $TiCl_2$ reacted with ammonia to form TiN_x. Therefore, the reaction of gaseous $TiCl_2$ with ammonia was examined.

Table 3. N/Ti atomic ratio and lattice constant of the TiN_x formed

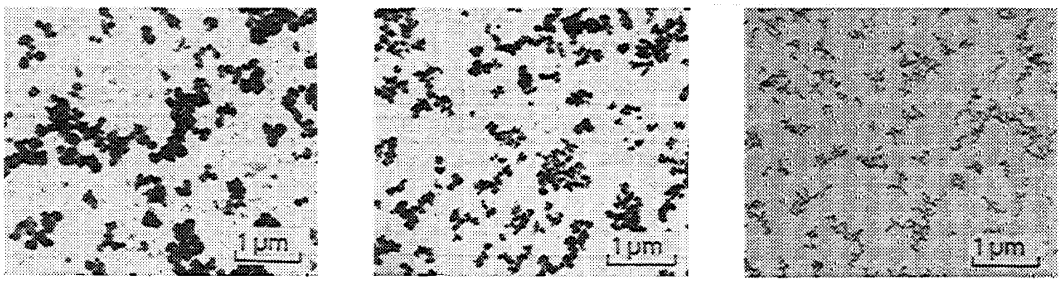
Formation temp/°C	x in TiN_x	a_0/Å
700	1.21	4.224
800	1.16	4.228
900	1.13	4.230
1000—1400	1.10	4.233

The $TiCl_2$ used was prepared by the disproportionation of commercial titanium trichloride ($TiCl_3$) *in vacuo* at 475 °C.[9] The chemical analysis gave Ti, 40.2; Cl, 59.7% (calcd for $TiCl_2$: Ti, 40.31; Cl, 59.69%). Gaseous $TiCl_2$ was formed by heating $TiCl_2$ at 800 °C and was carried by a stream of argon (50 cm^3/min) into the reaction zone held at a specified temperature. Ammonia was simultaneously introduced at a flow-rate of 100 cm^3/min through a separate tube into the reaction zone.

The products formed were TiN_x and NH_4Cl at 1000 °C and TiN_x, NH_4Cl, and a small amount of HCl at 1100 °C. The HCl formed at 1100 °C was considered to be formed by the reduction of $TiCl_4$, formed by the disproportionation of $TiCl_2$,[8,10] with hydrogen resulting from the thermal dissociation of ammonia. The results indicate that gaseous $TiCl_2$, formed by the reduction of gaseous $TiCl_4$ with hydrogen, reacts with ammonia to form TiN_x.

From these results, the reaction process of $TiCl_4$ with ammonia in the vapor phase can be represented as follows: The reaction of gaseous $TiCl_4$ with ammonia occurs first to form $TiCl_4 \cdot 5NH_3$. Above about 220 °C, the $TiCl_4 \cdot 5NH_3$ decomposes to TiClN. Above about 430 °C, the TiClN reacts with ammonia to form TiN_x. Above about 1100 °C, in addition to these reactions, the reaction of $TiCl_2$, formed by the reduction of $TiCl_4$ with hydrogen resulting from the thermal dissociation of ammonia, with ammonia occurs to form TiN_x.

Properties of the TiN_x Formed. The N/Ti atomic ratios of TiN_x formed at 700—1400 °C are shown in Table 3. Prior to this examination, the presence of residual NH_4Cl in the TiN_x, obtained after the removal of NH_4Cl at 400 °C in an argon stream, was checked by chemical analysis,[11] after the fusion of the TiN_x sample with sodium carbonate. From the results, the NH_4Cl content in the TiN_x was 6.9% for the TiN_x formed at 700 °C, 5.9% at 800 °C, 3.6% at 900 °C, 1.5% at



(a) 1200 °C (b) 1300 °C (c) 1400 °C

Flg. 2. Electoron micrographs of the $TiN_{x(x=1.10)}$ formd at various temperatures.

1000 °C, 1.0% at 1100 °C, 0.5% at 1200 °C, 0.2% at 1300 °C, and trace at 1400 °C. Further separation of the NH_4Cl at higher temperatures could not be carried out, by considering the thermal stability of the TiN_x formed, as described later. For the evaluation of the N/Ti atomic ratio of the TiN_x formed, the initial weight of the sample was corrected by subtracting the amount of NH_4Cl contained, because the NH_4Cl was vaporized during the oxidation.

Kato *et al.*[1] reported that the N/Ti atomic ratio of the TiN_x formed by a vapor-phase reaction of the $TiCl_4$–NH_3–H_2–N_2 system at 700—1500 °C was 1.1—1.4. Vorob'ev *et al.*[12] reported that the stoichiometric TiN was identified as a main component of the reaction products of gaseous $TiCl_4$ with ammonia at 800—1100 °C. But, the details of this study are not available.

It has been known that the TiN_x phase has a NaCl structure.[1,3] The lattice constant of TiN_x formed at each temperature is also shown in Table 3.

The TiN_x formed by the reaction of gaseous $TiCl_4$ with ammonia above 1000 °C were examined by electron microscopy. The typical micrographs of the TiN_x are shown in Fig. 2.

As seen from Fig. 2, the TiN_x formed at 1400 °C is uniform, ultrafine powders with the particle diameters of the order of 1/100 μm. The range of the particle sizes of the TiN_x formed at lower temperatures was found to be wide.

Finally, to obtain knowledge of the thermal stability of the TiN_x formed, the N/Ti atomic ratios of the samples obtained by heating $TiN_{1.21}$ at various temperatures in an argon atmosphere for 1 h were examined. The results are shown in Fig. 3. In addition, it was found that the residual NH_4Cl in the TiN_x was compeletely removed by the heating at 1100 °C.

The results indicated that when the TiN_x formed was heated in an argon atmosphere at temperatures higher than 500 °C, the N/Ti atomic ratio decreased and became close to that of the stoichiometric nitride; The value of x was 1.02 at the heating temperatures of 900—1100 °C.

The lattice constants of the TiN_x with various x values, obtained in this work, are shown in Fig. 4.

The N/Ti atomic ratio of TiN_x obtained after heating $TiN_{1.21}$ in an argon atmosphere at each temperature was found to be lower than that of the TiN_x formed by the vapor-phase reaction at the same temperature (Table 3). The facts are considered to be due to the presence of nitrogen during the reaction. This consideration was supported by the fact that no change in the N/Ti atomic ratio of the $TiN_{1.10}$ formed at 1000 °C by the vapor-phase reaction was observed after the heating at 1000 °C in an ammonia stream for 1 h.

The present work was partially supported by a Grant-in-Aid for Scientific Research No. 56470058 from the Ministry of Education, Science and Culture.

Preparation of Poly(dicarbon monofluoride) from Petroleum Coke

Nobuatsu WATANABE,* Yoshinori ASHIDA, and Tsuyoshi NAKAJIMA
Department of Industrial Chemistry, Faculty of Engineering, Kyoto University, Sakyo-ku, Kyoto 606
(Received March 31, 1982)

Graphite fluoride containing more than 60% poly(dicarbon monofluoride) $(C_2F)_n$ was prepared from petroleum coke heat-treated at 2700 °C at a temperature between 337 and 460 °C. The interlayer spacings and F/C ratios of these graphite fluorides were in the ranges of 0.82—0.74 nm and 0.58—0.68, respectively. The $(C_2F)_n$ content in graphite fluoride also increased with increasing fluorine pressure.

During the studies on the chemical composition and crystal structure of graphite fluoride,[1] a new compound, poly(dicarbon monofluoride) represented by the formula $(C_2F)_n$ has been found. The $(C_2F)_n$ is formed at a low temperature between 350 and 400 °C from a carbon material with high crystallinity such as natural graphite. Various kinds of artificial carbon materials are generally used in the industrial field. In most cases, these carbons are amorphous, having much smaller crystallites than natural graphite; however, the growing of small crystallites is attained by heat treatment at 2600—2800 °C. In this study, the preparation of $(C_2F)_n$ is attempted from petroleum coke heat-treated at high temperatures.

Experimental

The starting carbon material was petroleum coke (GL coke) of less than 46 μm, heated-treated at temperatures between 1500 and 2700 °C in a graphitization furnace. Structural parameters of these carbon materials are listed in Table 1. With increasing heat treatment temperature, the parameter indicating the interlayer spacing, C_0(004) decreased from 0.690 to 0.672 nm while those indicating the crystallite size, L_c and L_a, increased very much. Half of C_0 (004) length is the distance between two carbon network layers. Fluorination of petroleum coke was made at temperatures of 330—590 °C using an automatic thermobalance specially designed for fluorine atmosphere.[2] Fluorination reaction was continued until no weight increase was observed, and the products were analyzed by elemental analysis and X-ray diffractometry.

Results and Discussion

Figure 1 is an example of the change in (001) X-ray diffraction patterns of graphite fluoride prepared from petroleum coke heat-treated at 2700 °C. The peak position shifted from 14.5° to 10.8° in 2θ (by Cu $K\alpha$) with decreasing reaction temperature. It is known that $(C_2F)_n$ is preferentially formed at temperatures of 350—400 °C from a carbon material having a large crystallite size like natural graphite and its (001) diffraction line

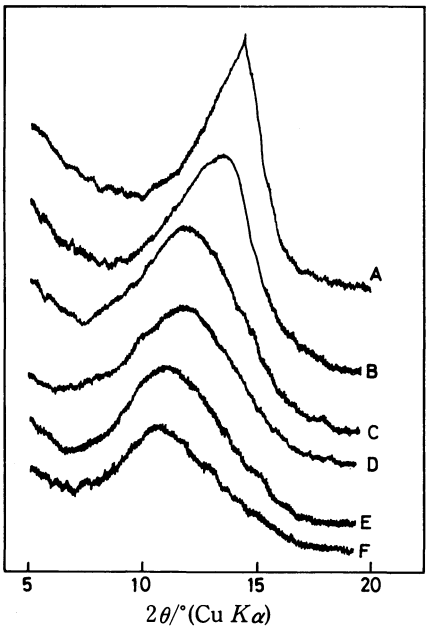

Fig. 1. (001) X-Ray diffraction patterns of graphite fluoride prepared from petroleum coke (PC 2700 °C). Reaction temperature: A: 590 °C, B: 550 °C, C: 467 °C; D: 426 °C; E: 370 °C, F: 337 °C.

appears at 10—11° in 2θ, whereas that for $(CF)_n$ is situated around 14—15°.[1] Figure 1 indicates that $(C_2F)_n$ is formed mainly below 400 °C, however, the peak profile of the product prepared at 337 °C is broader than that of the product prepared at 590 °C, probably because of the simultaneous formation of a small amount of $(CF)_n$. But only a slight change of the peak positions was observed for graphite fluoride prepared from the sample heat-treated at 1500 °C. Even in the reaction at low temperatures such as 330 °C, a product with the peak position much higher than 10° in 2θ was prepared, as shown in Fig. 2. This result shows no formation of $(C_2F)_n$ from this petroleum coke under any

conditions.

As already reported,[1] since $(CF)_n$ is formed even at low temperatures between 400 and 350 °C from a carbon material with low crystallinity or at a disordered place such as surface of a carbon particle, it is very difficult to obtain pure $(C_2F)_n$ from the artificial carbon materials. The $(C_2F)_n$ content in a product is estimated from the F/C ratio of the product by assuming only $(CF)_n$ as an impurity. By representing

the amounts of $(C_2F)_n$ and $(CF)_n$ as X and 1-X, respectively, F/C ratio is related with X by the equation $F/C = 1 - 0.5X$. However, as graphite fluoride has CF_2 and CF_3 groups on the surface, the actual content is expected to become slightly higher than the value calculated by the above equation. From Fig. 3, graphite fluoride containing $(C_2F)_n$ by more than 60% is obtained from petroleum coke heat-treated at 2700 °C, that is: at 337—380 °C, $(C_2F)_n$: 70—80% and at 380—460 °C, $(C_2F)_n$: 60—70%. The sample heat-treated at 2300 °C gives graphite fluoride with $(C_2F)_n$ content of about 50% at 350—430 °C. Graphite fluorides prepared from petroleum coke heat-treated at 2100 and 1860 °C contain only about 40—50% $(C_2F)_n$ and only $(CF)_n$ is prepared at any temperature from

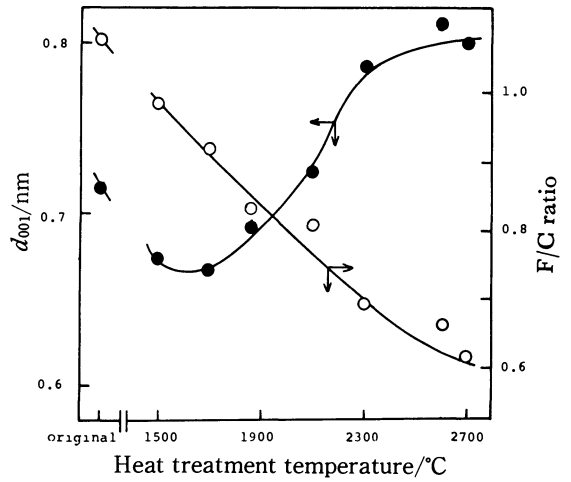

Fig. 6. Variation of the interlayer spacings and F/C of graphite fluoride as a function of heat treatment temperature.
Reaction conditions : 370 °C, F_2, 267×10^2 Pa.

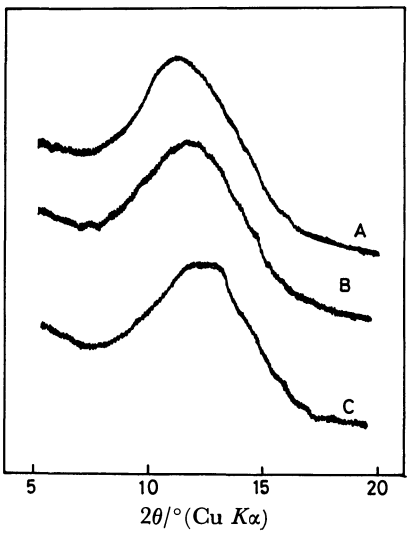

Fig. 7. Effect of fluorine pressure on (001) X-ray diffraction patterns of graphite fluoride prepared from petroleum coke (PC 2700 °C) at 430 °C.
A: 533×10^2 Pa, B: 267×10^2 Pa, C: 133×10^2 Pa.

petroleum coke heat-treated at 1500 °C. It is found by comparison of Fig. 3 with Table 1 that in order to obtain graphite fluoride with a $(C_2F)_n$ content of more than 60%, it is necessary to use petroleum coke with crystallite sizes, $L_c(002)$ and $L_a(110)$, of more than 100 nm.

The interlayer spacings d_{001} of graphite fluoride are *ca.* 0.9 nm for $(C_2F)_n$ and 0.6 nm for $(CF)_n$.[1] Figure 4 shows an increase of d_{001} values with increasing content of $(C_2F)_n$ in graphite fluoride as a function of reaction temperature. The d_{001} of graphite fluoride prepared below 400 °C is about 0.8 nm; this is smaller by 0.1 nm than the reported value 0.9 nm.[1] It is due to the overlapping of two diffraction peaks corresponding to $(C_2F)_n$ and $(CF)_n$. Such a tendency of d_{001} with decreasing temperature is also observed for graphite fluoride prepared from the sample treated at 1500 °C; however, in this case it would be attributable to the lower crystallinity of the prepared $(CF)_n$. Figure 5 shows more clearly the overlapping of two diffraction lines originating from $(C_2F)_n$ and $(CF)_n$. With increasing heat treatment temperature of petroleum coke, the half width of (001) diffraction line changes along more symmetric hyperbola as a function of temperature in accordance with increasing content of $(C_2F)_n$ in graphite fluoride. The hyperbola with a broad width has a maximum point at 430 °C, while in the case of graphite fluorides prepared from natural graphite, the maximum point of hyperbola with a narrow width is situated at 490 °C.[1] This indicates that $(C_2F)_n$ is preferencially formed from a carbon material with higher crystallinity. It is more distinctly shown in Fig. 6, which gives the change in the interlayer spacings d_{001} and F/C ratios of graphite fluoride as a function of crystallinity of a starting carbon material.

The dependence of $(C_2F)_n$ formation on fluorine pressure is given in Fig. 7, in which the peak position of (001) diffraction line shifts to lower angles with increasing fluorine pressure. That is, the interlayer spacing d_{001} increased from 0.72 to 0.80 nm and F/C ratio decreased from 0.67 to 0.64 with increase in the fluorine pressure from 133×10^2 to 533×10^2 Pa. These data mean that $(C_2F)_n$ is more easily formed under higher fluorine pressure. This is consistent with the previous result obtained for graphite fluoride prepared from natural graphite.[1]

Direct Synthesis of Cyclic Carbonates in the Presence of Organometallic Compounds. Catalyses by Systems from IVA, VA, and VIA Group Compounds and Lewis Base

Ryoki NOMURA,* Masahiro KIMURA, Satoshi TESHIMA, Akira NINAGAWA, and Haruo MATSUDA
Department of Petroleum Chemistry, Faculty of Engineering, Osaka University, Yamada-oka, Suita, Osaka 565
(Received November 2, 1981)

In the cycloaddition of carbon dioxide to oxiranes to form cyclic carbonates in the presence of organometallic halides of group IVA, VA, and VIA, catalytic activities of organometallic halides are in the order Sb>Te>Sn≫Bi, Ge, and Si. An improvement of their catalytic activities is achieved by addition of an equimolar amount of Lewis base. In binary catalyst systems, the order of catalytic activities is in the order Sn>Te>Sb≫Bi, Ge, and Si. Organotin halide–base systems show the highest catalytic activity.

In our previous papers, we reported that pentavalent organoantimony halides such as Ph_4SbBr and Ph_3SbBr_2 are highly effective catalysts for the cycloaddition reaction of carbon dioxide (CO_2) to oxiranes to afford corresponding cyclic carbonates (1,3-dioxolan-2-ones).[1] The striking feature of organoantimony catalysts in the cycloaddition is attributable to the covalent nature of the antimony-halogen bonds[1] in contrast with ammonium halides such as tetraethylammonium chloride.[2]

In the present study, we carried out cycloadditions catalyzed by triphenyl derivatives of Sn^{IV}, Ge^{IV}, Si^{IV}, and Bi^{V} and by dimethyl and diphenyl derivatives of Te^{IV}, expecting a similar effect of metal-halogen bonds as in the pentavalent organoantimony halide-catalyzed cycloaddition. Further, an attempt was made to improve the catalytic activity of the organometallic halides by incorporation of an equimolar amount of Lewis base such as triethylamine (TEA), pyridine (Py), and triphenylphosphine (TPP) to the organometallic halides and it was found that the binary catalysts effectively enhance the catalytic activity, especially in the case of the organotin halides.

Some recent papers have claimed good catalytic activities of pairs of heavy metal halide and Lewis base[3] but do not explain the effect of added bases in detail. Therefore, we also attempted to discuss the effect of added bases.

Results and Disscussion

Catalytic Activities of Organometallic Halides of Groups IV, V, and VI. The cycloaddition of CO_2 to methyloxirane (propylene oxide, PO) was carried out in a stainless-steel autoclave at 100 °C under a fixed initial pressure of CO_2, 50 kg/cm², to compare catalytic activities of organometallic halides with one another,

TABLE 1. RELATIVE CATALYTIC ACTIVITIES OF THE ORGANOMETALLIC HALIDES–BASE SYSTEMS IN THE CYCLOADDITION REACTION OF CO_2 TO METHYLOXIRANE AT 100 °C

Catalyst	Relative rate constant[b]

and relative rate constants are summarized in Table 1 for the catalysts employed. The catalytic activities of the organometallic halides are in the order

$$Sb > Te > Sn \gg Bi, Ge, Si. \quad (1)$$

Only the organotellurium compounds compare with the organoantimony catalysts in activity under the conditions examined. However, the reaction mixture became red-brown as reaction proceeded. Although organotin halides could not cause the cycloaddition at 100 °C, they gave 4-methyl-1,3-dioxolan-2-one (propylene carbonate, PC) at a significant rate, when reaction was carried out at 120 °C.[4]

The dependence of the catalytic activities of the organometallic halides on the polarity of the metal-halogen bonds may be expected, since the organometallic halides used in this study are considered to have relatively covalent metal-halogen bonds similarly to the organoantimony halides.[1] With regard to Sn, Sb, and Te compounds, the length of the metal-chlorine bond was reported to be in the order $Sb^{V}>Te^{IV}>Sn^{IV}$,[5,6] and it can be seen that the catalytic activity of the organometallic halides decreases with decrease in the bond length.

If the organometallic catalyst can be formed *in situ*, some simplification of the process for synthesis of the cyclic carbonate may be achieved. Among the organometallic halides examined, Me_2TeI_2 can be prepared by heating a mixture of tellurium powder and methyl iodide at 80 °C.[7] We attempted a cycloaddition reaction with a mixture of methyl iodide and tellurium which is expected to afford Me_2TeI_2 *in situ*. When methyl iodide and tellurium were added in a mole ratio of more than two, a quantitative yield of PC was obtained as shown in Table 2. However, the question whether Me_2TeI_2 is really formed *in situ*[8] and catalyzes the reaction remains to be solved. We also attempted the cycloaddition with combinations of tin metal-butyl[9] or -methyl iodide and antimony metal-methyl iodide, but they were not effective at all even at 120 °C.

Improvement of the Catalytic Activities of the Organometallic Halides by Addition of Lewis Bases. Generally, group IV organometallic halides are found to be less active for the cycloaddition reaction than organoantimony and organotellurium compounds. Thus, in order to improve the catalytic activity of the organometallic halides, an equimolar amount of Lewis base such as TEA, Py, and TPP was added to the organometallic compounds.[10] A marked rate enhancement was observed as shown in Table 1, *e.g.*, relative rate constants for Ph_3SnBr (or Ph_3SnI)–base systems are obviously larger than those for Ph_3SnBr (or Ph_3SnI) by a factor of $>10^2$. The order of the catalytic activities for the binary catalyst systems changed from (1) to

$$Sn > Te > Sb \gg Bi, Ge, Si. \quad (2)$$

The most active binary systems, such as Ph_3SnBr–TEA and Me_2TeI_2–TPP, surpassed Ph_4SbBr which is the most effective among the organoantimony compounds,[1] and could give the cyclic carbonate quantitatively even under atmospheric pressure of CO_2 at 60 °C, as shown in Fig. 1.

Effect of Added Bases. Tertiary amines or phosphines themselves have been known to show catalytic activity for the cycloaddition reaction,[11] but their catalytic activity is low as shown in Table 1 under the

Table 2. The cycloaddition reaction of CO_2 to PO in the presence of tellurium and methyl iodide[a]

Methyloxirane: 50 mmol, organometals [Mt]: 0.15 M, initial pressure of CO_2: 50 kg/cm^2. A: Ph_3SnBr–TEA at 100 °C. B: Ph_3SiBr–TEA (●) and Ph_3GeBr–TEA (○) at 120 °C.

relevant conditions. Consequently, the enhanced catalytic activity of the binary systems can be said to result from a cooperative effect of the organometallic halide with the base.

In order to understand the synergic effect of the organometallic compound with the base, the Ph_3SnBr–TEA system, showing a high rate enhancement, was examined in detail. Pseudo-first-order rate constant k_ϕ was plotted against the molar ratio of [TEA]/[Ph_3SnBr] as shown in Fig. 2. It can be seen from Fig. 2 that k_ϕ linearly increases with molar ratio, reaches a maximum value at molar ratio 1.0, and follows a gradual decrease. This characteristic curve indicates that the effective enhancement of the catalytic activity results from a 1 : 1 complexation between Ph_3SnBr and TEA.[5,12] Consequently, in the binary systems the pseudo-first-order rate constant k_ϕ may be divided into the respective contributions of organometallic halides alone, of bases alone, and of the organometallic halide–base complex and k_ϕ can be expressed as in Eq. 5 by using the equilibrium constant K shown in Eq. 3:

$$\text{Mt} + \text{base} \overset{K}{\rightleftharpoons} \text{Mt–base(complex)}, \quad (3)$$

$$k_\phi = k_{\phi\,\text{Mt}} + k_{\phi\,\text{base}} + k_{\phi\,\text{complex}} \quad (4)$$

$$= k_{\phi\,\text{Mt}} + k_{\phi\,\text{base}} + k_{\text{complex}} K[\text{Mt}][\text{base}], \quad (5)$$

$$k_{\phi\,\text{complex}} = k_{\text{complex}}[\text{complex}], \quad (6)$$

where Mt denotes the organometallic halide. From the results shown in Table 1, the contribution from base alone is negligible, and then Eqs. 7 and 8 can be introduced:

$$k_\phi = k_{\phi\,\text{Mt}} + k_{\text{complex}} K[\text{Mt}][\text{base}] \quad (7)$$

$$= k_{\phi\,\text{Mt}} + [\text{Mt}]^2 k_{\text{complex}} K([\text{base}]/[\text{Mt}]). \quad (8)$$

These equations indicate that the catalytic activity of the complex, $k_{\text{complex}}K$, can be calculated from the increment, $\Delta k_\phi/\Delta[\text{base}]$, in the linear part of the curve in Fig. 2.

Similar curves were also obtained for Ph_3GeBr– and Ph_3SiBr–TEA systems at 120 °C, as illustrated in Fig. 2, and for Ph_3SbBr_2–TEA and Me_2TeI_2–TPP systems at 100 °C. The calculated values of $k_{\text{complex}}K$ for each organometallic halide–base system are listed in Table 3. It is found that the value for Ph_3SnBr–TEA system is larger than those for the other binary systems, and that the value for Ph_3SbBr_2–TEA system is negligibly small.

Table 3. The catalytic activity of the complexes in the cycloaddition reaction of CO_2 to PO[a]

Binary system Mt–Base	$k_{\text{complex}}K/\text{M}^{-2}\,\text{min}^{-1}$ [b]
Ph_3SnBr–TEA	160[c]
Ph_3GrBr–TEA	0.38[d]
Ph_3SiBr–TEA	0.43[d]
Ph_3SbBr_2–TEA	0.24[c]
Ph_3BiBr_2–TEA	0.24[d]
Me_2TeI_2–TPP	4.3[c]

a) The catalytic activity of the complexes is defined in Eq. 8. b) The value of $k_{\text{complex}}K$ was calculated from the linear relation between k_ϕ and molar ratio (base/Mt) shown in Fig. 2. c) Obtained at 100 °C. d) Obtained at 120 °C.

Tetravalent organotin halides are known to react with bases such as amines or phosphines to give a pentacoordinated trigonal bipyramidal complex.[12,13] Such complexation would increase the polarity of the Sn-halogen bonds; in other words, it activates the Sn-halogen bonds. Further, there remains one active coordination site in the complexed tin atom because tin atom can generally uses six coordination sites.[12]

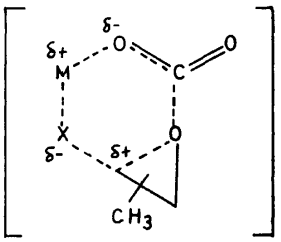
Pentavalent organoantimony compounds are also known to afford a hexacoordinated complex with bases.[10] However, their electron acceptability has been reported to be smaller than that of tetravalent tin compounds.[1,14] In addition, such a hexacoordination may result in a decrease of the polarity of the Sb-halogen bonds in contrast with pentacoordination.[5,12,15] Thus, the complexation is suggested to play a less significant role in the catalytic activity of the Ph_3SbBr_2–base systems than with the Ph_3SnBr–base systems.

On the basis of the results obtained, a reaction pathway as indicated by the set of Eq. 3 and the following two equations

$$CO_2 + PO \rightleftharpoons CO_2\text{–PO}, \quad (9)$$

$$CO_2\text{–PO} + \text{Mt(or Mt–base)} \longrightarrow \text{PC} + \text{Mt(or Mt–base)}, \quad (10)$$

is tentatively proposed. The intervention of the CO_2–PO complex has been deduced on the basis of appearance of a new absorption band in UV spectrum of the saturated solution of CO_2 in PO,[16] similarly to the CO_2–phenylaziridine systems.[19] A plausible intermediate is also shown in Scheme 1.



Scheme 1.

Experimental

Materials. The organometallic halides, Ph_3SnCl,[20] Ph_3SnBr,[21] Ph_3SnI,[21] Ph_3GeBr,[22] Ph_3SiBr,[23] Ph_3SbBr_2,[1] Ph_4SbBr,[1] Ph_3BiBr_2,[24] Me_2TeCl_2,[7] Me_2TeBr_2,[7] and $(p\text{-}CH_3C_6H_4)_2TeCl_2$[25] were prepared by the reported methods and checked by elemental analysis. Methyloxirane (PO) and ethyloxirane (1,2-butylene oxide, BO) was dried and stored over calcium hydride. The Lewis bases used as additive were distilled or recrystallized before use. The solvents were used after rectification.

Analysis. Analytical gas chromatography (GC) was performed on a Shimadzu GC-4BPTF gas chromatograph with an FID detector and on a GC-3BT with a TCD detector.

Reaction Procedures. Under a Pressure of CO_2: The cycloaddition reaction of CO_2 to PO was carried out in a 50 ml stainless-steel autoclave under the conditions as described previously.[1] The initial pressure of CO_2 was always 50 kg/cm^2.

Under Atmospheric Pressure of CO_2: The cycloaddition reaction of CO_2 to ethyloxirane was carried out under atmospheric pressure of CO_2 at 60 °C. The organometallic halides (0.5 mmol), the base (if solid (TPP)) and a magnetic stirring bar was placed in a 50 ml three-necked flask equipped with a condenser, a CO_2 inlet connected to a 1000 cm^3 balloon filled with CO_2, and a rubber septum (SGA Scientific Inc.) through which sample for GC analysis was taken. The flask was evacuated and flashed by CO_2 three times, and then 50 mmol of ethyloxirane and 0.5 mmol of the base (if liquid (TEA and Py)) was introduced through the septum by the syringe technique. The reaction was monitored by GC. The only detectable product was 4-ethyl-1,3-dioxolan-2-one (1,2-butylene carbonate).

The authors are greatly thankful to Messrs. Kiyoshi Ogawa and Hirohiko Katayama for their assistance in the preparation of the organotellurium and organogermanium compounds.

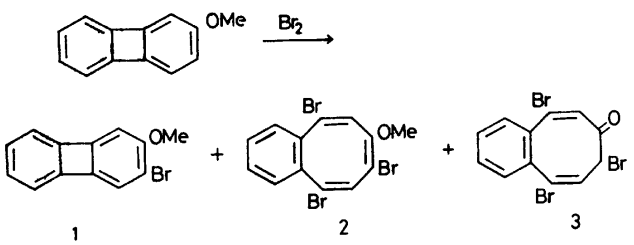
Bromination of Methoxybiphenylenes

Hiroto KIDOKORO, Masaru SATO, and Seiji EBINE*
Department of Chemistry, Saitama University, Urawa, Saitama 338
(Received December 28, 1981)

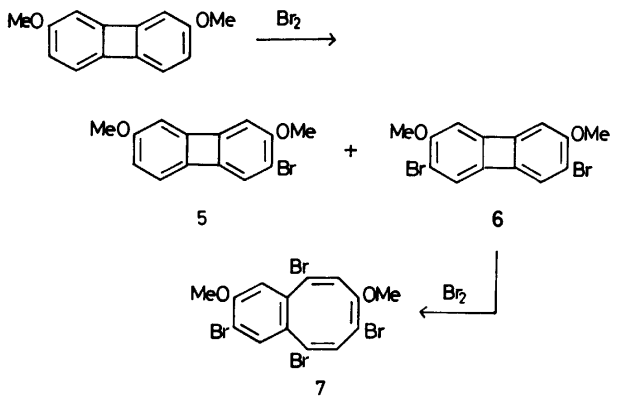
Bromination of 2-methoxybiphenylene derivatives did not give biphenyl derivatives but benzocyclooctene derivatives. 1-Methoxybiphenylene, on the other hand, was brominated to give the benzobicyclo[4.2.0]octadienone derivatives.

Biphenylene is a condensed ring aromatic hydrocarbon of special interest, because its central four-membered ring is expected to have contribution of an antiaromatic cyclobutadiene structure. According to expectation, biphenylene has been evidenced to have some specific reactivity in addition to the reactivity common to other condensed ring aromatics.[1] For example, biphenylene was brominated in the presence of pyridine to give a monobromobiphenylene (substitution product) in 49% yield,[2] and in the absence of the catalyst to give benzocyclooctene derivatives (benzene ring-opened products) as the main products.[3] Photobromination of biphenylene gave also a benzobicyclo[4.2.0]octadienone derivative (addition product) besides two products described above.[4] On the other hand, a 2-substituted biphenylene was brominated at the 3-position regioselectively to give a 2-substituted 3-bromobiphenylene,[1] which was reported to be brominated further with the C_{4a}–C_{4b} bond fission to give biphenyl derivatives (four-membered-ring-opened products).[5,6] We here report the systematic reexamination on bromination of methoxybiphenylenes.[7]

2-Methoxybiphenylene was treated with 1.6 molar equivalents of bromine in carbon tetrachloride at 40 °C to give 3-bromo-2-methoxybiphenylene (**1**), tribromo compound **2**, and tribromo ketone **3** in 30, 14, and 6% yields, respectively. The structure of **3** was first assigned as 5,8,10-tribromo-7,(8*H*)-benzocyclooctenone by the following spectral data. IR (KBr): 1680 cm^{-1}. ^1H NMR ($CDCl_3$): δ 4.81 (d, 1H, J=9.6 Hz, H-8), 6.73 (d, 1H, J=9.6 Hz, H-9), 7.18 (s, 1H, H-6), and 7.2—8.0 (m, 4H, Ar-H). ^{13}C NMR ($CDCl_3$): δ 53.5 (C-8) and 185.2 (C-7). The isolation of **3** suggests an intermediate formation of 5,7,10-tribromo-8-methoxybenzocyclooctene (**2**) as its precursor. Monobromo compound **1** was further brominated in dichloromethane to give the same tribromo compound **2**, mp 118—119 °C in 70% yield. A tribromo compound having the same mp as that of **2** was previously prepared by bromination of **1** in acetic acid and assigned by McOmie and co-workers to 2′,4,6-tribromo-3-methoxybiphenyl (**4**) based on its IR and UV spectra.[5] We also reexamined the bromination of **1** under the same conditions described by the above authors[5] and obtained the same product as **2** in 43% yield, along with the starting biphenylene in 13% recovery. The ^1H NMR spectrum of **2** showed two olefinic doublets (J=1.2 Hz) at δ 6.53 and 6.66 in a similar magnetic field to the corresponding protons of 5,10-dibromobenzocyclooctene (δ 6.51, $J_{6,9}$=1.6 Hz).[3] The UV spectrum of **2** also resembles that of 5,10-dibromobenzocyclooctene rather than 2,2′-dibromobiphenyl (Fig. 1). In addition, **2** was converted with trifluoroacetic acid to tribromo ketone **3** in 63% yield, whose structure was conclusively determined by X-ray crystallographic analysis.[8] On the basis of these data the tribromo compound **2** should not be assigned to 2′,4,6-tribromo-3-methoxybiphenyl (**4**), but 5,7,10-tribromo-8-methoxybenzocyclooctene.

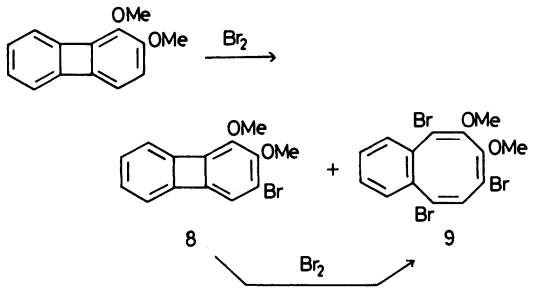


In order to generalize the fact that the further bromination of bromomethoxybiphenylenes gives brominated benzocyclooctenes, the bromination of other 2-methoxybiphenylenes was then examined. 2,7-Dimethoxybiphenylene was treated with 2 molar equivalents of bromine in dichloromethane to give 3-bromo-2,7-dimethoxybiphenylene (**5**) and 3,6-dibromo-2,7-dimethoxybiphenylene (**6**) in 30 and 20% yields, respectively, in partial agreement with McOmie *et al.*[6] who obtained only **6** in 46% yield under similar conditions. Compound **6** was further treated with 1.5 molar equivalents of bromine to give 2,5,8,10-tetrabromo-3,7-dimethoxybenzocyclooctene (**7**) in 89% yield. The ^1H NMR spectrum of **7**, like that of **2**, showed two olefinic doublets at δ 6.57 and 6.66 (J=1.2 Hz).

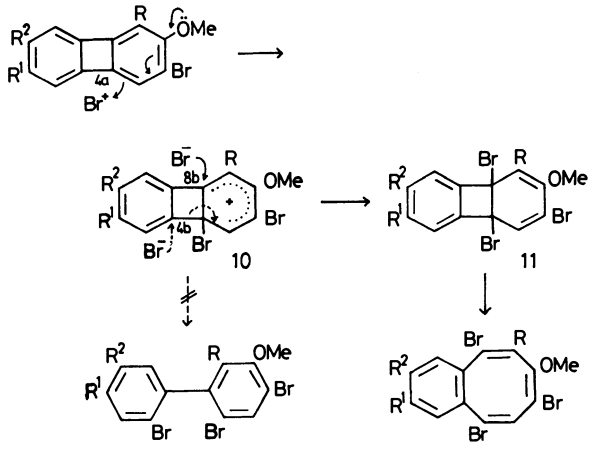


1,2-Dimethoxybiphenylene reacted with an excess of bromine to give 3-bromo-1,2-dimethoxybiphenylene (**8**) and 5,8,10-tribromo-6,7-dimethoxybenzocyclooctene (**9**) in 81 and 6% yields, respectively. Further bromina-

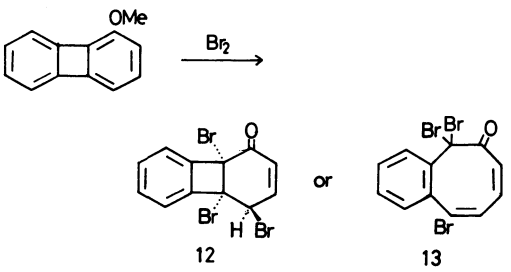
tion of **8** gave **9** in a low yield. The structure of **9** was assigned by the following ^{1}H NMR spectrum (CCl_4): δ 3.56 (s, 3H, OCH_3), 3.71 (s, 3H, OCH_3), 6.81 (s, 1H, H-9), and 7.44 (s, 4H, Ar–H). The UV spectra of **7** and **9** were closely similar to that of **2** (Fig. 2).



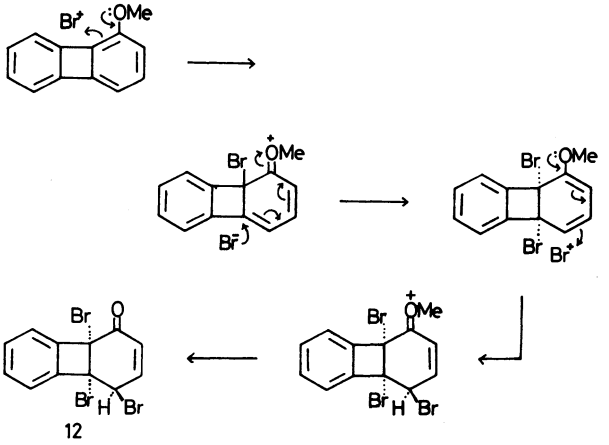
The bromination of biphenylene having one or two methoxyl groups at the 2- and other positions proceeds generally as follows. On treatment with bromine, biphenylene derivatives having an electron-releasing group at the 2-position give 3-substituted products predominantly.[1b] In agreement with this previous finding, 2-methoxy-, 1,2-dimethoxy- 2,7-dimethoxybiphenylenes undergo bromination at the 3- and 6-position to give 3-bromo and 3,6-dibromo derivatives **1**, **8**, and **6** respectively. On the other hand, biphenylene itself undergoes bromine addition followed by benzene ring-opening to give brominated benzocyclooctenes, because of latent antiaromatic character of the central four-membered ring. The above brominated methoxybiphenylenes (**1**, **6**, and **8**) are more electron-deficient than unbrominated methoxybiphenylenes and behave like biphenylene itself on further bromination: **1**, **6**, and **8** react with bromine to give first biphenylenium ions (**10**) and then dibromo adducts **11**, which undergo spontaneously ring-opening to give bromomethoxybenzocyclooctenes **2**, **7**, and **9** as shown in the following scheme. The bromide ion attacks **10** at the 4b-position and the subsequent C_{4a}–C_{4b} bond fission to **4** does not take place.



Bromination of 1-methoxybiphenylene proceeded in a somewhat different manner from that of 2-methoxybiphenylenes. Thus, 1-methoxybiphenylene was treated with an excess of bromine to give colorless crystals, mp



165—167 °C (decomp) in 25% yield, along with two kinds of unstable oils. The MS spectrum [M^+ *m/e* 404/406/408/410 (1.3/3.7/3.7/1.3%)] and IR spectrum (ν_{CO} 1683 cm^{-1}) suggest that the product is tribromo ketone **12** or **13**. The following ^{1}H NMR spectrum of the tribromo ketone is consistent with the structure **12**, rather than **13**: δ 5.35 (d, 1H, J=6.8 Hz), 5.93 (d, 1H, J=10.7 Hz), 6.98 (dd, J=10.7 and 6.5 Hz), and 7.1—7.8 (m, 4H, Ar–H). The ^{13}C NMR spectrum gave a further structual support showing the presence of three aliphatic carbon (47.7, 70.7, and 72.0 ppm) and two olefinic carbon signals (124.6 and 142.3 ppm). The stereochemistry of **12** was suggested by setting up the molecular model having a minimum steric strain. The formation of **12** on bromination of 1-methoxybiphenylene would be explained by the pathway described below.



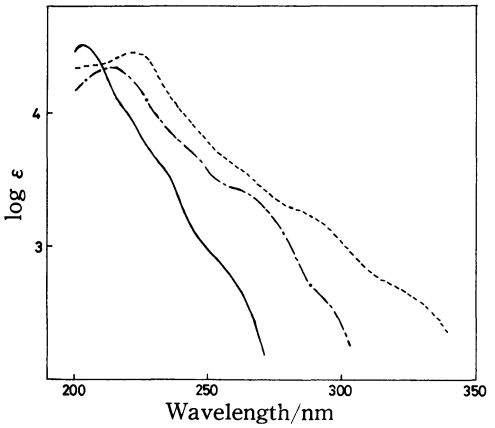


Fig. 1. UV spectra of 2,2′-dibromobiphenyl (——), 5,10-dibromobenzocyclooctene (– – –), and tribromo compound **2** (------).

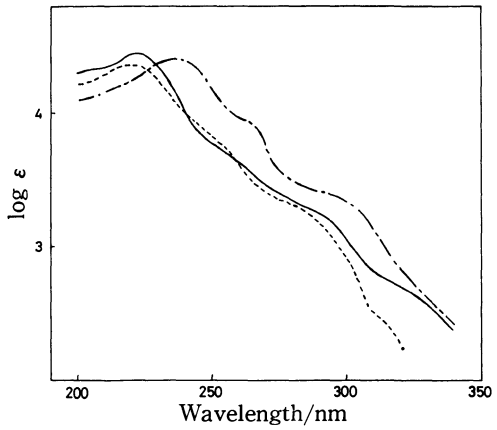

Fig. 2. UV spectra of **2** (——), **7** (– – –), and **9** (------).

The easy conversion of methoxybiphenylenes to methoxybenzocyclooctene derivatives stimulated the reexamination on bromination of 2,3-dimethoxybiphenylene, because the resulting bromodimethoxybenzocyclooctenes would be useful precursors to new benzocyclooctene-7,8-diones. It was previously reported that bromination of 2,3-dimethoxybiphenylene gave 1,4-dibromo-2,3-biphenylenedione.[6] The present reexamination on bromination of 2,3-dimethoxybiphenylene under various conditions, however, gave the same result as previously reported, no expected benzocyclooctene-7,8-dione being detected.

Experimental

Bromination of 2-Methoxybiphenylene in Carbon Tetrachloride. To a solution of 2-methoxybiphenylene (2.03 g, 11 mmol) in carbon tetrachloride (20 ml) was added a solution of bromine in carbon tetrachloride (37 g of 5% w/w solution, 11 mmol) under nitrogen. The mixture was stirred for 10 min at room-temperature and warmed at 40 °C for 50 min. A solution of bromine in carbon tetrachloride (10 g of 5% w/w solution, 6 mmol) was further added to the solution, whereupon the color of bromine was discharged almost instantaneously. The solution was washed with a saturated aq solution of sodium hydrogencarbonate and dried (anhyd $MgSO_4$). The yellow-brown oil which remained after evaporation was chromatographed on silica gel by elution with hexane–toluene (2 : 1). The following products were eluted successively. 3-Bromo-2-methoxybiphenylene (**1**) (860 mg, 30%): yellow needles, mp 100—101 °C (from cyclohexane–ethanol) (lit,[6] 102—103 °C). IR (KBr): 1420, 1254, 1233, and 746 cm^{-1}. ^1H NMR ($CDCl_3$): δ 3.92 (s, 3H, OCH_3), 6.3—6.9 (m, 6H). 5,7,10-Tribromo-8-methoxybenzocyclooctene (**2**) (538 mg, 14%): colorless needles, mp 118—119 °C (from ethanol–cyclohexane). Found: C, 37.01; H, 2.15%. Calcd for $C_{13}H_9Br_3O$: C, 37.09; H, 2.15%. UV (EtOH): 223 nm (log ε 4.46). IR (KBr): 1637, 1620, 1340, 1251, 1189, and 768 cm^{-1}. ^1H NMR ($CDCl_3$): δ 3.66 (s, 3H, OCH_3), 6.53 (d, 1H, J=1.2 Hz, H-6) 6.66 (d, 1H, $J_{6,9}$=1.2 Hz, H-9), 7.38 (s, 4H, Ar–H). ^{13}C NMR ($CDCl_3$): δ 57.2 (q), 98.8 (s), 122.7 (s), 126.2 (s), 128.3 (d), 128.6 (d), 128.9 (d), 129.1 (d), 129.5 (d), 133.1 (d), 136.7 (s), 137.4 (s), and 149.8 (s). MS (70 ev): M^+ [*m/e* 418/420/422/424 (3.5/8/8/3.5%)], M^+-Br [*m/e* 339/341/343 (52/100/49%)]. 5,8,10-Tribromo-7,(8*H*)-benzocyclooctenone (**3**) (274 mg, 6%): yellow cubes, mp 138—139 °C (from hexane–acetone). Found: C, 35.42; H, 1.77%. Calcd for $C_{12}H_7Br_3O$: C, 35.42; H, 1.73%. UV (CH_3CN): 213 (log ε 4.24) and 225sh nm (4.20). IR (KBr): 1683, 1595, 1138, 965, 860, and 765 cm^{-1}. ^1H NMR ($CDCl_3$): δ 4.81 (d, 1H, J=9.5 Hz, H-8), 6.73 (d, 1H, J=9.5 Hz, H-9), 7.18 (s, 1H, H-6), and 7.2—8.0 (m, 4H, Ar–H). ^{13}C NMR ($CDCl_3$): δ 53.6 (d, C-8), 120.7 (s), 128.3 (d), 129.6 (d), 130.3 (d), 131.0 (d), 132.5 (d), 133.5 (d), 134.3 (s), 137.0 (s), 137.9 (s), and 185.2 (s, C-7). MS (75 eV): M^+ [*m/e* 404/406/408/410 (0.02/0.04/0.04/0.02%)], M^+-2Br [*m/e* 246/248 (100/97%)].

5,7,10-Tribromo-8-methoxybenzocyclooctene (2). To a solution of **1** (0.25 g, 0.96 mmol) in dry dichloromethane (10 ml) was gradually added a solution of bromine (0.23 g, 2.8 mmol) in dry dichloromethane (7 ml) at 0 °C under nitrogen. The mixture was then kept for 1 h at a room-temperature. After evaporation, the residue was subjected to TLC on silica gel by elution with hexane–benzene. **2** (0.28 g, 70%) was obtained as colorless crystals, mp 118—120 °C.

5,8,10-Tribromo-7(8H)-benzocyclooctenone (3). To a solution of **2** (28 mg) in a small amount of chloroform-*d*, was added trifluoroacetic acid (0.5 ml). The solution was then warmed to 70—80 °C. After evaporation, the crystalline residue was recrystallized from hexane–acetone giving the tribromo ketone **3** (17 mg, 63%).

Bromination of 2,7-Dimethoxybiphenylene. To a solution of 2,7-dimethoxybiphenylene (0.25 g, 1.2 mmol) in dry dichloromethane (10 ml) was added a solution of bromine in dichloromethane (20 ml of 0.3% v/v solution, 1.2 mmol) at −50 °C under nitrogen. The solution was then stirred for 1 h at a room-temperature. After evaporation, the residue was passed through a short column packed with alumina in order to remove a tar. The yellow crystals obtained were purified by TLC on silica gel by elution with benzene, affording the following products, the unreacted starting material (28 mg, 11%) and 3-bromo-2,7-diemthoxybiphenylene (**5**) (102 mg, 30%), colorless crystals, mp 100—101 °C (from hexane–acetone). Found: C, 57.66; H, 3.72%. Calcd for $C_{14}H_{11}BrO_2$: C, 57.75; H, 3.82%. UV (CH_3CN): 250 (log ε 4.56), 258 (4.85), and 369 nm (3.67). IR (KBr): 1615, 1575, 1473, 1456, 1418, 1280, 1270, 1224, 1029, 1013, and 800 cm^{-1}. ^1H NMR ($CDCl_3$): δ 3.73 (s, 3H, OCH_3), 3.85 (s, 3H, OCH_3), 6.0—6.6 (m, 3H), 6.45 (s, 1H, H-8), and 6.72 (s, 1H, H-1). MS (70 eV): M^+ [*m/e* 290/292 (100/98%)], M^+-CH_3 [*m/e* 275/277 (70/68%)], and M^+-CH_3-CO [*m/e* 247/249 (44/43%)]. 3,6-Dibromo-2,7-dimethoxybiphenylene (**6**) (86 mg, 20%), colorless leaflets, mp 166—168 °C (lit,[6] 170—171 °C). ^1H NMR ($CDCl_3$): δ 3.84 (s, 6H, OCH_3), 6.47 (s, 2H, H-1,8), and 6.73 (s, 2H, H-4,5).

2,5,8,10-Tetrabromo-3,7-dimethoxybenzocyclooctene (7). To a solution of **6** (86 mg, 0.23 mmol) in dry dichloromethane (10 ml) was added a solution of bromine in dichloromethane (6 ml of 0.5% v/v solution, 0.58 mmol). The solution was stirred for 1 h at a room-temperature, then washed with water, and dried (anhyd $MgSO_4$). After evaporation, the residue was purified through TLC on silica gel by elution with toluene–hexane (1 : 1). The title compound (109 mg, 89%) was obtained as yellow cubes, mp 200—203 °C (decomp). Found: C, 31.96; H, 1.97%. Calcd for $C_{14}H_{10}Br_4O_2$: C, 31.73; H, 1.90%. UV (CH_3CN): 220sh (log ε 4.15) and 266 nm (4.41). IR (KBr): 2950, 1638 (w), 1620 (w), 1592, 1497, 1355, 1248, and 1049 cm^{-1}. ^1H NMR ($CDCl_3$): δ 3.65 (s, 3H, OCH_3), 3.90 (s, 3H, OCH_3), 6.57 (d, 1H, J=1.3 Hz, H-6), 6.66 (d, 1H, J=1.3 Hz, H-9), 6.80 (s, 1H, H-4), and 7.64 (s, 1H, H-1). MS (75 eV): M^+ [*m/e* 526/528/530/532/534 (0.8/3.0/5.5/3.0/0.8%)] and M^+-Br [*m/e* 447/449/451/453 (35/100/95/35%)].

Bromination of 1,2-Dimethoxybiphenylene. To a solution of 1,2-dimethoxybiphenylene (0.25 g, 1.2 mmol) in dry dichloromethane (40 ml) was slowly added a solution of

bromine in dichloromethane (27 ml of 0.5% v/v solution, 2.7 mmol) under ice-cooling. After being stirred for 1 h, the solution was washed with water and dried (anhyd $MgSO_4$). The solvent was evaporated and the resulting yellow oil was purified through TLC on silica gel by elution with hexane–benzene. 3-Bromo-1,2-dimethoxybiphenylene (**8**) (0.25 g, 81%), colorless crystals, mp 67—68 °C (from hexane–acetone). Found: C, 57.66; H, 3.72% . Calcd for $C_{14}H_{11}BrO_2$: C, 57.75; H, 3.81%. UV (CH_3CN): 257 (log ε 4.56), and 282 nm (4.09). IR (KBr): 2970, 1587, 1475, 1396, 1248, 1028, and 746 cm^{-1}. ^1H NMR ($CDCl_3$): δ 3.81 (s, 3H, OCH_3), 4.00 (s, 3H, OCH_3), 6.55 (s, 1H, H-4), and 7.44 (s, 4H, Ar–H). MS (75 eV): M^+ [*m/e* 290/292 (100/100%)] and M^+-CH_3 [*m/e* 275/277 (47/44%)]. 5,7,10-Tribromo-8,9-dimethoxybenzocyclooctene (**9**) (29 mg, 6%), yellow leaflets, mp 116—117 °C (from hexane–acetone). Found: C, 37.33; H, 2.51%. Calcd for $C_{14}H_{11}Br_3O_2$: C, 37.28; H, 2.46%. UV (EtOH): 220 nm (log ε 4.37). IR (KBr): 2970, 1307, 1294, and 1009 cm^{-1}. ^1H NMR (CCl_4): δ 3.59 (s, 3H, OCH_3), 3.71 (OCH_3), 6.81 (s, 1H, H-9), and 7.44 (s, 4H, Ar–H). MS (70 eV): M^+ [*m/e* 448/450/452/454 (3.2/9.2/9.2/3.2%)], M^+-Br [*m/e* 367/369/371 (37/76/38%)] and M^+-2Br [*m/e* 290/292 (96/100%)].

*5,7,10-Tribromo-8,9-dimethoxybenzocyclooctene (**9**).* To a solution of 3-bromo-1,2-dimethoxybiphenylene (30 mg, 0.1 mmol) was added a solution of bromine (25 mg, 0.16 mmol) in dichloromethane (1.6 ml) under stirring. The solution was stirred for 3 h at a room-temperature. After the usual work-up, followed by TLC on silica gel by elution with benzene–hexane, the oily product was separated into the title compound (9 mg, 19%) and the starting material (14 mg, 47%).

*4,4a,8b-Tribromo-1,4,4a,8b-tetrahydrobiphenylen-1-one (**12**).* To a solution of 1-methoxybiphenylene (0.10 g, 0.55 mmol) in dichloromethane (5 ml) was added under stirring a solution of bromine in dichloromethane (0.5%v/v solution) at 0 °C under nitrogen until the bromine-color of the reaction mixture remained unchanged (27 ml, 2.6 mmol). The solution was then stirred for 2 h at a room-temperature. After the usual work-up, an orange oil obtained was purified by measn of TLC by elution with toluene. In addition to an unstable red oil (55 mg) and an unstable orange oil (44 mg) [IR (Neat): 1697, 1668, and 757 cm^{-1}, ^1H NMR ($CDCl_3$): δ 6.34 (d, 1H, J= 10.3 Hz), 7.01 (d, 1H, J=10.4 Hz), 7.59 (s, 4H), and 7.1—7.6 (m)], the title compound (55 mg, 25%) was obtained as colorless crystals, mp 165—167 °C (decomp) from hexane). Found: C, 35.31; H, 1.77%. Calcd for $C_{12}H_7Br_3O$: C, 35.42; H, 1.74%. UV (CH_3CN): 257 (log ε 4.56) and 282 nm (4.09). IR (KBr): 1683, 1611, 1467, 800, and 750 cm^{-1}. ^1H NMR ($CDCl_3$): δ 5.35 (d, 1H, J=6.8 Hz, H-5), 5.93 (d, 1H, J= 10.7 Hz, H-3), 6.98 (dd, 1H, J=10.7 and 6.8 Hz, H-4), and 7.1—7.8 (m, 4H, Ar–H). ^{13}C NMR ($CDCl_3$): δ 47.7 (d), 70.7 (s), 72.0 (s), 121.3 (d), 123.0 (d), 124.6 (d), 131.9 (d), 132.0 (d), 141.6 (s), 142.3 (d), 143.3 (s), and 186.9 (s). MS (70 eV): M^+ [*m/e* 404/406/408/410 (0.4/1.0/1.0/0.4%)], M^+-Br [*m/e* 325/327/329 (18/38/18%)], $M^+-Br-CO$ [*m/e* 297/299/301 (13/26/13%)], and M^+-2Br [*m/e* 246/248 (40/38%)], and $M^+-3Br-CO$ [*m/e* 139 (100%)].

Aldol Condensations Catalyzed by Co(II) Complexes of Pyridine-containing Copolymers

Ken-ichi WATANABE* and Atsushi IMAZAWA
Department of Chemistry, Faculty of Science, Tokyo Metropolitan University, Fukazawa, Setagaya-ku, Tokyo 158
(Received December 24, 1981)

The cross aldol condensations of aldehydes and ketones catalyzed by Co(II) complexes of pyridine-containing copolymers proceed under neutral conditions in DMF or DMSO to afford α,β-unsaturated ketones without any by-product. The solid complex catalysts are capable of repeated use. The reactions of aromatic aldehydes and ketones give good results but not those of aliphatic compounds. Effects of substituent groups in chalcone formation are observed. The catalytic reaction features with the polymer-complex catalysts are compared with that with Co(II)-pyridine complex. The polymer-complex-catalyzed aldol condensations are discussed briefly in relation to the enzymatic reaction of Class II aldolase (metalloenzyme).

Aldol condensation reactions are generally catalyzed by strong bases or acids. Recently, we have found that the condensation reactions are catalyzed by 2,2'-bipyridine complexes of the first-row transition metals[1] and Co(II) complexes of polymers[2] under neutral conditions. The reactions of aldehydes and ketones with these complex catalysts afford only cross condensation products, α,β-unsaturated ketones, in satisfactory yields. With regard to polymer-catalyzed aldol condensations, catalysis of ion exchange resins have been known, but the product yield of the reactions is low along with some by-products.[3] In this paper, the scope and limitation of the aldol condensation reactions promoted by the Co(II) complexes of pyridine-containing copolymers will be described in detail together with the catalytic behavior of the polymer complexes. Some consideration is also given to the catalysis of Class II aldolase.

Results and Discussion

Polymer Complex Catalysts. The polymers employed for the ligand are as follows:
Poly(4-vinylpyridine):[4] PVP, crosslinked poly(4-vinylpyridine):[4] VP, crosslinked 4-vinylpyridine-styrene copolymer:[5] VP–St (1 : 3), crosslinked 4-vinylpyridine-methyl methacrylate copolymer:[6] VP–MMA (1 : 3), crosslinked 4-vinylimidazol-methyl acrylate copolymer:[7] VIm–MA (1 : 10).

These polymers were prepared by conventional methods in the literature cited.[4-7] 1,4-Divinylbenzene was used as a crosslinking agent, 1 mol% to the polymers, and the crosslinked polymers were insoluble in the common organic solvents. The metal(II) complexes of these polymers were prepared by adding a solution of cobalt(II) acetate in *N,N*-dimethylformamide (DMF) to the swelled polymers in DMF and subsequent stirring at room temperature for 24 h. The cobalt(II) complexes thus obtained were reddish to light purple in color and the content of the Co(II) ion in the complexes was calculated from the difference of the initial amount to the residual untrapped amount of the Co(II) ion. The estimated ratio of the Co(II) ion to the pyridine or imidazol moiety in the complexes was about 1 : 1, which suggested the existence of vacant coordination sites for the ligand reactions (Table 1). In the IR spectra of the copolymer VP–St, absorption at 1600 cm^{-1} was observed and was attributed to the pyridine ring. This absorption shifted to 1620 cm^{-1} in the case of the Co(II) complex of the polymer.

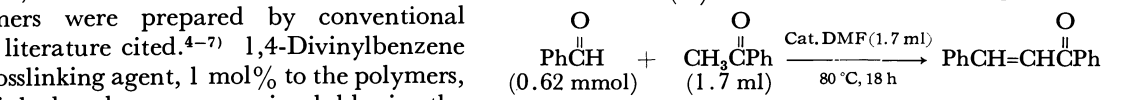
Effects of Cross Linkage and Copolymer. In order to examine the activity of the Co(II)–polymer-complex catalysts thus prepared, aldol condensations of benzaldehyde with excess of acetophenone were carried out in the presence of the catalyst in DMF at 80 °C for 18 h. The amount of Co(II) ion in the polymer complex used was about 16 mol% of the aldehyde employed. After the reaction, the catalyst was removed from the reaction mixture by filtration. No change in appearance of the catalyst was observed. The filtrate was analyzed by means of GLC to determine the yield of the reaction product, 1,3-diphenyl-2-propen-1-one (chalcone). To isolate the chalcone, the filtrate was evaporated *in vacuo*

Table 1. Co(II)–polymer complexes

Ligand (crosslinked)	py-Unit (mmol/g)	Co(II) ion (mmol/g)	py-Unit to Co(II) ion
VP	6.0	4.0	1.5
VP–St	2.38	2.4[a]	0.99
VP–MMA	3.5	3.5	1.0
VIm–MA	1.4	1.55	0.9

a) $Ni(OAc)_2$ complex: 1.9 mmol/g.

Table 2. Aldol condensations with Co(II)–polymer complex catalysts



No.	Catalyst		Yield/%[a]
1	Co(II)–PVP	[Co(II) : py=1 : 1.5]	41
2	Co(II)–VP	[Co(II) : py=1 : 1.5]	53
3	Co(II)–VP–St	[Co(II) : py=1 : 1]	100 (84)
4	Co(II)–VP–MMA	[Co(II) : py=1 : 1]	(84)[b]
5	Co(II)–VIm–MA	[Co(II) : Im=1 : 0.9]	(64)[c]
6	Co(II)–py	[Co(II) : py=2 : 3]	80
7	Co(II)–Im	[Co(II) : Im=1 : 1]	(75)

a) By GLC analysis, based on benzaldehyde used. The values in parentheses are isolated yields. b) 84% in DMSO and 59% in MeOH (isolated). c) 83% in DMSO (isolated); 81% by reused catalyst in DMSO.

to give a yellow oil which was treated by preparative TLC, determined by means of mp, IR, and NMR. For example, in the reaction with the complex Co(II)–VP–St, the yield of chalcone by GLC was 100% and the isolated yield was 84%, mp 55—58 °C. The reaction conditions and the results are summarized in Table 2 together with some other data for comparison. The reaction did not proceed in the absence of the catalyst, and all the ligand polymers themselves without the Co(II) ion showed no catalytic activity. The reactions did not proceed at room temperature even over prolonged reaction periods in the presence of the polymer-complex catalyst. Only PVP was soluble in DMF and the Co(II)–PVP complex catalyst as a solution in DMF (Co(II) : pyridine unit=1 : 1.5) was used for the reaction No. 1 (homogeneous). The Co(II) ion itself showed some catalytic activity (No. 8). The PVP ligand seemed to enhance the reaction somewhat by co-ordination of the pyridine ring to Co(II) ions (No. 1). Crosslinking further enhanced the catalytic activity as observed in the reaction with Co(II)–VP (No. 2), affording higher product yield (53%) than that with Co(II)–PVP (41%) though it was not as good as that obtained with the Co(II)–py complex (No. 6, 80%). On the other hand, the crosslinked copolymer of 4-vinylpyridine and styrene Co(II)–VP–St showed a predominant result (No. 3, 100%). The reaction with the ion exchange resin Amberlite IR-120 (No. 9) afforded chalcone in low yield (36%) accompanying a considerable amount of the self-condensation product of acetophenone, 1,3-diphenyl-2-buten-1-one, and other by-products under similar reaction conditions (GLC). On the contrary, no side reactions were observed with the Co(II)–VP–St catalyst. The $Ni(OAc)_2$–VP–St copolymer was also prepared (Table 1, footnote), but, it showed almost no catalytic activity for chalcone formation under similar reaction conditions.

Various Aldol Condensations with Co(II)–VP–St Catalyst. It was proved above that the Co(II)–VP–St-copolymer-complex in DMF was the most effective catalyst system for the reaction. Therefore, various aldol condensations with this catalyst were subsequently investigated. The reaction conditions were similar to that of Table 2. The reaction products were isolated and identified as α,β-unsaturated ketones, and no side reactions were observed. The results of the reactions of *p*-substituted benzaldehyde or *p*-substituted acetophenones are shown in Table 3, and the reactions with some aliphatic carbonyl compounds are summarized in Table 4. The purity of the products thus obtained was consistently high, probably because the polymer-complex-catalyzed reactions took place under neutral conditions.

In general, reactions between aromatic aldehydes and ketones gave good results, but not those of aliphatic compounds. The reactions shown in Table 3 yielded the corresponding chalcones and the product yields were remarkably affected by the substituent groups of either aldehydes or ketones: reactants having electron-attractive substituents gave high yields (products: **a**, **b**, **g**, **h**) and those having electron-donative ones gave low yields (products: **e**, **f**, **i**). The reaction of 2-butanone with benzaldehyde gave only 1-phenyl-1-penten-3-one (Table 4, **k**), though the yield was low. This regioselectivity was the same for reactions catalyzed by Co(II)–bpy complex, namely base-catalyzed type.[1]

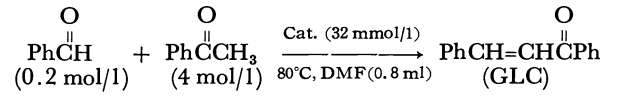
Catalysis of the Copolymer Complexes. On the basis of the above studies, the scope of the catalytic ability of the Co(II) copolymer complex is fairly wide, though it is limited for reactions with aliphatic carbonyl compounds. In order to examine this catalysis feature in detail, the polymer-complex-catalyzed reaction was compared with a pyridine-complex-catalyzed reaction under similar reaction conditions. As the polymer- and



pyridine-complex catalysts, Co(II)–VP–St and Co(II)–4-isopropylpyridine complexes (1 : 1) were employed respectively. The yield of chalcone was determined by GLC analysis: the correlation of the yield with reaction

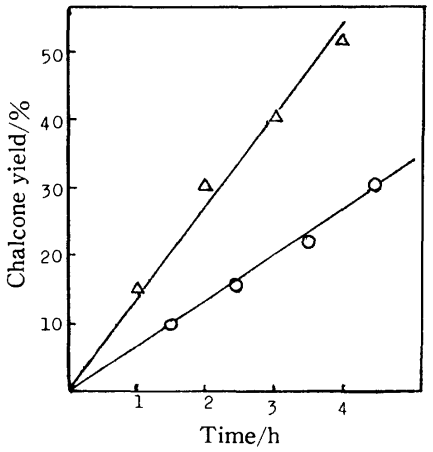


Fig. 1. Reaction profile of the aldol condensations of benzaldehyde and acetophenone catalyzed by polymer and monomer Co(II) complexes.
—○—: Co(II)–VP–St, —△—: Co(II)–*i*-Pr-py (1 : 1).

time is shown in Fig. 1. The catalytic activity of the polymer complex was lower than that of the pyridine complex for the initial stage of the reaction. However, Co(II)–VP–St is superior to Co(II)–py in the reactions for 18 h as shown in Table 2 (100% and 80%). Further, in an equimolar reaction, Co(II)–VP–St was also superior to Co(II)–py. When 0.62 mmol of benzaldehyde and acetophenone was used respectively under similar reaction conditions to that of Table 2 (18 h), the reaction with Co(II)–VP–St gave chalcone in a 70% yield (isolated), but Co(II)–py gave only 50% yield (isolated).

As mentioned above, the electron-attractive groups in the aromatic aldehydes or ketones enhance the reactivity of the substrates in these reactions (Table 3) as well as acid or base catalyzed aldol condensations.[17] On the contrary, no substituent effect was observed in the reactions with Co(II)–bpy complex (1 : 1) catalyst under similar reaction conditions, *e.g.* chalcone 81%, *p*-$NO_2C_6H_4CH$=CHCOPh 88%, *p*-ClC_6H_4CH=CHCOPh 72%, *p*-$CH_3OC_6H_4CH$=CHCOPh 88% *etc.*[1] Therefore, the fact that the substituent effect is observed in the aldol condensations with the polymer complex may be one of the unique features of the polymer complex catalyst though the reason of it is not clear.

Concerning the reaction solvent, an aprotic polar solvent such as DMF or DMSO was favorable (Table 2, footnote), and almost no reaction product was obtained in C_6H_6. Further, it was notable that no reaction took place in neat reaction. These facts suggest that an adequate solvent makes the polymer complex swell enough to ingest the substrates into the polymer and so helps good catalysis. A polymer complex catalyst has an advantage of being removed easily from the reaction mixture by filtration and so it can be used repeatedly. In our catalyst system, the polymer complex catalysts were also proved to be reusable with retention of almost the same catalytic activity (Tables 2 and 3, footnote).

Aldol condensations in biological systems are known to be catalyzed by aldolase enzymes, Class I and Class II;[18] the latter is a metalloenzyme containing zinc(II) ion in the active sites. In the reaction of Class II aldolase, however, catalysis of the enzyme has not been elucidated enough, although some models of the reaction mechanism have been proposed by biochemists.[19–21] We also prepared $Zn(OAc)_2$–VIm–MA (Zn : VIm= 1 : 1.35) complex by a procedure similar to that for Co(II) complex, and the yield of chalcone was 40% (isolated) under similar reaction conditions. The effect of a pyridine- or imidazol-containing copolymer as ligand may be important in the metalloenzyme if there is an interaction between metal(II) ion and imidazol ring of a histidine residue, since imidazol as well as pyridine can form π-bonding by coordination to the metall(II) ion.[22] The facts described in this paper might indicate the possibility that polymer complexes can be developed and applied to the aldolase model reaction system. Our catalyst system may present a new model for understanding the Zn(II) ion catalysis in the Class II aldolase.

Experimental

Instruments. The NMR and IR spectra were taken with a Hitachi Perkin-Elmer R-20A spectrophotometer (60 MHz) and a Hitachi 215 Grating Infrared spectrophotometer respectively. The GLC was carried out with a Hitachi K-53 gas chromatograph with a flame ionization detector, using a 1 m stainless steel tube column packed with 10% Carbowax 20 M on Diachrom A (career gas, N_2; temp 220—270 °C). The product yields were determined by GLC and NMR analysis using *p*-$CH_3OC_6H_4COCH_2Ph$ (or PhCOPh) and $Cl_2CHCHCl_2$ as the internal standard respectively. The atomic absorption spectra was taken with a Shimadzu Atomic Absorption-Flame Emission Spectrophotometer AA-640-13.

Preparation of Co(II) Complex of Copolymer VP–St. 4-Vinylpyridine (1.05 g, 10 mmol), styrene (4.17 g, 40 mmol), divinylbenzene (66 mg, 0.5 mmol), 2,2′-azobisisobutyronitrile (82 mg, 0.5 mmol), and benzene (10 ml, solvent) were mixed together in a 20 ml ampule. The contents were degassed by a vacuum system, and the ampule was sealed off under vacuum and heated at 70 °C for 40 h. The transparent copolymer thus obtained was washed with benzene in a Soxhlet extractor (10 h), dried under reduced pressure at 70 °C, yield 3.06 g. Found: C, 88.08; N, 3.06; H, 7.70%. Calcd (pyridine: benzene unit=1 : 3.2): C, 89.31; N, 3.02; H, 7.50%. The copolymer (1.043 g) was swelled in 16 ml of DMF and then added to a solution of $Co(OAc)_24H_2O$ (3 mmol, 1.5 × pyridine unit) in 5 ml DMF, and stirred for 24 h at room temperature. The reddish purple copolymer complex thus obtained was filtered off and washed with 179 ml of warm DMF. The filtrate and the washings were combined and the content of Co(II) ion in the solution was determined by atomic absorption spectrophotometry. The content of Co(II) ion in the polymer complex was calculated as 2.4 mmol; accordingly the pyridine unit co-ordinated to the Co(II) ion unit was 0.99 (Table 1). The polymer complex was washed with diethyl ether and dried under reduced pressure at 70 °C, yield 1.23 g.

General Procedure for Aldol Condensations. The complex catalyst, Co(II)–VP–St (51 mg) was kept in 0.5—1.7 ml DMF for swelling in 10 ml flask, then benzaldehyde (63 mg, 0.62 mmol) and excess acetophenone (1.7—2.5 ml) were added together into the flask and stirred at 80 °C for 18 h. The polymer catalyst was removed by filtration and the filtrate condensed to some extent under reduced pressure for GLC analysis. The yield of chalcone was calculated on the basis

of the benzaldehyde used (Table 2). In the reaction for Fig. 1, the reaction mixture was analyzed directly without filtration of the catalyst. To isolate the chalcone or its derivatives, the filtrate was evaporated *in vacuo* to expel the solvent, aldehyde and the excess ketone; the residue was then submitted to preparative TLC on silica gel (developed with hexane–ethyl acetate) and the reaction product extracted with ethyl acetate, dried and weighed (Tables 3 and 4).

Michael Additions Catalyzed by Metal(II) Complexes

Ken-ichi WATANABE,* Ken-ichi MIYAZU, and Kazuo IRIE
Department of Chemistry, Faculty of Science, Tokyo Metropolitan University, Fukazawa, Setagaya-ku, Tokyo 158
(Received January 22, 1982)

Michael-addition reactions have been found to proceed in the presence of the $Ni(OAc)_2$ or $Co(OAc)_2$–2,2′-bipyridine complex in DMF under neutral conditions at room temperature without any by-product. The reactions of chalcone and its derivatives with nitromethane generally gave good results. The effects of metal(II) ions, ligands, counter ions, and solvents on the catalysis were examined, and the features of the metal-complex-catalyzed Michael reactions were studied, with some considerations also being given to the catalysis mechanism.

Michael-addition reactions are generally carried out in the presence of strong base catalysts; reactions carried out under such drastic conditions have sometimes caused side reactions.[1] Recently, we have found that the reactions are catalyzed by the Ni(II) or Co(II)–2,2′-bipyridine(bpy) complex in DMF to afford addition products without any by-product; a brief note has already been reported.[2] With regard to Michael reactions catalyzed by metal complexes, Saegusa and his co-workers[3] employed the copper(I) isocyanate complex; however, acceptor compounds in the reactions were limited since the dimerization of olefins occurred. Nelson and his co-workers[4] employed the $Ni(acac)_2$ complex for the reaction of β-diketones with acceptor compounds, mainly α,β-unsaturated ketones. In this complex-catalyzed reaction, the complex catalyst and donor compounds are limited to $Ni(acac)_2$ and β-diketones, and the reactions are heterogeneous catalytic system in dioxane or dichloromethane. In our homogeneous catalytic system, for example, the reactions of α,β-unsaturated ketones with nitromethane proceed smoothly in the presence of the complex catalysts under neutral conditions at room temperature, without any by-product. The preparation of the complex catalysts is simple, the Michael reactions proceed under very mild conditions, and the reaction products are easily isolated in relatively pure form because there are no side reactions. The most important factors for the catalytic reactions are kinds of metal-ion species, ligands, counter ions of the complexes, and solvents. In this paper, the results of an examination of these factors and the scope and limitation of the complex-catalyzed Michael reactions will be described in detail; some considerations of the reaction mechanism will also be presented.

Results and Discussion

Effects of the Complex Catalysts. First of all, various kinds of metal complex catalysts were examined in the addition reaction of nitromethane to 1,3-diphenyl-2-propen-1-one(chalcone) in a DMF solvent. The reaction conditions are shown as follows:

$$\underset{(1\ \text{mmol})}{PhCH{=}CHC(=O)Ph} + \underset{(4\ \text{ml})}{CH_3NO_2} \xrightarrow[\text{DMF, rt, 42 h}\ (2\text{—}5\ \text{ml})]{\text{M(II)–L(1:1)}} PhCH(CH_2NO_2)-CH_2-C(=O)Ph$$

The metal-ion species (M(II)) employed for the reaction were Co(II), Ni(II), Cu(II), and Zn(II), while the ligands (L) were 2,2′-bipyridine (bpy), 4,4′-dimethyl-2,2′-bipyridine (dim-bpy), 1,10-phenanthroline (phen), 6-nitro-1,10-phenanthroline (6-NO_2-phen), and ethylenediamine (en). Equimolar amounts of the metal(II) salt and the ligand compound were added to DMF; then the complex formation was observed by means of the color changes. This complex solution was subsequently used as a catalyst for the reaction without the isolation of the complex as a crystal form. The amount of the complex catalyst used for the reaction was 16 mol% of chalcone. The homogeneous reaction mixture was stirred for 42 h at room temperature. No by-products were formed in the reactions (examined by TLC, GLC, and isolation), the amount of chalcone consumed after the reaction was determined by means of GLC analysis; the yield of the reaction product was then calculated. The product was 1,3-diphenyl-4-nitro-1-butanone, which was further isolated and determined by means of mp, IR, and NMR. For example, in the reaction with the Ni(II)–bpy (1 : 1) complex, the yield of the product, as determined by GLC, was 86%, and the isolated yield was 82% (mp 100—101 °C). The details of the method of GLC analysis and the isolation of the product will be described in the Experimental section.

The reaction did not proceed with only metal(II) ions, without the ligand, but the ligand compounds themselves showed a weak catalytic activity; *e.g.*, bpy itself without the metal(II) ion afforded the product in a 15% yield (GLC) under similar reaction conditions. The reaction also did not proceed without any solvent (heterogeneous). An aprotic and polar solvent, such

a) Reaction conditions: rt, 42 h, DMF. b) Complex: M(II): L=1 : 1. c) Calculated from GLC analysis. d) In DMSO, 84%; HMPA, 78%; MeOH 6% (under similar reaction conditions).

as DMF or DMSO, was favorable for this catalytc! reaction, while an alcohol such as MeOH was entirely inadequate. However, when the amount of the solvent used was in a large excess (*e.g.*, 10 ml), the product yield decreased apparently. In all the reactions, a large excess of nitromethane (4 ml) was employed; otherwise, the product yield was very poor, as will be described below. The results of the reactions with various complex catalysts are summarized in Table 1. According to the results shown in Table 1, the catalysis of the $Ni(OAc)_2$–bpy (1 : 1) complex is best. On the contrary, the Cu(II) or Zn(II)–bpy (1 : 1) complex shows extremely poor catalytic activity under similar reaction conditions. It is also observed that the Cl^- or NO_3^- anion is unfavorable as the counter ion of the complex catalyst as far as Ni(II) or Co(II)–bpy is concerned. The ligands of dim-bpy and phen may exert a steric effect on the reactions, and 6-NO_2-phen has probably both steric and electronic effects (0%). Ethylenediamine is not effective as the ligand of the complex for this reaction (21%).

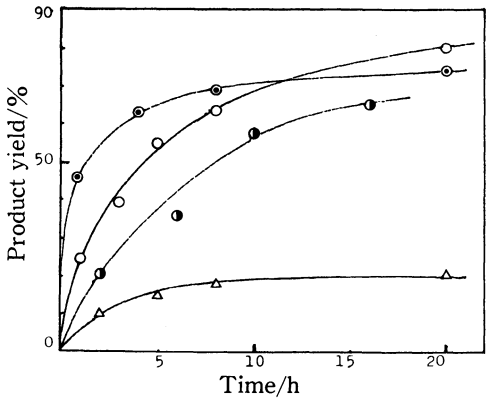

Fig. 1. Reaction profile of chalcone and nitromethane with Ni(II) complex catalysts (rt, in DMF).
○: Ni(II)–bpy(1 : 1); 16 mol% to chalcone, ⊙: (II)–$(bpy)_2$(1 : 2); 16 mol% to chalcone, △: Ni(II)–en(1 : 1); 16 mol% to chalcone, ◑: Ni(II)–bpy (1 : 1), 8 mol% to chalcone.

In order to examine this ligand effect further, the reactions of chalcone and nitromethane with some Ni(II) complex catalysts were followed over a period of 20 h by means of GLC analysis. The complexes employed were 16 mol% of $Ni(OAc)_2$–bpy, $Ni(OAc)_2$–$(bpy)_2$, $Ni(OAc)_2$–en, and 8 mol% of $Ni(OAc)_2$–bpy to chalcone. The reaction conditions were similar to those shown in Table 1. The correlations of the reaction time with the product yields are shown in Fig. 1. The figure displays a feature of the catalytic reactions reasonably well. The Ni(II)–$(bpy)_2$ complex, prepared by the addition of a two-fold mol quantity of bpy to the Ni(II) ion, accelerates the reaction in the first stage, but not in the later half. On the other hand, in the case of a low concentration of the Ni(II)–bpy (1 : 1) catalyst (8 mol%), the reaction is slow, but proceeds steadily throughout the reaction time. The reaction with Ni(II)–bpy (1 : 1) affords the product in an 80% yield for 20 h in Fig. 1 and in an 86% yield for 42 h (Table 1). In the reaction with Ni(II)–en (1 : 1), the yield of 20% is reached within just 20 h (Fig. 1), and a 21% yield within 42 h (Table 1). Therefore, the reaction time of 20 h seems to be generally enough for this complex-catalyzed Michael addition. It may be concluded that the $Ni(OAc)_2$–bpy–DMF system is the best combination for the complex-catalyzed Michael additions in this study. Some considerations of the enhanced effects of the bpy ligand and the OAc^- counter anion will be described below.

Various Michael Additions with the Ni(II) or Co(II)–bpy Complex. On the basis of the observations mntioned above, the reactions of various kinds of acceptor and donor compounds were carried out with the $Ni(OAc)_2$ or $Co(OAc)_2$–bpy (1 : 1) complex in DMF. The reaction conditions were similar to those shown in Table 1 except for the reaction time. In these experiments, all the reaction products were isolated and determined; they were found to be 1 : 1 adducts of the donor and acceptor compounds, except for one case. No by-product was observed in any of the reactions. The results are summarized in Table 2. In general, Ni(II) and Co(II) ion species each seem to display their own individual characteristics. For instance, the Co(II)–bpy complex is almost inactive in Reaction No. 1 (66 h, 50%) as compared with Ni(II)–bpy (18 h, 82%), but it shows almost the same activity in Reactions

Table 2. Various Michael additions with Ni(II) or Co(II)–bpy complex catalyst[a)]

a) Reaction conditions: M(II)–bpy(1 : 1), rt, in DMF. b) Reaction product: 1 : 1 adduct except for in No. 10. c) In the case of 50 °C, 90 h: 20%. d) A large excess to the acceptor. e) Crude.

No. 2 and No. 3. The influence of the electron-attractive substituents of chalcone (NO_2, Cl) on the product yield are observed to some extent (Nos. 2 and 3). An inductive effect of the methyl group in the acceptor is observed in Reaction No. 7 (low reactivity). Reaction No. 9 with aniline did not proceed without the complex catalyst under these reaction conditions, although aniline itself might behave as a base catalyst. In the reaction of acrylonitrile with malononitrile, only 1,3,3,5-tetracyanopentane was obtained (No. 10). Besides the

$$CH_2{=}CHCN + CH_2(CN)_2 \longrightarrow NCCH_2CH_2{-}\overset{\overset{CN}{|}}{\underset{\underset{CN}{|}}{C}}{-}CH_2CH_2CN$$

reactions in the Table, the reactions of chalcone with acetophenone, *p*-nitroacetophenone, or dimethyl malonate were examined, but they did not proceed at all, not even at 80—100 °C. This complex-catalyzed Michael reaction seemed to be independent of the reaction temperature. When Reaction No. 7 was carried out at 50 °C for 90 h, the yield of the product was 20%, lower than that at room temperature, while Reaction No. 6 at 80 °C for 44 h gave a 37% yield (see Table 2).

Catalysis of the Metal(II) Complexes. With regard to the enhanced effect of the bpy ligand on the complex catalysis, several studies of other organic reactions have previously been reported.[5] According to their accounts, the net plus charge of the M(II) ion will increase upon the π-back donation of the M(II) ion to the bpy ligand in the complex; then, the resulting enhanced coordination force of the substrates to the M(II) ion will naturally accelerate the reactions. The ligand effects on the complex-catalyzed Michael reactions are also explainable by a similar π-back donation in the Ni(II) or Co(II)–bpy complexes. In the case of our study, no such reaction occurred with only the M(II) ion itself, but bpy complexes of the Ni(II) or Co(II) ion showed considerable catalytic activity. On the other hand, the ethylenediamine ligand with no π-back donation showed a very poor ligand effect on the complex catalysis.

In the course of the reaction, it is presumed that the substrates are activated by coordination to the M(II) ion of the complex catalysts. Therefore, the coordination of 4′-nitrochalcone to the Ni(II)–bpy complex was examined by means of the electronic absorption spectra, as is shown in Fig. 2. A solution of $Ni(OAc)_2$ in DMF showed an absorption maximum at 430 nm. When bpy was added to this solution (1 : 1), a new absorption maximum appeared at 630 nm which was attributed to the d-d band of Ni(II)–bpy chelation. When chalcone was added to this solution of the complex, the absorption maximum shifted to 620 nm. This fact might suggest that chalcone entered the first coordination sphere of the Ni(II) ion. Since no absorption shift was observed upon the addition of nitromethane to this complex solution, the interaction between the Ni(II) ion and nitromethane seemed to be extremely weak. Consequently, a high concentration of nitromethane (excess) might be required for satisfactory reactions. Therefore, in all the reactions shown in Tables 1 and 2, a large excess of nitromethane or other donors had to be employed. For example, in the reaction of chalcone and excess nitromethane (4 ml) with the Ni(II)–bpy complex, the yield of the product was 82% (Table 2, No. 1), but it decreased to 45% when an equimolar amount of nitromethane (1 mmol) was used under similar reaction conditions. On the other hand, if the coordination of chalcone is weakened or interrupted for some reason, the reaction will be very slow. According to the examination of some reaction solvents, MeOH was not suitable for the reaction (Table 1, footnote d). Therefore, the electronic absorption spectroscopy of this system was also carried out. A solution of the Ni(II)–bpy complex in MeOH showed an absorption maximum at 580 nm (Fig. 2). However, no shift of the absorption maximum was observed at all upon the addition of chalcone to this solution. This fact suggested that the coordination of chalcone to the Ni(II) ion was extremely weak or was interrupted by the stronger coordination of the methanol molecules. Actually, the yield of the reaction product in MeOH was only 6% for 42 h. The coordination of 4′-nitrochalcone was confirmed by the UV spectra, as above, and the yields in Reactions No. 2 and No. 3 (Table 2) were high. Therefore, it is presumed that the effects of electron-attractive groups in chalcone derivatives enhance their reactivity without any interruption of their coordination.

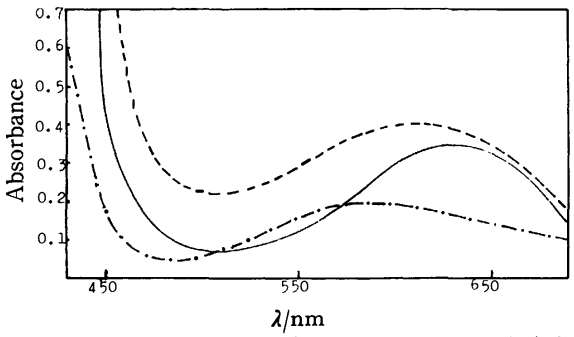

Fig. 2. Electronic absorption spectra of Ni(II)–bpy complexes in DMF or MeOH.
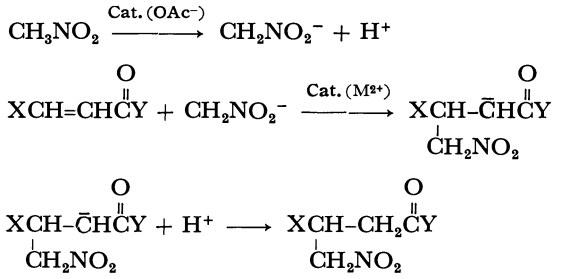
——: Ni(II)–bpy in DMF (λ_{max}=630 nm), ——: Ni(II)–bpy-4′-nitrochalcone (λ_{max}=620 nm), ·—·: Ni(II)–bpy in MeOH (λ_{max}=580 nm).

As for the behavior of the donor compound represented by nitromethane, it is considered that deprotonation occurs to form a donor anion in the first stage of the reaction; this process is also assisted by the metal complex. In our reaction system, the function of the M(II)–bpy complex catalyst as a base may be attributable not to the bpy ligand, but to the counter anion OAc^-, since bpy is not free because of the coordination in the complex. The IR spectra of $Ni(OAc)_2$ showed an absorption maximum of OAc^- at 1500 cm^{-1}, but it shifted to 1560 cm^{-1} in the spectra of the $Ni(OAc)_2$–bpy complex, which suggested the location of OAc^- at the outersphere of the complex, as in the case of [Ni(II)–bpy] $(OAc)_2$. Accordingly, both OAc^- and CH_3NO_2 are located considerably far from the central M(II) ion, although they have very weak interaction with the M(II) ion. In this situation, CH_3NO_2 may be catalyzed by OAc^- to form the $CH_2NO_2^-$ anion. Thus, the dual role of the complex catalyst, the simultaneous

activation of the acceptor by the M(II) ion and the donor by the OAc^- anion, should be emphasized.



Experimental

Instruments. The GLC analysis was carried out with a Hitachi K-53 gas chromatograph with a flame ionization detector, using a 1.0 m stainless steel tube column packed with 10% Carbowax 20 M on Diachrom A (career gas, N_2; injection temp, 240 °C; oven temp, 220 °C). The NMR and IR spectra were taken with a Hitachi Perkin-Elmer R-20 A spectrophotometer (60 MHz) and a Hitachi 215 Grating Infrared spectrophotometer respectively, the UV spectra, with a Hitachi EPS-3 T spectrophotometer.

Materials. The anhydrous metal(II) acetates were provided by Kojundo Chemical Research, and the hydrous metal(II) salts, by Wako Pure Chemicals. All the ligand compounds were provided by the Tokyo Kasei Co. Chalcone and its derivatives were prepared by aldol condensations with the Co(II)-bpy complex catalyst in DMF, according to the methods described in our previous report.[6] The other compounds in Table 2 were all commercially available.

Reactions of Chalcone and Nitromethane with Metal(II)-complex Catalysts (Tables 1 and 2). To a solution of metal(II) salt (0.16 mmol) in 2 ml of DMF, equimolar amounts of the ligand compound were added (M^{2+} : L = 1 : 1). The color of the solution changed upon the complex formation. Then, 1 mmol of chalcone and 4 ml of nitromethane were added to the solution of the catalyst, after which the homogeneous reaction mixture was stirred for 42 h at room temperature. After the reaction, diethyl ether was added to the solution to precipitate the complex catalyst, and the supernatant was sampled for the GLC analysis (internal standard: α-(*p*-methoxyphenyl)acetophenone). Thus, the product yield was calculated from the quantity of chalcone unreacted, which was itself determined by comparing the relative peak area of chalcone *vs.* the internal standard with those shown in the calibration chart. The procedure for the isolation of the reaction product was that in which the reaction mixture was extracted with ethyl acetate, the organic layer was washed with water and then evaporated *in vacuo* to give a yellow oil. It was treated by the preparative TLC of silica gel (hexane–ethyl acetate), and the product was extracted with ethyl acetate and recrystallized with ethanol; 1,3-diphenyl-4-nitro-1-butanone, mp 100—101 °C (lit,[7] 101—102 °C), IR 1690 cm^{-1} (C=O), 1550 cm^{-1} (NO_2); ^{1}H-NMR ($CDCl_3$): δ 3.45 (d, 2H, CH_2–CO), 4.78 (d.d., 2H, CH_2–NO_2), 7.40—8.09 (m, aromatic).

Experiment for Fig. 1 (Reaction Profile). The reaction profile of chalcone and nitromethane with some complex catalysts was examined as follows: $Ni(OAc)_2$ and bpy (0.4 mmol each) were weighed in a volumetric flask (10 ml), DMF was added to the flask to dissolve the catalyst, and the solution was kept standing overnight at room temperature. Then, 2.5 mmol of chalcone and DMF were added to bring the flask up to the mark. The DMF solution (1 ml) was poured into each sample tube, and a further 1 ml of nitromethane was added to each sample tube. The reaction mixture was sampled from time to time, and a small quantity of methanol was added to a portion of the reaction mixture which was then stored in a freezer. The procedure of the GLC analysis of each sample was similar to that shown in Table 1.

UV Spectroscopy (Fig. 2). $Ni(OAc)_2$ (1.5 mmol) was dissolved in DMF (25 ml), and the UV spectra of this solution were measured. Then, to this solution 1.5 mmol of bpy was added and the UV spectra were measured again (absorption max., 630 nm). Next, 4′-nitrochalcone (0.6 mmol) was added to this complex solution, whereupon the absorption maximum was observed to shift to 620 nm. In the case of the methanol solvent, a similar procedure was carried out.

Confirmation of the Sector Rule of the Benzenoid Chromophore

Sanji HAGISHITA* and Kaoru KURIYAMA
Shionogi Research Laboratories, Shionogi and Co., Ltd., Fukushima-ku, Osaka 553
(Received January 29, 1982)

1,2,3,4,4a,9,9a,10-Octahydroanthracene and tetralin derivatives with known absolute configurations were synthesized to estimate the contribution of a methyl substituent at the third sphere to the Cotton effect induced in the benzenoid transitions. The contributions were estimated from the CD spectra obtained based on the conformation of the skeleton deduced by Force Field Theory and the assumption that the contributions are additive. A large contribution was observed for the 1-*quasiequatorial*-methyl group in the ^1L_b benzenoid transition and for the 2-*axial*-methyl group in the ^1L_a benzenoid transition. The sign agreed well with the rule proposed by Snatzke except for the contribution of ring B in the ^1L_a benzenoid transition.

Snatzke *et al.* have proposed a refined sector rule for the benzene chromophore.[1,2] Although they described the sign of the contribution of the substituent in each section, the magnitude remained unclear. CD spectra of tetralin derivatives have been reported[3,4] but the data could not give the contribution of the substituent itself, owing to the ambiguity of the contribution of the tetralin skeleton. Further, the sign of the ^1L_b CD band could not be predicted in the molecule, which is complicated because of the presence of two rotational contributions of opposite signs, as in the case of (*S*)-(−)-anhalonine.[5] The present work studied the contributions of the chiral second and third spheres on the assumption that the contributions are additive. We chose substituted 1,2,3,4,4a,9,9a,10-octahydroanthracenes to find the contribution of 1-*quasiaxial*, 1-*quasiequatorial*, and 2-*axial* substituents,** since ring B would be fastened in the half chair conformation[6] due to ring C. Further, to find the contributions of the 2-*equatorial*-methyl group and the chiral second sphere, (+)-2,3-dimethyltetralin was synthesized and the CD spectrum was compared with that of (−)-2-methyltetralin.[4,7]

Synthesis

Wittig reaction of (4a*S*,9a*R*)-(+)-1,2,3,4,4a,9,9a,10-octahydro-9-anthracenone[1] [(+)-**1**] gave (+)-exo-olefin (+)-**2** in fairly good yield. Hydroboration of (+)-**2** gave three isomers: the first isomer (+)-**3** was isolated as the *p*-nitrobenzoate (+)-**6**; the second (+)-**5** was purified by preparative TLC and the third (+)-**4** was obtained as the (−)-ω-camphanic ester (−)-**7**.

Methyl derivatives (+)-**8**, (+)-**9**, and (+)-**10** were obtained by reduction of the tosylate of (+)-**3**, (+)-**4**, and (+)-**5**, respectively. The configuration of the methyl group and the ring juncture could be determined as follows.

Pyridinium chlorochromate oxidation of alcohol derivatives, (+)-**3**, (+)-**4**, and (+)-**5** gave the expected aldehyde (+)-**11**, (+)-**12**, and (+)-**13**, respectively. Further as a by-product, the *trans*-ketone (+)-**1** was obtained from (+)-**3** and (+)-**4**. The other isomer of the ketone (+)-**14** was isolated from (+)-**5**. The structure of (+)-**14** was assigned to be the *cis*-ring juncture by comparison with the physicochemical properties of (+)-**1**, since the C-9a position was only possible place to change. Then we could decide that (+)-**3** and (+)-**4** had the *trans*-ring juncture and (+)-**5** had the *cis*-ring juncture.

Further, the first isomer (+)-**3** was oxidized with the Jones' reagent giving the carboxylic acid (+)-**15** and (+)-**1**. From (+)-**15** the amino derivative (+)-**17** was obtained by the Curtius rearrangement. The coupling constant was 5 Hz between the protons at 9 and 9a of the carboxylic acid (+)-**15**. And the signal of the proton at 9 was observed as singlet in the amino derivative (+)-**17**. This small coupling constant led us to deter-

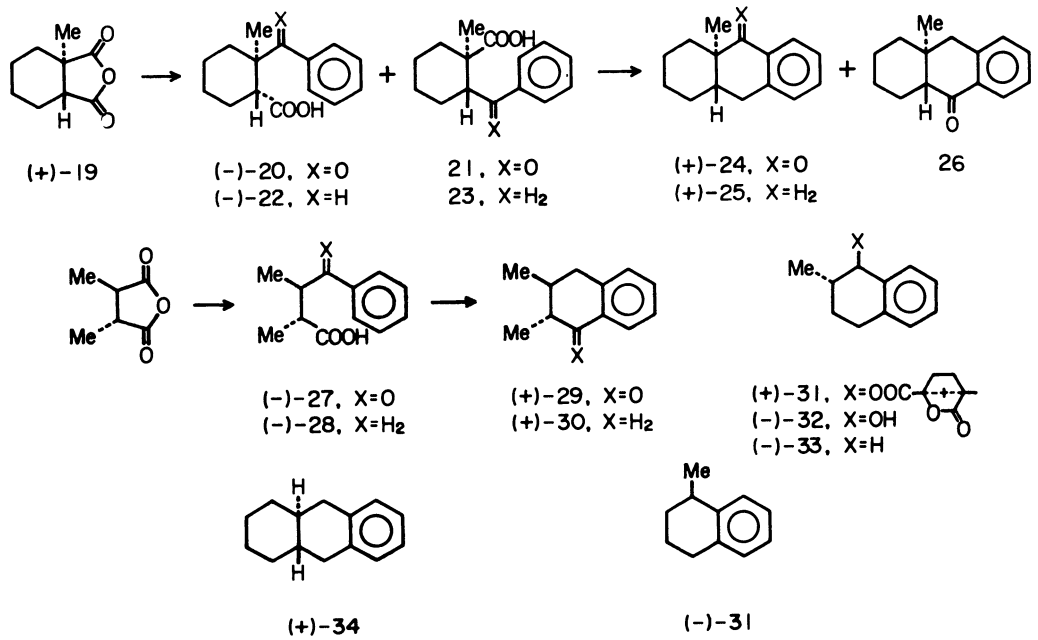

Scheme 2.

mine the configuration of the first isomer (+)-**3** to be 4a*S*, 9*R*, 9a*R* as shown in (+)-**3** of Scheme 1.

Reduction of the oxime of (+)-**1** gave almost selectively one *trans*-amino derivative (+)-**18**. The coupling constant was 8 Hz between the protons at **9** and **9a** and larger than that of the above amino isomer (+)-**17**. Further, reduction of (+)-**1** gave almost selectively one *trans*-isomer (+)-**16** of the alcohols with $NaBH_4$ or by the Meerwein-Pondorf-Verley method. The coupling constant was 6 Hz. Though the other *trans*-isomer could not be isolated, the signal of the proton at 9 was observed as singlet. Thus we can deduce that both major isomers have *quasiequatorial* substituent as (+)-**18** and (+)-**16**. The signals in a region of the methylene group of (+)-**17** and (+)-**18** showed quite similar pattern to those of (+)-**4**, (+)-**7** and (+)-**9**. This led us to determine their configuration to be 4a*S*, 9*S*, 9a*R*.

The second isomer (+)-**5** was deduced to have the *cis*-ring juncture as mentioned above and from the signals in a region of the methylene group in the NMR spectrum but the configuration of the substituent was remained unclear.

Friedel-Crafts reaction of benzene with (+)-(1*R*,2*R*)-*trans*-1-methyl-1,2-cyclohexanedicarboxylic anhydride[8)] [(+)-**19**] gave two isomers, **20** and **21** in a 10 : 1 ratio. Racemic **20** could be isolated by fractional recrystallization but not the optically active form. However, since both (−)-**20** and (−)-**21** lead to the same object compound **25**, the mixture of (−)-**20** and (−)-**21** was employed for further reaction without separation. Thus,

the angular methyl compound (+)-**25** was obtained as shown in Scheme 2.

(+)-(2*S*,3*S*)-2,3-Dimethyltetralin (+)-**30** was prepared from (+)-(2*R*,3*R*)-dimethylsuccinic acid[9] according to the procedure cited for racemic **30**.[10] The synthesis of partially optical active (−)-(1*R*,2*S*)-2-methyl-1-tetralol (−)-**32** has been reported previously,[4,7] but we obtained optically pure (−)-**32** from the ω-camphanic ester (+)-**31** more easily.

Results and Discussion

CD and UV spectra of the prepared compounds are shown in Table 1 with the data for (+)-(4a*S*,9a*S*)-*trans*-1,2,3,4,4a,9,9a,10-octahydroanthracene[2] [(+)-**34**] and (−)-(1*R*)-1-methyltetralin [(−)-**35**],[4] which we also prepared. Four benzenoid transitions, ^1L_b, ^1L_a, ^1B_b, and ^1B_a, were found for the UV spectra and two, ^1L_b and ^1L_a, for the CD spectra. Assuming that the contributions of the substituent are additive, we can obtain the contributions, $\delta\Delta\varepsilon$ and δR, by subtracting the Δε values and rotational strengths, R, of (+)-**34** from the substituted 1,2,3,4,4a,9,9a,10-octahydroanthracenes. Further we can estimate the contribution of the 2-*equatorial*-methyl group by subtracting the Cotton effect of (+)-**33** from that of (+)-**30**. The contribution of ring B can be calculated by subtracting the contribution of the 2-*equatorial*-methyl group from the Cotton effect of (+)-**33**. However, *trans*-1,2,3,4,4a,9,9a,10-octahydroanthracene is not always rigid in conformation. Substituent groups often exert an influence on the conformation of ring B for deformation from a half-chair conformation. We deduced the stable conformation using the Force Field Theory, MMI,[11] with the results shown in Fig. 1. The 2-*equatorial*-methyl group in **30** and **33** does not cause the deformation of ring B from a half-chair form, and the *equatorial*-methyl forms **30a** and **33a** were more stable than the *axial*-methyl forms **30b** and **33b**, respectively. Also, the 2-*axial*-methyl group in compound **25** does not lead to as much deformation.

The 1-*quasiaxial*-methyl form **35a** was more stable than the 1-*quasiequatorial* **35b** as pointed out before[4,12] and the deformation from the half-chair form is smaller in the 1-*quasiaxial*-methyl **35a** than in 1-*quasiequatorial* **35b**. Further, ring B of **8a** is more twisted from the half-chair form than that of **35a** owing to an additional peri-effect.

The theory suggests that the 1-*quasiequatorial*-methyl compound **9** has a twist-boat conformation **9a** rather than a half-chair form.

We measured the temperature-dependent CD spectra of (+)-**8**, (+)-**9**, and (−)-**35**, which are shown in Table 2. The rotational strength of (+)-**8** and (−)-**35** were constant within experimental error with temperature changes, although the band at 272 nm became smaller at lower temperature in (−)-**35**. Next, (−)-**35** was

a) These contributions were differences between the values of (+)-**8** and (+)-**34**.

considered to be fixed in the 1-*quasiaxial*-methyl form, which is a stable conformer, since the sign of the Cotton effect of (−)-**35** was the same as that of (+)-**8** in the region of the ^1L_b benzenoid transition. On the other hand, Cotton effects of (+)-**9** depended on the temperature and changed from negative at room temperature to positive at lower temperature as shown in Fig. 2. The analysis[12] showed that the conformational free-energy difference ($\Delta G°$) was 2.3 kJ/mol, assuming that (+)-**9** was composed of two conformers.

Since the introduction of the 2-*axial*- or the 2-*equatorial*-methyl group did not deform the half-chair conformation, we could obtain the contributions $\delta\Delta\varepsilon$ and δR of the 2-*axial*- and 2-*equatorial*-methyl groups and ring B, as mentioned above.

The contribution of the 1-*quasiaxial*-methyl group may be estimated either by subtracting the Cotton effects of (+)-**34** from those of (+)-**8** or by subtracting the contribution of ring B from the Cotton effect of (−)-**35**. The contribution obtained from both estimations had the same sign in δR in both regions of the benzenoid transitions, but the magnitudes differed and the $\delta\Delta\varepsilon$ values were ambiguous in sign. The chemical shift of the methyl group of (−)-**35** was lower than that of (+)-**8** and almost the same as that of (+)-**9**. This may suggest that compound (−)-**35** is composed of two conformers. But the Force Field Theory suggested that the more stable *quasiaxial*-methyl form **35a** showed less deformation from a half-chair form than that of **8a**. The proton at the C-1 position of (+)-**8** would cause more deformation of ring B owing to the *peri*-effect. Although the rotational strength of (−)-**35** was not influenced much by temperature, we adopted the difference of the Cotton effect of (−)-**35** at −190 °C from the contribution of ring B as the contribution of the 1-*quasiaxial*-methyl group.

As mentioned before, the Cotton effect of (+)-**9** depended on temperature. We estimated the stable conformer to be a twist-boat form from the Force Field Theory. Also, to estimate the conformation of (+)-**9**, we measured the CD spectra of 1,3,5(10)-estratriene,*** which was regarded as the 1-*quasiequatorial*-2-*equatorial*-dimethylene derivative with a half-chair conformation. The half-chair form of (+)-**9** can be regarded as the derivative with one 1-*quasiequatorial*-methyl and two 2-2-*equatorial*-methylene groups, in other words, it has one 2-*equatorial*-methylene group more than the steroid, if the methyl and the methylene groups in the 1-*quasiequatorial*-position make the same contribution to the Cotton effect. We estimated the contribution of the 2-*equatorial*-methylene group from the CD spectra of (+)-**34** to be small. We then compared the CD spectra of the steroid and (+)-**9**. The CD spectra of the steroid resembled that of (+)-**9** at room temperature rather than that at low temperature. This means that (+)-**9** is in equilibrium between the twist-boat and the half-chair forms, and the twist-boat form is the stable one. Therefore, we could not estimate the contribution of the 1-*quasiequatorial* group by direct comparison, but the negative Cotton effect was deduced for the unstable conformer from the Cotton effect at room temperature. The contributions of the 1-*quasiequatorial*-methyl group were larger than those obtained by subtracting the Cotton effects of (+)-**34** from those of (+)-**9** at room temperature. These results are summarized in Table 3. The sign of the contribution agreed well with Snatzke's sector rule except for ring B in the ^1L_a region, although the contribution of the 1-*quasiequatoria*-methyl group was not clear.

In the ^1L_b benzenoid transition, the 1-*quasiaxial*-, 2-*axial*- and 2-*equatorial*-methyl groups showed smaller contributions than the 1-*quasiequatorial* group. In the ^1L_a benzenoid transition, the 2-*equatorial*-methyl group contributed more than the 1-*quasiaxial* and 2-*axial*-methyl groups. Since ring B is not always in the complete half-chair conformation, the contribution is not directly attributable to the methyl group but contains the contribution of the deformation of ring B by the substituent. These apparent contributions should be useful for predicting the position and orientation of the substituent of the tetralin derivatives.****

*** In cyclohexane, 274 nm ($\Delta\varepsilon$ −0.124), 271 (+0.028), 266.5 (−0.085), 260 (−0.042).

**** We tried to analyze the contribution using the CNDO/S molecular orbital model[13] and the dipole velocity method[14] but have some doubt about the reliability and accuracy of the calculation owing to the quantitative instability with a number of configurations.

Experimental

Melting points are uncorrected. Optical rotations were determined with a Perkin-Elmer Model 141 polarimeter, using a 1.0-dm microcell. CD curves were obtained using a JASCO Model J-40 spectropolarimeter. Infrared spectra were recorded on a JASCO-DS-402G spectrophotometer. ^{1}H NMR spectra were measured with Varian A56/60D spectrometer using tetramethylsilane as the internal standard. UV spectra were obtained on a Hitachi Model 323 spectrometer.

*(4a*S, *9a*R*)-(+)-9-Methylene-1,2,3,4,4a,9,9a,10-octahydroanthracene, (+)-2.* Methyltriphenylphosphonium bromide (31 g) was added to a suspension of potassium *t*-butoxide (15 g) and the (+)-ketone (**1**, 5.8 g) in dry ether (400 ml) under a nitrogen atmosphere. The mixture was stirred overnight and poured onto ice water. The organic phase was separated and the aqueous phase was extracted with ether. The combined organic phases were washed with dimethyl sulfoxide–water (1 : 1) and then water, dried (Na_2SO_4) and concentrated *in vacuo*. The residue was crystallized from ether and the crystals were removed by filtration. The filtrate was chromatographed on thick silica gel plate (Merck Co., precoated, 2 mm) in hexane and then distilled at 121 °C at 0.9 mm Hg, 5.4 g (94.0%); $[\alpha]_D^{24.5}$ +140.3 ±1.7° (*c* 1.047, $CHCl_3$); IR (film) 888 cm^{-1}; NMR ($CDCl_3$) δ=0.9—2.5 (m, 10H), 2.5—3.1 (m, 2H), 4.97 (s, 1H), 5.49 (s, 1H), 7.0—7.3 (m, 3H), 7.4—7.8 (m, 1H); UV_{max} (hexane) 298^{sh} nm (ε 758), 288 (864), 281 (843), 250 (11300), 222^{sh} (10500), 211 (21700); CD (hexane) 283 nm ($\Delta\varepsilon$ +0.933), 243 (+4.88), 211.5 (+11.3), 190! (−7.24). Found: C, 91.00; H, 9.06%. Calcd for $C_{15}H_{18}$: C, 90.85; H, 9.15%.

Hydroboration of (+)-2. A solution of diborane in tetrahydrofuran, which was prepared from $NaBH_4$ (5.3 g), boron trifluoride etherate (44 g) and diglyme (130 ml), was added to a solution of the (+)-olefin (**2**, 5.40 g) in tetrahydrofuran (100 ml) with ice-cooling. The mixture was stirred at 0 °C for 2 h. Water was added dropwise carefully with ice-cooling. 3 mol dm^{-3} NaOH (22 ml) and then 30% hydrogen peroxide (25 ml) were added. The mixture was stirred for 4 h and allowed to stand for 2 d. Water (200 ml) was added. The mixture was extracted with ether. The solution was washed with water, dried (Na_2SO_4) and concentrated *in vacuo*. The small portion of residue was distilled at 160 °C (bath temperature) at 0.2 mmHg through a short-path distillation apparatus, $[\alpha]_D^{23.5}$ +73.0 ±0.8° (*c* 0.958, MeOH). Found: C, 83.69; H, 9.49%. Calcd for $C_{15}H_{20}O$: C, 83.28; H, 9.32%.

*(4a*S, *9*R, *9a*R*)-(+)-1,2,3,4,4a,9,9a,10-Octahydro-9-anthracenylmethyl* p-*Nitrobenzoate, (+)-6.* *p*-Nitrobenzoyl chloride (18 g) was added to a cold solution of the above (+)-alcohols (**3**, **4** and **5**, 5.6 g) in pyridine (80 ml). The mixture was allowed to stand at room temperature overnight, poured into water and extracted with ethyl acetate. The solution was washed with dilute HCl, aqueous $NaHCO_3$ and water, dried (Na_2SO_4) and concentrated *in vacuo*. The residue was crystallized from ether and recrystallized from ethyl acetate–ethanol, 0.432 g, mp 126—128 °C; $[\alpha]_D^{24}$ +136.1 ±2.1° (*c* 0.867, $CHCl_3$); IR ($CHCl_3$) 1724, 1530 cm^{-1}; UV_{max} (dioxan) 340^{sh} nm (ε 280), 261 (13300), 218^{sh} (12100), 207.5 (17100); CD (MeOH) 325 nm ($\Delta\varepsilon$ +0.018), 264.5 (+2.75), 259 (+2.58), 210 (+6.30). Found: C, 72.20; H, 6.39; N, 3.78%. Calcd for $C_{22}H_{23}NO_4$: C, 72.31; H, 6.34; N, 3.83%.

*(4a*S, *9*R, *9a*R*)-(+)-9-Hydroxymethyl-1,2,3,4,4a,9,9a,10-octahydroanthracene, (+)-3.* The (+)-ester (**6**, 2.6 g) was hydrolyzed with KOH (2 g) in water (10 ml) and methanol (20 ml) by heating under reflux for 2 h and treated as usual. The alcohol was crystallized from hexane, 1.5 g, mp 85—86 °C, $[\alpha]_D^{24}$ +105.5 ±1.4° (*c* 1.071, MeOH); IR (nujol) 3300, 1056 cm^{-1}; NMR ($CDCl_3$) δ=0.7—2.2 (m, 11H), 2.3—3.2 (m; 3H), 3.62 (dd, *J*=5, 11 Hz, 1H), 7.11 (s, 4H). Found: C, 83.28; H, 9.49%. Calcd for $C_{15}H_{20}O$: C, 83.28; H, 9.32%.

*(4a*S, *9*R, *9a*S*)-(+)-9-Hydroxymethyl-1,2,3,4,4a,9,9a,10-octahydroanthracene, (+)-5.* The mother liquor of the *p*-nitrobenzoate **6** was hydrolyzed as above. The oily residue (1.5 g) was chromatographed on thin silica gel plate (Merck Co., precoated, 0.5 mm) in hexane–ether (3 : 1). The fraction of the smaller R_f value was distilled at 160 °C at 0.2 mmHg through a short-path distillation apparatus, 300 mg; $[\alpha]_D^{24}$ +30.9 ±0.6° (*c* 0.941, MeOH); IR (film) 3350 cm^{-1}; NMR ($CDCl_3$) δ=0.8—2.4 (m, 10H), 2.6—3.3 (m, 3H), 3.87 (dd, *J*=7, 11 Hz, 1H), 4.22 (dd, *J*=6, 11 Hz, 1H), 6.9—7.5 (m, 4H); UV_{max} (MeOH) 274 nm (ε 600), 266 (566), 261^{sh} (405), 255^{sh} (278), 217^{sh} (8020), 213 (9140), 197.5 (44400), 195^{sh} (43000); CD (MeOH) 272.5 nm ($\Delta\varepsilon$ −0.215), 265.5 (−0.212), 259.5 (−0.136), 210 (−1.61). Found: C, 83.22; H, 9.40%. Calcd for $C_{15}H_{20}O$: C, 83.28; H, 9.32%.

*(−)-Camphanyl Ester of (4a*S, *9*S, *9a*R*)-(+)-9-Hydroxymethyl-1,2,3,4,4a,9,9a,10-octahydroanthracene, (−)-7.* A solution of the fraction with the larger R_f value (0.18 g) in pyridine (3 ml) was added to (−)-ω-camphanoyl chloride (0.362 g) in pyridine (3 ml). The mixture was allowed to stand at room temperature overnight, poured into water and extracted with ether. The solution was washed with ice-cold dilute HCl, aqueous $NaHCO_3$ and water, dried (Na_2SO_4) and concentrated *in vacuo*. The residue was chromatographed on thin silica gel plate (Merck Co., precoated, 0.5 mm) in hexane–ether (5 : 1). The development was repeated three times. The fraction of the smaller R_f value (−)-**7** was recrystallized from hexane, 181 mg, $[\alpha]_D^{22}$ 0°, $[\alpha]_{365}^{22}$ −5.9 ±0.3° (*c* 1.107, $CHCl_3$); mp 129.0—130.0; IR (Nujol) 1790, 1744 cm^{-1}; NMR ($CDCl_3$) δ=0.63 (s, 3H), 0.71 (s, 3H), 1.03 (s, 3H), 0.7—2.9 (m, 17H), 4.32 (dd, *J*=12, 3 Hz, 1H), 4.77 (dd, *J*=12, 4 Hz, 1H), 6.9—7.4 (m, 4H). Found: C, 75.33; H, 8.04%. Calcd for $C_{25}H_{32}O_4$: C, 75.73; H, 8.13%.

The fraction with the larger R_f value, the ω-camphanic ester of (+)-**3**, was recrystallized from hexane, 57.7 mg, mp 154 °C; $[\alpha]_D^{22}$ +76.9 ±1.0° (*c* 0.844, $CHCl_3$); IR (nujol) 1789, 1722 cm^{-1}; NMR ($CDCl_3$) δ=0.76 (s, 3H), 0.96 (s, 3H), 1.07 (s, 3H), 0.6—2.6 (m, 15H), 2.7—3.2 (m, 2H), 4.23 (dd, *J*=6, 12 Hz, 1H), 4.52 (dd, *J*=6, 12 Hz, 1H), 6.9—7.3 (m, 4H). Found: C, 74.90; H, 7.99%. Calcd for $C_{25}H_{32}O_4$: C, 75.73; H, 8.13%.

*(4a*S, *9*S, *9a*R*)-(+)-9-Hydroxymethyl-1,2,3,4,4a,9,9a,10-ocatahydroanthracene, (+)-4.* The ester [(−)-**7**, 400 mg] was hydrolyzed with 5% KOH in methanol (10 ml) by heating under reflux for 2 h. The residue was distilled at 160 °C (bath temperature) at 0.2 mmHg through a short-path distillation apparatus, 157 mg; $[\alpha]_D^{21}$ +76.4 ±0.8° (*c* 1.017, MeOH) IR (film) 3370, 1046 cm^{-1}; NMR ($CDCl_3$) δ=0.7—2.2 (m, 10H), 2.3—2.8 (m, 3H), 3.73 (dd, *J*=11, 3 Hz, 1H), 4.01 (dd, *J*=11, 3 Hz, 1H), 6.9—7.4 (m, 4H). Found: C, 82.63; H, 9.24%. Calcd for $C_{15}H_{20}O$: C, 83.28; H, 9.32%.

*(4a*S,*9*R,*9a*R*)-(+)-9-Methyl-1,2,3,4,4a,9,9a,10-octahydroanthracene, (+)-8.* A solution of *p*-toluenesulfonyl chloride (1.3 g) in pyridine (10 ml) was added to a solution of the (+)-alcohol (**3**, 30)1 mg in pyridine (3 ml) at −5——10 °C over a period of 1 h. The solution was allowed to stand at 4 °C overnight, poured into ice-cold dilute HCl and extracted with ether. The solution was washed with cold dilute HCl, aqueous $NaHCO_3$ and water, dried (Na_2SO_4) and concentrated *in vacuo*, 402 mg. The crystalline tosylate was used for the next preparation without further purification.

A solution of the optically active tosylate (400 mg) in dry

tetrahydrofuran (15 ml) was added to a slurry of $LiAlH_4$ (0.4 g) in tetrahydrofuran (5 ml) with ice-cooling. The mixture was then heated under reflux for 5 h. Excess $LiAlH_4$ was decomposed with a solution of methanol in ether and then dilute HCl. The mixture was chromatographed on thin silica gel plate (Merck Co., precoated, 0.5 mm) in hexane and distilled at 110 °C (bath temperature) at 0.2 mmHg giving a colorless oil, 141.5 mg; $[\alpha]_D^{23}$ +90.2 ±1.1° (*c* 1.282, hexane); IR (film) 755 cm^{-1}; NMR ($CDCl_3$) δ=1.08 (d, J=7 Hz, 3H), 0.9—3.2 (m, 10H), 7.05 (m, 4H). Found: C, 89.65; H, 10.15%. Calcd for $C_{15}H_{20}$: C, 89.94; H, 10.06%.

*(4a*S,*9*R,*9a*S*)-(+)-9-Methyl-1,2,3,4,4a,9,9a,10-octahydroanthracene, (+)-**10**.* The *cis*-alcohol [(+)-**5**] was treated as above. The oily residue was chromatographed on thin silica gel plate (Merck Co., precoated, 0.5 mm) in hexane and distilled at 110 °C at 0.2 mmHg; $[\alpha]_D^{22}$ +43.0 ±0.6° (*c* 1.146, hexane); CD 273.5 nm ($\Delta\varepsilon$ −0.158), 266.5 (−0.133), 260 (−0.064), 217 (+0.621); IR (film) 755 cm^{-1}; NMR ($CDCl_3$) δ=0.5—3.3 (m, 13H), 1.31 (d, J=7 Hz, 3H), 6.9—7.4 (m, 4H). Found: C, 89.13; H, 9.90%. Calcd for $C_{15}H_{20}$: C, 89.94; H, 10.06%.

*(4a*S, *9*S, *9a*R*)-(+)-9-Methyl-1,2,3,4,5a,9,9a,10-octahydroanthracene, (+)-**9**.* The *trans*-alcohol [(+)-**4**] was treated as above. The residue was chromatographed on thin silica gel plate (Merck Co., precoated, 0.5 mm) in hexane and distilled at 120 °C (bath temperature) at 0.2 mmHg through a short-path distillation apparatus. The distillate crystallized quickly, mp 65—68 °C; $[\alpha]_D^{22}$ +99.1 ±0.9° (*c* 1.018, hexane); IR (nujol) 763, 744 cm^{-1}; NMR ($CDCl_3$) δ=0.5—2.8 (m, 3H), 1.28 (d, J=7 Hz, 3H), 6.9—7.4 (m, 4H). Found: C, 89.66; H, 10.47%. Calcd for $C_{15}H_{20}$: C, 89.94; H, 10.06%.

*Oxidation of Alcohols (+)-**3**, (+)-**4**, and (+)-**5**.* *1)*: A solution of the (+)-*cis*-alcohol[(+)-**5**, 199 mg] in dichloromethane (6 ml) was added to a mixture of anhydrous sodium acetate (26 mg) and pyridinium chlorochromate (311 mg) in dichloromethane (5 ml) in one portion. The mixture was stirred at room temperature for 2 h. Ether was added. The mixture was chromatographed on florisil (20 g) in ether. The residue was chromatographed on thin silica gel plate (Merck Co., pre-coated plate) in benzene.

The fraction of the larger R_f value; oil (44.4 mg); IR (film) 1723 cm^{-1}; NMR ($CDCl_3$) δ=1.0—3.1 (m, 12H), 3.41 (dd, J=6, 2 Hz, 1H), 6.9—7.4 (m, 4H), 9.59 (d, J=2 Hz, 1H); This fraction was the aldehyde derivative **13**.

The fraction of smaller R_f value (42.4 mg) was recrystallized from pentane; mp 79—81 °C; $[\alpha]_D^{25}$ +40.8 ±0.6 (*c* 1.046, $CHCl_3$); IR (Nujol) 1677, 749, 738 cm^{-1}; NMR ($CDCl_3$) δ=1.2—2.9 (m, 10H), 2.99 (d, J=5 Hz, 1H), 7.1—7.6 (m, 3H), 8.15 (dd, J=8, 1 Hz, 1H); UV_{max} (heptane) 355 nm^{sh} (ε 118), 342 (174), 330 (192), 316 (209), 298 (1580), 288 (1650), 278^{sh} (1110), 251^{sh} (9620), 245 (12500), 204 (30400); CD (heptane) 374 nm ($\Delta\varepsilon$ +0.115), 357 (+0.348), 343.5 (+0.494), 330.5 (+0.424), 318 (+0.227), 307.5 (+0.064), 296 (−0.082), 286 (−0.109), 243 (+1.42), 222 (+0.594), 210.5 (−4.30), 193 (+7.79). Found: C, 83.70; H, 8.14%. Calcd for $C_{14}H_{16}O$: C, 83.96; H, 8.05%. This was the *cis*-ketone (+)-**14**.

2): The (+)-alcohol [(+)-**3**, 105 mg] was treated as above. The fraction of the larger R_f value (49.8 mg) could not be crystallized and was contaminated with other compounds but the following band and signal were observed; IR (film) 1720 cm^{-1}; NMR ($CDCl_3$) δ=9.61 (d, J=6 Hz). The fraction of the smaller R_f value (25.7 mg) was recrystallized from pentane and was identical with the authentic sample, (+)-**1**.

3): The alcohol [(+)-**4**, 117 mg] was treated as above. The fraction of the larger R_f value (64.3 mg) was recrystallized from pentane; mp 79—81 °C; $[\alpha]_D^{25}$ +15.2 ±0.4 (*c* 1.246, $CHCl_3$); IR (Nujol) 1728, 751 cm^{-1}; NMR ($CDCl_3$) δ=0.8—2.9 (m, 12H), 3.28 (dd, J=9, 6 Hz, 1H), 6.8—7.3 (m, 4H), 9.38 (d, J=5 Hz, 1H); UV_{max} (heptane) 296 nm (ε 103), 273 (400), 266 (408), 262^{sh} (325), 253 (266), 218^{sh} (8390); CD (heptane) 325 nm^{sh} ($\Delta\varepsilon$ −0.524), 313^{sh} (−1.15), 305 (−1.43), 296.5 (−1.38), 271.5 (−1.02), 265 (−0.709), 260 (−0.412), 225.5 (−1.02), 201.5 (+9.30). Found: C, 84.01; H, 8.54%. Calcd for $C_{15}H_{18}O$: C, 84.07; H, 8.47%.

The fraction of the smaller R_f value (9.5 mg) was recrystallized from pentane and was identical with the authentic sample, (+)-**1**.

*Reduction of (+)-**1**.* *a)*: $NaBH_4$ (0.3 g) was added in small portions to a suspension of (+)-**1** (0.317 g) in methanol (10 ml) at −10 °C. The mixture was stirred for 2 h. Dilute HCl was added. The crystals were collected by filtration, washed with water, dried and recrystallized from methanol, 0.212 g, mp 142—143 °C; $[\alpha]_D^{25}$ +119.4 ±1.0° (*c* 1.016, $CHCl_3$); IR (Nujol) 3380, 3350 cm^{-1}; NMR ($CDCl_3$) δ=0.8—3.2 (m, 12H), 4.26 (d, J=6 Hz, 1H), 6.8—7.3 (m, 3H), 7.3—7.7 (m, 1H); UV_{max} (MeOH) 273 nm (ε 407), 266 (395), 260^{sh} (294), 217^{sh} (7410), 212 (8530), 197.5 (36400); CD (MeOH) 274 nm ($\Delta\varepsilon$ +0.138), 268 (+0.155), 263 (+0.146), 215 (+2.88). Found: C, 82.80; H, 9.13%. Calcd for $C_{14}H_{18}O$: C, 83.12; H, 8.97%.

b): A mixture of (+)-**1** (0.570 g) and aluminum isopropoxide (0.60 g) in isopropyl alcohol (15 ml, freshly distilled over aluminum isopropoxide) was heated at refluxing 4 h. The rate of the distillation was about 5 to 10 drops a minute. Finally the solvent was distilled off *in vacuo*. Dilute HCl was added. The mixture was extracted with ether. The solution was washed with water, dried (Na_2SO_4) and concentrated *in vacuo*. The residue was chromatographed on thin silica gel plate (Merck Co., precoated) in benzene and recrystallized from methanol. This was identical with the above product.

From the mother liquor of procedures *a*) and *b*), the other isomer could not be isolated but a singlet was detected at δ=4.35 in $CDCl_3$.

*(4a*S, *9*R, *9a*R*)-(+)-1,2,3,4,4a,9,9a,10-Octahydroanthracene-9-carboxylic Acid, (+)-**15**.* Jones' reagent (0.5 ml) was added to a solution of the (+)-alcohol [(+)-**3**, 226 mg] in acetone (5 ml) with ice-cooling. Water was added. The mixture was extracted with ethyl acetate. The solution was washed with water, dried (Na_2SO_4), concentrated *in vacuo* and recrystallized from hexane; 112.4 mg, mp 182—183 °C; $[\alpha]_D^{24}$ +209.1 ±2.2° (*c* 0.657, MeOH); IR (Nujol) 1690 cm^{-1}; NMR ($CDCl_3$) δ=0.8—3.1 (m, 12H), 3.73 (d, J=5 Hz, 1H), 7.15 (s, 4H), 10.90 (s, 1H). Found: C, 77.56; H, 7.98%. Calcd for $C_{15}H_{18}O_2$: C, 78.23; H, 7.88%.

The mother liquor was chromatographed on thin silica gel plate (Merck Co., pre-coated plate) in benzene. The elute was recrystallized from hexane and was identical with the authentic sample, (+)-**1**.

*(4a*S, *9*R, *9a*R*)-(+)-9-Amino-1,2,3,4,4a,9,9a,9,10-octahydroanthracene, (+)-**17**.* A mixture of the (+)-carboxylic acid [(+)-**15**, 140 mg] and oxalyl chloride (1 ml) was stirred at room temperature for 3 h. The volatile materials were removed by distillation *in vacuo*.

A solution of the acid chloride in dry tetrahydrofuran (3 ml) was added to a cold solution of NaN_3 (0.25 g) in water (5 ml). The mixture was stirred at 0 °C for 3 h and extracted with ether. The solution was washed with water, dried (Na_2SO_4) and concentrated *in vacuo*.

Dry benzene (5 ml) was added. The solution was heated under reflux for 3 h and concentrated *in vacuo*.

A solution of the isocyanate in *t*-butanol and triethylamine (1 ml) was heated under reflux for 12 h and the volatile

materials were removed by distillation *in vacuo*.

Concentrated HCl (5 ml) was added. The mixture was heated at 100 °C for 18 h. After cooling, the mixture was washed with ether, treated with charcoal and concentrated *in vacuo*. The residue (57.5 mg) was recrystallized from ethyl acetate, mp 270—271 °C.

Dilute NH_4OH was added. The mixture was extracted with dichloromethane. The solution was washed with water, dried (Na_2SO_4) and concentrated *in vacuo*. The residue was distilled at 100 °C at 0.2 mmHg giving a colorless oil (28.7 mg). $[\alpha]_D^{23}$ +82.1 ±0.8° (*c* 1.092, $CHCl_3$); IR (film) 3370, 3290 cm^{-1}; NMR ($CDCl_3$) δ=0.7—2.3 (m, 12H), 2.6—3.2 (m, 2H), 3.76 (s, 1H), 7.0—7.4 (m, 4H); UV_{max} (MeOH) 272 nm (ε 411), 265 (424), 261^{sh} (347), 211^{sh} (9100), 195 (42200); CD (MeOH) 271.5 nm ($\Delta\varepsilon$ +0.409), 264 (+0.458), 216 (+2.45). Found: C, 83.20; H, 9.71; N, 6.69%. Calcd for $C_{14}H_{19}N$: C, 83.53; H, 9.51; N, 6.96%.

*(4a*S, *9*S, *9a*R*)-(+)-9-Amino-1,2,3,4,4a,9,9a,10-octahydroanthracene, (+)-**18**.* A mixture of the (+)-ketone [(+)-**1**, 507 mg], NH_2OH–HCl (411 mg), pyridine (4 ml) and ethanol (6 ml) was heated under reflux for 16 h, poured into water and extracted with ether. The solution was washed with water, dried (Na_2SO_4) and concentrated *in vacuo*.

A small amount of raney-Ni was added to a solution of the oxime in methanol (20 ml), a solution of Na_2HPO_2 (0.85 g) in water (5 ml), and 2 mol dm^{-3} NaOH (5 ml). After the bubbling had settled, the mixture was shaken under hydrogen atmosphere. The catalyst was filtered and washed with methanol. Dilute HCl was added. The crystals were collected by filtration, shaken with aqueous K_2CO_3 and extracted with dichloromethane. The solution was dried (Na_2SO_4) and concentrated *in vacuo*. The residue was recrystallized from hexane, 57.1 mg, mp 48—50 °C; $[\alpha]_D^{24}$ −96.3 ±0.9° (*c* 1.019, MeOH); IR (Nujol) 3390, 3300 cm^{-1}; NMR ($CDCl_3$) δ=0.7—2.8 (m, 12H), 3.49 (s, broad, 1H), 6.9—7.3 (m, 3H), 7.4—7.8 (m, 1H); CD (MeOH) 272 nm ($\Delta\varepsilon$ +0.199) 265 (+0.199), 217 (+2.41). Found: C, 83.52; H, 9.22; N, 6.87%. Calcd for $C_{14}H_{19}N$: C, 83.53; H, 9.51; N, 6.96%.

*Friedel-Crafts Reaction of (+)-**19** with Benzene.* Anhydrous $AlCl_3$ (8.5 g) was added in one portion to a solution of the anhydride[8] [(+)-**19**, 2.16 g] in benzene (20 ml). The mixture was heated under reflux with vigorous stirring for 3 h and poured into ice-cold HCl. The organic phase was separated and the aqueous phase was extracted with benzene. The combined organic phases were washed with water, dried (Na_2SO_4) and concentrated. The residue was chromatographed on silica gel (Merck Co., grade 1, 50 g) in ethyl acetate. The NMR spectrum showed it to be a mixture of *ca.* 10 : 1 of (−)-**20** and **21**. They could not be separated from each other by fractional recrystallization or TLC.

Racemic **20** was isolated by recrystallization twice from benzene–hexane; mp 138—139 °C; IR (Nujol) 1694, 1680 cm^{-1}; NMR ($CDCl_3$) δ=1.40 (s, 3H), 1.3—2.1 (m, 8H), 3.82 (m, 1H), 7.3—7.6 (m, 3H), 7.7—8.0 (m, 2H). Found: C, 72.22; H, 7.33%. Calcd for $C_{15}H_{18}O_3$: C, 73.15; H, 7.37%.

*(1*R, *2*S*)-(−)-2-Benzyl-2-methyl-1-cyclohexanecarboxylic Acid, (−)-**18**.* The (−)-ketone [(−)-**20**, 378 mg] was hydrogenolyzed by the same procedure cited for 2-benzoyl-1-cyclohexanecarboxylic acid.[1] The oily residue was distilled at 150 °C (bath temperature) at 0.2 mmHg through a short-path distillation apparatus. The NMR spectrum showed contamination by a small amount of **23**.

Racemic **22**: mp 133—135 °C; IR (Nujol) 1692 cm^{-1}; NMR ($CDCl_3$) δ=1.24 (s, 3H), 0.9—1.9 (m, 8H), 2.0—2.8 (m, 3H), 7.20 (s, 5H). Found: C, 77.54; H, 8.79%. Calcd for $C_{15}H_{20}O_2$: C, 77.55; H, 8.68%.

*(4a*R, *9a*S*)-(+)-4a-Methyl-1,2,3,4,4a,9,9a,10-octahydro-10-anthracenone, (+)-**24**.* The ring-forming reaction was carried out according to the procedure cited for 2-benzyl-1-cyclohexanecarboxylic acid.[1] The oily product, quantitative yield, was distilled at 140 °C at 0.5 mmHg through a short-path distillation apparatus and was contaminated with a small amount of **26**.

Racemic **24**: oil; IR (film) 1688 cm^{-1}; NMR ($CDCl_3$) δ=1.07 (s, 3H), 1.1—2.4 (m, 1H), 2.68 (s, 1H), 2.80 (d, *J*=5 Hz, 1H), 7.0—7.7 (m, 3H), 7.9—8.2 (m, 1H). Found: C, 83.62; H, 8.45%. Calcd for $C_{15}H_{18}O$: C, 84.07; H, 8.47%.

*(4a*S, *9a*S*)-(+)-4a-Methyl-1,2,3,4,4a,9,9a,10-octahydroanthracene, (+)-**25**.* The (+)-ketone [(+)-**24**] was hydrogenolyzed as above. The crude oily residue was chromatographed on thin silica gel plate (Merck Co., precoated, 0.5 mm) in hexane and distilled at 80 °C (bath temperature) at 0.2 mmHg through a short-path distillation apparatus, and crystallized then recrystallized from hexane mp 52—53 °C; $[\alpha]_D^{22}$ +81.5 ±0.4° (*c* 1.277, hexane); IR (film) 743 cm^{-1}; NMR ($CDCl_3$) δ=0.81 (s, 3H), 1.0—1.9 (m, 10H), 2.51 (br, s, 3H), 7.05 (s, 4H). Found: C, 89.99; H, 10.02%. Calcd for $C_{15}H_{20}$: C, 89.94; H, 10.06%.

*(2*R, *3*R*)-(−)-2,3-Dimethyl-4-phenyl-4-oxobutanoic Acid, (−)-**27**.* Mp 88—89 °C; $[\alpha]_D^{25}$ −1.22 ±0.20°, $[\alpha]_{365}^{25}$ −107.2 ±0.5° (*c* 2.035, MeOH).

*(2*R, *3*S*)-(−)-2,3-Dimethyl-4-phenylbutanoic Acid, (−)-**28**.* Bp 145 °C at 1.5 mmHg. $[\alpha]^{25}$ −28.8 ±0.4° (*c* 1.510, MeOH).

*(2*S, *3*S*)-(+)-2,3-Dimethyl-1,2,3,4-tetrahydro-1-naphthalenone, (+)-**29**.* Mp 34—36 °C; $[\alpha]^{25}$ +49.6 ±0.3° (*c* 2.353, hexane).

*(2*S, *3*S*)-(+)-2,3-Dimethyl-1,2,3,4-tetrahydronaphthalene, (+)-**30**.* The product was crystallized from hexane with cooling in a Dry Ice–acetone bath. The crystals were collected at that temperature. The crystals were recrystallized by the same method and then distilled, $[\alpha]_D^{25}$ +103.9 ±0.9° (*c* 1.139, hexane). The NMR spectrum did not show the signal attributable to *meso*-2,3-dimethyl-1,2,3,4-tetrahydronaphthalene.

*(+)-ω-Camphanic Ester of (1*R, *2*S*)-2-Methyl-1,2,3,4-tetrahydro-1-naphthol, (+)-**31**.* The (+)-alcohol (**32**) was treated according to the procedure cited for **4**. The ester was recrystallized five times from methanol; mp 128.5—129.5 °C; $[\alpha]_D^{25}$ +31.0 ±0.6° (*c* 1.020, $CHCl_3$); IR (Nujol) 1789, 1737 cm^{-1}; NMR ($CDCl_3$) δ=0.95 (s, 3H), 1.04 (d, *J*=6 Hz, 3H), 1.06 (s, 3H), 1.09 (s, 3H), 1.5—3.0 (m, 9H), 5.94 (d, *J*=6 Hz, 1H), 7.18 (s, 4H). Found: C, 73.40; H, 7.65%. Calcd for $C_{21}H_{26}O_4$: C, 73.66; H, 7.65%.

*(1*R, *2*S*)-(−)-2-Methyl-1,2,3,4-tetrahydro-1-naphthol, (−)-**32**.* Mp 55—56 °C; $[\alpha]_D^{24}$ −92.9 ±0.7° (*c* 1.375, benzene); (lit,[7] −91.6); CD 274.5 nm ($\Delta\varepsilon$ −0.030), 269 (−0.055), 261.5 (−0.045), 205! (−2.85).

*(2*S*)-(−)-2-Methyl-1,2,3,4-tetrahydronaphthalene, (−)-**33**.* $[\alpha]_D^{25}$ −103.4 ±1.3° (*c* 1.281, dioxan).

We thank Dr. Eiji Osawa and Dr. Masumi Yamakawa for allowing us to use a program of MMI and Mr. Tatsuo Iwata for assistance in performing the CD measurements.

Synthesis of 3-Acylfurans Using 3-(Phenylthio)propanal Dimethyl Acetal as a New Synthon. Syntheses of Ipomeanine and Isoegomaketone

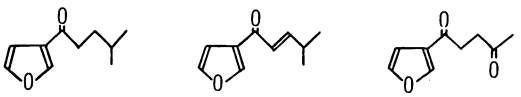
Eiji WATANABE, Naohiro IMAI, Katsuhiko INOMATA, Hideki KINOSHITA,* and Hiroshi KOTAKE
Department of Chemistry, Faculty of Science, Kanazawa University, Kanazawa 920
(Received February 25, 1982)

It was found that 3-(phenylthio)propanal dimethyl acetal is a very useful starting material for the preparation of 3-acylfuranoterpenes. Syntheses of two naturally-occurring furans, isoegomaketone and ipomeanine were described.

In the past, a large number of 3-acylfurans have been found in nature.[1] A few methods of their syntheses have been reported[2] except those starting from 3-furyl type synthons,[3] however, a convenient and effective method of 3-acylfurans have not been reported yet.

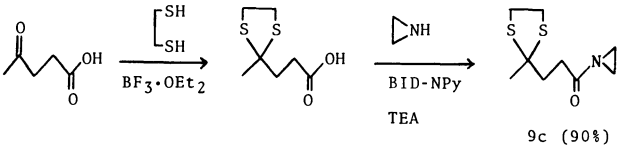
In the previous paper,[4] it has been reported that the readily available 3-(phenylthio)propanal ethylene acetal (**2**) was proved to be very useful starting material for the preparation of 3-acylfurans. Syntheses of some 3-acylfurans were exemplified and one of naturally-occurring furanoterpenes, perillaketone (**1**) was synthesized in good yield starting from compound **2**.

In order to demonstrate more usefulness of this new method, its application to synthesis of more complex naturally-occurring furanoterpenes was investigated. The target compounds selected are isoegomaketone (**12b**) originally isolated from *Perilla furutescens* Brit.[5] and ipomeanine (**13**) which was produced by cerato-stomella.[6] In this paper, the syntheses of both furanoterpenes **12b** and **13** are described.



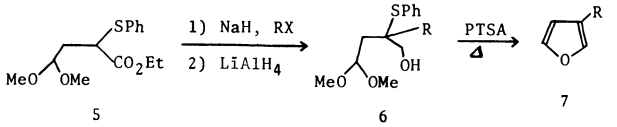
1 12b 13

The synthesis of ipomeanine (**13**) was examined according to Scheme 1. Acylation of compound **2** was performed by treatment of a lithiated **2** with acylaziridine **9c** at −78 °C to afford the desired product **3** in 65% yield. Compound **9c** was prepared by the reaction of commercially available levulinic acid with 1.2 equivalent of 1,2-ethanedithiol in the presence of boron trifluoride etherate followed by condensation reaction of the thiacetalized acid obtained with aziridine by 3-(5-nitro-2-oxo-1,2-dihydro-1-pyridyl)-1,2-benziso-thiazole 1,1-dioxide (BID-NPy)[7] in good yield as shown in the following scheme.

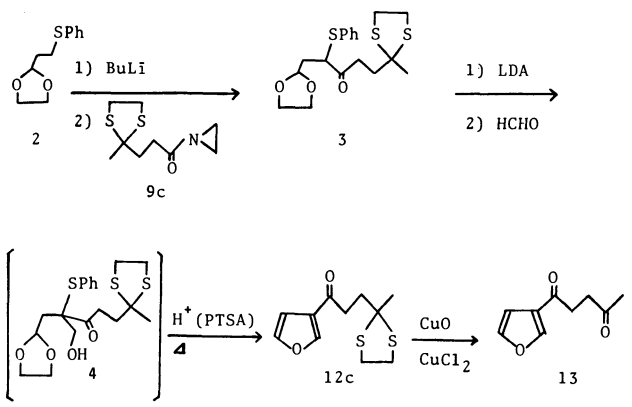


The 3-acyl-3-(phenylthio)propanal ethylene acetal **3** was treated with an equimolar amount of lithium diisopropylamide (LDA) in THF at −50 °C to room temperature followed by the passing of a large excess of gaseous formaldehyde into the reaction solution at room temperature. The resulting crude keto alcohol **4** was refluxed in benzene in the presence of a catalytic amount of *p*-toluenesulfonic acid (PTSA) for a couple of hours to give the desired product **12c** in only poor yield (36% based on **3**). All attempts to improve the yield of conversion of compound **4** to the furan derivative **12c** under various conditions were unsuccessful. The thioacetal group of **12c** was deprotected by treatment with $CuCl_2$ and CuO in refluxing wet acetone[8] to give the final product, ipomeanine, 1-(3-furyl)-1,4-pentanedione (**13**) in 89% yield.

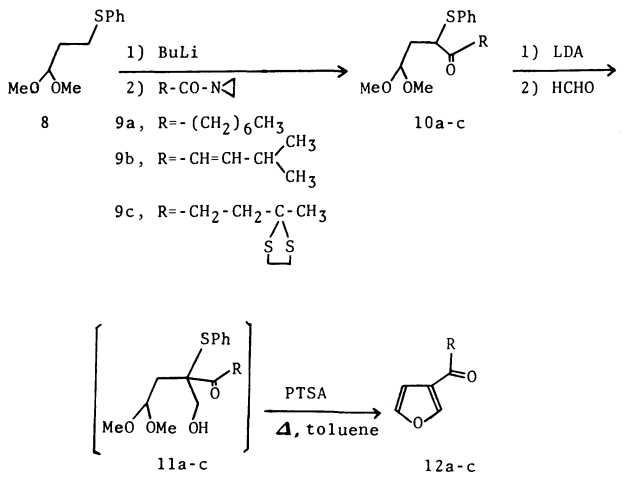
Previously, we had reported that treatment of 2-alkyl-4,4-dimethoxy-2-phenylthio-1-butanol (**6**) easily derived from ethyl 4,4-dimethoxy-2-(phenylthio)butyrate (**5**), with PTSA in refluxing benzene gave 3-alkyl-furan (**7**)[9] in excellent yield as shown below. These findings



suggested that compound **6** was a more favorable starting material for the cyclization to furan ring. From this fact, we have thought that 3-(phenylthio)-propanal dimethyl acetal (**8**) was more effective synthon for the preparation of 3-acylfurans than compound **2** (Scheme 2). The starting material **8** was prepared by the reaction of 3-(phenylthio)propanal, which was easily obtained from equimolar quantities of acrylaldehyde and benzenethiol at 0 °C and used without further purification, with trimethyl orthoformate (1.1



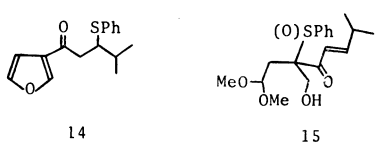
Scheme 1.



Scheme 2.

equiv.) in dry methanol in 85% yield. First of all, as a model experiment synthesis of 3-octanoylfuran (**12a**) was undertaken. Compound **8** was allowed to react with 1.1 equivalent of BuLi in THF at −78 °C followed by treatment with 1-octanoylaziridine (**9a**) to give the expected acyl compound **10a** in 64% yield. Compound **10a** was lithiated with 1.2 equivalent of LDA at −78 °C in THF followed by reaction with a large excess of formaldehyde to give the corresponding hydroxymethyl derivative **11a**, which was refluxed in toluene for 50 min in the presence of 6 mol percent of PTSA. The desired 3-octanoylfuran (**12a**) was obtained in 67% yield from **10a**. Many attempts to improve the yield of **12a** from **11a** were examined under various conditions. Subsequently, successive removal of the methanol formed *in situ* using Soxhlet's extractor where a large amount of boric acid was placed gave an outstanding result. Namely, the yield of **12a** was raised up to 84% yield under the same reaction conditions as used before. This good result prompted us to employ compound **8** as the starting material for the preparation of more complex furanoterpenes such as **12b** and **13**.

In a manner similar to the preparation of **12a**, treatment of **9b**—**c** gave the corresponding 3-acylfurans **10b**—**c** in 65% and 67% yields, respectively. Next, they were allowed to react with LDA at −78 °C and treated with formaldehyde as mentioned above to give the desired products **11b**—**c**. The resulting crude **11c** was transformed into the protected 3-acylfuran **12c** in 63% yield based on **10c**. This yield was greately raised compared with the result starting from compound **3**. Compound **12c** was converted to ipomeanine **13** according to the procedure as shown before.



14 15

Similarly, when the crude material **11b** was refluxed in toluene including a small amount of PTSA, the reaction was accompanied by formation of 3-[4-methyl-3-(phenylthio)pentanoyl]furan (**14**) as by-product besides **12b**. In order to solve this problem, compound **11b** was converted into sulfoxide **15** with *m*-chloroperbenzoic acid, which was treated with PTSA in refluxing toluene. Unfortunately, the desired product was only produced in an unsatisfactory yield from **10b**. Next, the crude **11b** was refluxed for 17 min in toluene in the presence of 1.5 equivalent of iodine to oxidize the benzenethiol liberated in the reaction to the disulfide, 6 mol percent of PTSA, and boric acid. Eventually, isoegomaketone, 1-(3-furyl)-4-methyl-2-penten-1-one (**12b**) was obtained in 62% yield based on **10b**.

As mentioned above, it is evident that 3-(phenylthio)-propanal dimethyl acetal (**8**) is synthetically versatile starting material for more complex 3-acylfurans.

Experimental

The NMR spectra were recorded on a JEOL/MH-60, and a JEOL/PMX-60. The chemical shifts are reported on the δ scale relative to TMS as an internal standard. The IR spectra were measured with a JASCO IRA-1 diffraction grating infrared spectrometer.

Materials. All the solvents were distilled according to the usual methods and stored over a drying agent. Thin-layer chromatography (TLC) was performed on Merck's Silica gel 60 PF_{254} (Type 7749).

*Preparation of Acylaziridine Derivatives (**9a**—**c**).* *1-[4,4-(Ethylenedithio)pentanoyl]aziridine (**9c**)*: To a solution of BID-NPy (610 mg, 2 mmol) and 4,4-(ethylenedithio)-pentanoic acid (384 mg, 2 mmol)[10] in dry CH_2Cl_2 (5 ml) was added a solution of triethylamine (TEA) (222 mg, 2.2 mmol) in dry CH_2Cl_2 (5 ml) at 0 °C under N_2. The reaction mixture was stirred for 1.5 h at 0 °C and a solution of aziridine (220 mg, 2 mmol) in dry CH_2Cl_2 (5 ml) was added to the above solution at 0 °C. The reaction mixture was warmed to room temperature, stirred for 30 min, and treated with 10%-$NaHCO_3$ (10 ml). The mixture was extracted with ether several times and the combined extracts were washed with brine, dried over Na_2SO_4, concentrated *in vacuo* to give a residue which was subjected to preparative TLC (solvent; AcOEt: hexane=1 : 5 v/v). Compound **9c** was obtained in 90% yield as an oily product (365 mg); IR (neat) 1689, 1143, 1117, 1088 cm^{-1}; NMR ($CDCl_3$) δ 1.80 (s, 3H), 2.11—2.38 (m, 2H), 2.60—2.85 (m, 2H), 2.24 (s, 4H), 3.33 (s, 4H).

Other 1-acylaziridine compounds **9a**—**b** were obtained from aziridine and the corresponding acyl chlorides in 69% and 58% yields, respectively.

9a: Oil IR (neat) 1693, 1373, 1145, 996 cm^{-1}; NMR ($CDCl_3$) δ 0.86 (t, 3H, J=6.6 Hz), 1.03—2.00 (m, 10H), 2.17 (s, 4H), 2.41 (t, 2H, J=7.0 Hz).

9b: Oil bp 55—65 °C/0.4 Torr); IR (neat) 1670, 1630, 1107, 973 cm^{-1}; NMR ($CDCl_3$) δ 1.06 (d, 6H, J=6.0 Hz), 2.25 (s, 4H), 2.08—2.81 (m, 1H), 5.96 (dd, 1H, J=2.0, 16.0 Hz), 7.00 (dd, 1H, J=6.0, 16.0 Hz).

*7,7-Ethylenedithio-4-oxo-3-(phenylthio)octanal Dimethyl Acetal (**3**).* To a solution of **2** (344 mg, 1.64 mmol) in dry tetrahydrofuran (THF) (5 ml) was added 1.1 equiv. of BuLi at −78 °C under N_2. The solution was warmed from −78 °C to −20 °C in a period of 2 h and cooled down at −78 °C again. A solution of **9c** (364 mg, 1.80 mmol) in dry THF (5 ml) was added to it at −78 °C and the reaction mixture was gradually warmed to room temperature and allowed to stand overnight. After quenching with buffer solution of pH 7 and 1 M-HCl, the resulting solution was extracted with ether. The organic layer was dried over Na_2SO_4 and evaporated *in vacuo* to give a residual oil. Purification with preparative TLC in which development was repeated twice with solvent system of

benzene–hexane–EtOAc (5 : 5 : 1 v/v) gave the desired product in 65% yield (oil, 408 mg): IR (neat) 1702, 1580, 1130, 1012 cm^{-1}; NMR ($CDCl_3$) δ 1.70 (s, 3H), 1.92—2,33 (m, 4H), 2.58—3.07 (m, 2H), 3.23 (s, 4H), 3.63—4.00 (m, 5H), 4.93 (t, 1H, J=7.0 Hz), 7.03—7.50 (m, 5H).

*3-(Phenylthio)propanal Dimethyl Acetal (**8**).* A mixture of acryladehyde (5.482 g, 88.1 mmol) and benzenethiol (8.833 g, 80.3 mmol) was stirred for 2 h at 0 °C. The reaction mixture was diluted with dry methanol (30 ml). A solution of trimethyl orthoformate (9.359 g, 88.3 mmol) in dry methanol (10 ml) and a small amount of PTSA were added to it. The reaction solution was stirred for 2 h, treated with solid $NaHCO_3$, evaporated under reduced pressure to give a residue which was taken up into ether. The ether solution was washed with brine, dried over Na_2SO_4, and concentrated *in vacuo*. Distillation of the residual oil gave pure product as an oily material. Yield, 15.88 g (85%): Bp 89—91 °C/0.3 Torr. IR (neat) 1566, 1112, 869, 734 cm^{-1}; NMR ($CDCl_3$) δ 1.87 (m, 2H), 2.93 (q, 2H, J=5.8, 8.6 Hz), 3.28 s, (6H), 4.46 (t, 1H, J=5.8 Hz), 7.09—7.33 (m, 5H).

*Preparation of 3-Acyl-3-(phenylthio)propanal Dimethyl Acetal Derivatives (**10a—c**).* To a solution of **8** (157 mg, 0.74 mmol) in dry THF (5 ml) was added 1.1 equiv. of BuLi at −78 °C under N_2. The reaction solution was gradually warmed to room temperature and cooled down at −78 °C again. A solution of **9** (150 mg, 0.89 mmol) in dry THF (4 ml) was slowly added to it. The reaction mixture was kept at −78 °C for 2 h, warmed to room temperature, and quenched with buffer solution of pH 7 and 1 M-HCl. The resulting mixture was extracted with ether. The combined ether extracts were dried over Na_2SO_4. After removal of the solvent a residual oil was purified by TLC using hexane–ether (6 : 1 v/v) as solvent to give pure product **10a** in 68% yield (oil). IR (neat) 1700, 1580, 1120, 1065 cm^{-1}; NMR ($CDCl_3$) δ 1.73 (s, 3H), 1.94—2.33 (m, 4H), 2.73—3.03 (m, 2H), 3.27 (s, 4H), 3.30 (s, 6H), 3.78 (t, 1H, J=7.2 Hz), 4.46 (t, 1H, J=5.4 Hz), 7.16—7.42 (m, 5H).

In the same procedure as the preparation of **10a**, compounds **10b—c** were obtained from compound **8** and the corresponding 1-acylaziridines **9b—c** in 65% and 67% yields, respectively.

10b: Oil, IR (neat) 1680, 1655, 1618, 1118, 1070, 1048 cm^{-1}; NMR ($CDCl_3$) δ 1.05 (d, 6H, J=7.0 Hz), 1.67—2.78 (m, 2H), 2.31 (s, 3H), 3.34 (s, 3H), 3.93 (t, 6H, J=6.0 Hz), 4.55 (t, 1H, J=6.0 Hz), 6.36 (d, 1H, J=16.0 Hz), 6.90 (dd, 1H, J=6.0, 16.0 Hz), 7.26—7.63 (m, 5H).

10c: Oil, IR (neat) 1700, 1580, 1120, 1065 cm^{-1}; NMR ($CDCl_3$) δ 1.73 (s, 3H), 1.94—2.33 (m, 4H), 2.73—3.03 (m, 2H), 3.27 (s, 4H), 3.30 (s, 6H), 3.78 (t, 1H, J=7.2 Hz), 4.46 (t, 1H, J=5.4 Hz), 7.12—7.42 (m, 5H).

*Preparation of 3-Acyl-3-hydroxymethyl Derivatives (**11a—c**).* To a solution of 1.2 equiv. of LDA in dry THF (4 ml) was added slowly a solution of **10a** (172 mg, 0.51 mmol) in dry THF (4 ml) at −78 °C under N_2. The reaction solution was gradually warmed to room temperature in a period of about 3 h. A solution of formaldehyde in THF (20 ml) where it was generated from 25 equiv. of paraformaldehyde by heating and absorbed in dry THF containing molecular sieves, was added in one portion to the solution at room temperature. The solution was allowed to stand overnight and the insoluble materials were filtered off. The filtrate was treated with buffer solution of pH 7 and 1 M-HCl, and extracted with ether. The organic layer was washed with brine, dried over Na_2SO_4, and concentrated in vacuo to give a crude **11a** (197 mg). It was used in the subsequent reaction without further purification.

Crude compounds **11b—c** were obtained in the same way as described for the preparation of **11a**.

*1-(3-Furyl)-1-octanone (**12a**).* A solution of the crude material **11a** (197 mg) obtained above in dry toluene (30 ml) was added in one portion under N_2 to a flask containing PTSA (5.2 mg, 6 mol percent), equipped with a Soxhlet's extractor where 6 g of boric acid were placed. The toluene solution was refluxed for 45 min, then cooled down with a cold-bath, treated with 5 ml of 10%-$NaHCO_3$, and extracted with ether. The organic layer was dried over Na_2SO_4 and concentrated under reduced pressure. A crude residue was subjected to preparative TLC (hexane–ether=4 : 1 v/v) to give the desired furan in 84% yield based on **10a** (65 mg, oil). IR (neat) 3125, 1650, 1150, 869 cm^{-1}; NMR ($CDCl_3$) δ 0.90 (t, 3H, J=6.0 Hz), 0.77—1.82 (m, 10H), 2.70 (t, 3H, J=7.6 Hz), 6.75 (m, 1H), 7.40 (m, 1H), 7.96 (m, 1H).

*Isoegomaketone (**12b**).* Compound **12b** was obtained in 62% yield based on **10b** from a crude material **11b** in the presence of 1.5 equiv. of iodine in a manner silmiar to the preparation of **12a**. A crude product was purified by preparative TLC using hexane–benzene–AcOEt–ether (7 : 1 : 1 : 1 v/v) as solvent. Its IR and NMR spectra were in accord with the reported values.[3c] IR (neat) 3140, 1660, 1610, 1147, 865 cm^{-1}; NMR ($CDCl_3$) δ 1.10 (d, 6H, J=7.0 Hz), 2.13—2.70 (m, 1H), 6.40 (d, 1H, J=16.0 Hz), 6.67—7.00 (m, 2H), 7.35 (m, 1H), 7.98 (m, 1H).

*3-[4,4-(Ethylenedithio) pentanoyl]furan (**12c**).* *Method A*: The desired product was prepared in 63% yield based on **10c** from a crude material **11c** in the same manner as described for the preparation of **12a** (15 mol percent of PTSA, reflux for 1 h). IR (neat) 3130, 1559, 1306, 865 cm^{-1}; NMR ($CDCl_3$) δ 1.79 (s, 3H), 2.00—2.46 (m, 2H), 2.89—3.27 (m, 2H), 3.30 (s, 4H), 6.70 (m, 1H), 7.19—7.38 (m, 1H), 7.89 (m, 1H).

Method B: A crude material **4** which was prepared from **3** in the same way as described for the preparation of **11c** was dissolved in 20 ml of dry toluene and refluxed for 30 min in the presence of PTSA (4 mg) under N_2. The reaction mixture was neutralized with $NaHCO_3$, washed with brine, and extracted with ether. The combined extracts were dried over Na_2SO_4 and concentrated *in vacuo* to give a crude product, which was purified by preparative TLC (36 mg, 25%).

*Ipomeanine (**13**).* A solution of **12c** (31 mg, 0.128 mmol) in 99%-acetone (15 ml) was refluxed for 1 h in the presence of $CuCl_2 \cdot 2H_2O$ (46 mg, 0.27 mmol) and CuO (43 mg, 0.54 mmol). An insoluble material was filtered off and the filtrate was concentrated under reduced pressure to give a residue. The residual oil was purified by preparative TLC using ether–hexane (1 : 4 v/v) as solvent to afford compound **13** in 89% yield (23 mg). IR (neat) 1714, 1668, 1561, 1149, 866 cm^{-1}; NMR ($CDCl_3$) δ 2.20 (s, 3H), 2.67—3.61 (m, 4H), 6.74 (m, 1H), 7.43 (m, 1H), 8.05 (m, 1H).

The 2,4-dinitrophenylhydrazone was prepared as a red crystalline material, mp 231—233 °C (lit, mp 231—234 °C).[6]

Vinyl Polymerization. 411. Experimental Supports for the Concept of Hard and Soft Hydrophobic Areas and Monomers in the So-called Uncatalyzed Polymerization

Tatsuro Ouchi,* Masaya Inaba, and Minoru Imoto
Department of Applied Chemistry, Faculty of Engineering, Kansai University, Senriyama, Suita, Osaka 564
(Received February 27, 1982)

We have proposed a concept of hard and soft hydrophobic areas (HA) and monomers. In order to verify such a concept, two series of experiments were carried out. Poly(styrene-alt-disodium maleate) (**1**) and poly(styrene-alt-sodium methyl maleate) (**2**) were used as initiating macromolecules for the copolymerizations of styrene/methyl methacrylate (MMA) and acrylonitrile/MMA. When **1** was used, MMA was more easily polymerized than styrene. Inversely, when **2** was used, styrene was more easily polymerized than MMA. Poly(styrene-co-sodium acrylate) (**3**) substances with various compositions were used as intiators for the copolymerizations. The produced copolymers of MMA and styrene were found to have a larger content of MMA as the mole ratio of acrylate in **3** became higher. Inversely, the produced copolymers of MMA and acrylonitrile had a larger content of acrylonitrile as the mole ratio of acrylate became higher. Those results could be reasonably explained by the concept of hard and soft hydrophobic areas and monomers.

Macromolecules having a hydrophilic group, such as starch, cellulose, polyamide and enzyme, can initiate the radical polymerization of vinyl monomers in water without any ordinary radical initiator. Such a simple and novel polymerization has been called an "uncatalyzed polymerization."[1-3] It has been clarified that the polymerization proceeds as follows: (i) the macromolecules form the hydophobic areas (HA) in a water phase, (ii) the vinyl monomer dissolves in the water phase and then is incorporated into HA, and (iii) in the HA, a radical polymerization proceeds.

Needless to say, the hydrophobicities of HA and monomers differ from each other. We called the more HA and hydrophobic monomers "hard," and the less HA and hydrophilic monomers "soft." The orders of hardness and softness of HA and monomers are expressed by Fig. 1.[2,4]

We have proposed "a concept of hard and soft HA and monomer," which means that the hard HA prefers to incorporate the hard monomer, while the soft HA prefers to incorporate the soft monomers.[2] This concept has been verified experimentally in several papers[2,4] by two methods, *i.e.*, by the coplymerization of styrene with methyl methacrylate (MMA) and by the selectivity of the monomer initiated with copolymers having different hydrophobicities.[5]

The present paper deals with the polymerizations of styrene, MMA, and acrylonitrile initiated by the water-soluble poly(styrene-alt-disodium maleate) (Copolymer **1**) or poly(styrene-alt-sodium methyl maleate) (Copolymer **2**), and with the copolymerizations of styrene with MMA and of MMA with acrylonitrile initiated with poly(styrene-co-sodium acrylate) (Copolymer **3**) substances with different compositions.

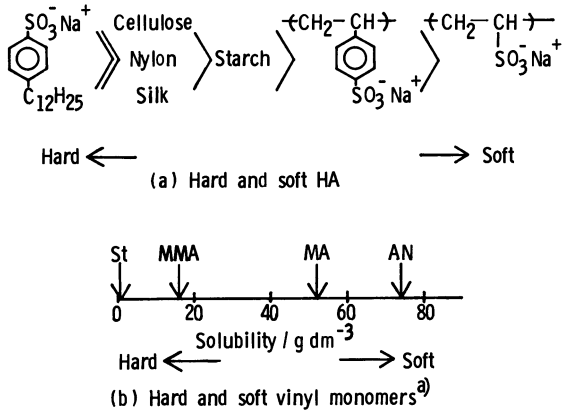

Fig. 1. Hard and soft HA and monomers.
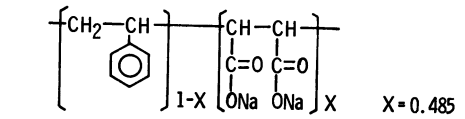
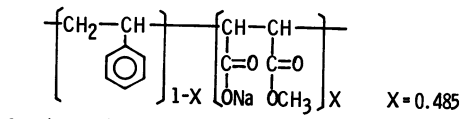
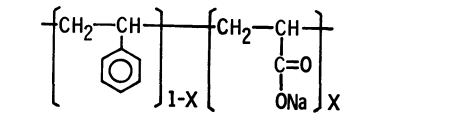
St: Styrene, MMA: methyl methacrylate, MA: methyl acrylate, AN: acrylonitrile. a) The numbers indicate the solubilities into water at 20 °C.



Copolymer 1, poly(styrene-alt-disodium maleate)



Copolymer 2, poly(styrene-alt-sodium methyl maleate)



Copolymer 3, poly(styrene-co-sodium acrylate)

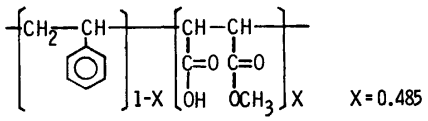
Experimental

Materials. The monomers were purified by the usual methods and distilled under a vacuum before use. Ion-exchanged and distilled water was used as the solvent.

Preparation of Poly(styrene-alt-disodium maleate) (Copolymer 1). Five cm^3 (43.3 mmol) of styrene and 4.25 g (43.3 mmol) of maleic anhydride (Manh) were dissolved in 5 cm^3 of benzene and then placed in a tube. The tube was sealed after thawing with nitrogen and heated at 60 °C for 100 h. After the reaction, the contents were poured into large amounts of hexane to precipitate the copolymer. The copolymer was twice

reprecipitated from acetone and benzene/hexane (1 : 2 by vol.). The yield was 99%. The mole fraction of Manh in the copolymer was determined by elemental analysis to be 0.485. Accordingly, the copolymer was mostly alternative. The molecular weight of the obtained poly(styrene-alt-Manh) was measured by the vapor-pressure osmometric method and found to be 1.79×10^4 in acetone at 37 °C. This copolymer was neutralized with calculated amount of a 1 mol dm^{-3} NaOH solution up to pH 10 and then freeze-dried.

Preparation of Poly(styrene-alt-sodium methyl maleate) (Copolymer 2). The poly(styrene-alt-Manh) described above was refluxed in dried methanol for 50 h and then poured into large amounts of water to precipitate the copolymer. By elemental analysis, the copolymer was found to be a monoester with the structure shown below. This acidic copolymer was changed into its sodium salt by neutralization with a 1 mol dm^{-3} NaOH solution at pH 10 and then freeze-dried.



Poly(styrene-co-sodium acrylate) (Copolymer 3). Four kinds of Copolymer **3** (x=0.291, 0.537, 0.698, 0.782) and poly (sodium acrylate) (x=1.00) were prepared and purified by the method reported in a previous paper.[5] Here, x means the mole fraction of the sodium acrylate unit in Copolymer **3**.

Copolymers **1**, **2** and **3** were confirmed by the KI or ESR method to contain no peroxide moiety nor free radical.

Procedures of Polymerization. The vinyl monomers, Copolymer **1**, **2**, or **3** and water were placed in a tube. The tube was sealed under a vacuum after thawing with nitrogen and then incubated at 85 °C with or without shaking. After a certain time, the contents of the tube were poured into a large amount of methanol in order to precipitate the polymer produced. The conversion of the monomer was calculated from the weight of the polymer.

Results and Discussion

Polymerization of Vinyl Monomers Initiated by the Copolymer 1 or 2. An aqueous solution of Copolymer **1** or **2** was shaken with styrene, MMA, or acrylonitrile at 85 °C for 3 h. The results obtained are listed in Table 1.

The HA formed by Copolymer **1** is softer than the HA formed by Copolymer **2**; the hardness of the monomer is in order of: styrene>MMA>acrylonitrile. Accordingly, styrene was more easily incorporated in the HA formed by Copolymer **2** than in that formed by Copolymer **1** and more easily polymerized by Copolymer **2** than by Copolymer **1**, but MMA was, inversely, more easily polymerized by Copolymer **1** than by Copolymer **2**. Acrylonitrile is too soft to be easily incorporated into either Copolymer **1** or **2**.

Table 1. Polymerization of vinyl monomers with the copolymer 1 or 2[a]

Copolymer	Conversion[b]/%		
	Styrene	MMA	Acrylonitrile
1	3.30	5.59	0.14
2	5.44	5.04	0

a) Monomer, 3 cm^3; copolymer, 0.03 g; H_2O 10 cm; 85 °C; 3 h; with shaking. b) Each conversion contains the thermal conversion.

Copolymerization of MMA with Styrene or Acrylonitrile by Copolymer 3. The copolymerizations of MMA with styrene or acrylonitrile initiated by Copolymer **3** with various compositions were carried out.

The HA formed by Copolymer **3** having a higher x fraction are softer than those formed by Copolymer **3** having a lower x fraction.

First, a mixture of styrene and MMA and an aqueous solution of Copolymer **3** was allowed to stand at 85 °C for 3 h. The copolymers produced from the upper monomer layer and the lower aqueous layer were

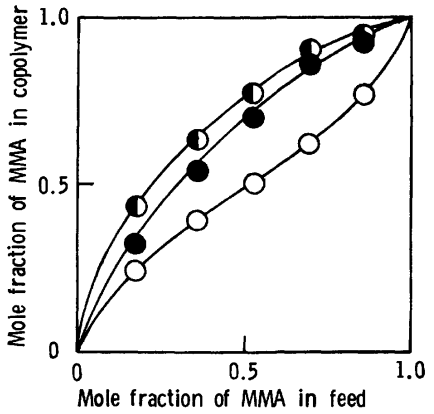


Fig. 2. Composition curves in the copolymerization of styrene and MMA on standing.

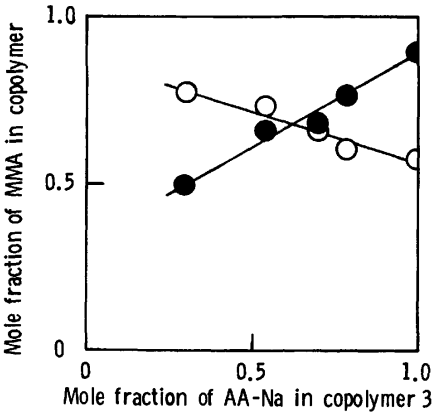

Fig. 3. Effects of the mole fraction of AA-Na in Copolymer **3** on the composition of copolymer produced in the water layer. Copolymer **3**, 0.03 g; H_2O, 10 cm^3; 85 °C; 8 h; on standing.
●: MMA, 1.5 cm^3; styrene, 1.5 cm^3 (mole ratio of MMA: styrene =0.48 : 0.52). ●: MMA, 1.5 cm^3; acrylonitrile, 1.5 cm^3 (mole ratio of acrylonitrile: MMA =0.38 : 0.62).

isolated separately. The conversions of the monomer mixture in the water phase were controlled as to be lower than 2.2%. The composition curves are shown in Fig. 2.

The curve of open circles indicates the composition curve of the copolymer produced in the monomer layer. Here, a usual thermal polymerization proceeds. Accordingly, the curve was very similar to that of an ordinary radical-copolymerization curve.

The black and half-black circles in Fig. 2 indicate the results obtained by Copolymer **3** having x values of 0.53 and 0.78 respectively. The latter copolymer forms a softer HA than the former copolymer. Accordingly, the copolymer of 0.78 of x is considered to incorporate MMA more easily than styrene. As is to be expected by the concept, the contents of MMA in the copolymer of MMA with styrene produced by Copolymer **3** of $x=0.78$ are larger than in those produced by Copolymer **3** of $x=0.53$.

A second support was given by the copolymerizations of MMA/styrene and MMA/acrylonitrile on standing, using Copolymers **3** with various compositions. The results obtained are shown in Fig. 3. In both copolymerizations, the mole ratios of the monomers in the feed were kept constant, while the composition of Copolymer **3** was varied. The abscissa of the figure indicates the x-value of Copolymer **3**. In the copolymerization of MMA and styrene, the curve shown by black circles was obtained. Clearly, the contents of MMA in the copolymer produced increased with the increase in the x-value.

Inversely, in the copolymerization of MMA and acrylonitrile, the contents of MMA in the copolymer produced decreased with the x-value.

These results can be explained by the difference in the incorporated amounts of the monomer into the HA formed by Copolymer **3** with various compositions. That is, they show the propriety of the concept of hard and soft HA and monomer.

Studies on 2-Aziridinecarboxylic Acid. VII.[1] Formation of Dehydroamino Acid Peptides *via* Isomerization of Peptides Containing 2-Aziridinecarboxylic Acid by Tertiary Amines

Kiichiro NAKAJIMA,* Hitomi ODA, and Kenji OKAWA
Department of Chemistry, Faculty of Science, Kwansei Gakuin University, Nishinomiya 662
(Received March 19, 1982)

Peptides containing 1-(α-aminoacyl)-2-aziridinecarboxylic acid were isomerized into the corresponding dehydroamino acid peptides by treatment with the tertiary amines, triethylamine or 1,4-diazabicyclo[2.2.2]octane (Dabco). Dehydrohydantoin derivatives were also prepared by treatment of benzyloxycarbonyl-2-aziridinecarboxylic acid derivatives with tertiary amines.

Recently many biologically active peptides containing dehydroamino acid (DHA) have been isolated and much attention has been directed to their synthesis. Literature concerning the synthesis of DHA peptides has mainly dealt with β-elimination of the O-leaving group of β-hydroxy α-amino acid derivatives,[2] and a more recent paper has reported Hofmann degradation reaction of 2,3-diaminopropionic acid derivatives.[3]

In the previous paper,[4] we reported the isomerization of peptides containing 2-aziridinecarboxylic acid (Azyline, Azy) and 3-methyl-2-aziridinecarboxylic acid (3-MeAzy) into the corresponding DHA peptides with NaI in an acetone solution. During our investigation on the reaction of Azy peptides with several amines, we found that they react with primary and secondary amines to form the corresponding amine adducts, α,β-diaminopropionic acid derivatives,[5] and the *trans*-acylation reaction occurs due to peptide bond cleavage.[5] Also, 1-acyl- and 1-(α-aminoacyl)-2-aziridinecarboxylic acid peptides are isomerized into the corresponding DHA peptides upon treatment with tertiary amines as in the reaction with NaI.

In the present study the reactions of Azy peptides with the tertiary amines, triethylamine and Dabco were observed in detail. The Azy and 3-MeAzy peptides used as the starting materials were synthesized by the mixed anhydride method from N-protected amino acid and Azy derivatives according to the procedure described

TABLE 1. YIELDS AND PROPERTIES OF AZY-PEPTIDES (**1**, **2**, **5**)

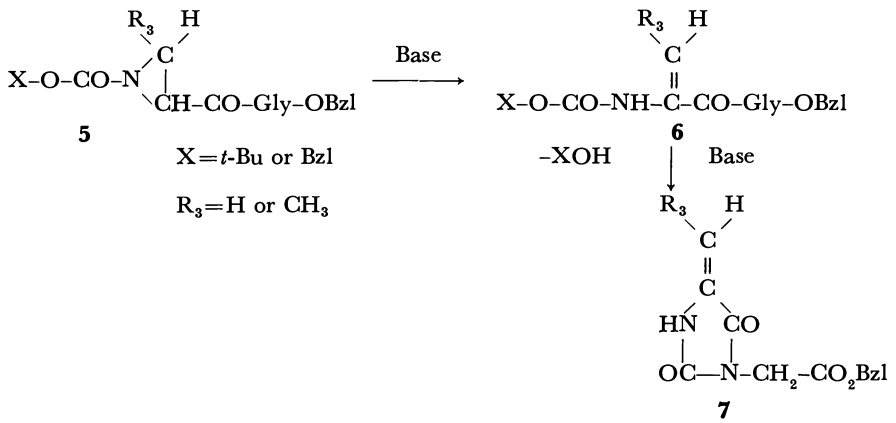
a) The reaction was carried out in a $CHCl_3$ solution at 35 °C and the base used was 2 equimolar against Azy peptide. The values in parenthesis are the reaction time/h. b) NMR spectrum in $CDCl_3$.



Scheme 2.

in our previous papers.[5-7)] Their properties and yields are summarized in Table 1 and the reaction procedure of the Azy peptides with amines is shown in Scheme 1.

Azy and 3-MeAzy peptides (**1a**—**f** and **2a**—**e**) were treated with 2 equimolar amount of tertiary amine (Et_3N or Dabco) in $CHCl_3$ solution at 35 °C for 3—24 h, and then the corresponding dehydroamino acid (DHA, ⊿AA) derivatives were isolated by silica-gel column chromatography. The DHA produced was identified by NMR.

In the NMR data, characteristic signals of the DHA structure appeared at δ 5.5—5.9 for the vinyl proton of dehydroalanine (⊿Ala), and at δ 1.4—1.7 as a doublet for the methyl proton and at δ 6.3—6.8 as a quartet for the β-proton of dehydro-α-aminobutyric acid (⊿Aba). ⊿Aba was of the (Z)-configuration. The product (**3**, **4**)

a) Reaction time/d.

of the isomerization of the Azy peptides are summarized in Table 2.

The reaction results show that 1-acyl-2-aziridinecarboxylic acid peptides (**1a**—**f**) were easily isomerized into the corresponding ⊿Ala peptides (**3a**—**f**) by the treatment of triethylamine, but contrary to our expectation, 1-acyl-3-methyl-2-aziridinecarboxylic acid peptides (**2a**—**e**) were not isomerized into the ⊿Aba peptides (**4a**—**e**), even after 7 d of treatment. Use of the more basic Dabco as an isomerizing reagent was necessary to obtaine ⊿Aba peptides (**4a**—**e**).

This isomerization reaction seems to be induced by a direct withdrawing of the α-proton of Azy or 3-MeAzy with base. The α-proton of unsubstituted Azy (**1a**—**f**) could be easily withdrawn by Et_3N treatment, but not that of the substituted 3-MeAzy (**2a**—**e**) because of the methyl group on the aziridine ring. Thus, the more basic Dabco was needed to withdraw the α-proton of 3-MeAzy for its isomerization.

We also examined the reaction of 1-benzyloxycarbonyl- and 1-*t*-butoxycarbonyl-2-aziridinecarboxylic acid peptides (**5a**—**d**) with amines. As shown in Scheme 2 and Table 3, the reaction of the Azy peptides blocked by urethane-type groups with tertiary amines afforeded not only the corresponding DHA peptides, but also dehydrohydantoin derivatives (**7a**, **7b**). Again, the 3-MeAzy peptides (**5c**, **5d**) were not isomerized with Et_3N and the benzyloxycarbonyl derivatives were more easily isomerized into the corresponding DHA peptides than the *t*-butoxycarbonyl peptides. The results of the dehydrohydantoin (**7**) formation reaction, which occurred *via* reaction of the DHA peptides produced by the reaction with tertiary amines, agreed very well with the results of the β-elimination reaction of O-activated Z-Ser- or Z-Thr- derivatives found by Campbell and Behr,[8)] us,[9)] and, Shin *et al.*[10)] Thus the benzyloxycarbonyl group of the aziridine is more labile than the *t*-butoxycarbonyl group in the basic conditions, that is, Z-Azy-Gly-OBzl (**5a**) and Z-3-MeAzy-Gly-OBzl (**5c**) isomerized more easily than Boc-Azy-Gly-OBzl (**5b**) and Boc-3-MeAzy-Gly-OBzl (**5d**) as shown in Table 3. The benzyloxycarbonyl group attached to the unsubstituted aziridinecarboxylic acid (**5a**) seemed to be very labile and Z-⊿Ala-Gly-OBzl could not be isolated after the reaction of **5a** with tertiary amine, even in Et_3N.

From the isomerization reaction of Azy and 3-MeAzy described above, it is concluded that Azy and 3-MeAzy has a distinctly different reactivity against tertiary amines and the isomerization by the tertiary amines, which can be used to the selective synthesis of DHA peptides, differs from that by NaI or the synthesis of DHA peptides *via* β-elimination of β-hydroxy α-amino acid.

Experimental

Uncorrected melting points are reported. The homogeneity of the products was checked by thin-layer chromatography on silica-gel plates. The optical rotations were determined at the D line on a Perkin-Elmer 141 polarimeter. The NMR spectra were obtained with a Hitachi R20B high-resolution NMR spectrometer, the chemical shifts being obtained using TMS as the internal reference. All the *N*-aminoacyl Azy and 3-MeAzy peptides used in this study were synthesized by the method described in literature,[6,7)] and their properties and yield are summarized in Table 1.

(2S)-Z-Azy-Gly-OBzl (5a). To a solution of (2*S*)-H-Azy-Gly-OBzl[11)] (1.63 g, 6.96 mmol) and Et_3N (0.97 ml, 6.96 mmol) in $CHCl_3$ (15 ml), was added Z-ON[1)] (1.95 g, 6.96 mmol) with stirring at 0 °C. After being stirred overnight at 25 °C, the solvent was removed *in vacuo* and the residue was dissolved in ethyl acetate. The ethyl acetate solution was washed with 10% citric acid, 1 M $NaHCO_3$ and water, and dried over Na_2SO_4, concentrated *in vacuo*. The residue was crystallized from ethyl acetate–hexane, 1.53 g (60%) of **5a** was obtained, mp 109—110 °C, $[\alpha]_D^{23}$ −50.6° (*c* 1.0, MeOH). NMR ($CDCl_3$) δ: 2.38 (1H q, J_{gem}=0.8 Hz, J_{trans}=3.5 Hz, Azy β-proton), 2.53 (1H q, J_{gem}=0.8 Hz, J_{cis}=6.3 Hz, Azy β-proton), 3.07 (1H q, J_{trans}=3.5 Hz, J_{cis}=6.3 Hz, Azy α-proton). Z-ON can be replaced with Z-Cl.[1)]

Found: C, 65.17; H, 5.50; N, 7.71%. Calcd for $C_{20}H_{20}O_5N_2$: C, 65.21; H, 5.47; N, 7.60%.

(2S)-Boc-Azy-Gly-OBzl (5b). To a solution of (2*S*)-H-Azy-Gly-OBzl[11)] (4.0 g, 17.1 mmol) and Et_3N (2.38 ml, 17.1 mmol) in $CHCl_3$ (50 ml), was added Boc-ON[1)] (4.63 g, 18.8 mmol) with stirring at 0 °C. After the reaction mixture had been worked up as described above, the product was crystallized from ethyl acetate–hexane, 3.51 g (61.3%) of **5b** was obtained. mp 71.0—72.5 °C, $[\alpha]_D^{23}$ −80.4° (*c* 1.0, MeOH). NMR ($CDCl_3$) δ: 2.30 (1H q, J_{gem}=0.8 Hz, J_{trans}=3.8 Hz, Azy β-proton), 2.49 (1H q, J_{gem}=0.8 Hz, J_{cis}=6.6 Hz, Azy β-proton), 3.03 (1H q, J_{trans}=3.8 Hz, J_{cis}=6.6 Hz, Azy α-proton).

Found: C, 61.22; H, 6.85; N, 8.35%. Calcd for $C_{17}H_{22}O_5N_2$: C, 61.07; H, 6.63; N, 8.34%.

(2S, 3S)-Z-3-MeAzy-Gly-OBzl (5c). To a solution of (2*S*, 3*S*)-H-3-MeAzy-Gly-OBzl[7)] (1.87 g, 7.54 mmol) and Et_3N (1.05 ml, 7.54 mmol) in $CHCl_3$ (15 ml), was added

Z–ON[1] (1.95 g, 7.54 mmol) with stirring at 0 °C. The reaction mixture was stirred overnight and worked up as described above. The product was crystallized from ethyl acetate–hexane, 2.10 g (72.8%) of **5c** was obtained, mp 62—64 °C, $[\alpha]_D^{23}$ −63.2° (*c* 1.0, MeOH). NMR ($CDCl_3$) δ: 1.28 (3H d, J=5.5 Hz, CH_3), 2.79 (1H m, 3-MeAzy, β-proton), 3.14 (1H d, J=7.0 Hz, 3-MeAzy, α-proton). Z–ON can be replaced with Z–Cl.

Found: C, 65.96; H, 5.83; N, 7.42%. Calcd for $C_{21}H_{22}O_5N_2$: C, 65.96; H, 5.80; N, 7.33%.

*(2S, 3S)-Boc-3-MeAzy-Gly-OBzl (**5d**).* To a solution of (2*S*, 3*S*)-H-3-MeAzy-Gly-OBzl[7] (1.25 g, 5.06 mmol) and Et_3N (0.70 ml, 5.06 mmol) in $CHCl_3$ (15 ml), was added Boc–ON[1] (1.40 g, 6.07 mmol) with stirring at 0 °C. The reaction mixture was stirred overnight and worked up as described above. The product was crystallized from ethyl acetate–hexane, 1.38 g (78.5%) of **5d** was obtained, mp 89.5—90.0 °C, $[\alpha]_D^{23}$ −70.0° (*c* 1.0, MeOH). NMR ($CDCl_3$) δ: 1.27 (3H d, J=5.5 Hz, CH_3), 2.74 (1H m, 3-MeAzy β-proton), 3.09 (1H d, J=6.4 Hz, 3-MeAzy α-proton).

Found: C, 62.21; H, 6.88; N, 8.01%. Calcd for $C_{18}H_{24}O_5N_2$: C, 62.06; H, 6.94; N, 8.04%.

*Z–Gly–ΔAla–NHBzl (**3b**). General Isomerization Procedure of Azy with Et_3N*: A solution of **1b** (100 mg, 0.27 mmol) and Et_3N (0.08 ml, 0.54 mmol) in $CHCl_3$ (5 ml) was stirred at 35 °C for 3 h. After the solvent had been removed *in vacuo*, the residue was dissolved in ethyl acetate. The ethyl acetate solution was washed with 10% citric acid and water, and then dried over Na_2SO_4, concentrated *in vacuo*. After the obtained residue was purified by the silica-gel column chromatography, the product was crystallized from $CHCl_3$–ether–hexane, 84.3 mg (84.3%) of **3b** was obtained, mp 117.5—118.5 °C.

*Z–Gly–ΔAba–Gly–OBzl (**4d**). General Isomerization Procedure of **3**-MeAzy with Dabco*: A solution of **2d** (200 mg, 0.45 mmol) and Dabco (102 mg, 0.91 mmol) in $CHCl_3$ (5 ml) was stirred at 35 °C for 24 h. After the reaction mixture had been worked up as described above, the residue was crystallized from ethyl acetate–hexane, 174 mg (87%) of **4d** was obtained, mp 101—102 °C [lit, mp 102—104 °C[4]].

*Benzyl 5-Methylenehydantoin-3-acetate (**7a**). Using Et_3N*: A solution of **5a** (200 mg, 0.54 mmol) snd Et_3N (0.15 ml, 1.09 mmol) in $CHCl_3$ (3 ml) was stirred at 35 °C for 12 h. After the reaction mixture had been worked up as described above, the residue was purified with silica-gel column chromatography and was crystallized from ethyl acetate–ether–hexane, 105 mg (75%) of **7a** was obtained, mp 171—172 °C. NMR ($CDCl_3$) δ: 4.32 (2H s), 4.92, (1H d, J=1.8 Hz), 5.15, 5.17 (4H 2s), 5.42 (1H d, J=1.8 Hz), 7.32 (5H s), 8.35 (1H bs).

Found: C, 60.05; H, 4.72; N, 10.72%. Calcd for $C_{13}H_{12}O_4N_2$: C, 59.99; H, 4.65; N, 10.77%.

*Z–ΔAla–Gly–OBzl (**6a**)* could not be prepared by this procedure.

Using Dabco: A solution of **5a** (200 mg, 0.54 mmol) and Dabco (121 mg, 1.08 mmol) in $CHCl_3$ (3 ml) was stirred at 35 °C for 6 h. After the reaction mixture had been worked up as described above, 112 mg (80%) of **7a** was obtained. **6a** could not be prepared.

*Boc–ΔAla–Gly–OBzl (**6b**). Using Et_3N*: A solution of **5b** (100 mg, 0.29 mmol) and Et_3N (0.08 ml, 0.58 mmol) in $CHCl_3$ (3 ml) was stirred at 35 °C for 24 h. After the reaction mixture had been worked up as described above, 95 mg (95%) of **6b** was obtained as an oily material. NMR ($CDCl_3$) δ: 1.48 (9H s), 4.12 (2H d, J=5.0 Hz) 5.15 (1H m) 5.18 (2H s), 6.00 (1H d, J=1.8 Hz), 6.78 (1H bt), 7.25 (1H bs), 7.32 (5H s).

Found: C, 61.15; H, 6.72; N, 8.28%. Calcd for $C_{17}H_{22}O_5N_2$: C, 61.07; H, 6.63; N, 8.34%. **7b** could not be prepared.

Using Dabco: A solution of **5b** (300 mg, 0.86 mmol) and Dabco (194 mg, 1.73 mmol) in $CHCl_3$ (5 ml) was stirred at 35 °C for 6 h. After the reaction mixture had been worked up as described above, 300 mg (100%) of **6b** was obtained as an oily material. **7b** could not be prepared.

*Z–ΔAba–Gly–OBzl (**6c**) and Benzyl 5-Ethylidenehydantoin-3-acetate (**7c**). Using Dabco*: A solution of **5c** (200 mg, 0.5 mmol) and Dabco (112 mg, 1 mmol) in $CHCl_3$ (3 ml) was stirred at 35 °C for 3 d. After the reaction mixture had been worked up as described above, the crude product of two components was subjected to silica-gel column chromatography developed by $CHCl_3$, yielding 136 mg (68%) of **6c**, mp 99—100 °C, and 38 mg (28%) of **7c**, mp 186—186.5 °C. **6c**: NMR ($CDCl_3$) δ: 1.70 (3H d, J=7.0 Hz), 4.16 (2H d, J=5.5 Hz), 5.12 (2H s), 5.20 (2H s), 6.52 (1H q, J=7.0 Hz), 6.76 (1H bs), 7.30 (10H s), 7.00 (1H bs), 7.15 (1H bs). **7c**: NMR ($CDCl_3$) δ: 1.83 (3H d, J=7.5 Hz), 4.35 (2H s), 5.19 (2H s), 5.98 (1H q. J=7.5 Hz), 7.32 (5H s), 9.05 (1H bs).

6c; Found: C, 66.02; H, 5.86; N, 7.23%. Calcd for $C_{21}H_{22}O_5N_2$: C, 65.96; H, 5.80; N, 7.33%.

7c; Found: C, 61.28; H, 5.20; N, 10.32%. Calcd for $C_{14}H_{14}O_4N_2$: C, 61.31; H, 5.15; N, 10.21%.

Using Et_3N: A solution of **5c** (200 mg, 0.5 mmol) and Et_3N (0.14 ml, 1 mmol) in $CHCl_3$ (3 ml) was stirred at 35 °C for 7 d. No reaction occurred and only **5c** was recovered.

*Boc–ΔAba–Gly–OBzl (**6d**). Using Dabco*: A solution of **5d** (200 mg, 0.57 mmol) and Dabco (128 mg, 1.14 mmol) in $CHCl_3$ (3 ml) was stirred at 35 °C for 4 d. After the reaction mixture had been worked up as described above, 170 mg (85%) of **6d** was obtained, mp 119.5—120.5 °C. NMR ($CDCl_3$) δ: 1.45 (9H s), 1.75 (3H d, J=7.0 Hz), 4.14 (2H d, J=5.5 Hz), 5.20 (2H s), 6.49 (1H q, J=7.0 Hz), 6.69 (1H bs), 7.34 (5H s), 7.28 (1H bs).

Found: C, 62.18; H, 6.81; N, 8.12%. Calcd for $C_{18}H_{24}O_5N_2$: C, 62.06; H, 6.94; N, 8.04%.

7d could not be prepared.

Using Et_3N: A solution of **5d** (100 mg, 0.29 mmol) and Et_3N (0.08 ml, 0.58 mmol) in $CHCl_3$ (3 ml) was stirred at 35 °C for 7 d. No reaction occurred and only **5d** was recovered.

Studies on 2-Aziridinecarboxylic Acid. VIII.[1] Total Synthesis of Actinomycin D and Its Serine Analogue *via* Ring-opening Reaction of 1-Benzyloxycarbonyl-2-aziridinecarboxylic Acid Moiety

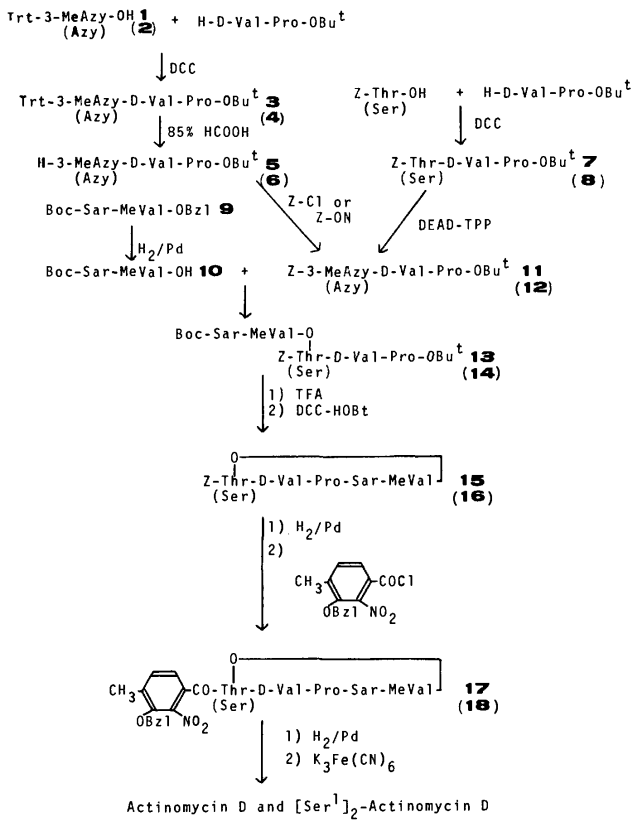
Kiichiro NAKAJIMA,* Takumi TANAKA, Masahiro NEYA, and Kenji OKAWA
Department of Chemistry, Faculty of Science, Kwansei Gakuin University, Nishinomiya 662
(Received April 16, 1982)

Direct synthesis of peptides containing 1-benzyloxycarbonyl-2-aziridinecarboxylic acid were carried out by the reaction of β-hydroxy-α-amino acid peptides with DEAD–TPP reagents, and key *O*-peptide intermediates of actinomycin D synthesis were prepared *via* a ring-opening reaction of the aziridine with *N*-protected dipeptide. Peptide lactone was prepared by the DCC–HOBt method, and the subsequent debenzyl procedure and oxydation procedure gave the title compounds in good yields.

In a previous paper,[2] we reported the synthesis of *O*-peptides *via* the ring-opening reaction of 1-aminoacyl-2-aziridinecarboxylic acid peptides with some carboxylic acids. We used this reaction for the total synthesis of actinomycin D,[3] but some problems remain with respect to the yield and the generality in the synthesis of the peptides containing 2-aziridinecarboxylic acid (Azy) and *O*-peptides.

This paper reports the direct synthesis of 1-benzyloxycarbonyl-Azy peptides from the corresponding serine and threonine peptides. By an application of the ring-opening reaction to the above Azy peptides, total synthesis of actinomycin D and its analogue were successfully carried out.

1-Benzyloxycarbonyl-Azy peptides are usually prepared from *N*-terminus-free Azy peptides derived from *N*-trityl-β-hydroxy-α-amino acid or peptides. But this rocedure requires many steps to obtain 1-benzyloxycarbonyl- or 1-*t*-butoxycarbonyl-Azy peptides.[4] Recently, A. K. Bose and co-workers reported[5] that the reaction of Z–Ser–$NHC_6H_4CH_3$ with diethyl azodicarboxylate (DEAD)-triphenylphosphin (TPP) reagents gave the β-lactam derivative in 53% yield, while the corresponding threonine derivative gave only the 3-methyl-2-aziridinecarboxylic acid (3-MeAzy) in 53% yield. We applied this DEAD–TPP procedure to synthesize Azy peptides, which are the significant intermediates in *O*-peptide synthesis.



Scheme 1.

The synthetic routes used in this study of actinomycin D and its analogue are summarized in Scheme 1. In the usual procedure, the key intermediate (2*S*,3*S*)-Z-3-MeAzy-D-Val-Pro-OBu^t (**11**) and (2*S*)-Z-Azy-D-Val-Pro-OBu^t (**12**) were prepared from the corresponding 1-trityl-3-MeAzy and 1-trityl-Azy-tripeptides (**3**, **4**). **3** and **4** were prepared by the coupling of (2*S*,3*S*)-Trt-3-MeAzy-OH (**1**) or (2*S*)-Trt-Azy-OH (**2**) with D-Val-Pro-OBu^t by the DCC method, followed by detritylation and 1-benzyloxycarbonylation with Z-Cl[1] or Z-ON[1] to obtain **11** and **12**. In the direct synthetic procedure of **11** and **12** by using DEAD–TPP procedure, the reactions of both Z–Thr (**7**) and Z–Ser tripeptide (**8**) with DEAD–TPP reagents gave only the corresponding **11** and **12** without any β-lactam in good yield (*ca.* 80%). The products of each procedure were completely identified. Next, we carried out the ester formation reaction between Boc–Sar–MeVal–OH (**10**) and **11** or **12** in CH_2Cl_2 solution at 50 °C for 7 d without boron trifluoride etherate, which had been necessary for the ring-opening reaction of 1-aminoacyl- or 1-benzoyl-Azy peptides.[2,3] The desired pentapeptide esters (**13**, **14**) were obtained in about 80% yields. After the *t*-butoxycarbonyl and *t*-butyl ester had been removed by treatment with trifluoroacetic acid, cyclization (2 mmol in 1 L THF, at 25 °C for 7 d) was carried out with the aid of DCC-HOBt[1] (10 mmol each) to obtain the cyclic pentapeptide lactones (**15**, **16**) in 66.2% (Thr) and 42.9% (Ser) yields. The benzyloxycarbonyl group of **15** and **16** was removed by catalytic hydrogenolysis. The reaction of the resulting N-terminus free pentapeptide lactones with 3-benzyloxy-4-methyl-2-nitrobenzoyl chloride[6] gave the corresponding **17** and **18** in 90 and 95% yields. Subsequent debenzylation of **17** and **18** by catalytic hydrogenolysis, followed by oxydation with potassium hexacyanoferrate(III) in a mixture of

TABLE 1. PHYSICAL PROPERTIES AND BIOLOGICAL ACTIVITIES OF ACTINOMYCIN D AND [SER^1]$_2$-ACTINOMYCIN D

a) From the data of J. Meienhofer[9)]. b) From the data of H. Brockmann *et al.*[8)] c) In methanol at *c* 0.23. d) In methanol at *c* 0.25. e) Ref. 7.

methanol and 0.067 M phosphate buffer, pH 7.1, gave actinomycin D and [Ser^1]$_2$-actinomycin D in 74 and 51% yields, respectively.

The synthetic actinomycin D was indistinguishable from the natural substance as to physical properties and biological activity against some bacteria, although [Ser^1]$_2$-actinomycin D had only about 10% of the natural activity against gram-positive bacteria. The physical and biological data are summarized in Table 1. The CD curves of the synthetic products are shown in Fig. 1. The CD curve of the synthetic actinomycin D agreed with that of the natural product[7)] in methanol solution, and its serine analogue also showed a very similar pattern. Thus, the serine analogue seemed to have a very similar conformation in a methanol solution, although it had only 10% activity against gram-positive bacteria, which agrees with Brockmann's data.[8)] As the presence of the methyl group of threonine seems to be significant for the appearance of the antibacterial activity, we are now trying to synthesize a variety of actinomycin peptide analogues for a study of the biological activity-structure relationship.

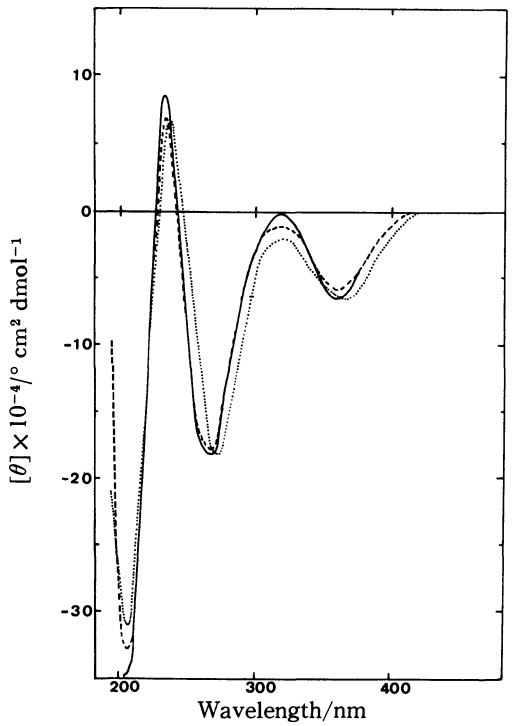

Fig. 1. CD spectra of natural actinomycin D (——), synthetic actinomycin D (----), and [Ser^1]$_2$-actinomycin D (·····) in methanol.

This study showed that the DEAD-TPP method for synthesizing Azy peptides is very convenient and shortens the step of the conventional Azy peptide synthetic procedure. Also, the method using the ring-opening reaction of aziridine is very useful for efficiently synthesizing peptide lactones.

Experimental

Melting points are uncorrected. Infrared spectra were obtained on a Hitachi EPI-G3 spectrometer, ultraviolet spectra on a Shimadzu UV-200 spectrophotometer. Optical rotations were determined at the D line on a Perkin-Elmer 141 polarimeter. The NMR spectra were obtained with a Hitachi R-20B High-resolution NMR Spectrometer, the chemical shifts being obtained using TMS as the internal reference. The homogeneity of the products was checked by thin-layer chromatography on silica-gel plates.

(2S)-1-Trityl-2-aziridinecarboxylic Acid (2). To a solution of (2*S*)-1-trityl-2-aziridinecarboxylic acid methyl ester[10)] (3.43 g, 10 mmol) in CH_3CN (40 ml), was added drop by drop a solution of 2 M LiOH (14.3 ml, 28.6 mmol) at 20 °C with stirring. After the solution was stirred for 24 h at 20 °C, the solvent was removed and the residue was dissolved in ethyl acetate. The solution was washed with 10% citric acid and water, dried over Na_2SO_4, and concentrated *in vacuo*. The obtained **2** was unstable and then was used immediately in the next coupling procedure.

[(2S)-1-Trityl-2-aziridinylcarbonyl]-D-valylproline t-Butyl Ester(4). Z-D-Valylproline *t*-butyl ester (4.05 g, 10 mmol) was hydrogenated over palladium in MeOH (50 ml) for 2 h to give N^a-free dipeptide. To a solution of 2 (3.17 g, 10 mmol) and N^a-free

dipeptide in CH_2Cl_2 (60 ml) was added a solution of DCC (2.06 g, 10 mmol) in CH_2Cl_2 (30 ml) at −10 °C with stirring. The reaction mixture was stirred for 3 h at −10 °C, and then overnight in a refrigerator. After *N,N'*-dicyclohexylurea (DCurea) was removed by filtration, the filtrate was concentrated *in vacuo*. The residue was dissolved in ethyl acetate, and the solution wss washed with 10% citric acid, 1 M $NaHCO_3$, and water, dried over Na_2SO_4, and concentrated *in vacuo*. 5.34 g (93.8%) of **4** was obtained as an amorphous powder, $[\alpha]_D^{23}$ −90.8° (*c* 1.0, MeOH).

Found: C, 73.53; H, 7.77; N, 7.38%. Calcd for $C_{35}H_{43}O_4N_3$: C, 73.79; H, 7.61; N, 7.38%.

N-*(Benzyloxycarbonyl)threonyl*-D-*valylproline* t-*Butyl Ester (7)*. *N*-(Benzyoxycarbonyl)-D-valylproline *t*-butyl ester (27 g, 66.7 mmol) was hydrogenated over palladium (10 g) in MeOH (200 ml) for 3 h to give N^{α}-free dipeptide. To a solution of *N*-(benzyloxycarbonyl)threonine (16.9 g, 66.7 mmol) and N^{α}-free dipeptide in CH_2Cl_2 (200 ml) was added a solution of DCC (13.8 g, 66.7 mmol) in CH_2Cl_2 (50 ml) at −10 °C. The reaction mixture was stirred at −10 °C for 3 h and was then kept overnight in a refirgerator. After removal of DCurea by filtration, the filtrate was concentrated *in vacuo*. The residue was dissolved in ethyl acetate, and the solution was washed with 10% citric acid, 1 M $NaHCO_3$, water, then dried over Na_2SO_4 and concentrated *in vacuo*. The residue was crystallized from ethyl acetate–hexane; 24 g (71%) of **7** was obtained: mp 91—92.5 °C, $[\alpha]_D^{23}$ −29.5° (*c* 1.1, MeOH).

Found: C, 61.85; H, 7.92; N, 8.21%. Calcd for $C_{26}H_{39}O_7N_3$: C, 61.76; H, 7.77; N, 8.31%.

N-*(Benzyloxycarbonyl)seryl*-D-*valylproline* t-*Butyl Ester (8)*. To a solution of *N*-(benzyloxycarbonyl)serine (957 mg, 4 mmol) and N^{α}-free dipeptide (from 1.62 g, 4 mmol of *N*-(benzyloxycarbonyl)-D-valylproline *t*-butyl ester) in CH_2Cl_2 (20 ml), was added a solution of DCC (825 mg, 4 mmol) in CH_2Cl_2 (20 ml) at −10 °C with stirring. After the reaction mixture was worked up as described in **7**, the residue was crystallized from ethyl acetate–hexane; 1.6 g (81.3%) of **8** was obtained: mp 141—142 °C, $[\alpha]_D^{23}$ −25.1° (*c* 1.0, MeOH).

Found: C, 60.90; H, 7.62; N, 8.45%. Calcd for $C_{25}H_{37}O_7N_3$: C, 61.08; H, 7.59; N, 8.55%.

N-*(t-Butoxycarbonyl)sarcosyl*-N-*methylvaline Benzyl Ester (9)*. To a solution of *t*-butoxycarbonylsarcosine (6.62 g, 35 mmol) and *N*-methylvaline benzyl ester (7.73 g, 35 mmol) in THF (100 ml) was added a solution of DCC (7.22 g, 35 mmol) in THF (80 ml) at −10 °C with stirring. After being stirred at 5 °C overnight, the DCurea was filtered off. The filtrate was concentrated *in vacuo* and the residue was dissolved in ethyl acetate, the solution was washed with 10% citric acid, 1 M $NaHCO_3$, water, then dried over Na_2SO_4 and concentrated *in vacuo*. The crude product was purified with silica-gel column chromatography (ethyl acetate–hexane, 1 : 5 v/v). 13.15 g (95.7%) of **9** was obtained as a syrup: $[\alpha]_D^{23}$ −81.6° (*c* 1.0, MeOH).

Found: C, 64.33; H, 8.19; N, 7.28%. Calcd for $C_{21}H_{32}O_5N_2$: C, 64.26; H, 8.22; N, 7.14%.

N-*(t-Butoxycarbonyl)sarcosyl*-N-*methylvaline (10)*. H_2 gas was bubbled through a solution of **9** (9 g, 23 mmol) in MeOH (80 ml) containing palladium (5 g) for 2 h with stirring. After the catalyst was filtered out, the filtrate was concentrated *in vacuo*. 6.95 g (100%) of **10** was obtained as a syrup: $[\alpha]_D^{23}$ −80.4° (*c* 1.0, MeOH).

Found: C, 55.49; H, 8.72; N, 9.35%. Calcd for $C_{14}H_{26}O_5N_2$: C, 55.61; H, 8.67; N, 9.27%.

[*(2S, 3S)-1-Benzyloxycarbonyl-3-methyl-2-aziridinylcarbonyl*]-D-*valylproline* t-*Butyl Ester (11)*. Via *Usual Procedure*: To a solution of **5**[3] (from 7.07 g, 12.1 mmol of **3**[3]) in $CHCl_3$ (40 ml) was added Et_3N (1.68 ml, 12.1 mmol) and Z–ON[1] (3.39 g, 12.1 mmol) at 25 °C with stirring. After the solution was stirred for 3 d, the solvent was removed *in vacuo*. The residue was worked up as described in **4**, and the crude product was purified by silica-gel column chromatography ($CHCl_3$) to give 4.91 g (83.1%) of **11** as a syrup: $[\alpha]_D^{23}$ −76.0° (*c* 0.9, MeOH). NMR ($CDCl_3$) δ: 1.28 (3H d, J=5.8 Hz, $=CHCH_3$), 2.83 (1H m, Azy; β-proton), 3.18 (1H d, J=6.6 Hz, Azy; α-proton). Z–ON can be replaced with Z–Cl.[1]

Found: C, 64.05; H, 7.65; N, 8.62%. Calcd for $C_{26}H_{37}O_6N_3$: C, 64.02; H, 7.83; N, 8.42%.

Via *DEAD–TPP Procedure*: To a solution of DEAD (174 mg, 1.0 mmol) and TPP (262 mg, 1.0 mmol) in an ice-cold dry THF (10 ml) was added **7** (200 mg, 0.4 mmol) at 0 °C with stirring. After being stirred for 1 h, the reaction was stopped by the addition of water (5 ml). The product was extracted with ethyl acetate and the solution was dried over Na_2SO_4 and concentrated *in vacuo*. The residue was dissolved in ether and the crystal which appeared, *N,N'*-bis(ethoxycarbonyl)hydrazine, were filtered off, then the filtrate was concentrated *in vacuo*. The residue was subjected to silica-gel column chromatography (AcOEt–hexane, 1 : 2 v/v). 169 mg (87.6%) of **11** was obtained as a syrup: $[\alpha]_D^{23}$ −74.9° (*c* 1.1, MeOH). The NMR spectrum of this product was identical with that from **11**.

[*(2S)-1-Benzyloxycarbonyl-2-aziridinylcarbonyl*]-D-*valylproline* t-*Butyl Ester (12)*. Via *Usual Procedure*: To a solution of **4** (2.34 g, 4.12 mmol) in abs. MeOH (30 ml) was added ice-cold 85% formic acid (15 ml). After this mixture was stirred for 3 h, the solvent was removed *in vacuo*. The residue was partitioned between ether and water. 1 M $NaHCO_3$ was added to the aqueous solution, producing an alkaline solution, and the isolated oil was extracted with ethyl acetate. After this solution was dried over Na_2SO_4, the solvent was removed *in vacuo* to give N^{α}-free tripeptide (**6**), which was used in the following reaction without further purification. To a solution of **6** in $CHCl_3$ (20 ml) was added Et_3N (0.55 ml, 3.91 mmol) and Z–Cl[1] (0.63 ml, 3.91 mmol) at −5 °C with stirring. After being stirred for 1 h, the reaction mixture was worked up as described in **11**; 1.62 g (83.3%) of **12** was obtained as syrup: $[\alpha]_D^{23}$ −26.0° (*c* 0.9, MeOH), NMR δ: 2.42 (1H q, J_{gem}=0.8 Hz, J_{trans}=3.0 Hz, Azy; β-proton), 2.53 (1H q, J_{gem}=0.8 Hz, J_{cis}=6.6 Hz, Azy; β-proton), 3.14 (1H q, J_{trans}=3.0 Hz, J_{cis}=6.6 Hz, Azy; α-proton).

Found: C, 63.15; H, 7.90; N, 8.59%. Calcd for $C_{25}H_{35}O_6N_3$: C, 63.41; H, 7.45; N, 8.87%.

Via *DEAD–TPP Procedure*: To a solution of DEAD (177 mg, 1.02 mmol) and TPP (267 mg, 1.02 mmol) in ice-cold dry THF (10 ml) was added **8** (200 mg, 0.407 mmol) at 0 °C with stirring. After the mixture was stirred for 1 h, the reaction was stopped by the addition of water (5 ml). The solution was worked up as described in **11**. The crude product was subjected to silica-gel column chromatography (AcOEt–hexane, 1 : 2 v/v). 161 mg (83.5%) of **12** was obtained as a syrup: $[\alpha]_D^{23}$ −25.4° (*c* 0.9, MeOH). The NMR spectrum of this product was identical with that of **12** given earlier.

[O-(t-*Butoxycarbonylsarcosyl*-N-*methylvalyl*)-N-*benzyloxycarbonylthreonly*]-D-*valylproline* t-*Butyl Ester (13)*. A solution of **11** (3.67 g, 7.53 mmol) and **9** (7.27 g, 24 mmol) in CH_2Cl_2 (60 ml) was refluxed for 7 d, and the solvent was removed *in vacuo*. The residue was dissolved in ethyl acetate and the solution was washed with 1 M $NaHCO_3$, and water, dried over Na_2SO_4, and then concentrated *in vacuo*. The residue was purified by silica-gel column chromatography ($CHCl_3$). 4.75 g (80%) of **13** was obtained as an amorphous powder: $[\alpha]_D^{23}$ −30.1° (*c* 1.0, MeOH).

Found: C, 60.92; H, 8.36; N, 8.81%. Calcd for $C_{40}H_{63}O_{11}N_5$: C, 60.82; H, 8.04; N, 8.87%.

[O-(t-*Butoxycarbonylsarcosyl*-N-*methylvalyl*)-N-*benzyloxycarbonylseryl*]-D-*valylproline* t-*Butyl Ester* (***14***). A solution of **12** (1.09 g, 2.3 mmol) and **9** (2.09 g, 6.9 mmol) in CH_2Cl_2 (20 ml) was refluxed for 7 d and the reaction mixture was worked up as described for **13**. 1.44 g (80.9%) of **14** was obtained as an amorphous powder: $[\alpha]_D^{23}$ −47.4° (*c* 1.0, MeOH).

Found: C, 60.16; H, 8.10; N, 9.13%. Calcd for $C_{39}H_{61}O_{11}N_5$: C, 60.37; H, 7.92; N, 9.03%.

N-(*Benzyloxycarbonyl*) *threonyl*-D-*valylprolysarcosyl*-N-*methylvaline Lactone* (***15***). A solution of **13** (1.51 g, 1.91 mmol) in TFA (20 ml) was stirred at 0 °C for 4 h; it was then concen trated *in vacuo*. The residue was dissolved in ethyl acetate and concentrated *in vacuo* (this procedure was repeated twotimes), and the residue was stored over KOH for 12 h in desiccator. The residue was dissolved in dry THF (100 ml), and Et_3N (0.27 ml, 1.91 mmol) was added at −5 °C; the mixture was diluted with THF (900 ml) and HOBt[1] (1.23 g, 9.53 mmol) was added. To a solution of the above mixture was added drop by drop a solution of DCC (1.97 g, 9.53 mmol) in THF (50 ml) at 0 °C for a period of 4 h with stirring. After the mixture was stirred for 5 d at 25 °C, the solvent was removed *in vacuo*. The residue was dissolved in ethyl acetate and the DCurea which appeared was filtered off. The filtrate was washed with 10% citric acid and 1 M $NaHCO_3$, and water, and then concentrat ed *in vacuo*. The residue was subjected to silica-gel column chromatography ($CHCl_3$–MeOH, 50 : 1 v/v). 0.78 g (66.2%) of **15** was obtained as an amorphous powder: $[\alpha]_D^{23}$ −25.4° (*c* 1.0, MeOH).

Found: C, 60.29; H, 7.68; N, 11.21%. Calcd for $C_{31}H_{45}O_8N_5$: C, 60.47; H, 7.37; N, 11.37%.

N-(*Benzyloxycarbonyl*) *seryl*-D-*valylprolylsarcosyl*-N-*methylvaline Lactone* (***16***). A solution of **14** (1.76 g, 2.27 mmol) in TFA (30 ml) was stirred at 0 °C for 4 h, and then was concentrated *in vacuo*. The residue was dissolved in ethyl acetate and concentrated *in vacuo* (this procedure was repeated two times), and the residue was stored over KOH for 12 h in desiccator. The residue was dissolved in dry THF (100 ml), and Et_3N (0.32 ml, 2.27 mmol) was added at −5 °C, this solution was diluted with THF (1.1 L), and HOBt (1.53 g, 11.35 mmol) was added. To a solution of this mixture, was added drop by drop a solution of DCC (2.34 g, 11.35 mmol) in THF (60 ml) at 0 °C for a period of 4 h with stirring. The reaction mixture was stirred at 25 °C for 5 d, and was worked up as described in **15**. The product was crystallized from ethyl acetate–hexane; 0.58 g (42.9%) of **16** was obtained: mp 228—231 °C, $[\alpha]_D^{23}$ −33.3° (*c* 1.0, MeOH).

Found: C, 60.01; H, 7.34; N, 11.92%. Calcd for $C_{30}H_{43}O_8N_5$: C, 59.89; H, 7.20; N, 11.64%.

(*3-Benzyloxy-4-methyl-2-nitrobenzoyl*) *threonyl*-D-*valylprolylsarcosyl*-N-*methylvaline Lactone* (***17***). A solution of **15** (342 mg, 0.56 mmol) in MeOH (15 ml) was hydrogenated over palladium black. After 2 h, the mixture was filtered and the filtrate was concentrated *in vacuo*. The residue was dissolved in $CHCl_3$ (10 ml) and then cooled to 0 °C. To the $CHCl_3$ solution was added Et_3N (0.093 ml, 0.67 mmol) and 3-benzyloxy-4-methyl-2-nitrobenzoyl chloride[6] (204 mg, 0.67 mmol) with stirring in the dark at 0 °C. After the reaction mixture was stirred for 1 h, the solvent was removed *in vacuo*. The residue was dissolved in ethyl acetate and the solution was washed with 10% citric acid, 1 M $NaHCO_3$ and water, dried over Na_2SO_4, and concentrated *in vacuo*. The crude product was purified with silica-gel column chromatography ($CHCl_3$) to give 375 mg (90.0%) of **17** as an amorphous powder: $[\alpha]_D^{23}$ −12.2° (*c* 0.5, MeOH).

Found: C, 60.70; H, 6.85; N, 11.32%. Calcd for $C_{38}H_{50}O_{10}N_6$: C, 60.79; H, 6.71; N, 11.19%.

(*3-Benzyloxy-4-methyl-2-nitrobenzoyl*) *seryl*-D-*valylprolylsarcosyl*-N-*methylvaline Lactone* (***18***). A solution of **16** (425 mg, 0.71 mmol) in MeOH (20 ml) was hydrogenated over palladium black. After 2 h, the mixture was filtered and the filtrate was concentrated *in vacuo*. The residue was dissolved in THF (10 ml) and then cooled to 0 °C. To the solution was added Et_3N (0.12 ml, 0.85 mmol) and 3-benzyloxy-4-methyl-2-nitrobenzoyl chloride[6] (259 mg, 0.85 mmol) with stirring in the dark at 0 °C. After being stirred for 1 h, the reaction mixture was worked up as described in **17**. 492 mg (95.0%) of **18** was obtained as an amorphous powder: $[\alpha]_D^{23}$ +19.9° (*c* 0.5, MeOH).

Found: C, 59.96; H, 6.54; N, 11.13%. Calcd for $C_{37}H_{48}O_{10}N_6$: C, 60.31; H, 6.57; N, 11.41%.

Actinomycin D. A solution of **17** (138 mg, 0.183 mmol) in MeOH (12 ml) was hydrogenated over palladium black in the dark. After 2 h, the mixture was filtered and the filtrate was added to an equal volume of stirred 0.067 M phosphate buffer pH 7.1 containing potassium hexacyanoferrate(III) (175 mg, 0.531 mmol). The mixture was stirred at 25 °C for 20 min. It was then partitioned between ethyl acetate and water, the aqueous layer being separated and extracted three times with ethyl acetate. The combined ethyl acetate layer was washed with 1 M $NaHCO_3$, 1 M HCl, and saturated NaCl, dried over Na_2SO_4, and concentrated *in vacuo* to afford a red crystalline residue, which was recrystallized from ethyl acetate–hexane to give actinomycin D, 84 mg (74%). Physical and spectral data are given in Table 1.

Found: C, 58.52; H, 6.94; N, 13.23%. Calcd for $C_{62}H_{86}O_{16}N_{12}\cdot H_2O$: C, 58.48; H, 6.97; N, 13.20%.

[*Ser*[1]]$_2$-*Actinomycin D.* A solution of **18** (184 mg, 0.25 mmol) in MeOH (15 ml) was hydrogenated over palladium black in the dark. After 2 h, the mixture was filtered and the filtrate was added to an equal volume of stirred 0.067 M phosphate buffer pH 7.1 containing potassium hexacyanoferrate(III) (238 mg, 0.724 mmol). The mixture was stirred at 25 °C for 20 min and worked up as described in actinomycin D. [Ser[1]]$_2$-actinomycin D was obtained 78 mg (51.0%) as a red crystalline substance from ethyl acetate–hexane. Physical and spectral data are given in Table 1.

Found: C, 61.09; H, 7.12; N, 14.27%. Calcd for $C_{60}H_{82}O_{16}N_{12}\cdot H_2O$: C, 61.00; H, 7.17; N, 14.23%.

Microbiological Assay. The results of the assay and the microorganisms employed are given in Table 1. The minimum amount of the compound necessary for the complete inhibition of growth was determined by the Stamp method using Mueller Hinton Ager.

Synthesis and Oxidative Cyclization of 3-(1-Cycloalkenyl)tropolones

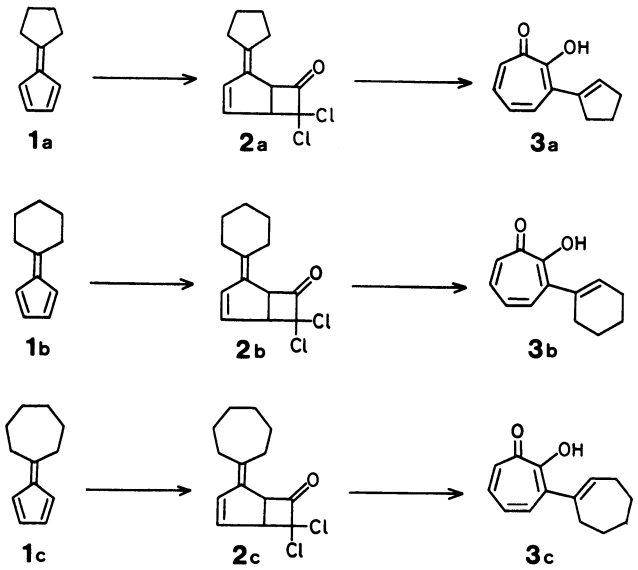
Kimiaki IMAFUKU* and Kyoko INOUE

Department of Chemistry, Faculty of Science, Kumamoto University, Kurokami, Kumamoto 860

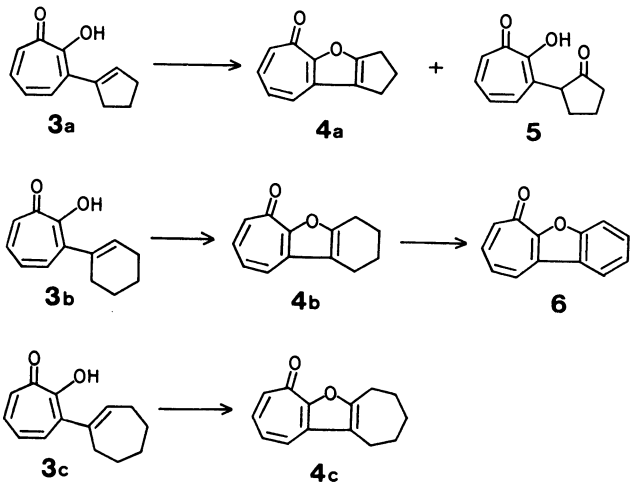
(Received March 29, 1982)

3-(1-Cyclopentenyl)-, 3-(1-cyclohexenyl)-, and 3-(1-cycloheptenyl)tropolones (**3a**, **3b**, and **3c**) were prepared by the hydrolysis of cycloadducts of dichloroketene to cyclopentylidene-, cyclohexylidene-, and cycloheptylidenecyclopentadiene, respectively. Compound **3a** was oxidized with performic acid to give 1,2,3,5-tetrahydrocyclohepta[*b*]cyclopenta[*d*]furan-5-one and 3-(2-oxocyclopentyl)tropolone. Oxidation of **3b** and **3c** gave 1,2,3,4-tetrahydro-6*H*-cyclohepta[*b*]benzofuran-6-one (**4b**) and 5,7,8,9,10,11-hexahydrodicyclohepta[*b*,*d*]furan-5-one, respectively. Dehydrogenation of **4b** with palladium catalyst gave 6*H*-cyclohepta[*b*]benzofuran-6-one.

Halogenated ketenes are versatile intermediates in organic synthesis.[1-3] In 1965, Stevens *et al.*[4,5] obtained tropolone in good yield by hydrolysis of the cyclopentadiene–dichloroketene adduct. This method is most interesting and useful synthetic method of tropolone and has been applied to synthesis of a variety of alkyl-substituted tropolones.[6-8] Hydrolysis of the fulvene–dichloroketene adducts also gave 3-alkenyltropolones.[9,10] These 3-alkenyltropolones were oxidized with peroxy acid or 2,3-dichloro-5,6-dicyano-1,4-benzoquinone to afford 8*H*-cyclohepta[*b*]furan-8-one.[10] On the other hand, hydrolysis of the spiro[2.4]hepta-4,6-diene–dichloroketene adduct gave 2,3-dihydro-8*H*-cyclohepta[*b*]furan-8-one.[11]



Scheme 1.



Scheme 2.

In this communication, we wish to report the synthesis of 3-(1-cycloalkenyl)tropolones by the hydrolysis of the cycloalkylidenecyclopentadiene–dichloroketene adducts and their oxidative cyclization with peroxy acid.

Results and Discussion

Synthesis of 3-(1-Cycloalkenyl)tropolones. The cycloaddition reaction of cyclopentylidenecyclopentadiene (**1a**)[12] with dichloroketene, produced *in situ* by the reaction of dichloroacetyl chloride with triethylamine, afforded a 1 : 1 adduct (**2a**) as a pale yellow oil. The IR spectrum shows a strong carbonyl absorption at 1800 cm^{-1}, which is reasonable for a cyclobutanone.[13] The assignment of the ^1H NMR spectrum was done in comparison with the spectra of 6,6-dimethyl-[9] and 6,6-diphenylfulvene–dichloroketene adducts.[14] The assignments are fit for the structure (**2a**): δ=1.5—2.0 (m, 4H, H-3′×2, H-4′×2), 2.1—2.6 (m, 4H, H-2′×2, H-5′×2), 3.95—4.20 (m, 1H, H-1), 4.62 (d, 1H, $J_{1,5}$=7.2 Hz, H-5), 5.8—6.0 (m, 1H, H-2), 6.49 (dd, 1H, $J_{2,3}$=6.0, $J_{1,3}$=1.8 Hz, H-3). Similarly, by the reactions of cyclohexylidenecyclopentadiene (**1b**)[12] and cycloheptylidenecyclopentadiene (**1c**) with dichloroketene, oily 1 : 1 adducts (**2b** and **2c**) were obtained, respectively. Their structures were also confirmed by the ^1H NMR spectral data.

Hydrolysis of the adduct (**2a**) with sodium hydroxide in aqueous acetic acid was carried out to give 3-(1-cyclopentenyl)tropolone (**3a**) in 26% yield. The ^1H NMR spectrum shows peaks at δ=1.7—2.3 (m, 2H, H-4′×2), 2.4—3.0 (m, 4H, H-3′×2, H-5′×2), 6.8—7.7 (m, 5H, H-2′,4,5,6,7), 9.50 (br, 1H, OH), supporting the structure. The elemental analysis also gave a satisfactory result. The adducts (**2b** and **2c**) were also hydrolyzed to afford 3-(1-cyclohexenyl)tropolone (**3b**) and 3-(1-cycloheptenyl)tropolone (**3c**) in 42 and 16% yields, respectively.

Oxidative Cyclization of 3-(1-Cycloalkenyl)tropolones with Peroxy Acid. Previously, we reported that the 3-alkenyltropolones were oxidized with peroxy acid or 2,3-dichloro-5,6-dicyano-1,4-benzoquinone to give 8*H*-cyclohepta[*b*]furan-8-one.[10]

3-(1-Cyclopentenyl)tropolone (**3a**) was oxidized with performic acid to give **4a** (mp 217—218 °C) and **5** (mp 97—99 °C) in 4.5 and 7.7% yields, respectively. From the elemental analysis and spectral data, the compound (**4a**) was assigned to 1,2,3,5-tetrahydrocyclohepta[*b*]cyclopenta[*d*]furan-5-one. This compound gave no coloration with iron(III) chloride. The IR spectrum shows a characteristic absorption at 1642 cm^{-1} for tropone carbonyl group. The ^1H NMR spectrum shows six protons at $\delta=2.3$—3.1 corresponding to three methylene groups in the five-membered ring and four protons for the aromatic seven-membered ring. On the other hand, the compound (**5**) was determined to be 3-(2-oxocyclopentyl)tropolone from its elemental analysis, spectral data, and coloration with iron(III) chloride. The IR spectrum shows a characteristic carbonyl absorption at 1745 cm^{-1} for a cyclopentanone. The ^1H NMR spectrum is also reasonable for the structure.

The 3-(1-cycloalkenyl)tropolones (**3b** and **3c**) were also oxidized with performic acid to afford 1,2,3,4-tetrahydro-6*H*-cyclohepta[*b*]benzofuran-6-one (**4b**) and 5,7,8,9,10,11-hexahydrodicyclohepta[*b*,*d*]furan-5-one(**4c**) in 38 and 26% yields, respectively. Their structures were determined by their elemental analysis and spectral data.

The compound (**4b**) was dehydrogenated with palladium catalyst to afford 6*H*-cyclohepta[*b*]benzofuran-6-one (**6**), which was confirmed by its elemental analysis and spectral data. The IR spectrum shows a tropone carbonyl absorption at 1635 cm^{-1}, the ^1H NMR spectrum showing aromatic protons as complex multiplet at $\delta=6.90$—8.05.

Experimental

The melting points were determined with a Yanagimoto MP-S2 melting-point measuring apparatus and are uncorrected. The IR spectra were taken on a JASCO IRA-1 spectrophotometer, the UV spectra on a Hitachi EPS-3T spectrophotometer. The ^1H NMR spectra were recorded with a Hitachi-Perkin-Elemer R-24 spectrometer (60 MHz).

*Cyclopentylidenecyclopentadiene (**1a**).* A mixture of cyclopentadiene (105 g, 1.6 mol) and cyclopentanone (143 g, 1.7 mol) was stirred overnight at room temperature in the presence of 40% methylamine solution (35 ml). The organic layer was washed with 1 M hydrochloric acid until the mixture was made slightly acidic. Then, the organic layer was washed with water and with saturated sodium chloride solution, dried over anhydrous sodium sulfate, and distilled under reduced pressure to give 77 g (36%) of cyclopentylidencyclopentadiene (**1a**) as an orange oil: bp 103—104 °C/18 Torr (lit,[12] 55—57 °C/2 Torr); NMR (CCl_4) $\delta=1.6$—1.9 (m, 4H), 2.5—2.9 (m, 4H), 6.20 (s, 4H).

*Cyclohexylidenecyclopentadiene (**1b**).* A mixture of cyclopentadiene (80 g, 1.2 mol) and cyclohexanone (127 g, 1.3 mol) was stirred overnight at room temperature in the presence of 40% methylamine solution (26 ml) and worked up, as mentioned above, to give 83 g (57%) of cyclohexylidenecyclopentadiene (**1b**) as an orange oil: bp 118—120 °C/17 Torr (lit,[12] 78—80 °C/2.5 Torr; NMR (CCl_4) $\delta=1.4$—1.9 (m, 6H), 2.3—2.8 (m, 4H), 6.36 (s, 4H).

*Cycloheptylidenecyclopentadiene (**1c**).* A mixture of cyclopentadiene (66 g, 1.0 mol) and cycloheptanone (134 g, 1.2 mol) was stirred overnight at room temperature in the presence of 40% methylamine (22 ml) and worked up, as mentioned above, to give 105 g (66%) of cycloheptylidenecyclopentadiene (**1c**) as an orange oil: bp 124—126 °C/18 Torr; NMR (CCl_4) $\delta=1.3$—1.9 (m, 8H), 2.2—2.9 (m, 4H), 6.2—6.5 (m, 4H).

*4-Cyclopentylidene-7,7-dichlorobicyclo[3.2.0]hept-2-en-6-one (**2a**).* A solution of triethylamine (56 g) in anhydrous hexane (500 ml) was added dropwise to a solution of **1a** (35 g) and dichloroacetyl chloride (41 g) in anhydrous hexane (700 ml) over a period of 3 h with stirring at room temperature. After additional stirring for 1 h, the mixture was allowed to stand overnight. The reaction mixture was washed with 1 M hydrochloric acid and with water, and dried over anhydrous sodium sulfate. After the evaporation of the solvent, the residue was distilled under reduced pressure to give 20 g (31%) of 4-cyclopentylidene-7,7-dichlorobicyclo[3.2.0]hept-2-en-6-one (**2a**) as a pale yellow oil: bp 125—127 °C/0.45 Torr; IR (neat) 1800 cm^{-1} (C=O); NMR (CCl_4) $\delta=1.5$—2.0 (m, 4H), 2.1—2.6 (m, 4H), 3.95—4.20 (m, 1H, H-1), 4.62 (d, 1H, $J_{1,5}=7.2$ Hz, H-5), 5.8—6.0 (m, 1H, H-2), 6.49 (dd, 1H, $J_{2,3}=6.0$, $J_{1,3}=1.8$ Hz, H-3).

*4-Cyclohexylidene-7,7-dichlorobicyclo[3.2.0]hept-2-en-6-one (**2b**).* A solution of triethylamine (40 g) in anhydrous hexane (250 ml) was added dropwise to a solution of **1b** (33 g) and dichloroacetyl chloride (32 g) in anhydrous hexane (250 ml) over a period of 3 h with stirring at room temperature. The reaction mixture was worked up, as mentioned above, to give 17 g (29%) of 4-cyclohexylidene-7,7-dichlorobicyclo[3.2.0]-hept-2-en-6-one (**2b**) as a pale yellow oil: bp 139—141 °C/0.45 Torr; IR (neat) 1800 cm^{-1} (C=O); NMR (CCl_4) $\delta=1.3$—1.9 (m, 6H), 2.0—2.7 (m, 4H), 3.95—4.15 (m, 1H, H-1), 4.74 (d, 1H, $J_{1,5}=6.6$ Hz, H-5), 5.92 (dd, 1H, $J_{2,3}=6.0$, $J_{1,2}=3.0$ Hz, H-2), 6.58 (dd, 1H, $J_{2,3}=6.0$, $J_{1,3}=1.8$ Hz, H-3).

*4-Cycloheptylidene-7,7-dichlorobicyclo[3.2.0]hept-2-en-6-one (**2c**).* A solution of triethylamine (46 g) in anhydrous hexane (500 ml) was added dropwise to a solution of **1c** (35 g) and dichloroacetyl chloride (34 g) in anhydrous hexane (700 ml) over a period of 3 h with stirring at room temperature. The reaction mixture was worked up, as mentioned above, to give 35 g (60%) of 4-cycloheptylidene-7,7-dichlorobicyclo[3.2.0]hept-2-en-6-one (**2c**) as a pale yellow oil: bp 151—152 °C/0.45 Torr; IR (neat) 1800 cm^{-1} (C=O); NMR (CCl_4) $\delta=1.3$—1.9 (m, 8H), 2.0—2.6 (m, 4H), 3.95—4.20 (m, 1H, H-1), 4.73 (d, 1H, $J_{1,5}=7.2$ Hz, H-5), 5.89 (dd, 1H, $J_{2,3}=6.0$, $J_{1,2}=2.4$ Hz, H-2), 6.57 (dd, 1H, $J_{2,3}=6.0$, $J_{1,3}=1.8$ Hz, H-3).

*3-(1-Cyclopentenyl)tropolone (**3a**).* A suspended solution of the cycloadduct (**2a**) (20 g) in acetic acid (99 g) and water (9 ml) containing sodium hydroxide (16 g) was refluxed for 10 h. The mixture was steam-distilled and the distillate was extracted with chloroform. The extract was washed with sodium hydrogencarbonate solution, water, and saturated sodium chloride solution. Evaporation of the solvent from the dried extract gave 4.0 g (26%) of 3-(1-cyclopentenyl)-tropolone (**3a**) as pale yellow needles (from hexane): mp 79—80 °C; IR ($CHCl_3$) 3140 (OH), 1616 cm^{-1} (C=O); NMR ($CDCl_3$) $\delta=1.7$—2.3 (m, 2H), 2.4—3.0 (m, 4H), 6.8—7.7 (m, 5H), 9.50 (br, 1H, OH). Found: C, 76.27: H, 6.45%. Calcd for $C_{12}H_{12}O_2$: C, 76.57; H, 6.43%.

*3-(1-Cyclohexenyl)tropolone (**3b**).* The cycloadduct (**2b**) (17 g) was hydrolyzed, as mentioned above, by refluxing for 10 h in acetic acid (71 g) and water (7 ml) containing sodium hydroxide (13 g) and steam-distilled to give 5.6 g (42%) of 3-(1-cyclohexenyl)tropolone (**3a**) as pale yellow needles (from hexane): mp 53—55 °C; IR ($CHCl_3$) 3140 (OH), 1615 cm^{-1} (C=O); NMR ($CDCl_3$) $\delta=1.4$—1.9 (m, 4H), 2.0—2.6 (m, 4H), 5.7—5.9 (m, 1H), 6.7—7.1 (m, 4H), 9.20 (br, 1H, OH).

Found: C, 77.21; H, 7.00%. Calcd for $C_{13}H_{14}O_2$: C, 77.20; H, 6.98%.

3-(1-Cycloheptenyl)tropolone (3c) The cycloadduct (**2c**) (35 g) was also hydrolyzed, as mentioned above, by refluxing for 10 h in acetic acid (157 g) and water (14 ml) containing sodium hydroxide (26 g) and steam-distilled to give 4.5 g (16%) of 3-(1-cycloheptenyl)tropolone (**3c**) as pale yellow needles (from hexane): mp 39—41 °C; IR ($CHCl_3$) 3120 (OH), 1614 cm^{-1} (C=O); NMR ($CDCl_3$) δ=1.5—2.0 (m, 6H), 2.1—2.6 (m, 4H), 5.65—5.95 (m, 1H, H-2'), 6.65—7.60 (m, 4H), 9.40 (br, 1H, OH). Found: C, 78.01; H, 7.27%. Calcd for $C_{14}H_{16}O_2$: C, 77.75; H, 7.46%.

Oxidation of 3-(1-Cyclopentenyl)tropolone (3a). 3-(1-Cyclopentenyl)tropolone (**3a**) (3.76 g) was added to a performic acid solution, prepared from 90% formic acid (50 ml) and 30% hydrogen peroxide (10 ml), and heated on a water bath for 2 h. The reaction mixture was alkalized with 20% sodium hydroxide solution and heated again on a water bath for 45 min. The mixture was slightly acidified with 3 M hydrochloric acid and extracted with chloroform. The extract was washed with water and dried over anhydrous sodium sulfate. After the evaporation of the solvent, the residue was chromatographed on four Wakogel B-10 plates (30×30 cm^2) with chloroform to afford two fractions. Crystals from the upper band were recrystallized from benzene to give 171 mg (4.5%) of 1,2,3,5-tetrahydrocyclohepta[*b*]cyclopenta[*d*]furan-5-one (**4a**): mp 217—218 °C; IR ($CHCl_3$) 1642 cm^{-1} (C=O); UV (CH_3OH) 227 (log ε 4.16), 286 (4.39), 313 nm (sh, 3.94); NMR ($CDCl_3$) δ=2.2—3.1 (m, 6H), 6.7—7.4 (m, 4H). Found: C, 77.24; H, 5.42%. Calcd for $C_{12}H_{10}O_2$: C, 77.40; H, 5.41%. Crystals from the lower band were also recrystallized from benzene to give 316 mg (7.7%) of 3-(2-oxocyclopentyl)tropolone (**5**): mp 97—99 °C; IR ($CHCl_3$) 3180 (OH), 1745 (C=O), 1618 cm^{-1} (C=O); NMR ($CDCl_3$) δ=1.5—2.8 (m, 6H), 3.42 (m, 1H, H-1'), 6.7—7.5 (m, 4H), 8.90 (br, 1H, OH). Found: C, 70.45; H, 5.93%. Calcd for $C_{12}H_{12}O_3$: C, 70.57; H, 5.92%.

Oxidation of 3-(1-Cyclohexenyl)tropolone (3b). 3-(1-Cyclohexenyl)tropolone (**3b**) (2.33 g) was added to a performic acid solution, prepared from 90% formic acid (25 ml) and 30% hydrogen peroxide (5 ml), and heated on a water bath for 2 h. The reaction mixture was alkalized with 20% sodium hydroxide solution and heated on a water bath for 45 min. The mixture was slightly acidified with 3 M hydrochloric acid and extracted with chloroform. The extract was washed with water and dried over anhydrous sodium sulfate. After the evaporation of the solvent, the residue was recrystallized from benzene to give 842 mg (38%) of 1,2,3,4-tetrahydro-6*H*-cyclohepta[*b*]benzofuran-6-one (**4b**): mp 174—176 °C; IR ($CHCl_3$) 1650 cm^{-1}; UV (CH_3OH) 229 (log ε 4.18), 284 (4.37), 313 nm (sh, 3.89); NMR ($CDCl_3$) δ=1.3—2.2 (m, 4H), 2.3—3.1 (m, 4H), 6.7—7.6 (m, 4H). Found: C, 77.69; H, 6.06%. Calcd for $C_{13}H_{12}O_2$: C, 77.98; H, 6.04%.

Dehydrogenation of 1,2,3,4-Tetrahydro-6H-cyclohepta[b]benzofuran-6-one (4b). A mixture of 1,2,3,4-tetrahydro-6*H*-cyclohepta[*b*]benzofuran-6-one (**4b**) (1.0 g) and 5% palladium-charcoal (2.0 g) in xylene (20 ml) was refluxed for 48 h. The catalyst was filtered off. The filtrate was chromatographed on three Wakogel B-10 plates (30×30 cm^2) with ethyl acetate. Crystals from the upper band gave 6*H*-cyclohepta[*b*]benzofura-6-one (**6**). Fraction from the lower band was a mixture of **4b** and **6**, and was rechromatographed. The fractions, corresponding to **6**, were combined and recrystallized from benzene to give 235 mg (24%) of **6**: mp 139—141 °C; IR ($CHCl_3$) 1635 cm^{-1} (C=O); UV (CH_3OH) 274 (log ε 4.40), 305 (4.18), 336 (sh, 3.89), 350 (sh, 3.78), 366 nm (sh, 3.61); NMR ($CDCl_3$) δ=6.90—8.05 (m). Found: C, 79.39; H, 4.07%. Calcd for $C_{13}H_8O_2$: C, 79.58; H, 4.11%.

Oxidation of 3-(1-Cycloheptenyl)tropolone (3c). 3-(1-Cycloheptenyl)tropolone (**3c**) (432 mg) was added to a performic acid solution, prepared from 90% formic acid (5 ml) and 30% hydrogen peroxide (1 ml), and heated on a water bath for 2 h. The reaction mixture was worked up, as mentioned above, and recrystalized from benzene to give 111 mg (26%) of 5,7,8,9,10,11-hexahydrodicyclohepta[*b*,*d*]furan-5-one (**4c**): mp 173—175 °C; IR ($CHCl_3$) 1648 cm^{-1} (C=O); UV (CH_3OH) 227 (log ε 4.18), 284 (4.37), 310 nm (sh, 3.91); NMR ($CDCl_3$) δ=1.6—2.2 (m, 6H), 2.4—3.1 (m, 4H), 6.7—7.4 (m, 4H). Found: C, 78.18; H, 6.79%. Calcd for $C_{14}H_{14}O_2$: C, 78.48; H, 6.59%.

Noriceane (Tetracyclo[5.3.1.$0^{2,6}$.$0^{4,9}$]undecane) and 3,5-Dehydronoriceane (Pentacyclo[5.3.1.$0^{2,6}$.$0^{3,5}$.$0^{4,9}$]undecane)[1]

Takeo KATSUSHIMA, Ryohei YAMAGUCHI, and Mituyosi KAWANISI*

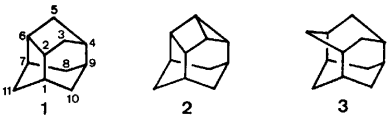
(Received April 14, 1982)

Heating a mixture of *endo, exo-* and *endo, endo*-2,4-dibromohomoadamantanes at 180 °C in hexamethylphosphoric triamide (HMPT) brings about a novel skeletal rearrangement with concomitant dehydrobromination to give tricyclo[5.3.1.$0^{4,9}$]undeca-2,5-diene (**5**) in 88% yield. Direct photoexcitation of **5** in diethyl ether induces an intramolecular [2+2] cycloaddition to produce 3,5-dehydronoriceane (**2**). The bicyclo[2.1.0]pentane moiety constrained in the cage structure of **2** shows almost the same ^{13}C–H coupling constants as those of bicyclo[2.1.0]-pentane itself. Finally hydrogenation of **2** over PtO_2 easily proceeds to afford noriceane, which is named after the structure of iceane.

Among 2486 possible tetracyclic ring systems of empirical formula $C_{11}H_{16}$,[2] tetracyclo[5.3.1.$0^{2,6}$.$0^{4,9}$]-undecane (**1**) has a unique skeleton which is a nor-analogue of iceane (tetracyclo[5.3.1.$1^{2,6}$.$0^{4,9}$]dodecane) (**3**).[3] Iceane is named after the structure of crystalline water and, hence, we can term **1** as noriceane. In addition to its unique structure, **1** is a member of the tetracyclic $C_{11}H_{16}$ hydrocarbons which can be rearranged to the most stable isomer, 2,4-ethanonoradamantane by $AlBr_3$ catalyst.[2] In connection with our continuing interest in synthesis and reactions of strained cage molecules,[4] we could synthesize a highly strained compound, 3,5-dehydronoriceane (**2**), which has the partial bicyclo[2.1.0]pentane structure fixed in the rigid cage structure. Thus, taking account of its expected high chemical reactivity,[5] **2** can be a useful precursor of noriceane derivatives. We now describe here synthesis of noriceane (**1**) as well as 3,5-dehydronoriceane (**2**) in detail.[6]



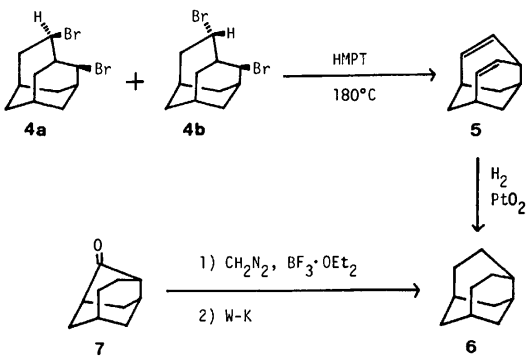
Scheme 1.

Results and Discussion

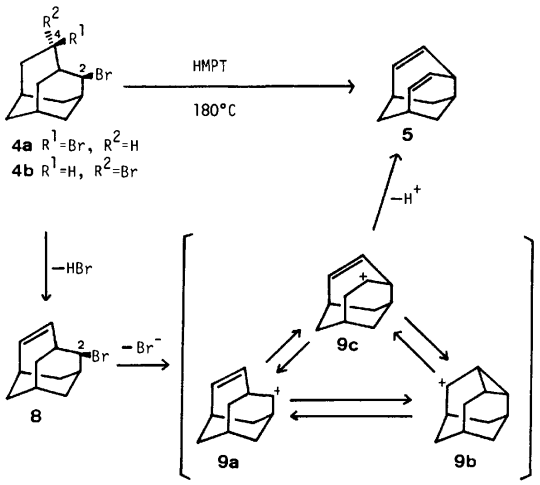
When a mixture of *endo,exo-*,and *endo,endo*-2,4-dibromo-homoadamantane (**4a** and **4b**)[4b] was heated at 180 °C in HMPT for 3 h, a novel skeletal rearrangement with concomitant dehydrobromination[7] took place to give a geometrically interesting diolefin, tricyclo[5.3.1.$0^{4,9}$]-undeca-2,5-diene (**5**) in 88% yield. The structure of **5** was confirmed by the following experimental results. Hydrogenation of **5** gave a saturated hydrocarbon, tricyclo[5.3.1.$0^{4,9}$]undecane (**6**). This hydrocarbon, **6**, was authentically prepared by reaction of protoadaman-tan-2-one (**7**)[8] with diazomethane under catalysis of $BF_3 \cdot OEt_2$ followed by Wolff-Kishner reduction of the resulting ring-enlarged ketone.[9]

On the other hand, *endo*-2-bromohomoadamant-4-ene (**8**), which was prepared by the elimination of one equivalent of hydrogen bromide under base-promoted reaction conditions,[4b] gave also **5** in 96% yield when heated at 180 °C in HMPT. Therefore, this novel skeletal rearrangement is supposed to proceed through a pathway such as shown in Scheme 3. Initially, the bromine atom on C_4 and its β-hydrogen were eliminated to give **8**. Subsequently, the loss of the remaining bromine atom on C_2 would lead to the homoallyl-cyclopropylcarbinyl rearrangement of carbocation inter-mediates (**9a**, **9b**, and **9c**) and only **9c** could release its β-hydrogen[10] to produce **5**. Although the mechanism of dehydrohalogenation with HMPT has not been estab-lished,[7] the degenerated homoallyl-cyclopropylcarbinyl rearrangement of **9a**, **9b**, and **9c** under stable ion conditions has been proposed.[11]

It can be expected from the geometry of **5** that the two

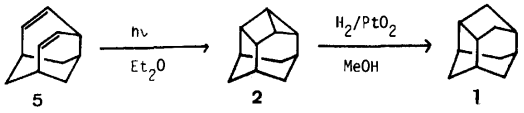


Scheme 2.



Scheme 3.

π-orbitals are juxtaposed to interact efficiently with each other. Indeed, the UV spectrum of **5** shows a π-π^* absorption at 231 nm (ε=1360 in EtOH) and indicates a homoconjugation between two olefinic moieties. Thus, direct irradiation of **5** in diethyl ether through quartz-filter by means of medium-pressure mercury lamp induced an efficient intramolecular [2+2] cycloaddition to afford 3,5-dehydronoriceane (**2**) in 87% yield. (Scheme 4) The IR spectrum of **2** showed an absorption band at 3100 cm^{-1} due to cyclopropane ring. In addition, the presence of C_{2v} symmetry was clearly indicated by the ^{13}C NMR spectrum which showed only 7 absorption signals.



Scheme 4.

The compound (**2**) has partially a bicyclo[2.1.0]-pentane moiety within the rigid cage structure and is expected to possess significant chemical reactivity.[12] The observed ^{13}C–H coupling constants of **2** are almost the same as those of bicyclo[2.1.0]pentane[13] itself (Fig. 1) and strongly suggest the high strained nature of **2**. Thus, **2** was easily hydrogenated over PtO_2 in MeOH to afford noriceane (**1**). The C_{2v} symmetry of **1** was also clearly established by ^{13}C NMR spectroscopy. This hydrogenation is in good agreement with the well-known fact that cleavage of the central bond of bicyclo-[2.1.0]pentane ring system easily occurs in a number of reactions.[12]

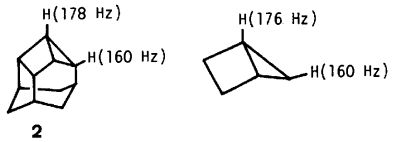


Fig. 1. ^{13}C–H coupling constants of **2** and bicyclo-[2.1.0]pentane.[13]

The fixed bicyclo[2.1.0]pentane ring in the cage structure of **2** is interesting in that any attacking species must approach the bicyclo[2.1.0]pentane unit from the *exo* side alone and, in addition, isomerization to cyclopentene derivatives is impeded on the stereochemical grounds.[10] Therefore, 3,5-dehydronoriceane (**2**) is expected to provide some information on reaction mechanism of bicyclo[2.1.0]pentane system which has been scarcely investigated.[5]

Experimental

All the temperatures were uncorrected. The melting points were measured in sealed capillaries. The IR spectra were obtained on a Shimadzu IR-27 spectrometer. The UV spectrum was recorded on a Hitachi ESP-spectrometer. The MS spectra were taken by using a Hitachi RMS-4 mass spectrometer. The exact mass spectrum was obtained on a Hitachi RMU-8GN mass spectrometer. The ^1H NMR spectra were obtained on a Varian EM-360 or EM-390 spectrometer and the ^{13}C NMR spectra were obtained on a Varian CFT-20 spectrometer, TMS being chosen as the inernal standard. ^{13}C–H coupling constants were measured by Gated decoupling method. Microanalyses were performed by Kyoto University Elemental Analysis Center.

Tricyclo[5.3.1.0^{4,9}]undeca-2,5-diene (5). A solution of a mixture of **4a** and **4b** (7.958 g; 25.8 mmol)[4b] in HMPT (100 ml) was heated at 180 °C for 3 h under nitrogen. To the cooled reaction mixture was then added hexane, and the organic layer was washed with water several times and dried (Na_2SO_4). The solvent was evaporated and the residue was chromatographed on alumina. Elution by hexane gave **5** (3.314 g, 88%): mp 155—158 °C. MS *m/e* (rel intensity): 146 (M^+, 84), 80 (100). IR (CCl_4): 3080, 2920, 1630, 1455, 1375, 910, 700 cm^{-1}. UV λ_{max} (EtOH): 231 nm (ε=1360). ^1H NMR δ (CCl_4): 6.00 (2H, d.d, J=9.0 and 5.4 Hz), 5.70 (2H, d.d, J=9.0 and 7.2 Hz), 2.93 (1H, d.t, J=8.7 and 5.1 Hz), 2.70—1.00 (9H, br complex m). ^{13}C NMR δ ($CDCl_3$): 137.0 (d), 132.8 (d), 39.4 (t), 38.2 (d), 32.2 (d), 26.9 (d), 24.0 (t). Found: C, 90.23; H, 9.66%. Calcd for $C_{11}H_{14}$: C, 90.35; H, 9.66%.

The same treatment of pure **4a** (622 mg; 2.02 mmol) in HMPT as above gave **5** (186 mg, 63%). Additionally the similar reaction of *endo*-2-bromotricyclo[4.3.1.1^{3,8}]undec-4-ene (**8**)[4b] (54 mg; 0.24 mmol) in HMPT (1 ml) to the above gave also **5** (33 mg, 96%).

Pentacyclo[5.3.1.0^{2,6}.0^{3,5}.0^{4,9}]undecane (2). A solution of **5** (201 mg; 1.39 mmol) in Et_2O (20 ml) was directly irradiated by 300-W medium pressure mercury lamp in a quartz vessel under nitrogen for 5 h. The solvent was evaporated and the residue was chromatographed on alumina. Elution by hexane gave **2** (175 mg, 87%): mp 183—186 °C. MS *m/e* (rel intensity): 146 (M^+, 52), 105 (67), 92 (89), 91 (60), 80 (100), 79 (93). IR (CCl_4): 3100, 2950, 1460, 1440, 1275, 1060, 895 cm^{-1}. ^1H NMR δ (CCl_4): 2.87—1.10 (14H, br complex m). ^{13}C NMR δ ($CDCl_3$): 43.3 (t), 38.3 (d), 33.1 (t), 30.3 (d), 22.5 (d), 20.0 (d), 7.3 (d). Found: C, 90.06; H, 9.81%. Calcd for $C_{11}H_{14}$: C, 90.35; H, 9.65%.

Tetracyclo[5.3.1.0^{2,6}.0^{4,9}]undecane (1). A solution of **2** (100 mg; 0.68 mmol) in MeOH (10 ml) was vigorously stirred in the presence of PtO_2 under hydrogen. After one equivalent of hydrogen was absorbed, the catalyst was removed by filtration. After removal of the solvent under reduced pressure the residue was chromatographed on alumina. Elution by pentane gave **1** (61 mg, 60%): mp 212—215 °C. MS *m/e* (rel intensity): 148 (M^+, 100), 119 (33), 92 (41), 91 (31), 80 (31), 79 (65). IR (CCl_4): 2910, 1465, 1065 cm^{-1}. ^1H NMR δ (CCl_4): 2.67—0.60 (16H, br complex m). ^{13}C NMR δ ($CDCl_3$): 41.9 (d), 40.9 (t), 38.1 (d), 33.7 (d), 30.9 (t), 30.5 (d), 29.5 (t). Found: C, 88.86; H, 11.04%. Calcd for $C_{11}H_{16}$: C, 89.12; H, 10.88%.

Tricyclo[5.3.1.0^{4,9}]undecane (6). A mixture of **5** (124 mg; 0.85 mmol) and a small amount of PtO_2 in MeOH (10 ml) was vigorously stirred under hydrogen. After two equivalents of hydrogen had been absorbed, the catalyst was removed by filtration and the solvent was evaporated. The residue was chromatographed on alumina. Elution by pentane gave **6** (85 mg, 66%): mp 242—246 °C. MS *m/e* (rel intensity): 150 (M^+, 100), 121 (43), 80 (43), 79 (50). IR (CCl_4): 2920, 1455 cm^{-1}. ^1H NMR δ (CCl_4): 3.10—0.90 (18H, br complex m). ^{13}C NMR δ ($CDCl_3$): 41.4 (t), 31.3 (t), 30.1 (t), 28.1 (t), 26.6 (d), 26.5 (d), 25.3 (d). Found: *m/e* 150.1382. Calcd for $C_{11}H_{18}$: M, 150.1408.

Preparation of 6 from Tricyclo[4.3.1.0^{3,8}]decan-2-one (7).[8] A solution of CH_2N_2 in Et_2O prepared from *N*-nitroso-*N*-methylurea (1.6 g) was added dropwise to a solution of **7**

(149 mg; 1.00 mmol) and a small amount of $BF_3 \cdot OEt_2$ in Et_2O (5 ml) under cooling with an ice–salt bath and then a small amount of acetic acid was added to the reaction mixture. The precipitates were removed by filtration and the filtrate was washed with aq $NaHCO_3$ and brine, and dried (Na_2SO_4). The solvent was evaporated and the residue was chromatographed on silica gel. Elution by hexane–Et_2O (9 : 1) gave the ring-enlarged ketone[9] (104 mg, 63%): MS *m/e* (rel intensity): 164 (M^+, 100). IR (nujol): 2930, 1710, 1460, 1375, 720 cm^{-1}. ^1H NMR δ ($CDCl_3$): 3.00—1.00 (16H, br complex m).

A mixture of the above ketone (41 mg; 0.25 mmol), KOH (200 mg; 3.56 mmol), 100% hydrazine hydrate (150 mg; 3.00 mmol) in diethylene glycol (0.6 ml) was stirred at 110 °C for 0.5 h and subsequently at 180 °C for 3 h. The sublimate on the condenser was collected and dissolved in pentane. The solution was washed with brine and dried (Na_2SO_4). Evaporation of the solvent gave crude **6** (30 mg, 80%). This compound was identical with **6** obtained by hydrogenation of **5** in every respect.

We thank Dr. Eiji Ōsawa for his valuable discussion and Dr. Ryusei Konaka of Shionogi Pharmaceutical Co. Ltd. for obtaining the exact mass spectrum of **6**. We are also indebted to Dr. David P. G. Hamon for providing IR and ^1H NMR spectra of tricyclo[5.3.1.$0^{4,9}$]-undecan-2-one. This work was partially supported by a Grant-in-Aid for Scientific Research from the Ministry of Education, Science and Culture (No. 434025).

Total Synthesis of a Macrocyclic Lactone Antibiotic A26771B and Its Isomers Using Carbohydrates

Kuniaki TATSUTA,* Yoshiya AMEMIYA, Yoshinobu KANEMURA, and Mitsuhiro KINOSHITA
Department of Applied Chemistry, Faculty of Science and Technology, Keio University, Hiyoshi, Kohoku-ku, Yokohama 223
(Received April 7, 1982)

Total synthesis and antibacterial activities of a macrocyclic lactone antibiotic A26771B (**1**) and all its isomers (**2**, **3**, and **4**) are discussed. The starting 8,9,10,12-tetra-*O*-benzyl-2,3,4,5,11-pentadeoxy-*aldehydo*-D-*xylo*-(*E*)-6-dodecenose derived from D-glucose reacted with racemic Wittig reagent, (3-hydroxybutyl)triphenylphosphonium iodide to give 1,3,4,5-tetra-*O*-benzyl-2,8,9,10,11,14,16-heptadeoxy-DL-*glycero*-L-*xylo*-hexadeca-6,12-dienitol, which was in turn converted into methyl 15-*O*-acetyl-6,7,8,9,10,11,12,13,14,16-decadeoxy-4,5-*O*-isopropylidene-DL-*glycero*-L-*threo*-(*E*)-2-hexadecenonate (**13**) through effective oxidation and β-elimination. Saponification followed by Yamaguchi's lactonization of **13** afforded two diastereomeric 16-membered-ring lactones which were converted into (5*S*, 15*R*)-A26771B (**1**) and its (5*S*, 15*S*)-diastereomer (**2**) by successive deacetonation, selective succinylation and oxidation. The other starting 2,3,4,6-tetra-*O*-benzyl-5-deoxy-*aldehydo*-D-*lyxo*-hexose, which was prepared from 2-deoxy-D-glucose, reacted with a Wittig reagent to give 8,9,10,12-tetra-*O*-benzyl-2,3,4,5,11-pentadeoxy-*aldehydo*-D-*lyxo*-6-dodecenose (**20**) followed by hydrolysis. Similar reaction sequence from **20** with the aforesaid series for **1** and **2** afforded the (5*R*, 15*R*)-isomer (**3**) and (5*R*, 15*S*)-isomer (**4**).

A 16-membered macrocyclic lactone antibiotic A26771B (**1**), produced by *Penicillium turbatum*, possesses a novel structure and an interesting antibacterial activity.[1] The first stereospecific total synthesis and the absolute configuration of **1** were disclosed in our laboratories[2] and followed by the elegant synthesis of the racemate by Takei *et al.*[3] The previous stereospecific synthesis was based on a convergent scheme involving both optically pure C-1—C-12 and C-13—C-16 portions, which were derived from D-glucose. Herein we describe in detail, the total synthesis of the antibiotic A26771B [(5*S*,15*R*)-isomer (**1**)], its diastereomers [(5*S*,15*S*)-isomer (**2**) and (5*R*,15*R*)-isomer (**3**)] and enantiomer [(5*R*,15*S*)-isomer (**4**)] in order to further study their structure-activity relationships. The key step was effective separation of the (15*R*)- and (15*S*)-diastereomers after coupling a racemic C-13—C-16 portion (**8**) to an optically active C-1—C-12 portion (**7** or **20**). The latter portion was in turn prepared from D-glucose derivatives, because the C-5 positions of **1** (or **2**) and **3** (or **4**) were stereochemically corresponding to C-2 position of 5-deoxy-D-glucose and C-5 position of 2-deoxy-D-glucose, respectively.

The synthesis of the antibiotic A26771B (**1**) and its (5*S*,15*S*)-diastereomer (**2**) was initiated from the C-1—C-12 portion (**7**), which was obtained from 2,3,4,6-tetra-*O*-benzyl-5-deoxy-*aldehydo*-D-*xylo*-hexose (**5**) and [5-(1,3-dioxolan-2-yl)pentyl]triphenylphosphonium bromide (**6**) by Wittig reaction and subsequent hydrolysis as described in the previous paper.[2] The second Wittig reagent **8** was prepared by a three-step sequence from 1,3-butanediol in a 72% yield. Reaction of **7** with the reactive ylide formed from **8** afforded a 1 : 1 mixture of the two diastereomeric 16-carbon products, 1,3,4,5-tetra-*O*-benzyl-2,8,9,10,11,14,16-heptadeoxy-DL-*glycero*-L-*xylo*-hexadeca-6,12-dienitol (**9**) in a 67% yield. The separation of the diastereomers was not overcome at this stage but done after lactonization as described later on. Catalytic reduction of **9** with hydrogen and palladium black gave the saturated alcohol **10**, which was selectively *t*-butyldimethylsilylated and then totally acetylated to afford the fully masked product **11**. Desilylation of **11** with difluoroacetic acid followed by successive catalytic oxidation of the resulting alcohol and esterification with diazomethane gave the methyl ester, methyl 3,4,5,15-tetra-*O*-acetyl-2,6,7,8,9,10,11,-12,13,14,16-undecadeoxy-DL-*glycero*-L-*xylo*-hexadeconate (**12**). Selective deacetylation of **12** accompanying the desired β-elimination with 4.5 equiv. of potassium *t*-butoxide and 2 equiv. of water followed by acetonation with 2,2-dimethoxypropane and *p*-toluenesulfonic acid in acetone gave the α,β-unsaturated ester, methyl 15-*O*-acetyl-6,7,8,9,10,11,12,13,14,16-decadeoxy-4,5-*O*-isopropylidene-DL-*glycero*-L-*threo*-(*E*)-2-hexadecenonate (**13**). Without water, the above-mentioned reaction gave a very low yield of the elimination product. The *E*-stereochemistry was defined by the 16 Hz coupling

constant of the vinylic protons. When treated with lithium hydroxide in 50% aqueous THF, **13** quantitatively furnished the corresponding hydroxy acid, which was submitted to lactonization. Yamaguchi's method[4] among others gave the best yield of the desired lactones **14** and **15**. Namely, the hydroxy acid reacted with 2,4,6-trichlorobenzoyl chloride in the presence of triethylamine in THF to give the corresponding mixed anhydride, which was treated with 4-dimethylaminopyridine in toluene at 95 °C. The two diastereomeric 16-membered-ring lactones **14** and **15** were obtained and separated in 45% and 40% yields by silica gel column chromatography. The lactone **14** was identical in all respects with a sample of the same structure stereospecifically synthesized from D-glucose as previously described,[2] and convertible into the antibiotic A26771B (**1**). Therefore, **14** and **15** were found to be (4*S*,5*S*,15*R*)- and (4*S*,5*S*,15*S*)-isomers, respectively. Hydrolysis of **14** and **15** with difluoroacetic acid in aqueous MeOH gave the diols, 6,7,8,9,10,11,12,13,14,16-decadeoxy-D-*glycero*-L-*threo*-(*E*)-2-hexadecenono-1,15-lactone (**16**) and the L-*glycero*-L-*threo*-isomer (**17**) in 94% and 92% yields, respectively. Selective succinylation of **16** and **17** with succinic anhydride and *N*,*N*-diisopropylethylamine in CCl_4 gave predominantly 5-*O*-succinyl compounds, which were oxidized with acetic anhydride and DMSO to afford (5*S*,15*R*)-A26771B (**1**) and the (5*S*,15*S*)-isomer (**2**) in 70% and 73% yields, respectively. The synthetic product **1** thus obtained was identical both spectroscopically and chromatographically with an authentic sample of the natural antibiotic.

Subsequently, the (5*R*,15*R*)- and (5*R*,15*S*)-isomers (**3** and **4**) were synthesized by the similar strategy to the aforesaid. The starting 2,3,4,6-tetra-*O*-benzyl-1-*O*-trityl-5-deoxy-D-*lyxo*-hexose (**18**) was prepared from 2-deoxy-D-glucose successively by tritylation, $NaBH_4$ reduction and benzylation in a 65% yield. Detritylation of **18** with 90% trifluoroacetic acid followed by oxidation with trifluoroacetic anhydride and DMSO in dichloromethane gave 2,3,4,6-tetra-*O*-benzyl-5-deoxy-*aldehydo*-D-*lyxo*-hexose (**19**), in a 78% yield, which had the opposite configuration only at the C-2 position in comparison with **5**. The Wittig reaction of **19** with the ylide derived from **6**, followed by hydrolysis with 70% trifluoroacetic acid, gave the 12-carbon skeletal aldehyde **20** in an 82% yield. The second Wittig reaction of **20** with the ylide formed from **8** gave a 1 : 1 mixture of the two diastereomeric compounds, 1,3,4,5-tetra-*O*-benzyl-2,8,9,10,11,14,16-heptadeoxy-DL-*glycero*-D-*arabino*-hexadeca-6,12-dienitol (**21**). Reduction of **21** to give **22**, followed by successive silylation and acetylation, afforded **23**, which was in turn converted into the corresponding methyl ester **24** as efficiently as described in the preparation for **12**. Selective deacetylation with β-elimination of **24**, followed by acetonation gave methyl 15-*O*-acetyl-6, 7, 8, 9, 10, 11, 12, 13, 14, 16-decadeoxy-4,5-*O*-isopropylidene-DL-*glycero*-D-*erythro*-(*E*)-2-hexadecenonate (**25**) as described in the preparation for **13**. Saponification of **25** with LiOH gave the corresponding hydroxy acid, which was cyclized as described for the preparation of **14** and **15** to afford, after column chromatography, the two diastereomeric lactones **26** [(4*S*,5*R*,15*R*)-isomer] and **27** [(4*S*,5*R*,15*S*)-isomer] in 47% and 39% yields. The independent conversion of the diastereomers **26** and **27** into the optically pure (5*R*,15*R*)-isomer (**3**) and (5*R*,15*S*)-isomer (**4**) involved the same reagents and reaction conditions through **28** and **29** as mentioned in the scheme for the aforesaid compounds **1** and **2**, and gave similar yields. Conclusive evidence for the stereochemical assignments at the C-5

and C-15 positions was provided by identification of **4** with the natural antibiotic A26771B (**1**) in all respects except for the sign of the optical rotation.

Biological investigation of the natural antibiotic A26771B and synthetic products **1**, **2**, **3**, and **4** revealed (Table 1) that all products exhibited in vitro antibiotic activities against Gram-positive and macrolide-resistant Gram-positive bacteria and the (5*R*,15*R*)-isomer **3** was approximately twice as active as A26771B (**1**). This lack of the essential stereochemical requirement for the antibiotic activity of this class of novel compounds was the most striking aspect, suggesting pliable possibility in chemical modification of macrolide antibiotics.

Experimental

Melting points were determined on a micro hot-stage Yanaco MP-S3 and were uncorrected. IR and UV spectra were recorded on Hitachi Perkin-Elmer 225 and JASCO UV IDEC-1 spectrometers, respectively, and ^{1}H-NMR spectra in $CDCl_3$ with TMS as internal standard on a Varian EM-390 (90 MHz) or a Bruker WM 250 spectrometer (250 MHz). Optical rotations were measured on a Carl Zeiss photoelectric polarimeter. Silica gel TLC and column chromatography were performed on Merck TLC 60F-254 and Wakogel C-200, respectively. In general, evaporation was carried out under reduced pressure below 30 °C.

*(3-Hydroxybutyl)triphenylphosphonium Iodide (**8**).* To a stirred and ice-cooled solution of 1,3-butanediol (5.0 g, 55 mmol) in acetonitrile (75 ml) were added *p*-toleunesulfonyl chloride (10 g) and triethylamine (10 ml), and stirring at room temperature was continued for 2.5 h. The resulting solution was partitioned between ether and water, and the organic layer was washed successively with saturated aqueous $NaHCO_3$ and NaCl solutions, dried and evaporated to a residue, which was chromatographed on silica gel (250 g) with 3 : 2 hexane–ethyl acetate to give a syrup of the corresponding tosylate (11 g, 82%).

To a solution of the tosylate (11 g) in acetone (110 ml) was added NaI (12.7 g), and the solution was stirred at 60 °C for 1 h. The precipitated salt was filtered and the filtrate was evaporated to a residue, which was partitioned between benzene and water. The organic layer was dried and evaporated to give a syrup of the iodo compound.

A solution of the syrup in benzene (40 ml) was stirred with triphenylphosphine (14 g) at 80 °C for 20 h under argon. The precipitated product was filtered and recrystallized from methanol–ethyl acetate to give needles of **8** (18.2 g, 90%): mp 149—152 °C.

Found: C, 56.97; H, 5.20; I, 27.61%. Calcd for $C_{22}H_{24}$OIP: C, 57.16; H, 5.23; I, 27.45%.

*1,3,4,5-Tetra-O-benzyl-2,8,9,10,11,14,16-heptadeoxy-*DL*-glycero-*L*-xylo-hexadeca-6,12-dienitol (**9**).* To a suspension of **8** (5.4 g, 11.7 mmol) in dry THF (54 ml) were added with stirring at room temperature, under argon, 2M sodium methylsulfinylmethanide solution prepared *in situ* from NaH (199 mg, 8.29 mmol) and DMSO (4.14 ml), and then a 1.6 M butyllithium solution in hexane (6.23 ml, 10 mmol). After 5 min, to the resulting orange solution was added a solution of **7** (3.57 g, 5.88 mmol) in dry THF (18 ml) with stirring, and stirring at room temperature was continued for 0.5 h. The reaction solution was diluted with water and extracted with ether. The combined extracts were then evaporated, and the residue was chromatographed on silica gel (300 g) with 4 : 1 hexane–ethyl acetate to give a colorless syrup of **9** (2.57 g, 67%): R_f 0.20 (3 : 1 hexane–ethyl acetate); $[\alpha]_D^{15}$ +45° (*c* 1.0, $CHCl_3$); ^{1}H-NMR δ=1.13 and 1.18 (3H in total, each d, Me-15, $J_{15,Me}$=6 Hz), 3.50 (2H, t, H-1, $J_{1,2}$= 6 Hz), 3.53—4.05 (4H, m, H-3,4,5 and 15), 4.21—4.80 (8H, m, PhC$\underline{H_2}$O×4), 5.34—5.78 (4H, m, H-6,7,12 and 13), 7.33 (20H, s, Ph×4).

Found: C, 80.01; H, 8.17%. Calcd for $C_{44}H_{54}O_5$: C, 79.72; H, 8.21%.

*3,4,5,15-Tetra-O-acetyl-1-O-(*t*-butyldimethylsilyl)-2,6,7,8,9,10,-11,12,13,14,16-undecadeoxy-*DL*-glycero-*L*-xylo-hexadecitol (**11**).* A solution of **9** (547 mg) in methanol (8 ml) was shaken with palladium black and 3-atm hydrogen at room temperature for 15 h, filtered and evaporated to give a crude solid (250 mg) of **10**: R_f 0.25 (6 : 1 chloroform–methanol).

To a stirred solution of crude **10** (250 mg) in dry pyridine (2.5 ml) was added *t*-butyldimethylsilyl chlorde (150 mg), and the solution was kept at room temperature. After 3 h, TLC indicated the absence of starting material. Acetic anhydride (0.67 ml) was added and the mixture stirred overnight at room temperature. After addition of EtOH, the solution was evaporated and the residue was dissolved in ethyl acetate. The solution was washed successively with saturated aqueous $NaHCO_3$ and NaCl solutions, dried, and evaporated. The residue was chromatographed on silica gel (25 g) with 5 : 1 hexane–ethyl acetate to give a syrup of **11** (370 mg, 77% from **9**): R_f 0.37 (3 : 1 hexane–ethyl acetate); $[\alpha]_D^{17}$ 0° (*c* 1.0, $CHCl_3$); ^{1}H-NMR δ=0.05 (6H, s, Me_2Si), 0.88 (9H, s, *t*-BuSi), 1.20 (3H, d, Me-15, $J_{15,Me}$=6 Hz), 2.02, 2.05, and 2.08 (12H in total, each s, OAc×4), 3.62 (2H, t, H-1, $J_{1,2}$=6 Hz).

Found: C, 61.10; H, 9.32%. Calcd for $C_{30}H_{56}O_9Si$: C, 61.19; H, 9.59%.

*Methyl 3,4,5,15-Tetra-O-acetyl-2,6,7,8,9,10,11,12,13,14,16-undecadeoxy-*DL*-glycero-*L*-xylo-hexadeconate (**12**).* To a solution of **11** (340 mg, 0.577 mmol) in acetonitrile (10 ml) was added 0.08 M difluoroacetic acid solution in 50% aqueous acetonitrile (5.1 ml), and the solution was left at 50 °C for 5 h,

neutralized with a saturated aqueous $NaHCO_3$ solution and then extracted with ether. The combined extracts were washed with a saturated aqueous NaCl solution, dried, and evaporated to give a syrup of the crude alcohol (274 mg): R_f 0.13 (3 : 2 hexane–ethyl acetate).

Subsequently, gaseous oxygen (600 ml/min) was bubbled into a solution of the syrup (274 mg) in 75% aqueous dioxane at 85 °C for 5 h in the presence of platinum black (150 mg).

The mixture was filtered, and the filtrate was evaporated to give a residue of the carboxylic acid.

The residue was dissolved in ether (5 ml), and an excess of etheral diazomethane solution was added. The resulting yellowish solution was stirred for 0.5 h at room temperature and then evaporated to the residue, which was chromatographed on silica gel (20 g) with 2 : 1 hexane–ethyl acetate to give a syrup of **12** (250 mg, 86% from **11**): R_f 0.24 (3 : 2 hexane–ethyl acetate); $[\alpha]_D^{16}$ +15° (*c* 1.0, $CHCl_3$); ^{1}H-NMR δ=1.23 (3H, d, Me-15, $J_{15,Me}$=6 Hz), 2.02, 2.05 and 2.08 (12H in total, each s, OAc×4), 2.60 (2H, d, H-2, $J_{2,3}$=6 Hz), 3.68 (3H, s, COOMe).

Found: C, 59.71; H, 8.21%. Calcd for $C_{25}H_{42}O_{10}$: C, 59.74; H, 8.42%.

*Methyl 15-O-Acetyl-6,7,8,9,10,11,12,13,14,16-decadeoxy-4,5,-O-isopropylidene-*DL-glycero-L-threo-*(*E*)-2-hexadecenonate (**13**).* To a solution of **12** (330 mg) in *t*-butyl alcohol (9.9 ml) were added water (0.024 ml) and 0.5 M potassium *t*-butoxide solution in *t*-butyl alcohol (14.8 ml) at room temperature. After 2 min, the reaction solution was neutralized with Dowex 50WX8 (H type) and filtered. The filtrate was evaporated to a residue, which was chromatographed on silica gel (15 g) with 1 : 1 hexane–ethyl acetate to give a syrup of the (*E*)-unsaturated ester (115 mg, 49%).

A solution of the syrup (84 mg) in dry acetone (1.7 ml) was stirred with 2,2-dimethoxypropane (3.4 ml) in the presence of TsOH (4.2 mg) at room temperature for 1.5 h, neutralized with triethylamine and then evaporated to a residue. The residue was partitioned between chloroform and water, and the combined organic layers were evaporated to give a syrup, which was chromatographed on silica gel (10 g) with 5 : 1 hexane–ethyl acetate to give a syrup of **13** (77 mg, 82%): R_f 0.36 (5 : 1 hexane–ethyl acetate); $[\alpha]_D^{18}$ −13° (*c* 1.0, $CHCl_3$); UV_{max} (MeOH) 212 nm (ε 10200); ^{1}H-NMR δ=1.20 (3H, d, Me-15, $J_{15,Me}$=6 Hz), 1.41 and 1.44 (each 3H, s, Me_2C), 2.03 (3H, s, OAc), 3.72 (1H, m, H-5), 3.77 (3H, s, COOMe), 4.10—4.20 (1H, m, H-4), 4.80—4.95 (1H, m, H-15), 6.13 (1H, dd, H-2, $J_{2,3}$=16 Hz, $J_{2,4}$=1.5 Hz), 6.89 (1H, dd, H-3, $J_{2,3}$=16 Hz, $J_{3,4}$=6 Hz).

Found: C, 66.52; H, 9.49%. Calcd for $C_{22}H_{38}O_6$: C, 66.30; H, 9.61%.

*6,7,8,9,10,11,12,13,14,16-Decadeoxy-4,5-O-isopropylidene-*D-glycero-L-threo-(E)-*2-hexadecenono-1,15-lactone (**14**) and* L-glycero-L-threo-*isomer (**15**).* A solution of **13** (132 mg, 0.33 mmol) in 50% aqueous THF (5.0 ml) was stirred with a 0.2 M LiOH solution in 50% aqueous THF (5.8 ml) at 30° for 2 d. The resulting solution was neutralized with Dowex 50WX8 (H type) to pH 4, and then filtered. The filtrate was extracted with ether. The extracts were washed with a saturated aqueous NaCl solution, dried and evaporated to give quantitatively the corresponding hydroxy acid (120 mg): R_f 0.29 (3 : 2 hexane–acetone).

To a mixture of the hydroxy acid (120 mg) and triethylamine (0.108 ml) in dry THF (1.2 ml) was added a solution of 2,4,6-trichlorobenzoyl chloride[4] (172 mg) in dry THF (1.7 ml), and the mixture was stirred for 1 h at room temperature. After removal of triethylamine hydrochloride under argon, the filtrate was diluted with dry toluene (175 ml). The resulting solution was added dropwise to the refluxing solution of 4-dimethylaminopyridine (258 mg) in dry toluene (35 ml) at 95 °C over a 6-h period with stirring under argon, and stirring at this temperature was continued for another 40 min. The reaction solution diluted with ether (500 ml) was washed successively with satu rated aqueous citric acid and $NaHCO_3$ solutions, dried, and then evaporated to give a residue. The residue was chromatographed on silica gel (15 g) with 20 : 1 hexane–ethyl acetate. The eluates between 57—78 ml (R_f 0.30 with 10 : 1 hexane–ethyl acetate) were collected and evaporated to give a solid. Recrystallization from acetone–ethanol–water afforded colorless needles of **14** (52 mg, 45%): mp 74—75 °C (lit,[2] mp 74—75 °C); $[\alpha]_D^{13}$ +7.0° (*c* 1.0, $CHCl_3$); UV_{max} (MeOH) 212 nm (ε 10300); ^{1}H-NMR δ=1.27 (3H, d, Me-15, $J_{15,Me}$=6 Hz), 1.42 (6H, s, Me_2C), 3.73 (1H, m, H-5), 4.12 (1H, dt, H-4, $J_{3,4}$=6.0 Hz, $J_{2,4}$=1.5 Hz), 5.03 (1H, m, H-15), 6.11 (1H, dd, H-2, $J_{2,3}$=16 Hz, $J_{2,4}$=1.5 Hz), 6.88 (1H, dd, H-3, $J_{2,3}$=16 Hz, $J_{3,4}$=6.0 Hz).

Found: C, 70.55; H, 9.77%. Calcd for $C_{19}H_{32}O_4$: C, 70.33; H, 9.94%.

The other eluates between 80—105 ml (R_f 0.25 with 10 : 1 hexane–ethyl acetate) gave a colorless syrup of **15** (45 mg, 40%): $[\alpha]_D^{13}$ +52° (*c* 1.0, $CHCl_3$); UV_{max} (MeOH) 211 nm (ε 9800); ^{1}H-NMR δ=1.26 (3H, d, Me-15, $J_{15,Me}$=6 Hz), 1.46 (6H, s, Me_2C), 3.85 (1H, m, H-5), 4.05 (1H, dull t, H-4, *J*=8 Hz), 5.04 (1H, m, H-15), 6.07 (1H, dd, H-2, $J_{2,3}$=16 Hz, $J_{2,4}$=0.5 Hz), 6.76 (1H, dd, H-3, $J_{2,3}$=16 Hz, $J_{3,4}$=8 Hz).

Found: C, 70.63; H, 9.74%. Calcd for $C_{19}H_{32}O_4$: C, 70.33; H, 9.94%.

*6,7,8,9,10,11,12,13,14,16-Decadeoxy-*D-glycero-L-threo-(E)-*2-hexadecenono-1,15-lactone (**16**).* A sample of **14** (33 mg) was dissolved in a mixture (0.5 ml) of difluoroacetic acid, methanol and water (4 : 3 : 1). The solution was stirred for 1 h at room temperature and then evaporated to a residue, which was chromatograhed on silica gel (3 g) with 3 : 1 hexane–acetone to give needles of **16** (27 mg, 94%): R_f 0.51 (3 : 2 hexane–acetone): mp 86—87 °C (lit,[2] 86—87 °C): $[\alpha]_D^{15}$ −43° (*c* 1.0, $CHCl_3$); UV_{max} (MeOH) 214 nm (ε 10900).

Found: C, 67.55; H, 9.97%. Calcd for $C_{16}H_{28}O_4$: C, 67.57; H, 9.92%.

*6,7,8,9,10,11,12,13,14,16-Decadeoxy-*L-glycero-L-threo-(E)-*2-hexadecenono-1,15-lactone (**17**).* A sample of **15** (25 mg) was hydrolyzed by the procedure described in the preparation of **16** and then worked up to give a syrup of **17** (21 mg, 92%): R_f 0.49 (3 : 2 hexane–acetone); $[\alpha]_D^{15}$ +12.5° (*c* 1.0, $CHCl_3$); UV_{max} (MeOH) 213 nm (ε 10600).

Found: C, 67.69; H, 10.01%. Calcd for $C_{16}H_{28}O_4$: C, 67.57; H, 9.92%.

*A26771B: 5-O-(3-Carboxypropionyl)-4-oxo-4,6,7,8,9,10,11,12,-13,14,16-undecadeoxy-*D-glycero-L-glycero-(E)-*2-hexadecenono-1,15-lactone (**1**).* To a suspension of **16** (19 mg, 0.067 mmol) in dry CCl_4 (0.95 ml) were added succinic anhydride (10 mg) and *N,N*-diisopropylethylamine (0.024 ml) under argon, and the mixture was stirred for 2 h at 50 °C. After addition of ethyl acetate and water, the aqueous layer was acidified to pH 1 with 1 M HCl. The organic layer was dried and then evaporated to a residue, which was purified by PLC with 8 : 1 chloroform–ethanol to give crude crystals of the corresponding succinate (19 mg): R_f 0.55 (8 : 1 chloroform–ethanol); mp 120—122 °C (hexane–ethyl acetate).

The crystals (9.0 mg) was dissolved in a mixture of acetic anhydride (0.064 ml) and dry DMSO (0.22 ml), and the solution was kept at 30 °C for 20 h. The resulting solution diluted with ethyl acetate was washed with water, dried and evaporated to a residue, which was purified by PLC with 8 : 1 chloroform–ethanol to give, after recrystallization from ethyl acetate–hexane, needles (6.1 mg, 51% from **16**) of A26771B

(**1**): R_f 0.57 (8 : 1 chloroform-ethanol); mp and mmp 125—126 °C (lit,[2] mp 125—126 °C); $[\alpha]_D^{12}$ −13° (*c* 0.2, MeOH); UV_{max} (MeOH) 223 nm (ε 13300); IR (KBr) 1750, 1725, 1720, 1710, 1705 (succinyl ester, lactone) and ≈1645 (C=C) cm^{-1}; ^{1}H-NMR δ=1.30 (3H, d, Me-15, $J_{15,Me}$=6.5 Hz), 2.73 (4H, m, succinyl C$\underline{H}_2$–C$\underline{H}_2$), 5.15 (1H, m, H-15), 5.33 (1H, t, H-5, $J_{5,6}$=5.5 Hz). 6.75 and 7.22 (each 1H, AB-q, H-2 and 3, $J_{2,3}$=15.5 Hz). Its UV, IR, and ^{1}H-NMR spectra and TLC behavior were identical with those of an authentic sample of the natural product.

Found: C, 62.79; H, 8.05%. Calcd for $C_{20}H_{30}O_7$: C, 62.81; H, 7.91%.

5-O-(3-Carboxypropionyl)-4-oxo-4,6,7,8,9,10,11,12,13,14,16-undecadeoxy-L-glycero-L-glycero-(E)-*2-hexadecenono-1,15-lactone* (**2**). Following the procedure described for **1**, from **17**, a syrup of **2** (9.7 mg, 51% from **17**) was obtained: R_f 0.57 (8 : 1 chloroform–ethanol); $[\alpha]_D^{17}$ +25° (*c* 0.2, MeOH); UV_{max} (MeOH) 223 nm (ε 10100); IR ($CHCl_3$) 1740, 1735, 1720, 1710, 1700 (succinyl ester, lactone) and ≈1620 (C=C) cm^{-1}; ^{1}H-NMR δ=1.29 (3H, d, Me-15, $J_{15,Me}$=6.5 Hz), 2.76 (4H, m, succinyl C$\underline{H}_2$–C$\underline{H}_2$), 5.09 (1H, m, H-15), 5.35 (1H, t, H-5, $J_{5,6}$=6 Hz), 6.76 and 7.16 (each 1H, AB-q, H-2 and 3, $J_{2,3}$=16 Hz).

Found: C, 62.69; H, 8.11%. Calcd for $C_{20}H_{30}O_7$: C, 62.81; H, 7.91%.

2,3,4,6-Tetra-O-*benzyl-1*-O-*trityl-5-deoxy*-D-lyxo-*hexose* (**18**). To a stirred and ice-cooled solution of 2-deoxy-D-glucose (1.05 g, 6.4 mmol) in dry pyridine (10.5 ml) was added trityl chloride (1.96 g), and stirring was continued at room temperature for 15 h. After addition of a few drops of water, the resulting solution was evaporated to a residue, which was partitioned between ethyl acetate and a saturated aqueous NaCl solution. The organic layer was dried and evaporated to give quantitatively a crude solid of the *O*-trityl compound (2.7 g).

To a solution of this crude compound (24.7 g) in 80% aqueous ethanol (250 ml) was added $NaBH_4$ (2.3 g), and the solution was stirred for 1 h at room temperature. After neutralization with Dry Ice, the solution was evaporated to a residue, which was chromatographed twice on silica gel (400 g and 1 kg) with 5 : 1 and 10 : 1 chloroform–methanol, respectively, to give a pure syrup of the corresponding alcohol (22 g, 88%): $[\alpha]_D^{19}$ −2.5° (*c* 2.0, $CHCl_3$): ^{1}H-NMR δ=1.27—2.05 (2H, m, H-5), 2.93—4.20 (11H, m, H-1,2,3,4,6 and OH×4), 6.94—7.82 (15H, m, trityl).

Found: C, 73.70; H, 7.00%. Calcd for $C_{25}H_{28}O_5$: C, 73.51; H, 6.91%.

A solution of this alcohol (10 g) in dry THF (130 ml) was added to NaH (3 g), and the mixture was stirred at room temperature. After 1 h, benzyl bromide (14.6 ml) was added, and stirring at 50 °C was continued for another 2 h. The reaction mixture was partitioned between benzene and water, and the organic layer was washed with a saturated aqueous NaCl solution, dried and evaporated to a residue. The residue was chromatographed on silica gel (600 g) with 10 : 1 hexane-ethyl acetate to give a syrup of **18** (14 g, 65% from 2-deoxy-D-glucose): ^{1}H-NMR δ=1.75—1.95 (2H, m, H-5), 3.42 (2H, t, H-6, $J_{5,6}$=6.0 Hz), 3.47 (2H, d, H-1, $J_{1,2}$=6.0 Hz), 3.70—3.95 (3H, m, H-2,3 and 4), 4.28—4.79 (8H, m, PhC$\underline{H}_2$O×4), 6.95—7.55 (35H, m, Ph×7). Without further purification, the syrup was used for the next step.

2,3,4,6-Tetra-O-*benzyl-5-deoxy*-aldehydo-D-lyxo-*hexose* (**19**). An ice-cooled solution of **18** (11.5 g, 15 mmol) in 90% aqueous trifluoroacetic acid (50 ml) was stirred for 1 h, and then evaporated to a residue, which was partitioned between chloroform and a saturated aqueous $NaHCO_3$ solution. The organic layer was washed with a saturated aqueous NaCl solution, dried and evaporated to a residue, which was chromatographed on silica gel (600 g) with 10 : 1 benzene–ethyl acetate to give a syrup of the de-*O*-tritylated compound (7.50 g, 95%): R_f 0.11 (5 : 1 hexane–ethyl acetate); $[\alpha]_D^{19}$ +7.5° (*c* 1.0, $CHCl_3$); ^{1}H-NMR δ=1.76—2.10 (2H, m, H-5), 2.10—2.34 (1H, m, OH-1), 3.50 (2H, t, H-6, $J_{5,6}$=6 Hz), 3.61—4.00 (5H, m, H-1,2,3 and 4), 4.40—4.79 (8H, m, PhC$\underline{H}_2$O×4), 7.30 (20H, m, Ph×4).

Found: C, 77.26; H, 7.27%. Calcd for $C_{34}H_{38}O_5$: C, 77.54; H, 7.24%.

A solution of the syrup (7.50 g, 14.2 mmol) in CH_2Cl_2 (14 ml) was added to a mixture of DMSO (2.0 ml), trifluoroacetic anhydride (3.0 g) and CH_2Cl_2 (14 ml) at −76° over a period of 15 min with stirring, and stirring at −76 °C was continued for another 1 h. After addition of triethylamine (5.7 ml) at this temperature, the resulting solution was partitioned between ethyl acetate and water. The organic layer washed successively with a saturated aqueous $NaHCO_3$ solution and water, dried, and evaporated to a residue, which was chromatographed on silica gel (200 g) with 5 : 1 hexane–ethyl acetate to give a syrup of **19** (6.12 g, 82%): R_f 0.35 (5 : 1 hexane–ethyl acetate); ^{1}H-NMR δ=1.80—2.20 (2H, m, H-5), 3.47 (2H, t H-6, $J_{5,6}$=6.0 Hz), 3.71—4.12 (3H, m, H-2,3 and 4), 4.32—4.84 (8H, m, PhC$\underline{H}_2$O×4), 7.30 (20H, s, Ph×4), 9.69 (1H, d, CHO, $J_{1,2}$=2 Hz). As this compound was considerably labile, it was used for the next step without further purification.

8,9,10,12-Tetra-O-*benzyl-2,3,4,5,11-pentadeoxy*-aldehydo-D-lyxo-*6-dodecenose* (**20**) *and Its Ethylene Acetal.* To an ice-cooled solution of **6** (11.3 g, 23.3 mmol) in dry THF (110 ml) was added, under argon, 2 M sodium methylsulfinylmethanide solution prepared *in situ* from NaH (533 mg) and DMSO (11.1 ml). After the solution had been stirred at room temperature for 0.5 h, to the resulting deep red solution was added a solution of **19** (6.12 g, 11.7 mmol) in dry THF (61 ml), and stirring at room temperature was continued for another 0.5 h. The reaction mixture was partitioned between ether and a saturated aqueous NaCl solution. The organic layer was evaporated to a residue, which was chromatographed on silica gel (700 g) with 5 : 1 hexane–ethyl acetate to give the ethylene acetal of **20** as a colorless syrup (7.14 g, 94%): R_f 0.52 (2 : 14 : 1 : 2 benzene–chloroform–ethyl acetate–hexane); $[\alpha]_D^{15}$ +2.5° (*c* 2.0, $CHCl_3$); ^{1}H-NMR δ=3.50 (2H, t, H-12, $J_{11,12}$=6.0 Hz), 3.70—3.95 (4H, m, C$\underline{H}_2$ of ethylene acetal).

Found: C, 77.75; H, 7.76%. Calcd for $C_{42}H_{50}O_6$: C, 77.51; H, 7.74%.

The syrup (6.52 g) was dissolved in 70% aqueous trifluoroacetic acid (32.5 ml) at 5 °C and the solution was kept at this temperature overnight. The resulting solution was partitioned between chloroform and a saturated aqueous $NaHCO_3$ solution, and the organic layer was washed with a saturated aqueous NaCl solution ,dried, and evaporated to a residue. The residue was chromatographed on silica gel (200 g) with 5 : 1 hexane–ethyl acetate to give a syrup of **20** (5.28 g, 87%): R_f 0.59 (2 : 14 : 1 : 2 benzene–chloroform–ethyl acetate–hexane). As this compound **20** was considerably labile, it was used for the next step without further characterization.

1,3,4,5-Tetra-O-*benzyl-2,8,9,10,11,14,16-heptadeoxy*-DL-glycero-D-arabino-*hexadeca-6,12-dienitol* (**21**). A sample of **20** (4.39 g, 7.24 mmol) was treated by the procedure described in the preparation of **9** and then worked up to give a syrup of **21** (3.2 g, 66%): R_f 0.20 (3 : 1 hexane–ethyl acetate); $[\alpha]_D^{16}$ +5.0° (*c* 1.0, $CHCl_3$); ^{1}H-NMR δ=1.18 and 1.20 (3H in total, each d, Me-15, $J_{15,Me}$=6.5 Hz). 3.47 (2H, t, H-1, $J_{1,2}$=6 Hz), 3.50—3.92 (4H, m, H-3,4,5 and 15), 4.12—4.85 (8H, m, PhC$\underline{H}_2$O×4), 5.35—5.90 (4H, m, H-6,7,12 and 13), 7.30 (20H, s, Ph×4).

Found: C, 80.00; H, 8.26%. Calcd for $C_{44}H_{54}O_5$: C, 79.72; H, 8.21%.

3,4,5,15-Tetra-O-*acetyl-1*-O-(t-*butyldimethylsilyl*)-*2,6,7,8,9,10,-11,12,13,14,16-undecadeoxy*-DL-glycero-D-arabino-*hexadecitol* (**23**). A sample of **21** (3.13 g, 4.72 mmol) was treated by the procedure described in the preparation of **11** through **10** and then worked up to give, through **22**, a syrup of **23** (2.17 g, 78%): R_f 0.44 (3 : 1 hexane–ethyl acetate); $[\alpha]_D^{17}$ +30° (*c* 1.0. $CHCl_3$); ^{1}H-NMR δ=0.02 (6H, s, Me_2Si), 0.85 (9H, s, *t*-BuSi), 1.19 (3H, d, Me-15, $J_{15,Me}$=6.0 Hz), 2.02, 2.05 and 2.08 (12H in total, each s, OAc×4), 3.65 (2H, t, H-1, $J_{1,2}$=6 Hz).

Found: C, 61.22; H, 9.26%. Calcd for $C_{30}H_{56}O_9Si$: C, 61.19; H, 9.59%.

Methyl 3,4,5,15-Tetra-O-*acetyl-2,6,7,8,9,10,11,12,13,14,16-undecadeoxy*-DL-glycero-D-arabino-*hexadeconate* (**24**). A sample of **23** (291 mg, 0.50 mmol) was treated by the procedure described in the preparation of **12** and then worked up to give a syrup of **24** (208 mg, 84%): R_f 0.20 (3 : 2 hexane–ethyl acetate); $[\alpha]_D^{15}$ +47° (*c* 1.0. $CHCl_3$); ^{1}H-NMR δ=1.20 (3H, d, Me-15, $J_{15,Me}$=6.0 Hz), 2.00, 2·03 and 2.11 (12H in total, each s, OAc×4), 2.52 (2H, d, H-2, $J_{2,3}$=6.0 Hz), 3.65 (3H, s, COOMe).

Found: C, 59.56; H, 8.20%. Calcd for $C_{25}H_{42}O_{10}$: C, 59.74; H, 8.42%.

Methyl 15-O-*Acetyl-6,7,8,9,10,11,12,13,14,16-decadeoxy-4,5*-O-*isopropylidene*-DL-glycero-D-erythro-(E)-*2-hexadecenonate* (**25**). A sample of **24** (271 mg, 0.54 mmol) was treated by the procedure described in the preparation of **13** and then worked up to give a syrup of **25** (91 mg, 42%): R_f 0.29 (5 : 1 hexane-ethyl acetate); $[\alpha]_D^{15}$ −7.5° (*c* 1.0, $CHCl_3$); UV_{max} (MeOH) 212 nm (ε 10800); ^{1}H-NMR δ=1.20 (3H, d, Me-15, $J_{15,Me}$= 6 Hz), 1.39 and 1.51 (each 3H, each s, Me_2C), 2.04 (3H, s, OAc), 3.77 (3H, s, COOMe), 4.16—4.28 (1H, m, H-5), 4.64 (1H, m, H-4), 4.80—4.95 (1H, m, H-15), 6.09 (1H, dd, H-2, $J_{2,3}$=15.5 Hz, $J_{2,4}$=1.5 Hz), 6.85 (1H, dd, H-3, $J_{2,3}$=15.5 Hz, $J_{3,4}$=6 Hz).

Found: C, 66.25; H, 9.84%. Calcd for $C_{22}H_{38}O_6$: C, 66.30; H, 9.61%.

6,7,8,9,10,11,12,13,14,16-Decadeoxy-4,5-O-*isopropylidene*-D-glycero-D-erythro-(E)-*2-hexadecenono-1,15-lactone* (**26**) *and* L-glycero-D-erythro-*isomer* (**27**). A sample of **25** (97 mg, 0.243 mmol) was treated by the procedure described in the preparation of **14** and **15**, and then worked up to give **26** (37 mg, 47%) and **27** (32 mg, 39%) having the R_f -values of 0.24 and 0.18 (10 : 1 hexane–ethyl acetate) respectively.

26: Needles from ether–hexane; mp 57—58 °C; $[\alpha]_D^{17}$ −60° (*c* 2.0, $CHCl_3$); UV_{max} (MeOH) 212 nm (ε 11700); ^{1}H-NMR δ=1.27 (3H, d, Me-15, $J_{15,Me}$=6 Hz), 1.38 and 1.52 (each 3H, each s, Me_2C), 4.16—4.26 (1H, m, H-5), 4.64 (1H, dt, H-4, $J_{3,4}$=7 Hz, $J_{2,4}$=1 Hz), 5.08 (1H, m, H-15), 6.04 (1H, dd, H-2, $J_{2,3}$=16 Hz, $J_{2,4}$=1 Hz), 6.86 (1H, dd, H-3, $J_{2,3}$= 16 Hz, $J_{3,4}$=7 Hz).

A Novel Synthesis of a Branched-chain Amino Sugar, Methyl 2-Amino-2,3-dideoxy-3-*C*-formyl-α-D-xylofuranoside-3′*R*,5-hemiacetal

Kuniaki TATSUTA,* Satoru MIYASHITA, Kohji AKIMOTO, and Mitsuhiro KINOSHITA

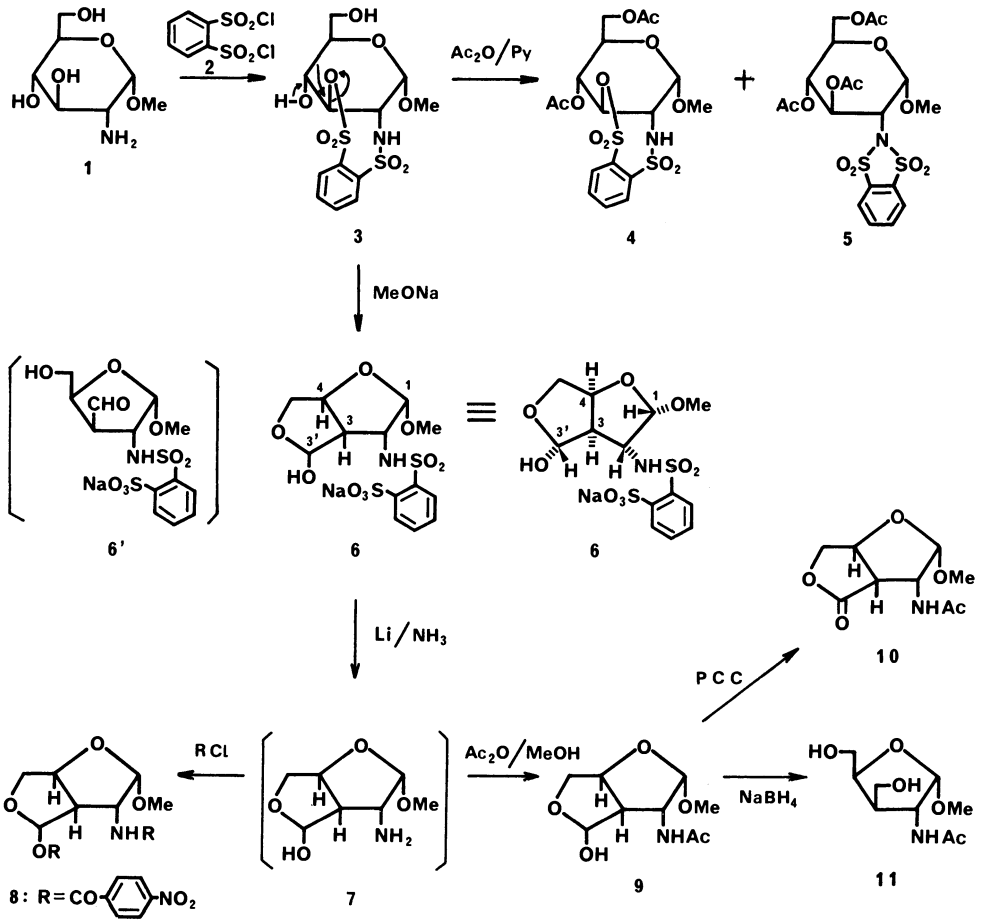
(Received April 14, 1982)

Methyl 2-amino-2*N*,3*O*-(*o*-benzenedisulfonyl)-2-deoxy-α-D-glucopyranoside, which was prepared from methyl 2-amino-2-deoxy-α-D-glucopyranoside and *o*-benzenedisulfonyl dichloride, was treated with sodium methoxide to afford exclusively a branched-chain amino sugar, methyl 2,3-dideoxy-3-*C*-formyl-2-(*o*-sulfobenzenesulfonyl)amino-α-D-xylofuranoside-3′*R*,5-hemiacetal sodium salt (**6**). Some derivatives were synthesized from **6**.

A variety of carbohydrates have been used for stereospecific syntheses of natural products as chiral sources.[1] However, little has been reported using amino sugars,[2] because of their scanty derivatives.

We now report a novel synthesis of branched-chain amino sugar, which may be useful for a suitably functionalized skeleton of alkaloids and β-lactam antibiotics. A noteworthy feature of this synthesis is that it does not require the use of extrinsic protecting groups. The key step was a skeletal rearrangement of the *N*,*O*-*o*-benzenedisulfonyl derivative **3**, where the *o*-benzenedisulfonyl group played simultaneously two roles as an *N*-protecting group and a leaving sulfonyl group. The reagent *o*-benzenedisulfonyl dichloride (**2**) was prepared from dipotassium *o*-benzenedisulfonate and phosphorus pentachloride in an 81% yield.[3] Methyl 2-amino-2-deoxy-α-D-glucopyranoside[4] (**1**) reacted with **2** to give exclusively methyl 2-amino-2*N*,3*O*-(*o*-benzenedisulfonyl)-2-deoxy-α-D-glucopyranoside (**3**) in an 87% yield. Acetylation of **3** gave the corresponding diacetate **4**, which, on longer reaction time, was gradually converted into the triacetate **5**. The ^{1}H-NMR of **5** showed no signal due to the NH group, supporting the *o*-benzenedisulfonimido structure **5**. The ^{1}H-NMR of **3** showed $J_{1,2}$=3.5 Hz, $J_{2,3}$=11.0 Hz and $J_{3,4}$=8.5 Hz, indicating that the chair form existed in the C_1^4 conformation, where the migrating C-4—C-5 bond can be *trans* coplanar to the C-3-benzenesulfonyloxy bond. Therefore, the sequential skeletal rearrangement of **3** seems to be facilitated by the breaking of parallel bonds to give, stereospecifically, a ring-contracted branched-chain furanoside **6**, through the aldehydo structure **6′**.[5] Furthermore, the ring



contraction of glycopyranosides through the possibly produced carbenium ion at their C-3 positions has been already reported to give stereospecifically 3-deoxy-3-*C*-formyl-xylo- or lyxo-furanosides.[5,6] When treated with sodium methoxide in methanol, **3** afforded a single product, methyl 2,3-dideoxy-3-*C*-formyl-2-(*o*-sulfobenzenesulfonyl)amino-*α*-D-xylofuranoside-3′*R*,5-hemiacetal sodium salt (**6**) in an 82% yield. Assignment of the absolute structure of **6** was based on the following aspects in addition to the aforesaid reaction mechanism: (i) the production of methyl 3-deoxy-3-*C*-formyl-*α*-D-xylofuranoside-3′,5-hemiacetal, for example, by solvolysis of methyl 3-*O*-(*p*-nitrobenzenesulfonyl)-*α*-D-glucopyranoside as reported by Austin *et al.*,[5] to support the stereochemistry at C-3 and C-4; (ii) the zero coupling constant between H-3 and H-3′ to show the dihedral angle to be approximately 90° supporting the *trans* configuration; (iii) the reasonable structure of the derivatives **7**—**11** as described later on. The characteristic signals (δ 101.72 ppm and 103.86 ppm) in the ^{13}C-NMR of **6** also supported the presence of two anomeric carbons. In the newly produced hemiacetal, however, an interconversion known as a mutarotation was not recognized at all even in H_2O or D_2O, indicating that the hydroxyl group at C-3′ was stereospecifically fixed in (*R*)-configuration.

Treatment of **6** with lithium in liquid ammonia afforded the crude amino furanoside (**7**), which was not purified because of its instability but characterized as the corresponding *p*-nitrobenzoyl derivative (**8**). Selective *N*-acetylation of the crude product **7** also gave crystalline methyl 2-acetamido-2,3-dideoxy-3-*C*-formyl-*α*-D-xylofuranoside-3′*R*,5-hemiacetal (**9**) in a 78% overall yield (from **6**). Compound **9** was oxidized with pyridinium chlorochromate to afford the *γ*-lactone, methyl 2-acetamido-2,3-dideoxy-3-*C*-carboxy-*α*-D-xylofuranoside-3′,5-lactone (**10**) in a 79% yield, and, on the other hand, reduced with sodium borohydride to yield the diol, methyl 2-acetamido-2,3-dideoxy-3-*C*-hydroxymethyl-*α*-D-xylofuranoside (**11**) in an 82% yield.

The application of these branched-chain derivatives to elaboration of *N*-containing natural products is an exciting prospect.

Experimental

Melting points were determined on a micro hot-stage Yanaco MP-S3 and were uncorrected. IR was recorded on a Hitachi Perkin-Elmer 225 spectrometer. ^{1}H-NMR spectra were recorded in $CDCl_3$ with TMS or D_2O with sodium 3-(trimethylsilyl)propionate-2,2,3,3-d_4 as internal standard on a Varian EM-390(90 MHz)or a Bruker WM 250 spectrometer (250 MHz), and ^{13}C-NMR spectra at 25.2 MHz or 62.9 MHz on a Varian XL 100 or a Bruker WM 250 spectrometer with TMS in $CDCl_3$ and dioxane in D_2O as internal standards. Optical rotations were measured on Carl Zeiss photoelectric polarimeter. Silica gel TLC and column chromatography were performed on Merck TLC 60F-254 and Wakogel C-200 or Kieselgel 60, respectively. In general, evaporation was carried out under reduced pressure below 30 °C.

Methyl 2-amino-2-deoxy-*α*-D-glucopyranoside[4b] (**1**) and *o*-benzenedisulfonyl dichloride[3] (**2**: mp 151—152 °C) were prepared according to the published procedures.

*Methyl 2-Amino-2*N,*3*O-*(*o*-benzenedisulfonyl)-2-deoxy-α*-D-*glucopyranoside (3).* To a stirred solution of **2** (10.0 g, 36 mmol) in pyridine (800 ml) was added dropwise a solution of monocarbonate of **1** (8.0 g, 31 mmol) in pyridine (80 ml) at room temperature over a period of 30 min, and stirring at this temperature was continued for another 30 min. After addition of ethanol (4.3 ml), the resulting solution was evaporated and co-evaporated with toluene to give a residue, which was chromatographed on silica gel (450 g) with 3 : 2 benzene–acetone to afford a solid. Recrystallization from ethyl acetate gave needles of **3** (10.7 g, 87%): R_f 0.37 (3 : 2 benzene–acetone); mp 131—132 °C; $[\alpha]_D^{18}$ +149° (*c* 1.0, acetone); IR (KBr): 1425, 1345, 1180, 1160 cm^{-1} (O–SO_2, N–SO_2); ^{1}H-NMR ($CDCl_3$): δ=3.44 (3H, s, OMe), 3.5—4.0 (5H, m, H-2,4,5 and 6), 4.88 (1H, d, H-1, $J_{1,2}$=3.5 Hz), 5.08 (1H, dd, H-3, $J_{2,3}$=11.0 Hz, $J_{3,4}$=8.5 Hz, *vice versa*), ≈5.7 (1H, a broad signal, NH), 7.6—7.9 (2H, m, aromatic), 8.2—8.3 (2H, m, aromatic).

Found: C, 39.84; H, 4.68; N, 3.23%. Calcd for $C_{13}H_{17}NO_9S_2$: C, 39.49; H, 4.33; N, 3.54%.

*Methyl 4,6-Di-*O*-acetyl-2-amino-2*N,*3*O-*(*o*-Benzenedisulfonyl)-2-deoxy-α*-D-*glucopyranoside (4) and Methyl 3,4,6-Tri-*O*-acetyl-2-amino-*N,N′-*(*o*-benzenedisulfonyl)-2-deoxy-α*-D-*glucopyranoside (5).* A solution of **3** (51.9 mg, 0.131 mmol) in pyridine (0.5 ml) was stirred with acetic anhydride (0.074 ml) at room temperature for 13 h. After addition of a few drops of ethanol, the resulting solution was evaporated to a residue, which was chromatographed on silica gel (5 g) with 3 : 1 benzene–ethyl acetate to give **4** (41 mg, 65%) and **5** (8.9 mg, 13%) having the R_f-values of 0.71 and 0.76 (3 : 2 benzene–acetone) respectively.

4: Cubics from ethyl acetate–hexane; mp 198—199 °C; $[\alpha]_D^{17}$ +135° (*c* 1.0, $CHCl_3$); IR (KBr) 1740, 1735, 1730 (OAc), 1425, 1360, 1345, 1185, 1175, 1145 cm^{-1} (O–SO_2, N–SO_2); ^{1}H-NMR ($CDCl_3$): δ=2.10 and 2.16 (each 3H, s, OAc), 3.49 (3H, s, OMe), 3.95—4.05 (2H, m, H-2 and 5), 4.15 (1H, dd, H-6, $J_{5,6}$=2.0 Hz, $J_{6,6'}$=12.5 Hz), 4.30 (1H, dd, H-6′, $J_{5,6'}$=4.5 Hz), 4.93 (1H, d, H-1, $J_{1,2}$=3.5 Hz), 5.21 (2H, m, H-3 and 4), 5.65 (1H, a broad signal, NH), 7.68 and 7.81 (each 1H, m, aromatic), 8.20 and 8.23 (each 1H, m, aromatic).

Found: C, 42.33; H, 4.41; N, 2.65; S. 13.19%. Calcd for $C_{17}H_{21}NO_{11}S_2$: C, 42.59; H, 4.41; N, 2.92; S, 13.37%.

5: Needles from benzene–hexane; mp 178—179 °C; $[\alpha]_D^{18}$ +118° (*c* 1.0, $CHCl_3$); IR (KBr): 1760, 1740, 1725, 1720 (OAc), 1430, 1365, 1190, 1180 cm^{-1} (N–SO_2); ^{1}H-NMR ($CDCl_3$): δ=2.09, 2.22 and 2.38 (each 3H, s, OAc), 3.50 (3H, s, OMe), 4.0—4.6 (3H, m, H-5 and 6), 4.84 (1H, dd, H-2, $J_{1,2}$=3.5 Hz, $J_{2,3}$=12 Hz), 5.02 (1H, d, H-1), 5.23 (1H, t, H-4, $J_{3,4}$=$J_{4,5}$=9.0 Hz), 6.38 (1H, dd, H-3), 7.9—8.1 (2H, m, aromatic), 8.5—8.7 (2H, m, aromatic).

Found: C, 43.65; H, 4.41; N, 2.84; S, 12.10%. Calcd for $C_{19}H_{23}NO_{12}S_2$: C, 43.76; H, 4.45; N, 2.69; S, 12.30%.

*Methyl 2,3-Dideoxy-3-*C*-formyl-2-(*o*-sulfobenzenesulfonyl)amino-α*-D-*xylofuranoside-3′*R,*5-hemiacetal Sodium Salt (6).* To a stirred and ice-cooled solution of **3** (5.76 g, 14.6 mmol) in dry methanol (115 ml) was added sodium methoxide (1.57 g, 29.2 mmol), and the solution was stirred at 50 °C overnight. After further addition of sodium methoxide (2.36 g, 43.7 mmol), stirring at 50 °C was continued for another 1 d. The resulting suspension was neutralized with Amberlite CG-50 (H type), filtered, and the filtrate evaporated to give a residue, which was chromatographed on silica gel (240 g) with 4 : 1 chloroform–methanol to give a solid of **6** (5.0 g, 82%): R_f 0.34 (4 : 1 chloroform–methanol); $[\alpha]_D^{19}$ +5° (*c* 1.0, MeOH); $[\alpha]_{365}^{19}$ −35° (*c* 1.0, MeOH); IR (KBr): 1340, 1170, 1140(N–SO_2, SO_3Na); ^{1}H-NMR (D_2O): δ=2.52 (1H, t, H-3, $J_{2,3}$=$J_{3,4}$≃7.5 Hz, $J_{3,3'}$=0 Hz), 3.08 (3H, s, OMe), 3.62 (1H, dd, H-2,

$J_{1,2}$=4.5 Hz), 3.84 (2H, broad s, H-5), 4.55 (1H, d, H-1), 4.77 (1H, m, H-4), 5.12 (1H, s, H-3′, $J_{3,3'}$=0 Hz), 7.55—7.80 (2H, m, aromatic), 8.05—8.20 (2H, m, aromatic); ^{13}C-NMR (62.9 MHz, D_2O) δ=55.24, 60.30 and 81.73 (C-2,3 and 4, *vice versa*), 55.70 (OMe), 71.61 (C-5), 101.72 and 103.86 (C-1 and 3′, *vice versa*), 130.97, 131.34, 132.94, 135.06, 136.37, and 141.69 (aromatic).

Found: C, 37.05; H, 3.89; N, 3.61%. Calcd for $C_{13}H_{16}NO_9S_2Na$: C, 37.41; H, 3.86; N, 3.36%.

Methyl 2-Amino-2,3-dideoxy-3-C-formyl-α-D-xylofuranoside-3′R,5-hemiacetal (7). A gaseous ammonia was introduced and trapped in a pre-cooled vessel containing **6** (2.17 g, 5.20 mmol) at −60 °C. To the resulting solution (about 60 ml) was added a piece of lithium metal (144 mg) by portions with stirring, and stirring at −50 °C was continued for 1 h. After careful addition of NH_4Cl (1.11 g), the mixture was allowed to evaporate to a residue, which was dried *in vacuo* to afford a crude solid (3.3 g) containing **7** with concomitant salts. As the product **7** was considerably labile, the solid was used for the next step without purification.

Methyl 2,3-Dideoxy-3-C-formyl-2-(p-nitrobenzoyl)amino-3′-C-(p-nitrobenzoyl)-α-D-xylofuranoside-3′R,5-hemiacetal (8). A crude solid of **7** (173 mg) was stirred with *p*-nitrobenzoyl chloride (400 mg) in pyridine (6.0 ml) at 70 °C overnight. After addition of ethanol, the resulting mixture was evaporated to give a residue, which was partitioned between ethyl acetate and a saturated aqueous $NaHCO_3$ solution. The combined organic layers were washed with a saturated aqueous NaCl solution, dried and evaporated to a residue, which was chromatographed on silica gel (15 g) with 4 : 1 benzene–ethyl acetate to afford, after recrystallization from ethyl acetate-hexane, needles of **8** (57 mg, 44% from **6**): mp 208—210 °C; $[\alpha]_D^{21}$ 0° (*c* 1.0, $CHCl_3$); $[\alpha]_{405}^{21}$ −35° (*c* 1.0, $CHCl_3$); IR (KBr): 1730 (ester), 1660 (amide I), 1600 (aromatic), 1525 (amide II), 1345 cm^{-1} (NO_2); ^{1}H-NMR ($CDCl_3$): δ=3.05 (1H, t, H-3, $J_{2,3}$=$J_{3,4}$=7.5 Hz, $J_{3,3'}$=0 Hz), 3.50 (3H, s, OMe), 4.19 (2H, broad s, H-5), 4.56 (1H, dt, H-2, $J_{1,2}$=4.5 Hz, $J_{2,NH}$=7.5 Hz), 5.0 (1H, m, H-4), 5.08 (1H, d, H-1), 6.82 (1H, d, NH), 6.93 (1H, s, H-3′), 7.9—8.4 (8H, m, aromatic); ^{13}C-NMR (25.2 MHz, $CDCl_3$): δ=54.71 (OMe), 56.03 and 56.65 (C-2 and 3), 73.20 (C-5), 80.68 (C-4), 103.21 and 103.41 (C-1 and 3′, *vice versa*), 123.16, 123.41, 128.00, 130.40, 134.88, 138.88, 149.32 and 150.22 (aromatic), 162.92, 164.92 (C=O).

Found: C, 53.12; H, 4.20; N, 8.63%. Calcd for $C_{21}H_{19}N_3O_{10}$: C, 53.28; H, 4.05; N, 8.88%.

Methyl 2-Acetamido-2,3-dideoxy-3-C-formyl-α-D-xylofuranoside-3′-R,5-hemiacetal (9). To a solution of a crude solid of **7** (1.0 g) in methanol (20 ml), were added triethylamine (0.22 ml) and, after 30 min, acetic anhydride (0.45 ml) with stirring at room temperature. After 1.5 h, the resulting solution was evaporated to a residue, which was chromatographed on silica gel (30 g) with 3 : 2 chloroform–acetone followed by recrystallization from acetone–hexane to give needles of **9** (267 mg, 78% from **6**): R_f 0.69 (3 : 1 ethyl acetate–methanol); mp 165 °C, $[\alpha]_D^{16}$ +58° (*c* 1.0, $CHCl_3$); IR (KBr): 1650 (amide I), 1550 cm^{-1} (amide II); ^{1}H-NMR ($CDCl_3$): δ=1.99 (3H, s, NAc), 2.55 (1H, t, H-3, $J_{2,3}$=$J_{3,4}$=7.5 Hz, $J_{3,3'}$=0 Hz); 3.48 (3H, s, OMe), 3.85—4.2 (3H, m, H-5 and OH), 4.21 (1H, dt, H-2, $J_{1,2}$=5.0 Hz, $J_{2,NH}$=7.5 Hz), 4.86 (1H, d, H-1), 4.7—4.9 (1H, m, H-4), 5.79 (1H, d, H-3′, $J_{3',OH}$=3.0 Hz, which collapsed to a singlet on addition of D_2O), 6.14 (1H, d, NH, which disappeared on addition of D_2O).

Found: C, 50.03; H, 6.87; N, 6.24%. Calcd for $C_9H_{15}NO_5$: C, 49.76; H, 6.96; N, 6.45%.

Methyl 2-Acetamido-2,3-dideoxy-3-C-carboxy-α-D-xylofuranoside-3′,5-lactone (10). To a vigorously stirred solution of **9** (1.75 g, 8.06 mmol) in dry $CHCl_3$ (35 ml) was added pyridinium chlorochromate (3.47 g, 16.1 mmol) by portions at room temperature, and stirring at this temperature was continued for 2 d. The turbid supernatant was pipetted off, and the precipitated mass was triturated several times with dichloromethane. The combined supernatants were evaporated to a residue, which was chromatographed on silica gel (150 g) with 2 : 1 chloroform–acetone followed by recrystallization from ethyl acetate-hexane to afford needles of **10** (1.37 g, 79%): R_f 0.29 (2 : 1 chloroform–acetone); mp 192 °C; $[\alpha]_D^{17}$ +100° (*c* 1.0, $CHCl_3$); IR (KBr): 1760 (lactone), 1650 (amide I), 1555 cm^{-1} (amide II); ^{1}H-NMR ($CDCl_3$ with a drop of D_2O): δ=2.02 (3H, s, NAc), 3.10 (1H, dd, H-3, $J_{2,3}$=5.0 Hz, $J_{3,4}$=6.0 Hz), 3.44 (3H, s, OMe), 4.40 (2H, d, H-5, $J_{4,5}$=3.0 Hz), 4.77 (1H, t, H-2, $J_{1,2}$=5.0 Hz), 4.90 (1H, dt, H-4), 5.08 (1H, d, H-1).

Found: C, 50.39; H, 6.14; N, 6.31%. Calcd for $C_9H_{13}NO_5$: C, 50.23; H, 6.09; N, 6.51%.

Methyl 2-Acetamido-2,3-dideoxy-3-C-hydroxymethyl-α-D-xylofuranoside (11). To a stirred solution of **9** (80 mg) in methanol (0.8 ml) was added $NaBH_4$ (28 mg) by portions at room temperature. After 30 min, the resulting solution was neutralized with Amberlite CG-50 (H type), filtered and then evaporated to a residue, which was chromatographed on silica gel (7.5 g) with 15 : 1 chloroform–methanol followed by recrystallization from benzene–hexane to afford needles of **11** (66 mg, 82%): R_f 0.13 (1 : 1 benzene–acetone); mp 113—114°; $[\alpha]_D^{19}$ +100° (*c* 1.0, $CHCl_3$); IR (KBr): —1650, 1610, 1555 cm^{-1} (amide); ^{1}H-NMR ($CDCl_3$): δ=2.04 (3H, s, NAc), 2.34 (1H, m, H-3), 3.43 (3H, s, OMe), 3.7—4.0 (5H, m, H-3′, 5 and OH), 4.20 (1H, dt, H-4, $J_{3,4}$=9.0 Hz, $J_{4,5}$=3.0 Hz), 4.42 (1H, ddd, H-2, $J_{1,2}$=5.0 Hz, $J_{2,NH}$=8.5 Hz, $J_{2,3}$=11.5 Hz), 4.71 (1H, t, OH, $J_{CH_2,OH}$=7.0 Hz, which disappeared on addition of D_2O), 4.95 (1H, d, H-1), 6.23 (1H, broad d, NH, which disappeared on addition of D_2O).

Found: C, 49.40; H, 7.59; N, 6.28%. Calcd for $C_9H_{17}NO_5$: C, 49.31; H, 7.82; N, 6.39%.

We are grateful to Prof. S. Umezawa, Institute of Bioorganic Chemistry, and Prof. H. Umezawa, Institute of Microbial Chemistry, for their generous support of our program. We also thank Mr. S. Nakada for elemental analyses and Miss Y. Suzuki for 250 MHz NMR analyses.

Syntheses and Properties of Di-, Tri-, and Tetracyclopropyltropylium and Di- and Tri-*t*-butyltropylium Ions

Koichi KOMATSU, Ken'ichi TAKEUCHI, Makoto ARIMA, Yoshinori WAKI, Shuzo SHIRAI, and Kunio OKAMOTO*

Department of Hydrocarbon Chemistry, Faculty of Engineering, Kyoto University, Sakyo-ku, Kyoto 606

(Received April 17, 1982)

The polysubstituted tropylium ions having cyclopropyl or *t*-butyl groups at the ring positions with the least steric hindrance, *i.e.* 1,3- and 1,4-dicyclopropyltropylium, 1,3- and 1,4-di-*t*-butyltropylium, 1,3,5-tricyclcpropyl- and 1,3,5-tri-*t*-butyltropylium and 1,2,4,6-tetracyclopropyltropylium ions (**4**), were synthesized, and their properties were compared with the known monosubstituted and unsubstituted cations. The ^{1}H and ^{13}C NMR spectra for the cyclopropyl derivatives and the ^{13}C NMR spectra for the *t*-butyl derivatives exhibited a gradual upfield shift for the seven-membered ring signals upon consecutive substitution. Accordingly, for the *t*-butyl derivatives, the pK_{R^+} values were found to linearly increase upon introduction of each substuent; for the cyclopropyl derivatives, a larger extent of the pK_{R^+} increase was observed with each substitution, and the pK_{R^+} of the tetrasubstituted derivative **4** amounted to 9.10 (50% aq MeCN, 25 °C), the highest value presently known for the hydrocarbon cations having the tropylium unit, although the cumulative substituent effect deviated from the linear additivity correlation as the substituent number increased. The substituent effects upon the reduction potential and the CT transition energy (pyrene as a donor) were also examined and shown to have the same tendency in general.

The stabilization of the carbocation by the cyclopropyl (c-Pr) group is now widely recognized.[1] Especially for the tropylium ion as the representative Hückel aromatic cation, our previous study on pK_{R^+} and one-electron reducibility indicated that the σ-conjugative stabilization by the c-Pr group is more than twice as effective as the stabilization by the *t*-butyl (*t*-Bu) group with its purely inductive electron donation, while the π-conjugative stabilization of the phenyl group was no more observable owing to the *ortho*-hydrogen repulsion.[2]

On the other hand, the detailed study on the reducibility of a series of polymethyltropylium ions revealed that the additivity of the substituent effect upon cation stability holds when no severe steric congestion is present around the tropylium ring, *i.e.* when the number of substituents does not exceed more than five.[3] Thus, we synthesized the tropylium ions substituted with two to four c-Pr groups and with two and three *t*-Bu groups at the ring positions where the effect of steric repulsion is minimized, and examined the additivity of the electronic effect of these substituents upon cation stability.

Syntheses. The 1,3- and 1,4-disubstituted (**2**) and 1,3,5-trisubstituted tropylium ions (**3**) each having the c-Pr (**2a**, **2b**, and **3a**) or *t*-Bu groups (**2c**, **2d**, and **3b**[4]) were synthesized as shown in Scheme 1, by the use of the conventional method involving the CuBr-catalyzed ring expansion of the substituted benzenes with diazomethane, followed by hydride abstraction.

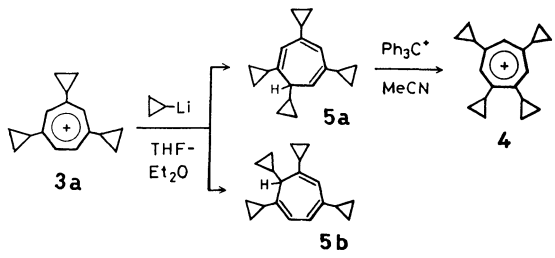
Scheme 1.

For the synthesis of the tetracyclopropyltropylium ion (**4**), we adopted a cation-anion combination reaction of the trisubstituted cation **3a** with cyclopropyllithium at −70 °C as shown in Scheme 2. 1,3,5,7-Tetracyclopropylcycloheptatriene (**5a**), which was isolated in 41% yield, was then treated with the trityl cation to give the 1,2,4,6-tetracyclopropyltropylium ion (**4**) in 85% yield. The 1,3,6,7-tetrasubstituted derivative **5b** with higher steric hindrance was isolated only in 8% yield.

Properties. The physical and spectral properties of the newly synthesized salts of the cations **2a—d**, **3a**, **b**, and **4** are shown in Table 1, together with the data for the unsubstituted (**6**) and monosubstituted cations (R–$C_7H_6^+$: R=c-Pr (**1a**), *t*-Bu (**1b**)) for the purpose of comparison.



Scheme 2.

Among these data, it is to be noted that in the ^{1}H NMR spectra for a series of c-Pr-substituted cations the signal for the tropylium-ring protons, which appears as a somewhat broadened singlet except for the cation **4**, is gradually shifted upfield with higher substitution. This upfield shift is supposed to reflect mostly the electronic effect of the increasing number of c-Pr substituents delocalizing the positive charge away from the cationic ring, in addition to the anisotropic ring-current effect of the c-Pr ring.[5] A similar general trend

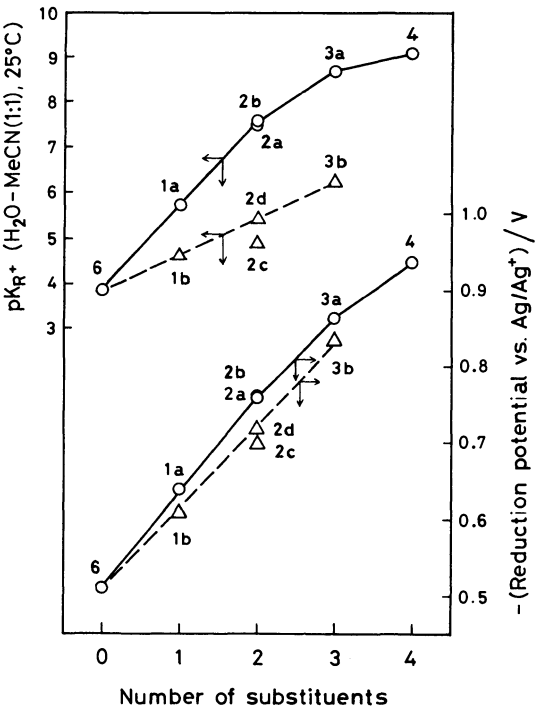

Fig. 1. Correlation of the pK_{R^+} and reduction potential with the number of substituent (○, c-Pr; △, *t*-Bu).

is observed for the ^{13}C NMR data shown in Table 2.

Compared with the case of c-Pr-substituted cations, the aromatic-ring proton signals in the ^1H NMR spectra of *t*-Bu derivatives do not exhibit any systematic upfield shift upon consecutive substitution, presumably due to the considerable steric compression effect of the bulky *t*-Bu groups. In the ^{13}C NMR spectra, however, the gradual upfield shift is again clearly observed for the ring-carbon signals, though the increment of the upfield shift upon each substitution is apparently smaller than that observed for a series of c-Pr derivatives.†

Based on these results of NMR measurements, it is now of particular interest to examine the additivity of the substituent effects of the c-Pr and *t*-Bu groups upon the cation stability expressed by the pK_{R^+} value. As shown in Table 3, the pK_{R^+} value increases upon consecutive c-Pr substitution and reaches the maximum value of 9.10 for the tetra-c-Pr derivative **4**. To our knowledge this is the highest pK_{R^+} value reported for the hydrocarbon cations having the tropylium unit.[6]

Also included in Table 3 are the data of reduction potentials determined by cyclic voltammetry (CV) and of charge-transfer (CT) band observed with pyrene as a π-donor. In our previous study,[2a,2b,3] the CT transition energy of various mono- and polysubstituted tropylium ions with pyrene as a donor was shown to exhibit a linear correlation with the one-electron reducibility of these cations in solution. For the present series of cations, a similar correlation seems to hold in general. However, for the highly substituted derivatives, the CT absorption bands become much too weak to allow the accurate determination of the absorption maxima, presumably due to the steric congestion between the donor and acceptor.

Thus, the more precisely measurable values of pK_{R^+} (limit of precision, $\pm$0.05) and reduction potential ($\pm$0.005 V) were plotted against the number of substituents to give the correlation shown in Fig. 1. From this plot is observed that, in contrast to the linear correlations obtained for the *t*-Bu derivatives, the pK_{R^+} of the c-Pr derivatives apparently deviates from the linear correlation line as the substituent number increases. This result seems to indicate that, for an aromatic cation like the tropylium ion, the additivity towards the cation stability holds for the substituents with the purely inductive electronic effect, whereas some saturation phenomenon exists for the cumulative effect of σ-conjugative substituents.†† The detailed discussion on the correlation between the pK_{R^+} and other indices corresponding to the electron affinity for a wider variety of stable cations will be made in a separate publication.[7]

† For the purpose of comparison, when we simply average the chemical shift values for the ring-carbons carrying no substituent, the following δ-values are obtained: **6**, 156.2; **1a**, 152.0; **2a**, 148.2; **2b**, 148.2; **3a**, 144.6; **4**, 141.6; **1b**, 154.1; **2c**, 151.8; **2d**, 151.7; **3b**, 149.5.

†† This phenomenon would be attributed to the decrease in population of the c-Pr groups taking the bisected conformation as the cationic ring becomes less electron-demanding with higher substitution. Especially in the case of the cation **4**, the parallel conformation rather than the bisected one may be sterically favored for the two neighboring c-Pr groups at C-1 and C-2. However, these groups are apparently not fixed in such geometry, as judged from the small chemical-shift difference (*ca.* 0.1 ppm) between H-3,7 and H-5; the c-Pr groups in hexacyclopropylbenzene, for example, have been reported to be freely rotating in solution though fixed in the parallel conformation in the crystalline state.[8]

Experimental

General. Melting points are uncorrected. The elemental analyses were performed by the Microanalytical Center, Kyoto University, Kyoto. The IR and UV spectra were recorded on Hitachi 215 snd Hitachi 200-10 spectrometers, respectively. The ^{1}H NMR spectra were taken with a Hitachi R-24 spectrometer with Me_4Si as the internal standard. The ^{13}C NMR spectra were recorded on a JEOL FX-100 spectrometer operated in the Fourier transform mode.

Materials. The di- and tricyclopropylbenzenes were prepared from the corresponding di- and trivinylbenzenes following the method of Effenberger and Kurtz.[9] The di- and tri-*t*-butylbenzenes were prepared by the Friedel-Crafts *t*-butylation of benzene with *t*-butyl chloride catalyzed by $FeCl_3$ or $AlCl_3$. Other materials used were of the reagent grade quality unless otherwise noted.

*1,3-Dicyclopropyltropylium Tetrafluoroborate (**2a**·BF_4^-).* A 0.43 M solution of diazomethane in CH_2Cl_2 (50 ml), prepared from *N*-methyl-*N*-nitrosourea,[10] was added dropwise to a stirred solution of 1,3-dicyclopropylbenzene (1.87 g; 11.8 mmol) in CH_2Cl_2 (10 ml) in the presence of CuBr (0.55 g; 3.9 mmol) at 40 °C over 30 min. After refluxing for 20 min, the mixture was filtered and evaporated to give 2.20 g of the crude product, which was found to contain about 20% of olefinic compounds by the ^{1}H NMR analysis. The hydride abstraction of the crude product with trityl tetrafluoroborate (1.00 g; 3.03 mmol) in MeCN (3 ml) and CH_2Cl_2 (3 ml), followed by precipitation with dry ether and recrystallization from MeCN, afforded 0.374 g (12.3% yield based on dicyclopropylbenzene) of the product, the ^{13}C NMR spectrum of which indicated the formation of both the 1,3- (**2a**) and 1,4-dicyclopropyltropylium (**2b**) ions in a ratio of 2 : 1. The fractional recrystallization from MeCN repeated twice yielded 0.050 g of **2a**·BF_4^- as white crystals. Found: C, 60.47; H, 6.01%. Calcd for $C_{13}H_{15}BF_4$: C, 60.50; H, 5.86%.

*1,4-Dicyclopropyltropylium Tetrafluoroborate (**2b**·BF_4^-).* In exctly the same way, 1,4-dicyclopropylbenzene was allowed to react with two-fold excess of diazomethane in CH_2Cl_2. The subsequent hydride abstraction and recrystallization from MeCN afforded **2b**·BF_4^- as white crystals in 10.6% yield. Found: C, 60.34; H, 5.77%. Calcd for $C_{13}H_{15}BF_4$: C, 60.50; H, 5.86%.

*1,3,5-Tricyclopropyltropylium Tetrafluoroborate (**3a**·BF_4^-).* Similarly, **3a**·BF_4^- was synthesized from 1,3,5-tricyclopropylbenzene in 10.0% yield as white crystals. Found: C, 64.73%; H, 6.57%. Calcd for $C_{16}H_{19}BF_4$: C, 64.46; H, 6.42%.

*1,3-Di-t-butyltropylium Perchlorate (**2c**·ClO_4^-).* In the same way, **2c**·ClO_4^- was synthesized through the ring-expansion of 1,3-di-*t*-butylbenzene with diazeomthane in heptane, followed by hydride abstraction with trityl perchlorate in 7.0% yield as white crystals. Found: C, 59.32; H, 7.72%. Calcd for $C_{15}H_{23}ClO_4$: C, 59.50; H, 7.66%.

*1,4-Di-t-butyltropylium Perchlorate (**2d**·ClO_4^-).* Similarly, **2d**·ClO_4^- was synthesized from 1,4-di-*t*-butylbenzene in 9.2% yield as white crystals. Found: C, 59.32; H, 7.72%. Calcd for $C_{15}H_{23}ClO_4$: C, 59.50; H, 7.66%.

*1,3,5-Tri-t-butyltropylium Perchlorate (**3b**·ClO_4^-).* Similarly, **3b**·ClO_4^- was synthesized from 1,3,5-tri-*t*-butylbenzene in 4.5% yield as white crystals. Found: C, 63.32; H, 8.72%. Calcd for $C_{19}H_{31}ClO_4$: C, 63.59; H, 8.71%.

*1,2,4,6-Tetracyclopropyltropylium Perchlorate (**4**·ClO_4^-).* An ethereal solution (5 ml) of 0.48 M cyclopropyllithium (2.4 mmol), prepared from cyclopropyl bromide and Li, was added dropwise to a stirred suspension of **3a**·BF_4^- (0.309 g; 1.04 mmol) in dry THF (4 ml) cooled at −70 °C over 5 min. After stirring at −70 °C for 10 min, the temperature was slowly raised to room temperature over 1 h. The mixture was hydrolyzed and worked up in the usual manner to give 0.30 g of the crude product, which exhibited three main spots at R_f 0.60, 0.49, and 0.34 on an analytical TLC plate developed with hexane–benzene (9 : 1) over SiO_2 (Merck, GF_{254}). From the fraction with R_f 0.60, we isolated, by the use of preparative TLC over SiO_2 (Merck, F_{254}, pre-coated), 1,3,5,7-tetracyclopropylcycloheptatriene (**5a**) (0.107 g; 40.9%) as a colorless oil: IR (neat) ν 3080 m, 3005 m, 1621 m, 1460 w, 1425 w, 1018 m cm^{-1}; ^{1}H NMR (CCl_4) δ 6.02 (br s, 1H, H-4), 5.45 (br s, 1H, H-2), 4.91 (br d, 1H, H-6), 1.93—0.95 (m, 5H, H-7+c-Pr-H$_\alpha$), 0.90—0.20 (m, 16H, c-Pr-H$_\beta$); ^{13}C NMR ($CDCl_3$) δ 144.7, 143.1, 136.8 (s×3, C-1,3,5), 123.7, 120.0, 117.5 (d×3, C-2,4,6), 47.2 (d, C-7), 18.2, 15.6, 14.9, 11.7 (d×4, c-Pr-C$_\alpha$), 8.6, 7.6, 7.1, 6.4, 5.4, 5.3, 4.0, 3.9 (t×8, c-Pr-C$_\beta$). From the fraction with R_f 0.49, we also obtained the colorless oil (0.0215 g; 8.2%), which was assigned as 1,3,6,7-tetracyclopropylcycloheptatriene (**5b**) on the basis of the following spectral data; IR (CCl_4) ν 3085 m, 3005 m, 1620 w, 1456 w, 1426 w, 1018 m cm^{-1}; ^{1}H NMR (CCl_4) δ 6.12 (br d, 1H, H-4), 5.82 (br d, 1H, H-5), 5.55 (br s, 1H, H-2), 2.00—1.10 (br m, 5H, H-7+c-Pr-H$_\alpha$), 1.00—0.30 (br m, 16H, c-Pr-H$_\beta$); ^{13}C NMR ($CDCl_3$) δ 141.4, 140.3. 140.0 (s×3, C-1,3,6), 122.1, 119.1, 118.5 (d×3, C-2,4,5), 50.4 (d, C-7), 19.5, 19.2, 18.1, 13.7 (d×4, c-Pr-C$_\alpha$), 8.7—3.8 (partially overlapped eight peaks, c-Pr-C$_\beta$).

To a stirred solution of **5a** (0.0965 g; 0.383 mmol) in MeCN (1 ml) was added trityl perchlorate (0.0800 g; 0.234 mmol) in one portion. After stirring at room temperature for 3 h, dry ether (20 ml) was added to cause the formation of precipitates, which were then filtered and purified by reprecipitation from MeCN–ether to give **4**·ClO_4^- (0.0684 g; 83.4%) as off-white crystals. Found: C, 64.24; H, 6.69%. Calcd for $C_{19}H_{23}ClO_4$: C, 65.04; H, 6.61%.

pK_{R^+} Measurements. The pK_{R^+} values were determined in H_2O–MeCN (1 : 1 by volume) at 25 °C according to the spectrophotometric method described in our previous paper in detail.[11] The buffer solutions were made up by mixing 0.1 M citric acid and 0.1 M Na_2HPO_4 in H_2O–MeCN (1 : 1) (pH 3.0—8.2), and 0.01 M Na_2HPO_4 and 0.01 M Na_3PO_4, with 0.02 M Na_2CO_3 added in H_2O–MeCN (1 : 1) (pH 8.0—11.0). The pH values were read on a Horiba H pH meter calibrated with standard buffers before use.

Cyclic Voltammetry. The measurements were carried out in MeCN by the instruments and method previously reported.[11] As the reduction potential, we took the value of the cathodic peak potential of the voltammogram obtained at the scan rate of 0.1 V/s. The potential was determined against the reference electrode, Ag/0.01 M $AgNO_3$ with 0.1 M Bu_4NClO_4 in MeCN, and calibrated with $E_{1/2}$ of ferrocene added as an internal standard immediately after each measurement.

Charge-transfer Spectra. The spectra were taken in exactly the same way as previously reported,[2b] for the solution of 1×10^{-3} M cation (acceptor) and 0.1 M pyrene (donor) in 1,2-dichloroethane.

Acetolysis of [4.2.2]Propellan-7-ylmethyl Tosylates

Yoshito Tobe,* Tetsuo Yonezawa, Kiyomi Kakiuchi, and Yoshinobu Odaira
Department of Petroleum Chemistry, Faculty of Engineering, Osaka University, Suita, Osaka 565
(Received April 21, 1982)

The acetolysis rates and products of [4.2.2]propellan-7-ylmethyl tosylates were determined in order to clarify the effect of the central and external cyclobutane bonds on the modes of the ring expansion of the cyclobutylmethyl moiety. Since the products obtained from the *endo* tosylate were the olefin and the acetate having 1,7-tetramethylenenorbornane skeleton, it is deduced that the ring expansion occurs selectively to afford [4.3.2]propellan-7-yl cation which is stabilized by the external cyclobutane bond. In contrast, the *exo* tosylate gave the products derived from both [4.3.2]propellan-7-yl and -8-yl cations which are subject to the participation of the external and central cyclobutane bonds, respectively.

It has been documented that the solvolysis of cyclobutylmethyl derivatives proceeds with σ participation of the cyclobutane bond.[1] Since the ring expansion occurs so as to stabilize the ring-expanded cation, the specificity in the modes of the ring expansion is affected markedly by the geometry of the cyclobutylmethyl moieties, especially, involved in polycarbocyclic systems.[2] We have been interested in the solvolytic rearrangements of the propellane derivatives having one or two cyclobutane rings, [*m.n*.2]propellanes ($m \geq 3$, $n \geq 2$), such as [4.3.2]-propellan-7-yl tosylates (**1a**) and (**2a**),[3a,b] [3.3.2]-propellan-9-yl tosylate (**3**),[3c] [4.2.2]propellan-7-yl derivatives (**4a** and **5a**).[3d] In the above studies, it has been pointed out that the propellane derivatives undergo solvolysis with participation of the central (a) or external (b) bond of the cyclobutane ring depending on the ring size of the propellane framework and the stereochemistry of the leaving group. In this connection, we wish to report here the acetolysis of [4.2.2]propellan-7-ylmethyl tosylates (**4b** and **5b**) and emphasize that the central (a) and external (b) cyclobutane bonds which are remote from the cation center play an important role in the ring expansion of the cyclobutylmethyl moiety by 1,2-shift of the bond (c) or (d).

The tosylates **4b** and **5b** were prepared from the alcohols **4c** and **5c** which were obtained by the lithium aluminium hydride reduction of the corresponding methyl esters **4d** and **5d**.[4] In order to establish the *exo*/*endo* stereochemistry of **4b**—**d** and **5b**—**d** unambiguously, the unsaturated esters **6** and **7** were prepared by the ring contraction of the ketone **8**[5] in the manner similar to that of preparation of **4d** and **5d**.[4] The stereochemical assignment of **6** and **7** was based on the ^{1}H NMR spectra and the lanthanoide-induced shift in the ^{1}H NMR as follows: whereas the vinyl protons of **6** appeared as overlapping doublets (J=2 Hz) at δ 6.22 ($\Delta\delta$=0), those of **7** appeared at δ 6.03 (d, J=2 Hz) and 6.21 (d, J=2 Hz) ($\Delta\delta$=0.18). Moreover, in the lanthanoide-shifted NMR using Eu(dpm)$_3$, the S values[6] for the vinyl protons of **6** were 2.9 and 2.0 while those of **7** were 6.5 and 2.5. These results indicate clearly that the methoxycarbonyl group of **7** is located at exo direction which is nearer to the vinyl group. It is therefore deduced that **6** and **7** are the *endo* and *exo* isomers, respectively. Finally, catalytic hydrogenation of **6** and **7** with Pd/C gave the esters **4d** and **5d**, respectively, thus establishing the stereochemistry of **4b**—**d** and **5b**—**d**.

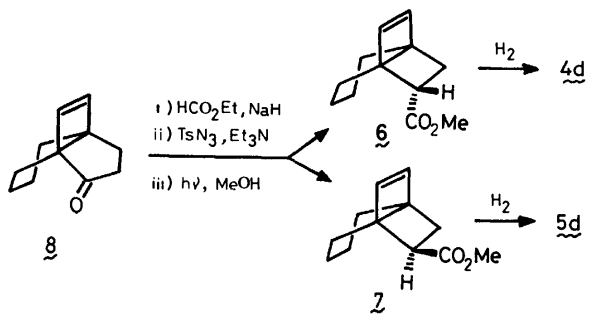
5d R = CO_2Me
5e R = CH_2OAc



The kinetic data for the acetolysis of **4b** and **5b** were summarized in Table 1. As shown in Table 1, the *endo* tosylate **4b** undergoes acetolysis at a rate slightly greater than that of the *exo* one **5b**, but the difference is rather small.

The acetolysis products from **4b** and **5b** after 10 half-lives were separated by column chromatography on silica gel and the subsequent preparative GLC separation. The combined yields of the products were almost quantitative and the distribution of the products were listed in Table 2 together with that from [4.3.2]-propellan-7-yl tosylates (**1a** and **2a**). The structures of the acetates **1b** and **2b** were established by the identity in GLC, ^{1}H NMR, and IR spectra with authentic

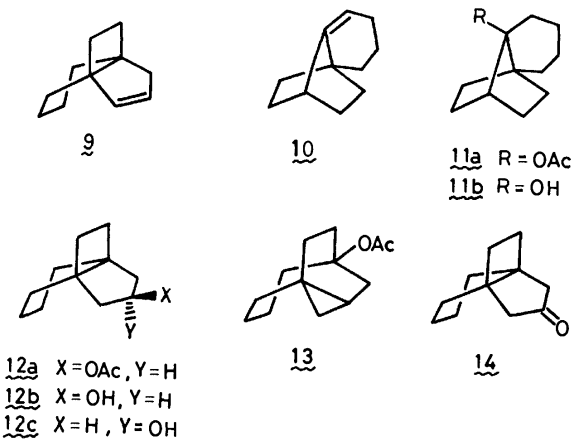
a) Unidentified tertiary acetate. b) Ref. 3a.

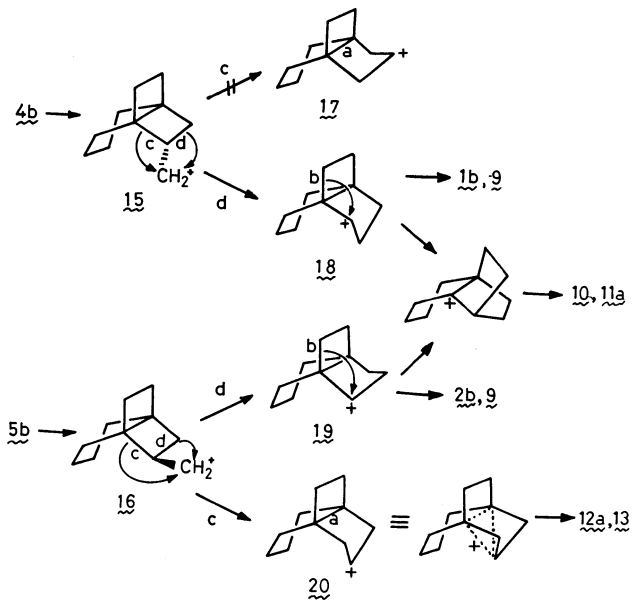


samples which were prepared by the acetylation of the alcohols **1c** and **2c**[3a] with acetic anhydride and pyridine. Similarly, [4.3.2]propell-7-ene (**9**) and tricyclo[5.2.2.$0^{1,6}$]undec-5-ene (**10**) were identified with the respective authentic materials.[3a] The structure of the acetate **11a** was confirmed by the lithium aluminium hydride reduction to the alcohol **11b**.[3a] The structure of [4.3.2]propellan-8-yl acetate **12a** was determined by the following chemical transformations: the lithium aluminium hydride reduction of **12a** followed by Jones' oxidation of the resulting alcohol **12b** gave propellan-8-one (**14**). The authentic sample of this ketone was obtained by the hydroboration-oxidation of the olefin **9** and the subsequent Jones' oxidation of the major alcohol **12c**.[7] The structure of the acetate **13** having tricyclo[4.3.2.$0^{1,8}$]undecane skeleton was elucidated on the basis of the spectroscopic data as well as mechanistic considerations. Although the two remaining acetates (unidentified **A** and **B**) were characterized to be tertiary acetates, the structures of them were not elucidated as yet.[9] In every case, the absence of unrearranged acetates **4e** and **5e** was checked by GLC and ^{1}H NMR spectra.

In contrast to the kinetic results, the product study of the acetolysis revealed clearly the effect of the cyclobutane bonds (a) and (b) on the modes of the ring expansion. As shown in Scheme 1, the ring expansion of the propellanylmethyl cations **15** and **16** would take place by 1,2-shift of the bond (c) or (d) to afford the [4.3.2]propellan-8-yl cations **17** and **20** or the [4.3.2]-propellan-7-yl cations **18** and **19**, respectively. It should be noted that one of each pair of the ring-expanded cations has boat conformation of the bicyclo[3.2.0]-heptane moiety (**17** and **19**) and the other has chair conformation (**18** and **20**). Since it has been shown that the magnitude of the long-range interaction of strained σ bond to carbonium ion centers is greatly dependent on the orientation of the participating bond and the p orbital of the cation center,[10] it is reasonable to consider that the cation **20** having chair conformation is subject to the long-range interaction (edge participation) of the central cyclobutane bond (a),[11] while the cation **17** having boat conformation is not stabilized by the participation of the bond (a). On the other hand, both [4.3.2]propellan-7-yl cations **18** and **19** are subject to the σ participation of the external cyclobutane bond (b).[3a] Moreover, the degree of the interaction may be almost independent of the conformation of the bicyclo-[3.2.0]heptane moiety, because it has been found that the σ participation is relatively insensitive to the chair/boat conformational change in bicyclo[3.2.0]hept-2-yl cations.[12]

As shown in Table 2, the *endo* tosylate **4b** gave the olefin **10** and the acetate **11a** having 1,7-tetramethylene-norbornane skeleton as the major products (total of **10** and **11a**; 82%) along with small amounts of [4.3.2]-propellane derivatives **1b** and **9** and unidentified **A**. Since these products except for **9** were obtained from the acetolysis of *endo*-[4.3.2]propellan-7-yl tosylate (**1a**), it is deduced that the ring expansion of the *endo* cation **15** occurs through 1,2-shift of the bond (d) selectively to afford the propellan-7-yl cation **18** which is stabilized by σ participation of the external cyclobutane bond (b). Interestingly, in the case of the *exo* tosylate **5b**, two new acetates **12a** and **13** derived from the propellan-8-yl cation **20** were formed in considerable amounts (total of **12a** and **13**; 41%) together with the products **9**, **10**, **11a**, unidentified **A**, and **B** which are derived from the propellan-7-yl cation **19**. Since while the cation **19** is stabilized by the σ participation of the external cyclobutane bond (b), the cation **20** is stabilized by the long-range interaction of the central cyclobutane bond (a), the ring expansion of the *exo* cation **16** occurs nonstereoselectively through 1,2-shift of the bond (c) as well as that of the bond (d).

It is thus deduced that the modes of the ring expansion of the propellan-7-ylmethyl cations (**15** and **16**) are critically governed by the *exo*/*endo* geometry of the cyclobutylmethyl moiety because the chair/boat conformation of the bicyclo[3.2.0]heptane moiety of the ring-expanded [4.3.2]propellan-7-yl and -8-yl cations (**17**—**20**) is dependent on the above geometry of **15** and **16**.



Scheme 1.

Experimental

All melting and boiling points are uncorrected. IR spectra were recorded on a JASCO IR-G spectrometer. Mass spectra were taken by using a Hitachi RMU-6E spectrometer. ^1H NMR spectra were obtained on a JEOL JNM-PS-100 spectrometer in CCl_4 solutions by using Me_4Si as an internal standard. Analytical GLC was carried out on a Hitachi 163 gas chromatograph (10% FFAP and 5% SE-30 columns) and preparative GLC separation was undertaken on a Varian Aerograph 920 gas chromatograph.

*Methyl [4.2.2]Propellane-7-carboxylates (**4d** and **5d**).* The esters **4d** and **5d** were prepared as described previpusly[4] and were separated by careful chromatography on silica gel with 2% ether–petroleum ether eluent.

4d: IR 1730, 1220, 1190, 1170, 1065 cm^{-1}; MS *m/e* (rel intensity) 194 (M^+, 55), 135 (84), 91 (100), 79 (94); NMR δ 1.12—2.58 (m, 14H), 3.20 (t, J=8 Hz, 1H), 3.64 (s, 3H). Found: C, 74.18; H, 9.41%. Calcd for $C_{12}H_{18}O_2$: C, 74.19; H, 9.34%.

5d: IR 1730, 1195, 1175, 1050 cm^{-1}; MS *m/e* (rel intensity) 194 (M^+, 60), 135 (100), 91 (90), 79 (90); NMR δ 1.10—2.72 (m, 14H), 3.08 (t, J=9 Hz, 1H), 3.64 (s, 3H). Found: C, 74.11; H, 9.29%. Calcd for $C_{12}H_{18}O_2$: C, 74.19; H, 9.34%.

*[4.2.2]Propellan-7-ylmethanols (**4c** and **5c**).* A solution of 3.0 g (15.5 mmol) of **4d** in 100 ml of ether was added dropwise to a suspension of 587 mg (15.5 mmol) of lithium aluminium hydride in 50 ml of ether and the mixture was stirred at room temperature for 1 h. Water was added carefully followed by 1 mol dm^{-3} HCl and the organic layer was separated. The aqueous layer was extracted with ether and the combined organic layer was washed with sodium hydrogencarbonate solution and water and then dried (Na_2SO_4). Evaporation of the solvent gave 2.4 g (93%) of **4c** as viscous oil, whose analytical sample was obtained by preparative GLC. In a similar manner, **5c** was prepared from **5d** in a 99% yield.

4c: IR 3300, 1010 cm^{-1}; MS *m/e* (rel intensity) 166 (M^+, 2), 93 (73), 91 (84), 79 (100); NMR δ 1.00—2.32 (m, 15H), 2.51 (quintet, J=8 Hz, 1H), 3.57, 3.60 (2d, J=6, 8 Hz, 2H). Found: C, 79.26; H, 11.01%. Calcd for $C_{11}H_{18}O$: C, 79.46; H, 10.92%.

5c: IR 3300, 1030, 1000 cm^{-1}; MS *m/e* (rel intensity) 166 (M^+, 5), 93 (77), 91 (80), 79 (100); NMR δ 1.10—2.64 (m, 16H), 3.64, 3.67 (2d, J=7, 8 Hz, 2H). Found: C, 79.37; H, 11.03%. Calcd for $C_{11}H_{18}O$: C, 79.46; H, 10.92%.

*[4.2.2]Propellan-7-ylmethyl Tosylates (**4b** and **5b**).* To a solution of 919 mg (5.54 mmol) of **4c** in 60 ml of pyridine cooled in an ice bath 2.11 g (11.1 mmol) of *p*-toluenesulfonyl chloride was added portionwise and the solution was allowed to stir for 1 h and then to stand in a refrigerator for 3 d. The mixture was poured onto water and extracted with ether. The extract was washed with 1 mol dm^{-3} HCl, sodium hydrogencarbonate solution, and water and then dried (Na_2SO_4). Evaporation of the solvent gave 1.66 g (94%) of **4b** as a white solid, which was purified by recrystallization from petroleum ether. Similarly, **5b** was prepared from **5c** in a 93% yield.

4b: Mp 68—69 °C; IR 1595, 1355, 1165, 935 cm^{-1}; NMR δ 1.08—1.64 (m, 9H), 1.76—2.22 (m, 5H), 2.42 (s, 3H), 2.63 (quintet, J=8 Hz, 1H), 3.96 (2d, J=7, 9 Hz, 2H), 7.25 (d, 2H), 7.68 (d, 2H). Found: C, 67.32; H, 7.53; S, 9.93%. Calcd for $C_{18}H_{24}O_3S$: C, 67.46; H, 7.55; S, 10.01%.

5b: Mp 34—35 °C; IR 1595, 1355, 1165, 940 cm^{-1}; NMR δ 1.10—2.32 (m, 14H), 2.40 (s, 3H), 2.58 (quintet, J=8 Hz, 1H), 3.99 (2d, J=6, 8 Hz, 2H), 7.20 (d, 2H), 7.60 (d, 2H). Found: C, 67.32; H, 7.54; S, 9.93%. Calcd for $C_{18}H_{24}O_3S$: C, 67.46; H, 7.55; S, 10.01%.

*Methyl [4.2.2]Propell-9-ene-7-carboxylates (**6** and **7**).* To an ice-cooled suspension of 480 mg of 50% sodium hydride (10 mmol) and 0.05 ml of ethanol in 20 ml of ether was added dropwise a mixture of 1.64 g (10.1 mmol) of the propellanone **8**[5] and 1.10 g (15 mmol) of ethyl formate and the mixture was stirred at room temperature for 3 h and then allowed to stand overnight. Water was added and the organic layer was separated which was washed once with water. The combined aqueous layer was washed with ether and then acidified with 1 mol dm^{-3} HCl. The oil separated was taken up in ether and the extract was washed with saturated sodium chloride solution. Evaporation of the solvent gave 1.5 g (78%) of the α-hydroxymethylene derivative of **8** as a pale yellow solid which was used without purification: IR 3040, 1690, 1600, 1200, 930, 780, 740 cm^{-1}.

p-Toluenesulfonyl azide (1.56 g, 7.9 mmol) was added dropwise to a solution of 1.5 g of the above hydroxymethylene ketone and 1.6 g (15.8 mmol) of triethylamine in 6 ml of dichloromethane cooled in an ice–salt bath (−5—−10 °C). The mixture was stirred at that temperature for 2 h. A solution of 530 mg (9.5 mmol) of potassium hydroxide in 6 ml of water was added and the mixture was stirred at room temperature for 15 min. The organic layer was separated and the aqueous layer was extracted with dichloromethane. The combined extract was washed with potassium hydroxide solution and water and then dried (Na_2SO_4). Evaporation of the solvent gave 1.5 g of the crude diazo ketone as a dark red oil (IR 3040, 2070, 1660, 1320, 780 cm^{-1}), which was dissolved in 100 ml of methanol and the solution was irradiated in a Pyrex vessel with a 500 W high-pressure mercury lamp for 22 h. Evaporation of the solvent followed by distillation at reduced pressure (bp 67—69 °C/133.3 Pa) gave 762 mg (50%) of a 1 : 2 mixture of **6** and **7** which were separated by chromatography on silica gel with 3% ether–petroleum ether eluent.

6: IR 3100, 3030, 1730, 1170, 760 cm^{-1}; MS *m/e* (rel intensity) 192 (M^+, 10), 133 (39), 105 (33), 91 (100); NMR δ 1.16—2.10 (m, 9H), 2.29 (dd, J=7, 12 Hz, 1H), 2.86 (dd, J=7, 8 Hz, 1H), 3.55 (s, 3H), 6.22 (d, J=2 Hz, 2H). Found: C, 74.70; H, 8.35. Calcd for $C_{12}H_{16}O_2$: C, 74.97; H, 8.39.

7: IR 3100, 3030, 1730, 1200, 790, 750 cm^{-1}; MS *m/e* (rel

intensity) 192 (M^+, 10), 133 (35), 105 (34), 91 (100); NMR δ 1.12—2.34 (m, 10H), 2.86 (dd, J=7, 10 Hz, 1H), 3.55 (s, 3H), 6.03 (d, J=2 Hz, 1H), 6.21 (d, J=2 Hz, 1H). Found: C, 75.16; H, 8.42%. Calcd for $C_{12}H_{16}O_2$: C, 74.97; H, 8.39%.

Hydrogenation of **6** *and* **7**. A sample of **6** (28 mg) and a catalytic amount of 5% Pd/C in 5 ml of ethanol was stirred under atmospheric hydrogen for 3 h. The catalyst was filtered off and the solvent evaporated to give 23 mg (82%) of **4b**. In a similar manner, hydrogenetion of **7** gave **5b** in a 96% yield.

Kinetic Measurements of Acetolysis of **4b** *and* **5b**. The rates of the acetolysis of **4b** and **5b** buffered with 2 equiv. of sodium acetate were measured by the titrimetric method as previously described.[3a] The results are summarized in Table 1.

Preparative Acetolysis of **4b** *and* **5b**. A solution of 1.47 g (4.59 mmol) of **4b** and 753 mg (9.18 mmol) of sodium acetate in 140 ml of acetic acid was heated at 80 °C for 23 h. The mixture was diluted with water and extracted with ether. The extract was washed with sodium hydrogencarbonate solution and water and then dried (Na_2SO_4). Evaporation of the solvent gave 751 mg (combined yield of the products; 98%) of a pale yellow oil. The products were analyzed by GLC (Table 2) and separated by chromatography on silica gel with ether–petroleum ether eluent followed by preparative GLC. Similarly, the acetolysis of 2.50 g (7.81 mmol) of **5b** gave 1.45 g of the products (combined yield; 94%) and the results are listed in Table 2.

1b: IR 1725, 1230, 1005, 955 cm^{-1}; MS *m/e* (rel intensity) 208 (M^+, trace), 148 (21), 120 (100); NMR δ 1.08—2.30 (m, 19H, s at 1.95), 4.86 (dd, J=4, 6 Hz, 1H). Found: C, 74.73; H, 9.97. Calcd for $C_{13}H_{20}O_2$: C, 74.96; H, 9.68.

2b: IR 1725, 1230, 1015 cm^{-1}; MS *m/e* (rel intensity) 208 (M^+, trace), 120 (100); NMR δ 1.10—2.24 (m, 19H, s at 1.96), 4.70 (t, J=8 Hz, 1H). Found: C, 74.58; H, 9.33. Calcd for $C_{13}H_{20}O_2$: C, 74.96; H, 9.68.

11a: IR 1725, 1230, 1160, 1125, 1000, 960 cm^{-1}; MS *m/e* (rel inrensity) 208 (M^+, 2), 148 (100), 120 (72); NMR δ 0.88—2.40 (m, 19H, s at 1.92), 3.65 (br t, J=3 Hz, 1H). Found: C, 75.01; H, 9.80. Calcd for $C_{13}H_{20}O_2$: C, 74.96; H, 9.68.

12a: IR 1730, 1225, 1005 cm^{-1}; MS *m/e* (rel intensity) 208 (M^+, trace), 120 (92), 92 (100), 91 (95); NMR δ 1.36—2.20 (m, 19H, s at 1.92), 5.30 (t, J=8 Hz, 1H). Found: C, 74.72: H, 9.79%. Calcd for $C_{13}H_{20}O_2$: C, 74.96; H, 9.68%.

13: IR 3040, 1720, 1230, 1025, 1005 cm^{-1}; MS *m/e* (rel intensity) 208 (M^+, trace), 120 (100); NMR δ 0.20 (t, J=4 Hz, 1H), 0.52—0.90 (m, 2H), 1.20—2.48 (m, 17H, s at 1.84). Found: C, 75.09; H, 9.78%. Calcd for $C_{13}H_{20}O_2$: C, 74.96; H, 9.68%.

Unidentified **A**: IR 1725, 1230, 1005, 955 cm^{-1}; MS *m/e* (rel intensity) 208 (M^+, trace), 148 (40), 123 (100); NMR δ 1.10—2.20 (m, s at 1.86). Found: C, 74.94; H, 9.64. Calcd for $C_{13}H_{20}O_2$: C, 74.96; H, 9.68.

Unidentified **B**: Mp 53—54 °C; IR 1715, 1240, 1220, 1030, 1000, 930 cm^{-1}; MS *m/e* (rel intensity) 208 (M^+, trace), 148 (69), 120 (100); NMR δ 1.20—2.52 (m, s at 1.84). Found: C, 74.65; H, 9.58%. Calcd for $C_{13}H_{20}O_2$: C, 74.96; H, 9.68%.

*[4.2.2]Propellan-7-ylmethyl Acetates (***4e** *and* **5e**). A solution of 100 mg (0.60 mmol) of **4c** in 2 ml of acetic anhydride and 5 ml of pyridine was stirred at room temperature for 5 h. Water was added and the solution was extracted with ether. The extract was washed successively with 1 mol dm^{-3} HCl, sodium hydrogencarbonate solution, and water and then dried (Na_2SO_4). Evaporation of the solvent gave 113 mg (91%) of **4e** as colorless oil. Similarly, **5e** was prepared from **5c** in a 88% yield.

4e: IR 1730, 1220, 1010 cm^{-1}; MS *m/e* (rel intensity) 208 (M^+, 3), 148 (100), 133 (100), 120 (67), 119 (73), 91 (77); NMR δ 1.20—1.74 (m, 9H), 1.84—2.25 (m, 8H, s at 1.92), 2.60 (quintet, J=8 Hz, 1H), 3.97 (d, J=8 Hz, 2H). Found: C, 74.90; H, 9.74%. Calcd for $C_{13}H_{20}O_2$: C, 74.96; H, 9.68%.

5e: IR 1730, 1220, 1020 cm^{-1}; MS *m/e* (rel intensity) 208 (M^+, 2), 148 (95), 133 (100), 120 (73), 119 (72), 91 (71); NMR δ 1.12—2.76 (m, 18H, s at 1.91), 4.06 (d, J=8 Hz, 2H). Found: C, 74.73; H, 9.67%. Calcd for $C_{13}H_{20}O_2$: C, 74.96; H, 9.68%.

Preparation of Authentic Sample of **1b** *and* **2b**. The acetates **1b** and **2b** were prepared from **1c** and **2c**[3a] in 90—95% yields in a manner similar to that described for **4e** and **5e**. The authentic samples thus prepared were identical in all respects (IR, NMR, and GLC) with the samples obtained from the acetolysis.

Lithium Aluminium Hydride Reduction of **11a**. The reduction of **11a** was carried out as described for the preparation of **4c** and **5c** to give the alcohol **11b** in a 92% yield which was identical with the authentic material.[3a]

Conversion of **12a** *to [4.3.2]Propellan-8-one (***14**). The reduction of **12a** was undertaken as described above to afford the alcohol **12b** (95%).

12b: IR 3300, 1060 cm^{-1}; MS *m/e* (rel intensity) 166 (M^+, trace), 138 (100), 120 (57), 109 (55); NMR δ 1.10—2.08 (m, 16H), 3.46 (br s, 1H), 4.33 (t, J=6 Hz, 1H). *p*-Nitrobenzoate of **12b** was prepared in a usual manner: mp 93—94 °C. Found: C, 68.46; H, 6.67; N, 4.45%. Calcd for $C_{18}H_{21}O_4N$: C, 68.55; H, 6.71; N, 4.44%.

A slightly excess of Jone's reagent was added dropwise to a solution of 46 mg (0.28 mmol) of **12b** in 2 ml of acetone and the mixture was allowed to stir at room temperature for 20 min. After evaporation of the solvent, the residue was dissolved in water and extracted with ether. The extract was washed with sodium hydrogencarbonate solution and water and then dried (Na_2SO_4). Evaporation of the solvent gave 44 mg (96%) of **14** which solidified on standing.

14: IR 1730, 1160 cm^{-1}; MS *m/e* (rel intensity) 164 (M^+, 13), 136 (82), 108 (100); NMR δ 1.20—2.16 (m, 12H), 2.20 (s, 4H). Semicarbazone: mp 209—211 °C. Found: C, 65.12; H, 8.60; N, 18.94%. Calcd for $C_{12}H_{19}ON_3$: C, 65.12; H, 8.65; N, 18.99%.

Preparation of Authentic Sample of **14**. To a suspension of 1.0 g (6.8 mmol) of the olefin **9** and 87 mg (2.3 mmol) of sodium borohydride in 10 ml of tetrahydrofuran was added dropwise under nitrogen 0.344 ml (2.72 mmol) of boron trifluoride etherate and the mixture was stirred at room temperature for 1 h. 0.2 ml of water, 0.75 ml of 3 mol dm^{-3} sodium hydroxide solution, and 0.75 ml of 30% hydrogen peroxide solution were added successively with caution and the mixture was allowed to stand overnight. The organic layer was separated and the aqueous layer was extracted with ether. The combined organic layer was washed with saturated sodium chloride solution and dried (Na_2SO_4). Evaporation of the solvent gave 1.1 g (97%) of a mixture of the alcohols **1c**, **2c**, and **12c** in a ratio of 2 : 1 : 10 (by GLC). **12c** was separated by silica-gel chromatography with 20% ether–pertoleum ether eluent.

12c: IR 3250, 1035 cm^{-1}; MS *m/e* (rel intensity) 166 (M^+, trace), 138 (100); NMR δ 1.28—2.04 (m, 16H), 3.23 (br s, 1H), 4.50 (t, J=7 Hz, 1H). *p*-Nitrobenzoate: Mp 113—115 °C. Found: C, 68.18; H, 6.57; N, 4.42%. Calcd for $C_{18}H_{21}O_4N$: C, 68.55; H, 6.71; N, 4.44%.

Jones' oxidation of 640 mg (3.86 mmol) of **12c** as described for the oxidation of **12b** gave 632 mg (100%) of the ketone **14** which was identical with the sample prepared from **12a**.

Reactivities of Stable Rotamers. X. Reactions of 9-(2-Formyl-1-naphthyl)fluorene Rotamers and Related Compounds[1,2]

Ryo Saito and Michinori Ōki*

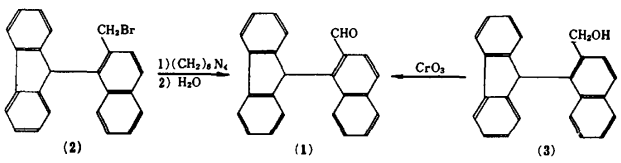
Department of Chemistry, Faculty of Science, The University of Tokyo, Bunkyo-ku, Tokyo 113

(Received April 30, 1982)

Rotational barrier (*ap*→*sp*) in 9-(2-formyl-1-naphthyl)fluorene was determined: $\Delta H^{\ddagger}$ 24.0 kcal/mol and $\Delta S^{\ddagger}$ −7.9 e.u. Oxidation of the aldehyde with chromium(VI) oxide was extremely slow in the *ap* form, whereas it proceeded smoothly in the *sp* form. As models of the 2 steps involved in the aldehyde oxidation, oxime formation of the aldehyde and oxidation of related alcohols were carried out to conclude that the second elimination step in the aldehyde oxidation is slow in the *ap* form because of the steric effect. Dehydration of the oxime of the aldehyde exhibited a large k_{sp}/k_{ap} value as well. Sodium tetrahydridoborate reduction and Grignard additions of the aldehyde were also carried out to show that the former gave a large k_{sp}/k_{ap} value whereas the latter exhibited rather a small k_{sp}/k_{ap}. The implication of the results is discussed.

Reactivity of rotational isomers is sometimes surprisingly different. We have demonstrated that deprotonation of 9-(2-methoxy-1-naphthyl)fluorene rotamers could differ by a factor of 1000.[3] Ionizing reactions of rotational isomers of 9-(2-bromomethyl-6-methylphenyl)-fluorene in ionizing-but-poorly-nucleophilic solvents exhibited striking difference: the *ap* form reacted to give a cyclized product, whereas the *sp* form was intact under the conditions.[4] Finding these differences, we were naturally interested in other reactions of rotamers and wished to extend to investigation to carbonyl compounds. This paper reports such an investigation on reactions of aldehydes and related compounds.

The synthesis of 9-(2-formyl-1-naphthyl)fluorene (**1**) rotamers was carried out in two ways. The first method is a Sommelet reaction[5] of 9-(2-bromomethyl-1-naphthyl)fluorene (**2**) which yielded a mixture of *ap*-**1** and *sp*-**1**. Chromatographic separation of the rotamers was found to be very difficult. However, as is discussed later, treatment of the rotameric mixture of **1** with chromium(VI) oxide oxidized the *sp*-form only, leaving the *ap*-



form intact. Thus this method is useful for the preparation of the *ap* isomer. The second method is oxidation of the corresponding alcohols (**3**). Since the separation of the rotamers of **1** was difficult, pure rotational isomers of **3**[6] were used. The high barrier to rotation in **3** enabled us to obtain *sp*-**1** and *ap*-**1** separately by this method.

Rotational Barriers and Populations of Rotamers. Conformations of the 9-arylfluorenes were determined by taking advantage of ^{1}H NMR spectral features. Due to the anisotropic effect of the fluorene ring, the proton in the 2-substituent of the naphthalene ring gives a high field signal if the conformation is *ap*, whereas it gives a signal at a low field if the conformation is *sp*. The chemical shift of the 8-proton of the naphthalene ring may also be used. It gives a low field signal in the *ap* conformation, whereas it gives a high field signal in the *sp*, due to the anisotropy effect of fluorene.

In order to discuss the reactivity of individual rotamers in a straightforward manner, it is necessary to establish that the conversion of one isomer to another is slow enough at a given temperature where a reaction is carried out. In this context, rotational barriers shall be discussed first together with populations of rotamers which can be obtained at the same time in the investigation of the barrier.

The rates of isomerization (*ap*→*sp*) of **1** are given in Table 1. From the results, $\Delta H^{\ddagger}$ 24.0±0.7 kcal/mol (1 cal=4.18 J) and $\Delta S^{\ddagger}$ −7.9±2.0 e.u. (1 e.u.=4.18 J/K mol) were obtained. Since the free energy of activation for rotation at ambient temperature is *ca.* 26.5 kcal/mol, we can claim that we look at the reactivities of individual rotamers if we run the reaction at ambient temperature within 24 h or at a lukewarm temperature for a shorter period. The equilibrium constant (*sp*/*ap*) is almost constant in the temperature range examined. The favoredness of the *sp* form may be ascribed to the steric effect including that for solvation, since the formyl group is polar and the oxygen in the formyl group can be larger than an sp^2 carbon.

Barrier to rotation of oximes (**5**) was not examined because they were sparingly soluble in nonpolar solvents. However, the height of the barrier may be assumed to be

Table 1. Rate constants for rotation and equilibrium constants of rotamers in 9-(2-formyl-1-naphthyl)fluorene (**1**)

Temperature/°C	$k(ap\rightarrow sp)/s^{-1}$	$K(sp/ap)$
55.6	1.28×10^{-5}	1.48
64.0	3.66×10^{-5}	1.49
73.2	9.58×10^{-4}	1.46
78.2	1.41×10^{-4}	1.49

Table 2. Rate constants for rotation and equilibrium constants of rotamers in 9-[2-(α-hydroxybenzyl)-1-naphthyl]fluorene (**7**)

Temperature/°C	$k(ap\rightarrow sp)/s^{-1}$	$K(sp/ap)$
96.4	1.28×10^{-5}	1.8
104.0	2.94×10^{-5}	1.8
114.0	9.37×10^{-5}	1.8
124.0	2.01×10^{-4}	1.8

almost equal to that of the aldehyde (**1**) because their steric structures are similar.

Barrier to rotation in 9-(2-cyano-1-naphthyl)fluorene (**6**) was determined at a temperature. At 77.0 °C in benzene-d_6, the nitrile gave a rate constant for rotation ($ap \rightarrow sp$) of 1.08×10^{-3} s^{-1}. From the value, the free energy of activation for rotation was calculated to be 25.4 kcal/mol. Thus we may neglect isomerization of the nitrile if reactions are carried out at room temperature for a few hours. The equilibrium constant (sp/ap) was 7.3 at the temperature. The reason for the favoredness of the *sp* form is not well understood at the moment. Molecular models suggest no significant congestion in the *ap* form.

The rate constant for rotation and equilibrium constants in 9-[2-(α-hydroxybenzyl)-1-naphthyl]fluorene (**7**) are given in Table 2. From the rate constants, $\Delta H^{\ddagger}$ 29.1 ± 1.1 kcal/mol and $\Delta S^{\ddagger}$ -2.7 ± 2.9 e.u. were obtained. The free energy of activation (*ca.* 30 kcal/mol) for rotation at ambient temperature assures again that conversion of a rotamer to another at temperature below 50 °C is negligible if the reaction is run during a reasonable period. Although $C_6H_5CH(OH)$ is a large group, the barrier to rotation and equilibrium constants are almost the same as those of **3** reported earlier.[6] The results will imply the followings. If, by rotation about the $C_6H_5CH(OH)$–naphthyl bond, a large group, either phenyl or hydroxyl, comes closely to the fluorene ring, the conformation will be extremely disfavored because of the steric effect. Therefore, this compound will take a conformation in which the hydrogen of the α-hydroxybenzyl group is close to the fluorenyl group, in the ground state. If this effect is operative, the *ap* form of compound **7** may be unfavorable relative to *ap*-**3** because of the decrease in entropy: this effect is ambiguous as far as the experimental data concern, because it is small. Infrared spectrum of *ap*-**7** as a 1.0×10^{-2} mol/L solution in carbon tetrachloride showed an absorption due to OH stretching at 3600 cm^{-1}, ε being 61.3. *sp*-**7** under similar conditions showed an absorption at 3620 cm^{-1} of ε 47.1. The absorption of *ap*-**7** at a relatively low frequency may indicate the presence of the OH···π bond as was the case of the primary alcohol (**3**).[6] The small *K* value implies that the *ap* form is stabilized relative to the *sp*: the cause is most probably the OH···π bond. The similar barrier height for rotation in **7** with that in **3** implies that the transition state energy is also similar. We may approximate the transition state for rotation by the interaction of the fluorene ring with the CH of the α-hydroxybenzyl group and the naphthalene ring.

Reactions. Reactions carried out in this work are summarized in the following scheme. Relative rates are given in Table 3.

Oxidation of a mixture of rotamers of **1** with chromium(VI) oxide in aqueous acetone yielded the corresponding *sp*-acid (**4**) within a few minutes but left *ap*-**1** intact. If the oxidizing mixture was left overnight, instead of the *ap*-carboxylic acid (**4**), a lactone (**8**) was obtained as a main product. The lactone can be formally formed by oxidation at the 9-position of fluorene and at the formyl group followed by lactonization. It is not clear which is the precedent reaction of the two oxidations, but we prefer the first oxidation at the 9-position of fluorene for the following reasons. Firstly there was no indication that the *ap*-**4** was produced. Secondly although the rotamers of **1** are stable in chloroform for at least 5 d at room temperature, their isomerization is detected if a pyridine solution is allowed to stand overnight. This is because the fluorene ring is proton donating. Although there is no strong base present in the system, water or acetone may act as a base to form a minute amount of the fluorenide anion which should be oxidized easily to form a 9-hydroxy compound. If the 9-hydroxyl group is introduced, the rotational barrier must be lowered, as are known in other cases,[7] to facilitate rotation at room temperature. Then the formyl group, in the *sp* conformation, must be easily oxidized.

Indeed, the lactone (**8**) could be better made by chromium(VI) oxide oxidation of the aldehyde (**1**) in the presence of pyridine. The lactone was formed by still another method. Air oxidation of the aldehyde in ethanol in the presence of potassium hydroxide afforded the lactone smoothly. Since oxidation of 9-alkylfluorenes with air in the presence of base to afford hydroperoxides is reported,[8] it will be natural to assume that the first step in the oxidation of **1** is the

Table 3. Relative rates of reactions of rotameric 9-(2-formyl-1-naphthyl)-fluorene and related compounds

Reaction	Compound	k_{sp}/k_{ap}
Oxidation with Cr(VI)	Aldehyde (**1**)	Very large
	Primary alcohol (**3**)	0.67
	Secondary alcohol (**7**)	*ca.* 34
	Secondary alcohol (**10**)	*ca.* 27

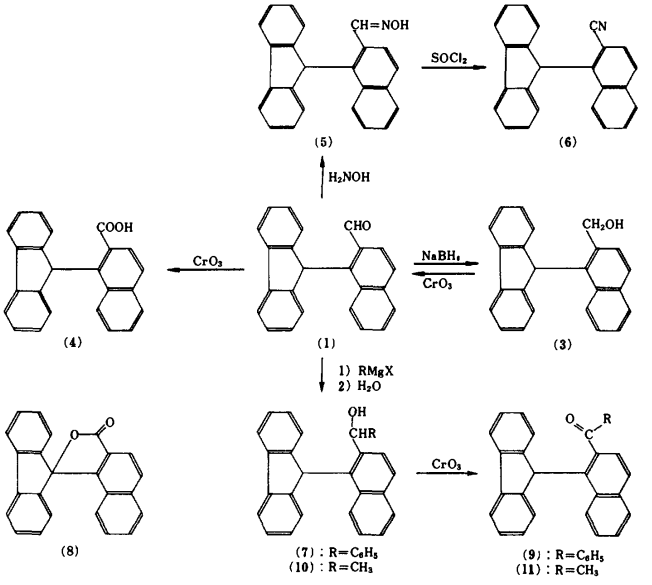
Reduction with $NaBH_4$	Aldehyde (**1**)	7.6
Addition of C_6H_5MgBr	Aldehyde (**1**)	1.8
Addition of CH_3MgI	Aldehyde (**1**)	1.7



formation of a 9-hydroperoxy compound. Inversion at the anion formed as an intermediate or rotation about the C_9–C_{naph} bond in the hydroperoxide will make the formyl group vulnerable to further oxidation or an intramolecular redox reaction may take place to produce the lactone.

The lack of reactivity of *ap*-**1** was of interest. We wished to clarify an important factor which retards the oxidation of *ap*-**1**. Oxidation of an aldehyde is known to proceed *via* three steps:[9] coordination of the aldehyde oxygen to chromium, addition of water to the complex, forming a tetrahedral intermediate, and final E2 type elimination of chromate of a lower oxidation number. Therefore, we examine every step by using model reactions.

The first step, ligation of the aldehyde to chromium, does not seem to be significantly different of the two rotamers. A molecular model indicates that the aldehyde oxygen is exposed and is vulnerable to the chromium(VI) oxide attack even in the *ap* conformation. The ligation may be assumed to proceed without significant hindrance both in *sp* and *ap* forms.

As a model for the second step, we chose oxime formation under acidic conditions. Under the circumstances, the oximation is known to proceed *via* protonation of the aldehydic oxygen and addition of hydroxylamine to the protonated species,[10] the latter step being rate-determining. The results which are summarized in Table 3 together with others indicate that even *ap*-**1** was smoothly oximated and the relative rate (k_{sp}/k_{ap}) was 3.7. The reactivity of the *ap* form is indeed lower than that of the *sp* but the difference is not so large as is seen in oxidation of the aldehyde (**1**). Thus we may rule out the possibility that the addition step to the carbonyl of **1** is the key for the slow oxidation of *ap*-**1**.

As a model for the last step of oxidation, we chose chromium(VI) oxide oxidation of the corresponding alcohols, because the mechanism of the oxidation is similar with that of the last step in the aldehyde-oxidation.[11] Interestingly the primary alcohol (**3**) gave k_{sp}/k_{ap} 0.67, whereas 9-[2-(α-hydroxybenzyl-1-naphthyl]fluorene (**7**) gave the relative rate of *ca.* 30. Products were the aldehyde (**1**) and a ketone (**8**). Oxidation of 9-[2-(1-hydroxyethyl)-1-naphthyl]fluorene (**10**) gave also a large k_{sp}/k_{ap} value. The results indicate that the secondary alcohols (**7** and **10**) show similar reactivity ratio with the aldehyde (**1**), whereas the primary alcohol (**3**) shows about the same reactivity for the rotamers or even the *ap* form is slightly more reactive than the *sp*. This striking difference for the two types of compounds can be understood if one looks at the molecular models of the *ap* forms (Fig. 1). The models suggest that, for the primary alcohol, a proton to be removed after ligation of the oxygen to chromium is readily available because one of hydrogens in the α-position is exposed without significant hindrance. In contrast, in the secondary alcohol, the hydrogen to be removed as a proton is buried in a pocket made by phenyl (or methyl), naphthyl, and fluorenyl groups. Therefore, should the oxidation occur for the compound, additional energy is required to deform the molecule to make the attack to the proton possible. If the difference in reactivities of

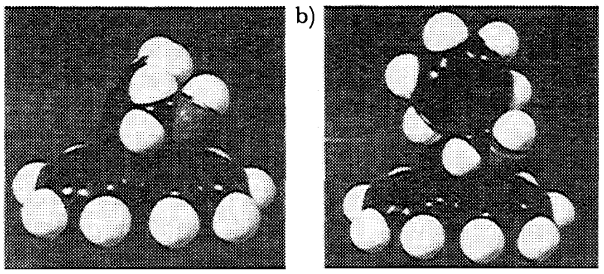


Fig. 1. CPK models of a) *ap*-9-[2-(hydroxymethyl-1-naphthyl)fluorene and b) *ap*-9-[2-(α-hydroxybenzyl)-1-naphthyl]fluorene.

ap-**3** and *sp*-**3** is significant, the cause may be the steric acceleration[12] because a tetrahedral carbon is larger than a trigonal carbon.

The situation of oxidation of aldehydes is close to that of the secondary alcohols, since it passes through a $RCH(OH)_2$ type intermediate. From the above results we conclude that oxidation of the *ap* form of the aldehyde (**1**) is very slow because of the steric effect in the last step relative to the *sp*. The key point of the last step in oxidation is that the transition state is space-demanding because of the concerted nature. Thus it becomes interesting to see whether other space-demanding reactions of the *ap* form are also slow relative to those of the *sp* form in this system.

As an example, we chose dehydration of oximes, since the reaction is known to be of E2 type if the conformation is anti (*Z*).[13] From the *ap* and *sp* aldehydes (**1**), only one form each of the oximes (**5**) was formed. Equilibration of the oxime by heating gave mixtures of the same composition of which components gave the identical NMR spectra with the starting material. This indicates that oximes are either both anti or both syn. There are various methods known for the determination of the stereochemistry of oximes. Of those, the NMR spectroscopic method is considered to be most reliable.[14] However, the chemical shifts in NMR spectroscopy may be affected by the ring current effect and the steric effect of the fluorene ring. Therefore, we prefered to use other methods, if available. Lanthanoid induced shifts (LIS) of syn and anti aldoximes are known.[15] However, attempted measurements of LIS of *sp* and *ap*-**5** failed because line-broadening occurred extensively when even a small amount of a shift reagent was added. In the preparation of aromatic aldoximes, the syn form is preferentially formed if the conditions are basic.[16] However, the syn oxime isomerizes to the anti form if acid is present. We therefore believe that we are dealing with the anti (*Z*) oximes. This assignment of stereochemistry is reasonable on the steric ground and is also consistent with the relative rates of dehydration discussed below.

Anti-oximes are easily dehydrated by acetic anhydride. However, heating was required for dehydration of oximes **5** with acetic anhydride. To avoid isomerization, more efficient dehydrating reagent is required. Dicyclohexylcarbodiimide is known to be an efficient dehydrating reagent.[17] However, to enhance the reactivity, triethylamine and copper ion are used in addition to the carbodiimide. As a result, the reaction

of *ap*-oxime afforded a mixture of various products. 1,1'-Carbonyldiimidazole is also known to be an efficient dehydrating reagent.[18] This reagent indeed dehydrated the oxime easily at room temperature. However, the product was found to be a mixture of *ap*- and *sp*-nitriles. We attribute the results to the basic property of imidazole which is formed by the reaction, although the basicity of imidazole is much lower than triethylamine. Thus it is necessary to carry out a reaction under non-basic conditions to avoid isomerization.

Finally we used thionyl chloride as a dehydrating reagent. It reacted smoothly to afford nitriles (**6**). The relative rate k_{sp}/k_{ap} is large 18 but not as large as that in oxidation of **1**, **7**, or **10**. We wish to attribute the results to the fact that the E2 type elimination takes place from a tetrahedral species in **1**, **7**, and **10**, whereas it occurs from a trigonal carbon in the oxime.

Sodium tetrahydridoborate reduction is claimed to take a four-membered ring transition state, carbonyl oxygen ligating to boron and hydride approaching the carbonyl carbon.[19] Therefore the transition state must be bulky in this reaction. It then is expected that *sp*-**1** will show a large reactivity relative to *ap*-**1**. The reduction proceeded smoothly from the both conformations to produce the primary alcohols (**3**). The relative rate k_{sp}/k_{ap} was 7.6. Although the difference is reduced somewhat from those in oxidation of the aldehyde (**1**) or the secondary alcohols (**7** and **10**) and dehydration of oximes (**5**), it is still significant. Space-demanding structure (transition state in this case) must be responsible to the result.

A Grignard addition reaction to a carbonyl compound is also cited very often that the transition state is a 4-membered ring and thus the reaction is concerted.[20] We have carried out the reaction of phenylmagnesium bromide with the aldehyde (**1**). Both conformations of **1** reacted smoothly to afford 9-[2-(α-hydroxybenzyl)-1-naphthyl]fluorene (**7**). However, the relative rate k_{sp}/k_{ap} was, to our surprise, low 1.8. Addition of methylmagnesium iodide also showed k_{sp}/k_{ap} of 1.7. Mechanism of Grignard addition to carbonyl compounds is complicated. A single-electron transfer process and a nucleophilic addition process are competing.[20] It may not be possible to exactly compare the reactivity of the aldehyde rotamers here, but it is at least clear that, in the reaction of *ap*-**1**, the process does not require much space. Ashby *et al.* depicted one of the Grignard reactions as it has coordination of oxygen to magnesium only.[21] The reaction of *ap*-**1** may be proceeding in this manner.

In conclusion, we wish to point out that, if a reaction passes through a bulky state, the relative rate k_{sp}/k_{ap} becomes very large in this system. Certain S_N2 type reactions of 9-(2-bromomethyl-6-methylphenyl)fluorene were also very slow in *ap* conformation relative to those in the *sp*.[4] Thus it is commonly noticed that the space-demanding reaction is slow in the *ap* of these systems. The technique may even be used for diagnosis whether a space-demanding transition state is really intervening in the reaction. If a reaction is not space-demanding, the k_{sp}/k_{ap} can be very close to unity in the system. Further study on other carbonyl compounds, which give a bulkier transition state, may exhibit even larger differences in reactivities.

Experimental

9-(2-Formyl-1-naphthyl)fluorene (1). a): To a solution of 1.00 g (3.1 mmol) of *ap*-9-(2-hydroxymethyl-1-naphthyl)-fluorene (**3**)[6] in 30 mL of acetone was added a little excess of the Jones reagent prepared from 2.7 g of chromium(VI) oxide, 4.6 mL of concentrated sulfuric acid, and 8 mL of water. The excessive chromium(VI) oxide was decomposed with methanol or ethanol. The precipitate was filtered off and the filtrate was poured into water. After the usual treatment, the product was chromatographed on silica gel (benzene eluent) to afford 0.98 g *ap*-**1**, mp 127—128.5 °C. Found: C, 89.73; H, 4.73%. Calcd for $C_{24}H_{16}O$: C, 89.97; H, 5.03%. ^{1}H NMR ($CDCl_3$, δ): 6.21 (1H, s), 7.07—8.10 (13H, m), 8.50—8.73 (1H, m), 8.95 (1H, s).

sp-**1**, mp 102.5—104 °C, was similarly prepared in 95% yield. Care was exercised to avoid further oxidation by limiting the amount of the Jones reagent. Found: C, 90.21; H, 4.73%. Calcd for $C_{24}H_{16}O$: C, 89.97; H, 5.03%. ^{1}H NMR ($CDCl_3$, δ): 6.03 (1H, d, J=8.1 Hz), *ca.* 6.70 (1H, s), 6.73—8.13 (13H, m), 10.85 (1H, s).

b): A mixture of 0.17 g (0.44 mmol) of a rotameric mixture of 9-(2-bromethyl-1-naphthyl)fluorene (**2**)[6] and 0.2 g (1.4 mmol) of hexamethylenetramine in 4 mL of chloroform was heated under reflux for 2 h with stirring. The precipitate was collected after cooling and was heated with 30 mL of 50% aqueous acetic acid at 100 °C for 1 h. The mixture was poured into water and extracted with ether. The ethereal extract was washed with aqueous sodium hydrogencarbonate and dried. After evaporation of the solvent, the residue was submitted to chromatography on silica gel but the separation was very tedious. The mixture was obtained as an oil in 78% yield. Pure *ap*-**1** could be obtained after oxidation as described below because the *ap* aldehyde resisted oxidtaion.

sp-*(2-Carboxy-1-naphthyl)fluorene (4).* To a solution of 1.00 g of *sp*-**1** in 30 mL of acetone, was added a little excess of the Jones reagent at room temperature. After 30 min, the reaction mixture was poured into water and was extracted with ether. After evaporation of the solvent, the residue was purified by chromatography on silica gel (dichloromethane solvent) to afford 80% *sp*-**4**, mp 228—230 °C. Found; C, 85.78; H, 4.59%. Calcd for $C_{24}H_{16}O_2$: C, 85.69; H, 4.79%. ^{1}H NMR ($CDCl_3$, δ): *ca.* 6.56 (1H, s), 6.62 (1H, d, J=8.0 Hz), 7.73—9.01 (13H, m).

Oxidation of a Rotameric Mixture of the Aldehyde (1). To a solution of 100 mg of a mixture (*ca.* 1 : 1) of *sp* and *ap* aldehydes (**1**) in 30 mL of acetone, was added the Jones reagent with stirring in small portions. The addition was terminated when the reddish-orange color persisted after 20 min. Methanol was added to destroy the excess of chromium(VI) oxide and the precipitate was removed by filtration. The filtrate was poured into water and the whole was extracted with ether. After washing and drying of the ether layer, the solvent was evaporated. The residue was submitted to chromatography on silica gel (benzene eluent) to give *ca.* 40 mg of *ap*-**1** and *ca.* 50 mg of *sp*-**4**. No *ap*-carboxylic acid was detected.

9-(2-Carboxy-1-naphthyl)-9-hydroxyfluorene Lactone (8).
a): A solution of 30 mg of a mixture of *ap* and *sp*-**1** in 10 mL of pyridine was mixed with 50 mg of chromium(VI) oxide and the mixture was allowed to stand for 10 h at room temperature. The excess of chromium(VI) oxide was decomposed with methanol and the product was taken up in ether. The

ethereal layer was washed with dilute hydrochloric acid and then with water. After evaporation of the solvent, the residue was recrystallized from benzene–hexane, mp 247.5—249 °C. The yield was almost quantitative. Found: C, 86.28; H, 4.12%. Calcd for $C_{24}H_{14}O_2$: C, 86.21; H, 4.12%. ^{1}H NMR ($CDCl_3$, δ): 6.83—8.13 (14H, m). IR (KBr): 1760 cm^{-1}. MS showed a molecular ion peak at *m/e* 334 while $C_{24}H_{14}O_2$ requires that at *m/e* 334.

b): A solution of 40 mg of a mixture of *sp*- and *ap*-**1** in 20 mL of ethanol was mixed with 0.1 mL of a solution made from 0.5 g of potassium hydroxide and 2 mL of water. The mixture was stirred for 1.5 h at room temperature and poured into water. The product was treated in the usual manner to give *ca.* 40 mg of the lactone.

*9-(2-Hydroxyiminomethyl-1-naphthyl)fluorene (**5**).* A solution of 0.150 g (0.47 mmol) of the *sp*-aldehyde (**1**) in 40 mL of ethanol was mixed with a solution of 0.1 g (1.2 mmol) of sodium acetate in 3 mL of water. A solution of 0.045 g (0.64 mmol) of hydroxylamine hydrochloride in 2 mL of water was added to the mixture and the whole was stirred at room temperature for 10 min. The mixture was concentrated *in vacuo* and was poured into water. The organic material was extracted with ether and the product was chromatographed on silica gel (benzene eluent). The *sp*-oxime, mp 170.5—171.5 °C, was obtained in 96% yield. Found: C, 85.96; H, 9.85; N, 4.08%. Calcd for $C_{24}H_{17}NO$: C, 85.94; H, 5.11; N, 4.18%. ^{1}H NMR ($CDCl_3$, δ): 5.89 (1H, s), 6.48 (1H, d, J=7.2 Hz), 6.67—8.00 (13H, m), 9.03 (1H, s). The OH proton was not detected in the spectrum.

The *ap*-oxime, mp 171.5—172.5 °C, was similarly prepared quantitatively. Found: C, 85.68; H, 4.88; N, 4.48%. ^{1}H NMR ($CDCl_3$, δ): 6.12 (1H, s), 6.94 (1H, s), 7.07—8.03 (13H, m), 8.45—8.63 (1H, m). The OH proton was not detected in the spectrum.

*9-[2-(α-Hydroxybenzyl)-1-naphthyl]fluorene (**7**).* A Grignard reagent was prepared from 0.25 g of magnesium, 1.13 mL of bromobenzene, and 10 mL of dry ether. A 1.4 mL portion of the Grignard reagent was added to 0.30 g of *ap*-**1** in 30 mL of ether and the mixture was decomposed after 10 min. After a usual manipulation, the product was chromatographed on silica gel (benzene eluent) to afford 0.36 g of *ap*-**7**, mp 176—177 °C. Found: C, 90.19; H, 5.37%. Calcd for $C_{30}H_{22}O$: C, 90.42; H, 5.56%. ^{1}H NMR ($CDCl_3$, δ): 4.88 (1H, s), 6.25 (1H, s), 6.50—8.00 (18H, m), 8.57 (1H, d, J=9.6 Hz). The OH proton was not detected in the spectrum.

sp-**7**, mp 175—177 °C, was similarly prepared in 97% yield. Found: C, 90.60; H, 5.33%. Calcd for $C_{30}H_{22}O$: C, 90.42; H, 5.56%. ^{1}H NMR ($CDCl_3$, δ): 5.87 (1H, s), 6.63 (1H, s), 6.40 (1H, d, J=9.0 Hz), 6.50—7.97 (18H, m). The OH proton was not detected in the spectrum.

*9-[2-(1-Hydroxyethyl)-1-naphthyl]fluorene (**10**)* was similarly prepared from the aldehyde (**1**) and methylmagnesium iodide almost quantitatively.

ap-**10**, oil. High resolution MS exhibited a molecular ion peak at *m/e* 336.1516, whereas $C_{25}H_{20}O$ requires 336.1514. ^{1}H NMR ($CDCl_3$, δ): 0.70 (3H, d, J=6.0 Hz), 3.82 (1H, q, J=6.0 Hz), 6.12 (1H, s), 7.03—8.03 (13H, m), 8.42—8.65 (1H, m). The OH proton was not detected in the spectrum.

sp-**10**, mp 120—124 °C. Found: C, 89.24; H, 5.88%. Calcd for $C_{25}H_{20}O$: C, 89.25; H, 5.99%. ^{1}H NMR ($CDCl_3$, δ): 1.79 (3H, d, J=6.6 Hz), 5.67 (1H, q, J=6.6 Hz), 6.12 (1H, s), 6.40 (1H, d, J=9.0 Hz), 6.76—8.00 (13H, m). The OH proton was not detected in the spectrum.

*9-(2-Benzoyl-1-naphthyl)fluorene (**9**).* A solution of 0.30 g of *ap*- or *sp*-**7** in 20 mL of acetone was oxidized with the Jones reagent as described in the preparation of the aldehyde (**1**). It took 30—60 min for the oxidation of the *ap*-isomer, whereas the oxidation of *sp*-**7** was over within several minutes.

ap-**9**, mp 123—124 °C. Found: C, 90.61; H, 4.94%. Calcd for $C_{30}H_{20}O$: C, 90.88; H, 5.08%. ^{1}H NMR ($CDCl_3$, δ): 6.08 (1H, s), 6.73—8.10 (18H, m), 8.68 (1H, d, J=9.0 Hz).

sp-**9**, mp 162.5—164 °C. Found: C, 91.10; H, 4.82%. Calcd for $C_{30}H_{20}O$: C, 90.88; H, 5.08%. ^{1}H NMR ($CDCl_3$, δ): 5.44 (1H, s), 6.57 (1H, d, J=9.0 Hz), 6.77—8.13 (18H, m).

*9-(2-Acetyl-1-naphthyl)fluorene (**11**)* was similarly prepared from the alcohol (**10**) by oxidation with chromium(VI) oxide. The *ap* form reacted much more slowly than the *sp* form.

ap-**11**, mp 108—109 °C. Found: C, 89.80; H, 5.21%. Calcd for $C_{25}H_{18}O$: C, 89.79; H, 5.43%. ^{1}H NMR ($CDCl_3$, δ): 1.60 (3H, s), 6.09 (1H, s), 7.07—8.07 (13H, m), 8.67 (1H, d, J=9.0 Hz).

sp-**11**, mp 103—105 °C. Found: C, 89.94; H, 5.23%. Calcd for $C_{25}H_{18}O$: C, 89.79; H, 5.43%. ^{1}H NMR ($CDCl_3$, δ): 2.77 (3H, s), 5.84 (1H, s), 6.56 (1H, d, J=8.4 Hz), 6.73—8.00 (13H, m).

*9-(2-Cyano-1-naphthyl)fluorene (**6**).* To a stirred solution of 0.15 g (0.45 mmol) of *ap*-**5** in 30 mL of dry ether was added 0.5 mL of thionyl chloride and the whole was stirred for 5 h at room temperature. The mixture was poured into water and extracted with ether. The extract was washed, dried, and evaporated. The residue was chromatographed on silica gel (benzene eluent) to afford 0.12 g of *ap*-**6**, mp 150.5—152 °C. Found: C, 90.75; H, 4.62; N, 4.44%. Calcd for $C_{24}H_{15}N$: C, 90.82; H, 4.76; N, 4.41%. ^{1}H NMR ($CDCl_3$, δ): 6.18 (1H, s), 7.07—8.07 (13H, m), 8.58—8.80 (1H, m).

The *sp* form, mp 165.5—167 °C, was prepared similarly in 71% yield. Since the dehydration of *sp*-**5** was much easier than that of the *ap* form, 0.1 mL of thionyl chloride and stirring for 2 h sufficed for the dehydration. Found: C, 91.08; H, 4.46%. Calcd for $C_{24}H_{15}N$: C, 90.82; H, 4.76%. ^{1}H NMR ($CDCl_3$, δ): 6.00 (1H, s), 6.58 (1H, d, J=9.0 Hz), 6.80—8.00 (13H, m).

Determination of Barriers to Rotation. A sample solution was prepared by dissolving 30 mg of the *ap* form of arylfluorenes in 0.4 mL of hexachlorobutadiene and was placed in an NMR sample tube. The tube was immersed in an appropriate boiling-solvent bath, the temperature of which was directly measured by a thermometer. The rate of isomerization was followed by ^{1}H NMR spectroscopy and was treated as a reversible first-order reaction. The rate constants thus obtained were put into the Eyring equation to obtain activation parameters. The following solvents were used for the bath (solvent and approximate boiling point given): acetone (55 °C), methanol (64 °C), 1,1,1-trichloroethane (73 °C), benzene (78 °C), dioxane (96 °C), toluene (104 °C), 1 : 1 chlorobenzene–toluene (114 °C), chlorobenzene (124 °C).

Determination of Spectra. Infrared spectra were recorded on a Hitachi EPI-G spectrophotometer. The wave numbers are not calibrated. The spectra of solid were obtained as KBr disks. The spectra of solution were obtained with a KBr cell of variable length. With solutions of *ca.* 0.2 M in carbon tetrachloride, the cell length was 0.25 mm and, with those of *ca.* 0.01 M, the cell length was 5 mm. ^{1}H NMR spectra were obtained with either a Hitachi R-20B or a Varian EM 390 spectrometer.

Competitive Reactions. Relative reactivities of rotamers were obtained by competitive reactions. Dehydration of oximes did not give clear results with this method. Thus the relative rate was checked by measuring the rates of reactions of individual rotamers. If one assumes that the rate expressions of the reactions of *sp* and *ap* rotamers are the same and that the rate is first order in the substrate, then

$$[\text{Relative reactivity}] = k_{sp}/k_{ap} = \frac{\log[sp]/[sp]_0}{\log[ap]/[ap]_0}$$

Competitive oximation of the aldehyde (**1**) was carried out by treating 30 mg each of *ap* and *sp* forms in 20 mL of ethanol with 0.5 mL of aqueous hydroxylamine hydrochloride, which was made by dissolving 130 mg of the salt in 10 mL of water, and 0.5 mL of aqueous sodium acetate, which was prepared by dissolving 300 mg of the salt in 5 mL of water. After 30 min at room temperature, the mixture was treated as described in the preparation of oximes and the unreacted starting materials were analyzed with the use of ^{1}H NMR spectra. The relative reactivity was obtained as an average of three runs.

Competitive oxidation of rotamers of 9-[2-(α-hydroxybenzyl)-1-naphthyl]fluorene (**7**) was carried out using 20 mg each of *sp*- and *ap*-**7** in 20 mL of acetone and 0.1 mL of the Jones reagent prepared as above. ^{1}H NMR showed the presence of 17.5% unreacted *sp* but at least 95% of the *ap* form was found unreacted.

Competitive oxidation of *ap*- and *sp*-9-[2-(1-hydroxyethyl)-1-naphthyl]fluorene (**10**) was carried out similarly. ^{1}H NMR showed the presence of 25.1% unreacted *sp* form whereas at least 95% of the *ap* form remained unreacted.

Competitive oxidation of 9-(2-hydroxymethyl-1-naphthyl)-fluorene (**5**) was carried out similarly. The relative reactivity is the average of three runs.

Competitive reduction of *sp*- and *ap*-9-(2-formyl-1-naphthyl)-fluorene (**1**) was carried out by treating a solution of 30 mg each of the rotamers in 20 mL of methanol with 1.0 mL of methanolic solution of sodium tetrahydridoborate, which was prepared by dissolving 20 mg of the hydride in 10 mL of methanol. After 10 min at room temperature, the mixture was manipulated in the usual manner and the unreacted materials were analyzed by ^{1}H NMR spectroscopy. The relative reactivity was obtained as an average of three runs.

Competitive Grignard reactions of *sp*- and *ap*-9-(2-formyl-1-naphthyl)fluorene (**1**) were carried out by treating 30 mg each of the aldehyde rotamers in 20 mL of ether with 0.1—0.2 mL of methylmagnesium iodide or phenylmagnesium bromide solution which was prepared as described for the preparation of **7** and **10**. After 10 min, the mixture was decomposed and the unreacted materials were analyzed by ^{1}H NMR spectroscopy. The relative reactivities are the averages of 2—3 runs.

Competitive dehydration of *ap*- and *sp*-9-(2-hydroxyiminomethyl-1-naphthyl)fluorene (**5**) was carried out by treating a solution of 20 mg each of the rotamers in 20 mL of dry ether with 0.1 mL of thionyl chloride at room temperature. After 1 h, the mixture was separated by TLC into oximes and nitriles. The unreacted oximes were analyzed by ^{1}H NMR spectroscopy. This operation gave 86.1% unreacted *ap* and less than 5% unreacted *sp*. This gave k_{sp}/k_{ap} of *ca.* 20.

*Relative Reactivity of 9-(2-Hydroxyiminomethyl-1-naphthyl)fluorene (**5**) toward Dehydration as Obtained by Individual Rate of Dehydration.* *ap*-**5** (20 mg) in 20 mL of ether was stirred with 0.1 mL of thionyl chloride at room temperature. The reaction was quenched at appropriate intervals. After 5 h, the conversion ratio was 48.4%. Under the same conditions the conversion ratio of the *sp* form was 82.3% after 40 min. If one assumes that the formation rate of the nitriles is expressed by the product of the concentrations of the reactants and the change in the concentration in thionyl chloride is neglected, the results give k_{sp}/k_{ap} of *c. a.* 16.

Reactivities of Stable Rotamers. XI. Rotamer Distributions and Some Addition Reactions to the Carbonyl in 9-[2-(Substituted carbonyl)-1-naphthyl]fluorene Rotamers[1)]

Ryo Saito and Michinori Ōki*

Department of Chemistry, Faculty of Science, The University of Tokyo, Bunkyo-ku, Tokyo 113

(Received May 25, 1982)

Rotational isomers (*sp* and *ap*) of several 9-[2-(substituted carbonyl)-1-naphthyl]fluorenes where the substituent is methyl, phenyl, hydroxyl, methoxyl, 1-imidazolyl, or others have been obtained as stable entities. Barriers to rotation in these compounds were *ca.* 26.5 kcal for the process *sp*→*ap* but those for the reverse (*ap*→*sp*) were dependent on the substituent, ranging from 23.8 to 25.3 kcal/mol at 55 °C. The difference is reflected in the populations of rotamers: if the substituent is a hydroxyl, the *sp*/*ap* value becomes as large as *ca.* 20. The relative instability of the *ap* form was attributed to twisting of the carbonyl plane from that of naphthalene. Infrared spectra support the twisting. Addition reactions to the carbonyl occur smoothly in the *sp* conformation but they do not occur to a detectable extent in the *ap* conformation, if the substituent on the carbonyl is larger than hydrogen. The results are attributed to the steric effect of the fluorene ring.

In a previous paper,[1)] we have demonstrated that some reactions which take space-demanding transition states are very slow in an *ap* conformation, relative to the *sp*, of 9-(2-formyl-1-naphthyl)fluorene (**1a**). In contrast, an addition reaction of hydroxylamine to the carbonyl of *ap*-**1a** proceeded with a rate comparable with that of the *sp* form. The results imply that the transition state for the addition is not bulky: it may be assumed that, in the transition state for the addition where a tetrahedral carbon is developing from a trigonal, the hydrogen of the formyl group comes closely to the fluorene ring to minimize the transition state energy.

Then a question arises: what will happen when a bulkier substituent than hydrogen has to take a position which is close to the fluorene ring in the transition state of a reaction in the *ap* form? From our previous work, we collect that 9-(2-*t*-butylphenyl)fluorene exists as an *sp* conformation only.[2)] 9-(8-Methyl-1-naphthyl)-fluorene gives an equilibrium constant (*sp*/*ap*) of 25.[3)] These results suggest that, if a bulky group has to take a position which is close to the fluorene ring during a reaction in the *ap* form, the free energy of activation is different by 2 kcal/mol (1 cal=4.18 J) or more between *sp* and *ap* conformations. This should give a very large k_{sp}/k_{ap} value and may result in chemoselective reactions which occur in *sp* conformations only. To achieve this end, we carried out a series of addition reactions to carbonyls in ketones and acid derivatives. This paper reports results of such an investigation together with populations of rotamers and barriers to rotation in these compounds.

Barriers to Rotation and Populations of Rotamers. The assignment of the conformation of 9-[2-(substituted carbonyl)-1-naphthyl]fluorene (**1**) relies upon ^1H NMR spectral features as reported in previous papers. If the substituent has proton(s) not far from the carbonyl, the proton signal of the *ap* form appears in a high field relative to the *sp* form because of the ring current effect of fluorene. If there is no proton close to the carbonyl in the substituent, we use the method of preparation because barriers to rotation are high enough to retain the conformation when the reaction is carried out at room temperature. As an auxilary support, we may use the chemical shift of the 8-proton in the naphthalene ring: in the *ap* conformation, the proton is close to the plane of fluorene to give a signal at a very low field, whereas, in the *sp* conformation, the 8-proton is over the fluorene ring to exhibit a signal at a high field. It is interesting to note that the 8-H signal appears as an apparent doublet in the *sp* conformation, whereas it is often a multiplet in the *ap*.

Barriers to rotation were measured at one temperature. The measurement was carried out for the isomerization of *ap* forms because the *ap*'s are always minorities at equilibrium. The results are summarized in Table 1 together with those of the corresponding aldehyde (**1a**).[1)] Inspection of Table 1 reveals that the barriers to rotation for the process *sp*→*ap* are almost the same whereas those for the *ap*→*sp* processes vary to some extent. Although

Table 1. Barriers to rotation and equilibrium constants in 9-[2-(substituted carbonyl)-1-naphthyl]fluorene (**1**) in benzene-d_6 at 55 °C

a) Hexachlorobutadiene solvent. b) Dimethyl-d_6 sulfoxide solvent.

solvents are different, at least we may compare the barriers including that for the carboxylic acid (**1d**). At any rate, reactivities of rotamers may be investigated without complication due to isomerization, if a reaction is carried out at room temperature, except for the *ap*-carboxylic acid (**1d**). Although not determined, other carbonyl compounds may be assumed to possess similar barriers to rotation.

The barriers of the carbonyl compounds are lower than the corresponding compounds carrying an sp^3-carbon substituent in the 2-position of the naphthalene ring.[4] This must be attributed to the relative size of the carbonyl group, since the van der Waals radius of a methyl group (2.0 Å) is known to be larger than the half-thickness of a π-system (1.8 Å), as discussed before.[1] The lowering of the transition state for rotation by introduction of a π-system, in place of a tetrahedral carbon, to the 2-position of naphthalene is more important than the effect in the ground state.

Similar barriers to rotation for the *sp*→*ap* process for all the compounds examined here mean that the energy difference between the ground state and the transition state for rotation is also similar. If we can assume that the main contribution to the transition state energy is the interaction of the carbonyl oxygen with the fluorene ring, then the ground state conformation will also have the carbonyl oxygen in similar situations. The barrier is highest when the substituent X is hydrogen. Similar barriers to rotation for all the compounds for the *sp*→*ap* process suggest that the lower barriers to rotation in **1b**, **1c**, and **1e** for the *ap*→*sp* process may be attributed to destabilization of the ground state in the *ap* form. Indeed, all the compounds, **1b**—**e**, have larger equilibrium constants (*sp*/*ap*) than **1a** in favor of the *sp* form.

Molecular models of these compounds suggest that, if the carbonyl group takes a planar conformation with the naphthalene ring, either the carbonyl-oxygen or the substituent X gives a severe interaction with the fluorene ring. Thus the carbonyl may not be coplanar with the naphthalene. In contrast, the formyl group can be coplanar with the naphthalene, if the hydrogen directs toward the fluorene ring. In order to get support for the suggestion by the model, infrared C=O stretching spectra were recorded. The results are given in Table 2.

Table 2. Infrared carbonyl stretching frequencies of 9-[2-(substituted carbonyl)-1-naphthyl]-fluorene (1)

Substituent	$\nu_{C=O}/cm^{-1}$			
	sp		*ap*	
	Solid	CCl_4 soln[a]	Solid	CCl_4 soln[a]
H	1672 1690 (sh)	1682 (329) 1700 (321)	1672	1692 (627)
CH_3	1688	1692 (378)	1700	1702 (279)
C_6H_5	1665	1688 (354)	1660	1665 (346)
OH	1680	1688 (934)	1700	1700 (374)
OCH_3	1708	1722 (560)	1720	1728 (459)

a) Numericals in parentheses are molecular extinction coefficients.

Although not observed for the benzoyl compound (**1c**), the carbonyl stretching frequencies for the *ap* forms are generally at higher wave numbers than those due to the *sp* forms. In contrast, the aldehydes (**1a**) show $\nu_{C=O}$ absorptions at about the same frequencies, though the *sp* form gives bifurcated bands probably due to the Fermi resonance. This suggests that the conjugation of the carbonyl with the naphthalene ring is diminished in these compounds and the two groups are not coplanar.[5] Benzophenone derivatives are insensitive to the steric environment because even the simplest example is not coplanar because of the steric effect.[6] Thus the population ratios and the relative barriers to rotation for the *ap*→*sp* process are explained by the destabilization of the *ap* forms.

Even though the above conclusion is reached, the instability of the *ap*-carboxylic acid (**1d**) relative to the *sp* form is unusual. We have tried to increase the population of the *ap* form by various methods, including solvent-change and acidification of a basic solution of **1d** in water, without success. Baeyer-Villiger oxidation of the aldehyde (**1a**) afforded formates instead of the corresponding acid probably due to the steric effect.[7] We suspect that extra stabilization is obtained by the dimeric hydrogen bonds in the *sp* conformation whereas the dimer is unfavorable in the *ap* conformation because of the steric effect.

Conformer distribution in 9-[2-(*p*-nitrophenoxycarbonyl)-1-naphthyl]fluorene (**1f**) is interesting because the *sp*/*ap* value is *ca.* 4 which is small relative to the corresponding methyl ester (**1e**). We wish to attribute the phenomenon to the charge-transfer interaction between the *p*-nitrophenyl group and the fluorene, which stabilizes the *ap* form of **1f**. Such a stabilization of the *ap* form in *p*-nitrobenzoate of 9-(2-hydroxy-1-naphthyl)-fluorene has been reported.[8]

Reactions. The reaction of carbonyl groups proceeds smoothly if the conformation is *sp*. Esterification of *sp*-carboxylic acid (**1d**) proceeded to give *sp* form of the methyl ester (**1e**). The *sp*-**1e** could be equilibrated by heating its solution. The conformational isomers (*ap* and *sp*) were separated. The attempted hydrolysis of the ester was too slow to be suitable for the comparative study of the reactivities of conformational isomers at room temperature. *p*-Nitrophenyl esters (**1f**), though they have been known to be hydrolyzed more easily than alkyl esters,[9] resisted hydrolysis as well. In an effort of searching more easily hydrolyzable acid derivatives, imidazolide (**1g**)[10] was prepared from the *sp*-acid. After equilibration, the rotational isomers (*ap* and *sp*) were isolated. Hydrolysis of the imidazolide in acidic aqueous acetone afforded *sp*-acid (**1d**) from the *sp*-imidazolide but the *ap* form resisted the hydrolysis at room temperature.

Addition of methylmagnesium iodide to *sp*-9-(2-acetyl-1-naphthyl)fluorene (**1b**) proceeds smoothly to afford *sp*-9-[2-(1-hydroxy-1-methylethyl)-1-naphthyl]-fluorene. Attempted isomerization of this compound failed to give any sign of the presence of its *ap* isomer: this type of rotamer distribution is known, if the aryl group in 9-arylfluorene carry a large group on one side.[2,3] In contrast, *ap*-**1b** did not show evidence that

he reaction occurred. Likewise, sodium tetrahydridoborate reduction of the acetyl compound (**1b**) proceeds smoothly if the conformation is *sp*, but does not proceed if the conformation is *ap*.

These reactivities of the substituted carbonyl compounds make a sharp contrast to those of the aldehyde (**1a**). In the aldehyde, the relative reactivities toward Grignard additions and sodium tetrahydridoborate reduction were 1.7 and 7.6, respectively.[1] Therefore, the addition reaction of the substituted carbonyl compounds (**1b** and **1g**) was definitely slow in the *ap* conformation. The reason for the difference must be of the steric origin. Molecular models suggest that, if it is the aldehyde, the change from the sp^2-carbon to the sp^3-carbon by addition is not too difficult because the hydrogen of the formyl group can direct toward the fluorene ring, the steric hindrance being not large. In contrast, if it is a ketone or an acid derivative, the formation of the tetrahedral carbon by addition is prohibitive, because either oxygen or carbon must become closely located to the fluorene ring. Thus the activation energy must be very high for the *ap* conformation, if the addition to the carbonyl is to occur.

From the stand point discussed above, it is interesting to note that the acid chloride (**1h**) is easily hydrolyzed to yield the corresponding carboxylic acid (**1d**) even in the *ap* conformation. It may be plausible to assume that the addition of water to the carbonyl moiety is also slow in *ap*-**1h**, although this is believed to be the initial step in the hydrolysis of acid chlorides.[11] It is possible that *ap*-**1h** dissociates to the acyl carbonium ion and the chloride ion, of which the former reacts with water to give the *ap*-carboxylic acid, although definitive support is lacking.

Experimental

*9-(2-Methoxycarbonyl-1-naphthyl)fluorene (**1e**).* A solution of 0.80 g *sp*-9-(2-carboxy-1-naphthyl)fluorene (**1d**)[1] in 70 mL of methanol was refluxed for 25 h with 2 mL of concentrated sulfuric acid. The mixture was concentrated and poured into water. After extraction with ether followed by washing and drying, the product was separated by silica gel chromatography (benzene eluent) to give 0.69 g of the *sp* ester and 0.09 g of the *ap*.

ap-**1e**, mp 130—131 °C. Found: C, 85.81; H, 5.11%. Calcd for $C_{25}H_{18}O_2$: C, 85.69; H, 5.18%. ^{1}H NMR ($CDCl_3$, δ): 2.83 (3H, s), 6.10 (1H, s), 7.10—8.10 (13H, m), 8.53—8.77 (1H, m).

sp-**1e**, mp 133—134 °C. Found: C, 85.73; H, 4.90%. Calcd for $C_{25}H_{18}O_2$: C, 85.69; H, 5.18%. ^{1}H NMR ($CDCl_3$, δ): 3.95 (3H, s), 6.20 (1H, s), 6.56 (1H, d, J=9.0 Hz), 6.70—7.96 (13H, m).

*9-[2-(1-Imidazolylcarbonyl)-1-naphthyl]fluorene (**1g**).* A mixture of 0.10 g of *sp*-**1d** and 5 mL of thionyl chloride was heated under reflux for 1 h and then excessive thionyl chloride was removed *in vacuo*. The residue was taken up in 20 mL of dichloromethane and was stirred with 0.1 g of imidazole for 30 min. The solvent was evaporated and the residue was purified by preparative TLC on silica gel (dichloromethane solvent) to give *sp*-**1g**, mp 133.5—138.0 °C (decomp), almost quantitatively. High resolution mass spectrum exhibited a molecular ion peak at *m/e* 386.1461, whereas the calculation for $C_{27}H_{18}N_2O$ requires 386.1420. ^{1}H NMR ($CDCl_3$, δ): 5.43 (1H, s), 6.62 (1H, d, J=9.0 Hz), 6.83—8.17 (16H, m).

When the reaction products taken up in dichloromethane was heated for 2 h, a *ca.* 5 : 1 mixture of *sp*- and *ap*-**1g** was obtained. This isomerization was probably catalyzed by imidazole. After evaporation of the solvent, the mixture was separated by preparative TLC as above to give pure *ap*-**1g**, mp 253—257 °C (decomp). High resolution mass spectrum exhibited a molecular ion peak at *m/e* 386.1462, whereas $C_{27}H_{18}N_2O$ requires 386.1420. ^{1}H NMR ($CDCl_3$, δ): 6.17 (1H, s), 6.60—8.20 (16H, m), 8.63—8.88 (1H, m).

*Acid Hydrolysis of Imidazolide (**1g**).* To a solution of 20 mg of *sp*-**1g** in 15 mL of acetone, 5 mL of water and 1 mL of concentrated hydrochloric acid were added and the mixture was allowed to stand overnight. The mixture was poured into water and extracted with ether. The ether extract gave *sp*-acid (**1d**) almost quantitatively.

A similar treatment of *ap*-**1g** gave no carboxylic acid but the imidazolide was recovered in good yield.

*9-[2-(p-Nitrophenoxycarbonyl)-1-naphthyl]fluorene (**1f**).* The acid chloride (**1h**) was prepared from 100 mg of the *sp*-acid (**1d**) and 5 mL of thionyl chloride as above. The chloride was dissolved in 20 mL of dichloromethane and stirred with 0.5 mL of pyridine and 100 mg (2.4 equiv.) of *p*-nitrophenol for 30 min at room temperature. After evaporation of the solvent, the residue was taken up in ether and washed with water. The ethereal layer was dried and evaporated. The residue was submitted to TLC on silica gel (2 : 1 benzene–hexane solvent) to give *ca.* 70 mg of *sp*-**1f**, mp 166—167 °C. Found: C, 78.65; H, 4.03; N, 3.06%. Calcd for $C_{30}H_{19}NO_4$: C, 78.76; H, 4.19; N, 3.06%. ^{1}H NMR ($CDCl_3$, δ): 6.38 (1H, s), 6.66 (1H, d, J=8.7 Hz), 6.7—8.3 (17H, m). IR (KBr disk): 1740, 1523, 1347 cm^{-1}.

The *sp* form of **1f** in benzene was refluxed overnight to give a 4 : 1 *sp* and *ap*-**1f**. The solvent was evaporated and the residue was submitted to TLC as above to give pure *ap*-**1f**, mp 162—163 °C. Found: C, 78.42; H, 3.96; N, 3.00%. Calcd for $C_{30}H_{19}NO_4$: C, 78.46; H, 4.19; N, 3.06%. ^{1}H NMR ($CDCl_3$, δ): 6.17 (1H, s), 6.33 (2H, d, J=9.0 Hz), 7.1—8.4 (15H, m), 8.57—8.85 (1H, m). IR (KBr disk): 1748, 1520, 1350 cm^{-1}.

Attempted Hydrolysis of p-*Nitrophenyl Ester (**1f**).* A solution of 30 mg of *sp*-**1f** in 5 mL of acetic acid was left to stand for a week at room temperature with 5 mL of water and 1 mL of concentrated sulfuric acid. No carboxylic acid (**1d**) was detected after this period and the ester was recovered almost quantitatively. Similarly *ap*-**1f** was recovered after attempted hydrolysis.

ap-*9-(2-Carboxy-1-naphthyl)fluorene* (ap-**1d**). The corresponding acid chloride (**1h**), prepared from 0.1 g of the *sp*-acid and 5 mL of thionyl chloride as described above, was dissolved in 20 mL of acetone and was treated with 5 mL of water at *ca.* 0 °C. After 1 h, the product was taken up in ether and evaporated. Preparative TLC on silica gel (ethyl acetate–dichloromethane 1 : 2) afforded *ca.* 5 mg of the *ap*-acid, mp 226—228 °C, and *ca.* 60 mg of *sp*-acid. High resolution MS showed a molecular ion peak at 336.1159, whereas the molecular formula $C_{24}H_{16}O_2$ requires 336.1151. ^{1}H NMR ($CDCl_3$, δ): 6.08 (1H, s), 7.07—8.07 (13H, m), 8.53—8.83 (1H, m).

*Addition of Methylmagnesium Iodide to 9-(2-Acetyl-1-naphthyl)-fluorene (**1b**).* A 2 mL portion of a Grignard reagent, which was prepared from 0.77 mL of methyl iodide, 0.25 g of magnesium, and 10 mL of ether, was added to 30 mg of *sp*-**1b**[1] and the mixture was allowed to stand for 1.5 h. The mixture was decomposed with 5% aqueous ammonium chloride and the product was treated in a usual manner. *sp*-9-[2-(1-Hydroxy-1-methylethyl)-1-naphthyl]fluorene, mp 133—134

°C was obtained almost quantitatively. Found: C, 89.20; H, 6.18%. Calcd for $C_{26}H_{22}O$: C, 89.11; H, 6.33%. ^{1}H NMR ($CDCl_3$, δ): 1.97 (6H, s), 6.81 (1H, s), 6.43 (1H, d, J=9.0 Hz), 6.63—8.00 (13H, m). The OH proton was not detected.

Similar treatment of *ap*-**1b** gave no sign of the reaction. The starting material was recovered almost quantitatively.

*Reduction of 9-(2-Acetyl-1-naphthyl)fluorene (**1b**) with Sodium Tetrahydridoborate.* A solution of 30 mg of *sp*-**1b** in 20 mL of methanol was mixed with 8 equivalents of sodium tetrahydridoborate. After 10 min, the mixture was poured into water and extracted with ether. The ethereal layer was washed and dried over magnesium sulfate. After evaporation of the solvent, the residue was found to be an almost pure *sp*-9-[2-(1-hydroxyethyl)-1-naphthyl]fluorene by its ^{1}H NMR spectrum.[1)]

The similar treatment of the *ap* form did not show any sign of the reduction. Although the same portions of sodium tetrahydridoborate were added three times to the mixture and the mixture was stirred for 80 more min at 0 °C and then for 1 h at room temperature, the *ap* form was recoved unreacted.

*Baeyer-Villiger Oxidation of 9-(2-Formyl-1-naphthyl)fluorene (**1a**).* To a solution of 20 mg of *ap*-**1a** in 20 mL of acetic acid was added 1 mL of a mixture prepared from 2 mL of 90% formic acid and 2 mL of 38% hydrogen peroxide. The whole was allowed to stand for 2 d and treated in a usual way. Purification of the product by chromatography on silica gel (benzene eluent) gave *ap*-9-(2-formyloxy-1-naphthyl)fluorene, mp 142—143 °C, almost quantitatively. Found: C, 85.73; H, 4.81%. Calcd for $C_{24}H_{16}O_2$: C, 85.69; H, 4.79%. ^{1}H-NMR ($CDCl_3$, δ): 5.90 (1H, s), 6.98 (1H, s), 6.90—8.07 (13H, m), 8.52 (1H, d, J=9.0 Hz). IR (KBr disk): 1740 cm^{-1}.

Similar treatment of *sp*-**1a** gave *sp*-(2-formyloxy-1-naphthyl)fluorene, oil, in *ca.* 50% yield. The *sp*-formate is relatively easily hydrolyzed and formation of *sp*-(2-hydroxy-1-naphthyl)fluorene was detected during silica gel TLC (benzene eluent). High resolution MS showed a molecular ion peak at *m/e* 336.1189, whereas calculation for $C_{24}H_{16}O_2$ requires 336.1151. ^{1}H NMR ($CDCl_3$, δ): 5.70 (1H, s), 6.45 (1H, d, J=9.0 Hz), 6.73—8.07 (13H, m), 8.47 (1H, s).

Barriers to Rotation. Pure *ap* isomer (30 mg) of the carbonyl compounds was dissolved in 0.4 mL of benzene-d_6 or dimethyl-d_6 sulfoxide and the solution was placed in an NMR sample tube. The tube was immersed in a boiling-acetone bath and the rate of isomerization was followed by ^{1}H NMR spectroscopy. The data were treated by assuming a reversible first order reaction to give a rate constant. The rate constant was put into the Eyring equation and the free energy of activation was obtained.

Spectral Measurement. Infrared spectra were obtained with a Hitachi EPI-G spectrophotometer. With solid samples, KBr discs were used. For the measurement of the spectra of solutions, the sample was dissolved in carbon tetrachloride to make up *ca.* 0.05 mol/L solution for the carbonyl region and a KBr cell of 0.25 mm length was used.

^{1}H NMR spectra were obtained with a Varian EM 390 spectrometer. The integration of peak areas was repeated several times and the average was used for the kinetic measurement.

The Enantioselective Michael Addition of Thiols to Cycloalkenones by Using (2*S*, 4*S*)-2-Anilinomethyl-1-ethyl-4-hydroxypyrrolidine as Chiral Catalyst

Keisuke SUZUKI, Akihiko IKEGAWA, and Teruaki MUKAIYAMA*

Department of Chemistry, Faculty of Science, The University of Tokyo, Hongo, Bunkyo-ku, Tokyo 113

(Received May 24, 1982)

Catalytic asymmetric addition of thiols to 2-cycloalkenone was studied by using the chiral amino alcohols, derived from L-hydroxyproline or (*S*)-proline, as base catalysts. Detailed investigation was carried out on the effects of the structure of the catalyst, the reaction medium, the temperature, and the concentration on the enantioselectivity. Good optical yields (47—88%) were achieved by the reaction of arenethiols and 2-cyclohexen-1-one in toluene at −5 °C, by using the catalyst (2*S*, 4*S*)-2-anilinomethyl-1-ethyl-4-hydroxypyrrolidine.

Considerable attention has been focused on the asymmetric synthesis in the past decade, and a remarkable progress has made it one of the powerful tools in the preparation of chiral natural products.[1] Most of the fruitful cases to date are classified as "stoichiometric asymmetric synthesis," that is, a stoichiometric amount of chiral source is effectively used with the aid of the electronic and steric factors to obtain the desired chiral compound in high optical purity. However, from the synthetic point of view it suffers a fatal and inevitable disadvantage, namely, the separation of the chiral source from the reaction products. In this sense the development of "catalytic asymmetric synthesis" is very attractive and highly desirable in synthetic organic chemistry.

Concerning the catalytic asymmetric synthesis, there have been reported only limited successful examples, and most of them belong to the following two classes of reactions: i) The chiral transition-metal complex catalyzed reactions including the fruitful asymmetric hydrogenations—in this field, a rapid progress has been made recently; Sharpless' V catalyzed oxidation,[2a] Kumada's Ni catalyzed cross-coupling reaction,[2b] Otsuka's aymmetric isomerization,[2c] and so on. ii) The chiral base catalyzed reaction——although this type of reactions has been known for years, successful cases are rare; Wynberg has successfully employed cinchona alkaloids as chiral catalysts in the asymmetric Michael addition of thiols or β-keto esters,[3a,3b] and Cram reported the highly stereoselective Michael addition of β-keto esters using chiral crown ethers complexed to potassium base.[3c]

Recently we reported several types of successful asymmetric reactions based on the chiral pyrrolidine derivatives,[4] and this prompted us to undertake the exploration of the catalytic asymmetric synthesis using optically active pyrrolidine derivatives as chiral catalysts. It was found that (2*S*,4*S*)-2-anilinomethyl-1-ethyl-4-hydroxypyrrolidine (**5a**) is a quite efficient catalyst for the asymmetric addition of arenethiols to 2-cyclohexen-1-one and the optical yield as high as 88% was realized under the specified conditions as briefly reported in the previous communication.[5] Herein, we describe the results of the detailed investigation on the effects of the structure of the catalyst, the reaction medium, the temperature, and the concentration on the enantioselectivity.

Results

Chiral Catalysts. Chiral catalysts employed in the present study are derived from natural amino acids, L-hydroxyproline and (*S*)-proline. (2*S*,4*S*)-1-Benzyloxycarbonyl-4-hydroxyproline (Z-allohydroxyproline)[6] was treated with Ac_2O-pyridine to give the acetate **1**, which was condensed with several kinds of amines to afford the corresponding amides **2a**—**e**, respectively. Hydrogenation of **2a**—**e** on 10% Pd-C in MeOH gave the amines **3a**—**e**, which were successively acylated (**4a**—**f**), and reduced ($LiAlH_4$-THF) to give the chiral catalysts **5a**—**f**. The chiral catalysts **5g** and **5h** were also prepared by the similar procedure starting from (2*S*,4*R*)-1-benzyloxycarbonyl-4-hydroxyproline[6] (**1g**) and (*S*)-1-benzyloxycarbonylprolinanilide (**2h**).[4] The catalyst **5i** was prepared by the reduction of the

amine **3a** with $LiAlH_4$ (Fig. 1).

The Structure of the Catalysts. Of the chiral bases **5a**—**i** thus prepared, the suitable structure of the catalyst for the asymmetric Michael addition of benzenethiol to 2-cyclohexen-1-one was pursued. The general reactions were carried out according to the following procedure: In the presence of 0.04 mmol of the catalyst (**5a**—**i**), 2-cyclohexen-1-one (5 mmol) in toluene (5 ml) and benzenethiol (4 mmol) in toluene (5 ml) were admixed and kept standing for 2 d. After the usual work-up (see Experimental section), the optical rotation of the resulting 3-phenylthio-1-cyclohexanone was measured in benzene at 21 °C.

The results are summarized in Table 1. The most noteworthy point is the pivotal role of the hydroxyl group in the enantioselection (entry 1, 7, 8). Obviously, the β-oriented hydroxyl group of the catalyst **5a** directs the stereochemical course of the present reaction, and either the absence or the difference of the orientation of the hydroxyl group of the pyrrolidine ring causes great diminution of the enantioselectivity. While the optical yields were fairly good in cases of the catalysts bearing an aromatic ring (**5a**, **5c**, **5d**), substantial decrease of the e.e. was observed when the catalyst (**5b**) lacked an aromatic ring. When the catalysts **5e**, **5i**, in which both of the amino groups are tertiary and secondary, respectively, were employed, the optical yields were reduced as compared with the case of the catalyst **5a** (entry 1, 5, 9). The poor chemical yield found for the entry 6 is attributable to the decrease of the basicity of the amine **5f** by virtue of the bulky substituent. Thus, it was noted that a slight change in the structure of the catalyst causes a great change in the optical yield in the present reaction and good results are obtained when the catalysts **5a**, **5c**, or **5d** were employed.

3	−5	90	70
4	−20	72	69

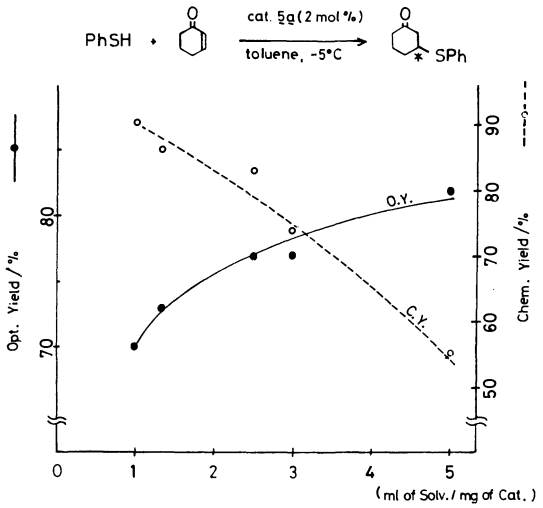

Fig. 2. Effect of the concentration.

Effect of the Reaction Medium. Next, we examined the effect of the reaction medium on the asymmetric induction. The addition of benzenethiol to 2-cyclohexen-1-one was performed in several kinds of solvents using **5a** as the chiral catalyst (Table 2).

It is noted that the optical yields were strongly dependent on the nature of the solvent used. Better results were obtained in nonpolar aromatic solvents (entry 5, 6) or carbon tetrachloride than the solvent like hydrocarbon or dichloromethane. In the case of ethanol, almost no enantioselection was observed.

Effect of the Reaction Temperature. In order to examine the influence of the reaction temperature on the optical yield, the aforementioned reaction was carried out in toluene at various temperatures ranging over −20 °C to 50 °C, and the results are shown in Table 3.

Although a slight decrease of the optical yield at a higher temperature (entry 1) was observed, the effect of the temperature is as a whole not so remarkable in

the present reaction.

Effect of Concentration. As the concentration of the reactants is considered to be a significant reaction parameter, the reaction was carried out at various concentration. With the molar ratio of each substrate held constant, the volume of the solvent employed was gradually increased. Figure 2 shows the chemical and optical yields dependence on the concentration.

An increase in the optical yield was observed under higher dilution condition at the expense of the reaction rate, and the concentration of 2 or 3 (ml toluene/mg catalyst) appears to strike the proper balance, producing the optically active adduct without suffering a significant decrease in the chemical yield.

Reaction with Various Thiols and Enones. Under the optimized conditions, the Michael additions of several other thiols to conjugated cycloalkenones were performed (Table 4).

The additions of aromatic thiols to 2-cyclohexen-1-one gave satisfactory results. Among them, the addition of *p-t*-butylbenzenethiol furnished the adduct in 88% optical purity where the *R* enantiomer was predominantly formed.[3a] On the other hand the alkanethiol (entry 6) gave a poor result, and this may be attributable to the difference of the pK_a values of the thiols. The addition of *p-t*-butylbenzenethiol to the other cycloalkenones gave the adducts in moderate optical yields.

Discussion

From the correlation between the structure of the catalyst and the enantioselectivity described above, we can now elucidate the mechanism of the enantioselection, briefly described in our previous paper.[5] Concerning this point, Wynberg *et al.* proposed a mechanism mainly based on the kinetic measurement and the structures of the substrates in their pioneering work on the cinchona alkaloid catalyzed asymmetric thiol addition.[3a] In our case, various sterically modified analogs of the base catalyst are readily available, and the elucidation of the mechanism depends mainly on the effects of the structure of the catalyst on the optical yields. From the experimental results, three notable points must be taken into consideration, namely, i) the role of the hydroxyl group of the catalyst, ii) the role of the aromatic ring, and iii) the absolute configuration of the predominantly formed enantiomer (*R*). With these in mind, and from the CPK model inspection, we propose the following mechanistic pathway (Fig. 3).

At the first stage of the reaction, the ammonium thiolate complex is formed, where the ammonium counterpart has a 5-5 fused rigid structure[4,5] by virtue of a hydrogen bonding as illustrated in **A**. This rigid structure is supposed to be a crucial factor in the enantioselection, because the enantioselectivity decreased when the substituent of the amine became more bulky, where the above structure is no longer a preferred one. Moreover, in a solvent like toluene, the thiolate anion is stabilized by π-π interaction, and the freedom of its location is further limited by the interaction with the aromatic ring of the catalyst. At the next stage, the approach of the cyclohexenone to the complex **A** takes place with a hydrogen-bond interaction between the carbonyl group and the hydroxyl group of the catalyst. In a protic solvent like ethanol, this interaction must be cancelled to result in no enantioselection. Finally, the attack of the thiolate anion to the enone occurs, where two pathways **B** and **C** are possible. In case of the pathway **C**, the steric congestion of the anilino

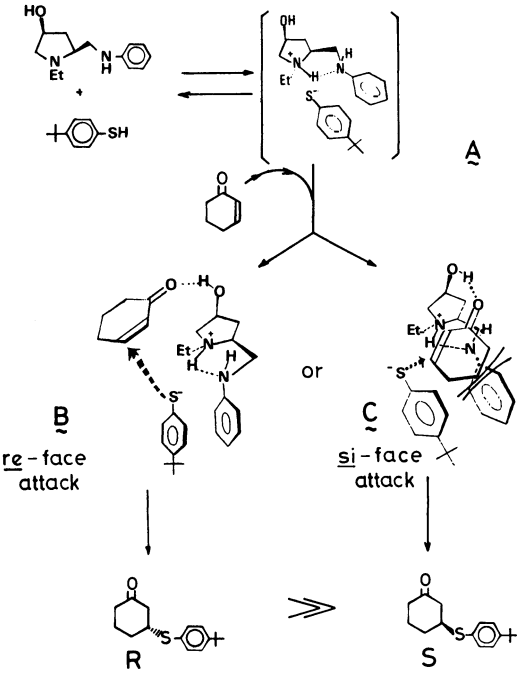

Fig. 3. Mechanism of the enantioselection.

group and the cyclohexenone ring may prevent the complex **A** and the enone from reaching the transition state, thus the preferential attack on the *re*-face of 2-cyclohexen-1-one, through the pathway **B**, takes place resulting in the predominant formation of the *R* enantiomer.

In conclusion, it is noted that the chiral amino alcohol **5a** is a highly efficient catalyst in the asymmetric Michael addition of aromatic thiols to 2-cyclohexen-1-one, and higher optical yields are realized in comparison with the earlier methods.

Experimental

General. Melting and boiling points are uncorrected. ^{1}H NMR spectra were recorded on a Varian EM-390 spectrometer with Me_4Si as an internal standard. IR spectra were taken on a Hitachi 260-30 spectrophotometer. MS data were obtained on a JEOL JMS-D 300 mass spectrometer at 70 eV. Optical rotations were measured on a JASCO DIP-181 polarimeter. All the solvents used were purified according to the standard procedure and stocked over molecular sieves 4A.

Materials. L-Hydroxyproline was kindly supplied from Ajinomoto Co., Inc., and was used without further purification. All the other reagents were commercially obtained and purified by distillation or recrystallization before use.

Preparation of (2S, 4S)-4-acetoxy-1-benzyloxycarbonylproline (1) To a suspension of (2*S*, 4*S*)-1-benzyloxycarbonyl-4-hydroxyproline[6] (10.8 g, 40.8 mmol) in CH_2Cl_2 (50 ml) was added acetic anhydride (6.50 g, 63.7 mmol), pyridine (13 ml) and catalytic amount of DMAP, and the resulting solution was stirred for 6 h at room temperature. The solvent was evaporated *in vacuo*, diluted with AcOEt, and washed with 2 mol dm^{-3} HCl saturated with NaCl. The organic layer was extracted with 4% aqueous $NaHCO_3$ solution, and the alkaline solution was washed with AcOEt, acidified with 6 mol dm^{-3} HCl and back-extracted with AcOEt (×3). The combined organic layer was washed with brine, dried over Na_2SO_4. Concentration under reduced pressure gave **1** as white crystals (9.39 g, 75%): mp 107—108 °C; $[\alpha]_D^{27}$ −58.7° (*c* 1.03, $CHCl_3$); IR (KBr disk) 1740, 1700, 1680, 1580, 1500, 770, and 700 cm^{-1}; NMR ($CDCl_3$) δ=1.9 (2H, s), 2.2—2.5 (2H, m), 3.6—3.7 (2H, m), 4.3—4.7 (1H, m), 5.1 (3H, s), and 10.5 (1H, s). Found: C, 58.76; H, 5.49; N, 4.47%. Calcd for $C_{15}H_{17}NO_6$: C, 58.63; H, 5.57; N, 4.56%.

(2S,4S)-2-Phenylcarbamoyl-1-benzyloxycarbonyl-4-pyrrolidinyl Acetate (2a). To a THF (40 ml) solution of the acetate **1** (9.10 g, 29.6 mmol) and *N*-methylmorpholine (3.00 g, 29.6 mmol) was slowly added a THF (5 ml) solution of pivaloyl chloride (3.31 g, 29.6 mmol) at −45 °C, and the mixture was gradually warmed to −15 °C during 30 min, stirred for further 30 min at the temperature, and cooled to −45 °C again. A THF (5 ml) solution of aniline (2.77 g, 29.7 mmol) was slowly added to this mixture, and the temperature was gradually raised to room temperature and kept for 4 h. Solvent was removed under reduced pressure, and the residue was taken up in AcOEt, washed successively with brine, ice-cold 1 mol dm^{-3} HCl, brine, ice-cold 4% $NaHCO_3$ solution, and dried over Na_2SO_4. After evaporation of the solvent, the residue was purified on a silica-gel column (AcOEt–hexane 3 : 2) to give white crystals in 75% (8.44 g) yield: mp 87—93 °C; $[\alpha]_D^{27}$ −65.4° (*c* 1.01, $CHCl_3$); IR (KBr disk) 3350, 1720, 1680, 1590, 1490, 750, and 690 cm^{-1}; NMR ($CDCl_3$) δ=1.9 (3H, s), 2.0—2.7 (2H, m), 3.4—3.7 (2H, m), 4.3—4.6 (1H, dd, J_1=3 Hz, J_2=9 Hz), 5.1 (3H, s), 6.9—7.5 (5H, m), and 7.2 (5H, m). Found: C, 66.16; H, 5.80; N, 7.30%. Calcd for $C_{21}H_{22}N_2O_5$: C, 65.96; H, 5.80; H, 7.33%.

(2S,4S)-1-Benzyloxycarbonyl-2-cyclohexylcarbamoyl-4-pyrrolidinyl Acetate (2b). A CH_2Cl_2 solution (2 ml) of the acetate **1** (152 mg, 0.50 mmol) was added at 0 °C to a solution of dicyclohexylcarbodiimide (107 mg, 0.52 mmol) in CH_2Cl_2 (1 ml) and the mixture was stirred for 20 min. Then a CH_2Cl_2 (1 ml) solution of cyclohexylamine (54 mg, 0.55 mmol) was added dropwise to the mixture, and the resulting mixture was stirred for 4 h, while gradually warmed up to room temperature, and stirred overnight. The reaction mixture was concentrated and the residue was suspended with AcOEt and filtered off. The filtrate was washed successively with 10% citric acid solution (5 ml×3), brine (5 ml×1), ice-cold 4% $NaHCO_3$ solution (5 ml×3), and brine (5 ml×1), dried over Na_2SO_4 and concentrated to afford crude crystals of the amide **2b** (220 mg), The crystals were further purified with SiO_2 TLC (AcOEt–hexane) to give white crystals in 95% (192 mg) yield. Mp 85—87 °C; $[\alpha]_D^{21}$ −37.6° (*c* 0.95, CH_2Cl_2); IR (KBr disk) 3330, 1740, 1700, 1660, and 730 cm^{-1}; NMR ($CDCl_3$) δ=0.7—2.1 (10H, m), 1.9 (3H, s), 2.1—2.9 (2H, m), 3.2—4.0 (3H, m), 4.4 (1H, dd, J_1=8 Hz, J_2=3 Hz), 5.1 (2H, s), 5.1—5.3 (1H, m), 6.0—6.4 (1H, broad), 7.5 (5H, s). Found: C, 65.19; H, 7.18; N, 7.47%. Calcd for $C_{21}H_{28}N_2O_5$: C, 64.93; H, 7.27; N, 7.21%.

(2S,4S)-1-Benzyloxycarbonyl-2-(2,6-xylylcarbamoyl)-4-pyrrolidinyl Acetate (2c): Yield 76%; mp 123—125 °C; $[\alpha]_D^{24}$ −54.9° (*c* 1.01, CH_2Cl_2); IR (KBr disk) 3260, 1740, 1710, 770, and 700 cm^{-1}; NMR ($CDCl_3$) δ=2.0 (3H, s), 2.2 (6H, s), 2.1—2.9 (2H, m), 3.5—4.1 (2H, m), 4.6 (1H, dd, J_1=9 Hz, J_2=3 Hz), 5.2 (2H, s), 5.1—5.4 (1H, m), 7.0 (3H, s), 7.3 (5H, s), and 7.8—8.3 (1H, broad). Found: C, 67.32; H, 6.52; N, 7.06%. Calcd for $C_{23}H_{26}N_2O_5$: C, 67.30; H, 6.39; N, 6.83%.

(2S,4S)-1-Benzyloxycarbonyl-2-(1-naphthylcarbamoyl)-4-pyrrolidinyl Acetate (2d): Yield 94%; $[\alpha]_D^{21}$ −26.1° (*c* 1.00, CH_2Cl_2); IR (KBr disk) 3300, 1740, 1700, 800, 780 and 700 cm^{-1}; NMR ($CDCl_3$) δ=1.9 (3H, s), 2.1—3.0 (2H, m), 3.8 (2H, d, J=6 Hz), 4.7 (1H, dd, J_1=9 Hz, J_2=2 Hz), 5.3 (2H, s), 5.2—5.4 (1H, m), 7.2—8.0 (12H, m), and 8.8—9.2 (1H, broad); MS, Found: *m/e* 432.1660. Calcd for $C_{25}H_{24}N_2O_5$: M, 432.1683.

(2S,4S)-1-Benzyloxycarbonyl-2-(methylphenylcarbamoyl)-4-pyrrolidinyl Acetate (2e): Yield 58%; $[\alpha]_D^{22}$ +81° (*c* 1.5, CH_2Cl_2); IR (neat) 3300, 1700, 1590, 1495, 770 and 700 cm^{-1}; NMR ($CDCl_3$) δ=2.0 (3H, s), 1.8—2.6 (2H, m), 3.1 (1.5H. s), 3.2 (1.5H, s), 3.4—4.5 (3H, m), 4.6—5.0 (1H, m), 5.0 (2H, s), and 6.9—7.3 (5H, m); MS, Found: *m/e* 396.1690. Calcd for $C_{22}H_{24}N_2O_5$: M, 396.1685.

(2S,4R)-1-Benzyloxycarbonyl-4-hydroxyprolinanilide(2g): Yield 47%; mp 146—147 °C; $[\alpha]_D^{26}$ −50° (*c* 1, MeOH); IR (KBr disk) 1700, 1685 cm^{-1}; NMR ($CDCl_3$–CD_3OD) δ=2.0—2.4 (2H, m), 2.95 (2H, s), 3.6 (2H, d, J=3 Hz), 4.35—4.55 (2H, m), 5.05 (2H, s), and 6.9—7.3 (10H, m). Found: C, 66.86; H, 5.81; N, 8.25%. Calcd for $C_{19}H_{20}N_2O_4$: C, 67.04; H, 5.92; N, 8.23%.

(2S,4S)-2-Phenylcarbamoyl-4-pyrrolidinyl Acetate (3a). The anilide **2a** (8.23 g, 21.7 mmol) and 10% Pd–C (800 mg) were stirred vigorously in MeOH (60 ml) under a H_2 atmosphere overnight. The reaction mixture was filtered through a Celite pad and the filtrate was concentrated to give **3a** in quantitative (5.33 g) yield: mp 64—72 °C; $[\alpha]_D^{22}$ −13.4° (*c* 1.06, EtOH); IR (KBr disk) 3350, 1720, 1660, 750, and 690 cm^{-1}; NMR ($CDCl_3$) δ=1.8 (3H, s), 2.3 (2H, dd, J_1=6 Hz, J_2=3 Hz), 2.6 (1H, broad), 3.0—3.4 (2H, m), 3.9 (1H, t, J=6 Hz), 5.1—5.3 (1H, m), 6.9—7.7 (5H,m), and 9.5—9.8 (1H, broad); Found C, 62.92; H, 6.65; N, 11.19%. Calcd for $C_{13}H_1N_2O_3$: C, 62.89; H, 6.50; N, 11.28%.

Similar treatment of **2b—e**, **2g**, and **2h** to that described

above gave the corresponding amines **3b**—**e**, **3g**, and **3h**, respectively. The yields and physical data are shown below.

(2S,4S)-2-Cyclohexylcarbamoyl-4-pyrrolidinyl Acetate (3b): Yield 100%; mp 122—123 °C (cyclohexane); $[\alpha]_D^{20}$ −11.4° (*c* 1.01, CH_2Cl_2); IR (KBr disk); 3300, 3200, 1730, and 1640 cm^{-1}; NMR ($CDCl_3$) δ=1.0—2.4 (13H, m), 1.95 (3H, s), 2.8—3.9 (4H, m), 5.0—5.3 (1H, m), and 7.2—7.5 (1H, m). Found: C, 61.18; H, 8.72; N, 10.91%. Calcd for $C_{13}H_{22}N_2O_3$: C, 61.39; H, 8.72; N, 11.02%.

(2S,4S)-(2,6-Xylylcarbamoyl)-4-pyrrolidinyl Acetate (3c): Yield 100%; $[\alpha]_D^{23}$ −38.3° (*c* 1.05, CH_2Cl_2); IR (KBr disk) 3330, 3225, 1720, 1640, and 785 cm^{-1}; NMR ($CDCl_3$) δ=2.0 (3H, s), 2.2 (6H, s), 2.3—2.5 (2H, m), 3.0—3.5 (3H, m), 3.8—4.0 (1H, dd, J_1=9 Hz, J_2=6 Hz), 5.1—5.4 (1H, m), 7.1 (3H, s), and 9.0—9.2 (1H, broad); MS, Found: *m/e* 276.1483. Calcd for $C_{15}H_{20}N_2O_3$: M, 276.1473.

(2S,4S)-2-(1-Naphthylcarbamoyl)-4-pyrrolidinyl Acetate (3d): Yield 100%; $[\alpha]_D^{21}$ +87° (*c* 1.0, CH_2Cl_2); IR (CH_2Cl_2) 3300, 1735, 1680, and 800 cm^{-1}; NMR ($CDCl_3$) δ=1.80 (3H, s), 2.1—2.6 (3H, m), 3.1—3.4 (2H, broad), 3.9—4.1 (1H, m), 5.1—5.4 (1H, m), and 7.1—8.3 (7H, m); MS, Found: *m/e* 298.1320. Calcd for $C_{17}H_{18}N_2O_3$: M, 298.1317.

(2S, 4S)-2-(Methylphenylcarbamoyl)-4-pyrrolidinyl Acetate (3e): Yield 95%; $[\alpha]_D^{23}$ −82.5° (*c* 1.0, CH_2Cl_2); IR (KBr disk) 3310, 1730, 1650, 1590, 1490, 780 cm^{-1}; NMR ($CDCl_3$) δ=1.7—2.2 (2H, m), 2.0 (3H, s), 2.5—3.9 (2H, m), 3.2 (3H, s), 4.3—4.6 (1H, broad), 4.8—5.1 (1H, m), and 7.0—7.5 (5H, m). Found: C, 63.69; H, 7.10; N, 10.29%. Calcd for $C_{14}H_{18}N_2O_3$: C, 64.10; H, 6.92; N, 10.68%.

(2S,4R)-4-Hydroxyprolinanilide (3g): Yield 100%; mp 149—150 °C (H_2O); $[\alpha]_D^{24}$ −38.5° (*c* 1, MeOH); IR (KBr disk) 3270, 1650, 1600, and 1500 cm^{-1}; NMR (CD_3OD) δ=1.7—2.2 (2H, m), 2.95 (2H, d, J=3 Hz), 3.95 (1H, t, J=8 Hz), 4.30 (1H, m), 4.65 (2H, s), and 6.8—7.5 (5H, m). Found: C, 63.32; H, 6.99; N, 13.28%. Calcd for $C_{11}H_{14}N_2O_2$: C, 64.06; H, 6.84; N, 13.58%.

(S)-Prolinanilide (3h): Yield 100%; mp 76—77 °C; $[\alpha]_D^{27}$ −71.0° (*c* 1.03, EtOH); IR (KBr disk) 3360, 3225, 1665, and 1600 cm^{-1}; NMR ($CDCl_3$) δ=1.1—2.2 (4H, m), 2.3—3.2 (3H, m), 3.5—3.9 (1H, m), 6.7—7.6 (5H, m); Found: C, 69.53; H, 7.58; N, 14.84%. Calcd for $C_{11}H_{14}N_2O$: C, 69.44; H, 7.42; N, 14.73%.

(2S,4S)-1-Acetyl-2-phenylcarbamoyl-4-pyrrolidinyl Acetate (4a). To a CH_2Cl_2 (5 ml) solution of **3a** was added a pyridine (9 ml) solution of acetic anhydride (1.12 g, 11.0 mmol) and a catalytic amount of 4-(dimethylamino)pyridine, and the solution was kept standing overnight at room temperature. The reaction mixture was diluted CH_2Cl_2, washed successively with 1 mol dm^{-3} HCl, brine, 4% aqueous $NaHCO_3$ solution and brine, and dried over Na_2SO_4. The solvent was removed under reduced pressure, and the purification of the residue with basic alumina thin layer chromatography (benzene–MeOH) gave **4a** as white crystals in 90% (2.55 g) yield. Mp 112—113.5 °C; $[\alpha]_D^{25}$ −115° (*c* 1.01, CH_2Cl_2); IR (CH_2Cl_2) 1730, 1680, 1590, 1490, 1220, and 1180 cm^{-1}; NMR ($CDCl_3$) δ=1.8—3.0 (2H, m), 1.8 (0.6H, s), 2.0 (2.4H, s), 2.1 (0.6H, s), 2.2 (2.4H, s), 3.5—3.9 (2H, m), 4.4—4.6 (0.2H, dd, J_1=9 Hz, J_2=3 Hz), 4.7—4.9 (0.8H, dd, J_1=9 Hz, J_2=3 Hz), 5.1—5.4 (1H, m), 6.9—7.7 (5H, m), 8.6—8.8 (0.2H, broad), and 9.3—9.6 (0.8H, broad); Found: C, 61.95; 6.41; N, 9.45%. Calcd for $C_{15}H_{18}N_2O_4$: C, 62.05; H, 6.25; N, 9.65%. The amides **4b**—**e**, **4g**, and **4h** were obtained according to essentially the same procedures as described above. The amide **4f** was obtained from **3a** by a similar procedure using pivaloyl chloride in place of acetic anhydride.

(2S,4S)-1-Acetyl-2-cyclohexylcarbamoyl-4-pyrrolidinyl Acetate (4b): Yield 79%; mp 107—109 °C (acetone–P.E.); IR (neat) 3300, 1740, 1660, and 1640 cm^{-1}; NMR ($CDCl_3$) δ=1.0—2.0 (10H, m), 2.0 (3H, s), 2.1 (3H, s), 2.1—2.9 (2H, m), 3.3—3.9 (4H, m), 4.1—4.6 (1H, m), 5.0—5.3 (1H, m), 6.5—6.8 (1H, broad); Found: C, 60.95; H, 8.10; N, 9.51%. Calcd for $C_{15}H_{24}N_2O_4$: C, 60.79; H, 8.16; N, 9.45%.

(2S,4S)-1-Acetyl-2-(2,6-xylylcarbamoyl)-4-pyrrolidinyl Acetate (4c): Yield 75%; mp 169—172 °C (THF-pentane); $[\alpha]_D^{21}$ −85° (*c* 1.1, CH_2Cl_2); IR (KBr disk) 3300, 1730, 1675, 1630, and 780 cm^{-1}; NMR ($CDCl_3$) δ=2.0 (3H, s), 2.1 (3H, s), 2.2 (6H, s), 2.0—3.0 (2H, m), 3.4—4.0 (2H, m), 4.8 (1H, dd, J_1=9 Hz, J_2=3 Hz), 5.1—5.4 (1H, m), 7.0 (3H, s), and 8.5—8.6 (1H, broad); Found: C, 64.16; H, 7.27; N, 8.72%. Calcd for $C_{17}H_{22}N_2O_4$: C, 64.13; H, 6.97; N, 8.80%.

(2S,4S)-1-Acetyl-2-(1-naphthylcarbamoyl)-4-pyrrolidinyl Acetate (4d): Yield 66%; mp 237—241 °C (EtOH); IR (KBr disk) 3320, 1730, 1670, 1630, and 800 cm^{-1}; NMR ($CDCl_3$) δ=1.6 (1.2H, s), 2.1 (2.8H, s), 2.2 (3H, s), 3.1—3.3 (1H, m), 3.6—4.0 (3H, m), 4.9—5.1 (1H, m), 5.3—5.5 (1H, m), 7.4—8.2 (7H, m), and 9.8—10.0 (1H, broad); Found: C, 66.87; H, 5.80; N, 8.05%. Calcd for $C_{19}H_{20}N_2O_4$: C, 67.04; H, 5.92; N, 8.23%.

(2S,4S)-1-Acetyl-2-methylphenylcarbamoyl-4-pyrrolidinyl Acetate (4e): Yield 91%; $[\alpha]_D^{23}$ +56° (*c* 0.51, EtOH); IR (neat) 1740, 1660, 1640, 780. and 700 cm^{-1}; NMR ($CDCl_3$) δ=1.9—2.5 (2H, m), 2.0 (6H, s), 3.2 (3H, s), 3.6 (1H, dd, J_1=12 Hz, J_2=4 Hz), 3.9 (1H, dd, J_1=12 Hz, J_2=2 Hz), 4.3 (1H, t, J=8 Hz), 4.9 (1H, m), 7.3 (5H, s); MS, Found: *m/e* 304.1422. Calcd for $C_{16}H_{20}N_2O_4$: M, 304.1422.

(2S, 4S)-2-Phenylcarbamoyl-1-pivaloyl-4-pyrrolidinyl Acetate(4f): Yield 72%; mp 134—135 °C; $[\alpha]_D^{24}$ −64.3° (*c* 1.02, CH_2Cl_2); IR (KBr disk) 3300,1740, 1700, 1600, 1500, 760, and 700, cm^{-1}; NMR ($CDCl_3$) δ=1.3 (9H, s), 2.0 (3H, s), 2.2—2.7 (2H, m), 3.7 (1H, dd, J_1=12 Hz, J_2=5 Hz), 4.2 (1H, dd, J_1=12 Hz, J_2=6 Hz), 4.8 (1H, dd, J_1=6 Hz, J_2=2 Hz), 5.1—5.3 (1H, m), 6.8—7.5 (5H, m), and 9.1—9.2 (1H, broad); Found: C, 64.89; H, 7.55; N, 8.28%. Calcd for $C_{18}H_{24}N_2O_4$: C, 65.04; H, 7.28; N, 8.43%.

(2S, 4R)-1-Acetyl-2-phenylcarbamoyl-4-pyrrolidinyl Acetate (4g): Yield 84%; $[\alpha]_D^{25}$ −43° (*c* 1.0, CH_2Cl_2); IR (neat) 3300, 1740, 1630, 1600, 1500, and 740 cm^{-1}; NMR ($CDCl_3$) δ=1.95 (3H, s), 2.00 (3H, s), 2.0—2.8 (2H, m), 3.4 (1H, dd, J_1=12 Hz, J_2=2 Hz), 3.9 (1H, dd, J_1=12 Hz, J_2=5 Hz), 4.7 (1H, t, J=7 Hz), 5.1—5.4 (1H, m), 6.8—7.6 (5H, m), and 9.5 (1H, broad); MS, Found; *m/e* 290.1236. Calcd for $C_{15}H_{18}N_2O_4$: M, 290.1266.

(S)-1-Acetylprolinanilide (4h): Yield 74%; $[\alpha]_D^{26}$−176° (*c* 1.1, CH_2Cl_2); IR (KBr disk) 3280, 1700, 1630, 1600, 1500, 760, and 700 cm^{-1}; NMR ($CDCl_3$) δ=1.6—2.7 (4H, m), 2.1 (3H, s), 3.3—3.6 (2H, m), 4.7 (1H, dd, J_1=8 Hz, J_2=2 Hz), 6.9—7.6 (5H, m), and 9.5—9.7 (1H, broad); MS, Found: *m/e* 232.1208. Calcd for $C_{13}H_{16}N_2O_2$: M, 232.1210.

(2S, 4S)-2-Anilinomethyl-1-ethyl-4-hydroxypyrrolidine (5a). Under an argon atmosphere, the acetate **4a** (500 mg, 1.73 mmol) in THF (30 ml) was added to a suspension of $LiAlH_4$ (520 mg, 13.7 mmol) in THF (5 ml) at 0 °C, and the mixture was refluxed for 18 h, and then quenched by the dropwise addition of saturated Na_2SO_4 solution at 0 °C. After removal of the inorganic material and concentration of the organic layer afforded an oil, which was further purified by basic alumina TLC (benzene–MeOH) and bulb-to-bulb distillation to give a colorless oil in 89% (338 mg) yield. Bp 150—170 °C/2 mmHg† (bath temp); $[\alpha]_D^{23}$ −58.1° (*c* 1.03, EtOH); IR (neat) 3375. 1600, 1500, 750, and 695 cm^{-1}; NMR ($CDCl_3$) δ=1.1 (3H, t, J=8 Hz), 1.5—1.9 (1H, m), 2.1—2.5 (3H, m), 2.5—3.0 (2H, m), 3.0—3.3 (4H, m), 4.1—4.5 (2H, m), and 6.5—7.3 (5H, m); Found: C, 70.90; H, 9.37; N, 12.54%.

† 1 mmHg ≈ 133.322 Pa.

Calcd for $C_{13}H_{20}N_2O$: C, 70.87; H, 9.15; N, 12.72%. Catalysts **5b**—**i** were also obtained by similar $LiAlH_4$ reductions.

(2S,4S)-2-(Cyclohexylaminomethyl)-1-ethyl-4-hydroxypyrrolidine (5b): Yield 81%; bp 140—155 °C/2 mmHg (bath temp); $[\alpha]_D^{21}$ −21° (*c* 1.7, MeOH); IR (neat) 3300 cm^{-1}; NMR ($CDCl_3$) δ=1.0 (3H, t, 6 Hz), 0.9—3.1 (21H, m), 3.3—4.4 (5H, m); MS, Found: *m/e* 227.2111 (M^++1). Calcd for $C_{13}H_{26}N_2O$: (M^+ +1), 227.2122.

(2S,4S)-1-Ethyl-4-hydroxy-2-(2,6-xylidinomethyl)pyrrolidine(5c): Yield 30%; bp 150—170 °C/0.2 mmHg (bath temp.); $[\alpha]_D^{21}$ −138° (*c* 0.9, CH_2Cl_2); IR (neat) 3350, 1470, and 765 cm^{-1}; NMR ($CDCl_3$) δ=1.2 (3H, t, J=8 Hz), 1.6—3.3 (9H, m), 4.0—4.3 (3H, m), and 6.8—7.0 (3H, m); MS, Found: *m/e* 248.1880. Calcd for $C_{15}H_{24}N_2O$: M, 248.1887.

(2S,4S)-1-Ethyl-4-hydroxy-2-(1-naphthylaminomethyl)pyrrolidine (5d): Yield 53%; $[\alpha]_D^{23}$ +1° (*c* 0.2, CH_2Cl_2); IR (neat) 3370, 1580, and 770 cm^{-1}; NMR ($CDCl_3$) δ=1.0 (3H, t, J=7 Hz), 1.5—3.8 (10H, m), 4.0—4.3 (1H, m), 5.0—5.6 (1H, broad), 6.4 (1H, dd, J_1=6 Hz, J_2=2 Hz), and 7.0—7.9 (6H, m); MS, Found: *m/e* 271.1747 (M^+ +1). Calcd for $C_{17}H_{23}N_2O$: (M^+ +1), 271.1809.

(2S,4S)-1-Ethyl-2-(N-methylanilinomethyl)-4-hydroxypyrrolidine (5e): Yield 82%; bp 150—160 °C/1 mmHg (bath temp); $[\alpha]_D^{23}$ −96° (*c* 0.94, EtOH); IR (neat) 3360, 1600, 1500, 750, and 695 cm^{-1}; NMR ($CDCl_3$) δ=1.1 (3H, t, J=6 Hz), 1.4—3.8 (10H, m), 2.9 (3H, s), 4.0—4.2 (1H, m), and 6.3—7.2 (5H, m); Found: C, 71.07; H, 9.76; N, 11.95%. Calcd for $C_{14}H_{22}N_2O$: C, 71.76; H, 9.46; N, 11.95%.

(2S,4S)-2-Anilinomethyl-4-hydroxy-1-(2,2-dimethylpropyl)pyrrolidine (5f): Yield 87%; bp 150—160 °C/0.4 mmHg (bath temp); $[\alpha]_D^{22}$ −56° (*c* 1.1, CH_2Cl_2); IR (neat) 3370, 1600, 1500, 750 and 690 cm^{-1}; NMR ($CDCl_3$) δ=0.8 (9H, s), 1.6—3.9 (10H, m), 4.0—4.3 (1H, m), and 6.3—7.1 (5H, m); Found: C, 73.42; H, 10.19; N, 10.90%. Calcd for $C_{16}H_{26}N_2O$: C, 73.24; H, 9.99; N, 10.68%.

(2S,4R)-2-Anilinomethyl-1-ethyl-4-hydroxypyrrolidine (5g): Yield 81%; bp 170—180 °C/5 mmHg (bath temp); $[\alpha]_D^{25}$ −39° (*c* 1.0, CH_2Cl_2); IR (KBr disk) 3380, 1600, 1520, 760, and 700 cm^{-1}; NMR ($CDCl_3$) δ=1.0 (3H, t, J=7 Hz), 1.4—4.4 (12H, m), and 6.3—7.3 (5H, m); MS, Found: *m/e* 220.1569. Calcd for $C_{13}H_{20}N_2O$: M, 220.1564.

(S)-2-Anilinomethyl-1-ethylpyrrolidine (5h): Yield 95%; bp 140—150 °C/3 mmHg (bath temp); $[\alpha]_D^{25}$ −53° (*c* 1.0, CH_2Cl_2); IR (neat) 3375, 1610, 1510, 755, and 700 cm^{-1}; NMR ($CDCl_3$) δ=1.1 (3H, t, J=8 Hz), 1.6—3.4 (11H, m), 3.9—4.4 (1H, broad), and 6.5—7.3 (5H, m); Found: C, 76.63; H, 9.91; N, 13.56%. Calcd for $C_{13}H_{20}N_2$: C, 76.42; H, 9.87; N, 13.71%.

(2S,4S)-2-Anilinomethyl-4-hydroxypyrrolidine (5i): Yield 93%; bp 170—180 °C/0.8 mmHg (bath temp); $[\alpha]_D^{25}$ +23.4° (*c* 1.02, $CHCl_3$); NMR ($CDCl_3$) δ=1.2—1.7 (1H, m), 1.9—2.5 (1H, m), 2.6—3.2 (8H, m), 4.1—4.4 (1H, m), and 6.4—7.2 (5H, m); Found: C, 67.86; H, 8.82; N, 14.10%. Calcd for $C_{11}H_{16}N_2O$: C, 68.72; H, 8.39; N, 14.57%.

General Procedure for the Michael Addition. Under an argon atmoshpere, a solution of the thiol (4 mmol) in the solvent (25 ml) and the cycloalkenone (5 mmol) containing the freshly distilled catalyst (0.08 mmol) in the solvent (25 ml) were mixed at the specified temperature and kept standing for two days at the temperature. The reaction mixture was washed successively with 1 mol dm^{-3} HCl (5 ml×3), brine (5 ml×1), 1 mol dm^{-3} NaOH (5 ml×3), brine (5 ml×1) and dried over anhydrous sodium sulfate. The solvent was evaporated under reduced pressure and the residue was chromatographed on silica-gel TLC (hexane–AcOEt). The adduct thus obtained was further purified by short path distillation using Kugelrohr apparatus.

The authors wish to thank Professor Hans Wynberg, the University of Groningen, for providing us valuable informations. Thanks are due to Mr. Masami Ishibashi for mass spectral measurements. Thanks are also due to the Ajinomoto Co., Inc. for the gift of L-hydroxyproline. The present work was supported by a Grant-in-Aid for Scientific Research No. 443006 from the Ministry of Education, Science and Culture.

Synthetic Studies of Rifamycins. V.[1] A Chiral Synthesis of an Ansa-chain Compound for the C-17—C-29 Portion of Rifamycin W†

Masaya NAKATA, Hiroyuki ENARI, and Mitsuhiro KINOSHITA*

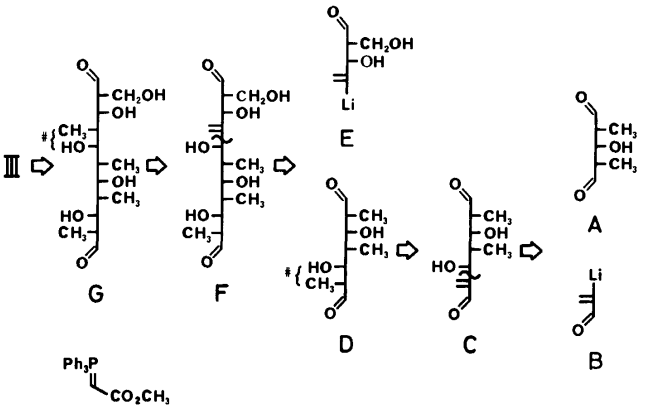
Department of Applied Chemistry, Faculty of Science and Technology, Keio University, Hiyoshi, Kohoku-ku, Yokohama 223

(Received May 24, 1982)

The chiral synthesis of methyl 5,7,9-tri-*O*-acetyl-2-*C*-(acetoxymethyl)-2,4,6,8,10,11,12-heptadeoxy-4,6,8,10-tetra-*C*-methyl-*aldehydo*-L-*glycero*-L-*talo*-L-*manno*-(*E*)-11-tridecenuronate 1-(dimethyl acetal) (III), a useful synthetic segment for the C-17-C-29 portion of rifamycin W, is described. The key intermediate, 3-*O*-(*t*-butyldimethylsilyl)-2,4,7-trideoxy-5,6-*O*-isopropylidene-2,4-di-*C*-methyl-*aldehydo*-D-*glycero*-D-*talo*-heptose (**28**) was synthesized in 30% yield from methyl 4,6-*O*-benzylidene-3-deoxy-3-*C*-methyl-α-D-glucopyranoside in 15 steps. The synthesis involves key steps of highly stereoselective Grignard reaction and regiospecific *cis*-epoxide ring-opening reaction. The condensation of **28** with 3,3-diethoxy-2-lithio-1-propene afforded about 1.6: 1 excess of the "Cram" product (**30**, 56% yield). The desilylation of **30** followed by homogeneous hydrogenation with $(Ph_3P)_3RhCl$ gave only the *erythro* product **34**. 3,5-Di-*O*-benzyl-2,4,6-trideoxy-2,4,6-tri-*C*-methyl-L-*glycero*-L-*manno*-heptodialdose 1-(diethyl acetal) derived from **34**, condensed with the lithium reagent prepared (in ether at −95——90 °C) from butyllithium and 3-*C*-(benzyloxymethyl)-3,5,6-trideoxy-5-iodo-1,2-*O*-isopropylidene-α-D-hexenofuranose, derived from 3-deoxy-3-*C*-hydroxymethyl-1,2 : 5,6-di-*O*-isopropylidene-α-D-allofuranose, to afford a 4 : 1 mixture of the "Cram" product and its epimer in 80% yield. The homogeneous hydrogenation of the mixture followed by the debenzylation gave the diastereomerically pure major product, which could be transformed into III in 6 steps.

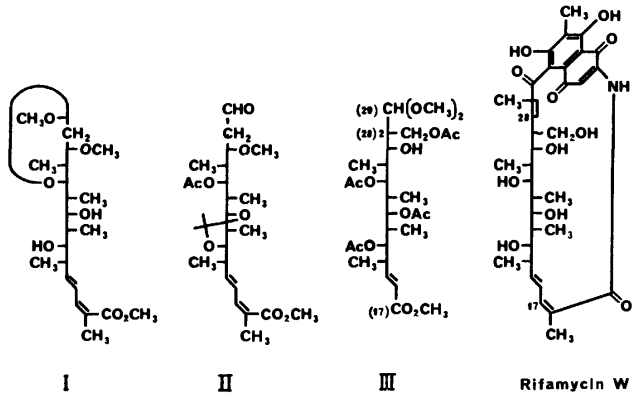
The first chiral synthesis of the ansa-chain portion of rifamycin S in the form of I was described in the preceding papers[1,2] from this laboratory. Recently, Nagaoka and Kishi[3] reported the highly stereocontroled synthesis of the optically active form of the ansa-chain compound II from (*S*)-(−)-3-*t*-butoxy-2-methyl-1-propanol. In this paper, we wish to report an improved convergent route for the chiral synthesis of the ansa-chain compound III, a useful synthetic segment for the C-17-C-29 portion of rifamycin W,[4] the biosynthetic progenitor of all the rifamycins.[5] Since the stereochemistry at C-28 of rifamycin W was unknown,[6] we assumed the configuration of the corresponding C-2 chiral center in III to be (*R*) by considering the facility of the synthesis. Naturally, when the opposite stereochemistry at C-2 of III was required, the chemical interchange of the acetoxymethyl and dimethoxymethyl groups at C-2 was considered feasible.

In keeping with the experimental results obtained in the synthesis of I,[1] our synthetic plan was made using the retrosynthetic analysis shown in Scheme 1. In the plan, it was expected that the starting symmetric dialdehyde **A** (a synthetic equivalent) is allowed to react successively with the lithium reagents, **B** and **E**, to afford predominantly the "Cram"[7] product **F** *via* the "Cram" product **C**, and the exo-methylene intermediates, **C** and **F**, are hydrogenated, under similar stereochemical control, to provide exclusively the *erythro*†† isomers, **D** and **G**, respectively. As the key intermediates corresponding to the synthetic equivalents, **A**, **B**, and **E**, in the planned convergence scheme, we chose the compounds, **28**, **29**, and **58**, respectively. The intermediates, **28** and **58** were obtainable by the chiral synthesis using appropriate sugar derivatives.



Scheme 1.

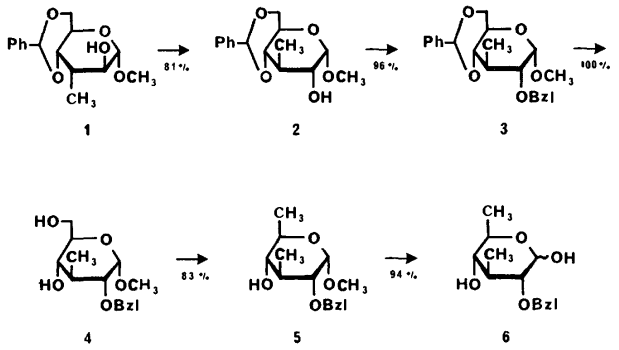
The key intermediate **28** was synthesized from 2-*O*-benzyl-3,6-dideoxy-3-*C*-methyl-D-glucopyranose (**6**) through the stereo- and regio-selective route. The compound **6** was prepared, through the route shown in Scheme 2, from methyl 4,6-*O*-benzylidene-3-deoxy-3-*C*-methyl-α-D-glucopyranoside (**2**),[8] which could be obtained on a large scale from methyl 4,6-*O*-benzylidene-3-deoxy-3-*C*-methyl-α-D-altropyranoside (**1**).[8,9]



† Presented at the 45th National Meeting of Chemical Society of Japan, Tokyo, April 4, 1982.

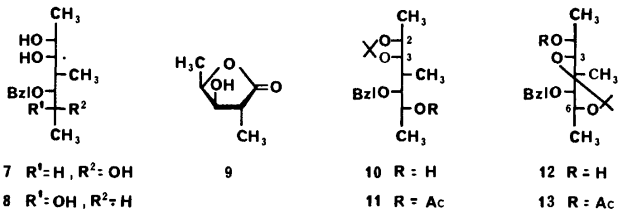
†† In this article, the substituents on the same side of the chain in a Fischer projection of acyclic molecule are prefixed as *erythro*, while those on opposite sides are prefixed as *threo*.

The *O*-benzylation of **2** followed by the debenzylidenation of the resulting **3** with methanolic hydrogen chloride afforded crystalline **4**, which was selectively 6-*O*-mesylated with 1.14 equiv. of mesyl chloride in pyridine and subsequently reduced with lithium aluminium hydride to give **5**. The acetolysis of **5** with acetic anhydride containing 0.15 equimolar amounts of sulfuric acid, followed by the hydrolysis with sodium hydroxide yielded **6** in 75% overall yield based on **2**.



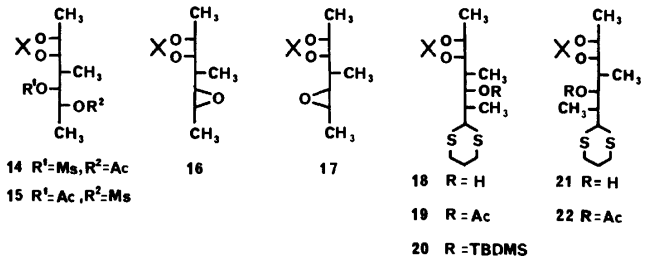
Scheme 2.

The Grignard reaction of **6** with 10 equimolar amounts of methylmagnesium iodide in ether afforded the product **7** (78%), its epimer **8** (1.5%), and the unchanged **6** (16%). The (6*R*)-configuration of the major product **7** was confirmed by the fact that **7** was transformed, through a sequence of reactions involving periodate-oxidation followed by successive debenzylation, acid hydrolysis, and bromine-oxidation, into the 1,4-lactone **9**, whose relative configuration was proved by ^{1}H-NMR analysis to be identical with that of (2*S*,3*S*,4*S*)-3-hydroxy-2-methyl-4-pentanolide[1] or its enantiomer.[10] The 2,3-acetonation of **7** with 1.5



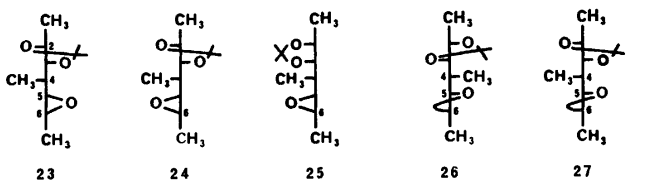
equimolar amounts of 2,2-dimethoxypropane (DMP) and 0.1 equimolar amounts of *p*-toluenesulfonic acid in DMF afforded, contrary to our expectation,[1] the mixture from which the two kinds of isomeric acetonides, **10** and **12** were isolated by column chromatography in 55% and 44% yields respectively. The structures of **10** (2,3-acetonide) and **12** (3,6-acetonide) were determined by the following facts: (i) **10** could be converted into the epoxide **16** through the sequence of reactions described later on, while **12** gave no epoxide in the same procedure as in the case of **10** and (ii) the debenzylated product obtained from **10** was cleaved with periodate reagent, while that from **12** was not affected by the same reagent. The ^{1}H-NMR spectra (250 MHz) of **10** and **12**, and of their acetates, **11** and **13**, showed signals in line with the structures as depicted. After many unsuccessful attempts, a 4.7 : 1 predominance of **10** was attained by the treatment of **7** with 2 equimolar amounts of DMP in acetone containing a catalytic amounts of concd sulfuric acid. Furthermore, **12** separated from **10** was treated with an equimolar amounts of zinc bromide in dichloromethane to give **10** in 94% isolated yield. The total yield of **10** thus amounted to 93%.

The acetylation of **10** with acetic anhydride and 4-(dimethylamino)pyridine (DMAP) in ethyl acetate afforded the 6-acetate **11** in 95% yield. The hydrogenolysis of **11** with hydrogen (palladium black) in ethanol followed by the immediate mesylation gave the 5-mesylate **14** in 92% yield after the chromatographic

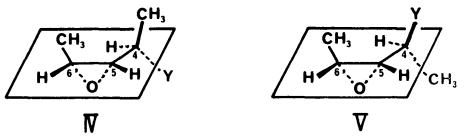


separation from the isomeric 6-mesylate **15** (5%), presumably resulted from the isomeric 5-acetate formed by the 6→5 *O*-acyl migration during the hydrogenolysis of **11**. The 5-mesylate **14** was then treated with sodium methoxide in chloroform to afford the *cis*-epoxide **16** in 81% yield after distillation. The 6-mesylate **15** also gave the diastereomeric *cis*-epoxide **17**. The reaction of **16** or **17** with 5 equiv. of 2-lithio-1,3-dithiane in THF at 5 °C afforded regiospecifically only the C-6-adduct **18** or **21** in 91% or 94% yield respectively. Since ring-opening of epoxides with nucleophiles is known to proceed with inversion at the center of addition,[11] the structures of **18** and **21** could be determined by the coupling features (double doublets) of the acetoxymethine protons in the ^{1}H-NMR spectra of their acetates, **19** and **22**.

The stereochemical control in this ring-opening process of *cis*-epoxide was truly remarkable. The analogous *cis*-epoxides, **23**,[12] **24**,[12] and **25**[13] also reacted with 2-lithio-1,3-dithiane to give only the corresponding



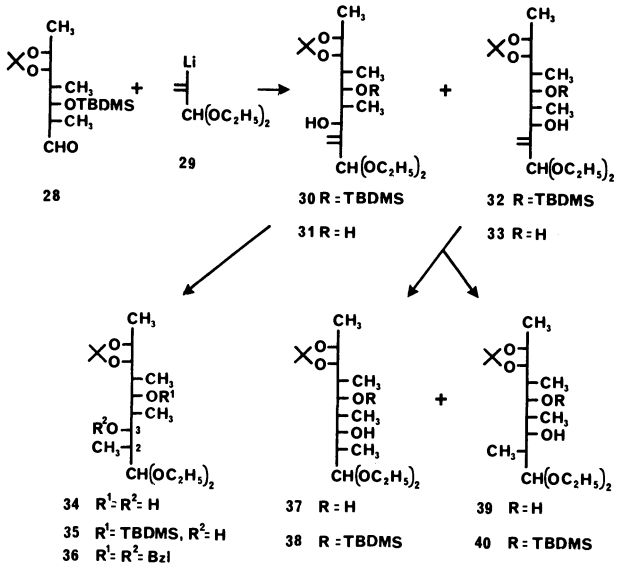
C-6-adducts in good yields. The high regioselectivity in ring-opening of these *cis*-epoxides was independent of the relative configurations at C-4 and C-5 and of the configurations of other chiral centers (C-2 and C-3). This result differed from the reported regioselectivities in the reactions of the *trans*-epoxides, **26** and **27**, with 2-lithio-1,3-dithiane. The epoxide **26** with *erythro*-configuration at C-4 and C-5 afforded a 3.1 : 1 mixture of C-6- and C-5-adducts,[1] while **27** with *threo*-configuration at C-4 and C-5 gave a 2.8 : 1 mixture of C-5- and



Scheme 3.

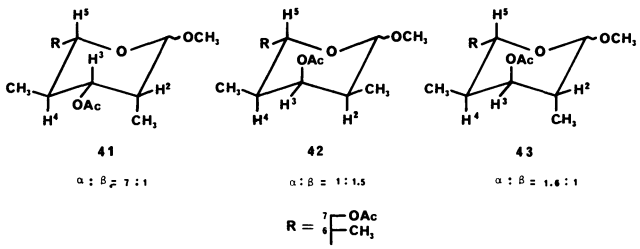
C-6-adducts.[10] Therefore, the regioselectivity of ring-opening in the *trans*-epoxides seemed to be affected by their C-4 configurations. The remarkable regioselectivity observed in the reactions of the *cis*-epoxides may be explained as follows. In the *cis* series, the free rotation of the ring-C-5-substituent ($CH(CH_3)Y$) about the C-4–C-5 bond axis should be restricted within narrow limits owing to larger nonbonding interaction of this group with the ring-methyl at C-6 than in the *trans* series. Therefore, each molecule of the *cis*-epoxides should have in the ground state a preferred conformation[14] which is rigidly held and resembles IV or V as depicted in Scheme 3. In this conformation, axial (β) attack at the C-5 position would involve the attacking group in an eclipsing interaction with the vicinal quasi axial 4-methyl group[15] or the 4-substituted Y, and addition will exclusively occur at the C-6-position, if the above-mentioned preferred reactant conformation is also favorable in the transition state of the reaction.

The *t*-butyldimethylsilylation of **18** provided, in 97% yield, the silyl ether **20**, whose dithioacetal group was cleaved with an 1 : 1 mixture of mercury(II)- and red mercury(II) oxide to generate the aldehyde **28** in 94% yield (or in 39.5% overall yield from **6**). The condensation of **28** with the lithium reagent **29** prepared from 3 equiv. of 2-bromo-3,3-diethoxy-1-propene[16] and 2.5 equiv. of butyllithium in THF at −110 °C was performed in THF at −110 °C to afford, after column chromatographic separation, **30** and **32** in 56 and 36% yields respectively based on **28**. The



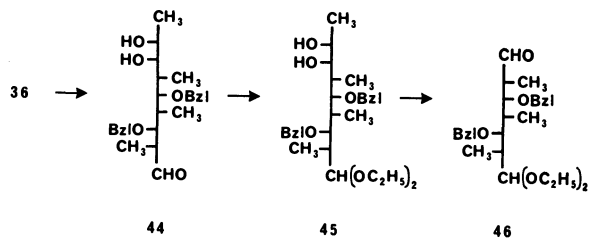
Scheme 4.

desilylation of **30** with tetrabutylammonium fluoride gave **31** in 98% yield. The homogeneous hydrogenation[1] of **31** with about 0.24 equimolar amounts of tris-(triphenylphosphine)chlororhodium (I)[17] in benzene under an atmospheric pressure of hydrogen yielded, in 93% yield, **34** as a sole hydrogenation product, whose diastereomeric homogeneity was confirmed by the TLC and 250 MHz ^{1}H-NMR analyses. The homogeneous hydrogenation of the silyl ether **30** proceeded more slowly and the reaction needed at least 1.5 equimolar amounts of the rhodium catalyst for its completion. The crude product **35** resulted in 79% yield was desilylated to afford the diastereomerically homogeneous **34**. In order to determine the configurations at C-2 and C-3 in **34**, **34** was transformed into the methyl L-heptopyranoside derivative **41** through the sequence of reactions involving deacetonation with pyridinium *p*-toluenesulfonate[18] (PPTS) in ethanol, followed by successive periodate-oxidation, sodium borohydride reduction, methanolysis with 0.5% methanolic hydrogen chloride, and acetylation. The structure shown for **41** was confirmed by the 250 MHz ^{1}H-NMR analysis

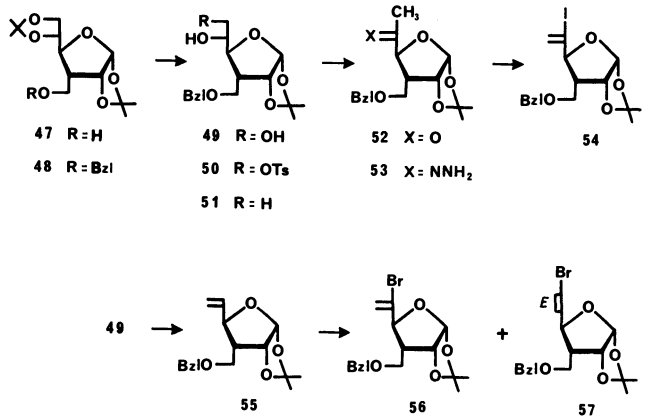


(using decoupling technique), indicating that the condensation of **28** with **29** yielded predominantly the "Cram" product **30**, which and whose desilylation product **31** were stereospecifically hydrogenated to afford the 2,3-*erythro* isomers, **35** and **34**, respectively. The minor methylene product **32** was shown to be the anti-"Cram" condensation product as follows. Unlike **31**, the desilylation product **33** from **32** afforded, on homogeneous hydrogenation, about 1 : 1 epimeric mixture of **37** and **39**, while the direct hydrogenation of **32** gave about 1 : 8 mixture of **37** and **39** *via* the corresponding mixture of **38** and **40**. The isolated **37** and **39** were transformed into the corresponding methyl L-heptopyranoside derivatives, **42** and **43**, by the procedure described in the transformation of **34** into **41**. The structures of **42** and **43** could also be well determined as depicted by the 250 MHz ^{1}H-NMR analyses.

The benzylation of **34** afforded **36** in 88% yield. The one stage deacetonation of **36** by the ethanolysis with ethanol (PPTS) or with ethanolic hydrogen chloride resulted in the low yield (≈55%) of **45**. Thus **36** was at first hydrolyzed with 75% dichloroacetic acid (DCA) and then the resulting aldehyde **44** was



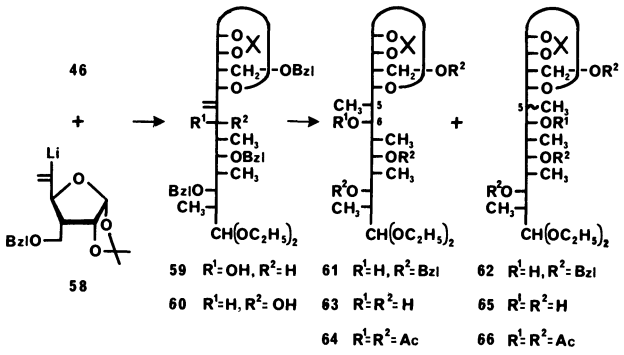
treated with ethanol in the presence of a catalytic amounts of *p*-toluenesulfonic acid to give **45** in 86% yield. The periodate-oxidation of **45** afforded the synthetic intermediate **46** in 81% yield. The lithium reagent **58** was prepared by the lithiation of the alkenyl halides, **54** and **56**, which were synthesized starting from 3-deoxy-3-*C*-hydroxymethyl-1,2:5,6-di-*O*-isopropylidene-α-D-allofuranose[19] (**47**) through the route shown in Scheme 5.



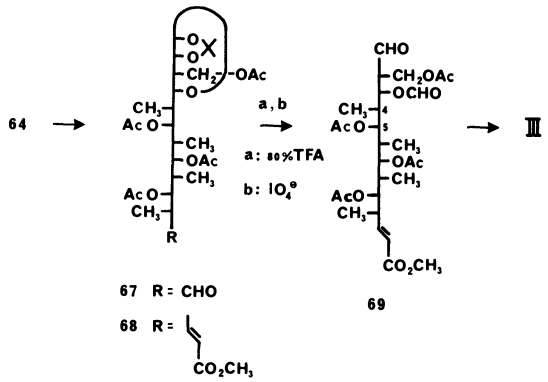
Scheme 5.

The benzylation of **47** followed by the selective hydrolysis of the resulting benzyl ether **48** with 75% acetic acid afforded the glycol **49** in 91% yield. The selective 6-*O*-tosylation of **49** followed by lithium aluminium hydride reduction gave **51** in 74% yield. The oxidation of **51** proceeded effectively with pyridinium chlorochromate (PCC) and molecular sieve 3A powder,[20] affording **52** in 92% yield. The methyl ketone **52** was converted into the alkenyl iodide **54** in 30% yield *via* the hydrazone **53**, according to the procedure of Barton *et al.*[21,8] The alkenyl bromide **56** was prepared from the 1,2-glycol **49**. The periodate-oxidation of **49** followed by the Wittig condensation with methylenetriphenylphosphorane in DMSO afforded **55** in 87% yield. The bromination of **55** with bromine in carbon tetrachloride followed by the elimination of hydrogen bromide with DBU in DMSO gave the isomeric alkenyl bromides, **56** and **57**, in 72 and 14% yields respectively after chromatographic separation.

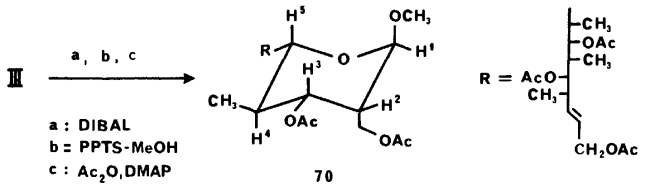
The condensation of **46** with the lithium reagent **58**, prepared from 3.1 equiv. of alkenyl iodide **54** and 3.1 equiv. of butyllithium in ether at −95——90 °C, was carried out in ether at −95——90 °C to afford a 4 : 1 mixture of **59** and **60** in 80% yield. The isomeric ratio was estimated by the 250 MHz ^{1}H-NMR analysis. On the other hand, the lithiation of the alkenyl bromide **56** had to be performed in THF at −95 °C, because **56** was virtually unreactive to butyllithium in ether at −100 °C. Thus, **46** was allowed to react in THF at −95 °C with **58**, prepared from 3.0 equiv. of **56** and 2.5 equiv. of butyllithium, to yield a mixture of **59** and **60** in 52% yield, and unchanged **46** was recovered in 29% yield. As in the case of the condensation of **28** with **29**, the major epimer **59** was anticipated to be the "Cram" product, and its structure was confirmed in the later stage of this ansa-chain synthesis. Since the preparative separation of **59** from **60** by column chromatography was impracticable in this stage, the epimeric mixture was directly hydrogenated with 2 equimolar amounts of the rhodium catalyst to give, in 82% yield, a diastereomeric mixture (**61** and **62**), which was debenzylated with lithium in liquid ammonia to afford, after column chromatographic separation, the isomerically homogeneous **63** (in 77% yield) and a minor fraction containing the isomeric mixture (**65**). The acetylation of **63** with



acetic anhydride and DMAP in ethyl acetate yielded the crystalline tetraacetate **64** in 91% yield. The acetylation product from the fraction of **65** was shown to be a 2 : 1 mixture of two C-5-epimeric acetates (**66**) by the TLC and ^{1}H-NMR analyses. The hydrolysis of **64** with 75% DCA followed by the Wittig condensation of the resulting aldehyde **67** with (methoxycarbonylmethylene)triphenylphosphorane gave **68** in 86% yield. The deacetonation of **68** with 80% trifluoroacetic acid (TFA) followed by the periodate-oxidation afforded the crystalline aldehyde **69**, which was treated with methanol containing a catalytic amounts of *p*-toluenesulfonic acid to give the target compound III in 43% yield based on **68**.



The configurations at C-4 and C-5 in **69** were determined by the following manner. The dimethyl acetal III was then reduced with a large excess of diisobutylaluminium hydride (DIBAL) in toluene at −78 °C. The methanolysis of resulting alylic alcohol with PPTS in methanol followed by the acetylation with acetic anhydride and DMAP afforded **70**, whose structure as depicted was confirmed by the 250 MHz ^{1}H-NMR analysis. Consequently, the structures shown for **64** and **59** were established. Furthermore, isomerically pure **59** and **61** were isolated by careful column



chromatography from the aforesaid condensation products and their hydrogenation products respectively, and it was confirmed that the "Cram" product **59**, as well as **30** and **31**, was stereospecifically hydrogenated to afford only the 5,6-*erythro* isomer **61**. It is interesting that, in the case of the anti-"Cram" products, **60**, **32**, and **33**, no remarkable stereoselectivity was observed.

Experimental

The melting points were determined on a micro hot-stage Yanaco MP-S3 and are uncorrected. The specific rotations were measured with a Carl Zeissphotoelectric polarimeter, using a 0.2-dm tube, in chloroform unless stated otherwise. The ^{1}H-NMR spectra were recorded with either a Varian EM-390 or a Bruker WM 250 spectrometer in $CDCl_3$ using TMS as the internal standard. The TLC was carried out on Merck TLC plates (60F-254, 0.25 mm). The column chromatography was performed on silica gel Wakogel C-200. In general, the evaporation of solvents was carried out under reduced pressure below 30 °C.

Methyl 2-O-Benzyl-4,6-O-benzylidene-3-deoxy-3-C-methyl-α-D-glucopyranoside (3). Sodium hydride (15.9 g, 55% emulsion in mineral oil) was washed free from the mineral oil with hexane and evaporated until the last traces of hexane were removed from the sodium hydride. The powdered residue was added to an ice-cooled solution of **2** (51.0 g, 0.182 mol) in dry DMF (360 ml). The mixture was stirred at room temperature for 0.5 h and then ice-cooled. Benzyl bromide (43.2 ml, 0.364 mol) was added dropwise to the stirred mixture over a period of 25 min. After the mixture had been stirred for 1.5 h at room temperature, it was poured into ice water (150 ml) and the new mixture was extracted with chloroform (200 ml × 3). The extracts were washed with a saturated aqueous NaCl solution, dried, and evaporated to a crystalline solid (102.8 g), which was chromatographed on silica gel (1.5 kg) with 15 : 1 benzene–ethyl acetate to afford a practically pure sample of **3** (64.4 g, 96%); mp 121—122.8 °C. Recrystallization from hexane gave an analytical sample as colorless needles: mp 121.7—122.1 °C; $[\alpha]_D^{27}$ +46° (c 2.14); ^{1}H-NMR δ=1.13 (3H, d, 3-Me, J=6.3 Hz), 2.0—2.5 (1H, m, H-3), 2.9—3.3 (2H, m, H-2 and 4), 3.37 (3H, s, OMe), 3.5—3.85 (2H, m, H-6 and 6′), 4.1—4.3 (1H, m, H-5), 4.5—4.6 (3H, sharp m, H-1 and OC<u>H</u>$_2$Ph), 5.41 (1H, s, C<u>H</u>Ph), and 7.2—7.5 (10H, m, 2 × Ph),

Found: C, 71.61; H, 7.11%. Calcd for $C_{22}H_{26}O_5$: C, 71.33; H, 7.08%.

Methyl 2-O-Benzyl-3-deoxy-3-C-methyl-α-D-glucopyranoside (4). A suspension of **3** (69.4 g) in dry methanol (700 ml) was stirred in an ice bath. 3.68 M HCl††† in methanol (102 ml) was then added to the suspension over a period of 10 min. After the mixture had been stirred at room temperature for 40 min, the reaction mixture was ice-cooled, neutralized (pH 6) with $NaHCO_3$ (43.5 g), and evaporated to a crystalline solid. The residue was repeatedly extracted with acetone (*ca.* 1 l) to remove insoluble matter. The acetone extracts were evaporated to afford **4** (50.0 g, 100%) as colorless crystals; mp 143.5—147 °C. Recrystallization from acetone gave a pure sample: Colorless needles, mp 143.8—144.6 °C; $[\alpha]_D^{27}$ +106° (c 1.20); ^{1}H-NMR δ=1.13 (3H, d, 3-Me, J=6.3 Hz), 1.8—2.2 (1H, m, H-3), 2.3—2.6 (1H, br, OH), 2.6—2.8 (1H, br, OH), 3.07 (1H, dd, H-2, $J_{1,2}$=3.3 Hz, $J_{2,3}$=9.6 Hz), 3.36 (3H, s, 1-OMe), 3.2—3.6 (2H, m, H-4 and 5), 3.6—3.8 (2H, m, H-6 and 6′), 4.5—4.6 (3H, sharp m, H-1 and OC<u>H</u>$_2$Ph), and 7.30 (5H, s, Ph).

Found: C, 63.64; H, 7.69%. Calcd for $C_{15}H_{22}O_5$: C, 63.81; H, 7.85%.

Methyl 2-O-Benzyl-3,6-dideoxy-3-C-methyl-α-D-glucopyranoside (5). To an ice-cooled solution of the crude sample of **4** (25.4 g, mp 143.5—147 °C) in dry pyridine was added mesyl chloride (8.00 ml, 0.1035 mol) over a period of 0.5 h and stirred under ice-cooling for 3 h. The reaction mixture was then poured into a cold saturated aqueous $NaHCO_3$ solution (250 ml) and the mixture was extracted with ethyl acetate (300 ml × 3). The extracts were combined, washed successively with a saturated aqueous $KHSO_4$ solution (300 ml × 5) and a saturated aqueous NaCl solution (300 ml × 2), dried, and evaporated. The residual pale yellow crude syrup (31.9 g) of the 6-mesylate was dissolved in dry ether (480 ml), and $LiAlH_4$ (7.5 g, 0.198 mol) was added portionwise to the solution under ice-cooling over a period of 10 min. After being stirred at room temperature for 3 h, $Na_2SO_4 \cdot 10H_2O$ (62.7 g, 0.195 mol) was added to the reaction mixture, and resulting insoluble matter was filtered and washed with chloroform (80 ml × 5). The filtrate and washings were combined and evaporated to a pale yellow syrup (33.5 g), which was chromatographed on silica gel (1 kg) with 2 : 1 benzene–ethyl acetate to afford a colorless syrup of **5** (20.0 g, 83%): $[\alpha]_D^{16}$ +101° (c 1.41); ^{1}H-NMR δ=1.11 and 1.22 (each 3H, each d, 3-Me and H-6, J=6.3 Hz), 1.7—1.9 (1H, br, 4-OH), 1.7—2.15 (1H, m, H-3), 2.79 (1H, m, H-4, $J_{3,4}$=$J_{4,5}$=9.3 Hz), 3.07 (1H, dd, H-2, $J_{1,2}$=3.3 Hz, $J_{2,3}$=10.5 Hz), 3.35 (3H, s, 1-OMe), 3.52 (1H, dq, H-5), 4.5—4.6 (3H, sharp m, H-1 and OC<u>H</u>$_2$Ph), and 7.30 (5H, s, Ph).

2-O-Benzyl-3,6-dideoxy-3-C-methyl-D-glucopyranose (6). To a solution of **5** (14.8 g, 0.0556 mol) in acetic anhydride (440 ml), concd H_2SO_4 (0.46 ml) was added dropwise under ice-cooling over a period of 15 min. After being stirred at 0 °C for 15 min, the reaction mixture was poured into a cold saturated aqueous $NaHCO_3$ solution (400 ml), and then extracted with ethyl acetate (300 ml × 3). The extracts were combined, washed successively with a saturated aqueous $NaHCO_3$ (400 ml × 2) and a saturated aqueous NaCl solution (400 ml × 2), dried, and evaporated to a yellow-brown syrup (18.7 g). To a solution of this syrup in dioxane (167 ml) was added dropwise 1 M aqueous NaOH solution (167 ml) and the mixture was kept at room temperature for 5.5 h. The reaction mixture was then neutralized (pH 7) with CO_2 gas and evaporated. The residue was triturated with acetone (600 ml) and the insoluble matter was removed by filtration. The filtrate was evaporated to afford crude **6** (13.2 g, 94% from **5**); colorless crystals, mp 141—145 °C. Recrystallization from benzene gave a pure sample of **6** as colorless needles; mp 148—150 °C; $[\alpha]_D^{17}$ +55° (c 1.18, EtOH, after 24 h); ^{1}H-NMR δ=1.14, 1.23, and 1.29 (6H, each d, 3-Me and 3 × H-6, J=6.3 Hz), 1.4—2.2 (2H, m, H-3 and OH), 2.7—3.4 (3H, m, H-2,4, and OH), 3.80 (1H, dq, H-5, $J_{4,5}$= 9.0 Hz), 4.4—4.7 (2H, m, OC<u>H</u>$_2$Ph), 4.95 and 5.17 (1H, each d, β and α anomeric H-1, $J_{1\alpha,2}$=3.3 Hz, $J_{1\beta,2}$=11.4 Hz), and 7.36 (5H, s, Ph); α/β=5/6.

††† 1 M = 1 mol dm^{-3}.

5-O-Benzyl-1,4,7-trideoxy-4-C-methyl-D-glycero-L-gulo-heptitol (7) and L-glycero Epimer (8). A solution of **6** (18.8 g, 0.0741 mol) in dry THF (56.0 ml) was added dropwise to a stirred ice-cooled ether solution of methylmagnesium iodide [prepared from magnesium turnings (18.0 g, 0.740 mol) and methyl iodide (46.1 ml, 0.74 mol) in dry ether (360 ml)] over a period of 15 min under argon. After being stirred at room temperature for 20 h, 1 M HCl (770 ml) was carefully added under ice-cooling, after which the mixture was extracted with chloroform (700 ml × 1, 300 ml × 2). The extracts were combined, dried and evaporated to a syrup (26.5 g), which was chromatographed on silica gel (1.6 kg) with 1 : 5 benzene–ethyl acetate to afford **7** (14.9 g, 75%), **8** (53 mg, 0.26%), a mixture of **7** and **8** (0.86 g, 4.3%), and unchanged **6** (2.9 g, 16%). The epimeric mixture (0.86 g) was again chromatographed on silica gel (130 g) with the same solvent system to give **7** (0.60 g) and **8** (0.24 g). The total isolated yields of **7** and **8** amounted to 78% and 1.5% respectively. **7** (R_f=0.34 in 1 : 5 benzene–ethyl acetate), colorless syrup; $[\alpha]_D^{21}$ −65° (*c* 1.00); ^{1}H-NMR δ=0.95 and 1.25 (3H and 6H, each d, 3 × Me, J=6.7 and 6.0 Hz), 2.0—2.6 (2H, m, H-4 and OH), 3.18 (1H, dd, H-5, J=2.1 and 4.5 Hz), 3.5—4.2 (4H, m, H-2,3,6, and OH), 4.59 (2H, ABq, OC$\underline{H}_2$Ph, J_{gem}=11.2 Hz), and 7.37 (5H, s, Ph).

8 (R_f=0.29 in 1 : 5 benzene–ethyl acetate), colorless syrup; ^{1}H-NMR δ=1.08 (3H, d, 4-Me, J=7.2 Hz), 1.24 and 1.28 (each 3H, each d, 2 × Me, J=6.0 Hz), 2.1—2.5 (1H, m, H-4), 3.33 (1H, dd, H-5, $J_{4,5}$=3.0 Hz, $J_{5,6}$=5.8 Hz), 3.55 (1H, dd, H-3, $J_{3,4}$=2.4 Hz, $J_{2,3}$=6.7 Hz), 3.74 (1H, dq, H-2), 4.01 (1H, dq, H-6), 4.59 (2H, s, OC$\underline{H}_2$Ph), and 7.36 (5H, s, Ph).

(2R,3R,4R)-3-Hydroxy-2-methyl-4-pentanolide (9). A solution of $NaIO_4$ (90 mg) in water (0.9 ml) was added to a solution of **7** (37.5 mg) in acetone (0.75 ml) under ice-cooling. After being stirred for 20 min, the resulting insoluble matter was filtered and washed with acetone. The filtrate and washings were combined, neutralized (pH 7) with $NaHCO_3$ and then evaporated. Chloroform (2 ml) was added to the residue and the solution washed with a saturated aqueous NaCl solution, dried, and evaporated. The residual syrup (29.7 mg) was hydrogenolyzed in methanol (0.6 ml) with palladium black at room temperature for 16 min under bubbling with H_2 gas to afford methyl 2,5-dideoxy-2-*C*-methylpentofuranoside (16.2 mg, 83%) after chromatographic purification (silica gel 1.5 g, 1 : 2 benzene–ethyl acetate). The methyl furanoside (16.2 mg) was hydrolyzed with 1 : 1 mixture of 1 M hydrochloric acid and 1,4-dioxane (0.16 ml) at room temperature for 18.5 h and the acid neutralized with $NaHCO_3$. The solution was treated with bromine (7.4×10^{-6} l) for 24 h at room temperature. The reaction mixture was extracted with ethyl acetate, and the extract was washed successively with saturated aqueous $Na_2S_2O_3$ and NaCl solutions, dried, and evaporated to a pale yellow liquid, which was purified by column chromatography (silica gel 0.7 g, 1 : 3 benzene–ethyl acetate) to give the lactone **9** (7.0 mg, 42% from **7**). The ^{1}H-NMR data (90 MHz) of **9** [δ=4.10 (1H, dd, H-3, $J_{2,3}$=$J_{3,4}$=4.8 Hz) and 4.62 (1H, dq, H-4, $J_{4,Me}$=6.6 Hz)] were very similar to the reported data.[1,10]

2,3- and 3,6-O-Acetonides (10 and 12). To an ice-cooled solution of **7** (24.8 g, 0.0924 mol) and DMP (22.7 ml, 0.185 mol) in dry acetone (500 ml) was added dropwise concd H_2SO_4 (25.0×10^{-6} l) over a period of 2 min. After being kept at 0 °C for 0.5 h, the reaction mixture was neutralized with solid Na_2CO_3. The insoluble matter was filtered and washed with acetone (10 ml × 5). The combined filtrate and washings were evaporated to a pale yellow syrup (38.2 g), which was chromatographed on silica gel (1.6 kg) with 20 : 1 chloroform–acetone to afford **10** (21.9 g, 77%) and **12** (4.8 g, 17%): **10** (R_f=0.43 in 20 : 1 chloroform–acetone), colorless syrup; $[\alpha]_D^{17}$ 0°, $[\alpha]_{365}^{17}$ −68° (*c* 1.10); ^{1}H-NMR (250 MHz) δ=1.04, 1.16, and 1.19 (each 3H, each d, 3 × Me, J=6.3, 6.3, and 7.0 Hz), 1.30 and 1.45 (each 3H, each s, CMe_2), 1.85—2.0 (1H, m, H-4), 2.95—3.0 (1H, br, 6-OH), 3.07 (1H, dd, H-5, $J_{4,5}$=2.8 Hz, $J_{5,6}$=5.3 Hz), 3.91 (1H, dq, H-6, $J_{6,7}$=6.3 Hz), 4.15—4.25 (2H, m, H-2 and 3), 4.65 (2H, s, OC$\underline{H}_2$Ph), and 7.3—7.4 (5H, m, Ph).

2-O-Acetyl Derivative (13) of 12. By the procedure described in the preparation of **11**, a sample of **12** (101 mg) was acetylated to afford **13** (111 mg, 96%): R_f=0.52 (10 : 1 benzene-ethyl acetate), colorless syrup; ^{1}H-NMR δ=0.81 (3H, d, 4-Me or H-7, J=7.5 Hz), 1.16 (3H, d, H-7 or 4-Me, J=7.1 Hz), 1.24 (3H, d, H-1, J=6.3 Hz), 1.30 and 1.33 (each 3H, each s, CMe_2), 1.8—2.2 (1H, m, H-4), 1.99 (3H, s, 2-OAc), 2.90 (1H, dd, H-5, J=0 and 2.3 Hz), 3.8—4.1 (2H, m, H-3 and 6), 4.50 (2H, ABq, OC$\underline{H}_2$Ph, J_{gem}=12.0 Hz), 4.82 (1H, dq, H-2, $J_{2,3}$=9.5 Hz), and 7.27 (5H, s, Ph).

6-O-Acetyl-1,4,7-trideoxy-2,3-O-isopropylidene-5-O-mesyl-4-C-methyl-D-glycero-L-gulo-heptitol (14) and 5-O-Acetyl-1,4,7-trideoxy-2,3-O-isopropylidene-6-O-mesyl-4-C-methyl-D-glycero-L-gulo-heptitol (15). A mixture of **11** (5.50 g, 15.7 mmol), pal-

ladium black (*ca.* 3 g), and ethanol (110 ml) was vigorously stirred at room temperature for 20 min under bubbling with H_2 gas, and the suspension filtered. The filtrate was evaporated to a colorless syrup (4.43 g), which was coevaporated with benzene (4 ml×5). The final residue (4.11 g) was immediately dissolved in dry pyridine (41 ml) and ice-cooled. Mesyl chloride (2.4 ml, 31.4 mmol) was added dropwise to the solution over a period of 10 min and the mixture was kept at room temperature for 2 h. The reaction mixture was poured into a cold saturated aqueous $NaHCO_3$ solution (50 ml), and extracted with ethyl acetate (70 ml×3). The extracts were combined, washed successively with saturated aqueous $KHSO_4$ (50 ml×5) and NaCl (50 ml×3) solution, dried, and evaporated to a crystalline residue (5.62 g). The residue was chromatographed on silica gel (560 g) with 5 : 1 benzene–ethyl acetate to afford **14** (4.89 g, 92%) and **15** (0.266 g, 5%): **14** (R_f=0.48 in 3 : 1 benzene–ethyl acetate), colorless needles; mp 78—83 °C; ^{1}H-NMR δ=1.13, 1.23, and 1.32 (each 3H, each d, 3×Me, J=6.6, 6.2, and 6.2 Hz), 1.36 and 1.47 (each 3H, each s, CMe_2), 1.8—2.2 (1H, m, H-4), 2.11 (3H, s, 6-OAc), 3.08 (3H, s, 5-OMs), 4.04 (1H, dd, H-3, $J_{2,3}$=6.0 Hz, $J_{3,4}$=7.4 Hz), 4.40 (1H, dq, H-2, $J_{1,2}$=6.2 Hz), 4.60 (1H, dd, H-5, $J_{4,5}$=2.7 Hz, $J_{5,6}$=7.8 Hz), and 5.16 (1H, dq, H-6, $J_{6,7}$=6.2 Hz): **15** (R_f=0.42 in 3 : 1 benzene–ethyl acetate), colorless syrup; ^{1}H-NMR δ=1.08, 1.23, and 1.39 (each 3H, each d, 3×Me, J=6.0, 6.4, and 6.0 Hz), 1.31 and 1.44 (each 3H, each s, CMe_2), 1.8—2.2 (1H, m, H-4), 2.13 (3H, s, 5-OAc), 2.96 (3H, s, 6-OMs), 3.72 (1H, dd, H-3, $J_{2,3}$=6.4 Hz, $J_{3,4}$=7.7 Hz), 4.26 (1H, dq, H-2, $J_{1,2}$=6.4 Hz), and 4.7—5.0 (2H, m, H-5 and 6).

*5,6-Anhydro-1,4,7-trideoxy-2,3-*O*-isopropylidene-4-*C*-methyl-*D*-glycero-*D*-manno-heptitol (**16**).* To an ice-cooled solution of **14** (4.86 g, 14.4 mmol) in chloroform (48 ml) was added 3.6 M sodium methoxide in methanol (1.0 ml) over a period of 5 min. After being stirred under ice-cooling for 45 min the mixture was neutralized with CO_2 gas, poured into cold water (30 ml), and then extracted with dichloromethane (20 ml×3). The extracts were washed with a saturated aqueous NaCl solution (30 ml×3), dried, and evaporated to a colorless oil (2.94 g). The oil was subsequently chromatographed on silica gel (88 g) with 5 : 1 benzene–ethyl acetate to afford oily **16** (2.69 g, 93%), which was subjected to bulb-to-bulb distillation to give a pure sample of **16** (2.34 g, 81%): R_f=0.50 (5 : 1 benzene–ethyl acetate); bp 45—56 °C (bath temp)/6 Torr††††; $[\alpha]_D^{20}$ +8° (*c* 1.49); ^{1}H-NMR δ=1.08 (3H, d, 4-Me, J=6.8 Hz), 1.21 (3H, d, H-1, J=6.0 Hz), 1.30 (3H, d, H-7, J=5.7 Hz), 1.36 and 1.47 (each 3H, each s, CMe_2), 2.72 (1H, dd, H-5, $J_{5,6}$=4.2 Hz, $J_{4,5}$=9.0 Hz), 3.06 (1H, dq, H-6), 4.02 (1H, dd, H-3, $J_{2,3}$=6.0 Hz, $J_{3,4}$=7.5 Hz), and 4.34 (1H, dq, H-2).

*** The elution speed was desired to be as fast as possible.

yellow syrup, which was shown to be isomerically homogeneous by TLC and ^{1}H-NMR analyses. A portion of this sample (15 mg) was chromatographed on silica gel (1 g) with 3 : 1 benzene–ethyl acetate to give a pure sample of **34** (14.4 mg): colorless syrup, R_f=0.31 (3 : 1 benzene–ethyl acetate); $[\alpha]_D^{24}$ +24° (*c* 0.72); ^{1}H-NMR (250 MHz) δ=0.82, 0.92, and 1.07 (each 3H, each d, 2,4,6-Me, J=7.0 Hz), 1.24 (3H, d, H-9, J=6.3 Hz), 1.23 and 1.25 [each 3H, each t, CH(OC$\underline{H}_2$Me)$_2$, J=7.0 Hz], 1.34 and 1.46 (each 3H, each s, CMe$_2$), 1.8—2.05 (3H, m, H-2,4 and H-6), 3.31 (1H, ddd, H-5, J=3.3 and 9.0 Hz, $J_{5.OH}$=9.0 Hz), 3.5—3.9 [4H, m, CH(OC$\underline{H}_2$Me)$_2$], 3.91 (1H, d, 5-OH), 4.02 (1H, dd, H-3, J=1.5 and 9.5 Hz, $J_{3,OH}$= 0 Hz), 4.25 (1H, dd, H-7, $J_{6,7}$=$J_{7.8}$=6.3 Hz), 4.44 (1H, d, H-1, $J_{1,2}$=6.0 Hz), 4.47 (1H, dq, H-8), and 4.59 (1H, s, 3-OH).

Found: C, 63.19; H, 10.27%. Calcd for $C_{19}H_{38}O_6$: C, 62.96; H, 10.57%.

(b): A sample of **30** (57.6 mg, 0.121 mmol) was hydrogenated in benzene (2.9 ml) with $(Ph_3P)_3RhCl$ (169 mg, 0.182 mmol) under atmospheric pressure of H_2 at room temperature for 20 h. The reaction product was treated with Florisil (13 g) and ether to afford crude **35** (45.7 mg, 79%) as a yellow syrup. This syrup was desilylated with 2 equimolar amounts of Bu_4NF in THF at 0 °C for 15 min and then worked up by the usual way to give a yellow syup (44.7 mg). This was chromatographed on silica gel (2.3 g) with 2 : 1 hexane–ethyl acetate to afford **34** (32.4 mg, 93% from **35**), which was isomerically homogeneous and identical with the sample of **34** obtained in (*a*).

*2,4,6,9-Tetradeoxy-7,8-O-isopropylidene-2,4,6-tri-C-methyl-*D-arabino-L-allo-*nonose Diethyl Acetal (37) and* L-altro *Epimer (39).* *(a)*: By the procedure described in the case of the homogeneous hydrogenation of **31**, **33** (0.473 g, 1.31 mmol) was treated with $(Ph_3P)_3RhCl$ (0.284 g, 0.307 mmol) in benzene for 17 h, and the reaction mixture was worked up to afford a yellow syrup (0.475 g). The syrup was chromatographed on silica gel (50 g) with 2 : 1 hexane–ethyl acetate to give **37** (0.179 g, 38%) as colorless needles, **39** (0.173 g, 37%) as colorless syrup, and a mixture of **37** and **39** (40 mg, 8.5%): **37**, R_f=0.40 (2 : 1 hexane–ethyl acetate); mp 69.5—72 °C (from hexane); $[\alpha]_D^{24}$ −19° (*c* 1.29); ^{1}H-NMR (250 MHz) δ=0.96 (3H, d, 4-Me, J=7.0 Hz), 1.03 (3H, d, 2-Me, J=7.0 Hz), 1.07 (3H, d, 6-Me, J=6.8 Hz), 1.22 and 1.24 [each 3H, each t, CH(OCH$_2$-$\underline{Me}$)$_2$, J=7.0 Hz], 1.26 (3H, d, H-9, J=6.3 Hz), 1.34 and 1.47 (each 3H, each s, CMe$_2$), 1.99 (1H, ddq, H-6, $J_{5,6}$=6.8 Hz, $J_{6,7}$=4.2 Hz), 2.04 (1H, ddq, H-4, $J_{3,4}$=7.0 Hz, $J_{4.5}$=7.0 Hz), 2.23 (1H, ddq, H-2, $J_{1,2}$=5.5 Hz, $J_{2,3}$=6.5 Hz), 3.44 (1H, ddd, H-5, $J_{5.OH}$=6.8 Hz), 3.53, 3.55, 3.70, and 3.76 [each 1H, each dq, CH(OC$\underline{H}_2$Me)$_2$, J_{gem}=10.0 Hz], 3.60 (1H, ddd, H-3, $J_{3.OH}$=3.5 Hz), 3.87 (1H, d, 5-OH), 4.25 (1H, dd, H-7, $J_{7,8}$=6.3 Hz), 4.43 (1H, dq, H-8), 4.50 (1H, d, H-1), and 4.61 (1H, d, 3-OH).

Found: C, 62.82; H, 10.29%. Calcd for $C_{19}H_{38}O_6$: C, 62.96; H, 10.57%.

(b): By the procedure described in the case of the hydrogenation of **30**, **32** (41 mg, 0.86 mmol) was treated with the rhodium catalyst (120 mg, 0.129 mmol) for 22 h, and the reaction mixture was worked up to afford a yellow syrup (a mixture of **38** and **40**). A solution of this syrup in THF (0.34 ml) was treated with 1.0 M *n*-Bu_4NF in THF (0.14 ml) at 0 °C for 15 min and then worked up to give a syrup, which was chromatographed on silica gel (4 g) with 2 : 1 hexane–ethyl acetate to afford **37** (1.7 mg, 6.6%), **39** (12.8 mg, 50%), and a mixture of **37** and **39** (2.3 mg).

Transformation of 34 into 41. To a solution of **34** (9.5 mg, 0.026 mmol) in dry ethanol (0.23 ml) was added a 0.026 M ethanolic PPTS solution (0.1 ml), and the mixture was stirred at 55 °C for 4 h. The reaction mixture was then neutralized with triethylamine and evaporated. The residue was chromatographed on silica gel (0.5 g) with 2 : 1 benzene–acetone to afford a colorless syrup (6.5 mg). To a solution of this syrup in acetone (0.065 ml) was added a solution of $NaIO_4$ (6.5 mg, 0.03 mmol) in water (0.065 ml) under ice-cooling. After being stirred for 20 min, the mixture was diluted with water and then extracted with ether. The extract was washed with a saturated aqueous NaCl solution, dried, and evaporated to a colorless syrup (5.4 mg). To a solution of this syrup in 95% ethanol (0.054 ml) was added $NaBH_4$ (1.8 mg, 0.048 mmol), and the mixture was stirred at room temperature for 30 min. The resulting mixture was neiutralzed with solid CO_2, concentrated, and extracted with chloroform. The extract was evaporated to a colorless syrup (5.5 mg,) which was dissolved in a 0.5% methanolic hydrogen chloride (0.055 ml). The resulting solution was kept at room temperature for 1 h, and the reaction mixture was neutralized with solid $NaHCO_4$ and evaporated. The residue was partitioned between ethyl acetate and water. The aqueous layer was saturated with NaCl and extracted with ethyl acetate. The combined organic layers were dried and evaporated to a colorless syrup (4.7 mg), which was dissolved in ethyl acetate (0.047 ml). To this solution was added acetic anhydride (0.01 ml) and DMAP (13.4 mg) and stirred at room temperature for 20 min. The reaction mixture was then diluted with ethyl acetate, and washed with a saturated aqueous NaCl solution, dried, and evaporated. The residue was chromatographed on silica gel (0.6 g) with 10 : 1 benzene–ethyl acetate to afford **41** (4.0 mg, 51% from **34**) as a colorless syrup: ^{1}H-NMR (250 MHz) δ= 0.84 and 0.86 (3H, each d, β- and α-4-Me, J=7.0 Hz), 0.90 and 0.97 (3H, each d, β- and α-2-Me, J=7.0 Hz), 1.09 and 1.12 (3H, each d, α- and β-6-Me, J=7.0 Hz), 1.95—2.05 (1H, m, H-4), 2.05 and 2.09 (0.75H, each s, 2×β-OAc), 2.06 and 2.07 (5.25H, each s, 2×α-OAc), 2.10—2.25 (2H, m, H-2 and 6), 2.98 and 3.41 (1H, each dd, β- and α-H-5, $J_{4,\beta\text{-}5}$=$J_{4,\alpha\text{-}5}$= 11.3 Hz, $J_{\beta\text{-}5.6}$=$J_{\alpha\text{-}5.6}$=2.0 Hz), 3.31 and 3.46 (3H, each s, α- and β-OMe), 3.96 and 3.99 (1H, each dd, α- and β-H-7, $J_{6,7}$= 7.5 Hz, $J_{7,7'}$=10.8 Hz), 4.31 (1H, dd, H-7′, $J_{6,7'}$=5.0 Hz), 4.29 (overlapped one of the double doublets of H-7′ proton, H-1β), 4.49 (d, H-1α, $J_{\alpha\text{-}1.2}$=1.5 Hz), and 4.59—4.93 (1H, each dd, β- and α-H-3, $J_{2,\beta\text{-}3}$=$J_{2,\alpha\text{-}3}$=5.3 Hz, $J_{\beta\text{-}3.4}$=$J_{\alpha\text{-}3,4}$= 10.5 Hz).

Transformation of 37 and 39 into 42 and 43. By the procedure described in the preceding paragraph, **37** (22.3 mg) and **39** (18.4 mg) were coverted into **42** (12.8 mg, 69% yield based on **37**) and **43** (9.7 mg, 63% yield based on **39**) respectively: **42**, ^{1}H-NMR (250 MHz) δ=0.83 and 0.84 (3H, each d, β- and α-4-Me, J=7.0 Hz), 0.86 (3H, d, 2-Me, J=7.0 Hz), 1.11 (3H, d, 6-Me, J=7.0 Hz), 1.73 (0.6H, ddq, β-H-2), 1.85 —2.05 (1.4H, m, α-H-2, α- and β-H-4), 2.0—2.15 (1H, m, H-6), 2.04, 2.05, 2.10, and 2.11 (6H, each s, 2×OAc), 3.33 and 3.47 (3H, each s, α- and β-OMe), 3.42 and 3.67 (1H, each dd, β- and α-H-5, $J_{4,\beta\text{-}5}$=11.0 Hz, $J_{\beta\text{-}5.6}$=2.1 Hz,

$J_{4,\alpha\text{-}5}=11.0$ Hz, $J_{\alpha\text{-}5,6}=1.9$ Hz), 3.93 and 3.98 (1H, each dd, H,α- and β-H-7, $J_{6,7}=8.0$ Hz, $J_{7,7'}=11.0$ Hz), 4.26 and 4.27 (1 each dd, α- and β-H-7', $J_{6,7'}=6.0$ Hz), 4.23 and 4.46 (1H, each d, β- and α-H-1, $J_{\beta\text{-}1,2}=9.0$ Hz, $J_{\alpha\text{-}1,2}=3.9$ Hz), and 5.12 and 5.22 (1H, each dd, α- and β-H-3, $J_{2,\alpha\text{-}3}=J_{\alpha\text{-}3,4}=3.1$ Hz, $J_{2,\beta\text{-}3}=J_{\beta\text{-}3,4}=3.0$ Hz); **43**, ^{1}H-NMR (250 MHz) $\delta=0.83$ and 0.88 (3H, each d, β- and α-4-Me, $J=7.0$ Hz), 0.98 and 1.04 (3H, each d, β- and α-2-Me, $J=7.0$ Hz), 1.10 and 1.12 (3H, each d, α- and β-6-Me, $J=7.0$ Hz), 1.9—2.2 (3H, m, H-2,4, and 6), 2.05, 2.06, 2.07, and 2.09 (6H, each s, 2×OAc), 3.34 and 3.47 (3H, each s, α- and β-OMe), 3.43 and 3.70 (1H, each dd, β- and α-H-5, $J_{4,\beta\text{-}5}=11.0$ Hz, $J_{\beta\text{-}5,6}=2.0$ Hz, $J_{4,\alpha\text{-}5}=10.0$ Hz, and $J_{\alpha\text{-}5,6}=3.0$ Hz), 3.96 and 4.00 (1H, each dd, α- and β-H-7, $J_{6,7}=8.0$ Hz, $J_{7,7'}=11.0$ Hz), 4.31 (1H, dd, H-7', $J_{6,7'}=5.2$ Hz), 4.38 and 4.55 (1H, each d, α- and β-H-1, $J_{\alpha\text{-}1,2}=1.8$ Hz, $J_{\beta\text{-}1,2}=2.5$ Hz). and 4.67 and 4.90 (1H, each dd, α- and β-H-3, $J_{2,\alpha\text{-}3}=J_{\alpha\text{-}3,4}=4.0$ Hz, $J_{2,\beta\text{-}3}=J_{\beta\text{-}3,4}=2.7$ Hz).

*3,5-Di-*O*-benzyl-2,4,6,9-tetradeoxy-7,8-*O*-isopropylidene-2,4,6-tri-*C*-methyl-*D*-arabino-*L*-manno-nonose Diethyl Acetal (**36**).* After a mixture of the crude **34** (0.353 g), NaH (0.119 g, 0.496 mmol) and dry DMF (3.6 ml) had been stirred at room temperature for 0.5 h, benzyl bromide (0.47 ml, 0.395 mmol) was added to the resulting solution over a period of 2 min under ice-cooling, and the mixture was stirred at 45 °C for 2 h. The reaction mixture was then poured into ice water (5 ml) and the new mixture was extracted with chloroform (8 ml×3). The extracts were washed with a saturated aqueous NaCl solution (10 ml×2), dried, and evaporated. The residual syrup (0.746 g) was chromatographed on silica gel (37 g) with 15 : 1 benzene–ethyl acetate to afford a practically pure sample of **36** (0.472 g, 88%). A part of this sample (14 mg) was chromatographed twice by using silica gel (1 g) with the same solvent system to give an analytical sample (12.5 mg) as a colorless syrup: $R_f=0.38$ (15 : 1 benzene–ethyl acetate); $[\alpha]_D^{24}=[\alpha]_{365}^{24}=0°$ (*c* 1.10); ^{1}H-NMR $\delta=0.9$—1.3 [18H, m, 2,4,6-Me, H-9, and CH(OCH$_2$Me)$_2$], 1.34 and 1.47 (each 3H, each s, CMe$_2$), 1.85—2.25 (3H, m, H-2,4, and 6), 3.2—4.0 [6H, m, H-3,5, and CH(OCH$_2$Me)$_2$], 4.2—4.8 (7H, m, H-1, 7, 8 and 2×OCH$_2$Ph), and 7.43 (10H, s, 2×Ph).

*3,5-Di-*O*-benzyl-2,4,6,9-tetradeoxy-2,4,6-tri-*C*-methyl-*D*-arabino-*L*-manno-nonose Diethyl Acetal (**45**).* A mixture of crude **36** (0.390 g) and 75% DCA (11.7 ml) was stirred at 0 °C for 20 min. The resulting solution was poured into an ice-cooled saturated aqueous NaHCO$_3$ solution (60 ml). The mixture was then extracted with ethyl acetate (40 ml×3), and the extracts were washed with a saturated aqueous NaCl solution (50 ml×2), dried, and evaporated to a yellow brown syrup of **44** (0.32 g, 95%). The syrup was thoroughly dried under reduced pressure for 18 h and dissolved in dry ethanol (2.4 ml). To this solution was added dried *p*-toluenesulfonic acid (2.4 mg, 0.0139 mmol). After being kept at room temperature for 3 h, the reaction mixture was neutralized (pH 7) with triethylamine and evaporated to a yellow-brown syrup (0.42 g), which was chromatographed on silica gel (20 g) with 3 : 1 benzene–ethyl acetate to afford **45** (0.312 g, 86% based on **36**) as a colorless syrup: $R_f=0.50$ (2 : 1 benzene–ethyl acetate); $[\alpha]_D^{31}$ +26° (*c* 1.36); ^{1}H-NMR $\delta=0.98$ (6H, d, 2×Me, $J=7.3$ Hz), 1.1—1.3 (12H, m, 2×Me and 2×OCH$_2$Me), 1.5—1.65 (2H, br, 2×OH), 2.0—2.45 (3H, m, H-2,4, and 6), 3.35—4.05 (8H, m, H-3,5,7,8, and 2×OCH$_2$-Me), 4.55—4.85 (5H, m, H-1 and 2×OCH$_2$Ph), 7.34 and 7.37 (each 5H, each s, 2×Ph).

Found: C, 71.41; H, 9.09%. Calcd for $C_{30}H_{46}O_6$: C, 71.68; H, 9.22%.

*3,5-Di-*O*-benzyl-2,4,6-trideoxy-2,4,6-tri-*C*-methyl-*L*-glycero-*L*-manno-heptodialdose 1-(Diethyl acetal) (**46**).* To an ice-cooled solution of **45** (0.172 g, 0.342 mmol) in acetone (1.7 ml) was slowly added a solution of NaIO$_4$ (0.183 g, 0.856 mmol) in water (1.8 ml). After being stirred at room temperature for 2 h, the mixture was diluted with water (2 ml) and extracted with ether (5 ml×3). The combined extracts were washed with a saturated aqueous NaCl solution (5 ml×2) dried and evaporated. The residual syrup (0.16 g) was chromatographed on silica gel (8 g) with 15 : 1 benzene–ethyl acetate to afford a pure sample of **46** (0.127 g, 81%): colorless syrup, $R_f=0.41$ (15 : 1 benzene–ethyl acetate): IR (CHCl$_3$, 0.15 M) 1719 cm^{-1}; ^{1}H-NMR $\delta=0.87$ and 0.92 (each 3H, each d, 2×Me, $J=7.2$ and 7.5 Hz), 1.1—1.3 (9H, m, Me and 2×OCH$_2$Me), 1.8—2.2 (2H, m, H-2 and 4), 2.5—3.0 (1H, m, H-6), 3.1—3.9 (6H, m, H-3,5, and 2×OCH$_2$Me), 4.25—4.55 (5H, m, 2×OCH$_2$Ph and H-1), 7.23 (10H, s, 2×Ph), and 9.72 (1H, s like, H-7, $J_{6,7}=0$ Hz).

*3-C-(Benzyloxymethyl)-3-deoxy-1,2:5,6-Di-*O*-isopropylidene-α-*D*-allofuranose (**48**).* By the procedure described in the benzylation of **2**, **47** (2.08 g, 7.57 mmol) was benzylated with NaH (22.7 mmol) and benzyl bromide (1.78 ml, 15.2 mmol) in DMF (21 ml). The crude product (3.73 g) was chromatographed on silica gel (138 g) with 20 : 1 toluene–ethyl acetate to afford **48** (2.58 g, 94%) as a pale yellow syrup: $[\alpha]_D^{15}$ +6°, $[\alpha]_{365}^{15}$ +15° (*c* 1.02); ^{1}H-NMR $\delta=1.32$, 1.34, and 1.48 (total 12H, each s, 2×CMe$_2$), 2.0—2.3 (1H, m, H-3), 3.5—4.1 (6H, m, H-4,5,6, and CH$_2$OBzl), 4.51 (2H, s, OCH$_2$Ph), 4.73 (1H, dd, H-2, $J_{1,2}=J_{2,3}=3.8$ Hz), 5.75 (1H, d, H-1), and 7.34 (5H, s, Ph).

Found: C, 66.12; H, 7.77%. Calcd for $C_{20}H_{28}H_6$: C, 65.91; H, 7.74%.

*3-C-(Benzyloxymethyl)-3-deoxy-1,2-*O*-isopropylidene-α-*D*-allofuranose (**49**).* A solution of **48** (2.55 g) in 75% acetic acid (26 ml) was stirred at 33 °C for 5 h and then evaporated to a yellow syrup (3.00 g), which was subsequently chromatographed on silica gel (68 g) with 1 : 2 toluene–ethyl acetate to afford **49** (2.19 g, 97%) as a pale yellow syrup: $[\alpha]_D^{17}$ +6°, $[\alpha]_{365}^{17}$ +10° (*c* 1.76); ^{1}H-NMR $\delta=1.29$ and 1.48 (each 3H, each s, CMe$_2$), 2.0—2.4 (1H, m, H-3), 3.4—4.0 (6H, m, H-4, 5,6, and CH$_2$OBzl), 4.54 (2H, s, OCH$_2$Ph), 4.64 (1H, dd, H-2, $J_{1,2}=J_{2,3}=3.7$ Hz), 5.75 (1H, d, H-1), and 7.38 (5H, s, Ph).

Found: C, 62.67; H, 7.31%. Calcd for $C_{17}H_{24}O_6$: C, 62.95; H, 7.46%.

*3-C-(Benzyloxymethyl)-3-deoxy-1,2-*O*-isopropylidene-6-*O*-tosyl-α-*D*-allofuranose (**50**).* To a solution of **49** (3.40 g, 10.5 mmol) in dry pyridine (17 ml) was added a solution of tosyl chloride (2.40 g, 12.6 mmol) in dry pyridine (4.8 ml) under ice-cooling. After being kept at room temperature for 3 h, the reaction mixture was poured into ice water (65 ml) and the mixture was extracted with ethyl acetate. The extract was washed successively with saturated aqueous KHSO$_4$, NaHCO$_3$, and NaCl solutions, dried, and evaporated to afford acrude sample of **50** (5.02 g) as a pale yellow syrup, which was suitable for the next synthesis. A pure sample of **50** was obtained by silica gel column chromatography with 9 : 1 benzene–ethyl acetate: $R_f=0.35$ (9 : 1 benzene–ethyl acetate); $[\alpha]_D^{15}$ +3°, $[\alpha]_{365}^{15}$ +8° (*c* 0.63); IR (CHCl$_3$) 1177 and 1365 cm^{-1}.

Found: C, 60.20; H, 6.27; S, 6.52%. Calcd for $C_{24}H_{30}O_8S$: C, 60.24; H, 6.32; S, 6.70%.

*3-C-(Benzyloxymethyl)-3,6-dideoxy-1,2-*O*-isopropylidene-α-*D*-allofuranose (**51**).* To an ice-cooled solution of the crude sample of **50** (5.02 g) in dry ether (50 ml) was slowly added powdered LiAlH$_4$ (0.796 g, 21.0 mmol) under stirring. The stirring was continued for 3 h under ice-cooling, and to the reaction mixture were added dropwise water (0.8 ml), 15% NaOH solution (0.8 ml), and water (2.4 ml) successively. The

resulting mixture was then filtered, and the filter cake was washed with ether. The filtrate and washings were combined, and evaporated to a syrup (3.1 g), which was chromatographed on silica gel (160 g) with 3 : 1 toluene–ethyl acetate to afford a pure sample of **51** (2.39 g, 74% based on **49**): colorless syrup, R_f=0.32 (3 : 1 toluene–ethyl acetate); $[\alpha]_D^{16}$ +7°, $[\alpha]_{365}^{16}$ +11° (*c* 2.35); ^{1}H-NMR δ=1.26 (3H, d. H-6, $J_{5,6}$=6.0 Hz), 1.28 and 1.48 (each 3H, each s, CMe_2), 1.9—2.25 (1H, m, H-3), 3.5—3.9 (4H, m, H-4,5, and $C\underline{H}_2OBzl$), 3.96 (1H, broad s, 5-OH), 4.53 (2H, ABq, $OC\underline{H}_2Ph$, J_{gem}=11.1 Hz), 4.66 (1H, dd, H-2, $J_{1,2}=J_{2,3}$=3.9 Hz), 5.74 (1H. d, H-1), and 7.35 (5H' s, Ph).

Found: C, 66.10; H, 7.70%. Calcd for $C_{17}H_{24}O_5$: C, 66.21; H, 7.85%.

*3-C-(Benzyloxymethyl)-3,6-dideoxy-1,2-O-isopropylidene-α-D-allofuranos-5-ulose (**52**).* To a stirred mixture of PCC (4.80 g, 22.3 mmol), molecular sieve 3A powder (5.57 g), and dry dichloromethane (19 ml) was added a solution of **51** (2.29 g, 7.43 mmol) in dichloromethane (4.6 ml) at room temperature. After being stirred at room temperature for 2.5 h, the reaction mixture was diluted with ether (25 ml) and filtered through a column filled with silica gel (60 g). Removal of the solvent gave almost pure sample of **52** (2.10 g, 92%) as a colorless syrup. A portion of this sample was chromatographed on silica gel with 10 : 1 benzene–ethyl acetate to afford an analytical sample of **52**: R_f=0.56 (3 : 1 toluene–ethyl acetate); $[\alpha]_D^{15}$ +3°, $[\alpha]_{436}^{15}$ +4°, and $[\alpha]_{365}^{15}$ 0° (*c* 2.09); IR ($CHCl_3$) 1720 cm^{-1}; ^{1}H-NMR δ=1.35 and 1.49 (each 3H, each s, CMe_2), 2.1—2.5 (1H, m, H-3), 2.20 (3H, s, H-6), 3.61 (1H, dd, one of the $C\underline{H}_2OBzl$, J_{gem}=9.1 Hz, J=4.6 Hz), 3.79 (1H, dd, one of the $C\underline{H}_2OBzl$, J=9.1 Hz), 4.11 (1H, d, H-4, $J_{3,4}$=9.7 Hz), 4.49 (2H, s, $OC\underline{H}_2Ph$), 4.73 (1H, dd, H-2, $J_{1,2}=J_{2,3}$=3.9 Hz), 5.90 (1H, d, H-1), and 7.34 (5H, m, Ph).

*3-C-(Benzyloxymethyl)-3,5,6-trideoxy-5-iodo-1,2-O-isopropylidene-α-D-ribo-5-hexenofuranose (**54**).* A mixture of **52** (1.02 g, 3.33 mmol), ethanol (10 ml), triethylamine (3.93 ml, 28.2 mmol), and 100% hydrazine hydrate (0.645 ml, 13.3 mmol) was refluxed for 10 min. The cooled reaction mixture was diluted with chloroform (33 ml), and the mixture was washed with water (20 ml). The aqueous layer was extracted with chloroform. The combined organic layers were washed with a saturated aqueous NaCl solution, dried, and evaporated to afford the hydrazone **53** (1.06 g, 100%) as a pale yellow syrup. To an ice-cooled mixture of **53** (1.06 g), dry THF (37 ml), and triethylamine (23.1 ml, 166 mmol) was added dropwise a solution of iodine (1.85 g, 7.30 mmol) in dry THF (18.5 ml). After being stirred at 0 °C for 5 min, the reaction mixture was diluted with ether (110 ml) and washed successively with 10% aqueous citric acid, saturated aqueous $Na_2S_2O_3$, and NaCl solutions, dried, and evaporated. The residual dark brown syrup (1.56 g) was chromatographed on silica gel (207 g) with 30 : 1 toluene–ethyl acetate to give colorless needles of **54** (0.407 g, 30%). Recrystallization from hexane afforded an analytical sample: R_f=0.34 (30 : 1 toluene–ethyl acetate); mp 67—67.5 °C; $[\alpha]_D^{15}$ +50° (*c* 1.25); IR (KBr) 1612 cm^{-1}; ^{1}H-NMR δ=1.35 and 1.50 (each 3H, each s, CMe_2), 2.1—2.45 (1H, m, H-3), 3.42 (1H, dd, one of the $C\underline{H}_2OBzl$, J_{gem}=9.4 Hz, J=5.5 Hz), 3.62 (1H, d, H-4, $J_{3,4}$=9.4 Hz), 3.76 (1H, dd, one of the $C\underline{H}_2OBzl$, J=9.4 Hz), 4.50 (2H, s, $OC\underline{H}_2Ph$), 4.73 (1H, dd, H-2, $J_{1,2}=J_{2,3}$=3.8 Hz), 5.88 (1H, d, H-1), 5.95 and 6.39 (each 1H, each d, $C=CH_2$, J=1.5 Hz), and 7.37 (5H, s, Ph).

*3-C-(Benzyloxymethyl)-3,5,6-trideoxy-1,2-O-isopropylidene-α-D-ribo-5-hexenofuranose (**55**).* To an ice-cooled solution of **49** (0.703 g, 2.17 mmol) in acetone (7 ml) was added a solution of $NaIO_4$ (0.695 g, 3.25 mmol) in water (7 ml). After being stirred under ice-cooling for 10 min, the mixture was diluted with water (7 ml) and extracted with ehter (7 ml×4). The combined extracts were washed with a saturated aqueous NaCl solution (7 ml), dried, and evaporated to afford a syrup of the crude aldehyde (0.614 g, 97%). A suspension of 55% NaH (0.275 g, 6.30 mmol) in dry DMSO (19 ml) was stirred at 75 °C for 45 min under argon and then cooled to room temperature. To this solution was added methyltriphenylphosphonium bromide (2.25 g, 6.30 mmol) and the mixture was stirred at room temperature for 0.5 h. A solution of the aforesaid crude aldehyde (614 mg) in dry DMSO (3.1 ml) was added dropwise to the ice-cooled resulting organge-yellow solution of the ylide over a period of 10 min. After the mixture had been stirred at room temperature for 0.5 h, it was poured into ice water (80 ml), and new mixture was extracted with ether. The extract was successively washed with water, a saturated aqueous NaCl solution, dried, and evaporated. The residue (1.55 g) was chromatographed on silica gel (31 g) with 20 : 1 benzene–ethyl acetate to afford **55** (0.544 g, 87% based on **49**) as a colorless syrup: $[\alpha]_D^{25}$ +16° (*c* 0.64); ^{1}H-NMR δ=1.33 and 1.51 (each 3H, each s, CMe_2), 1.9—2.3 (1H, m, H-3), 3.47 (1H, dd, one of the $C\underline{H}_2OBzl$, J_{gem}=9.3 Hz, J=5.3 Hz), 3.78 (1H, dd, one of the $C\underline{H}_2OBzl$, J=9.3 Hz), 4.19 (1H, dd, H-4, $J_{3,4}$=6.8 Hz, $J_{4,5}$=10.4 Hz), 4.50 (2H, s, $OC\underline{H}_2Ph$), 4.71 (1H, dd, H-2, $J_{1,2}=J_{2,3}$=3.8 Hz), 5.15 (1H, dd, H-6(*E*), $J_{5,6}$=10.3 Hz, J_{gem}=*ca.* 1 Hz), 5.26 (1H, dd, H-6(*Z*), $J_{5,6}$=16.5 Hz), 5.38 (2H, d and ddd, H-1 and H-5), and 7.36 (5H, s, Ph).

Found: C, 70.19; H, 7.54%. Calcd for $C_{17}H_{22}O_4$: C, 70.32; H, 7.64%.

*3-C-(Benzyloxymethyl)-5-bromo-3,5,6-trideoxy-1,2-O-isopropylidene-α-D-ribo-5-hexenofuranose (**56**) and 3-C-(Benzyloxymethyl)-6-bromo-3,5,6-trideoxy-1,2-O-isopropylidene-α-D-ribo-(E)-5-hexenofuranose (**57**).* To a stirred cooled (−10 °C) solution of **55** (0.541 g, 1.86 mmol) in carbon tetrachloride (5.4 ml) was added dropwise a solution of bromine (0.298 g, 1.86 mmol) in carbon tetrachloride (0.96 ml) over a period of 20 min. After being at −10 °C for 5 min, a saturated aqueous $NaHCO_3$ solution was added to the reaction mixture. The organic layer was separated and the aqueous layer was extracted with chloroform. The combined organic layers were washed with a saturated aqueous NaCl solution, dried, and evaporated. The residue was chromatographed on silica gel (25 g) with 40 : 1 toluene–ethyl acetate to afford dibromide (0.675 g, 81%) as a pale yellow syrup. The TLC (40 : 1 toluene–ethyl acetate) of this sample revealed it to be a mixture of two diastereomers with R_f=0.31 and 0.27. To a solution of the dibromide (0.674 g) in dry DMSO (4.7 ml) was added a solution of DBU (0.457 g, 3.00 mmol) in dry DMSO (2.0 ml), and the mixture was stirred at room temperature for 2 h. The reaction mixture was then diluted with water (35 ml) and extracted with ether (20 ml×4). The extracts were combined, successively washed with water and a saturated aqueous NaCl solution, dried, and evaporated. The residue (0.56 g) was chromatographed on silica gel (28 g) with 30 : 1 toluene–ethyl acetate to afford a mixture of **56** and **57**(0.496g, 90 %)and the starting dibromide (43 mg, 6.4%). The mixture of **56** and **57** was again chromatographed on silica gel (74 g) with 8 : 1 hexane–ethyl acetate to give **56** (0.401 g, 72%) and **57** (80 mg, 14%): **56** (colorless needles), R_f=0.29 (8 : 1 hexane–ethyl acetate), mp 71—72 °C (heptane); $[\alpha]_D^{17}$ +53° (*c* 1.13); IR ($CHCl_3$) 1630 cm^{-1}; ^{1}H-NMR δ=1.33 and 1.49 (each 3H, each s, CMe_2), 2.3—2.7 (1H, m, H-3), 3.47 (1H, dd, one of the $C\underline{H}_2OBzl$, J_{gem}=9.3 Hz, J=5.3 Hz), 3.77 (1H, dd, one of the

$C\underline{H}_2OBzl$, J=9.3 Hz), 4.20 (1H, d, H-4, $J_{3,4}$=10.5 Hz), 4.50 (2H, s, $OC\underline{H}_2Ph$), 4.73 (1H, dd, H-2, $J_{1,2}=J_{2,3}$=3.5 Hz), 5.64 and 5.91 (each 1H, each d, C=CH_2, J=2.1 Hz), 5.88 (1H, d, H-1), and 7.35 (5H, s, Ph).

*A Mixture of 8,10-Di-O-benzyl-3-C-(benzyloxymethyl)-3,5,7,9,11-pentadeoxy-1,2-O-isopropylidene-7,9,11-tri-C-methyl-5-methylene-*L*-erythro-*D*-altro-α-*D*-ribo-dodecodialdofuranose-(1,4)12-(Diethyl acetal) (**59**) and* L-erythro-D-allo-α-D-ribo *Epimer (**60**).* To a cooled (−90—−94 °C) solution of **54** (0.588 g, 1.41 mmol) in dry ether (13 ml) was added 1.28 M butyllithium in hexane (1.1 ml, 1.41 mmol) over a period of 3 min under argon. After being stirred at the same temperature for 45 min, a solution of **46** (0.209 g, 0.458 mmol) in dry ether (0.42 ml) was added to the mixture over a period of 2 min, and stirring was continued at the same temperature for 0.5 h. To the reaction mixture was added a saturated aqueous NH_4Cl solution (3 ml), and the separated aqueous layer was extracted with ether (6 ml×2). The organic layers were combined, washed with a saturated aqueous NaCl solution, dried, and evaporated. The residual yellow syrup (0.673 g) was chromatographed on silica gel (70 g) with 20 : 1 toluene–acetone to afford the following fractions: Fr-1, a mixture of **46**, **55**, and **54**(95.7 mg); Fr-2, **55**(0.152 g); Fr-3, *ca.* 4: 1 mixture of **59** and **60** (0.272 g, 80%). The Fr-3 showed on the TLC (20 : 1 toluene–acetone) the major spot (**59**, R_f=0.29) and the minor one (**60**, R_f=0.31); ^{1}H-NMR (250 MHz) δ=0.90, 0.93, and 1.08 (each 0.6H, each d, 7,9,11-Me, J=7.0 Hz), 0.96, 1.00, and 1.02 (each 2.4H, each d, 7,9,11-Me, J=7.0 Hz), 1.15 (3H, t, $OCH_2\underline{Me}$, J=7.0 Hz), 1.18 (2.4H, t, $OCH_2\underline{Me}$, J=7.0 Hz), 1.20 (0.6H, t, $OCH_2\underline{Me}$, J=7.0 Hz), 1.34 (3H, s, CMe_2), 1.46 (2.4H, s, CMe_2), 1.50 (0.6H, s, CMe_2), 2.0—2.4 (4H, m, H-3, 7,9, and 11), 3.3—3.95 (10H, m, H-6,8,10, and 2×$OC\underline{H}_2Me$, and $C\underline{H}_2OBzl$, 6-OH), 4.04 (0.8H, d, H-4, $J_{3,4}$=10.5 Hz), 4.15 (0.2H, d, H-4, $J_{3,4}$=10.5 Hz), 4.35—4.85 (7H, m, 3×$C\underline{H}_2Ph$, and H-12), 4.77 (1H, dd, H-2, $J_{1,2}=J_{2,3}$=4.0 Hz), 5.28 and 5.29 (each 0.2H, each s, C=$C\underline{H}_2$), 5.32 and 5.44 (each 0.8H, each s, C=$C\underline{H}_2$), 5.82 (1H, d, H-1), 7.32 and 7.33 (15H, each s, 3×Ph).

*3,5,7,9,11-Pentadeoxy-3-*C*-(hydroxymethyl)-1,2-*O*-isopropylidene-5,7,9,11-tetra-*C*-methyl-*L*-erythro-*D*-altro-β-*L*-talo-dodecodialdofuranose-(1,4) 12-(Diethyl acetal) (**63**) and Its Isomeric Mixture (**65**).* A sample (0.231 g, 0.310 mmol) of the epimeric mixture (**59** and **60**) obtained in the preceding experiment was dissolved in dry benzene (12 ml). To this solution was added $(Ph_3P)_3RhCl$ (0.573 g, 0.619 mmol), and the solution stirred under an atmospheric pressure of H_2 at room temperature for 1 d. The reaction mixture was then evaporated and the residue was passed through Florisil (100—200 mesh, 40 g) with ether. The effluent was evaporated to afford a pale yellow syrup of the crude hydrogenation product (0.189 g, 82%). To a solution of this product in dry ether (3.8 ml) was added liquid ammonia (19 ml), and then lithium (0.070 g, 10 mmol) was added under cooling (−78 °C). After the mixture had been stirred at the same temperature for 50 min, the excess lithium was destroyed by addition of solid NH_4Cl. The mixture was then diluted with ether (10 ml) and allowed to concentrate spontaneously. The residue was taken with ether (10 ml), and the solution washed with a saturated aqueous NaCl solution (3 ml×2), dried, and evaporated. The residual syrup was chromatographed on silica gel (10 g) with 2 : 1 benzene–acetone to afford **63** (colorless syrup, R_f=0.25 (2 : 1 benzene–acetone), 93 mg, 77%) and a colorless syrup [R_f=0.51 (2 : 1 benzene–acetone), 17 mg] containing **65**.

*8,10-Di-O-benzyl-3-C-(benzyloxymethyl)-3,5,7,9,11-pentadeoxy-1,2-O-isopropylidene-5,7,9,11-tetra-C-methyl-*L*-erythro-*D*-altro-β-*L*-talo-dodecodialdofuranose-(1, 4) 12-(Diethyl acetatal) (**61**).*

(a): A sample (60 mg) of the aforesaid crude hydrogenation product from a mixture of **59** and **60** was at first chromatographed on silica gel (6 g) with 35 : 1 chroloform–acetone to afford a pale-yellow syrup (42 mg). This was again chromatographed on silica gel (8.4 g) with 7 : 1 *s*-BuCl–ethyl acetate to give **61** (31 mg) and a product (8.4 mg) shown to be **62** by ^{1}H-NMR analysis: **61**, colorless syrup, R_f=0.31 (7 : 1 *s*-BuCl–ethyl acetate); $[\alpha]_D^{17}$ +16° (c 0.92); ^{1}H-NMR (250 mHz) δ=0.76, 0.92, 0.97, and 1.08 (each 3H, each d, 5,7,9,11-Me, J=7.0 Hz), 1.17 and 1.19 (each 3H, each t, 2×$OCH_2\underline{Me}$, J=7.0 Hz), 1.32 and 1.50 (each 3H, each s, CMe_2), 1.65—1.80, 1.90—2.05, and 2.05—2.30 (each 1H, 1H, and 3H, each m, H-3,5,7,9, and 11), 3.3—4.0 (10H, m, H-6,8,10, 2×OCH_2Me, $C\underline{H}_2OBzl$, and 6-OH), 4.4—4.75 (9H, m, H-2,4,12, and 3×$OC\underline{H}_2Ph$), 5.77 (1H,d, H-1, $J_{1,2}$=3.5 Hz), 7.32 and 7.34 (15H, each s, 3×Ph).

Found: C, 72.06; H, 8.43%. Calcd for $C_{45}H_{64}O_9$: C, 72.16; H, 8.61%.

62, colorless syrup, R_f=0.38 (7 : 1 *s*-BuCl–ethyl acetate); ^{1}H-NMR (250 MHz) δ=0.90, 0.92, 0.93, and 1.04 (each 3H, each d, 5,7,9,11-Me, J=7.0 Hz), 1.17 and 1.20 (each 3H, each t, 2×$OCH_2\underline{Me}$, J=7.0 Hz), 1.32 and 1.50 (each 3H, each s, CMe_2), 1.90—2.00 (1H, m, H-5), 1.95—2.25 (3H, m, H-7,9, and 11), 2.25—2.40 (1H, m, H-3), 3.15 (1H, d, 6-OH, $J_{6,OH}$=1.0 Hz), 3.3—3.65 (4H, m, one of the CH_2OBzl, and three of the 2×$OC\underline{H}_2Me$), 3.7—3.9 (2H, m, one of the $C\underline{H}_2OBzl$, and one of the 2×$OC\underline{H}_2Me$), 3.74 (1H, dd, H-6 or 8, J=2.3 and 11.0 Hz), 3.85 (1H, dd, H-6 or 8, J=0 and 9.5 Hz), 3.95 (1H, dd, H-10, $J_{9,10}$=0 Hz, $J_{10,11}$=9.0 Hz), 4.01 (1H, dd, H-4, $J_{3,4}$=10.3 Hz, $J_{4,5}$=2.3 Hz), 4.35—4.7 (6H, m, 3×$OC\underline{H}_2Ph$), 4.56 (1H, d, H-12, $J_{11,12}$=3.5 Hz), 4.69 (1H, dd, H-2, $J_{1,2}=J_{2,3}$=3.8 Hz), 5.79 (1H, d, H-1), and 7.2—7.4 (15H, m, 3×Ph).

(b): By the procedure described in the preparation of the mixture of **59** and **60**, a crude condensation product (213 mg) was obtained from **54** (155 mg) and **46** (66.1 mg). This sample was chromatographed on silica gel (32 g) with 20 : 1 toluene–acetone to afford the six fractions: Fr-1, **54** (30.1 mg); Fr-2, **54**+**46** (5.9 mg); Fr-3, **46**+**55** (11.5 mg); Fr-4, **55** (38.3 mg); Fr-5, **60** (major)+**59** (minor) (18.6 mg, 17.2% yield); Fr-6, **59** (63.5 mg, 58.7% yield). Thus obtained chromatographically pure sample (10 mg, 0.013 mmol) of **59** was hydrogenated in dry benzene (0.5 ml) with $(Ph_3P)_3RhCl$ (24.8 mg, 0.0268 mmol) at room temperature under an atmospheric pressure of H_2 for 14 h. The reaction mixture was evaporated and the residue was passed through Florisil (1 g) with ether and evaporated to a syrup whose TLC showed only one spot of **61**. The chromatographic purification (silica gel, 1 g, 3.5 : 1 hexane–ethyl acetate) gave a colorless syrup of **61** (8.6 mg, 86%).

*6,8,10-Tri-O-acetyl-3-C-(acetoxymethyl)-3,5,7,9,11-pentadeoxy-1,2-O-isopropylidene-5,7,9,11-tetra-C-methyl-*L*-erythro-*D*-altro-β-*L*-talo-dodecodialdofuranose-(1, 4) 12-(Diethyl acetal) (**64**).*

To a mixture of **63** (81 mg, 0.169 mmol), DMAP (99 mg, 0.810 mmol), and ethyl acetate (0.81 ml) was added acetic anhydride (0.096 ml, 1.02 mmol). The mixture was stirred at room temperature for 23.5 h and then poured into a cold saturated aqueous $NaHCO_3$ solution (2 ml). The mixture was extracted with ethyl acetate (3 ml×3) and the extracts were washed with a saturated aqueous NaCl solution, dried, and evaporated. The residue was chromatographed on silica gel (10 g) with 10 : 1 benzene–acetone to afford **64** (99 mg, 91%) as colorless needles: R_f=0.38 (6 : 1 benzene–acetone); mp 100—102 °C; $[\alpha]_D^{19}$ 0°, $[\alpha]_{365}^{19}$ +60° (*c* 1.09); IR ($CHCl_3$, 0.15M) 1732 cm^{-1}; ^{1}H-NMR δ=0.9—1.3 (18H, m, 5,7,9,11-Me, and 2×$OCH_2\underline{Me}$), 1.33 and 1.46 (each 3H, each s, CMe_2), 2.00, 2.02, 2.03, and 2.08 (12H, each s, 4×OAc), 1.9—2.6 (5H, m, H-3,5,7,9,11), 3.3—4.25 (8H, m, H-4,12, $C\underline{H}_2OAc$ and 2×$OC\underline{H}_2Me$), 4.5—5.2 (4H, m, H-2,6,8, and 10), and 5.72 (1H, d, H-1, $J_{1,2}$=2.3 Hz).

Found: C, 59.12; H, 8.17%. Calcd for $C_{32}H_{54}O_{13}$: C, 59.42; H, 8.42%.

*C-5-Epimeric Actates (**66**).* The syrup (17 mg), R_f=0.51) obtained in the preparation of **63** was acetylated by the procedure described in the preparation of **64**. The crude product was purified by silica gel column chromatography with 2 : 1 toluene–ethyl acetate to afford a sample of **66** (16 mg): colorless syrup, R_f=0.50, 0.45 (1 : 1 hexane–ethyl acetate); ^{1}H-NMR (250 MHz) δ=0.9—1.05 (12H, m, 4×Me), 1.19 and 1.20 (2H and 4H, each t, 2×$OCH_2\underline{Me}$, J=6.8 Hz), 1.32 and 1.50 (each 1H, each s, CMe_2), 1.34 and 1.49 (each 2H, each s, CMe_2), 2.00, 2.05, 2.05, and 2.06 (each 1H, each s, 4×OAc), 2.01, 2.03, 2.09, and 2.10 (each 2H, each s, 4×OAc), 1.9—2.5 (5H, m, H-3,5,7,9, and 11), 3.35—3.80 (4H, m, 2×$OC\underline{H}_2Me$), 3.96 (2H/3, dd, H-4, J=5.0 and 10.0 Hz), 4.03 (1H/3, dd, H-4, J=1.0 and 10.0 Hz), 4.1—4.2 (2H, m, H-12 and one of $C\underline{H}_2OAc$), 4.29 (1H/3, dd, one of $C\underline{H}_2OAc$, J=7.8 and 10.8 Hz), 4.39 (2H/3, dd, one of $C\underline{H}_2OAc$, J=4.8 and 10.8 Hz), 4.55—4.7 (2H, m, H-2 and $C\underline{H}OAc$), 4.89 (2H/3, dd, $C\underline{H}OAc$, J=4.8 and 7.5 Hz), 5.0—5.15 (4H/3, m, 2×$C\underline{H}OAc$), 5.72 and 5.75 (1H/3 and 2H/3, each d, H-1, J=3.8 Hz).

*Methyl 6,8,10-Tri-O-acetyl-3-C-(acetoxymethyl)-3,5,7,9,11,12,-13-heptadeoxy-1,2-O-isopropylidene-5,7,9,11-tetra-C-methyl-*L*-erythro-*D*-altro-β-*L*-talo-(E)-12-tetradecenofuranuronate-(1,4)(**68**).* A mixture of **64** (86 mg, 0.133 mmol) and 75% DCA (1.7 ml) was stirred at 0 °C for 40 min. The resulting solution was poured into a cold saturated aqueous $NaHCO_3$ solution (20 ml) containing solid $NaHCO_3$. The mixture was then extracted with ethyl acetate (20 ml×2, 10 ml×1), and the extracts were washed with a saturated aqueous NaCl solution (20 ml×2), dried, and evaporated to afford colorless needles of **67** (74 mg, 97%): mp 97—102 °C. To a solution of this crystals (74 mg) in dry toluene (2.2 ml) was added (methoxycarbonylmethylene) triphenylphosphorane (90 mg, 0.27 mmol), and the mixture was stirred at 95—98 °C for 4 h under argon. The reaction mixture was concentrated to a yellow syrup which was chromatographed on silica gel (13 g) with 3 : 2 *s*-BuCl–ethyl acetate to give **68** (73 mg, 89%) as a pale yellow syrup: R_f=0.34 (3 : 2 *s*-BuCl–ethyl acetate); $[\alpha]_D^{18}$ +5°, $[\alpha]_{365}^{18}$ +15° (*c* 1.02); IR ($CHCl_3$, 0.1 M), 1725, 1650, 1220, and 984 cm^{-1}; ^{1}H-NMR (250 MHz) δ=0.90 (3H, d, 5-Me, J=7.0 Hz), 0.95 (3H, d, 7-Me, J=7.0 Hz), 0.96 (3H, d, 9-Me, J=7.0 Hz), 1.09 (3H, d, 11-Me, J=7.0 Hz), 1.32, and 1.45 (each 3H, each s, CMe_2), 1.8—2.0 (1H, m, H-5), 1.94, 2.01, 2.03, and 2.09 (each 3H, each s, 4×OAc), 2.1—2.3 (2H, m, H-3,7), 2.4—2.6 (2H, m, H-9,11), 3.71 (3H, s, COOMe), 3.84 (1H, dd, H-4, $J_{3,4}$=10.2 Hz, $J_{4,5}$=1.3 Hz), 4.13 and 4.24 (each 1H, each dd, $C\underline{H}_2OAc$, J_{gem}=11.0 Hz, J=6.1 and 8.1 Hz), 4.64 (1H, dd, H-2, $J_{1,2}$=$J_{2,3}$=3.8 Hz), 4.82 (1H, dd, H-8, $J_{7,8}$=5.3 Hz, $J_{8,9}$=8.5 Hz), 4.90 (1H, dd, H-10, $J_{9,10}$=2.0 Hz, $J_{10,11}$=9.2 Hz), 5.18 (1H, dd, H-6, $J_{5,6}$=9.9 Hz, $J_{6,7}$=0.9 Hz), 5.77 (1H, d, H-13, $J_{12,13}$=15.0 Hz), 5.77 (1H, d, H-1), and 6.75 (1H, dd, H-12, $J_{11,12}$=9.0 Hz).

Found: C, 59.43; H, 7.63%. Calcd for $C_{31}H_{48}O_3$: C, 59.22; H, 7.69%.

*Methyl 5,7,9-Tri-O-acetyl-2-C-(acetoxymethyl)-2,4,6,8,10,11,-12-heptadeoxy-4,6,8,10-tetra-C-methyl-*aldehydo-L-glycero-L-talo-L-manno-(E)-11-tridecenuronate 1-(Dimethyl acetal) (III).* A mixture of **68** (30.0 mg, 0.0477 mmol) and 75% TFA (0.3 ml) was kept in a refrigerator for 24 h. The reaction mixture was poured in to a cold saturated aqueous $NaHCO_3$ solution, and the mixture was extracted with ethyl acetate. The extract was washed with a saturated aqueous NaCl solution, dried, and evaporated toa colorless syrup, which was dissolved in acetone (0.56 ml) and ice-cooled. To this solution was added a solution of $NaIO_4$ (40.8 mg, 0.191 mmol) in water (0.5 ml), and the mixture was stirred at room temperature for 2.5 h. The reaction mixture was diluted with water, and extracted with ethyl acetate. The extract was washed with a saturated aqueous NaCl solution, dried, and evaporated to give the crude crystalline aldehyde **69**. The crude **69** was dissolved in dry methanol (0.56 ml) and to this, a 0.095 M methanolic *p*-toluenesulfonic acid (0.01 ml) was added. After being stirred at room temperature for 24 h, the reaction mixture was neutralized with triethylamine and evaporated. The residue was then chromatographed on silica gel (Kieselgel 60, 3 g) with 1 : 1 toluene–ethyl acetate to afford III (12.3 mg, 43% based on **68**) as a colorless syrup: $[\alpha]_D^{16}$ −8° (*c* 0.98); IR ($CHCl_3$), 1726 and 1652 cm^{-1}; ^{1}H-NMR (250 MHz) δ=0.89 (3H, d, 4-Me, J=7.0 Hz), 0.92 and 0.97 (each 3H, each d, 6- and 8-Me, J=7.3 and 7.0 Hz), 1.07 (3H, d, 10-Me, J=6.4 Hz), 1.65—1.85 (1H, m, H-4), 1.96, 2.00, 2.04, and 2.07 (each 3H, each s, 4×OAc), 2.1—2.2 (1H, m, H-2), 2.2—2.4 (2H, m, H-6 and 8), 2.45—2.65 (1H, m, H-10), 3.30 (1H, d, 3-OH, J=3.9 Hz), 3.41 and 3.44 (each 3H, each s, 2×OMe), 3.51 (1H, ddd, H-3, $J_{2,3}$=10.0 Hz, $J_{3,4}$=1.0 Hz), 3.71 (3H, s, COOMe), 3.98 and 4.24 (each 1H, each dd, $C\underline{H}_2OAc$, J=6.0 and 3.8 Hz, J_{gem}=11.6 Hz), 4.62 (1H, d, H-1, $J_{1,2}$=4.0 Hz), 4.85 (1H, dd, H-7, $J_{6,7}$=$J_{7,8}$=7.0 Hz), 4.98 (1H, dd, H-9, $J_{8,9}$=2.0 Hz, $J_{9,10}$=9.8 Hz), 5.02 (1H, dd, H-5, $J_{4,5}$=10.0 Hz, $J_{5,6}$=1.3 Hz), 5.79 (1H, dd, H-12, $J_{10,12}$=0.7 Hz, $J_{11,12}$=16.0 Hz), and 6.76 (1H, dd, H-11, $J_{10,11}$=9.3 Hz).

Found: C, 57.31; H, 7.72%. Calcd for $C_{29}H_{48}O_{13}$: C, 57.60; H, 8.00%.

*Transformation of III into **70**.* A solution of III (10.2 mg, 0.0169 mmol) in dry toluene (1 ml) was cooled at −78 °C and to this was added portionwise 1.76 M DIBAL in hexane (0.258 ml, 0.454 mmol) over a period of 9 h under argon. After being stirred for additional 1 h, the mixture was warmed up to room temperature and was added 50% acetic acid (0.05 ml). The precipitates formed was filtered and washed with acetone. The filtrate and washings were combined and evaporated to afford a colorless syrup (4.6 mg). To a solution of this syrup in dry methanol (0.16 ml) was added 0.022 M methanolic PPTS solution (0.05 ml), and the mixture was stirred at 55 °C for 24 h. The reaction mixture was then neutralized with triethylamine and evaporated to a colorless syrup (4.2 mg) of cyclic methyl acetal derivative. A solution of the acetal in ethyl acetate (0.1 ml) was treated with acetic anhydride (0.008 ml, 0.08 mmol), DMAP (8.2 mg, 0.067 mmol) at 24 °C for 2 h. The reaction mixture was worked up by the usual way. The crude product was chromatographed on silica gel (1 g) with 3 : 2 toluene–ethyl acetate to afford **70** (2.7 mg, 27% from III) as a colorless syrup: R_f=0.38 (3 : 2 toluene–ethyl acetate); ^{1}H-NMR (250 MHz) δ=0.82 (3H, d, 4-Me,

J=6.3 Hz), 0.93 and 0.99 (each 3H, each d, 6- and 8-Me, J= 7.5 and 7.5 Hz), 1.02 (3H, d, 10-Me, J=7.3 Hz), 1.65 —1.85 (1H, m, H-4), 1.97, 2.03, 2.05, 2.05, and 2.09 (each 3H, each s, 5×OAc), 2.05—2.25 (2H, m, H-6 and 8), 2.25—2.40 (1H, m, H-2), 2.35—2.50 (1H, m, H-10), 3.36 (3H, s, OMe), 3.49 (1H, d, H-5, $J_{4,5}$=10.0 Hz, $J_{5,6}$=0 Hz), 4.06 and 4.28 (each 1H, each dd, 2-C$\underline{H}_2$OAc, J_{gem}=11.0 Hz, J=10.0 and 83. Hz), 4.35—4.55 (2H, m, 2×H-13), 4.69 (1H, d, H-1, $J_{1,2}$= 2.0 Hz), 4.95—5.05 (2H, m, H-7 and 9), 5.05 (1H, dd, H-3, $J_{2,3}$=5.0 Hz, $J_{3,4}$=11.0 Hz), and 5.55—5.60 (2H, m, H-11 and 12).

We wish to thank Mr. Saburo Nakada for carrying out the elemental analyses. We also would like to thank Miss Yukiko Suzuki of the Institute of Bio-organic Chemistry for the measurements of the 250 MHz ^{1}H-NMR spectra, and Miss Shioko Kurihara for her technical assistance. This research was supported by a Grant-in-Aid for Scientific Research No. 56550595 from the Ministry of Education, Science and Culture, Japan and the Institute of Microbial Chemistry.

Study of Ion Transport across Amphoteric Ion Exchange Membrane. I. Electroconductive Membrane Permeability

Akira YAMAUCHI,* Shigeru TSURUYAMA, Harumi MASUMORI, Yoshihiko NAGATA, Kozue KAIBARA, and Hideo KIMIZUKA

Department of Chemistry, Faculty of Science, Kyushu University, Hakozaki, Higashi-ku, Fukuoka 812

(Received January 13, 1982)

Basic ion transport characteristics of a homogeneous amphoteric ion exchange membrane (Kanegafuchi Chem. Ind. 1.0-PA-29) were studied by measuring the membrane potentials and conductances. Concentration cell systems of NaCl, KCl, $CaCl_2$, and $SrCl_2$ with a concentration range of 10^{-1}—10^{-3} mol dm^{-3} were studied and the electroconductive membrane permeabilities were estimated from the electrochemical data. Generally, Cl^- is slightly more permeable than cations under the present experimental conditions, except the result that K^+ is more permeable at low concentrations. Unlike the usual uniform cation exchange membrane of which transport characteristics to ions strongly depend upon the number of ionic charges, a "1.0-PA-29" amphoteric membrane exhibits different transport properties for the NaCl and KCl systems. In the NaCl system, the membrane was constantly anionic selective, while in the KCl system, biphasic ion selectivities were observed depending upon the external KCl concentration. Fundamental electrochemical properties of the membrane systems were discussed by examining the dependencies of membrane permeability on external electrolyte concentrations and on differences in ionic species. The present result suggests that the ionic size is one of the critical factors determining the transport characteristics across amphoteric ion exchange membrane.

Amphoteric membranes are specified upon a fact that both cationic and anionic sites are attached as ion exchange groups to polymeric substances which build up membrane phase. Since the early work on mosaic membranes by Sollner,[1] many studies on the amphoteric membranes were carried out with the charge-mosaic membrane systems.[2-4] In these investigations, unusual properties of the mosaic system, which cannot be observed in uniform ion exchange membranes, such as the piezodialysis and circulating electric current were found out. On the other hand, the layered type membrane systems in which the cation and anion exchange membranes form a contiguous layers were also studied.[5-7] Especially, the interesting current-voltage characteristics of the layered membrane have been extensively investigated.

These two types of amphoteric membranes or composite membranes have been investigated with several interests. From the theoretical point of views, Kedem and Katchalsky treated generally the transport phenomena observed in these systems on the basis of nonequilibrium thermodynamics in their series of papers.[8-10] Weinstein *et al.* also developed the theoretical model for the charge-mosaic membrane based on nonequilibrium thermodynamics[11] and the experimental verification of their model was carried out.[12] Practical applications of these membranes have been also extensively discussed. Large salt fluxes resulted from the structure of charge-mosaic membrane were paid an attention to utilize for the water conditioning processes. The layered membrane was also considered to be a generalized model involving the surface adsorption phenomena; therefore, the layered model was employed to solve the fouling phenomena which are serious problems in the electrodialysis processes. Many investigators have also taken a great interest in the biological membrane as an amphoteric ion exchange membrane and made an attempt to explain the mechanisms of bioelectrical phenomena in relation to the amphoteric properties of cell membranes.

Experimental studies on amphoteric ion exchange membranes were hitherto performed with the system where the cationic and anionic sites are macroscopically separated each other (see *e.g.*, Refs. 7 and 12). The physicochemical properties of amphoteric membranes should be examined on the system where the cationic and anionic sites are dispersed homogeneously within membrane phase.[13] However, investigations for the basic characteristics of the homogeneous type amphoteric membrane have not been systematically carried out yet. In the present and following papers of this communication series, the basic transport properties of amphoteric ion exchange membranes will be discussed from the theoretical and experimental points of views using the homogeneous type membrane recently developed by a Kanegafuchi Chemical Industry Co., Ltd.[14]

Experimental

The amphoteric ion exchange membrane used in the present experiments is coded as a "1.0-PA-29," which was developed by a Central Research Laboratory of Kanegafuchi Chemical Industry Co., Ltd. and kindly supplied for our experiments. This membrane was developed for the membrane treatment to separate organic substances having a low molecular weight from inorganic salt mixture. A brief sketch of the membrane preparation is as follows.[14] Support membranes were prepared on a glass surface from a dope containing poly(vinyl chloride) (degree of polymerization: 1000) of 11 wt% dissolved in a tetrahydrofuran/*N*,*N*-dimethylformamide (1/1.6 in weight) mixture. On this support membrane, partially chloromethylated polystyrene of 0.5 wt% dissolved in a chloroform/ethanol (1/2 in weight) mixture were applied as a functioning membrane base; chloromethyl groups in polymer were partially treated with trimethylamine. After this step, crosslinking and sulfonation processes were performed by sulfuric acid. Concentration of sulfuric acid and reaction time were controlled to realize the minimum salt rejection rate, which is known to be minimized under the conditions where anionic to cationic exchange capacity ratio approaches to unity.[13,14] All the membrane preparation processes described above were carried out by means of the dip coating techniques. Primary permeation test of the membrane showed that the rejection rates, [(feed

concentration—permeate concentration)/feed concentration] × 100%, under the operating pressure of 20 kg cm^{-2} were about 30% for 0.2% NaCl solution and over 93% for 2% sucrose solution, respectively. The ion exchange capacity estimated by ordinary titration method and by elementary analysis was 1 mequiv. (g-wet membrane)$^{-1}$ and the cationic/anionic exchange capacity ratio was ranged 1.0 ± 0.2. The thickness of membrane was 0.1 mm when the membrane was immersed in electrolyte solutions used in the present study. The closest distance between cationic and anionic exchange sites can be roughly estimated to be *ca.* 0.75 nm when the total ion exchange capacity is 2 mequiv. and the degree of swelling is 0.5. Then Eguchi *et al.* suggested that the mosaic membrane model [11] is unsuitable for the analysis of transport characteristics in the present membrane.[14]

In the present preliminary experiments, the electrochemical properties were studied on the concentration cell systems using NaCl, KCl, $CaCl_2$, and $SrCl_2$ as electrolytes. Experimental setup was the same as that reported elsewhere.[15,16] The amphoteric membrane was placed in the measurement cell to separate solution phases I and II, and the electrolyte concentration of phase I was varied from 10^{-1} to 10^{-3} mol dm^{-3}, while that of phase II was kept constant at 10^{-2} mol dm^{-3}. In this study, the membrane potentials and conductances were measured by a Takeda Riken TR 6856 high input impedance voltmeter and a Yokogawa-Hewlett-Packard 4255A (connected with 4440B) impedance bridge circuit, respectively. All experiments were carried out at the regulated room temperature (25 ± 1 °C).

Results and Discussion

Before the measurements were carried out, the sample membrane was checked on locally uniform properties of electrochemical data in the NaCl system and both sides of the membrane showed the identical electrochemical properties. The volume flow was also checked in the NaCl system; under the present experimental conditions, effects of solvent flow cause about 5% changes in transport parameters at most, which were within experimental errors.[17] More complete treatment involving the effects of solvent flow will be presented elsewhere based on nonequilibrium thermodynamics.

Membrane potential data as a function of the mean electrolyte activity of phase I are summarized in Fig. 1. In general, a 1.0-PA-29 amphoteric ion exchange membrane was more permselective to chloride ions than to metal cations under the present experimental conditions and this tendency became evident with increasing electrolyte concentration of phase I. Apparent transport numbers of Na^+ are nearly constant at 0.4, but those of Ca^{2+} and Sr^{2+} decrease from 0.45 to 0.29 and from 0.42 to 0.29, respectively, when the electrolyte concentrations of phase I are varied from 10^{-3} to 10^{-1} mol dm^{-3}. On the other hand, the KCl system exhibits biphasic ion selectivity behavior above and below the concentration of 10^{-2} mol dm^{-3} as illustrated in Fig. 1; apparent transport numbers of K^+ ranged from 0.42 to 0.46 and from 0.51 to 0.54 at lower and higher concentration ranges, respectively. In case of the usual cationic or anionic ion exchange membrane, the selectivity to ions is monophasic and the number of ionic charge is a dominant factor determining the ionic

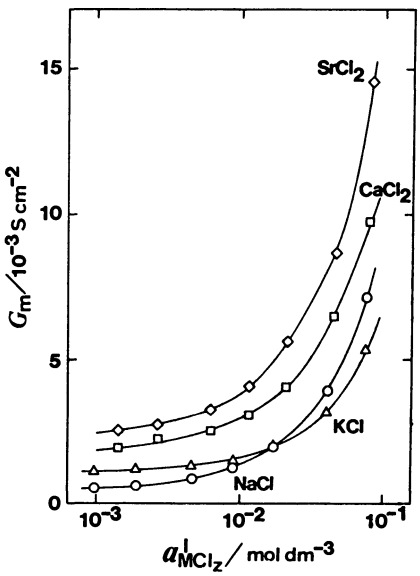

Fig. 2. Membrane conductance data as a function of mean electrolyte activity of phase I.
Symbols are the same as in Fig. 1.

permselectivity, so the membrane potential responses to univalent cations are almost the same irrespective of ionic species. On the basis of present results, there seems to be a possibility to discriminate Na^+ from K^+ by means of the amphoteric type ion exchange membrane.

The membrane conductance data are given in Fig. 2. Conductances continuously increase with increasing electrolyte concentrations of phase I in all the systems. It should be noted that the membrane conductances of 2-1 electrolyte systems are twice as high as those of 1-1 electrolyte systems.

According to the previous theory,[18] the present systems are described by the following modified phenomenological equation:

$$\begin{bmatrix} J_M \\ J_{Cl} \end{bmatrix} = - \begin{bmatrix} P_{M\cdot M} & P_{M\cdot Cl} \\ P_{Cl\cdot M} & P_{Cl\cdot Cl} \end{bmatrix} \times \begin{bmatrix} a_M^{II} \exp(ZFV/2RT) - a_M^{I} \exp(-ZFV/2RT) \\ a_{Cl}^{II} \exp(-FV/2RT) - a_{Cl}^{I} \exp(FV/2RT) \end{bmatrix}, \quad (1)$$

where J is the ionic flux, a is the activity, Z is the charge of metal cation M, and V is the transmembrane potential; F, R, and T indicate the usual physical meanings; the subscripts M and Cl refer to metal cations, Na^+, K^+, Ca^{2+}, and Sr^{2+}, and to anion, Cl^-; the superscripts I and II indicate the solution phases separated by the membrane phase, respectively. $P_{M\cdot M}$, $P_{M\cdot Cl}$, $P_{Cl\cdot M}$, and $P_{Cl\cdot Cl}$ are the membrane permeability matrix elements representing the partial contributions to the membrane transport processes due to the inter-ionic correlations indicated by the subscripts. In the present study, the electroconductive membrane permeabilities, defined by the following equations as a function of the permeability matrix elements, were estimated from the electrochemical measurements:

$$P_M = P_{M\cdot M} - P_{Cl\cdot M}/Z, \quad P_{Cl} = -ZP_{M\cdot Cl} + P_{Cl\cdot Cl}, \quad (2)$$

where P_M and P_{Cl} are the electroconductive permeabilities to metal cation and chloride ion, respectively. Electrochemical properties of the membrane system are described by use of the electroconductive membrane permeability:

$$\begin{aligned} I &= -ZFP_M[a_M^{II} \exp(ZFV/2RT) - a_M^{I} \exp(-ZFV/2RT)] \\ &\quad + FP_{Cl}[a_{Cl}^{II} \exp(-FV/2RT) - a_{Cl}^{I} \exp(FV/2RT)] \\ &= -t_M G_m(V - V_M) - t_{Cl} G_m(V - V_{Cl}) \quad (3) \\ &= -G_m(V - V_0) \end{aligned}$$

$$V_0 = t_M V_M + t_{Cl} V_{Cl}, \quad (4)$$

where I is the electric current across membrane, G_m is the membrane conductance, t is the transport number, and V_0 is the membrane potential in absence of membrane current; V_M and V_{Cl} are the Nernst equilibrium potentials for metal cation and chloride ion, respectively. Therefore, the electroconductive membrane permeabilities, P_M and P_{Cl}, are calculated by the next equations with the membrane potential and conductance data:

$$P_M = \frac{t_M G_m RT}{Z^2F^2(a_M^{I}a_M^{II})^{1/2}} \frac{ZF(V - V_M)/2RT}{\sinh[ZF(V - V_M)/2RT]}$$

$$P_{Cl} = \frac{t_{Cl} G_m RT}{F^2(a_{Cl}^{I}a_{Cl}^{II})^{1/2}} \frac{-F(V - V_{Cl})/2RT}{\sinh[-F(V - V_{Cl})/2RT]}. \quad (5)$$

The electroconductive permeability having a dimension of cm s^{-1} represents an electrically migrating speed of ions across the membrane phase and indicates a measure of the membrane permselectivity to ions.

Calculated results of these conductive permeabilities to metal cations and chloride ions are given in Figs. 3 and 4. In Fig. 5, the metal cation to chloride ion permeability ratios are plotted as a function of electrolyte activity in phase I. As expected from the membrane potential data, the conductive membrane permeabilities to chloride ions, P_{Cl}, exceeded those of cations, P_M. In the present study, the order of conductive membrane permeabilities to ions are as follows: $P_{Cl}(Ca^{2+},Sr^{2+}) > P_{Cl}(Na^+,K^+) \geq P_K > P_{Na} > P_{Ca},P_{Sr}$. These results may not be caused by unbalanced distribution of cationic and anionic exchange groups, since the membrane preparation processes are controlled to minimize the salt rejection rate and, accordingly, the capacity ratio is close to unity (see experimental section and Refs. 13 and 14). Furthermore, P_{Cl} also exceeded P_M even in 2-1 electrolyte systems in which cations seem to interact more strongly with fixed charges. Physical meanings of the electroconductive membrane permeabilities, P_M and P_{Cl}, are expressed as:[16,18,19]

$$P_M = \frac{RT\bar{U}_M}{\delta} \frac{\bar{C}_M}{(a_M^{I}a_M^{II})^{1/2}}, \quad P_{Cl} = \frac{RT\bar{U}_{Cl}}{\delta} \frac{\bar{C}_{Cl}}{(a_{Cl}^{I}a_M^{II})^{1/2}}, \quad (6)$$

where $\bar{U}$ and $\bar{C}$ are the integral average values of ionic mobility and concentration within membrane of thickness of δ. Membrane potential is expressed as a function of the permeability ratio[18] and the biphasic response observed in the KCl system seems to be due to the concentration dependent change in $\bar{U}_K$ and $\bar{U}_{Cl}$, since it is reasonable to consider $\bar{C}_K$ is nearly equal to $\bar{C}_{Cl}$. The permeability ratios, namely the relative membrane permeabilities, seem to decrease with the

increasing cationic size. The ratios of hydrated ionic radii of metal cations to chloride ion are as follows: Na^+/Cl^-, 1.08; K^+/Cl^-, 1.00; Ca^{2+}/Cl^- and Sr^{2+}/Cl^-, 1.24. Thus it is suggested that the ionic size plays an important role to determine the ionic transport characteristics of amphoteric membrane.

Ion exchange membranes capable to separate ions of opposite charges have been practically used in various fields. It is also possible to exclude multivalent ion permeations by means of the membrane surface finishing with polyionic substances as in the case of ion exchange membranes selective to univalent ions used for the desalination processes. Further studies to improve the ionic selectivity of membranes and to aim at the perfect separation of two ions have been extensively continued. One possible way to realize the higher ionic selectivity is to introduce the exchange groups which can interact with specific ions, and the other is to apply the sieve effects to discriminate ionic sizes. The sieve effects are typically illustrated in the membrane systems having antibiotics and crown compounds as ionophores.[20,21] Even in case of the usual uniform ion exchange membrane, there exists indeed a difference in permeability to ions of the same charge determined by ionic mobility and concentration within membrane (see Eq. 6); however, the uniform ion exchange membrane is not so selective to generate the different membrane potential responses to each ionic species. It is the most noticeable difference between uniform and amphoteric ion exchange membranes with high charge densities that potential responses of the former are expressed by the Nernst relation characterized by the number of ionic charges, while those of latter are strongly affected by ionic size effects.

The transport mechanisms of amphoteric ion exchange membrane in which both cationic and anionic exchange groups are homogeneously dispersed within membrane phase seem to differ from those of mosaic membrane in which both the exchange groups form blocks of respective charges. Eguchi *et al.* suggested that salt permeation processes across the 1.0-PA-29 membrane are not controlled by coupling flow mechanisms which are remarkable features of the charge-mosaic membrane and they concluded that the analysis based on the mosaic model cannot be applicable to the present membrane.[14]

The present results indicate that the number of ionic charge is not a dominant factor to determine the ionic transport characteristics across the amphoteric ion exchange membrane. On the other hand, the membrane potentials, as a fundamental transport property, of usual polymeric ion exchange membrane with the same fixed charges, either the cationic or anionic exchange type, depend completely upon the number of ionic charge of permeant ions, and accordingly it is very difficult to endow a permselectivity to ions with the same charge. The 1.0-PA-29 amphoteric ion exchange membrane exhibits a possibility to discriminate Na^+ from K^+ as indicated in the membrane potential data and the permeability values. The origin of these permselectivities of amphoteric ion exchange membrane would be based on the discrimination of the hydrated radius of permeant ion. The effects of ionic size on transport characteristics, namely the sieve effect, across amphoteric ion exchange membrane are more clearly illustrated by the experimental results using symmetric tetraalkylammonium salts, which will be reported in the following communication. These transport characteristics of amphoteric membrane may be partly involved in the functions of biological membrane having a steep ionic selectivity, although the specific proteinic substances are known to control the complex and delicate ion transport mechanism.

We thank members of Central Research Laboratory of Kanegafuchi Chemical Industry Co., Ltd., especially Dr. Tamiyuki Eguchi for preparing and supplying the amphoteric membrane used in this work. This work was supported in part by a Grant-in-Aid for Scientific Research from the Ministry of Education, Science and Culture.

The Photoreduction and Photosensitized Reduction of Dyes Bound to a Surfactant Micellar Surface

Yoshiharu Usui* and Kazuhiko Saga
Department of Chemistry, Faculty of Sciences, Ibaraki University, Bunkyo, Mito 310
(Received January 26, 1982)

The photochemical reduction of thionine(Th) and Methylene Blue(MB) bound to anionic sodium dodecyl sulfate(SDS) micelles in an aqueous solution was inhibited at the lower concentration range of a reductant anion, EDTA, because of the electrostatic repulsion between the micelles and the reductant. The concentration dependence of EDTA on the quantum yield of photoreduction has shown to be, anomalously a sigmoidal type: this is explained by mechanistic interpretation based on the cooperative effects of the ionic strength and the essential concentration of EDTA. The enhancement effect for the quantum yield of the photoreduction of eosine bound to a cationic micelle by the EDTA anion was conversely observed, because of the electrostatic attraction. When 10-dodecyl) (Acridine Orange) was incorporated into SDS micelles in water containing EDTA and ascorbic acid, and the mixture was excited, the photosensitized reduction of MB bound to the micelles occurred. It was found that the quantum yield of the sensitized reduction depended on the concentration of MB and was larger than the yield on the direct excitation of MB.

Mechanistic investigations of photooxidation, photoreduction, and photosensitization in a heterogeneous system such as micelles, vesicles and emulsions, are important from the several points of view regarding photobiological phenomena (photoreception, photodynamic action, *etc.*) and solar-energy utilization, as modefied by the photosynthetic phenomenon. In recent years, an increasing number of such studies have focused on the photochemical and photophysical properties of molecular assembly systems. For example, some specific micellar effects on the properties of the excited state have been investigated and reported for cases of excimer and exciplex formation,[1-4] excitation-energy transfer,[3-6] and electron-transfer phenomena.[3,4,7-9] However, the mechanistic study of the photochemical reaction between the micellar surface and the bulky phase has been rather insufficient in contrast to the many studies at the interior site of a micelle.

Previously, we attempted to study the effect of an anionic reductant, EDTA, on the photoreduction of Methylene Blue bound to sodium dodecyl sulfate micelles, semiquantitatively.[10] The photoreduction was considerably inhibited because of the electrostatic repulsion between the anionic reductant and the micelles. Further, the concentration dependence of EDTA on the quantum yield was shown as a sigmoidal type——a so-called micellar effect. In the present work, we have performed a detailed mechanistic investigation of the micellar effect which was observed on the photoreduction and the photosensitized reduction of organic dyes bound on the surface of ionic surfactant micelles from the standpoint of reaction kinetics.

Experimental

Materials. The thionine ($C_{12}H_{10}ClN_3S$; Th), Methylene Blue ($C_{16}H_{18}ClN_3S$; MB), and Eosine Yellowish ($C_{20}H_6O_5Br_4Na_2$; E) were recrystallized twice from methanol, 1-butanol, and ethanol respectively. The 10-dodecyl (Acridine Orange) ($C_{29}H_{44}N_3Br$; DAO) was prepared as previously described and was purified by means of alumina-column chromatography and recrystallization from a 1 : 1 ether and ethanol mixed solution.[11] The sodium dodecyl sulfate (SDS) was recrystallized twice from methanol. The ethylenediaminetetraacetic acid disodium salt (EDTA) was used without further purification.

Apparatus and Procedure. A degassed sample in a $1\times1\times4$ cm^3 cell was irradiated by means of a steady illumination apparatus with a 300W tungsten lamp at 25 °C. The experimental procedure used to determine the quantum yield of dye-photoreduction was similar to that described previously.[12] Flash-photolysis experiments were carried out by using a pulsed dye laser (Phase-R: 2100B, Dye: G4, FWHM of pulse: $\approx$500 ns) and a monitoring system composed of a monochromator, a transient recorder, and a spectral data-analyser (Union Giken, RA-415).

Results and Discussion

Preliminary investigations of the photoreduction rate of Methylene Blue bound to anionic SDS micelles (MB/S) by EDTA trianion (HY^{3-}) were carried out at pH=8.0. The photoreduction of MB/S by HY^{3-} at a higher concentration proceeded at a rate which was proportional to the light quantities absorbed by the dye with a stationary irradiation. Then, in a way similar to that used for the reaction in an aqueous homogeneous solution, the quantum yield (Φ_{MB}) was determined from the slope of the linear relationship between $\ln(e^A-1)$ and time (A is the absorbance of the dye).[10,13] The reaction was significantly inhibited in a lower concentration range of the reductant, and the concentration dependence of HY^{3-} on Φ_{MB} was shown as a sigmoidal curve (Fig. 1). This inhibition may be supposed to be due to the environmental effect on the micellar periphery, *i.e.*, the so-called micellar effect.[10] In order to check the phenomenon as the electrostatic effect between the ionic micelle and the reductant, a kinetical investigation of the anomalous concentration effect on the photoreduction must be considered in the cases of several combinations of dyes, surfactants, and reductants.

Effect of the HY^{3-} Concentration on the Quantum Yield of Dye Photoreduction. As is shown in Fig. 1, we have observed that the rate of Th by HY^{3-} under the lower concentration at pH=8.0 was considerably retarded by the addition of SDS; *i.e.*, the photoreduction of thionine

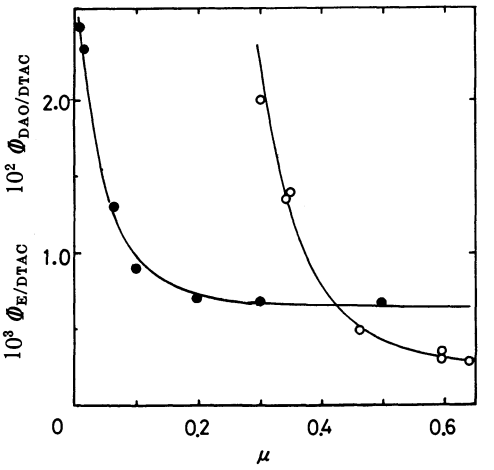

Fig. 3. Ionic strength effect on the photoreduction yield of E/DTAC and DAO/DTAC at a constant concentration of EDTA.
●: [E]=10 μM, [DTAC]=20 mM, $[HY^{3-}]$=10 mM, ○: [DAO]=5 μM, [DTAC]=25 mM, $[HY^{3-}]$=10 mM. (NaCl was used for adjustment of μ.)

bound to SDS micelles (Th/S+HY^{3-} system) is inhibited just as the case of the MB/S+HY^{3-} system.[10] On the contrary, the photoreduction of Eosine Y (E) by HY^{3-} was enhanced by binding to an oppositely charged cationic micelle of dodecyltrimethylammonium chloride (DTAC) at the lower concentration of HY^{3-} of 1.0×10^{-4}M (1 M=1 mol dm^{-3}): *i.e.*, the quantum yield for E/DTAC photoreduction was 5.5×10^{-3} at [DTAC]=30 mM and pH=8.0, and five times larger than the value without DTAC. Although the photoreduction occurs *via* electron transfer between a bound triplet dye and HY^{3-} because there is no fluorescence quenching of the bound MB/S by HY^{3-}, the observed decay constant (1.2×10^{5} s^{-1}) of the triplet dye bound to the micelles of 2×10^{-4} M was scarcely affected by the addition of HY^{3-} in the lower-concentration range, thus exhibiting the inhibition of photoreduction shown in Fig. 1. The fluorescence of Methylene Blue and thionine bound to anionic SDS micelles is scarcely quenched by adding 0.36 M of $S_2O_3^{2-}$ or 0.1 M of SCN^- anion, which quench these dyes efficiently in an aqueous solution.[10] Judging from the above results, it seems that the reaction of triplet dyes with HY^{3-} was inhibited because of the electrostatic repulsion between the anionic SDS micelles and the reductant anion, HY^{3-}.

Effect of the Ionic Strength on the Photoreduction Yield. With the concentration of dye and HY^{3-} fixed at 10 μM and 5 mM respectively, the effect of the ionic strength (μ) on the quantum yield of the photoreduction of dye was investigated over the wide range of $0\lesssim\mu\lesssim1$. Figure 2 shows that $\Phi_{Th/S}$ or $\Phi_{MB/S}$ tends to the constant value of a maximum yield with μ : *i.e.*, there is a positive μ-effect. In order to confirm that a neutral salt effect for the electrostatic repulsion between HY^{3-} and triplet Methylene Blue or thionine bound on an anionic SDS micelle is responsible for the positive μ-effect, we tried to produce a μ-effect on the system of E/DTAC+HY^{3-}. Interference with the electrostatic attraction force between HY^{3-} and a cationic DTAC micelle fixing triplet eosine, *i.e.*, a negative μ-effect was observed during the reaction (Fig. 3). A comparison of the results shown in Figs. 2 and 3 shows that these remarkable opposite effects support the idea that the μ-effect on the electrostatic interaction between the micelle ion and

the HY^{3-} anion is very sensitive to the yield of photoreduction.

$\Phi_{Th/S}$ value around $\mu=0.8$ at $[HY^{3-}]=5$ mM in Fig. 2 is smaller by a factor of ten than the yield of thionine reduction obtained in an aqueous homogeneous solution at $\mu=0.8$, and also smaller than the yield at the concentration of HY^{3-} of 0.16 M in a micellar solution where the calculated ionic strength relative to EDTA is 0.80. Thus, it may be supposed that both the HY^{3-} concentration and ionic strength of the reductant affect the yield of photoreduction in a Th/S+HY^{3-} or MB/S+HY^{3-} system. Also, the μ-effect on the photoreduction of 10-dodecyl (Acridine Orange) (DAO) dissolved in cationic DTAC micelles with HY^{3-} was performed where the DAO was anchored in the micelles. As is shown in Fig. 3, a μ-effect on the yield similar to that in the case of E/DTAC+HY^{3-} system was observed, but the effective values of μ were larger than the case of the photoreduction occurring on the micellar surface (the E/DTAC+HY^{3-} system).

Effect of the HY^{3-} Concentration on the $\Phi_{Th/S}$ under a Constant Ionic Strength. In a degassed aqueous solution of Th and HY^{3-}, the effect of the HY^{3-} concentration on the yield of the photoreduction was checked. The Φ_{Th} increased with the HY^{3-} concentration and tended to constant saturation value. A fairly linear relationship of $1/\Phi_{Th}$ against $1/[HY^{3-}]$ was obtained. Judging from the kinetical results and the results of an investigation previously reported,[10,13,14] the following scheme and equation of Φ_{Th} can be obtained:

$$Th \xrightarrow{h\nu} {}^1Th^* \xrightarrow{\phi_{st}} {}^3Th + EDTA \longrightarrow \begin{cases} Th^- + EDTA^+ \ (k_e^r) \\ Th + EDTA \ (HY^{3-}) \end{cases} k_e^s$$

$$\Phi_{Th} = \frac{\phi_{st} k_e^r [HY^{3-}]}{k_d' + k_e^s [HY^{3-}]} \qquad (1)$$

The k_e^r and k_e^s values were obtained from the plot of Φ_{Th}^{-1} *vs.* $[HY^{3-}]^{-1}$ to be 2.3×10^8 mol^{-1} dm^3 s^{-1} and 2.8×10^8 mol^{-1} dm^3 s^{-1} respectively, using ϕ_{st} (0.55) and k_d' (8.0×10^4 s^{-1}) values.[14,15]

In the case of the Th/S+HY^{3-} system, at a constant ionic strength of 0.1 or 0.8, the dependence of $\Phi_{Th/S}$ on the concentration of HY^{3-} shows not the sigmoidal curve, but the usual saturation-type one as was checked in an aqueous solution. The results are expressed as a linear relationship between $1/\Phi_{Th/S}$ and $1/[HY^{3-}]$ in Fig. 4. By analogy with the kinetical treatment for the data obtained in the MB/S+HY^{3-} system,[10] $\Phi_{Th/S}$ can be tentatively expressed at a constant μ as follows:

$$\Phi_{Th/S} = \frac{\phi_{st} k^r [HY^{3-}]_s}{k_d + k^s [HY^{3-}]_s} = \frac{\phi_{st} k^r A(\mu) [HY^{3-}]}{k_d + k^s A(\mu) [HY^{3-}]}, \qquad (2)$$

where the HY^{3-} concentration on the surface of a micelle, $[HY^{3-}]_s$, is assumed to be proportional to the concentration of HY^{3-} added, *i.e.*, $[HY^{3-}]_s = A(\mu)[HY^{3-}]$. $A(\mu)$ is a constant, depending on the ionic strength of the solution. The intersystem crossing probability, ϕ_{st}, of Th/S is assumed to be the same (0.55) as that in an aqueous solution referring in the case of MB/S photoreduction.[10] k_d is the decay constant of the bound triplet dye. k^r and k^s are the reaction and quenching-rate parameters respectively for the reaction of triplet dye with HY^{3-} on the surface of a micelle. From the values of an intercept of the line in Fig. 4 and the ϕ_{st} value of Th, the reactivity ratio, k^r/k^s for Th bound with HY^{3-} was obtained as 0.06 at a constant μ value of 0.1; this is smaller than the value (0.83) in an aqueous solution. At a constant μ value of 0.8, k^r/k^s equals 0.7—1.0, which is comparable to the value obtained in an aqueous solution. Judging from the finding that the value of the degree of the fluorescence depolarization, P (0.24) of thionine at $\mu=0.8$ was almost the same as the value at $\mu=0.1$, it was supposed that the molecular rotation of the dye was still restricted and that the dye was bound to the micelles even at such a high ionic strength as 0.80 ($P=0.095$ in an aqueous solution). Therefore, the micellar effect of the inhibition for the photoreduction might be responsible for the decrement in the k^r/k^s value as a parameter for the reactivity ratio of the bound dye. Incidentally, the concentration effect of HY^{3-} on $\Phi_{Th/S}$ did not obey any relationship such as Eq. 2 at a given concentration of electrolytes.

Kinetic Analysis for $\Phi_{Th/S}$ Values from the Ionic-strength Effect. As for the kinetic treatment of the intramicellar photochemical processes, several theoretical considerations have been given.[9,16–21] Mostly, these studies have dealt with the reaction between molecules

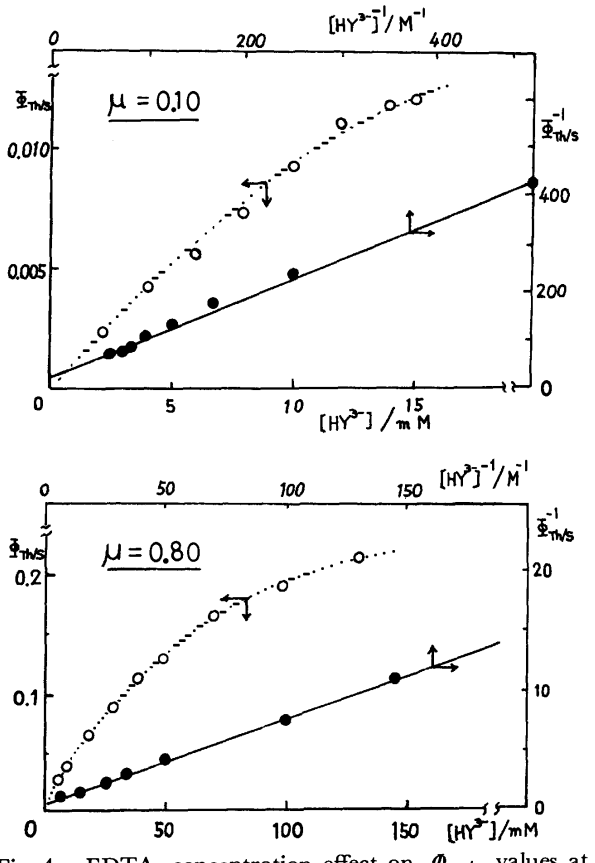

Fig. 4. EDTA concentration effect on $\Phi_{Th/S}$ values at constant μ of 0.1 and 0.8. [Th]=10 μM, [SDS]=20 mM, pH=8.0.

or ions which are located on a micellar surface or at the micellar interior. In our systems, the treatment for the positional situation should be considered as that of the reaction of excited dye bound on the Stern layer or the outer layer (Gouy-Chapman layer) of an ionic micelle with HY^{3-} located in the aqueous bulk phase. Further, from the standpoint of the quantitative explanation of the anomalous effects on the photoreduction yield, it can not yet be decided how much these theoretical models suggested for the reactions on the micelle are applicable to the present situation of the systems.

Thus, for the reaction molecules far from a micellar surface, we attempted to use the well-known model of the electrostatic interaction introduced by Debye and Hückel. Since a spherical micelle is held at $\mu \lesssim 0.4$ at the dilute solution of SDS ($\approx$10 mM. CMC is 8.1 mM), let us assume approximately that such a deformation of the micelle occuring at $\mu > 0.4$ does not affect on the following kinetic treatment.[22] Then, the distribution of HY^{3-} at a distance, r, apart from a center of the charged micelle under a given ionic strength, μ, is denoted as $n_Y(r,\mu)$, which means the number of molecules per cm^3, and it is expressed by the Boltzmann equation, using the Debye-Hückel's theory. At an infinite ionic strength, $n_Y(r,\mu)$ is denoted as $n_Y(r,\infty)$, in which the value of the number on HY^{3-} ions in the bulk phase, n_{Yb}, can be taken as approximately equal, because the electrostatic repulsion is negligible at an infinite ionic strength when a large amount of electrolytes is added, *i.e.*, this is the neutral salt effect. This means that $n_Y(r,\mu)$ converges to n_{Yb} according to the following Boltzmann equation upon an increase in r or μ to infinity:

$$n_Y(r,\mu) = n_{Yb} \exp(-eZ\Psi/kT), \tag{3}$$

where Z indicates the charge number and where the following potential, Ψ, obeys the well-known Poisson-Boltzmann equation:

$$\Psi = \frac{Ze}{4\pi\varepsilon r} \exp(-\sqrt{\beta} r) \tag{4}$$

$$\beta = 2 \times 10^3 N_A e^2 \mu / \varepsilon kT.$$

[Abbreviations: Ze-central charge, ε-dielectric constant, N_A-Avogadro number, k-Boltzmann constant, T-absolute temperature] Denoting the HY^{3-} concentration at the distance (r_{Th}) of the Th binding site on the surrounding micelle as $[HY^{3-}]_{Th}$, the relation of $[HY^{3-}]_{Th}$ with $A(\mu)$ in Eq. 2 can be written as:

$$[HY^{3-}]_{Th} = \left(\frac{n_Y(r_{Th},\mu)}{n_{Yb}}\right)[HY^{3-}] \equiv A(\mu)[HY^{3-}]. \tag{5}$$

Using Eq. 5, $\Phi_{Th/S}$ can be expressed approximately as Eq. 6 at a lower concentration of HY^{3-} from Eq. 2;

$$\Phi_{Th/S} \approx \frac{\phi_{st} k^r}{k_d}[HY^{3-}]_{Th} = \frac{\phi_{st} k^r A(\mu)}{k_d}[HY^{3-}]. \tag{6}$$

When the electrostatic potential, Ψ, on the surrounding micelles becomes small at a long distance of r, the treatment by the Debye-Hückel theory can be performed for the following evaluation.[23,24] When $eZ\Psi < kT$, the Ψ of Eq. 3 satisfies the Poisson-Boltzmann equation; a similar treatment is also possible for the cases on an ionic sphere of macromolecules. Using Ψ in the $n_Y(r,\mu)$-Boltzmann equation, the correlation of $n_Y(r,\mu)$ with μ is given as follows:

$$n_Y(r,\mu) = n_{Yb} \exp(-Ae^{-\alpha\sqrt{\mu}}), \tag{7}$$

where $A = Ze^2/4\pi\varepsilon rkT$ and $\alpha = r\sqrt{2\times 10^3 N_A e^2/\varepsilon kT}$.

The charge number of micelles was estimated from the product of the aggregation number of SDS (62) and the fraction of charge (0.17).[25] Putting the charge numbers of HY^{3-} and micelles as $-3e$ and $-10e$ respectively, the numerical values of A and α are $210r^{-1}$ and $0.325r$ at a given parameter of the distance, r. $A(\mu)$ defined in Eq. 5 can be calculated as the function of μ from the $n_Y(r,\mu)/n_{Yb}$ ratio in Eq. 7. Further, for the observed ionic strength effect on $\Phi_{Th/S}$, the dependence of $\Phi_{Th/S}$ on μ can be compared with that of $A(\mu)$ on μ, normalizing the $A(\mu)$ value to $\Phi_{Th/S}$ at a given parameter, r, because $\Phi_{Th/S}$ is proportional to $A(\mu)$, as is shown in Eq. 6. The correlation of the μ-effects on both $A(\mu)$ and $\Phi_{Th/S}$ is investigated in the region of r=10—30 Å; the degree of coincidence is shown in Fig. 5. The figure shows that the correlation is fairly good around r=18—20 Å, about three times of the micellar radius;[25] *i.e.*, it is shown to be the thionine binding position where the bound triplet dye will react with HY^{3-}. For the case of MB/S+HY^{3-}, the similar results are obtained, as is shown in Fig. 5.

In the plots of $\Phi_{Th/S}$ against μ in Fig. 5, $\Phi_{Th/S}$ is taken as a function of μ at a given concentration of HY^{3-}, *i.e.*, $\Phi_{Th/S}(\mu)$. Putting the ratio of $\Phi_{Th/S}(\mu)$ to the normalized quantum yield, $\Phi_{Th/S}(\mu)_N$, as $\gamma(\mu)$, *i.e.*, $\gamma(\mu) = \Phi_{Th/S}(\mu)/\Phi_{Th/S}(\mu)_N = A(\mu)/A(\mu)_N$, the relation of $[HY^{3-}]_S = A(\mu)[HY^{3-}] = \gamma(\mu)A(\mu)_N[HY^{3-}]$ can be obtained. Thus, the quantum yield given in Eq. 2 can be written as:

$$\Phi(\mu) = \frac{\phi_{st} k^r \gamma(\mu)[HY^{3-}]}{(k_d/A(\mu)) + k^s \gamma(\mu)[HY^{3-}]}. \tag{8}$$

The $\gamma(\mu)$ factor indicates a correction for the ionic strength by the HY^{3-} anion itself. Now, estimating the $\gamma(\mu)$ value from Fig. 2 at the ionic strength corresponding

a) Concentrations of HY^{3-} examined in Fig. 1. b) $\gamma(\mu)$ was estimated from the μ-effect in Fig. 2 at the μ-values corresponding to the HY^{3-} concentrations in column a). c) Quantum yields observed in Fig. 1 at the concentration in column a). d) Calculated quatum yields from Eq. 9 (see text).

to the HY^{3-} concentration which were examined in the experiment on the HY^{3-}-concentration effect on $\Phi_{Th/S}$, and calculating the vaue of $\gamma(\mu)[HY^{3-}]$, we can plot $1/\Phi(\mu)$ against the $1/\gamma(\mu)[HY^{3-}]$ values. Since the linear relationship was observed for the double reciprocal plots, the following numerical equation can be written by using the values of the slope and intercept:

$$\Phi(\mu) = \frac{\gamma(\mu)[HY^{3-}]}{0.36+1.8\gamma(\mu)[HY^{3-}]}. \quad (9)$$

On the other hand, by multiplying the correction factor $\gamma(\mu)$ by the values of $[HY^{3-}]$, which are examined in Fig. 1, we can compare the values of the quantum yield with that observed for the HY^{3-} concentration effect, as is shown in Table 1, where a fair coincidence of both the numerical equation 9 and the observed yield is obtained. Thus, since the quantum yields were quantitatively evaluated by the correction of the ionic strength upon the concentration effect of HY^{3-}, the relationship between the calculated $\Phi_{Th/S}$ values in Table 1 and the concentration of HY^{3-} can be shown as the sigmoidal curve in Fig. 1 (dotted line), and the cooperative effect of the HY^{3-} concentration and the ionic strength on the photoreduction for the micellar system can be considered to hold, judging from the agreement between the calculated curve and the observed values shown in Fig. 1.

Photoreduction of 10-Dodecyl (Acridine Orange), DAO in Micelles by HY^{3-}. DAO is a little soluble in water and is likely to be incorporated into SDS micelles. From an eye to comparing a micellar effect on the photoreduction with the different binding situation of dyes, the effects of HY^{3-} concentration and ionic strength were investigated in the cases of the DAO/S or DAO/DTAC+HY^{3-} systems.

The photoreduction of DAO/S by HY^{3-} was not observed either at a high ionic strength (0.6) or at a high concentration of the reductant (200 mM). For the DAO/DTAC+HY^{3-} system, the photoreduction yield (Φ_{DAO}) in the micellar solution was found to be about 5 times larger than that in a mixture of 30% ethanol and water ($[HY^{3-}]=10$ mM). Such an enhancement was also observed to a considerable extent in the case of the E/DTAC+HY^{3-} system because the electrostatic attraction between the cationic micelles and the HY^{3-} anion was more effective on the surface. Since the DAO/DTAC fluorescence quenching by added bromide ions increased about thirty times over that for the mixture of 30% methanol and water, the Acridine Orange chromophore must be located near the surface in a micellar particle. It was considered that the efficient quenching was due to the electrostatic attraction between the micelle and the bromide ion.

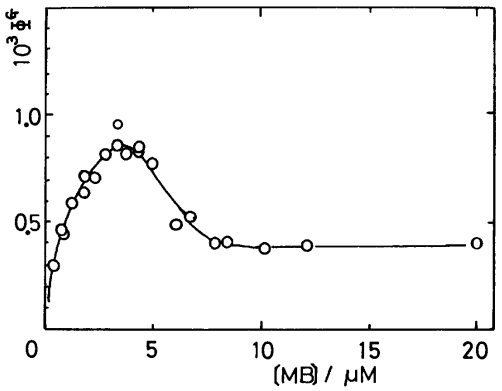

Fig. 6. Concentration effect of Methylene Blue on 10-dodecyl (Acridine Orange)-sensitized reduction yield Φ^G. [DAO]=8 μM, [SDS]=8 mM, $[HY^{3-}]=10$ mM.

When the ionic strength effect on Φ_{DAO} was compared to that in the case of the E/DTAC+HY^{3-} system, as is shown in Fig. 3, a decreasing effect on Φ_{DAO} by μ was observed in the higher region of 0.3—0.5, where the effect reached saturation in the case of the E/DTAC+HY^{3-} system. This result might be caused by the different position of the binding site of these dyes. At a constant μ, the effect of the HY^{3-} concentration on Φ_{DAO} was analysed by holding the linear relationship between $1/\Phi_{DAO}$ and $1/[HY^{3-}]$. Thus, it was confirmed that the results could also be explained by Eq. 8 in the case of the DAO/DTAC+HY^{3-} system.

Photosensitized Reduction of Methylene Blue by 10-Dodecyl (Acridine Orange) in SDS Micellar Solution. When DAO was incorporated into MB/S micelles (DAO/S/MB) and was excited, the photosensitized reduction of the MB bound at the surface by HY^{3-} occurred. The quantum yield of the sensitized reaction, Φ^G, depends on the MB concentration and is larger than that of the direct excitation of MB, Φ_R at the optimal concentration region, as is shown in Fig. 6. At the higher concentrations of MB over 10 μM, the quenching of DAO fluorescence by MB becomes considerable, involving the phenomenon of the DAO-sensitized fluorescence of MB *via* the dipole-dipole interaction (Förster mechanism), as has been reported previously.[5] If triplet MB can be formed from the singlet-excited state of MB produced by the singlet energy transfer on the micelles, the quantum yield of the photoreduction, Φ^G, must be smaller that that by the direct excitation of MB as a part of the

efficiency of the energy transfer. When the decrement at a higher concentration of MB in Fig. 6 is due to the contribution of the singlet energy transfer, the sensitized reaction mechanism can be discussed from the stand-points of both singlet and triplet energy transfer between DAO and MB on the micelles. The DAO-sensitized reduction of MB by ascorbic acid as a reductant also occurred in a homogeneous solution and more efficiently in a DAO/S/MB micellar solution ($\Phi^{G}_{max} \simeq 0.1$, pH=3.0). Similarly, the quantum yield of the sensitized reduction of DAO/S/MB depended on the concentration of MB and was larger than that of the direct excitation of MB bound in micelles. By laser-flash photolysis it was found that triplet DAO was rapidly quenched by the MB on the micelles. The observed decay constant of triplet DAO in micelles is $9.5 \times 10^2\ s^{-1}$ without MB and $1.4 \times 10^4\ s^{-1}$ with MB (5 μM), at pH=6.2. This may suggest that the increase in the yield Φ^{G} in the lower-concentration region of MB is responsible for the triplet energy transfer from DAO to MB. Further mechanistic investigations are required to elucide the reason why the value of Φ^{G} is larger than that of Φ^{R} in the micellar system.

Glass Formation in the HI + Water System

Yoshifumi AKAMA and Hitoshi KANNO*
Department of Chemistry, Meisei University, Hino, Tokyo 191
(Received February 12, 1982)

Glass transition temperature (T_g) of aqueous HI solution was measured as a function of HI concentration. The T_g data of aqueous HI solution suggest an anomalously low T_g value for glassy bulk pure water. Double-glass-transition phenomenon is observed at the water-rich edge of glass-forming composition range.

Recent papers of Angell *et al.*[1,2] and of Lesikar[3-5] have shown that the glass transition temperature (T_g) can be a useful diagnostic tool for clarifying various thermodynamic properties of solutions. In addition, there is gathering evidence[6-8] that spectroscopic and structural studies of aqueous solutions in the glassy state can give unique information unobtainable from investigations at ordinary temperatures, *e.g.*, Kanno and Hiraishi[8] have recently showed that unambiguous detection of low frequency Raman bands, which are hidden or obscured by the strong Rayleigh scattering wing in a Raman spectrum for the liquid state, becomes possible in a Raman spectrum for the glassy state. Therefore, accumulation of glass formation data for various aqueous solutions should be worthwhile as the first step for adding aqueous solutions in the glassy state to our objectives of solution chemistry.

In this study, the glass formation of the HI+water system was investigated as a function of HI concentration. As iodide ion is a typical structure breaker and HI is a structurally simple acid, glass formation data of this system will be useful to see effects of various factors (*e.g.*, ionic radius, structure making or breaking properties of ions) on the glass-forming ability of aqueous solutions.

Experimental

Sample of hydriodic acid with various concentrations were prepared from an encapsulated 57 wt% HI aqueous solution and distilled water by simple mixing of the required amounts of them. Sample solutions got colored with pale yellow due to slight decomposition of HI soon after the mixing. T_g measurements were usually made within an hour after sample preparation. As the sample solution left standing for 2 d gave the same T_g value as the one obtained immediately after the preparation, we concluded that the trace of HI decomposition has a negligible effect on the glass formation and T_g value to the sample.

A sample solution (*ca.* 0.05 ml) in a 2 mm diameter Pyrex glass tube, in which an alumel-chromel thermocouple junction was inserted, was vitrified in liquid nitrogen. The overall cooling rate was about 1000 K/min. A simple differential thermal analysis technique was used to measure T_g.[1] Benzene was used as the reference material, and the temperature difference between the vitrified sample and the reference was recorded together with the temperature of the quenched sample. T_g and T_c (crystallization temperature) values were taken to represent the onset of transition as shown in Fig. 2. DTA measurements were carried out at a heating rate of about 5 K/min in the glass transition temperature region. T_g values were found to be reproducible in this study to within 0.5 K and the accuracy of temperature reading is estimated to be ± 1 K from a determination of melting points of several guaranteed grade reagents (absolute ethanol, acetone, and chloroform). Quenched samples were checked for crystallinity by visual inspection. Any incompletely vitrified samples were associated with loss of transparency. Visual inspection showed that the glass-forming composition region of HI+water system ranges from *ca.* 40 to 57% (wt% HI). The upper limit of the glass-forming composition range was not well established because of the non-availability of higher HI concentrations (>57%) in this study. The glass transition was also observed for incompletely vitrified samples, and this arises from the fact that the residual portion which remains uncrystallized in the quenching process becomes a glassy state.

Results and Discussion

The results of T_g and T_c are shown in Fig. 1 together with the phase diagram of the HI+H_2O system as an inset. It is clearly seen that the solution near the first eutectic composition is prone to supercooling to a vitreous state. This tendency is in accordance with many other binary systems.[1,9-11] In fact, most liquid mixtures which have glass-forming composition regions are usually glass-forming at the first eutectic composition.

In the glass-forming composition region of aqueous HI solution, T_g increases almost linearly with increase in HI concentration, ranging from -140 ± 1 °C at 40 wt% HI to -124 ± 1 °C at 57 wt% HI. Simple linear composition dependence of T_g is usually observed for a nearly ideal solution.[6] With this system, we may regard the solution as an ideal or quasi-ideal solution of water and $HI\cdot4H_2O$. A simple least-square curve fitting yields the following formula for the concentration dependence of T_g:

$$T_g = 0.91X - 177, \quad (1)$$

where X is concentration of HI in wt% and T_g in °C.

The estimation of T_g for a pure non-glass-forming liquid from T_g data of binary mixtures by extrapolation is now well established and the T_g values estimated give concordant results.[2,4] Rasmussen and MacKenzie[12] measured glass transition temperatures of several binary aqueous solutions: water+methanol, water+glycerol, and water+ethylene glycol. The extrapolation of the obtained T_g data to pure water gives -137 ± 2 °C as the T_g of glassy bulk water. Angell and Sare[1] also gave a similar value from studies of a large number of aqueous electrolyte solutions. This value is almost identical with the glass transition temperature (−139 °C) obtained[13] for an amorphous solid water made by the vapor deposition method. All these data, therefore, suggest that T_g of bulk pure water will be very close to −138 °C if a glassy bulk water is successfully formed

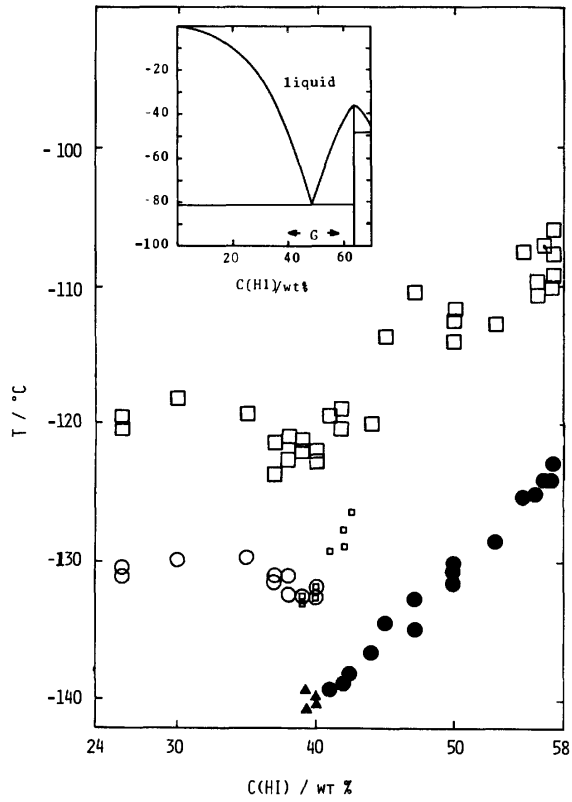

Fig. 1. Variation of T_g and T_c as a function of HI concentration (C). The inset shows the phase diagram of the HI+H_2O system [from: J. Timmermans, "Physico Chemical Constants of Binary Systems," Interscience Publishers, Inc., New York (1960), Vol. 4, p. 466].

and subjected to T_g measurement. However, it is interesting to note that Eq. 1 predicts T_g of glassy bulk pure water to be −177 °C, far below the T_g value (−138 °C) expected from other data.[1,12,13]

There have been a few interesting observations[14,15] which might offer a clue to clarifying this anomalously low T_g value. In a recent positron annihilation study of a γ-irradiated ice, Eldrup[14] reported that mono-vacancies produced by γ-irradiation become mobile at −175±5 °C. Another suggestive coincidence, though it might be merely accidental, is that the glass transition in a glassy crystal ice, which is claimed to be associated with proton disorder in the ice crystal,[15] occurs at −173 °C. In addition, the T_g values so far reported for the vapor deposited amorphous ice and glassy bulk water scatter from −170 to −120 °C,[15] although recent data are clustering around −138±2 °C. We cannot, at present, give any clear-cut explanation to this low T_g (−177 °C) expected from a simple extrapolation based on Eq. 1 for the glassy bulk water. However, we conjecture, though rather intuitively, that hydronium ions stabilized in the glassy HI solution may be responsible for this low T_g. In fact, the T_g data of HX solutions (X=F, Cl, and Br)[16] also predict that the glass transition of a glassy bulk water should be lower than −139 °C. Furthermore, a recent finding of polymorphism of amorphous ice[17] adds a new possibility and complication to a clear-cut explanation. The T_g measurement on a high density amorphous ice will be very valuable in clarifying this situation.

Another interesting feature in the glass formation of the HI+water system is the observation of the double glass transition phenomenon at both boundaries of the

glass-forming composition range. In the water-rich side of the glass-forming boundary, thermal effect of the first glass transition grows with increase in HI concentration and the two glass transitions gradually merge into a single large glass transition around 42 wt% HI (see (b), (c), and (d) DTA curves in Fig. 2).

As it is difficult to see clearly the second glass transition in the DTA traces shown in Fig. 2, we carried out the following additional experiment to confirm that there are really two glass transitions in these DTA traces: just after recording the first T_g and T_c curves as usual in the first run, the sample was requenched to the liquid nitrogen temperature and then a DTA trace was recorded again. The schematic DTA traces thus obtained are shown in Fig. 3, where we clearly see the second glass transition in the second warm-up DTA trace. This phenomenon reflects the phase separation in the supercooled solution. However, it is difficult at present to determine whether the observed double glass transition is a reflection of a "real" liquid-liquid immiscibility or of a simple pseudo-phase separation produced in the process of vitrification.

The first phase-separated portion, which is very unstable in the liquid state as evidenced by its immediate crystallization after the first glass transition in the warm-up DTA trace, is considered to be a water-rich phase because the T_g and T_c values of the other phase-separated portion are very close to those of the solution with the eutectic composition. Therefore, the phase separation must be described as: the solution → a water-rich phase+a phase of eutectic composition. The closeness of T_g of the water-rich phase to that of a vapor-deposited amorphous ice indicates that the composition of the water-rich phase should be very close to pure water.

The fact that the double glass transition phenomenon in aqueous solution has been observed only at the edge of the glass-forming composition region, seems to suggest that the phenomenon is associated with a metastable immiscibility. Two mechanisms have been postulated for the phase separation in supercooled solutions and glasses.[18,19] The invariance of the concentration of one phase (the phase of eutectic composition) in the phase-separated glasses in this study indicates that the observed phase separation in the $HI+H_2O$ system is due to the nucleation and growth mechanism.

It is to be noted here that there have been several attempts to detect a possible liquid-liquid immiscibility in the $LiCl+H_2O$ system at low temperatures and normal pressure.[20-22] Despite of two positive reports,[20,21] recent works have given rather a negative view for phase separation in the $LiCl+H_2O$ system.[22]

In contrast to the good reproducibility of the two-glass-transition phenomenon in the water-rich side of the glass-forming composition range, the double glass transition phenomenon in the vicinity of *ca.* 57 wt% HI solution is not good in reproducibility; even the sample which has shown two glass transitions in the first run does not necessarily give two glass transitions in the second run. Therefore, this "seemingly two" glass transition may not be due to phase separation. As the quenched sample is translucent, we come to conclude that it is in an incomplete glassy state and is not a phase-separated glass. It may be considered that the rearrangement motion of micro-crystals in the quenched sample is the cause for the second T_g-like heat anomaly in the DTA trace though no detailed mechanism is known.

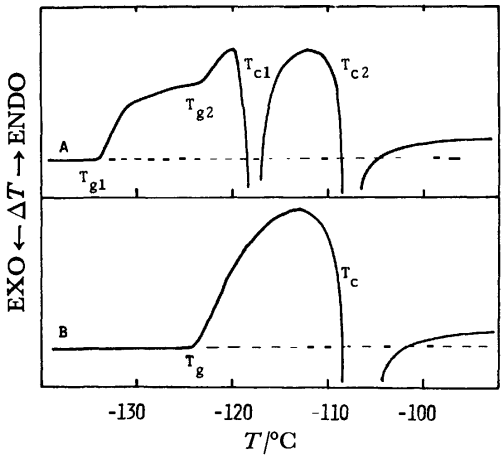

Fig. 4. DTA traces of the glassy aqueous HI solution (HI≈57 wt%).
(A): There are two glass transitions, (B): there is only one glass transition.

Lastly we point out the importance of crystallization temperature, to which little attention has been paid, as an auxiliary diagnostic parameter in the study of glass-forming properties of aqueous solutions. In fact, two crystallization peaks are observed in the concentration range where two glass transitions are observed. It can be seen in Fig. 1 that the solution at HI concentrations less than 40 wt% will divide into two phases (one is ice and the other the solution of eutectic composition) in the crystallization process, the latter phase being glass-forming in the rapid cooling. This is supported by the observation that the T_g value of the portion uncrystallized is very close to the T_g of the solution at HI=48 wt% (the eutectic composition). The invariance of T_c in this non-glass-forming composition range is also an additional support for the conclusion.

We are thankful to Professor C. A. Angell at Purdue University for his criticism on the first draft. This work was in part assisted by a Grant-in-Aid for Scientific Research from the Ministry of Education, Science and Culture.

The Reactions of Singlet NH Radicals with Methyl and Ethyl Alcohols in the Liquid Phase

Jun KAWAI, Shigeru TSUNASHIMA,* and Shin SATO†

Department of Applied Physics, Tokyo Institute of Technology, Ookayama, Meguro-ku, Tokyo 152

† *Research Laboratory for Nuclear Reactors, Tokyo Institute of Technology, Ookayama, Meguro-ku, Tokyo 152*

(Received March 4, 1982)

The reactions of the singlet NH($a^1\Delta$) radicals with alcohols were studied by the photolyses of hydrogen azide in liquid methyl and ethyl alcohols at the temperature of Dry Ice–methyl alcohol and at 0 °C. The main products were nitrogen, ammonia, and oxime ethers; acetaldehyde oxime *O*-ethyl ether from ethyl alcohol and formaldehyde oxime *O*-methyl ether from methyl alcohol. The relative yields of the products were independent of the changes in the reaction temperature and in the concentration of the hydrogen azide examined. Methoxyamine or ethoxyamine, a possible insertion product of the singlet NH into the O–H bond of alcohol, was detected as a form of oxime ether by the reactions with the aldehyde eventually formed. It was concluded that the singlet NH radicals can effectively insert into the O–H bond of the alcohol.

Recently, it was shown that the singlet NH radicals, NH($a^1\Delta$), inserted into the C–H bonds of hydrocarbons and carboxylic acids to form amines and amino acids respectively and added to the double bond of olefins to form aziridines.[1–7] These reactions are essentially the same as those observed in the reactions of O(^{1}D) and $CH_2(^1A_1)$.[8,9] An insertion reaction into the O–H bond of an alcohol may be expected to occur; however, the reaction has not been examined in the case of NH.

In order to investigate the reactions of methylene with alcohol, Ogoshi and Takezaki photolyzed ketene in the presence of methyl alcohol vapor at 40 °C. The main products were dimethyl ether and ethyl alcohol. If these products were formed by the insertion into the C–H and O–H bonds of methyl alcohol, the efficiencies of these two processes should be almost equal.[10] Using diazomethane as the source of methylene, Kerr *et al.* found that the insertion of methylene into the O–H bond of alcohol was more efficient than that into the primary C–H bond and reported the values of the relative efficiencies as follows: 21.8 (methyl alcohol), 21.2 (ethyl alcohol), 14.9 (isopropyl alcohol), and 10.9 (*t*-butyl alcohol).[11]

The present paper reports the results obtained in the photolyses of hydrogen azide in liquid methyl and ethyl alcohols at the temperature of Dry Ice–methyl alcohol and at 0 °C.

Experimental

The experimental methods and the apparatus used were essentially the same as those described in the previous papers.[1–3]

Ethyl alcohol (Amakasu Kagaku Sangyo Co., 99.5%) and methyl alcohol (Tokyo Kasei Co., 99.5%) were used after having been degassed at −60 °C and −80 °C respectively and distilled at room temperature *in vacuo*. Further purified ethyl alcohol was also used to check the possibility of interference by acetaldehyde, *i. e.*, ethyl alcohol was treated with Ag_2O for several days and distilled from NaOH solution. The alcohols were stored under vacuum after purification. Hydrogen azide was prepared and purified by the method described in the previous papers.[1–3] Methyl alcohol-d_4 (Merck Sharp and Dohme, Canada Ltd.) was used without further purification except for low temperature distillation *in vacuo*. 2-Amino-1-ethanol and methoxyamine hydrochloride were purchased from the Tokyo Kasei Co. and used as supplied.

A Pyrex tube of 10 mm o.d. was used as a reaction cell. About 1 ml of a methyl or ethyl alcohol solution of hydrogen azide was irradiated with a medium pressure mercury lamp (Toshiba H400-P) at 0 °C or at the temperature of Dry Ice–methyl alcohol. Uncondensable products at −196 °C were analyzed with a combination of a Toepler pump, a gas buret, and a CuO furnace at 300 °C. The volatile products at room temperature were transferred in a trap containing NaOH coated glass wool *in vacuo* together with the reactants. After the treatment with NaOH, the products uncondensable at −40 °C (ethyl alcohol) or −60 °C (methyl alcohol) were analyzed by GLC using a column packed with Amine 220 on NaOH coated Celite 545 (Gasukuro Kogyo Co., 5 m in length). For the analysis of less volatile products, a KOH solution of methyl alcohol was added to the reaction mixture and directly injected into a gas chromatograph equipped with FID (Hitachi 023). A column packed with Tenax GC (Gasukuro Kogyo Co., 1 m in length) was used. *s*-Butyl alcohol was used as the standard. For the identification of the products, a GC-mass spectrometer (Nichiden Varian, TE 600) and an NMR (Varian 390) were used.

Results

The products obtained in the photolysis of hydrogen azide in liquid methyl or ethyl alcohol were fractionated into three parts; uncondensable products at −196 °C, products more volatile than the solvent, and the less volatile products than the reactants. The uncondensable product at −196 °C was nitrogen for both methyl and ethyl alcohols. A negligibly small amount of hydrogen was also formed. The yield was less than 2% of that of nitrogen. No methane formation was detected by the mass spectrometric analysis. Ammonia formation was observed in the second fraction both for methyl and ethyl alcohols. From this fraction, formaldehyde oxime *O*-methyl ether and methoxyamine were detected in the case of methyl alcohol. The yield of the latter was about 1/100 of that of the former. No formaldehyde was detected. The identification of formaldehyde oxime *O*-methyl ether was based on the following results:

a) The molecular weight of the product was 59. The mass spectrum is shown in Table 1.

b) The product did not form a salt with hydrogen azide as well as with hydrogen chloride.

c) This product was also obtained without treat-

ment with NaOH.

d) When methyl alcohol-d_4 was used, the molecular weight of the product increased to 64. This result suggested that the product had five hydrogen atoms.

e) The mass spectrum and the retention time of GLC of this compound agreed with those of the product obtained by the reaction of methoxyamine hydrochloride with KOH and formaldehyde. (see Table 1).

In the case of ethyl alcohol, a similar product, having a molecular weight of 87, was found to be formed in the second fraction along with ammonia. From the mass spectrum shown in Table 1, this product was identified to be acetaldehyde oxime *O*-ethyl ether. In the case of the mixture of methyl and ethyl alcohols, two new products were observed to be formed along with ammonia, formaldehyde oxime *O*-ethyl ether, and acetaldehyde oxime *O*-methyl ether. Their molecular weights were both 73. One of the new products gave the same mass spectrum and the retention time as those obtained

a) Obtained at the temperature of Dry Ice–methyl alcohol with photolysis time of 60 min.

from the product formed by the reaction of methoxyamine hydrochloride with KOH and acetaldehyde. This product was identified to be acetaldehyde oxime *O*-methyl ether. The other was concomitantly identified to be formaldehyde oxime *O*-ethyl ether. No acetaldehyde was detected in the case of ethyl alcohol.

From the less volatile fraction, no retrievable products were obtained in the case of methyl alcohol. In the case of ethyl alcohol, 2-amino-1-ethanol was observed to be formed. The assignment was based on comparisons of its mass spectrum and retention time with those of the authentic sample. $CH_3CH{=}NCH_2CH_2OH$, a possible product formed by the reaction of 2-amino-1-ethanol with acetaldehyde, could not be observed. The yield of this product should be less than 1/10 of that of 2-amino-1-ethanol, if any.

Tables 2, 3, and 4 show the yields of the products relative to that of nitrogen obtained under various experimental conditions. The relative yields were almost constant for the changes in the concentration of hydrogen azide and in the reaction temperature examined.

Discussion

As shown in Tables 2, 3, and 4, the relative yields of the products were independent of the changes in the concentration of hydrogen azide. This trend is similar to those obtained in the cases of olefin and carboxylic acid.[5–7)] The following reaction mechanism can be considered to explain the results obtained in the case of ethyl alcohol:

$$HN_3 + h\nu \longrightarrow {}^1NH + N_2 \quad (1)$$

$${}^1NH + C_2H_5OH \longrightarrow NH_2CH_2CH_2OH \quad (2a)$$

$$\longrightarrow [CH_3CH(NH_2)OH]$$

$$\longrightarrow NH_3 + CH_3CHO \quad (2b)$$

$$\longrightarrow C_2H_5ONH_2 \quad (2c)$$

$$\longrightarrow {}^3NH + C_2H_5OH \quad (2d)$$

$$C_2H_5ONH_2 + CH_3CHO \longrightarrow CH_3CH{=}NOC_2H_5 + H_2O \quad (3)$$

$$C_2H_5ONH_2 \longrightarrow CH_3CHO + NH_3 \quad (4)$$

$${}^3NH + HN_3 \longrightarrow NH_2 + N_3 \quad (5)$$

$$NH_2 + HN_3 \longrightarrow NH_3 + N_3 \quad (6)$$

$$2N_3 \longrightarrow 3N_2 \quad (7)$$

Here, ^1NH and ^3NH represent the NH radicals in the singlet state ($a^1\Delta$) and the triplet state ($X^3\Sigma^-$) respectively.

The insertion of a singlet NH radical into the C–H bond at the β position will give 2-amino-1-ethanol (Reaction 2a). 1-Amino-1-ethanol may be formed by the insertion into the C–H bond at the α position; however, this compound is known to be unstable and to decompose to acetaldehyde and ammonia (Reaction 2b). Ethoxyamine may be formed by the insertion into the O–H bond of alcohol (Reaction 2c). Neither ethoxyamine nor acetaldehyde formation was detected in this study. Instead of these products, acetaldehyde oxime *O*-ethyl ether was found to be one of main products. This product may be formed by the condensation reactions of alkoxyamine and aldehyde (Reaction 3).[12)] Reaction 4 is included in the mechanism in order to take into account the possibility that ethoxyamine is unstable and also k_{2b} is smaller than k_{2c}. This point will be discussed later. Although ethoxyamine was not detected in the case of ethyl alcohol, methoxyamine, a possible insertion product into the O–H bond of methyl alcohol, was detected as a minor product. This difference might be explained by the difference in the stability of the alkoxyamine.

Reaction 2d is included in the mechanism to explain the fact that the amount of ammonia formed was more than that of acetaldehyde oxime *O*-ethyl ether or formaldehyde oxime *O*-methyl ether. The deactivation process has been considered in the cases of hydrocarbons and carboxylic acids.[1–7)] The reaction of the triplet NH radicals is assumed to be a hydrogen-atom abstraction from hydrogen azide (Reaction 5). The triplet NH radicals might also abstract a hydrogen atom from ethyl alcohol;

$${}^3NH + CH_3CH_2OH \longrightarrow NH_2 + CH_3CHOH$$

$$\Delta H = 10\ \text{kJ/mol}^{13)} \quad (8)$$

although the reaction is slightly endothermic. If CH_3CHOH radicals abstract a hydrogen atom from hydrogen azide;

$$CH_3CHOH + HN_3 \longrightarrow CH_3CH_2OH + N_3 \quad (9)$$

Reaction 8 followed by Reaction 9 would be indistinguishable from Reaction 5.

In the above reaction mechanism, a hydrogen atom abstraction by the singlet NH radicals was neglected:

$${}^1NH + CH_3CH_2OH \longrightarrow NH_2 + CH_2CH_2OH \quad (10a)$$

$$\longrightarrow NH_2 + CH_3CHOH \quad (10b)$$

$$\longrightarrow NH_2 + CH_3CH_2O \quad (10c)$$

All these reactions are energetically possible. If resultant alcohol radicals abstracted a hydrogen atom from hydrogen azide, Reactions 10's would be indistinguishable from Reaction 2d. If all these radicals recombined with NH_2, Reactions 10a—c would be hard to discriminate from Reactions 2a—c, respectively. If one of these assumptions were the case, it would be difficult to estimate the extent of the participation of the abstraction reactions. In the intermediate case, that is, if some of the alcohol radicals abstracted a hydrogen atom and the rest recombined with NH_2

radicals, the relative yields of the products should depend on the concentration of hydrogen azide. This case is most probable if the singlet NH radicals abstracted a hydrogen atom from alcohol. The concentration dependence observed, however, was different from that expected. Similar reaction mechanism may be considered in the case of methyl alcohol except for Reaction 2a.

Assuming the above reaction mechanism, the following relations can be expected to hold:
for the case of ethyl alcohol,

$$([NH_2CH_2CH_2OH] + 4[NH_3] - 2[CH_3CH{=}NOC_2H_5])/[N_2] = 1.0 \quad (11)$$

for the case of methyl alcohol,

$$(4[NH_3] - 2[CH_2{=}NOCH_3])/[N_2] = 1.0 \quad (12)$$

Using the values shown in Tables 2, 3, and 4, the left-hand-sides of Eqs. 11 and 12 were calculated to be 1.0 ± 0.1 and 0.81 ± 0.13 respectively; *i.e.*, the total yields of the products observed were successfully explained by the above mechanism.

Similar to alkoxyamine, 2-amino-1-ethanol may react with acetaldehyde:

$$NH_2CH_2CH_2OH + CH_3CHO \longrightarrow CH_3CH{=}NCH_2CH_2OH + H_2O \quad (13)$$

Reaction 13, however, should be unimportant under the present experimental conditions, since the material balance was good and no $CH_3CH{=}NCH_2CH_2OH$ formation was observed in the ethyl alcohol solution.

In the case of propionic acid, the singlet NH radicals inserted into the C–H bonds of α and β positions with almost equal rates.[6,7] For the insertion into the C–H bonds of paraffin, however, the relative rates of the insertion into the primary, secondary, and tertiary C–H bonds were 1.0, 1.9, and 2.3 respectively.[3] That is, the insertion rate slightly depends on the strength of the C–H bond. If this relation held in the case of ethyl alcohol, k_{2b} would be equal or slightly larger than $(2/3)k_{2c}$. The amount of acetaldehyde formed by Reaction 2b should be almost equal to that of 2-amino-1-ethanol. The yield of 2-amino-1-ethanol was about a half of that of acetaldehyde oxime *O*-ethyl ether. This was the main reason why Reaction 4 was included in the mechanism. The validity of Reaction 4 is unknown at present. Another possible assumption is that the singlet NH radicals can abstract two hydrogen atoms at once from ethyl alcohol to form ammonia and acetaldehyde:

$$^1NH + C_2H_5OH \longrightarrow NH_3 + CH_3CHO \quad (14)$$

Reaction 14 is indistinguishable from Reaction 2b. Similar reactions which involve the abstraction of two hydrogen atoms have been considered in the case of the reactions of $O(^1D)$ with ethane or ethylene. The extent of the reaction is about 3% of the total $O(^1D)$ reactions in the liquid Ar.[14] For the case of the singlet NH, the concentration dependence of the ammonia formation could also be explained by the presence of the similar reaction in the case of the olefin, but not in the case of the paraffin. If Reaction 14 were included in the mechanism instead of Reaction 4, k_{2c} should be equal to $k_{2b}+k_{14}$ to explain the observed material balance.

In the above discussions, acetaldehyde was assumed to be formed by Reactions 2b and 4. Since acetaldehyde is known as a possible impurity in ethyl alcohol, it is possible to consider that the impurity affects Reaction 3. This possibility was, however, dismissed because of the following facts:

a) No aldehyde was detected in this study, although this result does not conclusively eliminate the possibility of the presence of aldehyde, because of possible condensation reactions of aldehyde in the present analytical system.

b) The amount of acetaldehyde oxime *O*-methyl ether did not decrease when more highly purified ethyl alcohol was used. (see Table 3).

c) When the acetaldehyde was assumed to be an impurity, Eq. 11 should be changed to Eq. 15:

$$([NH_2CH_2CH_2OH] + [CH_3CH{=}NOC_2H_5] + 4[NH_3] - 3[NH_3]_{2b})/[N_2] = 1.0 \quad (15)$$

Here, $[NH_3]_{2b}$ represents the amount of ammonia formed by Reaction 2b. If $[NH_3]_{2b}$ is assumed to be equal to $[NH_2CH_2CH_2OH]$, the left-hand-side of Eq. 15 becomes 1.3.

Assuming Reaction 4 and $k_{2a}=k_{2b}$, the relative efficiencies of Reactions 2a—d can be estimated to be 0.1_6, 0.1_6, 0.5_0, and 0.1_8 respectively. That is, the main reaction of the singlet NH with ethyl alcohol is the insertion into the O–H bond. For the case of methyl alcohol, the insertion into the C–H or O–H bond was calculated to be 85% of the reaction of NH radicals. The efficiencies could not be estimated seperately, because of the presence of Reaction 4. The insertion into the O–H bond, however, may be more important than the C–H bond of methyl alcohol.

The authors are much obliged to Professors Takeshi Nakai and Yoshihiko Morooka for the NMR measurements and helpful discussions.

Preparation and Electrical Properties of $Eu(II)_xNb(IV)O_{2+x}$

Kenji Ishikawa, Gin-ya Adachi,* and Jiro Shiokawa
Department of Applied Chemistry, Faculty of Engineering, Osaka University, Yamadaoka, Suita, Osaka 565
(Received March 17, 1982)

Nonstoichiometric compounds, Eu_xNbO_{2+x}, were prepared. A cubic tungsten bronze type structure was found in the single phase region of Eu_xNbO_{2+x} ($0.5 \leqq x \leqq 1.0$). Magnetic susceptibility measurements showed that the oxidation state of europium in the bronzes was bivalent. The Eu_xNbO_{2+x} was a metallic conductor in the temperature range 4.2—300 K. Thermoelectromotive force measurements (100—350 K) indicated that the charge carriers were electrons and that the effective mass of the electrons increased with decreasing x in Eu_xNbO_{2+x}.

Europium niobium bronzes, Eu_xNbO_{2+x}, where x lies between 0.50 and 1.00 are tungsten bronze type compounds. At values of x greater than 0.65, the niobium bronzes crystallize in the cubic tungsten bronze type structure and exhibit the metallic properties of bluish luster and electronic conduction.[1,2] At values of x less than 0.65, the structure is the tetragonal tungsten bronze type and the bronzes are nonmetallic.[1-5] In the bronzes, Nb^{4+} ions co-exist with Nb^{5+} ions and the number of Nb^{4+} ions, which is equal to the number of conduction electrons for the cubic bronzes, is controlled simply by controlling the europium concentration, since the bronzes are expressed by a formula $Eu^{2+}Nb^{4+}_{2x-1}Nb^{5+}_{2-2x}O^{2-}_3$. However, the number of Nb^{4+} ions is also controlled by removing lattice oxygens from the bronzes, and the lattice oxygen should be removed until all the Nb^{5+} ions is reduced to Nb^{4+}, *i.e.*, $Eu^{2+}_x Nb^{4+}O^{2-}_{2+x}$. In this paper chemical and physical properties of Eu_xNbO_{2+x} are discussed and compared with those of Eu_xNbO_3.

Experimental

Preparative. A fully mixed powder of Eu_2O_3 (purity 99.9%: Shin-etsu Chemical Co.,), Nb_2O_5 (purity 99.9%: Wako Chemical Industries, Ltd.,), and Nb (purity 99.9%: Wako Chemical Industries, Ltd.,) was pressed into pellets. The pellets were packed into a Mo box and sealed in a silica tube under vacuum. The pellets were degassed under vacuum at 450 K for 3 h before the sealing procedure. The silica tube was set up in a vertical furnace and heated at 1423—1473 K for 6 h. The sample was ground in an agate mortar, re-pressed into pellets, degassed, sealed in a silica tube under vacuum, and heated again at 1423—1473 K for 30 h. The reaction was completed during the procedure described above and assumed to proceed as follows.

$$0.5xEu_2O_3 + (0.4-0.1x)Nb_2O_5 + (0.2+0.2x)Nb \longrightarrow Eu_xNbO_{2+x} \quad (1)$$

However, in practice a small excess of niobium metal was used to compensate for a slight oxidation of the samples during the synthetic procedure.

Analyses. The phase purity and the structure type of the samples were analyzed by X-ray powder diffraction with a Rigaku Denki "Rotor-flex diffractometer."

The Eu/Nb ratios, namely x in Eu_xNbO_{2+x}, were determined by fluorescence X-ray analysis with a Rigaku Denki "Ultra Trace unit," and the O/Nb ratios were obtained by weighing the samples before and after complete oxidation and assuming the following oxidation reaction,

$$Eu_xNbO_{2+x} + 0.25(x+1)O_2 \longrightarrow 0.5xEu_2O_3 + 0.5Nb_2O_5. \quad (2)$$

Magnetic and Electrical Measurements. The magnetic moments of the samples were obtained from magnetic susceptibility measurements with a Shimadzu magnetic balance "MB-11" under a He atmosphere in the temperature range 4.2 to 300 K.

Electrical resistivity measurements were done for the polycrystalline sintered bars with a simple four-probe d.c. method in a helium atmosphere from 4.2 to 300 K. The heating rate of each measurement was below 1 K/min. The dc currents was produced with a Takeda Riken dc generator "TR-6141," and the potential difference between the two potential leads was recorded with a Yokogawa Denki "Type 3036 X-Y recorder;" the resistivity measurements were carried out in the ohmic region of the current. Since the measured voltage included a thermally generated emf, the dc current was stopped at regular time intervals and the emf was separated. The shape and size of the samples and the attachment of electrical leads used were the same as those described in the previous paper.[1]

Thermoelectric Power Measurements. Thermoelectric powers of the rectangular samples of about 2 mm^2 in cross section and about 4 mm long were measured under a He atmosphere in the range 100—373 K. The temperature difference between both side of the sample was adjusted to fall within 10 K. The absolute Seebeck coefficient was obtained after compensating the emf of copper action as the electrode of our apparatus and given according to the following equation:

$$S = S_{Cu} - \Delta V/\Delta T, \quad (3)$$

where S_{Cu} was the absolute Seebeck coefficient of Copper,[6] ΔV was the thermoelectric voltage of the sample, and ΔT was the temperature difference between both sides of the samples.

Results and Discussion

The phases and analytical data for Eu_xNbO_{2+x} and Eu_xNbO_3 obtained are listed in Table 1, which shows that the single phase region of Eu_xNbO_{2+x} is from $x=0.5$ to $x=1.0$. The niobium bronze Eu_xNbO_3 of $x=0.50$—0.65 has a tetragonal form[1-5] and for $x=0.65$—1.00 has a cubic form,[1,2] while Eu_xNbO_{2+x} has a cubic form in the single phase region.

Lattice constants of the cubic phased Eu_xNbO_{2+x} and Eu_xNbO_3 are plotted in Fig. 1 as a function of the europium concentration x. The lattice constants of Eu_xNbO_3 increases almost linearly with an increase in x.[2] The least-squares fitting generates the following equation:

$$a(\text{cubic}) = 3.874 + 0.1515x(\text{Å}). \quad (4)$$

Lattice constants of Eu_xNbO_{2+x} also increase with an increase in x in the range from $x=0.5$ to $x=1.0$, but

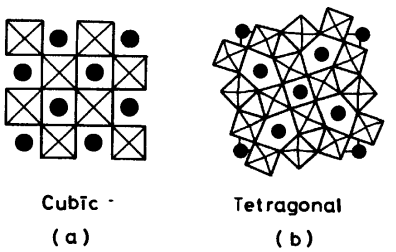

Fig. 2. Schematic diagram for the cubic and the tetragonal Eu_xNbO_3.
The bivalent europium cation can occupy the positions expressed by the black circles.

the change is not linear and the constants of Eu_xNbO_{2+x} are greater than those of Eu_xNbO_3 on a fixed composition especially below $x=0.7$. Below $x=0.5$, an unknown phase appeared in addition to a cubic phase of $a=3.982$ Å, and the tetragonal phase which was found in the Eu_xNbO_3 of $x=0.5$—0.65 was not observed.

The phase change of Eu_xNbO_3 from a cubic to a tetragonal form is explained as follows. The crystal structure of the cubic and the tetragonal niobates are revealed in Figs. 2 (a) and (b). A bivalent europium cation occupies a body-centered site of the cubic lattice (Fig. 2 (a)) and the site expressed by the black circle in the tetragonal cell (Fig. 2 (b)). Since the lattice constant decreases with a decrease in the europium concentration for the cubic Eu_xNbO_3, the maximum ionic radius to be able to occupy the body-centered site of the perovskite structure also decreases with decreasing the europium concentration, and at $x=0.65$ the maximum ionic radius becomes equal to the ionic radius of Eu^{2+}. At $x=0.65$, the lattice constant "a" is 3.987 ± 3 Å and the tolerance factor[7] "t" is 1.01. The tolerance factor is defined by the following equation:

$$t = (r(Eu^{2+}) + r(O_2^-))/\sqrt{2}\,a, \qquad (5)$$

where $r(Eu^{2+})$ (1.45 Å: 6th coordination) and $r(O^{2-})$ (1.40 Å: 6th coordination) are ionic radii[8] of Eu^{2+} and O^{2-} and a (3.987 Å for $Eu_{0.65}NbO_3$) is a cubic lattice constant. Below $x=0.65$ $t>1$, the body-centered site of the cubic Eu_xNbO_3 can no longer accomodate a bivalent europium cation, and the cubic phase transforms to the tetragonal phase. This can provide room for a bivalent europium cation in the limited range from $x=0.5$ to $x=0.65$.[1-5]

The above discussion is also applicable to Eu_xNbO_{2+x}. The lower limit of the lattice constant for the cubic Eu_xNbO_{2+x} seems to be almost the same as the lattice size of $Eu_{0.65}NbO_3$. However, the tetragonal phase,

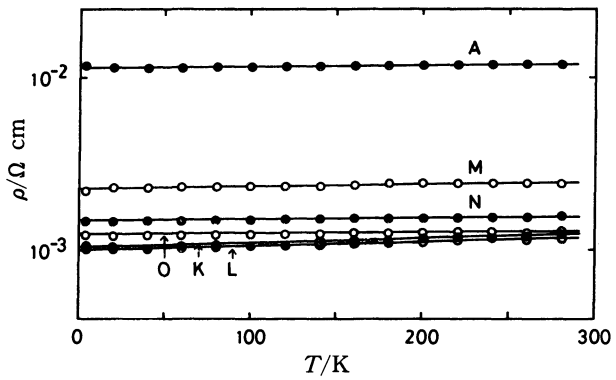

Fig. 3. Temperature dependence of resistivity for Eu_xNbO_{2+x}.

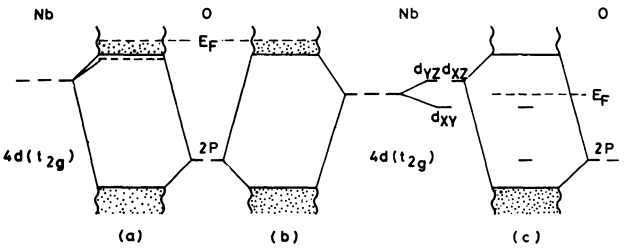

Fig. 4. Energy-level diagram for Eu_xNbO_{2+x} and Eu_xNbO_3.

which was found for Eu_xNbO_3 at x=0.5—0.65, was not found and an unknown phase was detected in the Eu_xNbO_{2+x} below x=0.5.

The electrical resistivity measurements for Eu_xNbO_{2+x} (Fig. 3) show that the cubic Eu_xNbO_{2+x} is a metallic conductor at x=0.5—1.0. These results are different from those of Eu_xNbO_3 in a low x region. In the case of Eu_xNbO_3, semiconduction was observed for the cubic samples at x=0.5—0.65[1-5] and metallic conduction was observed for the cubic samples at x=0.65—1.0.[1,2]

The difference in the electrical conduction between Eu_xNbO_{2+x} and Eu_xNbO_3 at x=0.5—0.65 is related to the distinction in their crystal structure. The difference on conduction manner owing to the structural difference was already discussed for Eu_xNbO_3 with a band model in the previous paper.[1]

An energy level diagram for Eu_xNbO_{2+x} is proposed in Fig. 4, which is assembled on the basis of Goodenough's model for Na_xWO_3.[9] The conduction band is composed of $4d(t_{2g})$ orbitals of niobium and 2p orbitals of oxygen. The $4d(t_{2g})$ levels of niobium, which are composed of $4d(t_{2g})$ orbitals around oxygen vacancies, are located below the conduction band.

The number of conduction electrons is equal to the number of Nb^{4+} as for Eu_xNbO_3,[1] and there is a Nb^{4+} per one formula of Eu_xNbO_{2+x}. Therefore, Eu_xNbO_{2+x} exhibits a metallic conduction (Fig. 3) as the cubic Eu_xNbO_3. However the mobility of an electron and an effective mass of electron for Eu_xNbO_{2+x} should be

different from those for Eu_xNbO_3, since positive charged oxygen vacancies are considered to attract the conduction electrons around the vacancies electrostatically.

The effective masses of electrons for metallic Eu_xNbO_{2+x} are roughly evaluated by a thermoelectric power measurement, assuming that all the 4d electrons of niobium are concerned to the electrical conduction. For the free-electron approximation, the Seebeck coefficient is given by the relation:[10]

$$S = \frac{2}{3}\left(\frac{\pi}{3}\right)^{2/3} \frac{m^* k^2 T}{e(h/2\pi)^2} N^{-2/3}. \quad (6)$$

The effective mass is obtained by comparison of the observed Seebeck coefficient with the calculated value ($m^* = m_0$). Figure 5 shows that the Seebeck coefficient of Eu_xNbO_{2+x} at various temperatures. Temperature dependence of the Seebeck coefficient for each Eu_xNbO_{2+x} is almost linear and this fact suggests that the behavior of the conduction electrons resemble that of the free electrons. The Seebeck coefficient of Eu_xNbO_{2+x} increases with decreasing x at each temperature (Fig. 5). The increase in the Seebeck coefficient means that the effective mass of the electrons of Eu_xNbO_{2+x} increases with decreasing x. In Table 2, effective electric masses of Eu_xNbO_{2+x} and Eu_xNbO_3 are listed. The effective electric mass for Eu_xNbO_{2+x} increases with decreasing x from $2m_0$ to $5m_0$. However, the effective mass for Eu_xNbO_3 is independent of x and about $2m_0$ for any sample obtained. An interpretation for the disagreement in masses of Eu_xNbO_{2+x} and Eu_xNbO_3 is as follows. The host lattice of Eu_xNbO_3, namely NbO_3, where the conduction electrons go through, is not changed with x, and the effective mass is not affected by x. On the other hand, Eu_xNbO_{2+x} has oxygen vacancies, and the lattice of Eu_xNbO_{2+x} is fairly different from that of Eu_xNbO_3 at low x. The conduction electrons are trapped near the oxygen vacancies through the electrostatic force; the electrostatic interaction of the electrons with the vacancies is strong at low x, because there exist many vacancies at low x. This is the reason why the effective mass of the electrons for Eu_xNbO_{2+x} increases with decreasing x.

Time-resolved Emission Spectra of 2-Acetylanthracene/Methanol/Hexane System. Evidence for the Photoassociation of a 1 : 2 Hydrogen Bonded Complex

Takashi TAMAKI
Research Institute for Polymers and Textiles, Yatabe-Higashi 1-1-4, Tsukuba, Ibaraki 305

(Received March 30, 1982)

Synopsis. The deconvolved time-resolved emission spectra of 2-acetylanthracene in hexane containing 0.1 mol dm^{-3} of methanol revealed a considerable time-dependent spectral shift associated with the photoassociation of the hydrogen-bonded complex which includes two methanol molecules.

The photodynamics of solvent-solute interaction have been extensively investigated. It is of particular interest that the fluorescence spectra of aromatic compounds, such as heterocycles, amines, and ketones, in nonpolar solvents are significantly perturbed by the addition of small amounts of polar solvents (<1% by volume).[1-8] This fluorescence perturbation is due to a specific solvent-solute interaction giving rise to a hydrogen-bonded (H-bonded) complex and/or an exciplex. Acylanthracenes are suitable for the purpose of this investigation, because their fluorescence characteristics (intensity, lifetime, and emission maximum) are very sensitive to the addition of alcohols to the nonpolar solutions.[9,10] This communication describes the time-resolved emission spectra (TRES) of 2-acetylanthracene (**2A**) in hexane containing 0.1 mol dm^{-3} of methanol at 20 °C under an air atmosphere. The results obtained are in excellent consistence with a photostationary study which indicated that at least two methanol molecules participate in the complex formation in the excited singlet state.[10b]

Experimental

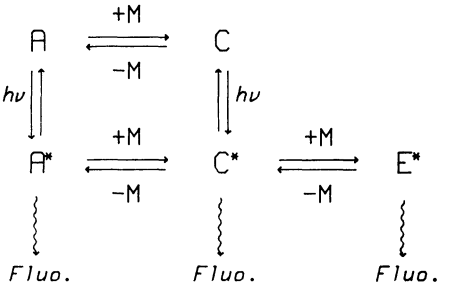
2A was the same as that used previously.[10] The hexane and methanol were Spectro- and GR-grade reagents, respectively. To a 3 cm^3 hexane solution of **2A** (3×10^{-5} mol dm^{-3}) was added 1.4×10^{-2} cm^3 of methanol. The nanosecond decay curves and corrected steady-state fluorescence spectra were obtained similarly to those described previously.[11] The fluorescence decay curves collected at every 5 nm from $\lambda=400$ to 520 nm were subjected to deconvolution analysis by an iterative nonlinear least squares method.[11] The decay function, $i(\lambda, t)$, was chosen to be a sum of three exponential terms,

$$i(\lambda,t)=\sum_j^3 C_j(\lambda)\cdot\exp\{-t/\tau_j(\lambda)\}$$

where $C_j(\lambda)$ and $\tau_j(\lambda)$ were treated as free parameters. This decay function gave a good fit between the observed and simulated decay curves at every wavelength and the three decay times were found to be 11 ± 1.6, 4.9 ± 0.1, and 2.1 ± 0.9 ns. The value of $C(\lambda)$ associated with the shortest decay time was negative at wavelengths above 490 nm and at the red end, $i(\lambda, t)$ showed a typical rise and decay, indicating that a large portion of the long wavelength emission results from an excited-state reaction. The deconvolved TRES were constructed by multiplying $i(\lambda, t)/\sum_j^3 C_j(\lambda)\tau_j(\lambda)$ by the corrected total fluorescence spectrum at the corresponding wavelength.[12,13]

Results and Discussion

Figure 1 shows the deconvolved TRES obtained at four delay times. These spectra are normalized at the maximum intensity. Time-dependent spectral shifts are clearly evident, whereas little spectral shift could be detected by convolved spectroscopy.[10b] The TRES in Fig. 1 can be compared with the spectra of the fluorescence origins which have been assigned to the system concerned, as shown in the following reaction scheme;[10b]



where M, A, C, and E are methanol, an uncomplexed **2A**, a 1 : 1, and a 1 : 2 complex respectively. Figure 2 shows the normalized steady-state fluorescence spectra of C and E obtained from the photostationary study, together with that of A, which is assumed to be the same as in pure hexane.

The spectrum at 24.3 ns shown in Fig. 1 has a remarkable resemblance to spectrum E shown in Fig. 2. In fact, this component spectrum is dominant even at 6—7 ns delay times. On the other hand, the TRES at shorter delay times can not be matched identically with

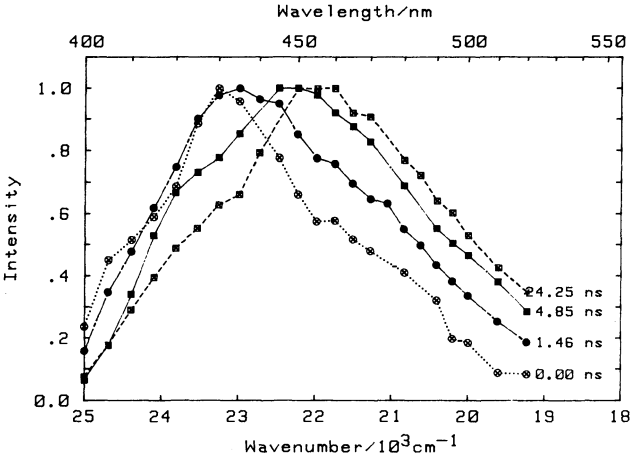


Fig. 1. Time-resolved emission spectra of 2-acetylanthracene in hexane containing 0.1 mol dm^{-3} of methanol at 20 °C. Normalized at the maximum intensity.

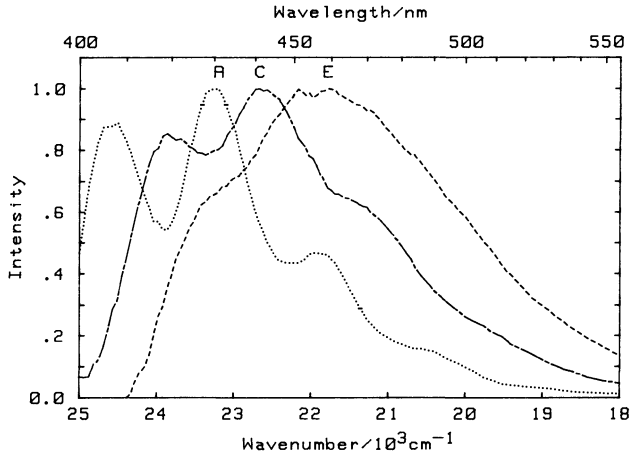

Fig. 2. Fluorescence spectra of three component origins involved in a 2-acetylanthracene/methanol/hexane system; A) an uncomplexed, C) a 1 : 1 complex, and E) a 1 : 2 complex. Normalized at the maximum intensity.

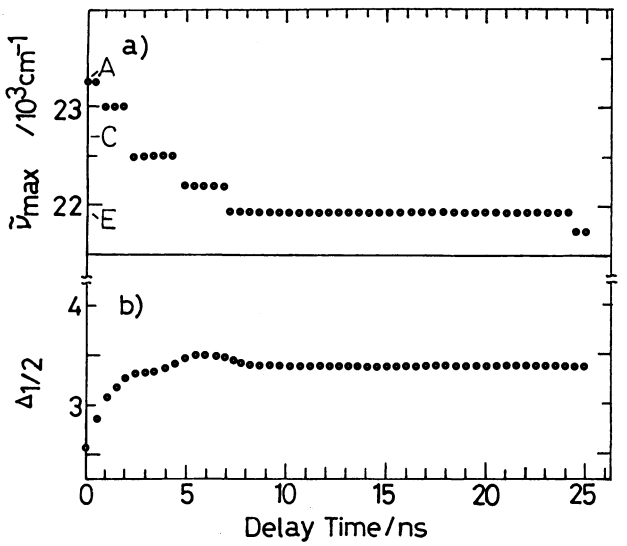

Fig. 3. Time-dependent changes in a) emission maxima ($\tilde{\nu}_{max}$) and b) half bandwidths ($\Delta_{1/2}$) of the TRES observed.

the individual component spectrum, but they can be simulated by superimposing the spectra from selected component sources with a variety of their contributions which depend on the delay time. Indeed, the TRES at 4.85 and 1.46 ns are approximately identical with the spectrum of C plus E (the relative fluorescence intensity of E to C, $F_{E/C} \simeq 1$) and of A plus C ($F_{C/A} \simeq 3.5$), respectively. It can be safely said that the contribution from E* is negligible for the TRES at delay times <2 ns. The spectrum at t_0 itself contains a considerable contribution from C* as well as from A* ($F_{C/A} \simeq 2$). This may result from the static formation of C prior to the pulse excitation.[14] About 1.7 times increase in the relative contribution from C* at 1.46 ns suggests that the dynamic formation of this component is important in this time region. It is also probable that at the longer delay times, the formation of E* prevails at the expense of C*.

The emission maxima, $\tilde{\nu}_{max}(t)$, and half bandwidths, $\Delta_{1/2}(t)$, of the observed TRES are shown in Figs. 3a and 3b, respectively. The emission maxima of the three components (A, C, and E) are also shown in Fig. 3a. From this figure, it is clear that the spectral relaxation of the TRES is substantially complete in 10 ns with the relaxed $\tilde{\nu}_{max}$ reaching the energy level of E. As is shown in Fig. 3b, $\Delta_{1/2}(t)$ first increases rapidly, then more slowly to a maximum value; later it decreases to a plateau value corresponding to the half bandwidth of the spectrum of E (*ca.* 3900 cm^{-1}), This variance of $\Delta_{1/2}(t)$ occurs just in the time period at which the spectral relaxation is occuring. These facts indicate that the observed TRES reflect the photodynamics of the specific H-bond interaction.

In conclusion, the excellent agreement between the photostationary and photodynamic studies strongly supports the validity of the reaction scheme postulated, which describes a step-wise photoassociation of the H-bonded complexes. It appears likely that the photoassociation of C occurs during the first 2 ns, followed by the formation of E. Finally, it should be mentioned that little effect on the fluorescence of **2A** could be detected when the methanol was replaced by acetonitrile. This confirms that H-bonding is responsible for the interaction. In pure methanol, the photostationary fluorescence of **2A** showed a large red-shift due to the combination of the specific H-bonding and nonspecific solvent relaxation.[10] However, the latter effect may be negligible for the present system and if any, the ultra fast relaxation of the surrounding solvent ($\approx 10^{-11}$ s) could not be associated with the TRES observed in the ns domain.

14) From absorption measurements, the static formation of C amounts to *ca.* 20% (*i.e.*, $[C]/[A] \simeq 0.27$) under the experimental conditions, indicating that the fluorescence efficiency of C is about 7 times greater than that of A. This fluorescence enhancement is the result of the inhibition of the intersystem crossing due to the displacement of the singlet energy level.[10,11]

The Evaluation of the Association Degree of Sodium Counterinos by Complexes between Sodium Dodecyl Sulfate and Bovine Serum Albumin, Mainly on the Basis of a Conductivity Measurement

Kunio TAKEDA

Department of Applied Chemistry, Faculty of Science, Okayama University of Science, 1-1 Ridai, Okayama 700

(Received January 20, 1982)

Synopsis. Bovine serum albumin was titrated conductometrically with sodium dodecyl sulfate (SDS). Plots of the specific conductance *versus* the SDS concentration revealed four inflections. The association degrees of sodium counterions by the complexes were evaluated from the changes in the increment of the specific conductance of SDS with the complex growth.

The interactions of proteins with surfactants have received extensive attentions.[1] More recently, the present author and others have demonstrated the usefulness of the conductivity method for detecting protein–surfactant complex formation,[2] while this method has also been frequently used to determine the critical micelle concentration (CMC) of ionic surfactants. In the process of the complex formation between sodium dodecyl sulfate (SDS) and bovine serum albumin (BSA), four inflection points appeared in the plot of the specific conductance versus the SDS concentration at a constant BSA concentration. It is confirmed that these inflections appear with an intimate correlation with the formation of the SDS–BSA complex and the subsequent conformational changes of the protein.[2] It can generally be expected that these critical conductance changes mainly reflect the degree of association of sodium counterions.[3-6] The behavior of the counterions, despite their intrinsic interest, is still a matter of uncertainty.

The aim of this paper is the evaluation of the association degree of the sodium counterions by the complex, mainly on the basis of the conductance change with the complex formation.

Experimental

The crystalline BSA was obtained from Miles Laboratories Inc., and its concentration was determined spectrophotometrically using $E_{1cm}^{1\%}=6.8$ at 282 nm.[7] The crystalline SDS was purchased from BDH Chemicals Ltd., and recrystallized twice from 1-butanol and once from pure water. The conductivity measurements were carried out with a Universal Bridge 4265B of Yokogawa-Hewlett-Packard.[2] All the measurements were made at 25.000±0.005 °C in buffer solutions (pH 7.0; ionic strength, 0.014) containing 3.33 mM of NaH_2PO_4 and 3.56 mM of Na_2HPO_4 (1 M=1 mol/dm^3 was used as the concentration unit).

Results and Discussion

The conductance change with the complex formation was reexamined in order to evaluate the association degree of the sodium counterions by the complexes. The slope of each linear part between the inflections is presented in the second column of Table 1. The slope becomes milder, step by step, as seen in Table 1. The four linear parts below the CMC are considered to be correlated with the same number of types of complexes depending on the surfactant concentration ranges. These types of complexes are considered to be identical with the four observed previously under other experimental conditions.[8-10] When the specific conductance due to the species composing the buffer is subtracted from the total of the system, the residual conductance, κ, can be expected just for the behavior of the surfactant and the protein. Here, it is important that the contribution of the protein to the conductance is negligibly

Table 1. Association degree of sodium counterions and other parameters of SDS–BSA complexes

Type of complex (Concentration ranges of total SDS)[a]	$d\kappa/dC_{DS}^{total}$ / $10^{-5}\ \Omega^{-1}\ M^{-1}$	$\mu_{complex}$ / $10^{-4}\ cm^2\ s^{-1}\ V^{-1}$	μ_{Na} / $10^{-4}\ cm^2\ s^{-1}\ v^{-1}$	γ_{Na}	α	$(1-\alpha)$
Complex 1	5.6	1.6[b]	4.2	0.86	1.01	−0.01
(below 1.9 mM)		1.2[c]			1.06	−0.06
		1.7[d]			1.00	0
Complex 2	5.2	2.5[b]	4.1	0.86	0.82	0.18
(between 1.9 and 4.6 mM)		2.0[c]			0.88	0.12
Complex 3	4.4	2.8[b]	4.1	0.84	0.67	0.33
(between 4.6 and 6 6 mM)		2.4[c]			0.71	0.29
Complex 4	3.6	3.6[b]	4.0	0.80	0.50	0.50
(between 6.6 and 8.0 mM)						
SDS micelle	2.3	4.3[e]	4.0	0.80	0.29[f]	0.71
(above 8.0 mM)						

a) The total SDS concentrations where the inflections appeared in the plot of the specific conductance *versus* the total SDS in the presence of 1.0×10^{-5} M BSA (see Ref. 2). b), c), and d) Calculated by means of Eq. 4 on the basis of the data in Refs. 8, 9, and 10 respectively. e) This is the $\mu_{micelle}$ value obtained through the use of Eq. 4 on the basis of the reference values.[8,12] f) Calculated by substituting $\mu_{micelle}$ in place of $\mu_{complex}$ in Eq. 3.

small compared with that of the surfactant.[2] If we define the degree of the dissociation of sodium counterions from the complexes, α, the conductance, κ, may be expressed as follows:

$$\kappa = \frac{F}{1000}(\mu_{Na}\gamma_{Na}C_{Na} + \mu_{DS}^{free}\gamma_{DS}^{free}C_{DS}^{free} + \alpha\mu_{complex}C_{DS}^{bound}), \quad (1)$$

where F: Faraday's constant, μ: mobility, γ: activity coefficient, C: concentration (M), Na: sodium ion, free DS: free dodecyl sulfate ion, and bound DS: bound dodecyl sulfate ion. If we introduce the relation: $C_{DS}^{bound}=C_{DS}^{total}-C_{DS}^{free}$ where C_{DS}^{total} is the total concentration of SDS, as is often done in binding studies of these systems, we can adopt the following relation: $C_{Na}=C_{DS}^{free}+\alpha(C_{DS}^{total}-C_{DS}^{free})$. Then, Eq. 1 can be rewritten as:

$$\kappa = \frac{F}{1000}\{(\mu_{Na}\gamma_{Na}+\mu_{complex})\alpha C_{DS}^{total} + [(1-\alpha)\mu_{Na}\gamma_{Na}+\mu_{DS}^{free}\gamma_{DS}^{free}-\alpha\mu_{complex}]C_{DS}^{free}\}. \quad (2)$$

The slope, $d\kappa/dC_{DS}^{total}$, in the plot of the specific conductance *versus* the total SDS concentration is given by:

$$d\kappa/dC_{DS}^{total} = \frac{F}{1000}(\mu_{Na}\gamma_{Na}+\mu_{complex})\alpha. \quad (3)$$

If we know μ_{Na}, γ_{Na}, and $\mu_{complex}$, we can determine the α-values.

Aoki has found step-by-step changes in the complex mobilities with the complex formation between SDS and horse serum albumin and has reported four types of their mobilities.[8] Decker and Foster have also obtained three types of mobilities of the complexes between BSA and sodium dodecylbenzenesulfonate in the low concentration range of the surfactant.[9] These mobilities are 10—20% slower than those found by Aoki in a similar concentration range of SDS. Pallansch and Briggs have reported the mobility of the smallest SDS–BSA complex;[10] it is consistent with the corresponding value reported by Aoki when the difference in ionic strength is corrected by Eq. 4. These data would indicate what magnitudes of mobilities the complexes have. According to these data, the mobilities of the present SDS–BSA complexes were obtained through the correction of only the difference in ionic strength by applying the following relation:[11,12]

$$\log\mu = -A\log I_S + B, \quad (4)$$

where A and B are constants and I_s is the ionic strength. The constant, A, was determined to be 0.095 according to the dependence of the mobility of the SDS micelle on the ionic strength obtained by Stigter and Mysels;[11] it was then used in the calculation. The value of μ_{Na} was obtained from the equivalent conductivity of the sodium ion reported by Mukerjee *et al.*[4] and by the subsequent interpolation of the log-log plot of μ_{Na} *versus* the ionic strength, such as in Eq. 4. The activity coefficient, γ_{Na}, of 0.80 was adopted in the vicinity of the CMC, on the basis of the results of Botre *et al.*[3] Its value in an infinite dilution of SDS was computed to be 0.89 under the present conditions (I_s=0.014) by the application of the usual Debye-Hückel approximation.[13] The values of γ_{Na} between 0.80 and 0.89 were determined using this relationship: $-\log\gamma = S\sqrt{C_{DS}^{total}}$ (S: constant), given by Shedlovsky *et al.*[14] All the parameters used are listed in Table 1.[15] This table also shows the values of α and the association degree of counterions by each complex, $(1-\alpha)$, calculated by means of Eq. 3 using these parameters. The value of α for the SDS micelle obtained by this treatment is in good agreement with the literature values (0.22—0.29).[11,14] This would suggest the rationality of the above calculation.

The association degrees $(1-\alpha)$ of the counterions by the complexes are quite small compared with that of the SDS micelle. As may be seen in Table 1, the value of $(1-\alpha)$ increases with the complex formation. The association degree is considered to give a measure of the interactions between SDS and BSA. The increase of surfactants bound to the protein needs low electrostatic field on the surface of the complex and must lead to an increase in $(1-\alpha)$. In spite of the increase in the association degree of the counterions, the polyelectrolytic nature of the complex is expected to be strengthened because of the acquisition of a high net charge introduced by the bound dodecyl sulfate ions. It should be noted that a similarity of the complex to the micelle also appears in the behavior of the counterions, although other such similar properties between them have previously been discussed.[5,6,16]

Effect of Temperature and Solvent on the 1,3-Dipolar Cycloaddition of Diazodiphenylmethane with Several Dipolarophiles

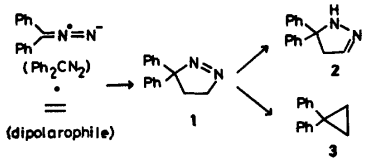
Yosuke Yoshimura, Jiro Osugi, and Masaru Nakahara*

Department of Chemistry, Faculty of Science, Kyoto University, Oiwake-cho, Kitashirakawa, Sakyo-ku, Kyoto 606

(Received March 27, 1982)

Synopsis. The title reaction is studied with a series of CN- or $COOCH_3$-substituted dipolarophiles. All the reactions obey the second-order rate law. The activation enthalpies and entropies are 44—52 kJ mol^{-1} and −(129—166) J K^{-1} mol^{-1}, respectively. The rate constants are insensitive to solvent. The reactivity and product of dimethyl maleate are anomalous.

In previous papers,[1,2] effects of temperature and solvent on the 1,4-cycloaddition reaction between tetracyanoethylene (TCNE) and styrenes have been investigated to shed light on the reaction mechanism. It is of considerable interest to compare the mechanism between 1,3-dipolar cycloaddition and 1,4-cycloaddition reactions. The cycloaddition reaction of diazodiphenylmethane (Ph_2CN_2) with some olefins has long been known,[3] and the first kinetic study of this reaction as a kind of 1,3-dipolar cycloaddition appeared two decades ago.[4] The reaction provides such adducts as 1-pyrazoline (**1**), 2-pyrazoline (**2**), and cyclopropane (**3**) depending on dipolarophiles used. The variety of these products is understood so far according to the following scheme:[5]



Scheme 1.

where **2** and **3** are formed from **1** by the H shift and the N_2 elimination, respectively. Until now there has been no thorough kinetic study where dipolarophiles are varied systematically so as to cover the product variety. It is worthwhile to examine the credibility of the Scheme 1 because some different scheme is proposed in a recent report on the 1,3-dipolar cycloaddition reaction of Ph_2CN_2 with TCNE in which the final product is of type **3**.[6]

Experimental

Materials. Ph_2CN_2 was obtained by the oxidation of benzophenone hydrazone with mercury(II) oxide (yellow).[3] Crude Ph_2CN_2 was recrystallized from petroleum ether in the form of needles, the melting point being 29 °C as reported;[3] crystals from methanol were of the form of flake with mp 22 °C. Dimethyl fumarate (DMF), dimethyl maleate (DMM), methyl acrylate (MA), fumaronitrile (FN), and acrylonitrile (AN) were supplied by Nakarai Chemicals, Ltd. and purified by the usual method. Maleonitrile (MN) was synthesized in a reported manner.[7] All solvents used were purified by the standard method.

Products. The adduct of each dipolarophile was identified by means of elemental analysis and by using the melting point, ^1H NMR, and IR data available in the literature: see Refs. 3, 8, and 9 for DMF, DMM, and MA and AN, respectively. FN and MN, which were studied here for the first time, gave 3,4-dicyano-5,5-diphenyl-2-pyrazoline, and unfortunately, the adduct could not be crystallized: NMR ($CDCl_3$) δ= 7.4, 7.2 (m 11H) and 4.81 (s 1H); IR (neat) 3300 (νNH) and 2220 cm^{-1} (νCN).

Kinetic Measurements. The disappearance of Ph_2CN_2 was followed around 525 nm by using a Hitachi Perkin-Elmer 139 UV visible spectrophotometer. Temperature was controlled to ±0.05 °C at 20, 25, 30, and 35 °C. Although Ph_2CN_2 is known to decompose (first-order reaction) at ambient temperature, the decomposition is so slow (1% in toluene at 25 °C for a period of 3.5 d) that it is negligible in the present work (each run finished within 6 h). All reactions studied obey the second-order rate law shown by

$$-\frac{d[Ph_2CN_2]}{dt} = k[Ph_2CN_2][\text{dipolhrophile}]$$

where [ ], t, and k denote the concentration, the time ,and the rate constant, respectively. The rate constants were determined from the second-order plots, *i.e.*, log $[Ph_2CN_2]/[\text{dipolarophile}]$ *vs.* t. Their uncertainty is about 1%.

Results and Discussion

In the temperature (T) range studied here, the values of $\ln(k/T)$ are linear against $1/T$. According to the Eyring equation[10] these linear relations lead to determination of the activation enthalpies (ΔH^*) and entropies (ΔS^*) listed in Table 1. In broad terms, ΔH^* and ΔS^* differ little from one dipolarophile to another in spite of the product diversity; there exist some differences which will be discussed later in relation to the molecular structure of the dipolarophile. Thus, all reactions studied can be classified into the same kind of 1,3-dipolar cycloaddition from the kinetic point of view. The similarity of the transition state in these reactions strongly suggest that not only DMM but also other dipolarophiles once produce the adduct of type **1** just

Table 1. Kinetic parameters for 1,3-dipolar cycloaddition of Ph_2CN_2 with various dipolarophiles in toluene at 25 °C

Dipolarophile[a]		A[b]	10^4k[c]	ΔH^*[d]	ΔS^*[e]
X(H)C=C(H)X	(DMM)	1	2.77	44±1	−166±1
X(H)C=C(X)H	(DMF)	2	53.3	44±1	−141±1
H(H)C=C(X)H	(MA)	3	19.8	44±3	−150±3
NC(H)C=C(H)CN	(MN)	2	25.0	47±1	−136±2
NC(H)C=C(CN)H	(FN)	2	9.97	51±1	−130±1
H(H)C=C(CN)H	(AN)	3	9.72	52±2	−129±2

a) X=$COOCH_3$. b) Adduct of Ph_2CN_2; see Scheme 1. c) mol^{-1} dm^3 s^{-1}. d) kJ mol^{-1}. e) J K^{-1} mol^{-1}.

Table 2. Rate constants (k) for 1,3-dipolar cycloaddition reactions of Ph_2CN_2 with DMM, DMF, and MA in several solvents at 25 °C

Solvent	$10^4\ k/mol^{-1}\ dm^3\ s^{-1}$		
	DMM	DMF	MA
PhMe	2.77	53.3	19.8
PhCl	2.57	62.3	21.5
$(ClCH_2)_2$	2.28	65.5	20.3
Me_2NCHO	3.36	96.3	31.0
MeCN	3.02	103.5	27.4

as illustrated by Scheme 1; when the adduct is of type **2** or **3**, type **1** exists only as an unstable intermediate. In the present work, low temperature (≈0 °C) experiments were carried out to find such an intermediate in the reaction mixture but not successful. Further consideration as to why the stability of type **1** depends so much on the substituents in the dipolarophile will be given later in this note.

These reactions seem to proceed by a concerted mechanism for the following reasons: 1) the values of ΔH^* and ΔS^* in Table 1 are in the ranges of the corresponding ones for some other 1,3-dipolar cycloadditions for which a concerted mechanism is concluded[11] and 2) the rate constants are insensitive to solvent polarity as seen in Table 2. The latter fact shows unlikelihood of a two-step machanism involving a zwitterionic intermediate; if the transition state has zwitterionic character to a significant extent, a rate factor of over 10^4 (*cf.* smaller than two in Table 2) would be expected in the range of solvent polarity covered in Table 2.[1,12]

Although differences in the kinetic parameters in Table 1 are relatively small, some of them are important. In the case of $COOCH_3$ substituted dipolarophiles, the *cis* form is less reactive than the *trans* form, while the former is more reactive than the latter in the case of CN-substituted ones. DMM is unique also with respect to the type of adduct. DMM is lower in reactivity than MN in spite of its lower ΔH^*, the reactivity difference being controlled by the entropy term. The anomalous behavior of DMM would be ascribed to the steric hindrance between the bulky $COOCH_3$ groups. Since such a steric hindrance prevents conjugation due to coplanarity between the pyrazoline ring and $COOCH_3$ group in the adduct of DMM (type **1** and *cis* form[13]), the H shift does not occur, and thus, the *cis* form of type **1** (produced by DMM) which is thermodynamically less stable than the *trans* form (produced by DMF) is isolated. With heat or a catalyst,[8] the adduct can be isomerized to type **2** which is the same as the adduct of DMF. The above consideration is supported by the fact that MN and FN give the same adduct (type **2**); the steric hindrance by a CN group is negligible compared with that by a $COOCH_3$ group.

13) It is widely accepted that the 1,3-dipolar cycloaddition is stereospecific. Although the product is described as the *trans* form without evidence in Ref. 8, the coupling constant $J_{3,4}$ is 7.5 Hz, which does not necessarily indicate the *trans* form.

Comment on Momentum Distributions of Valence Electrons of Atoms and Simple Molecules

Isao H. SUZUKI* and C. E. BRION†
Electrotechnical Laboratory, Sakura-mura, Niihari-gun, Ibaraki 305
†*Department of Chemistry, University of British Columbia, Vancouver, B.C., V6T 1Y6, Canada*
(Received April 23, 1982)

Synopsis. The relationship between vertical ionization potentials and experimental electron momentum distributions of individual valence orbitals has been examined in some series of orbitals with the same characteristics of atoms and simple molecules. It has been found that effectively pure s- and p-orbitals show trends consistent with the predicitions of the virial theorem.

The symmetric noncoplanar configuration of the binary (e,2e) method is powerful for studies of molecular electronic structure. This technique provides not only binding energy spectra of valence electrons of atoms and molecules but also their orbital momentum distributions (MD).[1–20] The relative (e,2e) cross-section is essentially given by the square of the Fourier transform of the wave function of the struck electron, in the plane wave impulse approximation including the target Hartree-Fock state.[1–3]

$$\sigma(q) \propto \left| \int \psi(r) \times e^{iqr} d^3r \right|^2.$$

In this expression ψ means the one-electron wave function describing the orbital of the struck electron prior to the (e,2e) reaction.

Most of the MD measured so far can be classified into s-type and p-type.[1–20] The former is for orbitals with isotropic spatial distributions, *e.g.*, atomic s-orbitals. The s-type MD shows a maximum at $q=0$ a_o^{-1}. The latter (*i.e.*, p-type) is for those with antisymmetric spatial distributions, *e.g.*, atomic p-orbitals. The p-type MD shows zero intensity at $q=0$ a_o^{-1} and exhibits a maximum at $q \cong 0.4$—1.0 a_o^{-1}.

The virial theorem predicts a relationship between total energy of a molecule and total kinetic energy of the bound electrons. This theorem does not apply to individual orbitals, but some relationship may exist between orbital energy and the kinetic energy of its orbital electron in a series of orbitals with similar characteristics.[21,22] It is interesting to examine the qualitative applicability of the virial theorem to individual orbitals. For this purpose the MD's observed by the binary (e,2e) method can be used as a measure of the kinetic energy of the orbital electron.

The aim of the present study is to discuss and to clarify the relationship between the measured MD and the orbital energy. The MD data used here are those for valence orbitals of rare gas atoms and of molecules which consist of one or two central atoms with or without a few hydrogen atoms: Ne, Ar, Kr, Xe (atoms), HF, HCl, HBr, HI, H_2O, NH_3, CH_4, H_2S, PH_3 (pseudo-atoms), N_2, CO, O_2, (diatomic molecules), and C_2H_2, C_2H_4, C_2H_6 (pseudo-diatomic molecules).[1–20]

Figure 1 shows the degree of correlation between q_{hw} and the square root of the vertical ionization potential

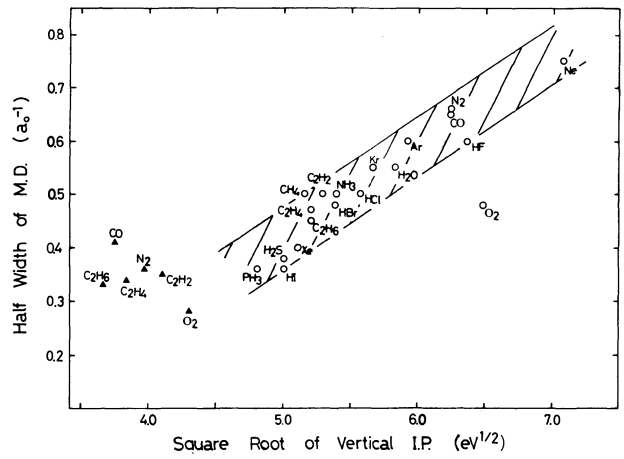

Fig. 1. Correlation between half width (q_{hw}) of s-type momentum distributions and vertical ionization potentials (IP) for valence orbitals. See text for definition of q_{hw} and for data marks (○ and ▲). The chemical formula of atoms and molecules are added to the data marks but the orbitals' symbols are omitted for clarity.

(IP). The q_{hw} means the momentum at which the s-type MD becomes a half of its maximum intensity. The vertical IP means the centroid of main and all satellite peaks belonging to the same hole state, if satellite peaks are observed in the ionizing process.[1,2] In this case accuracy of the IP is ± 1—2 eV. This centroid IP corresponds to the orbital energy when the ground state of the target atom or molecule is well described with a single configuration.[1,2] The open circles (○) indicate the data for the orbitals mainly composed of atomic 2s, 3s, 4s, and 5s-orbitals.[1–20] The solid triangles (▲) indicate the data for the orbitals mainly consisting of bonding combination of atomic 2p-orbitals.[13–20] The error in the estimation of q_{hw} is about five times the sizes of the circles or triangles shown.

The data shown with the open circles represent a linear relationship between the q_{hw} and the square root of the vertical IP. This feature means that a high q_{hw} corresponds to a high IP (a large negative orbital energy in Koopmans' theorem). Thus, the orbital showing a higher q_{hw} has a spatial distribution which tends to be contracted to regions of larger potential energy, *i.e.*, nearer to the nuclei. The orbital with a lower q_{hw} is distributed more in regions of lower potential energy. This fact shows that the virial theorem qualitatively holds for individual orbitals at least in the series of the orbitals studied here which have the s-type MD and consist mainly of atomic s-orbitals. An exception is $O_2 2\sigma_g$ orbital. This is probably due to correlation effects in the neutral ground state as well as in the ionic state.

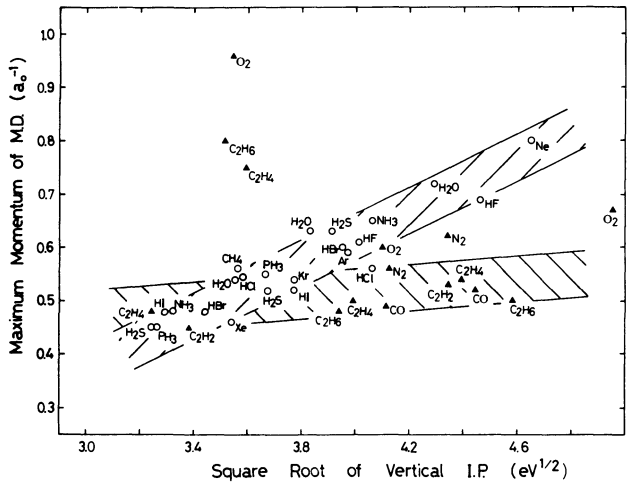

Fig. 2. Correlation between maximum momentum (q_m) of p-type momentum distributions and vertical ionization potentials (IP) for valence orbitals. See text for definition of q_m and for data marks (○ and ▲).

The relation between the solid triangles' data and the IP is complicated. The virial theorem can not be applied to this type of the orbitals.

Figure 2 shows correlation between q_m and the square root of the vertical IP. The q_m indicates the momentum at which the p-type MD is a maximum. The open circles (○) are data for the orbitals of the atoms and the pseudo-atoms. The solid triangles (▲) are data for the orbitals of the diatomic and seudo-diatomic molecules. The errors in estimation of q_m are about four times the sizes of the circles or the triangles shown.

From Fig. 2, it is seen that the q_m for the atoms and the pseudo-atoms has nearly a linear dependence on the square root of the vertical IP. One of the open circles (datum for HCl 5σ orbital) is slightly lower than the hatched area for the atoms and the pseudo-atoms' data. However, the datum point marginally overlaps with the area if the error of q_m is taken into account. This near linear dependence suggests that the virial theorem can qualitatively be applied to individual orbitals in the series of the orbitals of the atoms and the pseudo-atoms showing the p-type MD's which have been examined in the present study.

The orbitals of the diatomic and pseudo-diatomic molecules showing p-type MD's are classified into two groups, antibonding orbitals and others. The former have two nodal planes bisecting the molecular axis and parallel to the axis. Then their wave functions rapidly vary in coordinate space, and the antibonding orbitals are expected to have considerably higher MD's. These orbitals here considered are O_2 $1\pi_g$, C_2H_4 $1b_{1g}$ and C_2H_6 $1e_g$ orbitals; q_m=0.96, 0.75, and 0.8 a_o^{-1}, respectively. The three data points of interest are plotted quite high above the hatched area for the atoms and the pseudo-atoms' data.

The second group of the orbital consist of the antibonding combination of atomic 2s-orbitals and π-bonding orbitals. Both have one nodal plane, bisecting the molecular axis or parallel to this axis. The q_m for these orbitals is slightly dependent on the IP. The π-bonding orbital is diffuse and has much weight of spatial distribution in the intermediate region of atoms. The orbitals of 2s antibonding combination is spatially distributed to the opposite regions to the molecular center. These characteristics are assumed to bring about the weak dependent feature of the q_m on the IP. The three data, O_2, $2\sigma_u$, O_2 $1\pi_u$, and N_2 $2\sigma_u$ orbitals, deviate slightly to higher q_m from the hatched area for this group of the orbitals.

(Received May 4, 1982)

Synopsis. Standard energy of combustion and standard enthalpy of vaporization of *N,N*-dimethylaniline have been determined by oxygen bomb combustion calorimetry and vaporization calorimetry, respectively. Derived standard enthalpies at 298.15 K are as follows: $\Delta H_c^\circ(1) = -(4767.8 \pm 3.2)$, $\Delta H_f^\circ(1) = (47.7 \pm 3.4)$, $\Delta H_v^\circ = (52.83 \pm 0.03)$, and $\Delta H_f^\circ(g) = (100.5 \pm 3.4)$ kJ mol^{-1}, respectively.

Despite the fact that *N,N*-dimethylaniline is one of the representative tertiary amines, literature data of standard thermodynamic quantities are meager. We have determined standard energy of combustion and standard enthalpy of vaporization, both at 298.15 K, by calorimetric methods. Results of these measurements are briefly reported in this note.

Experimental

Materials. Commercial *N,N*-dimethylaniline (Wako, Special Grade) was purified by treatment with acetic anhydride, hydrochloric acid, tin(II) chloride, and aqueous sodium hydroxide, followed by extraction with diethyl ether, drying with sodium hydroxide, fractional distillation at reduced pressure (twice) and drying with calcium hydride. Gas-liquid chromatographic analysis using PEG 20M as liquid phase gave the purity of 99.96 mass per cent.

Combustion Calorimetry. An isoperibol rotating bomb calorimeter with a platinum-lined bomb of Osaka University, described elsewhere,[1,2] was used without rotating the bomb. The calorimeter was calibrated by burnig thermochemical standard benzoic acid (U. S. National Bureau of Standards, SRM 39i) under certificate conditions. Mean and standard deviation of the mean (sdm) for the energy equivalent of the empty calorimetric system ε(calor)[5] was determined to be (15161.67 ± 0.74) J K^{-1} from eleven calibration experiments.

N,N-Dimethylaniline, which had been placed in a glass vacuum system together with activated molecular sieve 4A, was transfered into a vessel, where inverted soft glass ampoules with a thin tubular stem had been located, by vacuum distillation, and then charged into the ampoules under the pressure of dry nitrogen. The fine neck of the ampoule was fused at the outside of the vacuum system with a small city-gas flame to seal the ampoule. The ampoule filled with a sample was placed in an open platinum crucible together with a small amount of paraffin oil which acted as a promoter, and combustion was started by igniting the oil at 3 MPa of oxygen pressure.

Complete combustion was achieved by reducing the mass of *N,N*-dimethylaniline to below 0.26 g, while adjusting the mass of the paraffin oil so that the resultant corrected temperature rise would be similar to that of the calibration experiments (1.84 K). Otherwise, the formation of soot in the crucibles or the formation of yellow colored bomb solution with irritating odor resulted. Only four experiments were successful.

Vaporization Calorimetry. A carrier-gas type vaporization calorimeter of Miyazaki University[3] was used. The calorimetric system was tested by measuring ΔH_v° of cyclohexane and decane. Mean and sdm of each of five determinations were (33.03 ± 0.04) and (51.36 ± 0.06) kJ mol^{-1} for cyclohexane and normal decane, respectively, while the recommended values[4] are (33.03 ± 0.04) and (51.35 ± 0.04) kJ mol^{-1}, respectively.

Auxiliary Quantities. Relative atomic masses were taken from the recommendation of the IUPAC Commission on Atomic Weights (1977). Densities, specific heat capacities, $(\partial U/\partial p)_T$ values, and specific energies of combustion of the paraffin oil and cotton fuse, are collected in Table 1. Internal volume of the bomb was 0.3469 dm^3.

Results and Discussion

Results of combustion calorimetric experiments on *N,N*-dimethylaniline are presented in Table 2. Molar standard energy of combustion given in this table refer to the following idealized combustion reaction at 298.15 K: $C_8H_{11}N(1) + (43/4)O_2(g) = 8CO_2(g) + (11/2) \cdot H_2O(1) + (1/2)N_2(g)$. Most of the symbols used in Table 2 are essentially similar to those used by Hubbard *et al.*[5] ΔU_Σ denotes the sum of contributions from items 81—85 and 87—94 as defined in Ref. 5. The mean and sdm of observed molar standard energies of combustion were $-(4762.2 \pm 1.3)$ kJ mol^{-1}.

Results of vaporization calorimetric experiments are summarized in Table 3. Molar enthalpy of vaporization ΔH_v was calculated with the equation: $\Delta H_v =$

a) R(heater)=50.608 Ω.

$I^2Rt(M/m)$, where I is the current made to flow through the heater with the resistance R of 50.608 Ω at 298.15 K for the duration t, and, m and M are the mass and the molar mass, respectively, of the material vaporized during the experiment. Mean and sdm for the nine experiments were $(52.83\pm0.01_3)$ kJ mol^{-1}. Since the vapor pressure of *N,N*-dimethylaniline is much lower than 10^4 Pa at 298.15 K, ΔH_v, thus derived, may be taken to be ΔH_v°.

Derived standard thermodynamic quantities at 298.15 K are as follows: $\Delta U_c^\circ(1)=-(4762.2\pm3.2)$, $\Delta H_c^\circ(1)=-(4767.8\pm3.2)$, $\Delta H_f^\circ(1)=(47.7\pm3.4)$, $\Delta H_v^\circ=(52.83\pm0.03)$, and $\Delta H_f^\circ(g)=(100.5\pm3.4)$ kJ mol^{-1}, respectively, where uncertainties are the overall values. The overall standard deviation of mean for $\Delta U_c^\circ(1)$ and $\Delta H_c^\circ(1)$, $s(\bar{U})_\Sigma$, was calculated with the equation: $s(\bar{U})_\Sigma=\Delta U_c^\circ(1)[\sum_{i=1}^{4}\{f_i s_r(i)\}^2]^{1/2}$, where $s_r(i)$ and f_i are the relative standard deviation of mean and the weight, respectively, of the i-th contribution, which follows: (1) The experimental value of $\Delta U_c^\circ(1)$; (2) the energy equivalent; (3) the certified specific energy of combustion of the thermochemical standard benzoic acid; and (4) the specific standard energy of combustion of the paraffine oil. By letting $f_1=f_2=f_3=1$, $f_4=2$, $s_r(1)=2.7\times10^{-4}$, $s_r(2)=0.5\times10^{-4}$, $s_r(3)=0.4\times10^{-4}$, and $s_r(4)=0.9\times10^{-4}$, $s(\bar{U})_\Sigma$ was calculated to be 1.6 kJ mol^{-1}. The overall uncertainties for $\Delta U_c^\circ(1)$ and $\Delta H_c^\circ(1)$ are $\{2s(\bar{U})_\Sigma\}$. The following CODATA key values for thermodynamics[6)] were used to calculate $\Delta H_f^\circ(1)$: $\Delta H_f^\circ(CO_2, g)=-(393.51\pm0.13)$ and $\Delta H_f^\circ(H_2O, 1)=-(285.830\pm0.042)$ kJ mol^{-1}, respectively, where uncertainties are those at the 95 per cent confidence level. The overall uncertainty for ΔH_v° is twice the sdm, $\{2s(\Delta H_v)\}$. The overall uncertainties for $\Delta H_f^\circ(1)$ and $\Delta H_f^\circ(g)$ are $[\{2s(\bar{U})_\Sigma\}^2+\{8\times0.13\}^2+\{5.5\times0.042\}^2]^{1/2}$ and $[\{2s(\bar{U})_\Sigma\}^2+\{8\times0.13\}^2+\{5.5\times0.042\}^2+\{2s(\Delta H_v)\}^2]^{1/2}$, respectively.

The large uncertainty assigned to $\Delta U_c^\circ(1)$ originates mainly from the relatively small masses of *N,N*-dimethylaniline used in the combustion experiments.

The only experimental value of $\Delta H_c^\circ(1)$ reported so far is the old value of Stohmann (-4782.4 kJ mol^{-1}),[7)] while estimated values, *e.g.* -4754.3[8,9)] and -4753.6[10)] kJ mol^{-1}, respectively, are less negative than the old experimental value.[7)] The present value is intermediate between the two groups. No other calorimetric value has been reported for ΔH_v°. The present value is higher than the value derived from the analysis of vapor pressure data, 49.8 kJ mol^{-1},[9)] by 3.0 kJ mol^{-1}.

Chemical Reaction Following Electroreduction of Benzophenones. 2. Relationship between the Rate Constant of Disproportionation and Spin Density

Naoyoshi EGASHIRA,* Yusaku TAKITA, and Fumiaki HORI
Department of Environmental Chemistry and Engineering, Faculty of Engineering, Oita University, 700 Dannoharu, Oita 870-11

(Received August 17, 1981)

Synopsis. Electroreduction of benzophenones in DMF in the presence of Li^+ was investigated by cyclic voltammetry. Most of these radical anions underwent disproportionation reactions. The relationship between the logarithm of the rate constant of the reaction and the spin density of the carbon atom at the carbonyl group was found to be linear.

In recent years there have been numerous investigations dealing with the behavior of radical anions generated in various ways.[1-3] Generally the radical anions undergo a dimerization[4,5] or a disproportionation reaction[6] in the presence of cations.

The authors reported in the previous paper[7] that the disproportionation of the electrogenerated radical anions of several substituted benzophenones **1** were accelerated by the addition of lithium iodide, and that a linear relationship was found between the logarithms of the rate constants of the disproportionation, ln k_{obsd}, evaluated from cyclic voltammetry (CV). This was confirmed by the digital simulation and the spin density, ρ_s, of the carbon atom at the carbonyl group of benzophenones. In this paper, we report that the above relationship is valid for the other benzophenones, **2** and **3**. Furthermore, a linear relationship between ln k_{obsd} and the electron density, q, of the oxygen atom at the carbonyl group was found for benzophenones **1**, **2**, and **3**.

Experimental

Chemicals. All the substituted benzophenones (**1a**, **1d**, **1e**, **2c**, **2d**, **2e**: Waco, **1b**, **1c**, **2a**: Aldrich, **1f**, **1g**, **2b**, **2f**, **3**: Tokyo Kasei) were purified by recrystallization. Benzyl alcohols used as authentic samples for a high performances liquid chromatography (HPLC) were prepared with the method of Meerwein-Pondorf: α-(4-biphenyl)benzyl alcohol **4**: mp 97.0—97.5 °C (lit,[8] 96 °C), IR(KBr) 3260 cm^{-1} (OH); α-(2-thienyl)benzyl alcohol **5**: mp 56.5 °C (lit,[9] 57—58 °C); IR (KBr) 3260 cm^{-1} (OH), α-(*p*-methoxyphenyl)benzyl alcohol **6**: mp 66—67 °C (lit,[10] 59—60 °C), IR (KBr) 3270 cm^{-1} (OH).

CV. CV was carried out in the same way as described in the previous paper.[7] The differecne between cathodic peak and the switching potentials was 0.1V. The sweep rate was 0.1V/s.

Controlled Potential Electrolysis. Reduction of 2.0 g of **2a** in 100 ml of DMF containing 3.0 g of LiI was carried out at the potential of the first wave, −1.80 V *vs.* SCE. After passing $2F$** of electricity, the catholyte was analyzed by HPLC.

Results and Discussion

The first wave of the voltammogram for **2a** is a reversible one-electron transfer: $i_{pa}/i_{pc}=1$ and $|E_{pc}-E_{pa}|=70$ mV. By the addition of LiI, i_{pa} decreases and i_{pc} increases slightly. Controlled potential electrolysis at −1.80 V *vs.* SCE in the presence of Li^+ gave **4**, a two-electron reduction product in 70% yield. All the remainder except the product was the starting material. These results show that the following disproportionation occurs:

$$R + e \rightleftharpoons R^{\cdot}$$
$$2R^{\cdot} \longrightarrow R^{=} + R,$$

where R is a reactant, $R^{\cdot}$ a radical anion and $R^{=}$ a dianion of a reactant.

The profile of the voltammogram for other benzophenones examined was similar to that of **2a**. The electrolysis of **2f** and **1f** gave **5** and **6** in 30% and 62% yield, respectively. In both cases, the remainder was mostly the starting material. From the above results we concluded that the following chemical reaction was disproportionation for all the benzophenones tested. The rate constants of disproportionation, k_{obsd}, were estimated from the voltammetric data of these compounds by using digital simulation (Table 1). The plots of ln k_{obsd} against ρ_s gave a straight line as shown in Fig. 1. It was confirmed that the k_{obsd} was predictable from the ρ_s.

The reaction rate of benzophenones having an electron-attracting substituent (**2a**, **2b**) and having a hetero atom (**2c**, **2d**) would tend to be slower than that of **1a**. **1b** and **3** exhibited reversible cyclic voltammograms even in the presence of 16-fold concentration excess of Li^+. This does not promote the reaction. The behavior of **1b** can be attributed to the 2-methyl group which inhibits mutual access to the carbon atom in the carbonyl group, and that of **3** to both steric hindrance (corresponding to the 2 and 2′ positions of

** F=96487 C mol^{-1}.

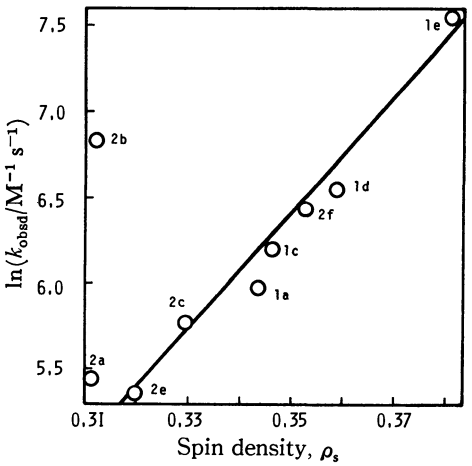

Fig. 1. Correlation between the rate constant of the disproportionation, k_{obsd}, and the spin density, ρ_s, for benzophenones.

1a) and the lowering of ρ_s.

Furthermore the plots of ln k_{obsd} against q were found to be linear. This suggested that ρ_s and q may bear a linear relationship to each other. Thus, the change in k_{obsd} with ρ_s and/or q is probably based on the change in association constants for the ion-pair formation between radical anions and Li^+. At present, unfortunately, no association constants of the ion-pairs have been obtained; and the contribution of ρ_s and q to k_{obsd} cannot be discussed separately.

Redox Reaction of the Central Metal Ions Coordinated to Tetra(*p*-sulfophenyl)porphine (TPPS). II. Photoreduction of [Fe(III)TPPS]$_2$O by Ethanol

Keiichiro HATANO* and Yoshitaka ISHIDA
Department of Pharmaceutical Sciences, Nagoya City University, Mizuho-ku, Nagoya 467
(Received November 26, 1981)

Synopsis. Iron(III) ion coordinated to TPPS was reduced to the divalent ion by ethanol on illumination of light. The reaction rates appear to obey the half-order kinetic of the metalloporphyrin in the buffered solutions of pH 7 to 11. A possible reaction mechanism is discussed.

The photochemical redox behavior of metalloporphyrins is of continuing interest due to their biomimetic functions as chlorophylls in photosynthesis and their possibilities as photosensitizers for solar energy conversion. Besides our study of the photoreduction of Co(III)-TPPS,[1] some recent work that is relevant to our present kinetic investigation of iron porphyrin photochemistry may be cited as follows: the photoreduction of Mn(III)-TPyP[2] and the Mn(IV) derivatives by ethanol or water studied extensively by Harriman and Porter,[3] and the photoreduction of hemin in ethanol–pyridine–water mixed solvents by Bartocci *et al.*[4]

Dimer formation for Fe(III), Mn(III), or Mn(IV) porphyrin in basic solutions is certain,[5] or at least suggested by the X-ray moleculer structures.[6,7] The coordination of water or alcohols to these metalloporphyrins is certain from the crystal structures.[8–10] This note describes some details of earlier data[11] of the photoreduction of Fe(III)TPPS, here we treat the μ-oxo dimer formation and the axial ligation of ethanol.

Figure 1 shows typical spectral changes of Fe(III)-TPPS in the deaerated aqueous ethanol during the photolysis in two separate experiments. The changes can be ascribed to the photoreduction of the central iron(III) ion of FeTPPS to the iron(II) ion, judging from the spectral characteristic of the product Fe(II)-TPPS, and the reoxidation of it to the original Fe(III)-TPPS by air introduction. Fe(III)TPPS restored by a cycle of the redox reactions is, though dependent on the irradiation time and other conditions, almost quantitative (>95%) in regular experiments. Furthermore, acetaldehyde detected in the irradiated solution as the oxidation product of ethanol confirms that the overall reaction is an autoxidation reaction of ethanol catalyzed by the Fe(III)⇌Fe(II) couple of FeTPPS. Some apparent isosbestic points are found in the spectral changes, but close inspection in the spectra reveals that the photochemical reaction is not a simple interconversion of Fe(II)- and Fe(III)TPPS but that some other minor species also take part. In particular, the spectrum of μ-oxo dimer in alkaline solution resembles closely that of the ethanol coordinated iron(III)-porphyrin species which are expected to be formed in the neutral aqueous solution with the addition of ethanol. Thus, several species having a similar absorption spectrum or very small abundance in the solution are considered to overlap into a spectrum represented by that of μ-oxo dimer. This situation does not allow the strict and accurate analysis of the reaction rates. However, the distinct absorption of Fe(II)TPPS in the Soret region and the known optical density can permit the plausible reaction mechanism elucidation unless the trace of spectra goes severely off from the quasi-isosbestic points in the spectral changes. The observed rates of the photoreduction fit approximately the following equation under the conditions of the constant photon flux and pH:

$$d[\text{Fe(II)TPPS}]/dt = k'[(\text{FeTPPS})_2\text{O}]^{1/2}[\text{ethanol}].$$

Figure 2 demonstrates the half-order rate dependence in the metalloporphyrin kinetics. The half-order kinetic is also confirmed by the experiments varying the initial concentrations of Fe(III)TPPS. Fleischer *et al.*[5] have studied the kinetics of the monomer-dimer equilibrium reaction of Fe(III)TPPS in aqueous

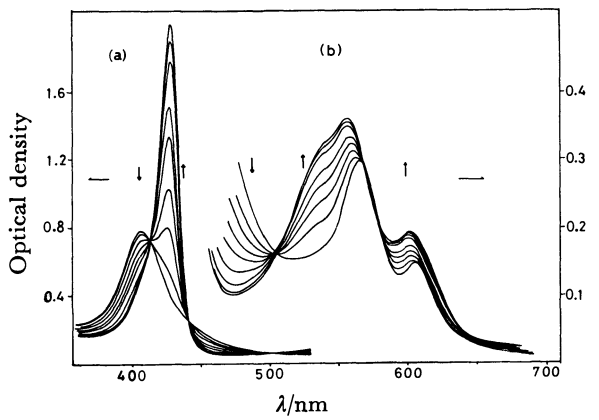

Fig. 1. Spectral changes of FeTPPS during photolysis. Experimental conditions and reaction times shown in the order of arrows are: (a) 3.8×10^{-6} M $(\text{FeTPPS})_2\text{O}$, 2.5 M ethanol, at pH 8.0, and 0, 10, 20, 30, 45, 60, 90, 120, and 210 min. (b) 4.5×10^{-5} M $(\text{FeTPPS})_2\text{O}$, 4.0 M ethanol, at pH 8.4, and 0, 10, 20, 30, 40, 55, 70, 90, 120 min. 1 M=1 mol dm^{-3}.

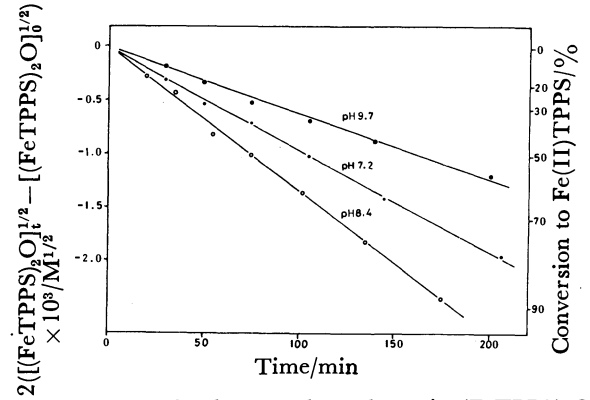

Fig. 2. The half-order rate dependence in $(\text{FeTPPS})_2\text{O}$ kinetics at various pH. The right hand scale shows % conversion of $(\text{FeTPPS})_2\text{O}$ to Fe(II)TPPS.

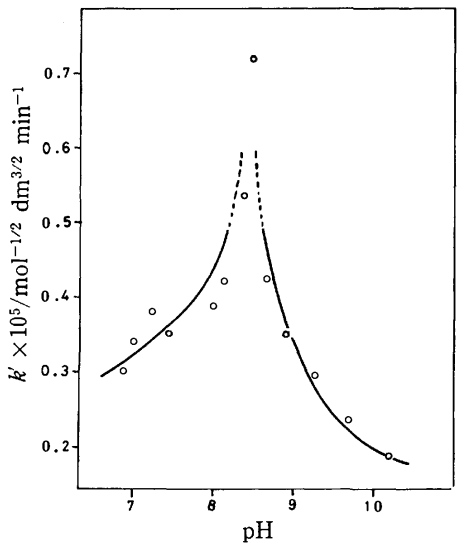

Fig. 3. The pH profile of the rate constants, k'. [Ethanol] $=2.5$ M.

solutions; the rate of the reaction is reported to be faster than that of the present photoreaction. Therefore, the rate-determining step of the photoreduction should not be the dissociation of dimer into monomer. The initial stage of the linkage chain hydrogen-bromine reaction has been classically analyzed as the half-order kinetic approximation in bromine concentration.[12] A similar interpretation can apply for the present reaction mechanism. Thus, a photoinduced electron transfer reaction is considered to be the rate-determining step involving a monomeric photosensitive species. The plausible representation of the reaction scheme to elucidate the kinetics is written as:

$$(\mathrm{FeTPPS})_2\mathrm{O} + \mathrm{H_2O} \rightleftharpoons 2\mathrm{Fe(III)TPPS(OH)}$$

$$\mathrm{Fe(III)TPPS(OH)} + \mathrm{C_2H_5OH} \rightleftharpoons \mathrm{Fe(III)TPPS(OH)(C_2H_5OH)}$$

$$\mathrm{Fe(III)TPPS(OH)(C_2H_5OH)} \xrightarrow{h\nu} \mathrm{Fe(II)TPPS} + \mathrm{CH_3\dot{C}HOH} + \mathrm{H_2O}.$$

The first-order kinetic in ethanol concentrations substantiates the coordination of one ethanol molecule to a photosensitive ferric species. The mechanistic representation is principally identical to the photoreduction of Co(III)TPPS.[1] The entity of the particular ternary complex coordinating an OH ion as the photosensitive species is supported by the kinetic studies in solutions of varying pH. As shown in Fig. 3, the volcano-shape profile of the rate constants, k', against pH indicates that there is an optimal concentration of hydroxide ion to stabilize the photosensitive species.

The overall quantum yield depends on the quantity of the photosensitive species in solutions. The highest observed quantum yield (*ca.* 0.01) is achieved at high ethanol concentration (5.2 M), optimal pH (8.5), and relatively low concentration of FeTPPS (1.6×10^{-6} M). The pursuit of higher values is hampered by the low solubility of FeTPPS in ethanol.

The reoxidation reaction occurs. The rate is too rapid to be followed by the traditional spectromeric device. This suggests that the reducing potential of Fe(II)TPPS is higher than that of Co(II)TPPS, toward the dioxygen molecule.

Experimental

FeTPPS was prepared as described.[5] Dark green powder was obtained by treatment of crude material in methanolic solutions with sodium methoxide several times. Found: C, 43.19; H, 3.04; N, 4.86; S, 10.57%. Calcd for $(\mathrm{FeTPPS\,Na_4})_2\mathrm{O}\ 16\mathrm{H_2O}$, $\mathrm{C_{88}H_{80}N_8S_8O_{41}Fe_2Na_8}$: C, 43.01; H, 3.29; N, 4.56; S, 10.44%.

Procedures and instruments employed in the experiments were the same as reported previously[1] except that a Wacom XD-501S xenon lamp was also used. The quantum yield was determined by comparison of spectrometric measurements to the CoTPPS case. Acetaldehyde was analyzed in the sample distilled in vacuo from the FeTPPS solution photolyzed for 45 h using a qualitative *p*-phenylenediamine–$\mathrm{H_2O_2}$ method[13] and a nitroprusside method[13] as a quantitative detection. Although both methods are not specific for acetaldehyde, the negligible amount of the porphyrin decomposition and the normal quantum yield (10^{-3} order) for alcohol oxidation support this assignment.

We thank Kuniko Uchiyama for experimental assistance.

Application of Coagulated Ion-exchanger Colorimetry to the Determination of Trace Amounts of Phosphate in Water

Kiichi Matsuhisa,† Kunio Ohzeki,* and Tomihito Kambara
Department of Chemistry, Faculty of Science, Hokkaido University, Sapporo 060
†*Division of Environmental Conservation, Graduate School of Environmental Science, Hokkaido University, Sapporo 060*
(Received March 30, 1982)

Synopsis. The combined use of finely divided anion and cation exchange resins reported previously[1] was partly modified and applied to the determination of trace amounts of phosphate in some environmental water samples, such as rain, snow, lake water and seawater. Both orthophosphate and total phosphate were determined and satisfactory results were obtained.

The ion-exchanger colorimetry developed by Yoshimura *et al.*[2] is an excellent method for trace analysis, in which a colored metal complex with negative or positive charge is concentrated on the corresponding ion-exchanger and determined spectrophotometrically in a 1-mm cell.

On the other hand, we reported a new type of ion-exchanger colorimetry,[3] in which a combination of finely divided anion and cation exchange resins was used. One of the characteristics of fine particle ion-exchangers is the coagulation. The coagulated resins are collected on a filter paper as a disk of thin layer, which is directly subjected to spectrophotometric analysis, no cell being required. Therefore, hereafter, we call the method the coagulated ion-exchanger colorimetry.

Experimental

Reagents. Phosphate, molybdate, antimony tartrate, and ascorbic acid solutions were prepared according to the previous report.[1]

Mixed Reagent: A 100-ml portion of 2.5 M (1 M=1 mol dm^{-3}) sulfuric acid was mixed with 30 ml of the ammonium molybdate solution and 10 ml of the potassium antimony tartrate solution. When a considerable amount of sulfuric acid was already contained in the sample solution, as in the case of hydrolyzable phosphate sample, the acid amount in the mixed reagent was reduced, so that a constant acidity in the final test solution was kept to 0.18 M.

Dipping Solution: The composition was the same as in the previous report.[1]

Mixed reagent and dipping solution were prepared fresh daily and stored in a thermostat kept at 25±1 °C.

Ion-Exchange Resin Suspension. The cation exchange resin suspension (CRS) and anion exchange resin suspension (ARS) were freshly prepared according to the method reported.[4] The exchange capacities were 11.8 μequiv. ml^{-1} for CRS and 7.0 μequiv. ml^{-1} for ARS, respectively. Both suspensions were kept at 25±1 °C.

Apparatus. A Shimadzu UV 140-01 spectrophotometer was used. A Toyo KG 25 filter holder was used with filter papers of No. 5B (Toyo Roshi). A vacuum gauge used was a NRK product, type STV-75. Decomposition vessels of 70-ml capacity (Uniseal) were used.

Procedure. A 50-ml aliquot of the test solution containing less than 0.3 μg of phosphorus as phosphate was taken into a 100-ml beaker and the solution was kept at 25±1 °C in a water bath. A 6.0-ml portion of the mixed reagent and 2.0 ml of the ascorbic acid solutions were added and the solution was stirred by means of a magnetic stirrer for 5 min. Finally, 4.0 ml of ARS and 2.0 ml of CRS were added and the mixture was stirred for 10 min. The coagulated resins were collected on a filter paper strip placed on the holder with suction under *ca.* 160 mmHg by running water. A disk of colored resin, 17 mm in diameter and about 0.3 mm in thickness, was formed. The filter strip was soaked in the dipping solution for 15 min. It was then fixed on a glass plate fitted on the one side of cell holder, which is nearer to the light source, *i.e.*, the light beam goes successively through the thin layer, filter paper, and finally glass plate. The absorbance of the resin phase was measured at 700 nm against a dry filter paper or another white paper.

Another disk of resin was prepared without addition of phosphate. The absorbance corresponding to the reagent blank including the resins was also measured. The net absorbance of the complex on the resin phase was obtained as the difference.

The main differences of the proposed procedure from the previous one[1] were in the following respects: firstly, 5 min were allowed for the development of the molybdenum blue complex (in the previous procedure, ARS and CRS were successively added immediately after the color developing reagents); secondly, resin suspensions with higher exchange capacities were used, namely, the total exchange capacities were 23.6 μequiv. for cation exchanger and 28.0 μequiv. for anion exchanger (in the previous procedure, the values were 10.4 and 15.2, respectively); thirdly, the suction pressure of *ca.* 4 times higher than that in the previous procedure was applied to collect the mixed resins.

Sample Preparation for Dissolved Orthophosphate (P-D, ortho). The sample water was filtered through No. 5C filter paper.

Sample Pretreatment for Total Phosphate (P, total). A 50-ml portion of sample water was used without filtration. According to the JIS method,[5] it was digested with hot sulfuric and nitric acids, neutralized, and finally diluted to 50 ml with water. In the case of seawater, a 10-ml portion of sample was digested. A large amount of precipitate was formed, which was removed by filtration. The filtrate together with washings were neutralized and diluted to 100 ml with water. The solution for the blank test was prepared according to the same procedure with deionized water, instead of sample solution.

Pretreatment of Seawater for Hydrolyzable Phosphate (P, hydro). Familiar Harvey's method[6] being partly modified, a 10-ml portion of seawater was taken into a Teflon crucible and 1.0 ml of 9 M sulfuric acid was added. The crucible was set in the jacket previously kept at 125 °C in an air-bath, and then allowed to stand for ca. 40 min at a room temperature. The sample solution was transferred into a 50-ml volumetric flask and diluted to the mark with water. The 5-ml portions of the solution were subjected to the standard addition method.

Results and Discussion

Stirring Time for Color Development. The thin layer with a constant coloration was obtained by

Table 2. Determination of phosphate in seawater[a)]

Date 1981	Sample amount ml	P-D, ortho ppb[b)]	P, total ppb[b)]	Sum of (P, hydro) and (P, ortho) ppb[b)]
Jun. 25	4.0	26.2 ± 1.2		
	2.0		31.1 ± 9.5	
Jun. 29	4.0	24.8 ± 5.8		
	2.0		37.0 ± 13.0	
Aug. 10	4.0	23.3 ± 2.7		
Aug. 15	4.0	21.5 ± 5.0		
Sep. 08	4.0	17.4 ± 5.0		
	1.0			41.1 ± 6.7[c)]
	1.0			41.8 ± 6.0[d)]
Sep. 16	2.0	17.7 ± 1.1		
	1.0			40.0 ± 1.1[c)]

a) Surface seawater at Ishikari bay. b) The standard addition method was applied and the 90% confidence limits ($n=4$) were calculated. c) 90-min heating. d) 250-min heating.

stirring the test solution in the range 5—30 min before the addition of CRS and ARS. When the resins were added immediately after the addition of the mixed reagent and ascorbic acid solution, a lower absorbance was observed.

Calibration Graph. The calibration graph was linear over the concentration range 1.0—6.0 ng P ml^{-1}. The mean absorbance with the standard deviation was 0.148 ± 0.005 ($n=3$) for 1.0 ppb P and 0.833 ± 0.012 ($n=5$) for 6.0 ppb P. The modified procedure having an improved sensitivity was advantageous in comparison with the previous one.[1)]

Determination of Phosphate. The results are summarized in Tables 1 and 2. The amount of orthophosphate is determined much more precisely than that of total phosphate, since no pretreatment except filtration is required. The application of the JIS method[5)] to the determination of total phosphate has been reported to be difficult.[7)] A large amount of precipitate formed in the course of acid digestion will cause the loss of phosphorus and poor reproducibility (Table 2).

On the other hand, the sum of hydrolyzable phosphate and orthophosphate (P, ortho)[8)] in seawater is fairly precisely determined (Table 2). Sample seawater was heated in the presence of sulfuric acid at 125 °C in a Uniseal decomposition vessel. A 90-min heating was enough to hydrolyze any phosphate present in seawater. The combined use of sulfuric acid and potassium peroxodisulfate for the determination of total phosphate was also examined, but no reliable result was obtained.

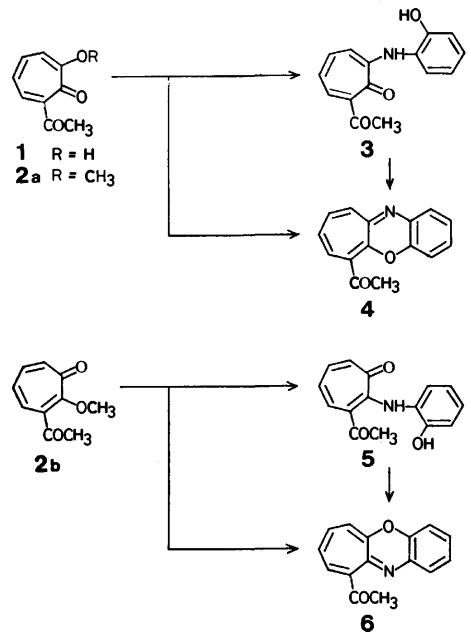
Reactions of 3-Acetyltropolone and Its Methyl Ethers with *o*-Aminophenol

Kimiaki IMAFUKU,* Akihiro SHIGENOBU, and Makoto OGURA
Department of Chemistry, Faculty of Science, Kumamoto University, Kurokami, Kumamoto 860
(Received April 3, 1982)

Synopsis. 3-Acetyltropolone (**1**) and 2-acetyl-7-methoxytropone (**2a**) reacted with *o*-aminophenol in ethanol to afford 2-acetyl-7-(*o*-hydroxyanilino)tropone (**3**). The reaction of 3-acetyl-2-methoxytropone (**2b**) gave 3-acetyl-2-(*o*-hydroxyanilino)tropone (**5**). The compounds **3** and **5** were cyclized to 6-acetyl- and 10-acetylcyclohepta[*b*][1,4]benzoxazines (**4** and **6**), respectively, by heating their acetic acid solutions in the presence of a trace amount of concentrated sulfuric acid. The compounds **4** and **6** were also obtained directly from **1** (or **2a**) and **2b**, respectively, by the reaction with *o*-aminophenol in acetic acid. The compound **5** exists as a tautomeric mixture with **5'**.

It is well known that the reactions of so-called ractive troponoids——2-methoxytropones or 2-chlorotropones ——with *o*-phenylenediamine,[1,2] *o*-aminophenol,[3] and *o*-aminobenzenethiol[4] afford 6*H*-cyclohepta[*b*]quinoxaline, cyclohepta[*b*][1,4]benzoxazine, and cyclohepta-[*b*][1,4]benzothiazine, respectively. These products are heterocyclic compounds containing two hetero-atoms with a 6,6,7-ring system. Previously, in a series of chemistry of 3-acetyltropolone, we reported the formation of a benzodiazaheptalene derivative with a 6,7,7-ring system, besides 5*H*- and 6*H*-cyclohepta[*b*]quinoxalines with a 6,6,7-ring system, by the reactions of 3-acetyltropolone methyl ethers with *o*-phenylenediamine.[5]

In the present work, the reactions of 3-acetyltropolone (**1**) and its methyl ethers (**2a** and **2b**) with *o*-aminophenol were carried out in expectation of the formation of an oxazepine ring—a 6,7,7-ring system. However, the reactions gave no oxazepine ring but gave acetyl-substituted (*o*-hydroxyanilino)tropones (**3** and **5**) and cyclohepta[*b*][1,4]benzoxazines (**4** and **6**).



Scheme 1.

Results and Discussion

In general, tropolones do not show any indication to react with nucleophilic reagents as well as phenols. However, tropolones bearing a strong electron-withdrawing group, such as nitro or nitroso group, react with nucleophiles to give 2-substituted tropones.[6] Recently, we found that 3-acetyltropolone (**1**) reacts with amines to afford 2-acetyl-7-aminotropones.[7] The refluxing of 3-acetyltropolone (**1**) with *o*-aminophenol in ethanol gave 2-acetyl-7-(*o*-hydroxyanilino)tropone (**3**) in 15% yield. The reactivity of **1** would be based on the electron-withdrawing effect of the acetyl group. The same reaction was carried out in acetic acid containing a trace amount of concentrated sulfuric acid to afford a cyclized product——6-acetylcyclohepta[*b*][1,4]benzoxazine (**4**)——in 3% yield. The compound (**3**) in acetic acid was refluxed in the presence of concentrated sulfuric acid to cyclize to **4**.

The refluxing of 2-acetyl-7-methoxytropone (**2a**) with *o*-aminophenol in ethanol gave **3** in 44% yield, the same reaction in acetic acid giving **4** in 33% yield. Similarly, the reaction of 3-acetyl-2-methoxytropone (**2b**) with *o*-aminophenol in ethanol gave 3-acetyl-2-(*o*-hydroxyanilino)tropone (**5**) in 31% yield, the reaction in acetic acid giving 10-acetylcyclohepta[*b*][1,4]benzoxazine (**6**) in 27% yield. The compound (**5**) was also converted to **6** in 55% yield by heating its acetic acid solution. The structures of all the products were determined by their elemental analyses and spectral data (see: Experimental part).

As shown in Fig. 1, the ^{1}H NMR spectrum of **5** in chloroform-d_1 shows two singlet peaks at δ 2.03 and 2.50 for =C(OH)–CH_3 and –C(=O)–CH_3 protons, respectively. These two singlet peaks indicate that **5** exists as a tautomeric mixture with **5'**. The spectrum in more polar solvent—methanol-d_4—shows only one singlet peak at δ 2.02 and the signal near δ 2.50, which

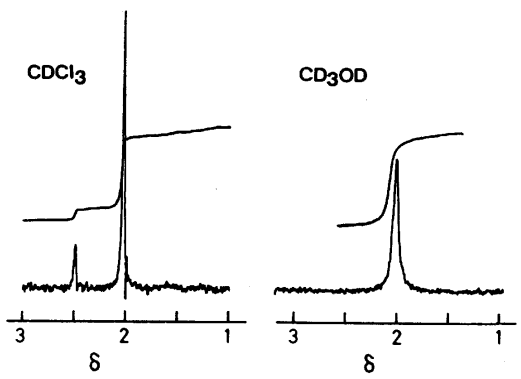


Fig. 1. The ^{1}H NMR spectra of **5** in chloroform-d_1 and methanol-d_4.

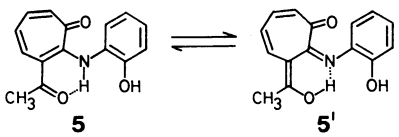

Scheme 2.

appeared in chloroform-d_1, is not observed. A similar keto-enol tautomerism of the acetyl group was observed in the spectrum of 6-acetyl-5*H*-cyclohepta[*b*]quinoxaline.[5]

The ^{1}H NMR spectrum of **4** measured in trifluoroacetic acid shows shift of the seven-membered ring protons by *ca.* 1.0 ppm and that of the benzene ring protons by *ca.* 0.1 ppm towards lower magnetic field than those in chloroform-d_1. Similar phenomena were observed in a parent compound——cyclohepta[*b*][1,4]benzoxazine,[3] and 6*H*-cyclohepta[*b*]quinoxaline.[2] These observations indicate that the positive charge is delocalized over both the seven-membered ring and the heterocycle but little over t he benzene ring. The spectrum of **6** also shows a similar tendency.

In this work, the expected 6,7,7-ring system, which is produced by the reaction at the acetyl group, was not isolated. This might be due to the instability of the oxazepine ring.

Experimental

The melting points were determined with a Yanagimoto MP-S2 melting-point measuring apparatus and are uncorrected. The IR spectra were taken on a JASCO IRA-1 spectrophotometer, and the UV spectra on a Hitachi EPS-3T spectrophotometer. The spectra in acidic medium were measured by adding three drops of 1M hydrochloric acid to the sample solution. The ^{1}H NMR spectra were recorded with a Hitachi-Perkin-Elmer R-24 spectrometer (60 MHz).

*Reaction of 3-Acetyltropolone (**1**) with* o*-Aminophenol. a)*: A mixture of 3-acetyltropolone (**1**) (200 mg, 1.2 mmol) and *o*-aminophenol (250 mg, 2.3 mmol) in absolute ethanol (15 ml) was refluxed for 6 h. After removal of the solvent, the residue was twice chromatographed on a Wakogel B-10 plate (30×30 cm²) with chloroform to afford 47 mg (15%) of 2-acetyl-7-(*o*-hydroxyanilino)tropone (**3**) as reddish orange plates (from benzene–hexane); mp 109—110 °C; IR ($CHCl_3$) 3380, 3260 1700, 1595 cm^{-1}; UV (CH_3OH) 232 (log ε 4.36), 360 (3.90), 433 nm (4.33); UV (CH_3OH+HCl) 236 (log ε 4.36), 359 (3.89), 433 nm (4.31); NMR ($CDCl_3$) δ=2.50 (s, 3H,$COCH_3$), 6.5—7.6 (m, 9H), 8.85 (br, 1H). Found: C, 70.45; H, 5.14; N, 5.44%. Calcd for $C_{15}H_{13}NO_3$: C, 70.58; H, 5.13; N, 5.49%.

b): Concentrated sulfuric acid (3 drops) was added to a solution of **1** (216 mg, 1.3 mmol) and *o*-aminophenol (287 mg, 2.6 mmol) in acetic acid (5 ml). The mixture was refluxed for 3 h. After removal of the acetic acid under reduced pressure, the residue was dissolved in chloroform, washed with saturated sodium hydrogencarbonate solution and twice with water, and dried over anhydrous sodium sulfate. The chloroform was evaporated off and the residue was chromatographed on two Wakogel B-10 plates (30×30 cm²) with chloroform to afford 10 mg (3%) of 6-acetylcyclohepta[*b*][1,4]benzoxazine (**4**) as dark brown plates (from benzene–hexane); mp 97—99 °C; IR ($CHCl_3$) 1705 cm^{-1}; UV (CH_3OH) 265 (log ε 4.38), 432 nm (4.31); UV (CH_3OH+HCl) 229 (log ε 4.39), 274 (4.36), 325 (3.85), 461 nm (3.92); NMR ($CDCl_3$) δ=2.38 (s, 3H, $COCH_3$), 5.7—6.2 (m, 4H, H-7,8,9,10), 6.4—7.3 (m, 4H, H-1,2,3,4). Found: C, 75.90; H, 4.77; N, 5.92%. Calcd for $C_{15}H_{11}NO_2$: C, 75.93; H, 4.67; N, 5.90%.

*Cyclization of 2-Acetyl-7-(*o*-hydroxyanilino)tropone (**3**).* A solution of **3** (178 mg) in acetic acid (5 ml) containing concentrated sulfuric acid (3 drops) was refluxed for 2 h. The reaction mixture was worked up, as mentioned above, to give 87 mg (53%) of **4**.

*Reaction of 2-Acetyl-7-methoxytropone (**2a**) with* o*-Aminophenol. a)*: A mixture of 2-acetyl-7-methoxytropone (**2a**) (206 mg, 1.2 mmol) and *o*-aminophenol (234 mg, 2.1 mmol) in absolute ethanol (15 ml) was refluxed for 4 h. The reaction mixture was worked up, as mentioned above, to give 135 mg (44%) of **3**.

b): A solution of **2a** (181 mg, 1.1 mmol) and *o*-aminophenol (217 mg, 1.9 mmol) in acetic acid (5 ml) containing concentrated sulfuric acid (3 drops) was refluxed for 4 h. The reaction mixture was worked up, as mentioned above, to give 79 mg (33%) of **4**.

*Reaction of 3-Acetyl-2-methoxytropone (**2b**) with* o*-Aminophenol. a)*: A mixture of 3-acetyl-2-methoxytropone (**2b**) (275 mg, 1.5 mmol) and *o*-aminophenol (328 mg, 3.0 mmol) in absolute ethanol (15 ml) was refluxed for 5 h. After removal of the solvent, the residue was twice chromatographed on two Wakogel B-10 plates (30×30 cm²) with chloroform to afford 122 mg (31%) of 3-acetyl-2-(*o*-hydroxyanilino)tropone (**5**) as reddish brown needles (from benzene–hexane); mp 149—150 °C; IR ($CHCl_3$) 3370, 3200, 1720, 1600 cm^{-1}; UV (CH_3OH) 252 (log ε 4.30), 425 nm (4.18); UV (CH_3OH+HCl) 396 nm (log ε 3.96); NMR ($CDCl_3$) δ=2.03 (s, =C(OH)-CH_3), 2.50 (s, -C(=O)-CH_3), 6.5—7.5 (m, 9H), 9.62 (br, 1H); NMR (CD_3OD) δ=2.02 (s, 3H, =C(OH)-CH_3), 6.5—7.5 (m, 9H). Found: C, 70.56; H, 5.22; N, 5.27%. Calcd for $C_{15}H_{13}NO_3$: C, 70.58; H, 5.13; N, 5.49%.

b): A solution of **2b** (178 mg, 1.0 mmol) and *o*-aminophenol (217 mg, 2.0 mmol) in acetic acid (5 ml) containing concentrated sulfuric acid (3 drops) was refluxed for 5 h. The acetic acid was evaporated off under reduced pressure and the residue was worked up, as mentioned above, to give 65 mg (27%) of 10-acetylcyclohepta[*b*][1,4]benzoxazine (**6**) as dark brown plates; mp 124—125 °C; IR ($CHCl_3$) 1700 cm^{-1}; UV (CH_3OH) 263 (log ε 4.28), 425 nm (3.95); UV (CH_3OH+HCl) 236 (log ε 4.27), 267 (4.15), 275 (4.13), 336 (3.80), 406 (3.78), 452 nm (sh, 3.73); NMR ($CDCl_3$) δ=2.40 (s, 3H, $COCH_3$), 5.5—6.5 (m, 4H, H-6,7,8,9), 6.6—7.0 (m, 4H, H-1,2,3,4). Found: C, 75.92; H, 4.83; N, 5.74%. Calcd for $C_{15}H_{11}NO_2$: C, 75.93; H, 4.67; N, 5.90%.

*Cyclization of 3-Acetyl-2-(*o*-hydroxyanilino)tropone (**5**).* A solution of **5** (106 mg) in acetic acid (5 ml) containing concentrated sulfuric acid (3 drops) was refluxed for 1.5 h. The reaction mixture was worked up, as mentioned above, to give 54 mg (55%) of **6**.

The present work was supported in part by a Grant-in-Aid for Scientific Research No. 56540308 from the Ministry of Education, Science and Culture.

Hydrogen Peroxide-catalyzed Ozonation of Refractory Organics. I. Hydroxyl Radical Formation

Keisuke NAMBA* and Shigeki NAKAYAMA
Product Development Laboratory, Mitsubishi Electric Corporation, Amagasaki, Hyogo 661
(Recieved November 30, 1981)

Synopsis. The kinetics of hydrogen peroxide-catalyzed ozonation was studied in aqueous solutions of various lower alcohols containing ethanol as a reference. The relative rates of degradation of alcohols obtained support the initiation of the reaction by hydroxyl radicals formed in the reaction between ozone and hydrogen peroxide.

The use of ozone for water treatments has been growing steadily in responce both to increasing requirement for environmental protection and to recent improvement in the efficiency of ozone generator.[1] Ozone is known to be efficient in decolorization of effluents containing organics, but believed generally to be ineffective toward removal of COD (Chemical Oxygen Demand) and TOC (Total Organic Carbon). This may be ascribed to the characteristics of ozone which reacts very rapidly with unsaturated compounds but slowly with saturated ones.

The authors have been studying catalytic ozonation to remove COD and TOC in effluents containing refractory organics, and developed several ozonation methods, *i.e.*, high-pH ozonation,[2] UV-irradiated ozonation[3] and hydrogen peroxide (H_2O_2)-catalyzed ozonation.[4] Of these methods, H_2O_2-catalyzed ozonation is the most practical because of its simplicity and economic advantage, and was commercialized to remove COD in the effluent from an electrodeposition process.

In a series of investigations on the reaction mechanism of H_2O_2-catalyzed ozonation, the authors found that hydroxyl radical is formed and acts as an initiator for the oxidation of refractory organics. The present paper reports an experimental result supporting the OH radical formation.

Experimental

Ozonation was carried out at room temperatures (22—27 °C) by using an apparatus shown in Fig. 1. Ozone was generated from oxygen (99.98%) in a Mitsubishi OS-1 ozonizer (max. capacity, 2 g-O_3/h). The stream of ozonized oxygen from the ozonizer, containing 20 g/m³ ozone, was passed at a constant flow rate of 1000 cm³/min through a 1000 cm³ gas absorption bottle (6.5 cm I.D.) filled with various solutions for ozonation. An ozone monitor was set up for measuring ozone concentration in the inlet and outlet gas stream.

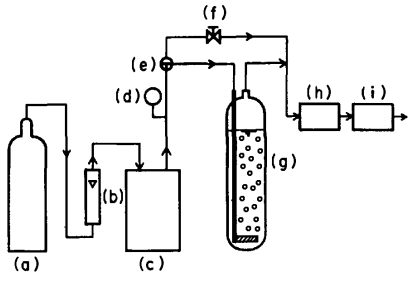

Fig. 1. Apparatus. (a): O_2-cylinder, (b): flow meter, (c): ozonizer, (d): pressure gauge, (e): three-way cock, (f): needle valve, (g): gas absorption bottle (reactor), (h): ozone monitor, (i): activated carbon column.

Aqueous solutions (*ca.* 1—10^{-1} mol/m³) of methanol, ethanol, 1-propanol, 2-propanol, 1-butanol, 2-methyl-1-propanol, 2-butanol, and 2-methyl-2-propanol were used for the ozonation. All chemicals were of commercially available reagent grade. H_2O_2 was added to the solution just before the ozonation. The pH of the solution was kept 7.5 during the ozonation by dosing sodium hydroxide; otherwise, the pH decreased gradually with the reaction time.

The concentrations of alcohols and the reaction products were measured by a gas chromatograph with a flame ionization detector and 2 m packed columns of PORAPAK-Q, -N and TENAX-GC. H_2O_2 concentration was measured by means of iodometry using ammonium molybdate.

Results and Discussion

The degradation of ethanol by ozone (feeding rate, 20 mg/min) in the presence of H_2O_2 (initial concentration, 5×10^{-1} mol/m³) is shown in Fig. 2. The effect of H_2O_2 on enhancement of the degradation of alcohols is remarkable. Figure 3 shows a typical reaction profile of H_2O_2-catalyzed ozonation: ethanol disappeared rapidly in the early stage of the reaction consuming about equimolar amount of ozone and acetaldehyde and acetic acid were formed in the later stage. TOC was also decreased after an induction period. The molar ratio of consumed H_2O_2 to consumed ozone was about 1/20. The amount of organics fleeing from the bottle during the ozonation was confirmed to be negligible. These results indicate clearly that H_2O_2 accelerates ozone

oxidation of ethanol.

The mechanism of the acceleration may be attributed to HO radical formation by the reaction of H_2O_2 with ozone, as was suggested by Taube and Bray.[5] In order to comfirm the assumption, the relative rate constants for the degradation of several lower alcohols were determined by competition kinetic measurements, and compared with the literature values.[6] Solutions containing two kinds of alcohols, with ethanol being the reference, were ozonized in the presence of H_2O_2, and relative rate constants were obtained, by assuming first order reaction rate with respect to concentration of alcohol, from the following equation:

$$k_{rel} = \frac{\ln([C_1]_f/[C_1]_i)}{\ln([C_2]_f/[C_2]_i)},$$

where C_1 and C_2 are the concentrations of objective alcohol and ethanol, respectively, the subscripts i and f denoting the conditions before and after the reaction, respectively. Figure 4 shows a typical profile of competitive degradation obtained with a mixed solution of ethanol and 2-methyl-2-propanol. The values of k_{rel} obtained are shown in Table 1 together with those obtained for the reactions between alcohols and HO radical.[6] It should be noted that both values agree quite well with each other, which means that the oxidation of alcohols is initiated by HO radical in the H_2O_2-catalyzed ozonation.

Table 1. Relative degradation rate constants of lower alcohols in water by H_2O_2-catalyzed ozonation and HO radical

Compound	k_{rel}	k_{ROH}/k_{EtOH} [a)]
Methanol	0.40	0.46
Ethanol	1	1
1-Propanol	1.51	1.48
2-Propanol	1.17	1.10
1-Butanol	2.12	2.19
2-Methyl-1-propanol	1.93	1.80—1.91
2-Butanol	1.53	1.31—1.69
2-Methyl-2-propanol	0.28	0.28

Synthesis of Polymethyl Crown Ethers. A New Class of Lipophilic Crown Ethers

Isao IKEDA, Shingo YAMAMURA, and Mitsuo OKAHARA*

Department of Applied Chemistry, Faculty of Engineering, Osaka University, Yamadaoka 2-1, Suita, Osaka 565

(Received February 15, 1982)

Synopsis. A new class of lipophilic polymethyl crown ethers were synthesized from oligopropylene glycols *via* the intramolecular cyclization, and the stability constants of some complexes in methanol were determined.

Crown ethers show a superior ability as catalyst in nucleophilic substitution reaction of solid-liquid phase-transfer systems. In the case of liquid-liquid systems, however, quaternary onium salts usually show a better performance than ordinary crown ethers. The differences in effectiveness as phase transfer catalysts between crown ethers and quaternary salts may be attributed to the difference of lipophilicity between crown complexed cations and quaternary onium cations.

To overcome this unsatisfactory ability of crown ethers, some investigators[1-4] introduced a lipophilic group, such as an alkyl group or an acyl group, into the crown ether molecule. Although these lipophilic crown ethers also show excellent performance in the extraction and the transportation of salts, their preparation is tedious and require the use of uncommon reagents.

Previously we reported a new method for the preparation of crown ethers by the intramolecular cyclization of substituted and unsubstituted oligoethylene glycols.[5-7] Now we have found that the intramolecular cyclization method could be successfully applied to the preparation of polymethyl crown ethers which have not been prepared previously except for tetramethyl-12-crown-4,[8] from oligopropylene glycols. Introduction of polymethyl groups on the crown ring endows an additional lipophilicity in a different way from the known substituents and may improve the function of the crown ethers. The raw materials, penta-, hexa-, and heptapropylene glycol, were isolated from polypropylene glycol #400 by fractional distillations.

In the cyclization reaction of oligopropylene glycols, three kinds of condensations may generally take place, since the glycols are made up of three combinations of primary and secondary hydroxyl groups, depending on the origin of the oligopropylene glycols. Among these three kinds of condensations, there should be differences in reactivity and selectivity. Therefore, it is necessary to determine the ratio of the primary to secondary hydroxyl groups in the glycols. ^{1}H-NMR of acetylated hexapropylene glycol, examined as an example, showed a sextet signal at δ=4.91 and no signal at around δ=4.0—4.6, indicating the absence of primary hydroxyl group at least in the extent of NMR precision [CCl_4, δ; 1.0—1.3 (two d, 18H), 1.96 (s, 6H), 3.2—3.7 (m, 16H), 4.91 (sxt, 2H)]. Good yields of the polymethyl crown ethers prove the successful application of the intramolecular cyclization method to glycols which have two secondary hydroxyl groups.

The yields of polymethyl crown ethers seemed to be somewhat low compared with those of the cyclization of oligoethylene glycols in which two primary hydroxyl groups were concerned. This depended on the production of allyl ethers as by-product *via* elimination reaction.

Scheme

To inspect the influences of polymethyl substitution on the complexation with metal cation, stability constants with sodium and potassium cations in methanol were determined and compared with those of unsubstituted crown ethers (Table 2). Polymethyl groups

Table 1. Preparation of polymethyl crown ethers

Crown ether	Yield[a] %	Bp θ_b/°C (Torr)
Pentamethyl-15-crown-5 (**2a**)	30	100 (0.1)
Hexamethyl-18-crown-6 (**2b**)	37	105 (0.05)
Heptamethyl-21-crown-7 (**2c**)	27	115 (0.05)

a) Yield of pure, isolated product; not optimized. b) Kugelrohr distillation. c) Satisfactory microanalyses obtained (C±0.34, H±0.06). The ^{1}H-NMR spectra (CCl_4) of **2** showed two signals at δ=1.04 (d, 3(n+2)H, CH_3) and at δ=3.0—4.0 (m, 3 (n+2)H, OCH_2CHO). The mass spectra showed the parent peak, m/e=117  and m/e=59  respectively.

Table 2. Stability constants of polymethyl crown ethers with metal cations

Crown ether	log K'[a]	
	Na^+	K^+
Pentamethyl-15-crown-5 (**2a**)	3.34	2.85
15-Crown-5	3.31	(3.34—3.55)[b]
Hexamethyl- 18-crown-6 (**2b**)	2.94	3.86
18-Crown-6	4.32[c]	6.10[c]
Heptamethyl-21-crown-7 (**2c**)	2.34	3.27
21-Crown-7	2.46	4.41[c]

a) In methanol, 25 °C. b) This value depends on the ratio of K^+ cation and the ligand. Considering the formation of 2 : 1 complex, log K'_1=3.36 and log K'_2=2.62 were obtained. c) Values reported in Ref.[9]

somewhat inhibit the complexation of crown ring with metal cations, probably due to the steric effect, and thence the rigidity of the crown rings. The stability constants of complexes, however, remained still high especially for hexamethyl-18-crown-6 with potassium cation, log $K'=3.86$, and for pentamethyl-15-crown-5 with sodium cation, 3.34. The catalytic activity and extraction activity of the polymethyl crown ethers are under investigation.

Experimental

The ^{1}H-NMR spectra were taken at 100 MHz on a JEOL JNM-PS-100 spectrometer using the tetramethylsilane internal standard. The infrared spectra were obtained on a Hitachi 260-10 spectrometer. The mass spectra were taken at an ionization potential of 70 eV on a Hitachi RMU-6E mass spectrometer.

Isolation of Oligopropylene Glycol. Commercial polypropylene glyco ♯400 were fractionally distilled to separate penta-, hexa-, and heptapropylene glycol (95—97 °C/0.05 Torr (1 Torr≈133.3 Pa), 116—118 °C/0.005 Torr and 155—158 °C/0.005 Torr, respectively). They showed a single peak in each gas liquid chromatogram (silicone gum SE30 10%, 270 °C).

Polymethyl Crown Ethers. General Procedure: A mixture of hexapropylene glycol (3.6 g, 0.01 mol), tosyl chloride (2.0 g, 0.01 mol) and dioxane (30 ml) was added to a suspension of pulverized potassium hydroxide (2.7 g, 0.04 mol) in dioxane (50 ml) over a period of 2 h under stirring at 60 °C, and stirred for an additional 4 h at the same temperature. The precipitate was separated off by filtration and washed twice with dioxane. After evaporation of the dioxane from the combined solution of filtrate and washings, the resulting viscous pale yellow liquid (4.2 g) was chromatographed on silica gel, and eluted with a mixture of hexane and acetone (95 : 5) to give a colorless liquid (**2b**, 1.3 g, 37%). The yields of the crown ethers are summarized in Table 1. Mutual relations of methyl groups on a macrocycle can not be resolved, because the raw oligopropylene glycols do not have regular structures, which are prepared by addition of propylene oxide to propylene glycol in alkaline conditions.

Isolation of Allyl Ethers. By-product allyl ethers were isolated from the crude product on a silica-gel column (hexane–acetone, 90 : 10), as a following fraction of the objective polymethyl crown ethers, IR (neat film); 3090, 1645, 1000, and 920 cm^{-1}, ^{1}H-NMR (CCl_4, δ); 3.98 (d+m, 2H), 5.02 (d+d, 1H), 5.18 (d+d, 1H), and 5.8 (m, 1H).

Reaction between Enamines and Schiff Basess.[1] Evidence for the Thermal [2+2] Cycloaddition Reaction

Yujiro NOMURA,* Muneaki KIMURA, Tomoyuki SHIBATA,
Yoshito TAKEUCHI, and Shuji TOMODA
Department of Chemistry, College of General Education, The University of Tokyo, Komaba, Meguro-ku, Tokyo 153
(Received February 25, 1982)

Synopsis. Reaction between 4-(1-phenyl-1-propenyl)morpholine and *N*-benzylideneanilines provided *N*-(3-aryl-2-methyl-1-phenylallylidene)anilines in 60—65% yields, which unequivocally established the initial [2+2] cycloaddition reaction between enamines and Schiff bases.

Thermal [2+2] cycloaddition reactions are generally prohibited by the Woodward-Hoffmann rule.[2] Several exceptions involving Schiff bases include reactions with electron-deficient double bonds, such as heterocumulenes, N=O bond, and C=C bond carrying highly electronegative substituents.[3] More recently, titanium(IV) chloride-mediated [2+2] cycloadditions between Schiff bases and ketene acetals, representative electron-rich olefins, have been reported.[4]

In our previous communications, we postulated thermal [2+2] cycloaddition reaction between *N*-benzylideneanilines and enamines, another class of highly nucleophilic olefins, as the most reasonable explanation for the formation of decahydroacridines[5] and hexahydro-4-azaindacenes[6] in acetic acid as the solvent. We wish to present herein direct evidence for the intermediacy of the [2+2] cycloadduct in the reaction between the enamine (**1**) and the Schiff bases (**2**) in acetic acid.

The reactions between *N*-benzylideneanilines (**2**) and 4-(1-phenyl-1-propenyl)morpholine (**1**) were performed at room temperature under nitrogen using acetic acid as the solvent. The products, *N*-(3-aryl-2-methyl-1-phenylallylidene)anilines (**3**), were obtained in 60—65% yield after recrystallization from methanol (Table 1).

Structural assignments of these products were based on elemental analysis, spectroscopic methods and independent synthesis of their hydrolyzed products. For example, **3a**, which had a sharp melting point (mp 108—109 °C), showed strong IR absorption bands at 1605 and 1590 cm^{-1}, one of which can be assigned to the conjugated imine moiety. On the other hand, the ^1H NMR spectrum, obtained as a solution in deuteriochloroform, exhibited two methyl doublets (in each case, $J=1$ Hz; assigned to allylic coupling with the olefinic proton) due to *syn-anti* isomerism about the C=N double bond (Table 2). The relatively large difference in the chemical shifts of the methyl group between the *syn* and *anti* isomers of **3a** ($\Delta\delta=0.58$) can be attributed to the strong shielding effect of the *N*-aryl ring (Ar^2) on the methyl protons in the *syn* isomer[7] which may most probably exist as the *s-trans* conformational isomer by steric reasons.

Since these spectral and analytical informations alone may not be sufficient to prove the structure **3a**, we hydrolyzed it with MeOH–HCl to obtain the α,β-unsaturated ketone (**4a**) virtually quantitatively (98% yield). The ^1H NMR spectrum of **4a** indicated one methyl doublet ($J=1$ Hz) in accord with nearly complete stereospecificity of the reaction leading to **3a**. This was also in agreement with the experimental observation that the stereoisomerism observed for **3** by ^1H NMR is due to *syn-anti* isomerism rather than *cis-trans* isomerism involving the olefinic C=C double bond. The structure of **4a** was confirmed by spectral (IR and ^1H NMR) comparison with an authentic sample prepared by the aldol condensation between *p*-chlorobenzaldehyde and propiophenone.[8]

The present reaction can be rationalized by the mechanism illustrated in Scheme 1. Reaction between **1** and **2** would produce the azetidine intermediate (**5**) either by concerted [2+2] cycloaddition or by stepwise cycloaddition *via* zwitterionic intermediate as **6**. The azetidine intermediate **5** would rapidly undergo deamination in the acid medium to afford 2-azetine derivative

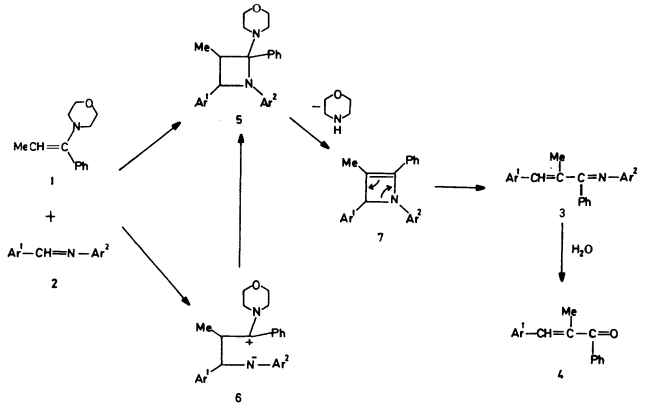

Scheme 1. Mechanism for the formation of **3**.

7, which would then collapse into the conjugated imine **3** by ring-opening process. Whether the [2+2] cycloaddition route is concerted or stepwise, it is intriguing that this route appears to be operative only in acetic acid.[9]

Experimental

Enamine (**1**) was prepared according to the procedure previously described.[10] *N*-Benzylideneanilines (**2**) were prepared by the known method.[11] Acetic acid was distilled over phosphorus pentaoxide under nitrogen. Melting points were uncorrected. IR spectra were recorded as nujol paste with a HITACHI EPS-3T Recording Spectrometer. ^{1}H NMR spectra were obtained on a JEOL JNM-MH-100 Spectrometer operated at 100 MHz. Elemental analyses were performed by Organic Analysis Laboratory of the University of Tokyo.

General Procedure for the Reaction between ***1*** *and* ***2***: A solution of **2** (41 mmol) in anhydrous acetic acid (100 ml) was slowly added to enamine (**1**) (10.4 g, 51 mmol) with stirring at room temperature under nitrogen. The resulting yellow precipitates, obtained after 7 h stirring, were collected by filtration and recrystallized from methanol to give product **3** in 60—65% yields (see Tables 1 and 2 for pertinent data of **3**).

α-Pentafluoropropionylation of Ketones and Aldehydes Using Hexafluoropropene Oxide. A Facile Synthesis of Fluorinated 1,3-Diketones

Takashi ISHIHARA,* Toshio SEKI, and Teiichi ANDO
Department of Industrial Chemistry, Faculty of Engineering, Kyoto University, Sakyo-ku, Kyoto 606
(Received March 29, 1982)

Synopsis. Hexafluoropropene oxide reacts smoothly with morpholine enamines from ketones and aldehydes at 0 °C to room temperature in anhydrous THF to give pentafluorinated 1,3-diketones in good yields. The keto-enol equilibrium in the products is generally in favor of their enol form.

Fluorinated 1,3-dicarbonyl compounds have proved to be of much value as intermediates in a variety of organic transformations and as extracting agents in inorganic syntheses.[1] Two types of methods have hitherto been used for preparing these compounds; (i) the base-promoted condensation of an ester with a ketone or an aldehyde, and (ii) the Lewis acid-catalyzed acylation of a fluorine-containing ketone with an acid anhydride. These reactions are, however, often accompanied by side reactions[1a,b,2] such as self-condensation or cleavage reaction, resulting in reduced yields of the desired fluorinated 1,3-dicarbonyl compounds. In our continuing studies to extend the utilities of hexafluoropropene and its oxide to organic syntheses, we have now found that hexafluoropropene oxide (HFPO) reacts smoothly with enamines from ketones and aldehydes under mild, neutral conditions.

This paper describes the α-pentafluoropropionylation of ketones and aldehydes using HFPO, which provides a convenient method for the synthesis of fluorinated 1,3-diketones.

Results and Discussion

In the present study the morpholine enamines from ketones and aldehydes were chosen as the starting enamine. The reaction of the enamines with HFPO took place exothermically, requiring the use of a solvent. Among the solvents examined, freshly distilled, anhydrous THF gave the best results. The reactions cleanly proceeded under the conditions described in the Experimental to afford the corresponding pentafluoro 1,3-diketones (**1**—**6**) in good yields. Table 1 summarizes the results of the reactions, together with the keto : enol ratios in the products. The use of anhydrous ether as solvent strikingly decreased the yields of the products. Thus, the reactions of the morpholine enamines from cyclohexanone, 3-pentanone, and acetophenone with HFPO in ether gave the corresponding 1,3-diketones in yields of no more than 25%. These results must be due to much less solubility of HFPO in ether than in THF.[3]

The IR and ^{1}H NMR analyses of the pentafluoropropionylated compounds (**1**—**6**) thus obtained revealed that, except for **5**, they possess an extremely high enolic character. The keto : enol ratios, listed in Table 1, were determined by comparing the integrated intensity of the vinylic hydrogen or of the enolic hydrogen in the enol form with that of the α-methylene or methyl group in the keto form (Table 2). Compounds **1**, **2**, **4**, and **6** exist nearly exclusively as enols and compound **3** exists as a nearly equimolar mixture of the two tautomers, whereas **5** exhibits only the keto character.

To be noted is that the resonance peaks due to the enolic hydrogens are sharp (half-height width *ca.* 3—6 Hz) and appear at very low fields, *i.e.*, at 13—17 ppm, as shown in Table 2. These absorptions can be inter-

preted as characteristic of 1,3-dicarbonyl compounds containing electron-withdrawing substituent groups, on the basis of the generalization suggested by Lintvedt and Holtzclaw[4] and of the observations made by Engel and Chappelow.[5]

The strong and broad absorptions in the regions of 1690—1560 and 3500—2200 cm^{-1} in the IR spectra of these fluoro 1,3-diketones also reveal the presence of the intramolecularly hydrogen-bonded enolic structure. The former absorption can be ascribed to the conjugate chelation[6] of the keto groups in the molecule.

In the reactions of the morpholine enamines from acetophenone, propiophenone, and phenylacetaldehyde with HFPO, pentafluoropropionylated enamines[7] were obtained when the reaction was quenched with a 5% $NaHCO_3$ aqueous solution, instead of an acid. Successive acid treatment of them gave the corresponding 1,3-diketones (**4**—**6**). These facts strongly suggest that the initial step of the reaction is the isomerization of HFPO[8] to pentafluoropropionyl fluoride by an enamine, followed by the acylation of the enamine with the acid fluoride to give the products.

Experimental

Infrared spectra were recorded with a Shimadzu IR-400 infrared spectrometer. A Varian EM-390 spectrometer was used to measure ^1H and ^{19}F NMR spectra, in solutions of CCl_4 with internal Me_4Si and external trifluoroacetic acid as a reference, respectively. Mass spectra were obtained with a Hitachi RMS-4 spectrometer.

The morpholine enamines from ketones and aldehydes were prepared according to the literature procedure.[9]

General Procedure for the Reaction of HFPO with Morpholine Enamines. Into a stirred solution of a morpholine enamine (25 mmol) in anhydrous THF (25 ml), which had been cooled to −20 to −15 °C, was introduced HFPO (16 mmol) under nitrogen at such a rate that the reaction temperature should not rise over 0 °C. After the introduction of HFPO was over, the whole mixture was stirred at room temperature for 20 h. In the case of the morpholine enamine from 3-pentanone, the temperature was maintained at −50 to −40 °C for 10 h and then at room temperature for 10 h. To the mixture was added 5% HCl (20 ml) dropwise under cooling with an ice–water bath. After stirred at room temperature for 2 h, the reaction mixture was poured into water (70 ml). The organic layer was separated and the aqueous layer was extracted with ether. The combined extracts were washed with water, dried (Na_2SO_4), and concentrated under reduced pressure. The residual oil was chromatographed on silica gel with hexane or benzene and, if necessary, the product was distilled *in vacuo* to give a pure 1,3-diketone.

When the reaction was quenched with a 5% $NaHCO_3$ aqueous solution, β-pentafluoropropionylated morpholine enamines were obtained as the product.

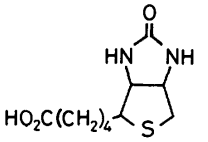
Acid Catalysis of the Transformation of 1-Methoxycarbonyl-2-imidazoline to 1-Methoxycarbonyl-2-imidazolidinone, a Carboxybiotin Model

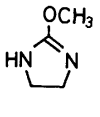
Hiroki KONDO,* Katsuhito MIURA, and Junzo SUNAMOTO
Department of Industrial Chemistry, Faculty of Engineering, Nagasaki University, Nagasaki 852
(Received April 26, 1982)

Synopsis. The transformation of 1-methoxycarbonyl-2-ethoxy-2-imidazoline into 1-methoxycarbonyl-2-imidazolidinone a 1-carboxybiotin model, is facilitated by acid.

Activation of biotin (**3**) through enolization of its urea moiety to form an isourea structure is an attractive hypothesis to account for the much higher reactivity of the coenzyme in enzymatic carboxylation reactions.[1] The putative enolbiotin may be generated by a variety of means, *e.g.*, phosphorylation by ATP of the urea moiety.[2] 2-Methoxy-2-imidazoline (**4**), a model for



3



4

enolbiotin, shows a much higher nucleophilicity than the corresponding keto compound toward carboxylic esters.[3] The problem is that the enol form is regarded much less stable thermodynamically, and hence is unlikely to be present in a significant amount.[4] In addition, the isolated intermediate of biotin carboxylation is always 1-carboxybiotin (in its methyl ester form) and it serves as a carboxyl donor in the subsequent transcarboxylase reaction.[5] Therefore, if the enolbiotin hypothesis is correct, the question how the carboxylated enolbiotin is converted to the keto form should be answered unequivocally. We found that 1-methoxycarbonyl-2-imidazoline (**1**) is readily converted to 1-methoxycarbonyl-2-imidazolidinone (**2**) in the presence of acid such as hydrochloric acid and trifluoroacetic acid.

Results and Discussion

1 is a stable, isolable 2-alkylisourea derivative, just like 1,3-diisopropyl-2-ethylisourea.[6] It was established that 2-alkylisoureas undergo an S_N2 reaction with a nucleophile such as phenol to give alkyl phenyl ether and urea.[7] Reaction of **1** under acidic conditions apparently follows a similar pathway. Thus, treatment of **1** with hydrochloric acid in chloroform at 30 °C converts **1** into **2** quantitatively (Eq. 1). Since the pK_a value of **4** in water is 9.1,[3] **1** should be present in the protonated form at 3-N position under the present conditions. The

a) Value in water. b) Equimolar to **1**. c) Thiophenol was added in 15-fold excess over **1**.

reaction can be carried out also in trifluoroacetic acid at 70 °C to produce **2** and ethyl trifluoroacetate (Table 1). Addition of 15-fold molar excess of thiophenol enhances the conversion rate by 18-fold, the reaction product being solely ethyl phenyl sulfide besides **2**. On the other hand, dimethyl hydrogenphosphate was found to be without effect under comparable conditions. These data indicate that the transformation reaction is highly dependent upon the acidity of the catalyst employed and the presence of a nucleophile as the ethyl acceptor (Table 1).[8] Picric acid is an exception. It has a pK_a value comparable to that of trifluoroacetic acid, but is by far the more effective than the latter. Thus, the rate constant for the transformation in DMSO-d_6 is 2×10^{-4} s^{-1} in the presence of equimolar picric acid at 25 °C. It should be noted that neither the reaction rate nor the reaction product (1-ethoxy-2,4,6-trinitrobenzene) is altered by the addition of excess thiophenol. This anomalous behavior of picric acid may be explicable in terms of formation of a picrate or the like with substrate prior to the transformation. This is reminiscent of a fact that in model as well as in enzymatic systems prior formation of a complex between substrate and catalyst is one of the driving forces for the efficient catalysis to occur.[9]

A similar acid catalysis of acyl transfer was observed for *O*-benzoyl-*N*,*N*-dimethyl-*N*′-(*N*-methyl-2,4-dinitroanilino)isourea, an isolable *O*-acylisourea derivative.[10] This reaction was accompanied by an intramolecular acyl migration to the imine nitrogen, though at low pH values such as 1 the proportion of the side reaction was suppressed to such an extent that the intermolecular reaction predominates by a large margin. It is noted that an analogous intramolecular alkyl migration has not been observed for **1** under the present conditions. The thermodynamic instability of 2-alkyl- or 2-acylisourea relative to the urea must be primarily responsible for the ready transformation of **1** into **2**,[4,11] and acid facilitates the reaction.[12] It would not be unrealistic to assume that the putative 1-carboxy-*O*-phosphoenolbiotin might be converted analogously to 1-carboxybiotin at the enzyme active site, possibly by general acid catalysis.

Experimental

2-Imidazolidinone (**5**) was obtained from Wako Pure Chemical Ind. 2-Ethoxy-2-imidazoline (**6**) was prepared according to a literature.[13] 1-Methoxycarbonyl-2-imidazolidinone (**2**) was synthesized by reaction of **5** with methyl chloroformate:[14] mp 179—181 °C (lit,[14] mp 180 °C). 1-Methoxycarbonyl-2-ethoxy-2-imidazoline (**1**) was prepared either by reaction of **6** with methyl chloroformate or by reaction of **2** with triethyloxonium tetrafluoroborate:[15] mp 67—69 °C (lit,[15] mp 67—70 °C). Reaction rates for the transformation of **1** into **2** were determined by ^{1}H NMR spectroscopy on a JEOL JNM-MH-100 spectrometer under conditions given in Table 1.

Photochemical Reactions in Polyethylene Glycol. 2.[1] Photo-induced Nucleophilic Substitution of Dimethoxybenzenes in the Presence of Polyethylene Glycol

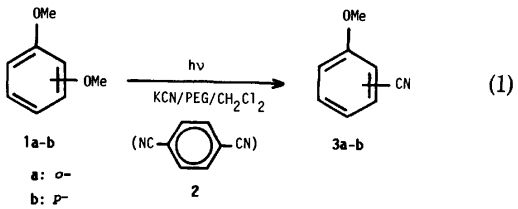
Nobutaka SUZUKI,* Yasuo AYAGUCHI, and Yasuji IZAWA
Department of Industrial Chemistry, Faculty of Engineering, Mie University, Tsu, Mie 514
(Received February 4, 1982)

Synopsis. Polyethylene glycol can replace crown ether as co-solvent for photochemical substitution reactions of dimethoxybenzenes with KCN in CH_2Cl_2 in either the presence or the absence of terephthalonitrile.

The chemistry of cyclic polyethers (crown ethers) is attracting keen interests of many investigators[2] because of the high selectivity of reaction by activated anion species in their circumstances. Many interesting photochemical reactions have been found to proceed in crown ether.[2]

In a previous report,[1] we described the first example of photochemical reaction that a much higher selectivity is obtained in PEG employed in place of crown ether in a photochemical nucleophilic substitution of anisole to give *o*- and *p*-methoxybenzonitriles (**3**). There have been known a few photochemical reactions in PEG or acyclic polyethers,[3,4] though photochemical nucleophilic substitutions of aromatic systems in protic solvents have been well documented.[1,5-8]

When a crown ether is present, photocyanation proceeds in aprotic solvents more easily than in protic solvents,[9] while addition of electron acceptor, such as terephthalonitrile (**2**), improves both the yield of photocyanation products and the specificity of substitution.[10] This report is concerned with photochemical cyanation of *o*- and *p*-dimethoxybenzenes (**1a** and **1b**) with KCN in an aprotic solvent, in the presence and absence of **2** when PEG is used as co-solvent (Scheme 1).



Scheme 1.

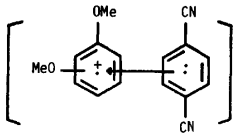
Results and Discussion

Photoreaction in a Quartz Cell in the Absence of **2**. Consumption of **1** in the presence of PEG was slightly slower than in the presence of crown ether. However, conversion yields[11] of **3** with PEG were comparable to that for **3a** and superior to those with crown ether for **3b** (see runs #1, 5, 7, and 12 in Table 1).

In comparison with the results obtained by Heijer *et al.*[8] in *t*-BuOH–H_2O, both the consumption and the conversion yield were worse for **1a** with PEG, but those for **1b** were much better.

Both the conversion of **1** and the formation of **3** were neither quenched by 1,3-pentadiene (≈50 mM) (1 M= 1 mol/dm^3) nor sensitized by acetone (≈50 mM) whose E_T (≈78 kcal/mol)[12] is high enough for sensitizing **1** to their triplet states. Fluorescence of **1** was not affected by either 1,3-pentadiene or acetone. These data suggest that the cyanations proceed through comparatively short-lived intermediates (probably S_1 state).[12]

Photoreaction in the Presence of **2**. Both the consumption of **1a** and conversion yield of **3a** with PEG were half as much as those with crown ether. However, those with PEG for the reaction of **1a** were similar to these with crown ether. Photolyses of **1b** with PEG were superior to those with crown ether and could be used for the preparation of **3b**. Both the conversion of **1** and the formation of **3** were quenched by 1,3-pentadiene[12] ($k_q\tau_0$/dm^3 mol^{-1}: 11 for **1a** and 6 for **1b**; 6 for **3a** and 16 for **3b**) and slightly sensitized with acetone.[12] These data suggest that the cyanations in the presence of **2** proceed through comparatively long-lived intermediates[12] (probably the T_1 state of **1** and/or of a charge transfer complex of **1** and **2** like **4**).[8]



4

Photoreactions in the Presence/Absence of **2**. Substitution of KCN with NaCN did not affect the consumption of **1** but did the conversion yields of **3a** (increased) and **3b** (decreased). This reflects the tolerance of PEG for the size of the cationic guests incorporated in it compared with crown ether.

Prolonged irradiation caused a slight decrease in the conversion yield of **3**. This implies that further reactions, *e.g.*, the cyanation of **3**,[13] may be faster than cyanations of **1**.[8]

Although, in Pyrex cells with PEG, consumption of **1** was much slower than in quartz cells, conversion yields of **3** increased remarkably, especially for **1b** (see runs #1 through 4 and 8 through 11 in Table 1). This phenomenon may result from a further photocyanation of **3**[8] in a quartz cell (see Table 2).

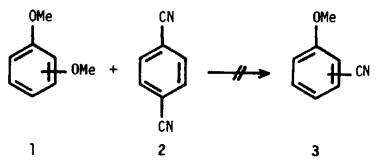
Table 2. Photodegradation of methoxybenzonitriles (**3a** and **3b**) in pyrex cells

Run	3	2 used (mM)	Conv. of 3/%		
			2 h	4 h	6 h
1	**3a**	—	10.7	12.3	19.9
2		150	41.0	59.7	69.2
3	**3b**	—	0	0.3	0
4		150	10.4	13.0	13.3

The photochemical decay rate of **3a** was much higher than that of **3b** in Pyrex cells and this tendency is more marked in quartz cells, especially in the presence of **2** (Schemes 2 and 3).

Suspected transformation of **1** and **2** to yield the corresponding **3** was excluded for these photocyanation reactions (Scheme 4).



1 2 3 (4)

Scheme 4.

Experimental

Instrumentation. All mps were taken with a microscope hot stage and are uncorrected. UV-visible spectra were recorded on a Shimadzu UV-200, fluorescence/phosphorescense spectra on a Hitachi MPF-2A, and GLC on a Yanagimoto Yanaco G-80F (FID). The GLC conditions used: Column A (5.0 mm×2.0 m, 5% PEG-20M on 60—80 mesh Gasport in a stainless steel column) was used for product analyses; column B (3.8 mm×3.0 m, 25% Apiezon L on 30—60 mesh fire brick in a glass column) was used to analyse the degradation of **1**.

Materials. Dimethoxybenzenes (**1a** and **1b**), terephthalonitrile (**2**), 18-crown-6, and KCN were purchased. CH_2Cl_2 was distilled from CaH_2. PEG #200 (Nakarai Chem. Co.) was dried azeotropically by toluene. Methoxybenzonitrile (**3a**[14] and **3b**[14]) were prepared according to the literature methods. 1,3-Pentadiene (bp 42—44 °C) and acetone were distilled before use.

General Experimental Procedures. A solution of **1** (10 mM), KCN (30 mM), and PEG (1 M) or 18-crown-6 in CH_2Cl_2 (10 cm^3) in the presence or absence of **2** (150 mM) was irradiated externally with a high-pressure mercury lamp (Eikosha P1H-300, 300 W) through a water-cooled quartz or Pyrex cell. The irradiated solution was analysed by GLC after washing with water to remove PEG and KCN. The results are given in Table 1.

Degradation of 3. Photodegradation of **3a** and **3b** (10 mM) was observed under conditions similar to those used for **1** (see Table 2).

Attempt of Photochemical Transformation of 1 and 2 to 3. A solution of **1** (10 mM) and **2** (10 mM) was irradiated and the mixture was analysed by GLC. No formation of cyanoanisoles (**3**) was observed.

Photosensitized Desulfurization of Heterocyclic Thioketones and Its Accompanied Chemiluminescence[1)]

Nobutaka SUZUKI,* Kaniti SANO, Satoshi WAKATSUKI, Noriyuki TANI, and Yasuji IZAWA
Department of Industrial Chemistry, Faculty of Engineering, Mie University, Tsu, Mie 514
(Received April 30, 1982)

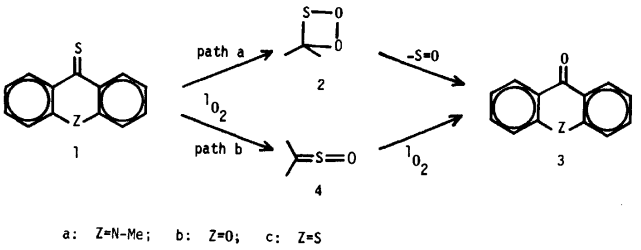
Synopsis. Photosensitized oxygenation of 10-methyl-9(10*H*)-acridinethione, 9*H*-xanthene-9-thione, and 9*H*-thioxanthene-9-thione at −78 °C gave the corresponding ketones, 10-methyl-9(10*H*)-acridinone, 9*H*-xanthen-9-one, and 9*H*-thioxanthen-9-one quantitatively in a 3—10 min-irradiation. Weak chemiluminescence was observed from the irradiated solution upon warming-up.

For photooxygenation of thiocarbonyl compounds, two alternative mechanisms have been proposed, *i.e.*, the 1,2,3-dioxathietane[2-6)] (path a) and the sulfine mechanisms[7-8)] (path b). Chemiluminescence (CL) has been expected to be accompanied with the decomposition of 1,2,3-dioxathietane (**2**)[9)] which is generated on sensitized photooxygenation of C=S compounds. The intermediate (**2**) is supposed to have a large energy enough for exciting the produced ketone (**3**) or added fluorescers to their S_1 excited states.[10)]

Since the first report by Schönberg and Mostafa,[2)] on photooxidation of thiobenzophenones and 4*H*-thiopyran-4-ones in sunlight, a number of reports on photooxidative desulfurization of C=S compounds (**1**) appeared:[2-8,11)] Sensitized photooxygenation of 4*H*-pyran-4-thiones and 4*H*-thiopyran-4-thiones by Ishibe *et al.*;[3)] of 2,2,4,4-tetramethyl-3-thioxo-1-cyclobutanone and dibenzyl thioketone by Worman *et al.*;[4)] of 9*H*-xanthene-9-thione, 9*H*-fluorene-9-thione, and alicyclic thioketones by Ramamurthy *et al.*[5)] Through the corresponding 1,2,3-dioxathietane intermediates (**2**) the reactions were supposed to proceed. Photooxygenation of sulfines (**4**)[11)] and O-alkyl thiocarboxylates[6)] was also claimed to proceed through the similar intermediates (path a).

Photooxygenation of di-*t*-butyl thioketone[7)] and 1,2-benzodithiole-3-thione[8)] was found by Tamagaki *et al.* to give the corresponding sulfines (**4**) and ketones (**3**), and hence, an alternative sulfine mechanism (path b) was proposed for the oxidation. On the other hand, Tamagaki *et al.* also reported that di-*t*-butyl sulfine was inert to singlet oxygen.[7)] Theoretical calculation of molecular orbitals suggests that the oxidation of thioketones proceeds stepwisely through the 1,2,3-dioxathietane (**2**) and its successive, radical decomposition to the ketone (**3**) and S=O.[9)] Energy liberated on the decomposition of **2** was calculated as *ca.* 92.1 kcal/mol[1,10)] which is large enough for exciting the ketones (**3**) produced or the added fluorescers to their S_1 excited state [67.3,[12)] 68.8,[13)] 67.2[14)] for **3a**, **3b**, and **3c** and 66.0,[14)] 64.9,[14)] and 50.2 kcal/mol[14)] for 9,10-diphenylanthracene (DPA), 9,10-dibromoanthracene (DBA), and rubrene, resp.].

For finding out such chemiluminescent intermediates (**2**) and for clarification of the oxygenation mechanism, namely, the 1,2,3-dioxathietane or the sulfine mechanism, investigation was carried out for the sensitized photooxygenation of aromatic thioketones, **1a**, **1b**, and **1c**, which would give fluorescent ketones, **3a**, **3b**, and **3c** resp. In the present paper, photosensitized oxygenation of 10-methyl-9(10*H*)-acridinethione (**1a**),[15)] 9*H*-xanthene-9-thione (**1b**),[16)] and 9*H*-thioxanthene-9-thione (**1c**)[17)] is described to give the corresponding ketones (**3a**—**c**) in quantitative yields with 3—10 min-irradiation.



Scheme 1.

Each solution of the heterocyclic thioketones (**1a**—**c**) with Methylene Blue as a sensitizer in CH_2Cl_2 was irradiated under flushing O_2 gas at −78 °C for 60 min with a tungsten-halogen lamp through an optical glass filter (<510 nm cut off) cooling with a Pyrex/water filter in a Pyrex or quartz cell. Samples taken during irradiation were analysed by GLC after standing at room temperature for 30 min. The results are shown in Table 1. These results show that the present oxygenation reactions yield the corresponding ketones (**3a**—**c**) in quantitative yields[18)] in a short time-irradiation. According to Zwanenburg *et al.*,[11)] photooxygenation of aromatic sulfine compounds needs fairly long time-irradiation (2.5—6 h/5—20 mM), and hence, we speculate in spite of Tamagaki's report[8)] that the present photooxygenation proceed predominantly through path a.

For detection of the expected chemiluminescence at the spontaneous decomposition of the 1,2,3-dioxathietane (**2**), efforts were made, when the intact irradiated solution (10^{-2}—10^{-4} M) or the solutions added into several fluorescers (rubrene, DPA, and DBA at 10^{-2}—10^{-4} M) were warmed up to room temperature. Weak chemiluminescence (*ca.* 10^{-8} einstein/mol) was detected (Table 2). Since it was so weak, the emission spectra could not be measured. Although they were very weak, these were the first examples of the detection of the chemiluminescence for the supposed 1,2,3-dioxathietane. The weakness of the light emitted may result from further photochemical decomposition of **2** once produced during irradiation.[19)]

Table 1. Photooxygenation of thioketones (**1a**—**c**)

1	Concn mM	MB (mM)	Irrad. time min	Product yield (3)[a)] %
1a;	10.1	1.0	3	85
1b:	11.4	1.1	10	100
1c:	10.9	1.2	5	100

a) Yields based on the starting materials used.

Table 2. Relative quantum yields of chemiluminescence of **1**

Additive [A]	[A]/[**1**]	Φ_{CL}(rel)		
		1a[a]	**1b**[a]	**1c**[a]
none	—	5	8	100
DBA[b]	1—10	17	25	17
DPA[b]	1—10	8	5	100
Rubrene	1—10	—	17	100

a) 10^{-2}—10^{-4} M. b) DBA: 9,10-Dibromoanthracene; DPA: 9,10-diphenylanthracene.

Table 3. Effect of inhibitors on photooxygenation of **1**

Inhibitors [I]	[I]/[**1**]	Φ_{CL}(rel)		
		1a[a]	**1b**[a]	**1c**[a]
DABCO[b]	25	Q[c]	Q	Q
β-Carotene	5	Q	Q	—
TBP[b]	25	—	N[d]	N

a) 10^{-2}—10^{-4} M. b) DABCO: 1,4-diazabicyclo[2.2.2]octane; TBP: 2,4,6-tri-*t*-butylphenol. c) Q: Quenched. d) N: No effect.

Influence of $^1O_2$-quenchers (DABCO[20] and β-carotene[20]) and a radical scavenger (2,4,6-tri-*t*-butylphenol)[20] on the oxygenation (see Table 3) suggests that the reactions proceed with $^1O_2$ non-radically.

Experimental

The thioketones (**1a—c**) were prepared by the reaction of the corresponding ketones (**3a—c**) (Nakarai Chem. Co.) with P_2S_5 according to the usual procedure: *10-Methyl-9(10H)-acridinethione* (**1a**), mp 268—273 °C (lit,[15] mp >260 °C); ν_{max} (KBr) 1580, 1500, 1220, 1180, 1000, and 740 cm^{-1}; δ_{ppm} (DMSO-d_6) 3.96 (s, 3H), 7.28 (m, 3H), 7.78 (m, 3H), and 8.88 (m, 2H); *m/z* 225 (M^+); *9H-xanthene-8-thione* (**1b**), mp 156—158 °C (lit,[16] mp 155—156 °C); ν_{max} (KBr) 1590, 1450, 1320, 1100, 770, and 740 cm^{-1}; *m/z* 212 (M^+); *9H-thioxanthene-9-thione* (**1c**), mp 193—205 °C (decomp) (lit,[17] mp 180—215 °C); ν_{max} (KBr) 1590, 1450, 1320, 1060, 740 cm^{-1}; *m/z* 228 (M^+).

Photosensitized Oxygenation. Each solution of the thioketones (**1a—c**) (*ca.* 10 mM) with Methylene Blue (*ca.* 1 mM: Nakarai Chem. Co.) in CH_2Cl_2 (distilled from CaH_2 before use) was irradiated under O_2 atmosphere at −78 °C for 60 min with a projector lamp (Silvania/Kondo tungsten-halogen lamp ELH 120 V/300 W at 100 V) through an optical glass filter (Toshiba Y-52, <510 nm cut off) and a Pyrex/water filter in a Pyrex or quartz cell (φ 10 mm). Aliquots were taken during irradiation and analysed by glc and tlc after standing at room temperature for 30 min. The conditions of GLC used were as follows: For **1a** and **3a**: Yanagimoto Yanaco G-80F with FID, 10% Silicone GE-SE-30 on Diasolid L (60—80 mesh) in a stainless steel column, 0.93 m × φ 4 mm, col. temp 250 °C, inj. temp 280 °C, carrier gas (N_2), 75.0 ml/min, internal standard, 9*H*-xanthene-9-thione. For **1b** and **3b**: Yanagimoto Yanaco G-1800F with FID, the same column as above; col. temp 250 °C, inj. temp 264 °C, carrier gas (N_2), 42.9 ml/min, internal standard, 9-benzylidene-9*H*-xanthene. For **1c** and **3c**: G-1800F, the same column as above, col. temp 250 °C, inj. temp 275 °C, carrier gas (N_2), 54.5 ml/min, internal standard, 9*H*-xanthen-9-one. The results are shown in Table 1.

Observation of the Chemiluminescence. Each irradiated cold solution as above (**1** : 10^{-2}—10^{-4} M) was poured into a quartz fluorescence cubette (1 cm) placed in front of photomultiplier tube (Hamamatsu R-105UH) and the integrated light intensity *vs.* time was recorded while the temperature of the solution rose to room temp (20 °C). The same cubette containing a fluorescer (DBA, DPA, or rubrene, 10^{-2}—10^{-4} M) was also used for the measurement. Quartz tubes were also applied for the irradiation instead of Pyrex cells in order to detect emission directly through it at ultraviolet range, with being warmed-up gradually from −78 °C. (See Table 2). The amounts of light emission are relative to CL of luminol in an aqueous solution.[24]

A Method for the Determination of Mutual Diffusion Coefficients of Electrolytes in Water by Means of Conductivity Measurements

Katsuyoshi KAMAKURA

Department of Industrial Chemistry, Toyama Technical College, Hongo-cho, Toyama 930-11

(Received July 18, 1981)

A method for determining diffusion coefficients of electrolytes was studied by the use of a conductance cell made of a Pyrex glass tube (4—7 cm in diameter and 6.5 cm in length). A pair of platinized platinum electrodes are sealed into the tube at a position 10 mm below the top of the glass tube. The diffusion was carried out from solution in the cell to an outer solvent, and the rate was measured from the decrease in conductance at a fixed position in the cell. In the graphical relation between the measured diffusion coefficient and the time, the differential diffusion coefficient at the initial concentration of the diffusing solution was estimated by extrapolation of the linear portion of the plot to time→0. The differential diffusion coefficients obtained in 0.1 mol dm^{-3} solutions at 25 °C were as follows: HCl, $(3.12\pm0.08)\times10^{-5}$; KI, $(1.909\pm0.020)\times10^{-5}$; NaCl, $(1.520\pm0.016)\times10^{-5}$; $\frac{1}{2}Na_2SO_4$, $(1.059\pm0.028)\times10^{-5}$; $CuSO_4$, $(0.610\pm0.033)\times10^{-5}$ $cm^2\ s^{-1}$.

The diffusion coefficients of electrolytes have been measured by a number of different methods. For example, the rate of diffusion from solution to solvent through a porous plate is measured.[1] The widely used methods such as the schlieren or the capillary method[2] were carried out on a system with a sharp boundary between the solution and solvent at the start of diffusion. A method for the determination of the diffusion coefficient of electrolytes by means of conductance measurements was already reported by H. S. Harned *et al.*[3] The apparatus is complicated because it has two electrode couples and also a shearing mechanism for the formation of the boundary between solution and solvent. Further, the measurement must be extended over several days. The capillary method is applied to the measurement of self-diffusion coefficients of various ions or molecules in water by means of isotopic tracers; the inner diameter of the cell should be very small in order to avoid random flow in systems with very small density-gradients. It was shown in a previous paper[4] that the system of sharp density-gradient is resistant to convection or to random flow. If the capillary method is applied to the measurement of mutual-diffusion coefficients, the inner diameter may be larger than that of the capillary used for measuring the self-diffusion coefficient.

The diffusion coefficient of an electrolyte in agar or gelatin gel had been measured by means of a glass tube cell, which is a type of conductance cell, developed in this laboratory.[5,6] The diffusion cell will be applied to the measurement of the mutual-diffusion coefficient of an electrolyte in water. This apparatus has a couple of electrodes, and the boundary between solution and solvent is formed by pouring solvent into a test tube outside the cell filled with solution. Consequently, the apparatus or the mechanism is simple, and the measurement is carried out within ten hours. In the present paper, we deal with cells of different inner diameters and apply them to the measurement of diffusion coefficients in water. In addition, the differential diffusion coefficient will be obtained by extrapolating the measured diffusion coefficients to time $t\rightarrow0$.

Principle of the Method

The diffusion cell is a conductance cell which is made of a glass tube equipped with platinized platinum wires. If the cell is filled with a solution and placed vertically in water, the solute diffuses into the outer water with the elapse of time. The diffusing solution in the cell gradually acquires a concentration gradient with time. The decrease in conductance at a fixed position in the cell can then be measured with the electrodes. The measured conductance is converted to concentration by a calibration curve. Under these conditions, the equation for diffusion in one dimension is

$$\frac{\partial c}{\partial t} = D\frac{\partial^2 c}{\partial x^2}, \tag{1}$$

where c is the concentration of the electrolyte at time t, D the diffusion coefficient, x the coordinate along which diffusion takes place. For this diffusion experiment, it may be assumed that (1) the concentration outside the cell is infinitely low during the diffusion experiment, and (2) the cell is infinite in length. Then the following equation is obtained by solving Eq. 1.

$$\frac{c_e}{2c_0} = \frac{1}{\sqrt{2\pi}}\int_0^{x/\sqrt{2Dt}} \exp(\xi^2/2)d\xi, \tag{2}$$

where c_e is the concentration of the diffusing solution at the electrodes, c_0 the initial concentration at the electrodes, and x the distance between the electrodes and the open end of the cell.

Next we will discuss the stability of the concentration gradient in the cell. The stability is related to the following factors: (1) the inner diameter of cell, (2) the density gradient in the cell, (3) the temperature variation, and (4) the vibration of the apparatus. As the inner diameter is reduced, the concentration gradient becomes stable independently of other factors. The density gradient is related to the concentration of diffusing solution or the kind of solute. In a previous paper it was shown that the intermediate layer between the upper and the lower convection keeps sharp stable density-gradient, when a two-layer system which consists of water (upper layer) and an aqueous solution (lower layer) is heated from one side and cooled from the opposite side.[4] The small temperature-variation during the diffusion experiment may not deform the concentration gradient, because this method is especially applied to the

system of a sharp density-gradient in the cell of small inner-diameter. The effect of vibration of the apparatus will also become small for a cell of small inner-diameter and for a system of sharp density-gradient. In spite of the above discussion, there will be turbulence of the concentration gradient in the vicinity of the top of the cell, especially during the pouring of the solvent. Therefore, the distance x_m measured by use of vernier calipers may not be appropriate for calculating the diffusion coefficient; then the effective distance x_e should be applied to Eq. 2. When c_e $(2c_o)^{-1}$ at time t is measured, the value of $x/(2Dt)^{0.5}$ is calculated from Eq. 1, and then the distance x is proportional to the square root of diffusion coefficient D. Then the effective x_e can be evaluated from

$$X_e = x_m(D/D_m)^{0.5}. \quad (3)$$

Here, D_m is the diffusion coefficient calculated from Eq. 2 by the use of x_m, and D is the true value of the diffusion coefficient.

Experimental

Materials. All the chemicals were of reagent grade, and were used without further purification. Anhydrides were dried at the following temperatures: KCl, 150 °C; NaCl, 250 °C; KI and Na_2SO_4, 110 °C. The salts were weighed out to give the solutions of indicated concentrations. The HCl solution was prepared by dilution after the determination of concentration by alkalimetry. Water used was distilled after passage through an ion-exchange column. Just prior to use, the water was boiled to remove dissolved gas. The solution was heated near to the boiling point in an Erlenmeyer flask with a glass tube (2 mm × 140 cm) through a rubber stopper, and then the solvent loss was within 0.1%.

Apparatus and Procedure. The diffusion cell is similar to that described previously.[6] The apparatus is shown in Fig. 1. The diffusion cell is made of a Pyrex glass tube (6.5 cm in length) equipped with platinized platinum electrodes at a position 10 mm below the top of the glass tube. The electrodes are wires 0.3 mm in diameter, 1 mm in length and 1.5 mm in distance between the wires.

A solution was poured into the cell, and the cell was set in the test tube (100 mm × 27 mm) in which water was previously placed so as to reach slightly below the top of the cell. The test tube was immersed vertically in a thermostat (Yamato BKR-41) at 25±0.05 °C. After about 20 min, water thermostated at 25 °C was poured into the test tube up to about 15 mm above the top of cell at a flow rate of 1.5 cm^3 min^{-1}, and the diffusion started.

Measurement of Conductance. The conductance was measured with a universal bridge (Yokogawa-Hewlett Packard 4255A) equipped with a variable condenser (0—1 μF).

Results and Discussion

Determination of Effective Distance. The diffusion experiment was carried out for 0.1 mol dm^{-3} KCl, and the apparent diffusion coefficient was calculated from Eq. 2 by the use of the measured distance, x_m, between the electrodes and the top of the cell. The apparent differential diffusion coefficient, D_m, at 0.1 mol dm^{-3} KCl was obtained by means of an extrapolation method which is described later. The effective distance, x_e, was determined by substituting x_m, D_m, and D (the value in the literature[7,8] instead of the true value) into Eq. 3, as is shown in Table 1. The ratios x_e/x_m were almost constant for cells of 4 mm in inner diameter, and the mean value was 104.5%. This fact may be taken to indicate that a small limited-amount of the solution is present on top of the cell, and that the concentration gradient is stable.

Differential Diffusion Coefficient. The diffusion coefficient was measured for different electrolytes. The typical relation between the diffusion coefficient D and the time t is shown in Fig. 2. The D values change slightly with time. The increase in D for Na_2SO_4 or $CuSO_4$ may be due to the dependence of diffusion coefficient on the concentration or due to the error caused by the vibration of apparatus or by the temperature variation. The decrease for KCl or NaCl seems to be caused by the increase of the concentration in the test tube in spite of assumption (1) for Eq. 2 or by the obstruction of electrodes (platinum wires) to the diffusion. The D with no such effects may be obtained by extrapolation of the linear portion of the plot to $t \to 0$. The diffusion coefficient D_e esti-

The measurements were carried out for the electrolytes in 1.000×10^{-1} mol dm^{-3} solns at 25 °C. ●: KCl, ◐: NaCl, ◑: $\frac{1}{2}Na_2SO_4$, ○: $CuSO_4$.

mated by extrapolation is regarded as the differential diffusion coefficient at the initial concentration of the diffusing solution.

Inner Diameter of Cell. Diffusion experiments were carried out for cells of different inner diameters, and the results are listed in Table 1. The standard deviations of D_e estimated for the cells of large inner diameter (7 mm) are large, compared with the values obtained for the cells of small inner diameters (6 and 4 mm). Therefore, other experiments were carried out for the cells of 4 mm in inner diameter.

Accuracy of the Method. The diffusion coefficient, D_e, estimated by the extrapolation and the diffusion coefficient, D_r, taken from other literature are given in Table 2. If the diffusion coefficient is small, the decrease in concentration at the electrodes during the diffusion experiment is also small, and the error in D_e may become large. For example, the c_e/c_o was 0.95 after 300 min for the diffusion of $CuSO_4$. The deviations of the D_e values from each D_r were within 2.5% except for $CuSO_4$.

An Evaluation of the Effective HLB of Surface-active Crown Compounds

Ping-Lin Kuo, Isao Ikeda, and Mitsuo Okahara*

Department of Applied Chemistry, Faculty of Engineering, Osaka University, Yamadaoka 2-1, Suita, Osaka 565

(Received March 1, 1982)

The hydrophilicity of surface-active crown compounds and their change upon the addition of electrolytes were investigated by measuring the phase-inversion temperature (PIT), the phenol index, and the cloud point. Sodium chloride and potassium chloride were observed to raise the hydrophilicity of 15-crowns and 18-crowns respectively, in contrast with their lowering effect on the hydrophilicity of usual poly(oxyethylene)-type nonionics. The effective HLBs of dodecyl crown ethers, estimated from both the PIT and the phenol index, were compared with those of poly(oxyethylene) dodecyl ethers, and the hydrophilicity of the crown rings were discussed in conjunction with that of the poly(oxyethylene) chain.

Although some studies of surface-active crown compounds have recently been made,[1–4] and a little fragmental information on the hydrophilicity of the crown ring have been given,[2–4] the function of this new type of hydrophilic group has not yet been fully clarified.

We have previously prepared long-chain alkyl crown ethers (**1**) and long-chain *N*-alkyl monoaza crown ethers (**2**),[5,6] which are the most typical surface-active crown compounds, and their surface-active properties[7,8] and the selective increase in the cloud points of their aqueous solutions upon the addition of electrolytes[9] have been reported.

In this paper, the effective HLBs of crown compounds and their changes upon the addition of electrolytes are evaluated by measuring the phase-inversion temperature (PIT), reported by Shinoda,[10–12] and the phenol index, proposed by Marszall;[13–16] they are also compared with those estimated from the cloud points in order to get information about the hydrophilicity of a crown ring.

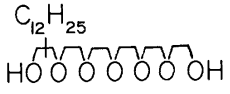
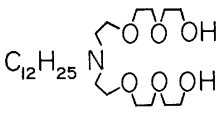
$R = C_8H_{17}, C_{12}H_{25}$ $m = 2, 3$





Experimental

Materials. Surface-active crown compounds (octyl-15-crown-5 (C_8O15C), octyl-18-crown-6 (C_8O18C), dodecyl-18-crown-6 ($C_{12}O18C$), *N*-octylmonoaza-18-crown-6 (C_8N18C), and *N*-dodecylmonoaza-18-crown-6 ($C_{12}N18C$)) were synthesized according to the reported method of intramolecular cyclization from the corresponding open-chain compounds (dodecyl-substituted hexaethylene glycol ($C_{12}O18H$), *N,N*-bis(8-hydroxy-3,6-dioxaoctyl)dodecylamine ($C_{12}N18H$)),[5,6] and their purity was ascertained by means of GLC. The monodispersed poly(oxyethylene) dodecyl ethers ($C_{12}H_{25}O(EO)_nH$, $n=4,5,6,7,8$) were supplied by the Nikko Chemical Co. The KCl, NaCl, and dodecane ($n_D^{25}=1.4195$) were commercial guaranteed-grade reagents.

Phenol Index. Because of the low hydrophilicity of crown compounds, the method reported by Marszall[13] was modified and a dilute phenol solution was used. Thus, a 0.5% aqueous phenol solution was added, drop by drop, to a 5-ml portion of a 0.025 M (mol dm^{-3}) aqueous solution of surface-active compounds at a constant temperature (5, 10, 15, 25 °C). The end point was determined as the aqueous solution became distinctly turbid. The number of milliliters of the phenol solution used to reach the end point of titration is given as its phenol index. Crown ethers, C_8O15C and $C_{12}O18C$, which have low cloud points were measured at 5, 10, and 15 °C, while other crown compounds were all titrated at 25 °C.

Phase-inversion Temperature (PIT).[11] A 4 wt%/system amount of surface-active crown compounds ($C_{12}O18C$, $C_{12}N18C$) or the corresponding open-chain compounds ($C_{12}O18H$, $C_{12}N18H$) were added to a dodecane/water mixture (1:1 by volume) to make an emulsion. The emulsion was heated under stirring while the temperature was being raised. The inversion of O/W into W/O on heating (about 1 °C/2 min) or of W/O into O/W on cooling was visually observed. The differences between these two inversion temperatures were within about 3 °C. Also, the temperature at which the electric conductivity of the emulsion dropped abruptly on heating was measured. The temperatures obtained by these two methods showed almost the same value; the average values were marked as PIT.

Results and Discussion

As for the hydrophilicity of the crown ring, Kuwamura[2,3] reported, from his study of the cloud point, that the acetal-type crown ring obtained from hexaethylene glycol and aldehyde is almost equivalent to 4 oxyethylene units in poly(oxyethylene) monoalkyl ether, and that the crown ring made of hexaethylene glycol and a triazine subunit exhibits almost the same performance as monoaza-18-crown-6 and 1,10-diaza-18-crown-6. Moroi[4] concluded, from a comparison of the CMCs, that a diaza-18-crown-6 ring is equivalent to 20 oxyethylene units in a polyoxyethylene-type nonionic surfactant with an identical alkyl-chain length.

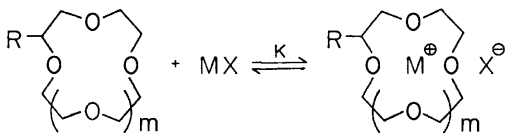
As the properties of surfactants are considered to be changed under the application conditions, the concept of effective HLB has been proposed[13,15,16] in

order to compare the hydrophilicity of surfactants under different conditions. The HLB of the usual nonionics with the poly(oxyethylene) group as hydrophile can be estimated by Griffin's equation[17] or other similar equations.[18] However, because of the lack of a hydroxyl group in the hydrophilic group, and because of the specific cyclic structure, the HLB values of crown compounds are considered to be different from those of the usual poly(oxyethylene) nonionics; they can not be estimated by the equations mentioned above.

The interaction of phenol with polyethylene glycols or nonionic surfactants in water has recently been studied in detail.[19–24] Though the phenol added to an aqueous solution of a nonionic surfactant increases the water-structuring, a major portion of it complexes with the poly(oxyethylene) chain[19] and is included in the micelle.[22] The phenol-micelle binding increases the micelle aggregation number and lowers the cloud point.[23,24] After a certain amount of a phenol solution is added, the solution of nonionics becomes turbid. Therefore, the nonionics having a higher hydration ability requires a greater volume of a phenol solution to induce turbidity.[13–16,19–21] Marszall utilized the correlation between the required amount of phenol and the hydrophilicity of a nonionics to estimate the effective HLB of the nonionics in the presence of additives.[13–16] Thus, it is reasonable to expect that the hydration ability of crown compounds and its change upon the addition of an electrolyte can be evaluated from an investigation of the interaction of the crown compound with phenol.

The phenol-index values of alkyl crown ether and *N*-alkyl monoaza crown ether were measured; the results are shown in Table 1. It was found that the phenol-index values of crown compounds increased with an increase in ring size and with a decrease in alkyl-chain length, and decreased with an increase in the temperature.

The phenomenon that the addition of alkali metal salts to an aqueous solution of nonionics reduces the phenol index has been reported[15,21] and interpreted to indicate that the presence of an electrolyte increases the micellar binding with phenol, probably as a result of lowering the solubility of phenol and surfactant and increasing the aggregation number of surfactant.[21] This means that the effective HLB of a nonionics decreases as a result of the salting-out effect of electrolytes. The phenol indices of crown compounds, however, increased upon the addition of KCl or NaCl to the aqueous solutions. Thus, the phenol index of crown compounds which have the hydrophilic group of the 18-crown ring (C_8O18C, C_8N18C) was significantly increased (by 14.80 and 4.18) with KCl, but by only 1.27 and 0.70 with NaCl. Conversely, the phenol index of C_8O15C, which has the 15-crown ring as the hydrophilic group, increased slightly (by 0.10) with KCl, but remarkably (by 0.86) with NaCl. The finding that the effective HLB of a crown compound in water selectively increased depending on the kind of salt and the ring size of the crown compound can be explained by the formation of the cationic complexes of crown compound shown in Eq. 1, and hence the increase in the hydration of surface-active species. These phenomena are in line with the tendency for salts selectively to increase the cloud point of an aqueous solution of crown compounds.[9]



(1)

Marszall reported that the nonionics with a given lipophilic group showing the same phenol-index value have the same effective HLB, and that the effective HLB of a nonionics in the presence of additives can be obtained from the plot of the phenol index versus HLB.[13–16]

In order to evaluate the effective HLB of crown compounds in the absence or presence of salt, the phenol-index values of $C_{12}H_{25}O(EO)_nH$ (n=4,5,6,7,8) at 5, 10, 15, and 25 °C versus their Griffin HLB values were plotted (Fig. 1). The effective HLBs of crown compounds were estimated from the phenol index using these plots; it was thus found that the effective HLB of *N*-dodecyl monoaza crown ether ($C_{12}N18C$) is 0.6 higher than that of dodecyl crown ether ($C_{12}O18C$). Under the conditions shown in Table 1, the extent of the effective HLB increase (1.8, 0.7) of 18-crowns ($C_{12}O18C$, $C_{12}N18C$) by KCl was larger than that by NaCl (0.3, 0.2). These salts increased the effective HLB of alkyl crown ether ($C_{12}O18C$)

Table 1. The phenol indices of alkyl-substituted crown and monoaza crown ethers in the absence and presence of K(Na)Cl[a]

Crown ether	t/°C	—	KCl	NaCl
C_8O15C	10	0.42	0.52	1.28
C_8O18C	25	1.28	16.08	2.55
C_8N18C	25	4.52	8.70	5.22
$C_{12}O18C$	25	—	16.22 (12.3)[b]	0.48 (10.6)[b]
	15	0.60 (−)	31.60 (12.1)[b]	1.95 (10.7)[b]
	5	2.44 (10.4)[b]	60.80 (—)	4.26 (10.7)[b]
$C_{12}N18C$	25	0.82 (10.9)[b]	5.00 (11.7)[b]	1.82 (11.2)[b]
	15	3.10 (11.0)[b]	7.78 (11.5)[b]	3.90 (11.1)[b]

a) The concentrations of KCl and NaCl are 0.5 M, while those of crown compounds are 0.025 M. b) The data in the parentheses are effective HLBs evaluated from phenol index using the plots shown in Fig. 1.

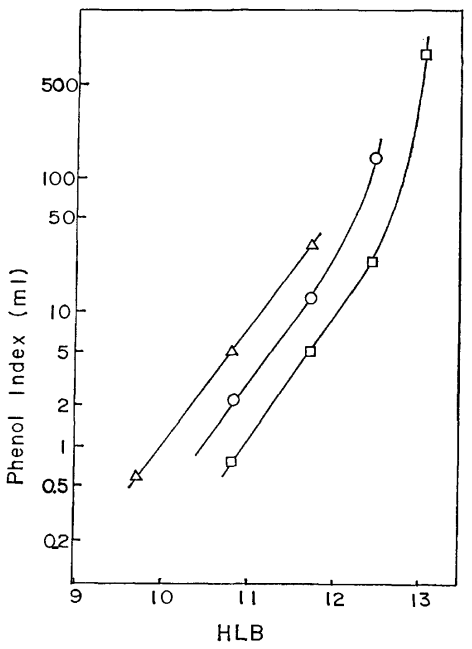


Fig. 1. The relationship between the phenol index and the HLB calculated by Griffin's method for $C_{12}H_{25}O$-$(EO)_nH$ (n=4,5,6,7,8) at 5 °C (—△—), 15 °C (—○—), and 25 °C (—□—).

more than that of *N*-alkyl monoaza crown ether ($C_{12}N18C$), much as with the tendency of the alkali-salt effect on the cloud point of these two kinds of crown compounds.

The O/W-type emulsion produced by using a proper nonionic surfactant as an emulsifier becomes unstable on heating and is inverted into a W/O-type emulsion. The temperature at which phase inversion occurs is called the PIT. The higher the HLB of the emusifier is, the higher PIT the emulsion exhibits. The PITs of $C_{12}O18C$ and $C_{12}N18C$ acting as the emulsifier for the dodecane/water system were 12 °C and 25 °C respectively, but those of the corresponding open-chain compounds, $C_{12}O18H$ and $C_{12}N18H$, were 82 °C and 83 °C respectively (Table 2). By adding KCl to the emulsion under the conditions described in Table 2, the PITs of two crown compounds, $C_{12}O18C$ and $C_{12}N18C$, increased by 27 °C, and 13 °C. Those of open-chain compounds, $C_{12}O18H$ and $C_{12}N18H$, decreased by 8 °C and 7 °C respectively in the same way as the PIT was observed to decrease in usual poly(oxyethylene) nonionics.[12] The fact that the PIT of the emulsion prepared by the use of a crown-compound emulsifier increased upon the addition of salts can also be explained by postulating that the salt enables alkyl crown ethers (**1**) or monoaza crown ethers (**2**) to form cationic complexes and to enhance their hydrophilicity, as has been described in the case of the phenol index.

The HLB of an emulsifier can be estimated from the PIT of the emulsion.[10,12] Using the plot of the PIT of 1:1 dodecane/water system emulsified with poly(oxyethylene) dodecyl ether[25] versus its Griffin HLB value, the effective HLB values of crown compounds were estimated from the PIT obtained under

Table 2. The PITs and effective HLBs of crown compounds and the corresponding open-chain compounds[a]

Compound	PIT(°C)		Effective HLB	
	—	KCl	—	KCl
$C_{12}O18C$	12	39	9.2	10.6
$C_{12}O18H$	82	75	12.8	12.4
$C_{12}N18C$	25	38	9.8	10.5
$C_{12}N18H$	83	75	12.9	12.4

a) The mole ratio of KCl to the surfactant is 3:1, and the concentration of surfactants is 4 wt%/system.

the same conditions; *i.e.*, the effective HLB values of $C_{12}O18C$ and $C_{12}N18C$ are 9.2 and 9.8, while those of $C_{12}O18H$ and $C_{12}N18H$ are 12.8 and 12.9 repectively. Upon the addition of KCl, the effective HLB values of $C_{12}O18C$ and $C_{12}N18C$ increased by 1.4 and 0.7 respectively, but those of the corresponding open-chain compounds, $C_{12}O18H$ and $C_{12}N18H$, decreased to almost the same extent, 0.4 and 0.5 respectively. Furthermore, KCl raised the effective HLB of $C_{12}O18C$ more than that of $C_{12}N18C$. This fact can be explained by the same reason that KCl raised the phenol index and cloud point of 18-crown ethers more than those of monoaza 18-crown ethers. Because of the restriction of emulsion stability, the amount of KCl added is limited to a triple mole of surfactant for PIT measurements. For the phenol-titration method, however, the concentration of KCl is 0.5 M, which corresponds to twenty times the molar amount of the surfactant. Therefore, in the presence of KCl, the extent of the increase in the effective HLB obtained by the phenol-titration method may be larger than that obtained by the PIT method.

Furthermore, it is well known that HLB also has a linear relationship with the cloud point below 100 °C.[13,26] The plot of the cloud point versus HLB for oligoethylene glycol dodecyl ether[18] was used to estimate the hydrophilicity of the crown ring, and it was found that the HLB values of $C_{12}O18C$ and $C_{12}N18C$ were 10.3 and 10.6 respectively, resembling the values obtained by the phenol-titration method, which is essentially similar to the cloud point method. Also, the fact that the effective HLB values of $C_{12}O18C$ and $C_{12}N18C$ obtained by the phenol-titration method were 0.9 and 1.2 larger than those obtained by the PIT method, is attributed to the deviation caused by different evaluating methods.

From the evaluations described above, the hydrophilicity of 18-crown-6 and monoaza-18-crown-6 rings with a dodecyl group can be concluded to be approximately equivalent to that of 4.0 and 4.5 units of oxyethylene chains respectively.

Effect of Adsorption by Cellulose Acetate Membrane on Reverse Osmosis of Some Monoamino Monocarboxylic and Monoamino Dicarboxylic Acids in Aqueous Solutions

Osami Tozawa* and Danji Nomura

Department of Food Science and Technology, Faculty of Agriculture, Kyushu University, Hakozaki, Higashi-ku, Fukuoka 812

(Received March 4, 1982)

Taft's polar and steric parameters, $\Sigma\sigma^*$, ΣE_s, and nonpolar parameter, ΣS^* governing the reverse osmosis of nonionized polar aliphatic and alicyclic organic compounds using a cellulose acetate membrane were also applicable to aliphatic monoamino monocarboxylic acids having zwitter ion structure. These three parameters were further extended so as to include the cases of sulfur-containing amino acids, hydroxy-substituted, and aromatic type amino acids. Reverse osmosis of monoamino monocarboxylic acids in binary aqueous solution systems containing L-alanine was carried out. As a result, added amino acids were adsorbed by the membrane when added in low concentration (<0.001 mol dm^{-3}), and the permeation of L-alanine was governed by the difference of Taft's polar parameter between L-alanine and the added amino acid. Reverse osmosis of monoamino dicarboxylic acids indicated that hydrogen ions were adsorbed by the membrane, and the adsorption isotherms of hydrogen ions were approximately represented by the Langmuir formula for each amino acid. The electrostatic repulsion between R^- ionic species in monoamino dicarboxylic acid and the negatively dissociated groups of the membrane was weakened by neutralization of the membrane by hydrogen ion adsorption, resulting in decreased amino acid rejection. It was noted that the ultraviolet spectrum and the titration curve of permeate of amino acids were different from those of the feed solution; relationship between this phenomenon and adsorption of hydrogen ions was investigated.

Reverse osmosis and ultrafiltration methods have been used for the concentration of protein solutions, purification of enzymes, *etc.* When enzymatic processes are conducted in an ultrafiltration reactor however, pretreatment of the membrane with deposition of inert proteinic gel onto the membrane surface is necessary because the enzyme is inactivated when adsorbed on the surface of a membrane.[1-3] It is further reported that the adsorption of solutes at a membrane-solution interface results in the formation of a gel layer; this causes difficulty in washing the membrane.[4] These studies indicate that adsorption of solutes by a membrane is one of the major problems in reverse osmosis and ultrafiltration processes.

It has been reported that a variety of substances can be adsorbed on cellulosic materials, *i.e.*, adsorption of *m*-aminobenzoic acid on cellulose acetate powder,[5] cellulose-triacetate and cellulose-acetate-butyrate on porous adsorbents (calcium silicate or aluminum silicate),[6] sulfobromophthalein sodium on regenerated cellulose membrane which immobilizes activated charcoal.[7] Literature further reports that surface flow of *p*-chlorophenol[8] and cumene[9] is caused by their adsorption on a cellulose acetate membrane. Little work has been done so far to explain the mechanism of ionic permeation through a membrane on which adsorption layer is formed.

The purpose of this study is to explain, on the basis of preferential sorption-capillary flow mechanism,[10] the effect of adsorption of ions at the membrane-solution interface during permeation of amino acids through a cellulose acetate membrane.

In the previous papers,[11-14] a number of the following facts were elucidated: (a) Factors governing the reverse osmosis of monoamino monocarboxylic acids in a single system; (b) effect of adsorption of an added amino acid on reverse osmosis of monoamino monocarboxylic acids in binary aq. solutions systems containing L-alanine and (c) the effect of adsorption of hydrogen ions on reverse osmosis of monoamino dicarboxylic acids in single system.

In this paper, the effects of adsorption of hydrogen ions is explained by measuring the UV spectrum and the titration curve of the permeate, are summarized along with previous work.

Transport Equations

Rejection, η is defined as follows:

$$\eta \equiv \frac{C_2-C_3}{C_2}, \tag{1}$$

where C_2 and C_3 refer to the concentration at the membrane-solution interface and in the permeate, respectively. Generally, C_2 differs from the concentration in the feed solution, C_1. C_2 can be expressed as[15]

$$C_2 = C_3 + (C_1-C_3)\exp\left(\frac{N_w+N_s}{c_1 k}\right), \tag{2}$$

where c_1 is the molar density of the feed solution, k is the mass transfer coefficient, and N_w and N_s refer to the molar flux of water and solute, respectively. k depends on the shape of the reverse osmosis cell and the streaming state of solution in the cell. On the cell used in this study, k can be represented as follows:[11]

$$k = 7.586\left(\frac{D}{l}\right)R_e^{0.420}S_c^{1/3}, \tag{3}$$

where D is the diffusivity, l is the inside diameter of the cell, R_e is the Reynolds number, and S_c is the Schmidt number. The solute transport parameter, $D/K\delta$ is defined as[15]

$$D/K\delta \equiv \frac{N_s}{C_2-C_3} = \frac{JC_3}{C_2-C_3} = J\left(\frac{1}{\eta}-1\right), \tag{4}$$

where J is the volume flux of permeate.

Experimental

Amino Acids and Membranes. Reagent grade amino acids were used. DDS-600, 800, 870, and 880 cellulose acetate membranes (Loeb type, De Danske Sukkerfabrikker, Denmark) were used. Cellulose acetate (Eastman 398-3) membranes were also prepared according to the method developed by Manjikian.[16]

Analysis and Procedures. The concentration of amino acid in single aq solution was measured with ninhydrin method using a Hitachi spectrophotometer, model 100-30. Amino acids in binary aq solution were analyzed by paper or thin-layer chromatography, using a DMU-33C densitometer (Toyo Kagaku Sangyo, Inc.). The concn of sodium chloride was measured with a MS conductivity bridge CD-35MII. Hydrogen ion concn was determined by using a Hitachi-Horiba F-7Lc pH meter. UV spectra were recorded with a UV-300 spectrophotometer (Shimadzu Seisakusho, Inc.). The titration curve was determined with a UCB-7 automatic titrator (Hiranuma Sangyo, Inc.). Experiments were conducted in a batch using a stirred reverse osmosis cell (Bio Engineering RO-3). The volume and effective membrane area were 200 cm^3 and 32.2 cm^2, respectively. The stirrer was rotated at 300 min^{-1} by magnetic force. When constant permeation of the membrane was achieved, a 2500 cm^3 volume reservoir was attached to the cell. The cell was immersed in a water bath kept at 30 °C. The operating pressure was 1.96 MPa. Figure 1 shows the relationship between η of 0.085 mol dm^{-3} of sodium chloride aq solution and the pure water permeability, A obtained by using a cellulose acetate membrane. Figure 1 shows that the property of a DDS-membrane is the same as that of a laboratory-made membrane. Before the experiments, membranes were always tested with distilled water and 0.085 mol dm^{-3} of sodium chloride aq solution, and the relationship shown in Fig. 1 was confirmed.

Results and Discussion

Factors Governing Permeation of Monoamino Monocarboxylic Acids in a Single System. A monoamino monocarboxylic acid existing as zwitter ion in aq solution posesses zero net charge. Therefore, Eq. 5 proposed by Matsuura *et al.*[17] for the solute transport parameter, $D/K\delta$ of nonionized polar aliphatic and alicyclic compounds is employed to determine the factors governing the reverse osmosis of monoamino monocarboxylic acids (0.001 mol dm^{-3}):[11,12]

$$\ln (D/K\delta) = \ln C^* + \rho^*\Sigma\sigma^* + \delta^*\Sigma E_s + \omega^*\Sigma S^*. \quad (5)$$

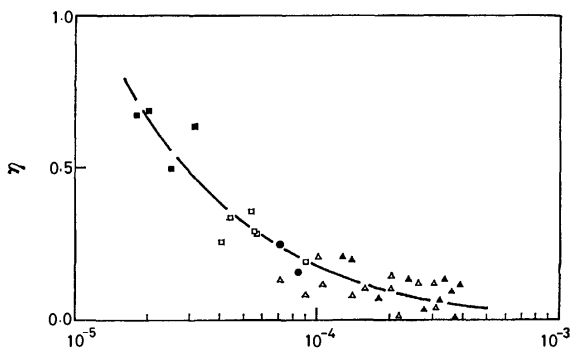

Fig. 1. Relation between η and A for 0.085 mol dm^{-3} of NaCl aq soln.
△: DDS-600, ▲: DDS-800, □: DDS-870, ■: DDS-880, ●: laboratory-made.

D is the diffusivity, δ is the effective thickness of the membrane, K is the reciprocal of the distribution coefficient, and $\ln C^*$ is constant, depending on the porous structure of the membrane surface, the chemical nature of the membrane material, and the nature of the functional group in the solute molecule; $\rho^*\Sigma\sigma^*$, $\delta^*\Sigma E_s$, and $\omega^*\Sigma S^*$ refer to polar, steric, and nonpolar effects, respectively; $\Sigma\sigma^*$, Taft's polar parameter; ΣE_s, Taft's steric parameter; ΣS^*, nonpolar parameter (modified Small's number); and ρ^*, δ^*, and ω^* are the characteristic proportionality constants associated with $\Sigma\sigma^*$, ΣE_s, and ΣS^*, respectively. ρ^* and ω^* do not depend on the porous structure of the membrane surface, whereas δ^* depends on the porosity of the membrane. $\Sigma\sigma^*$ and ΣE_s for a variety of substituents are tabulated in Taft's table,[18] however, the number of substituents listed is not enough, on the other hand, ΣS^* is applicable to substituents composed of hydrocarbons only.[9] Therefore, in order to apply Eq. 5 to sulfur-containing, hydroxy-substituted, and aromatic type amino acids, it is necessary to correlate the characteristic parameters ($\Sigma\sigma^*$, ΣE_s, and ΣS^*) with other physical quantities. The proportion of the ionic bond in an optional substituent can be calculated by measuring the polarity between diverse atoms.[19] $\Sigma\sigma^*$ was a correlation on the basis of the ionic bond proportion. Steric effects depend on the size and shape of the solute molecule. Hence, ΣE_s was correlated on the basis of the molecular weight of the substituent. On the other hand, a nonpolar effect would depend on a hydrophobic interaction energy between the membrane and solute, called an interaction energy of London-van der Waals dispersion force. ΣS^* was a correlationship of interaction energy. The values of the parameters obtained are tabulated in Table 1. The nonpolar effect is considered negligible if the molecular structure of the solute contains a straight chain involving no more than three carbon atoms not associated with a polar functional group.[17] For glycine and L-alanine, Eq. 5 can be reduced to

$$\ln (D/K\delta) = \ln C^* + \rho^*\Sigma\sigma^* + \delta^*\Sigma E_s. \quad (6)$$

As $\Sigma\sigma^*$ and ΣE_s in L-alanine are zero, $\ln C^*$ can be expressed as

$$\ln C^* = \ln (D/K\delta)_{\text{L-alanine}}. \quad (7)$$

From Eqs. 6 and 7, we have

$$\delta^* = \frac{\ln (D/K\delta)_{\text{glycine}} - \ln (D/K\delta)_{\text{L-alanine}} - \rho^*(\Sigma\sigma^*)_{\text{glycine}}}{(\Sigma E_s)_{\text{glycine}}}, \quad (8)$$

where the reaction constant in the hydrolysis reaction of the ester (=1.465)[18] was employed as a numerical value of ρ^*. From Eq. 5, ω^* can be expressed as follows:

$$\omega^* = \frac{\ln (D/K\delta) - \ln C^* - \rho^*\Sigma\sigma^* - \delta^*\Sigma E_s}{\Sigma S^*}. \quad (9)$$

ω^* is correlated with the number of carbon atoms in

a substituent, N_c, as shown in Fig. 2. ω^* of aliphatic amino acids having straight chain and hydroxy-substituted amino acids varies as the number of carbon atoms, but ω^* of aliphatic amino acids having branched chain, sulfur-containing amino acids and aromatic amino acids varies inversely with the number of carbon atoms. These relations are approximated by a first-order equation as follows:
for the former,

$$\omega^* = -2.66\times10^{-3} + (1.05\times10^{-3})(N_c), \quad (10)$$

for the latter,

$$\omega^* = 1.19\times10^{-3} - (2.54\times10^{-4})(N_c). \quad (11)$$

By using Eqs. 4, 5, 7, 8, 10, and 11, rejection values of each amino acid are calculated, and compared with the real values, as is shown in Fig. 3. The calculated values are in fair agreement with the real values, which shows that polar, steric, and nonpolar effects all play some role in the reverse osmosis of monoamino monocarboxylic acids. It is further noted that the order of rejection of amino acids is nearly consistent with Matsuura and Sourirajan's data[20] (Laboratory-made Batch 316 (10/30)-type cellulose acetate membrane).

Interaction between Two Monoamino Monocarboxylic Acids on a Membrane-solution Interface. The reverse osmosis of fourteen kinds of solution consisting of L-alanine (0.001 mol dm^{-3}) and added amino acids (0.00025—0.004 mol dm^{-3}) of aliphatic, hydroxy-substituted, sulfur-containing, and aromatic types has been reported in a previous paper.[13] The results show that the rejection of L-alanine is almost constant in the concentration range (0.001—0.004 mol dm^{-3}) in all the systems, except when the concentration of the acids is decreased to 0.00025 mol dm^{-3}, the rejection of L-alanine increases considerably. Rejection of the added amino acids is almost constant through out the con-

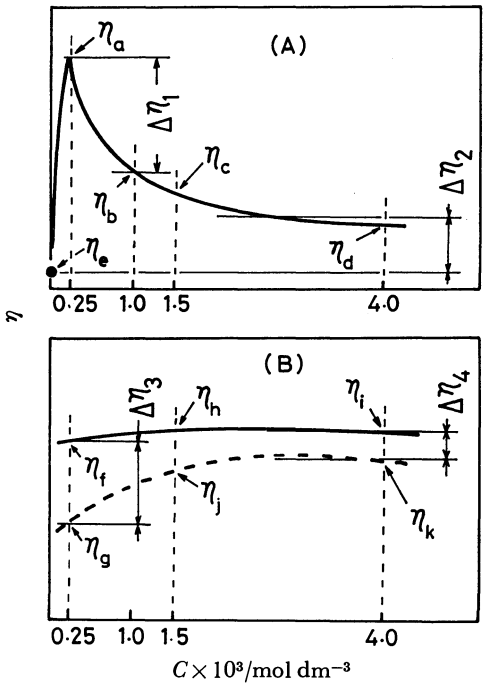

Fig. 4. Schematic diagram of reverse osmosis.
(A): L-Alanine, (B): added amino acid, solid line: binary system, broken line: single system.

centration range of 0.00025—0.004 mol dm^{-3} in most of the systems. On the other hand, in a single system, rejection of amino acids is almost constant in the concentration range of 0.001 to 0.004 mol dm^{-3}, but decreases when the concentration of the amino acid decreases below 0.001 mol dm^{-3}. Figure 4 shows the schematic diagram of the reverse osmosis systems mentioned above. The four equations shown below represent the change in the rejection pattern of these amino acids:

$$\Delta\eta_1 \equiv \eta_a - \eta_b, \quad (12)$$

$$\Delta\eta_2 \equiv (\eta_c+\eta_d)/2 - \eta_e, \quad (13)$$

$$\Delta\eta_3 \equiv \eta_f - \eta_g, \quad (14)$$

$$\Delta\eta_4 \equiv (\eta_h+\eta_i)/2 - (\eta_j+\eta_k)/2, \quad (15)$$

where η_a, η_b,$\cdots\eta_j$, and η_k are shown in Fig. 4. $\Delta\eta_1$, $\Delta\eta_2$, $\Delta\eta_3$, and $\Delta\eta_4$ are used in order to summarize experimental data of rejection in many systems. $\Delta\eta_1$, $\Delta\eta_2$, $\Delta\eta_3$, and $\Delta\eta_4$ in each system are tabulated in Table 2. A glance at Table 2 shows that $\Delta\eta_1$, $\Delta\eta_2$, $\Delta\eta_3$, and $\Delta\eta_4$ are positive in most of the systems. Therefore, the rejection of both L-alanine and the added amino acids is higher in a binary system than in a single system. On the other hand, $\Delta\eta_1$ is greater in systems consisting of L-alanine and aliphatic amino acid than in the other systems. $\Delta\eta_1$ is correlated by $\Sigma\sigma^*$ of each added amino acid, as shown in Fig. 5. When $\Sigma\sigma^*$ of the added amino acid and that of L-alanine are close to each other, rejection of L-alanine increases considerably, but when they are further apart, rejection of L-alanine is not much effected. In the single systems shown in Fig. 6, rejection of some amino acids, (especially aliphatic amino acids) shifts from positive to negative as the concn. of feed solution decreases from 0.001 to 0.00025 mol dm^{-3}. It has been reported

Table 2. Difference between amino acid rejection in binary and single systems[a)]

in the literature that the molar surface tension increment of aliphatic amino acids decreases as the length of the hydrocarbon side chain increases. For example, the molar increment of surface tension is positive for glycine and alanine, but negative for 2-aminobutyric acid, valine, and 2-aminohexanoic acid, showing that 2-aminobutyric acid, valine, and 2-aminohexanoic acid are positively adsorbed at the liquid surface in accordance with Gibbs' theorem.[21,22] These facts reflect that the typical behavior of amino acids is attributed to the surface flow of amino acids caused by the formation of an adsorption layer of amino acids on a surface of the membrane near 0.00025 mol dm^{-3}. On the basis of the assumption mentioned above, the relation between $\Delta\eta_1$ and $\Sigma\sigma^*$ of added amino acids shown in Fig. 5 is explained below. In the first place, for systems consisting of L-alanine and aliphatic amino acids, L-alanine interacts with the adsorption layer of the aliphatic amino acid. But, L-alanine does not have

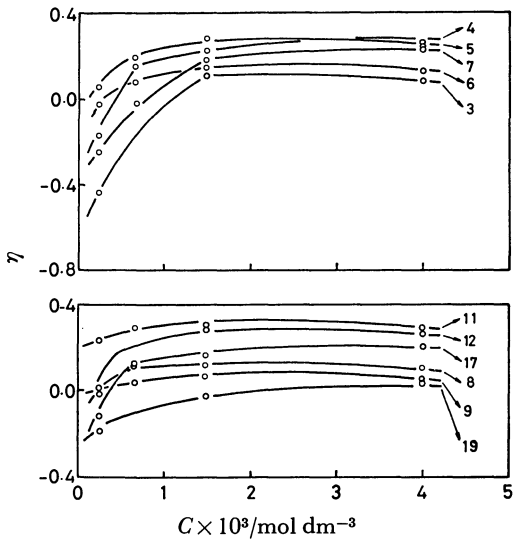

Fig. 6. Effect of concentration on rejection for single system.

a strong affinity for the adsorption layer because the Taft's polar parameter of the aliphatic amino acid and that of L-alanine are close to each other, *i.e.*, the acidity of the aliphatic amino acid is approximately equal to that of L-alanine. Therefore, rejection of L-alanine increases at the concn of the added amino acids (0.00025 mol dm^{-3}). In the case of systems consisting of L-alanine and added amino acids of hydroxy-substituted, sulfur-containing, and aromatic types, the adsorption layer is formed, but, L-alanine has a strong affinity for the adsorption layer according to Taft's polar parameter, hence, rejection of L-alanine is uneffected.

Hydrogen Ion Adsorption during Permeation of Monoamino Dicarboxylic Acids. The results of the reverse osmosis of monoamino dicarboxylic acids in aq solution have been reported in a previous paper in order to study the adsorption of hydrogen ions on the membrane.[14] Figure 7 shows the result of reverse osmosis of L-glutamic acid. The high pH of the L-glutamic acid permeate solution (16 cm^3 of initial permeate) as compared to that of feed solution is prominent in the low concentration range. This can be explained on the basis that a cellulose acetate membrane is slightly negatively charged,[23] therefore, hydrogen ions become adsorbed on its surface. In the case of the initial permeate, rejection increases as the concentration of the feed solution decreases. This behavior is considered to be due to the higher electrostatic repulsion force between the membrane and the R^- ion of L-glutamic acid. An electrostatic repulsion force is also reported in case of lower organic acids,[24] however, these authors considered the cellulose acetate membrane to be a non charged membrane, and they used a dielectric exclusion force to explain the above phenomenon. To confirm this fact that a cellulose acetate membrane has a weak ion-exchange character, an experiment on the adsorption of Methylene Blue and erioglaucine A on the membrane was carried out. As a result, positively charged oxidation type ions were more abundantly adsorbed than non charged reduction type ions. The adsorption model is shown in Fig. 8 in order to describe quantitatively the adsorption of hydrogen ions under the reverse somosis. Hydrogen ions produced from a monoamino dicarboxylic acid and hydroxide ions enter the membrane, whereas, only hydrogen ions are adsorbed, resulting in the dissociation of a part of the water within the membrane. We assume the dissociation of water to explain this phenomenon because the ionic product of water represented by Eq. 16 has to be applied to the permeate:

$$K_w = [H^+][OH^-]. \quad (16)$$

Applying a material balance of hydrogen and hydroxide ions to a unit volume of solution which permeate through the membrane, we obtain

$$[H^+]_3 = [H^+]_1 - [H^+]_a + [H^+]_d, \quad (17)$$

$$[OH^-]_3 = [OH^-]_1 + [OH^-]_d, \quad (18)$$

where subscripts 1, 3, a, and d refer to the feed solution, permeate, adsorption, and dissociation, respectively. $[H^+]_1$ is essentially the hydrogen ion concentration in the amino acid solution not permeated through the membrane whose amino acid concentration is the same as that of the permeate. However, in this study we consider it as the hydrogen ion concentration in the feed solution because the rejection is low; in other words, C_1 is approximately equal to C_3. Assuming that the hydrogen ion and hydroxide ion concentrations in the pores of membrane are iden-

tical with those in the permeate, the electrical neutrality condition can be expressed as follows:

$$[H^+]_3 + [R^+] = [R^-] + 2[R^{2-}] + [OH^-]_3 + [X^-], \quad (19)$$

where $[R^+]$, $[R^-]$, and $[R^{2-}]$ are the concentrations of each ionic species in the monoamino dicarboxylic acid, and $[X^-]$ is the concentration of the negatively dissociated group not adsorbed by hydrogen ions. Inserting Eqs. 17 and 18 in Eq. 19, we have

$$[H^+]_1 - [H^+]_a + [H^+]_d + [R^+] = [R^-] + 2[R^{2-}] + [OH^-]_1 + [OH^-]_d + [X^-]. \quad (20)$$

Here, we have

$$[H^+]_d = [OH^-]_d. \quad (21)$$

From Eqs. 20 and 21, the electrical neutrality condition in the pores can be represented also as follows:

$$[H^+]_a = [H^+]_1 - [OH^-]_1 + [R^+] - [R^-] - 2[R^{2-}] - [X^-]. \quad (22)$$

Using Eqs. 16, 17, 18, and 21, amount of adsorbed hydrogen ion, M can be derived as follows:

$$M = \int_0^V [H^+]_a dV = \int_0^V \left[K_w\left(\frac{1}{[H^+]_3} - \frac{1}{[H^+]_1}\right) + [H^+]_1 - [H^+]_3\right] dV, \quad (23)$$

where V is permeate volume. When the permeation proceeds to the permeate volume where $[H^+]_a$ is zero, *i.e.*, $[H^+]_1$ is equal to $[H^+]_3$, the adsorption of hydrogen ions stop. Then $[H^+]_1$ is in equilibrium with an equilibrium amount of adsorbed hydrogen ions, M_e. Figure 9 shows the adsorption isotherm of hydrogen ions of each amino acid. The adsorption isotherm may be represented by the Langmuir formula given by

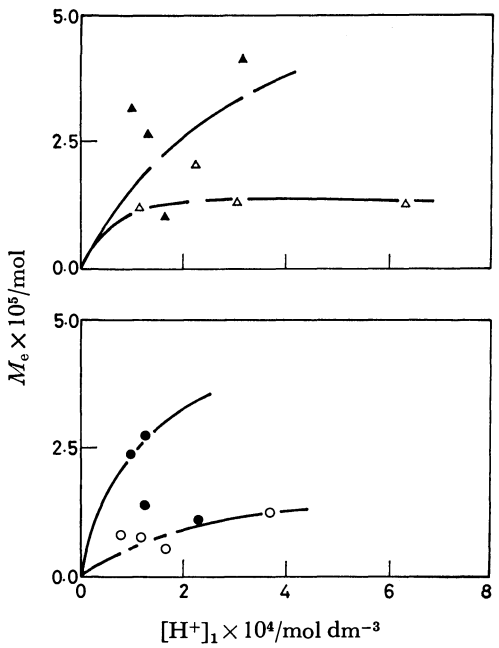

Fig. 9. Adsorption isotherm of the hydrogen ion.
○: L-Glutamic acid, △: L-aspartic acid, ▲: DL-2-aminoadipic acid, ●: DL-2-aminopimelic acid, membrane : DDS-600.

$$M_e = \frac{ab[H^+]_1}{1 + a[H^+]_1}, \quad (24)$$

where a and b are constants. Figure 9 shows some variation because the data were taken from the permeate solution, whereas, in the case of the sorption method, the adsorption of hydrogen ions could hardly be noted. The amount required to saturate the unit volume of the membrane is about 0.03 mol dm^{-3} for L-glutamic acid and L-aspartic acid. This value is in fair agreement with the fixed-charge concentration, 0.010 mol dm^{-3} reported by Igawa *et al.*[25] The effect of the adsorption of hydrogen ions in the case of monoamino dicarboxylic acids permeation is shown in Fig. 10. In the case when the membrane approaches equilibrium quickly, an electrostatic repulsion force between the ionic species R^- and the dissociated groups of the membrane is weakened by the neutralization of the membrane with hydrogen ions, resulting in a decrease of the rejection and approaches a constant value as permeation proceeds. On the other hand, when the amount of adsorbed approaches equilibrium slowly, rejection is almost constant because the charge density of the membrane is not changed so much with adsorption of hydrogen ions.

Ultraviolet Spectrum and Titration Curve of Permeate of Amino Acids. UV spectra of the permeate of each monoamino dicarboxylic acid are shown in Fig. 11. The initial permeates exhibit their absorption maxima at a wavelength of 255 nm, however, the absorption maxima disappear as the permeation proceeds. When the concentration of the feed solution is high, the above maxima are smaller. The permeate volume of each amino acid where the absorption maxima vanish, is roughly the same as that in which $[H^+]_a$ is zero, as mentioned earlier. As a general rule, the absorption of the carboxyl group is obscured by the amino auxochrome whose absorption is very strong, therefore, the absorption maxima do not appear in α type of amino acids. But as mentioned above, the absorption maxima appear in amino acid solutions permeated through the

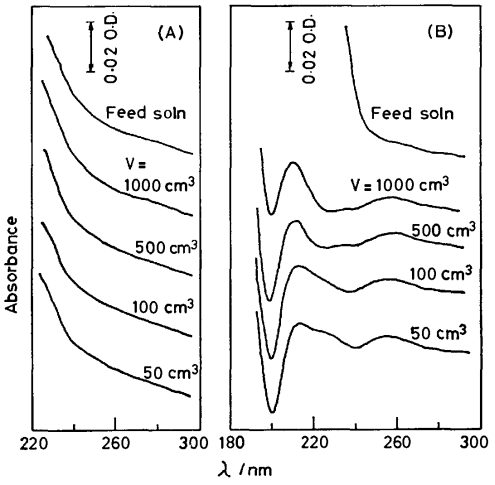

Fig.12. UV spectra of permeate of amino acids. (A): L-Glutamic acid (C_1=0.001 mol dm^{-3}, pH_1=7.0 by NaOH), (B): L-glutamic acid (C_1=0.01 mol dm^{-3}, pH_1=3.37), membrane; (A): laboratory-made, (B): DDS-990 ($A=4.2\times10^{-5}$ mol cm^{-2} s^{-1} MPa^{-1}, η_{NaCl}=0.89).

membrane. This happens because the absorption strength of the amino auxochrome is weakened with the decrease of the hydrogen ion concentration in solution by adsorption of hydrogen ions. When the pH of a monoamino dicarboxylic acid aq solution is adjusted to 7 with sodium hydroxide, the hydrogen ions in the solution disappear; as a result, the adsorption does not occur. Therefore, the absorption maxima do not appear in the permeate, as shown in Fig. 12-A. Monoamino dicarboxylic acid permeates, through high-rejection membrane exhibit their absorption maxima in wavelength 212 nm and 255 nm, as shown in Fig. 12-B. Also, the maxima are not inclined to disappear as the permeation proceeds. This is because 1000 cm^3 of the permeate volume is not high enough to attain equilibrium. On the other hand,

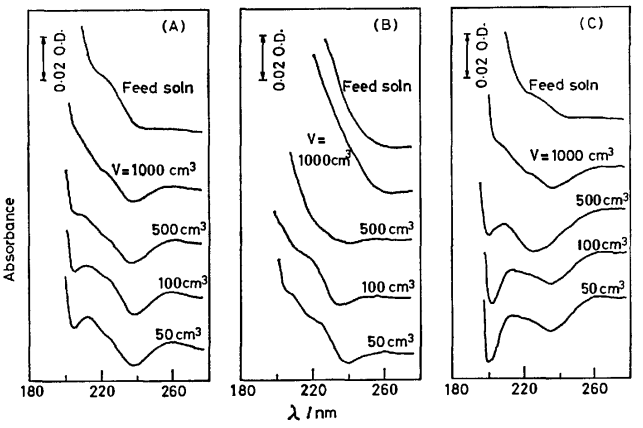

Fig.13. UV spectra of permeate of amino acids. (A): Glycine (C_1=0.001 mol dm^{-3}, pH_1=5.85), (B): L-alanine (C_1=0.001 mol dm^{-3}, pH_1=5.71), (C): L-alanine (C_1=0.001 mol dm^{-3}, pH_1=3.80 by HCl), membrane : laboratory-made.

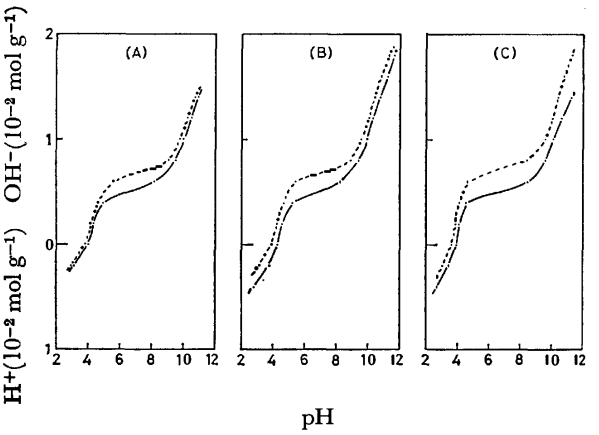

Fig.14. Titration curve of amino acids. (A): L-Glutamic acid (C=0.00075 mol dm^{-3}), (B): L-glutamic acid (C=0.00044 mol dm^{-3}), (C): L-aspartic acid (C=0.00061 mol dm^{-3}), ——: permeate, ----: standard soln, membrane; (A): DDS-600, (B),(C): laboratory-made.

the UV spectra of the permeate of some monoamino monocarboxylic acids are shown in Fig. 13. Glycine exhibits an absorption maximum at 211 nm and 260 nm, and L-alanine at 260 nm, but acquires the UV spectrum of the feed solution as the permeation proceeds. In the case of a monoamino monocarboxylic acid, hydrogen ions in zwitter form are adsorbed; as a result, the above maximum appears. When the L-alanine aq solution is acidified with hydrochloric acid, the permeate exhibits its strong absorption maximum at 211 nm and 260 nm. Figure 14 shows the titration curve of monoamino dicarboxylic acids. Here, the amino acid concentration of the permeate is the same as that of a standard solution. The titration curve of the permeate is located below that of the standard solution because the hydrogen ion concentration of the permeate is lower than that of the standard solution. From Fig. 14, it can be seen that the dissociation constants of the amino acids in the permeate is the same as that in the standard solution.

Estimation of Parameters, G_{11}, G_{22}, and G_{12} in the Kirkwood-Buff Solution Theory on the Basis of the Concentration Fluctuation Data Obtained from Rayleigh Scattering

Tadashi KATO, (the late) Tsunetake FUJIYAMA, and Hiroyasu NOMURA*,†

Institute for Molecular Science, Myodaiji, Okazaki 444

†*Department of Chemical Engineering, Faculty of Engineering, Nagoya University, Chikusa-ku, Nagoya 464*

(Received March 8, 1982)

A concentration fluctuation value obtained from Rayleigh scattering intensity was confirmed to give a thermodynamic quantity of an equilibrium system. An observation of concentration fluctuation by a light scattering method was found to be the most direct and useful way of determining a concentration derivative of a chemical potential. For methanol, ethanol, and 1-propanol–carbon tetrachloride systems, the Kirkwood-Buff parameters, G_{11}, G_{22}, and G_{12}, were determined by the use of concentration fluctuation data. The structure of these systems was discussed on the basis of the calculated Kirkwood-Buff parameters.

The solution theory of Kirkwood and Buff is only one theory so far reported which can describe a thermodynamic properties of a solution for the whole concentration range.[1–4] This theory relates thermodynamic quantities of a system to the radial distribution function $g(r)$ through a "concentration fluctuation." In this theory, a parameter G_{ij} plays an important role, which is defined as,

$$G_{ij} = \int_0^\infty \{g_{ij}(r) - 1\} 4r^2 dr, \tag{1}$$

where $g_{ij}(r)$ is the radial distribution function between species i and j. It is important to notice that $g_{ij}(r)$ is a microscopic expression of the structure of a solution. In the case of a binary solution, the parameters G_{11}, G_{22}, and G_{12} appear in this theory. As $g_{ij}(r)$ is an observable quantity by an X-ray or a neutron diffraction method, G_{ij} is also an observable by these methods in principle. In practice, however, these measurements can not give separately each value of $g_{ij}(r)$. Therefore, it is of much importance to determine the G_{11}, G_{22}, and G_{12} values experimentally from macroscopic quantities such as molar volume, compressibility, concentration dependences of chemical potential, and other thermodynamic quantities. Because of the difficulty of obtaining the $(\partial\mu_2/\partial x_2)_{P,T}$ value experimentally with high accuracy, however, such attempts have been reported in only a few papers.

Ben-Naim estimated the concentration dependence of G_{ij} in binary solutions of ethanol and water based on the concentration dependence of the vapor pressure.[5] Similarly, Donkersloot[6] has determined G_{ij}'s for binary solutions of cyclohexane–2,3-dimethylbutane, methanol–water, and ethanol–water. He also calculated the zero-angle X-ray scattering intensities from the G_{ij} values so obtained and compared them with the experimental data.[6,7]

Kato and Fujiyama have discussed the local structures in various solutions on the basis of the quantitative analysis of the concentration fluctuation, $V^*\langle(\Delta x_2)^2\rangle$, obtained from the Rayleigh scattering intensities[8–14] where V^* refers to the volume of the region in which concentration fluctuation is considered. If V^* is large enough to permit the application of statistical mechanics, $V^*\langle(\Delta x_2)^2\rangle$ can be directly related to the concentration derivative of the chemical potential.

In the present work, we will evaluate the Kirkwood-Buff parameters G_{11}, G_{22}, and G_{12}, for binary solutions of methanol–carbon tetrachloride, ethanol–carbon tetrachloride, and 1-propanol–carbon tetrachloride by the use of the concentration fluctuation data obtained from the Rayleigh scattering intensity measurement.[14] We will emphasize the usefulness and reliability of the concentration fluctuation data obtained from the light scattering experiment. At the same time, the structure of the carbon tetrachloride–alcohol systems will be discussed on the basis of the calculated Kirkwood-Buff parameters.

Concentration Fluctuation Obtained from Rayleigh Scattering Intensity and Thermodynamic Property

We first examine the concentration fluctuation values obtained from a light scattering experiment. The concentration fluctuation of a solution can be expressed in terms of the excess chemical potential μ_2^{E} [14] or of the excess free energy G^E as

$$N\langle(\Delta x_2)^2\rangle = \frac{x_1 x_2}{1 + \frac{x_2}{RT}\left(\frac{\partial\mu_2^{E}}{\partial x_2}\right)_{P,T}} \tag{2}$$

or

$$N\langle(\Delta x_2)^2\rangle = \frac{x_1 x_2}{1 + \frac{x_1 x_2}{RT}\left(\frac{\partial^2 G^E}{\partial {x_2}^2}\right)_{P,T}} \tag{3}$$

$$G^E = x_1\mu_1^{E} + x_2\mu_2^{E}, \tag{4}$$

where x_1 and x_2 are the mole fractions of 1 and 2, respectively, μ_1^{E} and μ_2^{E}, the excess chemical potentials of 1 and 2, respectively, R the gas constant, P the pressure, and T the temperature. N of the left of Eq. 1 or 2 is the total number of molecules in the volume V^* ($N=\rho V^*$, ρ: the number density of the solution). Equation 2 enables us to calculate the $(\partial\mu_2^{E}/\partial x_2)_{P,T}$ values using the $N\langle(\Delta x_2)^2\rangle$ values obtained from the light scattering experiment[14] and compare them with those obtained from the vapor-liquid equilibrium experiments.[15] In these calculations, μ_2^{E} was calculated from the vapor pressure data, and was plotted against the concentration. The $(\partial\mu_2/\partial x_2)_{P,T}$ value was derived graphically. The Gibbs-Duhem relation, $x_1(\partial\mu_1/\partial x_2) + x_2(\partial\mu_2/\partial x_2) = 0$, was carefully taken

into account in this process. The results are illustrated in Fig. 1. As shown in Fig. 1, the $-(\partial\mu_2^E/\partial x_2)_{P,T}$ values obtained from these two different procedures agree with each other satisfactorily within their experimental errors. In other words, V^* is ascertained to be large enough to permit the application of statistical mechanics.

In most reports on solution chemistry, G^E is given by a polynomial formula. For example, the excess Gibbs' free energy for the methanol–carbon tetrachloride is given by two relations, one proposed by Scatchard *et al.*[16] and the other by Moelwyn-Hughes *et al.*[17] These empirical formulae give almost the same G^E values. However, if we calculate the concentration fluctuation values $N\langle(\Delta x_2)^2\rangle$, using these two empirical formulae through Eq. 3, the results are completely different with each other. Of course they don't agree with those obtained from the light scattering data shown in Ref. 14. These situations are illustrated in Fig. 2. The results indicate that the given polynomial formulae of G^E do not well express their second derivative, *e.g.*, $(\partial^2 G^E/\partial x_2^2)_{P,T}$ with sufficient accuracy. In other words, it is not easy to predict the concentration fluctuation values from the observed free energy data, although it is possible in principle. By the same reason, it is also difficult to predict the chemical potential values from the concentration fluctuation values obtained by light scattering experiments.[18]

Thus, we can conclude as follows:

(1) A concentration fluctuation value obtained from Rayleigh scattering intensity is a thermodynamic quantity of an equilibrium system.

(2) An observation of concentration fluctuation by a light scattering method is the most direct and useful way of determining a concentration derivative of a chemical potential.

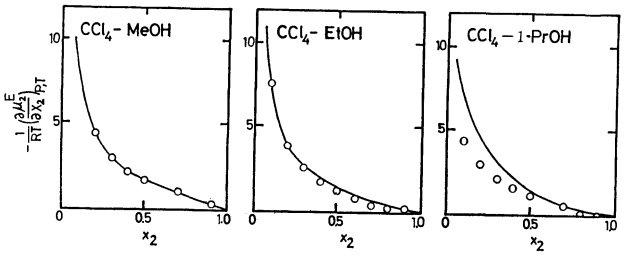

Fig. 1. Plots of $-(1/RT)(\partial\mu_2^E/\partial x_2)_{P,T}$ *vs.* x_2 (suffix 2 refers to alcohol).
○: Calculated from concentration fluctuation data by light scattering, ——: calculated from vapor-liquid equilibrium data.

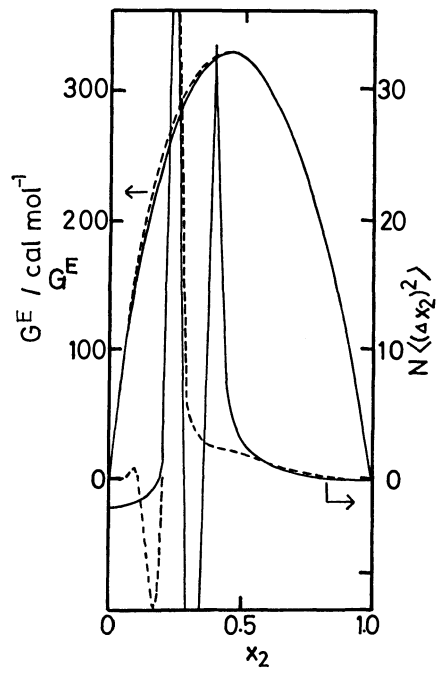

Fig. 2. Excess Gibbs' free energy calculated by empirical formulae proposed by Scatchard *et al.*[16] (——) and Moelwyn-Hughes *et al.*[17] (……) and concentration fluctuation values $N\langle(\Delta x_2)^2\rangle$ calculated from Eq. 3 for carbon tetrachloride–methanol system at 35 °C.

Determination of the Kirkwood-Buff Parameters, G_{11}, G_{22}, and G_{12}, for CCl_4–Methanol, CCl_4–Ethanol, and CCl_4–1-Propanol Systems

According to the Kirkwood-Buff theory, the partial molar volumes v_1, v_2, the isothermal compressibility, κ_T, and the concentration derivative of the chemical potential, $(\partial\mu_2/\partial x_2)_{P,T}$ can be expressed as functions of G_{11}, G_{22}, G_{12}, ρ_1, and ρ_2 where ρ_1 and ρ_2 are the number densities of 1 and 2, respectively. Therefore, G_{11}, G_{22}, and G_{12} can be obtained from these thermodynamic quantities.[5] For numerical calculations, the following data were used.

The concentration derivative of the chemical potential, $(\partial\mu_2/\partial x_2)_{P,T}$ was calculated from the data on the concentration fluctuation obtained from Rayleigh scattering.[14]

Density data for carbon tetrachloride–methanol,[16,19,20] carbon tetrachloride–ethanol,[21] and carbon tetrachloride–1-propanol[20] systems are found in the literature. From these data, the partial molar volumes of each system are calculated.

The isothemal compressibility can be expressed in terms of the adiabatic compressibility, κ_s, the thermal expansion coefficient, α, and the isobaric heat content, C_P, as

$$\kappa_T = \kappa_s + \frac{TV\alpha^2}{C} \qquad \alpha \equiv \frac{1}{v}\left(\frac{\partial v}{\partial T}\right)_P. \tag{5}$$

The isobaric heat content for the solution was calculated from that of the pure component and the temperature dependence of the mixing enthalpy.[22] The expansion coefficent for the carbon tetrachloride–methanol system was calculated from the temperature dependence of the density.[23] For the carbon tetrachloride–ethanol and carbon tetrachloride–1-propanol systems, the data of the temperature dependence of the density can not be found in the literature. So, we evaluated α values from those for the pure alcohol and carbon tetrachloride taking into account the concentration dependence of α for the carbon tetrachloride–methanol system.

The adiabatic compressibility is related to the sound velocity, u_s, by the Laplace equation:

$$\kappa_s = \frac{1}{du_s^2}, \tag{6}$$

where d is the density. The sound velocities for the carbon tetrachloride–ethanol and carbon tetrachloride–1-propanol systems were measured using an ultrasonic interferometer which was operated at a fixed frequency of 5.000 MHz. For the carbon tetrachloride–methanol system, the data of Nomura *et al.*[23] were used.

Discussion

Limiting Values of G_{11}, G_{22}, and G_{12}. Figures 3—5 show the concentration dependences of G_{11}, G_{22}, and G_{12}. For the pure liquids, 1 and 2, G_{11} and G_{22} are expressed as

$$G_{11}^{\circ} = -\frac{1}{\rho_1} + \kappa_{T_1} kT$$

$$G_{22}^{\circ} = -\frac{1}{\rho_2} + \kappa_{T_2} kT.$$

It can be seen from Fig. 3 that the limiting value of G_{11} at $x_2 \to 0$ coincides with G_{11}° value for pure carbon tetrachloride which is $G_{11}^{\circ} = -94.3$ cm^3 mol^{-1}. At the same time, each limiting value of G_{22} at $x_1 \to 0$ coincides with the G_{22}° value for each alcohol ($G_{22}^{\circ} = -37.6$ cm^3 mol^{-1} for methanol, -55.8 cm^3 mol^{-1} for ethanol, and -72.6 cm^3 mol^{-1} for 1-propanol).

The limiting value of G_{12} at $x_1 \to 0$ and $x_2 \to 0$ are expressed as

$$\lim_{x_1 \to 0} G_{12} = \frac{1}{\rho_2} - \bar{v}_1^{\circ} + G_{22}^{\circ}$$

$$= -93.4 \text{ cm}^3 \text{ mol}^{-1} \text{ (MeOH–CCl}_4\text{)}$$

$$= -92.8 \text{ cm}^3 \text{ mol}^{-1} \text{ (EtOH–CCl}_4\text{)}$$

$$= -92.8 \text{ cm}^3 \text{ mol}^{-1} \text{ (1-PrOH–CCl}_4\text{)},$$

$$\lim_{x_2 \to 0} G_{12} = \frac{1}{\rho_1} - \bar{v}_2^{\circ} + G_{11}^{\circ}$$

$$= -38.4 \text{ cm}^3 \text{ mol}^{-1} \text{ (MeOH–CCl}_4\text{)}$$

$$= -57.0 \text{ cm}^3 \text{ mol}^{-1} \text{ (EtOH–CCl}_4\text{)}$$

$$= -84.8 \text{ cm}^3 \text{ mol}^{-1} \text{ (1-PrOH–CCl}_4\text{)},$$

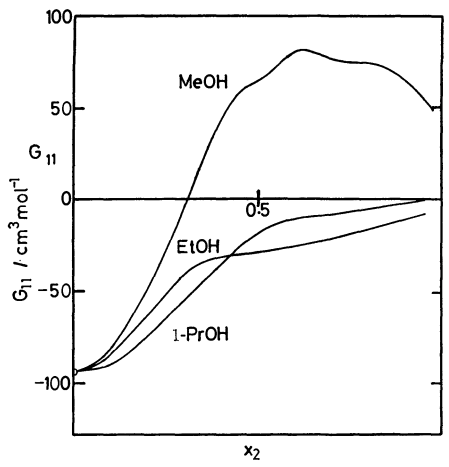

Fig. 3. Concentration dependence of G_{11}.

where $\bar{v}_1^{\circ}$ and $\bar{v}_2^{\circ}$ are the partial molar volumes at infinite dilution. Figure 5 shows that the values of G_{12} tend smoothly to these limiting values. The behavior of these limiting values of G_{11}, G_{22}, and G_{12}, on each side, indicates that the estimation of these value

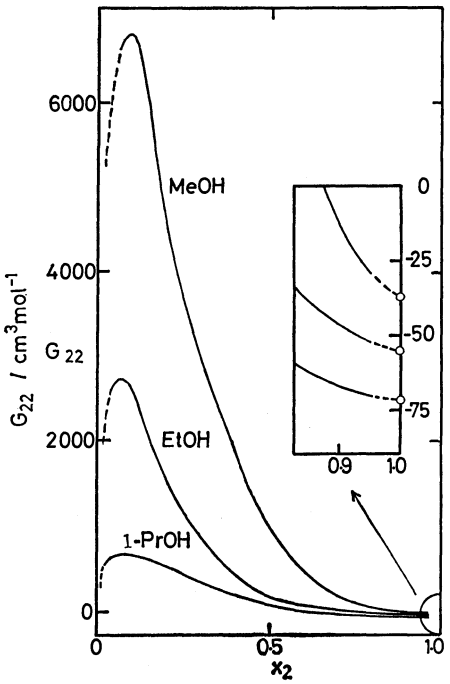

Fig. 4. Concentration dependence of G_{22}.

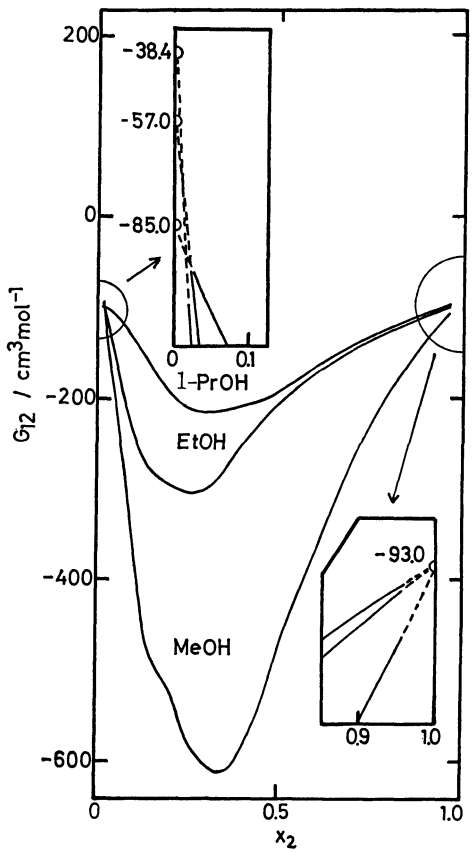

Fig. 5. Concentration dependence of G_{12}.

is reasonable.

Concentration Dependences of G_{11}, G_{22}, and G_{12}. The results shown in Figs. 3—5 may be summarized as follows:

(1) G_{11} is only slightly dependent on the concentration at $x_2<0.1$ especially for the 1-propanol system.

(2) The concentration dependence of G_{11} is similar to that for ordinary binary solutions such as cyclohexane–2,3-dimethylbutane obtained by Dunkersloot.[6]

(3) The magnitudes of G_{22} are much larger than those for ordinary solutions especially in the low concentration range of alcohol and are in the order methanol>ethanol>1-propanol. The magnitude of G_{22} rapidly decreases as the alcohol concentration increases.

(4) G_{12} acquires a minimum value. The magnitudes of the minimum values are in the order 1-propanol>ethanol>methanol.

Interpretation of G_{11}, G_{22}, and G_{12}. Evaluation of the parameters G_{11}, G_{22}, and G_{12} enables us to discuss the solute-solute, solvent-solvent, and solute solvent interactions independently. G_{ij} should be related to the intermolecular interactions and local structures formed in a solution.

It is preferable to discuss the quantity $g_{ij}(r)$ included in G_{ij}, but it cannot be done easily at this stage. Therefore, we will discuss G_{ij} from the standpoint of fluctuations. The parameters G_{11}, G_{22}, and G_{12} can be expressed in terms of the mean numbers of molecules in the volume V, N_1, and N_2, as[24]

$$G_{11} \equiv \int \{g_{11}(r)-1\}\mathrm{d}^3r = v\frac{\overline{N_1^2}-(\overline{N}_1)^2}{(\overline{N}_1)^2} - v_1$$

$$G_{22} \equiv \int \{g_{22}(r)-1\}\mathrm{d}^3r = v\frac{\overline{N_2^2}-(\overline{N}_2)^2}{(\overline{N}_2)^2} - v_2 \qquad (7)$$

$$G_{12} \equiv \int \{g_{12}(r)-1\}\mathrm{d}^3r = v\frac{\overline{N_1N_2}-\overline{N}_1\overline{N}_2}{\overline{N}_1\overline{N}_2}.$$

Equation 7 corresponds to the following relations;

$G_{11}+\bar{v}_1$: number fluctuation of solvent molecules,

$G_{22}+\bar{v}_2$: number fluctuation of solute molecules,

G_{12} : correlation of number fluctuation between solute and solvent molecules.

The large negative value of G_{12} for the alcohol–carbon tetrachloride system indicates the large negative correlation of the number fluctuation between solute and solvent molecules. Similarly, the abrupt increase of G_{22} in the low alcohol concentration range suggests a sudden increase of the correlation between alcohols in the solution. The magnitude of the correlations are in the order methanol>ethanol>1-propanol. On the other hand, G_{11} is slightly dependent on the concentration at $x_2<0.1$. This shows that the structure existing in carbon tetrachloride is held in the solution at the low concentration of alcohol, especially in the case of 1-propanol. These results correspond to the fact that the intermolecular interaction between alcohols is much stronger than that between carbon tetrachlorides in the binary solution of alcohol and carbon tetrachloride.

Concluding Discussion. From the discussion of the preceeding paragraphs the properties of the binary solution of alcohol and carbon tetrachloride may be summarized as follows.

1) The behavior of carbon tetrachloride molecules is not singular but quite normal.

2) All the peculiar properties of the solution come not from the intermolecular interaction between alcohol and carbon tetrachloride, but from the strong interaction between the alcohol molecules as can be seen from the magnitudes of G_{22} and G_{12}.

3) The magnitude of the interactions between the alcohol molecules is in the order methanol>ethanol>1-propanol. For the 1-propanol system, the interaction between the alcohol molecules is weaker.

4) The singular behavior of the alcohol molecules arises from the fact that the alcohol molecules are surrounded by carbon tetrachloride molecules as can be seen from the sharp maximum of G_{22} at low concentrations of alcohol. The above conclusions strongly suggest the formation of a local structure composed of alcohol molecules in the carbon tetrachloride solution. The detailed discussion concerning the local structure formation can be made only when each $g_{ij}(r)$ included in G_{ij} can be quantitatively related to the specific intermolecular interactions in a solution. Work along this line is in progress.

The Investigation of Energy Efficiency of the ZnO Semiconductor Photoelectrode by Photothermal Measurement

Yasuhisa MAEDA, Akira FUJISHIMA,* and Kenichi HONDA

Department of Synthetic Chemistry, Faculty of Engineering, The University of Tokyo, Bunkyo-ku, Tokyo 113

(Received March 11, 1982)

The energy efficiency of a polycrystalline ZnO photoanode in an electrolyte solution containing redox agents was investigated by measuring the temperature change of the electrode surface. The results of photothermal measurements show that the energy efficiency depends on the kind of redox agents used. Reducing agents with more positive potentials gave larger energy efficiencies, but the potential must be negative enough to decrease ZnO dissolution.

A number of photoelectrochemical cells using semiconductor electrodes have been reported for the photodecomposition of water and the conversion of solar energy into electricity.[1-17] The energy conversion and quantum efficiencies of photoelectrochemical cells are needed for effective utilization of solar energy. However, during the course of a photoelectrochemical reaction only a portion of the photons absorbed by the semiconductor can be utilized by the electrode reaction, while the remaining portion is converted to heat. Thus, photothermal measurements of a semiconductor electrode during the course of electrolysis can be used to determine the energy efficiency (*i.e.* the ratio of the chemical or electrical power output to the radiant power input).

We have developed a new method to determine the quantum efficiency and the energy efficiency by measuring the temperature change of the surface of a semiconductor electrode with a thermistor.[18-21] When a semiconductor is illuminated with a pulse of monochromatic light having a photon energy E and an average absorbed intensity I for a period of time t, the relationship between the temperature change and the applied potential is represented by Eq. 1, which applies in a limited photocurrent region

$$E\frac{\Delta T}{\Delta T^\circ} = \frac{Q_{s.c.} + T\Delta S}{It} + \eta e(V - V_{FB}), \qquad (1)$$

where ΔT is the temperature change of the semiconductor surface with an applied potential V (*vs.* a reference electrode), ΔT° is the temperature change of the semiconductor surface for an open circuit, ΔS is the entropy change of the semiconductor electrode reaction, $Q_{s.c.}$ is the heat evolved in the semiconductor due to radiationless processes, η is the quantum efficiency of the photoelectrode reaction, and V_{FB} is the flatband potential (*vs.* a reference electrode).

Under constant illumination conditions, *i.e.* EIt= constant, a plot of $E(\Delta T/\Delta T^\circ)$ *vs.* $(V-V_{FB})$ yields a straight line, whose slope is the quantum efficiency, η and whose intercept gives the quantity $(Q_{s.c.}+T\Delta S)/It$ and also $E(\Delta T/\Delta T^\circ)$ when $V=V_{FB}$.

The energy conversion efficiency, therefore, can be obtained when we know the value of the entropy change $T\Delta S$ associated with the electrode reaction.

In previous papers,[18-21] we investigated only the quantum efficiency of photoelectrode reactions from the slope of the linear plot of $E(\Delta T/\Delta T^\circ)$ *vs.* $(V-V_{FB})$, but we had not made a detailed analysis of the energy efficiency.

In this paper, during the course of photoelectrochemical reactions at a ZnO polycrystalline electrode in an electrolyte solution containing redox agents, we determined both the quantum and energy efficiencies. The significance of the intercept and the value of energy efficiency are discussed from the point of view of redox potential.

Experimental

The semiconductor electrode used was a sintered polycrystalline ZnO prepared by pressing reagent-grade ZnO powder at a pressure of 150 kgf/cm²† and then heating at 1300 °C for 3 h in air. After making an ohmic contact with an In–Ga alloy, a copper wire was attached with silver epoxy resin. All surfaces except one were covered with epoxy resin. The exposed polycrystalline face of ZnO was etched in concentrated HCl for 10 s, and then washed with water. The procedure for the photothermal measurement was described in previous papers.[18-21] A platinum electrode was used as the counter electrode and a saturated calomel electrode (SCE) was the reference electrode. A potentiostat (Nikko Keisoku) was used to control the potential of the ZnO electrode with respect to SCE. The supporting electrolyte was 0.2 M Na_2SO_4 (1 M=1 mol dm^{-3}) and all the redox agents used were of reagent-grade.

Results and Discussion

Figure 1 shows the plots of $E(\Delta T/\Delta T^\circ)$ *vs.* V during the course of photoelectrochemical reactions of the ZnO polycrystalline electrode in the electrolyte solution containing one of four different kinds of reducing agents. The electrode was irradiated for 10 s with monochromatic light provided by a 340 nm interference filter. The values of $E(\Delta T/\Delta T^\circ)$ were different for each reducing agent at a given potential. The slopes of the linear plots of $E\ \Delta T/\Delta T^\circ$ *vs.* V, *i.e.* the quantum efficiencies of the photoelectrode reactions, were 0.90 for each reducing agent except S^{2-} for which the slope was 0.80. In the case of S^{2-} the smaller value might be due to the optical absorption of sulfur generated by the oxidation of sulfur ion at the electrode/electrolyte interface. The values obtained by extrapolating the linear portion of $E(\Delta T/\Delta T^\circ)$ *vs.* V to the flatband potentials which were obtained from the onset potentials of the photocurrents depended on the kind of reducing agent. The onset potential was the lowest potential at which a photo-

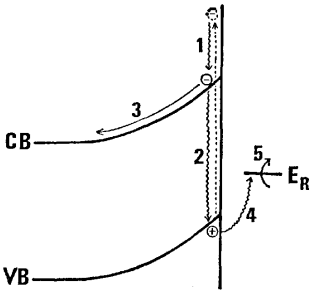

Fig. 2. The state of heat generating during the course of photoelectrode reaction.

current was measurable. As shown in Fig. 1, the onset potentials in the case of S^{2-}, $S_2O_3^{2-}$, H_2Q, and Br^- were -1.0, -0.60, -0.50, and -0.50 V *vs.* SCE, respectively. That of S^{2-} was more negative relative to others because of the higher pH value of this electrolyte.

The heat generated during the course of the photoelectrode reaction consists of five components evolved in the processes shown in Fig. 2, namely (1) radiationless transition within the conduction band (*i.e.* when the photon energy absorbed is in excess of the band gap energy), (2) electron-hole recombination, (3) electron transport from the surface to the bulk through the space charge layer in the conduction band, (4) charge transfer reaction between the hole in the valence band and the redox species in the electrolyte solution, and (5) entropy change of the redox reaction. The Joule heat in the solution due to the current flow is very small and can be neglected.

When one photon with energy E is absorbed by the electrode surface, the photoelectrochemical reaction proceeds with a quantum efficiency η at an applied electrode potential V, and the heat generated by the five processes discussed above are as follows: (1) $E-E_g$ (E_g: the band gap of the semiconductor), (2) $E_g(1-\eta)$ (if the semiconductor is not a fluorescent or phosphorescent material), (3) $\eta e(V-V_{FB})$, (4) $\eta(E_v-E_R)$ (E_R: redox potential, E_v: energy position of the valence band), and (5) $\eta T\Delta S$.

In the supporting Na_2SO_4 electrolyte solution, the photoelectrode reaction results in the dissolution of the ZnO electrode,[22]

$$ZnO + 2p^+ \longrightarrow Zn^{2+} + \frac{1}{2}O_2.$$

However, when electrolyte solution contains a redox agent, the oxidation of the reducing agent and the dissolution reaction proceed competitively. It is probable that $\eta e(E_v-E_R)$ and $T\Delta S$ represent the heat due to these two photoelectrode reactions. Therefore, by using the competitive oxidation ratio[23] of a reducing agent $\alpha(0\leqq\alpha\leqq1)$ and the five types of heat losses, Eq. 1 can be as follows;

$$\begin{aligned} ITE(\Delta T/\Delta T°) = {} & (E-E_g) + E_g(1-\eta) + \eta\alpha(E_v-E_R) \\ & + \eta(1-\alpha)(E_v-E_D) + \eta\alpha T\Delta S \\ & + \eta(1-\alpha)T\Delta S' + \eta e(V-V_{FB}), \end{aligned} \quad (2)$$

where E_D is the decomposition potential of ZnO (the value thermodynamically calculated[24] is $+0.65$ V *vs.* SCE), ΔS is the entropy change of the oxidation reaction of a reducing agent, and $\Delta S'$ is the entropy change of the dissolution reaction of ZnO.

From the measurement of reaction heat (Peltier heat) by using a platinum electrode,[25] the values of $T\Delta S$ for the redox reaction employed were found to be a fairly small fraction of $E(\Delta T/\Delta T°)$. For example, the Peltier heat for the oxidation of S^{2-} and H_2Q was below one fifth of that for the oxidation of $Fe(CN)_6^{4-}$ which was the biggest value, 0.4 eV, we observed. However, it was difficult to determine the accurate value of the Peltier heat for each electrode reaction by a metal electrode. Therefore, we could not say the exact values for the Peltier heat, but we thought that $T\Delta S$ and $T\Delta S'$ in these cases might be negligible.

When the quantum efficiencies of photoelectrode reactions are the same in different electrolyte solutions, the value of the intercept at the flatband potential,

$$\begin{aligned} Q = {} & (E-E_g) + E_g(1-\eta) \\ & + \eta\alpha(E_v-E_R) + (1-\alpha)(E_v-E_D), \end{aligned} \quad (3)$$

is expected to depend on the competition ratio α, and the redox potential E_R. Q was plotted against redox potential in Fig. 3 for H_2Q, $S_2O_3^{2-}$, SO_3^{2-}, and S^{2-} all which have more negative redox potentials than the decomposition potential of ZnO, 0.65 V *vs.* SCE. As shown in this figure, Q was smaller as the redox potential was more positive. The nearly linear relationship between the redox potential and Q is evident. The slope of this line $\eta\alpha$ is about 0.85, a value almost the same as the quantum efficiency in each electrolyte solution which was 0.90. Therefore the competitive ratio was close to 1, and we conclude that the main photoelectrode reactions in these solutions are as follows:

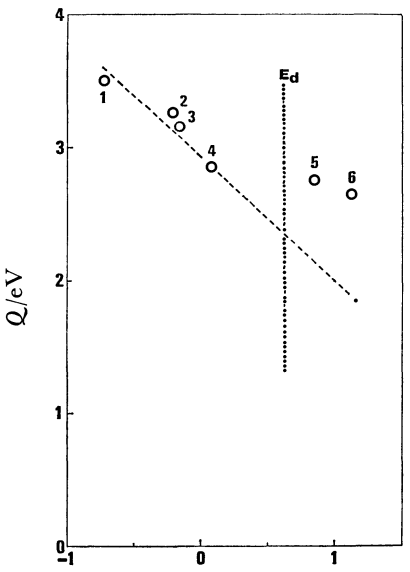

Fig. 3. Relationship between Q and redox potential. No. 1: 0.5 M Na_2S, No. 2: 0.5 Na_2SO_3, No. 3: 0.5 M $Na_2S_2O_3$, No. 4: 0.5 M H_2Q, No. 5: 0.5 M KBr, No. 6: 0.5 M KCl in 0.2 M Na_2SO_4.

$$H_2Q + 2p^+ \longrightarrow Q + 2H^+$$
$$2S_2O_3^{2-} + 2p^+ \longrightarrow S_4O_6^{2-},$$
$$2SO_3^{2-} + 2p^+ \longrightarrow S_2O_6^{2-},$$
$$S^{2-} + 2p^+ \longrightarrow S.$$

In case of Br^- and Cl^- which have a more positive oxidation potential than the decomposition potential of ZnO, +0.65 V *vs.* SCE, Q was smaller as the redox potential was more positive, but the degree of the decrease in Q was smaller in comparison to that for H_2Q, $S_2O_3^{2-}$, SO_3^{2-}, and S^{2-} which have more negative redox potentials. This suggests that the competitive ratios of Cl^- and Br^- are small, and that in these solutions the dissolution reaction of ZnO is faster than the oxidation of Cl^- and Br^-. In this figure, it is evident that Q depends on the competition ratio and redox potential of the reducing agents.

From the point of view of thermodynamics[24,26] a reducing agent with a redox potential more negative than the decomposition potential of a semiconductor can decrease photoelectrocorrosion of the semiconductor. In fact using the rotating ring-disk electrode technique, we reported that a reducing agent with a more negative redox potential has a larger competition ratio and can better stabilize the ZnO electrode.[27] The present measurements confirm this relationship for the stabilization of the ZnO electrode.

The electrochemical photocell in which a photosemiconductor works with a counter electrode in a redox couple solution is called as the regenerative photocell. In the photocell absorbed light energy is converted to electrical energy. The ideal maximum energy conversion efficiency ϕ_v is represented as follows,

$$\phi_v = \frac{|E_{FB} - E_R|}{E} \times 100 \ (\%), \tag{4}$$

where E_{FB} is the flatband potential, E is absorbed light energy. $|E_{FB} - E_R|$ means the maximum photovoltage in the regenerative cell.

Table 1. Energy efficiencies for the photooxidation of each reducing agent on ZnO polycrystal electrode

Redox agent	(E_r *vs.* SCE)/V	Q/eV	ϕ_T/%	ϕ_V/%
S^{2-}	−0.72	3.50	2.8	7.9
SO_3^{2-}	−0.22	3.25	10.8	10.7
$S_2O_3^{2-}$	−0.16	3.15	12.5	12.2
H_2Q	+0.08	2.85	20.8	16.1

$$\phi_T = \frac{3.6 - Q}{3.6} \times 100 \ (\%), \quad \phi_V = \frac{|E_{FB} - E_r|}{3.6} \times 100 \ (\%)$$

On the other hand, from the photothermal data the energy conversion efficiency ϕ_T can be obtained by using the value of Q,

$$\phi_T = \frac{E - Q}{E} \times 100 \ (\%). \tag{5}$$

The energy efficiencies for the reducing agents S^{2-}, SO_3^{2-}, $S_2O_3^{2-}$, and H_2Q under irradiation of monochromatic light 340 nm (3.6 eV) were given from the values of Q as shown in Table 1.

The meaning of ϕ_T can be considered as follows. When the competitive oxidation ratio α is 1.0, the value of Q is expressed from Eq. 3 as below,

$$Q = \eta(E_v - E_R) + E - E_g\eta. \tag{6}$$

Therefore

$$\frac{E - Q}{E} = \frac{\eta\{E_g - (E_v - F_R)\}}{E}. \tag{7}$$

Since $|E_g - E_v|$ equals almost to the flatband potential, the next equation is given,

$$\frac{E - Q}{E} = \frac{\eta|E_{FB} - E_R|}{E}. \tag{8}$$

Therefore, from Eq. 8 the energy efficiency ϕ_T can be derived as the product of the quantum efficiency (which is obtained from the slope of the photothermal measurement) and the maximum photovoltage under monochromatic light irradiation. In the case of ZnO, the value of quantum efficiency is near 1, so ϕ_T is expected to equal to ϕ_v. In Table 1 energy efficiencies ϕ_v are also shown.

The values of ϕ_T and ϕ_v are similar in the case of each reducing agent. It was ascertained that a reducing agent with a more positive redox potential gave larger energy efficiency.

We conclude that the photothermal measurement technique provides information on the energy efficiency and the stabilization of a semiconductor electrode by redox agents.

Resonance Raman Spectra and Inter-radical Vibrations of Chloranil Anion Radical Dimers

Susumu MATSUZAKI, Tetsuya MITSUISHI, and Koichi TOYODA*

Department of Chemistry, Faculty of Science, Kumamoto University, Kumamoto 860

(Received March 15, 1982)

Resonance Raman spectra of chloranil anion radical dimers were measured in ethanol at 140 K by an exciting radiation within the CT band, and all the Raman lines observed were shown to be totally symmetric. Two strong Raman lines at 114 cm^{-1} and 168 cm^{-1} have been assigned to inter-radical stretching vibrations of the dimer. The relative intensity of these lines changed depending on the counter ion species. Formation of two dimers has been supposed to explain the spectral behavior. Influence of 18-crown-6 on the spectra was investigated. The result strongly suggests that one dimer gives two inter-radical Raman lines. Two interpretations are proposed for the simultaneous resonance enhancement of these Raman lines: mechanical coupling of the inter- and intra-radical vibrations or distorsion of the D_{2h} eclipsed dimer structure. Other five lines at higher frequencies have been assigned to intra-radical vibrations of the dimer.

A number of organic ion radicals are known to form dimers in the solution under appropriate conditions of temperature and concentration, and the monomer-dimer equilibrium has been studied by electronic absorption spectra.[1-3] Recently resonance Raman spectra of some ion radical dimers have been measured by exciting radiations close to the CT band, and new broad Raman lines have been observed at lower frequencies.[4-6] The Raman lines are assigned to the stretching vibrations of the inter-radical bond of the dimer because of the remarkable resonance enhancement by the CT transition of the dimer. In the case of tetracyanoethylene anion radical dimer, $(TCNE^{\cdot-})_2$, in 2-methyltetrahydrofuran (MTHF),[6] two inter-radical Raman lines were observed at *ca.* 150 cm^{-1} and 180 cm^{-1}, which showed obvious change of the relative intensity depending on the counter ions (Na^+, K^+, Rb^+, and Cs^+). Formation of two different dimers has been proposed as the most probable interpretation of the spectral behavior.

Structure of organic ion radicals in the solution has been investigated by ESR spectra, but the dimer has the singlet ground state so that no ESR signals are observed. Electronic spectra have also given little information about the detailed structure of the dimer because the absorption bands are broad and structureless. Vibrational spectroscopy will be, at present, the most suitable tool for the structural investigation of the dimer in the solution. Resonance Raman spectra particularly have the advantage that the inter-radical vibrations are observed directly. The spectra will give information about the structure of the ground state as well as the excited state when the nature of the resonance Raman effect in the dimer is elucidated by accumulation of the data.

In this paper, we present the resonance Raman spectra of chloranil anion radical dimer, $(CA^{\cdot-})_2$, in ethanol and discuss the result from the standpoint of the dimer structure.

Experimental

Commercially available chloranil (CA) was crystallized twice from dry benzene and sublimed twice *in vacuo*. Commercially available alkaline iodide (M·I) was dried *in vacuo* at 110 °C for 12 h to avoid the decomposition of radicals by moisture in the salts. Alkaline metal salts of chloranil (M·CA) were prepared from CA and M·I by the method of Torrey and Hunter in dry acetone or acetonitrile:[7] M= Li, Na, K, Rb, and Cs. It is well known that M·CA usually contains the solvent in preparation.[8] The salts, therefore, were dried over P_2O_5 in an evacuated desiccator for a week. IR spectra of the salts agreed well with those reported in the literature.[9] The salt was dissolved in dry ethanol of spectroscopic grade *in vacuo* to give the sample solution (*ca.* 10^{-3} mol/dm^3).

A glass cryostat with quartz windows was used for both Raman and electronic absorption measurements. The cryostat was cooled by flowing cold N_2 gas. Raman spectra were recorded on a JASCO R-800 Raman spectrometer equipped with a NEC GLG-108 He–Ne laser and GLG-3200 Ar^+ laser. Electronic spectra were recorded on a Hitachi 200-20 spectrophotometer.

Results and Discussion

Observed Spectra. In the visible spectra of Na·CA (Fig. 1), only an absorption band of $CA^{\cdot-}$ is observed at room temperature, but another new peak appears at 670 nm when the solution is cooled to 140 K. This peak is assigned to the CT band of $(CA^{\cdot-})_2$.[3]

Time-dependence of the Raman spectra observed at room temperature showed that $CA^{\cdot-}$ in ethanol was gradually decomposed even in oxgen-free atmosphere. The spectra of the monomer, therefore, were measured at 200 K because the radical was practically

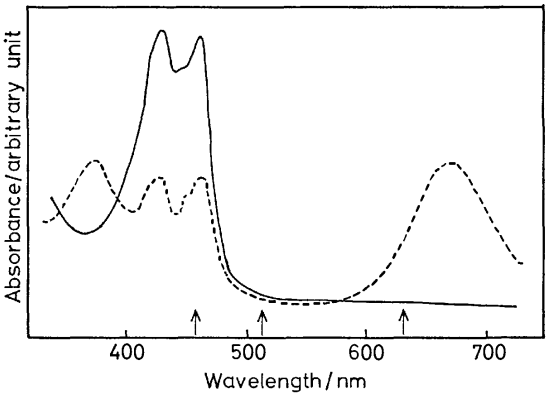

Fig. 1. Electronic absorption spectra of Na·CA in ethanol.
——: Room temperature, ----: 140 K.

stable and the dimer formation was still negligible at this temperature. Several Raman lines of $CA^{\cdot-}$ were observed with 457.9 nm excitation within the first absorption band of the radical. The frequencies are given in Table 1 together with the frequencies and assignment reported by Girlando, *et al.*[9] The table shows that the frequency of ν_1 in ethanol differs remarkably from that in acetone and in the powder sample.[10] This mode is C=O stretching, and the difference probably arises from the hydrogen bond formation between the radical and the solvent.

Figure 2 shows the temperature-dependence of the Raman spectra of Na·CA by 632.8 nm excitation within the CT band of the dimer. No Raman lines of the sample are observed at 200 K because very few dimers are formed at this temperature and the monomer Raman lines show no practical resonance enhancement by this exciting radiation. When the solution is cooled to 140 K, seven new lines appear.[11] This spectral change is reversible and reproducible. None of these Raman lines, on the other hand, are observed at 140 K when excited with the Ar^+ 514.5 nm line which is far from the CT band. These Raman lines, therefore, are undoubtedly resonance enhanced by the CT transition of the dimer. All of them were found to be totally symmetric by the depolarization ratios (*ca.* 1/3). The result shows that the resonance enhancement originates from the Franck-Condon type term of the scattering tensor.[12] The Raman frequencies of the dimer are given in Table 2 together with the corresponding frequencies of the monomer. Raman lines at 114 cm^{-1} and 168 cm^{-1} are much broader than those at higher frequencies and will be assigned to inter-radical vibrations by comparison with those observed in other dimers.[4-6] The relative intensity of 114 cm^{-1} line to 168 cm^{-1} line is dependent on the counter ions in the order, $Li^+ \simeq Na^+ > K^+ > Rb^+$ (Fig. 3).[13] The result shows that a kind of association of the dimer and the cations is present in ethanol because it is not expected that the spectra of free dimers are affected by the counter ion. Ethanol has a large dielectric constant, so that the association should be very weak. The spectral change is similar to that observed in $(TCNE^{\cdot-})_2$ in MTHF[6] except that the magnitude of the change is rather small in the present case. Therefore, in the preliminary report of the present investigation,[14] we gave the same interpretation as the case of $(TCNE^{\cdot-})_2$; *i.e.*, two different

Raman intensities of the dimers are normalized by that of 168 cm^{-1} line.

dimers were present in the solution and the ratio of the equilibrium concentrations was dependent on the counter ions. If this is the case, it is most probable that the difference in the dimers arises from that in the pairing mode of the dimer and the counter ion, *i.e.*, solvent-separated ion pairs and free ions: contact ion pairs are probably excluded because of the large dielectric constant of ethanol. It was also implicitly assumed in the report that the respective Raman lines corresponded to the same inter-radical vibrational mode of the different dimers. However, the large frequency difference ($>50\ cm^{-1}$) in the two Raman lines seems to be unexplainable from this standpoint because the structures of the free dimer and the loosely ion-paired dimer are not expected to be so different from one another. Furthermore, strength of the association between the component cation and anion in the ion-paired dimers probably decreases continuously to the state of the free dimer in such a polar solvent as ethanol, and the dimers are not expected to be present as two distinct species. It is, therefore, necessary to examine the possibility that one dimer gives two inter-radical Raman lines.

For the purpose of this examination, spectral change by the addition of crown ether (18-crown-6) was investigated for K·CA in ethanol. It is well known that the crown ether forms very stable complexes with K^+; therefore, practically all of the cations are expected to be complexed by the crown ether. It has been reported that crown ethers inhibit the dimer formation of K·TCNE in MTHF, where ion pair formation is indicated by ESR.[15] Also in the present case, crown ether was expected to affect strongly the Raman spectra if the solution contained the ion-paired dimers of distinct structures. However, no drastic changes were observed when 18-crown-6 was added in large excess, but only a minor change occurred in the relative intensity of the two Raman lines (Fig. 4). The resulting spectrum is quite similar to that of Li·CA which is expected to have the strongest tendency to give free dimers because of the largest solvation energy of Li^+ among all the alkali metal cations. The change occurred probably because the crown ether weakened the interaction between the component cation and anion of the ion-paired dimer and allowed the dimer to be in the state of practically free dimers: this is also supported by the fact that the solubility of K·CA considerably increased by addition of the crown ether. The result shows that both of the two Raman lines are attributable to one dimer, *i.e.*, they correspond to the different vibrational modes of the dimer: mechanism of the simultaneous resonance enhancement of two inter-radical Raman lines will be discussed in the next section. The spectral change by the counter ion or the crown ether will be interpreted as follows. Observed Raman spectra correspond to the statistical average over the many dimers of various interaction strengths between the component cation and anion. If the average deviates by the counter ion or the crown ether and if the relative intensity of the Raman lines is different from each other in the respective dimers, spectral changes probably occur as observed in this investigation. Temperature dependences of the spectra were investigated in the range, 140 K—160 K, but practically no dependences were observed. The result may also be an evidence against the assumption of the presence of two dimers because the equilibrium of the dimers should be dependent on the temperature.

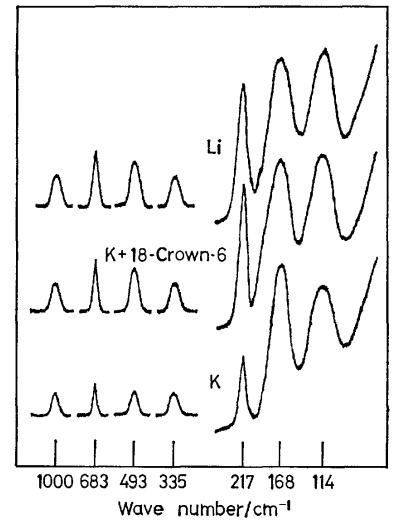

Fig. 4. Spectral change of K·CA by addition of 18-crown-6.

Normal Vibrations and Resonance Raman Effect. When two N-atomic radicals form a dimer, six of the 12 translational and rotational degrees of freedom of the radicals are frozen to produce six inter-radical vibrations of the dimer, because the resulting dimer only possesses six translational and rotational degrees of freedom. The inter-radical vibrational modes are easily obtained for the case of dimers of D_{2h} eclipsed structure by the *out-of-phase* combination of the corresponding translational and rotational motions of the component radicals: *e.g.*, the combination of the rotational motions around y-axis gives a librational mode of b_{1u} symmetry. The normal vibrations thus obtained are shown in Fig. 5: Q_1 (a_g), out-of-plane stretching mode; Q_2 (b_{1g}) and Q_3 (b_{2g}), in-plane slipping modes; Q_4 (a_u), in-plane twisting mode; Q_5 (b_{1u}) and Q_6 (b_{2u}), out-of-plane librational modes. The totally symmetric stretching mode, Q_1, is expected to show remarkable resonance enhancement by the Franck-Condon type term of the scattering tensor,[12] because the potential curves along this normal coordinate are probably much different from one another in the ground and CT excited states: the dimer is stabilized by the CT interaction in the ground state whereas in the CT excited state the component radicals should merely contact with each other in the solvent cage.[16] The two low frequency Raman lines will be assigned to this normal mode, but there is one totally symmetric vibration in the case of the eclipsed dimer structure. Two interpretations are possible for the simultaneous resonance enhancement of the two inter-radical Raman lines as discussed in the following.

The first interpretation is given on the basis of the intensity borrowing by the mechanical coupling of

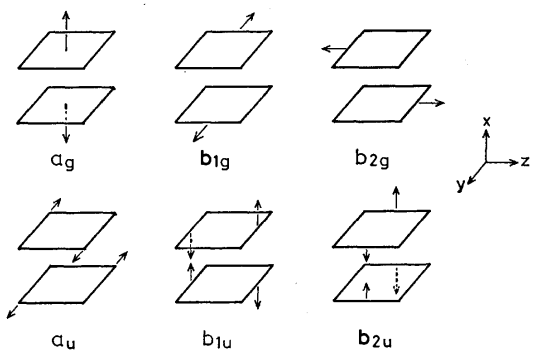

Fig. 5. Inter-radical vibrations of dimer of D_{2h} eclipsed structure.
Rectangles represent planer radicals, and arrows show the displacements: y- and z-axes are parallel to the molecular short and long axes respectively, and x-axis is perpendicular to the molecular plane.

the inter- and intra-radical vibrations. The number of the normal vibrations of the N-atomic radical is 3N−6, so that the resulting dimer possesses 2(3N−6) intra-radical vibrations. The i-th normal coordinates (Q_A^i and Q_B^i) of radicals A and B are combined with one another to produce new normal coordinates ($Q_\pm^i$): $Q_\pm^i=(1/\sqrt{2})(Q_A^i\pm Q_B^i)$. The combination gives totally symmetric vibrations only for the following two cases. When Q_A^i and Q_B^i are a_g modes, the *in-phase* combination (Q_+^i) remains totally symmetric and *out-of-phase* combination (Q_-^i) gives an IR-active mode of b_{3u} symmetry.[17] Q_+^i may couple with Q_1, but such a coupling is expected to be small because the former is the in-plane vibration whereas the latter is the out-of-plane one. When Q_A^i and Q_B^i are out-of-plane bending modes of b_{3u} symmetry, on the other hand, the *out-of-phase* combination gives totally symmetric vibrations. Such out-of-plane a_g modes are expected to couple considerably with Q_1 and to show resonance enhancement through the intensity borrowing by the mechanical coupling. Chloranil has three b_{3u} modes (ν_{28}, ν_{29}, and ν_{30}),[9] and the frequencies of ν_{28} and ν_{29} have been reported to be 695 cm^{-1} and 220 cm^{-1} respectively. The Raman lines at 683 cm^{-1} and 217 cm^{-1} will be reasonably assigned to the *out-of-phase* combination modes of ν_{28} and ν_{29} respectively. The third b_{3u} mode, ν_{30}, has not yet been observed for $CA^{\cdot-}$, but the frequency of the neutral molecule has been reported to be 88 cm^{-1}.[9] This mode may, therefore, have a frequency around 100 cm^{-1} also in the case of the radical. If Q_1 and the *out-of-phase* combination mode of ν_{30} strongly couple with each other, two Raman lines of comparable intensities will be observed in the low frequency region as in the present case. It is well known that, in general, the extent of the mechanical coupling of vibrational modes increases with a decrease in the difference of their frequencies. It is, therefore, expected that Raman line at 217 cm^{-1} has stronger intensity than that at 685 cm^{-1}: this expectation agrees well with the result obtained (Fig. 3).

The second interpretation is given on the basis of the distorsion of the dimer from the D_{2h} eclipsed structure. If the component radicals slip along y- or z-axis, the dimer has the slipped structure of C_{2h} symmetry; therefore, the dimer has two totally symmetric inter-radical modes. The slipped structure is occasionally met in the crystal structure of organic ion radical salts,[18] and the dimer in the solution may possess this structure. At this stage, it is not clear which interpretation is valid. The experiment of isotopic shifts may give conclusive information but $(CA^{\cdot-})_2$ seems to be unsuitable for this purpose because the inter-radical Raman lines are broad and the molecular weight is heavy: TCNE is a probable candidate for the purpose.

The remaining three Raman lines at 1000 cm^{-1}, 493 cm^{-1}, and 335 cm^{-1} will be assigned to ν_3, ν_4, and ν_5, respectively, as shown in Table 2. The mechanism for the resonance enhancement of these lines is not elucidated at present: measurements of the excitation profile may give some information. No distinct features have been observed in the region of ν_1 and ν_2. This result is probably attributed to the low sensitivity of our instrument in this region.

Penetration of Leucine and Norleucine into Lecithin Monolayers from Underlying Aqueous Solutions

Masayuki NAKAGAKI and Emiko OKAMURA*

Faculty of Pharmaceutical Sciences, Kyoto University, Yoshida-Shimoadachicho, Sakyo-ku, Kyoto 606

(Received March 20, 1982)

The surface pressure of the monolayers of dimyristoyl phosphatidylcholine(DMPC) on leucine and norleucine solutions was measured and the amounts of these amino acids which had penetrated into the DMPC monolayer were calculated by means of a successive approximation. Although the amounts of leucine and norleucine adsorbed onto the solution surface were nearly equal and were larger than that of lysine, the amount of leucine which had penetrated into the DMPC monolayer was remarkably small. That of norleucine was not so small, but was still smaller than that of lysine except for the region where the molecular area of DMPC is large. The partial molecular areas of amino acid, $\overline{A}_2$, and DMPC, $\overline{A}_3$, were calculated in each case. The value of $\overline{A}_2$, was the largest in the case of leucine and the smallest in the case of lysine, which means that the area occupied by lysine is smaller than that of norleucine because the interaction of ε-amino group with DMPC contracts the mixed monolayer. The change in the value of $\overline{A}_3$ due to the interaction with amino acid, however, was not large, which means that the change in the state of DMPC itself is not large and rather independent of the kind of amino acid.

It has been widely accepted that biomembranes such as protoplasmic membranes essentially consist of bimolecular lipid layers in which some proteins are dissolved.[1] The study of the penetration of proteins into lipid monolayers is, therefore, considered to be one of the useful techniques for the investigation of the structure and functions of biomembranes.[2,3] In order to discuss the interaction between lipids and proteins from this point of view, the penetration of L-lysine into lecithin monolayers was studied in our previous work.[4]

L-Leucine and L-norleucine have four carbon atoms in the side chains, which is the same as in the case of L-lysine. Leucine has a branched carbon chain, whereas norleucine does not. The side chain of lysine has an amino group at the end of the carbon side chain of norleucine. The effect of the ε-amino group of lysine and that of the branched carbon chain are, therefore, expected to become clear by the comparison of the features of the penetration of these amino acids into lecithin monolayers. In this work, the surface tension of aqueous solutions as well as the surface pressure of the solutions has been measured, and the amounts of these amino acids adsorbed onto the surface and penetrated into the monolayers, respectively, have been calculated. This will facilitate discussion of the interaction between these amino acids and lecithin.

Experimental

Materials. L-Leucine and L-norleucine from Nakarai Chemicals, Ltd., were dissolved in redistilled water. L-α-Dimyristoyl phosphatidylcholine (DMPC) from Sigma Company was used as lecithin; it was dissolved in distilled chloroform and preserved in a refrigerator until use. The stock solution was prepared every few days in order to avoid disintegration.

Surface-tension Measurement. Surface tension of amino acid solution, γ, was measured by the capillary-height method. The surface pressure of amino acid, F, was obtained by Eq. 1:

$$F = \gamma_0 - \gamma, \quad (1)$$

where γ_0 is the surface tension of pure water. The temperature of the solution was kept at 25±0.5 °C.

Surface-pressure Measurement. The surface pressure of the DMPC monolayer was measured by Wilhelmy's plate method. The details of this method were described in our previous paper.[4] The temperature of the solution was kept at 25±0.5 °C.

Results

Surface Tension of Amino Acid Solution. Figure 1 shows the surface tension of leucine or norleucine solution. The surface tension of lysine solution (Fig. 1 in Ref. 4) is also shown by a broken line. It is seen that the surface tension of the solution decreases slightly with the increase in the concentration of amino acid, C_2, both in the case of leucine and of norleucine. The extent of decrease was a little larger than that of lysine, but there were no differences between leucine and norleucine.

Surface Pressure-Area Curves of the DMPC Monolayers. Figure 2 shows the surface pressure-area curves of the DMPC monolayers spread on leucine solutions of various concentrations. The curve shifted only at the low surface pressure region when the concentration, C_2, was high. On the other hand, the surface pressure increased with increase in C_2, when norleucine solution was used, as shown in Fig. 3.

The Amount Which Had Been Adsorbed onto the Solution Surface or Which Had Penetrated into a DMPC Monolayer. The change of the surface pressure against the concentration of solution was obtained from the surface pressure-area curves (Figs. 2 and 3); this change is shown in Fig. 4 for leucine or in Fig. 5 for norleucine. The closed circles represent the values when no monolayer exists at the interface, as obtained from Fig. 1. It is seen from these two figures (Figs. 4 and 5), that the change of the surface pressure is very small in the case of leucine, and that in the case of norleucine the surface pressure increases with the increase in the concentration, C_2.

The amount which had been adsorbed onto the liquid-air interface or which had penetrated into a DMPC monolayer, Γ_2, was calculated by the following equation:

$$\Gamma_2 = (1/RT)(1-\overline{A_3}/A_3)(\partial F/\partial \ln C_2)_{A_3}, \quad (2)$$

where R, T are the gas constant and the absolute temperature, respectively, $\overline{A_3}$ is the partial molecular area of DMPC which was approximated by the molecular area of DMPC on pure water, $A_3°$, by Pethica.[5] This equation, proposed by Pethica, has been used in order to calculated the amount of solute molecules penetrated into lipid monolayers.[6,7] Values of Γ_2 thus calculated are shown in Figs. 6 (a) and (b). It is seen that the amounts adsorbed onto the liquid-air

interface of leucine and norleucine are nearly equal and are larger than that of lysine, whereas the amount of leucine penetrated into the DMPC monolayer is remarkably small and that of norleucine is not so small but is still smaller than that of lysine.

On the other hand, both the amount of leucine and of norleucine penetrated into a monolayer vary with the area per molecule of lecithin at constant C_2, as is shown in Figs. 7 (a) and (b). It is seen that the amount which penetrated is larger at the higher concentrations, and it is smaller at the smaller areas per molecule of lecithin, the latter suggesting that the molecules which have penetrated are excluded by the compression of the monolayer. It is also found that the amount of leucine which penetrated is always smaller than that of lysine, but the amount of norleucine which penetrated becomes larger than that of lysine when the area per molecule of lecithin is large.

Discussion

The Mixed Monolayers of DMPC and Leucine or Norleucine. It may be considered that a mixed monolayer of DMPC and leucine or norleucine is formed as the result of the penetration of these amino acids into a DMPC monolayer. The mole fraction of leucine or norleucine in this mixed monolayer, X_2, and the average area per molecule of the monolayer, A_{23}, are given by:

$$X_2 = \frac{\Gamma_2}{\Gamma_2+\Gamma_3} \tag{3}$$

and

$$A_{23} = \frac{1}{(\Gamma_2+\Gamma_3)N_A} \tag{4}$$

respectively, where Γ_3 is the moles of DMPC per unit area ($=1/(A_3\times N_A)$), and N_A is the Avogadro number. The relation between X_2 and A_{23} is shown in Fig. 8 (a) in the case of leucine and in Fig. 8 (b) in the case of norleucine. The values of A_{23} vary with the surface pressure and with the mole fraction. The value of A_{23} increases with the increase in X_2 at each surface pressure in the case of leucine, and also in the case of norleucine, although the values of A_{23} stop increasing and start decreasing at a large X_2, as is shown for norleucine at the surface pressure of 5 mN m^{-1}. The curve with a maximum point is of the same shape as lysine,[4] although the slope of this curve is not so sharp as in the case of lysine.

The partial molecular area of DMPC on the solution, $\overline{A}_3$, obtained from Fig. 8, was not equal to that on pure water, $A_3°$, in the cases of both leucine and norleucine. The amount which penetrated, Γ_2, was,

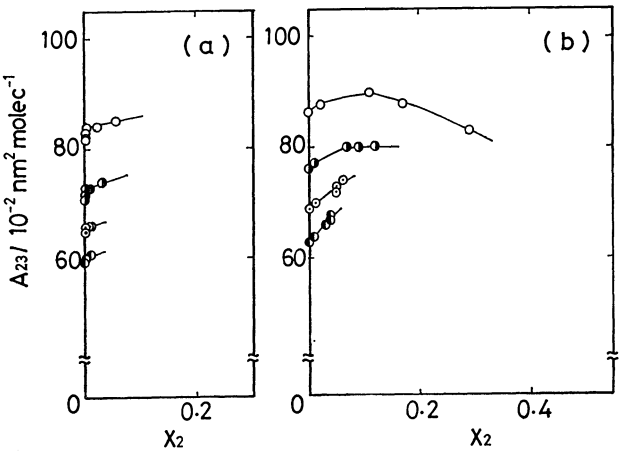

Fig. 8. The relation of the average area per molecule of an amino acid–DMPC monolayer, A_{23}, and the mole fraction of amino acid, X_2.
Obtained from Fig. 7. (a): Leucine, (b): norleucine. F/mN m^{-1}: ○; 5, ◑; 10, ⊙; 15, ◐; 20.

therefore, recalculated by substituting in Eq. 2 the value of $\overline{A}_3$ instead of $A_3°$, as described in Ref. 4. The amount thus obtained is shown in Figs. 9 (a) and (b). The features of the curve of Γ_2 as a function of A_3 did not vary, although the value of Γ_2 was a little smaller than that in Figs. 7 (a) and (b).

The Interaction between Leucine or Norleucine and DMPC. The mole fraction of leucine or norleucine, X_2, and the average area per molecule of the monolayer, A_{23}, were calculated again, by using recalculated values of Γ_2. The recalculated relation between X_2 and A_{23} is shown in Figs. 10 (a) and (b) in the cases of leucine and norleucine, respectively. From this figure, the relation between X_2 and A_{23} can be described as follows:

(1) for leucine,

$$A_{23} = A_3° + 1.7 + 38.4X_2 \quad (5)$$

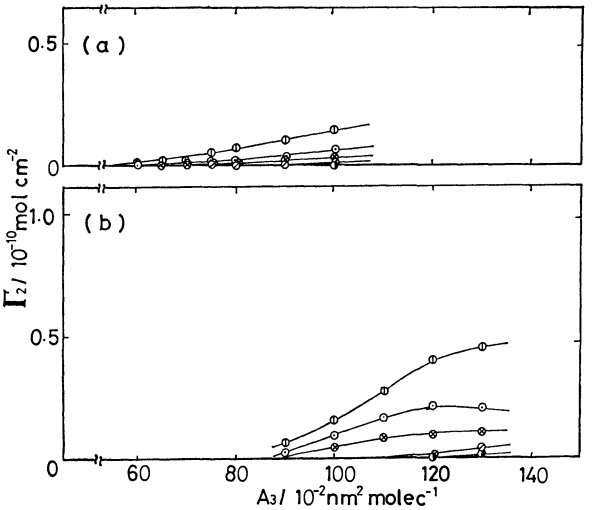

Fig. 9. The relation of the amount of amino acid penetrated, Γ_2, obtained by using the corrected value of $\overline{A}_3$, and the area per molecule of DMPC, A_3.
(a): Leucine, (b): norleucine. C_2/mol dm^{-3}: ◑; 0.01, ⊘; 0.02, ⊗; 0.05, ⊙; 0.07, ⓘ; 0.10.

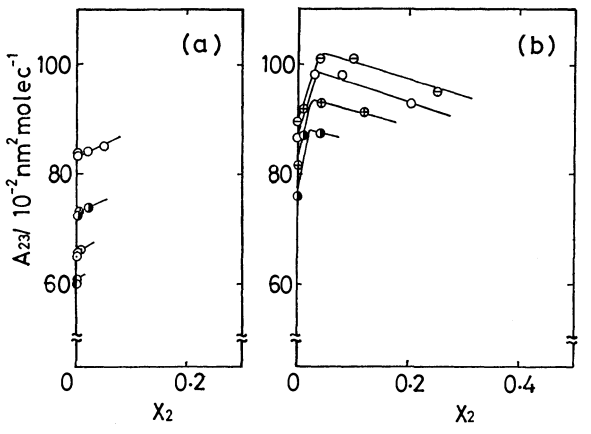

Fig.10. The relation of the average area per molecule of an amino acid-DMPC monolayer, A_{23}, and the mole fraction of amino acid, X_2.
Obtained from Fig. 9. (a): Leucine, (b): norleucine. F/mN m^{-1}: ⊖; 4, ○; 5, ⊕; 7, ◑; 10, ⊙; 15, ◐; 20.

at each surface pressure, F, when the values of X_2 are smaller than 0.10, and

(2) for norleucine,

$$A_{23} = A_3° + 13.0 - 27.0X_2 \quad (6)$$

in the region where F is smaller than 10 mN m^{-1} and the values of X_2 are from 0.04 to 0.30.

From these equations, the partial molecular area of amino acid, $\overline{A}_2$, and that of DMPC, $\overline{A}_3$, are written as follows:

$$\begin{cases} \overline{A}_2 = A_3° + 40.1 \\ \overline{A}_3 = A_3° + 1.7 \end{cases} \quad \text{(for leucine)} \quad (5a)$$

$$\begin{cases} \overline{A}_2 = A_3° - 14.0 \\ \overline{A}_3 = A_3° + 13.0 \end{cases} \quad \text{(for norleucine).} \quad (6a)$$

These are shown in Fig. 11. The values of $\overline{A}_2$ and $\overline{A}_3$ in the case of lysine as well as the molecular area of DMPC on pure water $A_3°$ (▲) are also shown in this figure. It is concluded from Fig. 11 that the interaction between leucine or norleucine and DMPC can be compared with that of lysine and DMPC as follows:

(1) The partial molecular area of amino acid, $\overline{A}_2$, is the largest in the case of leucine, and the smallest in the case of lysine. This would mean that the area occupied by lysine is smaller than that of norleucine, because the interaction of ε-amino group with DMPC contracts the mixed monolayer, while leucine occupies a larger area because of the branching of the carbon chain.

(2) The increase in the partial molecular area of DMPC, $\overline{A}_3$, due to the interaction with amino acid, is not large in comparison with the change in $\overline{A}_2$. This means that the change in the state of DMPC itself is not large, irrespective of the kind of amino acid.

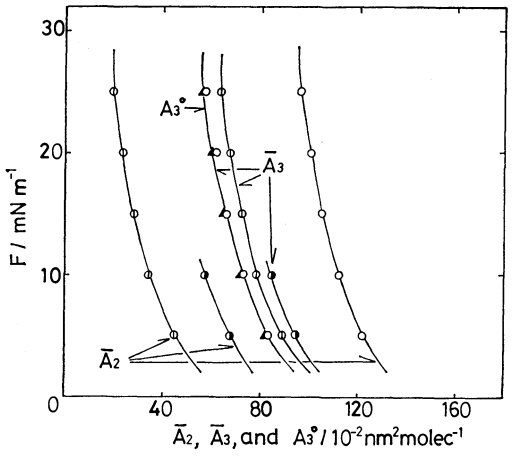

Fig.11. The relation of the surface pressure, F, and the partial molecular areas of amino acid, $\overline{A}_2$; DMPC on solution, $\overline{A}_3$; and DMPC on water, $A_3°$.
○: Leucine, ◑: norleucine, ⓘ: lysine. Symbols(▲) designate the values of $A_3°$.

(Received March 26, 1982)

The crystal structure of the hexakis(2,3,6-tri-*O*-methyl)-α-cyclodextrin (abbreviated to methyl-α-CDx)–benzaldehyde (1:1) complex, $C_{54}H_{96}O_{30}\cdot C_7H_6O$, was investigated by the X-ray method. The crystal is monoclinic with the space group $P2_1$ and $Z=2$; the cell dimensions are $a=11.604(1)$, $b=23.832(3)$, $c=13.539(1)$ Å, and $\beta=106.11(1)°$. The structure was determined by inspection of a Patterson map and a trial-and-error method combined with the rigid-body least-squares technique, and refined by the block-diagonal least-squares method to the final *R*-value of 0.10 for 3597 reflections ($\sin\theta/\lambda \leqq 0.49$). The methyl-α-CDx molecule is in the shape of a distorted and truncated hexagonal cone. The guest benzaldehyde molecule is fully included within the host cavity. The carbonyl group is located at the center of the cavity, while the phenyl group is located at the base-side of the host cone. Methyl-α-CDx molecules, of which *pseudo* hexagonal axis is inclined by an angle of 17.0° against the crystallographic a axis, are stacked along the a axis to form a head-to-tail channel-type structure.

The complex formation of many compounds, especially pharmaceuticals, with cyclodextrins and their derivatives has been intensively investigated as the cyclodextrins increase solubility and chemical stability of guest compounds.[1,2] These effects of cyclodextrins have been interpreted on the basis of the inclusion phenomena of various guest compounds into cyclodextrins. Previously, we reported on the crystal structure of the α-cyclodextrin–benzaldehyde complex,[3] in which the benzaldehyde molecule is included in the column formed by the stack of α-cyclodextrin rings. Permethylated α-cyclodextrin (hexakis(2,3,6-tri-*O*-methyl)-α-cyclodextrin, abbreviated to methyl-α-CDx) also forms a crystalline complex with benzaldehyde. In this paper, we deal with the crystal structure of the methyl-α-CDx–benzaldehyde (1:1) complex, which will be discussed mainly in comparison with the structure of the α-cyclodextrin–benzaldehyde complex and the methyl-α-CDx–*p*-iodoaniline complex.[4]

Experimental

Crystals of the methyl-α-CDx–benzaldehyde (1:1) complex were obtained by standing an aqueous solution at 40 °C, which contains methyl-α-CDx and benzaldehyde in a 1:1 molar ratio. Measurements of lattice parameters and reflection intensities were carried out on a Nicolet P3/F diffractometer with graphite-monochromated Cu $K\alpha$ radiation. By using the θ-2θ scan technique, 3597 independent reflections with $|F_o| \geqq 3\sigma(F)$ were collected up to 100° in 2θ. No corrections were made for absorption or extinction effects.

Crystal Data: $C_{54}H_{96}O_{30}\cdot C_7H_6O$, F.W.=1331.7, monoclinic, space group $P2_1$, $Z=2$, $a=11.604(1)$, $b=23.832(3)$, $c=13.593(1)$ Å, $\beta=106.11(1)°$, $V=3597.1$ Å^3, $D_x=1.229$, $D_m=1.22$ g cm^{-3}.

Determination and Refinement of the Structure

The orientation of the *pseudo* hexagonal axis of methyl-α-CDx was deduced by inspection of a Patterson map. The rotational parameter around the molecular axis and the translational parameters along the crystallographic a and c axes were determined by the trial-and-error method. After the correction of the position and orientation of each 2,3,6-tri-*O*-methylglucose residue by the rigid-body least-squares technique, atomic parameters of methyl-α-CDx were refined by the block-diagonal least-squares method. At this stage, the benzaldehyde molecule was found on a Fourier map. Successive block-diagonal least-squares refinement of the structure converged the *R*-value to 0.10. The quantity minimized was $\Sigma w(|F_o|-|F_c|)^2$ with $w=1.0$ for all the reflections. The atomic scattering factors were taken from the "International Tables for X-Ray Crystallography."[5] The final atomic coordinates and B_{eq} values are given in Table 1. Tables of anisotropic temperature factors, observed and calculated structure factors, bond distances and angles, and conformation angles in methyl-α-CDx are on file with The Chemical Society of Japan (Document No. 8259). The computation was carried out on a FACOM M-200 computer at the RIPS Center, Tsukuba.

Description and Discussion of the Structure

Outline of the Structure. The structure and numbering scheme of the complex is shown in Fig. 1. Methyl-α-CDx is in the shape of a distorted and truncated hexagonal cone. The guest benzaldehyde molecule is included in the cavity of methyl-α-CDx. The carbonyl group is located at the center of the cavity, while the phenyl group is located at the O(2), O(3) side. Methyl-α-CDx molecules are stacked along the a axis to form a head-to-tail channel-type structure as shown in Fig. 3.

Conformation of Methyl-α-CDx. Average bond distances and angles over six 2,3,6-tri-*O*-methylglucose residues are shown in Fig. 2. Geometrical data of the methyl-α-CDx ring are given in Tables 2 and 3. The C(6)–O(6) bonds in the G4 and G5 residues are in a *gauche-gauche* conformation, while the others have a *gauche-trans* conformation. All O(2)–C(7) bonds are

O(2,G2)···C(8,G2)	3.47	O(2,G5)···C(8,G6)	3.38
O(2,G3)···C(8,G3)	3.54	O(2,G6)···C(8,G1)	3.24

III. Tilt-angles[a)]

Residue	ϕ/°	Residue	ϕ/°
G1	27.9	G4	22.9
G2	23.7	G5	26.1
G3	1.7	G6	3.8

a) The tilt-angle is defined as the angle made by the plane through the six O(4) atoms and the plane through O(4′), C(1), C(4), and O(4) of each residue.

jacent residues vary in the range 4.08—4.32 Å. These O(4) atoms are roughly coplanar with a maximum deviation of 0.23 Å. The O(2)···O(3) distances (3.27—3.46 Å) between adjacent residues are significantly larger than those found in α-cyclodextrin complexes.[3)] This may be ascribed to the large tilt of the four residues (G1, G2, G4, and G5), which results from the repulsive interaction between the C(8) methyl group and the O(2) atoms of the adjacent residue. The C(8) methyl group is located at a position nearly equidistant from the two vicinal O(2) atoms; 3.18—3.53 Å between C(8) and O(2), and 3.23—3.43 Å between C(8) and O(2) of the adjacent residue.

TABLE 3. LEAST-SQUARES PLANE THROUGH SIX O(4) ATOMS AND DEVIATIONS FROM THE PLANE

The plane equation is of the $AX+BY+CZ=D$ form where X, Y, and Z are the coordinates in Å units along the a, b, and c* axes, respectively.

$0.9506X-0.1139Y+0.2889Z=0.9720$

Deviations of atoms from the plane

	l/Å		*l*/Å
O(4,G1)	0.14	O(4,G4)	0.16
O(4,G2)	−0.21	O(4,G5)	−0.23
O(4,G3)	0.06	O(4,G6)	0.06

TABLE 4. INTERMOLECULAR DISTANCES BETWEEN METHYL-α-CDx AND BENZALDEHYDE

Distance	*l*/Å	Distance	*l*/Å
O(4,G1)···C(6,BA)	3.89	C(5,G5)···O(1,BA)	3.59
C(5,G3)···O(1,BA)	3.91	O(4,G5)···C(2,BA)	3.93
C(5,G4)···O(1,BA)	3.63	C(8,G6)···C(4,BA)	3.86
O(4,G4)···C(2,BA)	3.79	C(8,G6)···C(3,BA)	3.94
C(5,G5)···O(1,BA)	3.82	C(6,G5)···O(1,BA)	3.73

The macrocyclic conformation of α-cyclodextrin and methyl-α-CDx has been discussed previously on the basis of the tilt-angle of each residue as well as the geometry of the O(4) hexagon.[3,4)] The tilt-angles (Table 2) were calculated as the angle made by the O(4) plane and the plane through C(1), C(4), O(4), and O(4′). The G3 and G6 residues are nearly perpendicular to the O(4) plane, while the other four residues are sharply inclined with the O(6) side nearer to the molecular axis of methyl-α-CDx. Although the average tilt-angle (17.7°) is somewhat larger than that of the *p*-iodoaniline complex (16.5°), the conformational feature of methyl-α-CDx is quite similar in both complexes.

Methyl-α-CDx-Guest Interaction. The guest benzaldehyde molecule is included within the methyl-α-CDx cavity. The carbonyl group is located at the center of the cavity, while the phenyl group is located at the O(2), O(3) side. The benzaldehyde molecule is sandwiched between the G3 and G6 residues, and the plane through benzaldehyde is nearly parallel to the longest diagonal of the methyl-α-CDx ring. The C(7,BA)–O(1,BA) bond of benzaldehyde is oriented toward the C(5,G4) atom. This inclusion geometry is similar to that of the iodophenyl group,[4)] in which iodine atom is located at the center of the cavity. Intermolecular distances between methyl-α-CDx and benzaldehyde are given in Table 4. The shortest distance of 3.59 Å is found between C(5,G5) and O(1, BA). The comparison of the inclusion geometry between the α-cyclodextrin complex[3)] and the present

complex shows that the permethylation of α-cyclodextrin remarkably affects the position and orientation of the guest molecule as well as the macrocyclic conformation of methyl-α-CDx. In the α-cyclodextrin–benzaldehyde complex, the benzaldehyde molecule is turned upside down in the cavity. Although the phenyl group is also located at the similar position, the carbonyl group protrudes from the cavity and is in contact with the next α-cyclodextrin molecule. Such orientation of the benzaldehyde molecule may be unfavorable in the methyl-α-CDx cavity. The protrusion of the carbonyl group from the O(2), O(3), side may be obstructed by the next methyl-α-CDx molecule, which partly blocks the O(2), O(3) side of the methyl-α-CDx ring. The introduction of methyl groups into the α-cyclodextrin ring enlarges the O(2), O(3) side of the cavity as indicated by the O(2)···O(3) distances, so that the guest molecule seems to be more loosely bound in the methyl-α-CDx cavity.

Molecular Packing. Methyl-α-CDx molecules are stacked along the a axis to form an endless column as shown in Fig. 3. This packing feature resembles that found in the *p*-iodoaniline complex.[4] But, the molecular axis of methyl-α-CDx, which is defined as the axis through the center of gravity of six O(4) atoms and perpendicular to the O(4) plane, is more inclined against the column axis: 3.7° in the *p*-iodoaniline complex and 17.0° in the benzaldehyde complex. Adjacent methyl-α-CDx rings along the column are shifted laterally with respect to each other within the molecular plane. Such a shift reduces the region of overlap of the molecule, and as a result, enables the close packing along the column axis. The distance between the O(4) planes of neighboring methyl-α-CDx molecules in the benzaldehyde complex is 0.32 Å shorter

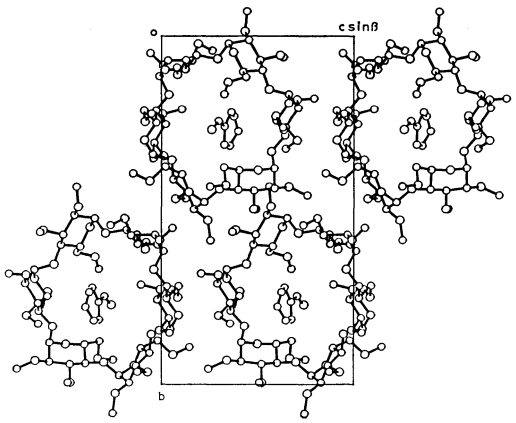

Fig. 4. Crystal structure viewed down along the a axis.

g	$1-x$,	$1/2+y$,	$1-z$

than the corresponding distance in the *p*-iodoaniline complex, although the repetition unit along the column differs by only 0.16 Å. In the α-cyclodextrin–benzaldehyde complex,[3] the α-cyclodextrin molecules stacked along the column axis are linked to one another *via* direct and water-mediated hydrogen bonds. Owing to the methylation of all hydroxyl groups, methyl-α-CDx forms no intermolecular hydrogen bonds, but instead, forms van der Waals contacts, most of which involve methyl groups as shown in Figs. 4 and 5.

Further Studies of Electroluminescence Spectra of the *n*-GaP Semiconductor Electrode in Relation with the Surface-trapped Holes

Yoshihiro NAKATO, Akira TSUMURA, and Hiroshi TSUBOMURA*

Department of Chemistry, Faculty of Engineering Science, Osaka University, Toyonaka, Osaka 560

(Received April 7, 1982)

Electroluminescence spectra of an *n*-type gallium phosphide (*n*-GaP) electrode caused in the presence of oxidants such as $[Fe(CN)_6]^{3-}$ and $S_2O_8^{2-}$ were measured as functions of the electrode potential, the solution pH, and the kind of crystal faces. The electroluminescence spectra consisted of two bands; one was assigned to arise from electronic transitions in the bulk and the other from those at the surface. It was found that the position and the spectral shape of the luminescence band arising from the surface were quite independent of various experimental conditions, while its intensity was strongly dependent on them. These results were explained well by the view that the luminescence band is caused by "surface-trapped holes" acting as a precursor of anodic dissolution reaction of the electrode, as proposed previously. The physicochemical model of the surface-trapped hole was discussed on the basis of the above results.

Extensive work has been done on the semiconductor photoelectrochemical cells in relation with solar energy conversion.[1-4] The main difficulty in this method arises from the fact that most of the available semiconductors with moderate bandgaps are more or less photocorrosive in electrolyte solutions.

The photoelectrochemical stability of semiconductor electrodes was first discussed on the basis of the thermodynamic decomposition potentials,[5-8] and later, much attention has been paid to the kinetic stability of the electrodes.[1,3-5,8] It is very important to understand the physicochemical nature of holes and electrons at the surface, which act as precursors or intermediates of the electrode reactions. Many workers have often pointed out the importance of surface states as arising from surface defects or impurities,[3,4] but the detailed nature of them on a molecular level has still been quite obscure.

We studied electrochemical and luminescent properties of an *n*-type gallium phosphide (*n*-GaP) electrode, and proposed a concept of "surface-trapped holes" as a precursor of various anodic reactions of the electrode.[9] We also studied electro- and photoluminescence spectra of other *n*-type semiconductors such as *n*-CdS, *n*-ZnO, and *n*-TiO_2, and reported that some of the luminescence bands were interpreted as arising from the surface-trapped holes similar to those of *n*-GaP.[10] In the present paper we will report the results of further detailed studies on the electroluminescence spectra of the *n*-GaP electrode.

Experimental

Electrodes were prepared by using single crystal wafers of *n*-GaP, cut perpendicular to the (111)-axis of the crystal, in a similar way to reported before.[9a] They were etched in hot aqua regia for about 20 s before use. The (111)-face (Ga-face) and the $(\bar{1}\bar{1}\bar{1})$-face (P-face) were distinguishable by microscopic inspection of the etched surface.[9a]

Electroluminescence was emitted when the *n*-GaP electrode was kept at cathodic potentials by use of a potentiostat in aqueous solutions containing an oxidant such as $S_2O_8^{2-}$ or $[Fe(CN)_6]^{3-}$. In general the luminescence arises *via* radiative recombination between holes injected by the oxidant in solution and electrons in the conduction band. The luminescence spectra were measured by using a Jobin-Yvon H20 monochromator and an HTV R316 photomultiplier cooled at −20 °C. The observed spectra were corrected with reference to the spectral sensitivity of the photomultiplier, which was measured by use of an Eppley thermopile. The peak wavelengths of the corrected spectra agreed well with those reported by other workers.[11,12]

Luminescence (or photoluminescence) was also emitted when the electrode in an electrolyte solution without oxidants was illuminated at the 365 nm band by use of a 500 W high pressure mercury lamp combined with a Shimadzu-Bosch-Lomb monochromator and appropriate light filters. The luminescence spectra were measured with the same detector system as used for the electroluminescence spectra.

The current-potential curves were obtained with a Nikko-Keisoku NPGS-301 potentiostat. Solutions were prepared by use of deionized water and reagent grade chemicals. They were stirred magnetically and deaerated by bubbling nitrogen during experiments. The pH of the solutions in the range of 3 to 11 was controlled by using an appropriate buffer mixture; acetate, phosphate, borate, or carbonate. The concentration unit, mol/dm^3, is abbreviated as M in the present paper.

Results

In Fig. 1, electroluminescence spectra from the Ga-face (——) and the P-face (—·—) of an *n*-GaP electrode caused by an oxidant, $[Fe(CN)_6]^{3-}$, and that from the Ga-face (----) caused by an oxidant, $S_2O_8^{2-}$, are shown, together with a photoluminescence spectrum (·····). The electroluminescence spectra from the Ga- and the P-face caused by $[Fe(CN)_6]^{3-}$ almost agree with each other except for a slight difference in a swelling near 1.4 eV. The position and the spectral shape of the photoluminescence spectrum were nearly independent of the electrode potential, the solution pH, and the kind of the crystal face.

In Fig. 2, the potential dependence of the electroluminescence spectra from the Ga-face caused by $[Fe(CN)_6]^{3-}$ at pH 5.5 is shown. It is seen that the spectra hardly change with the electrode potential except for slight differences in the extent of the swelling near 1.4 eV. Similar results were observed in solutions of other pH values, and also for the spectra from the P-face. The electroluminescence spectra caused by $[Fe(CN)_6]^{3-}$ also hardly depended on the solution pH except for the slight difference in the swelling near 1.4 eV, as seen from a comparison of Figs. 1 and 2.

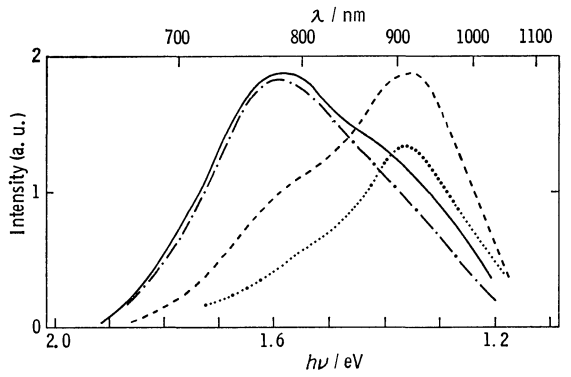

Fig. 1. Electro- and photo-luminescence spectra of an *n*-GaP electrode: Spectra from the Ga-face (——) and the P-face (—·—) generated at −2.2 V *vs.* SCE in a 0.1 M NaOH aqueous solution containing 0.1 M $K_3[Fe(CN)_6]$ and 0.1 M $K_4[Fe(CN)_6]$; that from the Ga-face (----) generated at −1.9 V *vs.* SCE in a 0.1 M NaOH solution containing 0.5 M $Na_2S_2O_8$; and that from the Ga-face (·····) generated by illumination in a 0.1 M NaOH solution.

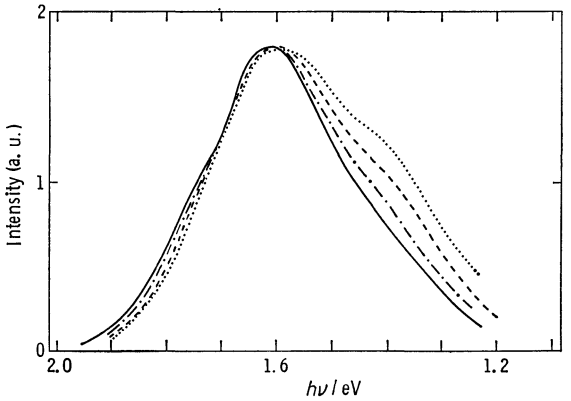

Fig. 2. Electroluminescence spectra from the Ga-face of an *n*-GaP electrode in a solution containing 0.1 M $K_3[Fe(CN)_6]$ and 0.1 M $K_4[Fe(CN)_6]$ at pH 5.5. The spectra were measured at −1.75 V *vs.* SCE (—·—), −1.60 V (——), −1.40 V (----), and −1.35 V (·····).

In Fig. 3, the potential dependence of the peak intensity (I) of the electroluminescence spectra in a $[Fe(CN)_6]^{3-}/[Fe(CN)_6]^{4-}$ solution at pH 4.4 is compared with that of the dark cathodic current (j). These results were obtained by scanning the potential cyclically in a limited range of the potential. The luminescence intensity *vs.* potential curves depended on both the scanning rate and the scanned range of the potential, though the general patterns were rather similar to each other.

Similar experiments were made in solutions of various pH. The results at pH 12.8 are shown in Fig. 4.

Discussion

In a previous letter,[10] it has been concluded that the photoluminescence spectrum of the *n*-GaP electrode arises mainly from electronic transitions in the bulk of the semiconductor, while the electroluminescence spectra caused by $[Fe(CN)_6]^{3-}$ arise mostly from electronic transitions at the surface. It has also been concluded[10] that the swelling of the electroluminescence spectra caused by $[Fe(CN)_6]^{3-}$ appearing at 1.4 eV (Figs. 1 and 2), where the photoluminescence peak just lies, is due to a small contribution of the luminescence band arising from the bulk.

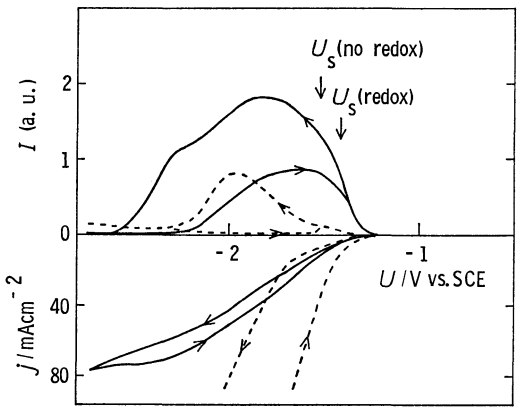

Fig. 3. Potential dependences of the peak intensity of the electroluminescence spectra (I) and the cathodic current (j) for the Ga-face (——) and the P-face (----) in a solution containing 0.1 M $K_3[Fe(CN)_6]$ and 0.1 M $K_4[Fe(CN)_6]$ at pH 4.4. The scan rate is 200 s/V. The U_s values indicated by arrows are for the Ga-face. The U_s (no redox) for the P-face is almost the same as that for the Ga-face.[9b]

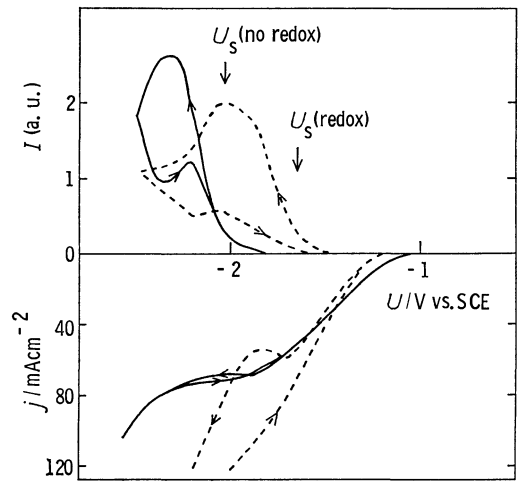

Fig. 4. Potential dependences of the peak intensity of the electroluminescence spectra (I) and the cathodic current (j) for the Ga-face (——) and the P-face (----) in a 0.1 M NaOH solution (pH 12.8). Other conditions are the same as in Fig. 3.

The electroluminescence spectrum caused by $S_2O_8^{2-}$ (a broken line in Fig. 1) shows a strong peak at 1.36 eV and a shoulder near 1.6 eV, suggesting that the luminescence spectrum arises mostly from the bulk, contrary to the spectrum caused by $[Fe(CN)_6]^{3-}$. According to the literature,[11,12] the $S_2O_8^{2-}$ ions are first reduced by electrons in the conduction band, and the resulting radical, $SO_4^{-}\cdot$, acts as a very strong oxidant. The above result can therefore be explained by assuming that holes injected by the $SO_4^{-}\cdot$ radicals are quite hot and a large part of them can diffuse into

the bulk.

As mentioned in the preceding section, the electroluminescence spectra caused by $[Fe(CN)_6]^{3-}$ hardly change with the electrode potential, the solution pH, and the kind of the crystal face, except for the differences in the extent of the swelling near 1.4 eV, *i.e.*, the extent of the contribution of the luminescence band arising from the bulk. This means that the position and the spectral shape of the luminescence band arising from the surface are quite independent of these experimental conditions. The changes of the contribution of the luminescence band arising from the bulk with the electrode potential and the pH can be explained qualitatively by taking account of the changes of the surface density of the electrons in the conduction band as well as those of the initial energy of the injected holes.

The intensity of the electroluminescence spectra at *ca.* 1.6 eV (*i.e.*, the intensity of the luminescence band arising from the surface), on the contrary, depends strongly on the electrode potential, the pH, and the kind of the crystal face, as seen in Figs. 3 and 4. In these figures U_s(redox) is a potential which was determined previously from the intercept of a Mott-Schottky plot with the abscissa,[9b] and thus $-eU_s$(redox) approximately indicates the energy of the conduction band edge at the electrode surface in contact with the $[Fe(CN)_6]^{3-}/[Fe(CN)_6]^{4-}$ solution under anodic bias.[9a] The U_s value in the absence of the redox couple, designated as U_s(no redox), is also included in Figs. 3 and 4. Since the deviation of U_s(redox) from U_s(no redox) was attributed to the accumulated surface-trapped holes and/or oxidative surface intermediates produced during the reaction of the holes with the solution,[9b,c] U_s(redox) is thought to approach U_s(no redox) as the electrode potential is shifted to the negative and the surface density of the electrons in the conduction band increases. Accordingly, we can roughly estimate that the flatband potential of *n*-GaP lies around U_s(no redox) even in the presence of the redox couple.

Based on this argument on the U_s and the previously reported assignment of the electroluminescence spectra peaked at 1.6 eV as being a recombination luminescence between the surface-trapped holes and the electrons in the conduction band,[9b,c] the main features of the results shown in Figs. 3 and 4 can be explained qualitatively as follows.

As seen in Fig. 3, when the electrode potential is swept from positive to negative in an acidic solution, the electroluminescence spectra from the Ga-face start to appear at a potential slightly less negative than U_s(no redox), and reach the maximum at a potential slightly more negative than the U_s(no redox), then decrease rather rapidly at more cathodic potentials. The slight shift of U_s(redox) from U_s(no redox) shown in Fig. 3 suggests that the surface-trapped holes and/or oxidative surface intermediates are accumulated under anodic bias only to a small extent in this case.[9b] Since the surface density of the electrons in the conduction band at anodic potentials are negligibly small, most of the surface-trapped holes formed through the hole injection by the oxidant, $[Fe(CN)_6]^{3-}$, should only be reduced again by the reductant, $[Fe(CN)_6]^{4-}$, at such potentials.[9b] The initial increase of the luminescence intensity when the electrode potential is swept from positive to negative can then be attributed to the increase of the surface density of the electrons in the conduction band. The decrease of the intensity at the more cathodic potentials can be explained by assuming that when the surface density of the electrons in the conduction band becomes very high, the electrode is covered with chemically reduced surface species, with which the injected holes or the oxidant in solution react effectively, not forming the surface-trapped holes.

The onset potential of the cathodic current at the Ga-face in an acidic solution lies very close to a potential at which the electroluminescence starts to appear (Fig. 3). Therefore, the cathodic current near the onset potential can be explained as due mostly to the electron transfer from the conduction band into the $[Fe(CN)_6]^{3-}$ ions *via* the injected holes. The direct electron transfer from the conduction band to the oxidant may partly contribute to the current. At potentials more negative than *ca.* −2.0 V *vs.* SCE, evolution of gas, most probably, hydrogen gas, was observed at the electrode surface. Since the hydrogen evolution is thought to proceed with adsorbed hydrogen atoms (or a kind of surface hydrides) as a reaction intermediate, the above fact means that a kind of surface hydrides is formed at highly negative potentials. This is in harmony with the above argument that the decrease in the electroluminescence intensity at highly negative potentials is due to the formation of certain chemically reduced surface species. The formation of surface hydrides at cathodic potentials was also discussed in the literature.[13–15]

The electroluminescence intensity *vs.* potential curve for the Ga-face shows hysteresis as seen in Fig. 3. From the discussions made so far, it is very plausible that the chemical structure of the electrode surface changes with the electrode potential from the more or less oxidative structures in an anodic region to the reductive ones in a cathodic region. The hysteresis can then be explained as being due to that the sweep rate of the electrode potential is faster than the rate of the chemical change at the electrode surface. This explanation is supported by a fact that the hysteresis becomes more prominent as the sweep rate becomes high.

The electroluminescence intensity *vs.* potential curve for the P-face in an acidic solution is rather similar in its essential pattern to that for the Ga-face (Fig. 3), and therefore can be explained similarly. The minor differences may be attributable to the differences in the quantity and the reactivity of the oxidative or reductive surface intermediates between the two faces.

The onset potential of the cathodic current at the Ga-face in a high pH solution lies considerably more positive than U_s(no redox) (Fig. 4). As reported in a previous paper[9b] and also seen from the large shift of U_s(redox) from U_s(no redox) shown in Fig. 4, the surface-trapped holes and, especially, the oxidative surface intermediates produced *via* the reaction of the holes with the solution are thought to be accumulated

in a large amount at the electrode surface under anodic bias in the case where it is in contact with the $[Fe(CN_6)]^{3-}/[Fe(CN)_6]^{4-}$ solution of high pH. The above-mentioned cathodic current can then be explained by assuming that some of the accumulated oxidative surface intermediates (possibly certain surface radicals[9a]) act as effective mediators for the electron transfer from the conduction band to the oxidant in solution.

The electroluminescence spectra from the Ga-face in a high pH solution start to appear at a potential only slightly more positive than U_s(no redox), contrary to the cathodic current (Fig. 4). Since the oxidative surface intermediates are accumulated much at the electrode surface in this case, as mentioned above, some of the $[Fe(CN)_6]^{3-}$ ions coming to the surface may be reduced by the conduction band electrons trapped at the accumulated surface intermediates, not causing the hole injection. The holes injected by the $[Fe(CN)_6]^{3-}$ ions may also be reduced by the electrons trapped at the surface intermediates. These considerations imply that the surface-trapped holes are not effectively formed in the presence of largely accumulated surface intermediates. Accordingly, the electroluminescence is thought to become detectable only when the surface density of the electrons in the conduction band becomes considerably high, *i.e.*, the electrode potential approaches U_s(no redox).

The onset potential of the cathodic current at the P-face lies less positive than that at the Ga-face (Fig. 4). The potential at which the electroluminescence starts to appear at the P-face also lies more positive than that at the Ga-face (Fig. 4). These results can be explained, according to the above arguments on the results for the Ga-face, by assuming that the density of the accumulated surface intermediates at the P-face is less than that at the Ga-face. This explanation is in agreement with a reported result[9b] that the shift of U_s(redox) from U_s(no redox) at the P-face is smaller than that at the Ga-face.

It is interesting to note in Fig. 4 that when the electrode potential is swept from positive to negative, the cathodic current at the P-face once decreases in the potential range where the electroluminescence just becomes strong. This can be explained by assuming that when the radiative recombination between the surface-trapped holes and the electrons in the conduction band becomes appreciable, the density of the surface intermediates (*i.e.*, the mediators of electron transfer, which are produced *via* the surface-trapped holes) decreases. Similar behavior was generally observed for both the Ga- and P-face in solutions of pH 6 to 11, *i.e.*, in cases where the density of the accumulated surface intermediates is estimated to be moderate. The large cathodic currents at the P-face on potential sweeps from negative to positive in Fig. 4 might be mediated by reductive surface species produced at cathodic potentials.

It is finally noted that the large differences in the dependence of the luminescence intensity on the potential between the Ga- and the P-face observed at any pH (Figs. 3 and 4) are in a sharp contrast to the similarities of the position and the spectral shape of the luminescence spectra (Fig. 1). The difference in the dependence of the luminescence intensity on the potential should imply that the luminescence spectra from the Ga- and the P-face arise from the surface of different chemical structures. The spectral similarity therefore shows that the luminescent species (*i.e.*, the surface-trapped holes) exist in such a way that their energy is almost independent of detailed differences in surface chemical structures between the Ga- and the P-face. This is difficult to explain if the surface-trapped holes are assumed to be holes trapped at certain surface sites such as kinks, steps, *etc.* The above result might rather be reasonably explained by a previously proposed model for the surface-trapped hole[9b,c] that it is an electron deficiency delocalized over a relatively wide range of the crystal lattice inside the surface. The energy of such an electron deficiency should not be affected much by the surface chemical structure.[16] The slight deviation of its energy from the valence band edge at the surface ($\approx$0.6 eV[9b,c]) is thought to be mainly attributable to the distortion of the crystal lattice at the surface.

16) If the surface of the *n*-GaP electrode is assumed to be covered with a very thin hydroxide or oxide layer,[9a] the energies of the valence electrons in the surface Ga–P bonds should lie relatively deep due to the stabilization (or the inductive effect) by adjacent, electronegative oxygen atoms. This implies that the electron deficiency (hole) is little distributed on the Ga–P bonds just at the surface and its energy is hardly affected by the surface chemical structure.

Asymmetric Adsorption of Alanine by Quartz Powder from Ethanol Solution

Shozo FURUYAMA,* Michio SAWADA, Kinji HACHIYA, and Tetsuo MORIMOTO
Department of Chemistry, Faculty of Science, Okayama University, Tsushima, Okayama 700
(Received March 25, 1982)

The asymmetric adsorption of the racemic alanine by the optically active quartz from ethanol solution at 8 °C was studied by the ^{14}C-tracer method and the newly developed ^{14}C-tracer·ninhydrin-colorimetry combination method. The preferential adsorption of L-alanine by levorotatory quartz (*l*-quartz) and D-alanine by dextrorotatory quartz (*d*-quartz) was confirmed. The asymmetric adsorptivity (A_s) falls in the range of 1.1—1.3, which is comparable with the value determined at −80 °C in the previous paper. The effects of water content in the ethanol solution and of the adsorption temperature upon the adsorption affinity of alanine to quartz were also measured. The cause for the asymmetric adsorption is discussed from the crystallographic point of view.

It has been a great concern of many workers whether quartz surface adsorbs racemic adsorbates asymmetrically, because this phenomenon may relate to the genesis of the first optically active molecules in nature.[1] Various results showing the asymmetric adsorption had been reported. However, their reliability was recently questioned.[2] In 1974, Bonner *et al.* reported that they had succeeded in obtaining the unambiguous evidence for the occurrence of this phenomenon by using the radioactive alanine hydrochloride in rigorously dehydrated *N,N*-dimethylformamide (DMF) solution.[3,4] In the previous work, we also confirmed the occurrence of the asymmetric adsorption of alanine and alanine hydrochloride from an ordinary or a rigorously dehydrated ethanol solution at −80 °C by using the ninhydrin-colorimetry technique.[5]

In the present study, we checked the effects of water content in solution and of adsorption temperature upon the adsorption affinity of alanine. The value of asymmetric adsorptivity, A_s, for alanine by quartz powder at 8 °C was determined by the ^{14}C-tracer method and the newly developed ^{14}C-tracer·ninhydrin-colorimetry combination (TN) method. The TN method has the advantage that it can determine the value of A_s by one adsorption experiment, as will be demonstrated later. The cause of the asymmetric adsorption by quartz is also discussed from the crystallographic point of view.

Experimental

Materials. Dextrorotatory (*d*-) and levorotatory (*l*-) quartzs ($[\alpha]_D=22°$) were purchased from Toyo Communication Equipment Co. Ltd. They were ground by an agate-motor into powders of two uniform sizes. Sample A has 105—53 μm of average particle size and 0.08 $m^2 g^{-1}$ of the BET surface area. The values for sample B are <53 μm and 0.38 $m^2 g^{-1}$ respectively. D- and L-(U-^{14}C)-alanine (20—40 and 150 mC_i $mmol^{-1}$ respectively) were supplied from Radiochemical Center Amersham. Reagent grade racemic alanine was dissolved in a 99.8% ethanol to obtain DL-alanine solutions of various concentrations. D- or L-(U-^{14}C)-alanine was then added to them to prepare the *DL- and D*L-alanine stock solutions, whose radioactivity ranged from 4000 to 6000 cpm (asterisk denotes ^{14}C). The rigorously deoxygenated ninhydrin-hydrindantin reagent was prepared as follows.[6] 20 cm^3 of lithium acetate buffer solution (pH=5.2±0.5) was added to 60 cm^3 of dimethyl sulfoxide. After 15 min agitation, 1.6 g of ninhydrin and 0.12 g of hydrindantin were dissolved successively in the solution (all these treatments were carried out under a highly deoxygenated nitrogen stream).

Procedure for ^{14}C-Tracer Method. 5 g of the *d*- or *l*-quartz powder was degassed in a Pyrex sample tube for 1 h at 150 °C under a vacuum of 10^{-3} Pa. After cooling in a dry box, the powder was transferred into a polyethylene bottle containing 5 cm^3 of *DL- or D*L-alanine solution. After a vigorous agitation, the sample was equilibrated for 2 h. Then its supernatant solution was centrifuged for 10 min and three aliquots (0.5 cm^3) of it were transferred into a glass bottle containing 2.0 cm^3 of PCS scintillant. The decrease in the radioactivity due to the adsorption was determined by an Aloka LSC-651 Scintillation Counter. The deviation in nine countings (three countings for each aliquot) was within 2%.

Procedure for ^{14}C-Tracer·Ninhydrin-Colorimetry Combination (TN) Method. 8 g of the *l*-quartz B was treated as above and placed in 20 cm^3 of *DL- and D*L-alanine solution. After the measurement of the decrease in the radioactivity, 5 cm^3 of the solution was transferred into a test tube and dried on a water bath. Then 5 cm^3 of the deoxygenated water and 3 cm^3 of the deoxygenated ninhydrin-hydrindantin reagent were successively added into the test tube. After being sealed, the test tube was heated at 100 °C for 15 min. The magnitude of the absorption at 570 nm ($\varepsilon=(2.22\pm0.04)\times10^5$ M^{-1} cm^{-1}) for the colored solution was measured to determine the decrease in the total alanine concentration due to the adsorption.

Results and Discussion

The amount of D-alanine adsorbed by the *d*-quartz B from 0.94×10^{-5} M *DL-alanine solution was measured by the ^{14}C-tracer method at 8 °C as a function of water content. The plot in Fig. 1 shows that the amount of D-alanine adsorbed decreases almost linearly with the increase in water content up to 10% and becomes negligible at 20%. However, this test showed that a rigorous dehydration of ethanol (for example to less than 100 ppm as in the previous work[5]) is not indispensable for the present purpose.

The adsorption isotherm for D-alanine by the *d*-quartz B was measured at 8 °C and −80 °C using various concentrations of *DL-alanine solutions. Figure 2 shows that D-alanine is more strongly adsorbed at −80 °C than at 8 °C, although the difference is not as prominent as expected from the large difference in the adsorption temperature. The small temperature dependence of the adsorption affinity of D-alanine to *d*-quartz means that the magnitude of the

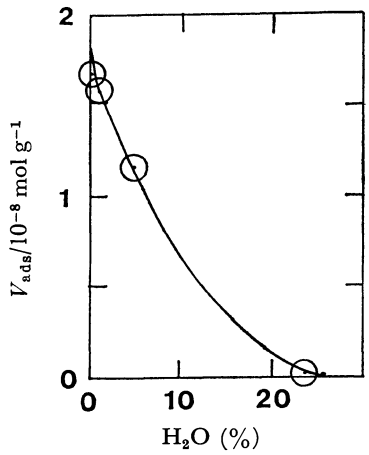

Fig. 1. Effect of water content in ethanol upon the amount of *D-alanine adsorbed (V_{ads}).
2 g of the *d*-quartz B was contacted with 10 cm^3 of (0.94×10^{-5} M) *DL-alanine solution for 2 h.

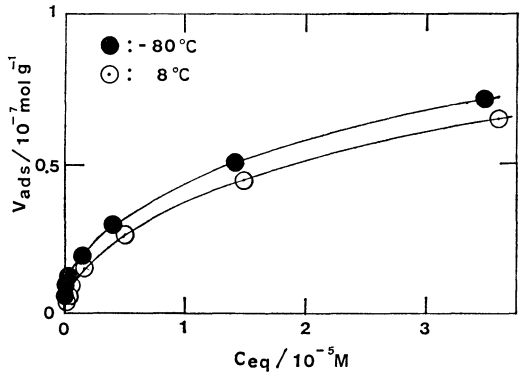

Fig. 2. Adsorption isotherm of *D-alanine on *d*-quartz B at 8 and −80 °C.
2 g of the *d*-quartz B was contacted with 10 cm^3 of ($(0.094-9.4)\times10^{-5}$ M) *DL-alanine solution for 2 h. The values for V_{ads} and C_{eq} are for the *D-alanine only.

isosteric heat of adsorption, q_{st}, for D-alanine is almost comparable with that for ethanol. However, since the concentration of D-alanine is almost 10^{-6} times as small as that of ethanol, it is certain that the adsorption affinity to *d*-quartz of D-alanine is much larger than that of ethanol. The entropy of adsorption for D-alanine, therefore, must be much larger than that for ethanol. The reason can be well explained if one borrows the term "chelate effect" which is frequently used in coordination chemistry.[7] As will be discussed later, a D-alanine molecule forms three hydrogen bonds with three surface hydroxyl groups when it is adsorbed by the *d*-quartz (two by the carboxyl group and one by the amino group). However, since these two groups are attached to the same molecule, the loss of the translational freedom by the adsorption is three per one molecule. On the other hand, nine translational freedoms are lost when the corresponding three ethanol molecules are adsorbed. This smaller number of losses of the translational degrees of freedom may be the principal cause for the larger entropy of adsorption, and thus the larger adsorption affinity, of D-alanine than those of ethanol. (That the number of losses in the rotational freedom for a D-alanine molecule is smaller than that for three corresponding ethanol molecules (three *vs.* nine) may partially contribute to the larger entropy of adsorption of D-alanine. The vibrational term, however, is essentially unrelated to the entropy of adsorption.) However, since the strengths of the hydrogen bonds of O-H---O and O-H---N are almost equal,[8] the magnitude of q_{st} for D-alanine (precisely speaking, the q_{st} per hydrogen bond in D-alanine) becomes nearly equal to that for ethanol.

By applying the Langmuir equation to the isotherm in Fig. 2, the monolayer capacity for DL-alanine is obtained as 1.8×10^{-7} mol g^{-1}. This, when combined with the value of the BET surface area (0.38 m^2 g^{-1}), yields a value of 3.5 nm^2 molecule^{-1} for the adsorption cross section for DL-alanine.

The asymmetric adsorptivity (A_s) is defined as follows:

$$A_s = \left(\frac{V_{ads}}{C_{eq}}\right)_{L(\text{or D})} \Big/ \left(\frac{V_{ads}}{C_{eq}}\right)_{D(\text{or L})} . \quad (1)$$

Here V_{ads} and C_{eq} denote the amount of alanine adsorbed and the equilibrium concentration respectively. The value of A_s for alanine by quartz was determined at 8 °C with the ^{14}C-tracer method. The result is summarized in Table 1. Table 1 shows that the *d*-quartz preferentially adsorbs D-alanine and the *l*-quartz adsorbs L-alanine, as found in the preceding experiments.[3-5] The value of A_s for alanine falls in the range of 1.1—1.3 at the higher alanine concentrations. This is almost the same as the value (1.2) determined at −80 °C by the ninhydrin-colorimetry in the previous paper,[5] but slightly lower than the value for alanine hydrochloride (1.4—1.7) from the rigorously dehydrated DMF solution determined by Bonner *et al.*[4] The present value is also apparently lower than the value ($\approx$2) determined by the present authors at −80 °C using the rigorously dehydrated ethanol solution.[5] The value determined at the lowest concentration is apparently small, although we do not know the reason.

To determine the A_s value by the tracer method or the ninhydrin-colorimetry alone, two separate adsorption experiments are necessary. For example, the A_s value obtained from the data of Bonner *et al.* is determined by the combination of the values of the amounts for the labeled enantiomer adsorbed by the *d*- and *l*-quartzs separately.[4] In the present study, the A_s value was obtained from the difference between the amounts of the two enantiomers adsorbed by the *d*- or *l*-quartz. However, since there is no guarantee that the surface properties of the two quartzs or the water content in the two alanine solutions are identical, it was feared that the A_s value might contain a large error. To eliminate this fear, we have developed the TN method by which the A_s value can be determined from one adsorption experiment. According to this method, the values of V_{ads} and C_{eq} of the labeled enantiomer are determined by the tracer method, while the values for the total alanine are obtained by the ninhydrin-colorimetry. The difference between the two measurements yields the values for the nonlabeled enantiomer. The results obtained by the TN method

are summarized in Table 2. The value of A_s (≈ 1.3) accords well with the value determined by the tracer method.

Now it becomes unambiguous that the *d*-quartz preferentially adsorbs D-alanine and the *l*-quartz adsorbs L-alanine. Our next step is to solve the question "on what plane does the asymmetric adsorption occur?" According to an electron-microscopic observation, the powdered sample seems to contain various planes randomly. Therefore the A_s value obtained on the powdered sample is not helpful to solve this question. We are obliged to discuss this matter solely from the crystallographic point of view.

The projections of silicon and oxygen atoms on the (0001) and (10$\bar{1}$0) planes of quartz are schematically represented in Figs. 3 and 4. As can be seen in Fig. 3, silicon and oxygen atoms locate in nearly the same level on the (10$\bar{1}$0) plane. However, it is shown in Fig. 4 that the configuration of silicon atoms on the (10$\bar{1}$0) plane of *l*- and *d*-quartz is identical, while that of oxygen atoms is mirror-symmetrical to each other. The (10$\bar{1}$0) plane is a chiral plane where the asymmetric adsorption of alanine may occur.

Many workers have shown that the surface of the

Pairs of 1 and 4′, 2 and 5′, 3 and 6′, and 4 and 1′ oxygen atoms exist in the same plane.
If the helix of oxygen atoms (1–2–3–4) is clockwise, the quartz is *l*-quatz.

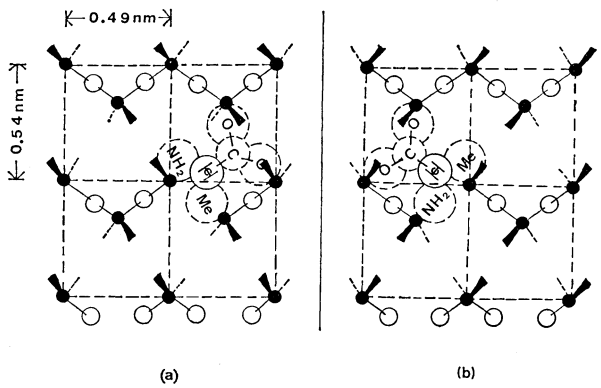

Fig. 4. Schematic representations of the (10$\bar{1}$0) plane of *l*-and *d*-quartzs, and of the configuration of the adsorbed L-alanine molecule.
(a): *l*-Quartz, (b): *d*-quartz, ●: silicon atom, ○: frame oxygen atom, ◄: surface hydroxyl group.

powdered quartz is covered by hydroxyl groups which can not be removed even by heating up to 150 °C.[9] If this is the case, the $(10\bar{1}0)$ planes of the present *l*- and *d*-quartz samples have the hydroxyl groups which are disposed mirror-symmetrically to each other, as shown in Fig. 4. The carboxyl, amino, and even methyl groups of the alanine molecule, when the molecule is adsorbed on the $(10\bar{1}0)$ plane, interact (*i.e.*, form the hydrogen bond) with the surface hydroxyl group. However, it may be the carboxyl group which interacts with the hydroxyl group most strongly and, therefore, principally determines the adsorbed structure of the alanine molecule. The pairs of the hydroxyl groups which can interact satisfactorily with the carboxyl group are limited. If an L-alanine molecule is put on the $(10\bar{1}0)$ plane of the *l*-quartz, as shown in Fig. 4, we notice that not only the carboxyl group but also the amino group can interact with the surface hydroxyl group very well, although the methyl group can not. However, if an L-alanine molecule is put on the *d*-quartz surface so that the carboxyl group preferably interacts with a pair of the hydroxyl groups, the amino group can not interact with the hydroxyl group well. Instead, the methyl group interacts with the hydroxyl group preferably. It is well known that the hydrogen bond between an amino group and a hydroxyl group is stronger than that between a methyl group and a hydroxyl group (16—29 kJ mol^{-1} against 11 kJ mol^{-1}).[8] It may not be unreasonable to conclude that the larger interaction between NH_2 and OH groups than that between CH_3 and OH groups is the principal cause (or at least one of the principal causes) for the preferential adsorption of L-alanine by the *l*-quartz than by the *d*-quartz. The same may be true for the preferential adsorption of D-alanine by the *d*-quartz rather than by the *l*-quartz.

The explanation above seems to work well. However, two questions are raised to the adsorption model. (1) If the asymmetric adsorption results from the different heat of formation for NH_2–OH hydrogen bond and for CH_3–OH hydrogen bond, the A_s value must be temperature dependent. Is the fact that the A_s value at 8 °C is apparently comparable with the value at −80 °C obtained in the previous study inconsistent with the above model?[5] (2) Does the present model work well even in aqueous solution where the alanine molecule dissociate to the dipolar ion $CH_3(H)C(COO^-)NH_3^+$? We can not answer the first question definitely, partly because the techniques and conditions adopted in the two experiments are quite different and, therefore, the certainty of the data can not bear the quantitative discussion. We should establish the experimental technique and condition to solve this question. As to the second question, we assert that the model works well even in the aqueous solution. However, if the strength of the NH_3^+–OH bond is weaker than the CH_3–OH bond, the asymmetric adsorptivity becomes opposite (*i.e.*, the *d*-quartz adsorbs preferentially the L-alanine and the *l*-quartz adsorbs the D-alanine). However, since the adsorption affinity of alanine falls drastically in the aqueous solution and the amount adsorbed of it by quartz is extremely low, as shown in Fig. 1, the experimental determination of the A_s value must be very difficult. The lateral electrostatic interaction between the adsorbed dipolar alanine ions can be neglected if the concentration of the adsorbed species is quite low.

The present authors thank Professor Emeritus Takao Kwan (The University of Tokyo) who first stimulated our interest in this study.

(Received April 21, 1982)

The molecular structure of 7,8-epoxyhalochamigrene, $C_{15}H_{23}OBr_2Cl$, has been confirmed by means of X-ray crystallographic analysis. The crystals are orthorhombic, with sixteen molecules in a unit cell with dimensions of $a=10.303$, $b=71.31$, and $c=9.061$ Å; the space group is $P2_12_12_1$. 4241 independent intensity data were collected on a four-circle diffractometer with graphite-monochromated Cu $K\alpha$ radiation. The structure was solved by the Monte Carlo direct method, using 20 reflections as a starting set, and was refined by the block-diagonal least-squares method. The final R value was 0.072. The molecular structure thus obtained corresponds to that proposed by Howard and Fenical on the basis of chemical and spectroscopic evidence. The four crystallographically-independent molecules have almost the same geometries. Of the two spiro-linked six-membered rings, the one having the epoxy group takes a half-chair conformation, while the other adopts a chair conformation. The crystal consists of alternating single and triple molecular layers parallel to the (010) plane; the latter layer has a molecular arrangement approximately of $P2_12_12_1$ symmetry.

A number of halogenated chamigrene derivatives[1] such as halochamigrene[2] have been isolated from the red algae of the genus *Laurencia*. 7,8-Epoxyhalochamigrene, which had already been obtained by oxidation of halochamigrene,[2a] was recently reported to exist also in nature, *e.g.*, in the red algae *L. nipponica*[3] and *L. okamurai*.[4] On the basis of the chemical and spectroscopic evidence, the **1** and **2** structures were proposed for halochamigrene and 7,8-epoxyhalochamigrene respectively;[2] however, there was no conclusive proof as to these structures. Therefore, in order to establish **1** and **2**, we have now undertaken an X-ray crystallographic study of 7,8-epoxyhalochamigrene.

Experimental

A colorless single crystal cut into a cube with an edge of about 0.2 mm was used for the X-ray experiment. The crystal data are summarized in Table 1. The unit-cell dimensions and diffraction intensities were measured on a Rigaku four-circle diffractometer with graphite-monochromated Cu $K\alpha$ radiation ($\lambda=1.54178$ Å). Because of the long b unit-cell edge, it was necessary to obtain high resolution of the diffraction peaks. For this purpose, a Rigaku RU-200 X-ray tube with a focal size of 0.3×0.3 mm^2 was employed (50 kV, 60 mA). The θ-2θ continuous-scan technique was applied at a θ scan rate of 10° min^{-1}; the scan width in θ was $(0.6+0.142\tan\theta)$°. The background was measured for 5 s at each end of the scan range. Three standard reflections, measured at intervals of every 200 reflections, showed no significant decrease in intensity during the course of the data collection. The intensities were corrected for the Lorentz and polarization factors, but not for absorption or extinction effect. In the range of 2θ values up to 120°, 4241 independent structure factors above the $3\sigma(F)$ level were selected for the structure determination.

Table 1. The crystal data

$C_{15}H_{23}OBr_2Cl$	Mol wt 414.61
Crystal system	Orthorhombic
Space group	$P2_12_12_1$
Cell dimensions	$a=10.303\,(2)$ Å
	$b=71.31\,(1)$ Å
	$c=9.061\,(8)$ Å
V	6658 Å^3
Z	16
D_c	1.655 g cm^{-3}
μ(Cu $K\alpha$)	76.8 cm^{-1}

Structure Determination

Because of the presence of eight independent bromine atoms, the heavy-atom method seemed somewhat troublesome to apply to the present structure; hence, the Monte Carlo direct method[5] was tried. The 20 reflections with the greatest $|E|$ values were chosen as a starting set. In order to extend each of the tentative-phase sets derived from random numbers, 12 cycles of the tangent procedure were performed using 1111 $|E|$ values above 1.30. Since the phase set extended from the 66thly-generated random set showed a low R_K value of 0.258 ($R_K=\Sigma||E_o|-k|E_c||/\Sigma|E_o|$), 10 additional cycles of the tangent procedure were carried out by the use of 1347 $|E|$ values above 1.20; the R_K value became 0.268. An E-map based on 1286 phases afforded all the 76 non-hydrogen atoms.

After the structure had been refined by the block-diagonal least-squares method with anisotropic temperature factors, the absolute configuration was determined by taking account of the anomalous dispersion of bromine and chlorine atoms for Cu $K\alpha$ radiation. The R ratio for the two enantiomeric structures, 1.018, rejected one of them at the 99.5% confidence level.[6] A difference Fourier map revealed all the 92 hydrogen atoms. Further least-squares refinements were performed including the hydrogen atoms and the anomalous dispersion effects. The weighting scheme used

was as follows:

$$w = 1/\{\sigma(F)^2 \exp(c_1X^2+c_2Y^2+c_3XY+c_4X+c_5Y)\},$$

where $X=|F_o|$ and $Y=\sin\theta/\lambda$. The c_1, c_2, c_3, c_4, and c_5 coefficients were evaluated from the $(\Delta F)^2$ distribution; $c_1=0.7702\times10^{-6}$, $c_2=8.060$, $c_3=0.01900$, $c_4=-0.4314\times10^{-2}$, and $c_5=-8.129$. In this manner, the R value reached 0.072. The final atomic parameters are listed in Table 2.[7]

The calculations were done on a HITAC M-200H computer at the Hokkaido University Computing Center, using our own programs. The atomic scattering factors and dispersion corrections were taken from the International Tables for X-Ray Crystallography.[8]

Results and Discussion

Molecular Structure. The molecular skeleton obtained is shown in Fig. 1, while the bond distances and angles and the torsion angles for the spiro[5.5]-undecane systems are given in Tables 3 and 4 respectively. From these results, it is concluded that the structure of 7,8-epoxyhalochamigrene, including the absolute configuration, corresponds to **2**; consequently the structure of halochamigrene is **1**. The four crystallographically-independent molecules have almost the same geometries. The average bond distances and angles for these four molecules are given in the last column of Table 3.
